Sire conception rate (SCR), a service-sire fertility evaluation implemented in August 2008, is based on up to 7 conventional-semen breedings for parities 1 through 5 (C_{cow}). The same procedure was used to derive SCR for other types of breedings: sexed semen for cows (S_{cow}) and conventional semen and sexed semen for primiparous heifers (C_{hfr} and S_{hfr}, respectively). For all 4 breeding types, SCR were based on breedings from 2006 through 2009. Service-sire age groups were consolidated for sexed-semen breedings because of a limited number of bulls. Only artificial-insemination Holstein bulls with ≥ 300 breedings overall and ≥ 100 matings during the last 12 mo in ≥ 10 herds were included. Number of bulls evaluated was 2,309 for C_{cow} breedings, 270 for C_{hfr} breedings, 25 for S_{cow} breedings, and 114 for S_{hfr} breedings; respective mean SCR reliabilities were 79, 82, 73, and 75%. Mean SCR for all breeding types was near 0, and standard deviations were 2.21% for C_{cow}, 2.57% for C_{hfr}, 2.39% for S_{cow}, and 4.34% for S_{hfr} breedings. Correlation between C_{cow} and S_{cow} SCR was 0.18, which resulted in a genetic correlation (r_g) for true SCR of 0.24; corresponding correlations for heifer breedings also were low: 0.08 and 0.11, respectively. Correlation between C_{cow} and C_{hfr} SCR was 0.67 (r_g of 0.82); correlation between S_{cow} and S_{hfr} SCR was 0.75 (r_g of 1.02). Among artificial-insemination organizations, absolute differences between mean SCR for conventional and sexed-semen breedings ranged from 1.44 to 4.52% for cows and 0.87 to 6.78% for heifers. Bull age effects were quite large for conventional semen but small for sexed semen. Results suggest that fertility rankings for sexed semen differ markedly from those for conventional semen and separate SCR are needed. Combining cow and heifer inseminations together in some manner would seem to be advantageous.

Key Words: sire conception rate, bull fertility, sexed semen

W31 Derivation of factors to estimate daily, fat, protein, and somatic cell score from one milking of cows milked three times daily. M. M. Schutz*[1] and H. D. Norman[2], [1]*Purdue University*, *West Lafayette, IN,* [2]*USDA-ARS Animal Improvement Programs Laboratory*, *Beltsville, MD*.

The objective of this research was to derive factors to predict daily fat (F) and protein (P) yield and somatic cell score (SCS) when milk is sampled once per d for cows milked 3 times (3x) per d. Daily milk weights were recorded automatically and samples were collected from 8 herds for each milking on test-day by Dairy Herd Improvement personnel. Following edits, 1721 records of 1236 first lactation (L1) cows and 2704 records of 1940 later lactation (L2) cows remained. Factors currently in use to adjust single milking F and P for milking interval (MINT) were applied. No adjustments are currently in use for SCS. Also, 2 methods were compared with estimate factors or equations to predict daily F, P, and SCS. First, factors were estimated as the ratio of the sum of daily yield to the sum of partial yield within a parity-MINT class (13 intervals in 2 parities) [Method 1] or as the sum of the ratios of daily yield to partial daily yield for each cow-day divided by the number of cow-days within parity-MINT class [Method 2]. Resulting factors from both methods were smoothed, applied to data, and residuals were regressed on days in milk (DIM). Regression equations (n = 112) were also developed within parity-MINT-DIM classes (2 × 7 × 8) [Method 3] to jointly account for MINT and DIM. Separate factors were derived for milking 1, 2, and 3 for each trait in L1 and L2. Method 3 resulted in consistently strongest correlations between estimated and actual yields, and smallest variances of estimates, and root mean squared errors (rMSE) for all components in milkings 1, 2, and 3 in L1 and L2. Method 3 resulted in rMSE of 0.14 (F, L1), 0.22 (F, L2), 0.09 (P, L1), and 0.14 (P, L2) kg for milking 1; compared with rMSE of 0.18, 0.27, 0.12, and 0.16 kg from current factors for the same traits in L1 and L2. Differences in rMSE were similar for F and P for milking 2 and 3 and for SCS for all milkings. Work is ongoing to determine whether equations from Method 3 will allow accurate estimation of daily milk, F, P, and SCS when applied to other herds.

Key Words: milking interval, adjustment factor, milking frequency

W32 Derivation of factors to estimate daily milk yield from one milking of cows milked three times daily. M. M. Schutz*[1], J. M. Bewley[2], and H. D. Norman[3], [1]*Purdue University*, *West Lafayette, IN,* [2]*University of Kentucky*, *Lexington,* [3]*USDA-ARS Animal Improvement Programs Laboratory*, *Beltsville, MD*.

The objective of this research was to derive factors to predict daily milk yield when milk is sampled once per d for cows milked 3 times (3x) per d. Milk weights for all 3 milkings were recorded automatically by 8 herds and collected by Dairy Herd Improvement supervisors on test-day. Following edits, 196,725 daily milk weight records of 2235 first lactation (L1) cows and 346,508 records of 3385 later lactation (L2) cows remained. Factors currently in use to adjust single milking yields for milking interval (MINT) were applied. Also, 3 methods were compared with estimate factors or equations to predict daily milk yield. First, factors were estimated as the ratio of the sum of daily yield to the sum of partial yield within a parity-MINT class (13 intervals in 2 parities) [Method 1] or as the sum of the ratios of daily yield to partial daily yield for each cow-day divided by the number of cow-days within parity-MINT class [Method 2]. Resulting factors from both methods were smoothed, applied to data, and residuals were regressed on days in milk (DIM). Regression equations (n = 112) were also developed within parity-MINT-DIM classes (2 × 7 × 8) [Method 3] to jointly account for MINT and DIM. Separate factors were derived for milking 1, 2, and 3 for each trait in L1 and L2. Method 3 resulted in consistently strongest correlations between estimated and actual yields, and smallest variances of estimates, and root mean squared errors (rMSE) for milkings 1, 2, and 3 in L1 and L2. Method 3 resulted in rMSE of 3.12 (Milking 1, L1), 3.26 (Milking 2, L1), 3.25 (Milking 3, L1), 4.52(Milking 1, L2), 4.72 (Milking 2, L2)and 4.57 (Milking 3, L2) kg; compared with rMSE of 3.58, 3.66, 3.59, 5.13, 5.41, and 5.09 kg, respectively, from current factors for the same milkings for L1 and L2. The multiple regression methodology (Method 3) appears to provide the most accurate prediction of daily milk weight from a single milking for herds milking 3x daily.

Key Words: milking interval, adjustment factor, milking frequency

W33 Genetic relationship between milk urea nitrogen and milk constituents in Holstein dairy cows. N. Ghavi Hossein-Zadeh*[1] and M. Ardalan[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Guilan*, *Rasht, Iran*, [2]*Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*, *Karaj, Iran*.

The objectives of this study were to estimate the heritability of milk urea nitrogen (MUN) concentration and describe the genetic and phenotypic relationship between MUN and other milk constituents in Iranian

Holstein dairy cows. Lactation records including MUN data obtained from 57301 dairy cows on 20 large dairy herds in Iran between January 2005 and June 2009. Genetic parameters were estimated using an animal model with covariates for days in milk and age at first calving, fixed effects for season of calving and effect of lactation number, and random effects for herd-test day, animal, permanent environment, and residual error. Coefficient of variation for MUN was 38.76%. Estimated heritability for MUN was 0.14. Phenotypic trend of MUN increased significantly over the years. Also, phenotypic correlations of MUN with milk production traits were close to zero. The genetic correlation was close to zero for MUN and lactose percentage (- 0.07); was moderately positive for MUN and net energy concentration of milk (0.24), fat percentage (0.23), protein percentage (0.34), total solids (0.29), solids-not-fat (0.31), and milk yield (0.25), and was negative for MUN and somatic cell score (- 0.14). Herd-test day explained 52% of the variation in MUN, which suggests that management adjustments at herd-level can reduce MUN. This study shows that it is possible to influence MUN by herd management and by genetic selection.

Key Words: milk urea nitrogen, dairy cattle, milk traits

W34 Genetic relationship between milk urea nitrogen and reproductive performance in Iranian Holsteins. N. Ghavi Hossein-Zadeh*[1] and M. Ardalan[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Guilan, Rasht, Iran*, [2]*Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran*.

The objective of this study was to describe the genetic and phenotypic relationship between milk urea nitrogen (MUN) and reproductive traits in Iranian Holstein dairy cows. Lactation records including MUN data obtained from 57301 dairy cows on 20 large dairy herds in Iran between January 2005 and June 2009. Genetic parameters for MUN and reproductive traits were estimated with an animal model using ASREML. Herd-test-day or herd-year-season along with age at calving and days in milk were included as fixed effects in all models. Heritabilities for MUN and reproductive traits were estimated separately for first lactation, second lactation, and third lactation. Estimated heritabilities for MUN varied from 0.18 to 0.21. Heritability estimates were low for reproductive traits and ranged from 0.02 to 0.06 for different traits across parities. Except for days open, phenotypic and genetic correlations of MUN with reproductive performance traits were close to zero. Genetic correlations between MUN and open days were 0.22 in first lactation, 0.33 in second lactation, and were 0.46 in third lactation. On the other hand, phenotypic correlations between MUN at different parities were moderate (0.29 to 0.34), but genetic correlations between MUN at different parities were high and ranged from 0.84 to 0.97. This study shows that it is possible to influence MUN by genetic selection.

Key Words: milk urea nitrogen, dairy cow, reproductive traits

W35 Adjusted phenotypic trend estimation for peak milk yield of Iranian Holsteins milked three times daily. H. Farhangfar*[1], M. Bashtani[1], and J. Modarresi[2], [1]*University of Birjand, Birjand, Iran*, [2]*Agricultural Jihad Organisation, Birjand, Iran*.

The main aim of this study was to estimate adjusted phenotypic trend for sample milk yield at peak time of thrice a day milking Iranian Holstein cows. A total of 212,889 sample milk yields (at third month of lactation) collected from 70,963 Iranian first lactation Holstein cows calving from 1997 to 2008 were used. All cows were milked 3 times a day: morning, noon and night. The number of herds was 739. The average milk samples were 10.792, 10.366 and 10.310 kg for morning, noon and night milking respectively. To analyze the data, a fixed statistical linear model was used. In the model, fixed effects of herd, year and season of calving, time of milking as well as covariables of Holstein gene percentage, first calving age and days in milk were included. In the model, 2-way interactions between season of calving and time of milking and between year of calving and time of milking were also taken into account. For fitting the model General Linear Model (GLM) procedure of SAS program was applied. Results indicated that all effects except days in milk had statistically significant ($P < 0.01$) influences on milk samples at peak time. Morning sample milk yield was revealed to be significantly different from night sample ($P < 0.05$) while no significant difference were found between morning and noon and between noon and night milk samples. Linear regression analysis of adjusted milk sample yields on year of calving ($R^2 = 0.974$) showed a positive significant ($P < 0.001$) phenotypic trend of 0.168 kg for sample milk yield over the period of time. As the phenotypic trend consisted of genetic (resulted from genetic selection for high producing cows) and environmental trends (good dairy herd management practices such as appropriate ration formulation, and good animal health), further research is needed in future to be carried out to estimate genetic part of phenotypic improvement of sample milk yield in Iranian Holsteins.

Key Words: Iranian Holsteins, phenotypic trend, milk sample

W36 REML estimates of heritability and repeatability for monthly test day milk yield of primiparous Iranian Holsteins. A. Seyed Dokht*[1], H. Farhangfar[2], A. A. Aslami Nezhad[1], and M. Tahmorespour[1], [1]*Ferdowsi University of Mashhad, Mashhad, Iran*, [2]*Birjand University, Birjand, Iran*.

In this research, a total of 634,949 monthly test day milk records collected from 72,523 Iranian Holstein first lactation cows calving between 1999 and 2008 were utilized to estimate heritability and repeatability using restricted maximum likelihood (REML) statistical approach. The records were obtained from 724 herds over 19 provinces in the country. All monthly test day records were obtained from 3-times a day milking cows. The average monthly test day milk yield in the whole data set was 29.11 kg (SD = 7.07 kg). A repeatability test day animal model was used. In the model, fixed contemporary group (combining province-herd-year of recording-season of recording), stage of lactation (10 stages), and covariables of Holstein gene percentage, days in milk nested in the stage of the lactation, and age of cow at recording (in month) were included. The random part of the model consisted of additive genetic, permanent environment and residual effects. The total number of animals (including daughters, sires and dams) in the pedigree was 101,601. DMU software was run in a Pentium 4 computer with 4 gigabyte memory to fit the animal model. Additive genetic, permanent environment and residual variance estimates were 4.352, 13.494 and 15.335 kg2 respectively. The results revealed that heritability and repeatability of monthly test day milk yield were 0.131 and 0.537 respectively. Low heritability of monthly test day milk yield obtained in this study indicates major part of the phenotypic variation for the trait under consideration is resulted from the temporary environment and model unexplained variation revealing that genetic selection based upon test day milk records may not be as cost effective as the traditional lactation model for which there is usually a higher heritability.

Key Words: Iranian Holsteins, genetic parameters, test day milk yield

W37 Correlation between milk components with regard to the season in Iranian dairy herds. A. Laki*, S. Babaei, N. Hedayat-

Evrigh, M. Dehghan-Banadaky, and K. Rezayazdi, *Department of Animal Science, Campus of Agriculture, University of Tehran*, *Karaj, Tehran, Iran*.

Previous studies showed a positive correlation between somatic cell count (SCC), fat and protein, and a highly significant negative correlation between SCC and lactose content. The aim of this study was to determine the correlation between milk components in different seasons in Iranian dairy herds. All test-day data (n = 126,357), including milk composition measured by infrared test method at the Tehran milk quality laboratory, were collected from 124 commercial Holstein dairy herds in the State of Tehran during a 4-year period (2004–2008). Overall means for fat, protein, SCC, lactose, total solids, solids-not-fat, and milk urea nitrogen were 3.54%, 3.15%, 424,370 cells/ml, 4.54%, 11.52%, 9.12% and 17.43 mg/ml respectively. The data showed a statistically significant ($P < 0.01$) positive correlation between SCC and fat (0.04) and protein content (0.11), and between fat and protein (0.17); and a highly significant negative correlation between SCC and lactose content (−0.26). With regard to season, the correlation between fat and protein was lowest in spring (0.11) and highest in fall (0.188). Also the correlation between lactose and SCC was lowest in summer (−0.23) and highest in fall (−0.28). The correlation between protein and SCC was the lowest in spring and the highest in fall (Table 1).

Table 1. Correlation coefficients between milk components in different season

Season	Fat & Protein	Fat & Lactose	Fat & SCC	Protein & Lactose	Protein & SCC	Lactose & SCC
Spring	0.11[b]	–0.02 [a]	0.05 [b]	0.04 [b]	0.09 [b]	–0.26 [b]
Summer	0.187 [b]	–0.08 [b]	0.06 [b]	–0.08 [b]	0.11 [b]	–0.23 [b]
Fall	0.188 [b]	–0.10 [b]	0.04 [b]	–0.14 [b]	0.13 [b]	–0.28 [b]
Winter	0.16 [b]	–0.03 [b]	0.03 [b]	–0.05 [b]	0.11 [b]	–0.27 [b]

[a]significant at ($P < 0.05$); [b]significant at ($P < 0.01$).

Key Words: correlation coefficient, milk composition, season

W38 Comparison of fixed and random regression test day models in genetic evaluation of Iranian Holsteins for protein yield. M. Bashtani*, H. Farhangfar, H. Naeemipour, M. R. Asghari, A. Arab, and M. Jafari Tarbaghan, *Birjand University*, *Birjand, Iran*.

The main objective was to compare 2 test day models (with fixed or random regressions) applied for genetic evaluation of protein yield trait in Iranian Holsteins. The data were 57,551 protein test day records from 7036 first parity Holstein cows calved between 2003 and 2006. Total number of herds (located in Razavi Khorasan province), sires, dams and animals in pedigree file were 138, 590, 6091 and 13117 respectively. Contemporary groups were defined based on combining herd - year - season of production - milking times (HYSM). The response variable was test day protein yield for which there was an average 918 gr (SD = 225.8 gr) in the whole data set. In fixed and random regression test day models, HYSM (fixed effect), calving age (linear and quadratic covariables), Holstein gene percentage (linear and quadratic covariables), and random effects of additive genetic and permanent environment were included. To take account of the shape of the lactation curve at phenotypic, genetic and environmental levels, orthogonal Legendre polynomials were also included in the models so that the order of the Legendre fit was level and cubic for fixed and random regression test day models, respectively. Fixed and random regression test day models were run using WOMBAT and DXMRR software, respectively. The results indicated there was a very high rank correlation coefficient (0.936) between predicted breeding values (PBV) which was statistically significant ($P < 0.001$). Averages PBV of progeny were found to be −0.209 and −0.037 gr for fixed and random regression test day models, respectively which were not significantly different from each other. It can therefore be concluded that fixed regression test day model could be used instead of random regression test day model in genetic evaluation of Iranian Holsteins for protein test day records in particular where computational capacity is limited for running a random regression test day model at the national scale.

Key Words: Iranian Holsteins, test day protein yield, random regression

W39 Estimation of udder composite in the Holstein population of Iran. M. R. Bakhtiarizadeh*, M. Moradi Shahr Babak, and A. Pakdel, *University of Tehran*, *Karaj, Tehran*.

The objective of the present study was to estimate the weights of udder type traits in udder composite (UC) of Holstein cattle in Iran. Records generated for first lactation Holstein dairy cows from 1991 to 2007 over 220 herds. The genetic parameters and relationships between udder traits and functional traits (milk yield, longevity, and somatic cell score (SCS)) were estimated and data (included udder type traits (udder depth (UD), fore udder attachment (FU), rear udder width (RUW), rear udder height (RUH), fore teat placement (FTP), rear teat placement (RTP), suspensory ligament (SL)), milk production, SCS and pedigree) were used by Animal Breeding Center in Iran. The genetic parameters were estimated by ASREML software and also SelAction software was used for estimating coefficient importance of functional traits. The equation Y = Rg*v was used for estimating UC. In this equation, Y is weight of udder type traits in UC trait, Rg is the genetic correlation between the udder type traits and functional traits and v is importance coefficient of functional traits that were estimated from SelAction software. Heritability estimates for the udder type traits ranged from 0.1 (FU) to 0.19 (RTP). Heritabilities were 0.05, 0.07, and 0.28 for longevity, SCS and milk production, respectively. The genetic correlation among udder type traits and longevity ranged from 0.41 (UD) to −0.33 (RTP), among udder type traits and SCS ranged from 0.85 (RUW) to −0.6 (FU), among udder type traits and production ranged from 0.34 (RUW) to −0.31(UD). The importance coefficient of functional traits were 0.55, 0.38 and −0.07 for milk production, longevity and SCS, respectively. Finally the UC trait has been shown as follows (PTA is predicted transmitting ability):
UC= (−0.091*PTAfu)+(0.015*PTAruh)+(−0.035*PTAruw)+(−0.015*PTAsl)+(0.134*PTAud) +(0.69*PTAftp) +(−0.015*PTArtp).
In this study breeding goal was to decrease SCS and increase milk production and longevity by applying the UC trait. Consequently, each trait that has a desirable relationship with functional traits in the breeding goal has a higher coefficient in UC trait.

Key Words: udder composite, type traits, genetic parameters

W40 Bayesian estimates of genetic parameters for cystic ovarian disease, displaced abomasum and foot and leg diseases in Iranian Holsteins via Gibbs sampling. N. Ghavi Hossein-Zadeh*[1] and M. Ardalan[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Guilan*, [2]*Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*.

The objective of this study was to estimate heritability and genetic correlations between cystic ovarian disease (COD), foot and leg diseases (FLD), and displaced abomasum (DA) within the first 3 lactations of

Holstein dairy cows. The records of 57,301 dairy cows on 20 large dairy herds in Iran between January 2005 and June 2009 were analyzed with univariate and bivariate threshold animal models, using Gibbs sampling methodology. The final model included the fixed class effects of herd-year, season of calving, parity of dam, the linear covariate effect of age at calving, and additive direct genetic effect of animal. Posterior means of heritability in first, second, and third lactations were 0.14, 0.18, and 0.20, respectively, for FLD; 0.08, 0.10, and 0.11 for COD; 0.05, 0.06, and 0.08 for DA. Posterior means of genetic correlations between diseases were low (from 0.02 to 0.12), within lactations; the largest estimates were for FLD and DA, and the lowest involved FLD and COD. Positive genetic correlations between diseases suggest that some general disease resistance factor with a genetic component exists. The results of this study indicated the importance of health traits for considering in the selection index of Iranian Holstein dairy cows.

Key Words: Bayesian methods, cystic ovarian disease, displaced abomasum

W41 Bayesian estimates of genetic parameters for metritis, retained placenta, milk fever, and clinical mastitis in Holstein dairy cows via Gibbs sampling. N. Ghavi Hossein-Zadeh*[1] and M. Ardalan[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Guilan*, [2]*Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*.

The objective of this study was to estimate heritability and genetic correlations between the liabilities of clinical mastitis (CM), milk fever (MF), metritis (MET), and retained placenta (RP) within the first 3 lactations of Holstein dairy cows. The records of 57,301 dairy cows from 20 large dairy herds in Iran between January 2005 and June 2009 were analyzed with univariate and bivariate threshold animal models, using Gibbs sampling methodology. The final model included the fixed class effects of herd-year, season of calving, parity of dam, the linear covariate effect of age at calving, and the random direct genetic effect of animal. Posterior means of heritability for liabilities in first, second, and third lactations were 0.06, 0.08, and 0.09, respectively, for CM; 0.10, 0.12, and 0.11 for MF; 0.09, 0.07, and 0.10 for MET, and 0.07, 0.08, and 0.08 for RP. Posterior means of genetic correlations between disease liabilities were low or moderate (from −0.01 to 0.26). The results of this study indicated the possibility of considering health traits in the selection index of Iranian Holstein dairy cows.

Key Words: Bayesian methods, clinical mastitis, metritis

W42 Genetic relationships between somatic cell count, milk production and udder conformation traits in Iranian Holsteins. M. R. Sanjabi*[1], A. Gholibaigi Fard[2], R. Vaez Torshizi[2], A. Lavaf[2], and A. H. Ahadi[1], [1]*Iranian Research Organization for Science and Technology, Tehran, Iran*, [2]*Azad University, Karaj, Iran*.

Heritabilities and genetic correlations between milk yield (MY), fat percentage (FP), protein percentage (PP), somatic cell count (SCC) and udder type traits in 10 dairy Holstein herds near Tehran on 3500 lactations were evaluated. The DFREML software was used for calculation of variance components and heritabilities of individual traits, and genetic correlations were estimated using Harvey's software. Heritabilities were low for SCC (0.04), moderate for MY (0.19) and FP (0.24), and high for PP (0.48). For type traits, heritability estimates ranged from 0.04 to 0.55. The estimated genetic correlation between SCC and udder type traits varied from −0.78 to 0.51 and estimated genetic correlations between SCC and MY, FP and PP were 0.15, 0.03, and 0.04, respectively. In general, the cows with shallow and tightly attached udders and closer teat placement had lower somatic cell count and lower risk of mastitis. In summary, it appears that selection for improved udder conformation will reduce SCC and clinical mastitis among cattle selected for high milk production.

Key Words: dairy cattle, genetic parameters, somatic cell count

W43 Microbiological quality of pasteurized milk from Minas Gerais state, Brazil. E. H. P. Andrade, M. O. Leite*, M. R. A. Moura, T. Roza, C. F. A. M. Penna, M. M. O. P. Cerqueira, L. M. Fonseca, and M. R. Souza, *Federal University of Minas Gerais*, *Belo Horizonte, Minas Gerais, Brasil*.

The objective of this work was to evaluate the microbiological quality of pasteurized milk from different regions of Minas Gerais state, Brazil, from 2006 to 2008, to verify compliance with Brazilian standards. This state is the largest dairy producer region in Brazil, with about 7 million metric tons of milk production for the year 2008. The analyzed parameters were: aerobic mesophilic microbial counting, total and thermotolerant coliforms, *Salmonella* spp. presence and *Staphylococcus* coagulase positive counting. It was observed that 42 (70%) of the 60 samples were in disagreement with Brazilian microbial standards with at least one parameter not in compliance with the requirements. Only 18 (30%) was in accordance to the legal requirements for all parameters evaluated. Of the total of samples used in this study, 18 samples (30%) presented more than the maximum allowance for aerobic mesophilic microbial counts, 35 (58.3%) were in disagreement for total coliforms, with 23 samples (38.3%) above the limit for thermotolerant coliforms, and 2 samples (3,3%) with *Salmonella* contamination.

Key Words: milk quality, microbiology

W44 The relationships between somatic cell count and bacteriology on milk quality and production in dairy goats. K. N. Baker*, S. D. Horner, D. K. Rucker, L. C. Nuti, and G. R. Newton, *Prairie View A&M University*, *Prairie View, TX*.

Somatic cell count (SCC) in milk is an indicator of mammary infections and a barrier for production of grade A milk. The relationships between mammary infection and SSC are not clear in goats. Two experiments were conducted to evaluate the incidences of sub-clinical mastitis on mammary health and milk production. The effects of a protective teat dip and intra-mammary infusion of antibiotics on milk production, composition, SCC and bacteriology were evaluated in a 2 by 2 factorial design. At dry-off and on d 3–5 of the next lactation, goats (n = 50) were screened for the presence of intra-mammary infections. At dry-off 80% of the halves sampled were negative for bacteria. This percentage increased to 84% at the start of the next lactation. Mammary treatments did not influence the incidence of mammary infection at the start of lactation when compared with halves receiving no treatments. Content of milk fat (5.77 ± 0.5%), protein (3.92 ± 0.04%), lactose (6.06 ± 0.07%) and SCC (721 ± 302/ml) were not affected by mammary treatments. Next, milk was collected from goats (n = 65) once a month from March through November to evaluate the relationships between milk production, SCC and bacteriology. SCC in uninfected halves displayed a curvilinear increase ($P < 0.01$) with lowest values recorded in March (260 ± 11.1/ml) and highest values observed in November at the end of lactation (2075 ± 11.1/ml). SCC in infected halves did not differ during the sampling period ($P > 0.1$) and was consistently higher than samples from uninfected halves. In March SCC was 1242 ± 556/ml in infected halves. Values remained elevated through out the sampling period, reaching a peak in November (3158 ± 556/ml). Milk production by infected and uninfected halves did not differ. Production was highest in March (1.18 ± 0.03 L/half) and steadily declined to a nadir in November (0.48 ± 0.03 L/half; $P < 0.01$). Therefore, sub-clinical mastitis contributes to elevated SCC levels through out lactation. However, elevated SSC in uninfected halves late in lactation may also influence the ability to produce and market grade A milk.

Key Words: milk, bacteriology, quality

W45 Biodiversity of enterococci in Egyptian dairy products. S. Awad*[1], C. Snauwaert[2,3], P. Vandamme[3], A. El Attar[1], and M. El Soda[1], [1]*Department of Dairy Science and Technology, Faculty of Agriculture, Alexandria University*, *Alexandria, Egypt*, [2]*BCCM/LMG Bacteria Collection, Ghent University, K.L. Ledeganckstraat 35, 9000 Ghent, Belgium*, [3]*Laboratory of Microbiology, Ghent University*, *K.L. Ledeganckstraat 35, 9000 Ghent, Belgium*.

Egyptian dairy products are generally produced under artisan conditions from raw milk without using industrial starter cultures. The main traditional cheeses are Ras (hard type), Domiati (soft type), and Mish; and the main fermented milk products are Zabady and Laban Rayeb. The quality of these products is strictly dependent on the microbial associations responsible for the fermentation, and the biodiversity of lactic acid bacteria. Enterococci are ubiquitous bacteria present in the environment and in the gastrointestinal tract of healthy animals and humans. To study the biodiversity of enterococci strains of the Egyptian Dairy products, 364 samples (raw & fermented milk and cheeses) were collected from farm houses, traditional cheese making factories and local markets in the Delta region, Egypt, and enterococci were isolated. All isolates were tested for their Gram reaction, catalase activity, and morphology. API and SDS-PAGE were used for identification of 784 isolates. Rep-PCR fingerprinting technique with the (GTG)5 primer and, in some cases pheS and 16S rRNA genes sequencing were also used to confirm the identification. These results confirm the importance of using molecular methods for exhaustive and precise identification of the microbial flora occurring in artisanal cheeses.

Key Words: Egyptian dairy products, (GTG)5-PCR, lactic acid bacteria

W46 Identification, characterization, and differentiation of bifidobacteria obtained from Ukraine. L. Tmanova*, A. Onyenwoke, and R. F. Roberts, *The Pennsylvania State University*, *University Park*.

Speciation of bifidobacterial isolates using traditional biochemical and phenotypic methods is tedious and often provides inconclusive results. DNA-based methods often yields clearer results. Ten freeze-dried bifidobacterial strains used as probiotics in Ukraine and identified by the supplier as *Bifidobacterium adolescentis* (2), *Bifidobacterium bifidum* (2), *Bifidobacterium longum* (4), *Bifidobacterium animalis* (1), and *Bifidobacterium infantis* (1) were characterized using polymerase chain reaction (PCR), pulsed field gel electrophoresis (PFGE) and allelic profiling. After anaerobic growth on MRS-cysteine (MRS) at 37°C for 72 h, single colony isolates were picked and evaluated using PCR primers specific for the genus, relevant species and for *B. animalis* ssp. *lactis*. All 10 isolates were identified as members of the genus *Bifidobacterium*. However, species-specific PCR revealed all 10 isolates were *B. animalis* ssp. *lactis*. Further evaluation using PFGE to assess strain relatedness showed all 10 isolates gave PFGE patterns identical to the type strain DSMZ 10140^T when digested with *Spe*I. When digested with *Xba*I, 9 of the isolates gave patterns identical to DSMZ 10140^T. One strain, RT09, had one extra band when digested with *Xba*I. Allelic profiling of the Ukrainian bifidobacterial strains, revealed 4 distinct groups.

Interestingly, 6 (60%) of the isolates fell into the same cluster as that containing the common commercial probiotic strain BB-12. Our results demonstrate the conventional phenotypic methods used to characterize these isolates were sufficient to assign the correct genus, but not the correct species. These findings highlight the importance of employing molecular methods when typing bifidobacterial isolates.

Key Words: *Bifidobacterium animalis* ssp. *lactis*, allelic profiling, probiotics

W47 Buffering capacity affects starter bacteria in nonfat probiotic yogurt. M. Michael, R. K. Phebus, and K. A. Schmidt*, *Kansas State University*, *Manhattan*.

Sodium acetate has been reported to increase acid production and growth yield of some lactic acid bacteria in the growth medium predominately due to its buffering capacity. A buffering agent in yogurt mix may counteract the lethal effect of acid accumulation on starter and probiotic bacteria resulting in greater microbial counts at the end of fermentation. The objective of this study was to determine if changes in yogurt mix's buffering capacity could enhance starter and/or probiotic counts at the end of fermentation. Four nonfat yogurt mixes were prepared with 0.25% sodium acetate (SA) and 4 with no supplement (NS). Mixes were inoculated with yogurt starter alone or yogurt starter and *B. animalis*, *L. acidophilus* or both probiotics, and fermented in a bioreactor at 40°C until pH 4.50. Buffering curves of mixes were generated and pH, titratable acidity (TA) and microbial enumeration were done on an hourly basis during fermentation. Two replications were done and differences in means were determined using LSD at $\alpha = 0.05$ with SAS. Results showed that SA-supplemented mixes had greater buffering capacity at pH <6.00 than that of NS mixes. At the end of fermentation, SA supplementation resulted in greater S. thermophilus counts (~4 to 5%) in yogurts fermented with starter and *B. animalis* or *L. acidophilus*, and greater *L. bulgaricus* counts (~6%) in yogurts fermented with starter and *B. animalis* as compared with NS yogurts. *B. animalis* growth was not affected by the supplementations or fermentation bacteria. No significant differences in *L. acidophilus* counts were observed at the end of fermentation based on supplementation or fermentation bacteria. At pH 4.50, SA-supplemented yogurts had greater TA compared with NS yogurts. In general, fermentation time was longer for SA-supplemented mixes or mixes fermented with *L. acidophilus*. These results suggest that SA supplementation increased the buffering capacity of yogurt mix which improved the starter bacteria counts at the end of fermentation; however, further research should address if SA supplementation of yogurt mix could improve the viability of starter and/or probiotic bacteria in yogurt during storage.

Key Words: yogurt, probiotics, buffering capacity

W48 Identification of lactic acid bacteria in Taiwanese ropy fermented milk and evaluation of their microbial ecology in different milk. K. N. Chen[1], S. Y. Wang[2], and M. J. Chen*[2], [1]*Tungnan University*, *Taipei, Taiwan*, [2]*National Taiwan University*, *Taipei, Taiwan*.

Taiwanese ropy fermented milk (TRFM) is a domestic fermented milk. Its real original is unknown, but it has spread from family to family in northern Taiwan. TRFM has a stringy texture, a good diacetyl flavor and a pleasant taste. The purpose of this study was to identify species of lactic acid bacteria (LAB) in TRFM and to study their microbial dynamics during the fermentation process. The effects of different type of milk on the microbial ecological profiles were also investigated in this study. Ten grams of TRFM starters were homogenized in a laboratory blender. Concentrations of the viable LAB and yeasts in suspensions were obtained by serial plating dilutions. A combination of conventional microbiological cultivation, polymerase chain reaction-denaturing gradient gel electrophoresis and DNA sequencing was used to identify microorganisms and study their microbial dynamics. Identification results indicated that *Lactococcus lactis* ssp. *cremoris* and *Leuconostoc mesenteroides* ssp. *mesenteroides* were the major LAB in TRSM. Interestingly, three groups were identified as *Lactococcus lactis* ssp. *cremoris* using r16S DNA sequencing, but they showed different DGGE patterns and assimilation of carbohydrates. In addition, the microbial dynamics study in different fermentation stages demonstrated that *Lc lactis* ssp. *cremoris* was the most dominant bacterial species in the samples, followed by *Leu. mesenteroides* ssp. *mesenteroides* with no differences among the fermentation stages. Finally, the microbial distribution profiles showed that the microbial ecology was different in bovine, caprine and reconstituted milk, which might further affect the characteristics of the product. In this study, we demonstrated that *Lc lactis* ssp. *cremoris* and *Leu. mesenteroides* ssp. *mesenteroides* were the major LAB in Taiwanese ropy fermented milk. The percentages of the prevalent LAB populations present at different stages during the sample fermentation were similar. we also showed that the type of milk had a great influence on the microbial ecology.

Key Words: ropy fermented milk, microbial ecology, DGGE

W49 Summary of a 2-year study involving screening, characterization, and environmental scanning of bacteria with the potential to produce ropy milk in a farm. A. Laubscher*[1], H. Guo[1], K. White[1], B. Rossi Paneto[1], A. Cano[1], R. Cano[2], and R. Jiménez-Flores[1], [1]*Dairy Products Technology Center, California Polytechnic State University*, *San Luis Obispo,* [2]*Biological Sciences Department, California Polytechnic State University*, *San Luis Obispo*.

Prevention of microbial contamination in raw milk is an important objective in farms where value added is tied with quality. Recent reports of ropy milk have made us aware again of the problem. Ropy milk is characterized by its viscosity and tendency to form a slimy thread. The viscous character of the milk is produced by a complex oligosaccharide present in the capsule of different microorganisms. Over 250 raw milk samples were received from plants throughout the southern states. Of the 5 types of colonies observed, only one appears to have the "ropy" characteristic of mucoid. Isolated mucoid strains were tested for ropy milk production by inoculation in UHT milk and incubation at 25°C for 36 h. The "ropy test" proved successful with 100% reproducibility, but it was discovered that not all mucoid isolates produce a positive RM test. Using API biochemical identification tests, over 80% of the 160 positive "ropy tests" are in the *Klebsiella* species. This result gives us the belief that the presence of ropy milk can be correlated to coliform counts. The objectives were to identify high-risk areas for contamination of the responsible bacteria, the correlation with coliform and *Escherichia coli* (E/C) counts, and development of a subjective or quantitative method to evaluate the risk of finding ropy milk producing bacteria. Ten locations were examined on the Cal Poly Dairy Farm, with bedding having the highest E/C counts and the most probable source for ropy-causing bacteria contamination on the farm. The threshold for the enumeration of ropy-causing bacteria was determined to be only 2.5 CFU/10 mL in a sterile milk sample was enough to turn the milk ropy. With tests performed in triplicate, the threshold of the ropy-causing bacteria is much higher in the presence of typical raw milk microorganisms, suggesting a poor competitive nature. Our results indicate that "ropyness" is a result of a presumptive *Klebsiella oxytoca/pneumoniae* (coliform) a poor-competing bacteria and ubiquitous under poor sanitary conditions, in particular those associated with biofilm formation.

Key Words: milk quality, *Klebsiella*, ropy milk

W50 Screening of *Lactobacillus casei* strains for the application of yogurt starter and probiotics. J. K. Choi*, J. H. Im, and G. B. Kim, *Department of Animal Science & Technology, Chung-Ang University*, *Anseong 456-756, South Korea*.

Lactobacillus casei is one of the most important probiotics, and it is widely used in functional foods and dairy products. As a trial for the development of a new starter culture, more than 200 lactic acid bacteria strains were isolated from raw milk and healthy human feces. The strains showing excellent growth and acid production ability in the 10% skim milk media were selected and identified as *Lactobacillus casei* by the result of API carbohydrate fermentation pattern and 16S rDNA sequence analysis. Among the selected strains, *L. casei* CU2604 and CU3204 were further investigated for their physiological characteristics as a starter culture comparing them with a commercial strain, *L. casei* Shirota. Both CU3204 and CU2604 strains showed good acid production and growth characteristics in milk, which are comparable with those of *L. casei* Shirota strain. However, *L. casei* CU2604 was the only selected strain that had a similar sugar fermenting pattern and PFGE band pattern compared with *L. casei* Shirota. Furthermore, CU2604 showed better tolerance to bile and to pH than *L. casei* Shirota. In addition, to assess the effect of *L. casei* strains in irritable bowel syndrome (IBS), the inhibitory effect of the selected strains against nitric oxide (NO) production of lipopolysaccharide (LPS)-stimulated RAW 264.7 cells was measured. Among the tested *L. casei* strains, *L. casei* MCL was observed to have the greatest NO inhibitory activity. Based on these results from this study, we anticipate the possible use of *L. casei* MCL strain as a new probiotic and CU2604 as a new starter culture.

Key Words: *Lactobacillus casei*, yogurt starter, probiotics

W51 Effect of yogurt consumption on the human intestinal microbiota. H. J. Kim*[1], S. J. Eom[1], Y. T. Ahn[2], J. H. Lee[2], C. S. Huh[2], and G. B. Kim[1], [1]*Department of Animal Science and Technology, Chung-Ang University*, *Anseong 456-756, South Korea*, [2]*Research and Development Center. Korea Yakult Co. Ltd.*, *Yongin 449-901, South Korea*.

In this study we investigated the effect of consumption of yogurt on the fecal microflora of 40 healthy volunteers. The subjects were randomly divided into experimental (n = 20) and control (n = 20) groups for a double-blind placebo-controlled clinical study. The experimental group consumed yogurt 2 times a day (150mL each) for 3 weeks and the control groups consumed the same amount of milk acidified with lactic acid. Fecal samples at defined time points before, during, and after the period of yogurt ingestion were collected and analyzed. The fecal population of lactobacilli and bifidobacteria was determined by culture-based methods using Rorosa SL agar and TOS-propionate agar media, respectively, and subsequent colony PCR for the confirmation of the target Genus. The comprehensive dynamics of intestinal microbiota in response to yogurt consumption was analyzed using a bacterial barcoded pyrosequencing.

The population of bifidobacteria in the fecal sample of experimental group increased from 9.65±0.56 to 10.20±0.41 (log_{10} cells/g wet feces, mean ± SD) during the ingestion of yogurt, but it tended to be normalized (9.67±0.84) when they stopped the ingestion. The similar tendency was observed in the population of lactobacilli during the experiment; however, there were no significant changes in the control group. Molecular analysis of the human fecal bacterial populations by pyrosequencing of 16S rRNA tags revealed that yogurt consumption induced significant alterations of the gut microbiota. The ratio of *Firmicutes* to *Bacteroidetes* was 1.23, 0.59, and 2.01 at the time points before, during, after the period of yogurt ingestion, respectively. This study provides evidence that the gut microbiota could be modulated by dietary intenvention such as yogurt ingestion and further studies should be done to better understand the modulation of the gut microbiota associated with health attributes in well-defined human clinical studies.

Key Words: yogurt, pyrosequencing, microbiota

W52 The effect of fermented yogurt on the prevention and treatment of diarrhea in animal models. J. H. Im*[1], J. K. Choi[1], M. H. Lee[2], J. H. Sim[2], C. S. Huh[2], and G. B. Kim[1], [1]*Department of Animal Science & Technology Chung-Ang University*, *Anseong 456-756, South Korea*, [2]*Research and Development Center. Korea Yakult Co., LTD.*, *Yongin 449-901, South Korea*.

Constipation is the most prevalent health condition in the world. Common symptoms are difficult stool passage, infrequent stools, or both. Dairy products such as milk and yogurt improve intestinal function. The objective of this study was to investigate the improvement of intestinal function, the prevention of constipation, and the curative value of supplying fermented milk products to mice and rats. Constipation was induced by oral administration of loperamide and experiments were executed for 5 consecutive days. All experiments separated research subjects into 3 groups; the control, the treatment of loperamide alone, and the treatment of low, medium, and high levels fermented milk. The results showed that the effects varied significantly among different levels of doses in that: 1) The digestive tract transfer rate showed that the control 44.2%, low levels 51.7%, medium levels 67.4%, high levels 67.7%; 2) Constipation preventive effect showed that the water and food intake, and the amount and number of feces decreased significantly with loperamide alone, low, medium levels ($P < 0.001$, $P < 0.05$, $P < 0.01$). However the treatment of loperamide with fermented milk increased the number of feces significantly at high level ($P < 0.05$), amount of feces increased significantly at low, high levels ($P < 0.05$, $P < 0001$), also water contents increased. 3) Effective treatment of constipation showed that the water and food intake decreased significantly; the number of feces increased significantly at medium level ($P < 0.001$), weight of feces showed similar results. Water contents increased significantly at medium, high levels ($P < 0.05$, $P < 0.001$). These results suggest that the repetitive ingestion of fermented yogurt is effective to prevent and treat constipation in animal models.

Key Words: animal trials, fermented yogurt, constipation

W53 Effect of milk fermented by *Lactobacillus rhamnosus* on an experimental infection with *Salmonella enterica* ssp. *enterica* serov. Typhimurium in gnotobiotic and conventional mice. A. H. Mendonça[1], M. M. O. P. Cerqueira*[2], J. R. Nicoli[2], M. O. Leite[2], M. R. Souza[2], L. M. Fonseca[2], R. M. N. Drummond[2], R. M. E. Arante[2], and C. F. A. M. Penna[2], [1]*Ministry of Agriculture*, *Brasília, Distrito Federal, Brasil*, [2]*Federal University of Minas Gerais*, *Belo Horizonte, Minas Gerais, Brasil*.

An experimental infection with *Salmonella enterica* ssp. *enterica* serov. Typhimurium was evaluated in gnotobiotic (GN) and conventional (CV) mice previously treated or not with milk fermented by a *Lactobacillus rhamnosus* strain isolated from healthy human newborn. Conventional mice received 0.1 mL probiotic milk (8.0 log CFU) daily, 10 d before the oral pathogenic challenge (5.0 log CFU). Then, probiotic treatment was continued until the end of the experiment. Probiotic treatment in germ-free mice consisted of a single dose at the beginning of the experiment

and a challenge 10 d later (3.0 CFU). Protective effect was observed in both GN and CV animals in terms of histopathology and morphometric data but in different anatomical site. This protection was observed in liver and intestines, respectively for GN and CV mice. However, *Salmonella enterica* ssp. *enterica* serov. Typhimurium populations were similar in the feces of both treated and control GN mice. Concluding, a protective effect by *L. rhamnosus* against experimental *Salmonella enterica* ssp. *enterica* serov. Typhimurium was observed. This protection was not due to the reduction of the population of pathogens in the intestine.

Key Words: fermented milk, *Lactobacillus rhamnosus*, probiotic

W54 Influence of bovine and caprine caseinomacropeptide on the viability of *E. coli* and *L. rhamnosus* in acidic conditions. G. Robitaille*, C. Lapointe, D. Leclerc, and M. Britten, *Food Research and Development Centre, Agriculture and Agri-Food Canada*, *St-Hyacinthe, QC, Canada*.

Caseinomacropeptide (CMP) is a 7-kDa phosphoglycopeptide fragment released from κ-casein during chymosin-induced renneting of milk. Bovine CMP differs from caprine CMP by 19 substitutions, 2 insertions, by glycosylation extent and the level of phosphorylation. The objective of the study was to analyze the effects of pepsin-treated CMP (CMPpt) on the survival of *E. coli* and *L. rhamnosus* in acidic conditions. To induce acid shock, bacterial cells were incubated at 37°C in PBS with or without additive (CMPpt, non-glycosylated CMPpt (aCMPpt) and glycosylated CMPpt (gCMPpt) isoforms) from bovine and caprine. Viability (CFU/mL) was determined at 0, 15, 30, 60 and 90 min. As expected, *E. coli* was sensitive to low pH. The bacterial viability decreased by more than 1.5 log within 15 min at pH ≤3.0. At pH 3.5, it took about 90 min to reach a similar decrease. When added to the media, CMPpt was bactericidal in a dose dependent manner, reducing survival by more than 90% within 15 min at ≥0.25 mg/ml. This indicates that the encrypted bioactive peptides within CMP are released by pepsin proteolysis and are bactericidal against *E. coli* at low pH. Moreover, the effectiveness of CMPpt to kill *E. coli* at pH 3.5 was not significantly affected by the presence of linked oligosaccharides or by the origin of the milk. This suggests that the active peptide is located in the N-terminal portion of the polypeptide, a region of high homology between species that does not carry any phosphate or oligosaccharide. Survival of *L. rhamnosus* at pH 2.9 decreased to about 5% within 60 min. Supplementation with bovine or caprine CMPpt has an inverse effect. It increased viability to values as high as 50%, with similar efficiencies for aCMPpt and gCMPpt. These results suggest that peptic digests of bovine and caprine CMP may act as antimicrobial agents against *E. coli* in a gastric context without any deleterious effect on the resistance of a probiotic to gastric pH.

Key Words: caseinomacropeptide, bacterial growth, gastric pH

W55 Screening of β-galactosidase-containing probiotic for the production of galacto-oligosaccharides and its optimal preparation conditions. Y. Gao, X. Mi, L. Feng, R. Zhong, B. Qian, and S. Zhang*, *Department of Food Science and Technology, School of Agriculture and Biology, Shanghai Jiao Tong University*, *Shanghai, China*.

As β-galactosidase carriers, whole probiotic cells were screened out for the production of galacto-oligosaccharides (GOS) and the optimal production conditions were investigated in this study. In this process, probiotics including 2 strains of *Bifidobacterium bifidum*, 2 strains of *Lactobacillus helveticus* and one strain of *Lactobacillus delbrueckii* ssp. *bulgaricus* were employed. A high-performance anion exchange chromatography with pulsed amperometric detection (HPAEC-PAD) was utilized for the sugar composition analyses in the prepared products. Results showed: top 3 GOS production prebiotics were *Bifidobacterium bifidum* BB03, *Bifidobacterium bifidum* BB02 and *Lactobacillus delbrueckii* ssp. *bulgaricus* with the production of GOS at 201.8 g/L100g, 160.1 g/L and 129.4 g/L, respectively. The optimal production conditions of *Bifidobacterium bifidum* BB03 were as follows: 0.20 g freeze-dried cells were transferred into a flask with 50 mL of lactose aqueous solution (473.4 g/L), shaken at the speed of 150 rpm and cultured at 37 centigrade for 8h. The fractions of GOS in this product were proved to be with 197.7 g/L dimer GOS and 4.1 g/L tetramer GOS. In addition, the production of galactose, glucose and the residual lactose in the product were presented to be 1.9 g/L, 94.3 g/L and 1.3 g/L, respectively.

Key Words: galacto-oligosaccharides, probiotic, HPAEC-PAD

W56 Characterization and partial purification of antimutagenic peptide produced by *Lactobacillus plantarum* CNU 2116. J. W. Jeong*[1], B. H. Yoon[1], D. J. Park[3], Y.-S. Son[2], and S. Oh[1], [1]*Division of Animal Science, Chonnam National University*, *Gwangju, South Korea*, [2]*Division of Bioscience & Technology, Korea University*, *Seoul, South Korea*, [3]*Korea Food Research Institute*, *Gyeonggi-do, South Korea*.

Intestinal lactic acid bacteria (LAB) are closely associated to the host's health because the presence of LAB are an important bio-defense factor in preventing colonization and subsequent proliferation of pathogenic bacteria in the intestine. Some probiotics such as *Lactobacillus* species can intoxicate the carcinogens including chemical mutagens. The antimutagenic activity of 24 LAB strains was investigated using 3 mutagens (4-nitroquinoline-N'-oxide, 4-NQO; N-methyl-N'nitro-N-nitrosoguanidine, MNNG; and 2-amino-3- methylimidasol quinoline, IQ). In the Ames test, dose-dependent activity was exhibited significantly against 4NQO, MNNG, and IQ. *Lactobacillus casei* KCTC 13086 and *L. plantarum* strains showed the highest anti-4NQO activity (62.1%) among the tested strains of LAB. The active substance was found to be sensitive to trypsin (71500 units/mL). This indicates that antimutagenic substance is proteinaceous in nature. The molecular weight of the antimutagenic peptide was estimated as an approximately 762 Da using tricine-SDS-PAGE. N-terminal amino acid residue sequence from the purified peptide was identified as NH_2 -Xaa-Leu-Glu-Xaa-Lys-Lys-Ala-Glu-Xaa-Ile-Thr-Thr. Compared with other sequences in the NCBI database using Blast program, we found no significant sequence similarity to previously reported antimutagenic peptides.

Key Words: antimutagenic activity, lactic acid bacteria, characterization

W57 Characterization of microorganisms isolated from biofilms formed on whey reverse osmosis membranes. A. C. Biswas*, M. Avadhanula, S. Anand, and A. Hassan, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University*, *Brookings*.

Microbial biofilm is a complex structure made up of organisms embedded in polymeric matrices of biological origin attached to a substratum. The present investigation was undertaken to characterize the multispecies microbial consortia isolated from reverse osmosis (RO) membranes drawn from active industrial whey filtration process at 2, 4, 6, 8, 10, 12, and 14 mo of age. The ability of the different bacterial isolates to produce capsule and slime, and increase whey viscosity as indications of exopolysaccharides (EPS) production was also studied. Results showed that *Bacillus* sp. was present on almost all RO membranes from 4 to 12 mo. *Enterococcus*, *Streptococcus*, *Staphylococcus*, *Micrococcus*, *Aeromonas*, *Corynebacterium*, and *Pseudomonas* species were also

encountered frequently. *Escherichia coli* and *Klebsiella oxytoca* were detected only on 8, 12 and 14 mo old membranes. Among all isolates, about 25% did not produce capsules or slime, or increased viscosity of whey, which indicated lack of EPS production. This reflects that strains not producing EPS can also be involved in biofilm formation. However, since the EPS production was only tested in planktonic cells, there is still a possibility that they produce EPS in biofilm matrices. Interestingly, the EPS production was more pronounced in isolates from older (8 to 14 mo old) as compared with newer (2 to 6 mo old) membranes. Studies also confirmed the ability of individual isolates to form biofilms under static in vitro conditions. Predominance of *Escherichia coli* and *Bacillus sp*. was observed during the reproduction of mixed species biofilms. The study provides useful information on the predominant bacterial species in biofilms formed on whey processing membranes. This will help in developing more effective cleaning and sanitation regimens.

Key Words: biofilm, exopolysaccharides (EPS), RO membrane

W58 Transcriptional analysis of a very broad spectrum lantibiotic produced by *Bifidobacterium longum* DJO10A. J. H. Lee*, X. Li, and D. J. O'Sullivan, *University of Minnesota*, *St Paul*.

Lantibiotics are bacteriocins produced by some gram-positive bacteria with a very broad antimicrobial spectrum. A reverse genomic analysis of *B. longum* ssp. *longum* DJO10A revealed the potential to produce a lantibiotic and subsequent analysis revealed it produced a small (<5 kDa) peptide, only on agar media, with an antimicrobial spectrum that included gram-negative bacteria. To further understand the regulation for production of this lantibiotic a full-genome microarray analysis with total RNA from both agar and broth cultures was conducted. This revealed a very different expression pattern between agar and broth cultures, including the lantibiotic-producing genes which were expressed much higher in agar. Interestingly, the expression of the 2-component regulatory genes in this operon, were relatively constant in both conditions, suggesting it should be functional in broth cultures. To further investigate this, a real-time PCR procedure, with a specific TaqMan probe targeting the lanA gene, was developed. This confirmed the broth and agar differential expression of *lanA* in different media, with MRS agar showing the highest gene expression. To obtain some crude lantibiotic compound, it was extracted from MRS agar using 95% methanol and partially purified via size fractionation with filtration systems. Different concentrations of this partially purified lantibiotic were used to investigate the expression of *lanA* in broth cultures. Strikingly, *lanA* gene expression was drastically increased in a dose dependant fashion in broth cultures, confirming that increasing the external signal in broth cultures allows the expression of the lantibiotic production genes, thus facilitating lantibiotic production in broth.

Key Words: bifidobacteria, lantibiotic, microarray

W59 Comparison of the Baird-Parker agar, Baird-Parker-RPF and Petrifilm Staph Express in the detection and enumeration of *Staphylococcus* coagulase positive in raw milk. A. K. R. Santos, M. O. Leite*, L. M. Fonseca, M. O. P. Cerqueira, M. R. Souza, C. F. A. M. Penna, and M. R. A. Moura, *Federal University of Minas Gerais*, *Belo Horizonte, Minas Gerais, Brasil*.

The reference methodology for *Staphylococcus* spp. enumeration recommends the use of Baird-Parker agar (BP); however, other culture media may produce results in shorter time, as Baird-Parker - RPF agar (bioMérieux, Marcy l'Etoile, France) and Petrifilm™ Staph Express Count Plate - PSE - (3M Microbiology Products, St. Paul, USA). Thus, this work was carried out to compare the efficiency of the forecited culture media for the enumeration of *Staphylococcus* spp. in 36 samples of raw milk. The experiment was designed in random blocks and the media were compared by the *t*-test. Mean *Staphylococcus* spp. count obtained by PSE (2.50 Log10 CFU/mL) was lower ($P < 0.05$) than those by BP (4.12 Log10 CFU/mL) and RPF (3.86 Log10 CFU/mL), being the latter 2 values considered similar ($P > 0.05$). The results showed viable the use of RPF, but not PSE, replacing BP for *Staphylococcus* spp. enumeration without altering the accuracy of the analysis.

Key Words: *Staphylococcus*, culture media, raw milk

W60 Influence of low pressure homogenization on growth of *Streptococcus thermophilus*. T. Muramalla[1] and K. Aryana*[1,2], [1]*Louisiana State University*, *Baton Rouge,* [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

The objective was to study the effect of low pressure homogenization on growth of *Streptococcus thermophilus*. Fat free milk was sterilized by autoclaving, chilled to 4°C, inoculated with *Streptococcus thermophilus* and homogenized at 0, 3.45, 6.90, 10.35, 13.80 MPa for 5 continuous passes. The control (0 MPa) and homogenized (3.45, 6.90, 10.35, 13.80 MPa) samples were individually inoculated in Lactobacilli MRS broth. Samples were plated in duplicate at 0, 2, 3, 4, 5, 6, 8, and 10 h using the pour plate technique. During 10 h incubation period the broth samples were kept at 37°C and plates were incubated aerobically at 37°C for 3 d. Entire experiments were replicated 3 times. Data were analyzed using proc mixed of SAS. The interaction effect of pressure x time was not significant. Both main effects pressure and time were significant ($P < 0.0001$). The homogenized samples (6.90, 10.35, 13.80 MPa) were not significantly ($P < 0.05$) different from each other but exhibited counts significantly ($P < 0.05$) higher than control (0 MPa). The homogenized samples treated to pressures of 6.90, 10.35, 13.80 MPa exhibited average counts of 11.84, 11.85, 11.83 log CFU/ml and control (0 MPa) had an average count of 11.70 log CFU/ml. The low pressure homogenization at 6.90, 10.35, 13.80 MPa had a slight yet positive significant effect on growth of *Streptococcus thermophilus*.

Key Words: dairy, culture, bacteria

W61 Influence of mild pulsed electric field conditions on the growth of *Streptococcus thermophilus*. N. Najim[1] and K. Aryana*[1,2], [1]*Louisiana State University Agricultural Center*, *Baton Rouge,* [2]*Louisiana State University*, *Baton Rouge*.

Pulsed electric field (PEF) processing involves the application of pulses of voltage for less than one second to fluid products placed between 2 electrodes. *Streptococcus thermophilus* is an important bacterium used for the production of fermented dairy products. Objective of this study was to determine the influence of a mild PEF condition on the growth of *Streptococcus thermophilus*. A range of mild pulsed electric field conditions were earlier screened by the authors to arrive at an optimum overall mild pulsed electric field condition for various probiotic characteristics. Freshly thawed *Streptococcus thermophilus* was suspended in 0.1% w/v sterile peptone water and treated in a pilot plant PEF system. The treatment was a mild PEF condition of positive square unipolar pulse of 3 µs, pulse period of 0.5 s and voltage of 1kv/cm. Control was run through PEF system but without receiving any pulsed electric field condition. Control and treated sample flow rates were kept constant at 60 mL/min. Samples were individually inoculated in lactobacilli MRS broth. Samples were plated in duplicate. Pour plates were incubated aerobically at 37°C for 3 d. Growth was determined hourly for 20 h. Experiments were replicated 3 times. The control and mild PEF treated samples had the same counts of 10.97 (+/− 0.25) log cfu/mL at 0 h. The

mild PEF treated samples reached the log phase an hour earlier than control. Although at most time points, counts were within the same log cfu/mL for the control and treated samples, the mild PEF treated samples had significantly ($P < 0.05$) higher counts compared with control for most of the time points over the 20 h of growth. The mild PEF condition enhanced growth of *Streptococcus thermophilus*.

Key Words: pulsed electric field, nonthermal, culture

W62 Effect of mild sonication on the growth of *Streptococcus thermophilus*. M. Moncada*[1,2] and K. Aryana[1,2], [1]*Louisiana State University Agricultural Center*, *Baton Rouge,* [2]*Louisiana State University*, *Baton Rouge*.

Mild sonication (20–40% amplitude) conditions have been reported to increase the transport of small molecules in solution enabling bacterial cell growth. *Streptococcus thermophilus* is an important lactic acid bacterium used for the production of some fermented dairy products. The objective was to study the influence of mild sonication on the growth characteristics of *Streptococcus thermophilus*. Freshly thawed culture was suspended in 0.1% peptone water and 18 mL of sample was sonicated using horn (diameter 13 mm) set at a maximum acoustic power output of 750 W, frequency 24 kHz. The treatments were amplitudes of 21, 27, 33 and 39%. In all treatments energy input into the system was kept constant at 1500 J. The control was sample not treated with mild sonication. Samples were inoculated in lactobacilli MRS broth. Samples were pour plated in duplicate. During 12 h incubation period the samples were kept at 37°C. Pour plates were incubated aerobically at 37°C for 3 d. Growth of control and treated samples were determined hourly over 12 h. Three replications were conducted. Data were analyzed using the PROC GLM of the Statistical Analysis Systems (SAS). The control and samples treated with 21% amplitude exhibited average counts of 14.55 and 15.01 log CFU/mL respectively at the end of the 12-h incubation. Similar increases in counts were observed in samples treated with 33% amplitude compared with control in which average counts at the end of the 12 h were 14.58 and 14.26 log CFU/mL respectively. With an increase in amplitude of mild sonication the counts declined but maintained higher than the control. It is concluded that the lowest sonication intensity studied (amplitude of 21%) had the best effect on increasing *Streptococcus thermophilus* counts.

Key Words: sonication, culture, growth

W63 Low pressure homogenization effects on bile tolerance of *Streptococcus thermophilus*. T. Muramalla*[1] and K. Aryana[1,2], [1]*Louisiana State University*, *Baton Rouge,* [2]*Louisiana State University Agricultural Center*, *Baton Rouge*.

The goal was to determine the influence of low pressure homogenization on bile tolerance of *Streptococcus thermophilus*. Fat free milk was autoclaved, chilled to 4°C, inoculated with *Streptococcus thermophilus* and homogenized at 0, 3.45, 6.90, 10.35, 13.80 MPa for 5 continuous passes. The control (0 MPa) and homogenized (3.45, 6.90, 10.35, 13.80 MPa) samples were individually inoculated in Lactobacilli MRS broth with oxgall bile. Samples were plated in duplicate at 0, 2, 3, 4, 5, 6, 8, and 10 h. During 10 h incubation period the broth samples were kept at 37°C. Pour plates were incubated aerobically at 37°C for 3 d. Entire experiments were replicated 3 times. Data were analyzed using proc mixed of SAS. The interaction effect of pressure × time was not significant while both the main effects pressure and time were significant ($P < 0.0001$). The homogenized samples (3.45, 6.90, 13.80 MPa) were not significantly ($P < 0.05$) different from each other but exhibited counts that were significantly ($P < 0.05$) higher than control (0 MPa). The homogenized samples treated to pressures of 3.45, 6.90, 13.80 MPa exhibited average counts of 10.72, 10.79, 10.81 log CFU/mL compared with control (0 MPa) which had an average count of 10.60 log CFU/mL. The low pressure homogenization at 3.45, 6.90, 13.80 MPa had a slight yet positive significant effect on bile tolerance of *Streptococcus thermophilus*.

Key Words: culture, homogenization, bacteria

W64 Acoustical emissions generated by bacteriophages sk1 and ml3 using *Lactococcus lactis* ssp. *lactis* C2 host. A. K. Wardani[1], C. L. Hicks*[2], and J. M. Stencel[3], [1]*University of Brawijaya*, *Malang, Indonesia*, [2]*University of Kentucky*, *Lexington,* [3]*Tribo Flo Separations*, *Lexington, KY*.

Lactococcus lactis ssp. *lactis* C2 bacteria in M17 medium, at 26°C for 8 h were infected with phages sk1 or ml3, and monitored using contact piezoelectric sensors attached to the sides of the growth vessel. The 2 sensors (5 to 50 kHz range) had individual characteristic and internal amplification mechanisms that were calibrated and adjusted to minimize background noise. After the sensors had been calibrated, the M17 medium was inoculated with *L. lactis* ssp. *lactis* C2 culture (1×10^9 cfu/mL), stirred for 1 min, and allowed to grow for approx. 90 min before infection (stirred for 1 min) with phages sk1 or ml3. Infection time was set to correspond with the start of the log growth phase. Infection level was 10^5 pfu/mL for both phages sk1 and ml3. Sound intensity from the growth chambers was measured in attojoules (aJ = 10^{-18} Joules) and plotted as the energy rate-per-detected acoustic wave. Acoustic peaks considered significant and beyond internal or external generated noise were those having greater than ± 3 times the sigma value of the general variation in acoustic intensity over the entire data set of each test. Energy rate data from control tests in which *L. lactis* ssp. *lactis* C2 was grown without phage sk1 or phage ml3 infections contained no acoustic peaks with intensities that exceeded the ± 3 sigma standard whereas phage sk1 or ml3 infected *L. lactis* ssp. *lactis* C2 culture contained multiple acoustic peaks with intensities that exceeded ± 3 sigma. The first peak for phage sk1 appeared at 33.2 ± 4.4 min whereas the first peak for phage ml3 appeared 40 min. Thus, the acoustic data from phage sk1 or phage ml3 infected *L. lactis* ssp. *lactis* C2 were considered to be the result of phage infection. The timings of the acoustic peaks from phage sk1 were sufficiently different from phage ml3, that these 2 phage could probably be distinguished by acoustic emission monitoring during phage infection of the bacteria.

Key Words: acoustic emission, bacteriophage, *Lactococcus*

W65 Viability of bifidobacteria and lactobacilli in skim milk with shiitake mushroom extract during refrigerated storage. O. Hassan*[1], O. S. Isikhuemhen[1], S. A. Ibrahim[1], A. AbuGhazaleh[2], and D. Song[1], [1]*North Carolina A &T State University*, *Greensboro,* [2]*Southern Illinois University*, *Carbondale*.

Probiotics, such as bifidobacteria and lactobacilli, have been demonstrated to help establish and support strong immune systems. A key growth source for these bacteria are certain carbohydrates, so food rich in these food components would presumably help probiotics to thrive. Shiitake mushroom (*Lentinus edodes*) contains antitumor oligosaccharides and polysaccharides which could enhance probiotics growth. The objective of this study was to exam the viability of selected probiotic cultures in skim milk in the presence of different levels of Shiitake mushroom extract during refrigerated storage. *Lactobacillus reuteri* CF2–7F, *L. reuteri* DMS 20016, *Bifidobacterium breve* and *B. adolescentis* were individually inoculated into skim milk supplemented with

different concentrations of mushroom extract (0%, 1%, 2%, and 4%) and stored immediately at 4°C for 4 weeks. Aliquots were withdrawn at one-week interval to determine bacterial population, pH and titratable acidity of the milk samples. Results showed that the viability of tested strains was significantly higher in milk supplemented with Shiitake mushroom extract ($P < 0.05$) compared with the control sample. All tested strains demonstrated culture stability upon refrigerated storage and exhibited no significant loss of viability during storage conditions for 2 weeks. After 4 weeks of storage, 2 log reduction of viable cells from an initial mean of 109/ml was observed. Samples had a mean initial pH of 6.5 and titratable acidity of 0.16. Both pH and titratable acidity showed negligible change at 4°C during 2-week storage. Our results suggest that shiitake mushroom extract can be used as a natural additive in dairy products to improve the viability of probiotics during refrigerated storage and to improve consumer health.

Key Words: bifidobacteria, lactobacilli, mushroom

W66 Microbiological quality of dairy protein supplements sold in Saudi Arabia markets. S. O. Aljaloud*[1], D. Song[2], A. M. Fraser[1], and S. A. Ibrahim[2], [1]*Clemson University*, *Clemson, SC*, [2]*North Carolina Agricultural and Technical State University*, *Greensboro*.

Whey proteins are becoming popular dietary supplements here in the US and around the world. However, these ingredients are typically not sterile. There is need to investigate the microbiological safety of these products. The objective of this study was to determine the microbiology quality of whey protein supplements sold in Saudi Arabia. Twenty different dairy protein supplements were purchased from local stores in Riyadh, the capital of Saudi Arabia. These products ranged from whey protein concentrate (5), whey protein isolate (4), why protein hydrolyzed (2), whey protein concentrate lactose free (3), whey protein concentrate mineral free (2) and casein isolates (4). Samples were analyzed for several microbial quality attributes including aerobic total plate count (ATPC), psychrotrophs (PC), *Enterobacteriaceae*, total coliforms, and fecal coliforms. The presence of selected pathogens such as *Staphylococcus aureus* and *Salmonella* were investigated. Our results showed that the average bacterial population for ATPC, PC and *Enterobacteriaceae*, were 4.1, 2.1, and 1.2 log cfu/mL, respectively. Coliform groups were found in 29% of samples while 10% were fecal coliform positive as revealed by the MPN method. *S. aureus* was located in at least 25% of samples, with a mean count of 2.1 log cfu/mL. Our results confirmed that there is potential health risk with the consumption of dairy protein supplements sold in Saudi Arabia. There is a need to develop a monitoring system to check the microbiological quality of dairy protein supplements on market to assure them safe to use.

Key Words: microbiological quality, dairy protein supplements

W67 Antimicrobial activity and composition of oregano essential oils from different climate zones of Colombia. L. Betancourt*[1,3], R. Patiño[2], V. Phandanauvong[2], C. Ariza-Nieto[2], and G. Afanador-Téllez[3], [1]*Universidad de La Salle*, *Bogotá, Colombia*, [2]*CORPOICA*, *Bogotá, Colombia*, [3]*Universidad Nacional de Colombia*, *Bogotá, Colombia*.

The antimicrobial activity of oregano essential oils has been showed in the literature; however, composition and antibacterial activity of oregano essential oils (OEO) from different climatic zones of Colombia have not been studied. The aim of this study was to characterize 4 chemotypes of OEO, *Origanum majorana* (OM), *Origanum vulgare* L (OVL), *Lippia origanoides* (LO) and *Origanum vulgare* H. (OVH, from Greece). Composition was analyzed by GC/Ms and its antibacterial activity through minimum inhibitory concentration (MIC) against *Lactobacillus acidophilus*, *Bifidobacterium breve*, *Salmonella enteritidis*, *Salmonella typhimurium* and *Escherichia coli* by broth dilution method. OVH from Greece presented the highest carvacrol content (90%), while the highest thymol was found in LO from Colombia (79%). OM was rich in Sabinyl compound (24%). OVL presented high thymol content (21%) and low carvacrol (4%). The best carvarol: thymol ratio was for OVH (25) and LO present the most very low (0.01). The amount of lowest precursors (gamma terpinene+para-cymene) was for LO (9%), but varieties of oregano produced in greenhouse conditions at high altitude (Savannah of Bogotá, 2650 AMSL)) had highest precursors content, 17% for OM and 41% for OVL. Carvacrol, OVH and LO showed the same MIC values against *S. enteritidis* (0.098 mg/ml). Carvacrol had better MIC against both *S. typhimurium* (0.098 mg/mL) and *E. coli* (0.0061 mg/mL), followed by OVH and LO. The lowest MIC against beneficial bacteria was for OM (6.25 mg/mL) against *L. acidophilus* and LO (50 mg/mL) against *B. breve*. These results clearly showed that OEO rich in thymol could have a desirable antibacterial effect on gastrointestinal tract.

Key Words: *Lactobacillus*, *Bifidobacterium*, *Salmonella*

W68 Effect of processing on the milk fat globule membrane constituents. X. Elías-Argote* and R. Jiménez-Flores, *California Polytechnic State University San Luis Obispo*.

The milk fat globule membrane (MFGM) proteins have been studied extensively using proteomic techniques to characterize them and to find out their structure within the membrane. The MFGM constituents have the potential to offer excellent health benefits; however, few studies have highlighted the effects of processing on the MFGM constituents and the repercussion it may have on their functionality. In this study, we have analyzed milk throughout traditional processing. These include collection, refrigeration, and 2 types of commercial pasteurization. In addition, this work also includes a potential pasteurization method using pulsed light treatment. Milk was collected before reaching the storage unit and kept at 37°C. Samples were processed at storage temperature (4°C), batch and high temperature short time (HTST) pasteurizations, and by pulsed light treatment. The cream was separated, and milk fat globule size distribution was determined using laser light scattering in the skim milk and cream fractions of the 4 treatments. The MFGM was then extracted and analyzed using 2D-PAGE and LC-MS. Microscopic evaluations were performed using confocal microscopy. As the heat treatment increased, more casein and whey proteins were absorbed onto the membrane and observed in the final product. The particle size reflects small diameter globules remaining in the skim milk and greater variability in the size distribution with heat treatments. We observed that MFGM proteins, especially adipophilin and butyrophilin, are affected differently by processing. Their concentration in the MFGM decreases as pasteurization temperature increases.

Key Words: MFGM, proteomics, protein interactions

W69 Evaluation of vacuum packaging on particle size, particle density and solubility of dry dairy powders. H. Eshpari* and P. S. Tong, *California Polytechnic State University*, *San Luis Obispo*.

Dry dairy ingredients can have a long shelf life if packaged and stored properly. Vacuum packaging can be an attractive method for keeping quality and provides added value; because of the inherent compactness of the products. Vacuum packaged dry dairy ingredients may also have added ease of handling for end users. However little is known about the impact of vacuum packaging on the properties of dry dairy ingredients. The objective of this study was to determine the effects of vacuum packaging on particle size, particle density and solubility of 4 types of dry dairy ingredients. Commercial samples of nonfat dry milk powder, whole milk powder, buttermilk powder, and milk protein Isolate were repackaged in duplicate using multi-wall foil side gusseted bags under varying degrees of vacuum (1, 0.7, 0.4 bar) and a control with no vacuum, and then stored for 3 mo at 37°C and 60% relative humidity. Each powder was sampled and analyzed in duplicate for particle size, particle density and solubility upon receiving and after 3 mo storage. After 3 mo storage there were no significant differences in solubility and particle density of the powders, regardless of the vacuum level, but some significant differences in particle size of the powders (Table 1). Moreover, the trend of change in particle size is different for different powders. The data suggest that the proposed vacuum packaging method may be beneficial to maintain the quality of the powders studied.

Table 1. Significant changes observed in the particle size of the samples after 3 months storage

Powder	Changes observed	P-value
Nonfat dry milk	no vacuum > before packaging	0.03
Whole milk	1 bar vacuum > before packaging	0.02
Whole milk	0.7 bar vacuum > before packaging	0.00
Whole milk	0.4 bar vacuum > before packaging	0.00
Whole milk	no vacuum < before packaging	0.00
Whole milk	no vacuum < 1 bar vacuum	0.00

Key Words: vacuum packaging, dry dairy powders, physical properties

W70 A new cold gelation method for producing calcium-fortified whey protein gels. Y. C. Tseng and C. L. Hicks*, *University of Kentucky*, *Lexington*.

Whey proteins, with versatile functionalities and excellent nutritional values, are widely utilized in food applications. In the presence of calcium ions or an acidulating agent, preheated whey proteins form gels at ambient temperature. However, to obtain a good texture, currently cold-set calcium-induced whey protein gels are prepared by introducing Ca^{2+} into a whey protein solution through dialysis, which is an inconvenient and time-consuming process. Thus, the objective of this research was to develop a new procedure for making homogeneous calcium-fortified cold-set whey protein gels. Whey protein isolate suspensions (7% w/v, pH 7) were prepared with distilled water and heated at 80°C for 30 min. After cooling to room temperature, calcium carbonate was added to the protein solutions at various concentrations (0, 5, 10, 15 m*M*). Gelation was induced by adding 30 m*M* glucono-delta-lactone (GDL) to the protein solutions at 24°C. The kinetic profile of the gelling system was studied using a Bohlin VOR rheometer. Finished gels were subjected to textural profile analysis and measurements of water holding capacity, pH and color. Within 2 h after the addition of GDL, all samples were shown to have significant increase in storage modulus (G'), indicating the formation of a viscoelastic gel network. Homogeneous cold-set gels were obtained from all treatments 5h after the initiation of gelation. Calcium level (0–15 m*M*) was shown to affect ($P < 0.05$) the pH, L value (lightness), and textural profile of the final gels. As Ca^{2+} increased, final pH values of the gels increased from 4.7 (calcium free samples) to 5.8 (samples w/ 15 m*M* $CaCO_3$) while the respective L values reduced from 72.4 to 70.8. Gel breaking strength was greatly reduced as calcium level increased, with values ranging from 595g to 349g, respectively. Results indicate that GDL combining with calcium carbonate can be utilized as an effective coagulating agent for making cold-set whey protein gels having fortified calcium levels, less cooked flavors and homogeneous texture, which may expand future food applications of whey proteins.

Key Words: cold gelation, whey proteins, calcium-fortified

W71 Use of caseinomacropeptide quantification by high performance liquid chromatography to estimate cheese whey addition in fermented milk beverages. E. H. P. Andrade, M. O. Leite, M. R. Souza, L. M. Fonseca*, M. M. O. P. Cerqueira, C. F. A. M. Penna, T. Roza, and N. M. A. Silva, *Federal University of Minas Gerais*, *Belo Horizonte, Brasil*.

The objective of this study was to evaluate quantification of caseinomacropeptide (CMP) as a method to estimate cheese whey addition in fermented milk beverages. Samples of fermented milk beverages were prepared in laboratory with 4 levels of whey (0, 10, 20 and 40%) and fermented with yogurt culture. After refrigerated storage (8–10°C) at different times (0, 7, 14, and 21 d) the samples were analyzed by high performance liquid chromatography (HPLC) according to official Brazilian method used to detect whey in milk and milk powder, based on caseinomacropeptide quantification. When the whey levels were analyzed along the storage time, there is no difference ($P > 0.05$) between fermented milk (0% of whey) and the fermented milk beverages added with 10 and 20% of whey for 0, 7, 14 and 21 d in refrigeration. However, for fermented milk beverage added with 40% of whey and stored by 21 d, the CMP concentration was higher than expected compared with the times before ($P < 0.05$). This increase in CMP quantity can be due to nonspecific proteolysis promoted for culture bacteria, especially *Lactobacillus*. Thus, it is possible to use CMP detection by HPLC according to official Brazilian method used to detect cheese whey in milk and milk powder as a method to quantify whey added to fermented milk beverages until 14 d of refrigerated storage.

Key Words: fermented milk beverages, whey, high performance liquid chromatography

W72 Comparison of solubility with methods for determining denaturation in whey protein. M. D. Allen* and P. S. Tong, *California Polytechnic State University*, *San Luis Obispo*.

Functional properties of whey proteins are very important for ingredient selection when incorporating in a food system. Solubility is one of the most important functional properties to consider when selecting a whey protein ingredient, especially for beverage systems. Processing parameters are known to have an effect on protein solubility and are often manipulated in efforts to improve solubility. Protein structures of whey proteins are considered to have an effect on solubility. Specifically, the degree of denaturation of whey proteins is thought to play a role in solubility. Previous studies concluded that bicinchoninic acid (BCA) assay and fluorescence spectroscopy are two relatively economical analytical methods that can be used to quantify denaturation of whey protein in liquid whey. The purpose of this current research is to compare these methods of quantifying denaturation to functional solubility of whey protein. A split plot experimental design was utilized with complete randomization. Raw bovine milk was skimmed and enzyme coagulated at natural pH to separate the whey. Liquid whey was then split into three plots and each received one of the following treatments: mild heat/ freeze dry, mild heat/spray dry and high heat/spray dry. Heat treatment was applied to liquid whey prior to a concentration step. Heat treated whey samples were then concentrated and dried accordingly. Powders were analyzed for denaturation using BCA and fluorescence spectroscopy and for solubility using an Insolubility Index. Statistical analysis of data indicates that there are differences among the three treatments for fluorescence spectroscopy, BCA and insolubility index, shown in Table 1. Peak intensity increases with denaturation in fluorescence spectroscopy, percent soluble at pH 4.6 decreases with denaturation in BCA analysis and mL soluble increases with denaturation by the insolubility index.

Table 1. Solubility and Measurements of Denaturation in Whey Powder

Treatment	Fluorescence Spectroscopy- Peak Intensity	BCA- %Soluble @ pH 4.6	Insolubility Index- mL Insoluble
Low Heat/Freeze Dry	173.85	93.24	0.587
Low Heat/Spray Dry	169.40	93.93	0.878
High Heat/Spray Dry	225.65	56.08	0.820

Key Words: whey protein, denaturation, solubility

W73 Whey protein fractionation with supercritical CO_2: Process optimization. L. M. Bonnaillie* and P. M. Tomasula, *USDA, Agricultural Research Services, Eastern Regional Research Center*, *Wyndmoor, PA*.

Supercritical CO_2 (SCO_2) fractionation of commercial whey protein isolates (WPI), containing 20% α-lactalbumin (ALA) and 55% β-lactoglobulin (BLG) protein (w/w), into 2 fractions enriched with either ALA or BLG, generates new whey protein ingredients with enhanced functional and nutritional properties. For example, ALA-rich protein products have improved nutritional properties for use in infant and geriatric foods, while BLG-rich products have enhanced gelling properties. Prefatory studies with HCl showed that ALA formed aggregates under acidic conditions at 50–70°C, while BLG remained mostly soluble. The separation of aggregated ALA was optimized around pH 4.2 and 60°C where the difference between the rates of aggregation of ALA and BLG was maximized. SCO_2 dissolved in concentrated WPI solutions in a high-pressure 1-L reactor generates carbonic acid that causes the selective precipitation of ALA, without tainting the 2 protein fractions with residual acid (pH 6) after depressurization. A turbine impeller ensured fast thermodynamic equilibrium. Solution pH was lowered with increased pressure, P, and reduced WPI concentration, C, according to extensive calibration performed with 1–28% (w/w) WPI solutions up to 14 MPa and extrapolated to 2–10% WPI solutions up to 34 MPa (pH 4.2–5). The kinetics of aggregation of ALA and BLG were followed for up to 4 h as a function of time, T, C and pH. A systematic kinetic study and modeling of the SCO2-induced precipitation of both proteins in the multi-parameter process enabled the optimization of processing conditions to both maximize ALA aggregation while keeping BLG precipitation low, and the optimization of protein recovery and purity in both fractions. In the 60–65°C range, up to 60%-pure ALA and 80%-pure BLG were obtained, with total protein recoveries of up to 98% and 90%, respectively. ALA purity is limited due to a noted increase in BLG precipitation at high SCO_2 pressure compared with HCl-treatment, caused by possible pressure and/or anti-solvent effects. Kinetic models will be useful to design scaled-up batch or continuous versions of the WPI/SCO_2 fractionation process.

Key Words: whey protein, fractionation, carbon dioxide

W74 Effect of applying power ultrasounds during the thermal denaturation of whey proteins in the presence of buttermilk. M. Saffon*[1], M. Britten[2], and Y. Pouliot[1], [1]*STELA Dairy Research Center, Institute of Nutraceuticals and Functional Food (INAF), Université Laval*, *Québec, QC, Canada*, [2]*Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada*, *St-Hyacinthe, Québec, Canada*.

The use of ultrasound treatments in food processing has been considered as an emergent potential alternative to heat treatments. It was hypothesized that power ultrasounds could affect heat-induced denaturation by

favoring aggregates remodeling or rearrangement during the aggregation process. Cheese whey and buttermilk were concentrated by ultrafiltration up to 9.5% (w/v) protein content. Mixtures with various whey to buttermilk protein ratios were adjusted to pH 4.6 and heated to 90°C for 25 min (including come-up time). Power ultrasounds (20 kHz probe) were applied for the last 15 min of the thermal denaturation treatment. After cooling, mixtures were homogenized 5 times at 9500 psi. Aggregated material was separated by centrifugation at 15000g for 20 min. Protein aggregation, water holding capacity (WHC), consistency index (k) and flow behavior index (n) were performed on the homogenized mixtures. All the experiments were repeated 3 times, statistical analysis of the data was performed using ANOVA and the results were considered significantly when $P < 0.05$. The use of power ultrasounds significantly increased the protein aggregation and this effect depended on the proportion of buttermilk protein in the mixture. The highest protein aggregation was obtained with 25:75 whey-buttermilk fractions (78.5% ± 1.8 and 87.0% ± 1.2 with ultrasound). Ultrasound treatment had no significant impact on the WHC of the aggregates and only a slight decrease (0.12 g water/g protein) was associated with increasing the buttermilk protein ratio. The use of ultrasound treatment significantly increased the k and decreased the n of the homogenized aggregate mixtures. The highest k was obtained with aggregates from 25:75 whey-buttermilk ratio (0.94 Pa.s ± 0.10 and 1.12 Pa.s ± 0.10 with ultrasound), which also displayed the lowest n (0.36 ± 0.04 and 0.30 ± 0.05 with ultrasound). Our results suggest that heat-denaturation in the presence of power ultrasounds may have affected the shape and size distribution of protein aggregates.

Key Words: whey, buttermilk, aggregation

W75 Partitioning of minerals and protein using dialysis at different temperatures. N. On-Nom*, A. Grandison, and M. Lewis, *University of Reading*, *Reading, Berkshire, UK*.

Partitioning of minerals and protein in pasteurized milk has been measured at different temperatures, using dialysis with PVDF membrane (MWCO of 250 kdal). Dialysis conditions of 4, 20 and 40°C from 24 to 96 h and at 60 and 80°C from 1 to 5 h were used to prepare a suitable soluble phase for estimating pH, ionic calcium and protein partitioning. Dialysis bags were placed into baby cans which contained milk sample, which were then heated for the required temperature and time. Immediately after heating, dialysates were removed as quickly as possible and then cooled for 24 h before pH and ionic calcium were measured. The results showed that pH and ionic calcium decreased as temperature increased. It was also observed there are slight increases in pH and ionic calcium when the time of dialysis was increased at the same temperature. To measure protein partitioning, reducing SDS-PAGE was used. Results showed that at 4°C, β-casein and traces of α-casein and κ-casein, as well as whey proteins (α-lactalbumin and β-lactoglobulin) were detected while only whey protein was found at 20, 40 and 60°C. No soluble protein was observed at all conditions of 80°C. However, it was found that the intensity of the protein bands increased with increasing dialysis time. In contrast, no proteins were detected in dialysates produced using Visking tubing, which had a lower MWCO of 12 kdal.

Key Words: dialysis, minerals, proteins

W76 Measurement of pH and ionic calcium at high temperatures and their effect on the heat stability of milk supplemented with calcium chloride. N. On-Nom*, M. Lewis, and A. Grandison, *University of Reading*, *Reading, Berkshire, UK*.

Calcium chloride was added to milk in the range (0 - 20 m*M* Ca) with no pH adjustment. These milk samples where then subjected to in-container heating in the range 60 to 120°C for 1 h. Dialysis was performed on these samples during heating to estimate pH and ionic calcium at each heating temperature. Dialysis bags were removed as soon as possible after the heat treatment. The heat treated samples were inspected to assess their heat stability and those which had coagulated were centrifuged to produce a coagulum and supernatant. The results showed that calcium addition decreased pH and increased ionic calcium and that further reductions in both pH and ionic calcium occurred as temperature increased. Coagulation was observed to take place at lower calcium additions as the temperature increased. Furthermore, no coagulation took place if the pH was maintained above 6.30 and ionic calcium was below 0.46 m*M*, respectively, both measured at the heating temperature. However, when the milk samples cooled, pH and ionic calcium recovered, but not quite to their original value. Dialysis allows measurement of pH and ionic calcium at the heating temperature, which should improve understanding of their role in heat stability. Analysis of supernatants from coagulated milk samples heated at 115°C showed that over 90% of the milk protein coagulated, with only small amounts of whey protein and soluble casein remaining in the supernatant.

Key Words: heat stability, calcium, dialysis

W77 Production of single cell oil during growth of *Aspergillus* species on whey. A. Akpinar-Bayizit*, L. Yilmaz-Ersan, and T. Ozcan, *Uludag University, Department of Food Engineering*, *Bursa, Turkey*.

Oils and fats, lipids, form a class of natural compounds that serve as sources of energy and are considered an important component of our food. The demand for oils and fats, in general, is largely met from plant and animal sources. In view of this, utilization of industrial waste material into high value biological material is a cause of raw material limitation and increasing world population. Thus, conversion of food processing wastes into high-value and beneficiary products via microbial and enzymatic processes is gaining importance as they are ready-to-use substrates. Microbial lipids (SCO) with similar properties to vegetable or animal oils can be produced by microorganisms utilizing various carbon sources. Dairy industry wastes are good substrates for waste valuation as they contain appropriate ingredients that support microbial growth. Whey is the serum separated during the curding of milk for cheese production and contains 5% lactose. This research was planned in order to use cheese whey in production of high-value microbial lipids by five *Aspergillus* species, namely *A. niger*, *A. oryzae*, *A. ruber*, *A. versicolor*, *A. parasiticus*. The lipid accumulation in biomasses of examined fungi varied from 1.10 to 7.72 g/100 g. The amount of saturated fatty acids was found highest in *A. parasiticus* (65.70%), whilst the highest amount of unsaturated fatty acids was in *A. niger* (62.72%). The fatty acid profile of SCO obtained from *A. parasiticus* and *A. versicolor* revealed a high percentage of unsaturated 20-carbon fatty acids. It was observed that longer chain polyunsaturated fatty acids, which are not found in whey, have been detected in SCOs of *Aspergillus* species. This sheds light on the possibilities of exploring these fungi, having the ability to synthesize longer chain fatty acids from oleic (octadecenoic) or linoleic (octadecadienoic) acids through desaturase and elongase activity, to be used as supplement to edible fats and oils, and for other non-edible industrial purposes.

Key Words: whey, single cell oil, *Aspergillus*

W78 The effect of lysine and methionine on milk protein mRNA expression of bovine mammary epithelial cells in vitro. X. Y. Li, J. Q. Wang*, D. P. Bu, H. Y. Wei, H. Hu, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*.

The objective of this study was to examine the effect of lysine and methionine supplementation on milk protein of bovine mammary epithelial cells in vitro. The lysine was added to the DMEM/F12 culture medium containing 10% fetal bovine serum (FBS) at concentrations of 0, 0.05, 0.2, 0.4, 0.8, 1.6, 3.2, 6.4, 12.8, 25.6 mmol/L and the methionine was also added to culture medium at concentrations of 0, 0.025, 0.1, 0.2, 0.4, 0.8, 1.6, 3.2, 6.4, 12.8 mmol/L. The cell proliferation and milk protein mRNA expression were detected by MTT colorimetric assay and RT-qPCR. Experiment with 48 h. This experiment was repeated 2 times. Within each experiment were repeated 3 replicates for each treatment .The results showed that 0.8 to 1.6 mmol/L lysine and 0.4 to 0.8 mmol/L methionine at 48 h significantly improved the proliferation of bovine mammary epithelial cells ($P < 0.0001$), the mRNA expression level of α_{s1}-casein, β-casein were all significantly higher than other group at these concentrations. Thus, the lysine and methionine may improve milk protein synthesis.

Key Words: lysine, methionine, bovine mammary epithelial cells

W79 Identification of bovine casein phosphorylation using TiO_2 enrichment in combination with nano-ESI-MS/MS. S. S. Li, Y. X. Yang, J. Q. Wang*, D. P. Bu, H. Y. Wei, L. Y. Zhang, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Protein phosphorylation is an important post-translational modification that regulates milk protein structure and function. The objective of this study was to analyze the presence of phosphorylated casein. Bovine milk proteins were first separated by sodium dodecyl sulfate PAGE. After in gels digestion and extraction, phosphorylated peptide were enriched by titanium dioxide and identified by ultra performance liquid chromatography coupled with nano electrospray ionization tandem mass spectrometry. This method ensured the identification of 20 phosphorylated peptides, including 7 phosphorylated forms of α_{s1}-casein, 8 α_{s2}-casein, and 5 β-casein. Eight phosphorylated sites derived from 3 α_{s1}-caseins, 3 α_{s2}-caseins and 2 β-caseins were also identified. Phosphates group were localized on residues Ser^{61}, Ser^{63} and Ser^{130} in α_{s1}-casein; Thr^{145}, Ser^{146} and Ser^{158} in α_{s2}-casein; and Ser^{50} and Thr^{56} in β-casein. These findings provide valuable information for the investigating of the bovine milk casein phosphorylation.

Key Words: bovine milk casein, phosphorylation, mass spectrometry

W80 Developmental changes in the bovine whey proteome during the transition from colostrum to milk. L. Y. Zhang[1,2], J. Q. Wang*[1], Y. X. Yang[1], S. S. Li[1], D. P. Bu[1], and L. Y. Zhou[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agriculture Science*, *Beijing, China*, [2]*Department of Animal Science, College of Agriculture, Hebei University of Engineering*, *Handan, China*.

Bovine milk whey proteins in colostrum are of more significance for newborn than whey proteins in milk, but no studies on the difference in whey protein patterns during the transition from colostrum to milk have been reported to date. This study separated whey proteins from d 1, day3, d 7 and d 21 after calving using 2-dimensional electrophoresis. Differentially expressed proteins in different collection time were identified using high-performance liquid chromatography tandem mass spectrometry (LC/MS/MS) and validated by enzyme linked immunosorbent assay (ELISA) to understand the developmental changes in the bovine whey proteome during the transition from colostrum to milk. Whey proteins from d 1 and d 3 were found to be the same except for immunoglobulin G. Seven proteins were found to be lower in d 7 and d 21 milk whey, including immunoglobulin G, immunoglobulin M, albumin, and lactotransferrin, which are involved in immunity and molecule transport. These proteins were detected using an advanced proteomic method, 2-dimensional electrophoresis coupled with LC/MS/MS, which confirmed that the changes in the differential expression proteins of bovine whey fraction did occur with increased concentrations of serum protein in colostral whey.

Key Words: bovine milk whey protein, colostrum, mass spectrometry

W81 Formation of nanofibers and hydrogels from a milk-derived peptide. M.-M. Guy[1], N. Voyer[2], S. F. Gauthier[1], and Y. Pouliot*[1], [1]*STELA Dairy Research Center, Institute of Nutraceuticals and Functional Foods (INAF), Université Laval*, *Québec, Canada*, [2]*Department of Chemistry and PROTEO Protein Structure, Function and Engineering Research Network, Université Laval*, *Québec, Canada*.

It has been previously shown that the N-terminal fragment of β-lactoglobulin, namely β-LG f1–8, isolated from a flocculated tryptic peptide mixture of whey protein isolate, undergoes self-assembly by a secondary structure transition to β-sheet conformation at basic pH. The objective of the present work was to investigate the physicochemical conditions that trigger self-assembly of peptide β-LG f1–8 and therefore lead to nanofibers and hydrogel formation. Nanostructures formed by self-assembly of peptide β-LG f1–8 in the pH range of 2.0 to 11.0 were studied by transmission electron microscopy (TEM). Hydrogel formation was studied as a function of pH and results evidence a link between hydrogel formation and charge distribution carried by the peptide structure. Finally, circular dichroism (CD) spectropolarimetry was used to characterize the effects of peptide concentration (0.4 to 2.0 mg/mL), temperature (20 to 80°C), and ionic strength (0 to 1 *M* NaCl) on the secondary structure of peptide β-LG f1–8. Hydrogels were obtained at peptide concentrations above 2.5 mg/mL. Peptide concentration and pH adjustment were shown to trigger self-assembly of β-LG f1–8 whereas temperature and ionic strength had only limited effects. Overall, results emphasize the role of particular molecular interactions in β-sheets self-assembly of peptide β-LG f1–8 and pH-dependent electrostatic interactions occurring between β-LG f1–8 units explain its propensity to self-assembly and flocculation in complex media such as whey protein tryptic hydrolysates.

Key Words: whey peptide, hydrogels, nanofibers

W82 Assessing learning outcomes: A comprehensive dairy cattle nutrition curriculum for practicing veterinarians. G. M. Schuenemann*, M. L. Eastridge, W. P. Weiss, J. D. Workman, S. Bas, and P. Rajala-Schultz, *The Ohio State University*, *Columbus*.

The purpose of the study was to assess the effectiveness of a team-based educational program designed to enhance the flow of applied, research-based, nutrition information to dairy veterinarians. A comprehensive dairy cattle nutrition curriculum was developed and participants from 11 veterinary practices located in 5 states (IN, NY, PA, NM, and OH), serving an estimated 186,150 dairy cattle in 469 herds, attended the 2 advanced nutrition modules (~2.5 d each and ~40 h of learning) in 2009. Nutrients, feeding transition cows, calves, and heifers (ration formulation/interpretation), dry mater intake, feed storage, metabolic diseases, evaluating cows (BCS, manure and lameness), metabolic blood profiles, record-keeping systems and feeding behavior were discussed. Educational materials were delivered through in-class lectures followed by case-based learning and group discussions. A farm visit and an out-of-class assignment were implemented. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained in both nutrition modules. Participants evaluated the program and provided feedback at the conclusion of each module. Veterinarians (100%) reported that the overall program, presentations and discussions were useful. Attendees found the presented information relevant for their work (agree = 60% and strongly agree = 40%) and of great immediate use to them (neutral = 6.5%, agree = 56% and strongly agree = 37.5%). The presented materials and the implemented educational delivery methods substantially increased the knowledge level of the attendees (16.9% points increase from pre-test to post-test scores; $P < 0.05$). Importance of feed particle size, ration evaluation, interpreting feed analysis, carbohydrate components, and metabolic profiling in fresh cows were listed as learned concepts that participants could apply in their practices. Results suggested that both nutrition modules were relevant and effective, offering new information with immediate field application. This program has important implications for dairy veterinarians since they are a vital source of information for dairy producers.

Key Words: dairy cattle nutrition, veterinary, CE

W83 A self-powered smart wireless identification and tracking sensor prototype for production agriculture applications. K. Dhakal*[1], J. F. Keown[1], and H. Sharif[2], [1]*Department of Animal Science*, *University of Nebraska-Lincoln,* [2]*Department of Computer and Electronics Engineering*, *University of Nebraska-Lincoln*.

There is a need for animal identification (ID) and disease traceability for proper livestock health and its management. An innovative solution, radio frequency identification (RFID) ear tag, has been developed to meet the United States Department of Agriculture (USDA) animal disease traceability requirement. The RFID ear tag supports animal identification, data management and real-time health monitoring within a reasonable distance. The prototype ear tag is a self–powered and capable of complete identification and tracking functions within a mile. It also possesses an integrated health sensor to monitor real time temperature and pulse rate. Information on animal health, breeding and vaccination records can also be retrieved from these small, economical and remotely accessible tags. Research is currently being conducted on the distance that animal ID can be transmitted under differing weather conditions, topographic features, interference from other radio transmissions and other electronic equipment. The research will show if a secondary transmission system will be needed to intercept the initial transmission to have the information downloaded at a central computer receiving station. With encrypted information for data privacy and its ability to harness energy from solar, thermal, and vibration energy the RFID ear tag would bring major impact in national economy as well as impact on the animal industry both in the United States and internationally.

Key Words: RFID, smart tag, tracking

W84 Impact of the 2009 economic crisis on Idaho dairies. M. Chahine*[1], G. E. Shewmaker[1], R. J. Norell[2], and C. W. Gray[1], [1]*University of Idaho*, *Twin Falls*, [2]*University of Idaho*, *Idaho Falls*.

A mail-in survey was conducted to evaluate the impact of the 2009 economic situation on Idaho dairies and to identify trends in forage use. The survey was mailed to every dairy producer registered in the state of Idaho (n = 518). The PROCSURVEYMEANS of SAS (SAS Inst. Inc., Cary, NC) was utilized to produce estimates of survey proportion in each category. Dairies were categorized as small ($n \leq 200$ cows; 48.8%), medium-sized (n = 201 to 1000 cows; 30.2%) or large ($n \geq 1000$ cows; 21.0%). Of the 518 surveys mailed, 98 surveys were returned for a response rate of 19%. The largest number of survey participants represented small (48.8%) dairies followed by medium-sized (30.2%) and large (21.0%) dairies. Small dairies averaged 87 cows, medium-sized dairies averaged 518 cows, and large dairies averaged 1697 cows. All respondents were dairy owners that used alfalfa hay in their lactating cow′s ration. Twenty-six percent of respondents indicated that cost and/or price limited the use of alfalfa hay on their dairies. A smaller percentage of respondents cited quality (14%), constraints from nutritionists (14%) and supply (9%) as important factors. During the crisis, 35% of respondents reduced the amount of alfalfa hay stored on their dairy. No significant reduction was encountered in the amount of alfalfa hay used in the ration while minerals, vitamins, additives, grains, and protein supplements were reduced. Dairies economized by culling heavily, eliminating new equipment purchases and capital expenditures that do not have short-term pay offs, lowering medication costs, purchasing cheaper semen, trimming labor, reducing employee benefits, purchasing cheaper teat dips and keeping low inventory of supplies. We conclude that during the crisis, dairy producers reduced the inventory of alfalfa hay stored on their facilities but did not decrease the amount included in the ration. Other components of the ration were, however, reduced. Dairy producers implemented a wide range of cost savings techniques. Most dairy producers are still worried about the future of the dairy industry.

Key Words: dairy, economic crisis, forages

W85 Nuisance fly production capacity of three types of manure handling systems. G. E. Higginbotham*[1], A. C. Gerry[2], C. C. Collar[3], and L. D. Reed[4], [1]*University of California Cooperative Extension*, *Fresno,* [2]*University of California*, *Riverside,* [3]*University of California Cooperative Extension*, *Hanford,* [4]*513 Fortuna Ave.*, *Modesto, CA*.

As dairy farms grow larger, producers struggle with handling large volumes of manure. Most manure handling systems include solids separators to remove fibrous particles from water used to flush alleys in cow housing areas. Inclined screens or settling basins are most common. Conventional settling basins have earthen or solid concrete sides and

a wood slatted weir at one end for particle separation. A novel settling basin design called a weeping wall has 214 cm high sides constructed with slotted steel hog flooring panels secured into reinforced concrete pillars. Slot spacing is 10 mm allowing effluent to weep from the slots while containing fibrous particles. Composting manure solids is an increasingly common practice on dairies. In this study, production of larval flies in manure compost piles (CP), conventional settling basins (SB), and weeping wall basins (WW) were compared at 6 dairies (3 SB and 3 WW) in the Central Valley of California. Two of the WW dairies used duplicate WW basins and one of the SB dairies used a duplicate SB. The other 3 dairies used a SB system. During the fly breeding season from June–August, manure samples (>20; 4 L total) from each system were collected weekly near inflow and outflow sections. Manure samples were washed thru a 16 mesh screen with larvae collected and identified. The most abundant fly species for all systems was the false stable fly (*Muscina stabulans*), however each system also produced house flies (*Musca domestica*) and stable flies (*Stomoxys calcitrans*). There was no difference ($P > 0.1$) in larval fly abundance of either SB or WW. Of the 3 systems, manure compost piles produced fewer total flies ($P < 0.0001$), as well as fewer house and stable flies ($P < 0.01$). For all dairies, neither overall fly production nor production of house and stable flies was different ($P < 0.05$) between SB with or without a WW. The use of a WW did not result in an increase in the production of nuisance or biting flies.

Key Words: house fly, manure, dairy

W86 Examining the dairy workforce in order to improve labor efficiency. L. A. Holden*, R. E. Bechtel, and G. A. Varga, *Penn State University*, *University Park*.

This research was part of a larger project examining the needs of the dairy workforce. The objective of this research was to determine the labor efficiency and key practices in a sample of Pennsylvania dairies to recommend strategies for improving workforce needs and labor efficiency. Data was gathered via a mail survey with a small monetary incentive for return and a series of survey mailings, postcard reminders, second survey mailings and final postcard reminders. Surveys were sent to 881 dairies representing approximately 15% of the largest dairies that were most likely to have hired labor in Pennsylvania. The response rate was 296 usable surveys plus 86 returned that indicated no longer in dairying for a usable response rate of 33.6%. All respondents had a herd size of at least 50 cows and average herd size was 259 ± 165.0 (n = 278). The average number of acres rented was 358 ± 277.1 (n = 251) and acres owned was 356 ± 210.3 (n = 264). Cows per worker was 41 ± 15.5 (n = 205) and pounds of milk sold per worker was 807,277 (n = 174). The average compensation for milkers was reported as $9.98/hr ± 1.69 (n = 188) and for managers was $13.23/hr ± 3.16 (n = 79). When asked about new milkers hired in the past 5 years only 13.13% of dairy owners were very satisfied with the quality of applicants and only 7.0% were very satisfied with the skill level of new milkers. Only 15.48% (n = 239) indicated that milkers had written job descriptions and only 21.67% (n = 96) indicated that workers received a monetary bonus. Survey results indicate opportunities exist for improving workforce practices such as written job descriptions, standard operating procedures and training for new workers as well as overall labor efficiency to increase cows per worker and milk sold per worker.

Key Words: dairy workforce, labor efficiency

W87 Effect of bedding material on flies, and behavior and innate immunity of calves reared in hutches. K. D. Gay*[1], S. D. Eicher[2], C. S. Wilcox[1,2], J. A. Bridges[1], M. H. Rostagno[2], S. E. Charley[1], M. J. Grott[1], R. E. Williams[1], and M. M. Schutz[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA-ARS Livestock Behavior Research Unit*, *West Lafayette, IN*.

Dairy calf hutches are often bedded with straw (STR), but sand (SND) and wood shavings (SHV) are becoming more common. The objective was to compare 3 beddings for presence of flies and measures of innate immunity and behavior of calves. Hutches were blocked by location and each of 3 hutches in a block was randomly assigned 1 of 3 treatments; SND, STR, or SHV. Twenty-eight heifer calves in the study were assigned sequentially by birth date to the next available hutch. The study was during a moderate summer (June to September 2008) at the Purdue Dairy Research and Education Center. Calves were observed twice weekly from birth until being weaned at approximately 8.5 wk of age. Blood samples were taken weekly and leukocytes analyzed for phagocytic function, CD14 (part of the LPS receptor) and CD18 (adhesion molecule) surface expression. Twice weekly, flies were counted manually on inside surfaces of hutches and counted on each leg of the calf after rising immediately before behavior observations. Bedding samples were collected to measure the presence of immature flies. Statistical models for fly counts and blood samples considered week and treatment. The percentage of cells that phagocytized beads, was least in wk 6 and 8 ($P < 0.05$). The percentage of cells expressing CD14 or CD18 increased over time ($P < 0.001$) and STR bedding resulted in more fluorescence of CD18 than did SHV ($P < 0.04$). Hutch fly counts were lowest ($P < 0.02$), but larvae counts were highest ($P < 0.02$) in hutches bedded with STR. It appears SND, STR, or SHV are acceptable bedding materials during moderate summer conditions in the Midwest, but fly larvae counts must be managed with STR.

Key Words: bedding, calf, immunology

W88 Management practices utilized by high-producing Kentucky dairy herds. C. O. Coombs and J. M. Bewley*, *University of Kentucky*, *Lexington*.

Dairy producers often make decisions based on what other producers in their region are doing. The objective of this research was to summarize management practices utilized by Kentucky Holstein herds with rolling herd average milk production greater than 10,000 kg per cow (n = 21) using records obtained from the Dairy Herd Improvement Association. Interviews were conducted on-farm and over the phone. Herd size ranged from 25 to 1590 lactating cows with a mean (±SD) of 186.54 ± 317.22. Daily milk production per cow ranged from 25.95 to 39.59 kg with a mean (±SD) of 32.56 ± 3.44. Test day somatic cell count ranged from 102,000 to 432,000 cells per ml with a mean (±SD) of 256,140 ± 56,170. Average days in milk ranged from 132 to 260 with a mean (±SD) of 212.38 ± 29.7. Days to first service ranged from 69 to 150 with a mean (±SD) of 103.04 ± 23.56. Pregnancy rate ranged from 9% to 20% with a mean (±SD) of 13.6% ± 2.80%. The most common management practices utilized by these producers were regular forage testing (100%), regular utilization of veterinary services for reproductive management (100%), fans or sprinklers (90%), artificial insemination for genetic improvement of lactating cows (86%), artificial insemination on heifers (86%), annual ration balancing (81%), annual hoof trimming (81%), sexed semen (71%), separate far-off and close-up dry cows (67%). The most common mastitis prevention methods utilized were drying teats before attaching milking units (100%), dry treating all quarters at dry-off (100%), pre-dipping (95%), post-dipping (95%), gloves worn by employees (81%), and automatic take offs (81%). When asked to identify the management practice that contributed the most to their milk production level, the most frequently cited reasons were (1) quality for-

ages (n = 4), (2) paying attention to detail (n = 4), (3) cow comfort (n = 3), and (4) balanced rations (n = 3). Generally, farmers in this study achieved high milk production levels by following recommended best management practices, paying attention to detail, and striving for optimal nutrition, milk quality, and cow comfort.

Key Words: best management practices, high milk yield, dairy survey

W89 Organic milk production in Maine: Attributes, costs, and returns. P. S. Heacock*, A. L. Cook, G. K. Criner, and L. A. Bragg, *University of Maine*, *Orono*.

Nearly one quarter of all commercial dairy farms in the state of Maine are certified organic producers. The objective of this study was to assess the current management and financial status of organic producers in the state. Management and financial information was collected from 30 organic dairy producers that completed the 2007 dairy cost of production survey implemented by the University of Maine and the Maine Milk Commission. Summary descriptive statistics were calculated by herd size. The farms were divided by herd size into 3 groups, small, medium and large with 9, 10, and 11 farms in each group respectively. The mean herd size was 30, 55, and 100 for the small, medium, and large farms with annual milk shipped of 130,780 kg, 341,755 kg, and 607,834 kg respectively. This equates to annual milk shipped per cow of 4,359 kg, 6,213 kg, and 6,087 kg for the small, medium and large farms. All farms relied primarily on family labor however the medium and large farms also had a substantial amount of hired labor. Full-time labor equivalents (FTE) for the farm size groups were 1.5, 3.0, and 3.2, with a mean cows per FTE of 20, 18, and 31 for the small, medium and large farms. Annual revenue per cow was $2,801, $4,269 and $4,565 for the 3 farm sizes. Purchased concentrate was the largest expense for all 3 farm sizes, however there was little difference between the 3 groups, ranging from 35 to 37% of total annual costs. Annual operating costs on a per cow basis were $1,963, $2,757, and $2,682 with annual overhead costs per cow of $824, $769, and $829 for the small, medium and large farms respectively. The return to family labor and ownership per cow was $13, $743, and $1,054 for the 3 farm sizes. Milk production per cow was highly correlated with profitability. Results showed that the larger organic dairy farms in Maine are benefiting from economies of size while the smaller operations rely on on-farm diversification and off-farm income to remain viable.

Key Words: organic, finances, herd size

W90 Effectiveness of genetic evaluations in predicting daughter performance in individual herds. H. D. Norman[1], J. R. Wright*[1], C. D. Dechow[2], and R. C. Goodling Jr.[2], [1]*Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*, [2]*Pennsylvania State University*, *University Park*.

Response to genetic selection has been demonstrated nationally for US dairy cattle, but producers are more likely to appreciate the value of genetic selection if trends within their own herds can be shown. Responses from 2004 through 2008 in individual herds by Holstein and Jersey cows were documented for yield (milk, fat, and protein), somatic cell score, productive life, and daughter pregnancy rate. Sire and dam predicted transmitting abilities (PTA) or parent average (PA) from evaluations before first calvings were the independent variables, and phenotypic performance (standardized first-parity yields, somatic cell score, lifetime days milked, and days open) was the dependent variable. Minimum number of cows with usable records per herd was 50. Mean coefficients for regression of standardized yield on PA for the same trait was 0.73 for milk, 0.79 for fat, and 0.69 for protein for 8,257 Holstein herds and 0.79, 0.72, and 0.73 for 441 Jersey herds. The majority of individual herd regression coefficients for yield traits were between 0.3 and 1.0; their standard deviations were between 0.38 and 0.47. Regression coefficients may have been < 1.0 because PA was based on all-parity yield whereas phenotypic yield was only from first parity or because the heritability assumed for calculating PTA was too high. Mean regression coefficients for somatic cell score, productive life, and daughter pregnancy rate were 0.82, 0.65, and 0.81, respectively, for Holsteins and 0.65, 0.56, and 0.85 for Jerseys; their corresponding standard deviations were 0.66, 0.75, and 1.07 for Holsteins and 0.77, 0.80, and 1.14 for Jerseys. Mean coefficients for regression of sire PTA on phenotypic performance ranged from 0.53 to 0.80; mean regression coefficients for dam PTA ranged from 0.43 to 0.86. Although standard errors were large, response to genetic selection on a within-herd basis could be demonstrated, which should help increase confidence in national genetic evaluations.

Key Words: herd prediction, yield, fertility

W91 Winter feeding strategies for lactating organic dairy cows. P. S. Heacock*, D. P. Marcinkowski, G. W. Anderson, M. R. Stokes, and R. Kersbergen, *University of Maine*, *Orono*.

In northern climates, the highest feed costs for organic dairies are seen during the non-grazing season. The objective of this project was to examine the effects of different forage and concentrate systems on the nutrition, production and economics of winter-fed, organic dairy cows. Two organic forage systems were compared, the first consisting entirely of grass haylage (GH) and the second consisting of grass haylage and corn silage with other summer annuals (CS). Two concentrate supplementation methods were also compared, the first consisting of a commercially available pellet (P) and the second a mixture of homegrown grains and commodities (C). Four rations were developed to support 31.75 kg of milk/day. Each ration consisted of one forage and one concentrate option. Twenty-eight Holstein cows were divided into 4 groups and fed the 4 rations in a 4 × 4 Latin square design. All of the feeds fed were organically certified and the cows were managed organically for the duration of the project. Few production differences were found between the treatments. Daily energy-corrected milk (ECM) was similar, averaging 28.25 kg for the GH-C, 28.04 kg for CS-C, 27.31 kg for GH-P and 26.80 kg for the CS-P ($P > 0.05$). Milk fat was lower with the CS-C ration and there was a difference in milk urea nitrogen (MUN) between all 4 treatments with 17.27 mg/dL for the GH-P, 14.80 mg/dL for the GH-C, 12.52 mg/dL for the CS-C and 11.20 mg/dL for the CS-P ration. Feed costs and income over feed costs (IOFC) varied greatly between the treatments. Daily feed costs averaged $9.18, $9.03, $7.87 and $7.25 for the CS-P, CS-C, GH-P and GH-C respectively. IOFC was $7.47, $8.47, 9.08 and 10.27 for the CS-P, CS-C, GH-P and GH-C respectively. Organic dairy producers have fewer feeding options so they must rely on high quality forages and homegrown grains for the majority of their nutrient needs. Results showed a financial advantage to haylage diets when compared with corn silage diets due to the high cost of organic protein sources.

Key Words: organic, nutrition, feed cost

W92 A milker's school for international refugees resettled in Idaho. J. C. Dalton*[1], K. S. Jensen[2], R. Manzo[3], and L. Whiteford[3], [1]*University of Idaho*, *Caldwell*, [2]*University of Idaho*, *Owyhee County*, [3]*International Rescue Committee*, *Boise, ID*.

Each year approximately 1,000 documented, work-authorized refugees are resettled in Idaho. These refugees originate from over 20 different countries, and speak more than 27 different languages. At the request of the International Rescue Committee in Boise, Idaho, University of Idaho Extension developed an introductory-level milker's school for international refugees resettled in Idaho. The program consisted of 4 h of classroom teaching, and was held in Caldwell, Idaho. Topics included udder anatomy, cow preparation and sanitation, milk letdown, milk removal and milking unit handling, mastitis, prevention of antibiotic residues in bulk tank milk, milking systems, and the role of the dairy industry in Idaho's economy. All material was presented in English and translated for refugees from Burma, Somalia, Eritrea, Uzbekistan, Nepal, Iraq, Afghanistan, Togo, and Bhutan. In 2009, 4 milker's schools were conducted, with 128 refugees attending. A certificate of completion was awarded to all participants at the conclusion of the program. Sixteen refugees are currently working at a dairy in Oregon. In anticipation of emergence from the economic recession and stabilization of the dairy economy, further educational opportunities are planned, including calving management and artificial insemination schools, to provide refugees with additional marketable skills necessary to secure employment on dairies. The delivery of this program provided: 1) an educational opportunity for international refugees resettled in Idaho, 2) participants the knowledge and skills necessary to succeed as dairy employees, and 3) increased the diversity in University of Idaho Extension programs.

Key Words: milker, refugee, dairy

W93 Limitations and opportunities of beef and dairy operations for the use of ethanol co-products. J. I. Navarro*[1], L. J. Snyder[1], R. P. Lemenager[1], and S. L. Lake[2], [1]*Purdue University*, *West Lafayette, IN*, [2]*University of Wyoming*, *Laramie*.

A survey instrument was developed to assess the attitudes and the potential for bio-fuel co-products use among beef and dairy producers. The main objective was to inventory resources that currently offer challenges and opportunities for the utilization of bio-fuel by-products by small and medium-sized beef and dairy producers. The survey was distributed at 10 of the Regional Beef meetings during the winter of 2006–2007 and at 5 of the Regional Dairy meetings during the spring of 2007 organized by Purdue University Extension. Participants represented 414 different operations. The instrument contained 22 questions related to demographic characteristics, resources available, average production characterization, production goals, management practices, soil quality and environmental concerns. Some of the most evident limitations identified by the survey participants were size of the operation, storage facilities and equipment required. An additional analysis of the 13 ethanol plants across Indiana and the location of the participants operation were performed to identify possible links between the availability of distiller's grains and the willingness use these as alternative feeds. The survey results indicated that the majority of the participants, 75% of the beef and 84% of the dairy operations, have considered using bio-fuel co-products as a source for livestock feed. This data suggests that there is an opportunity for the use of co-products to lower feed cost and improve profitability in the beef and dairy industries if viable methods were implemented for small and medium-sized producers to utilize ethanol co-products.

Key Words: cattle producers, ethanol co-products, feed alternatives

W94 Farm animal welfare: Assessing public concern and attitudes. D. R. Deemer[1], J. A. Pempek*[1], L. M. Lobao[1], G. J. Coleman[2], and M. L. Eastridge[1], [1]*The Ohio State University*, *Columbus,* [2]*Monash University*, *Clayton, Victoria, Australia*.

Farm animal welfare has long concerned animal scientists, social scientists, and the food animal industry. However, relatively little is known about the US population's recent views regarding farm animal welfare. Much of our knowledge is based on case-studies or other research with limited generalized inferences. Among the questions consistently raised by analysts is the relationship between the public's knowledge of farm animals and their attitudes and food consumption behavior. Our research addresses the gap in the literature by examining the public's knowledge of farm animals, as well as other key covariates and their relationship to attitudes and food consumption behavior. Data are from a large, random sample of the Ohio population (N=1,000) and a comparative smaller nationwide sample taken during 2007. Along with variables measuring knowledge about farm animal production, we evaluated the relevance of key demographic variables, such as rural-urban residence, gender, income, and ethnicity. Multiple regression models using different dependent variables of animal welfare attitudes and behavior were employed. These models explained about 20% of the variance in attitudes, similar to studies of general attitudes. Across these models, the most consistent correlates of greater concern with farm animal welfare were gender (women) and urban residence, with standardized betas values ranging from (−0.130 to −0.207) for gender and from (−0.003 to −0.146 for urban residence). Based on these and other control variables of income and ethnicity, knowledge of farm animal production had little impact on attitudes and behavior. These results suggest that educational outreach to improve knowledge of farm animal production may have limited impact on attitudes and behavior relating to farm animal welfare.

Key Words: farm animal welfare, attitudes, behaviors

W95 Reproductive indicators in dairy cattle enterprises with different technological level. A. Pacheco Cervantes, D. V. Mariscal Aguayo*, H. Estrella Quintero, M. Huerta Bravo, R. Rangel Santos, and R. Núñez Domínguez, *Universidad Autónoma Chapingo*, *Jalisco, México*.

The objective of the study was to assess the reproductive behavior of family dairy enterprises that used Chapingo-Agropec Star, the technological development model for advice and consulting. The farms were stratified in 2 technological levels, transition and business, based on the following components: education, bovine equivalent, equivalent irrigation area, and production technology. The information used for the study was obtained from the general report generated by Agropec Star software which was captured by advisors of the farms. The database was made up of 17 enterprises with a total of 2,041 Holstein cows from 1996 to 2008. Age at first parturition (EPP), interval from calving to first estrus (IPC), interval from calving to first service (IPS), services per conception (SPC), days open (DA), and calving interval (IEP) were the evaluated variables. Effects in the statistical model included technological level (NT), number (NP), year (AP), and season (EP) of calving, and significant interactions ($P < 0.05$). The technological level affected ($P < 0.05$) IPS and IPC. Furthermore, the technological level interaction by year of calving not only affected these 2 variables (IPC and IPS) but also influenced EPP. Intervals at first estrous and first service interval presented at the technological business level (63.8 ± 6.2, 75.7 ± 5.5) were lower than the transitional technological level (90.8 ± 2.7, 91.1 ± 2.3). No significant differences ($P > 0.05$) were found for DA; however there was a tendency ($P > 0.08$) for an improvement in the reproductive behavior of the family business system.

Key Words: farms, Holstein, stratification

W96 Case study: Characterization of lying behavior in dairy cows transitioning from a freestall barn to a compost bedded pack barn. C. Gravatte*, C. Coombs, and J. Bewley, *University of Kentucky*, *Lexington*.

Cows devoid of ample lying time exhibit both physiological and behavioral signs of stress. Some dairy producers have begun using a new housing system, called a compost bedded pack barn. The key component of a compost bedded pack barn is an open resting area generally bedded with sawdust, dry fine wood shavings, or other organic materials. Compared with freestalls, cows have more room for movement and are able to lie down in a more natural manner. Our hypothesis states lying times would increase in a herd transitioning from a freestall barn to a compost bedded pack barn. The lying times of 11 lactating Holstein-Friesian cows were measured using an activity monitor in a commercial dairy herd. Cows were divided among 3 milk production categories (high, medium, and low). An IceTag animal activity monitoring sensor (IceRobotics Ltd., Edinburgh, Scotland, UK), which measures posture (lying versus standing) and steps, was attached to a hind leg of each cow above the fetlock. The MIXED procedure of SAS was used to fit a model describing the differences in hours lying between the 2 housing systems. Because of a delay in barn construction, more days were recorded (n = 872) for the freestall barn than the compost bedded pack barn (n = 212). LSMeans for hours lying were 9.7 ± 0.4 h/d and 13.5 ± 0.5 h/d for cows housed in the freestall barn and compost bedded pack barns, respectively ($P < 0.0001$). Older cows (Parity 2) spent significantly more ($P < 0.01$) time lying (12.7 0.6 h/d) than younger cows (parity 1) cows (10.5 0.4 h/d). Additionally, lying times were significantly shorter for cows with a locomotion score of 3 (10.5 0.5 h/d) than for cows with a locomotion score of 1 (12.2 0.7 h/d, $P < 0.05$) or 2 (12.2 0.0.7 h/d, $P < 0.05$). Although other factors may have affected lying behavior as the cows progressed through lactation and environmental conditions varied, lying times were significantly longer after the cows were housed in the compost barn. These results are representative of one dairy operation, though the significant increase in lying time demonstrates a need for further research.

Key Words: precision dairy farming, compost bedded pack barn, lying time

W97 Composting school: An educational tool to bring together dairy producers and other community members. M. E. de Haro Martí*[1] and J. A. Robbins[2], [1]*University of Idaho*, *Gooding*, [2]*University of Idaho*, *Jerome*.

Composting organic waste is an environmentally sound technique used around the world. Several studies have demonstrated the benefits of compost as soil amendment, sustainable waste treatment, and sound agricultural practice. In fall 2008 a unique "Composting School" program was held at the Gooding County Extension Office in response to stakeholder's questions and to teach them composting techniques and use. The program included 2 sessions that were conducted at the Gooding County Extension Office in late summer and early fall 2008. Two novelties made this program different from others offered in Idaho. First, the targeted audience was very heterogeneous including dairy producers, home owners, small farmers, and owners of horses, llamas, hogs, and sheep. The second idea included a hands-on section addressing composting techniques. After receiving theoretical training about composting, participants had the opportunity to build different systems for on-farm, home, and worm composting on site. During the second session, participants received a deeper overview of on-farm composting including mortality composting and compost use. Participants continued with the hands-on section by turning the piles and analyzing the performance of the different composting techniques built during the first session. The performance analysis detected a significant difference ($P < 0.01$) in temperature between the on-farm composting techniques and the home techniques. None of the 6 home composting units reached temperatures required by the Processes to Further Reduce Pathogens (PFRP). All 3 on-farm composting units reached PFRP. Forty-two participants attended the program. The program evaluations demonstrated that 50% of the respondents learned "a great deal," and 88% indicated they would adopt 2 or more techniques not used before attending the school. A permanent composting facility display remains at the Gooding Extension Office and is used with new programs.

Key Words: composting, waste management, extension

Food Safety 2

W98 Efficacy of ultraviolet light systems for control of microorganisms in poultry and beef brine and marinade solutions. K. L. Beers*, P. E. Cook, C. W. Coleman, and A. L. Waldroup, *MCA Services*, *Rogers, AR*.

Brine and marinade solutions injected into raw beef and poultry products have increasingly become a food safety concern due to continuous injection and recycling of the solution, allowing for a significant microbial increase. This results in several food safety issues including transfer of microorganisms into the sterile muscle of the products and deterioration of the injection solution as microorganisms increase to unacceptable levels. Safe Foods Corporation conducted a series of 8 individual trials, either in a laboratory setting (MCA Services, Rogers, AR) or at USDA-inspected processing facilities, to investigate the effects of using commercially available UV light (UVL) systems, specifically, Fresh*Light* models 210 and 220, for control of naturally occurring and inoculated pathogens in these solutions. The laboratory testing included inoculation of solutions with pathogenic bacteria including *Salmonella typhimirium*, *E. coli* O157:H7 and *Listeria innocua*. Processing plant trials involved evaluating solutions for naturally occurring organisms. The flow rate in the UVL systems ranged from 30 to 150 L/minute depending on the UVL model and application. In all 8 trials, regardless of the bacteria evaluated (naturally occurring organisms or inoculated pathogens), location of testing (laboratory or processing facility) or the UVL system utilized, the original level of microorganisms in the solutions was significantly reduced by >2 logs/mL (99%) to as much as 6 logs/mL (99.9999%) at standard plant operating conditions. In some trials, the UVL system eliminated all microorganisms from the solutions. In conclusion, the commercially available Fresh*Light* 210 or 220 is fully capable of consistently controlling, and/or eliminating, microorganisms from poultry and beef brine and marinade solutions while providing the processor with an affordable means of significantly improving the safety and quality of their injected products.

Key Words: Fresh*Light*, ultraviolet light, brines and marinades

W99 Antimicrobial susceptibility profile of enterotoxigenic *Staphylococcus* sp. recovered from foodborne outbreaks in Minas Gerais state, Brazil, from 1998 to 2002. J. F. Veras, C. F. A. M. Penna, M. R. Souza, M. O. Leite, L. M. Fonseca, L. S. Carmo, and M. M. O. P. Cerqueira*, *Federal University of Minas Gerais state*, *Belo Horizonte, Minas Gerais, Brazil*.

The aim of the present study was to evaluate the antimicrobial susceptibility profile of the *Staphylococcus* sp recovered from 16 outbreaks involving milk and dairy products that took place from 1998 to 2002 in the State of Minas Gerais, Brazil. These outbreaks were investigated by Fundação Ezequiel Dias (FUNED), Brazil and in 16 food poisoning outbreaks, 14 (87.5%) were due to cheese consumption and 2 (12.5%) were due to raw milk intake. For the isolated food, the main agents were enterotoxigenic *Staphylococcus* sp and *Salmonella* sp, *Shigella* sp. and fecal coliforms. The average of *Staphylococcus* sp strains was 8.6×10^7 CFU/g or mL (7.93 log CFU/g or mL). The enterotoxins detected isolately were SEB and SEC, and in association were SEA + SEB. For antimicrobial susceptibility profile of 152 samples recovered, at least 48 samples (31.57%) were resistant to one or more antimicrobial. It was observed that 18.42% (28) of these samples were resistant to penicillin G, 12.5% (19) to erythromycin, 7.9% (12) to tetracycline, 6.5% (10) to oxacillin, 5.92% (9) to cephalosporin, 3.28% to gentamycin, and same percentage to chloramphenicol. *S. aureus* showed the highest percentage to antibiotic resistance.

Key Words: antimicrobial, susceptibility, enterotoxigenic *Staphylococcus* sp.

W100 Occurrence and antimicrobial resistance of *Campylobacter jejuni* isolated from poultry carcasses commercialized at the Federal District area, in Brazil. A. P. Santana*, D. C. Ruy, H. M. Moura, and S. Perecmanis, *Universidade de Brasília*, *Brasilia, DF, Brasil*,

Worldwide, campylobacteriosis is a disease that causes diarrhea in humans and poultry have been identified as a significant source of the *Campylobacter jejuni*. Frequently this disease is associated with the consumption of contaminated poultry meat or cross-contaminated with other foods. In Brazil, there are few researchers studying the occurrence of this microorganism and analyzing antimicrobial resistance in this type of food, however, not at the Federal District area. The aim of this work was to verify the occurrence of *C. jejuni* in cooled carcasses of poultry commercialized in the Federal District, as well as to analyze the antimicrobial resistance. From a total 101 samples of cooled carcasses were analyzed, 9 of them were acquired in popular markets without previous sanitary inspection and 92 samples with. Considering the 101 samples, *C. jejuni* was detected in 17.82% of samples (18 carcasses), all from markets with previous sanitary inspection. However, *C. jejuni* was not detected in any of the 9 samples from popular markets without sanitary inspection. In this study, a total of of 18 strains were isolated from the carcasses but only 16 were successfully not cultivated in plates. The 16 strains of *C. jejuni* were submitted to the antimicrobial analysis to 8 drugs (nalidixic acid, streptomycin, gentamycin, erythromycin, amoxicillin, chloramphenicol, ciprofloxacin and tetracycline). All 16 (100%) strains of *C. jejuni* were resistant to ciprofloxacin, 15 (93.75%) were resistant simultaneously to nalidixic acid, streptomycin, tetracycline and gentamycin, 14 (87.5%) of strains were resistant to amoxicillin, 11 (68.75%) were resistant to erythromycin and the minor resistance observed was to chloramphenicol 6 (37.5%). Considering the presence of antimicrobials resistance, these results were similar to other countries, however superior in percentage of resistance, except for ciprofloxacin and nalidixic acid. These results suggest imperfections in many phases of processing of poultry carcasses and a possible problem of public health due the high resistance observed.

Key Words: resistance, *Campylobacter jejuni*, chicken meat

W101 Antibacterial activity of trans-cinnamaldehyde, eugenol, carvacrol, and thymol on *Salmonella* Enteritidis and *Campylobacter jejuni* in chicken cecal contents *in vitro*. A. Kollanoor Johny*[1], M. J. Darre[1], M. I. Khan[2], A. M. Donoghue[3], D. J. Donoghue[4], and K. Venkitanarayanan[1], [1]*Department of Animal Science, University of Connecticut*, *Storrs,* [2]*Department of Pathobiology and Veterinary Science, University of Connecticut*, *Storrs,* [3]*Poultry Production and Product Safety Research Unit, ARS, USDA*, *Fayetteville, AR,* [4]*Center for Excellence in Poultry Science, University of Arkansas*, *Fayetteville*.

Salmonella Enteritidis and *Campylobacter jejuni* are 2 major food-borne pathogens that are transmitted through poultry products. These pathogens colonize the chicken cecum leading to contamination of carcasses during slaughter and subsequent processing operations. We investigated the antimicrobial efficacy of 4 GRAS-status, plant-derived molecules

namely, trans-cinnamaldehyde (TC), eugenol (EUG), carvacrol (CAR) and thymol (THY) against *Salmonella* Enteritidis and *Campylobacter jejuni* in chicken cecal contents in vitro. The plant molecules were added at different concentrations (ranging from 10 to 75 m*M* for *S.* Enteritidis and 10 to 30 m*M* for *C. jejuni*) to autoclaved chicken cecal contents inoculated with ~7.0 $\log_{10}$ CFU/mL of *S.* Enteritidis or *C. jejuni*. The pathogen populations in the cecal contents after 15 s, 8 h and 24 h of incubation at 39°C were determined. Duplicate samples of treatments and control were included, and the study was replicated 3 times. *C. jejuni* was more sensitive to all the molecules than *S.* Enteritidis ($P < 0.05$). All molecules were highly bactericidal, with the lowest concentration of TC (10 m*M*) significantly reducing ($P < 0.05$) *S.* Enteritidis populations by > 6.0 $\log_{10}$ CFU/mL after 8 h and > 8.0 $\log_{10}$ CFU/mL after 24 h of incubation. TC at 25 m*M* completely inactivated ($P < 0.05$) *S.* Enteritidis by 8 h of incubation. On the other hand, TC at all tested concentrations (10, 20, and 30 m*M*) completely killed *C. jejuni* ($P < 0.05$) after 8 and 24 h of incubation. CAR and EUG completely inactivated *S.* Enteritidis and *C. jejuni* at 50 and 75 m*M* and 20 and 30 m*M*, respectively. THY was also equally effective in killing both pathogens. The results indicate that these aforementioned molecules could potentially be used to reduce *S.* Enteritidis and *C. jejuni* in chicken ceca, however follow up in vivo studies are necessary.

Key Words: *Salmonella*, *Campylobacter*, antimicrobial, plant-derived molecules

W102 Effects of dietary antimicrobials on fecal shedding of *Campylobacter, Salmonella*, and Shiga-toxin producing *Escherichia coli* in production swine. J. E. Wells*, N. Kalchayanand, E. D. Berry, and W. T. Oliver, *USDA, ARS, US Meat Animal Research Center*, *Clay Center, NE*.

Antimicrobials are used in swine diet to improve growth and reduce disease. Increasing pressure to remove antimicrobials from swine diets could alter efficiency, but little information is reported on the impact of feeding antimicrobials on zoonotic pathogen shedding. Barrows (n = 160) were sorted by weight into 2 treatments, and fed growing, grow-finishing, and finishing diets from age 10 to 14 wk, 14 to 18 wk, and 18 to 22 wk, respectively. For each feeding phase, diets were prepared without (A-) and with (A+) dietary antimicrobials (chlortetracycline, 10 to 18 wk; bacitracin, 18 to 22 wk). At wk 10, 14, 18, 19, 20, and 22, fecal swabs were collected from each animal for *Campylobacter* and *Salmonella* spp. and fecal grabs were collected from one-quarter of the piglets for Shiga-toxigenic *Escherichia coli* and Shiga-toxin gene analyses. *Salmonella* was only observed early in the study at low prevalence and was not affected by treatment. *Campylobacter* was not found in piglets at wk 10, but prevalence increased over the study for both treatments. In the growing and grow-finishing phases (wk 14 and 18), *Campylobacter* was present in 23 and 7% ($P = 0.04$) and *stx* genes were present in 25 and 17% ($P = 0.05$) of samples from A- and A+ groups, respectively. In the finishing phase, time was an interaction with treatments. *Campylobacter* did not differ between treatments for pooled wk 19 and 20 (15 vs. 9.4%, A- and A+; $P = 0.09$) but was different for wk 22 (19 vs. 38%, A- and A+; $P = 0.007$). The prevalence of *stx* genes was not different between treatments for wk 19 (39 vs 26%, A- and A+; $P = 0.06$), but by wk 20 and 22 *stx* gene prevalence was different (49 vs. 68%, A- and A+; $P = 0.01$). Shiga-toxin producing *E. coli* serogroups O26, O103, and O145 were isolated from 7.2% of the samples with fewer positives found at end of trial ($P > 0.1$). Diets with chlortetracycline reduced pathogen shedding, but switching to bacitracin at 18 wk of age increased pathogen shedding with time compared with the A- group.

Key Words: antibiotics, food safety, pathogens

W103 Persistent effect of thymol and diphenyliodonium chloride against *Campylobacter coli* in vitro. N. A. Krueger*, R. C. Anderson, T. R. Callaway, T. S. Edrington, and D. J. Nisbet, *USDA-ARS Southern Plains Agriculture Research Center, Food and Feed Safety Research Unit*, *College Station, TX*.

Campylobacter are important foodborne pathogens that may colonize the gut of food producing animals. The objective of this experiment was to determine if a single administration of the purported deaminase inhibitors, thymol and diphenyliodonium chloride (DIC), each may effectively reduce *Campylobacter coli* concentrations during consecutive batch culture of mixed populations of swine gut bacteria. Gut bacteria present in freshly collected fecal material (0.3 g) were mixed with 150 mL anaerobic (100% N_2) Bolton broth and inoculated with approximately 10^6 colony-forming units (CFU) of an overnight grown (in Bolton broth) *C. coli* culture. Ten-milliliter volumes were distributed in triplicate to crimp top tubes preloaded with 0.1 mL volumes of water, thymol or DIC to achieve a single initial treatment of either 0, 1.0 m*M* thymol or 0.01 m*M* DIC and were incubated at 39°C. After 8 h incubation, 1 mL was withdrawn from each tube and inoculated into a second series of tubes containing 9 mL fresh anaerobic Bolton broth but without treatment additions. The second tube series was then incubated for 8 h after which time the process was repeated to achieve the completion of 5 consecutive batch cultures. Log_{10}transformations of *C. coli* CFU determined at the beginning and end of each culture series were subjected to a general ANOVA. Results revealed a treatment × time × series interaction ($P < 0.0001$). Counts measured upon initiation of the first incubation series averaged 5.73 ± 0.05 (SD) $\log_{10}$ CFU mL^{-1} but declined ($P < 0.05$) more than 3.4 $\log_{10}$ CFU mL^{-1} from this value by the end of the first culture series for thymol and DIC-treated cultures and never recovered thereafter; being below our detection limit (1.3 $\log_{10}$ CFU mL^{-1}) by the end of the third transfer series. Conversely, *C. coli* counts in nontreated cultures were not reduced from initial values until the end of the third cultures series, at which time C. coli counts were 2.7 $\log_{10}$ CFU mL^{-1} lower ($P < 0.05$) but always above our level of detection. Results demonstrate that a single initial treatment of thymol or DIC effectively and persistently reduced *C. coli* during anaerobic culture in vitro.

Key Words: *Campylobacter*, food safety, swine

W104 Evaluating different gas delivery methods that create a microaerophilic environment for culturing *Campylobacter jejuni*. M. D. Haines*, K. N. Eberle, C. D. McDaniel, and A. S. Kiess, *Mississippi State University*, *Mississippi State*.

Most techniques used for culturing *Campylobacter* species require a microaerophilic gas atmosphere. Currently there are several different methods available to deliver the appropriate microaerophilic gas environment. The objective of this experiment was to evaluate *Campylobacter jejuni* growth using 3 different gas delivery methods (Anoxamat, Campy EZ Gas-Pak, and Zip-Lock bags). Approximately 50 to 100 *Campylobacter* cells were suspended in brucella broth and spread plated onto Campy-Cefex agar plates. Plates were placed into either Mart anaerobic canisters or zip-lock bags for culturing. The microaerophilic gas was delivered to the plates in the Mart anaerobic canisters by either the Anoxomat AN2CTS Mark II System or through the activation of 3 Campy EZ Gas-Paks. For plates being incubated in zip-lock bags, the microaerophilic gas was delivered by directly flushing the bag with a pre-mixed gas; once the bag was full it was sealed. The canisters and zip-lock bags were then placed into a low temperature incubator for 24 h, at 42°C. After the 24 h incubation period, plates were counted. The entire experiment was then repeated. The results indicated that no difference in colony counts existed between the methods evalu-

ated. Colonies on plates which had the gas delivered by the Campy EZ Gas Pak method were much smaller in size than colonies on plates that had the gas delivered by the other 2 methods. In conclusion, all 3 gas delivery methods were able to produce similar *Campylobacter* results between experimental runs. Additionally, the smaller colonies from the EZ Gas-Pak method could be a result of our media choice or the anaerobic chamber used. It is important to consider these issues when deciding on the appropriate microaerophilic gas delivery method to use for culturing *Campylobacter*.

Key Words: *Campylobacter*, microaerophilic, gas delivery

W105 Aflatoxicosis in Haiti: Detection and detoxification strategies. M. E. Filbert* and D. L. Brown, *Cornell University*, *Ithaca, NY*.

Aflatoxins are carcinogenic, immunosuppressive agents produced by *Aspergillus* mold in crops. Haiti's climate facilitates fungal growth, threatening staple foods such as peanuts and maize, which are highly susceptible to aflatoxin contamination. The danger of aflatoxin poisoning is of concern in Haiti where food is scarce and consumption of the toxin is inevitable. Because of serious health risks, the maximum allowable level of aflatoxin in agricultural commodities (except milk) intended for human consumption is 20 μg aflatoxin/kg product. The overall objective of this research project was to determine the nature and extent of aflatoxicosis in a malnourished population. There are no food safety standards or regulations on any level of food production in Haiti. Our laboratory has not yet found Haitian peanuts from any source that did not exceed allowable aflatoxin limits. Initial peanut samples taken in northern Haiti in 2005 and analyzed using ELISA-aided fluorometry, averaged 797.5 ± 218.5 μg/kg and ranged from 380 to 1567 μg/kg. In 2006, sampled peanuts from a public market found to average 412.5 ± 32.1 μg/kg; peanuts from a farmer's stored supply averaged 125 ± 7.1 μg/kg. A visibly unspoiled sample from a local farm was tested, averaging 26.8 ± 7.0 μg/kg. Another post-sorting sample taken in early 2007 averaged 0.20 ± 0.10 μg/kg, revealing the effectiveness of selection and sorting methods in the elimination of aflatoxin. Peanut butter samples collected in 2009 averaged 236.4 ± 196.7 μg/kg and ranged in levels from 7.3 to 720 μg/kg, validating the need for implementation of sorting methods at every level of food production. An ongoing study using urine will assess aflatoxin catabolism in a malnourished population. Health risks can be reduced by determining contamination levels and understanding aflatoxin metabolism. The results of this study will provide the information needed to meet the long-term goals of implementing food preparation procedures to remove aflatoxin as a barrier to the nutritional support and recovery of malnourished individuals.

Key Words: aflatoxin, peanuts, Haiti

W106 Conjugated linoleic acid does not modify liver histology and hepatic triglyceride content in young pigs. I. Fernandez-Figares*[1], A. Martin[2], M. Lachica[1], R. M. Nieto[1], and J. F. Aguilera[1], [1]*CSIC, Spanish Research Council*, *Granada, Spain*, [2]*Servicio de Anatomia Patologica, HU Virgen de las Nieves*, *Granada, Spain*.

Interest in feeding CLA to pigs has increased in the last decade as a result of its potential to improve growth parameters as well as to reduce body fat (J Anim Sci. 79:1821–8). Interestingly, in mice, adipose tissue reduction was accompanied by liver enlargement and esteatosis (Diabetes. 49:1534–42). In pigs, however, there is no evidence of enhanced liver weight after CLA administration (J Anim Sci. 86:102–11). Therefore, the aim of the present work was to evaluate possible adverse effect of feeding CLA supplemented diets to pigs on liver fat content and histology. Twenty gilts (20 kg BW) were individually penned and fed at 95% ad libitum barley-soybean meal based diets (12% CP, 0.81% lysine and 14.8 MJ ME / kg DM) containing 1% CLA (60% CLA isomers, half *cis*-9, *trans*-11 and half *trans*-10, *cis*-12 in FFA form, BASF) or linoleic acid. At 50 kg, pigs were slaughtered and liver samples immediately frozen in liquid nitrogen and preserved at −80°C until analysis. Thawed liver samples were homogenized and TG extracted with 2:1 chloroform/methanol using the Folch method and dissolved in isopropanol. TG content was determined quantifying the glycerol content, using an enzymatic colorimetric assay. For histology, the livers were thawed and fixed in 10% buffered formaline. After routine processing, livers were embedded in paraffin, sectioned at 5 μm and stained with hematoxylin-eosin and reticulin stain. Triglycerides data were analyzed as one-way ANOVA in a completely randomized design with treatment as the fixed effect. Significance was set at $P < 0.05$ and differences among means were determined using a Tukey's *t*-test. Overall, no differences in triglyceride content was encountered when CLA fed pigs were compared to control pigs (2.1 and 1.6 mg/g, respectively; $P > 0.10$). In the histological study, all livers showed normal histology, without evidence of inflammatory changes, fibrosis or esteatosis.

Key Words: CLA, pig liver, triglycerides

W107 Use of *Pleurotus oestreatus* to change the nutritional quality of maize stover. O. D. Montañez-Valdez*[1], J. M., Tapía-Gonzalez[1], G. Rocha-Chavez[1], J. A. Martínez-Ibarra[1], C. E. Guerra-Medina[2], E. O. Flores-García[2], and J. H. Avellaneda-Cevallos[3], [1]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [2]*Universitario de la Costa Sur de la Universidad de Guadalajara*, *Autlán, Jalisco, México*, [3]*Universidad Técnica Estatal de Quevedo*, *Santo Domingo. Quevedo, Los Ríos, Ecuador*.

A study was conducted to evaluate the effect of *Pleurotus oestreatus* on chemical composition of maize stover. Maize stover treated and untreated with *Pleurotus oestreatus*, were obtained from a commercial facility. Ten samples of maize stover used previously as substrate to culture edible fungus were collected randomly. The negative control group consisted of the pasteurized maize stover untreated with *Pleurotus oestreatus*. All samples were analyzed to determinate dry matter (DM), organic matter (OM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), cellulose (C), hemicellulose (HC) and lignin (L). Data were analyzed by mean comparison using a Student's *t*-test. No differences ($P \geq 0.05$) between treatments were found for DM, CP, C and HC; however, treated maize stover ($P \leq 0.02$) showed higher percentages of OM (89.07 vs. 84.83), NDF (69.65 vs. 63.74), and ADF (48.18 vs. 43.68) as well as a lower L value (9.20 vs. 12.22). The growth of *Pleurotus oestreatus* on maize stover changes its chemical composition by increasing organic matter content and modifying cell wall components, this may improve the nutritional quality of agricultural byproducts. This process may allow using *Pleurotus oestreatus*-treated maize stover for ruminant feeding

Key Words: agricultural byproducts, white rot fungi, chemical composition

W108 Effect of the fermented apple pomace (manzarina) on the rumen epithelia growth with lamb feedlot diets. C. Rodríguez-Muela*[1], H. E. Rodríguez-Ramírez[1], A. Grado[1], A. Corral[1], O. Ruiz-Barrera[1], A. Arzola[1], and R. Bocourt[2], [1]*Universidad Autónoma de Chihuahua*, *Chihuahua, México*, [2]*Instituto de Ciencia Animal*, *La Habana, Cuba*.

The objective of this research was to evaluate the effect of manzarina (mzn) in the development of the ruminal epithelia, antioxidant activity and blood chemistry profiles of sheep plasma. Four treatments (Tr) were designed (n = 24, 12 males and 12 females): Tr1, males with 10.9% mzn diet (DM basis); Tr2, females with mzn diet; Tr3, males with basal diet; Tr4, females with basal diet. Basal diet contained (DM basis) 38.5% alfalfa hay, 12.4% soybean meal, 42.5% steam rolling corn, 2.0% animal fat, 3.1% molasses, 0.7% salt and 0.8% vitamin and mineral premix. Lambs remained in individual cages (0.5 × 1.0m), with water and food ad libitum by 58d. Two samples of blood were taken every 30 d (beginning, intermediate and at the end of the experiment), to determinate antioxidant activity (AA by Ferric Reductive Ability of Plasma) and the blood chemistry profiles (BC). Animals were slaughtered and 4 samples were taken of rumen wall to measure the long and wide of papillae on ruminal epithelia. Data of AA and BC was analyzed with a mixed model (fixed effects: Tr, sampling, sex and their interactions). An experimental unit nested in Tr as random effect was used. A hierarchical model was used to analyze long and wide of papillae. Effects of Tr, sex and their interaction were nested in the sampling rumen area. Results showed that AA of Tr1 was greater ($P < 0.06$) than AA of Tr2 animals on sampling 3 (24.34 vs. 21.79 mM Fe_2). There was an increment over time ($P < 0.05$) of leucocytes in all animals (7.52×10^3 uL^{-1} to 9.14×10^3 uL^{-1}). Leucocytes began to increase at 30th day of feeding period, with values inside the normal rank of these animal species without treatment effect ($P > 0.05$) for the remaining BC indicators. Animals of Tr1 had greater ($P < 0.05$) long of papillae (3.04 ± 0.07 mm) than Tr3 animals (2.43 ± 0.05 mm). Wide of papillae was greater ($P < 0.05$) in the animals consuming mzn diet (1.99 ± 0.02 mm) versus animals consuming diet without mzn (1.90 ± 0.02 mm). We conclude that the use of the manzarina in lamb feedlot diets improved the AA in plasma and stimulated the growth of the Rumen Epithelia.

Key Words: antioxidant, leucocytes, papillae

W109 Effects of ensiling king grass with *Albizia lebbeck* on fermentation and nitrogenous compounds of silage mixtures. T. Clavero* and R. Razz, *Centro de Transferencia de Tecnologia en Pastos y Forrajes, Universidad del Zulia*, *Maracaibo, Estado Zulia, Venezuela*.

King grass (*Pennisetum purpureum* × *Pennisetum typhoides*) silage is low quality with low nitrogen concentration. This study determined whether addition of albizia (*Albizia lebbeck*) would improve the quality or nitrogen status of the silage in a tropical dry forest in northwest Venezuela. The treatments for silage making were: 100% king grass (KG), 30% albizia (A):70% KG, 50% A:50% KG, 70% A:30% KG, 100% A. Chopped fresh plant materials of at least 1 cm length were ensiled into a laboratory silos and stored at 25°C for 45 d. After opening silos, dry matter (DM), pH, total nitrogen content (TN), protein nitrogen (PN), soluble nitrogen (SN), PN/TN, ammonia nitrogen (AN), neutral detergent fiber nitrogen of total nitrogen (NNDF/TN), and acid detergent fiber nitrogen of total nitrogen (NADF/TN) were determined. The experiment was a completely randomized design with 3 replications. Significant means were separated with Tukey test. Silage DM increased ($P \leq 0.01$) with increasing proportion of albizia in the mixtures, and was greatest (25.21%) with 70%. All levels of albizia showed decreases in pH values ($P \leq 0.01$), showing the lowest value (3.41) with 100% albizia. Values of NADF/TN and NNDF/TN were not affected by treatments ($P \geq 0.05$). The TN, PN, SN and PN/TN contents increased linearly ($P \leq 0.01$) as the percentage of albizia increased in the mixtures. A small amount of AN was detected in silage, however, throughout there were not significant differences ($P \geq 0.05$) between 50 and 100% mixing levels of albizia. These results indicated that mixing albizia with king grass in the silage making was shown to be successful in the improvement of fermentation quality and nitrogen levels in silages.

Key Words: silage mixtures, *Albizia lebbeck*, nitrogenous compounds

W110 Detection of mycophenolic acid and roquefortine C mycotoxins in Canadian corn silage. H. V. L. N. Swamy*[1] and N. A. Karrow[2], [1]*Alltech Canada*, *Guelph, ON, Canada*, [2]*University of Guelph*, *Guelph, ON, Canada*.

Academic research to date has been focused on 5 silage *Penicllium* mycotoxins that are implicated in animal disorders—mycophenolic acid (MPA), patulin (PAT), penicillic acid (PA), PR toxin (PR), and Roquefortine C (RFC). It is critical that this academic research is complemented by the analysis of these mycotoxins in silage collected from commercial dairy farms. Nine corn silage samples (year 2008 crop) were collected

from Ontario dairy farms and each sample was divided into 2 equal parts. One part was submitted to TLR International Laboratories (the Netherlands) for MPA, PAT and RFC analyses while the other part to Trilogy Analytical Laboratories Inc. (USA) for PR analysis. Among these 9 samples, 3 each were collected from well, moderate and poorly managed silage bunks/silos. The bunks were classified as well, moderate or poor based on the silage density and face management. Following Penn State procedure, silage samples were collected from 12 different points of silage face and then were mixed thoroughly before taking one representative sample for analysis. The detection limits for MPA, PAT, PR and RFC were 25, 50, 500 and 10 ppb, respectively. MPA, PAT and RFC were analyzed by liquid chromatography with double in-line mass spectrometers (LC-MS/MS) and PR was analyzed by thin layer chromatography (TLC). None of the samples indicated any detectable levels of PR toxin. The detection limit for PR, however, was high (500 ppb) and future efforts should be made to analyze this mycotoxin with LC-MS/MS so that detection limit of at least 50 ppb is achieved. Two of the silages obtained from poorly managed bunks/silos indicated detectable levels of *Penicillium* mycotoxins. One sample was contaminated with 70.8 ppb MPA and the other with 27.1 ppb RFC. The levels of MPA, PAT and RFC were below the detection limits for the remaining silage samples. To the best of our knowledge, these are the first reported *Penicillium* mycotoxins in commercial corn silage produced in Canada. Silages, therefore, should be tested for *Penicillium* mycotoxins along with vomitoxin (DON) to assess the total animal toxicity.

Key Words: silage, *Penicillium*, mycotoxins

W111 Fermentation profile over nine months of storage of brown midrib and non-brown midrib hybrid corn silage. K. E. Nestor Jr.*, P. Krueger, J. Anderson, J. Brouillette, and K. Emery, *Mycogen Seeds, Inc.*, *Indianapolis, IN*.

The objective of this study was to examine the difference in fermentation patterns and changes in nutrient content in silages made from brown midrib hybrids (bmr) or non brown midrib hybrids over time of storage. A total of 19 bmr corn hybrids and 24 non bmr corn hybrids were collected from 15 plot locations in the Midwest and Northeast regions of the United States. At each plot location at least one bmr and one non-bmr were collected together. Ten samples of each hybrid were chopped and collected into vacuum sealed bags and then stored in an environmentally controlled room until analysis. Samples were sent to Cumberland Valley Analytical Services on a monthly basis for analysis. Each sample was analyzed for dry matter (DM), crude protein (CP), soluble protein (SolP), net energy of lactation (NEL), acid detergent fiber (ADF), neutral detergent fiber (NDF), lignin, starch, sugar, 7 h in vitro starch degradability (DegStarch), pH, titratable acid, lactic acid, acetic acid, total volatile fatty acids (TotVFA), ammonia, and 30 h NDF digestibility (DNDF). Data by month was analyzed by paired *t*-test and pooled hybrid data was analyzed by ANOVA. When the data was pooled across all time points the bmr hybrids were higher ($P < 0.001$) in CP, NEL, DNDF and higher ($P < 0.01$) in acetic acid and TotVFA and higher ($P < 0.05$) in lactic acid. The bmr hybrids were lower ($P < 0.001$) in ADF, NDF, lignin and lower ($P < 0.01$) in ammonia and lower ($P < 0.05$) in DegStarch. Within month of fermentation, there were several, but inconsistent differences between the hybrids in several of the parameters measured. The fermentation patterns of each hybrid class were similar. Other than the differences in nutrient content, the results of this study suggest that bmr hybrids are not different than non-bmr hybrids in fermentation patterns over time of storage.

Key Words: silage, bmr, fermentation

W112 Herbage mass, botanical and chemical composition of forage sorghum and annual legumes in monoculture and intercropped. R. W. Colbert, E. Valencia*, and J. Beaver, *University of Puerto Rico, Mayaguez*, *Mayaguez, Puerto Rico*.

Forge sorghums (*Sorghum bicolor* cv. Brown midrib) and the legumes lablab (*Lablab purpureus* cv. Rongai) and velvet bean (*Mucuna pruriens* cv. Vine 90d) are excellent forages for the dairy industry in Puerto Rico. Brown midrib (BMR) is low in crude protein (CP; 6%) at 90 d harvest, limiting its use in the industry. There is potential to increase CP by intercropping legumes with BMR, but this has not been documented. This study was conducted to assess the effect of monoculture or intercropping BMR, Rongai and Vine 90d on herbage mass (HM), botanical and chemical composition. Treatments were BMR, Rongai and Vine 90d, and BMR-Rongai and BMR-Vine 90d intercropped. Experimental plots (25 m^2) were planted in May and August, 2008 in a randomized complete block with 5 replicates. Herbage mass was estimated in a 2 m^2 area 90 d after planting. Dried sub-samples (500 g) were ground in a Willey mill and used for CP and neutral detergent fiber (NDF) and acid detergent fiber (ADF) analysis. Data were analyzed using PROC Mixed in SAS and mean separation when significant was conducted with Fisher LSD. There were no differences ($P > 0.05$) for HM between BMR intercropped with legumes and BMR in monoculture. Herbage mass was 8.9, 8.8, and 8.4 Mg ha^{-1}, for BMR-Rongai, BMR-Vine 90d, and BMR, respectively. Botanical composition for Rongai did not vary ($P > 0.05$) in HM between May and August, with means values of 2.7 and 3.9 Mg ha^{-1} in intercropping and monoculture, respectively. Vine 90d presented the lowest ($P < 0.05$) HM, 2.8 and 1.3 Mg ha^{-1} for May and August, respectively. Both NDF and ADF ($P > 0.05$) were not different with values of 60.1 and 63.9% and 40.1 and 46.5%, for BMR-Rongai and BMR-Vine 90d, respectively. However, there were differences ($P < 0.05$) in CP for monoculture and intercrops. The CP for Rongai, Vine 90 d, and BMR in monoculture were 14.1, 11.1, and 6.0%, respectively. When intercropped, CP for BMR-Rongai and BMR-Vine 90d were 9.8 and 9.1, 3 percentage units greater ($P < 0.05$) than BMR. In conclusion, BMR intercropped with Rongai and Vine 90d improved its nutritive value from a ruminant nutrition perspective.

Key Words: brown midrib, Rongai, Vine 90 d

W113 Comparisons among predictive equations and NIR for determination of in vitro indigestible NDF of hay crop silages. R. Ward*[1], S. Weaver[1], and R. A. Patton[2], [1]*Cumberland Valley Analytical Services*, *Maugansville, MD*, [2]*Nittany Dairy Nutrition*, *Mifflinburg, PA*.

There may be advantages to using indigestible NDF (INDF) values in ration balancing programs if they could be derived in a time efficient and economical fashion. NIR holds promise as a means of generating this information. To investigate the accuracy of NIR compared with predictive equations, a data set of 130 hay crop silages with indigestible NDF determined at 120 h of incubation by the Tilley and Terry method was developed. Types of silages were 19 grass, 27 legume, 20 mixed mainly grass (MMG), 26 mixed mainly legume (MML) and 38 small grain silages. Using this data, chemically determined INDF was compared against equations developed using analyzed nutrients from a smaller data set for all hay crop silages and for individual forage types, as well as calculation of INDF as lignin*2.4. The mean square predicted error statistic of Bibby and Toutenburg was used to compare predictions with observed values. The overall determined equation was INDF = 1.409 + (2.838 * lignin %DM), $R^2 = 0.82$. For grass silage, the equation was INDF = (1.720 * ADF %DM) - 40.101, $R^2 = 0.96$, while legume was INDF = 8.803 + (2.045 * lignin), $R^2 = 0.97$, for MMG INDF = 6.336 + (3.052 * starch %DM) + (0.337 * Ash %DM), $R^2 = 0.99$, for MML INDF

= (1.267 *ADF %DM)-23.971, R^2 = 0.97, and for small grain, INDF = 15.987 + (0.528 * NDICP %DM), R^2 = 0.99. Using an equation of lignin*2.4 (R^2 = 0.77) considerably under predicts the amount of INDF in hay crop silages whether determined at 120 or 240 h of incubation. We conclude that there is a strong relationship of lignin to INDF for hay crop silages. Further these results suggest that NIR is a better predictor of INDF than equations and that feed specific equations are better than general equations using only lignin as a predictor.

Table 1.

						Error Due To	
Model	Mean	Std Dev	RMSPE	% Mean	Bias	Regression	Random
Observed	18.11	4.87	-	-	-	-	-

W114 Relating dry matter density to dry matter loss within corn silage bunker silos. K. E. Griswold*[1], P. H. Craig[2], J. S. Graybill[1], and S. K. Dinh[1], [1]*Penn State Cooperative Extension*, *Lancaster,* [2]*Penn State Cooperative Extension*, *Dauphin*.

The objective was to refine the relationship between dry matter (DM) density and DM loss within corn silage bunker silos. Poly-weave nylon bags (36 per silo) containing chopped brown mid-rib (BMR) corn were buried in 3 bunker silos during filling on the same farm. Bags were blocked by depth from the end of the bunk, 10.6 m (front), 27.8 m (center), and 44.9 m (back), level from the silo floor, 0.6 m (bottom), 1.5 m (middle), and 2.15 m (top), and within level, location from the east wall, 0.9 m (I), 4.7 m (II), 8.4 m (III), and 12.2 m (IV). Upon feed-out, all bags at a specific depth were retrieved and silage cores for DM density were obtained at each bag position. Cores were collected using a 5.08 cm diameter stainless-steel coring tube driven by a gas-powered drill. Corn and silage DM was determined using a Koster moisture tester. Data were analyzed using PROC MIXED and RSREG within SAS. The model included the fixed effects of depth, level, location, all interactions, and the random effect of bunk. Significance was set at $P < 0.05$, and trends at $0.05 < P < 0.10$. There were no significant interactions. Density was affected ($P < 0.0001$) by depth, level, and location. Density was 201, 253, and 255 kg DM/m^3 for the front, center, and back, respectively. Density was 284, 268, and 224 kg DM/m^3 for the bottom, middle and top, respectively. Density was 219 and 211 kg DM/m^3 for I and IV compared with 260 and 254 kg DM/m^3 for II and III, respectively. DM loss % was affected ($P < 0.001$) by depth and level but not location. Loss was 9.2, 6.5, and 7.3% for the front, center, and back, and 6.5, 5.0 and 8.4% for the bottom, middle and top, respectively. There was a linear inverse relationship (R^2 = 0.18) between loss and density. Response surface regression of DM density and DM% versus DM loss also showed an inverse relationship (R^2 = 0.28). These results suggest a large degree of variation in DM loss is not associated with the DM density and DM% of the corn silage within a bunker silo.

Key Words: corn silage, density, loss

W115 Silo-King improves dry matter (DM) recovery and lowers the yeast, mold, and clostridia populations in high quality alfalfa balage. D. H. Kleinschmit*, D. P. Casper, D. J. Schauff, G. P. Gengelbach, K. E. Lanka, D. F. Jones, G. Ayangbile, and D. A. Spangler, *Agri-King, Inc.*, *Fulton, IL.*

High quality alfalfa balage is an excellent forage source for dairy cattle, however it may be susceptible to microbial deterioration and DM loss during ensiling. Silo-King is a silage fermentation aid designed to both improve the initial fermentation process via enhanced production of lactic acid and inhibit the growth of spoilage organisms so it may be an appropriate additive to aid in the production of high quality balage. On May 20, 2008 a total of 12 bales of alfalfa balage were made, with 6 bales (541 ± 9.43 kg) untreated (UNT) and 6 bales (524 ± 9.30 kg) treated with Silo-King via baler mounted applicator at a rate of 0.033% of fresh forage weight (SK) and wrapped with 8 mils of plastic. The nutrient content of both treatments before ensiling were similar. After 65 d of ensiling, final weights for determination of DM recovery and core samples for nutrient analysis and microbial counts were obtained from each bale. The experiment was analyzed as a completely randomized design with ANOVA being conducted with the MIXED procedure of SAS. The model was y = treatment + rep with rep being the random variable and least squares differences used for means separation. Even though nutrient content and 30-h in vitro DM digestibility were not altered by treatment in this study, UNT succumbed to more ($P < 0.01$) DM loss compared with SK (0.56 vs. 0.05% for UNT and SK, respectively). This was likely due to a tendency for SK to have a lower ($P < 0.10$) pH compared with UNT (5.35 vs. 5.25 for UNT and SK, respectively). Balage treated with SK had lower ($P < 0.02$) populations of clostridia (2067 vs. 97 colony forming units (cfu)/g of forage for UNT vs. SK, respectively) and yeasts (3317 vs. 25 cfu/g for UNT vs. SK, respectively) and a tendency for less ($P < 0.06$) molds (1203 vs. 7 cfu/g for UNT vs. SK, respectively). Based on the results in this study, the use of Silo-King as a forage enhancer is a viable tool to preserve the valuable DM in high quality balage and to enhance its feeding value by almost eliminating the presence of undesirable organisms, such as yeasts, molds, and clostridia.

Key Words: alfalfa, inoculants, yeasts

W116 Nutritional value of corn silage associated with additives. R. H. de Tonissi e Buschinelli Goes*[1], E. S. Myagi[2], K. A. de Souza[1], K. A. G. Nogueira[1], R. A. Patussi[1], M. G. de Menezes Gressler[1], C. E. Dambros[2], and E. R. de Oliveira[1], [1]*Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*, [2]*Universidade Federal de Goiás*, *Goiânia, GO, Brasil*.

Corn plant, cut at 90 d, was ensiled in 72 experimental silos in randomized design, in factorial 4 × 6 square (4 treatments and 6 d-opening) with 3 replicates, and the averages compared by Tukey's test at 5% probability, for evaluate the nutritional value of corn silage associated with additives. The corn silage was associated with additives at 5% in natural matter, and the treatments were: soybean hulls (CS+5%SH), rice meal (CS+5%RM) and crushed sunflower (CS+5%SC). The control was 100% of the corn plant (CS). The silos were opened at 0, 28, 56, 84, 112 and 140 d of fermentation. The pH reduced from 28 d of fermentation, with lowest value (3.39) at 112 d. All additives reach a pH favorable to preservation of forages. There was effect ($P < 0.05$) for additive and time of opening for dry matter (DM), crude protein (CP), ether extract (EE), NDF and total carbohydrates (TC). Crushed sunflower increased DM of silage on day zero, independent of the additive DM decreased to 140 d of fermentation. The CP increased with additive addiction. Crushed sunflower increased the CP, in 71% (average 13.3%), CS had a mean of 7.7% and CS+5%SH and CS+5%RM (9.1 and 9.6%). Crude protein was higher for the 112 and 140 d after ensiling. The addition of soybean hulls reduced the concentration of EE (1.5%) and crushed

sunflower and rice meal increased EE (24.8 and 10.9%); because chemical composition of the additive. The NDF decreased according ensilage time. The lower values of NDF occurred at 112 d (63.02, 65.46, 57.83 and 60.98% for CS, CS+5%SH, CS+5%RM and CS+5%SC, respectively). The levels of total carbohydrates remained stable over the days of fermentation for addition of soybean hulls, rice meal and CS (averages 85.5, 75.2 and 86.5%). CS+5%SC had the lowest values of TC for all opening days (mean 58.4%). Ash content was increased for addition of soybean hulls and rice meal (4.2 and 3.9%), while the CS+5%SC and corn silage presents average of 3.5 and 3.4%. Ash decreased after 56 d of fermentation. The addition of 5% soybean hulls, rice meal and crushed sunflower improve the nutritional value of corn silage

Key Words: crude protein, ether extract, chemical composition

W117 Nutritive value and fermentation parameters of warm-season grass silage. J. M. B. Vendramini*[1], A. T. Adesogan[2], M. L. A. Silveira[1], L. E. Sollenberger[2], O. C. M. Queiroz[2], and W. F. Anderson[3], [1]*University of Florida*, *Ona,* [2]*University of Florida*, *Gainesville,* [3]*USDA ARS*, *Tifton, GA*.

The objective of this study was to investigate the nutritive value and fermentation characteristics of different species of warm-season grass silages treated with or without inoculants in Florida. Nine forage species and cultivars, elephantgrass (*Pennisetum purpureum*), Mulato (*Brachiaria* sp.), bahiagrass (*Paspalum notatum*), stargrass (*Cynodon nlemfuensis*), Tifton 85 bermudagrass (*Cynodon* sp.), Jiggs bermudagrass (*Cynodon dactylon*), Coastcross 2 bermudagrass, Florakirk bermudagrass, and Floralta limpograss (*Hemarthria altissima*) were treated with or without (control) a microbial inoculant solution (Si-All) in a split-plot arrangement with 3 replicates. Plots were harvested on July 17 and October 9 2008. Forage was packed into mini-silos at a density of approximately 450 kg fresh forage/m^3 and ensiled for 84 d. The data were analyzed using PROC MIXED of SAS with forage species (main plot) and inoculant treatment (sub-plot) as fixed effects. Replicate and its interactions were considered random effects. The means were compared using the PDIFF statement of SAS. In the summer, NDF concentration was greater for the bermudagrasses than the average of other species (68 vs. 65%, $P < 0.01$, SE = 1). Mulato had the lowest NDF concentration (57%, $P < 0.03$, SE = 0.8) and the greatest IVTD concentration (63%, $P < 0.05$, SE = 1) compared with other treatments. Limpograss silage had the lowest pH (6.5, $P < 0.07$, SE = 0.3) and the greatest lactic acid concentrations (2.6%, $P < 0.01$, SE = 0.1). Elephantgrass silage had decreased lactic acid concentration (0.1%, $P < 0.001$, SE = 0.01) with greater pH (8.3, $P < 0.01$, SE = 0.3) than the other species. Inoculated silages had a lesser lactic acid concentration than control (0.62 vs. 1.84%, $P < 0.001$, SE = 0.2). In the fall, elephantgrass silage pH was less (7.2 vs. 8.8, $P < 0.06$, SE = 0.6) and the concentrations of total volatile fatty acids (4.6 vs. 0.4%, $P < 0.01$, SE = 0.2), lactic acid (1.5 vs. 0.2%, $P < 0.05$, SE = 0.5) and acetic acid (2.1 vs. 0.2%, $P < 0.001$, SE = 0.3) greater than in the bermudagrasses. There was no effect ($P > 0.10$) of the inoculant on the nutritive value and silage fermentation parameters in the fall.

Key Words: warm-season grass, silage, nutritive value

W118 Chemical composition and nutritive value of some cowpea (*Vigna unguiculata* L. Walp) haulm varieties. U. Y. Anele*, J. Hummel, O. M. Arigbede, C. Böttger, and K.-H. Südekum, *University of Bonn*, *Bonn, Germany*.

A study was carried out to evaluate the chemical composition, in vitro gas production, in vitro apparent and true substrate degradability, efficiency of microbial crude protein (CP) production, CP flow to the duodenum, methane production, protozoa population, and short chain fatty acids production of the haulms of 6 cowpea varieties. The study was arranged in a 2 × 2 × 2 factorial design, with 3 replicates. Three improved (ITA2, ITA6 and ITA8) and 3 commercial (Oloyin, Peu and Sokoto) cowpea varieties harvested in Nigeria during the wet and dry seasons were used for the study. After an initial gas test to evaluate 96 h gas production profiles of haulms with and without polyethylene glycol (PEG), the time to half maximal gas production was calculated and a second incubation conducted with fermentation stopped at substrate specific half time and 24 h for each substrate. True substrate degradability was measured from incubated residues and combined with gas volume to estimate the partitioning factor. Crude protein flow to the duodenum was estimated by combining gas volume with the measured ammonia nitrogen in the incubated fluid. Addition of PEG did not have any effect ($P > 0.05$) on all the variables determined. Interaction between group (improved vs commercial) and season was observed for the CP ($P = 0.002$), lignin ($P = 0.003$) and hemicellulose ($P = 0.030$) contents of the haulms. A group × season interaction was observed for some of the variables at both substrate specific half time and 24 h. On the average, the commercial cowpea haulms had greater microbial mass and produced less methane than the improved cowpea haulms. The improved cowpea haulms were less degraded in the rumen and as a result ensured greater amount of CP flow to the duodenum. The results validated that cowpea haulm is an important agro-based by-product that is adequate in protein and energy to sustain ruminant animal production in Nigeria and other Sub-Saharan African countries during the extended dry season.

Key Words: in vitro gas production, legume, protein value

W119 Silage characteristics, and nutritive value of sugar beet tops and crown harvested by two different methods. M. Raisianzadeh*[1], M. Danesh[2], H. Fazaeli[3], and M. Nourozi[1], [1]*Khorasan Agriculture and Natural Resources Research Center*, *Iran*, [2]*Ferdosi University of Mashhad*, *Iran*, [3]*Animal Science Research Institute*, *Karaj, Iran*.

Two areas of 500 m^2 in each of 3 sugar beet farms, that were different according to plant covers were selected. In one area, sugar beet tops and crowns (SBTC) before harvesting (method 1) but in another one SBTC were cut after harvesting of tuber (method 2).Costs and quality of obtained SBTC compared. The SBTC collected in method 1, had better quality than that of the method 2 but because of more labor used for method 1, it was more costly when compared with method 2. In a completely randomized block experiment, with 2 treatments (2 methods of SBTC collectives) and 4 replications the SBTC was ensiled with addition of 10%molasses and 2% urea to study its silage characteristics. In the last stage, digestibilities of silages obtained from each harvesting methods were compared. Result showed that SBTC silage collected by method 1 had better quality with higher organic matter and crud protein but lower pH ($P < 0.05$).The protein fractions including true protein and non protein nitrogen were significantly ($P < 0.05$) different between the treatments. Silages from method one, had higher quality compared with silages from method 2 and hence they had different pH and organic matter ($P < 0.05$). Silage made from TC cut before harvesting had higher ($P < 0.05$) crude protein, true protein and NPN contents, may be due to the lower percentage of SB crowns produced in the first method. Also highest levels of DM, OM, d.value digestibility percentage were observed in the first method.

Key Words: sugar beet tops and crowns, harvesting methods, silage characteristics

W120 Dry matter of corn at harvest alters whole plant chemical composition and predicted milk yields. P. M. Walker[1], J. M. Carmack*[1], L. H. Brown[2], and F. N. Owens[2], [1]*Department of Agriculture, Illinois State University*, *Normal,* [2]*Pioneer Hi-Bred International, A DuPont Business*, *Johnston, IA*.

Objectives of this trial were to determine effects of plant maturity (DM) on nutrient composition, projected milk per acre and milk per ton. Six commercial Pioneer corn hybrids (105 to 116 d CRM) with 24 rows per hybrid to minimize cross pollination effects were planted on May 12, 2009 near Normal, IL. Plants (replicate sets of 5 plants per harvest date) from each hybrid were randomly harvested in the 4 middle rows and cut 7 inches above ground level twice each week starting August 10 until DM content reached 50% (October 12). Sets of harvested plants were chopped, sampled, dried, and assayed via calibrated NIR analysis. By regression analysis from 25 to 45% DM, effect of plant DM on nutrient composition averaged across hybrids was examined. Using linear, quadratic, and cubic regression analysis, effects of harvest DM on milk yield per ton and per acre were calculated (based on Milk 2006 equations) for each hybrid and date. Finally, stepwise regression was used to determine the relative importance of specific nutrients and measurements on milk per ton and milk per acre. For each 1% increase in harvest DM, the percentage of starch in DM increased by 2% ($P < 0.01$) while decreases ($P < 0.01$) were detected for NDF (1.1%), sugars (0.7%), and ash (0.1%). Because hybrids differed in nutrient composition on various harvest dates, milk per acre and milk per ton were altered by harvest DM, and ranking of hybrids changed with harvest date. Compared with harvest at 30% DM, harvest at the optimum DM content (between 33 and 36% for these hybrids) increased projected milk yield by 5 to 13% per ton. Harvest between 33 and 40% DM increased milk yield per acre by 7 to 25% above harvest at 30% DM. Hybrid ranking at 35% DM differed from that at 30% DM ($R^2 = 0.62$; NS). Across hybrids and harvest dates, milk per ton depended primarily (($P < 0.01$) on starch content and NDFD (partial $R^2 = 0.82$ and 0.06) while milk per ton varied with starch and protein yields (partial $R^2 = 0.86$ and 0.07). Results from this trial suggest that milk per ton and acre will vary with harvest dry matter, and starch content and yield will affect projected milk yields.

Key Words: NDF, corn silage, maturity

W121 Effect of bunker silo sidewall plastic on fermentation, nutrient content and digestibility of corn silage. K. E. Griswold*[1], E. E. McDonell[2], L. Kung Jr.[2], and P. H. Craig[3], [1]*Penn State Cooperative Extension*, *Lancaster,* [2]*University of Delaware*, *Newark,* [3]*Penn State Cooperative Extension*, *Dauphin*.

The effect of sidewall plastic (SP) on fermentation, nutrient content and digestibility of corn silage was investigated in 20 dairy farm bunker silos, 10 without and 10 with SP. Samples were collected at 5 sites in each silo. Approximately 0.65 m from an outside wall at 3 levels, bottom ≈0.65 m from floor, top ≈0.65 m from top, and middle ≈equidistant to bottom and top. The fourth site was ≈1.3 m from the outside wall and ≈0.65 m from the floor. The fifth site, serving as an internal control, was collected equidistant to the walls and 2.0 m from the floor. At each site, 3 samples were collected in a triangular pattern using a stainless-steel coring tube. Samples were stored on ice until analysis. Data were analyzed using PROC MIXED within SAS. The model included fixed effects of plastic, location, interaction of plastic by location, and random effect of farm. Significance was set at $P < 0.05$, and trends at $0.05 < P < 0.15$. There were no interactions. Silage was wetter ($P < 0.0001$) at the wall bottom compared with all other sites, and was drier ($P < 0.0001$) in the center compared with all other sites. Silage tended ($P = 0.10$) to be drier in SP silos (31.8% DM) compared with silos without SP (29.5% DM). Data were then sorted by presence or absence of SP and analyzed with a model including fixed effect of location, random effect of farm, and single DF contrast of center versus wall samples. Silos without SP tended to have less acetic acid ($P = 0.08$) and less ethanol ($P = 0.01$) in wall samples versus the center while there were no differences between wall and center samples in SP silos. Silos with SP had less lactic acid ($P < 0.02$) in wall samples versus the center while silos without SP showed no difference between wall and center samples. The 30-h NDF digestibility was not different between wall and center samples in SP silos, but was less ($P < 0.04$) in wall samples versus the center for silos without SP. These results suggest that use of sidewall plastic in bunker silos alters fermentation, and may produce drier corn silage with greater digestibility.

Key Words: corn silage, sidewall plastic, digestibility

W122 Quality traits of the stem from corn hybrids for silage production according to the maturity stage. M. Zopollatto*[1], L. G. Nussio[1], J. O. Sarturi[2], C. M. M. Bittar[1], P. Schmidt[3], and G. B. Mourao[1], [1]*University of Sao Paulo*, *Piracicaba, Brazil*, [2]*University of Nebraska*, *Lincoln*, [3]*Federal University of Parana*, *Curitiba, Brazil*.

The objective of this study was to evaluate the stem quality traits from corn hybrids for silage production harvested across maturity stages. A randomized block design, with an 8x6x2 factorial scheme based on 8 harvesting times, 6 corn hybrids and 2 harvesting years (2001/02 and 2002/03) was performed. The hybrids CO 32, semi-hard endosperm; AG 5011, soft endosperm; P 3041, hard endosperm; DKB 333B, semi-hard endosperm; AG 1051, soft endosperm and Z 8550, semi-soft endosperm were harvested when they reached 50% tasseling, 15 d later and weekly, totaling 8 harvesting times. Plant was fractionated in leaf, stem, cob, grain and husk. Stem portion was analyzed for CP, NDF, digestible NDF (dNDF) and IVTDDM using the NIRSystems 5000 spectrophotometer. Variables were analyzed using the PROC MIXED procedure (SAS), and the averages compared by the Student *t*-test, with 5% level of significance. Maturity advance resulted in decreases ($P < 0.05$) in stem dNDF (55.2 to 39.6%), CP (7.0 to 4.23%) and in IVTDDM (66 to 53.7%). For the NDF content and digestible DM production (DDMP), the hybrids showed different responses along the maturity stage. At the ensiling stage (30–35% DM – between 5th and 6th harvesting time, from 94 to 112 d after seeding), stem NDF, dNDF, CP, IVTDDM and DDMP were 71.1 to 78.5% DM, 40.9 to 48.5% DM, 3.81 to 4.97% DM, 55.8 to 64.1% and 2.333 to 4.529 kg/ha, respectively. At the ensiling stage, Z8550 showed the most desirable stem quality characteristics for silage production, the lowest ($P < 0.05$) NDF (71.1% DM, SEM = 0.86) content and the highest ($P < 0.05$) stem dNDF (48.5% DM, SEM = 0.74), IVTDDM (64.1% DM, SEM = 0.96) and DDMP (3.651 kg/ha, SEM = 237). Hybrids P 3041, DKB 333B and AG 1051 also presented the highest ($P < 0.05$) stem DDMP at the ensiling stage, 4.107 (SEM = 285), 4.257 (SEM = 237) and 4.529 (SEM = 237), respectively. Monitoring the stem quality traits of corn hybrids for silage is an important tool for selecting corn hybrids based on the influence on the nutritive value of the whole plant.

Key Words: digestibility, fiber, harvesting time

W123 Butyric acid in commercially analyzed legume silage samples. L. R. Jones*[1] and R. T. Ward[2], [1]*American Farm Products, Inc.*, *Ypsilanti, MI,* [2]*Cumberland Valley Analytical Services, Inc.*, *Maugansville, MD*.

Butyric acid production by clostridia bacteria in hay crop silages has been associated with fermentation failure, significant dry matter losses, and reduced dry matter intake. A data set of 563 forage samples submitted for commercial analysis was evaluated for fermentation and descriptive statistics. Samples coded as either legume or legume grass mixes and having a dry matter level of 25–45% were included in the data set. Forage samples were analyzed for dry matter (DM), crude protein (CP), ammonia as a percent of CP (ammCP), lignin as a percent of NDF (ligninNDF) Ash, pH, lactic acid (LA), and butyric acid(BA) content. In the data set, 26% of samples had BA levels > 0.1% DM (BA1), 14% had BA levels > 0.5% DM (BA5) and 10% had BA levels > 1.0% DM (BA10). The incidence of BA was evaluated for 3 DM contents: < 32.5% (L), 32.5% 37.5% (M), and >37.5% (H), as well as pH levels of < 4.25 (LL), 4.25–4.75 (L), 4.75–5.25 (M) and >5.25 (H). For the L DM level, incidence of each butyric acid level (BA1, BA5, and BA10) increased as pH increased (17%, 0%, 0% for LL; 37%, 16%, 6% for L; 68%, 45%, 35% for M and 71%, 71%, 65% for H, respectively). For the M DM level, incidence of each BA level increased as pH increased (9%, 0%, 0% for LL; 13%, 3%, 1% for L; 42%, 22%, 17% for M and 56%, 44%, 38% for H). BA levels are highly correlated ($P < 0.0001$) with pH (r = 0.43), LA (r = −0.39), ammCP (r = 0.76), ADF (r = 0.38), NFC (r = −0.33). Samples with higher BA levels have higher pH, ammCP, and ADF levels and lower LA and NFC levels. Terminal pH was highly correlated ($P < 0.0001$) with LA (r = −0.62), ammCP (r = 0.50), ligninNDF (r = 0.40), ash (r = 0.35). LA accounts for 38% of the variation of pH. LA levels were highly correlated ($P < 0.0001$) with ammCP (r = −0.37), ADF (r = 0.38) and NFC (r = 0.34). Ammonia (ammCP) is correlated with all factors associated with BA possibly due to the proteolytic activity of clostridia organisms responsible for BA production. Across all DM levels, BA is prevalent when pH is not reduced; however, there is an interaction of DM level and pH level necessary to inhibit BA production.

Key Words: silage, butyric acid

W124 Environmental factors affecting changes in dry matter content of corn planted for summer or fall silage harvest in a subtropical climate. J. K. Bernard*[1], B. T. Scully[2], and J. S. Barlow[1], [1]*University of Georgia*, *Tifton,* [2]*USDA-ARS*, *Tifton, GA*.

A 3-yr trial was conducted to determine the environmental factors related to changes in the dry matter (DM) content of temperate corn (*Zea mays*) planted for summer or fall harvest as silage in a subtropical climate. Corn was planted in late March or early April (Pioneer 31Y42 and Masters Choice 590) for July harvest followed by a second crop planted in July (AgraTech 760 and Pioneer 33M52) for harvest in late October. When corn reached half-milk line stage of maturity, 3 replicate plots of corn plants were hand harvested every hour from 0600 through 1800 h. The corn plants were chopped using a field chopper to 1.9 cm theoretical chop length. A subsample of the chopped material was dried in a forced air oven for 60 h at 55°C to determine the DM content. Environmental temperature and relative humidity (RH) were continuously measured inside (IN) and outside (OUT) of the corn canopy. During the summer, the DM content increased 1.7% after 0900 and increased linearly throughout the remainder of the day. In the fall, the DM content increased 1.5% after 1000 and 1.7% after 1200 before peaking at 1500 and then declining. Temperature-humidity index (THI), THI^2, and RH^2 were computed for use in the statistical analysis. The RH ($P = 0.02$) and RH^2 ($P < 0.01$) measured IN were negatively correlated with DM content across both seasons. During the summer, the DM content was negatively correlated ($P < 0.02$) with RH and RH^2 measured IN and OUT and positively correlated ($P < 0.01$) with temperature, THI, and THI^2 IN and OUT. However, only RH and RH^2 measured IN were negatively correlated ($P < 0.05$) with DM content in the fall. Stepwise regression analysis of data was conducted across seasons as well as within season. Across seasons, the final equation was $\%DM = 32.49 - 0.001RH^2(IN) + 4.884THI(IN) - 0.026THI^2(IN) + 0.107RH(OUT) - 4.859THI(OUT) + 0.026THI^2(OUT)$ ($R^2 = 0.50$, $P < 0.0001$). Results of this trial indicate that the DM content of the whole corn plant changes differently in the summer compared with fall, primarily in response to changes in the RH inside the canopy.

Key Words: corn silage, DM content, drying rate

W125 Relationship of vomitoxin levels in corn silage to in vitro dry matter digestibility. R. Ward[1] and R. A. Patton*[2], [1]*Cumberland Valley Analytical*, *Maugansville, MD*, [2]*Nittany Dairy Nutrition*, *Mifflinburg, PA*.

There is increasing awareness of the damage that can be caused by Fusarium mycotoxin ingestion by dairy cattle. One reason for detected mycotoxins may be greater usage of BMR corn silage varieties. It is hypothesized higher digestibility may result in greater susceptibility to corn plant molds. Vomitoxin (DON) has often been used as a marker for contamination by Fusarium mold species. To investigate this, a data set composed of all corn silages submitted to Cumberland Valley Analytical Services for DON analyses was prepared. There were 1948 silages in the data set with 185 being identified as BMR varieties; 1068 were confirmed positive to DON. DON was measured using HPLC at 220 nm UV detection. Limit of detection was 0.5 ppm. Assessment of differences for levels of DON between silage types was by Proc Mixed of SAS. Incidence of infection was investigated using logistic regression. Samples identified as BMR had 1.135 ppm of DON and normal contained 1.295 ppm ($P = 0.24$). When non-positive samples were excluded, BMR contained 2.386 ppm (n = 155) and normal silage 2.303 ppm DON (n = 913;$P = 0.72$). Of BMR samples submitted, 83.8% were positive, but only 51.8% for normal silage. Logistic regression found that BMR was 1.419 times more likely to be infected than normal corn silage ($P < 0.004$). Caution should be applied to these statistics as these samples were screened as having problems and are not random. To further investigate the influence of NDF digestibility (NDFd) on DON levels, groups were constructed based on the following scheme: (1) >65% NDFd; (2) 60–64.99%; (3) 55–59.99%; (4) 50–54.99%; (5) 45–49.99; (6) <45%. Mean DON levels for the groups are (1) 1.177 ppm, (2) 1.140 ppm, (3) 1.215 ppm, (4) 1.470 ppm, (5) 2.022 ppm, and (6) 0.982 ppm. Only group 5 was significantly different from the others ($P < 0.05$), although group 2 tended to be lower than groups 3 and 4 also ($P < 0.10$). We conclude that although BMR corn silage may have a higher incidence of DON than normal corn silage, levels of infection are not different, and it would not be due to differences in NDFd. Further work will be needed on a random basis to verify the infective rate of BMR corn.

Key Words: DON, mycotoxins, corn silage

W126 Fermentation and ruminal degradability of corn silage inoculated with *Lactobacillus buchneri*. F. C. Basso[1], R. A. Reis*[1], D. M. Figueiredo[1], D. A. Mota[2], K. A. Magalhães[1], T. F. Bernardes[3], and J. F. H. Rodrigues[1], [1]*UNESP/FCAV*, *Jaboticabal, São Paulo, Brazil*, [2]*UFAM*, *Parintins, Amazonas, Brazil*, [3]*UFRA*, *Pará, Belém, Brazil*.

The aim of this trial was to evaluate the effect of *L. buchneri* doses on fermentation and ruminal degradability of corn silage. *L. buchneri* (NCIMB 40788) was applied to corn hybrid Maximus at: SLB - control (not inoculated); LB1 – 5×10^4, LB2 - 1×10^5, LB3 - 5×10^5, LB4 - $1 \times$

10^6 CFU/g of forage. Four plastic buckets (7 L) per treatment were filled with 4 kg of treated corn, sealed and stored at room temperature. After 130 d of fermentation, buckets were opened, spoiled forage discarded and the remainder was homogenized and placed in plastic buckets, and maintained in a closed room at room temperature. For determination of aerobic stability (AS) the silage temperature was measured every half hour by a data logger during the aerobic exposition (288 h) and room temperature was measured by data logger distributed near the buckets. Samples were collected to evaluate dry matter content (DM), pH values, acetic acid concentration (%DM), lactic acid (%DM), counting of yeasts and molds (Log CFU/g) in potato dextrose agar and ruminal degradability (measured by in situ procedure by 48 h). Nylon bags (9 x14 cm) with a pore size of 40μm were filled with 5 g of DM of silage samples. The statistical analysis included one-way ANOVA and Tukey's test ($P < 0.05$). The DM content was higher in the SLB and LB1 treatments ($P < 0.05$). The pH value, lactic acid (%DM) and molds did not differ significantly among silages. Acetic acid concentrations were higher in treated silages ($P < 0.05$). The number of yeast was lower in the silages with *L. buchneri* ($P < 0.05$). Aerobic stability of corn silage increased with *L. buchneri* ($P < 0.05$). The inoculant did not affect the ruminal degradability (%DM) of corn silages ($P < 0.05$). All doses reduced yeasts and improved aerobic stability.

Table 1. Fermentation, microbial dynamic and ruminal degradability of corn silage with *L. buchneri*

Treatments	DM	pH	Acetic Acid	Lactic Acid	Yeasts	Molds	AS	Degradability
SLB	32.04a	3.9a	0.80b	6.62a	4.71a	3.71a	46.3b	59.23a
LB1	32.03a	4.0a	1.06ab	6.7a	1.71b	2.97a	154.9a	58.45a
LB2	29.03b	3.95a	1.24a	6.5a	1.7b	2.45a	151.7a	55.83a
LB3	29.08b	4.0a	1.18a	6.88a	1.25b	2.97a	223.9a	55.92a
LB4	29.62b	4.0a	1.34a	6.47a	2.31b	2.69a	165.2a	57.5a
CV (%)	2.67	1.45	16.73	20.33	32.78	32.43	8.81	4.91

Means followed by equal letters are not different by Tukey test ($P>0.05$).

Key Words: heterofermentative bacteria, microbial dynamics, yeasts

W127 Dispersion of an inert marker in water on freshly chopped whole plant corn by two methods to simulate addition of an inoculant. J. M. Lim*, M. C. Santos, J. P. Rigueira, M. C. Der Bedrosian, and L. Kung Jr., *University of Delaware*, *Newark*.

Silage inoculants are often added in a liquid form to the forage mass at harvest. A common method of application is to add the inoculant with a sprayer system at the chopper in the field. Applying the inoculant via a "shower" method to the top of a forage mass in a forage truck or wagon is also practiced. Even distribution of an inoculant using the shower method has been questioned. Thus, the objective of this study was study the distribution of an inert marker applied to harvested whole plant corn using 2 methods. Forage was either 1) untreated (C) or treated with water containing dysprosium chloride (DY) via a 2) shower method (SHO), or 3) a spray (SPR) method. Dysprosium was applied to achieve a target of 2 ppm/kg of forage DM for treatments 2 and 3. Treatment via SHO was by manually pouring water with DY on the top surface of a forage in truck (7.25 t of wet forage) with a surface dimension of 5 × 2.7 m (length × width). For SPR, water was applied via a conventional sprayer system at the chopper. Application of water in both methods was set to achieve 2.2 L of water/t of wet forage. For all treatments forage was unloaded at the silo and spread and packed over a surface of about 13 × 6 m (length × width) in the bunker silo. Treatments were replicated twice with 9 samples randomly collected after packing. Control samples were collected from forage loads that were untreated. The concentration of DY in forage samples was determined using inductively coupled plasma spectrometry. Recovery of elemental DY in a spiked forage sample was 97 ± 2%. The concentrations of DY differed among treatments and were 0.09 ± 0.21, 0.47 ± 0.50 and 2.1 ± 0.66 ppm/kg of forage DM for C, SHO, and SPR respectively ($P < 0.0001$). The average concentration of DY for SPR was closer to the theoretical target (2 ppm/kg) and was less variable (CV of 31 vs. 106%) than for SHO. The results of this study suggest that distribution of an inoculant in water has the potential for better distribution if it is applied at the chopper compared with a shower method on the forage truck.

Key Words: silage, inoculant

W128 Treating first-cutting alfalfa in Michigan with Silo-King reduces heating during the ensiling process. D. P. Casper, G. P. Gengelbach*, M. E. Donaldson, D. F. Jones, D. H. Kleinschmit, K. E. Lanka, and D. J. Schauff, *Agri-King, Inc.*, *Fulton, IL*.

The generation of heat through the oxidation of carbohydrates during the ensiling process can dramatically affect forage quality. A field survey evaluated the post-ensiling temperature rise of 1st cutting alfalfa ensiled in bunker silos during 4 crop years (2005, 2006, 2008, and 2009) in Michigan. Bunker temperatures were measured once weekly for 4 weeks following ensiling using a 51-cm compost thermometer. Treatments were untreated Control (CON), competitor inoculant currently used by producer (COMP) or Silo-King (SK). The number of bunkers sampled, by treatment, for each year was: 2005 (9, 0, 11), 2006 (7, 7, 16), 2008 (21, 11, 11), and 2009 (27, 29, 18) for CON, COMP, and SK, respectively. The highest temperature recorded in the weeks post-ensiling was considered the peak temperature (PT). Data on PT were analyzed using a completely randomized design having a factorial arrangement of treatments using the PROC MIXED procedure of SAS. The interaction of Treatment by Year was non-significant ($P > 0.10$), so data were pooled and analyzed for the main effects of Treatment and Year. The lowest PT ($P < 0.01$) were for alfalfa bunkers treated with SK (42.4, 40.6, and 32.5°C, for CON, COMP, and SK, respectively) compared with CON and COMP treated bunkers, which were similar. The PT for bunkers varied across Year with 2005 and 2009 being similar ($P > 0.10$) and the highest, 2006 intermediate and 2008 being the lowest ($P < 0.06$) (40.4, 37.6, 36.8, and 39.2°C for 2005, 2006, 2008, and 2009, respectively). The rise in PT that normally occurs during the ensiling of 1st cutting alfalfa in bunkers can be prevented by treating the forage with Silo-King. Over the years, Silo-King performance was consistent and repeatable in reducing the PT of bunkers through inhibiting heat generation by preventing the oxidation of carbohydrates by plant respiration and spoilage organisms during the ensiling process.

Key Words: alfalfa silage, silage inoculant, silo heating

W129 Effect of harvest moisture, bale wrapping, and an organic acid on forage quality in grass. E. Allen*, K. Martinson, and C. Sheaffer, *University of Minnesota-Twin Cities*, *St. Paul*.

The relationship between forage moisture at baling and chemical composition has not been evaluated in grass hay intended for equine feed. Mold in hay is a serious risk and is known to cause respiratory problems in horses. The objective was to determine the relationship between moisture at time of baling, wrapping, and the application of an organic acid preservative on forage quality and mold growth in grass hay. Thirty-six 1.2 × 1.5 m first cutting orchardgrass round bales were randomized in a complete block design using 4 replicates of 3 target moistures: < 150

g/kg (LM), 200–250 g/kg (MM), and 300–350 g/kg (HM) (wet basis). In field bale moisture was estimated with a bale moisture probe. At baling, a commercially available organic acid hay preservative (Fresh CUT Plus) was applied at 4.5 kg/ton to bales containing MM and HM. After baling, bales were cored and samples were analyzed for chemical composition. Four LM (without preservative), 8 MM (4 with and 4 without preservative) and 4 HM (without preservative) moisture bales were individually wrapped with 6 mils of plastic. After 10 weeks, cores were taken on each bale to determine forage quality and mold counts. Data was analyzed using Proc Mix in SAS and mold counts were log-transformed. Actual moistures for hay baled at the targets of LM, MM, and HM averaged 120, 200, and 260 g/kg respectively. After 10 weeks, moisture content of MM and HM wrapped bales were maintained, while moisture of unwrapped bales decreased to 130 and 180 g/kg, respectively ($P = 0.01$). For all treatments, no changes over time were observed for CP (90 g/kg), ADF (390 g/kg), NDF (590 g/kg), and DE (2.04 Mcal/kg). For MM and HM, wrapping reduced ($P < 0.001$) mold growth (1,700 and 5,700 cfu/g, respectively) compared with no wrapping (4 million and 3 million cfu/g, respectively). The preservative did not reduce or inhibit mold growth at any moisture. Reducing mold growth and maintaining forage quality was achieved by baling dry hay (<150 g/kg moisture) and wrapping wet hay (200–350 g/kg moisture).

Key Words: harvest moisture, bale wrapping, organic acid

W130 Effects of sulfite-based preservatives on preservation and aerobic stability of alfalfa haylage and corn silage. C. J. Fu*, T. W. Clark, and D. V. Dhuyvetter, *Ridley Nutrition Solutions, Ridley Inc.*, *Mankato, MN*.

Experiments were conducted to determine the effects of forage preservatives on alfalfa (*Medicago* L.) haylage and corn (*Zea mays* L.) silage preservation and aerobic stability. Preservatives included sulfite-based commercialized and experimental products in liquid and dry forms. Experiments included laboratory and field trials of varying size that included 18-L pail and 20-ton bag testing. All experiments were completely randomized experimental design with 2 to 4 replications. Products were applied according to the label instruction and the same rates were applied for experimental products. For laboratory trials, whole plant corn at 40% DM with about 19 mm cut and first cutting alfalfa at 50%DM with 13 mm cut were harvested with a convention pull-type harvester. The packing density was 0.2 Kg DM per liter. For the field trial, first cutting alfalfa at 30% DM with 13 mm cut was harvested with the same type harvester and packed in 2.74 m wide Ag-Bag(Ag-Bag International Ltd.). Treatments included control (CONT) carrier only, liquid preservative (LIQP), bunk stabilizer dry form (STAD), experimental liquid preservative (EXPL), and experimental bunk stabilizer dry form (EXSTA). The mini-silo haylage test showed that EXPL significantly increased the lactic acid percentage of total VFA compared with CONT and LIQP, and showed a 5 to 10 times reduction in yeast and mold count ($P < 0.05$). The 82 d bag haylage test indicated that EXPL increased DM recovery from 93% to 98% ($P < 0.05$) compared with CONT. Laboratory aerobic stability tests of corn silage showed EXSTA held temperature lower by 11 to 16°C compared with CONT and STAD ($P < 0.05$) either at ambient (21°C) or warmer (27 to 35°C) temperatures. Furthermore, EXSTA reduced yeast and mold counts by 100 to 1000 times compared with those of STAD and CONT, respectively ($P < 0.01$). From these experiments, it can be concluded that EXPL and EXSTA have potential to improve alfalfa haylage and corn silage preservation in addition to bunk stability.

Key Words: alfalfa haylage, corn silage, preservatives

W131 Effect of alfalfa entries selected to tolerate agricultural machinery traffic on forage yield and regrowth. J. Santillano-Cázares*[1] and J. L. Caddel[2], [1]*Universidad Autónoma de Baja California*, *Mexicali, Baja California, México*, [2]*Oklahoma State University*, *Stillwater*.

It has been suggested that wheel traffic reduces alfalfa (*Medicago sativa* L.) yields and stand persistence. Thus, efforts have been made to select alfalfa cultivars to tolerate wheel traffic. The objective of this research was to determine if selected alfalfa entries out produced forage yields and regrowth rate non traffic-selected entries. The experiment was conducted on one of Oklahoma State University's experimental stations, in Stillwater, OK. Soil textures in the station were sandy-loam and loam. Twenty alfalfa entries were planted at 20 kg ha-1 on March 2002. The alfalfa entries tested included commercial varieties and experimental lines. Alfalfa entries included alfalfas selected for wheel traffic tolerance and not selected for wheel traffic tolerance. Entries were subjected to either traffic or no traffic. Traffic treatment was applied by driving the front and rear tires with a 100 horse power tractor over the plots during 3 years, 5 d after each harvest. The treatment structure was a 2 × 20 factorial and treatments were assigned by using a RCBD in a split-plot design structure, with 6 replications. Main plots were the traffic treatments and subplots were the alfalfa varieties. Plot size was 1 × 5 m (5 m^2) and the size of the sampling area was 0.6 × 5 m (3 m^2). Forage yields were measured in 2002, 2003, and 2004 from 1 × 5 m (5 m^2) plots. Regrowth was estimated only in the first harvest year of the study (2002) by measuring stem height from soil level to the tips of the stems, 5 d after harvest. The alfalfa entry × wheel traffic interaction was not significant ($P > 0.05$) for forage yields or regrowth rate. No interaction indicates that the selected entries were injured about the same as the normal entries (without selection) when driven on 5 d after harvests. It was concluded that under the actual environmental and management conditions of this study, alfalfa selection for traffic tolerance was ineffective. However, it clearly demonstrated that wheel traffic reduced alfalfa yields and should be avoided when possible.

Key Words: wheel traffic, alfalfa selection, yield

W132 Influence of maturity on leaf fiber and protein fractions of different alfalfa varieties. A. Palmonari*, M. Fustini, G. Canestrari, G. Biagi, and A. Formigoni, *Università di Bologna*, *Bologna, Italy*.

Impact of leaves on the hole plant fibrous and protein fractions in alfalfa is usually affected by harvesting systems and the preference for forage quantitative production.
Leaves are very rich in nitrogen and protein, being active in photosynthesis. On the other hand, leaves are more subject to the co-association between lignification and decreased amount of protein and soluble carbohydrates. Aim of this study was to determine how plant maturity influences fibrous and protein fraction in alfalfa leaves. Four alfalfa varieties (P, M, L, BC) were collected at three different stages of maturity (10, 20, and 30 d of age). All samples were collected using scissors, trying to preserve the integrity of the hole plant. After drying at 65°C, leaves were separated from stalks, ground, and analyzed chemically for NDF, ADF, ADL, CP, SolP, NPN, and NDIP. Data were analyzed using two-way ANOVA with alfalfa variety and time as the main effects. From Day 10 to Day 30, NDF decreased from 24.1 to 23.1%, while ADF and ADL increased from 16.2 to 18.0% and from 5.7 to 7.8%, respectively ($P < 0.01$). Among tested varieties, P contained ($P < 0.01$) less ADL (5.2 vs. 6.8, 6.9, and 7.7% for M, L, and BC, respectively) and ADF (15.7 vs. 17.6, 17.1, and 18.1% for M, L, and BC, respectively) and more NDF (24.4 vs. 23.5, 22.8, and 23.3% for M, L, and BC, respectively).

Average values of CP, SolP, NPN, and NDIP in alfalfa leaves were 28.8, 10.4, 9.7, and 28.3%, respectively. As expected, from Day 10 to Day 30, CP (−29%), SolP (−38%), NPN (−42%), and NDIP (−21%) decreased ($P < 0.01$). Variety of alfalfa had no significant effect on leaf protein content. These data suggest that maturity strongly influences the composition of alfalfa leaves. In conclusion, this study produces evidence that maturity increases ADL and reduces protein in leaves, thus reducing their nutritional value. Interestingly, maturity had no effect on ADF content of P leaves, suggesting a higher nutritional value of this variety.

Key Words: alfalfa leaves, maturity, chemical composition

W133 Effect of a bacterial inoculant on the quality of and nutrient losses from corn silage produced in farm-scale silos. O. C. M. Queiroz*[1], A. T. Adesogan[1], K. G. Arriola[1], and M. F. Queiroz[2], [1]*Department of Animal Sciences, University of Florida*, *Gainesville,* [2]*Department of Animal Sciences, UNESP*, *Jaboticabal, SP, Brazil*.

This project aimed to determine effects of applying an inoculant containing homofermentative and heterofermentative bacteria on the fermentation and aerobic stability of and nutrient losses from corn silage produced in farm-scale silos. Corn forage was harvested at 34% DM, treated without (Control) or with 1 × 106 cfu/g of *Lactobacillus buchneri* and *Pediococcus pentosaceus*, packed (45 tons) in quadruplicate into 3.7-m-wide Ag bags, and ensiled for 166 d. Silage removed from the bags (500 kg/d) was separated into spoiled (visibly darker, heating or moldy) and good portions and weighed for 35 d. Weekly composites were analyzed for chemical composition, aerobic stability (time to 2°C above ambient temperature) and fungal counts. The experiment had a completely randomized design. Data were analyzed with a model including treatment, time, and the interaction. Inoculation did not affect the chemical composition of the spoiled or good silage but decreased the quantity (5.7 vs. 12.9 kg/d; $P = 0.002$) and percentage (3.4 vs. 7.8; $P = 0.004$) of spoiled silage by over 50%. Losses of CP (0.23 vs. 0.92 kg/d; $P = 0.03$), gross energy (433 vs. 1842 kcal/d; $P = 0.02$), and NDF (1.34 vs. 4.12 kg/d; $P = 0.04$) in spoiled silage were less in inoculated versus Control silages. Inoculated silages had a lower pH (3.91 vs. 3.99; $P = 0.01$), lactate concentration (0.69 vs. 0.86%; $P = 0.04$), lactate: acetate ratio (0.61 vs. 1.41%; $P = 0.04$) and a greater acetate (1.15 vs. 0.73%; $P = 0.04$) concentration than the Control silage. Inoculated silages tended to have fewer yeasts (2.59 vs. 4.62, log cfu/g; $P = 0.07$) than Control silages, but aerobic stability did not differ (14.7 vs. 9.5 h; $P = 0.71$). The inoculant inhibited the growth of yeasts and substantially reduced the amount of spoilage and the associated energy and nutrient losses.

Key Words: *Lactobacillus buchneri*, *Pediococcus pentosaceus*, inoculant

W134 Changes in cell wall fractions and in vitro dry matter digestibility, of corn silage associated with additives. R. H. de Tonissi e Buschinelli Goes*, K. A. de Souza, K. A. G. Nogueira, D. de Faria Pereira, T. da Cunha Cornélio, M. G. de Menezes Gressler, E. R. de Oliveira, and K. C. da Silva Brabes, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

Corn plant, cut at 90 d after planting, was ensiled in 72 experimental silos in a completely randomized design, in a factorial square 4 × 6 (4 treatments and 6 d opening) with 3 replicates; and the averages compared by Tukey test at 5% probability, for evaluate the changes in cell wall fractions and in vitro dry matter digestibility (DMD) of corn silage associated with additives. The corn silage was associated with additive at 5% in natural matter, and the treatments were: soybean hulls (CS+5%SH), rice meal (CP+5%RM) and sunflower crushed (CS+5%SC). The control was composed of 100% of the corn plant (CS). The silos were opened 0, 28, 56, 84, 112 and 140 d. The pH showed ($P < 0.05$) reduction from 28 d of fermentation, with 112 d to the lowest value (3.39). All additives were able to reach a pH favorable to preservation of forages. There was a significant effect ($P < 0.05$) for inclusion of additives and time of opening, where the NDF decreased in their levels. The lower values of NDF occurred at 112 d (63.02, 65.46, 57.83 and 60.98% for CS, CS+5%SH, CS+5%RM and CS+5%SC, respectively). Reduction of NDF indicates the solubilization of the wall cell. There was effect ($P < 0.05$) of time of ensiling for hemicellulose (HCEL), and ADF. The HCEL reduced when increases the time of silage, no difference between the opening d 0 to 112; with average of 29.36%. ADF reduced to the extent until at 140 d, with value of 34.9%. Lignin and cellulose had effect for addition of additive ($P < 0.05$), where the addition of soybean hulls, rice meal and sunflower crushed reduced the lignin content of corn silage, averaging 10.6, 8.7 and 11.0%, respectively. The lignin content of corn silage was 12.2%. The addition of soybean hulls increased the cellulose content of silage, while the levels for CS, CS+5%RM and CS+5%SC, were 26.4, 24.3, 24.8%. DMD ($P < 0.05$), improved after 84 d of ensiling, with values of 69.3%. The DMD for day zero was 62.9%. The addition of 5% of additives changes the composition of the cell wall of corn silage. The in vitro digestibility of dry matter increased according to the time of ensiling.

Key Words: sunflower crushed, rice meal, soybean hulls

W135 Effect of oxygen barrier film on the storage temperature and top losses of corn silage in stack silo. F. C. Basso[1], R. A. Reis*[1], T. F. Bernardes[2], E. C. Lara[1], F. B. Assis[1], M. Nogueira[1], and A. P. T. P. Roth[1], [1]*UNESP/FCAV*, *Jaboticabal, São Paulo, Brazil*, [2]*UFRA*, *Bélem, Pára, Brazil*.

The aim this trial was to study the effect of the oxygen barrier film on the storage temperature and top losses of corn silage in stack silo. One trial was carried out on 1 commercial farm in Jaboticabal, Brazil, in 2009. Whole-corn crops were harvested at around the 50% milk-line stage and ensiled in stack silo. The covering treatments were: a sheet of 200-µm-thick black-on-white polyethylene film (ST) and a sheet of 45-µm-thick transparent oxygen barrier film (OB) plus a sheet of ST over the OB film. The stack silo was divided in 2 parts along the length: half was covered with ST film and half with OB plus ST film. Both films were secured with soil around the silo. During silo filling, 20 bags (10 for each treatment) containing 3.5 kg of herbage and one data logger were buried at the peripheral zone (15 cm of depth) of the silo to determine storage temperature and top losses of silage during the conservation period. After 45 d of fermentation, the bags were removed during feedout. The bags were weighed to determine dry matter (DM) losses. The DM content, number of yeasts and molds and pH value were measured. The storage temperature of corn silage under OB film always was lower than under ST film after 13 d of fermentation. The storage temperature was lower in corn silage under OB film until 5.1°C. The DM content was 25.86% in corn silage covered with ST film and 27.31% in corn silage under OB film ($P < 0.05$). The corn silage under the OB film had fewer molds compared with the silage under the ST film (3.93 vs. 4.61 Log_{10} CFU/g, respectively - $P < 0.05$). The number of yeasts (5.27 Log_{10} CFU/g under OB film vs. 5.93 Log_{10} CFU/g under ST film) and pH value (4.09 under OB film vs. 4.07 under ST film) did not differ ($P > 0.05$) between silages. The DM losses were 7.39% in silage covered with OB film, while in corn silage under ST film the DM losses were 10.18%, but this difference was not significant ($P >$

0.05). Oxygen barrier film plus polyethylene film reduced the storage temperature and the number of molds.

Key Words: polyethylene film, polyamide film, aerobic stability

W136 Effects of microbial inoculant on fermentation, microbial dynamics and aerobic stability of corn silage. F. C. Basso[1], R. A. Reis*[1], E. C. Lara[1], F. B. Assis[1], M. Nogueira[1], A. P. T. P. Roth[1], and T. F. Bernardes[2], [1]*UNESP/FCAV*, *Jaboticabal, São Paulo, Brazil*, [2]*UFRA*, *Bélem, Pára, Brazil*.

The aim of this trial was to evaluate the effects of microbial inoculant on fermentation, microbial dynamics and aerobic stability of corn silage. Whole-plant corn (350 g/kg) was ensiled in quadruplicate laboratory silos (7L) after the following treatments: untreated (control), *Lactobacillus buchneri* NCIMB 40788 (LB - 1×10^5 CFU/g of fresh forage), *Bacillus subtilis* (BS - 1×10^5 CFU/g of fresh forage), *Propionibacterium acidicipropionici* MA26/4U (PA - 1×10^5 CFU/g of fresh forage), *Lactobacillus plantarum* MA18/5U (LP - 1×10^5 CFU/g of fresh forage), *L. buchneri* plus *L. plantarum* (LBLP), *B. subtilis* plus *L. plantarum* (BSLP) and *P. acidicipropionici* plus *L. plantarum* (PALP). After 96 d of ensilage, silos were opened, spolied forage discarded and the remainder was homogenized and placed in plastic buckets and maintained in a closed place at room temperature. To determine aerobic stability (AS), silage temperature was measured every half hour by a data logger inserted in the center of mass during the aerobic exposure and room temperature (average 24°C) was measured by data logger placed near the experimental silos. Dry matter content (DM), pH value, ammonia nitrogen (NH3/TN) content and yeasts and molds counts (Log CFU/g) in potato dextrose agar were measured. The statistical analysis included one-way ANOVA and Tukey's test ($P < 0.05$). The DM, NH3/TN and molds counts were not different among treatments. The pH value was lower in silages without inoculant and with *P. acidicipropionici* ($P < 0.05$). The corn silage with *L. buchneri*, *L. buchneri* plus *L. plantarum*, *B. subtilis* and *P. acidicipropionici* had lower number yeasts and improved aerobic stability ($P < 0.05$). The microbial inoculant with heterofermentative bacteria and the association between *L. buchneri* plus *L. plantarum* is effective in decreasing the numbers of yeasts and improves the aerobic stability of corn silage.

Table 1. Fermentation, microbial dynamic and aerobic stability of corn silage with microbial inoculant.

Treatments	DM	pH	NH3/NT	Yeasts	Molds	AS
Control	34.92	3.81b	5.17	3.99a	3.80	23.33d

W137 In vitro gas production and microbial protein synthesis in alfalfa-timothy mixtures. F. Hassanat*[1], G. Tremblay[2], G. Allard[3], G. Bélanger[2], A. Bertrand[2], Y. Castonguay[2], R. Michaud[2], and R. Berthiaume[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Qc, Canada*, [2]*Agriculture and Agri-Food Canada*, *Quebec, Qc, Canada*, [3]*Faculté des sciences de l'agriculture et de l'alimentation, Université Laval*, *Quebec, Qc, Canada*.

Forage diets containing an optimal balance between crude protein (CP) and nonstructural carbohydrates (NSC) sources maximize microbial protein (MP) yield and minimize NH_3 output, which would improve metabolizable protein availability to animals. Impact of increasing the ratio of NSC:CP on in vitro gas production (IVGP) and MP yield was investigated by increasing the proportion of grass in legume:grass mixtures. In a completely randomized block design, triplicates of alfalfa:timothy mixtures of 100:0, 75:25, 50:50, and 25:75 (DM basis) were incubated for 24h using ANKOM^{RF} gas production monitoring system in separate days. Gas production data were fitted to a Michaelis-Menten model to estimate gas production parameters. Incubation residues were refluxed with neutral detergent fiber (NDF) solution to isolate MP from undegradable residues. Linear ($P_{lin.}$) and quadratic ($P_{quad.}$) components of the effects of treatments were determined. Increasing timothy proportion linearly increased NSC and NDF but reduced CP concentration; maximum changes with highest timothy proportion compared with alfalfa alone were +44% for NSC, +49% for NDF, and −48% for CP. These changes increased IVGP from 308 to 352 mL gas g^{-1} OM ($P_{lin.} < 0.01$), increased time to ferment 50, 75 and 90% of the substrate ($P_{quad.} < 0.05$) and reduced maximal degradation rate from 0.18 to 0.16% h^{-1} ($P_{lin.} < 0.01$). In vitro true dry matter degradability was highest for alfalfa alone and decreased ($P_{lin.} < 0.01$) as timothy proportion increased. The amount of substrate available to rumen microbes was therefore reduced when the proportion of timothy increased which in turn reduced MP yield ($P_{lin.} < 0.05$). However, when expressed on a CP basis, MP yield increased ($P_{quad.} < 0.05$) with increasing timothy proportion. The reduction of NH_3 concentration ($P_{lin.} < 0.01$) with increasing timothy proportion suggests that the dietary protein was utilized more efficiently for MP synthesis. Although MP yield per g dry matter was highest for alfalfa alone, the 25:75 alfalfa:timothy mixture supplied the best NSC:CP ratio for efficient in vitro MP synthesis.

Key Words: in vitro gas production, forage mixture, microbial protein

W138 Prediction of Tanzânia grass dry mass production using agrometereological parameters. L. C. Araujo*[1], P. M. Santos[2], J. R. Pezzopane[2], and P. G. da Cruz[1], [1]*"Luiz de Queiroz" College of Agriculture/USP*, *Piracicaba, São Paulo, Brazil*, [2]*Embrapa Southeast Cattle*, *São Carlos, São Paulo, Brazil*.

Mathematical models that predict the effect of climatic variables over forage production may be used as a decision support toll on farms. The objective of this study was to determine the effect of climatic events on *Panicum maximum* cv. Tanzânia (Tanzânia grass) production and parameterize models to predict forage accumulation rate. Tanzânia grass was cultivated in São Carlos, SP, Brazil (21°57′42″ S, 47°50′28″ W, altitude 860 m). Pastures were fertilized during the raining season and rotationally grazed all around the year. Data from 53 periods of pasture growth, between 1999 and 2005, were used to verify its relation with climatic variables. Daily temperature (maximum, minimum and mean), rain and solar radiation were monitored. Growing degrees days was calculated considering 17°C as lower basal temperature. Potential evapotranspiration (Eto) and actual evapotranspiration (Eta) were calculated based on water balance for every 5 d. Growth index (GI) was calculated using minimum temperature, solar radiation and the relationship between Eta/Eto. To estimate the effect of water availability on forage production, the relationship between Eta and Eto was used as a factor to penalize the accumulation of energy, measured as growing degree days or solar radia-

tion. Linear and exponential regression analysis was done to determine the relationship between forage accumulation rate (dependent variable) and climatic parameters (independent variable). Results confirm that herbage accumulation rate depends on climatic variables. The coefficient of determination was higher when both energy and water availability was considered on the model: Eta (R^2 = 0.85), growing degree days corrected by Eta/Eto (R^2 = 0.83) and GI (R^2 = 0.81). It was concluded that Eta, growing degree days corrected by Eta/Eto and GI may be used to predict Tanzânia grass herbage accumulation rate when climate is the major limitation factor for forage production.

W139 Effects of chemical additives on the ensilage of sugarcane. A. F. Pedroso*, W. Barioni Jr., G. B. Souza, and V. R. Del Santo, *Brazilian Agricultural Research Corporation - Embrapa*, *São Carlos, SP, Brazil*.

The objective was to evaluate efficacy of chemical additives at controlling alcoholic fermentation and DM losses and increasing aerobic stability (AE) of sugarcane silages. Mechanically harvested sugarcane (12 mo old; 22° Brix; DM: 330 g/kg) was ensiled in 15 × 30 cm PVC tubes (4 replicates/treatment). Nine treatments were applied to the forage at ensiling (fresh basis): untreated - Control; urea (5 g/kg) + sodium benzoate (0.5 g/kg) - UB1; urea (7.5 g/kg) + benzoate (0.5 g/kg) - UB2; urea (5 g/kg) + benzoate (0.75 g/kg) - UB3; urea (7.5 g/kg) + benzoate (0.75 g/kg) - UB4; sodium propionate at rates of 1, 2 and 4 g/kg - PROP1, PROP2 and PROP3, respectively; calcium hydroxide (10 g/kg) - CA. Additives were applied in aqueous solutions. Minisilos were weighed and sampled on d 0 and 78 d after ensiling. Dry matter loss (DML) was calculated and aerobic stability was defined as the time (h) that elapsed before the temperature of aerated silages exceeded room temperature by 2°C. Data were analyzed as a completely randomized design and differences among means were tested using *t*-test. Control silage presented characteristic high ethanol content, high DML and poor AE (Table 1). Silage treated with CA had 90% less ethanol and 69% lower DML relative to control ($P < 0.05$). Ethanol content and DML did not differ ($P > 0.05$) between the lowest doses of urea + benzoate (UB1) and CA and higher doses of urea and benzoate (UB2, UB3, UB4) were not more effective than UB1. Among propionate treatments, only PROP3 reduced ($P < 0.05$) simultaneously ethanol content and DML in the silage compared with control (64% and 76% less, respectively). Only CA improved ($P < 0.05$) silage AE compared with control. pH values differed among treatments but all values indicated adequate conservation.

W140 Effect of cutting management (PM vs. AM) and maceration on forage total nonstructural carbohydrates concentration and cattle preference. G. Raggio*[1], A. L. Tucker[1], M. Mongeon[2], R. Bergeron[1], and R. Berthiaume[3], [1]*Campus Alfred Université de Guelph*, *Alfred, Ontario, Canada*, [2]*Ministry of Agriculture, Food and Rural Affairs*, *Alfred, Ontario, Canada*, [3]*Dairy and Swine Research & Development Centre, Agriculture and Agri-Food Canada*, *Lennoxville, Canada*.

The aim of this study was to assess the effect of hay made from forage cut at sundown (PM) or sunup (AM) and macerated or not (control) on forage nonstructural carbohydrates (NSC) and cattle preference. Half of a timothy-alfalfa field at the late bud stage was cut at 18:00 whereas the second half was cut at 0600 h the next morning. Half of both the PM and AM cut were then macerated at 0900 h on d 2 with the remaining quarters being left to wilt without maceration (control). Hay was field dried, baled, and chopped before usage. A preference trial was conducted over 6 consecutive days with 6 Holstein heifers. During adaptation, hay from each treatment was offered alone as meals. Four treatments were used: AM control, AM macerated, PM control and PM macerated. Each possible pair of the 4 treatments (n = 6) was randomly assigned to the animals (one pair d-1), over 6 consecutive days. Two heifers at a time were moved to an adjacent pen separated in 2, offered 2 kg of each type of hay in adjacent tubs, and allowed 30 min to eat. Intake was calculated as the difference between hay offered and leftover. Hay samples were collected during the 6 experimental days and pooled by treatment. Heifer positions in the pen, treatments and treatment positions (left or right) were randomized daily. Data were analyzed as a multidimensional scaling and also by ANOVA with a model including animal effects and hay. Orthogonal contrasts were used to test for cutting time, maceration and cutting time × maceration effects. Feed composition (DM basis) was not affected by treatments (DM 88 ± 0.7%, CP 10 ± 0.7%, ADF 39 ± 1.0%, NDF 64 ± 1.8%). However, cutting time (AM vs. PM) tended to affect NSC concentration (24 vs. 25 ± 0.4%, $P = 0.09$). Overall, cutting in PM vs. AM (1359 vs. 754 ± 112 g DMI, $P = 0.01$) and macerating vs. control (1521 vs. 592 ± 112 g DMI, $P < 0.01$) increased hay consumption. There was no interaction between cutting time and maceration. These results suggest that both mowing in the PM and maceration were effective at increasing short-term dry matter intake.

Key Words: preference, cattle, conditioning

W141 Effect of leukemia inhibitory factor on feed intake and body temperature in sheep. J. L. Sartin*[1], D. L. Marks[2], B. K. Whitlock[3], J. A. Daniel[4], and B. P. Steele[1], [1]*Auburn University*, *Auburn, AL,*[2]*Oregon Health Sciences University*, *Portland,* [3]*University of Tennessee*, *Knoxville,* [4]*Berry College*, *Mt Bery, GA*.

Leukemia inhibitory factor (LIF) has been suggested to function as a potent inhibitor of feed intake in rodents. These studies were designed to determine whether LIF was found in the ovine hypothalamus and whether LIF inhibited feed intake in sheep. Sheep hypothalami were used to clone LIF to indicate presence of the gene in the hypothalamus. The sequence was similar to published data. Another group of sheep were provided intracerebroventricular (ICV) cannulas and injected with doses of LIF at 250, 500, 1000 and 2500 ng per sheep, ICV. Feed intake was inhibited by the 1000 and 2500 ng dose (trt, $P < 0.0001$; time × trt, $P < 0.02$). All doses of LIF elevated temperature above 40 C, indicating a fever. In a second experiment, the sheep were injected ICV with 2500 ng LIF, and blood samples collected at 10 min intervals for 6 h for assay of luteinizing hormone (LH), growth hormone (GH) and 30 min interval samples assayed for glucose and free fatty acids. There was no effect of LIF on GH. There was no effect of trt for LH, but there was a time × trt interaction indicating reduced LH ($P < 0.0001$). There was an effect of trt and a time × trt interaction indicating elevated plasma free fatty acids ($P < 0.03$; 0.001) and glucose ($P < 0.006$; 0.0001), opposite to the effects of LIF in rodent models. The effects of LIF on feed intake and other parameters is similar to the effects of LPS and leads to a hypothesis that LIF expression in response to LPS may be a component of the mechanism for feed intake inhibition in disease.

Key Words: appetite, free fatty acids, luteinizing hormone

W142 Effects of late gestation metabolizable protein (MP) supplementation on ewe organ and blood parameters. T. J. Swanson*[1], L. A. Lekatz[1], T. L. Neville[1], M. L. Van Enom[2], C. S. Schauer[2], K. R. Maddock Carlin[1], C. J. Hammer[1], and K. A. Vonnahme[1], [1]*North Dakota State University*, *Fargo*, [2]*Hettinger Research Extension Center*, *Hettinger, ND*.

To examine the effects of maternal MP supplementation in late gestation on blood and organ parameters multiparous ewes (n = 45) were allotted randomly to one of 3 treatments, 75% (LOW), 100% (CON), or 125% (HIGH) of MP requirements fed from d 100 to d 130 of gestation. Blood samples were drawn before initiation of diets and before slaughter for chemistry panel analysis. Body measurements including loin eye area, back fat, and body wall thickness where taken using ultrasound before treatment initiation and before slaughter to examine changes in body condition. At d 130 ewes were slaughtered and dissected. Ewes carried singletons and twins therefore fetal number was included as a main effect. There was no effect of treatment or fetal number on final BW, loin eye area, back fat, body wall thickness, eviscerated body weight (EBW), or weights of blood, perirenal fat, thyroid, and adrenals ($P \geq 0.06$). There was a treatment effect on heart weight with CON being heavier than LOW and HIGH which were not different ($P \leq 0.01$). Kidney weight was also affected by treatment with LOW being lighter compared with HIGH and CON which were not different ($P \leq 0.01$). Ewes carrying twins had increased liver, mammary, and gravid uterus weights ($P \leq 0.03$). Ewes with singletons had increased lung weights compared with ewes carrying twins ($P \leq 0.03$). When organ weight was examined as a proportion of EBW (g/kg) there was no difference in heart, perirenal fat, kidney, lung, or thyroid masses ($P \geq 0.06$). Ewes carrying twins had increased blood, liver, mammary, and gravid uterus weights as a proportion of EBW ($P \leq 0.02$). Initial chemistry panel results showed no differences in parameters of interest. Treatment decreased aspartate aminotransferase and blood urea nitrogen ($P \leq 0.01$) in LOW ewes compared with HIGH and CON ewes which did not differ. Change in gamma-glutamyl transpeptidase was greater in ewes carrying twins ($P \leq 0.01$). Results indicate that litter size and dietary MP supplementation during late gestation alters ewe organ weights.

Key Words: gestation, metabolizable protein, organ weights

W143 Effect of to PFKM and TFDP2 gene expression on muscle growth in sheep. J. W. Buchanan*[1], M. L. Thonney[2], and R. G. Mateescu[1], [1]*Oklahoma State University*, *Stillwater*, [2]*Cornell University*, *Ithaca, New York*.

Muscle growth rate in response to testosterone is an important characteristic of meat producing species utilized in production agriculture. The onset of puberty and subsequent testosterone release in males causes differential gene expression within sexually dimorphic muscles, resulting in measurable hypertrophy. Phosphofructokinase muscle type (PFKM) and transcription factor Dp-2 (TFDP2) are 2 genes recently shown to have significantly higher transcript levels in callipyge lambs. PFKM is a kinase directly involved in glycolysis, and TFDP2 is a transcription factor that has been implicated in the initiation of the cell cycle as well as DNA replication. The objective of this project was to compare the expression of these 2 genes in 2 different skeletal muscles in sheep. Muscle samples were collected from 18 sets of twins, with one individual from each set castrated at birth. Each set of twins was randomly assigned to 4 groups corresponding to 77, 105, 133, and 161 d of age at slaughter. Total RNA was extracted from semitendinosus (non-sexually dimorphic) and splenius (sexually dimorphic) muscle samples collected from each individual. Two-step reverse transcription polymerase chain reaction (RT-PCR) utilizing oligo(dT) primers was used to synthesize complimentary DNA. A quantitative polymerase chain reaction (q-PCR) was then performed to quantify the amount of PFKM and TFDP2 mRNA transcript in the muscle samples. The difference in gene expression between the SP and ST muscles was analyzed using the General Linear Model procedure of SAS to determine the effect of sex, age class and their interaction. No statistically significant difference was found in PFKM or TFDP2 mRNA level between the 2 muscles in rams and wethers at any age. Identifying genes that control muscle hypertrophy has the potential to create increased gains and efficiency in populations utilizing a marker assisted selection program. Further expression analysis is needed to determine the response of other candidate genes controlling hypertrophy in sexually dimorphic muscles.

Key Words: gene expression, muscle growth, sheep

W144 Excessive maternal selenium intake induces inflammatory response in the ovine fetal gut. H. Wang*[1], J. Zhao[1], Y. Huang[1], X. Yan[1], A. Meyer[2], M. Du[1], K. Vonnahme[2], L. Reynolds[2], J. Caton[2], and M. J. Zhu[1], [1]*Department of Animal Science, University of Wyoming*, *Laramie,* [2]*Department of Animal Science, North Dakota State University*, *Fargo*.

Selenium (Se) is a coenzyme for glutathione peroxidase and thioredoxin reductase, and its dietary supplementation has anti-inflammatory effects.

Many areas of North Dakota and other states have soils enriched in Se, rendering sheep and cattle grazing in these areas ingesting excessive Se. The objective was to evaluate the effects of higher energy diets and elevated Se intake on inflammatory response in lamb ileal tissues, a major immune organ. Rambouillet ewes (age = 240 ± 17 d; initial BW = 52.1 ± 6.2 kg) were fed either a control diet (adequate Se: 11.5μg Se.kg $BW^{-1}.d^{-1}$) or a high Se diet (77.0 μg Se.kg $BW^{-1}.d^{-1}$) with Se provide as Se-enriched wheat millrun. On 40 d of gestation (dG) ewes in each Se group were assigned randomly to 100%, or 140% of dietary requirements except for Se. At parturition, offspring were removed before nursing and raised independent of the dams until necropsy at 20 d of age. Offspring ileal tissues were sampled for immunoblotting and qRT-PCR analyses. Control, high energy (COB) and control, high Se (SEC) had no major difference in inflammatory signaling compared with control, normal Se (CC). However, high inflammatory signaling was detected in high energy, high Se (SEOB) group, as shown by increased ($P < 0.05$) mRNA expression of tumor necrosis factor (TNF)α and chemotaxis interleukin (IL)8. Consistent with this, phosphorylation of c-Jun N-terminal kinase (JNK), a primary inflammatory signaling, was greater ($P < 0.05$) in ileal tissue from offspring of SEOB treated dams. Both mRNA and protein content of transforming growth factor (TGF) β was also greater ($P < 0.05$) in SEOB lambs. No difference in mRNA expression of IL6, CD14, IL1α and β, and toll-like receptor (TLR) 2 and 4 were observed. In conclusion, high Se or maternal gestational high energy diet had no major effects on inflammatory signaling, but combining high energy diet with excessive Se induced inflammatory response in offspring intestine.

W145 Serum concentrations of ghrelin, IGF-I, and prolactin in Rambouillet lambs during the preweaning period. C. D. Felker*, M. J. Hendricks, K. A. Jurado, A. D. Stapp, L. E. Camacho, and D. M. Hallford, *New Mexico State University*, *Las Cruces*.

During a 60-d preweaning period in each of 2 yr, Rambouillet lambs (n = 75 and 52 for yr 1 and 2, respectively) were used to examine effects of sex (77 females, 50 males) and type of birth (TOB; 46 single, 81 multiple lambs) on serum concentrations of ghrelin (total), IGF-I, and prolactin (PRL). Lambs were born in mid-March of each year and were weighed on the day of birth (d 0; 5.1 ± 0.1 kg) and at weaning (60 d, 20.1 ± 0.4 kg). Serum was harvested by centrifugation from blood collected (jugular venipuncture) on d 1, 14, 28, 42, and at weaning. Data were examined by ANOVA for a randomized complete block design with a 2 (sex) x 2 (TOB) factorial arrangement, sampling day as a repeated measure, and year as the block. Males were heavier at birth than females ($P < 0.001$), but weaning weight and ADG were similar ($P > 0.35$). Single lambs were heavier ($P < 0.001$) at birth and weaning and had greater ADG ($P < 0.001$) than multiple lambs. Serum ghrelin was similar ($P > 0.24$) in male and female and in single and multiple lambs. However, ghrelin declined during the preweaning period with values of 557, 373, and 358 (±9) pg/mL (quadratic, $P < 0.001$) on d 1, 28, and 60, respectively. Serum PRL and IGF-I were influenced ($P < 0.05$) by sex × day and TOB × day interactions. Males and females had similar ($P = 0.23$) IGF-I on d 1; but on d 14, 28, 42, and at weaning, males had greater ($P < 0.05$) IGF-I than did females. Serum IGF-I was greater ($P < 0.02$) in single than in multiple lambs on all sampling days. Serum PRL was similar ($P > 0.10$) in male and female lambs throughout preweaning. However, single lambs had greater ($P < 0.001$) serum PRL concentrations than did multiple lambs on d 42 and at weaning. In general, PRL and IGF-I tended to increase in a quadratic ($P < 0.01$) fashion across the preweaning period. Correlation coefficients determined on d 60 between serum IGF-I, PRL, and ghrelin concentrations and preweaning ADG were 0.65, 0.44, and −0.26 ($P < 0.005$), respectively. Sex of lamb, type of birth, and age should be considered when evaluating serum hormone profiles in rapidly growing lambs.

Key Words: sheep, growth, hormones

W146 Patterns of fat growth in the primal cuts of beef composites. L. A. Goonewardene*[1], Z. Wang[2], R. W. Seneviratne[1], J. A. Basarab[1], J. Stewart-Smith[3], J. L. Aalhus[4], M. A. Price[2], and E. K. Okine[2], [1]*Alberta Agriculture and Rural Development*, *Edmonton, AB, Canada*, [2]*University of Alberta*, *Edmonton, AB, Canada*, [3]*Beefbooster Inc.*, *Calgary, AB, Canada*, [4]*Agriculture and Agri-Food Canada*, *Lacombe, AB, Canada*.

Beef composites (C) have combined favorable traits of pure breeds. The objective was to compare the growth rates (GR) and partitioning patterns of total fat (F), inter muscular (IM), body cavity (BC) and subcutaneous (SC) fat in 5 primal cuts of serially harvested Beefbooster composites (SM = C of small breeds n = 37, AH = C of Angus and Hereford n = 69 and GLC = C with Gelbvieh, Limousin or Charolais terminal sires n = 71) from 274 to 456 d (d) of age in relation to composite type and primal cut. Analysis of covariance obtained the slopes (GR/d) for total F, IM, BC and SC fat within each cut and C type. The GR of total fat deposition in AH was 24.7% higher ($P < 0.10$) than SM and 23.6% higher than GLC. The GR of total fat in the chuck was over 3 times higher than the loin and short loin and over twice the GR of the rib and round in each composite. The GR of IM fat in the chuck and rib was higher ($P < 0.10$) than BC and SC fat, but the GR of SC fat was higher than IM in the round and loin in each composite. The round and rib had similar GR for IM fat in SM and GLC but in the AH a 40.5% difference in GR for IM fat was observed. Pronounced differences were observed in the GR of SC fat between composites in the round and loin, and AH had higher ($P < 0.10$) GR compared with SM and GLC was in between. The difference in the fattening patterns in the 3 composites was most pronounced in the SC depot followed by the IM with little change in the BC depot. Selective breeding and the development of beef composites have primarily resulted in changes in SC fat partitioning in the 5 primal cuts and IM fat in the chuck. More fat trim at retail may be needed in the AH compared with SM and GLC.

Key Words: fat, growth, beef

W147 Prepartum supplementation in primiparous beef cows affected hepatic IGF-I mRNA expression in female calves. J. Laporta*[1], A. L. Astessiano[1], A. Scarsi[1], R. Pérez-Clariget[1], G. Quintans[2], and M. Carriquiry[1], [1]*School of Agronomy, UdelaR*, *Uruguay*, [2]*Instituto Nacional de Investigación Agropecuaria*, *Treinta y Tres, Uruguay*.

We examined the effect of supplementation during the last month of gestation of primiparous cows, on hepatic gene expression of growth hormone receptor (GHR), insulin–like growth factor–I (IGF–I) and IGF binding protein–3 (BP3) of their calves. The experiment was conducted in INIA Treinta y Tres (33°15′S 54°28′W) using 20 crossbred (Angus/Hereford) calves (n = 5 per treatment and sex). Cows, ranked by body weight (BW) and body condition score, were blocked by calving day and assigned randomly to control or supplement treatments. Supplemented cows were offered (1 kg/100 kg BW, 4.5 kg/d) a mix (67:33% as–fed basis; 16% CP, 11% ADF) of sorghum grain and protein concentrated from 33 ± 1.4 d prepartum until calving. Before, during and after the supplementation period, cows grazed together a native

pasture paddock (60 ha) with an average forage mass available of 1345 kg DM/ha (10.4% CP, 45.2% ADF). Calf BW, and liver samples were collected at weaning. Total RNA was extracted and mRNA abundance determined by SYBR Green RT–PCR in real time and normalized to hypoxanthine phosphoribosyl transferase (HPRT) expression. Means from a mixed model analysis were considered to differ when $P < 0.05$. Prepartum supplementation, calf sex, or their interaction did not afect BW at weaning (155 ± 11 kg at 180 ± 1.4 d). The expression of HPRT mRNA was not affected by supplementation, calf sex or their interaction. Although GHR, BP3 and IGF–I mRNA did not vary with supplementation, GHR expression tended ($P = 0.08$) to be greater and IGF–I mRNA was greater ($P = 0.04$) in female than male calves. There was an interaction ($P < 0.05$) between treatment and calf sex for IGF–I and BP3 mRNA, supplementation increased their expression only in females. Results suggest that prepartum supplementation during periods of limited forage availability of native pastures, through its effect in the fetal stage or the suckling period, could affect potential growth of female beef calves at weaning.

Key Words: liver, prepartum nutrition, RTP–CR

W148 Glucagon-like peptide 2 may mediate growth and development of the bovine gastrointestinal tract. E. E. Connor*[1], R. L. Baldwin[1], A. V. Capuco[1], C. M. Evock-Clover[1], S. E. Ellis[2], and K. S. Sciabica[3], [1]*USDA-ARS, BARC*, *Beltsville, MD*, [2]*Clemson University*, *Clemson, SC*, [3]*Beckman Coulter, Inc.*, *Brea, CA*.

Glucagon-like peptide 2 (GLP-2), secreted by enteroendocrine cells, promotes growth, reduces apoptosis, and enhances blood flow, nutrient absorption, and barrier function in intestinal epithelium of monogastric species. Regulatory functions of GLP-2 in the ruminant gastrointestinal tract (GIT) are unknown. Our objectives were to characterize expression of GLP-2 pathway members throughout bovine GIT including proglucagon (GCG) mRNA, the parent peptide from which GLP-2 is derived through cleavage by prohormone convertase (PCK1), PCK1 mRNA, GLP-2 receptor (GLP2R) mRNA, and mRNA for dipeptidyl peptidase IV (DPP4), the enzyme that inactivates GLP-2. Gene expression was evaluated in rumen, reticulum, omasum, abomasum, duodenum, jejunum, ileum, cecum, and rectum collected at slaughter from prepubertal heifers, mature cows in early, mid, and late lactation, and non-lactating cows (n = 3/stage) by a multiplex gene expression profiling assay based on traditional RT-PCR that uses a universal priming strategy. Further, mRNA expression of 14 genes involved in nutrient transport, enzyme activity, blood flow, apoptosis, and proliferation were evaluated in the 9 GIT tissues for association with GCG and GLP2R mRNA. Results indicated that mRNA expression of GCG, PCK1, GLP2R, and DPP4 varies across the 9 GIT tissues ($P < 0.001$), with greatest expression in intestines, and generally non-detectable levels in forestomachs. Expression of DPP4 and GLP2R mRNA varied by developmental stage or lactational state ($P < 0.05$) in intestinal tissues. Expression of GCG or GLP2R mRNA was correlated with markers of proliferation, apoptosis, blood flow, enzyme activity, and urea transport, depending on tissue type, supporting involvement of GLP-2 in these processes in ruminants. Lastly, GLP2R protein was localized to cells lining the intestinal crypts by immunohistochemistry, consistent with distribution in monogastric species. Our findings support a functional role of GLP-2 in bovine GIT and its potential use to improve intestinal function and nutrient absorption in ruminants.

Key Words: cattle, gene expression, GLP-2

W149 Effects of maternal metabolizable protein supply on fetal organ weights. T. L. Neville*[1], L. A. Lekatz[1], T. J. Swanson[1], M. L. Van Emon[2], C. S. Schauer[2], K. R. Maddock Carlin[1], C. J. Hammer[1], and K. A. Vonnahme[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University*, *Fargo,* [2]*Hettinger Research Extension Center, North Dakota State University*, *Hettinger*.

Objectives were to investigate the effects of maternal MP supply during gestation on fetal target organ weights. Multiparous ewes (n = 45; 15/treatment) were fed an isocaloric and isonitrogenous diet that contained either 75% (LOW), 100% (MOD), or 125% (HIGH) of MP requirements from d 100 to 130 of gestation. At d 130 ewes were harvested and fetuses dissected. Ewes carried singletons and twins, therefore fetal number was included in the model. Fetal weight, curved crown rump, heart girth, eviscerated BW, brain, and several target tissues were not affected by maternal MP supply during gestation ($P \leq 0.06$). Fetal right ventricles (mm) from LOW ewes were thicker ($P = 0.05$) than MOD ewes with those from HIGH ewes being intermediate. Fetuses from HIGH and LOW ewes had thicker ($P = 0.01$) right ventricles than MOD ewes (0.095, 0.098, and 0.082 ± 0.004 mm/g brain weight for HIGH, LOW and MOD respectively). Fetuses from LOW ewes had lighter ($P = 0.01$) ovaries (g/g brain weight) than MOD and HIGH ewes. Singleton lambs from LOW ewes had lighter ($P = 0.02$) adrenal glands than singleton lambs from MOD ewes and twins from LOW ewes with all other lambs being intermediate. Total gastrointestinal tract was heavier ($P \leq 0.03$) in twin lambs from LOW ewes compared with singleton lambs from LOW and twins from HIGH ewes with all other lambs being intermediate. These data indicate maternal dietary MP during the last trimester impacts fetal organ growth near term.

Key Words: fetal lambs, metabolizable protein, organ weights

W150 Nutrient restriction from early to mid-gestation in the cow increases offspring adipocyte size at slaughter. C. B. Tousley[1], N. M. Long*[1,2], S. P. Ford[1,2], W. J. Means[2], B. W. Hess[2], and M. Du[2], [1]*Center for the Study of Fetal Programming*, *University of Wyoming, Laramie,* [2]*Depertment of Animal Science, University of Wyoming*, *Laramie*.

Multiparous Angus × Gelbvieh cows were used to evaluate effects of nutrient restriction on adipose tissue morphology of beef steers and heifers at standard production endpoints. At 45 d after AI from a single sire, pregnancy was confirmed, and cows (n = 8 per treatment) were allotted randomly to be individually fed a control diet (C,100% of NRC recommendations), nutrient restricted (NR,70% of C NEm), or NR + protein supplement (NRP,NR + protein to equal C metabolizable AA). At 185 d of gestation (dG), all cows were comingled and fed the C diet. Bull calves were castrated at birth and all calves weaned at 210 d of age, backgrounded for 28 d, and then placed in the feedlot. Steers and heifers were harvested on separate days at an average 12th rib fat thickness of 7.6 mm. Selected organ weights and carcass characteristics were determined. Adipose tissue from selected depots was collected and fixed in paraffin and adipocyte diameters determined by image analysis. There was no difference ($P < 0.23$) in BW or BCS between C, NRP, and NR cows at 45 dG, which averaged 489.74 ± 17.7 kg and 5.35 ± 0.13, respectively. At 185 dG, C and NRP cows had similar BW (566.1 ± 14.8 and 550.2 ± 14.8) and BCS (6.34 ± 0.27 and 5.59 ± 0.27), but BW (517.9 ± 14.8) and BCS (4.81 ± 0.27) of NR cows were less ($P < 0.05$). There were no treatment differences ($P < 0.26$) in live BW, carcass characteristics or organ weights of steers and heifers at slaughter. In contrast, average adipocyte diameters of NR offspring increased or tended to increase (Table 1) in finished steers and heifers, which could contribute to altered adiposity and metabolism in later life.

Table 1. Average adipocyte diameter (um) from selected depots of offspring (4 steers and 4 heifers per treatment) at slaughter

	Control	NRP	NR
Subcutaneous	74.5 ± 2.6[a,]	81.6 ± 2.5[ab]	86.9 ± 2.7[b]
Perirenal	113.5 ± 3.5[c]	115.6 ± 3.5[c]	124.69 ± 3.8[d]
Mesenteric	113.03 ± 3.8C[a]	121.37 ± 3.5[ab]	129.28± 3.5[b]
Omental	117.2 ± 4.5[a]	114.4 ± 4.2[a]	129.6 ± 4.3[b]

[a,b]Means differ $P \leq 0.05$; [c,d]Means differ $P < 0.10$.

Key Words: prenatal programming, adipocyte size, cows

W151 Two messenger RNA targets, Programmed Cell Death Protein 4 and Phosphatase and Tensin Homolog, of microRNA-21 are expressed in cultured bovine adipocytes. S. L. Pratt*, T. A. Burns, and S. K. Duckett, *Clemson University*, *Clemson, SC*.

Adipogenesis is regulated in part by post-transcriptional gene regulation through small non-coding inhibitory RNA, microRNA (miRNA), via translational repression or RNA interference. We have shown miR-21 expression to increase in adipocytes compared with preadipocytes as differentiation progresses, and this miRNA is known to promote cell survival and hypertrophic growth, in part, by the translational inhibition of Programmed Cell Death Protein 4 (PDCD4) and Phosphatase and Tensin Homolog (PTEN). Neither the protein nor message for PDCD4 or PTEN has been reported to be expressed in, or involved in adipogenesis/adipocyte function. Our objective was to detect and quantify the mRNA for bovine PDCD4 and PTEN in primary bovine cell cultures. Bovine preadipocyte cell lines generated from subcutaneous adipose tissue obtained from 18 mo old Angus steers were cultured to confluence and held 2 d in Dulbecco's modified eagles medium (DMEM) containing 10% fetal calf serum (FCS), and 2X antibiotiotic/antimycotic (AB/AM). Cells were differentiated using a 2- step process by culture for 2-d in DMEM containing 5% FCS, 2X AB/AM, insulin at 2.5 ug/ml, 0.25 uM dexamethasone, 5 uM troglitasone and 0.5 mM isobutylmethylxanthine (IBMX) for 2-d followed by a 4-d or 10-d incubation in DMEM containing 5% FCS, 2X AB/AM, insulin, and troglitasone. tcRNA was isolated for each cell line at 2-d confluence (Control), and after 2-d (D2), 4-d (D6) and 10-d (D12) of differentiation. tcRNA was used in real time qRT-PCR to determine expression levels for the respective message for bovine PTEN and PDCD4. Expression levels for PTEN and PDCD4 across all days ranged from −0.8- to 1.0-fold compared with Control ($P > 0.05$). In contrast, miR-21 was previously shown to be upregulated during the same stages of adipogenesis. We hypothesize that miR-21 downregulates the proteins PDCD4 and PTEN by translational inhibition during adipogenesis allowing cells to survive and undergo hypertrophic growth required for lipid filling.

Key Words: miRNA, adipogenesis, qRT-PCR

W152 MicroRNA-21 and its messenger RNA targets Programmed Cell Death Protein 4 and Phosphatase and Tensin Homolog are expressed in bovine adipose tissue. S. L. Pratt*, E. Curry, T. A. Burns, and S. K. Duckett, *Clemson University*, *Clemson, SC*.

MicroRNA (miRNA) are small non-coding RNA that regulate adipocyte function, both in vivo and in vitro by translational repression or RNA interference of targeted messenger RNA. miR-21 expression increases in adipocytes compared with preadipocytes, and this miRNA promotes cell survival and hypertrophic growth, in part, by the translational inhibition of Programmed Cell Death Protein 4 (PDCD4) and Phosphatase and Tensin Homolog (PTEN). Neither PDCD4 nor PTEN has been reported to be expressed in, or involved in adipocyte function. Our objectives were to detect and quantify 1) miR-21 and 2) PDCD4 and PTEN in adipose tissue isolated from Angus steers (289 kg) finished on pasture only (PA; n = 6) or on a high-concentrate diet (C; 85% concentrate/15% roughage; n = 7). Fat samples (s.c.; 5 g per sample) were removed from the tail head area of each carcass at slaughter, rinsed with sterile saline, frozen in liquid nitrogen and stored at −80°C. Protein extracts were subjected to SDS-PAGE, Western blotting and immunodetection with PTEN and PDCD4 antisera. tcRNA was used in real time qRT-PCR to determine expression levels for miR-21, PTEN, and PDCD4. Western blotting and immunodetection with antisera to PTEN and PDCD4 detected proteins ~50 and 60 kDa, respectively. Message levels for PTEN and PDCD4 increased 3.2- and 6.7-fold, respectively in PA compared with C treatment ($P < 0.05$); in contrast miR-21 expression was repressed in PA compared with C ($P < 0.05$). These data show that miR-21, PTEN and PDCD4 are expressed in bovine adipose tissue. Message level for PTEN and PDCD4 in mature adipose tissue may be regulated at the transcriptional level, and low levels of concentrate in the diet may increase the PTEN and PDCD4 message under chronic conditions which would stimulate increased adipocyte cell mortality and turnover. PTEN and PDCD4 protein expression may be increased due to increased message levels and to the decrease in miR-21 expression which negatively regulates the translation of both messages.

Key Words: miRNA, adipose tissue, qRT-PCR

W153 Both growth hormone and signal transducer and activator of transcription 5b inhibit glycerol-3-phosphate dehydrogenase activity and CCAAT/enhancer binding protein α mRNA expression in differentiating bovine preadipocytes. L. Zhao*, B. A. Corl, and H. Jiang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

It has been long known that growth hormone (GH) inhibits adipogenesis in various animals, including cattle. However, the underlying mechanism remains poorly understood. The objective of this study was to determine if GH inhibits bovine adipogenesis by activating the signal transducer and activator of transcription 5b (STAT5b), a transcription factor known to be activated by GH in many tissues including the adipose tissue. Two studies were conducted to achieve this objective. In one study, preadipocytes from adipose tissue explants of cattle were induced to differentiate in the presence or absence of 10 ng/mL GH and 100 ng/mL GH for 6 d before differentiation assessment. In the other study, the preadipocytes were induced to differentiate in the presence of 10 or 100 multiplicities of infectivity (MOI) of adenovirus expressing constitutively active STAT5b (STAT5bCA) or β-galactosidase (LacZ) as a control for 6 d before differentiation assessment. Differentiation was assessed by measuring glycerol-3-phosphate dehydrogenase (G3PDH) activity, and mRNA expression of CCAAT/enhancer binding protein α (CEBPα), peroxisome proliferator-activated receptor γ (PPARγ), and fatty acid binding protein 4 (FABP4). Both concentrations of GH inhibited G3PDH activity ($P < 0.05$, n = 5) and decreased mRNA expression of CEBPα compared with the no-GH control ($P < 0.05$, n = 5). Neither GH concentration altered mRNA expression of PPARγ or FABP4 compared with the no-GH control. The STAT5bCA adenovirus at 100 MOI inhibited the G3PDH activity ($P < 0.05$, n = 4) and decreased mRNA expression of CEBPα compared with the LacZ adenovirus or the no-adenovirus control ($P < 0.05$, n = 4). The STAT5bCA adenovirus did not change mRNA expression of PPARγ or FABP4. In summary, both GH and STAT5bCA overexpression inhibited G3PDH activity and CEBPα mRNA expression in differentiating bovine preadipocytes.

Key Words: growth hormone, STAT5b, bovine preadipocyte

W154 Primary preadipocytes can be isolated, propagated, and differentiated from bovine intermusclar fat harvested 48 h postmortem. T. A. Burns*, S. K. Duckett, and S. L. Pratt, *Clemson University*, *Clemson, SC*.

Traditionally, primary cell cultures are isolated from tissues collected at slaughter using collagenase digestion or tissue explantation methods. Although we have previously been successful isolating and differentiating bovine preadipocytes from slaughtered cattle, the abattoir is not a conducive environment for aseptic tissue collection. Therefore, the objective of this study was to isolate, propagate, and successfully differentiate bovine preadipocytes collected from refrigerated rib sections 48 h postmortem. Sections of intermuscular fat were excised and minced using sterile instruments, rinsed with Hanks' Balanced Salt Solution (HBSS), and digested in 25 mL HBSS containing 2 mg/mL collagenase, type I, and 40 mg/mL bovine serum albumin under constant shaking at 37°C for 120 min. Cells were plated at 1×10^4 cells/cm^2, passaged every 2–4 d when 60% confluent, and were frozen after 4 passages. To test a cell line's ability to differentiate, cells were thawed, passaged 3 times, and seeded in wells at 1×10^5 cells/cm^2. Cells were allowed to reach confluence, held for 2 d, and differentiated on d 0 with Dulbecco's modified eagles medium containing 10% fetal calf serum, 2X antibiotic/antimycotic, insulin at 2.5 μg/mL, 0.25 μ*M* dexamethasone, 20 μ*M* troglitasone, 0.5 m*M* isobutylmethylxanthine, and 10 m*M* acetate. Undifferentiated cells were harvested on d 2 (CON) and treated cells were harvested on d 2 (D2), 6 (D6), and 12 (D12) for fatty acids and RNA. Gross morphology of differentiating cells displayed characteristic shape change from fibroblastic to spherical. Using GLM procedure of SAS, duplicate fatty acid data were analyzed across 3 cell lines by time. Total fatty acids were not different between CON and D2, but increased ($P < 0.05$) on D6 and D12 compared with CON. On a percentage basis, C16:0, C18:0, and C18:2 decreased ($P < 0.05$) and C18:1c9 increased ($P < 0.05$) by D12. In addition, differentiation-associated genes were increased ($P < 0.05$) in treated cells. This evidence suggests that cells harvested 48 h postmortem are capable of propagating and differentiating for use in in vitro studies.

Key Words: preadipocyte, isolation, differentiation

W155 *Trans*-10, *cis*-12 conjugated linoleic acid induces adipogenic gene expression in single and co-cultures of bovine preadipocytes and myoblasts. S. H. Choi*[1], K. Y. Chung[2], G. Go[1], C. W. Choi[3], B. J. Johnson[2], and S. B. Smith[1], [1]*Department of Animal Science, Texas A&M University*, *College Station,* [2]*Department of Animal and Food Science, Texas Tech University*, *Lubbock,* [3]*National Institute of Animal Science*, *Suwon, Gyunggi, Korea*.

A limited number of studies have investigated the differentiation of bovine adipocytes and myoblasts in single cultures, and there is even less information about the interaction between adipocytes and myoblastic cells in a coculture system. We hypothesized that preadipocyte differentiation would be depressed by differentiating myoblasts, where preadipocytes would promote adipogenic gene expression in myoblasts in a coculture system. We also determined the effects of arginine, a biological precursor of nitric oxide, and/or *trans*-10, *cis*-12 conjugated linoleic acid (CLA) on adipogenic gene expression of bovine preadipocytes and myoblasts. Muscle-derived satellite cells and preadipocyte were isolated from 14-mo old crossbred steers. Both bovine satellite (BSC) and preadipocytes (PA) cells were cultured with 10% FBS/DMEM and 1% antibiotics during the proliferation period (3 d). After proliferation, BSC and PA were treated with 3% of horse serum (HS) DMEM and 5% FBS/DMEM with antibiotics respectively, for 4 d. Finally, single or combined BSC and PA were cultured with 40 μ*M* *trans*-10, *cis*-12 CLA and/or 5 m*M* arginine for 2 h. Cocultured PA had significantly less AMPK ($P = 0.04$) and SCD ($P = 0.04$) gene expressive than single-cultured PA. Arginine stimulated, and CLA depressed SCD gene expression. Arginine significantly stimulated PPARγ gene expression ($P = 0.06$) in cocultured PA compared with other treatments. SCD gene expression was significantly increased by arginine in both single- ($P < 0.001$) and cocultured ($P < 0.01$) PA. Conversely, C/EBP-β gene expression was significantly enhanced by coculture in BSC in the absence or presence of arginine or CLA. PPARγ gene expression tended to be increased by coculture in BSC. We conclude that arginine and CLA had similar effects in single and cocultured PA and BSC, but the effects were stronger in cocultured cells.

Key Words: co-culture, preadipocytes, satellite cells

W156 Growth hormone stimulates liver expression of fibroblast growth factor 21 mRNA in cattle. J. Yu*[1,2], A. Wang[2], S. Eleswarapu[2], and H. Jiang[2], [1]*Sichuan Agricultural University*, *Yaan, Sichuan, China*, [2]*Virginia Polytechnic Institute and State University*, *Blacksburg*.

Fibroblast growth factor 21 (FGF21) is a novel endocrine regulator of glucose homeostasis, lipid metabolism, insulin sensitivity, and obesity. In addition, FGF21 is known to inhibit growth hormone (GH)-induced signaling through the signal transducer and activator of transcription 5 (STAT5). In the body, FGF21 mRNA is expressed predominantly in the liver. In this study, we tested the hypothesis that FGF21 expression in the liver is induced by GH. Nonlactating and nonpregnant cows were injected subcutaneously with 500 mg of recombinant bovine GH in a slow-release formula. Liver biopsy and blood samples were collected from each cow one week before and 24 h after the injection. Liver FGF21 mRNA abundance after GH injection was 21 times that before the injection ($P < 0.05$, n = 5), as measured by real-time RT-PCR. The GH injection tended to increase serum concentration of FGF21 ($P = 0.09$, n = 5), as measured by an enzyme-linked immunosorbent assay. The bovine FGF21 gene promoter contains 3 putative STAT5 binding sites. Electrophoretic mobility shift assays showed that all of them could bind to the STAT5 protein from bovine liver. Chromatin immunoprecipitation assays demonstrated that GH injection stimulated binding of STAT5 to the FGF21 promoter in the liver ($P < 0.05$, n = 4). Co-transfection analyses indicated that reporter gene expression from the bovine FGF21 promoter could be induced by GH in a STAT5-dependent manner. Taken together, these data suggest that GH stimulates expression of FGF21 mRNA in cattle and that the stimulation may be mediated by the transcription factor STAT5.

Key Words: growth hormone, fibroblast growth factor 21, STAT5

W157 Abundance of growth hormone secreteagogue receptor and PPARy2 in longissimus dorsi of beef cattle. C. L. Delvaux*, J. S. Jennings, and A. E. Wertz-Lutz, *South Dakota State University*, *Brookings*.

Objectives of this experiment were to determine the presence and abundance of growth hormone secreteagogue receptor (GHS-R) and PPARy2 in longissimus dorsi of beef cattle fed to achieve differences in composition of gain. Beef steers (n = 72) of similar age, weight (292 ± 1.44 kg), and genetic background were used. At trial initiation (d 0), 8 steers were harvested. The remaining 64 steers were allotted, by weight, to pen, and treatment was assigned randomly. Treatments were 1) 60% forage; 40% concentrate diet fed during the growing period (0–112 d) followed by 10% forage; 90% concentrate diet during the finishing period (113–209 d) (GRW-FNSH) or 2) 10% forage; 90% concentrate

diet fed for the duration of the experiment (0–209 d) (FNSH-FNSH). Steers were allowed ad libitum consumption regardless of dietary treatment. Eight steers per treatment were harvested on d 88, 116, 165, and 209. Tissue samples from the longissimus dorsi were collected 48 h subsequent to harvest and frozen. Protein separation and quantification was determined using SDS-PAGE and Western blotting techniques. Abundance of GHS-R and PPARy2 was quantified using the LI-COR system and standardized to β-Actin. Protein abundance data were analyzed statistically using the MIXED procedure of SAS evaluating diet, age at harvest, and their interaction. Differences in composition of gain have been reported previously. Abundance of GHS-R differed ($P < 0.001$) as a result of age at harvest, and dietary treatment tended ($P = 0.11$) to influence GHS-R abundance. Differences in GHS-R abundance relative to age at harvest, and potentially as a result of differential growth, warrants further investigation. The PPARy2 was not sufficiently abundant in longissimus dorsi and could not be quantified. The PPARy2 is exclusively associated with adipose tissue, and therefore not expected to be abundant in longissimus dorsi tissue. Degradation of PPARy2 also may have occurred as samples were not collected until 48 h postmortem.

Key Words: growth hormone secreteagogue receptor, PPARy2, longissimus dorsi

W158 Effect of estradiol-17β on protein synthesis and degradation rates in fused bovine satellite cell cultures. E. Kamanga-Sollo, M. E. White*, M. R. Hathaway, W. J. Weber, and W. R. Dayton, *University of Minnesota*, *St. Paul*.

Although androgenic and estrogenic steroids are widely used to enhance muscle growth and increase feed efficiency in feedlot cattle, their mechanism of action is not well understood. While in vivo studies indicate that Estradiol-17β (E2) affects muscle protein synthesis and/or degradation, in vitro results are inconsistent. We have examined the effects of E2 treatment on protein synthesis and degradation rates in fused bovine satellite cell (BSC) cultures. Additionally, to learn more about the mechanisms involved in E2-enhanced muscle growth, we have examined the effects of compounds that interfere with binding of E2 or IGF-I to their respective receptors on E2-induced alterations in protein synthesis and degradation rates in BSC cultures. Treatment of fused BSC cultures with E2 results in a concentration-dependent increase ($P < 0.05$) in protein synthesis rate and a decrease ($P < 0.05$) in protein degradation rate. The pure estrogen antagonist ICI 182 780 suppresses ($P < 0.05$) E2 -induced alterations in protein synthesis and degradation in fused BSC cultures. The G-protein coupled receptor (GPR)-30 agonist, G1, does not affect either synthesis or degradation rate establishing that GPR30 does not play a role in E2-induced alterations in protein synthesis or degradation. JB1, a competitive inhibitor of IGF-I binding to the Type 1 insulin-like growth factor receptor (IGFR-1), suppresses ($P < 0.05$) E2-induced alterations in protein synthesis and degradation. In summary our data show that E2 treatment directly alters both protein synthesis and degradation rates in fused BSC cultures via mechanisms involving both the classical ER and IGFR-1.

Key Words: estradiol-17β, satellite cells, protein turnover

W159 Effect of trenbolone acetate on protein synthesis and degradation rates in fused bovine satellite cell cultures. E. Kamanga-Sollo, M. E. White*, M. R. Hathaway, W. J. Weber, and W. R. Dayton, *University of Minnesota*, *St. Paul*.

Although androgenic and estrogenic steroids are widely used to enhance muscle growth and increase feed efficiency in feedlot cattle, their mechanism of action is not well understood. While in vivo studies have indicated that androgens affect protein synthesis and/or protein degradation rate in muscle, results from in vitro studies have been inconsistent. Consequently, we have examined the effects of trenbolone acetate (TBA), a synthetic androgen, on protein synthesis and protein degradation rates in fused bovine satellite cell (BSC) cultures. Additionally, we have examined the effects of compounds that interfere with binding of TBA or insulin-like growth factor (IGF)-I to their respective receptors on TBA-induced alterations in protein synthesis and protein degradation rates in BSC cultures. Treatment of fused BSC cultures with TBA results in a concentration-dependent increase ($P < 0.05$) in protein synthesis rate and a decrease ($P < 0.05$) in protein degradation rate, establishing that TBA has a direct effect these parameters. Flutamide, a compound that prevents androgen binding to the androgen receptor, suppresses ($P < 0.05$) TBA -induced alterations in protein synthesis and degradation in fused BSC cultures, indicating the androgen receptor is involved. JB1, a competitive inhibitor of IGF-I binding to the Type 1 IGF receptor (IGFR-1), suppresses ($P < 0.05$) TBA-induced alterations in protein synthesis and degradation indicating that this receptor also is involved in the actions of TBA on both synthesis and degradation. In summary our data show that TBA acts directly to alter both protein synthesis and degradation rates in fused BSC cultures via mechanisms involving both the androgen receptor and IGFR-1.

Key Words: trenbolone acetate, satellite cells, protein turnover

W160 Zilpaterol HCl enhances adenosine monophosphate-activated protein kinase α (AMPKα) expression in bovine skeletal muscle. R. J. Tokach*, K. Y. Chung, and B. J. Johnson, *Texas Tech University*, *Lubbock*.

Zilpaterol HCl (ZH), a β-2 adrenergic agonist, has been used for enhancing muscle growth in feedlot cattle. The aim of these in vivo and in vitro experiments was to determine the effect of ZH on changes in enzymes and growth factors important in skeletal muscle growth. We hypothesized that AMPKα expression increased in animals or cells treated with ZH. Thirteen month old calf-fed Holstein steers implanted with an estrogen-based implant were used in randomized complete block design with a 2 × 2 factorial arrangement of treatments. Main effects included; ZH 0 or 20 d before slaughter and either a 3-d or 10-d withdrawal period (WD). Semimembranosus muscle (SM) was collected within 10 min of harvest for analysis of AMPKα and IGF-I protein and mRNA abundance. Western blot analysis revealed that the protein content of AMPKα in muscle from ZH-treated cattle with a 3-d withdrawal increased ($P < 0.05$) as compared with the control group. There was no significant difference of AMPKα in muscle from the ZH-treated cattle with a 3-d withdrawal as compared with the ZH-treated cattle with a 10-d withdrawal. Real-time quantitative PCR was used to measure the relative level of mRNA. The mRNA for AMPKα tended to increase in muscle from ZH-treated cattle with a 3-d withdrawal ($P = 0.12$) as compared with the control group. Withdrawal time resulted in a decrease in IGF-I mRNA. Primary cultures of bovine satellite cells (BSC) isolated from the SM were harvested after 120 h of either ZH, ZH antagonist (ICI-118,551), or ZH plus ICI-118,551 exposure for AMPKα and IGF-I protein and mRNA analysis. AMPKα abundance increased in BSC treated with ZH as compared with the control, ICI-118,551, and ZH plus ICI-118,551 treated BSC. IGF-I mRNA relative units (3.7 ± 0.6) increased in BSC treated with ZH as compared with the control (0.8 ± 0.4) and the addition of ICI-118,551 (0.9 ± 0.2) ameliorated these changes ($P < 0.05$). These data indicate that ZH alters mRNA and protein concentrations of AMPKα in SM, and these effects may be mediated through the β 2 adrenergic receptor.

Key Words: AMPKα, bovine satellite cells, zilpaterol hydrochloride

W161 Steroidal implants and zilpaterol HCl alter serum urea-N and NEFA responses in finishing beef steers. S. L. Parr*[1], M. L. Galyean[1], K. Y. Chung[1], J. P. Hutcheson[2], and B. J. Johnson[1], [1]*Texas Tech University*, *Lubbock,* [2]*Intervet / Schering-Plough Animal Health*, *De Soto, KS*.

British × Continental steers (n = 168; 7 pens/treatment; initial BW = 362 kg) were used to evaluate the effect of dose of trenbolone acetate (TBA) and estradiol-17β (E_2) and feeding of zilpaterol hydrochloride (ZH) on serum urea-N (SUN) and NEFA concentrations. A randomized complete block design was used with a 3 × 2 factorial arrangement of treatments. Main effects were implant (no implant [NI]; Revalor-S [REV-S; 120 mg TBA + 24 mg E_2]; and Revalor-XS [REV-X; 200 mg TBA + 40 mg E_2]) and ZH (0 or 8.3 mg/kg of DM for 20 d with a 3-d withdrawal before harvest). Blood was drawn from 2 steers per pen (n = 84/d) on d −1, 2, 6, 13, 27, 55, 83, 111, and 131 relative to implanting and d −1, 11, and 19 relative to ZH supplementation. Steers were fed for 153 or 174 d depending on block. Overall ADG (1.4, 1.7, and 1.8 kg for NI, REV-S and REV-X, respectively) and G:F (0.16, 0.18 and 0.19) were increased ($P < 0.05$) as TBA and E_2 dose increased. Carcass-adjusted ADG (1.5 vs. 1.7 kg for 0 and 8.3 mg/kg ZH respectively) and G:F (0.17 vs. 0.19) were increased ($P < 0.05$) by ZH. Serum urea-N increased ($P < 0.05$) over time (no implant × day interaction, $P = 0.16$). Implanting decreased ($P < 0.05$) SUN from d 2 through d 131 and SUN tended ($P = 0.08$) to be less for REV-S than REV-X at d 13 but was otherwise not different among implants. Feeding ZH decreased ($P < 0.05$) SUN. Serum NEFA concentrations were not affected by implants ($P = 0.44$). There was a day × ZH interaction ($P = 0.06$) for NEFA; steers not fed ZH had similar ($P > 0.10$) NEFA concentrations on d −1, 11, and 19, whereas ZH steers had increased ($P < 0.01$) NEFA concentrations at d 11 of ZH feeding. We conclude that implanting decreased SUN but a greater dose of TBA and E_2 did not result in further changes in SUN. Moreover, feeding ZH affected steer metabolism by decreasing SUN and increasing serum NEFA. These metabolic responses during ZH may aid in explaining steer performance and carcass responses to ZH.

Key Words: beef steers, estradiol-17β, zilpaterol hydrochloride

W162 Canonical relationships of body shape of grazing bulls under tropical conditions. H. J. Fernandes*[1], L. O. Tedeschi[3], M. F. Paulino[2], M. O. Porto[2], and L. M. Paiva[1], [1]*State University of Mato Grosso do Sul*, *Aquidauana, Brazil*, [2]*Federal University of Viçosa*, *Viçosa, MG, Brazil*, [3]*Texas A&M University*, *College Station*.

The objective of this study was to analyze and compare the changes of body shape, using body measurements (BM) of Nellore crossbred bulls (n = 20) under grazing conditions using canonical equations. Animals were grazing *Brachiaria decumbens* Stapf and received either mineral (control; C) or 3 concentrate supplementation programs (different protein patterns). Animals in the programs T1, T2, and T3 received 1.2 kg of a concentrate containing 32, 25, and 9% of CP during the nursing phase, 1.5 kg of isonitrogenous concentrate (35% CP) with 8, 4, and 0% of urea during the dry season, and 2.0 kg of isonitrogenous concentrate (27% CP) with 6, 3, and 0% of urea during the rainy season; respectively. The BM were taken every 28 d and included hooks width, pins width, pelvic girdle length, rump height, abdomen width, body length, height at withers, and rib depth. The first and the second canonical variables for each phase and for the entire experimental period was developed using all BM. The most important BM to explain the differences in animal′s body shape were rump height, height at withers, pins width, and rib depth for the nursing phase; rib depth, body length, abdomen width, and pelvic girdle length for the dry season; rump height, body length, abdomen width, and hooks width for the rainy season; and rib depth, pins width, rump height, and height at withers for the complete experimental period. Dietary supplementation did not affect the animal′s body shape in the nursing phase. Animals in the C program had heavier hindquarter during the dry season, and during the rainy season they were higher, longer, and wider than animals receiving concentrate supplementations. The animals in the T1 program tended to be higher and longer than animals in the other supplementation programs (T2 and T3). The results of the complete experimental period indicated animals in the C program tended to be shorter and wider, suggesting animals with smaller mature size likely due to malnutrition. Further studies should evaluate the relationship between body shapes and variations in body composition of the animals.

Key Words: biometrics, cattle, growth

W163 Comparison of mathematical functions to describe the growth of grazing bulls in tropical conditions. H. J. Fernandes*[1], L. O. Tedeschi[2], M. F. Paulino[3], A. G. Silva[3], and L. M. Paiva[1], [1]*State University of Mato Grosso do Sul*, *Aquidauana, Brazil*, [2]*Texas A&M University*, *College Station*, [3]*Federal University of Viçosa*, *Viçosa, MG, Brazil*.

The availability of forage throughout the year is not constant and it can change the pattern of growth of grazing animals. The goal of this study was to evaluate different mathematical functions to characterize the growth of grazing Nellore crossbred bulls (n = 20) under tropical conditions. The animals had initial and final BW of 129 ± 28.1 and 405 ± 62.0 kg, initial age of 130 ± 30 d, and grazed *Brachiaria decumbens* Stapf during 420 d. BW was recorded every 28 d. Five mathematical functions (multiphase, linear, logarithmic, Gompertz, and Logistic) were used to describe the BW of the bulls. The multiphasic equation used 3 phases: 2 linear phases in which the difference was the ADG and a third phase represented by a Logistic model. The time points (thresholds) between these phases were assumed to be parameters of the function. The assessment of the adequacy of the mathematical functions was performed using the coefficient of determination, the simultaneous *F*-test of identity of the parameters, the concordance correlation coefficient, and the square root of the mean square error of prediction (MSEP). The analysis of the paired MSEP and the difference of Akaike′s Information Criterion (AIC) between mathematical functions were used to compare accuracy and precision of the functions. Adequacy of the mathematical functions (Table 1), the paired MSEP and the difference of AIC indicated the multiphasic function was more accurate and precise than the other functions in describing the growth of grazing beef cattle in tropical conditions. This was likely because of the effect of the dry season on the growth pattern of the animals. Other multiphasic functions should be evaluated to define the most appropriate equation for each production condition.

Table 1. Adequacy statistics of the functions[1]

Functions	r^2	P- value	CCC	RMSEP
Multiphase	0.993	0.617	0.996	6.83
Linear	0.961	0.678	0.980	16.1
Gompertz	0.916	< 0.001	0.945	25.0
Logarithmic	0.902	< 0.001	0.936	26.7
Logistic	0.861	< 0.001	0.886	34.0

[1]r^2 = coefficient of determination, *P* – value = probability of the *F*-test for intercept equal to zero and slope equal to one, CCC = concordance correlation coefficient, RMSEP = square root of the MSEP.

Key Words: beef cattle, grazing, seasonality

W164 Expression of specific genes regulating mammary growth in pre-pubertal Holstein heifers. F. Soberon*, M. J. Meyer, and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

In a previous study, we demonstrated that calves fed greater nutrients from milk replacer from birth to 100 kg BW had significantly increased mammary epithelial cell proliferation compared with calves fed a more restricted diet. Additional work has demonstrated the presence of a putative stem cell population that has been considered nutritionally responsive and might account for the observed cell proliferation. One objective of this study was to identify genetic markers of stem cells associated with the proliferation. Further, changes in mammary growth rate occur from birth to puberty, such as the change from allometric to isometric growth during the peri-pubertal period. The second objective of this study was to evaluate genes that might be responsible for signaling this change in mammary growth from an allometric to an isometric rate. Heifers (n = 66) reared on one of 2 dietary treatments (TRT), restricted (R) 650 g/d or elevated 950 g/d gain, were harvested at 100, 150, 200, 250, 300, or 350 kg BW. Mammary samples (n = 5 to 8) were excised from the mid parenchyma tissue (MPT) and extra parenchyma tissue (EPT), snap frozen and stored at −80°C. Gene expression in mammary tissue was determined by RT-PCR. Data were analyzed using a mixed model with 18S RNA as a covariate. Telomerase transcriptase was used as a marker for stem cells. Further SERPINB5 (maspin) was analyzed as a marker of myoepithelial cell development and a possible signal for changes in growth rate of the mammary gland. Telomerase expression in EPT was lowest ($P < 0.05$) at 100 kg BW for both treatments and tended ($P < 0.1$) to decrease in R at 350 kg BW. Telomerase expression did not differ between TRT in MPT but was lower at 100 and 150 kg BW ($P < 0.05$). Expression of SERPINB5 was significantly increased in EPT at 250 kg BW for both TRT whereas SERPINB5 expression in MPT remained constant among all weight groups. We suggest that SERPINB5 signals the end of allometric growth by arresting the effect of estrogen in the cells extending into the fat pad, but has no effect on the developed parenchymal tissue.

Key Words: mammary growth, calves, serpinb5

W165 Effects of meal timing on anabolic hormone status and energy metabolism in neonatal Holstein calves. K. C. Simon, C. C. Williams*, L. R. Gentry, B. F. Jenny, R. M. Doescher, and A. H. Dolejsiova, *LSU AgCenter*, *Baton Rouge, LA*.

A study was conducted to determine effects of feeding time on metabolic hormone secretion, growth, and energy metabolism in neonatal dairy calves. Twelve Holstein bull calves were randomly assigned to 1 of 2 dietary treatments which included milk replacer fed at a fixed meal time (REG) or a varied meal time (IRR). Body weights were measured every 2 wk from birth to 8 weeks. Serial blood collections were conducted biweekly from wk 2 through 8 at 0530, at 0, 15, 30, 45, 60, 75, 90, 105, 120, 135, and 150 min relative to regularly scheduled feeding time. Plasma was analyzed for ghrelin, leptin, growth hormone (GH), and insulin-like growth factor-1 (IGF-1). Rumen fluid was collected biweekly from wk 2 through 8 for analysis of volatile fatty acids (VFA) and pH. Treatment did not affect ($P > 0.10$) body weight or average daily intake. Mean plasma ghrelin, leptin, GH, and IGF-1 concentrations were not affected ($P > 0.10$) by treatment. A treatment by week interaction was observed ($P < 0.05$) for total plasma ghrelin concentrations, with total plasma ghrelin concentrations higher at wk 2 and 4 in REG calves. Total plasma ghrelin concentrations decreased ($P < 0.05$) in all calves as they aged. A treatment by time interaction was observed ($P < 0.10$) for IGF-1, and a treatment by week by time interaction was observed ($P < 0.10$) for GH and IGF-1. Growth hormone decreased as calves aged, while IGF-1 increased. There was no treatment effect ($P > 0.10$) on rumen VFA concentrations, but acetate, propionate, and butyrate increased ($P < 0.05$) with age. No treatment effect was observed ($P > 0.10$) on rumen pH. At wk 4 and 8, intravenous glucose tolerance tests were performed to assess glucose half life ($T_{1/2}$), glucose clearance rate (k), and insulin concentrations. REG calves had greater ($P < 0.05$) $T_{1/2}$ and lower ($P < 0.05$) k. Peak insulin concentrations were higher ($P < 0.05$) for REG calves. These data suggest that feeding time does not affect overall growth and feed intake but does have an effect on some of the regulatory mechanisms that control them.

Key Words: dairy calves, feeding times, energy metabolism

W166 Effect of supplementing fatty acids to prepartum Holstein cows and milk replacer enriched with linoleic acid on calf performance. M. Garcia*, L. F. Greco, M. G. Favoreto, R. S. Marsola, L. T. Martins, D. Wang, W. W. Thatcher, J. E. P. Santos, and C. R. Staples, *University of Florida*, *Gainesville*.

The aim of this study was to evaluate supplementing linoleic acid (LA) to cows during the last 2 mo of pregnancy and their calves from birth to 60 d of age on calf performance. Cows (n = 96) were fed diets formulated to supply minimum amounts of LA and supplemented without fat, with saturated fatty acids (SFA; Energy Booster 100, MSC) at 1.75% of dietary DM, or with Ca salts of unsaturated fatty acids enriched in LA (UFA; Megalac-R, Church and Dwight, Co.) at 2% of dietary DM. Within 2 h of birth, calves were fed 4 L of colostrum from their own dam or from a dam of the same dietary treatment using an esophageal feeder. Calves were blocked by gender and dam diet and assigned randomly to receive a milk replacer (MR) with low (0.56% LA) or high concentration of LA (1.78% LA, DM basis) for 60 d. Milk replacer (20% fat and 29% CP) was fed twice daily at 6.7 g of fat per kg of metabolic BW and amounts were adjusted weekly. A single grain mix of minimum LA concentration (18.7% CP and 4.2% fat) was offered in ad libitum amounts starting at 31 d of age. Calves fed the high-LA MR had greater ($P < 0.05$) ADG (0.50 vs. 0.45 kg/d) and efficiency of gain (0.63 vs. 0.58 kg of gain per kg of DMI) than calves fed the low-LA MR over the entire period. These benefits occurred during the period of feeding MR alone and during the period of feeding MR and grain mix. Calves born from cows fed SFA prepartum had better ($P = 0.01$) ADG than calves born from cows fed UFA (0.50 vs. 0.45 kg/d due to a tendency ($P = 0.07$) to consume more DM (1.45 vs. 1.40% of BW. Calves fed the high-LA MR had a lower ($P < 0.01$) mean concentration of plasma BHBA (0.9 vs. 1.4 mg/dL). Calves born from dams fed fat tended ($P = 0.07$) to have a greater concentration of BHBA (1.2 vs. 1.0 mg/dL). Mean concentration of plasma NEFA was not affected by MR or prepartum dam diet (190 mEq/L). Increasing average intake of LA from 2.8 to 8.8 g/d from the MR improved calf performance.

W167 The effect of automated feeder system feeding curves (dilution/weaning age) on growth and health of calves fed milk replacer. T. J. Earleywine*, B. L. Miller, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

Forty-seven (47) Holstein bull calves with an average initial weight of 43.7 kg were employed in a 49-d trial to evaluate 2 feeding curves on an automated milk replacer (MR) dispensing unit (Förster Technik, Vario Milk Powder Feeder). Calves were allotted to treatment based upon weight and blood gamma globulin status. Calves assigned to both curves were fed a 25% protein/20% fat MR powder to provide equal amounts (24.6 kg DM) through weaning. MR contained milk, soy and

plasma protein sources. Calves were fed either a 12% solids solution MR providing on average 676 g DM per d for 6 wk (12sol/6wk) or a 15% solids solution MR providing on average 822 g DM per d for 5 wk (15sol/5 wk). Calves were on test through 7 wk to limit the effect of weaning age on growth parameters. MR was medicated with 0.28 g neomycin and 0.14 g oxytetracycline/kg. Calf starter (20% CP as-fed) was fed throughout this 49 d trial. Calves were housed by treatment in 2 group pens. There was a trend for increased total gain ($P = 0.08$) for the 15%/5 week treatment. MR intakes and health data were similar ($P \geq 0.37$). Scour score is a 1 - 4 scale (1 = normal, 2 = loose, 3 = water separation, 4 = 3 with severe dehydration). Respiratory score equals days treated with antibiotics for respiratory infection. Data were analyzed by the MIXED procedure in SAS.

W168 The effect of automated feeder system feeding curves (weaning age) on growth and health of calves fed milk replacer. T. J. Earleywine*, B. L. Miller, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

Thirty-six (36) Holstein bull calves with an average initial weight of 43.9 kg were employed in an 84-d trial to evaluate 2 feeding curves on an automated milk replacer (MR) dispensing unit (Förster Technik, Vario Milk Powder Feeder). Calves were allotted to treatment based upon weight and blood gamma globulin status (calf is experimental unit). Calves assigned to both curves were fed a 28% protein / 20% fat MR powder (15% solution) to provide equal amounts (49.1 kg DM) through weaning at 8 or 7 wk. 8-wk weaned calves were offered on average 1021 g MR daily. 7-wk weaned calves were offered on average 1262 g MR/d. MR was medicated with 0.22 g neomycin:0.11 g oxytetracycline/kg. Calf starter (22% CP as-fed) was fed throughout this 84 d trial. As calves were housed by treatment in 2 group pens, starter intake could not be statistically analyzed. 7-wk weaned calves had strong trends for increases in total 8 wk weight gain ($P = 0.06$) and in 12 wk weight gain ($P = 0.08$). Hip height had a strong trend for increase ($P = 0.07$) and heart girth gain was increased ($P = 0.03$) for calves assigned to the 7-wk feeding curve. Data were analyzed by the MIXED procedure in SAS.

W169 Strategies for feeding full potential rates of calf milk replacer: Two feedings daily and weaned at 7 weeks vs. three feedings daily and weaned at 6 weeks. B. L. Miller*, T. J. Earleywine, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

Thirty-eight (38) Holstein bull calves with an average initial weight of 47.9 kg were employed in an 83-d trial to evaluate 2 strategies for feeding full potential rates of milk replacer (MR). The strategies evaluated included: 2 feedings daily with calves weaned at 7 wk (2X/7wk) or 3 feedings daily with calves weaned at 6 wk (3X/6wk). Calves were allotted to treatment based upon weight and blood gamma globulin status. Calves were fed a milk replacer (28% protein / 20% fat) to provide equal total amounts (48.2 kg) of DM per strategy. Actual consumption of MR by treatment is provided. 2X/7wk calves were fed 568 g of MR per feeding or 1135 g of MR daily. 3X/6wk calves received 454 g of MR per feeding or 1362 g of MR daily. During the final wk, 2X/7wk and 3X/6wk calves were offered 568 or 454 g of MR respectively in one feeding (amount = to one feeding during the prior week). MR contained all milk protein and was medicated with 0.22 g neomycin and 0.11 g oxytetracycline/kg. Calf starter (22% CP as fed) was fed throughout this trial. Total gain and body measurements were improved for calves assigned to the 3X/6wk strategy. Data were analyzed by the MIXED procedure in SAS.

Table 1. Strategy

Item	2X/7wk	3X/6wk	P-value	CV

W170 Factors affecting pregnancy rate of recipient mares to embryo transfer. L. D. Wallace*, K. J. Stutts, and D. W. Ricks, *Sam Houston State University*, *Huntsville, TX*.

The objective of this study was to determine the effects of age of mare and degree of asynchrony between donor and recipient on pregnancy rate (PR) to embryo transfer in recipient mares. Light-horse mares (n = 34) between 3 and 16 yr of age were used as recipients. Mares were subjected to an artificial photoperiod. Cyclic recipients were examined by palpation and ultrasound at regular intervals and daily during estrus. Reproductive tracts of recipients were examined for follicular activity, ovulation, presence of a corpus luteum, uterine edema, and fluid in the uterine lumen. When necessary, ovulation was hastened by administration of hCG. Fresh, cooled, or frozen semen from various stallions was used to inseminate donors. Embryos were recovered 7 to 8 d after ovulation by non-surgical uterine lavage. Embryos were transferred non-surgically to recipient mares between 5 and 9 d post ovulation. Recipients were examined for pregnancy by ultrasound on d 25 and 110. PR was analyzed by chi-squared analysis using the frequency procedure. Pearson correlation coefficients were used to determine the relationship between PR and level of asynchrony. Age of recipient had a significant effect on PR to embryo transfer. Mares age 3–9 yr (76.0%) had a higher ($P < 0.02$) PR at d 25 of pregnancy than mares age 10–16 yr (33.3%). Mares age 3–9 yr also had a numerically higher PR at d 110; however this difference was not significant. A negative relationship ($P < 0.03$) existed between asynchrony and PR at d 25 ($r = -0.51$) and d 100 ($r = -0.39$) indicating a decrease in pregnancy rate as asynchrony between the estrous cycle of the donor and the recipient increased in terms of days. Level of asynchrony ranged from 0 to 6 d. Results of this study indicate that PR to embryo transfer is lower in older recipient mares (age 10–16 yr) compared with younger mares (age 3–9 yr) and PR is decreased as asynchrony between the donor and recipient increases from 0 to 6 d.

Key Words: equine, embryo transfer, recipients

W171 Growth models for horses differ based on date of birth. A. L. Graeff* and W. B. Staniar, *The Pennsylvania State University*, *University Park*.

Understanding growth patterns may be critical in balancing the economic and perceived athletic benefits of large size against the associated risk of skeletal abnormalities. Thoroughbred growth data indicate that models of growth should be different depending on the time of year an animal is born. Our objective was to compare parameter estimates of a sigmoidal (Richards) growth model fit to a large database of Thoroughbred weight and wither height measurements. Data for this study consisted of 35,285 weight measurements and 26,063 height measurements from 2,184 horses. Data were collected from 1977 to 2007 on farms located in the United Kingdom, Ireland, and the United States. Data were divided into consecutive 30 d periods approximating month of birth as January (J30), February (F60), March (M90), April (A120) and May (M150). Growth curves were fit to each data set using a nonlinear mixed model with fixed effects associated with the main parameters (A, b, k, M), and random effects associated with individual horses added to the A and M parameters. Differences in parameter estimates between data sets were evaluated by ANOVA with Bonferroni corrected multiple comparisons and considered significant at $P < 0.05$. There were differences in parameter estimates between all 5 data sets defining specific growth curves for each. Most striking were differences in the b, k, and M parameters, each representing shape characteristics of the growth curve over time. An overall representation of these may be described as a sequential change moving from relatively slow early and moderate later growth in the J30 and F60 to rapid early and slow later growth in the M150. The M90 and A120 data sets were intermediate. Little emphasis should be placed on the A parameter as it represents mature size and 99% of the data for this study is from horses < 4 years of age. The growth models developed in this study confirm the influence of month of birth on growth patterns demonstrated in previous Thoroughbred growth studies. Further, these models of growth will be useful in investigating hypotheses related to the impact of the environment, and more specifically management on modifying equine growth.

Key Words: equine, growth model, Thoroughbred

W172 The impact of molasses-based blocks versus sweet feed on blood glucose in horses. C. D. Gunkel*, J. S. Drouillard, L. W. Murray, and T. L. Slough, *Kansas State University*, *Manhattan*.

This study compared circulating blood glucose concentrations (GLC) in horses fed molasses-based blocks or a textured sweet feed. Six 4-yr-old Quarter horse geldings (488 ± 20 kg BW) equipped with continuous glucose monitors (Dexcom, San Diego, CA) were used in a switch back experiment conducted over 2 6-d periods with a 4-d washout phase between periods. Treatments consisted of a sweet feed concentrate (SF) fed twice daily or ad libitum access to a molasses-based block (BL) supplement. Long-stemmed prairie hay and salt blocks were offered ad libitum. SF was fed at 700 and 1400 h, gradually increasing meal size to 0.82-kg over the first 3 feedings. Motion-sensing cameras were placed above each block feeder, generating time-stamped photographs to document time and duration of BL usage. Horses consumed 1.2 kg/d of BL and had GLC of 75.4 ± 2.3 mg/dL. Horses consumed 1.46 kg/d SF and had mean GLC of 53.4 ± 4.2 mg/dL. In the BL group, daily min to max GLC values varied by 74.2 mg/dL, while the SF group varied by 86.7 mg/dL. Technical difficulties with glucose monitors resulted in large blocks of missing data for 2 animals, so 4 of 6 animals were modeled. The ARIMA procedure of SAS Version 9.1 was used to examine cross-correlations between min spent at BL and GLC per 15-min period, providing information on the delay between BL intake and glucose appearance in blood. No significant correlation was detected in one horse, while 3 horses showed significant correlation ($P \leq 0.05$). Lag patterns varied from an instantaneous effect to delays of 15 min to 4.5 h. The ARIMA procedure was used to obtain a Box-Jenkins model of GLC measurements and GLC per 15-min period with a SEM that accounted for serial correlation (non-independence) among GLC readings over time, and a 95% confidence interval was calculated. Mean, min, and max GLC values and SEM were highly variable among horses, thus no significant treatment effects were detected.

Key Words: low-moisture block, glucose, molasses

W173 Short-term selenium depletion and oxidative stress in the horse. M. Brummer*, S. H. Hayes, J. E. Earing, S. M. McCown, and L. M. Lawrence, *University of Kentucky*, *Lexington*.

Various compounds such as vitamin A, E and C, catalase, superoxide dismutase and the seleno-enzyme, glutathione peroxidase (GSH-Px) contribute to the total antioxidant capacity (TAC) of the body. Our objec-

tive was to investigate the relationship between Se status and indicators of antioxidant defense and oxidative damage in adult, idle horses. We hypothesized that low Se status would result in lower TAC and more oxidative damage. Serum malondialdehyde (MDA) concentration was used as indicator of oxidative damage. Twenty 4 mature horses were kept on low Se pasture (0.04 ppm Se; DM) with access to salt. Sixteen of these horses received no supplementation (P), while 8 horses (PC) received 1.8 kg concentrate per day (0.3 ppm Se; DM). Blood samples were obtained from all horses after 4 mo on their respective diets. Data were analyzed using the PROC CORR and PROC TTEST procedures of SAS 9.1. Serum Se concentration ranged from 69 – 193 ng/mL and were higher for horses in PC ($P < 0.0001$). A serum Se concentration above 130 ng/mL is indicative of adequate Se status. All horses in P had serum Se concentration below 130 ng/ml and were considered to have low Se status. Serum GSH-Px activity was not correlated with serum Se and no difference existed between P and PC. TAC was not correlated with serum Se or serum GSH-Px activity and did not differ between P (mean ± SE; 1.011 ± 0.43 m*M* Trolox equivalents) and PC (0.981 ± 0.45 m*M* Trolox equivalents). No correlation was found between MDA concentration and serum GSH-Px activity or serum Se concentration. A trend existed ($P = 0.078$) for higher MDA concentration in PC (28.89 ± 0.041 μMol MDA) than P (27.59 ± 0.021 μMol MDA). It has been suggested that GSH-Px may play a small role in the total cellular antioxidant system, and based on these results, the same may be true for the extracellular total antioxidant system. In addition Se status did not affect the measure of oxidative damage used in this study, possibly because the horses were not challenged by an oxidative stressor such as exercise or infection.

Key Words: glutathione peroxidase, TBARS, antioxidant

W174 In vivo digestibility and mean retention time estimates of young and mature horses receiving the same diet. J. E. Earing*, S. H. Hayes, M. Brummer, S. M. McCown, A. G. Parks, and L. M. Lawrence, *University of Kentucky*, *Lexington*.

Forages are important sources of nutrients for mature horses, however little research has been conducted to evaluate fiber utilization in young, growing horses. This study compared in vivo digestibility and mean retention time (MRT) estimates in yearling and mature horses fed the same diet. Six yearling colts and 6 mature geldings (average age, 14 y) were used. Horses received a 75%:25% forage: concentrate diet consisting of timothy cubes (9.8% CP, 63.7% NDF, 38.0% ADF), sweet feed (20.9% CP, 19.7% NDF, 9.7% ADF), and supplement pellet (35.0% CP, 13.5% NDF, 7.9% ADF). Yearlings and geldings were offered the same amount of feed on a metabolic body weight (MBW; $BW^{0.75}$) basis. All animals were dosed with Yb-labeled hay and CoEDTA. Feces were collected in a collection harness every 4 h for 3 d. Each 4 h subsample was analyzed for Yb and Co content. The remaining fecal material was compiled daily by horse; a subsample was retained for dry matter digestibility (DMD), NDF digestibility (NDFD), and organic matter digestibility (OMD) analysis. The MRT was estimated using the equation of Blaxter et al. (1956). The effect of age on digestibility and passage was determined using Proc GLM of SAS; each pair of animals was treated as a block. Feed refusals were minimal and marker dose was completely consumed. Feed intake (as % MBW) was similar between the yearlings and geldings. Mean in vivo DMD, NDFD, and OMD were 62.7% and 55.6% ($P = 0.019$), 47.7% and 36.9% ($P = 0.014$), 65.6% and 57.6% ($P = 0.031$) for the yearlings and geldings, respectively. The MRT of the fluid phase of digesta was 23.5 h for the yearlings and 21.4 h for the geldings ($P = 0.149$). The MRT of the particulate phase was 26.2 h and 22.7 h for the yearlings and geldings, respectively ($P = 0.019$). Yearlings in this experiment were better able to digest the forage-based diet than the geldings. This difference may be due to the longer MRT for the particulate phase in the yearlings and may be a biological mechanism which allows for increased nutrient digestion during growth.

Key Words: yearlings, markers, passage rate

W175 Effect of grazing fall pasture on indicators of hindgut pH and fermentation characteristics in horses. A. C. Pearson, P. D. Siciliano*, S. J. McLeod, and V. Fellner, *North Carolina State University*, *Raleigh*.

Six stock-type geldings ranging in age from 5 to 8 yr and weighing 553 ± 37 kg (mean ± SD) were used in a completely randomized 2-period switch-back design to determine the effect of grazing fall pasture having moderate non-structural carbohydrate concentration (NSC; 11.3 ± 1.4%), or fed hay made from the same pasture having lower NSC concentration (6.8%), on parameters reflecting hindgut pH and fermentation characteristics. Horses were initially assigned to one of 2 dietary treatments: pasture fed (PF; n = 3) or hay fed (HF; n = 3). The PF horses had access to tall fescue pasture from 1300 to 700 the following day, followed by stall confinement from 700 to 1300 each day for 14 d. The HF horses were fed tall fescue hay at a rate of 2% of body weight (as-fed) one time per d at 1300 each day for 14 d. Following the first 14-d period treatments were switched for an additional 14 d period so that all horses receive all treatments. At 700 on d-7 of each period pH was measured in feces of individual horses and individual batch cultures using each horse's fresh feces as inoculum and alfalfa meal as substrate were performed. Acetate, propionate and butyrate concentrations were measured in culture media following 48 h of incubation. Differences in response variables between treatments within horses were analyzed using a paired *t*-test and results are expressed as the mean of differences between treatments within horses (±SE). Fecal pH was 0.30 ± 0.14 pH units lower ($P = 0.042$) when horses consumed pasture compared with hay. Batch culture media acetate and butyrate concentration, expressed as a molar percent, did not differ between treatments. Batch culture media propionate concentration decreased ($P = 0.002$) by 5.1 ± 1.1 molar % and the acetate:propionate ratio increased ($P = 0.02$) by 0.55 ± 0.21 when horses were fed pasture compared with hay. These results suggest pasture containing moderate amounts of NSC can alter indicators of hindgut pH and some fermentation characteristics. The implications of these findings on hindgut health requires further investigation.

Key Words: horse, non-structural carbohydrates, pasture

W176 Summary of equine pastures utilizing a line point transect to measure vegetative cover to reduce sediment and nutrient losses, enhancing pasture quality. A. Swinker*[1], D. Foulk[1], J. Malot[2], S. Truax[2], J. Weld[1], and M. Harper[1], [1]*Pennsylvania State University*, [2]*USDA Natural Resources Conservation Service, Harrisburg, PA*.

Twenty horse farms representative of the industry (7 to 99 horses) from Pennsylvania, northern Virginia and Maryland were surveyed. Farm surveys were conducted to quantify equine pasture quality, to analyze the pasture conditions under the management systems and the "efficiency" of those practices. Data were recorded using an Excel spread sheet; SPSS was used to determine frequencies. Existing pasture condition tools used for conservation and sediment loads were evaluated. None of the surveyed horse farms utilized an intensive grazing system, 2 (10%) of the farms used a pasture grazing system that grazed 24 h 7 d /week and were overstocked; 80% of the farms limited grazing or restricted the horse's grazing times. Only 3 farms rested pastures for at least 2 weeks before re-grazing. Equine pasture data were obtained using the

"Line Point Transect" and "Pasture Condition Scoring" methods. Percent vegetative canopy cover, % basal stem cover, % pasture forage, % forage canopy, number of forage species and the Pasture Condition Score were recorded. Overall, surveyed farms averaged 87% canopy cover (range 53–100%), 45% basal stem cover (69–21%), 56% good quality forage (89–11%), 63% canopy from good forage (97–13%), 19 plant species including weeds (range 35–12), 5 forage species (7–2) and averaged 25.5 on Pasture Condition Score with a range of 5–40. Past studies report soil loss reduction will be greater if the initial canopy cover is less than 70%. One of the surveyed farm's pastures contained 53% cover; this contributed to a loss of 30 tons of sediment per hectare per year; a second farm with a 75% canopy had a 10-ton loss; and there were 7 farms with percent canopy in the 80s resulting in a 5-ton loss. The remaining 9 farms had over 90% vegetative canopy. Eighty percent of the surveyed horse farms maintained acceptable vegetative cover of desirable and weed species reducing nutrient and sediment loss. More strategies are needed to preserve vegetative cover to enhance pasture quality and help to reduce sediment and nutrient loss.

Key Words: equine pasture, condition, sediment loss

W177 Segregation of AB_098561: c.1470G>A SNP of the serotonin transporter gene (*SLC6A4*) in Mangalarga Brazilian horses. L. Arneiro*[1,2], M. Mota[1,2], and R. Curi[2], [1]*Universida Estadual Paulista*, *Jaboticabal, São Paulo, Brasil*, [2]*Universidade Estadual Paulista*, *Botucatu, São Paulo, Brasil*.

In equines (*Equus caballus*), behavioral changes are important because of the uses of these animals in different modalities such as jumping, running, dressage, etc. It is considered that the gene coder of serotonin transporter has influence on behavioral traits in animals, controlling the serotonin reabsortion in the synaptic gaps. The aim of this study was to evaluate the segregation of SNP AB_098561: c.1470G > A of gene SLC6A4 in a representative sample of Mangalarga bred in São Paulo state. The idea was to determine if there is application potential of the association studies between molecular markers and economic interest traits for this breed. Thus, 151 animals of both sexes were genotyped by PCR-RFLP from the amplification of 359-bp gene fragment and digestion with *Hha*I restriction enzyme. Using PopGene 1.32 program, allele frequencies (0.079 for the A allele and 0.921 for the G allele), chi-squared (1.075), observed (0.159) and expected heterozygosity (0.147), Shannon gene diversity index (0.277), fixation index F (−0.086) and Ewens-Watterson selective neutrality (0.853), were estimated. From the results it was concluded that the studied population is in Hardy Weinberg equilibrium for the locus in question, showing the absence of selection in favor of one allele. However, the observed value for the selective neutrality test is near the superior limit (0,99), not excluding the possibility of using the marker in association studies with behavioral traits. However, it must be emphasized that due to the extremely low frequency of allele A, studies involving a larger sample of animals should be done.

Key Words: equine, gene, serotonin

W178 The use of equine blood parameters to identify chronic exposure to feed-borne *Fusarium* mycotoxins: A field study. M. Mortson*, C. K. Girish, and T. K. Smith, *University of Guelph*, *Guelph, Ontario, Canada*.

Feed-borne mycotoxins consumed at low levels over an extended period of time may have an effect on equine performance and breeding ability and may potentially cause immunosuppression. An equine biomarker that indicates an exposure to a wide range of *Fusarium* mycotoxins including deoxynivalenol (DON, vomitoxin), zearalenone, and T-2 toxin has not yet been identified. A field study was conducted to identify a potential biomarker in equine blood that reflects chronic exposure to low levels of feed-borne *Fusarium* mycotoxins. This was done by identifying any correlation between serum gamma-glutamyltransferase (GGT), urea, and immunoglobulin A (IgA), and the presence of naturally occurring *Fusarium* mycotoxins in forages and concentrates. A total of 30 horses from 18 Ontario horse farms and 1 New Jersey horse farm participated in the study. Blood samples were collected from each horse as well as a sample of hay and concentrate. Serum GGT, urea, and IgA were measured and a correlation analysis was completed. Mycotoxin concentrations were determined by a combination of HPLC and GC/MS methodology. DON was present in feed samples collected at 18 farms with an average concentration of 0.48 mg/kg. The range was from 0.13 mg/kg to 1.5 mg/kg. 15-acetyl DON was the second most prevalent *Fusarium* mycotoxin in feed samples (n = 6) followed by zearalenone (n = 5). No significant correlations were identified between the concentrations of *Fusarium* mycotoxins in the samples collected and the equine blood parameters analyzed. It can be concluded that feed-borne mycotoxins are present in many horse feeds on farms in Eastern North America. Biomarkers for chronic *Fusarium* mycotoxicoses, however, remain to be identified.

Key Words: *Fusarium*, mycotoxins, equine

W179 Influence of velocity on stride variables of the Wilbur-Cruce Mission horse intermediate gait. M. Nicodemus*[1] and J. Beranger[2], [1]*Mississippi State University*, *Mississippi State,* [2]*American Livestock Breeds Conservancy*, *Pittsboro, NC*.

Wilbur-Cruce Mission horse (WCM) is a strain of Spanish Colonial horse that originated from the Arizona mountains. Due to the breed's sure-footedness, the WCM is assumed to be gaited like other Spanish Colonial breeds. Study objectives were to determine the relationship between trotting velocities and the WCM stride variables and whether at trotting velocities the WCM can perform a 4-beat stepping gait. Nine WCM were worked from the ground along the arena railing at both a slow (3.0 ± 0.3 m/s) and fast (4.7 ± 0.4 m/s) trotting velocity. Horses were filmed along the long side of the arena. Frame-by-frame analysis was performed documenting hoof contact and lift-off for 10 strides for both velocities. Stride variables were given as a % of stride duration. Student's paired *t*-tests were performed to determine gait symmetry and differences between stride variables at the slow and fast velocity ($P < 0.05$). Stance durations between left and right variables were not significantly different indicating gait symmetry, and thus, left and right stride variables were collapsed ($P < 0.05$). At the fast velocity the WCM performed a shorter stride duration and suspension, while demonstrating a longer stride length and diagonal bipedal support ($P < 0.05$, Table 1). Stance durations, stride rate, and diagonal advanced placement (DAP) and completion (DAC) remained consistent between velocities. While other Spanish Colonial horses were found to perform 4-beat stepping gaits at similar velocities, the WCM performed at both velocities a trot. Although similarities can be found between this study and other trotting studies, velocity changes for the WCM, unlike that of other trotting studies, did not impact stance durations, DAP, and DAC. With less than 100 horses representing the breed, these stride variables can be applied in distinguishing the WCM from other Spanish Colonial breeds and assist in further breed development.

Table 1. Means ± SD for WCM stride variables at a slow and fast trotting velocity

	Slow Velocity	Fast Velocity
Stride Duration (ms)	783 ± 25[a]	689 ± 26[a]
Stride Length (m)	2.3 ± 0.2[b]	3.2 ± 0.2[b]
Stride Rate (strides/s)	1.3 ± 0.1	1.4 ± 0.1
Fore Stance (%)	43 ± 3	42 ± 3
Hind Stance (%)	43 ± 3	42 ± 3
DAP (%)	0 ± 0	0 ± 0
DAC (%)	0 ± 0	0 ± 0
Diagonal Bipedal Support (%)	85 ± 1[c]	83 ± 1[c]
Suspension (%)	15 ± 1[d]	17 ± 1[d]

Similar superscripts indicate significant differences ($P < 0.05$) between velocities.

Key Words: Spanish Colonial horse, stride variables

W180 Nutraceutical extracts affect oxidative stress and antioxidant status in intensely exercising horses. D. Smarsh*, N. Liburt, J. Streltsova, K. McKeever, and C. Williams, *Rutgers, The State University of New Jersey*, *New Brunswick*.

Many nutraceuticals are used as equine supplements without their efficacy having been scientifically tested. Black tea, cranberries, orange peel and ginger are a few of those nutraceuticals that warrant further study. The objective of this study was to test the effects of single doses of black tea, cranberry, orange peel and ginger extract on markers of oxidative stress and antioxidant status following exercise in horses. Study 1: Nine mature, healthy unfit Standardbred mares were administered 2 L of either placebo (water; W), orange peel extract (O; 30g extract), or decaffeinated black tea extract (T; 28g extract). Study 2: the same mares were administered 2 L of either placebo (water; W), cranberry extract (C; 30g extract), or ginger extract (G; 30g extract). In each study mares were given the extracts via nasogastric tube 1 h before performing a graded exercise test (GXT), in a randomized crossover design with at least 7 d between GXTs. Blood samples were collected at rest, at fatigue, 1, and 24-h post-exercise and analyzed for lipid hydroperoxides (LPO), total glutathione (GSH-T), glutathione peroxidase (GPx), α-tocopherol (TOC), β-carotene (BC), and retinol. Data was statistically analyzed using a repeated measures ANOVA. Study 1: There was no effect ($P > 0.05$) of treatment for LPO, GSH-T, GPx, TOC or BC. Retinol was higher for both T ($P = 0.0006$) and W ($P = 0.004$) than for O. Study 2: There was no treatment effect ($P > 0.05$) for LPO, GPx, GSH-T, RET, BC or TOC. These results show that a single dose of black tea may be beneficial in increasing antioxidant status in exercising horses, however, effects on oxidative stress were not found with any of the nutraceuticals. Further investigation is needed as to whether long-term supplementation would enhance these effects.

Key Words: antioxidant, black tea, equine

W181 Whole farm balance of nitrogen and phosphorus on horse farms in the Chesapeake Bay watershed. M. T. Harper*, A. Swinker, and K. B. Kephart, *Pennsylvania State University*, *University Park*.

Whole farm nutrient balances of inputs and outputs can be used to assess the risk of non-point source pollution and identify pollution reduction strategies. Many nutrient balance studies have been conducted on livestock and poultry farms. To our knowledge this is the first study to characterize nitrogen (N) and phosphorus (P) balance on horse farms. Nitrogen and P inputs and outputs on 13 horse farms in the Chesapeake Bay watershed were estimated to determine the risk of non-point source pollution. Annual amounts of imported fertilizer, hay, concentrate, and bedding were recorded for each of the farms based on estimates reported by farm managers. Samples of hay, concentrate, and bedding from each farm were analyzed for N and P. Small square bales were weighed and multiplied by the number of bales received. Bedding volumes were multiplied by respective nutrient concentrations to estimate mass values. Manure nutrient exports but not the sale of horses were included in the calculation of nutrient output. Four of the 13 farms did not export manure. Four farms exported a portion of their manure estimated by the farm owner. Five farms exported all collected manure which was estimated to be (24 kg/d/head) × (% time in a stall). Nutrient exports were estimated by multiplying the manure amount by the analyzed nutrient value of the composite manure samples or fecal samples from each farm. The mean farm balance ((import-export/import) × 100) of N and P for all farms was 75 ± 7.9% and 52 ± 17%, for farms exporting some manure was 87 ± 11% and 80 ± 17%, and for farms exporting all manure was 46 ± 6.8% and −8 ± 23.3%, respectively. The overall mean balance per animal unit was 42.8 ± 6.7 kg for N and 7.3 ± 2.7 kg for P. The overall mean balance per hectare was 118.7 ± 21.7 kg for N and 17.2 ± 5.7 kg for P. No farms achieved N balance. Only farms exporting all collected manure were able to be in P balance. Manure must be exported and/or fewer nutrients must be imported to approach nutrient balance. It appears that to achieve whole farm nutrient balance, horse operations must export a large proportion of the manure generated by the farm.

Key Words: nitrogen and phosphorus, horse, nutrient balance

W182 Effect of dietary energy manipulation on mares and their foals: Foaling parameters. K. N. Winsco[1], J. L. Lucia*[1], C. J. Hammer[2,3], and J. A. Coverdale[1], [1]*Department of Animal Science, Texas A&M University*, *College Station,* [2]*Department of Animal Sciences, North Dakota State University*, *Fargo,* [3]*Center for Nutrition and Pregnancy*, *Fargo, ND*.

To determine the effect of dietary DE manipulation on foaling parameters, 30 Quarter Horse mares (538 to 695 kg of BW and 4 to 19 yrs of age) were blocked by expected foaling date. All mares were allowed ad libitum access to coastal bermudagrass pasture and randomly assigned within block to 1 of 2 dietary treatments: pasture (P) or pasture + concentrate (PC; concentrate fed at 0.75% BW on an as-fed basis). Dietary treatments began 110 d before expected foaling date and were terminated at parturition. When parturition was observed, the following foaling parameters were recorded: time of water break to birth, time to stand, and time of birth to placenta expulsion. Total length of gestation was calculated and placenta weight was recorded. Additionally, total volume, specific gravity, and Brix % of colostrum were measured. Physical measurements were also obtained which included mare BW, foal BW, foal wither and hip height, and foal body length. All data were analyzed using PROC GLM of SAS. There was no influence of dietary treatment on foaling parameters; however, time from birth to placenta expulsion tended ($P = 0.06$) to be longer in P mares. There was also no effect of treatment ($P \geq 0.46$) on foal physical measurements obtained following parturition, although foals from P mares tended ($P = 0.06$) to exhibit greater hip height compared with foals from PC mares. Ratio of placenta to mare BW, placenta to foal BW, and the ratio of foal BW to mare BW were not affected by treatment ($P \geq 0.16$). There was no influence of dietary treatment on total colostrum volume ($P \geq 0.56$). There was an influence of DE manipulation on colostrum quality indicated by greater specific gravity and refractometer values (Brix %; $P \leq 0.01$) in P mares compared with PC. In summary, these data indicate that dietary

DE manipulation of mares in late gestation affects colostrum quality, but not volume. Furthermore, maternal DE manipulation did not influence foaling parameters or foal physical characteristics.

Key Words: mares, energy, foaling

W183 Comparison of a commercially available glucometer to a standardized laboratory method for glucose analysis in healthy horses. K. O'Diam*[1], J. Sylvester[2], and K. Cole[1], [1]*The Ohio State University*, *Columbus*, [2]*MARS Horsecare US, Inc.*, *Dalton, OH*.

Extremes in blood glucose concentrations can be detrimental to a horse's health. Elevated blood glucose and insulin levels for extended periods of time are associated with equine metabolic syndrome and laminitis while decreased blood glucose concentrations may result in seizures. The ability to quickly and accurately determine blood glucose levels in the field can facilitate important management decisions. Blood samples (n = 432) obtained from 6 healthy horses for use in a separate study were used to determine the accuracy of a commercially available hand-held point-of-care (POC) glucometer in comparison to a standard laboratory method for glucose analysis. Blood samples were collected via jugular catheter into heparinized tubes and 0.6 μL of whole blood was immediately analyzed by a POC glucometer (POC/WB). Plasma was separated by centrifugation and analyzed using an automated biochemistry analyzer (CHEM). In addition, plasma glucose concentrations were also determined using the POC glucometer (POC/PL), although the POC glucometer was designed for use with whole blood. Statistical analyses were performed on paired data using correlation and mixed procedures of SAS. Overall, mean glucose concentrations determined by POC/PL, CHEM and POC/WB were 101.4mg/dL, 97.0 mg/dL and 95.5 mg/dL, respectively. Both POC/PL and POC/WB were positively correlated with the standard laboratory method (CHEM; r = 0.78 and 0.73, respectively; $P < 0.0001$). A positive correlation was also observed, to a lesser extent, between POC glucometry using whole blood (POC/WB) and plasma (POC/PL; r = 0.59; $P < 0.0001$). These data suggest that hand-held POC glucometers may be useful in the field for determining blood glucose levels in horses.

Key Words: glucose, glucometer, horse

W184 Effects on lactation performance when slick hair gene is simulated in dairy cattle in the tropics. R. M. Mejía*[1,2], J. A. Ortuño[1], G. J. Lascano[2], and M. Vélez[1], [1]*Zamorano University*, *El Zamorano, Honduras*, [2]*The Pennsylvania State University*, *University Park*.

In the tropical and subtropical regions, high temperatures affect dairy cattle, reducing the metabolic activities of the animal and decreasing the blood flow to the udder. Cattle with the slick hair gene tolerate high temperatures and humidity much better than normal haired cows. The objective of the present study was to determine if the effect on lactation performance of slick hair gene cows can be simulated through hair clipping. The experiment was conducted in Zamorano University, Honduras located at 800 m.a.s.l. (average year-round temperature of 23° C). Thirty two multiparous crossbred, Holstein, Jersey and Brown Swiss lactating cows were monitored through 140 d of lactation. Cows were blocked according to their age, body condition score and milk production and assigned randomly to two different coat treatments. Treatments consisted of normal-haired (NH; n=16) and clipped-hair lactating cows (CH; n=16). Hair was clipped from the cow′s barrel, neck and legs at the beginning of the experiment and on d 60. CH and NH cows were kept under the same environmental conditions. Rectal temperature (at 1400 h) and milk yield (kg/d) were measured once weekly. All data were analyzed according to a randomized complete block design with repeated measures using the MIXED procedure of SAS. NH cows had lower temperatures (35.2 vs.36.4° C ± 0.58; P = 0.01). There was a significant interaction effect between time and treatment (P = 0.05) that was maintained consistently throughout the experiment. Milk yield (kg/day) was higher when cows were clipped (13.4 vs. 10.8 ± 0.26; P = 0.003). The decrease in rectal temperature and increase in milk production reflects the capacity of CH cows to mimic lactation performance of slick-haired gene cows resulting in an enhanced lactation performance.

Key Words: slick hair gene, clipped-haired cows, lactation performance

W185 Effects of a direct-fed microbial product on milk production by crossbred dairy cows in the Brazilian Cerrado. R. D. Sainz*[1], C. U. Magnabosco[2,3], R. A. Carnevalli[3], R. Guimamães Jr.[2], M. M. S. Mamede[4,3], J. R. Costa Jr.[5,3], and E. A. Filgueiras[6], [1]*University of California*, *Davis,* [2]*Embrapa Cerrados*, *Planaltina, DF, Brazil*, [3]*Embrapa Arroz e Feijão*, *Santo Antonio de Goiás, GO, Brazil*, [4]*Associação Goiana de Criadores de Zebu*, *Goiânia, GO, Brazil*, [5]*Universidade Estadual de Goiás*, *Goiânia, GO, Brazil*, [6]*Bioformula*, *Goiânia, GO, Brazil*.

Thirty-two Girolando (crossbred Holstein x Gir) dairy cows were randomized as to percentage Holstein, age, parity, stage of lactation and current production level into control and treated groups. Cows averaged 63% Holstein, 2.6 parities, 174 days of lactation and 13.3 kg/d milk. Treated group cows received 2 g/d of a product (Bioformula, Goiania, Brazil) containing live yeast (1×10^9 CFU/g), mannan oligosaccharide (10%), and *Lactobacillus acidophilus*, *Bacillus subtilis*, and *Enterococcus faecium* (2×10^7 total CFU/g), whilst controls received 2 g/d of the carrier alone. Cows grazed *Brachiaria brizantha* pastures and received up to 5 kg/d grain supplement according to production level. Milk production was monitored weekly for six weeks. Five control and four treated cows had mastitis during the experiment and their data were excluded. Data were analyzed by ANOVA, with treatment as main effect and previous level of production as the covariate. When previous level of production was included, all other factors (percentage Holstein, age, parity and stage of lactation) became non-significant. Average milk yields for the first three weeks were 11.1 and 11.7 kg/d (SD = 0.97) for control and treated cows, respectively (P = 0.15). For the second three weeks, average milk yields were 10.8 and 11.9 kg/d (SD = 0.86) for control and treated cows, respectively (P = 0.01). Therefore, direct-fed microbials had no effect in the first three weeks of treatment, but for the second three weeks milk production was increased by 10%. These results suggest that probiotics have the potential to increase milk production by crossbred dairy cows under tropical conditions.

Key Words: probiotics, dairy, tropical

W186 Digestibility of fresh sugarcane-based diets with slow-release non protein nitrogen addition for limit-fed dairy heifers in the tropics. G. J. Lascano*[1], M. Velez[2], J. M. Tricarico[3], and A. J. Heinrichs[1], [1]*The Pennsylvania State University*, *University Park*, [2]*Zamorano University*, *El Zamorano, Honduras*, [3]*Alltech Inc.*, *Nicholasville, KY*.

Sugarcane presents interesting characteristics for feeding ruminants in the tropics, such as perennial growth, reduced harvesting requirements, and peak yield and nutritive value that coincide with dry periods when forage is scarce. An experiment was conducted to determine the effect of replacing soybean protein (SBM) with non-protein N in limit-fed dairy heifers in the tropics. Eight Holstein heifers (237.6 ± 5.45 kg BW) were allocated to 2 dietary treatments in a cross over design. Treatments were control (C; 23% SBM) and O (Optigen, fed at 3% of DMI; Alltech Inc.). The forage to concentrate ratio was 50:50 (DM-basis) and fresh chopped sugarcane the sole source of forage. Each experimental period (2) lasted 15 d with 4 d of total feces and urine collection. Diets provided similar intakes of ME, allowed for 800 g/d of ADG, and chemical composition was held constant across all diets. Data were analyzed using a mixed-effects model with repeated measures. Compared to O, diet C tended to have greater total tract apparent digestibility (TAD) of DM (71.2 vs. 68.6 ± 0.63%; P = 0.06) and ash (47.4 vs 38.3 ± 3.81%; P = 0.08). Total tract apparent digestibility values in C-fed were greater than in O-fed heifers for OM (73.9 vs. 71.3 ± 0.64%; $P < 0.01$), CP (76.9 vs. 75.2 ± 0.72%; P = 0.04), hemicellulose (50.5 vs. 43.3 ± 1.89%; $P < 0.01$), and starch (98.6 vs. 97.2 ± 0.48%; P = 0.03). However, TAD of NDF was similar (44.9 ± 1.93%; P = 0.26) and TAD of ADF was lower (P = 0.03) in C (27.7± 2.15%) than in O heifers (33.3 ± 2.15%). Excretion of urine, wet and dry feces, and water intake were similar between treatments. Retained N was similar between treatments (65.5 ± 3.53%; P = 0.47), and thus no differences were found in N dynamics. We conclude that when O replaced SBM it tended to decrease DM and decreased OM, CP, hemicellulose, and starch TAD, but did not affect NDF and increased TAD of ADF. Even though control diets were more digestible overall, individual nutrient digestibility was not greatly affected, suggesting that replacing SBM with slow-release non-protein N is possible in sugarcane-based diets in the tropics.

Key Words: sugarcane, tropics, limit-feeding, dairy heifer

W187 System dynamics ex ante decision support for caprine initiatives in Southern Mexico. K. C. McRoberts*[1], C. F. Nicholson[4], R. W. Blake[3,1], T. W. Tucker[1], and G. Díaz Padilla[2], [1]*Cornell University*, *Ithaca, NY*, [2]*Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias*, *Xalapa, Veracruz, México*, [3]*Center for Latin American and*

Caribbean Studies, Michigan State University, *East Lansing*, [4]*California Polytechnic State University*, *San Luis Obispo*.

Researchers and development practitioners at the Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias (INIFAP) Xalapa team were trained in systems thinking and dynamic modeling techniques during an institutional capacity-building course. Course participants contributed expert knowledge to improve a system dynamics model designed to assess impacts on farmer profits of value-added agricultural production by a smallholder marketing cooperative. The dynamic biophysical and socioeconomic model consisted of nine modules that represented the aggregate community goat flock and a processing and marketing cooperative. The primary objective of the model was to assess strategies to increase net income from caprine production in highland communities. This adaptable model was designed as an *ex ante* impact assessment mechanism for INIFAP to evaluate the opportunities and limitations of value addition. Model analyses indicated that manufacture of goat's milk products by the cooperative could increase community net income from caprine activities under a wide variety of environmental and market conditions. Increases in net income from dividend payments during the dry season could partially mitigate seasonality from other income sources. Model sensitivity analyses indicated that the exogenous effects of seasonal rainfall on forage supply were more important to system performance than feedback processes (e.g., reinvestment of profits). System performance was measured by elements that likely influence farmer and cooperative decision-making: returns to labor, time required until the cooperative was financially solvent, dividend payments, and buyer orders for aged cheese cancelled due to supply delays. The analyses also indicated potential risks and factors that could limit cooperative success. The most important included the size and reliability of the market for premium aged cheese, the cooperative's policy of payments for milk and dividends, milk production costs, cheese production costs, and the composition and productivity of the goat flock. These factors and forage quality should receive priority in future research.

Key Words: caprine production, system dynamics, processing cooperative

W188 Biomass production and nutritional value of wheat and oat hydroponic forages sowed at three densities. J. A. Rivera-Ahumada[1], A. S. Juárez-Reyes[1,4], H. Bernal-Barragán[2,4], M. A. Cerrillo-Soto*[1,4], F. G. Ríos-Rincón[3,4], A. Estrada-Angulo[3,4], and M. Guerrero-Cervantes[1,4], [1]*Universidad Juárez del Estado de Durango*, *Durango, Dgo., México*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, México*, [3]*Universidad Autónoma de Sinaloa*, *Culiacán, Sinaloa, México*, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *Durango, Dgo, México*.

A study was conducted to evaluate the biomass yield, CP, ME, metabolizable protein (MP) content, and gas fermentation parameters of wheat and oat hydroponic forages. Seeds were sowed at three densities (400, 600 and 800 g seeds) and manually placed in 40 × 40 cm plastic trays in triplicate. A controlled 5 × 4 m green house was used to grow the germinated hydroponic seeds and after 10 and 12 d, the forages were harvested. Two hundred mg of samples were incubated by triplicate in 100 ml calibrated glass syringes for 0, 3, 6, 9, 12, 24, 48, 72 and 96 h. Data were fitted to the equation: $Y=a + b*(1-e^{-ct})$ to estimate the gas produced from the soluble fraction *a*, the gas produced from the slowly degradable fraction *b* and the constant rate of gas production *c*. The ME content (Mcal kg^{-1} DM) was calculated by: $(2.20+0.136Gas\ production_{24h}+0.057CP+0.0029EE^2)/4.184$. The MP content was estimated according to the Intestinal Digestible Protein French System. Data were analyzed according to a factorial design to test the effects of 3 seed densities (400, 600, 800 g), 2 species (wheat and oat) and their interactions. There was a species × density interaction for biomass yield, CP and *b* fraction ($P < 0.05$). Biomass yields of wheat hydroponic forage with the higher density was 3.7 fold of that grown with the lower density, whereas an increment of 1.8 fold was registered in the oat hydroponic forage. Higher seed density in oats resulted in decreased CP (from 18.0 to 13.2%) and ***b*** (from 58.9 to 45.5ml of gas/200 mg DM) values, respectively. Values for in vitro gas production at 24 h, constant rate of gas production ***c***, ME and MP contents were higher ($P < 0.01$) for hydroponic wheat (60.5 mL/200 mg DM, 6.7% h^{-1}, 2.7 Mcal ME kg^{-1} DM and 80.6 g MP kg^{-1} DM) than for hydroponic oat (44.3 mL/200 mg DM, 5.7% h^{-1}, 2.2 Mcal ME kg^{-1} MS and 64.2 g MP kg^{-1} DM). According to our results, wheat hydroponic forage has a better nutritive value than its counterpart.

Key Words: hydroponic forage, in vitro gas production, nutritive value

W189 Growth potential of village chicken in Nigeria. J. A. Olupona*, O. O. Adejinmi, and A. M. Raji, *Federal College of Animal Health and Production Technology, Institute of Agricultural Research and Training*, *Ibadan, Oyo, Nigeria*.

The growth potential of village chickens in Nigeria was evaluated by comparing their growth performance under intensive and semi-intensive system of management. Preliminary investigation by the author revealed that 86.75% of village chickens are kept under semi-scavenging system of management in Ibadan southwest local government of Nigeria whereas birds are provided with small amount of grains and by-products to supplement their scavenging. Chicks (n=52), 8 wk old were collected from villages in Ibadan south west local government and individually raised in cages. Chicks (n=56) remained with the farmers and were raised under semi- scavenging conditions. On-farm made growers mash (18%CP) was fed to chicks raised under intensive condition and birds were treated against common diseases and parasites. Data were collected on feed intake, weight gain and feed efficiency. All measured and calculated parameters were tested for normality using proc univariate, normal and plot procedure of SAS and later analyzed using ANOVA. Village and system of management significantly ($P < 0.05$) influenced growth rates. Feed intake, weight gain and feed efficiency for birds under intensive conditions were significantly ($P < 0.05$) greater than for birds under semi-scavenging conditions. Phenotypic variance for daily weight gains, and growth rate were lower for intensively managed birds than for semi intensive system Correlation coefficients of growth traits measured between intensive and semi-scavenging conditions were low (r=0.16-0.49; $P < 0.05$), probably indicating that the effect of environment and its interaction on genotype had a strong impact. It is concluded that growth potential of village chicken can be enhanced by providing sufficient feed under semi- scavenging conditions.

Key Words: village chicken, semi-scavenging, intensive

W190 Effects of demographic characteristics and attitudes of consumers on table egg consumption. M. Bejaei* and K. M. Cheng, *The University of British Columbia*, *Vancouver, BC, Canada*.

In addition to regular (white and brown) eggs, alternative types of table eggs (e.g., free-run, free-range, organic eggs) are also available in Canadian market and their market growth rate has been high during the last decade in British Columbia (BC). Despite this growth there is insufficient data about consumers' attitudes and preferences relating to this differentiated egg market. The objective of our research was

to identify the consumers' attitudes and demographic characteristics toward different types of table eggs. We used an online interactive survey questionnaire to gather information from adult BC residents. Email addresses of 1027 potential subjects were randomly selected and 702 completed surveys were processed. The survey was conducted in June 2009 according to the regulations of UBC Behavioural Research Ethics Board. PASW Statistics 17 (SPSS) was used to analyze the survey data. Different statistical tests were applied to the responses (e.g. ANOVA, Pearson correlation, Bonferroni correction). Our results indicated that the consumption of cage-free eggs has changed in BC in 2009 in comparison to a Print Measurement Bureau consumer survey in 2007. Almost a third of the consumers used free-range eggs at home in BC in 2009. Individuals with a higher educational level or higher income consumed more free-range eggs and fewer white regular eggs than those with a lower educational level or lower income. Consumers who rated the nutritional value of white regular eggs as high (score 4 or 5 in a five point Likert scale) consumed more white regular eggs. Consumers did not act according to the same priorities when they were selecting different types of eggs. Price was the main factor in selection of white regular or brown regular eggs; bird welfare, environmental concerns and having access to healthy food were main factors in the selection of cage-free eggs; and nutritional value and having access to healthy food were main factors in consumption of nutrient enhanced eggs. Because of the results of this research egg producers are more capable of designing a marketing mix plan to develop their market share in the future.

Key Words: table eggs, consumer attitudes, demographic characteristics

W191 Effect of dry ammoniation on the chemical composition and digestibility in vitro in the mesocarp of the fruit and empty bunches of African oil palm. N. Castro-Ucross[1], J. Vergara-Lopez[2], and O. Araujo-Febres*[1], [1]*Universidad del Zulia, Facultad de Agronomía, Departamento de Zootecnia*, *Maracaibo, ZU, Venezuela*, [2]*Instituto Nacional de Investigaciones Agricolas*, *Maracaibo, ZU, Venezuela*, [3]*Universidad del Zulia, Facultad de Agronomía, Departamento de Zootecnia*, *Maracaibo, ZU, Venezuela*.

Venezuela has about 52,384 ha planted with African oil palm, of which 27,100 ha had a total production of fresh empty fruit bunch of about 334,262 MT (with empty bunches representing 25% and mesocarp 11% of total weight). This study was conducted to evaluate the effect of dry ammoniation on the chemical composition and digestibility in vitro of the mesocarp of the fruit and the empty fruit bunches of african oil palm at Catatumbo municipality of Zulia state, Venezuela. Five levels of urea (0, 15, 30, 45 and 60 g/kg DM) and two incubation times (14 and 28 d) were applied to the products. The study was conducted as complete randomized experiment with a factorial arrangement 2×2×5, with 3 replications. Dry matter (DM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), lignin (Lig) and in vitro dry matter digestibility (IVDMD) were determined. Data were analyzed using ANOVA. Dry matter content decreased ($P < 0.01$) as urea levels increased. The lowest values of NDF, ADF and Lig were found in the empty fruit bunch (32.9, 29.6 and 7.1%, respectively) and the correlation analysis demonstrated a downward trend in fiber content as urea levels and incubation time increased. The CP content was greatest ($P < 0.01$) in the mesocarp at 28 d of incubation, and it increased 4% units when comparing 0 vs 60 g of urea addition. The IVDMD was greater in the empty fruit bunch (61.7%, $P < 0.01$) than in the mesocarp (39.5%). Dry ammoniation positively changed the chemical composition and digestibility of oil palm by- products, with the empty fruit bunch being the most affected of the byproducts.

Key Words: African oil palm, dry ammoniation, dry matter digestibility

W192 Nutritive value of Henequen (*Agave fourcroydes* Lem.) pulp as ruminant feed. E. González–García*[1,2], O. Cáceres[2], F. Ojeda[2], and R. Delgado[2], [1]*INRA, UMR 868, Élevage des Ruminants Regions Chaudes*, *Montpellier 34090, France*, [2]*Estación Experimental de Pastos y Forrajes 'Indio Hatuey'*, *Matanzas 44280, Cuba*.

Henequen (*Agave fourcroydes* Lem.) is a highly resistant and succulent plant (genus *Agave*; family Agavaceae) with sword-shaped leaves of 1.2 to 1.8 m long in a form of rosette. It's extensively planted in Mexico (Yucatan) and Cuba (Varadero) basically to profit their leaves′ fiber (so-called Henequen) for rope and twine productions. The remained pulp is an industrial by-product that, if not used, may constitute an environmental problem. We evaluated its nutritive value (NV), fresh (HPF) or ensiled (HPE), as a ruminant feed with potential to be used in a planned integration of livestock and agro industry productions locally in the north-center of Matanzas, Cuba (23°08′22″N 81°17′10″W). Two metabolic trials of 21 d each (14 d adaptation, 7 d data collection) were conducted for evaluating HPF and HPE, respectively. For each trial, 6 adult castrated Pelibuey wethers (BW = 35 ± 2.3 kg) were used, randomly housed in individual metabolism crates and the INRA French system of ad libitum (10% of refusal from previous day) feed supply and total feces collection was implemented. Feeds (HPF or HPE) were daily and individually distributed into 2 equilibrated meals (0800 and 1630). Data were analyzed for each trial by separate using an ANOVA. The experimental unit was the wether, included in the model as a random effect. Comparisons between HPF and HPE were avoided. Despite a limiting DM content (16.8 and 20% for HPF and HPE, respectively), either HPF or HPE showed acceptable NV for ruminants due to good voluntary intake (Ø: 96% of reference feedstuff) which was likely due to the high energetic potential (>2.5 mcal/ kg DM) (Table 1). However, CP content was low for both states of presentation (72 and 60 g/ kg DM for HPF and HPE, respectively) which also determined low levels of protein arriving to the small intestine (PDIMN and PDIME). This by-product of Henequen industrial processing (pulp) could be considered as an energetic raw material for ration formulation in ruminant feeding systems. However, some strategies such as drying (i.e. meal) are recommended to increase feasibility of manipulation and conservation during long periods of time.

Table 1. Nutritive value of henequen pulp, fresh (HPF) or ensiled (HPE)

State of presentation	DM, %	CP, g/kg DM	CF, g/kg DM	ME, mcal/ kg DM	PDIMN, g/kg DM	PDIME, g/kg DM	Ca, g/kg DM	P, g/kg DM
HPF	16.8	72	204	2.62	51.1	73.1	58.0	4.0
HPE	20.0	60	280	2.50	48.0	68.0	50.0	0.4

PDIMN, microbial protein to be synthesized from degraded dietary N when energy is not limiting; PDIME, microbial protein synthesized from rumen fermented OM when degraded N is not limiting.

Key Words: nutritive value, ruminant, Henequen

W193 Economic weight of some production and functional traits of dairy cattle. F. Szabó*[1], Z. Fekete[1], J. Wolf[2], and M. Wolfová[2],

[1]*University of Pannonia Georgikon Faculty*, *Keszthely, Hungary*, [2]*Institute of Animal Science*, *Uhrinéves, Prague, Czech Republic*.

The objective of this study was to evaluate the marginal and relative economic values of 7 traits for dairy cattle. The importance of the study derives from more than 68% of cattle in Hungary belonging to the dairy industry. The study was conducted in 2009 using a bioeconomic model based on the program ECOWEIGHT (Wolf et al., 2005). Data were collected for typical dairy farms of about 330 Holstein- Friesian cows with annual milk yield close to 7,000 kg. Cows were managed in loose-housing systems with parlor milking, representing current commercial dairy enterprises. A total mixed ration based on maize silage and concentrates with some alfalfa hay was offered to 4 groups (first-, second-, third- phases of the lactation and a dry group). Besides the dairy enterprise, calf and replacement rearing were also taken into consideration. Income came from milk, calves, culled cows, and sale of manure. About 50% of the total cost was related to feed and the remainder was due to factors such as management, reproduction and health services, labor, interest and amortization. Annual revenues and costs were used for the economic calculations. Gross margin was the difference between income and variable costs. Marginal economic value of a given trait was defined as the partial derivative of the profit function and was standardized by multiplying by the genetic standard deviation of the trait. The relative economic values for traits were expressed as percentages of the standardized economic value of 305-d milk yield. The relative economic importance of the traits were as follows: 305-d milk yield, 100%; length of productive life, 52%; conception rate of cows, 35%; 305-d protein yield, 35%; 305-d fat yield, 21%; stillbirth, 13%; and pregnancy rate of replacements, 3%. It can be concluded that milk yield is currently the most economically important trait in Hungary.

Key Words: 305-d milk-, protein- and fat yield, length of productive life, conception rate

Lactation Biology 2

W194 Effect of feeding level and milking frequency in early lactation on milk production in dairy cattle. A. G. Rius*, J. K. Kay, C. V. C. Phyn, S. R. Morgan, and J. R. Roche, *DairyNZ*, *Hamilton, New Zealand*.

The objective was to evaluate the effects of feeding level (FL) and milking frequency (MF) in early lactation on milk production in grazing dairy cattle. Multiparous Holstein-Friesian cows (n = 120; ~31 DIM) offered an unrestricted allowance of fresh pasture (UnRes) and milked twice daily (2X) were randomly assigned to one of 4 treatments for 21 d in a 2 by 2 factorial arrangement - 2 FL of pasture (UnRes or a 50% restriction: Res) and 2 MF (once daily: 1X or 2X). After the treatment period, all animals received a generous allowance of pasture and were milked 2X for the remainder of lactation. Body weights (BW) and body condition scores (BCS) were recorded and milk samples collected once weekly. Main effects and interactions during treatment, and for 8 wk post-treatment, were tested using mixed models (GenStat 12.1). Interactions between FL and MF were detected ($P < 0.01$) for milk and protein yields during the treatment period. Decreases due to 1X were greater ($P < 0.01$) in UnRes than in Res cows for milk (4.8 vs. 2.2 kg/d), and protein (0.17 vs. 0.06 kg/d) yields. Upon cessation of treatments milk production was greater ($P < 0.01$) in UnRes cows compared with Res cows (18.4 vs. 17.1 kg/d) and in 2X compared with 1X (18.3 vs. 17.2 kg/d), but there was no interaction. Similarly, UnRes cows had greater ($P < 0.01$) fat (0.79 vs. 0.74 kg/d) and protein (0.67 vs. 0.62 kg/d) yields and 2X cows had greater ($P < 0.01$) fat (0.78 vs. 0.75 kg/d) and protein (0.66 vs. 0.63 kg/d) yields. Relative to their UnRes comparison, Res cows were lighter and thinner ($P < 0.01$; BW: 440 vs. 484 kg and BCS: 3.86 vs. 4.03; 10-point scale) and relative to 1X, 2X cows were lighter ($P < 0.01$; 460 vs. 468 kg) by the end of the treatment period. In summary, reducing milking frequency and the level of nutrition for 21 d in early lactation impaired milk production.

Key Words: milking frequency, grazing, milk production

W195 Expression of key metabolic indicators of energy metabolism across mammary gland development and lactation in dairy cows. L. J. Ren, H. L. Tong, Q. Z. Li, and X. J. Gao*, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

Appropriate energy supply is critical to normal growth and development of the mammary gland. To understand how key indicators of mammary gland metabolism change with physiological state, 39 primiparous dairy cows were allotted in 13 groups according to stage of mammary development (mo 2, 12, 14 of virgin, mo 2, 4, 6 of pregnancy, d 7, 50, 140, 280 of lactation and d 3, 30 of involution, and 3 animals per group). Mammary gland tissue samples were collected by paracentesis and the contents of important indicators in different periods including hexokinase(HK), glucose-6-phosphatase dehydrogenase (G-6-PDH), isocitrate dehydrogenase(ICDH), Na^+K+-ATPase, $Ca^{2+}Mg2$+-ATPase, triglyceride(TG), glucose(Glc), lactose(LAC), energy charge and NADPH were detected. LAC, energy charge and NADPH were detected by HPLC. Others were detected by the testing kits. In this test, qRT-PCR was used to detect those important genes which were related to lactation, including β–actin, sterol regulatory element binding protein-1(SREBP-1), acetyl CoA carboxylase(ACC), D-glucose transport 1(Glut1), AMP-activated protein kinase(AMPK), phosphoenolpyruvate carboxykinase(PEPCK), β–casein and signal transducers and activators of transcription 5(Stat5) in different mammary gland development periods of dairy cow. The results showed the different indicators reached the highest at different periods. For example, the activities of ICDH and G-6-PD both reached the highest at d 7 of lactation, but the activity of Na^+K+-ATPase reached the highest at d 280 of lactation. qRT-PCR showed that the expression of these genes was significantly higher at the period of lactation than other periods. In conclusion, according to the changes of metabolism indexes and the expression of these important genes, we can conclude energy metabolism in the course of mammary gland development and lactation of dairy cows.

Key Words: dairy cow, mammary gland, energy metabolism

W196 Insulin stimulates glucose uptake by regulating cell viability and expression of glucose transporter 8 gene in bovine mammary epithelial cells. K. Zhao, H. Y. Liu*, and J. X. Liu, *Institute of Dairy Science, MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University*, *Hangzhou 310029, P.R. China*.

Glucose transporter 8 (GLUT8) is expressed at high levels in the bovine mammary gland. Because the classical insulin responsive glucose transporter GLUT4 is not detected in the mammary gland of dairy cows, GLUT8 is postulated to be an alternative insulin responsive transporter. In this study, bovine mammary epithelial cells (BMEC) were used to examine the effect of insulin on cell viability and glucose uptake, and to verify the possible role of GLUT8 in insulin-regulated glucose uptake. The BMEC were cultured in DMEM/F12 medium containing 10% FCS, and treated with different levels of insulin (0, 5, 50, and 500 ng/ml) for 48 h after 24 h starvation without FCS. Viability of the cells was determined by MTT method. Glucose uptake and mRNA expression were determined by enzymatic coloring glucose oxidase/peroxidase assay, and by SYBR green method of real-time PCR, respectively. The viability of the cells was enhanced with the increasing level of insulin ($P < 0.05$), with highest value at 500 ng/ml. Compared with control, insulin (500 ng/ml) increased glucose uptake ($P < 0.05$), while expression of GLUT8 gene was elevated in all insulin-treated groups ($P < 0.05$). As predicted, expression of the GLUT1 gene, the predominant glucose transporter, was not affected by insulin ($P > 0.05$). In addition, insulin-induced glucose uptake was totally suppressed by the protein synthesis inhibitor, cycloheximide ($P < 0.05$). Pretreatment with LY294002, a specific inhibitor of PI3-K, for 30 min, significantly reduced the insulin-stimulated glucose uptake ($P < 0.05$). In contrast, SB203580, an inhibitor of p-38 MAPK, did not influence the insulin-induced glucose uptake ($P > 0.05$). These results indicate that GLUT8 is an insulin responsive transporter in BMEC. Insulin may stimulate glucose uptake primarily via regulating cell viability and thus expression of GLUT8 in BMEC. This effect may be mediated through PI3-K- linked signaling pathways.

Key Words: insulin, glucose transporter 8, bovine mammary epithelial cell

W197 Pathogen-specific and dose-dependent response of the bovine mammary gland to lipopolysaccharide from *E. coli* and lipoteichoic acid from *S. aureus*. R. M. Bruckmaier*, E. T. Arnold, and O. Wellnitz, *Veterinary Physiology, Vetsuisse Faculty, University of Bern*, *Bremgartenstr. 109a, 3001 Bern, Switzerland*.

Lipoteichoic acid (LTA) and lipopolysaccharide (LPS) are proinflammatory cell wall components expressed by gram-positive or gram-negative

bacteria, resp. This study was performed to investigate if intramammary challenge with LTA from S. aureus or LPS from *E. coli* elicits a different immune response. Five cows per group with somatic cell counts (SCC) below 100 × 103/ml were intramammarily challenged in one quarter with 10 or 20 μg of LTA or 0.2, 1, or 10μg LPS in 10 mL saline solution (0.9%). At 0, 6, and 12 h after challenge biopsy samples of the mammary gland or milk cells from 1 L of milk were taken for mRNA expression measurements of immune factors by quantitative RT-PCR. Additionally, from cows that received no biopsy small milk samples (~5mL) were taken hourly. Differences between treatments and time points were considered as significant if $P \leq 0.05$. SCC increased in all treatments within 4 h. The increase of SCC, tumor necrosis factor α (TNFα), and lactate dehydrogenase (LDH) in milk was dose dependent. TNFα concentration in milk did not increase in LTA-treated quarters. mRNA expression of TNFα, interleukin (IL)-8 and IL-1β increased dose dependently in mammary tissue and in milk cells. This effect was more pronounced in milk cells compared with the tissue within the same dosage. The results show that LPS induced a stronger response of the measured factors than LTA in dosages with the induction of a similar SCC response. A low dosage of LTA induced a SCC increase but hardly any response of the measured factors. In addition, milk cells showed a stronger immune response to the same concentration of LPS than the mammary tissue. This reflects the situation during an infection of the mammary gland where the first reaction of the immune system is realized by the somatic cells which are already present in the milk before challenge. Then the bacteria or endotoxins must exceed a certain level to induce an immune response of milk cells as well as of mammary tissue. In conclusion, the immune response of the mammary gland is dependent on toxin type and dosage.

Key Words: mastitis, lipoteichoic acid, lipopolysaccharide

W198 Greater milk yield is related to increased DNA and RNA content but not to mRNA abundance of selected genes in sow mammary tissue. C. Farmer*[1], M. F. Palin[1], J. F. Trott[2], and R. C. Hovey[2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre*, *Sherbrooke, QC, Canada*, [2]*Dept. of Animal Science, University of California*, *Davis*.

The relationship between greater sow milk yield and mammary development, expression of selected genes in mammary tissue and serum hormone concentrations in lactating sows was studied. Crossbred sows were separated into 2 groups according to weight gains of their piglets up to d 21 of lactation. Groups were: 1) lower milk yield (LOW, n = 14) or 2) higher milk yield (HI, n = 14), representing lactation weight gains of 4.47 and 5.24 kg/pig, respectively. Jugular blood samples were obtained from all sows on d 3 (for prolactin determination) and 23 (for measures of prolactin, leptin, insulin, glucose and free fatty acids) of lactation. Milk samples were collected on d 3 and 22 of lactation for compositional and leptin analyses. At weaning (d 23), sows were killed and their mammary glands collected, dissected and composition determined. Mammary parenchymal tissue was analyzed for the mRNA abundance of selected genes, namely, porcine prolactin (pPRL), pPRL receptor (all isoforms and the long isoform alone), STAT5A, STAT5B, whey acidic protein and leptin. On d 3 of lactation, jugular concentrations of prolactin tended to be greater ($P = 0.1$) while dry matter and leptin in milk were less ($P < 0.05$) in HI than LOW sows. There was a tendency for HI sows to have more parenchymal tissue per teat ($P < 0.1$) than LOW sows. Parenchymal tissue contained less fat ($P < 0.05$) and there was more DNA and RNA per teat in HI than LO sows ($P < 0.05$). On the other hand, the expression of selected genes within mammary tissue was unaffected ($P > 0.1$) by treatment. Sow milk yield therefore directly reflects mammary gland composition in late lactation.

Key Words: genes, milk yield, sow

W199 5′-untranslated region haplotypes of beta-2-microglobulin exon IV in Chinese Holstein dairy cows and its association with IgG1 concentration and mass in milk. C. Zhang*1,2, G. Liu[1], J. Wang[1], D. Bu[1], L. Zhou[1], S. Zhao[1], and Y. Yang[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*College of Animal Science and Technology, Yangzhou University*, *Yangzhou, China*.

Production and transfer of IgG into milk is an important area of study because of its biological functions including opsonization, complement fixation, prevention of adhesion of pathogenic microbes to endothelial lining, inhibition of bacterial metabolism, agglutination of bacteria, and neutralization of toxins and viruses. In the mammary gland, IgG is transferred selectively from serum into milk by a neonatal Fc receptor (FcRn)-mediated mechanism. Beta-2-microglobulin (β2MG) is an integral component of the FcRn heterodimer, which has prominent roles in IgG transfer across mammary epithelial cells. This study examined mutations in the 5′-untranslated region (5′UTR) of β2MG exon IV and its association with variation of IgG1 concentration and mass in milk. One hundred and eighty-nine Holstein dairy cows in lactation were used to determine the genetic diversity of 5′UTR. Two single nucleotide polymorphisms (SNPs) and insertion/deletion (indel) of 2 base pairs were identified by sequencing the 5′UTR of β2MG exon IV and were assigned into 4 haplotypes. These haplotyes were evaluated with respect to IgG1 concentration and mass in the milk. These results demonstrated a significant association between β2MG genotypes and concentration and mass of the milk IgG1 ($P < 0.05$). Dairy cows homozygous with a double base-pair deletion (H3H3) had similar serum IgG1 concentration with other genotypes, but significantly lower milk IgG1 concentration and mass ($P < 0.05$). These results suggest that β2MG genotypes might serve as a marker of IgG1 production and distribution.

Key Words: beta-2-microglobulin gene, immunoglobulin G1, path analysis

W200 How does increased milking frequency stimulate milk production? M. Dehghan-Banadaky*, M. Eslamizad, K. Rezayazdi, H. Kohram, and R. Heydari, *University of Tehran*, *Karaj, Tehran, Iran*.

We tested the hypothesis that frequent milking stimulates milk production through increased prolactin secretion. Multiparous (n = 105) and primiparous (n = 15) Holstein cows were used in a completely randomized design and assigned at calving to 1 of 3 treatments as follows: 1) 6 times a day milking for the entire lactation (6X); 2) 6 times a day milking for 90 DIM, then switched to 3 times subsequently (6X-3X); and 3) 3 times a day milking for the entire lactation (3X). Milk production was recorded every other day for the first 60 DIM and subsequently on 2 consecutive days a week. Blood samples were taken from each cow on 15, 30, 60, 90, 120, 150, 210, and 270 DIM. Plasma prolactin concentrations were determined using a double antibody radioimmunoassay procedure. Data were statistically analyzed using the repeated measures option in Proc Mixed of SAS with cow as a random effect. Milk and fat corrected milk (FCM 3.5%) yield were greater in 6x and 6x-3x cows than in 3x treatments (41.03, 42.3; 40.11, 40.60 VS 37.97, 38.40 kg/d, respectively). Plasma concentrations of prolactin were 57.73 ± 1.32, 59.62 ± 1.64, and 58.87 ± 1.73 ng/ml in 6x, 6x-3x, and 3x cows, respectively. Increased milking frequency did not alter the concentration of plasma prolactin at any sampling time ($P = 0.53$). In

conclusion, results of the present study did not support the hypothesis that increased milking frequency stimulates milk production through increased prolactin.

Key Words: milking frequency, prolactin, Holstein cow

W201 Impact of duration of milk storage in the mammary gland on milk composition throughout milking . M. Dutreuil[1,2], C. Cébo[3], J. Guinard-Flament[2,1], and C. Hurtaud*[1,2], [1]*INRA UMR1080 Production du lait*, *Saint-Gilles, France*, [2]*Agrocampus Ouest UMR1080 Production du lait*, *Rennes, France*, [3]*Unité GABI*, *Jouy-en-Josas, France*.

Our objective was to study the effect of duration of milk storage in the mammary gland on milk composition throughout milking. Three durations of milking storage were studied on 6 dairy cows averaging 118 ± 22 DIM: 13-, 20-, and 24-h. The trial was carried out according a double Latin square 3′3 with 14 d periods. Yield and composition were measured on milk samples collected every min during morning milking on d 10 of each period. Statistical analysis was carried out using the Proc Mixed procedure in SAS software with repeated statement. Milk yield, lactose content, milk protein yield and content remained unchanged between treatments. Milk fat content and lipolysis did not vary according to the duration of milk storage. In contrast, there is a significant interaction between duration of milk storage and kinetics of milk ejection for 2 parameters: fat yield and specific MFG area. Milk fat yield increased during the whole milking for the 13-h milk storage whereas it started to decrease at the end of milking for 20- and 24-h milk storages. The specific MFG area decreased less during milking for the 24-h milk storage. The lipolysis, measured by method of copper soap, decreased during milking whereas the milk fat content and milk fat globule diameter increased (respectively from 1.45 to 7.55% and from 3.1 to 4.1 μm). Variations in the profile of milk fatty acids were also noticed as an increase in desaturation activity of the mammary gland (increase of C14:1/C14:0 ratio) during milking. In conclusion, there is a great change in milk composition during milking. But duration of milk storage in the mammary gland induced no important change on the kinetics of milk secretion.

Key Words: milk composition, milk fat globule, milking

W202 Effects of Actigen supplementation on mRNA levels of mucin and markers of gut health in the jejunum of broiler chicks. K. M. Brennan*, T. Ao, J. L. Pierce, and K. A. Dawson, *Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech Inc.*, *Nicholasville, KY*.

Previous studies in our lab have indicated that the addition of Actigen, a yeast-derived feed supplement, to the diet positively affects gut health including increasing goblet cell size and small intestinal mucin secretion. Based on these data, the objective of this study was to compare the effects of supplementing Actigen and bacitracin methylene disalicylate (BMD) in the diet on mRNA levels of mucin and mucin-regulating genes in the jejunum of 6-week old chickens. Dietary treatments included 1) corn-soy control diet; 2) Diet 1 plus Actigen; 3) Diet 1 plus BMD. Chicks (n = 7) from each dietary treatment were randomly selected and killed at d42. Jejunum samples were rinsed and placed in RNAlater, then transferred to −20°C freezer until further analysis. Total RNA was isolated from stored tissue, treated with DNase and reverse transcribed into cDNA. mRNA levels of target genes were measured using real-time PCR and normalized to the housekeeping gene mitochondrial ribosomal protein L48 (MrpL48). Target genes included mucin 2 (cMUC2), keratinocyte growth factor 7 (KGF7), interleukin 18 (IL18), tumor necrosis factor α (TNFα) and toll-like receptors 2 and 5 (TLR2 and TLR5), 2 key markers for pathogenic insult in the gut. cMUC2 mRNA levels tended to be 1.29-fold greater in Actigen and BMD-treated birds than controls ($P < 0.10$). mRNA levels of mucin-regulating genes, IL18 and KGF7, were similar between Actigen and BMD treated birds. TLR2 and TLR5 mRNA levels were greater (1.20-fold and 1.23-fold, respectively) in BMD-treated birds than control. These data indicate that Actigen and BMD have similar effects on the mRNA levels of mucin and mucin-regulating genes in the jejunum of broiler chicks.

Key Words: mucin, broiler, gene expression

W203 Age changes in gastrointestinal pH in broilers. R. Angel*[1], B. Humphrey[2], and W. Saylor[3], [1]*University of Maryland*, *College Park,* [2]*California Polytechnic State University*, *San Luis Obispo,* [3]*University of Delaware*, *Newark*.

pH was measured in the different segments (crop, proventriculus, gizzard, duodenum, jejunum, ileum, ceca, large intestine) of the gastrointestinal tract (GIT) of broiler chickens, at different ages over 15 studies done over 2 years. Direct comparisons (same source of birds, same water and feed) of intestinal pH between broilers in batteries and floor pens were done. At least 2 and up to 5 birds by age and study were sampled. In 3 initial studies the pH was measured using 2 protocols: In situ, by inserting the pH probe (2 measurements) into the middle area of each region; and Ex situ, by inserting the pH probe (2 measurements) into intestinal contents diluted in distilled, deionized water (1:2.5 wt:wt ratio). Feed was also diluted in water (1:2.5 feed to water ratio) for pH determination (2 measurements) and facility water pH documented. Statistical analysis was run within study and between studies as one way ANOVA. Facility water pH was used as a covariate. The in situ method resulted in lower pHs for most GIT segments measured and always resulted in lower standard deviations. Given this the remaining of the work was done using only in situ measurements. Variability between birds was high. For example, at 5 d of age, where 5 birds were sampled, crop, gizzard, proventriculus, duodenum, jejunum, and ileal pH was 5.32, 2.37, 2.14, 5.99, 6.07, and 7.12, respectively and the standard deviation was 0.54, 0.92, 0.24, 0.28, 0.14, 0.12. pH decreased $P < 0.05$ after 5 d of age primarily in the proventriculus and gizzard (pH at 14 d of age was 1.15 and 1.90 in the proventriculus and gizzard, respectively). By 18 d of age the pH in the proventriculus and gizzard was similar ($P > 0.05$) to that at 5 d of age (2.50 and 2.64, respectively). By 46 d of age crop, gizzard, proventriculus, duodenum, jejunum, and ileal pH was not different ($P > 0.05$) from those at 5 d (5.85, 2.04, 2.36, 5.87, 5.97, and 7.15, respectively). It is possible that differences between ages were not found due to the high variation seen between birds. No clear patterns of change were seen between battery and floor pen raised broilers. Facilities water pH has the most impact on crop pH.

Key Words: broilers, gastrointestinal, pH

W204 Adaptive response in intestinal function in species with different dietary habits. D. J. Batchelor*[1], J. Brand[2], and S. P. Shirazi-Beechey[1], [1]*University of Liverpool*, *Liverpool, UK*, [2]*Monell Chemical Senses Center*, *Philadelphia, PA*.

The domestic cat (*Felis catus*) a carnivore, naturally eats a very low carbohydrate diet. In contrast the dog (*Canis familiaris*) a carno-omnivore is adapted to eat a varied diet. While cats appear to suffer from carbohydrate malabsorption following ingestion of high carbohydrate meals, dogs are able to cope with the diet containing higher levels of carbohydrate. The major aims were to determine expression (this includes function) of intestinal sodium/glucose cotransporter, SGLT1, and the brush border membrane disaccharidases, sucrase, lactase and, maltase in response to such contrasting diets. We first cloned and sequenced cat SGLT1, to determine its amino acid sequence and facilitate the production of a suitable antibody to cat SGLT1. We then measured the expression, and/or kinetics of SGLT1, sucrase, maltase and lactase, as appropriate, either by quantitative immunohistochemistry of fixed tissues or in purified brush border membrane vesicles. Intestinal tissues of healthy cats, n = 10 and dogs, n = 12 were provided by the University of Pennsylvania School of Veterinary Medicine and Monell Chemical Senses Center in Philadelphia. Animals had been euthanized, with the approval of the University Animal Care and Use Committee, for using the tissues for research purposes. Results: Feline SGLT1 amino acid sequence is closely related to that in other species; most notably to canine SGLT1. SGLT1 expression is 2-fold higher in the intestine of dogs compared with cats ($P < 0.001$), this is reflected in 2-fold increase in Vmax. Sucrase and maltase activity are (both 3-fold, $P = 0.0015$ and < 0.001, respectively) higher in dog intestine compared with cat; with dogs also retaining higher (1.6-fold, $P = 0.019$) lactase activity. The higher expression of SGLT1 and disaccharidases in dog intestine is not due to any structural changes; villus height and crypt depth are the same in cats and dogs. This study shows that dogs, in contrast to cats, have a higher capacity to digest and absorb carbohydrates.
Financial support of the Biotechnology and Biological Sciences Research Council and Pfizer Ltd is gratefully acknowledged.

Key Words: intestinal adaptation, glucose transport, disaccharidase

W205 Performance, nutrient utilization and gizzard development of broiler starters fed diets containing ground or whole corn. Y. Singh, T. J. Wester, G. Ravindran, and V. Ravindran*, *Massey University, Palmerston North, New Zealand*.

The influence of including 20% whole corn, differing in grain hardness, on the performance, nutrient utilization and gut characteristics of broiler starters was investigated. The experimental design was a 3 × 2 factorial arrangement of treatments evaluating corn hardness (hard, semi hard or soft) with diets based on ground corn or 20% of ground corn replaced by whole corn. The 3 corn cultivars were ground in hammer mill to pass through a 4 mm sieve and 6 diets were developed. Following mixing, all diets were cold pelleted. Each diet was fed to 6 replicate cages (8 birds per cage) from d 1 to 21 post hatch. Body weights and feed intake were recorded on a cage basis at weekly intervals. Mortality was recorded daily and data was corrected for mortality. Corn hardness and whole corn inclusion had no effect ($P > 0.05$) on the weight gain. Corn hardness had significant effect ($P < 0.05$) on feed intake and feed per gain, while these 2 parameters were unaffected ($P > 0.05$) by the inclusion of whole corn. Birds tended ($P = 0.08$) to consume more of the diets based on hard-corn than those based on soft-corn. Feed intake of diets based on semihard-corn did not differ ($P > 0.05$) from those based on hard- or soft-corns. Feed per gain of birds fed diets based on soft-corn was lower ($P > 0.05$) than those fed diets based on semihard-corn. Feed per gain of birds fed diets based on hard-corn was similar ($P > 0.05$) to those fed diets based on hard- and soft-corn. Inclusion of whole corn increased ($P < 0.05$) relative gizzard weights. The relative gizzard weights of birds fed hard- and semihard corn diets were higher ($P < 0.05$) than those fed the soft corn diets. Dietary AME was not influenced by dietary treatments. Ileal nitrogen digestibility was influenced ($P < 0.05$) by hardness, with soft corn diets having higher digestibility. Overall, these results indicate that 20% of whole corn can be substituted for ground corn in broiler starter diets with no adverse effects on growth performance

Key Words: whole corn, gizzard, broiler

W206 The effect of dietary vitamin C on growth performance, meat quality, immune function and antioxidant capacity of broilers. F. Z. Liu*, Z. Y. Niu, X. H. Wang, Y. N. Min, and H. Y. Wang, *College of Animal Science and Technology, Northwest A &F University, Yangling,Shaanxi, 712100 P. R. China*.

The purpose of this study was to evaluate the effect of dietary vitamin C on growth performance, meat quality, immune function and antioxidant capacity of 42-d-old broilers. Two hundred forty one-day-old broiler chicks were randomly divided into 3 treatments with 8 replicates of 10 birds. Birds were fed a corn-soybean meal basal diet supplemented with 0, 150, or 300 mg/kg vitamin C. The trial period was 42 d. We determined the index of growth performance, meat quality, immune function and antioxidant capacity of broilers in the experiment. Dietary Vitamin C supplementation significantly increased the ADG and ADFI of broilers ($P < 0.05$), but feed/gain ratio was not significantly affected ($P > 0.05$). Compared with the control diet, adding 300 mg/kg of vitamin C increased the breast muscle weight, declined the abdominal fat weight and liver weight ($P < 0.05$). The trail groups significantly increased the b* value of breast muscle, reduced the L* value of leg muscle ($P < 0.05$), and also had beneficial effect on the water-holding capacity and tenderness of leg muscle, and improved the quality of the chicken meat. Adding 300 mg/kg of vitamin C improved thymus index, bursa of Fabricius index and Newcastle disease antibody level compared with control-fed birds ($P < 0.05$). Compared with the control group, the vitamin C concentration in serum and breast muscle, the SOD, GSH-PX activity and A-TOC level were significantly higher in the 300 mg/kg supplementation ($P < 0.05$).

Key Words: vitamin C, growth performance, broilers

W207 Quality and oxidative stability of vitamin E enriched chicken meat. Z. Y. Niu[1], X. H. Wang[1], Y. N. Min[1], F. Z. Liu*[1], and H. Y. Wang[2], [1]*College of Animal Science and Technology, Northwest A &F University, Yangling, Shaanxi, 712100 P. R. China*, [2]*Yulin Municipal Animal Husbandry Bureau, Yulin, Shaanxi, 719300 P.R. China*.

The objective of this work was to evaluate the quality and oxidative stability of vitamin E enriched-chicken meat. Two hundred forty one-day-old Avian broiler chicks were allocated to 3 treatments, one is the control group fed the basal diet, the other 2 fed the dietary vitamin E supplementation diet, containing 100, 200 mg/kg vitamin E respectively. Broilers were raised to 42 d. We determined the meat quality, the activities of antioxidant enzymes in serum and tissues and the MDA concentration of the breast muscle during the refrigeration. The result showed the dietary vitamin E supplementation has a positive effect on the meat quality of broiler chickens. The 100 mg/kg vitamin E supplementation increased the tenderness, yellowness (b*) of the breast muscle, declined the water-loss rate, lightness (L*) and yellowness (b*) of the leg muscle significantly ($P < 0.05$). Dietary vitamin E supplementation increased the concentration of vitamin E in serum and muscle, and then took effect on the antioxidation enzyme system, improved the activity of SOD and T-AOC, declined the MDA generation. The 200 mg/kg vitamin E supplementation had significantly improved the antioxidation ($P < 0.05$) and had more active effect than the 100 mg/kg supplementation. Dietary vitamin E supplementation improved the oxidative stability of meat refrigerated at 4°C, deferred the lipid oxidation. The TBARS in breast muscle of the dietary vitamin E supplementation group was significantly lower than the control group at the 8th d ($P < 0.05$).

Key Words: vitamin E, meat quality, broilers

W208 Dietary preferences of acids and salts in piglets. J. A. Suárez*[1], E. Roura[2], and D. Torrallardona[1], [1]*IRTA-Centre Mas de Bover, Constantí, Spain*, [2]*Lucta S.A., Barcelona, Spain*.

Compromised voluntary feed intake of piglets in the post-weaning period might be improved by increasing feed palatability. Eighteen double choice tests with a total of 600 post-weaned pigs (20–25 kg BW), were conducted to determine preference for 14 acids and 4 salts compared with a control (REF) diet. Each test was performed using 8 or 9 pens (replicates) of 3–4 pigs that were offered simultaneous access to 2 feeding hoppers (REF diet or diet containing one of the products (AC) being tested). Each test was performed during 3 consecutive 4d-periods, in which low, medium and high inclusion rates of the AC were evaluated, respectively. The AC were tested at 0.5, 1 and 1.5% of inclusion, except for benzoic and succinic acids that were tested at 0.25, 0.5 and 1%, and potassium diformate that was tested at 0.5, 1 and 2%. The preference for each AC and dose compared with REF was calculated as the percentage contribution of the AC diet to total feed intake. Mean preference values were compared with the neutral value of 50% using the Student's *t*-test. Values are presented in brackets ordered by increasing doses and those

with an asterisk are significantly ($P < 0.05$) different from 50%. Acids that improved feed preference (%) include the medium doses of citric (59.0, 69.8*, 56.8) and tartaric acids (54.2, 73.4*, 67.5) and the high doses of potassium diformate (57.2, 58.5, 65.9*) and sodium propionate (55.1, 58.1, 58.2*). There were no significant effects on feed preference with ascorbic (47.8, 49.6, 41.9), benzoic (45.0, 48.4, 50.8) and malic (50.0, 48.9, 34.8) acids or sodium butyrate (42.4, 51.1, 48.3). Finally, negative effects on feed preference were found with all the doses of acetic (32.5*, 29.9*, 16.6*) and caproic (29.1*, 27.8*, 22.1*) acids and some doses of butyric (35.9, 43.5, 21.2*), caprilic (33.0, 33.2*, 14.7*), formic (39.9, 35.6*, 24.9*), lactic (51.3, 38.4, 35.6*), phosphoric (28.9*, 34.4*, 35.6), propionic (52.1, 37.0, 25.6*) and succinic (36.9*, 41.6, 51.9) acids and calcium formate (29.9*, 35.8*, 38.1). We conclude that some AC significantly affect feed preference in pigs.

Key Words: acidifiers, palatability, feed intake

W209 Impact of different nutrients on the development of hyperhomocysteinemia in neonatal piglets. M. E. Côté-Robitaille*[1,2], C. L. Girard[1], F. Guay[2], and J. J. Matte[1], [1]*Dairy & Swine R & D Centre, Agriculture and Agri-Food Canada*, *Sherbrooke(STN-Lennoxville), QC, Canada*, [2]*Department of Animal Sciences, Laval University*, *Quebec city, QC, Canada*.

The present experiment aimed to determine if the rapid post-natal development of hyperhomocysteinemia in piglets can be regulated by exogenous dietary provision of nutrients involved in homocysteine (Hcy) metabolism as methyl donors (betaine and choline), methyl user (creatine), or for catabolism (vitamin B_6). Those nutrients were given either separately or in association. Twenty sows were artificially inseminated and fed gestation and lactation diets supplemented with folic acid (10 mg/kg) and vitamin B_{12} (200 ug/kg). At birth, piglets were identified and weighed. A blood sample was also taken before ingestion of colostrum to measure plasma Hcy concentration. Eight piglets in each litter received daily an oral liquid bolus of one of the 8 following treatments: 1) saline, 2) betaine (50 mg/kg BW), 3) choline (70 mg/kg BW), 4) creatine (300 mg/kg BW), 5) pyridoxine (200 ug/kg BW), 6) treatments 2 and 5, 7) treatments 3 and 4, 8) treatments 2, 3, 4 and 5. During lactation, piglets were weighed and blood samples were collected on d 1, 7, 14 and 21. Growth from birth to 21 d of age was not influenced by treatments ($P = 0.13$). Overall plasma concentration of Hcy was very low at birth (2.49 ± 0.17 μ*M*), increased sharply at 8.33 ± 0.93 μ*M* within 24 h and at 14.21 ± 0.99, 18.28 ± 1.00 and 18.05 ± 0.81 μ*M* at 7, 14 and 21 d of age, respectively. Treatment 8 decreased ($P = 0.05$) plasma Hcy concentration by 23% as compared with treatment 1 but there was no interaction between treatments and age ($P = 0.11$). Hcy profiles in other treatments did not differ ($P = 0.09$) from that of saline. Therefore, plasma Hcy concentrations were markedly reduced by combination of all nutrients. Nevertheless, even minimum values remained high (over 15 μ*M*) as compared with other species (3 to 10 μ*M*, in cows, rats and humans) and the question remains, as whether hyperhomocysteinemia, an unhealthy condition for those young and fragile animals, is harmful for piglets or inversely, whether a greater reduction of plasma Hcy is beneficial. This need to be assessed with further criteria of post-natal growth and development using a large number of animals.

Key Words: homocysteine, growth, suckling piglets

W210 Effects of fermented soybean meal on growth performance, nutrient digestibility, blood profiles and fecal microorganisms in weanling pigs. J. H. Lee*, J. S. Yoo, H. J. Kim, Q. W. Meng, S. M. Hong, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of 2 types of fermented soybean meal on growth performance, nutrient digestibility, blood profiles and fecal microorganisms in weanling pigs. A total of 144 [(Landrace × Yorkshire) × Duroc] pigs (6.66 ± 0.29kg) were randomly allocated to 6 treatments with 6 replications per treatment and 4 pigs per pen. The experiment lasted for 6 weeks and consisted of 2 phases. The dietary treatments were as follows: Phase1 (0–3 wk) 1) FSA1 (basal diet + 5% fish meal + 5% fermented soybean meal with *Aspergillus oryzae*), 2) FSB1 (basal diet + 5% fish meal + 5% fermented soybean meal with *Bacillus subtilis*), 3) SPC (basal diet + 5% fish meal + 5% SPC), 4) FSA2 (basal diet + 2.5% fish meal + 7.5% fermented soybean meal with *Aspergillus oryzae*), 5) FSB2 (basal diet + 2.5% fish meal + 7.5% fermented soybean meal with *Bacillus subtilis*), 6) FSB3 (basal diet + 1% fish meal + 9% fermented soybean meal with *Bacillus subtilis*); phase 2 (3–6 wk) 1) FSA1 (basal diet + 2% fish meal + 4% fermented soybean meal with *Aspergillus oryzae*), 2) FSB1 (basal diet + 2% fish meal + 4% fermented soybean meal with *Bacillus subtilis*), 3) SPC (basal diet + 2% fish meal + 4% SPC), 4) FSA2 (basal diet + 1% fish meal + 5% fermented soybean meal with *Aspergillus oryzae*), 5) FSB2 (basal diet + 1% fish meal + 5% fermented soybean meal with *Bacillus subtilis*), 6) FSB3 (basal diet + 6% fermented soybean meal with *Bacillus subtilis*). During phase 1 (0–21d), the ADG was higher ($P < 0.05$) in the SPC group than the FSB3 group and its G:F ratio was increased ($P < 0.05$) when compared with other treatments. The DM and N digestibility was highest ($P < 0.05$) in the FSB1 group during wk 0–3. The DM and N digestibility were highest in the FSB2 group. Fermented soybean meal had no effects on the blood profiles except that it led to lower creatinine levels ($P < 0.05$) in the FSM group. Overall, the results of this experiment revealed that fermented soybean meal could partially replace fish meal in the diets of weanling pigs.

Key Words: fermented soybean meal, digestibility, weanling pigs

W211 Effects of probiotics (Agarie) supplementation on growth performance, nutrient digestibility, fecal microbial, fecal noxious gas emission and blood characteristics of finishing pigs. J. H. Jung*, J. H. Lee, J. P. Wang, X. Ao, S. M. Hong, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of probiotics (Agarie) supplementation on growth performance, nutrient digestibility, fecal microbial content, fecal noxious gas emission and blood characteristics of finishing pigs. A total of 60 pigs [(Landrace × Yorkshire) × Duroc, initial body weight 56.48 ± 1.66kg)] were used for this 42 d feeding trial. Dietary treatments included 1) CON (basal diet), 2) P1 (CON + 0.1% probiotics) and 3) P2 (CON + 0.2% probiotics). There were 3 dietary treatments with 5 replicate pens per treatment and 4 pigs per pen. There was no significant difference in the ADG observed among the groups ($P > 0.05$). The G:F ratio was higher in the P2 group than the CON group ($P < 0.05$). P2 treatment showed a higher dry matter and energy digestibility value than the CON and P1 groups ($P < 0.05$). No significant differences were observed in the fecal Lactobacillus levels among the groups; however, the fecal *Escherichia coli* levels were lower in the P2 group than the CON group ($P < 0.05$). The ammonia, H_2S and total mercaptan levels were higher in the P1 and P2 groups than the CON group ($P < 0.05$). Blood characteristics were not affected by probiotics ($P > 0.05$). In conclusion, the results showed that supplementation of the diet with 0.2% probiotics influenced the G:F ratio, dry matter,

energy digestibility, fecal *Escherichia coli* and fecal noxious gas levels in growing pigs.

Key Words: probiotics, digestibility, pigs

W212 Effect of type of grinding of barley and alfalfa hay on jejunal histology and crude mucin excretion of growing rabbits. C. Romero[1], N. Nicodemus[1], J. D. Rodriguez[1], A. I. Garcia[2], G. G. Mateos*[1], and C. de Blas[1], [1]*Universidad Politecnica de Madrid*, *Madrid, Spain*, [2]*NUTRECO Poultry and Rabbit Research Center*, *Casarrubios del Monte, Spain*.

The aim of this work was to test the effects of particle size of barley and alfalfa hay on jejunal histology and mucin dynamics in fattening rabbits. The basal diet contained 27.5% alfalfa hay, 24.0% barley, 19.9% sunflower meal and 15.0% sugar beet pulp. There were 4 treatments arranged in a factorial structure 2 × 2 with grinding (coarse, 4.5 mm vs. fine, 1.5 mm) and ingredient (barley vs. alfalfa hay) as main effects. Percentage of large particles (>0.315 mm) ranged from 48.8 to 54.1% DM as diets contained finely or coarsely ground ingredients. Thirty-two rabbits (8 rabbits/treatment) were fed these diets from weaning (35 d; 877 ± 81 SD g BW) to slaughter (46 d; 1430 ± 180 SD g BW). Villi height decreased by 13.1% when rabbits received the diet containing alfalfa hay ground coarsely (704 vs. 612 μm; $P < 0.05$). Moreover, rabbits fed diets including coarse alfalfa hay had deeper crypts (121 vs. 92.1 μm; $P < 0.05$) and lower villus to crypt ratios (5.08 vs. 7.66; $P < 0.001$) compared with those fed the diets based on fine alfalfa hay. An increase in crude mucin excretion (from 12.6 to 21.7 g DM; $P < 0.01$) was observed in rabbits fed the coarse barley diet when alfalfa hay was ground coarsely. Nitrogen concentration in crude mucin excreted was unaffected by treatment (4.00% DM on average). In parallel with results for crude mucin, an increase in sialic acid excretion (from 43.2 to 72.2 mg; $P < 0.01$) was observed in rabbits fed the coarse barley diet when alfalfa hay was also ground coarsely. The present work determines a mean value of 4.45 g N/kg DMI for endogenous ileal nitrogen flow in growing rabbits when results of both crude mucin excretion and its N content are considered. In conclusion, the diet containing coarsely ground barley (4.5 mm) and finely ground alfalfa hay (1.5 mm) slightly enhanced jejunal mucosa morphology and decreased ileal crude mucin excretion.

Key Words: growing rabbit, dietary particle size, crude mucin

W213 Effects of freeze-dried *Lactobacillus reuteri* M8 on growth performance and intestinal microflora in broiler chickens. D. Y. Zhang, H. F. Ji*, S. X. Wang, J. Wang, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences*, *Beijing, China*.

The objective of this study was to evaluate the effect of supplementation of freeze-dried *Lactobacillus reuteri* M8 on growth performance and intestinal microflora of broilers. The strain M8 was isolated from the cecum mucosa of healthy Beijing You Fowl in our laboratory. Ninety, one-day-old, unsexed Avian broilers (45.20 ± 0.10 g BW) were randomly distributed into 3 groups with 3 replicates per group and 10 broilers per replicate comprising of control (basal diet), 20 mg/kg zinc bacitracin supplementation (antibiotic diet), and 0.3% freeze-dried *L. reuteri* M8 supplementation treatment. The experiment lasted 42 d. The ADG, ADFI, and feed conversion ratio were determined at 21 and 42 d, the intestinal microflora was measured at the end of the experiment. The results showed that there were no significant differences on ADG, ADFI, and feed conversion ratio among the treatments during the first 3 wk. However, birds fed the diet containing freeze-dried *L. reuteri* M8 had improved ($P < 0.05$) ADG compared with control fed broilers (82.77 vs. 77.85 g/d) and the antibiotic fed group (82.77 vs. 79.55 g/d) during 21 to 42 d of age, and there was no difference between control diet and antibiotic diet. Feeding the diet containing freeze-dried *L. reuteri* M8 significantly increased the number of *Lactobacilli* in the cecum mucosa compared with either control (9.87 vs. 8.76 cfu/g, $P < 0.01$) or antibiotic (9.87 vs. 9.68 cfu/g, $P < 0.05$) groups. While no difference in the number of *Lactobacilli* existed in faeces. The numbers of *Escherichia coli* in the cecum mucosa and feces were not significantly affected by diet. This experiment indicated that *L. reuteri* M8 would be a beneficial bacterium with regard to enhancing growth performance and improving intestinal bacteria of broilers.

Key Words: *Lactobacillus reuteri*, growth performance and intestinal microflora, broiler chickens

W214 Weaned piglet responses to *Escherichia coli* K88$^+$ (ETEC) oral challenge when fed diets containing a *Saccharomyces cerevisiae* fermentation product with or without in-feed antibiotics. E. Kiarie*[1], S. Bhandari[1], D. O. Krause[1], M. Scott[2], and C. M. Nyachoti[1], [1]*University of Manitoba*, *Winnipeg, MB, Canada*, [2]*Diamond V Mills*, *Cedar Rapids, IA*.

Ninety weaned piglets (17 d of age; 5.5 ± 0.19 kg BW) were used to investigate the effects of a *Saccharomyces cerevisiae* fermentation product on the growth performance and gastrointestinal (GIT) measurements upon *Escherichia coli* K88$^+$(ETEC) oral challenge. Pigs (3/pen) were randomly allotted to one of 6 diets with 5 replicate pens/diet. Treatments were: negative control (NC, no additives), positive control (PC, 0.04% chlortetracycline + 0.004% Denagard, Novartis Inc., Canada), *S. cerevisiae* fermentation product (NC+0.2% XPC, Diamond V Original XPC, Cedar Rapids, IA), and PC+XPC (0.1, 0.2, or 0.4% XPC). On d 7, pigs were orally inoculated with a 6 mL dose of 2×10^9cfu/ml of ciprofloxacin-resistant ETEC. On d 10 and 14, performance measures were recorded and GIT samples were obtained. Before challenge, pigs receiving additives (PC, XPC, PC+XPC) had higher ($P < 0.05$) ADG and G:F compared with NC pigs (227, 194, 234, 242, 237 vs. 161 g/d; 0.79, 0.77, 0.85, 0.82, 0.88 vs. 0.66 g/g, respectively). Pigs fed NC+0.2% XPC did not differ ($P > 0.10$) in performance from PC+0.2% XPC pigs. After challenge (d 8–10), ADG and ADFI were higher ($P < 0.05$) for pigs receiving additives compared with NC (187, 170, 371, 231, 233 vs. 138 g/d; 291, 357, 409, 351, 397 vs. 312 g/d, respectively). Day 8–14, ADG and ADFI were higher ($P < 0.05$) for pigs receiving all additives compared with NC (348, 260, 369, 362, 364 vs. 222 g/d, 344, 379, 434, 399, 416 vs. 331 g/d respectively). Large intestine mass tended to be less ($P < 0.10$) for pigs receiving additives (19.5 vs. 22.8 g/kg BW). Pigs fed NC+0.2% XPC had less ($P < 0.05$) large intestine mass than those receiving PC+XPC (16.4 vs. 17.7, 23.4, 18.6). Results suggest that XPC supports weaned piglet growth performance during an ETEC challenge with or without in-feed antibiotics.

Key Words: *E. coli* K88, piglet performance, *S. cerevisiae* fermentation product

W215 Developing an efficient *E. coli* expression system for producing a recombinant antimicrobial peptide plectasin. M. Y. Xie[1], L. H. Sun[1], Z. Zhao[1], X. J. Xia[1], and X. G. Lei*[1,2], [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Cornell University*, *Ithaca, NY*.

Plectasin is the first identified defensin-type antimicrobial peptide and was isolated from the saprophytic ascomycete fungus *Pseudoplectania nigrella*. Because plectasin has potent activity against gram-positive

bacteria, in particular *Streptococcus pneumonia*, with no hemolytic effect and low toxicity, it has great nutritional and therapeutic potentials. The objective of this study was to develop an efficient *E. coli* expression system to produce a recombinant plectasin. Based on the published plectasin sequence, we obtained the full-length double-stranded gene by PCR after we synthesized and annealed 2 overlapping single-stranded DNA fragments. The full-length DNA fragment was ligated into an expressing vector pET-32a(+) (Merck, Shanghai, China) and delivered into the *E. coli* strain Rosetta cells (DE3) (Merck, China). A Trx-plectasin fusion protein with a molecular mass of approximately 22.4 kDa was produced by the transformants, and represented over 60% of the total bacterial protein. This fusion protein was readily cleaved by enterokinase, resulting in the designated plectasin peptide with a molecular mass of approximately 4.4 kDa. Using a microdilution broth method, we found similar antimicrobial activity between our recombinant and the native plectasin. In conclusion, we have successfully developed an efficient *E. coli* expression system to produce a functional antimicrobial peptide plectasin for further animal tests and industrial applications.
Supported by the 863 program (2007AA100602 and 2007AA100601-6), and by the Chang Jiang Scholars Program of the Chinese Ministry of Education (XGL).

Key Words: plectasin, gene expression, protein purification, antimicrobial peptide

W216 In vivo evaluation of charcoal to prevent post-weaning pig diarrhea in an *Escherichia coli* K88 challenge experiment. C. Ionescu*[1], S. Meshkibaf[2], S. Bhandari[2], F. Zhu[2], E. Khafipoor[2], M. C. Nyachoti[2], D. Bravo[1], and D. O. Krause[2,3], [1]*Pancosma*, *Geneva, Switzerland*, [2]*Department of Medical Microbiology and Infectious Diseases, University of Manitoba*, *Winnipeg, MB, Canada*, [3]*Department of Animal Science, University of Manitoba*, *Winnipeg, MB, Canada*.

Pig post-weaning diarrhea is a leading cause of morbidity and mortality in the industry. The pathophysiology is commonly linked to *Escherichia coli* K88 (ETEC). Sub-therapeutic doses of antibiotics in diets has traditionally been used to prevent disease. With the rise of resistance, this practice is no longer acceptable. An ETEC challenge model was used to investigate the efficacy of non-activated charcoal (NAC) to prevent disease. The NAC had been selected for its binding properties to ETEC. Thirty-six pigs (19 ± 2 d old) were allotted to 6 treatments in a completely randomized design. The treatments were as follows: Basal diet (NC); NC + 0.15% Aureo SP-250 (PC); NC + 0.1, 0.5, 1, or 2% NAC. Pigs initial weights were 6.19 ± 0.22 kg. On d 7, all pigs were orally challenged with 6 mL of ETEC (≈109/mL). Post-challenge, fecal scours were measured daily (0, normal to 3, severe diarrhea). Seven days post-challenge, the pigs were euthanized and gut samples taken to enumerate ETEC and generic E. coli. The ETEC was levofloxacin resistant allowing for differential enumeration. ANOVA was made for treatment comparison and linear correlation coefficients were calculated between NAC doses and the different parameters. PC had the best ADG, ADFI, and G/F ($P < 0.05$). There was no correlation between NAC dose and ADG ($P = 0.43$) or ADFI ($P = 0.12$). There was a correlation between NAC doses and fecal scours ($R^2 = 0.96$, $P < 0.01$). This data was confirmed by correlation observed between NAC dose and ETEC counts in colon ($R^2 = 0.75$, $P = 0.055$) but not generic E. coli ($P = 0.32$). We conclude that NAC can be an effective dietary agent to reduce scouring in ETEC infected piglets. NAC does not appear to have negative effects on ADG and ADFI in antibiotic free diets.

Key Words: charcoal, ETEC, pig

W217 Effects of feed-borne *Fusarium* mycotoxins and an organic mycotoxin adsorbent on immune cell dynamics in the jejunum of broiler breeder pullets infected with *Eimeria maxima*. G. N. Girgis*, J. R. Barta, N. A. Karrow, H. J. Boermans, C. K. Girish, and T. K. Smith, *University of Guelph*, *Guelph, Ontario, Canada*.

Adverse effects of feed-borne *Fusarium* mycotoxins on the performance and metabolism of poultry have been described in the literature. There is a lack of information, however, regarding the effects of these mycotoxins on intestinal immune response to infections. Intestinal epithelium could be exposed to high concentrations of mycotoxins following ingestion of contaminated feed. An experiment was conducted to investigate the effects of feed-borne *Fusarium* mycotoxins and a polymeric glucomannan mycotoxin adsorbent (GMA) on immune cell dynamics in the jejunum of broiler breeder pullets using an *Eimeria maxima* infection model. Four groups of female Ross 308 broiler breeder chicks were fed a control diet, a diet naturally contaminated with *Fusarium* mycotoxins, contaminated diet plus GMA, or control diet plus GMA. Contaminated diets contained up to 6.5 μg/g deoxynivalenol (DON), 0.47 μg/g 15-acetyl-DON and 0.73 μg/g zearalenone. Pullets received a primary oral inoculation (1,000 oocysts/bird) with *E. maxima* USDA strain 68 at 2 weeks of age and a secondary oral inoculation (30,000 oocysts/bird) with the same strain at 4 weeks of age. The percentages of immune cell subsets in jejunal tissues collected at d 0, 3, 6 and 14 post-primary infection and d 0, 1, 2, 3 and 6 post-secondary infection were evaluated by immunohistochemistry and image analysis using ImageScope software. Data were analyzed by ANOVA and Tukey's test was used to compare least squares means among treatments ($P \leq 0.05$). Diet-related differences in $CD4^+$ cell, $CD8^+$ cell and macrophage recruitment pattern into the jejunum were observed following both the primary and secondary infections. It could be concluded that feed-borne *Fusarium* mycotoxins and GMA have the potential to modulate immune response to coccidial infections.

Key Words: *Fusarium* mycotoxins, coccidia, immune cells

W218 The granulated barley provided during growing or finishing period improves the carcass quality and increases the intramuscular fat content in muscle of heavy pigs. A. Daza[1], M. A. Latorre*[2], and C. J. López-Bote[3], [1]*Universidad Politécnica de Madrid*, *Spain*, [2]*Universidad de Zaragoza*, *Spain*, [3]*Universidad Complutense de Madrid*, *Spain*.

A total of 48 Duroc × (Large White × Landrace) gilts of 46.8 ± 1.39 kg of body weight (BW) were used to study the effect of the diet on growth performance, carcass characteristics and intramuscular fat content in the Longissimus dorsi muscle. Experimental diets were provided ad libitum according to the following treatments: i) a control diet with 3,210 kcal metabolizable energy (ME)/kg, 13.73% crude protein (CP) and 0.62% digestible lysine (Lys) from 45.6 to 127.8 kg BW (group C), ii) the control diet from 47.0 to 91.8 kg BW and granulated barley with 3,020 kcal ME/kg, 10.2% CP and 0.26% Lys from 91.8 to 129.7 kg BW (group C+GB) and iii) granulated barley from 47.9 to 93.1 kg BW and the control diet from 93.1 to 135.1 kg BW (group GB+C). The dietary treatment was replicated 8 times and the replicate was a pen with 2 gilts. The C group grew faster ($P \leq 0.05$) and tended to have better feed conversion ratio ($P \leq 0.10$) than GB+C group with C+GB group being intermediate. The GB+C gilts showed a compensatory growth during the finishing period. Although no effect was observed on carcass weight and yield, carcass length was higher ($P \leq 0.01$) in GB+C and C+GB than in C group and ham length and weight were higher ($P \leq 0.05$) in GB+C than in C gilts. Also, C group had lighter ($P \leq 0.001$) forelegs, loins and sirloins than GB+C and C+GB groups. The weight

and yield of total main lean cuts (ham+foreleg+loin+sirloin) was higher ($P \leq 0.001$) in GB+C than in C gilts with C+GB being intermediate. The subcutaneous backfat thickness was higher in C+GB than in C gilts with GB+C being intermediate ($P \leq 0.001$) and the C+GB and GB+C gilts had higher intramuscular fat content in meat than C gilts ($P \leq 0.001$). The dietary treatment had no influence on color, shear force or cooking losses of the loin but thawing losses were lower ($P \leq 0.05$) in GB+C and C+GB than in C gilts. It is concluded that gilts fed granulated barley during growing period had the best carcass quality characteristics. Also, granulated barley provided during growing or finishing period increased intramuscular fat percentage in gilt meat.

Key Words: barley, carcass quality, pigs

W219 Broiler energy choice feeding with same protein levels and ambient housing temperatures. S. Cerrate*, R. Ekmay, C. Salas, and C. Coon, *University of Arkansas*, *Fayetteville*.

Cobb male broilers (28 d of age) previously fed same starter diet were offered a single diet (control) and isoproteic choices between 2.950 and 3.250 kcal/g diets from 29 to 50 d. The control and dietary energy choices were fed to broilers housed in one of 2 ambient temperatures: 21 ± 1°C (normal temperature) and 30 ± 0.6°C (heat stress). Broilers housed at 21°C fed isoproteic choices varying in ME content had similar BW gain, feed intake (FI), feed conversion, ME intake and energy conversion as did birds fed the control diet. Broilers housed at 30°C fed the isoproteic choices varying in ME content had better BW gain, feed conversion and energy conversion compared with broilers fed the control diet. There was a marked preference (78.9% of FI) for the high energy diet (3.250 kcal/g) over the low energy diet (2.950 kcal/g) for broilers housed at 21°C, but this preference was less accentuated for broilers housed at 30°C (65.2% of FI). A potential explanation for broilers selecting diets with less ME in heat stress conditions compared with diet selection for broilers housed at 21°C may be related to the broiler trying to reduce gastrointestinal energy cost especially if hot ambient temperatures decrease fat and protein digestion as suggested by previous research. These data indicate that broilers in heat stress prefer reduced ME diets compared with broilers housed at 21°C.

Key Words: choice feeding, environmental temperature, energy requirement

W220 Effects of dietary creep feeding on performance, blood characteristics and behavior in sows and piglets. H. D. Jang*, J. H. Lee, T. X. Zhou, L. Yan, S. M. Hong, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of dietary creep feeding on performance, blood characteristic and behavior in sows and piglets. In total, data were obtained from 30 sows (Landrace × Yorkshire) and their litters. Sows were randomly assigned with 1, 2 or 3+ parities to 1 of 3 creep feeding treatment groups. Dietary treatments included 1) CON (no creep feeding), 2) TRT1 [creep feed (DE 4,000kcal/kg) from 5d of age until weaning (21d)], and 3) TRT2 [high energy creep feed (DE 5,000kcal/kg) from 5d of age until weaning (21d)]. The behavior of sows (nursery, eating, standing) and piglets (sucking, sleeping, fighting) in each treatments was observed throughout this experiments. Each piglet was weighted and bled on 5, 10, 15 and 21 d after birth to evaluate the ADG and IgG concentration of piglet. In addition, all sows were also bled on the lactation and weaning day to evaluate, epinephrine, nrepinephrine and cortisol concentration, rectal temperature of each sows was also measured at the same time. In herein study, dietary TRT1 and TRT2 significantly decreased the Epinephrine, norepinephrine and cortisol concentration compared with the control group ($P < 0.05$). Higher piglet IgG concentration was observed in the TRT1 and TRT2 group compared with the control ($P < 0.05$). Dietary TRT1 and TRT2 led a lower diarrhea score of piglets than those of the control treatment ($P < 0.1$). A higher piglet ADG was detected in the TRT2 ($P < 0.1$) compared with the CON treatment. No significant difference was observed on the rectal temperature of sows, the behavior of the piglet and sows among treatments. In conclusion, creep feeding can increase the immunity of piglet and decrease the diarrhea score of piglets. A higher energy creep feeding can significantly increase the growth performance of piglet compared with the those without creep feeding, while the creep feeding with lower energy show intermediate.

Key Words: creep feed, behavior, sow

W221 Crude glycerin in market turkey diets. S. L. Noll*[1], K. Koch[2], and J. Brannon[1], [1]*University of Minnesota*, *St. Paul,* [2]*North Dakota State University*, *Fargo*.

Crude glycerin (CG) is produced as a co-product of the conversion of fats into biodiesel and contains 80–88% glycerol. Two studies were conducted to examine CG as a source of energy in growing diets of market turkey toms. In the first trial, CG replaced an equivalent amount of corn in diets of low and high nutrient density (LND vs. HND). Glycerin was added at levels of 2, 4, 6, and 8%. As glycerin replaced corn, diet Lys, Met, and Thr were adjusted to the control diet (0% CG) for each nutrient density series. The base diet contained corn, soybean meal, poultry byproduct meal, and distillers dried grains with solubles (20%). Diets were adjusted for age and fed to toms during 8–19 wks of age. Diets were fed as mash. A factorial analysis included CG and nutrient density. In Trial 2, the objectives were to compare performance of toms fed diets with CG replacing fat and corn in diets fed as mash or pellets and to determine the effect of CG on pellet quality. The base diet was similar to Trial 1. The source of fat was sunflower oil. The study was of a factorial design with factors of feed form (mash or pellets) and CG (0, 3, and 6%). Each diet was fed to 8 replicate pens of tom turkeys (Large White, Nicholas) during 11–19 wks of age. In trial 1, BW was decreased by 2.9% at 19 wks for the LND series as compared with the HND regimen or by feeding CG in excess of 4% ($P < 0.05$). Cumulative feed efficiency during 8 to 19 wks of age was increased for the LND as compared with HND (2.85 vs. 2.59) while no effect was observed for CG addition ($P < 0.05$). A significant interaction of nutrient density and CG was observed during 17–19 wks of age for feed/gain. In Trial 2, BW was not affected by diet. Pellet quality in general was poor. A significant interaction of feed form and CG occurred for cumulative feed efficiency ($P < 0.05$). The interaction was primarily due to a lowered feed intake of the pelleted diet containing 6% glycerin as compared with the response at 0 and 3% CG. The improvement in feed/gain with pelleting indicated an important role of reduction in feed wastage by the feeding of pellets even if they are of poor quality. Inclusion of up to 6% crude glycerin was possible without a negative effect on performance.

Key Words: turkey, glycerin, feed form

W222 The effect of vetch heat treatment on free amino acids profile in plasma, muscle and liver of growing chickens. I. Fernandez-Figares*, M. Lachica, R. M. Nieto, and J. F. Aguilera, *CSIC, Spanish National Reseach Council*, *Granada, Spain*.

The aim of the present work was to evaluate the effect of feeding heat processed vetch meal to growing chickens on free amino acid (AA) levels in different tissues. Eight 4-week-old White Rock male growing chickens (mean LW 500 (s.e. 9.3) g) were given, for 3 d by crop intubation in 2 daily meals, 2 isoenergetic (13.1 MJ ME/ kg DM) and isonitrogenous (120 g CP/ kg DM) semisynthetic diets based on vetch seed meal, as a single source of protein, untreated or previously autoclaved at 120°C for 30 min. The paired-feeding level used was above that of maintenance (684 kJ EM/kg $LW^{0.75}$; Arch. Zootec. 36: 165–72). Four hours after the last meal, they were slaughtered by cervical dislocation and samples of

right biceps muscle and liver were frozen in liquid nitrogen and stored at −20°C until analysis. Also, heparinized blood samples were taken and plasma was obtained by centrifugation and finally frozen at −20°C. Samples were homogenized and deproteinized (by ultrafiltration) before analysis for free AA by HPLC, using the Waters Pico Tag method. Data were analyzed as one-way ANOVA using SAS software. The chickens were in a positive energy balance, but the diets supplied insufficient amounts of all essential AA, with an imbalanced profile (Anim. Prod. 57: 309–18). Heat treatment increased significantly ($P < 0.05$) plasma His and Met and decreased Ile, Ser and Pro. In muscle, birds fed heat-treated vetch had a tendency ($P = 0.05$–0.10) to increase Met and Trp and to decrease Thr and Lys. In liver, heat treatment increased ($P = 0.01$–0.05) free essential AA with the exception of Arg, Ile ($P = 0.013$–0.14) and Thr ($P = 0.99$). Previous work of this laboratory has shown that heat treatment increases the digestion and net absorption of total N and AA of some grain legumes, presumably by destruction of toxic constituents which stimulate endogenous protein excretion (Anim. Sci.60: 493–7). Consequently, liver free amino acid pool was more sensitive than muscle or plasma pools to this increased net AA absorption.

Key Words: free amino acids, legume, chicken

W223 Use of near infrared spectroscopy and color for identification of soybean meals by origin. P. García-Rebollar, N. Núñez-Romero, S. Santos-Rosell, R. Lázaro, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Madrid, Spain*.

Recent work has shown that chemical composition and nutritional value of soybean meals (SBM) differ among origins. Near-infrared reflectance spectroscopy (NIRS) has demonstrate its potential to identify and classify food products, and color has also been used to detect improper processing conditions. The objective of this work was to evaluate NIRS and color methods and its application in the feed mill industry to permit rapid and accurate origin (Argentine, ARG; Brazil, BRA; USA) identification of commercial SBM. A total of 290 SBM unground samples of known origin (ARG, n = 84; BRA, n = 74; USA, n = 132) were scanned using a spectrophotometer (Foss NIRSystems 5000) over the range 1100–2500 nm. Color (CIELAB system) was recorded using a Minolta colorimeter (model CR-300). On the basis of spectral data, a Principal Component Analysis was performed and outliers with a Mahalanobis distance greater than 3 were removed. The 3 sets of SBM spectra were split using the CENTER algorithm (WinISI v.1.50) into a calibration set (ARG, n = 61; BRA, n = 53; USA, n = 86) used to develop linear discriminant models (PLS2-DA procedure), and an external validation set (ARG, n = 20; BRA, n = 16; USA, n = 43). The best discriminant model yielded a SECV of 0.2515 and over 97% of correctly classified samples in the training set (100% for ARG; 96% for BRA, and 98% for USA, respectively), whereas in the validation step 100% of the samples were correctly classified. Color parameters of SBM samples differed ($P < 0.001$) among origins, with the BRA meals being redder than the ARG and USA meals (7.6 vs. 6.5 vs 5.9, respectively). The yellowness and luminosity were higher for the USA meals (26.5 and 71.1) than for the South American meals (25.1 and 67.3 for ARG; 24.4 and 65.3 for BRA), respectively. The results obtained show that NIRS is a reliable method of origin identification of commercial SBM samples at the reception stage in the feed mill industry, and that color can help to confirm these results.

Key Words: soybean meal origin, color, near infrared spectroscopy

Nonruminant Nutrition: Mineral

W224 Bioavailability of copper sources to broiler chicks when fed below the copper requirement. K. C. Klasing* and A. Naziripour, *University of California*, *Davis*.

Tribasic copper chloride (TBCC) has been shown to have better bioavailability than copper sulfate pentahydrate (CS) when fed at levels in excess of the requirement. Our objective was to determine if this relationship holds at levels below the Cu requirement. After depleting Cu levels for 7 d, 3 pens of 4 chicks/pen were fed a purified diet or a sorghum-soy diet supplemented with either 0, 1, 3, 4.5 or 6 ppm Cu. LPS was injected in order to initiate an acute phase response and bioavailability was calculated by common-intercept multiple linear regression. Prior to LPS, TBCC resulted in greater ($P < 0.05$) bioavailability as indicated by weight gain and tendon Cu levels with both diet types. Following LPS injection, TBCC resulted in greater bioavailability based on the plasma acute phase protein, ceruloplasmin ($P = 0.01$; slope ratio = 1.26). Bioavailabilities of the Cu sources did not differ for hematocrit or liver Cu. In general, these results indicate higher bioavailability of TBCC when dietary Cu is deficient in both healthy and inflammatory-stressed chicks.

Key Words: copper, bioavailability, poultry

W225 Effects of tribasic copper chloride on intestinal absorption ability and mucosal immunity of broiler chickens. Y. Ding[1], R. She*[1], H. Bao[1], D. Han[1], Z. Yue[1], J. Tian[1], P. Yu[1], R. Li[1], J. Yin[1], and C. Liang[2], [1]*China Agricultural University, Beijing, China,* [2]*Micronutrients, Indianapolis, IN.*

In recent years there has been increasing interest in the growth-promoting effect and immune-enhancing role of the copper. The objective of this study was to determine the effect of tribasic copper chloride (TBCC) on intestinal absorption ability and mucosal immune responses in chickens. One hundred and eighty 1-day-old broiler chickens were randomly divided into 4 groups, and were fed the following diets respectively: a basal diet with no supplemental copper (negative control), a basal diet + 188 mg of Cu/kg of diet from TBCC (TBCC group), a basal diet + subtherapeutic antibiotics (positive control), and a basal diet + TBCC+ subtherapeutic antibiotics(mixed addition group). Fifteen chickens of each group were randomly selected and killed on day 7, 21, 35, and samples of the duodenum were immediately collected and fixed. The height and width of the villus and the crypt depth were measured and the number of goblet cells, which determined the absorptive capacity of intestine, was counted. The results showed that the TBCC group had significantly increased villus height and crypt depth at the age of 7 day compared with the control group ($P < 0.05$). The number of goblet cells of duodenum was higher ($P < 0.05$) in the TBCC group than in the negative control group at the age of 7 day. The number of intestine intraepithelial lymphocyte (iIEL) cells and the IgA-secreting cells were counted to reflect the mucosal immunity level. The results showed that the numbers of iIEL in duodenum of TBCC group were increased significantly than the control groups ($P < 0.05$) on day 7. In the duodenum, the IgA-secreting cells of TBCC group were increased significantly compared with the other three groups ($P < 0.01$) on day 35. In conclusion, the results of the experiment indicated that TBCC could effectively enhance the small intestine to absorb nutrients and improve the mucosal immunity of the chickens, especially for the young chicks. These findings demonstrated that TBCC could be considered to replace antibiotics in modulation of the immune response for animal health.

Key Words: copper, broiler chicken, absorption ability and mucosal immunity

W226 Productive performance and egg quality of laying hens as a response to dietary copper supplementation. M. J. González*[1], J. J. Bañuelos[1], M. Huerta[1], S. Carrillo[2], and J. M. Cuca[3], [1]*Universidad Autónoma Chapingo*, *Texcoco, México, México*, [2]*INCMNSZ*, *México, DF, México*, [3]*Colegio de Posgraduados*, *Texcoco, México, México*.

This study was carried out to: 1) Evaluate the productive performance and egg quality as a response to dietary copper (Cu) supplementation, and to 2) Calculate the dietary optimal Cu levels to minimize feed conversion (DOLFC) and to maximize egg mass (DOLEM) or profits (DOLP). Methodology: 250 Hy-Line W36 hens, from 23 to 34 weeks of age, were allocated in five treatments with five replicates each. Treatments consisted of five supplemented Cu levels (0, 75, 150, 225 and 300 mg Cu/kg diet) from copper sulfate as a source of Cu. A sorghum-soybean basal diet was calculated to fulfill the Hy Line W36 nutrient requirements. A completely randomized design, with an orthogonal contrast analyses, was used to detect linear and quadratic tendencies of the experimental variables as a response to Cu levels. Econometric and regression models were applied to calculate DOLFC, DOLEM and DOLP. Results of contrast analyses showed ($P \leq 0.05$) linear and quadratic effects on feed intake (FI), egg mass (EM), feed conversion (FC) and laying percentage (LP). The dietary Cu optimal levels were calculated at 129.5 mg Cu/kg diet for DOLFC; 117.1 mg Cu/kg diet for DOLEM, and 120.6 mg Cu/kg diet for DOLP. The DOLP was sensible to egg price variation. A comparison of the dietary Cu optimal levels with the control values for FC (2.07), EM (44.2 g), and LP (79.6%) showed a performance improvement of 13.5%, 13.1% and 11.3%, respectively. Egg quality showed no effect ($P > 0.05$) for egg weight. Nevertheless, height of albumin and Haugh units diminished ($P \leq 0.05$) with increasing dietary Cu levels. Shell thickness improved ($P \leq 0.05$) with Cu supplementation. Conclusions: 1) Dietary Cu supplementation improves productive performance and shell thickness; 2) Dietary Cu optimal levels are specific for each biological or economic goal.

Key Words: hens, copper, performance

W227 Effect of organic trace mineral sources on production and egg quality of white egg laying hens. L. M. Macalintal*, A. H. Cantor, T. Ao, J. L. Pierce, A. J. Pescatore, K. A. Dawson, M. J. Ford, W. D. King, and H. D. Gillespie, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington*.

The effects of supplementing white laying hens with graded levels of organic and inorganic sources of Cu, Mn, Fe, Zn and Se on egg production and quality were studied. The organic sources used were proteinates of Cu, Mn, Fe and Zn (Bioplex, Alltech, Inc.) and selenium yeast (SelPlex, Alltech, Inc.). Seven treatments consisted of feeding corn-soybean meal diets alone (basal) or supplemented with Cu, Mn, Fe and Zn at 25, 50, or 100% of the NRC (1994) requirements provided by either inorganic salts or organic sources. Selenium was provided at 0.075, 0.15 and 0.3 mg/kg as either sodium selenite or selenium yeast in the diet containing 25, 50 and 100% of the NRC requirements, respectively. At each stage of growth or production, other nutrient levels were adjusted to meet the dietary requirements. Eight replicate groups of 16 chicks at day 1 of age were randomly assigned to each treatment. At 17 weeks of age, pullets were transferred to laying cages using 12 pullets per replicate and the mineral treatments were continued for 28 weeks of production. Egg quality parameters were assayed monthly on samples of six eggs per replicate group. During the 28 weeks of production, overall body weight gain (465 g/hen), feed intake (93.0 g/hen/d) and hen-day egg

production rate (85.0%) were not affected by treatments. During Weeks 17-20, hens fed organic minerals at 50% of the NRC requirement had higher egg production (94.2%) than those fed the basal diet (90.3%) or inorganic minerals at the 25% level (90.4%). Average egg weight at 26 wk of production was significantly higher for hens fed organic minerals at the 100% rate compared with all other treatments. Compared with the basal treatment, no improvements in shell breaking strength, % shell and specific gravity were observed due to mineral supplementation.

Key Words: trace minerals, mineral proteinates, egg production

W228 Layer excreta mineral content: Organic versus inorganic dietary trace mineral sources. S. Leeson[1], A. E. Sefton*[2], and K. A. Jacques[2], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Alltech Inc.*, *Nicholasville, KY*.

Regular inorganic mineral premixes used in layer diets can result in levels of mineral in manure that are of environmental concern. Previous trials have shown that reduced levels of more available organic mineral forms do not harm performance or well being and can substantially reduce manure minerals. This experiment evaluated performance, egg quality and mineral excreta content of Lohmann layers fed inorganic or reduced amounts of organic copper (Cu), manganese (Mn) and zinc (Zn) sources over a laying cycle. Hens (720) at 18 wks of age were randomly allocated to cages of 5 birds assigned to diets containing either inorganic (sulfate) or organic (Bioplex, Alltech Inc.) sources of Cu, Mn and Zn. Mineral concentrations from supplemental sources in the inorganic control and organic mineral diet, respectively, were Cu, 5 and 0.6; Mn, 100 and 12.6; Zn, 60 and 14 ppm. The experiment consisted of 13, 28 day periods. Response variables were egg production, total egg number, egg weight, shell deformation, albumen height, feed intake, body weight, feather scoring and excreta mineral content. The data were subjected to ANOVA with means separated using Tukey's test. In general, diet treatment did not affect bird performance. Body weights, feed intake and feather scores were similar for both treatments ($P > 0.05$). There were marked reductions in the levels of Zn, Mn and Cu in excreta ($P < 0.01$) when birds were fed Bioplex vs. inorganic minerals (Zn, 149 vs. 354; Mn, 116 vs. 407; Cu, 18 vs. 38 ppm). It was concluded that layers performed equally well throughout a laying cycle when fed a diet containing either inorganic or Bioplex mineral sources. There was a very significant decrease in Zn, Mn and Cu in excreta when hens were fed a diet containing Bioplexes during the laying cycle.

Key Words: layers, trace minerals, excreta

W229 The effect of selenium source and supplementation level on vitelline membrane strength and glutathione peroxidase activity in the liver and shell gland of laying hens. A. A. Aljamal*[1], C. A. Fassbinder-Orth[2], and S. E. Scheideler[1], [1]*University of Nebraska-Lincoln*, *Lincoln,* [2]*Creighton University*, *Omaha, NE*.

The objective of this study was to investigate the effects of selenium source and level on production parameters of laying hens, effects on vitelline membrane strength, and effects on GSH-Px activity in the liver and shell gland of hens. A total of 120 White Bovan hens were fed the experimental diets for 8 weeks from 35 to 42 wks of age. A total of 30 cages were used in the trial with 6 cages/ treatment. Cages were blocked by side, north and south, each side with a total of 15 cages. Hens were fed a corn-soybean meal basal diet supplemented with: (0, 0.2 ppm Sel-Plex, 0.2 ppm sodium selenite, 0.4 ppm Sel-Plex, or 0.4 ppm sodium selenite) for a total of 5 dietary treatments, with the basal level of Se in the diet being 0.2 ppm. Feed intake and egg production were measured daily. Egg weights, specific gravity, and Haugh units were taken weekly. Aged and fresh albumen and yolk pH were measured biweekly. The experimental design of the trial was a randomized completely blocked design. Vitelline membrane strength was measured at weeks 5, 6, 7, and 8 of the trial. At the end of the study, 2 hens/ cage were euthanized to measure GSH-Px activity of the liver and shell gland tissues. Feed intake and egg production increased as dietary Sel-Plex supplementation increased in the diet ($P < 0.05$). Dietary treatments had no significant effect on egg weight, specific gravity, Haugh unit, or hen weight. Using Selenite at 0.2 ppm or Sel-Plex at 0.4 had the same effect to improve the VMS ($P = 0.0592$). Using 0.4 ppm Sel-Plex had a significant effect in decreasing the aged albumen pH but this was only significantly different from the treatment supplemented with 0.4 ppm selenite ($P = 0.0577$). Neither Sel-Plex nor selenite had any effect on GSH-Px activity in the liver and shell gland of the hens. Our research indicates that 0.4 ppm Se from Sel-Plex significantly improved egg quality in aged albumen pH and VMS measurements.

Key Words: laying hens, Sel-Plex, egg production

W230 Effects of altered calcium and phosphorus intake on growth performance and bone characteristics in growing pigs. L. A. Pettey*, K. M. Martorana, T. D. Moore, and J. M. Krumheuer, *California Polytechnic State University*, *San Luis Obispo*.

A two stage growth study was conducted to quantify the effects of altered calcium (Ca) and phosphorus (P) levels on growth performance and bone characteristics in growing pigs and to compare the sensitivity of various bones to changes in Ca and P intake. Pigs (n=112; 21.4 kg BW) were randomly allotted by weight to one of two dietary treatment groups: 1) NRC levels of Ca and P as control; and 2) as 1 with Ca and P increased to 120% of NRC. Pigs were fed diets for 2 weeks before six pigs from each group were harvested for collection of all skeletal bones. Increased Ca and P intake had no effect ($P > 0.10$) for ADG or Ca and P content of leg bones. Following the feeding of high and low Ca and P diets, 96 of those pigs were randomly allotted in a RCB design to one of three diets: 1) a corn-SBM based diet as control (0.62% Ca, 0.54% P), 2) as 1 with 0.74% Ca and 0.63% P, 3) as 1 with 10% added soybean hulls to decrease ME by 100 kcal/kg. Prior level of Ca and P intake was used as a blocking factor. Pigs were fed diets for 4-wk prior to collection of all skeletal bones. As expected, soy hull addition increased ($P < 0.05$) ADFI, thus increasing Ca and P intake ($P < 0.05$) compared with pigs fed the control, but similar ($P > 0.10$) to pigs fed a high Ca and P diet. Pigs with increased Ca and P intake (Diets 1 and 2) had greater ($P < 0.05$) ADG compared with pigs fed the control diet. Prior level of Ca and P intake had no effect ($P > 0.10$) on growth or bone traits. Increasing Ca and P intakes tended to increase ($P < 0.08$) the weight of ribs, metacarpal, metatarsal, humerus and femur. On a concentration basis (g/kg) all bones from pigs with increased Ca and P intakes were higher ($P < 0.05$) in ash, Ca, and P compared with pigs fed the control diet. The percentage increase in bone ash most closely correlated to Ca and P intake for rib bones ($R^2 = 0.92$), yet positive correlations were observed for femurs ($R^2 = 0.82$), humerus ($R^2 = 0.78$) and metacarpal/metatarsal bones ($R^2 = 0.74$). Overall, mineral content of specific bones increase differently to increasing levels of Ca and P intake in growing pigs.

Key Words: calcium, phosphorus, bone

W231 Effect of mineral source and mannan-oligosaccharide supplementation on mineral metabolism on young growing pigs. A. Lebel*[1], F. Guay[1], and P. Groenewegen[2], [1]*Universite Laval*, *Quebec, Qc, Canada*, [2]*Alltech Canada*, *Guelph, On, Canada*.

The objective of this study was to evaluate the effect of mineral source and mannan-oligosaccharide supplementation on the digestibility and net utilization of zinc and copper in young growing pigs. Twenty eight barrows (25.7 kg, SEM 1.2) were assigned to one of 4 diets in a randomized complete block design. Corn soybean diets were supplemented with 10 ppm of copper and 100 ppm zinc from organic (Bioplex) or inorganic (Sulfate) sources, and with (0.1%) or without mannan-oligosaccharide (Bio-Mos, MOS) according to a 2 x 2 factorial design. Animals were maintained in individual metabolic crates for an adaptation period of 3 days following by a collection period of 5 days for the total collection of urine and feces. Pigs fed organic mineral supplemented diets had higher feed intake (2,247 vs. 2,068 g/d, SEM 86, $P < 0.05$), copper intake (56.5 vs. 50.7 mg/d, SEM 2.2, $P < 0.07$) and zinc intake (325 vs. 293 mg/d, SEM 10, $P < 0.04$) than those fed diets supplemented with the inorganic minerals. The higher zinc and copper intakes in the organic treatment led to higher copper retention (32.0 vs. 22.4 mg/d, SEM 2.5, $P < 0.01$) and a trend for higher zinc retention (170 vs. 142 mg/d, SEM 10, $P < 0.07$). There was also a trend for a reduction in fecal copper excretion (23.8 vs. 27.7 mg/d, SEM 1.5, $P < 0.09$). These results explain the increased digestibility (45 vs. 56%, SEM 2, $P < 0.01$) and net utilization (44 vs. 55%, SEM 2, $P < 0.01$) of copper when fed in the organic form. However, these effects tended to be more pronounced when the diet did not contain MOS (interaction, mineral form × MOS, $P < 0.09$, without MOS 41 vs. 59% and with MOS 48 vs. 54%, SEM 3 for digestibility; without MOS 40 vs. 57% and with MOS 48 vs. 54% for net utilization). Mineral form and MOS supplementation had no significant effect on zinc digestibility or net utilization. These results suggest that organic mineral supplementation is an effective method to improve the digestibility and net utilization of copper, and reduce its total excretion but these effects would be less pronounced when the diet is supplemented with MOS.

Key Words: copper, zinc, mannan-oligosaccharide

W232 Enrichment of Japanese quail eggs with organic selenium. R. A. Gravena, R. H. Marques, J. D. T. Silva, F. H. Hada, J. Picarelli, J. Roccon, S. A. Queiroz, and V. M. B. Moraes*, *São Paulo State University*, *SP - Brazil*.

The aim of this study was to evaluate the effect of diets supplemented with organic selenium (Se) on the deposition of this mineral in the yolk and albumen of Japanese quail eggs. One hundred 92 quail were randomly distributed into 4 treatment groups with 6 replicates of 8 birds in each pen. The birds were placed on 1 of 4 dietary treatments (0, 0.35, 0.70 and 1.05 mg organic Se/kg feed) for 4 lay cycles. Three eggs were collected per treatment at 56 d. The Se content of egg yolks and albumen were determined using microwave digestion followed by AAS. The Se concentration in egg yolk was not affected by supplementing diets with organic Se ($P > 0.05$). The Se levels in albumen increased linearly ($y = 3.09308 + 9{,}63459x$; $r^2 = 0.52$) with the increase of supplemented Se in diets ($P < 0.0001$), which can be explained by the interaction of organic Se deposition with the proteins in albumen. These results suggest that supplementing the diets of Japanese quail with organic Se can improve the nutritional value of their eggs.

Table 1. Se concentration in the yolk and albumen in quails eggs supplemented with organic Se

	Se concentration		
Se levels (mg/kg diet)	Yolk (µg/kg yolk)	Albumen (µg/kg albumen)	Se concentration in albumen (%)
0	68.60	3.07	–
0.35	89.27	6.47	110.75
0.70	67.25	9.90	222.47
1.05	72.41	13.16	328.66
CV (%)	25.68	46.73	–
P value	0.76^{ns}	0.0001*	–

Key Words: albumen, organic selenium, quail

W233 Improved piglet birth weight by feeding sows an organic trace mineral blend. J. Zhao*[1], L. Greiner[2], M. Vazquez-Anon[1], C. D. Knight[1], and R. J. Harrell[1], [1]*Novus International Inc.*, [2]*Innovative Swine Solutions*.

The objective of this study was to examine the benefits of feeding sows an organic trace mineral blend (OTM, Mintrex, Novus International Inc.) on piglet birth weight and uniformity. Two sister farms with a common grandparent farm were fed either an inorganic control (ITM) or an OTM blend (Zn, Mn, and Cu), which replaced 50% of the ITM, with the target levels of Zn, 165ppm, Cu, 16.5ppm, and Mn, 38.5ppm in final diets. Treatment was initiated at weaning and continued through growing and entry into the breeding herd. After 2.5 years, about 30 litters were selected for each parity (P1, P2, P3+4, P5 and above). Individual piglet weight (within 24 hours after birth and before cross-fostering) was collected in a two-week period in August and December, 2009. The number of total born was not different on selected litters (12.9 vs. 13.0 ± 0.27, $P = 0.84$). The mean piglet weight was greater for sows fed OTM (1.36 vs. 1.25 vs. ± 0.02 kg, $P < 0.001$). Piglet uniformity was not different between treatments ($P = 0.45$). Benefits of OTM on piglet weight were more profound from P2 to P4 with average piglet weight of 1.13 vs. 1.22 kg for P1 ($P = 0.15$), 1.27 vs. 1.38 kg for P2 ($P = 0.04$), 1.23 vs. 1.38 kg for P3+4 ($P = 0.002$), and 1.19 vs. 1.25 kg for P5 and above ($P = 0.50$) for sows fed the control and OTM, respectively. In summary, sows fed OTM had heavier piglets compared to sows fed ITM and there is no difference on piglet uniformity between treatments.

Key Words: birth weights, sow, organic trace mineral,

W234 Dietary calcium affects neonatal bone development and mesenchymal stem cell activity. A. Mahajan[1], L. S. Alexander[1], B. S. Seabolt*[1], D. E. Catrambone[2], J. P. McClung[2], J. Odle[1], T. W. Pfeiler[3], E. G. Loboa[3], and C. H. Stahl[1], [1]*Laboratory of Developmental Nutrition, North Carolina State University*, *Raleigh,* [2]*Military Nutrition Division, US Army Research Institute of Environmental Medicine*, *Natick, MA,* [3]*Joint Department of Biomedical Engineering at University of North Carolina-Chapel Hill and North Carolina State University*, *Raleigh*.

Effects of dietary calcium (Ca) deficiency on skeletal integrity and endocrine parameters are well characterized in growing and mature pigs; however, little work has examined Ca nutrition during the neonatal period. We examined the effects of neonatal Ca nutrition on bone integrity, endocrine parameters, and mesenchymal stem cell (MSC) activity. Neonatal pigs (24 ± 6h post-partum) were pair-fed either a Ca adequate (Ca+) or a 30% Ca deficient (Ca-) liquid formula diet for 18 d. There were no differences in growth rate or feed efficiency based on dietary Ca level and all pigs grew at a rate similar to sow-reared pigs.

As anticipated, Ca deficiency reduced (P < 0.05) both BMD and bone flexural strength. The anticipated increase ($P < 0.05$) in plasma PTH levels was not evident until the end of the study. Surprisingly, dietary Ca level did not affect plasma Ca or 1,25(OH){2} vitamin D concentrations throughout the study. Calcium deficiency reduced ($P < 0.05$) the in vivo proliferation of MSC isolated from bone marrow by approximately 50%. To further assess the impact of Ca nutrition on MSC activity, cells isolated from these pigs were cultured in homologous sera, under both proliferative and adipogenic conditions for 6d. Under proliferative culture conditions, Ca- sera reduced MSC proliferation and Ca+ MSC had greater expression of osteocalcin and Runx2 mRNA. Under adipogenic culture conditions, MSC cultured in Ca- sera had greater Oil Red O staining and Ca+ MSC also had greater Oil Red O staining than did there Ca- counterparts. Ca- MSC cultured with Ca- sera under adipogenic conditions had 2-fold greater expression of PPARG2 mRNA than any other treatment group. Concentrations of calcitropic hormones were not different between Ca+ and Ca- sera, but we identified 22 differentially expressed proteins in these sera. The results indicate that neonatal Ca restriction may have long-term effects on bone integrity via programming of MSC. The results indicate that neonatal Ca nutrition is crucial for bone integrity and suggest that early life Ca restriction may have long-term effects on bone integrity via its effects on MSC activity.

Key Words: calcium, mesenchymal stem cells, pig

W235 Serum from pigs fed a high-Se diet inhibits growth of human lung cancer cells. J. G. Li[1], J. Shi[1], K. N. Wang[1], G. Gao[2], X. J. Xia[1], and X. G. Lei*[1,3], [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Chengdu Municipal Ctr for Disease Control and Prevention*, *Chengdu, China*, [3]*Cornell University*, *Ithaca, NY*.

Supranutritional levels of Se may decrease risks of human lung cancer, but may increase risks of diabetes. Pigs are an excellent model for humans. The objective of this study was to determine if serum from pigs fed a high-Se diet inhibited growth of human lung cancer cells. A total of 16 weanling pigs were fed a Se-deficient (0.03 mg Se/kg) corn-soy basal diet and the basal diet plus 3 mg Se/kg (as sodium selenite) for 16 wk. At the end, serum collected from individual pigs was pooled by the treatment groups and filtered through a 0.22-μm membrane for cell culture. While serum insulin and insulin-like growth factor 1 concentrations were similar between the two groups of pigs, serum Se concentration and serum lactate dehydrogenase (LDH) activity was lower ($P < 0.05$) and higher ($P < 0.05$), respectively, in the Se-deficient pigs than those fed 3 mg Se/kg. Based on cell viability, the optimal serum level for the cell growth was 17 and 15%, respectively, for serum from pigs fed the basal diet and the diet plus 3 mg Se/kg. Compared with the Se-deficient serum (16%), the high-Se serum (16%) from pigs fed 3 mg Se/kg decreased ($P < 0.05$) cell viability, promoted ($P < 0.05$) apoptosis, and increased medium LDH activity. In conclusion, serum from pigs fed a high-Se diet may have anti-cancer potential.
This work was partially supported by NSFC Projects 30628019, 30700585, and 30871844, and the Chang Jiang Scholars Program (XGL).

W236 Effect of sodium selenite and turmeric powder on Gompertz nonlinear function in broilers reared under heat stress. A. Zeinali*[1], H. Kermanshahi[1], H. Ziaie[2], H. Farhangfar[3], and A. Riasi[3], [1]*Ferdowsi University*, *Mashhad, Khorasan, Iran*, [2]*Agriculture and Natural Resources Research Center*, *Birjand, South Khorasan, Iran*, [3]*Birjand University*, *Birjand, Khorasan, Iran*.

An experiment was conducted to study the effect of organic and inorganic antioxidant on Gompertz nonlinear function in broilers reared under heat stress. So, 180 one-day old chickens (male and female) were used in a completely randomized block design with 6 treatments and 3 replicates. The experimental diets were (T1) control diet ; (T2) control diet + 5 g/kg turmeric powder; (T3) control diet + 10 g/kg turmeric powder; (T4) control diet + 0.3 mg/kg sodium selenite; (T5) control diet + 0.3 mg/kg sodium selenite + 5 g/kg turmeric powder; and (T6) control diet + 0.3 mg/kg sodium selenite + 10 g/kg turmeric powder. Broilers were subjected to heat stress (35°C) during the fifth and sixth weeks. The results showed that diets including 10 g/kg turmeric powder significantly increased final weight (Wf), weight at inflection time (Wt) and time at inflection time (t) ($P < 0.05$). However, the difference between 10 and 5 g/kg turmeric powder levels was not significant. The interaction between selenium and sex was significant on Wf in such a way that male chickens fed with selenium had higher Wf.

Key Words: selenium, turmeric powder, nonlinear model

W237 Modelling the fate of dietary phosphorus in the digestive tract of growing pigs: a way to optimize phytase efficacy in releasing dietary P. M. P. Letourneau-Montminy*[1], A. Narcy[2], M. Magnin[3], and C. Pomar[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Qc, Canada*, [2]*INRA UR83*, *Nouzilly, France*, [3]*BNA Nutrition Animale*, *Chateau-Gontier, France*.

A mathematical model simulating the fate of all forms of dietary phosphorus (P) in the digestive tract of the growing pig was developed to provide ways to improve dietary P utilization. It was developed using in vitro and in vivo information. Three compartments are distinguished into the model: 1) the stomach in which dietary forms of P can be solubilised and phytic P (PP) hydrolyzed by phytases, 2) the proximal small intestine in which intense absorption occurs and 3) the distal small intestine in which P may form insoluble complexes with calcium that reduces its absorption. Flows between compartments of all forms of P are assumed to follow mass action laws parameterized with experimental data. The prediction capabilities of the model were assessed by comparing actual and simulated apparent total tract digestibility of P (ATTD), considering experiment effect, based on pig published data not used for model development. It revealed adequate prediction of P digestibility in diets supplemented or not with plant or microbial (Aspergillus niger) phytase (ATTDobserved = 5.53 + 0.87 x ATTDpredicted, n=281, nexp=66 R2=0.85, RSD=4.2% relMSPE=9.4%). Model sensitivity and behavior analysis showed that the hydrolysis of PP by phytases is largely dependent on PP solubility. Phytic P enters into the model in non-solubilised forms (PPns) and is then solubilised (PPs) according to the stomach pH. The equilibrium between PPns and PPs is also represented allowing PPns to solubilise after PPs has been hydrolysed by phytase. The simulation of a corn-soybean meal control diet supplemented with 1000 FTU/kg of A. niger phytase resulted in a 60% PP hydrolysis. This diet was used as control to study the effectiveness of phytase in releasing P from phytate. PPs hydrolysis is improved by increasing stomach mean retention time (74%) and by lowering its pH (66%). Based on the present simulation study, PP hydrolysis is mainly limited by the solubilisation of PPns. Further studies are needed to highlight and to quantify the impact of other factors that may interfere with PP solubility in the digestive tract of pigs.

Key Words: modelling, phytase, pigs

W238 Expression of borate transporter (NaBC1) mRNA by growing pigs is sensitive to dietary boron levels. S. F. Liao*, J. S. Monegue, M. D. Lindemann, G. L. Cromwell, and J. C. Matthews, *Department of Animal and Food Sciences, University of Kentucky*, *Lexington*.

Metabolic studies indicate that homeostatic control of elemental B in animals primarily involves the absorption and excretion of borate through gastrointestinal and renal epithelia, respectively. Recently a borate transporter, NaBC1 (SLC4A11), has been identified in the basolateral membranes of mammalian epithelial cells. A nutrient balance study was conducted to determine the effect of B supplementation on DM, N, Ca, and P digestibilities of growing barrows (initial BW=74.0±9.8 kg) commonly fed a corn-soybean meal diet without P supplementation for 12 d and then supplemented with either (n=8) 0 (Basal), 50, or 100 ppm B (prilled sodium borate pentahydrate) for 12 d (7-d adaptation, 5-d collection). Supplementation of B did not affect nutrient digestibilities. To determine (1) if pig jejunal (J) and ileal (I) epithelia, and kidney (K) express NaBC1 mRNA and (2) if expression is sensitive to dietary B concentration, total RNA was extracted from individual tissue homogenates prepared from all the pigs killed at the end of the balance study. The cDNA sequences of the RT-PCR products (130 base pairs each) generated from each tissue shared 100% identity to each other and to the putative pig NaBC1 sequence (GenBank no. XM_001924562). Subsequent real-time RT-PCR analysis quantified the relative amount of NaBC1 mRNA (NaBCl:18S) expressed. Compared to the Basal level, 50 ppm supplemental B tended ($P = 0.11$) to increase (248%) J, did not affect ($P = 0.83$) I, and decreased ($P = 0.02$) K NaBC1 mRNA contents, whereas 100 ppm supplemental B did not affect ($0.23 \leq P \leq 0.42$) the expression by any tissue. The tissue NaBC1 mRNA content did not differ ($P \geq 0.19$) between pigs fed B at 50 vs. 100 ppm. The finding that pig J, I, and K express NaBC1 mRNA is novel. Despite no effect on measured digestibilities, that 50 ppm supplemental B differentially altered NaBC1 mRNA content suggests that NaBC1 expression may be responsive to borate levels in digesta, blood, or both.

Key Words: borate transporter (NaBC1, SLC4A11), nutrient-gene interaction, pig

W239 Evaluating trace mineral level and form in diets fed gilts: effects on ovulation rate, embryonic survival and mineral composition of conceptus products. W. L. Pope[1], B. J. Middendorf[1], H. S. Cárdenas[1,2], D. C. Mahan[1], and K. A. Jacques*[3], [1]*OARDC, Department of Animal Sciences, The Ohio State University*, *Columbus,* [2]*College of Medicine, The Ohio State University*, *Columbus,* [3]*Alltech Inc.*, *Nicholasville, KY*.

Crossbred gilts (n=210) (Large White × Landrace) × PIC boar (line 280) were utilized to examine whether the previously observed increase in litter size after replacing inorganic trace elements with an organic source was due to improved ovulation rate, embryonic survival and/or fetal survival. At 45-kg body weight, gilts were randomly assigned to one of four dietary treatments; 1) industry levels of inorganic trace elements (Cu, 15; Fe, 120; Mn, 40; Zn, 120; Se, 0.3 ppm), 2) NRC levels of organic Cu, Fe, Mn, Zn (Bioplex) and Se (Sel-Plex) (Alltech Inc.), 3) industry levels of organic and 4) 1.5 times industry levels of organic trace elements. Due to space limitations of the barn, the design of this experiment was accomplished in 9 reps over a 2-year period. Within each replicate, the treatments were rotated so that differences due to pens or locations were randomized throughout the experiment. Gilts were individually penned and at about 130 kg were naturally mated at 12 and 24 h after onset of estrus. Boars had at least 3 days rest between matings. Gilts were slaughtered at day 30 of gestation. Resulting conception rate, ovulation rate, total embryos, total live embryos and embryonic survival were unaffected by treatment with overall means of 88.8, 16.9 (corpora lutea), 13.8, 13.6 and 80.3%, respectively. Macro and microelement content of embryonic and endometrial tissues collected at slaughter and of allantoic and amnionic fluids were analyzed in a subset (n=12) of gilts from each treatment group. Amounts of macro and microelements were altered ($P<0.05$) in numerous comparisons of endometrial or embryonic tissues and in allantoic or amniotic fluids of gilts fed organic versus inorganic trace elements. As the form or amount of trace minerals in the diet had no effect on ovulation rate, number of live embryos and embryonic survival, any improvement in litter size must be attributable to events occurring after 30 days of gestation.

Key Words: trace minerals, ovulation rate, fetal survival

W240 Cloning of porcine pancreatic α-amylase gene and characterization of the enzyme over-expressed in *Pichia pastoris*. T. Qin[1], H. Zhao[1], X. Xia[1], and X. G. Lei*[1,2], [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Cornell University*, *Ithaca, NY*.

α-Amylase (α-1,4-glucan-4-glucanohydrolase, EC.3.2.1.1) catalyzes the hydrolysis of α-(1,4) glycosidic linkages in starch and various malto-oligosaccharides, and may be used to improve feed carbohydrate utilization by animals. The objective of this study was to develop an efficient expression system to produce porcine pancreatic α-amylase (PPA). The full-length cDNA encoding the PPA was isolated from porcine pancreas by RT-PCR and cloned into the pPICZαA (Invitrogen, Shanghai, China) expression vector. The pPICZαA-PPA plasmid was transformed into *Pichia pastoris* (X33) cells, and transformants were screened by SYBR-green quantitative real-time Q-PCR (ABI 7900HT, Applied Biosystems, Foster City, CA). After the transformants were induced by 0.5% methanol for 3 d, the extracellular PPA protein containing a his-tag appended to the C terminus was purified using Ni Sepharose High Performance affinity column (GE Healthcare, Piscataway, NJ). The purified recombinant PPA showed a molecular mass of approximately 58 kDa, an optimal temperature of 50°C, an optimal pH of 7.5, K_m of 65 mg/ml (soluble starch), and V_{max} of 1.7 mg/min, respectively. After an exposure to 50° for 30 min, the recombinant PPA lost nearly 50% activity. The recombinant enzyme was more sensitive to the inhibition by Cu^{2+} than Fe^{3+}, Ca^{2+}, or Zn^{2+}. In conclusion, we have cloned the PPA gene and produced a relative high level of the functional enzyme in *P. pastoris*.

Key Words: porcine, pancreatic, α-amylase, *Pichia pastoris*, gene expression

W241 Heterologous expression of a truncated bovine lactoferrin gene in *E. coli* to produce a novel antimicrobial peptide. L. H. Sun[1], Y. Liu*1,2, H. Zhao[1], M. Y. Xie[1], J. Xing[1], X. J. Xia[1], and X. G. Lei[1,2], [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Cornell University*, *Ithaca, NY*.

Antibiotic resistance has become a major concern for the animal feed industry and human medicine worldwide. As a promising alternative of antibiotics, LfcinB is a peptide of 25 amino acids that originates from the N-terminus (Phe17 to Phe41) of bovine lactoferrin. Because LfcinB has a broad spectrum of potent antimicrobial activity, it is highly toxic to heterologous expression hosts like *E. coli* cells. The objective of this experiment was to develop an efficient expression system to produce an inactive or non-toxic precursor of LfcinB in *E. coli*. A DNA fragment encoding the N-terminal 121 amino acids of bovine lactoferrin that contained the LfcinB peptide was synthesized and inserted into an expression vector pET-30a(+) (Merck, Shanghai, China). The construct

was transformed into *E. coli* strain Rosetta (DE3) cells. As shown by the SDS-PAGE, a truncated bovine lactoferrin with a molecular mass of approximately 19.2 kDa was produced by the transformants, and the yield accounted for 30% of the total cell protein. We are currently investigating if LfcinB can be released from the overly-produced truncated bovine lactoferrin by pepsin at the acid pH in the stomach of animals. In summary, our approach in producing the LfcinB precursor may offer advantages of convenience and cost over other expression systems.
Supported by the 863 program (2007AA100602 and 2007AA100601-6) and by the Chang Jiang Scholars Program of the Chinese Ministry of Education (XGL).

Key Words: lactoferrin, lactoferricin, gene expression, antimicrobial peptide

W242 Cloning and expression of palustrin-OG1 in *E. coli*. Y. G. Xie*, Y. F. Liu, C. Luan, F. F. Han, and Y. Z. Wang, *Institute of Feed Science, Zhejiang University*, *Hangzhou, Zhejiang, China*.

Palustrin-OG1 is a novel antimicrobial peptide (AMP) isolated from the skin of the frog *Odorrana grahami*. It is a 31 amino acid peptide with antibacterial activities against a broad spectrum of microorganisms, especially against *S. aureus* ATCC 25923. With increasing resistance to existing antibiotics, it is imperative to develop new therapeutics such as AMPs. So far there have been no reports about its structure and antibacterial mechanism. In order to obtain enough amount of palustrin-OG1 for biological and structural studies, the gene encoding mature peptide of palustrin-OG1 was deduced from its amino acid sequence according to the codon bias of *E. coli* and synthesized with the method of gene splicing by overlapping extension PCR(SOE–PCR). Palustrin-OG1 gene was recombined to the expression vector pET32a(+) homologously to construct the recombinant expression plasmid pET32a(+)–OG1. The recombinant plasmid was then transferred into *E. coli* BL21 (DE3) and induced for 3h by IPTG with the final concentration of 1 m*M*. The soluble form fusion protein expressed in *E. coli* was up to 57.97mg/L. After ultrasonic disruption of cells, the soluble protein was purified by nickel column chromatography and desalted through Sephadex G25 column chromatography. Palustrin-OG1 was released from purified fusion protein after cleavage by enterokinase for 16h. The agar diffusion test showed the released palustrin-OG1 exerted activity against *S. aureus* ATCC25923. The integration strategy such as codon bias, homologous recombination and protease cleavage would provide an effective platform for biological and structural studies or production of AMPs as therapeutics.

Key Words: palustrin-OG1, fusion expression, *E. coli*

W243 Activated carbon does not reduce or prevent the effects of zearalenone in gilts. D. Srichana*[1], T. Srichana[2], W. Suttitham[1], P. Panja[1], A. Sumrit[3], and D. R. Ledoux[4], [1]*Department of Agricultural Technology, Faculty of Science & Technology, Thammasat University*, *Pathumtani, Thailand*, [2]*Faculty of Pharmaceutical Sciences, Prince of Songkla University*, *Songkla, Thailand*, [3]*Plant Pathology Research Group, Office of Plant Protection Research and Development, Department of Agriculture*, *Bangkok, Thailand*, [4]*Division of Animal Science, University of Missouri*.

The objective of this research was to produce activated carbon (AC) and evaluate its efficacy as an absorbent for zearalenone (ZEA) in swine diets. Three experiments (Exp.) were conducted to achieve this objective. In Exp. 1, 5 methods (M1 to M5) for producing AC were evaluated and included; M1), coconut shells (CS) treated with KOH (2:1) then heated at 400°C for 1 h and 800°C for 3 h; M2), CS treated with K_2CO_3 (1:1) then heated at 110oC over night and 800oC for 3 h; M3), CS treated with K_2CO_3 (2:1) then heated at 110°C over night and 800°C for 3 h; M4), CS heated at 400°C for 1 h then heated at 800°C for 3 h; and M5), CS heated at 110°C over night and then heated at 800°C for 3 h. Nitrogen gas was let in at 5 l/h during both heat treatments. Methylene blue indexes were not different among the 5 methods ($P > 0.05$), however ash content was different ($P < 0.05$) and ranged from 1.5% for M4 to 3.9% for M1. In Exp. 2, an in vitro procedure was used to evaluate the efficacy of the 5 ACs, from Exp. 1, to adsorb ZEA. The ZEA was analyzed using HPLC-fluorescence. ZEA adsorption by ACs produced by M3, M4 and M5 were not different ($P > 0.05$) and averaged 97%, whereas ZEA adsorption by ACs produced by M1 and M2 averaged 87 and 54%, respectively. Based on these results and production costs, the AC produced by M4 was chosen for evaluation in Exp. 3 which was conducted to evaluate the ability of M4 AC to ameliorate or prevent the effects of ZEA in 19 wk old gilts fed a diet contaminated with ZEA for 4 wks. The treatments were arranged as a 2 × 2 factorial in a CRD (4 replicates). The main factors were levels of AC (0 or 1% in diet) and concentrations of ZEA (0 or 1.165 ppm) in diets. Feed intake and FCR of the gilts were significantly higher ($P < 0.05$) in pigs fed diets containing 1% AC. Diets containing ZEA did not affect production performances, uterus weight and liver weight. The gilts fed diets containing ZEA had red swollen vulvas throughout the experimental period. However, no residues of ZEA or α-zearalenol were found in muscle, uterus or liver tissues of pigs fed ZEA. The data indicated that 1% AC, produced by M4, did not alleviate the effects of ZEA in gilts.

Key Words: zearalenone, activated carbon, gilt

W244 Gender effect on nutrient digestibility and reproductive organ sizes by zearalenone feeding with different levels of Calibrin-Z enterosorbent in young pigs. Z. B. Yang*[1], S. Z. Jiang[1], and F. Chi[2], [1]*Shandong Agricultural University*, *Tai-an, Shandong, PRC*, [2]*Amlan International*, *Chicago, IL*.

We previously reported addition of 1 ppm zearalenone (ZEA) reduced dietary protein (CP) and energy (GE) utilization in gilts and the reduced CP and GE were improved by addition of clay enterosorbent (CE). In present study, a total of 36 pigs (L × Y × D; 18 M, 18 F; 8.84 ± 0.21 kg) were used to study the genders' response to ZEA feeding. Pigs were divided into 6 treatments and fed diets contained 0 or 1 ppm ZEA with addition of different levels of CE (Calibrin-Z). Pigs were fed treatment diets (Table 1) individually in metabolic cages for 21 d. Vulva and testicle sizes were measured at 3-d intervals, and total feces were collected and pooled on 3-d bases for CP, GE, Ca, and P digestibility determination. Vulva sizes increased ($P < 0.01$) with ZEA feeding and the increased vulva sizes were reduced linearly as dietary CE increased. No treatment differences were observed with testicle size in male pigs. No treatment effect was obtained on ADG, ADFI and FE; however, the female pigs showed a poorer FE ($P = 0.01$) than the male pigs. There were differences ($P < 0.01$) on GE, Ca, and P digestibility between treatments but not on CP digestibility. Pigs fed Diet 3 showed lower Ca and P digestibility ($P < 0.01$) as compared with the pigs fed Diet 1. Additions of CE to ZEA contaminated diet improved ($P < 0.01$) GE, Ca, and P digestibility compared with the pigs fed ZEA alone (Diet 3). And the increased nutrient digestibility was improved as the dietary CE levels increased. A gender effect on CP, GE, Ca, and P digestibility ($P < 0.05$) was observed in the study with no interactions between treatments and sexes. For nutrient digestibility, a gender effect was observed with ZEA feeding (Diet 1 vs. Diet 3) where female pigs showed a decrease ($P < 0.01$) of CP digestibility, and male pigs showed decreases ($P < 0.01$) of Ca and P digestibility. The study showed that the reduced nutrient

digestibility by ZEA feeding maybe gender dependent in young pigs. Also, the increased vulva sizes and the reduced nutrient digestibility resulting from ZEA feeding can be ameliorated by Calibrin-Z.

Table 1. Treatments and Results

Treatment	ZEA, ppm	Calibrin-Z, %	Vulva Size, mm^2	DCP, %	DGE, %	DCa, %	DP, %
Diet 1	0	0	52^{c}	88.4	88.4^{c}	67.3^{a}	57.7^{a}
Diet 2	0	0.1	51^{c}	88.6	88.7^{c}	66.8^{ab}	55.8^{cd}
Diet 3	1	0	190^{a}	87.5	88.3^{c}	65.5^{c}	55.0^{d}
Diet 4	1	0.1	142^{ab}	88.2	88.9^{bc}	66.2^{bc}	55.4^{d}
Diet 5	1	0.2	124^{b}	88.3	89.3^{ab}	67.1^{ab}	56.4^{bc}
Diet 6	1	0.4	110^{b}	88.8	89.4^{a}	67.0^{ab}	56.9^{ab}

DCP - digestible CP; DGE - digestible energy; DCa - digestible Ca; DP - digestible P.

W245 Effects of dietary *Fusarium* mycotoxins on intestinal lymphocyte subset populations, cell proliferation and histological changes in avian lymphoid organs. C. K. Girish*, T. K. Smith, H. J. Boermans, P. Anil Kumar, and G. N. Girgis, *University of Guelph, Guelph, Ontario, Canada*.

An experiment was conducted to investigate the effects of dietary *Fusarium* mycotoxins on gut immunity, cell proliferation, and histology of avian lymphoid organs. The efficacy of a polymeric glucomannan mycotoxin adsorbent (GMA) was also determined. Seventy-two 1-d-old male turkey poults were fed corn, wheat, and soybean meal-based diets for 21 d. Diets included control grains, contaminated grains and contaminated grains + 0.2% GMA. The major contaminant was deoxynivalenol (DON, vomitoxin; 3.9 µg/g) with lesser amounts of zearalenone (0.67 to 0.75 µg/g) 15-acetyl-deoxynivalenol (0.34 µg/g) and HT-2 toxin (0.078 to 0.085 µg/g). The T and B-lymphocyte populations and crypt cellular proliferation in duodenum, jejunum, ileum and cecal tonsils were measured immunohistochemically on d 14 and 21. Histological changes were recorded after 14 and 21 d of feeding. Feeding contaminated grains significantly ($P = 0.004$) increased the percentage of B-lymphocytes in ileum on day 14, and reduced ($P = 0.04$) the percentages of $CD8^{+}$-lymphocytes in cecal tonsil on d 21. GMA supplementation prevented these effects. The feeding of contaminated diets also caused a reduction ($P = 0.03$) in ileal crypt proliferating cells and a significant (P=0.003) increase in spleen secondary follicle on d 21. In conclusion, feeding grains naturally contaminated with *Fusarium* mycotoxins results in adverse effects on gut immunity and mucosal cell proliferation. The feeding of GMA can prevent some of these effects.

Key Words: *Fusarium* mycotoxin, intestinal lymphocyte, immunohistochemistry, lymphoid organ, turkey

W246 Effects of purified zearalenone on serum metabolites and antioxidant status in young gilts. S. Z. Jiang[1], Z. B. Yang*[1], and F. Chi[2], [1]*Shandong Agricultural University, Tai-an, Shandong, PRC*, [2]*Amlan International, Chicago, IL*.

The study was designed to investigate the adverse effects of dietary zearalenone (ZEA) on oxidative stress and organ damage in young female pigs. A total of 20 gilts (L × Y × D; 10.36 ± 1.21 kg BW) were fed a commercial diet for 7 d adaptation and then divided into 4 groups. Diets were a corn-soy-fishmeal based with an addition of 0, 1, 2, or 3 ppm ZEA to the basal diet. Pigs were fed the test diets ad libitum for 18 d. All measurements and analyses were based on individual pig. Vulva length, width, and height were measured at 4-d intervals. Serum samples were collected for enzyme activities and antioxidant status analyses. Genital organs, liver, kidney and spleen were isolated, weighed, and the relative organ weights were calculated. Results showed that gilts fed different levels of ZEA had no effect on weight gain and feed intake. The vulva length, width and height were increased linearly as dietary ZEA concentrations increased ($P < 0.01$). Relative organ weights including genital organs, liver, and kidney weights were increased linearly as dietary ZEA increased ($P < 0.01$). Serum aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, γ-glutamate transferase, urea, and creatinine in the serum were all linearly increased as dietary ZEA increased in test diets ($P < 0.05$). Malondialdehyde concentrations in both serum and liver were also increased linearly by increased dietary ZEA ($P < 0.001$). Unlike the liver and kidney, relative spleen weight was decreased linearly as dietary ZEA concentrations increased ($P < 0.01$). Activities of total superoxide dismutase and glutathione peroxidase in the serum and liver ($P < 0.05$) were also reduced linearly as dietary ZEA increased. Results suggested that besides genital organs, the liver, kidney and spleen may also be target tissues in young gilts fed diets containing 1 to 3 ppm ZEA for 18 d. The reduced relative spleen weights suggested potential detrimental effect on pig immunity by feeding ZEA. Elevated key liver enzymes in the serum suggested a progressive liver damage by feeding ZEA, and the damage was probably mediated by the lower antioxidant enzymes in the liver and serum.

W247 A survey of free and conjugated deoxynivalenol in the 2008 Ontario corn crop. S.-T. Tran*[1], G. Stewart[2], and T. K. Smith[1], [1]*University of Guelph, Guelph, ON, Canada*, [2]*Ontario Ministry of Agriculture, Food and Rural Affaires, Guelph, ON, Canada*.

Deoxynivalenol (DON, vomitoxin), one of the most important mycotoxins produced by many *Fusarium* species, is found as a common contaminant of crops worldwide. DON can reduce production efficiency and cause serious economic losses to livestock and poultry producers. Recent studies have described the presence of conjugated forms of DON (glycosides and fatty acid). The aim of the current study was, therefore, to investigate the natural occurrence of free and conjugated DON in Canadian corn. Free and conjugated DON were determined by HPLC and ELISA kits (AgraQuant DON kit) in 86 corn samples collected from the 2008 Ontario crop. Free DON was found in all samples and concentrations determined by ELISA were similar to values determined

in most samples using HPLC. Conjugated DON, however, was not detected in 15 samples. Levels of DON ranged from 0.01 to 14.00 μg/g. Samples highly contaminated with DON did not necessarily show a high concentration of conjugated DON. The highest levels of free DON were found in corn samples from the south and south-west regions of Ontario while samples from eastern region were less contaminated with 8 of 13 samples found to contain 0.01 μg/g. Conjugated DON was found mainly in corn from the east-central region with 5 of 6 samples showing high levels of conjugated DON. Low levels of conjugated DON (<10%) were detected in the majority of corn samples from the south-west region (13 of 19 samples) and from the central region (23 of 36 samples). The reasons for the differences between regions could be due to climatic conditions or plant genetics. The current survey of free and conjugated DON in the 2008 Ontario corn crop emphasizes the potential challenges in understanding the hazard posed by DON contaminated feedstuffs. Although much research has been carried out since the original discovery of free and conjugated DON, the significance of these mycotoxins for animal health remains to be determined.

Key Words: deoxynivalenol, conjugated, corn

W248 Impact of ochratoxin A (OTA) and zearalenone (ZEA) on growth performance and pig physiology. U. Hofsteter* and I. Rodrigues, *Biomin Holding GmbH*, *Herzogenburg, Austria*.

The objective of this study was to evaluate the negative impact of OTA and ZEA on piglets and to investigate the effects of a mycotoxin deactivator. A total of 48 female crossbred weaning piglets were divided into 6 groups: negative control; positive control (2kg/mt); toxin group (500μg/kg OTA, 250μg/kg ZEA); trial group 1 (500μg/kg OTA, 250μg/kg ZEA, 0.5kg/mt); trial group 2 (500μg/kg OTA, 250μg/kg ZEA, 1kg/mt); trial group 3 (500μg/kg OTA, 250μg/kg ZEA, 2kg/mt). Data was analyzed using the General Linear Model Procedure of SAS in a completely randomized design. Comparison of the group averages was done using Duncan's Multiple Range Test. Uterus, ovaries, kidneys and liver were evaluated for histopathological changes. Significantly heavier ($P<0.05$) pigs compared to the toxin group resulted from the addition of the mycotoxin deactivator in the OTA and ZEA contaminated diets. The relative weight of the different organs tended to be lower (uterus and liver showed $P<0.1$, ovaries and kidneys were not significant) in pigs fed contaminated diets, but no incidence of vulvovaginitis was observed within the groups. Pigs fed the control and diets with 0.10% and 0.20% of the feed additive had normal uterine body and horn, which are characterized by thick endometrium and enlarged glands. The ovaries from pigs fed the contaminated diets exhibited only one young tertiary follicle with several atretic follicles, an indication of degeneration. Although relative kidney weights did not vary within the groups, renal lesions were microscopically observed in pigs fed OTA and ZEA. Respectively one pig from group 3 to 6 exhibited nephrotoxicosis, the primary toxic response to OTA, which is characterized by degenerative changes such as swollen, pale, vacuolated cells in the renal tubular epithelium. Livers from pigs fed the control diets had normal cells whereas those fed OTA and ZEA contaminated diets showed liver sinusoids with red blood cells, a sign of congestion. The combination of OTA and ZEA showed a negative impact on performance and physiological parameters which were overcome by the addition of the mycotoxin deactivator.

Key Words: ochratoxin A, zearalenone, physiology

W249 Adverse effects of feed-borne *Fusarium* mycotoxins on performance and serum chemistry of rabbits. M. A. Hewitt*, G. N. Girgis, C. K. Girish, and T. K. Smith, *University of Guelph*, *Guelph, Ontario, Canada*.

The effects of *Fusarium* mycotoxins on performance and metabolism of livestock and poultry have been described in the literature. There is a lack of information, however, regarding the effects of *Fusarium* mycotoxins on rabbits. An experiment was conducted to investigate the impact of feed-borne *Fusarium* mycotoxins on performance, hematology and serum chemistry of male New Zealand White rabbits. Rabbits were fed either a control diet or a diet containing corn and wheat naturally contaminated with *Fusarium* mycotoxins. The contaminated diet contained 5.0 μg/g deoxynivalenol (DON) and 0.24 μg/g 15-acetyl-DON. At the end of the 12 days experimental period, there were trends towards reduced body weight gain and feed efficiency in rabbits fed the contaminated diet. Serum urea concentrations were significantly higher ($P = 0.02$) in rabbits fed the contaminated diet compared to controls. Increased serum concentrations of urea in cattle and uric acid in poultry have been described to be a result of altered protein metabolism following ingestion of *Fusarium* mycotoxin-contaminated diets.

Key Words: rabbit, *Fusarium* mycotoxins, urea

W250 Enrichment of eggs of Japanese quail with α-tocopherol. R. H. Marques, R. A. Gravena, J. D. T. Silva, F. H. Hada, J. Roccon, J. Picarelli, S. A. Queiroz, and V. M. B. Moraes*, *São Paulo State University*, *SP - Brazil*.

The objective of this study was to evaluate the effect of diets supplemented with vitamin E on the concentration of α-tocopherol in egg yolks of Japanese quail. One hundred 92 70-d-old quail were randomly distributed into 4 treatment groups with 6 replicates of 8 birds in each pen. The birds were placed on 1 of 4 dietary treatments (0, 200, 400 and 600 IU vitamin E/kg feed) for 4 lay cycles. Three eggs were collected per treatment at 56 d. Levels of α-tocopherol in yolk determined by high performance liquid chromatography showed a linear relationship ($y = 0.223 + 0.0015x$, $R^2 = 0.9256$), with dietary vitamin E supplementation levels ($P < 0.05$). In treatments using diets supplemented with 600 IU vitamin E/kg feed, α-tocopherol reached a value of 479.05% above control values, suggesting that the nutritional value of eggs can be enhanced by the addition of vitamin E to diets.

Table 1. Effect of vitamin E in quail diet on concentration of α-tocopherol in egg yolk

Vitamin E	α-tocopherol concentration in yolk (mg/g)	% increase
Control	0.191	-
200 IU	0.579	203.14
400 IU	0.789	313.08
600 IU	1.106	479.05
Probability	0.001*	-
F values	273.52	-
CV[1] (%)	14.68	-

[1]Coefficient of variation, * significant ($P < 0.001$).

W251 Expression of kyphosis in young pigs is altered by carryover effects of sow vitamin D status. L. A. Rortvedt*, L. A. Zappitelli, J. L. Reichert, J. R. Booth, and T. D. Crenshaw, *University of Wisconsin*, *Madison*.

Kyphosis, or 'hump-backs', is an idiopathic disease that may affect 30% of pigs. The UW Swine Center had a flare-up and subsidence of kyphosis over 4 mo that affected ~20% of pigs. The incidence was consistent with unintentional omission of vitamin D (D) from all diets. This experiment was designed to determine if kyphosis was expressed in pigs produced by sows fed no supplemental D. Crossbred (LR × LW), multiparious sows (n = 8) were fed corn-SBM diets supplemented with either 280 (+D) or 0 (-D) IU vitamin D_3/kg diet from breeding through lactation. At weaning (4 wk), 6 pigs (3, +D; 3, -D) were scanned using DXA (GE Lunar Prodigy) to determine whole body bone mineral content (BMC, g/pig) then killed to assess femur properties. The other 75 pigs were weaned and randomly assigned by weight within sow groups to diets that supplied either 120% (HCaP) or 80% (LCaP) of required Ca and P. Pig diets had no added D. At 9 wk all pigs were fed HCaP diets until termination at 13 wk. Serum Ca and P were assessed at 4 and 9 wk. A subset of pigs were scanned and killed at 9 (n = 12) and 13 (n = 25) wk. Kyphosis was evident at 9 wk in 4 of 19 pigs from –D litters fed LCaP, but not in other groups. At 13 wk, 5 of 15 pigs in –D litters fed LCaP and 5 of 17 pigs from +D litters fed LCaP showed kyphosis. No pigs fed HCaP showed kyphosis regardless of sow D diets. Growth, BMC, and serum P were reduced ($P < 0.05$) in pigs fed LCaP compared with HCaP, but reductions were greater (interaction, $P < 0.05$) in pigs from sows fed -D diets. Evidence of sow diet effects were detected in BMC of pigs at 13 wk. In conclusion, kyphosis was induced in pigs fed diets without supplemental D and marginal Ca P. Evidence of kyphosis occurred at a younger age if pigs were produced by sows fed -D diets.

Table 1.

Vitamin D, IU/kg	280	280	0	0

W252 Incorporating whole grain sorghum in broiler rations. C. Marr*, C. M. Rude, M. A. Barrios, R. Rierson, and R. S. Beyer, *Kansas State University*, *Manhattan*.

Commercial poultry producers streamline feed production and lower costs by utilizing fewer ingredients in feed rations. This reduces opportunities to utilize nontraditional grains or by products when prices decline since storage bins and specialized handling equipment may require investment that is not used at full capacity. It may be possible to incorporate some ingredients into formulations to realize savings without changing the manufacturing process if the ingredients could be used without excessive processing. Because grain sorghum is sometimes priced competitively with corn, work was conducted to determine methods of incorporating whole sorghum directly into feed rations. A typical corn-soy broiler starter formula was adjusted to incorporate 15% grain sorghum, substituting mostly for the corn fraction. The cereal grains were ground and mixed into a mash control ration. The treatments included 0, 5, 10 and 15% whole sorghum, substituted on a 1:1 basis for the ground sorghum. Cobb 500 broiler chicks were placed in Petersime battery units, 6 per pen, 8 reps per treatment, with feed and water provided ad libitum. All feed was overlaid with a screen of 1-inch mesh to prevent the chicks from segregating the feed. The trial was conducted for 21 d, during which BW and FI were determined for day 7, 14, and 21. At each week, the data indicate that adding whole grain sorghum decreased BWG and FC compared to ground sorghum. At 5% added whole grain sorghum, the effects were smaller and were not significant at each period. The data suggest that whole sorghum particles could be difficult for new chicks to process since the digestive system is not fully functional compared to adult birds which possess a mature gizzard capable of grinding large feed particles. It was observed that the chicks were attracted to the dark sorghum berries which were consumed immediately if the feed was stirred. Because the birds appeared to consume all of the diet, it was assumed that selective feeding did not affect performance. Additional studies are required to determine if adding whole sorghum to pelleted rations during the grower phase will decrease selection and affect broiler performance.

Key Words: sorghum, whole grain, broiler

W253 Water consumption and performance of broilers receiving Mate (*Ilex paraguariensis*) infusions. A. M. C. Racanicci*[1], J. F. M. Menten[2], and J. Rabello[1], [1]*University of Brasília (UnB)*, *Brasília, DF, Brazil*, [2]*University of São Paulo (ESALQ)*, *Piracicaba, SP, Brazil*.

Aqueous extracts of mate are known to be an important source of phenolic compounds with a strong antioxidant capacity in chicken meat products. The objective of this study was to offer infusions of mate in substitution of water to broilers and evaluate performance and oxidative stability of cooked meat balls. One hundred male Cobb broilers were allotted in cages and distributed randomly to 4 treatments with 5 repetitions of 5 birds. From 11 to 21 d of age, birds were fed conventional corn-soybean meal diets ad libitum and received water (CON) or infusions prepared with hot water (90 °C) and 3 concentrations of mate 0.1, 0.5 or 1.0% as experimental treatments (MA0.1, MA0.5 and MA1.0). Birds received liquids in trough drinkers and the consumption was measured every two days. At 21 d of age, body weight (BW) and feed consumption were recorded to calculate individual weight gain (WG), feed intake (FI) and feed conversion ratio (FCR). Breast meat from 8 birds per treatment was used to prepare meat balls (30 g ± 0.5 g), cooked in boiling water for 8 m and stored in the dark in a cold room (4 °C) for 3 d. Progression of lipid oxidation in meat balls was evaluated by analyzing TBARS (thiobarbituric acid reactive substances; expressed in µmol of malondialdehyde (MDA) per kg of meat). Averages of BW and WG obtained from CON, MA0.1 and MA1.0 (966.8, 966.4, 984. g and 63.6, 63.2 and 61.6 g/d, respectively) were similar ($P > 0.05$), however, MA0.5 showed reduced values (907.2 g and 57.9 g/d, respectively) compared to CON and MA0.1. Averages of FI were not affected ($P > 0.05$) by treatments (86.2, 88.2, 83.6 and 84.4 g/d, respectively) but FCR was affected negatively ($P < 0.05$) by MA0.5, which showed the higher average (1.45) compared to CON and MA1.0 (1.36 and 1.37). The substitution of water by mate infusions did not affect ($P > 0.05$) liquid consumption, however, was effective to protect meat balls from lipid oxidation during storage. This effect can be demonstrated by lower TBARS ($P < 0.05$) in meat balls from MA0.1, MA0.5 and MA1.0 (36.63, 34.35 and 34.23 µmol MDA/kg of meat, respectively) compared to CON (48.88 µmol MDA/kg of meat).

Key Words: natural antioxidants, mate, liquid consumption

W254 Effect of fiber separation from ground corn flour on nutritional value of poultry diets. R. Srinivasan* and A. Corzo, *Mississippi State University*, *Mississippi State*.

In a previous demonstrational study, the Elusieve process, a combination of sieving and elutriation (air classification), was found to be effective in fiber separation from ground corn flour. Corn flour was sieved into

four size fractions and the three biggest size fractions were air classified (aspirated) individually to separate fiber from each of the three size fractions. The material remaining after fiber removal is called enhanced corn flour. Ground corn flour is a major ingredient in diets for swine and poultry, which do not digest fiber very well because they are non-ruminant animals. Fiber separation could increase the nutritional value of corn flour for broilers and could decrease the usage of expensive dietary ingredients such as oil/fat and enzymes. The objective of this study was to determine the effect of fiber separation on nutritional value of poultry diets by carrying out broiler feeding trials. Fiber separation increased starch content in corn flour by 3.0% points. The grow-out study encompassed the period between 0 to 21 d of age using Ross × Ross 308 males obtained from a commercial hatchery. Day-old chicks were randomly placed in each of 24 floor pens (15 birds/pen; 360 birds total). There were 2 different dietary treatments (regular corn diet and enhanced corn diet) with each treatment being replicated 12 times. Diets were formulated to be isocaloric, isonitrogenous, and similar in calcium, phosphorus and all limiting amino acids. Data were analyzed by the GLM procedure of SAS (2004) and treatment effects were separated using Tukey's multiple comparisons test option of SAS (2004) using an α of 0.05. The body weight gain of chicks was significantly higher (by 4.3%) and feed conversion ratio was significantly lower (by 3 points) when fed with enhanced corn diet compared with the regular corn diet. Thus, fiber separation from corn flour increases nutritional value of broiler diets.

Key Words: fiber, separation, elusieve

W255 The effect of using different levels of corn gluten meal in free range chickens diet. C. B.-V. Rabello*, A. F. da Silva, S. B. P. de Lima, H. Pandorfi, M. B. dos Santos, C. da Costa Lopes, and M. d. C. M. M. Ludke, *Universidade Federal Rural de Pernambuco*, *Recife, Pernambuco, Brasil*.

The objective of this work was evaluated the effect of inclusion of the corn gluten meal (CGM21) on performance and carcass yield of free range chickens. A total 240 free range chickens, females with 32 days-old, were distributed according with completely randomized design, five levels of inclusion of the CGM21 and 4 replicates. One reference diet based on corn and soybean meal was formulated and three test diets containing 7, 14 and 21% CGM21 (21% crude protein). The birds were housed in breeding system semi-intensive with access to the piquete containing pasture. Feed intake, weight gain and feed conversion were evaluated weekly. The Carcasses were evaluated (weight and yield) at 84 d, when eviscerated carcass (with head and feet), eviscerated carcass (without head + feet), thighs, drumsticks, wings, back, edible offal (liver, heart and gizzard), and abdominal fat were measured. The assay had two periods: grower phases (32 to 63 d of age) and finish phase (64 to 84 d of age). Data underwent regression analysis. In the growth phase the weight gain (WG), feed intake (FI) and feed conversion (FC) were not affected by increasing CGM21 inclusion in diets, but in the final (64 to 84 d of age) and total period (32 to 84 d of age) showed effect about the CA with better results when we included 10.0 and 9.8% of CGM21, respectively; the WG in the total period had quadratic effect with the better level of inclusion of CGM21 of 9.0%;. In the evaluation of carcass weights of carcass, breast, thigh, wing, back, neck, heart, gizzard and abdominal fat did not show significant effects. The liver and drumstick of birds had similar response, with higher weights when they were included: 11.65 and 9.63% of GM21, respectively. The yield of breast, wing, back, thigh, heart and gizzard were not affected, but the drumstick, liver and abdominal fat showed a quadratic effect with the highest level 13.7%, 8.5% and 10.8% of the inclusion of CGM21, respectively. The inclusion of gluten meal for free-range chickens can not exceed the level of 10% from at growth phase (63 days old), but can use around 21% in the initial phase (28 days old).

Key Words: growth performance, free-range chicken, carcass yield

W256 Effects of feeding low-density diets to Hy-Line W-36 laying hens on production performance. S. A. dePersio*[1], K. W. Koelkebeck[1], C. M. Parsons[1], P. L. Utterback[1], C. W. Utterback[1], N. O'Sullivan[2], K. Bregendahl[2], and J. Arango[2], [1]*University of Illinois*, *Urbana*, [2]*Hy-Line International*, *Dallas Center, IA*.

An experiment was conducted using 480 Hy-Line W-36 hens (18 wk of age) to determine whether feeding diets of different nutrient densities would affect egg production performance. At 18 wk of age hens were moved from a floor grow out facility to a caged layer building, weighed, and allotted to 6 replicate groups of 16 hens each (2 adjacent cages containing 8 hens per cage, 60.9 x 58.4 cm) per treatment diet in a completely randomized design so that mean body weight was similar for each treatment. Treatments consisted of 5 diets formulated to contain 85 (Diet 1), 90 (Diet 2), 95 (Diet 3), 100 (Diet 4), and 105 (Diet 5) % of the energy and nutrient recommendations stated in the 2009 Hy-Line W-36 management guide. Egg production performance was measured for 22 wk from 18 to 40 wk of age. At Week 14, egg production of hens fed Diet 1 (85% of control) dropped greatly to 57.6%. It was decided to switch these hens to the control diet (Diet 4). After this, egg production of Diet 1 hens began recovering and was stable by Week 17. Hens fed the control diet (Diet 4) came into production sooner than the other treatments, but by Week 5 all treatments had similar egg production. Overall average hen-day egg production for Diets 1 through 5 was 76.1, 80.6, 81.3, 84.2, and 82.1%, respectively. Hens fed Diets 1, 2, and 3 had lower ($P<0.05$) egg production than those fed the control diet. Hens fed Diets 2 and 4 consumed more ($P<0.05$) feed than those fed Diets 1 and 5. Feed efficiency was the greatest ($P<0.05$) for hens fed Diets 4 and 5. Egg weight was heavier for hens fed Diet 5 vs. Diets 1 and 2, while egg mass was greater for hens fed Diets 4 and 5 vs. Diets 1 and 2. The results of this study show that feeding Hy-Line W-36 hens diets formulated to contain lower nutrient density specifications (85% of control) than recommended may compromise early production performance.

Key Words: laying hens, low density diets, egg production

W257 Effect of prebiotic on performance and some blood parameters of partridge. H. Hashemipour, V. Khaksar, H. Kermanshahi, and A. Golian*, *Ferdowsi University of Mashhad*, *Khorasan Razavi, Iran*.

In modern poultry production, newly hatched chicks have no contact with maternal feces and so no maternal spectrum of antigens is present. In this situation, chicks can be affected by a number of pathogenic intestinal microorganisms, and fortifying diets with prebiotics can alleviate this problem. This experiment evaluates the effect on the performance, carcass characteristics and some blood parameters of the chukar partridge (*Alectoris chukar chukar*) of dietary supplementation with a prebiotic (Fermacto). Eighty day-old mixed sex chicks in a completely randomized design with two treatments (with or without 0.18% Fermacto) and four replicates of 10 birds each was used. The experimental period lasted 16 weeks in two phases of starter (0-8 weeks) and grower (9-16 weeks). Performance data recorded biweekly and carcass characteristics and some blood parameters were measured at the end of the experiment. Data revealed that the supplementation of Fermacto significantly ($P<0.05$) increased breast and gastrointestinal tract percentages, decreased the back-neck percentage, lowered blood triglyceride and total cholesterol and increased blood calcium levels in

the Fermacto-treated group. Under the conditions of this study, it was concluded that the dietary supplementation of 0.18% Fermacto might offer some beneficial effects in chukar partridges to improve their carcass quality and some blood parameters.

Key Words: prebiotics, performance, partridge

W258 Influence of diet quality on nutrient digestibility and productive performance of weanling pigs. J. D. Berrocoso*, C. H. Zúñiga, M. P. Serrano, L. Cámara, and G. G. Mateos, *Universidad Politécnica de Madrid*, *Madrid, Spain*.

The effect of ingredient composition of the diet on nutrient digestibility and growth performance was studied in piglets. There were 6 experimental prestarter diets (27-47 d of age) with similar NE and AA content. The positive control diet contained 40% cooked corn (HPC), 14% lactose (LAC), and 10% fish meal (FM). Two other experimental diets had the same composition than the control diet but the HPC was substituted by either raw corn (RC) or cooked rice (HPR). Two extra diets were similar to the positive control diet but contained only 7% LAC or 4% FM. Finally, there was a control negative diet with 40% RC, 7% LAC, and 4% FM. From 47 to 68 days age, half of the pens received a standard SBM-raw corn-lard diet and the other half a diet with similar nutrient profile that included 1.3% LAC, 5% FM, 20% HPC, 2% soy protein concentrate, and 1% soybean oil. Each treatment was replicated 6 times (6 pigs per box). Type of diet did not affect growth performance of pigs at any stage. Piglets fed the rice diet had lower incidence of diarrhea (DI) from 27 to 47 d of age than those fed the raw corn control diet ($P < 0.1$), with DI of pigs from the other treatments being intermediate. At 36 days of age, CP digestibility was not affected by dietary treatment but the CTTAD of GE, DM, and OM was lower ($P < 0.05$) for piglets fed raw corn than for piglets fed HPR with piglets fed HPC being intermediate. Also, an increase in the LAC content of the diet improved ($P < 0.05$) digestibility of these dietary components. Feeding program diet did not affect digestibility of any of the nutrients at 57 d of age. It is concluded that piglets weaned at 27 d of age performed similarly when fed diets containing raw corn and low levels of LAC an FM than when fed more complex diets but DI was reduced with the inclusion of cooked rice. Also, 47 d-old pigs (>11 kg BW) do not need to include any sophisticated ingredients in the diet, for optimal performance.

Key Words: cooked cereal, piglet nutrient digestibility, incidence of diarrhea

W259 Effects of different level of fish meal on growth performance, intestinal microbiology, and blood parameters of weaned pigs. H. F. Ji*, J. Wang, D. C. Shan, S. X. Wang, D. Y. Zhang, F. M. Wang, L. Hou, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences*, *Beijing, China*.

This study was undertaken to determine the effect of one commercial fish meal (CP, 65.5% DM) as protein sources on growth performance and blood parameters of weaned pigs. Sixty piglets (Large White × Landrace) weaned at 28 d of age (7.32 ± 0.86 kg BW), were assigned randomly to 4 treatments (n=15) in a completely randomized design. The 4 treatments included 1 basal diet (control) and 3 diets with different level of fish meal (2%, 5%, and 8% of diet). The experiment lasted thirty three days. Body weight and feed consumption of animals were determined on d 0 and 33 of the study to calculate ADG and G:F. The incidence of diarrhea in piglets was observed and recorded 3 times per day during the study. Fresh fecal samples were collected to evaluate shedding of *E. coli* and *Lactobacillus* and blood samples were collected from jugular vein to measure ω-3 fatty acid and C-reactive protein (CRP) at the end of the experiment. Utilization of fish meal improved ($P < 0.05$) overall ADG and G:F in comparison with the control. Along with the increase of fish meal in the diets, ADG and G:F were all increased significantly ($P < 0.05$). The incidence of diarrhea was significantly decreased ($P < 0.05$) by dietary fish meal inclusion during 0-10 d postweaning, while the diarrhea incidence was 0% when fish meal was included in the diet during 11-33 d postweaning. Fecal samples from pigs receiving diets containing fish meal had greater ($P < 0.05$) *Lactobacillus* counts than those from control pigs, and no difference existed in *E. coli* counts. The eicosapentaenoic acid (EPA, C20:5) and docosahexaenoic acid (DHA, C22:6) content of the blood increased ($P < 0.05$) with increasing fish meal in the diet. Piglets fed the diet containing 8% fish meal had the lowest ($P < 0.05$) CRP production. The current results indicated that fish meal as a protein sources in diets of young pigs enhanced growth performance by increasing ADG and G:F and decreasing the incidence of diarrhea, and improved intestinal microbes, ω-3 fatty acid level and physiological status.

Key Words: fish meal, weaned pig

W260 Energy value of cassava products and their use in weaning-growing pigs. E. Salcedo[1], L. Mestra[1], T. Rivero*[1], Y. Avellaneda[1], G. Afanador[1,2], and C. Ariza-Nieto[1], [1]*CORPOICA*, *Bogota, Colombia*, [2]*Universidad Nacional de Colombia*, *Bogota, Colombia*.

This study evaluated the digestible energy (DE) value of cassava meal, cassava meal extruded, and cassava foliage from 6 varieties of cassava harvested in 3 microregions of Colombia and evaluated their use in wean to finishing pigs. The DE was determined using the mobile nylon bag technique (MNBT). Samples, 1 g, ground through a 0.5-mm mesh, were enclosed in nylon bags (25 × 40 mm; 48 µm). Following pre-digestion (0.1 N HCl; pepsin 754.8 IU/1;4 h), eight bags of each feedstuff were inserted via a T-cannula placed in the duodenum. The material, remaining in the bags after passing through the digestive tract, was pooled within pig and feedstuff and used to estimate DE. The effect of cassava meal was evaluated in diets for weaning to growing pigs and its economic implication was estimated. Twenty (20) pigs with an average body weight of 15 kg were randomly assigned to one of the two treatments groups (with cassava, without cassava) in a phase feeding system approach; pre-starter (15-20 kg), starter (20-50 kg) and growth (50-70 kg). Pigs were individually weighed every other week until slaughter. Feed intake and feed conversion were record at the end of each phase. Data were analyzed as a completely randomized design using the GLM procedure of SAS. The digestible energy coefficient of cassava foliage was low (18.2%) compared to cassava meal (87.8%). The extrusion process increased the energy coefficient of the cassava meal (93.3%); therefore, the DE in pigs of cassava meal extruded was greater (3519 kcal/kg) compared to cassava meal (3309 kcal/kg). Cassava meal grown in Valley of Sinu river, Cordoba, Colombia showed the greatest energy value (3634 Kcal/Kg) and its inclusion at a rate of 25% in wean to growth pig diets showed that body weight gain, feed intake, and feed conversion were not significantly affected (P>0.05), The economic analysis showed that the inclusion of cassava meal significantly (P<0.05) reduced the cost of feed per kilogram of diet, because cassava meal price was 55% less than corn. Additionally, the cost per kilogram of pigs fed cassava meal was reduced (-$0.25) compared to pigs on the control group.

Key Words: cassava meal, digestible energy, pigs

W261 Effect of three feeding programs on body reserves gain of gestating sows. A. García-Rendón[1], J. López[2], A. G. Borbolla*[2], and E. Toledo[2], [1]*Granjas Covadonga*, *Estado de México, México*, [2]*Departamento de Producción Animal: Cerdos. Facultad de Medicina Veterinaria y Zootecnia. Universidad Nacional Autónoma de México*, *Coyoacán, D.F. México*.

An elevated number of pigs weaned/sow/year is essential to maintain pig farm productivity and efficiency. This is related to the amount and type of body reserves in the sow. During lactation, body reserves of sows are intensively mobilized for milk production, due to an insufficient feed consumption. Feeding programs during gestation therefore, must be designed to optimize protein deposition and avoid excessive fat accumulation. The objective of this study was to evaluate 3 different feeding programs on protein and fat gain of pregnant sows over 2 gestation cycles. Three hundred and 40 sows were assigned randomly to 3 treatments: Tr. 1: feed allowance based on visual body condition at mating. Tr. 2: Feed allowance based on body condition evaluated by weight and back fat using an ultrasound device. Tr. 3: Feed allowance according to the expected net maternal gain established by NRC (1998). Body condition was determined using Noblet (1990) formulas. Variables were analyzed with ANOVA, using a significance level of ($P < 0.05$). Initial and final weights ± SE in both gestation cycles were not different ($P > 0.05$) for the 3 feeding programs (Cycle 1. Tr.1:193.7 ± 3.05 and 253.8 ± 4.9 Kg, Tr.2:197.5 ± 3.6 and 257.4 ± 4.7 Kg, Tr. 3:198.0 ± 3.5 and 260.2 ± 4.8 Kg, respectively; Cycle 2. Tr.1: 211.4 ± 2.80 and 268.60 ± 2.7 Kg, Tr.2: 218.3 ± 3.6 and 271.1 ± 3.1 kg, Tr.3: 219.7 ± 2.9 and 275.6 ± 3.1 Kg, respectively). Accordingly, total weight gain during gestation was similar ($P > 0.05$) for all treatments in both cycles (Cycle 1. 60 ± 2.5 Kg; Cycle 2. 57.5 ± 1.5 Kg). As well on net maternal gain no differences ($P > 0.05$) were observed in any cycle (Cycle 1. 32.6 ± 2.0 Kg; Cycle 2. 30.4 ± 1.5 Kg). Differences ($P < 0.05$) over feed consumption and total body fat gain during the 2 gestation cycles are shown in Table 1. As for protein gain no differences ($P > 0.05$) were observed in both cycles (Cycle 1. 6.08 ± 0.5 Kg; Cycle 2. 5.1 ± 0.2 Kg). The use of a suitable feeding program during gestation, besides optimizing body reserves gain (fat and muscle), can improve sow output, and therefore increase its productivity, and longevity in the farm.

Table 1. Effect of feeding program on feed consumption and body composition of gestating sows.

	Gestation 1			Gestation 2		
	Treatment 1	Treatment 2	Treatment 3	Treatment 1	Treatment 2	Treatment 3
Total feed consumption, Kg	263.7 ± 1.3[a]	269.1 ± 3.4[b]	287.8 ± 1.2[c]	271.5 ± 0.3[d]	292.7 ± 3.1[e]	293.6 ± 1.4[e]
Body fat gain, Kg	6.4 ± 0.7[a]	9.1 ± 0.8[b]	8.5±0.9[a,b]	9.4 ± 0.5	9.9 ± 0.5	10.1 ± 0.5

[a,b,c,d,e]Means with different superscript letter differ (P < 0.05) for the same gestation.

W262 Effect of triticale on blood chemistry and performance of commercial growing turkeys. H. Zarghi, A. Golian*, and H. Aghel, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

A trial was conducted to study the performance of male broiler turkeys fed diets with triticale replaced for corn at the levels of 0, 25, 50, 75 and 100%. Each diet was fed to five groups of twelve male birds each. The diets were provided isocaloric and isonitrogenous for each period of 30- 53, 54-83, 84-94 and 95-116 d of age. Feed and water were fed ad-libitum. Similar weight gain, feed intake and feed conversion observed in birds fed control or diets contained up to 75% triticale replaced for corn. However, the average daily weight gain decreased, feed intake and feed conversion increased when 100% of corn was replaced with triticale during all periods (P<0.05). Although, carcass yield decreased in birds fed triticale contained diets, small intestine and large intestine weight and blood serum TG increased, whereas serum HDL and LDL decreased when measured at 116 d of age ($P < 0.05$). This study revealed that the turkey producers may substitute up to 75% of the corn with triticale in grower and finisher diets without adverse effect on performance.

Key Words: turkey performance, triticale, blood chemistry

W263 Influence of origin on in vitro protein and dry matter digestibility of soybean meal. S. Santos-Rosell, P. García-Rebollar, N. Núñez-Romero, M. P. Serrano, and G. G. Mateos*, *Universidad Politécnica de Madrid*, *Madrid, Spain*.

Previous works have demonstrated that the origin of the beans might affect the nutrient content and availability of soybean meals (SBM). In vitro procedures can be used to predict the *in vivo* ileal digestibility of SBM in broilers. The present research was conducted to determine the influence of origin (USA; Brazil, BRA; Argentine, ARG) on in vitro digestibility of N and DM of SBM. An adaptation of the Boisen and Fernandez (1995) method consisting on a two-step enzymatic hydrolysis simulating digestion in the stomach and small intestine followed by measurement of the remaining residues for the two digestion steps was used. The one-step method (stomach digestion) was an incubation of the SBM samples with pepsin at pH 2. The two-step method consisted in including a second multi-enzyme hydrolysis process (pancreatin at pH 7) to the pepsine digestion to simulate ileal digestibility. On DM bases, the BRA meals (n = 7) had higher CP content (55.9 vs. 54.3 and 53.1%; P < 0.001) than the USA (n = 8) and ARG (n = 7) meals. After the one-step enzymatic digestion (stomach), N digestibility was higher (67.7 vs. 65.8 and 64.9%, $P < 0.01$) for BRA meals than for USA and ARG meals. Also, DM digestibility (57.6 vs. 56.1 vs. 55.1; $P < 0.05$) was higher for BRA than for USA meals with the ARG meals being intermediate. When the two-step hydrolysis process (stomach and small intestine) was used, USA SBM had higher N digestibility (88.2 vs. 87.5 vs. 86.4; $P < 0.05$) than BRA meals and ARG meals were intermediate. Also, DM digestibility was higher (71.0 and 71.5 vs. 69.2; $P < 0.05$) for USA and ARG than for BRA meals. In conclusion, the in vitro hydrolysis methodology showed that the contribution of the small intestine to total digestion of N and DM is lower for BRA SBM than for USA and ARG meals and that those differences might be associated to different nutritional values for poultry of commercial available SBM differing in origin.

Key Words: soybean meal origin, in vitro digestibility, nutritional value

W264 Cloning of the porcine selenoprotein V gene and its RNA abundance in different tissues of young pigs fed three levels of dietary selenium concentrations. Q. S. Zhang[1], H. Zhao[1], J. C. Zhou[1], K. N. Wang[1], J. Y. Tang[1], X. J. Xia[1], and X. G. Lei*1,2, [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Cornell University*, *Ithaca, NY*.

Porcine selenoprotein V (Sel V) gene sequence and regulation of its expression remain unknown. In this study, we cloned a 1,233 base pair cDNA coding for the porcine Sel V gene and determined responses of its mRNA abundance to dietary Se concentrations. A total of 24 male pigs (5-wk old, 9.2 ± 0.4 kg BW) with a Se-deficient (0.03 mg Se/kg) corn-soy basal diet (BD) supplemented with 0, 0.3 and 3.0 mg Se/kg as Se-enriched yeast for 16 wk. At the end, pigs were killed to collect blood and nine tissues for total RNA isolation to conduct quantitative real-time Q-PCR analysis. While dietary Se supplement (0.3 or 3 mg/kg) exerted no significant effect on final body weights of pigs, it increased ($P < 0.05$) GPX activities and Se concentrations in both blood and liver. Among all the tissues assayed, testis had the highest ($P < 0.05$) and thyroid had the second highest ($P < 0.05$) Sel V mRNA levels that were not significantly different among the three dietary Se concentrations. Compared with pigs fed 0.3 and 3 mg Se/kg, pigs fed BD exhibited a lower ($P < 0.05$) Sel V mRNA level in kidney, but higher ($P < 0.05$) Sel V mRNA levels in hypothalamus and muscle, respectively. Only kidney Sel V mRNA levels were different ($P < 0.05$) between pigs fed 0.3 and 3 mg Se/kg. In conclusion, effects of dietary Se concentrations on Sel V gene expression varied with tissues in pigs.

W265 Phosphate status impacts bone integrity and stem cell proliferation in neonatal pigs. L. S. Alexander*, B. S. Seabolt, and C. H. Stahl, *North Carolina State University*, *Raleigh*.

Mesenchymal stem cells (MSC) are essential to postnatal bone growth and our previous research indicates that dietary phosphate (PO_4) level impacts proliferation of these cells in vivo. To determine the effect of early PO_4 nutrition on bone integrity and MSC activity, fifteen pigs (1.5 + 0.2 kg) between 24 and 36 hr old were divided into 3 dietary treatment groups. Over a 12 d period, pigs were either fed a PO_4 adequate diet or 1 of 2 diets that exceeded PO_4 requirements. Blood collected at d 6 and d 12 was analyzed for sera PO_4, Ca, and PTH concentrations. Remaining sera was pooled from each treatment group to determine the impact of sera on MSC proliferation in vitro. At the conclusion of the trial, tibias were collected for bone measures and MSC were isolated from bone marrow of individual animals. While sera PO_4 did not differ between treatment groups at either time point, a dose response was noted in sera Ca ($P < 0.05$) and PTH ($P < 0.05$) concentrations at d 6, with adequate animals having the lowest sera PTH concentrations and correspondingly higher circulating Ca when compared to the other groups. Although, the tibias of animals receiving the PO_4 adequate diet were larger ($P < 0.05$) and thicker ($P < 0.1$) than the bones of those animals receiving excess PO_4, ash percentage did not differ between groups. Proliferation of MSC treated for 24 hr in sera from each group was effected by PO_4 status ($P < 0.1$) of the animal and tended to be influenced by PO_4 status of the sera. Because circulating PO_4 did not differ between groups, the changes in bone measures, sera mineral and hormone concentrations, and MSC proliferation would suggest possible differences in PO_4 utilization. Additional research is needed to further clarify how PO_4 status affects MSC activity and the subsequent alterations in bone integrity.

Key Words: pig, phosphate, bone

W266 The effect of calcium and phosphorus supplementation on production traits of laying hens. T. D. Knezacek*, J. P. Dahiya, K. V. Schwean-Lardner, and H. L. Classen, *University of Saskatchewan*, *Saskatoon, Canada*.

Research in our laboratory found short term feeding of high calcium (Ca) levels could increase bone mineralization. Though not investigated, this response may benefit bird welfare by reducing cage layer fatigue and bone breakage. Consequently, research investigating the relationship between Ca and available phosphorus (AP) was completed to determine the effect of increasing levels of these minerals on laying hen performance. Rations were fed to 864 Lohmann LSL Lite hens in 4 phases from 19-31, 31-43, 43-55 and 55-67 wks of age. From 19-31 wks of age, all hens were fed the same diet (3.80% Ca, 0.45% AP). The remaining phases each had 12 dietary treatments consisting of 4 levels of Ca and 3 levels of AP (3.80-4.27% Ca, 0.40-0.50% AP; 3.80-4.74% Ca, 0.35-0.55% AP; and 3.80-5.20% Ca, 0.30-0.60% AP, respectively). Egg weight, specific gravity and feed intake were measured at 4 wk intervals. Overall, level of Ca and AP inclusion had no effect on hen-day egg production, egg quality, egg weight, egg specific gravity, feed intake, feed to egg mass ratio or bird mortality. Ca level affected hen body weight at 66 wks of age (P=0.0309), with birds fed the lowest Ca level being lighter (1.752 kg) than birds fed the highest Ca level (1.818 kg). Hens fed higher levels of AP had poorer feed efficiency (P=0.0180) due to reduced egg production later in the cycle and feed intake that was similar to lower levels of AP. Though not statistically significant, hens fed higher Ca levels had a greater incidence of fatty-liver hemorrhagic syndrome. There was also a trend for higher mortality due to cage layer fatigue in low Ca and low Ca-AP diets. There were no significant interactions between level of Ca and AP supplementation. In conclusion, Ca and AP supplementation in later-phase layer rations did not affect hen performance suggesting a variety of Ca:AP ratios will meet the requirements for egg production.

Key Words: calcium, phosphorus, egg production

W267 The effects of strain and dietary phosphorus level on large tom turkey performance. B. N. West*, K. G. S. Lilly, K. R. Beaman, L. K. Shires, S. A. Loop, and J. S. Moritz, *West Virginia University*, *Morgantown*.

There are several challenges associated with maintaining a competitive edge in commercial poultry production. Choosing the appropriate genetic strain of turkey can significantly impact feed conversion and carcass yield, thus profitability. In addition, environmental impacts of production agriculture (especially manure disposal) are becoming increasingly more scrutinized and consequently regulated. Dietary phosphorus levels can also significantly impact diet cost. The objective of this study was to determine differences between strain use and dietary phosphorus level in a research setting that mimics commercial production. This was a 2x2 factorial design utilizing two strains (Nicholas and Hybrid) and two levels of dietary phosphorus (high and low) in finishing diets (d-105 through d-138). All birds were reared at the newly renovated West

Virginia University turkey research facility and all diets were manufactured at a commercial feed mill. Male poults (1216) were randomly placed in one of 16 pens and randomly assigned one of four treatments. Live weight gain (LWG), feed intake, feed conversion ratio (FCR), and percent mortality were recorded from d-1 through d-138. Both strains had similar finishing weights and mortality percentages (P>0.05), but the Hybrid strain had a significantly better FCR (P<0.05). An enzyme linked to protein degradation, Lysine-Ketoglutarate Reductase (LKR), had greater expression in Nicholas than Hybrid toms (d-1 through d-136), thus supporting an inferior FCR in the Nicholas strain. Changes in dietary phosphorus in finishing diets did not affect performance or litter phosphorus content, thus indicating potential to decrease feed cost but not environmental impacts.

Key Words: turkey, phosphorus, genetic strain

W268 Impact of breeder mineral nutrition on chick development. L. F. Araujo*[1], C. S. S. Araujo[3], L. C. G. S. Barbosa[3], L. V. B. Pereira3,1, S. Hubbard[3], and M. T. Kidd[2], [1]*University of Sao Paulo*, *Pirassununga, SP, Brazil*, [2]*University of Arkansas*, *Fayetteville,* [3]*Mississippi State University*, *Mississippi State*.

The objective of this research was to investigate chick development measured as chick quality, and growth rates of chicks, from broiler breeders fed supplemental minerals. Breeders received a control diet (vitamin and mineral premix devoid of Se) or diets containing supplemental Se (0.3 mg/kg), Zn (30 mg/kg), Mn (40 mg/kg) from organic sources, and the combination of the three minerals. Organic minerals were supplied as crystalline metal glycinate (zinc and manganese) and selenium proteinate. All dietary treatments were supplied in mash form. Breeders were housed in a floor pen facility with 40 pens (8 replications/treatment). Each pen was equipped with 1 feeder, nipple drinkers and 1 nest. Each pen contained three females which were inseminated before eggs were collected. A total of 450 eggs (90 eggs per treatment) and 800 eggs (160 eggs per treatment) were obtained and set at 31 and 42 wks of age, respectively. Chick quality characteristics included dehydration, navel condition (open navel, small navel, and large navel), wet chicks, dried yolk, red hocks, and bone strength. Furthermore, as characteristics of growth rate, it was evaluated relation between chick length and body weight at process age, and eggs production in broiler breeders. At hatch, chicks were wing banded by treatment and chick quality was assessed. Ten chicks per treatment at d 1 were euthanized and their tibias were collected to evaluate bone strength. No significant differences were noted among treatments for dehydration, navel conditions, wet chicks, dried yolk and red hocks. However, progeny from breeders fed supplemental minerals showed bigger bone strength than birds from hens fed control treatment ($P < 0.05$). Furthermore, BW increased at process age according to chick length. Chicks from hens supplemented with Mn showed an increase on BW at process age and this improvement was related to chick length at hatch. Mineral supplementation resulted in an improvement at eggs production. Chick development is positively affected by breeder mineral nutrition.

W269 The effect of feeding corn distillers dried grain with solubles to sows in gestation and lactation on sow productivity. M. Roux*, S. Kitt, and R. Moser, *JBS United, INC.*, *Sheridan, IN*.

One thousand and twenty sows (340/treatment PIC Line C29) and their pigs were used to evaluate the effects of feeding corn distillers dried grains with solubles (DDGS) in gestation and lactation over multiple reproductive cycles on sow productivity. Sows were blocked by parity (avg. 2.1) and allotted to 1) non-DDGS corn-soybean meal (SBM) control diet or two levels of DDGS 2) 15%/7.5% and 3) 30%/15% in gestation/lactation, respectively. All gestation diets were formulated to contain 0.62% SID lysine and 3,340 kcal/kg ME. Lactation diets were formulated to contain 1.11% SID lysine and 3,460 kcal/kg ME. Treatments were initiated at an average of 47 days prior to farrow and continued through the subsequent gestation and lactation. At the end of the first lactation, sows fed the highest level of DDGS (30% in gestation/15% in lactation) had less back fat (BF), reduced ADFI, and greater weight loss ($P < 0.05$); but trended to have a reduced wean-to-estrus interval (WEI, $P < 0.08$) compared to sows fed the non-DDGS diet. There were no differences among treatments in litter response variables (total born, born alive, birth weight, wean weight, number weaned, pre-wean mortality, $P > 0.10$). Sows fed high DDGS in the subsequent gestation and lactation responded to dietary treatments in a similar fashion as in the previous lactation with respect to body weight loss, BF, ADFI, and return-to-estrus. There was no difference in subsequent litter performance (total born, born alive, birth weight, wean weight, number weaned, and pre-wean mortality, $P > 0.10$). At trial completion, DDGS samples were pooled by month and screened for mycotoxins. Average vomitoxin and zearalenone levels were 3.06 ppm ± 1.12 and 0.11 ppm ± 0.04, respectively. Overall, supplementation of DDGS in gestation and lactation diets with moderate mycotoxin levels had little impact upon reproductive and lactation performance.

Key Words: DDGS, sow, lactation

W270 The effect of feeding corn distillers dried grain with solubles to sows in gestation and lactation on sow productivity. M. Roux*, S. Kitt, and R. Moser, *JBS United, INC.*, *Sheridan, IN*.

One thousand and twenty sows (340/treatment PIC Line C29) and their pigs were used to evaluate the effects of feeding corn distillers dried grains with solubles (DDGS) in gestation and lactation over multiple reproductive cycles on sow productivity. Sows were blocked by parity (avg. 2.1) and allotted to 1) non-DDGS corn-soybean meal (SBM) control diet or two levels of DDGS 2) 15%/7.5% and 3) 30%/15% in gestation/lactation, respectively. All gestation diets were formulated to contain 0.62% SID lysine and 3,340 kcal/kg ME. Lactation diets were formulated to contain 1.11% SID lysine and 3,460 kcal/kg ME. Treatments were initiated at an average of 47 days prior to farrow and continued through the subsequent gestation and lactation. At the end of the first lactation, sows fed the highest level of DDGS (30% in gestation/15% in lactation) had less back fat (BF), reduced ADFI, and greater weight loss ($P < 0.05$); but trended to have a reduced wean-to-estrus interval (WEI, $P < 0.08$) compared to sows fed the non-DDGS diet. There were no differences among treatments in litter response variables (total born, born alive, birth weight, wean weight, number weaned, pre-wean mortality, $P > 0.10$). Sows fed high DDGS in the subsequent gestation and lactation responded to dietary treatments in a similar fashion as in the previous lactation with respect to body weight loss, BF, ADFI, and return-to-estrus. There was no difference in subsequent litter performance (total born, born alive, birth weight, wean weight, number weaned, and pre-wean mortality, $P > 0.10$). At trial completion, DDGS samples were pooled by month and screened for mycotoxins. Average vomitoxin and zearalenone levels were 3.06 ppm ± 1.12 and 0.11 ppm ± 0.04, respectively. Overall, supplementation of DDGS in gestation and lactation diets with moderate mycotoxin levels had little impact upon reproductive and lactation performance.

W271 Amino acid transporter mRNA abundance in porcine mammary tissue during pregnancy and lactation. R. Manjarin*[1], J. P. Steibel[1], V. Zamora[2], N. Am-in[3], R. Kirkwood[1], C. Ernst[1], P. Weber[1], N. P. Taylor[1], and N. L. Trottier[1], [1]*Michigan State University*, *East Lansing,*[2]*Colegio de Postgraduados*, *Montecillo, Estado de Mexico, Mexico*, [3]*Chulalongkorn University*, *Bangkok, Thailand*.

The objective of this study was to test the hypothesis that mRNA abundance of genes encoding for mammary synthesized milk proteins α-lactalbumin and β-casein is positively correlated with mRNA abundance of specific amino acid transporter genes during late pregnancy and lactation. Four sows (parity 5) were selected one week before farrowing and fed a corn-soybean meal-based diet for lactation. Mammary tissue was collected by biopsy 4 d prior to farrowing (−4 d), and on d 5 (early) and 17 (peak) of lactation. Gene expression of amino acid transporters $b^{0,+}$AT (SLC7A9), y^+LAT1 (SLC7A7), y^+LAT2 (SLC7A6), $ATB^{0,+}$ (SLC6A14), CAT-1 (SLC7A1) and CAT-2b (SLC7A2), and of mammary synthesized milk proteins β-casein (CSN2) and α-lactalbumin (LALBA) was assessed by measuring mRNA abundance using relative quantitative PCR. Coefficient of variability (R^2) and mixed model analysis were used for data analysis. Compared to early lactation, CAT-1 mRNA abundance was lower ($P < 0.05$) on −4 d and higher ($P < 0.05$) on peak lactation. For $ATB^{0,+}$ and y^+LAT2, mRNA abundance was lower ($P < 0.001$ and $P < 0.01$, respectively) on −4 d compared to early lactation, and did not differ at peak lactation. Transcript abundance of transporters CAT-2b, y^+LAT1 and $b^{0,+}$AT did not differ between −4 d and early lactation or between peak and early lactation. For β-casein, mRNA abundance was lower ($P < 0.01$) on −4 d compared to early lactation, and tended to be higher ($P = 0.06$) at peak lactation. Compared to early lactation, α-lactalbumin mRNA abundance was lower ($P < 0.0001$) on −4 d, but did not differ at peak lactation. CAT-1, y^+LAT2 and $ATB^{0,+}$ mRNA abundance was positively correlated with mRNA abundance of β-casein ($P < 0.001$; $R^2 = 0.65$, 0.60 and 0.63, respectively) and with mRNA abundance of α-lactalbumin ($P < 0.001$; $R^2 = 0.53$, 0.79 and 0.79, respectively). In conclusion, gene expression of amino acid transporters CAT-1, $ATB^{0,+}$ and y^+LAT2 is upregulated during lactation in porcine mammary gland and positively correlated to expression of genes encoding for the mammary synthesized milk proteins β-casein and α-lactalbumin.

Key Words: amino acid, transporter, sow

Physiology and Endocrinology: Endocrinology and Metabolism

W272 Effects of lactation and pregnancy status on concentrations of insulin and IGF-1, and correlations with metabolic indicators in Holstein dairy cattle. I. M. Thompson*[1], R. L. A. Cerri[1], I. H. Kim[2], A. D. Ealy[1], P. J. Hansen[1], C. R. Staples[1], and W. W. Thatcher[1], [1]*University of Florida*, *Gainesville,*[2]*Chungbuk National University*, *Cheongju, South Korea*.

Objectives were to develop and characterize an experimental platform to evaluate lactation and pregnancy effects for subsequent transcriptome analyses in dairy cattle. Pregnant heifers (n=34) were assigned randomly after calving to a lactating group (L, n=17) and a non-lactating group (NL, n=17). The L was fed a TMR (1.65Mcal NEL/kg, 16.5% CP). The NL was fed a maintenance ration (1.45 Mcal NEL/kg, 12.2% CP). Blood was collected thrice weekly for 8 wk and analyzed for insulin, IGF-1, NEFA, BHBA, glucose, and BUN. Cows were pre-synchronized and enrolled in a timed (T)-AI protocol, but only 10 in the L and 12 in the NL were TAI. On d 17 after GnRH/TAI, cows were slaughtered and reproductive tissues collected. Analysis of variance for main effects, and simple and partial correlations were performed. Mean plasma concentrations of insulin postpartum did not differ between NL and L (1.28 vs. 1.24 ng/mL), but a Pregnancy × Lactation interaction ($P < 0.01$) was detected, because of increased insulin concentrations in lactating pregnant compared with non-lactating pregnant. Concentration of IGF-1 was lower ($P < 0.01$) for L compared with NL (135.2 vs. 203.4 ng/mL), and also different ($P = 0.01$) between cyclic and pregnant (144.5 vs. 194.1 ng/mL). Insulin was not correlated ($P > 0.10$) with any of the metabolites measured in both simple and partial correlations. Concentrations of IGF-1 had a +0.25 correlation ($P < 0.01$) with glucose, but this correlation was not significant when adjusted for lactation. A negative correlation ($P < 0.01$) between IGF-1 and NEFA (r = –0.33), and BUN (r = –0.25) was detected. Among metabolites, the highest correlation was between BHBA and BUN ($P < 0.01$; r = +0.586). In conclusion, lactation\diet and pregnancy status altered concentrations of IGF-1 in plasma, but insulin was not affected. Concentrations of IGF-1 in plasma were better predictors of metabolite concentrations than insulin.

Key Words: lactation, pregnancy, IGF-1

W273 Comparison of body condition score, body weight and milk yield and composition of Holstein and crossbred dairy cows. L. G. D. Mendonca*, C. C. Abade, E. M. da Silva, and R. C. Chebel, *Department of Veterinary Population Medicine, University of Minnesota*, *Saint Paul*.

Objectives were to compare body condition score (BCS) and body weight (BW) changes and milk yield and composition between Holstein and crossbred cows. Cows (Holstein = 45 and crossbred = 46) were enrolled in the study 45 d before expected calving date. Cows received a BCS and were weighed at 45 and 15 d before expected calving date, immediately after calving (0 days in milk, DIM), and at 28 and 56 DIM. Milk yield and composition during the first 3 mo postpartum were recorded and yield of energy corrected milk (ECM) was calculated. Holstein cows had smaller ($P < 0.01$) BCS than crossbred cows throughout the study (3.1 ± 0.1 vs. 3.4 ± 0.1) but there was no interaction between breed and study day ($P = 0.42$). Body weight was not affected by breed ($P = 0.63$) or by the interaction between breed and study day ($P = 0.16$). Average milk yield was ($P = 0.03$) greater for Holstein cows (38.9 ± 1.1 vs. 34.8 ± 1.5 Kg/d) and the interaction between breed and mo of lactation affected ($P < 0.01$) milk yield because milk yield of Holstein cows was only greater ($P < 0.01$) on the third mo of lactation (44.4 ± 1.3 vs. 37.6 ± 1.6 Kg/d). Milk fat concentration was not (P = 0.43) different between breeds (4.1 ± 0.1%), but Holstein cows had greater ($P < 0.01$) fat yield (1.5 ± 0.1 vs. 1.3 ± 0.1 Kg/d). Holstein cows had ($P < 0.01$) smaller milk protein concentration (3.1 ± 0.1 vs. 3.4 ± 0.1%) and protein yield was ($P < 0.01$) affected by the interaction between breed and study day because on the third mo of lactation Holstein cows had ($P < 0.01$) greater protein yield (1.3 ± 0.1 vs. 1.0 ± 0.1 Kg/d). Average ECM yield on the first 3 mo postpartum was greater ($P < 0.01$) for Holstein than crossbred cows (40.0 ± 1.0 vs. 35.6 ± 1.3 Kg/d) and there was a tendency ($P = 0.07$) for the interaction between breed and mo of lactation to affect ECM yield because Holstein cows had ($P < 0.01$) greater ECM yield on the third mo (42.5 ± 1.2 vs. 35.6 ± 1.6 Kg/d). Linear somatic cell count was not ($P = 0.33$) affected by breed. Although Holstein cows produced more milk in the first 3 mo of lactation, this does not appear to be in detriment of BCS or body weight.

Key Words: crossbred cow, milk yield, body condition score

W274 Association between peripartum cortisol, haptoglobin, non-esterifed fatty acid and milk yield in Holstein cows. J. M. Huzzey*[1], T. R. Overton[1], D. V. Nydam[1], and R. J. Grant[2], [1]*Cornell University*, *Ithaca, NY*, [2]*W.H. Miner Agricultural Research Institute*, *Chazy, NY*.

The objective of this study was to evaluate the relationship between peripartum indicators of stress, inflammation and energy status with milk yield. Blood and fecal samples from 414 Holstein dairy cows were collected weekly beginning 3 weeks before until 1 week after calving. Plasma was analyzed for cortisol, haptoglobin (Hp) and non-esterified fatty acid (NEFA) and fecal samples were analyzed for cortisol metabolites (11,17-dioxoandrostanes). A range of cut-points were evaluated for each metabolite and their relationship to milk yield [305 mature equivalent (305ME) predicted from the second test day (averaging 63 DIM)] was assessed using mixed models. Fecal cortisol metabolites (FCM) were not associated with 305ME in primiparous (PP) cows. Multiparous (MP) cows with FCM > 250 ng steroid/g fecal DM during wk −3 or −2 relative to calving had on average a 966 kg lower 305ME ($P \leq 0.05$) relative to cows below this cutpoint. Projected 305ME was 1162 kg lower among MP cows with FCM > 70 ng steroid/g fecal DM during wk +1 (P = 0.001). There was no association between plasma cortisol and milk yield at any period relative to calving for either MP or PP cows. Projected 305ME tended to be 1322 kg lower (P = 0.07) in PP cows with Hp > 1.1 g/L during wk −3. MP cows with Hp > 1.1 g/L during wk −2, −1 or +1 had on average a 1496 kg lower projected 305ME ($P \leq 0.05$). There was no association between prepartum NEFA and 305ME in PP cows, however, PP cows with NEFA > 600 mEq/L during wk +1 had a 851 kg greater projected 305ME (P = 0.02). MP cows with NEFA > 500 mEq/L during wk −3, −2, or −1 had on average a 1371 kg lower projected 305ME ($P \leq 0.01$). During wk +1, MP cows with NEFA > 600 mEq/L had a 517 kg lower projected 305ME (P = 0.05). High concentrations of these metabolites before or after calving, particularly among MP cows, may suggest that opportunities exist to improve milk yield.

Key Words: milk yield, haptoglobin, cortisol

W275 Relationship between IGF-I polymorphism and metabolic and endocrine profiles of dairy cows on grazing conditions during the transition period. G. Ruprechter*[1], A. Meikle[1], P. Nicolini[1], and

M. Carriquiry[2], [1]*School of Veterinary Sciences, UDELAR*, *Montevideo, Uruguay*, [2]*School of Agronomy, UDELAR*, *Montevideo, Uruguay*.

Primiparous Holstein cows (n=42) of a Uruguayan commercial farm, blocked by calving date, were used to evaluate the effect of a IGF-I polymorphism (C/T position 512) located in the promoter region of the gene (variant A/B), on metabolic and endocrine profiles during the transition period. Cows were distributed as follows: AA (n=15), AB (n=15) and BB (n=12). Cows grazed a mixture of ryegrass (*Lolium multiflorum*) and alfalfa (*Medicago sativa*) and were supplemented with a ration including corn silage, high moisture corn grain, and sunflower meal (12, 5 and 2 kg DM, respectively). The diet offered had 17% crude protein and 1.7 Mcal/kg DM of net energy of lactation. Blood samples and BCS data (scale 1-5) collected at −7, 30, and 60 days of lactation. Genotyping of IGF–I was performed using PCR–RFLP. Nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHB) concentrations were determined spectrophotometrically and IGF-I and insulin concentrations by RIA. Means from repeated measure analyses were considered to differ when $P < 0.05$. There were no differences in BCS among IGF–I genotypes. However, plasma levels of NEFA, BHB, and insulin were affected ($P < 0.04$) by IGF–I genotype. Concentrations of NEFA and BHB were greater in AA than BB cows, being levels intermediate in heterozygous cows (0.44, 0.41, and 0.33 ± 0.03 mmol/L and 0.30, 0.26, and 0.23±0.02 mmol/L for NEFA and BHB of AA, AB, and BB cows, respectively). Insulin concentrations were less in AA than BB cows, and intermediate in AB cows (2.77, 3.21, and 3.98 ± 0.33 μUI/mL, for AA, AB, and BB, respectively). The IGF-I genotype did not affect ($P = 0.39$) differentially circulating IGF-I in blood (86.4, 97.7, and 94.6 ± 7.3 ng/mL, for AA, AB, and BB, respectively). There was no interaction ($P > 0.12$) between IGF-I genotype and day of lactation for any of the variables studied. Although plasma concentrations of IGF-I were not affected by IGF-I genotype, energy status of BB genotype cows appeared to be improved during early lactation.

Key Words: SNP, energy balance, dairy cattle

W276 Effects of intravenous glucose infusion and nutritional balance on serum concentrations of NEFA, glucose, insulin, and progesterone in non-lactating dairy cows. F. Vieira*[1], C. Lopes[1], B. Cappellozza[1], A. Scarpa[1], R. Cooke[2], and J. L. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, SP, Brazil*, [2]*Oregon State University*, *Burns*.

The objective of this study was to evaluate serum concentrations of non-esterified fatty acids, glucose, insulin, and progesterone in non-lactating dairy cows according to nutritional balance and glucose infusion. Ten non-lactating, ovariectomized Gir × Holstein cows were stratified by body weight (BW) and body condition score (BCS) on d −28 of the study, and randomly assigned to: 1) negative nutrient balance (NB) and 2) positive nutrient balance (PB). All cows were inserted with an intravaginal progesterone releasing device on d −14, which remained in cows until the end of the study. Cow BW and BCS were assessed again on d 0. On d 0, cows within nutritional treatment were randomly assigned to receive, in a crossover design containing 2 periods of 24 h each: 1) intravenous glucose infusion (GLUC; 0.5 g of glucose/kg of BW, over a 3 h period), or 2) intravenous saline infusion (SAL; 0.9% solution over a 3 h period). Prior to the beginning of each period, all cows were fasted for 12 h. Blood samples were collected, relative to the beginning of the infusion, at −12 and −11.5 (beginning of fasting), and at −0.5, 0, 0.5, 1, 2, 3, 4, 5, and 6 h. Following the last blood collection of period 1, cows received (PB) or not (NB) concentrate and returned to respective pastures. Changes in BCS and BW were greater in NB cows compared to PB cows (−0.60 and −0.25 ± 0.090 for BCS, respectively; −22.4 and 1.2 ± 6.58 kg for BW, respectively). Cows receiving GLUC had greater glucose concentrations from 0.5 to 3 h relative to infusion compared to SAL cows. Insulin concentrations were greater in PB cows assigned to GLUC compared to SAL cohorts at 0.5 and 3 h following infusion, whereas NB cows assigned to GLUC had greater insulin concentrations compared to SAL cohorts at 0.5, 1, 2, and 3 h. Progesterone concentrations were greater in PB cows assigned to GLUC at 2, 3, and 4 h following infusion compared to SAL cohorts. In conclusion, the effects of glucose infusion on serum concentrations of insulin and progesterone in non-lactating dairy cows were dependent on cow nutritional status.

Key Words: glucose infusion, insulin, progesterone

Physiology and Endocrinology: Hormonal Regulation of the Estrous Cycle in Dairy Cattle

W277 Effects of treatments with hCG or GnRH on serum progesterone (P4) and conception rates (CR) in lactating dairy cows submitted to timed artificial insemination (AI) or embryo transfer (ET). P. Justolin*[1], P. Morelli[1], M. Reis[1], O. Sá Filho[1], F. Aragon[2], M. Veras[2], S. Soriano[3], and J. L. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, SP, Brazil*, [2]*Pioneiros Veterinary Clinic*, *Carambei, PR, Brazil*, [3]*Colorado Dairies*, *Araras, SP, Brazil*.

The effects of treatments with GnRH or hCG 7 d after induced ovulation on P4 and CR in lactating Holstein cows submitted to AI or ET were evaluated. A total of 993 protocols for synchronization of ovulation, performed in 684 lactating Holstein cows (169.8±4.4 DPP; 37.9±0.3 Kg milk/day), were initially used in this study. Synchronization protocols consisted in CIDR insert + GnRH on d −10, CIDR withdrawal + PGF2α on d −3, and estradiol cypionate on d −2. On d −2, cows were assigned to receive either AI on d 0 or ET on d 7. On d 7, ovaries of all cows were evaluated by ultrasonography (US), and only cows with presence of CL remained in the study (834 protocols performed in 661 cows). Within each breeding-technique (BT) group, cows were assigned to receive either (1) no treatments (Control), (2) GnRH on d 7 (GnRH), or (3) hCG (2,500 IU) on d 7 (hCG). Blood samples were collected from a subgroup of 179 cows on d14 for P4 analysis (P4d14). Pregnancy was evaluated by US on d 31 ± 3. The P4d14 was greater in gonadotropin-treated than in Control cows ($P < 0.01$), but did not differ ($P > 0.1$) between GnRH and hCG groups (Control: 4.86±0.36; GnRH: 6.22±0.35; hCG: 6.88±0.36 ng/mL). The CR was greater ($P < 0.05$) in ET than in AI cows (45.2% [168/372] vs. 31.6% [146/462]), in primiparous than in multiparous (42.7% [141/330] vs. 34.3% [173/504]). There was an interaction ($P < 0.05$) between BT and treatment on CR, in manner that treatments affected the CR at ET (Control: 38.1% [48/126]; GnRH: 52.4% [65/124]; hCG: 45.1% [55/122]; $P < 0.05$), but not at AI (Control: 30.1% [47/156]; GnRH: 32.2% [50/155]; hCG: 32.4% [49/151]; $P > 0.1$). Rectal temperature on d 7 negatively affected CR (y = EXP[16.7 - 0.4 • ×] / 1 + EXP[16.7 - 0.4 • ×]; $P < 0.01$). Thus, treatments with GnRH or hCG on d 7 increased P4d14 and improved CR of cows submitted to ET, but not to AI, and rectal temperature on d 7 negatively affected CR regardless of BT or treatment.

Key Words: embryo transfer, lactating cows, conception rate

W278 Effect of the treatment with GnRH seven days after embryo transfer (ET) on reproductive performance in lactating dairy cows. P. Morelli*[1], P. Justolin[1], M. Reis[1], O. Sá Filho[1], F. Aragon[2], M. Veras[2], S. Soriano[3], and J. L. Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, SP, Brazil*, [2]*Pioneiros Veterinary Clinic*, *Carambei, PR, Brazil*, [3]*Colorado Dairies*, *Araras, SP, Brazil*.

The effects of treatments with GnRH 7 d after ET on conception rate (CR) in lactating Holstein cows were evaluated. A total of 350 lactating Holstein cows (192.9 ± 7.6 DPP; 35.1 ± 0.8 Kg milk/day), were initially submitted to a synchronization of ovulation protocol consisting of CIDR insert + GnRH on d −10, CIDR withdrawal + PGF2α on d −3, and estradiol cypionate on d −2. On d 7, ovaries of all cows were evaluated by ultrasonography (US), and those cows with presence of luteal tissue (n = 285) received one fresh embryo into the uterine horn ipsilateral to the CL and an i.m. injection of 100 µg of gonadorelin (GnRH). On d14, cows were randomly assigned to receive (G7+14; n = 147) or not (G7; n = 138) an additional treatment with GnRH. Rectal temperature was measured in all cows immediately after morning milking of d 7 (RTd7) and d 14 (RTd14). Pregnancy was evaluated by US on d 31 ± 3 (US1) and 62 ± 3 (US2). The CR was calculated by dividing the number of pregnant cows by the number of cows receiving an embryo on d 7. The CR-31d was not affected by treatment (G7: 48.5% [67/138]; G7+14: 42.9% [63/147]; $P > 0.1$), but tended to be positively affected by milk production (y = EXP[-0.01 + 0.8 • ×] / 1 + EXP[-0.01 + 0.8 • ×]; $P = 0.06$). The CR-62d was not affected by treatment (G7: 39.8% [55/138]; G7+14: 37.4% [55/147]; $P > 0.1$), but was positively affected by milk production (y = EXP[-1.2 + 0.02 • ×] / 1 + EXP[-1.2 + 0.02 • ×]; $P = 0.04$) and tended to be negatively affected by RTd14 (y = EXP[23.1 - 0.6 •×] / 1 + EXP[23.1 - 0.6 • ×]; $P = 0.05$). In summary, treatment with GnRH 7 d after ET did not improve reproductive performance of dairy cows that received a previous GnRH treatment concurrently with ET.

Key Words: embryo transfer, lactating dairy cows, conception rate

W279 Effect of moment of induced ovulation and progesterone (P4) for resynchronization on fertility of Holstein cows in a 5-d timed AI program. R. S. Bisinotto*, E. S. Ribeiro, L. T. Martins, R. S. Marsola, L. F. Greco, C. A. Risco, W. W. Thatcher, and J. E. P. Santos, *University of Florida*, *Gainesville*.

The effects of the interval from GnRH to insemination (AI) at first AI and supplemental P4 for resynchronization on pregnancy per AI (P/AI) were evaluated. In study 1, cows received 2 injections of prostaglandin (PGF) at 46 and 60 d in milk (DIM). The timed AI protocols began with an injection of GnRH at 72 DIM, and an injection of PGF 5 and 6 d later. Cows were randomly assigned to receive the final GnRH either 56 h after the first PGF of the protocol and AI 16 h later (5d-OVS56, n=634) or GnRH and AI 72 h after the first PGF (5d-COS72, n=593). The proportion of cows in estrus on the day of AI was greater (P=0.003) for the 5d-COS72 than 5d-OVS56 (40.6 vs. 32.4%). P/AI did not differ between treatments on d 32 (5d-OVS56=46.4 vs. 5d-COS72=45.5%) or 60 after AI (5d-OVS56=40.7 vs. 5d-COS72=38.6%). In study 2, nonpregnant cows on d 32 after the first AI received either an intravaginal P4 insert (RCIDR, n=341) or no P4 (RCON, n=334) from the GnRH to the first PGF of the resynchronization (d 0 GnRH, d 5 and 6 PGF, d 7.5 GnRH, 16 h timed AI). Ovaries were scanned (n=340) at the first PGF and final GnRH to detect premature ovulation. Blood was sampled (n=398) at AI and 7 d later for analysis of P4. Synchronization to the protocol was considered when cows had no premature ovulation and when concentrations of P4 at AI and 7 d later were, respectively, <1.0 ng/mL and >2.26 ng/mL. P/AI was greater ($P < 0.05$) for RCIDR than RCON on d 32 (RCON=43.1 vs. RCIDR=51.3%) and d 60 after AI (RCON=37.8 vs. RCIDR=45.5%). Only 5.6% (19/340) of the cows ovulated prematurely, and it tended ($P = 0.09$) to be greater for RCON than RCIDR cows (RCON=7.5 vs. RCIDR=3.6%). Concentrations of P4 on the day of AI and 7 d later (RCON = 0.25 and 2.88; RCIDR = 0.32 and 2.72 ng/mL) did not differ between treatments. Synchronization to treatments did not differ and were 57.8% for RCON and 61.4% for RCIDR. Results indicate that administration of the final GnRH simultaneously with AI does not impair fertility of cows subjected to a 5-d timed AI protocol and that supplementation with P4 during resynchronization improves P/AI.

Key Words: dairy cow, progesterone, timed AI

W280 Evaluation of a mechanistic, dynamic, metabolic model of regulation of reproductive processes in dairy cattle. P. Celi[2], I. Lean[2], H. Raadsma[2], A. Rabiee[2], and J. P. McNamara*[1], [1]*Washington State University*, *Pullman,* [2]*University of Sydney*, *Camden, NSW, Australia*.

The objective was to conduct and initial evaluation of a conceptual research model which describes functional control at the metabolic level, of reproductive processes in dairy cattle; and is suitable for evaluation of data, concepts and hypotheses regarding underlying genetic, nutritional and physiological control of reproduction. This research model used an existing, extensively evaluated model of bovine metabolism (Molly, UC Davis), including glucose, amino acids and fatty acids by muscle, adipose, visceral and mammary tissues. Equations for pulses of LH release, FSH, follicular growth, estrogen and progesterone concentrations in cycling and pregnant animals, ovulation, fetal growth and early embryonic mortality were developed from literature values. The model links glucose with LH release; glucose and IGF1 with follicular growth; and also describes effects of feed intake, metabolic rate and milk production on liver metabolism of estrogen and progesterone. This initial evaluation was a standard evaluation of behavior and sensitivity—did the variables respond in a similar fashion and rate to those in the literature that were not used for the model construction. The statistical standard compared the model output to observed data, and adequacy was decided if the output was within one least significant difference (LSD) based on $P <$ 0.05. Hormonal concentrations during cycling and pregnancy simulated literature values within 1 LSD. Increased metabolic rate (a function of milk production or feed intake) increased degradation of estrogen and progesterone, shortening length of estrus and decreasing progesterone in early pregnancy. The behavior was in the proper direction and magnitude for these variables within 1 LSD ($P < 0.05$) of published values. The model can be useful to frame specific hypotheses on control of reproductive processes by genetic and nutritional mechanisms: and to form a framework of more specific models at cellular and molecular levels of the processes of reproduction in the dairy cow.

Key Words: reproduction, nutrition, research model

W281 Effects of different ovulatory stimulus (GnRH vs. estradiol cypionate) on follicular dynamics of a progesterone-based timed AI protocol in Holstein cows. R. M. Ferreira, H. Ayres*, L. U. Gimenes, and P. S. Baruselli, *Department of Animal Reproduction, University of São Paulo*, *São Paulo, SP, Brazil*.

The aim of this study was to evaluate the effects of estradiol cypionate (EC) at progesterone (P4) device removal, GnRH 56h later or both on follicular dynamics in Holstein cows. At random stages of the estrous cycle (D0), 57 Holstein cows received 2mg estradiol benzoate (Estrogin , Farmavet, Brazil) and one P4 device (CIDR , Pfizer, Brazil). On D8, device was removed and all animals received 25mg dinoprost (Lutalyse, Pfizer, Brazil) plus 400 IU eCG (Folligon , Intervet, Brazil). On the same day (D8), cows were randomly allocated to one of three treatments, as follows: 1) ECP (1 mg; n=18) at P4 device removal; 2) GnRH (0.1mg gonadorelin; n=19) 56h after P4 device removal, and 3) ECP at P4 device removal and GnRH 56h later (n=20). Ultrasound examinations were performed at D0, D8, and every 12 h from P4 removal to disappearance of the ovulatory follicle, or 96 h after P4 withdrawal, whichever occurred first. The diameter of the ovulatory follicles (ØOF), time to ovulation after P4 removal (TOV), ovulation rate (OR) and number of ovulations (Nov) were also evaluated. Statistical analyses were performed with logistic regression by PROC GLIMMIX of SAS. The treatments affected the average TOV (EC=70.8^{a} vs. GnRH=77.3^{b} vs. EC+GnRH=65.3h^{a}; $P < 0.01$) and the ØOF (EC=13.0^{b} vs. GnRH=14.8^{a} vs. EC+GnRH 14.1mm^{ab}; $P = 0.02$). No differences were found on OR [EC=83.3% vs. GnRH=85.0% vs. EC+GnRH=90.0%; $P = 0.71$] and Nov (EC=1.1 vs. GnRH=1.3 vs. ECP+GnRH=1.3, $P = 0.20$). Also, analyses of contrast showed that cows receiving EC had an earlier TOV than cows treated with GnRH ($P < 0.01$). These data suggest that EC+GnRH can be used as an ovulatory stimulus, and its administration at P4 device removal induces ovulation about 70h later. Thus, if TAI is done 56h after P4 device removal, the ovulation will occur around 16–12 h after TAI, an adequate moment to achieve satisfactory pregnancy per AI.
We acknowledge Pfizer and Fazenda Campestre.

Key Words: estradiol cypionate, GnRH, Follicular dynamics

W282 Dose of equine chorionic gonadotropin necessary to cause multiple ovulation and increase in progesterone concentration following a synchronization protocol in lactating dairy cows. A. C. Denicol*[1], F. A. Rivera[1], L. G. D. Mendonca[2], C. D. Narciso[1], G. Lopes Jr.[1], R. G. S. Bruno[1], and R. C. Chebel[1,2], [1]*Veterinary Medicine Teaching and Research Center, University of California*, *Tulare,* [2]*Department of Veterinary Population Medicine, University of Minnesota*, *Saint Paul*.

Objective was to establish a minimum dose of equine chorionic gonadotropin (eCG) capable of inducing multiple ovulation and accessory corpora lutea (CL) and increasing concentrations of progesterone (P4) in lactating dairy cows. Forty-eight lactating Holstein cows were randomly assigned to one of three treatments at the beginning of a timed AI (TAI) protocol: control (n = 10), eCG6 (n = 19) and eCG8 (n = 19). The TAI protocol consisted of GnRH (100 µg i.m.), 7 d later prostaglandin (PG) F2α (25 mg i.m.), and 72 h later GnRH (100 µg i.m.) and TAI. Cows in the eCG6 and eCG8 treatments received 600 and 800 IU of eCG i.m., respectively, 48 h after the first GnRH. Blood was sampled and ovaries were scanned at the time of each injection of the TAI protocol, 48 h after the first GnRH injection, and 7 d after TAI. Concentrations of estradiol on the day of PGF2α injection was not (3.6 0.1 pg/mL; $P = 0.70$) affected by treatment, but the number of follicles > 10 mm on the day of the second GnRH was ($P = 0.03$) greater for eCG8 cows (control = 1.8 ± 0.2, eCG6 = 1.6 ± 0.2, eCG8 = 2.2 ± 0.2). Although the proportion of cows with a CL 7 d after TAI was not ($P = 0.19$) different (control = 100, eCG6 = 73.7, eCG8 = 84.2%), eCG8 cows tended ($P = 0.14$) to be more likely to have an accessory CL (control = 10.0, eCG6 = 15.8, eCG8 = 36.8%). Twelve cows (control = 2, eCG6 = 4, eCG8 = 6) failed to synchronize their estrous cycles and were removed from further analysis. The cumulative CL volume of eCG8 cows was ($P < 0.01$) larger than control and eCG6 cows (control = 7.5 ± 2.0, eCG6 = 5.0 ± 1.2, eCG8 = 10.9 ± 1.5 cm3), and eCG8 cows had ($P < 0.01$) greater P4 concentration 7 d after AI (control = 1.5 ± 0.5, eCG6 = 1.3 ± 0.3, eCG8 = 3.0 ± 0.4 ng/mL). We conclude from this experiment that a dose of 800 IU of eCG is capable of inducing accessory CL and increasing P4 concentration in lactating dairy cows following a TAI protocol.

Key Words: lactating dairy cow, equine chorionic gonadotropin, progesterone

W283 Effect of presynchronization with GnRH or hCG 7 d before resynchronization of ovulation initiated 25 d after a previous timed AI on fertility of lactating dairy cows. J. O. Giordano*, J. N. Guenther, G. Lopes Jr., M. M. Herlihy, A. B. Nascimento, M. C. Wiltbank, and P. M. Fricke, *University of Wisconsin*, *Madison*.

To determine the effect of presynchronization on fertility to resynchronization of ovulation (Resynch), lactating cows on a commercial dairy initiated Resynch 25 d after a prior TAI using GnRH and cloprostenol (PGF) as follows: (d 0, 200 µg GnRH; d 7, 750 µg PGF; 56 h, 100 µg

GnRH; 16 h, TAI). At the prior TAI, cows were randomly assigned to one of three treatments to receive: 2,000 IU hCG (Chorulon) 7 d before initiation of Resynch (HGPG, n=346); 200 µg GnRH 7 d before initiation of Resynch (GGPG, n=361); or no presynchronization (C, n=375). Cows diagnosed not pregnant at 32 d after prior TAI received the PGF injection of the Resynch and continued the protocols. Pregnancy was diagnosed at 32 and 53 d after Resynch TAI to determine pregnancies per AI (P/AI). Based on logistical regression analysis, treatment tended ($P = 0.07$) to affect P/AI 32 d after TAI [HGPG = 33.0% (114/346); GGPG = 30.8% (111/361); C = 25.3% (95/375)]. Based on statistical contrasts, HGPG cows had more ($P = 0.02$) P/AI than C cows, whereas P/AI for GGPG vs. C cows tended ($P = 0.10$) to differ and HGPG vs. GGPG cows did not ($P = 0.53$) differ. Pregnancy loss from 32 to 53 d after Resynch TAI was not affected by parity and did not differ ($P = 0.29$) among treatments [HGPG = 6.3% (7/112); GGPG = 9.9% (11/111); C = 4.3% (4/93)]. Treatment did not affect ($P = 0.13$) P/AI at 53 d after TAI when all treatments were included in the model; however, when analyzed separately, HGPG cows tended to have more ($P = 0.08$) P/AI 53 d after Resynch TAI than C cows [30.5% (105/344) vs. 23.9% (89/373)]. Based on a subset of cows, ovulation to the last GnRH injection of Resynch did not differ among treatments [HGPG = 89.3% (176/197); GGPG = 89.8% (168/187); C = 89.9% (177/197)]. We conclude that presynchronization with hCG or GnRH 7 d before initiation of Resynch did not affect synchronization rate, but that hCG increased fertility whereas GnRH tended to increase fertility compared to Ovsynch initiated 25 d after a prior TAI.

Key Words: hCG, resynchronization, fertility

W284 Milk estradiol and pedometer activity during estrus in dairy cows. N. Kendall, D. Scholey, and G. Mann*, *University of Nottingham*, *School of Biosciences, Division of Animal Sciences, Sutton Bonington Campus, Loughborough, LE12 12RD, UK*.

While it is well established that elevated concentrations of estradiol are responsible for the induction of estrus, the relationship between concentration of estradiol and intensity of estrus is less clear. In this study we have used pedometer activity to quantitatively measure estrous activity at insemination and related this to peak concentrations of milk estradiol during the previous 24h period to determine if estrus intensity is affected by estradiol concentration. The study was carried out in 37 lactating, naturally cycling Holstein Friesian cows maintained under a commercial herd management regimen. Cows were milked by robot and a milk sample taken and pedometer activity data collected at each milking. Cows were inseminated on the basis of observed estrus and/or elevated pedometer activity and daily milk progesterone measurements undertaken to confirm that cows were at the correct stage of the cycle when insemination took place and pedometer and milk estradiol measurements were made. Validated measurements were obtained from a total of 61 estrus periods during which peak pedometer activity was 310 ± 19 steps per hour (range 89 - 776 steps per hour) and peak milk estradiol concentration 4.6 ± 0.2 pg/ml (range 1.8 - 9.1 pg/mL). There was no association between peak concentration of milk estradiol and peak pedometer activity ($P = 0.59$). Furthermore, comparison of successful and unsuccessful inseminations revealed no differences in either milk estradiol (4.3 ± 0.4 vs. 4.8 ± 0.3 pg/mL) or pedometer activity (290 ± 40 vs. 318 ± 22) in cows conceiving or failing to conceive. However, in cows (n = 26) in which measurements were made during successive estrous periods, there were significant ($P < 0.01$) associations in both milk estradiol ($R^2 = 0.28$) and pedometer activity ($R^2 = 0.25$) between previous and subsequent estrous periods. These results demonstrated that while both estradiol concentrations and pedometer activity at estrus appear to exhibit some repeatability within cows, the peak concentration of estradiol in milk was not correlated with estrus intensity.

W285 Effect of treatment with human chorionic gonadotropin (hCG) and/or intravaginal progesterone (CIDR) on day 5 after AI on fertility in lactating dairy cows. A. B. Nascimento*, J. N. Guenther, F. P. Dalla Costa, M. M. Herlihy, A. Keskin, G. Lopes Jr., and M. C. Wiltbank, *University of Wisconsin*, *Madison*.

Secretion of progesterone (P4) from the corpus luteum (CL) is essential for pregnancy in cattle. Our previous research indicates that lactating dairy cows synchronized with Double-Ovsynch, have much lower P4 after ovulation than heifers (P4 < 50% of heifer, P4 from Day 6 to 13 after AI) in spite of ovulating a similar size follicle. Treatment of these cows on Day 5 after AI with both hCG (to induce an accessory CL) and a CIDR can increase P4 to heifer concentrations. Our primary hypothesis is that supplementation with P4 after AI (hCG and/or CIDR) will increase % of dairy cows pregnant to timed AI. Further, we hypothesized that CIDR treatment until Day 22 after AI would synchronize estrus in non-pregnant cows (~Day 25), produce a more optimal time to begin Ovsynch (Day 7 of new cycle), and increase % pregnant at second timed AI. Lactating Holstein cows (n=794) were synchronized with Double-Ovsynch (First Ovsynch: GnRH-7d-$PGF_2\propto$-3d-GnRH)-7d-(Breeding Ovsynch: GnRH-7d-$PGF_2\propto$-56h-GnRH-16h-AI). On Day 5 after AI cows were randomly assigned to receive no treatment (Control), CIDR, 2,000 IU hCG or CIDR+hCG. The CIDR was removed on Day 22 after AI and pregnancy diagnosis was performed by ultrasound on Day 32 after AI, with resynch initiated on Day 32. A high % of cows were pregnant to first AI (379/794 = 47.7%) with no treatment effects ($P = 0.82$; Control: 98/197 = 49.7%; CIDR: 95/195 = 48.7%; hCG: 95/201 = 47.3%; CIDR+hCG: 91/201 = 45.3%). Non pregnant cows after first AI (n=313) were evaluated for % pregnant to second AI to test the second hypothesis. There were also no differences ($P = 0.66$) on % pregnant to second AI (Control: 26/78 = 33.3%; CIDR: 28/72 = 38.9%; hCG: 24/76 = 31.6%; CIDR+hCG: 26/87 = 29.9%). In conclusion, the results from first AI did not support our primary hypothesis but indicate no impact of P4 supplementation in lactating dairy cows synchronized with Double-Ovsynch in spite of the low circulating P4 in these cows.

Key Words: progesterone, CIDR, hCG

W286 A comparison of conception rates between new and re-used Eazi-Breed CIDRs. R. Giles*[1], G. Seidel[2], C. McConnel[2], and K. McSweeney[1], [1]*Bovine Reproductive Specialists*, *Loveland, CO,* [2]*Colorado State University*, *Fort Collins*.

Intravaginal progesterone (CIDR) inserts can help acyclic dairy cows return to normal cyclicity and successful ovulation for timed AI. However, CIDRs are relatively expensive and the cost per pregnancy would be decreased if CIDRs could be effectively used again. The objective of this study was to determine whether Eazi-Breed CIDRs used within an OvSynch program could be re-used efficaciously in cows diagnosed as acyclic. The study was conducted on 3 dairies (A, B, C) in northern Colorado from January 2009 through January 2010. Enrolled cows were limited to lactations 1-4 and times bred 1-4. Lactating dairy cows (dairies A, N = 631; B, N = 349; and C, N = 378) were scanned ultrasonographically prior to the start of an OvSynch program and diagnosed as being cystic (follicle greater than 25 mm and absence

of corpus luteum (CL)), or without a CL. All cows received 100 μg of GnRH im, and were scanned 7 days later. Cows observed as being persistently cystic or without a CL (acyclic) for two weeks in a row were enrolled into a CIDR sync program. This program involved CIDR (1.38 g progesterone) insertion and im administration of 100 μg GnRH on day 0, CIDR removal and im administration of 25 mg PGF2α on day 7, im administration of 100 μg GnRH 56 h following CIDR removal, and AI 16-18 h later. Cows with odd numbered ear tags received re-used CIDRs and even numbered cows received new CIDRs. Pregnancy status was determined on day 32-39 by ultrasonography. Conception rates (day 32-39) with new CIDRs were slightly higher in both categories (Cystic: new-37/106 (34.9%), re-used-35/114 (30.7%); Acyclic: new-194/559 (34.7%), re-used-184/579 (31.8%)). None of these differences was significant (P>0.1) nor was there a significant difference for all re-used (31.6% pregnant) vs. all new CIDRs (34.7% pregnant; one-tail chi-squared; Fisher-Yates correction). No treatment × dairy effect was noted, although overall pregnancy rates were lower ($P < 0.05$) at dairy C (29.4%) than dairies A (35.0%) or B (37.2%).

Key Words: CIDR, acyclic, OvSynch

W287 Progesterone concentration required for establishment of pregnancy following embryo transfer in lactating Holstein cows. A. G. Kenyon*[1], L. G. D. Mendonca[3], G. Lopes Jr.[1], J. R. Lima[1], J. E. P. Santos[2], and R. C. Chebel[1,3], [1]*Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare,* [2]*Department of Animal Sciences, University of Florida*, *Gainesville,* [3]*Department of Veterinary Population Medicine, University of Minnesota*, *Saint Paul*.

Objectives were to determine minimal progesterone (P4) concentration from estrous cycle d 4 to 28 necessary for establishment of pregnancy following embryo transfer (ET) in lactating Holstein cows. Cows at 30 ± 3 DIM were synchronized (d −35 PGF2α, d −28 CIDR, d −21 PGF2α and CIDR removal, d −9 GnRH, d −2 PGF2α, d 0 GnRH) and on d 0 were randomly assigned to the low progesterone (LP4, n = 28) or control (n = 55) treatments. Cows in the LP4 received 2 injections of PGF2α, on d 4 and 5, and a CIDR insert starting on d 5, which was replaced every 7 d until d 28. Blood was sampled on d −9, −2, 0, 4, 7, 14, 21, and 28 and ovaries were examined with ultrasound on d −9, −2, and 7. On d 7, all LP4 cows and control cows bearing a corpus luteum (CL) received ET. Pregnancy was diagnosed on d 28 and 67 d after ET. Proportion of cows ovulating to the GnRH on d −9 (50.6%; P=0.76) and that had luteolysis after PGF2α on d −2 (78.1%; P = 0.99) were not different between treatments. Progesterone concentrations on d −9 (6.10 ± 0.34 ng/mL; P=0.52), d −2 (0.47 ± 0.05 ng/mL; $P = 0.87$), and d 0 (1.54 ± 0.14 ng/mL; $P = 0.97$) were not different between treatments. Total CL volume on d 7 was ($P < 0.01$) smaller for LP4 cows (1.9 ± 0.6 vs. 6.1 ± 0.4 cm3). Proportions of cows pregnant at 28 (27.3 vs. 0%; $P < 0.01$) and 67 (13.0 vs. 0%; $P = 0.05$) d after ET were greater for control cows. Average P4 from d 4 to 28 was greater for control cows (3.7 ± 0.2 vs. 1.7 ± 0.3 ng/mL; $P < 0.01$), but there was ($P > 0.01$) an interaction between treatment and day as in d 4 (1.6 ± 0.2 ng/mL; $P = 0.40$) and 7 (2.4 ± 0.1 ng/mL; $P = 0.17$) there were no differences, but on day 14 (5.5 ± 0.4 vs. 2.0 ± 0.5 ng/mL; $P < 0.01$), 21 (3.5 ± 0.6 vs. 1.8 ± 0.7 ng/mL; $P = 0.06$), and 28 (5.4 ± 0.6 vs. 1.6 ± 0.8 ng/mL; $P < 0.01$) control cows had greater P4. Average P4 < 1.8 ng/mL from d 4 to 28 and P4 concentration < 2.5 ng/mL on d 14 were not conducive to establishment of pregnancy.

Key Words: progesterone, Holstein cow, embryo survival

W288 A comparison between sexed and conventional semen and some reproduction items in Iranian Holstein dairy herds. A. A. Naserian*[1], F. Karavan[2], and A. Razavi[3], [1]*Ferdowsi University of Mashhad*, *Mashhad, Iran*, [2]*Nemoneh dairy farm*, *Gorgan, Iran*, [3]*Karaj Islamic Azad University*, *Karaj, Iran*.

The aim of this study was a comparison between sexed and conventional semen and some reproduction items in Iranian Holstein dairy farms in northeast of Iran. Data were collected from computerized management software of every herd from January 2006 through December 2008. All herds, 5–10 percentage of heifers were bred with sexed semen. The female calves were bred at age 14–15 mo with 126–130 Cm height. The diets were balanced to meet or exceed the minimum nutritional requirements of heifers for a gain 0.75–0.8 Kg/d (NRC 2001). The data were analyzed with ANOVA by using the general linear model of SAS 2003. The means were comparison by the Tukey method. The results have been shown in the Table 1.Therefore, sexed semen in a new tool for producing more female calves in commercial dairy herds.

Table 1. Reproduction items amongst sexed and conventional semen heifers

Item	sexed	conventional	SEM	P-value
Age of breeding (month)	14.97	15.23	0.138	0.543
Times of AI	1.61	1.41	0.021	0.283
Birth difficulty (score)	1a	1.94b	0.016	0.001
Heifer height at breeding (cm)	125.12	126.33	1.718	0.261
Female calves (%)	85.81a	48.12b	0.981	0.001
Pregnancy length (month)	8.88	9.16	0.134	0.110

Key Words: sexed semen, conventional semen, reproduction items

W289 Dose reduction of fluorogestone acetate through partition of sponges in a program of estrus synchronization. J. L. Cordero[1], T. Sánchez[1], P. Molina[1], R. Nieto[1], J. Peralta[2], M. Cárdenas[3], O. Mejía[4], J. Nuñez[4], E. García*[5], and J. L. Figueroa[1], [1]*Programa de Ganadería, Colegio de Postgraduados*, *Texcoco, México*, [2]*ICAP, Medicina Veterinaria y Zootecnia*, *UAEH, Hidalgo, México*, [3]*INNSZ*, *México City*, [4]*CEIEPO UNAM*, *Tres Marías, México*, [5]*CUCSUR, UADG*, *Autlán Jalisco, México*.

The objective of the experiment was to determine the effect of dose reduction in sponges impregnated with fluorogestone acetate (FGA) through the partition of the same, in the main reproductive variables of Dorset ewes. Forty-four ewes were randomly assigned in four groups: Complete sponge control group, 40 mg of FGA (n=11); half sponge group, theoretically with 20 mg of FGA (n=11); one-quarter sponge group theoretically with 10 mg of FGA (n=11), and one-eighth sponge group theoretically with 5 mg FGA (n=11). Sponges remained inserted for 12 days, and 10 days after insertion all groups received a dose of 15 mg of prostaglandin (PGF2α). There was a 100% of estrous onset for groups with 40, 20 and 10 mg of FGA, but not for the 5 mg group with 81% ($P \leq 0.05$). There were no differences ($P \geq 0.05$) among treatments for gestation rate (40 and 10 mg of FGA= 100%, 20 mg of FGA= 82%, and 5 mg of FGA= 60%). Concerning to LH secretion, differences existed only in amplitude among 5 mg of FGA group (65 ± 6.40 ng mL^{-1}), compared with 40, 20 and 10 mg of FGA groups (41± 9.21; 38 ±7.94, and 23 ± 4.68 ng mL^{-1}, respectively). Under the present experimental conditions we conclude that doses of 40, 20 and 10 mg of FGA can effectively synchronize estrus in the breeding season however, 5 mg of FGA resulted in alterations in LH secretion.

Key Words: progesterone, luteinizing hormone, Dorset ewes.

W290 Neuroendocrine regulation of rearing behavior in the native Thai hen. O. Chaiyachet[1], D. Chokchaloemwong[1], N. Prakobsaeng[1], N. Sartsoongnoen[2], S. Kosonsiriluk[3], I. Rozenboim[4], M. E. El Halawani[3], T. E. Porter[5], and Y. Chaiseha*[1], [1]*Suranaree University of Technology*, *Nakhon Ratchasima, Thailand*, [2]*Nakhon Ratchasima Rajabhat University*, *Nakhon Ratchasima, Thailand*, [3]*University of Minnesota*, *St. Paul*, [4]*The Hebrew University of Jerusalem*, *Rehovot, Israel*, [5]*University of Maryland*, *College Park*.

Prolactin (PRL) circulating levels change during the avian reproductive cycle and vasoactive intestinal peptide (VIP) is the avian PRL releasing factor. This study investigated the changes in the VIP/PRL system of hens rearing their young as compared to hens deprived of rearing their chicks. The numbers of VIP-immunoreactive (VIP-ir) neurons in the nucleus infundibuli hypothalami (IN) and nucleus inferioris hypothalami (IH) of native Thai hens rearing chicks (R) were compared with those of non-rearing chicks (NR; n=4). Plasma PRL levels were determined by enzyme-linked immunosorbent assay. The numbers of VIP-ir neurons in the IN-IH on the day of hatch, and on days 4 (RD4), 7 (RD7), 10 (RD10), and 14 (RD14) of rearing were 59.4±5.9, 53.9±3.4, 30.3±1.0, 12.9±1.1, and 13.8±0.8 cells, respectively. When hens were not allowed to rear chicks, the number of VIP-ir neurons decreased as compared to their respective hens rearing chicks ($P<0.05$, NRD4=28.7±4.1; NRD7=15.3±6.6; NRD10=11.1±3.6; NRD14=14.8±2.5 cells). During the rearing period (week 1-5; n=6), PRL levels of R hens were compared (RW1 vs NRW1; 34.2±1.8 vs 27.4±1.7; $P<0.05$, RW2 vs NRW2; 37.8±7.8 vs 26.4±5.2; $P<0.05$, RW3 vs NRW3; 41.1±8.6 vs 18.5±1.5; $P<0.05$, RW4 vs NRW4; 36.3±9.6 vs 31.3±5.3, RW5 vs NRW5; 39.2±5.0 vs 27.9±4.3 ng/ml). These results indicate, for the first time, a role for the VIP/PRL system in the rearing behavior in gallinaceous avian species. It is concluded that the VIP/PRL system is not only a key regulator of incubation behavior as it is well established but it may also be involved in the regulation of rearing behavior in native Thai chicken.

Key Words: birds, rearing behavior, PRL

W291 Cloning and characterization of chicken 5-hydroxytryptamine (5-HT) receptors 1A and 1B. C. F. Wong*, A. H. Y. Kwok, J. C. W. Ho, Y. Wang, and F. C. Leung, *The University of Hong Kong*, *Hong Kong, HKSAR, China*.

The aim of this study is to clone and characterize 5-hydroxytryptamine (5-HT; serotonin) receptors, HTR1A and HTR1B, from chicken. 5-HT is a monoamine neurotransmitter derived from tryptophan and is believed to be involved in a broad range of biological activity including mitogenesis of smooth muscle cells, psychological disorders like schizophrenia, anxiety and depression, and neuroendocrine functions like regulation of ACTH, glutamate and dopamine release, via interaction with a large family of G protein-coupled receptors. However, these receptors were not well studied in avian species. In this study, the full-length genes were cloned from chicken by PCR. HTR1A gene encodes a putative 413-amino acid protein, which shares 80%, 80% and 78% identity with human, chimpanzee and mouse homologues, respectively. Similarly, HTR1B gene encodes a putative 379-amino acid protein, which shares 82%, 82% and 86% identity with human, chimpanzee and mouse homologues respectively. Using a pGL3-CRE luciferase reporter system, activation of both HTR1A and HTR1B by 5-HT were found to inhibit forskolin-stimulated luciferase activity in CHO cells, suggesting that both HTR1A and HTR1B are functionally coupled to Gi protein(s). Further characterization of HTR1A and HTR1B will shed light on the study of biological functions of 5-HT in chickens.

Key Words: chicken, 5-hydroxytryptamine, 5-hydroxytryptamine receptor

W292 Ergovaline and other ergopeptine alkaloids inhibit vesicular glutamate transporter (VGLUT)-mediated activity of bovine synaptic vesicles. Y. Xue*[1], J. R. Strickland[2], J. A. Boling[1], and J. C. Matthews[1], [1]*University of Kentucky*, *Lexington,* [2]*USDA-ARS, Forage-Animal Production Research Unit*, *Lexington, KY*.

L-Glutamate (Glu) is the major excitatory neurotransmitter responsible for the glutamatergic neurotransmission in the vertebrate central nervous system, including the gastrointestinal tract (GIT) of cattle. The vesicular Glu transporters VGLUT1 and VGLUT2 concentrate (50 m*M*) Glu (K_m = 1 to 4 m*M*) into synaptic vesicles (SV) for subsequent release into the synaptic cleft of glutamatergic neurons. To test the hypothesis that ergopeptine alkaloids inhibit VGLUT activity of bovine cerebral SV, a SV Glu uptake (vacuolar H^+ ATPase-dependent) model was developed. The effect of ergopeptine alkaloids on VGLUT activity was tested on SV isolated from cerebral tissue of Angus-cross steers that were naive to ergot alkaloids. Data were analyzed by ANOVA using GLM. Immunoblot analysis (n = 8) validated the presence of VGLUT1, VGLUT2, synaptophysin 1, and vacuolar H^+ ATPase proteins in purified SV. Functional analysis of the mean (n = 3, ± SE) SV VGLUT activity (50 μ*M*) was ATP- and vacuolar H^+ ATPase-dependent, and saturatable (apparent K_m = 1.53 ± 0.18 m*M*). IC_{50} experiments (n =3) revealed that VGLUT Glu uptake (50 μ*M*) was inhibited ($P \leq 0.048$) by ergopeptine alkaloids: bromocriptine (2.83 ± 0.59 μ*M*) < ergotamine (20.5 ± 2.77 μ*M*) < ergocornine (114 ± 23.1 μ*M*) < ergovaline (137 ± 6.55 μ*M*). Subsequent ergovaline K_i experiments (n = 3; Glu = 0.05, 0.10, 0.50, 1, 2, 4, 5 m*M*) demonstrated no change ($P = 0.332$) in apparent K_m. However, the V_{max} of Glu uptake was decreased ($P = 0.016$) when evaluated in the presence of 50, 100, and 200 μ*M* ergovaline, suggesting that ergovaline inhibits SV VGLUT activity through a non-competitive mechanism. The findings of this study suggest cattle with fescue toxicosis may have a reduced glutamatergic neurotransmission capacity. Thus GIT functions, including feed intake and digestion, may be impaired in cattle consuming ergopeptine alkaloids.

Key Words: bovine, ergot alkaloids, fescue toxicosis, glutamate transport, glutamatergic neurotransmission

W293 Comparison of the somatotropic axis of two precocial free-ranging ice seal species: harp (*Phoca groenlandica*) and hooded (*Cystophora cristata*). C. E. Anderson*[1], J. P. Richmond[1], J. M. Burns[2], and S. A. Zinn[1], [1]*University of Connecticut*, *Storrs,* [2]*University of Alaska-Anchorage*, *Anchorage*.

To determine if components of the somatotropic axis in marine mammals are associated with differing life history and maternal investment strategies, blood samples and morphometrics were collected from 35 free-ranging North Atlantic ice seals [hooded seals (*Cystophora cristata*), n = 15; and harp seals (*Phoca groenlandica*), n = 20] ranging in age from newborn to adult. For each species, animals were categorized as nursing, late nursing, weaned, and adult based on size, umbilical status, and pelage. Within a species, there were 5 individuals per category except there were no hooded seal pups categorized as late nursing due

to the 4 –d lactation. Radioimmunoassays were used to quantify serum IGF-1 and GH, using bovine and human antisera, respectively. Data were analyzed with the Proc Mixed function of SAS and included species and age as independent variables. On average hooded seals gained 24 ± 11 kg BW (6 kg/d) and 3.4 ± 0.2 cm of blubber during the 4-d nursing period ($P < 0.01$), without an increase in length (99.6 ± 3 cm; $P = 0.92$). During the 12-d lactation harp seal pups increased BW 34 ± 1.5 kg (8 to 42 kg; 2.8 kg/d), standard length 25 ± 3 cm (76 to 101 cm), and blubber depth 3.8 ± 0.2 cm ($P < 0.01$). Concentrations of GH were similar in hooded seal neonates and late nursing pups (7.5 and 6.24 ± 2.0 ng/mL; $P = 0.66$), but declined in harp seals for these periods ($P = 0.01$; 18.9 to 5.6 ± 2.0 ng/mL). Average IGF-1 was similar in neonates of both species (250 ± 44 ng/mL; $P = 0.52$) and increased in both harp and hooded seals during nursing (434 and 345 ± 44 ng/mL; $P = 0.01$). Coinciding with the post-weaning fast, harp seal IGF-1 rapidly declined from 434 to 120 ± 44 ng/mL, whereas GH increased from 5.6 to 12.4 ± 2.0 ng/mL ($P < 0.01$). Adult hooded seals were larger (293 ± 22 vs. 109 ± 22 kg) with greater IGF-1 (289 vs. 108 ± 32 ng/mL; $P < 0.01$) than adult harp seals, but there were no differences in GH (5.2 ± 1.2 ng/mL; $P > 0.10$). Concentrations of IGF-1 and GH reflect nutrient intake and growth rate during nursing and the post weaning fast in these precocial pinnipeds.

Key Words: pinnipeds, insulin-like growth factor-1, growth hormone

W294 Effects of age and sex on hematologic and serum biochemical values of broiler chickens. A. Viveros*[1], A. Brenes[2], I. Arroyo[1], M. Bascuñana[1], A. Angosto[1], and M. L. Fermin[1], [1]*Facultad de Veterinaria, UCM*, *Madrid, Spain*, [2]*Instituto del FRIO-ICTAN, CSIC*, *Madrid, Spain*.

Due to lack of reference values for avian blood profiles, hematological and serum biochemical reference values may provide valuable information about the health status of broiler chickens. An experiment was conducted to study the effects of age and sex on hematological and serum biochemical values for 7 weeks of age. A total of 120, 1-d-old male and female broiler chickens (Cobb strain), were randomly assigned to 20 cages (6 chicks per cage). Blood samples were collected weekly by cardiac puncture and analyzed for red blood cell count (RBC), hemoglobin content (Hb), packed cell volume (PCV), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), and white blood cell count (WBC), heterophil (He), basophil (Ba), eosinophil (Eo), lymphocyte (Ly), monocyte (Mo) and thrombocyte counts. Serum biochemical analysis included total protein, albumin, glucose, triglycerides, cholesterol, bile acids, uric acid, amylase, CPK, LDH, AST, calcium, phosphorus, and sodium. This study showed that age affects the hematological and serum biochemical values of the male and female broiler chicks. With increasing of age, the erythrocytic parameters (except MCV and MCH) and leukocytic parameters (except lymphocyte) were increased ($P < 0.001$), but MCV, MCH and absolute count of lymphocyte were decreased ($P < 0.001$). Regarding serum biochemical values, glucose, total protein, albumin, triglycerides, cholesterol, bile acids, CPK, LDH, AST, and phosphorus concentrations were increased ($P < 0.001$) and uric acid and amylase levels were decreased ($P < 0.001$) during breeding period. In comparison to male broilers, female broilers had higher ($P < 0.05$) RBC, Hb, and PCV levels ($P < 0.05$), and lower ($P < 0.001$) MCV, MCH, and heterophil values. Likewise, compared to male broilers, female broilers had higher ($P < 0.01$) levels of total protein, albumin, triglycerides, amylase, CPK, and AST, and lower ($P < 0.05$) levels of bile acids and uric acid. In conclusion, this study provided new information about age and sex-related changes of hematological and serum biochemical values in broiler chickens.

Key Words: chickens, hematological values, serum biochemical parameters

W295 Serum metabolite response of hens submitted to a second molt using soy hulls. H. Mazzuco*, L. S. Lopes, A. Coldebella, and V. S. Avila, *EMBRAPA Swine & Poultry*, *Concordia, SC, Brazil*.

In our previous study, similar physiological responses were observed for some blood metabolites of hens submitted to alternative and conventional molting methods. The present research was conducted to assess selected blood serum metabolites in laying hens induced to a second molt at the end of their 2nd laying cycle. 450 Hy-Line W-36 hens housed two per cage (759 cm2/bird) were molted at 142 wks of age and assigned to 5 treatments in a randomized complete block design (9 replicates/10 hens). The treatments were: Full-fed (FF), Conventional molt (CM, 10 d fasting) and alternative molt diets consisting of 95%, 85% or 75% of soy-hulls. Hens consumed the molting diets (except CM group) during 10 d and then were all fed cracked corn for 8 d followed by a pullet developer diet for 10 d. The serum metabolites evaluated were total calcium (TCa), ionized calcium (iCa), glucose (GLU), cholesterol (CHO), tryglicerides (TGL), high-density lipoproteins (HDL) and low-density lipoproteins (LDL). Samples of blood (5 mL) were taken from each hen and processed using a commercial kit on days 10 and 28 of molt, when birds were 143 and 146 wk-old, respectively. All data were subjected to ANOVA considering the effects of day of molt, treatment and interactions. Significant treatment × day of molt effects were observed in CHO ($P < 0.05$), HDL and LDL profiles ($P < 0.05$ and $P < 0.01$, respectively). CHO were higher for CM hens at 10 d of molt but not at 28 d, when FF hens showed higher levels. Lower levels of HDL were found in FF hens at 28 d of molt compared to the molted hens and at 10 d of molt, LDL levels were higher for FF. Treatment effect ($P < 0.01$) was observed for TCa and TGL. Highest levels of TCa and TGL at both days of molt were observed on FF hens. Day of molt influenced GLU and iCa ($P < 0.0001$) and higher levels at 28 d than 10 d were observed for both variables. During a second molt, changes in the circulating levels of blood metabolites reflected the dietary effects and for some, followed related patterns observed on hens in their first molt.

Key Words: blood calcium, serum lipoproteins, third cycle

W296 Pulmonary vascular pressure profiles in broilers selected for susceptibility to pulmonary hypertension syndrome: Age and gender comparisons. R. F. Wideman*, M. L. Eanes, K. R. Hamal, R. Klintworth, and N. B. Anthony, *University of Arkansas*, *Fayetteville*.

Broilers that are susceptible to pulmonary hypertension syndrome (PHS, ascites) have an elevated pulmonary arterial pressure (PAP) when compared with PHS-resistant broilers. Two distinctly different syndromes, pulmonary arterial hypertension (PAH) and pulmonary venous hypertension (PVH), both are associated with increases in PAP. Pulmonary arterial hypertension occurs when the right ventricle must elevate the PAP to overcome increased resistance to flow through restrictive pulmonary arterioles upstream from the pulmonary capillaries. In contrast, PVH is commonly caused by increased downstream (post-capillary) resistance. The sites of resistance to pulmonary blood flow are deduced by making contemporaneous measurements of the PAP and the wedge pressure (WP), and calculating the trans-pulmonary pressure gradient (TPG = PAP-WP). We obtained PAP, WP and TPG values from 8,12,16,20 and 24 wk old anesthetized male and female broilers from a PHS-susceptible line (IACUC Protocol #08036). Pressures were

recorded as a catheter inserted into a wing vein was advanced to the right atrium, right ventricle, main trunk of the pulmonary artery, and onward until the WP was obtained. Gender and age interactions were evaluated using the SigmaStat ANOVA package. To further characterize the relationship between PAP, WP and TPG the data also were pooled into three cohorts to compare vascular pressures in birds having the lowest PAP values (n = 52; range: 12 to 22.9 mmHg), intermediate PAP values (n = 63; range: 23 to 32.9 mmHg), and highest PAP values (n = 62; range: 33 to 62 mmHg). Within each of the age, gender and PAP cohort comparisons, broilers with elevated PAP consistently exhibited the hemodynamic characteristics of PAH (elevated PAP and TPG combined with a normal WP) but not PVH (elevated PAP and WP combined with a normal or reduced TPG). Susceptibility to PHS can be attributed primarily to pulmonary arterial hypertension associated with increased pre-capillary (arteriole) resistance.

W297 Regulatory effects of individual essential amino acids on casein synthesis rates in bovine mammary tissue slices. J. A. D. R. N. Appuhamy*, T. R. Wiles, and M. D. Hanigan, *Department of Dairy Science, Virginia Polytechnic Institute and State University*, *Blacksburg*.

In mammalian cells, amino acids are able to stimulate protein synthesis by phosphorylating mammalian target of rapamycin (mTOR) and ribosomal protein S6 (rpS6), and dephosphorylating eukaryotic elongation factor 2 (eEF2). Little work has explored the effects of these signals on milk protein synthesis in bovine mammary glands. The objective of this study was to investigate the effects of individual essential amino acid (EAA) deficiencies on cellular signals and protein synthesis rates in mammary tissue slices. Slices were prepared from the rear quarter of four lactating cows immediately after slaughter and incubated in serum free DMEM/F12 media containing all EAA (+EAA); media deprived of Arg, His, Ile, Leu, Lys, Met, Phe, Thr, Trp, or Val; or media deprived of all EAA (-EAA). After 1 h, 2D5-Phe was dosed into media and incubations continued for another 30 min. Cell lysates were subjected to Western immunoblotting analysis to determine total and phosphorylated mTOR (Ser2448), rpS6 (Ser235/236), and eEF2 (Thr56) and GC-MS analysis to determine 2D5-Phe enrichment (proportional to protein synthesis rates) in protein precipitated at pH=4.6 (enriched for casein). The –EAA treatment caused the phosphorylation state (PS) of mTOR and rpS6 to decrease by 46 and 76%, respectively, PS of eEF2 to increase by 136%, and protein synthesis to decrease by 46%. Phosphorylation of mTOR was positively correlated (r=0.80) with Phe enrichment. Deprivation of Leu resulted in the greatest reduction of PS for mTOR (46%) and rpS6 (51%) whereas Met deprivation was associated with the greatest PS increase for eEF2 (64%). The greatest reductions in protein synthesis were associated with Ile (58%), Leu (47%), and Met (45%) deprivations. Essential amino acids, in particular Leu and Met had substantial regulatory effects on protein synthesis efficiency in bovine mammary tissues, and a significant proportion of the signaling appeared to be mediated by mTOR.

Key Words: essential amino acid deprivation, casein synthesis rate, mTOR

W298 In vivo effects of insulin and dietary protein level on signaling proteins for protein synthesis in the mammary glands of lactating dairy cows. W. A. D. Nayananjalie*[1], A. G. Rius[1], D. Kirovski[2], J. A. D. R. N. Appuhamy[1], J. Escobar[1], and M. D. Hanigan[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*University of Belgrade*, *Serbia*.

Insulin and amino acids have been found to significantly enhance muscle protein synthesis by signaling through mammalian target of rapamycin (mTOR) and in turn ribosomal protein S6 (rpS6), eukaryotic initiation factor 4E binding protein 1 (4EBP1), and eukaryotic elongation factor 2 (eEF2). Insulin also stimulates mTOR through Akt. Increased phosphorylation (PhS) of Akt, mTOR, rpS6 and 4EBP1 and decreased PhS of eEF2 stimulates protein synthesis. We hypothesized that insulin and amino acid supply would also cause a change in the PhS of these proteins to promote protein synthesis in bovine mammary glands. The effects of infused insulin and varying dietary protein on total and phosphorylated forms of Akt, mTOR, rpS6, 4EBP1, and eEF2 in mammary tissues of lactating dairy cows were examined. Cows were fed two levels of dietary crude proteins (17.5 or 14.0% of dietary DM) and infused with two levels of insulin (0 or 1 μg/kg BW) under euglycemic conditions in a 2 × 2 factorial design. At the end of each treatment period mammary tissue biopsies were harvested. Tissue homogenates were subjected to Western immunoblotting analysis for total and phosphorylated forms of Akt (Ser473), mTOR (Ser2448), rpS6 (Ser235/236), 4EBP1 (Thr37/46), and eEF2 (Thr56). Increasing dietary protein level increased ($P = 0.02$) PhS of Akt. Neither dietary protein nor insulin had significant effects on PhS or total mTOR expression. However, increased dietary protein and insulin infusion significantly increased both the PhS ($P < 0.01$) and total 4EBP1 ($P = 0.03$) expression. Total rpS6 expression ($P = 0.02$) but not PhS was increased when insulin was infused. Increased dietary protein was associated with greater total eEF2 ($P = 0.04$) expression. Increased rpS6 expression and increased PhS of 4EBP1 should stimulate protein synthesis, but the lack of change in mTOR PhS would not be stimulatory.

Key Words: insulin, dietary protein, signaling protein

W299 A novel multiplex real-time PCR assay for bovine liver pyruvate carboxylase 5′ UTR variants during the transition to lactation. H. M. White*, S. L. Koser, and S. S. Donkin, *Purdue University*, *West Lafayette, IN*.

Pyruvate carboxylase (PC; EC 6.4.1.1) is a key enzyme in glucose and energy metabolism. The bovine PC gene contains three promoter sequences (P3, P2, and P1 from 5′ to 3′) and is regulated by physiological changes such as the onset of calving and feed restriction. Expression of P1 is glucogenic and lipogenic tissue specific and codes for 5′ UTR A, B, C, and F whereas P2 and P3 are expressed in several tissues and code for 5′ UTR E and D, respectively. The objective of this study was to develop a multiplex real-time RT-PCR assay for bovine PC 5′ UTR variants and to characterize their expression during the transition to lactation. The multiplex assay was designed to quantify the PC coding region, 5′ UTR D, E, and F mRNA, as proxy measures for their relative promoter activities. Combined expression of 5′ UTR A, B, and C mRNA was determined by difference. Liver biopsy samples were collected from eight multiparous Holstein cows at −28, +1, and +28 days relative to calving (DRTC). Expression of PC mRNA was increased ($P < 0.05$) by 6-fold at +1 DRTC compared to precalving levels. Expression of variants from P1 was greater ($P < 0.05$) than variants from P2 or P3. Expression of 5′ UTR F from P1 was decreased ($P < 0.05$) and the combined expression of 5′ UTR A, B, and C from P1 increased ($P < 0.05$) at +1 DRTC. There was no effect ($P \geq 0.05$) of DRTC on 5′ UTR D or E mRNA expression. Increased expression of PC mRNA at calving is due to an increase in activity of PC promoter 1 and a lack of change in activity of PC promoters 2 and 3. These data suggests that the onset of calving leads to activation of factors specific to targets on bovine PC promoter 1.

This project was supported by National Research Initiative Competitive Grant no. 2009-35900-05970 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: pyruvate carboxylase, multiplex qPCR, transition cow

W300 Embryo quality characteristics from superovulated cows receiving a blend of bioactive peptides and oligosaccharides to support immune function (Grade One). G. H. L. Marquezini[1], V. R. G. Mercadante[1], M. M. Ward*[2], A. R. Spell[3], J. A. Carter[3], N. D. Paton[4], and G. C. Lamb[1], [1]*University of Florida*, *Marianna, FL*, [2]*Provimi North America, Inc.*, *Brookville, OH*, [3]*Advanced Reproductive Associates*, *Daphne, AL*, [4]*Provimi Holding, BV*, *Rotterdam, Netherlands*.

We determined whether supplementation of a blend of bioactive peptides and oligosaccharides to support immune function (Nutrition Horizons Grade One; Brookville, OH; US Patent no. 6,962,718) would alter quality, stage, and fertilization rate of embryos recovered after superovulation. Angus and Brangus cows were superovulated using follicle stimulating hormone as NIH-FSH-P1 and were stratified by breed before random assignment to treatment: 1) donors received 6 Grade One capsules (13 g/capsule) containing a blend of bioactive peptides and oligosaccharides (NHG1; n = 35); or 2) donors received 6 placebo capsules (13 g/capsule; Control; n = 37). Superovulation was initiated with a CIDR on d 0, 8 injections of FSH at 12 h intervals initiated on d 4, plus two injections of PGF 12 h apart on d 7. At 0 and 12 h after detected estrus cows received an AI. Boluses were inserted into the esophagus utilizing a balling gun. Cows received two boluses at CIDR insertion (d 0), at the first (d 4), and third (d 5) injection of FSH. Embryos were collected 7 d after first detected estrus and were recovered by nonsurgical embryo collection procedure and embryos were classified by stage and quality. Data was analyzed with PROC MIXED using flush as the experimental unit. Total ova (14.1 ± 1.8) and transferable embryos (5.2 ± 1.1) per flush for NHG1 and Control, did not differ. Mean number of grade 1 (2.5 ± 0.8) and 2 (2.7 ± 0.5) and no differences existed between treatments for degenerate (1.9 ± 0.4) or unfertilized ova (7.0 ± 1.4). However, the percentage of grade 1 embryos collected compared to recovered transferable embryos was greater ($P = 0.062$) for NHG1 (39.4%) than Control (23.4%). In addition, the percentage of grade 2 embryos collected compared to recovered transferable embryos was greater ($P < 0.05$) for Control (76.6%) than NHG1 (59.9%). We conclude that the number of transferable embryos collected per flush did not differ between treatments; however, the quality of transferable embryos was improved after embryo donor cows received NHG1 prior to embryo collection.

Key Words: embryo transfer, superovulation, immune function

W301 Evaluation of a distinct white Angus crossbred phenotype in southern Florida. P. G. M. A. Martins*[1], R. Cassiolato[1], F. Frigoni[1], M. M. Salin[1], D. B. Araujo[1], M. Meneghetti[1], G. C. Lamb[1], D. G. Riley[2], B. H. Carter[2], T. H. Friend[2], and J. D. Arthington[1], [1]*University of Florida, Range Cattle Research and Education Center*, *Ona,* [2]*Texas A&M University, Department of Animal Science*, *College Station*.

A distinct beef phenotype has emerged from offspring of Angus × Brahman × Charolais cows being mated to Simbrah bulls. A proportion of these female offspring, when mated to black Angus bulls, produced offspring with white hair coats. This phenotype persists in a majority of these heifers through a second cross with black Angus bulls resulting in white Angus crossbred calves with 75% black Angus genetics. The white hair coat of these offspring is thought to be derived from the dilution gene effects from the Charolais and Simmental breeds. The objectives of these initial studies were to compare body temperature and grazing behavior among these white and black phenotypes. In the first study, vaginal temperatures were assessed over 2 consecutive yr (n = 5 black and white phenotypes/yr). Temperatures were recorded over 5 consecutive summer days using an automated temperature logger (5.9 × 16.3 mm) placed in an intravaginal device. During the assessment period, heifers grazed a single pasture with no access to shade. In the second experiment, voluntary forage DMI was assessed in a fully shaded facility using weaned, yearling heifers (n = 9 black and 6 white) over a 42-d evaluation period. Heifers were provided free choice access to ground hay with grain supplement provided at 0.5% BW. Grazing behavior was evaluated in a subset of these heifers (n = 5 black and 5 white) by observing time spent in and out of shade and standing or lying over 10 individual 12-h observation periods (twice weekly; 5 wk). Average peak vaginal temperatures were 1.1 °C greater ($P < 0.001$) in black vs. white heifers (40.5 and 39.4 °C). There were no differences ($P = 0.15$) in voluntary forage intake when heifers were evaluated under full shade (1.49 vs. 1.27% BW for black and white heifers, respectively; SEM = 0.115); however, pasture observations during the summer daylight hours revealed that black heifers spent 7.4% more ($P < 0.01$) time in the shade compared to white heifers. These results suggest that Angus (50 to 75% black Angus) crossbred heifers with a white hair coat have a reduced non-shaded peak body temperature compared to black Angus cohorts. This reduction in body temperature may result in greater grazing times during the summer months in southern Florida.

Key Words: Angus, coat color, grazing

W302 The relationship of pulmonary arterial pressure with feed efficiency, performance, temperament, and feeding behavior in growing beef cattle. T. D. Maddock*, G. H. L. Marquezini, V. R. G. Mercadante, and G. C. Lamb, *University of Florida*, *Marianna*.

We examined whether pulmonary arterial pressure (PAP) has a relationship with feed efficiency, performance, temperament, or feeding behavior in growing beef cattle. Calves (n = 213; bulls, n = 107; heifers, n = 106; Angus and Angus-cross, n = 118; Charolais, n = 38; Zebu and Zebu-cross, n = 57; initial BW = 317 (SD = 39) kg) were placed in a feed intake facility and after 21 d of adaptation, daily DMI was recorded for 70 d. Diets (NEm = 1.34 Mcal/kg; NEg = 0.77 Mcal/kg; CP = 117 g/kg) were offered ad libitum. Ultrasound 12th rib LM area and fat depth (BF) and PAP (mg Hg) were measured on d 0 and 70. Chute score and exit velocity were measured on d 0, 35, and 70. Residual feed intake (RFI) was calculated by regressing ADG and mid-metabolic BW on daily DMI. Animals were classified as high, average, or low PAP (> 0.5 SD, ± 0.05 SD, and < 0.5 SD from the mean, respectively; mean PAP = 37.0, 32.6, 28.2, respectively). Least squares procedures using PROC MIXED of SAS were used to examine the effect of PAP group on other variables. Pearson correlation coefficients among traits were determined using the CORR procedure of SAS. There was no association between PAP and RFI, DMI, ADG, or G:F, but PAP was positively correlated to initial BF (r = 0.29, $P < 0.001$) and final BF (r = 0.19, $P = 0.009$) and was negatively correlated with chute score (r = –0.18, $P = 0.01$). Cattle with high PAP had lower RFI than those with average ($P = 0.03$) and low ($P = 0.04$) PAP. Cattle with low PAP had lower DMI, ADG, and G:F than cattle with average ($P = 0.008$, $P = 0.005$, $P = 0.05$, respectively) and high PAP ($P = 0.005$, $P < 0.001$, $P = 0.005$, respectively). Cattle with high and average PAP had a greater number of daily feeding events (consumed > 100 g DM) than low PAP cattle ($P = 0.02$, $P = 0.002$, respectively). There was no effect of PAP group on other feeding behavior traits, including daily feeding duration or eating rate (g DM/min). There was not a strong association between

PAP and performance traits, but calves with low PAP had lower intake, performance and subsequently lower feed efficiency.

Key Words: beef cattle, feed efficiency, pulmonary arterial pressure

W303 Technical and economic performance of a beef cattle production system: A case study in Bahia State, Brazil. F. A. Barbosa*[1], D. S. Graça[2], V. J. Andrade[2], I. M. Cezar[3], and R. C. Souza[2], [1]*University of Brasília (UnB)*, *Brasilia,DF, Brazil*, [2]*School of Veterinary Medicine, Federal University of Minas Gerais (UFMG)*, *Belo Horizonte, MG, Brazil*, [3]*Anhanguera-Uniderp University*, *Campo Grande, MS, Brazil*.

A case study on the transition from beef cattle breeding, rearing and fattening system to a cow-calf production system was assessed in the State of Bahia, Brazil, including production and economic performance over a four year period (January 2000 to December 2004). Production and economic data were collected using control software (Congado) and analyzed by electronic spreadsheets (Microsoft Excel). The system was developed exclusively on a grazing system of 2,926 hectares with a base herd comprised of Zebu (Tabapuã breed) and crossbred *Bos taurus* × *Bos indicus* cattle. During the rainy season the herd was fed mineral supplement based on a specific formulation for each animal category. Introduction of technologies related to pasture, feeding supplementation, breeding program, animal health practices, associated with technical-administrative management improved the animal performance indexes. Mean stocking rates ranged from 0.9, 1.3, 1.5, 1.4 to 1.5 heads/ha in 2000, 2001, 2002, 2003 and 2004, respectively. Annual mean rates of pregnancy, birth and weaning were 88.8%, 85.1% and 82.6%, respectively. As result of introduction crossbreeding, the mean weights at weaning and at slaughtering of males achieved 228.87 and 485.16 kg, respectively, with mean age at slaughtering of 24.6 months. Total accumulated cost was US 1,799,623.57. The total income of US 1,734,569.69 was not enough to pay the opportunity cost, resulting in a negative return on invested capital (RIC). The activity yielded total operating profit of US 484,194.82 during the five years evaluated. Mean RICs were 10.78% and 1.29% on operating and total profit, respectively. Estate valuation changed the return on the invested capital accumulated from the business to 9.75%. The implantation of a series of technologies improved animal performance indexes in the semi-intensive complete cycle system. The economic results indicated that the activity paid all operating costs but could not totally pay the opportunity cost.

Key Words: animal performance indexes, cost, profitability

W304 Economic efficiency and productivity of life-cycle beef cattle production systems in Bahia State, Brazil. F. A. Barbosa*[1], D. S. Graça[2], V. J. Andrade[2], I. M. Cezar[3], and R. C. Souza[2], [1]*University of Brasília (UnB)*, *Brasília, DF, Brazil*, [2]*School of Veterinary Medicine, Federal University of Minas Gerais (UFMG)*, *Belo Horizonte, MG, Brazil*, [3]*Anhanguera-Uniderp University*, *Campo Grande, MS, Brazil*.

Economic efficiency and productivity of three life-cycle cattle production systems were simulated using four different calving rates (CR): SCC - 87%; −4CR- 83%; −2CR - 85%; +2CR - 89%. This evaluation used case study data and simulated the effect of variation in calving rates on economic returns. Production and economic data were collected using control software (Congado) and analyzed by electronic spreadsheets (Microsoft Excel). The base system (SCC) was developed on grazing system of 2,926 hectares composed of Zebu cattle (Tabapuã breed) and crossbred *Bos taurus* × *Bos indicus* cattle (n=3453). Data were collected from this herd from January of 2000 to December of 2002. During the rainy season the herd was fed mineral supplement based on a specific formulation for each animal category. Systems −4 CR, −2CR and +2CR were simulated based on adjusted calving rates fluctuations according to energy requirement and herd composition during a three year periods. Liveweight sold were 149, 146, 144 and 141 kg/ha/year for −4CR, −2CR, SCC and +2CR, respectively. Accumulated profit were US 329,490.77; 311,271.28; 306,842.04 and 297,082.63 for −4CR, −2CR, SCC and +2CR, respectively. Returns over accumulated invested capital were 7.8, 7.4, 7.3 and 7.0% for −4CR, −2CR, SCC and +2CR, respectively. Calving rate fluctuation modified the economic efficiency and productivity of simulated production systems. Economic efficiency and productivity results decreased as calving rate increased.

Key Words: calving rate, cost, profitability

W305 Economic viability of breed Nelore and crossbreed F1 Nelore × Brahman produced in feedlot. R. A. Mandarino*, F. A. Barbosa, I. S. Silva, J. M. S. Diogo, and L. A. Chaves, *University of Brasília (UnB)*, *Brasília, DF, Brazil*.

The experiment evaluates the costs of production and economic viability of the feedlot, divided into two genetic groups and subjected to three diets. The experiment was conducted from August to November 2009, lasting 96 days. We used 42 bulls with an average age of 23 months, and 21 breed Nellore (NEL) and 21 crossbreed NellorexBrahman (NBR). Each genetic group was divided into three diets, with 7 animals each: SIL - corn silage and concentrate (corn grain, soybean meal, soybean hulls, urea and mineral supplement) at a ratio of 25:75 (in dry matter), PEL - exclusive diet of pellets; GRN - diet with whole grain corn and pellets. The experiment was conducted in a completely randomized in a 2 × 3 factorial, divided as follows: NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN. The feeding costs were calculated using the daily offered quantity for each treatment and divided by the respective number of bulls. The labor costs and depreciation were divided by the bulls. The total operating cost (TOC) was calculated by summing the costs for food, labor costs (US 10.20 / beef) and depreciation (US 3.80/beef). The net margin per kg of carcass was obtained by difference between total revenue/kg and TOC/kg. The average initial body weights (IP) were: 350.7, 350.6, 355.8, 379.2, 375.7 and 376.1 kg for NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN respectively. Mean weight (PF) were: 500, 464.4, 479.6, 510.7, 571.8 and 501.5 kg for NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN respectively. TOC for Nellore in the period were US 215.0, 182.1, 195.4, 165.2, 180.3 and 222.6 to NBRSIL, NBRPEL, NBRGRN, NELGRN, NELPEL and NELSIL, respectively. The total operating cost per kg carcass were US 2.20, 2.06, 1.96, 1.64, 1.86 and 1.90 to NBRSIL, NBRPEL, NBRGRN, NELGRN, NELPEL and NELSIL, respectively. The net margin per kg of carcass were US 0.52, 0.65, 0.76, 1.08, 0.86 and 0.82 for NBRSIL, NBRPEL, NBRGRN, NELGRN, NELPEL and NELSIL, respectively. All treatments were economically viable, and the NEL with numerically higher net margin than the NBR, and diet GRN exceeding PEL and SIL.

Key Words: beef cattle, costs, genetic group

W306 Monitoring diet quality and body condition in beef cows grazing Arizona rangeland. D. R. Tolleson* and D. W. Schafer, *The University of Arizona*, *Tucson*.

Nutrition is the highest input cost in beef production. Monitoring the nutritional status of range cows is difficult. Near infrared spectroscopy (NIRS) of feces has been used to predict diet quality in cattle. When fecal NIRS is coupled with decision support software such as the Nutritional

Balance Analyzer (NutbalPro); nutritional status and animal performance can be monitored. Few reports on the applicability of these two methods exist for the southwestern US. Approximately 120 Hereford and 90 CGC composite (50% Red Angus, 25% Tarentaise, 25% Charolais) cows grazing in a single herd were used in a study to determine the ability of fecal NIRS/NutbalPro to project body condition score (BCS, 1 = thin, 9 = fat) under commercial scale rangeland conditions in central Arizona. Cattle were rotated across the 31,000 ha allotment at 10 to 20 day intervals. Fecal samples were collected in the pasture ~ monthly at the midpoint of each grazing period. A sample consisted of ~100g feces each from 5 to 10 animals of each breed. Samples were frozen and later analyzed by NIRS for prediction of diet crude protein (CP) and digestible organic matter (DOM). Fecal sampling occurred from November 2007 to October 2009. Cattle BCS was recorded for 10 to 30 individuals from each breed type at the time of fecal sampling beginning in November 2008. Along with fecal NIRS predicted diet quality, animal breed type and reproductive status characteristics, and environmental conditions were input to the NutbalPro software for each fecal sampling/BCS date (November 2008 to October 2009). Diet quality varied from a minimum of 5.24% CP and 56.89% DOM in January 2009 to a maximum of 14.61% CP and 62.87% DOM in August of 2008. Diet quality was related to observed seasonal changes and precipitation events. Projected BCS averaged 0.2 ± 0.06 score different than observed BCS (R^2 = 0.75, SE = 0.19, $P < 0.01$). The greatest difference in projected versus observed BCS occurred during periods of lowest diet quality. Body condition was predicted accurately enough to be useful in monitoring the nutrition of range beef cows under the conditions of this study.

Key Words: beef cattle, rangeland, near infrared spectroscopy

W307 Influence of residual feed intake, breed of sire and dam on the performance and carcass characteristics of early weaned steers during the feedlot phase. C. O. Trejo*, D. B. Faulkner, J. M. Dahlquist, and T. G. Nash, *University of Illinois*, *Urbana*.

Improving feed efficiency through management practices has become of more importance to the beef industry. The objectives were: (1) evaluate the effect of breed of sire and dam on the performance and carcass characteristics of early weaned steers (EW) during the feedlot phase; and (2) evaluate the effect of residual feed intake (RFI), breed of sire and dam on meat tenderness of EW. One hundred and fifty eight Angus (A), Simmental (S), Angus-Simmental, and Simmental-Angus steers were used across two different years. Animals were early weaned at 56 d of age. Animals were allotted to pens by weight and fed a common diet. Forty five steers classified in the high (H) RFI group and 113 steers in the low (L) RFI group. No differences were detected for initial weight (IW), adjusted final weight (AFW), and average daily gain (ADG). Steers in the H RFI group were 12% less efficient ($P < 0.0001$) than steers in the L RFI group. RFI differed ($P < 0.0001$) between H and L RFI groups. High RFI steers ate 1.5 kg more of expected feed intake. For carcass characteristics, only kidney, pelvic, and heart fat % (KPH) differed ($P = 0.0051$) between RFI groups. Meat tenderness did not differ between the RFI groups. Breed of sire had no effect on the performance characteristics. Breed of dam differed for IW ($P < 0.0001$), AFW ($P = 0.0014$), and RFI ($P = 0.0433$). For RFI, steers from S dams ate 0.5 kg/d less of expected feed intake. Steers from A sires had 0.33 cm ($P < 0.0001$) more of carcass back fat (BF) than steers from S sires. Progeny of A sires reported higher ($P = 0.0002$) marbling score (MS) than the progeny of S sires. Breed of dam had an effect in carcass characteristics. Steers from S dams had heavier HCW ($P = 0.0014$). Similar to breed of sire effects, BF ($P = 0.0003$) and MS ($P < 0.0001$) was higher in carcasses of steers from A dams. Breed of sire and dam interaction was significant only for MS. Pure bred A steers had the highest MS ($P < 0.05$). Identifying steers with L RFI potential and understanding the contribution of cross breeding can help improve feed efficiency without negative affecting carcass traits.

Key Words: residual feed intake, breed of dam, breed of sire

W308 Supplemental corn dry distillers grains plus soluble on performance of steers grazing native range. M. F. Martínez-Pérez, D. Calderón-Mendoza, F. Loya-Holguin, A. Soto-Gaspar de Alba, C. Murdock, A. M. Encinias, and S. A. Soto-Navarro*, *New Mexico State University*, *Las Cruces*.

Medium- to high-quality rangeland forage is low in available energy in relation to its rumen degradable protein content. To complement forage quality, energy and phosphorus are usually supplemented to cattle grazing medium to high-quality forage. Supplementation with feedstuffs rich in digestible fiber (energy) and phosphorus, such as corn distiller grains plus solubles (DDGS), could alleviate the deficiencies of growing forage. We hypothesized that supplementation of DDGS to cattle grazing native range during the summer season will alleviate nutritional deficiencies, and will improve cattle grazing performance. To evaluate effects of DDGS supplementation level on performance of steers grazing native range during the forage growing season, 72 (206 ± 23.6 kg; 2008) and 60 (230 ± 11.3 kg; 2009) English crossbred steer calves were used in a grazing experiment. The grazing period lasted 56 and 58 d and started on August 11 and 20 for 2008 and 2009, respectively. Steers were blocked by BW into light, medium, and heavy. Each block was divided into 4 grazing groups. Each grazing group (6 steers in 2008 and 5 in 2009) was assigned to 1 of 4 DDGS supplementation levels: 1) 0% supplementation (no supplement), 2) 0.2%, 3) 0.4% and 4) 0.6% of BW. Total amount of supplementation per paddock for 7 d was calculated and divided by 3 to determine amount of DDGS to be fed as it was offered 3 times weekly. Supplement intake (0, 0.42, 0.82, and 1.25 ± 0.03 kg/d, for 0, 0.2, 0.4, and 0.6% of BW, respectively), and ADG (0.64, 0.75, 0.80, 0.86 ± 0.03 kg/d for 0, 0.2, 0.4, and 0.6% BW, respectively) increased linearly ($P < 0.01$) with increasing DDGS supplementation level. Levels of DDGS supplementation did not affect ($P = 0.43$) supplement conversion (4.18, 6.72, and 6.03 ±1.26 kg as-fed supplement/kg of increased BW gain for 0.2, 0.4, and 0.6% BW, respectively). Supplemental DDGS improved performance of steers grazing native range during summer in the Southern Plains.

Key Words: DDGS, grazing native range, steers

W309 Predicted mineral intake utilizing both water and forage analysis varies by source and location of livestock water in Eastern Montana. J. T. Mulliniks*[1], J. Muscha[2], S. I. Lodge-Ivey[1], and M. K. Petersen[2], [1]*New Mexico State University*, *Las Cruces,* [2]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory*, *Miles City, MT*.

Livestock water can play an important role in contributing to mineral intake of cows grazing rangelands. Mineral analysis of both forage and water is needed to accurately assess mineral intake compared to animal requirements. Therefore, 93 pasture and water source combinations were sampled in May 2009 with the objective to predict total mineral intake (forage intake and water consumption) on a DM basis at the 22,257 ha USDA-ARS Fort Keogh Livestock and Range Research Laboratory in Miles City, MT. Mineral intake was predicted of a lactating beef cow with an estimated water and forage intake of 43.15 L/d (25.4 kg/d) and 2.4% of BW, respectively. Mineral content from hand plucked forage samples were analyzed from 43 pastures representing 3 geographical locations: north (N), southeast (SE), and southwest (SW). All drinking water locations from each pasture were sampled for mineral analysis

(Midwest Labs Inc.) from four sources: springs, pumped ground water, reservoirs, and flowing surface water. Location, source and the location by source interactions were evaluated and analyzed as a 3 × 4 factorial arrangement of treatments. Predicted intake of chloride, copper, dietary anion-cation difference (DACD), phosphorus, and potassium was affected ($P < 0.05$) by geographical location. Differences ($P < 0.05$) in mineral consumption due to water source were found in 5 analyzed minerals (Ca, Cl, DACD, Fe, and Mg). Location by source interactions ($P < 0.05$) were found for fluoride, sodium, and sulfur. Predicted fluoride and sulfur intake concentrations were at or above the maximum tolerable concentrations in the ground water sources in most pasture locations. Copper and zinc were below requirements for a lactating beef cow; whereas, most minerals were found at safe intake concentrations and met a lactating cow requirements. These results suggest that developing a mineral supplement to meet grazing livestock′s requirement should take into account both forage and water mineral content.

Key Words: beef cow, mineral intake, water analysis

W310 The environmental impact of corn-fed vs. grass-fed beef finishing systems. J. L. Capper*[1] and R. A. Cady[2], [1]*Department of Animal Sciences, Washington State University*, *Pullman,* [2]*Elanco Animal Health*, *Greenfield, IN*.

System productivity fundamentally influences the environmental impact of animal agriculture. A partial life cycle assessment model was used to quantify the effect of finishing beef steers in a corn-fed (conventional) or grass-fed system on resource use and methane output. The model was based on nutrient requirements and metabolism of Angus x Hereford steers grown from 254 kg at weaning to 635 kg at slaughter. Corn or grass-based diets were formulated according to NRC with growth rates based on ad libitum intake at age-appropriate bodyweights. Inputs included feed composition and quantity, crop and pasture yields, energy and fertilizer use for cropping, and fossil fuel use for transport. Steers finished on pasture have an added energy requirement for grazing activity, thus increasing daily maintenance requirements (Table 1). Grass-based diets promote greater ruminal acetic acid production, increasing daily enteric methane production. The reduced growth rate of grass-fed steers increases finishing period length, each additional day increasing both total energy requirements and methane emissions. The differential in energy yield per acre between pasture and corn increases the land use for grass-fed beef. Energy use, methane emissions and land area per kg of beef are considerably increased in grass-fed vs. corn-fed beef production systems. The results demonstrate that the popular perception of grass-fed beef as being more sustainable than corn-fed beef does not align with true sustainability when producing an equivalent amount of food from each system.

Table 1. Comparison of energy inputs, methane output and cropland required to finish beef steers in corn-fed or grass-fed systems

	Corn-fed	Grass-fed
Start weight (kg)	254	254
Finished weight (kg)	635	635
Growth rate (kg/d)	1.61	0.87
Finishing period length (d)	237	438
Daily maintenance energy (MJ)	26	33
Daily growth energy (MJ)	30	15
Total energy use (MJ)	47,123	118,308
Total methane emissions (kg)	53	149
Energy MJ/kg beef	133	333
Methane kg/kg beef	0.15	0.42
Total land required (ha)	0.21	2.70

Key Words: beef production, environmental impact, methane

W311 Assessment of thermal signatures of nose-clip weaned calves using digital infrared thermography. H. T. Boland*[1,2], S. Bowers[2], and S. T. Willard[2,3], [1]*Mississippi State University, Prairie Research Unit*, *Prairie,* [2]*Mississippi State University, Department of Animal and Dairy Sciences*, *Mississippi State,* [3]*Mississippi State University, Department of Biochemistry and Molecular Biology*, *Mississippi State*.

Anti-suckling nose-clips (NC) are used for two-stage, low-stress weaning. Different NC types are available including adjustable size NC (ADJ) and "one-size fits all," non-adjustable NC (ONE). A study was conducted in which beef calves (n=24, BW=242 ± 6 kg) were randomly assigned to be weaned with ADJ, ONE, or weaned conventionally by abrupt remote separation (CTRL). Digital infrared thermal imaging (DITI) is a non-invasive diagnostic tool for evaluating surface temperature gradients. The objective of this study was to investigate the use of DITI to determine whether temperature differences exist between calves weaned by different methods. Imaging was conducted using a FLIR P60 thermal camera and images were analyzed using ThermaCAM Researcher Pro (version 2.7). The lateral (LAT, inside the nostril) and anterior (ANT) surface temperature maximum of the nose, and eye temperature were recorded. The NC were placed on calves (d −5) and worn for 5 d prior to separation from dams (d 0). Images were taken at initial placement of NC and after removal on d 0. Blood was also collected on d −5 and 0, and serum analyzed for cortisol. Ambient temperature (AMB) ranged from 21.3 to 29.0°C at the time of imaging. Both LAT and ANT were positively correlated to one another ($r = 0.80$, $P < 0.01$) and to AMB ($r = 0.56$ and 0.55, respectively; $P < 0.01$). Cortisol and ANT tended to be positively correlated ($r = 0.24$, $P = 0.10$). Eye temperature (indicative of core body temperature) did not differ ($P > 0.10$) between treatments or days. There were no differences ($P > 0.10$) between CTRL, ONE or ADJ treatments in mean LAT (35.6, 34.6, or 35.0°C, respectively) or ANT (34.4, 33.9, 34.1°C, respectively). From d −5 to 0, ANT increased ($P < 0.01$) within all treatments; however, AMB ($P < 0.01$) also increased which may have impacted surface temperature. In ADJ and ONE calves the LAT increased ($P < 0.01$) from d −5 to 0, but not in CTRL calves ($P > 0.10$) which may be explained by minor inflammation that developed within the nostril of calves wearing NC. This suggests that DITI may be useful in evaluating effects of NC on nasal tissue. Effect of breathing on nostril imaging needs further examination.

Key Words: thermography, nose-clips, weaning

W312 Selenium incorporation and depletion in beef heifers grazing pastures with very high selenium levels grown in saline soils. S. O. Juchem*[1,2], S. E. Benes[2], P. H. Robinson[1], P. Vasquez[2], M. Brito[2], G. Getachew[1], and P. Chilibroste[3], [1]*University of California*, *Davis*, [2]*California State University*, *Fresno*, [3]*Facultad de Agronomía*, *Paysandú, Uruguay*.

Salinization of soils in parts of the westside of the San Joaquin Valley (CA, USA) has led to cultivation of salt tolerant forages such as 'Jose' tall wheatgrass (TWG) (*Thinopyrum ponticum* var. 'Jose') and creeping wildrye (CWR) (*Leymus triticoides* var. 'Rio'). Our objective was to measure tissue selenium (Se) concentrations and performance of beef heifers grazing TWG and CWR forages containing very high levels of Se (>3 mg/kg DM). Twenty 6 m old Angus heifers were allocated to two grazing areas, where each ~9 ha TWG or CWR area was divided into 2 subplots, with each subdivided into 4 paddocks that were rotationally grazed at 14 d intervals for 165 d. Blood was sampled at −25, 20, 45, 70, 91, 134 and 165 d of grazing, and muscle and liver biopsies were at −25, 91 and 165 d. Body weight (BW) was recorded before grazing and at 20, 45, 70, 91, 134 and 165 of grazing. At the end of grazing, heifers were moved to a feedlot and fed a ration that contained low levels of

Se (<0.25 ppm). Samples of liver, blood and recording of BW were at 23, 81, 136 and 208 d after grazing, whereas muscle was sampled at 81, 136 and 208 d. An additional blood sample was collected at 41 d. TWG had a higher level of metabolizable energy (6.7 vs. 6.0 MJ/kg DM) and Se (4.0 vs. 2.8 mg/kg DM), but lower CP level (7.9 vs. 9.0% DM) than CWR. BW gain was similar for TWG and CWR heifers (0.27 vs. 0.36 kg/d). Se accumulation in blood occurred quickly, increasing more than 3 fold by 20 d of grazing in TWG heifers (0.094 vs. 0.410 ppm Se), and CWR heifers had lower blood Se during the entire grazing period. Se accumulation in liver and muscle had similar patterns as in blood, but at slower rates. Se concentrations decreased after grazing (P<0.01), but rates of Se mobilization from blood, liver and muscle differed. By 81 d post grazing, concentrations of Se were reduced by 77% in liver, 49% in blood but only 31% in muscle. Results suggest that TWG and CWR production using saline drain water can be a viable alternative for salinized soils. In addition, muscle Se depletion occurs slowly enough to allow slaughter of beef cattle with enriched levels of Se in beef.

Key Words: salinity, selenosis

W313 Influence of shading of feedlot pens on performance of growing bull-calves during winter in northwest Mexico. R. Barajas*[1], B. J. Cervantes[1,2], M. Verdugo[1], M. A. Espino[1,3], E. A. Velazquez[1], J. A. Romo[1], and L. R. Flores[1], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*Ganadera Los Migueles SA de CV*, *Culiacan, Sinaloa, Mexico*, [3]*Técnología de Máxima Producción, S.A. de C.V.*, *Culiacan, Sinaloa, Mexico*.

The objective of this study was to determine the influence of shading in feedlot pens on feedlot performance of growing bull-calves during winter in northwest Mexico. Sixty bull-calves (BW = 225 ± 1.2 kg) were used in a 105-d feedlot experiment. In accordance to a randomized complete block design, bull-calves were blocked by initial-BW (light and heavy), and in groups of five were assigned to receive one of two allotment schedules which consisted the treatments: a) Six 6 × 12 m pens with no shade (control), and b) Six 6 × 12 m pens provided with 6 × 4 m of metallic-sheets ceiling (shade). Experimental data were analyzed by ANOVA for a randomized complete block design. Final BW was improved ($P = 0.05$) for calves allowed shade compared with controls (399 vs. 380 kg). ADG was increased ($P = 0.04$) 12% in shaded animals (1.655 vs. 1.477 kg/d for shaded and control, respectively). Dry matter intake was not affected ($P > 0.80$) by treatment (8.319 vs. 8.322 kg/d). Feed to gain ratio was increased ($P < 0.01$) in 11% for shaded bull-calves (5.015 vs. 5.619 kg of DM/kg of BW gain, for shade and control, respectively). Retained net energy for maintenance from the diet, was 12% higher ($P = 0.07$) in shaded bull-calves (1.957 vs. 1.747 Mcal/kg of DM for shade and control, respectively). Animals in control no shade treatment expenses 8% more NEm ($P = 0.06$) that expected (observed/expected NEm ratio = 0.92). It is concluded that use of shading on feedlot pens improves performance of growing bull-calves in northwest Mexico during the winter season.

Key Words: bull-calves, feedlot performance, shade

W314 Preliminary evaluation of grandsire marbling potential and ultrasound use on backgrounding and finishing performance, and carcass merit. C. J. Mueller*[1,2], T. DelCurto[1,2], R. R. Mills[1], C. P. Sullivan[1,2], and G. L. Tschida[1,2], [1]*Oregon State University*, *Corvallis*, [2]*Eastern Oregon Agricultural Research Center*, *Union*.

Forty-one crossbred calves (285 ± 32 kg) were backgrounded and finished to determine the impact of grandsire marbling potential and ultrasound use on predicting carcass merit. Dams were sired by either a high marbling EPD Angus bull (HIGH; Marbling EPD: +0.44, Acc: 0.23) or a low marbling EPD Angus bull (LOW; Marbling EPD: +0.02, Acc: 0.30) as evaluated by the American Angus Association, then bred to a common sire. Weaned calves were backgrounded on a barley-based diet in a common pen for 60 d. Calves were ultrasonographed for marbling (UMARB), muscle depth (UMD), and backfat (UBF) at the beginning (d0) and end of the backgrounding period (d60), and again at 72 d into the feedlot phase (d135). Gain and carcass data were evaluated as a 2 × 2 factorial design with grandsire and sex as main effects and calf age as a covariate. Correlations between ultrasound measurements and carcass data were used to determine the relevancy of ultrasound timing to carcass merit. Daily gain was similar ($P > 0.10$) between grandsire groups during both phases. Heavier carcass weights, increased backfat, and larger ribeye area (REA; $P < 0.05$) were evident in HIGH calves. No differences ($P > 0.10$) were detected for KPH, marbling score or yield grade between LOW and HIGH calves. A strong ($r > 0.50$) positive relationship between UBF, carcass backfat, and yield grade at d60 and d135 ($P < 0.05$) emerged across grandsires. Final marbling score had a weak positive relationship with UMARB at d0 and d60 ($P < 0.05$), but a strong positive relationship at d135 ($P < 0.05$). HIGH calves had stronger positive relationships between UMARB and final marbling score during both the backgrounding and finishing phases as compared to LOW calves. Though this data set is limited, it indicates that grandsire marbling potential may impact carcass merit through factors other than marbling, and use of ultrasound during the backgrounding phase to predict final carcass merit may be limited and dependent on marbling predisposition.

Key Words: marbling, ultrasound, beef cattle

W315 Growth and carcass merit of purebred Jersey steer calves finished on grain-based diets at two different energy levels. C. J. Mueller*[1,2], G. L. Tschida[1,2], and V. B. Cannon[1], [1]*Oregon State University*, *Corvallis*, [2]*Eastern Oregon Agricultural Research Center*, *Union*.

Twenty purebred Jersey steers were used to evaluate lifetime growth and carcass development while finished on different caloric-dense diets. Steers were grouped by weight (GRP = LIGHT, HEAVY) then randomly assigned to either a 70% (F70) or an 85% (F85) concentrate finishing diet. Data were analyzed as a 2 × 2 factorial design with GRP and finishing diet as main effects. Daily rations were distributed by pen during the growing phase and individually during the finishing phase. Growth data from the growing phase (168 d) were analyzed as LIGHT (77 ± 8 kg) versus HEAVY (97 ± 8 kg) only, since finishing treatments were yet to be applied. Growing phase ADG was not different ($P > 0.10$) between LIGHT (0.89 kg/d) and HEAVY (0.97 kg/d), respectively. LIGHT calves tended ($P < 0.10$) to consumer less feed per day versus HEAVY calves. During the finishing phase ADG for F85 steers (0.91 kg/d) was greater ($P < 0.05$) than F70 steers (0.82 kg/d). Intake was not different ($P > 0.10$) between F70 (7.77 kg) and F85 steers (7.65 kg), whereas G:F was lower ($P < 0.05$) for F70 steers (0.11 kg/kg) compared to F85 steers (0.12 kg/kg). Ultrasonography was used to track carcass changes and showed no differences ($P > 0.10$) in backfat accretion (+4.22 mm vs. +4.20 mm), muscle depth (+13.03 mm vs. +14.57 mm) or marbling score (+166 units vs. +177 units) for F70 and F85 steers, respectively. Ultrasound indicated that changes in muscle depth plateaued around 14 mo of age, while fat deposition continued to increase. Actual carcass data showed no differences ($P > 0.10$) in backfat (0.61 cm vs. 0.58 cm) or KPH (2.48% vs. 2.58%) between F70 and F85 steers, respectively. Ribeye area for F85 steers (23.98 cm^2) was greater ($P < 0.05$) than F70 steers (21.39 cm^2), whereas marbling score tended to be greater ($P < 0.10$) for F85

steers (640, modest) versus F70 steers (590, small). Calculated yield grade (2.97 and 2.77) and retail yield (49.93% and 49.58%) were not different ($P > 0.10$) between F70 and F85 steers, respectively. Jersey steers have the ability to produce highly marbled carcasses, but carcass quality must be valued against low growth efficiency.

Key Words: carcass, growth, Jersey steers

W316 Stocking rate and botanical composition effects on the physical characteristics of the streamside zones of pastures. D. A. Bear*[1], J. R. Russell[1], D. G. Morrical[1], M. Tufekcioglu[1], T. M. Isenhart[1], and J. L. Kovar[2], [1]*Iowa State University*, *Ames,* [2]*USDA-ARS National Laboratory for Agriculture and the Environment*, *Ames, IA*.

Grazing management that allow cattle to congregate near pasture streams may increase sediment, phosphorus, and pathogen loading of the streams by removing vegetation and depositing manure near the streams. To assess stocking rate and pasture characteristics effects on the risk of pollution of pasture streams, forage sward height (SH), bare and manure-covered soil, and forage species were measured within 15.2 m of the stream along each bank at up to 30 locations separated by 30.5 m in 13 pastures on 12 beef cow-calf farms in southern Iowa bimonthly from May through November for 3 yr. Stream bank erosion measurements were collected during spring, summer, and fall seasons by 1.6 × 76.2 cm fiberglass pins inserted perpendicular to the bank at 1 m intervals from the base to the top of each bank at 10 transects located at 32 m intervals along the stream. Cattle stocking records were maintained year-round by farm operators. The REG procedure of SAS analyzed bare and manure-covered ground proportions and erosion by stocking rates. Bare ground was weakly related ($r^2 = 0.15$) to annual stocking rate per stream m (cow-d/m), whereas manure-covered ground was more highly related ($r^2 = 0.35$) to period cow-d/m. In stepwise multiple regressions, forage SH decreased as tall fescue, legumes, bluegrass, and period stocking rate of cow-d/m increased ($r^2 = 0.56$). Proportions of bare soil increased as proportion of reed canarygrass decreased and legumes increased ($r^2 = 0.35$). Proportions of manure-covered ground increased as the cow-d/m per sampling period and the proportions of tall fescue and bluegrass in the vegetation increased, and decreased as proportions of broadleaf weeds and sedge increased ($r^2 = 0.47$). Annual stream bank erosion rates were not correlated ($r^2 = 0.001$) to annual cow-d/m or cow-d/ha. Erosion occurred primarily during the spring season, indicative of the freeze-thaw cycle and hydrological effects. Grazing management that alter temporal/spatial distribution of cattle may decrease nonpoint source pollution risks of pasture streams by maintaining forage SH and decreasing manure deposition within the streamside zones of pastures.

Key Words: hydrology, management, riparian areas

W317 Incidence of bovine Enterovirus, Coronavirus, and group A rotavirus, and concentration of total coliforms in Midwestern pasture streams. D. A. Bear*, Y. I. Cho, J. R. Russell, S. M. Ensley, and K. J. Yoon, *Iowa State University*, *Ames*.

The occurrence of bovine enteric pathogens and total coliform (TC) contamination in streams of 13 Midwestern cow/calf pastures was studied during the 2007-2009 grazing seasons. Water samples (n = 1274) were collected biweekly at upstream (UP) and downstream (DOWN) locations on each stream. Incidence of bovine Enterovirus (BEV), Coronavirus (BCV), and group A Rotavirus (BRV), and concentrations of TC were evaluated. Cattle presence in pastures on the day of sampling, and 2, 3, 4, 5, 6, and 7 d prior were evaluated for association of virus detection and TC. Cattle presence in pastures were analyzed for BEV, BCV, and BRV incidence by the FREQ procedure of SAS, Proc GLM analyzed TC differences by farm and UP and DOWN sites, and Proc REG regressed TC by stocking densities. Mean incidences of BEV, BCV, and BRV in all samples were 3.91, 1.12, and 0.49%, respectively, over the three grazing seasons. There were no differences ($P > 0.10$) for BEV, BCV, and BRV incidences between farms or samples collected from UP or DOWN locations. Incidence of BEV in combined samples were related ($P < 0.05$) to cattle presence in pastures on the day of sampling and 3 and 4 d prior to sampling, and tended ($P < 0.10$) to be related to cattle presence in pastures 2, 5 and 6 d prior to sampling. BCV or BRV incidences were not related ($P > 0.10$) to cattle presence in pastures at any time throughout the grazing seasons. In UP samples, BEV tended ($P < 0.10$) to be related to cattle presence in pastures on the day, and 2 and 4 d prior to sampling. Whereas, in DOWN samples, cattle presence in pastures on the day of sampling only tended ($P < 0.10$) to be related to BEV incidence. Mean TC were 1269 and 1417 colony-forming units (CFU)/100ml, respectively, for UP and DOWN samples. Differences ($P = 0.02$) were observed between farms, but not between sites on farms ($P = 0.31$), for concentrations of TC and were not related to cattle stocking rates of pastures. Preliminary results indicate that while BEV incidence may be related to cattle presence, but BCV and BRV incidences and TC were not related to cattle presence in pastures.

Key Words: enteric viruses, nonpoint source pollution, water quality

W318 Borax and Octabor treatment of stored swine manure: Reduction in hydrogen sulfide emissions and phytotoxicity to agronomic crops. M. Yokoyama*[1], S. Hengemuehle[1], D. Penner[1], J. Michael[1], C. Spence[2], T. Whitehead[2], R. von Bernuth[1], D. Rozeboom[1], and M. Cotta[2], [1]*Michigan State University*, *East Lansing,* [2]*USDA, Agricultural Research Service*, *Peoria, IL*.

Gaseous emissions from stored manure have become environmental and health issues for humans and animals as the livestock industry becomes more specialized and concentrated. Of particular concern is hydrogen sulfide, which is being targeted for regulatory control in concentrated animal farm operations. There are few technologies to control hydrogen sulfide emissions which are cost effective, safe for farmers and animals, and environmentally sustainable. Borax treatment (1%) is effective in reducing hydrogen sulfide emissions from stored swine manure. The objective of this study was to treat stored swine manure with lower amounts to reduce hydrogen sulfide emissions and determine the phytotoxicity of the treated manure as a fertilizer for crops. Ten treatments (0.1, 0.25, 0.5, 1.0% borax and 0.05, 0.1, 0.125, 0.25 and 0.5% Octabor and negative control, 0.0%) were evaluated in plastic carboys (19 L) with swine manure and monitored for hydrogen sulfide emissions for 30 d. 16S and PCR was used to quantify total bacteria and sulfate reducing bacteria. Treated manures were used as fertilizer for growing corn, wheat, soybean, alfalfa and dry beans for 42 d in a greenhouse. Hydrogen sulfide emissions decreased (25-50%) with borax and Octabor treatment and the decrease was dose dependent. Significant interactions ($P \leq 0.05$) between plant injury vs. plant boron content, plant boron content vs dry wt yield, and plant injury vs. dry wt yield was observed. The ranking of crop tolerance to borax and Octabor treated swine manure was: alfalfa, corn, wheat, soybean, dry beans. Borax and Octabor were bioavailable for plants with no soil accumulation. A significant reduction in total bacteria ($P \leq 0.01$) and sulfate reducing bacteria ($P \leq 0.05$) was observed for higher treatments. Borax and Octabor treatment (0.1-0.25%) of stored swine manure was tolerated by crops without injurious effects.
Supported by MAES, CMPM/MCGA, AAI and U.S. Borax, Inc.

Key Words: borax, octabor, swine manure, hydrogen sulfide

W319 Effect of dietary adipic acid and dried distillers grains plus solubles in combination with post-excretion amendment with sodium bisulfite on nitrogen loss from stored laying hen excreta. T. J. Applegate*[1], C. Romero[2], M. E. B. Abdalllh[3], R. Angel[4], and W. Powers[5], [1]*Purdue University*, *W Lafayette, IN,* [2]*Universidad Politecnica de Madrid*, *Madrid, Spain*, [3]*University of Khartoum*, *Khartoum, Sudan*, [4]*University of Maryland*, *College Park,* [5]*Michigan State University*, *E Lansing*.

Effects of dietary adipic acid (AA; 0 or 1%) or dried distillers grains plus solubles (DDGS; 0 or 20%) was determined on laying hen (Hyline W36) performance and egg characteristics from 26 to 34 wk of age (2 × 2 factorial arrangement of diets; 36 cages/diet; 2 hens/cage). All data were analyzed as a factorial experiment utilizing PROC MIXED procedure of SAS. Egg production, feed intake, and egg specific gravity were unaffected by diet. Hens fed diets with 20% DDGS produced 1.4% heavier eggs ($P < 0.02$), but was unaffected by AA. Egg shell percentage was reduced by 2.4 or 1.8% with either dietary AA or DDGS, respectively ($P < 0.02$). To determine the influence of diet and manure amendment on N loss during storage, excreta was collected during 2, 2-d collections by pooling 6 pens/diet (n=6 pools/collection), mixing and dividing into 2 equal portions for 14-d storage experiments with or without 8.8 kg/ 100 m2 of PLT (sodium bisulfite). Initial excreta pH was reduced by 0.2 pH units when hens were fed 1% AA or 20% DDGS ($P < 0.05$). The effect of feeding hens AA on manure pH was maintained for 7 d, but was lost by 14 d of storage; whereas the effect of feeding 20% DDGS on manure pH was maintained for 14 d of storage ($P < 0.01$). These dietary influences on manure pH during storage however were unrelated to N loss. While diet supplementation with adipic acid had no influence on manure N loss during storage, manure from hens fed 20% DDGS lost 32% more N during the first 7 d of storage vs. manure from hens eating no DDGS ($P < 0.02$). Surface amendment of manure with PLT resulted in a 41% reduction in manure N loss during the first 7 d of storage and a 14.7% reduction from 7 to 14 d of storage ($P < 0.05$). In conclusion, manure amendment with PLT resulted in a 26% reduction in N loss during manure storage for 14 d. Conversely, feeding hens diets containing 20% DDGS resulted in a 16.5% greater manure N loss during the same time period.

Key Words: sodium bisulfite, dry distillers grains plus solubles, nitrogen loss

W320 Evaluation of a silvopastoral system with *Alnus acuminata* on pasture productivity, milk production and economic returns in a high tropical ecosystem. A. Conde*[1], R. Hernandez[1], L. L. Betancourt[1], D. A. Castañeda[1], J. A. Umaña[1], T. Carvajal[2], and L. Sanchez[3], [1]*Universidad de La Salle*, *Bogotá, Colombia*, [2]*Universidad UDCA*, *Bogotá, Colombia*, [3]*CORPOICA*, *Bogotá, Colombia*.

The effect of introducing alders *Alnus acuminata* in pastures with a spatial distribution of 10 × 5 m was assessed in terms of on forage yield and quality, milk production and composition and economic efficiency. The study was carried out in a farm located in Usme Colombia (74°06′ W, 4°28′ N), with an elevation of 2650 m.a.s.l, ambient temperature between 6 to 12 °C and mean rainfall of 900 mm/yr. When the study began, the alders were five years old, with an average height of 2.5 m and a mean shade diameter of 3.5 m. A total of 12 Holstein cows in the third year of lactation were distributed randomly into two pasture treatments: T1-trees in the pasture and T2- pasture without trees, in a simple crossover design. All paddocks in the rotation were grazed every 60 d. Dry matter (DM) yield and botanical composition of grazed pastures were estimated using the double sampling and dry weight rank method, respectively. Milk production was recorded daily and fat, protein and lactose were analyzed weekly. The two pastures treatments were composed of *Pennisetum clandestinum* H. (68%), *Holcus lanatus* L. (8%), *Trifolium pratense* L. (6%), and weeds (18%). Forage on offer was higher in pastures with trees (2687 kg DM/ha) than in pastures without trees (1702 kg DM/ha). Forage on offer in the pastures with trees had higher crude protein (14%) than in pastures without trees (11%). There were no differences ($P > 0.05$) in daily milk yield and in milk composition (fat, protein and lactose) due to treatments. However, milk production per ha in pastures with trees (10163 kg/ha/yr) was higher ($P < 0.05$) than in pastures without trees (5081 kg/ha/yr), due to higher carrying capacity (1108 versus 569 kg LW/ha). The investment made on the silvopastoral system with alders was recovered in the fifth year after establishing the trees and the annual rate of return was 55% higher than in the pasture without trees.

Key Words: forage yield, forage quality, stocking rate

W321 Feeding native laying hens diets containing palm kernel meal with or without enzyme supplementations: 2. Manure nitrogen and microbial counts. Adrizal*[1], Yusrizal[1], S. Fakhri[1], Yatno[1], and C. R. Angel[2], [1]*Faculty of Animal Husbandry, University of Jambi*, *Jambi 36361, Jambi, Indonesia*, [2]*Department of Animal and Avian Sciences, University of Maryland*, *College Park*.

The objectives of this study were to evaluate effects of feeding native laying hens diets containing palm kernel meal (PKM) on nitrogen (N) excretion, excreta ammonia (NH_3), and excreta microbial counts. Hens (180, 48 wk old) were assigned to 180 cages (one bird per cage). Each of 12 diets was assigned at random to 15 cages. The 12 diets were the results of a factorial arrangement of 3 levels of PKM (0, 15, and 30%), 2 levels of fiber enzyme (0 and 0.03%), and 2 levels of a phytase-protease mixture (0 and 0.035%). Diets contained 2,753 to 2,758 kcal ME/kg and 17.5 to 18.4% CP and were fed for 10 wk. A 16L:8D lighting program was used. The results showed that at wk 4, excreta DM (but not N), increased as dietary PKM levels increased (19.4 vs. 21.9 vs. 23.0% for 0, 15, and 30% PKM, respectively; $P \leq 0.005$). There were no effects of enzyme supplementation on excreta DM and N. Lower excreta NH_3 due to increased PKM was observed at wk 4 and 10 ($P \leq 0.0001$). Ammonia reduction was also caused by fiber enzyme supplementation at wk 4 (197.9 vs. 161.7 ppm, at 0 and 0.03%, respectively) ($P \leq 0.05$). Interaction effect of fiber enzyme with PKM on NH_3 was observed at 4 and 10 wk ($P \leq 0.005$). Interactions were also observed on NH_3 between the phytase-protease mixture and PKM at 10 wk, between the fiber enzyme and PKM at 4 and 10 wk, and between the phytase-protease mixture and the fiber enzyme at 4 wk. Increasing dietary levels PKM from 0 to 15 to 30% resulted in increased *Lactobacillus* counts (107.8 vs. 106.8 vs. 169.8 $\times 10^8$ cfu, respectively) at wk 4. At 10 wk, dietary PKM levels did not clearly affect *Lactobacillus* counts, but reduced enteric bacteria (4.2 vs. 2.6 vs. 2.8 $\times 10^8$ cfu, respectively) ($P \leq 0.005$). Although enzyme had no clear effect on microbial growth, interaction effects of PKM and fiber enzyme on *Lactobacillus* and enteric bacteria or PKM with phytase-protease mixture on *Lactobacillus* counts were seen. Dietary PKM helped reduce N excretion, NH_3 emission, and favored nonpathogenic microbial growth.

Key Words: palm kernel meal, native laying hen, enzyme supplementation, excreta nitrogen, ammonia, excreta microbial count

W322 Effect of dietary protein concentration on ammonia emission from dairy manure. C. Lee*[1], A. N. Hristov[1], C. Dell[2], G. Feyereisen[3], J. Kaye[1], and D. Beegle[1], [1]*Pennsylvania State University*, *PA,* [2]*USDA-ARS*, *PA,* [3]*USDA-ARS*, *MN*.

The objective of this experiment was to investigate the effect of dietary crude protein concentration on ammonia (NH_3) volatilization from dairy cow manure. Two types of manure were prepared by feeding lactating dairy cows diets with 16% (DM basis; HighCP) or 14% CP (LowCP). The manure was used in 2 experiments. In Exp. 1, 400 g of each manure (1.7:1.0, feces:urine) was placed in sealed steady-state flux chambers connected to a photoacoustic infrared gas analyzer and incubated for 5 d at 25°C to measure the NH_3 emitting potential of manure. Ammonia emission rates were 202 and 132 (mg/h; $P < 0.001$) for HighCP and LowCP manure, respectively. Cumulative NH_3 emission was 45% less ($P < 0.001$) for LowCP compared with HighCP manure. In Exp. 2, LowCP and HighCP manure was applied to 61 × 61 × 61 cm lysimeters collected from a Hagerstown silt loam (fine, mixed, mesic Typic Hapludalf) in a complete randomized design. Manure was applied to each lysimeter immediately after mixing feces and urine (same ratio as in Exp. 1). The manure application rate was 9.3 g of N/lysimeter, corresponding to a field application rate of 300 kg N/ha. The HighCP manure had higher N content (4.4 vs. 2.8%, DM basis) and proportion of ammonium and urea-N in total manure N (51.4 vs. 30.5%) than the LowCP manure. As a result, more LowCP than HighCP manure (2.36 vs. 1.65 kg) was applied to each lysimeter. After manure application, NH_3 emissions were measured using a photoacoustic infrared gas analyzer at 3, 8, 23, 28, 50 and 100 h. Ammonia emission was greater ($P < 0.05$) from HighCP- than from LowCP-manure amended soil. The area under the cumulative (100 h) NH_3 emission curve for LowCP was smaller than the area for HighCP manure (56.8 and 114.8 mg $NH_3/m^2/min \times h$, respectively; $P < 0.05$). In conclusion, manure from dairy cows fed a 14% CP diet had decreased NH_3 emitting potential and resulted in 50% lower NH_3 emission when applied to soil, compared to manure from cows fed a 16% CP diet.

Key Words: dietary protein, ammonia emission, dairy manure

W323 Origin of ammonia nitrogen volatilized from dairy manure. C. Lee* and A. N. Hristov, *Pennsylvania State University*.

The objective of this experiment was to trace the origin of ammonia-N (NH_3-N) volatilized from dairy manure during storage. The experiment was conducted with ^{15}N-labeled or unlabeled feces and urine collected from dairy cows fed a 16% crude protein, 32% NDF diet. Ruminal microbes and consequently feces and urine were labeled with ^{15}N by dosing $^{15}NH_4Cl$ into the rumen. Two types of manure were prepared: FLM, ^{15}N-labeled feces and unlabeled urine; ULM, unlabeled feces and ^{15}N-labeled urine. Feces and urine were mixed in a 1:1 ratio (as-is basis) and incubated for 10 d at room temperature in a closed chamber system (n=4). Volatilized NH_3 was trapped in 0.5M sulfuric acid. The source of NH_3-N was estimated as: ^{15}N-enrichment (atom % excess) of NH_3-N ÷ ^{15}N-enrichment of ^{15}N-labeled urine or feces. Labeled and unlabeled feces or urine had similar N concentration (0.48 ± 0.01 and 1.01 ± 0.02%, respectively), but differed in ^{15}N-enrichment (0.090 vs. 0.005 and 0.133 vs. 0.0007 atom % excess, respectively). Total N, NH_3-N, and urea-N concentrations were similar between FLM and ULM. Cumulative NH_3 emissions were also similar between FLM and ULM (1,371 vs. 1,328 mg, $P = 0.51$). On average, 89% of the manure N lost during the incubation was recovered as ammonium in the acid trap. The proportion of NH_3-N originating from fecal N (FLM) was negligible in the first 48 h of the incubation, represented 0.04 ± 0.006 by d 5, and then gradually increased to 0.11 ± 0.019 of the emitted NH_3-N by d 10 (logistic regression model; adjusted $R^2 = 0.91$, $P < 0.001$). The proportion of NH_3-N originating from urinary N (ULM) represented 0.94 ± 0.027 at 24 h, 0.97 ± 0.002 at 48 h, 0.91 ± 0.004 at 72 h, and gradually decreased to 0.87 ± 0.005 at d 10 (exponential decay model; adjusted $R^2 = 0.92$, $P < 0.001$). This experiment demonstrated that the main source of NH_3-N volatilized from cattle manure during the initial 10 d of storage is urinary N, representing on average 90% of the emitted NH_3-N. The contribution of fecal N was relatively low, but gradually increased to about 10% by d 10, as mineralization of fecal N progressed.

Key Words: nitrogen-15, urine and feces, ammonia

W324 Air velocities in poultry houses raising large broilers. D. G. Overhults[1], A. J. Pescatore*[1], I. Lopes[1], G. Morello[1], J. P. Jacob[1], M. Miller[2], J. Earnest Jr.[1], and R. S. Gates[3], [1]*University of Kentucky*, *Lexington,* [2]*Kentucky Poultry Federation*, *Winchester,* [3]*University of Illiniois*, *Champaign*.

As part of a Kentucky poultry house energy efficiency project, bird level air velocities were measured in tunnel ventilated broiler houses used by three commercial broiler complexes. Although tunnel fans consume a considerable amount of energy, they also can generate significant airflow over the flock, creating a wind chill effect that mitigates heat stress related problems. Air velocities were recorded in 21 houses (9, 5, and 7 from complexes A, B, and C, respectively) raising 2.8-kg broilers. All but one house had a dropped cathedral ceiling. Velocity measurements were taken at four equally spaced locations across the house about 50 cm above the litter and 21 m upstream from the tunnel fans. Velocities were measured with no birds in the houses. Overall velocities averaged 2.50 m/s and ranged from 1.81 to 3.19 m/s. All but one house had velocities greater than 2.0 m/s (400 fpm), with eight houses exceeding 2.5 m/s (500 fpm) and two exceeding 3.0 m/s (600 fpm). In Complex A, the nine 12.2 × 152.4 m houses each had eight 1.22 m diameter exhaust fans with discharge cones. Three of the houses had an additional 1.32 or 1.37 m diameter exhaust fan, again with discharge cones. The additional fan produced higher air velocities in two of the three houses. Four houses (13.1 × 155.4 m) producing for Complex B each had ten 1.22 m diameter exhaust fans. A fifth shorter house (13.1 × 140.2 m) had only nine 1.22 m fans but had the lowest air velocity due to poor performing fans. The seven houses raising for Complex C (12.8 × 128m) all had at least eight exhausts fans of 1.22 m or greater in diameter. The presence of discharge cones, as well as the size and number of fans, did not consistently impact velocities which ranged from 2.05 to 2.82 m/s, with an average of 2.42 m/s for Complex C.

Key Words: air velocity, tunnel ventilation, broilers

W325 Effect of LED lights on growth performance of broiler chicks. R. D. Rierson*, C. M. Rude, M. A. Barrios, and R. S. Beyer, *Kansas State University*, *Manhattan*.

Light emitting diode (LED) light sources are relatively new and potentially beneficial to poultry producers due to lower energy cost. To test the efficacy of LEDs as a light source for growing broilers, the following experiment was completed, utilizing 5 treatments with different light intensities. Light intensities varied from 5 to 25 lx, in increments of 5 lx. There were 4 replications of each treatment, with 20 birds per pen for a total of 400 d old male Cobb 500 broiler chicks. Experiments were carried out in a single building using pens that were 5 × 12 feet in area. Pens were separated using black plastic to keep stray light from interfering with neighboring pens. Chicks were grown on the floor on used litter. The chicks were fed a standard NRC corn soy starter diet and were grown to 21 d of age. The light source for the experiment were white LEDs that were bunched into clusters and hung at 24 inches above the floor litter. Dimmers were installed in each pen to allow ease of adjusting lux intensities. Birds were raised for the first 3 d using incandescent ceiling bulbs, and on d 4 the LED lights were lowered to

treatment intensities and the overhead lights were turned off. The LED lights were left on a 24 h light schedule, but during daylight hours the curtains were occasionally dropped to prevent birds from overheating. All pens were given ad libitum access to feed and water. BWG and feed consumption was collected at 21 d. BWG under 5 to 25 lx was 1472g, 1480g, 1481g, 1536g, and 1541g, respectively, and the differences were not statistically significant when analyzed with the GLM procedure in SAS with an α of 0.05. Feed to gain ratios were not affected. It was observed that birds raised under higher intensities of light exhibited more physical activity than those raised under lower light intensity. No cannibalism was documented. The data concluded that it is possible to raise broilers under as low as 5 lx of light, from LED sources.

W326 Comparison of nutrient and microbial profiles in foaming and non-foaming swine manure pits. J. Rehberger*, E. Davis, A. Veldkamp, T. Parrott, and T. Rehberger, *Danisco*, *Waukesha, WI*.

Swine manure samples were collected from foaming and non-foaming deep pit storage units from three production systems and the nutrient and microbial compositions of these samples were assessed. Manure samples were obtained by sampling the entire depth of the manure storage pit with a 3 m-long PVC sampling rod and classified as having none (less than 2.5 cm of foam on the manure surface, n = 30), low (2.5 to 15.2 cm of foam on the manure surface, n = 25), or high (greater than 15.2 cm of foam on the manure surface, n = 14) levels of foam. Terminal restriction fragment length polymorphism (TRFLP) analysis was performed to assess microbial communities using four restriction enzymes; *Bfa* I, *Hae* III, *Msp* I, and *BstU* I. Manure samples obtained from deep-pit storage systems with a high degree of foaming had greater ($P < 0.05$) concentrations of fiber-bound protein compared to manure samples from non-foaming pits and those with a low degree of foam. Foaming pit samples also had a greater abundance ($P < 0.05$) of *Alphaproteobacteria*, *Betaproteobacteria*, *Deltaproteobacteria*, and *Actinobacteria* compared to non-foaming pit samples. Additionally, liquid and foam phases from three deep-pit swine manure storage systems experiencing foaming were sampled to compare differences in nutrient and microbial compositions between the liquid and foam portions. The concentration of crude fat was greater ($P < 0.05$) in foam samples compared to samples of the liquid portion, as were concentrations of copper, iron, and zinc. The liquid portions had a greater abundance ($P < 0.05$) of *Actinobacteria* and *Alphaproteobacteria* compared to foaming portions, and there was a greater abundance ($P < 0.05$) of *Flexibacter* in the foam as compared to the liquid portions. The divergent microbial communities present in foaming and non-foaming deep-pit swine manure systems coupled with greater fiber-bound nitrogen content in foaming pits suggests that differences in nutrient abundance and subsequent changes in the microbial environment may be factors associated with the foaming phenomenon.

Key Words: manure, pit, foam

W327 The effect of dietary alfalfa silage to corn silage ratios on cow performance and ammonia nitrogen emission. C. Arndt*[1], M. A. Wattiaux[1], and J. M. Powell[2], [1]*University of Wisconsin*, *Madison*, [2]*US Dairy Forage Research Center*, *Madison, WI*.

The objective was to determine the effect of varying alfalfa silage (AS) to corn silage (CS) ratio in a 55:45 forage:concentrate ratio (% DM) total mixed ration on performance of lactating cows and ammonia nitrogen (NH_3-N) emission. Sixteen multiparous Holstein cows (mean ± SD) 77 ± 35 DIM and 640 ± 84 kg of BW were blocked by DIM and randomly assigned to balanced 4 x 4 Latin squares. Cows were housed in modified tie-stall barns with 4 chambers designed to house 4 cows per chamber. Air samples were collected for about 17 h/d, on 3 consecutive days of each period and analyzed for NH_3 with a Photo-acoustic Multi-gas Monitor (Innova Model 1412). Dietary treatments were 20:80 (AS20), 40:60 (AS40), 60:40 (AS60), and 80:20 (AS80). As AS increased, expeller soybean meal substituted for soybean meal to maintain RUP above 6%. Dietary CP content of the diets increased with an increased proportion of AS in the diet and averaged 16.8, 17.2, 17.5, and 18.2% of diet DM for AS20, AS40, AS60, and AS80, respectively. No difference was observed for DMI (26.7 kg/d), milk yield (40.8 kg/d), milk efficiency (milk yield/DMI; 1.53), fat content (3.85%), protein yield (1.20 kg/d) and MUN (16.2 mg/dL). A linear and quadratic response was observed for fat yield which averaged 1.51, 1.59, 1.60 and 1.57 kg/d for AS20, AS40, AS60 and AS80, respectively, with the AS20 diet being lower than the other diets ($P < 0.05$). True milk protein content decreased ($P < 0.05$) from 3.01% in AS20 to 2.96% in AS40 and AS60, and was further reduced to 2.88% in AS80 compared to other treatments. Nitrogen intake increased linearly (701 to 791 g/d) with increasing proportion of AS in the diet whereas milk N decreased linearly (190 to 183g/d). No difference was observed in NH_3-N emission rate among treatments (averaging 0.70 ± 0.16g N/cow/h). Similarly, there was no difference in NH_3-N emission per unit of N intake (0.023 ± 0.006g NH_3-N/g N intake) or per unit of milk N (0.089 ± 0.020g NH_3-N/g milk N). Despite higher N intakes with increasing proportion of AS in the diet, no difference in ammonia emission was observed from cows fed and managed in a tie stall barn.

Key Words: forage, ammonia, emission

W328 Effect of inoculant and molasses on silage fermentation quality, protein fractions, nutritive value and aerobic stability in high dry matter alfalfa. M. Khorvash*[1], F. Hashemzadeh Cigari[1], G.-R. Ghorbani[1], and A. Taghizadeh[2], [1]*Isfahan University of Technology*, *Isfahan, Isfahan, Iran*, [2]*Tabriz University*, *Tabriz, East Azarbayjan, Iran*.

Microbial inoculants, containing lactobacillus plantarum and Propionibacterium acidipropionici (Lalsil) and molasses (0 and 50 g/kg) as a 2 × 2 factorial arrangement were studied on ensiled alfalfa fermentation indices, N fractions (Cornell net carbohydrate and protein system), in vitro degradability and aerobic stability. Forth cut of Alfalfa was wilted to 370 g/kg DM, chopped and ensiled for 90 days. Lalsil decreased pH, NDF, ADF and acetate but increased water soluble carbohydrate (WSC) and lactate: acetate ($P < 0.05$). Molasses addition also decreased pH, lactate: acetate and crude protein, but increased NDF and ADF. Ammonia-N content of the silages were decreased when treated with Lalsil but increased with molasses addition ($P < 0.05$). Lactate, butyrate and propionate were the same between treatments ($P > 0.05$). Inoculation without molasses improved silage fermentation quality more effective than other treatments. Protein fractions evaluation by CNCPS system showed that molasses decreased fraction A in the ensiled forage ($P < 0.05$). Both additives increased fraction B1 content of silages ($P < 0.05$). Fraction B2 was higher in inoculated silages than uninoculated silages ($P < 0.05$). No difference was observed for fraction B3 content among treatments. Fraction C was lower in inoculated silage than uninoculated, but was increased with molasses addition ($P < 0.05$). In vitro 12 h DM degradability assessed with Ankom DaisyII incubator, were highest in silages treated with Lalsil and not added with molasses. However, in vitro 48 h DM degradability were the same among treatments. All the silages treated with additives had better fermentation characteristics and remained more stable than control, after aeration. Silage treated with molasses or inoculant had the lowest rate of mold and yeast growth and pH value was increased rapidly in control but not in treated silages.

In conclusion, molasses and microbial inoculation improved silage fermentation parameters, decreased proteolysis and aerobic stability of high dry matter alfalfa.

Key Words: alfalfa silage, inoculant, CNCPS

W329 The effect of feed management software on whole farm nutrient balance. B. A. Stewart*, B. E. Cox, R. E. James, K. F. Knowlton, M. L. McGilliard, and C. C. Stallings, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Feeding nutrients more closely to a cow's nutrient requirements will reduce excretion of nitrogen and phosphorus by dairy cattle. The impact of improved feeding accuracy on whole farm nutrient balance through the use of feed management software was studied on 18 dairy herds located in Virginia. Nine herds began using the TMR Tracker feed management software in 2006 and were compared to 9 control herds not using feed management software. Each of the treatment herds was visited on a monthly basis. Annual inputs of nitrogen and phosphorus from purchased feed, fertilizer and animals were recorded from 2005 through 2008. Nitrogen and phosphorus exported from the farm as milk, animals, sold manure and feed were recorded. Whole farm nutrient balance was calculated using University of Nebraska software. After 2008, eight treatment herds and four control herds remained. Herd sizes averaged 290 and 325 for treatment and control farms. Milk production averaged 29.4 and 26.1 kg/d per cow respectively. Crop hectares averaged 326 and 284 respectively. Data were analyzed using proc mixed of SAS with repeated years, using 2005 data as a covariate. Measures of surplus (input-output) and ratio (input/output) were analyzed per farm and per cow. Measures on a per farm basis did not differ between treatment and control herds. Annual phosphorus ratios averaged 1.9 ± 0.9 (SD) and annual nitrogen ratios averaged 3.0 ± 1.5 (SD). On a per cow basis, annual phosphorus surplus averaged 16.1 ± 2.6 (SD) kg/yr and annual nitrogen surplus averaged 138.4 ± 12.7 (SD) kg/yr. Due to the large variation observed the use of feed management software did not have an effect on whole farm nutrient balance.

Key Words: whole farm nutrient balance, phosphorus, nitrogen

W330 Determining water usage on dairies. J. C. Potts*, B. J. Bradford, J. F. Smith, and M. J. Brouk, *Kansas State*, *Manhattan*.

A meta-analysis was performed on 65 studies that recorded water intake by dairy cattle. The meta-analysis was utilized to develop a prediction equation for water intake in lactating dairy cattle. Studies were selected based on quantitative measurements of DMI, water intake (WI), and milk yield. Published papers were selected throughout the world but they mainly came from the *Journal of Dairy Science*. Many of the studies used more than one parameter to determine WI values leading to 137 data points from the 65 studies. With the addition of Na in the meta-analysis, 41 data points were available from the studies to examine the effects of Na on WI. The effects of DMI, diet DM%, dietary Na, and levels of milk production on WI were evaluated. Including data from cows with higher levels of milk production (>30kg/d) improved the correlation (R^2 0.725) between WI and milk production. The meta-analysis results were then compared to on-farm measurements. Fresh water and waste water data from 11 freestall (FS) and 12 dry lot (DL) Kansas dairies were collected over a 9-year period (2000-2008). Fresh water usage was recorded from water pumping records. Data were first summarized annually by operation and then converted to a per cow per day basis prior to analysis. Data were then analyzed by using the proc mixed procedures of SAS. Fixed effects included in the model were dairy type (FS or DL) and year was considered a random effect. The DL dairies averaged 186 L/cow/day and were lower ($P < 0.05$) than the FS dairies which averaged 237 L/cow/day. Differences between DL and FS dairies may have been due to differences in waste management or cow cooling systems. Estimated drinking water accounted for 70% of the total water usage on DL dairies and 55% on FS dairies. Based on this data facility type may influence total water usage in dairy facilities.

Key Words: water intake, facilities, meta-analysis

W331 Dietary CP and tannin extracts impact ammonia emissions from manure deposited on dairy barn floors. J. M. Powell[1], M. J. Aguerre*[2], and M. A. Wattiaux[2], [1]*US Dairy Forage Research Center*, *Madison, WI*, [2]*University of Wisconsin*, *Madison*.

The impact of dietary CP and Quebracho-Chestnut tannin extracts on dairy cow performance and N partitioning are reported elsewhere at this meeting. Mixtures of feces/urine from these studies were applied to lab-scale ventilated chambers to measure ammonia-N emissions (ANE) from simulated concrete barn floors. Feces and urine were collected separately from lactating Holstein cows fed 2 levels of dietary CP (%DM): low protein, LP=15.5 and high protein, HP=16.8; each at 4 levels (%DM) of dietary tannin: T1=0, T2=0.45, T3=0.90 and T4=1.80. Feces and urine having a total weight of 16g were mixed in their excreted mass ratios (g/g) and applied to chambers. ANE were measured 1, 3, 6, 12, 24, 36 and 48h after application. Although patterns of ANE were similar over time, the 48h cumulative ANE (CANE, mg) was lower (P<0.05) for manure from the LP diets (12.1) than from the HP diets (24.7). As a percent of total N (%TN) and urinary N (%UN) applied, losses from the LP diets (16.9 and 46.2) were lower than from the HP diets (27.7 and 56.3). Tannins impacted CANE, %TN and %UN for both the LP and HP diets. For the LP diets, the non-tannin ration (T1) had CANE, %TN and %UN of 14.6, 19.6 and 48.0, respectively vs. 11.2, 16.1 and 45.7, respectively for the tannin-containing rations (average of T2, T3 and T4). Results were similar for the HP diets, except for %UN. Average CANE and %TN for manure from the HP non-tannin ration were 27.5 and 29.1, respectively vs. 23.7 and 27.2 for the HP tannin-containing rations. %UN was lower however for manure from the HP non-tannin ration (52.4) compared to the HP tannin-containing rations (57.5). These differences were likely due to overall higher excretions of urinary N by cows fed HP diets, and therefore higher amounts of urine N applied. For the LP diets, lowest CANE, %TN and %UN occurred at T2 and T4. For the HP diets, lowest CANE, %TN also occurred at T2 and T4, but %UN was lowest at T1 and T2 due to reasons mentioned above. The addition of tannin extracts to dairy rations can reduce ammonia emissions from dairy barns, but relative reductions depend on the amount of CP fed and therefore urinary N excretion.

Key Words: tannins, CP, ammonia emissions

W332 Emissions from a dairy waste management system in south-central Idaho. M. E. de Haro Martí*[1], R. E. Sheffield[2], and M. Chahine[3], [1]*University of Idaho*, *Gooding*, [2]*Louisiana State University*, *Baton Rouge*, [3]*University of Idaho*, *Twin Falls*.

This study evaluated the concentrations and emission rates of ammonia and hydrogen sulfide from a wastewater storage pond, manure processing area, and composting area from a 5,000 cow freestall scrape dairy located in south-central Idaho over a six months period. Pollutant concentrations were measured using an Ultraviolet Differential Optical Absorbance Spectrometer and emission rates were calculated using backward Lagrangian modeling via the WindTrax model. Measurements were collected continuously at a final 15-minute integration time. Average summertime concentrations adjacent to a 9.8-ha wastewater

storage pond were found to be 556.3 ppb for ammonia and 33.4 ppb for hydrogen sulfide, with emission rates averaging 28.5 μg/m^2/s and 4.3 μg/m^2/s, respectively. During the cold period, concentrations were found to average 366.3 ppb for ammonia and 310 ppb for hydrogen sulfide, with emission rates averaging 18.4 μg/m^2/s and 41.5 μg/m^2/s, respectively. Average concentrations downwind of a 13.3 hectare composting area during the warm period were found to be 472.2 ppb for ammonia and 83.1 ppb for hydrogen sulfide, with average emission rates of 33.4 μg/m^2/s and 15.9 μg/m^2/s, respectively. During the cold season, average downwind concentrations were 270.7 ppb for ammonia and 461.7 ppb for hydrogen sulfide, and emission rates averaged 17.3 μg/m^2/s and 81.6 μg/m^2/s, respectively. Significant seasonal variability in both concentrations and emission rates of all pollutants were observed between warm and cold periods.

Key Words: ammonia, hydrogen sulfide, emissions

W333 Nutritive value and silage conservation of mango industrial by products as animal feed in ruminants. A. Conde*[3,1], A. P. Sandoval[2], M. C. Cueto[1], N. M. Rojas[3], and L. M. Arevalo[4], [1]*Universidad de la Sabana*, *Bogotá, Colombia*, [2]*Corpoica*, *Nataima, Colombia*, [3]*Universidad de La Salle*, *Bogotá, Colombia*, [4]*Universidad UDCA*, *Bogotá, Colombia*.

Mango by-products were evaluated in order to define its potential as animal feed in ruminants. Seed and peels from Tommy Atkins and Keitt varieties in different days of industrial process were collected in Frutol Ltda, a fruit industrial company, located in Espinal - Tolima Colombia and analyzed in terms of chemical composition (dry matter DM, crude protein and its fractions A, B1, B2, B3 and C, residual insoluble ethanol RIE, NDF, ADF, lignin, structural carbohydrates: B2 and C, non structural carbohydrates (NSC): A and B, extract ether, ash and gross energy) and ruminal degradation kinetics with the methodology and model proposed by Orskov and McDonald. Tannins and saponins as antinutritive factors were analyzed. The effects of mango by-products as a feed supplement in dairy cows were simulated using the net carbohydrate and protein model, CNCPS. Different silage conservation conditions were evaluated in order to establish the best fermentation process. Peels showed better nutritional quality than seeds due to NSC, in special sugar fraction. Tommy Atkins variety had higher contents of DM, NSC and lower contents of NDF and lignin than Keitt. Higher degradability was found in peels 94%, 99% than in seeds 40%, 54% in Keitt and Tommy, respectively, when Orskov model parameters were estimated. Tannins and saponins were not detected. The principal problem in silage conservation was the low content of DM in mango agro-industrial by-products which was overcome with the 15% inclusion of rice meal before fermentation process. Simulations in the mechanistic CNCPS model predict that mango peels could be a good supplement in dairy cows because its metabolizable energy supply.

Key Words: carbohydrate fractions, mango by-products, silage conservation

W334 The ability of essential oils to inhibit *Salmonella* growth. K. S. Macklin*, J. T. Krehling, Z. T. Williams, and M. A. Bailey, *Auburn University*, *Auburn, AL*.

Salmonella is one of the leading causes of bacterial origin food borne illness in the US. This genus of bacteria is often associated with poultry and the ability to limit or eliminate it is of importance to the consumer as well as to the poultry industry. Historically antibiotics have been added to poultry feed to improve gut health and bird weight gain. Typically antibiotics are not added to control *Salmonella*. Regardless, there is growing sentiment by consumer and government groups to prohibit the use of antibiotics in animal agriculture. This has prompted the need to find a viable alternative to antibiotics; one such alternative is essential oils (EO). EO have been shown to inhibit bacterial growth in vitro and alter the intestinal microbial profile in vivo. In this trial, 13 different subspecies of *Salmonella* were tested against 11 essential oils and 3 antibiotics in a disc diffusion test. The tested EO consisted of red thyme, white thyme, tea tree, black pepper, tarragon, clove bud, Spanish sage, lemongrass, Comoric basil, cinnamon bark and cinnamon leaf. Antibiotics tested included penicillin G at 2 and 10 units, tetracycline at 30ug and chloramphenicol 30ug. EO discs were created by adding 5 ug of each oil onto a 6mm sterile disc and allowed to dry. Trypticase soy agar with 5% sheep blood plates were spread plated with each *Salmonella*. EO impregnated discs were than placed onto each agar plate (4/plate). Plates were then incubated aerobically at 37C for 24 hours. At that time the zone of growth inhibition (if any) for each disc was determined. In this trial, *Salmonella* isolates were considered susceptible if the zone of inhibition was greater then 15mm in diameter, anything less than is considered resistant. All of the essential oils and antibiotics were tested in triplicate against each *Salmonella* isolate. Among the EO tested, the three that *Salmonella* was most susceptible to were cinnamon bark, red thyme and white thyme oils. *Salmonella* isolates were resistant to tea tree, black pepper, tarragon, sage, and Comoric basil oils. The remaining four EO showed variable activity against the different subspecies of *Salmonella* tested.

Key Words: *Salmonella*, essential oils, disc diffusion

W335 Prediction of pregnancy by increased physical activity measured prior to timed insemination. A. H. Sanders*, A. De Vries, and J. Block, *University of Florida*, *Gainesville*.

This study considered activity increases close to timed-AI (TAI) following Ovsynch as predictors of pregnancy. Identifying cows with a greater probability of pregnancy could improve TAI efficiency through select use of semen. Data were 632 breeding records and activity recorded at twice daily milkings as average steps/hr by S.A.E. Afikim pedometers. The percent deviation of activity from the previous 10d rolling average of the same (a.m. or p.m.) milking session was calculated for the day before and day of TAI (4 milkings). At 32d after TAI, pregnancy was diagnosed by ultrasound. Overall, 45% of cows were pregnant. Logistic regression was used to evaluate the effect of activity deviations (AD) on probability of pregnancy (P32). When AD was modeled as a continuous effect, the AD from the first milking on the day of TAI (TAI-AM), and the second milking the previous day (PRE-PM) were significant predictors of P32 but model fit for PRE-PM was poor. For TAI-AM, 5 thresholds for AD were considered for dichotomizing activity signals. Zero, mean AD and mean plus SD (56.8% and 128.7% increase in AD) were 3 thresholds. ROC analysis was used to estimate an optimized threshold. Model fit for ROC was improved by ignoring AD <19.5%, which is the SD of a normal distribution with $\mu=0$ and lower half defined by recorded AD <0 (i.e baseline or non-estrus AD). The resulting optimal threshold was at 84.2% increase in AD (AUC=0.62). Finally, SD_{base} (19.5% increase in AD) was also considered as a threshold. For TAI-AM, the adjusted OR for P32 was significant when the mean AD or those thresholds greater than the mean were applied to AD, but OR was maximized (2.28) with the ROC determined threshold. The binomial probability for P32 was 39% (CI = 35-44%) for cows with AD below this threshold (n=465) and 60% (CI = 52-57%) for cows with AD above this threshold (n=167). For PRE-PM, adjusted OR for P32 was also maximized (1.55) with 84.2% threshold for AP, but fit was poor and CI for binomial probabilities overlap at all thresholds considered. With twice daily milking, AD for the milking interval prior to TAI is a useful indicator of probability of pregnancy.

Key Words: activity, pregnancy diagnosis, pedometer

W336 The influence of lipidic sources on the cholesterol plasma levels of beef heifers. M. C. A. Santana*[1], T. T. Berchielli[1], R. A. Reis[1], G. M. P. Melo[2], and P. H. M. Dian[2], [1]*São Paulo State University*, *Jaboticabal, São Paulo, Brazil*, [2]*Camilo Castelo Branco University*, *Descalvado, São Paulo, Brazil*.

This research aims to evaluate cholesterol responses under different lipid sources and supplementation frequencies. This research was conducted throughout a 4-mo period during the dry season. The experiment was completely random, using a 3 × 2 factorial arrangement (3 supplements and 2 supplementation frequencies). The supplements were derived from 3 different sources, soybean grains, soybean oil and protected fat (Megalac-E), the 2 supplement frequencies were (A) Monday, Wednesday and Friday and (D) daily. In the 4-mo experimental period, August–November, blood samples were taken from the jugular vein after the morning feeding. Subsequently, these samples were centrifuged and stored until the cholesterol blood level was evaluated. In all treatments, no cholesterol differences were observed in August and November ($P > 0.05$). The animals that were given soybean oil supplements Monday, Wednesday and Friday showed lower cholesterol plasma concentration values ($P < 0.05$) in September. The Megalac–E that was supplied daily presented a higher cholesterol level in comparison to the daily supplement of soybean grain in October ($P < 0.05$). Overall, this data indicated that the cholesterol blood level can be influenced according to the feeding strategy during the dry season.

Table 1. Cholesterol plasma levels of heifers supplemented with different lipid sources at two different frequencies

	D–SG	A–SG	D–SO	A–SO	D–ML	A–ML
August	194^{Aab}	181^{Aa}	224^{Aab}	222^{Aa}	221^{Aab}	245^{Aa}
September	250^{ABa}	220^{ABa}	296^{Aa}	210^{Ba}	292^{Aa}	280^{Aa}
October	171^{Bb}	197^{ABa}	199^{ABb}	193^{ABa}	257^{Aab}	214^{ABab}
November	161^{Ab}	168^{Aa}	163^{Ab}	164^{Aa}	185^{Ab}	$169A^{Ab}$

Lowercase in columns and capital letters in rows differ ($P < 0.05$).

D = daily; A = alternately; SG = Soybean; SO = Soy oil, and ML = Megalac-E .

Key Words: soybean grain, soybean oil, protected fat

W337 Substitution of soybean meal by inactive dry yeast in diets of beef cattle: nutrient intake and productive performance. A. F. Campos[1], O. G. Pereira*[1], S. C. Valadares Filho[1], K. G. Ribeiro[2], and L. O. Rosa[1], [1]*Federal University of Vicosa*, *Viçosa, Minas Gerais, Brazil*, [2]*Federal University of Jequitinhonha and Mucuri Valleys*, *Diamantina, Minas Gerais, Brazil*.

The objective of this study was to evaluate the nutrient intakes and productive performance of Nellore cattle fed diets containing different levels of inactive dry yeast (0, 25, 50, 75 and 100%, DM basis) in substitution of soybean meal. Diets consisted of 60% corn silage and 40% concentrate (DM basis), formulated to be isonitrogenous (12% CP, DM basis). Thirty-five Nellore steers non-castrated, with initial live weight of 350 kg were allotted in a randomized blocks design with seven replicates. The animals were kept in individual pens of approximately 10 m2, with protected feeders and waterier. The experiment lasted 84 days, divided in three periods of 28 days after 15 days of adaptation. There was a negative linear effect ($P < 0.05$) of yeast levels on dry matter and crude protein intakes, kg/d, while DMI as percentage of the BW had a quadratic effect with maximum intake of 1.81% BW at 26.98% of yeast level. Quadratic effects ($P < 0.01$) of yeast levels were observed on NDF intake, with maximum intakes of 4.36 kg/d and 0.82% BW at 36.19 and 39.37% of yeast, respectively. The ADG decreased linearly ($P < 0.05$) as yeast levels increased in diets. However, no effects of yeast levels ($P > 0.05$) were observed on ether extract intake, dressing percentage, carcass daily gain and feed conversion, which were, on average 0.215 kg/d, 56.3%, 0.90 kg/d, and 7.57, respectively. Our results suggest that soybean meal might be replaced by inactive dry yeast until 30% of concentrate. However, the utilization of this co-product depends of economic factors.

Financial support by CNPq and FAPEMIG.

Key Words: average daily gain, crude protein, carcass dressing

W338 Changes on growth performance and ruminal variables of finishing Dorper × Pelibuey lambs fed a sorghum grain diet plus an exogenous phytase. G. Buendía-Rodríguez[1], S. S. González–Muñoz*[2], R. Basurto-Gutiérrez[1], M. M. Crosby-Galván[1], L. A. Adame-López[1], and L. J. Montiel-Olguín[1], [1]*CENIDFyMA INIFAP*, *Ajuchitlán, Querétaro, México*, [2]*Colegio de Postgraduados*, *Montecillo, Edo. de México, México*.

The objective of this study was to evaluate the effect of an exogenous phytase (FINASE, AB Enzymes, from *Trichoderma reesei*; 40,000 FTU/g) on lambs fed a 70% ground sorghum grain diet. Thirty-six Dorper × Pelibuey lambs (24.09±2.95 kg BW) were fed the sorghum diet plus 0, 12.5, 25.0 and 37.5 g phytase/t diet, during 75 days. The experimental design was completely randomized, with four treatments and nine replications per treatment. Data collected over time was analyzed as repeated measurements using the MIXED option of SAS, and means were compared with the Tukey test. Variables were average daily gain (ADG), dry matter intake (DMI), feed conversion (FC), concentration of bacteria and volatile fatty acids (VFA) in the rumen, plus phosphorus fecal excretion (PFE). Phytase did not change ($P \geq 0.05$) ADG (199, 228, 232, 206 g/d), DMI (1068, 1127, 1126, 1212 g/d), FC (5.59, 5.01, 4.89, 6.40), or ruminal bacteria concentration (2.91, 3.15, 3.00, 3.06; 10^{10}/mL). However, phytase addition increased ($P \leq 0.05$) propionate concentration in the rumen (23.40^{c}, 24.68^{bc}, 31.37^{a}, 30.43^{ab} m*M*) and PFE (1.10^{b}, 1.18^{ab}, 1.37^{a}, 1.21^{ab} g/d). Therefore, it may be concluded that propionate ruminal concentration as well as phosphorus fecal excretion were affected when an exogenous phytase was added to a 70% sorghum grain diet, fed to finishing Dorper × Pelibuey lambs.

Key Words: phytase, finishing lambs, growth and ruminal variables

W339 Thawed semen quality of beef bulls supplemented with calcium soaps of polyunsaturated fatty acid. H. O. Patino*, M. M. H. Ramirez, R. M. Gregory, and D.d. Ré, *Universidade Federal de Rio Grande do Sul*, *Porto Alegre, RS, Brazil*.

Twenty Hereford, Angus, Brangus and Braford mature bulls (950 kg average body weight) were used in a completely randomized design to evaluate the effect of supplementation with calcium soaps of polyunsaturated fatty acids (CSPUFA) on the semen quality undergone the cryopreservation process and subsequent thawing. Bulls were fed diets with similar levels of crude protein and metabolizable energy consisting of green forage and concentrate supplemented with CSPUFA or energy supplement (ES). For 75 days bulls in the CSPUFA treatment received Megalac-E (200 g/day) and bulls in the ES treatment received Cassava

meal (750 g/day). Bulls were naturally stimulated by cows and semen samples were collected with an artificial vagina every 15 days. Then collected semen was evaluated, diluted and frozen in 0.5 mL straws for later thawing. Assessments of sperm motility, hypo osmotic swelling test (HO), heat resistance test (TTR) and staining with Trypan blue were performed to evaluate the quality of thawed semen. The type of supplement did not affect HO (53.7%) and TTR (27.8%) after freezing. Thawed semen of bulls supplemented with CSPUFA had a 22% increasing in sperm motility (37.5 vs. 30.5%; $P = 0.10$), percentage of spermatozoa with normal acrosome (48.0 vs. 39.2%; $P < 0.05$) and number of live spermatozoa (51.5 vs. 42.2%; $P < 0.05$) in relationship to thawed semen of bulls supplemented with cassava meal. Energy supplementation in the form of calcium soaps of polyunsaturated fatty acids may increase the resistance to the processes of sperm cryopreservation and subsequent thawing, increasing the sperm motility, percentage of live spermatozoa and percentage of spermatozoa with normal acrosome

Key Words: bypass fat, thawed semen, cassava meal

W340 Effects of non-protein nitrogen in diets containing 15% wet distillers grains with solubles and steam-flaked corn on feedlot cattle performance and carcass characteristics. C. H. Ponce*[1], M. S. Brown[1], N. A. Cole[2], C. L. Maxwell[1], J. O. Wallace[1], and B. Coufal[1], [1]*Feedlot Research Group, Department of Agricultural Sciences, West Texas A&M University*, *Canyon,* [2]*USDA ARS Conservation and Production Research Laboratory*, *Bushland, TX*.

Our previous data suggest that the non-protein nitrogen (NPN) need in diets with 15% wet distillers grains with solubles (WDGS) for optimum growth performance may be slightly less than in 0% WDGS diets. The objective of the present study was to more clearly define the NPN need in diets with 15% WDGS. Steer calves (n = 296; initial BW = 344 kg) previously grown for approximately 75 d were adapted to a common finishing diet, blocked by BW, and assigned to 36 soil-surfaced pens (18 m^2 of pen space and 33 cm of bunk space/animal). Treatments included a control diet without WDGS (contained 3% NPN from urea, and cottonseed meal) and 15% WDGS with either 1.5, 2.25, or 3.0% NPN (0.52, 0.78, and 1.04% urea, respectively). Steers were implanted on d 1 with Revalor-XS and were fed twice daily for 165 d. The WDGS was obtained 3 times/wk from a local plant, and grain composition of WDGS averaged 22% sorghum and 78% corn. Overall DMI was 6.1% higher ($P = 0.001$) for steers receiving WDGS than for the control. Similarly, steers fed WDGS had 8% greater ADG ($P < 0.008$) on either a live or a carcass-adjusted basis than the control. However, overall gain efficiency on either a live or adjusted basis was not different among treatments ($P > 0.15$). Dietary NPN concentration did not influence growth performance ($P > 0.21$). Hot carcass weight was 10.9 kg lighter for the control than for 15% WDGS ($P = 0.01$), whereas dressing percentage tended ($P = 0.12$) to increase in a linear manner as NPN increased in diets with WDGS. Remaining measured carcass characteristics were not altered by treatment ($P > 0.16$). The control group tended to have ($P < 0.12$) fewer average Choice and higher and more low Choice carcasses than those fed WDGS, but the distribution of remaining quality and yield grades did not differ among treatments. Data suggest that growth performance may not be improved by including more than 1.5% added NPN in diets with 15% WDGS derived from a blend of corn and sorghum grains.

Key Words: wet corn distillers grains, growth performance, beef cattle

W341 Effects of nutrient restriction and ruminally undegradable protein supplementation during early to mid-gestation on beef cow offspring intestinal growth. A. M. Meyer*[1], P. Moriel[2], W. J. Means[2], M. Du[2], B. W. Hess[2], and J. S. Caton[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University*, *Fargo*, [2]*Department of Animal Science, University of Wyoming*, *Laramie*.

Thirty-six Angus × Gelbvieh cows were blocked by parity and randomly allocated by BW to 1 of 3 dietary treatments from d 45 to 185 of gestation: a hay-based control (CON) diet formulated to meet NRC requirements for mid-gestation; a nutrient restricted (NR) diet providing 70% of CON NE_m; or an NR diet fed with a ruminally undegradable protein supplement (NRP) formulated to provide similar essential AA flow to the duodenum as CON. After concluding the dietary treatment period, cows were managed as a single group through calving and weaning. Calves were placed in the feedlot by sex and maternal dietary treatment, and managed similarly during the growing and finishing phases. Steers and heifers were slaughtered at 448 ± 1.0 (mean ± SE) and 466 ± 1.1 d of age, respectively. Detailed necropsies of the small intestine were performed and jejunal samples were collected. Data were analyzed using slaughter group as a block. Slaughter weight (552.4 ± 10.2 kg) did not differ ($P = 0.76$) among maternal treatments. Ileal mass (g) tended to be greater ($P = 0.12$) and proportional mass (g/kg BW) was greater (1.55 vs. 1.26 ± 0.09 g/kg BW; $P = 0.02$) for offspring of CON cows than NR, although liver, duodenal, jejunal, and total small intestinal mass did not differ ($P \geq 0.38$) among treatments. Offspring born to NR cows had greater ($P < 0.05$) jejunal length than CON and NRP, whereas NR had shorter ($P = 0.03$) ileal length compared with CON. Total small intestinal length was greater ($P = 0.02$) for offspring from NR cows than NRP (3,754 vs. 3,448 ± 92 cm). Per unit of BW, ileal length was less ($P < 0.09$) in NR compared with CON and NRP. There were no differences ($P \geq 0.20$) in small intestinal density (g/cm tissue) due to treatment. Additionally, offspring jejunal DNA, RNA, and protein concentration (mg/g tissue) and content (total g) did not differ ($P \geq 0.74$) among maternal treatments. In this study, maternal nutrition of beef cows during early to mid-gestation affected small intestinal length, but not mass, of market-weight offspring.

Key Words: developmental programming, intestine, ruminally undegradable protein

W342 Time of collection affects starch losses in Nellore and crossbred cattle in commercial feedlots. M. Caetano*[1], A. J. C. Nuñez[2], G. B. Mourão[1], and D. P. D. Lanna[1], [1]*University of Sao Paulo, ESALQ*, *Piracicaba, Brazil*, [2]*University of Sao Paulo, FZEA*, *Pirassununga, Brazil*.

Grain sources, grain processing and different feed formulations have been extensively studied in order to improve the efficiency of starch utilization and animal performance. Starch digestion is closely and directly related to fecal starch content (FS%), however we have observed large variations in FS% through a 24-h period in experimental animals. The objective of this study was to determine the magnitude and variability of starch losses in commercial feedlots, as well as the influence of collection period, diet starch content, grain particle size after grinding, genetic group and starch source (corn or sorghum) on pH and FS%. Samples (n=935) were collected on 9 commercial feedlots, with 13 different diets using ground corn or sorghum as starch sources. Diets contained between 40 and 88% concentrate and starch contents between 14.6 and 45.9% in the dry matter (DM). Animals were classified as Nellore or European crossbreds. Morning collections were taken between 0700 and 1200 h and afternoon collections between 1300 and 1800 h. Diets and feces were immediately put on ice and analyzed for DM, ash and starch. Diets were also analyzed for particle size while feces were analyzed for

pH. The average values for FS% were 9.8±7.50% and the range was 0.1% to 41.6% in the DM. There was a difference ($P \leq 0.05$) between FS% for samples collected in the morning or afternoon for both Nellore and crossbred (7.5% and 6.6% in the morning vs. 2.2% and 4.7% in the afternoon, respectively). There was an interaction between genetic group and period of collection ($P \leq 0.01$), however there was no difference in FS% between diets with corn or sorghum ($P \geq 0.29$). There was a linear and quadratic increase ($P \leq 0.06$) in FS% as starch content of the diet increased and no effect of particle size in FS% for both sources ($P \geq 0.21$). Fecal pH was higher for corn than for sorghum (6.55 vs. 6.04; $P \leq 0.01$), and there was a negative correlation between FS% and fecal pH ($r = -0.57$ for corn and $r = -0.51$ for sorghum; $P \leq 0.01$). In conclusion, FS% differs depending on time of sample collection, demonstrating the importance of standardization of sampling procedures.

Key Words: beef cattle, corn, sorghum

W343 Parenteral supplementation of cross bred Brahman steers with copper and zinc in the western plains of Venezuela. R. E. Mora*[1], A. M. Herrera[1], D. L. Sánchez[1], C. F. Chicco[2], and S. Godoy[2], [1]*Universidad Nacional Experimental del Táchira*, *Venezuela*, [2]*Universidad Central de Venezuela*.

To evaluate parenteral Cu and Zn supplementation on daily body gain (DBG), body measurements (BM) and blood chemistry of cattle, an experiment was carried out in the western plains of Venezuela, with 60 cross bred Brahman steers with an average BW of 201.6±20 kg. The animals were uniformly divided in four groups and assigned to four treatments: 1) oral mineral supplementation (OMS); 2) OMS with injected Cu (OMS-Cu); 3) OMS with injected Zn (OMS-Zn); and 4) OMS with injected Cu and Zn (OMS-Cu-Zn). Fifty mg of Cu and 80.2 mg of Zn/100 kg were injected subcutaneously every 73 and 28 days, respectively. The experiment lasted 129 days. The animals were kept under grazing conditions, in pastures of *Brachiaria arrecta* and *B. mutica* with a stocking rate of 0.9 animal/ha. In addition animals had access to a complete mineral mix and to a broiler litter, molasses and urea supplement (800 g/d) with 23.2% PC. Body weight changes were measured every 28 days. At the same time blood and forage samples were taken for chemical analyses. Changes in heart girth (HG) and wither height (WH) were measured at the beginning and at the end of the experiment. Data were analyzed by ANOVA in a complete randomize design using a 2 × 2 factorial arrangement. Forage contained 4.0 ± 1.4% CP; 77.8 ± 2.7% NDF; 5.6 ± 2.5 ppm Cu and 22.5 ± 6.2ppm Zn. Poultry litter supplement had 71.5 ppm Cu and 328.8 ppm Zn. No differences were found among treatments for DBG, with an average of 363.1±273.8 g/d, showing ($P < 0.05$) an interaction time × Cu, with greater gains of supplemented animals in the transition dry-wet season (552.6 ± 201 vs. 487.4 ± 131.1 g/d), and lower in the wet season, when compared with the unsupplemented animals (535.9 ± 263.9 vs. 632.1 ± 191.6 g/d). No differences in BM and blood chemistry were found. It is concluded that under the conditions of the experiment, subcutaneous Cu and Zn supplementation had no effect on animal performance and blood chemistry.

Key Words: parenteral supplementation, daily gain, body measurements

W344 Effect of wheat distillers dried grains with solubles (DDGS) as a replacement for barley grain and barley silage on ruminal pH and fermentation in finishing beef cattle. Y. L. Li*[1,2], W. Z. Yang[1], M. L. He[1], T. A. McAllister[1], and K. A. Beauchemin[1], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

A study was conducted to evaluate whether wheat DDGS can partially, or entirely, replace grain and forage in a finishing diet fed to growing beef cattle without increasing the risk of ruminal acidosis. Eight ruminally fistulated Angus heifers were assigned to a replicated 4×4 Latin square design with 4 treatments: control, low (25%), med (30%) and high (35%) DDGS (% of dietary DM). The diets consisted of barley silage, barley concentrate, and wheat DDGS in ratios of 15:85:0, 10:65:25, 5:65:30 and 0:65:35 (DM basis), respectively. Heifers were fed once daily for ad libitum intake. Ruminal pH was monitored continuously for 5 d each period using a wireless system (LRCpH). Mean ruminal pH linearly ($P < 0.01$) decreased from 5.94, 5.88, 5.70, to 5.75 as DDGS was substituted for barley silage. Duration of which pH<5.8 was longer for med (14 h) and high (13 h) DDGS diets than for control (10 h) and low DDGS (10 h) diets. Total VFA concentration (m*M*) quadratically increased ($P = 0.04$) and was the highest for med DDGS (149) and lowest for control (135) and high DDGS (135) diets. Molar proportion of acetate linearly ($P < 0.01$) decreased, whereas that of propionate tended to linearly ($P = 0.06$) increase with the increase of DDGS and decrease of silage, so that the fermentation changed to a more glucogenic pattern. Concentration of NH_3-N tended to ($P = 0.07$) be higher for DDGS diets (averaged 10.6 m*M*) than for the control diet (6.5 m*M*). The results indicate that replacing barley grain and silage with wheat DDGS in finishing diets may improve feed efficiency and growth rate due to a more glucogenic fermentation. However, animals may experience more rumen acidosis, suggesting that fiber from wheat DDGS was not physically effective.

Key Words: wheat DDGS, ruminal fermentation, beef cattle

W345 Effect of levels of canola meal supplementation on intake and apparent digestibility in wethers. F. Hentz*, G. V. Kozloski, T. Orlandi, G. F. E. Pacheco, S. C. de Àvila, and P. S. Castagnino, *Universidade Federal de Santa Maria*, *Santa Maria, RS, Brasil*.

The effect of increasing levels of supplementation of meal from biodiesel production canola (44.4% CP and 29.5% NDF; DM basis) on intake and apparent digestibility by wethers was evaluated. Eight Texel wethers were used in a replicated 4x4 Latin square design with 15-d periods (10-d adaptation, 5-d collection). Wethers were housed in metabolism cages and fed a basal diet consisting of sudangrass ad libitum (10% refusals). Treatments were sudangrass only (control), or supplemented with 5, 10 or 15 g/kg BW of canola supplement (90% canola meal, 10% finely ground corn), offered twice daily at 0800 and 1700 h. Feed, orts and fecal output were recorded daily on day 10 to 15 and samples collected and composited within animal and period. Data were analyzed using the PROC GLM procedure of SAS. Forage DMI decreased linearly ($P < 0.05$) from 531 to 326 g/d as supplement intake increased. Total DMI, which included forage and supplement and nitrogen intake increased linearly ($P < 0.05$) from 531 to 778 g/d and 10 to 36 g/d, respectively. Apparent digestibilities of DM, OM, and NDF were similar for all treatments and averaged 0.69, 0.76 and 0.66, respectively, whereas N apparent digestibility increased linearly ($P < 0.01$) from 0.74 to 0.87 as supplement levels increased. In conclusion, supplementation with canola meal exerts a negative effect on forage intake while improves total nutrient intake by wethers.

Key Words: biodiesel byproducts, intake, digestibility

W346 Evaluation of including elevated levels of wet distillers grains in diets of beef steers. J. M. Carmack*[1], P. M. Walker[1], J. D. Fehr[1], R. L. Atkinson[2], and L. A. Forster[3], [1]*Department of Agriculture,*

Illinois State University, *Normal,* [2]*Animal Science, Food and Nutrition, Southern Illinois University*, *Carbondale,* [3]*Archer Daniels Midland Co*, *Decatur, IL*.

Few studies have been conducted evaluating inclusion rates of modified wet distillers grains with solubles (DGS) above 55% of the diet DM for finishing beef steers. The objective of this trial was to compare feedlot performance and carcass characteristics of feedlot steers fed increasing levels of DGS. The treatments (percent DM basis) were: 80 shelled corn/5 soybean meal/15 corn silage (CON), 25 DGS/60 shelled corn/15 corn silage (25 DGS), 40 DGS/45 shelled corn/15 corn silage (40 DGS) and 70 DGS/15 shelled corn/15 corn silage (70 DGS). Angus cross steers (n=140; 367±31 kg BW) were stratified by weight to 20 pens. Treatments were randomly assigned to pens with unequal pen replication. Seventy head were harvested on d 165 when 90% were estimated to have reached low choice or higher quality grade. The remaining 70 head were harvested on d 200 when 90% were estimated to have reached low choice or higher quality grade. Steers fed 70 DGS had higher ($P < 0.05$) ADFI and DMI compared to steers fed CON and 25 DGS. Mid trial G:F, end of trial G:F and final wt were lower ($P < 0.05$) for 70 DGS steers than steers fed CON, 25 DGS and 40 DGS. ADG tended to be higher ($P = 0.07$) for CON, 25 DGS and 40 DGS steers. No significant differences were observed for KPH percent and liver score. Dressing percent, carcass wt, ribeye area, and quality grade were lower ($P < 0.05$) for 70 DGS steers compared to other treatments. CON and 25 DGS steers had higher ($P = 0.02$) yield grades and 25 DGS steers had higher ribfat ($P = 0.02$) than 40 or 70 DGS steers. No significant differences in quality grade between treatments were observed (CON=100%, 25 DGS=97%, 40 DGS=100%, 70 DGS=87%) but 70 DGS steers did trend lower ($P = 0.07$) with 12% grading select. Results from this study suggest that steers fed DGS at 25 or 40% of the diet (DM) have similar or improved performance compared to control steers while steers fed 70 DGS have reduced performance but similar quality grades.

Key Words: high levels distillers grains, feedlot performance, carcass

W347 Performance, feed intake, residual feed intake and feed:gain ratio in progeny of Nellore steers housed in individual or group pens. M. L. Nascimento*[1], R. R. Tullio[2], M. M. Alencar[2], J. S. Lima[3], L. D. C. Vieira[4], M. L. P. Silva[4], and D. P. D. Lanna[1], [1]*University of Sao Paulo*, *Piracicaba, Sao Paulo, Brazil*, [2]*Embrapa Pecuaria Sudeste*, *Sao Carlos, Sao Paulo, Brazil*, [3]*Rural Federal University of Pernambuco State*, *Garanhuns, Pernambuco, Brazil*, [4]*State University of Sao Paulo*, *Jaboticabal, Sao Paulo, Brazil*.

Feed is the most expensive input within any livestock production system, including beef cattle. Residual feed intake (RFI), defined as the difference between observed intake and that predicted from average weight and daily gain, has been proposed as a criterion for genetic selection. There have been very little studies with this trait in *Bos indicus* breeds. The objective of this study was to assess the phenotypic variability in RFI in Nellore cattle. In addition to that, we re-evaluated the effect of housing type (group and individual pen) on ADG, G:F, DMI, and RFI. Hundred fourteen Nellore steers, progeny of eighteen bulls, were fed individually for 77 days, where 41 housed in individual pens and 73 in group pens with electronic gates feeders. The diet contained 40% corn silage and 60% concentrate on a dry matter basis, and was supplied ad libitum, twice a day. Animals were classed as low or high RFI if their RFI fell 0.5 SD or more below or above the mean (zero). There was no difference among ($P > 0.05$) between animals housed in individual or group pens for average daily gain (1.21 versus 1.23 kg/d, respectively), DMI (9.46 versus 9.44 kg DM/d, respectively), G:F (8.06 versus 7.83 kg/kg, respectively) and RFI. Housing type effects may be more evident under once daily feeding rather than with the twice daily interactions adopted in the present study. This study shows that individual pens may be used as long as animals are stimulated to come to the bunk more than once daily.

Key Words: beef cattle, intake, feeding

W348 Residual feed intake in progeny of Nellore bulls. M. L. Nascimento*[1], R. R. Tullio[2], M. M. Alencar[2], J. S. Lima[3], L. D. C. Vieira[4], M. L. P. Silva[4], and D. P. D. Lanna[1], [1]*University of Sao Paulo*, *Piracicaba, Sao Paulo, Brazil*, [2]*Embrapa Pecuaria Sudeste*, *Sao Carlos, Sao Paulo, Brazil*, [3]*Rural Federal University of Pernambuco State*, *Garanhuns, Pernambuco, Brazil*, [4]*State University of Sao Paulo*, *Jaboticabal, Sao Paulo, Brazil*.

Residual feed intake (RFI), defined as the difference between observed intake and that predicted from average weight and daily gain, has been proposed as a criterion for genetic selection. There have been very little studies with this trait in Bos indicus breeds. The objective of this study was to assess the phenotypic variability in RFI in Nellore cattle. Hundred thirty-eight Nellore steers, progeny of eighteen bulls, were fed individually for 77 days. The diet contained 40% corn silage and 60% concentrate on a dry matter basis, and was supplied ad libitum. The prediction equation was DMI = 0.1105 × Average $BW^{0.75}$ + 1.32 × Average Daily Gain (ADG). Animals were classed as low or high RFI if their RFI fell 0.5 SD or more below or above the mean (zero), where 39 were classed in the low RFI and 43 in the high group. Individual values of RFI ranged from –3.44 to 3.84 kg/d. Mean RFI for the low and high RFI groups were −1.11 and 1.06 kg/d, respectively; by definition, weights and ADG were similar between RFI groups. There was a difference among RFI groups for intakes and feed:gain where the high RFI group had intake 27.6% greater ($P < 0.0001$) than the low RFI steers (10.44 versus 8.18 kg of dry matter/d) and 0.5 percentage points more on a % BW basis. Furthermore, the high RFI group showed worse feed:gain ratio. The bulls were different from each other ($P < 0.05$) for ADG, feed intake and feed:gain (kg of dry matter/d and % BW). These results show the phenotypic variability in RFI and other traits among progeny of Nellore bulls.

Key Words: beef cattle, intake, genetic selection

W349 Effects of supplemental vitamin E with different oil sources on growth, health, and carcass parameters of preconditioned beef calves. C. J. Mueller*[1,2], C. Sexson[1], and R. R. Mills[1], [1]*Oregon State University*, *Corvallis*, [2]*Eastern Oregon Agricultural Research Center*, *Union*.

This trial was designed to evaluate the impact of supplemental vitamin E with or without different oil sources during a 35-d preconditioning period. Sixty-four (224 ± 33 kg) Angus-cross calves were stratified by weight and sex then randomly allotted to one of four treatments: CON (corn-soybean meal (base) diet with no added vitamin E or oil), SE (base diet plus 150 IU supplemental vitamin E), ELA (SE diet plus 1.5% safflower oil) and ELNA (SE diet plus 1.5% linseed oil). Following preconditioning, calves were shipped to a feedlot where they received a modified live intranasal vaccine for Infectious Bovine Rhinotracheitis (IBR) and Parainfluenze-3 (PI_3) on d37 and d56 to stimulate immune activity. Blood samples were obtained after preconditioning (d35), post-transit to the feedlot (d36), post-initial vaccination (d42), and post-secondary vaccination (d63 and 70) to quantify glucose and antibody titers. Weights were collected throughout the study with carcass data collected at harvest. Gain and carcass data were evaluated as a

randomized complete block design with sex as block, using the following preplanned contrasts: CON vs. vitamin E (mean of SE, ELA, and ELNA), SE vs. OIL (mean of ELA and ELNA), and ELA vs. ELNA. No differences ($P > 0.10$) were detected for ADG or body weights during the preconditioning and finishing periods. No differences ($P > 0.10$) were detected for carcass measurements between treatment contrasts, with the exception of backfat tending ($P < 0.10$) to be greater in SE calves versus OIL calves. Morbidity rates were less than 1% and consistent across treatments. Supplementation of vitamin E resulted in greater amounts of IBR titer at d35 and d36 ($P < 0.05$). The SE calves had higher PI_3 titers ($P < 0.05$) at d35 compared to OIL calves, but were similar ($P > 0.10$) through the feedlot phase. No differences ($P > 0.10$) were detected for PI_3 titers or glucose after the preconditioning period for any contrast. Supplementation of preconditioning diets with vitamin E with or without dietary essential fatty acids showed limited improvement in gain and immune response indicators in weaned calves.

Key Words: vitamin E, preconditioning, cattle

W350 Level of ammonia-nitrogen required to maximize ruminal microbial efficiency. Y. Liang* and M. S. Kerley, *University of Missouri*, *Columbia*.

Microbial efficiency (MOEFF) in the rumen is a function of dilution rate (D), with achievement of maximum efficiency dependent upon adequate supply of peptides and ammonia-nitrogen. Equations predicting maximum MOEFF at varying D were used to predict microbial requirements for peptides and ammonia nitrogen. The objective of this experiment was to determine accuracy of these prediction equations to estimate ammonia-nitrogen requirement of ruminal microbes. Our hypothesis was that MOEFF and organic matter digestion, when peptide-nitrogen supply was adequate and ammonia-nitrogen was limiting, would respond to increasing supply of ammonia nitrogen. Diets consisting of corn, Soyplus, bloodmeal and urea were formulated to provide adequate RDP (peptides) and inadequate to adequate levels of ammonia-nitrogen. Four diets were fed to continuous culture fermenters, varying in urea content (0, 0.2%, 0.45%, 0.7% urea on dry matter basis). The 0.7% urea diet was calculated to provide adequate ammonia-nitrogen. Ammonia, pH and VFA concentrations, organic matter and protein digestion and MOEFF were measured. As RDN (urea) increased digestibility of OM (linear, $P < 0.09$), MOEFF (linear, $P = 0.15$) and protein (quadratic; $P < 0.05$) increased. Increasing RDN level increased ammonia (quadratic, $P < 0.02$), butyrate (linear, $P < 0.01$) and total volatile fatty acid (linear, $P < 0.1$) concentrations. No differences were measured for pH, acetic and propionic acid concentrations or acetic to propionic acid ratio among treatments. Measured RDP and RDN were similar to predicted values. We concluded that increasing VFA concentrations, organic matter digestibility and MOEFF as RDN increased in diets occurred due to availability of ammonia-nitrogen increasing. Elevation of ammonia-nitrogen in 0.07% urea diet was believed to have occurred because ammonia-nitrogen requirement was met, as predicted. Requirement for RDN has been well established and this research demonstrated that ruminant diets can be balanced to supply required levels of RDN.

Key Words: MOEFF, rumen degradable nitrogen, ruminal fermentation

W351 Effects of polyunsaturated fatty acid supplementation (PUFA) on forage intake and digestibility in beef cows. R. F. Cooke*, A. B. Scarpa, F. M. Nery, F. N. T. Cooke, and D. W. Bohnert, *Oregon State University - EOARC*, *Burns*.

The objective was to compare DMI and in situ forage digestibility in beef cows supplemented or not with a rumen-protected PUFA source. Three Angus × Hereford cows (724 ± 39 kg of BW) fitted with ruminal cannulas were allocated to a 3 × 3 Latin Square design containing 3 periods of 21 d each. Treatments consisted of grain-based supplements without (CO) or with the inclusion (10%; as-fed basis) of a PUFA source (PF; Megalac-R, Church and Dwight, Princeton, NJ) or a saturated fatty acid source (SF; Megalac, Church and Dwight). Treatment intakes were formulated to be iso-caloric and iso-nitrogenous, and offered daily at a rate of 0.7% of BW/cow/d. Within each experimental period, mixed alfalfa-grass hay was offered in amounts to ensure ad libitum access from d 1 to 13, and hay DMI was recorded daily. Data collected from d 8 to 13 were used to determine treatment effects on hay and total DMI. From d 14 to d 21, cows were restricted to receive 90% of their voluntary hay DMI. Immediately before treatment feeding on d 16, polyester bags containing 4 g of hay (DM basis) were suspended within the rumen of each cow, and incubated in triplicates for 0, 4, 8, 12, 24, 36, 48, 72, and 96 h. After removal, bags were washed, dried for 96 h at 50°C in forced-air ovens and weighed. Triplicates were combined and analyzed for NDF content. Hay and total DMI were reduced ($P < 0.05$) in PF cows compared to SF and CO cows (2.19, 2.30, and 2.31% of BW for forage DMI, SEM = 0.29; and 2.86, 2.98, and 3.05% of BW for total DMI, SEM = 0.29). However, no treatment effects were detected ($P > 0.48$) for ruminal degradation rate of hay DM (6.81, 7.48, and 6.86%/h for CO, PF, and SF; SEM = 0.40) and hay NDF (6.05, 6.43, and 6.17%/h for CO, PF, and SF; SEM = 0.30). Similarly, no treatment effects were detected ($P > 0.63$) for effective ruminal degradability of hay DM (64.53, 64.93, and 64.94% for CO, PF, and SF; SEM = 0.38) and hay NDF (71.24, 71.76, and 71.57% for CO, PF, and SF; SEM = 0.36). In conclusion, PUFA supplementation did not impact forage digestibility, but decreased forage and total DMI in beef cows.

Key Words: forage digestibility, polyunsaturated fatty acids, beef cattle

W352 Use of real-time ultrasound (RTU) measurements and carcass traits to assess internal fat in residual feed intake (RFI)-indexed Brahman bulls under grazing conditions. C. A. Hughes*[1], J. A. Carter[1], T. D. A. Forbes[2], F. M. Rouquette, Jr.[3], L. O. Tedeschi[4], R. D. Randel[3], and F. R. B. Ribeiro[1], [1]*Texas A&M University-Commerce*, *Commerce,* [2]*Texas AgriLife Research*, *Uvalde,* [3]*Texas AgriLife Research*, *Overton,* [4]*Texas A&M University*, *College Station*.

This study evaluated RTU and carcass traits to determine total internal fat (IFAT) of Brahman bulls (n = 16) grazing Coastal bermudagrass ([*Cynodon dactylon* (L.) Pers]) at two stocking rates (SR) for 60 d. Prior to the grazing trial, animals were fed a high roughage diet for 70 d, stratified as efficient (LRFI) or inefficient (HRFI), and randomly assigned to high (HSR) or low (LSR) SR pastures. RTU measurements were collected 5 d prior to harvest off pasture and consisted of KPH depth (uKPH), backfat thickness (uBF), ribeye area (uREA), rump fat (uRUMP), i.m. (uIMF), and BW. Bulls were harvested at 16 to 18 mo of age and about 450 kg. Shrunk BW (SBW) was recorded after an 18 h fast prior to harvest. At harvest KPH and internal organs were separated, dissected, and weighed. Total internal fat was determined by adding the KPH and physically separated organ fat weights. After a 48-h chill complete carcass data was collected. Data were analyzed using a split-plot design in a 2 × 2 factorial arrangement with pastures within SR as random factors. Prediction equations were developed using the PROC REG procedure with the stepwise selection. There were no interactions or main effects of SR ($P > 0.05$) and RFI ($P > 0.05$) on any of the carcass traits or RTU measured; except for carcass backfat

that was significant ($P = 0.051$) with LRFI bulls having more backfat than HRFI bulls (0.22 vs. 0.13 cm, respectively). A linear regression to predict IFAT from KPH and uRUMP (R^2 of 0.61 and square root of mean square error of 1.54 kg) was developed. The stepwise selection indicated a partial R^2 of 0.53 for KPH and 0.08 for uRUMP. A previously published equation to predict IFAT from KPH accounted for 53% of the IFAT variation of our data. No differences between RFI and SR using RTU were detected for Brahman bulls harvested direct off pasture. The RTU may improve the predictions of IFAT when KPH is available. A second year of data will be used to improve the precision of the IFAT predictive equations.

Key Words: ultrasound, internal fat, carcass

W353 Effects of co-ensiling direct-cut grass with corn modified wet distillers grain plus solubles on beef steer diet digestibility. R. P. Arias*[1], L. J. Unruh-Snyder[1], E. J. Scholljegerdes[2], A. N. Baird[1], K. D. Johnson[1], D. Buckmaster[1], R. P. Lemenager[1], and S. L. Lake[3], [1]*Purdue University*, *West Lafayette, IN*, [2]*USDA-ARS Northern Great Plains Research Laboratories*, *Mandan, ND*, [3]*University of Wyoming*, *Laramie*.

Four crossbred beef steers fitted with ruminal cannulas (BW = 556 ± 31 kg) were used in a 4 × 4 Latin square to evaluate the effects of feeding co-ensiled corn modified wet distiller's grain plus solubles (WDG) with direct-cut grass (DC; 30% DM; 40% Tall Fescue) on diet digestibility characteristics. Steers were fed for four 14-d periods (10-d for adaptation and 4-d of samples collection). Diets were formulated to be isocaloric and isonitrogenous and consisted of: 1) a corn silage control-diet supplemented with soybean meal (CON); 2) DC co-ensiled with WDG in a 3:1 (DM basis; CO-EN); 3) Haylage (DC ensiled without WDG) mixed with WDG at feeding (H+WDG); 4) Haylage mixed with corn dry distiller's grain plus solubles (DDG) at feeding (H+DDG). Dry matter and N intake did not differ ($P > 0.05$) across treatments, however, steers fed the CON diet had lower ($P < 0.01$) NDF intake compared to other treatments. Apparent total tract DM and N digestibility were greatest ($P = 0.02$), and total fecal DM and N excretion were lowest ($P = 0.02$) for steers fed the CON diet compared to all other diets. Steers fed the H+DDG diet had lower ($P = 0.02$) rumen ammonia concentration compared to the CON and H+WDG diets, with the CO-EN diet being intermediate. The CON diet also had greater ($P = 0.03$) total VFA concentrations and lower ($P = 0.03$) acetate:propionate compared to the all other diets. Results from this study suggest that although the feeding value of the CON diet was higher; there was a similar feeding value between direct-cut grass co-ensiled with WDG, and haylage diets fed with either WDG or DDG added at the time of feeding.

Key Words: distillers grains, co-ensiled, digestibility

W354 Acetate utilization in young crossbred calves is age-dependent. K. Pike*, W. A. D. Nayananjalie, T. R. Wiles, M. A. McCann, D. E. Gerrard, and M. D. Hanigan, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Early weaning is a management strategy for reducing lifetime feed intake in beef cattle. As the age at weaning decreases, however, the ability of the calf to utilize energy substrates may limit the effectiveness of this approach. Volatile fatty acids are critical in ruminant metabolism and acetate is the primary energy yielding substrate. We hypothesized that acetate clearance rates would provide information on postabsorptive capacity of young calves to utilize acetate. Four Angus × Simmental bull calves weighing 113±9 kg at 87 ± 2 days of age and 4 calves weighing 133±10 kg at 111±5 days of age were given a bolus infusion of acetate (4 mmol of acetate/kg of BW) over a 5 min period via an indwelling jugular catheter. Blood samples (5 ml) were collected from the jugular catheter at 5 min intervals over the first 30 min post-infusion and at 15 min intervals over the next 60 min. Blood samples were placed on ice immediately after collection and plasma was prepared and stored at −20° C until analysis. Plasma acetate levels were determined by isotope dilution using gas chromatograph-mass spectrometry. Acetate clearance rates were determined for each calf by fitting an exponential decay curve to the observed acetate concentration data using the NLIN procedure of SAS. Resulting clearance rates were analyzed using the MIXED procedure of SAS. Although, differences in clearance rates between older (0.003 ± 0.0002) and younger animals [0.002 ± 0.0002 ($\min \times BW^{.075}$)$^{-1}$)] was not significant ($P = 0.26$), greater basal blood acetate concentrations for the younger animals (2.9±0.6 vs. 6.8±0.6 mmol, respectively; $P < 0.01$) are consistent with the numerical reductions in clearance rates. These data suggest that utilization of acetate by tissues of calves is age-dependent and suggest that the weaning age may be limited by the ability of the tissues absorb acetate from the peripheral circulation.

Key Words: acetate, calves, clearance rate

W355 Ergot alkaloids induce vasoconstriction of bovine foregut vasculature. A. P. Foote*[1], J. L. Klotz[2], D. L. Harmon[1], L. P. Bush[1], and J. R. Strickland[2], [1]*University of Kentucky*, *Lexington*, [2]*USDA-ARS, FAPRU*, *Lexington, KY*.

Alkaloids produced by the *Neotyphodium coenophialum* endophyte in association with tall fescue (*Lolium arundinaceum*) are imputed to cause peripheral symptoms of fescue toxicosis. We hypothesized that theses compounds could correspondingly affect foregut vasculature. The objective of this study was to determine vasoconstrictive potentials of ergovaline (ERV), ergotamine (ERT), ergocryptine (ERP), ergocristine (ERS), ergonovine (ERN), ergocornine (ERO), lysergic acid (LSA), and an ethanol-extract of ground endophyte-infected fescue seed (EXT) on right ruminal artery and vein. Segments of right ruminal artery and vein were collected from the ventral coronary groove of predominately Angus heifers (n = 7) shortly after slaughter and placed in a modified Krebs-Henseleit buffer on ice. Vessels were cleaned of excess connective tissue and fat, sliced into 2-3 mm segments and suspended in a multi-myograph chamber with 5 mL of continuously oxygenated Krebs-Henseleit buffer (95%O_2/5% CO_2; pH 7.4; 37°C). Arteries and veins were equilibrated to 1.0 g and 0.5 g respectively for 90 min followed by addition of 120 m*M* KCl. Increasing concentrations of each compound were added to the respective chamber every 15 min following buffer replacement. Data were normalized as a % of the contractile response induced by KCl and were analyzed as a completely randomized design using PROC MIXED of SAS. No venous response was observed until 1×10^{-5} *M* and no arterial response was observed until 1×10^{-6} *M* for ERV and ERT, 1×10^{-5} *M* for ERP, ERO, and ERN, and 1×10^{-4} *M* for ERS. Alkaloid, concentration, and vessel affected contractility ($P < 0.05$). A greater arterial maximal response was observed for ERO, ERT, ERV, and EXT ($P < 0.05$) and the arterial and venous responses were not different for ERN, ERP, ERS, and LSA ($P > 0.05$). These results indicate that ergot alkaloids have potential to alter blood supply and drainage from the bovine foregut and the differential artery and vein responses may contribute to the fescue toxicosis syndrome.

Key Words: ruminal artery and vein, vasoconstriction, tall fescue

W356 Comparison of methods to predict carcass composition in grass and grain fed Angus steers. G. Acetoze*, G. D. Cruz, and H. A. Rossow, *University of California*, *Davis*.

Interest in grass finished beef has been increasing. However more research is needed to apply grass finishing to current beef production systems. Methods to predict carcass composition were developed based on data from grain finished cattle. However data are limited on the accuracy of using these methods for grass finish cattle. The objective of this study is to examine the effects of grass or high grain diets on the carcass composition of Angus steers and compare results from two methods for determining carcass composition. Carcass composition was estimated using specific gravity (SG) and composition of 9-11th rib section (RS) from the right side (Lunt et al., 1985), to compare the percentages of muscle, fat and bone of 14 grain-fed and 13 pasture-fed Angus steers. Steers were slaughtered when their estimated quality grade by ultrasound was greater than low select. Average yield and quality grades for grass finish steers were 58% and high select, and 63% and average choice for grain finish steers. Average live weights at slaughter were 610 and 630 kg with standard deviations of 87 and 78 kg for grass and grain diets, respectively. Pasture was a mix of white clover and ryegrass (15.8% crude protein, 49.8% NDF) and the feedlot diet was a 90% corn, 10% alfalfa finishing diet (13.0% crude protein, 26.3% NDF) on a dry matter basis. Data were analyzed with the general linear models procedure of SAS (SAS Institute, 2004) for method, type of diet and method diet interaction with bodyweight as a covariate. Muscle and fat % were significantly different (P< 0.05) for method used to estimate carcass composition with least squares means for muscle of 60.3% and 52.0% and fat of 24.1% and 31.7% for RS and SG, respectively. Bone % for diet and method, interaction between diet and method and use of body weight as a covariate for muscle, fat and bone % were not significant. These results imply that carcass composition is different for grass and grain finish steers. However, equations estimating muscle and fat % may need to be re-evaluated for grass finish steers.

Key Words: grass finish, carcass composition

W357 Rumen bacterial population dynamics of steers grazing winter wheat forage and a yeast culture supplement. D. W. Pitta*[1], W. E. Pinchak[1], S. E. Dowd[2,4], J. Osterstock[3], V. Gontcharova[2], E. Youn[4,5], K. Dorton[6], I. Yoon[6], B. R. Min[1], J. D. Fulford[1], T. A. Wickersham[7], and D. P. Malinowski[1], [1]*Texas AgriLife Research*, *Vernon,* [2]*Research and Testing Laboratory*, *Lubbock,* [3]*Texas AgriLife Research*, *Amarillo,* [4]*Medical Biofilm Research Institute*, *Lubbock,*[5]*Texas Tech University*, *Lubbock,* [6]*Diamond V Mills*, *Cedar Rapids, IA,* [7]*Texas A&M University*, *College Station*.

A study was conducted to study the dynamics in rumen bacterial populations using bTEFAP technique in steers grazing winter wheat with and without yeast supplementation on the Southern Great Plains of Vernon, Texas over a 75-day period. Experimental design included 14 (Angus × Hereford) ruminally cannulated steers grazing a basal winter wheat forage and grouped into 3 treatments based on yeast supplementation i.e., treatment 1 (control; n=4), treatment 2 (7% yeast; n=5) and treatment 3 (14% yeast; n=5). Both fiber and liquid fractions of rumen samples were collected on day 14, 28, 56 and 76 to investigate their associated bacterial populations. Wheat forage grazed in the first 30 days was vegetative and had a higher nutritive value (crude protein of 21% and In vitro dry matter digestibility of 80%) while the wheat forage grazed in the latter half of the Experiment was reproductive (neutral detergent fiber of 50%). Using BLASTn search, sequences were compared to databases and assigned to genera based on the similarity indices. The number of bacterial genera identified increased with time from day 14 (93, 109) to day 76 (271, 233) in both fiber and liquid fractions respectively. *Prevotella* was the most predominant genera in both solid (up to 50%) and liquid (up to 60%) fractions on all sampling days. *Rikenella* was the second most abundant genus in both fractions, progressively increased with time from 8 to 20%, with increasing in fiber content. There was an increase in the number of bacterial genera identified in the yeast supplemented steers and the increases were mostly confined to the minor genera (<0.9% of 16S rDNA sequences found). Yeast supplementation increased *Ruminococcus* (a major genus) consistently with time and minor genera like *Lactobacillus, Lactococcus, Megasphaera, Atopobium and Enterococcus* which fall under Lactic acid bacteria cluster. In summary, yeast supplementation influenced major genera only to a limited extent but more prominent changes in the minor genera. Changes in the major genera were attributed more to the changes in nutritional quality of wheat forage.

Key Words: wheat, yeast supplementation, bTEFAP pyrosequencing

W358 Expression of phosphate transporter in small intestine, kidney, and parotid salivary gland of cattle fed differing levels of phosphorus from wet distiller's grains. A. P. Foote*[1], B. D. Lambert1,2, J. A. Brady[2], M. S. Brown[3,4], J. B. Osterstock[4], J. C. MacDonald[3,4], and N. A. Cole[5], [1]*Tarleton State University*, *Stephenville, TX*, [2]*Texas AgriLife Research*, *Stephenville*, [3]*West Texas A&M University*, *Canyon*, [4]*Texas AgriLife Research*, *Amarillo*, [5]*USDA-ARS, CPRL*, *Bushland, TX*.

Phosphorus (P) in the diets of animals in confined animal feeding operations (CAFOs) is of great importance with the increasing concern of environmental impact of animal agriculture. Excess phosphorus in diets of cattle is excreted in the manure and, if improperly managed, can be washed into local surface water causing an increase in algae growth, while a dietary deficiency can lead to poor growth and other detrimental symptoms. The objective of this study was to determine the expression of NaPi-IIb in the small intestine and parotid salivary gland and NaPi-IIa in the kidney of cattle fed increasing levels of P (0.29, 0.38, and 0.52% P; 0, 30 and 60% wet distillers grain, respectively). Samples of parotid salivary gland and kidney along with the mucosa of the duodenum, proximal jejunum, distal jejunum, and ileum were collected at slaughter and immediately frozen in liquid nitrogen. Relative amounts of NaPi-IIa or NaPi-IIb mRNA were determined using RT-PCR. Expression of NaPi-IIa in the kidney was not affected by diet ($P = 0.15$). Expression of NaPi-IIb was highest in the ileum and proximal jejunum ($P = 0.058$). NaPi-IIb expression in the parotid and small intestine were also not affected by varying dietary P ($P > 0.2$). It appears that dietary P may play a lesser role in regulation of P transporter expression in ruminants than in other animal species.

Key Words: phosphorus, transporters

W359 Supplemental vitamin E concentration in beef finishing diets containing wet distillers grains with solubles: feedlot performance and carcass characteristics. D. B. Burken*[1], K. G. Hanger[1], R. B. Hicks[1], D. L. VanOverbeke[1], J. L. Wahrmund[1], B. P. Holland[2], J. J. Martin[3], P. K. Camfield[3], and C. J. Richards[1], [1]*Oklahoma State University*, *Stillwater*, [2]*South Dakota State University*, *Brookings*, [3]*Oklahoma Panhandle State University*, *Goodwell*.

The objective of this study was to evaluate feedlot performance and carcass characteristics of finishing beef steers fed diets containing wet distillers grains with solubles (WDGS) and supplemented with vitamin E to target improvements in meat quality. One hundred ninety–nine steers (BW = 363 ± 31.1 kg) of mixed *Bos indicus*, *Bos taurus*, and *Bos indicus x Bos taurus* breeding were blocked by BW and randomly assigned to 1 of 4 supplemental vitamin E levels (0, 125, 250, and 500 IU/hd/day) fed for the last 97 d of the feeding period. Two blocks were

fed for a total of 129 d and 3 blocks were fed for a total of 150 d. Steers were fed a rolled corn-based finishing diet with 35% WDGS and 7% ground alfalfa (DM basis). Individual BW were measured initially on two consecutive days, the initial day of vitamin E supplementation, and the day of harvest. Carcass data were collected at harvest. There were no differences in ADG, G:F, and DMI for the pre-vitamin E supplementation period, the vitamin E supplementation period, or over the entire feeding period ($P \geq 0.11$). Final BW, HCW, and carcass-adjusted final BW did not differ among treatments ($P \geq 0.06$). Carcass characteristics (LM area, fat thickness, calculated YG, and KPH) were not affected by treatment ($P \geq 0.13$). Percentage of cattle grading upper 2/3 choice, low choice, and select did not differ ($P \geq 0.57$), nor did percentage calculated yield grades 2, 3, and 4 ($P \geq 0.07$). Data from this study illustrate that vitamin E can be supplemented in WDGS diets during the last 97 days of the feeding period to target improvements in meat quality with no adverse effects on animal performance or carcass characteristics.

Key Words: beef cattle, feedlot, vitamin E

W360 Abomasal direct infusion of L-arginine and *trans*-10, *cis*-12 conjugated linoleic acid affect to lipogenic gene expression and enzymes activities in angus steers. S. H. Choi*[1], G. Go[1], D. T. Silvey[1], L. A. Gilmore[1], K. Y. Chung[2], B. J. Johnson[2], G. Wu[1], and S. B. Smith[1], [1]*Department of Animal Science, Texas A&M University*, *College Station,* [2]*Department of Animal and Food Science, Texas Tech University*, *Lubbock*.

This study was conducted with a cattle model to exam the hypothesis that direct abomasal infusion of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) and/or arginine would depress lipogenic enzymes activities and lipogenic gene expression in bovine subcutaneous adipose tissues. Sixteen Angus steers were assigned randomly to four treatments: direct infusion into the abomasums with L-arginine (50 g/d) or L-alanine (100 g/d; isonitrogenous control) and/or *trans*-10, *cis*-12 CLA (100 g/d) in steers fed a corn-based finishing diet. Infusion program was: the 1st period (15 d), steers were infused L-arginine or L-alanine, the 2nd period (15 d), steers were infused each amino acids and/or *trans*-10, *cis*-12-CLA. Subcutaneous adipose tissue and blood samples were collected at beginning and end periods. The BW gain and ADG were significantly decreased ($P = 0.03$) by abomasal infusion of CLA and feed:gain was significantly increased ($P = 0.01$). The activities of 6-phosphogluconate-dehydrogenase, glucose-6-phosphate-dehydrogenase and fatty acid synthase were not affected by arginine or CLA infusion. Arginine depressed NADP-malic enzyme (ME) activity, but this was reversed by co-infusion of CLA (arginine x CLA, $P= 0.02$). The concentration of *cis*-9, *trans*-11 and *trans*-10, *cis*-12 CLA in plasma was increased by CLA infusion, and arginine infusion increased plasma arginine. AMP-activated protein kinase (AMPK) and stearoyl Co-A desaturase (SCD) gene expression were significantly enhanced ($P \leq 0.025$) by arginine infusion but decreased PPARγ gene expression. CLA significantly depressed C/EBP-β gene expression. Because arginine increased AMPK gene expression and depressed PPARγ gene expression and ME activity, we predict that over time, arginine would depress adiposity. Unexpectedly, these effects were antagonized by CLA.

Key Words: conjugated linoleic acid, arginine, beef cattle

W361 Effects of different casein supplements on concentration of soluble non-ammonia nitrogen in the liquid phase of ruminal and omasal digesta in Korean native steers. C. W. Choi*[1], H. G. Lee[2], Y. K. Oh[1], S. C. Lee[1], M. K. Song[3], S. H. Choi[4], and S. B. Smith[4], [1]*National Institute of Animal Science, RDA*, *Suwon, Korea*, [2]*Department of Animal Science, Pusan National University*, *Mirang, Korea*, [3]*Chungbuk National University*, *Cheongju, Korea*, [4]*Texas A&M University*, *College Station*.

Three ruminally and duodenally fistulated Korean native steers were used to study the effect of different casein supplements on concentration of soluble non-ammonia N (SNAN) from the rumen and to compare SNAN estimates based on ruminal (RD) and omasal digesta (OD) samplings. The treatments in a 3 × 3 Latin square design consisted of a basal diet (control) of rice straw and corn based concentrate (30:70) and two casein protein supplemented diets. Crude protein intake for control (0.65kg/d of dry matter (DM)) was increased to 0.82 or 0.81kg/d of DM by replacing the basal diet with intact casein (0.24 kg/d) or acid hydrolyzed casein (0.46 kg/d), respectively. For SNAN analysis, digesta was collected from both the rumen and the omasum at 2 h intervals after a morning feeding, sequentially centrifuged to eliminate microbes, and precipitated with trichloroacetic acid followed by centrifugation. Different N fractions i.e., free amino acids (AA), peptides and soluble protein in RD and OD were assessed using the ninhydrin assay. Acid hydrolyzed casein supplement decreased ($P = 0.05$) rumen pH compared with control. Casein supplements increased (at lease $P < 0.05$) concentrations of peptide and total SNAN, whereas different casein types did not affect mean concentration of SNAN fractions in both RD and OD. Mean concentrations of free amino acid (58.1 vs. 46.8 mg N/L) and total SNAN (158.6 vs. 143.9 mg N/L) were significantly ($P < 0.05$) higher in OD than those in RD. In both RD and OD, despite relatively high concentration of free amino acid N, peptide N constituted the largest proportion of total SNAN suggesting that hydrolysis of peptides to AA rather than hydrolysis of soluble proteins to peptides or deamination of AA to ammonia is the most limiting step in rumen degradation.

Key Words: soluble non-ammonia nitrogen, casein supplements, omasal digesta:

W362 Similar performance and carcass quality of beef bulls weaned at 3 or 6 months of age when slaughtered at a fixed body weight. M. Vestergaard*[1], A. M. Graumann[2], F. Strudsholm[2], and C. F. Børsting[3], [1]*Aarhus University*, *Tjele, Denmark*, [2]*Agrotech A/S*, *Skejby, Denmark*, [3]*Danish Cattle Research Centre*, *Tjele, Denmark*.

In order to utilize dry beef cows to graze extensive pastures, where low yield of grass does not allow proper management and performance of cow-calf combinations, there could be prospective in using an earlier rather than a traditional weaning age. The present experiment focuses on the weaned calves and study the effects of three mo (3M) compared with six mo (6M) weaning age on growth performance and carcass quality. Furthermore, three feeding strategies were included at both weaning ages: concentrates ad lib (CON), total mixed ration of concentrate and first cut grass silage ad lib (TMR), and separately fed concentrate at a fixed amount (4 kg/d) and first cut grass silage ad lib (SEP). The pelleted concentrate and silage had a DM content of 87 and 39%, respectively, and an energy content of 8.7 and 7.7 MJ NE/kg DM, respectively. A total of 83 bull calves in 14 blocks of 6 were included. Each block represented a breed and included Hereford, Angus, Simmental, Charolais, Limousin and crossbreds of these breeds. Within breed a fixed BW at slaughter was chosen in order to produce carcasses of similar fatness degree. The mean BW across all breeds was 560 kg, ranging from 520 kg with Hereford to 610 kg with Charolais. The actual BW at weaning was 145 (3M) and 251 kg (6M) ($P < 0.001$). At 6 mo of age, 3M calves were 17 kg heavier than 6M calves ($P < 0.05$). DMI from 6 mo of age to slaughter (7.30 kg), ADG (1.63 kg/d), age at slaughter (370 d), carcass wt (314.5 kg), dressing percentage (58.1), and EUROP carcass conformation and fatness were not different between 3M and 6M bulls. There

were no major interactions between weaning age and feeding strategy. NE per kg DM was higher for CON than TMR and SEP rations ($P < 0.001$). DMI was highest in TMR ($P < 0.001$) leading to the highest Gain to Feed ratio in CON and lowest in TMR ($P < 0.001$). Carcass characteristics were not affected except carcass fatness that was lowest in CON ($P < 0.01$).

Key Words: beef production, weaning age, feeding strategy

W363 Development of a fescue toxicosis model using a fescue seed extract. A. F. Koontz*[1], L. P. Bush[2], J. L. Klotz[3], K. R. McLeod[1], F. N. Schrick[4], and D. H. Harmon[1], [1]*Department of Animal and Food Sciences, University of Kentucky*, *Lexington,* [2]*Department of Plant and Soil Sciences, University of Kentucky*, *Lexington,* [3]*Forage-Animal Production Research Unit, USDA-ARS*, *Lexington, KY,* [4]*Department of Animal Science, University of Tennessee*, *Knoxville*.

This study was designed to examine the efficacy of a fescue seed extract for inducing fescue toxicosis in cattle. Four growing Holstein steers (BW = 309±36kg) surgically fitted with ruminal cannulas were utilized in a four phase crossover design experiment. The basal diet consisted of endophyte free fescue hay fed ad libitum. In phases 1 & 2, steers were ruminally dosed twice daily with 1kg either ground endophyte infected seed (S_{E+}) or ground endophyte free fescue seed (S_{E-}) for 7 d in order to develop a baseline of physiological responses during fescue toxicosis. In phases 3 & 4, steers were ruminally dosed twice daily with an extract from endophyte infected seed (E_{E+}) or endophyte free fescue seed (E_{E-}) for 7 d. During d 4-7 of each phase room temperature was increased to 32°C (HS). Steers on both S_{E+} and E_{E+} had reduced serum prolactin on D7. Steers on S_{E+} and E_{E+} had a reduction in total intake ($P < 0.05$) during HS, while there was no difference between treatments during thermoneutrality. Rate of intake was also reduced for S_{E+} and E_{E+} during HS. Consequently, animals on S_{E+} and E_{E+} tended to lose weight (−2kg) while animals on S_{E-} and E_{E-} tended to gain weight (+8kg). Skin temperature was higher ($P < 0.01$) during HS for both S_{E-} and S_{E+}. Core body temperature was higher ($P < 0.0001$), for extract treated animals as compared to those dosed with ground seed for both E+ and E-. Heart rate measurements show the opposite effect for both form and endophyte comparisons. There was no effect of treatment on respiration rate at thermoneutrality, however, HS tended to increase respiration rate for all treatments ($P < 0.1$) with E+ dosed animals higher than E- ($P = 0.0002$), as well as S animals higher than E ($P = 0.0012$). Blood pressure was only measured during E treatment. Systolic pressure was unaffected by treatment ($P = 0.203$), while diastolic pressures were higher for E_{E+} ($P = 0.008$). HS resulted in a reduction in systolic and diastolic pressure for E_{E+} ($P < 0.05$), while E_{E-} pressures were unchanged. These data indicate a fescue seed extract model is able to mimic the symptoms of fescue toxicosis induced by seed.

Key Words: bovine, fescue, model

W364 Flint corn grain processing and protein adequacy in rations for feedlot finished Nellore bulls. A. M. Pedroso*, M. S. Peres, F. A. P. Santos, G. B. Mourao, and T. G. Neri, *ESALQ/USP*, *Piracicaba, SP, Brazil*.

This trial was designed to evaluate processing methods of flint corn grain and increasing urea levels effects on performance of finishing Nellore bulls fed rations containing 12% grass hay and 88% concentrate (%DM) for 101 d. Rations contained 3 urea levels (0.5; 1.0 or 1.5% DM) and 73.5 to 75% corn grains, either steam flaked (SF), dry rolled (DR) or fine ground (FG). 178 Nellore bulls, with 343 kg average initial LBW were used in a complete randomized blocks design with a 3x3 factorial arrangement. Animals were kept in 36 concrete floor pens. Parameters evaluated were dry matter intake (DMI), average daily gain (ADG), feed efficiency (FE – kg ADG/kg DMI), dressing percentage (DP), fat thickness (FT) and rib eye area (REA). Data were analyzed using PROC MIXED of SAS. Bulls fed SF flint corn showed 20.5% and 11.7% better FE than bulls fed DR and FG respectively ($P < 0.05$). Fine grinding of flint corn increased cattle feed efficiency in 7.9% compared with dry rolling ($P < 0.05$). SFC resulted in higher DP than FGC and DRC as well as higher REA than DRC ($P < 0.05$). Increasing urea levels resulted in linear increases ($P < 0.05$) on DMI, ADG and FE. There was an interaction of grain processing and urea levels for ADG ($P < 0.06$). Cattle fed DR and FG responded to urea up to 1% while cattle fed SF responded to urea up to 1.5% of diet DM. Increases in energy values with steam flaking and fine grinding were higher with the flint corn used in this trial than the increase reported by the literature for dent corn.

Table 1. Performance of finishing Nellore Bulls fed flint DR, FG or SF and different urea levels

	SFC	FGC	DRC	0.5% U	1.0% U	1.5% U	SEM	Effect (Pr>F) - Corn × Urea	Linear Regression (urea levels)

Key Words: feedlot, flint corn grain processing, protein adequacy

W365 Effects of ruminal energy-protein synchronization on intake, nutrient digestibility, performance, carcass traits and composition of carcass gain in beef heifers. M. S. Duarte, P. V. R. Paulino*, G. S. Viana, E. A. Fonseca, L. H. P. Silva, J. P. I. S. Monnerat, R. Mezzomo, J. Cavali, J. F. Lage, I. M. Oliveira, S. C. Valadares Filho, and M. F. Paulino, *Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

This study was carried out aiming to evaluate the effects of ruminal energy–protein synchronization on intake, nutrient digestibility, feed conversion, animal performance, carcass traits and composition of carcass gain of beef heifers. Twenty crossbred heifers (average BW of 240 kg) were used. At the beginning of the trial, four animals were slaughtered as reference group and the sixteen remaining animals were randomly assigned to 4 treatments, in a 2 × 2 factorial design: two levels of concentrate (40 and 80%, based on dry matter) and two levels of rumen undegradable protein (RUP – 48.8 and 27.2% of the diet CP). At the end of the trial, the animals were slaughtered. There was no interaction (P>0.05) between concentrate and RUP level on any variable studied. Dry matter intake (DMI), nutrients intake and nutrients digestibility were not affected ($P > 0.05$) by RUP level. The animals fed the highest RUP level had higher ($P < 0.05$) average daily gain (ADG) and therefore greater feed conversion than the animals fed the lowest RUP level (1.18 kg/d; 6.44 and 0.96 kg/d; 7.38, respectively). Concentrate level did not affect ($P > 0.05$) DMI, feed conversion and ADG. The animals fed 80% concentrate diets had higher intake of TDN and EE, and lower intake of NDF ($P < 0.05$) compared to the animals fed 40% concentrate diets. The digestibilities of all nutrients, except the NDF, were greater ($P < 0.05$) for the 80% concentrate diets. There was no effect ($P > 0.05$) of RUP level on carcass traits and composition of carcass gain. Similarly, concentrate level did not affect ($P > 0.05$) the composition of carcass gain. The animals fed 80% concentrate diets had larger ($P < 0.05$) rib eye area than the animals fed 40% concentrate diets. Although feeding more

RUP led to improved feed conversion and increased ADG, the interaction of RUP and dietary energy level was not an important attribute in formulating beef heifer′s diet as no effect of ruminal energy-protein synchronization on performance, intake, nutrient digestibility, carcass traits and composition of carcass gain were detected.

Key Words: feedlot, performance, rumen undegradable protein

W366 The effects of restrictive feeding over the winter on the performance of prepartum crossbred beef cows. K. M. Wood*, I. B. Mandell, and K. C. Swanson, *University of Guelph*, *Guelph, Ontario, Canada*.

Eighty-seven mature pregnant beef cows, primarily of Angus and Simmental breeding, were used in a randomized complete block design to investigate the effects of restrictive feeding on performance over two separate winters. Cows were randomly assigned to one of three dietary treatments: Control (CON; n =24); fed free choice grass/alfalfa haylage, constantly restricted (CONST; n= 32); fed haylage at 1.8% of bodyweight, and stepwise (STEP; n = 31); fed haylage at 1.6% of bodyweight for 56 d and then fed 2% of bodyweight for 56 d. Individual feed intakes were recorded using the Calan gate system. Cows were weighed every 14 d to adjust intake and ultrasounded for rump fat, backfat and % intramuscular fat and body condition scored (BCS) on d 1, 56, 112. Calf birthweight was also recorded. Data were analyzed using Proc Mixed in SAS; the model included the effect of block (year of experiment), parity and dietary treatment, as well as the random effect of pen. Contrast statements were used to compare CON versus CONST and STEP, and CONST versus STP with significance declared at $P \leq 0.05$. Total DM intakes were similar ($P = 0.84$) for total DM intake between CONST and STEP; however cows fed CON had the greatest ($P < 0.001$) DM intakes. Average daily gains over the entire experiment were 1.1 ± 0.06 (LSM ± SEM) for CON, 0.83 ± 0.05 for CONST and 0.87 ± 0.05 for STEP and were greater ($P \leq 0.001$) for CON than the two restrictive treatments. There were no differences ($P > 0.17$) amongst dietary treatments for changes in backfat or calf birthweight. Cows fed CON deposited more ($P < 0.001$) rump fat and had a greater ($P < 0.001$) gain in BCS than cows fed CONST or STEP. Cows fed CONST or STEP did not differ (P = 0.95) for change in rump fat and CONST tended ($P = 0.08$) to have greater increase in change in BCS. In conclusion, method of restrictive feeding did not affect the overall performance of pregnant beef cows and may be an acceptable alternative to feeding free-choice haylage rations to prepartum beef cows over the winter.

Key Words: beef cows, restrictive feeding, winter rations

W367 Comparison of wheat dried distillers grains with solubles, alone or in combination with barley grain, as protein and energy sources for beef stocker calves grazing fall pasture and winter field bale grazing. L. P. Clark*[1] and H. A. Lardner[1,2], [1]*University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Western Beef Development Centre*, *Humboldt, Saskatchewan, Canada*.

Two experiments were conducted to evaluate and compare supplementing wheat dried distiller′s grains with solubles (DDGS) alone or in combination with barley grain on the performance of beef calves in a fall pasture (EXP1) or winter bale grazing (EXP2) program. In each experiment, weaned, cross-bred calves (n=54) were stratified by body weight and randomly allocated to 1 of 3 supplement strategies in a replicated (n=3) completely randomized design. In EXP1, calves (initial BW 211.9 ± 1.23 kg) were supplemented at 0.8% BW either (i) barley+canola meal (70:30 blend); (ii) barley+wheat DDGS (70:30 blend) or (iii) 100% wheat DDGS. In EXP2, calves (initial BW 205.8 ± 0.42 kg) were supplemented at 1.2% BW either (i) 100% wheat DDGS; (ii) 100% barley or (iii) wheat DDGS+barley (50:50 blend). The fall pasture study (EXP 1) was conducted on an 18 ha crested wheatgrass (*Agropyron cristatum*) pasture divided into 9, 2-ha paddocks. The winter bale grazing study (EXP 2) was conducted on a 5.4 ha paddock further divided into 9, 0.6 ha paddocks. In EXP2 calves had ad libitum access to grass-legume hay (12.5% CP, 57% NDF) fed in round bale feeders. Calves were weighed at start, every 14 d and end of both experiments. All weights were adjusted for a 4% shrink. Paddock was the experimental unit and data were analyzed using the Mixed model procedure of SAS. Average daily gains did not differ ($P = 0.33$) between supplement groups during the 33-d graze period on crested wheatgrass (EXP1) or the 109-d (EXP2) winter bale graze period ($P = 0.41$). These data suggest that wheat DDGS compared to barley supplementation will result in similar performance of stocker calves grazing fall pasture or winter bale grazing.

Key Words: wheat dried distillers grains with solubles, calves, grazing

W368 Carcass characteristics of Nellore heifers finished on pasture system with partial substitution of soybean meal for sunflower crushed seeds. S. L. N. Cerilo*, R. H. de Tonissi e Buschinelli de Goes, H. L. Lima, A. R. M. Fernandes, K. A. de Souza, K. C. da Silva Brabes, A. F. Marquez, and E. R. de Oliveira, *Universidade Federal da Grande Dourados*, *Dourados,MS, Brasil*.

The carcass characteristics of Nellore heifers finished in *Brachiaria humidicola* pasture, supplemented with partial substitution of soybean meal by sunflower crushed seeds were evaluated in the dry season. Twenty-four animals were used with initial body weight (BW) of 300 kg and initial body condition (BC) of 2 (in score 1 to 5), with approximately 24 months of age, were distributed at random into four paddocks of 3000 m^2, in a complete randomized design. The supplement was fed at 0.8% BW/animal/day. The supplements were based in corn and soybean meal, which soybean meal was replaced by sunflower crushed seeds in the proportions of 0, 20, 40 and 60%. All the concentrate containing 20% CP, varying oil levels (2.5, 4.7, 7.0, 9.2%). The animals were weighed and monitored for BC every 21 days and slaughtered at 378.5 kg and 3.8 of body condition. There was no difference ($P > 0.05$) between the levels of substitution for hot carcass weight (HC), cold carcass weight, carcass yield, carcass length, liver, fat thickness (FT), yield estimated grade (YG=72.92-0.489FT-0,02HC +0.119LEA), and Brazilian commercial cuts (BCC= 60,33-0,015HCW-0,462FT+0.11LEA), which presents a average of 197.05 kg, 193.33 kg, 52.03%, 1.2m, 3.59 kg, 4.52 mm, 74.18% and 62.14%, respectively. Effect ($P < 0.10$) was observed for the inclusion of sunflower crushed seeds for fat accumulation in peri-renal and loin eye area (LEA). The animals supplemented only corn and soybean meal presents a lower peri-renal fat (1.87kg), the substitution of 40% of sunflower crushed seeds, showed accumulation of 3.02 kg and those receiving 20 and 60% had an average of 2.69 and 2.05 kg, these values may be associated with oil levels of supplement. The loin eye area showed values of 69.2, 58.2, 57.8, 64.0 cm^2, and LEA/100 kg BW of 18.48, 15.01, 15.50, 17, 25, for the replacement levels of 0, 20, 40, 60%, respectively, which shows that the weight and size of animals can influence the area of loin eye. Partial substitution of soybean meal with sunflower crushed seeds, does not alter the carcass characteristics of Nellore heifers finished in grazing systems.

Key Words: fat thickness, loin eye area, yield grade

W369 Changes in ruminal parameters, of steers supplemented with sunflower crushed seeds in partial substitution of soybean meal. H. L. Lima*, R. H. de Tonissi e Buschinelli de Goes, S. L. N. Cerilo, A. L. Teodoro, K. A. de Souza, L. da Silva Fernandes, M. G. de Menezes Gressler, and E. R. de Oliveira, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

To evaluate the effect of partial substitution of soybean meal with sunflower crushed seeds on the ruminal pH and ammonia of steers supplemented at pasture, we used four animals fitted with permanent ruminal cannula, with initial weight of 300 kg, randomly divided into individual paddocks of *B. brizantha* cv. Marandu in 4 × 4 Latin square and a split-plot; the averages was compared by Tukey test at 5% probability. The supplements were provided in the amount of 0.8% BW/animal/day and consisting of corn, soybean meal and mineral, with 20% of crude protein. The soybean meal was replaced in the proportions of 0, 20, 40, and 60% for sunflower crushed seeds. The estimated ether extract of the supplements were 2.5, 4.7, 7.0, 9.2%, respectively. The determination of pH and ammonia ($N\text{-}NH_3$) occurred in the rumen at 0, 2, 4, 6 and 8 hours after supplementation. There was no effect ($P > 0.05$) for pH according to the level of substitution of soybean meal for sunflower crushed seeds and time of collection. This values had an average of 6.41, exceeding the limits of 6.2, for the occurrence of inhibition of fiber digestion. For contents of $N\text{-}NH_3$ have a significant effect ($P < 0.05$), and a quadratic response ($Y = 15.42 + 2.77x - 0.31x^2$, $r^2 = 0.55$), where the ammonia peaks occurred between 2 and 4 hours after the supplement supplied, with values of 22.56 and 21.40 mg/dL, these may be associated with the solubility of food constituents of the supplements, which have medium to high ruminal degradability. The $N\text{-}NH_3$ values remained above the limits of 10 mg/dL, which maximizing dry matter intake of animals, and digestion for grazing animals. Supplementation of steers on pasture with sunflower crushed seeds in partial replacement of soybean meal does not alter the ruminal pH and ammonia.

Key Words: supplement, pH, ammonia

W370 Effect of supplemental fat sources on rumen fermentation of a high-concentrate diet using a dual-flow continuous culture system. R. C. Araujo*[1], S. Calsamiglia[2], M. Rodríguez-Prado[2], S. Cavini[2], and A. Ferret[2], [1]*ESALQ, Universidade de São Paulo*, *Piracicaba, SP, Brazil*, [2]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

The negative effects of dietary fats on fiber digestion have been used as a criteria to limit the content of fat and degree of unsaturation in ruminants. However, the relevance of reduced fiber digestion in high-concentrate beef diets is questionable. Six 1320-mL dual-flow continuous culture fermenters were used in a complete randomized design (2 periods of 5 d adaptation and 3 d sampling each) to determine the effects of including 4.86% (DM basis) of hydrogenated palm oil (HIDROPALM, Norel S.A., Madrid, Spain), soybean oil, or olive olein on rumen fermentation of a high-concentrate diet. Temperature (38.5°C), and liquid (10%/h) and solid (5%/h) dilution rates were constant. The pH was allowed to fluctuate with an upper limit of 6.4, but average pH was not affected by treatments (average of 5.66). Fermenters were fed 95 g DM/d in 2 equal portions. Diets consisted of 10% barley straw, 45% ground corn, 22.6% barley, 16.2% soybean meal, 1.35% mineral and vitamin premix, and 4.86% supplemental fat source (DM basis). Diets were formulated to achieve 8.0% EE, with similar CP (14.4%) and NDF (16.9%) concentrations (DM basis). Data were analyzed using PROC MIXED of SAS and differences declared at $P < 0.05$ by Tukey test. True DM (average of 69.2%), CP (average of 77.4%), NDF (average of 19.2%) and ADF (average of 13.0%) degradabilities were not affected by treatments. No differences were observed for ammonia (average of 0.03 g/d), non-ammonia (average of 2.76 g/d), dietary (average of 0.50 g/d) and bacterial (average of 2.28 g/d) N flows. Total volatile fatty acids concentration (105.2 m*M*), acetate (average of 37.5%), and propionate (average of 53.0%) proportions as well as the acetate:propionate ratio (average of 0.70) were not affected by treatments. Results indicate that inclusion of soybean oil or olive olein at 4.86% of dietary DM does not affect rumen fermentation of a typical high-concentrate feedlot diet when compared with hydrogenated palm oil.

Key Words: hydrogenated palm oil, olive olein, soybean oil

W371 Dried distillers grains as a protein supplement to cattle consuming Bermudagrass hay. Z. J. Rambo*, J. E. Sawyer, C. L. Skaggs, and T. A. Wickersham, *Texas A&M University*, *College Station*.

We compared 3 protein supplements, cottonseed meal (CSM), dried distillers' grains (DDG), and DDG plus urea (DDGU), in steers fed Bermudagrass hay (7.4% CP). Ruminally and duodenally fistulated steers (463 kg) were used in a 13 × 4 incomplete Latin square with 13 treatments and 4 periods. Treatments were arranged as a 4 × 3 factorial plus a negative control (NC), which received no supplement. The factorial consisted of 4 levels of supplemental N (52, 104, 156, and 208 mg N/kg BW) from each of three sources of supplemental N (CSM, DDG, and DDGU; 49.6, 31.0, and 47.5% CP). Periods were 17 d long, with 10 d for adaptation, and 7 d for collection. A source by N level interaction ($P = 0.05$) was evident for forage OM intake. Forage OM intake increased quadratically ($P = 0.02$) with increasing amounts of CSM, numerically ($P = 0.16$) with increasing amounts of DDGU, and were not influenced by increasing amounts of DDG. Forage OM intake increased from 39.5 g/kg $BW^{0.75}$ for NC to 43.4, 45.3, 45.9, and 41.9 g/kg $BW^{0.75}$ for 52, 104, 156, and 208 mg N/kg BW from CSM, respectively. Total digestible OM intake increased (linear; $P < 0.01$) with increasing level of supplementation for all three sources. Total digestible OM intake was 21.0 g/kg $BW^{0.75}$ for NC and 27.7, 27.3, and 28.4 g/kg $BW^{0.75}$ for CSM, DDG, and DDGU, respectively, at the highest level of N. Organic matter digestion increased (linear; $P \leq 0.03$) for all sources. At the highest level of supplementation OM digestibility averaged 59% versus 53% for steers receiving NC. There was a source by level interaction ($P = 0.03$) for ruminal ammonia concentration. This interaction is explained by linear increases ($P \leq 0.05$) in ammonia concentrations for all three sources; however, increases were greatest for DDGU, followed by CSM, and DDG. When N was provided at 208 mg N/kg BW, ruminal ammonia averaged 4.84, 3.29, and 8.61 m*M* for CSM, DDG, and DDGU, respectively. Dried distillers' grains were effective at increasing total digestible OM intake although the mode of action differed from CSM.

Key Words: Bermudagrass, dried distillers grains, protein

W372 Effect of residual feed intake, gender, and breed composition on blood urea nitrogen concentration in an Angus-Brahman multibreed herd. R. O. Myer*[1] and M. A. Elzo[2], [1]*University of Florida*, *NFREC, Marianna*, [2]*University of Florida*, *Gainesville*.

Blood urea N can be used as an indicator of N use and excretion by an animal. The objective of this research was to asses the effect of residual feed intake (RFI) and post weaning growth rate on blood plasma concentration of urea N (PUN) in 188 bulls, heifers, and steers (mean = 296.5 kg, SD = 37.3 kg) ranging from 100% Angus to 100% Brahman. Calves were assigned to pens in a GrowSafe feeding facility by sire group and

sex, and self-fed a total mixed ration (corn, cottonseed hulls, chopped grass hay, cottonseed meal, molasses, and mineral-vitamin supplement; 90% DM, 14% CP, 1.5 mcal/kg DM NEm, and 0.9 mcal/kg DM NEg). The pre-trial adjustment period lasted 21 d. Individual daily feed intake was collected during the 70 d feeding trial; BW were recorded every 2 wk. Blood (jugular) was drawn on d 0 and d 56 for PUN. Residual feed intake (RFI) was computed as the difference between actual and expected intakes. The RFI groups were high (RFI > mean + 0.5 SD), medium (RFI between mean ± 0.5 SD), and low (RFI < mean - 0.5 SD; SD = 2.0 kg DM/d). Data (PUN) were analyzed using a mixed model. Fixed effects were sex of calf, RFI group, and Brahman fraction of calf; daily feed intake and mean exit velocity were covariates. Random effects were sire and residual. Overall ADG was 1.25 ± 0.26 kg/d. Brahman had higher d 0 and d 56 PUN concentrations than Angus ($P < 0.01$). Sex affected both d 0 and d 56 PUN ($P < 0.01$) concentrations with bulls having the lowest and heifers the highest. Day 0 PUN concentration was negatively associated with ADG ($P < 0.01$). Only d 56 PUN concentration was related to RFI ($P = 0.02$), indicating that more feed efficient animals also had lower PUN.

Key Words: beef cattle, feed efficiency, blood urea

W373 Body composition and tissue deposition in Nellore, F1 Simmental × Nellore and F1 Angus × Nellore steers fed at maintenance or ad libitum with two levels of concentrate in the diet. I. M. Oliveira*, P. V. R. Paulino, M. I. Marcondes, C. A. Neves, S. C. Valadares Filho, E. Detmann, J. Cavali, V. R. M. Couto, and N. K. P. Souza, *Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

The objective of this study was to evaluate the effects of feeding regimen (FR) and genetic group (GG) on body weight gain (EBWG) composition and tissue deposition rate in beef steers. Forty eight steers, 18 months old, were used (20 Nellore (NE), 20 F1 Simmental × Nellore (NS) and 20 F1 Angus × Nellore (NA) with initial BW of 265.6±6.4 kg; 325.3±4.7 kg and 324.6±6.0 kg, respectively). Four animals from each GG were slaughtered at the beginning of the trial in order to estimate initial body composition. A 3 × 3 factorial arrangement was used, being 3 GG and 3 FR (maintenance and ad libitum with 2 concentrate allowance levels: 1 and 2% of BW), with 6 replicates for the ad libitum treatments and 4 animals fed at maintenance. After 136 days on feed all animals were slaughtered and their body and carcass composition were directly determined. There was no interaction ($P > 0.05$) between GG and FR on any variable assessed. Animals fed at maintenance had larger ($P < 0.05$) proportions of bones and muscle in the carcass than the ad libitum fed animals (19.7; 65.11 vs. 15.2%; 60.5% respectively) and less fat (17.97 vs. 23.45%). NE carcass had larger proportion of muscle (62.74%) and smaller ($P < 0.05$) proportion of fat (19.94%) than that observed in the carcass of the crossbred animals (61.10 and 22.19%). The rate of tissue deposition (adipose and muscular) in the carcass was lower in NE animals (168.55 and 152.08 g/d) and in those fed with 1% of concentrate (192.42 and 200.89 g/d) when compared to crossbred animals (229.11 and 259.51 g/d) and those fed with 2% of concentrate (225.43 and 246.50 g/d). Protein accretion in the EBWG was largest ($P < 0.05$) in the animals that received more concentrate (201.51 vs. 166.02 g/d, for 1 and 2% of BW on concentrate, respectively). NE animals deposited less fat and protein ($P < 0.05$) in the EBWG (477.22 and 145.81 g/d, respectively) than crossbred animals (660.68 and 202.75 g/d), while NA had more ($P < 0.05$) fat deposition in the EBWG than NS animals (720.28 vs. 601.08 g/d).

Key Words: feedlot, empty body weight, crossbred cattle

W374 Effect of supplementing a combination of lysine and methionine on growing cattle performance and carcass composition. N. D. Luchini*[1] and M. J. de Veth[2], [1]*Adisseo*, *Alpharetta, GA*, [2]*Balchem Corporation*, *New Hampton, NY*.

Lysine (Lys) and methionine (Met) have been identified as the two amino acids (AA) most limiting growth of beef cattle. The objective of this study was to determine the effect of supplementing metabolizable Lys and Met on growth and carcass composition of growing bulls. One hundred and twenty bulls (333 ± 52 kg; mean ± SD), randomly allocated to one of two treatments were fed a basal diet composed of corn grain, distillers grains, grass hay and a mineral/vitamin premix at 56.8, 14.8, 25.2 and 3.2% DM, respectively with no supplemental AA (CON) or the basal diet with supplemental Lys (4.59 g/kg DM of a lipid-encapsulated Lys (AminoShure-L) and Met (1.24 g/kg DM of the isopropyl ester of 2-hydroxy-4-(methylthio) butanoic acid (Metasmart) (L+M). Using CNCPS V.6.1, estimated concentrations of Lys and Met in metabolizable protein were 5.43% and 1.95% for CON and 6.41% and 2.18% for L+M. The AA products were mixed with ground corn and mixed into the TMR. Daily DMI was recorded for each animal using the GrowSafe feeding system. Bulls were weighed on 2 successive days at the start and end of the study. Ultrasound (for carcass quality) was made at the start and end of the study. Data was analyzed using the PROC Mixed procedure of SAS and pretreatment measurements were used as a covariate. For average daily gain (ADG) and backfat thickness there was an interaction with the covariate (pretreatment body weight (BW) and backfat thickness, respectively) and therefore covariates were treated as categorical variables with two levels (low and high groups). L+M increased BW gain ($P < 0.05$) and tended to increase DMI ($P < 0.15$) compared to CON. ADG (kg/d) increased ($P < 0.01$) in the high BW (1.88 and 1.68) for L+M and CON, respectively There was an increase (17%; $P = 0.02$) in backfat thickness for the high group of animals on L+M treatment compared to the CON. There were no effects of L+M on longissimus muscle area or intramuscular fat. Results indicate that supplementing a balanced ratio of the two most limiting AA can improve growth and ADG of growing bulls.

Key Words: beef cattle, lysine, methionine

W375 Effect of protein and energy supplementation on voluntary intake and ruminal parameters in steers. F. P. Portilho* and L. F. Barros, *University of Brasilia*, *Brasília, DF, Brazil*.

Supplementation may have associative effects (positive or negative) between the forage and concentrate with important consequences on the efficiency of nutrient use. This study aimed to evaluate the effects of different amounts of protein and energy supplement on the behavior of the parameters pH and N-NH3 in rumen fluid and on the voluntary intake and degradability of dry matter (DM) and NDF) of forage in cattle receiving hay Coast-cross (*Cynodon dactylon*). We used five steers with mean of 290 kg of BW, cannulated in the rumen, fed ad libitum hay of Coast-cross, and minerals. Five treatments were evaluated, consisting of 4 levels of daily protein and energy supplementation (0.25, 0.50, 1.00 and 1.50 kg DM to 100 kg BW / day) of corn meal, soybean meal and urea, and one control treatment received only hay and mineral mix ad libitum. Data were collected from voluntary intake, degradability of dry matter and NDF of hay, the pH and N–NH3. The intake was calculated daily by the leftovers. The potential degradation in situ was made according to Mertens (1993). The pH of the samples was measured according to the technique described by Fenner 1965, adapted by VIEIRA (1980). The experimental design used was the Latin square (5 × 5) and analysis were performed using SAS (1990) GLM procedure. The highest level of protein and energy supplementation (1.5 kg DM to 100 kg BW /

day) reduced the pH, reducing ruminal degradation of DM and NDF of Coast-cross hay, however, insufficient to modify intake. The highest concentrations of ruminal N–NH3 were observed at the highest levels of intake of protein-energy supplement (1.0 and 1.5 kg DM to 100 kg BW / day). These levels of supplementation, concentrations of ruminal N–NH3 remained longer near the plateau and decreased slower than the other treatments supplemented. There was no additive effect of intake of different amounts of protein-energy supplement on the intake of DM and NDF of hay. The rumen degradation of DM and NDF was not influenced by intake of protein-energy supplement to the level of 1.0 kg DM to 100 kg BW / day.

Key Words: steers, intake, degradation

W376 Energy requirements adjusted by milk yield of beef cows in Uruguay. V. Gutiérrez Castro*, M. Carriquiry Fossemale, and A. C. Espasandín Mederos, *Facultad de Agronomía, UdelaR*, *Montevideo, Uruguay*.

Maintenance energetic cost is affected by body composition, weight (BW) and metabolic activity of organs, such as mammary gland, therefore, the potential of milk production has been associated with maintenance requirements. Thirty-two beef cows (Hereford, n=10; Angus, n=10; F1, n=12) were used to predict maintenance requirement based on milk yield in grazing conditions. The experiment was carried at the Experimental Station Bernardo Rosengurtt (Cerro Largo, 32°35′S, 4°15′W). Cows grazed native pastures with two different forage allowances average of 10 vs. 6 kg DM/100 kg BW/d for HI and LO, respectively). Milk yield and composition were measured once a month from 30 to 120 days postpartum. Cows were milked and separated from their calves 12 overnight before being milked using an portable machine (previous injection with oxytocin, 10 IU/cow). Milk was weighed and a sample obtained for protein, fat, and lactose analyses. Data were analyzed with a mixed model that included forage allowance, cow and calf breed, calf sex, and forage allowance by breed interaction as fixed effects, cow within breed as a random effect, and days postpartum as a covariate. Cow BW and milk production were affected ($P < 0.05$) by breed and forage allowance. Cow BW was greater for F1 than purebred cows in both HI and LO (average 460 vs. 434 ± 7 for F1 vs. purebred cows, respectively). Milk peak productions were greatest for F1 cows in HI and lowest for purebred cows in LO (9.3, 9.1, 8.4, and 6.1 ± 0.6 kg/d for F1 and purebred cows in HI and LO, respectively). These differences influenced energy requirements during lactation with the greatest values in HI forage allowances (18.7 to 14 Mcal/d and 13.8 to 8.9 Mcal/d from first to fourth month postpartum, for HI and LO, respectively) and F1 cows (18.7 to 14.8 Mcal/d and 17 to 13.3 Mcal/d from first to fourth month postpartum, for crossbred and purebred cows, respectively). Forage allowances affected maintenance requirement adjusted by milk yield by modifying BW and body condition score, and milk production, being only greater for F1 cows in HI forage offers.

Key Words: milk, beef cattle, Mcal/d

W377 Productive performance during fattening phases of Nellore and F1 Nellore x Brahman fed with three different diets. I. S. Silva*, F. A. Barbosa, J. M. S. Diogo, R. A. Mandarino, and F. C. E. Botelho, *Faculty of Agronomy and Veterinary Medicine, University of Brasília - UnB*, *Brasília/DF, Brazil.*

The experiment evaluates productive performance in fattening cattle, divided into two genetic groups and subjected to three diets in a feedlot. The experiment was conducted from August to November 2009, lasting 96 days, 14 days of adaptation of animals. The herd was composed of 42 bulls with an average age of 23 months, 21 breed Nelore (NEL) and 21 crossbreed Nelore × Brahman (NBR). Each genetic group was divided into three diets, with 7 animals each: SIL - corn silage and concentrate (corn grain, soybean meal, soybean hulls, urea and mineral supplement) at a ratio of 25:75 (dry in matter), PEL - exclusive diet of pellets; GRN - diet with whole grain corn and pellets. The experiment was conducted in a completely randomized in a 2 × 3 factorial, divided as follows: NBRSIL, NBRPEL, NBRGRN, NELSIL, NELPEL and NELGRN. In all treatments the food supply was ad libitum divided into three treatments daily. The average initial body weights (BWI) were: 350.7, 350.6, 355.8, 379.2, 375.7, 376.1 kg, for NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN respectively. The final body weights (BWF) averages were: 500.0, 464.4, 479.7, 410.8, 471.9 and 501.5 kg for NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN, respectively. The average hot carcass yield (HCY) was 58.51, 58.44, 57.34, 58.4, 58.61 and 58.05 for NBRSIL, NBRPEL, NBRGRN, NELSIL, NELPEL and NELGRN, respectively. The genotypes and diets did not affect the PI, PF and HCY ($P > 0.05$). The average daily gain (ADG) was 1.346 and 1.219 kg for NEL and NBR, respectively, without differences in the genetic group. There was influence of diet on the weight gain SIL was higher than PEL and similar to the GRN, 1.470, 1.093 and 1,299 kg, respectively ($P < 0.05$). The dry matter intake averaged was 9.25 and 9.65 kg /animal/day for NEL and NBR, respectively. The feed conversion was 7.17 and 8.26 for NEL and NBR, respectively ($P > 0.05$). The genetic group had no influence on average daily gain and hot carcass. The diet affected the average daily gain with better results for SIL and GRN, but had no differences for yield and hot carcass weight.

Key Words: carcass yield, genetic group, weight gain

W378 Effects of feeding monensin or polyclonal antibody preparation against lactate–producing rumen bacteria on blood lipoprotein concentrations of feedlot cattle. J. R. Rochesel*[1,2], F. S. Parra[1], M. D. B. Arrigoni[1], C. L. Martins[1], S. R. Baldin[1], L. M. N. Sarti[1], R. S. Barducci[1], N. R. B. Consolo[3], D. D. Millen[1], R. D. L. Pacheco[1], D. Tomazella[1], A. L. Campanini[1], F. A. S. Miquilin[1], and A. M.Lopes[1], [1]*São Paulo State University (UNESP)*, *Botucatu, São Paulo, Brazil*, [2]*Supported by FAPESP*, *São Paulo, São Paulo, Brazil*, [3]*University of São Paulo (USP)*, *Pirassununga, São Paulo, Brazil*.

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to test the effects of feeding polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria or monensin (MON) on blood lipoprotein concentration of feedlot cattle fed high-concentrate diets. Ninety-six 9-mo-old bullocks (285.9 ± 38.7 kg) were assigned to 24 pens (4 bullocks/pen) and used in a completely randomized design with a 2 x 2 factorial arrangement of treatments using repeated measures over time, replicated 6 times. Factors were inclusion or not of PAP or MON, at a dose of 300 mg•kg^{-1} of DM or at 30 mg•kg^{-1} of DM, respectively. Blood samples were collected from jugular vein of 48 animals (2 bullocks/pen) chosen randomly to evaluate the concentrations of cholesterol (CHL), triglycerides (TRG) and VLDL, LDL and HDL in each phase of feeding: adaptation (ADP), growing (GRO) and finishing (FNS). No significant ($P < 0.05$) PAP and MON main effects or interactions were observed for any of the variables measured. Nevertheless, it was observed ($P < 0.05$) a phase main effect for CHL, HDL, LDL, VLDL and TRG. Bullocks presented greater ($P < 0.05$) concentration of CHL in the GRO and FNS phases when compared to ADP phase (GRO=124.24, FNS=112.02 vs. ADP=68.97 mg•dL^{-1}). Likewise, greater ($P < 0.05$) concentration of HDL was found in the GRO and FNS phases (GRO=76.22, FNS=74.59 vs. ADP=37.13 mg•dL^{-1}). LDL concentration increased ($P < 0.05$) from ADP to GRO phase (27.54 vs. 52.34 mg•dL^{-1}); however, its concentration decreased ($P > 0.05$) in the FNS phase at similar concentrations (31.84 mg•dL^{-1}) as those in ADP phase. Furthermore, VLDL and TG concentrations decreased ($P < 0.05$) in the FNS phase. Concentration of HDL remained unaltered in FNS when compared to GRO phase, while VDLD and LDL concentrations were reduced. Thus, the feed additives tested had no effect on blood lipoproteins concentration; however the concentrations were altered by diet energy level. With respect to blood lipoproteins, feeding PAP may be eventually an alternative to substitute MON.

Key Words: blood, lipoproteins, feed additives

W379 Effects of feeding polyclonal antibody preparations against lactate–producing rumen bacteria or monensin on feeding behavior of feedlot cattle. T. M. Mariani[1,2], R. D. L. Pacheco[1], M. D. B. Arrigoni[1], C. L. Martins[1], S. R. Baldin[1], L. M. N. Sarti[1], R. S. Barducci[1], T. M. Mariani[1], J. R. Ronchesel[1], F. S. Parra[1], D. Tomazella[1], J. P. S. T. Bastos[1], E. S. Ogawa[1], and D. D. Millen*[1], [1]*São Paulo State University (UNESP)*, *Botucatu, São Paulo, Brazil*, [2]*Supported by FAPESP*, *São Paulo, São Paulo, Brazil*, [3]*University of São Paulo (USP)*, *Piracicaba, São Paulo, Brazil*.

This study was designed to test monensin (MON) and polyclonal antibody preparations (PAP) against lactate-producing rumen bacteria on feeding and rumination efficiencies of DM and NDF of Brangus (BR) and Nellore (NE) cattle. The experiment was designed as a 2 × 2 factorial arrangement using repeated measures over time, replicated 4 times (4 bullocks/pen), in which 32 9-mo-old bullocks (254.1 ± 12.7 kg) of each of two breeds (BD) evaluated were fed diets containing either MON at 30 mg•kg^{-1} of DM or PAP at 300 mg•kg^{-1} of DM for 144-d. Measures over time were taken according to the phases evaluated: adaptation (ADP), growing (GRO), finishing 1 (FN1) and finishing 2 (FN2). The level of concentrate fed in those phases was 55%, 70%, 80% and 85%, respectively. Visual appraisal was made every five minutes during 24-h, and the feeding behavior (eating and ruminating times) data collected in min was used to calculate the efficiencies. It was evaluated in min per kilo of DM and NDF the feeding efficiency of DM (FEDM) and NDF (FENDF) and rumination efficiency of DM (REDM) and NDF (RENDF). No significant ($P > 0.05$) feed additive (FA) main effects were observed for any of the efficiencies evaluated. However, it was observed a BD main effect ($P < 0.05$) for some variables, in which BR bullocks presented better FEDM (29.75 vs. 35.65 min•kg^{-1} of DM), REDM (52.07 vs. 62.92 min•kg^{-1} of DM) and RENDF (191.64 vs. 257.43 min•kg^{-1} of DM) when compared to NE cattle. In addition, it was found an interaction ($P < 0.05$) between BD and phases for FENDF, where BR bullocks were more efficient than NE bullocks only in the FN1 (86.79 vs. 141.41 min•kg^{-1} of DM) and FN2 (95.81 vs. 166.66 min•kg^{-1} of DM) phases. FEDM, REDM and RENDF got better ($P < 0.05$) from ADP to FN1 phase; however, bullocks were less efficient ($P < 0.05$) in FN2 when compared to FN1 phase. Bullocks fed PAP presented similar efficiencies when compared to those fed MON. Overall, BR cattle were more efficient than NE in terms of FEDM, REDM and RENDF, and for FENDF when diets contained levels of concentrate of 80% or more.

Key Words: efficiencies, feedlot, Zebu

W380 Effects of feeding polyclonal antibodies preparations against lactate–producing rumen bacteria or monensin on blood gas profile, DMI fluctuations and rumenitis incidence of feedlot cattle. R. D. L. Pacheco*[1,2], D. D. Millen[1], M. D. B. Arrigoni[1], C. L. Martins[1], S. R. Baldin[1,2], L. M. N. Sarti[1], R. S. Barducci[1], T. M. Mariani[1], J. R. Ronchesel[1], F. S. Parra[1], D. P. D. Lanna[3], J. P. S. T. Bastos[1], and G. B. Mourão[3], [1]*São Paulo State University (UNESP)*, *Botucatu, São Paulo, Brazil*, [2]*Supported by FAPESP*, *São Paulo, São Paulo, Brazil*, [3]*University of São Paulo (USP)*, *Piracicaba, São Paulo, Brazil*.

This study was designed to test monensin (MON) and polyclonal antibody preparations (PAP) against lactate-producing rumen bacteria on blood gas profile, DMI fluctuations (DMIF) and rumenitis (RUM) incidence of Brangus (BR) and Nellore (NE) cattle. The experiment was designed as a 2 × 2 factorial arrangement using repeated measures over time, replicated 6 times (4 bullocks/pen), in which 48 9-mo-old bullocks of each of two breeds (BD) evaluated were fed diets containing either MON at 30 mg•kg^{-1} of DM or PAP at 300 mg•kg^{-1} of DM for 112-d. Measures over time were taken according to the phase: adaptation (ADP), growing (GRO) and finishing (FNS). The DMIF was calculated as the difference in DMI between consecutive days on the first four days of GRO and FNS phases. At harvest RUM incidence was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). A significant ($P < 0.01$) feed additives (FA) and BD main effects were found for bicarbonate (PAP = 28.35 vs. MON = 26.72 mmol•L^{-1}; BR = 28.10 vs. NE = 26.96 mmol•L^{-1}), total CO_2 (PAP = 29.67 vs. MON = 27.95 mmol•L^{-1}; BR = 29.38 vs. NE = 28.24 mmol•L^{-1}) and base excess in extracellular fluid (PAP = 4.16 vs. MON = 2.49 mmol•L^{-1}; BR = 3.89 vs. NE = 2.77 mmol•L^{-1}). Likewise, BR cattle and bullocks receiving PAP had ($P < 0.01$) higher blood pH in the ADP phase than NE (7.423 vs. 7.404) and bullocks fed MON (7.427 vs. 7.400), respectively. Bullocks receiving PAP showed greater ($P <$

0.01) DMIF in GRO phase than those fed MON (0.339 vs. 0.243 kg); however, was not observed ($P > 0.05$) any difference between FA in the FNS phase. No significant BD ($P > 0.05$) main effect was found for DMIF. Moreover, NE presented greater ($P < 0.05$) incidence of RUM than BR (2.60 vs. 1.26); on the other hand, no significant FA ($P > 0.05$) main effect was observed. Thus, feeding PAP may be eventually an alternative to MON to reduce the risk of acidosis, because even showing greater DMIF, it improved the blood gas profile without impacting negatively rumen wall epithelia in terms of RUM.

Key Words: feedlot, MON, PAP

W381 Effects of feeding polyclonal antibodies preparations against lactate–producing rumen bacteria or monensin on blood lipoproteins concentrations and fatty acid profile of feedlot cattle. D. D. Millen*[1,2], R. D. L. Pacheco[1], M. D. B. Arrigoni[1], C. L. Martins[1], S. R. Baldin[1], L. M. N. Sarti[1], R. S. Barducci[1], T. M. Mariani[1], J. R. Ronchesel[1], F. S. Parra[1], D. P. D. Lanna[3], J. P. S. T. Bastos[1], G. B. Mourão[3], and A. M. Lopes[1], [1]*São Paulo State University (UNESP)*, *Botucatu, São Paulo, Brazil*, [2]*Supported by FAPESP*, *São Paulo, São Paulo, Brazil*, [3]*University of São Paulo (USP)*, *Piracicaba, São Paulo, Brazil*.

This study was designed to test monensin (MON) and polyclonal antibody preparations (PAP) against lactate-producing rumen bacteria on blood lipoprotein concentrations (BL) and fatty acid profile (FAP) of Brangus (BR) and Nellore (NE) cattle. The experiment was designed as a 2 x 2 factorial arrangement, replicated 6 times (4 bullocks/pen), in which 48 9-mo-old bullocks of each of two breeds (BD) evaluated were fed diets containing either MON at 30 mg•kg^{-1} of DM or PAP at 300 mg•kg^{-1} of DM for 112-d. Before slaughter blood samples for BL analysis were collect from jugular vein. At harvest, samples from s.c. adipose tissue were collected for FAP analysis. No significant ($P > 0.05$) feed additives (FA) main effect was observed for cholesterol concentration in LM and for BL, with the exception of HDL ($P < 0.05$), where bullocks receiving PAP had greater concentrations than those fed MON (59.85 vs. 54.04 mg•dL^{-1}). With respect to BD, NE bullocks presented ($P < 0.01$) lower VLDL concentration. Regarding FAP, no significant ($P > 0.05$) FA and BD main effect was found, with the exception of trans–vaccenic acid, where bullocks receiving MON and BR cattle had greater ($P < 0.05$) concentrations than those fed PAP (2.40 vs. 1.77 g•100g^{-1}) and NE (2.44 vs. 1.73 g•100g^{-1}), respectively. However, it was found significant ($P < 0.05$) interaction between BD and FA for C14:0, C16:0, C18:1, C18:2, CLA, C18:3 n-3, SFA, MUFA, and PUFA. Despite greater ($P < 0.05$) concentration of SFA than NE fed MON, NE bullocks receiving PAP presented greater ($P < 0,05$) concentrations of some UFA including C18:2, C18:3 n-3, PUFA (1.85 vs. 1.61 g•100g^{-1}), and CLA (0.58 vs. 0.49 g•100g^{-1}). On the other hand, feeding MON led to greater ($P < 0.05$) concentrations of C18:1 and MUFA, and lower ($P < 0.05$) C14:0 and C16:0 than PAP in NE bullocks. No differences were detected ($P > 0.05$) between BR cattle fed either FA. Thus, feeding PAP may be an alternative to MON, as feeding PAP increased the concentration of some UFA beneficial to human health, what may have led to greater concentrations of HDL in blood.

Key Words: feedlot, HDL, fatty acid

W382 Economic analysis of beef steer finishing diets containing elevated levels of wet distillers grains with solubles. J. M. Carmack*[1], P. M. Walker[1], J. D. Fehr[1], R. L. Atkinson[2], and L. A. Forster[3], [1]*Department of Agriculture, Illinois State University*, *Normal,*[2]*Animal Science, Food and Nutrition, Southern Illinois University*, *Carbondale,* [3]*Archer Daniels Midland Co*, *Decatur, IL*.

With increased production of ethanol in the Midwest over the past several years, increased supplies of wet distillers grains with solubles (DGS) has created an opportunity to decrease feed costs through their inclusion in finishing diets. This study consisted of an economic analysis (as fed basis) of a feeding trial conducted at Illinois State University in which 140 Angus cross steers were fed diets containing 0, 25, 40 or 70% DGS (percent DM basis). The treatments were: 80 shelled corn/5 soybean meal/15 corn silage (CON), 25 DGS/60 shelled corn/15 corn silage (25 DGS), 40 DGS/45 shelled corn/15 corn silage (40 DGS) and 70 DGS/15 shelled corn/15 corn silage (70 DGS). Seventy head were harvested on d 165 when 90% were estimated to have reached low choice or higher quality grade. The remaining 70 head were harvested on d 200 when 90% were estimated to have reached low choice or higher quality grade. Cost of feedstuffs, expressed as cents/kg were: 2.81:kg shelled corn, 7.54:kg soybean meal, 1.22:kg DGS, 0.59 corn silage, 8.86:kg trace mineralized salt, 4.13:kg limestone and 1.13/hd/d Rumensin/B1 premix. Average $:cwt of carcass was different ($P < 0.05$) with CON = 25DGS = 40DGS > 70DGS. Gross return:steer was lower ($P = 0.01$) for 70 DGS compared to the other treatments with no differences between CON, 25 DGS and 40 DGS diets. Differences were observed ($P < 0.05$) for total cost of feed:steer to harvest with CON > 25DGS > 40DGS > 70DGS. Gross dollar return over feed cost:steer was different ($P = 0.01$) as follows: 25 DGS = 40DGS > 70DGS > CON. Diets containing either 25 or 40% DGS (DM basis) returned more gross dollars over feed cost. Based on the analysis of this study, diets containing higher levels of DGS can return more dollars over feed cost.

Key Words: finishing diets, distillers grains, economic analysis

W383 Interactive effects of yeast and yeast cell wall material on feedlot performance during the receiving period of stressed beef cattle. D. N. Finck*[1], S. L. Parr[1], T. R. Young[1], J. A. Carroll[2], J. R. Corley[3], A. G. Estefan[3], and B. J. Johnson[1], [1]*Texas Tech University, Dept. of Animal and Food Sciences*, *Lubbock,* [2]*USDA-ARS, Livestock Issues Research Unit*, *Lubbock, TX,* [3]*Lesaffre Feed Additives*, *Milwaukee, WI*.

The objectives of this experiment were to determine the effect of live yeast and yeast cell wall supplements on performance and health of cattle during the receiving period. Newly-weaned crossbred steers (n = 184; 9 pens/treatment; initial BW = 203 kg) were blocked by BW and randomly assigned to pen (4 pens/block; 5 or 6 hd/pen). Pens within a block were randomly assigned to one of four treatments: 1) control (CON; no yeast additive), 2) live yeast (LY; 5 g•hd^{-1}•d^{-1} live yeast product), 3) yeast cell wall (YCW; 5 g•hd^{-1}•d^{-1} yeast cell wall product), 4) live yeast + yeast cell wall (LY+YCW; 5 g•hd^{-1}•d^{-1} live yeast and 5 g•hd^{-1}•d^{-1} yeast cell wall). A randomized complete block design was used; data were analyzed either as 4 separate treatments, or treatments 2 and 3 were combined to analyze the overall effect of yeast product inclusion level (0, 5, and 10 g inclusion). Daily DMI was recorded and individual BW were collected every 14 d for the 56 d feeding period. Steers receiving 5 g of LY or YCW showed a 7% numerical increase in ADG and a 7.7 kg increase in BW at d 56. Cumulative DMI was increased ($P < 0.05$) for the LY, YCW, and LY+YCW compared to CON (5.47, 6.02, 5.96, and 5.89 kg/d, respectively). Interim DMI differed for d 0 to 28 (5.03, 5.59, and 5.42 kg/d for 0, 5, or 10 g LY or YCW, respectively; $P = 0.02$, quadratic), d 0 to 42 (5.17, 5.75, and 5.62 kg/d; $P = 0.02$), and cumulative (5.46, 5.99, and 5.88 kg/d; $P = 0.03$). Steer morbidity and mortality were not affected by LY or YCW supplementation ($P > 0.10$). Collectively, these data indicated that the use of LY or YCW additives increase total

feed consumed by the steers during the first 56 d of the feeding period, which contributed to a trend for increased growth rate.

Key Words: receiving, steers, yeast

W384 Condensed tannins supplementation on feedlot performance of growing bulls. R. Barajas*[1], B. J. Cervantes1,2, A. Camacho[1], E. A. Velazquez[1], M. A. Espino[1,3], F. Juarez[1], L. R. Flores[1], and M. Verdugo[1], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*Ganadera Los Migueles SA de CV*, *Culiacan, Sinaloa, Mexico*, [3]*Técnología de Máxima Producción, S.A. de C.V.*, *Culiacan, Sinaloa, Mexico*.

This study was conducted to determine the influence of condensed tannins on feedlot performance of growing bulls. An 84-days feedlot experiment involving sixty bull-calves 183.94 ± 1.2 kg was performed. Animals were blocked by starting weight and in groups of five placed in ground flour pen (2 × 12 m). The experiment was conducted as a randomized complete block design. Treatments were: 1) Feedlot diets without additional tannins containing 0.56% of additional urea (CTRL); 2) Diets with 0.56% additional urea, added with equivalent of 0.20% of condensed tannins (TAN); and 3) Diets with 1.12% additional urea and 5% less canola meal than CTRL diets, and added with equivalent of 0.20% of condensed tannins (TAN-U). Supplementary condensed tannins were provided in form of an extract of condensed tannins from quebracho trees (SilvaFeed ByPRO; Indunor, S.A., Buenos Aires, Argentina). Both diets containing tannins increased ($P < 0.01$) ending weight, and average daily gain respect to bull-calves fed the unsupplemented CTRL diets. The ADG of TAN and TAN+U treatments were 14.8% and 12.6% higher ($P = 0.05$) than control, respectively. DMI was not affected by treatments ($P > 0.15$). Feed/gain ratio was enhanced ($P = 0.08$) by the two tannins contained treatments. TAN treatment reduced ($P < 0.01$) in 18.5% blood urea nitrogen in relationship to CTRL, while BUN values in TAN+U were similar ($P > 0.10$) to CTRL bull-calves. It is concluded, that supplementation with 0.2% of condensed tannins of quebracho trees improves feedlot performance of growing bull.

Key Words: condensed tannins, bulls, feedlot performance

W385 Factors influencing intake: Diet composition and carcass characteristics in finishing yearling steers. M. G. Dib*[1], G. E. Erickson[1], T. J. Klopfenstein[1], and M. L. Spangler[1], [1]*University of Nebraska*, *Lincoln,* [2]*Archer Daniels Midland*, *Columbus, NE*.

The effects of dietary components and carcass characteristics on average daily DMI were investigated using 930 individually fed yearling steers representing 13 experiments using a Calan gate system. Dietary treatments considered in the current study included the percentage of corn, either dry or high moisture (DRC_HMC), byproducts, and forage in the diets. Carcass and performance traits evaluated were 12th rib fat thickness (FAT), marbling score (MARB), calculated USDA Yield Grade (YG), HCW, and ADG. Pearson correlations between DMI and FAT, MARB, YG, HCW, and ADG were 0.16, 0.10, 0.15, 0.48, and 0.50, respectively, and were significant at the 0.05 level. The Mixed procedure of SAS was used to obtain coefficients for the regression of DMI on each carcass trait individually fitting experiment as a random variable. Estimated regression coefficients for FAT, YG, MARB, and HCW were 107.2 mm ±13.5, 1.15 calculated USDA YG ± 0.12, 0.003 marbling score unit±0.0009 and 0.01 kg±0.0004 respectively. The Mixed procedure of SAS was used to obtain regression coefficients for varying levels of the two dietary treatments. The most appropriate model included experiment as a random effect and the nested effect of forage within level of DRC_HMC. The inclusion rate of byproducts was not fit in the model but accounted for the balance of the diets. Nested effects were necessary in the current study given the inability to uncouple differing dietary treatments across experiments. Significant estimates were 0.89 (SE±0.45), 1.86 (SE±0.48), 2.06 (SE±0.48), 1.07 (SE±0.48), 0.61 (SE±0.29), 1.06 (SE±0.38), 0.99 (SE±0.35), 0.70 (SE±0.33) and 1.83 (SE±0.46) for 60:5 (corn:forage), 66:5, 76:5, 65:7, 0:7.5, 52.5:7.5, 67.5:7.5, 82.5:7.5 and 83.5:7.5, respectively ($P < 0.05$). The model accounted for 30% of the variation in DMI. Results show a positive and moderate correlation between DMI and both HCW and ADG and weak relationships with carcass characteristics.

Key Words: carcass traits, dry matter intake, feedlot cattle

W386 Effect of increased Rumensin dosage level and timing on performance of steers fed in confinement to harvest. G. J. Vogel*, *Elanco Animal Health*, *Greenfield, IN*.

One-thousand nine-hundred eleven crossbred steers (357 kg) were randomly allotted to 18 pens in a randomized complete block design of 3 treatments with 6 replications to evaluate the effects of an elevated level of Rumensin. Experimental treatments included: 1) Rumensin fed at 36.4 mg/kg of the diet, (R); 2) Rumensin fed at 48.5 mg/kg of the diet, (HR); and 3) Rumensin fed at 36.4 mg/kg of the diet before reimplant and then at 48.5 mg/kg of the diet post reimplant, (R-HR). All treatments were fed Tylan at 9.5 mg/kg of the diet. Reimplanting occurred on d 65 of the 151 d long study. A 2 ration step-up program was used to adapt steers to the final diet by d 22. Steers were fed 3 times daily. The final diet was formulated to contain 1.65 Mcal NEg/kg, 13.2% CP, 20.9% NDF, 7.9% EE, 0.72% Ca and 0.52% P. Performance parameters were analyzed using PROC MIXED with treatment as fixed effects and block as random effects. HR resulted in an improvement ($P < 0.02$) in feed to gain of 3.8 and 3.2%, respectively, over R and R-HR. Feed intake was not affected by feeding the elevated level of Rumensin. Carcass traits were not affected by treatment. These data indicate that feeding elevated levels of Rumensin for the entire finishing period enhance animal performance.

Table 1. Effect of increased Rumensin dosage

	Treatments				
	R	HR	R-HR	SEM	P
Final BW, kg	595.3	600.8	596.6	4.5	0.66
DM Intake, kg	9.49	9.41	9.49	0.11	0.70
Daily Gain, kg/d	1.58	1.63	1.59	0.03	0.17
Feed / Gain	6.01[a]	5.78[b]	5.97[a]	0.04	0.02

Key Words: Rumensin, monensin level, cattle

W387 Blood gas profile, rumenites and liver abscesses incidences of feedlot bullocks fed high-concentrate diets containing monensin or polyclonal antibodies preparations against lactate-producing rumen bacteria. L. M. N. Sarti*[1,2], R. S. Barducci[1], M. D. B. Arrigoni[1], C. L. Martins[1], S. R. Baldin[1], D. D. Millen[1], R. D. L. Pacheco[1], T. M. Mariani[1], J. R. Ronchesel[1], F. S. Parra[1], A. L. Campanini[1], J. P. S. T. Bastos[1], D. Tomazella[1], and F. A. S. Miquilin[1], [1]*São Paulo State University (UNESP)*, *Botucatu, São Paulo, Brazil*, [2]*Supported by FAPESP*, *São Paulo, São Paulo, Brazil*.

This study was designed to test the effects of polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria or mon-

ensin (MON) on blood gas profile (BGP), rumenites (RUM) and liver abscesses (LVA) incidences of feedlot bullocks fed high concentrate diets. Nine-mo-old Brangus (BR) bullocks (n=72) (261.04 ± 34.73 kg) were assigned to 24 pens (3 bullocks/pen) and used in a completely randomized design with 2 × 2 factorial arrangement of treatments using repeated measures over time, replicated 6 times. Factors were inclusion or not of PAP or MON, at a dose of 300 mg/kg DM or at 30 mg/kg DM, respectively. Measures over time were taken according to the phase: adaptation (ADP), growing (GRO) and finishing (FNS). Blood samples were collected from jugular vein of 48 animals (2 bullocks/pen) chosen randomly. At harvest RUM incidence was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). No significant ($P > 0.05$) PAP or MON main effects were observed for RUM. On the other hand, feeding PAP reduced ($P < 0.01$) the LVA (5.56% vs. 19.44%), but no significant ($P > 0.05$) MON main effect was found (13.89% vs. 11.11%). No significant ($P > 0.05$) MON main effect was observed for any of the BGP variables; however, a significant ($P < 0.01$) PAP main effect was found, in which bullocks receiving PAP presented lower concentrations of bicarbonate (BICARB; 25.83 vs. 27.35 mmol/L), base excess in blood (BEB) and in the extracellular fluid (BEECF) than cattle fed no PAP. A significant ($P < 0.01$) interaction between PAP and MON was observed, in which bullocks receiving both feed additives presented lower blood pH than bullocks fed either PAP or MON (7.38 vs. 7.42 and 7.43, respectively). The phase affected ($P < 0.01$) the concentrations of BICARB, BEB and BEECF, where greater concentrations were observed in the GRO phase, followed by ADP phase, which had greater concentrations than FNS phase. Thus, even reducing the LVA, feeding PAP reduced the buffering capacity of the blood.

Key Words: blood, MON, PAP

W388 Effect of intermittent roughage delivery and roughage type on intake and digestibility by beef steers fed concentrate diets. A. Lopez[1], J. I. Arroquy*[1,2], M. Avila[2], H. Coria[3], and O. Hernandez[3], [1]*CONICET*, *Santiago del Estero, Argentina*, [2]*INTA EEA Santiago del Estero*, *Santiago del Estero, Argentina*, [3]*FAyA - Univ. Nac. Santiago del Estero*, *Santiago del Estero, Argentina*.

The objective of the trial was to evaluate the effect of three roughage delivery systems and two roughage sources on dry matter intake and digestibility by beef steers. Six ruminally fistulated beef steers (BW = 287 ± 35 kg) were used in a six treatments by four periods (6 × 4) trial. Treatment structure was 2 × 3 factorial. First factor was roughage delivery in a total mixed ration (TMR) or the same proportion of ingredients but forage offered once every 3-d (FE3D) or 6-d (FE6D) separated of the concentrate. The second factor consisted of two forages in the ration: middle-quality alfalfa hay (AH) vs. cotton plant byproducts (CPB). Roughage source was incorporated in the diet at 11% and 7% in DM basis to AH and CPB, respectively. There were not roughage delivery system × roughage source interaction for total (TDMI), concentrate (CDMI), and roughage (RDMI) DM intake, as well as total tract DM digestion (DMD) and total digestible DM intake (TDDMI). Roughage delivery system did not affect TDMI (73.6, 90.7, and 85.2 [SEM = 13.9] g/ kg BW0.75 for TMR, FE3D, and FE6D respectively), CDMI (67.0, 82.2, and 74.5 [SEM = 14.4] g/kg BW0.75 for TMR, FE3D, and FE6D respectively), RDMI (6.6, 6.9, and 6.4 g/kg BW0.75 [SEM = 1.1] for TMR, FE3D, and FE6D respectively), TDDMI (51.7, 69.7, and 62.1 g/kg BW0.75 [SEM = 8.7] for TMR, FE3D, and FE6D respectively) and DMD (696.5, 768.4 vs. 729.2 g/kg BW0.75 [SEM = 22.5] for TMR, FE3D, and FE6D respectively). Forage source affected RDMI ($P < 0.01$; 8.8 vs. 4.5 g/ kg BW0.75 [SEM = 0.8]). Whereas TDMI (85.7 vs. 80.6 [SEM = 8.5] g/ kg BW0.75 for AH and CPB respectively), CDMI (76.9 vs. 72.2 [SEM = 8.8] g/kg BW0.75 for AH and CPB respectively), TDDMI (62.9 vs. 59.4 g/kg BW0.75 [SEM = 5.5] for AH and CPB respectively) and DMD (730.9 vs. 731.7 g/kg BW0.75 [SEM = 18.4] for AH and CPB respectively) were similar among roughage sources. According to our experiment it is concluded that roughage portion of a finishing ration might be supplied in a discontinuous way without any effect on DM intake and digestibility utilizing either a middle-quality or low-quality roughage source.

Key Words: roughage delivery, finishing diet, digestibility

W389 Effect of wheat straw level and processing method on site and extent of digestion by cattle consuming finishing feedlot diets. J. A. Valdez*[1], J. O. Chirino[1], M. F. Montaño[1], N. G. Torrentera[1], E. G. Alvarez[1], J. F. Calderón[1], O. M. Manriquez[1], M. A. Lopez[1], V. M. Gonzalez[1], A. Perez[1], J. Salinas[2], and S. A. Soto-Navarro[3], [1]*Universidad Autónoma de Baja California*, *Mexicali, BC, MX*, [2]*Universidad Autónoma de Tamaulipas*, *Victoria, TAM, MX*, [3]*New Mexico State University*, *Las Cruces*.

Holstein steers (n = 4; 216 kg BW), fitted with cannulas in the rumen and proximal duodenum, were used to evaluate wheat straw inclusion level (7 and 14%; DM basis) and roughage processing method (ground vs. pellet) on characteristics of digestion of steam-flaked corn finishing diets. The experimental design was a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments. Wheat straw was ground in a tub grinder with a 3.81 cm screen, while the pellet dimensions were 2 cm long × 0.5 cm diameter. An interaction was detected between straw level and processing method for DM intake ($P < 0.01$). With 14% straw, processing method did not affect ($P = 0.83$) DM intake. With 7% straw, DM intake was lower (2.3%, $P < 0.01$) for pelleted straw than for ground. Digestibility of ruminal OM (6%), true ruminal N digestibility (9.7%), total tract OM (3.9%), and total tract N (4.2%)were greater ($P \leq 0.05$) for diets that contained 7% wheat straw than for those that contained 14%. Ruminal starch digestibility (88.7, and 84.9 ± 0.74%, for pelleted and ground, respectively) was greater ($P = 0.04$) and ruminal pH (5.44, and 5.76 ± 0.22, for pelleted and ground, respectively) was lower ($P = 0.05$) for diets that contained pelleted straw than for those that contained ground straw. Steers fed 7% wheat straw had greater OM and N digestibility. The greater ruminal starch digestibility and lower pH of steers consuming pelleted wheat straw might be responsible for the lower DM intake observed for steers consuming pelleted wheat straw at 7%. Wheat straw is a viable roughage source for feedlot diets. However, when included at low levels, the pelleted form does not elicit the optimum rumen function stimulation.

Key Words: digestion, processing, wheat straw

W390 Milk production response to incremental levels of crude glycerol on diets of grazing dairy cows. R. Echeverria, A. Mackinnon, J. Rotulo, and P. Chilibroste*, *Universidad de la Republica, EEMAC*, *Paysandu, Uruguay*.

An experiment was carried out to determine milk production response of Holstein dairy cows to incremental levels of crude glycerol in the diet. The experiment was conducted between June 15 and July 31 of 2009 at the Experimental Station M. A. Cassinoni, Agronomy Faculty, Republic University, Uruguay. A complete randomize block design was set up and a repeated measurement in time model used to analyze the data. Thirty six autumn-calving dairy cows were blocked by parity, days in milk, milk production and body weight and randomly allocated to one of the following treatments: T0 = control diet, T1= 0.72 kg of glycerol/cow/day and T2= 1.44 kg of glycerol/cow/day. Control diets were based on grazing of a daily strip of oat plus 5 kg DM of a commercial concentrate (18.2% CP, 14% FDA, 25% NDF and 7.3% ASH) offered half at each milking. The crude glycerol (3.5% humidity, 6.9% ash, 1,5% fat and 17% methanol) was mixed with the concentrate just before each milking session. Cows body weight and milk production at the beginning of the experiment were 585±57, 576±67, 564±49 and 24.4±3.2, 24.9±4.3, 26±3.1, for T0, T1 and T2, respectively. Cows fed glycerol (T1 and T2) produced 2.15 L extra milk than control cows (T0=23.5 L; $P < 0.05$). Milk production of glycerol fed cows was not significantly different (25.4 vs. 25.9 for T1 and T2, respectively). A marginal response of 2.6 L extra milk per kg extra of glycerol was obtained with a supplementation of 0.72 kg of glycerol/cow/day. Milk response to crude glycerol in this experiment was higher than responses obtained with other energy sources which open opportunities to the use of this byproduct on diets of dairy cows.

Key Words: crude glycerol, dairy cows, milk production

W391 Nutrient balances in California dairy farms. 2. Factors associated with feed conversion and nitrogen utilization efficiencies. A. R. Castillo*[1], N. Silva del Rio[2], and N. St-Pierre[3], [1]*University of California Cooperative Extension*, *Merced,* [2]*University of California Cooperative Extension*, *Tulare,*[3]*The Ohio State University, Department of Animal Sciences*, *Columbus*.

The aim of this survey was to study dietary factors associated to nitrogen utilization efficiency and feed conversion in lactating cows on commercial farms. Forty dairies in Merced, California (mean 787 ± 592 lactating cows/farm) were characterized based on the total salt (TS) in drinking water (mean 560 ± 343 TS mg/L) and 3.5% fat-corrected milk yield/cow (MY) (mean 31.8 ± 5.2kg/d). TS were estimated by oven drying (105°C, 24 h), and MY and fat content on DHIA information. Duplicated samples of Total Mixed Rations (TMR) were collected on 2 non-consecutive days and wet chemistry analyzed. TMR nutrient content per farm (% DM, NDF, ADF, Lignin, N, Fat, Ash, non-fiber carbohydrates [NFC], was analyzed for each production group (n = 118). CP balance (CPB) was estimated according to the NRC, 2001. DMI per farm was calculated for each lactating group based on the total daily amount of TMR supplied, divided by the number of cows in each feeding group, and corrected by estimated refusal. Pearson correlation analysis was used to study the linear association of feed conversion (FC = MY/DMI) and nitrogen utilization efficiency (NUE = N milk/N intake), and TS, MY, DMI, TMR nutrient content, number of TMR/dairy for lactating cows, and cow number/dairy. A correlations table shown results were only r > 0.30 and $P < 0.05$ are reported. FC and NUE were positively associated to MY, NFC and number of TMR/dairy, and both were negatively associated to CPB. FC and NUE were also negatively associated to dietary NDF and N concentrations, respectively. FC and NUE were high and positive correlated.

Table 1. Correlation table: factors associated with FC and NUE

	MY	%NDF	%N	%NFC	CPB	TMR/dairy	FC
FC	0.88**	–0.33*	ns	0.37*	–0.35*	0.39**	–
NUE	0.70**	ns	–0.64**	0.55**	–0.70**	0.36**	0.86**

ns = non-significant, *$P < 0.05$, **$P < 0.01$.

Key Words: dairy farms, feed conversion, nitrogen utilization efficiency

W392 Effects of glucose, propionate, insulin and gut peptides on neuropeptide mRNA concentrations in the ovine hypothalamus. A. E. Relling*[1,3], K. Lee[1], S. C. Loerch[1], and C. K. Reynolds[2], [1]*The Ohio State University*, [2]*University of Reading*, *UK*, [3]*Universidad Nacional de La Plata*, *Argentina*.

The effects of glucose, propionate, or hormones of splanchnic origin on appetite regulating neuropeptides in the hypothalamus of ruminants have not been described. Therefore, the objective of the present study was to measure the effect in vitro of glucose, propionate, insulin, cholecystokinin (CCK), glucagon-like peptide-1 (GLP-1), or polypeptide YY (PYY) on hypothalamic mRNA concentrations for neuropeptide Y (NPY), agouti-related peptide (AgRP), and proopiomelanocortin (POMC). In an incomplete block design, hypothalamic tissue from market lambs was obtained at slaughter and immediately incubated in culture media for 2 h at 36°C. Treatments included a control Dulbecco's Modified Eagle Medium (DMEM) containing 1 m*M* glucose (n=8) or DMEM with the following additions: 10 m*M* glucose (n=8), 1 m*M* propionate (n=4), 1 n*M* insulin (n=4), 120 pM GLP-1 (n=4), 100 p*M* PYY (n=4), 80 p*M* CCK (n=4), or 10 m*M* glucose plus 1 n*M* insulin (n=4). The abundance of mRNA for NPY, AgRP, and POMC was measured using quantitative reverse transcriptase PCR, and normalized to peptidylprolyl isomerase B mRNA expression in the same sample. Dunnett's mean separation was performed to compare treatment means to the control using mixed model procedures testing the random effects of lamb and block, and the fixed effects of treatment. There was a 4-fold increase in POMC mRNA concentration for the media containing glucose plus insulin ($P < 0.05$), but NPY or AgRP mRNA concentration was not affected. There were no effects observed for the other treatments ($P > 0.20$). Results of the present study suggest insulin is required for effects of glucose on hypothalamic POMC expression in sheep. Therefore, it is likely that the effect on the neuropeptides that regulate dry matter intake are due to additive effects of multiple signals, not solely changes in single hormone and metabolite concentrations.

Key Words: hypothalamic neuropeptides, gut peptides, insulin

W393 Relationship between prolamin content and in situ starch digestibility of barley grain. M. Oba*[1], D. Gibb[2], and T. McAllister[2], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

The objective of this study was to evaluate the relationship between prolamin content and in situ digestibility at various incubation times for barley grain. Forty lots of barley grain samples were obtained from

an agronomic study evaluating effects of seeding and fertilization rates at two locations in Alberta (Beaverlodge and Lacombe). Barley grain was ground through 6-mm screen of the Wiley mill before in situ incubation. In situ digestibility of starch was determined after 0, 3, 6, and 24 h of incubation in the rumen of three non-lactating cows fed a 75% concentrate diet. Barley grain samples from Beaverlodge contained more prolamin than those from Lacombe (2.6 ± 0.1 vs. 1.3 ± 0.1%; $P < 0.001$). However, barley grain from Beaverlodge was greater in 6-h in situ digestibility compared with those from Lacombe (60.1 ± 1.1 vs. 56.7 ± 1.1%; $P < 0.05$). Prolamin content of barley grain (% dry matter) was not correlated to in situ starch digestibility at 0-h ($r = 0.15$), 3-h ($r = -0.17$), or 6-h ($r = 0.19$) of incubation, but was positively correlated to 24-h in situ digestibility ($r = 0.37$; $P = 0.05$). Prolamin content of barley grain was not correlated to in situ DM digestibility at any incubation time. These results indicate that growing environment potentially affects prolamin content of barley grain, but that prolamin in barley grain may not negatively affect starch digestion in the rumen.

Key Words: barley grain, starch digestibility, prolamin

W394 Effect of crude glycerin supplementation on the performance of dairy cows under high altitude tropical conditions. L. Mestra[1], Y. Avellaneda*[1], P. Medina[1], G. Garcia[1], C. Ariza-Nieto[1], D. Cifuentes[1], D. Galindo[1], J. Palomino[1], and G. Afanador[1,2], [1]*CORPOICA*, *Bogota, Colombia*, [2]*Universidad Nacional de Colombia*, *Bogota, Colombia*.

This study evaluated the effect of crude glycerin (10% moisture, 87% glycerol and <0.5% methanol) supplementation on dairy cow performance under grazing conditions during the first stage of lactation. The experiment was carried out at the Colombian Corporation for Agricultural and Livestock Research located at 2650 above mean sea level. Pastures of *Pennisetum clandestinum* + *Lolium perenne* (cutting age, 45 days) sward were grazed by cows in a strip-grazing system. Cows had access to corn silage and an energy-protein nucleus (22.1% CP and 2.0 Mcal/kg NEmilk) which offer was adjusted according to the expected lactation curve. A total of 12 Holstein cows were randomly assigned to three glycerin levels (0, 300, 500 ml/day). Cows were individually weighed every other month. Feed intake and milk production were recorded daily. Additionally milk samples were collected at 0, 90 and 150 days of the study to determine fat, protein and lactose content. Data were analyzed as a completely randomized design with repeated measures over time using the MIXED procedure of SAS (Ver. 9.0, SAS Institute, Cary, NC, USA). Glycerin level did not affect productive performance ($P > 0.05$) of the dairy cows, although cows supplemented with 300 and 500 ml/day increased milk production by 10% and 6.3%, respectively compared to control group. Body weight gain was higher in cows supplemented with glycerin at 300 ml/d (0.108 kg/d) when compared to cows without glycerin (0.067 kg/d). The percentage of lactose was higher ($P < 0.05$) in milk of cows supplemented with crude glycerin compared to control group (4.8% vs. 4.4%). At the end of the experiment (150 days) milk fat showed a tendency ($P = 0.095$) to be higher in the group of cows supplemented with glycerin (3.7%) compared to the control group (3.1%). Thus, it can be concluded that there is a trend in the improvement of milk quality of cows supplemented with crude glycerin.

Key Words: glycerin, dairy cow, milk quality

W395 Effect of the germinated corn on feed intake, milk production, milk quality and blood metabolites of lactating cows. B. W. Kim*[1], J. W. Ju[1], J. K. Choi[2], and J. S. Shin[1], [1]*Kangwon National University*, *Chuncheon, Kangwon-Do, South Korea*, [2]*Dae Han Feed Company*, *Incheon, South Korea*.

This study was conducted to evaluate the effect of germinated corn on the feed intake, milk production, milk quality and blood metabolites of lactating cows. Five lactating cows were randomly assigned to 3 replicates of 3 treatments to determine the effects of feeding 0 (control), 10 (T1), 20% (T2) of the germinated corn in partial replacement of alfalfa hay and commercial concentrate in the diet. The trial lasted for 3 months. The feed intake was not significantly affected. However, the lactating cows fed on the germinated corn consumed more feed: 21.5kg in T1 and 21.7kg in T2 than those in the control (20.9 kg). The T1 and T2 resulted in a 5.8 and 11.1% increase in milk production, respectively, compared to the control ($P < 0.05$). The feed efficiency improvements were observed in treatments with germinated corn by 3.0 and 7.4% in T1 and T2, respectively. No significant difference was found in milk fat and lactose contents, but milk protein and solid-not-fat contents were higher in T1 and T2. The somatic cell counts were significantly lower for the cows fed on the germinated corn (78.67×10^3 /mL in T1 and 79.68×10^3 /mL) than those fed the control diet (158.33×10^3 / mL). Thus, these findings indicate that germinated corn can be useful as feed supplementation for increasing milk production and milk quality of lactating cows.

Key Words: germinated corn, feed intake, lactating cows

W396 Influence of hypocalcemia on plasma biochemical parameters, lipid mobilization, and liver lipid infiltration in cows. W. G. Chamberlin*, J. R. Middleton, J. N. Spain, G. C. Johnson, and M. R. Ellersieck, *University of Missouri*, *Columbia*.

This study was conducted to evaluate the effects of calcium status at calving on plasma metabolites and liver lipid infiltration in Holsteins. One hundred multiparous Holsteins were assigned to one of two groups 1) hypocalcemic (n=51; ionized calcium [iCa] <1.0 mmol/L) or 2) normocalcemic (n=49; iCa >1.0 mmol/L) based on whole blood iCa concentrations at calving. Cows were blocked by parity and calving date (3.5 for hypocalcemic, 2.8 for normocalcemic). Blood samples were collected to measure iCa, NEFA, and serum chemistry profiles at −14d, calving, 3d, 7d, 14d, 21d, and 35d. Liver biopsies were collected from 22 cows (8 hypocalcemic and 14 normocalcemic) on the day of calving, and 7 and 35 days postpartum for analysis of lipid infiltration in the hepatocytes. Data are reported as LSMeans ± SE. On day 0, [iCa] differed with hypocalcemic cows having lower whole blood [iCa] (0.88 ± 0.01 mmol/L) versus normocalcemic cows (1.08 ± 0.01 mmol/L; $P < 0.0001$). Hypocalcemic cows also had lower mean total plasma calcium concentrations on day 0 than normocalcemic cows (7.03 ± 0.08 mg/dl vs. 8.20 ± 0.08 mg/dL; $P < 0.0001$). Hypocalcemic cows had lower plasma phosphorus levels on days 0 (3.96 ± 0.16 mg/dL), 7 (5.33 ± 0.17 mg/dL), 14 (5.10 ± 0.18 mg/dL), and 21 (5.75 ± 0.18 mg/dL) versus normocalcemic cows on days 0 (4.7 ± 0.17 mg/dL; $P = 0.002$), 7 (5.81 ± 0.17 mg/dL; $P = 0.05$), 14 (5.67 ± 0.18 mg/dL; $P = 0.03$), and 21 (6.28 ± 0.18 mg/dL; $P = 0.04$). Hypocalcemic cows had significantly higher mean NEFA concentrations on days 0 (1034.4 ± 61.04 uEq/L) and 21 (613.42 ± 61.42 uEq/L) versus normocalcemic cows on days 0 (823.17 ± 62.65 uEq/L; $P = 0.01$) and 21 (444.67 ± 63.48 uEq/L; $P = 0.02$). Hypocalcemic cows also had more lipid in the hepatocytes on day 35 (17.33 ± 3.36%) than normocalcemic cows (6.98 ± 2.6%; P = 0.02). No differences were detected between groups for total or direct bilirubin concentration, gamma glutamyl transferase or aspartate aminotransferase activity ($P > 0.05$). These data provide evidence of an association between calcium status at calving, fat mobilization, and liver lipid infiltration.

Key Words: transition, hypocalcemia, liver

W397 Effects of a low energy diet prepartum on subclinical ketosis in dairy cows. L. A. Vickers*[1], D. M. Weary[1], D. M. Veira[2], and M. A. G. von Keyserlingk[1], [1]*Animal Welfare Program, University of British Columbia*, *Vancouver, British Columbia, Canada*, [2]*Agriculture and Agri-Food Canada*, *Agassiz, British Columbia, Canada*.

Despite decades of research the dairy industry remains challenged with high rates of disease after calving, often attributed to prolonged periods of negative energy balance (NEB). In an effort to reduce NEB it is common practice to provide an energy dense diet 3 wks before calving, but this may lead to over consumption of energy and actually increase the risk of metabolic disease post-partum. The aim of this trial was to compare the metabolic status of transition cows on a traditional pre-calving diet (NE_L=1.45 Mcal/kg) versus a low energy, high forage diet (NE_L=1.34 Mcal/kg). Cows were randomly assigned to either the control diet (cows were switched to the close up ration 3 wks prepartum) or the treatment diet (cows remained on the low energy diet until parturition). After parturition, all cows were fed a common lactation diet (NE_L =1.65 Mcal/kg). Treatment groups were balanced for parity, previous 305-day milk production and body condition score. DMI was measured daily from 3 wks before to 2 wks after calving for 78 multiparous Holstein cows. Blood BHBA was measured daily for 10 d after calving. The MIXED procedure in SAS was used to test the fixed effect of treatment on BHBA for each day postpartum, and on DMI in the prepartum and the postpartum period. Cows on the low energy diet prepartum had lower BHBA levels than did control cows (0.48 ± 0.03 vs. 0.65 ± 0.03mmol/L; $P < 0.0001$). Using a threshold of $1.0 \leq$ BHBA ≤ 1.4 mmol/L, fewer cows on the low energy diet prepartum were diagnosed as having subclinical ketosis compared to cows on the control diet (4.8% vs. 20.6%; χ^2 =7.17, $P = 0.007$). Cows on the low energy diet had lower DMI compared to the cows on the close up diet (13.57 ± 0.09 kg/d vs. 16.45 ± 0.12 kg/d; $P < 0.05$) and consumed slightly less DM in the first 2 wks postpartum (18.64 ± 0.41 vs. 17.65 ± 0.40 kg/d; $P < 0.05$). Feeding a low energy diet before calving can reduce the risk of subclinical ketosis.

Key Words: transition diets, intake, subclinical ketosis

W398 Impacts of maternal selenium supply and nutritional plane on offspring intestinal vascularity. R. D. Yunusova*, A. M. Meyer, T. L. Neville, K. A. Vonnahme, C. J. Hammer, J. J. Reed, D. A. Redmer, L. P. Reynolds, and J. S. Caton, *Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University*, *Fargo*.

Objectives were to investigate the effects of maternal nutritional plane and Se supply during gestation on offspring intestinal vascularity. Rambouillet ewe lambs (n = 82 in Exp. 1, n = 84 in Exp. 2; approximately 240 d of age; 52 kg BW at breeding) were allocated to a 2 × 3 factorial. Treatments included dietary Se (adequate Se [ASe, 9.5 (Exp.1) or 11.5 (Exp. 2) μg/kg BW] or high Se [HSe, 81.8 (Exp. 1) or 77.0 (Exp. 2) μg/kg BW]) initiated at breeding and nutritional plane (60% [RES], 100% [CON], and 140% [HIGH] of requirements) initiated at d 50 (Exp. 1) or d 40 (Exp. 2) of gestation. Ewes were fed pelleted diets and housed individually indoors. At parturition, lambs were immediately removed and fed artificial colostrum for the first 20 h followed by ad libitum milk replacer. At 180 ± 2 d (Exp. 1) and 20 d (Exp. 2) of age lambs were euthanized and tissues were harvested. Collected jejunal tissues were perfusion fixed with Carnoy's solution, paraffin embedded, and vascular structures were visualized microscopically. Data were analyzed for effects of Se supply, nutritional plane, and their interaction. In Exp. 1, capillary area density (% tissue) was greater ($P = 0.08$) in 180-d old offspring from ewes fed HSe compared with ASe (15.3 vs. 13.8 ± 0.6%, respectively). In addition, area per capillary (μm^2) was greater ($P \leq 0.09$) in CON compared with RES. In Exp. 2, capillary surface density ($\mu m/\mu m^2$) was greater ($P \leq 0.05$) in 20-d old offspring from ewes fed CON than RES. Maternal nutritional plane tended ($P \leq 0.11$) to alter total small intestinal vascularity (mL), with lambs from CON being greater than RES. Area per capillary was affected by the interaction of Se × nutritional plane ($P = 0.09$). In offspring from ewes fed ASe, RES had greater area per capillary than CON and HIGH, whereas area per capillary was not affected by nutritional plane in HSe offspring. In conclusion, maternal Se supply and nutritional plane during gestation resulted in measurable changes in offspring intestinal vascularity at both 20 and 180 d of age. Additional work is needed to determine impacts on intestinal function and nutrient uptake.

Key Words: intestine, maternal nutrition, selenium

W399 Performance of high-yielding dairy cows supplemented with fat or concentrate under hot and humid climates. U. Moallem*[1], G. Altmark[2], H. Lehrer[1], and A. Arieli[2], [1]*Agriculture Research Organization*, *Bet Dagan, Israel*, [2]*Faculty of Agriculture, Hebrew University*, *Rehovot, Israel*.

Multiparous Israeli-Holstein mid-lactation cows were used to examine the effects of energy source under hot and humid conditions on performance, metabolic heat production (MHP) and efficiency. Cows (n = 42) were individually fed and assigned into 3 groups: 1) control - were fed a lactating-cow ration (1.75 Mcal NEL/kg DM); 2) HG - supplemented with 0.825 kg/d per cow of ground corn grain (2.7% of diet); 3) HF - supplemented with 0.300 kg/d per cow of calcium salts of fatty acids (1.5% of diet). Indirect MHP was calculated as: metabolizable energy intake – (energy output in milk + energy retention in body-mass + energy for maintenance). Data were analyzed as repeated measurements using the PROC MIXED procedure of SAS. Mean daily maximum ambient temperature, relative humidity and temperature-humidity index (THI) were 31.5°C, 86.6% and 76.8, respectively. DMI was lower in HF and HG than in controls, and milk yields were higher in the control group than in HG. Milk-fat percentage was 0.38 units higher and fat yields were 11% greater in HF than in HG. Fat-corrected milk (FCM) yield was 5.5% higher in HF than in HG, but not than in control. Body weight gain (kg/d) of the HG cows tended to be higher than that of the others. Efficiency of conversion of DM or energy intake to milk and FCM was higher in HF than in other groups; however, when taking the energy retention in body-mass into account, no difference in energy utilization between HF and HG were observed. Indirect MHP was similar in HG and HF cows, and lower than in controls. HF cows channeled more metabolizable energy for milk production (43.1, 40.5 and 41.6% for HF, HG and control groups, respectively). In contrast, HG cows directed more energy for body-mass retention (1.89, 0.53, and 0.99% for HG, HF and control, respectively). In conclusion, increasing the energy density in diets of heat-stressed mid-lactation cows over 1.75 Mcal/kg DM was not effective in enhancing production; however, HF increased the efficiency for milk production. Moreover, HF cows prioritized milk-fat production, whereas HG cows channeled more energy for body-mass retention.

Key Words: heat stress, fat supplementation, energy partitioning

W400 Concentrations of plasma metabolites and hormones in periparturient Holstein cows fed two sources of fat. C. Caldari-Torres[2], E. D'Agosto[1], M. C. Perdomo[1], C. R. Staples[1], and L. Badinga*[1], [1]*University of Florida*, *Gainesville,* [2]*Virginia Tech*, *Blacksburg*.

This study examined the effect of feeding diets enriched in saturated fatty acids (SFA; RBF Cargill, 91% saturated fat, 1.5% of DM) or linoleic acid (LA, Prequel 21, Virtus Nutrition, 63% n-6 FA, 1.8% of DM) to transition Holstein cows (n = 18) on plasma metabolites and hormones related to energy metabolism. Dietary treatments were initiated at approximately 28 d prior to calculated calving date and continued through 49 d postpartum. Blood samples were collected weekly beginning 1 wk before estimated calving date through 7 wk postpartum. Plasma NEFA concentration increased ($P < 0.01$) between wk 1 before (231 ± 88 μeq/L) and wk 1 after parturition (829 ± 80 μeq/L) and returned to pre-calving concentrations by wk 7 postpartum (404 ± 80 μeq/L). Blood NEFA concentrations in cows consuming the LA-enriched diet tended to be lower ($P = 0.06$) than those receiving the SFA-supplemented diet at wk 3 and 4 postpartum. Blood glucose concentrations were consistently greater ($P < 0.01$) across wk in cows fed the LA-enriched diet compared to those consuming the SFA-supplemented diet. Concentrations of plasma insulin were only numerically greater for cows fed additional LA (0.73 vs. 0.67 ng/mL). Mean peripheral concentration of IGF-I decreased ($P < 0.01$) from 130.8 ± 14.7 ng/mL at 1 wk before calving to 60.9 ± 13.4 ng/mL at 2 wk after calving, and then increased to 119.8 ± 13.4 ng/mL by wk 7 postpartum. Pre- and postpartum plasma IGF-I concentrations were greater ($P < 0.01$) in Holstein cows fed the LA-enriched diet than those consuming the isocaloric control diet supplemented with SFA. Plasma IGF-I concentration at wk 7 postpartum was positively correlated (r = 0.58, $P < 0.01$) with conception rate to first insemination. Results indicate that peripartum supplementation of LA may improve the metabolic status and increase the risk of pregnancy of early postpartum dairy cows.

Key Words: fat, hormone, cattle

W401 Weaning dairy cows to a new diet: The effectiveness of a gradual dry-off procedure. K. L. Proudfoot*, D. M. Weary, and M. A. G. von Keyserlingk, *University of British Columbia*, *Vancouver, British Columbia, Canada*.

Gradual dietary transitions for animals are typically favored over abrupt switches. However, a common method to end the lactation of a dairy cow (i.e. dry-off) is to abruptly switch cows from a high to low energy diet. Gradual weaning at dry-off may be beneficial, but no work has assessed if it is equally effective at reducing milk output. Here we assessed the effect of a gradual versus abrupt switch from a lactating cow diet (60:40 forage:concentrate ratio) to grass hay on dry matter intake (DMI) and milk yield. Four pens of 6 cows were followed for 14d. Cows were paired, with one cow from each of 2 treatments based on parity and previous milk yield. During the first 2d (baseline) both treatments were fed the same lactation diet of 60% forage. Cows on the gradual treatment were switched to a diet 10% higher in forage every 2d until d9; cows on the abrupt treatment were switched directly to 100% forage on d9. Each cow had access to one feed bin that recorded DMI. Data were summarized into 5 periods: Four 2-d periods before treatments were switched to 100% forage and one 4-d period following the switch (d10 to 14). Differences between treatments were tested using Proc Mixed in SAS with the feed bin was the experimental unit and period as a repeated measure. The model included pair, pen, period, treatment and period × treatment interaction. No baseline differences were detected between cows on the gradual and abrupt treatment for milk yield (15.5±1.2 vs. 14.8±1.2 kg/d, $P = 0.74$) or DMI (18.0±0.5 vs. 17.7±0.5 kg/d, $P = 0.67$). The gradual increase in % forage resulted in treatment × period interactions for both milk yield ($P < 0.01$) and DMI ($P < 0.01$); as % forage in the diet increased cows on the gradual treatment produced less milk and had lower DMI than did the cows on the abrupt treatment. After both groups were switched to the 100% forage diet no differences were detected between cows on the gradual and abrupt treatment for milk yield (9.3±0.9 vs. 7.5±0.9 kg/d, $P = 0.17$) or DMI (10.4±0.4 vs. 10.2±0.4 kg/d, $P = 0.64$). These results indicate that a gradual dietary transition at dry-off is as effective at reducing DMI and milk yield as an abrupt switch in diet.

Key Words: dry-off, weaning

W402 Effects of feeding different levels of guar meal on performance of Holstein dairy cows. A. Vatandoust[1], A. A. Naserian*[2], F. Boldaje[1], and S. Zerhdaran[1], [1]*University of Gorgan*, *Gorgan, Iran*, [2]*University of Mashhad*, *Mashhad, Iran*.

Eight multiparous (n = 2) early lactating Holstein cows were used in a 4 × 4 Latin square design to determine effects of different levels of guar meal on the performance of dairy cows. Treatments were including 4 levels of guar meal: T1) 0, T2) 4, T3) 8, T4) 12% of DM that substitute to soybean meal. Treatments effect on DMI (kg/d) were not significant ($P > 0.05$). Milk yield were increased for cows fed T2 compared with other treatments (43.392, 46.480, 44.100 and 43.080, respectively) ($P < 0.05$). Milk fat (%) was increased for T2 compared with T3 and T4 ($P < 0.05$), but had no difference between T1 and T2 ($P > 0.05$). Milk protein was not influenced by treatments ($P > 0.05$). Treatments effect on pH were significant ($P < 0.05$), cows fed T2 had lower pH than control (6.58 vs. 6.36). It was concluded that substitution 4% of soybean meal with guar meal had the best effect on performance.

Table 1. Effects of different levels of guar meal on DMI, rumen pH, milk yield and composition

	T1	T2	T3	T4	SE	P-value
DMI (kg/d)	26.805	26.975	26.717	26.968	0.445	>0.05
Milk yield (kg/d)	43.392b	46.480a	44.100b	43.080b	0.806	<0.05
Milk Fat (%)	3.717ab	4.101a	3.380b	3.424b	0.162	<0.05
Milk protein (%)	2.803	2.592	2.688	2.715	0.110	>0.05
rumen pH	6.588a	6.367b	6.381ab	6.406ab	0.070	<0.05

T1, T2, T3 and T4= levels of guar meal (0, 4, 8 and 12% of DM respectively). SE= standard error of means.

Key Words: guar meal, lactating Holstein cow, soybean meal

W403 Feed sorting and feeding behavior of transition dairy cows fed glycerol as a replacement for corn. E. R. Carvalho*, N. S. Schmelz, H. White, and S. S. Donkin, *Purdue University*, *West Lafayette, IN*.

Feed sorting is a natural behavior of dairy cows that can result in inconsistencies in nutritive value of a TMR. The objective of this work was to study the effects of glycerol on the feed sorting and feeding behavior of transition dairy cows. Twenty-six multiparous Holstein cows were paired by expected calving date and fed diets containing either high moisture corn or glycerol from −28 through +56 days relative to calving (DRTC). Glycerol was included at 11.5 and 10.8% of the ration DM for the pre- and post-partum diets, respectively. Cow activity was continuously videotaped for 24 h on −17, −10, +8, +15 and +50 DRTC. Feeding behavior was evaluated for 1 h intervals at 0, 1, 5.5, and 11 h relative to feed delivery and feed sorting was determined during the next 24-h period by measuring the particle size distribution of feed consumed at 4, 8, 12 and 24 h post feeding. The TMR at feeding and

at each time post feeding was size separated across 18, 9, and 1.18 mm screens and a bottom pan to yield long, medium, short, and fine particles, respectively. Adding glycerol to the prepartum diet increased ($P \leq 0.05$) the DM% retained as long particles and reduced ($P \leq 0.05$) short and fine particles but did not change the medium particles ($P \geq 0.05$). Feed intake did not differ ($P \geq 0.05$) between diets and was 14.7 ± 0.4 and 20.2 ± 0.5 kg/d for the pre- and post-partum intervals, respectively. Glycerol increased ($P \leq 0.05$) the preference for long particles during the prepartum period (17.8 vs. 9.2%, glycerol vs. control) and increased ($P \leq 0.05$) sorting against short (37.3 vs. 42%, glycerol vs. control) and fine particles (13.6 vs. 17.9%, glycerol vs. control). There was no effect of glycerol on preference for medium particles ($P \geq 0.05$). There was no effect ($P \geq 0.05$) of diet on feed sorting after parturition as well as on feeding behavior during the whole study. The data indicate that although glycerol in transition diets has no effect on overall DMI, there is increased preference for long particles that occurs during the prepartum interval.

Key Words: glycerol, sorting, transition cows

W404 Impact of climate on chemical composition and in vitro organic matter digestibility of semi-arid barley grain varieties determined by gas production technique. E. Abdi Ghezeljeh[1,2], M. Danesh Mesgaran*[1], H. Nasiri Moghaddam[1], H. Fazeli[3], and A. R. Vakili[1], [1]*Ferdowsi University of Mashhad*, *Iran*, [2]*East Azarbaijan Research Center for Agriculture and Natural resources*, *Tabriz, Iran*, [3]*Animal Science Research Institute*, *Karaj, Iran*.

The objective of this study was to investigate the effect of three semi-arid climates (cold, moderate and warm with the annual temperature range of –20 to 22, –2 to 24, and 2 to 35°C respectively) on crude protein (CP), starch (ST), soluble sugar (SC), bulk density, acid detergent fiber (ADF) and organic matter digestibility (OMD) of sixteen barley grain varieties obtained in year 2008 (10 samples per each variety). Samples were ground (1 mm) and the chemical compositions were determined as proposed by standard methods. Three ruminally fistulated sheep (49.5 ± 2.5 kg) were used as rumen liquor donor for gas production technique. The animals were fed 0.8 kg DM alfalfa hay and 0.5 kg DM concentrate (165 g CP/kg of DM). Rumen fluid was collected before the morning feeding and strained through 4 layers of cheesecloth into a CO_2-filled flask. In vitro incubation of the samples was done using a manual pressure transducer technique. Approximately 200 mg of each sample was weighed into 120 ml serum bottles (n= 4). The bottles were pre-warmed at 39°C before the injection of 30 ml rumen fluid-buffer mixture into each bottle followed by incubation in a water bath at 39°C. Gas produced were recorded at 72 h after the incubation. These data were used to estimate the organic matter digestibility of the samples. Starch content of cold region varieties was significantly ($P < 0.05$) higher (65.65%) than those of warm region (55.29). The samples obtained from the warm climate had the highest amount of crude protein (11.68%), while it was the lowest (10.57%) in the cold region samples. Soluble sugar contents of moderate climate varieties was more than the cold and warm climate samples and the differences were significant ($P < 0.001$). Varieties of the cold and warm climates had the highest (80.03%) and the lowest (78.03%) organic matter digestibility ($P < 0.05$), respectively.

Key Words: barley grain, climate, digestibility

W405 Effect of flax oil and flax hulls on mRNA abundance of antioxidant enzymes and lipogenic-related genes in the mammary gland of dairy cows. M. F. Palin*, H. V. Petit, D. Beaudry, C. Côrtes, N. Gagnon, P. Lacasse, and C. Benchaar, *Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada*, *Sherbrooke, Quebec, Canada*.

Flax oil is a good source of n-3 fatty acids and flax hulls are rich in plant lignans which are strong antioxidants. Flax lignans induce the expression of peroxisome proliferator-activated receptor gamma (PPARG) in 3T3-L1 adipocytes and feeding rats with flax seed upregulates hepatic expression of antioxidant enzymes such as superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GPX). In this study, we determined the effect of dietary flax oil and/or flax hulls on mRNA levels of antioxidant enzymes (CAT, GPX1, GPX3, SOD1, SOD2 and SOD3) and lipogenic-related genes (acetyl-Coenzyme A carboxylase alpha (ACACA), fatty acid synthase (FASN), lipoprotein lipase (LPL), PPARG1, PPARG2, stearoyl-CoA desaturase (SCD) and sterol regulatory element binding transcription factor 1 (SREBP1c)) in the mammary gland of dairy cows. Eight Holstein cows were assigned to 4 dietary treatments in a double 4 × 4 Latin square design (21-d periods). Treatments were a control diet without flax products (CO), CO with 500 g/d flax oil infused in the abomasum (CO500), CO with 10% flax hulls in the DM (HU) and HU with 500 g/d flax oil infused in the abomasum (HU500). Biopsies of the mammary gland were taken on d 21 of each period. Relative quantitation of gene expression was performed using real-time PCR analyses and the comparative CT method. Addition of flax hulls increased mRNA abundance of ACACA, FASN, LPL, PPARG1, SCD and SREBP1c ($P < 0.05$) genes in the mammary gland and flax oil reduced mRNA abundance of the same genes ($P < 0.05$). The mRNA level of CAT, GPX1, GPX3, SOD1 and SOD3 decreased ($P < 0.05$) with flax oil addition. Flax hulls reduced ($P < 0.05$) mRNA abundance of GPX3, SOD2 and SOD3 genes. In conclusion, flax oil and flax hulls can modulate the expression of genes in the mammary gland of cows. However, contrasting effects were observed with flax oil reducing, while flax hulls increasing mRNA abundance of lipogenic-related genes

Key Words: flaxseed, gene expression, dairy cows

W406 An effective method for total RNA isolation from ruminal contents. P. Wang*[1,2], M. Qi[2], L. B. Selinger[1], T. A. McAllister[2], and R. J. Forster[2], [1]*University of Lethbridge*, *Lethbridge, AB, Canada*, [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre*, *Lethbridge, AB, Canada*.

Gene expression analyses including RT-PCR, microarrays and metatranscriptomics are techniques that could significantly expand our understanding of the rumen microbial ecosystem. The ability to isolate and stabilize representative RNA samples is critical to obtaining reliable results in all of these procedures. In this study, we established an improved RNA isolation method for extracting high quality total RNA from both liquid and solid phases of ruminal contents. This method is based on liquid nitrogen-mortar disruption and acid guanidinium-phenol-chloroform extraction combined with column purification. Yield of total RNA using this procedure was as high as 150 μg per gram of ruminal content. The typical large subunit/small subunit (LS/SS) rRNA ratio ranged from 1.8 to 2.0 with an RNA integrity number (Agilent) greater than 8.5. The rRNA profile associated with solid ruminal contents was more complex than that associated with the fluid, exhibiting broader rRNA peaks with discrete shoulders. This result is consistent with the isolation of both prokaryotic and eukaryotic rRNA from the particle-associated microbial consortia. The addition of RNAprotect reagent (Qiagen) to the samples resulted in partially degraded RNA, with LS/SS rRNA ratio lower than 1.0, and noticeable smearing of the RNA bands upon electrophoresis. We therefore recommend that this reagent not be used for the isolation of RNA from rumen samples. The integrity of total RNA isolated by our optimized procedure was tested by

reverse transcription PCR. We detected three *Fibrobacter succinogenes* S85 glycoside hydrolase transcripts: (*celF*, *cel3* and *xynD*) from RNA isolated from the solid phase of ruminal contents. Our research team is currently applying this new technique to obtain high quality ruminal RNA to characterize the rumen microbiome on a metatranscriptomics level, using next generation sequencing.

Key Words: total RNA, rumen, RNA quality

W407 Supplementation of embryo recipients heifers with rumen bypass fat. H. O. Patino*, J. C. C. Angel, M. M. H. Ramirez, R. M. Gregory, and D. d. Ré, *Universidade Federal de Rio Grande do Sul*, *Porto Alegre, RS, Brazil*.

Forty-four Angus × Hereford embryo recipients heifers (385 kg average body weight) were used in a completely randomized design to evaluate the effect of bypass fat supplementation on performance and plasma parameters. Embryo recipient heifers were kept in the same paddock of improved native pasture and individually feeding daily with isocaloric energy supplements. The treatments were: functional supplement, with inclusion of 150g of calcium soaps of fatty acids (CSFA)(Megalac-E); energy supplement, without inclusion of calcium soaps and without supplementation. Heifers estrus synchronization was performed using two PGF2α doses with an interval of 11 days. Seven days after estrus detection embryo transfer was performed. Blood samples were collected on the embryo transfer day and pregnancy confirmation day as well. The supplement type offered did not affect pregnant rate (34%) and plasma insulin concentration (14.1 μIU/mL; $P > 0.05$). Between the date of embryo transfer and the date of pregnancy confirmation heifers supplemented with CSFA had a 49% increase in ADG in relationship to heifers supplemented with energy supplement and without supplementation (0.90 vs. 0.64 vs. 0.57 kg/day; $P < 0.05$). On embryo transfer day and pregnancy confirmation day heifers supplemented with CSFA had a 17% and 33% increase in plasma cholesterol concentration in relationship to heifers supplemented with energy supplement and without supplementation (171 vs. 147 vs. 147 mg/dL; 198 vs. 154 vs. 143 mg/dL; $P < 0.05$). On embryo transfer day and pregnancy confirmation day heifers supplemented with CSFA had a 48% and 71% increase in plasma progesterone concentration in relationship to heifers supplemented with energy supplement and without supplementation (5.4 vs. 3.6 vs. 3.7 ng/dL; 7.3 vs. 5.8 vs. 4.3 ng/dL; $P < 0.05$). Daily weight gain, plasma cholesterol and progesterone concentration of embryo recipient heifers were increased by inclusion of calcium soaps of fatty acids into energy supplements.

Key Words: progesterone, cholesterol, pregnancy rate

W408 Effects of infusing different doses of free α-linolenic acid to the duodenum on the immune function of lactating dairy cows. P. Sun, J. Q. Wang*, G. Yang, and Khas-Erdene, *State Key Laboratory of Animal Nutrition*, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*.

The purpose of this study was to determine the effects of infused a high C18:3 free fatty acid mixture to duodenum on the immune function of dairy cows. A crossover design was adopted and four primiparous Chinese Holstein cows (BW = 476 ± 6 kg, DIM = 100 ± 2 d) fitted with duodenal cannulas were divided into two treatments, in which homogenized aqueous mixtures of α-linolenic acid (LNA; 82.4% cis-9, cis-12, cis-15 18:3; 14.7% cis-9, cis-12 18:2; 2.8% cis-9 18:1) or control containing only the emulsifying ingredients were used. The control infusate contained 15 g/d of xanthan gum, 5 g/d sodium alginate, and 25 g/d of Tween 80 in 10 liters of water. Each period lasted 5 wk, during which two cows received 0, 100, 200, 300, and 400 g/d of LNA for 1 wk each, and the other two cows received only the carrier infusate. Blood was collected at the end day of each infusion amount and concentrations of serum IgA, IgG, IgM, prostaglandin E2 (PGE2) and Th1/Th2 cytokines were determined using bovine ELISA Kit. The results showed that increasing the supply of LNA to the small intestine increased serum IgG and Th1 cytokines including interferon-γ ($P < 0.05$), whereas the concentrations of PGE2 and Th2 cytokines, such as interleukin (IL)-4 decreased ($P < 0.05$) when infused no more than 300 g/d. However, the influence was affected by the higher dose of LNA at 400 g/d as the incidence of diarrhea occurred in some dairy cows. Throughout the whole experiment, no difference was observed in serum IgA and IgM. This study demonstrated that post-ruminal infusion of LNA affected the naïve T lymphocytes and modified the balance of Th1/Th2 type immune response, which suggest immunomodulatory properties of LNA.

Key Words: lactating dairy cow, α-linolenic acid, immune function

W409 Supplementation of methionine hydroxy analog, trace mineral chelates and dietary antioxidants in the diet of dairy cows for milk production, milk composition, and hoof status. G. Conti[1], G. Castillo*[3], M. Gallardo[2], S. Toffano[3], and M. Vazquez-Anon[3], [1]*University of Veterinary Medicine - Universidad del Litoral*, *Santa Fe, Argentina*, [2]*CICV National Institute for Agricultural and Livestock Technology (INTA)*, *Buenos Aires, Argentina*, [3]*Novus International*, *St. Louis, MO*.

In the Argentinean Central Dairy Region during Fall of 2009, 266 lactating dairy cows in a commercial herd were randomly assigned to a control or a treatment group. The treatment group consisted of a mixed supplementation of methionine hydroxy analog (12 g/head/day; MFP), mineral chelates (2 g/d of Mintrex-Zn (320 mg/d Zn), 2 g of Mintrex-Cu (300 mg/d of Cu), 2 g/d of Mintex- Mn (260 mg/d of Mn)) and dietary antioxidants (5 g/d/h Feedgard) in order to evaluate lactation performance and hoof health response. 266 primiparous and multiparous cows (132± 90 DIM and 2.94± 1.8 lactations) were on trial for a minimum of 90 and maximum of 180 d. Cows were fed twice a day after milking an isoenergetic (1.82 Mcal NEL) and isoproteic (17% CP) diet consisted of 30% corn silage, 30% alfalfa, 20% corn, and 20% soybean meal, and a mixture of vitamins and trace minerals. Minerals were formulated according to NRC 2001. The treatment cows produced 9% more milk (32.6 vs. 29.7 l/d $P < 0.05$), 4% FCM (30.5 vs. 27.8 kg/d; $P < 0.05$), milk fat (1.15 vs. 1.06 kg/d; $P < 0.05$) and protein yield (1.1 vs. 0.99 kg/d; $P < 0.05$) than control cows. There were no differences in milk composition or body condition between treatments. Treatment cows showed fewer hoof injuries ($P < 0.05$) due to lower incidence in heel (49%), white line (46%), and sole (59%) injuries and dermatitis (46%). The locomotion score showed fewer treatment cows with grades 2 to 4 (29.15% vs. 45.7% $P< 0.05$). From this study it can be concluded that the combination of methionine hydroxy analog, chelated trace minerals, and dietary antioxidant significantly improved milk yield and hoof health status

Key Words: methionine and mineral chelates, antioxidant, hoof health status

W410 Effects of *Bacillus subtilis* natto on the immune function of weaned calves. P. Sun, J. Q. Wang*, and H. T. Zhang, *State Key Laboratory of Animal Nutrition, Institute of Animal Science*, *Chinese Academy of Agricultural Sciences, Beijing, China*.

The effects of *Bacillus subtilis* natto on the immune function of weaned calves were investigated in this study. Twenty-four Holstein male calves

of 7 ± 1 d of age were randomly allotted to three treatments of eight calves. The calves were weaned when their starter intake reached 2% of their body weight. The *Bacillus subtilis* natto including Na type and N1 type was mixed with milk before weaning or mixed with the starter diets directly to the calves after weaning in the two experimental treatments and no *Bacillus subtilis* natto was fed to the control group. The experiment ended on the seventh week after weaning, when blood was collected and IgA, IgE, IgG, IgM and cytokine levels including interleukin (IL)-4, IL-10 and interferon-γ (IFN-γ) were determined in the serum of all the calves. Data were analyzed using the ANOVA procedure of SAS. No difference was observed in serum IgE concentration in the two *Bacillus subtilis* natto supplemented treatments (52.87 and 53.30 mg/L for Na and N1 group) compared to the control (56.37 mg/L). IgA and IgM in the serum of the calves were not different, whereas serum IgG was greater ($P < 0.05$) in the *Bacillus subtilis* natto supplemented calves than in the control calves. Furthermore, calves fed with Na type of *Bacillus subtilis* natto were found to secrete more IFN-γ ($P < 0.05$) but tended to produce less IL-4 ($P < 0.1$) in the serum than the control calves, although serum IL-10 was not affected. This study demonstrated that *Bacillus subtilis* natto did not stimulate IgE-mediated allergic reactions, but induced nonspecific immune responses associated with increased serum IgG and IFN-γ levels in the probiotic-fed calves, which suggests that the probiotic characteristics of *Bacillus subtilis* natto (especially for Na type) benefit the immune function.

Research was supported by Youth Foundation from Institute of Animal Science (2009qn-8).

Key Words: *Bacillus subtilis* natto, immune function, calf

W411 Nutrient balances in California dairy farms. 1. Effects of salt content in drinking water and milk yield per cow on nutrient utilization efficiency. A. R. Castillo*[1], N. Silva del Rio[2], and N. St-Pierre[3], [1]*University of California Cooperative Extension*, *Merced,* [2]*University of California Cooperative Extension*, *Tulare,* [3]*The Ohio State University, Department of Animal Sciences*, *Columbus*.

The aim of this survey was to study nutrient utilization efficiency and feed conversion in lactating cows on commercial farms. Forty dairies in Merced, California (mean 787±592 lactating cows/farm) were selected to study the effect of total salt in drinking water (TS) and average milk yield (MY, as 3.5% fat-corrected milk yield/cow) in each dairy farm on TMR nutrient content, feed management, feed conversion (FC=MY/DMI) and nitrogen utilization efficiency (NUE=N milk/N intake). Data was analyzed as 2 x 2 factorial with high TS (HTS) and low TS (LTS), and high MY (HMY) and low MY (LMY) as the main factors. The four treatments were: HTS-HMY, HTS-LMY, LTS-HMY, and LTS-LMY. Levels of TS were, 809 and 307 mg/L for HTS and LTS, respectively. Levels of MY were 35.9 and 27.6 kg/cow per day per dairy farm for HMY and LMY, respectively. The mean TMR nutrient content were: ADF (23.6%), lignin (4.3%), nitrogen (2.8%), fat (4.5%), and ash (8.3%) and not affected by water TS or MY. Differences were observed with TMR NDF content (34% and 36%) and non-fiber carbohydrates (NFC, 36% and 33%) for HMY and LMY, but not affected by water TS. The TMR DCAD content was affected by water TS (HTS=23 and LTS=29mEq/100 g DM). But, the other variables were different only for H and L milk yield, as follow: FC (HMY=1.5, LMY=1.25), ENU (HMY=0.26, LMY=0.22), cow number/dairy (HMY=1061, LMY=513), TMR/dairy for lactating cows (HMY=3.7, LMY=2.2).

Key Words: dairy farms, feed conversion, nitrogen utilization efficiency

W412 Evaluation of estimated diet energy intake and impact on energy use of the lactating dairy cow. K. J. Clark*[1], P. J. Kononoff[1], and L. O. Tedeschi[2], [1]*University of Nebraska-Lincoln*, *Lincoln,* [2]*Texas A&M University*, *College Station*.

A meta-analytical procedure was used to evaluate the impact of observed intakes of diet net energy for lactation (NE_L) on use of energy by lactating dairy cows. Data from nine nutrition experiments, which included 29 dietary treatments and 778 observations collected at the University of Nebraska-Lincoln Dairy Research Unit, were used. All studies were cross-over designs in which cows were fed diets for either 21 or 28 d periods. Data were analyzed using SAS and a random coefficient model to account for the random effects of different experiments. For each experiment, TMR and fecal samples were collected, dried, ground, and analyzed for DM, CP, ash, NDF, NFC, ether extract (EE) and ADF. Diet concentration of total digestible nutrients (TDN) and NE_L were computed using NRC (2001) equations. Total NE_L use was estimated based on maintenance and lactation requirements plus energy needed to meet observed BW changes. Apparent digestibility of nutrients was estimated based on the concentration of indigestible ADF in the TMR and feces. Apparent digestibility (mean ± SD) was 61.5 ± 8.3, 64.0 ± 9.1, 42.4 ± 13.6, 88.5 ± 7.5, and 82.6 ± 10% for DM, CP, NDF, NFC, and EE, respectively. Mean DMI and 3.5% FCM averaged 23.9 ± 4.7 and 35.4 ± 12.4 kg/d, respectively. The TDN and concentration of NE_L in each diet were estimated to be 65.9 ± 17.4% and 1.58 ± 0.55 Mcal/kg, respectively. Results suggested NE_L intake was a weak predictor of NE_L use ($R^2 = 0.01$). The resulting regression equation was y = 32.0 +0.12 x; where y = NE_L use (Mcal/d) and x = measured NE_L intake (Mcal/d). Although also poor, DMI served as a better predictor of NE_L use ($R^2 = 0.16$). The resulting regression equation was y = 12.9 +0.98 x; where y = NE_L use (Mcal/d) and x = measured DMI (kg/d). These results suggested the measured NE_L intake of the ration is not a good predictor of NE_L utilization in the animal.

Key Words: energy, lactation, digestibility

W413 Regulation of hepatic gluconeogenic enzymes by dietary glycerol in transition dairy cows. H. M. White*, E. R. Carvalho, and S. S. Donkin, *Purdue University*, *West Lafayette, IN*.

Nutritional status is a known regulator of gluconeogenic gene expression. Glycerol can replace corn in diets fed to dairy cow and is linked to increased rumen propionate production. The effect of dietary glycerol on the regulation of gluconeogenic enzymes is unknown. The objective of this study was to examine the effect of glycerol on expression of pyruvate carboxylase (PC), cytosolic phosphoenolpyruvate carboxykinase (PEPCK-C), mitochrondrial phosphoenolpyruvate carboxykinase (PEPCK-M), and glucose-6-phosphatase. Twenty-six multiparous Holstein cows were fed either a control diet or a diet where corn grain was replaced by glycerol from −28 through +56 days relative to calving (DRTC). Liver tissue was collected via percutaneous liver biopsy at −28, −14, +1, +14, +28, and +56 DRTC for RNA analysis. Expression of PC mRNA was increased ($P < 0.05$) by 6-fold at +1 and by 4-fold at +14 DRTC relative to precalving levels. Dietary glycerol did not alter ($P \geq 0.05$) expression of PC mRNA expression. Expression of PEPCK-C was increased ($P < 0.05$) by 2.5-fold at +14 and 3-fold at +28 DRTC compared to +1 DRTC. Overall, dietary glycerol increased ($P < 0.05$) PEPCK-C expression compared to cows fed control diets (2.94 vs. 1.61 ± 0.8 arbitrary units, main effect of glycerol vs. control, respectively). The ratio of PC to PEPCK-C was increased ($P < 0.05$) by 3-fold at +1 DRTC in all cows. There was no effect ($P \geq 0.05$) of diet or DRTC on PEPCK-M or glucose-6-phosphatase mRNA. There were no interactions of dietary treatment and DRTC for any transcript measured. Substituting

corn with glycerol increased the expression of PEPCK-C mRNA during transition to lactation and suggests that dietary energy source alters hepatic expression. The observed increase in PEPCK-C expression with glycerol feeding may indicate regulation of hepatic gene expression by changes in rumen propionate production.

Key Words: glycerol, gluconeogenesis, transition cow

W414 Effects of dietary betaine on milk yield and milk composition of mid-lactating dairy cows. S. E. Peterson*[1], J. K. Kinch[1], J. E. Williams[1], M. A. McGuire[1], M. Chahine[2], and P. Rezamand[1], [1]*Univeristy of Idaho*, *Moscow,*[2]*University of Idaho*, *Twin Falls*.

Betaine, naturally found in plants and an oxidative product of choline, is converted to acetate in the rumen, and transferred to the mammary gland where it may be used for milk fat synthesis. The objective of this study was to determine the effect of supplemental dietary betaine on bovine milk yield and milk composition. Eighteen Holstein dairy cows (126 ± 5 DIM) were randomly assigned to a sequence of treatments in a 4x4 Latin square design with four treatments of betaine at 0, 25, 50, and 100 g/d, added to a standard lactation ration. Animals were fed individually using Calan gates, and feed intake and milk yield recorded daily. Each period lasted 16 d with milk sampled on the last day of each period. Milk composition was determined by a standard DHIA laboratory and milk fatty acids were determined by gas chromatography. Data were analyzed using the MIXED procedure in SAS and significance was determined at $P < 0.05$. Dry matter intake was altered (quadratic effect $P = 0.024$) by dietary betaine (18.8, 18.6, 18.4, 19.4 ± 0.98 kg/d for 0, 25, 50, and 100 g betaine/d, respectively). Further, milk yield was increased (quadratic effect $P < 0.001$) by supplemental betaine (22.6, 22.9, 22.4, 24.0 ± 0.89 kg/d for 0, 25, 50, and 100 g betaine /d, respectively). However, no significant effect of dietary betaine was detected on body weight or condition score ($P > 0.08$ for both). Percentages of milk fat, lactose, SNF, and SCC were not altered ($P > 0.29$ for all) whereas milk true protein content was decreased (quadratic effect $P = 0.025$) by betaine supplementation (3.35, 3.27, 3.27, and 3.28 ± 0.07% for 0, 25, 50, and 100 g betaine/d, respectively). Daily yields of milk protein, fat, or lactose did not differ with betaine supplementation ($P > 0.13$ for all). Further, no significant effect of dietary betaine was detected on milk fatty acid composition. Overall, inclusion of dietary betaine at 100 g/d increased dry matter intake and milk yield but decreased milk protein percent (at all levels of inclusion), whereas milk fatty acid profile remained unaltered. Further studies are needed to determine the optimum rate of supplemental betaine for dairy cows.

Key Words: betaine, milk yield, milk composition

W415 The effect of forage level and lipid supplement on selected strains of rumen bacteria in continuous culture fermenters. P. Gudla*[1], A. Ishlak[1], A. A. AbuGhazaleh[1], D. Hastings[1], K. Jones[1], E. Gastal[1], J. Trushenski[1], and S. Ibrahim[2], [1]*Southern Illinois University*, *Carbondale,* [2]*North Carolina A&T University*, *Greensboro*.

Previous studies have shown that trans fatty acids production in the rumen are influenced by lipid supplements and forage levels. The objective of this study was to evaluate the effects of forage level and lipid supplement on selected strains of rumen bacteria believed to be involved in biohydrogenation. A single-flow continuous culture system consisting of four fermenters was used in a 4 × 4 Latin square design with a factorial arrangement of treatments, with four 10 d consecutive periods. Treatment diets were: 1) high forage diet (70:30 forage to concentrate; HF), 2) high forage plus lipid supplement (HFL), 3) low forage diet (30:70 forage to concentrate; LF), and 4) low forage plus lipid supplement (LFL). The lipid supplement was a blend of fish oil and soybean oil added at 1 and 2 g/100g DM, respectively. The forage source was alfalfa pellets. During 10-d incubations, fermenters were fed treatment diets three times daily (45g/d, divided equally between three feedings) as TMR diet. Samples collected at 3 h post morning feeding on d 10 were used for quantitative PCR analysis. Data were analyzed with the PROC MIXED procedure of SAS. The DNA concentrations of *Anaerovibrio lipolytica* and *Butyrivibrio fibrisolvens* vaccenic acid subgroup (Butyrivibrio VA) were affected ($P < 0.05$) by forage level but not lipid supplement. The DNA concentrations of *Anaerovibrio lipolytica* (1.668, 2.597, 0.045 and 0.093 pg/40 ng of total DNA for treatments 1 to 4, respectively) and Butyrivibrio VA (0.324, 0.296, 0.011 and 0.014 pg/10 ng of total DNA) were significantly lower with the low forage diets. The DNA concentrations of *Butyrivibrio fibrisolvens* stearic acid producer subgroup (Butyrivibrio SA) were not affected ($P > 0.05$) by forage level or lipid supplement (149.4, 136.3, 123.2 and 158.3 pg/10 ng of total DNA). In conclusion, lipid supplement had no effects on the tested rumen bacteria and forage level affected both Butyrivibrio VA and *Anaerovibrio lipolytica*.

Key Words: forage level, lipid supplement, bacteria

W416 Changes in the parameter estimates for the linear relationships of milk and milk component yields with dry matter intake of dairy cows during the last decade. J. S. Lee*[1], S. Y. Lee[1,2], K. S. Ki[3], H. S. Kim[3], and S. Seo[1], [1]*Department of Animal Biosystem Sciences, Chungnam National University*, *Daejeon, South Korea*, [2]*Institute of Agricultural Science, Chungnam National University*, *Daejeon, South Korea*, [3]*Dairy Science Division, National Institute of Animal Science, RDA*, *Cheonan, South Korea*.

The parameter estimates from a meta-analysis is heavily dependent on the database used. Due to genetic improvement and changes in management of dairy cows, the parameter estimates of variables may vary with different time frames. The objective of this study is thus to compare the parameter estimates for linear relationships of milk and milk component yields with DMI obtained using data from two different time frames. For the parameter estimates of dairy cows before the year of 2000, previous published equations by others were used. For the data after the year 2007, we developed a database containing experimental observations for DMI and milk yield of dairy cows from the research articles published in the *Journal of Dairy Science (JDS)* from Dec. 2007 until Feb. 2010 (volumes 90 through 93). The database is composed of a total of 427 treatment means from 114 studies. The mean (±SD) DMI, BW, milk yield, milk fat yield (MFY), and milk protein yield (MPY) were 22.36 (±3.54), 637.76 (±52.49), 34.51 (±6.88), 1.22 (±0.26) and 1.07 (±0.21) kg, respectively. Using a simple linear regression, MY = 5.875 (±1.601) + 1.281 (±0.071) DMI ($R^2 = 0.436$) was obtained. Compared to a previous published equation based on the data published in *JDS* (from volumes 1 through 82), no significant difference was observed for the slope (1.281 vs. 1.378), but the intercept was significantly different (5.875 vs. −1.022; $P < 0.05$). Linear relationships of milk and milk component yields with DMI were also estimated using a random coefficient model with study as a random effect: MY = 12.678 (±2.382) + 0.998 (±0.106) DMI, MFY = 0.348 (±0.112) + 0.039 (±0.005) DMI, and MPY = 0.387 (±0.084) + 0.031 (±0.004) DMI. Compared to the previous parameter estimates using a similar approach with data published in *JDS* (volumes 73 through 83), no significant differences in the estimates of slope and intercept were observed. The results from this study suggest that average milk yield from dairy cows has been significantly increased during the last decade even though response of milk production to an increase in DMI has not been improved.

Key Words: milk yield, dry matter intake, dairy cows

W417 Effects of chemical treatment of whole barley grain with sodium hydroxide on nutrient intake and digestibility in midlactation of Holstein dairy cows. M. Khorashadizadeh*, A. A. Naserian, and R. Valizadeh, *Ferdowsi University of Mashhad, Excellence Center for Animal Science, Faculty of Agriculture, Mashhad, Khorasan Razavi, Iran*.

Nine multiparous midlactation Holstein cows (131.44±9.32 DIM, 30.2±5.14 kg daily milk yield) were fed a total mixed ration supplemented with ground barley grain (control), or whole barley grain treated with sodium hydroxide (10%) and dried in different periods including: dried immediately (0h) or after 48h storage in plastic bags (48h). Sodium hydroxide was used at the level of 3.5% (DM). Each period lasted 3 week; experimental analyses were restricted to the last week of each period. Diets were formulated according to NRC 2001. Cows were housed in tie stalls and fed the TMR two times a day to allow 5 to 10% orts (as-fed basis), and dry matter intake (DMI) was recorded at the last week of each period. Data were analyzed as a 3 × 3 Latin square using the GLM procedure of SAS (2001). The model included effects of diet, period and cow. Least squares means are reported throughout and significance was declared at $P < 0.05$. Diets had no effects on DMI (21.49, 22.35 and 20.19 ± 0.67 kg/d for control, 0h and 48h respectively), CP intake (3.4, 3.55 and 3.41± 0.16 kg/d for control, 0h and 48h respectively), NDF intake (7.69, 8.25 and 7.32 kg/d for control, 0h and 48h respectively) but OM intake (20.52, 19.78 and 18.45 ±0.56 kg/d for control, 0h and 48h respectively) and ADF intake (5.24, 5.65 and 4.63 kg/d for control, 0h and 48h respectively) decreased in 48h diet. The digestibility of DM (67.66, 69.22 and 67.77±1.7% for control, 0h and 48h respectively), OM (68.66, 70.22 and 69.22±1.6% for control, 0h and 48h respectively), NDF (59.44, 60.66 and 58.33 ±2.4% for control, 0h and 48h respectively) and CP (68.44, 70.11 and 69.89±1.9% for control, 0h and 48h respectively) were similar between diets, but ADF digestibility (57, 64.77 and 51.44±3.5% for control, 0h and 48h respectively) decreased in 48h diet in comparison with 0h diet; however 0h diet had more NDF digestibility than control diet. The results of the current experiment reveals that chemical treatment of whole barley grain with sodium hydroxide for 48h had negative effects on ADF intake and digestibility

Key Words: sodium hydroxide, whole barley grain, dairy cows

W418 Effect of glucogenic and ketogenic feeding strategies on metabolic status in postpartum transition cows. M. Larsen* and N. B. Kristensen, *Faculty of Agricultural Sciences, Aarhus University*, *Tjele, Denmark*.

We have previously found that abomasal glucose infusion in postpartum transition cows prevented the characteristic fall in glucose and insulin concentrations. Nine Holstein second lactation cows implanted with permanent indwelling catheters in the major splanchnic blood vessels were used to study the effect of glucogenic and ketogenic feeding strategies on metabolic status in postpartum transition cows. At calving, cows were assigned to 1 of 3 feeding strategies: a glucogenic strategy (GLUCO; 56.5% NaOH treated wheat, 25.8% grass-clover silage and 17.7% concentrate mix), a ketogenic strategy (KETO; 40.5% fodder beets, 25.8% grass-clover silage, 15% NaOH treated wheat and 18.7% concentrate mix) or a keto-glucogenic strategy (MIXED) with 100% alfalfa haylage at the calving day followed by a 6 day gradual shift to the glucogenic diet. Eight hourly sets of arterial, portal vein, and hepatic vein samples were collected starting 30 min before morning feeding at 12 ± 4 days before calving as well as 4, 15, 29 days in milk (DIM). The statistical model included treatment, DIM and treatment × DIM, where DIM within cow was considered as a repeated measure. All treatments were associated with decreasing ($P < 0.01$) arterial concentrations of glucose and insulin from prepartum to 4 DIM, whereas the β-OH-butyrate concentration did not change ($P = 0.12$). The arterial insulin concentration decreased more ($P = 0.04$) from prepartum to 4 DIM with MIXED as compared to KETO. Concomitantly, the arterial glycerol concentration increased more ($P \leq 0.05$) from prepartum to 4 DIM with MIXED as compared to the other treatments. The portal-arterial (P-A) glucose concentration difference increased ($P < 0.01$) from negative prepartum to positive at 4 DIM with all treatments; however, the positive P-A concentrations difference with KETO at 4 DIM tended ($P \leq 0.10$) to be lower than with the other treatments. In conclusion, the tested feeding strategies induced relatively modest changes in metabolic status in the very early postpartum phase. Thus, the potential for effectively manipulating the metabolic status using farm applicable feeding strategies seems limited.

Key Words: transition, glucose, metabolism

W419 Ruminal degradation dynamics of barley protein meal, corn distiller grains and soybean meal. S. Arriola*, C. Blatcher, M. McGilliard, and M. D. Hanigan, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

The aim of this study was to determine the ruminal degradation dynamics of barley protein meal (BPM), corn distiller grains (CDG) and soybean meal (SBM). Three ruminally cannulated lactating cows were housed in individual stalls and fed a diet formulated to meet NRC nutrient requirements during a 15 d adaptation period. Five grams of BPM, CDG or SBM were ground through a 2 mm screen, sealed in Dacron bags, dried overnight at 60° C, and weighed. Forty-eight, 24, 16, 8, 4, 2, and 0 h before simultaneous removal, two bags with each feedstuff were placed in the rumen of each of the cows. After removal from the rumen, bags were washed, dried, and analyzed for dry matter (DM), N, and amino acid (AA) content. Ruminal degradation parameters for DM, crude protein (CP) and AA were estimated using the NLIN procedure of SAS. Resulting parameter estimates were analyzed using the MIXED procedure. BPM had the greatest soluble DM and CP fractions (64.8% DM and 76.8% CP), CDG was intermediate (45.1% DM and 40.1% CP), and SBM the lowest (31.8% DM and 13.9% CP). Degradation rates of DM were the greatest for SBM intermediate for BPM and the slowest for CDG. The CP degradation rates were similar between SBM and BPM, but lower for CDG. Finally, rumen undegraded DM was the lowest for BPM (23.9%). Ruminally undegraded DM was lower for SBM (27.4%) than CDG (40.4%). The same pattern was observed for the CP fraction, with BPM having the lowest undegraded CP (11.8%), SBM intermediate values (34.4%) and CDG the greatest (39.3%). In accord with DM and CP, the predicted essential AA percent remaining in the undegraded fraction was the lowest for BPM, as compared to SBM and CDG. These results show that BPM was not as good of a ruminal bypass protein source as SBM and CDG. The high solubility of the BPM was likely due to addition of the solubles to the product and drying conditions used in the pilot plant. The final commercial product may have different characteristics.

Key Words: barley meal, rumen degradation, protein

W420 Effects of storage temperature and pre-mixing on yeast cell viability. M. L. Sullivan*[1], W. K. Sanchez[2], I. Yoon[2], and B. J. Bradford[1], [1]*Kansas State University*, *Manhattan,* [2]*Diamond V Mills, Inc*, *Cedar Rapids, IA*.

Active dry yeast (ADY) products are commonly fed in the dairy industry, but little research has been done regarding quality control for such products. The objectives of this study were to measure the effects of

short-term high temperature storage on ADY viability and determine the impact on viability when storing yeast mixed with a vitamin/trace mineral pre-mix (VTM). Commercially available ADY products (n=5) were acquired through normal distribution channels, stored at 4°C upon receipt, and shipped to Medallion Labs for analysis of yeast colony forming units (CFU). ADY were mixed in duplicate with ground corn or VTM to achieve a targeted concentration of 2.2×10^8 CFU/g. One product was omitted due to its low CFU concentration. For each product, samples mixed in corn and VTM were stored at ambient temperature (22°C) while replicates were stored in an incubator at 40°C for 2 wk. Of the 5 products sampled, 2 arrived with CFU concentrations below the product guarantees. Products were mixed based on actual CFU concentration, and mixed samples met the targeted CFU concentration. There were no differences in CFU concentrations between corn and VTM samples immediately after mixing or after storage at ambient temperature. However, high-temperature storage significantly decreased CFU concentration ($P < 0.001$). There was also an interaction ($P = 0.02$) of pre-mix substrate and storage temperature, with VTM maintaining higher CFU concentrations than corn when subjected to high-temperature storage (7.4 vs. 7.1 $\log_{10}$ CFU/g). This could be the result of minerals, such as zinc, that sustained cell wall viability, antioxidant vitamins present in the VTM, or the difference in water activity of the substrates (Corn = 0.51; VTM = 0.45). Results indicated that yeast viability in ADY products was greatly diminished when stored at 40°C for 2 wk, but the reduction was less severe when mixed with a VTM premix.

Key Words: trace mineral, viability, yeast

W421 Replacement of high moisture corn or soy hulls by soy molasses in dairy cow diets. L. L. Bitencourt[1], N. M. Lopes[1], V. A. Silveira[1], G. Pessoa Júnior[1], O. F. Zacaroni[1], G. S. Dias Júnior[1], C. O. Faria[4], J. R. M. Silva[3], R. A. N. Pereira[2], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras*, *Lavras, Brazil*, [2]*Empresa de Pesquisa Agropecuária de Minas Gerais*, *Lavras, Brazil*, [3]*Instituto Federal de Educação Ciência e Tecnologia do Norte de Minas Gerais*, *Januária, Brazil*, [4]*Better Nature Research*, *Ijaci, Brazil*.

Soy molasses (SM) is the by-product of protein isolation from defatted soy flakes. Two experiments evaluated strategies of feeding SM to dairy cows. The composition of SM (Sementes Selecta SA, Goiânia, Brazil) was (% of DM): 7.9 CP, 0 NDF, 4.1 EE and 10.8 ash. The DM content was 69.5% of as fed. Trial 1 evaluated SM as a replacement for high moisture corn (HMC). Treatments were (% of diet DM): Control with 21.5 HMC, SM1 with 17.2 HMC and 4.5 SM, and SM2 with 12.8 HMC and 9.1 SM. Diets also contained 41.8% corn silage, 5.4% tifton, 19.9% soybean meal, 8.3% whole cottonseed, 16.6% CP, 31.5% NDF, and 6.1% EE. Twenty-four Holsteins were paired blocked based on parity and yield and assigned to a treatment for 28 days, following a standardization period. Data obtained at the end of the standardization was used as covariate in the statistical model. Response variables were measured on the fourth week. Daily milk protein yield was 0.903 kg for Control, 0.871 kg for SM1, and 0.772 kg for SM2 ($P = 0.01$ linear), and milk yield was 30.2, 27.7 and 26.9 kg, respectively ($P = 0.04$ linear). There were no detectable treatment effects upon fat yield ($P = 0.80$), DMI ($P = 0.96$), MUN ($P = 0.97$), plasma glucose ($P = 0.72$), daily excretion of allantoin in urine ($P = 0.55$), and total tract digestibility ($P > 0.54$). Trial 2 evaluated the replacement of soy hulls (SH) by SM. This trial also used 24 cows, in a covariate adjusted randomized block design, with response evaluated on the fourth week after a standardization period. The Control treatment had 11.6% of SH on diet DM. The SM treatment contained 8.4% of SH and 3.3% of SM. Diets also contained 42.2% corn silage, 4.1% tifton, 20.6% soybean meal, 6.9% whole cottonseed, and 11.7% HMC. Milk yield was 27.6 kg for Control and 27.8 kg for the SM treatment ($P = 0.91$). There were no detectable treatment effects on DMI, milk solids content, solids production, MUN, feed efficiency, and milk energy secretion ($P > 0.28$). Replacing HMC with SM did not improve cow performance and replacing SH with SM, in a constant corn starch diet, had no effect on cow performance.

Key Words: soy molasses, sugars, byproducts

W422 Abomasal oligofructose infusion induced hindgut acidosis in Holstein steers. S. R. Mainardi*, B. A. Hengst, S. J. Nebzydoski, L. M. Nemec, and T. F. Gressley, *University of Delaware*, *Newark*.

Excessive microbial fermentation of carbohydrates in the large intestine of dairy cattle can result in post-ruminal acidosis which can negatively impact animal health and performance. This study evaluated whether abomasal infusion of a fermentable carbohydrate could be used to induce hindgut acidosis. Six ruminally cannulated Holstein steers were used in a crossover design study with 14-d treatment periods. Steers were fed a lactating cow ration ad libitum. On d 13 steers were treated with 0 (Control) or 1 (Oligo) g/kg BW oligofructose (Beneo P95, Orafti Active Food Ingredients, Tienen, Belgium) pulse-dosed into the abomasum in 1 L water. Fecal samples, blood samples, rectal temperature, heart rate, and respiratory rate were taken at 0, 3, 6, 9, 12, 24, and 48 h relative to the abomasal infusion. Fecal samples were used to determine dry matter (DM) percentage, pH, consistency score (1=liquid to 5=coarse), and volatile fatty acid (VFA) concentrations. Plasma or serum concentrations of metabolites (β-hydroxybutyric acid, blood urea nitrogen, and non-esterified fatty acids) and inflammatory markers (copper, serum amyloid A, and haptoglobin) were determined. There was no effect of treatment on DM intake, rectal temperature, heart rate, respiratory rate, or blood measures ($P > 0.10$). Fecal pH tended to be lower for Oligo than Control steers (6.76 vs. 7.02, $P = 0.06$). Treatment by time interactions were found for fecal score, DM, lactate and acetate ($P < 0.05$), and tended to occur for fecal propionate and butyrate ($P < 0.10$). Fecal score was lower for Oligo than Control steers at 6 and 9 h ($P < 0.01$). Compared to Control steers, fecal DM was reduced in Oligo steers at 6 h but was increased at 9 and 12 h ($P < 0.05$). The greatest difference for all VFAs occurred at 12 h, when concentrations of lactate, acetate, propionate, and butyrate were 0.5, 47, 11, and 4.0 m*M* in Control steers and 5.2, 76, 15, and 6.8 m*M* in Oligo steers, respectively. In conclusion, abomasal infusion of 1 g/kg BW oligofructose induced excessive microbial fermentation in the hindgut of steers without causing an acute inflammatory response.

Key Words: acidosis, hindgut, oligofructose

W423 Effect of processing of corn grain on mean particle size, particle distribution and ruminal starch degradability. S. Emanuele*[1], L. Carver[1], L. Davis[1], D. Lundquist[1], and J. Firkins[2], [1]*Quality Liquid Feed*, *Dodgeville, WI,* [2]*Ohio State University*, *Columbus*.

The objective of this trial was to determine the variability in rumen degradable starch (RDS) among corn samples and develop a regression equation to predict ruminal starch degradability. Eighty-seven corn samples were collected from 60 dairy operations in 11 states. Corn samples consisted of dry, high moisture and steam-flaked corn. Dry corn samples consisted of whole, rolled, crimped or ground samples and high moisture corn consisted of whole, rolled or ground samples. Steam-flaked corn was either rolled or flaked. Samples were collected from October 2008 to February 2009. Samples were analyzed, as-received, by Dairyland Labs, Arcadia, WI for in vitro ruminal and total tract dry matter and starch disappearance. Ruminal dry matter and starch

degradability was measured by a 12-h fermentation in rumen fluid. Total tract dry matter and starch degradability was measured by an 8 h digestion in acid pepsin and lipase enzymes which followed the 12-h ruminal fermentation. The median for RDS was 67.2% with a range of 25.4% to 91.6%. The median for total tract starch degradability was 74.4% with a range of 50.8% to 91.4%. The 12-h RDS was influenced by processing method ($P < 0.07$), being greatest for steam-flaked corn (71.2%) and ground dry corn (66.5%). RDS was influenced by particle size within processing method ($P < 0.05$). RDS varied from 53% to 67% for high moisture corn. The distribution of particle sizes also influenced starch degradability. Samples with a greater percentage of very fine particles tended to have greater starch degradability. RDS for dry corn varied from 50% to 73%. A 12-h ruminal starch degradability for fine ground dry corn can be estimated from mean particle size by the regression equation: Y = (76.1) + MPS X (−0.0073). Based on this data set, ruminal starch degradability is highly variable and influenced by processing method and particle size within processing method. This may lead to an over-estimation of rumen degradable starch (RDS) in the diet if processing method and particle size are not used in equations to predict ruminal starch degradability of corn samples.

Table 1. Effect of corn source and particle size on starch degradability

Item	Dry Corn	Dry Corn	Dry Corn	HM Corn	HM Corn	HM Corn	SF-Corn	SF-Corn	P-value
Processing Method	Crimped	Rolled	Ground	Whole	Rolled	Ground	Flaked	Rolled	
Particle Size	Coarse	Medium	Fine	Coarse	Medium	Fine	Medium	Medium	
12-hr Starch Degradability	48.5b	56.8ab	66.5ab	60.1ab	58.1ab	62.1ab	63.5ab	71.2a	0.05
SE	10.7	5.4	4.0	5.4	2.4	2.8	3.1	5.4

W424 Comparison of the effects of several nutrients on dairy cow milk fat content. G. Maxin*[1], F. Glasser[2], and H. Rulquin[1], [1]*INRA-Agrocampus ouest*, *Rennes, France*, [2]*INRA*, *Theix, Saint-Genes-Champanelle, France*.

Dietary changes can alter dairy cow milk fat production through modifications in the supply of nutrients. Indeed, several nutrients act as precursors or inhibitors of mammary fat synthesis, and they vary simultaneously following dietary changes. This meta-analysis aims to compare the effects of these nutrients on milk fat content (MFC). The effects of six nutrients were compared: acetate (C2), propionate (C3), butyrate (C4), glucose, trans10,cis12-CLA (CLA) and long-chain fatty acids (LCFA). A database was compiled from the studies involving digestive infusions (or rumen-protected forms) of these nutrients in dairy cows. It contained 142 comparisons between a nutrient infusion and a control. Response models of MFC (in g/100g milk) to the supply of each nutrient (in kg/d) were established. The nutrients differed in their effects on MFC: C2, C4 and LCFA increased MFC whereas C3, glucose and CLA decreased it. To compare the effects of these nutrients on MFC, we had to adjust the response models to in vivo variations in the nutrient supplies, observed following dietary changes. From published data, we estimated the maximal variations in the supply of these nutrients following dietary changes: 1.0 kg/d for C2, 1.0 kg/d for C3, 0.5 kg/d for C4, 1.5 kg/d for glucose, 1.5 g/d for CLA and 1.3 kg/d for LCFA. By applying the response models to these values, we estimated the maximal in vivo responses of MFC (g/100g milk) to the nutrients: +0.25 for C2, −0.48 for C3, +0.40 for C4, −0.43 for glucose, −0.36 for CLA, and +0.56 for LCFA. The individual responses of the nutrients were moderate and had the same magnitude. These results suggest that several of these nutrients could contribute to the changes in MFC observed following dietary changes.

Key Words: milk fat content, dairy cows, nutrients

W425 Phosphorus feeding for primiparous cows. V. R. Moreira*[1], L. K. Zeringue[1], C. Leonardi[2], and M. E. McCormick[1], [1]*Louisiana State University Agricultural Center*, *Franklinton,* [2]*Louisiana State University*, *Baton Rouge*.

The objective of this study was to evaluate production performance of two groups of 20 primiparous cows fed diets containing either 0.35% or 0.39% ± 0.01% P (DM basis) from 3 to 45 DIM (treatment period). Both groups of cows were fed 0.39% ± 0.01% P thereafter until 110 DIM (carry-over period). Both treatment diets contained 17.7% ± 0.35% CP, 26.8% ± 0.92% NDF, 16.6% ± 0.46% ADF, and 0.76% ± 0.05% Ca as analyzed (average ± standard deviation), and 1.61 Mcal/kg DM as estimated by the NRC (2001) model. Pregnant heifers were brought to the barn at least 20 days before expected calving. Cows were housed in a free-stall barn fit with electronic gates. Close-up TMR containing 0.33% ± 0.03% Ca and 0.28% ± 0.004% P (DM basis) was fed until two days after calving date. Treatments were randomly assigned to cows before the beginning of the experiment. Intake and milk yield were recorded daily. Weekly averages during treatment period (week 3 to 6) and carry-over period (week 7 to 15) were analyzed as repeated measurements using the Mixed procedure (SAS, version 9.2). Dry matter intake was 17.7 and 18.9 kg/cow/d (SEM = 0.45 kg/cow/d) for cows fed 0.35% P and 0.39% P respectively during the treatment period ($P = 0.08$). This difference increased slightly (21.6 vs. 22.9 kg/cow/d, SEM = 0.48 kg/cow/d) during carry-over period ($P = 0.06$). Milk yield was not significantly different, but differences between the two groups were similar to those observed in DMI during both periods (≈ 1.2 kg/cow/d). That was probably a result of greater variability in milk yield (SEM = 1.29 kg/cow/d) than in DMI. Milk yield of cows fed 0.35% P in the diet DM peaked on week 13, 2 weeks later than those cows fed 0.39% P (35.9 vs. 37 kg/cow/d, respectively). Cows from both treatments peaked intake at 14 weeks post-partum with 22.4 and 24 kg/cow/d for diets containing 0.35% P and 0.39% P, respectively. Cow performance was not significantly different between the two levels of P fed during this trial, however, the narrow difference in dietary P between treatments (0.04 percentage units) may warrant further investigation, given the tendency in higher DMI resulted in 1.2 kg/cow/d numerically higher milk yield with 0.39% vs. 0.35% P.

Key Words: phosphorus, dairy, primiparous

W426 Milk production and components of Holstein dairy cows fed diet supplemented with whole barley grain treated with sodium hydroxide. M. Khorashadizadeh*, A. A. Naserian, and R. Valizadeh, *Ferdowsi University of Mashhad, Excellence Center for Animal Science, Faculty of Agriculture, Mashhad, Khorasan Razavi, Iran*.

To examine the effects of chemical treatments of whole barley grain on milk production and components of dairy cows, 9 multiparous cows (131.44 ± 9.32 DIM, 30.2 ± 5.14 kg daily milk yield) fed a total mixed ration supplemented with ground barley grain (control), or whole barley grain treated with sodium hydroxide (10%) and dried in different periods including: dried immediately (0h) or after 48h storage in plastic bags (48h). Sodium hydroxide was used at the level of 3.5% (DM) of barley grain. Each period lasted 3 week; experimental analyses were restricted to the last week of each period. Diets were formulated according to NRC

2001. Cows were housed in tie stalls and fed the TMR 2 times a day to allow 5 to 10% orts (as-fed basis). Milk production was recorded at the last week of each period and milk samples were collected at the last 2 d of each period. Data were analyzed as a 3 × 3 Latin square using the GLM procedure of SAS (2001). The model included effects of diet, period and cow. Least squares means are reported throughout and significance was declared at $P < 0.05$. Table 1 shows the results of milk production and components. Chemical treatments of whole barley grain increase milk production, but the concentration of fat, protein, lactose, solid not fat (SNF) and milk urea nitrogen (MUN) did not change in diets. The results of the current experiment reveals that chemical treatment of whole barley grain with sodium hydroxide had no significant effects on milk components, but milk production increased when treated whole barley grain included in diets.

Table 1. Effects of chemical treatments of whole barley grain with sodium hydroxide on milk production and components

	Treatments				
parameter	control	0h	48h	P-value	SE
Milk (kg/d)	26.69a	27.58ab	28.16b	0.04	0.37
4% FCM 1(kg/d)	23.84a	24.38ab	25.47b	0.02	0.39

W427 Effects of dietary cobalt supplementation and vitamin B_{12} injection on lactation performance by dairy cows. M. S. Akins*[1], S. J. Bertics[1], M. T. Socha[2], and R. D. Shaver[1], [1]*University of Wisconsin*, *Madison*, [2]*Zinpro Corporation*, *Eden Prairie, MN*.

The objective of this study was to determine lactation performance of primi- and multiparous dairy cows fed different levels and sources (inorganic and organic) of Co or given weekly vitamin B_{12} injections. Forty-five primi- and multiparous cows 60 d prepartum were blocked by parity (1 or >1) and expected calving date, then randomly assigned to 1 of 5 treatments in a randomized complete block design. The treatments were: no supplemental Co (Control), 25 mg Co from Co carbonate (CoCarb), 25 mg (LCoGH) or 75 mg (HCoGH) Co from Co glucoheptonate, and Control plus weekly 10 mg vitamin B_{12} injections (IB12). Cows were on trial until 150 days in milk. Cobalt (ppm DM) in the lactation diet was 1.0, 1.9, 2.3, and 5.2 for Control, CoCarb, LCoGH, and HCoGH, respectively. Far-off, close-up, and lactating diets were 13.8, 15.1, and 18.0% CP and 48.8, 40.2, and 32.9% NDF (DM basis), respectively. Intake was not affected ($P > 0.10$) by treatment and was 19.4 ± 0.5 and 23.1 ± 0.8 kg DM/d for primi- and multiparous cows, respectively. Fat-corrected milk (FCM) was not affected ($P > 0.10$) by treatment for primiparous cows (35.4 ± 1.4 kg/d), but for multiparous cows, CoCarb (42.4 ± 1.7 kg/d) produced less ($P = 0.04$) than LCoGH (47.5 ± 1.8 kg/d). Multiparous cows on IB12 tended to have lower FCM than the mean of LCoGH and HCoGH ($P = 0.10$). Milk yield for primi- ($P = 0.85$) and multiparous cows ($P = 0.21$) on Control did not differ from the mean of CoCarb, LCoGH, and HCoGH. Milk fat percent ($P = 0.048$) and milk urea nitrogen ($P = 0.005$) were greater for primiparous cows on CoCarb than LCoGH. Multiparous cows on IB12 tended ($P = 0.10$) to have higher milk protein percent than the mean of LCoGH and HCoGH, but protein yield did not differ ($P = 0.73$). Body weight and condition score and calculated energy balance were not affected by treatment ($P > 0.10$). Addition of Co above requirements or vitamin B_{12} injections did not improve lactation performance, because vitamin B_{12} status was likely adequate.

Key Words: cobalt, vitamin B_{12}, dairy cow

W428 Carry-over effects reveal that late lactation dairy cows require longer than 30 d to respond to Diamond V Original XP. W. K. Sanchez*[1], C. S. Dei[1], J. Miller[1], G. Poppy[1], and N. St-Pierre[2], [1]*Diamond V*, *Cedar Rapids, IA*, [2]*The Ohio State University*, *Columbus*.

Objectives were to evaluate responses to Diamond V Original XP Yeast Culture (XP) in late lactation dairy cows on commercial farms. Eight Holstein herds in Central California were used to study the effects of feeding a TMR supplemented with 56 g/d XP compared to an unsupplemented Control TMR (C). Herds were paired by test day and milking frequency to form 4 Latin squares with 3 periods of 30 d each, with the extra (final) period being used to estimate carryover effects. A total of 28,690 cows in 37 pens averaging 275 DIM were used in the study. Data were analyzed using a mixed model with the random effects of pair, dairy(pair), dairy × pair × treatment × prior and residual, and the fixed effects of dietary treatments and carryover. Pen was the experimental unit. Carryover effects were evident for milk ($P = 0.0005$), 3.5% FCM ($P = 0.0006$), and milk/DMI ($P = 0.01$). This means that the treatment the herd was on in the prior 30 d affected milk, FCM and milk/DMI response in the subsequent 30 d. Differences in least squares means showed advantages for XP vs. C in milk (31.2 vs. 29.1 kg; $P < 0.05$), FCM (31.4 vs. 30.1; $P = 0.11$), and milk/DMI (1.35 vs. 1.28; $P = 0.12$). No differences in DMI, milk fat % and SCC were observed. The significant carryover effect indicates that XP should be fed longer than 30 d to observe effects in late lactation and cross-over designs used to study the effects of XP (and possibly other rumen modifiers) should have longer than 30-d periods. The biological explanation of this delayed effect is not clear, but results are consistent with other research and field experiences that show a delay in the response of either adding or removing a rumen modifier from the diet.

Key Words: Diamond V XP, lactation, dairy nutrition

W429 Effect of dietary OmniGen-AF on milk somatic cell count and the ability of isolated blood neutrophils to kill pathogens. C. R. Rill*[1], T. Lu[1], J. E. Williams[1], B. Hatch[1], B. Shafii[1], P. Rezamand[1], J. Chapman[2], and M. A. McGuire[1], [1]*The University of Idaho*, *Moscow,* [2]*Prince Agri. Products Inc.*, *Quincy, IL*.

Mastitis results from the invasion of pathogens into mammary tissue and is characterized by inflammation and elevated milk somatic cell counts (SCC). Neutrophils are the primary innate defense mechanism for mammary tissue. The purpose of this study was to examine the effect of feeding a commercially available feed additive on SCC and neutrophil killing ability. Sixteen lactating dairy cattle (59-177 DIM; mean 100 ± 10 SEM) were randomly blocked by treatments based on parity, DIM, and milk production. Diets fed were identical with the exception of an experimental mix fed at 227 g/d containing carrier only or carrier plus OmniGen-AF at 56 g/d. Milk samples were collected 3 d before through d 17 of feeding and submitted to a certified lab for milk SCC analysis. Neutrophils from each animal were isolated from blood after 48 d of feeding and evaluated in vitro for their ability to kill three common mastitis causing microorganisms. Somatic cell data were log transformed, and mean differences were analyzed during d 5 through d

17 of initiation to feeding using ANOVA procedures on a relative basis to d −3 through d 4 of feeding. Neutrophil killing differences on d 48 of feeding were also assessed via ANOVA. Daily milk weights were not affected ($P = 0.24$) by OmniGen-AF feeding (31 vs. 35 kg; SEM = 1.84). Mean relative log SCC score was less ($P = 0.0349$) for OmniGen-AF treatment vs. control (0.85 vs. 1.31, respectively; SEM = 0.22). No differences were detected for the ability of neutrophils from control vs. OmniGen-AF fed animals to kill *Staphylococcus aureus* (35 vs 41%) or *Escherichia coli* (98 vs. 97%). However, killing of *Streptococcus uberis* was improved (15 vs. 73%; $P < 0.0001$). These results indicate the feeding of OmniGen-AF to enhance immune function may warrant further investigation.

Key Words: immunity, mastitis, feed additive

W430 Effects of two processed grain sources in preparturient diets on health and performance of Holstein dairy cows during transition period. E. Qashqayi*, H. Amanlou, D. Zahmatkesh, F. Niazi, and N. Aghaziarati, *Zanjan University*, *Zanjan, Iran*.

In order to evaluate the effect of two processed grain sources on health and performance in the periparturient period, thirty two multiparous Holstein cows averaging 719 ± 31.8 kg body weight (BW) were used in a randomized complete block design and randomly assigned to 1 of 2 treatments. The experimental diets were 1) 13.06% extruded branless wheat (EBW) on a DM basis and 2) 13.06% steam flaked barley (SFB) on a DM basis. The diets were fed as total mixed ration (TMR) and feeding started on average 21 ± 4.06 d prior to expected parturition. After parturition animals received the same lactation diet until 21 d. The results showed that prepartum dry matter intake was higher in cows fed diet 1 (EBW) than in cows fed diet 2 (SFB) (13.7 vs. 11.3 kg, $P < 0.001$) and was also higher in postpartum period (17.46 vs. 16.13 kg, $P < 0.001$). There were no differences in urinary pH and fecal pH, but fecal score in cows fed EBW was higher compared with cows fed SFB during last wk prepartum (3.43 vs. 3.19, $P < 0.05$). BW and body condition score (BCS) were not affected by treatments during periparturient period. Although there were no significant differences between treatments, cows fed the EBW had greater milk yield at 3 week (30.2 vs. 28.4, $P < 0.16$), 1 month (32.7 vs. 30.7, $P < 0.14$) and 2 month (44.2 vs. 44.1, $P < 0.96$). The treatments did not influence serum concentration of glucose, non-esterified fatty acid (NEFA), cholesterol, total protein, albumin, globulin, urea nitrogen, calcium and phosphorous in periparturient cows. Postpartum incidence of retained placenta, milk fever, ketosis, mastitis, dystocia, and metritis were not affected by prepartum diets. There was no effect on parturition condition, calf birth weight and calf condition. Considering higher dry matter intake and performance in EBW group, it appears that feeding extruded branless wheat can be useful in adaptation from gestation to lactation in transition Holstein cows.

Key Words: grain processing, transition period, productivity

W431 Influence of inoculation and storage time on in vitro gas production of high moisture corn. P. C. Hoffman[1], N. M. Esser*[1], R. D. Shaver[1], W. K. Coblentz[2], M. P. Scott[3], A. L. Bodnar[3], R. Schmidt[4], and B. Charley[4], [1]*University of Wisconsin*, *Madison,* [2]*US Dairy Forage Research Center*, *Marshfield, WI*, [3]*Iowa State University*, *Ames,* [4]*Lallemand Inc.*, *Milwaukee, WI*.

The hydrophobic prolamin (zein) proteins, which encapsulate high moisture corn (HMC) starch, are altered by genetic-maturity origin and fermentation. The effect of protein alteration on in vitro digestibility of HMC has not been thoroughly investigated. To assess influences of protein alteration, as effected by inoculation and storage time, on in vitro gas production of HMC, quadruplicate samples of two random HMCs (A and B) containing 25.7 and 29.3% moisture were ground (± 900 um), inoculated (I) with or without 600,000 cfu/g of LB 40788 (Lallemand Inc., Milwaukee, WI), ensiled, and stored for 0, 15, 30, 60, 120 and 240 d. The HMCs were re-ground through a 4-mm screen, inoculated with rumen fluid from two cannulated cows fed 35% concentrate. Samples were incubated for 36 h in an in vitro gas production (GP) system fit with wireless transponders. Total, 0-12, 12-24, and 24-36 h GP was evaluated with lag (h) and fractional rate (h^{-1}) estimated using a segmented non-linear model. Total GP of A, AI, B and BI were modestly altered by storage time and HMC (A vs. B). Larger alterations of 0-12 h GP (% of total) were observed for A, AI, B and BI, with 0 and 240 d GP at 52.0, 52.0, 59.4, 59.5 and 58.6, 60.2, 71.9 and 71.6%, respectively. Fractional rates of digestion were faster for corn B, and increased with storage time but were not affected by inoculation. Fractional rates were best correlated (r = −0.64, 0.58, 0.62, −0.70, 0.64) to pH, acetate, lactate, prolamin and NH_3-N contents of HMC and 0-12 h GP was best correlated (r = −0.73, 0.77, 0.72) to pH, lactate and NH_3-N. Lag times were shorter (1 h) for HMC B but lag time was not influenced by storage time or inoculation. Gas production pools, fractional rates and lag time were poorly correlated to ADF, NDF, ADF-CP and NDF-CP. Data suggest genetic-maturity origin and storage time alter in vitro gas production of HMC.

Key Words: high moisture corn, gas production, inoculant

W432 Comparing a 60-d dry period with far-off and close-up diets with a 40-d dry period with a single diet on milk production and body condition score. J. C. Plaizier*, L. Lippins, M. L. Connor, and D. O. Krause, *Department of Animal Science, University of Manitoba*, *Winnipeg, MB, Canada*.

It has been suggested that reducing the dry period from 60 d to 40 d and feeding a single diet during a short dry period, instead of separate far-off and close-up diets, do not reduce or can increase milk production in the subsequent lactation. This was tested in an experiment with 11 blocks of 2 Holstein dairy cows. Cows were either dried off 60 d or 40 d before the expected calving date. Cows with the 60-d dry period received a far-off diet until 21 d before the expected calving date, and a close-up diet from that day onwards until calving. Cows with the 40-d dry period received the close-up diet during the entire dry period. After calving, all cows received the same lactation diet. On average, the far-off diet contained 1.29 Mcal/kg of Net Energy for Lactation, 12.4% crude protein, and 42.9% neutral detergent fiber. On average the close-up diet contained 1.42 Mcal/kg of net energy for lactation, 12.9% crude protein, and 41.7% neutral detergent fiber. The diet fed to lactating cows contained, on average, 1.71 Mcal/kg of Net Energy for Lactation, 18.1% crude protein, and 33.9% neutral detergent fiber. Diet compositions are on a dry matter basis. Cows with the 40-d dry period had lower milk yields (41.7 vs. 45.0 kg/d), higher milk fat (4.16 vs. 3.80%), and lower milk protein yields (1.34 vs. 1.45 kg/d) during the first 3 mo of lactation than cows with the 60-d dry period. During this period, milk protein content and milk fat yield were not affected by the dry cow management, and averaged 3.40% and 1.75 kg/d, respectively, across treatments. The dry cow management had no effect on body condition scores (1 to 5 scale), which were, on average, 3.45, 3.25, 2.99, 2.79, and 2.76, at drying-off, calving, 3 wk after calving, 6 wk after calving, and 9 wk after calving, respectively. The current study did not show beneficial effects of reducing the dry period from 60 to 40 d and feeding a single diet during the 40-d dry period.

Key Words: dry period, milk production, body condition score

W433 Influence of inoculation and storage time on alteration of the starch-protein matrix in high moisture corn. P. C. Hoffman*[1], N. M. Esser[1], R. D. Shaver[1], W. K. Coblentz[2], M. P. Scott[3], A. L. Bodnar[3], R. Schmidt[4], and B. Charley[4], [1]*University of Wisconsin*, *Madison,* [2]*US Dairy Forage Research Center*, *Marshfield, WI*, [3]*Iowa State University*, *Ames,* [4]*Lallemand, Inc*, *Milwaukee, WI.*

The fates of hydrophobic prolamin (zein) proteins, which encapsulate corn starch creating vitreous endosperm, have not been investigated in high moisture corn (HMC). To assess influences of inoculation and storage time on hydrophobic proteins in HMC, quadruplicate samples of two random corns (A and B), containing 25.7 and 29.3% moisture were ground (± 900 um), inoculated (I) with or without 600,000 cfu/g of LB 40788 (Lallemand Inc., Milwaukee, WI), ensiled, and stored for 0, 15, 30, 60, 120 and 240 d. Nutrient composition (CP, prolamin, starch, ADF, NDF), fermentation (pH, lactate, acetate) and protein degradation markers (buffer-soluble CP, NH_3-N) were evaluated. At 0 and 240 d, α, β, γ and δ zein regions were profiled using HPLC. Data were evaluated as a split-split plot using the PROC MIXED procedures of SAS. Inoculation and storage time reduced pH, and altered lactate and acetate contents of HMC. Lactate and acetate contents of A, AI, B and BI at 240 d were 0.40, 0.32, 1.11, 0.73 and 0, 0.35, 0.30 and 0.87% of DM, respectively. Buffer-soluble CP of HMCs increased from 1.5-2.0% of DM at 0 d to > 4.0% of DM at 240 d. Inoculation had no effect on buffer-soluble CP, but increased NH_3-N content of HMC. Corn A contained more prolamin (5.8 vs 4.6 g of prolamin/100 g starch) than corn B. Peak areas for 6 α, γ and δ zein regions were higher for corn A and fermentation (0 vs 240 d) reduced all zein subunits with the exception of 2 α and 1 δ region. Fermentation reduced (>50%) 27 kDa γ zein which cross links and lies peripheral to α zein. Despite altering lactate and acetate contents, inoculation had no effect on hydrophobic proteins in HMC endosperm. Data suggest altering fermentation acids via inoculation has a minimal effect on hydrophobic proteins in HMC, but hydrophobic proteins in HMC are highly influenced by origin and storage time (proteolysis).

Key Words: high moisture corn, prolamins, inoculant

W434 Amylopectin to amylose ratio in hulless barley in relation to intestinally absorbed protein supply to dairy cattle: A preliminary study. P. Yu*, Z. Niu, and D. Damiran, *Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objectives of this study were to investigate the relationship between the amylopectin to amylose ratio in hulless barley and intestinally absorbed protein supply to dairy cattle. The total intestinally absorbed protein supply to dairy cattle was determined according to the DVE/OEB system. The total intestinally absorbed protein supply was contributed from (1) the absorbable fraction of microbial crude protein (AMCP); (2) the absorbable fraction of ruminally undegraded feed protein (ARUP); and a correction factor for endogenous protein lost during the digestion process (ENDP). The results showed that the amylopectin to amylose ratio had no correlation with AMCP (R = −0.2928; $P = 0.4816$) and ENDP (R = 0.1952; $P = 0.6432$), but it has significant correlation with ARUP (R = −0.9759; $P < 0.0001$). The total intestinally absorbed protein supply from hulless barley has significant and negative correlation with the amylopectin to amylose ratio with R = −0.7807 ($P = 0.0222$). These results indicated that the amylopectin to amylose ratio in starch granule not only affects starch fermentation and utilization, but also affect protein value in hulless barley.

Key Words: amylopectin to amylose ratio, intestinally absorbed protein supply, hulless barley

W435 Effect of flax hulls in the diet and infusion of flax oil in the abomasum on absorption of the mammalian lignan enterolactone in dairy cows. H. V. Petit*[1], C. Côrtes[1], R. Kazama[2], D. da Silva-Kazama[2], G. T. D. Santos[2], L. M. Zeoula[2], N. Gagnon[1], and C. Benchaar[1], [1]*Dairy and Swine R & D Centre*, *Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada*, [2]*Departamento de Zootecnia*, *Universidade Estadual de Maringa, Maringa, Brazil*.

Six rumen fistulated lactating cows were used in a 6 × 6 Latin square design to investigate the effects of abomasal infusion of flax oil on absorption of the mammalian lignan enterolactone (EL) in cows supplemented or not with plant lignans. The activity of β-glucuronidase was determined in ruminal fluid, urine, plasma, and milk. Treatments were: flax hulls supplementation (without: CON vs. with 15.9% in the DM: FHU) and 3 amounts of flax oil infused in the abomasum (0, 250 and 500 g/d). Experimental periods consisted of 21 d with 14 d of adaptation. Milk samples were collected twice daily on week 3 and pooled for EL assay. Blood was withdrawn from the jugular vein 6 h postfeeding on d 20. Rumen contents were sampled on d 21 before feeding and 2, 4, and 6 h postfeeding and urine samples were taken 2 h postfeeding. Concentration of EL in ruminal fluid was determined at 0 h (baseline) and on samples pooled for 2, 4, and 6 h. All data were analyzed using the MIXED procedure of SAS according to a 6 × 6 Latin square design with repeated measurements for enzyme activity. Concentrations of EL in urine, milk, ruminal fluid, and plasma were significantly higher ($P < 0.001$) for cows fed flax hulls while the abomasal infusion of flax oil had no effect ($P > 0.05$). Cows fed FHU tended ($P = 0.06$) to have higher fecal β-glucuronidase activity than those fed CON and flax oil infusion had no effect ($P > 0.10$). There was an interaction ($P < 0.05$) between hulls and oil for β-glucuronidase activity in ruminal fluid before and post-feeding. Cows fed the CON diet with no flax oil had higher ruminal β-glucuronidase activity before feeding than those fed flax hulls with no flax oil and there was no difference among the other treatments. This study suggests that the lower activity of β-glucuronidase in the rumen of cows fed FHU than in that of cows fed CON may result of an inhibitory effect of oil present in flax hulls on the microbial population involved in the absorption of mammalian lignans. Moreover, these data suggest that β-glucuronidase activity in the small intestine is not inhibited by the presence of flax oil.

Key Words: enterolactone, lignans, flax

W436 Evaluating various meal criteria methods for analyzing chewing data. D. D. Maulfair*, G. I. Zanton, and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

When analyzing chewing data collected from cows housed in tie-stalls it is necessary to separate eating bouts into meals using an inter-meal interval or meal criteria. The objective of this study was to improve the existing method of calculating meal criteria by 1) fitting the data with a nonlinear mixed model, which acknowledges that period, treatment, and animal effects are common across the nonlinear profiles and should be accounted for at the time of fitting the nonlinear model and in addition to being used to calculate LSMEANS in proc mixed; 2) producing a meal criterion specific to each treatment at the time of fitting the nonlinear model; 3) making use of as much of the raw data as possible to limit the impact of the choice of bin width. In this study 3 different meal criteria were used to evaluate chewing behavior in lactating dairy cattle; 5 min, 7 min, and a calculated meal criterion based on the chewing data of the study. Eight multiparous, Holstein cows (90 ± 32 days in milk; 4 rumen cannulated) were randomly assigned to replicated 4 × 4 Latin squares. Cows were fed diets that varied in chop length of dry grass hay. Diet forages and their percentage of diet DM were: corn silage (29.4), hay-

lage (17.6), and grass hay (11.8). Observed meal criteria for the short, medium, long, and extra long diets were 7.6, 13.8, 10.5, and 11.2 min; the interval for the short treatment was less than for the other diets ($P < 0.05$). Eating and chewing time per day and per kg of DMI increased by up to 25.3 min/d and 1.0 min/kg DMI as meal criteria increased, but this did not affect any conclusions about differences between treatments. Number of meals/d decreased by as much as 3.4 as meal criteria increased, but there were no differences between diets in the number of meals/d for any of the meal criteria. It appears that the meal criteria value is not essential to obtain accurate conclusions about ration changes from chewing data collected in tie-stalls, but it does impact the values recorded for treatment means.

Key Words: chewing, meal criteria, particle size

W437 The effect of rumen-protected methionine and choline on reproductive performance of Holstein dairy cows. M. Ardalan*, K. Rezayazdi, and M. Dehghan-Banadaky, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*, *Karaj, Iran*.

The objective of this study was to investigate the effect of feeding ruminally protected sources of methionine and choline on the reproductive indices of Holstein dairy cows. Forty Holstein dairy cows (10 cows per treatment= 6 cows in 1st lactation and 4 cows in 2nd lactation) in their first and second lactation were used from 4-week prepartum through 20-week postpartum and randomly assigned to receive one of the following treatments: 18 g/d of rumen protected methionine (RPM), 60 g/d of rumen protected choline (RPC), 18 g/d of RPM + 60 g/d of RPC, and neither supplement (control). Cows were housed in individual tie stalls and cared for under experimental procedures and protocols approved by the veterinary organization of Iran. The forage was 57% of the total DM of dry period diet and 44% of the total DM of lactation diet. Reproductive data were recorded, including days open, days to first estrus, number of pregnant cows and number of services per conception. Statistical analysis of reproductive data was performed using the general linear models procedure (Proc GLM) of SAS and the statistical model included the effects of treatment, parity, and treatment × parity. The treatments significantly affected services per conception and open days of lactating dairy cows ($P < 0.05$), but did not affect significantly on days to first estrus and number of pregnant cows. RPM+RPC-fed cows had the lowest open days, days to first estrus and services per conception compared with other groups ($P < 0.05$). Parity and treatment × parity had not significant effects on the reproductive indices of dairy cows. Results indicate that the supplementation of RPM and RPC can improve reproductive performance of Holstein dairy cows.

Key Words: rumen-protected methionine, rumen-protected choline, reproductive performance

W438 Effects of the source and amount of sulfur in prepartum diets on performance of periparturient Holstein cows. E. Manidari, H. Amanlou, M. Frozanmehr, H. R. Mirzaei Alamouti*, and E. Mahjoubi, *University of Zanjan*, *Zanjan, Iran*.

Twenty four multiparous Holstein cows (body weight (BW), 687.9 ± 32.33 kg) were used in a completely randomized design and assigned to 3 diets: 1) 0.21% sulfur (control, without sulfur supplementation), 2) 0.41% sulfur (with 0.79% magnesium sulfate) and 3) 0.41% sulfur (with 0.57% magnesium sulfate + rumen protected methionine (25 g/d, Mepron, Degussa Corp., Kennesaw, GA)). Cows were individually fed the total mixed ration with similar net energy for lactation (1.58 Mcal/kg dry matter), crude protein (13.3%) and dietary cation-anion difference (−32 meq/kg dry matter) from 21.9 ± 2.47 d relative to expected calving until calving. After calving, all cows received the same lactation diet until 21 d in milk. Colostrum production and composition were determined until 12 h after calving. Milk production and composition were determined 3 times per day until 21 d in milk. Data were analyzed using MIXED Procedure from SAS and cows nested in the diets were as random effects. Different variance-covariance error structures were tested for data measured over time as repeated measures. Diet with 0.41% sulfur from magnesium sulfate (diet 2) compared with diets 1 and 3 significantly decreased dry matter intake at periparturient period (8.7 vs. 7.4 and 9.7 ± 0.36 at prepartum and 10.7 vs. 8.1 and 10.9 ± 0.65 kg/d at postpartum, for the diets 1, 2,and 3, respectively). Colostrum production was lower ($P < 0.01$) for the diet 2 compared with the others (11 vs. 18 and 16.3 ± 2.45 kg, for the diets 1 and 3, respectively). The Diet 3 significantly increased protein and ash content in colostrum but fat content was not affected. Cows fed the diet 2 had lower ($P < 0.01$) milk yield (19.7 vs. 24.5 and 24.9 ± 1.15 kg/d) and milk components yield compared those fed diets 1 and 3, but milk components concentration were not affected. Cows fed the diet 2 significantly lost BW and body condition score. In summary, increasing sulfur concentration (0.41% of DM) using magnesium sulfate in close-up diets compared with other diets used in this study depressed performance of periparturient cows.

Key Words: sulfur, prepartum diet, periparturient Holstein cows

Small Ruminant: Sheep Production 2

W439 The effects of high dietary protein levels in Afshari ewes during late gestation. H. Amanlou, A. Karimi, and E. Mahjoubi*, *Zanjan University*, *Zanjan, Iran*.

It has been shown that due to declining DM intake during prelambing period, protein intake can be compromised unless dietary crude protein (CP) levels are increased. However results on the impacts of increasing the dietary CP level in prelambing ewes are contradictory. Thus, the aim of current study was to investigate the effects of dietary crude protein (CP) level in late pregnancy on colostrum production, colostrum components and lamb survival. Forty-one Afshari ewes were randomly assigned to three treatment groups in a completely randomized design since 3 weeks before lambing. The experimental diets were isoenergetic and included: 1) 120 g CP/kg DM (n = 14), 2) 140 g CP/kg DM (n = 13), and 3) 160 g CP/kg DM (n = 14). The offering high CP level did not influence dry matter intake (DMI) between treatments during last 3 weeks before lambing (1.81 ± 0.14, 1.77 ± 0.26 and 1.83 ± 0.21, treatments 1 to 3, respectively; $P > 0.05$). Increasing dietary CP did not affect colostrum volume (1379.2 ± 79.38, 1398.2 ± 43.85 and 1410.3 ± 67.2 kg, respectively; $P > 0.05$), however, significantly increased crude protein content of colostrum (118.8 ± 10.6, 121.5 ± 14.5 and 142.3 ± 12.7 g/kg, respectively; $P < 0.05$). Fat, lactose and SNF content of colostrum were not affected by treatments. It also decreased lamb birth weight (4.85, 4.61 and 4.11 kg, respectively; $P < 0.05$). Although increasing CP level had no effect on lamb survival rate from birth to weaning, it was numerically lower for treatment groups 2 and 3 (100, 95.23 and 86.66%, respectively). A tendency was detected for lower BW at weaning (34.6, 32.7 and 29.4 kg, respectively; $P < 0.12$) with added CP level. In general, because of the adverse effect of high dietary protein nutrition during late gestation on lamb birth weight and expense of protein in diet, feeding high protein diet to pregnant ewes with aim to increase colostrum production and lamb survival rate in Afshari ewes is not recommended.

Key Words: prelambing, Afshari ewe, CP level

W440 Fertility and prolificity of primiparous Suffolk ewes bred by fixed-timed artificial insemination or artificial insemination at detected estrus. G. Jasso-Diaz[1], O. Mejia[2], J. I. Aguilera-Soto*[1], F. Mendez[1], M. A. Lopez-Carlos[1], R. Rincon[1], and C. F. Arechiga[1], [1]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico*, [2]*Universidad Nacional Autonoma de Mexico*, *Mexico, D.F.*

The purpose of the present study was to determine and compare fertility in Suffolk female sheep (n = 29) exposed to two different insemination procedures: 1) timed-artificial insemination (TAI) or 2) artificial insemination by detection of estrus (AIDE). In both treatments: 1) Timed artificial insemination sheep (n = 15) were treated with an intravaginal sponge containing 20 mg of fluorogestone acetate (FGA) from d −12 to 0, followed by an eCG intramuscular injection on day of sponge removal. Fixed-time intrauterine insemination was performed 56 h after intravaginal sponge removal at d 0 (without detection of estrus). 2) Insemination based on detection of estrus (AIDE; n = 14), female sheep were inseminated based on detection performed at 24 and 36 h after intravaginal sponge removal and eCG injection and inseminated at 48 h. Pregnancy diagnosis was determined firstly by non return to estrus (TAI= 93.3%; 14/15 ewes vs. AIDE=72.7%; 8/11 ewes), with non-significant differences within treatments ($P > 0.05$). Pregnancy diagnosis was performed at 45 d post-insemination by real time ultrasonography (5Mhz) confirming previous pregnancy diagnosis (93.3% vs. 72.7% for TAI and AIDE, respectively). Prolificity was not affected by insemination procedure (1.42 vs. 1.25, for TAI and AIDE, respectively). In conclusion, use of timed insemination did not compromise pregnancy, neither prolificity in Suffolk female ewes.

Key Words: sheep, artificial insemination, estrus detection

W441 Intake and performance of sheep supplemented with brewer waste (ensiled and dried) grazing under the rainy season of tropical. F. P. Portilho*, S. L. S. Cabral Filho, H. Louvandini, and B. A. O. Macedo, *University of Brasilia*, *Brasilia, DF, Brazil*.

At reduced costs industrial wastes enable usage of protein mineral mixtures as ingredients in the formulation to improve the productive capacity. The protein supplementation with residue of brewery provide rapid weight gain in the finishing phase on pasture, avoiding a possible protein deficiency in the case of high stocking rates and lower availability of fodder. The objectives of this study were to evaluate the dry matter intake and performance of finishing sheep in pasture during the rainy season and to evaluate replacement of traditional protein source (soybeans meal) by sources of low degradability in the rumen like cotton meal and brewery waste (dried and ensiled). We used forty male sheep of Santa Inês breed, with average weight of 22.04 ± 3.14 kg, grazing on Aruana grass (*Panicum maximum*), receiving supplementation of 100 g / animal / day for four treatments, plus a control without supplementation. Treatments were represented by supplementation offered for sheep grazing at the end of the rainy season during 30 days (between March and April). The treatments were composed as follows: T1) mostly of dried brewer grain (RDC), T2) by silage of waste brewery (SRC), T3) by cotton meal (FA), T4) by soybean meal (FS) and T5) without supplement (control–FSM). The experimental design was randomized blocks. Differences were observed for final weight between treatments evaluated ($P < 0.01$). The dry matter intake and weight gain varied among the treatments and there were differences ($P < 0.05$) in weight gain while comparing supplements (RDC, SRC, FA and FS) and control (FSM), with 0.131, 0.123, 0.101, 0.082 and 0.022 kg / day respectively. The feed efficiency had better trend for RDC and the worst one for the control animals (FSM). However, there were no differences ($P > 0.05$) among the treatments for feed efficiency. Therefore, the use of brewer waste in the diet of lambs at the end of the wet season can be an economical alternative as a substitute for soybean meal and yield good performances, as well as additional intake effects.

Key Words: brewer grains, supplementation, sheep

W442 Intake and performance of sheep supplemented with dried brewer grains, cottonseed meal and soybean meal grazing under tropic rainy season. F. P. Portilho* and S. L. S. Cabral Filho, *University of Brasilia*, *Brasilia, DF, Brazil*.

The usage of supplements in the rainy season provides benefits to the plants and animals. The objective of this study was to evaluate the DMI and performance of lambs during the rainy season, kept in the Tifton 85 pasture, and supplemented with different mixtures (energy and protein) with high (soybean meal) and low rumen degradable protein (dried brewery waste and cottonseed meal). Between March and April of 2007, 32 Santa Inês ewes, with average BW of 26.4 ± 4.9 kg, were kept on pasture forage of *Cynodon dactylon* cv. Tifton 85 and received supplementation of 100 g /ewe/ day. Treatments consisted of 2 formulations of protein supplements with dried brewery waste (DBW) and cottonseed meal

(CM), an one energy supplement with soybean and maize meal (SMM), and a control test with only a mineral mix (MM). The experimental design was completely randomized. We observed differences in DMI (% BW), which decreased for treatments in the following order: DBW > CM > SMM > MM (P <0.05). The results of ADG were higher for the energetic supplementation (SMM) with 149.16 g / d compared with CM and MM at 69.58 and 62.08 g / d, respectively (P <0.01), and without changes for RDC (103.75 g / day). For the feed efficiency, there were significant differences (P <0.05), with better results for SMM with 12.09 and the worst for CM, with an average of 19.18 among all treatments. We observed an increase of pasture consumption (CP) of 0.456 and 0.336 kg / day for DBW and CM having an additional effect of stimulating consumption of grass from these supplements and mild increase of 0.025 kg / day for SMM, causing a substitution effect with stimulus. Therefore, by not existing different performance between SMM and the DBW, it becomes economically viable the usage of DBW.

Key Words: brewer grains, cotton meal, soybean meal

W443 Evaluation of rhizoma peanut hay (*Arachis glabrata*) in sheep diets: Chemical composition, in vitro degradability, intake, and digestibility. A. A. Rodríguez*, G. Emmanuelli, W. González, and P. Randel, *University of Puerto Rico*, *Mayaguez*.

The effects of inclusion of *Arachis glabrata* (AG) on the chemical composition, in vitro degradability, and intake and digestibility by sheep of tropical grass hay (TGH) was determined. The legume was harvested, sun dried, and manually mixed with TGH at three different proportions: 100:0, 50:50, and 0:100 w/w. Triplicate samples from each combination were analyzed to determine OM, inorganic matter (IM), CP, ADIN, available CP (ACP), NDF, ADF, and lignin (L) content. IVDMD and in vitro NDF (IVNDFD) degradability were determined after 48 h of incubation. Data were analyzed using the GLM procedure of SAS in a randomized complete design and means separated with Bonferroni t-test. To determine forage consumption and digestibility a 3 by 3 Latin square experiment was conducted using crossbred lambs as experimental units. Lambs were assigned to the three diets. Each experiment period consisted of a 7-day diet adjustment and 5 d of data collection. OM content was lower and IM content was higher ($P < 0.05$) in mixtures containing 100% AG than 50% or 0%. CP, ACP, ADIN, ADF, and L increased as percentage of AG increased in the mixtures, but NDF content decreased. IVDMD also increased ($P < 0.05$) as proportion of AG increased, but IVNDFD decreased ($P < 0.05$). Forage consumption was similar ($P < 0.05$) in lambs fed 100% and 50%AG (1020 vs. 1056 g/d, respectively), however, while animals fed TGH alone had the lowest DM consumption (956 g/d). Daily consumption as % of animal body weight was lower ($P < 0.05$) in lambs fed TGH alone (3.17%) than those fed 50 (3.46%) or 100% AG (3.33%). Sheep fed diets containing increasing levels of AG had higher ($P < 0.05$) DMD (100% AG =62.7%, 50% AG=58.1%), CPD (100% AG=65.7%, 50% AG=62.8%) and NDFD (100% AG=57.7%, 50% AG= 53.1%) than animals fed TGH alone (DMD=54.4%, CPD=58.7%, NDFD=46.9%). In summary, CP, NDF contents and IVDMD were improved as percentage of AG increased in TGH:AG mixtures. Inclusion of AG at 50% of the total forage offered in TGH-based diets increased forage dry matter intake in sheep, while DM, CP and NDF digestibilities increased at both higher levels of AG.

Key Words: legumes, *Arachis glabrata*, sheep

W444 Metabolic profile in pregnant ewes fed oat straw-based diets supplemented with wheat hydroponic forage. E. Herrera-Torres[1], M. Cerrillo-Soto*[1,4], A. Juárez-Reyes[1,4], H. Bernal-Barragan[2,4], F. Ríos-Rincón[3,4], O. Reyes-Estrada[1], M. Murillo-Ortiz[1,4], G. Névarez-Carrasco[1,4], and M. Guerrero-Cervantes[1,4], [1]*Universidad Juárez del Estado de Durango*, *Durango, Dgo., México*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, México*, [3]*Universidad Autónoma de Sinaloa*, *Culiacán, Sinaloa, México*, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*.

A study was conducted to determine the effect of supplementing wheat hydroponic forage (WHF) to pregnant ewes fed oat straw-based diets on serum glucose, non-esterified fatty acids (NEFA) and blood urea N (BUN) at late gestation. Thirty-nine primiparous Katahdin ewes (T1 = 43.8 ± 4.8, T2 = 39.2 ± 1.4, T3 = 38.1 ± 3.0 kg BW) were randomly assigned to 3 experimental dietary treatments: T1: 72% oat straw (OS), 28% WHF, T2: 64% OS, 13% WHF, 5% cotton seed meal (CSM) and 18% rolled corn (RC), and T3: 70% OS, 8% CSM and 20% RC. Diets were calculated to meet ewes requirements according to the Intestinal Digestible Protein French System (T1 = 85, T2 = 76 and T3 = 76g/d of metabolizable protein, respectively). Jugular blood samples were collected in vacutainer tubes early in the morning before feeding monthly. Glucose, NEFA and BUN were quantified with colorimetric procedures. Statistical analysis was based on a completely randomized design for repeated measurements. Highly significant interactions ($P < 0.001$) between month and treatment were registered in serum glucose and NEFA concentrations. Ewes fed diets with more WHF (T1) had less serum glucose concentrations during the third month of pregnancy ($P < 0.05$) than ewes fed T2 and T3. Values for NEFA were similar ($P > 0.05$) between treatments; nonetheless, a numerical increment in serum NEFA was observed in ewes fed T1 in the fifth month of pregnancy. No interactions ($P > 0.05$) between month and treatment were registered in BUN, therefore, just the means of concentrations of the BUN are presented and they were: 10.2, 10.2 and 11.3 (mMol/L) for T1, T2 and T3, respectively. The observed plasma levels of glucose, urea, and NEFA indicated that an increased intake of energy may be outlined mainly for ewes fed T1 to ensure an adequate nutritional status of the animals during late pregnancy.

Table 1. Least squares means of the concentrations of blood metabolites in pregnant ewes (mMol/L)

Month of gestation	T1	T2	T3	SE±
		Glucose		
3	2.9[b]	3.6[a]	4.2[a]	0.18
4	2.9[a]	3.2[a]	3.3[a]	0.18
5	2.2[a]	2.3[a]	2.5[a]	0.18
		NEFA		
3	0.38[a]	0.36[a]	0.46[a]	0.13

W445 Performance and voluntary intake of ewe lambs in integrated crop livestock systems in the dry season. S. L. S. C. Filho*[1], B. A. O. Macedo[1], F. P. Portilho[2], H. Lovandini[1], and C. M. Pimentel[1], [1]*University of Brasilia*, *Brasília, Distrito Federal, Brazil*, [2]*EMBRAPA CERRADO*, *Brasília, Distrito Federal, Brazil*.

The objective of this study was to evaluate the performance of lambs at pasture, comparing nutritional quality of pastures that were reserved (set aside) during the raining season with those that were grazed after silage

or grain production. Four treatments were tested: *Brachiaria humidicula* with corn (BC), reserved *Brachiaria humidicula* pasture (RB), *Panicum maximum* cv. Aruana with corn (AC) and reserved *Panicum maximum* cv. Aruana pasture (RA). Thirty two crossbred Santa Inês × Ille de France ewe lambs aged from three to six months and weighing 22 ± 4.47 kg were used. The experimental design was completely randomized with two replicates per treatment, using eight experimental units (0.25ha), with four ewe lambs (testers) each. Voluntary intake and digestibility were measured with Cr_2O_3 and indigestibility ADF markers. The corn grain yield was 5.9 ± 1.1 t/ha and 4.1 ± 0.7 t/ha for BC and AC, respectively, with estimated silage yield for these treatments being 33.8 ± 6.0 t/ha and 31.3± 6.0 t/ha, respectively. There was no difference between the treatments ($P > 0.05$) in terms of CP, NDF and ADF of the pasture over the experimental period. The availability of dry matter before grazing was 3191, 3562, 3048 and 6565 kg/ha for the treatments BC, RB, AC and RA, respectively with daily weight gain being 108.5 ± 28.9; 38.5 ± 18.9; 89.5 ± 30.4 and 37.4 ± 4.5 g/day, respectively. The treatments with corn showed improved performance compared to the reserved pastures ($P < 0.05$). No significant differences were found between treatments for voluntary intake ($P > 0.05$), the average being 591.8 ± 175.44 g DM/animal/day. The dry matter digestibility for BC and RB was 43.7 ± 9.2 and 44.9 ± 6.9%, and for AC and RA was 51.1 ± 8.4 and 37.4 ± 4.5%. The AC treatment showed higher digestibility than RA, and digestibility of these did not differ from BC and RB ($P < 0.05$). The integrated pasture-crop system promoted higher performance of ewe lambs in the dry season compared to reserved pasture management, as well as providing additional silage or grain for the sheep farm.

Key Words: integrated crop livestock systems, humidicula, dry season management

W446 The effect of persimmon (*Diospros kaki* L.) vinegar supplement on feed intake, digestibility, and ruminal fermentation indices in sheep. J. H. Shin[1,2], Y. D. Ko[1], and S. C. Kim*[1,3], [1]*Department of Animal Science, Gyeongsang National University*, *Jinju, South Korea*, [2]*Department of Animal Sciences, University of Florida*, *Gainesville,* [3]*Institute of Agriculture and Life Science, Gyeongsang National University*, *Jinju, South Korea*.

This study estimated the effect of fermented persimmon (Diospros kaki L.) extract (FPE) supplement on feed intake, digestibility, nitrogen (N) balance, and rumen fermentation indices in sheep. Five male sheep (Corriedale × Polwarth, BW = 48.6 kg) were housed at metabolism crates and assigned to a 5 × 5 Latin square design with consecutive five 20-d periods which consisted of 14-d of adaptation and 6-d of data collection. The sheep were fed a diet containing concentrate and rice straw in a 3:7 ratio ad libitum. The five treatments were FPE supplemented at 0 (Control), 5, 10, 20, and 30 g/kg of concentrate. Tukey test and polynomial contrasts were used to identify differences ($P < 0.05$) and estimate the effects of FPE supplement level, respectively. Intakes of DM, OM, NDF, ADF, and nitrogen free extract (NFE) increased quadratically ($P < 0.05$) with increasing intake of FPE supplement and maximized (828, 710, 418, and 288 g/d, respectively) at 10 g/kg FPE. The digestibilities of DM, OM and NFE increased quadratically ($P < 0.05$) by increasing amount of FPE supplement, and sheep fed 5 and 10 g/kg diets had greater (52 vs. 49%, 55 vs. 52%, 60 vs. 55%; $P < 0.05$) DM, OM, and NFE digestibilities than Controls. By increasing FPE supplement concentration, N intake and fecal N increased linearly ($P < 0.05$), whereas N digestibility, retained N, and retained N ratio increased quadratically ($P < 0.05$). Retained N was maximized ($P < 0.05$) in sheep fed 5 and 10 g/kg diets (2 and 1.7 g/d). There was a quadratic increase ($P < 0.05$) of mean rumen ammonia N concentration and a linear increase ($P < 0.01$) in mean rumen VFA and acetate concentrations. The mean concentration of rumen propionate in sheep fed all FPE supplemented diets was greater (2.2 vs. 1.78 mmol/dL; $P < 0.05$) than Control, but the mean ratio of rumen acetate to propionate in sheep fed 5 and 10 g/kg diets was lower (2.6 vs. 2.9; $P < 0.05$) than that of Control sheep. In conclusion, FPE supplemented at 5-10 g/kg of concentrate improved feed intake, digestibilities of DM, OM and NFE, N metabolism, and rumen fermentation indices of sheep.

Key Words: persimmon, digestibility, sheep

W447 Prediction of rumen pH and digestibility of diets containing soybean hulls fed to ram lambs by the Small Ruminant Nutrition System. R. S. Gentil*[1], I. Susin[1], A. Cannas[2], A. V. Pires[1], C. Q. Mendes[1], E. M. Ferreira[1], G. H. Rodrigues[1], A. S. Atzori[2], and L. O. Tedeschi[3], [1]*Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/ University of São Paulo*, *Piracicaba, São Paulo, Brazil*, [2]*University of Sassari*, *Sassari, Sardinia, Italy*, [3]*Texas A&M University*, *College Station*.

The Small Ruminant Nutrition System (SRNS) predicts feed values based on carbohydrate and protein fractions and their digestion rates, forage, concentrate and liquid passage rates, microbial growth, and physically effective fiber (peNDF). Data from four experiments with lambs were used to compare observed OM digestibility (OMD), NDF digestibility (NDFD), and pH with predictions made by the SRNS model v. 1.8.7. All experiments were designed to study soybean hulls (SH), a byproduct that is rich in digestible fiber but poor in peNDF. SH substituted corn meal in experiments 1, 2 and 3 and coastcross hay in experiment 4. To compare OMD and NDFD estimates with measured values, two values of degradation rate of B2 carbohydrate fraction (potentially digestible NDF) of SH (kd = 8, as in the SRNS feed library, and 14%.h^{-1}) were used. In the SRNS the kd of B2 carbohydrate fraction is reduced if pH decreases below 6.2. Thus, OMD and NDFD were predicted by using the rumen pH predicted by the SRNS (pH = 5.425 + 0.04229 x peNDF) or a fixed value of 6.46. The digestibility predictions were more precise and accurate when kd was assumed to be 14%.h^{-1} and fixed pH were used (OMD: mean bias (i.e. observed-predicted values; MB) = 0.57%, $r^2 = 0.70$ and root of mean square prediction error (RMSPE) = 3.05%; and for NDFD: MB = 2.25%, $r^2 = 0.52$, RMSPE = 5.24%). Rumen pH was slightly overpredicted (MB = −0.03, $r^2 = 0.61$, RMSPE = 0.17%). Thus, the SRNS predictions had good precision and accuracy for rumen pH, while OMD and NDFD digestibility were correctly predicted only if the kd of the B2 carbohydrate fraction of SH was greater than that reported in the SRNS feed library and not reduced when pH decreased.

Key Words: digestibility, rumen pH, SRNS

W448 Okara as a protein supplement for early lactating ewes. L. B. Harthan* and D. J. C. Cherney, *Cornell University*, *Ithaca, NY.*

Livestock producers must use cost-efficient feedstuffs if they are to remain profitable in the face of decreasing market prices and increasing feed prices. The objective was to evaluate the feeding value of wet okara, waste pulp remaining after production of soy milk, as a protein supplement for lactating ewes with twin lambs. A 4 × 4 Latin square replicated twice was conducted to examine the influence of concentrate mix (okara or not) and type of forage (silage or hay) on ewe milk composition and growth of lactating lambs. Ewes (multiparous; 55 to 74.8 kg) were 12.5 ± 3.5 DIM, and were raising twins. The 4 diets were formulated to have the same TDN (% of DM).Treatment periods were 14 days (7 days adaptation and 7 days collection), and ewes were fed

1 of 4 diets: a wheat middling and corn concentrate with mixed grass hay (TSH), okara and corn with mixed grass hay (OSH), soybean and wheat middlings fed with hay crop silage (TSS), and okara and corn with hay crop silage (OSS). Forages were fed separately from concentrate mixes. Ewes fed hay diets (TSH and OS) had lower forage DM intakes than ewes fed hay crop silage (TSS and OSS; $P > 0.05$). Intake of okara supplement was much higher ($P < 0.05$) with OSH (3.64 kg/d) than with OSS (1.70 kg/d) possibly a result of the high moisture content of the okara. There was no difference in supplement intake between TSH and TSS. Despite differences in DMI, there were no differences among diets for either ewe daily gain or lamb daily gains. There were no differences in ewe milk compositions among the diets. Based on similar ewe growth efficiencies, and average weekly gain of lambs, okara is an effective source of protein for lactating ewes.

Key Words: okara, protein, lamb

W449 Use of pinto bean waste on finishing hair-type lambs. G. Villalobos, F. Castillo*, D. Dominguez, H. Castillo, and J. A. Ortega, *Universidad Autonoma de Chihuahua*, *Chihuahua, Chihuahua, Mexico*.

Feeds price increment has obliged sheep producers to look for new alternatives in animal feeding; one of them is waste pinto bean grain. The objective was to evaluate the effect of three waste pinto bean grain levels (in concentrate dry matter) on dry matter intake (DMI), average daily gain (ADG) and gain efficiency (GE) of finishing hair lambs. Treatments were: Control (C= 0%), low waste pinto bean (LWB= 12.5%) and high waste pinto bean (HWB= 25%). Seventy two crossbred hair lambs (Dorper × Pelibuey and Kathadyn × Pelibuey) were used (36 females and 36 males), all lambs being twins, with 18.69 ± 3.89 Kg initial body weight and 75 ± 6 d old. Lambs were fed ad libitum with isoenergetic and isonitrogenous (2.6 Mcal/Kg ME; 17.9% CP) diets (80:20 concentrate:forage ratio) during 70 d, with an adaptation period of 18 d. Lambs were assigned to blocks by initial body weight (3 lambs per block, 4 female blocks and 4 male blocks by treatment) and then randomly assigned to the treatments (C, LWB and HWB; n= 24 per treatment) and were weighted every 14 d for ADG. In the last 5 d of each period DMI was measured for each block and then GE was estimated. Data for DMI, ADG and GE was analyzed with PROC MIXED in a completely random block arrangement where the treatment, gender and their interaction effects were evaluated, likewise a tendency analysis was made for each variable. For DMI (Kg) a quadratic effect was found ($P < 0.05$), but treatments were not different ($P = 0.0657$) (C= 1.22, LWB= 1.14 and HWB= 1.05). Data for ADG (Kg) showed a quadratic response for each treatment ($P < 0.05$) (C=0.26, LWB=0.23 and HWB=0.21) during the test. Final body weight lsmeans (Kg) were C= 37.67, LWB= 34.22 and HWB= 33.27. For GE (Kg) a clear general tendency was not found, with no differences between treatments ($P = 0.6001$) during the test (C= 6.53, LWB= 6.94 y HWB= 6.94). Gender and its interaction treatment by gender effect were not found ($P > 0.05$) for any variable. The best productive performance of treatments in this research was found for C, so that the waste pinto bean grain use on finishing hair lambs is not a recommendable alternative for this productive stage.

Key Words: hair lambs, waste pinto bean grain, feedlot lambs

W450 Effect of cull-chickpeas on apparent digestibility and energy concentration of feed in growing Pelibuey sheep. A. Estrada-Angulo*[1,4], H. Bernal-Barragán[2,4], M. A. Cerrillo-Soto[3,4], E. Gutiérrez-Ornelas[2,4], A. S. Juárez-Reyes[3,4], J. F. Obregon[1,4], J. J. Portillo-Loera[1,4], and F. G. Rios[1,4], [1]*FMVZ-Universidad Autonoma de Sinaloa*, *Culiacan, Sinaloa, Mexico*, [2]*FA-Universidad Autonoma de Nuevo Leon*, *Monterrey, Nuevo Leon, Mexico*, [3]*FMVZ-Universidad Juárez del Estado de Durango*, *Durango, Durango, Mexico*, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *Culiacán, Sinaloa, Mexico*.

A study was performed to determine the effect of cull chickpeas (CCP) substituting corn-soybean meal on apparent digestibility and energy concentration in growing sheep. Five Pelibuey males (30.0 ± 1.1 kg BW) were used in a 5 × 5 Latin square design with 6-day adjustment and 4-day collection phases. Experimental diets consisted of: 1) control; Sudan hay (10%), whole corn grain (67.6%), soybean meal (13.1%), sugarcane molasses (6%), sodium bicarbonate (0.6%) and mineral premix (2.7%); 2) CCP15; CCP (15%), whole corn grain (58.1%), soybean meal (7.6%); 3) CCP30; CCP (30%), whole corn grain (48.5%), soybean meal (2.2%); 4) CCP45; CCP (45%), whole corn grain (35.7%); and 5) CCP60, CCP (60%), whole corn grain (20.7%). All diets were isoenergetic (3.60 Mcal of DE/kg). Crude protein content for treatments 1, 2 and 3 was 16.0% while CP content for treatments 4 and 5 was 17.2 and 19.3%, respectively. Dry matter intake was adjusted to 1000 g/head/day (500g at 0800; 500 g at 1500). Fecal and feed samples were oven dried and analyzed for DM, OM, CP, and apparent digestibility of DM. Digestible energy content (Kcal/kg) was calculated by: 43.97 (digestible DM %) - 94. Data were analyzed by ANOVA. No treatment effects ($P > 0.05$) were registered in DM fecal excretion (140.6, 139.7, 148.4, 150.3, and 150.3 g/d) or apparent DM digestibility (85.9, 86.0, 85.2, 85.0 and 85.0%) for Control, CCP15, CCP30, CCP45 and CCP60, respectively. Meanwhile, neither the DE concentration (3.68, 3.69, 3.65, 3.64 and 3.64 Mcal/kg DM) nor the observed/calculated DE ratio (1.02, 1.03, 1.01, 1.01, and 1.01) differed ($P > 0.05$) among treatments. Data suggested that a whole corn grain-soybean meal mixture can be substituted up to 60% with CCP without affecting apparent digestibility of DM and energy concentration in diets for growing Pelibuey sheep.

Key Words: hair sheep, cull chickpeas, apparent digestibility

W451 Fiber digestibility of a finishing lamb diet supplemented with Fibrozyme. D. Domínguez, J. E. Cruz*, G. Villalobos, H. Castillo, L. Durán, E. Santellano, and L. Carlos, *Universidad Autónoma de Chihuahua*, *Chihuahua, Chihuahua, México*.

Fibrolytic enzymes can enhance rumen microbial enzyme activity under low ruminal pH conditions improving fiber digestion. This study evaluated the effect of Fibrozyme addition on fiber digestion of a finishing lamb diet. Six crossbreed lambs (Charolais × Pelibuey; 30 ± 6.1 kg) fitted with ruminal cannula were individually housed and randomly assigned to three levels of Fibrozyme (Alltech Inc.): 0.0 (T-0.0), 0.1 (T-0.1) y 0.2 g/kg of body weight (T-0.2) added to concentrate. The experimental design was a replicated 3 ×3 Latin square. Lambs were fed ad libitum with a diet containing 2.9 Mcal ME/kg DM and 15.9% CP, based on 20% alfalfa hay and 80% concentrate (% DM). Each experimental period last 17 d, with an adaptation phase of 7 d. Dry matter intake (DMI) was determined daily and individually from 8th to 12th d. Ruminal pH was determined on 13th d at 0, 1, 2, 4, 8, 12, 18 and 24 h after morning feeding. Fecal samples were taken on 15th to 17th d, to determine fiber digestibility using indigestible ADF. Content of NDF and ADF were sequentially determined in period composite samples of forage, concentrate, and fecal grabs. Dry matter intake and digestibility data were analyzed with PROC GLM, while ruminal pH data were analyzed as repeated measurements on time using PROC MIXED. DMI was similar among treatments (1.44, 1.48 and 1.48 kg, respectively; $P > 0.05$). Rumen pH for all treatments was lower than 6.0 during 14 h (from 4th to 18th h after feeding). Dry matter digestibility was not affected by treatments (76.6, 75.1, and 77.6%, respectively; $P > 0.05$). However, NDF and ADF digestibility was higher for T-0.2 vs.

T-0.0 and T-0.1 (15.0 vs. 12.7 and 8.9%; and 17.3 vs. 11.2 and 13.3%, respectively; $P < 0.05$). Hemicellulose digestibility was similar among treatments (14.4, 8.8 and 14.7%, respectively; $P > 0.05$). Adding Fibrozyme at 0.2 g/kg of body weight to finishing lambs diet improved fiber digestibility.

Key Words: Fibrozyme, fiber digestibility, hair lambs

W452 Effect of variety and maturity state of oat hay on performance of ewe lambs. D. Domínguez[1], S. Ramírez*[1], J. J. Salmerón[2], R. González[2], G. Villalobos[1], J. A. Ortega[1], and L. Carlos[1], [1]*Universidad Autónoma de Chihuahua*, *Chihuahua, Chihuahua, México*, [2]*INIFAP*, *Cuauhtémoc, Chihuahua, México*.

Oat hay is an important forage source in the sheep industry of Chihuahua, México. This study evaluated the effect of genotype and maturity stage on nutritional value of oat hay and their effect on performance of ewe lambs. Karma (K), Cevamex (C) and Bachiniva (B) oat varieties were cultivated under non irrigated conditions and harvested at soft-dough (SDS) and hard grain stage (HGS). Ninety hair ewe lambs of commercial crosses with an initial average weight of 30.2 ± 2.5 kg were randomly assigned to six treatments (n=15, 5 pens and 3 lambs per pen) in a 3 × 2 factorial design. Animals were fed ad libitum a 80:20 forage:concentrate diet (% DM) containing 2.4 Mcal ME/kg DM and 16.0% CP. Production of DM per hectare (DM/ha), and content of CP, NDF, ADF, and ADL were determined for oat varieties. Dry matter intake (DMI) was determined daily per pen, while body weight, average daily gain (ADG) and gain efficiency (GE) were recorded individually every 14 d, and apparent digestibility of DM, CP and NDF at the final of the study. Data was analyzed as a complete random blocking design in a factorial arrangement, using PROC MIXED. There was no effect of oat variety on DM/ha, but it was higher for HGS (5,211 vs. 4,293 kg/ha; $P < 0.05$). Genotype and maturity stage did not affect chemical composition. Content of CP, NDF, ADF and ADL for SDS and HGS were: 11.5 and 10.2; 51.8 and 51.1; 28.4 and 27.7; and 2.75 and 2.90%, respectively. DMI, final body weight, ADG and GE were not affected by treatments, average for SDS and HGS were: 1.29 and 1.22; 36.4 and 35.5; 0.116 and 0.110 kg; and 14.2 and 14.3, respectively. Dry matter and NDF digestibility was higher ($P < 0.05$) for C-SDS (67.6 and 59.5%), while CP digestibility was similar among treatments. Harvesting and feeding oat hay at SDS showed small benefit on nutritive value of forage, but did not improve animal performance.

Key Words: oat variety, maturity stage, ewe lambs

W453 Influence of substitution of alfalfa hay for dried grape pomace on performance and carcass characteristics of growing sheep. Y. Petriz-Celaya*, J. F. Calderon-Cortes, C. Perez, M. F. Montaño, and A. Plascencia, *Instituto de Investigaciones en Ciencias Veterinarias, Universidad Autónoma de Baja California*, *Mexicali 21100, Baja California, México*.

The comparative feeding value of unfermented dried grape pomace (DGP; 1.09 Mcal/kg of DE, 12% CP) was evaluated in an 84-d feeding trial involving 16 individually fed ewe lambs (17.2 kg initial wt). In the experimental diets DGP replaced (DM basis) 0, 10, 20 or 30% of late bloom alfalfa hay. Lambs were allowed ad libitum access to feed and water. Feed intake and orts were recorded daily. Initial and final shrunk weights were obtained following a 12-h withdrawal of feed. The trial analyzed as a randomized block design experiment. Substitution of DGP for alfalfa hay did not affect ($P > 0.10$) ADG, DMI/ADG, hot carcass wt, and dressing %, however DMI was slightly higher with T2 (10%) and T4 (8%) than T1, and ribeye muscle area was 11% greater with T4 than with T1. We conclude that DGP can replace up to 30% of late bloom alfalfa hay in diets for lambs without adversely affecting animal growth and carcass characteristics.

Table 1. Effect of the substitution of alfalfa hay by dried grape pomace on growing sheep performance and carcass characteristics

Grape pomace, %	T1, 0	T2, 10	T3, 20	T4, 30	SEM
Final wt, kg	26.16	26.40	25.32	26.28	0.94
ADG, g	0.11	0.11	0.10	0.11	0.01
DMI, kg/d	1.15a	1.27b	1.12a	1.24b	0.03
DMI/ADG	10.85	11.66	11.63	11.62	0.55
Hot carcass wt, kg	11.5	13.5	12.5	13.3	0.74
Dressing, %	44.17	51.49	49.35	50.75	3.07
Ribeye muscle, cm2	4.09a	3.78a	3.84a	4.53b	0.19

[ab]Means in the same row that do not have a common superscript differ ($P < 0.05$).

W454 Effect of a basal creep feed diet modification on the preferences in pre-weaning piglets. J. Figueroa*[1], D. Solà-Oriol[1], X. Manteca[1], C. Chetrit[2], and J. F. Pérez[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*, [2]*Bioibérica SA*, *Barcelona, Spain*.

Oronasal and postingestive experience play an important role in creep feeding intake. The aim of the present trial was to study the effect of basal creep feed diet modifications on creep-feed preference in sucking piglets. A total of 80 litters (10-12 piglets/sow) were used in a 6-day double choice-feeding test (DCFT) (22 to 28d-old piglets). The preference for 4 different modified diets was compared with that for a simple diet (CT) by using a DCFT. The CT diet included corn, barley and wheat (54.7%), sweet whey (14.12%), soybean protein concentrate (16.6%) and spray dried porcine plasma (5%). The modified diets included the flavored commercial creep-feed diet (COM) commonly used on the farm, and 3 different modifications of the CT diet, based on the incorporation of garlic flavor (0.075%, GAR) or the replacement of soybean meal by porcine digestible peptides (1.5%, PDP, Palbio 50RD), and of soybean oil by a intestinal porcine fat (T1Fat). Choice feeding test was conducted in the farrowing pens by using two small creep-feeders containing the two diets (side by side). Feeds were offered ad libitum in mash form. Preference was calculated as the percentage contribution of the test diet to the total creep feed intake. Litters showed a total creep feed intake of 476 g/d (SD 267 g/d). Preference values for PDP diet (50.1%) or T1Fat diet (60.0%, $P = 0.074$) were not significantly different from CT. CT diet was significantly preferred to the GAR diet (40.9%, $P < 0.01$) and the current COM diet (36.1%, $P < 0.001$). Our results suggest that the addition of new flavors or ingredients may affect the palatability of piglet′s creep feed diets. Piglets showed a preference for simple diets and neophobia or innate aversion to new flavors.

Key Words: palatability, choice-feeding, creep feed

W455 Nutritional value of Brazilian crude glycerol and semi-purified glycerol on starting pigs diets. I. Moreira*, P. L. de Oliveira Carvalho, L. M. Piano, J. B. Toledo, A. C. Furlan, C. de L. C. Filho, and T. M. P. da Cruz, *Universidade Estadual de Maringá*, *Maringa, Paraná, Brazil*.

One experiment was carried out to determine the nutritional value of four different types of glycerol. Two different types of crude glycerol from soybean oil (CGS), and animal fat + soybean oil (CGA), and two different types of semi-purified glycerol from soybean oil (SPGS), and animal fat + soybean oil (SPGA) were used. Glycerol is the main co-products of biodiesel production (esterification technologies using vegetable oil or animal fat). Gross energy (kcal/kg) of CGS, CGA, SPGS, and SPGA (as-fed basis) were 5,247; 5,242; 3,760; and, 3,217 respectively. A digestibility trial using 56 crossbred barrows with 19.20 ± 1.52 kg of initial body weight was conducted. The trial consisted of a randomized experimental design (4 × 3 factorial scheme) with four different types of glycerol and three levels of glycerol in the diet. Four experimental units (one pig) per diet were used. Glycerol levels used in the digestibility trial were 4%, 8%, and 12% of the basal diet (corn + soybean based) calculated according to NRC (1998). The digestibility coefficient (%) values of four different types of glycerol were: dry matter (CGS = 93.10, CGA = 80.55, SPGS = 95.87, SPGA= 89.44); organic matter (CGS = 90.27, CGA = 89.05, SPGS = 106.87, SPGA = 100.89); gross energy (CGS = 96.60, CGA = 98.11, SPGS = 100.88, SPGA = 100.09); metabolization coefficient of gross energy (CGS = 87.54, CGA = 85.98, SPGS = 89.69, SPGA = 91.15). The digestible (DE) and metabolizable energy (ME) values of glycerol were estimated by regression (Adeola, 2001) of DE and ME intake vs. glycerol intake. The values (as-fed basis) of DE and ME (kcal/kg) obtained were: CGS = 5,070 and 4,593; CGA = 5,143 and 4,507; SPGS = 3,793 and 3,373; SPGA = 3,220 and 2,932, respectively. The results indicate that all types of Brazilian glycerol used in this study are highly available energy source for starting pigs feeding.
Financial support: CNPq (Brazil).

Key Words: co-product, digestibility, glycerine

W456 Prediction of carcass composition in crossbred pigs using the real-time ultrasound: Comparison of the interpreting results. L. L. Lo*, M. E. Tai, and C. C. Tsai, *Chinese Culture University*, *Taipei, 111 Taiwan, ROC*.

Efficient use of the real-time ultrasound to predict carcass composition is important. The objective of the study was to compare the interpreting results of the ultrasound images from the farm and laboratory when predicting backfat thickness and longissimus muscle area of the pigs. Ultrasound images were obtained from 147 three breed (Duroc, Yorkshire, and Landrace) terminal crossbred pigs (71 gilts and 76 barrows) using an Aloka SSD 500 real-time ultrasound. All pigs were raised under commercial farm environment, and slaughter at an average age of 205 days for an average weight of 117 kg. The day prior to slaughter, two transverse images at the tenth rib and the last rib were taken and interpreted from each pig, and the images also were taped to be interpret in the laboratory by a trained operator later on. Carcass backfat thickness and longissimus muscle area at the tenth and the last rib were measured at a commercial slaughter plant using the standard procedure. All data were analyzed using a linear model that included fixed effects of year, herd, sex, and method. Phenotypic correlations between ultrasonic and carcass measured backfat thickness at the tenth and the last rib ranged from 0.828 to 0.849 when interpreting the ultrasound data in the field, and ranged from 0.797 to 0.836 when interpreting that in the laboratory. Ultrasound and carcass measured longissimus muscle area were slightly lower correlated when interpreting the results in the laboratory (r = 0.646-0.719) with that in the field (r = 0.722-0.755). There were no significant differences between the two methods for backfat thickness and longissimus muscle area ($P > 0.10$). When including ultrasound backfat thickness and longissimus muscle area in the regression equation for predicting carcass lean, interpreting results from the farm and laboratory gave the similar accuracies. Therefore, obtaining the real-time ultrasound images from the farm and interpret in the laboratory can be an optimal way in application of the real-time ultrasound technology for swine.

Key Words: interpreter, real-time ultrasound, carcass composition

W457 The effect of type of housing during gestation on gilt farrowing and piglet performance. R. Muns*, J. L. Ruiz de la Torre, E. G. Manzanilla, X. Manteca, and J. Gasa, *SNiBA, Departament Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona*, *Barcelona, Spain*.

The objective was to evaluate the impact of gestation housing on gilt farrowing and piglet performance. Fifty-three gilts from a commercial farm were randomly distributed to one of the following treatments: T1) pen-grouped gestation (10 gilts/pen with an automatic feeding system) or T2) stall-allocated gestation. Back fat (BF) was measured ultrasonically

4 days before and 20 days after farrowing. Farrowing was monitored and the interval from 1st to last piglet born recorded. Piglets were weighted on farrowing day (day 0), day 1, day 2 and day 20 of lactation and rectal temperature (RT) was measured at birth. On day 2, litters were fixed at 12 piglets. Mortality before and after day 2 were registered. Data was analyzed with a one-way ANOVA with type of housing as main effect using SAS program. T1 sows had more BF at the beginning (18.7 vs. 14.6mm ± 3.42; $P < 0.001$) and at the end of lactation (15.0 vs. 12.9mm ± 4.86; $P < 0.003$) together with a shorter farrowing duration (2.5 vs. 3.0h ± 0.93; $P = 0.077$). Piglets initial BW did not differ between groups (mean value of 1.29 ± 0.310kg; $P = 0.485$). T2 piglets had more RT at birth than T1 (38.7 vs. 37.5°C ± 1.34; $P < 0.001$) and had an increased BW gain on day 1 (58.7 vs. 41.6g ± 67.68; $P = 0.059$). T2 gilts weaned more piglets (11.73 vs. 11.37 ± 0.673; $P = 0.020$) with less piglet mortality from day 2 to 20 (0.21 vs. 0.56 piglet/litter ± 0.528; $P = 0.114$). Although T2 gilts had a 30 min. longer farrowing, their piglets were born with higher RT. This fact could help piglets to had a better colostrum intake resulting in higher energy and immunological status which may explain the enhanced surviving at weaning. According to our results, we conclude that for gilts, the transition from a pen-housing gestation to a stall-farrowing allocation may suppose a bigger stress compared to a transition from stall-housing gestation. That stress could have a negative repercussion on offspring body temperature at birth, compromising its colostrum intake.

Key Words: gilts, gestation housing, piglets

W458 Performance of starting pigs fed on crude glycerol in Brazil. I. Moreira*[1], P. L. de Oliveira Carvalho[1], L. M. Piano[1], J. B. Toledo[1], A. G. Gallego[2], and G. Moresco[1], [1]*Universidade Estadual de Maringá*, *Maringa, Paraná, Brazil*, [2]*Universidad Del Tolima*, *Ibagué, Tolima, Colombia*.

This experiment was carried out to investigate the utilization of two types of crude glycerol which were obtained from soybean oil (CGS), and animal fat + soybean oil (CGA) on starting pigs performance. Glycerol is the main co-products of biodiesel production (esterification technologies using vegetable oil or animal fat). In Brazil, the primary feedstock for glycerol production is soybean oil. Chemical composition (as-fed basis): CGS (DM = 97.46%; CP = 0.06%; GE = 5,247 kcal/kg and ash = 4.45%) and CGA (DM = 94.55%; CP = 0.05%; GE = 5,242 kcal/kg and ash = 4.26%). In the performance trial, 90 piglets (BW = 15.18±0.67 to 30.28±1.68 kg) were allotted in a completely randomized design in 2 × 4 factorial scheme, with different levels (3, 6, 9, and 12%) of two types of crude glycerol (CGS and CGA) in the diet. An additional control diet was formulated containing no glycerol (0%). Five pens with two pigs/pen for each treatment resulting in 10 observations per treatment. Experimental diets were formulated according to NRC (1998) as isoprotein and isoenergetic. Performance data of 0, 3, 6, 9, and 12% of CGS were, respectively: ADFI = 1.601, 1.650, 1.602, 1.532, and 1.572 kg; DWG = 0.889, 0.937, 0.901, 0.851, and 0.850 kg; F: G ratio: 1.81, 1.75, 1.78, 1.80, and 1.854, and, in the same way, performance data of CGA were, respectively: DFI = 1.601, 1.599, 1.645, 1.546, and 1.646 kg; DWG = 0.889, 0.851, 0.934, 0.855, and 0.929 kg; F: G ratio: 1.81, 1.88, 1.76, 1.82, and 1.77. There were no interaction among levels of CG and types of crude glycerol, and the regression analysis indicates no effects ($P \geq 0.05$) of crude glycerol inclusion on piglet performance (DFI, DWG and F: G ratio). The results suggest that it is feasible to use up to 12% of both sources of CG on starting piglet diet, without impairing performance.

W459 Fatty acid profile in different tissues of newborn piglets. M. Sini, M. G. Manca, A. Nudda, and G. Battacone*, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*.

Objective of the present study was to investigate fatty acid deposition in different tissues of newborn piglets and its relationship with fatty acid composition of diet of gestating sows. Six Landrace × Large White sows in second or third parity were bred with semen from a Landrace boar. During gestation, sows were individually housed in crates and fed a concentrate for gestating sows and gilts administered according to feed requirements during periods of fetal development. Immediately after parturition, one piglet per litter was stunned, exsanguinated and dissected. Brain, liver, hearth, thigh muscle of piglets and sows were weighed and samples were taken for fatty acid profile. Content of each fatty acid in organs and feed was expressed as a percentage of total FAME. Data were analyzed with one-way ANOVA using tissue as the main effect. The fatty acid profile was significantly different between tissues. Particularly, the highest content of PUFA n-3 was observed in brain (8.68 g/100 g of FAME) . This result is probably due to the higher concentration of DHA (8.49 g/100 g of FAME) that actually represents 97% of total n-3 FA in the brain. The content of DHA is high also in liver where it represents about 85% of total n-3 fatty acid. The content of PUFA n-6 was higher in hearth (29.16 g/100 g of FAME) than other tissues, maybe due to the higher content of linoleic and arachidonic acid (13.13 and 15.24 g/100 g of FAME, respectively). High values of arachidonic acid were also observed in brain where it is about 93% of total n-6 fatty acid. The concentration of unsaturated fatty acid was higher in hearth where they account for 2/3 of total fatty acid, while saturated fatty acid were higher in brain and muscle (48.41 and 47.54 g/100g of FAME, respectively). The research highlighted differences in long chain fatty acid composition between tissues of newborn piglets, especially for FA synthesized ex-novo.

Key Words: fatty acid, piglets, tissues

W460 Effect of terminal sire genotype and gender on growth performance and carcass traits of European-Chinese pigs. J. Viguera[1], M. Sánchez*[1], S. Garrido[1], J. Peinado[1], F. Flamarique[2], and L. Alfonso[3], [1]*Imasde Agroalimentaria S.L.*, *Madrid, Spain*, [2]*Grupo AN*, *Navarra, Spain*, [3]*Universidad Pública de Navarra*, *Navarra, Spain*.

A total of 168 pigs (half castrated male and half female) of 25.4 ± 4.1 kg of initial BW from Youna crossbreds sows (Gene +, France) was used to evaluate the effect of two terminal sire genotypes (MUS vs. PIE) on performance and carcass traits. There were fourteen replicates of six pigs per treatment. Data were analyzed as a completely randomized design by GLM of SAS. The model included the terminal sire genotype and sex as main effects. All pigs were reared under similar environmental and nutritional conditions, and were slaughtered at 102.3 ± 8.65 kg BW. MUS pigs grew faster than PIE pigs (782 vs. 711 g/d; $P < 0.01$). No significant differences in feed intake were detected. Therefore, MUS pigs showed lower feed conversion than PIE pigs (2.81 vs. 3.07 g feed/g gain; $P < 0.01$). MUS pigs showed longer carcasses and hams than PIE pigs (80.9 vs. 78.7 cm and 50.6 vs. 49.5 cm, respectively; $P < 0.01$). However, PIE pigs showed higher shape factor (1.46 vs. 1.43; $P < 0.01$) and had greater carcass yield (77.8 vs. 77.1%; P = 0.04), ham yield (27.8 vs. 27.1%; $P < 0.01$), and loin yield (7.40 vs. 6.91%; $P < 0.01$) than MUS pigs. Castrated males grew faster (777 vs. 716 g/d; $P = 0.02$) and ate more feed (2.30 vs. 2.08 kg/d; $P<0.01$) than females. Likewise, castrated males had more backfat and fat thickness at Gluteus medius muscle (21.2 vs. 18.1 mm and 17.3 vs. 13.4 mm, respectively; $P < 0.01$) but lower ham yield (27.0 vs. 27.8%; $P < 0.01$) and loin yield (6.79 vs. 7.52%; $P < 0.01$) than females. Results showed that Youna

crossbreds with MUS pigs perform better but have lower primal cut yields than Youna crossbreds with PIE pigs.

Key Words: European-Chinese pigs, growth performance, carcass traits

W461 The effect of aeration on the slurry quality and microbial communities in liquid swine manure during the digestion. M. Heo*[1,2], K. H. Park[2], D. Y. Choi[2], H. S. Kang[2], and S. Oh[1], [1]*Division of Animal Science, Chonnam National University*, *Gwangju, South Korea*, [2]*Animal Environment & Systems Division, National Institute of Animal Science R.D.A.*, *Suwon, South Korea*.

Liquid swine manure can be converted to a liquid fertilizer by aeration. We examined the temporal changes in the microbial community and associated characteristics that occurred by aeration during the digestion. Liquid swine manure, collected from the swine barns of the National Institute of Animal Science (NIAS), was subjected to 2 treatments: one in which the manure was not aerated (the control sample) and the other in which the manure was aerated continuously at a rate of 3.0 $m^3 \bullet h^{-1} \bullet t^{-1}$ (the aerated sample). The study was conducted in an outdoor research field at NIAS for 20 weeks (May to September). In the aerated sample, the concentration of volatilized NO_3 decreased from the 6th week, with a concomitant steep increase in the NH_4^+-N and NO_3^--N concentrations. The pH increased for the first 4 weeks and then decreased, and the decline was sharp in the 6th week. In the control sample, the concentration of volatilized NH3 continuously increased from the beginning, and the NH_4^+-N concentration slowly decreased. Nitrate was barley detected, and the pH was stable. There was a decrease in the number of bacteria, including Lactic acid bacteria, *Actinomyces*, coliformic bacteria, and *Salmonella*, and in the number of fungi; *Salmonella* could not be detected from the 18th week. *Bacillus* sp., *Acinetobacter* sp., *Pseudomonas* sp. (*Pseudomonas putida*), *Alcaligenes* sp., *Sphingobacterium* sp., *Brevundimonas diminuta*, and *Aeromonas hydrophila* were found in the aerated sample, but not in the control. In the aerated sample, *Bacillus* sp. were predominantly found in the 1st week; *Bacillus cereus* and *Baciilus pumilus*, in the 5th week; and *Bacillus cereus* and *Bacillus subtilis*, in the 6th week. This indicates that aeration promotes the growth of bacteria that are effective in reducing ammonia, and that *Bacillus* sp. are the most effective. Further research on the optimal cultivation conditions for the identified bacteria species would help in increasing the application of liquid fertilizers prepared from liquid swine manure.

Key Words: slurry, swine manure, microbila community

W462 Growth performance of pigs finished on brewers-grade rice. O. J. Gekara* and T. V. Dunbar, *University of Arkansas at Pine Bluff*, *Pine Bluff*.

The objective of this study was to determine whether brewers-grade rice can replace corn or milo in finishing pig diets without compromising animal performance. Seventeen finishing pigs of Yorkshire × Duroc breeding were randomly assigned to either brewers-grade rice/soybean meal mixture (RSB) or corn/milo based control (CON). The pigs were 157 days old at the start of the experiment and weighed 87.9±3.4 kg. The experiment lasted 28 days and finished pigs weighed 119.0±3.2 kg. Variables determined included ADG, ADFI, F:G ratio, apparent DM digestibility, and back fat thickness. There was no ($P > 0.10$) treatment × sex interaction for all variables measured. Compared to CON pigs, RSB pigs gained faster (1.26 vs. 0.95 kg/d), had better F:G ratio (0.38 vs. 0.29), higher apparent DM digestibility (91.0 vs. 74.0%), and lower ($P < 0.001$) cost of gain (0.98 vs. 1.62 $/kg gain). Back fat thickness for the two layers, 1 and 2, was similar ($P > 0.10$) for both groups (11.6 vs. 22.7 mm, respectively). Results of this study suggest that brewers-grade rice can be a suitable alternative to corn or milo for finishing pigs with no adverse effects animal performance. In conclusion, hog producers in the Mississippi Delta (southeast Arkansas) where rice is abundant and relatively cheaper than corn or milo may derive substantial savings on feed costs with the use of brewers-grade rice as an energy source. However, more research is needed to determine the effect of growth performance on grade and carcass quality.

Key Words: brewers-grade rice, finishing pigs, pig performance

W463 Differential expression of porcine sperm microRNAs and their association with sperm morphology and motility. E. Curry*[1], T. J. Safranski[2], and S. L. Pratt[1], [1]*Clemson University*, *Clemson, SC,* [2]*University of Missouri*, *Columbia*.

Although miRNAs have been shown to alter translation in nearly every biological process examined to date, little is known as to the identity of miRNA in porcine gametes or their potential involvement in reproductive processes. Recent investigations have demonstrated that the miRNA synthesis pathway is necessary for differentiation of mature sperm in mice; however, the specific miRNAs responsible for spermatogenesis have not been identified. The objective of this study was to determine the identities and compare the expression levels of miRNAs in control porcine sperm samples which exhibited >75% motility and <15% poor morphology (C; n= 7), samples with >15% abnormal morphology (AB; n= 7), and samples exhibiting <68% motility (LM; n= 8). qRT-PCR was performed in quadruplicate on 10 ng sperm RNA using the mirVana qRT-PCR miRNA Detection Kit (Ambion, Austin, TX) to compare expression levels of 10 specific miRNAs that are predicted to target genes that code for proteins involved in spermatogenesis, sperm structure, motility, or metabolism. Statistical analysis was performed using REST-2005 software with significance at $P < 0.05$. Results showed increases in the expression of four miRNAs, let-7a, −7d, −7e, and miR-22, in the AB group while miR-15b was decreased compared to C ($P < 0.05$). Two miRNAs, let-7d and let-7e, were increased in the LM group when compared to C ($P < 0.05$). Although the precise role of miRNA in sperm remains to be determined, their presence alone denotes an essential biological function. It is feasible that they are remnants of spermatogenic processes, stored for a later role in fertilization, or are delivered to the oocyte to influence early embryonic development. While there is no single cause of male infertility, the identification of miRNAs associated with sperm motility, structural integrity, or metabolism could lead to the development of a microarray or real time-based diagnostic assay to provide an assessment of male fertility status.

Key Words: microRNA, sperm, porcine

W464 Prediction of carcass composition in crossbred pigs using the real-time ultrasound: Choices of probing and measuring sites. L. L. Lo*[1], C. C. Tsai[1], M. E. Tai[1], R. S. Lin[2], and T. H. Huang[3], [1]*Chinese Culture University*, *55 Hwa-Kang Road, Taipei, Taiwan, ROC*,[2]*National ILan University*, *ILan, Taiwan, 260 ROC*, [3]*Taiwan Farm Industry Co., Ltd.*, *Pingtung, 900 Taiwan, ROC*.

Development of an optimum method for predicting carcass composition is essential for improving pig carcass performance. Real-time ultrasound data of backfat thickness, and longissimus muscle area were obtained from 147 three breed (Duroc, Yorkshire, and Landrace) terminal crossbred pigs (71 gilts and 76 barrows) using an Aloka SSD 500 real-time ultrasound machine to find the optimum probing and measuring sites between ultrasound measurements at the tenth and the last ribs for predicting carcass composition. All pigs were raised under

the commercial farm environment, and slaughter at an average age of 205 days for an average weight of 117 kg. The day prior to slaughter, two transverse images were taken at the tenth rib and the last rib from each pig. The backfat at two points, 1/2 and 3/4 the lateral length of the loin muscle perpendicular to the skin surface were measured. The correlation between ultrasonic and carcass measured fat thickness at the last rib were similar to those of the tenth rib at 1/2 and 3/4 point locations (r = 0.828-0.859). Ultrasonic and carcass measured longissimus muscle area was slightly higher correlated at the 10th rib compared with that of last rib. The best correlations between carcass lean percentage and ultrasound measurements were obtained with 3/4 point fat thickness at the tenth rib (r = −0.45) and with longissimus muscle area at the last rib (r = 0.47). When predicting carcass lean yield, the regression equation included the tenth rib ultrasound backfat measured at 3/4 point location and the tenth rib longissimus muscle area, gave the highest accuracy (R^2 = 0.892). Results from this study indicated that the tenth rib site and 3/4 point of the lateral length of the loin muscle can serve as the probing and measuring sites for prediction of carcass lean yield.

Key Words: ultrasound, carcass composition, pig

W465 Association between lactation feed intake and wean to service interval of sows. L. Anil*[1], S. S. Anil[2], and S. K. Baidoo[1], [1]*Southern Research and Outreach Center, University of Minnesota*, *Waseca,* [2]*Veterinary Population Medicine, University of Minnesota*, *St Paul.*

Previous studies have indicated the effect of inadequate lactation feed intake on subsequent reproductive performance of sows in breeding herds. However, most of them have used average feed consumption during the entire lactation, ignoring the effect of stage of lactation. The number of days of inadequate feed intake could be a better indicator of inadequate lactation feed intake. Factors such as parity, body condition of the sow at the end of gestation and litter size influence the quantity of feed consumed during lactation. The objective of the present study was to determine the association of number of days of <3 kg of feed consumption during the first 14 days of lactation with wean to service interval (WSI), accounting for the effects of parity and body condition of the sow prior to farrowing. This study involved 504 sows (289 sows housed in pens with electronic sow feeders and 215 sows in gestation stalls). Data with 990 parities of these sows with one or two farrowings, collected from the PigCHAMP database of the research unit were used for the analysis (Poisson regression, Proc genmod, SAS v 9.1). The average lactation feed intake and average WSI in the database were 6.0 kg and 7 days respectively. The number of days of 0 kg feed consumption increased by 4% ($P < 0.05$) with every day increase in WSI suggesting the negative relationship between daily lactation feed intake and WSI. The number of days of <0.5, <1.0, <1.5, <2.0, <2.5 and <3.0 kg of feed consumption within the first 14 days of lactation increased by 4.0, 3.1, 1.7, 1.9, 1.6 and 0.8% respectively ($P < 0.05$ all) for every day increase in WSI. This study confirms the negative relationship between lactation feed intake and WSI and indicates the need to ensure adequate lactation feed intake on all days during early lactation to prevent prolongation of wean to service interval.

Key Words: lactation feed intake, wean-to- service interval, sows

W466 Effect of terminal sire genotype and gender on growth performance and carcass traits of European-Chinese pigs destined to the dry-cured industry. M. Sánchez*[1], J. Viguera[1], C. Carrasco[1], J. Peinado[1], F. Flamarique[2], and L. Alfonso[3], [1]*Imasde Agroalimentaria S.L.*, *Madrid, Spain*, [2]*Grupo AN*, *Navarra, Spain*, [3]*Universidad Pública de Navarra*, *Navarra, Spain*.

A total of 160 pigs (half castrated male and half female) of 23.7 ± 5.0 kg of initial BW from Youna crossbreds sows (Gene+, France) was used to evaluate the effect of Duroc boar terminal sire (T line, fatter vs. P line, leaner) on performance and carcass and meat quality traits. There were eight replicates of ten pigs per treatment. All pigs received a common diet based on cereals and soybean meal ad libitum, and were slaughtered at the same age (177 d of age) with 116.5 ± 10.4 kg of final BW. Data were analyzed as a completely randomized design by GLM of SAS. The model included the boar terminal sire and sex as main effects. The slaughter weight was used as a covariate for carcass quality traits. Pigs from P sire line had lower feed conversion (2.85 vs. 2.98 g feed/g gain; $P < 0.05$) than pigs from T sire line. Ham yield tended to be higher in the P line pigs (26.73 vs. 26.46%; $P = 0.07$). However, no significant differences between P and T sire line pigs were found for backfat. Also, loins from T line pigs had higher redness value than those from P line pigs (4.16 vs. 3.52; $P = 0.04$), but no significant differences were observed between genotypes for lightness and yellowness of loin. Castrated males ate more feed (2.63 vs. 2.36 kg/d; $P < 0.01$), showed higher feed conversion (3.05 vs. 2.78 g feed/g gain; $P < 0.01$) and fatter carcasses (21.3 vs. 18.7 mm; $P < 0.01$) than females. Besides, females had higher carcass yield (76.19 vs. 75.35%; $P < 0.01$), ham yield (26.82 vs. 26.36%; $P < 0.01$), and loin yield than castrated males (7.98 vs. 7.99%; $P < 0.01$). It is concluded that Youna crossbreds with P sire line pigs perform better than T sire line pigs. However, no major differences were found between the male sire lines on carcass and meat quality traits of European-Chinese pigs destined to dry-cured product industry.

Key Words: European-Chinese pigs, pig performance, carcass quality

W467 Effect of hyperprolific Chinese sow genetic on sow performance. J. Viguera[1], M. Sánchez*[1], J. Sánchez[1], P. Medel[1], F. Flamarique[2], and L. Alfonso[3], [1]*Imasde Agroalimentaria S.L.*, *Madrid, Spain*, [2]*Grupo AN*, *Navarra, Spain*, [3]*Universidad Pública de Navarra*, *Navarra, Spain*.

A total of 58 primiparous sows was used to evaluate the effect of two hyperprolific Chinese genetics (Taizumu vs.Youli) on sow performance. All sows received ad libitum a common liquid diet from mating until weaning of piglets. Observations included body weight and fat depth at P2 at mating and every 4 weeks until weaning, feed intake during lactation, number of piglets born alive and weaned per sow and weight of litter at birth after cross-fostering and at weaning. Data were analyzed as a completely randomized design by GLM of SAS. At farrowing, Youli sows were heavier than Taizumu sows (88.8 vs. 81.2 kg; $P = 0.07$), a near significant trend. No other differences were detected on body weight or backfat during the experiment. Taizumu sows had a higher number of piglets born alive (13.84 vs. 10.87 piglets; $P < 0.01$), but with smaller body weight (1.24 vs. 1.41 kg; $P = 0.02$) and less uniformity (79.41 vs. 81.75%; $P = 0.02$) than Youli sows. However, Youli sows weaned a higher number (10.35 vs. 9.62 piglets; $P < 0.01$) of heavier piglets (7.22 vs. 6.71 kg; $P = 0.01$) than Taizumu sows. Moreover, Youli sows ate more feed (289.6 vs. 272.2 g/d; $P = 0.04$) than Taizumu sows during lactation. Under our experimental conditions it can be concluded that Youli sows had higher number of piglets born alive, but Taizumu sows weaned a higher number of heavier piglets.

Key Words: hyperprolific Chinese sows, piglet performance

W468 Influence of crowding stress during the nursery period on growth performance of gilts and barrows. J. H. Cho*, H. J. Mon-

egue, M. D. Lindemann, and G. L. Cromwell, *University of Kentucky*, *Lexington*.

Stocking density and/or floor space allowance can influence pig performance and, consequently, profitability. The objective of this study was to determine the effects of stocking density and floor space allowance during the nursery period on growth performance of gilts compared to barrows. Gilts were then retained to examine continuing effects on growth with the intent of following them through reproduction. During a 6-wk crowding period, a total of 240 pigs (120 gilts and 120 barrows; mean age of 21 d; 6.8 ± 1.0 kg BW) were allotted to 3 space allowances (SA) in a 2 × 3 arrangement (sex [gilts vs barrows] and SA [SA1, 6 pigs in a full pen: 1.22 × 2.44 m^2, 0.50 m^2/pig; SA2, 12 pigs in a full pen: 0.25 m^2/pig; SA3, 6 pigs in a half pen: 1.22 × 1.22 m^2, 0.25 m^2/pig)]. Feeder space and water nipple availability was identical for each pig in all treatments; diets were nutritionally adequate (NRC, 1998). During the grow-finish period, gilts had adequate floor space (6 pigs in a pen; 0.93m^2/pig). For the 6-wk nursery period, crowding reduced ADG ($P < 0.01$) in gilts (577, 536, and 558 g/d for SA1, SA2, and SA3, respectively) and barrows (578, 539, and 527 g/d). While ADFI and F/G were not affected by stocking density or SA, there was a much larger change in ADFI among treatments (gilts: 907, 845, 884; barrows: 916, 891, 858 g/d) than there was in F/G. (gilts: 1.57, 1.58, 1.58; barrows: 1.58, 1.65, 1.63). There was no sex by SA interaction on performance measures. During the grow-finish period, when gilts were housed at the same density in pens with the same space, there were no differences ($P > 0.10$) in ADG (890, 864, and 891 g/d), ADFI (2,677, 2,559, and 2,636 g/d), or F/G (3.01, 2.96, and 2.96) based on previous nursery housing treatment. These results demonstrated that crowding stress during the nursery period negatively affected growth performance of both gilts and barrows during that period of stress, but a continued effect of that stress was not manifested in gilts when subsequently housed in adequate space during the grow-finish period.

Key Words: nursery pigs, crowding stress

W469 Feed intake of gilts following intracerebroventicular injection of the novel hypothalamic RFamide (RFa) neuropeptide, 26RFa. C. J. Rogers*[1], N. L. Heidorn[1], C. R. Barb[2], G. J. Hausman[2], M. J. Azain[1], R. Rekaya[1], and C. A. Lents[1], [1]*University of Georgia*, *Athens,* [2]*USDA-ARS Richard B. Russell Agriculture Research Center*, *Athens, GA*.

RFamide (RFa) peptides have been implicated in a broad spectrum of biological processes including energy expenditure and feed intake. 26RFa is a recently discovered hypothalamic neuropeptide that altered the release of pituitary hormones and stimulated feed intake via a NPY-specific mechanism in rats. Voluntary food intake in the pig is regulated by changes in NPY, and we speculate that 26RFa is involved in the process. Thus, we tested the hypothesis that 26RFa stimulates food intake in the domestic pig. Prepuberal gilts (73 ± 17 kg BW) were fitted with intracerebroventricular (i.c.v.) cannulas and housed in individual pens. Pigs were allowed ad libitum access to feed for 7 d prior to treatment to establish a base line for voluntary feed intake. On the day of the experiment, feeders were removed from all pens at 0900 h. Beginning at 1100 h, gilts received i.c.v injection of either 10 (n = 8), 50 (n = 7) or 100 μg (n = 7) of 26RFa in 0.9% saline. Control animals received either 100 μg of NPY (n = 5) or 0.9% saline alone (saline; n = 5). Feeders were placed in all pens immediately after the last i.c.v. injection (1200 h) and cumulative intake was determined at 4, 8 and 24 h. Treatment had no effect on feed intake at 4 h. Feed intake of saline treated gilts at 8 h was not different when compared with 26RFa treated animals. However, NPY treated pigs ate more at 8 h (1.64 ± 0.20 kg) than saline treated pigs (1.07 ± 0.20 kg; $P < 0.05$) or pig receiving either 10 μg (0.90 ± 0.16 kg; $P < 0.01$) or 50 μg (1.13 ± 0.16 kg; $P < 0.06$) of 26RFa. Feed intake at 8 h of pigs treated with 100 μg (1.27 ± 0.17 kg) of 26RFa was not different from either NPY or saline treated animals. There were no differences between treatments in feed intake at 24 h. We conclude that 26RFa is not an orexigenic neuropeptide in the pig. Further study is needed to determine the effects of i.c.v. injection of 26RFa on hormone release from the anterior pituitary gland of the gilt.

Key Words: feed intake, 26RFa, hypothalamus

W470 Increasing productivity and disease control on swine farms trough management tools: A field study. G. Rocha-Chavez*[1], J. Castañeda[2], A. Sepulveda[1], J. G. Michel-Parra[1], M. A. Pinto[2], O. Montañez[1], A. Martínez[1], and J. M. Tapia- Gonzalez[1], [1]*Universidad de Guadalajara*, *Cd Guzman, Jalisco, Mexico*, [2]*Private Practice*, *Tamazula, Jalisco, Mexico*.

Current swine production systems use genetic and other technological tools to increase effectivity and profitability, however, emergent and old diseases are always devastating potential capacity of swine business. The present paper discuss a field study that combine a series of management tools that increased competitiveness in a porcine farm. Although this model has been implemented in different swine production systems, we describe the field experience of a small farm located at the southern part of Jalisco state in Mexico. A Farrow-to-finish 200-sow farm was selected for the present study. The farm was PRRS and PCV positive with glasser disease and mycoplasm persistent outbreaks. A very low feed efficiency and kg/sold/sow/year was present at the farm before intervention as well as high production costs (see table for more parameters). The following tools were implemented for 2 years: (1) Closed herd: the genetic progress was achieved by means of artificial insemination with no live animal introduction whatsoever. (2) Close monitoring of reproduction management: Heat detection and insemination was priority number one on morning chores. (3) Autovaccination program: A professional and well controlled autogenous vaccination program was implemented using exclusively row material from the farm. (4) Employers management program: an incentive-based program was implemented on the premise of happy workers are efficient partners.

Table 1. Production parameters at a pig farm before or after implementing selected management tools

Production parameter	Before	After
Wean to finish mortality, %	7.3 [a]	1.9 [b]
Farrowing rate, %	78.3 [a]	87.7 [b]
Feed efficiency, (feed to gain ratio)	3.7 [a]	2.8 [b]
Veterinary Services/Medicine per Cwt, US$	9.27	6.32
Total Cost per Cwt of Pork Produced, $	164.00 [a]	117.00 [b]

SYMPOSIA AND ORAL PRESENTATIONS

Animal Health: Respiratory Health, Viruses

767 Newly received feedlot heifers managed with three respiratory disease protocols. J. L. Wahrmund*[1], D. B. Burken[1], B. K. Wilson[1], S. J. Terrill[1], D. L. Step[2], C. R. Krehbiel[1], C. L. Goad[3], and C. J. Richards[1], [1]*Oklahoma State University, Department of Animal Science*, *Stillwater,* [2]*Oklahoma State University, Department of Veterinary Clinical Sciences*, *Stillwater,* [3]*Oklahoma State University, Department of Statistics*, *Stillwater*.

Commingled heifers were purchased and administered ruminal temperature monitoring devices in LA (n = 180, BW = 248.7 ± 35.7 kg) and KY (n = 162, BW = 243.9 ± 21.4 kg). Within purchase group, heifers were allotted to 12 pens for 56 d. Pens were assigned to 3 bovine respiratory disease (BRD) management treatments with pulls based on: visual signs (CON, n = 110), visual signs and(or) elevated ruminal temperature (TEMP, n = 116), or visual signs after metaphylactic tulathromycin treatment (MET, n = 116). Antimicrobial treatments for BRD included tulathromycin, fluoroquinolone, and ceftiofur-HCl. Effects of management and number of BRD treatments required were analyzed using the MIXED procedure of SAS. Heifers on CON, TEMP, and MET treatments were treated 0.55, 1.47, and 1.27 times for BRD, respectively. Final BW of TEMP heifers was 5.3 kg greater ($P < 0.05$) than CON, and MET heifers gained 0.12 kg/d more than CON heifers ($P < 0.05$). Interactions of management × number of BRD treatments required were observed ($P < 0.05$) for final BW and overall ADG. Final BW of CON heifers requiring one or 2 BRD treatments were 12.9 kg and 38.6 kg less ($P < 0.05$), respectively, than those never treated. Final BW of MET heifers requiring no additional BRD treatment were 18.9 kg greater ($P < 0.05$) than those requiring 3 treatments. Final BW of TEMP heifers receiving 2 or less treatments were not different ($P > 0.05$); however, BW of those treated 3 times was 15.1 kg less ($P < 0.05$) than those treated once. CON heifers requiring zero or one treatment gained 0.58 kg/d more ($P < 0.05$) than heifers requiring 2. MET heifers receiving no additional treatments gained 0.23 kg/d more ($P < 0.05$) than those receiving 3. TEMP heifers treated once or twice gained 0.46 kg/d more ($P < 0.05$) than heifers treated 3 times. Of heifers treated once for BRD, MET heifers gained 0.16 kg/d more ($P < 0.05$) than CON heifers. Of heifers treated twice, MET and TEMP heifers gained 0.64 kg/d more ($P < 0.05$) than CON. Management did not affect ($P > 0.05$) ADG of heifers treated 3 times. Ruminal temperature monitoring and metaphylactic antimicrobial treatment have positive effects on feedlot health and performance.

Key Words: disease, performance, temperature

768 Muscle gene expression in an acute model of bovine respiratory disease. R. L. Mills*, L. Carlos-Valdez, L. O. Burciaga-Robles, D. Stein, D. L. Step, R. W. Fulton, U. DeSilva, and C. R. Krehbiel, *Oklahoma State University*, *Stillwater*.

Bovine respiratory disease (BRD) has been shown to negatively impact carcass characteristics by leading to lighter carcasses, decreased *longissimus dorsi* (LD) area, and poorer carcass quality. To understand the effects of BRD on muscle gene expression, 8 beef steers (284 ± 37.4 kg) were exposed to 2 calves persistently infected with bovine viral diarrhea virus type 1b (BVDV) for 72h followed by intratracheal inoculation with *Mannheimia hemolytica* (MH). Muscle biopsies were taken from the LD before exposure to pathogens (PRE) and 24 h (24H) following inoculation. Total RNA was extracted, reverse transcribed, and expression levels analyzed using quantitative PCR. Glutamine synthetase (GS) was induced (+8.12, $P < 0.001$) and regulatory factor X-associated ankyrin-containing protein (RFXANK) and a homolog of tropomyosin 4 (TPM4) tended to be upregulated (+2.61 and +1.48, respectively; $P < 0.10$) in the 24H group. Glutamine synthetase induction is a hallmark of muscle deterioration. RFXANK is a regulatory protein known to bind major histocompatibilty complex class II (MHCII) promoters inducing MHCII expression involved in antigen presentation. Tropomyosin 4 is an actin-binding protein shown to affect muscle contraction in striated and smooth muscle tissue in humans. Results indicate that muscle proteolysis is occurring based on GS expression. MHCII may be upregulated in muscle histiocytes as demonstrated by increased levels of RFXANK transcripts. Glutamine status has been shown to affect immune status; therefore, the induction of these 2 proteins may be indicative of cooperation between macrophages and myofibers. These results suggest that cattle challenged with BRD pathogens may experience acute cachexia within 24h post-infection with BVDV and MH. Such myopathy may partially explain lighter carcass weights associated with cattle treated for BRD.

Key Words: beef cattle, bovine respiratory disease, skeletal muscle

769 Bovine respiratory disease related metabolic fingerprints in beef steers. S. J. Terrill*, R. D. Madden, J. W. Dillwith, L. O. Burciaga-Robles, D. L. Step, R. W. Fulton, A. W. Confer, M. Montelongo, and C. R. Krehbiel, *Oklahoma State University*, *Stillwater*.

Bovine respiratory disease (BRD) is the most costly disease in North American feedlots; however, diagnosis is subjective. Metabolomics, or the study of the total metabolic profile of a biological tissue or fluid, may provide a way for objective diagnosis. The objective was to identify biomarkers of BRD using metabolomic techniques (i.e., GC/MS). Twenty-four Angus crossbred steers were divided into 4 treatment groups in a completely randomized design (n = 6). Treatments were: 1) exposure to 2 BVDV persistently infected (PI) steers for 72 h (BVDV); 2) exposure to the 2 PI-BVDV steers for 72 h and intratracheal challenge with *Mannheimia hemolytica* on d 0 (BVDV+MH); 3) intratracheal challenge with *M. hemolytica* on d 0 (MH); and 4) no challenge (CTRL). Blood samples were collected at −72, 12, 24, and 48 h of *M. hemolytica* challenge. Using a GC/MS platform, total metabolic fingerprints of plasma were obtained. Normalized abundance values were analyzed and means separated using Tukey's procedure (GeneSpring MS 1.2; Agilent Technologies, Santa Clara, CA), and metabolites were identified using the NIST '05 MS Database (NIST, Gaithersburg, MD). At 12 h after infection, glutamic acid was lower ($P = 0.003$) across all treatments compared with CTRL, whereas threonic acid was greater ($P = 0.04$). Citric acid was greater ($P < 0.001$) in BVDV+MH and BVDV steers compared with CTRL. BVDV+MH steers had greater ($P = 0.003$) levels of isoleucine than CTRL, but the MH treatment had lower ($P = 0.003$)

isoleucine. At 48 h after infection, valine and leucine were lower ($P < 0.01$) in BVDV+MH cattle compared with CTRL, but greater ($P < 0.01$) in BVDV steers. Phenylalanine was lower (P 0.006) in both BVDV+MH and MH steers compared with CTRL, but was greater ($P = 0.006$) in BVDV steers. Glycine was lower ($P = 0.02$) in both BVDV+MH and BVDV treatments. There were no significant changes detected at 24 h after infection. Results suggest significant changes in AA profiles at 12 and 48 h after BVDV exposure and *M. hemolytica* infection. GC/MS metabolic fingerprinting is a promising technique that may provide for better diagnosis and identification of BRD.

Key Words: amino acids, bovine respiratory disease, metabolomics

770 Evaluating timing of weaning stress on response to BVD2 vaccinations in Angus calves. E. D. Downey*[1], E. C. Conrad[1], J. F. Ridpath[2], R. G. Tait Jr.[1], and J. M. Reecy[1], [1]*Iowa State University*, *Ames,* [2]*National Animal Disease Center/ARS/USDA*, *Ames, IA*.

This study was designed to evaluate the impact of environmental factors and genetic controls on response to vaccination against bovine viral diarrhea virus type 2 (BVDV2) in Purebred American Angus beef cattle. This study utilized 362 Angus calves born in the spring (n = 211) and fall (n = 151) of 2007. Two doses of modified live Bovishield Gold-5 (initial and booster) were administered 3 weeks apart. The herd was managed with 2 calving seasons, fall and spring. Calves, from each season, were allotted to one of 2 weaning/vaccination management protocols based on dam management group. In protocol 1, calves were weaned at initial vaccination. In protocol 2, calves were weaned at the time of booster vaccination. Viral neutralizations were conducted using cytopathic BVDV2 to determine antibody titer at initial vaccination, at booster vaccination, and 3 weeks post booster vaccination. Titer levels at initial vaccination were significantly influenced by calf age ($P < 0.001$), calving season ($P < 0.001$), and gender ($P < 0.05$). There was no significant difference ($P = 0.219$) in the initial titer level between the 2 protocol groups. Response to initial vaccination was calculated by finding the difference between the booster titer score and the initial titer score; response to booster vaccination was the difference between the titer score 3 weeks post booster injection and at booster injection. The overall response was calculated as the titer score 3 weeks post booster injection minus initial titer score. Response to initial vaccination, response to booster vaccination and overall response were significantly ($P < 0.001$) affected by the titer level at the beginning of the specified response period. All 3 response variables were significantly ($P < 0.05$) different across the 2 weaning protocol. The interaction between weaning protocol and the respective titer level was significant ($P < 0.05$) or suggestive ($P < 0.10$) of an effect on all 3 response variables. Based on this preliminary data, management of weaning/vaccination stress in conjunction with titer level at initial vaccination can affect the antibody response developed in Angus calves.

Key Words: beef cattle, vaccination, weaning

771 Alterations in the somatotropic axis during an infectious bovine rhinotracheitis viral (IBRV) challenge in beef steers. S. M. Falkenberg*[1], T. B. Schmidt[1], D. H. Keisler[2], J. L. Sartin[4], J. O. Buntyn[1], and J. A. Carroll[3], [1]*Mississippi State University*, *Mississippi State*, [2]*University of Missouri*, *Columbia*, [3]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX*, [4]*Auburn University College of Veterinary Medicine*, *Auburn, AL*.

The objective of this trial was to identify the cytokine response following IBRV exposure and the impact on the somatotropic axis, 12 steers (228.82 ± 22.15 kg) were randomly assigned to a Control (CON) or an IBRV challenged group. Prior to the challenge steers were fitted with an indwelling rectal probe and a blood sample was obtained. On d 0, IBRV steers received an intra-nasal dose of IBRV (2 mL/nostril; Cooper strain, 1×10^7 PFU/mL) and CON steers received an intra-nasal dose of saline (2 mL/nostril). IBRV steers were placed in a paddock isolated from the CON cattle as well as all other cattle on the research farm. The first 48 h post-challenge, blood was collected via single jugular venipuncture. At 72 h post-challenge steers were fitted with indwelling jugular catheters, and then moved to individual stanchions. Blood samples were intensively collected on d 4–8 post-challenge. IBRV steers had elevated rectal temperatures as compared with CON steers ($P < 0.05$) starting on d 2, peaking on d 4 (40.8 ± 0.54 vs. 39.5 ± 0.54°C), and returning to baseline on d 6. The response patterns for cortisol (CORT), interferon-γ (IFN-γ), and growth hormone (GH) all followed a similar pattern for IBRV steers starting on approximately d 2, peaking on d 4, and tapering off on d 6. The peak concentration on d 4 for CORT (pg/mL; 136.96 ± 67.70 vs. 74.5 ± 45.76), IFN-γ (ng/mL; 133.41 ± 126.45 vs. 27.98 ± 10.38), and GH (ng/mL; 48.43 ± 7.66 vs. 32.74 ± 12.67) for the IBRV steers as compared with CON. While there was a difference ($P < 0.05$) in GH concentrations between the IBRV and CON steers, IGF-1 concentrations did not differ ($P > 0.05$) between the 2 groups. Collectively the data revealed alterations in the somatrotrophic axis that were not associated with a large increase in circulating concentrations of pro-inflammatory cytokines. We conclude that the low dose of the virus used in the present study, while sufficient to elicit a febrile response, it did not result in the calves becoming septicemic which would explain the lack of a detectable cytokine response.

Key Words: cattle, cortisol, cytokines

772 Identification of genetic regions associated with bovine viral diarrhea-persistently infected cattle. R. Zanella*[1], J. Wenz[1], E. Casas[2], J. S. Neibergs[1], D. Moore[1], and H. L. Neibergs[1], [1]*Washington State University*, *Pullman*, [2]*United States Meat Animal Research Center*, *Clay Center, NE*.

Bovine viral diarrhea virus (BVDV) is one of the etiologies involved in bovine respiratory disease (BRD). BVDV infection can also cause reproductive disorders and acute fatal hemorrhagic disease resulting in poor performance and economic losses to the cattle industry. Infection with BVDV can be transient or persistent. Transient infections are temporary and last until the animal builds immunity to the virus. Persistent infections (BVD-PI) occur when a cow and her fetus are infected with BVDV at approximately 40 to 140 d of gestation. BVD-PI animals shed virus throughout their lives. Previous studies have found bovine chromosomes (BTA) 2 and 26 to be linked to BRD. The objective of this research was to determine if these regions were associated with BVDV-PI infection. Ear notches of 8624 commercial beef calves were tested by qtRT-PCR for the presence of BVDV. Calves positive for BVDV were confirmed to be BVD-PI by ELISA at the Washington Animal Disease Laboratory. Sixty-five BVD-PI calves, their dams, and 60 contemporary calves (controls) from the same herd were genotyped for 6 microsatellites on BTA 2 and 7 microsatellites on BTA 26. Allele frequencies were compared between BVD-PI calves and controls, dams of BVD-PI calves and controls with a Fishers exact test. BTA 26 was associated with persistent infection when BVD-PI calves ($P = 0.01$) and dams of BVD-PI calves ($P = 2.8 \times 10^{-6}$) were compared with controls. Strong evidence for an association with BTA 2 and persistent infection was demonstrated for BVD-PI calves ($P = 1 \times 10^{-10}$) and the dams of BVD-PI calves ($P = 1 \times 10^{-13}$). These results are congruent with the BRD linkage results and suggest that BTA 2 and BTA 26 harbor loci that influence both BRD and BVD-PI.

Key Words: BVD-PI, loci, association

773 Economic analysis of persistently infected bovine viral diarrhea disease prevalence in Washington beef herds. J. S. Neibergs*, H. L. Neibergs, J. Wenz, and D. Moore, *Washington State University*, *Pullman*.

Studies have identified that bovine viral diarrhea virus (BVDV) causes economic losses throughout the beef production chain primarily through persistently infected (PI) calves. The purposes of this study were to identify BVDV-PI prevalence in Washington cow-calf herds, identify herd health management risk factors associated with positive PI prevalence, determine economic losses, and to evaluate the economic efficacy of disease management. A state-wide voluntary BVDV-PI testing program tested 8,624 calves from 60 herds, identifying 80 (0.92%) BVDV-PI calves in 8 herds (13.3%). Two herds had catastrophically high prevalence with 13% and 52% PI positive calves. Washington PI prevalence was substantially higher than comparable studies. Managers with positive herds were interviewed to collect production and economic performance data using NCBA SPA economic methods. Herd economic losses ranged from $1.34 to $236.75 per cow. Total ranch losses ranged from $482 to $20,124 reflecting differences in losses due to the proportion of BVDV-PI calves in the herd. Losses are the market value losses of removing PI calves from the commercial production chain and detected losses in reproduction efficiency through the SPA analysis. The presence of PI calves was due to poor bio-security practices in the 2 herds with catastrophic prevalence. Purchased replacements were not quarantined or BVDV-PI tested. Two PI cows produced PI calves among the other herds. Specific risk factors were not identified in the remaining herds. BVDV health management recommendations are: to test calves to determine herd prevalence, test replacements and quarantine new animals, and implement a BVDV vaccination program. Annual testing of all calves is not economically effective, because once a herd is determined to be BVD-PI free to eliminate production losses, the regional market does not provide a price premium for tested negative calves. New cost effective disease control methods such as genetic selection for disease resistance are needed to reduce BVDV-PI prevalence and its associated economic losses.

Key Words: BVD-PI, economics, prevalence

774 Pre-arrival management of newly received beef calves with or without exposure to a persistently infected bovine viral diarrhea virus type I calf affects health, performance, bovine viral diarrhea virus type I titers, and circulating leukocytes. J. T. Richeson* and E. B. Kegley, *University of Arkansas*, *Fayetteville*.

Calves persistently infected (PI) with bovine viral diarrhea virus (BVDV) are a major source of the virus; however, consequences of exposure to a PI-BVDV calf in preconditioned (PC) vs. auction market (AM) cattle may differ. Our objective was to compare treatments of PC or AM origin, with (PI) or without (CON) exposure to a PI-BVDV calf in a 2 × 2 factorial arrangement to evaluate effects on health and performance in a randomized block design using the MIXED procedure of SAS. Four sets (block) of PC steers (n = 236) from 3 ranches were selected randomly, weaned, dewormed, vaccinated, tested for PI-BVDV status, and kept on the ranch for ≥42 d. Subsequently, PC calves were transported to a stocker unit (SU), weighed (251 ± 2 kg), bled, and assigned randomly to treatment (PCPI or PCCON) with no additional processing. Simultaneously, 4 sets of AM calves (n = 292) were assembled for delivery to the SU within 24 h of PC arrival. The AM calves were weighed (245 ± 1.3 kg) and administered the same processing procedures as PC; however, bull calves were castrated, stratified by sex, and AM calves were assigned randomly to treatment (AMPI or AMCON). Calves were fed identically and followed the same antibiotic treatment protocol. Daily gain for the entire 42 d was greater ($P < 0.001$) for PC (1.2 kg) than AM (0.85 kg). There was an exposure effect ($P = 0.002$) on ADG from d 28 to 42; CON gained 1.12 kg vs. 0.90 kg for PI. Morbidity rate was greater ($P < 0.001$) in AM (70%) than PC (7%). Treatment with a third antibiotic occurred more often ($P = 0.04$) for PI, likewise the greatest number of chronic cattle were AMPI ($P = 0.06$). BVDV type I titer levels were greater on d 0 for PC (treatment × day, $P < 0.001$), and seroconversion to BVDV on d 0 was 100% for PC vs. 23% in AM. Neutrophil:lymphocyte was greater ($P < 0.001$) for AM on d 14 and 28. Results suggest that PC gain faster and require fewer antibiotic treatments; whereas, PI-BVDV exposure reduced gain and increased antibiotic treatment cost, particularly in AM.

Key Words: beef calves, preconditioned, BVDV

ASAS Western Section Symposium: Perinatal Programming of Offspring Quality 1: Basic Concepts and Experimental Evidence

775 Key principles of developmental programming of later life events: Observations in primate development. P. W. Nathanielsz*[1], L. Cox[1], T. McDonald[1], S. Ford[2], K. Mitsuya[1], and M. Nijland[1], [1]*Center for Pregnancy and Newborn Research, The University of Texas Health Science Center*, *San Antonio*, [2]*University of Wyoming*, *Laramie*.

Mammals pass more biological milestones before birth than the rest of life. Critical developmental phases are windows of potential susceptibility to adverse gene-environment epigenetic influences that may predispose to chronic later life diseases e.g., hypertension, obesity, and diabetes. Compelling human epidemiological and animal research studies clearly demonstrate that a suboptimal intrauterine environment alters the trajectory of development and epigenetically modifies cell function. The controlled animal studies to evaluate normal and abnormal fetal development have mostly been conducted in rodents or sheep. There are, however, considerable differences in pregnancy between primates and other species. Rodents are polytocous species delivering up to 16 altricial pups which with their placentas are a biomass equivalent to a woman delivering a sixty pound baby. Many fetal stages of development in precocial species occur postnatally in rodents when oxygenation, metabolic and hormonal status differ significantly. The developmental challenges most extensively investigated are poor maternal nutrition and maternal stress. Developmental programming represents a convergence of environmental influences on genotype. This presentation will focus on our studies in baboon fetal and postnatal life with offspring of control (CTR) ad lib fed baboons and baboons undergoing maternal nutrient reduction (MNR) that eat 70% of the global diet consumed by CTR females in pregnancy and lactation. At term, MNR reduces islet cell number and protein content of insulin and key growth factors such as IGF-I and IGF-II. Gene array studies show dysregulation of several pathways in the placenta, liver, kidney and brain – many of these pathways involve nutrient signaling and energy generation and utilization. These changes and epigenetic marks resulting from altered methylation will be discussed.

776 Epigenetic transgenerational actions of environmental factors on reproduction and disease: The ghosts in your genome. M. K. Skinner*, *Washington State University*, *Pullman*.

Transgenerational effects of environmental factors (e.g., nutrition and endocrine disruptors) significantly amplify the impact and health hazards of these factors. One of the most sensitive periods to exposure is during embryonic gonadal sex determination when the germ line is undergoing epigenetic programming and DNA re-methylation. A model endocrine disruptor tested was vinclozolin, which acts as an anti-androgenic compound. Previous studies have shown that this endocrine disruptor can effect embryonic testis development to subsequently cause an increase in spermatogenic cell apoptosis in the adult. Interestingly, this spermatogenic defect is transgenerational (F1, F2, F3 and F4 generations) and shown to be due in part to a permanent altered DNA methylation of the germ-line. This appears to involve the induction of new imprinted-like DNA methylation sites that regulate transcription distally. Differential DNA methylation regions were identified with ChIP-Chip analysis in F3 generation sperm. The impact of these epigenetic changes have on the genome used transcriptome analysis. The expression of hundreds of genes were found to be altered in the embryonic testis and surprisingly this altered transcriptome was similar for all generations (F1-F3). All tissues examined had a transgenerational transcriptome effect that was tissue specific. In addition to detection of the male testis disorder, as the animals age transgenerational effects on other disease states were observed including tumor development, prostate disease, kidney disease and immune abnormalities Therefore, the transgenerational epigenetic mechanism appears to involve the actions of an environmental compound at the time of sex determination to alter the epigenetic (i.e., DNA methylation) programming of the germ line permanently that then alters the transcriptomes of developing organs to induce disease development transgenerationally. Similar Transgenerational effects have now been observed with nutrition, BPA and phthalates. The suggestion that environmental factors can reprogram the germ line to induce epigenetic transgenerational disease is a new paradigm in disease etiology.

777 Even her uterus can't protect you. Stress in life: A multi-species review. D. C. Lay Jr.*, *USDA-Agricultural Research Service, Livestock Behavior Research Unit*, *West Lafayette, IN*.

All environments can pose challenges to animals which cause stress; they meet these challenges by making behavioral and physiologic adjustments. These adjustments include behavioral responses of fighting or hiding; and physiologic adjustments which include such processes as regulation of blood glucose, altered cardiac function and others that help the animal to react to the stress and to bring the body back to its normal state. However, when this occurs to animals which have developing ova, are pregnant, or caring for young; there is a potential for the stress to also influence the development of these individuals. Although the literature is not always consistent in how the individuals are affected, alterations due to early exposure to stress have been shown in mice, guinea pigs, poultry, swine, sheep, cattle, horses and humans, to name a few. It is clear that stress during these early developmental stages can alter how the animals respond to stressors later in life, with changes seen in both their behavior and physiologic responses to stressors. In mammals, the uterus is an affective barrier to many of the external threats to which the fetus may be exposed; however it is clear it is not full-proof. In avian species, stress responses can alter the hormonal content of the yolk which then later alter the development of the embryo. One theory suggest that alterations due to stress are adaptive, preparing the offspring for a stressful environment. The timing of such events during fetal and neonatal development is critical to the integrity and normal function of all animals. The observation that stress can alter the later responses of so many species of animals is profound. In addition, the fact that exposure to stress can have deleterious effects to all the livestock and poultry species which we raise, necessitates our complete understanding. It also may provide a mechanism with which we could facilitate animals' adaptation to environments in which they will be housed in the future.

Key Words: stress, development, programming

778 Fixed-time AI conception rates in beef cows resulting from reduced 2-shot prostaglandin intervals on day 5 of a 5-d CIDR-Co-synch estrus synchronization. J. L. Seabrook*, R. K. Peel, G. E. Seidel, and J. C. Whittier, *Colorado State University*, *Fort Collins*.

The objective of this study was to quantify fixed-time AI (TAI) pregnancy rates resulting from reduced intervals between 2 25 mg dinoprost tromethamine (PG) injections on d 5 of a 5-d CIDR-Co-synch estrus synchronization program. Angus and Angus-influenced commercial cows (n = 873) maintained on native pasture at 3 locations were randomly assigned to treatments, blocking for BCS and postpartum interval (PPI). On experimental d 0 all cows received 100 μg GnRH i.m. and a CIDR (1.38 g progesterone). On d 5, CIDRs were removed and cows were administered 2 injections of 25 mg PG i.m. either 2, 4 or 6 h ± 30 min apart. On d 8, 72 ± 3 h after the first PG injection, all cows received 100 μg GnRH i.m. and were TAI. Conception rates were determined by rectal ultrasonography 40 ± 2 d following TAI. The TAI conception rate was 59.7% for the 6 h interval group, 51.4% for the 4 h interval group ($P = 0.05$), and 50.6% for the 2 h interval group ($P = 0.04$). Body condition score ($P = 0.06$) was a marginally significant source of variation for TAI conception rate; shorter PPI intervals negatively affected pregnancy rate ($P = 0.02$). Reducing the interval between PG injections from 6 to 4 or 2 h resulted in a 9-percentage point (15%) reduction in TAI conception rates for cows in this 5-d CIDR-Co-synch estrus synchronization protocol.

Key Words: beef cow, CIDR Co-synch, prostaglandin interval

779 Effect of castration technique on beef calf performance and residual feed intake. T. M. Warnock*[1], T. A. Thrift[1], M. Irsik[1], M. J. Hersom[1], T. D. Maddock[2], and G. C. Lamb[2], [1]*University of Florida*, *Gainesville,* [2]*University of Florida*, *Marianna*.

The objective of this study was to examine whether castration method would alter daily feed and water intake, calf performance, and residual feed intake. Brangus (n = 45) and Angus (n = 30) male calves weighing 226 ± 34 kg (200 + 26 d of age) were placed in a GrowSafe 4000 feed intake facility 7 d post weaning (15 calves/pen; 7–8 calves/feed node). Body weight gain and DMI were recorded over an 84-d period. Calves were offered a mixed diet (TDN = 67.3% and CP = 12.2%, DM = 89%) ad libitum. Calves were adapted to the facility for 21 d before the start of the trial. Shrunk BW was recorded on d 0, 14, and 84; full BW was recorded on d 7, 28, 42, 56, and 70. On d 0 calves were assigned to one of 5 treatments (n = 15/treatment): 1) control steers were castrated surgically before weaning at an average age of 52 d (8–85 d) (CON); 2) intact bulls (BULL); 3) bulls castrated surgically (SUR); 4) bulls castrated by the Callicrate Bander (No-Bull Enterprises, LLC, St. Francis, KS; BAN); and 5) bulls castrated using the Henderson castration tool (Stone Mfg & Supply Co., Kansas City, MO; HEN). During the first 14 d post castration, BAN calves gained BW slower ($P = 0.009$) than CON calves (0.10 vs. 0.68 kg/d) and tended to gain BW slower ($P = 0.08$) than BULL calves (0.12 vs. 0.48 kg/d). Additionally, CON calves gained more BW ($P = 0.04$) than HEN and SUR calves, 0.68, 0.24, and 0.22 kg/d, respectively. DMI was similar ($P > 0.10$) among castration methods 14 d post castration. BAN calves had decreased ($P = 0.04$) average daily water intake compared with BULL, CON, and SUR calves (28.39 vs. 38.86, 45.20, and 39.18 L/d respectively) and tended to drink less ($P = 0.08$) than HEN calves (28.39 vs. 37.20 L/d). During the experiment, all treatments had similar ($P > 0.10$) ADG and residual feed intake. Our results suggest that method of castration did not have a long-term impact on performance or efficiency of weaned calves.

Key Words: beef cattle, castration, performance

780 Effect of preconditioning average daily gain on feedlot performance and carcass characteristics of beef cattle. J. D. Savell*, T. A. Thrift, and M. J. Hersom, *University of Florida*, *Gainesville*.

A study was conducted to evaluate the effect of preconditioning ADG (PCADG) on feedlot performance and subsequent carcass characteristics in beef cattle. Steers (n = 1,100, BW = 254 ± 28 kg) and heifers (n = 421, BW = 241 ± 25 kg) from a single ranch were shipped 370 km to be preconditioned in North Central Florida. Calves were preconditioned on 8 ha bermudagrass pastures and acclimated to a high energy starter ration with a DMI target of 3% of live BW. Calves were preconditioned for 43 ± 9 d and then shipped 2,365 km to a feedyard to be finished in Western Kansas that utilized the Micro Beef Technologies ACCU-TRAC Electronic Cattle Management system. The effect of increasing PCADG was evaluated against the dependent variables (feedlot ADG, feed efficiency, days on feed, cost of gain, HCW, quality grade, ribeye area (REA), REA/100 kg, and yield grade) and regression analysis was performed. Feedlot ADG was similar ($P = 0.54$) across varying levels of PCADG. Feedlot feed efficiency improved ($P < 0.05$) for both steers (0.62 kg of feed/kg of gain) and heifers (0.46 kg of feed/kg of gain) as PCADG increased. Days on feed decreased ($P < 0.01$) by 7.2 d for each 1.0 kg increase in PCADG. Cost of gain decreased ($P < 0.05$) 9.8 cents/kg for each 1.0 kg increase in PCADG. As PCADG increased by 1.0 kg/d, HCW increased ($P < 0.001$) by 19.5 kg. Quality grade ($P = 0.24$) and yield grade ($P = 0.29$) were not affected by PCADG. Calves that gained more during preconditioning had greater ($P < 0.001$) actual REA but smaller ($P < 0.01$) REA/100 kg value. Preconditioning ADG was not a good predictor of feedlot ADG. Improvements in feedlot feed efficiency associated with high gaining calves during preconditioning resulted in fewer days on feed and reduced cost of gain in the feedlot. As PCADG increased, HCW increased, REA increased, and REA/100 kg decreased. Quality grade and yield grade were minimally affected by PCADG.

Key Words: carcass, performance, preconditioning

781 Effect of estimated Brahman percentage on preconditioning performance, feedlot performance and carcass characteristics of beef cattle. J. D. Savell, T. A. Thrift, and M. J. Hersom*, *University of Florida*, *Gainesville*.

A study was conducted to evaluate the effect of Brahman percentage in beef calves on preconditioning and feedlot performance and subsequent carcass characteristics. Steers (n = 1,100, BW = 254 ± 28 kg) and heifers (n = 421, BW = 241 ± 25 kg) from a single ranch were shipped 370 km to be preconditioned in north central Florida. Upon arrival, Brahman percentage was estimated to be 0, 1/8, 1/4, or 3/8 Brahman influence by 2 evaluators, with a third evaluator resolving any discrepancies. Phenotypic evaluation of Brahman percentage was made based on the visual appearance of the underline and size of the hump. Length, shape, and orientation of the ear were also used to estimate Brahman percentage. Calves were preconditioned for 43 ± 9 d and shipped 2,365 km to a feedyard to be finished in Western Kansas that utilized the Micro Beef Technologies ACCU-TRAC Electronic Cattle Management system. The effect of increasing estimated Brahman percentage was evaluated

against the dependent variables (preconditioning ADG, feedlot ADG, G:F, days on feed, cost of gain, HCW, quality grade, ribeye area [REA], REA/100 kg, and yield grade) and regression analysis was performed. As Brahman percentage increased by 1/8, preconditioning ADG increased ($P < 0.05$) by 0.03 kg/d. Feedlot ADG was similar ($P = 0.12$) across varying levels of Brahman percentage. Days on feed, G:F, and cost of gain were similar across levels of Brahman percentage ($P > 0.05$). Hot carcass weight declined ($P < 0.001$) by 8.78 kg as Brahman percentage increased by 1/8. Quality grade also decreased ($P < 0.01$) as Brahman percentage increased. Actual REA decreased ($P < 0.01$) as Brahman percentage increased, but no differences in REA/100 kg were observed. Cattle that exhibited 1/8 Brahman influence had a greater decrease ($P < 0.05$) in numerical values for yield grade than those estimated to be 0 or 1/4 Brahman, and were similar ($P > 0.05$) to those estimated to be 3/8 Brahman. As Brahman percentage increased preconditioning ADG increased, feedlot performance was minimal impacted, and HCW and quality grade declined.

Key Words: Brahman, carcass, performance

782 Breed and winter nutrition effects on body weight, condition, and blood metabolite patterns of cows grazing bahiagrass pastures. S. W. Coleman*, M. J. Williams, C. C. Chase, and D. G. Riley, *USDA ARS Subtropical Agricultural Research Station*, *Brooksville, FL*.

Generally the largest economic costs for cattle production are for winter feed. This 2-yr study evaluated 2 winter nutrition programs on Angus, Brahman, and Romosinuano purebred cows (n = 298, aged 3 to 16 yr) rotationally grazing bahiagrass pastures at STARS. Treatments (TRT) began after weaning and were replicated (R) over 3 farms. Treatments were: TRT1) peanut/bahiagrass hay fed free choice from first frost and supplemented with heavy blackstrap molasses at 2.2 kg/hd/day from weaning until end of breeding (~June 15); and TRT2) bahiagrass hay supplemented with urea-fortified molasses (16% protein equivalent) at 2.2 kg/hd/d from weaning until Jan 15 and then 4.5kg/hd/d of 50% heavy blackstrap molasses and 50% soybean hulls until end of breeding. At monthly intervals, all cows were weighed (BW), scored for body condition (BCS), and blood samples were collected by jugular puncture (5 cows per breed-TRT-rep group) and analyzed for plasma urea N (PUN), glucose (GLU), and non-esterified fatty acids (NEFA). Data were analyzed on cows that calved using Proc Mixed of SAS. The statistical model included fixed effects of cow breed (BR), cowage, TRT, month (M) and R; year (Y) was random, and cow was a repeated effect. Three-way interactions (Y × TRT × M and Y × TRT × R) were significant ($P < 0.001$) for all responses, and the BR × TRT × M interaction was significant for BW, BCS, and NEFA. Important differences included: 1) cow BW was always lower for TRT2 than TRT1 (avg. 505 vs. 487 kg, $P < 0.002$), especially during winter when supplement was fed, yet PUN was higher ($P < 0.01$) for TRT2 in May, June and Sept-Dec for 2002, but no differences were noted in 2003 until Nov; and 2) Plasma levels of NEFA escalated to near 1 mEQ/L at calving and then declined to 0.40, except for Brahman cows who maintained higher (0.58 mEQ/L, $P < 0.01$) levels than the other breeds from 60 d postpartum until weaning, probably due to inadequate intake to support milk production.

Key Words: cow-calf, winter supplementation

783 Genetic mechanism underlying the effect of breed on fatty acid composition in Angus and Charolais finishing steers. A. K. Sexten*, J. W. Dillwith, D. R. Stein, C. R. Krehbiel, and R. G. Mateescu, *Oklahoma State University*, *Stillwater*.

Genetic variability in beef fatty acid composition consists of differences between breeds and between animals within breed. The effect of breed on fatty acid profile in beef was evaluated in longissimus muscle (LM) from Angus (n = 19) and Charolais (n = 14) feedlot finished steers. Steers were fed a total of 140 d before slaughter. Longissimus muscles were biopsied on d 127 of the finishing period between the 12th and 13th ribs and fatty acid composition was determined. Lipids were extracted in triplicate with a 2:1 (v/v) methanol:chloroform solution then acid and base derivatized before separation by gas chromatography on an Agilent 5890 gas chromatograph with 7673 autosampler. Percent composition of each fatty acid was calculated and the effect of breed was analyzed using the general linear model of SAS. Hot carcass weights did not differ, however, Angus steers had higher marbling scores ($P = 0.01$) and more backfat ($P = 0.01$) than Charolais steers. Although percent of saturated fatty acids did not differ between Angus (44.9%) and Charolais (44.0%) steers, Angus steers LM had a higher percent of monounsaturated fatty acids (43.7 vs. 39.4%; $P = 0.01$) and a lower percent of polyunsaturated fatty acids (11.1 vs. 16.3%; $P = 0.03$), omega-3 fatty acids (0.58 vs 0.82%; $P = 0.04$) and omega-6 fatty acids (10.5 vs. 15.5%; $P = 0.03$). Microarray analysis utilizing a long oligo bovine array was also performed. Preprocessing and normalization of data was accomplished using the R-project statistical environment with the Bioconductor and LIMMA package through the GenePix AutoProcessor (GPAP 3.2). Nine genes were found to be significantly ($P = 0.01$) differentially expressed (DE) between Angus and Charolais LM. Ontology analysis of the DE genes was carried out using GFINDer with KEGG analysis utilized to identify the most relevant biological pathways. These results provide insight into the challenge of developing and implementing a program to improve the healthfulness of beef utilizing existing natural genetic variation to manipulate fat composition through breed selection.

Key Words: beef, fatty acid, gene expression

Breeding and Genetics: Milk and Carcass Composition

784 Feasibility of a genetic evaluation for milk fatty acids in dairy cattle. H. Soyeurt*[1,2], V. M.-R. Arnould[1], S. Vanderick[1], and N. Gengler[1,2], [1]*University of Liege, Gembloux Agro-Bio Tech, Animal Science Unit*, *Gembloux, Namur, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Brussels, Belgium*.

Recent development of equations based on mid-infrared (MIR) spectrometry for the prediction of milk fatty acid (FA) contents allows their measurement on a large scale during performance recording. The objective was to show that a genetic evaluation for milk FA in dairy cattle is feasible in the Walloon region of Belgium and to report first results. Estimated breeding values (EBV) and associated reliabilities (REL) were computed using a multi-trait test-day animal model similar to the one used for the routine genetic evaluation for yield traits. Studied traits were first lactation test-day milk, fat and protein yields, fat (FAT) and protein contents, and content of saturated fatty acids in milk (g/100g of milk, SAT). More than 6,700,000 records were available for common production and content traits and 194,000 records were used for SAT. Used variance components were estimated using REML. The average SAT content was 2.79% with a standard deviation (SD) of 0.50%. A total of 1,707 Holstein bulls used in Walloon Region had REL superior to 0.49 for all studied traits. REL for SAT ranged from 0.53 to 0.99. A total of 1,217 bulls had REL superior to 0.74. SD of EBV for SAT was 0.20%. The maximum and minimum SAT EBV values were 0.89% and −0.69%, respectively. To have a direct measure of the part of FAT that is not due to SAT, a new trait (dSAT) was post-evaluated and defined as difference between expected SAT EBV for a given FAT EBV and the estimated EBV for SAT. This new trait can be assumed to be a direct predictor of the content of unsaturated fatty acids in fat. The interest is that this trait cannot be accurately predicted directly by MIR. The maximum and minimum EBV for dSAT for the 1,707 bulls were −0.28% and 0.24%, respectively. Based on these results, a genetic evaluation for milk fatty acids is feasible. In the bull population used recently, a genetic variability for dSAT exists and could be used to improve the milk fat composition.

Key Words: genetic parameter, milk, fatty acid

785 Heterogeneity of residuals variances of milk fatty acids in dairy cattle. V. M.-R. Arnould*[1], H. Soyeurt[1,2], S. Vanderick[1], and N. Gengler[1,2], [1]*University of Liège, Gembloux Agro-Bio Tech*, *Gembloux, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Belgium*.

Routine genetic evaluation for milk fatty acids is under development in the Walloon Region of Belgium. The objective of this study was to test the heterogeneity of residual variances and therefore indirectly the potential need to adjust for this heterogeneity if it exists. The residuals were computed as the difference between the observed and the estimated values using a multi-trait random regression test-day model, similar to the Walloon routine model, used for first lactation only milk yield, quantities and percentages of protein (PROT) and fat (FAT), content of saturated fatty acids in milk (g/100g of milk, SAT) and, content of monounsaturated fatty acids in milk (g/100g of milk, MONO). Residuals were considered homogeneous inside strata defined, among others, by weeks of lactation, by days in milk and by calendar months of test date. About 6,687,000 records were available for milk yield and for FAT and PROT parameters. For SAT and for MONO, about 184,000 records were available in this database. Means of residuals were stable and close to zero for all traits. Variances were more variable for MONO and SAT than for milk yield, for example. Daily and weekly variances tended to decrease at the end of the lactation (50%). When the variances were computed by month of test date, some variations were observed and some periods of year were more marked. In conclusion, the observed residual variances were less stable for MONO and SAT. We can conclude that introduction for heterogeneous residual variance is more important for the new traits (MONO, SAT) than it was for the old, traditional ones.

Key Words: routine genetic evaluation, heterogeneity of residual variances, milk fatty acids

786 Relationships between feedlot growth and carcass traits in Angus: Tri-County Steer Carcass Futurity. L. D. Leachman*, D. R. Notter, S. P. Greiner, and R. M. Lewis, *Virginia Tech*, *Blacksburg*.

The objective was to characterize growth and carcass traits and associated genetic parameters in 2,199 steers and 424 heifers sired by registered Angus bulls and evaluated under feedlot conditions in the 2002–2006 Iowa Tri-County Steer Carcass Futurity Program. Traits evaluated were initial (IBW) and slaughter BW (SBW; kg), and carcass backfat thickness (CFAT), marbling score (CMAR) and ribeye area (CREA). Univariate and bivariate sire models were fitted with ASReml3. Fixed effects included contemporary group (CG) and linear and quadratic effects of age at IBW nested within season and year of feedlot delivery. Random effects were sire and residual. The CG consisted of sex, pen, dam breed-type, owner, and feedlot. Delivery seasons were January–April, May–August and September–December. Data were edited to CG and sire families with at least 5 animals. Trait sample means (SD) for steers were: IBW, 289 (40.3) kg; SBW, 543 (46.4) kg; CFAT, 1.21 (0.33) cm; CREA, 79 (7.2) cm^2; and, CMAR 1057 (89.0). Heifers weighed less, had smaller CREA, and more fat. Phenotypic variances, heritabilities and correlations are shown in Table 1. All traits were moderately to highly heritable. Cattle with heavier IBW had heavier SBW and larger CREA at harvest. Heavier SBW was strongly associated with larger CREA and with a tendency for less CMAR. More CFAT was related moderately to smaller CREA. Given their heritabilities, and the size and direction of most correlations, feedlot traits are clearly amenable to selection.

Table 1. Phenotypic variances (P-var), heritabilities, and genetic and phenotypic correlations[1]

	IBW	SBW	CFAT	CREA	CMAR
P-var	711	1933	0.0918	50	6751
IBW	**0.50±0.11**	0.69±0.09	0.03±0.19	0.35±0.15	−0.07±0.16
SBW	0.58±0.02	**0.45±0.10**	0.04±0.20	0.63±0.12	0.25±0.17
CFAT	0.06±0.03	0.13±0.02	**0.27±0.08**	−0.34±0.18	−0.11±0.19
CREA	0.26±0.02	0.41±0.02	−0.12±0.02	**0.39±0.09**	0.23±0.18
CMAR	−0.09±0.03	0.07±0.03	0.12±0.02	−0.03±0.03	**0.46±0.10**

[1]Heritabilities in bold on diagonal; genetic and phenotypic correlations above and below the diagonal.

Key Words: feedlot, performance, cattle

787 Heritabilities, genetic and phenotypic correlations among Warner-Bratzler shear force and repeated objective measurements of temperament in fed cattle. R. L. Weaber[1], T. M. Taxis*[1], W. R. Shafer[2], L. L. Berger[3], D. B. Faulkner[4], M. M. Rolf[1], D. L. Dow[1], J. F. Taylor[1], and C. L. Lorenzen[1], [1]*University of Missouri*, *Columbia*, [2]*American Simmental Association*, *Bozeman, MT*, [3]*University of Nebraska*, *Lincoln*, [4]*University of Illinois*, *Urbana*.

Tenderness is a primary meat palatability attribute affecting consumer satisfaction of beef. Beef cattle temperament has been associated with a variety of performance measures. Performance data and pedigree records were provided by the American Simmental Association (ASA) to elucidate the relationship between temperament and tenderness in *Bos taurus* breeds. Data included WBSF records from ASA's carcass-merit program and a subset collected at the University of Illinois (UI). Exit velocities were recorded when cattle went on trial (EV1) and 42 d later (EV2). Single animal and single sire contemporary groups (CG) were removed from the data set leaving 2,819 WBSF, 917 EV1 and 976 EV2 phenotypes in 176 CG for evaluation. A pedigree was formed with 13,418 animals including 2,488 sires. Phenotypic means (SD) were 36.65 N (10.56 N) for WBSF, 1.74 m/s (0.76 m/s) for EV1 and 1.65 m/s (0.79 m/s) for EV2. A tri-variate animal model with CG, sire and dam breed composition as fixed effects and animal as random effect was fit to estimate variance components. Phenotypic correlations (SE) estimated between WBSF with EV1 and EV2 were −0.05 (0.05) and −0.03 (0.04), respectively, and between EV1 and EV2 was 0.59 (0.02). Heritabilities (SE) for WBSF, EV1 and EV2 were 0.19 (0.06), 0.30 (0.11) and 0.25 (0.10) respectively. Genetic correlations estimated between WBSF with EV1 and EV2 were 0.02 (0.38) and −0.30 (0.36) respectively. Given the high genetic correlation between EV1 and EV2 of 0.99 (0.07) a repeated records analysis was conducted for EV with an uncorrelated random effect for animal using the same fixed effects as before. A likelihood ratio test was used to determine that the repeated records model implemented provided a better fit ($P < 0.0001$) to the data than did the tri-variate model. Heritabilities were 0.19 (0.06) and 0.39 (0.08) for WBSF and EV, respectively, with a genetic correlation of −0.10 (0.20). The near zero genetic correlation and moderate heritabilities suggest producers can select to improve temperament and/or WBSF without substantial correlated response.

Key Words: heritability, beef temperament, tenderness

788 Development and validation of an Angus-specific IGENITY profile for marbling, backfat thickness, hot carcass weight, ribeye area, yearling weight, and heifer pregnancy rate based on a whole genome scan. B. W. Woodward*[1], D. J. Garrick[2], R. L. Fernando[2], S. Northcutt[3], B. Bowman[3], S. W. Bauck[1], R. D. Schnabel[4], and J. F. Taylor[4], [1]*Merial Limited*, *Duluth, GA*, [2]*Iowa State University*, *Ames*, [3]*American Angus Association*, *St. Joseph, MO*, [4]*University of Missouri*, *Columbia*.

Genomic markers are now being widely used in the selection of beef and dairy breeding animals via various commercial products with a wide range in price. The objective of this study was to develop a cost effective, yet informative low-density panel of SNPs derived from the Illumina Bovine SNP50 specifically for Angus cattle. Target traits were marbling, backfat thickness, hot carcass weight, ribeye area, yearling weight, and heifer pregnancy rate. Multiple methods were initially evaluated for SNP selection and the method of choice involved a 2-stage process combining Bayesian model averaging and semi-parametric models. There were 41,028 SNP genotypes for 1,710 bulls born between 1955 and 2003. Predictability was assessed as the correlation between genomic predictions and EPD in training and cross-validation sets of animals, and by validating on a new set of 275 younger bulls. EPD were from the American Angus Association. Correlations between molecular breeding values and EPD for marbling, backfat thickness, hot carcass weight, ribeye area, yearling weight, and heifer pregnancy rate in cross-validation bulls were 0.71, 0.68, 0.73, 0.68, 0.71, and 0.32, respectively. Corresponding correlations in the group of 275 bulls were 0.66, 0.38, 0.73, 0.68, 0.76, and 0.20. Therefore, correlations for both groups of validation bulls indicate this SNP panel derived from the SNP50 could provide a powerful tool for genomic selection.

Key Words: SNP, whole genome, selection

789 The economics of using DNA markers for beef bull selection in the seedstock sector. A. L. Van Eenennaam*[1], J. H. van der Werf[2], and M. E. Goddard[3,4], [1]*University of California*, *Davis,* [2]*University of New England*, *Armidale, NSW, Australia*, [3]*Victorian Department of Primary Industries*, *Bundoora, VIC, Australia*, [4]*University of Melbourne*, *Parkville, VIC, Australia*.

The objective of this study was to estimate the value derived from using DNA test information to increase the accuracy of beef sire selection in a closed seedstock nucleus herd. Breeding objectives for commercial production systems targeting 2 diverse markets, a domestic market where steers are finished on pasture, or a high value export market where steers are finished on concentrate rations and marbling has a high value, were examined considering both maternal (self-replacing) and terminal herds. Selection index theory was used to predict the response to conventional selection based on phenotypic performance records, and this was compared with including information from 2 hypothetical marker panels. In one case the marker panel explained a percentage of additive genetic variance equal to the heritability for all traits in the breeding objective, and in the other case to half this amount. Discounted gene flow methodology was used to calculate the value of DNA test information over that derived from conventional selection for the modeled seedstock herd. Results were ultimately calculated as discounted returns per DNA test purchased by the seedstock operator. DNA testing using these hypothetical marker panels increased the selection response between 33 and 171%. The value of this improvement relative to that obtained using traditional performance recording ranged from AU$156–681 per commercial bull, and AU$9,203–35,823 per stud bull. If the entire bull calf crop was tested to achieve these gains, the value of genetic gain derived from DNA testing ranged from AU$367–1,386 per test. These values assumed commercial producers were willing to pay a price premium for genetically superior bulls and some level of industry vertical integration such that market signals from the processor and feedlot were transferred up the chain to commercial and seedstock producers. All values were sensitive to index accuracy in the absence of DNA information. The development of selection indexes including DNA-based predictions of economically relevant traits not currently included in genetic evaluations will be required to assess the value of DNA information for the beef industry.

Key Words: DNA marker, beef bull, accuracy

790 Studies on the application of dielectric spectroscopy for the measurement of process cheese functionality. J. Amamcharla*[1], L. E. Metzger[1], O. Grace[2], and C. Jones[2], [1]*Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University*, *Brookings,* [2]*Biosystems and Agricultural Engineering, Oklahoma State University*, *Stillwater*.

This study evaluated the potential of dielectric analysis of process cheese for prediction of the textural (hardness) and melting properties. Process cheeses (n = 24) with similar composition (fat, protein, moisture, and salt) were procured from a commercial manufacturer (Bongards' Creameries, MN). Dielectric properties (permittivity (ε′) and loss factor (ε″)) of the process cheeses were collected over the frequency range 0.2 – 3.2 GHz at a constant temperature (25°C). Dielectric measurements were made using an open-ended high temperature dielectric Probe (model: 8710–2036; Agilent Technologies, Englewood, CO) connected to a vector network analyzer (model: N5320A; Agilent Technologies). The system was calibrated using distilled water at 25°C, air and a short circuit mode. Dielectric spectra were collected in triplicate at 4 different locations on each sample. The replicates with a standard deviation less than 4% were selected and averaged to get a single dielectric spectrum for each sample. A decrease in the ε′ and ε″ was observed as the incident frequency increased for all process cheeses. Partial least square regression (PLSR) models were developed using the dielectric spectra of process cheeses to predict the hardness (gf), melting point (°C) and modified Schreiber melt diameter (mm) of process cheese. Penetrometer, dynamic stress rheometry (DSR), and modified Schreiber melt (MSM) test were used as respective reference methods. The PLSR models were validated using the full cross-validation method. Root mean square error of crossvalidation was found to be 1.41°C, 1.25 mm, and 11.64 gf for DSR melt point, MSM diameter, and hardness of process cheese, respectively. Correlation coefficients of 0.94, 0.91, and 0.91 were observed for process cheese functional parameter and the dielectric spectra. Practical utility of the calibration models were evaluated using the range error ratio (RER). The RER was found to be > 8 for the 3 functional properties, indicting a limited to good practical utility. Further validation of the results on a larger data set will be necessary.

Key Words: dielectric spectroscopy, process cheese, functional properties

791 The effect of NaCl/KCl substitution on Halloumi cheese during storage: Chemical composition, proteolysis, texture profile, and microstructure. M. M. Ayyash* and N. P. Shah, *Victoria University*, *Melbourne, VIC, Australia*.

The effect of partial substitution of NaCl with KCl on chemical composition, LAB count, organic acids profile, proteolytic pattern, texture profile, and microstructure of Halloumi cheese was investigated. Halloumi cheeses were made and kept in 4 different brine solutions (at 18%) including NaCl only (HA), 3NaCl:1KCl (HB), 1NaCl:1KCl (HC), and 1NaCl:3KCl (HD) and then stored at 4oC for 56 d. Chemical composition, proteolysis, texture profile and microstructure were analyzed. No significant ($P > 0.05$) effect was observed between control and experimental cheeses in terms of composition and LAB count and pH values at the same storage period. At same salting treatment, moisture content decreased significantly while LAB count significantly ($P < 0.05$) increased. There was a significant ($P < 0.05$) difference in ash, sodium and potassium contents among cheeses at the same storage period. However, these parameters increased ($P < 0.05$) during storage at same salt treatment. There was no significant ($P > 0.05$) difference in lactic and citric acid contents among cheeses. In contrary, there was a significant ($P > 0.05$) difference in acetic acid concentration among cheeses. There were no significant ($P > 0.05$) differences in WSN, TCA-SN, and PTA-SN of experimental cheeses at same storage period. However, these parameters increased ($P < 0.05$) during storage at same salt treatment. Peptide pattern and urea-PAGE also showed no significant difference among experimental cheeses. There was no significant difference in TPA parameters between cheeses at same storage period. At same salt treatment, hardness, and cohesiveness decreased ($P < 0.05$) and adhesiveness increased ($P < 0.05$) during storage period. ESEM images showed compact and closed texture in all experimental cheeses. Our results showed that Halloumi cheeses can be stored in brine solution partly substituted with KCl without any adverse effect on their quality.

Key Words: Halloumi cheese, NaCl/KCl, chemical composition

792 Influence of NaCl reduction on the properties of Cheddar cheese. K. V. Grant*[1], S. Govindasamy-Lucey[2], J. A. Lucey[1], J. J. Jaeggi[2], M. E. Johnson[2], and S. A. Rankin[1], [1]*University of Wisconsin*, *Madison*, [2]*Wisconsin Center for Dairy Research*, *Madison*.

Reducing sodium in processed foods is a current trend in the food industry. The goal of our research is to develop reduced NaCl Cheddar cheese with acceptable body and flavor. To better understand the many roles of NaCl in cheese we studied the properties of Cheddar cheese with 3 NaCl levels: normal (1.7%), reduced (1.2%), low (0.7%). Curds were prepared using traditional Cheddar manufacturing, then subdivided into 6 batches and salted at the 3 levels, each in duplicate. Analysis was performed at 4 d, 3 wk, 5 wk, 3 and 6 mo. Within the first 5 wks of ripening there were significant differences in cheeses. Differences in moisture content and water activity were found: 37.0% and 0.970; 36.2% and 0.959; and 34.1% and 0.955 in normal, reduced and low NaCl cheese, respectively. The starter culture numbers also differed by 5 wks of ripening: 1.49×10^9, 1.04×10^9, and 7.44×10^8 CFU/mL for normal, reduced, and low NaCl cheese, respectively. Texture profile analysis revealed a significantly softer ($P < 0.01$) texture of low NaCl Cheddar compared to reduced and normal NaCl cheeses at 3 and 5 wks. Rheological small amplitude oscillatory shear tests indicated differences in loss tangent (LT) values during heating. A LT value of 1 is often used as a melting point. At 5 wks of aging the temperature where LT=1 was 50.4, 48.4 and 47.4°C for normal, reduced and low NaCl cheeses. Sensory analysis of the cheese was performed using a trained sensory panel (n=16) after 5 wks of ripening. Panelists found the lower NaCl cheeses to be significantly more acidic ($P < 0.005$) with a higher total off-flavor intensity ($P < 0.05$) and lower Cheddar flavor acceptability ($P < 0.005$).
This work shows that reducing the NaCl level in Cheddar cheese impacted starter culture growth, texture, meltability and flavor acceptability. The wide-ranging impact of NaCl reduction on cheese suggests that a range of approaches, such as addition of flavor enhancers and antimicrobials will be needed to increase the acceptability of low NaCl cheeses. This study provides a benchmark for our ongoing work on approaches to improve low NaCl Cheddar cheese. Results for cheese aged 3 and 6 mo will be reported.

Key Words: low sodium, Cheddar cheese

793 Influence of sodium gluconate on flavor and microbiology of low fat Cheddar cheese. D. J. McMahon*[1], C. J. Oberg[2], L. Moyes[2], R. E. Miracle[3], and M. A. Drake[3], [1]*Western Dairy Center, Utah State University*, *Logan,* [2]*Microbiology Department, Weber State University*, *Ogden, UT,* [3]*Southeast Dairy Foods Research Center, North Carolina State University*, *Raleigh.*

Low fat cheese manufactured using *Lactococcus lactis* ssp. *lactis* generally develops a flavor profile during aging uncharacteristic of Cheddar cheese. Such cheeses can have rosey aroma and taste as well as a pronounced burnt-brothy-bitter taste. The objective of this research was to determine if sodium gluconate (SG) addition during cheesemaking could ameliorate low fat cheese flavor. Cheese (in duplicate) was made using 700 kg of milk using a stirred curd method with SG added during salting to produce 4 blocks that were about 6% fat, 53% to 54% moisture, 1.7% to 1.8% salt, pH 5.0 to 5.3, and SG addition levels of 0% (control), 0.8%, 1.6% and 2.4%. The cheese was stored at 6°C and analyzed monthly for total lactic acid bacteria (LAB), lactococci, and nonstarter LAB (NSLAB) (i.e., *Lactobacillus casei*-type bacteria) using selective media. Cheese was analyzed at 4 and 6 mo for flavor profile using descriptive sensory analysis (15-point scale) and for compounds suspected of contributing to rosey and burnt off-flavors in low fat cheese. Adding SG did not change the LAB, lactococcal or NSLAB populations. Irrespective of SG addition, lactococcal populations gradually decreased during the first 5 mo of storage to about 10^4 cfu/g while NSLAB increased from their initial low level to high levels (10^7 to 10^8 cfu/g) within 30 d and remained the dominant LAB throughout storage. At 4 mo, cheeses all had rosey and burnt flavors with no differences ($P > 0.05$) in flavor except for a slight trend ($P < 0.05$) for increased saltiness with SG (3.5 for 2.4% SG cheese compared with 3.2 for control). At 6 mo, similar results were obtained and some bitterness was detected (absent at 4 mo) with the 1.6% and 2.4% SG cheeses having less ($P < 0.05$) apparent bitterness than the control cheese (0.5 compared with 1.0). Phenyl ethanal, phenyl ethanol, sotolone, or furaneol varied between replicates but not between treatments ($P > 0.05$). Homofuraneol and phenyl acetic acid were lower ($P < 0.05$) in the cheeses with 1.6% and 2.4% SG than in the control or cheese with 0.8% SG. This suggests that adding SG might be masking the bitter taste associated with burnt flavor in low fat Cheddar cheese.

Key Words: low fat, burnt flavor, microflora

794 Optimization of the manufacture of a no-fat added reduced-sodium processed cheese (Requeijão cremoso). L. M. Spadoti, A. G. F. Van Dender, P. B. Zacarchenco*, F. K. H. S. Trento, A. T. S. Alves, T. Q. Mendes, R. C. S. C. Ormenese, M. A. Morgano, and K. Yotsuyanagi, *Instituto de Tecnologia de Alimentos-ITAL*, *Brazil*.

The increased incidence of cardiovascular diseases caused by hypertension and obesity have heightened consumer awareness of nutrition and healthy eating. Within this context, the demand for foods with reduced levels of fat and/or sodium has greatly increased. Requeijão cremoso is a genuinely Brazilian processed cheese with a mild flavor, clear and shiny in color, and a creamy and elastic texture forming long strings. However, as with most cheeses, it is a source of fat and salt (sodium chloride). In view of the high consumption of this cheese in Brazil, and the current demand for healthier foods, no–fat added reduced-sodium requeijão (NFARSR) similar to the traditional product as to the main characteristics of flavor, texture and composition would be an important alternative to meet the needs of the changing market. In this study, the fat in requeijão was replaced by whey protein concentrate (WPC34%), while sodium reduction was achieved by replacing 40% of the sodium chloride by potassium chloride and by partially replacing the traditional, sodium phosphate-based emulsifying salt (Joha S9) by a potassium phosphate-based emulsifying salt (Joha S9K). The objective of this study was to optimize the use of the emulsifying salt combination (JohaS9+JohaS9K) to reduce the sodium level of an existing no–fat requeijão developed at Tecnolat–ITAL. For this purpose, a 2^2 factorial design with 2 factors (JohaS9 and JohaS9K), 2 levels (+1, −1) with 3 repetitions at the central point was used, resulting in 11 experimental trails. The results were evaluated by the surface response method to assess physical–chemical, sensory and instrumental texture parameters. Analysis of the surface response graphs, and especially the comments made by sensory panelists regarding flavor and texture, showed that RB4 – made with a mixture of 1.0% JohaS9 and 0.8% Joha S9K – was the NFARSR formulation that best met the preset specifications.

Key Words: reduced-sodium, processed cheese, cheese

795 Consumer flavor preferences and level of aged Cheddar cheese flavor. D. J. McMahon* and R. Wadhwani, *Western Dairy Center, Utah State University*, *Logan.*

Development of new cheese products such as low fat cheeses often have the goal of duplicating the flavor of the full fat counterpart. Sensory panels involving untrained consumers are often used to determine if a desired flavor profile is obtained Four sets of cheeses were obtained that including cheeses from 2 different manufacturers (designated A and B) that were labeled as mild, medium, sharp or extra sharp were purchased locally. A second set of Cheddar cheeses (designated C and D) were obtained from Utah State University (USU) that were 3, 6 and 12 mo of age and designated as mild, medium and sharp. All cheeses were tested by a trained descriptive cheese panel to produce a flavor profile for each cheese. Then 2 different consumer sensory panels (n = 120 for each panel) were conducted in which consumers were asked about their cheese flavor preferences, their cheese buying frequency, the form of cheese they buy and how they use cheese. They were then presented with 2 sets of cheeses (one commercial and one USU cheese) for overall liking using a 9-point hedonic scale and for flavor, texture, chewiness, and level of sharpness using a 5-point Just About Right (JAR) scale with 1 being "too little," 3 being "just about right" and 5 being "too much" of the attribute. Panelist responses were recorded via computer keyboard using SIMS 2000 software. The cheese panelists were from 18 to 35 years of age, with >60% being frequent cheese consumers. The majority of the panelists stated that they preferred to buy medium Cheddar cheese followed by sharp aged, mild with extra sharp being the least preferred. The 4 sets of cheeses had different flavor profiles ($P < 0.05$) and their overall liking scores were significantly different ($P < 0.05$) and ranged from a high of 6.82 for cheese A-mild to 4.87 for cheese B-sharp. The other top-ranked cheeses were C-mild, D-mild, B-medium. The 4 sharp cheeses had the lowest scores ($P < 0.05$). On the JAR scale the cheese with scores closest to JAR were C-medium, D-medium, A-medium for flavor; C-medium. C-sharp, and A-sharp; while for chewiness it was A-mild, C-medium and C-sharp. JAR thus matched better with consumer stated preferences.

Key Words: Cheddar, flavor, sensory

796 Nutritional and organoleptic quality of Cheddar cheese prepared from goat and buffalo milk blends. M. Nasir*, H. Jabeen, M. Abdullah, M. A. Jabbar, and M. A. Ali, *University of Veterinary and Animal Sciences*, *Lahore, Punjab, Pakistan*.

The goat milk in developing countries like Pakistan is not usually processed and its value in human nutrition has so far received very little factual attention from researchers and manufacturers. Thus the present

research project was designed to assess the feasibility of buffalo milk replacement with goat milk for Cheddar cheese manufacturing. Goat and buffalo milk were blended at various levels (25:75, 50:50, 75:25; goat milk: buffalo milk) and used along with 100% buffalo and 100% goat milk for Cheddar cheese preparation. The cheese thus prepared was subjected to different physicochemical analysis i.e., fat, protein, lactose, ash, total solids, SNF, amino acids, fatty acids, organic acids, pH, acidity and sensory evaluation at 0, 30, 60, 90 and 120 d of storage intervals. The data thus obtained was analyzed through ANOVA technique by applying 2-way CRD and the level of significance was defined as $P \leq 0.05$. Buffalo milk contained significantly ($P \leq 0.05$) more total solids and fat and less protein content as compared with goat milk. Therefore the addition of goat milk resulted in decreased fat and total solids, however there was progressive increase in protein content in cheese with the level of goat milk. pH and acidity of the cheese were not affected by the milk type, however there was decrease in pH and increase in acidity with storage period. Although, there was significant ($P \leq 0.05$) change in various fatty acids, organic acids and amino acid with level of goat milk in cheese samples, yet it had non-significant ($P \geq 0.05$) effect on the overall sensory quality of the finished product except for the attributes of flavor and overall acceptability beyond 50% goat milk level in samples; having significantly ($P \leq 0.05$) lower scores. The highest scores for most of the sensory parameters were awarded to the samples at 90 d storage interval. Thus, it is concluded that the Cheddar cheese with good nutritional profile and high acceptable quality can be made with up to 50% replacement of buffalo milk with goat milk, and may be recommended for commercial application.

Key Words: goat milk, Cheddar cheese, sensory quality

797 Ability of Smart Nose to discriminate *tina* biofilms contributing to produce unique volatile compounds in inoculated milk. S. Carpino*[1], I. Stampelou[2], G. Belvedere[1], C. Pediliggieri[1], and G. Licitra[3,1], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*Wageningen University*, *the Netherlands*, [3]*DACPA, University of Catania*, *Catania, Italy*.

Wooden equipment is used in the traditional cheese making process of PDO Ragusano cheese and no starters are added in the cow raw milk. A source of aromatic components in milk might be the biofilm microflora released from the traditional wooden vat called *tina*, used during cheese making, as well as the flora naturally present in raw milk. Thus, the objectives of this work were to investigate the potential role of the *tina* biofilm to generate aroma compounds when inoculated into milk and to assess the ability of a Smart Nose to discriminate them by analyzing the aroma profiles of the inoculated milks. Pasteurized milk was used to avoid the interference of aroma compounds generated by the natural microflora present in raw milk. In this study, *tina* biofilms isolated from 3 different farms were inoculated in milk and incubated at conditions simulating the ones of the real cheese making of Ragusano before brining. The inoculated milk samples were analyzed through Smart Nose and the data were statistically treated by Principal Component Analysis (PCA). The PCA results showed first of all a good separation of the inoculated milks from the blank one (non-inoculated milk), highlighting a significant influence of *tina* biofilm on the developed milk aroma profile. In addition, all inoculated milk samples showed a clear separation among them, thus showing that each *tina* biofilm had a different behavior regarding aroma releasing when inoculated into milk under certain conditions. Certain volatile compounds were detected by GC-MS analysis in all 3 inoculated samples while these were totally absent in the blank, showing that were produced by the biofilm. Moreover, it was observed that the microbiological composition of each *tina* biofilm gave respectively a different aroma contribution. In conclusion, it was shown that Smart Nose is able to discriminate quite well aromatic profiles attributed exclusively to the biofilm bacteria during the first steps of cheese making.

Key Words: *Tina* biofilm, aroma profile, Smart Nose

798 Segmentation of scanning electron microscopy images using incremental learning. G. Impoco[1], L. Tuminello[1], M. Caccamo*[1], and G. Licitra[1,2], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*DACPA, University of Catania*, *Catania, Italy*.

This study tested a method for automatic quantification of digital micrographs based on statistical classification of pixels and incremental learning. Ten scanning electron microscope (SEM) images of Ragusano cheese were used as training set and the main microstructural features were gathered in 3 morphologically meaningful classes: fat globules, whey pockets, and protein matrix. A series of 10 numerical values (descriptor) was associated to each pixel. Images were partitioned into significant regions (segmentation) by clustering pixel descriptors using the k-means algorithm. According to the resulting clusters, an initial automatic classification associated each region to a specific microstructural feature. The classified images, used as reference labelings, were used to automatically learn a Bayesian statistical model which associates to each pixel its probability to belong to a certain feature class. This model was used to classify again input images. Output classifications were presented in color to a SEM specialized operator, who could select misclassified regions and associate them with a different, more appropriated label (re-labeling). New statistics obtained from the re-labeled regions were integrated into the model. The updated model was used to re-classify input images. This process of supervised re-labeling and automatic pixel classification was iterated until satisfactory results were obtained. We compared incremental learning to off-line image labeling, where the input images are manually labeled only for the initial training of the model, from a single reference data set. Experimental data showed that incremental learning gives better results than off-line learning. The training phase is less burdensome and time consuming for the user, and it can be adapted to new image samples without executing from scratch the long and tedious initial training.

Key Words: image analysis, SEM, cheese microstructure

799 Improvements and validation of mid-infrared predictions of milk fatty acid. H. Soyeurt*[1,2], S. McParland[3], D. Berry[3], E. Wall[4], N. Gengler[1,2], F. Dehareng[5], and P. Dardenne[5], [1]*University of Liege, Gembloux Agro-Bio Tech, Animal Science Unit*, *Gembloux, Namur, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Brussels, Belgium*, [3]*Teagasc Moorepark Dairy Production Research Centre*, *Fermoy, Cork, Ireland*, [4]*Sustainable Livestock Systems Group, Scottish Agricultural College*, *Penicuik, Midlothian, United Kingdom*, [5]*Agricultural Walloon Research Centre, Quality Department*, *Gembloux, Namur, Belgium*.

The development of mid-infrared equations to predict the milk fatty acid (FA) content of milk allows prompt analysis of large numbers of samples. The first aim was to improve these predictions by comparing 6 statistical approaches. The second one was to validate the new equations using an independent sample set. The calibration set contained 239 spectrally different Belgian milk samples collected for over 2 years from several cows and breeds. FA were quantified by gas chromatography (GC). Statistical approaches tested were 1) partial least squares regression (PLS), 2) PLS and first derivative, 3) PLS and repeatability file (RF), 4) PLS, first derivative and RF, 5) PLS, second derivative, and 6) PLS, second derivative and RF. This last file contained spectra obtained from the same samples using 5 spectrometers. Cross-validation (CV) used 20 groups from the calibration set. Methods were compared using the ratio of the standard deviation of GC values to the standard error of CV (RPD). An external validation permitted a second comparison and was done using 362 samples collected for one year from multiple breeds and cows in Belgium, Ireland, and Scotland. Different RPD values were obtained by the 6 methods. Generally the equations developed using method 4 gave better results suggesting the adaptation of the methodology to the studied FA. It confirms by the obtained validation coefficients of determination. Highest values were observed for the equations with the highest RPD values except for C18:0. The ability to predict FA using method 4 gave superior results to those shown in previous publications.

Key Words: mid-infrared, milk, fatty acid

800 Evaluation of a faster extraction and purification procedure for the analysis of vitamin D in fortified milk. T. C. Schoenfuss*[1] and O. Shimelis[2], [1]*University of Minnesota*, *St. Paul,* [2]*Sigma-Aldrich*, *Bellefonte, PA*.

Current methods to analyze vitamin D in milk require lengthy sample preparation steps to extract vitamin D before analysis by chromatographic methods like HPLC. The approved method from Standard Methods for the Examination of Dairy Products requires multiple days to accomplish and includes over-night saponification, liquid-liquid

extraction, dry down of over 135 mL of hexane under nitrogen, and solid phase extraction before HPLC. Various direct extraction techniques have been attempted but have not been adopted by the industry due to low extraction rates. The goal of this project was to develop a quicker, simpler method to quantify vitamin D in milk by combining new technologies. The method developed involved precipitating protein in 10 mL of milk with 10 mL of ethanol, sonicating for 1 min at 70% amplitude with a sonic horn immersed in the sample to break up complexes, and 2 liquid extractions with 15 mL hexane. The hexane extracted was dried down under nitrogen with a TurboVap LV Evaporator (Caliper LifeSciences, Hopkinton, MA) and reconstituted in 1 mL hexane. Solid phase extraction with an adsorbent designed for fatty acid methyl esters (Ag-Ion SPE tube, Sigma-Aldrich, Bellefonte, PA), and reverse phase HPLC of the eluent was done with several different columns and mobile phases that all allowed separation of D2 and D3. Vitamin D2 and D3 were observed to have different affinities for the solid phase extraction column, especially in the presence of fat, and the extraction rate from milk for D3 was up to 30% lower than D2. This extraction procedure can be completed in 1 d. This work highlights promising improvements for vitamin D analysis in milk that could reduce the time and solvents necessary.

Key Words: vitamin D, milk, extraction

801 Structural comparison of bovine and camel chymosin in relation to cheesemaking properties. K. B. Qvist*[1], J. L. Jensen[2], J.-C. N. Poulsen[2], M. Harboe[1], H. van den Brink[1], A. Mølgaard[2], and S. Larsen[2], [1]*Chr. Hansen*, *Hørsholm, Denmark*, [2]*Department of Chemistry, University of Copenhagen*, *Copenhagen, Denmark*.

By initiating milk coagulation, rennet enzymes are essential in cheesemaking. Bovine chymosin (BC) has long been considered the most suitable rennet, but recently it has been shown that *Camelus dromedarius* chymosin (CC) provides several benefits over bovine chymosin (BC), having a 7-fold higher ratio between milk clotting and general proteolytic activity. The objective of this work was to investigate the structural background for the improved selectivity of CC. Crystals of fermentation produced CC were grown with the hanging drop vapor diffusion technique. Data were collected by radiation with x-rays at 1.04 Å, and reduced with the XDS software, followed by flagging of reflections for free R-factor calculation, using the CCP4 suite. Molecular replacement was done with the Phenix software suite using the BC structure 1CMS as template. Cycles of manual fitting and refinement were done with Coot and Phenix, respectively. Validation was done with the WHAT IF package. The structure of CC, without the first 10 residues was obtained at 1.85 Å resolution, with a free R-factor of 0.21. The overall fold was similar to that of BC, but with notable differences in the details. L32V and E290D substitutions provide more space for bulky amino acids at the P1 and P1' positions, respectively. A further 7 substitutions in the extended binding region may contribute to selectivity differences. Also, in CC a surface patch, at positions 244–254, previously implicated in binding the positively charged sequence 98–102 of κ-casein (KC), was less negatively charged than in BC. This mirrors the fact that 98–102 in camel KC is more positively charged than in bovine KC. A patch near the edge of the cleft, at positions 289–300 was significantly more negative in CC. Finally, differences in the location of the N-terminal were observed. In conclusion, several structural differences likely to affect cheesemaking properties were identified.

Key Words: camel chymosin, 3-D structure, renneting

802 Detection of proteolysis in milk. A. S. Grandison*[1], L. M. Chove[2], and M. J. Lewis[1], [1]*University of Reading*, *Reading, Berkshire, UK*, [2]*Sokoine University*, *Morogoro, Tanzania*.

The quality of raw milk is affected by proteolysis during storage. It occurs through either bacterial or native proteases. Plasmin, the major protease occurring in milk, forms part of a complex system which hydrolyses the caseins and thus affects the quality of dairy products. These effects may be positive, as in cheese ripening; or negative as in the production of bitter off-flavors in dairy products or age-gelation in UHT milk. The enzyme system is very heat resistant and cannot be eliminated by pasteurization or even UHT processing. The aim of this study was to develop a simple method to detect protease activity in milk. Analysis of pH 4.6 or 6% trichloracetic acid (TCA) soluble extracts of milk by trinitrobenzene sulfonic acid (TNBS), reverse phase high performance liquid chromatography (RP-HPLC), gel electrophoresis and fluorescamine methods was carried out to determine their relative suitability for the detection of proteolysis in milk during storage for up to 7 days. Trypsin or plasmin were added to UHT sterilized milk at different levels to promote/accelerate proteolysis. This was due to the high cost of plasmin, hence trypsin was used for initial trials as it has a similar mode of action to plasmin. The TNBS, fluorescamine and RP-HPLC methods gave highly correlated results ($R^2 > 0.93$), clearly demonstrating increased proteolysis during storage. Gel electrophoresis revealed that the breakdown products from trypsin were similar to plasmin. The most obvious phenomenon was that γ-caseins, formed as a result of β-casein degradation, subsequently disappeared due to extensive proteolysis in the trypsin samples. Similar trends were found for both the pH 4.6 and 6% TCA soluble extracts. The amido methyl coumarin (AMC) method, which is specific for plasmin activity, was found to be very sensitive in the determination of proteolysis by plasmin, but is also very expensive. On balance, the TNBS method was recommended on the basis of accuracy, reliability, simplicity and cost.

Key Words: proteolysis, plasmin, trypsin

803 Genotyping of κ-casein and β-lactoglobulin genes in Chinese Holstein dairy cows, Jersey and water buffalo. D. X. Ren*[1], S. Y. Miao[1], Y. L. Chen[1], C. X. Zou[2], X. W. Liang[2], and J. X. Liu[1], [1]*Institute of Dairy Science, Zhejiang University*, *Hangzhou 310029, P. R. China*, [2]*Water Buffalo Institute, Chinese Academy of Agricultural Science*, *Nanning 530001, P. R. China*.

The present work is carried out to analyze the polymorphism of κ-casein and β-lactoglobulin genes in Chinese Holstein dairy cows, Jersey and water buffalo. The DNA was extracted from the blood samples of 82 Holstein, 56 Jersey and 48 buffalo. Identification and genotyping of κ-casein and β-lactoglobulin gene was conducted by PCR-RFLP assay. Different restriction endonucleases, *Hinf*I and *Hae*III, were used. The PCR product of the primer specific for κ-casein and β-lactoglobulin gave the specific band at size 379, and 252 bp, respectively. After digestion of PCR product with restriction enzymes, different genotypes of κ-casein and β-lactoglobulin were obtained, the fragment size of which is shown in Table 1. Among the examined Holstein cows, κ-casein genotype of AA, BB, and AB was 45.83, 8.34, and 45.83%, and corresponding genotype for β-lactoglobulin was 19.1, 20.6, and 60.3%, respectively. For Jersey, the κ-casein genotype of AA, BB, and AB was 0, 80, and 20%, and the corresponding value was 36.8, 22.8, and 40.4%for β-lactoglobulin, respectively. However, all buffalo samples were homozygous for the κ-casein and β-lactoglobulin, with all genotype as BB. In summary, allele of κ-casein gene was mainly A in Holstein dairy cows and B in Jersey, while β-lactoglobulin was mainly A in both Holstein cows and Jersey. However, water buffalo were monomorphic

for the κ-casein and β-lactoglobulin genes, possessing only allele B in homozygosis form.

Table 1. Fragment size corresponding to different genotypes of κ-casein and β-lactoglobulin after digestion of PCR product with restriction enzymes

Milk protein	Genotypes	Size of fragments from digestion of PCR product with restriction enzymes (bp)
κ-casein	AA	156, 132, 91
	BB	288, 91
	AB	288, 156, 132, 91
β-lactoglobulin	AA	144, 108
	BB	108, 74, 70
	AB	144, 108, 74, 70

Key Words: genetic polymorphism, κ-casein, β-lactoglobulin

804 Impact of plasmin hydrolysis of caseins on the minimum coagulation temperature observed for milk during renneting. B. Coude*, Y. Lu, and J. Lucey, *University of Madison*, *Madison, Wisconsin*.

The rennet coagulation of milk involves 2 different stages. The primary stage is the enzymatic phase in which rennet hydrolyzes κ-casein. The second stage is an aggregation of renneted micelles but this aggregation reaction is highly temperature dependent and does not occur at temperatures < 18°C. It is not clear why the aggregation reaction is so temperature dependent. We believe that at low temperature β-casein may protrude from the surface of casein micelles thereby, creating an additional barrier to aggregation. We hypothesized that removal of β-casein, that is close to the micelle surface, should allow rennet coagulation to occur at lower temperatures. We used plasmin enzyme to hydrolyze β-casein since it is more susceptible to hydrolysis than α-caseins while κ-casein is resistant to breakdown. We studied the impact of plasmin hydrolysis of caseins on the minimum temperature at which the rennet coagulation reaction could occur in milk. Human plasmin (0.01mg/ml) was added to reconstituted skim milk. Milk samples were incubated with plasmin at 37°C for 0.5 to 6 h. Hydrolysis was terminated by adding soybean trypsin inhibitor. The extent of degradation of caseins was determined with SDS-PAGE. Degradation of α- and β-caseins after incubation with plasmin for 0.5 to 6 h ranged for about 10 to 40%, and about 30 to 60%, respectively. Rennet was added to milk at different temperatures: 32, 25, 20, 15, 10 and 5°C. Coagulation was visually determined (Berridge method) as well as monitored by dynamic low amplitude oscillatory rheology. The minimum rennet coagulation temperature for control milk (without plasmin hydrolysis) was ~20°C. Milk that was hydrolyzed with plasmin at 37°C for 0.5 or 1 h could undergo rennet coagulation at ~15°C. Milk that was hydrolyzed with plasmin at 37°C for 2 h and up to 6 h could undergo rennet coagulation at temperatures as low as 5°C. In conclusion, these results support the hypothesis that at low temperature, β-casein on the micelle surface inhibits the aggregation of renneted micelles.

Key Words: plasmin, hydrolysis, rennet coagulation

805 Bilingual audiovisual technology improves dairy animal care and quality assurance. B. Butler*, S. Torres, J. Valles, C. D. Reinhardt, and D. U. Thomson, *Kansas State University*, *Manhattan*.

The Beef Cattle Institute at Kansas State University (BCI) has developed bilingual educational tools based on audiovisual technology to improve technical knowledge within livestock operations. The Dairy Animal Care and Quality Assurance (DACQA) program is available in a package of 36 multimedia modules with a total length of 2hrs and 42 min of training material to train animal care givers in areas of animal health, productivity and well-being. This quality assurance program promotes the best management practices for dairy animal care and husbandry through each area of the milk production operation, including proper management of feedstuffs and nutrition; pharmaceutical usage and administration; cattle handling guidelines; identification; record keeping and animal marketing decisions. The information in the modules is presented in a simple and colloquial communication to assure effective transmission of information. Two of the DACQA modules (one module addressing animal health practices and one module addressing animal handling) were presented to 10 professional dairy care workers who had a preference for learning in either English (n = 7) or Spanish (n = 3); a 10-question examination with questions relating to each specific module was given before and after viewing each of the modules. Test scores improved by 28% from pre-viewing to post-viewing ($P < 0.01$; pre-viewing score = 7/10; post-viewing score = 9/10); there was no effect of module or language preference or their interaction ($P > 0.37$). These results concur with previous data we have generated which demonstrated a 25% increase in knowledge of beef quality assurance best management practices following viewing of this type of module. With the audiovisual technology available, the industry not only addresses current topics related to producing safe and wholesome dairy products, but also supports a welfare-centered and economically sustainable dairy industry.

Key Words: bilingual, dairy, training

806 Impact of a practical dairy farm management training workshop on the knowledge level of participants. E. Ashraf*[1], Z. Hayat[1], M. Z. U. Khan[2], S. U. Ansari[1], I. Hussain[1], F. A. Atif[1], M. Arif[1], and M. Luqman[1], [1]*University College of Agriculture*, *University of Sargodha, Sargodha-40100, Pakistan*, [2]*University of Veterinary & Animal Sciences*, *Lahore, Pakistan*.

The dairy industry is an important part of the economy in developing countries. There is a dire need for trained human resources for the development of this sector. Five d training workshop was organized for demonstration of dairy management practices. Participants (n = 36) were randomly selected across the country. The objectives were to evaluate the knowledge level of participants after making them aware of the latest feeding and management techniques practiced in the dairy industry, and to identify factors that are directly related to their learning. The pre and post test each comprising of 20 multiple choice questions was given to the participants at the start and end of the training. There was a significant improvement in the knowledge level after attending the training since the Mean = 5.03, $t = 9.39$, SE = 3.21 with p-value <0.1. On average there was a 25% increase in the marks of the participants. Complete regression model was run with the independent variables of age, experience, and education on the difference of the pre and post tests and model was statistically significant $F(3, 32) = 2.75$ $P < 0.1$. Age was the only significant predictor in the model and showed negative effect on the difference of marks of the participants, and explains 20% of the total variance. This explained the phenomenon that as age increases the impact of training on the knowledge level decreases. Another regression model was run on the marks after the training. The model was statistically significant $F(3, 32) = 4.20$ $P < 0.1$. It was revealed that education level plays a central role in the knowledge improvement and was a good predictor which explained 28% of the total variance in the data. Correlation of the variables also confirmed the results and showed that only education is positively significantly correlated with the marks of the participants after completing training. The other 2 variables, age and experience, showed a negative relationship with the marks of the participants. It is concluded that older participants with lower education levels could not perform well in short training programs and need separate extensive and long-term training sessions.

Key Words: training, knowledge, dairy

807 A stochastic evaluation of reproductive management programs for dairy herds. J. O. Giordano*, P. M. Fricke, M. C. Wiltbank, and V. E. Cabrera, *University of Wisconsin*, *Madison*.

A Markov-chain simulation model was developed to compare the net present value (NPV, $/cow/d) generated by different reproductive management programs (RP) in a dairy herd. The daily NPV of a specific RP was calculated by adding the discounted expected monetary values (DEMV) of that proportion of cows that become pregnant at each successive AI service until a maximum predefined DIM plus the DEMV of that proportion of cows not becoming pregnant to the RP. The DEMV for a lactation defined by DIM at pregnancy was calculated based on the value of milk produced, feed cost, expected value of a new born calf, and cost of culling. Economic, productive, and reproductive values were user–defined for each RP evaluated. The model sequentially estimated the percentage of cows eligible for breeding, becoming pregnant, and not becoming pregnant at each AI service based on the service rate (SR) and conception rate (CR) of each RP. Total AI service cost including pregnancy diagnosis (PD) was applied to all cows until pregnancy or culling for reproductive failure. For synchronized AI services, total cost was calculated by adding the individual cost of: treatments, labor, AI, and PD. Total cost for estrous services was calculated by adding the individual cost of heat detection, AI, and PD. A decision tree then compared the NPV for different RPs. A comparison among commonly used programs with typical reproductive values (Table 1) indicated that a Presynch–Ovsynch (PS–Ov) protocol with 100% TAI (A) for 1st service was stochastically dominant over RP (B) and (C). Utilization of this model by commercial dairy herds may facilitate selection of economically optimal RP based on farm-specific parameters.

Table 1. Net present value for commonly used reproductive programs

	1st AI					
	ES		TAI			
	(%)		(%)		NPV ($/cow/d)	NPV ($/1000-cow/y)
Program	SR[2]	CR[2]	SR[2]	CR[2]	Mean±SD (Range)	Difference from maximum
(A)100% TAI PS-Ov & Ovsynch	-	-	100	[36,43,50]	6.93±0.03(6.87–6.99)	Max
(B)ES[1] + TAI PS-Ov & Ovsynch	[26,49,55]	[30,35,39]	[74,51,45]	[20,30,41]	6.83±0.03(6.76–6.89)	−36,500
(C)100% ES[1]	[45,55,65]	[28,33,36]	-	-	6.81±0.02(6.77–6.84)	−43,800

[1]ES = estrous service, [2]Triangular distribution [min, most likely, max].

808 Optimization of insemination and replacement decisions under herd constraints. A. De Vries*, *University of Florida*, *Gainesville*.

Existence of herd constraints such as a limited number of replacement heifers or a milk quota implies that optimal insemination and replacement decisions for individual animals are not independent. Historically, calculation of such optimal decisions has shown to be difficult. A linear programming model was developed to evaluate optimal replacement and insemination decisions for dairy heifers and cows considering herd constraints. The model considered 3 semen types (for example sexed dairy, conventional dairy, conventional beef), 5 levels of milk production, and 10 parities including heifers. Each parity had 20 voluntary culling opportunities for non-pregnant animals. Heifers and cows were allowed a maximum of 18 insemination opportunities. Time step between insemination decisions depended on service rate. Time step for culling decisions include the start of the parity and before each insemination opportunity. The model contained 3,700 decision variables. Genetic value of heifer calves was a function of service sire net merit, age of the dam, and level of milk yield of the dam. Inputs were lactation curves, milk price, feed costs, insemination costs, service rates, conception rates, dystocia costs, involuntary culling risks, and other variable and fixed costs. To illustrate, profit/cow per yr in a closed herd with choice from 3 semen types was $368. Conventional semen was used in 13% of the heifer inseminations and 47% of the cow inseminations. Sexed semen was used in 74% of the heifer inseminations and 11% of the cow inseminations. Average milk yield was 32 kg/cow per d. Setting the milk quota to 30 kg/cow per d resulted in $293 profit/cow per yr with 97% of all slots filled. The optimum insemination mix included less conventional semen, more beef semen, more sexed semen in cows but less in heifers. The linear programming model formulation allows for exploring realistic optimal replacement and insemination decisions when herd constraints need to be considered.

Key Words: culling, insemination, herd constraint

809 Animals and Food Security: Blending land-grant missions through international engagement in Romania. P. D. Ebner* and M. A. Russell, *Purdue University*, *West Lafayette, IN*.

This international service-learning course works in villages with Heifer Project Romania and uses extension activities to enhance the capabilities of US land grant universities to better conduct their missions domestically and abroad. Students work in bi-national teams across agricultural and community disciplines to apply their knowledge and experience to make a difference. This course builds upon established collaborations with Heifer Project Romania and 3 agricultural sciences and veterinary medical universities in Romania to develop intercultural competencies. Extension educators have the expertise to facilitate the organization of local associations to better prepare the community for the future. Funding agencies around the globe seek to serve private or public organizations that have the capacity to implement their projects. Through these activities, teams bring home the ideas and technologies of other countries and develop international networks to make our domestic clientele competitive in the future. The authors have conducted similar courses and experiences in Paraguay and Ecuador.
Students develop an ability to effectively communicate with others regardless of culture and backgrounds, the capacity to work effectively as part of bi-national, problem-solving teams, and the capability to apply social, economic, political, and environmental principles to serve in an international rural village or their own county. With focus on environmental stewardship and protection systems, participants learn and apply topics of large scale composting (with manure), swine and poultry nutrition, ruminant nutrition, livestock diseases, livestock care standards, and environmental regulations for livestock production (European Union). Students develop experience in designing smaller-scale management systems and facilities that provide more flexibility to their livestock owners in their home counties. We will share both qualitative and quantitative methods of assessing learning and the development of intercultural competencies as well as the agronomic practices.

Key Words: international extension, environmental protection, intercultural competencies

810 Avian embryology posters as a teaching aid. T. A. Hess*[1], J. P. Blake[2], W. D. Berry[2], and R. A. Voitle[2], [1]*School of Forestry and Wildlife Sciences*, *Auburn, AL*, [2]*Auburn University, Poultry Science Department*, *Auburn, AL*.

A project was undertaken that documented the embryonic development of both chickens and game birds (bobwhite quail and ringneck pheasants). There is a vast amount of information about the developmental stages of avian embryos (due primarily to the ability to incubate eggs away from the dam); this project condensed an enormous amount of knowledge into a readily accessible visual source for educational purposes. After incubating eggs in a staggered schedule, embryos were extracted from the shells at specific stages of development. Embryos were collected for each day of incubation for each species (chicken, bobwhite quail, ringneck pheasant). Pictures were taken of the embryos (Nikon D70S Camera; AF Micro Nikkor 60mm lens; Nikon SBR200 ring flash; CS920 Photographic Copy Stand). Posters were developed commercially incorporating photography and text describing the physiological changes, to stand as representations of the developmental stages. These posters were then provided to meet the educational needs of the poultry industry, game bird producers, and educational systems (middle through high schools) across Alabama. Knowing the many stages of avian embryonic development is useful information for both the seasoned poultry producer as well as those studying embryology. Game bird producers, often an underserved portion of the poultry community, can use these posters to train hatchery personnel or to provide game bird-based embryological training to local schools.

Key Words: embryology, chicken, game birds

811 Alternative fuel demonstrations on Pennsylvania turkey, broiler and duck farms burning poultry litter, wood pellets and wood chips vs. propane. P. H. Patterson*, R. M. Hulet, and D. E. Buffington, *The Pennsylvania State University*, *University Park*.

Propane costs, grower profitability and concerns about combustion gases (CO2, H2O) and litter quality were instrumental in establishing 4 poultry farm fossil fuel alternative demonstrations. Two turkey houses, 15.2 × 183m with 17,000 birds/house were originally fitted with 30 brooders/house. A 586kW (2 mill BTU/hr) boiler made by Bio-Fuel Technologies www.Bio-FuelTechnologiesLLC.com was installed between the houses with 8 ceiling mounted heat exchangers/house. The chain grate fuel delivery allows this farm to burn spent turkey litter. We are currently monitoring propane and litter consumption, litter and air quality and bird performance. On 2 broiler farms a FarmTek 234kW (800,000 BTU/hr) hot air furnace http://www.farmtek.com/farm/supplies/cat1a;ft1_heaters_accessories.html was installed in the middle of one house with 2 61cm air tubes and fans pushing heat to both ends. The furnaces are fueled by hardwood pellets from Energex Pellet Fuel, Inc. www.energex.com. One house per farm has the 234kW furnace, while the other has

the original propane equipment to compare fuel consumption and bird performance. Farm A houses are 14.6 × 152m with 30,000 birds each and 11 radiant tube heaters/house. Farm B houses are 13.4 × 152m with 27,000 birds each and 4 wall mount space heaters. A duck farm with 2 houses 13.7 × 137m upgraded the original 6 propane space heaters/house with 12 hot water heat exchangers and a 264kW (900,000 BTU/hr) boiler made by Total Energy Solutions LLC www.gototalenergy.com. The fuel is a course hardwood chip. The farm broods 9400 birds in the first 45.7m to 18d, and finishes at 39d in the remaining 91m. They grow 13 flocks/house/yr, and finish birds at 3.3kg. Monitoring continues and outreach has included 3 field days and 2 presentations to state government and sponsors. An overview of the farms, their installations and YouTube videos are planned for our extension webpage http://poultryextension.psu.edu/. Further descriptions of the alternative fuel systems and their performance will be submitted for publication and presented at in-state meetings.

Key Words: alternative fuel, demonstrations, poultry performance

812 Equine rotational grazing demonstration: Field observations and extension program impact. A. O. Burk*, N. M. Fiorellino, K. M. Wilson, T. A. Shellem, and M. E. Dwyer, *University of Maryland*, *College Park*.

An equine rotational grazing demonstration site was constructed to temporally assess performance of the vegetation and horses within the rotational system and to train horse farm operators to adopt environmental protection best management practices (BMPs). Four Thoroughbred geldings (initial BW 476.4 ± 5.4 kg; initial BCS 4.9 ± 0.9 units) were rotationally grazed between April 2009 and January 2010 using 4 0.49 ha mixed grass/legume pastures, one 0.08 ha mixed grass heavy use paddock, and one 0.04 ha sacrifice area. Mean pasture vegetative cover over the observational period was 78 ± 3% with the majority represented by grasses (69%), and to a lesser extent legumes (6%) and weeds (3%). Horses spent an average of 80.1 ± 6.5% of days grazing pasture with June and July having the most days grazing (100%) and December and January having the least days grazing (38.8% and 51.6%, respectively). Horse were moved onto and off of pasture when grass height averaged 11.1 ± 1.1 and 6.9 ± 1.3 in, respectively. Horse BW peaked in November ($P = 0.009$) while BCS remained unchanged. Assuming 2% DM intake, pasture or supplemental hay met nutritional requirements for horses at maintenance, with the exception of sodium, zinc and copper. Amount of hay offered when horses were housed in the sacrifice lot was highest during May, December, and January. In regards to extension education, 3 2 h events were held at the site in April, June, and August drawing 141 participants. After attending the events, the majority of participants (≥51%) indicated a significant to very significant increase in their knowledge of 9 of 16 topics related to environmental protection BMPs. More than 80% of participants indicated they would adopt 12 of 15 BMPs with lowest rates observed for maintaining a stocking density of 0.6 ha horse $^{-1}$ (58.1%), applying herbicides as needed (69.8%), and use of heavy use pads in muddy areas (79.5%). Use of the equine rotational grazing demonstration site has been a valuable tool to increase our knowledge of the performance of a rotational grazing system for horses and in increasing the adoption of environmental protection BMPs by horse farm operators.

Key Words: extension, horse, environment

813 Milk production and feed efficiency in dairy cows fed corn silage hybrids varying in fiber digestibility. L. E. Chase*, *Cornell University*, *Ithaca, NY*.

A trial with lactating dairy cows was conducted to examine the relationships between corn silage hybrid fiber digestibility, milk production, dry matter intake and feed efficiency. Brown midrib (BMR), NutriDense (ND) and a conventional (C) hybrid were used. Twenty cows were assigned to each treatment at 7–12 d after calving and individually fed the treatment rations for 10 weeks. The same ration was fed to all cows with the only difference being the corn silage hybrid used. This ration contained 59% corn silage, 5.5% straw and 35.5% grain. Nutrient composition of this ration averaged 46.5% DM, 17.4% CP and 34.1% NDF. Nutrient composition of the BMR hybrid was 32.9% DM, 8.4% CP, 38.6% NDF and 36.5% starch. The ND hybrid was 32.9% DM, 8.36% CP, 41.3% NDF and 33.6% starch. The conventional hybrid was 36.3% DM, 7.8% CP, 38.3% NDF and 39% starch. NDF digestibility (30-h) values were 59.6, 46.8 and 49.4% for the BMR, ND and C hybrids. Data analysis was done using the GLM procedure in SAS with a covariate. Cows fed the BMR corn silage had greater DMI (26.1 kg/day; SEM = 0.32) than either the ND (23.5 kg/day) or the C (24.2 kg/day) hybrids ($P < 0.001$). Daily milk production was also greater (46.6 kg/day; SEM = 0.71)) for cows fed the BMR hybrid ($P < 0.0047$). Milk production was not different between the C (43.6 kg/day) and ND (43.5 kg/day) hybrids. Milk fat did not differ between the 3 hybrids. Milk true protein was lower in cows fed the ND ration (2.67%; SEM = 0.027) than cows fed either the BMR (2.77%) or C (2.78%) rations ($P < 0.007$). Feed efficiency (kg 3.5% FCM/kg DMI) was greater for cows fed the ND ration (1.87; SEM = 0.028) compared with either BMR (1.76) or C (1.74) rations ($P < 0.002$). Dairy cows fed BMR corn silage had higher milk production in this trial. However, cows fed the ration containing ND corn silage had significantly higher feed efficiency.

Key Words: corn silage, feed efficiency

814 Performance of dairy cows fed high water soluble carbohydrate sorghum silage. S. Amer* and A. F. Mustafa, *McGill University*.

Twelve lactating Holstein cows were used in a cross- over study (n = 2) to determine the performance of dairy cows fed high water soluble carbohydrate sorghum silage (SS, sweet sorghum, cultivar CSSH45) relative to alfalfa silage (AS). The sweet sorghum cultivar contained 8% water soluble carbohydrates while the regular counterpart (CFSH30) contained 3% water soluble carbohydrates. Sweet sorghum was harvested at early heading stage while alfalfa was a second cut crop. Experimental periods consisted of 14 d of diet adaptation and 8 d of data collection. Two isonitrogenous diets with 50:50 forage: concentrate ratio were formulated. Sweet sorghum silage and AS constituted 70% of the forage in each diet. Two lactating Holstein cows fitted with ruminal cannulas were used to determine the effects of dietary treatments on ruminal fermentation parameters. Relative to AS, SS contained 58% more NDF, 70% less CP but similar ADF concentration. Cows fed SS consumed ($P < 0.05$) less DM (23.3 vs. 26.1kg/d) and CP (4.1 vs. 4.7 kg/d) but more ($P < 0.05$) NDF (9.1 vs. 7.9 kg/d) than those fed AS. Milk yield (33.5 vs. 36.7 kg/d) was higher ($P < 0.05$) for cows fed AS than for those fed SS. However, energy-corrected milk was similar for both dietary treatments (average 37 kg/d). Cows consumed SS produced milk with greater ($P < 0.05$) concentrations of fat and total solids but lower ($P < 0.05$) concentrations of lactose and SNF. Ruminal pH was higher ($P < 0.05$) whereas ruminal NH3-N was lower ($P < 0.05$) for cows fed SS than those fed AS. Total VFA concentration and molar proportions of propionate and butyrate were greater ($P < 0.05$) whereas molar proportion of acetate was lower ($P < 0.05$) for cows fed SS than for those fed AS. It was concluded that SS when compared with AS, had a negative impact on feed intake and milk yield, whereas energy corrected milk and milk efficiency were similar.

Key Words: sweet sorghum silage, alfalfa silage, dairy cows

815 Effects of water soluble carbohydrate content of ensiling characteristics, chemical composition and in vitro digestibility of sorghum silage. S. Amer*[1], P. Seguin[1], F. Hassanat[2], R. Berthiaume[2], and A. Mustafa[1], [1]*McGill University*, *Ste-Anne-de-Bellevue, QC, Canada*, [2]*Dairy and Swine Research and Development Centre*, *Lennoxville, QC, Canada*.

A study was conducted to determine the effects of water soluble carbohydrate (WSC) concentration on ensiling characteristics, chemical composition and in vitro digestibility of forage sorghum in a completely randomized study. A low (2.5% of DM) and a high (8% of DM) WSC forage sorghum cultivars were field-grown (3 plots per cultivars) and harvested at early heading stage. Following harvest, forages were ensiled in mini-silos for 0, 2, 4, 8, 16, and 45 d. Results showed that both silages went through a rapid fermentation as indicated by the significant decline in pH between d 0 d 16 post-ensiling. However the decline in pH at all ensiling times was greater for high than low WSC sorghum silage. Lactic acid concentration followed a trend similar to that of pH. Chemical analysis of the 45-d silages showed that high WSC sorghum silage contained 11% less CP and 35% less acid detergent lignin than low WSC sorghum. However, NDF and ADF concentrations were similar for both silages. Asymptotic gas production and degradation rate were both higher for high than for low WSC sorghum silage. In vitro true DM digestibility was greater for high than for low WSC sorghum silage while in vitro NDF digestibility was unaffected by WSC concentration. In vitro protein synthesis as well as molar proportions of volatile fatty acids were similar for both types of sorghum silage. We concluded that increasing WSC concentration improved the fermentation and digestibility of forage sorghum silage.

Key Words: water soluble carbohydrate, sorghum silage, in vitro digestibility

816 A meta-analysis approach to model the effect of increased organic matter digestibility on milk solids production from dairy cows fed fresh ryegrass. D. Pacheco*[1], R. E. Vibart[1], and B. A. Barrett[2], [1]*Food, Metabolism & Microbiology*, *AgResearch Grasslands, Palmerston North, New Zealand*, [2]*Forage Improvement*, *AgResearch Grasslands, Palmerston North, New Zealand*.

Research efforts are underway to produce temperate forages with increased digestibility of NDF (NDFd) and organic matter (OMd) as a means for increasing the feeding value (FV: intake x nutritive value) of grazed forage. A database of feed composition and milk production comprising 132 treatment means from publications in which lactating dairy cows were fed at least 70% of the daily DMI as fresh perennial ryegrass (*L. perenne*) was collated. A 2 step approach using the MIXED procedure in SAS to account for random effects of study allowed quantifying the effect of OMd and other significant variables on the 2 elements of FV: prediction of DMI, and prediction of the feed conversion efficiency (FCE) expressed as milk solids yield (g of milk protein plus

milk fat) per kg of DMI. Initial bivariate data exploration determined that DMI had significant ($P < 0.01$) linear relationships with days in milk (DIM), body weight (BW) and OMd; and a quadratic effect of DIM was also apparent. The best model (RMSPE = 1.13; adjusted $r^2 = 0.62$) was DMI = 0.0188 (SE 0.0044) x BW (kg) + 0.0328 (0.015) x DIM - 0.0002 (0.00006) x DIM^2 + 0.0662 (0.0289) x OMd (g/100 g). Exploration of the relationships of FCE with variables in the database determined that FCE and DIM had a linear, negative relationship ($P < 0.01$). Feed conversion efficiency and OMd had a significant ($P < 0.05$) albeit weak relationship, with OMd values having little effect on FCE when DIM were greater than 200. The best model (RMSPE = 4.44; adjusted $r^2 = 0.94$) was FCE = 54.38 (SE 19.80) −0.254 (0.04) x DIM + 0.855 (0.24) x OMd. In seasonal, spring calving dairy systems such as the one predominating in New Zealand, the potential responses in milk production from ryegrass with greater OMd need to be assessed accounting for the timing of the expression of the improved forage trait. Improvements in OMd need to be achieved as early as possible during lactation to benefit both DMI and FCE. Responses in milk solids yield to greater OMd occurring after ryegrass transitions from vegetative to reproductive may be compromised by decreasing FCE in advanced lactation.

Key Words: ryegrass, digestibility, milk production

817 Effects of microbial corn silage inoculants on silage fermentation, microbial contents, aerobic stability, and milk production under field conditions. N. B. Kristensen*[1], K. H. Sloth[2], O. Højberg[1], N. H. Spliid[1], C. Jensen[3], and R. Thøgersen[3], [1]*Aarhus University*, *Tjele, Denmark*, [2]*Agro Tech A/S*, *Aarhus, Denmark*, [3]*Danish Agricultural Advisory Service*, *Aarhus, Denmark*.

The present study aimed to investigate the effects of 2 corn silage inoculation strategies (homofermentive vs. heterofermentive) under field conditions and to monitor responses in silage variables and milk production over the feeding season from January to August. Thirty 9 commercial dairy farms and 7 contractors participated in the study. Farms were randomly assigned to 1 of 3 treatments: Control (non active), Lactisil (inoculation with 1×10^5 *Lactobacillus pentosus*/g fresh crop and 2.5×10^4 *Pediococcus pentosaceus*/g fresh crop, Chr Hansen A/S; Hørsholm, Denmark), and Lalsil Fresh (inoculation with 3×10^5 *Lactobacillus buchneri* NCIMB 40788/g fresh crop (Lallemand Animal Nutrition, Blagnac, France). Data were analyzed by the MIXED procedure in SAS using a model containing the fixed effects of treatment, time, and their interaction. Contractor by treatment was designated as a random effect. Inoculation with Lactisil was without effect ($P > 0.10$) on any of the measured fermentation variables and aerobic stability except for a trend ($P < 0.10$) on ethanol. Inoculation with Lalsil Fresh doubled ($P < 0.01$) the aerobic stability (temperature increase 2.5°C above ambient 19.0 ± 0.5°C) being 37, 38, and 80 ± 8 h for control, Lactisil, and Lalsil Fresh, respectively. Lalsil Fresh increased ($P < 0.01$) silage pH and contents of acetic acid, propionic acid, propanol, propyl acetate, 2-butanol, propylene glycol, ammonia and free amino acids. Lalsil Fresh increased ($P < 0.01$) the counts of total lactic acid bacteria and reduced ($P < 0.01$) yeast counts. Inoculation treatment did not affect ($P = 0.49$) milk production at the farms when comparing actual test day results with predicted milk production based on the previous 2 yr test data. Under field conditions, the homofermentive inoculant was generally without effects on corn silage fermentation whereas heterofermentative inoculation increased aerobic stability and the silage contents of numerous fermentation variables.

Key Words: corn silage, fermentation, inoculation

818 Some factors with influence on the silage acidity and the aerobic stability. Y. Acosta Aragón*[1], K. Schoendorfer[2], S. Pasteiner[1], A. Schatzmayr[2], and G. Boeck[2], [1]*Biomin Holding GmbH*, *Herzogenburg, Lower Austria, Austria*, [2]*Biomin Research Center*, *Tulln, Lower Austria, Austria*.

The aim of this study was to quantify the influence of different silage quality parameters on the decrease of the pH value in the silage and the aerobic stability. Seven different trials with different substrates were ensiled under laboratory conditions in buckets (5 L). The products under study were the biological silage inoculants Biomin BioStabil Plus (grass, alfalfa) and Biomin BioStabil Mays (whole crop maize and wet corn grain silages), blends of homo- and heterofermentative lactic acid bacteria (L. plantarum, E. faecium and L. brevis), as well a product A (similar blend). The opening of the model silos occurred after 90 d. The changes in the pH values, the fermentation acid contents, ethanol, as well as the aerobic stability (AS) during 7 d (Honig, 1990), the dry matter (DM) losses and an organoleptic assessment using a negative point system according to the DLG- Schlüssel (2006) were measured. The database created with the results of the trials was analyzed using one way ANOVA and post hoc tests (Duncan, $P < 0.05$), as well as regressions to find out which fermentation parameters (DM; content of glucose and fructose, ethanol, propandiol, acetic, propionic, butyric acid and total acid; and the proportions between acetic acid and total acid, between lactic acid and total acid; thereafter named as variables entered) have an influence on the pH value content and the AS. According to the results exposed above, the acidification of the silages is determined by different parameters, in which the Lactic acid content plays an important role. The inclusion of the product tested bettered the acidification in the grass silages. The end pH- value was not affected by the use of additives in alfalfa and corn silages. Only the parameters acetic acid and ethanol played a negative role in the decreasing of the end pH-value. The AS is influenced negatively mainly by the DM, fructose, ethanol and the proportion of lactic acid to the total acid. The acetic and butyric acid content as well as the proportion between acetic and lactic acid and between acetic and the total amount of acid plays a positive role.

Key Words: silage, acidity, aerobic stability

819 Effect of herbage mass and pasture allowance on perennial ryegrass sward structure and milk yield during the grazing season. A. I. Roca-Fernández*[1], M. O'Donovan[2], J. Curran[2], and A. González-Rodríguez[1], [1]*Agrarian Research Centre of Mabegondo*, *La Coruña, Galicia, Spain*, [2]*Moorepark Dairy Production Research Centre*, *Fermoy, Co. Cork, Ireland*.

The effect of herbage mass (HM) and pasture allowance (PA) on dairy systems varies as the grazing season progresses due to changes in the sward structure. The longer term effects of HM and PA on milk output and grass production must be studied to identify the optimum level of HM and PA to graze. The aim of this study was to investigate the effect of 2 pre-grazing HM (Low, L-1600 and High, H-2400 kg DM ha^{-1}) and 2 PA (Low, L-15 and High, H-20 kg DM cow-1 d^{-1}) on the sward composition of perennial ryegrass in the upper and lower sward horizon (<and >4 cm) and its influence on milk yield. The study was conducted at Moorepark in rotationally grazed pastures, with each treatment assigned farmlets from April to October. Sixty-four spring calving Holstein-Friesian cows (primiparous and multiparous) were balanced on calving date and milk yield. Cows were randomized in a block design with a 2x2 factorial arrangement of treatments (LL, LH, HL and HH). Daily fresh herbage was allocated. Milk yield was recorded daily and milk composition twice weekly. Data was analyzed using PROC MIXED in SAS. The variables included in the model were HM,

PA and the interaction between HM and PA. The low HM treatments completed 9 grazing rotations compared with 7 rotations for the high HM treatments. Mean stocking rates achieved were of 4.0 (LL), 3.85 (LH), 4.01 (HL) and 3.93 cows ha^{-1} (HH). Sward utilization was greater ($P < 0.001$) when animals offered low PA (98.0%) compared with high PA (89.9%). Stem and dead DM yield were lower ($P < 0.001$) in the upper sward horizon for the low HM (221 and 170 kg ha^{-1}, respectively) compared with high HM (388 and 303 kg ha^{-1}, respectively). Grazing swards with low HM showed a tendency to increase ($P < 0.07$) milk yield and increased ($P < 0.05$) milk protein yield. The high PA had a positive effect ($P < 0.001$) on milk yield (19.5 vs. 18.1 kg day^{-1}, respectively) and milk solids (1.45 vs. 1.36 kg cow^{-1}, respectively) compared with low PA. The highest performance values were achieved by grazing swards at low HM and allocating cows at high PA which is linked to increased nutritive value in the swards.

Key Words: herbage mass, pasture allowance, sward structure

820 High reliance on grass for an improved milk fatty acids composition. A. I. Roca-Fernández*[1], A. González-Rodríguez[1], O. P. Vázquez-Yáñez[1], and J. A. Fernández-Casado[2], [1]*Agrarian Research Centre of Mabegondo*, *La Coruña, Galicia, Spain,* [2]*Agrarian and Fitopathologic Laboratory of Galicia*, *La Coruña, Galicia, Spain*.

Milk from grazing dairy cows had a higher content of polyunsaturated fatty acids (PUFA), especially more conjugated linoleic acid (CLA), and lower proportions of saturated fatty acids (SFA) than milk from silage-fed cows. Nevertheless, few researches are made trying to evaluate the influence of grazing time in milk fatty acids (FA) composition and its variation across the grazing season. The aim of this study was to investigate the effect on milk FA profile of different proportions of grazing in the ration of dairy cows and its variation across the season. Sixty-one autumn calving Holstein-Friesian dairy cows were balanced on calving date and milk yield and randomly assigned to one of 3 grazing treatments (G0: zero-grazing, G12: 12-h grazing and G24: 24-h grazing). Daily milk yields and weekly milk composition were registered from each cow. Sward characteristics and grass quality of each paddock was determined by NIRS System 5000 and milk FA composition was performed using gas chromatography. Daily herbage allowance was higher ($P < 0.05$) in G24 than in G12 (20.94 and 10.76 kg DM cow^{-1} day^{-1}, respectively). Grazing swards 24-h caused a decrease ($P < 0.05$) in short and medium chain fatty acids (SCFA, 8.34 and MCFA, 39.24 g 100 g^{-1} of FA in milk, respectively) and an increase ($P < 0.05$) in long chain fatty acids (LCFA, 42.29 g 100 g^{-1} of FA in milk). The highest ($P < 0.05$) content of monounsaturated and polyunsaturated fatty acids in milk (MUFA, 25.20 and PUFA, 4.24 g 100 g^{-1} of FA, respectively) were observed in G24. The CLA content showed an increase ($P < 0.05$) with grazing time, ranging from 0.72 to 1.23 g 100 g^{-1} of FA in milk for G12 and G24, respectively. The FA profile of milk showed some seasonality across the grazing season. In spring, the levels of CLA were 3 times higher in milk from cows grazing grass 24-h than in cows fed silage while at the end of the summer and in autumn these differences were reduced at half. High reliance on grass for sustainable dairy production systems might be a good tool to increase the added value of milk with an improved on milk FA composition.

Key Words: dairy cow, milk fatty acids composition, grazing time

821 Effect of stocking rate on sward characteristics and milk performance in sustainable dairy farms from humid areas. A. I. Roca-Fernández*, A. González-Rodríguez, and O. P. Vázquez-Yáñez, *Agrarian Research Centre of Mabegondo*, *La Coruña, Galicia, Spain*.

Stocking rate (SR) is one of the most important factors to control in sustainable dairy production systems from humid areas due to its influence on daily herbage allowance (DHA), herbage mass (HM), pasture dry matter intake (PDMI) and sward quality as well as its role on milk performance. The aim of this study was to investigate the effect of SR on PDMI, sward characteristics and milk yield of 44 spring (S, 15th February) and 28 autumn (A, 30th October) calving Holstein-Friesian cows grazing in rotationally grazed pastures of perennial ryegrass and white clover, stocked at medium (M, 3.9 cows ha^{-1}) and high SR (H, 5.2 cows ha^{-1}). Cows were balanced on calving date and milk yield and randomized in a block design with a 2x2 factorial arrangement of treatments (MS, MA, HS and HA). Milk yield and composition were determined. Pasture production, quality and sward utilization were measured during the grazing season. Cows grazed a total area of 19.2 ha, divided into 32 experimental paddocks. The medium SR completed 4 grazing rotations compared with 5 rotations for the high SR. The DHA and PDMI were lower ($P < 0.05$) in HA (14.9 and 10.3 kg DM d^{-1}, respectively) compared with MA (18.4 and 14.1 kg DM d^{-1}, respectively). The low herbage intake in HS was compensated with a higher ($P < 0.05$) sward quality (ADF, 291 g kg^{-1}; NDF, 518 g kg^{-1}; IVOMD, 781 g kg^{-1}) compared with MS (ADF, 310 g kg^{-1}; NDF, 529 g kg^{-1}; IVOMD, 756 g kg^{-1}). An improved on sward utilization was obtained in HS (83%) compared with MS (79%), enough to achieve a higher ($P < 0.05$) milk yield (HS, 25.3 vs. MS, 24.3 kg day^{-1}). The HA showed a detrimental effect on milk yield per cow (18.5 kg day^{-1}) but increased the amount of pasture harvested per hectare. There were differences ($P < 0.05$) for milk protein (HA, 32.0 and MA, 30.6 g kg^{-1}) and fat (HA, 39.9 and MA, 37.0 g kg^{-1}). This could be attributed to the higher pasture crude protein (HA, 153.8 and MA, 139.7 g kg^{-1}) to achieve a higher herbage quality. Increasing the SR is achieved higher sward utilization, grass quality, milk yield and milk quality in both, spring and autumn calving.

Key Words: dairy cow, stocking rate, sward characteristics

Growth and Development: Regulation of Adipogenesis and Adipose Tissue Development

822 Adipogenic differentiation state-specific gene expression as related to bovine carcass adiposity. C. L. Pickworth*[1], S. C. Loerch[1], F. L. Fluharty[1], D. H. Poole[2], S. G. Velleman[1], and J. L. Pate[2], [1]*The Ohio State University*, *Wooster,* [2]*The Pennsylvania State University*, *State College*.

The regulation of site and rate of fat deposition in cattle is not well defined. The study objective was to investigate adipogenic differentiation state-specific gene expression in feedlot cattle (>75% Angus; <25% Simmental parentage) of varying adipose accretion patterns. Four groups of 4 steers were selected from a group of 80 steers via ultrasound to have low backfat-low intramuscular fat (LBF-LIM), low backfat-high intramuscular fat (LBF-HIM), high backfat-low intramuscular fat (HBF-LIM), or high backfat-high intramuscular fat (HBF-HIM). Adipose tissue from the subcutaneous (SQ) and intramuscular (IM) depots were collected at harvest. The relative expression of adipogenic differentiation state-specific genes were evaluated using quantitative PCR. Data were analyzed using the mixed model of SAS and gene expression data were analyzed using covariate analysis with ribosomal protein L19 as the covariate. No interactions were observed ($P > 0.10$) between IM and SQ adipose accretion for any of the variables measured. Therefore, only the main effects of high and low accretion within a depot and the effects of depot are reported. No differences ($P > 0.10$) in mRNA between high and low adipose accretion within a depot were detected for any of the genes in spite of differences ($P < 0.001$) in cell density, diameter, and carcass measures. Preadipogenic delta like kinase 1 mRNA was higher ($P < 0.001$) in the IM than the SQ adipose tissue; conversely, differentiating and adipogenic genes (lipoprotein lipase, peroxisome proliferator activated receptorγ, fatty acid synthetase, and fatty acid binding protein 4) were higher ($P < 0.001$) in the SQ than the IM depot. Intramuscular adipocytes were smaller ($P < 0.001$) than SQ adipocytes and had greater ($P < 0.001$) expression of preadipogenic markers, indicating that more hyperplasia was occurring in the IM while the SQ was undergoing differentiation and hypertrophy. Adipogenic differentiation state-specific gene expression was not different in cattle with various phenotypes but adipogenesis in the SQ and IM adipose tissues appears to occur independently.

Key Words: gene expression, adipose, differentiation

823 Palmitoleic acid (C16:1) changes fatty acid profiles and alters gene expression in bovine adipocyte cultures. T. A. Burns*, S. K. Duckett, and S. L. Pratt, *Clemson University*, *Clemson, SC*.

Our objective was to determine if differences in fatty acid profiles or gene expression exist when adipocytes are exposed to increasing levels of C16:1. Three primary preadipocyte cell lines were isolated, propagated, and frozen for use in this study. Thawed cells were passaged 4 additional times and plated at a density of 1×10^5 cells/cm^2. Cells were allowed to reach confluence and held for 2 d. On D0, primary differentiation media [Dulbecco's modified eagles medium (DMEM) containing 10% fetal calf serum (FCS), and 2X antibiotic/antimycotic (AB/AM), insulin at 2.5 μg/mL, 0.25 μ*M* dexamethasone, 20 μ*M* troglitasone (TRO), 0.5 m*M* isobutylmethylxanthine, and 10 m*M* acetate] was applied for 2 d and replaced with secondary differentiation media [DMEM, 10% FCS, 2X AB/AM, insulin at 2.5 μg/mL, 5 μ*M* TRO, 10 m*M* acetate, containing 1 of 4 levels of C16:1(0, 50, 150, or 300 μ*M*)] from D2 to D12. Cells were harvested on D6 and D12 for fatty acid analysis using gas chromatography and gene expression by RT-qPCR. At 0 μ*M* C16:1, there was no effect of harvest day on levels of C16:1, C18:1c11, or total mg fatty acids. However, these fatty acids and total fatty acids increased ($P < 0.05$) linearly in response to increasing C16:1 supplement. Additionally, they were elevated ($P < 0.05$) in 50, 150, and 300 μ*M* C16:1-supplemented cells harvested on D12 compared with D6. In contrast, C16:0, C18:0, C18:1c9, decreased ($P < 0.05$) in response to increasing C16:1 in the media and were not affected by harvest day. The ratio of C18:1c9/C18:0 decreased ($P < 0.05$) in response to increasing C16:1 supplementation. Stearoyl-CoA desaturase (SCD) and fatty acid synthase mRNA expression was reduced ($P < 0.05$) on D6 in C16:1-supplemented groups for each cell line. Therefore, C16:1 may have a regulatory role in the transcription of SCD and fatty acid synthesis. In conclusion, supplementing cells with C16:1 produced changes in fatty acid composition of bovine adipocytes by D6 and influenced mRNA expression.

Key Words: adipocyte, palmitoleic acid, gene expression

824 Effect of fatty acids on adipocyte differentiation specific genes expression. P. Cheguru*, M. E. Doumit, G. Murdoch, and R. A. Hill, *University of Idaho*, *Moscow*.

Adipocyte differentiation has been extensively studied in vitro by using a standard hormonal cocktail induction treatment that includes dexamethasone, insulin and cAMP inducers like IBMX (isobutyl methyl xanthine). Pioneer work by Amri et al. (J. Lipid Res. 1991, 32; 1449–1456) provided evidence that fatty acids can also induce adipocyte-specific gene expression. We report here that long-chain fatty acids in the presence of insulin were able to induce lipid accumulation in mouse 3T3-L1 preadipocyte cell lines. 3T3-L1 cells were treated with either oleic acid (C18:1) or linoleic acid (C18:2) in the presence or absence of insulin. Confluent cells grown in complete growth medium were incubated with fatty acids in the presence or absence of insulin. Medium was changed every 2 d. Cells were stained with Oil Red O and RNA was collected on d 0, 2, 4, 6 and 8. Control cells were grown in complete growth medium only. Simultaneously, cells treated with hormonal cocktail containing dexamethasone, insulin and IBMX were observed at each time point. Oil Red O staining results showed that cells treated with fatty acids and insulin accumulated more lipid than cells treated with fatty acids alone or control cells. Cells treated with hormonal cocktail accumulated more lipid than other treatments. Adipocyte differentiation involves upregulation of PPARγ(peroxisome proliferator activated receptor γ), C/EBPα (CCAAT enhancer binding protein α), FABP4 (fatty acid binding protein 4) and SREBP-1c (sterol regulatory element binding protein-1c). Other genes like Pref-1 (preadipocyte factor-1) and GATA2 (GATA binding protein 2) will be downregulated. We hypothesize that long chain fatty acids can upregulate PPARγ, C/EBPα and FABP4 and downregulate Pref-1 gene expression. Lipid staining results confirm that cells treated with fatty acids and insulin had different metabolic changes than cells treated with fatty acids alone or control. We expect significant changes in adipocyte specific gene expression in cells treated with fatty acids and insulin at each time point.

Key Words: adipocyte differentiation, long-chain fatty acids, gene expression

825 Expression of genes associated with adipocyte differentiation differs with age and adipose tissue depot during growth. G. Go*, D.

T. Silvey, S. H. Choi, L. A. Gilmore, G. Ghahramany, and S. B. Smith, *Texas A&M University*, *College Station*.

We hypothesized that major subcutaneous (s.c.) adipose tissue depots would exhibit different developmental patterns of gene expression over time. Four Angus steers at each 9, 12, and 14 mo were harvested and s.c. adipose tissue samples were collected from over the chuck, rib, loin, sirloin, round, brisket, flank, and plate. AMPKα, CPT-Iβ, SCD, GPR43, PPARγ, and C/EBPβ were analyzed with qRT-PCR. Data were analyzed using the general linear model of SAS statistical analysis program. When significant, means were separated by Fishers protected least significant difference method. Over time, the major backfat depots, loin, rib, and sirloin s.c. adipose tissues, had the highest SCD (Δ9 desaturase) gene expression, whereas, anterior depots, brisket, plate, and flank s.c. adipose tissues, expressed less SCD RNA ($P < 0.001$). AMPKα gene expression was the greatest in round and the least in loin and rib s.c. adipose tissues. There were few significant differences in gene expression over time. However, across tissues, AMPKα and GPR43 (short chain fatty acid receptor) decreased over time, and CPT-Iβ, PPARγ, and SCD gene expression was greatest at 14 mo of age (all $P < 0.07$). We conclude that there were few differences across adipose depots in adipogenic expression, although age of steer had major effects on gene expression.

Key Words: adipogenic genes, subcutaneous adipose tissue

826 Hedgehog signaling mediates adipogenesis in C3H10T1/2 cells via down-regulation of COUP-TFII. W. F. Yue*, J. X. Zhao, M. J. Zhu, and M. Du, *Department of Animal Science, University of Wyoming*, *Laramie*.

Effective manipulation of depot specific adipose accumulation will dramatically enhance animal production efficiency. In human, adipogenesis plays a central role in the pathogenesis and pathophysiology of metabolic syndromes. Chicken Ovalbumin Upstream Promoter Transcription Factor II (COUP-TFII) is expressed during the early stages of adipocyte differentiation. Hedgehog signaling is known to inhibit adipogenesis. We hypothesized that hedgehog signaling inhibits adipogenesis through regulating COUP-TFII expression. C3H10T1/2 multipotent cells were used. Addition of cyclopamine (3.6 μ*M*), an inhibitor of the hedgehog signaling, promoted the mRNA expression of COUP-TFII, while addition of sonic hedgehog (20 n*M*) which stimulates hedgehog signaling decreased COUP-TFII expression by 38.1 ± 2.61% ($P < 0.05$). The mRNA expression of COUP-TFII was correlated with the expression of peroxisome proliferator-activated receptor (PPAR) γ, with cyclopamine treatment increasing PPARγ protein content by 73.4 ± 14.56% ($P < 0.05$). In addition, both CCAAT/enhancer binding protein (C/EBP) α and β, 2 transcription factors known to induce adipogenesis, were induced by 109.6 ± 18.20% and 137.0 ± 44.05% ($P < 0.05$) respectively when hedgehog signaling was inhibited by cyclopamine. In conclusion, hedgehog signaling decreases COUP-TFII expression and adipogenesis in C3H10T1/2 cells. COUP-TFII expression may stimulate early adipogenesis. Because hedgehog signaling is central to the morphogenesis and pattern formation during early animal development, hedgehog may regulate depot specific adipogenesis through COUP-TFII associated signaling pathways.

Key Words: COUP-TFII, adipogenesis, hedgehog

827 Characterization of fat mass and obesity associated gene (FTO) expression in the broiler chicken. A. Tiwari*, S. M. Krzysik-Walker, G. L. Hendricks III, and R. Ramachandran, *The Pennsylvania State University*, *University Park*.

Fat mass and obesity associated gene (FTO), also known as *Fatso* is a member of the Fe-II and 2-oxogluterate-dependent dioxygenase superfamily. The FTO gene product is highly conserved across vertebrate species and is ubiquitously expressed in multiple tissues. Studies in humans and rodents suggest that FTO is involved in regulation of food intake and lipolytic activity in adipose tissue. Mutations in a FTO intron have been associated with obesity and related metabolic disorders in humans. While the physiological role of FTO is beginning to be understood in mammals, the chicken homolog of FTO has not been described. Objectives of the present study were to clone full length chicken FTO cDNA and to quantify FTO expression in primary metabolic tissues, adipose, liver and skeletal muscle to determine if age or feeding status affect FTO expression in male broilers. Using rapid amplification of cDNA ends (RACE), we cloned the full length chicken FTO cDNA. Chicken FTO cDNA and its deduced protein sequences were found to be 68% and 69% homologous to that of human FTO, respectively. Using Western blotting, we detected FTO protein in hypothalamus, adipose tissue, liver, skeletal muscle, spleen, kidney, heart and testes of broiler chickens. Quantification of FTO protein by Western blotting revealed significantly greater expression in liver (ANOVA, $P < 0.05$; n = 5/treatment) of 8 week old broilers fasted for 48 h compared with *ad libitum* fed chickens maintained on standard commercial broiler feed. No significant difference in FTO protein expression, however, was found in 4-week-old versus 8-week-old broiler tissues (ANOVA, $P > 0.05$; n = 5/age group). We conclude that FTO is expressed in multiple chicken tissues and that FTO expression is influenced by feeding status in the broiler chicken. We are currently investigating the physiological role of FTO in broiler chicken metabolism.

Key Words: metabolism, liver, energy balance

828 Effect of nutrition and chronic infusion of leptin on intake and body composition of *Bos indicus* heifers at puberty. M. V. Carvalho, J. D. Magalhães, L. U. Gimenes, G. P. Rodrigues, and L. F. P. Silva*, *Universidade de São Paulo*, *Pirassununga, SP, Brazil*.

The amount of fat in the carcass has been proposed as a regulator of initiation of puberty in cattle. To test if changes in energy intake and in leptin concentration is capable of altering body composition at puberty, 36 prepubertal Nelore heifers, 18 to 20 mo-old, 275.8 ± 17.2kg BW and BCS of 5 ± 0.5 (1 to 9 scale) were randomly assigned to each of 3 treatments (n = 12): H (high energy diet), L (low energy diet), and LL (low energy diet + oLeptin). Diets were formulated to promote weight gain of 0.4kg/day (groups L and LL) or 1.2kg/day (H group). After 21 d of adjustment, heifers in LL group received subcutaneous injections of oLeptin at 4.8μg/kg BW twice a day, for 56 d. Groups H and L received similar injections of 2mL saline solution. Age at puberty was considered to be the age on first detection of a corpus luteum, confirmed by plasma concentrations of progesterone of >1ng/ml. Heifers were slaughtered during the luteal phase after the first estrus cycle. Individual intake was estimated using the markers chromic oxide and indigestible NDF for estimate total fecal excretion and digestibility, respectively. Leptin administration had no effect ($P > 0.05$) on dry matter intake, body weight gain, body composition and efficiency of energy use. High energy intake accelerated puberty and modified body composition at puberty. Heifers from the H group had heavier carcass weight (222 vs. 181.5 kg, $P < 0.01$), higher BCS (6 vs. 4.5, $P < 0.01$), larger longissimus muscle area (59 vs. 53 cm^2, $P < 0.01$), and greater subcutaneous fat thickness (5.4 vs. 3.4 mm, $P < 0.01$), than heifers from the L and LL groups together. Carcasses from the H group also had higher ether extract content (24.2 vs. 21.3, $P < 0.01$) than carcasses from the L and LL groups together. Animals receiving a high energy diet also had better efficiency of energy

use (0.25 vs. 0.16, $P < 0.01$). High energy intake during the prepubertal phase increased BW and carcass fat content at puberty, and improved the efficiency of dietary energy usage. These results do not support the hypothesis that puberty occurs at a constant percentage of body fat.

Key Words: carcass fat, cattle, maturity

829 Assessing heat load and dissipation using digital infrared thermography and serum cortisol profiles in horses during the summer months. Y. Dupre[1], A. Strohm[2], E. Keis[2], J. Harney[2], K. Moulton*[2], and P. L. Ryan[2], [1]*Tuskegee University*,[2]*Mississippi State University*.

During the summer months in southeastern United States environmental factors including high ambient temperature, high relative humidity and radiant energy contribute to heat stress in cattle, but little is known about this condition in horses. The objectives of this study were to evaluate heat load and dissipation in horses during the summer, determine whether coat color is a factor, and assess physiological responses by monitoring systemic cortisol. Fifteen mares (3–18 years) were assigned to one of 5 coat color categories (n = 3/group; bays, browns, gray, paint, palomino) and maintained on pastures with the same shade cover. Heat load was assessed using digital infrared thermal imaging (FLIR T400 camera) and rectal temperatures were recorded 4x/d (0600, 1200, 1600, 2000 h), 2 d/week for 6 weeks (June–July, 2009) along with ambient temperature, wind speed and humidity. Five regions of interest (ROI; flank, shoulder, eye, muzzle, perineum) were imaged at each time point. Minimum (MIN), maximum (MAX), average (AVE) and standard deviation (STDEV) thermal signatures were assessed for each ROI. Blood was collected at 0600, 1600 and 2000 h for serum cortisol. Data was analyzed using GLM procedures of SAS. LS means were calculated and separated using Fisher's LSD ($P < 0.05$). Bay and brown horses had the highest thermal signatures (AVE/MAX) at 1200 and 1600 h in all ROIs except the perineum and eye compared with all other groups ($P < 0.05$). Shoulder and flank regions had the highest AVE/MAX (~40°C) compared with other ROIs. For combined ROIs, bay/brown mares had the highest MAX value ($P < 0.01$). Grey mares had the greatest perineum MAX value (37.15–37.7°C) throughout the day ($P < 0.05$) compared with other groups (34.32–37.56°C) as well as the highest rectal temperature ($P < 0.05$). Serum cortisol was lower in paint horses ($P < 0.05$) compared with other coat colors at each time point, and declined from a high at 0600 to a low at 2000 h ($P < 0.05$) in all coat groups. In conclusion, coat color affects heat load and dissipation in horses, which is influenced by the darker color consistent with heat absorption. Lower serum cortisol was consistent with low thermal signatures in paint horses (pale skin pigment).

Key Words: heat stress, thermography, equine

830 Effects of selenium supplementation and prolonged exercise on antioxidant gene expression in equine skeletal muscle. S. White*, L. K. Warren, S. E. Johnson, and J. Bobel, *University of Florida*, *Gainesville*.

Twelve untrained Thoroughbred horses (mean ± SE; 11 ± 1 y; 565 ± 11 kg) were used to evaluate antioxidant gene expression in skeletal muscle in response to prolonged exercise after receiving 2 levels of dietary selenium (Se). Horses were randomly assigned to diets containing either 0.1 mg Se/kg DM (n = 6; CON) or 0.3 mg Se/kg DM (n = 6; SE) for 36 d. Horses were individually fed 1.6% BW/d of coastal bermudagrass hay (0.02 mg Se/kg DM), 0.4% BW/d of whole oats (0.24 mg Se/kg DM) and a mineral/vitamin premix containing no Se. Sodium selenite was added to achieve either 0.1 or 0.3 mg Se/kg DM in the total diet. On d 35, horses underwent 2 h submaximal exercise in a free-stall exerciser (total distance 26 km; heart rate 135 ± 39 bpm). Biopsies of the middle gluteal muscle were obtained before Se supplementation was initiated, before exercise, and at 6 and 24 h post-exercise. Gene expression in skeletal muscle was determined by quantitative RT-PCR using 18S as a reference gene. Differences in mRNA expression due to treatment and exercise were analyzed using the GLIMMIX procedure of SAS (v. 9.2). Muscle expression of *MT1B* ($P = 0.001$) and *MT3* ($P = 0.001$) both increased over 6-fold from pre- to 24 h post-exercise, indicating exercise was sufficient to elicit oxidative stress. Muscle expression of *TrxR1* was unchanged at 6 h but increased ($P = 0.02$) 2.5-fold at 24 h post-exercise, whereas *GPx1* and *GPx3* did not change through 24 h post-exercise. Expression of *SOD1* and *SOD2* were unchanged through 6 h post-exercise, but expression of both genes increased ($P = 0.001$ *SOD1*; $P = 0.0003$ *SOD2*) in CON horses and *SOD2* decreased ($P = 0.04$) in SE horses from 6 to 24 h post-exercise. Level of dietary Se had no overall effect on expression of *MT1B*, *MT3*, *TrxR1*, *GPx1*, *GPx3*, *SOD1*, or *SOD2* in muscle following exercise. Prolonged exercise in untrained horses appears to upregulate mRNA expression of some antioxidant enzymes in skeletal muscle. Short-term Se supplementation above the current NRC requirement did not alter selenoprotein expression in skeletal muscle, but may influence expression of other antioxidant enzymes following exercise.

Key Words: horse, selenoprotein, skeletal muscle oxidative damage

831 Fatty acid composition of synovial fluid in horses fed long chain polyunsaturated fatty acids: A pilot study. T. N. Ross*, T. M. Hess, J. D. Kisiday, C. W. McIlwraith, T. Engle, D. K. Hansen, J. Rexford, N. Schauermann, and C. Mulligan, *Colorado State University*, *Fort Collins*.

Studies utilizing oral α linolenic acid (ALA) and its metabolic derivatives, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), indicate a potential regulatory role in reducing joint inflammation by mediating cytokine production in arthritic human patients and plasma prostaglandin levels in arthritic horses. The primary study objective was to determine if dietary long chain fatty acids are incorporated into the synovial fluid of mature horses fed one of 3 dietary treatments. Twenty-one mature mixed breed mares, between 5 and 14 yr of age, with no history of joint disease and free of lameness were blocked by age, weight and body condition score and randomly assigned into one of 3 dietary treatment groups. Group 1 (FISH) received 69 mg/kg BW of n-3 EPA/DHA via a commercial fish oil supplement (Magnitude; JBS United, Sheridan, IN) daily; Group 2 (FLAX) received 68.6 mg/kg BW of n-3 ALA via a flaxseed supplement (Nutra-Flax) daily and Group 3 (CONT) did not receive n-3 supplementation. Total ration composition of n-3 fatty acids were approximately 143.5 mg/kg BW (FISH), 142.5 mg/kg BW (FLAX) and 78.7 mg/kg BW (CONT), respectively. On d 90, approximately 3 mL of synovial fluid was extracted from the right carpus of each horse and immediately placed into a 7 mL EDTA tube. Aliquots were assayed for fatty acid composition using gas chromatography. Data were analyzed using ANOVA, with significant differences ($P < 0.05$) further analyzed using Fisher's LSD test. Synovial fluid samples from the FISH group presented EPA and DHA in their synovial fluid, whereas the FLAX and CONT groups did not express detectable concentrations. The absence of EPA and DHA in the FLAX-fed group indicates inefficient conversion of these fatty acid metabolites from ALA. This is the first documented study evaluating synovial fluid fatty acid composition in horses receiving a dietary n-3 fatty acid supplement. Results indicate oral supplementation of EPA and DHA alters synovial fluid fatty acid composition. The presence of DHA and EPA in synovial fluid may potentially modify inflammatory processes in the joint.

Key Words: polyunsaturated fatty acids, horse, synovial fluid

832 Cushing's syndrome down-regulates glucose transporter mRNA abundance in the distal jejunum in the horse. A. Buckley, N. Taylor, R. Manjarin*, H. C. Schott, A. D. Woodward, and N. L. Trottier, *Michigan State University*, *East Lansing*.

Cushing's syndrome is commonly associated with the development of laminitis in the horse. High levels of glucocorticoids are known to induce insulin resistance and reduce cellular glucose uptake, however, the mechanisms are not known. Decreased capability for pre-cecal glucose absorption may increase carbohydrates flow to the large intestine in Cushing afflicted-horses, altering the hindgut microflora and increasing susceptibility to laminitis. The objective of this study was to test the hypothesis that horses affected by Cushing's Syndrome have lower mRNA abundance of genes encoding for glucose transporters and insulin receptor in the jejunum enterocytes, compared with healthy animals. Tissue from the distal jejunum was obtained from 8 adult horses (4 affected with Cushing's Syndrome and 4 healthy controls) shortly following euthanasia. The mucosa was gently separated from the sero-muscular layer, flash-frozen in liquid N, and stored at −80°C for RNA isolation. Gene expression of glucose transporters GLUT1 (SLC2A1), GLUT2 (SLC2A2), GLUT4 (SLC2A4), GLUT5 (SLC2A5), SGLT (SLC5A1) and insulin receptor (INSR) was assessed by measuring mRNA abundance using relative quantitative PCR. Succinate dehydrogenase complex subunit A (SDHA) and hypoxanthine phosphoribosyltransferase (HPRT) were used as reference genes in the study. Mixed model was used for data analysis. Compared with healthy control horses, mRNA abundance of insulin receptor and insulin-dependent glucose transporter GLUT4 decreased ($P < 0.01$) in distal jejunum of Cushing's horses. For GLUT1, GLUT2, GLUT5 and SGLT1, mRNA abundance did not differ between Cushing and control horses. Results indicate that Cushing's syndrome downregulates the gene expressions of insulin-dependent glucose transporter GLUT4 and insulin receptor in the distal jejunum of the horse. These results may offer a physiological mechanism for increased susceptibility to nutritionally induced laminitis in Cushing-afflicted horses.

Key Words: Cushing, horse, insulin

833 Proteomic analysis of synovial fluid and plasma from horses fed a high or low starch diet. E. A. Nowelsky*[1], J. K. Morrissey[1], D. S. Gibson[2], P. A. Harris[3], and W. B. Staniar[1], [1]*The Pennsylvania State University*, *University Park,* [2]*University of Colorado Denver*, *Aurora,* [3]*Equine Studies Group, Waltham Centre for Pet Nutrition*, *Melton Mowbray, UK*.

A tentative link has been suggested between osteochondrosis (OC) and feeding high starch diets in growing horses. The pathology of OC is multifactorial and it is therefore appropriate to explore using a technique that allows for characterization and quantification of the plasma (PL) and synovial fluid (SF) proteomes. The objective of this study was to determine if the concentration of dietary starch influences the proteomes of SF and PL and to isolate, identify and characterize proteins that are differentially present in relation to diet or sample type. Six yearlings, maintained on dry lot with ad libitum access to <5% starch hay, were used in this crossover study design conducted over 12 weeks with four 21-d periods. During periods 2 and 4, yearlings were split into 2 treatment groups, with one group receiving high starch feed (~40% starch on a DM basis)(HSF) and the other group receiving low starch feed (<10% starch on a DM basis)(LSF). All yearlings received LSF in periods 1 and 3. SF and PL samples were taken every 21 d and analyzed using 2D gel electrophoresis. Progenesis SameSpots software was used to analyze spot intensities using ANOVA and differences were considered significant at $P < 0.05$. Select spots were chosen for mass spectrometry. Changes in protein expression ranged from a 1.2 fold–2.5 fold change. Seven proteins were higher as a result of dietary treatment. Four of the 7 proteins, identified as isoforms of immunoglobulin gamma, were higher in SF from animals fed HSF. Two proteins, identified as isoforms of albumin, were higher in HSF samples. Fibrinogen, haptoglobin and clusterin were higher in PL. Alpha 1 antitrypsin was higher in SF. The grouping of isoforms and proteins with similar characteristics on the gel was useful in achieving the goals of this study. Proteins identified in this study initially do not have a clear mechanistic link with OC. This study demonstrates a novel approach to investigate protein expression changes in PL and SF that may affect joint health. The fluid specific proteomic profiles and individual proteins identified may be useful in future examination of equine biological fluids.

Key Words: equine, nutrition, proteomics

834 Effects of a 24-h feed withdrawal on SGLT1, GLUT5, and PepT1 gene expression in the small intestine and right ventral colon of the horse. B. E. Aldridge*, T. B. Lescun, and J. S. Radcliffe, *Purdue University*, *West Lafayette, IN*.

Fourteen horses were used to determine the effects of a 24 h feed withdrawal (FW) on gene expression in the small intestine and right ventral colon (RVC). Prior to FW, horses were fed hay ad libitum for 8 weeks. Following this adaptation period, horses were randomly allotted to either 24 or 0 h FW (7 horses/trt) with water provided ad libitum. Following 0 or 24 h of FW, horses were killed and segments of proximal jejunum (13.7 m proximal to the ileo-cecal junction), distal jejunum (9.1 m proximal to the ileo-cecal junction), ileum (5 cm proximal to the ileo-cecal junction) and right ventral colon (30 cm distal to the cecocolic junction) were removed for gene expression analysis of the sodium dependent glucose transporter (SGLT1), fructose transporter (GLUT5) and di- and tri-peptide transporter (PepT1) by using quantitative RT-PCR normalized to GAPDH. The GLM procedure in SAS was used to determine statistical differences between the intestinal sections of fed and non-fed horses, where horse served as the experimental unit. Horses maintained on a hay diet, had 82% more GLUT5 expression ($P < 0.05$) in the proximal jejunum (PJ), than horses subjected to a 24 h FW. However, in horses subjected to a 24 h FW, distal jejunal (DJ) SGLT1 expression increased ($P < 0.1$) 205% and PepT1 expression increased 288%, although this only approached a trend ($P = 0.13$). SGLT1, GLUT5 and PepT1 expression were not affected ($P > 0.1$) by FW in the ileum and right ventral colon. To compare gene expression across sections, the relative abundance was normalized to the distal jejunum. The PJ contained 13, 3.8 and 1.4- fold greater expression of SGLT1 ($P < 0.05$), GLUT5 ($P < 0.05$) and PepT1 ($P < 0.05$) compared with the DJ. Expression of SGLT1, GLUT5 and PepT1 were 34, 19 and 15% lower in the ileum than in the DJ, and 91, 63 and 84% lower in the RVC compared with the DJ. This data indicates that SGLT1, GLUT5 and PepT1 are expressed throughout the small intestine and in the RVC of the horse at varying concentrations, and that they are differentially regulated by a 24-h feed withdrawal.

Key Words: horse, gene expression, intestine

835 Effects of omega-3 fatty acid supplementation on plasma, red blood cell and muscle cell fatty acid compositions in horses. J. K. Rexford*, T. M. Hess, N. L. Schauermann, T. E. Engle, D. K. Hansen, K. D. Allen, and C. M. Mulligan, *Colorado State University*, *Fort Collins*.

The objective of this study was to examine the effects of dietary omega-3 fatty acid supplementation on plasma, red blood cell and muscle omega-3

fatty acid compositions in horses. Twenty-one mares were blocked by age, body weight and body condition score and randomly assigned to one of 3 dietary treatments. Treatments consisted of: 1) 142.5 mg/kg BW of n-3 fatty acids via a fish oil supplement and diet (FISH; Magnitude; JBS United, Sheridan, IN); 2) 142.5 mg/kg BW of n-3 fatty acids via a flaxseed meal from the supplement and diet (FLAX; Nutra-Flax^{TM}); and 3) control (CON) no supplemental fatty acid with 78.7 mg/kg BW of omega-3 fatty acids from the diet (mostly hay for all groups). Treatments were supplemented for 90 d. Blood samples and muscle middle gluteal biopsies were taken on d 0, 30, 60, and 90 of supplementation. Plasma and cell fatty acid profiles were analyzed via gas chromatography. Plasma linoleic acid (LA) and α linolenic acid (ALA) were 10 and 40% lower ($P < 0.008$) respectively in the FISH compared with FLAX and CON supplemented horses. Plasma eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) were only detected in the FISH supplemented horses and increased 29% ($P < 0.001$) and 17% ($P < 0.005$) from d 30 to d 60. Red blood cell LA and ALA were not different between treatments. Red blood cell EPA and DHA were only detected in the FISH supplemented horses, where EPA increased 4% ($P < 0.005$) from d 30 to d 60. Red blood cell DHA increased 36% ($P < 0.004$) between d 30 and d 90. Muscle LA was 15% lower in the FISH supplemented horses compared with the other treatments. Muscle ALA was 42% lower ($P < 0.030$) in the FISH supplemented horses, compared with FLAX and CON groups. Muscle EPA was 32% higher ($P < 0.001$) in FISH supplemented horses compared with other treatments and increased by 40% from d 30 to d 60. Muscle DHA was 43% higher ($P < 0.001$) in the FISH supplemented horses compared with other treatments and increased by 38% between d 30 and 90. This is the first study to demonstrate that dietary fatty acid supplementation will affect muscle fatty acid composition in horses.

Key Words: equine, eicosapentaenoic acid, docosahexaenoic acid

836 Effects of an experimental feed additive on neutrophil-mediated killing of *Streptococcus equi* and on markers of innate immune function in horses. A. Rowson*[1], D. Sherwood[2], Y. Wang[1], S. Puntenney[1], and N. E. Forsberg[1], [1]*OmniGen Research LLC*, *Corvallis, OR,* [2]*Oregon State University*, *Corvallis*.

Effects of an experimental feed additive (OmniGen-EQ) on immune markers in horses was tested. Eighteen horses were assigned to 2 treatment groups which consisted of a control group and a treated group (9 animals/treatment). The control group consisted of 3 mares and 6 geldings which ranged in age from 2 to 17 years. The treatment group consisted of 3 mares and 6 geldings which ranged in age from 1 to 16 years. Animals on the control diet were allowed free-choice access to hay plus 1.8 kg/head/day of a supplement which contained approximately 18% crude protein, 2% crude fat and 6% crude fiber on an as-fed basis. Animals on the treated group received the same diet except for supplementation with the experimental product such that each horse received an intake of 108 g per day. Animals were individually fed supplement and maintained on treatment for 28 d. Blood samples were taken on d 0, 14 and 28 and neutrophils were isolated using Percoll gradient centrifugation. Ability of freshly isolated neutrophils to kill (phagocytose) an equine pathogen (*Streptococcus equi*) were assessed on d 28 using a pathogen killing assay. Killing assays were performed at ratios of 1 neutrophil:30 *S. equi* (1:30) and 1:60. Neutrophil RNA was isolated using Trizol and concentrations of L-selectin, interleukin-8 receptor (IL-8R) and RPL-19 mRNAs were assessed using quantitative (SYBR-green) reverse transcriptase PCR. RPL-19 mRNA was used as the background gene. Data were analyzed by ANOVA with effects consisting of Treatment, Day and Error. One horse on the control treatment died on d 25 due to colic. The additive improved neutrophil killing efficiency ($P < 0.05$) by 16 and 22% at dilutions of 1:30 and 1:60, respectively. Feeding OmniGen-EQ had no effect on neutrophil L-selectin and IL-8R mRNAs on d 14; however, concentrations of both mRNA species were increased several-fold ($P < 0.05$) after 28 d of feeding. These data demonstrate that feeding the experimental additive to horses improves markers of innate immune function.

Key Words: immunity, horse, neutrophil

837 Effects of OmniGen-AF on development of humoral immune responses in beef cattle and in rats following a vaccination program. S. B. Puntenney*, Y. Wang, A. Rowson, and N. E. Forsberg, *OmniGen Research LLC*, *Corvallis, OR*.

Two experiments were completed in which effects of OmniGen-AF on development of titer were examined. In the first study, male rats (8/trt) were assigned to a control diet (Teklad 8604) or to a diet containing OmniGen-AF (0.5% w/w) for 54 d after which all animals were given the control diet through d 87. Animals were vaccinated twice with an *E. coli* vaccine on d 10 and 24 of the study and blood was sampled from rats on d 0, 24, 37, 54, 73 and 87. *E. coli* titer within the IgG1 fraction was determined by ELISA. In the second study, Angus calves (ca. 250 kg) were assigned to one of 2 treatments (20 animals/trt): a control ration and to the same ration but supplemented with OmniGen-AF (56 g/hd/d) beginning at d 0. Animals were maintained on rations for 60 d and vaccinated with the Novartis Virashield vaccine on d 14 and again 1 mo later. A subset of animals (10/trt) was also vaccinated with the Epitopix SRP (*Salmonella*) vaccine following initial feeding with OmniGen-AF. Serum neutralization assays against the BVDV-1, BVDV-2 and IBR were completed by the Oregon State University College of Veterinary Medicine Diagnostic Laboratory. Titer directed against the SRP vaccine was assessed by Epitopix. IgG1 *E. coli* titer in rats was significantly ($P < 0.05$) elevated on d 24, 37 and 54 of the study. No differences between treatments ($P > 0.05$) were noted following withdrawal of the additive on d 54 of the study. OmniGen-AF increased development of BVDV-1 and *Salmonella* titer by almost 2-fold; however, these effects were not significant ($P = 0.112$ and 0.118, resp). BVDV-2 titer was not detectable in either treatment group. OmniGen-AF increased IBR titer significantly ($P < 0.05$). In previous studies, we reported that OmniGen-AF increased ($P < 0.05$) development of *E. coli* titer in calves vaccinated with the Pfizer J5 *E. coli* vaccine. These studies extend those observations and indicate that pre-feeding OmniGen-AF may increase humoral immune responses to vaccines. Further work is needed to determine conditions under which one might reliably derive benefit to humoral immunity.

Key Words: immunity, OmniGen-AF, vaccination

838 Passive immunity to a commercial *E. coli*-SRP vaccine in beef cattle colostrum from cows grazing native range. B. W. Wileman*[1], D. U. Thomson[1], K. C. Olson[2], and L. A. Pacheco[2], [1]*College of Veterinary Medicine, Kansas State University*, *Manhattan,* [2]*College of Animal Sciences and Industry, Kansas State University*, *Manhattan*.

E. coli O157:H7 is a contaminant of beef and associated with food-borne illnesses in humans. Initial colonization of the calf with the organism is believed to occur shortly after birth. Recently an *E. coli* SRP vaccine received conditional licensure in the United States for the control of *E. coli* O157 in cattle. The objective of this study was to determine if *E. coli* O157:H7SRP specific antibodies from vaccinated cows can be passively transferred to beef calves in native range conditions. Cows (n = 20) were randomly assigned to treatments: SRP vaccine or placebo control. Vaccines were administered 60 and 30 d before projected calving date. Samples were collected at the time of calving from cows (fecal, blood and colostrum) and calves (pre-suckle blood sample). Blood samples were obtained from calves at 6, 12, and 24 h and at 7, 14 and 21 d postpartum. Serum total protein (STP) and *E. coli* O157:H7 SRP antibody levels were measured. Dam vaccine history had no effect on the calf STP level ($P > 0.05$). However, length of time postpartum had a significant effect on the calf STP levels ($P < 0.001$). A vaccine treatment by time postpartum interaction was observed for the calf serum *E. coli* O157:H7 SRP antibody levels ($P < 0.01$). This interaction was explained by no vaccine treatment difference in calf serum *E. coli* O157:H7 SRP antibody levels pre-suckle, but a significant increase in calf *E. coli* O157:H7 SRP post-suckle titers in the calves born to SRP vaccinated cows compared with calves born to placebo cows. The results from this study show successful *E. coli* O157:H7 SRP antibody passive transfer in beef calves under natural conditions and indicates that early immunization against *E. coli* O157:H7 could play a role in preventing animals from shedding the organism at harvest. Further research is needed to study possible cross protection of this vaccine in other cattle diseases.

Key Words: immunity, colostrum, vaccine

839 Effect of colostrum supplementation on health and performance of pre-weaned and post-weaned dairy calves. B. Ozer*[1], M. Chahine[1], C. M. Matuk[1], M. E. de Haro Martí[2], and M. Nelson[1], [1]*University of Idaho*, *Twin Falls*, [2]*University of Idaho*, *Gooding*.

The objective of this study was to determine the effect of a commercially available colostrum supplement on health parameters in Holstein dairy heifers. Fifty 7 Holstein female calves raised on a commercial facility in southern Idaho were randomly assigned to one of 2 treatments which consisted of maternal colostrum (MC, n = 27) or maternal colostrum supplemented with bovine-serum based colostrum supplement (MCS, n = 30). All colostrum treatments (3.8 L) were administered using an esophageal tube within 1 h of birth. A second feeding of colostrum (2 L) was administered 8 h following first feeding. Blood samples were collected at 24 ± 3 h of age and tested for total serum protein (TSP). Pre-weaned period rectal body temperature was measured every other day. Health evaluations were conducted daily by study personnel until calves were 3 mo of age. Pre-weaned fecal (FC), dehydration (DH) and respiratory (RS) scores were recorded. TSP concentrations were significantly greater ($P < 0.01$) in calves fed MC (TSP = 6.17 ± 0.09 g/dL) compared with calves fed MCS (TSP = 5.84 ± 0.09 g/dL). Rectal body temperature did not differ between MC and MCS and averaged 39.0°C ± 0.03. No differences were detected in pneumonia, diarrhea, or mycoplasma incidence which averaged 61.7%, 10.5%, and 38.3% respectively. MCS calves had a greater ($P < 0.006$) incidence of abnormal RS score (58.5%) compared with MC (27.3%). FC and DH scores did not differ between treatments and averaged 27.6% and 12.7% respectively. Thus in this study, adding a supplement to maternal colostrum did not achieve any positive effect on performance and health parameters of dairy calves.

Key Words: colostrum, colostrum supplement, total serum protein

840 Evaluation of immunological status of newborn dairy calves when respective dams were fed a stepwise moderate energy diet or a controlled energy diet during the dry period. J. S. Osorio*[1], P. Ji[1], G. Invernizzi1,2, J. K. Drackley[1], and J. J. Loor[1], [1]*University of Illinois*, *Urbana,* [2]*University of Milan*, *Milan, Italy*.

Decreases in dry matter intake and increases in concentrations of non-esterified fatty acids and cortisol during the periparturient period have been associated with an impaired immunological status in dairy cows. Controlling energy intake during the dry period has been proposed to diminish these conditions during early lactation. The extent of these effects on the immunological status of newborn calves is unknown. Holstein cows (n = 12) were randomly assigned to a stepwise moderate energy (ME) diet (1.49 Mcal/kg) or a controlled energy (CE) diet (1.30 Mcal/kg) during the close-up period (−21 to 0 d relative to calving). All cows were fed CE during the far-off period (−50 to −21 d relative to calving). At birth, calves were separated from dams and during the first 24 h received at least 3.8 L of dam's colostrum with minimum 60 mg/dL of solids density. Blood samples were taken at birth (Pre-colostral) and 48 h (Post-colostral) using vacutainer tubes with ACD, EDTA, or serum. RNA was extracted from isolated blood peripheral neutrophils, and whole blood phagocytosis was assessed through flow cytometry (BD Biosciences LSR II). Body weight, withers height, and hip height were recorded at birth. Data were analyzed using the MIXED procedure of SAS (v. 9.2). Results indicated that dams that were fed a CE diet during the complete dry period gave birth to heavier ($P = 0.01$) calves than ME cows. Preliminary analysis of whole blood phagocytosis showed no difference in percentage of phagocytozing cells from either pre ($P = 0.88$) or post ($P = 0.72$) colostral blood samples from calves born from dams on either diet. However, the phagocytosing population of cells behaved differently between CE and ME treatments when observed from pre- to post-colostral blood samples. All phagocytosing cells were clumped in pre-colostral samples regardless of dam's diet, but only cells from calves born to dams fed CE divided into 2 populations from the post-colostral blood samples. Further analyses are being conducted to fully discern the biological meaning and significance of these results.

Key Words: calves, phagocytosis, immunology

841 Characterization of immune and metabolic responses in the blood of dry cows induced with sub-acute ruminal acidosis (SARA). A. D. Kroeker*[1], S. Li[1], S. Shekhar[1], A. Ceballos[2], E. Khafipour[1], D. O. Krause[1], J. C. Plaizier[1], and J. C. Rodriguez-Lecompte[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*Cornell University*, *Geneseo, NY*.

Subacute ruminal acidosis (SARA) increases lipopolysaccaharide endotoxin (LPS) in the rumen, due to lysis of gram-negative bacteria. This LPS can translocate into the blood during SARA, which causes inflammation. The objective of this study was to determine the systemic immune and metabolic responses in the blood of cows with 2 forms of SARA. Six dry, non-pregnant, dairy cows were used in a Latin Square with 3 periods of 4 wk. During wk 1–3 of all periods cows received the control diet containing 70% forage and 30% mixed concentrates (DM basis). During wk 4, cows either received the control diet(T1) control diet), treatment 2 (T2, alfalfa pellet-induced SARA (API_SARA), 45% mixed concentrate, 32% alfalfa pellets, and 23% other forages), or treatment 3 (T3) (GPI_SARA, 38% wheat-barley pellets, 32% other mixed concentrate, and 30% forages). Blood cell, serum chemistry, acute-phase proteins (fibrinogen, serum amyloid A (SAA), haptoglobin (Hp, and LPS binding protein (LBP), and peripheral blood leukocyte cell surface marker (CD14) parameters were evaluated. The durations of the rumen pH below 5.6 were 56.4, 225.2 and 298.7 min/d for control, API_SARA, and GPI_SARA, respectively. This shows that both forms of SARA resulted in similar depressions of rumen pH, and that SARA was induced. Treatments did not affect leukocyte and differential count, red blood cells, hemoglobin, mean corpuscular volume (PCV), mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, and clinical chemistry parameters. However, PCV decreased in T2 and T3 cows. Also, urea was lower in T2 cows 9 d after the beginning of treatment. There were increases in SAA and LBP in T3. There were no changes in the total protein to fibrinogen ratio, suggesting no inflammatory activity; however, the albumin to globulin ratio increased in T3 cows during the second period of the study. No differences were found the proportion of peripheral blood neutrophils and monocytes expressing CD14. In conclusion, our results suggest that immunological and metabolic parameters were not affected by SARA

Key Words: SARA, LPS, CD14

842 Comparison of long-term progestin-based protocols to synchronize estrus in postpartum beef cows. J. M. Nash*, D. A. Mallory, C. C. Selby, K. G. Pohler, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri*, *Columbia*.

The objective of the experiment was to compare follicular dynamics, ovulatory response to GnRH, steroid hormone concentration patterns, and synchrony of estrus and ovulation among estrous-cycling and anestrous postpartum beef cows following treatment with long-term progestin-based protocols. Beef cows (n = 40) were assigned to treatments based on age, days postpartum, BCS and estrous cyclicity status. Blood samples were taken 10 and 1 d before treatment to determine estrous cyclicity status (progesterone ≥0.5 ng/mL estrous cycling). CIDR Select (T1, n = 20) treated cows received a controlled internal drug-release insert (CIDR;1.38 g progesterone) from d 0 to 14 followed by GnRH (100 μg, i.m.) on d 23, and PG (25 mg, i.m.) on d 30. Cows assigned to the 14-d CIDR-PG (Show-Me-Synch T2, n = 20) treatment received a CIDR insert from d 0 to 14 and PG on d 30. Ultrasound was used to determine response to GnRH for T1 treated cows or follicle turnover for T2 treated cows coincident with timing of GnRH for T1; follicle size at AI; and pregnancy diagnoses. T1 treated cows had a higher ovulatory response to GnRH than cows in T2 ($P < 0.001$; T1 = 17/20, 85% ovulatory response; T2 = 1/20, 5% follicle turnover); however, progesterone at PG did not differ between treatments ($P = 0.17$). Mean diameter of the dominant follicle at GnRH, PG and AI did not differ between treatments ($P > 0.05$). Estrous response, determined from Heatwatch, during the 2 synchronized periods, following CIDR removal and after PG, did not differ ($P = 1.0$) between treatments. Variances for interval to estrus after CIDR removal and PG were similar for both treatment groups ($P > 0.05$). Synchronized AI conception rates did not differ between T1 and T2 treated cows ($P > 0.05$; 72% vs. 58%, respectively); and there was no difference in synchronized AI pregnancy rates between treatments ($P > 0.05$; T1 = 68%; T2 = 55%). In summary, CIDR Select and Show-Me-Synch protocols were equally effective at synchronizing estrus in postpartum beef cows.

This project was supported by National Research Initiative Competitive Grant no. 2005-55203-15750 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: AI, beef cow, CIDR insert

843 Comparison of long-term progestin-based protocols to synchronize estrus prior to fixed-time AI in beef heifers. D. A. Mallory*, J. M. Nash, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri*, *Columbia*.

This experiment was conducted to compare pregnancy rates resulting from fixed-time AI (FTAI) after administration of either one of 2 long-term controlled internal drug release (CIDR)-based protocols. Heifers from a single location were assigned to treatments by age, BW, and reproductive tract score (RTS; 1 = immature to 5 = estrous cycling). Heifers assigned to the CIDR Select treatment protocol (n = 192) received a CIDR insert (1.38 g progesterone) from d 0 to 14, followed by GnRH (100 μg, i.m.; Cystorelin) 9 d after CIDR removal (d 23) and prostaglandin $F_{2\alpha}$ (PG; 25 mg, i.m.; Lutalyse) 7 d after GnRH (d 30). Heifers assigned to the 14-d CIDR-PG treatment protocol (Show-Me-Synch; n = 200) received a CIDR insert from d 0 to 14 followed by PG 16 d later (d 30). Artificial insemination was performed at predetermined fixed times for heifers in both treatments at 72 or 66 h after PG for the CIDR Select and Show-Me-Synch groups, respectively. All heifers were administered GnRH (100 μg, i.m.) at the time of AI. Heifers were exposed for a 42 d natural service clean-up period beginning 10 d after FTAI. There were no differences between treatments for age ($P = 0.74$), BW ($P = 0.92$), or RTS ($P = 0.67$). FTAI pregnancy rates tended ($P = 0.07$) to be greater among Show-Me-Synch (124/200; 62%) compared with CIDR Select (98/192; 51%) treated heifers. Final pregnancy rates did not differ ($P = 0.72$; CIDR Select, 85%; Show-Me-Synch, 83%) between treatments. Based on the odds ratio, Show-Me-Synch treated heifers were 1.62 times more likely to conceive to FTAI than heifers synchronized with CIDR Select. Pretreatment estrous cyclicity status did not affect ($P = 0.32$) FTAI pregnancy rate; however, estrous cycling heifers assigned to Show-Me-Synch had a tendency to have higher FTAI pregnancy rates (63%) than those assigned to CIDR Select (53%; $P = 0.06$). In summary, both long-term progestin based protocols were effective in synchronizing estrus before fixed-time AI in beef heifers.

This project was supported by National Research Initiative Competitive Grant no. 2005-55203-15750 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: AI, beef heifer, CIDR

844 Comparison of long- versus short-term progestin-based protocols to synchronize estrus and ovulation prior to fixed-time AI in postpartum beef cows. D. A. Mallory*, J. M. Nash, M. R. Ellersieck, M. F. Smith, and D. J. Patterson, *University of Missouri*, *Columbia*.

This experiment was designed to compare pregnancy rates in postpartum beef cows resulting from fixed-time AI (FTAI) after treatment with long- versus short-term controlled internal drug release (CIDR)-based protocols to synchronize estrus and ovulation. Angus cows were assigned to treatments by age, BCS, and days postpartum (DPP). Cows assigned to the long-term 14-d CIDR-PG (Show-Me-Synch; n = 99) treatment protocol were administered CIDR inserts (1.38 g of progesterone) from d 0 through 14. Prostaglandin $F_{2\alpha}$ (PG, 25 mg, i.m.) was administered 16 d after CIDR removal, on d 30 of treatment. Cows assigned to the short-term treatment protocol (7-d CO-Synch + CIDR; n = 104), received GnRH (100 μg, i.m.) and CIDR inserts on d 0. CIDR inserts were removed 7 d later at the time PG was administered (d 7). Blood samples were collected on d −9 and immediately before treatment initiation to determine pretreatment estrous cyclicity status of cows (progesterone ≥0.5 ng/mL; Show-Me-Synch, 54/99 = 55%; 7-d CO-Synch + CIDR 51/104 = 49%; $P = 0.52$). Continuous estrus detection was performed using HeatWatch; transmitters were fitted at PG and removed at AI. AI was performed at predetermined fixed times (72 h, Show-Me-Synch; 66 h, 7-d CO-Synch + CIDR) and all cows were administered GnRH (100 μg, i.m.) at AI. There were no differences ($P > 0.10$) between treatments for age, BCS, or DPP. Pregnancy rates were greater ($P < 0.01$) among cows that exhibited estrus before FTAI than for those that did not (52/73 = 71% and 55/130 = 42%, respectively). Pregnancy rates resulting from FTAI did not differ between treatments ($P > 0.10$); technicians ($P > 0.10$); AI sires ($P > 0.10$); or on the basis of pretreatment estrous cyclicity status ($P > 0.10$). Final pregnancy rates did not differ between treatments ($P = 0.53$). In summary, pregnancy rates resulting from FTAI following treatment with Show-Me-Synch and 7-d CO-Synch + CIDR were similar among postpartum beef cows.

This project was supported by National Research Initiative Competitive Grant no. 2005-55203-15750 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: AI, beef cow, CIDR

845 Effect of $PGF_{2\alpha}$ administration at CIDR insertion on AI pregnancy rates in beef heifers. B. L. Sparks*[1], S. L. Lake[2], J. Berry[2], K. Heaton[3], R. P. Lemenager[1], L. A. Horstman[1], K. S. Fisher[1], P. J. Gunn[1], and G. A. Bridges[1], [1]*Purdue University*, *West Lafayette, IN,* [2]*University of Wyoming*, *Laramie,* [3]*Utah State University*, *Logan*.

The objective of this study was to compare 3 estrous synchronization protocols in beef heifers. Heifers managed at 5 locations were assigned to the 7 d Select Synch + CIDR & timed-AI (TAI; 7dSS; n = 298), 5 d Select Synch + CIDR & TAI (5dSS; n = 366), or an experimental 7 d protocol where $PGF_{2\alpha}$ (PGF) was given at CIDR insertion (7dMOD; n = 373). On d −7, the 7dSS treatment received a CIDR and GnRH (100 μg), while the 7dMOD treatment received a CIDR and PGF (25 mg). On d −5, the 7dMOD treatment received GnRH and the 5dSS treatment received a CIDR and GnRH. On d 0, CIDR were removed and all heifers received 2 25 mg doses of PGF given 8 h apart. Estrus was detected twice daily for 60 h after CIDR removal and heifers detected in estrus were AI by the AM/PM rule. At 72 h after CIDR removal heifers not detected in estrus were TAI and received GnRH. Bulls were placed with the heifers 7 d after TAI for the remainder of the breeding season. Pregnancy was diagnosed approximately 35 d after TAI and bull removal, respectively. The effect of treatment, location, and the interaction on estrous response, interval to estrus, conception rate, TAI conception rate, overall AI and breeding season pregnancy rate were analyzed using SAS. The treatment by location interaction was not significant for any variable, thus data were pooled. Estrus response was greater ($P < 0.05$) in the 7dSS (67.1%) and 7dMOD (69.4%) treatments than the 5dSS (56.0%) treatment. Interval to estrus was shorter ($P < 0.01$) in the 7dSS (46.7 ± 0.5 h) and 7dMOD (47.7 ± 0.7 h) treatments compared with the 5dSS (51.9 ± 0.5 h) treatment. Conception rate of heifers in estrus was greater ($P < 0.05$) in the 5dSS (61.9%) and 7dMOD (66.4%) treatments than the 7dSS (50.0%) treatment. Conception rate to TAI did not differ between treatments (45.8%). More ($P < 0.05$) heifers became pregnant to AI in the 5dSS (57.1%) and 7dMOD (58.7%) treatments than the 7dSS (47.3%) treatment. Breeding season pregnancy rates were similar between treatments (86.4%). In conclusion, the 5dSS and 7dMod protocols yielded greater AI pregnancy rates in beef heifers than the 7dSS protocol.

Key Words: beef, estrous synchronization, heifer

846 Influence of inducing luteal regression prior to a fixed-time AI CIDR protocol in postpartum beef cows on pregnancy success. G. A. Perry*, B. L. Perry, and J. H. Krantz, *Department of Animal & Range Sciences*, *Brookings, SD*.

Most fixed-time insemination protocols utilize an injection of GnRH at the beginning of the protocol to initiate a new follicular wave. However, the ability of GnRH to initiate a new follicular wave is dependent on the stage of the estrous cycle. We hypothesized that administering $PGF_{2\alpha}$ 3 d before initiating a fixed-time AI protocol would improve synchrony of follicular waves and result in greater pregnancy success. Therefore, our objective was to determine whether inducing luteal regression 3 d before a fixed-time AI protocol would improve pregnancy rates. Multiparous crossbred cows at 2 farms (n = 296 and n = 97) were randomly assigned to one of 2 treatments: 1) $PGF_{2\alpha}$ (25mg; i.m.) on d −9, GnRH (100μg; i.m.) and insertion of a CIDR on d −6, $PGF_{2\alpha}$ (25mg; i.m.) and CIDR removal on d 0 (PG-CIDR) or 2) GnRH (100μg; i.m.) and insertion of a CIDR on d −5 and CIDR removal with $PGF_{2\alpha}$ (25mg; i.m.) at CIDR removal and 4 to 6 h after CIDR removal (5d CIDR). Cows were time-inseminated between 66 and 72 h (PG-CIDR) or 70 to 74 h (5d CIDR) after CIDR removal. Pregnancy rates to fixed-time AI were determined by ultrasonography 76 to 82 d after AI in herd 1 and 35 d after AI in herd 2. In herd 1, PG-CIDR cows were longer postpartum ($P < 0.01$; 71 ± 1.2 d) than 5d CIDR cows (65 ± 1.1 d). In herd 2, there was no difference ($P = 0.58$; 79 ± 2.0 and 81 ± 2.0 d for PG-CIDR and 5d CIDR, respectively). There were no differences between treatments ($P = 0.07$), locations ($P = 0.35$), or treatment by location ($P = 0.19$) on BCS. Pregnancy rates were 59% (89/149) and 46% (68/147) for PG-CIDR and 5d CIDR in herd 1, respectively ($P = 0.02$); and 77% (37/48) and 67% (33/49) for PG-CIDR and 5d CIDR in herd 2, respectively ($P = 0.28$). When data from both herds were combined pregnancy rates remained different between protocols [$P = 0.01$; PG-CIDR = 126/197 (64%); 5d CIDR = 101/196 (52%)]. In summary, pregnancy rates resulting from fixed-time AI were improved by inducing luteal regression 3 d before initiation of a fixed-time AI protocol.

Key Words: estrous synchronization, fixed-time AI, beef cows

847 Influence of luteal regression prior to GnRH on LH pulse frequency and synchrony of follicular growth. J. K. Grant*[1], F. M. Abreu[2], and G. A. Perry[1], [1]*Department of Animal & Range Sciences*, *Brookings, SD,* [2]*USDA-ARS Ft. Keogh*, *Miles City, MT*.

Research has reported that luteal regression before a GnRH injection decreased progesterone concentrations and increased synchrony of follicular growth and estrus. The objective of this study was to determine the effects of luteal regression before a GnRH injection on LH pulse frequency and synchrony of follicular growth. Angus-cross beef heifers (n = 15) were assigned to one of 3 treatments: 1) $PGF_{2\alpha}$ on d −9, GnRH and insertion of a CIDR on d −6, and $PGF_{2\alpha}$ and CIDR removal on d 0 (PG-CIDR), 2) $PGF_{2\alpha}$ on d −9, GnRH on d −6, and $PGF_{2\alpha}$ on d 0 (PG-No CIDR), or 3) GnRH and insertion of a CIDR on d −7 and $PGF_{2\alpha}$ and CIDR removal on d 0 (7d CIDR). Follicular growth was determined daily by transrectal ultrasonography. Blood samples were collected daily for determination of progesterone concentrations. On d 4 after CIDR insertion (d −3 for 7d CIDR and d −2 for PG-CIDR and PG-No CIDR), blood samples were collected every 15 min for 8 h to determine LH pulse frequency. There was a treatment ($P = 0.04$), time ($P < 0.01$), and treatment x time ($P < 0.01$) interaction on progesterone concentrations. PG-No CIDR had decreased concentrations compared with PG-CIDR and 7d CIDR, which were similar. There was a tendency ($P = 0.09$) for LH pulse frequency to be greater among PG-CIDR (3.4 ± 0.24) and PG-No CIDR (3.4 ± 0.24) compared with the 7d CIDR (2.6 ± 0.40), but area under the curve ($P > 0.76$) and mean LH concentrations ($P > 0.76$) did not differ. Follicular growth rates did not differ between treatments ($P > 0.14$), but there was a tendency for decreased variance in growth rate among PG-CIDR (0.03) compared with PG-No CIDR ($P = 0.1$; 0.10) and 7d CIDR ($P = 0.06$; 0.20). In addition, variance in dominant follicle size on d 0 was decreased in PG-CIDR (0.2) compared with PG-No CIDR ($P < 0.01$; 7.8) and 7d CIDR ($P = 0.01$; 5.1). In summary, luteal regression before a GnRH injection tended to increase LH pulse frequency and decrease variation in follicle growth and decreased variation in follicle size on d 0.

Key Words: LH, estrous synchronization, follicular growth

848 The influence of two doses of PGF2α given at 2 or 12 hour intervals on luteolysis and pregnancy rate to timed AI with the 5-d CO-Synch + CIDR program. L. H. Cruppe*[1], M. Maquivar[1], E. M. Jinks[1], G. E. Fogle[1], M. L. Mussard[1], A. V. Pires[2], and M. L. Day[1], [1]*The Ohio State University*, *Columbus*, [2]*University of São Paulo*, *Piracicaba, SP, Brazil*.

The objectives of these experiments were to assess the impact of the interval between 2 PGF2α doses in the 5-d CO-Synch + CIDR on

reproductive performance (Expt 1) and luteal regression (Expt 2) in beef cows. Cows were assigned, within parity, by days postpartum to treatments. Blood samples for progesterone (P4) analysis were collected on d −15 and −5 to classify cows as cyclic or anestrus. All cows received 100 µg of GnRH (Cystorelin) at the time of CIDR insertion on d −5. In Expt 1, all cows (n = 254) received their first 25 mg dose of PGF i.m. (Lutalyse) on d 0 (h 0) and at the time of CIDR withdrawal and tail paint application. A second dose of PGF was given at either h 2 (2hPGF) or h 12 (12hPGF). At h 72, cows received 100 µg GnRH and timed-AI (TAI). Blood samples were collected on d 3 (h 72), 10 and 15 and analyzed for P4, and h 72 samples from cows that were not detected in estrus were analyzed for estradiol (E2) concentration. In Expt 2, cows (n = 31) received the 2hPGF and 8hPGF treatments as described, with the exceptions that the CIDR was withdrawn at h −2 and the second GnRH/TAI was not performed. Rather, estrous detection was performed from d 0 to d 7 and blood samples for P4 collected at h 0, 2, 4, 12, 14, 24, 48, 72 and 96. Ultrasonography performed on d −5, −1, 3 and 10 was used to detect existing CL, induction of ovulation with the initial GnRH, regression of CL with PGF and formation of a new CL, respectively. In Expt 1, TAI pregnancy rate did not differ between 2h- and 12hPGF treatments (60.8% vs. 58%). Concentrations of P4 on d 3, 10 and 15 did not differ between treatments or pregnancy status. Concentration of E2 at h 72 did not differ with pregnancy status. In Expt 2, P4 concentrations, incidence and timing of estrus, luteal regression and other ovarian characteristics determined by ultrasonography did not differ between treatments. In conclusion, reduction of the interval to the second PGF dose from 12 to 2 h in the 5-d CO-Synch + CIDR treatment did not influence TAI pregnancy rate or the occurrence of luteal regression.

Key Words: cattle, PGF2α, timed-AI

849 Use of two coincident doses of PGF2α with the 5-d CO-Synch + CIDR estrous synchronization program. L. H. Cruppe*[1], L. A. Souto[1], M. Maquivar[1], P. Gunn[3], M. L. Mussard[1], D. Wolfenson[4], A. V. Pires[2], G. A. Bridges[3], and M. L. Day[1], [1]*The Ohio State University*, *Columbus*, [2]*University of São Paulo*, *Piracicaba, SP, Brazil*, [3]*Purdue University*, *West Lafayette, IN*, [4]*The Hebrew University*, *Rehovot, Israel*.

The aim of this study was to determine the effect of timing of the second dose of PGF2α (PGF) in the 5-d CO-Synch + CIDR program on timed-AI (TAI) pregnancy rate. Spring-calving crossbred beef cows (n = 662) at 5 locations were assigned, within parity (primi- or multiparous), by days postpartum to treatments. At 4 locations, blood samples for progesterone analysis were collected on d −15 and −5 of the experiment to determine if cows were cyclic or anestrus. All cows received 100 µg of GnRH (Cystorelin) at the time of CIDR insertion on d −5. On d 0 (h 0), the CIDR was withdrawn, tail paint applied, and all cows received their first 25 mg dose of PGF i.m. (Lutalyse). A second dose of PGF was administered either immediately following the first injection, coincident with CIDR withdrawal (CoPGF; n = 218), h 2 (2hPGF; n = 226) or h 8 (8hPGF; n = 218). At h 72, all cows received 100 µg GnRH, TAI and a tail paint score (TPS; 1 = paint absent; 2 = partial disappearance; 3 = paint undisturbed). Estrus detection and AI were performed from d 16 to 24 after TAI in 4 of 5 herds and then cows were exposed to intact bulls for the remainder of the breeding season. Pregnancy rate to TAI was determined via ultrasonography between d 28 to 43 of the breeding season and final pregnancy rate was determined after the breeding season. Data were analyzed using Glimmix procedure of SAS. Pregnancy rates to TAI did not differ and were 69.7% in the CoPGF, 65.5% in the 2hPGF and 66.1% in the 8hPGF treatments. Irrespective of treatment, TAI pregnancy rate was greater ($P = 0.05$) in multiparous (68.6%) than primiparous (59.8%) cows. There were no interactions of treatment with reproductive status, location, AI technician and sire for TAI pregnancy rate. The proportion of animals with TPS 1 (57.1%), 2 (19%) or 3 (23.9%) did not differ among treatments; however, TAI pregnancy rates were greater ($P < 0.01$) in animals with TPS 1 (73.3%) and 2 (72.2%) than with TPS 3 (48.1%). In conclusion, 2 coincident doses of PGF at CIDR withdrawal in the 5-d program results in similar TAI pregnancy rates as when given either 2 or 8 h apart.

Key Words: cattle, PGF2α, timed-AI

850 Evaluation of beef cow and calf separation systems to improve reproductive performance of first-calf cows. P. G. M. A. Martins*, D. B. Araujo, and J. D. Arthington, *University of Florida, Range Cattle Research and Education Center*, *Ona*.

Our objectives were to compare the effects of a traditional 48-h calf withdrawal to early-weaning and repeated 48-h calf withdrawals on time to first postpartum ovulation and measures of cow and calf performance. Sixty-four primiparous, Brahman x British crossbred cow-calf pairs were randomly allotted to 3 treatments: EW (early weaned; cows and calves permanently separated); IW (interval weaned; cows and calves separated for 48 h on 4 occasions at 20 d intervals); and CON (control; cows and calves separated a single time for 48 h). Treatments were initiated at the start of a 90-d breeding season (average days postpartum = 97 ± 19 d). Blood samples were collected on 10 d intervals over 100 d for determination of progesterone concentrations. Resumption of cyclicity was defined as 2 consecutive samples with concentrations of progesterone ≥1.5 ng/mL. Cow and calf BW was determined at the start (d 0), middle (d 50), and end (d 100) of the study. Pregnancy was diagnosed by transrectal ultrasonography at 44 d after the end of the breeding season. By d 30 of the breeding season, there were more EW cows cycling than IW and CON cows ($P = 0.03$; 90.9, 61.9, and 66.7% cycling for EW, IW, and CON cows, respectively). Calf BW did not differ at the beginning of the breeding season (average BW = 96 ± 4.1 kg) but was greater ($P < 0.001$) for EW vs. IW and CON calves at the end of the study (d 100; 142, 143, and 142 kg for EW, IW, and CON calves, respectively; SEM = 5.3). In the first year of this experiment, early calf weaning improved cow and calf BW gain and hastened the time to first postpartum ovulation compared with cows subjected to single or repeated 48-h calf withdrawals.

Key Words: cow, calf, weaning

851 Comparison of RFI evaluated as heifers with RFI reevaluated again as mature cows. S. L. Morgan*[1,2], D. A. Neuendorff[1], A. W. Lewis[1], J. P. Banta[1], T. D. A. Forbes[3], A. L. Loyd[2], and R. D. Randel[1], [1]*Texas AgriLife Research*, *Overton,* [2]*Texas AgriLife Research*, *College Station,* [3]*Texas AgriLife Research*, *Uvalde.*

Although the idea of residual feed intake (RFI) was introduced over 45 yrs ago, it is only recently that this topic has acquired great interest. Many studies have investigated the creditability of RFI evaluated in weaned cattle and their subsequent performance in the areas of reproduction, meat science and genetics. However, relatively few studies have evaluated the repeatability of this post–weaning RFI in mature cattle. This study was designed to examine the correlation between post–weaning and mature RFI in *Bos indicus* cows. After the breeding season, 37 multiparous Brahman cows (3–7 yrs of age) with previous RFI data and palpated to be in the first trimester of gestation, were retrained to eat from a Calan gate system. Cows were fed twice daily (0800 and 1600) a 2.5% BW/d diet for 70d with body weight and body condition scores recorded weekly and feed adjusted accordingly. Using the past and present data, RFIs for the initial (RFI1) and repeat (RFI2) trials were calculated. Females were classified according to their RFI values, with a negative RFI = efficient and positive RFI = inefficient. Chi-squared test revealed that 62.2% remained in the same classification, while 37.8% changed, $P = 0.04$. To further investigate repeatability, cows were sorted into High (>0.5 SD), Intermediate (<0.5 SD >) and Low (<0.5 SD) RFI groups. The change in classification groups were determined to be (±0) 51.35%, (±1) 43.24% and (±2) 5.41%, $P < 0.001$. A positive Pearson correlation ($r = 0.51$, $P < 0.001$) was also observed between RFI1 and RFI2 value rankings within yr cohorts, concluding that post-weaning RFI may be a moderately accurate predictor of mature feed efficiency.

Key Words: RFI, repeatability, cow

852 Level of maternal winter supplement and feed restriction during postweaning development influences circulating concentrations of IGF-I in heifers during the peripartum and rebreeding period. A. J. Roberts*, R. C. Waterman, T. W. Geary, L. J. Alexander, and M. D. MacNeil, *USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT*.

Objective of this research was to evaluate effects of 2 levels of supplemental feed provided to cows during late gestation and 2 levels of feed provided to their daughters during postweaning development on circulating concentrations of IGF-I in the daughters before calving, after calving and before breeding. Heifers were produced over a 3-yr period from dams that were fed levels of harvested feed from mid and late gestation (Dec to March) that were expected to provide marginal (MARG) or adequate (ADEQ) nutrition while grazing dormant winter forage through this period. After weaning, heifers were fed to appetite (CON) or restricted (REST) to 80% of that consumed by CON on common BW basis during a 140-d period ending 1-mo before breeding. Heifers were managed together through breeding to Dec when they were separated so CON could be fed like ADEQ cows and REST could be fed like MARG cows up to 2 to 3-wk before start of calving in March. Concentrations of IGF-I (determined by RIA) in serum samples (n = 828) obtained 8 to 12-d before start of calving, 2 to 4-wk after calving and 0 to 18-d before start of breeding were analyzed by the MIXED procedure of SAS using a model for repeated measures. Concentrations of IGF-I were influenced by interaction of dam and heifer treatments, being greater ($P < 0.05$) in CON heifers from ADEQ or MARG fed dams and REST heifers from MARG dams than in REST heifers from ADEQ dams. Concentrations of IGF-I were greater ($P = 0.05$) in heifers that gestated male than female calves, and in heifers that subsequently became pregnant than those that did not ($P < 0.001$). Results provide support that the dietary treatments imposed on cows resulted in a uterine programming effect in their heifers, as was evident by differences in circulating concentrations of IGF-I in heifers that were restricted fed during postweaning development.

Key Words: heifer development, IGF-I, uterine programming

853 Winter grazing system and supplementation of beef cows during late gestation influence heifer progeny. R. N. Funston*, D. M. Larson, A. F. Summers, J. L. Martin, and D. C. Adams, *University of Nebraska West Central Research and Extension Center*, *North Platte*.

A 2 × 2 factorial study evaluated effects of cow winter grazing system and last trimester supplementation on heifer progeny. Composite cows (yr 1 n = 109; yr 2 n = 114; yr 3 n = 116) grazed either range (WR) or corn residue (CR) during winter and within grazing treatment received 0.45 kg/d (DM) 28% CP cubes (PS) or no supplement (NS). Heifer calves (yr 1 n = 56; yr 2 n = 56; yr 3 n = 54) grazed dormant pasture for 114 d post-weaning and were individually fed for 87 d before natural service breeding (45 d). Dam PS reduced ($P = 0.04$) heifer birth date and CR increased ($P = 0.07$) heifer birth BW. Both PS and CR increased ($P \leq 0.05$) heifer weaning BW, however, adjusted weaning BW was only lower ($P = 0.03$) if the dam grazed WR with NS. Heifer ADG during

the individual feeding period was greater ($P = 0.03$) in heifers from CR NS dams. Heifers from PS dams were younger ($P = 0.09$) at puberty and more tended ($P = 0.11$) to be pubertal by breeding if the dam grazed WR with PS. Heifers from WR NS dams weighed less ($P \leq 0.09$) at breeding and pregnancy diagnosis than WR PS. Pregnancy rate tended ($P = 0.13$) to be greater for heifers born to PS dams. Individually fed heifer DMI was not affected ($P = 0.17$) by treatment, however, heifers from dams that grazed CR with PS gained the least ($P = 0.03$) during individual feeding and had the lowest ($P = 0.04$) G:F. In contrast, there were no differences ($P > 0.10$) in efficiency when expressed as RFI. The heifer's first calf production was unaffected ($P > 0.10$) by dam treatment. Heifers from dams that grazed WR with NS had lower ($P = 0.01$) BW before the second breeding season but similar ($P = 0.97$) pregnancy rates. Cows grazing CR with NS produced the most valuable heifer calf at weaning, however, heifers from cows that grazed WR with NS cost the least to develop per pregnant heifer. Winter grazing system and late gestation supplementation impacted heifer progeny BW, feed efficiency, and reproduction.

Key Words: fetal programming, maternal nutrition, supplementation

854 Gastrointestinal nematode egg shedding rates in temperate adapted Angus and tropically adapted Brahman and Romosinuano calves at weaning. C. C. Chase, Jr.*[1], L. C. Gasbarre[2], S. W. Coleman[1], D. G. Riley[1], and E. E. Connor[2], [1]*USDA-ARS-STARS*, *Brooksville, FL,* [2]*USDA-ARS-BFGL*, *Beltsville, MD*.

Gastrointestinal nematode egg shedding rates were determined at weaning for 3 years in temperate adapted *Bos taurus* (Angus, n = 107), tropically-adapted *Bos taurus* (Romosinuano, n = 126), and tropically-adapted *Bos indicus* (Brahman, n = 87) calves in the subtropics (Florida). Each year, fecal samples were obtained from purebred calves on the day of weaning and the next day. Purebred calves were born and raised at 2 locations (i.e., 2 farms) until after weaning. Eggs per gram of feces were determined for each calf each day and the average of the 2 d was analyzed. The Proc Mixed procedure of SAS was used for statistical analyses and the model included the effects of location, year, breed, sex, and interactions. Location ($P < 0.10$), year ($P < 0.05$), breed ($P < 0.003$), and sex ($P < 0.10$) affected average eggs per gram of feces. Angus had the highest average eggs per gram of feces (179 ± 22.6); Brahman had the lowest average eggs per gram of feces (88 ± 24.0); and Romosinuano had intermediate eggs per gram of feces (compared with Angus and Brahman; 149 ± 21.6). There was however, a 3 way interaction among year by breed by sex ($P < 0.02$). Analysis by year indicated that although average eggs per gram of feces was consistently ranked from Angus > Romosinuano > Brahman over the 3 years, that only in year 2 was breed and breed by sex significant. Breed by sex ($P < 0.01$) in year 2 was due to extremely low average eggs per gram of feces in both male and female Brahman (25 ± 45.4 and 58 ± 48.4) compared with both Angus (183 ± 45.4 and 195 ± 48.4) and Romosinuano (245 ± 36.0 and 39 ± 37.4). In the subtropics, tropically-adapted *Bos taurus* (Romosinuano) and tropically-adapted *Bos indicus* (Brahman) in particular appear to offer some resistance to gastrointestinal nematodes compared with temperate adapted *Bos taurus* (Angus).

Key Words: *Bos indicus*, tropical, GI nematodes

855 Effect of calving season on net returns and risk of cow-calf production in western Canada. T. K. Sirski[1], D. G. Brewin[1], S. L. Scott*[2], A. D. Iwaasa[3], H. A. Lardner[4], and H. C. Block[2], [1]*University of Manitoba, Winnipeg, Canada*, [2]*Agriculture and Agri-Food Canada, Brandon Research Centre, Brandon, Canada*, [3]*Agriculture and Agri-Food Canada, Semiarid Prairie Agricultural Research Centre, Swift Current, Canada*, [4]*Western Beef Development Centre, Lanigan, Canada*.

Data from a 3-site study on the effects of calving season (CS) on cow-calf production in western Canada were used in a Monte Carlo simulation to evaluate net returns and risk. At each of the 3 locations (Brandon, MB (BR), Lanigan, SK (LA), and Swift Current, SK (SC)), production data were collected from crossbred cows (n = 120, BR; n = 100, LA; n = 50, SC) for 2 production cycles running from the start of one CS through to the beginning of the next CS. Cows were allocated to early calving (EC; March) or late calving (LC; June), with 2 replicates per CS per location. Each production cycle was divided into 4 feeding phases: drylot, bale grazing, swath grazing and pasture. Costs were compiled for each CS for feed and straw use, veterinary services, drugs and vaccines, equipment use, labor, land rental and fencing. Costs for mineral, salt, breeding, taxes, water, trucking, marketing and facilities were based on provincial publications for cow-calf costs of production. Revenues for each calving system were calculated using the study′s production data and prices provided by CanFax Research Services (Calgary, AB) for 2000–2009. To simulate the stochastic nature of key input variables, including weaning weight, steer and heifer price, cull cow price and days in each feeding system, 5000 iterations of the @Risk add-in (Palisade Co., Ithaca, NY) for MS Excel were used. Simulated net returns were higher ($P < 0.05$) for LC than those for EC at all 3 locations. In SC, the variance for LC was greater ($P < 0.05$) than that for EC, indicating greater risk within the system. At BR and LA, the variances were not affected ($P > 0.05$) by CS. Results indicate that CS impacts net returns at each location and the risk posed by each CS differs with location.

Key Words: calving season, risk, stochastic simulation

856 Estrous response and pregnancy rates of beef heifers exposed to bulls during an estrus synchronization protocol that included a 14-d CIDR, PGF2α, and, timed AI and GnRH. J. G. Berardinelli*[1], S. Tauck[1], J. Wilkinson[1], J. Olsen[1], T. Gibbs[1], K. C. Davis[1], J. Dafoe[2], and D. Boss[2], [1]*Montana State University*, *Bozeman,* [2]*Northern Agricultural Research Center*, *Havre, MT*.

The objective was to evaluate estrus synchronization responses and AI pregnancy rates (PR) of beef heifers exposed to bulls during a protocol that included a controlled internal drug release device (CIDR) for 14 d, PGF2α (PG), and, timed AI (TAI) and GnRH. Three trials were conducted in 2 consecutive yr (Yr 1 and 2) at 2 locations (L1 and 2). In each trial, heifers were stratified by birth date, BW, BCS, and presence of a corpus luteum and assigned randomly to be exposed (BE; n = 110) or not exposed (NE; n = 110) to bulls. Heifers were exposed to bulls on the day of CIDR insertion (D −32) and remained with bulls until PG injection (D 0). CIDRs were removed 14 d (D −18) after insertion. On D 0 heifers received PG and bulls were removed from BE heifers. Heifers were observed for estrus during the next 60 h from 0600 to 2400 h daily in 2 trials (Yr 1 and 2, L1) and am:pm in the other trial (Yr 2, L2). Heifers that showed estrus by 60 h after PG were bred by AI 12 h later. Heifers that did not show estrus by 60 h were TAI at 66 to 72 h after PG and given GnRH. Proportionate data were analyzed by chi-squared analyses and intervals to estrus after PG were analyzed by ANOVA using PROC GLM of SAS. Model included treatment, YR, location and their interactions. Fewer ($P < 0.05$) BE heifer showed estrus and had longer ($P < 0.05$) intervals to estrus in Yr 1 at L1 and than NE heifers (Yr 1, L1) or BE and NE heifers in Yr 2 at L1 and 2). Thus, more ($P < 0.05$) NE heifers in YR at L1 were bred by AI 12 h after PG than BE heifers in Yr1 at L1 and BE and NE heifers in Yr2 at L1 and 2. Overall AI pregnancy (PR) tended ($P = 0.06$) to be greater for BE (66%)

than NE (54.5%) heifers. Pregnancy rate for BE heifers was greater ($P = 0.055$) than that for NE heifers bred 12 h after estrus; whereas, PR to TAI did not differ between BE and NE heifers. These results indicate that AI PR for heifers inseminated 12 h after estrus may be improved by exposing heifers to bulls during an estrus synchronization protocol that included CIDR for 14 d, followed 18 d later with PGF2α (PG), and, TAI and GnRH.

Key Words: biostimulation, CIDR, estrus synchronization

857 The relationship of cow size to calf weaning weight in a commercial cow/calf operation in the southern Great Plains. G. L. Mourer*, C. P. McMurphy, E. Devuyst, and D. L. Lalman, *Oklahoma State University*, *Stillwater*.

Recent increases in cow/calf enterprise production costs have resulted in renewed interest in identifying critical factors that influence efficiency of production. A better understanding of the relationship of cow size and weaning weight is necessary before informed culling or selection decisions based on cow size can be made. A total of 737 individual cow and calf weaning records collected over 6 yr from a commercial Angus and Angus x Hereford commercial cowherd were evaluated. Cows calved in spring or fall seasons and grazed native tallgrass prairie or bermudagrass pasture year around with supplemental protein during winter and supplemental grass hay when ice or snow covered standing forage. Calves were weaned at 212 ± 20 d regardless of calving season. Means ± SD for cow age, cow BW at weaning, cow BCS at weaning, calf birth weight, calf BW at weaning, calf weight as a percentage of cow BW at weaning (BWW) were 4.96 ± 1.75, 581 kg ± 83, 4.71 ± 0.67, 35.61 kg ± 5.53, 211 kg ± 38.35, 0.42 ± 0.07, respectively. The mixed procedure of SAS was used with cow sire breed, calf sire breed, sex of calf and calving season declared as fixed effects and year of birth used as a random effect. Cow BW at weaning was adjusted to a constant BCS (5.0) and age (5.0 yr) before analysis. Weaning weight was influenced by direct sire, but not maternal sire. SimAngus sired calves were 29.5 kg and 21.8 kg heavier than Charolais and Angus sired calves, respectively ($P < 0.05$). For every 0.45 kg increase in birth weight, weaning weight was increased by 0.86 kg ($P < 0.05$). Spring calving cows weaned 17.7 kg heavier calves than fall calving cows ($P < 0.05$). An increase in cow BW of 45.6 kg resulted in an increase in calf weaning weight of 4.56 kg ($P < 0.05$). Further research is needed to determine if this marginal increase in calf weaning weight per 45.6 kg of increased cow weight is economical.

Key Words: cow size, weaning wt, southern Great Plains

858 Infrared thermography for detection of hoof lesions in dairy cattle. A. Orman[1] and M. I. Endres*[2], [1]*University of Uludag*, *Bursa, Turkey*, [2]*University of Minnesota*, *St. Paul*

Lameness is one of the most important health, economic, and welfare problems in dairy farms today. The objective of this study was to investigate the use of infrared thermography (IRT) for detection of different types of hoof lesions. Early detection of lesions could result in a reduction of severe cases of lameness. A total of 139 lactating dairy cows housed either in a tie-stall or a free stall barn were used. Thermal images of the rear feet were taken with a HSI3000AS (Palmer Wahl) camera and evaluated using Wahl HSI 3000 Imager software. Hoof lesions identified in the study included white line disease (WLD), sole ulcer (SU) and digital dermatitis (DD). Hoof temperatures at the coronary band (CB) and the skin (S) were recorded. Cows were scored for locomotion on a scale of 1 to 5, with 1 = normal and 5 = severely lame. Results for temperature (°C) and locomotion scores (mean (SD)) are reported on Table 1. CB temperatures were higher for all types of hoof lesion ($P < 0.05$) than for healthy hooves. S temperature was higher for WLD ($P < 0.01$) compared with healthy hooves. ΔT (temperature difference between coronary band and skin) was higher ($P < 0.01$) in SU hooves than healthy hooves. Locomotion scores (LS) were similar to healthy cows for all groups except for WLD cows ($P < 0.01$). These results indicate that IRT has potential as a method for detection of hoof lesions, but further research is needed.

Table 1.

Lesion	CB Temp	Skin Temp	ΔT	LS
WLD	34.1(2.3)*	33.2(2.0)**	0.9(0.9)	3.0(0.8)**
SU	33.8(1.6)*	31.6(2.3)	2.1(0.8)**	3.0(0.9)
DD	33.1(1.6)*	31.9(1.5)	1.2(0.7)	2.4(0.7)
Healthy	32.6(1.9)	31.5(1.7)	1.1(0.9)	2.2(0.7)

*$P < 0.05$; **$P < 0.01$ (within column).

859 Relationship between udder and leg hygiene score and somatic cell count. M. Q. Shahid*, E. M. Shane, and M. I. Endres, *University of Minnesota*, *St. Paul*.

The objective of this prospective observational study was to evaluate the relationship between cow hygiene and somatic cell count. In addition, the association between milk production and somatic cell count was investigated. Five commercial dairy herds with sand bedded freestalls were used. Herd size ranged from approximately 450 to 1500 lactating cows. Cows were enrolled in the study during January and February 2008. Composite lower rear leg and udder hygiene scores (scale of 1 to 5, with 1 = clean and 5 = very dirty) were collected from approximately 4100 cows during 4 visits spaced 3 mo apart. Scores were recorded and determined by one individual throughout the entire study. Monthly somatic cell count (SCC) values were collected during each visit. Data were analyzed in a model that included effects of animal, sampling period, somatic cell scores (SCS), parity and DIM. The relationship between SCS and hygiene scores was analyzed using PROC MIXED analysis. Hygiene scores (LSMean (SE)) were 2.78 (0.58). Mean SCC and SCS were 294,000 (828,000) cells/ml and 2.76 (1.98), respectively. The analysis indicated that an increase in hygiene scores was associated ($P < 0.0001$) with an increase in SCS. The regression coefficient for SCS and hygiene score was 0.17. A unit increase in hygiene score was associated with a 59,000 cells/ml increase in somatic cell count. The other variables which were significantly associated with SCS were parity, DIM and total milk yield ($P < 0.0001$). Daily milk yield was 39.0 (11.6) kg/cow. The regression coefficient of SCS with parity, DIM and milk yield were 0.35, 0.002 and −0.019, respectively. Every 9,700 cells/ml increase in somatic cell count was associated with a 1 kg reduction in milk yield. Results of this study indicate that striving to maintain cows cleaner can contribute to improved milk quality and milk yield in freestall housed dairy herds.

Key Words: milk quality, SCC, hygiene

861 Association between stall surface and various welfare measurements on dairy herds utilizing recycled manure solids for bedding freestalls. A. W. Husfeldt* and M. I. Endres, *University of Minnesota*, *St. Paul*.

The objective of this observational study was to investigate the association between stall surface and various animal welfare measurements on dairy operations that utilize recycled manure solids as bedding material. The study included 34 dairy operations with herd sizes ranging from 100 to 3800 lactating cows. Forty 5 percent of the herds had mattresses and 55% percent had deep bedded stalls. Farms were visited once between July and October 2009. Approximately 50% of the lactating herd was scored for hygiene (scale of 1 to 5 with 1 = clean, 5 = very dirty), hock lesion prevalence (scale of 1 to 3, with 1 = no lesion, 2 = hair loss, 3 = swollen hock) and lameness prevalence. Lameness prevalence was evaluated by locomotion scoring (1 = normal locomotion, 5 = severely lame; ≥ 3 = lame). Hygiene scores (mean(SD)) were 2.6(0.3), hock lesion prevalence was 60.1(20.8) percent, and severe hock lesion (score 3) was 10.5(8.8). Lameness prevalence was 16.1(9.9) percent and severe lameness prevalence (score 4 and 5) was 5.2(5.0) percent. Hygiene scores (LSmean(SE)) for mattress and deep bedded herds were 2.6(0.05) and 2.5(0.04), respectively. There was an association ($P = 0.05$) with stall surface. Hock lesion prevalences (score 2 and 3) for mattress and deep bedded herds were 63.8(2.5) and 46.7(1.9) percent, respectively. There was an association ($P < 0.001$) between stall surface and hock lesion prevalence. Severe hock lesion prevalences (score 3) were 14.0(1.0) and 6.6(0.7) percent for mattress and deep bedded freestalls, respectively. Stall surface was associated ($P < 0.001$) with severe hock lesion prevalence. Lameness prevalences were 20.6(1.1) and 16.7(0.8) percent for mattress and deep beds, respectively. Stall surface was associated with lameness prevalence ($P < 0.001$). Severe lameness prevalences (scores 4 and 5) for mattress and deep bedded stalls were 6.5(0.5) and 5.1(0.4) percent, respectively and they were also associated with stall surface ($P = 0.04$). Based on these results it appears that deep bedded freestalls with recycled manure solids provide better animal welfare than recycled solids on top of mattresses.

Key Words: welfare, lameness, stall surface

862 Shade utilization and distribution of dairy cows in response to environmental conditions. A. L. Adams*, T. H. Friend, G. A. Holub, S. M. Garey, and C. L. Terrill, *Texas A&M University*, *College Station*.

The means by which dairy cows respond to heat stress is important to cow comfort. The objective of this study was to determine the effects of environmental conditions on shade utilization and pen distribution of cows. Three pens of dairy cows, averaging 186 cows per pen, were

observed for 72 consecutive hours during one trial in June and one trial in August in the Texas panhandle. The number of cows standing or lying in the shade, open lot, and at the bunk was recorded at 1 h intervals. Environmental conditions were also recorded. Soil temperatures at 5.1 cm below the surface were recorded every hour in transects starting under the shade structure and continuing 3.0 m, 6.1 m, 9.1 m, and 12.2 m from the eastern and western sides of the shade structure. Cow locations and shade use were analyzed in a mixed model. A significant increase in shade utilization occurred at 1200 – 1400 h ($P < 0.0001$). Shade utilization increased as cloud cover decreased ($P = 0.011$), wind speed decreased ($P = 0.0034$), and black globe temperatures increased ($P = 0.025$). Temperature-humidity index (THI) did not have a significant effect on shade use ($P = 0.19$). When black globe temperatures were high and the proportion of cows in the shade increased, cows spent more time standing ($P = 0.054$; $P = 0.015$, respectively). Cloud cover ($P = 0.45$), THI ($P = 0.74$), and wind speed ($P = 0.96$) did not affect the proportion of cows standing. Cows spent the most time at the feed bunk at 1900 – 2000 h ($P = 0.0004$). When cloud cover and wind speed were high, cows spent more time at the feed bunk ($P < 0.0001$; $P = 0.005$, respectively). Cows tended to spend more time at the feed bunk when THI was low ($P = 0.076$), but black globe temperatures did not have an effect ($P = 0.97$). Soil temperatures under the shade structures were consistently cooler than soil temperatures in the lots and were negatively related to the proportion of cows lying in the shade. These results suggest that multiple environmental parameters need to be considered when determining the comfort and well-being of dairy cows.

Key Words: dairy, behavior, heat stress

863 Associations between housing systems and animal welfare measurements assessed by survival analysis. K. M. Lobeck*, M. I. Endres, S. M. Godden, and J. Fetrow, *University of Minnesota*, *St. Paul*.

The objective of this study was to determine when dairy cattle become lame in cross-ventilated (CV) freestall barns compared with naturally ventilated (NV) freestall barns. Data were collected from October 2007 to August 2009 on 4 commercial herds. Twenty-five cows were enrolled per season at calving time starting from fall 2007 until summer 2008 for a total of 100 cows per farm. Cows were enrolled in the study for an entire lactation or up to 1 year. Cows were scored every 2 mo for BCS (scale of 1 to 5 with 1 = thin, 5 = obese), hock lesion (scale of 1 to 3, with 1 = no lesion, 2 = hair loss, 3 = swollen hock) and lameness. Lameness was evaluated by locomotion scoring (1 = normal locomotion, 5 = severely lame; ≥ 3 = lame). CV animals reached median cumulative lameness incidence at 360 DIM, whereas NV animals reached median cumulative lameness incidence at 328 DIM ($P < 0.001$). Cows housed in NV barns were 2.9 times more likely to become lame than those housed in CV barns ($P < 0.001$). Each additional parity was associated with a 32% increase in the hazard of becoming lame ($P = 0.002$). Each additional 0.25 increase in body condition score resulted in a 7% decrease in hazard of becoming lame ($P = 0.03$). Cows that calved summer 2008, winter 2008, and spring 2008 were 7.3 times, 5.5 times, and 4.7 times ($P < 0.001$) more likely to become lame than fall 2007 cows, respectively. Cows that calved summer 2008 were 1.6 times more likely to become lame than those that calved spring 2008 ($P = 0.006$). For severe lameness (score 4 and 5), cows housed in NV barns were 2.2 times more likely to become lame than NV barns ($P = 0.03$). There was a trend for parity to increase the hazard of becoming lame by 27% ($P = 0.06$). There was also a trend for cows with hock lesions to be 1.9 times more likely to be lame than those without any hock lesion ($P = 0.09$). There was no difference between NV and CV barns for hock lesion incidence. Parity was associated with a 14% increase in hazard of having a hock lesion ($P = 0.001$). These results indicate that animals housed in CV barns were less likely to become lame than those housed in NV barns, however, there were no differences in hock lesion incidence.

Key Words: lameness, welfare, hock lesion

864 Feed management practices on California dairies. N. Silva-del-Río*[1], J. M. Heguy[2], and A. Lago[3], [1]*University of California Cooperative Extension*, *Tulare County,* [2]*University of California Cooperative Extension*, *Stanislaus and San Joaquin Counties,* [3]*APC, Inc*, *Ankeny, IA*.

The aim of this study was to obtain information on current feed management practices for the high milk yield pens on California′s Central Valley dairies. In summer 2009, a feed management survey was mailed to dairy producers in Tulare, Stanislaus, and San Joaquin counties; the first, third, and seventh largest producing dairy counties in California, respectively. Producers received an envelope containing an invitation letter, a one-page survey, and a pre-paid return envelope. Response rate was 16.9% (120/710). Herd size ranged from 160 to 6,600 cows (median = 950). Dairies fed total mixed rations (TMR) once (28.8%), twice (64.0%), or 3 or more times daily (7.2%). Two dairies reported that TMR was fed 6 times per day. Feed was pushed daily between 1 and 4 times (47.7%), 5 and 8 times (42.4%), and 9 or more times (9.9%). Overall, 44.5% of the producers fed for refusals. Targeted refusals were: 2% or less (50.0%), 2 to 5% (34.0%), or more than 5% (16.0%). Refusals were fed to heifers on 79.6% of dairies. TMR particle length was evaluated in 57.2% of the dairies: weekly (19.2%), monthly (21.7%), and occasionally throughout the year (13.3%). In 2008, dairies reformulated the ration fed to high producing cows 1 to 3 times (30.1%), 4 to 6 times (28.8%), 7 to 9 times (6.8%), and 10 or more times (34.3%). Four dairies reported reformulating the ration at least 20 times. Thirty-nine dairies cited a single reason for ration reformulation: new forage analysis (n = 21), new feedstuff (n = 11), new DM results (n = 3), and price (n = 4). Most dairies (62.9%) indicated 2 or more reasons for reformulating diets. Feed management software is used in 39.3% of the dairies to track dry matter intake (n = 42), cost of errors by feeders (n = 36), cost of feed and ingredient order in the mixer (n = 33), feed delivery time (n = 24), and inventory (n = 23). Some dairies routinely evaluated feed efficiency (n = 53) and milk urea nitrogen (n = 31). Only 24 dairies reported having written feed management protocols. Although dairy owner and manager responses are subjective, survey results help us to identify areas where feed management can be improved, such as feed bunk management and record keeping.

Key Words: feeding management, survey, dairies

860 Relationship between environmental climate and physiologic response under stress conditions of dairy cows measured using thermal imaging in southeastern Sicily. G. Azzaro[1], R. Petriglieri[1], R. Ben Younes[2], M. Caccamo*[1], S. Carpino[1], G. Cascone[3], A. D'Emilio[3], R. Mazzarella[3], and G. Licitra[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*Production Animale, Institut National Agronomique de Tunisie*, *Tunisia*, [3]*DIA, Catania University*, *Catania, Italy*, [4]*DACPA, Catania University*, *Catania, Italy*.

The influence of heat stress and physiologic response of dairy cows on performance have been reported in several studies. This study was part of a wider experiment aiming to assess the influence of the combination of environmental climate and floor material on physiological and productive performance of dairy cows. Thirty lactating dairy cows (137 ± 60 DIM; 38.26 ± 6.8 Kg/d milk yield) in a Sicilian herd were grouped

based on milk yield level and lactation stage. Cows in each group were randomly assigned to 2-level treatment of floor (concrete vs rubber) in the alleys in the barn and observed from June through September 2009 under heat stress condition. During this period, temperature humidity index (THI) was measured every 30 min using a thermologger. The physiological response to heat stress was measured every 2 weeks at 3 p.m. in terms of rectal temperature (RT) and respiratory rate (RR). At the same time, temperature of the entire body surface (BS), muzzle (MS), eyes (ES), and rump (RS) were measured using digital infrared thermal imaging. To capture thermal images of the entire body surface, cows were constrained ahead a panel cooled with water. The entire body surface was automatically selected through binarization using ImageJ software, whereas rump, eyes, and muzzle areas were manually selected from pictures. Daily average THI was highly correlated with RT and RR (0.57 and 0.48, respectively), whereas the highest correlation was with BS and RS (0.79 and 0.71, respectively). Both MS and ES were not correlated. Moderate correlations were found between RT and RR with BS (0.47 and 0.45, respectively). Same results were found for RS. No correlation was found between RT and RR with MS, whereas ES had a low ($P < 0.05$) correlation. The high correlation found in this study between BS with environmental temperature and physiologic response of cows makes the thermal imaging method on the entire body surface a promising non-invasive technique to assess heat stress effect.

Key Words: heat stress, body temperature, thermal imaging

Production, Management and the Environment: Environment 2

865 Effects of heating broiler hatching eggs during 6 or 11 days of storage on hatchability. J. T. Brake*[1], M. Güçbilmez[2], S. Özlü[2], R. Shiranjang[2], and O. Elibol[2], [1]*North Carolina State University, Department of Poultry Science, Scott Hall, Raleigh,* [2]*Department of Animal Science, Faculty of Agriculture, University of Ankara, Ankara, Turkey*.

The effects of heating hatching eggs during pre-incubation storage was studied. Freshly collected hatching eggs from 2 young broiler breeder flocks were stored for 1 d in a hatchery egg storage room at 18C and 75% RH in paper egg flats. The eggs were then transferred to plastic setter trays and either remained in the storage room (Control) or were subjected to a heat treatment regimen of 26C for 2 h, 37.8C for 3 h, and 26C for 2 h in a Petersime setter at either 1 or 6 d of storage before being returned to the storage room. A portion of the eggs were heated when transferred to setter trays (Heat 1-6 d) and stored for 5 d more while a portion of the eggs were heated at transfer to setter trays and then stored for 10 d more (Heat 1-11 d). Another group of eggs was heated after 6 d of storage (Heat 6-11d) and then stored 5 d more before incubation. Control eggs stored for 6 d or 11 d were o-incubated in each experiment. The same process was repeated for Experiments 1 and 2 (29 and 28-wk-old breeders, respectively). All eggs were set in a single incubator. A tray of 150 eggs constituted a replicate and 6 or 12 replicate trays (900 or 1800 eggs in total) were set per heating treatment in Experiments 1 and 2, respectively. Data for 6 d and 11 d of storage were subjected to a one-way ANOVA separately where storage treatments were compared to heating treatments. The hatchability of fertile eggs decreased ($P < 0.05$) with length of egg storage in both experiments due to increased ($P < 0.05$) early deads (Exp. 1 and 2) and late deads (Exp. 2). There was no benefit of heating eggs during 6 d of storage (Heat 1-6d) but hatchability of fertile eggs stored for 11 d was increased ($P < 0.05$) by heating at either 1 (Heat 1-11d; 89.2%) or 6 d (Heat 6-11d; 92.4%) of storage as compared to control (83.8%). The heating at 6d of the 11 d storage period produced the numerically best results in both experiments. These data demonstrated that heating eggs before and/or during storage for 11 d reduced early embryonic mortality and increased fertile hatchability of eggs from younger broiler breeder flocks.

Key Words: egg storage incubation, egg storage, egg storage time

866 Assessment of microbial communities involved in decomposition of specified risk material using a passively aerated laboratory-scale composter. S. Xu*[1,2], T. A. McAllister[2], J. J. Leonard[1], and O. G. Clark[3], [1]*University of Alberta, Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada*, [3]*McGill University, Ste-Anne-de-Bellevue, QC, Canada*.

The occurrence of bovine spongiform encephalopathy (BSE) in Canada has resulted in the implementation of regulations to remove specified risk material (SRM) from the food chain. Composting may be a viable alternative to rendering for SRM disposal. A study was conducted to assess SRM decomposition during composting, as well as the microbial communities involved. Two matrices (beef manure + barley straw or beef manure + wood shavings) were composted in 6 passively aerated, laboratory-scale composters (n = 3 per matrix) with SRM samples and thermocouples implanted at 3 depths. Data were analyzed using the Mixed procedure of SAS, with time and compost depth treated as repeated measures. Both compost types heated rapidly, exceeding 55°C after 3 d, with oxygen concentration remaining over 16% on 12 out of 15 d. At completion, wood shavings compost had higher water ($P < 0.001$) and total carbon ($P = 0.005$) contents and lower electrical conductivity ($P < 0.001$) as compared with straw compost. Approximately 50% of SRM was decomposed after 15 d of composting, with 30% of this occurring within the first 5 d. Phospholipid fatty acid (PLFA) analysis revealed that gram-positive bacteria were predominant in compost at d 5. Gram-negative bacteria had declined by d 5 but recovered by d 15. Fungi appeared to be suppressed at temperatures above 55°C and did not appear to recover in wood shavings compost. At d 5, Actinomycetes had increased in straw compost, but declined in wood shavings compost. By d 15, they had increased in both compost types. Although temporal changes were evident, compost matrices or depth within the composter did not obviously influence microbial communities or SRM decomposition. These results suggest that SRM decompose rapidly during composting and that both mesophilic and thermophilic microbial communities play a role in this decomposition.

Key Words: bovine spongiform encephalopathy, composting, phospholipid fatty acid analysis

867 Effect of improved production efficiency on pork's carbon footprint: Derived environmental benefits of ractopamine in the US swine herd. G. Boyd*[1], D. Anderson[2], A. Sutton[3], C. Hogan[1], and A. Marks-Callahan[4], [1]*Camco, Broomfield, CO,* [2]*Colorado State University, Fort Collins,* [3]*Purdue University, West Lafayette, IN,* [4]*Elanco Animal Health, Greenfield, IN*.

Increasing production efficiency in swine can improve environmental stewardship. Ractopamine (RAC; Paylean) is an approved feed ingredient that enhances feed efficiency, increases growth rate and increases leanness in finishing swine. Assumptions driving derived environmental benefits are that (1) increased leanness of RAC-fed pigs results in fewer animals needed to produce the same amount of pork protein, and (2) improved feed conversion leads to lower land requirement for feed production thereby decreasing resource, energy, and fuel demands. These changes, in addition to a reduction in manure output, lower greenhouse gas (GHG) emissions. The objective was to quantify these annual savings in metric tons of CO_2-equivalents (tCO_2e). The derived environmental benefits associated with RAC were quantified using a published meta-analysis of RAC growth performance response and 2008 US swine production data, assuming that all finishing pig diets in the US included either 5 or 10 mg RAC/kg feed for the last 28 d. Total GHG emission savings were quantified using emission factors for energy and fossil fuel demands associated with the cradle-to-gate portion of the pork production chain. Results of the calculations are as follows: The number of finisher pigs and sows required to produce the same amount of pork protein was reduced by 5.3% and 6.3% with the inclusion of 5 or 10 mg RAC/kg feed, respectively. Days-to-market were reduced by 3.0 and 2.8, respectively. Derived GHG emissions savings were 1.87 million or 2.23 million tCO_2e/yr, respectively with approximately 63% from reduced manure, 32% from reduced feed production, and 4% from pig housing. The GHG emissions due to RAC manufacture and distribution accounted for less than 0.01% of the calculated savings. Use of 5 or 10 mg RAC/kg feed in finisher pig diets for the last 28 d of feeding significantly aids in mitigating GHG emissions from pork operations.

Key Words: production, environment, swine

868 Analysis of the association of number of piglets born alive with sow level and management factors. S. S. Anil*[1], L. Anil[2], J. Deen[1], S. K. Baidoo[2], M. E. Wilson[3], and T. L. Ward[3], [1]*Veterinary Population*

Medicine, University of Minnesota, *St Paul,* [2]*Southern Research and Outreach Center, University of Minnesota*, *Waseca,* [3]*Zinpro Corporation*, *Eden Prairie, MN*.

Genetics, management and nutritional factors influence the production performance of breeding female pigs. Trace minerals are important to maintain high production performance and claw integrity. The bioavailability of trace minerals depends on both the quantity and form (organic or inorganic). This study analyzed the association of small litter size at birth (≤10 vs. > 10 piglets born alive) with factors of parity, mummies, stillborn, housing system, form of trace mineral supplementation and claw lesions (white line and side wall defects), using multivariate logistic regression model (Proc logistic, SAS v 9.1), using 1010 parity records. These records pertained to 1, 2 or 3 parities of 518 sows of mixed parity, housed in group pens with electronic sow feeders (n = 296) and conventional gestation stalls (n = 222). The sows were randomly allocated to 2 groups and fed either a control diet (ITM, inorganic sulfate minerals, n = 257; Zn −125 ppm, Mn - 40 ppm and Cu - 15 ppm) or a treatment diet containing complex trace minerals as a partial substitution of inorganic minerals (CTM, n = 261; Zn - 50 ppm, Mn −20 ppm and Cu - 10 ppm), fed at isolevels of total trace mineral supplementation. Information on farrowing performance was collected from the PigCHAMP database of the research unit. Claw lesions of these sows were assessed at mid-gestation by the same person in 1, 2 or 3 parities. Results indicated that the likelihood of <10 live born piglets was lower ($P < 0.05$) in sows of parities 1 and 2 (OR 0.39) and in sows of parities 3–5 (OR 0.29) compared with sows of parity > 5. Mummies and preweaning mortality were positively and total sidewall lesion was negatively associated with the likelihood of having <10 live born piglets ($P < 0.05$ for all). Sows receiving the diet containing ITM were 40% more ($P < 0.05$) likely to have < 10 live born piglets compared with sows fed CTM. These results are indicative of the relationship between sow level and nutritional factors with litter size at birth.

Key Words: trace mineral supplementation, production, sow

869 Nutritional evaluation of kernel meal from non-toxic genotype and of detoxified kernel meal from toxic genotype of *Jatropha curcas* in rat. Y. Chen[1], J. X. Liu[1], H. Y. Liu*[1], H. P. S. Makkar[2], and K. Becker[2], [1]*Institute of Dairy Science, Zhejiang University*, *Hangzhou 310029, P.R. China*, [2]*Institute for Animal Production in the Tropics and Subtropics (480b), University of Hohenheim*, *Stuttgart 70593, Germany*.

Two genotypes of *Jatropha curcas* are known, toxic and non-toxic. Phorbol esters are main toxic substances in the seeds of the toxic genotype. *Jatropha* kernel meal after oil extraction is rich in protein (50–62%), and contents of essential amino acids except lysine are comparable to that of soybean meal. After removing phorbol esters and heat-labile antinutrients such as lectins, the meal could be used as a source of protein for animal feeding. Twenty-four male Sprague-Dawley (SD) rats, at an age of 21 d and weighting on average 70 g, were used to evaluate the nutritional value of the kernel meals from the non-toxic genotype and the toxic genotype after detoxification. Four dietary treatments were designed for growth and nitrogen balance trials. Protein-free basal diet consisted of following ingredients (%): cornstarch 80, oil 10, cellulose 5, salt 4 and multivitamin complex 1. In the other 3 diets, part of cornstarch was replaced by casein (CAS), heated meal from the non-toxic genotype (NTM), and detoxified *Jatropha* meal (DTM) at 10% crude protein in diets. Amino acid composition was similar among diets CAS, NTM and DTM. All data were analyzed using the GLM procedure of SAS software system with rat as the repeated subject. No significant difference was observed ($P > 0.05$) in feed intake of rats fed DTM and NTM (300 vs. 343 g) diets, but both intakes were significantly lower than that of rats on diet CAS (406 g). Weight gains of rats fed diets DTM (43 g) and NTM (62 g) were also significantly lower than that of rats on CAS (133 g). Protein efficiency ratio was 3.08, 1.35 and 1.78; and protein retention efficiency was 74.0, 37.8 and 45.1% for diets CAS, DTM and NTM, respectively. True digestibility and biological value of diet NTM were 84.5 and 65.6%, respectively, slightly higher ($P > 0.05$) than those of DTM (81.9 and 61.6%). In summary, the inferior growth rate in both diets containing NTM and DTM is attributed to low intake, while their digestibility and biological value are comparable to those of most of the seed meals.

Key Words: *Jatropha* kernel meal, toxicity, biological assay

Ruminant Nutrition: Dairy: Fats and Carbohydrates

870 Insulin signal transduction in adipose tissue of peripartal dairy cows fed two levels of dietary energy prepartum. P. Ji*, J. S. Osorio, J. K. Drackley, and J. J. Loor, *University of Illinois*, *Urbana*.

Homeorhesis plays a major role in controlling nutrient partitioning from late prepartum through early lactation during which the fetus or mammary gland are the main targets of energy flow. Coincidently, the responsiveness of peripheral tissues such as adipose to insulin is diminished during early lactation. However, it remains unclear if prepartal dietary energy level affects adipose tissue responsiveness and what molecular mechanisms might be involved. To test the adipose responsiveness to insulin in late gestation, subcutaneous adipose tissue was biopsied at −10 and 7 d relative to parturition from dairy cows fed controlled energy (high straw, CE; NEL = 1.30 Mcal/kg) or moderate-energy (ME; NEL = 1.49 Mcal/kg) diets during the close-up period. Adipose tissue explants were initially incubated in DMEM medium at 37°C with 5% CO2 for 30 min as an adaptation period. Explants serving as negative controls were removed after adaptation. Remaining explants were transferred to wells containing fresh DMEM medium for a time-course (15, 30, or 60 min) insulin challenge (1 μg/L). Total cellular protein was isolated from duplicate explant cultures (both control and challenged) for quantification of tyrosine phosphorylation of IRS1 (IRS1-pY) and Thr308-phosphorylation of Akt (Akt-pThr308). IRS1-pY residue serves as the docking site for the SH2 domain of the protein, which mediates signal transduction of insulin; Akt is phosphorylated and activated in the Thr308 motif and plays a pivotal role in the PI3K pathway that is activated upon insulin stimulation. Total IRS1 phosphorylation was used to normalize the IRS1-pY data. Preliminary results revealed significant main effects of dietary energy level ($P < 0.01$) and incubation time ($P < 0.01$). IRS1-pY phosphorylation was higher in tissue from cows fed ME vs. CE after 15 min and 60 min, leading to a diet × time effect ($P < 0.05$). In tissue from cows fed CE, the response to insulin peaked at 30 min after challenge. Overall, results indicated that level of dietary energy affected the sensitivity of adipose tissue to exogenous insulin in vitro.

Key Words: Insulin response, IRS1, peripartal dairy cow

871 Duodenal infusion of α-linolenic acid affect fatty acids metabolism in mammary gland of lactating dairy cows. G. Yang, J. Q. Wang*, D. P. Bu, Khas-Erdene, Q. S. Liu, L. Y. Zhou, P. Sun, and K. L. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, P. R. China*.

Increasing the α-linolenic acid (LNA; 18:3 *cis*-9, *cis*-12, *cis*-15) plasma concentration might affect fatty acids (FA) metabolism in the mammary gland. Objective was to determine the effects different arterial concentration of 18:3 *cis*-9, *cis*-12, *cis*-15 (18:3n-3) would have on mammary uptake and synthesis of FA in lactating dairy cows duodenally infused with LNA, via arterial-rectificative venous concentration (AC-RVC) differences and mammary gland balance. Four primiparous lactating Chinese Holstein cows fitted with duodenal cannula were administered 2 treatments in a crossover design: rich-LNA fatty acid infusion at varying concentrations (0, 100, 200, 300, and 400 g/d) vs. basal infusate control. Arterial concentration of 18:3n-3 quadratically increased (29.24, 134.1, 218.3, 219.3, and 216.4 mg/L plasma) as LNA infusion levels increased from 0 to 400 g/d. The mammary extraction rate and uptake of 18:3n-3 was linearly increased as LNA infusion increased. The AC-RVC differences of 18:3n-3 and total FA increased more rapidly than arterial concentrations with all treatments. Increasing LNA infusion linearly increased the balances of 10:0 and 12:0, while linearly decreased the 14:1 and 15:0 balances, which suggested an inhibitory effect on termination process with 12 carbon during FA synthesis in mammary gland. Increasing arterial concentration of 18:3n-3 affects uptake and synthesis of FA in the mammary gland of lactating dairy cows. It is also suggested that the use of arterial-rectificative venous concentration differences maybe an acceptable way to investigate mammary gland metabolism of FA.

Key Words: α-linolenic acid, mammary gland metabolism, dairy cows

872 Effects of different rumen inert fatty acids on fermentation, anti-oxidative status, and microbiota in the rumen, in the absence or presence of dietary antioxidant. Y. M. Wang[1], J. H. Wang[1], C. Wang*[1], J. X. Liu[1], H. Cao[2], F. C. Guo[2], and M. Vázquez-Añón[3], [1]*Institute of Dairy Science, Zhejiang University*, *Hangzhou 310029, P.R China*, [2]*Novus International Research Center*, *Beijing 100085, P. R. China*, [3]*Novus International, Inc.*, *St. Louis, MO 63147, USA*.

In vitro gas test was employed to evaluate the effect of fatty acids of different degrees of saturation on rumen fermentation of sheep in vitro, in the absence or presence of dietary antioxidant (AOX; Agrado plus, Novus International). The experiment was carried out in a 2 × 2 factorial design, with fatty acid type (at 0 and 50% saturation) as one factor and AOX (0 or 500 mg/kg) as another one. Calcium salt of long-chain fatty acids (50% unsaturated fatty acids, UFA) was supplemented as a source of UFA, and palm acid was supplemented as the source of saturated fatty acid (SFA). Substrate consisted of 100 mg corn powder and 100 mg Chinese wild ryegrass hay. Fermentation patterns and anti-oxidative status were not affected by fatty acid type. Inclusion of UFA significantly increased the populations of protozoa relative to total bacterial 16S rDNA, but showed negative effect on *Fibrobacter succinogenes*. Addition of AOX significantly increased gas production and organic matter digestion at 24h incubation. Molar proportion of propionate tended to increase at the expense of acetate due to AOX addition. Addition of AOX tended to decrease malondialdehyde value and increase superoxide dismutase activity. An interaction between AOX and fatty acid type was observed on *Ruminococcus flavefaciens* and *R. albus*. Addition of AOX to UFA-treated substrate significantly increased these 2 bacteria, but not in SFA treatment. In summary, supplementation of UFA results in inferior effect on fiber-digesting bacteria, while this negative effect can be alleviated by AOX addition, but not in SFA treatment. Rumen fermentation and anti-oxidative status tended to be improved by AOX addition, regardless of the fatty acid type.

Key Words: fatty acid type, antioxidant, rumen fermentation

873 Incorporation of essential and non-essential fatty acid into distinct lipid classes in cultured bovine and porcine liver slices. C. Caldari-Torres*, A. J. Lengi, M. L. McGilliard, D. M. Shepherd, J. A. Stamey, and B. A. Corl, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Ruminants, compared with non-ruminants, segregate fatty acids into specific lipid classes, allowing for essential fatty acid (EFA) conservation. The mechanisms involved in this selective esterification of fatty acids (FA) remain undefined. The aim of this study was to examine FA esterification patterns in ruminant and non-ruminant liver slices. We performed in vitro culture of bovine and porcine liver slices with radiolabeled FA to track esterification of EFA and non-EFA into lipid

classes. Liver slices were incubated in media containing radiolabeled non-EFA ([1-^{14}C]16:0 or [1-^{14}C]C18:1), or EFA ([1-^{14}C]C18:2 or [1-^{14}C] C18:3). In a preliminary study C18:1 incorporation by bovine liver slices increased linearly with time ($R^2 = 0.95$, $P < 0.001$) and tissue weight ($R^2 = 0.96$, $P < 0.001$). Mean FA incorporation was higher for porcine than for bovine liver slices (23.9 versus 15.9 ± 1.8 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.03$). Liver cultures of both pig and cattle incorporated non-EFA more readily than EFA (22.9 vs 16.9 ± 1.6 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P < 0.001$). Pigs esterified a higher proportion of FA into triglycerides (TG) than phospholipids (PL) (3.7 vs. 2.2 ± 0.3 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P < 0.001$). Cattle did not exhibit preferential esterification of FA into either lipid class, but esterified more non-EFA into TG compared with PL (1.3 vs. 0.9 ± 0.3 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.002$). A higher proportion of EFA than non-EFA was incorporated into PL by cultured bovine liver slices (1.4 vs. 0.9 ± 0.3 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.02$). There were no differences in esterification patterns of EFA and non-EFA into the TG lipid class of cattle, or the PL or TG lipid classes of pigs. An increase in PL/TG ratio was observed when bovine liver slices were cultured with EFA, compared with non-EFA (1.09 vs. 0.69 ± 0.1 nmol•2 h^{-1}•150 mg $tissue^{-1}$, $P = 0.001$). There was no difference in PL/TG ratio in porcine liver slices cultured with EFA or non-EFA. Results suggest that liver esterification patterns of cattle and pigs differ, with esterification patterns of ruminants possibly facilitating greater EFA esterification into PL.

Key Words: fatty acid, liver, cattle

874 Effects of feeding increasing levels of concentrate on milk fatty acid composition in grazing dairy cows. L. Antonacci[1], G. A. Gagliostro*[1], V. I. Cejas[2], and M. A. Rodriguez[2], [1]*Instituto Nacional de Tecnología Agropecuaria (INTA)*, *Balcarce, Provincia de Buenos Aires, Argentina*, [2]*Instituto Nacional de Tecnología Industrial (INTI)*, *San Martín, Buenos Aires, Argentina*.

Increased intake of concentrate may shift rumen biohydrogenation of C18:3 and C18:2 fatty acids (FA) toward 10t C18:1 reducing the t11 C18:1 (VA) and 9c, 11t C18:2 (CLA) contents in milk. Twelve Holstein cows grazing spring pastures (alfalfa 70%, orchardgrass 30%) were blocked by days in milk (DIM) and randomly assigned to 3 treatments in a replicated Latin square. At the start of the experiment the 6 cows from square 1 (514 kg LW) were producing 28.2 kg milk/d and averaged 35 DIM. In Square 2, LW, milk yield and DIM were 554 kg, 31.3 kg/d and 197 d respectively. Periods lasted 19 d., the first 14 d as adaptation and the last 5 d for sampling period. Treatments (C3, C6, and C9) were 3 levels (3, 6, and 9 kg/d) of concentrate (90.4% DM) containing (g/kg DM) CP (160), starch (351), soluble carbohydrates (149), ether extract (39.7) and NDF (248). Supplements were thoroughly consumed by cows. Data were analyzed with effect of square, period, cow within square; treatment, interaction between period and treatment (NS) and residual error. Cows from C9 produced more milk (27.5 vs. 23.6 kg/d) and protein (885 vs. 735 g/d) compared with C3 ($P < 0.05$) without depressing milk fat content (29.9 g/kg) or pasture intake (11.94 kg DM/cow/d) ($P < 0.69$). Concentration (g/100g FA) of de novo (C4:0-C15:1, 21.78), preformed (>17:0, 48.2), saturated (59,41) or unsaturated (40.34) FAs were not affected whereas that of t10 C18:1 resulted lower ($P < 0.03$) in C9 (0.52) compared with C6 (0.59) and C3 (0.58). Milk fat content (g/100g FA) of VA (3.23; 3.76 and 3.72) and CLA (1.93; 2.01 and 1.92) resulted high in all treatments (C3, C6 and C9) and not affected by concentrate intake ($P > 0.24$). The atherogenicity index of milk fat averaged 1.84 (±0.12) across treatments ($P > 0.77$). When pasture represented from 82 to 58% of total DM intake of cows increasing concentrate intake from 3 to 9 kg/cow/d had only minor effects on t10 C18:1 concentration in milk without depressing VA and CLA contents.

Key Words: grazing dairy cows, concentrate levels, milk fatty acid

875 Effects of dietary fat supplements and forage:concentrate on feed intake, feeding and chewing behavior of Holstein dairy cows. S. Kargar, M. Khorvash, M. Alikhani, and G. R. Ghorbani*, *Isfahan University of Technology*, *Isfahan, Iran*.

Hydrogenated palm oil and yellow grease as saturated and unsaturated fat supplements, respectively, were investigated for effects on feed intake, diurnal fluctuation of eating and ruminating, meal patterns, and chewing behavior. Eight multiparous Holstein dairy cows were used in a replicated 4 × 4 Latin square experiment with 21 d periods. Treatments were 1) no supplemental fat and 34:66 forage:concentrate (F:C) ratio (Control), 2) 2% hydrogenated palm oil and 34:66 F:C ratio (HPO), 3) 2% yellow grease and 34:66 F:C ratio (YG), and 4) 2% yellow grease and 45:55 F:C ratio (YGHF). All data were analyzed using the MIXED procedure of SAS (SAS, 2003). Preplanned statistical contrasts were used to test the effect of fat supplementation (Control vs. HPO + YG); the effect of source of fat supplement (HPO vs. YG); and the effect of forage to concentrate ratio within diets supplemented with yellow grease (YG vs. YGHF). Dry matter intake (DMI) was not affected by fat supplementation regardless of type of fat (27.0 ± 1.11; $P = 0.81$), but cows fed diets with larger F:C ratio ate 7.5% less (25.3 vs. 27.2 ± 1.11; $P \leq 0.002$) . There were no treatment effects on meal patterns by fat supplementation (15.0 ± 0.9; $P = 0.76$), source of fat (15.0 ± 0.9; $P = 0.26$), and F:C ratio (16.0 ± 0.9; $P = 0.41$) but intermeal interval (69.0 ± 4.8; $P \leq 0.04$), eating rate (0.074 ± 0.004; $P \leq 0.03$), and meal size (1.76 ± 0.12; $P \leq 0.001$) were lower in cows fed yellow grease and eating rate was less for the diet with greater NDF content (0.064 ± 0.004; $P \leq 0.001$). Total chewing time (minutes per kilogram of DMI) was not affected by fat feeding (29.9 ± 1.6; $P = 0.85$) nor type of fat supplementation (29.9 vs. 29.8 ± 1.6; $P = 0.93$) but was more for the diet with greater F:C ratio and NDF content (34 ± 1.6; $P \leq 0.01$). In the current study, DMI was not decreased while meal size decreased. Our findings agree with the conclusion that chewing activity might be determined largely by dietary forage NDF content.

Key Words: chewing behavior, forage to concentrate ratio, fat

876 Effects of rapidly rumen fermentable source of starch in prepartum diet on metabolism and performance of multiparous Holstein cows during the periparturient period. H. R. M. Alamouti*[1], H. Amanlou[1], and K. Rezayazdi[2], [1]*University of Zanjan*, *Zanjan, Iran*, [2]*University of Tehran*, *Karaj, Tehran, Iran*.

Thirty-four multiparous Holstein cows were used in a completely randomized design and assigned to 1 of 2 treatments to evaluate the effects of 2 diets varying in ruminal fermentable source of starch, namely ground corn (GC) and rolled wheat (RW), on metabolism and performance of multiparous cows in the periparturient period. The cows were fed diets as a total mixed ration (TMR) with similar energy and crude protein content including 1) 185.7g/kg GC, or 2) 185.7g/kg RW from −22.10 ± 7.1 d relative to expected calving until calving. After calving, all cows received the same lactation diet until 28 d. Cows were group fed from the beginning of the study to −7 d relative to expected calving, fed individually from d −7 to 7 d in milk (DIM), and again group fed to 28 DIM. Dry matter intake (DMI), energy intake, energy balance (EB) and body condition score (BCS) were not different between treatments. The pre-partum diets affected ($P < 0.05$) urinary pH during the last week pre-partum. The RW diet increased ruminal propionate concentration

compared with the GC diet in periparturient period. There was no effect of pre-partum starch source on overall plasma concentration of glucose, nonesterified fatty acid (NEFA), β-hydroxybutyrate (BHBA), albumin, triglyceride (TG), cholesterol, aspartate aminotransferase (AST), insulin, and cortisol during the periparturient period. Cows fed the RW diet during the pre-partum period had greater calcium during 28 d ($P = 0.09$) of lactation compared with cows fed the GC diet. Multiparous cows fed the RW diet produced greater milk protein content ($P = 0.08$). Multiparous cows fed the RW diet had lower milk urea nitrogen (MUN) than cows fed the GC diet ($P < 0.05$). The results of this study show that a rapidly fermentable source of starch (wheat grain) can be included in pre-partum diets without compromising dairy cow metabolism and performance and can smooth the transition of multiparous Holstein cows from gestation to lactation.

Key Words: periparturient period, rapidly fermentable carbohydrates, Holstein cows

877 Effects of cereal grain level in early lactating diets on metabolism and performance of Holstein cows. H. amanlou[1], N. Fazli[1], S. S. Mosavi[1], H. R. Mirzaei Alamouti*[1], and M. Moeini[2], [1]*University of Zanjan*, *Zanjan, Iran*, [2]*Abhar Islamic Azad University*, *Zanjan, Abhar, Iran*.

Acidosis is a major constraint in consumption of cereal grains (CG) in early lactating Holstein dairy cows diet. The objective of this study was to determine effects of CG (corn + barley mix) levels in early lactating cows diet on dry matter intake (DMI), milk yield and contents, chewing activity, apparent dry matter digestibility and plasma metabolites concentration. Sixteen multiparous Holstein cow, body weight (BW), 605 ± 25.82 kg and body condition score (BCS), 3.09 ± 0.06, were used in a completely randomized design and assigned to 3 diets; 1) 31% CG and 38% nonfiber carbohydrate (NFC), 2) 25.5% CG and 35.5% NFC and 3) 20% CG and 33% NFC. Cows were individually fed the total mixed ration with similar net energy for lactation (1.7 Mcal/kg) and crude protein (19.2%) from 20 ± 2.2 d in milk during 6 week. Milk yield and content were determined 3 times per day. Daily DMI and weekly nutrient intake were determined. Blood was sampled into heparinized tubes from the coccygeal vein at the beginning and final day of the study and plasma metabolites were measured. Data were analyzed using MIXED Procedure from SAS and cows nested in the diets were as random effects. Different variance-covariance error structures were tested. No significant differences observed between the diets in DMI, BCS, BW and apparent dry matter digestibility. Cows fed the diet 3 had lower ($P < 0.01$) chewing activity than the others diets. Milk yield; 31.4, 36.2 and 39.4, milk fat percentage; 3.7, 3.09 and 3.46, for the diets 1, 2 and 3, respectively, and milk fat and lactose yield were significantly ($P < 0.05$) different between the diets. Plasma glucose concentration was lower ($P < 0.05$) in cows fed the diet 3 than the diets 1 and 2 (58.34 vs. 66.6 and 65.8 mg/dL). Plasma concentration of calcium, phosphorous, total protein, albumin and nonesterified fatty acids were not different. In summery, this study showed that cereal grains can be replaced with byproduct feeds high in digestible fiber in early lactating dairy cow diets without compromising lactation performance and metabolism.

Key Words: early lactation, cereal grain, Holstein cow

878 Effects of dietary chromium propionate on glucose metabolism and insulin sensitivity in growing cattle. J. W. Spears*[1], C. S. Whisnant[1], G. B. Huntington[1], K. E. Lloyd[1], K. Krafka[2], and A. Lamptey[2], [1]*North Carolina State University*, *Raleigh,* [2]*Kemin AgriFoods North America, Inc.*, *Des Moines, IA*.

Thirty-six Angus and Angus × Simmental heifers, averaging 291 kg, were used to determine the effects of dietary Cr (as Cr propionate) on glucose metabolism and serum insulin concentrations following glucose administration. Heifers were stratified by weight within a breed and randomly assigned to treatments. Treatments consisted of 0, 3, 6, or 9 mg supplemental Cr/d from Cr propionate. Based on DMI the daily doses of Cr were equivalent to 0.47, 0.94, and 1.42 mg supplemental Cr/kg DM. Heifers were individually fed a corn-silage based diet at a level of 2% of BW. Each heifer was also fed 0.45 kg of a ground corn supplement daily that served as a carrier for supplemental Cr. Glucose tolerance tests were performed on d 44 of the study. Glucose was infused via jugular catheters at a level of 0.45 g/kg $BW^{0.75}$ over a course of 1 to 2 min. Blood samples were collected at −10, 0, 5, 10, 15, 30, 45, 60, 90, 120, 150, and 180 min relative to glucose dosing for glucose and insulin determination. Area under the glucose response curve was lower (1603 vs. 1964 mg.dL/min; $P = 0.03$) in heifers supplemented with Cr from 0 to 45 min following glucose challenge. Serum insulin concentrations were lower ($P < 0.01$) in Cr-supplemented heifers than in controls following glucose infusion. The molar ratio of insulin to glucose was affected by treatment ($P = 0.02$), being higher in controls, and time ($P = 0.01$). Serum insulin and serum insulin to glucose ratios did not differ among heifers supplemented with 3, 6, or 9 mg Cr/d. Results indicate that Cr propionate supplementation increased tissue sensitivity to insulin in growing heifers. Based on insulin sensitivity, Cr requirements of growing heifers do not exceed 3 mg Cr/d or 0.47 mg Cr/kg DM.

Key Words: chromium, cattle, insulin

879 The effect of rumen-protected choline on milk yield and composition of Holstein dairy cows. M. Ardalan*, M. Dehghan-Banadaky, and K. Rezayazdi, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*, *Karaj, Iran*.

Forty Holstein dairy cows in their first and second lactation were used in a lactation study from 4-week prepartum through 10-week postpartum to investigate the effect of feeding ruminally protected source of choline on productive performance of Holstein dairy cows. Cows (20 cows per treatment = 12 cows in 1st lactation and 8 cows in 2nd lactation) were housed in individual tie stalls. Animals were randomly assigned to receive one of the following treatments, using block randomization based on parity: 60 g/d of rumen-protected choline product (RPC) or without supplement (control). The repeated measurements of milk yield and composition were analyzed as a linear mixed model (Proc Mixed) with the best fitted covariance structure of SAS. The statistical model included the fixed effects of treatment, parity, time (week of lactation), treatment × time, and the random effect of cow within treatment and parity. The error covariance structure used for the repeated measures was the first-order heterogeneous autoregressive structure. The treatments significantly affected actual milk yield, 4% fat-corrected milk (FCM), and energy-corrected milk (ECM) across lactation weeks ($P < 0.05$). The actual milk yield, FCM, and ECM were greater for RPC-fed cows than control group ($P < 0.05$). The treatments had significant effect on protein percentage of milk and RPC-fed cows had greater percentage of milk protein than controls ($P < 0.05$). Treatments significantly affected lactose percentage of milk across lactation weeks and RPC-fed cows had greater amount than control cows ($P < 0.05$). The treatments did not significantly affect milk percentages of total solids (TS) and solids-not-fat (SNF). The supplementation of RPC resulted in an increase in milk urea nitrogen ($P < 0.05$). Results indicated that the supplementation of RPC can improve the lactation performance of dairy cows.

Key Words: rumen-protected choline, lactation performance, milk yield

880 Impact of biotin on production performance of lactating dairy cows: A meta-analysis. B. Chen* and J. X. Liu, *Institute of Dairy Science, Zhejiang University*, *Hangzhou 310029, P. R. China*.

A meta-analysis of the impact of biotin on production outcomes of dairy cattle was conducted following a search of the literature. Studies included in the data file met all the following criteria to improve the accuracy of the analysis: (1) publications were in English and Chinese; (2) the populations studied were lactating dairy cows; (3) the details on production outcomes were provided enough for analysis of biotin effect; and (4) addition level of biotin was at 0.96 mg/kg DM or 20 mg/d. Since the strict criteria of literature selection, only 11 studies were identified with 7 containing production data. Data for each trial were extracted and analyzed using meta-analysis software in Stata. Subsequently, meta-regression was used to investigate sources of heterogeneity of response, and Sub-group meta-analysis to get the conclusion. Estimated effect sizes of biotin were calculated on DMI, milk production, milk fat percent, and milk protein percent. Biotin had positive effect on the DMI, but the effect was influenced by DMI per body weight (BW). When the DMI was higher than 3.3% of BW, the biotin significantly improved DMI; however, the experiments with the DMI lower than 3.3% of BW was so few that they could not be used to draw a conclusion. Biotin had the effect on milk production, but the heterogeneity test I^2 was equal to 89.7%, indicating that this effect was not consistent. The meta-regression revealed that the effect of biotin on the milk production was significantly associated with the productive capacity of animals ($P = 0.013$). The sub-group analysis of dairy cattle with milk yield higher than 35kg/d indicated that biotin could improve milk performance of high-yielding animals, but the heterogeneity was also high ($I^2 = 78.3\%$). The effect size test of the dairy cattle with low yield ($P = 0.28$) did not exhibit the statistical significance. There is no effect of biotin on the milk fat percent ($P = 0.27$) and milk protein percent ($P = 0.80$).

Key Words: biotin, milk production, lactating dairy cow

881 Effects of acidified by-products and pre-partum DCAD on serum calcium, post-partum health and performance when fed to prepartum transition dairy cows. D. J. Rezac*[1], E. Block[2], D. Weber[2], M. J. Brouk[1], and B. J. Bradford[1], [1]*Kansas State University*, *Manhattan,* [2]*Arm & Hammer Animal Nutrition*, *Princeton, NJ*.

Two products designed to deliver supplemental anions were evaluated for their effects on total serum calcium, postpartum health events, DMI, and performance of transition dairy cows relative to a control diet that did not contain supplemental anions. Diets differed in dietary cation-anion difference (DCAD) and anion source. Treatments were diets including BIO-CHLOR (BC, DCAD +2.5 mEq/100g DM; n = 14), SoyChlor (SC, DCAD −0.2 mEq/100g DM; n = 15), and control (CON, +18.8 mEq/100g DM; n = 13). Treatments began 21 d before expected calving

and continued through parturition; upon calving, all animals received the same diet. Milk yield was measured through 21 d in milk and milk samples were collected daily between 5 and 21 d in milk. Data were analyzed using mixed models with repeated measures. Prepartum DMI was 9.0, 8.5, and 7.5 kg/d for CON, BC, and SC treatments, respectively. Prepartum intake tended to be lower for SC than CON ($P = 0.09$), but postpartum intake and milk yield were similar among treatments. Milk protein, lactose, and urea nitrogen concentrations were highest for SC and lowest for BC with CON being intermediate ($P < 0.05$). Postpartum plasma glucose tended to be greater for cows fed CON vs. the anion supplemented diets ($P = 0.08$; 67, 57, and 64 mg/dL for CON, BC and SC, respectively). Serum calcium concentrations did not differ between dietary treatments and only tended to be different ($P = 0.07$) over time; values were not indicative of hypocalcemia. With limited sample size, no significant effects of treatment were detected for incidence of postpartum health disorders or plasma BHBA concentration. Although DMI tended to be depressed in the prepartum period by SC, this intake depression was not accompanied by negative effects on performance or health in the postpartum period. Results suggest that cows were not adequately stressed to cause hypocalcemia and/or DCAD values near 0 were insufficient to improve postpartum health and performance.

Key Words: dietary cation-anion difference, peripartum, hypocalcemia

883 Effect of feeding potassium carbonate on milk fatty acids in early lactation cows. J. H. Harrison*[1], R. L. Kincaid[1], E. Block[3], and T. Jenkins[2], [1]*Washington State University*, *Puyallup,* [2]*Clemson University*, *Clemson, SC,* [3]*Arm & Hammer Animal Nutrition*, *Princeton, NJ*.

Thirty Holstein cows (15 per treatment) were used in a continuous design lactation study to evaluate the effectiveness of potassium carbonate as a cation source to increase dietary DCAD from ~25 to 42 units, mEq/100g. The study was conducted from mid August to mid December 2007. Cows were fed individually via Calan feeding gates one of 2 treatment diets formulated to be equal in all nutrients except potassium. The formulated potassium level of the control diet was 1.2% of DM and increased to 2.0% of DM using potassium carbonate (DCAD Plus, Church & Dwight, Princeton, NJ) for the DCAD + treatment. Diets consisted of (% DM): alfalfa hay (13.4), corn silage (12.1), blue grass straw (8.6), corn distillers grains with solubles (10.3), whole cottonseed (6.2), and concentrate (49.4). Cows were assigned at random to one of the 2 dietary treatments at ~15 DIM and continued through ~105 DIM. Milk samples from 8 cows per treatment during wk 2, 5, and 9 of lactation were analyzed for individual fatty acids. Milk composition data were analyzed as a mixed model with the fixed effects of treatment, week, and their interactions, and the random effect of cows within treatment, using an AR(1) correlation structure for the errors.. Milk fat % and yield were significantly different ($P < 0.01$) between treatments (4.31% and 1.75 kg/d for DCAD+ and 3.96% and 1.55 kg/d for control). The added dietary potassium carbonate decreased unsaturated and trans fatty acids, and increased C18:0 in milk. The following milk fatty acids were significantly lower (% of total fat) in milk of cows receiving potassium carbonate: C16:1, t6, t8 C18:1, t10 C18:1, c9, t11 CLA. The concentration of C18:0 in milk fat was significantly greater at 14.2% for DCAD+ fed cows compared with 12.6% for control cows. The results indicate that added dietary potassium carbonate affects milk fat % and milk fatty acid profile in early lactation cows, and suggests a role of potassium at the rumen level in the process of bio-hydrogenation.

Key Words: milk fatty acids, milk fat, potassium carbonate

884 Effects of rumen-protected choline on performance and hepatic fat metabolism in periparturient dairy cattle. R. Zom[1], J. van Baal[1], M. J. de Veth[2], R. M. A. Goselink[1], H. C. A. Widjaja-Greefkes[1], J. A. Bakker[1], and A. M. van Vuuren*[1], [1]*Wageningen UR Livestock Research*, *Lelystad, the Netherlands*, [2]*Balchem Corporation*, *New Hampton, NY*.

The effects of rumen-protected choline (RPC) on feed intake, milk yield, milk composition and hepatic fat metabolism were evaluated in periparturient dairy cows. Multiparous cows (38) were blocked in pairs. Cows within each block were assigned at random to either RPC (60 g RPC/day; Reashure, Balchem Corp.) or control group (no RPC). Treatments were applied from 3 weeks antepartum until 6 weeks postpartum. Cows received ad libitum forage mixtures of corn silage, grass silage and straw (ante- and postpartum ration containing 12% and 15% CP and 5.5 and 6.5 MJ/kg DM NEL, respectively). Concentrates fed through concentrate feeders, were gradually increased from 0.6 kg/day (3 weeks antepartum) up to 2 kg at calving and up to 9.6 kg at 18 d postpartum. Feed intake and milk yield were recorded daily, and milk composition (fat, protein) was determined weekly. Liver biopsies were taken from 8 pairs of cows at 3 weeks ante- and 1, 3 and 6 week postpartum to measure hepatic TAG and mRNA expression levels of relevant genes by quantitative PCR, using β-Actin as housekeeping gene. Gene expression (relative to antepartum level) and TAG were tested by ANOVA; all other treatment effects were tested by mixed model analysis using the REML procedure. Feed intake and milk protein yield were significantly higher at the start of lactation for cows receiving RPC (P=0.03). No significant effect on milk production (average 40.8 kg/d) or milk composition (average 45 g fat and 33 g protein per kg milk) in the first 6 weeks of lactation were observed. RPC reduced hepatic TAG concentrations in week 1 (P=0.04) and week 3 (P=0.12) postpartum. RPC supplementation upregulated mRNA levels of transcription factor PPARδ (mediator of lipogenic genes) and counteracted the downregulation of organic cation/carnitine transporter SLC22A5/OCTN2 expression in liver. In addition, RPC decreased the expression of carnitine palmitoyltransferase 1A (involved in mitochondrial fatty acid uptake). These data suggest that the reduction in hepatic TAG concentrations when supplementing RPC coincides with an altered hepatic fatty acid metabolism.

Key Words: dairy cattle, choline, fatty liver

885 Dietary cation-anion difference for lactating dairy ewes. A. Schlageter, G. Caja*, M. Ben Khedim, A. A. K. Salama, S. Carné, and E. Albanell, *Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*.

A total of 40 ewes of 2 dairy breeds (Manchega, n = 20, Lacaune, n = 20) at mid lactation (84 ± 27 DIM) were used to determine the effects of diets differing in dietary cation-anion difference (DCAD) on their lactational and acid-base performances. DCAD (mEq/100 g DM) values were calculated as $(Na^+ + K^+) - (Cl^- + S^{2-})$. Ewes were allocated to 8 groups of 5 animals and blocked by breed, BW and milk yield (Manchega, 71.0 ± 7.7 kg BW and 0.59 ± 0.15 L/d; Lacaune, 69.2 ± 8.0 kg BW and 0.97 ± 0.17 L/d). Dietary treatments were applied for 10 wk and consisted of total mixed rations in which the DCAD value was modified from anionic to cationic values being: 7, 26, 45 or 64 mEq/100 g DM. Individual dry matter intake (DMI) was measured at wk 5 and 10 using polyethylene glycol (PEG 6000) as indigestible external marker. Milk yield and milk composition were recorded weekly and biweekly, respectively. Jugular blood samples for acid-base balance were taken and analyzed at wk 4, 8 and 10. The DMI and DMI/kg $BW^{0.75}$ showed linear ($P < 0.005$) and quadratic ($R^2 = 0.96$ to 0.99, $P < 0.01$) responses by effect of DCAD. Maximum intake was calculated between 40 and

45 mEq/100 g DM. Milk yield showed a positive linear response (R^2 = 0.78 to 0.80, $P < 0.05$) to DCAD but ECM did not vary. There were no significant effects of treatment in milk composition. Moreover, we observed differences in acid-base blood indicators according to diet and breed. Manchega ewes showed a neutral stage, while Lacaune ewes passed from metabolic acidosis (anionic treatments) to a neutral stage (cationic treatments). Urine pH showed a linear response ($P < 0.001$) by effect of DCAD and was a representative indicator of the DCAD values in the ration. Blood Cl^- and K^+ showed linear ($P < 0.001$) and quadratic ($P < 0.05$) responses by effect of DCAD in Lacaune ewes, increasing both ions in the anionic treatments. According to the obtained results, diets containing DCAD values in the range of 40 to 50 mEq/100 g DM are recommended for lactating dairy ewes. High yielding dairy ewes were more sensitive to DCAD than low yielding ewes as result of their greater feed intake.

Key Words: cation-anion balance, dairy ewes, nutrition

886 Effects of feeding organic minerals (Availa-4 and 4-Plex) on milk production and reproductive performance in lactating dairy cows: A meta-analysis. A. R. Rabiee[1], I. J. Lean*[1], M. A. Stevenon[2], and M. T. Socha[3], [1]*SBSibus*, *Camden, NSW, Australia*, [2]*EpiCentre, Massey University*, *Palmerston North, New Zealand*, [3]*Zinpro Performance Minerals*, *Eden Prairie, MN*.

We evaluated the effectiveness of supplementation with the organic minerals (OMs) Availa-4 and 4-Plex (Zinpro Corporation) on milk production and milk components, and reproductive performance in lactating dairy cows using effect size meta-analytical methods that weight responses by size of study and precision of response. Twenty papers and reports on the effects of OMs were considered. In some, but not all studies, equal amounts of inorganic minerals were fed to controls. Criteria for inclusion in the study were data on the form of OMs, number of cattle, an adequate description of randomization, production and reproduction, and associated measures of variance (SE or SD), and/or P values. The OMs significantly increased milk production by 0.93 kg (95% CI = 0.61 to 1.25, $P < 0.001$), milk fat by 0.04 kg (95% CI = 0.02 to 0.05, $P < 0.001$) and milk protein by 0.03 kg (95% CI = 0.02 to 0.04, $P < 0.001$) per day. There was a small, non-significant reduction in milk SCC in cows supplemented with OMs. All production outcomes, except milksolids (yield) and milk SCC, were heterogeneous. Meta-regression analysis showed that feeding before calving, feeding for a full lactation after calving and the use of other supplements (yeast, monensin, rBST) increased the responses over feeding after calving only, feeding for part of lactation or not using other supplements, respectively. Supplementation of cows with OMs significantly reduced days open (WMD = 13.5 d; $P = 0.006$) and number of services per conception (WMD = 0.27; $P = 0.02$) in lactating dairy cows. The risk of pregnancy on d 150 of lactation was greater in cows fed OMs (RR = 1.07, $P = 0.07$), but OMs had no significant effect on the interval from calving to first service and 21 d pregnancy rate. There was no evidence of heterogeneity for each of the reproductive outcomes evaluated.

Key Words: meta-analysis, dairy cows, organic minerals

Sexed Semen Symposium: Applying Sexed Semen in Cattle

887 Current status of sexed semen technology. G. Seidel*, *Colorado State University*, *Fort Collins*.

For practical purposes, sexed semen first became commercially available in North America in 2006, using the Beltsville method of flow cytometry/cell sorting. No other method has proven effective for sexing semen. Several million doses of sexed semen have been produced to date at the industry standard of ~90% purity. Purity can be adjusted to exceed 95%, but sort rates decrease greatly at >90% purity, and thus achieving such purity becomes very expensive. Sort rates increase at 75–80% purity compared with 90% and decrease costs accordingly. Sort rates at 90% purity can exceed 5,000 live sperm/sec of each sex per sorter nozzle. When considering processing losses and other logistical issues, about 7–8 insemination doses of 2,000,000 sperm of each sex can be produced per sorter nozzle/h under ideal conditions. This sperm dose became the industry standard as the optimal compromise between cost and fertility. Doubling the number of sexed sperm/insemination dose only increases pregnancy rates 2–4% for most bulls. Under good management, proper semen handling, etc., for most bulls in properly controlled experiments, pregnancy rates with sexed semen at 2,000,000 sperm/dose generally fall between 70 and 90% of those of unsexed semen at conventional doses of ≥10,000,000 sperm. Numbers of good embryos recovered when superovulated donors are inseminated with sexed semen of most bulls are approximately half of numbers recovered after using conventional semen AI. ET pregnancy rates per embryo produced with sexed semen are normal. Calves produced via AI of sexed semen do not differ ($P > 0.1$) in any respect from those produced via conventional semen, although there is less dystocia with female than male calves. Procedures for sexing bovine sperm have improved in several small but important ways over the past decade. Further improvements in efficiency resulting in decreased costs are likely. The biggest challenge will be to improve fertility of sexed semen.

Key Words: sexed semen, bovine, fertility

888 The evolution of sex-sorted semen in the US dairy industry. J. M. DeJarnette*, *Select Sires, Inc.*, *Plain City, OH*.

The introduction of sex-sorted semen in the US was accompanied by a deliberate effort not to oversell expectations. Results of early adopters typically met or exceeded expectations and spurred increased demand. High sperm loss limited the genetic caliber of sires offered, however high milk and heifers prices minimized concern for this limited supply product. As market acceptance and sorting experience grew, the genetic quality of sires offered also increased. Notable improvements in sorting efficiency has further facilitated the ability to offer higher levels of sire genetics but remains a limitation to use of the most elite sires. Market dynamics abruptly changed in 2009 when rapidly growing production capacity was met with a ~50% reduction in milk prices. Demand for sexed-semen immediately responded in kind. As the market begins to recover, producer philosophies for application of sexed semen appear to have experienced a more permanent evolution. Greater consideration is now given to semen price and to the genetic potential of both male and female. The economic value, real or perceived, of female calves from genetically superior lactating cows has stimulated greater interest in this application. Use of conventional beef semen in lower genetic value dairy cows has gained in popularity but use of sexed beef semen is unlikely until conception rate issues are resolved. Numerous research efforts have attempted to improve the conception rates of sex sorted semen with only modest evidence of success and little evidence that equality to conventional semen is achievable. Appropriate selection of sires submitted for sorting remains the most reliable method of influencing the fertility potential of sex sorted semen, which in most non-biased trials remains at 70 to 80% of conventional. Reduced purity products increase sorting efficiency and allow for more economical pricing of sexed semen, but with no improvement in conception rates, the economic implications of fewer females must be closely scrutinized. Sex sorting technology appears to have achieved a permanent place in the dairy industry, though efficiencies and applications are likely to continue to evolve.

Key Words: sexed semen, flow cytometry, economics

889 Implications of sex-sorted dairy semen for genetic change. B. G. Cassell*, *Virginia Polytechnic Institute and State University, Blacksburg*.

Sex-sorted semen can increase selection intensity of dams of replacements, but many dairy herds have no genetic evaluations for female selection. Genomic predictions from low density SNP chips may overcome this limitation in the future. Dairy herds that routinely use recently proven bulls in AI sampling programs increase genetic merit of service sires by about $25 Net Merit $;per year through genetic trend. Younger animals in such herds are genetically superior to older animals, and increased use of young animals as dams of replacements would improve genetic progress in the absence of genetic evaluations. First parity dams produce about 33% of calves born in typical herds, while second and third or later parity dams produce about 26% and 41% of calves born. With 26, 40, and 67 mo of age at calving and slightly higher frequencies of single female births to first parity dams through fewer twins, average age of dam of single birth heifers is about 45.7 mo with conventional semen. Use of sexed semen for first service only in heifers reduces average age of dam to 44 mo, while single heifer births/100 deliveries increases from 47.1 to 52.2. Genetic merit of dams increases a negligible $4 in Net Merit $ over conventional semen. If all heifer matings use sexed semen, age of dam drops to 41.9 mo, but genetic merit only increases by $8. Significantly more heifer calves result, as single heifer birth rates increase to 60.2/100 deliveries. Herds could eliminate 70% of third and greater parity cows as dams of replacements while maintaining heifer birth rates equal to conventional semen use. A variety of uses of these cows could diversify and improve dairy farm income. Elimination of older cows as dams of replacements reduces age of dam of replacements to 34.9 mo and increases genetic merit of dams by about $23. This change more than doubles genetic change per year in the dam-daughter path compared with conventional semen, primarily because of shorter generation intervals. However, improvement in this path could be offset by relative small reductions in genetic merit of service sires.

Key Words: sex-sorted, genetic change

890 Economic aspects of the use of sexed semen in dairy heifers and cows considering herd constraints. A. De Vries*, *University of Florida*, *Gainesville*.

Selective use of sexed semen in heifers and cows may increase genetic progress from the daughter-dam path and allows all calves from low producing cows to be sold because they are not needed to replace culled cows. Economic aspects of the insemination mix in dairy heifers and cows was evaluated with a linear programming model. The model considered 3 semen types (sexed dairy, conventional dairy, conventional

beef), 5 levels of milk production, and 10 parities including heifers. Each parity had 20 voluntary culling opportunities for non-pregnant animals. Heifers were allowed 5 insemination opportunities and cows 10. The model contained 2,425 decision variables. Genetic value of heifer calves was a function of service sire net merit, age of the dam, and level of milk yield of the dam. Heifers were assumed to be genetically equal. Inputs were lactation curves, milk price, feed costs, insemination costs, service rates, conception rates, dystocia costs, involuntary culling risks, and other costs. All bull calves and crossbred calves were sold, as well as excess heifer calves. The optimal decisions resulted in $335 profit/cow per yr when only conventional semen was allowed without a constraint on the number of heifer calves. Additional choice of sexed semen increased profit/cow per yr to $339 with sexed semen being used in the first inseminations in heifers and higher producing first parity cows. Profit/cow per yr increased to $368 when beef semen was offered as a third choice but fewer dairy heifer calves were born than were needed to replace culled cows. Setting the number of born heifer calves equal to the number needed to replace culled cows, profit/cow per yr was $321 considering only conventional dairy semen. Sexed semen was not used when offered. When beef semen was also offered, profit/cow per yr increased to $353 with beef semen used in lower producing cows and conventional semen and some sexed semen in higher producing cows and heifers. The optimal insemination mix often included sexed semen but depended greatly on the relative value of dairy bull calves, dairy heifer calves and crossbred calves.

Key Words: sexed semen, economics

891 Use of n-alkanes to estimate intake and digestibility of vegetative crops by young sheep. H. Dove* and W. M. Kelman, *CSIRO Plant Industry*, *Canberra, ACT, Australia*.

The development of longer-season wheat cultivars in Australia has allowed increasing use of wheat as a grazing resource in winter, replacing either pasture or forage oats. There are few data for diet composition, intake or forage digestibility in young sheep grazing wheat forage, especially in comparison with oats or pasture. Over 2 years, we used the n-alkane method to estimate diet composition (year 2), OM intake, fecal output and diet digestibility in 30 kg Merino sheep. In July of year 1, sheep grazed wheat, oats or a phalaris-based pasture for 22d at 33 animals/ha. In year 2, they grazed wheat for 34d at 33 animals/ha, within a larger fertilizer-response study. In each year, data were analyzed as replicated randomized blocks using plot mean data. There were no fertilizer effects on intake variables in year 2, so overall means are reported. In year 1, OM intakes did not differ significantly between sheep grazing oats (1162 g/d), wheat (1403 g/d) or pasture (1510 g/d). However, fecal OM excretion was significantly greater ($P = 0.01$) in animals grazing pasture (362.1 g OM/d) than crop (mean 146.2 g OM/d). OM digestibility of the pasture was thus significantly less (0.758; $P < 0.05$) than for either oats (0.861) or wheat (0.901), which did not differ. Digestible OM intakes (mean 1140 g OM/d), liveweight gains (mean 254 g/d) and liveweight gains/kg OM intake (mean 189 g/kg OMI) did not differ between treatments. Crop growth in year 2 was reduced by drought and by the end of the grazing period, crop biomass was < 400 kg DM/ha and constrained intake. The crop also contained more weeds. Nevertheless, alkane-based estimates of diet composition showed that 89% of forage intake was from wheat. Herbage intake (862 g OM/d), whole-diet digestibility (0.762) and liveweight gain (162 g/d) were all less than in year 1. Liveweight gains/kg of OM intake were very similar (190 g/kg OMI) to year 1, suggesting that reduced liveweight gains were due to lower intakes. The results also indicate that in year 1, the digestibility of crop forage was greater than pasture, but OM and DOM intakes by young sheep were similar across forages.

Key Words: alkanes, intake, wheat forage

892 Effect of level of intake on digestibility of NDF of soybean hull diets in sheep. D. C. Hein, M. L. Thonney*, D. A. Ross, and D. E. Hogue, *Cornell University*, *Ithaca, NY*.

Including soybean hulls in ruminant diets increases feed intake and production. This is likely due to the high fraction of digestible NDF (dNDF) in soybean hulls, which may optimize VFA production for rumen health. High feed intakes, however, decrease digestibility. Therefore, the objective of this project was to quantify the effect of level of feed intake on digestibility of NDF in soybean hull diets. Diets were fed at intake levels of 2, 3, or 4% of BW (%BW). Each intake level was fed to 8 pens of 2 weaned, 17-kg ram lambs (24 pens) and to 8 pens of 1 mature, 66-kg, non-lactating ewe (24 pens). On an as-fed basis, the lamb diet included 71.7% soybean hulls, 21.5% soybean meal, 4.5% molasses, 1% vitamin-mineral premix, 0.5% calcium carbonate, 0.5% chromic oxide, 0.25% vitamin E premix, and 0.025% Deccox, while the ewe diet contained 72% soybean hulls, 20% corn, 2% soybean meal, 4.5% molasses, 1% mineral-vitamin premix, and 0.5% chromic oxide. After a 10-d adaptation period, feces were collected for 2 d. Uneaten feed was recorded to determine actual feed intake. The fecal samples and 2 feed samples from each experiment were dried and ground for determination of NDF, dry matter, and chromic oxide concentrations. Apparent dry matter digestibility (DMD) and dNDF were quantified using chromic oxide as a marker. In ram lambs, with actual intakes ranging from 1.7 to 4.1%BW, regression analyses showed a linear effect with apparent DMD decreasing ($P < 0.001$) by 8.1 ± 1.16 percentage units and dNDF decreasing ($P < 0.001$) by 12.1 ± 1.57 percentage units for each percentage unit increase in DMI as %BW. In mature ewes, with actual intakes ranging from 1.6 to 3.9%BW, digestibility values at low intakes were not as high as in lambs and the depression in digestibility was less pronounced, with DMD decreasing ($P = 0.034$) by 2.9 ± 1.28 percentage units and dNDF decreasing ($P = 0.009$) by 4.5 ± 2.00 percentage units for each percentage unit increase in DMI as %BW. These experiments demonstrated a linear decrease in digestibility of NDF with increasing intake that accounted for 75 to 85% of the associated depression in apparent DM digestibility.

Key Words: digestion, NDF, sheep

893 Evaluation of feeding value of corn distillers dried grains with solubles for sheep. G. Abdelrahim*[1], J. Khatiwada[1], N. Gurung[1], J. Vizcarra[1], and C. Kerth[1], [1]*Alabama A & M University*, *Normal, AL,* [2]*Tuskegee University*, *Tuskegee, AL*, [3]*Auburn University*, *Auburn, AL*.

Corn distillers dried grains with solubles (DDGS) which have become very popular over the past 15 yr due to their energy value in relation to corn, price, flexibility in feeding, and reduction in incidence and duration in acidosis, are a by-product of the fuel ethanol industry. The objectives of this study were to evaluate the effects of varying levels of dietary DDGS inclusion on: dry matter intake, average daily gains, and carcass composition of sheep. Twenty-four lambs (40.1 ± 48.6 kg initial BW, and 8 to 9 mo of age) were obtained and used in a randomized complete-block design (n = 2 replications per treatment). Diets, on a dry matter basis, were: control, 10% DDGS, and 20% DDGS. All diets contained 50% fescue/bermudagrass mix hay, and 50% of the respective concentrate mixes. The concentrate mixes containing DDGS were formulated to be isonitrogenous at 16% crude protein. The DDGS replaced corn and soybean meal in the concentrate mixes so that diets contained desired amounts of DDGS. Lambs were allowed 7-d adjustment period, followed by 7-d transition period to the DDGS diets. After 135-d feeding period final weight was determined, lambs were slaughtered, and carcass characteristics were measured. Both growth and carcass quality data were analyzed as a completely randomized design. Final body wt (62.5, 61.3, and 63.0) was not different between treatments ($P > 0.05$). Also, no differences were observed ($P > 0.05$) in hot carcass wt (30.7, 30.1, and 30.3), cold carcass wt (30.8, 30.0, and 30.2), body wall fat (2.0, 2.2, and 2.0), ribeye area (6.55, 7.0, 7.0), 12th rib fat (0.9, 1.1, and 0.85), and kidney and pelvic fat (2.3, 1.89, 2.13) between treatments. Based upon the findings of this research, DDGS can replace a portion of the ground corn and soybean meal commonly fed to lambs, and maintains or enhances performance.

Key Words: distillers dried grains with solubles, sheep, performance

894 The effect of processing type of feedstuff on the fattening performance of Awassi ram lambs. H. Ustuner*, S. Dikmen, and I. I. Turkmen, *University of Uludag*, *Bursa, Turkey*.

The objective of this study was to investigate the effect of processing type of feed on the fattening performance of Awassi ram lambs. A total of 26, 3-mo-old Awassi ram lambs were used and randomly allocated into 3 groups (group 1, fed with mash feed, n = 8; group 2, fed with

pellet feed, n = 9; group 3, fed with extruded pellet feed, n = 9). Lambs were individually fed with the same ingredient of concentrate feed (2.5 Mcal/kg) and had free access to water until 43 kg of slaughter weight. The initial live weight of lambs were similar ($P > 0.05$) 29.56 ± 1.27, 29.89 ± 1.07 and 28.89 ± 0.83 for group 1, 2 and 3, respectively ($P > 0.05$). At the end of fattening period the final live weights of lambs were also similar ($P > 0.05$). The results showed that total weight gain and average daily gain (ADG) of ram lambs during the study were 12.75 ± 1.05 kg and 180.90 ± 17.70 g for group 1, 12.78 ± 0.90 kg and 25.10 ± 21.50g for group 2, and 14.56 ± 0.55 kg and 287.80 ± 23.40 g for group 3, respectively. The difference of ADG among groups were significant ($P < 0.01$). The best feed conversion rate (FCR) was estimated for the lambs in group 3 (6.50 ± 0.30) while the other FCR results were greater than group 3 (8.20 ± 0.50 and 6.90 ± 0.40 for group 1 and group 2, respectively) ($P < 0.05$). Lambs fed with extruded pellet feed (group 3) tend to have lower fattening period (19 d less) than group 1 ($P = 0.07$). The results of the current study shows that feeding of Awassi ram lambs with extruded feed had positive effects on fattening performance, feed conversion rate and fattening period, which are economically important for sheep farms.

Key Words: Awassi lambs, extruded feed, fattening performance

895 Effect of anaerobic enzyme matrix on fiber digestibility. H. M. Gado*[1] and B. E. Borhami[2], [1]*Ain Shams University*, *Department of Animal Production, Faculty of Agriculture, Cairo, Egypt*, [2]*Alexandria University*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Alexandria, Egypt*.

The intend of this study was to verify the effect of nutritive value aerobic constancy of rice straw. Also, if it could be enhanced by addition of exogenous cellulases, hemicellulase, protease and α amylase enzymes (ZAD) preparations at ensiling. Rice straw was chopped to 5 cm without treatment (control) or after treatment with ZAD (1 or 3 L/ 1 ton of DM of rice straw) including 30 kg of sugar cane molasses and 20 kg of DDGS. The enzymes were sprayed on the rice straw at ensiling (50% of water was added). Ten 500-kg replicates of chopped (5 cm) rice straw were ensiled for 30 d in plastic bales. Five plastic bales per treatment were used for chemical analysis and 5 for aerobic constancy monitoring. The silage juice was analyzed for organic acids, pH, water-soluble carbohydrates (WSC), ammonia-N, and soluble N. Samples were analyzed for crude protein (CP), neutral detergent fiber (NDF), and acid detergent fiber (ADF). In vitro digestibility of DM (IVDMD), NDF (IVNDFD), and ADF (IVADFD) were determined. Materials treated with ZAD had lower ($P < 0.05$) DM losses, and lower ($P < 0.05$) pH and ammonia-N concentration than control silages. Residual WSC concentration was greater ($P < 0.01$) in ZAD treated silages either 1 or 3 L than in control silages. Compared with control silages, NDF concentration was lower ($P < 0.01$) in silages treated with 3 L followed 1 L of ZAD. Aerobic constancy was increased ($P < 0.05$) by ZAD. ZAD at 3L increased the IVDMD and IVNDFD at 6 and 48 h. The 48-h IVADFD was also increased ($P < 0.01$) by treatment with 3L ZAD. These results show that 3L ZAD applied at ensiling can improve the digestibility, fermentation, and aerobic constancy of rice straw silage.

Key Words: nutritive value, rice straw, ZAD

Teaching/Undergraduate and Graduate Education Symposium: Beyond PowerPoint: Use of Technology in the Classroom

896 AG*IDEA: A national consortium of universities for offering distance education program in agriculture. K. L. Esbenshade*[1] and D. L. Boggs[2], [1]*North Carolina State University*, *Raleigh*, [2]*Kansas State University*, *Manhattan*.

AG*IDEA (Agriculture Interactive Distance Education Alliance) is a national consortium of universities offering programs and courses in agriculture and related disciplines. Chartered in 2008, AG*IDEA consists of 15 member universities, with 15 additional universities intending to join. AG*IDEA is an affiliate of Great Plains IDEA operating under their policies and guiding principles, and has a Board of Directors, an Executive Committee, and annual meetings. Institutional membership requires approval of the administrative head for agriculture, and the institution's chief academic and fiscal officers. Programs (such as degrees, certificates, concentrations, etc.) are developed by faculty and approved by the Executive Committee, and include proposed coursework, a budget and an assessment plan. Courses and programs are approved at each university, where students enroll, pay a common price which includes tuition and fees, and obtain their degrees. Programs in Agricultural Education, Agricultural Mechanization, Food Safety and Defense, Grasslands Management and Swine Science have been approved to be offered through AG*IDEA. Other programs in various agricultural disciplines are under development. Information regarding the national consortium can be obtained at www.agidea.org.

Key Words: distance education, AG*IDEA, academic programs

897 Using cell phones to engage your audience. P. A. Curtis* and M. O. Kloepper, *Auburn University*, *Auburn, AL*.

Get your audience involved without the expense of proprietary response systems. Two applications that can be used in your class or for your presentation will be showcased. Attendees are encouraged to bring a cell phone to use during this presentation. Learn how to make this conference more engaging and informative for yourself and others.

898 Use of e-portfolios for outcomes assessment in the animal sciences. C. M. Wood*, J. W. Knight, and E. A. Dunnington, *Virginia Tech*, *Blacksburg*.

The Department of Animal and Poultry Sciences (APSC) at Virginia Tech (VT) has been conducting outcomes assessment since 1991. Currently, each degree program must develop a mission statement that relates directly to student learning outcomes; specific learning outcomes that may be revised based upon information collected; direct and indirect measures of the learning outcomes; and findings for measures assessed. Examples of student work are an excellent source of direct measures of learning outcomes but the collection, storage and analysis of such work can be daunting. E-portfolios, an electronic version of traditional collections of student work, are one method of addressing these concerns. E-portfolios, which can be maintained indefinitely, are 2-dimensional matrices into which electronic files are loaded. They are an integral part of Scholar, VT's implementation of Sakai, an open-source educational software package. The APSC assessment e-portfolio consists of 7 columns that correspond to the undergraduate program's specific learning outcomes (communication skills, leadership skills, critical thinking and reasoning, independent learning, subject matter expertise, and knowledge of contemporary issues) plus capstone activities, and 15 rows representing courses and other sources of electronic evidence such as extracurricular accomplishments. Collection of student work began fall semester 2009. A total of 262 students enrolled in 2 courses submitted 3 pieces of evidence: a 4-year plan of study, a resume and a cover letter. Initial feedback from instructors and students indicate that placing files into the e-portfolio is straightforward. Development of procedures for optimizing use of the e-portfolio in outcomes assessment is in progress. We believe that e-portfolios are an excellent model for documenting student learning based on faculty-defined outcomes and for assessing student development over time. Additionally, students have the opportunity to construct their own e-portfolios using the evidence they placed into the APSC matrix.

899 Use of SoftChalk to create professional appearing content that will creatively engage students. M. O. Kloepper*[3,4], P. A. Curtis[3], and D. R. Mulvaney[1,2], [1]*Coll. of Agr., Auburn University*, *Auburn, AL,* [2]*Anim. Sci.*, *Auburn, AL,* [3]*Poult. Sci.*, *Auburn, AL,* [4]*IT Specialist*, *Auburn, AL*.

Creating content for e-learning can be cumbersome, time consuming and challenging for faculty. In addition, less than meritorious results may be obtained after considerable amount of time and effort. Our objective is to discuss the merits and experiences of using SoftChalk as a powerful tool to create and advance web-based learning environments. SoftChalk is a simple and easy to use tool that shows provides easy to use steps for organizing classroom and module content. Output can be customized to look both interesting and professional in a matter of minutes. Educational content can be placed online and accessed by student or other viewers. Packaging educational materials with SoftChalk puts fun and enjoyment into digitizing course content, scientific research results, and expert information. The presenters will show various examples of content created with SoftChalk and enable participants' valuable insight into relevant applications for enhancement of teaching and learning.
Partially supported by USDA NIFA Higher education Challenge grant 2007–38411–18136 - Development of a distance education consortium among southern universities.

Key Words: Soft Chalk software, e-learning, web-based teaching

900 Using Second Life for poultry science. M. O. Kloepper* and P. A. Curtis, *Auburn University*, *Auburn, AL*.

A 3-dimensional poultry space has been created digitally and includes a farm, egg processing facility, processing line, and more. This teaching resource has been created by using a virtual world platform, Second Life. Usage of 3-D applications for educational purposes is on the rise but many educators are unaware of the potential for utilizing this format. On-site tours of poultry facilities are difficult, if not impossible, to obtain. Virtualization provides an inside look of plant operations safely and comfortably. It provides a method for close inspection of angles not allowed or possible in a real world facility. Imagine *seeing* a piece of equipment in action, from all sides, zooming in and out, as well as up and down, from any perspective that you want by moving your computer mouse. 3-D digital world components are imagined. Consider it an "explosion of creativity". This presentation will showcase the virtual space called Eagle Island in Second Life, highlight its history, animations and 3-D teaching resources, discuss collaborative efforts using the virtual space, and share plans for future endeavors.

901 On-line text, a new technology use in animal science courses. G. M. Hill* and J. E. Link, *Michigan State University*, *East Lansing*.

Meeting the demands of freshmen courses in animal science has resulted in innovation and utilization of new technologies. With the ever changing type of student that enrolls in beginning courses, faculty members are challenged to provide up-to-date materials, a broader look at animal agriculture, and the latest technologies. Faced with the reality that introductory animal science books are limited in number, incomplete for the species to study and not up-to-date, we pursued the opportunity to write our own book that matched our lecture and laboratory lessons and could be improved even within the semester of use. Our on-line publisher is Great River Technologies of Dubuque, Iowa. We began by taking photographs in all our laboratories, creating illustrations to demonstrate difficult concepts, developing ideas for interactive exercises, writing questions for self-study and outlining and writing the text. Photographs needed to be of high quality and resolution for their utilization, and we were required to obtain permission from students in the photos to be used in the text. These photos were not used as a substitute for laboratory periods, but to support the laboratory sessions and provide study materials. The publisher provided a portion of the finished artwork and contacted publishing houses for permission to use illustrations and artwork of others. The publisher contacted bookstores on our campus and arranged for students to purchase an access code from the store or directly from the publisher via credit card. The price was the same for students regardless of purchase location and overall, less than the cost of a textbook. Limitations for such a project include making materials simple enough for the naïve student yet challenging for those with a livestock background, working with artists who have no concept of animal agriculture, allotting time for preparation, and finding areas that are not as completely covered as anticipated.

Key Words: undergraduate education, on-line text

902 Asynchronous distance education in feed science. C. R. Stark and P. R. Ferket*, *North Carolina State University*, *Raleigh*.

The growing demand for courses in the field of animal feed manufacturing, combined with diminishing classroom space initiated the development of a distance education (DE) curriculum in the Feed Science program at North Carolina State University (NCSU). Feed industry businesses are looking for cost effective methods to train middle management and production employees while limiting their time away from the workplace (AFIA, 2007). Feed Manufacturing Technology (FM 425), the first DE course offered in Feed Science at NCSU, has been offered since 2005 over 15 semesters to 201 students, both on- and off-campus. The total enrollment in FM 425 has more than doubled (40 versus 17 students) in the last 5 years (2005 to 2010) as compared with the previous 5 years (2000 to 2004). In addition to the increased enrollment, 34% of the students who enrolled in the DE courses were on-campus. The asynchronous instructional format allowed students the flexibility to view on-line lectures, watch videos, complete assignments, and take exams at their own pace. Students indicated they enrolled in DE courses because the courses were not constrained to a scheduled place or time. The addition of the Feed Mill Operations and Leadership (FM 460) course in the fall of 2008 increased the DE enrollment in the Feed Science curriculum by 28%. The success of these courses has led to the development of 7 new DE courses in the Feed Science curriculum, which can be applied toward an undergraduate or graduate certificate in Feed Science (www.feedmill.ncsu.edu). The Feed Science DE program has a consistent course format within all courses regardless of the instructor. Each learning module contained an introduction, video lecture, lecture notes, assignment, and self test. There was no difference in student evaluation responses between students who took the DE courses versus all the other on-campus courses. The success of these courses confirm that DE can be used to expand and develop specialized programs such as Feed Science, while providing extension and outreach opportunities to the feed industry.

Key Words: asynchronous, distance education, feed science

Animal Behavior and Well-Being: Dairy, Sheep, and Beef

903 Behavioral changes of dairy cows during drying-off using abrupt cessation of milking. K. A. Painter, K. E. Leslie*, and E. H. Tatone, *University of Guelph*, *Guelph, ON, Canada*.

The dry period between successive lactations is crucial for regeneration of productive function of mammary tissue, preparation for high production, and to prevent new intramammary infections (IMI). With continually increasing production levels over time, the stress of abrupt drying-off could be a welfare concern, as well as an increased risk period for new IMI. The objectives of this study were to document standing and lying behaviors through the process of drying-off, and to evaluate the associations between parity (lactation 1 relative to lactation 2 and above) and production level (>27 kg/d compared with <22 kg/d) and changes in these activities. From June to October 2009, a total of 76 cows in a commercial free-stall herd, milking 3 times per day, were enrolled onto this study. Each cow was fitted with a HOBO data logger (HOBO Pendant G Data Logger, Onset, Pocasset, MA) on the outside of the right hind leg, parallel to the floor (longitudinally). The HOBOs were programmed to start data collection at 7am, 2 d before drying-off (d-2), and to continue for 6 d following drying-off (d6). Cows received their last milk-out at the second daily milking (d0, noon). The HOBO recorded time-stamped standing and lying behavior (including lying side) at one minute intervals, allowing for the calculation of total lying time per day. Simple univariable analysis by 2-sample *t*-tests was used to compare production level and parity against total lying time. Upon completion of the full data set, multivariable analysis will be performed. Cows drying-off at high production had significantly lower lying times compared with cows at lower production levels on d1 ($P < 0.05$; 634.71 ± 211.04 vs. 747.04 ± 166.86 min) and d3 ($P < 0.005$; 724.58 ± 138.81 vs. 836.15 ± 116.03 min). Lactation 1 cows also showed significantly ($P < 0.001$) lower lying times of almost 3 h compared with multiparous cows on d1 (572 ± 195.04 vs. 751.61 ± 170.66 min). In conclusion, these data suggest that abrupt cessation of milking at drying-off is associated with changes in standing and lying behaviors, indicative of increased discomfort. These behavioral changes appear to be influenced by production level at the time of drying-off and by parity. Management interventions in the process of drying-off may be warranted.

Key Words: drying-off, behaviour, lying and standing time

904 Short-term overcrowding affects the lying and social behavior of lactating Holstein dairy cows. P. D. Krawczel*[1,2], L. B. Klaiber[1], R. E. Butzler[1], L. M. Klaiber[1], H. M. Dann[1], C. S. Mooney[1], and R. J. Grant[1], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY,* [2]*The University of Vermont, Department of Animal Science*, *Burlington*.

Reduced access of resources, due to overcrowding, may affect lactating dairy cows′ daily time budgets detrimentally. The objective of this study was to determine the differences in feeding, ruminating, lying, and social behaviors of Holstein dairy cows housed at stocking densities of 100 (1 cow per freestall and headlock), 113, 131, and 142%. Multiparous cows (n = 96) and primiparous cows (n = 40) were assigned to 4 pens in a 4-row barn. Pens were balanced for parity, milk production, days in milk, and somatic cell count. Treatments were imposed by reducing resting and feeding space for 14 d using a 4 × 4 Latin square design. Time spent feeding and ruminating were quantified by 24 h of direct observation beginning at 0800 on d 11. Dataloggers recorded lying behavior (time and bouts) of 12 focal cows per pen at 1-min intervals during the final 5 d of each period. Social aggression was defined as the number of successful displacements from the feed bunk during the 2 h after cows returned to the pen after milking. Displacements were recorded after 9 milkings over the last 4 d of each period. Pen means (n = 16) were analyzed using MIXED procedure of SAS. Feeding (3.7 ± 0.2 h/d) and ruminating (7.2 ± 0.2 h/d) did not differ among stocking densities ($P > 0.5$). Overcrowding did change the location of rumination; a greater percentage (95.1 ± 2.4) of the total rumination ($P < 0.01$) occurred within a freestall at 100% compared with 131% (89.6 ± 2.4) or 142% (87.3 ± 2.4). Lying time was reduced by 0.8 h at 131% and 0.7 h at 142% ($P < 0.02$) compared with 100 or 113%. Lying bouts (11.3 ± 0.6 per d) were not affected by stocking density ($P = 0.57$). Relative to 100% (13.2 ± 2.5 per 2 h), social aggression was greater at 142% (20.4 ± 1.8 per 2 h; $P = 0.03$) and tended to be greater at 131% (15.8 ± 3.5 per 2 h; $P = 0.10$). Decreased lying time and increased aggression at the feed bunk during short-term overcrowding suggests increased stocking densities may alter the time budgets of lactating dairy cows. The long-term ramifications of these changes are unknown and should be addressed to ensure management practices ensure the welfare of lactating dairy cows.

Key Words: dairy cow, stocking density, behavior

905 Early detection of lameness through pedometric activity and lying behaviour of dairy cattle. J. H. Higginson*[1], S. T. Millman[2], G. Cramer[1,3], K. E. Leslie[1], A. M. B. de Passille[4], T. F. Duffield[1], and D. F. Kelton[1], [1]*University of Guelph*, *Guelph, ON, Canada*,[2]*Iowa State University*, *Ames,* [3]*Cramer Mobile Bovine Veterinary Services*, *Stratford, ON, Canada*,[4]*Agriculture and Agri-Food Canada*, *Agassiz, BC, Canada*.

The objective of this pilot study was to examine changes in dairy cow activity around lameness events, a component of a larger ongoing investigation to determine the efficacy of pedometric activity for early lameness detection. The commercial Pedometer Plus system (SAE Afikim, Israel) provides information regarding the number of steps taken, the duration of lying time, and the number of lying bouts. The device was affixed to the hind limbs of 130 lactating cows and data was collected twice daily during milking. Hooves were examined for lesion identification every 3 mo and trimmed every 6 mo. In addition, Between these, lameness cases identified by the producer were evaluated by a veterinarian, treated, and causal factors recorded. To date, 5 cows with new cases of digital dermatitis were identified. Activity and lying behavior were analyzed during 2 time periods - 7 d before lameness identification and exam, and 7 d following exam, with exam day excluded. A paired *t*-test demonstrated a difference in activity between time periods ($P = 0.03$). On average (±sd), cows performed 65.1 (±4.1) steps/hour before lesion identification and 76.2 (±5.6) following identification. The mean number of lying bouts between time periods was not different ($P = 0.79$), with mean lying of 10.0 (±0.7) bouts/day before the lameness exam and 9.9 (±0.6) following the lameness exam. Lying duration also did not differ ($P = 0.54$), with 693.1 (±28.0) minutes/day before the lameness exam and 675.1 (±34.5) minutes/day following the exam. Our preliminary results suggest that during the 7 d before identification of digital dermatitis, cows are less active. Continued enrolment will determine if other hoof lesions show similar changes. Further evaluation of activity around lameness events will determine if early detection through the use of pedometry is possible.

Key Words: lameness, pedometry, activity

906 Behavioral responses to feeding regimens, housing and heat stress in dairy calves. A. L. Adams*, T. H. Friend, G. A. Holub, S. M. Garey, and C. L. Terrill, *Texas A&M University*, *College Station*.

There is concern that accelerated feeding programs may adversely influence calves during periods of environmental heat stress. The objective of this study was to determine the effects of housing, feeding regimens, and heat stress on activity and utilization of shade by dairy calves. Fifty-five Holstein bull calves 1–3 d of age were randomly assigned to 1.85 m^2 individual pens that were either indoors in a climate-controlled environment (n = 28) or outdoors in a covered barn (n = 27) for 7 wk. Within each of the 2 housing treatments, calves were assigned to one of 3 feeding regimens: milk replacer increased by 0.1% of BW weekly, n = 17; consistent amount of milk replacer at 1.1% of BW, n = 18; or milk replacer decreased by 0.1% of BW weekly, n = 20. Calves were fitted with pedometers and released into a 15.24 m × 9.14 m partially shaded (9.14 m × 3.05 m) outdoor open-field test pen for 1 h every 7 d in the early afternoon in July and August. Behavior was classified as active, standing, lying or in-shade at 5-min intervals. Recorded steps, shade use (0 = in-shade, 1 = not in-shade), and mean activity scores (0 = lying, 1 = standing, 2 = active) were analyzed as repeated measures in an autoregressive covariance mixed model. Feed regimen did not affect the number of steps taken, shade use, or activity of the calves. An increase in steps occurred over time with 454 ± 25.35 steps for wk 1 and 717 ± 24.49 steps for wk 7 ($P < 0.0001$). Calves housed outdoors took more steps (618 ± 17.88) than calves housed indoors (559 ± 17.39; $P = 0.0039$). Calves averaged significantly ($P < 0.0001$) fewer steps (465 ± 13.84) during field tests with high (≥83) temperature-humidity index (THI) values than during field tests with low (<80) THI (718 ± 40.14 steps). Calves spent less time in the shade as they aged ($P < 0.0001$), when the THI was low ($P < 0.0001$), and if they were housed outdoors ($P = 0.0011$). Calves housed indoors tended to be more active than calves housed outdoors ($P = 0.094$). These results suggest that accelerated feeding programs do not impose additional thermal stress on calves.

Key Words: calves, behavior, heat stress

907 Behavior of two cow genotypes (Holstein vs. Jersey) in two milk production systems (grazing vs. confinement). A. I. Roca-Fernández*[1], C. P. Ferris[2], E. R. Vance[2], and A. González-Rodríguez[1], [1]*Agrarian Research Centre of Mabegondo*, *La Coruña, Galicia, Spain,*[2]*Agri-Food and Biosciences Institute*, *Hillsborough, Co. Down, UK*.

Diverse milk production systems exist in Europe, ranging from low input grazing systems to high input confinement systems. The impact of these systems on dairy cow behavior has not been extensively examined. The aim of this study was to compare the behavioral activities of 2 cow genotypes (Holstein-Friesian, H-F vs. Jersey × Holstein-Friesian crossbred, Jx) when managed within 2 contrasting milk production systems (grazing, G vs. confinement, C). One hundred 20 spring calving cows (H-F, n = 60 and Jx, n = 60) were balanced on calving date and milk yield and randomly assigned to one of 2 milk production systems (G, n = 60 and C, n = 60) in a block design with a 2 × 2 factorial arrangement of treatments. Cows were scanned on 3 occasions in a 6 week period (P1, end July; P2, middle August; P3, end August) and the behavioral activities of cows were registered at 20-min intervals, between 16.00 and 22.00 h and 7.00–14.00 h. The behavior of each cow was recorded, according to the following activities: lying, eating, standing and ruminating. There were differences ($P < 0.001$) between periods for time spent lying, eating and ruminating in relation to daylight, while time spent standing did not show any difference. Cows on the grazing system spent more time lying and ruminating in P3 (272 and 165 min., respectively) than in P1 (152 and 122 min., respectively) and time spent eating was lower in P3 (485 min.) than in P1 (553 min.). Breed had no effect on any of the behaviors recorded. Nevertheless, a tendency to spend more time eating and ruminating was observed in Jx (354 and 195 min., respectively) than in H-F (343 and 184 min., respectively). System showed an effect ($P < 0.001$) on dairy cow behavior. Cows on the grazing system spent more time grazing (522 min.) than those on the housing system spent eating (175 min.). Cows on the confinement system spent more time lying (405 vs. 212 min., respectively), standing (301 vs. 87 min.) and ruminating (246 vs. 134 min., respectively) than did those in the grazing system. Greater synchrony of dairy cows behavior was observed at pasture than in the confinement system.

Key Words: milk production systems, cow genotypes, feeding behavior

908 Diet palatability influences the feeding behavior of sheep. I. R. Ipharraguerre*[1] and J. J. Villalba[2], [1]*Lucta SA*, *Barcelona, Spain*, [2]*Utah State University*, *Logan*.

The aim of this study was to assess whether the feeding pattern displayed by sheep exposed to a monotonous ration is modified when the same ration is presented in a diversity of flavors. Thirty-five 2-mo old lambs were randomly assigned to 5 groups (7 lambs/group). One group of lambs [Diversity (D)] was fed simultaneously an unflavored ration of alfalfa and barley (75:25) and the same ration mixed (0.2%) with one of 3 flavors: 1) sweet, 2) umami, and 3) bitter. The other 4 groups (Monotony) received just one of the 4 rations [i.e., unflavored control (C); sweet (S); umami (U); and bitter (B)]. All animals were fed their respective rations ad libitum from 0800 to 1600 for 60 d. Feed consumption was measured throughout the study. Data were analyzed as a split-plot design with repeated measures using a mixed-effect model with animal (random) nested within group. On d 55, intake was estimated every 30 min for 8 h. On d 56, scan samples were taken at 5-min intervals to assess the incidence of offered feeds on feeding events. On average, lambs in D consumed 4 to 8% more feed than lambs in the other groups ($P < 0.008$). Lambs in D showed lower intakes than the other groups during the 2 peaks of food consumption: 30 min ($P < 0.008$) and 270 min ($P < 0.007$) after offering the rations. In contrast, lambs in D consumed more feed than lambs exposed to monotonous flavors at 60 ($P < 0.05$), 90 ($P < 0.07$), 120 ($P < 0.10$), and 180 min ($P < 0.05$) post-feeding. No differences among groups, however, were detected in the proportion of scans recorded during the feeding cycle. Thus, differences in total feed consumption were likely supported by changes in the rate, but not the frequency, of feeding events. Within group D, diet preferences were umami > sweet > bitter (33 > 28 > 26 g/kg of metabolic BW; $P < 0.01$) and plain > bitter (31 vs. 26 g/kg of metabolic BW; $P < 0.01$). Exposure to diverse flavors in the same ration has the potential to increase feed intake and foster an even utilization of feed across time by reducing peaks and nadirs of feed consumption compared with exposure to monotonous rations.

Key Words: behavior, flavor, intake

909 Early experience to flavor diversity influences food selection and intake by sheep. J. J. Villalba*[1] and I. R. Ipharraguerre[2], [1]*Utah State University*, *Logan,* [2]*Lucta SA*, *Barcelona, Spain*.

The objective of this study was to determine whether early experiences to flavor diversity or monotony influence intake and preferences for novel feeds by sheep. Thirty-five 2-mo old lambs were randomly assigned to 5 groups (7 lambs/group). One group of lambs [Diversity (D)] was fed

simultaneously an unflavored ration of alfalfa and barley (75:25) and the same ration mixed (0.2%) with one of 3 flavors: 1) sweet, 2) umami, and 3) bitter. The other 4 groups (Monotony) received one of the 4 rations [i.e., unflavored control (C); sweet (S); umami (U); and bitter (B)]. All animals were fed ad libitum from 0800 to 1600 for 60 d. Afterward, all groups received alfalfa hay for 46 d. Following, preference tests were conducted over 5 d by offering simultaneously novel feeds of either (1) high energy content (beet pulp, corn, milo, oats), (2) high protein content (wheat gluten meal, rabbit pellets, soybean meal, Calfmanna), or (3) beet pulp mixed with secondary compounds [condensed quebracho tannins (10%), quillaja bark saponins (2%), and sagebrush terpenes (3%)]. Data were analyzed as repeated measures using a mixed-effect model with animal (random) nested within group. On average, lambs in D consumed more feed ($P < 0.01$) than lambs in the other groups (118, 113, 113, 109, and 109 g/kg of metabolic BW for lambs in D, B, U, C and S, respectively). No differences in ADG were detected among groups for the first 33 d of exposure, but from d 34 to 60 lambs in D grew faster ($P < 0.04$) than lambs in the other groups (0.30, 0.20, 0.22, 0.19, and 0.20 kg/d for lambs in D, B, U, C and S, respectively). Lambs in C preferred beet pulp compared with lambs in U and B ($P < 0.04$); lambs in B preferred oats compared with lambs in D, C, and S; lambs in S preferred corn compared with lambs in B ($P < 0.05$); and lambs in D preferred milo compared with lambs in N and S ($P < 0.06$). Thus, exposure to diverse flavors in the same ration may influence intake and selectivity and contribute to modify initial acceptability and preference for novel feeds by lambs.

Key Words: early experience, flavor, intake

910 Preference in cattle offered a ground switchgrass and alfalfa hay blend flavored with sucrose or citric acid. S. J. Chavez*, S. Freeman, and G. B. Huntington, *North Carolina State University*, *Raleigh*.

Intake of feed can be influenced positively or negatively by flavor. The objective was to evaluate preference for sucrose or citric acid addition to a ground hay blend (switchgrass:alfalfa = 3:1, as fed). Flavors were dissolved in 50 mL deionized water for blending. Sucrose hay (SU) had 100g sucrose added per kg hay. Citric acid hay (CA) had 50 g citric acid added per kg hay. Control hay (CON) had 50 mL deionized water added per kg hay. Hays were mixed 3 d before the experimental period and stored at room temperature. Eleven Angus-cross steers and 1 heifer (initial BW = 283 ± 25 kg) were housed under a roof on expanded metal flooring with access to 6 feed slots designated I through VI, west to east. Cattle were offered 1 kg of supplement (47.5% each, soybean hulls and corn with 5% trace mineralized salt, as fed) at 0800 daily. Orts were removed and weighed at 0800. Cattle were offered 0.6% BW treatment hay at each feed slot and treatments (SU, CA, and CON) were randomly assigned to 2 of the 6 locations at 0830 daily. Cattle were given a 14-d adaptation to CON followed by a 7-d preference trial. Preference was determined by disappearance where greater disappearance was taken to mean animal preference. Cattle preferred SU (3.42 ± 0.04 kg/d) over CON (2.8 ± 0.04 kg/d, $P < 0.01$) and CA (0.32 ± 0.04 kg/d, $P < 0.01$) and preferred CON over CA ($P < 0.01$). Feeding location I was preferred more than III ($P < 0.03$). This difference was seen since CA was randomly assigned 4 out of the 7 d from position III. Cattle searched for SU and consumed SU in entirety in both locations before consuming CON or CA. Cattle consumed SU over CON and CA independent of location. Cattle searched for the SU and consumed SU immediately after SU was presented in both locations. Cattle may search for food that stimulates taste receptor cells for sweetness over other flavors. Adding sweet flavors to cattle feeds would increase intake of forages with lower nutritional values such as switchgrass.

Key Words: cattle, preference, flavor

911 Characterization of feeding behavior traits and associations with feed efficiency in beef heifers fed a high-grain diet. E. Mendes*, G. Carstens, and L. Tedeschi, *Texas A&M University*, *College Station*.

Few studies have characterized meal criterion in beef cattle, which is an estimate of the longest nonfeeding interval that is considered to be part of a meal. Objectives of this study were to quantify meal criteria, and to examine within-animal repeatability of feeding behavior traits and their associations with residual feed intake (RFI) in beef heifers fed high-grain diets. An electronic feed intake system (GrowSafe; DAQ4000E version 9.25) was used to record individual bunk visit frequency (BVF) and duration (BVD) for 62 heifers (initial BW = 286) fed a high grain diet (3.1 Mcal ME/kg DM) for 81 d. A mixture 2-pool distribution model (R mixdist package 0.5–2) was fitted to log10-transformed interval lengths between BVF. The intersection of the 2 distributions, which The intersection of the 2 distributions, which represents intervals within and between meals, was computed as the meal criteria and used to calculate meal frequency (MF) and duration (MD). RFI was calculated as the difference between actual and expected DMI from linear regression of DMI on ADG and mid-test $BW^{0.75}$. The overall means (±SD) for BVF and MF were 50 ± 8.9 and 8 ± 1.5 events/d, respectively; 61 ± 17.3 and 129 ± 26.6 min/d for BVD and MD; respectively, and 6 ± 1.1 for number of bunk visits per meal (BVM). The pooled meal criteria calculated on the 62 animals in this study was 12.5 min. RFI was positively correlated ($P < 0.05$) to BVF (0.42), BVD (0.41), MD (0.32), and BVM (0.44), but not with MF (0.03). Feed behavior traits for period 1 (d 1 to 40) were regressed on feed behavior traits on period 2 (d 41 to 81) to access within-animal repeatability of these traits. The r^2 of the regression equations for BVF, BVD, MF, MD were 0.63, 0.76, 0.73, 0.77, respectively, and for number of bunk visits per meal was 0.55. These results suggest that within animal repeatability of feed behavior traits are high and that they may be useful indicator traits for RFI in beef cattle.

Key Words: feed behavior, residual feed intake

912 Approaches for assessing temperament in calves post-weaning. K. L. Barkley*[1], L. D. Pullen[1], A. M. Kopanko[1], A. E. Tanner[1], S. R. Blevins[1], M. L. Wahlberg[1], C. W. Swecker Jr[1], J. P. S. Neel[2], W. M. Clapham[2], and R. M. Lewis[1], [1]*Virginia Tech*, *Blacksburg,* [2]*USDA-ARS*, *Beaver, WV*.

Cattle under routine management express behaviors that may represent stress or anxiety. Our objectives were to develop reliable measures of calf behavior, and to determine whether these measures change under repeated handling. A factorial design of 2 measurement protocols [regular (R), irregular (I], and 3 recording periods, each 1 mo apart, was used. The R measurements were collected over 3 consecutive d; I measurements were collected on d 1 within each period. Twenty Angus-cross heifer calves, 2 wk post-weaning, were randomly assigned to each protocol. Calves were weighed, calmly moved into a squeeze chute, and their heads caught. Behavior was scored from 1 (docile) to 5 (aggressive) by 3 observers. Heart rate (HR), and blood and fecal samples, were then collected. Exit velocity (EV) was obtained on release from the chute over 2 m. Calves were penned individually with the same human presence, and again scored. Plasma cortisol concentrations were determined by EIA. Data were analyzed with ANOVA. Protocol, period, and their interaction, were compared on d 1. Period, day, and

their interaction were fitted within R. Both scores were included as covariates to assess cortisol. Chute (0.33 ± 0.16; $P = 0.04$) and pen (0.52 ± 0.12; $P < 0.001$) scores and HR (20 ± 5 beat/min; $P < 0.001$) were less and EV slower (0.43 ± 0.09 s; $P < 0.001$) in R than I. Chute score decreased across periods in R but increased in I ($P = 0.03$). In R in a period, chute score declined with d (0.34 ± 0.14; $P = 0.05$), with little change in pen score, EV or HR ($P > 0.17$). Chute and pen score were highly correlated in R (0.56; $P < 0.001$); less so in I (0.31; $P = 0.04$). Plasma cortisol was 39% higher at period 1 than 3 ($P < 0.001$). It increased with chute and pen score ($P = 0.01$). Plasma cortisol in R was 22% higher at d 1 than 3. It increased with chute score ($P = 0.01$). Repeated handling reduced ill temperament and signs of stress. Chute score is quickly assessed, indicative of anxiety, and could be used to monitor husbandry practices.

Key Words: temperament, cortisol, calves

913 Relationship of temperament at calving and distribution of beef cows grazing foothill rangeland. D. W. Bailey*[1], H. C. VanWagoner[2], D. Jensen[2], D. L. Boss[2], and M. G. Thomas[1], [1]*New Mexico State University*, *Las Cruces,* [2]*Montana State University*, *Havre*.

The objective of this study was to determine if docility score measured at calving was related to measures of cattle grazing distribution in foothill rangeland of northern Montana. We hypothesized that cows with aggressive temperaments would travel farther horizontally and vertically from water and use steeper slopes than docile cows. A herd of Hereford and Tarentaise crossed cows (n = 186) and a herd of Angus, Charolais, Hereford, Piedmontese, Salers, and Tarentaise crossed cows (n = 191) were observed at calving and assigned a temperament score (1 = calm and 6 = dangerous and extremely aggressive) for 5 years. Both herds were also visually observed during grazing, and their locations were recorded in multiple pastures with rugged topography for 5 years. Only cows that had 2 or more calves in their lifetime were included the analyses. Mean temperament, number of calves and breed were used to explain differences in the average recorded terrain use with a mixed model analysis. Temperament at calving was not related to horizontal or vertical distance traveled to water and slope use in either herd. For the Hereford and Tarentaise crossed cows, breed and number of calves affected both horizontal and vertical distance traveled to water ($P < 0.05$). Cows with more Tarentaise breeding traveled farther than cows with predominantly Hereford breeding. Tarentaise cows traveled 58 ± 2 m vertically from water while Hereford cows traveled 50 ± 2 m. Cows with 3 or more calves during their lifetime (56 ± 2 m) traveled farther ($P < 0.01$) vertically from water than cows with only 2 calves (48 ± 2 m). For the other herd, vertical distance traveled to water was affected by the number calves ($P = 0.01$) with cows with 4 or more calves traveling farther than cows with 2 or 3 calves. We rejected our hypothesis and concluded that docility at calving was not related to terrain use during grazing.

Key Words: docility, behavior, breed

ASAS Western Section Symposium: Perinatal Programming of Offspring Quality 2: Evidence for impacts of maternal nutrition on livestock production

914 Maternal malnutrition induces metabolic reprogramming in offspring. S. P. Ford*[1], L. Zhang[1], L. A. George[1], Y. Ma[1], N. M. Long[1], A. B. Uthlaut[1], and P. W. Nathanielsz[2], [1]*Center for the Study of Fetal Programming, Department of Animal Science, University of Wyoming*, *Laramie,* [2]*Center for Pregnancy and Newborn Research, University of Texas Health Sciences Center*, *San Antonio*.

Evidence suggests that both maternal undernutrition and overnutrition negatively impacts fetal growth and development and postnatal health in mammals. Maternal nutrient restriction from early to midgestation in ewes (NR ewes) results in fetal IUGR (~30% weight reduction) at midgestation compared with ewes fed to NRC requirements (Control, C ewes). If NR ewes are then fed to requirements from mid gestation to term, their offspring are born at weights similar to C ewes, suggesting accelerated fetal growth rate from mid to late gestation. These offspring exhibit increased appetite, insulin resistance and adiposity during post natal development. By 8 mo of age, these NR offspring are heavier, and have increased carcass fat and reduced skeletal muscle mass compared with C offspring. In contrast, if ewes are overfed from 60 d before conception and throughout gestation (obese, OB ewes) their fetuses are macrosomic (enlarged) at midgestation, and then exhibit reduced growth rates from mid-gestation to term. As with lambs from NR ewes, Lambs from OB ewes exhibit birth weights similar to those of ewes fed to requirements. Also similar to NR offspring, OB offspring develop an increased appetite, insulin resistance, and obesity in early adulthood. Interestingly, fetuses gestated by NR and OB ewes experience similar alterations in pancreatic growth and development throughout gestation. At midgestation, both NR and OB fetuses exhibit marked increases in pancreatic β-cell numbers compared with C fetuses, but by late gestation, β-cells numbers have decreased dramatically to reach numbers much lower than that of C fetuses. This talk will compare and contrast the specific prenatal and postnatal impacts of maternal nutrient restriction and overfeeding on conceptus development and offspring health.

Key Words: maternal malnutrition, fetal development, postnatal health

915 Impacts of maternal nutrition in farm animal species on growth characteristics of their offspring. M. Du*, M. J. Zhu, and S. P. Ford, *Department of Animal Science, University of Wyoming*, *Laramie*.

Meat animals spend about one third of their life inside the uterus, and more importantly, all major developmental events are accomplished during the fetal stage. Proper maternal nutrition is crucial for fetal development and the growth characteristics of offspring. Maternal under-nutrition during mid to late gestation reduces birth weight, muscle weight and fatness of offspring at birth, but increases fatness at slaughter, resulting in a permanent impairment of growth performance of offspring. On the other hand, the impact of maternal over-nutrition on fetal development and offspring growth performance is more complicated depending on whether placental function is impaired. If maternal obesity and over-nutrition impairs the function of placenta, the nutrient delivery to fetuses is limited, resulting in poor fetal development and offspring growth characteristics. One the other hand, maternal obesity and over-nutrition without impairment of placental function provides excessive macronutrients to fetuses, which often results in macrosomia and slightly improves the growth performance of offspring. Inflammation associated with maternal obesity may promote adipogenesis (formation of adipocytes) at the expense of myogenesis (formation of muscle cells) and osteogenesis (formation of bone tissue), increasing the fatness but also the marbling of offspring carcasses

Supported by USDA-NRI and NIH Wyoming INBRE.

Key Words: maternal nutrition, growth, offspring

916 Maternal nutrition and developmental programming: Impacts on development and function of the gastrointestinal system in offspring. J. S. Caton*, A. M. Meyer, D. A. Redmer, K. A. Vonnahme, and L. P. Reynolds, *Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo*.

Developmental programming is the concept that a perturbation during a sensitive period of development can have lasting consequences in offspring. Maternal nutrition is one of the primary factors impacting growth and development of the gravid uterus, and altered maternal nutrient supply has resulted in compromised offspring. Growth, development, and vascularization of the gastrointestinal tract are often overlooked but are essential processes underlying nutrient uptake and expenditure, immunological competence, neonatal survival, postnatal growth, and metabolic regulation via a cadre of hormones and growth factors. Tissue vascularization is crucial for nutrient transport both to and from the intestine; thus angiogenesis, or the formation of blood vessels, is critical for proper intestinal function. Data indicate that maternal nutrition can alter vascular measurements in late term fetal, early postnatal, and at market weight in ruminant offspring. Additionally, intestinal development during the perinatal period includes growth via cell proliferation, hypertrophy, as well as changes in vascularization. Fetal intestinal growth, inflammatory responses, and/or vascularity, measured near term, have been altered by changes in maternal nutrient supply. In addition, nutrient digestibilities and enzyme activities have been altered in offspring from nutrient compromised dams. Maternal nutritional effects on intestinal vascularity have been accompanied by changes in mRNA expression of vascular endothelial growth factor (VEGF) synthesis, and soluble guanylate cyclase (endothelial nitric oxide, NO receptor), implying possible regulatory roles of VEGF and NO systems. Nutritional modulation or other therapeutics may provide means to stimulate intestinal blood flow and/or angiogenesis, affording potential opportunity to overcome growth or health challenges in compromised ruminants.

Key Words: developmental programming, intestine, maternal nutrition

917 Programming reproductive tract development. F. F. Bartol*[1] and C. A. Bagnell[2], [1]*Auburn University*, *Auburn, AL*, [2]*Rutgers, The State University of New Jersey*, *New Brunswick*.

Female reproductive tract (FRT) development begins prenatally and is completed postnatally. This developmental program is defined by patterns of gene expression in FRT tissues during organizationally critical fetal and perinatal periods. Data for cattle, sheep and pigs show that transient exposure to steroid hormone receptor-modulating agents from birth (postnatal day = PND 0) can disrupt the normal developmental program and alter the developmental trajectory of FRT tissues with lasting consequences. Data for the pig (*Sus scrofa domesticus*) show that postnatal endometrial development and programming are marked by the onset of estrogen receptor (ESR1) expression in nascent glandular

epithelium and stroma by PND 2. Factors affecting ESR1 expression and activation in porcine uterine tissues between birth and PND 14 affect the uterine developmental program and can alter endometrial function and reduce uterine capacity in adults. Maternal effects on neonatal FRT development can be communicated through signals transmitted in milk via a lactocrine mechanism. Studies involving relaxin (RLX), a prototypical milk-borne morphoregulatory factor in the pig, were conducted to test the lactocrine hypothesis for maternal programming of porcine FRT development. Developmental programs were compared for uterine and cervical tissues obtained on PND 2 or PND 14 from gilts allowed to consume colostrum versus those fed a milk replacer from birth, in the presence and absence of exogenous RLX. Results indicated that a lactocrine-driven mechanism, essential to support normal FRT developmental programs, evolves in the uterus and cervix between birth and PND 2. In the absence of lactocrine signaling during this period, normal uterine and cervical ESR1 expression, as well as that of other markers of RLX action and/or estrogen receptor activation including vascular endothelial growth factor-A and matrix metalloproteinase-9, are markedly ($P < 0.01$) reduced by PND 2 and remain low through PND 14, even when replacer-fed gilts are allowed to consume colostrum after PND 2. Lactocrine signaling deserves consideration as an element of the FRT programming equation.

Key Words: female reproductive tract, lactocrine, programming

Beef Species Symposium: Upcoming Environmental Policies and Their Effects on Beef Production

918 Environmental issues: What every beef producer needs to know. T. McCann Thies*, *National Cattlemen's Beef Association*, *Washington, DC*.

The current environmental regulatory climate in Washington is intense. Effects of animal agriculture operations on the environment are being scrutinized increasingly by the US Environmental Protection Agency, Congress, the courts, and environmental groups. The presentation will discuss the political climate in Washington with regard to environmental issues, and will summarize briefly many of the environmental issues that confront the beef industry.

919 Alberta's experiences with greenhouse gases: The beef protocols. J. Basarab*, *Department of Agricultural, Food and Nutritional Science, University of Alberta*, *LaCombe, AB, Canada*.

Protocols have been developed to lessen green house gases. These protocols include feeding edible oils to cattle, reduced days in the feedlot, reduced age at slaughter and selection for low RFI in beef cattle. How are greenhouse gases quantified using one or two examples? What are the economic returns for reducing greenhouse gases? We are conducting this research to reduce costs, improve production efficiency and ultimately profit.

920 Integration of environmental mandates into ranching and farming operations. P. Genho*, *FMC*, *Salt Lake City, UT*.

From a rancher's perspective, how will they adapt ranch management practices to comply with mandated legislation related to the environment?

921 Telomere maintenance mechanisms in normal, immortalized, and transformed chicken cells. T. H. O'Hare* and M. E. Delany, *Department of Animal Science, University of California, Davis*.

Telomeres protect the ends of linear chromosomes in eukaryotes. A specialized holoenzyme consisting of an RNA and a protein catalytic subunit, telomerase, adds the telomeric TTAGGG repeat to the chromosome ends thus mitigating telomere shortening. A recent study (O'Hare and Delany, 2009) investigated variation within and among the telomeric array profiles of normal, immortalized, and transformed chicken cells. An immortalized chicken embryo fibroblast (CEF) cell line, DF-1, exhibited ~3-fold more telomeric content (17%) as compared with normal chicken cells (5%). Interestingly, DF-1 had been reported to be telomerase-negative (Christman et al., 2005). The current study confirmed that DF-1 cells are telomerase-negative and found that a chemically transformed CEF cell line, OU2, is telomerase-negative. The telomeric profile of this transformed line indicates a content of ~5%. Given their lack of telomerase activity, we hypothesize DF-1 and OU2 are using the alternative lengthening of telomeres (ALT) pathway to maintain or lengthen their telomeres. Gene expression of telomerase components, telomere-regulating, and ALT-related proteins was examined. The expression profiles of DF-1 and OU2 were compared with telomerase-negative mortal CEFs, telomerase-positive virally transformed DT40 cells, and gastrula stage embryos. These results provide evidence supporting the existence of the ALT pathway in DF-1 and OU2 cells.

This project was supported by NRI competitive grant no. 2005–35205–16679 from the USDA National Institute of Food and Agriculture Animal Genome Program.

Key Words: telomere, telomerase, alternative lengthening

922 Genetic analysis of walking ability and mortality in the turkey. C. D. Quinton[1], B. J. Wood*[1,2], and S. P. Miller[1], [1]*Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, Canada*, [2]*Hybrid Turkeys, Kitchener, Canada*.

Genetic selection for fitness is a potential method to improve overall liveability in the turkey. A method in which fitness can be defined is mortality and the potential to survive to slaughter. In this study the heritability (h^2) was calculated for survival (SURV) to slaughter/maturity (23 weeks) and hip and leg strength (H/L) and their relationship (both phenotypic and genetic) to walking ability (WALK) and bodyweight (BW). The heritabilities of the binary traits were also transformed to a liability scale. Consequently there are heritabilities on both the observed and liability scales. Genetic parameters were estimated with multiple-trait restricted maximum likelihood in ASReml 3.0 using a series of 3-trait animal models. The table shows the results of the analysis with walking score having a moderate heritability similar to body weight. Survival and hip/leg health had lower heritability on the observed scale, but a moderate h^2 on the liability scale. The liability scale heritability estimates were moderate which would predict a good response to selection. All survival traits had high genetic correlations with each other, but negative genetic correlations with weight. Genetic correlations were stronger than corresponding phenotypic correlations. Walking score has good heritability and has high positive genetic correlation with survival, as well as moderate genetic correlations with hip and leg health. As a consequence walking score would be a good indicator trait for selection to improve both survival and hip and leg health.

Table 1. Heritability (h^2), common environment (c^2) and genetic[1] and phenotypic[2] correlations between survival, walking score, hip and leg strength and bodyweight

	SURV3	WALK4	H/L5	BW6
h^2 observed	0.166	0.224	0.080	0.248
h^2 liability	0.190		0.174	
c^2	0.034	0.074	0.041	0.350
Correlations				
SURV	-	0.864	0.808	–0.435

923 Factors affecting spermatozoa morphology in beef bulls. C. A. Roberts*, T. W. Geary, M. D. MacNeil, R. C. Waterman, A. J. Roberts, and L. J. Alexander, *USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT*.

The objective of this study was to evaluate factors affecting sperm morphology of bulls (n = 908) collected at 320 d of age. Bulls were a composite breed (50% Red Angus, 25% Charolais, and 25% Tarentaise) born from 2002 to 2008 to dams fed levels of feed during mid and late gestation that were expected to provide marginal or adequate nutrition while grazing dormant winter forage. After weaning, bulls were fed to appetite (CON) or restricted (REST) to 80% of that consumed by CON on BW basis. Semen samples were collected using an electroejaculator and evaluated using standard BSE procedures. Spermatozoa morphology was evaluated by classifying 100 spermatozoa per bull at 400X magnification into the following categories: normal spermatozoa, knobbed acrosome, head defects, distal midpiece reflex, dag defect, bowed midpiece, proximal droplet, distal droplet, coiled principle piece, and bent principle piece. Each morphological trait, along with scrotal circumference (SC), gross motility, and percent progressive motility was analyzed using MTDFREML and pedigree information from 8163 relatives born from 1974 to 2008 to provide heritability estimates. Heritability estimates for these traits were: SC ($h^2 = 0.67$), normal sperm ($h^2 = 0.18$), dag defect ($h^2 = 50$), bowed midpieces ($h^2 = 0.19$), proximal droplets ($h^2 = 0.37$), bent principle pieces ($h^2 = 0.18$), gross motility ($h^2 = 0.20$), and progressive motility ($h^2 = 0.20$). The moderate heritability of percent normal sperm and several of the other sperm defects suggest that selection for improved sperm morphology is possible. Further analysis with MTDFREML determined genetic correlations between the above traits and pre-weaning gain direct, pre-weaning gain maternal, post-weaning gain, and scrotal circumference. Maternal pre-weaning gain was highly correlated with scrotal circumference ($r = 0.70 \pm 0.24$) but pre-weaning gain direct ($r = 0.29 \pm 0.20$) and post-weaning gain ($r = 0.01 \pm 0.17$) were not. Scrotal circumference and post-weaning gain were not highly correlated with morphology and therefore are not good indicators of spermatozoa morphology. Neither in utero nor postweaning diet affected any of the traits measured.

Key Words: bull, spermatozoa morphology, heritability

924 Bayesian QTL inference and gene identification for first service conception rate in Brangus heifers. S. O. Peters*[1,5], K. Kizilkaya[2,4], D. J. Garrick[2], R. L. Fernando[2], J. M. Reecy[2], Z.-L. Hu[2], R. L. Weaber[3], G. A. Silver[1], and M. G. Thomas[1], [1]*New Mexico State University*, *Las Cruces,* [2]*Iowa State University*, *Ames,* [3]*University of Missouri*, *Columbia,* [4]*Adnan Menderes University*, *Turkey*, [5]*University of Agriculture, Abeokuta*, *Abeokuta, NGR*.

First service conception (FSC) like many binary fertility traits is of low heritability, but strongly impacts production costs in beef cattle operations. The objectives of this study were to conduct a Bayesian-based whole genome QTL scan for FSC in Brangus (3/8 Brahman x 5/8 Angus) heifers and to identify candidate genes from a hypothalamic transcriptome reference resource. Yearling heifers (n = 830 from 67 sires) were estrous synchronized with progesterone-based protocols, artificially bred, then later palpated for pregnancy status (57.3% FSC rate). Heritability was estimated to be 0.21 ± 0.1. Genotypes for each heifer were obtained from BovineSNP50 Infinium beadchips. Simultaneous association of all SNP with FSC were tested in a GenSel Bayes C analysis using a mixture model that treated SNP effects as random with an assumed fraction 0.001 indicating an association. Fixed effects for analysis of FSC included birth year, calving season, contemporary group, and covariates of yearling age and weight. Model frequency >0.01 was assumed indicative of QTL association. Eight regions on chromosomes 6, 8, 26 and 29 were associated with variation in FSC (model frequency ≥0.03). The strongest evidence of association (model frequency 0.17) was a SNP mapped to position 28.6 Mb on BTA 8. Since the hypothalamus is a regulatory tissue of the reproductive endocrine axis, the transcriptome of this tissue was sequenced using the Illumina Genome Analyzer II (RNA-Seq) and aligned with bovine genome (Ver. 4.0) to evaluate presence and level of expression of potential candidate genes among pre and postpubertal heifers. Several annotations were identified within a 1.5 Mb region flanking this SNP on BTA 8 using Alpheus. Five genes with differential hypothalamic expression were identified and ontology of these genes included neuron function and gene regulation. Cumulatively, results warrant fine mapping this region of chromosome 8 to help determine functionality in regulating FSC.

Key Words: candidate gene, fertility, QTL

925 Impact of sire birth weight potential on birth and weaning traits when mated to virgin heifers. G. K. Mantz* and P. Nyren, *North Dakota State University Central Grasslands Research Extension Center*, *Streeter*.

The objective of this study was to examine the effect that mating virgin heifers to sires of varying birth weight potential (BWP) has on birth and weaning traits of offspring. In June, 2008, 98 virgin heifers 13 to15 mo of age were stratified by frame score and weight within frame score. Heifers were assigned randomly to 2 treatment groups. Treatments were based on sire BWP: 1) moderate BWP (MBWP) sires - Angus sires with birth weight (EPD between −1.6 and +0.4 kg, and 2) very low BWP (VLBWP) sires - Lowline sires. Pre-calving heifer weights were obtained 18 February 2009. Calves were born March through May of 2009. Birth weights and a calving difficulty (CD) score (1 = unassisted, 2 = hand pull, 3 = jack pull, 4 = Caesarean, 5 = abnormal presentation) were recorded within 24 h of calving. Calf weaning weights and post-calving dam weights were recorded in October of 2009. Weaning weights were adjusted to a constant 205-d weaning age. There was a calf sex by sire BWP interaction for birth weight ($P = 0.01$) and CD score ($P = 0.03$). Bull calves from MBWP sires were heavier at birth than bull calves from VLBWP sires (40vs. 34 kg; $P = 0.0002$) and had a greater CD score (1.7 vs. 1.1; $P = 0.01$). Birth weights did not differ ($P = 0.92$) between heifer calves sired by the MBWP sires (33 kg) and those sired by VLBWP sires (32 kg). All heifer calves from both sire groups were born unassisted (CD = 1). Calf weaning weight was affected ($P < 0.0001$) by sire BWP, and calf sex ($P = 0.01$). Offspring of MBWP sires were heavier at weaning than those of VLBWP sires, 243 and 213 kg, respectively. Steer calves were heavier at weaning (235 kg) than heifer calves (220 kg). Weaning weight for calves from MBWP and VLBWP sires were 217 and 195 kg, respectively. Dams nursing calves of VLBWP sires lost less weight than dams nursing calves of MBWP sires (28 vs. 43 kg; $P = 0.04$). In summary, using VLBWP sires reduced birth weight and calving difficulty in bull calves and reduced dam weight loss. However, calves sired by VLBWP sires weighed less at weaning than calves sired by MBWP sires.

Key Words: birth weight, calving difficulty, heifers

926 Use of random regression models for the genetic analysis of farrowing survival in pigs. C. Y. Chen*[1], I. Misztal[1], S. Tsuruta[1], W. O. Herring[2], J. Holl[2], and M. Culbertson[2], [1]*Department of Animal and Dairy Science, University of Georgia*, *Athens,* [2]*Smithfield Premium Genetics Group*, *Rose Hill, NC*.

The objective was to compare estimates of genetic parameters for number of stillborns (NSB) in relation to litter size (LS) using random regression models (RRM). Records of a single Duroc population were obtained from 4 nucleus farms from 2004 to 2008. Data from first parity (P1, n = 6,575) litters and second to fifth parity (P2–5, n = 6,259) litters were analyzed separately. Fixed effects included farm-year-season as contemporary groups, parity (for P2–5 only), and fixed cubic regression coefficients on LS with Legendre polynomials. Random effects were additive genetic and permanent environmental effects (for only P2–5). Heterogeneous residual variances were considered in the models. Legendre polynomials (RRM-L), linear splines (RRM-S), and degree 0 B-splines (RRM-BS) with regressions on LS were applied. Parameter sets used for respective models were quadratic polynomial, knots at LS 5, 9, and 13, and intervals of LS 5–7, 8–10, and 11–13 for P1. For P2–5 the same parameters were linear polynomial, knots at LS 6 and 12, and intervals of LS 5–7 and 8–13. Estimates of genetic parameter were similar with the 3 models. For P1, average heritabilities were 0.14, 0.06, and 0.07 in LS 5, 9, and 13, respectively. For P2–5, heritabilities were 0.18, 0.05, and 0.06 with repeatabilities of 0.19, 0.11, and 0.21. For P1, average genetic correlations between LS 5–9, 5–13, and 9–13 were 0.53, −0.29, and 0.65, respectively. For P2–5, correlations averaged for RRM-L and RRM-S were 0.75, −0.21, and 0.50, respectively. The correlation was 0.66 between LS 5–7 and 8–13 for RRM-BS. Based on the analysis, NSB at low and high LS appear to be different traits although genetic parameters for NSB in first and later parities are similar.

Key Words: litter size, pigs, random regression, stillbirth

927 Effectiveness of genetic predictions of Holstein gestation length and relationship to lactation yield for the subsequent lactation. H. D. Norman*, J. R. Wright, and R. H. Miller, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

To determine if genetic evaluations of gestation length (GL) were reliable and repeatable, Holstein bulls used to develop those evaluations were stratified into 7 groups according to predicted transmitting ability (PTA) for service-sire GL based on calvings from 1998 through 2004: ≤ –3.00, –3.00 to –2.01, –2.00 to –1.01, ... 1.00 to 1.99, and ≥ 2.00 d. An independent set of 261,598 first-parity cows later mated to the

same bulls were grouped by the service-sire PTA GL groups (group size of 8,317 to 73,324 gestations), and their GL were examined to determine effectiveness of PTA GL. The model included fixed effects for service-sire group, conception date, conception date squared, and herd-year. Mean GL for mates by service-sire group (from lowest to highest PTA) were 275.3, 276.4, 277.7, 278.7, 279.6, 280.7, and 281.8 d. Yield in the subsequent lactation was also examined for mates by service-sire group. Least squares differences by service-sire group were –84, –79, –14, 15, 28, 50, and 0 kg for standardized milk yield; –2, –3, –1, 1, 1, 1, and 0 kg for fat yield; and –2, –2, 0, 1, 1, 1, and 0 kg for protein yield. The relationship between PTA for service-sire GL and yield appeared to be curvilinear as yield decreased for the ≥2.0 d PTA group. Phenotypic relationship between GL and standardized yield in the subsequent lactation also was examined using 9 cow GL groups: ≤275, 276, 277, ... 282, and ≥283 d. Group size ranged from 17,493 to 64,876 gestations. The model included fixed effects for GL group, conception date, conception date squared, and herd-year. Least squares differences by GL group were −528, –287, –218, –194, –128, –122, –90, –90, and 0 kg for standardized milk yield; –19, –10, –8, –7, –5, –4, –4, –3, and 0 kg for fat yield, and –11, –6, –4, –3, –2, –2, –2, –2, and 0 kg for protein yield. Cows mated to bulls with PTA for longer service-sire GL and cows with longer GL phenotypes were more productive in the lactation following gestation.

Key Words: gestation length, genetic evaluation, lactation yield

928 Estimation of genetic parameters for measures of calf survival and health in a population of Holstein dairy calves in New York state. L. Henderson*[1], F. Miglior[2,3], A. Sewalem[2,3], D. Kelton[1], A. Robinson[4], and K. E. Leslie[1], [1]*Department of Population Medicine, University of Guelph*, *Guelph, Ontario, Canada, N1G 2W1*, [2]*Guelph Food Research Centre, Agriculture and Agri-Food Canada*, *Guelph, Ontario, Canada, N1G 5C9*, [3]*Canadian Dairy Network*, *Guelph, Ontario, Canada, N1K 1E5*, [4]*Department of Animal and Poultry Science, University of Guelph*, *Guelph, Ontario, Canada, N1G 2W1*.

The objectives of this study were to estimate the genetic parameters of calf survival and health for a population of Holstein calves from New York (NY) State, as well as to associate the EBV determined in the current study with traits from on-going genetic evaluations used in Canada and the US. Data were recorded for 7,372 heifer calves at a commercial rearing facility in NY, from arrival at 1 to 7 d of age for the duration of stay at the facility. Performance and disease up to weaning, and mortality before and after weaning, were recorded. Analyzed data were limited to daughters of sires with at least 10 calves originating from farms which had sent at least 5 calves to be raised at the facility. As such, calves from 264 sires and 36 herds were studied using survival analysis and 2-trait model (survival from arrival to weaning and from weaning to exit) for calf survival and 3-trait sire model for calf health (preweaning undifferentiated respiratory disease, umbilical diseases, and bloat). In general, there was increased risk of mortality for calves with very light or heavy weight at arrival, low serum total protein, low weaning weight and for calves born in a difficult parturition. The heritability from the survival analysis was 0.063, where the heritability from the linear model was 0.001 for survival to weaning and 0.036 for survival from weaning to exit. The genetic correlation between the 2 latter traits was 0.58. In the genetic analysis of health traits, the heritability estimates were 0.09 for bovine respiratory disease, 0.14 for umbilical diseases and 0.04 for bloat. The genetic correlation between bovine respiratory disease and umbilical diseases was 0.62. Significant associations between proofs for survival and health traits with proofs for routinely evaluated traits in Canada and the US were found. Results suggest that there are significant differences among Holstein sires for calf survival from weaning to the growing period and for calf health during the preweaning period.

Key Words: calf survival, calf health, multiple-trait model

929 Estimation of genetic parameters for workability traits. A. Sewalem*[1,2], F. Miglior[1,2], and G. Kistemaker[2], [1]*1Agriculture and Agri-Food Canada, Guelph Food Research Center*, *Guelph, ON, Canada*, [2]*Canadian Dairy Network*, *Guelph, ON, Canada*.

The aim of this study was to estimate the genetic parameters of milking temperament for Canadian Holsteins and to assess the correlation with other traits of economic importance. Cows were evaluated for this trait during milking and given a subjective score based on a 5 point linear scale (1 = Very Nervous, 2 = Nervous, 3 = Average, 4 = Calm and 5 = Very Calm). The phenotypic frequency of each score was 1.45%, 9.80%, 49.20%, 35.43% and 4.13%, respectively. The model included the fixed effects of herd-year, season of calving, age at calving, months in milk and random effects of animal and residual. The estimated additive genetic and residual variances were 0.0042 and 0.0285, respectively. The resulting heritability value was 0.128%. Correlations between bull EBV for milking temperament with EBV for production, type and other traits were calculated for the Holstein breed. Correlations were essentially low for production traits and functional herd life (0.038 - 0.048), favorable for most type traits (0.09 – 0.15) as well as milking speed (0.14) but undesirable for type traits related to feet and legs (−0.02), lactation persistency (−0.07), calving ease (−0.11) and somatic cell score (0.18). Low and undesirable correlations were also observed for most fertility traits (−0.026 to −0.114).

Key Words: milking temperament, variance component estimation, breeding value correlations

930 Health treatment rates of Holstein cows selected for large versus small body size. J. C. Becker*, B. J. Heins, G. D. Marx, and L. B. Hansen, *University of Minnesota*, *St. Paul*.

Holsteins selected for large versus small body size since 1966 were evaluated for incidence rates of health treatment from the Northwest Outreach and Research Center, Crookston, of the University of Minnesota. All health treatments were recorded for cows from 1983 to 2005. Treatments were recorded for 12 categories of health disorders. Records were for 544 first lactations, 366 s lactations, and 445 third and greater lactations, and the 3 lactation groups were analyzed separately. A chi-squared test was conducted separately for genetic lines for first, second and third and greater lactations. For first lactation, cows in the small line had significantly ($P < 0.01$) fewer displaced abomasums (5% versus 16%) and significantly ($P < 0.05$) less ketosis (5% versus 9%) than cows in the large line. The small line and large line did not differ significantly for mastitis, locomotion, milk fever, and early reproduction problems during first lactation. For second lactation, cows in the small line had significantly ($P < 0.05$) fewer hoof disorders (15% versus 24%), displaced abomasums (8% versus 2%), and respiratory disorders (0.5% versus 3%) than cows in the large line. The small line and large line did not differ significantly for mastitis, ketosis, milk fever, and early reproduction problems during second lactation. For third and greater lactations, cows in the small line had significantly ($P < 0.01$) fewer hoof disorders (17% versus 38%) than cows in the large line. Cows in the small and the large line did not differ significantly for incidence of mastitis, displaced abomasums, ketosis, milk fever, respiratory disorders, and early reproduction problems during third and greater lactations.

Key Words: body size, health traits, genetics

931 Sequential evaluation of longitudinal conformation data in dairy cows. N. Gengler*[1,2], S. Vanderick[1], and C. Bastin[1], [1]*University of Liège - Gembloux Agro-Bio Tech*, *Gembloux, Belgium*, [2]*National Fund for Scientific Research*, *Brussels, Belgium*.

Current genetic evaluation for Holstein type data in the Walloon Region of Belgium is based on a multi-trait animal model for repeated data and missing traits using a transformation based on multiple diagonalization. Currently used data covers 33 traits observed in all lactations if at least one classification was done for a given cow before it was considered mature. A total of 102,875 records were available for first parity and 30,378 records for second or later parities in January 2010. With a total of 117,013 classified cows, the number of repeated records was 16,240, with repetitions within and across lactations. Based on a request from the field and to make better use of available longitudinal data along an age at classification gradient, research was performed to develop an adapted model. In this study a random regression model was developed that was equivalent to a multi-lactation (first vs. later) model allowing repeated classifications inside parity but with some fixed effects spanning across parities. The random regressions were defined as constant and linear regressions on parity number −1. A 2 step approach was developed, for solving and variance components estimation. In this approach, a model based on the current genetic evaluation model modified to host single-trait random regressions was the first step. The second step consisted in the joint multiple-trait analysis of the meta-data (regression coefficients) provided by the first step. The proposed approach has very interesting potential for the analysis of data with large numbers of traits as trait reduction techniques can be integrated in the procedure.

Key Words: type traits, equivalent model, sequential evaluation

932 Fitness of Boer, Kiko, and Spanish does managed on humid, subtropical pasture in central Tennessee. R. Browning Jr.*[1] and M. L. Leite-Browning[2], [1]*Tennessee State University*, *Nashville*, [2]*Alabama A&M University*, *Huntsville*.

Records for Boer (n = 132), Kiko (n = 92), and Spanish (n = 79) does across 6 yr of production were processed to assess doe fitness traits among meat goat breeds when managed on southeastern US pastures. Does were mated in a complete 3-breed diallel each fall for spring kidding. A total of 1042 doe-yr units were observed with does ranging from 2 to 8 yr of age and managed together in a semi-intensive manner. Herd health records were analyzed for each production year. Does were treated for foot scald and foot rot upon observed lameness. The herd was not vaccinated for foot rot. Breeds differed ($P < 0.01$) for lameness cases treated during the year. Boer required more ($P < 0.01$) treatments for lameness (1.8 ± 0.1 cases/doe) than Kiko (0.6 ± 0.1 cases/doe) or Spanish (0.9 ± 0.1 cases/doe). A larger ($P < 0.01$) proportion of Boer required single (75 ± 5%) or multiple foot treatments (49 ± 4%) annually compared with Kiko (36 ± 5%; 17 ± 4%) or Spanish (45 ± 5%; 24 ± 4%). Does received a tactical anthelminic treatment at parturition. Individual does presenting clinical symptoms of endoparasitism during the year received need-based treatment. Breeds differed ($P < 0.01$) for need-based anthelmintic treatment. Need-based dewormings were more numerous for Boer (0.8 ± 0.1 cases/doe) than for Kiko (0.4 ± 0.1 cases/doe) or Spanish (0.3 ± 0.1 cases/doe). A larger ($P < 0.01$) proportion of Boer required single (53 ± 4%) or multiple need-based dewormings (23 ± 4%) per year compared with Kiko (26 ± 4%; 4 ± 3%) or Spanish (23 ± 3%; 7 ± 2%). Fecal egg counts to assess endoparasite loads 3 mo postpartum were higher ($P < 0.01$) for Boer dams (660 eggs/g) than for Spanish dams (362 eggs/g); Kiko dams were intermediate (500 eggs/g). A smaller proportion ($P < 0.01$) of Boer does weaned 3-mo-old kids (49 ± 3%) and stayed in the herd (64 ± 3%) annually compared with Kiko (78 ± 3%, 85 ± 2%) and Spanish does (77 ± 3%, 84 ± 2%). Significant differences were evident among meat goat breeds for doe fitness under southeastern US pasture conditions.

Key Words: meat goats, breed, fitness

Companion Animals Symposium: Comparative Enrichment: Implications for Health and Behavior

933 The role of training and enrichment. C. Dikeman*, *Omaha's Henry Doorly Zoo*, *Omaha, NE*.

Animal scientists have an extraordinary burden to promote the health and well-being of all animals in their care. With more than 100 million guests visiting zoos, and the US companion-animal population extending to well over 350 million, the role humans play in promoting the health and well-being of companion and exotic animals in captivity is increasingly important. Additionally, an estimated 6–8 million dogs and cats enter US animal shelters annually, with many of those animals surrendered by owners for behavioral problems. Promoting species, or breed appropriate behaviors through proper training and environmental enrichment, regardless of animal housing, should be a paramount concern for all animal scientists working with livestock, exotic animals, laboratory animals, shelter animals, or privately owned pet animals. Improving the psychological well-being of an animal can improve the viability that animal has to a program and could aid in the reduction of owner surrendered animals to shelters. The objectives of this symposium will be to explore the important role that training and environmental enrichment provide to captive and companion animals including shelter animals, laboratory animals, pets, and zoo animals, and to encourage and promote the development of training and enrichment protocols and ideals within animal science and husbandry programs.

Key Words: training, enrichment, behavior

934 Animals make us human: A look at the emotional lives of animals. T. Grandin*, *Colorado State University*, *Fort Collins*.

Some scientists may question if animals have true emotions similar to humans. Research clearly shows that the emotional systems in all mammals are similar. Human psychiatric drugs such as Prozac have similar effects on dogs. All mammals have the same neurotransmitters and similar subcortical brain structures where the emotional systems are located. The basic emotional systems in mammals have been extensively mapped. Unfortunately, most of these studies are in the neuroscience literature that is seldom read by animal scientists and veterinarians. The emotional circuits for fear have been the most studied. Lesioning the amygdala will block both conditioned and unconditioned fear behaviors. Jaak Panksepp has identified 3 other core emotional systems of seeking (approaching a novel stimulus), rage, and panic (separation anxiety). He also lists 3 additional emotional systems of play, lust (sex drive), and care (mother young nurturing behavior). Neuroscientists have located the specific subcortical brain regions that control these emotional systems. Animals in barren environments will often engage in repetitive stereotypical behavior. Figuring out which emotional system is driving their behavior will make it possible to design more effective environmental enrichments. For example, a gerbil will often engage in repetitive digging that still continues after the gerbil is given more substrate to dig in. The digging behavior stops when the gerbil is given a shelter so it is hidden from aerial predators in the sky. This behavior is driven by an instinctual fear of predation. The gerbil futilely keeps digging unless it is given enough substrate to form a hiding place. An understanding of the emotional systems that are driving a behavior will greatly improve animal welfare.

Key Words: environmental enrichment, animal welfare, emotion

935 Bringing out their wild side—Enriching the lives of captive exotic animals. M. S. Edwards*, *California Polytechnic State University*, *San Luis Obispo*.

Enrichment is a dynamic process for enhancing animal environments within the context of a species' behavioral biology and natural history. The goal of environmental changes is to increase the animal's behavioral choices and draw out species–appropriate behaviors, thus enhancing animal welfare (AZA Behavior Scientific Advisory Group, 1999). Application of management techniques encouraging species–typical behavior is not a recent phenomenon among animal care professionals, yet significant expansion in the field began in the 1980s (Mellen and MacPhee, 2001). Not unlike the integration of animal health, reproduction or nutrition sciences into exotic animal husbandry, current application and systematic review of environmental enrichment practices is objectively based in disciplines of ethology, psychology and animal science (Shepherdson, 1998). The inherent value of enrichment to captive exotic animal welfare is recognized by both regulatory and professional organizations. USDA regulation of environmental enhancement to promote psychological well–being of nonhuman primates was adopted in 1991 (9 CFR 3.81). Institutions accredited by the Association of Zoos and Aquariums are required to have a formal written enrichment program that promotes species–appropriate behavioral opportunities (AZA, 2010). Potential enrichment techniques are as diverse as a species′ behavioral repertoire. Success of enrichment efforts are enhanced when approached systematically. Goal definition, program implementation, documentation of response criteria to facilitate objective evaluation and continued refinement are hallmarks of a self-sustaining enrichment program (Mellen and MacPhee, 2001). Complex environments and enrichment techniques are not inconsistent with visitor recreation, wildlife conservation, and conveying an education message. Methods based in enrichment implementation and evaluation have been utilized to enhance visitor experience and advance institutional goals (Kuhar et al., 2010). Natural history and biology define physiological and psychological boundaries within which science-based enrichment, inseparable from animal husbandry, operates.

Key Words: nondomestic, zoo, welfare

936 Improving the lives of laboratory dogs and cats through enrichment and training. B. M. Vester Boler*, *University of Illinois*, *Urbana*.

In 2007, over 22,000 cats and 72,000 dogs were used for animal research in the United States. Current housing guidelines are written for the welfare of these animals, but some undesirable behaviors persist. Providing supplemental enrichment may help lessen unwanted behaviors, such as destructiveness, aggression toward humans and other animals, stereotypies, and self-mutilation. Because the animals are in a research setting, however, toys used for enrichment must meet a specific set of standards, including being able to be cleaned and sanitized, not influencing study results (e.g., consumption during nutritional studies), and safe for the animal to play with while unsupervised. Social interaction within the colony and with humans also appears to be beneficial, leading to decreased stereotypies, less vocalization, reduced stress for the animal and caretakers, and even beneficial effects in cognitive health of aged animals. It is suggested, but not well studied, that training of laboratory animals for routine procedures and as a means of social interaction with humans also may be beneficial. Training of simple commands has been

used in shelters to decrease return relinquishments; as such, laboratory facilities that put their animals up for adoption upon completion of studies may benefit from similar training. In conclusion, more can be done beyond the minimum standards required for laboratory dog and cat housing and socialization that will benefit the animal caretakers and the animals themselves. Finding behavioral and social enrichment activities that meet the requirements of the animal facilities and the research program are vital for sustainability and success.

Key Words: laboratory dogs, enrichment, laboratory cats

937 Do our pets live enriched lives? C. Dikeman*, *Omaha's Henry Doorly Zoo*, *Omaha, NE.*

With over 170 million cats and dogs residing in US households, it seems a contradiction that the question about their husbandry should even be considered a topic for discussion. An estimated 8 million pets enter animal shelters annually with a high percentage of those facing euthanasia. Studies have indicated behavior problems in pets as main causes of owner relinquishments to shelters. Aggression (51%), and inappropriate elimination (43%) were reported as the main causes of owner relinquishments of dogs and cats, respectively (Salman et al., 2000). Both problems may be attributed to the misunderstanding and mismanagement of natural species-appropriate behavioral development. While humans have evolved to share an increasing social bond with these species, we have not mastered the husbandry of living with species of the order Carnivora. While this order is diverse, all carnivores are predatory. Innate carnivorous behavioral patterns include communication, social and territorial, and predatory behaviors (Case 1999, 2003). Carnivores have evolved with keen visual, olfactory, and auditory senses, in addition to musculoskeletal adaptations, that support their predatory ancestry. If one considers the natural history of the canine and feline, including the deliberate breeding to produce breeds displaying unique phenotypes, and temperaments, it becomes clear that our pampered pets live typical lifestyles that fail to support the innate behavioral patterns that naturally dictate their behaviors. Many behavioral problems in pets may be prevented by providing environments that support their species-appropriate natural behaviors. Environmental enrichment is a process for enhancing environments that support behavioral biology (Young, 2003). The concept of providing for psychological well being has been a focus of captive animal management for the last several decades; however, its application in the management and husbandry of domestic pets has not been well studied or applied. Five types of environmental enrichment (social, occupational, physical, sensory, and nutritional) can be utilized in common households to enhance the well-being of our pets, thus promoting the human-animal bond.

Key Words: behavior, enrichment, companion animals

938 Bird Enrichment—Above and Beyond. E. Insalaco*, *Denver Zoo*, *Denver, CO*.

Enrichment is a process through which changes to an environment are made with the goal of modifying behavior in an animal. This usually involves encouraging natural, species specific behavior, or discouraging inappropriate behavior. At Denver Zoo, the purpose of our facility wide behavior program is to ensure that behavioral components are incorporated into all animal care. Advances in enrichment and other behavioral practices are often seen in mammal care programs more often that those of other taxa, including birds. However, there are opportunities for avian enrichment and behavior management that are equally as effective and advantageous as those we have seen in mammalian programming. This presentation will talk about the Denver Zoo behavioral husbandry framework and philosophy, and how it applies to all taxa. In addition, the presentation will focus on behavior programs that have been implemented with several bird species both at Denver Zoo and other facilities, and will look at not only enrichment, but at training and behavior research opportunities as well.

939 Training and enrichment: Stepping into the future. N. Irlbeck*[1,2], [1]*Colorado State University*, *Fort Collins,* [2]*Denver Zoological Gardens*, *Denver*.

Several years ago I had the privilege of working with Dr. Temple Grandin on a project at the Denver Zoo. The goal of the project was to determine vitamin E status of nyala and bongo at the zoo. Temple wanted to develop a crate to restrain the animals so they could be bled. For valid samples the animals needed to be bled in a stress-free state. When requesting permission to work with the 2 antelope, zoo administrators argued with Temple that they were wild animals and that what she wanted to do could not be done. Temple persisted and eventually they acquiesced to letting her try. Temple and her students use operant conditioning to gradually coax the animals into the crate and allow them to be bled. If the animals allowed this behavior without avoidance, they were rewarded with a food candy treat. It worked! Fast forward 15 years and the students of today have grown up in an environment where Animal Planet and Walt Disney are household phrases. Because less than 2% of today's population has anything to do with animal agriculture, these young men and women may have experiences with a dog, cat or at most a horse. And yet, the yearnings to work with animals cannot be denied and under the influence of media many seek to work with exotic species. Because of minimal animal experiences in other than home or family settings, young people tend toward a more anthropomorphic attitude when handling animals. These anthropomorphic tendencies have the potential of creating a more emotional response when working and dealing with animals. Public outcry over horse slaughter is a perfect example. The protection of animals was originally legislated in 1966 under the auspices of the Animal Welfare Act. With the merging of a population of young men and women that view animals as part of their family, along with a greater public awareness of animal handling, the animal-human bond has become increasingly important. There is a need to facilitate a safe interaction between human and animals. Training and behavioral enrichment are just 2 steps on the path to creating a more mentally stimulating environment for animal species.

Key Words: training, enrichment

CSAS Symposium: Issues in North American livestock transport

940 Effects of vehicle design on the welfare and meat quality of pigs under Canadian transport conditions. L. Faucitano*[1], S. Torrey[1], R. Bergeron[2], T. Widowski[2], T. Crowe[4], J. A. Correa[3], J. P. Laforest[3], E. Tamminga[2], and H. W. Gonyou[5], [1]*Agriculture & Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*University of Guelph*, *Guelph, ON, Canada*, [3]*Laval University*, *Quebec City, QC, Canada*, [4]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [5]*Prairie Swine Centre*, *Saskatoon, SK, Canada*.

It is generally acknowledged that pot-belly (PB) trailers and some specific compartments within this vehicle are worse than others in terms of animal losses. However, there is no real alternative truck with such a large loading capacity (230 pigs). Furthermore, the effect of each compartment on animal welfare has not been clearly established. The effects of the PB trailer design on the stress response and meat quality of pigs was studied between June 2007 and July 2008 within a large pan-Canadian study on swine transportation. Twenty-three transport trials were conducted in Quebec and in the Prairies in 2 different seasons of the year (summer and winter). In the Quebec trials, a PB trailer was compared with a double-decked (DD) truck equipped with a moving upper deck during 2 h transportation. In the Western trials, the PB trailer alone was evaluated during 8 h transportation. In the Quebec trials, higher ($P < 0.05$) digestive tract temperatures (DTT) were recorded in the PB trailer for pigs located on the top deck while waiting at the farm in both seasons, and in pigs located in the rear compartments of the top and middle decks during transport in summer. Unloading from the PB trailer took longer ($P < 0.001$) than from the DD truck and took longer from the upper deck compartments, especially in summer. Higher pHu values were found in the loin and ham muscles ($P < 0.01$ and $P < 0.001$, respectively) of pigs transported on the PB trailer compared with the DD truck. In the Western trials, higher ($P < 0.05$) DDT were recorded in pigs located in the rear compartments of the top deck and of the belly before departure from the farm. Loading took longer ($P < 0.05$) for the bottom-nose and top deck in summer and for the belly in winter. Unloading took longer ($P < 0.001$) from these same locations, regardless of the season. Loin and ham pHu values were higher and drip loss values lower in pigs located in the bottom-nose ($P < 0.05$). In conclusion, it appears that the effects of PB design on animal welfare and meat quality in pigs are related to the greater exertion required to negotiate the multiple internal ramps and poor ventilation at some locations.

Key Words: transport, stress, pork quality

941 Contributions of research to the practical aspects concerning long-term road transport of horses. C. L. Stull*, *University of California, Davis*.

Road transport is a common practice in many facets of the horse industry including sport and competitive events, breeding programs, marketing and slaughter channels, and biomedical purposes. The physiological and behavioral responses of horses have been recently studied with contributing factors such as duration, space allowance, cross-tying restraint, feed and water availability, injuries, trailer design, and environmental factors. Data collected (1998) on 306 slaughter horses showed these horses to generally be Quarter Horses or Thoroughbred breeds with a mean age of 11.4 + 0.4 years old and mean weight of 432 + 3.3 kg. The number of injuries sustained was 3.5 times greater ($P < 0.05$) in double-deck (29%) compared with single deck semi-trailers (8%). Stress parameters such as cortisol, immune, or body weight showed smaller responses ($P < 0.05$) between pre- and post-transport samples with horses provided with higher floor area (1.4 to 1.54 m^2/horse). As trip duration increased from approximately 6 to 30 h, muscle fatigue and dehydration were incrementally increased, especially during trips over 27 h. Both engineering- and performance-based standards were developed from research studies and implemented in the federal regulations to ensure the humane movement of equines to slaughter facilities within the US and into Canada. The practice of cross-tying horses individually in stalls is common during road transport of race and show horses. A study designed to compare cross-tied horses with horses traveling loose in small compartments for 24 h showed elevations ($P < 0.05$) in cortisol concentrations, white blood cell counts, and glucose concentrations in the cross-tied horses during transport and recovery. The study supports allowing horses to travel loose in small compartments without elevating their heads by cross-tying. Data from these studies and previous studies suggest that long-term road transportation compromises immune function, thus predisposing transported horses to respiratory disorders.

Key Words: equine, transport, stress

942 Cattle transport in North America—Current welfare research and future directions. K. S. Schwartzkopf-Genswein*[1], L. A. González[2], and T. Crowe[3], [1]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*, [2]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [3]*University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

The transport of live cattle is known to be stressful and therefore can have a direct impact on animal production and welfare, and on food safety and quality. Consequently, there has been increased focus on animal welfare during transport at an international level, in both legislation and trade discussions. Unfortunately few studies assessing the impact of transport on cattle under North American conditions are available from which to provide science-based information to the industry, policy makers and trade personnel. Understanding the objectives, challenges and constraints of current industry practices is integral in designing relevant scientific studies to assess the effects of transport on animal well-being. The combination of human, animal and environmental factors needs to be carefully considered and include: animal handling at loading and unloading, driver experience and training, delays during transport; cattle age, breed, sex, health and physiological status; climate and microclimate, trailer design, loading density, length and condition of transport and condition. All these factors will affect production, body weight loss, morbidity and mortality during and after transport (e.g., lameness and downer animals, incidence of disease), and meat quality and safety. Research is needed to access the inter-relationships between these factors in a systematic fashion. Simulated as well as commercial transport studies that employ animal and microclimate monitoring will aid in facilitating such research.

Key Words: cattle, transport, welfare

943 Conditions within B-train trailers transporting broiler chickens in Western Canada. N. A. Burlinguette, J. M. Watts, L. J. Graff, M. L. Strawford, K. P. C. Hui, T. G. Crowe*, H. L. Classen, and P. J. Shand, *University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

Conditions within commercial trailers transporting broiler chickens were recorded during travel from production site to processing facility. Data were collected for typical commercial trailer vent and tarp settings

for B-train trailers used in Western Canada, over a range of ambient conditions from −20°C to +10°C, on 14 separate occasions. Data loggers, capable of recording temperature and humidity, were positioned throughout the trailers and programmed to record conditions at 1-min intervals. Data were analyzed to characterize the conditions within the trailers and to identify locations where extremes occurred. The difference between the on-truck conditions (temperatures and humidity levels) and the respective ambient conditions were calculated for each sensor and grouped by truck vent and tarp configuration. Temperature and humidity gradients within the trailers were visualized using 3-D mapping software. During the summer, temperatures and humidity levels followed the ambient conditions with modest accumulations of heat and moisture. Minimal gradients in temperature and humidity were present, when both sides of the cargo area were exposed. Gradients in temperature were much more pronounced during the winter, when tarps covered the sides of the loads. While the vent configurations had an effect on the temperatures and humidity levels within the load, some general trends did emerge. When both tarps were lowered (colder ambient conditions), heat tended to accumulate, resulting in a relative warm spot, near the front along the midline of the front trailer. Localized warm conditions developed along the midline, near the rear of the second trailer. Cold regions within the load were restricted to areas adjacent to the side tarps, where cold air could infiltrate into the load, particularly along the sides of the load at the rear and bottom of the front trailer plus the front and bottom of the rear trailer. The air within the load was more humid under cold ambient conditions.

Key Words: transportation, broiler chickens

944 Fatigue: a major cause of commercial livestock truck accidents. J. A. Woods*, *J. Woods Livestock Services*, *Blackie, Alberta, Canada*.

Between 1994 and June 2007, accident reports on 415 commercial livestock truck accidents were tabulated in the United States and Canada. The objective of the data collection was to establish the most common cause of commercial accidents involving livestock and determine if there were specific high risk loads to provide accident prevention education and identify possible future research needs. Data was collected from internet searches, Google alerts, news reports, newspaper articles, industry sources, and government agencies. Tabulated data included time of day, month of the year, animal species and type, position of trailer following the accident, average death loss, location of the accident, number of vehicles involved, cause of accident and trailer style. Not all of the reports contained all of the information. Fifty-six percent of the accidents involved cattle, 27% involved pigs, 11% poultry and the balance were other species. Double deck, "pot belly" trailers, were the most common trailer configurations accounting for 73%. Double, straight deck trailers were involved in 12% of the accidents. October, followed by November were the most common months for accidents, with July documenting the least amount of accidents. Weather had relatively little effect on the number of accidents compared to other factors. Evaluation of the data showed that 59% of the accidents occurred during the early morning hours between midnight and 9:00 am while 80% involved a single vehicle. Driver error was blamed for 85% of the wrecks. The data showed that in 83% of the accidents the trailer rolled over onto their side and of those, 84% tipped over on their right side. This data is consistent with circumstances linked to fatigue related motor vehicle accidents. It was determined that drivers fatigue was the leading cause of commercial livestock truck accidents in North America. Recommendations from this study are to incorporate fatigue management programs into livestock transporter training programs, industry literature and company policies. Future research recommendations include trailer design modifications and loading configurations.

Key Words: accidents, livestock, transportation

945 Renneting properties of milk containing high molecular weight oat β–glucan. N. Sharafbafi*[1], S. M. Tosh[2], M. Alexander[1], and M. Corredig[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Agriculture Agri-Food Canada*, *Guelph, Ontario, Canada*.

The effect of concentration and molecular structure of high molecular weight oat β–Glucan (BG) on renneting properties of concentrated skim milk gels were investigated. Incorporation of BG (0.15, 0.3, 0.6, and 0.9% w/w in permeate) into twice-concentrated skim milk resulted in bulk phase separation of gelling systems as shown by reduction in turbidity parameter (1/l*) and diffusion coefficient using diffusing wave spectroscopy (DWS). However, by controlling the kinetics of gelation and phase separation (using shear in renneted milk before BG addition), it was possible to create casein networks with entrapped BG. $CaCl_2$ was added to reduce time of gelation (TG), and increase textural properties, where high concentrations of BG (≥0.6%) resulted in weakening of protein gel network. The effects of shear and the presence of $CaCl_2$ on microstructure and rheological behavior of the renneted gels containing BG were monitored using DWS combined with small deformation rheology. In addition, BG distribution in the rennet gel network was observed by differential staining technique, (Calcofluor and Rhodamine B, for BG and protein, respectively) using confocal laser scanning microscopy. The results showed that the onset of protein interactions, illustrated by the turbidity parameter, and the aggregation point, measured by the diffusion coefficient, were strongly affected by increase in BG concentration. BG-containing gels exhibited a significantly lower elastic modulus (G′) compared with their control counterparts ($P \leq 0.05$). Increase in BG concentration delayed the TG, and reduced gel firmness due to the non-interacting nature of the BG polymer. In contrast, the addition of $CaCl_2$ reduced the TG and produced a firmer gel in both control and BG added samples. BG addition could improve the texture and nutritional value of calorie-reduced cheeses, whose hard texture has traditionally been a barrier to their production.

Key Words: beta-glucan, gelation, rheology

946 Interactions of milk proteins with tea polyphenols. S. Haratifar*, G. Paliyath, and M. Corredig, *University of Guelph*, *Ontario, Canada*.

Few reports are available on the effects of polyphenols when present in milk. A recent study has claimed that the presence of milk decreases the content and the bioavailability of polyphenols during in vitro digestion (Cilla et al., Food Chemistry, 2009). However, little attention has been paid to the interactions occurring between casein micelles and polyphenols. The objectives of this study were to observe the impact of the protein/polyphenol interaction on the functional properties of milk such as enzyme renneting as well as observing the impact on the tea polyphenol bioavailability. The molecular details of the interactions between tea polyphenols and milk proteins were quantified using reverse phase C18 HPLC. Tea polyphenols strongly interact with casein micelles and result in low recoveries especially at lower concentrations of polyphenols, but it does not necessarily cause low bioavailability. This was confirmed also by measuring in vitro digests. The effect of the interactions of different concentrations of tea polyphenols on rennet induced aggregation of milk was studied. The experiments were carried out using a controlled stress rheometer at a constant strain of 0.01 and frequency of 1 Hz at 30°C. A frequency sweep test was run after the gelling of the samples until 80min to determine the frequency dependence of the elastic (G′) and viscous modulus (G″) of the gels. The gelation point was determined as the onset of the increase in the G′. The results showed that at low concentrations of tea polyphenols (<0.25mg/ml, i.e., below saturation of the casein micelles), the G′ modulus increased similarly to that of control milk (35 min ± 5). At higher concentrations, the polyphenols not only delayed the gelling point of milk to 60 min ± 4, but they also affected the structure formation, as could be noted by a lower G′ of the mixture compared with milk. These experiments clearly identify the need for a better understanding of the effect of tea polyphenols on the functionality of casein micelles, before milk can be used as an appropriate platform for delivery of bioactive compounds.

Key Words: polyphenols, interactions, gelling

947 Anticarcinogenic properties of milk fat globule membrane. R. Zanabria*[1], A. M. Tellez[1,2], M. Griffiths[2,1], and M. Corredig[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*Canadian Research Institute for Food Safety (CRIFS)*, *Guelph, ON, Canada*.

Milk fat globule membrane (MFGM) comprises a tri-layer mixture of glycoproteins, phospholipids and enzymes which protects fat globules from coalescence and enzymatic degradation. Though present in small amounts, MFGM is the main source of polar lipids in milk (65%) and it is one of the major components of buttermilk, the by-product of butter manufacture. Objective of this work was to determine the effect of MFGM on the proliferation of a human adenocarcinoma cell line. Milk was collected using a catheter from healthy animals to minimize bacterial contamination and lipopolysaccharide (LPS) presence, and the cream separated by centrifugation. MFGM fractions were isolated washing the cream twice with endotoxin free water and consecutive freeze-thawing and ultracentrifugation. The bioactivity of MFGM isolate on the HT-29 cell line was tested after verifying LPS-absence using the Chromogenic endpoint test. Two different methods were employed to test the MFGM effect on cell proliferation. The BrdU colorimetric test revealed a dose-dependent DNA synthesis decrease in exponentially growing cells exposed to 10 μg of MFGM protein/mL. Up to 53% inhibition was measured after 72h when 100 μg of MFGM protein/mL was used. The results were corroborated using the Sulforhodamine B proliferation assay. In the latter, the amount of MFGM required to produce the same effect almost doubled (200 μg MFGM protein/mL achieved a 57% reduction) after 48h incubation. When cells were similarly treated with commercially available anticarcinogenic compounds (0.1mM/L melphalan and 20 μmol/ L N-Acetyl-D-sphingosine) the reduction in cell growth was 25 and 40% respectively; hence, showing the potential bioactivity capacity of the raw MFGM fractions. Though the study of the mechanism whereby untreated MFGM exerts its anticarcinogenic activity is still undergoing, the results indicate that MFGM isolates have an inhibitory effect on colon cancer cells, most likely through the extracellular signaling pathways. Analyses are in progress to evaluate apoptosis and/or differentiation as possible causes for these properties along with the effect of milk processing over the MFGM bioactivity.

Key Words: milk fat globule membrane, anticarcinogenic, bioactivity

948 Gelation properties of casein micelles during combined renneting and mesophilic bacterial fermentation: Effect of concentration by ultrafiltration. E. Salvatore*[1,2], M. Alexander[2], A. Pirisi[1], and M. Corredig[2], [1]*Agris Sardegna, Dipartimento per la Ricerca nelle Produzi-*

oni Animali, *Olmedo, Italy*, [2]*Department of Food Science, University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this study was to determine the effect of concentration of milk by ultrafiltration on the rheological and chemical properties of combined cultured and rennet milk gels. Pasteurized skim milk (1X; control) with ≈3.7% of total protein was concentrated by ultrafiltration to produce retentates with protein levels of ≈7.4% (2X), and ≈11.1% (3X). All samples were acidified with a mesophilic lactic culture (0.1 g/L), renneted with liquid rennet at a final concentration of 0.00296 IMCU/mL, and incubated at 30°C. Acidification was monitored by recording the pH continuously over the gelation period, and the development of the gel structure was observed by means of small deformation rheology and diffusing wave spectroscopy (DWS). Furthermore, the levels of soluble Ca^{++} were determined during incubation period. The gelation time, defined as the point when the loss tangent (tan δ) = 1, was between 105 and 109 min, corresponding to a pH value of ≈6.5, and was not significantly different among the samples ($P > 0.05$). When measured by DWS, the gelation point was almost superimposable with that found in the rheological measurements. After gelation, the value of G′ showed a significant increase up to pH 5.64, 5.92, 6.18 for 1X, 2X and 3X respectively, and these values were significantly different among treatments ($P < 0.05$). Significant differences ($P < 0.05$) were also found in the pH at maximum value of tan δ. The values of soluble Ca^{++} suggested that the variations between samples were due to the different rates of release of Ca^{++} from the casein micelles. The results clearly show the details of the changes occurring during a mixed coagulation process and allow for a better understanding of the physical and chemical processes that happen during the making of quark-type cheeses.

Key Words: milk gels, rheological properties, light scattering

949 Production of α-lactalbumin enriched concentrate from serum whey. C. Marella*, P. Salunke, L. E. Metzger, and K. Muthukumarappan, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

Whey proteins are known for their valuable functional, nutritional and therapeutic properties. Bovine α-Lactalbumin (α-LA) has high homology to human α-LA and has well documented therapeutic uses. Hence development of α-La concentrate with reduced levels of β-lactoglobulin (β-LG) is of high interest to manufacturers of infant formula and whey protein based therapeutic formula. In production of α-LA enriched WPC from cheese whey, the purity of α-LA in the final product is heavily influenced by the presence of glycomacropeptide. Serum whey produced by microfiltration of milk is largely absent in glycomacropeptide. Production of α-LA enriched concentrate from serum whey should result into higher purity and yield. The objective of the present study was to develop α-LA enriched concentrate from serum whey. Wide pore Ultrafiltration experiments were conducted using four (30, 40, 100 kD polyvinylidene fluoride and 300 kD polyethersulfone) membranes and three levels of operating pressure (138, 207 and 276 kilo Pascal (kPa)). In the process serum whey was concentrated to a volume reduction (VR) of 5 and 10. Purity, yield of α-LA and α-LA/ β-LG ratio were used as the parameters indicative of process efficiency. At VR of 5, purity of α-LA obtained in the permeate stream ranged from 52 – 96% while the yield of α-LA ranged from 15-55%. At VR of 10, there was a marginal decrease of 3-7% in purity and 20 – 35% increase in yield of α-LA. For separation of α-LA from serum whey there appears to be an optimum operating pressure. From the present results, it appears that 207 kPa pressure is optimum resulting into a 10-25% higher yield when compared to the yield obtained at other pressures used in this study. The results from this study will be helpful in production of highly purified α-LA enriched concentrate from serum whey. Regardless of the membrane used in this study, use of 207 kPa operating pressure resulted in α-La enriched product with purity ranging from 52 – 96%.

Key Words: α-lactalbumin, wide pore ultrafiltration, serum whey

950 Evaluation of correlations between chemical compositions and sensory properties in Turkish Set-type yogurts. Z. Guler[1] and Y. W. Park*[2], [1]*Mustafa Kemal University*, *31034 Antakya, Hatay, Turkey*, [2]*Fort Valley State University*, *Fort Valley, GA*.

Food quality of yogurt is affected by many factors, including levels of titrable acidity, free fatty acid, aroma compounds, nutritional values, and sensory properties. Ten most popular brands of commercial Turkish set-type yogurts were collected from retail outlets in Hatay, Turkey to determine correlations between chemical compositions and sensory properties of the products. Free fatty acids (FFA) and volatile compounds (VC) were analyzed using a GC-MS (Agilent GC model 6890) and MS (Agilent Mass Selective Detector 5973 N; Palo Alto, CA, USA). Columns used for FFA and VC separation were DB-FFAP-column (30 m × 0.25mm id × 0.25μm film thickness) and HP-INNOWAX capillary column (30 m × 0.32mm id × 0.25μm film thickness), respectively. Intensities and overall acceptability of sensory attributes were measured on 4-point and 9-point hedonic scales. The results revealed that increased volatile compounds (acetaldehyde, acetic acid) and acidity attributed to sour flavor, resulting in decreased overall acceptability of the yogurts. Aromatic volatiles such as 2-nonanone (fruity, musty), 2-tridecanone (fruity, green) and ethyl acetate (fruity) were negatively correlated, whereas diacetyl, C4 to C12 FFA and texture were positively correlated with overall acceptability. 2-Nanonane was negatively correlated with atypical flavor, since ketones having higher carbon numbers are responsible for heated milk flavor. Butanoic (rancid, cheesy), hexanoic (pungent, sour), octanoic (waxy, goaty), decanoic (rancid, fatty) and dodecanoic (fatty) acids were positively correlated with overall acceptability and formation of the specific aromatic flavors of set-type Turkish yogurts. Yogurt flavor intensity appeared to be closely related to titratable acidity, acetic acid, C4 to C10 content, ratio of acetaldehyde to diacetyl, and to a lesser extent to fat and protein contents.

Key Words: Turkish yogurt, chemical composition, sensory property

951 Wooden vat to produce PDO Ragusano cheese is a living system. G. Licitra*[1,2], L. Tuminello[2], N. Fucà[2], P. Campo[2], S. Lortal[3], and S. Carpino[2], [1]*D.A.C.P.A. University of Catania*, *Catania, Italy*, [2]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [3]*UMR Science et Technologie du Lait et de l'Oeuf*, *Rennes Cedex, France*.

Tina is the traditional wooden vat daily used for the cheese making process of the P.D.O. Ragusano cheese. A previous study has shown the biofilm microstructure and has demonstrated the safety and efficiency of the *tina* as natural inoculation system in the cheese making process. Ragusano cheese is produced from November to May, when native pastures are available; so the *tina* is not used during the summer period. The aim of the present work was to verify the presence and survival of the biofilm on the inner surface of the dried inactive *tina*. Samples were taken, in October, from 2 dried *tinas* belonging to 2 different farms; the biofilm of those *tinas* had been previously (Lortal et al., 2009) analyzed when the same *tinas* were used for the Ragusano cheese production. By using a sterile blade 2 small wood micropieces (15 × 5 × 1 mm about) were removed from 2 opposite sides of the internal surface of each *tina*. *Tina* samples were analyzed by scanning electron (SEM) and confocal laser scanning microscope (CLSM). SEM and CLSM images showed a rich biofilm constituted by big and close microbial communities immersed in an abundant exopolysaccharide matrix which provides the necessary nutrients to the bacteria and protects them from the external environmental conditions. CLSM images highlighted that biofilm is mainly made of live bacteria. Heterogeneous bacterial colonies cover uniformly the whole surface of the *tina* forming a compact multilayered biofilm with a thickness of about 20 - 30 µm. The biofilm goes through the surface in the external wood vessels which look fully stuffed by bacteria and exopolysaccharide matrix. SEM images showed also the presence of biofilm inside the *tina* sample as far as 400–600 µm from the surface. This study demonstrated that at the end of the summer period a microbial biofilm still survives and maintains an intact and well organized structure.

Key Words: biofilm, wooden vat, Ragusano cheese

952 Survival of *Lactobacillus acidophilus* in Boursin-like cheese after gastric and enteric conditions in vitro. A. M. Liserre*[1], P. B. Zacarchenco[1], K. M. O. dos Santos[2], F. C. A. Buriti[2], L. S. Gonçalves[1], and L. R. Monteiro[1], [1]*Instituto Tecnologia Alimentos. Av. Brasil*, *Campinas, SP, Brasil*, [2]*EMBRAPA, Centro Nacional de Pesquisa de Caprinos e Ovinos*, *Sobral, Ceará, Brasil*.

In this study, Boursin-like cheeses were made from goat's milk at the facilities of EMBRAPA Caprinos (Brazilian Agricultural Research Corporation) in the town of Sobral, Brazil. The objective was the evaluation of the survival of probiotics in the cheese after treatment in simulated gastric and enteric juices. The cheeses added with *Lactobacillus acidophilus* were evaluated after 14 d refrigerated storage to quantify the surviving probiotics after treatment simulating gastrointestinal conditions. For this purpose, cheese samples were added to an acid solution at pH 2.5 containing pepsin (3g/L) for 120 min. Next, the pH was changed to 5.6 for another 120 min and finally changed to pH 7.5 for the last 120 min. During the enteric fluid simulation steps the samples were additionally added with bile in a proportion adequate to obtain a final concentration of 3g/L, so as to simulate small intestine conditions. Probiotic counts in the cheese samples after 14 d storage were 7.74 log CFU/g. After the test simulating gastrointestinal conditions, the counts had been reduced to 4.02, 2.42 and <2.00 log (detection limit) CFU/g in the cheeses exposed to gastric (pH 2.5) and enteric (pH 5.6 and pH 7.5) fluids, respectively. Brazilian legislation requires a minimum of 10^8 to 10^9 viable cells per daily portion of a probiotic product. The portion size of 30g of the cheese contained around 10^8 viable cells before the simulation tests but, after action of the gastrointestinal juices the counts were lower than the detection limit of the test, yielding an unsatisfactory result.

Key Words: probiotic, goat milk, cheese

953 Addition of probiotic bacteria modifies the biodiversity of other lactic acid bacteria in Cheddar cheese. B. Ganesan*[4,3], B. C. Weimer[1], G. Rompato[2], J. Pinzon[1], P. Desai[2,3], C. Brothersen[4,3], and D. J. McMahon[4,3], [1]*University of California*, *Davis,* [2]*Center for Integrated BioSystems, Utah State University*, *Logan,* [3]*Department of Nutrition, Dietetics, and Food Sciences, Utah State University*, *Logan,* [4]*Western Dairy Center, Utah State University*, *Logan*.

Bacteria in cheese face abiotic stresses during manufacture and storage that impact their abilities to produce flavors, survive, and interact with other bacterial populations. Apart from the added starter cultures non-starter lactic acid bacteria (NSLAB) are derived from milk handling, cheese equipment, and human contact. Occasionally, flavor adjunct bacteria are added at the beginning of cheese manufacture to modify the flavor of the product. Probiotic bacteria are added to foods with the goal of reaping the microbes' human health benefits; however, addition to cheese poses new stress conditions that may change the characteristics of the microbe. In this study, probiotic bacteria (lactobacilli and bifidobacteria) were added during Cheddar cheese manufacture to determine their survival during the aging process in different milk fat levels. Starter culture and NSLAB populations were determined using real time-quantitative PCR using primers specific for the different bacterial genera or species of interest. Bifidobacteria were initially added at 2.5×10^6 CFU/g cheese and survived the aging process with a small population reduction after 280 d. Added *Lactobacillus acidophilus* populations (10^7 CFU/g cheese) and NSLAB populations (10^8 CFU/g cheese) increased significantly ($P < 0.05$) by 10 to 100-fold during the same time. Analysis of the added probiotic and starter culture using propidium monoazide for differentiating live and dead bacteria by PCR indicated that these microbes not only survived, but increased in numbers significantly ($P < 0.05$) by 10 to 100-fold over aging independent of fat level. In conclusion, probiotic bacteria are capable of surviving throughout the cheese-making and aging process, indicating that delivery via hard cheeses is possible.

Key Words: lactic acid bacteria, probiotic, survival

954 Production of microcapsules of *Lactobacillus acidophilus* to add in dairy products. A. M. Liserre*[1], P. B. Zacarchenco[1], C. R. Meneze[3], A. E. C. Antunes[2], G. M. B. Q. Cardozo[1], and I. Moreno[1], [1]*Tecnolat/ Instituto de Tecnologia de Alimentos*, *Campinas, São Paulo, Brasil*, [2]*UNICAMP; Universidade Estadual de Campinas - Limeira*, *Limeira, São Paulo, Brasil*, [3]*Universidade de Santa Maria*, *Rio Grande do Sul, Brasil*.

Probiotics have attracted attention because of their benefits to human health. However, studies indicate that probiotics may not survive well in dairy products and during their passage through the gastrointestinal tract, due to stress factors such as acidity, low storage temperature, and presence of lactic and acetic acids, bile salts and digestive enzymes.

Microencapsulation is a technology used to improve viability of probiotic. The objective of this study was the development of *Lactobacillus acidophilus* microcapsules with cellulose acetate phthalate, maltodextrin, glycerol, Hi-maize, Tween 80 and skim milk powder prepared by the spray dryer technique. In vitro release of probiotics from the microcapsules was investigated using citrate-phosphate buffer solution (pH 4.5) and in phosphate buffer solution (pH 6.0 and pH 7.5). Aliquots were removed after 60, 120 and 180 min agitation at 150 rpm at 37°C. The number of released cells was determined by pour plating in MRS LP (37°C/72h) under anaerobiosis. Changes in bead integrity with time at pH 7.5 were monitored by optical microscopy and photographed. The spray dryer technique was efficient to obtain probiotic encapsulated cellulose acetate phthalate based microcapsules. The viability of probiotic were very good showing counts of 5.70, 8.85 and 9.37 log CFU/g after 180 min of dissolution at pH 4.5, 6.0 and 7.5, respectively. Microcapsules promoted a controlled release of probiotics in different pH values, because the highest retention of cells occurred at pH 4.5. Theses microcapsules can be applied to dairy products because at the pH of milk (pH 6.0) the release of probiotics was high.

Key Words: probiotic, microencapsulation, acetate phthalate cellulose

955 Novel immunostimulatory activities of CpG oligodeoxynucleotides from *Streptococcus thermophilus*. T. Shimosato*[1], M. Fujimoto[1], M. Tohno[2], T. Sato[3], H. Otani[1], and H. Kitazawa[4], [1]*Shinshu University*, *Kamiina, Nagano, Japan*, [2]*National Institute of Livestock and Grassland Science*, *Nasushiobara, Tochigi, Japan*, [3]*Yokohama City University*, *Yokohama, Kanagawa, Japan*, [4]*Tohoku University*, *Sendai, Miyagi, Japan*.

We previously reported the strong immunostimulatory effects of a CpG oligodeoxynucleotide (ODN), designated MsST, from the lacZ gene of *Streptococcus (S.) thermophilus* ATCC19258. However, there is no evidence of an anti-inflammatory response after IL-33 increase following treatment with CpG ODNs, which act via TLR9. Therefore, in this study, we focused on induction of IL-33 by CpG ODNs and examined the effects of MsST stimulation on mouse splenocytes and peritoneal macrophages.Here we show that 24 h of stimulation with MsST in mouse splenocytes and peritoneal macrophages strongly induces expression of interleukin (IL)-33, a cytokine in the IL-1 superfamily. Other IL-1 superfamily members, including IL-1α, IL-1β and IL-18, are downregulated after 24 h of stimulation of MsST. We also found that MsST-induced IL-33 mRNA expression is inhibited by the suppressive ODN A151, which can inhibit Toll-like receptor 9 (TLR9)-mediated responses. We speculate that upregulation of IL-33 in response to exposure to an external stimulus such as MsST may serve as an endogenous danger signal that alerts cells in the innate immune system to tissue damage during bacterial challenge. Our findings suggest that IL-33 is an important regulator that acts on macrophages via TLR9. Although our understanding of IL-33 is currently limited, it seems reasonable to suggest that IL-33 might counterbalance the activities of proinflammatory cytokines . In conclusion, we found a novel immunoregulatory mechanism mediated by CpG ODNs that induces IL-33. Understanding how IL-33 mediates immunoregulation via MsST activation should help in the development of therapeutic ODNs for treatment of inflammatory disease by the strong induction of IL-33. Exploiting this property may also prove useful in the design and production of new physiologically functional foods.

Key Words: CpG ODN, IL-33, *Streptococcus thermophilus*

956 Toll-like receptor 2 participates in the intestinal epithelial regulating activity of *Lactobacillus kefiranofaciens* M1 isolated from fermented milk product kefir. Y. P. Chen*, W. S. Hong, T. Y. Dai, I. N. Huang, and M. J. Chen, *National Taiwan University*, *Taipei, Taiwan, R.O.C.*

Toll-like receptors (TLRs) are pattern recognition receptors (PRRs) that recognize microbial components and endogenous ligands. Among different TLRs, TLR2 recognizes the broadest range of microbial component, including lipoteichic acid, peptidoglycan, lipopeptide and so on. TLR2 has been known to manipulate important immune function in many kinds of immune cells. However, the physiological significance of TLR2 expressed in intestinal epithelial cells is unclear. In this report, we found that TLR2 was participated in important regulatory roles of *Lactobacillus kefiranofaciens* M1, which was originally isolated from fermented milk product kefir and showed intestinal protective activity in vitro and in vivo. We cultured intestinal epithelial cell (IEC) line Caco-2 onto permeable transwell insert for 28 d until fully polarization and monolayer formation. We found that apical adding of *Lb. kefiranofaciens* M1 increased both the apical and basolateral production of intestinal restitution chemokine CCL-20 in IEC monolayer in a dose dependent and time course manner. The CCL-20 production was further blocked by using TLR2 specific neutralizing antibody. In the experimental colitis model, we used dextran sodium sulfate (DSS) to damage intestinal epithelium and to induce colitis in both wild type and TLR2 knockout mice. *Lactobacillus kefiranofaciens* M1 could ameliorate DSS-induced colitis in wild type mice group by assessing stool consistency, bleeding score, colon length shortening, histological scoring and *ex-vivo* cytokine production pattern of colon segment, while it had no such effect in TLR2 knockout mice group. In summary, *Lb. kefiranofaciens* M1 can regulate IEC restitution chemokine CCL-20 production in vitro and ameliorate DSS-induced colitis in vivo through TLR2. The data indicates that TLR2 plays an important role of *Lb. kefiranofaciens* M1 in regulating intestinal homeostasis.

Key Words: toll-like receptor, probiotics, intestinal epithelial cell

957 Inhibitory effect of Taiwanese ropy fermented milk in an ovalbumin-induced allergy mouse model. I. N. Huang*[1], T. Y. Dai[1], S. Y. Wang[2], and M. J. Chen[1], [1]*Department of Animal Science and Technology, National Taiwan University*, *Taipei, Taiwan*, [2]*Experimental Farm, National Taiwan University*, *Taipei, Taiwan*.

Taiwanese ropy fermented milk (TRFM) has a sticky consistency, which is made with the microbial action of mesophilic lactic acid bacteria (LAB). In our previous studies, we isolated and identified microorganisms from TRFM using a combination of polymerase chain reaction-denaturing gradient gel electrophoresis (PCR-DGGE) and 16S rDNA sequencing. In this study, we assayed the anti-allergic abilities of TRFM and its dominant microorganisms (*Lactococcus lactis* ssp. *cremoris* and *Kluyveromyces marxianus*). The in vitro results depicted that both *L. lactis* ssp. *cremoris* and *K. marxianus* could induce Th1 (TNF-α, IL-6) and Treg (IL-10) cytokines in RAW 264.7 macrophages and murine splenocytes, which might inhibit the Th2 response and IgE production. The OVA-sensitized animal test demonstrated that oral administration of both strains generally tended to reduce serum total IgE in OVA-sensitized BALB/c mice compared with the control groups. In conclusion, the data presented clearly indicate the anti-allergic activities of TRFM microorganisms. Suppression of IgE production by oral feeding of *L. lactis* ssp. *cremoris* and *K. marxianus* probably occurs because of elevation of Th1 and Treg cytokines leading the skewness of Th1/Th2 balance toward Th1 dominance.

Key Words: allergy, lactic acid bacteria, yeast

Lactation Biology 2

958 Regulation of mammary epithelial cell proliferation and gene expression by *Semen Vaccariae* active monomer. Z. Y. WAN, H. L. TONG, Q. Z. LI, and X. J. GAO*, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

Semen Vaccariae is a traditional Chinese herb that is widely used to increase lactation. However, the underlying changes in gene expression that drive the increased milk production by *Semen Vaccariae*, especially the specific active monomer, remain an open question. Our lab has successfully separated active monomer dibutyl phthalate (DBP) from *Semen Vaccariae* to study its role in lactation. A model DT CASY Cell Counter was used to study the effect of increasing concentrations of DBP on proliferation and viability of primary cultured dairy cow mammary epithelial cells (DCMEC) harvested from a lactating cow at d 140 (n = 3). QRT–PCR and Western blot were used to study changes in mRNA and protein of *prlr, erα, akt1, socs2, pparγ* and *elf5*at 6, 12, 24, 36, 48, and 72 h. miRNAs (21,125b,143 and 195) and secretion of β–casein and lactose were detected by qRT–PCR analysis and RP-HPLC. Each assay was performed in 5 independent experiments using 3 different treatments and the data were analyzed with SPSS by ANOVA. The results showed that DBP (0.5 mg/ml) increased proliferation and viability of DCMEC significantly ($P < 0.05$). DBP acted similarly to prolactin (PRL). It increased the expression of *prlr, erα, akt1* and *elf5*, but repressed the expression of *pparγ*. DBP promoted the expression of *socs2* mRNA, but inhibited the expression of *socs2* protein. Both DBP and PRL repressed the expression of miRNA–125b, miRNA–143 and miRNA–195 in DCMEC. DBP repressed the expression of miRNA–21, while the influence of PRL on miRNA–21 was uncertain. Both DBP and PRL enhanced the expression of β–casein ($P < 0.05$) and the secretion of lactose ($P < 0.05$) significantly. In conclusion, *Semen Vaccariae* active isomer increased proliferation and secretion of milk components by DCMEC. This is the first demonstration that miRNA expression can be changed by DBP and PRL. Further studies to uncover the lactogenic targets of DBP will help to shed light on the genetic mechanisms of mammary gland development and lactation.
This work was supported by the Innovation Team of the Northeast Agricultural University (Grant No. LXT005–1–2).

959 Deletion of thyroid hormone responsive spot 14 exacerbates the anti-lipogenic affect of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) in the mammary gland. K. J. Harvatine*[1], Y. R. Boisclair[2], and D. E. Bauman[2], [1]*Penn State University*, *University Park,* [2]*Cornell University*, *Ithaca, NY*.

Inhibition of milk fat synthesis by fatty acid (FA) intermediates originating from ruminal biohydrogenation has been extensively studied in the cow and more recently in the mouse. In both species, *trans*-10, *cis*-12 conjugated linoleic acid (CLA) reduces milk fat concentration and markedly reduces milk fat concentration of de novo synthesized FA. During CLA treatment mammary lipogenic capacity is decreased by a coordinated downregulation of genes involved in milk fat synthesis. We also identified downregulation of thyroid hormone responsive spot 14 (S14) in mammary tissue of both the cow and mouse during CLA treatment. The functional role of S14 in CLA-induced inhibition of fat synthesis was tested using wild-type (WT) and S14 null mice in a randomized block design with a 2x2 factorial arrangement of treatments (genotype x CLA). Starting at 6–8 d of lactation, S14 null and WT dams nursing 6–8 pups received oral doses of water (control) or 20 mg/d of CLA for 5 d. Pups and dams were weighed daily. On the last day of treatment dams were milked and killed. The effect of genotype, CLA, and genotype by CLA interaction was tested. Milk fat of S14 null mice was 25% lower than that of WT dams ($P < 0.001$) and CLA treatment reduced milk fat concentration in both genotypes ($P = 0.03$). However, there was a marked interaction of genotype and CLA treatment for milk concentration of de novo synthesized FA ($P < 0.001$), where the WT dams reduced milk concentration of FA less than 16 carbons in length by 27% while S14 null mice reduced FA less than 16 carbons by 72%. In agreement, mammary lipogenic capacity measured as ^{14}C glucose incorporation into lipids by mammary tissue explants was decreased 23% in WT dams and 82% in S14 null dams. Mammary lipogenesis of S14 null dams is hyper-responsive to CLA treatment demonstrating a possible indirect effect of S14 on regulation of lipogenesis. Therefore, S14 may modify the activity of a second CLA responsive mechanism.

Key Words: milk fat, conjugated linoleic acid, lipogenesis

960 The role of SREBP-1 in lipogenesis in bovine mammary epithelial cells. L. Ma* and B. A. Corl, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Sterol regulatory element binding proteins (SREBPs) are a family of transcription factors that regulate lipid metabolism. There are 3 isoforms, SREBP-1a, SREBP-1c and SREBP-2, among which SREBP-1a and SREBP-1c regulate fatty acid synthesis. The objective of this study was to determine the role of SREBP-1 in lipogenesis in bovine mammary epithelial cells. Bovine mammary epithelial cells (MACT) were used in this study. After reaching 80% confluence in a flask, cells were trypsinized and reseeded to plates at a density of $2X10^4$ cells/cm^2. After incubation in base medium (DMEM+10% FBS) overnight, cells were transfected using small interfering RNAs (siRNA), against SREBP-1 (SSI), Cyclophilin B as positive control (POS), a non-targeting sequence as negative control (NEG), and no siRNA as untreated control (UNT), according to protocol (Dharmacon Inc.). Cells were harvested for mRNA measurement after 24 h, for measurement of protein and acetate incorporation after 72 h. After treatment with SSI at concentrations of 5, 25, 50, 75, and 100 n*M*, the expression of SREBP-1 mRNA was reduced 76%, 84%, 90%, 91%, and 92%, respectively. In POS, the expression of Cyclophilin B mRNA decreased 74%, 90%, 95%, 94%, and 96%, respectively. SSI reduced precursor SREBP-1 protein (10, 586, 705, and 505 ± 241 for SSI, POS, NEG, and UNT, respectively; $P < 0.07$) and mature form of SREBP-1 (0, 376, 453, and 260 ± 85 for SSI, POS, NEG, and UNT, respectively; $P < 0.05$) compared with controls. Acetate incorporation also decreased to 0.31 nmol/4 h with SSI at 5 n*M*, compared with 0.41, 0.56, and 0.43 ± 0.02 nmol/4 h, for POS and NEG, and UNT, respectively ($P < 0.01$). SSI at 5 n*M* reduced SREBP-1 mRNA and protein by 76% and 98%. When SREBP-1 decreased, there was a significant decrease in acetate incorporation, thus SREBP-1 might regulate milk fat through the de novo fatty acid synthesis pathway.

961 Effects of t10,c12 CLA dose on mammary gland development, adiposity, and inflammation in mice. M. R. Foote*, S. L. Giesy, G.

Bernal-Santos, D. E. Bauman, and Y. R. Boisclair, *Cornell University*, *Ithaca, NY*.

The t10,c12 CLA isomer has been shown to have a wide range of potential health benefits including anticarcinogenic and antiadipogenic effects in animal models. Despite evidence of beneficial effects in the rat, dietary t10,c12 CLA was recently shown to impair mammary gland development and to accelerate mammary tumorigenesis in the mouse. The level of dietary t10,c12 CLA (0.5% of the diet) in this study was typical of levels shown to result in white adipose tissue inflammation and insulin resistance, 2 factors known to promote mammary cancer. To evaluate the possibility that lower t10,c12 CLA doses might inhibit lipogenesis without detrimental effects on mammary development, FVB wild-type mice received a diet containing 0%, 0.1%, 0.2%, or 0.5% t10,c12 CLA (n = 8 to 10 per treatment) from 24 d to 49 d of age. As expected, the 0.5% CLA dose resulted in increased hepatic triglyceride content and weight and increased plasma insulin ($P < 0.05$). In addition, the 0.5% dose caused abnormal mammary gland development (i.e., reduced ductal elongation combined with ductal hyperplasia) in parallel with dramatic mammary gland inflammation characterized by increased expression of monocyte chemoattractant protein 1 (MCP-1), egf-like module containing, mucin-like, hormone receptor-like 1 (EMR-1), tumor necrosis factor α (TNF-α), and interleukin 6 (IL-6) ($P < 0.05$ for all). The 0.1% CLA dose did not affect any of these metabolic and inflammatory end-points or any indices of mammary gland development ($P > 0.05$ for all). The 0.1% CLA dose, however, was as effective as the 0.5% dose in decreasing gonadal fat weights and fatty acid synthase expression in adipose tissue ($P < 0.05$). Our results establish that a low dose of t10,c12 CLA decreases adiposity without impeding mammary gland development or causing inflammatory and metabolic complications. These results show, for the first time in the mouse, that the positive effects of t10,c12 CLA on adiposity can be dissociated from negative effects on mammary development, metabolism, and inflammation.

Key Words: CLA, mammary gland

962 Impact of time of milk storage in the udder on fat. M. Dutreuil[1,2], C. Cébo[3], J. Guinard-Flament[2,1], and C. Hurtaud*[1,2], [1]*INRA UMR1080 Production du lait*, *Saint-Gilles, France*, [2]*AGROCAMPUS OUEST UMR1080 Production du lait*, *Rennes, France*, [3]*INRA Unité GABI*, *Jouy-en-Josas, France*.

Our objective was to study the effect of duration of milk storage on milk fat globule (MFG) secretion to better understand relationships between milk yield, milk fat and MFG secretion. Four milking frequencies were studied in 6 dairy cows averaging 118 ± 22 dim: 2 milkings/d separated by 11- and 13-h intervals (2M11–13) or by 4- and 20-h (2M4–20) and 1 milking/d (1M24). The experimental trial was a double Latin square 3 × 3 with 2 wk periods. In post-experiment, milking frequency of 36-h (1M36) was repeated twice. Compared with 2M11–13, 1M24 reduced milk and milk fat yields and increased fat content, without any effect on the size of MFG which agrees with previous research. 2M4–20 had no significant effect on milk fat yield and content but tended to increase the size of the MFG. Lipolysis, measured on morning milk, was weaker with 1M24. Milk fatty acid composition was not modified by milking frequency. When data were analyzed according to kinetics of milk storage duration (from 4 to 36-h), the highest fat content and the largest diameters of MFG were obtained on milks from 4- and 36-h milking (respectively 62.8 g/kg and 4.15 µm and 57.7 g/kg and 4.09 µm). Such observations could have 2 origins: the richness in residual milk of the 4-h milk and the coalescence of MFG related to the long storage duration in the 36-h milk. Independently, for each duration of milk storage, there was a relationship between MFG size and fat yield (R^2 from 0.31 to 0.81). Conversely, the relationship between MFG size and fat content was confirmed whatever duration of milk storage ($R^2 = 0.55$). Speed of secretion of milk fat (storage of 4 h excluded) was also well correlated with MFG size ($R^2 = 0.62$). For the 36-h milk, this relationship was also observed but with a significantly different slope suggesting a phenomena of MFG coalescence in response to the increased intra-mammary pressure. Duration of milk storage induces changes in MFG size under factors which interact.

Key Words: milk fat, milk storage, milk fat globule

963 IGF-I regulates the expression of GLUT12 in bovine mammary epithelial cells. Y. Shao* and F.-Q. Zhao, *Department of Animal Science, University of Vermont*, *Burlington*.

Insulin-like growth factor-I (IGF-I) is a potent mitogen for mammary epithelial cells and plays an important role in mammary development. Glucose is an energy source for mammary epithelial cell proliferation and glucose uptake is mediated by facilitative glucose transporters in mammary epithelial cells. The objective of this study was to investigate the role of IGF-I in regulating the expression of the main glucose transporters GLUT1, GLUT8 and GLUT12 in bovine mammary epithelial cells. In the first experiment, Mac-T cells were treated for 12 h with increasing concentrations of IGF-I (20, 50, 100, 200 and 400 ng/mL). mRNA levels of GLUT1, GLUT8, GLUT12 and IGFBP3 were determined by real-time PCR. IGFBP3 mRNA increased 6- to 13-fold in all groups treated with 50 ng/mL or higher concentrations of IGF-I compared with non-treatment group ($P < 0.001$), indicating that Mac-T cells are responsive to IGF-I. There were no treatment effects on GLUT1 and GLUT8 mRNA, but mRNA levels of GLUT12 decreased by 75% in all groups treated with 50 ng/mL or more IGF-I relative to control group ($P < 0.001$). In the second experiment, Mac-T cells were treated with 100 ng/mL of IGF-I for 3, 6, 12, 18, 24 and 48 h. Interestingly, mRNA of GLUT12 decreased to 21–35% after 3 to 12 h treatment but returned to the same levels as in the non-treatment group after 48 h. In summary, these data indicate that IGF-I may regulate the expression of GLUT12, but not GLUT1 and 8 in bovine mammary epithelial cells.

Key Words: glucose transporter, IGF-I, mammary epithelial cells

964 Mammary mitochondrial function is associated with lactation Performance in inbred mice. J. Wei*, S. Kiser, J. George, D. Anderson, and D. Hadsell, *Baylor College of Medicine*, *Houston, TX*.

Milk production in dairy cattle is influenced by genetics. In rodent models of lactation, oxidative metabolism and mitochondrial number/activity are increased dramatically with secretory activation. In addition, different inbred mice have different abilities to support litter gain through lactation implying that genetic background regulates milk synthesis capacity. However, comparison of mammary mitochondrial function among these inbred mice has not been studied. We hypothesized that variation in lactation capacity of different mouse strains is due to difference in mammary mitochondrial function. The FVB and C57BL/6 (C57) mice representing higher and lower lactation performance were used to assess mammary mitochondrial function and biogenesis. Lactation performance was assessed by crossfoster litter weight gain for the first 8 d of lactation. Mammary tissue was collected at Day 10 postpartum. mRNA levels of mitochondrial associated genes and mitochondrial DNA (mtDNA) copy number were measured using quantitative PCR (qPCR). Litter gain was higher with the FVB dams (26.81 ± 0.64g) than with the C57 (22.01 ± 1.82g) ($P = 0.026$). Mammary mitochondrial ATP synthesis activity was 68% higher in FVB mice compared with C57 ($P < 0.001$). Mammary mtDNA copy number per cell was

70% higher in the FVB compared with the C57 ($P < 0.05$). Mammary mRNA levels of Ppargc1a (131.73%), Nrf1 (49.63%), Gabpa (51.34%), Tfb1m (71.65%), Tfb2m (92.37%), Nnt (5052.74%), Sirt1 (79.83%), and Sod2 (34.63%), in the lactating mammary gland were all higher ($P < 0.05$) in FVB mice compared with C57. Mammary mRNAs for Tfam (65.61%) and Ucp3 (61.07%) were lower ($P < 0.05$) in the FVB mice. Significant difference in the expression levels of these transcriptional factors regulating mammary mitochondrial biogenesis and ATP synthesis activity implicates their important roles in lactation performance. The lower expression of the mammary Ucp3 and Tfam in the FVB mice may also suggest novel regulatory mechanisms of mammary mitochondrial functions in lactation.

965 Temporal changes in the mammary mitochondrial proteome of the mouse suggest that increases in a limited number of proteins are necessary to support increased ATP synthesis during early lactation. D. Hadsell*[1], W. Olea[1], R. Matsunami[2], and D. Engler[2], [1]*Baylor College of Medicine*, *Houston, TX,* [2]*The Methodist Hospital Research Institute*, *Houston, TX*.

The regulation of mammary mitochondrial biogenesis and function across the lactation cycle is not well understood. This study employed differential in-gel electrophoresis coupled with MALDI-tof/tof mass spectrometry to relate changes in mammary cell mitochondrial function during lactation to changes in the proteins that comprise this organelle. Our hypothesis was that changes in mammary cell mitochondrial biogenesis and function during lactation would directly correlate with coordinated changes in the proteins that make up the oxidative phosphorylation (OXPHOS) pathway and that some of these proteins might also be linked to PPARGC1α and AMP kinase. Markers of mammary mitochondrial biogenesis and function were measured in mammary tissue and mitochondria collected from lactating mice at d 2, 8, 14, 21, 28, and 35 postpartum. Mitochondrial ATP synthesis activity increased ($P < 0.05$) during early lactation and then declined with prolonged lactation. Staining of mammary tissue sections for succinate dehydrogenase activity indicated that mitochondrial number increased ($P < 0.05$) 5-fold during early lactation. Western blotting for the transcriptional co-activator PPARGC-1α and immunofluorescent staining for phospho AMP kinase demonstrated that these proteins were most abundant on d 2 postpartum. Analysis of the proteome identified 154 proteins that changed ($P < 0.05$) throughout the lactation cycle. Of these, only 3 members (NDUFAF3, UQCRB, and ATP6V1B2) of the OXPHOS pathway were increased during early lactation. In contrast, 23 OXPHOS proteins increased ($P < 0.05$) during mid lactation, while most of these same proteins decreased ($P < 0.05$) during late lactation. There were 6 proteins within the data set that could be directly linked to PPARGC1α through analysis for interacting networks. The results suggest that the increased ATP synthesis activity of the mammary mitochondria during early lactation results from changes in only a limited number of rate limiting proteins.

Meat Science and Muscle Biology Symposium: Impact of Pre- and Post-Slaughter Handling on Meat Quality

966 Handling of pigs and the effect on muscle metabolism prior to harvest. M. J. Ritter* and S. N. Carr, *Elanco Animal Health*, *Greenfield, IN*.

Market weight pigs are subjected to numerous stressors during the marketing process from loading at the farm to stunning at the packing plant. These stressors have important implications for animal well-being and fresh pork quality traits. The objectives of this presentation are to review: 1) pre-harvest stressors in pigs; 2) common measures of stress during handling and transportation; and 3) effects of pre-harvest stressors on metabolic changes and fresh pork quality traits. Pre-harvest stressors can be encountered during loading, transportation, unloading, lairage, and movement to the stunning area. Although the majority of the work in this area has focused on animal handling procedures, other areas of interest include the mixing of unfamiliar pigs, transport floor space, transport time, lairage time, and environmental conditions. Genetics, previous experiences, and the physical condition of the animal will impact how pigs respond to these stressors. Measures of stress during handling and transportation include: body temperature, heart rate, respiration rate, blood acid-base balance (pH, lactate, bicarbonate, and base-excess), stress hormones (cortisol, epinephrine, and norepinephrine), enzyme activity (creatine kinase and lactate dehydrogenase), and muscle glycolytic potential. The magnitude of the change in these parameters is dependent upon stressor intensity, duration, and frequency. For example, recent work by Hambrecht et al. (2005) and Ritter et al. (2009) reported that multiple concurrent pre-harvest stressors have additive effects on body / carcass temperature, blood lactate, and muscle lactate values in market weight pigs. It is well documented that aggressive handling immediately before harvest increases early postmortem temperature and the rate of pH decline in muscle, resulting in pork with high drip loss (Hambrecht et al., 2004a; 2004b; 2005). However pre-harvest stressors that reduce muscle glycogen during loading at the farm may have beneficial effects on ultimate pH and water-holding capacity (Edwards, 2009). Therefore, improvements in pre-harvest handling do not always translate to improvements in fresh pork quality traits.

Key Words: pig, pre-harvest stress, pork quality

967 Pre-slaughter stress in ruminants and its relationship to meat quality. D. M. Ferguson*[1] and R. D. Warner[2], [1]*CSIRO Livestock Industries*, *Armidale, NSW, Australia*, [2]*Victorian Department of Primary Industries*, *Werribee, VIC, Australia*.

The production of meat that consistently meets consumer expectations requires vigilance and control at all points in the supply chain. In particular, control is required during the critical period from farm or pen to slaughter as the inevitable stress that all livestock experience can result in losses to meat quality. Livestock are exposed to multiple and often novel stressors, some repeated (e.g., handling), during the pre-slaughter phase. Animals can vary enormously in their response to these stressors, depending on their prior experience and genetic predisposition to stress. The variable nature of pre-slaughter stressors and the animalsâ€ response presents major challenges to the design of studies quantifying the impacts of these on animal welfare and meat quality. Furthermore, it creates difficulties in the development of control strategies to mitigate these impacts. The stress-mediated depletion of muscle glycogen and the subsequent dark-cutting condition in meat has been well documented and is perhaps indicative of significant pre-slaughter stress. Despite improved pre-slaughter management, there is still evidence of acute increases in the incidence of dark cutting in consignments of cattle. These spikes cannot be explained by changes in pre-slaughter practices or other known stress mediating factors. Recent research in ruminants has revealed that pre-slaughter stressors can also negatively affect meat quality traits such as sensory panel scores and water holding properties independent of any change to ultimate pH or rate of pH fall. In this paper, we review the impacts of pre-slaughter stress on beef and sheepmeat quality traits and discuss recent developments in strategies to minimize the occurrence and effects of pre-slaughter stress.

Key Words: ruminant, pre-slaughter stress, meat quality

968 Impact of early pre- and post-mortem processing on poultry meat quality. S. Barbut*, *University of Guelph*, *Guelph, Ontario, Canada*.

Over the past decade there have been some major changes in the way poultry is handled. Three of the main ones have been the introduction of mechanical catching on a large commercial scale, controlled atmosphere stunning (CAS), and electrical stimulation (ES). Although the changes have been introduced to reduce manual labor, increase efficiency, address animal welfare issues, and in the case of ES also to shorten time to deboning, one of the major drivers is still meat quality. Efforts have also been directed to improve transportation conditions, restrict feed withdrawal and rest period after transportation; all can contribute to reduce stress and improve to meat quality. These factors are very important in general and also because some birds are known to be more susceptible to stress and show the pale, soft and exudative (PSE) syndrome which up to now is not dealt with by genetics. The new generation of mechanical catchers can handle a large number of birds and reduce wing and other damages if done correctly. CAS is becoming more popular in Europe but it should be remembered that meat quality issues are strongly depended on the method used (single vs multiple phase, gas mix) and way birds are handled. Electrical stunning is still the most common method but variations between high and low voltages / frequencies as well as the use a two phase stunning can be seen around the world. Most new plants are using ES (i.e., not common a decade ago), and together with an appropriate chilling regimen can allow broiler meat deboning with 3-4 hrs. The review will focus on how such developments have been made based on better understanding of meat science, animal physiology, and animal welfare.

Key Words: poultry, meat, stress

969 Processing practices and perceived pork quality. T. Ngapo*, *Agriculture and Agri-Food Canada*, *St Hyacinthe, Quebec, Canada*.

It is well known that potentially good sensory quality of pork brought to slaughter can readily be destroyed by post-mortem processing, but can the quality be further improved? Control of post-slaughter processes, such as, chilling regimens and aging, are vital to both realizing a good eating experience and to achieving a product of consistently good sensory quality. Pork is a relatively tender meat and achieves about 80% of its maximal tenderness in 5 d, twice as fast as that of beef. Consequently many of the post-mortem processes currently used were developed on the basis that an aging period is not required longer than the time to get the meat from slaughter to plate, estimated at about 6 d in North America. These processes have little changed in the last few decades,

but consumer perceptions have, with complaints of blandness leveled against modern lean meat. Accordingly, studies with the specific objective of improving the sensory quality of pork have come to the forefront of meat research in the last few years as avenues for improvement, rather than maintenance, of sensory quality are now being sought. Hence, this bibliographic review of the impact of early post-mortem processing on perceived quality aims to provide insight into potential sources of amelioration of the eating quality of fresh pork. These processes include suspension, chilling, boning, electrical stimulation and aging.

Key Words: pork, post-mortem processing, quality

Nonruminant Nutrition: Feed Additives

970 Benefits of a synthetic antioxidant on improving growth performance in broiler chicks. J. Zhao*, F. Yan, C. Atwell, D. Macaraeg, M. Vazquez-Anon, J. D. Richards, R. J. Harrell, S. Carter, and T. Hampton, *Novus International Inc.*

This study examined the benefits of a synthetic antioxidant (AOX, AgradoPlus, Novus International Inc., St. Charles, MO) on improving performance in broilers. A total of 1152 ROSS 308 male birds were randomly allotted to one of the 4 dietary treatments with 12 pens per treatment and 24 birds per pen. The trial was a 2x2 factorial design with 2 types of soybean oil (fresh vs. oxidized) with or without AOX (0.025%). Oxidized soybean oil was produced by bubbling oxygen in a heated container up to 48 h to reach a target peroxide value (PV) of 200mEq/kg and 6 mEq/kg in the final diets. In the starter phase (d0–10), feed efficiency was significantly impaired with oxidized oil treatments ($P = 0.001$). Birds fed AOX gained more ($P < 0.05$) and ate more ($P < 0.05$) regardless of oil type (interaction, $P > 0.10$). In the grower phase (d10–23), birds fed oxidized oil gained less, ate less, and had lower overall performance index ($P < 0.05$) than birds fed fresh oil. Dietary AOX eliminated the negative effects of oxidized oil on performance ($P < 0.05$). The best performance was observed on birds fed fresh oil with AOX. Overall (d0–39), oxidized oil decreased feed efficiency (6%, $P < 0.001$), weight gain (7.5%, $P < 0.001$), and feed intake (2.3%, $P = 0.11$) compared with birds fed fresh oil. Birds fed AOX ate more ($P = 0.01$) regardless of oil type (interaction, $P = 0.34$), and gained more ($P < 0.001$) especially in birds fed oxidized oil (interaction, $P = 0.05$). The final body weight was 2.848, 2.876, 2.637, and 2.743 kg for birds fed fresh oil without and with AOX and for birds fed oxidized oil without and with AOX, respectively. In summary, oxidized oil impaired weight gain, feed intake, and feed efficiency. Birds fed AOX had better weight gain and feed efficiency regardless of oil type, and the benefits of AOX were more profound in oxidized oil groups.

Key Words: antioxidant, broiler, performance

971 Probiotic, prebiotic and yeast supplementation in broiler diets from 1 to 42 days of age: 1. Productive performance and economic efficiency. S. A. Riad[1], H. M. Safaa*[1], F. R. Mohamed[1], S. S. Siam[2], and H. A. El-Minshawy[3], [1]*Animal Production Department, Faculty of Agriculture, Cairo University*, *Giza 12613, Giza, Egypt*, [2]*Poultry Breeding Department, Animal Production Research Institute*, *Dokki, Giza, Egypt*, [3]*Ministry of Agriculture*, *Dokki, Giza, Egypt*.

A total of 630 Arbor Acres broiler chicks at one-day old was used to study the effect of probiotic, prebiotic and/or yeast supplementation on the productive performance traits and economic efficiency. Chicks were divided randomly into 6 treatments and housed at deep litter in an open house system. Each treatment replicated 3 times (35 chicks per replicate). Treatments were as follows: T1 (control; chicks fed corn-soy basal diet) and in the other treatments diets were supplemented with 1g probiotic/kg diet as *Lactobacillus acidophilus* (T2), 1g yeast/kg diet as *Saccharomyces cervisiae* (5×10^{12} CFU/g; T3), 1g prebiotic/kg diet as mannan-oligosaccharide (T4), 1g probiotic+1g prebiotic/kg diet (T5) or 1g yeast+1g prebiotic/kg diet (T6). Basal diet contains 23.1% CP and 3103 Kcal AME/kg for the starter diet (0–21 d) and 20.0% CP and 3207 Kcal AME/kg for the finisher diet (21–42 d). Body weight at 42 d was heavier ($P \leq 0.0001$) by about 29.5, 21.2, 12.4, 11.3 and 9.9% than control in the T6, T5, T4, T3 and T2, respectively. Moreover, feed conversion ratio was 2.08, 1.80, 1.84, 1.82, 1.63, 1.61 for T_i (i = 1, 2, ... 6, respectively). For all traits, the best values were obtained in T6 followed by T5 then T4. Also, T6 gave the best relative economic efficiency (14.86% more than control group). It could be recommended from this study to supplement the biological additives to broiler diet from 0 to 42 d of age as above mentioned because it has a positive effect on the broiler performance and the economic efficiency.

Key Words: probiotic, prebiotic, yeast, broiler performance, economic efficiency

972 Starter feed supplementation level effects of coated sodium butyrate (ADIMIX) on growth performance of broilers. R. D. Malheiros* and P. R. Ferket, *North Carolina State University*, *Raleigh*.

Dietary supplementation of butyric acid (BA) has been shown to support enteric development and intestinal health of neonatal animals, but BA′s benefit to overall growth performance is variable because of its volatility in finished feed. ADIMIX (Nutriad, Inc.) is a coated sodium butyrate product (30% activity) that is less volatile and has more favorable handling characteristics for feed manufacturers than the concentrated BA. Commercial broilers were randomly assigned to 32 floor pens containing 30 birds each and provided feed and water ad libitum until 49 d. Starter feed (pellet-crumbled) treatments consisting of 4 dietary supplementation levels of ADIMIX (0, 0.015, 0.03, and 0.06% BA) were subjected to 8 replicate pens per treatment from 1 to 14 d. Subsequently, all birds were fed pelleted grower and finisher diets that did not contain ADIMIX. Body weight (BW) and feed intake was determined at 7, 14, 21, 42, and 49 d and feed/gain (FCR) was calculated. At 3, 8, and 14 d, 4 birds/treatment were sampled for gut histology evaluation. There were no treatment effects on mortality rate. BW at 14 d increased linearly ($P < 0.01$) as the level of BA increased (457 g vs 470 g for 0 vs 0.06% BA), but no effects on 1–14 d FCR was observed. Histomorphometic analysis was associated with early treatment effects on BW. The positive starter feed treatment effects were observed throughout the experiment, with 0.015% BA (0.05% ADIMIX) resulting in a 3% and 2% improvement in 42 d BW ($P < 0.02$) and 49 d BW ($P < 0.10$), respectively. A linear improvement in 1–42 d FCR by up to 3% was also observed as the level of BA increased in the Starter feeds. Dietary supplementation of BA as ADIMIX in starter feeds has a lasting positive effect on broiler growth performance.

Key Words: broilers, butyric acid, growth performance

973 Investigation on the effects of antibiotic growth promoters alternatives on broiler performance. M. Shivazad*[1,2], N. Ghazvini[2], and S. N. Mousavi[2], [1]*University of Tehran*, *Tehran, Iran*, [2]*Varamin-Pishva branch, Islamic Azad University*, *Varamin, Iran*.

A study was conducted to evaluate the effects of organic acid (butyric acid and propionic acid), probiotics (*Pediococcus acidilactici*), prebiotics (mannanoligosaccharides) and formalin as potential alternatives to antibiotic growth promoters (AGP) in broiler chickens. Dietary treatments included an antibiotic free diet (CTL-), a positive control (CTL+) containing antibiotic (Avilamycin) and an antibiotic free diet containing butyric acid (Baby C4), Mannanoligosaccharides (BioMOS), Propionic acid (Formycin Gold), Probiotics (Bacto cell) or Formalin (37% formaldehyde). Feed intake was not affected by dietary treatments. Addition of Avilamycin significantly improved weight gain during 1–14 d but the effect was not continued. Birds fed BioMos and butyric acid were significantly heavier than negative controls during 14–28, 28–42 and 1–42 d ($P < 0.05$). Butyric acid treatments improved FCR throughout

the experiment. Avilamycin and probiotics improved FCR for d 1–14 and 1–42. BioMos had highest breast meat percentage among all treatments ($P < 0.05$). Dietary treatments had no significant effect on jejunum morphology (villus length, villus width and crypt depth). The results of this study indicated that addition of butyric acid and MOS to the diet could be an alternative to the use of antibiotics as growth promoters in broiler production.

Key Words: broiler, antibiotic growth promoters, probiotics

974 Dietary supplementation of *Spirulina platensis* in Austra-White chicken improves proximate composition of meat. A. Kollanoor Johny*[1], K. P. Sreekumar[2], S. C. Nair[2], and P. Kuttinarayanan[3], [1]*Department of Animal Nutrition, College of Veterinary and Animal Sciences, Kerala Agricultural University*, *Mannuthy, Kerala, India*, [2]*Department of Animal Physiology, College of Veterinary and Animal Sciences, Kerala Agricultural University*, *Mannuthy, Kerala, India*, [3]*Center of Excellence in Meat Science and Technology, College of Veterinary and Animal Sciences, Kerala Agricultural University*, *Mannuthy, Kerala, India*.

Spirulina platensis, a blue-green alga is generally regarded as a rich source of protein, fats, vitamins and minerals. Although there are a few studies indicating its potential to enhance color of egg yolk and meat, the effect of Spirulina on the proximate composition and minerals including zinc and iron, of chicken meat has not been explored. The study was undertaken to determine the effect of dietary Spirulina on the proximate composition of chicken meat. Twelve, Austra-White male (egg-type) chicken were divided randomly into 2 groups of 6 birds each; control and experimental and were reared in battery cages with ad libitum access to feed and water. They were fed iso-nitrogenous and iso-caloric standard layer rations with the experimental group receiving 2.5% of dried Spirulina powder for a period of 6 mo, starting from the third month of age. At the completion of the trial, birds were sacrificed to collect meat and blood samples for proximate, mineral and serum analyses. The experiment was replicated 2 times. Spirulina-fed group showed significant improvement ($P < 0.05$) in total protein, fat and ash content of the meat samples. The concentrations of zinc, iron, magnesium, manganese, sodium, and potassium in meat did not differ between the groups, however, the serum concentrations of zinc and iron in the spirulina-treated group were significantly higher ($P < 0.05$) compared with that in the control. Analysis of plasma lipid profile revealed significant lowering of plasma total lipids and cholesterol ($P < 0.05$). Results of the study indicate that dietary supplementation of *Spirulina platensis* improves the proximate composition of chicken meat.

Key Words: *Spirulina platensis*, Austra-White chicken, meat, minerals

975 Increased fiber digestion and decreased fecal output in pigs fed fibrolytic bacteria. C. Ziemer*[1], S. Arcidiacano[2], A. Ragauskas[3], and M. Morrison[4,5], [1]*National Laboratory for Agriculture and the Environment, ARS, USDA*, *Ames, IA,* [2]*U.S. Army Natick Soldier Center*, *Natick, MA,*[3]*Institute of Paper Science and Technology, Georgia Institute of Technology*, *Atlanta, GA,* [4]*Department of Animal Science, Ohio State University*, *Columbus,* [5]*CSIRO Livestock Industries*, *St. Lucia, QLD, Australia*.

Fiber digestibility increases when pigs are fed for longer periods of time, suggesting adaptation of intestinal microbiota with increased concentrations of fiber utilizing bacteria. We investigated whether feeding fiber utilizing bacteria to pigs would result in improved fiber digestion and reduce fecal output. Treatments were arranged as a 2 × 4 factorial with 2 diets and 4 bacterial treatments, with random assignment of pigs. Pigs, housed as 2 groups of 24, were fed either conventional or 20% distillers dried grains with solubles + 10% soybean hulls diet ad libitum with free water access. Treatments consisted of no bacteria (A) or one of 3 *Bacteroides* isolates (B, C and D); isolated from fecal enrichments with cellulose and xylan. Bacteria were fed to pigs once daily (0900 h) using a 50:50 mixture of bacteria in growth medium and food grade glycerol (dosage of 10^{10} bacterial cells/d). After 3 weeks, 24 pigs, at a time, were moved into metabolism crates for 11 d. On d 7 to 11 total dietary intake, fecal output, and urinary output were measured and feed, feed refusals and feces were sampled to determine nutrient digestibilities. Blood was taken on d 1 and 11 to analyze plasma for energy metabolites. Data were analyzed as 2 × 2 × 4 randomized block design with 2 groups of pigs, 2 dietary treatments and 4 bacterial treatments; no interactions were significant and these were removed from final model. Initial pig BW averaged 61.1 kg, after 50 d the final pig BW averaged 103.6 kg. Feed intake was not affected by diet or bacterial treatment. The effects of increased fiber in the diet were as expected. Treatment B resulted in the most desirable effects when fed to pigs. Fecal output (g/d, $P = 0.13$) and fecal output/intake (g/g, $P = 0.07$) were decreased when treatment B (by 19.8% and 19.4%, respectively) was fed compared with no bacteria (A). Plasma glucose (mg/dL, $P = 0.10$) and cholesterol (mg/dL, $P = 0.14$) were increased in pigs fed B compared with no bacteria (A) by 5.3 and 10.4%, respectively. Bacterial treatment B demonstrated promise as a method to improve utilization of high fiber diets fed to pigs while maintaining performance.

Key Words: pig, fiber digestion, fecal output

976 Effects of dietary resveratrol supplementation on egg production and egg yolk lipid peroxidation. K. Sahin*[1], F. Akdemir[2], C. Orhan[1], M. Tuzcu[3], A. Hayirli[4], and N. Sahin[1], [1]*Department of Animal Nutrition & Nutritional Disorders, Faculty of Veterinary Medicine, Firat University*, *Elazig 23119, Turkey*, [2]*Department of Animal Nutrition & Nutritional Disorders, Faculty of Veterinary Medicine, Dicle University*, *Diyarbakir 21100, Turkey*, [3]*Department of Biology, Faculty of Science, Firat University*, *Elazig 23119, Turkey*, [4]*Department of Animal Nutrition & Nutritional Disorders, Faculty of Veterinary Medicine, Atatürk University*, *Erzurum 25240, Turkey*.

Resveratrol, a polyphenol derived from red grapes, berries, and peanuts, have anti-inflammatory, antioxidant, and immunomodulatory activities. The objective of this study was to investigate the effects of dietary resveratrol supplementation on performance and serum and egg yolk antioxidant status in quails (*Coturnix coturnix japonica*). A total of 150 5-wk-old quails were allocated randomly to 3 dietary treatments: basal diet and basal diet supplemented with 200 and 400 ppm resveratrol. Each diet was offered to 10 cages of 5 birds in each, for 12 wks. Serum and egg samples were collected at the beginning (wk 4) and end (wk 16) of the experimental period for tumor necrosis factor (TNF-α), malondialdehyde (MDA), vitamin A and vitamin E. Data were subjected to ANCOVA using the MIXED Procedure. There was no treatment effect on feed intake and egg production as well as egg quality. There was no dietary resveratrol supplementation effect on serum and egg yolk vitamin A levels. Serum MDA (0.56 vs. 0.88 mg/l, $P < 0.03$) and TNF-α (18.24 vs. 21.43 pg/ml, $P < 0.008$) levels were lower and serum vitamin E level (5.72 vs. 3.56 mg/l, $P < 0.008$) was higher for quails supplemented with resveratrol than for quails fed the basal diet. Serum MDA ($P < 0.02$) and TNF-α ($P < 0.05$) levels decreased linearly and serum vitamin E level ($P < 0.01$) increased linearly with increasing dietary resveratrol supplementation. Egg yolks from quails supplemented with resveratrol contained less MDA than those from

quails fed the basal diet (0.21 vs. 0.15 μg/g, $P < 0.002$). In response to increasing dietary resveratrol level, egg yolk MDA content decreased linearly ($P < 0.0003$). To our knowledge, this is the first experiment dealing with antioxidant and anti-inflammatory effects of resveratrol in poultry. In conclusion, inclusion of resveratrol up to 400 ppm into quail diets enhanced antioxidant status of birds and improved egg stability, which could be important to consumers.

Key Words: resveratrol, antioxidant status, Japanese quail

977 The effect of feeding Original XPC to turkey breeder hens and progeny on starter poult performance and early breast muscle development. P. R. Ferket*[1], R. D. Malheiros[1], M. J. Wineland[1], J. L. Grimes[1], and D. T. Moore[2], [1]*North Carolina State University*, *Raleigh,* [2]*Diamond V, Inc.*, *Cedar Rapids, IA*.

This study investigated the use of a *Saccharomyces cerevisiae* fermentation product in turkey breeder diets and subsequent progeny diets. A commercial breeder farm provided 2 diets to Hybrid Converter breeder hens starting at 29.5 weeks of age before the onset of lay: control diet or the control diet containing 0.075% XPC. At approximately 33.5 weeks of age, eggs were collected from both breeder flocks and transported to NC State University where they were incubated. Male poults were randomly divided at hatch into 4 treatments with 10 pens/treatment and 15 poults/pen. Treatments were arranged as a 2X2 factorial, consisting of 2 dietary XPC levels for breeders (0 and 0.075%) and 2 dietary XPC levels for progeny (0 and 0.125% 1–42 d and 0.0625% 43–63 d). Poults were raised in a curtain-sided, floor pen facility, and provided feed and water ad libitum. Body weights (BW) and feed consumption was determined at 21, 42, and 63 d and feed/gain (FCR) calculated. At 14 and 42 d, 4 poults/treatment were sampled for breast muscle yield. There were no significant ($P > 0.05$) breeder effects or breeder × progeny treatment interaction effects on BW or FCR throughout the experiment. However, the positive effects of dietary XPC supplementation on the growth performance of progeny was highly significant ($P < 0.0001$). BW of progeny fed XPC was greater than controls at 21 d (579 g vs. 509 g, $P < 0.0001$), 42 d (2595 g vs. 2417 g, $P < 0.0001$) and 63 d (6057 g vs. 5480 g, $P < 0.0001$). However, FCR of progeny fed XPC was better than controls only from 1 to 21d (1.59 vs. 1.71 $P < 0.0001$). Dietary XPC supplementation increased % breast muscle yield at 14 d (15.22% vs. 12.31%, $P < 0.0001$), but no significant effects were observed on % breast muscle at 42 d. Feeding poults XPC during the starter phase improves feed intake and body weight gain for the entire period and improves feed conversion and breast muscle yield early in the phase.

Key Words: turkeys, fermentation product, growth performance

978 Use of a *Bacillus amyloliquefaciens* probiotic in broiler farms. J. J. Mallo*[1], M. I. Gracia[2], P. Honrubia[1], and G. Sedano[3], [1]*Norel SA*, *Madrid, Spain*, [2]*Imasde Agroalimentaria SL*, *Madrid, Spain*, [3]*Nutyser SL*, *Burgos, Spain*.

Ten farms involving 2,240,000 male and female broilers were used to evaluate the efficacy of a probiotic (Ecobiol; EU Zootechnical Feed Additive number 4b1822; containing $1x10^9$ CFU of *B. amyloliquefaciens* CECT 5940 per g) on animal performance. The probiotic was added to the feed at a ratio of 1 kg/ton. Feeds were presented in pelleted form and analyzed for the probiotic concentration. In 9 farms, the former productive results of the farms were used as control, and they were compared with the productive results of the farm when the probiotic was added to the feed. In one farm, 3 buildings (10,000 broilers each) received the control feed and 3 buildings received the probiotic. In this farm, samples of feces were taken to analyze lactobacilli and coliform bacteria (CFU/g) at d 7 and 35. The experimental data were tested for homogeneity, pooled and combined in a meta-analysis. Parameters analyzed were final body weight (g), feed conversion (feed/gain) and mortality (%) for the whole period. At the end of the experimental period broilers fed the probiotic showed better feed conversion (−3.0%, 2.01 vs. 1.95 g/g; $P = 0.0262$) and less mortality rate (−36%; 8.3 vs. 5.3%; $P < 0.0001$) than controls. No significant differences were observed in body weight (2,632 vs. 2,678 g; $P = 0.3701$). Probiotic supplementation of diets increased Lactobacilli counts of feces at 7 d (8.14×10^8 vs. 1.73×10^9 CFU/g; $P = 0.0013$) and at 35 d of age (2.46×10^8 vs. 5.45×10^8 CFU/g; $P = 0.0024$). Coliform bacteria counts were significantly decreased by the use of the probiotic at 7 d (5.74×10^7 vs. 2.94×10^7 CFU/g; $P = 0.0268$) but only numerically at 35 d (1.56×10^7 vs. 9.74×10^6 CFU/g; $P = 0.1627$). It is therefore concluded that the probiotic tested improves feed conversion and reduces mortality in farms, possibly because of a better intestinal balance.

Key Words: probiotic, *Bacillus amyloliquefaciens*, broiler

979 Chemical and nutritive composition of low-fiber canola: The effects of seed coat color and enzyme supplementation. W. Jia*[1], M. Mogielnicka[1], A. Rogiewicz[1], G. Rakow[2], D. Hickling[3], and B. A. Slominski[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*Agriculture and Agri-Food Canada*, *Saskatoon, Saskatchewan, Canada*, [3]*Canola Council of Canada*, *Winnipeg, Manitoba, Canada*.

Canola breeding programs undertaken to improve meal quality without compromising oil content in the seed has led to the development of yellow-seeded *Brassica napus* and *B. juncea* canola. The objective of the current study was to evaluate the chemical and nutritive composition of meals derived from black- and yellow-seeded *B. napus* canola and canola-quality yellow-seeded *B. juncea*. In comparison with its black-seeded counterpart, meal derived from yellow-seeded *B. napus* canola contained more protein (49.8 vs. 43.8% DM), more sucrose (10.2 vs. 8.8% DM) and less dietary fiber (24.1 vs. 30.1% DM). Lower fiber content in yellow-seeded *B. napus* canola was reflected in lower content of lignin with associated polyphenols (3.7 vs. 7.1% DM). *B. juncea* canola showed intermediate levels of crude protein, sucrose and dietary fiber (47.4, 9.2 and 25.8%, respectively). Seed fractionation study demonstrated that the reduction in fiber content of yellow-seeded *B. napus* was a consequence of a bigger seed size, which averaged 3.9, 2.9 and 2.5 mg/seed, respectively, for yellow- and black-seeded *B. napus* and *B. juncea* canola, a lower contribution of the hull fraction to the total seed mass (11.0 vs. 15.9 and 13.7 g/100 g of seed), and a lower fiber content of the hull fraction (5.0 vs. 9.1 and 8.2 g/100 g of seed). The nutritive value of canola meal samples was investigated with broiler chickens fed corn/soybean meal-based diets containing 30% of meals from 3 to 17 d of age. A significantly higher ($P < 0.05$) total ileal digestibility of amino acids (88.8%) was observed in birds fed the yellow-seeded *B. napus* diet when compared with those fed diets containing black-seeded *B. napus* (83.5%) or *B. juncea* (84.2%) canola. In a second study, meal AME_n values for yellow- and black-seeded *B. napus*, and *B. juncea* were determined with broiler chickens (from 14 to 19 d of age) and were 2190, 1904, and 1736 kcal/kg DM, respectively. Enzyme addition significantly increased the AME_n values from 1943 to 2249 kcal/kg DM, on average, with the most pronounced effect observed for *B. juncea* canola (from 1736 to 2356 kcal/kg DM).

Key Words: canola meal, chemical composition, nutritive value

980 Pre-hatch colonization of the chick gut with probiotic bacteria. J. E. de Oliveira*[1], J. M. B. M. van der Vossen[2], A. M. T. Ouwens[2], E. Hangoor[1], and T. A. Scott[1], [1]*Provimi*, *Velddriel, the Netherlands*, [2]*TNO*, *Zeist, the Netherlands*.

Poultry are believed to hatch with minimal amounts of intestinal bacteria present. Gut microflora is believed to be established during or after hatch. This is considered to be a key event with consequences that affect not only the bird's health and performance, but also relates to food safety risks with establishment of food borne pathogens, particularly into the ceca. The current view is that establishment and maintenance of "good" or probiotic microbiota can minimize or prevent overgrowth of pathogens. This study was designed to test the viability to colonize the chick intestine with probiotic bacteria before hatch. Embryonized (E17) chicken eggs were in ovo inoculated with medium containing *B. subtilis* (P1) or *E. faecium* (P2), and compared with embryos from non-inoculated eggs (control). Number of bacteria was calculated as cell equivalents (CE) based on amount of bacterial DNA determined by qPCR at 48 h after inoculation in the embryo's gizzard content, and at hatch (96 h after inoculation) in the ceca content. Ceca results were also confirmed by plate culturing. P1 inoculation greatly increased bacteria number compared with the controls in both, the gizzard (1×10^5 vs. 3×10^2 CE/mL, respectively, $P < 0.01$) and the ceca (4.5×10^4 vs. 3×10^3 CE/mL, $P < 0.05$). Similar increase was found for P2 in both, the gizzard (4×10^5 vs. 4×10^3 CE/mL, $P < 0.05$) and in the ceca (8×10^7 vs. 1×10^7 CE/mL, $P < 0.01$). Culturing of ceca contents showed that P1 inoculation significantly increased the number of total bacteria colonies compared with the control (respectively, 3×10^9 vs. 6×10^7 CFU/mL, $P < 0.05$), with P2 showing intermediate value (1×10^9 CFU/mL). Based on these findings we concluded that the chick intestine can be colonized with probiotic bacteria before hatching. Future research will focus in determining if chicks that hatch with gut probiotic bacteria are less susceptible to pathogenic bacteria such as *Salmonella*, *Campylobacter* and *Clostridia*.

Key Words: probiotic, gut colonization, chicken

981 Methionine hydroxy-analogue as antioxidant defence enhancer. Q. Swenen[1,3], J. Buyse[1], P.-A. Geraert[2], Y. Mercier*[2], N. Everaert[1], A. Stinckens[1], H. Willemsen[1], L. Yue[1], and E. Decuypere[1], [1]*K.U. Leuven*, *Laboratory for Livestock Physiology, Immunology and Genetics, Department of Biosystems. Kasteelpark Arenberg 30, 3001 Leuven, Belgium*, [2]*Adisseo France S.A.S*, *F-92160 Antony, France*, [3]*University of Hasselt*, *Center for Environmental Sciences, Agoralaan building C, 3590 Diepenbeek, Belgium.*

DL-Methionine (DLM) and the DL-methionine hydroxy-analog (HMTBA) are 2 bio-available methionine sources commonly used in the poultry feed industry. Previous studies on absorption and metabolism demonstrated that when compared with DLM, HMTBA metabolism produces more cysteine (Martin-Venegas et al., 2006) which is implicated in glutathione synthesis, one of the major intracellular antioxidant defense mechanisms. The present experiment involved 4 groups of broilers fed different diets: high (23%) or low (18%) dietary protein level and 2 methionine sources (DLM or HMTBA 0.25%) in a factorial design. As expected, the high protein level led to an improved zootechnical performance compared with that on the low protein diet. Whatever the protein level considered, higher slaughter weights were obtained with HMTBA than with DLM. Oxidative status was assessed in plasma by superoxide dismutase (SOD), uric acid and lipid peroxidation and in liver by total, as well as reduced and oxidised glutathione levels. Results showed that irrespective of the dietary protein level, HMTBA-fed birds were characterized by a higher plasma SOD activity compared with that of DLM-fed birds. Moreover, higher plasma levels of uric acid and lower lipid peroxidation were observed with the high protein-HMTBA combination compared with all other treatments. Hepatic concentrations of reduced glutathione as well as total glutathione were significantly higher in the low protein-HMTBA treatment compared with all other treatments. This work allows concluding that HMTBA, besides being a viable alternative dietary supplement for DLM, also improves both extra- and intracellular antioxidant status.

Key Words: methionine sources, antioxidant, glutathione

982 Comparative in vitro antimicrobial activity and mechanism of bovine lactoferricin-derived synthetic peptides. Y. Liu*, Y. Xie, F. Han, Y. Gao, C. Luan, and Y. Wang, *Zhejiang University*, *Hangzhou, Zhejiang, China*.

Lactoferricins are positively charged, highly basic peptides exhibiting multifunctional immunoregulation of antibacterial, antifungal, antiendotoxin, and antiviral activities. Lactoferricin B (LFcinB), a 25 residue peptide derived from N-terminal part of bovine lactoferrin, causes depolarization of the cytoplasmic membrane in susceptible bacteria, but the exact mode of action of LFcinB is not fully understood. In the present study, synthetic bovine lactoferricin and 2 derivatives with 15–residue and 11–residue peptides were prepared to investigate their antimicrobial nature and mechanism. The antimicrobial properties of the peptides were measured against *Escherichia coli* ATCC25922, *Escherichia coli* K88, *Staphylococcus aureus*, *Salmonella typhimurium*, *Salmonella choleraesuis* and *Pseudomonas aeruginosa* and hemolytic activity of these peptides were examined using the erythrocytes of pig. We found that 15-residue and 11-residue bovine lactoferricin almost maintained the same level of growth inhibition as LFcinB against tested bacteria in the minimal inhibitory concentrations (MIC) range of 16–128 μg/mL and the minimal bactericidal concentrations (MBC) range of 64–256 μg/mL. Also, the 11-residue lactoferricin was found to have the lowest hemolytic activity compared with the intact peptide. The mechanism of lactoferricin on *E. coli* and S. aureus was investigated by imaging the cells with scanning electron microscopy (SEM). After 1 h of exposure to MIC of LFcinB, a profound effect on the cell morphology of *E. coli* was observed. Compared with the control, the LFcinB-exposed cells became filamentous and elongated. The cells increased over 4-folds in length, and did not appear to be dividing in a regular manner. S. aureus cells exposed to MIC of LFcinB for 1 h appeared to be significantly smaller and somewhat paler than the cells not exposed to LFcinB. These results showed that LFcinB has a minor permeabilizing effect on the cytoplasmic membrane of both gram-positive and gram-negative bacteria, indicating a possible intracellular target.

Key Words: bovine lactoferricin, antimicrobial activity, mode of action

983 Microbial programming in the gut of neonatal pigs. D. Petri* and A. G. Van Kessel, *University of Saskatchewan*, *Saskatoon, Canada*.

To investigate possible long-term effects of first colonizing bacteria on post weaning gut commensal microbiota composition, a gnotobiotic study was conducted using 27 germ-free piglets derived by caesarian

section. Pigs were assigned to one of 4 isolators and were inoculated with either *L. delbrueckii* (L), *S. infantarius* (S), *C. perfringens* (C) or *E. coli* (E). Piglets were conventionalized on d 7 with sow feces, merged and transferred to group pens. On d 20 of age, piglets were weaned and on d 28 samples of digesta were collected from the stomach, jejunum and colon. Using 16S rRNA gene-based molecular methods, analysis of anal swabs taken on d 4 confirmed monoassociation of S, C and E pigs and di-association with *E.coli* for L pigs. Data was analyzed as a 2x2x4 factorial ANOVA (gender, litter, treatment; SPSS17 GLM function with Tukey's HSD). A significant gender effect ($P = 0.03$) was observed for ADG between d 7 and d 28. DNA was extracted from contents and qPCR used to quantify bacteria as a percentage of log10 total bacteria 16S rRNA gene copies per g of contents. In the stomach, Bifidobacterium spp. were significantly lower ($P = 0.05$) in E vs. L (60.4% vs. 70.8%) and showed a trend ($P = 0.07$) toward a gender effect. Enterobacteria tended ($P = 0.08$) to be lower in L (90.6%) vs. C (96.0%). In the jejunum, enterobacteria were not different between E (85.0%) and L (86.7%) but these were lower ($P < 0.01$ and $P = 0.02$, respectively) than in C (92.7%). Clostridium cluster 1 spp. in E (97.0%) were significantly lower ($P = 0.03$) than in L (109.0%). Bifidobacterium spp. tended ($P = 0.07$) to be lower in C (54.4%) than L (66.1%). Lactobacillus spp. also showed a significant gender effect ($P < 0.01$) and a trend ($P = 0.06$) toward Lactobacillus spp. levels in treatment S (93.4%) being lower than in treatment L (98.5%). Enterobacteria showed a trend ($P = 0.07$) toward a litter effect. In colon a gender by treatment interaction ($P = 0.02$) was observed for Bifidobacterium spp. Early postnatal microbial colonization pattern and gender affect postweaning gut microbial profile.

Key Words: intestinal microbiota, qPCR, gnotobiotic

984 Efficacy of water-soluble antioxidants on chicken embryos challenged by hypoxia. J. E. de Oliveira*[1], Y. Li[2], H. Willemsen[2], E. Decuypere[2], and T. A. Scott[1], [1]*Provimi*, *Velddriel, the Netherlands*, [2]*Department of Biosystems*, *K.U. Leuven, Belgium*.

Searching for natural antioxidants (AO) is challenging because many sources, doses and conditions fail to demonstrate consistent results in vivo. Chick embryo models can be used as tools to indicate bioavailability and bioactivity of feed additives. This trial was designed to investigate the effect of in ovo administration of increasing doses of vitamin E analog Trolox (VEA) or grape extract (GRP) on development and antioxidant capacity (AOC) of chick embryos. Chicken eggs were challenged at 14 d of incubation (E14) by partially sealing egg shell pores to induce mild hypoxia. Embryos were challenged by hypoxia as a way to induce oxidative stress. At E17, a group of 120 eggs was assigned to one of the following treatments: control (CTR, no AO); injection with VEA at 3 concentrations (10, 30 or 100 ppm); injection with GRP at 2.5, 12.5 or 25 ppm, or injection with the combination of VEA 10 ppm and GRP 2.5 ppm (COMB). Sixteen embryos from each treatment were sampled at E18 and E19 to measure embryo yolk-free body mass (YFBM), yolk-sac mass (YKM), and liver mass (LM). Liver samples were analyzed for levels of superoxide dismutase (SOD), catalase (CAT), reduced glutathione (GSH), and glutathione disulphide (GSSG) to indicate AOC. VEA 10 and 30 ppm significantly increased YFBM in both ages compared with CTR ($P < 0.01$), with all other treatments showing intermediate values. There was no treatment effects on YKM or LM. Liver AOC showed VEA 30 ppm and GRP 12.5 ppm with higher CAT then CTR ($P < 0.01$), with other treatments showing intermediate values. SOD results at E18 showed GRP 25 ppm, COMB, and VEA 100ppm having significantly higher values then CTR ($P < 0.05$), with other treatments showing intermediate values. For GSH at E18 there were differences only among VEA levels, with VEA 10 ppm being significantly lower than CTR ($P < 0.01$). No differences were found for SOD or GSH at E19, or for GSSG at both ages. We concluded that hypoxia-challenged chick embryos are good models to test AO, and that VEA 30 ppm, GRP 12.5 ppm and COMB improved growth and liver AOC of challenged chicken embryos.

Key Words: antioxidants, chick embryo, hypoxia

985 Growth response, carcass evaluation and hematology of broilers fed graded levels of enzyme treated cocoa bean shell based diets. M. D. Olumide, O. A. Ogunwole*, and O. A. Adebiyi, *Department of Animal Science, University of Ibadan, Ibadan, Nigeria*.

Cocoa bean shell (CBS) is a waste from cocoa processing industries in Nigeria and it constitutes a serious disposal problem. Previous trials revealed that addition of enzyme reduces the theobromine (anti-nutrient in CBS). Hence, this study focused on evaluating the growth response, carcass characteristics and hematological parameters of broilers fed graded levels of enzyme treated CBS based diets. A total of 150 birds at 1d of age were allotted to 5 dietary treatments (3 replicates/treatment, 10 birds/replicate) in a completely randomized design. The treatments were: A (0% CBS-control diet); B (5% CBS with enzyme); C (10% CBS with enzyme); D (15% CBS with enzyme) and E (20% CBS with enzyme). Each of the diet was fed ad libitum to the experimental birds. The trial lasted 8 weeks. The feed intake, weight gained, carcass characteristics and hematological indices were then evaluated. There were significant differences ($P < 0.05$) in feed intake, weight gain and carcass characteristics of broilers fed the experimental diets. The results revealed that enzyme treated CBS can effectively replace up to 15% maize in the diets of broilers without any adverse effects.

Key Words: broiler, cocoa bean shell, hematology

986 Evaluation of the efficacy of Myco-Ad in preventing aflatoxin toxicity in broiler chicks.. C. A. Mallmann[1], P. Dilkin[1], L. Giacomini[1], R. H. Rauber[1], and D. Zaviezo*[2], [1]*Universidade Federal de Santa Maria, Laboratorio de Analises Micotoxicologicas (LAMIC)*, *Santa Maria, RS, Brasil*, [2]*Special Nutrients*, *Miami, FL*.

The dietary use of 0.25% Myco-Ad has been proven to effectively prevent the toxic effects of aflatoxin B1 (AFB), ochratoxin and T-2 toxin in broilers. Studies were conducted to evaluate the AFB adsorption capacity of Myco-Ad and its efficacy in preventing the deleterious effects of high levels of AFB in broiler chicks; as part of the regulatory anti-mycotoxin additives (AMA) approval process in Brazil. Three hundred day-old Cobb male chicks were placed in battery cages randomly distributed into 5 treatments with 6 replications each and fed a basal corn-soy diet containing or exceeding NRC recommendations. All ingredients used were tested free of mycotoxins contamination. Treatments were: 1 basal diet; 2 basal + 0.5% Myco-Ad; 3 basal + 2.8 ppm AFB; 4 basal + 2.8 ppm AFB + 0.25% Myco-Ad and 5 basal + 2.8 ppm AFB + 0.5% Myco-Ad. AFB was obtained from a culture material containing 96.4% AFB; 1.61% Aflatoxin B2 and 1.99% Aflatoxin G1 produced in LAMIC. Myco-Ad adsorption capacity of 1 ppm AFB was above 95% and 97% at 0.25 and 0.5%, respectively. Results at 21 d of age indicated that broiler fed 2.8 ppm AFB contaminated diet presented significant ($P \leq 0.05$)lower feed intake (31%), smaller body weight (29%), heavier liver weight (56%) and lower plasma protein levels (54%) than chicks fed the control diet. The addition of Myco-Ad (0.25–0.5%) significantly($P \leq 0.05$) improved feed intake (32–40%), body weight (24–33%), liver size (17–30%) and plasma proteins (19–33%) observed in chicks fed the AFB contaminated diet. The addition of 0.5% Myco-Ad to the chick diet did not show any statistical difference in performance, relative liver weight

or total plasma proteins compared with the control diet, demonstrating its lack of interference with the absorption of nutrients. These results indicated that 0.25% Myco-Ad was effective in preventing the toxic effects of AFB in broiler chicks; and therefore met the requirements for AMA registration in Brazil.

Key Words: Myco-Ad, aflatoxin

987 Efficiency of feed additives to reduce the effects of chronic exposure to aflatoxin and deoxynivalenol on growth and immune status of pigs. A. C. Chaytor*[1], M. T. See[1], J. A. Hansen[2], A. L. P. de Souza[2], D. C. Kendall[2], T. F. Middleton[3], and S. W. Kim[1], [1]*North Carolina State University*, *Raleigh*, [2]*Murphy-Brown LLC*, *Rose Hill, NC*, [3]*AgProvision LLC*, *Kenansville, NC*.

Three feed additives with potential ability to detoxify mycotoxins were tested to determine the effects on growth and immune responses of pigs fed diets containing aflatoxin (AF, 180 μg/kg) and deoxynivalenol (DON, 900 μg/kg) for 42 d. Gilts (n = 225, 8.8 ± 0.4 kg BW) were allotted to 5 treatments: PC (positive control without AF and DON); NC (negative control with AF and DON); A (NC + a clay based additive); B (NC + a clay and yeast cell wall based additive); and C (NC + a clay and enzyme based additive). Each treatment had 15 replicates with 3 pigs per pen. Feed intake and BW were recorded weekly, and blood was sampled on d 28 and d 42. On d 42, pigs were killed to obtain liver, kidney and spleen. Pigs in NC had smaller ($P < 0.05$) body weight (24.6 kg) and ADG (374 g) than PC (26.6 kg and 423 g) but were not different from others (25.4 kg and 393 g). Pigs in NC tended to have a smaller ADFI (753 g, $P = 0.090$) and gain:feed (0.495, $P = 0.052$) than PC (816 g and 0.520) but were not different from others (775 g and 0.507). On d 42, pigs in NC had a greater ($P < 0.05$) monocyte count (1432/μL) than PC (968), A (1053), and B (952). Pigs in NC tended to have a greater basophil count (158/μL) than PC (91, $P = 0.088$), but were not different from others. Pigs in NC tended to have a greater serum IgG (1.02 mg/mL) than PC (0.89, $P = 0.074$), and A (0.83, $P = 0.010$). Pigs in NC had a greater ($P < 0.05$) serum IgM (0.2 mg/mL) than PC (0.17) and A (0.17), and tended to have a greater (0.093, $P = 0.099$) serum IgM than B (0.18) and C (0.18). Serum TNF-α was not affected by dietary treatments. Pigs in NC had a greater ($P < 0.05$) % liver weight (14.9%) than PC (12.3%) and B (12.7%). Collectively, feeding 180 μg/kg AF and 900 μg/kg DON to pigs for a 42 d period reduced growth performance and increased immune challenges. Use of these feed additives tended to ameliorated the immune challenges but without affecting the growth performance.

Key Words: alfatoxin, deoxynivalenol, pigs

988 Discrepancies between in vitro and in vivo fumonisin binding with organoclays. J. N. Broomhead*, *Amlan International*, *Chicago, IL*.

An in vitro binding and an in vivo chicken study were conducted to test the efficacy of 2 experimental and 1 commercial organically modified clays (OMC) in binding fumonisin B_1 (FUM). In vitro mycotoxin binding was conducted at physiological conditions of the stomach (pH 3.0) followed by the intestine (pH 6.5) at 1000:1 binder-to-toxin ratio. The in vivo study consisted of 200 d-old male broiler chicks assigned to 8 treatments with 5 replicate pens of 5 chicks each. The 3 OMC were either fed alone (0.5% dietary inclusion) or in combination with 70 ppm FUM supplied from naturally contaminated corn. Chicks were placed in battery-brooders and fed experimental diets for 21 d. On d 21, 3 birds per replicate were killed with CO_2, weighed, and livers removed and weighed from 3 birds per pen for determination of relative liver weight. After weighing, the livers were frozen and then 2 livers per pen were later analyzed for sphinganine (SA) and sphingosine (SO) concentration. In vitro FUM binding results were high and did not vary greatly between OMC (85 to 96% FUM bound). Replacing the normal dietary corn with FUM contaminated corn (70 ppm dietary FUM) reduced ($P < 0.005$) body weight gain (BWG) and feed intake, and increased ($P < 0.0001$) liver SA and SA:SO ratio. Relative liver weight and feed conversion were not significantly affected by treatments ($P > 0.05$). Inclusion of one of the experimental clays to the FUM diet significantly decreased ($P < 0.0005$) BWG and increased ($P < 0.0001$) SA and SA:SO ratio compared with the FUM, alone, treatment. In conclusion, none of the OMC ameliorated the toxic effects of FUM to the broilers. Also, the in vitro FUM binding procedure used may not be a good predictor of in vivo efficacy and in vivo studies should always be conducted to validate in vitro results.

Key Words: fumonisin, in vitro, in vivo

989 Comparison study of alternative cryoprotectants for cryopreserving bull spermatozoa. M. M. Awad*, *Animal Production Dept. Faculty of Agriculture, Suez Canal University*, *Ismailia, Egypt*.

Mammalian spermatozoa experience osmotic stress when the glycerol is added to the cells before freezing and removal from the cells after thawing. To minimize osmotic damage, alternative cryoprotectants, having lower molecular weights and greater membrane permeability than glycerol, were evaluated to determine their effectiveness for cryopreserving bull spermatozoa. The primary goal of this study was to compare glycerol as the most common cryoprotectant of bull spermatozoa to ethylene glycol and methyl as alternative cryoprotectants. Bull semen was diluted with tris-egg yolk extender containing 3% glycerol, 3, 2 and 1% ethylene glycol and 3, 2 and 1% methyl. Bull semen was frozen in pellets form using the cold surface of cattle fat. Computer assisted sperm analysis (CASA) assay was used to study the post-motility properties of bull spermatozoa. Bull spermatozoa exhibited higher percentages ($P < 0.01$) of all motile spermatozoa properties when frozen in extender containing 3% glycerol compared with 3, 2 and 1% ethylene glycol or 3, 2 and 1% methyl cryoprotectants. It is concluded that glycerol concentrations of 3% in the extender is the most suitable cryoprotectant for cryopreservation of bull spermatozoa.

Key Words: cryopreservation, bull spermatozoa

990 Effects of anti-lipid peroxidation supplements on frozen-thawed boar spermatozoa. B. D. Whitaker*, R. Taupier, and S. J. Casey, *Ferrum College*, *Ferrum, VA*.

This study evaluated the effects of 2 anti-lipid peroxidation supplements when added to the thawing and incubation medium of frozen-thawed boar spermatozoa. Semen pellets were thawed and incubated for 1 h in media with either 1.0 m*M* α-tocopherol or diethylenetriamine (DETA, nitric oxide analog). After incubation, the acrosome reaction was inducted using calcium ionophore A23187 and acrosomes were evaluated using Wells-Awa staining. The amount of spermatozoa with fragmented DNA was evaluated using silver staining after single-cell gel electrophoresis. The 1.0 m*M* DETA supplementation had a significantly higher ($P < 0.05$) percentage of acrosome reacted spermatozoa (84.4 ± 4.1%) compared with the control (78.3 ± 4.2%) and the 1.0 m*M* α-tocopherol supplementation (78.0 ± 3.9%). There was no difference between the control and the 1.0 m*M* α-tocopherol supplementation. The control had a significantly higher ($P < 0.05$) percentage of spermatozoa with fragmented DNA tails (59.3 ± 4.3%) compared with the 1.0 m*M* DETA (28.7 ± 4.1%) and the 1.0 m*M* α-tocopherol supplementation (28.0 ± 3.8%). There was no difference between the 1.0 m*M* DETA and the 1.0 m*M* α-tocopherol supplementation. These results indicate that supplementing with either 1.0 m*M* DETA or α-tocopherol during semen thawing protects against DNA fragmentation and increases the percent of spermatozoa capable of completing the acrosome reaction.

Key Words: swine, antioxidant, sperm

991 Reproductive performance of sows inseminated with various doses of frozen-thawed semen. K. S. Fisher*[1], T. S. Stewart[1], P. H. Purdy[2], H. D. Blackburn[2], W. L. Singleton[1], B. L. Sparks[1], P. J. Gunn[1], and G. A. Bridges[1], [1]*Purdue University*, *West Lafayette, IN,* [2]*National Animal Germplasm Program, NCGRP, ARS, USDA*, *Fort Collins, CO*.

Genebanks have a limited supply of frozen-thawed boar semen (FTS), thus it is critical to determine the optimal dose of FTS required for reproductive proficiency. Crossbred sows (n = 106) were used in 3 replicates to determine the efficacy of 4 doses of FTS with a single AI. After weaning, estrous detection was conducted using a boar and sows received a single transcervical insemination 24 h following the onset of estrus. At AI, sows were randomly assigned to receive FTS from 1 of 2 boars (boar 1, n = 36; boar 2, n = 61) at a post-thawing dose of 0.25 (n = 24), 0.50 (n = 25), 0.75 (n = 24), or 1.0 (n = 24) × 10^9 motile cells. Thirty d after AI, sows were slaughtered and viable fetuses and corpora lutea were counted. The effects of replicate (REP), boar, dose, and all interactions on pregnancy rate and number viable fetuses were evaluated using the Glimmix and Mixed procedures of SAS. Pregnancy rate did not differ among semen doses (0.25- 25%, 0.5- 44%, 0.75- 54%, 1.0- 42%), but was decreased ($P < 0.05$) for boar 1 (22.2%) compared with boar 2 (52.5%). The number of viable fetuses recovered was decreased ($P < 0.05$) for boar 1 (4.6 ± 1.4) compared with boar 2 (8.6 ± 0.7). There was a REP x dose interaction ($P < 0.05$) for number of fetuses. The 1.0 and 0.75 doses resulted in the greatest number of fetuses in REP 1 and REP 3, respectively, with no difference among doses in REP 2. Across replications, a linear effect of dose on viable fetuses was observed ($P < 0.05$) and a tendency for a quadratic effect ($P < 0.1$). To ascertain the dose most appropriate to use if semen was limited, the total viable fetuses per sow inseminated was multiplied by the number of potential doses available if only 1 × 10^9 motile sperm cells existed. Although only non-significant differences among doses were found (0.25- 0.91 ± 2.1, 0.50- 3.4 ± 1.7, 0.75- 4.8 ± 1.7, 1.0- 3.3 ± 1.7), results suggested, from the perspective of maximizing both the number of sows that can be inseminated with a limited supply of semen and reproductive proficiency, that the optimal dose of semen to utilize per insemination was between 0.50 and 0.75 × 10^9 motile sperm cells.

Key Words: germplasm preservation, semen, swine

992 Analysis of proteomic changes during sperm capacitation associated with sperm fertility. Y. J. Park*, S. A. Oh, W. S. Kwon, S. J. Yoon, Y. H. Kim, E. A. Mohamed, Y. A. You, and M. G. Pang, *Department of Animal Science & Technology and BET Research Institute, Chung-Ang University*, *Ansung, Gyeonggi-Do, Korea*.

Spermatozoa are required to undergo the processes of capacitation before fertilization. Since spermatozoa are transcriptionally silent, the functional metamorphosis of these cells during capacitation is accomplished entirely by post-translational modifications. Despite the importance of this process, very few studies have attempted to define the precise nature on the molecular level. The objective of this study was to characterize the supposed differences in fertility with respect to capacitation-related proteins. We undertook differential proteome profiling before and after capacitation of spermatozoa from fertile bulls with extreme non-return rates (NRR): a low fertility group (45.10±4.95) and a high fertility group (82.45±6.26). For identification of capacitation related proteins associated with fertility, capacitation was induced by 10 μg/mL heparin for 20 min and was confirmed by chlorotetracycline assay where significantly increasing in capacitated sperm was observed. Two-demensional gel electrophoresis (2-DE) was carried out with triplicate samples of pooled spermatozoa before and after capacitation from 3 low and 3 high fertility bulls. Protein expression levels were compared using PD-Quest software. The marked difference in spot intensity was arbitrarily set as a >3-fold difference following analysis data from the software manufactures. Twelve protein spots showed differences

between high and low fertility groups and seven of these proteins were identified by LC/MS-MS. Glyceraldehyde 3-phosphate dehydrogenase, phosphatidylethanolamine-binding protein 1, bovine mitochondrial F1-ATPase complexed with Aurovertin B and actin-related protein T2 were more expressed in high fertility group. On the other hand phospholipid hydroperoxide glutathione peroxidase, ropporin and enolase 1 were more expressed in high fertility group. These proteins are in correlation with sperm physiology, and these proteins may be used as sperm fertility markers.

Key Words: fertility, capacitation, proteome

993 Prognosis of bull fertility using sperm penetration assay. Y. J. Park*, S. A. Oh, S. J. Yoon, W. S. Kwon, Y. H. Kim, E. A. Mohamed, Y. A. You, and M. G. Pang, *Department of Animal Science & Technology and BET Research Institute, Chung-Ang University*, *Ansung, Gyeonggi-Do, Korea*.

The prediction of sperm fertility is of paramount importance for breeding animal herds when artificial insemination is applied. While the fertility assays provide valuable quantitative data, they yield limited information concerning the functional competence of the spermatozoa. The objective of this study was to standardize a method for predicting in vivo fertility in bulls using the in vitro penetration assay. To increase the assay sensitivity, each step in the procedure was standardized. We found that maximum penetration of hamster zona-free oocytes (SPA) obtained from heparin-treated (10 μg/mL) sperm cells for 20 min ($P <$ 0.05). The SPA result showed significant correlation with historic average non-return rate (NRR) ($P < 0.05$). To determine the normal range for the SPA, lower limits of the sperm fertility index from SPA were established as 2.55 to cut-off more than 70% NRR using the receiver operating characteristic curve. The overall accuracy was 93.33% for the low and high NRR, sensitivity and specificity were 92.86 and 93.75 respectively. The protocol increases the potential to discriminate between bulls with good and poor fertility. Although the conditions for the capacitation and penetration of the spermatozoa are greatly different from the in vivo situation, nevertheless the test provides meaningful information on the bull fertility.

Key Words: sperm, fertility, sperm penetration assay

994 Semen quality index of broiler breeder cockerels subjected to different collection techniques. A. Ijaz*, M. U. Sohail, H. Rehman, M. Aleem, A. Riaz, and M. S. Yousaf, *University of Veterinary and Animal Sciences*, *Lahore, Pakistan*.

Present study aims at evaluating 3 different semen collection techniques; abdominal-massage, live-mount and dummy-mount technique, in broiler breeder cockerels. Six cockerels (50 week old), randomly selected from a natural breeder farm, were kept in individual floor pens. After one week of acclimatization, cockerels were trained for semen collection using the abdominal-massage technique and dummy-mount technique. Thereafter, the cockerels were subjected to abdominal-massage, live-mount and dummy-mount technique in phases for 14 d each, with 2 weeks period of rest among techniques. Semen was daily collected from 6 cockerels pooled. Semen was evaluated for number of semen ejaculates, semen volume per ejaculate, visual appearance of semen, sperm motility and sperm concentration. Visual appearance of semen was indexed as watery, milky or opaque. Diluted semen was placed on pre-warmed slide and examined under microscope for motility. Sperm concentration was estimated using Neubauer hemocytometer. Data regarding semen volume, visual appearance, sperm motility and concentration were analyzed using ANOVA, while data regarding number of ejaculates were subjected to chi-squared test. Live-mount technique gave higher ($P < 0.01$) number of ejaculates and volume per ejaculate (44, 0.26 ± 0.24) compared with abdominal-massage technique (26, 0.04 ± 0.01) and dummy-mount technique (37, 0.15 ± 0.03). Visual appearance index of semen, sperm motility and sperm concentration remained unaffected ($P > 0.05$) independent of the techniques employed. In conclusion, live-mount technique is better for cockerel semen collection compared with abdominal-massage and dummy-mount technique.

Key Words: cockerel, semen, collection method

995 Effect of supplemental sialic acid on the fertility of in vitro stored turkey semen. J. A. Long* and T. Conn, *Beltsville Agricultural Research Center*, *Beltsville, MD*.

The fertility of turkey semen stored for longer than 6 h in vitro is dramatically lower than that of fresh semen. Previously we have shown that physiological changes occur on the sperm membrane when turkey semen is held for 24h at 4°C. In particular, the carbohydrate content of the sperm glycocalyx undergoes significant alterations, including loss of terminal sialic acid residues. The objective of the present study was to determine if the glycocalyx can incorporate exogenous sialic acid and whether incubation with sialic acid in vitro will improve the fertility of stored turkey semen. Semen was collected from toms and extended with Beltsville Poultry Semen Extender supplemented with 0, 60, 70, 80, 90 or 100 μg/ml of sialic acid. At 30 min intervals for up to 3h, aliquots were removed, stained with LFA (a sialic acid-specific lectin), counterstained with propidium iodide (PI) and assessed by cell flow cytometry. The mean fluorescence intensity (MnFI) of viable (PI negative) sperm was compared with control sperm samples at each interval. Significantly higher MnFI occurred at 30 and 60 min ($P < 0.05$) in the presence of sialic acid; however, further increases in MnFI were not noted at later time points. A dose-response effect ($P < 0.05$) occurred for the 60, 70 and 80 μ/ml treatments only. Twelve-week fertility trials were conducted using semen held at 4°C for 24h with and without sialic acid. Of the 5 doses evaluated, 80 μg/ml supported the highest fertility rates (mean 81.2 ± 9.1%) for the first 6 weeks of insemination. Taken together, these data suggest a possible strategy for improving the fertility of in vitro stored turkey semen.

Key Words: glycocalyx, NANA, semen storage

996 Vitrification of bovine blastocysts: Effects of cooling with an aluminum block submerged in liquid nitrogen versus liquid nitrogen cooled air and lowering sodium and calcium concentrations in vitrification media. S. G. Kruse* and G. E. Seidel, *Colorado State University*, *Fort Collins*.

Our objective was to improve procedures for vitrifying bovine blastocysts produced using standard in vitro procedures. In Experiment 1, we studied a new base medium with lowered sodium and calcium concentrations based on the hypothesis that this would result in a lower chance of sodium and calcium toxicity. Base media contained either 1) normal concentrations of sodium (120 m*M*) and calcium (2 m*M*) (CONT; n = 151) or 2) 60 m*M* sodium choloride + 60 m*M* choline chloride and 0.5 m*M* calcium (LOW; n = 139). Blastocysts were exposed to 5 M ethylene glycol made in CONT or LOW base medium (V1) for 3 min at 22°C and moved to 6.5 M ethylene glycol + 0.5 M galactose + 18% Ficoll made in CONT or LOW base medium (V2) at 22°C and immediately loaded into 0.25 mL straws. After 35 s, embryos were vitrified by either 1) standard cooling in liquid nitrogen cooled air (AIR) for 1 min or 2) cooling via contact of straw walls with columns drilled into an aluminum block immersed in liquid nitrogen (BLK) for

2 min, and then directly plunged into liquid nitrogen. Embryos were warmed by holding straws in air at 22°C for 10 s, placing them in a water bath at 37°C for 20 s, mixing embryos with 1.0 M galactose diluent in the straw for 2 min and expelling into CONT or LOW base medium. Embryos were recovered, rinsed through holding medium, and cultured in chemically defined medium for 24 h before evaluation. Post warming survival did not differ ($P > 0.1$) between base medium (CONT = 22.5%; LOW = 25.9%). Experiment 2 was conducted as Experiment 1 (some overlap of embryos used) except the AIR (n = 134) versus BLK (n = 138) comparison was made. There was no difference ($P > 0.1$) in survival due to vitrification method (AIR = 32.1%; BLK = 31.9%). We recommend use of the BLK vitrification method as it is both easier to use and more consistent.

Key Words: blastocyst, vitrification, bovine

997 Efficacy of embryo transfer in lactating dairy cows during summer using fresh or vitrified embryos produced in vitro with sex-sorted semen. B. M. Stewart[1], J. Block[2,4], P. Morelli[1], A. E. Navarrette[1,3], M. Amstalden[3], L. Bonilla[4], P. J. Hansen[4], and T. R. Bilby*[1,3], [1]*Texas AgriLife Research and Extension, Texas A&M System*, *Stephenville*, [2]*OvaTech, LLC*, *Gainesville, FL*, [3]*Texas A&M University*, *College Station*, [4]*University of Florida*, *Gainesville*.

Objective of the study was to determine whether transfer of fresh or vitrified embryos produced in vitro with sex-sorted semen could improve pregnancy rates during summer in lactating dairy cows versus artificial insemination (AI). Lactating dairy cows (n = 722) were enrolled during summer at 2 commercial dairies in Texas. Cows were randomly assigned to one of 3 treatments: AI (n = 227), embryo transfer-vitrified (ET-V; n = 279) or embryo transfer-fresh (ET-F; n = 216). Embryos were produced in vitro using sex-sorted semen and cultured in BBH7 culture medium until d 7 after insemination. For vitrification, grade 1 expanded blastocysts were vitrified using the open-pulled straw method. Fresh embryos were grade 1 blastocysts and expanded blastocysts. Cows were submitted to an estrous synchronization protocol and either time-AI or AI following detected estrus (day of estrus = d 0). On d 7, cows were ultrasounded for presence or absence of a corpus luteum (CL). A vitrified or fresh embryo was transferred to cows with CL in ET-V and ET-F groups. Cows were synchronized if progesterone was <1 ng/mL on d 0 and presence of CL on d 7. There was no treatment by farm interactions. At initial pregnancy diagnosis (40 ± 7 d), proportion of cows pregnant was greater ($P < 0.01$) for ET-F versus both ET-V and AI for all cows (42.1 vs. 29.3 and 18.3%) and synchronized cows (45.5 vs. 30.9 and 22.9%). Also, proportion of cows pregnant was greater for ET-V than AI among all cows ($P < 0.01$) and tended ($P = 0.10$) to be greater among synchronized cows. At second pregnancy diagnosis (97 ± 7 d), proportion of cows pregnant among all cows was greater ($P < 0.05$) for ET-F and ET-V versus AI (36.4 and 25.7 vs. 17.0%) and ET-F was greater ($P < 0.05$) than ET-V. Among synchronized cows, proportion of cows pregnant was greater for ET-F than ET-V and AI (39.4 and 27.0 vs. 21.2%); there was no difference between ET-V and AI. There was no effect of treatment on embryo loss. Transfer of vitrified and fresh embryos produced in vitro using sex-sorted semen can improve fertility in lactating dairy cows during summer.

Key Words: embryo, heat stress, dairy

998 The importance of fibroblast growth factors on bovine embryo development in vitro. S. D. Fields*, P. J. Hansen, and A. D. Ealy, *University of Florida*, *Gainesville*.

The objective was to test the hypothesis that fibroblast growth factors (FGF) regulate early embryonic development. The first 2 experiments were performed to determine if embryo-derived FGFs are required during development. In Exp 1, bovine embryos were produced in vitro and cultured in modified synthetic oviductal fluid (mSOF) containing either 20 μ*M* SU5402, an FGF receptor inhibitor, or carrier (0.2% DMSO) at D 0 or 4. There was no effect of SU5402 on cleavage rate at Day 3. SU5402 reduced ($P = 0.04$) the percent of oocytes that were blastocysts on D 7 compared with controls when added at D 0 (5.9 ± 2.1 vs. 16.9 ± 2.4) but not when added at Day 4. Exp 2 tested if blocking FGF action at the blastocyst stage would affect subsequent cell number. D 8 blastocysts were placed into individual culture drops of mSOF containing 0.2% DMSO or 20 μ*M* SU5402. SU5402 decreased ($P = 0.04$) the number of cells at D 11 (211.1 ± 27.5 vs. 297.8 ± 25). Exp 3 was performed to test if supplemental FGF2 would enhance development to the blastocyst stage. Embryos were cultured in mSOF containing 0, 5, or 100 ng/mL FGF2. There was no effect of FGF2 on cleavage or percent of oocytes that were blastocysts at D 7 or 8. For Exp 4, 8–16 cell embryos were placed in fresh mSOF containing 0, 5, or 100 ng/mL FGF2 at D 5 after insemination. There was no effect of concentration of FGF2 on percent of oocytes that were blastocysts at D 7 or 8, number of trophectoderm cells or inner cell mass cells, or the ratio. Effects of higher concentrations of FGF2 were examined in Exp 5. Embryos received 0 ng/mL of FGF2 or 500 ng FGF2 at D 0, D 4, or D 0 and 4. There was no effect of FGF2 on cleavage. Addition of FGF2 at both D 0 and 4 (27.4 ± 1.3) increased ($P \leq 0.03$) the percent of oocytes that became blastocysts on D 7 compared with control (19.7 ± 1.3) or FGF2 on D 4 (20.4 ± 1.3), but did not differ from FGF2 treatment on D 0 (23.2 ± 1.3). In summary, FGFs are important for normal blastocyst development. One of these, FGF2, increased the competence of embryos to become blastocysts at high concentrations.
This work was supported by NRICGP Grant# 2008–35203–19106 and 2009–34135–20049 from USDA-CSREES.

999 Changes in cotyledonary vascular architecture with advancement of placentomal (PLAC) type during gestation in the ewe. S. Hein*[1], A. Uthlaut[1], P. W. Nathanielsz[1,2], and S. P. Ford[1], [1]*Center for the Study of Fetal Programming, Dept. of Anim. Sci., University of Wyoming*, *Laramie,* [2]*Center for Pregnancy and Newborn Research, Dept. of OB/GYN, University of Texas Health Sciences Center*, *San Antonio*.

PLAC advance morphologically from Type A to Types B, C, or D during the second half of gestation in sheep in association with exponential fetal growth. Several research groups have attempted to understand the changes in the cotyledonary vascular bed with advancing PLAC type using routine histological evaluation of individual PLAC sections which fail to provide a 3 dimensional view of the vascular architecture, leading to conflicting results. We utilized vascular casting to visualize cotyledonary capillary bed 3-dimensional structure. Six multiparous ewes of similar age and body condition were necropsied at d135 gestation and a Type A, B, C, and D PLAC collected from each. The cotyledonary arterial vasculature of each PLAC was perfused with Biodur (Heidelberg, Germany), forming a flexible vascular cast. The surrounding tissue was removed by storage in a 5% KOH solution for 4–6 weeks. The vascular cast images were then visualized on a tabletop Scanning Electron Microscope (TM-1000), and analyzed for capillary area density (CAD, cotyledonary capillary area/cotyledonary area) and capillary diameter (CD) using ImageJ (NIH). Data are M Â ± SEM; differences determined by ANOVA. Cotyledonary CAD and CD (Table 1) and arteriole branching increased as PLAC progressed from type A

to type D. The cotyledonary villous capillary trees of later stage PLAC (C and D) extend for greater distances along villi, became increasingly organized, and consolidated into large nodes. These changes suggest an increased capacity for maternal to fetal nutrient transfer with PLAC advancement in late gestation.

NIH INBRE P20RR016474.

Table 1. CAD and CD of Differing Placentome Types

	A	B	C	D	P-value

1000 Effects of anabolic implants on growth and carcass traits of feedlot steers and heifers: A meta-analysis. C. D. Reinhardt*[1] and L. R. Corah[2], [1]*Kansas State University*, *Manhattan,* [2]*Certified Angus Beef*, *Manhattan, KS*.

Data from 82 studies (60 steer and 22 heifer studies) were compiled and analyzed to evaluate the effects of anabolic implants on feedlot performance and carcass traits. Dependent variables in the model included ADG, G:F, DMI, dressing percentage, HCW, and marbling score. Categories created for type and dosage of active compound were: low dose primarily estrogenic hormone (E2; LOW), moderate dose E2 (MOD), intermediate dosage combination E2 + trenbolone acetate (TBA; INT), and full-strength TBA or E2 + TBA (HIGH). Treatment categories were: no implant, single MOD, single HIGH, delayed HIGH, initial and terminal MOD, initial and terminal INT, initial LOW and terminal HIGH, initial MOD and terminal HIGH, initial INT and terminal HIGH, and initial and terminal HIGH. Implant treatment was the fixed effect in the model, and trial was a random effect. Increasing the implant dosage (potency of individual implants or reimplant vs. single implant) increased ADG, G:F, and HCW in both steers and heifers ($P < 0.01$). Increasing implant dosage in steers decreased marbling score ($P < 0.01$) but did not affect yield grade ($P = 0.11$). Increasing implant dosage in heifers decreased yield grade and marbling score ($P < 0.01$) so that when marbling score was adjusted to a common yield grade, there was no effect of implant on marbling score ($P = 0.52$). The percentage of Prime and Choice carcasses increased at a decreasing rate with increased marbling score, fitting the equation: Percent Prime + Choice = (sin[-2.2144 + 0.00548 * Marbling score]) * 100; (R2 = 0.86). Implants reduce marbling content of steers, but high-potency implant programs will have a decreasing impact on quality grade in cattle with high average marbling score compared with cattle with low average marbling score.

Key Words: carcass, feedlot, implant

1001 Factors affecting *Certified Angus Beef* acceptance in spring-born, black-hided beef calves. G. D. Fike*[1], M. E. King[1], L. R. Corah[1], and W. D. Busby[2], [1]*Certified Angus Beef LLC*, *Wooster, OH*, [2]*Iowa Tri-County Steer Carcass Futurity*, *Lewis*.

Logistic regression was used to determine factors affecting *Certified Angus Beef* (CAB) acceptance in black-hided beef calves (n = 966) born during the springs of 2002 to 2007 at a central Missouri ranch. After weaning, all calves were fed, implanted and managed similarly each year in a southwest Iowa feedlot and were harvested when visually determined to have one cm of fat cover. Calves born in 2006 were excluded from the analysis because percent Angus of the calf could not be determined. For categorical variables, the odds ratio (OR) for each variable category was the odds of calves in that category qualifying for the CAB program compared with calves in the reference category (OR = 1). The OR for continuous variables was the odds of calves qualifying as CAB for each unit increase in the continuous variable. Gender and percent Angus of the calf significantly affected CAB acceptance. Steers were 0.59 times as likely to qualify as CAB as heifers. Calves that were 0–25% or 26–50% Angus were 0.45 and 0.38, respectively, times as likely to meet CAB requirements as were calves that were 51–100% Angus. CAB acceptance tended ($P = 0.06$) to be influenced by time of birth within the calving season. The oldest calves (born during the first 21 d) tended to be twice as likely to be CAB than the youngest calves (born >63 d into the calving season). As adjusted final weight (OR = 1.014) and back fat thickness (OR = 2.93) increased, the odds of CAB acceptance were higher. The odds of CAB acceptance were lower in calves with higher feedlot ADG (OR = 0.35) and heavier delivery weight/d of age (OR = 0.003). These data indicate that CAB acceptance is affected by gender, percent Angus, delivery weight/d of age, ADG, back fat thickness and adjusted final weight and tends to be influenced by time of birth in spring-born, black-hided beef calves.

Key Words: CAB acceptance, spring-born beef calves, percent Angus

1002 Effect of time of birth within the spring calving season on performance and carcass traits of beef calves fed in the Iowa Tri-County Steer Carcass Futurity. G. D. Fike*[1], M. E. King[1], L. R. Corah[1], and W. D. Busby[2], [1]*Certified Angus Beef LLC*, *Wooster, OH*, [2]*Iowa Tri-County Steer Carcass Futurity*, *Lewis*.

Calves (n = 1,369) from a central Missouri ranch born from 2002 to 2007 were used to determine the effect of birth sequence within a spring calving herd on feedlot performance and carcass traits. After weaning, all calves were fed, implanted and managed similarly each year in a southwest Iowa feedlot in the Iowa Tri-County Steer Carcass Futurity program and were harvested when visually determined to have 1 cm of fat cover. Calving sequence periods were defined as: d 1–21 (early = E); d 22–42 (mid-early = ME); d 43–63 (mid-late = ML); d > 63 (late = L). The effect of birth sequence on continuous outcomes was quantified using one-way ANOVA. Chi-squared analysis was used to determine the effect of birth sequence on rates. E calves were heavier at feedlot delivery than ME, ML and L calves (328.2, 321.7, 310.8 and 291.4 kg, respectively; $P < 0.05$). Adjusted final and hot carcass weights were greater for E than for L calves (554.2 vs. 538.6 kg and 341.1 vs. 332.5 kg, respectively; $P < 0.05$), but were similar to ME and ML calves. The percentage of Angus in the E calves was greater than ME, ML and L calves (49.3, 44.9, 39.4 and 43.3%, respectively; $P < 0.05$). Disposition scores were lower for E and ME calves than for L calves ($P < 0.05$). ADG for E calves was less than ML calves (1.46 vs. 1.53 kg/d; $P < 0.05$), but not different from ME or L calves. L calves had better feed efficiency than E and ME calves (6.72, 7.14 and 7.03 kg/kg, respectively; $P < 0.05$). Marbling scores were greater for E and ME calves than ML and L calves ($P < 0.05$). The percentage of calves grading USDA Choice decreased as calves were born later in the calving season ($P = 0.009$), and *Certified Angus Beef* (CAB) acceptance rate followed a similar pattern in black-hided calves ($P < 0.0001$). Calves born during the first 21 d of the spring calving season had heavier delivery, adjusted final and carcass weights; greater marbling scores and a higher percentage grading Choice and CAB than their latest born counterparts.

Key Words: beef calves, carcass and performance, CAB acceptance

1003 Effects of roughage source and dried corn distiller's grains concentration on feedlot performance and carcass characteristics. C. L. Maxwell*[1], M. S. Brown[1], N. A. Cole[2], B. Coufal[1], J. O. Wallace[1], J. Simroth-Rodriguez[1], and S. Pratt[1], [1]*West Texas A&M University*, *Canyon,* [2]*USDA ARS Conservation and Production Research Laboratory*, *Bushland, TX*.

Physical attributes of roughages used in finishing diets may impact the extent of ruminal digestion of dried distillers grains (DDG) and growth performance. Crossbred steers (n = 380) were adapted to a common finishing diet, blocked by BW, implanted with Revalor-S (120 mg of

trenbolone acetate and 24 mg of estradiol), and assigned to treatments of roughage source (sorghum-sudan hay [SH] or sorghum-sudan silage [SS]) and DDG concentration (0 or 20% of diet DM). Cattle were housed in 40 soil-surfaced pens with at least 16.7 m^2 of pen space and 30.5 cm of bunk space/animal. Roughages were included on an equal NDF basis. All diets contained 3.4% non-protein N from urea (1.2% urea) and cottonseed meal was utilized as a protein source in 0% DDG diets. Cattle were fed twice/d for 108 d (initial BW = 410 ± 13 kg). Steers fed 20% DDG ate 4.1% more DM than steers fed 0% DDG (10.42 vs. 10.85 kg, $P = 0.007$), but SS or SH did not influence DMI ($P = 0.55$). Overall shrunk ADG on a live basis was not altered by treatment ($P > 0.57$). Gain efficiency on a live basis was not altered by SS or SH ($P = 0.77$), but steers fed 0% DDG were 2.8% more efficient than steers fed 20% DDG ($P = 0.008$). There was a roughage source × DDG interaction for carcass-adjusted ADG and gain efficiency, dressing percentage, hot carcass weight, and LM area ($P < 0.08$). Adjusted ADG was increased 7% by 20% DDG with SS ($P = 0.05$), but not with SH ($P = 0.39$). Gain efficiency was reduced ($P = 0.03$) 4.8% by 20% DDG with SH, but was not altered ($P = 0.71$) with SS. Dressing percentage was reduced by 20% DDG with SH (63.0 vs. 62.4, $P = 0.02$) and increased by 20% DDG with SS (62.4 vs. 63.3, $P < 0.001$). Hot carcass weight was not altered by DDG with SH, but was increased 8 kg by 20% DDG with SS. The LM area was increased by 20% DDG with SS ($P = 0.02$), but not with SH ($P = 0.29$). Marbling score was higher when DDG was fed with SS or SH (380 vs. 390, $P = 0.06$). Results suggest that rate of gain on a carcass basis can be improved by feeding DDG with SS, but performance can be reduced when DDG is fed with SH.

Key Words: feedlot cattle, growth performance, dried distiller's grains

1004 The relative importance of weaning management and vaccination history on finishing performance and carcass characteristics of beef calves. M. J. Macek*[1], K. C. Olson[1], J. R. Jaeger[2], T. B. Schmidt[3], D. U. Thomson[1], J. W. Iliff[1], and L. A. Pacheco[1], [1]*Kansas State University*, *Manhattan,* [2]*Western Kansas Agricultural Research Center*, *Hays,* [3]*Mississippi State University*, *Starkville*.

Angus × Hereford calves (n = 437; average initial BW = 208 ± 25 kg) were stratified by BW, sex, and age and assigned randomly to 1 of 3 weaning treatments that corresponded to length of time between maternal separation and shipping to a feedlot: 45, 15 or 0 d. Within each weaning treatment, calves were assigned randomly to 1 of 2 BRD-vaccination treatments: vaccinated 14 d before maternal separation and again at weaning (PRE) or vaccinated on the d of arrival at the feedlot and again 14 d later (POST). On a common shipping date, calves were transported 3 h to an auction market and held for 12 h. Calves were then transported 1 h to a feedlot. All calves were fed the same diets ad libitum during the weaning (PRESHIP), receiving, and finishing phases of the experiment. Steers were fed to a harvest endpoint of 11.5 mm subcutaneous fat over the 12th rib and harvested in 3 groups. Calves weaned 45 d PRSHIP required fewer ($P = 0.02$) days on feed than calves weaned 15 or 0 d PRESHIP. Calf ADG during finishing was greater ($P < 0.01$) for 45- and 15d calves than for 0-d calves, whereas ADG was similar ($P = 0.26$) between PRE and POST. Consequently, 45-d calves had greater ($P < 0.01$) harvest BW than 15- or 0-d calves. Carcass weight tended to increase ($P < 0.02$) as the length of the weaning period increased. Marbling score, USDA yield grade, 12th-rib fat thickness, REA, and KPH were similar ($P \geq 0.22$) between weaning and vaccination treatments. Likewise, incidence of liver abscesses was similar ($P < 0.47$) between weaning and vaccination treatments. Incidence of lung lesions was not affected ($P > 0.81$) by weaning treatment; however, POST tended ($P < 0.09$) to have greater incidence of lung lesions than PRE. Ranch-of-origin weaning for 45 d was associated with increased carcass weight but similar growth performance during finishing and carcass merit compared with weaning for 15 d. PRESHIP BRD vaccination did not improve growth performance or carcass merit of ranch-direct cattle relative to BRD vaccination deferred until feedlot arrival.

Key Words: carcass merit, preconditioning, weaning

1005 Effects of degree of respiratory disease vaccination on health and growth performance of ranch-direct beef calves during weaning and receiving. M. J. Macek*[1], J. R. Jaeger[2], T. B. Schmidt[3], D. U. Thomson[1], J. W. Bolte[2], L. A. Pacheco[1], N. A. Sproul[1], L. R. Hibbard[1], G. J. Eckerle[1], and K. C. Olson[1], [1]*Kansas State University*, *Manhattan,* [2]*Western Kansas Agricultural Research Center*, *Hays,* [3]*Mississippi State University*, *Starkville, MS*.

Angus × Hereford calves (n = 430; initial BW = 230 ± 31.8 kg) were stratified by sex, age, and BW and assigned randomly to 1 of 4 treatments: 0, 1, 2, or 3 BRD vaccinations before feedlot placement (NOVACC, VACC1, VACC2, or VACC3, respectively). Calves were removed from their dams 29 d before feedlot placement; they were weighed, vaccinated for clostridial diseases, treated for internal and external parasites, and placed in a ranch-of-origin weaning facility. Calves on VACC1, VACC2, and VACC3 treatments were given an initial BRD-vaccination at that time. Calves were revaccinated according to their respective treatments at 14-d intervals during the ranch-of-origin weaning phase of the experiment (PRESHIP). On a common shipping date, calves were transported 3 h to an auction market and held for 12 h. Calves were then transported 1 h to a feedlot. During the PRESHIP period, NOVACC calves tended ($P = 0.06$) to have greater incidence of undifferentiated fever than VACC1, VACC2, or VACC3 calves. Consequently, NOVACC calves had greater ($P < 0.01$) drug-therapy costs PRESHIP than other treatments. Calf ADG, DMI, and G:F during the PRESHIP period were similar ($P \geq 0.61$) between treatments. Upon arrival at the feedlot, calves were weighed and assigned to a receiving pen based on treatment. Calf BW was similar ($P \geq 0.48$) between treatments at feedlot placement, 27 d post-receiving, and 55 d post-receiving; moreover, calf ADG during receiving was similar ($P < 0.92$) between treatments. Degree of BRD vaccination had no affect ($P \geq 0.71$) on DMI or G:F during the receiving period. Incidence of undifferentiated fever among VACC2 calves was greater ($P < 0.01$) than that among NOVACC, VACC1, or VACC3 calves during the receiving period; therefore, drug-therapy costs of VACC2 cattle were greater ($P < 0.01$) than that of NOVACC, VACC1, and VACC3 cattle. Vaccination for BRD, regardless of degree, improved health of calves during the PRESHIP period but not DMI, ADG, or G:F. Degree of BRD vaccination influenced calf health during receiving but not DMI ADG, or G:F.

Key Words: beef calves, health, preconditioning

1006 Influencing steer performance through maternal nutrition. A. F. Summers*[1], K. H. Ramsay[2], and R. N. Funston[1], [1]*University of Nebraska West Central Research and Extension Center*, *North Platte*, [2]*Rex Ranch*, *Ashby, NE*.

A 2-yr study was conducted to determine the effects of maternal nutrition on male progeny. Two locations of a commercial ranch in the Nebraska Sandhills were used with crossbred spring-calving multiparous cows at one location (yr1 = 754; yr2 = 700) receiving higher levels of supplement (HN) and cows at the second location (yr1 = 673; yr2 = 766) being fed lower levels of supplement (LN). Cows were managed in a year-round grazing system with HN cows receiving the equivalent of

1.1 kg/d supplement (28% CP) and LN cows receiving 0.4 kg/d supplement delivered 3 times weekly from December through February and then meadow hay through calving in March and April. After weaning, a random group (yr 1 = 100, yr 2 = 100) of male progeny from each management regimen were placed in a feedlot and slaughtered 218 d later. There were significant ($P < 0.05$) interactions between yr x treatment for performance and carcass characteristics. There was no difference ($P = 0.17$) in initial BW between HN and LN calves. Re-implant and final BW were greater ($P = 0.09$; 0.07) for HN calves compared with LN calves (437 vs. 428 ± 3 kg; 625 vs. 614 ± 4.4 kg). Calf ADG tended ($P = 0.12$) to be greater for HN calves. Calves from yr1 had greater ($P < 0.01$) ADG from initiation to re-implant, whereas yr2 calves had greater ($P = 0.02$) ADG from re-implant to slaughter. Steer HCW and marbling score were greater ($P = 0.07$; 0.05) for HN calves. Steer 12-th rib fat, LM area, final yield grade, and percent USDA Choice were similar ($P > 0.10$) among treatments. Final yield grade and percent grading USDA Choice were greater ($P < 0.01$) for yr2 calves compared with yr1. The proportion of HN calves and yr2 calves grading USDA quality grade of modest or greater was greater ($P = 0.07$; < 0.01) compared with LN calves (21 vs. 11%) and yr1 calves (24 vs. 8%), respectively. Level of dam nutrition during the last trimester of gestation influenced subsequent steer progeny final BW, HCW, and percent USDA average Choice or greater in this study.

Key Words: maternal nutrition, carcass quality, beef cattle

1008 Incidence of quality defects in market beef and dairy cows and bulls sold through livestock auction markets in the Western United States. J. K. Ahola*[1], H. A. Foster[3], D. L. VanOverbeke[4], K. S. Jensen[2], R. L. Wilson[2], J. B. Glaze[2], T. E. Fife[2], C. W. Gray[2], S. A. Nash[2], R. R. Panting[2], and N. R. Rimbey[2], [1]*Colorado State University*, *Fort Collins,* [2]*University of Idaho*, *Moscow,* [3]*Independent Contractor, California Beef Council*, *Sacramento,* [4]*Oklahoma State University*, *Stillwater*.

The incidence of Beef Quality Assurance-related defects in market beef and dairy cows and bulls selling at auction was determined during 2 seasons in 2008. Traits were evaluated by 9 trained personnel during sales at 10 livestock auction markets in Idaho (n = 5; beef and dairy), California, (n = 4; dairy only), and Utah (n = 1; beef and dairy). Overall, 18,949 unique lots (8,213 beef cows, 1,036 beef bulls, 9,177 dairy cows, and 523 dairy bulls,) consisting of 23,479 head (9,299 beef cows, 1,091 beef bulls, 12,429 dairy cows, and 660 dairy bulls,) were evaluated. Market cattle weighed 548 ± 103.6 kg (beef cows), 751 ± 176.1 kg (beef bulls), 658 ± 129.7 kg (dairy cows), and 731 ± 150.8 kg (dairy bulls). Mean BCS for beef cattle (9-point scale) was 4.7 ± 1.24 (cows) and 5.3 ± 0.94 (bulls), and for dairy cattle (5-point scale) was 2.6 ± 0.76 (cows) and 2.9 ± 0.56 (bulls). Some 16.5% of beef cows and 4.1% of beef bulls were thin (beef BCS 1 to 3) while 34.8% of dairy cows and 10.4% of dairy bulls had a dairy BCS of 2.0 or less. Among beef cattle, 85% of cows and bulls were considered to not be lame. However, 45% of dairy cows and 26% of dairy bulls were considered lame. Hot-iron brands were observed in 60.6% of beef cows and 57.3% of beef bulls, but only in 27.9 and 29.1% of dairy cows and bulls, respectively. Some stage of ocular neoplasia was observed in 0.6% and 0.3% of beef cows and bulls (respectively) and 0.25% of dairy cows and 0.0% of dairy bulls. Cattle classified as visibly sick included 0.84% of beef cows, 2.95% of dairy cows, 0.10% of beef bulls, and 1.15% of dairy bulls. Lots that were no-saled included 0.15% of beef cow lots, 1.5% of dairy cow lots, and no bull lots. Results suggest that incidence rates of quality defects among both market beef and dairy cattle selling at auction in the Western United States are substantial.

Key Words: auction market, Beef Quality Assurance, market cows

1009 Effects of quality defects in market beef and dairy cows and bulls on selling price at auction in the Western United States. J. K. Ahola*[1], H. A. Foster[3], D. L. VanOverbeke[4], K. S. Jensen[2], R. L. Wilson[2], J. B. Glaze[2], T. E. Fife[2], C. W. Gray[2], S. A. Nash[2], R. R. Panting[2], and N. R. Rimbey[2], [1]*Colorado State University*, *Fort Collins,* [2]*University of Idaho*, *Moscow,* [3]*Independent Contractor, California Beef Council*, *Sacramento,* [4]*Oklahoma State University*, *Stillwate*.

The relative effect of Beef Quality Assurance-related defects observed in market beef and dairy cows and bulls on selling price at auction was determined during 2 seasons in 2008. The BQA-related traits were evaluated by 9 trained personnel among 18,949 lots (23,479 head) offered for sale at 10 livestock auction markets in Idaho, California, and Utah. The mean sale price ± SD (per 45.45 kg) for market beef cows, beef bulls, dairy cows, and dairy bulls was $45.15 ± 9.42, $56.30 ± 9.21, $42.23 ± 12.26, $55.10 ± 9.07, respectively. Linear regression models were developed based on type and(or) sex to evaluate the effect of each quality-related trait on selling price. Dummy variables were used to test for observer bias, regional differences, and selected traits. Premiums and discounts were determined in comparison to a par animal. Compared with a BCS of 5 (9-point scale), beef cows with less condition were discounted ($P < 0.0001$), while slight premiums ($P < 0.05$) were estimated for BCS 6, 7 and 8 cows. Compared with BCS 3.0 dairy cows (5-point scale), more body condition resulted in premiums ($P < 0.001$), while dairy cows with a less-than-desirable BCS of 2.0 or 2.5 were discounted ($P < 0.0001$). Beef cows weighing less than 455 kg were discounted ($P < 0.0001$) compared to cows weighing 545 to 635 kg, and heavier beef cows received ($P < 0.05$) a premium. Compared to dairy cows weighing 636 to 727 kg, cows less than 636 kg were discounted ($P < 0.0001$) while heavier cows (727 to 909 kg) received premiums ($P < 0.01$). Both beef and dairy cows with any amount of visible lameness were discounted ($P < 0.0001$). Cancer eye in the precancerous stage tended (P = 0.05) to discount beef cows and heavily discount ($P = 0.002$) market dairy cows; while the cancerous stage extremely discounted ($P < 0.0001$) all cows. Animals that were visibly sick were discounted ($P < 0.0001$) substantially. Results suggest that improving BCS and BW increases sale price on a per kg basis. However, visibly sick animals, or those with severe quality defects, were discounted considerably.

Key Words: auction market price, Beef Quality Assurance, market cows

1010 Performance of medium and small frame steers under pasture and pasture-feedlot finishing. G. K. Mantz* and P. Nyren, *North Dakota State University Central Grasslands Research Extension Center*, *Streeter*.

This study evaluated the performance of Medium Frame (MF) and Small Frame (SF) steers under 2 finishing systems: 1) Full-season pasture finishing; and 2) Early-season grazing followed by feedlot finishing. Forty yearling steers were frame-scored. Frame scores 4, 5, and 6 were classified as MF and frame scores 2 and 3 classified as SF. Day 1 (14 May 2009) the steers were placed in 6 native range pastures, 3 supplied with a salt-limited, sunflower screening-oat supplement and 3 non-supplemented. Each pasture contained approximately equal numbers of MF and SF steers (average BW 373 and 297 kg, respectively). Frame within pasture was the unit of replication. On d 48 all steers were weighed and half of the MF and SF in each pasture (chosen at random within frame and pasture) were removed for feedlot finishing and divided into 2 pens of MF and 2 pens of SF steers with pens as unit of replication. Pasture-

finish steers were removed from pasture on d 152, weighed and scanned by ultrasound for percent intramuscular fat (IMF). Feedlot steers were harvested when ultrasound indicated 4.00% IMF or 12.8 mm of back fat. The first 48 d on pasture, supplementation did not affect ADG (P = 0.40) and ADG for MF and SF steers was 1.0 and 0.8 kg, respectively (P = 0.17). For pasture-finish steers in the d 48 to d 152 period, ADG was greater in supplemented than control pastures (0.9 vs. 0.7 kg; P = 0.002) and ADG was greater for MF than SF steers (0.9 vs. 0.7 kg; P = 0.001), but no frame by supplement interaction was found (P = 0.81). Pasture-finish steers average IMF of 3.7% was not impacted by frame (P = 0.70) or supplement (P = 0.78). In the feedlot, MF steers tended to have greater final BW (614 vs. 511 kg; P = 0.14) and hot carcass weight (372 vs. 310 kg; P = 0.14) than SF steers. However, MF and SF steers did not differ in ADG (1.5 vs. 1.4 kg; P = 0.27), days on feed (123 vs. 131 d; P = 0.66) DM G:F (0.116 vs. 0.119; P = 0.94) or yield grade (2.8 vs. 2.6; P = 0.40). All feedlot steers produced USDA choice carcasses. Results show MF and SF steers can both perform well under pasture and pasture-feedlot finishing systems.

Key Words: feedlot, frame size, pasture finishing

1011 Comparing the environmental impact of the US beef industry in 1977 to 2007. J. L. Capper*, *Department of Animal Sciences, Washington State University*, *Pullman*.

Historical livestock production is commonly perceived to be inherently more environmentally sustainable than modern agricultural practices. This study modeled the environmental impact of the 1977 US beef industry, which produced 10.6 billion kg beef from 38.7 million head slaughtered, compared with that of 2007 (11.9 billion kg beef produced from 33.7 million head). The deterministic environmental impact model integrated resource inputs and waste outputs from animal nutrition and metabolism, herd population dynamics and cropping parameters using a life cycle assessment approach. Rations were formulated according to NRC for growing animals (steers, heifers) at breed-appropriate bodyweights and growth rates; and for the supporting population (cows, bulls, herd replacements). System boundaries extended from the cow-calf operation to arrival at the slaughter plant, thus all operations and transport within these limits were included. Resource inputs included feedstuffs, water, land, fertilizers and fossil fuels. Waste outputs included manure and greenhouse gas emissions. The total animal population required to produce one billion kg of beef in 2007 was reduced by 27% compared with 1977. The decrease in population size conferred reductions in total feed energy, feedstuffs and land use of 10%, 17% and 27% respectively. Water use per billion kg beef was reduced by 15% between 1977 and 2007. Compared with the 1977 beef industry, fossil fuel energy for beef production was reduced by 11% per unit in 2007. Methane and nitrous oxide emissions per billion kg beef produced in 2007 were reduced by 17% and 13% respectively. The total carbon footprint (expressed as CO_2-equivalents per billion kg beef) was therefore reduced by 14% in 2007 compared with 1977. This analysis clearly demonstrates that improvements in US beef industry productivity conferred by advances in slaughter weight, growth rate, nutrition and management have considerably reduced the environmental impact of modern beef production, thus improving the sustainability of livestock production.

Key Words: beef production, environmental impact, carbon footprint

Production, Management and the Environment: General

1012 A mobile modified atmosphere killing unit for small flock depopulation. A. B. Webster* and S. R. Collett, *University of Georgia*, *Athens*.

In addition to having methods for depopulation of commercial poultry flocks to contain outbreaks of serious avian disease, there is need to have an efficient and humane method to dispose of small flocks that might fall within an affected area. A modified atmosphere killing (MAK) chamber mounted on a trailer to be pulled by a pickup truck was designed for small flock depopulation. The atmosphere inside the chamber is controlled automatically using gas sensors. A portable gasoline generator drives the electronic systems so no external electrical supply is required. The chamber (152.5 cm W × 152.5 cm L) has a total interior volume of about 2.1 m^3, with a 1 m^3 section to hold birds below gas injection nozzles distributed 44.5 cm above the floor around the perimeter of the chamber. The chamber rises to a height of 51 cm to provide sufficient head space to load birds through 4 doors, 2 on each side of the chamber. The loading doors can be sealed shut and the trailer sanitized by a disinfectant solution pumped from a self-contained 114 L tank before the trailer leaves the premises to deliver a killed flock to a disposal site. A hydraulic lift facilitates dumping of carcasses. The MAK trailer was tested in several trials using spent layer breeder hens, spent laying hens, and turkey hen broilers. CO_2 levels during loading were targeted at 45–50%. The highest rate of loading was 2.8–3.4 s per bird during trials with the spent layer breeders. Since the floor capacity of the chamber is about 100 birds, this rate of loading is unlikely to cause birds to be overlain by others before onset of unconsciousness. Chamber temperature and RH during turkey trials ranged from 24 to 29 C and RH from 55 to 85%. Maximum loads ranged from 305 to 440 hens (total wt. 567–609 kg), and 79 turkeys, (555–560 kg). In its final configuration, the MAK unit was able to maintain effective stunning/killing atmospheres during use. Loading could be continuous when CO_2 was used but N_2 required birds to be killed a layer at a time to prevent piling of conscious birds.

Key Words: depopulation, poultry, small flock

1013 Overview of lighting in Kentucky broiler houses. D. G. Overhults[1], A. J. Pescatore[1], I. Lopes[1], G. Morello[1], J. P. Jacob*[1], J. Earnest, Jr.[1], M. Miller[2], and R. S. Gates[3], [1]*University of Kentucky*, *Lexington,* [2]*Kentucky Poultry Federation*, *Winchester,* [3]*University of Illinois*, *Champaign*.

Floor level illuminance was measured in the brood area of 37 broiler houses on 25 farms in 5 different production complexes in Kentucky. A light meter was used to measure light intensity under both "bright" and "dimmed" light conditions that were typically used during flock growout. Measurements were taken between light fixtures at each of the 4 water lines and at the center line of the house. All houses had lights installed above the 2 feed lines. Some houses had additional lights at the center line of the house. In general, lighting type and intensity was inconsistent from farm to farm. A variety of incandescent (IN), compact fluorescent (CFL), cold cathode (CC), and high pressure sodium (HPS) bulbs were used. Fixture spacings over the feed lines varied from 10 to 30 feet. Bulb sizes varied from 5 W CFL to 100 W IN. Two complexes used only CFL lights, usually with 2 alternating size bulbs in each light string. Dimming was accomplished by turning off the larger size bulbs. Various electronic dimmers were used to dim CC and IN bulbs. Under bright light conditions, average light intensity was 11.0 lx, but the range was large. Bright light intensities ranged from 3.2 to 49.5 lx, with the intensity on most farms being concentrated in the mid to lower part of that range. The highest intensity occurred in a house that was using oversized CFL bulbs. Dim light intensities were all less than 6 lx with most farms operating at less than 3 lx. Where IN lights were used, energy cost savings for converting to CC or CFL systems were estimated. Depending on the farm, changing existing IN bulbs to CC or CFL bulbs may save 8,000 - 12,000 kWh/house/year. The payback period for conversion is affected by number of light fixtures, size of bulbs, lighting program, dimming system, range of illuminance, and electric power rates. Various estimates of payback periods generally fell in the range of 6 mo to 2 years. Estimates of payback periods did not include installing any additional fixtures that might be needed to maintain or increase the existing light intensity levels.

Key Words: light intensity, broilers, energy

1014 Evaluation of the effect of supplementing complex trace minerals on the development of claw lesions in stall-housed sows. S. S. Anil*[1], L. Anil[2], J. Deen[1], S. K. Baidoo[2], M. E. Wilson[3], and T. L. Ward[3], [1]*Veterinary Population Medicine, University of Minnesota*, *St Paul,* [2]*Southern Research and Outreach Center, University of Minnesota*, *Waseca,* [3]*Zinpro Corporation*, *Eden Prairie, MN*.

Claw lesions are very common in pigs and are reported to be associated with lameness. Trace minerals such as Cu, Zn and Mn are critical in the keratinization process and thus may affect the generation and development of lesions. Both the quantity and form (organic or inorganic) determine the bioavailability of the trace minerals. The objective of the present study involving 129 sows (mixed parities) was to evaluate the effect of supplementing complex trace minerals on the development of lesions in different claw areas (side wall, heel, sole, heel-sole junction, white line and overgrown dew claw and toe) of stall-housed gestating sows. The sows were allocated randomly to 2 groups and fed either a control diet (inorganic sulfate minerals, ITM; n = 66; Zn 125 ppm, Mn, 40 ppm and Cu, 15 ppm) or a diet containing complex trace minerals (CTM; n = 63) as a partial substitution of inorganic minerals (Zn, 50 ppm, Mn, 20 ppm and Cu at 10 ppm) fed at isolevels of total trace mineral supplementation. The lesions in different claw areas of these sows were scored by a trained person in 2 consecutive parities at mid-gestation, using a mechanical chute designed for the purpose. The total score for each claw area was obtained by adding the scores for that area in different claws. The proportions of sows showing either similar scores or lower scores in the second claw lesion examination in the sows fed CTM or ITM were compared using 2-sample proportion test (SAS v. 9.1). A higher ($P < 0.05$) proportion of sows fed CTM (95 vs. 82%) had a decrease in the severity or no change in severity of heel-sole junction lesion score. The proportions of sows with similar or lower scores for total lateral claw lesions, long toes, heel lesions, white line lesions and vertical side wall lesions were higher in the sows fed CTM, though not statistically significant ($P > 0.05$). These data suggest a protective effect of complex trace minerals on claw lesions in stall-housed sows.

Key Words: claw lesions, stall housing system, trace minerals

1015 Correlation between production traits and sexual behavior in white-faced yearling rams. V. A. Uthlaut*, G. E. Moss, R. H. Stobart, B. A. Larson, and B. M. Alexander, *University of Wyoming*, *Laramie*.

Of the 196,000 rams in the US, approximately 23% are expected to be non-performers. This results in an annual loss of $13.5 million to

US sheep producers. The objective of this study was to determine the discriminating value of production traits so that measures of production may be used as indicators of reproductive performance. White faced rams consigned to the Wyoming ram test in 2008 (n = 33) and 2009 (n = 41) were tested for expression of sexual behavior while being evaluated for production performance. At the time of behavior testing, rams were 10 mo to 1 yr of age. In 2009, rams were fed using the Grow-Safe feeding system and feeding behavior was correlated to sexual behavior. Sexual performance was evaluated by exposing individual rams to 2 ewes in estrus for 30 min for a maximum of 3 times. Sexual behavior was categorized as: anticipatory (ano-genital sniffs, Flehmen response, fore-leg kicks and nudges) and consummatory (mount attempts, mounts and ejaculations) behavior. Rams exhibiting consummatory behavior were not re-tested. Rams were classified low (LP; n = 18), intermediate (IP; n = 23) or mounting (M; n = 33) according to the level of sexual behaviors exhibited. Rams classified as LP and IP exhibited total anticipatory behaviors ≤9 (mean = 4.8 ± 2.7) or ≥10 (mean = 23.7 ± 10.7), respectively, but did not exhibit mounting behavior. M rams mounted a ewe at least once (anticipatory mean = 43.5 ± 24.7; consummatory mean = 9.5 ± 7.0). For production traits, each ram was assigned an index ratio based on body weight gain and adjusted for wool characteristics. Data were analyzed using GLM and CORR procedures of SAS. Sexual behavior classification did not influence ($P \geq 0.5$) index ratio, feed consumed per day, or number of feed intake episodes. Although anticipatory and consummatory behaviors (r = 0.48; $P < 0.05$) and test index ratio and feed consumption (r = 0.50; $P < 0.05$) were highly correlated, sexual behaviors were not significantly correlated with the index ratio (r = 0.08; $P = 0.5$). Measures of production performance do not appear to be reliable predictors of sexual behavior in yearling rams.
USDA-NRI 2007–55618–18176

1016 Optimal livestock gross margin for dairy insurance contract design. M. Valvekar, V. E. Cabrera*, and B. W. Gould, *University of Wisconsin*, *Madison*.

Volatility in milk and feed prices are a major source of dairy farm risk. Since August 2008 a new federally reinsured insurance program referred to as Livestock Gross Margin Insurance for Dairy Cattle (LGM-Dairy) has been available to many US dairy farmers to help manage the variability in dairy income over feed costs. In the design of the desired insurance contract, the dairy farmer has to decide on the percentage of monthly milk production to be covered by this insurance contract. The objective of this paper was to develop an algorithm and a user friendly software system to identify the optimal LGM-Dairy contract for a risk neutral dairy farmer in terms of monthly coverage at the lowest premium such that a target guaranteed income over feed cost (TGIOFC) is obtained. We optimize our nonlinear programming model via the use of a generalized reduced gradient method. The premium solver platform, V5.0 (Frontline systems, Incline Village, Nevada) within the Excel software system was used for optimization. The analysis was done for a representative 120 herd size dairy farm producing 8,873 kg milk per cow per yr. Wisconsin statistical data indicated that similar sized dairy farms require an income over feed cost (IOFC) of at least $110 per Mg milk to be profitable during the coverage period. Using these data for the July 2009 insurance contract to ensure $110 per Mg milk, the least premium cost contract was found to have a premium of $1.22 per Mg milk produced insuring approximately 52% of the annual production with variable monthly production covered over the September 2009 to June 2010 period. This premium represented 1.10% of the desired TGIOFC. An alternative non-optimal strategy, defined as a contract insuring the same proportion of milk as the optimal (52%), but with constant percentage coverage each month of the insurance contract was analyzed. The premium for non-optimal strategy was found to be almost twice the level obtained under the optimal solution representing 1.9% of TGIOFC.

Key Words: risk management, price risk, revenue insurance

1017 Do hyphenated techniques permit the speciation of metal glycinate complexes? C. Ionescu*[1], V. Vacchina[2], R. Lobinski[3], S. Oguey[1], and D. Bravo[1], [1]*Pancosma*, *Geneva, Switzerland*, [2]*UT2A*, *Pau, France*, [3]*CNRS*, *Pau, France*.

Trace elements inclusion as feed additives is based on their metal content. This is mainly due to the unavailability of analytical methods differentiating trace element sources. The objective was to develop a method allowing specific determination of Zn, Cu, Mn and Fe glycinate complexes (BT) from sulfate (SU), citrate (CI) or histidinate (HI), preserving BT molecular integrity. A mixture of the 4 BT standards was used to optimize the analytical conditions. Five couplings were tested: size exclusion liquid chromatography with coupled to inductively coupled plasma spectrometry (SE HPLC-ICP-MS); hydrophilic interaction liquid chromatography (HILIC) with ICP-MS; Zwiterionic (ZIC)-HILIC with ICP-MS and capillary electrophoresis (CE) coupled either with electrospray mass spectrometry (ESI MS/MS) or ICP-MS. The SE HLPC-ICP-MS, HILIC-ICP-MS or ZIC-HILIC-ICP-MS coupling did not permit separation of BT from SU. Coupling of CE with ICP-MS gave the best results. All BT electropherograms contained a single peak. The 4 BT injected simultaneously were separated suggesting an efficient electrophoretic separation. The ICP-MS signal specificity was proven comparing experimental vs. theoretic trace elements isotopic ratios and peak absence in the blank. BT Cu was well separated from SU, CI and HI. BT Zn was well separated from SU and HI but not from CI. BT Mn was well separated from SU but there was an overlapping with CI and HI. BT Fe was well separated from SU or CI but not from HI. However, CI and HI were reconstructed complexes and not standards. BT molecular integrity was checked using CE ESI-MS(/MS) coupling. BT polymers were destroyed explaining the single peak in CE-ICP-MS electropherograms. BT sulfate ligand was lost but metal-glycine link was preserved. These results make capillary electrophoresis a promising tool for the quantification of BT. Providing validation of the method, the coupling CE-ICP-MS may allow the quantitative speciation of BT in feedstuffs.

Key Words: traceability, glycine complex, chelate

1018 Determination of metal glycinate in premixes using capillary electrophoresis coupled with an inductively coupled plasma mass spectrometry detector (CE-ICP-MS). C. Ionescu*[1], V. Vacchina[2], S. Oguey[2], R. Lobinski[3], and D. Bravo[1], [1]*Pancosma*, *Geneva, Switzerland*, [2]*UT2A*, *Pau, France*, [3]*CNRS*, *Pau, France*.

Previous results have shown that capillary electrophoresis coupled to inductively coupled plasma mass spectrometry (CE-ICP-MS) was a promising tool for metal glycinate (BT) speciation. The objective was to validate this method and to use it to determine BT concentration in mixes. The analytical conditions developed included an electrolyte made of 20 m*M* ammonium acetate (pH 7.4), a voltage of 30 kV and a hydrodynamic injection of 1 s. Specificity of the method was previously discussed. The analytical figures of merit of the approach were then determined. The calibration curve, made of 6 points, was linear ($R^2 > 0.995$). The repeatability (n = 10 for concentrations in the middle range of the calibration curve) was below 12%. In the absence of Certified Reference Material, accuracy was evaluated by analyzing quality control samples in the lower, medium and upper range of the calibration curve

(n = 3). It was generally below 15%. Detection limits, calculated as 3 times the STD of the blank plus the blank, were between 0.05 and 0.2 μg metal.mL^{-1} depending on the BT due to the specific sensitivity of ICP MS. The coupling CE-ICP-MS was then used to quantify BT in four kinds of premixes based on either minerals (as sulfates), choline chloride, amino-acids or acid salts. The BT concentrations in premix were set as follows: BT Zn 8.9 mg/g, BT Cu 6.4 mg/g and BT Mn 18.7 mg/g. The electropherograms of the 4 premixes containing Cu, Zn and Mn BT were made of one peak absent from the corresponding control premix and matching the migration time of a BT standard. Concentrations in the premixes ranged from 8.8 - 9.1 mg/g for BT Zn, 6.3 - 6.6 mg/g for BT Cu and from 18.4 - 18.9 mg/g for BT Mn. These results show that BT can be analyzed and quantified in premixes, giving some new opportunities to the feed producers to introduce BT with precision in their diets and progress on the effective dose of these products.

Key Words: traceability, glycinate complexes, chelates

1019 Determining the optimal age for recording the retinal vascular pattern image of lambs. M. A. Rojas-Olivares[1], G. Caja*[1], S. Carné[1], A. A. K. Salama[1], N. Adell[2], and P. Puig[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*, [2]*Universitat de Girona*, *Girona, Spain*.

A total of 143 newborn lambs of Ripollesa breed were used for assessing the optimal age at which the vascular pattern of the retina can be used as reference for identification and traceability. Retinal images (RI) from both eyes were recorded in duplicate using an OptiReader camera (Optibrand, Fort Collins, CO) at d 1, 8, 30, 90, 180 and 360 of age. Digital images (n = 2,544) were treated with the Optibrand Data Management Software (v. 4.1.3) and intra- and inter-age comparisons of pairs of RI were made using Optibrand's matching score (MS). A MS <70 was used as exclusion criterion (0.989 sensitivity, probability of a correct match; and, 0.995 specificity, probability of a correct non-match). Three Spanish commercial categories of harvesting lambs were used for evaluating RI as a tool for tracing live lambs: "lechal" milk-fed lambs (1-mo, 12 kg BW), "recental" fattened light lambs (3-mo, 25 kg BW) and "ovino mayor" fattened heavy lambs (6-mo, 35 kg BW). Values of MS did not show normal distribution as raw data or after different transformations, and were treated with a model based on the one-inflated bivariate β distribution by using the R computing software (www.r-project.org). Using likelihood ratio test to compare data, intra-age RI analysis showed that MS increased from d 1 to 180 (81 to 96, respectively). Percentage of RI with MS >70 increased from d 1 to 90 (76 to 100%) and steadied thereafter. No images before d 30 were satisfactory to be used as a reference. Inter-age RI for 1-mo "lechal" lambs showed that the 8-d RI tended to show a better traceability than those taken at 1-d of age (91.4 vs. 83.7%, respectively; $P = 0.070$). For 3-mo "recental" lambs, RI taken at 30-d of age traced better than RI taken at 8-d of age (99.2 vs. 89.8%, respectively; $P < 0.05$). Finally, for "ovino mayor" 6-mo lambs, the RI taken at 90-d of age showed the best traceability (99.2%) which was higher than those taken at 8-d (81.4%; $P < 0.05$), but did not differ from those taken at 30-d of age (94.8%; $P > 0.05$). In conclusion, retinal imaging was an accurate tool for auditing the identity and traceability of live lambs of different commercial categories.

Key Words: retinal image, identification, traceability

1020 Predicting probability of pregnancy using all activity signals prior to pregnancy diagnosis. A. H. Sanders*, A. De Vries, and J. Block, *University of Florida*, *Gainesville*.

Increased physical activity can signal estrus in dairy cattle. Activity in the milking interval before AI can indicate an improved probability of pregnancy. This study considered the addition of activity data collected between AI and pregnancy to the prediction of pregnancy probability. Data were 632 breeding records from the University of Florida research herd, and activity recorded at twice daily milkings as avg. steps/hr since last milking by S.A.E. Afikim pedometers. The percent deviation of each activity record from the previous 10d rolling average of the same (a.m. or p.m.) milking session was calculated. Using a threshold of 84.2%, deviations were re-coded as binary signals of increased activity. All inseminations were timed AI (TAI) following Ovsynch. All were in late morning by one inseminator. At 32d after TAI, pregnancy (P32) was determined by ultrasound. Overall, 45% of cows were pregnant. Logistic regression was used to evaluate the effect of 4 signal profiles on probability for P32. Signal profiles were no signal (NONE, n = 228), signal only on morning of AI (TAI, n = 98); no signal on morning of AI, but at least one signal before pregnancy diagnosis (POSTAI, n = 234); and signal on morning of TAI, and at least one other signal before pregnancy diagnosis (BOTH, n = 70). The lowest P32 was for POSTAI (18.4%; CI = 13.9–23.9), and the highest (80.6%; CI = 71.6–87.3) was for TAI. An additional later signal (BOTH) significantly reduced P32 compared with TAI (OR = 0.05.). A signal after AI (POSTAI+BOTH) significantly reduced P32 compared with cases with no later signal (NONE+TAI) irrespective of signal before TAI (OR = 0.13). First post-AI signals averaged 17d after TAI, with median = 19d and mode = 21d. Activity signals can provide information about probability of pregnancy before pregnancy diagnosis by ultrasound or palpation. Further study is needed to determine the potential value of this information, if used to initiate early intervention in cows predicted to be not pregnant.

Key Words: activity, pregnancy, pedometer

1021 Development of a model for heat stress response in primiparous sows during critical stages of reproduction. E. A. Coate*, M. C. Lucy, P. A. Eichen, and D. E. Spiers, *University of Missouri-Columbia*, *Columbia*.

Heat stress has detrimental effects on physiological status of sows that is compounded near farrowing and during lactation. A study was designed to identify superior determinants of heat response that encompasses these periods. Setup included primiparous sows (n = 15) housed in the Brody Environmental Center (University of Missouri) beginning the last 3 weeks of gestation through post-weaning period. Specific analysis periods were:1) several days before parturition, 2 and 3) 2 periods during mid-lactation, and 3) early postweaning. All animals were exposed to the same daily ambient temperature (Ta) cycle of 23.8–30.9°C. Daily measurements at 0800, 1200, 1600 and 2000 included rectal temperature (Tre) and respiration rate (RR). Skin temperature was recorded for ear, tail, rump, and shoulder sites using infrared thermography (Raytek, Santa Cruz, CA). Third order polynomial regression models were used to examine curvilinear Tre and RR relationships to Ta and skin temperatures across all periods. The range of correlation between Tre and RR to Ta was extremely low and not always significant ($P < 0.05$) at 0.03–0.14 and 0.09–0.31, respectively. In contrast, the combined relationship ranges for rump and shoulder temperatures were 0.15–0.42 (Tre) and 0.19–0.36 (RR). Although nearly all skin temperature relationships were significant at $P < 0.05$, there was a reduction in values from Periods 1 and 2 to Periods 3 and 4. Curvilinear relationships of Tre to skin temperatures exhibited a shift from Period 1 (preparturition) to Periods 2, 3, and 4, as characterized by a more than a 1°C shift in both skin and rectal temperatures. Similar comparisons for RR showed again the 1°C increase in skin temperature relative to RR. However,

there was no reliable shift in RR across periods. Skin temperature is possibly superior to ambient temperature in predicting thermal status because the pig utilizes shifts in its microenvironment (i.e., lying on the floor vs standing) without changing its general environment.

Key Words: pig, reproduction, heat stress

PSA Emerging Issues Symposium: Social Sustainability of Egg Production

1022 The egg industry—Market context and sustainability issues. J. A. Mench*, D. A. Sumner, and J. T. Rosen-Molina, *University of California*, *Davis*.

The egg industry is being pressured from many directions to change its production practices, particularly to address concerns about hen welfare in conventional cage systems. Responding to similar pressures, in 1999 the European Union banned conventional laying cages starting in 2012. This now impending European ban has led to the development of several alternative housing systems. These include non-cage systems like aviaries, and modified (enriched or furnished) cages that include perches, areas in which the hens can forage and dust bathe, and nests. Understanding the European experience is valuable as the United States considers alternatives. In the United States the proportion of eggs produced in alternative systems is small (less than 5 percent of output) but growing, at least in part due to market and political incentives for systems that provide hens with more behavioral freedom than conventional cages. Animal welfare, however, is only one element of a sustainable production system. Other elements include those related to public values, the environment, economics, worker health, and food safety and quality. Eggs are a primary source of animal protein globally, and the United States is the third largest producer of eggs in the world, behind China and the European Union. The national table egg flock comprises about 280 million hens housed in all regions, but with approximately 60% of eggs produced in the 10 leading states. Adopting new housing systems will have substantial effects on costs and other aspects of egg production on both a regional and national scale, with potential negative impacts that need to be carefully considered. This paper discusses the US egg industry in the context of legislation and standards related to hen housing systems. It also addresses initiatives by retailers, non-governmental organizations, and private certification organizations to shape production practices in the egg industry, and how those initiatives might affect various aspects of the sustainability of egg production.

Key Words: sustainability, egg production, housing systems

1023 Economic and market issues on the sustainability of egg production in the united states: analysis of alternative production systems. D. A. Sumner*[1], H. R. Gow[2], D. R. Hayes[3], W. A. Matthews[1], F. B. Norwood[4], J. T. Rosen-Molina[1], and W. N. Thurman[5], [1]*University of California*, *Davis,* [2]*Michigan State University*, *East Lansing,* [3]*Iowa State University*, *Ames,* [4]*Oklahoma State University*, *Stillwater,* [5]*North Carolina State University*, *Raleigh*.

Conventional cage housing evolved as a cost-effective egg production system. Imposing housing alternatives raises marginal production costs and requires sizable capital investment. Farm-level cost increases of about 40% per dozen for shifts from conventional cages to relatively low-cost barn housing are consistent with California data. Data on costs per dozen associated with such alternatives as furnished cages are not readily available for the United States and European data are difficult to extrapolate to the US industry structure. Even if mandated by government or major buyers, a shift to alternative housing systems would likely occur with lead-times of at least 5 years (consistent with the recent California schedule) and therefore egg producers and input suppliers would have considerable time to build new facilities and plan new systems. A small share of US consumers now pay high retail premiums for eggs from hens housed in alternative systems. Data from consumer experiments indicate that some consumers who do not now buy specialty eggs would be willing to pay significant premiums. However, current data does not allow easy extrapolation to understand the willingness to pay for such eggs by the vast majority of conventional egg consumers. US egg consumption tends to be relatively unresponsive to price changes, with farm level price increases of 40% likely to reduce consumption by less than 10%. This combination of parameters suggest that, unless low-cost imports grew rapidly, imposed changes to higher-cost hen housing systems would raise US egg prices considerably, while reducing egg consumption only marginally. Eggs are a low-cost source of animal protein and low-income consumers would be hardest hit. But, since egg expenditures are a very small share of the consumer budget, the real-income loss per consumer would be small in percentage terms. Finally, the high egg prices implied by alternative hen housing systems raise complex issues about linking policy costs to policy beneficiaries.

Key Words: egg economics, layer housing costs, economics of animal welfare

1024 The impact of different housing systems on egg safety and quality. P. S. Holt*[1], R. H. Davies[2], J. Dewulf[3], R. K. Gast[1], J. K. Huwe[4], D. R. Jones[1], D. Waltman[5], and K. R. Willian[6], [1]*USDA/ARS Egg Safety and Quality Research Unit*, *Athens, GA,* [2]*Veterinary Laboratory Agencies*, *Weybridge, United Kingdom*, [3]*Veterinary Epidemiology, Ghent University*, *Ghent, Belgium*, [4]*USDA/ARS Animal Metabolism Research Unit*, *Fargo, ND,* [5]*Georgia Poultry Laboratory*, *Oakwood,* [6]*Chemistry Department, Tuskegee University*, *Tuskegee, AL*.

A move from conventional cages to either an enriched cage or a noncage system may affect the safety and/or quality of the eggs laid by hens raised in this new environment. The safety of the eggs may be altered either microbiologically through contamination of internal contents with *Salmonella enterica* serovar Enteritidis (*S. enteritidis*) and/or other pathogens, or chemically due to contamination of internal contents with dioxins, pesticides, or heavy metals. Quality may be affected through changes in the integrity of the shell, yolk, or albumen along with changes in function, composition or nutrition. Season, hen breed, flock age, and flock disease/vaccination status also interact to affect egg safety and quality and must be taken into account. An understanding of these different effects is prudent before any large scale move to an alternative housing system is undertaken.

Key Words: egg safety, egg quality, alternative housing

1025 Environmental impacts and sustainability of egg production systems. H. Xin*[1], R. S. Gates[2], A. R. Green[2], F. M. Mitloehner[3], P. A. Moore Jr.[4], and C. M. Wathes[5], [1]*Iowa State University*, *Ames*, [2]*University of Illinois*, *Urbana-Champaign*, [3]*University of California*, *Davis*, [4]*USDA-ARS*, *Fayetteville, AR*, [5]*University of London*, *United Kingdom*.

As an integral part of a systemic assessment toward "*Social Sustainability of Egg Production*," we reviewed the current state of knowledge about environmental impacts of different egg production systems, and identified knowledge gaps requiring further research. Highlights of the current knowledge include: 1) High-rise (HR) cage houses generally have lower air quality and emit more ammonia than manure-belt (MB) cage houses; 2) Manure removal frequency in MB houses greatly impacts ammonia emissions; 3) Emissions from manure storage are largely affected by storage conditions including ventilation rate, manure

moisture content, air temperature, and stacking profile; 4) More baseline data on air emissions from (6) HR and (2) MB houses are being collected in US; 5) Non-cage (NC) houses generally have reduced air quality (ammonia and dust levels) than cage houses; 6) NC houses tend to be colder during cold weather due to lower stocking density than caged houses; 7) NC houses are more energy intensive in winter; 8) Hens in NC houses are less efficient in resource (feed, energy and land) utilization, leading to greater carbon footprint; 9) Excessive application of hen manure to cropland can lead to nutrient runoff to water bodies; 10) Hen manure on open range may be subject to runoff during rainfall, although quantitative data are lacking; 11) Mitigation technologies exist to reduce generation and emission of noxious gases and dust, however work is needed to evaluate their economic feasibility and optimize design; and 12) Dietary modification shows promise for emissions mitigation. The identified knowledge gaps and research needs include: 1) Indoor air quality, barn emissions, thermal conditions and energy use for alternative hen housing systems (1-story floor, aviary, and enriched cage systems) along with conventional housing systems under US production conditions; 2) Environmental footprint for different egg production systems in US through life cycle assessment; 3) Process-based models for predicting air emissions and their fate; and 4) Further exploration of practical means to mitigate air emissions from different production systems.

Key Words: hen-housing system, environmental footprint, emissions mitigation

1026 Values and public acceptability dimensions of sustainable egg production. P. B. Thompson*[1], M. Appleby[5], L. Busch[1,2], L. Kalof[1], M. Miele[3], B. Norwood[6], and E. Pajor[4], [1]*Michigan State University*, *East Lansing,* [2]*Lancaster University*, *Lancaster, UK*, [3]*Cardiff University*, *Cardiff, Wales, UK*, [4]*Calgary University*, *Calgary, AL, Canada*, [5]*World Society for the Protection of Animals*, *London, UK*, [6]*Oklahoma State University*, *Stillwater*.

A variety of standards regimens have emerged as key arenas where conflicting values and visions for sustainability in egg production are negotiated and action for reform is pursued. These include: Federal regulatory standards for food safety and environmental impact; State, local and Federal standards for air and water quality; Private standards for animal welfare and other variables set by producer groups and retailers. This paper reviews what is known about public attitudes and preferences with respect to standards for egg production and identifies key gaps in knowledge about what the public thinks. What people do as "consumers" (when they spend their money) is not always a good predictor of what they will do as "citizens" (how they will vote, how they will express their views, and what financial or other support they will lend to various forms of social activism). Inconsistent indicators of "what people want," or what they would find acceptable are thus common. Several measures indicate that political support for environmental quality and animal welfare has been growing steadily in the US public, but food safety rates very high as an area of concern in studies that ask respondents to comparatively rank concerns or expectations from the food system. Beyond economic indicators of consumer choice, we have few data that permit judgments about the relative importance or preferred trade-offs that might be made among the various dimensions of sustainable egg production. We have limited ability to forecast scenarios for mobilization of public opinion in support of or in response to specific policy initiatives or patterns of change in production methods. We do not know how subsets of the public would interpret results from scientific studies on environmental, animal welfare, food safety, health or economic dimensions of egg production. We have very limited data on public attitudes to support standards development that would be intended to improve public confidence in the sustainability of egg production.

Key Words: standards, public opinion, politics

1027 Hen welfare in different housing systems. D. C. Lay Jr.*[1], R. M. Fulton[2], P. Y. Hester[3], D. M. Karcher[2], J. B. Kjaer[4], J. A. Mench[5], B. A. Mullens[6], R. C. Newberry[7], C. J. Nicol[8], N. P. O'Sullivan[9], and R. E. Porter[10], [1]*USDA-Agricultural Research Service, Livestock Behavior Research Unit*, *West Lafayette, IN*, [2]*Michigan State University*, *East Lansing*, [3]*Purdue University*, *West Lafayette, IN*, [4]*Fed. Agri. Res. Centre*, *Celle, Germany*, [5]*University of California*, *Davis*, [6]*University of California*, *Riverside*, [7]*Washington State University*, *Pullman*, [8]*University of Bristol*, *United Kingdom*, [9]*Hy-Line International*, *Des Moines, IA*, [10]*University of Minnesota*, *St. Paul*.

Egg production systems have become subject to heightened levels of scrutiny due to animal welfare concerns. Multiple factors such as disease, skeletal and foot health, pest and parasite load, behavior, stress, affective states, nutrition, and genetics influence the level of welfare laying hens experience. Although the need to evaluate the influence these factors is recognized, research into these areas is still in the early stages. We compare conventional cages, furnished cages, non-cage systems, and outdoor systems. Attributes of each system are shown to impact welfare and those systems which have similar attributes are impacted similarly. For instance, environments, such as non-cage and outdoor systems, in which hens are exposed to litter and dirt provide a greater opportunity for disease and parasites. The more complex the environment the more difficult it is to clean, and the larger the group size the more easily disease and parasites are able to spread. Environments, such as conventional cages, which limit movement, can lead to osteoporosis; but environments which have increased complexity, such as non-cage systems, expose hens to an increase incidence of bone fractures. More space allows for hens to perform a greater repertoire of behaviors, although some deleterious behaviors such as cannibalism and crowding, which results in smothering, can occur. Less is understood about the stress which each system imposes on the hen, but it appears that each system has its unique challenges. Selective breeding for desired traits such as improved bone strength and decreased feather pecking and cannibalism may help to improve the welfare of laying hens. It appears that no single housing system is ideal from a hen welfare perspective. Although environmental complexity increases behavioral opportunities, it also introduces difficulties in terms of disease and pest control. In addition, environmental complexity creates opportunities for the hens to express behaviors that are actually detrimental to their welfare. As a result, any attempt to evaluate the sustainability of a switch to an alternative housing system requires careful consideration of the merits and shortcomings of each housing system.

Key Words: poultry, welfare, housing

1028 Valuing stakeholder input in setting research priorities for sustainable egg production. J. C. Swanson*, *Michigan State University*, *East Lansing*.

The importance of stakeholder input in setting future goals for sustainable animal production systems should not be overlooked by the agricultural animal industries. Stakeholders play an integral role in setting the course for an array of factors affecting producers, from influencing consumer preferences to setting public policy. The Social Sustainability of Egg Production Project included a stakeholder workshop to consider and integrate diverse values into the project white papers, which frame the issues and research priorities for the future of sustainable egg produc-

tion. Representatives from the environmental, food safety, food retail, consumer, animal welfare, veterinary, general farm and egg production sectors participated, along with members of the project coordination team, in a 1.5 d workshop to explore and construct a vision for socially sustainable egg production. This presentation will present information about how this vision can be integrated into the science while taking account of the realms of social, political, environment, technology, culture and economics.

Key Words: egg production, sustainable, stakeholder

1029 Characterization of physical factors affecting ruminal lipolytic activity *in vitro*. H. D. Edwards*[1], M. D. Hardin[1], R. K. Miller[1], N. A. Krueger[2], R. C. Anderson[2], and D. J. Nisbet[2], [1]*Texas A&M University, College Station,* [2]*USDA/ARS, Southern Plains Agriculture Research Center, Food and Feed Safety Research Unit, College Station, TX.*

Hydrolysis of dietary lipids to free fatty acids (FFA) is a prerequisite for ruminal biohydrogenation, a bacterial mediated process that rapidly and extensively saturates unsaturated FFA thus limiting the absorption and ultimate assimilation of these healthy nutrients into ruminant produced foods. To learn how to better enrich, isolate and study lipolytic bacteria from the rumen, we investigated the effects of various physical treatments on ruminal lipase activity of ruminal microbes (in 1 mL freshly collected ruminal fluid) during cultivation in 9 mL anaerobic salts medium containing 10% clarified ruminal fluid and 1% olive oil. We found that mean ± SD (n = 3) rates of FFA production (μmol mL^{-1} h^{-1}) were enhanced ($P < 0.05$) more than 20-fold when ruminal populations were incubated (48 h) in the presence of glass beads (0.22 ± 0.10 versus 0.01 ± 0.01 for cultures incubated with or without glass beads, respectively). Rates of lipolysis, however, were unaffected ($P > 0.05$) whether cultures were incubated with or without added H_2 (50% in CO_2). In a subsequent experiment, we found that rates of FFA accumulation by mixed populations of rumen bacteria incubated with glass beads as described above were more rapid ($P < 0.05$) when cultures were incubated horizontally than when incubated upright (0.62 ± 0.06 versus 0.31 ± 0.16 μmol mL^{-1} h^{-1}, respectively). When fluid fractions (10% vol/vol) from these initial cultures were transferred and incubated similarly in fresh culture medium, rates of FFA accumulation decreased by more than 24% compared with rates measured during the initial culture series. Conversely, when bead fractions were transferred to a subsequent culture series, rates of FFA accumulation increased more than 83% from those measured in the initial series. Results indicate that inclusion of glass beads to culture media provides an effective solid support matrix to promote both interfacial activation of lipase activity and colonization by lipase producing bacteria.

Key Words: rumen, lipolysis, food quality

1030 Potential for water intake to predict dry matter intake in finishing beef steers. M. H. Ramos*[1], M. S. Kerley[1], M. Brankovic[2], J. Gillespie[2], and C. Huisma[2], [1]*University of Missouri, Columbia,* [2]*GrowSafe, Airdrie, CA.*

Potential to predict individual dry matter intake (DMI) with accuracy would have production, selection and research application. Present equations cannot explain more than approximately two-thirds of variation of DMI. Correlation between DMI and water intake is known to be positive and relatively strong. The objective of this research was to determine the correlation between water intake and DMI by feedlot cattle. Cattle (n = 164 and metabolic body weight = 100 kg) were fed for 120 d a diet containing 59% barley, 10% brewer's grains, 8% DDGs, 19% silage and 4% supplement. Diet had a CP value of 15% and NEg of 1.36 Mcal/Kg. Water intake and DMI were both individually measured using GrowSafe intake system and GrowSafe Beef in pen weighing system. The equation used was: dmi = 36.1674 + 2.1624waterintake −0.2072waterbodycomposition −17.6386adg −2.1292waterintakeadjuster (R2 = 0.84; CV = 3.59; RootMSE = 0.42). Regression was done using PROC REG (SAS) with DMI as a dependent variable and wati, watcomp, adg and watdelta as independent variables. The PROC REG was used with backward and forward selection with a $P = 0.15$ used to identify parameters to stay in the model. Also PROC REG was used to identify the lowest AIC "an information criteria" and all variables were used. The equation developed had an R2 = 0.84 compared with actual DMI. Intake equation using effective energy equation had a R2 = 0.40 and NRC (1996) had a R2 = 0.44, with NRC equation underpredicting DMI. Water intake was correlated to DMI and improved accuracy of DMI prediction.

Key Words: DMI, water, intake

1031 Effect of calving season and finishing system on performance of beef steers in western Canada. H. C. Block[1], A. D. Iwaasa[2], L. C. Thompson[3], H. A. Lardner*[3], and S. L. Scott[1], [1]*Agriculture and Agri-Food Canada, Brandon Research Centre, Brandon, MB, Canada,* [2]*Agriculture and Agri-Food Canada, Semiarid Prairie Agricultural Research Centre, Swift Current, SK, Canada,* [3]*Western Beef Development Centre, Lanigan, SK, Canada.*

Steers (n = 124) from a 3-site Canadian study of effects of calving season [CS; early (EC; March) vs. late (LC; June)] on cow-calf production were allocated to 2 finishing systems [FS; rapid (RF) vs. slow (SF)]; with 2 pens of 13–17 steers per treatment. Effects of CS, FS, and their interaction on performance and carcass characteristics were evaluated. The RF was an 84-d backgrounding period followed by a high-barley grain finishing diet. The SF used more forage with longer backgrounding, pasture in June and July, and swath-grazing in August and September, followed by a high-grain finishing diet. The endpoint was 8 mm ultrasound backfat or 750 kg bodyweight (BW). Data were analyzed as a 2 × 2 factorial. The initial BW of EC steers was 18.2 kg heavier ($P < 0.01$). There were CS × FS interactions ($P \leq 0.01$) for time on feed, age at slaughter, DMI, ADG, total gain (TG), and final BW. Compared with ECRF, LCRF steers were on feed 21% longer, were 18% older at slaughter, consumed 38% more total DM, and had 19% higher ADG, 48% higher TG, and 19% heavier final BW (all $P \leq 0.05$). The ECSF steers were on feed 117% longer, were 60% older at slaughter, consumed 202% more total DM, and had 17% lower ADG, 83% higher TG, and 39% heavier final BW (all $P \leq 0.05$). The LCSF steers were on feed 81% longer, were 46% older at slaughter, consumed 160% more total DM, and had 8% lower ADG, 67% higher TG, and 29% heavier final BW (all $P \leq 0.05$). Feed efficiency (G:F) was 65% better for RF steers ($P < 0.01$) and 5% better for LC steers ($P < 0.01$). Yield grade was unaffected ($P = 0.23$ to 0.77). There was a reduction ($P = 0.04$) in AA quality grades with SF. The expected effect of the high-forage SF on slowing growth and increasing total DM, age, and final BW, and lowering G:F, was amplified for EC and attenuated for LC steers, indicating CS impacts selection of optimal FS.

Key Words: beef steers, calving season, finishing system

1032 Effects of a bacterial inoculant on fermentation of barley or corn silage and on the growth performance of steers fed the ensiled crop. W. Addah*[1,2], J. Baah[2], P. Groenewegen[3], E. K. Okine[1], and T. A. McAllister[2], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Agriculture and Agri-Food Canada Research Centre, Lethbridge, AB, Canada,* [3]*Alltech Canada, Inc., Calgary, AB, Canada.*

Barley and corn silages are principal components of backgrounding diets in North America. Responses of these forages to inoculants designed to enhance the ensiling process may differ, owing to differences in forage composition. Whole-crop barley (*Hordeum vulgare*) and corn (*Zea mays*)

were inoculated with a mixture of *Lactobacillus plantarum*, *Enterococcus faecium* and *Pediococcus acidilactici* to assess their impact on silage fermentation and growth performance of feedlot steers. Barley (B; 45% DM) and corn (C; 35% DM) forages were swathed, chopped (0.95 mm) and sprayed with water (control: CB, CC) or inoculant (inoculated: IB, IC) at a rate of 1.0×10^5 cfu/g DM. The forages were ensiled in laboratory-scale silos for fermentation analysis and in large silage bags that were opened after 63 (C) or 77 d (B). The bagged silages were used in backgrounding diets fed to steers (n = 25) for 84 d. Data were analyzed by the mixed procedure of SAS for main effects of inoculation, silage type, and their interaction. Terminal pH was lower ($P < 0.001$) in corn than in barley silage, and in inoculated silages compared with controls. Water soluble carbohydrate, propionic and acetic acid contents were lower in IB than in CB (38.2 vs. 60.2, 2.03 vs. 2.50, and 10.1 vs. 14.1 g/kg DM, respectively; $P \leq 0.037$) and lactic acid was higher (85.7 vs. 52.7 g/kg DM; $P = 0.001$), but these variables did not differ between IC and CC. Despite corn silage having lower pH, more acetic acid and more lactic acid-producing bacteria compared with barley silage ($P \leq 0.036$), its NH_3-N content was higher ($P = 0.001$). Yeasts were detected (4.44 $\log_{10}$ cfu/g DM) in corn silage but not in barley (<1 $\log_{10}$ cfu/g DM). Inoculation did not affect ($P \geq 0.236$) DMI or growth performance of steers, but steers fed barley silage had greater DMI ($P = 0.038$), ADG ($P = 0.002$) and feed conversion efficiency ($P < 0.001$) than those fed corn silage. In this study inoculant improved fermentation of barley, but not corn, during ensiling, but had no impact on animal performance during backgrounding.

Key Words: barley, corn, silage inoculant

1033 Interactions between animal age and media fatty acids on subcutaneous and intramuscular adipose tissue explants from Angus steers. D. T. Silvey*[1], G. Go[1], L. A. Gilmore[1], S. B. Smith[1], B. J. Johnson[3], and M. Doumit[2], [1]*Intercollegiate Faculty of Nutrition, Texas A&M University*, *College Station,* [2]*University of Idaho*, *Moscow,* [3]*Department of Food and Animal Science, Texas Tech University*, *Lubbock*.

Pasture feeding depresses adipose tissue development in beef cattle. Therefore, we hypothesized that specific fatty acids would differentially depress lipogenesis in explants of bovine subcutaneous (s.c.) and intramuscular adipose (i.m.) tissues. Angus steers were harvested at 12, 14, and 16 mo of age and i.m. and s.c. adipose tissue explants from the 5-8th thoracic rib region were dissected and cultured in media. In both depots, two concentrations (0 μ*M* and 40 μ*M*) of five fatty acids, stearic acid (18:0), oleic acid (18:1 n-9), *trans*-vaccenic acid (18:1 *trans*-11), conjugated linoleic acid (CLA, 18:2 *trans*-10, *cis*-12), and alpha-linolenic acid (18:3 n-3) were added to the media. After 48 h of culture, lipogenesis using [U-^{14}C]glucose and [1-^{14}C]acetate was measured. Lipogenesis from glucose decreased between 12 and 16 mo of age in s.c. adipose tissue (from 8.9 to 4.0 nmol per 2 h per 100 mg; $P = 0.001$) and i.m. adipose tissue (from 4.4 to 2.7 nmol per 2 h 100 mg; $P = 0.08$). Lipogenesis from acetate did not change over time in s.c. adipose (approximately 56 nmol per 2 h 100 mg; $P = 0.23$), but increased over time in i.m. adipose tissue (from from 11.3 to 17.1 nmol per 2 h 100 mg; $P = 0.02$). *Trans*-vaccenic acid increased lipid synthesis from glucose 81% ($P = 0.05$), CLA, 18:2 *trans*-10, *cis*-12 61% ($P = 0.02$), and α-linolenic acid 84% ($P = 0.02$) in s.c. adipose tissue. Stearic acid decreased lipid synthesis from glucose by 61% ($P = 0.03$) in i.m. adipose tissue. In s.c. adipose tissue only, stearic acid increased lipogenesis from acetate by 250% ($P = 0.03$). We conclude that fatty acids differentially affect lipid synthesis in i.m. and s.c. adipose tissues, which may account for the affects of pasture and grain feeding on adiposity.

Supported in part by grants from the National Cattlemen's Beef Association and the Angus Foundation.

Key Words: CLA, beef, adipose

1034 Characterization of feed efficiency traits and relationships with serum metabolites, cortisol and IGF-I in growing Brangus heifers. R. R. Gomez*, G. E. Carstens, T. H. Welsh Jr., P. A. Lancaster, L. J. Slay, and W. K. Krueger, *Texas A&M University*, *College Station*.

Physiological indicator traits that are biologically associated with residual feed intake (RFI) may be useful indicator traits. The objective of this study was to examine the relationships between RFI, and temperament and serum metabolites and hormones in growing heifers. A 4 yr study (n = 114–119 heifers/yr) was conducted with Brangus heifers (Initial BW = 273 ± 28 kg) that were weaned for 26 ± 9 d before being adapted to a high roughage diet (ME = 2.0 Mcal/kg DM) diet. Individual DMI were measured using Calan gate feeders and BW measured at 7-d intervals during the 70-d studies. RFI was calculated as the residual from the linear regression of DMI on mid-test $BW^{0.75}$ and ADG. On d 0 of the studies, blood samples were collected and exit velocity (EV; rate of distance traveled on exiting a chute) measured. Serum samples were assayed for complete blood counts (WBC, RBC, hemoglobin, Hb), metabolites (glucose, albumin, creatine, blood urea nitrogen, BUN; β-hydroxybutyrate, BHB) and hormones (cortisol, insulin-like growth hormone I, IGF-I). Across all heifers, RFI was positively correlated with DMI (0.67) and F:G (0.52), but not with ADG or initial BW. Heifers with low RFI (<0.5 SD from mean RFI) consumed 14% less DMI and had 11% lower F:G than heifers with high RFI (>0.50 SD from mean RFI). EV was positively correlated ($P < 0.05$) with cortisol (0.24) and negatively correlated ($P < 0.05$) with DMI (−0.15), but was not correlated with RFI or F:G. RFI was weakly correlated ($P < 0.05$) multiple serum parameters including WBC (0.18), Hb (−0.11), total protein (−0.12), albumin (−0.10), creatinine (−0.13) and β-hydroxybutyrate (0.14). These same serum parameters, with the exception of Hb (0.16, −0.26), were not significantly correlated with F:G or ADG. Serum cortisol and IGF-I were not correlated with either RFI or F:G. These results suggest that the serum metabolites and hormones evaluated in this study have limited utility as indicator traits for RFI in growing heifers.

Key Words: feed efficiency, cortisol, beta-hydroxybutyrate

1035 Effects of source and level of dietary roughage and ractopamine (Optaflexx) supplementation on growth performance, carcass traits, and beef quality. D. Glanc*, K. Swanson, C. Campbell, and I. Mandell, *University of Guelph*, *Guelph, Ontario, Canada*.

A high moisture corn/SBM based finishing ration was used to examine the effects of roughage source (corn silage, alfalfa hay), level of dietary roughage (8, 16, 24%), and ractopamine supplementation (none, Optaflexx) on growth performance, carcass traits, and beef quality for finishing 108 steers and 24 heifers (initial BW = 308 kg). Cattle were allocated by gender to 12 management regimen subclasses. Optaflexx was fed over the last 28 d on feed with cattle marketed after a common time on feed. Growth performance data were recorded (ADG, feed intake for individual cattle, and feed efficiency). Carcass measurements were recorded at a commercial packing plant with a primal rib and semitendinosus (ST) muscle from each animal processed at the University of Guelph Meat Laboratory for carcass and meat quality evaluations. Tenderness was determined using shear force assessment of product aged 7, 14, and 21 d. Treatment did not influence ($P > 0.37$) ADG with gains ranging from 1.73 to 1.79 kg/d across all main effects. While hot carcass weights (HCW) were not affected ($P > 0.49$) by roughage

source or use of Optaflexx, HCW were greater ($P < 0.01$) feeding the 8 vs. 16 and 24% roughage diets. Body composition was determined via rib dissection with no differences ($P > 0.11$) in % lean, fat, and bone across source and level of dietary roughage and use of Optaflexx. Source and level of dietary roughage and inclusion of Optaflexx did not affect color ($P > 0.41$) or shear force ($P > 0.20$) values for longissimus (LM) and ST steaks. However, hay diets tended to increase pH ($P > 0.01$) in LM steaks, but had no effect ($P > 0.41$) on ST steaks. Inclusion of up to 24% roughage in finishing diets may not negatively impact gains, carcass characteristics or beef quality; however, feeding 8% roughage in the diet increased HCW. Source of dietary roughage and supplementation of Optaflexx over the last 28 d on feed had minimal effects on gains, body composition, and meat quality.

Key Words: ractopamine, roughage level, shear force

1036 Natural and conventional diet and management effects on steer feedlot performance, carcass traits and economics [1]. M. M. Thompson*[1], C. S. Schauer[1], V. L. Anderson[2], B. R. Ilse[2], R. J. Maddock[3], and K. K. Karges[4], [1]*Hettinger Research Extension Center*, *North Dakota State University, Hettinger,* [2]*Carrington Research Extension Center, North Dakota State University*, *Carrington,* [3]*Department of Animal Sciences*, *North Dakota State University, Fargo,* [4]*Poet Nutrition, Inc.*, *Sioux Falls, SD*.

Seventy-six naturally raised Angus-cross steers were used to determine the effects of natural (NAT) vs. conventional (CON) diet and management strategies on feedlot performance, carcass traits and economics. Animals were stratified by BW and allotted to one of 12 pens (6 pens/treatment). Grow-finish diets were formulated to provide 1.14 Mcals NE_g/kg, 13% CP (DM basis; growing) and 1.43 Mcals NE_g/kg, 12.9% CP (DM basis; finishing) respectively. The NAT supplement contained active yeast and the CON supplement contained monensin. Two estrogenic implants (Ralgro, Component ES) were utilized in sequence in CON steers. Data were analyzed as a completely randomized design (PROC MIXED, SAS) with pen serving as experimental unit. Initial BW (BW = 248 ± 1.5 kg) was not different ($P = 0.31$) between treatments. Feed intake during the background phase was greater for NAT ($P = 0.02$); however, CON had greater DMI during finishing ($P = 0.001$). Conventional steers had greater ADG and heavier BW during the grow-finish periods ($P \leq 0.02$). Conventional animals had lower feed costs ($P = 0.005$) and gained more efficiently ($P \leq 0.02$) than NAT steers. Although 12th rib fat and yield grades were similar across treatments ($P \geq 0.39$), other carcass traits measured differed ($P \leq 0.04$). Conventional steers had $42.88 greater carcass value and $0.23/kg lower breakevens ($P \leq 0.02$) vs. NAT steers. Despite a $72.65 difference in pen closeouts, feeding losses were similar across treatment ($P = 0.13$). These data suggest that cattle managed with NAT production practices require higher market prices for equal returns to feeding to compensate for slower growth rates and greater cost of gain.

Key Words: conventional, natural, steer

1037 Effect of calving season and wintering system on cow performance. W. A. Griffin*[1], T. J. Klopfenstein[1], D. C. Adams[2], G. E. Erickson[1], L. A. Stalker[2], J. A. Musgrave[2], and R. N. Funston[2], [1]*University of Nebraska*, *Lincoln,* [2]*University of Nebraska West Central Research and Extension Center*, *North Platte*.

A 4-year study using two hundred seventeen cows/year (5/8 Red Angus, 3/8 Continental) was conducted to evaluate effects of calving season and wintering system on cow performance. Cows were assigned to one of 5 treatments: 1) spring calving cows (SP) wintered on native range, 2) SP wintered on cornstalks, 3) summer calving cows (SU) wintered on native range, 4) SU wintered on cornstalks, and 5) fall calving cows (FA) wintered on cornstalks. Calves were weaned at 221, 298, and 247 d of age for SP, SU, and FA, respectively. Cow BW and BCS were recorded 3 times during production: 21 d pre-calving, 50 d post calving (pre-breeding), and weaning. Data were analyzed as a completely randomized design and binomial measurements were analyzed using proc freq. Wintering system did not affect calf weaning BW ($P = 0.72$), cow BW ($P = 0.57$), cow BCS ($P = 0.61$) or rebreeding rates ($P = 0.86$). Across calving season, pre-breeding BW was lowest for SP (480 kg), intermediate for SU (570 kg), and greatest for FA (589 kg; $P < 0.01$). At weaning BW was lower for SP compared with SU ($P = 0.03$) and FA ($P = 0.14$) which were similar ($P = 0.64$). At pre-calving BW was greatest for FA (629 kg; $P < 0.01$), intermediate for SU (569 kg), and lowest for SP (533 kg; $P < 0.01$). Cow BCS in the different calving seasons followed the same pattern as BW. Rebreeding performance was numerically lower for FA (90.2%; $P = 0.22$) compared with SP and SU (93.2 vs. 94.3%). Calf ADG from birth to weaning was greatest for SP and lowest for SU ($P < 0.01$). However, calf BW at weaning was greatest for SU (254 kg; $P < 0.01$) compared with SP (238 kg) and FA (234 kg) due to differences in weaning age. In the current study, wintering system did not affect cow performance. Calving season significantly affected cow BW, BCS, and influenced rebreeding performance. In addition wintering system effected calf BW and ADG.

Key Words: calving season, cow-calf systems, wintering system

1038 Eating pattern of Holstein bulls and steers fed high-concentrate rations using a computerized concentrate feeder. M. Devant*[1], S. Marti[1], and A. Bach[2,1], [1]*Department of Ruminant Production, IRTA*, *Barcelona, Spain*, [2]*ICREA*, *Barcelona, Spain*.

A total of 132 animals (initial BW = 220 ± 22 kg and age = 172 ± 0.4 d) were used to study the effect of castration on eating pattern. Animals were randomly allocated in 6 pens with 2 pens for each treatment: 44 intact bulls, 44 steers castrated at 3 mo of age (CAS3), and 44 bulls castrated at 8 mo of age during the study (CAS8). The study finished at 285 d of life. Each pen had one computerized concentrate feeder (GEA WestfaliaSurge, Germany), one straw feeder, and one drinker. Concentrate and straw were offered ad libitum. Animals were weighed every 14 d and concentrate eating pattern was averaged for each 14-d period. The statistical model included initial BW as a covariate, treatment, period, and the interaction between treatment and period, as fixed effects, and animal as a random effect. Overall, average BW was 305 ± 58.3 kg, ADG 1.4 ± 0.53 g/d, feed efficiency 22 ± 9.1%, daily intake 6.3 ± 1.01 kg/d, daily feeder visits 6.3 ± 1.29 /d, meal size 1.1 ± 0.25 kg, meal duration 10.2 ± 2.20 min, inter-meal time 244.8 ± 55.38 min, and eating rate 112 ± 16.9 g/ min. Daily intake, meal size, and eating rate increased ($P < 0.001$) with age. The CAS8 steers grew and ate less concentrate ($P < 0.001$) the first 2 wk following castration than bulls or CAS3 steers. Meal size (1.3 ± 0.05 kg) and meal duration (12.4 ± 0.47 min) were greater ($P < 0.001$) in bulls during these 2 wk than in CAS3 steers (1.0 ± 0.05 kg and 9.7 ± 0.46 min, respectively) and CAS8 steers (0.8 ± 0.05 kg and 7.8 ± 0.47 min, respectively). In contrast, bulls visited the feeders less frequently (5.3 ± 0.34 /d) during these 2 wk than CAS3 steers (6.7 ± 0.34 /d) and CAS8 steers (7.7 ± 0.34 /d). Daily intake increases with age mainly through an increase in meal size and eating rate in combination with a slight increase in the number of daily feeder visits rather than an increase in meal duration. Surgical castration at 8 mo of age reduces daily intake, meal size and duration, and increases the number of daily feeder visits.

Key Words: beef, monitoring, eating pattern

1039 Formation of trans-18:1 and CLA isomers in rumen and digesta of bulls fed different polyunsaturated fatty acid diets. D. Dannenberger*[1], K. Nuernberg[1], X. Shen[2], G. Nuernberg[1], and R. Zhao[2], [1]*Leibniz Institute for Farm Animal Biology*, *Dummerstorf, Germany*, [2]*Nanjing Agricultural University*, *Nanjing, P.R. China*.

The understanding of mechanisms underlying the biosynthesis of individual trans-18:1 and CLA isomers in the rumen of cattle are important because the ruminal outflow affects the availability of bioactive fatty acids for incorporation into milk and muscle. The aim of the study was to investigate the formation of rumen and digesta trans C18:1 and CLA isomers for final deposition in tissue lipids of bulls by feeding different polyunsaturated fatty acids (PUFA). Twenty-five German Simmental bulls were divided into 3 groups in the experiment and fed diets high in n-3 and n-6 PUFA. The diet affected the biosynthesis of individual trans-18:1 and CLA isomers of the bulls. The isomer t-11c-13 CLA was detected as the most abundant isomer in the rumen of n-3 rich diet-fed bulls compared with n-6 rich diet-fed bulls. However, the main isomer in muscle lipids c-9,t-11 CLA was synthesized to a low extent in the rumen of n-3 fatty acid rich-fed bulls compared with higher concentrations of this isomer in the rumen of n-6 fatty acid rich-fed bulls. The second most abundant isomer in muscle lipids t-7,c-9 CLA was not detected in the rumen samples of bulls fed all 3 diets, however abundantly t-7,c-9 CLA was identified in the duodenum. The sum of trans 18:1 fatty acids in the rumen was not affected by the diet, however there was an obvious variation for some individual trans fatty acids. The concentration of trans-10–18:1 was significantly higher in the rumen of n-3 fatty acid rich-fed bulls compared with n-6 fatty acid rich-fed bulls. The results indicated that biosynthesis of trans C18:1 fatty acids and CLA isomers in rumen and duodenal digesta gives the opportunity of regulation the postruminal deposition of bioactive fatty acids in tissue lipids.

Key Words: rumen, digesta, CLA

Ruminant Nutrition: Beef: Forages and Grazing

1040 Effects of self-fed byproducts on animal performance, carcass traits and fatty acid profiles of pasture reared finishing cattle. D. D. Kiesling*, D. G. Morrical, D. R. Strohbehn, M. S. Honeyman, D. W. Busby, D. Maxwell, and J. S. Sellers, *Iowa State University*, *Ames*.

The objective of this study was to evaluate self-fed byproducts on pasture reared finishing cattle. Major effects studied were animal performance, carcass traits and fatty acid (FA) profile with specific emphasis on conjugated linoleic acid (cis-9, trans-11–18:2; CLA). Eighty-two crossbred yearling steers were utilized in a 2 × 2 factorial design with implanted and non-implanted cattle fed either Diet 1: corn/dried distillers grain with solubles (DDGS) or Diet 2: soyhulls/DDGS. Self-feeders were available to cattle that continually grazed cool-season grasses at 5.6 animals/ha. Ribeye facings were extracted for lipid content and esterified for FA analysis by gas chromatography. Data presented is from the first year of this 2 year trial, which second year data has yet to be analyzed. Average daily gains (ADG) over the entire trial of cattle fed Diet 1 were greater (1.59 kg/d vs. 1.52 kg/d, $P = 0.09$) compared with cattle fed Diet 2. Diets did not affect dressing percentage, yield grade or quality grade. As expected, implanted cattle gained faster (1.66 kg/d vs. 1.46 kg/d, $P < 0.0001$) than non-implanted cattle. No differences were observed among implant treatments relative to marbling scores (1031.0 vs. 1016.0, non-implanted vs. implanted, respectively, $P = 0.29$). However, percentage of cattle grading low choice or better was higher in non-implanted cattle (77.5% vs. 47.6%, $P = 0.005$). Cattle fed Diet 2 did have greater CLA levels (0.66 g/100g FA vs. 0.44 g/100g FA, $P < 0.0001$). However, supplementation of byproducts does lead to reduced levels of CLA when compared with grass-finished cattle. Neither diet nor implant treatments had an effect on total lipid, total saturated fatty acid (SFA), polyunsaturated fatty acid (PUFA) or monounsaturated fatty acid (MUFA). In conclusion, pasture reared cattle perform comparably to feedlot cattle in the yard and on the rail when supplemented with byproducts. As well, greater CLA levels can be achieved especially when fed a low starch diet such as soyhulls.

Key Words: beef cattle, by-products, fatty acid profile

1041 Diets containing thirty percent wheat straw or orchard grass hay fed at either ad libitum or restricted intake prepartum have modest effects on postpartum performance. N. B. Litherland*, M. L. Raeth-Knight, and J. G. Linn, *University of Minnesota*, *St Paul*.

The objectives of this study were to investigate the effects of forage type (wheat straw vs. orchard grass hay) and DM amount fed (ad libitum vs. 30% DMI restriction) prepartum on postpartum performance. A 2 × 2 factorial design with 10 cows per treatment was used to determine the effects of forage type in a TMR (wheat straw (WS) vs. orchardgrass hay (GH)) and amount fed (ad libitum (A) vs. 30% intake restriction (R) in DM based on NRC, 2001. Treatments included WS TMR A (WSA); GH TMR A (GHA); WS TMR R (WSR); GH TMR R (GHR). The WS TMR (DM basis) contained 30% WS, 21% corn silage, 10% alfalfa hay, 18% ground corn, 17% soybean meal, and 4% molasses (14.8% CP, 1.5 NE_L Mcal/kg, 37% NDF). The GH TMR contained 30% GH, 46% corn silage, 10% alfalfa hay, 10% soybean meal, and 4% molasses (15% CP, 1.5 NE_L Mcal/kg, 40% NDF). Cows received one lactation diet after calving (CP 17.8%, NE_L 1.6 Mcal/kg, NDF 26%). Cows were housed in a tie-stall barn, fed once daily prepartum and fed and milked twice daily postpartum. Thirty 6 cows were used in the final analysis using the Mixed procedure in SAS. As designed, dry matter intake as a percent of body weight was higher ($P < 0.05$) in WSA and GHA vs.WSR and GHR prepartum, but there was no difference postpartum. Fat corrected milk yield tended to be higher ($P = 0.10$) from GHR cows. Postpartum energy balance was less negative ($P = 0.04$) for GHA for wk 1 to 4. Milk fat production tended ($P < 0.08$) to be higher for GHR cows. Liver total lipids, body weight, body condition score, milk fat:protein, and fecal dry matter, did not differ among treatments. Feeding behavior was observed by 24 h video surveillance and 10 min video scans for 5 d pre- and postpartum. Cows fed WSA or WSR tended ($P < 0.06$) to have more eating bouts on d 2 and 4 postpartum than cows fed GHA or GHR. Results indicate that forage type and amount of DM fed have modest effects on performance and behavior of cows in tie stall barns if diets are formulated to meet NRC, 2001 requirements.

Key Words: restricted intake, ad libitum intake, transition cow

1042 In situ digestibility of grass hay after heifer diets were abruptly switched from 35 or 70% concentrate to 100% forage. L. A. Voigt*[1], R. L. Endecott[1], R. C. Waterman[2], and J. A. Paterson[1], [1]*Montana State University*, *Bozeman,* [2]*USDA-ARS*, *Miles City, MT*.

Twelve ruminally-cannulated Hereford-cross heifers (non-pregnant, 2-yr-old, 508 ± 2 kg) were randomly assigned to 3 individually-fed, pre-experiment diets (4 heifers/diet). Diets were: 1) all forage, (CONTROL); 2) 35% concentrate, (35%), and 3) 70% concentrate (70%). Heifers were fed the diets for ~100 d before the start of the trial. Pre-experiment diets consisted of grass-alfalfa hay (11.8% CP) and corn (9.8% CP), with soybean meal-urea supplement added to make the diets isonitrogenous at 13% CP. On d 0, diets were abruptly switched to grass hay (6.2% CP, fed at 2% BW). In situ digestibility runs were conducted starting on d −8 and ran continuously (d 1, 4, 7, 10, 13, 16, 19, 22) after the diet switch. Duplicate sample bags filled with 5 g of grass hay and a blank bag were incubated for 0, 24, 48, and 96 h. Pre-experiment diet × in situ run interactions occurred ($P \leq 0.04$) for OM and NDF digestibility. Organic matter digestibility of grass hay before the diet switch (d −8) was lower ($P \leq 0.10$) for 70% than for 35% or CONTROL; 48-h: 68.5, 66.7, and 53.0 ± 2.3%; 96-h: 76.3, 75.2, and 61.6 ± 1.0% for CONTROL, 35%, and 70%, respectively. A comparable pattern was observed for NDF digestibility; 48-h: 67.7, 65.6, and 48.8 ± 2.8%; 96-h: 77.0, 75.9, and 58.9 ± 1.1% for CONTROL, 35%, and 70%, respectively. In contrast, after the diet switch (d 1), OM digestibility of grass hay was higher for 70% than for 35% or CONTROL ($P \leq 0.10$; 48-h: 66.5, 66.0, and 69.0 ± 1.7%; 96-h: 75.9, 76.1, and 77.6 ± 0.7% for CONTROL, 35%, and 70%, respectively). Digestibility of NDF was likewise higher for 70% than 35% or CONTROL; 48-h: 65.5, 64.4, and 67.8 ± 2.2%; 96-h: 76.2, 76.3, and 78.1 ± 0.8% for CONTROL, 35%, and 70%, respectively. Organic matter and NDF digestibilities in subsequent in situ runs were similar ($P > 0.10$), regardless of pre-experiment diet. Rate of digestion was not influenced by pre-experiment diet ($P = 0.74$; avg 4.3 ± 0.002%/h). Forage digestibility was depressed when heifers were fed a high-concentrate diet; however, this effect disappeared within 48 h of feeding an all-forage diet.

Key Words: forage digestibility, diet switch, beef cattle

1043 Evaluation of annual ryegrass (*Lolium multiflorum*) in two fall grazing systems on forage quality and beef heifer performance. J. M. Kelzer*[1], R. S. Walker[2], S. L. Bird[3], and R. D. Mathison[3], [1]*University of Minnesota*, *St. Paul*, [2]*Extension Regional Center, University of*

Minnesota, *Andover*, [3]*North Central Research and Outreach Center, University of Minnesota*, *Grand Rapids*.

Effects of fall grazing stockpiled and windrowed annual ryegrass on forage quality and beef heifer performance were evaluated. One renovated, 2-ha pasture was seeded with annual ryegrass (*Lolium multiflorum*) in late June and treated with herbicide in August for weed control. In late September, stockpiled forage from one-half of the pasture was cut into single windrows while the other half was left standing. Weaned Angus beef heifers (n = 48) averaging 186 ± 7 kg initial BW were randomly assigned to 1 of 2 grazing treatments (3 replications per treatment; 8 heifers per replication): 1) stockpiled annual ryegrass (STO), and 2) windrowed annual ryegrass (WIN). Forage samples were collected to determine change in forage quality over time and weekly DM loss following grazing. Heifers were weighed at trial initiation, weekly, and at trial completion to measure animal performance. Percent forage DM at trial completion was 41.8 ± 2.8 and 38.4 ± 7.5% for STO and WIN, respectively. Final concentration of CP was greater ($P < 0.01$) for STO compared with WIN (13.6 vs. 11.4 ± 0.5%). Final concentrations of NDF (56.0 vs. 66.5 ± 0.5%) and ADF (36.5 vs. 42.3 ± 0.5%) were lower ($P < 0.01$), while TDN (60.4 vs. 55.9 ± 0.5%) and relative feed value (100.7 vs. 78.4 ± 1.3) remained greater ($P < 0.01$) for STO compared with WIN over time. Forage DM loss was estimated at 6.3 ± 4.0% and 2.5 ± 1.0% for STO and WIN. Heifers on STO grazed 5 d longer ($P < 0.01$) than WIN (45 vs. 40 d). Although final BW (206 vs. 201 ± 8 kg) and ADG (0.43 vs. 0.37 ± 0.04 kg) were similar for STO and WIN, overall BW gain was greater ($P < 0.05$) for STO (19.2 vs. 14.9 ± 1.5 kg). Results suggest grazing stockpiled and windrowed annual ryegrass may be viable systems to extend fall grazing; however, forage maturity can reduce forage quality to levels that may limit beef heifer performance.

Key Words: beef cattle, grazing system, annual ryegrass

1044 Effects of pen cleaning frequency and feeding high distillers grains and wheat straw on nutrient mass balance and performance of feedlot steers. A. R. Rich*, G. E. Erickson, T. J. Klopfenstein, M. K. Luebbe, and W. A. Griffin, *University of Nebraska*, *Lincoln*.

A summer experiment compared feeding wet distillers grains plus solubles (WDGS) with wheat straw to corn on steer performance, manure N, and N loss. Crossbred steer calves (365 ± 5kg) were stratified by BW, and assigned randomly to 16 pens (8 steers/pen) and fed for 145 d from May to October. Four treatments were tested as a 2 × 2 factorial with factors being diet and pen cleaning frequency (monthly or at the end of the feeding period). Diets consisted of 85% corn, 5% molasses, and 5% wheat straw (CON) or 70% WDGS and 25% wheat straw (BYP). Both diets contained 5% supplement. Nitrogen excretion was determined by difference between N intake and N retention. Total N lost was calculated by subtracting manure and runoff N from excreted N. Runoff was drained, quantified, and analyzed from retention ponds when rainfall occurred. No interactions ($P > 0.25$) between diet and cleaning frequency were observed for performance. Steers fed CON had greater DMI, ADG, HCW, marbling, and fat depth ($P < 0.02$) compared with BYP. Due to decreased ADG, steers fed BYP were fed an additional 14 d for performance, but mass balance data are for 145 d only. Cleaning frequency had no impact ($P > 0.35$) on cattle performance. Feeding BYP increased ($P < 0.01$) N intake and N excretion compared with CON due to differences in CP between diets (23.5 vs 11.6%), and was not impacted by cleaning frequency. Runoff N was not impacted ($P > 0.10$) by diet or pen cleaning treatments. Amount of DM, OM, and N removed in manure was almost doubled ($P < 0.01$) by feeding BYP compared with CON. Likewise, cleaning pens monthly almost doubled ($P < 0.01$) DM, OM, and N removed in manure. Despite increases in manure N, N losses were greater ($P < 0.01$) for BYP compared with CON. However, cleaning pens monthly decreased ($P < 0.01$) N losses by 8.4 kg and % N lost from 72.5 to 49.4% compared with cleaning once at the end. Feeding 70% WDGS with 25% wheat straw decreases ADG and G:F and increased N losses.

Key Words: cleaning frequency, nitrogen, wet distillers grains plus solubles

1045 Restricting intake of replacement heifers by limiting hay access time. W. J. Sexten* and D. K. Davis, *University of Missouri*, *Columbia*.

Spring-born replacement beef heifers are often developed using hay offered ad libitum with limited supplementation from weaning until breeding. The objective of this experiment was to evaluate restricted hay access time on replacement heifer performance and hay intake. Spring-born Red Angus crossbred heifers were randomly assigned to 8 h (8H) or 24 h (24H) access to hay in year 1 (YR1) (n = 52) and year 2 (YR2) (n = 64). Three pens per treatment were used in YR1 with a 107 d development period beginning 19 December 2007. During YR2 4 pens per treatment were used during the 93 d development period initiated 7 January 2009. Development periods concluded 4 April 2008 and 10 April 2009. Each pen was offered one large round bale of hay in a bale feeder. As hay was consumed another bale was offered in a second feeder. As the second bale was consumed the first feeder was moved and a third bale added. This rotational system was used throughout development. Hay not consumed was considered wasted. 8H access was restricted using polywire around hay feeding area. Heifers were fed 2.0 kg/animal per d of supplemental DM consisting of 93.7% distillers dried grains with solubles, 4.1% limestone and 2.2% mineral. Hay was 10.4% CP, 39.3% ADF and 60.3% NDF in YR1 and 10.4% CP, 41.3% ADF and 60.6% NDF in YR2. Data were analyzed as a randomized complete block design using the mixed procedure of SAS. Initial and final heifer weight was greater ($P < 0.02$) in YR1 than YR2 with no differences due to access time. Access time and year tended ($P = 0.09$) to interact for development ADG. In YR1 24H had greater ($P < 0.05$) ADG than 8H while in YR2 no differences ($P > 0.10$) were observed due to access time. Yearling pelvic area and reproductive tract score were not different ($P > 0.10$) due to access time or year. Total hay DMI was greater ($P < 0.01$) in YR1. Total hay DMI and daily hay DMI were reduced ($P < 0.01$) by 10.9% due to 8H. Prebreeding weight, yearling pelvic area and reproductive tract score were not influenced by restricting hay access time however development ADG was reduced in YR1. Restricting hay access time can reduce hay DMI of developing replacement heifers.

Key Words: beef heifer, hay, restricted intake

1046 Effect of stocking rate on nutrient quality of cornstalk residue. J. A. Gigax*, C. D. Buckner, L. A. Stalker, T. J. Klopfenstein, and S. J. van Donk, *University of Nebraska*, *Lincoln*.

A grazing trial compared the effect of stocking rate on corn residue removal and nutrient quality over a 65 d period. Treatments included no removal (control), light grazing (0.4 animal unit months/ha), and heavy grazing (0.8 animal unit months/ha), that were applied to 6 6.6 ha paddocks (2 replications) on a 53 ha center pivot irrigated field of corn residue from mid-December to mid-February. Residue samples were collected before and after grazing at 10 locations within each paddock using a 1/2 m^2 quadrat. After collection samples were sorted by plant part (leaf, stem, husk, cob, and grain), and analyzed for DM, OM, CP, and in vitro organic matter disappearance (IVOMD). No 3 or 2-way

interactions were observed for amount of residue OM (kg/ha; $P \geq 0.61$), but amount of residue was affected by plant part and time collected ($P \leq 0.02$). Of residue remaining before grazing, stems make up the greatest proportion (42.1%) followed by leaves (33.8%), cobs (14.1%), and husks (9.9%). Little removal of stems (2% of original amount) was observed. Cobs and leaves were moderately removed from the light stocking rate (40.1% and 34.4%, respectively) and heavy stocking rate (28.5% and 20.7%, respectively) compared with control (19.2% and 0.1%, respectively). Proportionally, most husks were removed from the heavy stocking rate treatment (87.8%), moderately for light stocking rate treatment (53.1%), and least for control treatment (32.2%). Husks (57.9%) and leaves (53.7%) had greater IVOMD than cobs (48.2%) and stems (49.0%; $P < 0.01$) and IVOMD decreased over collection time ($P = 0.03$). Leaves (5.4%) and husks (4.2%) had the greatest CP content compared with cobs (3.9%) and stems (3.0%; $P < 0.01$). Cattle grazing corn residue removed primarily husk, leaf, and to a lesser extent, cobs. Husk and leaf have greater IVOMD and CP than cob or stem.

Key Words: corn residue, grazing, cattle

1047 Ruminal pressure and pH dynamics of bloated steers grazing winter wheat forage. W. E. Pinchak*[1], D. W. Pitta[1], D. P. Malinowski[1], J. D. Fulford[1], T. A. Wickersham[2], and J. Coverdale[2], [1]*Texas AgriLife Research*, *Vernon,* [2]*Texas A&M University*, *College Station*.

We undertook an experiment to quantify ruminal pressure (mbar), pH and temperature to phenotypic timing and duration of frothy bloat in rumen cannulated steers grazing wheat pasture during the bloat prone period in North Texas through use of an inter-reticulo/rumen biotelemetry bolus system (Kahne Ltd, N .Z.). Environmental conditions (temperature, UV radiation, solar radiation, humidity, dew point wind speed and direction and precipitation) were measured via a recording weather station (WatchDog 2770, Spectrum Technologies, Inc., Plainsville, IL, USA) to determine their relationships to timing, frequency, severity and duration of bloat. Bloat (bloat score 1) was observed in 3 of 12 cannulated Angus cross steers (mean BWT 235 kg) of common ancestry and provenance by 7 February 2010. Analyses of ruminal biotelemetry data quantified cumulative increases in intraruminal pressure from about 1200 h on 8 Feb through most of 9 Feb. Pre-bloat intraruminal pressures of the 3 bloat prone steers on 4 Feb exhibited rapid cyclicity at 5 min sampling intervals throughout the 24 h period. In contrast, from 7 through 9 Feb, the cyclicity decreased, distinct plateaus at peak pressures up to 120 min and decreased amplitude among 5 min sampling periods were found. Peak sustain pressure occurred from evening of 8 Feb throughout 8 Feb. Unlike reports for frothy/foamy bloat in feedlot cattle there was not a concomitant decrease in ruminal pH. The opposite was observed where pH increased during the peak bloat on 9 Feb in all 3 steers. This bloat event was preceded by 3 d of cloudy conditions, high humidity (>60%) and temperatures above freezing. Peak bloat on 9 Feb was accompanied by a cold front, below freezing temperatures and frost. We suggest these preliminary results reinforce our frothy bloat research model where rapid changes in environmental conditions are primary catalysts to bloat onset and duration. Interestingly, finding an increase in pH with increasing ruminal pressure would suggest possible accumulation of ruminal ammonia and reinforces the long suggested role of soluble proteins in wheat pasture frothy bloat.

Key Words: ruminal pressure, pH, biotelemetry, environment

1048 Rumen bacterial diversity dynamics associated with changing from bermudagrass hay to grazed winter wheat diets. D. W. Pitta*[1], W. E. Pinchak[1], S. E. Dowd[2,4], J. Osterstock[3], V. Gontcharova[2], E. Youn[4,5], K. Dorton[6], I. Yoon[6], B. R. Min[1], J. D. Fulford[1], T. A. Wickersham[7], and D. P. Malinowski[1], [1]*1Texas AgriLife Research*, *Vernon,* [2]*Research and Testing Laboratory*, *Lubbock, TX,*[3]*Texas AgriLife Research*, *Amarillo,* [4]*Medical Biofilm Research Institute*, *Lubbock, TX,* [5]*Texas Tech University*, *Lubbock,* [6]*Diamond V Mills*, *Cedar Rapids, IA,* [7]*Texas A&M University*, *College Station*.

Bacterial populations in the rumen adapt to a wide range of changing dietary composition, nutrient density, and environmental conditions. The objective of this study was to explore the distinct bacterial niches associated with the fiber and liquid fractions of rumen contents in animals transitioned from bermudagrass hay diet to a grazed wheat diet. Briefly the experiment involved sampling of fiber and liquid rumen fractions and whole rumen contents of 14 (Angus × Hereford) ruminally cannulated steers sequentially fed bermudagrass hay (*Cynodon dactylon*; 34 d) and grazing wheat forage (28 d) to characterize and elucidate changes in bacterial diversity utilizing 16S bTEFAP pyrosequencing technique. Bermudagrass hay was a conserved C4 perennial grass with a lower protein (11%) and higher fiber (67%) content when compared with grazed winter wheat (*Triticum aestivum*), a C3 annual grass with higher protein (20%) and a large (66%) soluble fraction. Significant differences in the OTU estimates (Chao1, Ace, and Rarefaction) were detected between fractions of both diets, with bermudagrass hay supporting greater diversity than wheat forage. Sequences were compared with a 16S database using BLASTn and assigned sequences to respective genera and genera-like units based on the similarity value to known sequences in the database. Predominant genera were *Prevotella* (up to 33%) and *Rikenella-like* (up to 28%) genera on the bermudagrass diet and Prevotella (up to 56%) genus on the wheat diet irrespective of the fractions. Principle component analyses accounted for over 95% of variation in 16S estimated bacterial community composition in all 3 fractions and clearly differentiated communities associated with each diet. In summary, bermudagrass hay diets clustered more clearly and were more diversified than wheat diets.

Key Words: bermudagrass hay, wheat, bTEFAP pyrosequencing

1049 Fermentable fiber levels in diets for natural beef cattle markets. M. J. Baker*, D. E. Hogue, M. L. Thonney, and D. J. Ketchen, *Cornell University*, *Ithaca, NY*.

Eligibility requirements for "natural" beef often state that antibiotics, including ionophores, cannot be fed. To reduce the incidence of acidosis in diets without an ionophore, feeders often increase the NDF concentration, which lowers intake of digestible nutrients with a resulting increase in cost of gain. However, if the NDF has high potential fermentability (pfNDF), then feed intake may increase and compensate for the lack of an ionophore. The purpose of this experiment was to evaluate the interaction between monensin and levels of pfNDF on growth and feed efficiency of yearling steers. Crossbred steers (n = 32, BW = 485 kg) were blocked by weight with 2 large and 2 small steers assigned to each of 2 slatted floor pens per diet (Table 1) and fed for 87 d. Diets contained 70% whole shelled corn, 0 or 10% soy hulls, and a high NDF pellet formulated to meet protein, mineral and vitamin requirements. One steer died of causes unrelated to the experiment and carcass data for 2 others were not obtained. There were no significant interactions or main effects for growth or feed intake responses (Table 1). Cattle fed the 20% pfNDF diet had a higher ($P < 0.10$, 5.8, 5.2 ± 0.185) quality grades than cattle fed the 15% pfNDF. There was an interaction between monensin and pfNDF in carcass fat deposition ($P < 0.05$). Adding monensin to 15% pfNDF diets increased backfat, worsened yield grade, and tended ($P = 0.13$) to increase marbling, with little effect of monensin for 20% pfNDF diets. Diets with 20% pfNDF without monensin supported growth and

carcass characteristics similar to higher energy diets with monensin. This provides an opportunity to sell to "natural" cattle markets while avoiding the typical reductions in performance that occur when no ionophore is included in the diet.

Table 1. Effect of pfNDF and ionophore on growth and carcass traits of steers

Monensin:	0	0	+	+	
pfNDF:	15%	20%	15%	20%	SE
n (steers)	8	8	7	8

1050 Chemical composition and in situ digestion kinetics of fodder tree leaves. J. I. Sultan*[1], U. B. Cheema[1], A. Javaid[1], and M. Yaqoob[2], [1]*Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan*, [2]*Department of Livestock Management, University of Agriculture, Faisalabad, Pakistan*.

This study evaluated the nutritional status of *Morus alba*, *Acacia nilotica*, *Syzygium cumuni* and *Ziziphus jujuba* tree leaves for use as supplement in ruminant animal feed. Chemical analyses revealed that DM ranged from 25% to 47% in *Morus alba* and *Syzygium cumunii*, organic matter was higher (94%) in *Syzygium cumuni* and *Ziziphus jujuba*. *Morus alba* had higher (23%) CP, whereas, NDF was greater in *Ziziphus jujuba* (32%). The ADF was higher in *Syzygium cumuni* (23%), while, acid detergent lignin was greater (7%) in *Morus alba* and *Syzygium cumuni*. Hemicellulose (15%) and ash content (10%) were higher in *Ziziphus jujuba* and *Morus alba*, respectively. Metabolizable energy was higher (10.5 MJ/kg) in *Morus alba* than the other species. Among minerals Ca and K was highest in *Acacia nilotica*, P in *Morus alba*, and Mg and Na in *Ziziphus jujuba*. In situ DM digestibility was higher (90.2%) for *Morus alba*, DM lag time was shorter (0.63 h) for *Acacia nilotica*, and rate of DM disappearance was lowest (5.34% per h) for *Syzygium cumuni*. Extent of DM digestion (98.26%) and NDF digestibility (84.10%) were higher for *Morus alba*. Shorter NDF lag time (0.71 h) and higher rate of NDF disappearance were evident for *Acacia nilotica*, but extent of NDF digestion was higher (96.80%) for *Morus alba*. Based on chemical composition and in situ digestion kinetics, *Morus alba* leaves proved the best supplement followed by *Acacia nilotica*, *Ziziphus jujuba* and *Syzygium cumuni* for the feed and optimum production of ruminants.

Key Words: Tree species; chemical composition, digestion, digestibility kinetics

1051 Productivity of lactating dairy cows as impacted by feeding lysine in a ruminally protected form. P. H. Robinson*[1], S. Juchem[1], and I. Shinzato[2], [1]*University of California*, *Davis,* [2]*Ajinomoto Co. Inc.*, *Tokyo, Japan*.

Increased milk production requires high intakes of crude protein in the diet, and/or improved supply and ratios of amino acids delivered to the duodenum to meet animal needs for milk and milk component synthesis. Our objective was to estimate the rumen escape potential of a ruminally protected Lys product (RPL) and to determine effects of feeding this product on feed intake and digestibility, as well as milk production and composition, of high producing dairy cows. The experiment was designed as a double (early and mid-lactation dairy cows) 2 × 2 factorial with 28 d experimental periods. All cows were fed the same total mixed ration (TMR), calculated to be first limiting in Lys, with treatment pens receiving 17 kg/pen/d of RPL (to deliver 38 g of Lys/cow/d) mixed into the TMR. Evaluation of the RPL suggested that this feeding level delivered between 18 and 22 g/cow/d of intestinally absorbable Lys. Control cows were fed the RPL without Lys (i.e., the fat matrix) at the same level as the fat matrix was fed in the RPL. Feeding the RPL did not influence dry matter (DM) intake in early lactation cows (26.3 kg/cow/d), but output of milk (48.0 vs. 50.0 kg/cow/d), as well as milk fat, true protein and lactose, and energy, were higher ($P < 0.05$) in lysine supplemented cows. In addition, the extent of body condition score (BCS) loss was lower ($P < 0.05$) with Lys supplementation (−0.069 vs. −0.0.035 units/28 d). In mid lactation cows, DM intake was also not influenced, and only milk fat and energy outputs increased ($P < 0.05$) with RPL feeding. BCS change was not influenced. Plasma Lys levels in cows of both parities were not impacted by RPL feeding, suggesting that Lys needs may not have been met at this level of supplementation. The contrast to an earlier study by our group, wherein milk fat synthesis was suppressed with Lys supplementation at an estimated 9 to 10 g/cow/d at the intestinal absorptive site in similar cows fed a very similar TMR, supports the hypothesis advanced in that study that body protein turnover is the first priority in early lactation cows followed by milk component synthesis.

Key Words: lysine, rumen protection, lactation

1052 The application of reliable wireless sensor provides better understanding of the rumen environment. J. Laporte-Uribe*, F. Brooks, M. Steer, P. Fernley, and M. Eivers, *Kahne Limited*, *Level 1, 64 Cook street, Auckland*.

During the last few years several techniques have evolved to obtain real-time information of the rumen environment. Kahne Limited has developed a wireless rumen bolus that does not required fistulated animals. Information such as pH, temperature, pressure is acquired telemetrically and in real-time. An experiment was designed to measure the reliability of the current sensors over time. Four fistulated and dry dairy cattle were placed in a 4 × 4 Latin-square design. Animals were fed fresh grass (ryegrass/clover) and in free range conditions, no attempt was made to manipulate the diet or the daily management practices. Measurement of pH, temperature and pressure were taken continuously for 7 d period, after which the probes were randomly changed. The sensors were calibrated at the beginning of the each run and at the end of the run, the drifting of probes was estimated by immersing the sensors in a battery of standard buffers solutions. Results were tabulated in a paired-*t*-test to observed differences between recordings. A linear mixed model (REML) was fitted to the results to evaluate the variance associated to the measurement of rumen variables; each single component of variability was taken into account and included in the model, date of sampling, time within date, animals effect, sensors and interactions of these factors. The drift of the pH electrodes at the end of each run (7 d) was minimal, less than 0.04 points of pH. The accuracy of temperature (0.20 oC) and pressure (1.50 mbar) sensors remained unchanged during the period of investigation. This experiment suggested that the Kahne sensors accounted for a very small amount of the variance associated to the recording of rumen environmental conditions, and supports the use of the wireless Kahne sensor technology as a reliable method to measure changes in the rumen environment.

Key Words: rumen pH, wireless sensor, continuous recording

1053 Top-dressing soybean meal in fresh cow, an end to the risks of dry matter intake decreases: Dry matter intake, milk production and nitrogen metabolism. M. Ghelich Khan*, H. Amanlou, and E. Mahjoubi, *Zanjan University*, *Zanjan, Iran*.

The objective of this study was to investigate the effects of high dietary crude protein (CP) levels on dry matter intake (DMI), milk production and nitrogen metabolism in fresh cows. As it has been proved in early lactation dairy cows there are negative energy and nitrogen balances. These shortages should be compensated for by adding a suitable feed stuff, since the produced colostrum contains high amounts of protein. Solvent-extracted soybean meal (SSBM) containing high energy and CP was selected for this purpose and the top-dressing method was employed to facilitate the task. Twenty-one Holstein fresh cows, free of clinically diagnosed transition disorders, were used in this experiment. The cows were randomly assigned to 1) basal diet (CP = 20.3%), 2) basal diet + 1 kg of top-dressing SSBM (CP = 21.8%) and 3) basal diet + 2 kg of top-dressing SSBM (CP = 24.4%). The cows were individually fed from immediately after parturition until wk 4 and were milked 6 times a day. DMI increased noticeably from treatment group 1 to 3 (17.53, 18.02 and 20.58 kg/d, respectively; $P < 0.05$). Average raw milk yields were 35.98, 36.87 and 42.27 kg/d, respectively, and tended to be significant ($P = 0.11$). Milk fat percentage decreased significantly (4.65, 4.51 and 3.86%, respectively; $P < 0.01$). 3.5% fat corrected milk yield increased while the treatments did not have noticeable differences (42.35, 42.52 and 45.24 kg/d, respectively). Milk protein and fat yields were not affected by treatments. Ruminal concentration of NH3-N and total VFA increased as dietary CP level increased but the differences in treatments were not significant. The treatments did not influence uric acid concentration, though a tendency was detected ($P < 0.15$). Urinary urea excretion increased by adding dietary CP causing noticeable differences in treatments (11.01, 16.01 and 19.72 mg/dl, respectively; $P < 0.01$). These results demonstrate that by adding top-dressing SSBM and using high levels of CP, DMI and milk production increase and at the same time ruminal condition and feces score stay in a desirable level.

Key Words: soybean meal (SSBM), top-dress, fresh cow

1054 Leucine had the highest regulatory effects on protein synthesis in bovine mammary epithelial cells when added to media deprived of other essential amino acids. N. A. Knoebel*[1], J. A. D. R. N. Appuhamy[1], J. Escobar[2], and M. D. Hanigan[1], [1]*Department of Dairy Science, Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University*, *Blacksburg*.

Protein synthesis responds to amino acid supply through several signaling proteins such as mammalian target of rapamycin (mTOR), ribosomal protein S6 (rpS6), eukaryotic initiation factor 4E binding protein 1 (4EBP1), and eukaryotic elongation factor 2 (eEF2). Increasing phosphorylation of mTOR, rpS6, and 4EBP1, and decreasing PS of eEF2 positively signal protein synthesis. Previous experiments in our laboratory showed that omission of Arg, Ile, Leu, Met, Thr, and Trp from media reduced casein synthesis rates in bovine mammary tissue slices. This study investigated the effects of the addition of essential amino acids (EAA) to media devoid of other EAA on phosphorylation state (PhS) of mTOR, rpS6, 4EBP1, and eEF2 in MAC-T cells to test the hypothesis that EAA can independently affect the PhS of key signaling proteins when media are deficient in other EAA. Cells were deprived of serum and EAA for 6 h and then cultured with media containing 3.5 m*M* all EAA (+EAA), no EAA (-EAA), Arg, Ile, Leu, Met, Thr, or Trp for 1 h. Cell lysates were analyzed by Western immunoblotting with antibodies against phosphorylated mTOR (Ser2448), rpS6 (Ser235/236), eEF2 (Thr56), and 4EBP1 (Thr37/46). The +EAA treatment significantly increased PhS of rpS6 by 1900% ($P < 0.0001$) and decreased PhS of eEF2 by 35% ($P = 0.016$) compared with that of -EAA. Addition of Leu alone significantly increased PhS of rpS6 by 785% ($P = 0.003$) and decreased PhS of eEF2 by 23% ($P = 0.033$) besides its association with 21% increase in mTOR PhS and 150% increase in 4EBP1 PhS. Addition of Ile and Met increased PhS of mTOR (25% each), 4EBP1 (138 and 127%), and rpS6 (273 and 134%) and decreased PhS of eEF2 (15 and 8%). Of the 6 EAA tested, Leu had the greatest signaling effects on PhS. Essential amino acids can independently affect PhS of key regulatory proteins regardless of the supply of other EAA.

Key Words: essential amino acids, protein synthesis, signaling proteins

1055 Hypophagic effects of propionate relative to acetate decrease as days in milk increase and plasma NEFA concentration decreases. S. E. Stebulis* and M. S. Allen, *Michigan State University*, *East Lansing*.

Thirty-one multiparous lactating dairy cows were used in a crossover experiment to evaluate factors related to responses to propionic acid infusion among cows. Cows between 3 and 40 DIM at the start of the experiment were blocked by calving date and randomly assigned to treatment sequence. Cows ranged from 23.4 to 49.5 kg/d milk yield, 513 to 760 kg body weight and 1.5 to 4.1 body condition score at the start of the experiment. Treatments were 1.0 *M* propionic acid (P) or 1.0 *M* acetic acid (A, control) adjusted to pH 6 with sodium hydroxide and infused intraruminally at 8.33 mmol/min from 6 h before feeding until 12 h after feeding. Feeding behavior was monitored for 12 h after feeding. The diet was formulated to contain 33.9% NDF and the primary starch source was coarsely ground corn. A preliminary period was used to measure factors potentially related to hypophagia from propionate. Propionate decreased dry matter intake (14.0 vs. 15.4 kg/12 h; $P < 0.001$) by decreasing meal size (2.18 vs. 2.63 kg; $P = 0.03$) and meal length (34.6 vs. 40.0 min; $P < 0.01$). Meal frequency and intermeal interval were not affected by treatment ($P > 0.20$). Propionate affected meal patterns following feeding; there was no difference in DMI in the first 6 h after feeding (9.1 kg, $P = 1.00$), but DMI was lower for P than A during the second 6 h after feeding (5.2 vs. 6.2 kg; $P < 0.01$). An interaction was detected between plasma NEFA concentration and treatment for DMI ($P = 0.09$); there was no difference in DMI for P vs. A at the lowest plasma NEFA concentration of 103 μEq/L (14.9 kg/12 h) but DMI was 1.8 kg greater for A compared with P at the highest plasma NEFA concentration of 1330 μEq/L (17.2 vs. 15.4 kg/12 h). There was a tendency for an interaction between treatment and DIM for DMI ($P = 0.11$) with a greater difference in DMI for P vs. A at 3 DIM (13.8 vs. 15.1 kg/12 h) than at 40 DIM (15.8 vs. 15.9 kg/12 h). Hypophagic effects of propionate relative to acetate decrease as DIM increase and plasma NEFA concentration decreases.

Key Words: propionic acid, feeding behavior, dry matter intake

1056 Effects of genetic improvements on efficiency of energy utilization in dairy cows. A. B. Strathe*[1], J. Dijkstra[2], J. France[3], and E. Kebreab[1], [1]*University of California*, *Davis*, [2]*Wageningen University*, *Wageningen, the Netherlands*, [3]*University of Guelph*, *Guelph, Ontario, Canada*.

In the last 3 decades, much progress in genetic improvements in milk production has taken place and numerous studies have been conducted on energy metabolism in dairy cows. This study investigated the effects of these improvements on key parameters of ME systems. These are net energy for maintenance (NE_M), efficiency of utilization of ME for milk production (k_l), growth (k_g) and efficiency of utilization of body stores for milk production (k_t). A large data set was collated by Kebreab et al. (2003) [J. Dairy Sci. 86:2904–2913] and further updated with data from the Netherlands. The data set contained a total of 701 individual cow observations from 38 calorimetry studies on Holstein-Friesian dairy cows. All energy related variables were selected for the study. Kebreab et al. (2003) estimated the 4 key parameters by deriving a function based on a linear relationship between milk energy and ME intake and correcting for tissue energy loss or gain. The function served as the basis of a full Bayesian hierarchical model where the between study variability in the 4 parameters was modeled by a multivariate normal distribution and the within study variability by a student t-distribution. The time trend was included as categorical variable with 3 levels differentiating the cows in experiments conducted before 1990, 1990–1995 and after 1995. In the analysis, an informative prior was introduced for the population parameter (NE_M ~N(0.45, 0.04)). The deviance information criterion (DIC) was used to compare models with varying complexity. There was a difference of 5 DIC units between the 2 models, favoring the simple model. Based on the data and an informative prior, the posterior distribution of NE_M, ME_M, k_l, k_g and k_t were estimated to be 0.34 (0.028) MJ/($kg^{0.75}$ BW d), 0.58 (0.034) MJ/($kg^{0.75}$ BW d), 0.58 (0.021), 0.89 (0.056), and 0.69 (0.047), respectively. The analysis does not support the hypothesis that genetic improvements in milk production from 1986 to 2007 have significantly altered key parameters. However, the ME_M value was higher than NRC recommendations (based on older data) and may reflect higher requirements in modern cattle.

Key Words: energy metabolism, lactation, meta-analysis

1057 Carbon dioxide, a greenhouse gas, is sequestered by dairy cattle. D. P. Casper*[1] and D. R. Mertens[2], [1]*Agri-King, Inc.*, *Fulton, IL,* [2]*USDA-ARS Dairy Forage Research Center*, *Madison, WI.*

The impact of dairy cattle on the environment is receiving considerable attention. Carbon dioxide (CO_2) is a greenhouse gas (GHG), which contributes to global warming in theory. When conducting whole body respiration calorimetry trials, CO_2 is measured to calculate the heat production of dairy cows. The objective of this study was to estimate the release of carbon (C) as CO_2 by dairy cattle when fed a wide range of diets. Data from 1,252 individual metabolism trials in the compiled Energy Metabolism Database by lactating dairy cows of different breeds and stages of lactation with milk >5 kg/d were used in the data analysis. Cows were fed diets that varied in forage types, grain sources, protein sources, and fat supplements. During the energy and nitrogen balance

trials, a 24 h composite of respired air was collected for 3 consecutive days and analyzed for CO_2, methane, and O_2 (adjusted to standard temperature and pressure). Data were analyzed using the means and linear regression procedures of SAS. Dry matter intake ranged from 3.9 to 29.4 kg/d with an average of 16.3 kg/d, while milk production ranged from 5.1 to 56.6 kg/d with an average of 23.0 kg/d. Carbon released as CO_2 ranged from 0.96 to 4.65 kg/d with an average of 2.82 kg/d. When related to milk yield only, the amount of CO_2 C kg released per kg of milk decreased curvilinearly with increasing milk yield: CO_2 g C/d = 0.369-.015*milk, (kg/d) + 0.00021*milk^2 (kg/d), R^2 = 0.76, SER = 0.03, $P < 0.01$. At a given level of milk production, improving feed efficiency by decreasing DMI will decrease the release of C as CO_2: CO_2 g C/d = 821.3 + 126.0*DMI, (kg/d) −1.18*milk, (kg/d), R^2 = 0.86, SER = 217.7, $P < 0.01$, while at a given DMI, improving milk yield will decrease the release of C as CO_2 by sequestering more C in the milk. The release of C as CO_2 by lactating dairy cows is dependent on the nutrient intake and the efficiency of conversion to milk. Dairy cows can sequester carbon in milk and reduce the effect of their CO_2 emissions on global warming.

Key Words: carbon dioxide, carbon sequestration, feed efficiency

1058 The variation in milk production by lactating dairy cows in a whole herd compared to groups within that herd. D. P. Casper*, K. E. Lanka, D. F. Jones, G. P. Gengelbach, D. H. Kleinschmit, and D. J. Schauff, *Agri-King, Inc.*, *Fulton, IL.*

The variation in milk production needs to be accounted for when formulating rations to meet the nutrient requirements of lactating dairy cows. The grouping strategy used on the dairy should allow for the development of rations that can closely match the nutrient requirements of each group. However, little information exists for factoring variation into ration formulation for single or multiple group TMR′s. The purpose of this study was to determine the variation in milk production by lactating dairy cows when expressed as the whole herd versus groups within that herd. Data for milk production and composition during the months of December 2009 and January 2010 were collected from 10 dairy herds based on monthly DHIA test. Cows producing less than 9.1 kg/cow/d were eliminated, which resulted in milk production and composition data from 7,178 cows (2,904 primiparous and 4,274 multiparous) in herds ranging from 59 to 3,533 lactating cows with 1 to 15 groups/herd. Overall, mean milk production was 34.4 kg and ranged from 9.1 to 73.1 kg/cow/d with a SD of 9.75 kg/cow/d and a CV of 28.4%. The difference in the CV and SD between the whole herd and groups within that herd were evaluated using the *t*-test procedure of SAS. The CV of milk production was significantly ($t < 0.01$) lower when cows were grouped compared with the whole herd CV, but this difference was small (3.03%). The SD of milk production was significantly ($t < 0.01$) lower when cows were grouped compared with the whole herd, but the difference was small (1.35 kg/cow/d). This study suggests that dairy farms are not grouping cows based on milk production; but, more likely, cows are being grouped based on reproductive status. Therefore, the variation in milk production within a group is approaching the variation across the entire herd. This variation in milk production has implications on ration formulation to meet the nutrient requirements of high producing dairy cows.

Key Words: milk variation, grouping strategy, lead feeding

1059 Reduced protein responses to sugar feeding may be due to microbial glycogen production. M. B. Hall*, *US Dairy Forage Research Center, USDA-ARS*, *Madison, WI.*

The goal of this in vitro study was to determine the influence of Isotrich spp. protozoa on the conversion of glucose (Glc) to glycogen (Glyc). In a 2 × 2 factorial, treatments were 1) ruminal inoculum mechanically processed to destroy Isotrich spp. (M+, verified microscopically) or not mechanically processed (M-), and 2) measurement of microbial Glyc accumulated by 3 h of fermentation with (L+; protozoa + bacteria) or without (L-; predominantly protozoa) lysis of the fermentation solids with 0.2 N NaOH for 15 min in a boiling water bath before Glyc analysis. Two 3 h in vitro fermentations were performed using Goering–Van Soest medium in batch culture vessels supplemented with 3 g Glc L^{-1}. Rumen inocula from 2 cannulated cows filtered through 4 layers of cheesecloth were combined, and maintained under CO_2 for all procedures. Fermentation vessel contents were transferred to centrifuge tubes using 0.9% NaCl, centrifuged twice at 13,000 × *g* for 45 min at 5°C, with pellet resuspended in 0.9% NaCl after the first centrifugation and supernatant decanted each time. Pellets were analyzed for Glyc using a Na acetate buffer, heat-stable α-amylase and measurement of released Glc. Values for samples at 3 h of fermentation were corrected for 0 h values representing α-glucan introduced with inocula. Microbial Glyc detected at 3 h of fermentation were 3.32 (4.69%), −1.42 (−2.01%), 6.45 (9.10%), and 3.65 (5.15%) mg (% of added Glc) for M-L-, M+L-, M-L+ and M+L+, respectively (SED = 0.50). M+ gave lower Glyc values than M- ($P < 0.01$), and L+ gave greater values than L- ($P < 0.01$); there was an interaction of L and M ($P = 0.02$). M+L- showed net utilization of α-glucan initially in the fermentation with no net Glyc production. Estimated bacterial Glyc was lower for M- (3.12 mg) than M+ (3.65 mg; $P < 0.01$). Although destruction of Glyc-accumulating protozoa decreased detected Glyc by ~40%, sequestration of Glc by bacteria accounted for 4–5% of dosed Glc, with Glyc synthesis also representing an energetic cost. Potential decreases in microbial growth related to Glyc could require changes in protein supplementation to maintain protein supply to the ruminant host.

Key Words: sugars, glycogen, rumen fermentation

1060 Liver transcriptomics in Holstein cows fed lipid supplements during the peripartal period. M. J. Khan*[1], E. Schmitt[1], M. A. Ballou[2], E. J. DePeters[3], S. L. Rodriguez-Zas[1], R. E. Everts[1], H. A. Lewin[1], J. K. Drackley[1], and J. J. Loor[1], [1]*University of Illinois*, *Urbana,* [2]*Texas Tech University*, *Lubbock,* [3]*University of California*, *Davis*.

Our objective was to determine the effects of saturated or marine oil supplementation on peripartal liver transcriptomics and relate these to blood metabolites and liver tissue composition. Treatments (n = 6/diet) were no supplemental lipid (control) or supplemental lipid from either Energy Booster (mainly 16:0 and 18:0) or fish oil. Treatment diets were fed from −21 d until 10 d relative to parturition. The doses of lipid used were 250 g/d prepartum or 1% of the previous day feed intake postpartum. Percutaneous liver biopsies were harvested at −10, 1, and 14 d relative to parturition. A 13,257 bovine oligonucleotide (70-mers) array was used for transcript profiling. Pre and postpartum feed intake, milk production, or body condition score were not affected by lipid supplementation. Blood NEFA ($P = 0.06$) and BHBA ($P < 0.05$) were lower postpartum in cows fed either lipid source but postpartal liver triacylglycerol did not differ in these cows (ca. 4% wet weight) relative to controls (4.5%). Initial ANOVA of data from d 1 postpartum comparing fish oil vs. control revealed 50 differentially expressed genes (DEG, $P < 0.01$) of which 13 were upregulated and 13 were downregulated by fish oil. Among downregulated genes were several metabolic enzymes including stearoyl-CoA desaturase (SCD), fatty acid binding protein 1 (FABP1), acyl-CoA synthase medium-chain 1 (ACSM1), and cAMP-dependent protein kinase type II-β regulatory chain (PRKAR2B).

In addition, genes associated with apoptosis/cellular stress (GADD45B) and cellular response to hypoxia (HIF1A) also were downregulated by fish oil. Preliminary results suggest that peripartal lipid supplementation affected blood metabolites and liver transcript profiles and did not hamper production or feed intake.

Key Words: transition cow, metabolism, gene expression

1061 Cattle differ in ability to adapt to small intestinal digestion of starch. H. A. Bissell[1] and M. B. Hall*[2], [1]*University of Wisconsin, Madison,* [2]*US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

The objective of this study was to evaluate the impact of post-ruminal starch digestion on inflammatory response in dairy cattle. Six cull, nonpregnant, nonlactating, multiparous cannulated Holstein dairy cows (BW 804 ± 101 kg) were fed a high forage diet ad libitum starting 15 d before the infusion period. Cows were infused abomasally 12 h per day for 3 d with approximately 8 L d^{-1} of 0.9% saline solution (CTRL; 2 cows) or a 0.9% saline suspension of 4 kg of corn starch with 4 g xanthan gum (ST; 4 cows) using peristaltic pumps. Fecal samples, blood samples, and other measures were taken every 4 h (offset daily by 1 h). Data were analyzed as repeated measures with cow within treatment as a random variable. Fecal pH data showed 2 distinct responses to ST (ST1 and ST2). Fecal pH of all cows averaged 6.90 before infusion. During infusion days, fecal pH remained at 7.0 ± 0.25 for CTRL, but declined in ST cows to 5.1 (ST1) and 4.9 (ST2) by the end of d 2, and diverged to 5.3 (ST1) and 4.6 (ST2) by the end of d 3. The increase in fecal pH for ST1 cows during d 3 suggests an increase in small intestinal digestion of starch, whereas a continuing decline in fecal pH for ST2 cows suggests that they did not adapt similarly. Fecal pH differed among CTRL, ST1, and ST2 ($P < 0.01$). Blood values for haptoglobin decreased for CTRL and ST1 with day of infusion, but increased for ST2 with d 3 values of 12.3, 7.8, and 24.5 mg dL^{-1}, respectively ($P = 0.04$). Fibrinogen mg dL^{-1} tended to differ by treatment x infusion day, rising from 109 to 198, 143 to 188, and 221 to 250 between d 1 and 3 of infusion for CTRL, ST1, and ST2, respectively ($P = 0.11$). Neither ceruloplasmin ($P = 0.38$) nor α-acid glycoprotein ($P = 0.46$) differed by treatment. Hematocrit tended to be greater for CTRL than ST (32.9 v 29.1%; $P = 0.08$). Rectal temperature showed treatment x day effects with increases from d 1 to 3 of 38.5 to 38.7, 38.4 to 39.0, and 38.9 to 39.1°C for CTRL, ST1, and ST2, respectively ($P < 0.01$); CTRL tended to be less than ST ($P = 0.09$). Respiration rates did not differ ($P = 0.46$). The basis for differing cow responses to post-ruminal starch load requires further evaluation.

Key Words: starch, digestion, dairy cattle

1062 Physiological effects of season and parity on production and nutritional quality of milk in camel (*Camelus dromedarius*) under pastoral environment of Pakistan. S. Ahmad*[1], M. Yaqoob[1], M. Q. Biilal[1], G. Muhammad[1,2], M. Younas[1], and J. I. Sultan[1,3], [1]*University of Agriculture, Faisalabad-Pakistan*, *Department of Livestock Management*, [2]*University of Agriculture, Faisalabad-Pakistan*, *Department of Clinical And Medicine*, [3]*University of Agriculture, Faisalabad-Pakistan*, *Institute of Animal Nutrition And Feed Technology*.

Relatively little is known about the actual situation of milk production and quality in the Thal area of Pakistan, particularly when regarding seasonal variation in milk composition and with different parities. Therefore, this study was planned to evaluate the effect of season and parity on milk production and compositional quality of camels kept under pastoral environment of Pakistan. Based on purposive sampling method, 200 she-camels were selected in thal area (District Jhang) and their composite milk samples were collected. The research was carried out in 2 periods. The first period was the summer period covering May–June–July months and the second one was the winter period covering December–January–February months. The collected milk samples were analyzed through standard procedures to determine the percentages of milk fat, protein, lactose, acidity and solids not fat (SNF). Mean daily milk production and mean percentages of fat, protein, lactose, acidity and SNF were found to be 5.50 ± 0.18L and 3.40 ± 0.19%, 3.30 ± 0.11%, 4.67 ± 0.13%, 0.20 ± 0.01% and 9.56 ± 0.18%, respectively. Season of the year and parity imparted significant effect ($P < 0.05$) on daily milk production. The values for milk production (6.20 ± 0.20L), fat (3.98 ± 0.23%), protein (3.43 ± 0.16%), lactose (4.92 ± 0.21%) and SNF (9.14 ± 0.39%) were significantly higher ($P < 0.05$) during winter season compared with summer. In 3rd parity, significantly highest ($P < 0.05$) daily milk production (6.59 ± 0.30 L) and percentages of fat (4.00 ± 0.27%), protein (4.61 ± 0.41%), lactose (5.50 ± 0.36%) and SNF (11.33 ± 0.39%) was observed whereas she-camels in 6th parity produced significantly lower ($P < 0.01$) milk volume (2.90 ± 0.56 L) and percentages of fat (2.70 ± 0.30%), protein (1.69 ± 0.68%), lactose (3.79 ± 0.39%) and SNF (8.02 ± 0.48%). However, acidity of camel's milk was not influenced by season and parity. Efficient feeding strategies during scarcity periods and culling after 5th parity are imperative measures for getting maximum milk of high nutritive value from this novel animal.

Key Words: season, parity, Pakistan

Swine Species Symposium: Optimizing Swine Production for Lactating Sows and Young Pigs

1063 Nutritional management of sows during the perinatal period. S. W. Kim*, A. Saraiva, and Y. Zhao, *North Carolina State University*, *Raleigh*.

With improved genetic potentials, sows produce a larger number of fetuses than before and these fetuses possess genetic potentials to grow faster than before. Recent comparison shows that a porcine fetus is 40% heavier than 40 years ago. Thus the nutritional management of sows has been updated to reflect these genetic changes. Our recent study quantified nutritional needs for sows to support the growth of fetuses and mammary glands during gestation. Amino acid needs for fetal growth and mammary growth during late gestation (d 70 to farrowing) increased 19-folds and 24 folds, respectively, compared with those needs during early gestation (until d 70). Considering these increases, daily requirement of true ileal digestible Lys for a primiparous sows increases from 7 g (until d 70) to 15 g (d 70 to farrowing). Required qualities of proteins (i.e., amino acid ratios) also change with an advance of pregnancy as maternal, fetal, and mammary tissues have their unique amino acid compositions. Thus, sows can be under a severe catabolic status during late gestation if the feed does not provide sufficient amounts and qualities of proteins especially during late gestation. Under a several catabolic status, sows can have a limited nutrient supply for the growth of fetuses. Sows under a conventional feeding program had increased litter weight variations at farrowing (19%) compared with early gestation (3.0%). Our recent study also shows that sows under a conventional feeding program have a dramatic increase in a systemic oxidative stress during late gestation compared with early gestation when measured by plasma Î ± -tocopherol (56% decrease), plasma retinol (57% decrease), and DNA damage in white blood cells (125% increase) which were sustained until the early lactation period. Increased oxidative damages in sows negatively affect the growth and health of fetuses. We proposed that sow feeding during late gestation should reflect the changed needs for amino acids and antioxidants because a proper feeding during late gestation will eventually help producing uniform and healthy piglets.

Key Words: amino acids, oxidative stress, sows

1064 Proper nutrition to optimize performance for lactating sows and young pigs. V. J. Pearson*, *Land O'Lakes Purina Feed LLC*, *Shoreview, MN*.

Feeding the sow for maximum reproduction involves recognizing that the nutrient requirements are different during different stages of the sow's reproductive life. Lactation, though only 2 to 6 weeks, is a critical stage of this sow's reproductive life. Feed intake at this stage is affected by genotype, lactation length, parity distribution, mycotoxins, environmental temperature, formulation of lactation feed, water availability and disease levels. The key point to optimize a sow's performance is proper feed management during lactation. The objective of the feeding program for lactating sows is to ensure that the sow consumes sufficient feed on a daily basis to meet her nutrient requirements such as protein, amino acids, energy, trace minerals, vitamins and major minerals. The nutrient requirements needed by the sow depend on her weight, milk yield and composition along with the environment she is in especially temperature. Since most of the information we need to make the proper calculations to feed the sow are not known the sow is fed to appetite. The appetite of a lactating sow is lower the first week and increases by 3 weeks. So optimizing feed intake of the sow is extremely important. Sows should have access to high quality water at all times; temperature should be kept at 19–22°C. Water flow rate of 0.7 to 1 L per minute should be adequate. Sow data has demonstrated that approximately 20% of sows show a feed decrease for 2 to 3 d at the beginning of the second week. This caused a longer weaning-to-estrus interval, reduced farrowing rates and resulted in smaller subsequent litter size. Data has indicated even one day of the sow's consumption dropping below 1.8 kg will increase the chances of her being removed from the herd by 50%. Thus the sow should never be purposely deprived of feed. A feed allowance of 1.0% of the sows body weight plus 0.57 kg for each pig in the litter is a good guide to the minimum levels lactating sows should be daily fed.

Key Words: swine, lactation, nutrition

1065 Gene x environment interactions affecting litter phenotype in commercial sows. G. R. Foxcroft*, *University of Alberta*, *Edmonton, Alberta, Canada*.

Variation in litter growth performance after birth may be pre-programmed during embryonic and fetal development, yet may only express itself in the late grow-finish stages of production. Two particular hypotheses will be explored in the context of efficient pork production from contemporary sow populations: 1) Selection for increased litter size has resulted in indirect negative effects of intrauterine crowding on placental development in early pregnancy, leading to reprogramming of fetal development, less efficient post-natal growth performance, and adverse effects on carcass quality at slaughter. 2) Sow metabolic state at breeding can also affect the quality of litters born, acting through epigenetic mechanisms to affect early embryonic development. Effects of prenatal programming on postnatal health and survivability are also important, and are mediated through developmental limitations in immune, metabolic and gastrointestinal function in the early postnatal period. Negative pre-natal programming effects on post-natal performance are consistently seen in hyper-prolific sows that produce total numbers of pigs born that exceed uterine capacity for optimal birth weight. However, available evidence indicates that differences among litters is the major source of variance in pig birth weight in mature sow populations producing between 10 and 15 pigs per litter, with apparent repeatability of a low birth weight phenotype in this sow population. These developmental complications underlie the problems of managing low birth weight pigs through lactation and the nursery stage of production. Production strategies that might address variation in litter average birth weight and post-natal performance of litters include: 1) segregated management of litters based on birth weight phenotype, and 2) nutritional strategies in gestation and lactation and interventions in the farrowing house targeted at low birth weight phenotypes.

Key Words: sow, litter, phenotype

1066 Decision-making using swine records. J. Deen* and S. S. Anil, *University of Minnesota*, *St Paul*.

For sow herds, the objective function of decisions has historically been a simple maximization problem. Sow farms have been viewed as a mostly fixed cost enterprise with marginal production being viewed as having a very high profit margin. This was due to the fact that piglets were considered generic commodities after transfer from the sow herd. Though we see remnants of this attitude in record-keeping systems and pricing methodologies, we are seeing a greater emphasis on individual animal qualities. The major decisions at the individual pig level of

retention, treatment or euthanasia have focused in greater detail on its varied repercussions. For instance, culling a sow not only affects that sow, it also affects the quality of progeny and the utilization of building capacity; the treatment of a pig may not only have an effect on itself but also on surrounding pigs, especially when infectious pathogen transfer is a concern.

Record-keeping has not kept up with these potential considerations. Assumptions of normality and the independence of effects on outcomes need to be re-examined. Both atomistic and ecologic effects of decisions need to be considered. To measure these effects, individual animal characteristics and complementary observational analytic methods need to be utilized. Such measurement regimens and analytic processes are laborious and often complex and rely on proper sampling and disciplined approaches. However, when we do such analyses we are finding that the assumptions of normality and equality of effects across the distribution are often erroneous. In fact, most insults and interventions affect subpopulations that can be best described as compromised individuals. For instance, the likelihood of being weaned alive and greater than 5 kilograms in weight can range from 8% for the lightest 10th percentile at birth to 96% for the heaviest 10th percentile. Such ranges and responses suggest that individualized records and care are needed to optimize rearing conditions and decision-making.

Key Words: reproduction, records, swine

Teaching/Undergraduate and Graduate Education: Graduate and Undergraduate Teaching 2

1067 Engaging agriculture students in the publication process through popular press magazines. E. L. Walker*, *Missouri State University*, *Springfield*.

Traditional lecture based courses may not be the most effective in incorporating all the concepts of higher order thinking. Therefore, an alternative teaching method was created and incorporated into an upper division animal science feeds and feeding class which challenges students to obtain peer reviewed data and present it in a "popular press" type format. The objectives of this assignment were to: 1) incorporate Blooms Taxonomy into the teaching method of class and 2) to assist undergraduate students in their understanding of core concepts discussed in class and, 3) apply a basic understanding of animal based research into a production based setting. There are 3 phases of this assignment: 1) assignment of pods based upon student interest, 2) edit and selection of papers, 3) publication of paper. Students are placed into pods designated by the instructor based upon the students' general research interest. Within the pod, students are required to discuss their research interests and formally edit one another's papers. After completion of the editing process, the most well written paper is selected from within each pod. Each of these papers is then sent electronically to every student in the class for a second formal editing process. After each student reads and formally edits the top pod papers, the class must vote on a single paper they feel has the best chance to get published in a popular press journal. In each of the 3 phases, students are graded by the instructor. Extra points are given to the author of the winning pod paper, then to the pod that produces the paper voted by the class as the best overall paper, and then is given to the entire class if the paper is accepted for publication. If of superior quality, the second place paper is also submitted for publication for no class credit. This project has been conducted for 3 years and 5 papers authored and edited by students have been published in popular press journals across 3 states. Popular press magazines can be a critical link between the scientific, university, and agriculture communities.

Key Words: writing skills, Bloom's Taxonomy, popular press

1068 Teaching and experiencing entrepreneurialism in animal sciences. M. E. Benson*[1], A. B. Culham[2], and G. M. Hill[2], [1]*Washington State University*, *Pullman,* [2]*Michigan State University*, *East Lansing*.

A USDA Challenge Grant provided the opportunity for students in animal sciences to develop their entrepreneurial skills. In this project, students integrated information from technical disciplines with skills necessary for successful business development in an entrepreneurial arena. Three objectives were to: 1) design and implement a curriculum in which students learned techniques and procedures applicable to discovery and evaluation of marketing options and new product launches for animal agricultural enterprises; 2) develop a working laboratory where implementation of learned practices are applied to actual marketing of a product(s); and 3) communicate the results of this project to other students, industry professionals and other educators. The project was initiated at Michigan State University (MSU) where the students brainstormed ideas and completed development of business plans for their proposed ventures. Input from industry professionals on topics such as marketing strategies and risk assessment for niche markets further assisted the students in the development of their business plans. The course has also been added at Washington State University (WSU) and working laboratories have been established at both sites. At MSU, students added value to wool produced from the MSU flocks by creating Spartan blankets that were marketed through a variety of channels. Revenues generated are sufficient to make this a self-sustaining venture and currently new products are being evaluated. Resources from product sales have also supported student research and travel activities. At WSU, students are developing their own ideas and business plans as well as participating as a group in the process of creating, producing, and marketing woolen blankets. At both sites, this project has met with enthusiastic responses from students, livestock industry stakeholders and alumni. It has brought visibility to the department while offering students the opportunity to consider business opportunities and challenges that extend beyond traditional animal agricultural enterprises.

Key Words: entrepreneurialism, business skills

1069 The role of animals in societies of the world: When culture and roles clash. M. Russell*[1], H. Frigola[1], K. Kanne[2], and S. Damron[3], [1]*Purdue University*, *West Lafayette, IN,* [2]*Northwestern University*, *Evanston, IL,* [3]*Oklahoma State University*, *Stillwater*.

This course serves as a university-level freshmen honors course and is an introduction of the importance of animals in various cultures and societies of the world. Factors which influence the role of animals in society including physical and biological adaptations of animals and the role of traditions, culture, religions, language, politics, geography, climatic, and socio-economics are discussed. Learning objectives are to: broaden students′ understanding of the roles animals play in cultures around the world; critically analyze ethical and moral debates of animal use in society; and prepare students to interact with people who use animals in ways different from themselves. This course is co-taught with faculty in animal sciences and anthropology. Guest presenters include foreign graduate students and visiting faculty as well as Purdue faculty who share their experiences and specialty areas of expertise. Topics are presented with some lecture and facilitated discussion and many videos/DVDs as examples from many international cultures as well as the USA culture itself. Students develop writing assignments and lead class discussions in two major topics: A Use & Society topic which discusses how culture, geography, climatic, and socio-economics as well as the animals′ morphology/physiology affect the use of animals. The Current Issue assignment applies topics discussed in class to a specific issue or concern regarding a current controversy or animal topic use. This topic critically analyses ethical and moral dilemmas related to this chosen current issue as it affects animals, people, and the environment. We will share pedagogy and learning assessment methods in this innovative approach to assist under-classmen in understanding why certain species and breeds are best suited for our US industries and the other factors that determine the appropriate use of animals in our changing societies. This is important to broadening the world view of our students and help them to be more successful in dealing with professional and public policy dilemmas in the future.

Key Words: animal roles, cultural conflict

1070 Enhanced learning of lactation physiology by undergraduates conducting a class-based research project. R. L. Wrenn*, S. J. P. Lee, and R. C. Hovey, *University of California, Davis*.

The integration of materials from experiential research presents unique opportunities to enhance classroom learning by undergraduates in the animal sciences. The objective of an ongoing project at UC Davis is to

use a student/class-run project to teach junior and senior students the physiological basis of lactation and the fundamentals of dairy animal management. Animal science undergraduates (up to 165 students) enrolled in a required lactation course (ANS 124) were given the task of coordinating and conducting a class-based, quarter-long (10-wk) research project involving hormone-induced lactation. Nulligravid Holstein heifers (n = 8) were administered daily injections (sc.) of estradiol-17β (0.075 mg/kg) and progesterone (0.25 mg/kg) for 7 d, followed by a single dose of dexamethasone (15 mg) on d18 of the protocol. Students were responsible for all aspects of the project under the guidance of the faculty mentor. Each student performed morning and evening chores (at least one at each time per student) including hormone injections, blood sampling, weighing, data collection, milking, and basic husbandry practices. Mammary gland growth was monitored through daily udder measurements, including distance between the teats and individual teat length, and from photographs. Students analyzed blood samples for changes in the level of α-lactalbumin by ELISA to establish the onset of lactogenesis. Milking began on d 20 and continued for approximately 30 d. Changes in milk compostion were determined by SDS-PAGE. The project afforded numerous opportunities within the classroom for discussions about the physiological changes associated with mammary growth, anatomy, endocrinology, lactogenesis, and galactopoiesis. At the end of the study each student composed a redrafted research paper, with individual students preparing scientific abstracts for additional public audiences. In conclusion, a student-run project involving induced lactation provides an excellent opportunity for undergraduates to gain hands-on research and dairy management experience that also enhances classroom learning.

Key Words: lactation, experiential learning, induced lactation

1071 Frameworks for learning: a case study of approaches for building capacity for distance education. D. R. Mulvaney*[1,2], P. A. Curtis[3], and M. O. Kloepper[3,4], [1]*Coll. of Agr., Auburn Univ.*, *Auburn, AL,* [2]*Dept. Anim. Sci., Auburn Univ.*, *Auburn, AL,* [3]*Dept. Poult. Sci., Auburn Univ.*, *Auburn, AL,* [4]*IT Specialist, Auburn Univ.*, *Auburn, AL*.

Developing digital capacity among faculty is a necessary prerequisite to emerging distance education programs. Trends in higher education clearly substantiate future students learners are considered digital natives and many faculty are considered immigrants in a digital world. Informal approaches for faculty development have been initiated across the college of agriculture with goals of creating cultures enabling faculty to adapt to new technologies having relevance to teaching. Our objectives will be to share some of our experiences, both successes and failures, at creating opportunities for faculty to develop comfort and skill in using digital technologies with relevance to teaching and learning. Approaches designed with features of faculty learning communities have included creation of an Agricultural Instructional Media Academy, frameworks for learning seminars, Go-The-Distance Pit-Stop discussion sessions, Blackboard initiatives, technology simulations, hands-on workshops, one-on-one facilitation / mentoring and creation of a satellite technology units on the ag campus. Concurrent to these efforts have been changes in centralization of distance learning administration, policy, adoption of AG-IDEA initiatives, IT support and available technologies, and pockets of interest and energy, all which are collectively shaping change in the culture and capacity for distance education. In summary, rate of technological change seemingly out-paces the development of digital capacity of faculty and programs yet one-at-a-time change has had impact.

Key Words: distance education, digital learning, faculty development

1072 Trends in distance education and technologies in higher education: A call for adaptive leadership. D. R. Mulvaney*[1,2], P. A. Curtis[3], and M. O. Kloepper[3,4], [1]*Coll. Agr., Auburn Univ.*, *Auburn, AL,* [2]*Dept. Anim. Sci.*, *Auburn, AL,* [3]*Dept. Poult. Sci.*, *Auburn, AL,* [4]*IT Specialist*, *Auburn, AL*.

The emerging educational landscape is characterized by change. Distance education stands to be a key transformative factor for undergraduate education in agriculture. An adaptive challenge for educators and institutions is how to anticipate and prepare for a future they have not fully experienced. The objectives of this presentation are to provide a concise overview of the trends in higher education with an emphasis on distance education and reinforce challenges surfaced from the 2006 National Academy of Science Leadership Summit to Effect Change in Teaching and Learning. Robust availability of technologies conducive to just in time, mobile learning models, generational shifts characterized by learners from a digital culture, campus cultures and policies to accommodate distance consortia and alliances such as AG-IDEA, development of digital immigrant faculty plus challenges of dealing with new vistas for practicing scholarship are but a few components of the evolving future for higher education. Technologies around data visualization, information retrieval, creation of knowledge objects, gesture prompted technologies, gaming simulation and virtual reality software will allow for reinvention of teaching and learning environments. Because the challenges and trends around the emerging technologies will have significant impact on the teaching, there is a call for new pedagogical models and adaptive leadership among faculty and administrators.
Partially supported by USDA NIFA Higher education Challenge grant 2007–38411–18136 - Development of a distance education consortium among southern universities.

Key Words: distance education, trends in education, animal sciences

SYMPOSIA AND ORAL PRESENTATIONS

Animal Health: Probiotics, Performance and Antioxidants

1073 Thiamine status of feedlot cattle fed high concentrate diet. T. Karapinar*, M. Dabak, and O. Kizil, *University of Firat, Faculty of Veterinary Medicine*, *Elazig, Turkey*.

Thiamine deficiency causes a decrease in transketolase activity and an increase in thiamine pyrophosphate (TPP) effect on the erythrocytes. The objective of this experiment was to determine if ruminal acidosis alters erythrocytic transketolase enzyme activity as an indicator of thiamine level in feedlot cattle. A total of 65 feedlot cattle (1–2 years old) were fed either high concentrate diet (HCD, n = 50) or low concentrate diet (LCD, n = 15). The HCD group was fed a mixture of 75% cracked barley, 8% bran, 7% cotton seed meal and 10% straw for at least the last 3 mo, whereas the LCD group was fed a mixture of 30% cracked barley, 10% bran, 10% sugar beet pulp, 10% cotton seed meal and 40% straw. Rumen fluid samples of all cattle were obtained by rumenocentesis to determine ruminal pH. After ruminal samples were obtained, blood samples were collected from a jugular vein for erythrocytic transketolase enzyme activity using the Clausen's colorimetric method. Mean pH values of ruminal fluid samples in the HCD and LCD groups were 5.3 and 6.1, respectively. The mean TPP effect % in the HCD group (47.16 ± 3.17) was significantly higher than in the LCD group (19.53 ± 2.51) ($P < 0.01$). Ruminants with functional rumen are considered to have no specific dietary thiamine requirement due to extensive thiamine synthesis by rumen microbes. Thiamine deficiency in both chronic ruminal acidosis and acute ruminal lactic acidosis may occur because of inadequate synthesis of thiamine, bacterial production of thiaminase in the acidotic ruminal fluid. Furthermore, a decrease in ruminal pH may result in the release of bacterial thiaminases. The present study demonstrated that thiamine deficiency could occur in ruminants fed under intensive fattening regimens.

Key Words: polioencephalomalacia, transketolase, vitamin B1

1074 The effect of five herbal extracts on performance, carcass characteristics and immune system in broilers. M. Alempour[1], S. Rahimi*[1], M. A. Karimi Torshizi[1], and A. Rahimi[2], [1]*Tarbiat Modares University*, *Tehran, Iran*, [2]*Islamic Azad University*, *Tehran, Iran*.

The purpose of this study was to evaluate the effect of 5 herbal extracts and Virginiamycin antibiotic on growth performance, carcass characteristics and immune system in broilers. A total of 720 1-d-old broiler chicks (ROSS 308) were assigned to 9 treatments with 4 replicates of 20 birds per pen as follows: the basal diet, and basal diet supplemented with 15 ppm Virginiamycin, 1% aqueous extract of garden thyme (*Thymus vulgaris*), garlic (*Allium sativum*), thyme (*Thymus kotschyanus*), sage (*Salvia officinalis*), peppermint (*Mentha piperita*), a blend of garden thyme and peppermint and blend of thyme and sage. Performance and feed conversion were calculated at 14, 28 and 42 d of age. At end of the experiment 2 birds from each replicate (8 birds per treatment) were randomly selected to evaluate the carcass characteristics, relative weight of lymphoid organs and fat pad. Greatest and least body weight were belonged to virginiamycin and sage, ($P < 0.05$) respectively. Lowest and highest feed conversion ratio were related to virginiamycin and control groups ($P < 0.05$) respectively. There was no difference in carcass characteristics, fat pad and digestive organs weight. Relative weights of lymphoid organs (spleen and bursa of Fabricius) as 2 immune indices were unaffected by the treatments. According to results of this experiment, the herbal extracts did not show significant difference in performance and lymphoid organs weight in broilers.

Key Words: herbal extract, performance, immune system

1075 Comparison the effect of five herbal extracts and virginiamycin on serum lipids and immune system in broilers. M. Alempour[1], S. Rahimi[1], M. A. Karimi Torshizi[1], and A. Rahimi*[2], [1]*Tarbiat Modares University*, *Tehran, Tehran, Iran*, [2]*Islamic Azad University*, *Tehran, Tehran, Iran*.

The objective of this study was to investigate the effect of 5 herbal extracts and virginiamycin on blood metabolites in broilers. A total of 720 1-d-old (Ross 308) male broiler chicks were assigned to 9 treatments with 4 replicates of 20 birds per pen as follows: the basal diet (control) and basal diet supplemented with 15 ppm virginiamycin, 1% aqueous extract of garden thyme (*Thymus vulgaris*), garlic (*Allivum sativum*), common thyme (*Thymus kotschyanus*), common sage (*Salvia officinalis*), peppermint (*Mentha piperita*), a blend of garden thyme and peppermint and blend of common thyme and common sage with the same dose in drinking water as a completely randomized design.. At the end of the experiment 2 birds from each replicate were randomly selected to measure total cholesterol (TC), LDL cholesterol, triglycerides (TG) and HDL cholesterol levels. Garlic (*Allivum sativum*) significantly reduced the levels of TC, LDL, TG (97.89, 21.49 and 37.45 mg/dl respectively) and significantly increased the level of HDL (68.91 mg/dl) ($P < 0.05$). According to results of this experiment the herbal extracts could have beneficial effect on blood lipids in comparison with the control and antibiotic fed birds. Garlic was the most effective treatment in this trial.

Key Words: broiler, blood factors, herbal extract

1076 Characterization of a yeast autolysate in vitro and effect on piglet performance in vivo. A. Ganner*[1], S. Masching[2], M. Pelz[1], and G. Schatzmayr[1], [1]*Biomin Research Center*, *Tulln, Austria*, [2]*Biomin Holding GmbH*, *Herzogenburg, Austria*.

Dietary yeast derivatives have been proposed to improve piglet health by preventing infectious diseases, by modulating the immune system and by controlling pathogenic bacteria such as *E.coli* and *Salmonella*. Aim of the study was an in vitro characterization of a yeast autolysate and its effect on piglet performance. As an in vitro model the murine macrophage cell line J774A.1 was used. Cells were incubated for 48 hours with LPS of *E. coli* 0127:B8 and the autolysate. TNF-alpha, IL-12, TGF-beta and IL-10 were determined in the supernatant of the cultures with ELISA. Additionally the autolysate was examined for its capacity to bind *E. coli* F4 with a quantitative microplate-based assay by measuring the optical density as growth parameter of adhering bacteria. Subsequently, a feeding trial was conducted to evaluate the efficacy of the autolysate on performance

of weaning piglets in a 56 days study. 40 piglets were divided into 2 groups with 2 replicates: control group A, group B (0.1%). Statistical analyses were performed with t-test, SPSS 18. TGF-beta was enhanced up to 100% in comparison to the control (LPS of *E. coli*); no induction of IL-10. IL-12 was inhibited 60 to 80%; no effect on TNF-alpha could be observed. In the microbiological assay *E. coli* F4 adhered with 10^6 CFU/mg to the autolysate. In the course of the feeding trial a positive influence could be observed by the autolysate. Weight on day 56 (43.13 kg) and daily weight gain (dwg 604g) were improved in comparison to the control (40.92 kg weight day 56, P = 0.048; 505g dwg, $P = 0.025$). Feed consumption was increased ($P \geq 0.05$), FCR (kg/kg) of the trial group was 1.74, of the control 1.71 ($P \geq 0.05$). Pathogen binding and modulation of the immune system, as shown in vitro, might have been reasons for the increase in performance of piglets in the feeding trial. In vitro and in *vivo* results indicate that this particular yeast autolysate is a health and performance improving agent.

Key Words: yeast autolysate, cytokines, piglet performance

1077 Effect of several feed additives on growth performance and microbial load in Escherichia coli challenged broilers. A. R. Valipouri[1], S. Rahimi*[1], T. Zahraei Salehi[2], and A. Rahimi[3], [1]*Tarbiat Modares University*, *Tehran, Iran*, [2]*University of Tehran*, *Tehran, Iran*, [3]*Islamic Azad University*, *Tehran, Iran*.

The objective of this study was to compare the effects of different feed additives on performance and microbial load in *E. coli* challenged broiler chickens. A total of 528 d-old Ross 308 male broilers were used to study the effect of antibiotic, probiotic, prebiotic and organic acid on performance, cecal coliform load, immune system and internal organs weight. The birds were placed into 6 groups with 4 replicates and 22 birds per pen. Six dietary treatments include: 1) negative control as basal diet without any antibiotic growth promoter and coccidiostat (Ctl-); 2) Diet 1+ 0.9 g/kg of feed Primalac (Prim); 3) Diet 1+0.1 g/kg of feed Bactocell (Bact); 4) Diet 1+15ppm virginiamycin (VM); 5) Diet 1+2 g/kg of feed Fermacto (Ferm); and 6) Diet 1+2 g/kg of feed Formycin (OA). At d 7 all birds were orally gavaged with a 0.5 mL of 10^7 CFU of mixed culture of pathogenic *E. coli* (O2K12 and O78K80) verified for presence of genes including stx1, stx2, eaeA and hlyA. Eight birds from each group were killed for detection of challenged bacteria in liver, spleen and cecum content at d 14, 28 and 42. Overall weight gain ($P < 0.01$) and feed conversion ($P < 0.05$) were significantly improved in VM (2460.00 and 1.64) and Prim (2337.25 and 1.70) groups compared with control group (2280.50 and 1.82). The challenged serotypes were recovered only from Ctl- (46%) and VM (25%) fed groups. Feed supplementation with probiotic, prebiotic or organic acid, significantly decreased coliform population at all intervals in comparison with Ctl- and antibiotic treatments ($P < 0.05$). Feed additives supplementation had no influence on the internal organs weight at all intervals.

Key Words: alternative, antibiotic, *Escherichia coli*

1078 Improvement of microbial flora of broilers digestive system by medicinal plants supplementation. A. Niknam, S. Rahimi*, J. Azimi, K. Seifi, M. Hoseinzade, and M. Moradi Nejad, *Tarbiat Modares University, Tehran, Iran.*

The objective of this study was to compare the effects of dietary administration of medicinal plants, with antibiotics and probiotics on microbial flora of digestive tract in broilers. A total of 210, day old male broiler chicks (Arbor Acres Plus) were randomly allocated into 7 treatments. The treatments were as follow: control; dry peppermint (*Mentha piperita*); thyme (*Thymus vulgaris*); basil (*Ocimum basilicum*) leaves; or garlic (*Allium sativum*) bulb (15kg/ton feed); Virginiamycin (150g/ton feed); and Primalac (1kg/ton feed). At 42 d of experiment 9 birds from each treatment were randomly selected and sacrificed. Samples were collected from crop and ileocecal section of intestine and diluted in phosphate buffer saline (PBS). Then, samples were plated onto Mann Rogosa Sharpe (MRS), MacConkey and Plate-count agar to enumerate lactobacilli, coliforms and total aerobic bacteria, respectively. Crop contents of garlic and peppermint treatments contained the highest and lowest number of lactobacillus bacteria (5.88 vs. 3.68 Log10 cfu/g), respectively ($P < 0.05$). There was no significant difference in number of coliforms in crop. The maximum and minimum number of total aerobic bacteria observed for control and basil treatments (5.69 vs. 3.93 Log10 cfu/g), respectively ($P < 0.05$). Supplementation of diet with garlic increased number of lactobacillus bacteria in ileum (8.76 Log10 cfu/g) compared with other treatments ($P < 0.05$). Primalac increased both coliforms and total aerobic bacteria in ileum higher than other treatments ($P < 0.05$), while lowest number of these bacteria belongs to basil and control treatments (9.34 and 8.96 vs. 8.24 and 8.08 Log10 cfu/g), respectively. Microbial changes in crop and ileum of chicken demonstrate that administration of medicinal plants can increase number of lactobacillus and improve bacterial balance in gut.

Key Words: medicinal plants, digestive system, broilers

1079 Peripartal intravaginal probiotics lowered uterine infections and improved reproductive performance of Holstein dairy cows. B. N. Ametaj*[1], Q. Zebeli[1], S. Iqbal[1], M. Gänzle[1], Y. Wang[1], D. J. Ambrose[2], and S. M. Dunn[1], [1]*University of Alberta, Edmonton, Alberta, Canada*, [2]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada*.

Uterine infections affect 1 in 2 dairy cows after parturition lowering their reproductive performance and increasing culling rates. The objective was to investigate the prophylactic effect of probiotic bacteria on postpartum metritis and the overall reproductive performance of dairy cows. Eighty pregnant multiparous and primiparous dairy cows 2 wk before the expected day of calving were assigned to one of 2 groups receiving: 1) 1 mL of carrier only (reconstituted skim milk), or 2) 1 mL of probiotic bacteria in reconstituted skim milk at 10^{10} to 10^{12} cfu/treatment. Intravaginal infusions were performed once during wk −2, −1, +1, +2, +3, and +4 relative to parturition with probiotic bacteria isolated from vaginal tracts of healthy cows, *Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138. All cows were observed for reproductive performance and reproductive disease until next pregnancy. Probiotic treatment lowered the incidence of uterine infections in both multiparous (17 vs 48%; $P < 0.01$) and primiparous (16 vs 58%; $P < 0.03$) cows. The interval from calving to conception tended to be shorter (93 vs 145 d; $P < 0.10$) in treated cows, and pregnancy rate at first insemination in multiparous cows tended to be higher ($P < 0.10$). Both multiparous and primiparous cows receiving probiotics had lower incidence of purulent ($P < 0.008$ and $P < 0.02$) and foul-smelling ($P < 0.06$ and $P < 0.05$) discharges on +3 wk. Moreover, multiparous cows had lower rate of uterine horn fluctuations ($P < 0.05$), smaller cervix size on wk +3 ($P < 0.001$) and +5 ($P < 0.06$), and lower uterine horn asymmetry on wk +3 ($P < 0.01$) and +5 ($P < 0.01$). There was a tendency for probiotic treatment to reduce early calving ($P < 0.11$), the number of medications per cow ($P < 0.09$), and the number of cows in the clean-up program ($P < 0.06$). Further research is warranted to understand the beneficial effects of intravaginal probiotics on reproductive performance of dairy cows.

Key Words: dairy cow, probiotics, uterine infections

1080 Changes in ruminal-rectal temperature relationship associated with consumption of endophyte infected tall fescue. B. Scharf*, J. S. Johnson, H. L. Vellios, R. L. Weaber, and D. E. Spiers, *University of Missouri*, *Columbia*.

Little is known about changes in ruminal temperature after consumption of endopyte infected tall fescue. Twenty-four Angus steers (318 ± 8 Kg BW) were housed in the Brody Environmental Center (University of Missouri), and randomly assigned to a diet with either endophyte infected tall fescue seed (E+; 40µg ergovaline/kg/d) or endophyte free seed (E-; 0µg ergovaline/kg/d). Animals were housed for 7d at an ambient temperature (T_a) of 21°C (TN) before heat stress (HS), which consisted of daily cyclic T_a (26°C night: 36°C day) for 7d. A telemetric, temperature transmitter (SmartStock, Pawnee, OK) was placed into the rumen (T_{rum}) of each animal before the study. Rectal temperature (T_{re}) and respiration rate (RR) were measured 6 times daily. At TN, no differences were found in RR, T_{re}, or T_{rum} between E+ and E- animals ($P = 0.11$). T_{rum} - T_{re} difference was also not significant across treatments, with T_{rum} maintained ~1.1°C higher than T_{re}. Both groups increased RR during HS ($P < 0.001$), with E+ steers maintaining the higher rate (89.8 vs 76.7 ± 3.2bpm; $P < 0.01$). Similarly, T_{re} increased for both groups during HS ($P < 0.01$), with E+ animals showing the greatest increase (0.9 vs 0.6 ± 0.1°C; $P < 0.01$). T_{rum} also increased with HS. However, T_{re} showed a much greater rise than T_{rum} (1.0 vs 0.2 ± 0.2°C). T_{rum} - T_{re} difference decreased from TN to HS (1.1 vs 0.6 ± 0.1°C), with large differences between treatments. E+ steers showed a large increase in T_{re} but only a minimal change in T_{rum} during HS for a small T_{rum} - T_{re} difference (0.12 ± 0.1°C). E- animals showed a smaller increase in T_{re} and a similar increase in T_{rum} resulting in a significantly higher T_{rum} - T_{re} value (0.67 ± 0.1°C) than for E+ animals ($P < 0.05$). Consumption of endophyte infected tall fescue seed caused a considerable increase in rectal temperature. Unexpectedly, ruminal temperature showed only a minimal increase which is likely due to a decline in feed intake and an associated reduction in heat production.

Key Words: cattle, heat stress, transmitters

1081 Effect of dietary antioxidants and prepartum cooling on oxidative status and neutrophil function of periparturient Holstein cows during summer in Florida. D. Wang*, J. H. Shin, M. Garcia, J. E. P. Santos, and C. R. Staples, *University of Florida*, *Gainesville*.

The objective of this study was to evaluate the effect of supplementation with 0 or 250 mg of Agrado Plus per kg of dietary DM (Novus International; St. Louis, MO) on oxidative status and neutrophil function of periparturient Holstein cows managed under cooled (C; shade, fans, and sprinklers) or noncooled (NC; shade alone) conditions prepartum. Primiparous (n = 22) and multiparous (n = 13) pregnant Holstein cows were assigned randomly to one of 4 treatments arranged in a 2 × 2 factorial design at 35 d before calculated calving date. Upon calving, all cows were housed in a cooled free-stall barn and remained on assigned diets. Blood was collected at −15, 1, 8, 15, and 29 DIM for oxidative markers. Phagocytosis and oxidative burst of neutrophils were measured in whole blood collected at −15, 0, 7, and 14 DIM. Rectal temperature of cooled cows was lower prepartum (39.2 vs. 39.7C). Mean erythrocyte glutathione peroxidase activity (GPx) corrected for packed cell volume were increased for NC vs. C multiparous cows fed the control diet (8,854 vs. 12,247 nmol/min/mL) but feeding antioxidants reversed this pattern (10,720 vs. 8697 nmol/min/mL); GPx in primiparous cows was not affected by treatments (diet by cooling by parity interaction, $P < 0.05$). Mean plasma concentrations of thiobarbituric acid reactive substances were reduced in NC vs. C cows fed the control diet (1.73 vs. 2.33 nmol/mL) but were unchanged by cooling cows fed antioxidants (1.83 vs. 1.78 nmol/mL). Mean concentrations of superoxide dismutase activity in erythrocytes were not affected by treatments. Cooled cows had fewer lymphocytes (3455 vs. 5411/uL). Mean phagocytosis and mean florescence intensity by neutrophils was increased by cooling multiparous cows (77.5 vs. 72.0% and 37.3 vs. 33.8, respectively) but was decreased by cooling primiparous cows (74.3 vs. 81.0% and 55.4 vs. 68.7, respectively). Cooling prepartum and feeding antioxidants influenced oxidative status and neutrophil function.

Key Words: antioxidant, immunity

1082 Isolation, characterization and antioxidant activity of an exopolysaccharide produced by *Enterobacter cloacae* Z0206. M. L. Jin*[1], Y. M. Wang[1], Z. Q. Lu[1], M. Huang[1], C. L. Xu[2], and Y. Z. Wang[1], [1]*Zhejiang University*, *Hangzhou, China*, [2]*Northwestern Polytechnical University*, *Xi'An, China*.

A water-soluble extracellular polysaccharide (EPS-1) was isolated from the submerged culture broth of *Enterobacter cloacae* Z0206 through fermentation, ethanol precipitation, anion-exchange and gel-permeation chromatography. Its structural characteristics were investigated by chemical analysis, high performance liquid chromatography (HPLC) and Fourier transform infrared (FTIR) spectrophotometer. Bioactivity tests were carried out to investigate the antioxidant activity of EPS-1. 40 ICR (Institute of Cancer Research) male mice (18 ± 2 g) were randomly divided into 4 groups of 10 each. Three immunosuppressed groups were administered with EPS-1 (0, 200 and 400 mg/kg body weight (BW)) by gavage once daily, and cyclophosphamide (CP) was given intraperitoneally at 50 mg/kg BW on the 12th day. Control mice received the same volume of 0.9% normal saline. The experiment lasted for 14 d. Activities of antioxidant enzymes such as glutathione peroxidase (GSH-Px), catalase (CAT) and superoxide dismutase (SOD) in liver were studied. The results indicated that the average molecular weight of EPS-1 was about 23982 Da. It was hypothesized that EPS-1 belongs to the α-type heteropolysaccharide with pyran group, consisting of glucose, mannose and galactose with a molar ratio of 6.860: 1.180: 0.455. CP, as expected, showed suppressive effect on antioxidant status. Compared with CP-treated animals, activities of GSH-Px, CAT and SOD were increased by 22.38% ($P < 0.05$), 16.89% ($P < 0.05$) and 5.67% ($P > 0.05$) respectively, and recovered to the normal levels in animals treated with EPS-1 (400 mg/kg BW). It is suggested that EPS-1 produced by *Enterobacter cloacae* Z0206 could provide protection against CP-induced oxidative damage in mice, and it may act as a potent antioxidant agent.

Key Words: polysaccharide, *Enterobacter cloacae*, antioxidant

1083 Chinese medical plants and extracts moderating effects on antioxidant status of small intestinal mucous and IEC-6 cells under heat stress. K. J. Guo[1,3], X. Z. Song[2], G. L. Cheng[1,3], W. L. Luan[1], F. H. Liu*[1,3], and J. Q. Xu[4], [1]*Department of Animal Science and Technology, Beijing University of Agriculture*, *Beijing, China*, [2]*College of Animal Science and Technology, Jiangxi Agricultural University*, *Nanchang, 330045, P.R. China*, [3]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*, [4]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine, China Agricultural University*, *Beijing, China*.

The aims of the study were to determine: 1. the effects of supplemental Chinese medicine additives on antioxidant status of intestinal mucous in piglets under heat stress; 2. the effects of active components of above studied medicine: *Herba Agastachis* essential oil and *Cortex Phellodendri* alkaloid on antioxidant status of IEC-6 cells after high-temperature treatment. In exp. 1, 16 35-d-old weaned Chinese experimental mini

piglets (6.50 ± 1.05kg) were randomly divided into 4 groups: Normal temperature control group, NTC; High temperature stress group, HTS; High temperature + 0.5% Chinese medicine additives group 1, CMA1 and High temperature + 0.5% Chinese medicine additives group 2, CMA2. NTC pigs were housed under the condition of 23°C and 60% humidity for 10days, while the other 3 groups were housed under the same conditions with NTC but treated with 40°C from 10:00 to 15:00 each day for 10 consecutive days. At the end of experiment, duodenum, jejunum, ileum samples of piglets were collected and SOD, GSH-PX activity, MDA contents of intestinal mucous were determined by kit. In exp. 2, IEC-6 cells were cultured under 37°C for 41 h as control and those under 37°C for 38 h and 41°C for last 3h as experimental group (EG). 200μg/mL, 100μg/mL, 50μg/mL essential oil or alkaloid were added into EG and the contents of SOD, GSH-PX activity, MDA were analyzed. The results showed: (1) Chinese medicine additives could significantly increase SOD ($P < 0.05$), GSH-PX ($P < 0.05$) activity and decrease MDA content ($P < 0.05$) in heat stressed piglets. (2) 200μg/mL essential oil and 100 μg/mL alkaloid significantly increased the levels of SOD ($P < 0.05$) and GSH-Px ($P < 0.05$) and decreased the content of MDA ($P < 0.05$) in IEC-6 cells treated by high temperature. In conclusion, Chinese medicine additives can play important role on improving the antioxidant status of intestinal mucous in piglets. *Cortex Phellodendri* alkaloid and *Herba Agastachis* essential oil are the main effective components.

Key Words: Chinese medical plants and extracts, heat stress, antioxidant function

1084 Immune responses and gene expression in red swamp crayfish (*Procambarus clarkii*), induced by selenium-enriched exopolysaccharide (Se-ECZ-EPS) from *Enterobacter cloacae* Z0206. X. X. Wang*, Z. Q. Lu, Y. F. Zhang, L. N. Zhu, Y. Ren, and Y. Z. Wang, *Feed Science Institute of Zhejiang University*, *Hangzhou city, Zhejiang province, China*.

Selenium-enriched exopolysaccharide (Se-ECZ-EPS), produced by *Enterobacter cloacae* Z0206, is an important polysaccharide but little information is available about the potential crustacean immune response to this compound. To investigate the modulation of immunity in crustaceans, we examined phenoloxidase activity (PO), respiratory bursts ability ($O2^{-1}$) and superoxide dismutase (SOD) levels, as well as expression profiles of several immune-related gene in red swamp crayfish (*Procambarus clarkii*) that were individually injected with Se-ECZ-EPS at 1 μg g^{-1}. The protection of crayfish against white spot syndrome virus (WSSV) by Se-ECZ-EPS was also investigated. During the experiment period, the water temperature was maintained at 22 ± 1°. Duncan's multiple comparison tests were used to compare significant differences among treatments. At 24, 48 and 72h post-injection, PO activities of crayfish in treatment groups were 0.26±0.03, 0.40±0.02 and 0.38±0.03 respectively, and significantly ($P < 0.05$) higher than those of control groups (0.16±0.03, 0.15±0.01 and 0.11±0.01). Respiratory burst levels were 0.74±0.05, 1.21±0.28 and 1.53±0.28 and SOD activities were 34.00±2.52, 43.60±3.41 and 42.00±5.76, respectively at 24, 48 and 72h post-injection, and were significantly($P < 0.05$) higher than those of their respective control groups; 0.61±0.04, 0.61±0.03 and 0.51±0.04 for respiratory burst, and 24.23±2.68, 24.91±2.46 and 24.97±2.98 for SOD activities. Among the examined genes, at 24h and 48h after Se-ECZ-EPS treatment, the mRNA expression of serine proteinase (9.94±1.86 and 2.97±0.69, respectively), HSP70 (9.38±1.91 and 12.96±1.02, respectively) and Mn-SOD (2.72±0.22 and 4.95±0.84, respectively) were significantly up-regulated ($P < 0.05$). No significant expression changes of proPO were observed from 24h to 72h. The survival rate of crayfish that received Se-ECZ-EPS was significantly higher than that of control group after 14 days (59.7% and 0%, respectively). It can be concluded that Se-ECZ-EPS is an efficient immunostimulant and can improve immunity of crayfish.

Key Words: immune responses, exopolysaccharide, *Procambarus clarkii*

1085 C-di-GMP signaling pathways are critical for acid resistance of *E. coli* O157:H7. M. J. Zhu*[1], B. L. Wang[1], W. Yue[1], V. K. Koseoglu[1], H. Wang[1], X. Fang[2], W. J. Means[1], R. J. McCormick[1], and M. Gomelsky[2], [1]*Department of Animal Science*, *Laramie, WY,* [2]*Department of Molecular Biology, University of Wyoming*, *Laramie*.

Surviving the acidic environment of gastrointestinal tract is important for *E. coli* O157:H7 pathogenesis. However, factors contributing to acid resistance remain poorly understood. The second messenger cyclic diguanosine monophosphate, c-di-GMP, affects various aspects of bacterial physiology. To test its role in acid resistance, strain O157:H7 and selected mutants in c-di-GMP metabolism were exposed to pH 3.5 for 15 min. Cell survival and mRNA levels (measured by qRT-PCR) of selected genes involved in c-di-GMP metabolism and acid resistance were analyzed. In the wild type, acid challenge resulted in increased mRNA levels of the newly identified c-di-GMP receptor gene, *ydiV* (7-fold) and the major c-di-GMP phosphodiesterase gene, *yhjH* (13-fold). Deletion of *ydiV* or *yhjH* impaired acid challenge survival by 600 and 35 fold, respectively. Consistent with this observation, expression of several genes responsible for acid resistance, *asr*, *dsbA* and *katP*, were decreased in the *ydiV* and *yhjH* mutants, compared with the wild type. Interestingly, overall expression profiles of the *ydiV* and *yhjH* null mutants were not identical. In the *ydiV* mutant, mRNA levels of *katG* were lower, whereas those of *gad*, *oxyR* and *cysB* were higher, compared with the *yhjH* mutant and wild type. Under neutral pH conditions, expression of all listed genes was not different among tested strains. In conclusion, in *E. coli* O157:H7, (i) acid stress strongly affects expression of genes involved in c-di-GMP metabolism; (ii) c-di-GMP signaling pathways are critically important for acid resistance, and (iii) c-di-GMP apparently affects acid resistance by several pathways.

Key Words: *E. coli* O157: H7, c-di-GMP, acid resistance

1086 Monensin level, supplemental urea, and administration of ractopamine on fecal shedding of *Escherichia coli* O157:H7 in feedlot cattle. Z. D. Paddock*, C. E. Walker, J. S. Drouillard, D. G. Renter, and T. G. Nagaraja, *Kansas State University*, *Manhattan*.

Inclusion of distiller's grains (DG) in cattle diets has been shown to increase fecal shedding *E. coli* O157. Therefore, factors affecting ruminal fermentation of DG may impact fecal shedding of *E. coli* O157. The effect of feeding monensin at the new maximum limit 44 mg/kg of feed on fecal shedding of *E. coli* O157 in cattle has not been determined. The objectives of the study were to evaluate the effects of monensin level (33 or 44 mg/kg DM), supplemental urea (0, 0.35, or 0.70% of DM; administered with the final diet of the step-up program), and ractopamine (0 or 200 mg/steer daily; administered during the last 42 d of the finishing phase) in a steam-flaked corn-based diet containing 30% wet sorghum DG on fecal shedding of *E. coli* O157. Seven-hundred and 20 crossbred beef steers (initial BW 453 ± 23.1 kg), housed in 48 pens (15 steers/pen), were assigned to dietary treatments in a randomized complete block design with a 2 × 3 x 2 factorial treatment arrangement. Fresh pen floor fecal samples (10 per/pen) were collected every 2 wk for 14 wk and cultured for *E. coli* O157. Fecal prevalence data were analyzed with repeated measures negative binomial regression (PROC GENMOD) to examine effects and interactions of sampling day, urea, monensin, and ractopamine. Cumulative fecal prevalence of *E. coli* O157 was 7.6%, and ranged from 1.6 to 23.6%. Cattle fed monensin at 44 mg/kg had lower ($P = 0.05$) *E. coli* O157 prevalence than cattle fed 33 mg/kg (4.3 vs 6.8%). Supplemental urea that could potentially alter ruminal fermentation had no effect on fecal shedding of *E. coli* O157 ($P = 0.87$). The effect of ractopamine was not significant ($P = 0.89$), but the power to detect an effect was low due to low *E. coli* O157 prevalence in the final phase of the study. Additional research is needed to confirm the reduction in fecal shedding of *E. coli* O157 in cattle fed 44 mg/kg monensin and to assess the effect of ractopamine on fecal shedding of *E. coli* O157.

Key Words: *E. coli* O157:H7, distillers grains, monensin

1088 Effect of feeding rumen undegradable intake protein on gut *Campylobacter* concentrations in fed cattle. R. C. Anderson*[1], T. A. Wickersham[2], W. E. Pinchak[3], N. A. Krueger[1], T. R. Callaway[1], T. S. Edrington[1], R. B. Harvey[1], and D. J. Nisbet[1], [1]*USDA/ARS, Southern Plains Agricultural Research Center, Food and Feed Safety Research Unit*, *College Station, Texas,* [2]*Texas A&M University*, *College Station,* [3]*Texas AgriLife Research*, *Vernon*.

Campylobacter are a leading bacterial cause of human foodborne illness worldwide, causing more than 2 million infections in the United States alone. These bacteria readily colonize the gut of food animals, but because they lack 6-phosphofructokinase, they do not ferment sugars and thus must derive a substantial proportion of their energy from amino acid catabolism. To test our hypothesis that diets promoting amino acid flow to the lower gut may increase intestinal carriage of *Campylobacter*, 10 ruminally and duodenally cannulated Angus steers, averaging 431 kg, were adapted (n = 5/diet) to diets formulated to achieve 0 or 30% dried distiller′s grains with solubles (DDG; DM basis). Control steers were maintained on the basal diet containing cracked corn, supplemental fat and cottonseed meal. Steers receiving DDG were adapted via incremental increases (every 14 d) to treatment diet and remained on the 30% WDGS diet for 7 d. Duodenal and fecal samples collected before the start of each step up period (on d 0, 14 and 27) and at the end of the final period (d 33) were enumerated for *Campylobacter* spp. via viable cell count and $\log_{10}$ transformations of resultant bacterial colony forming units (CFU) were analyzed for effects of diet, period and their interaction by a repeated measures ANOVA. Fecal *Campylobacter* concentrations ranged from 1.6 to 3.0 $\log_{10}$ CFU/ml (SEM = 0.5) but did not differ ($P > 0.05$) due to diet, period or their interaction. Similarly, main effects of diet or period were not observed ($P > 0.05$) on duodenal *Campylobacter* counts but in this case a diet × period interaction was observed, due to higher recovery of duodenal *Campylobacter* from the WDGS-fed steers during the 2nd (3.1 $\log_{10}$ CFU/ml) than the 1st or 3rd periods (1.4 and 1.3 $\log_{10}$ CFU/ml, respectively). No other differences in duodenal *Campylobacter* concentrations were observed, with values ranging from 1.6 to 2.3 $\log_{10}$ CFU/ml (SEM = 0.5). These results do not support our hypothesis that diets high in rumen undegradable intake protein will increase proliferation of *Campylobacter* in the bovine gut.

Key Words: *Campylobacter*, distillers grains, pathogen

1089 Development of a broader spectrum phage cocktail to decrease *Salmonella* shedding in livestock. J. Zhang[1], B. L. Kraft[1], Y. Pan[2], S. K. Wall[1], A. C. Saez*[1], and P. D. Ebner[1], [1]*Purdue University*, *West Lafayette, IN*, [2]*Zhejiang University*, *Hangzhou, China*.

Salmonella shedding in many livestock species can increase significantly following transport and lairage. These increases in shedding can

amplify the amount of *Salmonella* that enters the processing facility and the likelihood of end product contamination. We previously produced an anti-*Salmonella* phage cocktail that reduced colonization in swine when the pigs were exposed to an environment heavily contaminated with *Salmonella* similar to what might be seen in a holding pen. The purpose of the current study was to increase the efficacy of the phage treatment by: 1) expanding its spectrum of activity; and 2) developing a more cost-effective microencapsulation technique. We collected samples from wastewater treatment facilities and isolated 20 distinct phages that were lytic against *Salmonella*. From this library we identified 10 phages that lysed *Salmonella enterica* Typhimurium, Enteriditis and Kentucky (3 serovars commonly associated with meat and poultry products). We characterized each phage by morphology and electron microscopy. The phages were microencapsulated using a sodium-alginate based method with or without poly-L-lysine which only reduced the cocktail titer by approximately one log (pre-microencapsulation: 10.4 $\log_{10}$ PFU/mL; post-microencapsulation with poly-L-lysine: 9.2 $\log_{10}$ PFU/mL; post-microencapsulation without poly-L-lysine: 8.9 $\log_{10}$ PFU/mL). Microencapsulated phages remained stable at both 4C and 22C with no appreciable drop in titer for up to 14 d (mean titer: 8.9 $\log_{10}$ PFU/mL). Taken together, these data indicate that multi-valent phage cocktails are easily produced and a cost-effective microencapsulation process adequately protects the phages over an extended period of time. Therefore, it may be possible to simultaneously treat large numbers of animals with phage therapy through feed or water.

Key Words: *Salmonella*, phage therapy, food safety

1090 Use of a biophotonic *E. coli* XEN-14 to determine time of contamination in the life cycle of the house fly, *Musca domestica* Linnaeus (Diptera: Muscidae). G. Schuster*[3], K. E. Moulton[1], P. R. Broadway[4], S. Willard[2], J. Behrends[4], and T. B. Schmidt[1], [1]*Department of Animal, Mississippi State University and Dairy Sciences*, *Mississippi State*, [2]*Department of Biochemistry, Mississippi State University*, *Mississippi State*, [3]*Agronomy, Texas A&M University-Kingsville*, *Kingsville*, [4]*Food Science, Nutrition, and Health Promotion, Mississippi State University*, *Mississippi State*.

Researchers have reported that the house fly (HF), *Musca domestica* Linnaeus (Diptera: Muscidae) is capable of carrying *E. coli* O157:H7, and thus serve as mechanical cross contamination vector. There is limited data identifying when during the life cycle that *E. coli* ingestion occurs. The objective of this trial was to utilize *E. coli* transformed with the XEN-14 gene cassette (BP-E.coli) to monitor the progression of *E. coli* contamination through the life cycle of the HF. HF larvae were incubated in 100-mL cup containing 50-g of sterile manure (72% moisture) inoculated with BP-E.coli at 1×10^4, 10^5, or 10^9 CFU for 24 or 48-h (larva), 7 d (pupae), and 10 d (fly). Post-incubation, larvae, pupae, and flies were imaged intact and macerated to determine uptake of BP-E.coli. After photonic imaging, larvae, pupae, and flies were serially diluted to quantify total CFU's of BP-E.coli ingested. Serial dilution of larvae exposed to BP-E.coli for 24 and 48-h revealed that 86% and 80% of larvae had ingested 3.1×10^5 and 1.9×10^6 CFU of BP-E.coli, respectively. There was no difference ($P > 0.05$) in terms of total CFU ingestion between the 2 incubation periods (24 vs. 48 h) or the inoculation concentration of BP-E.coli for larvae. Serial dilution of pupae 7-d post incubation revealed that 53% of pupae were positive for BP-E.coli (6.9×10^2 CFU), there was no difference ($P > 0.05$) in ingestion of BP-E.coli by pupae between the 3 inoculation concentrations. Serial dilution of adults 10 d post-incubation revealed that 13.8% of adults emerge from the pupae stage contaminated with 3.9×10^2 CFU of BP-E.coli, no difference ($P > 0.05$) in the BP-E.coli retained by the adult between the 3 concentrations. Results of this trial suggest that HF can ingest *E. coli* before pupating and emerging with high concentrations of *E. coli*.

Key Words: *E. coli*, house fly, biophotonic

1091 Effect of crust freezing on the survival of *Escherichia coli* and *Salmonella* Typhimurium in raw poultry products. B. D. Chaves*, I. Y. Han, and P. L. Dawson, *Clemson University*, *Clemson, SC*.

Escherichia coli and *Salmonella* spp. are ubiquitous to the poultry production environment and hence their transmission to poultry products is a concern. Industry has widely used freezing as a strategy to halt pathogen growth and more recently, crust freezing has been claimed to improve operations, quality, and even safety of poultry products. Purpose: To determine the effect of crust freezing and the presence of skin on the survival of *E. coli* and *S.* Typhimurium in raw poultry products. A completely randomized experiment was designed. Ampicillin-resistant *E. coli* JM 109 and nalidixic acid-resistant *S.* Typhimurium were used in the trials. A set of cultures was subjected to cold-shock stress by storage at 4 °C for 10 days. Commercial chicken breasts without skin and chicken thighs with skin were inoculated with each bacterium in separate experiments being either cold-shocked or non-cold-shocked prior to inoculation. Samples were crust frozen at −85 °C for 20 min or completely frozen at −85 °C for 60 min. *E. coli* and *S.* Typhimurium were recovered in duplicated plates of appropriate selective (Violet Red Bile Glucose Agar and BG Sulfa, respectively) and non-selective media (Tryptic Soy Agar) containing the corresponding antibiotic. ANOVA of the log reductions and injury extent values from three replicates were performed. No significant differences ($p>0.05$) were observed in the reduction of cold-shocked or non-cold-shocked bacteria on products that were crust- or completely frozen, with or without skin. Reductions tended to be greater for *S.* Typhimurium than for *E. coli*, although none of the final reductions were greater than the desired target (1 log). Bacterial cell injury was not significantly different ($p>0.05$) among any of the treatments. The treatments did not show practical significance for initial reduction of these pathogens thus freezing nor crust freezing should not be considered strategies for the reduction of these pathogens on poultry. However, additional studies are underway to compare crust freezing to refrigeration for inhibition of bacteria on raw poultry products.

Key Words: crust-freezing, poultry, pathogens

1092 Heating wash water for shell eggs...Is it necessary? S. L. Christian*[1], P. A. Curtis[1], L. K. Kerth[1], M. T. Musgrove[2], and K. E. Anderson[3], [1]*Auburn University*, *Auburn, AL*, [2]*UDSA-ARS*, *Athens, GA*, [3]*North Carolina State University*, *Raleigh*.

Current egg washing regulations state that wash water should be at 32.2°C or higher, shall be at least 6.7°C warmer than the internal temperature of eggs to be washed, and approved cleaning compounds should be used in the wash water (Voluntary Grading of Shell Eggs 7 CFR § 56.76 (f)). These regulations were made when eggs were immersed in water. Studies have shown that immersion washing leads to an increase in microbial load, not the temperature of the wash water. Also, previous research has proven that cool wash water temperatures utilized in an in-line operation did not add to the internal microbial content of the egg. Therefore, the objective of this research was to evaluate the effectiveness of using detergent formulated for cool water in a commercial in-line shell egg processing facility with a temperature of approximately 20°C versus an identical system utilizing a traditional detergent and temperatures. Samples were gathered during normal processing hours over the course of 3 consecutive days and for 3 separate weeks (9

replicates). Egg samples (15 eggs/treatment) were randomly selected from the collector belt before the eggs were washed from both lines and after they were washed but before they reached the packer belt. Eggs were also gathered at the beginning, middle and end of each shift over the course of 2 shifts; therefore, eggs were collected 6 times per day per line (12 treatments total). Water samples (50 mL) were collected from each wash tank at the same time egg samples were taken. Exterior egg shells, egg contents, and wash water samples were evaluated using Aerobic Count Plates and *Enterobacteriaceae* Petrifilms to determine the aerobic microorganisms and Enterobacteriaceae loads. A storage study was also performed in which the eggs were stored at 4°C for 0, 2, 6 and 10 weeks and the microbial load of the exterior egg shells and contents were determined. Cool water washing of shell eggs did prove to be a viable solution for processing shell eggs.

Key Words: shell eggs, cool water, *Enterobacteriaceae*

1093 Multiplication of *Salmonella* Enteritidis in egg yolks after inoculation outside, on, and inside vitelline membranes and storage at different temperatures. R. K. Gast*, R. Guraya, J. Guard, and P. S. Holt, *Egg Safety and Quality Research Unit, USDA-ARS*, *Athens, GA*.

Prompt refrigeration to restrict bacterial growth can reduce the risk of egg-borne transmission of *Salmonella* Enteritidis to consumers. A recently published federal rule for *S*. Enteritidis control requires eggs to be refrigerated within 36 after they are laid, but allows ambient temperature storage until this time. Although the nutrient-rich interior of the yolk is a relatively infrequent location for initial *S*. Enteritidis deposition in naturally contaminated eggs, migration across the vitelline membrane can result in rapid bacterial multiplication inside eggs stored at warm temperatures. The objective of the present study was to measure the multiplication of *S*. Enteritidis in egg yolks after introduction at 3 different locations and subsequent storage at a range of temperatures. Using an in vitro egg contamination model, approximately 100 cfu of a phage type 13a strain of *S*. Enteritidis were inoculated either inside yolks, onto the exterior surface of vitelline membranes, or into the adjacent albumen. After storage of samples from each inoculation group at 10°, 15°, 20°, and 25°C for 24 h, *S*. Enteritidis was enumerated in yolks. For all 3 inoculation locations, the final *S*. Enteritidis levels in yolks increased significantly with increasing storage temperatures. At all storage temperatures, significant differences in *S*. Enteritidis multiplication were observed between inoculation sites (yolk inoculation > vitelline membrane inoculation > albumen inoculation). At 25°C, final $\log_{10}$ *S*. Enteritidis concentrations of 7.76 cfu/ml (yolk inoculation), 2.01 cfu/ml (vitelline membrane inoculation) and 0.76 cfu/ml (albumen inoculation) were attained in yolks after storage. These results demonstrate that, even when the initial site of *S*. Enteritidis deposition is outside the egg yolk, substantial multiplication supported by yolk nutrients can occur during the first day of storage and the risk of bacterial growth increases at higher ambient storage temperatures. This reinforces the value of rapid refrigeration for protecting consumers from egg-transmitted illness.

Key Words: *Salmonella* Enteritidis, eggs, multiplication

91 Genome-wide analysis of cecal gene expression in *Salmonella*-challenged and probiotic-treated neonatal chicks. S. E. Higgins*[1], A. D. Wolfenden[2], G. I. Tellez[2], B. M. Hargis[2], and T. E. Porter[1], [1]*University of Maryland*, *College Park*, [2]*University of Arkansas*, *Fayetteville*.

Salmonella spp. often cause no clinical signs in infected poultry flocks, however, it is the most common food-borne pathogen in human infections. While some probiotics have been proven to be effective for improvement of health and to reduce enteric pathogens of poultry, the mechanisms of action of these beneficial microflora are not completely understood and have been postulated to involve elicitation of innate host defense mechanisms. Presently, we evaluated global gene expression in the cecae of neonatal chicks following *Salmonella* challenge and probiotic treatment to determine gene expression and potential gene networks involved in reduction of *Salmonella* by probiotic treatment. In this study, day-of-hatch chicks were challenged with *Salmonella enterica* ssp. Enteritidis (SE), and treated one h later with a poultry-derived, *Lactobacillus*-based probiotic culture (FloraMax-B11, B11). Twelve and 24h post-treatment, cecae were collected for *Salmonella* detection and RNA isolation. Cecal RNA samples were then analyzed using long oligonucleotide microarrays containing probes for 21,120 genes. At both 12 and 24h, SE was significantly reduced by 4 or 3 $\log_{10}$ respectively in the B11-treated chicks as compared with the challenged chicks ($P < 0.05$). Microarray analysis revealed gene expression differences among all treatment groups. At 12h, 170 genes were expressed at significantly different levels ($P < 0.05$), with a minimum difference in expression of 1.2 fold. At 24h, the number of differentially regulated genes with a minimum 1.2 fold change was 201. Pathway analysis revealed that at both time points, genes associated with the NFκB complex were significantly regulated, as well as genes involved in apoptosis, such as *growth arrest-specific 2* (*GAS2*) and *cysteine-rich, angiogenic inducer, 61* (*CYR61*). Probiotic-induced differential regulation of the genes *GAS2* and *CYR61* may result in increased apoptosis in the cecae of chicks. Because *Salmonella* is an intracellular pathogen, we suggest that increased apoptosis may be a mechanism by which B11 reduces *Salmonella* infection.

Key Words: *Salmonella*, probiotic, microarray

1094 Microbiological difference of eggs from traditional cage and free range production. D. R. Jones*[1], K. E. Anderson[2], and M. T. Musgrove[1], [1]*Egg Safety and Quality Research Unit, USDA-ARS*, *Athens, GA,* [2]*Department of Poultry Science, North Carolina State University*, *Raleigh*.

Eggs from alternative production systems are a growing market share in the US. Meeting consumer requests for greater diversity in retail egg options has resulted in some unique challenges such as understanding the food safety implications of eggs from alternative housing practices. A study was conducted to determine what, if any, differences exist between nest run cage and free range produced eggs. A flock of hatch mate brown egg layers were maintained in traditional caged and free range production with egg and environmental sampling every 6 wks from 20 to 79 wks of age. Aerobic, coliform, and yeast and mold populations were monitored. Traditional caged (TC) egg shells had the highest aerobic levels compared with free range nest box (FRNB) and free range floor eggs (FRF) (3.90, 3.55, and 3.48 log cfu/mL, respectively). FRNB and FRF egg shell coliform levels were greater than TC (1.64, 1.40, and 0.25 log cfu/mL, respectively). FRF egg shell yeast and mold levels were greatest (2.49 log cfu/mL). Range grass (RG) microbial levels were greatest for all populations monitored compared with cage swabs (CS) and nest box swabs (NBS). CS maintained the lowest levels of coliforms and yeast and molds throughout the study but had elevated levels of aerobic bacteria. Seasonal effects were also seen for all monitored populations with summer and fall having the highest levels. Understanding the differences in microbial populations present on traditional cage and free range produced eggs can lead to the development of effective cleaning procedures for free range eggs thus enhancing food safety.

Key Words: egg, cage, free range

Horse Species Symposium: Pathogenic and Reproductive Dysfunction in Horses

1095 Monitoring pathogen progression during uterine infection in the mare using biophotonic imaging technology and *lux*-modified bacteria. P. L. Ryan*, D. L. Christiansen, R. M. Hopper, F. K. Walters, K. Moulton, J. Curbelo, and S. T. Willard, *Mississippi State University*.

Premature birth is the leading cause of prenatal morbidity in humans with an incidence of 12.5% (Berhman, 2006). Moreover, 40% of premature births may be attributed to antenatal infection (Lettieri et al., 1993) of which *Escherichia coli* (*E. coli*) has been identified as the most common organism isolated from pregnant women (Lavanya and Jogalakshmi, 2002). In cattle, the rate of uterine infection has been estimated to be from 2.2 to 37.3% (Kelton et al., 1998) with *E. coli* being the most common isolated bacteria in cows with postpartum uterine infections. Similarly, placental infection due to opportunistic pathogens such as *Streptococcus equi* subspecies *zooepidemicus* and *E. coli* are common causes of abortion, still birth and premature delivery in horses (Giles et al., 1993). Moreover, pathogen progression during uterine infections and placentitis may involve invasion of endometrial and fetal tissues, including the brain, leading to increased pro-inflammatory cytokine expression resulting in onset of premature delivery and/or fetal neurological damage (LeBlanc et al., 2002). However, little is known about bacterial pathogenesis during uterine infections in the equid species. Recently, transgenically modified bacteria transformed with the pAK1-*lux* plasmid have been utilized to better understand pathogen progression in the late-term pregnant ewe and mare. A Peltier cooled slow scan CCD camera and a XR/MEGA-10Z bioluminescence imaging camera were employed in these studies to detect *lux*-expressing bacteria. This presentation will explore the use of biophotonic imaging technology and *lux*-modified bacteria to better understand pathogen progression and invasion during uterine infections in pregnant mares, and rate of pathogen clearance postpartum following therapy. The data will demonstrate that bioluminescence and real-time imaging provide a novel means of understanding pathogenesis of bacterial-induced placentitis and preterm birth in horses. Application of this novel imaging technology with *lux*-modified organisms may facilitate the development of more targeted therapeutic interventions.

Key Words: uterine infection, biophotonic imaging, mare

1096 Contagious equine metritis: An insidious threat to the US horse breeding industry. P. J. Timoney*, *Maxwell H. Gluck Equine Research Center*, *Lexington, KY*.

The objective of this presentation is to assess the significance of contagious equine metritis (CEM) as a threat to the economy of the US horse industry.

CEM has given rise to international concern since it was first recognized as a novel venereal disease of equids in 1977. Initial reports highlighted the dramatic clinical features of the disease and how readily transmissible it was. The etiologic agent was identified as a previously undescribed bacterium, *Taylorella equigenitalis*. International concerns over CEM centered on the ease with which this bacterium could be disseminated, the significance of *Taylorella equigenitalis* as a cause of short-term infertility in the mare and existence of the carrier state in the stallion and the mare. The first known outbreak of CEM in the USA was in Kentucky in 1978. The economic impact on the state′s TB industry was substantial. Prior to 2008, additional small-scale outbreaks occurred in Missouri in 1979, Kentucky in 1982 and Wisconsin in 2006, all traced to the importation of carrier animals. On each occasion, appropriate measures were taken to eliminate the infection, resulting in the US regaining its CEM-free status. With the exception of the 1978 occurrence in Kentucky, none of the subsequent outbreaks impacted significantly on the horse industry. That changed dramatically in 2008 after discovery of a culture positive QH stallion in Kentucky. Subsequent investigations turned up 22 carrier stallions and 5 carrier mares in 8 states. Shipment of infective semen and indirect venereal contact in stallion collection centers were major factors in the spread of *Taylorella equigenitalis*. Trace-back investigations of some 991 exposed and carrier stallions and mares in 48 states have failed to confirm the origin of this latest CEM event. Neither clinical evidence of CEM nor decreased pregnancy rates were reported in infected/exposed mares. In light of these findings, was the considerable expense incurred in investigating the latest CEM occurrence warranted? Only time will tell whether the disease has once again been eradicated from the US and if the cost of regaining CEM-free status was justified.

Key Words: CEM, impact, eradication

1097 Use of fluorescent *in situ* hybridization (fish) to identify endometritis pathogens in the mare. M. R. Petersen*, H. Lehn-Jensen, and A. M. Bojesen, *Faculty of Life Sciences*, *Copenhagen, Denmark*.

Presence of bacteria in the uterus as a cause of infertility was suggested more than 80 years ago. Nielsen, JM 2005 demonstrated that the diagnostic sensitivity and specificity by culture was improved when a endometrial biopsy was used compared with a swab. As *Streptococcus equi* ssp. *zooepidemicus* (*S. zoo*) was isolated more often using a biopsy compared with a swab, we decided to determine location of *S. zoo* within the endometrium. FISH can be used to demonstrate the spatial distribution of bacteria within infected tissue. Endometrial biopsies were analyzed from young non-infected research mares and from broodmares from which S. zoo had been isolated. Experimental infections in research mares with S. zoo were carried out and biopsies recovered at specific time points. Using FISH S. zoo could be localized in endometrial biopsies from mares positive for S. zoo. In the research mares large number of bacteria were localized at the luminal epithelia following inoculation, but no bacteria could be visualized at 96 h. In biopsies from chronically infected broodmares the bacterial localization was markedly different. In all of the biopsies from broodmares S. zoo was localized in distinct foci, either below the epithelial lining, within the endometrial crypts or deep in the stratum compactum, but never at the luminal epithelia as seen in the experimentally infected mares. Since this initial study we have performed FISH to visualize S.Zoo in biopsies from broodmares treated with antibiotics. Streptococci are in general sensitive to the antibiotics used for treatment of endometritis, but treatment failure of chronic cases have been described. Eventhough the mares were treated with antibiotics streptococci could still be visualized deep in the endometrium. Since the general perception has been that endometritis is a superficial infection, treatment has not been focused on bacteria localized deeper in the endometrium. We therefore suggest a treatment regimen for chronically infected mares utilizing antibiotics with a capacity to penetrate cell membranes allowing deep tissue penetration.

Key Words: endometritis, FISH, horse

1098 Chronic equine endometritis: What is missed with traditional diagnostics. M. M. LeBlanc*, *Rood and Riddle Equine Hospital, Lexington, KY*.

Endometritis, a major cause of mare infertility arising from failure to remove bacteria, spermatozoa and inflammatory exudate post-breeding, is often undiagnosed. Defects in genital anatomy, myometrial contractions, lymphatic drainage, mucociliary clearance, cervical function, angiosis (damage to arterioles) or inflamm-aging (increased levels of pro-inflammatory cytokines associated with aging) underlie susceptibility to endometritis. Diagnosis is made through detecting uterine fluid, vaginal discharge, abnormal inter-estrous intervals, inflammatory uterine cytology and positive uterine culture. However, these signs may be absent in gram-negative infections. Hypersecretion of an irritating, watery, neutrophilic exudate underlies classic, easy-to-detect streptococcal endometritis. In contrast, biofilm production, tenacious exudate, and focal infection may characterize chronic endometritis, commonly caused by gram-negative organisms, fungi and staphylococci. Clinical signs of chronic endometritis may include dry, splotchy vaginal mucosa, hyperechoic lines visualized ultrasonographically, or absence of intrauterine fluid during estrus only to appear after ovulation. Gram-negative uterine pathogens can be missed on culture swab while cytological specimens may only contain heavy debris and few, if any, neutrophils. Culture of uterine biopsy tissue, or small volume uterine lavage efflux are twice as sensitive as guarded swabs in detecting gram-negative organisms. Uterine biopsy, a technique that has lost favor in equine veterinary practice, may detect deep inflammatory and degenerative changes, such as angiosis, lymphatic lacunae or destructive fibrosis while endoscopy reveals focal lesions invisible on ultrasound. New treatments designed to improve pregnancy rates in mares with endometritis have been evaluated recently. These include lavage one hour before breeding, cloprostenol post breeding, cervical dilators, intrauterine chelators (tris-EDTA), mucolytics (DMSO, kerosene, n-acetyl-cysteine), corticosteroids (predisolone, dexamethasone) and immunomodulators (cell wall extracts of Mycobacterium phlei and Propionibacterium acnes).

Key Words: equine, endometritis, diagnostics

International Animal Agriculture 1

1099 Challenges for the Mexican animal industry. M. Huerta-Bravo*, R. Núñez-Domínguez, and R. Ramírez-Valverde, *Universidad Autónoma Chapingo*, *Chapingo, México*.

Livestock production challenges have worldwide impact due to globalized economies. The objective is to identify these challenges for the Mexican animal industry and to propose specific tasks for government, producers, and researchers to solve them. Statistical data and information about Mexican livestock was analyzed to identify challenges and define tasks. We must recognize that animals play an important and changing role for humankind since their domestication, and that they are providers of the most nutritive foods. Mexico faces a deficit in most animal products coupled with food consumption pattern favoring health problems such us iron and zinc deficiencies, obesity, and chronic-degenerative diseases. Population growth and income improvement will increase food deficit. Future animal production increases have several challenges: less agricultural land per capita, climate change, high economical and technological dependence on supplies for animal production, food security at risk due to poverty and low food sovereignty, conservation and sustainability of genetic diversity, use of arable land and grains to produce biogas, and low or less federal funds for animal production, research, and technological development. Government tasks include strategies to achieve food security and sovereignty, to provide healthier and nutritive foods from livestock, to increase efficiency of agricultural production systems, to convert animal wastes to products, to restore environment and to increase support for research and development. Producers should recognize that their well-being is a priority but depends on an efficient farm with animal welfare and minimum environmental impact. Researcher's tasks should focus on key elements that insure sustainability of production systems. Human values, faithful application of laws, and efficient administrators are key elements to achieve the well-being of our families.

Key Words: Mexico, animal industry, food security

1100 Effect of varying dietary energy levels during last trimester of pregnancy on the performance of Sahiwal heifers. M. Abdullah*, M. Fiaz, M. E. Babar, J. A. Bhatti, T. N. Pasha, and M. A. Jabbar, *University of Veterinary and Animal Sciences*, *Lahore, Pakistan*.

To study the effect of feeding diets with different energy levels during the last trimester of pregnancy on the performance of Sahiwal heifers, 5-6 mo pregnant Sahiwal heifers (n=16) were assigned to four dietary treatments having 4 heifers on each treatment. Iso-nitrogenous (CP=14.1%) diets having varying energy, viz; A=100% (Control), B=88%, C=112% and D=124% of NRC recommended levels for pregnant heifers were fed to the respective groups until calving. After calving, all heifers were fed a similar diet having CP and energy level as recommended by NRC for lactating animals. Data were analyzed using ANOVA. Pre-calving weight gain was higher ($P \leq 0.05$) in treatment C and D (486 ± 13 and 497 ± 05 g/d, respectively) as compared to A and B. Heifers fed control diet (A) also had greater ADG ($P \leq 0.05$) than those fed diet B (444 ± 07 vs. 397 ± 08 g/d, respectively). A similar trend was observed in feed efficiency. Body condition score at calving in heifers fed diet-D (3.87 ± 0.07) was greater ($P \leq 0.05$) than that of diets A (3.60 ± 0.09) and B (3.50 ± 0.04) whereas it was also greater ($P \leq 0.05$) in heifers fed diet C (3.75 ± 0.03) than that of diet B. Birth weight of calves born from heifers fed different experimental diets did not differ. Daily milk yield in heifers fed control diet was greater (5.87 ± 0.06 kg) than that of other diets, whereas, it was similar among diet C (4.68 ± 0.10 kg) and diet D (4.72 ± 0.14 kg) but lower in diet B (4.2 ± 0.07 kg) as compared to other experimental diets, whereas milk composition among animals fed different experimental diets did not differ ($P \leq 0.05$). The performance of heifers fed only ad libitum green fodder kept under farm management in terms of weight gain (300 ± 0.09 g/d), BCS (3.12 ± 0.12) and milk yield (2.56 ± 0.28 kg/d) was lower than that of those fed experimental diets. It is concluded that feeding extra energy during the last trimester of pregnancy improved weight gain and body condition score but first lactation yield was optimum in heifers fed a diet having an energy level as per recommendations of NRC.

Key Words: dietary energy, milk yield, Sahiwal heifers

1101 Development of the organic beef foodchain in the Mexican tropics—Eight years of experience. P. Fajersson*[1] and P. Parada[2], [1]*Colegio de Postgraduados, Campus Veracruz*, *Veracruz, Veracruz, Mexico*, [2]*Carnes La Rumorosa*, *Poza Rica, Veracruz, Mexico*.

The global organic market, recently a niche market, is currently the fastest growing segment of the mainstream market. Mexico has a law for organic production and also regulations based on the European norms adapted to local conditions. Despite a 25% growth rate of the domestic organic food market during 2009, the products are mainly sold within the captured market, due to inadequate information to consumers and lack of marketing. In the state of Veracruz, a pioneer effort to develop the organic beef food chain, based on a strategic alliance between academia, cattle ranchers and an organic certification agency started in 2002. It was incorporated into The Gulf of Mexico States Accord in order to extend the project regionally. Twenty producers began their organic certification in 2002, guided by the academics and the certification agent. Two producers had previously conditioned their ranches to organic production and in 2003 obtained the certification of their foodchains. Mexico lack political backing of organic agriculture, but even so organic beef producers have managed to achieve a 15% added value to their products. After eight years, technical difficulties and increasing costs of production and postharvest processing have been overcome and the quality of the organic beef is excellent .An upscale restaurant in Veracruz organized a gourmet dinner with 50 invited expert guests, who gave the beef highest marks. The beef is sold to organic markets and stores, some with restaurants, in seven states. Producers have been slow to conclude their certification, which has led to the loss of three important international market opportunities; upscale restaurants and hotels in Scandinavia, Hong Kong and participation in a 12 million dollar beef business in Florida. This due to inability to comply with the quantities required on time. Producers and university students are the principal participants in training courses organized. The state of Chiapas has earmarked ;130 000 dollars for an organic beef project, and in Campeche 130 producers are lined up to begin organic beef projects like the one in Veracruz. In conclusion, the impact of the project is growing steadily, but political endorsement and promotion are required to detonate the organic beef food chain in Mexico.

Key Words: organic beef, tropics, foodchain

1102 Wool comfort factor variation in Australian crossbred sheep. A. E. O. Malau-Aduli* and D. J. Deng Akuoch, *School of Agricultural Science/TIAR, University of Tasmania*, *Hobart, Tasmania 7001, Australia*.

Comfort factor (CF) is defined as the percentage of wool fibers with diameter less than 30 microns. Our objective was to investigate the effects of sire genetics, nutrition, level of supplementation and gender and their interactions on CF in crossbred sheep either grazing or supplemented with dietary protein. Correlations between CF and other wool traits were also investigated. Texel, Coopworth, White Suffolk, East-Friesian and Dorset sires were mated with 500 Merino ewes at a ratio of 1:100 in individual paddocks. Five hundred of the crossbreds were raised on pasture until weaning at 12 weeks of age. Forty of the weaners with initial BW range of 23-31 kg (average of 27 ± 3.2 kg) were fed with lupins or canola at 1 or 2% BW for 6 weeks in a 5 × 2 × 2 × 2 factorial experimental design. CF and other wool quality traits were commercially measured at the Australian Wool Testing Authority. Data were analyzed in SAS using MIXED models procedures with sire fitted as a random effect, whereas sire breed, nutrition, supplement, level of supplementation and gender and their interactions were fitted as fixed effects. We found that neither supplement ($P > 0.14$) nor level of supplementation ($P > 0.16$) influenced CF which did not differ between pasture-fed and supplemented sheep. However, highly significant effects of sire breed ($P < 0.01$), gender ($P < 0.01$) and interactions between sire breed × level of supplementation ($P < 0.01$), sire breed × gender ($P < 0.03$) and supplement × level of supplementation ($P < 0.01$) on CF were detected. White Suffolk crosses had the highest CF (90.1 ± 8.7%) and East-Friesian crosses the least (81.5±10.1%). Males fed canola at 1%BW had the highest CF (90.8 ± 7.0%), while females fed lupins at 1%BW had the least (81.1 ± 10.8). White Suffolk sired males ranked the highest (91.1 ± 10.5%) and East Friesian females the least (74.7 ± 7.9%). CF was significantly correlated with fiber diameter (−0.89), spinning fineness (−0.95) and wool curvature (0.33). Our findings provide useful information to sheep farmers in crossbreeding dual purpose sheep that will also deliver desirable wool comfort outcomes to the fabric industry.

Key Words: wool comfort factor, pasture-fed sheep, protein supplements

1103 Supplementation of Starbio probiotic and yeast on milk production and nutrient digestibility of lactating Holstein cows fed a ration containing cassava meal. E. Sulistyowati*, I. Badarina, and E. Soetrisno, *Animal Science Dept., College of Agriculture, University of Bengkulu (UNIB)*, *Bengkulu, Indonesia*.

The aim of this research was to evaluate the effects of Starbio probiotic and yeast on milk production and nutrient digestibility of lactating Holstein fed a ration containing cassava meal in a rural area farm in Bengkulu, Indonesia. There were eight lactating Holstein Cows which were assigned in a replicated Latin Square (2 × 4 × 4) to receive four treatments: basal diet of 65% field grass and 35% concentrate containing cassava meal, as control (SR0); basal diet + Starbio 1% of concentrate (SR1); basal diet + 20 g yeast (SR2); and basal diet + Starbio 1% of concentrate + 20 g yeast (SR3). The application was run for four 3-wk periods. Yeast supplementation (SR2) increased milk production ($P < 0.05$) for as much as 2.13 kg/d, equivalent to 24.85%. The highest milk fat content (4.10%) was found with the combination of these probiotics (SR3). Nutrient (dry matter, organic matter, crude protein, fiber, and ether extract) consumptions and nutrient digestibility were not different ($P > 0.05$) among treatments. However, digestibilities were relatively high, ranging from 80.93 to 85.55%. The most efficient ratio between dry matter intake and milk production was found in SR2 (1.64). In conclusion, yeast supplementation for as much as 20 g/d into a basal diet with 35% concentrate containing cassava meal resulted in the highest increase in milk production (2.13 kg/d) with slightly lower milk fat (4.05%), combined with the most efficient ratio of milk production and dry matter intake (1.64) in lactating Holstein cows.

Key Words: Starbio, yeast, milk production, nutrient digestibility, Holstein cows

1104 Effects of protease supplementation on growth performance of broilers fed corn-soy-DDGS based diets. F. Yan*[1], L. Garibay[2], J. Arce[2], C. Lopez-Coello[2], D. Camacho[1], M. Vazquez-Anon[1], M. Manangi[1], N. Odetallah[1], and S. Carter[1], [1]*Novus International Inc.*, *St. Charles, MO*, [2]*Universidad Michoacana de San Nicolas de Hidalgo*, *Morelia, Mich, Mexico*.

A floor pen study was conducted to determine the effects of a protease enzyme (CIBENZA DP100, Novus International Inc.) on growth performance of broilers fed corn-soy-DDGS based diets from 1 to 46 d of age. Four treatments in a 2 × 2 factorial arrangement were evaluated with 2 levels of CP (positive control and 7.5% reduction) with or without protease at 0.05%. The positive control diet was formulated with corn soybean meal and 14% DDGS to contain 22%, 21%, and 18.5% CP for starter (1–21 d), grower (22–35 d), and finisher (36–46 d) respectively, and the 7.5% reduction in CP along with the limiting amino acids Lys, Met, and Thr, were achieved primarily through decreasing amount of soybean meal and adjusting supplemental synthetic amino acids. A total of 1400 Ross male broilers were randomly distributed into 28 pens (50 birds per pen) at 1 d of age with 7 pens per treatment. Birds were weighed at 7, 14, 21, 28, 35, and 46 d; feed conversion ratio (FCR), feed intake, and mortality were also determined at each weigh day. Body weights were significantly reduced by lowing dietary CP at 14, 21, 28, 35 and 46 d ($P < 0.05$), and protease supplementation significantly increased body weights at 35 d ($P < 0.05$) regardless of dietary CP levels. A significant interaction was observed between dietary CP and protease for FCR at 14 and 21 d where protease improved FCR when it was added to the diet with the control CP level ($P < 0.05$), but not to the diet with the reduced CP level. At 35 and 46 d of age, protease significantly improved FCR by 5.2 and 4.3 points respectively ($P < 0.05$), irrespective of dietary CP level. Regardless of protease supplementation, reducing dietary CP level increased mortality. In summary, use of a protease in a corn-soy-DDGS based diets improved FCR of broilers throughout the trial, and the effect was independent of dietary CP levels at 35 and 46 d of age.

Key Words: protease enzyme, amino acids, broiler

1105 Effects of a novel phytase on phosphorus digestibility in corn-soybean meal diets fed to weanling and growing pigs. F. N. Almeida* and H. H. Stein, *University of Illinois*, *Urbana*.

Two experiments were conducted to evaluate the effects of a novel bacterial 6-phytase expressed in a strain of *Aspergillus oryzae* (Ronozyme HiPhos, DSM Nutritional Products, Parsippany, NJ) on the apparent total tract digestibility (ATTD) of P in corn-soybean meal diets fed to weanling and growing pigs. In Exp. 1, 6 diets were formulated. The positive control (PC) was a corn-soybean meal diet that contained dicalcium phosphate to bring the total concentration of P to 0.66%. A negative control (NC) diet (0.36% P) without dicalcium phosphate was also formulated. Four additional diets similar to the NC diet were formulated to contain microbial phytase at levels of 500, 1,000, 2,000, or 4,000 phytase units (FYT) per kg. The 48 weanling pigs (initial BW: 13.5 ± 2.45 kg) were placed in metabolism cages and randomly allotted to the 6 dietary treatments in a randomized complete block design. Feces were collected for 5 d. The total P output and the P concentration in feces were reduced (linear, quadratic, $P < 0.01$) as phytase was added to the NC diet. The ATTD of P was greater ($P < 0.01$) for the PC diet (60.5%) than for the NC diet (40.5%) and increased (linear, quadratic, $P < 0.01$) as phytase was added to the NC diet (40.5 vs. 61.6, 65.1, 68.7, and 68.0%). The breakpoint for the ATTD of P (68.4%) was reached at a phytase inclusion level of 1,016 FYT/kg. In Exp. 2, 6 diets were formulated as in Exp. 1. A total of 24 growing pigs (initial BW: 36.2 ± 4.0 kg) were randomly allotted to the 6 dietary treatments in a balanced 2 period changeover design. The total P output and P concentration in feces were reduced (linear, quadratic, $P < 0.01$) as phytase was added to the NC diet. The ATTD of P was greater ($P < 0.01$) for the PC diet (59.4%) than for the NC diet (39.8%) and increased (linear, quadratic, $P < 0.01$) as phytase was added to the NC diet (39.8 vs. 58.1, 65.4, 69.1, and 72.8%). The breakpoint for the ATTD of P (69.1%) was reached at a phytase inclusion level of 801 FYT/kg. Ronozyme HiPhos effectively improved the ATTD of P and reduced P excretion in both weanling and growing pigs.

Key Words: phosphorus, pigs, phytase

1106 Enzyme complex containing NSP-enzymes and phytase improves the growth performance and bone mineralization of piglets fed wheat and barley-based diet. A. Preynat*[1], J. M. Gomez[2], and G. Uzu[1], [1]*Adisseo France SAS*, *92160 Antony, France*, [2]*PRIMEX SAS*, *La Gare de Baud, BP21, F-56440 Languilic, France*.

The experiment was conducted to investigate the benefits of a multi-enzyme complex (Rovabio Max) containing carbohydrolases and phytase activities on the performance and bone mineralization of piglets. A total of 240 weaned 28 d-old piglets (Pietrain x Landrace x Large White) were allocated into 4 experimental treatments (10 replicates per treatment, 6 animals per pen) in a randomized complete block design. The animals were fed according to 2 phases: weaner (28–42d) and starter (43–70d) diets. Diets were formulated as follow: a positive control (PC) diet formulated to be adequate in nutrient and a negative control (NC) diet with a decrease in digestible phosphorus (−1.5 g/kg digP), total calcium (−1.0 g/kg Ca) and net energy (−70 kcal/kg). NC diet was supplemented or not with enzymes at 2 rate of incorporation (0.2 and 0.3 L/t). Bodyweight and feed intake were determined at 28, 42 and 70 d. One femur bone from 10 pigs per treatment was collected for ash content determination at 70 d. During the weaner period, feed to gain ratio of NC groups was degraded compared with PC group ($P < 0.01$). During the starter period, animals fed NC diet had the lowest performances (average daily feed intake (ADFI) and average daily gain (ADG); $P < 0.01$) than PC group. ADFI and ADG were significantly improved irrespective of the level of enzyme supplementation of the NC diets. On total period, ADFI (775, 731, 782 and 771 g/d for PC, NC, NC+0.2 and NC+0.3, respectively; $P < 0.05$), final body weight (31.3, 29.4, 31.3 and 31.1 kg; $P < 0.01$) and ADG (566, 518, 566, 561 g/d; $P < 0.01$) were comparable between NC+enzyme to those observed in the PC group. Moreover, the ash content was fully compensated by enzyme supplementation: 14.7, 11.2, 14.0 and 14.4 g/100g. These results confirm the efficiency of multi-enzyme complex to reduce the digP, Ca and energy specifications of wheat and barley-based diets without performance losses in piglets.

Key Words: NSP-enzymes, phytase, piglets

1107 Effect of dietary calcium concentration and microbial phytase addition on P utilization and growth performance in weaned pigs. A. Narcy[1], M. P. Letourneau Montminy*[2], E. Bouzouagh[1,4], N. Meme[1], M. Magnin[3], and J. Y. Dourmad[4], [1]*INRA UR83*, *Nouzilly, France*, [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, Qc, Canada*,

[3]*BNA Nutrition Animale*, *Chateau-Gontier, France*, [4]*INRA UMR1079 Agrocampus*, *St-Gilles, France*.

The study was conducted to assess the effect of microbial phytase according to various dietary calcium (Ca) concentrations on growth performance, femur characteristics and phosphorus (P) digestive and metabolic utilization in piglets fed with low-P diets (available $P = 0.22\%$). After a 5-d adaptation period on a standard diet, 40 male piglets weaned at 28 d of age (initial BW = 8.7 ± 0.8 kg) were blocked by weight and allotted to one of the 6 dietary treatments in a 29-d experiment. A 3x2 factorial arrangement was used with maize-soybean meal diets formulated to contain combinations of 3 concentrations of Ca: 0.50, 0.75 and 1.00% with or without the addition of 1000 FTU/kg of Natuphos microbial phytase. Increasing dietary Ca concentration linearly reduced ($P < 0.05$) final BW (19.4, 19.1, 18.7kg) and BW gain (406, 396, 379 g/d) whereas feed intake was unaffected by the diet. Phytase significantly improved ($P < 0.001$) femur dry matter, ash weight and ash concentration (9.53, 20.1 and 9.71% respectively). P digestibility increased ($P < 0.001$) in diets supplemented with phytase (55.1 vs. 75.2%) whereas it decreased linearly ($P < 0.001$) when dietary Ca increased (67.4, 65.0, 63.1%). The lack of interaction between dietary Ca concentration and phytase addition indicate that Ca equally depressed P digestibility in diets supplemented or not with phytase. As a result, Ca did not modify the release of phytate-P by phytase. However, in piglets receiving diets with phytase, P urinary losses increased 13-fold when Ca was reduced from 1.0 to 0.5% (CaxPhytase, $P < 0.001$) while P retention was reduced by 8.3% (CaxPhytase, $P < 0.01$). These results suggest that although decreasing dietary Ca concentration can ameliorate P digestibility, it may also cause an imbalance between metabolic Ca and P that leads to extra P urinary losses and impairs P retention.

Key Words: calcium, phytase, piglet

1108 The role of sodium in the physiological response of growing broilers to phytate and phytase. A. J. Cowieson*[1], M. R. Bedford[1], P. H. Selle[3], and V. Ravindran[2], [1]*AB Vista*, *Marlborough, Wiltshire, UK*, [2]*Massey University*, *Palmerston North, New Zealand*, [3]*University of Sydney*, *Sydney, New South Wales, Australia*.

A total of 240 Ross 308 broilers were used to investigate the effect of sodium (0.15 or 0.25%), phytate-P (0 or 0.32%) and phytase (0 or 500FTU/kg; 2 × 2 × 2 factorial) on endogenous amino acid flow using the enzyme-hydrolyzed casein method. The ingestion of phytate increased endogenous amino acid flow (~30%; $P < 0.001$) compared with the phytate-free control diets. Phytase reduced endogenous amino acid flow only when fed in concert with phytate resulting in a significant phytate × phytase interaction. Instructively increasing dietary sodium concentration from 0.15% to 0.25% reduced ($P < 0.001$) endogenous amino acid flow by around 10%. This blunting of endogenous flow was particularly evident in diets which contained phytate, resulting in a significant sodium × phytate interaction for several amino acids including Thr and Ser. Further, high sodium concentrations muted the effect of phytase resulting in a significant sodium × phytase interaction for some amino acids. Three-way interactions were rare. The concentration of Asp, Thr, Ser and some other amino acids was increased in the endogenous protein in response to the ingestion of phytate. Both sodium and phytase essentially restored the composition of endogenous protein to that of the phytate-free control. Further, as both sodium and phytase had similar effects there were significant interactions between sodium and phytase for most amino acids, such that one was only effective in the absence of the other. These data confirm previous reports that phytate is a nutritional aggressor causing quantitative and qualitative changes in endogenous protein flow. However, this is the first report which has shown that dietary sodium concentrations play a role in the severity of this antinutritional effect and consequently may blunt the efficacy of exogenous phytase. The mechanism is obscure though it has been previously demonstrated that sodium can disrupt phytate:protein complexes, thus mitigating one of the mechanisms by which phytate exerts its antinutritional effect.

Key Words: phytate, phytase, sodium

1109 Effect of a thermo-tolerant xylanase on performance in broilers fed diets with different energy and amino acid densities. C. L. Wyatt*[1], T. J. Walsh[1], M. R. Bedford[1], A. J. Cowieson[1], and S. Davis[2], [1]*AB Vista*, *Chapel Hill, NC*, [2]*Colorado Quality Research Inc.*, *Wellington, CO*.

A total of 1632 Ross 708 male broilers were used to investigate the effect of feeding a thermo-tolerant xylanase (XYL; ECONASE XT) in pelleted diets with different energy and amino acid densities on performance and carcass yield to d49. All diets contained Quantum Phytase. This was a 2 by 2 by 2 factorial design with 2 energy (HiE; LoE −96 kcals/kg), 2 AA (HiAA; LoAA −15%) and 2 XYL levels (0 or 100g/mt) fed with 12 reps/trt containing 17 birds/pen. Significant main effects for dietary energy and XYL ($P < 0.10$) were found for FCR but not bwt gain. Significant interactions were found for AA by XYL, and E by AA by XYL ($P < 0.10$) for FCR. Birds fed HiE and HiAA diets containing XYL had 5 pts better FCR compared with birds fed the LoE and LoAA diets with XYL. There were no significant effects on bwt gain and mortality. Percent breast yield and % hot carcass were significantly improved with the HiAA diets compared with the LoAA diets but there was no effect of dietary E or XYL. There was an interaction between dietary E x AA for yield with birds fed HiAA and LoE diets having better % yield compared with birds fed the LoAA and LoE diets. The data would support previous findings from our holo-analysis that there are several key dietary factors impacting the response to feeding XYL in a corn based diet on FCR with a significant improvement in high density diets.

Key Words: xylanase, broilers, dietary energy

1110 Additions of glucanase, xylanase and phytase to low-energy low-lysine diets for broilers including canola meal and DDGS as alternative ingredients. S. Gómez*[1,2] and M. L. Angeles[1], [1]*INIFAP*, *Ajuchitlán, Colón, Qro, México*, [2]*FESC-UNAM*, *Ajuchitlán, Colón, Qro. México*.

An experiment was carried out to evaluate the productivity, ileal digestibility of nutrients and villi morphology of broilers fed diets based on sorghum and soybean meal (SSBM) including canola meal (CM) and DDGS and added with glucanase, xylanase and phytase enzymes. One hundred and 20 Ross B308 males, individually fed, from 35 to 49 d were assigned to 6 dietary treatments: 1) SSBM diet including 10% CM and 8% DDGS containing 3218 kcal of ME and 0.91% digestible Lys, 2) SSBM, 10% CM, 8% DDGS low-energy (2900 kcal of ME/kg) low-Lys (0.82%) diet, 3) As 2, added with 300 ppm glucanase (Ronozyme VP), 4) As 2) added with 300 ppm of xylanase (Ronozyme WX), 5) As 2) added with 150 ppm of glucanase and 150 ppm of xylanase, and 6) As 5) plus 150 ppm of phytase (Ronozyme-P (CT); Ca and available P were also adjusted in this diet. The daily weight gain was lower and feed conversion ratio was higher ($P < 0.05$) for broilers fed diet 2) with no added enzymes compared with broilers fed diet 1); these variables were partially recovered with added glucanase and xylanase and almost fully recovered when glucanase, xylanase and phytase were combined (Diet 6). The ileal digestibility of dry matter, ashes and nitrogen were lower ($P < 0.05$) for diet 2) compared with diet 1), and

were improved for glucanase, xylanase and glucanase-xylanase added diets. The greatest ashes digestibility was for the glucanase, xylanase and phytase added diet (6) and there was a trend for greater dry matter and nitrogen ileal digestibility in broilers fed the enzyme combination. The height, thickness and area of the villi were reduced in diet 2 ($P < 0.05$), but were totally recovered when the enzymes were combined. In the duodenum, maltase and sacarase specific activities were increased ($P < 0.05$) when enzymes were combined. In summary, the addition of glucanase, xylanase and phytase to low-energy, low-Lys diets including canola meal and DDGS improved the growth, nutrient digestibilities, villi morphology and endogenous enzymes activities in the duodenum of broiler chickens.

Key Words: broilers, enzymes, growth

1111 Allzyme SSF increased AME_n of the corn-soy diet and improved performance of boilers. T. Ao*, J. L. Pierce, B. Hoskins, M. Paul, A. J. Pescatore, A. H. Cantor, M. J. Ford, and W. D. King, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington, KY*.

Allzyme SSF is a naturally fermented product with activities of multiple enzymes such as carbohydrase and phytase. A study was conducted to investigate the effect of supplementing Allzyme SSF on AME_n and retention of P and DM of the diets and growth performance of broiler chicks in a 21d period. Dietary treatments included: 1) corn-soy reference diet containing 3150 kcal ME_n /kg and 0.45% nonphytate P; 2) corn-soy low P and ME diet containing 3000 kcal ME_n /kg and 0.25% nonphytate P; 3) diet 2 + 200 g Allzyme SSF /MT diet; 4) diet 2 + 400 g Allzyme SSF /MT diet. A total of 192 1-d old chicks were randomly assigned to 4 dietary treatments with 8 replicate groups of 6 chicks per treatment. Chicks were housed in starter cages in an environmentally controlled room with an ad libitum access to feed and water. Celite (acid-insoluble ash) was used as an internal marker with an inclusion rate of 1% for the assay of AME_n and retention of P and DM on d 20 by using 24h fecal collection. Chicks fed the low P and ME diet had lower ($P < 0.01$) weight gain and higher ($P < 0.01$) feed to gain ratio compared with other treatment groups. Dietary supplementation of Allzyme SSF in low nutrient diet at both levels increased ($P < 0.01$) weight gain and decreased ($P < 0.01$) feed to gain ratio of chicks. AME_n of the low nutrient diet was increased ($P < 0.01$) by supplementing Allzyme SSF at both levels. The retention of P and DM was significantly increased by supplementing 400 g/MT Allzyme SSF. Data from this trial indicate that supplementation of Allzyme SSF in corn-soy diet can improve the performance of broiler chicks by increasing AME_n value and retention of P and DM of the diet.

Key Words: AME_n, broiler, Allzyme SSF

1112 Effects of multiple dietary manipulations on the mass balance of N and P during the swine finishing phase. T. Walraven*, S. Carter, J. Jarret, M. Bible, and H. Kim, *Oklahoma State University*, *Stillwater*.

Eighty-eight crossbred (D × (L × Y)) pigs (32 kg BW) were used to evaluate the effects of reducing dietary CP, Ca, and P with the addition of phytase on the mass balance of N and P during a 94-d finishing period. Pigs were stratified by sex, weight, ancestry, and randomly allotted to 1 of 2 dietary treatments. Pigs were housed in an environmentally controlled building with 4 identical rooms (22 pigs/room, 2 rooms/treatment). Dietary treatments consisted of a fortified corn-soybean meal diet and a Reduced Excretion (REx) diet. REx had a 3.0% unit reduction in CP with Lys, Thr, and Met added as needed and a reduction of available P of 0.10% with phytase inclusion. Also, in the REx diet, monocalcium phosphate replaced dicalcium phosphate and CaCl replaced 50% of $CaCO_3$. Diets were formulated to similar SID lysine. The estimation of mass balance, on a per pig basis, assumed that N and P entered the finisher via the feed and pigs, and exited via the slurry, exhaust air, and pigs. On d 0 and 94, 6 and 24 pigs (6/room), respectively, were ground to estimate initial and final body composition. Feed intake and composition were used to estimate N and P entering via feed. Slurry volume and composition, and NH_3-N emission were used to estimate N and P exiting via slurry and air. The amount of N and P entering via pigs was similar ($P > 0.10$). However, N (5.4 vs. 4.5 kg) and P (1.0 vs. 0.81 kg) in the feed were reduced ($P < 0.03$) for the REx diet. Thus, REx reduced total N (6.4 vs. 5.4 kg; $P < 0.08$) and P (1.2 vs. 0.98 kg; $P < 0.04$) entering by 15 and 20%, respectively. REx did not affect ($P > 0.10$) the amount of N and P exiting via the pigs. However, N (3.2 vs. 2.3 kg) and P (0.64 vs. 0.40 kg) exiting via slurry and NH_3-N (0.27 vs. 0.15 kg) in exhaust air were reduced ($P < 0.05$) for pigs fed REx. Thus, REx reduced total N and P exiting by 16 and 20%, respectfully. The proportion of N and P entering the finisher that exited via the pigs increased from 47 to 55% for N and 49 to 60% for P for pigs fed REx compared with those fed the control diet.

Key Words: pig, nutrient, mass balance

1113 Predicting variations in total and phytic phosphorus in raw materials of plant origin. C. Gady*[1], S. Virden[2], and P. A. Geraert[1], [1]*Adisseo SAS*, *Antony, France*, [2]*Adisseo USA Inc.*, *Alpharetta, GA*.

The assessment of phosphorus value of ingredients contributes to the optimization of phosphorus nutrition and reduction of phosphorus release into the environment. The main objectives of this study were to measure phytic phosphorus (phytic P) in relation to the total phosphorus (total P) in a range of ingredients and to investigate the prediction of those variations by near infrared spectroscopy (NIRS). A total of 227 samples mainly representing cereals, cereals by-products, oilseeds and oil meals were collected worldwide during one year. All samples were analyzed for their concentrations in total and phytic P using mineralization and enzymatic methods respectively. Additionally, using NIRS, these samples were also analyzed for their absorbances from 1100 to 2500 nm. For all the analyzed samples, prediction models were then calculated to determine correlation between absorbances to both total and phytic P, using mPLS regression. Due to the wide range of ingredients studied, results showed that phytic P content represents from 18% (cassava) to 83% (rice bran) of the total P content. There were also large variations intra-species in the ratio phytic P/total P (and corresponding concentrations in phytic P in % as fed) which ranged from 64 to 87% (0.14-0.30) in corns, from 64 to 80% (0.16-0.27) in wheats, from 66 to 95% (0.54-0.98) in rapeseed meals and from 59 to 69% (0.36-0.57%) in soybean meals. Prediction models developed using NIRS explained 93 and 92% of the variations measured in total and phytic P with standard error of 0.05 and 0.04%. When comparing nonphytic phosphorus calculated from chemistry vs. NIRS of samples external to database, we confirmed differences by 0.01, 0.02, 0.07 and 0.02% as fed for corn, wheat, rapeseed meals and soybean meals respectively. This study confirmed the need for better qualifying major ingredients for their nonphytic phosphorus contribution to feed formulation. With respect to the range measured among ingredients, the feasibility study using NIRS showed that the tool may contribute to better mastering those variations.

Key Words: total phosphorus, phytic phosphorus, near infrared reflectance spectroscopy

1114 A heat-tolerant β-mannanase: Its biochemical properties and effect on broiler growth performance. H. Y. Hsiao*, D. M. Anderson, L. Liu, and M. E. Jackson, *ChemGen Corp.*, *211 Perry Parkway, Gaithersburg, MD*.

β-Mannanase from *Bacillus lentus* has been shown to improve broiler growth performance and body weight uniformity as well as reduce circulating acute phase protein levels when fed a diet containing soybean meal. Due to its sensitivity to heat, the application of β-mannanase to pelleted feed is limited to spraying liquid enzyme post-pelleting; therefore, improved thermal tolerance would greatly expand its application. Recently, a heat-tolerant β-mannanase (HT) from *Bacillus lentus* is selected and its biochemical properties are described here. The heat tolerance of β-mannanase-HT in a dry formulation was evaluated at the feed mill of Kansas State University. β-Mannanase-HT is shown to have retained 95% and 90% activity when conditioned at 88°C (190°F) with 30 and 60 s of residence time, respectively. β-Mannanase-HT was also found to retain 60% of its activity after incubation under simulated conditions of the gizzard (pH 3.0, 40°C for 60 min with the presence of 2.8 mg/ml pepsin) and intestine (pH 6.7, 40°C for 120 min with the presence of 1.8 mg/ml pancreatin), consecutively. This result, along with the fact that the pH optimal of β-mannanase-HT is 6.5, suggests that β-mannanase-HT might remain active for a longer duration in a bird's digestive tract. A 42-d male broiler (Cobb × Cobb) trial was conducted to determine the dosage effect of β-mannanase-HT. The testing diet was a typical corn and soybean meal-based diet. Two thousand chicks were allocated in a randomized complete block design to five treatments, with 8 pens per treatment. The mortality and weight adjusted feed conversion (WAFC) of birds supplemented with β-mannanase–HT at four different levels of 22, 44, 66 and 88 MU/ton of feed were determined to be 1.784, 1.770, 1772 and 1.765, respectively; each of the enzyme groups was significantly better than the WAFC of the Control group at 1.927(linear, $P < 0.05$). It can be concluded that a newly developed form of β-mannanase is heat stable and efficacious in raising broilers.

Key Words: heat-tolerant, β-mannanase, broiler

Nonruminant Nutrition Symposium: Nutrient and Non-Nutrient Sensing and Signaling in the Gastrointestinal Tract

1115 Bitter taste receptors and gastrointestinal chemosensing. C. Sternini*[1], H. E. Raybould[2], L. M. Rinaman[3], and E. Rozegurt[1], [1]*UCLA, School of Medicine*, *Los Angeles, CA,* [2]*UC Davis, School of Veterinary Medicine*, *David, CA,* [3]*University of Pittsburgh*, *Pittsburgh, PA*.

Bitter taste has evolved as a warning signal against the ingestion of toxins, playing a crucial role in survival. The gastrointestinal (GI) lumen lining is exposed to nutrients and non-nutrients and might use the same mechanisms mediating oral taste signaling to detect harmful substances. This is supported by the discovery that signaling molecules transmitting bitter taste in the tongue are expressed in the GI mucosa, including the bitter taste receptors family, T2Rs, and the heterotrimeric G-protein subunits, α-gustducin (αGust) and α-transducin (αTrans). We identified transcripts for T2Rs, αGust and αTrans in the mammalian GI mucosa and in enteroendocrine STC-1 cell line, by RT-PCR. We showed that αGust and αTrans immunoreactivities (IR) are localized to set of enteroendocrine cells producing CCK, GLP1, PYY or ghrelin, peptides involve in food intake and GI function. T2R138-IR, the phenylthiocarbamide receptor, is also localized to GI epithelial cells. Intragastric administration of T2R agonists in rodents activates neurons in the brainstem via a vagal pathway. Selective T2R agonists inhibit food intake when administered intragastrically and induce conditioned flavor avoidance as measured with the 2-bottle choice paradigm, suggesting that GI T2Rs represent a second line of defense in the lumen. T2R agonists induce increase in intracellular calcium and CCK release in STC-1 cells and intraluminal T2R ligands significantly increased pCAMKII-IR, a marker of cell activation, in duodenal CCK cells and in the nodose ganglia. This suggests that T2R activation of enteroendocrine cells release CCK and activate vagal neurons. Overall, these findings support the concept that the GI mucosa lining is equipped with a chemosensory machinery for the detection of harmful substances, including food-borne toxins, drugs, and bacteria. We propose that activation of GI T2Rs by toxins induces a cascade of events triggering intracellular calcium increase and release of signaling molecules from enteroendocrine cells that in turn activate neuronal pathways responsible for initiating a protective response to guard the body from environmental hazards.

Key Words: enteroendocrine cells, vagal afferents

1116 T1R-mediated taste transduction mechanisms. S. C. Kinnamon*, *University of Colorado Denver*, *Aurora*.

Taste buds in the oral cavity are the chemosensory end organs that guard the entrance to the alimentary canal. Each taste bud comprises approximately 50–100 individual taste cells that detect the chemicals that elicit the sweet, salty, sour, bitter, and umami (glutamate) taste qualities. During the past decade, considerable progress has been made in identifying the receptors involved in the transduction of each taste quality. Ion channels are involved in the detection of salts and acids, while G protein coupled receptors (GPCRs) and second messengers mediate the transduction of bitter, sweet, and umami taste stimuli. Two classes of GPCRs have been identified, the T2R bitter receptors and the T1R receptors for sweet and umami stimuli. Three T1Rs have been identified, T1R1, T1R2, and T1R3. T1R3 combines with T1R1 (T1R1/T1R3) to bind glutamate and 5′-ribonucleotides, while T1R3 combines with T1R2 (T1R2/T1R3) to bind sugars, synthetic sweeteners, and sweet proteins. These receptors share similar downstream signaling effectors. The canonical transduction pathway involves Gβγ activation of PLCβ2, production of the second messengers IP3 and diacylglycerol, release of Ca^{2+} from intracellular stores, and Ca^{2+}-dependent activation of a monovalent-selective cation channel, TRPM5. These events lead to membrane depolarization and release of ATP as a transmitter to activate gustatory afferent nerve fibers. Genetic knockout of PLCβ2, IP3R3, and TRPM5 each severely compromises both sweet and umami taste responses, validating their central role in the transduction process. The Gα that mediates sweet and umami transduction is Gα-gustducin, which activates PDE to decrease intracellular cAMP. Although the exact role of cAMP in transduction is not clear, gustducin knockout mice have reduced responses to both sweet and umami stimuli. My lab has shown recently that α-gustducin knockout mice have elevated cAMP levels in taste buds, suggesting that gustducin is tonically active in the absence of taste stimuli. We suggest that α-gustducin tonically activates PDE to keep cAMP levels low and prevent chronic adaptation to taste stimuli.

Key Words: gustducin, T1R3, TRPM5

1117 Gut sensors for spices and odorants. T. Braun[1], P. Voland[2], L. Kunz[1], C. Prinz[2], and M. Gratzl*[1], [1]*Institute of Anatomy, Ludwig Maximilian University Munich*, *Munich, Germany*, [2]*II. Med. Dept., Technical University Munich*, *Munich, Germany*.

Enterochromaffin cells release serotonin in response to mechanical stimulation or in response to certain nutrients in the lumen of the intestine. The secreted serotonin then stimulates sensory components of the enteric nervous system, ultimately controlling gut peristalsis as well as water and chloride transport by enterocytes. Microarray gene chip data suggested that enterochromaffin cells might express olfactory G-protein-coupled receptors that are typically found in the nose. Laser capture-microdissected human intestinal enterochromaffin cells and a cell line derived from human enterochromaffin cells were found to express the same 4 olfactory receptor genes by RT-PCR: OR73, hOR17–7/11, OR1G1, and hOR17–210. Thymol, which binds to OR1G1, is a component of thyme spice. Thymol triggers a transient rise in intracellular calcium and a dose-dependent increase in serotonin release, whereas phenol does not. Other odorant ligands showed similar responses: eugenol and isoeugenol (binds OR73), methylsalicylate (receptor unknown), geraniol (binds hOR17–7/11 and OR1G1), bourgeonal (binds hOR17–7/11 and hOR17–4), and helional (binds hOR17–7/11 and hOR17–40) increased intracellular calcium, and stimulated serotonin release by exocytosis. Our study indicated that enterochromaffin cells express olfactory receptors that may be stimulated by odorant ligands in the intestinal lumen to release serotonin. The results suggest that luminal odorants may influence gut motility and secretion.

1118 Amino acid sensing in the gut epithelium. D. G. Burrin* and B. Stoll, *USDA Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

Amino acids are elemental substrates for cellular protein synthesis in the body. Amino acids are present in the diet and absorbed across the intestinal epithelium into the portal blood by a family of transport proteins that are specific for different structural properties of amino acids. Our previous work has shown that dietary amino acids are also extensively metabolized by the gut epithelium and in the case of glutamate, used as a major oxidative fuel. However, recent evidence shows that amino acids are more than just nutrients or metabolic substrates, but also functions as signaling molecules in intestinal physiology and cell metabolism. The recent discovery of novel proteins reveals the molecular mechanism of

how gut epithelial cells "taste" or recognize specific amino acids. One such group of proteins is the taste receptors, which is a small family of 3 G-protein-coupled receptors (T1R1, T1R2 and T1R3) that form heterodimeric complexes that bind glutamate and sugars. Another more well known group of proteins, the metabotropic glutamate receptors are also expressed throughout the gastrointestinal tract. Both the taste and metabotropic receptors are localized on epithelial, endocrine and neuronal cells and when activated stimulate signal processes that are involved in gastric emptying, secretion and insulin release. Dietary glutamate increases vagal afferent nerve activity in the brain and is blocked by cholinergic inhibitors suggesting that these processes are mediated via extrinsic nerve pathways. Arginine is an amino acid that is conditionally essential in the neonate and can be extensively metabolized in the intestine. Recent studies suggest that arginine specifically stimulates protein synthesis in intestinal epithelial cells via activation of mammalian target of rapamycin (mTOR) and downstream signaling targets, p70S6 kinase and 4EBP-1. The mechanism whereby arginine activates mTOR does not involve production of nitric oxide, a key signaling product of arginine metabolism. The presentation will discuss these 2 examples of amino acid sensing mechanisms in the gut and the implications for animal growth and development.

Key Words: glutamate, arginine, enteroendocrine cells

1119 Nutrient sensors expressed in gut enteroendocrine cells regulate nutrient-responsive secretion of satiety hormones. S. Shirazi-Beechey*, K. Daly, A. Moran, and J. Dyer, *University of Liverpool*, *Liverpool, UK*.

The gastrointestinal (GI) tract is a sensory organ that responds to signals arising in its lumen. Intestinal nutrient sensing plays an important role in controlling GI function including regulation of gastric emptying, gut motility and nutrient absorption. In addition, molecular events in the lumen of the GI tract induce satiety hormone release from enteroendocrine cells that lead to activation of systemic, hormonal and/or neural pathways involved in the regulation of food intake and appetite. I shall describe mechanisms by which the intestinal epithelium senses nutrients i.e., sugars and short chain fatty acids resulting in secretion of gut hormones that regulate nutrient absorption and food intake. We showed that the sweet taste receptor (T1r2 + T1r3) and its coupled G-protein, gustducin, are expressed in intestinal enteroendocrine cells and act as the intestinal glucose sensor. We then demonstrated that dietary sugars and artificial sweeteners increase expression of intestinal glucose absorptive capacity in wild type mice, but not in T1r3 or gustducin knockout mice. In addition it has been shown that these knockout mice have deficiencies in secretion of glucagon-like peptide 1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP) in response to orally ingested carbohydrate, or when glucose was directly administrated into the intestinal lumen. Such data indicate that sweet taste receptor in intestinal enteroendocrine cell detects extracellular sugar and then responds with secretion of gut hormones. It is proposed that dietary fiber can increase GLP-1 release providing potential mechanisms for the stimulation of satiety and suppression of hunger. Dietary fiber is fermented in the large intestine to short chain fatty acids, acetate, propionate and butyrate. It has been shown that GPR41, and GPR43 may act as the SCFA sensor. Work in our laboratory has shown that these GPRs are expressed in the large intestinal endocrine cells. Furthermore exposure of L-type enteroendocrine cells to either SCFA or a compound known to specifically activate GPR43 results in secretion of GLP-1.

Key Words: nutrient sensing, intestine, GLP-1

1120 Effect of artificial sweeteners on the expression of swine intestinal Na^+/glucose co-transporter 1, SGLT1. A. Moran*[1], D. Batchelor[1], C. Ionescu[2], D. Bravo[2], and S. Shirazi-Beechey[1], [1]*University of Liverpool*, *Liverpool, UK*, [2]*Pancosma*, *Geneva, Switzerland*.

A shorter suckling period in piglets leads to several disorders including nutrient malabsorption, diarrhea, malnutrition and dehydration. We have shown that a low concentration of a combination of artificial sweeteners, saccharin and neohesperidin dihydrochalcone (Sucram) included in piglets' diets enhances the expression of intestinal SGLT1 and the gut capacity to absorb glucose. We determined previously that the sweet taste receptor comprised of T1R2+T1R3 is expressed in intestinal enteroendocrine cells and that dietary sugars and artificial sweeteners act in the intestine, on the sweet taste receptor, and its coupled G-protein gustducin, to elicit upregulation of SGLT1. Our studies in mouse intestine showed that only those artificial sweeteners that activated mouse lingual epithelium sweet taste receptor led to upregulation of intestinal SGLT1. Aim: to determine effects of sucralose, cyclamate, aspartame and acesulfame K (aceK) on intestinal SGLT1 expression. Five groups of 28 d old piglets (n = 8 per group) were weaned onto a commercial diet lacking any artificial sweeteners, with their drinking water containing either no sweetener, sucralose (2 mM), cyclamate (10 mM), aspartame (1 mM) or aceK (10 mM). All consumed the same amount of food and water. Subsequently, they were sacrificed by euthanasia under ethical permission. SGLT1 expression was assessed at levels of mRNA, protein and function. Results: there was a 2.73- ($P = 0.003$), 3- ($P < 0.0001$) and 2.8- ($P = 0.0005$) fold increase in SGLT1 expression in response to inclusion of sucralose, cyclamate and aspartame in the drinking water respectively compared with that in the control. AceK had no effect on SGLT1 expression. Results indicate that intestinal sweet taste perception in pig is different to some other species. These are due to sequential differences in amino acid residues of sensor proteins interacting with artificial sweeteners, the knowledge of which is essential for designing species-specific sweeteners. The data also highlight the potential of using other artificial sweeteners, having assessed the lowest effective concentrations, as food supplements.

Key Words: SGLT1, artificial sweetener, piglet's diet

Physiology and Endocrinology: Feed Intake, Metabolism and Maternal Nutrition

1121 Expression of neuropeptide Y and its receptors as affected by nutrition and leptin infusion in Zebu heifers. J. Diniz-Magalhães, M. V. Carvalho, A. B. S. Machado, R. A. Ribeiro, and L. F. P. Silva*, *Universidade de São Paulo*, *Pirassununga, SP, Brazil*.

Leptin has been proposed to act via NPY in the hypothalamus to modulate the effect of nutrition on sexual maturation. The objective was to evaluate the effect of oLeptin infusion and of high or low energy intake on the expression of neuropeptide Y (NPY), and 2 NPY receptors, NPY-Y1 and NPY-Y2. Thirty 6 prepubertal Nelore heifers, 18 to 20 mo-old, 275.8 ± 17.2kg BW and BCS of 5 ± 0.5 (1 to 9 scale) were randomly assigned to each of 3 treatments (n = 12): H (high energy diet), L (low energy diet), and LL (low energy diet + oLeptin). Diets were formulated to promote weight gain of 0.4 kg/day (groups L and LL) or 1.2 kg/day (H group). Heifers were fed ad libitum once a day, they were weighed and had their BCS evaluated twice weekly. After 21 d of adjustment, heifers in LL group received subcutaneous injections of oLeptin at 4.8µg/kg BW twice a day, for 56 d. Groups H and L received similar injections of 2mL saline solution. Age at puberty was considered to be the age on first detection of a corpus luteum by twice weekly transrectal ultrasonography, confirmed by plasma concentrations of progesterone of >1ng/ml. Twenty 4 heifers were slaughtered at the time of puberty for harvesting of the hypothalamus. Total RNA was extracted with Trizol, treated with DNaseI and reverse transcribed to cDNA. Expression of transcripts of NPY, NPY-Y1 and NPY-Y4 was quantified by real-time PCR. Changes in gene expression were calculated by relative quantification with the ΔΔCt method, using the gene ribosomal protein L-19 as the reference gene. There was no effect of leptin administration on expression of NPY ($P = 0.70$), NPY-Y1 ($P = 0.72$) and NPY-Y4 ($P = 0.96$) at the time of puberty. However, high energy intake reduced expression of NPY-Y1 ($P = 0.02$), without affecting expression of the other 2 genes. Downregulation of NPY-Y1 could indicate lower sensibility of the hypothalamus to NPY action. NPY is a well known inhibitor of puberty therefore this result indicates that a reduction in NPY-Y1 expression could permit attainment of puberty at a younger age in Zebu heifers.

Key Words: *Bos indicus*, hypothalamus, puberty

1122 Blocking µ-opioid receptors alters short-term feed intake and oro-sensorial preferences of weaned calves. C. Montoro*[1], I. Ipharraguerre[2], and A. Bach[1,3], [1]*Ruminant Production, IRTA*, *Caldes de Montbui, Barcelona, Spain*, [2]*LUCTA S.A.*, *Barcelona, Spain*, [3]*ICREA*, *Barcelona, Spain*.

In rats and humans, opioids play a role in controlling short-term regulation of feed intake through oro-sensorial reward mechanisms. Thirty-four Holstein calves (BW = 86.5 ± 1.73kg, age = 77 ± 0.6 d) were housed in individual pens and submitted to 4 treatments to determine whether naloxone, a µ-opioid receptor antagonist, affects feed intake and oro-sensorial preferences in weaned calves. The study was conducted in 2 periods with 17 animals per period. Treatments followed a 2 × 2 factorial arrangement combining a fasted (FA) or fed (FE) state with an i.v. injection of saline (0.9% NaCl) solution (S) or naloxone (1 mg/kg of BW; N). Each factor combination involved 8 animals, except FA-S and FE-N which had 9 calves. All calves were offered a double choice of the same feed unflavored or flavored with a sweetener (Luctarom SFS-R, Lucta) *ad libitum*. Feed consumption was recorded every 60 min during 6 h (from 0800 to 1400) following the morning feed offer. Data were log-transformed and analyzed using a mixed-effects model with repeated measures. Calves in the FE-N group tended ($P = 0.10$) to consume less concentrate (3.97 ± 0.398 log g/h) than FE-S (4.86 ± 0.422 log g/h), FA-N (5.30 ± 0.422 log g/h), and FA-S (5.07 ± 0.398 log g/h). Furthermore, S calves showed a preference for the sweetened feed ($P < 0.05$) whereas N calves did not show any preference (Table 1). These data suggest that µ-opioid receptors are involved in short-term feed intake regulation by mediating oro-sensorial feed preferences and may interact with energy-mediated mechanisms in regulating the amount of feed consumed.

Table 1. Feed consumption rate (log of g/h) as affected by treatments

Treatment	Unflavored concentrate	Sweetened concentrate	P-value
FA-S	4.78±0.417	5.36±0.42	0.02
FA-N	5.31±0.442	5.29±0.44	0.93
FE-S	4.36±0.442	5.36±0.44	<0.001
FE-N	4.14±0.417	3.79±0.42	0.15

Key Words: taste, intake, regulation

1123 Evidence that nesfatin-1 is a satiety factor in the pig and that the hypothalamus controls its expression in adipose tissue. C. A. Lents*[1], C. R. Barb[2], G. J. Hausman[2], L. Lee-Rutherford[2], C. J. Rogers[1], N. L. Heidorn[1], R. S. Cisse[1], and M. J. Azain[1], [1]*University of Georgia*, *Athens,* [2]*USDA-ARS Richard B. Russell Agriculture Research Center*, *Athens, GA*.

Two experiments (Exp) were conducted to test if nesfatin-1 is part of the adipose tissue-hypothalamic loop regulating appetite and energy balance of the pig. In Exp 1, prepuberal gilts were adapted to a twice-daily feeding schedule (0800 and 1600 h) and received intracerebroventricular (i.c.v.) injection of 100 µg of either recombinant human leptin or nesfatin-1 (nearly equal mass to leptin) in 0.9% saline. Control animals received 0.9% saline alone (n = 4/group). Four hours after i.c.v. injection, feeders were placed in all pens (1600 h) for determination of cumulative intake at 4, 20, 44, and 68 h after feed presentation. Food consumption of nesfatin-1 treated pigs was suppressed ($P < 0.01$) during the first 20 h compared with saline controls (0.54 ± 0.3 and 3.15 ± 0.3 kg, respectively), but was not different from leptin-treated pigs (1.04 ± 0.3 kg). Although food intake of nesfatin-1 and leptin-treated pigs was increasing ($P < 0.05$) after 20 h, it was still less ($P < 0.001$) at 68 h than that observed for saline-treated pigs (4.04, 4.50 and 8.76 ± 0.31 kg for nesfatin-1, leptin and saline, respectively). Subcutaneous (SC) adipose in the pig is innervated by hypothalamic neurons that are sensitive to secreted adipokines. Nesfatin-1 is proposed to work through the melanocortin 3/4 receptor (MC3/4R) pathway, which when activated alters gene expression in fat. In Exp II, gilts received i.c.v. injection of 10 µg of the MC3/4R agonist NDP-MSH or 0.9% saline alone (n = 9/group). Pigs were sacrificed 24 h later and SC adipose tissue was collected for isolation of RNA. Abundance of mRNA for nesfatin was quantified with real-time RT-PCR. Relative differences in expression were calculated by the REST procedure with 18S rRNA as the reference control. mRNA for nesfatin in SC adipose tissue of NDP-MSH treated pigs was reduced 1.7 fold ($P = 0.05$) compared with saline-treated pigs. We conclude that nesfatin-1 is a satiety factor in the pig and that activation of the MC3/4R pathway suppresses expression of nesfatin-1, which may be mediated by sympathetic neuronal outflow to adipose tissue.

Key Words: nesfatin-1, feed intake, swine

1124 Endocannabinoid and PPARα signaling gene network expression in liver of peripartal cows fed two levels of dietary energy prepartum. M. J. Khan*, D. E. Graugnard, and J. J. Loor, *University of Illinois*, *Urbana.*

Fatty acid ethanolamides (FAE) have anorexic and anti-inflammatory properties and are endogenous ligands for cannabinoid receptors subtype 1 (CNR1) or 2 (CNR2). Some FAE mediate peripheral metabolic effects in non-ruminants through the activation of PPARα. Because of the potential for endogenous FAE to mediate inflammation and satiety at the level of the liver, we sought to establish the longitudinal mRNA expression of *CNR1*, *CNR2*, *PPARA*, *FAAH*, *ASAH*, several PPARα targets (*CPT1A*, *ANGPTL4*, *FGF21*), and *RXRA* in cows (n = 14/diet) assigned to a control (high-straw, S; NEL = 1.34 Mcal/kg) or moderate-energy (ME; NEL = 1.62 Mcal/kg) diet during the dry period and until parturition. A percutaneous liver biopsy was collected at −14, 7, 14, and 30 d relative to parturition for transcript profiling via quantitative PCR. Normalized/log-transformed data were analyzed using ANOVA. Estimated prepartal energy balance (EBAL) in cows fed ME was greater ($P < 0.05$) and averaged 159% of requirements compared with 102% in cows fed S. However, EBAL during the first week postpartum tended ($P = 0.10$) to be lower in cows fed ME (83% vs. 89% of requirements) which had greater ($P = 0.06$) serum NEFA (560 vs. 351 mEq/L). *CNR2* expression remained high (diet × time $P < 0.05$) with ME by d 7 after which it decreased to levels similar to cows fed S. Following a decrease from −14 to 7 d, *PPARA* and RXRA increased ($P < 0.05$) gradually through 14 d regardless of diet. However, cows fed ME had overall greater ($P < 0.05$) *RXRA*. The PPARα targets *ANGPTL4* (3-fold) and FGF21 (20-fold) increased dramatically between −14 and 7 d in cows fed ME (diet × time $P < 0.05$). Thereafter, expression of both genes declined and reached lowest levels at 30 d regardless of prepartal diet. Whereas *CPT1A* decreased between −14 and 7 d and then reached peak expression by 30 d with S, expression increased gradually between −14 and 14 d with ME (diet × time $P < 0.05$). Preliminary results revealed a potential role of negative EBAL and high NEFA induced by prepartal energy overfeeding on endocannabinoid signaling and PPARα activation.

Key Words: metabolism, inflammation, transition cow

1125 Endoplasmic reticulum (ER) stress gene network expression in liver of peripartal cows fed two levels of dietary energy prepartum. M. J. Khan*, D. E. Graugnard, and J. J. Loor, *University of Illinois*, *Urbana*.

X-box binding protein 1 (XBP1) is a key regulator of the mammalian unfolded protein response or ER stress response. We examined expression of genes associated with the ER stress response in cows assigned (14/diet) to a control (high-straw, S; NEL = 1.34 Mcal/kg) or moderate-energy (ME; NEL = 1.62 Mcal/kg) diet prepartum and until parturition. A percutaneous liver biopsy was collected at −14, 7, 14, and 30 d relative to parturition for transcript profiling via quantitative PCR. Normalized/log-transformed data were analyzed by ANOVA. Estimated prepartal energy balance (EBAL) in cows fed ME was greater ($P < 0.05$) and averaged 159% of requirements compared with 102% in cows fed S. However, EBAL during the first week postpartum tended ($P = 0.10$) to be lower in cows fed Me (83% vs. 89% of requirements) which had greater ($P = 0.06$) serum NEFA (560 vs. 351 mEq/L). *XBP1* was 185% greater at −14 d in cows fed S and increased 24% by d 7 postpartum (diet × day $P < 0.05$) after which it decreased close to prepartal levels by 14 d but still was 93% greater in cows fed S vs. ME. There was a diet × time effect ($P < 0.05$) for the expression of *EIF2AK3*, a kinase induced by ER stress leading to a halt of translation, due to a decrease between −14 and 7 d in cows fed S which also had greater (25%) *EIF2AK3* at −14 d. *EIF2AK3* returned to prepartal levels by 14 through 30 d. The stress-induced transcription factor DDIT3 decreased ($P < 0.05$) between −14 and 7 d regardless of prepartal diet after which it remained below prepartal values. Expression of stearoyl-CoA desaturase (*SCD*), whose downregulation in rodent liver leads to robust ER stress, was lower at −14 d with S but increased by 4-fold at 7 d leading to a diet × time effect ($P < 0.05$). There was no change in *SCD* between −14 and 7 d in cows fed ME, but expression increased gradually to peak values at 30 d. Despite differences in EBAL and NEFA postpartum, preliminary results indicated moderate effects of prepartal energy level on ER stress at calving potentially driven the by marked upregulation of *SCD* postpartum.

Key Words: transition cow, metabolism, transcriptomics

1126 Effects of a hyperinsulemic euglycemic clamp administered during heat stress or pair feeding on plasma ghrelin concentrations of lactating dairy cattle. S. E. Cossel*, M. E. Field, M. V. Skrzypek, S. R. Sanders, L. H. Baumgard, R. P. Rhoads, and M. L. Rhoads, *University of Arizona*, *Tucson*.

The objective of this study was to measure the effects of a hyperinsulinemic euglycemic clamp (HEC) on plasma ghrelin (GHR) concentrations during heat stress (HS) or pair feeding (PF). Lactating Holstein dairy cows (n = 11; 136 ± 8 DIM; 560 ± 32 kg BW) were housed in environmentally controlled chambers and assigned to 1 of 2 treatment groups. During period 1 (9 d), both groups were maintained in thermal neutral (TN) conditions (18°C; 20% RH) and fed ad libitum. During period 2 (9 d), cows were exposed to: 1) HS (n = 6; cyclical temperatures; 31.1–38.9°C; 20% RH) with ad libitum feed or 2) TN conditions while being PF to match the intake of the HS cows (n = 5). On d 8 of each period, 7 control (CON) blood samples were collected at 30-min intervals for each group. On d 9 of each period, a HEC was conducted and 7 blood samples were collected at 30-min intervals beginning 240 min after the administration of an insulin bolus. Rectal temperatures (RT) and respiration rates (RR) increased during the HS period compared with the TN period (39.7 ± 0.1 vs. 38.3 ± 0.1°C; $P < 0.01$ and 90 ± 2 vs. 38 ± 2; $P < 0.01$, respectively), while DMI decreased (15.1 ± 0.4 vs. 19.75 ± 0.4 kg; $P < 0.01$). The RT and RR of PF animals did not differ from TN conditions, while DMI decreased as designed. Plasma GHR concentrations were not affected by HS or PF alone (CON-HS or CON-PF vs. CON-TN concentrations). Likewise, mean plasma GHR concentrations in CON samples were similar to those from the HEC during the TN and HS treatments. In contrast to the HS group, PF cows had lower mean plasma GHR concentrations during the HEC compared with CON (187.2 ± 53.9 vs. 336.6 ± 53.9 pg/mL, respectively; $P < 0.01$). During the HEC of both the HS and PF treatments, plasma GHR concentrations increased from the beginning to the end of the sampling period ($P < 0.03$ and $P < 0.01$, respectively). Thus, regardless of similar feed intake, profiles of plasma GHR concentrations differed between PF and HS cows.

Key Words: ghrelin, dairy, glucose

1127 Effects of heat stress on insulin action in lactating Holstein cows. M. V. Skrzypek*[1], R. P. Rhoads[1], S. R. Sanders[1], K. Flann[1], L. Cole[1], J. W. Perfield[2], M. R. Waldron[2], and L. H. Baumgard[3], [1]*University of Arizona*, *Tucson,* [2]*University of Missouri*, *Columbia,* [3]*Iowa State University*, *Ames*.

Multiparous cows (n = 12; parity = 2; 136 ± 8 DIM, 560 ± 32 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn and subjected to 2 experimental periods

(P): 1) thermoneutral (TN) conditions (18°C, 20% humidity) with ad libitum intake for 9d and 2) heat-stress (HS) conditions (cyclical temperature 31.1–38.9°C, 20% humidity: min THI = 73, max THI = 80.5) and ad libitum intake (n = 6) or pair-fed (PF in TN conditions, n = 6) for 9d. Rectal temperature (Tr) and respiration rate (RR) were measured thrice daily at 0430, 1200 and 1630h. To evaluate insulin sensitivity, an 8-h hyperinsulinemic-euglycemic clamp (HEC) was performed on d9 of P1 and P2. The HEC was a primed, continuous infusion of bovine insulin (3.8 μg/kg BW/h followed by 2 μg/kg BW/h) and euglycemia maintained by varying intrajugular exogenous glucose infusion rates. During P2, HS cows had ($P < 0.01$) a 1.48°C increase in Tr and a 2.4-fold increase in RR compared with PF cows. HS reduced ($P < 0.01$) DMI by 8 kg/d and by design PF cows had similar intake reductions. Milk yield was decreased similarly (30%) in HS and PF cows and both groups entered into a similar (−4.5 Mcal/d) calculated negative energy balance during P2. Compared with P1 ($P < 0.05$), basal glucose levels increased (5%) in PF cows but decreased (5%) in HS cows. Basal NEFA levels increased (34%, $P < 0.01$) in PF cows compared with P1, but did not change from P1 to P2 in HS cows. The HEC increased ($P < 0.01$) plasma insulin levels similarly for both treatments during both periods (0.6 vs. 5.9 ng/ml). The overall rate of glucose infusion (ROI) to maintain euglycemia during the HEC did not differ between treatments, but was markedly reduced (29%; $P < 0.01$) during P2. Compared with P1, the ratio of ROI to basal glucose concentration decreased (21%; $P < 0.01$) in PF cows, but did not differ in HS cows during P2. Because a comparable ROI was needed to maintain a smaller blood glucose pool in HS cows, the HEC data imply HS cows have greater glucose disposal as a result of enhanced insulin action.

Key Words: heat stress, insulin

1128 The effect of insulin glargine on the metabolism of lactating Holstein cows. L. A. Winkelman*, D. M. Barbano, M. E. Van Amburgh, and T. R. Overton, *Cornell University*, *Ithaca, NY*.

Two studies were conducted to determine the effects of an insulin analog, insulin glargine (SRI) (Lantus , Sanofi-Aventis), on metabolism of lactating Holstein cows. In study one, 16 multiparous cows (213 ± 10 DIM) were divided into 2 groups and randomly assigned to one of 4 treatments (control, 0.1 IU SRI/kg BW (L), 0.2 IU/kg BW (M), and 0.4 IU/kg BW (H)). Subcutaneous (SQ) injections of SRI or water were given at 0900 h. Cows were fed hourly and milked at 1500, 2300, and 0700 h. Blood samples were taken hourly via jugular catheter for 24 h after treatment injections. Administration of increasing doses of SRI resulted in a linear ($P = 0.004$) decrease in plasma glucose (66.0, 62.3, 61.0, 54.1 mg/dl glucose for control, L, M, and H doses, respectively). Endogenous insulin secretion decreased linearly ($P = 0.028$) with SRI dose (1.04, 0.88, 0.79, 0.64 ng/ml for control, L, M, and H doses, respectively). In study 2, 3 multiparous cows (101 ± 22 DIM) fitted with indwelling intercostal arterial and mammary vein catheters were used to determine effects of SRI in a 2-period crossover design. Periods lasted 4 d with a 2 d washout in between periods. In period one, 2 cows received 0.15 IU/kg BW of SRI, 2x/d at 12-h intervals, while the remaining cow was a control. Treatments were reversed in period 2. On d 4 of each period, simultaneous blood samples were taken from the arterial and venous catheters hourly for 12 h. Dry matter intake, milk yield, and all major milk components, except lactose, were not different ($P > 0.10$). Lactose content ($P = 0.094$) and yield ($P = 0.091$) were higher for the control treatment. Casein content and yield did not differ between treatments ($P > 0.10$), but whey content ($P = 0.012$) and yield ($P = 0.015$) were higher for SRI. Arterial and venous glucose were lower ($P < 0.10$) for SRI (arterial: 63.1, 56.9 mg/dl for control vs. SRI, respectively; venous: 45.4, and 40.7 mg/dl for control vs. SRI, respectively). Based on these studies, insulin glargine is able to lower plasma glucose across different doses and its effect on milk protein composition warrants further research.

Key Words: insulin, glucose

1129 The effects of maternal obesity and overnutrition on ovine fetal adipose tissue lipid composition. N. M. Long*[1,2], D. C. Rule[2], P. W. Nathanielsz[3], and S. P. Ford[1,2], [1]*Center for the Study of Fetal Programming*, *University of Wyoming, Laramie,* [2]*Department of Animal Science*, *University of Wyoming, Laramie,* [3]*Department of Obstetrics and Gynecology*, *University of Texas Health Sciences Center, San Antonio*.

The effects of maternal obesity and overnutrition on fetal adiposity and adipose tissue composition were evaluated. Multiparous ewes were allotted by BW and age and fed either 100% of NRC recommendations (Control; C) or 150% of NRC (Obese; OB) from d 60 before conception until necropsy on d 135 of gestation. Fetal body weights and fetal adipose depot weights were recorded. Fatty acid (FA) composition of perirenal, pericardial, and subcutaneous (SC) adipose tissue of 7 male twin fetuses per group was determined by GLC. Data were analyzed using the GLM procedure of SAS. Fetal BW tended to be reduced ($P = 0.08$), and eviscerated weight (EFW) was lower ($P = 0.05$) for fetuses from OB than C ewes (4.78 ± 0.23 vs. 5.40 ± 0.25 kg and 3.56 ± 0.18 vs. 4.12 ± 0.18 kg, respectively). Pericardial and perirenal adipose tissue weight as a % of EFW was greater ($P < 0.05$) in fetuses from OB than C ewes (0.195 ± 0.001 vs. 0.191 ± 0.001%; 0.81 ± 0.01 vs. 0.68 ± 0.01%, respectively). 12th rib fat thickness was greater ($P < 0.01$) in fetuses from OB than C ewes (0.9 ± 0.1 vs. 0.5 ± 0.1 mm). Total FA concentrations were greater ($P < 0.01$) in the perirenal adipose tissue of OB fetuses than C fetuses (913.4 ± 29.8 vs. 731.6 ± 29.8 mg/g tissue). Concentrations of 18:0, 18:1 c-9 and 18:1 c10/c11 in perirenal adipose tissue were greater ($P < 0.05$) in fetuses from OB than C ewes. Only 18:1 c-9 was greater ($P < 0.05$) in pericardial adipose tissue of fetuses from OB than C ewes. Total FA in SC adipose tissue tended to be greater ($P = 0.09$) in fetuses from OB than C ewes (114.5 ± 24.9 vs. 50.0 ± 24.9 mg/g tissue). Concentrations of 16:0, 18:1 c-9, and 20:4 n-6 were greater ($P < 0.03$) in SC adipose tissue from fetuses of OB than C ewes. Maternal obesity resulted in greater fetal adiposity and altered FA composition of adipose tissue in late gestation which could lead to permanent alteration in adipose tissue function.

Key Words: maternal obesity, fatty acid composition, adipose tissue

1130 Influence of metabolizable protein supplementation during late gestation on vasoreactivity of maternal and fetal placental arteries in sheep. L. A. Lekatz*[1], M. L. Van Emon[2], P. K. Shukla[3], S. T. O'Rourke[3], C. S. Schauer[2], K. M. Carlin[1], and K. A. Vonnahme[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University*, *Fargo,* [2]*Hettinger Research Extension Center, North Dakota State University*, *Hettinger,* [3]*Department of Pharmaceutical Sciences, North Dakota State University*, *Fargo*.

To examine the effects of metabolizable protein (MP) intake during late gestation on the vasoreactivity of placental arteries, 18 pregnant ewes received 100% (CON), 75% (LOW), or 125% (HIGH) of MP requirement from d 100 to 130 of gestation. On d 130, several caruncular (CAR) and cotyledonary (COT) arteries from placentomes of similar size and in close proximity to the umbilicus were selected for vasoreactivity studies. Arterial rings were suspended in organ chambers filled with 25 mL of physiological salt solution aerated with a mixture

of 95% O_2 and 5% CO_2 and kept at 38.6°C. Optimal tension was found by progressively stretching the rings until the contractile response to KCl (20 mM) was maximal. The presence or absence of endothelium was verified by testing the ability of bradykinin (BK; 10^{-7} M) to produce endothelium-dependent relaxation during contraction evoked by norepinephrine (10^{-6} M). Contractile dose response curves (DRC) were obtained by contracting with increasing concentrations of KCl and phenylephrine (PE). Rings were contracted with U46619 (10^{-8} M) and the DRC to either BK or sodium nitroprusside (SNP) was obtained in endothelium intact and endothelium removed rings, respectively. There was no effect on the KCl DRC in CAR arteries ($P \geq 0.36$). KCl exhibited a treatment × dose interaction in COT arteries where arteries from CON and LOW ewes were more ($P = 0.01$) sensitive to KCl compared with arteries from HIGH ewes. There was no effect of PE in CAR or COT ($P \geq 0.12$) arteries. There was no effect on either BK or SNP in CAR ($P \geq 0.56$) arteries. The COT arteries from CON and LOW ewes tended ($P = 0.09$) to be more sensitive to BK compared with arteries from HIGH ewes; however, there was no effect of SNP in these arteries ($P = 0.87$). This indicates that BK-induced vasodilation in COT arteries cannot solely be explained by a nitric oxide donor. Perhaps the vasodilator action of BK is through downstream affects of an endothelial derived hyperpolarizing factor and/or prostacyclin. Further analyses are needed to determine how protein supplementation impacts vascular function in the placenta.

1131 Maternal nutrient restriction (NR) upregulates phosphoenolpyruvate carboxykinase (PEPCK) expression in the livers of aged female offspring. L. Zhang*[1], Y. Ma[1], N. Tuersunjiang[1], L. A. George[1], S. P. Ford[1], and P. W. Nathanielsz[2], [1]*Center for the Study of Fetal Programming*, *Univ. of Wyoming, Laramie,* [2]*Center for Pregnancy and Newborn Research*, *Univ. of Texas Health Sciences Center, San Antonio*.

Undernutrition often occurs in pregnant ruminants under range conditions. Maternal NR during pregnancy is linked to offspring insulin resistance and metabolic disease. In 2003, ewes carrying singleton fetuses were fed a control (C, 100% NRC recommendations) or NR (50% NRC) diet from 28 to 78d of gestation. After d78, all ewes were fed 100% NRC until lambing. C and NR lambs were managed together and assigned to this study in 2009, when female offspring of NR (n = 4) and C (n = 4) ewes were subjected to ad lib feeding for 12 wks. As previously reported (George et al., Ann. Mtg. Soc. Gynecol. Invest, 2010, abstract), feed efficiency, weight gain, glucose clearance and insulin resistance were greater ($P < 0.05$) in ewes from NR dams. After the feeding trial, ewes were necropsied, the liver quickly removed and tissue from the left lobe frozen in liquid nitrogen. Protein and mRNA expression of PEPCK and glucose-6-phosphatase (G6Pase) were quantified via Western blotting and Real-time PCR. Additional liver tissue was placed in a tissue cassette, fixed with paraformaldehyde and paraffin embedded for immunohistochemistry. Both mRNA and protein expression of PEPCK were elevated ($P < 0.05$) in NR vs C ewe offspring (4.6 ± 0.9 vs 1.9 ± 0.6 and 0.8 ± 0.1 vs 0.5 ± 0.1 arbitrary units, respectively). In contrast, no differences were observed between C and NR groups in G6Pase at the mRNA or protein levels (2.1 ± 0.7 vs 2.2 ± 0.3 and 0.6 ± 0.1 vs 0.6 ± 0.03 arbitrary units, respectively). PEPCK and G6Pase binding was localized to the cytoplasm of hepatic cells. Enhanced gluconeogenesis was associated with the greater glucose clearance index, weight gain and feed efficiency in these aged NR offspring during ad lib feeding. Further, lower insulin sensitivity in NR offspring may impair suppression of hepatic gluconeogenesis, fitting with the upregulation of PEPCK observed in this study.

Key Words: maternal undernutrition, aged offspring, liver glucoconeogenesis

1132 Maternal nutrient restriction (NR) from early to mid-gestation increases pancreatic β-cell number at mid-gestation but pancreatic weight and β-cell numbers are reduced by late-gestation. L Zhang*[1], L. A. George[1], S. P. Ford[1], and P. W. Nathanielsz[2], [1]*Center for the Study of Fetal Programming*, *Univ. of Wyoming, Laramie,* [2]*Center for Pregnancy and Newborn Research*, *Univ. of Texas Health Sciences Center, San Antonio*.

Both maternal obesity (MO) and NR are associated with increased rates of obesity and diabetes in offspring. We reported that MO in ewes results in increased fetal pancreatic β-cell numbers at mid-gestation, but reduced β-cell numbers by late gestation. Here we compare these data to a sheep model of early to midgestation maternal NR. Multiparous ewes were assigned to a control group (C, 100% NRC recommendations) or an NR group (50% NRC) from 28 to 78 d of gestation (dG). A subgroup of ewes was necropsied on 78 dG (C = 5, NR = 5), and the rest (C = 5, NR = 5) were fed 100% NRC from 78 to 135 dG and necropsied. A fetal blood sample was collected for insulin quantitation, and the fetal pancreas weighed and the splenic end paraffin embedded for determination of β-cell numbers per unit area. At 78 dG, NR fetal weight was lower ($P < 0.05$) than C fetuses (230.7 ± 10.3 vs. 312.0 ± 22.6 g). While no difference was observed in pancreatic weight on 78 dG, β-cell numbers per unit area islet tissue, were increased ($P < 0.05$) in NR versus C fetuses (134.9 ± 11.4 vs. 89.8 ± 9.9). No treatment difference in fetal weight was observed on d135 which averaged 4034.1 g, however, pancreatic weights of d135 NR fetuses were lower ($P < 0.05$) than those from C fetuses (2.8 ± 0.2 vs. 3.8 ± 0.3 g). The β-cell numbers were also markedly decreased ($P < 0.01$) in d135 fetuses from NR versus C ewes (113.3 ± 4.7 vs. 187.3 ± 19.3). Blood insulin levels from all d78 fetuses were below assay sensitivity, whereas on 135 dG concentrations were lower ($P = 0.07$) in fetuses from NR versus C ewes (1.8 ± 0.2 vs. 4.8 ± 1.4 mIU/L). These results suggest that maternal NR from early to midgestation, like MO, initial increased pancreatic growth and β-cell numbers, but lead to reductions in pancreatic growth and β-cell numbers by late gestation, possibly leading to pancreatic dysfunction in postnatal life.

Key Words: maternal nutrient restriction, fetal pancreatic development, sheep

1133 Effects of supplementing transition cow diets with different levels of dietary glycerol on performance, efficiency, and blood metabolites. J. Boyd*[2], J. Bernard[1], and J. West[1], [1]*The University of Georgia*, *Tifton,* [2]*US Dairy Forage Research Center*, *Madison, WI.*

A study was conducted to determine the effects of dietary glycerol on dry matter intake (DMI), milk yield and components, blood metabolites, and efficiency in the transition cow. The study was conducted from Feb. to Oct. of 2008 using 48 cows (25 primiparous and 23 multiparous). The study ran from 3wk prepartum to 8wk postpartum with a randomized block design using a 2 × 2 factorial. Treatments were prepartum control and postpartum control (CC); prepartum control and postpartum 400g/h/d glycerol (CG); prepartum 200g/h/d glycerol and postpartum control (GC); prepartum 200g/h/d glycerol and postpartum 400g/h/d glycerol (GG). Cows were assigned to treatment by previous or predicted production values, parity, and estimated calving date. Diets were corn silage based and balanced to be isocaloric and isonitrogenous. Data was analyzed using Proc MIXED of SAS with contrasts and 2 and 3 way interactions. Postpartum DMI ($P = 0.15$) was 16.1, 17.3, 18.7, and 16.7 kg/d (±0.81) for CC, CG, GC, and GG respectively. Milk yield ($P = 0.59$) was 32.4, 34.4, 35.0, and 34.8(±1.70) for CC, CG, GC, and GG respectively. Milk protein percentage ($P = 0.08$) was 3.4%, 3.9%, 3.8%, and 4.0% (±0.18) for CC, CG, GC, and GG respectively. Efficiency defined as (ECM/DMI) [$P = 0.15$] was 2.11, 2.09, 1.98, and 2.25 (±0.08) for CC, CG, GC, and GG respectively. No statistical effect on serum glucose (average 66.1 mg/dl) or blood urea N (average 15.2 mg/dl) was observed. Non-esterified fatty acids and B-hydroxybutyrate concentrations were not affected by treatment averaging 0.62 mEq/L and 8.0 mg/dl respectively. The inclusion of glycerol in the diet resulted in a numerical improvement in milk yield and components compared with CC. GG resulted in a numerical improvement on efficiency compared with CC, CG, and GC. Researchers observed that the use of dietary glycerol as an energy source may be useful in improving production and efficiency in the transition cow though further research is needed to determine the optimum levels.

Key Words: transition cow, glycerol, efficiency

1134 The influence of *Bacillus pumilus* 8G-134 on milk production of dairy cows in early lactation. J. D. Ferguson*[1], Z. Wu[1], D. W. Remsburg[1], and K. Mertz[2], [1]*University of Pennsylvania, School of Veterinary Medicine*, *Kennett Square,* [2]*Danisco Animal Nutrition*, *Waukesha, WI.*

The usage of direct-fed microbials (DFM) has become common in the dairy industry, but questions regarding their value remain prevalent. The efficacy of 3 different DFM feeding regimens on lactation performance was determined. Forty Holsteins (24 multiparous) were randomly assigned to one of 4 dietary treatments for the last 2 wk prepartum and the first 22 wk postpartum. The treatments included a placebo (CO), a *Propionibacterium* DFM prepartum followed by a *Lactobacillus* DFM postpartum (PL), and a DFM comprised of *Bacillus pumilus* 8G-134 offered at 5×10^9 (BL) or 1×10^{10} (BH) CFU/d. The TMR was the same for all treatments and fed to treatment groups once a day to 5% refusal. The treatment products were top dressed daily. Daily samples of TMR and orts were collected from each group and analyzed monthly. Cows were milked twice a day, and milk from AM and PM milking was analyzed for composition once a week. Milk production was compared between treatments using the Mixed Model Procedure of SAS. Group DMI was similar among treatments. Milk yield was higher for BL and BH than for CO and PL, and milk fat content was higher for PL, BL, and BH than for CO. The increase in milk yield with *B. pumilus* 8G-134 and the increase in milk fat for all DFM treatments indicate the benefits of these DFM.

Table 1. Lactation performance of dairy cows receiving different direct-fed microbials

Item	CO	PL	BL	BH	SEM	P
Milk, kg/d	33.8[a]	33.3[a]	35.5[b]	35.1[b]	0.6	0.04

1135 Utilization of wet brewers grains as a replacement for corn silage in lactating dairy cow diets. C. L. Mahnken*, B. J. Bradford, T. G. Rozell, and M. J. Brouk, *Kansas State University*, *Manhattan.*

Eight primiparous (192 DIM) and 4 multiparous (191 DIM) mid-lactation Holstein cows were used to evaluate replacing corn silage (CS) and soybean meal with a blend of wet brewers grains (WBG) and cracked corn on a short-term basis. Milk production, composition, DMI and production efficiency were evaluated. Cows were allotted to a 4 × 4 Latin Square with 3 replications blocked by parity, days in milk and energy corrected milk (ECM). Four diets were evaluated; 0 WBG (0% WBG and 24% CS of diet DM), 12 WBG (12% WBG and 12% CS), 18 WBG (18% WBG and 6% CS), and 24 WBG (24% WBG and 0% CS). Crude protein and starch levels were balanced between diets by varying the levels of cracked corn and soybean meal. Fifteen day periods were used, d11–15 were designated for collection. Orts were collected daily and TMR was fed at 5 to 10% above previous day's intake. Cows were milked 3x/day and milk weights recorded at every milking. Milk samples, body weights and BCS were taken −2 and −1d pre-trial to obtain baseline data and d14 and 15 of each period. During collection, TMR and orts were taken d1, 3 and 5. Fecal grab samples were taken d12–15 at 8 h intervals and advanced 2 h every 24 h period to account for diurnal variation. Dry matter intake was similar ($P = 0.21$) among treatments (20.3, 20.8, 20.9 and 21.2 kg/cow) for 0 WBG, 12 WBG, 18 WBG AND 24 WBG respectively, however CP intake of 24 WBG was greatest ($P = 0.03$) while 0 WBG was lowest. NDF intake was lower for 0 WBG compared with all other treatments and 24 WBG was higher than 12 WBG ($P = 0.005$). Dietary fat intake was different ($P < 0.001$) across all treatments, increasing with WBG inclusion. Inclusion of WBG had no effect ($P = 0.19$) on milk production (30.5, 31.5, 31.6 and 32.1 kg/cow), fat percent or amount, protein percent, SNF, lactose or SCC, but protein yield and MUN were lower ($P = 0.04$) with 0 WBG compared with 18 WBG and 24 WBG. Efficiency of production did not differ ($P = 0.86$) among treatments. Results suggest WBG fed in conjunction with grass hay can replace CS in lactating cow diets for a short-term period.

Key Words: by-product, production efficiency, forage replacement

1136 Methane suppressing effect of flaxseed in diets containing hay or silage. Y.-H. Chung*, M. L. He, S. M. McGinn, T. A. McAllister,

and K. A. Beauchemin, *Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*.

Including flaxseed (flax) in the diet of cattle can increase n-3 fatty acid content of milk and meat. Our study investigated the potential of flax to reduce enteric methane (CH_4) emissions from cows when added to diets containing hay or silage. Effects of forage type and flax inclusion on ruminal fermentation and apparent nutrient digestibility were also studied. Twelve ruminally cannulated, non-lactating Holstein cows were used in a replicated 4 × 4 Latin Square design with 21-d periods. Experimental diets (50:50 forage to concentrate ratio; DM basis) were formulated as a 2 × 2 factorial using either alfalfa-grass (mostly grass, chopped) mixed hay or barley silage as the forage source with or without 15% (ration DM; provided 5.2% added fat) ground flax as a partial replacement of barley grain. Diets were fed once daily as a total mixed ration. Enteric CH_4 production was measured for 3 d using the sulfur hexafluoride tracer gas technique. Without flax inclusion, cows produced 31, 26 or 29% less ($P \leq 0.5$) CH_4 when fed hay compared with silage (207 vs. 300 g CH_4/head/d, 19.6 vs. 26.4 g CH_4/kg of DMI, or 30.4 vs. 42.9 g CH_4/kg of digestible DMI, respectively). The lower CH_4 emissions per unit of intake from cows fed hay, as compared with those fed silage, may be partially attributable to lower ruminal pH due to sorting of the hay diet. Including flax in the hay diet did not further suppress CH_4 emissions whereas, including flax in the silage diet reduced ($P \leq 0.5$) daily g CH_4 per head by 36% and CH4 production per kg DMI and per kg digestible DMI by 33 and 28%, respectively. Flax inclusion lowered CH_4 emissions of cows fed the silage diet in part by depressing ($P \leq 0.5$) fermentation of ruminal fiber and total tract fiber digestibility, a response not observed with the hay diet. Our study demonstrated that including 15% ground flax in a barley silage-based diet, with an aim of enhancing n-3 fatty acid content of meat, is an effective practice to mitigate enteric CH_4.

Key Words: forage type, flaxseed, enteric methane emissions

1137 Effects of live yeast culture supplementation (*Saccharomyces cerevisiae*) and nutritional management on ruminal pH and fermentation in early lactation dairy cows. R. M. Al Ibrahim*, V. P. Gath, C. McCarney, P. Duffy, and F. J. Mulligan, *University College Dublin*, *Dublin 4, Ireland*.

The aim of this study was to investigate the potential effect of yeast culture (YC) on rumen physiology of dairy cows nutritionally managed to have an abrupt introduction to pasture after calving or a more gradual introduction to pasture. Eight Holstein dairy cows in early lactation fitted with ruminal cannulas were randomly allocated to a 2 × 2 factorial experimental arrangement. Treatments were supplementation with YC (2.5 g/cow/d × 10^9 CFU of *S. cerevisiae*^{1026}/g; supplemented, Y or control, C; n = 4) and nutritional management (abrupt introduction to pasture, AP; or TMR for the first 21 DIM and then gradual introduction to pasture, GP; n = 4). Cows on pasture (perennial ryegrass) were supplemented with pasture lactating compound (±YC) at rate of 3.5 kg DM/cow/d twice daily. Rumen fluid samples were harvested on d 8, 9, 10 and 22, 23, 24 PP to assess volatile fatty acids (VFA), ammonia-N, lactic acid and protozoal count. Internal pH meters were installed in the rumen of cows to continuously monitor rumen pH during the sampling days. Data were analyzed using the Mixed procedure in SAS v 9.1, 2004. A higher total VFA concentration during the both first and second measuring periods was detected in Y group in comparison with C group. Protozoal count was higher ($P = 0.009$) in GP than AP groups during the first measuring period while no effect was detected in the second measuring period. Rumen pH and lactic acid in the first measuring period were not affected by YC supplementation while nutritional management had an effect with higher pH ($P = 0.001$) and lower ($P = 0.007$) lactic acid in GP than AP groups. Whereas, during the second measuring period Y and GP groups had higher pH and lower lactic acid in comparison with C and AP groups. Results suggested that dietary supplementation with YC during early lactation increased the rumen pH and total VFA and decreased lactic acid while the abrupt introduction to pasture after calving reduced the rumen PH and increased lactic acid with no effect on rumen VFA.

Key Words: dairy cows, nutrition changes, yeast culture, rumen fermentation

1138 Effect of supplemental corn dry distiller grains plus solubles on digestibility of steers grazing native range during summer growing season. M. F. Martínez-Pérez[1], D. Calderón-Mendoza[2], N. J. Dupass[1], A. Islas[1], J. Armendariz[1], A. M. Encinias[1], F. Loya-Olguin[2], and S. A. Soto-Navarro*[1], [1]*New Mexico State University*, *Las Cruces,* [2]*Universidad Autónoma de Baja California*, *Mexicali, BC, Mexico*.

Sixteen English-crossbred steers (360 ± 28.9 kg) fitted with ruminal cannulas grazing native range during the summer growing season were used in a completely randomized design to evaluate effects of corn distiller grains plus solubles (DDGS) supplementation level (0, 0.2, 0.4, and 0.6% BW) on forage intake, digestibility, and rumen fermentation characteristics. The experiment was conducted during the first and second weeks of October 2008. Steers grazed a single native range pasture with supplements offered individually once daily at 0700. Forage OM, NDF, CP, and EE intake decreased ($P \leq 0.05$) linearly with increasing DDGS supplementation level. Total CP and EE intake increased ($P < 0.01$) with increasing DDGS supplementation level. Digestibility of OM, CP, and NDF increased (linear; $P < 0.01$) with increasing DDGS supplementation level while digestion of EE increased (linear and cubic effect; $P \leq 0.04$) with increasing DDGS supplementation level (40.81, 54.31, 50.99, and 70.07 ≥ 3.89% for 0, 0.2, 0.4, and 0.6% of BW, respectively). Forage masticate in situ soluble linearly increased ($P < 0.01$) and slowly degradable CP fraction linearly decreased ($P > 0.01$) with increasing DDGS supplementation level. Forage in situ masticate DM and NDF disappearance rate increased (quadratically; $P \leq 0.05$) and DDGS in situ DM disappearance rate increased (linearly; $P > 0.03$) with increasing supplementation levels. Forage and DDGS UIP (% of CP), ruminal pH, and VFA concentration were not affected ($P \geq 0.25$) by DDGS supplementation level. These results indicate that DDGS supplementation improved total CP and EE intake and digestibility of OM, NDF, CP, and EE of steers grazing native range during the forage growing season. Therefore, DDGS represent a viable supplement for cattle grazing native range during the forage growing season when forage has medium or high quality.

Key Words: DDGS supplementation, grazing native range, steers

1139 Effect of replacing grain and silage with wheat distiller grain on intake, digestibility and urine purine derivatives in finishing beef cattle. Y. L. Li*1,2, W. Z. Yang[1], T. A. McAllister[1], and K. A. Beauchemin[1], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Our objective was to evaluate the effects of wheat dried distillers grains′ with solubles (DDGS) when used to partially replace barley grain and forage or to entirely replace forage in the finishing diet of beef cattle. Effects on intake, digestibility, and purine derivatives (PD) in urine (as an indication of microbial protein synthesis) were evaluated. Eight ruminally fistulated Angus heifers were assigned to a replicated 4 × 4

Latin square design with 4 treatments: control, low (25%), med (30%), and high (35%) DDGS (DM basis). The diets consisted of barley silage, barley concentrate, and wheat DDGS in ratios of 15:85:0, 10:65:25, 5:65:30 and 0:65:35 (DM basis), respectively. The dietary contents (% DM) of CP were higher for DDGS diets (mean ± SD, 21.3 ± 1.6) than for the control (11.5) diet, but all diets had similar NDF contents (mean ± SD, 23.2 ± 1.1). DMI (kg/d) was lower ($P < 0.01$) for the high DDGS diet (7.9) than for other 3 diets (9.1). Increasing DDGS content of diets linearly reduced ($P < 0.01$) starch intake. Total digestibility (% intake) of DM quadratically ($P < 0.01$) changed with the highest digestibility for high DDGS (79) and the lowest for low DDGS (76). There were linear ($P < 0.01$) increases in the total digestibilities of CP, NDF and starch with increasing DDGS and decreasing silage in the diet. Total excretion of PD (mmol/d) quadratically ($P = 0.02$) increased with the highest excretion for low (282) and med DDGS (295) diets and the lowest for control (231). It was concluded that partially replacing barley grain and silage with wheat DDGS improved total digestibilities of CP and NDF, as well as microbial protein synthesis. Entirely removing silage from a finishing diet may improve feed efficiency due to lower DMI and higher digestibility, but further work is needed to determine whether the risk of acidosis is also increased.

Key Words: wheat DDGS, intake, digestibility

1140 Feeding wheat distillers grains compared with corn distillers grains in diets for lactating dairy cows: Effect on milk production and rumen fermentation. M. M. Abdelqader* and M. Oba, *University of Alberta*, *Edmonton, AB, Canada*.

In western Canada, dried distillers grains with soluble (DDGS) is produced from mixtures of corn and wheat at variable ratios, and used as a source of dietary crude protein. The objective of this study was to determine the effect of feeding corn DDGS (CDG), wheat DDGS (WDG), and a 50:50 mixture of both (CWDG) on dry matter intake, milk production, milk composition, and feed efficiency of dairy cows in mid-lactation. Sixteen multiparous and 16 primiparous lactating Holstein cows were used in a replicated 4 × 4 Latin square with 3-wk periods. Dietary treatments were a control diet containing canola meal as the primary protein source (CON) and diets containing CDG, WDG, or CWDG. The treatment protein sources supplied 35% of dietary crude protein, and all diets were formulated for similar protein (17.9%) and fat (4.5%) contents. Dry matter intake tended to be higher when cows were fed WDG diet compared with CDG (25.4 vs. 22.9 kg/d; $P = 0.08$), but milk yield was not affected by treatment and averaged at 36.3 kg/d. As such, feeding CDG tended to increase feed efficiency compared with WDG (milk yield / dry matter intake; 1.64 vs. 1.45; $P = 0.08$). However, no differences in DMI and milk yield were observed between CON and diet containing DDGS. Furthermore, concentrations of milk fat, protein, lactose, and milk urea nitrogen were not affected by treatment, and averaged at 3.59%, 3.11%, 4.54%, and 10.7 mg/dL, respectively. Rumen pH was not affected by dietary treatment and averaged at 6.19. However; cows fed CDG had lower ($P = 0.03$) NH3-N concentration in the rumen compared with those fed the WDG and CWDG diet (9.4 vs. 12.9 and 12.5 mg/dL, respectively). In conclusion, regardless type of grain source, DDGS can be used as an alternative protein source in diets for lactating dairy cows, but type of grain from which DDGS is produced may affect feed efficiency.

Key Words: corn DDGS, wheat DDGS, feed efficiency

1141 *Megasphaera elsdenii* effects on adaptation to concentrate diets. L. K. Thompson*[1], P. H. Henning[2], and J. S. Drouillard[1], [1]*Kansas State University*, *Manhattan*, [2]*MS-Biotech*, *Centurion, South Africa*.

Crossbred (n = 80; 408 ± 66 kg initial BW) steers were used in a randomized complete block experiment to evaluate effects of oral dosing of *Megasphaera elsdenii* strain NCIMB 41125 (ME). Cattle fed forage diets for 3 wk after arrival were allotted to factorialized treatments consisting of step-up regimen (17 or 8 d) and oral drenching with a placebo or 10^{11} cfu ME. Diets consisted of alfalfa hay and steam-flaked corn, with 36 mg/kg monensin. The 17-d regimen used 5 diets (45, 35, 25, 15, and 6% roughage) with diet changes on d 5, 9, 13, and 17. The 8-d regimen used 3 diets (45, 25, and 6% roughage) with diet changes on d 4 and 8. On d 1, steers were weighed, orally dosed with ME or Placebo, placed in individual pens, and fed ad libitum for 63 d. Feed offered and refused were measured daily to determine daily DMI. On d 64, cattle were consolidated into pens of 10 animals each (2 pens/treatment) and fed until harvest on d 95. ME cattle maintained more consistent intakes ($P = 0.07$) during the initial 3 d of concentrate feeding compared with Placebo cattle. ME cattle tended to have greater ADG in the first 63 d ($P = 0.11$), particularly with the accelerated step-up (interaction, $P = 0.11$). HCW increased ($P = 0.10$) with ME, but were not affected by step-up regimen or the interaction between ME and step-up regimen. Liver abscess rates tended ($P = 0.14$) to be greater for cattle on the accelerated step-up. A single oral dose of *Megasphaera elsdenii* strain NCIMB 41125 can be used effectively to transition cattle from forage to high-grain diets in 8 d.

Table 1. Effects of *Megasphaera elsdenii* on intake and carcass characteristics

1142 Effects of adding a mycotoxin-sequestering agent on milk aflatoxin M1 concentration and the performance and immune response of dairy cattle fed an aflatoxin B1-contaminated diet. O. C. M. Queiroz*, A. T. Adesogan, C. R. Staples, J. Hun, M. Garcia, L. F. Greco, and L. J. Oliveira, *Department of Animal Sciences, University of Florida*, *Gainesville*.

The objective was to examine effects of adding 2 doses of a montmorillonite-based mycotoxin adsorbent on milk aflatoxin M1 (AFM1) concentrations and the performance and innate immune response of dairy cows fed an aflatoxin B1 (AFB1)-contaminated diet. Eight lactating cows were used in an experiment with a duplicated 4 × 4 Latin square design with 12-d periods. Treatments included the following: 1) Control diet (C); 2) Toxin diet (T) containing C and 75 μg/kg of AFB1; 3) Low-clay (LC) diet containing T and 0.2% Calibrin A (Amlan International, Chicago, IL); and 4) High-clay diet (HC) containing T and 1% Calibrin A. Milk production and DMI were recorded daily, and milk was sampled twice daily on d 5, 9, 10, 11, and 12 in each period. Blood samples were collected on d 5 and 9 of each period. The model included treatment, square and period effects and significance was declared at $P < 0.05$. Dietary treatments did not affect DMI, milk yield, or feed efficiency.

Feeding T instead of C tended to reduce 3.5% FCM yield (19.0 vs. 20.8 kg/d; $P = 0.08$, SE = 0.79) and reduced milk fat yield (0.67 vs. 0.74 kg/d; SE = 0.03) and milk protein concentration (3.28 vs 3.36%; SE = 0.03). Concentrations of AFM1 in milk of cows fed the T and LC diets were similar (0.63 and 0.65 μg/kg) and greater than those of cows fed the HC diet (0.48 μg/kg; SE = 0.04), but cows fed C had trace levels (0.03 μg/kg; SE = 0.04). Haptoglobin concentration was greater (22.0 vs. 14.4; SE = 1.9) and β2-integrin expression (220 vs. 130; $P = 0.1$; SE = 32) tended to be greater in cows fed diet T instead of C, but values for cows fed LC, HC and C did not differ. Feeding HC or LC instead of T prevented the increased innate immune response and decreased FCM yield caused by T, but milk AFM1 concentration was only reduced by feeding HC instead of T.

Key Words: mycotoxin adsorbent, aflatoxin, immunity

1143 The effect of rumen-protected methionine and choline on productive performance of Holstein dairy cows. M. Ardalan*, M. Dehghan-Banadaky, and K. Rezayazdi, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*, *Karaj, Iran*.

Forty Holstein dairy cows in their first and second lactation were used in a lactation study from 4-week prepartum through 10-week postpartum to investigate the effect of feeding ruminally protected sources of methionine and choline on productive performance of Holstein dairy cows. Cows (10 cows per treatment = 6 cows in 1st lactation and 4 cows in 2nd lactation) were housed in individual tie stalls. Animals were randomly assigned to receive one of the following treatments in a 2 × 2 factorial design 4-week before their expected calving dates, using block randomization based on parity: 18 g/d of rumen-protected methionine product (RPM), 60 g/d of rumen-protected choline product (RPC), 18 g/d of RPM + 60 g/d of RPC, or neither supplement (control). The repeated measurements of milk yield and composition were analyzed as a linear mixed model (Proc Mixed) with the best fitted covariance structure of SAS. The statistical model included the fixed effects of treatment, parity, time (week of lactation), treatment × time, and the random effect of cow within treatment and parity. The error covariance structure used for the repeated measures was the first-order heterogeneous autoregressive structure. The supplementation of RPC significantly affected milk yield, FCM, and ECM across lactation weeks ($P < 0.05$). The actual milk yield, FCM, and ECM were greater for RPC-fed cows than other treatment groups ($P < 0.05$). The RPM and RPC have significant effects on the lactose percentage of milk across lactation weeks, but the treatments did not significantly affect fat and protein percentages of milk. Also, RPC significantly affected fat, protein, and lactose yields of milk across lactation weeks ($P < 0.05$). There was a significant interaction effect of RPM × RPC for lactose percentage of milk ($P < 0.05$). In general, the RPM × RPC × time had not any significant effect on milk yield and composition. The results of this study indicated the positive effect of RPC supplementation on the productive performance of dairy cows.

Key Words: rumen-protected methionine, rumen-protected choline, productive performance

Ruminant Nutrition Symposium: Acidosis: New Insights Into the Persistent Problem

1144 Role of fermentation acid absorption in the regulation of ruminal pH. J. R. Aschenbach*[1], G. B. Penner[2], F. Stumpff[3], and G. Gäbel[4], [1]*University of Veterinary Medicine Vienna*, *Vienna, Austria*, [2]*University of Saskatchewan*, *Saskatoon, Canada*, [3]*Free University of Berlin*, *Berlin, Germany*, [4]*University of Leipzig*, *Leipzig, Germany*.

Diets with high energy density are rapidly fermented to acids (short chain fatty acids, SCFA; lactic acid) within the rumen. The resulting release of protons can constitute a challenge to the ruminal ecosystem and animal health. Health upsets resulting from acidogenic diets are classified as subacute and acute acidosis based on the degree of ruminal pH dysregulation. While increased acid production is a nutritionally desired effect of increased concentrate feeding, the accumulation of protons in the rumen is not. Consequently, mechanisms of proton removal and their quantitative importance are of major interest. From the 1950′s, salivary buffers (bicarbonate, phosphate) have been identified as important mechanisms for ruminal proton removal. However, it appears that a larger proportion of protons is removed from the rumen by transport processes across the ruminal epithelium. Proceeding initially from exclusively diffusional absorption of fermentation acids, several protein-dependent mechanisms have been discovered over the last 2 decades. Although the molecular identity of these proteins is mostly uncertain, acetate absorption proceeds to a major part via acetate-bicarbonate exchange in addition to another nitrate-sensitive, bicarbonate-independent transport mechanism and lipophilic diffusion. Propionate and butyrate also show partially bicarbonate-dependent transport modes. In sheep, susceptibility to subacute ruminal acidosis was positively related to the efficiencies of protein-mediated acetate uptake and diffusional butyrate uptake. The latter seemed attributable to high rates of butyrate metabolism in the epithelial cells. Finally, SCFA absorption also accelerates urea transport via UT-B into the rumen which via ammonium recycling may remove protons from the rumen to the blood.

Key Words: nutrient absorption, ruminal acidosis, short chain fatty acids

1145 Molecular adaptation of ruminal epithelia to highly fermentable diets. G. B. Penner*[1], M. A. Steele[2], and B. W. McBride[2], [1]*University of Saskatchewan*, *Saskatoon, Canada*, [2]*University of Guelph*, *Guelph, Ontario, Canada*.

Feeding highly fermentable diets to ruminants is one strategy to increase energy intake. However, the increase in short-chain fatty acid (SCFA) production and reduced ruminal pH associated with highly fermentable diets imposes a metabolic challenge to the ruminal epithelia. In response to greater SCFA supply, the ruminal epithelia respond with coordinated actions of altered cell function and proliferation. While the proliferative response is well documented, emerging evidence at the mRNA level indicates that temporal changes in epithelial cell function is the initial response. It is not surprising that gene expression analysis has identified pathways involved in fatty acid metabolism, ion transport, and intracellular homeostasis to be the pathways dominantly affected during adaptation and following adaptation to a highly fermentable diet. It is widely acknowledged that intraepithelial metabolism of SCFA, particularly butyrate, helps to maintain the concentration gradient between the cytosol and lumen thereby facilitating absorption. Current data suggests that for butyrate metabolism, 3-hydroxy-3-methyglutaryl-CoA synthase 1 is the regulatory point with transient up and downregulation during diet adaptation. Interestingly, rate-limiting enzymes involved in cholesterol biosynthesis appear to be downregulated during diet adaptation. In addition to nutrient transport and utilization, genes involved in the maintenance of tight cell junctions and induction of the inflammatory response have been identified as differentially expressed genes during adaptation to highly fermentable diets. This may have important implications on ruminal epithelial barrier function and the inflammatory response associated with subacute ruminal acidosis.

Key Words: adaptation, gene expression, rumen epithelia

1146 Animal productivity and health responses to hind-gut acidosis. T. F. Gressley*[1], M. B. Hall[2], and L. E. Armentano[3], [1]*University of Delaware*, *Newark*, [2]*US Dairy Forage Research Center*, *Madison, WI*, [3]*University of Wisconsin*, *Madison*.

Microbial fermentation of carbohydrates in the large intestine of dairy cattle is responsible for 5 to 10% of total tract carbohydrate digestion. When dietary, animal, and/or environmental factors contribute to abnormal, excessive flow of fermentable carbohydrates to the large intestine, hind-gut acidosis can occur. Hind-gut acidosis is characterized by increased rates of production of volatile fatty acids (VFA) including lactic acid, decreased digesta pH, and damage to gut epithelium as evidenced by the appearance of mucin casts in feces. In parallel to ruminal disorders, it is possible that hindgut acidosis can also be classified as acute or sub-acute. In the more severe situations, hind-gut acidosis is characterized by an inflammatory response; the resulting breach of the barrier between animal and digesta may contribute to laminitis and other disorders. In a research setting, hind-gut acidosis has been evaluated using pulse-dose or continuous abomasal infusions of varying amounts of fermentable carbohydrates. Continuous low dose infusions of pectin or fructans (1 kg/d) into lactating cows resulted in decreased diet digestibility, increased intake variation, decreased milk fat percentage, decreased milk urea N concentration, and increased fecal N output, without affecting fecal pH or VFA. Pulse dose fructan infusions (1 g/kg BW) into steers resulted in watery feces, decreased fecal pH, and increased fecal VFA, without causing an inflammatory response. Daily 12 h abomasal infusions of a high dose of starch (~4 kg/d) have also induced hind-gut acidosis as indicated by decreased fecal pH and watery feces. Evidence of hind-gut acidosis has also been noted on farms as detected by fecal signs of excessive fermentation (watery or foamy appearance) or of epithelial damage (presence of mucin casts). In summary, hind-gut acidosis occurs as a result of relatively high rates of large intestinal fermentation, likely as a result of digestive dysfunction in other parts of the gut. A better understanding of the relationship of this disorder to other animal health disorders is needed.

Key Words: acidosis, hind-gut

1147 Bovine endotoxicosis: Does acidosis cause inflammatory responses? P. H. Andersen*, *Copenhagen University*, *Copenhagen, Denmark.*

Endotoxins (LPS) are structural parts of the gram-negative bacteria membrane and belong to the group of pathogen-associated molecular patterns (PAMP), that are instantly recognized by the innate immune system. LPS and gram-negative bacteria are generally present in the rumen of cattle, and it is now widely accepted, that the LPS concentration increases when grain is added to the diet. LPS in even very minute amounts (10 ng per kg BW) elicit an inflammatory response in cattle.

Clinical and biochemical signs such as decreased GI motility, anorexia, increased concentrations of acute phase proteins, leukocytosis and leukopenia appear in endotoxicosis as well as in acute ruminal acidosis. In cattle, fever is not a consistent sign of endotoxicosis. If ruminitis is present, the ruminal barrier may become leaky. In experimentally induced acute ruminal acidosis, increased amounts of LPS can be detected in the portal vein and sometimes also in the systemic circulation. Controversy exists whether this is the case also in cows with subclinical ruminal acidosis. However, concentrations of the acute phase protein serum amyloid A increase in subclinical ruminal acidosis, and results from recent in vitro experiments have shown that the permeability of the rumen epithelium to LPS increases in the presence of LPS and low pH. Whether the inflammatory signs detected in ruminal acidosis may be ascribed to the occurrence of ruminitis, to the consequences of increased translocation of LPS from the inflamed rumen epithelium to the portal blood system, or to combination of these, is however not yet entirely clear. Interestingly, large variations in the clinical susceptibility of cattle to LPS are reported from various studies on rumen acidosis and mastitis. Cows may be divided into "moderate" and "severe" responders. The detoxifying capacity of the macrophages in the liver may play a role, but the causative factors are far from elucidated. It is suggested that further investigation of the response of cattle to LPS or other PAMP challenges may provide a basis for the identification of indicators of robustness or health.

Key Words: endotoxin, ruminal acidosis, inflammation

Author Index

Numbers following names refer to abstract numbers: a number alone indicates an oral presentation, an M prior to the number indicates a Monday poster, a T indicates a Tuesday poster, and a W indicates a Wednesday poster.

The author index is created directly and automatically from the submitted abstracts. If an author's name is typed differently on multiple abstracts, the entries in the author index will reflect these discrepancies. Efforts have been made to make this index consistent; however, error from author entry contributes to inaccuracies.
