Objectives were to evaluate the effects of feeding pomegranate extract (POMx) rich in polyphenols on performance, health, nutrient digestion, and immunocompetence of calves. Holstein calves (n = 67), at 2 ± 1 d of age were randomly assigned to 0 (control), 5 (POMx5), or 10 g/d (POMx10) of POMx containing 16.9% gallic acid equivalent. Calves received colostrum in the first 24 h, pasteurized milk thereafter until d 61, and grain was fed ad libitum for the first 70 d of age. Calves were housed in individual hutches and grain intake, attitude and fecal scores, incidence and duration of health disorders, and health treatments cost were evaluated. Body weight (BW) was measured at 2, 30 and 70 d of age. Concentrations of glucose and 3-hydroxybutyrate (BHBA) were measured in plasma. Nutrient digestion was measured using total fecal collection. Neutrophil phagocytic and killing activities and antibody response to ovalbumin were measured. Cytokine production by peripheral blood mononuclear cells was measured. Feeding POMx had no effect on intake or BW gain in the first 30 d of age, but grain intake and BW gain reduced ($P < 0.05$) with increasing addition of POMx after d 30, which resulted in calves that were 1.8 and 4.3 kg lighter at 70 d of age for POMx5 and POMx10, respectively, compared with controls. Feeding POMx did not influence DM, organic matter or starch digestibility, but it reduced ($P < 0.01$) protein and tended ($P = 0.06$) to affect fat digestion. Plasma concentrations of glucose and BHBA, attitude and fecal scores, rectal temperature, incidence of fever, health treatment cost, neutrophil phagocytic and killing activities did not differ among treatments. Feeding POMx increased ($P < 0.05$) interferon-γ, interleukin-4, and IgG to ovalbumin vaccination. These results suggest that feeding POMx top dressed onto the grain suppresses grain intake and digestibility of protein. Nevertheless, POMx enhanced mitogen-induced cytokine production and response to vaccination which might benefit immune competence of calves and potentially health.

Key Words: calf, polyphenols, pomegranate

391 Effect of high-protein milk replacer followed by high-protein starter on transcript profiles in ruminal tissue of Holstein bull calves. A. Naeem*, J. K. Drackley, J. Stamey, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, and J. J. Loor, *University of Illinois*, *Urbana*.

The calf must be adapted to its nutrition from milk or milk replacer to make the metabolic, nutritional, and behavioral changes to become a functional ruminant in a period of 6 to 8 wk after birth. Objective of this study was to evaluate ruminal epithelium transcriptomics in response to high-protein/low-fat milk replacer followed by high-protein starter for 10 wk. From 3 through 42 d of life, male Holstein calves were fed reconstituted control milk replacer (20% CP, 20% fat; 0.567 kg solids/calf) or a high-protein/low-fat milk replacer (28.5% CP, 15% fat; at ca. 2% of body weight). All calves were weaned on d 43. Calves in the control group were then fed a control starter containing 16% CP through d 70 of life. In contrast, calves in the high-protein/low-fat group were fed a starter containing 22% CP through d 70 of life. Groups of calves in control and high-protein/low-fat treatments were harvested after 43 (wk 5) and 71 d (wk 10) of feeding. Ruminal epithelium samples harvested from 5 animals in each group at each time point were used for transcript profiling using a 13,257 bovine oligonucleotide (70-mers) array. Preliminary ANOVA of wk 10 data revealed 75 differentially expressed genes (DEG, $P < 0.01$) due to diet. Among DEG, the most enriched biological functions were cellular process (n = 34) and regulation of biological process (n = 17). In addition, genes with a 2-fold change between treatments were related to physiological processes including protein degradation (e.g., PGA3, pepsinogen 3, group I A) and growth (e.g., RDH10, retinol dehydrogenase 10). Preliminary results show that feeding a high-protein/low-fat milk replacer followed by a high-protein starter caused alterations in ruminal epithelium gene expression profiles.

Key Words: transcriptomics, development, metabolism

392 Field evaluation of the effects of free-access feeding of acidified milk replacer on the growth performance of dairy replacement heifers and veal calves. C. G. Todd*[1], K. E. Leslie[1], S. T. Millman[2], T. J. DeVries[3], N. G. Anderson[4], and J. M. Sargeant[1], [1]*Department of Population Medicine, University of Guelph*, *Guelph, Ontario, Canada*, [2]*Veterinary Diagnostic and Production Animal Medicine, Biomedical Sciences, Iowa State University*, *Ames,* [3]*Department of Animal and Poultry Science, University of Guelph, Kemptville Campus*, *Kemptville, Ontario, Canada*, [4]*Ontario Ministry of Agriculture, Food and Rural Affairs*, *Elora, Ontario, Canada*.

The objective of this research was to determine the effects of free-access feeding of acidified milk replacer on pre and post-weaning growth of Holstein replacement heifers and veal calves. The study was conducted at a commercial dairy operation in central Ontario. Heifer calves were reared as replacement animals and male calves were marketed as grain-fed veal. Calves (n = 495) were randomly assigned at birth to 1 of 2 milk feeding programs: free-access (ad libitum) feeding of acidified milk replacer (ACID, n = 250) or conventional (3 L fed twice daily) feeding of milk replacer (CONV, n = 245). Calves were fed milk replacer containing 24% crude protein and 18% fat. Formic acid was used to acidify the milk replacer for the ACID treatment. The target pH for acidified milk replacer was between 4.0 and 4.5. Calves were gradually weaned from milk replacer at approximately 6 weeks of age (mean ± SD: 41.1 ± 7.7 d of age). Body weight, hip width, hip height, body length and heart girth were measured at birth and weaning. A post-weaning body weight measurement was also collected for each calf (mean ± SD for heifer calves: 283.3 ± 57.2 d of age; mean ± SD for veal calves: 235.0 ± 25.1 d of age). There was no difference between the ACID and CONV calves for any of the measurements collected at birth. The ACID calves had significantly higher pre-weaning body weight gain compared with the CONV calves (28.2 vs. 21.2 kg, SE = 0.9, $P < 0.05$), as well as greater change in hip width (3.6 vs. 2.5 cm, SE = 0.1, $P < 0.05$), hip height (8.5 vs. 7.0 cm, SE = 0.4, $P < 0.05$), body length (11.9 vs. 9.5 cm, SE = 0.7, $P < 0.05$) and heart girth (12.4 vs. 9.8 cm, SE = 0.4, $P < 0.05$). The ACID and CONV calves did not differ for post-weaning weight gain (heifer calves: 224.7 vs. 226.8 kg, SE = 6.0, $P > 0.05$, respectively; veal calves: 257.1 vs. 257.2, SE = 2.0, $P > 0.05$, respectively). These results indicate that free-access feeding of acidified milk replacer supports improved body weight gain and structural growth during the pre-weaning period, but does not affect post-weaning weight gain.

Key Words: milk replacer, free-access feeding, acidification

393 Comparison of raw colostrum, colostrum replacer, and pasteurized colostrum on IgG, growth, and health of dairy calves. C.

L. Wilson* and L. E. Davis Rincker, *Eastern Kentucky University*, *Richmond*.

Colostrum consumption is key to the health and survival of dairy calves. However, feeding raw colostrum can spread disease from dam to calf. Pasteurized colostrum and colostrum replacer can be used when disease spread is a concern. A direct comparison between pasteurized colostrum and colostrum replacer is lacking. The primary objective was to determine serum immunoglobulin G (IgG) concentration of calves fed colostrum replacer (CR, 150 g globulin protein/dose), pasteurized colostrum (PC), and raw colostrum (RC). Other objectives were to evaluate intake, growth, feed efficiency, and health of calves. Male and female dairy calves born at Eastern Kentucky University Stateland Dairy Center were randomly assigned to 1 of 3 treatments (n = 11/trt): RC, PC, or CR and fed their respective treatment twice (1.89 L/feeding) on d 1 of life. Calvings were monitored so that calves did not suckle the dam. High quality (green) colostrum, as measured by a colostrometer, was pooled for the RC and PC treatment. Blood was collected before colostrum feeding and again between 46 and 60 h for analysis of serum IgG. Calves were raised similarly after 1 d of age and data was collected until weaning at 7 wk of age. Statistical analysis used the GLM procedure of SAS. Calves fed RC or PC had greater concentrations of serum IgG than CR ($P < 0.01$), but no difference existed between RC and PC. Average fecal scores and rectal temperatures taken daily during the first 2 wk of age were not different. Total intake of starter and milk replacer, initial and final growth parameters, feed efficiency, and average daily gain were not different. No major health challenges were noted in these calves. It is possible that if CR calves had been exposed to major illneses, health and growth parameters may have been compromised due to low immunity. Results indicate that if properly pasteurized, PC does not compromise immunity, health or growth parameters.

Key Words: colostrum, calf, immunoglobulin

394 Effect of the ingredients on acid binding capacity and ph of calves starter ration. Y. Tu*[1], Q. Y. Diao[1], S. S. Feng[2], Y. Zhou[1], and Q. Yun[1], [1]*Feed Research Institute of Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Beijing University of Agriculture*, *Beijing, China*.

This experiment was conducted to study on the effects of the ingredients and its acid binding capacity (ABC) or pH on the ABC or pH of calves starter ration. Nine feed raw ingredients (5–7 samples each) including corn, wheat bran, soybean meal, whey powder, $CaHPO_4$, limestone, salt, mineral premix and vitamin premix, which were ordinarily used in the northern China, were mixed with calves starter rations based on $L_{27}(3^{13})$ orthogonal test table. The ABC and pH of the ingredients and starter rations were determined, and then multiple regression method was used to analyze the data. The results showed that, 1) the ABC of limestone was highest (2040.00), while that of salt was lowest (0.40). The order of ABC from high to low was soybean meal, wheat bran, corn in plant feed ingredients, which were 47.82 ± 4.51, 27.31 ± 3.47, 7.11 ± 0.54, respectively; 2) The pH of minerals were alkaline, and that of corn, wheat bran and soybean meal were 5.79 ± 0.23, 5.65 ± 0.20 and 5.92 ± 0.11, respectively; 3) All the ingredients had significant effect on the ABC and pH of starter ration ($P < 0.05$). 4) When the ABC of starters was Y_1(mmol/100 g), pH of starters were Y_2(mmol/100 g), and the proportions in starter and ABC of soybean meal, wheat bran, whey powder, $CaHPO_4$, limestone, salt, vitamin premix, corn were X_1-X_8 (%) and a_1-a_8(mmol/100 g), respectively, the regression equation $Y = f(a_iX_i)$ was: $Y_1 = 1.0944a_1X_1+0.4817a_2X_2+ 1.2354a_3X_3-0.1568a_4X_4+ 0.1136a_5X_5+ 62.5969a_6X_6+ 60.2618a_7X_7+ 0.9150a_8X_8$($S_{Y.X}$ = 1.85603,R^2 = 0.9945, $P < 0.0001$); $Y_2 = 1.0792b_1X_1+ 0.9830b_2X_2+ 0.7687b_3X_3+ 1.0101b_4X_4+ 0.8997b_5X_5-0.3266b_6X_6- 27.0485b_7X_7+ 1.0142b_8X_8$($S_{Y.X}$ = 0.05691, R^2 = 0.9999, $P < 0.0001$). These results indicate that in the range of the experiment design, the suitable content of ingredients in calves starter ration were: soybean meal ≤20%, wheat bran 0–10%, whey powder ≤20%, CaHPO4 ≤2%, limestone ≤2%, salt 0–1.0%, vitamin premix 0–0.04%. There were significant multiple linear correlation between the ABC or pH of calves starter ration and content, ABC or pH of ingredients.

Key Words: calves starter ration, acid-binding capacity and pH, mathematical model

395 Study on in vitro evaluation of acidifier and its effect on growth in calves fed milk replacer. Y. Tu*, Y. Zhou, Q. Yun, Y. Q. Fu, and Q. Y. Diao, *Feed Research Institute of Chinese Academy of Agricultural Sciences*, *Beijing, China*.

This experiment was conducted to study on the in vitro evaluation method of acidifiers in calves milk replacer, and then validated the effect of the acidifier in calves using feeding trials. In the in vitro test, antibacterial activity in vitro (Y1), pH of 1% acidifier solution (Y2), buffering capacity of 1% acidifier solution (Y3), volume of acidifier solution to reduce the pH of milk replacer solution from 6.3 to 5.0 (Y4) and buffering capacity of milk replacer solution added acidifier (Y5) were chosen as the indices to evaluate the effect of the tested acids including formic acid, acetic acid, citric acid, fumaric acid, lactic acid and hydrochloric acid. Eighteen and 12 healthy neonatal Chinese Holstein male calves were assigned randomly to Treatment A1, A2, A3 in trial A and Treatment B1, B2 in trial B, respectively, and each treatment had 6 calves. The pH of milk replacer solution were reduced by hydrochloric acid from 6.3 to 5.5 or 5.0 in Treatment A1 or A2, respectively, and was reduced by formic acid from 6.3 to 5.0 in Treatment B2. Body weight, feed efficiency and the incidence of diarrhea were determined. The results indicated that, in the in vitro test, Y1 were highest when hydrochloric acid (95.12%) or formic acid (94.19%) was used, Y2 was lowest in hydrochloric acid solution, Y3 was best in hydrochloric acid solution, Y4 was least when formic acid solution used, and Y5 was best in acetic acid solution. So formic acid and hydrochloric acid were selected to be the acidifier in calf milk replacer. In the feed trails, comparing with that in Treatment A1, ADG improved 5.2% and 12.1% in Treatment A2 and A3. The incidence of diarrhea was 9.7% in Treatment A3, which decreased by 29.7% comparing with the 13.8% in Treatment A1. ADG of calves was significantly higher in Treatment B2 than that in Treatment B1 ($P < 0.05$), the incidence of diarrhea decreased by 37.5% in Treatment B2 (16.2%) than that in Treatment B1 (25.9%). It is concluded that, the growth performance of calves may be improved by using hydrochloric acid or formic acid as acidifier in milk replacer, and the in vitro evaluation method of acidifier was viable.

Key Words: calf milk replacer, acidifier, in vitro evaluation

396 Simulated straw bedding intake and effect of high and low cereal grain starters on rumen development of neonatal Holstein calves. W. B. Fokkink*[1], T. M. Hill[1], H. G. Bateman II[1], J. M. Aldrich[1], R. L. Schlotterbeck[1], and A. F. Kertz[2], [1]*Nurture Calf Research, Provimi North America*, *Lewisburg, OH,* [2]*ANDHIL, LLC*, *St. Louis, MO*.

Our hypothesis was that simulated straw bedding intake would be minor and that calves fed a texturized high cereal grain starter (TEX) would have greater rumen papillae development than calves fed a fine particle, pelleted, low cereal grain starter (PEL). Male Holstein calves (initially 45 ± 1.1 kg BW, 2 d of age; 4 calves/treatment) were fed TEX or PEL and long-stem wheat straw over a 56-d trial. Starter TEX contained

37% whole corn, 25% whole oats, 35% supplement pellets (containing 68% soybean meal, 16% wheat middlings, and 16% other ingredients) and 3% molasses. Starter PEL contained 43% dried distillers grains, 26% wheat middlings, 15% soybean hulls, 10% fine rolled corn, and 6% other ingredients. Starters contained equal concentrations of CP (20% DM basis), Ca, P, and salt. Calves were fed a 27% CP, 17% fat milk replacer at 0.66 kg DM daily and weaned at 35 d. Calves were fed wheat straw, starter, and water ad libitum and housed in individual pens with geotextile fabric over rock as flooring with no bedding. After sacrifice on d 56, gastro intestinal tracts were divided at the pyloric sphincter (stomach and intestine sections) and weighed. Rumen wall and rumen papillae samples were measured. Data were analyzed as a completely randomized design. Straw intake averaged 7 g/calf daily or 0.8% of total intake, and did not differ by starter type. Calves fed TEX had greater final BW and greater ADG than calves fed PEL. Empty stomach weight was greater for calves fed TEX. Intestine and digesta weights were lower and stomach and intestine plus digesta weights were lower for calves fed TEX vs. PEL. Rumen papillae length was greater for calves fed TEX vs. PEL. Feeding a texturized high cereal grain diet developed rumen papillae better and contributed to less stomach, intestine, and digesta as a percent of BW than feeding a fine particle, pelleted low cereal grain diet.

Key Words: calf, rumen, starters

397 Growth and health of calves pre- and post-weaning fed milk replacers with differing levels of neomycin sulfate and oxytetracycline. N. B. Litherland*[1], B. Ziegler[2], D. Schimek[2], D. Carlson[3], D. Ziegler[4], M. L. Raeth-Knight[1], G. G. Golombeski[1], H. Chester-Jones[4], and J. G. Linn[1], [1]*University of Minnesota*, *St Paul,* [2]*Hubbard Feeds Inc.*, *Mankato, MN,* [3]*Milk Products Inc.*, *Chilton, WI,* [4]*University of Minnesota Southern Research and Outreach Center*, *Waseca*.

New regulations for the use of medicated milk replacers (MR) containing neomycin sulfate (NEO) and oxytetracycline (OXY) have resulted in a need to explore the effects of amount and duration of antibiotic feeding on calf growth and health. Previous work by our group showed removal of antibiotics from MR at 14 d reduced growth compared with feeding antibiotics through 42 d. The aims of this study were to evaluate growth and health of calves fed MR containing varying amounts of antibiotics for 0, 14, 26, or 42 d. Holstein heifer calves (n = 100, 2 to 4 d of age) were assigned randomly to 1 of 4 MR programs. All calves were fed 20% CP, 20% fat MR at 0.57 kg/d (as-fed powder weight) from d 1–35 and 0.28 kg/d from d 36–42. Four different antibiotic amounts and durations were included in the above MR to yield 4 treatments; TRT1 - 400 g NEO/200 g OXY per ton of MR on d 1–42; TRT2 - 0 g NEO/0g OXY per ton of MR on d 1–42; TRT3 - 1600 g NT/1600 g OXY per ton of MR on d 1–14; TRT4 - 1600 g NEO/1600 g OXY per ton of MR on d 1–14 and d 16- 28. Calves were fed MR twice daily from d 1–35, and once daily from d 36–42. An 18% CP (as-fed) texturized calf starter was offered free choice along with water throughout the study. Calves were housed in individual pens within a naturally ventilated barn. Average daily gain and total body weight gain was lower ($P < 0.05$) for TRT2 when compared with TRT1 and TRT4. Total starter intake and total dry matter intake was lower ($P < 0.05$) for TRT 2 compared with TRT1 and TRT 4 through 42 d of age. Dry matter required for gain was higher ($P < 0.05$) for TRT2 compared with all other treatments. Fecal scores were not different and averaged 1.3 across treatments. Scouring days (fecal score of 4) were significantly higher ($P < 0.05$) for TRT 2 compared with TRT 4 through d 42. Calves fed increasing amounts and duration of NT and OT grew more efficiently, ate more starter, and had fewer days scouring than calves fed no antibiotics. The future of antibiotic use in calf MR is unclear. Non-medicated MR additives that promote growth and health should be explored.

Key Words: dairy calf, neomycin sulfate, oxytetracycline

398 Meta-analysis for designing an empirical model to predict growth of neonatal Holstein calves through eight weeks of age. H. G. Bateman II*[1], T. M. Hill[1], J. M. Aldrich[1], R. L. Schlotterbeck[1], and J. L. Firkins[2], [1]*Nurture Research Center, Provimi North America*, *Lewisburg, OH,* [2]*The Ohio State University*, *Columbus*.

A data set was constructed from individual animal means gathered in the Nurture Research Center (a curtain-sided, naturally ventilated nursery) and used in a meta-analysis to parameterize an empirical model predicting growth measures. This data set contained 993 observations from 20 research trials in all seasons. Growth measures gathered included average daily gain (ADG) pre-weaning, post-weaning, and through 8 weeks of age. Independent variables gathered included: age at weaning (WEAN), total starter intake (SI), total milk replacer intake (MRI), milk replacer CP % (MRCP) and fat % (MRfat) contents, number of days with abnormal fecal scores (AFS), average environmental temperature pre-weaning (temp-pre), post-weaning (temp-post), and through 8 weeks of age (temp-all), minimum (mintemp) and maximum (maxtemp) during the entire 8 weeks, BW at d 0 (BW0), and initial serum protein concentration (SERP). Additionally the interactions of SI, MRI, and MRCP and MRfat were considered for the model. Backward elimination multiple regressions were conducted using a mixed model with a random effect of trial. Terms least probable to differ from zero were removed sequentially from the model except that when interactions terms appeared in the model their constituent terms remained regardless of level of significance. When all terms were significant at $P < 0.05$ variance inflation factor (VIF) was calculated. If VIF was greater than 100 the term with the lowest probability of being different from zero was removed until the VIF was 100 or less. The final model for total ADG indicated that increasing SI or MRI improves calf growth. Also increasing MRCP increased growth but increasing MRfat depressed growth due to the interactions among SI, MRI, and MRfat. Growth of neonatal dairy calves appears more controlled by nutrient intake and their interactions than surrogates for health status of the calves (AFS and SERP) or environmental temperature.

Key Words: calf, growth, meta analysis

399 Effect of different fiber sources on performance and feed intake of Holstein calves. L. Castells*[1], A. Bach[1,2], and M. Terré[1], [1]*Department of Ruminant Production, IRTA*, *Caldes de Montbui, Spain*, [2]*ICREA*, *Barcelona, Spain*.

The objective of this study was to evaluate the effect of different fiber sources on performance and feed intake of Holstein calves. Sixty Holstein male calves (initial BW = 43.9 ± 5.86 kg) were randomly assigned to one of 3 different dietary treatments that consisted on a common starter plus alfalfa hay (A), rye-grass (R), and no access to forage (C). All calves were offered 2 L of milk replacer (MR) at 12.5% DM twice daily via a bottle until 50 d of age, and then only one daily dose of 2 L of MR at 12.5% DM during the week before weaning (57 d of age). Starter, MR, and forage intakes were recorded daily and BW was recorded weekly. Calves were individually housed using wood shavings as bedding material. Intake data were transformed using square root to achieve a normal distribution and were analyzed using a mixed-effects model with repeated measures that included initial BW as a covariate, and dietary treatment, week of study and their 2-way interaction as fixed effects, and the animal as a random effect. Starter

intake tended to be greater ($P = 0.05$) in R (1.2 ± 0.03 kg/d) than in A calves (0.9 ± 0.03 kg/d), but no differences were observed between C calves (1.0 ± 0.03 kg/d) and the other 2 treatments. Forage intake was greater ($P < 0.05$) in A (144 ± 0.26 g/d) than in R calves (59 ± 0.26 g/d) . Total dry matter intake (DMI) tended to be greater ($P = 0.10$) in R (1.7 ± 0.03 kg/d) than in C (1.4 ± 0.03 kg/d) and A calves (1.5 ± 0.03 kg/d). No differences were observed among treatments on ADG and feed efficiency. Offering forages to calves does not compromise total DMI, and it may foster consumption of starter, especially when the forage offered is rye-grass.

Key Words: forage, calves, performance

400 Effect of housing and management on dairy calves less than two months of age. T. M. Hill*, H. G. Bateman II, J. M. Aldrich, R. L. Schlotterbeck, D. L. Carr, and A. B. Chestnut, *Nurture Research Center, Provimi North America*, *Lewisburg, OH*.

Housing (hutches, naturally ventilated nursery), bedding (straw, sand), and summer cooling with fans were management conditions evaluated in 3 trials. Holstein calves (42 ± 2 kg BW) initially 2 to 4 d of age were managed at the Nurture Research Center in southwest Ohio. Calves were fed milk replacer (27% CP, 17% fat fed at 0.657 kg DM per calf daily), starter (20% CP DM, textured, fed free-choice), and water (free-choice). Measurements were for 56 d. In Trial 1, 28 calves per treatment were bedded with straw and housed either in poly hutches or wire mesh nursery pens. This trial was conducted from September to March. The average temperature was 8°C and ranged from −17 to 31°C. In Trial 2, 16 calves per treatment were managed in wire mesh nursery pens bedded with straw, in nursery pens bedded with sand, or in poly hutches bedded with sand. This trial was conducted from May to September. The average temperature was 21°C and ranged from 7 to 33°C. In Trial 3, 26 calves per treatment were housed in wire mesh nursery pens and bedded with straw with or without supplemental cooling with fans between 8AM and 5 p.m. This trial was conducted from May to September. The average temperature was 22°C and ranged from 8 to 34°C. Data were analyzed by trial as completely randomized block designs with calf as the experimental unit. Differences were declared at $P < 0.05$. In Trial 1, daily gain of calves in nursery pens was 7% greater than that of calves in hutches. In Trial 2, daily gain and starter intake of calves in the nursery with straw bedding were greater and scouring was less than calves bedded with sand in the nursery or hutches. In Trial 3, daily gain, feed efficiency, and hip width change were greater and breaths per minute were less for calves cooled with fans than calves that were not cooled. Straw bedding was preferred to sand, nursery pens were preferred to hutches, and summer daytime cooling with fans was preferred to no cooling.

Key Words: bedding, temperature, cooling

401 The effect of oral supplementation of selenium on passive transfer of immunoglobulins in dairy calves. B. Nelson*[1], S. M. Godden[2], B. W. McBride[1], T. F. Duffield[1], and K. E. Leslie[1], [1]*Department of Population Medicine, University of Guelph*, *Guelph, ON, Canada*, [2]*Department of Veterinary Population Medicine, University of Minnesota*, *St. Paul*.

The objective of this study was to evaluate the effects of oral selenium supplementation by the addition of sodium selenite to colostrum or colostrum replacer, on the success of passive transfer of immunoglobulin G (IgG) and on whole blood selenium status. During the summer of 2008, a total of 122 Holstein calves were enrolled at the Transition Management Facility, Emerald, Wisconsin. Calves were randomly assigned to receive either colostrum from their dam, or a commercially available colostrum replacer product. Calves were further randomized to receive selenium (sodium selenite) or placebo added to their respective colostrum treatments, at a concentration of 3 ppm. Blood samples were collected from every calf at birth, before feeding of colostrum, and again 24 h following feeding of colostrum. Whole blood samples were analyzed for selenium concentration using a fluorometric method. Serum samples were analyzed for IgG concentration using a radial-immunodiffusion assay. Statistical analysis was conducted using linear regression techniques in STATA. Calves that received colostrum or colostrum replacer with selenium had significantly increased whole blood selenium concentrations compared with placebo calves (μg/mL: 0.31; 0.22 ; $P < 0.001$). Calves fed colostrum from their dam had significantly higher serum IgG concentrations 24 h following colostrum feeding than calves fed the colostrum replacer product (g/L: 35.95; 17.6 ; $P < 0.001$). There were no significant differences in serum IgG at 24 h between calves fed maternal colostrum with or without selenium supplementation and calves fed colostrum replacer with or without selenium supplementation (g/L; 36.02, 35.87; 18.72, 16.58, respectively). From the results of this study, selenium supplementation of colostrum or colostrum replacer for improvement of passive transfer of IgG is not warranted.

Key Words: selenium, colostrum, passive transfer

402 Effects of endophyte-infected fescue seed on physiological parameters of mature female meat goats. A. R. Boyer*[1], T. L. Mays[1], G. W. Webb[1], M. A. Brown[2], and E. L. Walker[1], [1]*Missouri State University*, *Springfield,* [2]*USDA Grazinglands Research Center*, *El Reno, OK.*

The objectives of the study were to determine if consumption of endophyte-infected (E+) fescue seed would affect thermoregulation and DMI in mature female goats. During a 4 wk study, a total of 18 goats (Boer type) were assigned to treatments (n = 6 per treatment); endophyte-free KY-31 (E-), endophyte-free STF-43 (E43-), or E+ seed. Goats were fed a ration consisting of a 2:1:1 ratio of alfalfa pellets, a commercial sweet feed, and 1 of 3 types of fescue seed. All goats were fed 2% of BW, and orts were collected and weighed daily on a DM basis. At the initiation of the study, age and BCS were recorded. Temperature loggers designed for intravaginal insertion were used and temperature (T) collected. Average temperatures for 0400, 1000, 1600, 2200 h were recorded. Urine, blood, and BW were collected weekly. Ergovaline levels in the urine increased after 1 wk on treatment ($P \leq 0.03$). Dry matter intake was affected by age ($P \leq 0.01$). A treatment × week interaction ($P \leq 0.05$) occurred in wk 1 of the study, with E43- having greater DMI than E-, and E+ being intermediate. Seed intake was affected ($P \leq 0.02$) in E+ throughout the study and in E- wk 1 and 4 of study. Treatment ($P \leq 0.03$), treatment × week ($P \leq 0.01$), and age ($P \leq 0.007$) also had an effect on seed intake for E+ and E- treatments. Intake of alfalfa pellets and sweet feed did not differ ($P \leq 0.56$) among treatments. No difference in ADG among treatments ($P \leq 0.22$) occurred. A date affect on T occurred at 1600 h ($P \leq 0.002$) in E- and E43- treatments and at 2200 h ($P \leq 0.0003$) in E- and E+ treatments. At 0400 h, E43- maintained a greater T than other treatment groups ($P \leq 0.03$). At 1000 h, there was a treatment × week interaction ($P \leq 0.01$) and E43-maintained a greater ($P \leq 0.06$) T than the other treatments. Treatment affected DMI, seed intake, T, and urine concentrations of ergovaline. However, goats may handle ergovaline differently than other species and more research is required to evaluate these potential differences.

Key Words: endophyte, goat, intake

403 The effects of protein supplement on leptin concentrations in lambs and meat goat kids grazing bermudagrass pastures in central Oklahoma. E. L. Walker*[1], S. A. Nusz[2], D. H. Keisler[3], and M. A. Brown[4], [1]*Missouri State University*, *Springfield,* [2]*Redlands Community College*, *El Reno, OK,* [3]*University of Missouri*, *Columbia,* [4]*USDA Grazinglangs Research Center*, *El Reno, OK*.

Lambs and kids weaned and pastured on bermudagrass (BG; *Cynodon dactylon*) may not receive enough protein to reach maximal growth during mid to late summer when protein in BG declines. Leptin is an adipocyte-derived hormone that increases as body condition increases and is involved in body temperature regulation. Our objective was to determine the affects of protein supplementation on leptin status in lambs and meat goat kids grazing on summer BG pastures. In 2007, 10 Boer type (BT) and 13 Spanish × Savanna (ST) kids (start bw = 14 ± 5 kg) and 23 Katahdin (KK), 14 Katahdin × Suffolk (KS), 14 Suffolk × Katahdin (SK), and 21 Suffolk (SS) lambs (start bw = 30 ± 5 kg; start age for sheep and goats = 100 ± 10 d) were used. In 2008, 27 BT and 28 ST kids (start bw = 18.8 ± 0.6 kg) and 11 KK, 15 KS, 21 SK, and 25 SS lambs (start bw = 25.8 ± 0.7 kg; start age for sheep and goats = 100 ± 5 d) were used. Animals were allotted by weight, breed, and gender to one of 2 treatments: 1.22 ha of BG with no protein supplement (NP; n = 2) or with 21% molasses-based protein blocks (PT, n = 2). Animals were weighed and blood samples collected every 2 weeks. Data were analyzed using proc mixed as a split plot design and the analysis included the fixed affects of treatment, species, breed nested within species, gender, and all possible interactions. In 2007, serum concentrations of leptin did not differ by treatment ($P = 0.94$) or between species ($P = 0.60$) or gender ($P = 0.29$). There was a breed within species interaction ($P = 0.01$). Serum leptin values tended to decline from June to August ($P = 0.10$). In 2008, serum leptin tended to be greater in PT than NP animals ($P = 0.08$) and greater in kids than lambs ($P \leq 0.001$). No breed within species interaction was observed ($P = 0.49$) nor did gender affect serum leptin ($P = 0.33$). There was a strong association between date and serum leptin concentrations ($P \leq 0.001$) and there was a breed by date within species interaction ($P = 0.009$). In both trials, serum leptin values declined from June to August as forage quality decreased throughout the summer.

Key Words: kids, lambs, leptin

404 Factors affecting birth, 60-day, and weaning body weights of commercial meat goat kids born in two different seasons. K. Andries* and E. Sherrow, *Kentucky State University*, *Frankfort*.

Little information is available on the impact of season of kidding on growth and performance of meat goat kids. However, seasonal market trends have many producers kidding in the late fall and winter. Because of this, a study was designed to evaluate kid performance using 2 kidding seasons. The objectives of the study were to evaluate kid growth from birth to weaning by comparing birth, 60 d, and weaning BW; rate of gain to weaning; and kid survival to weaning in 2 alternative kidding seasons. Five hundred and 40 3 Boer sired commercial meat goat kids born in either fall (October, November, and December) or spring (March, April, and May) of 2005 through 2007 were available for this study. Data collected included, birth type; sex; and birth, 60 d, and weaning weight. Data was analyzed using Proc Mixed in SAS. Season of birth had a significant effect on birth and weaning weight, and ADG between 60 d and weaning. Birth type was significant for all traits except ADG between 60 d and weaning. Single born kids were heavier at birth than twin or triplet born kids (3.91, 3.47, 3.20 kg, respectively). Spring born kids were lighter than fall born kids at birth and weaning (3.37 vs. 3.68 kg for birth and 16.86 vs. 18.09 kg for weaning, respectively). Fall born kids gained faster between 60 d and weaning (170 vs. 130 g/d, respectively). The interaction between year and birth type was significant for birth weight and the sex by birth type interaction was significant for 60 d weight and ADG to 60 d. Season of birth did not have an effect ($P = 0.105$) on survival to weaning, however type of birth was significant ($P < 0.001$) for survival. Single born kids were more likely to survive to weaning than all other birth types. Twin born kids were second most likely to survive and triplet and quadruples were similar in survival to weaning. This project indicates that season of birth and birth type have an effect on performance for meat goat kids.

Key Words: meat goat, preweaning growth, season of birth

405 Relationship between body measurements and milk yield and a method to predict the milk production of Saanen goats. S. Dikmen*, A. Orman, H. Üstüner, and M. M. Ogan, *University of Uludag*, *Bursa, Turkey*.

Type traits are functional traits in dairy goats and have an indirect effect on production. Because of moderate to high heritability of these traits, they are valuable tool in breeding program of dairy cattle. In dairy cattle these measurements are used for prediction of some production traits. Despite the wide use of evaluations for type in goats, little is known about the association between body conformation and production traits. The objective of this study was to investigate the relationship between body measurements and milk yield in Turkish Saanen goats and to develop a method to predict the lactation milk yield. A total of 40 goats were used for this study. Body condition score (BCS), live weight (LW) and a total of 24 body measurements were recorded 7 d after birth. Milk yield was recorded fortnightly and 60, 90, 120, 150, 180, 210, 240 d and lactation milk yield (LM) were estimated using these records. Lactation milk yield was 689.8 ± 38.0 kg in 298.1 ± 2.3 d. The effects of birth month (February or March), birth type (single or twin), BCS, LW (kg), age (month), parity, DIM (day) and all interactions were investigated using PROC MIXED of SAS. The correlations between body measurements and milk yield were also determined. The effects of BCS ($P < 0.05$), LW ($P < 0.01$) and DIM ($P = 0.08$) on LM were found significant and these effects were determined as a base model for regression analysis. Afterward, LM corrected for age and stepwise regression analysis was used for identifying the most reliable model which has the highest determination coefficient degree ($r^2 = 0.45$) on age corrected LM (CLM) of Saanen goats. The prediction model of CLM was determined as; CLM = −460.5 + (−379.6 × BCS) + (51.9 × Chest depth) + (−21 × Abdomen depth) + (29.9 × Abdomen width) + (31.7 × Shoulder joint - tuber coxae angle) ($P < 0.001$). Based on these results, this equation could be used to predict the CLM of Saanen goats. However, more data are needed to increase the reliability of the model.

Key Words: milk yield, prediction, Saanen

406 Effects of prepubertal growth rate of dairy ewe lambs on their subsequent lamb and milk production. D. L. Thomas* and Y. M. Berger, *University of Wisconsin-Madison*, *Madison*.

A study was conducted at the Spooner Ag Research Station of UW-Madison with 252 dairy ewe lambs born from 2004 to 06 to determine if ad libitum feed intake during the prepubertal period would be detrimental to their subsequent production. The lambs were of East Friesian and/or Lacaune breeding. They were raised on milk replacer and a high concentrate ad libitum diet until 30 d of age. At 50 d of age, they were randomly assigned to 1 of 2 growth treatments: full (F) or restricted (R) feed. Both treatment groups were fed a 13% CP grain mix of whole shelled corn and a high protein pellet in straw-bedded pens. Full treatment lambs received as much of the grain mix as they could consume, and R lambs received ~70% of the average per head intake of the F lambs. Treatments continued for ~100 d until lambs were ~5 mo of age. Ewe lambs were mated to lamb first at ~1 yr of age, and lamb and milk production was recorded through 2008. At the end of the treatment period, R lambs were 6.5 kg lighter ($P < 0.05$) than F lambs. However, R lambs had greater ($P < 0.05$) ADG from the end of the treatment period to their first mating and from their first mating to their first lambing and were slightly heavier ($P < 0.10$) than F ewes at first lambing. Ewe fertility and litter size were very similar between the F and R ewes when lambing at 1 yr of age and at older ages. Lactation traits (lactation length; yield of milk, protein and fat; and % protein and fat) were not significantly different between treatments, but mean values were actually slightly higher for F ewes compared with R ewes for all lactation traits (e.g., +9.2 kg for lactation milk yield). There were no differences between treatments for the proportion of ewes remaining in the flock on June 30, 2009 or the average age at which ewes left the flock. The results of this study indicate no detrimental effects of ad libitum prepubertal feeding of dairy ewe lambs to 5 mo of age.

Key Words: lactation, prepubertal, sheep

407 Milk production and lamb growth of hair sheep weaned at 63 or 90 d of age in an accelerated lambing system in the tropics. R. W. Godfrey* and K. Facison, *University of the Virgin Islands*, *St Croix*.

This study was designed to evaluate the impact of weaning age on lamb and ewe productivity in an accelerated lambing system. During a fall and summer lambing, St. Croix White ewes (n = 19 and 22) and lambs (n = 30 and 34), and Dorper × St Croix White ewes (n = 18 and 27) and lambs (n = 31 and 39) were used. Lambs were assigned to be weaned at 63 (CTRL; n = 70) or 90 d of age (LATE; n = 64) based on breed, sex and litter size. In the summer 8 ewes/group were evaluated for milk production at 28, 63, 76 and 90 d postpartum (PP) using oxytocin and 4 h lamb removal. After weaning lambs were fed concentrate (2% BW/d) and grazed guinea grass. Ewes grazed guinea grass at all times. Weights were analyzed using breed and weaning age as main effects. Milk production was analyzed using breed, days PP and weaning age in a repeated measures model. Season was not significant for any trait so data were pooled. Ewe weight at breeding before the first lambing was the same ($P > 0.10$) as at the subsequent breeding (40.9 ± 1.1 vs. 41.9 ± 1.1 kg, respectively). At the start of the subsequent breeding 43% of LATE and 10% of CTRL ewes were nursing lambs ($P < 0.0004$). Pregnancy rate at the subsequent breeding, determined by ultrasound, was not different ($P > 0.10$) between LATE and CTRL ewes (97.4 vs. 97.8%, respectively). At weaning LATE lambs were heavier ($P < 0.0001$) than CTRL lambs (14.5 ± 0.4 vs. 11.2 ± 0.4 kg, respectively). There was no breed x weaning age interaction. At 90 d of age LATE and CTRL lambs had similar ($P > 0.10$) weights (14.5 ± 0.4 vs. 13.9 ± 0.4 kg, respectively). Milk production on d 63 was not different between breed or weaning age ($P > 0.10$). By d 76 and 90 milk production of LATE ewes had decreased to 84 ($P < 0.07$) and 66% ($P < 0.0002$) of d 28 levels. Weaning at 90 d of age can be done in an accelerated lambing system with no detrimental effect on ewe productivity. Late weaning led to a decrease in the amount of time that lambs received high cost, imported feed without a reduction in their growth. There is potential to have a positive impact on the economics of producing hair sheep in the tropics.

Key Words: hair sheep, weaning, milk production

408 Economic impacts of ram mating behavior. L. K. Gardiner*, B. S. Rashford, J. P. Hewlett, and B. M. Alexander, *University of Wyoming*, *Laramie*.

Little is known about producers' perceptions of ram performance and ranch-level economic impacts of improved ram management. This research combines a survey of Wyoming sheep producers and a partial budget analysis to better understand producers' perceptions and the economic consequences of ram performance. We used a modified Dillman sampling design with a stratified random sample based on flock size to collect survey data on Wyoming sheep producers. Five strata were defined according to the number of bred ewes owned: small operations (<30 ewes), small to medium (30–49 ewes), medium (50–99 ewes), medium to large (100–299 ewes), and large operations (>300 ewes). The National Agricultural Statistics Service administered the survey to assure a statistically valid stratified sample. The survey′s respondents represent approximately 40% of Wyoming sheep producers. The number of responses from each stratum is consistent with the actual distribution of sheep operations in Wyoming. Current ram management practices

and opinions about the importance of ram performance are included in the survey. Analysis of the data shows the majority of producers believe breeding competence is critical to flock productivity (56% of respondents strongly agree) and testing ram performance is important for profitability (45% of respondents strongly agree). Survey data suggests that producers may not be integrating beliefs into management. For example, 77% of the respondents listed age and not libido as the primary reason for culling rams. Less than 10% of respondents listed ram libido as an important criteria for ram selection. Budget analysis indicated smaller high-performing ram batteries may increase profits. Profit increases are sensitive to the cost of identifying ram performance, operation type, and the flow of genetic characteristics. Our results suggest a need for producer education and research concerning the economic impacts of ram performance.

Key Words: sheep, economics, libido

Animal Behavior and Well-Being: Swine and Poultry

T1 Recognition of maternal amniotic fluid by pre-weaning piglets. J. Figueroa*, D. Solà-Oriol, R. Davín, J. F. Pérez, and X. Manteca, *Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain.*

Pigs have a very developed olfactory system that allows them to recognize cues from the environment within the first days after farrowing. Amniotic fluid is a cue that piglets use to recognize their own mother and guide them to this key resource post-natally. The aim of this study was to estimate if sucking piglets of different ages have the ability to discriminate between their own mother's amniotic fluids versus an alien one. Forty male/female pigs from 10 litters (4 piglets/litter) were used to test their attraction for 3 olfactory stimuli (triple-choice feeding test) using a Triple-U-Testing Arena (TUTA), located in an isolated room on d 4, 14 and 21 after farrowing. Olfactory tested cues included strips impregnated with their own maternal amniotic fluid (MAF), alien amniotic fluid (AAF) and water in the middle as a control. The position of MAF and AAF were rotated in each test. Piglets were tested in litter-pairs to avoid fear and distractive behaviors. Each test lasted 7 min, during which, the time spent by piglets in nasal contact with each strip was measured by direct observation. Data were analyzed using the GLM procedure of SAS. Latency time accounted to more than 6 min of the 7 min test. Older piglets became increasingly agitated, looking for alternative routes to escape and they also had more play and exploring behaviors at the TUTA. Piglets showed preferential responses toward MAF at d 4 (10.32 s/couple) and 14 (2.57 s/couple) as compared with AAF (4.75, $P < 0.01$ and 0.98, $P < 0.05$ s/couple) and water (0, $P < 0.01$ and 0.54, $P < 0.01$ s/couple). No differences were observed at d 21. These results show that piglets are able to discriminate between their mother′s amniotic fluid and amniotic fluid from other sows during their first weeks of life. This attraction might keep piglets protected near to the sow and also teach them to follow cues of maternal pregnancy feeding. Attraction for amniotic fluid begins to disappear as piglet needs and motivation changes with age.

Key Words: amniotic fluid, piglets, preference

T2 The effect of colostrum supplementation on piglets′ body temperature recovery and lactation performance. R. Muns*, J. L. Ruiz de la Torre, P. S. Agostini, X. Manteca, and J. Gasa, *SNiBA, Departament Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona*, *Barcelona, Spain*.

The objective of this paper was to evaluate the effect of helping piglets′ colostrum intake on lactation performance. Fifteen Danbred sows from a commercial farm were distributed to 3 treatment groups based on BW, parity and back fat thickness 4 d before farrowing. After farrowing piglets with less than 1.250 kg BW (n = 56) were treated (T1: no intervention, n = 24; T-2: administration of manually milked sow's colostum (10 mL/animal), n = 18; T-3: single doses of a commercial product (Calostrene/ANIVET) fed on d 0, n = 14). All piglets (n = 172) were weighted on farrowing day (d 0), d 1 and d 21 of lactation; rectal temperature was measured at birth and d 1. Piglet mortality was also recorded. Data of treated piglets were analyzed using the GLM procedure of SAS with piglet being the experimental unit. Piglet′s initial BW did not differ statistically among groups (mean value of 1.028 g/piglet, $P = 0.9$). T2 piglets tended to show higher BW gain after 24h of birth than T1 piglets (78.7 vs. 44.9g ± 62.63; $P = 0.08$). Piglets rectal temperature at 24h of life was higher for T2 and T3 compared with T1 (38.8 and 39.1 vs. 38.2°C ± 0.73; $P < 0.05$). Compared with T1 (3.624g), treated piglets total weight gain from d 0 to d 21 were 8.5 and 14.9% numerically higher for T2 and T3, respectively ($P = 0.3$); meanwhile corresponding values for all piglets improved by 6.1% and 9.7% for T2 and T3, respectively, over a 4.158 g/piglet for T1 ($P = 0.3$). Although T-2 had the lowest numerical mortality (when considering all the piglets) during lactation compared with T-1 and T-3 (7.9 vs. 10.6 and 9.6%; $P = 0.9$) it did not differ statistically among groups. These results show the importance of guaranteeing the colostrum intake by small piglets during the first hours of life enhancing its body temperature recovery and tending to improve its weight gain during the first 24h of live.

Key Words: piglet, colostrum, body temperature

T3 Comparison of pig restraint and sampling methods on blood lactate concentration. B. Buzzard*[1], L. N. Edwards[1], R. D. Goodband[1], D. B. Anderson[2], T. E. Engle[2], and T. Grandin[2], [1]*Kansas State University*, *Manhattan,* [2]*Colorado State University*, *Fort Collins*.

The objective of the study was to examine the effects of restraint and blood sampling method on blood lactate concentration (LAC) in pigs. Restraint methods were snaring or restraint with sorting boards. Blood was sampled from 120 pigs (58 barrows, 62 gilts) at approximately 165 d of age (126.1 ± 2.9 kg) over 2 consecutive days. Each day, 30 pigs were sampled per method. All pigs were housed in one barn and pigs in adjacent pens were not sampled simultaneously. Snaring consisted of a trained handler snaring each pig while blood was collected via jugular venipuncture (approx. 7 mL). Restraint with sorting boards consisted of a trained handler restraining each pig with 2 sorting boards and the side of the pen to form a 3-sided barrier reducing pig movement. The distal ear vein was pricked with a 20-gauge needle to obtain several drops of blood for LAC analysis. LAC was measured using a hand-held lactate analyzer. The duration of restraint and a behavior score (1–4, 1 = no vocalization or movement and 4 = constant movement, vocalization and struggle) for each pig were recorded during sampling. LAC was compared between the 2 sampling methods and duration of restraint was used as a covariate in the analysis. Results indicated that pigs that were snared had greater ($P = 0.04$) LAC than pigs that were restrained using the sorting board method, 2.4 ± 0.1 and 2.1 ± 0.1 m*M* respectively. Both measurements of LAC were considerably lower than baseline LAC reported in published literature. There was a positive correlation (r = 0.42, $P = 0.001$) between duration and LAC for pigs that were restrained by snaring; the longer the restraint duration, the greater the LAC. Positive correlations were observed between duration and behavior score (r = 0.41, $P = 0.001$), duration and LAC (r = 0.64, $P < 0.001$) and behavior score and LAC (r = 0.26, $P = 0.05$) in pigs restrained with sorting boards. In the boarded group, longer durations and higher behavior scores were related to increased LAC. Restraint duration should be kept at a minimum when both methods are used.

The sorting board sampling method is a potential technique to use when sampling small quantities of blood in pigs.

Key Words: lactate, restraint, pig

T4 The effect of alleyway width on gestating sow welfare in a free-access stall system. L. A. Mack*[1], M. F. Elischer[1], S. D. Eicher[2], A. K. Johnson[3], D. C. Lay, Jr.[2], B. T. Richert[1], and E. A. Pajor[4], [1]*Purdue University*, *West Lafayette, IN*, [2]*LBRU, USDA-ARS*, *West Lafayette, IN*, [3]*Iowa State University*, *Ames*, [4]*University of Calgary*, *Calgary, AB, Canada*.

Free-access stalls allow sows to choose the protection of a stall or use of a shared alleyway. This study investigated the effect of alleyway width on production and physiological variables in gestating sows. At ~33 d of gestation, 21 sows (n = 168) were equally assigned to 1 of 3 pens that had 7 free-access stalls. Each pen had a shared alleyway of 0.91, 2.13, or 3.05 m wide. Sows were moved to farrowing ~5 d before expected farrowing date. Back fat (BF), BW, BCS, and lameness (LM) were measured on d 35, 65, and 101. Sows' body lesions were scored weekly. Blood samples were collected on d 30, 66, and 100. Data were analyzed in SAS using a mixed model with a post-hoc Tukey adjustment. Although similar basally, overall BF was greater in 0.91 m sows than 2.13 m sows ($P < 0.05$) and increased in all groups over time ($P < 0.05$). Sow BW increased over time ($P < 0.0001$) but did not differ by treatment. BCS showed no overall treatment or time differences, but on d 35 0.91 m sows had a higher BCS than 3.05 m sows ($P < 0.05$). Lameness increased slightly in 2.13 and 3.05 m sows immediately after mixing and decreased afterward in 3.05 m sows ($P < 0.05$). Upper body lesions increased immediately after mixing and then decreased in all treatments ($P < 0.0001$). Lower body lesions showed no differences by treatment or time. Cortisol increased after mixing and then decreased ($P < 0.01$), but no treatment differences were observed. Neutrophil percentage was greater ($P < 0.05$) and the neutrophil: lymphocyte ratio tended to be greater ($P < 0.08$) in 0.91 m sows than the 3.05 m sows. No other leukocyte populations differed by time or treatment. Overall, the 3 alleyway widths were similar, but 0.91 m sows had greater back fat implying decreased activity and musculation due to space restrictions. The sows in 0.91 m alleyway also showed increased neutrophil percentage suggesting a slightly greater stress level.

Key Words: sow housing, welfare, stress

T5 A comparison of two farrowing environments on piglet performance. A. R. Hanson*, P. M. Walker, and J. P. Holt, *Illinois State University*, *Normal*.

Traditional farrowing stalls have been designed to maximize piglet survival, with minimal concern regarding sow welfare. Standard litter data (birth weight, number born alive, etc.) from farm records were evaluated in an observation study utilizing a 200 sow (Chester White cross and Landrace cross) operation over a 6 y period (1449 litters) to compare 2 stall types, free stalls with movable sides (F), or traditional, fixed bow-bar stalls (B), on piglet performance and welfare. The F stalls were closed (in a straight position) ~1d before expected date of parturition and opened up to a triangular shape at ~3d post farrowing giving sows the ability to turnaround. Sows were placed into stalls 3–7 d before their expected date of parturition (n = 740 for B and 709 for F) and fed the same diet. Data were statistically analyzed, assuming a completely randomized design, using SPSS ANOVA procedures with year, season and room used as covariates and stall type as the independent variable. Sow parity was known for a limited number of litters (351), so a separate test was conducted using year, season, room, and parity group (PG) as covariates. When data were analyzed with PG excluded, there were differences favoring the B stall for birth performance and weaning performance ($P < 0.05$). Adjusted weaning weight was greater ($P < 0.05$) in B stalls compared with F stalls (mean = 61.22 ± 10.8 kg and 57.429 ± 11.56 kg, respectively). Number of pigs crushed was not impacted by any independent variable in this study (mean = 1.03 ± 1.24 and 1.01 ± 1.48 pigs/litter for B and F stalls, respectively). Data analysis suggested that larger sows may have been allotted to B stalls due to the difficulty for them to turnaround in F stalls successfully. Therefore, PG was included as a covariate to account for sow size, assuming that larger sows were multiple parity sows. Consequently, differences between the stalls became nonsignificant ($P > 0.05$). These results indicate that success in farrowing stalls may be affected by an interaction between sow size and stall design. Stalls which offer increased sow movement can be used without negative effects on piglet performance.

Key Words: farrowing stall, sow housing

T6 Behavior of Duroc pigs on sudangrass (*Sorghum bicolor*) pastures. S. Pietrosemoli*[1,2], J. C. Guevara[2], A. Lobo[3], J. Cardona[3], W. Maradiaga[3], and J. T. Green[4,2], [1]*Animal Science Department, North Carolina State University*, *Raleigh,* [2]*Alternative Swine Research and Extension Project*, *Raleigh, NC*, [3]*Universidad Nacional de Agricultura*, *Catacamas, Olancho, Honduras*, [4]*Crop Science Department, North Carolina State University*, *Raleigh.*

To evaluate the effect of weekly movement of shade and drinking structures on pig behavior, 72 Duroc pigs (castrated males and females; 32 and 97 kg initial and final live weight, respectively) were used during 5 weeks (July - August 2009) at the Center for Environmental Farming System (CEFS) in Goldsboro, NC. Twelve pigs were randomized to each of 6 sudangrass 0.16 ha paddocks (135 m^2 /pig), and were managed under 2 different strategies: Stationary (S) or Mobile (M) shade and drinking structures, in M shade and drinkers were moved on a weekly basis. Animals were kept under a continuous grazing system, with ad libitum access to a concentrated feed (16% PC) and water. Pig behavior was registered by one trained observer through direct observation (12 min/paddock) of the activity of the animals from outside the paddock twice a week, 5 times/day: 8:00 and 10:00 a.m. and 12:00, 2:00 and 4:00 p.m. Animals activities were categorized as eating, drinking, lying/resting, walking, grazing and rooting, and were expressed as percent. The experimental design was a completely randomized block, with 3 field replicates. Data was square root (x+1) transformed before performing ANOVA through PROC GLM of SAS v9.1. Pigs spent most of their time lying/resting (65.8 ± 2.1%, eating 8.64 ± 0.9%, drinking 3.02 ± 0.4%, walking 14.69 ± 1.5% grazing 5.49 ± 0.9% and rooting 2.4 ± 0.4%). Shade and drinkers movement strategies did not show an effect in any of the animal activities. The time of the day influenced animal behavior ($P < 0.05$), pigs being more active in the morning, as can be observed from lying/resting pattern 8:00 a.m.: 39.5%; 10:00 a.m.: 47.1%; 12:00 p.m.: 86.9%; 2:00 p.m.: 87.3% and 4:00 p.m.: 68.2%. In conclusion, these results suggest that pigs are more active during the cooler time of the day and that movement of shade and drinking structures had no effect on pig behavior.

T7 Effects of postnatal serotonin agonism on fear response and memory. R. L. Dennis* and H. W. Cheng, *Livestock Behavior Research Unit, USDA-ARS*, *West Lafayette, IN*.

The neurotransmitter serotonin (5-HT) acts as a neurogenic compound in the developing brain. Early administration of a 5-HT agonist alters

the development of serotonergic circuitry, altering behaviors mediated by 5-HT signaling, such as memory, fear and aggression. The present study was designed to investigate the effects of early 5-HT agonism on later behaviors. White leghorn chicks were given an injection of 5-MT (5-HT agonist) at 2.5mg/kg (low dose), 10mg/kg (high dose) or saline (control) on day of hatch and a second dose 24 h later. Chicks (n = 13/treatment) were tested for fear response and memory at 2 wks of age. Chicks were subjected to a social isolation fear test for 20 min, time to first vocalization, number of vocalizations, time to first leap and number of leaps were recorded. ANOVA using SAS proc mixed revealed that chicks injected with low dose of 5-HT agonist had significantly shorter latency to time of first vocalization and a greater number of vocalizations compared with control birds ($P < 0.05$). Chicks treated with the high dose of 5-HT agonist tended to exhibit the same pattern of behavioral change ($P < 0.10$). No difference was found in latency to or frequency of leaps. In a memory test, chicks were placed in a running wheel and presented with an imprinted object (white box with a red light) and a novel object (blue box with a white light). The distance traveled in the wheel toward each object was measured. Analysis of variance results revealed that chicks from all groups traveled a similar distance toward a familiar object. However, control chicks walked the least toward a novel object, low dose chicks tended to walk further toward a novel object ($P < 0.10$), and high dose chicks walked significantly farther for a novel object ($P < 0.05$). No difference was found between treatments in a tonic immobility fear test ($P > 0.05$). Body weight and fluctuating asymmetry of the shank, and shank absolute length and width did not differ among treatments ($P > 0.05$). Our data show that later behaviors including fear and memory can be altered by early alteration of the 5-HT system without altering growth development, such as body weight, leg size and bilateral symmetry.

Key Words: serotonin, postnatal, behavior

T8 Influence of increasing-dim and bright, and split-dark-bright lighting on broiler mobility and stress. R. J. Lien*, J. B. Hess, and S. F. Bilgili, *Auburn University*, *Auburn, AL*.

The objectives were to determine lighting and strain effects on mobility and stress responses for tray pack (TP) and breast yield (BY) broilers exposed to programs meeting either US or EU lighting guidelines. Forty males were placed by strain in each of 2 1.5 by 3.7 m pens in 12 light controlled rooms. An increasing-dim (ID) treatment (23L:1D, 1–7 d; 12L:12D, 8–14 d; 14L:10d, 15–21 d; 17L:7D, 22–28 d; 20L:4D; 29–35 d; 23L:1D; 36–48 d; 2 FC to 7 d and 0.25 thereafter) was provided in 4 rooms. An increasing-bright (IB) treatment (23L:1D, 1–7 d; 12L:12D, 8–14 d; 14L:10D, 15–21 d; 16L:8D, 22–28 d; 18L:6D, 29–45 d; 23L:1D, 46–48 d; 2 FC throughout) was provided in 4 rooms. A split-dark-bright (SDB) treatment (16L:4D:2L:2D and 2 FC) was provided in 4 rooms. Sitting or standing on 15 cm high raised platforms (decking), the ability to climb onto raised platforms to feed, tonic immobility (TI), and heterophil:lymphocyte ratios (H:L) were determined at approximately 3 and 6 wk. Gait scores and latency to lie durations were determined during wk 7. Data were analyzed by GLM of SAS with a statistical significance level of $P < 0.1$. At 3 wk, decking was greatest in IB treatment (11.0%), least in SDB (6.7%), and intermediate in ID (8.7%)($P = 0.03$). Decking was greater in the TP (11.5%) than BY (6.7%) strain at 6 wk ($P = 0.001$). Feeding on raised platforms was greater in the TP (1.67) than BY strain (1.34) at 3 wk ($P = 0.004$). TI was greater in the ID (267 s) and IB (283 s) than the SDB treatment (201 s) at 6 wk ($P = 0.09$), and nearly greater in the TP (194 s) than BY (128 s) strain at 3 wk ($P = 0.13$). At 3 wk, H:L was greatest in the IB treatment (0.52), least in SDB (0.40), and intermediate in ID (0.43)($P = 0.06$). Gait scores and latency to lie durations were not affected ($P > 0.1$) by treatment or strain. In this study, lighting treatments and broiler strains inconsistently affected measures of mobility and physiological or psychological stress.

Key Words: broiler, lighting, stress

T9 The use of lidocaine as an analgesic to study immediate pain associated with hot blade beak trimming in 1- and 10-day old White Leghorn chicks. M. Cho*[1], K. Schwean-Lardner[1], A. Livingston[2], and H. L. Classen[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Department of Veterinary Biomedical Sciences, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

Hot blade (HB) beak trimming (BT) is commonly used by the poultry industry to reduce feather pecking and cannibalism. As there is a poor understanding of pain immediately post HB trimming, research was conducted using lidocaine as an analgesic and behavioral observation as an indicator of a pain response to BT. An initial study used behavioral observation and the known analgesic effects of lidocaine to select 0.4 mL of 0.02% lidocaine with epinephrine (LE) as an effective dose for 1-d old chicks. Based on 1-d old chick results and body weight, 0.4 mL of 0.04% LE was set as a suitable dose for 10-d old chicks. Trials with 1- and 10-d old chicks compared the effect of LE with BT (removal of 1/3 of beak), saline with BT, BT with needle insertion, no BT with needle insertion and LE without BT on bird behavior for 135 min post HB trimming. Leghorn chicks (40 1-d, 30 10-d) were assigned to treatment groups and 1 chick per treatment was assigned to each of 8 and 6 replications, respectively. Behavior was analyzed using the SAS GLM procedure and a priori contrasts to evaluate the effects of liquid injection, LE injection and BT on chick behavior (% of time; $P \leq 0.10$). Less walking behavior was seen in 1- (2.2 vs. 3.8%) and 10- (2.1 vs. 3.6%) d old chicks with liquid injection. LE injection to BT chicks did not affect behavior in contrast to those trimmed with either saline injection or needle insertion indicating that pain is not associated with the period immediately post treatment in 1- and 10-d old chicks. However, BT decreased standing (16 vs. 21%) and feed pecking (6.3 vs. 9.4%) and increased resting (66 vs. 59%) behavior in 10-d old chicks in comparison to untrimmed chicks suggesting that physical trauma other than pain impacts chick behavior. In conclusion, these results suggest a painless phase post HB trimming at 1- and 10-d of age but that trimming continues to affect behavior in comparison to untrimmed birds.

Key Words: poultry welfare, pain, feather pecking

T10 Comparison of an enriched and barren environment on welfare related fear behaviors of commercial laying hens. C. J. Davis*, H. Taira, M. M. Beck, and P. A. Skewes, *Clemson University*, *Clemson, SC*.

In response to the debate over laying hen welfare, this study was conducted to determine the effects of housing environment on 2 welfare related fear behaviors of commercial laying hens. Emergence test [EM] and tonic immobility test [TI]) were used to determine the fearfulness of the laying hens. Nine hundred day-old Leghorn chicks were randomly assigned to either a floor pen environment or a commercial cage housing environment. The cage chicks were housed in 20 commercial battery brooder cages (25 per cage) up until 4 weeks of age and then moved to 39 battery grower cages (10 per cage). At 16 weeks of age, the pullets were moved into 39 commercial layer cages (8 per cage) for the remainder of the experiment. The floor pen birds were continuously housed in 14 individual floor pens (28 per pen) enriched with perches, dust baths, and nest boxes. Behavioral assessments were conducted at wk 17, 21, 25, 29

and 33. Both behavioral assessments were conducted on 10 hens from the cage environment and 10 hens from the pen environment. Cages and pens were selected randomly. The latency to emerge from a box was recorded in the EM and the latency to recover from tonic immobility was recorded during TI. Comparison of environmental treatments with a 2 sample *t*-test showed a shorter mean EM and TI duration in birds housed in the enriched environment ($P < 0.001$). The mean emergence duration for cage birds was 320.6 ± 30.0 s compared with 155.9 ± 30.0 s for floor pen birds. The mean tonic immobility duration for cage birds was 384.3 ± 35.8 compared with 212.2 ± 35.1 for pen birds. In addition to the overall treatment difference, there were significant differences at specific sample times. Although previously it was found that the effect of rearing environment was not consistent with fear responses for chicks and pullets, it appears that the housing environment had a consistent effect on fear response for the adult laying hens. In this study, hens from the enriched environment showed less fear than those from the barren environment.

Key Words: tonic immobility, emergence test, laying hen welfare

T11 The behavior of Japanese quail fed diets supplemented with passionflower. J. D. T. Silva, F. H. Hada, R. H. Marques, R. A. Gravena, V. K. Silva, S. A. Queiroz, and V. M. B. Moraes*, *São Paulo State University*, *Jaboticabal, SP, Brazil*.

This study evaluated the effect of passionflower (*Passiflora alata*), phytotherapic properties with anxiolytic and sedative, on the diet on the behavior of Japanese quail in the reproductive phase. Twenty-four female and 8 male 35-d-old birds were mated in a completely randomized design consisting of 2 treatments (0 and 500 mg passionflower/kg feed) with 4 replicates of 4 birds (3 female:1 male) for 120 d. During the observation period, a 4 camera CCTV surveillance system was mounted in the roof of the facility, that recorded the behavior of quails. The behavioral parameters (eating, drinking, feather preening, comfort movement, avoid and escape, aggressiveness, crouching) were tabulated over 5-h time spans made every 14 d, for a total of 6 observation periods for each cage. The assessment of focal bird behavior was accomplished by marking the birds with non-toxic paint. The inclusion of passionflower in the diet of the breeding quail increased consumatory behaviors of birds in time spent by eating (from 25.92 to 27.19%), drinking (from 13.45 to 17.26%), feather preening (from 9.10 to 14.95%), comfort movement (from 13.02 to 17.08%) and crouching (from 7.35 to 14.46%) ($P < 0.0001$). Expressions of avoid and escape (from 14.08 to 6.20%) and aggression (from 17.07 to 2.85%) were reduced ($P < 0.0001$). It was concluded that passionflower enhances the positive expression of behaviors related to the welfare of Japanese quail during breeding.

Table 1. Average percent time spent by birds on behaviors as affected by diets supplemented with and without passionflower

Passionflower (mg)	Eating	Drinking	Feather preening	Comfort movement	Avoid and escape	Aggressiveness	Crouching
0	25.92 [b]	13.45 [b]	9.10 [b]	13.02 [b]	14.08 [a]	17.07 [a]	7.35 [b]
500	27.19 [a]	17.26 [a]	14.95 [a]	17.08 [a]	6.20 [b]	2.85 [b]	14.46 [a]
P	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001	<0.0001
CV (%)	1.88	4.01	6.47	1.24	7.26	5.38	15.25

Means followed by same letter in column do not differ by Fisher's test ($P \leq 0.05$).

T12 Strain differences among six varieties of fowl in two fear tests. G. S. Archer* and J. A. Mench, *University of California, Davis*.

Fear tests are often used to assess the well-being of chickens. It is important to examine how genetics may affect behavioral responses during fear testing. We conducted 2 fear tests to examine the responses to induction of tonic immobility (TI) test and inversion after catching (INV), on 6 different varieties of fowl: red Junglefowl (JF, n = 17), red Junglefowl/Rhode Island Red crosses (JFC, n = 20); 3 different single-comb White Leghorn (SCWL) varieties (HyLine CV20, n = 20, a commercial egg layer; UCD-03, n = 20, an inbred line of MHC recombinants; Mono-PNU, n = 20, which lacks the MHC II receptor), and featherless chickens (FL, n = 20, derived from multiple crosses). Data were analyzed using GLM or Kruskal-Wallis. JF and FC required more inductions ($P < 0.05$) than CV20 and Mono-PNU during TI. The UCD-03 also required more ($P < 0.05$) inductions than Mono-PNU. Latency to first head movement during TI was longer ($P < 0.05$) in CV20 (54.3 s) than in all other varieties (15.8 s). Latency to right was longer ($P < 0.05$) in CV20 (301 s) and Mono-PNU (517 s) than JF (112 s) and FL (225 s) varieties. UCD-03 had a shorter ($P < 0.05$) duration of wing flapping (3.9 s) and fewer total flaps (15.9) than all other varieties during INV (9.4 s, 55.2 flaps). UCD-03 (3 flaps/sec) and Mono-PNU (3.6 flaps/sec) wing flapped less intensely ($P < 0.05$) than all other varieties (5.9 flaps/sec) except JFC (5.2 flaps/sec), while FL flapped (6.8 flaps/sec) more intensely ($P < 0.05$) than all varieties except JF. Factor analysis revealed that there were 2 factor loadings for each variety but that the variables measured loaded differently for each variety. These results demonstrate that different varieties of fowl react differently during different fear tests and different types of fear responses predominate in different varieties.

Key Words: fear, chicken, genetics

T13 Behavior expression of testosterone treated cockerels in response to social grouping. S. S. Askari Rankouhi*, M. A. Karimi Torshizi, R. Vaez Torshizi, A. Niknam, and A. Maghsoudi, *Tarbiat Modares University*, *Tehran, Iran*.

For many years it is demonstrated that testosterone hormone increase sex secondary
characters and also, enhance aggressive behavior of animals. The objectives of this study were evaluation of sex secondary character expression in testosterone injected birds as affected by un-injected pen-mates' behavior. Total of 60 1-d-old male broilers (Arian - Iranian Hybrid) were divided into two identical groups (30 birds per group). Chicks of the first group received 25 mg of testosterone enanthate by intramuscular injection. Birds of the second group were injected by sterile physiological serum and were considered as control group. A week post injection, a third experimental group was formed by mixing 10 birds form each of the two initial groups, therefore the three final experimental groups were un-injected control, testosterone injected and blend of injected and un-injected birds. The length of neck feathers, size of comb (mm) and attack toward wood stick or hand (number of attacks per minute) were evaluated at days 21 and 42 of age. The testosterone injection caused significant differences in all measured variables compared to control un-injected birds at 21 days of age ($P < 0.05$). Interestingly, at 42 days of age the effects of testosterone on measured variables were influenced by the composition of pen-mate individuals. The testosterone induced changes on above mentioned sex secondary characters were rapidly restored in those injected birds which had un-injected pen-mates, while testosterone induced sex secondary

characters stayed unchanged in all-injected birds group ($P < 0.05$). The results of the present study showed the impact of social behavior of pen-mates on the expression of physiological and behavioral changes induced by testosterone injection in cockerels.

Key Words: testosterone, cockerels, social behavior

T14 Results from the Washington State bovine viral diarrhea virus voluntary control project. J. R. Wenz*, D. A. Moore, H. L. Neibergs, and J. S. Neibergs, *Washington State University*, *Pullman*.

Control of bovine viral diarrhea virus (BVDV) in beef cow-calf herds has been predicated on the identification and removal of persistently infected (PI) animals. Calves are born PI following exposure to BVDV during approximately 40 to 140 d of gestation and are the primary source of BVDV in the herd. The purpose of the BVDV voluntary control project was to educate producers, facilitate herd ear notch testing and implementation of control measures. From January 2008 to December 2009, 12 producer meetings were held at county and state beef producer meetings and a brochure detailing the project was mailed to 1700 members of the Washington Cattlemen's Association. Sixty herds from 18 counties enrolled and completed testing. Ear notch samples were screened by PCR on pools of up to 36 and PI positive samples were identified by a positive commercial antigen capture ELISA test. All PI animals were ELISA positive on 2 ear notch samples collected 2 to 3 weeks apart. Of the 60 herds tested 13.3% had at least one PI. Prevalence of PI animals was 0.81% (80/9881). For calves tested, 0.092% (79/8624) were PI and 1/1257 (0.08%) other cattle (yearlings, bulls, open cows) tested were PI. Only 2/79 (2.5%) dams of PI calves were PI. Two herds contributed 87% of the PI calves. In one herd 12.7% of 213 calves were PI and 52% of 83 calves were PI in the other. Excluding these 2 herds resulted in a PI calf prevalence of 0.12%. The herd prevalence was higher than previous reports from the US and may have been due to enrollment bias (suspected BVD in herd, subsidized testing). The prevalence of PI in calves, excluding the high prevalence herds, was similar to previous reports. A yearling PI was identified, highlighting the importance of testing all animals that may contact pregnant cows in the herd. Except for the herd with 52% PI calves, all PI animals were immediately removed from the herd. Three PI positive herds screened the subsequent year's calf crop and no PI calves were found. Low enrolment in the project suggests cow-calf producers in the state did not perceive sufficient risk posed by BVDV to warrant the cost of whole herd testing.

Key Words: BVDV, persistent infection, beef

T15 Effects of source and level of energy on the immune competence and response to an infectious bovine rhinotracheitis virus (IBRV) challenge in cattle. L. R. Schwertner*[1], L. E. Hulbert[1,2], J. A. Carroll[2], M. L. Galyean[1], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University*, *Lubbock,* [2]*Livestock Issues Research Unit, USDA–ARS*, *Lubbock, TX.*

Objectives were to evaluate how dietary energy level and source affect immune competence and response to an IBRV challenge in cattle. Forty–8 crossbred beef steers were stratified by BW within 2 periods and randomized to 1 of 3 dietary treatments (8 steers/treatment within period). Treatments were: a 70% concentrate diet fed ad libitum (70AL); a 30% concentrate diet fed ad libitum (30AL); and 70% concentrate diet restricted to the NEg intake of 30AL (70RES). Ex vivo immune competences were evaluated after treatments were applied for 28 d, after which cattle were moved into individual pens (d 28 to 40) and intranasally challenged with IBRV on d 30. On d 34, all cattle were offered a 50% concentrate diet ad libitum until d 50. Both energy source ($P < 0.02$) and level ($P < 0.04$) affected peripheral blood mononuclear cell synthesis of tumor necrosis factor-α (TNF- α), with cell culture supernatant concentrations averaging 2,264, 1,887, and 1,241 pg/mL for 70AL, 70RES, and 30AL, respectively. Neither whole blood killing of *Mannheimia hemolytica* nor neutrophil oxidative burst in response to *M. hemolytica* were affected by treatments. Rectal temperature following IBRV peaked 3 d post challenge and returned to baseline by d 6, but it was not affected by treatment. After switching cattle to the 50% concentrate diet on d 4 after the IBRV challenge, there were no differences in DMI while the cattle were individually penned. When cattle were group–penned 10 d after the IBRV challenge, the 70RES cattle had greater DMI ($P < 0.04$). Following the IBRV challenge, serum glucose concentrations did not differ among treatments; however, the 70AL cattle had greater blood urea N concentrations ($P < 0.01$). There was a treatment × time interaction ($P < 0.01$) for NEFA; such that cattle fed the 70AL had elevated NEFA on d 3 and 5 after IBRV. Data indicate that cattle fed higher energy diets and to an extent a higher percentage of concentrates had a more pronounced pro-inflammatory response, but other aspects of innate immune competence were not influenced by level or source of energy.

Key Words: bovine, dietary concentrate, immune

T16 The effects of dam parity and antibiotics on immune parameters and gastrointestinal bacterial diversity in weanling pigs. E. E. Hinkle*, H. Tran, J. W. Bundy, R. Moreno, P. S. Miller, J. Walter, and T. E. Burkey, *University of Nebraska*, *Lincoln*.

The progeny of first parity (P1) dams may have reduced growth performance compared with the progeny derived from mature dams (≥P2). A 42-d experiment was conducted to evaluate the effect of dam parity and antibiotics on immune parameters and the gastrointestinal (GIT) microbiota among progeny derived from P1 or P4 dams. Weaned pigs (n = 96, 6.02 ± 0.07 kg) initially derived from P1 or P4 dams were allotted to 2 dietary treatments: control (CTL) or antibiotic (50 g/ton Mecadox; AB). This created a 2 × 2 factorial with the following treatments: 1) P1, CTL; 2) P1, AB; 3) P4, CTL; and 4) P4, AB (6 pigs/pen, 4 pens/trt). Blood samples were collected on d 0 and weekly thereafter for quantification of serum immunoglobulin (Ig) G and A via porcine specific ELISA. There was no effect of parity or AB, or their interaction ($P > 0.05$) for IgG concentrations; however, a parity × AB interaction ($P < 0.05$) was observed for circulating IgA where P1 pigs had decreased serum IgA concentrations when fed AB, while P4 pigs had greater serum IgA concentrations when fed AB. The fecal microbiota at d 7 and 42 was characterized by denaturing gradient gel electrophoresis. Bionumerics software was used to calculate similarity and diversity indices. The similarity index represents the percentage of the microbial fingerprint that is similar within a group (P1 vs. P4). The diversity indices (Shannon′s and Simpson′s) of the gut microbiota can be inferred from DGGE fingerprints by using Shannon′s and Simpson′s indices. A greater Shannon′s index signifies a more diverse microbial population, while a lower Simpson′s index indicates a greater microbial diversity. No differences were observed in bacterial population similarity on d 7 or 42. Significant differences (Shannon′s, $P = 0.03$; Simpson′s, $P = 0.09$) in bacterial species diversity were observed on d 7 and 42 among progeny derived from P1 compared with P4 dams, while AB administration had no effect. The results obtained in our study suggest that immune parameters and gastrointestinal bacteria may be affected by dam parity.

Key Words: bacterial diversity, dam parity, immunoglobulins

T17 Serum IgG concentrations and performance, incidence of diseases, and risk of death in pre-weaned Holstein calves. M. C. Perdomo* and J. E. P. Santos, *University of Florida*, *Gainesville*.

Holstein calves, 782 females and 200 males, housed in individual hutches received 5.7 L of frozen-thawed colostrum in the first 24 h of life. From d 1 to 21 of age, calves were fed 1.9 L of pasteurized whole milk 3 times daily, and twice daily thereafter until 60 d of age, when they were weaned. Calves were fed grain ad libitum, and amounts offered and refused were measured daily during the first 70 d of age. Body weights (BW) were measured on d 1, 30 and 70 of age. Blood was sampled 48 h after colostrum feeding and serum was analyzed for concentrations of total immunoglobulin (Ig) G using a single-radial immunodiffusion assay. Rectal temperature was taken daily in the first 10 d of age, and again at every diagnosis of disease. Feces were scored daily for detection of diarrhea. Respiratory disease was evaluated based on respiration rate, nasal discharge, and coughing reflex. Duration of disease events and treatment costs were measured. Hazard of death was analyzed using the Cox′s proportional model using IgG and gender as predictors for survival. Failure of passive transfer (PT; IgG < 1.5 g/dL) was used as predictor of grain intake, BW, grain conversion into BW, and treatment cost. Rate of death decreased ($P < 0.01$) 29% for every 1 g/dL increase in serum IgG concentration (hazard rate = 0.71, 95% CI = 0.56–0.90). Calves with failure (IgG < 1.5 g/dL) or adequate (IgG > 1.5 g/dL) PT had, respectively, 11.9 and 5.7% mortality ($P < 0.02$), and 45.2 and 35.9% more than 1 disease event ($P < 0.05$). Disease treatment costs ($/calf) were 6.05 and 4.90 for failure and adequate PT ($P = 0.08$). For calves with failure and adequate PT, BW gain in the first 30 d (295 vs. 330 g/d, $P = 0.02$) and BW at d 60 (73.4 vs. 75.5 kg; $P = 0.05$) differed; however, failure of PT did not influence ($P > 0.10$) BW gain from 30 to 60 d (693 vs. 666 g/d), grain dry matter intake in the first 30 d (104 vs. 107 g/d) or from 30 to 60 d (901 vs. 914 g/d), or efficiency of conversion of grain into BW. Improving IgG absorption decreased the risk of mortality and treatment costs, and improved weaning weight, but it did not influence grain intake or feed conversion.

Key Words: calf, health, IgG

T18 Effects of live and killed *Mycoplasma gallisepticum* vaccines prior to an F-strain *Mycoplasma gallisepticum* overlay on the reproductive and digestive organ characteristics of commercial layers. R. Jacob*[1], E. D. Peebles[1], J. D. Purswell[2], and S. L. Branton[2], [1]*Mississippi State University*, *Mississippi State,* [2]*USDA-ARS, Poultry Research Unit*, *Mississippi State, MS*.

The effects of prelay vaccinations of ts-11 strain *Mycoplasma gallisepticum* (MG), MG-Bacterin, or their combination, when overlaid with F strain MG (FMG) post-peak production, on the digestive and reproductive organ characteristics of commercial layers were investigated. A total of 160 Single Comb White Leghorn layer hens were used. In each of 16 isolation units (pens), 10 birds were housed, with 4 replicate units in each of 4 treatments. The following treatments were utilized at 10 wk of age (woa): 1) Control (no vaccinations); 2) ts-11 strain MG, (Mycoplasma Gallisepticum Vaccine); 3) MG-Bacterin (MG-Bac); and 4) ts-11 strain MG /MG-Bacterin combination. At 45 woa, the birds in 2 replicate pens were challenged with a 99th passage of FMG, increasing the number of treatments to 8. A completely randomized experimental design was used. PCR tests using choanal swab samples confirmed the presence of MG in vaccinated birds and its absence in non-vaccinated birds. Necropsies were performed at the end of the trial (58 woa), using 2 birds per replicate pen (4 birds per treatment). Parameters examined included BW; liver, ovary, oviduct and small intestine weights; ovarian follicular hierarchy; and the lengths and weights of the components of the oviduct and small intestine. Results indicated that there were no significant treatment differences ($P > 0.05$) for any of the parameters investigated. Mean relative oviduct weight in control birds with and without FMG and birds given the combinatorial treatment with and without FMG were 4.18, 4.00, 4.00, 4.23% (SEM = 0.24), respectively. In conclusion, the individual or combinatorial use of ts-11 strain MG vaccine and MG-Bacterin, when administered during prelay, are effective in preventing possible adverse effects on the reproductive and digestive organs in response to a post-peak production challenge of FMG.

Key Words: layers, *Mycoplasma gallisepticum*, vaccine

T19 Discovery of differentially expressed microRNAs in porcine reproductive and respiratory syndrome (PRRS) virus infected alveolar macrophages. J. A. Hicks, N. Trakooljul, and H. C. Liu*, *North Carolina State University*, *Raleigh*.

Porcine reproductive and respiratory syndrome (PRRS) has a major impact on the swine industry. PRRS is characterized by abortions in pregnant sows and respiratory disease, particularly in young pigs. The causative agent is the arterivirus, porcine reproductive and respiratory syndrome virus (PRRSV). Determination of alterations in host gene expression upon PRRSV infection will provide a better understanding of the pathogenesis of the virus. It is now well-established that small RNAs are an important class of gene regulators. MicroRNA (miRNA, ~22nt) is a family of small RNAs that post-transcriptionally regulate gene expression. Studies have found that viral infections induce changes in the expression of miRNAs of infected host cells. These miRNAs often target genes associated with the immune response. The goal of the present study is to determine changes in host miRNA expression during PRRSV infection. Alveolar macrophages (SAMs) were isolated from seven 8-wk-old pigs. SAMs were maintained for 24hrs in RPMI 1640 with 10% FBS and then infected with PRRSV strain VR-2332 at an m.o.i. = 10. Infected and uninfected SAMs were collected at 24 or 48 h p.i. MiRNA expression analysis was carried out using the miRScript RT-PCR system. Over 40 miRNAs were found to be differentially expressed at either 24 h or 48 h p.i. upon PRRSV infection compared with non-infected cells. The expression of these miRNAs is dynamic, as some miRNAs are altered early (24hrs p.i.) while other miRNAs are differently expressed late (48hrs p.i.) upon infection. Among these are known immune miRNAs, including miR-146a and members of the miR-17–92 cistron, as well as miRNAs which have not previously been associated with viral infections, such as miR-130b and miR-342–3p. Target prediction and subsequent validation via luciferase assay of selected miRNAs suggest that these miRNAs target not only immune genes but also genes associated with intracellular signaling and trafficking. Our data indicates that miRNAs play a role(s) during PRRSV infection by affecting gene expression associated with PRRSV pathogenesis.

Key Words: PRRSV, microRNA, gene regulation

T20 Development of mouse monoclonal antibodies specific for chicken interleukin-18 (IL-18). Y. H. Hong*[1], H. S. Lillehoj[2], S. H. Lee[2], M.-S. Park[2], J. LaBresh[3], D. Tompkins[4], and C. Baldwin[4], [1]*Department of Animal Science and Technology, Chung-Ang University*, *Anseong, Gyeonggi-do Republic of Korea*, [2]*Animal and Natural Resources Institute, Agricultural Research Service-USDA*, *Beltsville, MD*, [3]*Kingfisher Biotech, Inc.*, *St. Paul, MN*, [4]*Department of Veterinary and Animal Sciences, Paige Laboratory, University of Massachusetts*, *Amherst*.

Two mouse monoclonal antibodies (mAbs) which are specific for chicken interleukin-18 (chIL-18) were produced and characterized

by enzyme-linked immunosorbent assay (ELISA), Western blotting, quantitative real-time PCR and functional assays. The mAbs specific for chIL-18 identified a 23 kDa yeast-expressed chIL-18 and a 66 kDa *E. coli*- MBP fusion protein by Western blot analysis. Bioassays for chIL-18 were carried out to evaluate its ability to induce IFN-γ production in primary chicken spleen cells, and nitric oxide (NO) secretion in the HD11 macrophage cell line. Two mAbs showed neutralizing activity. Taken together, we have developed mouse monoclonal antibodies specific for chicken IL-18. These immune reagents will be useful tools to analyze IL-18 secretion during infections and to do basic and applied research for poultry.

This project is funded by USDA-CSREES proposal 2005-01812 and was carried out as part of the US Veterinary Immune Reagent Network, http://www.umass.edu/vetimm.

Key Words: chicken, IL-18, monoclonal antibody

T21 Influence of two different doses of infectious bovine rhinotracheitis virus (IBRV) on immune and physiological parameters in steers. S. M. Falkenberg*[1], T. B. Schmidt[1], T. Elsasser[4], J. L. Sartin[3], J. O. Buntyn[1], and J. A. Carroll[2], [1]*Mississippi State University*, *Mississippi State*, [2]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX*, [3]*Auburn University College of Veterinary Medicine*, *Auburn, AL*, [4]*Bovine Functional Genomics, USDA-ARS*, *Beltsville, MD*.

To evaluate the effects of IBRV on immunological and physiological parameters of cattle, 18 Holstein steers (450.11 ± 75.70 kg) were randomly assigned to either a Control group (Cg) or 1 of 2 IBRV challenged groups. Prior to the challenge, steers were fitted with indwelling rectal probes, BW recorded, and a blood sample obtained. On d 0, steers received either an intra-nasal dose of IBRV [3 mL/nostril (IBR1) or 4mL/nostril (IBR2); Cooper strain, 1 X 10^7 PFU/ml] or saline (3 mL/nostril; Cg). IBRV steers were placed in a paddock that was isolated from the Cg as well as all other cattle on the research farm. Blood samples were collected via jugular venipuncture every 24 h on d 1 and 2, and every 12 h on d 3, 4, 5, 6, and 7 post-challenge. All IBRV steers had elevated rectal temperatures ($P < 0.05$) as compared with Cg by d 2, returning to baseline on approximately d 5. Serum was analyzed for interleukin-6 (IL-6), interferon-γ (IFN-γ), tumor necrosis factor-α (TNF-α), growth hormone (GH) and insulin-like growth factor-1 (IGF-1). An increase in IFN-γ for the overall effect of IBRV as compared with the Cg ($P < 0.05$) was observed though no differences were found for IFN-γ in IBR1 vs. IBR2. Where a numerical increase in the mean concentrations of TNF-α and IL-6 were measured in IBRV vs Cg, the response was not different ($P > 0.05$). Furthermore, no differences ($P > 0.05$) in mean concentrations of GH and IGF-1 were found between Cg and IBRV. Results indicate that both doses of IBRV elicited immune responses; however there were no measured differences between the 2 dose concentrations. Collectively, the data suggest that measurable immune responses to IBRV at the doses chosen may be highly selective in regard to cytokine and metabolic parameters.

Key Words: cytokines, IBRV, dose response

T22 The effect of thymol on reactive oxygen species production by bovine neutrophils. L. M. Nemec*, C. Wu, S. Cordova, K. Davison, and T. F. Gressley, *University of Delaware*, *Newark*.

Neutrophils produce intracellular and extracellular reactive oxygen species (ROS) to destroy engulfed and extracellular bacteria, respectively. However, extracellular ROS production during mastitis can also damage healthy tissue and impede recovery. This study evaluated the effect of the antioxidant thymol on intracellular and extracellular ROS production by bovine neutrophils. Neutrophils were activated with phorbol myristate acetate (PMA) or zymosan in the presence of 0, 0.0001, 0.001, 0.01 or 0.1 g/L thymol. Neutrophil ROS production was assessed by measuring luminescence or fluorescence (arbitrary units) every 5 min for 75 to 120 min following addition of 1 of 4 reagents: luminol (LUM) for measurement of total ROS (intracellular+extracellular); isoluminol (ISO) for extracellular ROS; methyl cypridina luciferin analog (MCLA) for extracellular superoxide; 5-(6)-chloromethyl-2′, 7′-dichlorodihydrofluorescein diacetate, acetyl ester (CMH2) for intracellular ROS. All activator/thymol combinations were assessed using neutrophils isolated from 4 different cows. Area under the curve (auc) for each activator/thymol/cow combination was calculated and log-transformed before statistical analysis. The MIXED model of SAS included fixed effects of thymol concentration and activator and random effects of assay date and cow. Least squares means and *P*-values for overall thymol effect and linear and quadratic thymol contrasts are presented in the table. Overall, addition of thymol to activated neutrophils decreased extracellular ROS and increased intracellular ROS, which may reduce tissue damage during mastitis without negatively impacting neutrophil killing.

Table 1. Effect of Thymol on Neutrophil ROS Production

	LUM, log(auc)	ISO, log (auc)	MCLA, log (auc)	CMH2, log (auc)
Thymol, g/L				
0	5.61	4.82	4.05	5.35

Key Words: neutrophil, thymol, reactive oxygen species

T23 Bovine hepatic and adipose retinol binding protein gene expression. P. Rezamand*, K. M. Hunt, R. D. Schramm, and M. A. McGuire, *University of Idaho*, *Moscow*.

Retinol is primarily transported in circulation to target organs by retinol-binding protein (RBP). The protein is relatively small (21 kDa), has one binding site for retinol in the all-trans form, is bound to transthyretin (TTR), and primarily synthesized in the liver. Circulating TTR and RBP may decrease in response to inflammation. Induction of transcription factor NF-IL6 by pro-inflammatory cytokine TNF-α results in down-regulation of the hepatic synthesis of proteins such as TTR. Our previous findings, however, indicated that circulating RBP concentration was greater in cows with a new intramammary infection (IMI) as compared with cows without a new IMI. Our objective was to determine whether there was a relation between hepatic and adipose mRNA expressions of RBP with that of TNF-α. Liver and intestinal adipose tissues were sampled from dairy cows (n = 28) at slaughter and frozen in liquid nitrogen. Total RNA was extracted from each tissue sample and cDNA was generated using the High Capacity Reverse Transcription Kit. Gene expressions of RBP, TNF-α, and β-actin, as a housekeeping gene, were measured in relative quantification using real time rt-PCR. Data were analyzed using original Ct values, adjusted to β-actin expression, in the MIXED and CORR procedures of SAS, and significance was determined at $P \leq 0.05$. Expression of RBP and TNF-α was detected in

all samples and for both genes, variations among cows were significant ($P < 0.001$). Relative to β-actin expression, RBP and TNF-α were more expressed in intestinal adipose than in liver ($P < 0.001$). Across tissues, RBP and TNF-α expressions were positively correlated (r = 0.66; $P < 0.001$). Within intestinal adipose, RBP and TNF-α expressions were weakly correlated (r = 0.38; $P < 0.001$). In the liver, however, mRNA expressions of RBP and TNF-α were strongly correlated (r = 0.64; $P < 0.001$). This implies that regulation of RBP at the transcription level may be independent from that of TTR, which is downregulated by pro-inflammatory stimuli via induction of transcription factor NF-IL6.

Key Words: bovine, retinol-binding protein, TNF-α

T24 Yeast supplementation alters the health status of receiving cattle. J. A. Carroll*[1], C. T. Collier[1], L. E. Hulbert1,3, J. R. Corley[2], A. G. Estefan[2], D. N. Finck[3], and B. J. Johnson[3], [1]*USDA-ARS, Livestock Issues Research Unit*, *Lubbock, TX,* [2]*Lesaffre Feed Additives*, *Milwaukee, WI,* [3]*Texas Tech University, Dept. of Animal and Food Sciences*, *Lubbock*.

Our objective was to determine if supplementation of yeast products during the receiving phase would improve the health status of beef calves before and following a low-dose lipopolysaccharide (LPS; 0.25 μg/kg BW) challenge. Twenty-four crossbred calves (203 ± 1.45 kg BW) were blocked by BW and assigned to 1 of 4 dietary treatments for 38 d before LPS exposure: 1) Control (Cont) calves fed an 83% concentrate diet; 2) Live Yeast (LY), calves fed the control diet with the addition of a LY; 3) Yeast Cell Wall (YCW), calves fed the control diet with the addition of a YCW product; and 4) LY plus YCW (LY/YCW). Calves on a common ration were group penned, and diets containing the yeast products were formulated to deliver 5 g•hd^{-1}•d^{-1} of either LY or YCW or 10 g•hd^{-1}•d^{-1} of the LY/YCW combination. On d 38, calves were fitted with jugular catheters and indwelling rectal probes, and moved to individual stanchions. On d 39, blood samples were collected at 30-min intervals from −2 to 8 h and then at 24 h relative to LPS challenge at 0 h. Rectal temperatures (RT) were collected at 1-min intervals from −24 to 24 h post-LPS. During the entire trial, basal RT before LPS tended ($P \leq 0.06$) to differ among groups with Cont calves having higher RT compared with LY/YCW ($P \leq 0.01$) and LY ($P \leq 0.04$) calves. After the LPS challenge, an interaction ($P \leq 0.05$) was observed such that RT remained higher in the Cont calves compared with all other groups. By 10 h post-LPS, RT were still greater ($P \leq 0.05$) in Cont calves compared with all other calves, and remained numerically higher throughout the study. Serum cortisol increased in all groups post-LPS with peak concentrations observed at 1 h. At 1 h post-LPS, serum cortisol concentrations were 26.5 ng/mL greater ($P \leq 0.04$) in Cont calves compared with LY/YCW calves. An interaction ($P \leq 0.01$) was observed for serum interferon-gamma (IFN) such that IFN concentrations tended ($P \leq 0.06$) to be greater in Cont calves compared with YCW calves before LPS exposure. These data indicate that supplementing the diet of receiving beef cattle with yeast products may improve their health during the early phase of the feedlot period, thus allowing for enhanced performance.

Key Words: cattle, immunity, yeast

T25 Impact of mature cow weights on farm profitability and economic weights of beef cattle traits. F. Szabó*[1], K. Keller[1], J. Wolf[2], and M. Wolfová[2], [1]*University of Pannonia Georgikon Faculty*, *Keszthely, Hungary*, [2]*Institute of Animal Science*, *Uhrinéves, Prague, Czech Republic*.

The impact of mature cow weight on the profitability of beef cattle farming and on the economic importance of 10 performance and functional traits was analyzed in Hungary. The examined traits were calving performance, stillbirth and calf losses till weaning, weight of calves at birth, at 120 and at 205 d of age, mature weight of cows, conception rates of heifers and cows and productive lifetime of cows. The cow weight was varied from 500 to 700 kg in 50 intervals. The economic efficiency of all farming systems was expressed as profit per cow and per year. The economic importance of a trait (marginal economic value) was defined as partial derivate of the profit function with respect to trait mean. The program package ECOWEIGHT was used for all calculations. The results showed that beef cattle farming with all cow weight classes could be profitable when including EU subsidies in the incomes of a FARM. Without subsidies, a positive profitable can be reached only when keeping small-framed cows (500 to 550 kg). In all modeled production systems, the most important trait was conception rate of cows followed by weaning weight of calves (at 205 d age) for light cows and productive life of cows in systems with heavy cows.

Key Words: beef cow, profitability, marginal and relative economic weight

T26 Carcass characteristics and chemical composition of *Longissimus* muscle of different genetic groups finished at tropical condition. R. H. de Tonissi Buschinelli de Goes*[1], D. M. Lambertucci[3], K. C. da Silva Brabes[1], A. B. Mancio[2], C. Mistura[4], and D. D. Alves[5], [1]*Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brasil*, [3]*Faculdade de Ciências Biomédicas de Cacoal*, *Cacoal, RO, Brasil*, [4]*Universidade do Estado da Bahia*, *Juazeiro, BA, Brasil*, [5]*Universidade Estadual de Montes Claros*, *Janaúba, MG, Brasil*.

The carcass characteristics and chemical composition of *Longissimus* muscle (LM) of steers at different genetic groups, grazing *Brachiaria brizantha* cv. Marandu, were evaluated. The animals were finished during the rainy season, receiving a protein/energetic supplement, of lower intake, contained corn and soybean meal, with 24% of CP; supplied at 1.1 kg/day. Eighteen beef steers (6 Nellore × Santa Gertrudis-SG, 6 Nellore × Simental-SI and 6 Nellore-NE) were slaughtered at 24 mo of age at 478 ± 6.2 kg. The experiment was analyzed as a complete randomized design and the averages compared by Tukey's test, at 5% of probability. There was no effect for genetic groups for slaughter weight, hot carcass weight (HCW), carcass yield, beef round weight, beef round yield, hind quarter with short ribs weight, spare rips, loin eye area (LEA), fat thickness (FT), yield grade estimated (YG = 72,92–0,489FT-0,02HCW+0,119 LEA), and Brazilian comercial cuts (BCC = 60,33–0,015HCW-0,462FT+0,11 LEA), with the averages of 478,8kg, 254.2kg, 53.05%, 118.6kg, 46.86%, 95.77kg, 13.41kg, 74.02cm^2, 4.09mm, 74.61% and 64.45%, respectively. It was observed difference ($P < 0.05$) for the percentages of moisture, ash, protein, total lipid and cholesterol between the genetic group, in LM. Fat for SG steers was of 3.24g/kg, while SI was of 2.58g/kg and NE of 2.29g/kg, however the fat thickness possesses lower value, what could be inferred that fat in the LM. Lipids could explain the low moisture presented by the crossbreeding animals (73.6%). The meat of the NE presented moisture of 74.1%, with ash of 1.10% and protein of 24.02%. The crossings of SG and SI of 0.98% and 1.02% for ash, 22.71% and 23.4% for protein, respectively. The SG presented a concentration of cholesterol of 48.29 mg/100g of total lipids; while the SI was 46.9 and the NE 46.44mg/100g. The difference in the cholesterol concentration in the muscle is probably associated with the structure of the cells that composes the muscle. The different genetic groups evaluated do not alter the carcass characteristics, but differ in chemical composition of *Longissimus* muscle

Key Words: yield grade, cholesterol, fat thickness

T27 Efficacy of day 23 GnRH for CIDR-Select estrus synchronization for beef heifers bred 12 hours after estrus or by fixed-time AI. J. L. Seabrook*, R. K. Peel, G. E. Seidel, and J. C. Whittier, *Colorado State University*, *Fort Collins*.

The objective of this study was to compare AI pregnancy rates resulting from administration of the CIDR Select synchronization protocol either with or without administration of d 23 GnRH. Angus and Hereford heifers at 4 locations were randomly assigned to treatments, blocking for body condition score and frame score. All heifers received 100 µg GnRH i.m. and a CIDR (1.38 g progesterone) d 0 – 14. Heifers assigned to the CIDR Select with GnRH received 100 µg GnRH i.m. on d 23; controls were processed through the facilities but did not receive GnRH. All heifers received 25 mg dinoprost tromethamine (PG) i.m. on d 30. The breeding protocol for Experiment 1, conducted at 3 locations (n = 270), was to breed heifers 12 ± 2 h after exhibition of estrus (n = 132); heifers that were not observed in estrus within 60 h from PG received 100 µg GnRH i.m. and were fixed-time AI (TAI) 60 ± 2 h after PG administration (n = 138). For Experiment 2, heifers at a fourth location (n = 326) were fitted with heat detection patches at the time of PG administration, which were scored when all were TAI 60 ± 2 h later. Treatment was not a source of variation in conception rates for heifers in Experiment 1: GnRH treated 56.4%, no GnRH 52.9% ($P = 0.58$). Heifers observed in estrus within 60 h after PG had a higher conception rate, averaged over the d 23 GnRH treatments, than heifers TAI (63.9%, 45.1% respectively; $P < 0.01$). Conception rates for heifers in Experiment 2 also were not affected by treatment: GnRH treated 57.1%, no GnRH 55.9% ($P = 0.83$). Patch score was correlated with a positive pregnancy diagnosis ($P < 0.01$); heifers with pristine patches had lower conception rates (34.8%) than those with fully worn patches (62.8%). Administering GnRH on d 23 of the CIDR-Select synchronization protocol was not associated with higher conception rates in these experiments.

Key Words: beef heifer, CIDR-Select, GnRH

T28 Fatty acid profile of feedlot Brangus bullocks fed with monensin or polyclonal antibodies. R. S. Barducci*[1,2], L. M. N. Sarti[1], M. D. B. Arrigoni[1], R. D. L. Pacheco[1], D. D. Millen[1], C. L. Martins[1], S. R. Baldin[1], F. S. Parra[1], J. R. Ronchesel[1], T. M. Mariani[1], J. P. S. T. Bastos[1], T. C. Putarov[1], D. Tomazella[1], and H. D. Rosa[1], [1]*FMVZ/UNESP*, *Botucatu, São Paulo, Brazil*, [2]*Apoio FAPESP*, *São Paulo, Brazil*.

This study was designed to test the effects of polyclonal antibody preparation (PAP) against lactate-producing rumen bacteria or monensin (MON) on fatty acid profile of feedlot Brangus (BR) bullocks. The experiment was designed as a 2 × 2 factorial arrangement, with 6 replications (3 bullocks/pen), which 72 9-mo-old bullocks (285.9 ± 38.7 kg) were distributed in 4 treatments and the animals were fed diets containing no additive (control), MON at 30 mg•kg^{-1} of DM, PAP at 450 mg•kg^{-1} of DM and PAP+MON (30 mg•kg^{-1} + 450 mg•kg^{-1}) for 112-d. Animals were adapted for 21-d before a high concentrate diet. The diet contained 47.5% high moisture corn, 20% citrus pulp, 12.8% soybean meal, 13.7% sugarcane bagasse, 4.6% Cynodon hay and 1.5% supplement. After slaughter, the carcass were chilled for 24-h and samples of back fat thickness of Longissimus dorsi muscle were collected from 48 animals (12 animals of each treatment) and stored for fatty acid profile analysis. No significant effects were observed among treatments ($P > 0.05$) for the variables of fatty acid profile. However, a significant ($P < 0.05$) PAP x MON interaction was observed for PUFA, which animals fed MON presented lower value ($P < 0.05$) than those fed PAP+MON (2.179 vs. 2.534 g/100g, respectively). Thus, the supplementation of PAP or MON separated was not a good alternative to improve fatty acid profile; however when both additives are fed together (PAP+MON) can be a useful tool to get better fatty acid profile, in this study there was a synergism between both additives.

Key Words: PAP, profile fatty acids, monensin

T29 Shelf-life characteristics of longissimus muscle of feedlot bullocks supplemented with vitamin D and E. S. R. Baldin*[1,2], F. S. Parra[1], J. R. Ronchesel[1], N. R. B. Consolo[3], M. D. B. Arrigoni[1], D. D. Millen[1], C. L. Martins[1], R. D. L. Pacheco[1], R. S. Barducci[1], L. M. N. Sarti[1], D. Tomazella[1], A. L. Campanini[1], J. M. P. Silva[1], A. S. C. Pereira[1], D. P. D. Lanna[4], [1]*FMVZ/UNESP*, *Botucatu, São Paulo, Brazil*, [2]*Apoio FAPESP*, *São Paulo, Brazil*, [3]*USP*, *Pirassununga, São Paulo, Brazil*, [4]*ESALQ*, *Piracicaba, Sã Paulo, Brazil*.

The objective of this study was to evaluate the effects of vitamins D and E supplementation on shelf-life characteristics: color, pH and fatty acid profile of longissimus muscle (LM) of feedlot bullocks. It was used 36 7-mo-old bullocks: 18 Nellore (NE) and 18 Canchim (CC; 5/8 Charolais, 3/8 Nellore), arranged in a 2 × 2 factorial design. During 47 d and 10 d before slaughter, 9 bullocks from each breed type were supplemented daily with vitamin E at 1300 IU and vitamin D at 7.5 × 10^6 IU, respectively. LM samples were harvested between 12th and 13th ribs and placed on polystyrene trays, covered with PVC plastic film and exposed to cooling, all of wich simulated retail display conditions. Temperature varied between 0°C and 4°C and light controlled (125 lx), during 7 d. Daily, samples were unpacked, exposed to the environment for 20 min and then, measurements of color and pH were taken. For the fatty acids profile analysis, it was collected subcutaneous fat subsamples at the day zero (PO) and at d 7 (P7). There was no effect ($P > 0.10$) of vitamin D and E supplementation for the variables in this study. There was an effect ($P < 0.05$) of period on color and pH, but on P3, samples of all treatments presented undesirable color for consumption. According to the fatty acids profile (g/100g), there was an effect of genetic group ($P < 0.05$) for: C14:0 (NE:23.75 vs. CC:25.83), C18:1 (NE:47.31 vs. CC:43.13), C18:2C9T11 (NE:0.79 vs. CC:0.67), SFA (NE:41.83 vs. CC:46.60), UFA (NE:56.59 vs. CC:51.77) and MUFA (NE:54.47 vs. CC: 49.59). Also, there was an effect of period ($P < 0.05$) on C18:1 (P0:44.78 vs. P7:45.76), C18:2C9T11 (P0:0.69 vs. P7:0.76) and C18:1T10T11T12 (P0:1.21 vs. P7:0.36). All in all, vitamin D and E supplementation did not improve shelf-life characteristics in this study.

Key Words: cooling, color, fatty acid profile

T30 Effect of Vitamin D and E supplementation on attributes of meat tenderness of feedlot bullocks. S. R. Baldin*[1,2], F. S. Parra[1], J. R. Ronchesel[1], N. R. B. Consolo[3], M. D. B. Arrigoni[1], D. D. Millen[1], C. L. Martins[1], R. D. L. Pacheco[1], R. S. Barducci1[1], L. M. N. Sarti[1], D. Tomazella[1], A. L. Campanini[1], F. A. S. Miquilin[1], A. S. C. Pereira[3], D. P. D. Lanna[4], [1]*FMVZ/UNESP*, *Botucatu, São Paulo, Brazil*, [2]*Apoio FAPESP*, *São Paulo, Brazil*, [3]*USP*, *Pirassununga, São Paulo, Brazil*, [4]*ESALQ*, *Piracicaba, Sã Paulo, Brazil*.

The study, conducted at São Paulo State University feedlot, Botucatu campus, was carried out to evaluate the effects of vitamins D and E supplementation on attributes of meat tenderness of 2 different genetic groups of feedlot bullocks. It was used 36 7-mo-old bullocks: 18 Nellore (NE) and 18 Canchim (CC; 5/8 Charolais, 3/8 Nellore), with average initial body weight of 234.53 ± 22.15 and 248.13 ± 34.67 kg, respectively, arranged in a 2x2 factorial design (supplementing vitamins x genetic group). Cattle were fed for 135 d, including 27 d of adaptation (AD). During 47 d before slaughter, 9 bullocks from each genetic group were daily supplemented with vitamin E at 1300 IU Also, the same bullocks 10 d before slaughter, were daily supplemented with vitamin D at 7.5 × 10^6 IU. On 10th d of vitamin D supplementation, blood samples were collected from jugular vein for plasmatic Ca evaluation. Rib eye samples were harvested between 12th and 13th ribs for analysis of Shear Force (SF), miofibrilar fragmentation index (MFI), total lipids (TL) and vitamin D and E meat concentrations. There was no effect ($P > 0.10$) of

vitamin D and E supplementation on SF, MFI, TL and vitamin D and E meat concentrations. Nevertheless, cattle fed with vitamin D and E had greater ($P < 0.05$) plasmatic Ca level in relation to control (189.7 vs. 152.40 mg/L). However, for genetic group, CC presented greater ($P < 0.05$) value of MFI than NE (69.07 vs. 62.61), and NE presented greater ($P < 0.05$) vitamin D and E meat concentrations (mg/kg) in relation to CC (0.19 vs. 0.03 and 2.88 vs. 1.29, respectively). The supplementation of vitamin D and E increased plasmatic Ca concentration, but it was not effective to enhance attributes of meat quality of 2 different genetic groups of feedlot bullocks.

Key Words: vitamin E, vitamin D, meat

T31 Influence of weaning strategy on growth and immunity in beef calves. L. B. Krebs*, A. Loyd, and E. G. Brown, *Stephen F. Austin State University*, *Nacogdoches, TX*.

The prevailing method of weaning calves involves abrupt separation from cows resulting in change in feed and living environment. These changes result in behavioral and physiological responses indicative of distress that are unfavorable to beef production and animal welfare. Twenty-six crossbred beef calves and their dams were used to evaluate stress and performance responses to 2 weaning strategies (2-stage and fenceline) independent of each other and in combination compared with traditional abrupt weaning. Cows and calves were assigned to treatments based on calf body weight and parity of the cow. Four days before weaning, one group of calves (n = 13) were fitted with an antisuckling device (2-stage) while remaining with the herd. At weaning, devices were removed and half of these calves were moved to a remote location (abrupt) and half placed in a pasture adjacent to their dam (fenceline). The calves not fitted with an antisuckling device before weaning (n = 13) were moved to a remote location or placed in a pasture adjacent to the dam in the same proportion as the previous group. Blood samples were collected on all cows and calves on d −4, 0, and 4 to measure white blood cell count, lymphocytes and neutrophils. Cows and calves were weighed on d −4, 0, and 28. Body condition scores were collected on cows on d −4, 14, and 28. No difference ($P = 0.38$) was observed for ADG in calves before weaning between treatments, but ADG was greater ($P < 0.001$) in fenceline weaned calves compared with abrupt separation. No differences ($P < 0.25$) were observed for white blood cell count, lymphocytes, neutrophils, or lymphocyte:neutrophil ratio in cows or calves. Average daily gain and body condition scores in the cows were not affected ($P < 0.20$) by weaning strategy. Results suggest that fenceline weaning may be an alternative to traditional weaning practices.

Key Words: weaning, fenceline weaning, immunity

T32 Effects of origin, breed, sex and season on productive performance of cattle arriving to feedlots located in northern Mexico (Mexicali, B.C.). L. C. Muñoz-Salas[1], C. F. Arechiga*[1], J. I. Aguilera-Soto[1], M. A. Lopez-Carlos[1], S. Mendez de Lara[1], F. Mendez-Llorente[1], M. Rincon[1], F. J. Gutierrez[1], C. A. Medina-Flores[1], L. Avendaño-Reyes[2], and A. Correa-Calderon[2], [1]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico*, [2]*Universidad Autonoma de Baja California*, *Mexicali, BC, Mexico*.

Objective of present trial was to determine the effects of place of origin and nutritional source, breed, sex, season and initial weight on productive performance of cattle arriving to feedlots located in northern Mexico. Average daily gain (ADG), feedlot feeding period (FFP), and carcass quality (CQ; i.e, dressing percentage) was evaluated. Cattle (n = 12,437), were allotted into 236 feedlots. The study included mostly heifers (n = 8,342), but also yearling bulls, steers and cows. Data was analyzed by SAS proc GLM including origin, breed, sex, year and initial weight as main effects. Feedlot feeding period and average daily gain was 95.2 d and 1.55 kg for cattle consuming forage; 114 d and 1.42 kg for cattle already consuming a mixed ration in another feedlot; 124 d and 1.42 kg for cattle coming from irrigated prairies; 131 d and 1.42 kg for cattle coming from commercial reception pens; and 133 d and 1.46 kg for cattle coming directly from pasture. Carcass quality was 60.9, 64.7, 61.1, 61.6 and 61.9%, respectively. Breed affected ADG, FFP, CQ ($P < 0.05$) whereas sex did not ($P > 0.05$). Summer season compromised productivity compared with the other seasons ($P < 0.05$). Initial weight entering feedlot also affected FFP and ADG. Heavier animals had a shorter feeding period and a greater weight gain. Thus, we conclude that cattle origin, breed, season and initial weight entering feedlot surely affected feedlot feeding period, average daily gain and dressing percentage.

Key Words: beef cattle, feedlot, Mexico

T33 Number of days to accurately measure individual feed intake in lactating females. K. A. Gray*, B. L. Winslow, M. H. Poore, and J. P. Cassady, *North Carolina State University*, *Raleigh*.

The objective of this study was to evaluate relationships among feed intake over different periods of time within a 104 d period in Angus females. Data were collected at the Upper Piedmont Research Station in Reidsville, NC. In February lactating Angus females (n = 35) began the feeding period weighing 470 ± 7.8 kg at 3 years of age while calves ranged in age from 7 to 70 d of age. All cows in this study were previously trained and adapted to the Calan gates for a period of 98 d when they were growing heifers. Cows were assigned the same gate as they had when they were heifers. Cows were allowed a 2-wk period of readaptation to Calan gates and were fed a roughage-based ration targeted to maintain body weight. Following readaptation, cows began a 104 d test. Feed offered was recorded daily and body weights for both cow and calf were taken every 14 d. Linear regression of weight on time was used to estimate ADG for cow and calf. Cow ADG was slight at 0.25 ± 0.025 kg/d and calf ADG was 0.84 ± 0.033. Average daily dry matter intake (DMI) was estimated for different periods of time within the 104 d test. Every combination of 28, 35, 42, 49, 56, 63, 70, 77 and 84 d period within the 104 d test was used to estimate different DMI for each period consisting of a total of 146 different periods. Correlations were then calculated among all combinations of DMI periods to determine if a shorter test trial would be sufficient to estimate DMI and to determine if feed intake differed due to stage of lactation. It was found that the best estimate for the 104 d DMI were the 4 84 d periods specifically the middle 2 84 d periods ($r_p = 0.99$). As duration of DMI periods decreased correlation between the period and 104 d DMI slightly decreased, as expected. Among the 10 42 d periods it was found that the correlation between the 42 d period and the 104 d DMI had only decreased to 0.90 - 0.95. It was concluded that DMI measured over 104 d and 42 d had a high correlation making it possible to decrease the duration of the testing time while maintaining accurate estimates of DMI.

Key Words: Angus cows, lactating, dry matter intake

T34 Effect of cutting time and maceration on nitrogen utilization of trefoil-grass hay by growing steers. A. F. Brito*[1], C. Lafrenière[2], and R. Berthiaume[2], [1]*University of New Hampshire*, *Durham,* [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*.

Feeding forage cut at sundown (PM) has been shown to improve N utilization by cattle. However, nutritional value of PM forage may be

compromised due to rainfall, prolonged wilting time, leaching, and respiration. Maceration can enhance field drying and reduce wilting time. A birdsfoot trefoil-grass field was divided in 4. Half was cut at 1800 h (PM) with 50% of the PM herbage macerated after 12 h (PMM) and left to wilt. The other half was cut at 0600 h (AM) the next morning with 50% of the AM herbage macerated after 4 h (AMM) and left to wilt. The 4 hays were field dried, baled at the same time, and chopped before feeding. Four steers were used in a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments to investigate the effects of forage cutting time (CT) and maceration (MAC) on N balance. Total collection of urine and feces were done for 6 consecutive days at the end of each 21-d period. Concentration (% DM) of CP averaged 11.6 (PM), 11.2 (AM), 10.2 (PMM), and 10.2 (AMM), while that of water soluble carbohydrates averaged 9.0 (PM), 7.0 (AM), 9.5 (PMM), and 8.1 (AMM). Intake of N was lowest in the macerated hays reflecting hay composition. Fecal N excretion (% of N intake) was greater (P = 0.04) in macerated vs. non macerated hays. Steers fed PM-cut hays had reduced (% of N intake) excretions of urinary N (P = 0.08) and manure N (P = 0.03), and enhanced retained N (P = 0.03). Significant CT x MAC interactions were observed for manure N and retained N as % of N intake, showing that non macerated PM-cut hay had the lowest excretion of manure N and the greatest N retention. Maceration had no effect on N retention by cattle fed trefoil-grass hay.

Table 1. Effect of cutting time and maceration on N intake (g/d) and N balance (% of N intake)

	Treatments					P		
Item	PM	AM	PMM	AMM	SED	CT	MAC	CT x MAC
N intake	129	112	106	108	4.93	0.08	<0.01	0.04
Fecal N excretion	40	43	46	44	1.77	0.63	0.04	0.08
Urinary N excretion	32	37	33	35	2.66	0.08	0.70	0.47
Manure N excretion	72	81	78	79	2.32	0.03	0.24	0.05
Retained N	28	19	22	21	2.32	0.03	0.24	0.05

Key Words: maceration, cutting time, steers

T35 Temperature during summer transport of Canadian feeder cattle at high and low loading densities. C. Goldhawk*[1,2], E. Janzen[1], L. González[4], T. Crowe[3], J. Kastelic[2], E. Pajor[1], and K. Schwartzkopf-Genswein[2], [1]*University of Calgary*, *Calgary, Alberta, Canada*, [2]*Agriculture and AgriFood Canada*, *Lethbridge, Alberta, Canada*, [3]*University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [4]*University of Manitoba*, *Winnipeg, Manitoba, Canada*.

A recent survey of cattle transport in Canada found that despite traveling similar distances, feeder cattle have greater shrink and spend more time on truck than fat cattle. These results create concern about the conditions during transport for feeder cattle. Preliminary temperature results are available from a larger study evaluating the effects of loading density during feeder cattle transport (700–900 kg BW). The temperature in the belly (B) and top deck (TD) of 7 commercial loads were monitored over an 11 h journey. Loading density (H = 0.767 m^2/animal; L = 0.876 m^2/animal) was alternated between compartments within loads, yielding 3 replicates of HB, 4 LB, 4 HTD and 3 LTD. Twelve temperature loggers were placed throughout each compartment, 1 on each side mirror of the truck and 1 on the ear tags of 4 focal animals in each compartment. Ambient temperature ranged from 10 to 34°C in the am and 24–34°C in the pm. The average temperature at the ceiling of a compartment was 2.3°C higher than the ambient temperature. On average, temperatures at the animal level were 0.78°C higher than at the ceiling of the compartments during stationary periods and 1.07°C higher than the ceiling temperature during transit. During transit, temperatures at animal level ranged from 13.7 to 29.6°C in the HB treatment and from 8.3 to 29.5°C in the HTD treatment. Similarly, during transit, temperatures at animal level ranged from 10.5 to 29.8°C in LB and from 12.5 to 31.3°C in LTD. The highest temperatures at animal level were recorded during prolonged stationary periods of 1.5–3.5 h (border crossing). During the first 10 min of the stationary period, before unloading the cattle for inspection, compartment temperatures at animal level rose by 0.9°C in the B and 2.4°C in the TD. Upon reloading, compartment temperature at animal level peaked after 20 min at 26–32°C and stayed within this range for the remainder of the stationary time at the border. Given the concurrent stressors experienced by cattle during transportation, the range of temperatures recorded during these loads warrant further investigation to determine the relationship between trailer microclimate and cattle well-being.

Key Words: cattle, transportation

T36 Comparative genomics: The Guinea Fowl satiety center. N. Bonner*, J. Tyus, and S. Nahashon, *Tennessee State University*, *Nashville*.

Genetic influence of the mechanisms driving feeding behavior and energy homeostasis in avians has not been fully elucidated; hence there is a paucity of such information in the Guinea Fowl (GF). Recent advances in genomics, proteomics and bioinformatics have made these mechanisms less difficult to evaluate, but assays aimed at developing GF genetic improvement programs continue to lag. The GF has tremendous potential as a viable poultry meat species in the US and globally. Generating genetic information for the GF is essential for its improvement and in comparative mapping of avian species of economic importance. The primary aim of this study was to compile a comprehensive database of genes expressed in GF center of satiety. Messenger RNA was isolated from ventromedial hypothalamus and pituitary of adult GF. Following reverse transcription, cDNAs were cloned into the pBluescript plasmid vector using the Stratagene cDNA Library Construction Kit. Approximately 1000 clones were selectively screened via blue-white selection, restriction digestion and PCR. Positive clones were cycle-sequenced by PCR and analyzed with the ABI PRISM 3100-Avant Genetic Analyzer. A second objective was to comparatively analyze GF gene fragments against homologs from other poultry species. Guinea fowl nucleotide sequences were subjected to sequence homology searches using the megablast option of NCBI's Basic Local Alignment Search Tool. Nucleotide sequence similarity between GF and other avian species averaged 76.5%. Nucleotide sequences exhibiting high homology (~80%) with other avian species averaged 685.6 bases in length and ranged from 293 to 1,025 bases. Nearly 12% of the nucleotide sequences analyzed showed no significant similarity to any available sequence data. Gene fragments generated from this work are currently being used to develop oligonucleotide primers for quantitative PCR and expressed sequence tags for selective breeding.

Key Words: Guinea Fowl genomics, satiety, hypothalamus

T37 Divergent selection for 4-week body weight in Japanese quail: Relationship between blood parameters and carcass characteristics. H. Beiki*, A. Pakdel, and M. Moradi Shahre Babak, *University of Tehran*, *Iran*.

The current study has been carried out to investigate the relationship between blood parameters and carcass characteristics in Japanese quail. Quail lines utilized were 2 lines divergently selected for high (HW) and low (LW) 4-wk body weight following 7 generations and also a control line (C). To investigate quail blood parameters, 15 quail from each line were selected randomly at 42-d of age. Blood samples were taken from the jugular vein just before slaughter and carcasses were measured individually. The plasma cholesterol content of HW line quail were significantly higher than for quail from the LW and C lines. There was a significant correlation (0.99) between serum hematocrit level and breast depth in the HW, LW and control (0.99) lines ($P < 0.01$). There was also a significant correlation between ovary weight and serum triglyceride level (TG) in the HW (0.82) and LW (0.87) lines ($P < 0.01$). Liver weight in the LW line was significantly correlated with TG level (0.82) ($P < 0.01$), and the correlation between testis weight and TG in the LW line (−0.96) was also significant ($P < 0.01$). The results of current study indicated that carcass characteristics and blood parameters of Japanese quail were greatly affected by short-term divergent selection. Thus, to prevent undesirable side effects of selection in this species, like those that have occurred in broilers, we must refine the breeding goal into a broader perspective and consider changes in physiological traits in the breeding goal.

Key Words: quail, divergent selection, blood parameters

T38 Genetic variation in physiological responses following heat stress in laying hens. J. N. Felver-Gant*[1], L. A. Mack[1], R. L. Dennis[2], and H. W. Cheng[2], [1]*Purdue University*, *West Lafayette, IN,* [2]*Livestock Behavior Research Unit, USA-ARS*, *West Lafayette, IN*.

Heat stress (HS), also known as hyperthermia, is a major problem experienced by poultry during high-temperature conditions. The ability to manage the detrimental effects of HS can be attributed to many factors, including genetics. The objective of the present study was to determine the variation of effects that HS poses on the well-being of laying hens. Ninety 28-wk-old White Leghorns of 2 strains were used; a line of individually selected hens for high productivity and survivability, DeKalb XL (DXL), and a line of group-selected hens, kind gentle bird (KGB). Hens were randomly paired, housed by strain and assigned to hot (H) or control (C) treatments for 14 d (mean: C = 24.3°C, H = 32.6°C). Physiological measures were collected at d 8 and 14. Behavior data was collected at d 1, 2, 6, 9, and 13. Compared with controls, H-hens core temperature (CT) was significantly higher at d 8 and 14 ($P < 0.05$). Heterophil:lymphocyte ratios were significantly higher in H-hens at d 14 ($P < 0.05$). H-hens had significantly reduced liver wt (LW) and spleen wt (SW) at d 8 and 14 ($P < 0.05$) and body wt (BW) at d 14 ($P < 0.05$). H-hens tended to have reduced BW at d 8 ($P < 0.10$) and heart wt (HW) at d 14 ($P < 0.10$). H-DXL had significantly reduced LW than H-KGB at wk 1 ($P < 0.05$). Behaviorally, H-hens opened their wings significantly more than C-hens ($P < 0.05$). C-hens did not initiate thermal panting. H-KGB hens exhibited panting behavior significantly more than H-DXL ($P < 0.05$). The data suggest that HS has detrimental effects on the physiology of laying hens. However, differences can be observed in the results of this study due to the genetic basis for variations in heat stress response.

Key Words: heat stress, genetics, laying hen

T39 Genome-wide copy number variation and temporal gene expression analysis in Marek's disease-resistant and -susceptible inbred chickens. Y. Yu[1], A. Mitra[1], H. Zhang[2], F. Tian[1], G. Liu*[3], and J. Song[1], [1]*University of Maryland*, *College Park,* [2]*USDA-ARS-ADOL*, *East Lansing, MI,* [3]*USDA-ARS*, *Beltsville, MD*.

Viruses that cause cancers are a great threat to human and animal health. Marek's disease (MD) in chickens is a lymphoproliferative disease caused by Marek's disease virus (MDV). The overexpression of Hodgkin's disease antigen in MD makes it an ideal model to study the progression mechanism of Hodgkin's disease in vivo. Three inbred chicken lines (L63, L72 and LM) with different reactions to MDV were used to perform array-based comparative genomic hybridization (CGH) and gene expression microarray experiments at different time points (5dpi, 10dpi and 21dpi) of virus infection, with the objective of comparing copy number variation (CNV) with MDV indicator traits. A total of 43 CNV were found in the 3 chicken lines with the total size ranging from 1.4 Mb in L72 to 1.6 Mb in LM. While only 22% of the sequence found within CNV regions in L63 (MD-resistant) and LM (intermediate in MD-resistance) is unique, about 62% is unique in L72 (MD-susceptible) chickens. Several anti-viral pathways, and particularly the NF-κB pathway, were found activated in the early cytolytic stage (5dpi) in L63 chickens. The array-CGH and gene expression microarray

results revealed a CNV loss located on chromosome 4 present in both L63 and LM chickens but absent in L72 chickens that is associated with the expression of a CD8α homolog before and after MDV infection. To our knowledge, this is the first time a CNV loss has been found that might be related to MD-resistance in chickens.

Key Words: copy number variation, microarray, genetics

T40 Broiler breeders with an efficient innate immune response are more resistant to coccidial infections. C. L. Swaggerty*[1], K. J. Genovese[1], H. He[1], J. R. Nerren[1], I. Y. Pevzner[2], and M. H. Kogut[1], [1]*United States Department of Agriculture*, *College Station, TX,* [2]*Cobb-Vantress, Inc.*, *Siloam Springs, AR*.

Coccidial infections cost the poultry industry an estimated $600 million in low carcass weights and prophylactic drugs per year. For the past several years we have characterized the innate immune response of 2 broiler breeder lines (A and B) and their F1 reciprocal crosses (C [B sire x A dam] and D [A sire x B dam]) and compared their resistance against Salmonella, Enterococcus, and Campylobacter challenges. In all cases, line A and cross D are more responsive and more resistant than line B and cross C. Now, we want to determine if the trend is also observed following separate challenges with the protozoan parasites, *Eimeria tenella* (ET), *E. maxima* (EM), or *E. acervulina* (EA). Fourteen-day-old chickens from lines A and B and cross C and D were challenged orally with 15–50 × 10^3 ET, 10–40 × 10^3 EM or 25–50 × 10^3 EA oocysts. Birds were sacrificed 6 d post-challenge and the appropriate region of the gut was removed and scored for lesions (ET in the ceca; EM in the mid-gut; EA in the duodenum) and final body weight (BW) compared with non-infected controls. Regardless of the challenge species or dose administered, line A and cross D birds were more resistant to intestinal pathology as demonstrated by lower lesion scores compared with B and C, respectively. As might be expected, the lower lesion scores in line A and cross D chickens were accompanied by higher final BW compared with line B and cross C chickens, thus reducing potential revenue loss associated with low carcass weights in coccidia-infected birds. The results from this study showed that in addition to improved resistance against bacterial infections line A and cross D chickens are also more resistant to coccidial infections compared with line B and cross C birds. Taken together with all of our earlier studies utilizing these lines, an efficient innate immune response protects against a broad range of food-borne and poultry pathogens including costly coccidial infections.

Key Words: genetics, coccidia, innate immunity

T41 Expression of the peptide transporter, PepT1, in chickens from high and low weight-selected lines and their F1 and F2 crosses. B. Zwarycz*, E. A. Wong, P. B. Seigel, and C. R. Mott, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

PepT1, a peptide transporter located in the brush border membrane of the small intestine of chickens, is important in the uptake of amino acids in the form of di- and tri-peptides. Thus, PepT1 plays an important role in growth and feed efficiency. The objective of this study was to determine PepT1 expression and inheritance in the duodenum, jejunum, and ileum of chickens selected for high or low body weight and their F1 and F2 progeny. Parental line chickens selected for 51 generations for high (H) or low (L) 8-week body weight were mated to produce 4 types of progeny. These were parental lines (LxL and HxH) and reciprocal F1 crosses (HxL and LxH). Only males were used in the analysis. On d7 posthatch, LxL chicks had the lowest body weights and the highest levels of PepT1 mRNA in the small intestine, whereas the HxH chicks had the heaviest body weights and lowest levels of PepT1 mRNA. The reciprocal F1 chicks were intermediate in body weight and PepT1 levels. An F2 generation, produced by random matings of LxH and HxL parents, had a greater range in body weights and PepT1 expression levels than the F1 crosses. This 3 generation mating study suggests polygenic inheritance for PepT1 in chickens

Key Words: chicken, PepT1, transporter

T42 Genetic properties of feed utilization efficiency parameters. S. E. Aggrey*[1], A. B. Karnuah[1], and N. B. Anthony[2], [1]*University of Georgia*, *Athens,* [2]*University of Arkansas*, *Fayetteville*.

Feed costs constitute about 70% of the total production costs; however, the efficiency of feed utilization has not kept up with the growth potential of today's broilers. Improvement in the efficiency of feed utilization will reduce the amount of feed required for growth, which will directly reduce production cost, increase profitability, and subsequently reduce the amount of manure produced. We estimated genetic parameters of feed conversion ratio (FCR) and residual feed consumption (RFC) in a random mating broiler control population using DFREML and determine nutrient factors that affect both traits. The heritability of FCR and RFC were 0.22 and 0.11, respectively with genetic correlation of 0.72. However, when maternal effects were included in the model, the genetic correlation increased to 0.98, probably suggesting that maternal components influence feed utilization efficiency and as a result both nuclear and mitochondrial genomes are important in deciphering the genetic factors affecting feed utilization efficiency. Among the nutrient factors, it was determined that protein energy and calcium retentions greatly affected feed efficiency.

Key Words: feed efficiency, genetic parameters, chicken

T43 Analysis of ascites susceptibility using genetic markers in commercial broilers. S. Krishnamoorthy*, N. Anthony, D. Rhoads, R. Wideman, and G. Erf, *University of Arkansas*, *Fayetteville*.

Although the ascites syndrome in chickens has been investigated for years, it continues to inflict financial losses within the global poultry industry. It is estimated that annually 5% of the 40 billion world broiler population succumbs to ascites, thus leading to yearly losses of millions of dollars. Efforts to curb the incidence of ascites are typically designed to slow early growth. This limits the bird's ability to show its true genetic potential and impacts later yields. In 1994, lines divergent for susceptibility to ascites were established from a commercial sire line through sibling selection of birds reared at local altitude, after testing sibs reared under simulated high altitude conditions. We used a whole genome SNP array to identify 7 potential regions associated with susceptibility. After 16 generations of selection, the selected lines changed in allele frequency for 2 regions on chromosome 9, as compared with each other and with the line of origin. Changes were consistent with patterns of susceptibility and resistance to ascites. In addition to the research populations, we determined that 2 ascites susceptible commercial lines are also segregating for resistance related alleles in these regions. The data support the predictive nature of these loci, in that the presence of a specific genotype is associated with resistance to ascites, which suggests that one or more genes within these regions might play an important role in ascites development. Future research will include reducing the incidence of ascites in susceptible commercial lines through marker-assisted selection.

Key Words: ascites, genetic markers

T44 Using quantitative PCR to investigate three candidate genes related to pulmonary hypertension in the chicken. A. A. Al-Rubaye*, N. B. Anthony, G. F. Erf, R. F. Wideman, and D. D. Rhoads, *University of Arkansas*, *Fayetteville*.

Idiopathic pulmonary arterial hypertension syndrome (IPAH) is a disease of humans and chickens that results from chronic high pulmonary arterial pressure. IPAH in broiler chickens results in right-sided congestive heart failure leading to ascites that, if not aggressively treated, will result in death. We have been mapping chicken genes affecting resistance or susceptibility to IPAH. Previously, we identified 2 regions on Gga9 and one on Gga27 that show significant linkage disequilibrium to IPAH in our lines. Within these regions we identified 3 candidate genes that are known to be related to susceptibility to pulmonary hypertension in humans. Those genes are ACE, HTR2B, and AGTR1. We are examining the expression of these 3 genes in chicken IPAH using reverse transcriptase quantitative PCR. Initial analyses have detected significant differences in the expression levels for 2 of the candidate genes in whole blood RNAs. We are expanding the analyses to include increased numbers of samples and a wider range of tissues.

This work was supported by grants from the Arkansas Biosciences Institute and NIH/NHLBI Grant 1R15HL092517 01.

Key Words: QPCR, pulmonary hypertension syndrome, chicken IPAH

T45 Selection of the best model for estimation of genetic parameters for growth traits in Iranian Moghani sheep. N. Ghavi Hossein-Zadeh*[1] and M. Ardalan[2], [1]*Department of Animal Science, Faculty of Agriculture, University of Guilan*, *Rasht, Iran*, [2]*Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran*, *Karaj, Iran*.

The objective of this study was to estimate the genetic parameters for birth weight (BW), 3 mo weight (3MW), 6 mo weight (6MW), 9 mo weight (9MW), and yearling weight (YW) of Iranian Moghani sheep using restricted maximum likelihood via the MTDFREML program. The data and pedigree information used in this research were collected at Breeding Station of Moghani sheep (Ardebil province, Iran) during 1987–2005. Six different animal models were fitted, differentiated by including or excluding maternal effects, and including or excluding a covariance between maternal and direct genetic effects. The estimates for direct heritability ranged from 0.31 to 0.54, 0.21 to 0.34, 0.13 to 0.25, 0.11 to 0.22 and 0.10 to 0.17 for BW, 3MW, 6MW, 9MW and YW, respectively. These estimates were substantially higher when maternal effects, either genetic or environmental, were ignored in the model. The results of this study show the importance of including maternal genetic and environmental effects when estimating genetic parameters for body weight traits in Moghani sheep.

Key Words: growth traits, genetic parameters, Moghani sheep

T46 Estimates of genetic trends for body weight traits of Moghani sheep obtained by a multivariate animal model analysis. N. Ghavi Hossein-Zadeh*, *Department of Animal Science, Faculty of Agriculture, University of Guilan*, *Guilan, Rasht, Iran*.

The objective of the present study was to estimate genetic changes for body weights at different ages in Moghani sheep. Traits included were birth weight (BW, n = 4208), 3 mo weight (3MW, n = 4175), 6 mo weight (6MW, n = 3138), 9 mo weight (9MW, n = 2244), and yearling weight (YW, n = 1342). The data and pedigree information used in the current research were collected at the Breeding Station of Moghani sheep (Ardebil province, Iran) during 1989–2005. Variance components were estimated from a 5-trait analysis, based on the best model of analysis for each trait, using the MTDFREML program. Level of significance for the inclusion of effects into the model of analysis was declared at $P < 0.05$. The final model included the fixed class effects of year-season (68 levels), sex of lamb and parity of dam, birth type (single, twin, triplet), the linear covariate effect of age of dam (from 2 through 7 years old) and random direct and maternal genetic effects. The most suitable model was determined based on likelihood ratio tests for each trait. Breeding values of individual animals were predicted with Best Linear Unbiased Prediction (BLUP) methodology and obtained from a multivariate animal model analysis and genetic trends were obtained by regressing the means of predicted breeding values on year of birth for each trait. Estimates of direct heritabilities for BW, 3MW, 6MW, 9MW, and YW were 0.29, 0.13, 0.14, 0.10, and 0.31, respectively. Estimates of maternal heritabilities were 0.29 for BW, 0.08 for 3MW, 0.11 for 6MW, 0.06 for 9MW, and 0.10 for YW. Direct genetic trends were positive and significant ($P < 0.05$) for BW, 3MW, 6MW, 9MW and YW and were 1.63, 69.20, 79.38, 66.83 and 110.22 g/year, respectively. Also, maternal genetic trend for BW, 3MW, 6MW, 9MW and YW were positive and significant ($P < 0.05$) and were 2.36, 49.18, 37.33, 17.73 and 9.67 g/year, respectively. The results showed that improvement of body weights of Moghani sheep seems feasible in selection programs.

Key Words: Moghani sheep, growth traits, genetic trend

T47 Association of polymorphisms in the FecB gene with litter size in Wadi sheep. Y. Ren*[1,2], Z. Shen[1,2], M. Li[3], N. Xiao[3], W. Dong[3], and S. Fu[1], [1]*Binzhou Animal Science & Veterinary Medicine Institute*, *Binzhou Shandong, China*, [2]*Research and Development Center of Wadi Sheep Breeding Technology*, *Binzhou Shandong, China*, [3]*Shandong Lvdu Biotechnology Co., Ltd.*, *Binzhou Shandong, China*.

Wadi sheep in the Shandong proving of China are known for fecundity and antireversion. About 20–30% Wadi sheep have 4 nipples, which leads to a tendency for fecundity and high galactosis. The FecB gene, a major gene for fecundity in the Booroola Merino breed, is caused by a 1-base mutation of BMPR-IB and increases litter size by increasing ovulation rate. Polymorphisms within the FecB gene of Wadi sheep and associations with litter size were analyzed by PCR-RFLP to study the fecundity of Wadi sheep on molecular level. This results showed that there was FecB mutation in Wadi sheep that was the same as in Booroola, and the frequencies of 3 genotypes (B/B, B/+, +/+) were 0.29, 0.56 and 0.15, respectively. An association between genotype frequencies and number of nipples was observed. Average litter sizes for the 3 genotypes were 2.81 ± 0.42, 2.49 ± 0.53 and 1.96 ± 0.28, respectively. Statistical analysis showed that litter size of Wadi sheep with B/B and B/+ genotype was significantly greater than that of sheep with the +/+ genotype ($P < 0.01$), but differences between the B/B and B/+ genotype were not significant. In conclusion, the FecB gene could of great interest in the Wadi sheep breed due to its association with fecundity.

Key Words: Wadi sheep, FecB gene, litter size

T48 Inbreeding effects on different weights and population structure of Santa Inês sheep. M. L. Santana Júnior*, V. B. Pedrosa, P. S. Oliveira, J. P. Eler, and J. B. S. Ferraz, *Animal Breeding and Biotechnology Group, Department of Basic Sciences, College of Animal Science and Food Engineering, University of São Paulo, C. Postal 23, 13635-970, Pirassununga, SP, Brazil*.

The aim of this study was to describe the population structure and inbreeding and to quantify its effect for different weights of Santa Inês sheep in Brazil. By this reason, 6,161 production data and 17,097 animals in the pedigree data, of 6 previous generations were utilized to evaluate birth weight (BW), weight at 60 d (W60) and weight at 180 d (W180). The genetic structure analysis of population was realized by the software ENDOG (v.4.6.), resulting in some level of inbreeding for 21.72% of the animals in the pedigree data, with a maximum value of 41.02%, and average of 10.74% for the inbreed individuals. The population average inbreeding was 2.33%, and the average kinship was 0.73%. The ancestral effective number was 156 animals, and the number of population founders was 211 individuals. Parameters related to genetic variability in this population must be monitored to prevent a decrease in genetic progress. The utilization of a program for directed mating, as is presently the case in this flock, is an appropriate alternative to keep the level of inbreeding under control.

Key Words: effective population size, inbreeding, generation interval

T49 Estimates of variances due to direct and maternal effects on birth weight in Moghani sheep. M. Bayeri Yar*[1], S. Alijani[1], T. Farahvash[2], and A. Rafat[1], [1]*University of Tabriz*, *Tabriz, East Azerbijan, Iran*, [2]*Islamik Azad University,Shabestar Branch*, *Tabriz, East Azerbijan, Iran*.

Data from a total of 6,758 Moghani lambs were collected from 1995 to 2006 at the Jafar Abad sheep breeding station in the Ardebil province of Iran. Data were analyzed by DFREML using an animal model. The full general model used was as follows: $Y = Xb + Z_a a + Z_m m + Z_p pe + e$. In particular, use of model 1 resulted in high estimates of additive genetic and direct heritability (0.33). Inclusion of maternal effects (models 2, 4 and 5) resulted in much smaller estimates of h^2. Comparing models with likelihood ratio tests showed that model 5 performed significantly better than other models. Based on use of the most appropriate model for birth weight (BW), the estimated ratios of variance components (±SE) were: h^2= 0.26 (± 0.01), m^2 = 0.09 (± 0.009), pe^2 = 0.06(±0.01). Maternal effects therefore included heritable components of phenotypic variance that will respond to selection. Although estimates of h^2 also varied between the models with different maternal effect structures, these differences were minor in comparison. It has been suggested that this antagonism will limit the potential for genetic improvement of commercial flocks through artificial selection. The idea that an evolutionary response to selection on birth weight could be similarly constrained through this mechanism is supported by the negative values estimated for rams. In conclusion, there were important maternal genetic effects influencing birth weight in this population.

Table 1. Estimates of (co)variance components, genetic and phenotypic parameters of BW from a univariate analysis

Models	h^2 (±SE)	m^2 (±SE)	pe^2 (±SE)	ram	logL
1	0.33(±0.01)	—	—	—	−796.45
2	0.31(±0.01)	0.22(±0.01)	—	—	−794.68
3	0.31(±0.01)	—	0.29(±0.01)	—	−793.78
4	0.28(±0.01)	0.19(±0.009)	0.02(±0.01)	—	−793.7
5	0.26(±0.01)	0.18(±0.01)	0.12(±0.01)	−0.97	−783.85

h^2: direct heritability; m^2: maternal heritability; pe^2: maternal permanent environmental variance; ram: direct-maternal genetic correlation.

T50 Estimation of additive and non-additive genetic parameters for growth traits of Moghani sheep. M. Bayeri Yar*[1], s. Alijani[1], and T. Farahvash[2], [1]*Univeraity of Tabriz*, *Tabriz, East Azerbijan, Iran*, [2]*Islamic Azade University, Shabestar Branch*, *Tabriz, East Azerbijan, Iran*.

A total 6,758 records from Moghani lambs were collected from 1995 to 2006 at the Jafar Abad sheep breeding station in the Ardebil province of Iran. Five traits were considered; birth weight (BW),weaning weight (WW), 6-mo weight (6W), 9-mo weight (9W), and yearling weight (YW). Data were analyzed using a single-trait animal model via the DFREML software. The model was: $Y = Xb + Z_a a + Z_m m + Z_p p + e$, where Y is a vector of observations; b is a vector of fixed effects; a is a vector of direct animal genetic effects; m is a vector of maternal genetic effects; p is a vector of maternal permanent environmental effects; e is a vector of residuals, and X, Z_a, Z_m and Z_p are incidence matrices relating records for trait to fixed, direct genetic, maternal genetic, and permanent environmental effects, respectively. Results of the univariate analyses are shown in Table1. Direct heritability for body weight increased after weaning. This study showed important effects of maternal effects on growth traits, which should be considered in genetic evaluations. Direct and maternal heritability estimates obtained in this study indicated that it would be possible to improve growth traits through genetic selection at all ages.

Table 1. Estimates of (co)variance components, genetic and phenotypic parameters of growth traits from a univariate analysis

Trait	h^2 (±SE)	m^2 (±SE)	p^2 (±SE)	$r_{a,m}$
BW	0.26(±0.01)	0.18(±0.02)	0.12(±0.01)	−0.97
WW	0.23(±0.02)	0.16(±0.01)	0.07(±0.03)	−0.95
W6	0.28(±0.07)	0.12(±0.01)	0.06(±0.02)	−0.89
W9	0.33(±0.07)	0.06(±0.02)	0.024(±0.01)	−0.869
YW	0.3(±0.1)	0.02(±0.005)	0.015(±0.008)	−0.79

h2: direct heritability; m2: maternal heritability; p2: maternal permanent environmental variance; ra,m: direct-maternal genetic correlation.

Key Words: Moghani sheep, genetic parameters, growth

T51 Estimation of variance components for reproductive traits of Moghani sheep. M. Bayeri Yar*[1], s. Alijani[1], and T. Farahvash[2], [1]*Univeraity of Tabriz*, *Tabriz, East Azerbijan, Iran*, [2]*Islamic Azade University, Shabestar Branch*, *Tabriz, East Azerbijan, Iran*.

A total of 3652 records were collected from 1995 to 2006 at the Jafar Abad sheep breeding station in the Ardebil province of Iran. Four traits were measured, including conception rate (CR), litter size (LS), mean litter weight per lamb born and mean litter weight of lambs at weaning. Mixed model methodology was used to analyze all traits using a multiple-trait animal model with repeated records. Covariance components and genetic parameters were estimated using the restricted maximum likelihood method based on a derivative-free algorithm (DFREML). Estimates of direct and maternal heritability, direct-maternal genetic correlation and fraction of variance due to permanent environmental effect of the ewe and ewe-mate, as well as phenotypic variances for each trait are shown in Table1. The low estimates of heritability for LS and CR may be due to the importance of random environmental effects on variability of the observations and due to the categorical expression of the trait. Because the heritability estimate was quite low, improvement of CR by selection would be difficult even though CR has great economic importance. Results showed that all traits were influenced by genetic effects and permanent environmental effects, and to improve these traits one should improve environmental effects in first step. Estimates of genetic variances and heritability are necessary for genetic

evaluation of sheep and also for choosing the best selection scheme. Economic weights of traits can be determined to build an advantageous overall selection index.

Table 1. Estimates of (co)variance components, genetic and phenotypic parameters of reproductive traits from a univariate analysis

Traits	Mean ± SD	h^2 (± SE)	m^2 (± SE)	Pe^2 (± SE)	ram
LS	1.4 (± 0.51)	0.08(± 0.01)	0.038(± 0.01)	0.25(± 0.05)	0.33
CR	0.7(± 0.25)	0.03(± 0.01)	—	—	—
LMWLB	4.85(± 0.78)	0.1(± 0.02)	0.03(± 0.02)	0.03(± 0.01)	0.31
LMWLW	22.86(± 5.14)	0.09(± 0.01)	0.05(± 0.01)	—	0.1

Direct (h2) and maternal heritability, direct-maternal genetic correlation (ram), fraction of variance due to permanent environmental (pe2).

Key Words: Moghani sheep, reproduction

T52 Determination of intrinsic tolerance for high dietary nitrate in ewes using hepatic gene expression. R. R. Cockrum*, K. J. Austin, and K. M. Cammack, *University of Wyoming*, *Laramie*.

Ruminants differ in their ability to efficiently reduce nitrate (NO_3^-) to nitrite (NO_2^-). It was hypothesized that these differences may be due to intrinsic differences in ability to metabolize NO_3^-. In a previous study, differentially expressed ($P < 0.05$) hepatic genes (n = 13) were identified in ewes determined as highly tolerant (n = 6) and lowly tolerant (n = 6) to 300 mg of NO_3^-/kg BW administered for an 8-d period. The objective of this study was to determine if those genes were also differentially expressed between highly tolerant and lowly tolerant ewes a priori to NO_3^- treatment, indicating a potential for marker–assisted selection. Thirteen genes involved in metabolism and stress response were identified as differentially expressed ($P < 0.05$) in liver samples from highly tolerant and lowly tolerant ewes after NO_3^- treatment using both 24k bovine oligonucleotide microarray and real–time RT–PCR techniques. Of those genes, 4 were up–regulated ($P \leq 0.05$; *HOPX*, *GPX3*, *ITIH4*, and *HP*), 8 were down-regulated ($P \leq 0.03$; *CYP25A1*, *PFKFB1*, *AOX1*, *ASL*, *SCP2*, *KIK-1*, *FADS2*, and *THRSP*), and *CSAD* tended ($P = 0.07$) to be down–regulated in lowly tolerant ewes compared with highly tolerant ewes. Relative expression of those genes was determined in liver samples collected from the same highly tolerant and lowly tolerant ewes before NO_3^- treatment. Relative expression levels were tested for treatment differences using the GLM procedure in SAS. No differences ($P > 0.05$) in expression before NO_3^- administration were detected, confirming that the changes in expression observed post–treatment were due to the NO_3^- administration. These results also indicated that selection for tolerance to high dietary NO_3^- cannot be made before exposure based on differences in expression of genes involved in metabolism or stress. Instead, differences in microbial populations in the rumen may be key to disparities observed in response to high dietary NO_3^-.

Key Words: nitrate toxicity, gene expression, tolerance

T53 Genetic parameters for growth traits in the progeny of Nubian, French Alpine Saanen, Toggenburgh, and Spanish goats mated naturally to Boer sires. A. Pérez*, J. S. Saucedo, L. Avendaño, J. F. Ponce, and M. F. Montaño, *Universidad Autónoma de Baja California, México, Instituto de Ciencias Agrícolas*, *Mexicali, Baja California, México*.

Data came from a commercial goat farm at Imperial Valley California. The objectives were to compare the performance of the progeny of goats involving inheritance of Nubian(N), French Alpine (A), Saanen (S) Toggenburgh (T), and Spanish (SP), (n = 160), and to estimate genetic parameters for growth traits. Traits analyzed were weight at birth BWT and weaning WWT, and average daily gain (ADG) from birth to weaning. Separate analysis for each trait used least squares mixed model SAS (1999). The analytical model included: breed of dam, age of dam, sex of the kid, season of parturition as fixed effects; sire × breed of dam interaction and the residual as random. The overall mean values for weight at birth and weaning were: 1.99 and 12.89 kg, respectively. The average values for weight at birth were (2.12 ± 0.66, 2.11 ± 0.56, 2.04 ± 0.55, 1.95 ± 0.63, 2.10 ± 0.55 and 1.98 ± 0.67, 1.97 ± 0.68, 1.93 ± 0.58, 1.83 ± 0.63, 1.96 ± 0.66) for males and females kids, respectively. The average values for weaning weight were (13.99 ± 0.59, 13.29 ± 0.53, 13.25 ± 0.54, 12.67 ± 0.51 and 13.51 ± 0.43, and 12.50 ± 0.59, 12.48 ± 0.50, 11.98 ± 0.58, 12.68 ± 0.56 and 12.60 ± 0.57 kg) for male and female kids, respectively. The estimated ADG from birth to weaning was 181 ± 0.32 g. The average values for daily gain were: 187 ± 0.46 and 175 ± 0.49 g for male and female kids, respectively. Estimates of heritability direct values were ($h^2 = 0.20 \pm 0.67$, $h^2 = 0.15 \pm 0.68$, and $h^2 = 0.25 \pm 0.64$) to BWT, WWT, and ADG, respectively.

Key Words: genetic parameters, growth traits, boer goat

T54 Student organization sponsored dog training classes provide experiential learning opportunity for students and community participants. L. K. Karr-Lilienthal*[1] and J. S. Morstad[3,2], [1]*University of Nebraska-Lincoln*, *Lincoln,* [2]*Union College*, *Lincoln, NE,* [3]*Prairie Skies Inc.*, *Lincoln, NE*.

The goal of this project was to determine the effectiveness of dog training classes organized by a student organization offered to members of the community at large. Students contracted a local professional dog trainer to provide training services. Two different class types were offered: an 8-week Canine Good Citizen (CGC) class for dogs taking a CGC test upon completion of the class and a 4-week basic obedience course. Using exit surveys, community participants and student organization members ranked a series of items on a 1 (strongly disagree) to 5 (strongly agree) scale. Students (n = 9) indicated completion of the course provided a better understanding of dog training (mean = 4.67), could see the importance of dog training in their future career (mean = 4.44, SD = 0.73), and would be interested in applying similar concepts in the training of their own dog (mean = 4.89, SD = 0.33). Students also indicated an understanding of the need for organizational (mean = 4.33, SD = 0.71) and communication skills (mean = 4.56, SD = 0.73) when working with the public. Students indicated assisting with the course allowed them to apply class content (mean = 4, SD = 0.87) and a desire for more hands on opportunities (mean = 4.56, SD = 0.73). The community dog handlers (n = 12) indicated they felt the class improved their dog′s behavior (mean = 4.7, SD = 0.6), the bond between them and their dog (mean = 4.7), and they would recommend it to others (mean = 4.8). They indicated that they felt the university was providing a valuable service by offering the class (mean = 4.75) and that they enjoyed interacting with the students (mean = 4.1). Participants in the 8-week course rated their interactions with the students higher than those in the 4-week course possibly due to both more students attending the 8-week course sessions and more time for interaction. Overall, providing community dog training classes improved student learning and improved community awareness and support of the companion animal programs offered at the University of Nebraska–Lincoln.

Key Words: dog, experiential learning, undergraduate

T55 Tail deflection as a measure of emotional state in canines. C. L. Terrill*, T. H. Friend, and J. E. Sawyer, *Texas A&M University*, *College Station*.

Previous research indicates that negative emotions may be processed in the right hemisphere of the brain and positive emotions in the left; which may be evident in lateral movement of the tail. Dogs and other species could use asymmetry of behavioral displays as a sign of dominance or aggression that is not normally noticed by people. If emotionally linked asymmetry of tail movement occurs, it may aid in reducing the nearly 4.7 million dog bites in the United States each year. The objective of this study was to determine if lateral tail movement in dogs varies with emotional state. Fourteen dogs (7 female, 7 male), ages 2 to 12 years old were selected for the study. Dogs were held in a wooden test box (1.83 × 0.91 × 1.22 m) with a 20 cm × 20 cm viewing slot in one end to reduce distractions until a test stimulus was presented. The dogs were individually exposed to 2 negative stimuli (unknown person, α dog) and 1 positive stimulus (owner) for 0.5 min per stimulus, with a 2 min break between each stimulus to mitigate any potential overlap of emotional response. Still photos of the first 2 full responses of each dog's tail were captured from video, and the maximum angle during each response was averaged to determine left and right deflection. Six of the 14 unknown person tests elicited barking and growling behaviors, indicating that tests were efficacious. Data were analyzed as a mixed model with stimulus as a fixed effect and subject as a random block. Orthogonal contrasts were used to compare positive with negative stimuli, and to compare the types of negative stimuli. Dogs' maximum tail deflections were markedly different among positive and negative stimuli ($P < 0.01$; 36.1° right, 36.0° left, and 34.6° ± 2.5° left for owner, unknown person, and α dog, respectively). Responses to negative stimuli were similar (α dog with unknown person; $P < 0.69$). These results suggest that right and left-brain asymmetry is measurable by quantifying maximum tail deflection in canines, and this methodology may be useful in behavioral studies to estimate positive and negative emotions.

Key Words: emotional state, tail wagging, canine

T56 Galactoglucomannan oligosaccharide (GGMO) supplementation affects nutrient digestibility, fermentation end-product production, and large bowel microbiota of the dog. T. A. Faber*[1], A. C. Hopkins[2], I. S. Middelbos[1], N. P. Price[3], and G. C. Fahey, Jr.[1], [1]*University of Illinois*, *Urbana,* [2]*Temple-Inland*, *Diboll, TX,* [3]*National Center for Agricultural Utilization Research, USDA*, *Peoria, IL*.

A galactoglucomannan oligosaccharide (GGMO) obtained from fiberboard production was evaluated as a dietary supplement for dogs. The GGMO substrate contained high concentrations of oligosaccharides containing mannose, xylose, and glucose, with the mannose component typically 46%. Adult dogs assigned to a 6x6 Latin square design were fed 6 diets, each containing a different concentration of supplemental GGMO (0, 0.5, 1, 2, 4, and 8%) that replaced dietary cellulose. Total tract dry matter (DM) and organic matter (OM) apparent digestibilities increased ($P < 0.0001$) linearly, while total tract crude protein (CP) apparent digestibility decreased ($P < 0.0001$) linearly as the dietary GGMO substrate concentration increased. Fecal concentrations of acetate, propionate, and total SCFA increased ($P \leq 0.0001$) linearly whereas butyrate concentration decreased ($P < 0.0009$) linearly with increasing dietary concentrations of GGMO. Fecal pH decreased ($P \leq 0.0003$) linearly as dietary GGMO substrate concentration increased whereas fecal score increased quadratically ($P \leq 0.0001$). Fecal phenol ($P \leq 0.05$) and indole ($P \leq 0.01$) concentrations decreased linearly with GGMO supplementation. Fecal biogenic amine concentrations were not different among treatments except for phenylethylamine, which decreased ($P < 0.0001$) linearly as dietary GGMO substrate concentration increased. Fecal microbial concentrations of *E. coli*, *Lactobacillus* spp., and *Clostridium perfringens* were not different among treatments. A quadratic increase ($P \leq 0.01$) was noted for *Bifidobacterium* spp. as dietary GGMO substrate concentration increased. Data suggest positive nutritional properties of supplemental GGMO when incorporated in a high quality dog food.

Key Words: dog, galactoglucomannan oligosaccharide, fermentation end-products

T57 Evaluation of cellulose and beet pulp as dietary fibers for use in raw meat-based diets fed to captive exotic felids. K. R. Kerr*[1], C. Morris[2], S. Burke[2], and K. S. Swanson[1,3], [1]*Division of Nutritional Sciences, University of Illinois*, *Urbana,* [2]*Henry Doorly Zoo*, *Omaha, NE*, [3]*Department of Animal Sciences, University of Illinois*, *Urbana.*

The optimal fiber type and level of inclusion in raw meat-based diets for captive exotic felids has not been determined. The effects of fiber type and level on total tract digestibility, fecal characteristics, and fecal fermentative end products were evaluated using jaguars (n = 4), cheetahs (n = 4), Malayan tigers (n = 4), and Siberian tigers (n = 4) using a factorial design. Dietary fibers [cellulose (C); beet pulp (BP)] were added to diets at 2% or 4% (as-is). Statistical analyses were conducted using Mixed Models procedure of SAS. Dry matter (DM) and organic matter (OM) digestibilities were lower ($P < 0.05$) in cats fed 4C (76.7%; 80.6%) compared with those fed 2C (81.9%; 86.3%), 2BP (80.39%; 85.2%), and 4BP (82.3%; 87.9%). Fecal DM percentage was higher ($P < 0.05$) and fecal scores were lower ($P < 0.05$; i.e., stools were drier) in cats fed C compared with cats fed BP, and in cats fed 2BP compared with cats fed 4BP. The ratio of fecal DM output to DM intake (g DM feces/g DM intake) was higher($P < 0.05$) in cats fed 4C compared with those fed 2C, 2BP, and 4BP. The ratio of fecal output as-is to DM intake (g feces as-is/g DM intake) was higher($P < 0.05$) in cats fed C compared with those BP. Fecal acetate, propionate, butyrate, total short chain fatty acid, and ammonia concentrations were lower ($P < 0.05$) in cats fed C compared with cats fed BP. The proportion of acetate was greater ($P < 0.05$) and the proportion of butyrate was lower ($P < 0.05$) in cats fed BP compared with cats fed C. Total fecal branched-chain fatty acid concentrations were higher ($P < 0.05$) in cats fed 2BP than cats fed 4BP and 2C, and higher ($P < 0.05$) in cats fed 4C compared with cats fed 4BP. To conclude, cellulose at the 4% level decreased diet digestibility and increased fecal DM output, thus beet pulp (2% and 4%) or cellulose (2%) may be preferred dietary fiber options for raw meat-based diets for captive exotic felids. However, cats fed beet pulp had wetter/looser stools, increased fecal as-is output, and higher concentrations of fecal fermentative end products, which may have implications for animal management and gut health.

Key Words: exotic felids, digestibility, fiber

T58 The influence of fish versus mammalian and avian protein sources on satiety hormone response in dogs. B. M. Vester Boler*[1], T. A. Faber[1], L. L. Bauer[1], K. S. Swanson[1], S. Smiley[2], P. J. Bechtel[2,3], and G. C. Fahey Jr.[1], [1]*University of Illinois*, *Urbana,* [2]*University of Alaska*, *Fairbanks,* [3]*USDA/ARS*, *Fairbanks, AK*.

Satiety is affected by macronutrient composition of the diet. Proteins, specifically, are the most satiating, and fish proteins have been reported to be more satiating than meat proteins. The objective of this study was to determine the effect of beef, chicken, pork, or fish protein pre-meals on postprandial satiety hormone and 24 h food intake responses. Ten purpose-bred, intact female hounds were used. Pork loin, beef loin, chicken breast, salmon fillet, and pollock fillet were tested. During phase I, dogs were fed 100 g of protein from each substrate mixed with 200 mL of water. Blood was collected before feeding the substrate (0 min), and at 5, 15, 30, 60, 90, and 120 min postprandial, and analyzed for glucose, insulin, total ghrelin, and glucagon-like peptide-1 (GLP1). Dogs were fed 2-times their metabolizable energy (ME) requirement of food 3 h following the feeding of the protein substrate, and orts were weighed at 30, 60, and 180 min, and 24 h, after food presentation to determine intake. During phase II, dogs were fed 100 g of substrate mixed with 200 mL of water. Two-times the ME requirement of food then was offered 3 h following the protein meal and orts were weighed at 30, 60, and 180 min, and 24 h, after food presentation. In phase I, glucose decreased over time ($P < 0.001$), but was lowest ($P = 0.01$) when dogs were fed pollock or chicken substrates. Insulin increased ($P < 0.0001$) over time, and tended to be greater ($P = 0.09$) when dogs consumed the salmon treatment. Food intake and GLP1 increased ($P < 0.001$) over time, but did not differ due to treatment ($P = 0.60$ and $P = 0.33$, respectively). Total ghrelin decreased ($P < 0.01$) over time, but did not differ ($P = 0.86$) due to diet. In phase II, food intake tended to be greater ($P = 0.06$) when dogs consumed the beef pre-meal compared with when dogs consumed the pork or pollock pre-meals. Protein source appears to influence blood markers of satiety in dogs, but has little effect on decreasing food intake.

Key Words: satiety, dog, protein source

T59 Dietary magnesium alters urinary histamine excretion in domestic felines. S. K. Martin*[1], C. E. Conway[1], M. R. C. de Godoy[1], D. L. Harmon[1], E. S. Vanzant[1], S. Zicker[2], R. M. Yamka[2], and K. R. McLeod[1], [1]*University of Kentucky*, *Lexington,* [2]*Hill's Pet Nutrition, Inc.*, *Topeka, KS*.

Magnesium (Mg) deficiency has been associated with increased histamine production in rats. Limitation of Mg with acidifying foods is common practice for management of urinary tract health in domestic cats. Nine healthy adult female shorthair cats were used in a 3 period random crossover experiment with fixed treatment sequences to test the effects of dietary Mg (0.06, 0.12, and 0.18% DM) on histamine in blood and urine. The dry-extruded test foods were fed in sufficient amounts to maintain ideal body weight and obtain a target urine pH of 6.3. Each experimental period was preceded by a 7d wash out period, in which the 0.06% Mg was fed, followed by a 14d feeding period of the appropriate food. Two 24h total urine collections were performed (d13: acidified, d14: unacidified; immediately iced) and blood was collected on d14. Dry matter intake ($P = 0.70$) and BW ($P = 0.30$) were not affected by treatment. Plasma Mg increased linearly with increasing dietary Mg (0.54, 0.56, 0.58 m*M*; $P = 0.001$). Urinary histamine excretion responded quadratically ($P = 0.02$) to treatment (3483, 3369, 3986 ng/d), whereas plasma histamine concentration ($P = 0.8$) was unaffected. Differences were not detected among treatments in total histamine, cellular + noncellular histamine, ($P = 0.70$) or antigen-induced ($P = 0.21$) histamine release in whole blood. Urine output ($P = 0.48$), pH ($P = 0.95$), NH3 ($P = 0.21$), and titratable acidity of urine ($P = 0.78$) were similar across treatments. These data suggest that dietary Mg concentration at 0.06- 0.12% has little effect on histamine in blood or urine, however, supplying Mg at 0.18% increased urinary histamine.

Key Words: cat, magnesium, histamine

T60 Dietary effects of dietary cation anion balance on histamine metabolism and urine acidity in domestic felines. S. K. Martin*[1], C. E. Conway[1], M. R. C. de Godoy[1], D. L. Harmon[1], E. S. Vanzant[1], S. Zicker[2], R. M. Yamka[2], and K. R. McLeod[1], [1]*University of Kentucky*, *Lexington,* [2]*Hill's Pet Nutrition, Inc.*, *Topeka, KS*.

Dietary cation anion balance (DCAB) has been extensively studied in relation to urinary pH and stone formation. However, there is a paucity of data concerning the relationship between DCAB and histamine; the latter has been suggested as a mediator of inflammation in human interstitial cystitis which displays similarities with feline idiopathic cystitis. Eight healthy adult female shorthair cats were used in a 3 period random crossover with fixed treatment sequences to test the effects of DCAB (6.3, 6.6, and 6.9 target urine pH) on histamine kinetics and urine acidity. Dry-extruded test foods were fed to maintain ideal body weight. Each experimental period (14d) was preceded by 7d wash out period in which the low DCAB diet was fed. Two 24hr total urine collections were performed (d13: acidified, d14: unacidified; immediately iced) and blood was collected on d14. Dry matter intake ($P = 0.73$), BW ($P = 0.62$), and urine output ($P = 0.50$) were similar across treat-

ment. Urinary pH (6.11, 6.37. 6.69) increased linearly ($P = 0.004$), while titratable acidity of urine (0.14, 0.13, 0.10 mL 0.1 *M* NaOH to achieve 7.4 pH) tended to decrease linearly ($P = 0.09$) with increasing DCAB. Urine NH_3 decreased linearly ($P = 0.03$) with increasing DCAB (445.7, 418.6, 324.5 mmol/L). Urinary histamine excretion ($P = 0.03$) and concentration ($P = 0.02$) increased linearly with increasing DCAB (6164, 8513, 8356 ng/d; 113.8, 129.9, 135.2 ng/mL); where as plasma histamine concentration ($P = 0.42$) was unaffected. Differences were not detected among treatments in antigen-induced ($P = 0.21$) histamine release in whole blood, however total, cellular + noncellular histamine release ($P = 0.07$) demonstrated a quadratic trend with treatment (12.7, 6.9, 11.2 ng/mL). These data indicate that DCAB alters urinary acidity and histamine excretion, but does not affect circulating plasma concentrations or antigen-induced release of histamine.

Key Words: cat, dietary cation anion balance, histamine

T61 The effects of graded arginine levels on nitrogen metabolism in the lean adult dog. C. E. Conway*[1], M. R. C. de Godoy[1], S. K. Martin[1], K. R. McLeod[1], N. Z. Frantz[2], R. M. Yamka[2], and D. L. Harmon[1], [1]*University of Kentucky*, *Lexington*, [2]*Hill's Pet Nutrition, Inc.*, *Topeka, KS*.

Arginine (ARG) is considered to be conditionally essential in the diet of adult omnivores, indicating that addition of supplemental ARG may be beneficial. These potential benefits include enhanced hepatic urea synthesis aiding ammonia clearance and increased glomerular flow rates via the vasodilatory effects of nitric oxide. The objectives of this study were to determine if feeding increased supplemental ARG affects indices of renal function, inflammation, and whole body nitrogen metabolism in the adult dog. Three isocaloric foods were used in this study: a control (0.99% total ARG on a DMB), control plus 0.5% supplemental ARG (1.42% total ARG on a DMB), and control plus 1.0% supplemental ARG (1.85% total ARG on a DMB). The foods were fed to maintain ideal body condition of 9 adult (ages 2–3 years) spayed Beagles (7.62 ± 0.67 kg) in a replicated 3x3 Latin Square design. Experimental periods were 28 d in length with blood collection on d 14 and 28, and total urine and fecal collections for the final 6 d of each period. Nitrogen intake was increased ($P < 0.0001$) by increasing supplemental ARG. Dry matter digestibility was 1.7% lower ($P = 0.0025$) for the 1.0% ARG food. Nitrogen digestibility was greatest ($P = 0.0013$) for the 0.5% ARG food. Nitrogen absorbed was greater ($P < 0.0001$) for both the 0.5% and 1.0% ARG foods than control, yet nitrogen retained ($P = 0.3188$) and urea excretion ($P = 0.3153$) did not differ between treatments. Inflammatory biomarkers, PGE2 and HMGB1, hormone IGF1, and kidney markers, ADMA, albumin, and MCP1, were evaluated in urine or serum samples. No differences were detected in any of these biomarkers indicating that increased supplemental ARG did not have an anti-inflammatory effect or improve markers of kidney function at the levels tested. Despite some subtle changes in N metabolism, it does not appear, based on the variables measured, that addition of dietary arginine to the adult dog at maintenance is beneficial.

Key Words: arginine, dog, nitrogen metabolism

T62 The effects of carob (*Ceratonia siluqua*) on some reproductive parameters of male New Zealand White rabbits. A. Ata, M. S. Gulay*, O. Yildiz-Gulay, and S. Gungor, *Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*.

Carob is used locally in many Mediterranean countries for its aphrodisiac properties. Thus, the aim of this study was to determine the effect of carob on reproductive parameters of male New Zealand White rabbits. The experiment consisted of 2 stages. The first stage was the adaptation period which 6–8 mo old rabbits were trained for the semen collection for 15 d. At the end of the first stage rabbits were divided into 2 groups of 8; a control and treatment groups administered daily with 10cc tap water and carob extract by oral gavages, respectively. Second stage of the experiment was 49 d (1 spermatogenesis duration). During second stage semen samples were collected weekly from all rabbits and samples taken at wk 1 and wk 7 were analyzed separately. There were no differences in control and treatment groups for ejaculate volume (0.71 ± 0.06 vs. 0.64 ± 0.03mL), ejaculate pH (7.01 ± 0.02 vs. 7.00 ± 0.01), sperm concentration (347.5 ± 45.1 vs. 380.9 ± 29.4 × 10^6 mL), percent progressive motility (78.9 ± 1.44 vs. 79.1 ± 0.91%), percent live spermatozoa by eosin-nigrosine staining mixture (EET; 82.5 ± 1.25 vs. 78.3 ± 3.06%), percent sperm membrane response by hypo-osmotic swelling test (HOS; 79.0 ± 1.21 vs. 74.9 ± 2.54%) and seminal plasma protein levels (2.6 ± 0.3 vs. 2.9 ± 0.3gr/dL) at the beginning of stage 2 ($P > 0.1$). Similarly, there were no differences in control and treatment groups for ejaculate volume (0.68 ± 0.06 vs. 0.63 ± 0.03 mL), ejaculate pH (7.06 ± 0.03 vs. 7.02 ± 0.02), percent progressive motility (78.0 ± 2.9 vs. 84.0 ± 2.12%), EET (80.1 ± 3.51 vs. 80.4 ± 2.41%), HOS (77.5 ± 2.37 vs. 80.9 ± 2.54%) and seminal plasma protein levels (2.6 ± 0.19 vs. 2.4 ± 0.25 g/dL) at the end of stage 2 ($P > 0.1$). However, sperm concentration (337.6 ± 43.4 vs. 460.7 ± 44.1 × 10^6 mL, $P < 0.05$) and percent changes on spermatozoa concentrations between groups (percentage of spermatozoa at the end of stage 2 ÷ percentage of spermatozoa at the beginning of stage 2; 98.9 ± 6.38 vs. 122.9 ± 6.56%, $P < 0.02$) were affected by the treatment at the end of stage 2. Data suggested that use of carob cures by boiling the fruit of carob has beneficial influences on sperm concentration in rabbits.

Key Words: carob, rabbit, spermatological parameters

T63 The effects of carob (*Ceratonia siluqua*) on some hematological parameters and organs of male New Zealand White rabbits. M. S. Gulay*[1], O. Yildiz-Gulay[1], A. Ata[1], A. Balic[2], and A. Demirtas[1], [1]*Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*, [2]*Sakarya Toyota Hospital*, *Sakarya, Turkey*.

Carob, also known as St. John's Bread, is used locally in many Mediterranean countries for its curative properties. However, the long-term use of carob may also have toxic effects. Thus, the present study was conducted to determine the effects of dietary carob on some hematological parameters and organs of male New Zealand White rabbits. Rabbits (6 to 8 mo old) were divided into 2 groups of 8 rabbits. Rabbits in the control group received 10cc tap water for 49 d. Rabbits in the treatment group received the same amount of carob cures by boiling the fruit of carob for 49 d. All treatments were given by oral gavage. At the end of the experiment, 10 mL of blood was withdrawn from the ear arteries of each rabbit and sacrificed. Total erythrocyte, leukocyte, plasma protein, percent hemoglobin, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, percent neutrophil, eosinophil, basophil lymphocyte and monocyte for rabbits in control and treatment groups did not differ and were 5.77 ± 0.22 and 6.37 ± 0.31 × 10^6/μL, 6.7 ± 0.99 and 7.34 ± 0.34 × 10^3/μL, 6.51 ± 0.20 and 6.48 ± 0.30 g/dL, 13.8 ± 0.32 and 13.7 ± 0.24 g%, 41.0 ± 1.59 and 40.8 ± 0.96%, 71.4 ± 2.8 and 64.6 ± 3.3 μm^3, 24.0 ± 0.7 and 21.8 ± 1.3 μg, 33.8 ± 1.18 and 33.7 ± 0.96%; 33.6 ± 4.54 and 38.4 ± 1.20%, 3 ± 0.89 and 2.8 ± 0.20%, 58.7 ± 4.73 and 53.8 ± 5.14%, and 4.7 ± 1.05 and 5 ± 1.04%, respectively. Liver, kidney, lung, heart and body weights between control and treatment groups were not significant ($P < 0.1$). Moreover, no apparent changes in liver, kidney, liver, heart, testis and brain were detected by gross post mortem and histopathologi-

cal examination to suggest toxic effect of oral use of carob extract for 49 d. Thus, the results suggested no toxic effect subacute use of carob extract in male New Zealand White rabbits.

Key Words: carob, rabbit, hematological parameters

T64 The effects of feeding *Pinus pinea* seeds on some blood values in male New Zealand White rabbits. O. Yildiz-Gulay*[1], M. S. Gulay[1], A. Ata[1], A. Balic[2], and A. Demirtas[1], [1]*Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*, [2]*Sakarya Toyota Hospital*, *Sakarya, Turkey*.

A trial involving 16 male New Zealand White rabbits was conducted to determine whether there is any effect of *Pinus pinea* seed supplementation on hematological parameters and organs. Rabbits (6 to 8 mo old) were divided into 2 groups of 8 rabbits. Rabbits in the control group received 10cc tap water for 49 d. Rabbits in the treatment group received 1 g/kg of *Pinus pinea* seeds in 10 mL of tap water for 49 d. All treatments were given by oral gavage. At the end of the experiment, 10 mL of blood was withdrawn from the ear arteries of each rabbits and sacrificed. No significant differences were detected in mean hemoglobin (13.8 ± 0.31 vs. 13.5 ± 0.25 g%), hematocrit (41.0 ± 1.59 vs 40.4 ± 0.87%), red blood cell count (5.8 ± 2.24 vs. 5.7 ± 2.51 × 10^6/μL), white blood cell count (6.70 ± 9.94 vs. 6.54 ± 3.54 × 10^3/μL), plasma protein (6.5 ± 0.20 vs. 6.3 ± 0.12 g/dL), mean corpuscular hemoglobin concentration (33.8 ± 1.18 vs. 33.5 ± 1.20 g/dL) percent neutrophil (34.5 ± 4.01 vs. 38.5 ± 3.66%), eosinophil (3.0 ± 0.89 vs. 2.0 ± 0.40%), basophil (0.60 ± 0.33 vs. 0.50 ± 0.29%), lymphocyte (57.2 ± 4.17 vs. 53.2 ± 2.92%) and monocyte (4.7 ± 1.05 vs. 5.8 ± 0.85%) of rabbits in control and treatment groups, respectively. Overall blood parameters remained within the physiological range in both groups. Liver, kidney, lung, heart and body weights between control and treatment groups did not differ. Moreover, no apparent changes in liver, kidney, liver, testis and brain were detected by gross post mortem and histopathological examination to suggest toxic effect of oral use of *Pinus pinea* seeds for 49 d. In conclusion, 49 d of *Pinus pinea* seed supplementation did not cause any negative effects on the parameters tested in this study.

Key Words: *Pinus pinea* seeds, hematological parameters, histopathology

T65 Spermatological parameters of male New Zealand White rabbits supplemented with *Pinus pinea* seeds. A. Ata, M. S. Gulay*, O. Yildiz-Gulay, S. Avki, and S. Gungor, *Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*.

The experiment was designed to evaluate whether supplementing male New Zealand White rabbits with *Pinus pinea* seeds affected spermatological parameters. Six to 8 mo old male rabbits (n = 16) were trained for semen collection for 15 d. Rabbits were assigned randomly to control and treatment groups (8 per group). Control and treatment groups were administered daily with 10cc tap water and 1 g/kg of *Pinus pinea* seeds in 10 mL tap water by oral gavage, respectively for 1 spermatogenesis duration (49 d). During the entire experimental period semen samples were collected weekly from all rabbits. During the experiment, 2 semen samples taken at wk 1 and wk 7 were combined and analyzed separately. There were no differences in control and treatment groups for initial values for ejaculate volume, ejaculate pH, progressive motility, head defect, tail defect, sperm concentration, percent live spermatozoa by eosin-nigrosine staining mixture (EET), percent sperm membrane response by hypo-osmotic swelling test (HOS) or seminal plasma protein levels ($P > 0.1$). Similarly, there were no differences in control and treatment groups for ejaculate volume (1.02 ± 0.13 vs. 0.90 ± 0.18 mL), ejaculate pH (7.02 ± 0.04 vs. 7.00 ± 0.02), progressive motility (75.7 ± 2.63 vs. 79.8 ± 1.94%), head defect (2.02 ± 0.09 vs 2.12 ± 0.09%), tail defect (13.0 ± 0.99 vs. 10.9 ± 1.22%), EET (73.3 ± 2.26 vs. 81.6 ± 4.98%), HOS (73.1 ± 2.28 vs. 77.1 ± 3.15%) and seminal plasma protein levels (2.3 ± 0.23 vs. 2.8 ± 0.34 g/dL) at the end of experiment ($P > 0.1$). However, sperm concentration (327.6 ± 44.3 vs. 464.7 ± 45.8 × 10^6 mL, $P < 0.05$) and percent changes on spermatozoa concentrations between treatment groups (percentage of spermatozoa at the end of experiment ÷ percentage of spermatozoa at the beginning of experiment; 97.2 ± 8.05 vs. 124.9 ± 5.74%, $P < 0.02$) were affected by the treatment at the end of experiment. Data suggest the daily dietary supplementation of *Pinus pinea* seeds to rabbits may improve sperm concentration in rabbits.

Key Words: *Pinus pinea* seeds, rabbit, spermatological parameters

T66 An x-ray system to assess Ragusano PDO quality. G. Impoco[1], C. Pasta[1], G. Portelli[1], G. Marino[1], M. Caccamo*[1], S. Carpino[1], and G. Licitra1,2, [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*D.A.C.P.A., University of Catania*, *Catania, Italy*.

Accept/reject judgments in Ragusano Protected Designation of Origin (PDO) quality assessment are highly subjective due to the lack of standard evaluation protocols. Moreover, assessment takes place on aging centers. X-ray scanning is a mature technology used in the industrial chain to inspect the inner structure of food. The use of x-ray images of cheese blocks was investigated to judge cheese quality, the main reason being that this technique is non-destructive. Moreover, evaluating quality on a common ground would open the possibility of devising quantitative image analysis tools, inspired by objective evaluation protocols. An evaluation scale was created to objectively score cheese blocks by visual inspection of x-ray images. According to inspectors' suggestions, 7 relevant criteria were chosen. Six inspectors assessed these parameters on a few test images of Ragusano PDO and assigned a weight to each of them. Then, a 7-item on a 9-point semantic differential scale was created. A data set of 223 images manually evaluated cheese blocks was collected. From this data set, 64 images were randomly extracted. Images were evaluated using the scale Furthermore, inspectors also assessed cheese acceptability only based on images by using a yes/no criterion. Two weeks later, inspectors observed the same 64 images only to evaluate cheese block acceptability, with no scale use. Results of both experiments were compared with the on-field evaluation to determine whether the scale was useful for quality assessment. The scale presented a final reliability with both Cronbach's α test and standardized Cronbach's α of about 0.81. Construct validity assessed on all 7 items resulted in a 2-factor solution that explained 79.5% of the scale variance. By using the scale, cheese acceptability evaluated by images was consistent with on-field evaluation for 62% of cheese blocks, whereas without the scale consistency dropped down to 37%.

Key Words: quality evaluation, cheese, x-ray imaging

T67 Effects of rapid visco analyzer on the functional properties of imitation mozzarella cheese. S. He[1,2], X. Li*[1,2], Y. Ma[3], C. Yao[2], and B.Wu[1,2], [1]*Key Laboratory of Dairy Science, Northeast Agricultural University, Ministry of Education*, *Harbin, Heilongjiang, China*, [2]*College of Food Science, Northeast Agricultural University*, *Harbin, Heilongjiang, China*, [3]*School of Food Science and Engineering, Harbin Institute of Technology*, *Harbin, Heilongjiang, China*.

A small-scale manufacturing method of imitation cheese was developed by a rapid visco analyzer (RVA). In this work, imitation mozzarella cheeses with similar chemical compositions, made by RVA at a stirring speed of 200, 300 or 450 rpm and by the Stephan cooker at 1,500 rpm, were investigated through functional properties, microstructure and sensory evaluation. A color measurement instrument (model ZE-6000, Nippon Denshoku Industries CO., Ltd., Japan) revealed that the increase of stirring speed in RVA method made the color more white. Within the range of speeds in the present study, the relationship between the minimum apparent viscosity (y, cP) and speeds (x, rpm) was best described by a linear model y = 0.9x + 685.3 (r2 = 0.968). Through free-oil release analysis, the fat leakage of imitation cheese at 450 rpm was significantly higher than the others. On the Texture profile analysis (TPA), the hardness of imitation cheese significantly increased, and the adhesiveness sharply decreased while the springiness and cohesiveness values remained unchanged. However, there was not a significant effect on functional properties of imitation cheeses between RVA at 450 rpm and Stephan cooker at 1,500 rpm. The microstructure of imitation cheeses observed by scanning electron microscopy, showed that increasing stirring speed seemed to reduce the fat globules size and form a uniform protein matrix. In the sensory evaluation, the imitation cheese manufactured by RVA at 450 rpm was not a significant difference with the control made by the Stephan cooker. The RVA can be used as a small-scale manufacturing tool for making the imitation cheeses with similar functional properties.

Key Words: imitation mozzarella cheeses, rapid visco analyzer (RVA), functional properties

T68 A sensor technology for monitoring and controlling syneresis in the cheese vat. T. G. Ferreira*[1], M. Castillo`, F. A. Payne[1], C. O'Donnell[3], and D. O'Callaghan[4], [1]*University of Kentucky*, *Lexington*, [2]*Universitat Autònoma de Barcelona*, *Spain*, [3]*University College Dublin*, *Ireland*, [4]*Moorepark Food Research Center, Teagasc, Fermoy, Co. Cork, Ireland*.

Cheese quality is affected by curd moisture content which is determined during the whey syneresis step. The syneresis step in cheese processing is currently controlled empirically by the processor as there are no on-line sensor technologies available for monitoring curd syneresis. A novel non-destructive optical sensor technology that is able to monitor both milk coagulation and curd syneresis in a stirred cheese vat has been developed. The objective of this study was to evaluate the performance of the sensor technology over a wide range of coagulation and syneresis rates. A 5-factor, fully randomized, fractional, factorial central composite design (CCD) was employed. The 5 experimental factors selected were milk coagulation temperature, milk pH, fat to protein ratio, calcium chloride addition level, and gel cutting time. The CCD consisted of a 2k-1 factorial (k = 5) with 2k axial points and 7 center points (33 runs). A homogeneous sample of curd and whey was removed from the cheese vat from 5 until 85 min after cutting on 10 min intervals. Fat, protein and total solids content of whey, curd, and milk were determined. Also, the weight of curd and whey produced was expressed as a percentage of the initial weight of milk to provide the actual curd and whey yield. A curd aliquot was pressed for determination of pressed cheese moisture content. Results confirmed previously observations for both curd moisture content and light backscatter ratio changes during curd syneresis. The largest change in curd moisture content was observed during the first 15–30 min of syneresis. However, significant moisture content changes were observed in pressed cheese samples at all different post-cutting times. These results clearly suggest an important role of syneresis end point selection on moisture content consistency of fresh, pressed cheeses. Successful validation and of the syneresis sensor technology scale up and subsequent transference to the industry will have a large impact on cheese production efficiency and cheese yield. Not only will the sensor have industrial applications, it could also serve as a powerful tool for research.

Key Words: on line sensor, syneresis, moisture content control

T69 Method to quantify retention of lipid soluble substances in a cheese curd model system. M. Tippetts* and S. Martini, *Utah State University*, *Logan*.

The purpose of this study was to find a way to quantify how much of an emulsion′s lipid soluble substances are retained in a cheese curd model

system by image analysis rather than alternate methods such as HPLC. Soybean oil (SBO) was the oil phase and it was saturated with Nile red, which is an indicator for liposoluble substances. The oil-in-water emulsion was made using a 1 wt % protein non-fat dairy powder aqueous solution, and a 5 wt% oil phase. The saturated Nile red SBO was added to the system as 0, 20, 40, 60, 80, and 100% of the total SBO. Each emulsion was homogenized using a microfluidizer. After emulsion formation 5 mL of the emulsion were pipetted into pre-heated 3.36 wt% protein milk protein concentrate solution. The ratio of emulsion to milk solution was 1:40. Curd was made and then samples were taken of each sample, placed in a mold and under UV light images were taken using an ethium bromide filter, which excited the Nile Red in the curd. The images were then analyzed using ImageJ software′s macro for RGB histogram. The intensities of red (histogram) for the mean and mode were plotted with respect to the concentration of Nile red. Data was fitted using linear regression with R2 values of 0.994 (mean) and 0.996 (mode). The correlation found for each measurement is: $y = 0.379x + 7.361$ and $y = 0.392x + 5.385$ for the mean and mode, respectively. These results show that a good linear correlation exists between the amount of Nile red added to the emulsion and the final red intensity found in the curd. Correlations found with the mode measurements seem to be more sensitive to changes in Nile red concentration due to the slightly steeper slope obtained in the linear correlation. Since Nile red is a lipid-soluble compound, this technique can be used to quantify the amount of lipid soluble substances retained in a model system for cheese curd.

Key Words: lipids, emulsion, cheese

T70 Effect of storage at ambient temperature on calcium lactate crystallization in Cheddar cheese. F. Su, P. Rajbhandari, and P. Kindstedt*, *University of Vermont*, *Burlington*.

Supermarkets sometimes hold cheese at ambient temperature in unrefrigerated aisle displays to enhance sales. Storage temperature is an important risk factor in calcium lactate crystal formation, but the effect of ambient storage followed by refrigerated storage has not been reported. In this study, Cheddar cheese was made at the University pilot plant and aged for 3 mo at 5°C. The cheese block (9 kg) was then sectioned into retail-sized (ca. 14.5 × 4.5 × 4.5 cm; 350 g) chunks and 9 chunks were randomly chosen for study. For each of the 9 samples, one of the large (ca 14.4 × 4.5 cm) surfaces was from the exterior of the 9 kg block and thus relatively rough due to curd granule junctions and press cloth indentations; the opposite surface was cut smooth with a wire cutting device. The samples were vacuum packed at 50 mbar and randomly assigned to 3 temperature treatments. Two sets of 3 samples were held at 20°C for either 24 or 48 h, respectively, before being stored at 1°C. A third set was immediately stored at 1°C, which served as the control. Digital photos of rough and smooth surfaces were taken triweekly for 28 wk and the number and area of crystal regions were determined by image analysis. Data were analyzed by repeated measures ANOVA. The number and area of crystal regions were significantly affected by surface roughness, storage temperature and storage time. Rough surfaces crystallized more profusely than smooth surfaces, and ambient storage for 24 or 48 h caused substantial reductions in crystal formation rates relative to control cheeses. The results indicate that short-term ambient storage rendered cheese surfaces less susceptible to crystallization, especially the rough surfaces that were heavily predisposed to crystallization. The mechanism for this effect is unclear but may involve temperature-induced alteration of the cheese surface and potential nucleation sites.

Key Words: Cheddar cheese, calcium lactate, storage temperature

T71 Effect of addition of calcium chloride and sodium chloride on aflatoxin M1 content during Egyptian Domiatti cheese processing. M. M. Motawee*[1], K. Genedy[1], and T. A. Nassib[2], [1]*National Organization for Drug Control and Research*, *Giza, Cairo, Egypt*, [2]*Faculty of Agriculture, Mansoura University, Mansoura, Egypt*.

Aflatoxins are highly toxic, mutagenic and carcinogenic compounds producing by some common molds as *Aspergillus flavus* and *Aspergillus parasiticus* during their growth on feedstuffs. Domiatti cheese is the most popular soft white pickled cheese in Egypt and makes up about of the 75% of the cheese produced and consumed in our country. The proportion of salt (5 to 14%) depends on the season of manufacture and on the temperature of cheese ripening. The present study was aimed to analyze the level of aflatoxin M1 (AFM1) by thin layer chromatography method in pasteurized milk, curd and whey after spiked milk with (AFM1) during Domiatti cheese processing. The results indicated that, the addition of $CaCl_2$ at the different concentration (0.01, 0.02, 0.03, 0.04 and 0.05%) had slight significant effect of AFM1 content in pasteurized milk. AFM1 content decreased from 1.4 ppb to 1.26 ppb with the addition of 0.01 and 0.05% of $CaCl_2$, respectively. While AFM1 content in curd was significantly ($P < 0.5$) increased from 6.7 to 7.5 ppb with the addition of 0.01 and 0.05 of $CaCl_2$ respectively. The increase of $CaCl_2$ concentration was accompanied with decrease of AFM1 content in whey of cheese. On the other hands, the addition of different concentration of NaCl (6, 8, 10 and 12% caused slight decreased of AFM1 in pasteurized milk from 1.38 ppb at 6% of NaCl to 1.26 ppb at 12% NaCl. Opposed results was showed in the curd, where AFM1 decreased from 6.7 ppb at 6% NaCl to 6.1 ppb at 12% NaCl. The same trend was observed in whey.

Key Words: aflatoxin M1, NaCl, $CaCl_2$, Domiatti cheese

T72 Effect of milk fat content on goat cheese proteolysis elaborated with the traditional method. D. Sánchez-Macías*, I. Moreno-Indias, L. E. Hernández-Castellano, A. Morales-delaNuez, A. Torres, M. D. Ruiz-Díaz, A. Argüello, and N. Castro, *Department of Animal Science, Las Palmas de Gran Canaria University*, *Arucas, Las Palmas, España*.

Three different milk fat contents (5%, 1.5% and 0.4%) were used to manufacture full-fat cheese (FFC), reduced-fat cheese (RFC) and low-fat cheese (LFC) goat raw milk cheese according to traditional hand-made cheese practices in Canary Islands (Spain). Cheeses were ripened for 1, 7, 14 and 28 d. Water-soluble proteins were extracted at 1, 7, 14 and 28 d of ripening and they were separated on SDS-PAGE gel. The SAS PROC MIXED procedure for repeated measurements was used to evaluate the effect of differing fat content and ripening time on the proteolysis. Tukey's test was used to evaluate the differences between groups. β-casein was the greatest proportion in all type of cheese and at all ripening time. α_{s2}-casein and α_{s1}-casein were the most abundant after β-casein. Quantitative analysis showed a general reduction in each casein as ripening progressed. In the 3 types of cheese, the degradative rates of intact caseins was higher throughout the period of ripening in the α_{s1}-casein (60–70%), followed by β-casein (38–45%) and then by α_{s2}-casein (25–40%) than d 1 of ripening. Furthermore, the rate of degradation during the experimental time was lower as the fat content decreased. At d 28, the percentage of total principal caseins remaining was 62, 66.5 and 70% in FFC, RFC and LFC, respectively. The remaining α_{s2}-casein and α_{s1}-casein in FFC and RFC were lower than in LFC. In contrast, β-casein also showed degradation along the ripening, differences in degradation between the 3 types of cheese were not significant at 28 d. α_{s1}-casein was degraded faster and cheese contained 28–40% at 28 d of ripening. α_{s2}-casein was degraded slower in LFC

than in FFC and RFC. The electrophoretic bands of degradation products increased with the ripening time in all cheeses. The appearance of these fragments was higher in FFC than RFC and LFC. This statement is correlated to previous information, that the degradation rate of caseins was increased as cheese was fatter resulting in a greater appearance of degradation bands in FFC.

Key Words: cheese, low-fat, proteolysis

T73 Impact of salt substitutes on the sensory characteristics of reduced sodium process cheese. A. Kommineni*, J. Amamcharla, and L. E. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University*.

Process cheese (PC) is an integral part of the American diet. However, consumption of PC is limited by its high sodium content (typically 1265 to 1596 mg/100g). A high dietary intake of sodium has been associated with hypertension. The major ingredient sources of sodium in PC are sodium based emulsifying salts, sodium chloride (NaCl) and natural cheese, contributing 38%, 39%, and 20% of the total sodium, respectively. As per the Code of Federal Regulations (CFR) the sodium content should be less than 950 to 1100mg/100g to be labeled as "reduced sodium" PC. One of the challenges in formulating an acceptable sensory quality reduced sodium PC is the elimination of bitter-metallic flavor that is typically associated with the potassium based salt substitutes. The objective of this study was to determine if new commercially available salt substitutes improve the flavor and acceptability of reduced sodium PC. Newly available salt substitutes (SOLO, NeutralFres, Modified potassium chloride (Nu-Tek: 14500 and Nu-Tek: 14510), potassium chloride) were utilized in the formulations. Metallic blockers and salt flavor enhancers were also incorporated in the formulation either in combination or alone along with salt substitutes to evaluate their ability to mask off-flavors. Potassium citrate was used as emulsifying salt in all the formulations. A triangle test was used to determine if there was any detectable difference in any sensory characteristic between control PC (1540 mg Na/100g) and reduced sodium PC. The reduced fat reduced sodium (RFRS) formulation containing NuTek-14510 and sodium gluconate was not significantly ($P < 0.05$) different from control PC. Similarly, low-fat- reduced-sodium (LFRS) formulation containing NuTek-14510, xylitol, and sodium gluconate was not significantly ($P < 0.05$) different from the control PC. The sodium content of the acceptable RFRS and LFRS were 700 and 710 mg/100g. In conclusion, Nu-Tek:14510 and sodium gluconate can be used to improve the flavor of reduced sodium PC.

Key Words: process cheese, sodium, salt substitutes

T74 Comparison of identified flavor compounds, texture and sensory properties in regular cream cheese and cream cheese made from whole milk powder. S. S. Jeon*, C. H. Chung, and H. S. Kwak, *Sejong University*, *Seoul, South Korea*.

This study was carried out to compare identified flavor compounds, texture and sensory analysis in regular cream cheese and cream cheese made from whole milk powder which were stored at 7°C for 4 weeks. To identify the flavor compounds, the cheeses were extracted and analyzed by solid phase microextraction (SPME) and gas chromatography-mass spectrometry (GC-MS), respectively. Tentatively identified flavor compounds were mainly 13 from acids, however, octadec-9-enoic acid and Z-11-tetradecenoic acid was not present. Z-7-tetradecenoic acid was produced only from the cheese made with whole milk powder. Two ketones, 1 amine, 1 alcohol and 2 alkene were produced from both cheeses, but 6-heptyltetrahydro-2H-pyran-2-one as lactone and 2,6,10,15,19,23-hexamethyl-,(all-E)-2,6,10,14,18,22-tetracosahexaene as alkene were produced only from cream cheese made from whole milk powder. Also 1 imide and 1 alkane were showed only from the sample cheese. The identified flavor components from the whole milk powder-made cheese were different from regular cream cheese due to heat treatment. However, in rheological properties, hardness, adhesiveness, cohesiveness, springiness and gumminess were not significantly ($P < 0.05$) different between control and sample. In sensory analysis, appearance, flavor, taste and texture properties were not significantly ($P < 0.05$) different between control and sample cheese. In addition overall acceptability in the cream cheese made from whole milk powder was similar to that in control. On the basis of our results, we conclude that the cream cheese made from whole milk powder showed almost no adverse changes in texture and sensory characteristics except few identified flavor components.

Key Words: cream cheese, whole milk powder, flavor, texture, sensory evaluation

T75 Identification of neutral volatile compounds, texture and sensory properties in cholesterol-removed cream cheese. S. S. Jeon*, S. J. Lee, and H. S. Kwak, *Sejong University*, *Seoul, South Korea*.

This study was carried out to identify neutral volatile compounds, and examine texture and sensory evaluation in cholesterol-removed cream cheese which was treated by closslinked β-cyclodextrin and stored at 7°C for 4 weeks. To identify the volatile compounds, the 4 week-stored cream cheeses were extracted and analyzed by solid-phase microextraction (SPME) and gas chromatography-mass spectrometry (GC-MS), respectively. Tentatively identified neutral volatile compounds were detected 12 acids, 2 ketones, 1 amine, 1 alcohol, 1 lactone and 1 alkene. The main components were acids, such as hexanoic acid, n-hexadecanoic acid, tridecanoic acid, octanoic acid, octadec-9-enoic acid, 9,12-octadecadienoic acid, n-decanoic acid, benzoic acid, dodecanoic acid, tetradecanoic acid, z-11-tetradecenoic acid and oleic acid. Other components were 2-tridecanone and 2-pentadecanone as ketones, 5-(p-aminophenyl)-4-(o-tolyl)-2-thiazolamine as amine, 4,6-di(1,1-dimethylethyl)-2-methyl phenol as alcohol, tetrahydro-6-pentyl-2H-pyran-2-one as lactone and 3,7,11,15-tetramethyl 2-hexadecene as alkene. The identified components from cholesterol-removed cream cheese were same as those from regular cream cheese. In rheological properties, hardness, adhesiveness, cohesiveness, springiness, gumminess and chewiness were not significantly ($P < 0.05$) different between control and cholesterol-removed cheese during storage at 7°C for 4weeks. In sensory analysis, appearance, flavor, taste and texture properties were also not significantly ($P < 0.05$) different between control and 4week storage periods. In addition, overall acceptability in the cholesterol-removed cheese was closely similar to that in control. On the basis of our results, we conclude that the cholesterol-removed cream cheese showed no adverse changes in flavor, texture and sensory characteristics.

Key Words: cream cheese, cholesterol removal, identification of flavor, sensory analysis

T76 Changes of Ragusano cheese aroma due to different levels of pasture intake. S. Carpino*[1], T. Rapisarda[1], I. Schadt[1], C. Pasta[1], G. Belvedere[1], and G. Licitra[1,2], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*D.A.C.P.A. Catania University*, *Catania, Italy*.

In the Hyblean region of Sicily, 3 groups of 15 Holstein cows have been selected in one dairy farm, during the pasture season. At the beginning of the experiment, milk production and fat content were not different between groups, averaging 26.1 ± 8.1 (kg/cow/day) and 4.0

± 0.6 (%), respectively. The control group (CNT) was exclusively fed a total mixed ration. The remaining groups had additionally pasture access, either for 6 h (LP) or for 16 h (HP). After a 2 weeks adaption period, milk of each group was collected separately, 4 times with a 15 d interval, and 2 Ragusano cheeses were produced. In total, 24 forms were made: 12 aged at 4 (4M) and 12 at 7 (7M) months. The aim of the study was to evaluate the effect of different levels of pasture intake on Ragusano cheeses aroma. Differences in volatile compounds were detected and analyzed by Smart Nose system (LDZ, Switzerland) with principal component analysis (PCA). Odor active compounds were also analyzed by gas chromatography–olfactometry extracted by both, steam distillation and headspace solid-phase microextraction. Odor active compounds were classified into "good" (G): flower, fresh, fruit, green, honey, nut, milk, butter, sweet, vanilla; "bad" (B): animal, broth, burnt, plastic, fried, potato, garlic, onion, rancid, and "not good, not bad" (N): hay, soil, mushroom, pungent, spicy. Differences between compound frequencies were evaluated using the Tukey's HSD test. Mean pasture intakes and standard deviation, relative to total dry matter intake, were 30.6 ± 6.9% in the LP group, and 68.1 ± 2.7% in the HP group. In both, 4M and 7M cheeses, CNT, LP and HP samples were clearly separated by PCA analysis, indicating differences in volatile composition. Feeding differences had no effect on the numbers of N or B odour active compounds, neither in the 4M nor the 7M cheeses. In the 4M cheeses, but not in the 7M cheeses, "good" compounds were more frequent when milk derived from the LP or HP compared with CNT ($\alpha = 0.05$; Q = 3.72). Pasture nutrition of cows might have less importance for aroma quality of 7M compared with 4M aged cheeses.

Key Words: Ragusano cheese, pasture, aroma compounds

T77 Enzyme accelerated ripening of Turkish Mihalic hard cheese: proteolysis and lipolysis. T. Ozcan* and E. Kurdal, *Uludag University, Department of Food Engineering*, *Bursa, Turkey*.

Mihalic cheese, a traditional Turkish hard cheese variety, is mostly produced around Bursa and Balikesir, and also known as Maglic, Mahlic or Kelle cheese. It is white with roundish holes, hard and crusty and made from high-fat sheep or cow milk. Ripening of hard cheese varieties is a slow and consequently an expensive process. During manufacturing and ripening proteolysis, glycolysis and lipolysis reactions, mainly driven by accelerating agents such as starter culture or enzymes, determine the sensory, chemical and textural properties of the cheese. The objective of the present work was to observe the effect of fungal lipase (Piccantase A from *Mucor miehei*), and a bacterial neutral protease from *Bacillus subtilis* (Fermizyme B500) alone or combined with a starter culture on the acceleration of the ripening process of Mihalic cheese made from cow's milk. Cheeses were analyzed at 2, 15, 30, 60 and 90 days of ripening. Casein fractions of Mihalic cheese samples were analyzed by urea polyacrylamide gel electrophoresis (PAGE) and lipolysis rates were measured as acid degree value (ADV). The proteolysis and lipolysis rate of Mihalic cheese samples displayed significant differences due to treatment and ripening period ($P < 0.01$). The highest lipolysis rate was noted monitored in lipase added cheese (as 5.56 ADV) with highest γ-casein ratio and β-casein degradation. Breakdown of casein was higher in starter + protease + lipase added cheese. At the end of ripening period, it was observed that α_s-casein ratios decreased in starter added, starter + protease added and protease added cheeses. Breakdown of β-casein continued throughout ripening, and there was an increase at the end of ripening regarding the ratios of other fractions. In view of sensorial acceptance, protease added cheeses having bitterness and crumbly textural properties due to intense breakdown of β-casein scored lower than lipase added samples.

Key Words: Mihalic cheese, proteolysis, lipolysis

T78 Seasonal variation in milk composition affects textural properties of low-moisture part-skim Mozzarella cheese. V. Jai*, U. Lund, and N. Farkye, *California Polytechnic State University*, *San Luis Obispo*.

The chemical composition of milk (specifically casein, fat and calcium contents) affects quality and functional properties of Mozzarella cheese. The objective of this study was to determine the effects of seasonal variation of milk components on texture properties of low-moisture part-skim (LMPS) Mozzarella in California. Concentrations of protein fractions (i.e., total protein (TP), true protein (TrP) and casein), fat, Ca, total solids (TS) and pH were measured in silo milk samples collected weekly over 15 mo from a dairy plant. LMPS mozzarella from the same plant was also collected biweekly during the same period. Seven days post manufacture the cheeses were analyzed for TP, fat, TS, total Ca, Ca in cheese filtrate, pH and texture properties e.g., hardness (g), cohesiveness, springiness, aggregation index (AGI) and % loss during shredding. Significant seasonal variation of casein, TP, Ca in milk were explained using a linear regression model equivalent to a basic single cosinor model with sine and cosine of week (converted into radians) as predictors ($y = \beta o + \beta 1 \cos(\text{time}) + \beta 2 \sin(\text{time}) + \varepsilon$) with *P*-values <0.05 and R-sq values >0.6. TP in cheese correlated positively with TP, TrP and casein in milk (Pearson correlation coefficient $r > 0.6$; $P < 0.001$). Ca in milk correlated positively with total Ca in cheese and cheese filtrate ($r > 0.4$; $P < 0.05$). Positive linear correlation between hardness, springiness and TP, casein in milk and cheese ($r > 0.3$; $P < 0.05$) were significant. Protein fractions and Ca in milk; TP and total Ca in cheese correlated negatively with the loss in shredding ($r < -0.5$; $P < 0.05$). The protein fractions in milk and cheese negatively correlated with AGI in cheese ($r < -0.45$; $P < 0.05$). Total Ca in cheese and milk correlated positively with springiness of cheese ($r > 0.4$; $P < 0.05$). Results show that concentrations of Ca and protein fractions in cheese milk significantly effect the texture and composition of LMPS mozzarella.

Key Words: low-moisture part-skim Mozzarella, seasonal variation of milk, textural properties

T79 A study of bioactive peptides in US Cheddar cheeses of different ages. Y. Lu*, S. Govindasamy-Lucey, and J. A. Lucey, *University of Wisconsin-Madison*, *Madison*.

Bioactive peptides (BP) have been found in fermented dairy products with various bioactive properties, such as, antihypertensive, angiotensin-I-converting-enzyme (ACE)-inhibitory, immunomodulatory, antimicrobial, mineral transport and opioid activities. The objective of this study was to determine the types and levels of BP produced during ripening of Cheddar cheese. Water-soluble extracts were prepared from Cheddar cheeses. Centrifugation and ultra-filtration were used to remove fat and to fractionate water-soluble extract into 2 fractions with molecular weight (MW) between 1000 to 3000 Da and MW ≤1000 Da, respectively. The fractions were subjected to HPLC -tandem mass spectrometry to identify peptides. HPLC - electrospray ionization (ESI) - time-of-flight (TOF) mass spectrometry was also used to identify peptides present in the fraction of MW ≤1000 Da. BP were identified by comparison with already published milk protein derived BP. A range of Cheddar cheeses of various ages was studied to identify the specific types and determine the levels of BP produced during ripening. In young (~6 d old) and mature (2 years old) Cheddar cheese, 8 and 34 ACE-inhibitory peptides, and 77 and 157 casein phosphopeptides, respectively, were found. With age more potent forms of ACE-inhibitory peptides were found. For some of the ACE-inhibitory peptides (including dipeptides, tripeptides, tetrapeptides and pentapeptides that had high ACE-inhibitory activity or low

IC_{50} values), the content appeared to increase with age as indicated by HPLC-ESI-TOF. Confirmation of the type and quantification of levels of BP in a range of different aged commercial Cheddar cheese is ongoing. Aged Cheddar cheese could be a good source of BP.

Key Words: bioactive peptide, angiotensin-I-converting-enzyme, mass spectrometry

T80 Effect of curd milling on the characteristics of Queso Fresco during storage. D. L. Van Hekken*[1], M. H. Tunick[1], N. Y. Farkye[2], J. B. Luchanski[1], S. Mukhopadhyay[1], and P. M. Tomasula[1], [1]*USDA, Agricultural Research Service*, *Wyndmoor, PA,* [2]*California Polytechnic State University*, *San Luis Obispo*.

Queso Fresco (QF) is one of the most popular fresh Hispanic-style cheeses in the US Manufacture of QF varies from country to country with many practicing fine milling of the curd before forming the cheese block. This study was undertaken to determine the effect of milling of the curd with different sized blades on the chemical, functional, and rheological properties of QF. QF was prepared from pasteurized, homogenized milk containing 0.1% of added $CaCl_2$. It was coagulated with chymosin and the curd was cooked at 39°C for 30 min and wet salted at 12.5% salt (wt salt/wt cheesemilk). Portions of the curds were then finely milled using different-sized meat grinder blades and hand-packed into molds for storage overnight at 4°C. Cheeses were removed from the molds the next day, sliced into smaller blocks, vacuum packaged, and stored at 4°C for up to 8 wks. Fresh QF contained 56.5 to 58.0% moisture, 22.2% fat, 15.7 to 17.6% protein, 2.5% lactose, and 2.4% salt. Moisture content decreased with aging ($P \leq 0.05$) because of wheying off; control QF (not milled or passed through grinder without blade) had the highest amount of wheying off (3%), while the finest milled QF had the lowest amount of wheying off (0.5%). All other properties were not affected significantly ($P \geq 0.05$) by the milling treatment or by storage for up to 8 weeks at 4°C. In QF, the homogenization step, know to alter milk protein-protein interactions, was sufficient to disrupt the cheese matrix and resulted in a crumbly cheese. The fine milling step did reduce the amount of whey lost from the cheese during storage but did not affect other functional or rheological properties of the QF.

Key Words: Queso Fresco, milling, wheying-off

T81 Pigments from nonthermal browning formed in Gouda and Parmesan cheeses. A. Lopez-Hernandez*[1], L. E. Rodriguez-Saona[2], M. M. Giusti[2], M. E. Johnson[3], D. A. Sommer[3], and S. A. Rankin[1], [1]*University of Wisconsin-Madison*, *Madison,* [2]*The Ohio State University*, *Columbus,* [3]*Wisconsin Center for Dairy Research*, *Madison*.

Under certain conditions, some cheeses develop a brown discoloration during the course of aging thus yielding changes in flavor and color. Parmesan and Gouda cheeses are some typical examples of the products where excessive browning and the concomitant caramel-like flavor have been noted. To date, very little definitive science exists to describe, define or control the reaction chemistry of non-thermal browning (NTB) in cheese from either the flavor or pigmentation perspective. Factors such as redox potential, available oxygen, the type and concentration of α-dicarbonyls, amino acid type and concentration, the presence of Mn^{2+} ions, and microbial tyrosinase activity are some of the suggested pathways proposed to explain the development of NTB. In the present work, the brown pigments from several Parmesan and Gouda cheese samples exhibiting various degrees of discoloration were extracted using methyl tert-butyl ether (MTBE) and further separated from the fat fraction by TLC. The L*, a* and b* values for the different samples were measured and ranged from 89.5 to 91.07, −0.923 to −2.14, and 1.14 to 3.99, respectively. The UV-Visible spectra of the colored compounds in the isolated fractions were characterized by the presence of unique absorption bands at 425, 451 and 472 nm. Attenuated total reflectance Infrared analyses (ATR-FT-IR) of the brown pigments revealed the presence of characteristic bands at 1103 and 1037 cm-1. These results suggest that the pigments may be comprised of lipid-containing moieties since those bands are very characteristic of in-plane C−H bending vibrations.

Key Words: browning, FT-IR, cheese pigments

T82 Whey ricotta: A scientific reevaluation. J. W.-M. Heick*, R. Jimenez-Flores, and H. Khalil, *California Polytechnic University*, *San Luis Obispo*.

Ricotta cheese is one of the first attempts in the dairy industry to utilize the whey left over during the manufacturing of chesses. Currently, ricotta is exclusively made from whole or skim milk and has a low commercial value. However, whey ricotta as made following the classic style (as described by Kosikowski) has great modern potential because it utilizes the by-product of cheese manufacturing (sweet or acid whey) and has an excellent nutritional profile and organoleptic properties. Our research focused on manufacturing high protein ricotta from whey while retaining the desired sensory and nutritional profile. An Italian style low acid cheese was manufactured at the Cal Poly Creamery, and the whey was collected after cutting at a pH of 6.60. The whey was then skimmed and/or ultrafiltrated before it was added to the steam kettle for processing. Three treatments were applied to the whey: fat skimming, ultra filtration and acidification, and the final ricotta was either pressed or left to drain naturally. Whey and ricotta samples were analyzed qualitatively and quantitatively for total protein before and after protein precipitation. Total protein was measured using the MilkoScan FT2 from FOSS, and the protein profiles were determined using sodium dodecyl sulfate PAGE (SDS- PAGE). Compositional analysis of the finished ricotta was conducted using the Babcock method for percent fat, Elementar rapid-n cube for protein, and CEM LabWave 9000 for moisture. The ricotta curd was analyzed along with the pre/post whey: skimming the whey resulted in a 80% drop in final fat content while ultrafiltration resulted in a increase in the effectiveness of protein removal from the post whey. Moisture levels were dependent on the whey treatments: 70–80% in non-pressed ricotta and 65–78% in pressed ricotta, protein content also varied with a range of 9–14%. Acidification occurred at 2 levels, high pH target of 5.5 resulted in the most neutral flavor while low pH 4.5 had more complete protein precipitation. The results highlight a practical methodology to manufacture a high quality whey cheese from by-product using equipment that is readily available to small cheese makers.

Key Words: whey, ultrafiltration, ricotta

T83 Evaluation of the addition of urea to refrigerated raw milk on the crude protein, milk fat, lactose, and total solids contents determined by mid-infrared spectrometry. E. G. Esteves[1], M. M. O. P. Cerqueira*[2], L. M. Fonseca[2], M. O. Leite[2], M. R. Souza[2], C. F. A. M. Penna[2], R. Rodrigues[2], and L. R. Abreu[3], [1]*Ministry of Agriculture*, *Brasília, Distrito Federal, Brasil*, [2]*Federal University of Minas Gerais*, *Belo Horizonte, Minas Gerais, Brasil*, [3]*Federal University of Lavras*, *Lavras, Minas Gerais, Brasil*.

To detect the effect of fraudulent addition of urea to refrigerated raw milk, 32 samples of milk from 32 samples of milk from bulk tanks were collected at different dairy farms. A control sample and 3 test samples added with different levels of urea (0.0723, 0.1445 and 0.2891 wt%) were made. Both, the bulk tank and the test samples were analyzed to determine the crude protein, lactose, milk fat, and total solids contents by mid-infrared spectrometry. The crude protein, lactose, and total solids contents increased in 0.110, 0.17, and 0.140 wt%, respectively, on a 0.2891 wt% of urea added to milk. On the same conditions, the milk fat content decreased in 0.032 wt%. The equations of linear regression among the urea levels added (in wt%) and the crude protein and the total solids contents (both in wt%) were established. The changes on refrigerated raw milk composition submitted to the addition of urea detected by mid-infrared spectrometry analysis show that this fraudulent addition can increase the profits of the dairy farmer when milk payment is applied by the dairy industry.

Key Words: urea, milk composition, mid-infrared spectrometry

T84 Cheese whey compositional analysis using infrared spectroscopy. F. A. Pinto[1], L. A. Clementino[1], D. L. S. Oliveira[1], L. R. Abreu[2], L. M. Fonseca*[1,3], R. Rodrigues[1,3], M. O. Leite[1,3], and M. M. O. P. Cerqueira[1,3], [1]*Federal University of Minas Gerais/Escola de Veterinária/DTIPOA*, *Belo Horizonte, MG, Brazil*, [2]*Universidade Federal de Lavras/DCA*, *Lavras, MG, Brazil*, [3]*Laboratory for Milk Quality Analysis*, *Belo Horizonte, MG, Brazil*.

Compositional analysis of whey is necessary for its best utilization. To perform physicochemical analysis, infrared spectroscopy techniques are useful, as they are fast and precise. The objective of this research was to evaluate infrared spectroscopy for measurement of cheese whey composition from typical Brazilian cheeses. Twenty-one samples of whey from Minas padrao cheese and 22 samples of whey from Prato cheese were analyzed, using standard methods and a filter infrared equipment (Combisystem 2300, Bentley). The results for fat, protein and total solids using infrared instrument based on filters and standard methods were compared by Friedman test for related samples. The mean values are presented in Table 1.

The differences between results from both methods were significant. The pasteurization process can affect the results, as compounds formed during heating may interfere with infrared spectrum readings, and the whey samples used for equipment calibration were made from raw milk. After a linear transformation of the results with curve approximation, measurement of whey composition from Minas padrao cheese by infrared and standard methods were statistically equivalent. Therefore, results show that it is necessary to perform an equipment calibration for cheese whey analysis using infrared equipment based on filter. However, for whey from Prato cheese, even after transformation, the difference was significant. This whey has a water excess, as showed by the high freezing point. Moreover, it has a dye that is added for typical orange color during Prato cheese production. Water and pigment may affect the absorption of infrared radiation by the whey constituents. Therefore, infrared spectroscopy based on filters can be used for component analysis of whey from Minas padrao cheese, as long as a calibration adjustment is used. For Prato cheese whey, the infrared method based on filters did not provide accurate results.

CNPq, FAPEMIG, Laboratory for Milk Quality Analysis, School of Veterinary Medicine, UFMG

Table 1. Compositional analysis of cheese whey using standard methods and infrared spectroscopy

	Minas Cheese Whey		Prato cheese whey

T85 Comparison of Mojonnier and Gerber methods for analyzing the fat content of fermented milk beverages. E. H. P. Andrade, M. O. Leite, C. F. A. M. Penna, M. R. Souza, L. M. Fonseca*, and M. M. O. P. Cerqueira, *Federal University of Minas Gerais*, *Belo Horizonte, Brasil*.

The objective of this study was to compare 2 methods to estimate fat content in fermented milk beverages. The samples of fermented milk beverages were collected in large supermarket chains from Belo Horizonte, Minas Gerais, Brazil. Both methods are described in Brazilian legislation, but Mojonnier is the official method to analyze fat content in milk beverages and Gerber is the official method to analyze fat content in fluid milk. Gerber is a simpler and easier method to perform than Mojonnier method. Thirty samples of fermented milk beverages were analyzed using the 2 methods. There was no difference ($P > 0.05$) between Mojonnier and Gerber methods for fat content measurement in these samples. So, both of them could be used to measure the fat content in fermented milk beverages.

Key Words: fermented milk beverages, Mojonnier method, Gerber method

T86 Quantitative analysis of the distribution of fat globules in milk. G. Impoco[1], N. Fucà[2], and G. Licitra*[1,2], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*DACPA, University of Catania*, *Catania, Italy*.

This study aims at devising image analysis methods to quantify the distribution of fat globules in confocal laser scanning microscope

(CLSM) images. Milk was collected from a local farm and subject to eight different treatments. Ten images were recorded for each milk specimen using CLSM at 40X and classified according to five parameters (small globules count, large globules count, globule density, presence of clusters, and distribution homogeneity). Each image was classified through visual inspection by assigning a numeric score to each parameter. Visual evaluation provided qualitative, subjective information. Automatic quantitative analysis was performed onto the same images to obtain objective, repeatable estimates. Each image was partitioned into cells. For each cell, nine numerical descriptors were computed (e.g., number of globules in a cell, area covered by globules). For each descriptor, a measurement was obtained at each cell. The variances of such measurements over all cells were recorded. Nine descriptors were thus obtained for each image. Factor analysis on manual evaluation data revealed that count of small and large globules were strongly inversely correlated (−0.85), as well as density and homogeneity to the presence of clusters (−0.40 and −0.61, respectively). Density and homogeneity had a moderate correlation factor (0.66). Principal component analysis showed that the first three components accounted for 80% of the total variance in scores. Factor analysis was also performed on software measurements. As expected, several descriptors were highly correlated since they capture similar aspects of the images. After grouping correlated factors, numerical description was consistent with qualitative parameters. Automatic classifications turned out to be a good interpretation of manual annotations. This suggests that quantitative characterization of dispersed phases of fluids in CLSM micrographs is promising.

Key Words: image analysis, milk treatments, milk microstructure

T87 Evaluation of Sprint rapid protein analyzer for total protein analysis of Cheddar cheese. H. M. Zhang*, P. Salunke, J. K. Amamcharla, and L. M. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

The Kjeldahl method is widely used as a reference method for protein measurement of numerous dairy products including cheese. However, it is labor intensive, time consuming, and utilizes hazardous chemicals. A new protein analysis instrument called the Sprint rapid protein analyzer (CEM Corporation) was recently developed. This instrument utilizes an automated protein-tagging technology and is rapid, easy to operate, and does not utilize hazardous chemicals. In previous research we have demonstrated that the Sprint method is applicable for analysis of milk and cream samples. The objective of this study was to evaluate the applicability of the Sprint method for the analysis of Cheddar cheese. In this study 6 Cheddar cheese samples were analyzed for protein in duplicate using the Sprint method and the Kjeldahl method at 1 week, 3, 6, 9, and 12 mo on ripening. The protein content of each sample measured by Kjeldahl analysis remained relatively constant throughout ripening (mean difference between 1 week and 12 months was - 0.23%), whereas the protein content of each samples measured by the Sprint method decreased during ripening (mean difference between 1 week and 12 months was 2.68%). The average protein differences between the methods (Sprint – Kjeldahl) at 1 week, 3, 6, 9, and 12 month samples was 2.04, 1.34, 0.90, 0.11, and -0.79%. These results indicate that the Sprint method over estimated the protein content during early ripening and underestimates the protein content after extended ripening. As Cheddar cheese ages the level of intact protein decreases and the level of hydrolyzed protein increases. Since the protein-tagging technology utilized in the Sprint method is influenced by protein hydrolysis it is not surprising that the results of this method are influenced by the age of the cheese. In order to utilize the Sprint method for protein analysis of Cheddar cheese the level of protein hydrolysis in the cheese needs to be controlled.

Key Words: Sprint rapid protein analyzer, Cheddar cheese, total protein

T88 Determination of true proteins in dairy products: A comparative study between Kjeldahl and Sprint protein analyzer. D. Zhao*, V. Jai, and N. Y. Farkye, *California Polytechnic State University*, *San Luis Obispo*.

True proteins (TP) in milk play a major role in yield, functionality and nutritional value of dairy products and products containing dairy components. It is standard practice in milk procurement for milk processing plants to pay premium for protein content of milk. However, in the dairy industry, TP is of greater economic value than total protein content hence the need for rapid determination of TP is of significant interest. In this study, the Sprint Rapid Protein analyzer, SPR (CEM Corporation, Matthews, NC) was compared with the standard Kjeldahl method to measure the TP in selected dairy products. The SPR is based on the Orange G dye binding method that measures the TP directly unlike Kjeldahl in which TP is calculated as the difference between total nitrogen and non-protein nitrogen multiplied by 6.38. Cheddar and mozzarella cheeses, and milk protein powders such as whey protein concentrate 80, milk protein concentrate, milk protein isolate, whole milk powder, and non fat dry milk were analyzed for true proteins by both the methods and the results were compared. The results were not statistically different for Cheddar cheese ($P > 0.05$), Mozzarella cheese ($P > 0.05$) and the milk protein powders ($P > 0.05$). The repeatability within the samples for Cheddar cheese, Mozzarella cheese and milk powders were similar in both methods (standard deviation 0.02–0.42 from Kjeldahl; and 0.04–0.49 for SPR). The relative standard deviation for all the products measured in both the methods was always less than 2%. Therefore, the precision and accuracy in measuring true protein by SPR in dairy products is comparable to Kjeldahl. The SPR offers rapid (less than 5 min), easy determination of true proteins in dairy products. It can be a good alternative to Kjeldahl in a dairy processing plant where faster results are needed

Key Words: true proteins, Kjeldahl, Sprint rapid protein analyzer

T89 Application of FTIR spectra for early detection of spore contamination in fluid milk. J. C. Huber-Rockow* and R. Jimènez-Flores, *California Polytechnic State University*, *San Luis Obispo*.

FTIR is shown to be a useful tool for the analysis of spores in several food products and processes. This research aims to improve milk safety and processing practices through the development of a fast and reliable FTIR method to document and quantify the metabolic changes in spores in raw milk and milk after a germination-induction heat treatment. In this study, basic FTIR-ATR spectral analysis and principal component analysis properly differentiates 11 reference strains of *Bacillus* in their 1200–900 cm^{-1} fingerprint regions (*B. megaterium*, *B. subtilis* (2), *B. pumilus*, *B. licheniformis* (2), *B. coagulans*, *B. circulans*, *B. amyloliquefaciens*). Subsequently, using the whole spectra generated by the FOSS MilkoScan FT2, we successfully identified individual strains at different stages of heat-induced germination in a milk system, however no significant difference between strains was identified. Further analysis will improve differentiation between strain variability and natural variability of milk. Completion of this work will continue to highlight the utility of FTIR as a tool for safety and quality screening in the dairy industry.

Key Words: FTIR, spores, milk quality

T90 Oxidation stability of milk rich in α-linolenic acid produced through duodenum infusion of high-linolenic perilla fatty acid into dairy cows. Q. S. Liu, J. Q. Wang*, D. P. Bu, E. Khas, G. Yang, L. Y. Zhou, P. Sun, and K. L. Liu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Our objective was to determine the effect of storage condition on oxidation stability of milk samples which were stored in dark under different storage conditions. The milk samples came from 4 primiparity Chinese Holstein cows infused with increasing amounts of high-linolenic perilla fatty acid into the duodenum (0, 100, 200, 300, 400 g/d), then stored in dark at either 4°C or 20°C for period of 0, 72, and 120 h. Data were analyzed statistically by using PROC MIXED of SAS. It was observed that at 0 h, the activity of total superoxide dismutase (T-SOD), total antioxidant capacity (T-AOC) in milk samples were tended to decrease linearly ($P = 0.21$, $P = 0.14$), but the content of thiobarbituric acid reactive substances (TBARS) was tended to increase linearly ($P = 0.18$) with the infusion increased, the oxidation stability of milk samples showed the tendency of decreasing at 0 h. Furthermore, the activity of T-SOD was not changed, the T-AOC decreased sharply $P = 0.0086$, the content of TBARS increased significantly ($P = 0.029$) with the infusion increased, the oxidation stability of milk decreased significantly when them stored at 4°C for 72 h, however, when stored for 120 h, the activity of T-SOD, T-AOC and the content of TBARS were not changed, which showed the oxidation stability of milk tended to remain stable at 4°C for 120 h. Milk samples stored at 20°C for 72 h, the activity of T-SOD, T-AOC tended to decrease ($P = 0.055$, $P = 0.07$). Content of TBARS tended to increase linearly ($P = 0.082$), which indicated that the oxidation stability of milk have the tendency of decreasing with the increasing amounts of α-linolenic acid, but for 120 h, the activity of T-SOD did not change significantly, the T-AOC tended to decrease quadratically ($P = 0.052$), the content of TBARS increased sharply ($P = 0.023$), therefore, the oxidation stability of the milk was decreased. Our results suggested that the oxidation stability of milk rich in α-linolenic acid produced through duodenum infusion perilla oil is decreased at the different storage conditions.

Key Words: milk samples, storage condition, oxidation stability

T91 Activity and viability of lactic acid bacteria in yogurts fortified with predigested non-germinated or germinated whole soy powder. U. Nsofor*[1,2] and Z. Ustunol[1], [1]*Michigan State University*, *E. Lansing,* [2]*Food and Drug Administration*, *College Park, MD.*

We have previously shown that pre-digestion and germination of soybeans hydrolyzes the non-bioavailable compounds into bioactive compounds and fermentation during yogurt manufacturing further increases their yield. The overall goal of this research was to determine the activity and viability of lactic acid bacteria in yogurt that has been fortified with predigested and non-germinated, or germinated soy powder, over the 6 week refregerated storage of the product. Swiss style reduced-fat strawberry flavored cow's milk yogurts fortified with germinated (GSP) or non-germinated (NGSP) spray dried whole soy powders (50:50 blend) and cultured with *Streptococcus salivarius* ssp. *thermophilus*, *Lactobacillus delbrueckii* ssp. *bulgaricus* and a probiotic *Lactobacillus acidophilus* NCFM were manufactured using standard yogurt manufacturing procedures. The soybean varieties utilized for yogurt making were Vinton 81 and DF 222. Treatments investigated were 50:50 blends of, GSP Vinton 81 + cow's milk, NGSP Vinton 81 + cow's milk, GSP DF 222 + cow's milk, NGSP DF 222 + cow's milk. All soy and all dairy yogurt controls were also included. Proximate analysis of all yogurt samples was conducted according to AOAC procedures. Activity and viability of the lactic acid bacteria was monitored at 7 d intervals over 6 weeks of refrigerated storage at 4°C. MRS, MRS-sorbitol and M17 agar were utilized to enumerate *Lactobacillus delbrueckii* ssp. *bulgaricus*, *Lactobacillus acidophilus* NCFM and *Streptococcus salivarius* ssp. *thermophilus*, respectively. The pH of each yogurt was determined at time of manufacture and also monitored at 7 d intervals for 6 weeks. The pH of the yogurts remained constant for up to 5 weeks of refrigerated storage. Cow's milk yogurt fortified with GSP DF 222 maintained highest ($P < 0.001$) activity and viability of lactic acid bacteria during the 6 weeks of the study, $>4 \times 10^7$ CFU/g. Activity and viability of the lactic acid bacteria was lowest in all soy yogurts during the same time frame, $<2.0 \times 10^6$CFU/g.

Key Words: yogurt, soy, lactic acid bacteria

T92 Sensory attributes of yogurt fortified with predigested, non-germinated or germinated whole soy powder. U. Nsofor*[1,2] and Z. Ustunol[1], [1]*Michigan State University*, *E. Lansing,* [2]*Food and Drug Administration*, *College Park, MD.*

Fortification of yogurt with soy and soy ingredients has been of interest to combine health benefits of soy with dairy ingredients. We have previously shown that pre-digestion and germination of soybeans hydrolyzes the non-bioavailable compounds into bioactive compounds and fermentation during yogurt manufacturing further increases their yield. The overall aim of this research was to determine the sensory attributes of cow's milk yogurt fortified with predigested and non-germinated, or germinated soy powder and compare these yogurts to their all soy and all dairy counterparts. Swiss style reduced-fat strawberry flavored cow's milk yogurts fortified with germinated (GSP) or non-germinated (NGSP) spray dried whole soy powders (50:50 blend) and cultured with *Streptococcus salivarius* ssp. *thermophilus*, *Lactobacillus delbrueckii* ssp. *bulgaricus* and a probiotic *Lactobacillus acidophilus* NCFM were manufactured using standard yogurt manufacturing procedures. The soybean varieties utilized for yogurt making were Vinton 81 and DF 222. Treatments investigated were 50:50 blends of, GSP Vinton 81 + cow's milk, NGSP Vinton 81 + cow's milk, GSP DF 222 + cow's milk, NGSP DF 222 + cow's milk. All soy and all dairy yogurt controls were also included. Proximate analysis of all yogurt samples was conducted according to AOAC procedures. A total of 112 untrained sensory panelists evaluated all 6 yogurt samples for appearance, body texture, flavor and overall acceptance on a 9-point hedonic scale. All yogurts had similar pH of 4.55 at the end of manufacturing. There were no significant differences in their compositional analysis. Sensory results showed there were no significant differences in appearance, body texture, flavor and overall acceptance between the cow's milk yogurt and the 50:50 blends containing germinated or non-germinated soy powder. There were also no noted differences in sensory attributes investigated between the 2 bean varieties (Vinton 81 and DF 222) studied. However, all soy yogurts were scored significantly lower ($P < 0.001$) than all other yogurts.

Key Words: yogurt, soy, sensory

T93 Effect of lactose content on the post-acidification of yogurt. V. Sikand*, P. S. Tong, and S. Roy, *California Polytechnic State University*, *San Luis Obispo*.

The manufacturing of yogurt involves fermentation of milk by *Lactobacillus delbrueckii* ssp. *bulgaricus* and *Streptococcus thermophilus*. Two important properties of yogurt are that it contains live cultures and lactic acid. Because of the high residual lactose content in yogurt, lactic acid can continue to be produced during its refrigerated storage by *Lactobacillus bulgaricus*. This phenomenon is called "post-acidification." Yogurt can become too acidic (sour) because of its continued acidification and negatively affect the properties of the yogurt. The objective of this research was to control post acidification by reducing the amount of lactose in milk used for preparing yogurt. Two non-fat yogurt mixes were formulated to contain 5% protein and varying degrees of lactose as follows: Control yogurt mix containing 7% lactose made by adding 5.66% w/w nonfat dry milk powder to fluid skim milk and experimental yogurt standardized to 2% lactose by adding milk protein isolate (MPI) containing 87% protein to UF permeate obtained from skim milk. The UF permeate was used because of its similar mineral composition to milk. These mixes were stirred for 5 h and kept overnight in a refrigerator for complete hydration. On the next day, these yogurt mixes were heated at 85°C for 30 min, cooled to 42°C, mixed with commercial frozen yogurt culture (DVS YC-X11), and incubated until it reached pH 4.6. Basic composition analyses of these yogurt mixes showed similar mean protein values. The control yogurt mix had 0.18% fat content, 7% lactose, and about 13% total solids, while the experimental yogurt mix had 0.31% fat, 1.9% lactose, and 7.9% total solids. Relative to the experimental yogurt mixes, the control yogurt mixes showed a significant decrease in pH level from 4.53 to 4.24 ($P < 0.001$) and an increase in the titratable acidity (TA) from 0.98 to 1.21 ($P < 0.001$) over a 21-d refrigerated storage. However, for the experimental yogurt mixes, the decrease in pH and increase in TA was not significant ($P > 0.001$). Our results showed that limiting lactose content in the UF permeate used for yogurt mix help in controlling post-acidification of lactic acid development.

Key Words: yogurt, post-acidification, lactose

T94 Effect of a satiety ingredient on the properties of resulting yogurts during storage. D. Olson*[1], K. Aryana[1,2], D. Alexander[3], and T. Emmick[3], [1]*Louisiana State University Agricultural Center*, *Baton Rouge,* [2]*Louisiana State University*, *Baton Rouge,* [3]*Kemin Health*, *Des Moines, IA*.

Slendesta is an ingredient used for weight management by inducing satiety. The effect of the Slendesta level (0 (control), 150, and 300 mg/227 g yogurt) on the characteristics of the resulting vanilla yogurts during 0, 1, 3, 5, and 7 wk of 4°C storage was investigated. The resulting vanilla yogurts were analyzed for color (L*, a*, and b* values), pH, extent of syneresis, viscosity, log *Lactobacillus bulgaricus* and *Streptococcus thermophilus* counts, and sensory properties (flavor, body/texture, and appearance/color scores). The Slendesta level was significant for L* value, pH, extent of syneresis, viscosity, log *Lactobacillus bulgaricus* count, and appearance/color score. Increasing Slendesta level decreased L* value, pH, and extent of syneresis but tended to increase viscosity and log *Lactobacillus bulgaricus* count. The 150 mg Slendesta level yogurt had significantly higher appearance/color scores than the control. Age had a highly significant effect on L* value, a* value, pH, extent of syneresis, viscosity, log *Streptococcus thermophilus* count, and log *Lactobacillus bulgaricus* count and a significant effect on both the body/texture score and the appearance/color score. The highest L* value and a* value occurred at wk 0 and 1, and the pH decreased after wk 0. Both the extent of syneresis and the viscosity had a general tendency to increase with storage time. Although both log *Streptococcus thermophilus* counts and log *Lactobacillus bulgaricus* counts decreased with storage, the relative decrease in counts was more rapid for the log *Lactobacillus bulgaricus* counts. Body/texture scores were significantly higher at 3 wk than at 0 wk, while appearance/color scores were significantly higher at 0 wk than at 3 wk. Slendesta positively influenced some characteristics of yogurt.

Key Words: satiety, weight management, yogurt

T95 Chemical and sensory characteristics of set-type yogurts made from sheep, goat, and their mixed milks during refrigerated storage. A. C. Gürsoy-Balci[1], Z. Güler[1], and Y. W. Park*[2], [1]*Mustafa Kemal University*, *Antakya, Hatay, Turkey*, [2]*Fort Valley State University*, *Fort Valley, GA*.

In the countries of the Mediterranean basin, sheep and goat milk and their products have formed a vital part of its economy and cultural heritage. Sheep and goat milk products can provide a profitable alternative to cow milk products owing to their specific taste, texture, typicality and healthy image. Six types of yogurts were manufactured from pure goat milk of Damascus breed, pure sheep milk of Awassi breed, and mixed milk (50% each) of the 2 species using CH-1 and YF-3331 yogurt starter cultures to study chemical composition and sensory properties of the products in relation to free fatty acids (FFA) and volatile compounds (VC) profiles. Upon manufacture, the yogurts were stored at 4oC for 1, 7, 14 and 21 d before conducting chemical and sensory analyses. FFA and VC were determined on a capillary gas chromatography using aluminum adsorption and static headspace techniques. Results showed that cultures significantly affected acetaldehyde ($P < 0.05$), acetone ($P < 0.05$) and diacetyl ($P < 0.01$) contents, responsible for characteristic yogurt flavor, whereas type of milk had no effects. Type of milk influenced ethanol level, which was highest in goat yogurt. Significant variations occurred in acetaldehyde and diacetyl contents during the storage. FFA of hexadecanoic, octadecanoic and decanoic acids were significantly ($P < 0.05$) affected by type of milk. Type of culture influenced ($P < 0.05$) levels of C2 to C15 FFA, while type of milk affected C2 to C14 FFA contents. The mixed milk yogurt contained mean concentrations of 3.96 µg/g diacetyl, 6.69 µg/g acetoin, 41.43 µg/g acetaldehyde, 2.83 µg/g ethanol, 1.77 µg/g ethanoic acid, 1.33 µg/g hexanoic acid, 2.51µg/g decanoic acid, and 1.08 µg/g octanoic acid, respectively. It was concluded that yogurts made from the mixed milk had the highest sensory scores in taste and smell traits.

Key Words: sheep and goat milk, yogurts, chemical characteristics

T96 Oxidative stability of yogurt from bovine and caprine milks enriched with different levels of n-3 fatty acids. D. Dlders*, A. Mora-Gutierrez, R. Attaie, and G. L. Goodie, *Prairie View A&M University, Prairie View, TX.*

Incorporation of n-3 fatty acids into daily diet results in beneficial effects on vision, neural development, and lowers incidents of diseases such as coronary heart disease. The intake of n-3 fatty acids is generally low in the typical Western diet. Dietary intake of yogurt supplemented with physiologically significant amounts of n-3 fatty acid would contribute to a healthy life. However, the incorporation of n-3 fatty acids in foods would have to be limited due to their oxidative instability. The objective of this study was to evaluate the oxidative stability of yogurt from bovine and caprine milks enriched with different level of Menhaden oil containing 38% n-3 fatty acids. Non-fat yogurt from bovine and caprine milks were supplemented with 0.1, 0.2, and 0.4% Menhaden oil followed by homogenization. Yogurt samples were stored in the dark for 30 d at 4°C, and oxidative deterioration of samples were assessed at different intervals using thiobarbituric acid (TBA) test. As the level

of n-3 fatty acids increased in samples the TBA value also increased, regardless of storage time. Significant chelating activity ($P < 0.05$) was detected in yogurt samples containing iron as a chelating agent at 100 ppm. Furthermore, the yogurt made from caprine milk exhibited stronger chelating activity than the yogurt from bovine milk ($P < 0.05$). The high content of β-casein in yogurt from caprine milk is suggested to be involved in protection of n-3 fatty acids against lipid oxidation induced by iron. Yogurt in general seems to be a suitable vehicle for n-3 fatty acid fortification, particularly yogurt made from caprine milk.

Key Words: yogurt, oxidative stability, omega fatty acids

T97 Evaluation of non-essential and heavy minerals in three species milks, Torba yogurts, and whey. H. Sanal[1], Z. Guler[1], and Y. W. Park*[2], [1]*Mustafa Kemal University*, *Antakya, Hatay, Turkey*, [2]*Fort Valley State University*, *Fort Valley, Georgia, USA*.

Among concentrated yogurts, Torba yogurt is made by straining in a special cloth bag, which is the most commonly consumed in Turkey. Mineral contents of milk and dairy products are influenced by many factors such as animal species, feeds, environment, milking and manufacturing processes. This study was to determine non-essential and heavy metal concentrations in cow (Holstein), ewe (Awassi) and goat (Damascus) milks and their regular yogurts, Torba yogurt and whey. A Varian Vista-MPX simultaneous inductively coupled plasma optical emission spectrometer (ICP-OES) was used to quantify silver, aluminum, arsenic, boron, beryllium, cadmium, nickel, lead, antimony, titanium, thallium and vanadium in ashed milks and their respective products. Barium was not detected in goat and cow milk and their products. Among all elements, boron was most abundant, and highest in the cow milk. Species differences were observed between levels of certain health-related elements such as As, B, Ba, Cd, Ni, Sb and Ti in milk and their products. Mean lead contents of all 3 species milks were 3.0 ppm. Average contents (ppm) of Ag, Al, As, B, Ba, Be, Cd, Ni, Pb, Sb, Ti, Tl and V in cow milk and its Torba yogurt were: 0.27, 0.32; 5.31, 6.73; 1.91, 3.29; 24.0, 23.3; 0.0, 0.0; 0.04, 0.06; 0.21, 0.18; 2.47, 2.72; 3.05, 3.22; 1.27, 2.32; 0.31, 0.47; 7.01, 7.18; 0.72, 1.30, respectively. Milk, regular yogurt and Torba yogurt revealed good sources of non-essential elements, especially boron, lead, thallium and vanadium. The daily intake of these elements from these milks and yogurts appeared to exceed the provisional tolerable daily intake. Daily intake of toxic elements from milks and yogurts ranged between 2.16% (Be) and 116% (Pb). A long-term exposure of these elements from foods and environment has to be continuously monitored to maintain at their minimum levels for food safety.

Key Words: cow-sheep-goat milk, Torba yogurt, non-essential elements

T98 Impact of acidulant addition on yogurt fermentation times and physiochemical properties. T. A. Boomgaarden* and K. A. Schmidt, *Kansas State University*, *Manhattan*.

Consumers desire products that minimize their environmental impact; therefore, in recent years, a greater emphasis has been made for sustainable production of agricultural products. This research aimed at developing a yogurt process with reduced fermentation time, thus reducing energy needs and creating a more sustainable manufacturing process. Yogurt was manufactured by pre-acidifying nonfat yogurt mix (13.5% solids) with citric acid, lactic acid or concentrated lemon juice (CA, LA, LJ) at 200 ppm before or after heat treatment to pH 6.2, followed by fermentation at 42°C in a BioFlo 3000 (New Brunswick Scientific Co., Inc.) to a target pH of 4.6. Yogurts were analyzed for *L. bulgaricus* and *S. thermophilus* counts at the beginning and end of fermentation. Three randomized replications were completed and all tests were done in duplicate and averages were reported. Results showed that CA or LJ added after heat treatment reduced fermentation time by 13% compared with the control; whereas, CA and LJ added before heat treatment had no effect. LA added before or after heat treatment increased fermentation time by 16%. Counts of *L. bulgaricus* and *S. thermophilus* were similar, with initial counts of 6.9 and 7.7 log CFU/mL respectively, and end counts of 7.1 and 7.7 log CFU/mL respectively. In addition, control yogurt and yogurts with CA and LJ added after heat treatment were manufactured and fermented in 90 mL sterile cups and assessed for pH, texture and rheological (G', G") characteristics at d 1. Statistically, the CA and LJ yogurts had less firmness (202 g and 212 g) and greater pH (4.58 and 4.57) compared with the control yogurt (231 g and 4.53). Control yogurt had greater G' and G" values at a frequency of 1 Hz than CA and LJ yogurts. These results show that partial acidification of the yogurt mix with CA or LJ after heat treatment reduced fermentation time but some physiochemical parameters, particularly texture, were affected. This new yogurt has potential for success in the marketplace because it appeals to consumers seeking sustainable products and could be easily implemented by manufacturers.

Key Words: yogurt, fermentation time, sustainable manufacturing

T99 Antioxidative peptides isolated from fermented whey proteins by lactobacilli and their effects on aged mice. Y. Bao*[1], X. Liang[1], L. Qin[1], R. Li[1], and M. Guo[2], [1]*Northeast Forestry University*, *Harbin, China*, [2]*University of Vermont*, *Burlington*.

Natural proteins can be partially hydrolyzed to produce peptides that may have biological functions. The objectives of the study were to prepare functional peptides from fermented whey protein concentrate (WPC) by *Lactobacillus plantarum A9* and *Streptococcus thermophilus* S33, and to characterize their antioxidative properties. The optimum conditions for producing antioxidative peptides were: inoculate rate 5%, culture ratio 1:1, fermentation temperature at 37°C and pH at 6.4, and fermentation time for 16 h. Two fractions were obtained using ultrafiltration and their relative molecular weights were 328 and 2,031, respectively. The induced model aged mice were treated by neck back subcutaneous injection of D-galactose every day for 45 d. The mice were given 3 different doses of whey protein peptides (WPP) at 100, 200 and 400 mg/kg body weight per day, respectively. The effects of WPP on the levels of catalase (CAT), malondialdehyde (MDA), superoxide dismutase (SOD), glutathione peroxidase (GSH-PX) in serum, liver and brain were evaluated after 45 d. The CAT, SOD and GSH-PX activities in the induced aged group decreased while MDA increased compared with control mice. However, the activities of CAT, SOD, and GSH-PX in the organs of induced aged mice fed with the WPP were significantly increased especially for the higher dose group ($P < 0.05$). The results showed that antioxidative peptides could be prepared from fermented WPC using *Lactobacillus plantarum A9* and *Streptococcus thermophilus S33* for functional foods applications.

Key Words: peptides, whey protein, fermentation

T100 Zinc-binding activity of yak casein hydrolysate and the structural characteristics of hydrolysate-Zn complex. X. Y. Mao*[1], X. Wang[1], J. Zhou[1], and P. S. Tong[2], [1]*College of Food Science & Nutritional Engineering, Key Laboratory of Functional Dairy of Chinese Ministry of Education, China Agricultural University*, *Beijing, China*, [2]*California Polytechnic State University*, *San Luis Obispo*.

The bioavailability of zinc is very important for its absorption. Many factors can affect the bioavailability of dietary zinc in dairy food systems. Some proteins or peptides can form complex with zinc, which makes zinc soluble and increases its absorption and bioavailability in intestinal basic conditions. The aim of this work was to: 1) determine the Zn-binding activity of yak casein hydrolysate and 2) verify that casein hydrolysate can really form complex which is soluble in a simulated intestinal environment. The capacity of yak casein hydrolysate to form complexes with zinc was quantified. Zinc chelation by casein hydrolysate was described by means of UV-visible spectrophotometry (UV-vis) and Fourier transform infrared spectroscopy (FTIR). Results showed that casein hydrolysate prepared with Alcalase and trypsin possessed the highest Zn-binding activity compared with casein hydrolysates prepared with pepsin, Flavozyme or papain ($P < 0.05$). The 6h-hydrolysate obtained with Alcalase, which is an endopeptidase from *Bacillus licheniformis*, showed the highest Zn-binding activity and significantly higher than that of the native proteins. The UV-vis absorption spectra showed that absorbance spectra changed between yak casein hydrolysate and its zinc complex in the area of 230–300 nm. The absorbance of casein hydrolysate-Zn complex at 270–300 nm was significantly lower than that of casein hydrolysate itself at the same wavelength. The oxygen atom of the carbonyl group in peptides could chelate with Zn^{2+} and lead to the hypochromic shift of its typical bands. Furthermore, FTIR spectra showed that the absorption at wave numbers between 1 450 cm^{-1} and 1 000 cm^{-1} increased when yak casein hydrolysate and Zn^{2+} formed complexes. Casein hydrolysate-Zn complex exhibited strong bands at the wave numbers of 1449 cm^{-1} and 1406 cm^{-1} that are the characteristic stretching mode of C = N. The FTIR spectra verify that some sites of yak casein hydrolysate can bind with zinc, and the formed substance is a Zn-binding complex which may be useful and practical in the prevention and treatment of Zn deficiency.

Key Words: yak casein hydrolysate, Zn-binding capacity, characterization

T101 Functional and volatile properties of milk serum protein concentrates. L. E. Coppola*[1], S. A. Rankin[1], M. S. Molitor[2], and J. A. Lucey[1], [1]*University of Wisconsin-Madison*, [2]*Wisconsin Center for Dairy Research*, *Madison*.

Microfiltration, commonly used in the dairy industry for removal of fat and bacteria from milk, can also be an effective tool to isolate milk serum proteins for the production of milk serum protein concentrate (MSPC). MSPC has less fat, undergoes fewer heat treatments, and is free of rennet and other by-products of the cheese-making process, likely causing it to have improved functionality over traditional cheese whey protein concentrate (WPC). Because solubility, turbidity, foaming, and volatile composition are vital characteristics for many food applications, this study compared these features of MSPC and WPC. Milk permeate was produced from pasteurized, unhomogenized skim milk at temperatures of ~5°C and ~23°C using polymeric, cross-flow microfiltration. Permeates were concentrated by ultrafiltration and spray dried to obtain MSPC powders of ~80% protein. The MSPC powders were compared with a traditional WPC80 from Swiss cheese whey made at Babcock Dairy Plant and 3 commercial WPC. SDS-PAGE results showed that protein composition was significantly different with the MSPC made at 5°C containing more β-casein than the other MSPC or WPC samples (~15% vs. <5%). Both MSPC were significantly ($\alpha = 0.05$) different in standard foaming, turbidity, and solubility tests than WPC samples. MSPC generated larger foam overruns (>2000% vs. <800%) and more stable foams (>14 min vs. <5 min), solutions were less turbid (>90% vs. <25% transmission), and powder had higher solubility compared with WPC samples (over pH range 3–7). Furthermore, MSPC made at 5°C had significantly larger foam overrun (>30000%) and greater foam stability (>2 h) than MSPC made at 23°C (<1200% overrun, stability <15 min). Analysis of volatile content of the powders by SPME-GC/MS showed that the number of different types of volatile compounds present in both MSPC was significantly lower than the number present in WPC samples. In addition, accelerated storage of MSPC at 50°C for 28 d resulted in fewer types of volatiles increasing in intensity during storage compared with WPC samples where many volatiles increased in intensity during storage. MSPC has distinctive flavor and performance attributes that may result in enhanced functionality in specific types of food applications.

Key Words: milk serum protein, protein concentrate, whey

T102 Volatile profiles of commercial starter distillates and diacetyl levels in selected dairy food. M. I. Rincon*, A. Lopez-Hernandez, M. S. Surianto, A. R. Rankin, and S. A. Rankin, *University of Wisconsin-Madison*, *Madison*.

Starter distillates are used as ingredients in the formulation of many dairy products such as cottage cheese, margarine, spreads, processed cheese, and sour cream to increase the levels of naturally occurring aroma compounds associated with lactic acid bacteria (LAB) fermentation. Diacetyl is a highly volatile product of the citrate metabolism of certain LAB including *Lactococcus lactis* ssp. *diacetylactis* and *Leuconostoc citrovorum* that imparts a high level of "buttery" flavor notes. In the US, starter distillates are regarded as generally recognized as safe and usage in food products is only limited by good manufacturing practices. Little is known but the volatile composition of starter distillates and the level of diacetyl in finished products. The objective of this work was to characterize the volatile constituents of 11 commercial starter distillates and to quantitate the levels of diacetyl in several commercial dairy products where starter distillates are used as flavorants. The headspace volatiles were assessed using a solid phase microextraction fiber and analyzed by GC-MS. The identity of the aroma compounds present in the samples was confirmed by matching the corresponding mass spectra with those in a NIST database and by comparing the retention times to those of authentic standards. The levels of diacetyl in the 11 commercial starter distillates ranged from 5,000 to 30,000 ppm. In addition to diacetyl, significant levels of acetoin, acetic acid, acetaldehyde, furfural, benzaldehyde, fatty acids, ethyl acetate were found. A total of 10 samples of cottage cheeses, margarines, spreads, and butter sprays were found to contain diacetyl in the range of 10 to 100 ppm. The results obtained in this work summarize the volatile composition of commercial starter distillates and the approximate levels of diacetyl in selected foods.

Key Words: diacetyl, starter distillates, volatiles in dairy products

T103 Sensory properties of chocolate flavored, protein fortified, fluid milk based recovery beverages produced using indirect and direct thermal processing. A. Lammert*[1], A. Olabi[2], K. Brooks[1], S. Vink[1], and P. Tong[1], [1]*California Polytechnic State University*, *San Luis Obispo,* [2]*American University of Beirut*, *Beirut, Lebanon*.

Protein′s role in post exercise muscle recovery is well documented and numerous beverages are commercially available. However, fluid milk is typically not the first ingredient. The objective was to determine differences between sensory properties of a chocolate flavored, protein fortified fluid milk based recovery beverage that contained 25 g of protein per 12 ounce serving using indirect and direct thermal processing methods. Beverages were formulated using milk, whey protein concentrate (WPC), fructose, sucrose, carrageenan, salts, flavors and

cocoa. WPC was mixed and hydrated for 30 minutes in the milk. The remaining dry ingredients were blended and added to the hydrated WPC/milk mixture and mixed for an additional 5 minutes. The mixture was UHT processed at 285°F for 3 seconds using indirect or direct heat and bottled in a clean fill hood. Descriptive sensory analysis using a trained panel was completed on two week old beverages and the characteristics evaluated were appearance, odor, flavor, texture, and aftertaste. Results were analyzed using repeated measures ANOVA. WPC brand had a significant effect ($P < 0.05$) on mostly the appearance attributes in addition to sweet odor, chalkiness, viscosity and astringent and chalky aftertastes. There was no effect ($P > 0.05$) on most odor and flavor attributes. Processing method had a significant effect on two appearance attributes and burnt odor, cooked flavor, chalky texture, and aftertaste. There was a significant WPC brand and processing method interaction ($P < 0.05$) for most appearance, texture and aftertaste attributes. Given the lack of major effects on odor and flavor attributes, our work indicated that chocolate protein fortified fluid milk based recovery beverages can be developed using different WPCs with minimal impact on sensory properties.

Key Words: fluid milk, descriptive analysis, whey

T104 Physicochemical properties of pomegranate flavored carbonated symbiotic beverage. H. Walsh*, J. Cheng, and M. Guo, *University of Vermont*, *Burlington*.

Drinkable yogurt is becoming popular in the US and other countries and is considered a functional food. Carbonation of drinkable yogurt may create a niche in the functional foods market. The objectives of this study were to develop a manufacturing technology for drinkable carbonated symbiotic yogurts, and to evaluate their physicochemical properties. Two flavors of yogurt drink: pomegranate (P) and vanilla (V) were formulated, each containing inulin as prebiotic and probiotic bacteria to produce symbiotic dairy beverages. The products were successfully stabilized with high methoxyl pectin and whey protein concentrate. The carbonation process was achieved using a pressurized carbonator for these yogurt drinks with approximately 3 volumes of food-grade carbon dioxide. The samples were sealed in glass containers to maintain carbonation levels. Three trials of each product were carried out and 3 replicates from each trial were taken for analysis. Protein fat, total solids and ash were determined using standard dairy analysis methods. Carbohydrate was determined by difference. Viscosity and pH were also analyzed using standard methods. Bottled samples were held at refrigerated temperatures (4°C) for 8 weeks to evaluate the stability of the product over time. Chemical composition of the carbonated beverages were as follows: Protein: 1.58 ± 0.05% (P), 1.59 ± 0.06% (V), Fat: 1.24 ± 0.2% (P), 1.18 ± 0.11% (V), Total Solids: 14.78 ± 0.11% (P), 14.93 ± 0.05% (V), Ash: 0.49 ± 0.02% (P), 0.46 ± 0.03% (V), Carbohydrate: 11.47 ± 0.12% (P), 11.69 ± 0.14% (V). The pH values of the beverage were 4.25 ± 0.04 and 4.22 ± 0.04 and viscosity values were 23.1 ± 3.2 and 25.8 ± 6.5 mPas, for pomegranate and vanilla samples, respectively. Intrinsic stability of the prototypes was maintained for at least 8 weeks. The new manufacturing technology for these prototypes may have potential for commercialization of symbiotic carbonated milk-based beverages.

Key Words: symbiotic, carbonation, beverage

T105 Development of symbiotic milk candy. J. McCarthy*, Z. Zhang, and M. Guo, *University of Vermont*, *Burlington*.

Milk candies made from dried milk are a popular item in Asian countries, but are uncommon in the United States. The objectives of this study were to develop a technology for making powdered milk based candy and analyze its chemical composition. With fortifications of probiotic bacteria as well as the prebiotic compound inulin, a new symbiotic milk candy was developed. A base powder mix was formulated using a combination of skim milk powder, whole milk powder, sugar, maltodextrin and inulin, along with antioxidants and probiotics (*L. acidophilus, L. rhamnosus, L. casei,* and *Bifidobacterium* ssp.) followed by thorough mixing. The mix was then pressed into hexagon tablets using the Colton 204 Rotary Tablet Press. Three trials of the prototype were prepared, and triplicates of each of the trials were analyzed for chemical composition using AOAC standard methods for content of protein, fat, total solids and ash. Carbohydrate content was determined by difference. Results were as follows: protein: 17.87 ± 0.19%; fat: 2.44 ± 0.07%; total solids: 96.93 ± 0.24%; moisture: 3.07 ± 0.24%; ash: 3.31 ± 0.47%; carbohydrates: 73.31 ± 0.37%. Each tablet weighed approximately 2 g and contained 150 mg of inulin and at least 10^9 probiotic cells. Results showed that this product is low in fat content and rich in high quality protein and may be a good vehicle for delivery of both prebiotics and probiotics.

Key Words: milk candy, symbiotic, milk powder

T106 Physicochemical properties of whey protein-based safe paper glue. J. Wang, J. Cheng*, and M. Guo, *University of Vermont*, *Burlington*.

Commercial paper glue products on the market may contain toxic organic compounds harmful to people and bad for the environment. To develop safe paper glues, whey protein-based glue prototypes were formulated using polymerized whey proteins (PWP) and other ingredients. Bonding strength, one of main indexes for glue products, was evaluated, along with the physicochemical properties of the prototypes compared with a commercial control sample. Reconstituted whey protein isolate (WPI) solution (10%, pH 7.0) was polymerized at 75°C for 15 min. The polymerized whey protein (PWP) was combined with PVA, (20%, w/w), emulsifier (propylene glycol) and antibacterial agent (1,2-benzisothiazolin-3-one). The best ratio of PWP solution to PVA solution was about 1.7 to 1.0 with 0.5% propylene glycol and 0.2% 1,2-benzisothiazolin-3-one. The experimental and control glues were sealed in plastic containers and held in an environment controlled chamber (23°C, 50% RH) for 6 mo to determine the bonding strength and physical properties and to evaluate the shelf life. Three trials of the glue prototype were carried out and 3 replicates from each trial were taken for chemical analysis. The bonding strength of the glue was evaluated according to a modified ASTM procedure (D1002–05) using an Instron Universal Testing Machine. Physicochemical properties, including viscosity as well as total solids, ash and protein content, were analyzed using AOAC standard methods. The bonding strength of the glue was 221.5 ± 5.06 N. Viscosity was 675.6 ± 34.6 mPa.s; total solids was 14.38 ± 0.04; ash was 0.27 ± 0.02%; and protein was 9.15 ± 0.07%. The bonding strength and viscosity of both whey protein-based safe paper glue and the control sample remained steady during 6-mo storage.

Key Words: paper glue, whey protein, physicochemical property

T107 Forage yield and quality assessment of tall fescue varieties. D. J. R. Cherney*[1], J. H. Cherney[1], and D. Parsons[2], [1]*Cornell University*, *Ithaca, NY,* [2]*University of Tasmania*, *Hobart, Tasmania, Australia*.

Tall fescue (*Festuca arundinacea* Schreb.) varieties available has increased dramatically in the past few years, and comparisons of varieties for yield and quality are needed. Our objective was to evaluate a method to compare yield and digestibility of entries cut on the same spring day by adjusting yield and digestibility to the same NDF level. Bias occurs if varieties are harvested either on the same day or at the same maturity stage on different days. A system is needed to compare relative yield and forage quality of a group of varieties at the optimum harvest date for each variety, based on total fiber content. This was accomplished by determining the linear rate of change of yield and quality over time. Five separate environments from 2003 to 2009, each with from 3 to 18 tall fescue varieties and 2 to 6 replicates, were sampled for yield and quality using a quadrat (0.06 m or larger) and clippers. Experimental design was an RCBD with a split plot feature, with varieties as the main plot and sampling dates as the sub plots. Sites were located in Chazy, Freeville, and Ithaca, NY. Each trial had at least 5 different spring sampling dates separated by 2 to 4 d between mid-May to early June. Rates of daily change were determined using regression analysis, and analysis of covariance was used to determine if slopes were equal. Rates of change per day of yield and quality were different ($P < 0.05$) across environments, but varieties within a given environment did not differ ($P > 0.05$) in NDF, in vitro NDFD, or yield rate of change per day. Across environments NDF concentration increased from 8 to 12 g/kg/day, while digestible fiber decreased from 7 to 12 g/kg/day. Rate of change in CP was very consistent, decreasing an average of 5.6 g/kg/day over all environments. Rate of change in DM yield was relatively consistent within each environment, but varied from 115 to 275 kg/ha/day across environments. Based on our results, it is possible to sample representative varieties during a period of linear change starting in mid-May and use this information to adjust yield and quality of all entries in a variety trial to their individual optimum harvest dates based on NDF content.

Key Words: tall fescue, digestibility

T108 Yield and chemical composition of forage soybeans relative to seeding rate and stage of harvest. B. G. Buller*, W. A. Storer, D. D. Kee, M. M. Fennel, M. A. Idlett, W. B. Brumbaugh, and F. M. LeMieux, *McNeese State University*, *Lake Charles, LA*.

Two experiments were conducted to evaluate a glyphosate resistant forage soybean (Big Fellow RR) in an effort to identify an alternative high protein forage for cattle producers along the Gulf Coast. The aim of this study was to identify the seeding rate and harvesting stage that optimized forage yield and chemical composition of this soybean. "Big Fellow RR" soybeans were evaluated at different seeding rates and harvesting dates at 2 locations (Lake Charles and Kinder, LA). Soybeans were planted in May of 2009. Both experiments were designed in a complete randomized block arrangement. Seeding rate ranged from 148,000 to 445,000 seeds per hectare. Stand counts, stalk diameter, plant height, and growth stage were evaluated at least twice monthly. Harvesting was conducted from August to mid October to determine responses in yield and chemical composition parameters. Seeding rate did not affect ($P > 0.1$) survival rate or yield in dry matter per hectare. Conversely, individual plant population, height, weight, stalk diameter, and CP were greater ($P < 0.05$), while ADF and NDF were lower ($P < 0.05$) in the lowest population. Percentages of starch, oil, and dry matter, across all seeding rates, increased ($P < 0.05$) between d 102 (R2) and 130 (R5). Dry Matter yield increased ($P < 0.05$) with time. These results indicate, contrary to popular opinion with producers, lower seeding rates may optimize forage cost efficiency and chemical composition. Conversely, higher seeding rates would aid in reducing stalk diameter. This study aided in clarification of ideal seeding rate, harvesting date and established the potential for production of forage soybeans along the Gulf Coast.

Key Words: soybean, forage, seeding rate

T109 Chemical constituents of *Cynodon* spp. varieties. C. L. Gordin, E. R. de Oliveira*, L. L. Freitas, F. W. Pedroso, R. H. de Tonissi e Buschinelli de Goes, B. Lempp, S. F. Luna, W. S. Prado, L. H. X. da Silva, C. W. S. Gavilan, and A. M. de Araújo Gabriel, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

The chemical composition of 3 *Cynodon* spp. varieties (Tifton 68, Tifton 85, and Jiggs), in different harvesting ages, were evaluated. The experiment was carried of December 2008 to February 2010, at the animal science sector of Dourados Federal University. Dry Matter, CP, NDF, and ADF determinations were processed at UFGD's Animal Nutrition laboratory. The experimental design consisted of random blocks with treatments organized in a split-plot arrangement that comprised 3 varieties (plots) and 4 harvesting ages (subplots) (28, 48, 63, and 79 d), with 4 replicates. The data were evaluated by the Scott-Knott's test at 5% probability using the SAS statistical package. Analysis was conducted on whole plant (T), leaf (F), and stem (C) fractions for each variety. There was difference ($P < 0.05$) for varieties, for NDF, ADF and CP in whole plant, NDF, ADF in leafs and CP in stem. Jiggs presents for whole plant averages of 77.02 ± 4.3, 36.40 ± 3.1 and 10.7% ± 2.6, for NDF, ADF and CP, respectively. NDF and ADF for Jiggs leaves were 78.4% ± 7.9 and 35.5% ± 6.0 and CP of stem was 8.2% ± 2.4. These data demonstrate that the greater values for fiber and lesser values for protein by Jiggs justify the highest value found for Dry Matter of whole plant (91.38%), this can be explained by age of harvesting and age of varieties. As for harvesting age, Jiggs variety showed a leaf ADF increase 30.20%, as it increase the harvesting times, with an average of 40.77% at 79 d. This may have contributed to increase ADF in whole plant for Jiggs. As we increase the fiber content of whole plant was reduced by 30% in crude protein. There were no differences ($P > 0.05$) for the other *Cynodon* varieties evaluated, with presents averages 72.9, 35.5, 13.1%, for NDF, ADF and CP in whole plant, 71.6 and 31.4 for NDF and ADF in leafs . CP stem in Tifton 85 and Tifton 68, was 10.6%. The harvest age does not alter chemical compositions of these *Cynodon* varieties. Jiggs variety presents lower nutritional values in relation to the contents found in Tifton 85 and Tifton 68.

Key Words: Jiggs, nutrients, Tifton

T110 Chemical composition evaluation of different *Cynodon dactylon*. F. W. Pedroso, E. R. de Oliveira*, L. L. Freitas, C. L. Gordin, R. H. de Tonissi e Buschinelli de Goes, B. Lempp, S. F. Luna, W. S. Prado, L. V. Moura, F. P. Monção, A. M. de Araújo Gabriel, and C. W. S. Gavilan, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

The aimed of this study was to determine which genotype and harvesting age among *Cynodon dactylon* would show the best chemical characteristics as parameters for feeding ruminant animals in the state of Mato Grosso do Sul, Brazil. The experiment was conducted at Agrarian Science College of Dourados Federal University, from August 2009 to January 2010. A random block design was used and treatments were arranged in a split-plot scheme with 3 genotypes (Tifton 68, Tifton 85, and Russell) representing plots, at 4 harvesting frequencies (28, 48, 63, and 79 d) as subplots, with 4 replicates. Evaluations were done after a uniform cut and the materials collected for the laboratory were processed as DM, NDF, ADF, and CP analyses. The data were evaluated by the Scott Knott's test at 5% probability using the SAS statistical package. The following variables were analyzed: entire plant (T), leaf (F), and stem (C), within each genotype. There was no difference ($P < 0.05$) for harvesting frequencies. There was no difference ($P > 0.05$) for leaf and stem DM, where Tifton 85 and Russell presents averages of 91.60; 91.66; 91.39; and 91.27%, respectively. There was a difference ($P < 0.05$) for NDF and ADF, for whole plant and leaf. Russell presents a higher values, with averages 80.41 and 37,26% for NDF and ADF, in whole plant, respectively; for leafs the averages was 82.65 and 34.02%, for NDF and ADF, respectively. The others genotypes present averages of NDF of 72.9 and 71.6, for whole plant and leaf, respectively; and 35.1 and 31.4% of ADF for whole plant and leafs. Russell variety presents higher fiber contents, it is suggested that Tifton 85 and Tifton 68 allow a better use of these nutrients. All the *Cynodon dactylon* evaluated can be used in ruminant feeding

Key Words: forage, genotype, nutrients

T111 Chemical composition of three grasses of *Cynodon dactylon*. L. L. Freitas, E. R. de Oliveira*, F. W. Pedroso, C. L. Gordin, R. H. de Tonissi e Buschinelli de Goes, B. Lempp, S. F. Luna, W. S. Prado, F. P. Monção, L. V. Moura, and A. M. de Araújo Gabriel, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

This experiment aimed to identify which *Cynodon dactylon* varieties would have the best harvesting intervals to produce the best chemical characteristics as a reference for use in ruminant feeding. The experiment was conducted at the animal nutrition laboratory located at Agrarian Science College, of Dourados Federal University, in Mato Grosso do Sul state, located at latitude: 22°14′S, and longitude: 54°49′W, between August 2009 and January 2010. In the initial period, the experiment was installed in the field: 3 varieties of *Cynodon dactylon* were planted (Tifton 85, Tifton 68, and Vaqueiro), with 4 replicates for each variety. Forage was harvested at 28, 48, 63, and 79-d harvest intervals. The materials collected were taken to UFGD's animal nutrition laboratory and were analyzed for DM, NDF, ADF, and CP analyses. A random block design was adopted, with treatments organized as a split-plot arrangement. The averages were evaluated by the Scott Knott′s test at 5% probability using the SAS statistical package. Analyses were conducted on whole plant (T), leaf (F), and stem (C) for each variety. There was effect ($P < 0.05$) for NDFC, ADFT, and CPF, for varieties. Vaqueiro variety presents averages of 85.31; 35.66; and 17.03%, for NDFC, ADFT, and CPF, respectively. Tifton 85 and Tifton 68, presents values of 77.31, 35.53, 14.76% and 77.23, 34.69 and 15.6% for NDFT, NDFC, ADFT, and CPF. For NDFT occurred variety x harvest intervals interaction, where NDFT from vaqueiro variety increased after 63 d of harvesting with average of 87.50%, 17% higher at 28 d of harvest, T-85 and T-68, does not change the NDFT when increases the harvesting days, which averages of 71.6 and 74.5%, respectively. These values are consistent with physiological growth of forages. All varieties, decrease CPF with harvesting days ($P < 0.05$). Vaqueiro in 28 d of harvest presents average of 21.97%, 28% higher in relation of values 79 d of harvest. T-85 and T-68 presents greatest CPF in 28 d of harvest, with values of 18.8 and 19.9%. Vaqueiro variety had the best response for chemical composition in relation to the other varieties, and responded to harvest date differently that T-85 and T-68.

Key Words: forage, Vaqueiro, Tifton

T112 Nutrient composition of tropical forages collected from intensively managed rotational grazing systems. J. C. Lopes*[1], R. B. Reis[2], A. L. Miller[1], and D. K. Combs[1], [1]*University of Wisconsin*, *Madison*, [2]*Universidade Federal de Minas Gerais*, *Belo Horizonte, Brazil*.

Tropical grasses are the primary forages grown for pasture in most regions of Brazil. They are generally characterized as high-yielding, low-quality forages for high producing livestock. This study was conducted to characterize the nutritive value and fiber digestibility of 5 tropical grasses that were produced under intensive rotational grazing management in the west of the southeastern region of Brazil. Samples of *Brachiaria brizanta* (cv. Braquiarão, cv. Marandu, cv. MG-5); *Cynodon dactylon* (cv. Coast-cross, cv. Tifton-85); *Cynodon nlemfuensis* (cv. Tifton-68); *Panicum maximum* (cv. Colonião, cv. Mombaça, cv. Tanzânia), and *Pennisetum purpureum* (cv. Cameron, cv. Napier) were collected from paddocks after less than 30 d of re-growth. Cutting height of each specie was in accordance with the recommendations using 95% of sward canopy light interception as the criterion. Data were analyzed as a split-plot in time using SAS Proc Mixed. For in vitro NDFD (IVNDFD) analysis, each sample were analyzed 3 times and digested, in duplicates, for 24, 30, and 48 h. CP, NDF and ADF ranged from 11 to 25%; 47 to 74% and 28 to 43% of dry matter, respectively. Means of 24, 30 and 48 h, in vitro NDF digestibility, were 35 ± 5, 44 ± 6, and 59 ± 5% of NDF, respectively across the forages. When averaged across 24, 30 and 48 h incubations times, IVNDF digestibility was greater for *Cynodon nlemfuensis* and *Brachiaria brizanta* than *Panicum maximum*, *Pennisetum purpureum*, and *Cynodon dactylon* (50 ± 10, 48 ± 11, 46 ± 11, 45 ± 12, and 42 ± 10% of NDF, respectively). There were no specie by incubation time interactions for IVNDFD ($P > 0.21$), which suggests that between 24 and 48 h, rates of IVNDFD disappearance were similar among forages. These results illustrate that when harvested early, tropical forages from intensively managed pastures can be relatively high in crude protein, low in fiber, and high in fiber digestibility.

Key Words: tropical grasses, NDF digestion, in vitro

T113 In vitro nutritional evaluation of spiny and spineless *Opuntia* cladodes. J. A. Santos-Haliscak[1], E. Gutiérrez-Ornelas*[1,4], M. A. Cerrillo-Soto[2,4], H. Bernal-Barragán[2,4], and O. La-O[3,4], [1]*Universidad Autónoma de Nuevo León*, *San Nicolás de los Garza, Nuevo León, México*, [2]*Universidad Juárez del Estado de Durango*, *Durango, Dgo., México*, [3]*Instituto de Ciencia Animal*, *La Habana, Cuba*, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *San Nicolás de los Garza, Nuevo León, México*.

The objective of this study was to evaluate nutritional properties of 3 spiny (SO) and 3 spineless (SLO) *Opuntia ficus-indica* varieties using in vitro gas production (GP), in vitro true DM digestibility (IVTDMD; DAISY[II]), and chemical composition techniques. Four field blocks with 10 Cactus cladodes of each variety were planted on September of 2006 at a planting distance of 0.5 m between plants and 2.0 m among varieties. Total cladodes produced from 3 plants in each experimental unit were collected on November of 2007. Samples were chopped, dried on 60°C oven and ground to pass 1 mm screen. Chemical composition analysis

included CP, NDF, lignin, ash and EE. Twenty-four *Opuntia* samples (200 mg DM) and one standard sample of alfalfa were incubated, by triplicate, in 100-mL calibrated glass syringes with rumen fluid obtained from 3 sheep fed alfalfa hay and concentrate (75:25). Gas volume was recorded at 0, 3, 6, 9, 12, 24, 48, 72 and 96h post-inoculation and data fitted to the model $P = a + b (1 - e^{-ct})$. The soluble fraction (a), the gas produced from the slowly degradable fraction (b) and the constant rate of GP (c) were estimated using PROC NLIN (SAS), and metabolizable energy (ME, Mcal kg^{-1} DM) was calculated in accordance to the following equation: $ME = (2.20 + 0.136GP_{24h} + 0.057CP + 0.0029EE2)/4.184$. Data were analyzed using a randomized block design, testing the effect of SO vs. SLO with orthogonal contrasts. There were no differences ($P > 0.05$) among *Opuntia* varieties for CP (8.5% ± 0.61), NDF (27.0% ± 2.1), lignin (4.0% ± 0.38) and ME (2.04 Mcal ± 0.07). Spineless cactus cladodes were higher ($P < 0.05$) than SO in ash (30.4 vs. 27.6% ± 0.88), IVTDMD (90.6 vs. 80.1% ± 1.1) and GP parameters a (13.4 vs. 9.3% ± 0.50) and b (61.0 vs. 53.9% ± 2.1), but SO were higher ($P < 0.05$) than SLO in their rate constant for GP c (7.7 vs. 4.8% h^{-1} ± 0.44) and EE (0.94 vs. 0.29% ± 0.048). Alfalfa forage standard had similar or lower GP kinetic values than both *Opuntia* groups. Except by the rate constant, SLO cladodes had better digestion kinetic values than SO varieties but CP and ME values were similar.

Key Words: *Opuntia*, fermentation parameters, gas production

T114 Simple sequence repeats markers on the characterization of *Lolium* and *Dactylis* accessions. C. J. Aguirre-Robert[1], B. Alarcón-Zúñiga*[1], M. R. Venegas-Ordóñez[1], O. Hernández-Mendo[2], S. S. González-Muñoz[2], and J. Burgueño-Ferreira[2], [1]*Colegio de Postgraduados*, *Montecillo, Edo. de México, México*, [2]*Universidad Autónoma Chapingo*, *Chapingo, Edo. de México, México*.

The objective of this study was to carry out an agronomic and molecular evaluation of 8 accessions of *Lolium* [Ansyl France, New Zealand, Uruguay, Netherland Barenza, USA Manhattan II (UMII), Canada Uri (CU4n), Australia Wimmera 62 and France Itaque]; and 3 of *Dactylis* [Canada Hercules, USA Potomac (UP) and USA Napier], in the Mexican Highlands. To evaluate morphological traits the experimental design was randomized complete blocks with a split-plot arrangement; data were analyzed using PROC MIXED and means compared with SLICE LSMEANS ($P \leq 0.05$). Ansyl France surpassed ($P \leq 0.05$) for plant height, dry weight, leaf dry weight, and stem weight per plant; CU4n for % of leaf and stem; UP for % and dry weight of dead material per plant; and UMII for number of stems. For the molecular evaluation, DNA was extracted (modified CTBA method), then PCR, amplification and electrophoresis. To determine population structure and genetic similarity among accesions, as well as the association between loci and morphological traits, data were subjected to cluster analysis (UPGMA), PROC PLS and Nei's unbiased genetic estimators (Pop Gen 32). Out of the 13 SSR-loci, 59 alleles were identified (4.5 alleles per locus). Besides, the UPGMA analysis showed 3 groups: per species (*D. glomerata*), per ploidy level (*L. hybridum* and *L. perenne*) and per genus (*Lolium*). This means that SSRs discriminated the genotypes per species, ploidy level and genus. The relationship between genetic distances of the 13 SSR-loci and the morphological characters, estimated by PMS biplots, indicated that SSR-loci expressed up to 14.3% of phenotypic variation of morphological traits among accessions. Therefore, it may be concluded that morphological traits and genetic distances from SSR-loci may be used for selecting genotypes with the best characteristics to establish a breeding program based on genetic and phenotypic characters, for *Lolium* and *Dactylis*.

Key Words: *Lolium*, *Dactylis*, molecular evaluation

T115 Correlations among shearing force and chemical compositions of wheat stems. Z. Yang, Z. Wang*, W. Yang, S. Jiang, and G. Zhang, *Shandong Agricultural University*, *Tai-an, Shandong, China*.

The objectives of this study were to investigate the relationship between shearing force and chemical compositions of wheat stems. Shearing force, a fracturing property of plant stem, is an important indictor of forage value. Three varieties (YanNong21; JiMai22; ShanNong15), which were plants from different plots, were collected, and each was divided into 4 treatments (150 replicate stems per treatment) by the diameter. After seed harvesting, each stem was cut into 3 16 cm segments for measuring stem diameter and shearing force of top, middle and bottom segments of stem. The top segment was measured from the stem apex, the bottom from the harvest base and the middle segment extended 8 cm above and below the midpoint of the stem. Each segment was sheared at the approximate midpoint ensuring that the location was between 2 nodes to prevent any influence of nodes on shearing force. Shearing forces of the 3 segments were averaged as the stem shearing force. Shearing force was measured with a C-LM3 meat shear made by the Mechanics Research Center of Dongbei Agricultural University and commonly used to measure tenderness of meat tissue. Range of shearing force was 0- 25.0 kg and deformation speed was 5 mm per second. Stems that had been measured for chemical compositions were analyzed by the SAS system, including dry matter (DM), neutral detergent fiber (NDF), acid detergent fiber (ADF), crude protein (CP), ether extract (EE), crude ash (CA), organic matter (OM), Lignin and cellulose. There was a positive relationship between DM and shearing force (r = 0.65), and the similar relationship for NDF (r = 0.85) and ADF (r = 0.90). Correlations were not found between shearing force and other chemical components such as CP (r = −0.19), EE (r = −0.36), CA (r = −0.29), OM (r = 0.54), Lignin (r = 0.26) and cellulose (r = 0.54). Shearing force was a direct indicator for estimating forage the chemical compositions, it can be used to predict forage value of wheat stems. Future research should evaluate correlation between shearing force and digestibility of DM, NDF or ADF.

Key Words: wheat stems, shearing force, chemical compositions

T116 Adaptation of *Brassica* spp. and fodder radishes as late season forages in the high desert region of Oregon. C. L. Engel*, B. A. Charlton, R. J. Roseberg, and R. A. Bentley, *Oregon State University, Klamath Basin Research and Extension Center*, *Klamath Falls*.

The objective of this study was to evaluate the yield potential and viability of winter triticale (TRT; n = 1), *Brassica* spp. (BRS; n = 6), and radish (RAD; n = 3) varieties, as late season forages. In 2009 3 planting dates (PD1, 2 and 3; July 30, Aug.14, & Aug. 28, respectively) were analyzed with 2 harvest dates (HD; approximately 60 and 90 d after planting) per PD (4 replications per variety). Plots were arranged in a randomized complete block design with a split plot. Varieties included: winter triticale (TRT; trical102); dwarf Siberian kale, Winfred (WIN, hybrid); purple top white globe turnip; Hunter (hybrid); New York turnip; pulsar rape (PR); graza radish; colonel radish (CR); and Terranova radish. Plots were seeded with a modified Great Plains drill at 4.5, 7.9, and 112.3 kg pure live seed/hectare (ha; for BRS, RAD, and TRT; respectively) into glyphosate treated small grain stubble. Plots were fertigated with 67.3 kg nitrogen and 22.4 kg sulfur/ha after plants reached the 2-leaf stage and were irrigated through Oct.15. Across all PD, TRT was the lowest yielding variety (3.70 ± 0.56, 2.51 ± 0.29, and 1.44 ± 0.49 t dry matter (DM)/ha; PD1, 2, and 3, respectively). The variety with the greatest yield differed by PD (WIN 7.49 ± 0.47, PR 5.31 ± 0.29, WIN 4.48 ± 0.43 t DM/ha; for PD 1, 2, and 3, respectively). For both PD 1 and 2, CR, BRS hybrids and PR yielded more than turnip and RAD variet-

ies ($P \leq 0.05$), but by PD 3 all BRS varieties yielded more than RAD varieties ($P \leq 0.05$), with turnip varieties tending to have higher yields among the BRS group. The 60 d HD yielded less ($P < 0.01$) than the 90 d HD for PD 1 and 3, only (5.31 vs. 6.30 ± 0.20 and 2.65 vs. 4.04 ± 0.19 t DM/ha; for 60 vs.90 d HD, PD 1 and 3; respectively). No PD × HD interaction occurred ($P \geq 0.16$). Both BRS and RAD produced good late season yields, and seem well-suited to extend the grazing season. For earlier PD, differences between varieties were as large as differences between species, but by PD3 the BRAS varieties produced greater yields than other species.

Key Words: *Brassica* spp., forage, fall

T117 Effects of age of regrowth and geographical location on forage protein and carbohydrate fractions, silicon content, and their impact on IVOMD of four tropical grasses. K. A. K. Lee*[1], J. R. Carpenter[1], B. W. Mathews[2], M. S. Thorne[1], and L. E. Sollenberger[3], [1]*CTAHR, University of Hawaii at Manoa*, *Honolulu,* [2]*CAFNRM, University of Hawaii at Hilo*, *Hilo,* [3]*Universtiy of Florida*, *Gainesville*.

In Hawaii, Kikuyugrass (KG) grown at higher elevations is lower in NDF and higher in IVOMD and CP than KG at the same age of regrowth in lower elevation sites with warmer climates. The impact of elevation on forage nutritive value may be confounded in part by differences in soil silicon (Si) between sites. The objectives of this study were to determine the effects of age of regrowth and geographical location on the nutrient composition, IVOMD, and silicon content of 4 tropical pasture grasses *Pennisetum clandestinum, Digitaria decumbens, Pennisetum purpureum*, and *Pennisetum americanum* × *Pennisetum purpureum*. Grasses were cultivated (3 plots each) at 2 different geographical locations and harvested repeatedly at 4, 8, and 12 weeks of regrowth. Grass samples were weighed and dried at 50°C in a forced draft oven then ground by a Wiley mill (1-mm mesh stainless steel screen). Nutrient analysis of forages was determined by Near Infrared Reflectance Spectroscopy (NIRs) and sub-samples analyzed for silicon (ICPES following sample preparation by the NaOH fusion and melt dissolution procedure), and 48 h IVOMD digestibility (2-stage technique of Moore and Mott). The ranges in percent CP, protein solubility, NDF, ADF, lignin, IVOMD, and silicon (ug/g) and digestion rate (%/hr) across the 4 grasses (for both locations and the 3 ages of regrowth) were 5.3–22.4, 17–54, 52.1–74.5, 31.8–49.2, 1.3–7.8, 39.6–75.4, 407–6703, and 2.65–10.81, respectively. There were differences ($P < 0.05$) between grass varieties, geographical locations, and ages of regrowth for the various nutrient components, IVOMD, and silicon content. IVOMD was positively correlated with CP (+0.730), and negatively correlated with NDF (−0.552) and ADF (−0.747), and NDF was negatively correlated with CP (−0.789). Silicon differed ($P < 0.01$) with geographical location and grasses varied ($P < 0.01$) in silicon level within location. These research results indicate that one must be cautious in using tropical grass data from other regions and growing conditions.

Key Words: tropical grasses, nutrient composition, silicon content

T118 Effect of time from rumen fluid collection to sample inoculation on estimates of in vitro NDF digestibility. J. C. Lopes*[1], R. B. Reis[2], and D. K. Combs[1], [1]*University of Wisconsin*, *Madison*, [2]*Universidade Federal de Minas Gerais*, *Belo Horizonte, Brazil*.

Run to run variability of in vitro NDF digestibility (IVNDFD) measures are reduced when forages are inoculated with a primed rumen inoculum that was held in a sealed flask until it reaches a pre-determined gas pressure. The time for the inoculum to reach this predetermined pressure is variable, ranging from 85 to 325 min. The objective of this study was to determine if the time variation to reach the predetermined gas pressure affects estimates of IVNDFD. An alfalfa silage was dried (60°C), ground (1 mm), and weighed (0.5 g DM) into Ankom F57 fiber bags. Rumen fluid was collected from 2 rumen-cannulated cows and strained through cheesecloth. Rumen fluid (250 mL), mixed with Van Soest buffer (250 mL), reducing solution (40 mL), and carbohydrate/nitrogen nutrient primer (1.25 mg/mL of rumen fluid) was fermented in sealed 1000 mL Erlenmeyer flasks until pressure corresponding to 0.3 mL of gas production/mL of inoculum was attained. Time from inoculum collection to the pre-determined gas pressure was recorded. The alfalfa samples were then inoculated with the standardized inoculum and digested, in duplicate, for 24, 30 or 48 h. Residual neutral detergent fiber was analyzed with a forage fiber analyzer, and NDFD determined. The procedure was repeated 16 times. Data were analyzed as randomized complete block with replication and unequal error variance using SAS Proc Mixed. Alfalfa silage sample was the experimental unit, fermentation time and residual error were random effects, and time point and repetition were fixed effects. IVNDFD estimates differed due to time of incubation (25, 34 and 43% of NDF, for 24, 30 or 48 h, respectively: $P < 0.01$) but did not differ ($P > 0.05$) due to time for inoculum to reach predetermined gas pressure. Residual variance of IVNDFD estimates at each time point did not differ ($P > 0.26$). These results suggest that the time required for the inoculum reach the pre-determined pressure varied widely from run to run but this had no effect on estimates of IVNDFD at 24, 30 or 48 h.

Key Words: NDF digestibility, forage fiber, in vitro

T119 Time course evaluation of NDF digestibility of hay crop silage and lignin as a predictor of indigestible fiber. R. Ward[1] and R. A. Patton*[2], [1]*Cumberland Valley Analytical Services*, *Maugansville, MD*, [2]*Nittany Dairy Nutrition*, *Mifflinburg, PA*.

An investigation was undertaken to determine appropriate incubation times for determination of IVNDFD of hay crop silages and to define lignin based equations that might predict NDF digestibility (NDFd) with high accuracy. Twenty-one hay crop silages were selected from Cumberland Valley Analytical Services samples to represent a range of lignin as a percentage of NDF (LigNDF). This data set included these silages: 3 temperate grass, 5 legume, 6 mixed mainly grass (MMG), 3 mixed mainly legume (MML), and 4 small grain silages. Three LigNDF groups (high, medium and low) were formed with a mean of 17.7%, 13.2% and 7.2% lignin as % NDF. In vitro digestibility was determined at 4, 12, 18, 24, 30, 48, 96, and 120 h in flasks by the method of Tilley and Terry. Differences among lignin groups and forage types were assessed using Proc mixed of SAS. Regression equations for IVNDFD were developed with Proc reg of SAS using stepwise elimination. Although differences among lignin groups were significant ($P < 0.01$), groups were not homogenous with respect to forage types. Forage type was also highly significant ($P < 0.01$). Hourly digestion rates for various forages were: small grain 1.06%, grass 0.97%, MMG 0.68%, MML 0.57% and legume 0.47% ($P < 0.01$). Across all forage types, NDFd was linear between 24 and 96 h. Incubation for 120 h was sufficient to remove digestible NDF. Indigestible NDF (INDF) as % of NDF was 10.3% for small grain, 17.6% for grass, 16.2% for MMG, 20.2% MML, and 23.6% for legume ($P < 0.05$). Overall, LigNDF was less well correlated (= 4.555 + (1.027 * LigNDF), $R^2 = 0.66$) with INDF than was lignin as % DM (= 1.409 +(2.838 * lignin %DM), $R^2 = 0.81$). However, the best equation for predicting 24 h IVNDFD included LigNDF (= 61.065 - (2.873*LigNDF) + (0.858 * CP%) + (0.48331 * NFC), $R^2 = 0.92$. These data suggest that equations for NDFd might be more accurate if based on forage type, that there is little evidence for earlier NDF

digestibility time points providing increased sensitivity for evaluation of NDF digestibility, and that NIR may offer rapid, accurate assessment of NDFd in hay crop silages.

Key Words: hay crop silage, in vitro NDFd

T120 Effect of a nutrient solution on the chemical composition and in vitro fermentation parameters of wheat hydroponic forage. H. Bernal-Barragán[2,5], R. Luevano-Escobedo[1], A. Elias-Iglesias[4,5], E. Gutiérrez-Ornelas[2,5], A. Estrada-Angulo[3,5], M. Guerrero-Cervantes[1,5], M. A. Cerrillo-Soto[1,5], and A. S. Juárez-Reyes*[1,5], [1]*Universidad Juárez del Estado de Durango*, *Durango, Durango, México*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, México*, [3]*Universidad Autónoma de Sinaloa*, *Culicán, Sinaloa, México*, [4]*Instituto de Ciencia Animal*, *La Habana, Cuba*, [5]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *Durango, Durango, México*.

A study was conducted to evaluate the chemical composition and the in vitro fermentation parameters of wheat (*Triticum aestivum* L.) hydroponic forage (WHF). Treatments consisted in utilizing either water or an organic nutrient solution containing 1.5% N, 1.0% P and 1.0% K during the process of pre-germination. Seed were soaked for 24 h in one of each solution, drained and allowed to rest for another 24 h. Germinated seeds (800 g) were then distributed in 40 × 40 cm plastic trays in triplicate and placed in a 5 × 4 m green house. The hydroponic forage was harvested at 8, 10, 12 and 14 d after germination. Samples of each day were composite, dried and milled and further analyzed for CP, NDF and ADF. The in vitro fermentation profile was estimated by incubating 200 mg DM of the hydroponic samples in 100 mL calibrated glass syringes. Gas production was registered at 0,3,6, 9,12,24,48, 72 and 96h and the data fitted to the model $P = a+b\ (1\text{-}e^{-ct})$, where *a* is the gas produced from the soluble fraction of feed, *b* is the gas produced from the slowly degradable fraction and ***c*** the constant rate of gas production. The ME content was estimated from in vitro gas production at 24 h. In vitro true dry matter digestibility (IVTDMD) was determined following the Daisy^{II} procedure. Data were analyzed according to a completely randomized design with factorial arrangement of treatments 2 × 4. The nutritive solution did not affect (*P > 0.05*) the studied variables, except for the ADF and IVTDMD where an interaction between factors were registered (*P < 0.05*). Digestibility of wheat treated with nutritive solution remained above 70% until d 12, but those treated with water were below 70% from d 10 on. Differences in CP (%), NDF (%), gas parameters *a* (ml/200 mg DM), *b* (ml/200 mg DM), ME (Mcal kg^{-1} DM) and biomass yield (kg) were registered among harvesting days. An increment (*P = 0.06*) was also registered in the constant rate *c* (% h^{-1}). This study indicated that the utilization of a nutrient solution on wheat seeds did not affect the nutritive value of wheat hydroponic forage.

Table 1. Nutritive value, in vitro fermentation profile and biomass yield of wheat hydroponic forage

	Harvesting days						
	8	10	12	14	SEM	Mean	Sig
CP	14	15	16	18	0,7	16	**

T121 Assessing digestibility of shredded *Juniperus monosperma* treated with 5% alkylation or 3% ammoniation. C. A. Roof*, S. H. Cox, and S. L. Lodge-Ivey, *New Mexico State University*, *Las Cruces*.

Encroaching shrubs such as *Juniperus monosperma* (JM) typically are managed via mechanical removal or treatment with herbicides. *Juniperus monosperma* leaves have a moderate nutritive value (6.0% CP, 71.7% NDF, DM basis) and shredding whole juniper shrubs may represent a potential drought feed. Traditional supplemental feeds such as hay or grain may be unavailable or cost-prohibitive during episodes of drought, and producers may prefer a less expensive alternative. Limited data exists regarding the use of shredded juniper as a drought feed resource. Therefore, the objective of the current study was to evaluate in vitro organic matter digestibility (IVOMD) of shredded JM. Using a completely randomized experimental design, approximately 100 g of JM plus enough water to equalize dry matter at 40% was added to glass jars with sealable lids. Treatments were 1) JM only (C), 2) JM plus ammonia sulfate and excess calcium oxide for reaction giving 3% ammoniation (DM basis; N) and 3) JM plus calcium hydroxide to provide 5% alkylation (DM basis; A). After treatments were added to JM, jars were covered with aluminum foil, sealed and incubated in an anaerobic glove box (approximately 90% CO2 and 10% H2 atmosphere) for 30 d. After incubation, treated JM was freeze-dried and ground to pass a 2mm screen. The resulting material was used to determine 96 h IVOMD. Ruminal fluid used was donated from a ruminally canulated cow (approximately 600 kg) maintained on sudan hay (11.3% CP, 66% NDF, DM basis). Data were analyzed using Proc GLM. In vitro organic matter digestibility for each treatment was (10.1, 12.1, 11.9 ± 0.41, A, C, N, respectively) and was influenced by treatment (*P* < 0.001). Alkylation decreased digestibility by 16.5% when compared with control while control and ammoniation did not differ(*P* = 0.82). Shredded JM includes not only leaf material but woody components resulting in low IVOMD. Although treatments of 5% alkylation or 3% ammoniation did not benefit overall JM digestibility, selection of the more desirable fractions, such as leaves and bark, by the animal could improve digestibility values.

Key Words: *Juniperus monosperma*, alkylation, ammoniation

T122 Yield and quality of grasses in three different dairy regions of El Salvador. E. E. Corea Guillén*[1], J. M. Flores Tensos[1], L. B. Leyton Barrientos[1], J. F. Alvarado Parameño[1], G. O. Castillo Benedetto[1], J. M. Castro Montoya[1], and J. A. Elizondo-Salazar[2], [1]*Departamento de Zootecnia, Facultad de Ciencias Agronómicas*, *Universidad de El Salvador, El Salvador*, [2]*Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias*, *Universidad de Costa Rica, Costa Rica*.

Grasses are a very important feed resource for dairy cattle in El Salvador as well as in all Central America. However, they are extremely variable in terms of yield and quality which depend on age at which they are grazed and geographical area in which they are grown. Thus many producers do not know what grasses to grow in a specific area of the country and at what age they should be grazed. For these reasons, a study was conducted to establish the grass that produces the highest yield and quality in the dairy regions of La Paz, Sonsonate and Chalatenango. Star grass (*Cynodon plectostachius*), Swazi grass (*Digitaria zwazilandensis*), and Pangola grass (*Digitaria decumbens*) were tested.

Grasses were sampled at 21, 28, and 35 d of regrowth to estimate yield per grazing period and for determination of DM yield, DM, CP, NDF, and ADF concentration. The experiment was arranged in a split-split-plot design with dairy regions as main plots, grass type as split-plots, and age of regrowth as split-split-plots. Variables were analyzed using the GLM procedure of SAS 9.1. Separation of means was done using the Duncan's multiple comparison procedure. There were differences ($P < 0.01$) between regions, grass type and age of grazing for all variables studied. The findings of the study suggest that even though there was great variability between regions, grasses, and days of regrowth; Star grass produced the highest yield and presented a higher nutritional value when compared with the other grasses.

Table 1. Yield and quality of grasses in three regions of El Salvador

	Available DM, kg/ha	DM, %	CP, %	NDF, %	ADF, %

T123 Effect of fertilization with swine wastewater on fermentative characteristics and losses of corn silage. M. T. Cangani, R. A. Oliveira, A. C. Ruggieri*, E. Urbinati, and F. C. Basso, *Unesp/FCAV*, *Jaboticabal, São Paulo, Brasil*.

The objective of this trial was to study in no-tillage system, the effect of sowing and covering fertilization with swine wastewater on fermentative characteristics and losses of corn silage. The experimental design was randomized blocks with 5 treatments and 4 replications. The treatments were: T1 - control without sowing and covering fertilization, T2 - chemical fertilization (urea, simple superphosphate and potassium chloride), T3 - raw swine wastewater, T4 - swine wastewater treated in anaerobic system (2 upflow anaerobic sludge blanket (UASB) reactors in series) and T5 - swine wastewater from aerobic post-treatment (sequencing batch reactor (SBR)). The chopped material was ensiled in plastic buckets (7 L) with sand and screen to determine the effluent losses (EL). The buckets were weighed, sealed and stored at room temperature. After 60 d of fermentation the silos were weighed to quantify the gas losses (GL), opened, spoiled silage discarded and the remainder was homogenized and sampled to determine dry matter (DM), pH and ammonia nitrogen (NH_3/TN). Statistical included ANOVA and Tukey's test ($P < 0.05$). The control silage showed lower gas losses, but did not differ significantly from other treatments ($P < 0.05$). The corn silages produced with swine wastewater treated in UASB reactors (T4) showed lower effluent losses ($P < 0.05$). The DM content not differ significantly among treatments T2, T3, T4 and T5 ($P < 0.05$). The treatment T5 showed the lowest NH_3/TN content ($P < 0.05$). The pH value did not differ significantly among treatments ($P < 0.05$). The corn silages produced with swine wastewater treated in the UASB reactors and pos-treated in aerobic SBR showed lower EL and NH3/TN, and the DM was similar that used chemical fertilization.

Table 1. Fermentative characteristics and losses of corn silage

Treatments	GL	EL	DM %	NH_3/TN	pH
T1	8.72	9.02 a	33.35 a	3.65 a	4.03

T124 Tannery sludge as a nutrient source for the tropical grass *Brachiaria brizantha*. C. H. B. Miranda*[1,2], [1]*Embrapa Labex USA*, *Lincoln, NE*, [2]*Embrapa Beef Cattle*, *Campo Grande, MS, Brazil*.

A field study was conducted to determine the potential value of tannery sludge as nutrient source for *Brachiaria brizantha* cv. Marandu. Five different rates (0, 1.65, 3.3, 6.6 and 13.2 Mg/ha) of air-dried (final moisture of 40%) and ground (2 mm sieve) sludge were applied to a pasture established in a Red Latosol soil in Campo Grande, Brazil. Sludge was from a tannery plant that recycles water and Cr during the first processing stages. Its nutrient content was (%) 13.3 Ca, 2.9 N, 0.52 P, 0.1 K, 4.6 Na, and 0.38 Cr. A control treatment with chemical fertilizer (2 Mg/ha of Ca, and 100 kg/ha of N, P and K, respectively) was also included. Treatments were distributed in a completely randomized block design, with 5 replications (a field plot 5m x4 m wide), and applied after cutting and removing the cut biomass. Re-growth material was cut 10 cm above ground 45, 90, 270 and 360 d later and analyzed for total dry mass production, plant quality (IVDMD, ADF, ADL, NDF, crude protein and lignin), and P, K, Ca, Mg, S, and Cr contents. Soil samples (0 to 20 cm depth) were collected before sludge application, and also a year later, and they were analyzed for Ca, P, K, pH and conductivity. Overall, forage yield was significantly higher ($P < 0.05$) in the rates of 6.6 and 13.2 Mg/ha of sludge (2.4 and 3.1 Mg/ha, respectively) than in the control without sludge amendment (1.6 Mg/ha), but significantly ower ($P > 0.05$) than that produced in the chemical fertilizer treatment (3.6 Mg/ha). There was increase in soil Ca contents in these sludge treatments (0.75 and 1.05 cmol/dm^3, respectively) compared with the control soil (0.4 cmol/dm^3), but not of P (average 0.49 mg/dm^3) or K content (average 0.08 cmol/dm^3). No significant differences ($P > 0.05$) in plant Cr content nor of soil conductivity were observed. Thus, it can be concluded that tannery sludge can be a good source of Ca, but it is a poor source of P and K. Further monitoring of Cr chemistry in the plant and in the soil is needed to assure the use of these sludge materials.

Key Words: agrindustrial residues, plant nutrition, forage

T125 Absorption and utilization of nitrogen by *Panicum maximum* cv. Massai. C. H. B. Miranda*[1,2], [1]*Embrapa Labex USA*, *Lincoln, NE*, [2]*Embrapa Beef Cattle*, *Campo Grande, MS, Brazil*.

An experiment was conducted to determine the response of *Panicum maximum* cv. Massai, a tropical forage grass, to increasing levels of N fertilizer and harvest date. This is a new variety, suitable for cattle, horses and sheep, that shows some quality constraints, which may be alleviated with proper N management. Treatments consisted of 4 N rates (0, 50, 100

and 200 kg N/ha), supplied as ammonium nitrate, and 5 harvest dates (21, 28, 35, 42, and 49 d after planting - DAP). A set of 20 replications was prepared for each treatment, distributed in a complete factorial experimental design, with 4 replications per treatment. Each replication was a pot with 4 kg of a Quartz-sandy soil, typical of the Brazilian Cerrados (savannah-like area), base of the beef cattle industry in the country. Nitrogen rates were applied a week before the transplanting of 4 seedlings per pot. The experiment was conducted in a greenhouse. Soil moisture was kept constant at 80% of soil field capacity throughout the experimental period. At every harvest date 4 replications per treatment were collected, and roots and above ground dry mass was separated, dried at 72°C for 72 h, weighed, and grounded, being analyzed for N content using Near Infrared Spectroscopy. ANOVA of the experimental results showed that there were significant effects ($P < 0.01$) of N rates, harvest date, and their interaction, for above-ground and roots dry mass and N accumulation. Plant yield within the harvests dates followed a polynomial quadratic pattern, with N uptake increasing up to 42 DAP, and dry matter accumulation increasing up to 49 DAP. On average, the efficiency of N utilization was around 4 mg of dry mass per mg of N taken per day. Further evaluations on plant quality are necessary to conclude which would be the best combination of N rate and harvest date for this forage grass.

Key Words: plant nutrition, tropical grasses, forage

T126 Comparisons among predictive equations and NIR for determination of in vitro indigestible NDF of corn silages. R. Ward*[1], S. Weaver[1], and R. A. Patton[2], [1]*Cumberland Valley Analytical Services*, *Maugansville, MD*, [2]*Nittany Dairy Nutrition*, *Mifflinburg, PA*.

An investigation was undertaken to assess the accuracy of NIR or equations based on analyzed nutrient content to predict in vitro indigestible NDF (INDF). A data set of 115 corn silages with indigestible NDF determined by 120 h Tilley and Terry incubations was developed. For application of equations based on forage type, silages were classified as BMR (n = 18, mean lignin = 2.06% DM), MED (n = 62, mean lignin = 2.81), and HI (n = 25, mean lignin = 3.51). Using this data, chemically determined INDF was compared against equations developed from a smaller data set by Proc Reg of SAS using the stepwise selection. Predictive equations were based on all corn silage types (general equation), individual corn silage type as well as calculation of INDF as lignin*2.4. The Mean Square Predicted Error statistic of Bibby and Toutenburg was used to compare predictions with observed values. The general equation was INDF = 2.065 + (1.378 * soluble protein %DM)- (0.352*NDF %DM) + (6.128 * lignin %DM), $R^2 = 0.98$. For BMR, the equation was INDF = (28.985 - (6.272 * fat %DM), $R^2 = 0.99$; MED was INDF = (1.838*ADF) - 36.688, $R^2 = 0.99$; and HI was INDF = 12.285 - (1.550 * Ash %DM),$R^2 = 0.99$. Forcing equations based on lignin and/or lignified NDF content resulted in no significant equations for BMR or HI corn silage. However, a general equation was better than feed type specific equations. Residual analysis indicated that as lignin content increases, feed type specific and lignin*2.4 equations become less accurate, while the general equation continues to perform satisfactorily. We conclude that NIR is a better predictor of INDF than equations and that for corn silages, a general equation is better than feed specific equations.

Table 1.

Model	Mean	Std Dev	RMSPE	% Mean	Bias	Error Due To Regression	Random
Observed	12.55	2.12	—	—	—	—	—

T127 Nitrogen lixiviation and uptake by forage maize with different fertilization and previous soil use. R. D. Améndola-Massiotti*[1], I. Cach-Gómez[1], M. E. Álvarez-Sánchez[1], J. A. Burgueño-Ferreira[2], and I. López-Cruz[1], [1]*Universidad Autónoma Chapingo*, *Chapingo, México*, [2]*Colegio de Postgraduados*, *Montecillo, México*.

In crop rotations of forage maize (*Zea mays*) and pastures, nitrogen (N) content of the soil declines during the maize crop. The present study was carried out at Chapingo (central temperate Mexico). The aim was to estimate the effect of 3 N rates (NF) in combination with 3 previous soil uses (SU, representing possible phases in the rotation) on the amount of N harvested with a forage maize crop and lost by lixiviation during that crop. Nine treatments were evaluated, combining NF: 0 (N0), 100 (N100) and 200 (N200) kg N/ha and SU: 3.5 years of permanent *Medicago sativa* and *Dactylis glomerata* pasture (P); 3.0 years of permanent pasture and 6.0 mo of annual *Avena sativa* and *Lolium multiflorum* pasture (PA); and 2.5 years of permanent pasture, 6.0 mo of forage maize crop and 6.0 mo of annual pasture (PMA). A randomized complete block split-plot design with 3 replicates was used; SU was assigned to whole units and NF to sub-units of 54 m^2. Response variables were N-uptake by the crop, N lixiviation (not measured at N0 treatments) and total N content of the soil at 2 depths, 0–30 and 30–60 cm. Analysis was performed using a mixed model and means were compared using orthogonal contrasts. The NF had a linear effect ($P < 0.05$) on N-uptake (274 ± 15 kg N/ha at N0, 44.9% lower than at N200) and lixiviation (98 ± 19 kg N/ha at N100, 73% lower than at N200); SU did not affect ($P > 0.05$) those variables. The N content in the top soil layer decreased ($P < 0.05$) with increasing time of annual crops (5461, 5095 and 4685 kg N/ha for P, PA and PMA), and it was higher ($P < 0.05$) in the 0–30 layer (5080 kg N/ha) than in the 30–60 layer (3437 kg N/ha). Average N content of soil decreased ($P < 0.05$) in 775 kg N/ha during the maize crop, due to N harvest, lixiviation and not measured gaseous losses. It is concluded that efficient N management is needed to reduce N losses during the forage maize phase of the rotation.

Key Words: pastures, alfalfa, soil nitrogen

T128 Biological nitrogen fixation in the tropical forage legume Stylo. C. H. B. Miranda*[1,2], J. R. Verzignassi[2], and C. D. Fernandes[2], [1]*Embrapa Labex USA*, *Lincoln, NE*, [2]*Embrapa Beef Cattle*, *Campo Grande, MS, Brazil*.

The forage legume *Stylosanthes* spp. is an excellent forage legume alternative for tropical areas because of its adaptation to acidic, low fertility soils, and, especially, because of its biological nitrogen fixation (BNF) potential. We compared dry mass production, total N content, and BNF of 4 field grown advanced genotypes of both *S. capitata* and *S. guianensis* taken from a breeding program being conducted at

Embrapa Beef Cattle, in Brazil, with the objective of selecting materials that represent increased BNF potential through symbiosis with native soil N-fixing bacteria. BNF was evaluated by comparison of their ^{15}N isotope natural abundance content and that of 5 non-fixing plants species naturally growing among them (^{15}N isotope dilution technique). Genotypes were planted in a randomized block experimental design, with 4 replications, in a Dark Red Latosol, without inoculation with N-fixing bacteria. Three hundred kg/ha of 0–20–20 NPK were applied at planting and re-applied a year latter, after a full harvest. Evaluation of second year biomass production, harvested at seed grain filling stage, indicated that genotypes of *S. capitata* produced ($P < 0.05$) more dry biomass (ranging from 14 to 16 Mg/ha, average 14.9 Mg/ha) than those of *S. guianensis* (9.8 to 13.1 Mg/ha, average 11.5 Mg/ha). They also showed larger ($P < 0.05$) N content (average 256 kg/ha, compared with 238 kg/ha), from which an average 65% (or 167 kg of N/ha) was originated from BNF, compared with 33% in *S. guianensis* (or 85 kg/ha). Such BNF may result in a significant contribution to quality improvement and maintenance of mixed tropical pastures, either by direct contribution as feed or as organic material that would add N to the soil. We conclude that *S. capitata* genotypes have high BNF potential and should be prioritized in a new variety selection program.

Key Words: pasture sustainability, plant biomass, plant nutrition

T129 Yield and quality of two tropical leguminous trees in the establishment year. E. Cortes-Diaz*, F. Amador-Solano, G. T. Gonzalez-Bonilla, J. L. Zaragoza-Ramirez, and P. Martinez-Hernandez, *Animal Science Department, University of Chapingo*, *Texcoco, Mexico*.

Leguminous trees planted into tropical grass-pastures can increase forage yield and quality offered to grazing sheep. The aim of the study was to determine forage yield and quality of *Leucaena leucocephala* cv. Cunningham (improved and introduced tree species) and *L. collinsii* (native tree species) in the establishment year and forage yield of the associated grass (*Brachiaria brizantha* cv. Libertad).Treatments were arranged in a 2 × 3 factorial: 2 leguminous trees, and 3 densities: 5000 (high), 3333 (medium) and 2500 (low) plants/ha; in a completely random design with 3 replications, experimental unit was a 256 m2 plot. Tree seeds were grown in a nursery for 4 mo, then transplanted in early summer (rainy season) into a year-before established grass pasture, planting was in rows 2 m apart and with 1, 1.5 and 2 m between plants within a row to achieve high, medium and low densities, respectively. At the time of planting grass was cut to a 5 cm stubble. Three harvests to determine yield and quality were done before the onset of dormancy season, these were at 47, 83 and 206 d after transplant and after each harvest ewe-lambs grazed all plots to leave a 5 cm grass stubble. Season yields and mean crude protein concentrations were analyzed. Statistical analysis was with a model for a factorial arrangement and 3 replications. Grass yield was 4909 kg DM/ha and similar ($P > 0.05$) across factors. *L. collinsii* gave 36 and 4.9 kg DM and CP/ha, respectively which were 2.6 and 1.8 times higher ($P < 0.05$) than in *L. leucocephala*, this last species showed 20.9% CP, 6 percent units higher ($P < 0.05$) than *L. collinsii*. It was concluded that in the establishment year tree density has no effect on any component while tree forage yield and quality can be different between species.

Key Words: *Leucaena leucocephala*, *Leucaena collinsii*, fodder trees

T130 Sequence similarities of genes from the lignin biosynthesis pathway in tropical grasses, maize and rice. D. M. Gerônimo, N. S. Oliveira, A. B. S. Machado, and L. F. P. Silva*, *Universidade de São Paulo*, *Pirassununga, SP, Brazil*.

Rapid decline in cell wall digestibility, due to lignifications, hinders efficient use of warm-season grasses. The objective was to partially sequence transcripts of the main enzymes involved in monolignol synthesis to determine similarity among tropical grasses, and other with more advanced genomic resources (maize and rice). Total RNA was isolated from bermudagrasss (*Cynodon dactylon* L. Pers. cv. Coastcross-1), and palisade grass (*Brachiaria brizantha* A. Rich. cv. Marandu) and treated with DNase 1. Degenerated oligonucleotide primers for glyceraldehyde-3-phosphate dehydrogenase (GAPDH), 4-coumarate-CoA ligase (4CL), cinnamate-4-hydroxylase (C4H), cinnamoyl-CoA-reductase (CCR), caffeic acid O-methyltransferase (COMT), and phenylalanine ammonia lyase (PAL) were designed based on conserved regions of maize, rice and guineagrass. Treated RNA was reverse transcribed and amplified with PCR, and PCR products were purified and sequenced in both directions. Quality and alignment of sequences were obtained using Phred and Cap3 softwares. Obtained sequences were compared using the BLAST program. There was a high degree of similarity between all grasses. Palisade grass and bermudagrass had overall nucleotide sequence similarity with maize of 94.2 and 93.8, respectively; and aminoacid sequence similarity of 96 and 88%, respectively. Comparing with rice sequence, palisade grass and bermudagrass had overall sequence similarity of 87.4 and 87.2, respectively; and aminoacid sequence similarity of 88 and 90.7%, respectively. Both tropical grasses had higher nucleotide and aminoacid sequence similarity with maize than with rice, indicating that maize genomic resources could be used for gene expression studies in these tropical grasses.

Table 1. Similarity among nucleotide and aminoacid sequence of tropical grasses, maize and rice

		Nucleotide, %		Aminoacid, %	
Grasses	Genes	Maize	Rice	Maize	Rice
Palisade grass	GAPDH	91	88	92	90
	4CL	—	—	—	—

T131 Ovine and caprine in vitro digestibility of *Peganum harmala*. L. N. Tracey*, L. B. Abbott, J. Browne-Silva, and S. L. Lodge-Ivey, *New Mexico State University*, *Las Cruces*.

The possibility of using small ruminants to reduce African rue (*Peganum harmala*; AR) on New Mexico rangelands is being evaluated. African rue is known to be toxic to guinea pigs, cattle and sheep; however, toxicity has not been documented in goats. The objective of this study was to examine the IVDMD and rumen fermentation of AR by sheep and goats in vitro. A completely randomized experimental design with a 2 × 4 factorial arrangement of treatments was used. Factors included ruminal fluid donated from sheep vs goats and 4 levels of AR:Sudan hay (0:100, 25:75, 50:50, 100:0; n = 8; DM basis) as substrate for a 48-h

Tilley-Terry in vitro digestion trial. Significant treatment (trt) by species interactions were observed for IVDMD and 48-h VFA concentrations ($P < 0.05$). Increasing levels of AR increased IVDMD for both sheep and goats ($P = 0.005$). However, when 50:50 was added goat IVDMD was 5.56% greater than sheep ($P = 0.03$). Sheep IVDMD was 5.72% greater than goat when 100:0 was digested ($P = 0.01$). Total VFA production varied by trt and species ($P < 0.001$) with sheep 0:100 and goat 25:75 resulting in the greatest total VFA production (198.5 and 192.3 mM, respectively). Digest of 100:0 resulted in the least total VFA with goat being the lowest at 131.1 mM. Acetate levels were highest in goat digests of 100:0 which was 23.0% greater than the lowest concentration (sheep 50:50). Propionate concentrations differed in both species except in the 50:50 concentration ($P = 0.76$). The acetate:propionate ratio differed in both species at each AR concentration ($P < 0.05$) with the greatest variation existing at 100:0 digest where A:P ratio was 48.4% higher in the goat digest than in sheep. Overall increase in digestibility with increasing AR concentration and VFA results suggest that rumen microbial activity is undiminished at 50:50 or less AR in small ruminants. Additional in vivo research is needed to determine the potential to control AR using targeted grazing with small ruminants.

Key Words: *Peganum harmala*, ovine, caprine

T132 Chemical composition and in vitro ruminal fermentation activity of three Mexican browse species during dry season. D. López, R. Rojo*, A. Z. M. Salem, J. L. Tinoco, J. F. Vázquez, B. Albarrán, F. González, and D. Cardoso, *Centro Universitario UAEM-Temascaltepec*, *Temascaltepec, Estado de México, México*.

Browse foliages from *Pithecellobium dulce*, *Heliocarpus velutinus* and *Guazuma ulmifolia* natives to the subtropical region of southern Mexico, were harvested during the dry season to determine chemical composition and some parameters of ruminal fermentation using ruminal inoculum of goats. Crude protein, NDFom, ADFom, in vitro gas production after 24 (GP_{24}), 48 (GP_{48}) and 96h (GP_{96}) of fermentation, IVDMD and IVOMD were determined while ME was estimated. Data were analyzed using the general lineal model (GLM) procedure in SAS for a completely randomized design and differences among means by Tukey test. Crude protein (*P. dulce*: 222.10, *H. velutinus*: 154.30 and *G. ulmifolia*: 147.76 g/kg) values were different among browse species ($P < 0.01$). *P. dulce* had the lowest NDFom: 435.22; and ADFom: 305.79), *H. velutinus* showed intermediate values (NDFom: 455.80 and ADFom: 323.57) and *G. ulmifolia* had the highest values (NDFom: 478.06 and ADFom: 368.46) g/kg. In vitro gas production, IVDMD, IVOMD and ME values varied among browse species ($P < 0.001$) (Table 1). *P. dulce* has the highest potential as a feed protein source in small ruminants during the dry period.

Table 1. In vitro ruminal fermentation parameters (g/kg DM) of some browse tree leaves

Parameters	*P. dulce*	*H. velutinus*	*G. ulmifolia*	SEM	*P*-value
GP_{24}	90.2[a]	69.5[b]	34.2[c]	8.2	<0.01
GP_{48}	153.3[a]	129.3[b]	81.0[c]	10.7	<0.01
GP_{96}	184.3[a]	156.8[b]	124.6[c]	8.6	<0.01
IVDMD	526.0[a]	528.5[ba]	460.2[b]	11.6	<0.04
IVOMD	559.9[a]	534.9[a]	464.6[c]	14.4	<0.01
ME (MJ/kg DM	9.60[a]	7.81[b]	5.37[c]	0.62	<0.01

Means in the same row with different superscripts differ (P <0.05). (GP) Gas production after 24, 48 and 96 h of fermentation (mL/g DM).

Key Words: browse species, chemical composition, ruminal fermentation

T133 Effect of forage species on ruminal fermentation in continuous culture. K. J. Soder*[1], M. A. Sanderson[1], and G. E. Brink[2], [1]*USDA-ARS, University Park, PA*, [2]*US Dairy Forage Research Center, Madison, WI*.

The objective of this experiment was to evaluate the effects of forage grass species on ruminal fermentation using a dual-flow continuous culture fermenter system. Four grass species [reed canarygrass (RCG, *Phalaris arundinacea* L.); quackgrass (QG, *Elytrigia repens*); orchardgrass (OG, *Dactylis glomerata* L.); and meadow fescue (MF, *Festuca pratensis* Hud.)] were compared in a 4 × 4 Latin square design. Four 10-d periods were conducted, using the first 7 d as adaptation and the last 3 d for sampling. Fermenters (1120–1140 mL in volume) were fed 11.25 g forage DM 4 times daily at 0700, 1030, 1430 and 2030 h. A corn-based supplement (8.7% CP, 10.6% NDF) was fed (15 g DM) twice daily at 0700 and 1430 h. Solids retention time was set at 24 h. The pH was measured at each feeding time. Fermenter effluent were collected at 1430 h on d 8 to 10 and subsampled for analyses of VFA, ammonia, and DM content. Fermenter contents were harvested on d 10 for analyses of DM and bacterial production. Apparent DM, OM, and NDF digestibilities were not affected ($P > 0.05$) by forage species, averaging 39.2, 42.6 and 77.0%, respectively, across all forage species. Apparent ADF digestibility was least ($P < 0.05$) for QG (53.5%). The pH was not affected ($P > 0.05$) by forage species, averaging 6.21 across all forage species. Total and individual VFA production and acetate to propionate ratio (A:P) were not affected ($P > 0.05$) by forage species with the exceptions of isobutyrate, which was greatest ($P < 0.05$) for OG, and isovalerate, which was least ($P < 0.05$) for MF. Ammonia production was greatest ($P < 0.05$) for QG and least for MF. Total N and ammonia flows (expressed as g/d) were greatest ($P < 0.05$) for QG and least for MF. Efficiency of bacterial protein synthesis (gN/kd DM truly digested) was greatest ($P < 0.05$) for RCG and QG. The impact of individual forage species on ruminal fermentation is critical to gaining a better understanding of digestive and ingestive behavior for improved pasture management recommendations.

Key Words: canopy structure, digestibility, forage species

T134 Yield, chemical composition and ruminal degradability of winter wheat grown under organic and conventional management. I. Mateos[1], M. J. Ranilla[1,2], A. Diaz[1], C. Palacios[1], C. Saro[1,2], M. L. Tejido[1,2], and M. D. Carro*[1,2], [1]*1Dept. Producción Animal, Universidad de León*, *24007 León, Spain*, [2]*Instituto de Ganadería de Montaña (CSIC-ULE)*, *Finca Marzanas, 24346 Grulleros, León, Spain*.

The objective of this study was to investigate differences in yield and nutritive value of organically and conventionally grown winter wheat crops. Each cultivation system was carried out in 3 plots bordering each other to assure similar soil properties. Whole-plant (WP) yield was determined in May 2009, and grain and straw yields were determined at maturity in July 2009. Samples were dried and chemical composition and in vitro dry matter digestibility were determined. Samples (500 mg) of each substrate were incubated with 50 mL of buffered rumen fluid at 39°C, and gas production was measured at 3, 6, 9, 12, 16, 21, 26, 31, 36, 48, 60, 72, 96, 120 and 144 h to estimate fermentation kinetics. Mean yield in conventional plots was 3.12, 1.28 and 1.06 t DM/ ha for WP, grain and straw, respectively. Organic cultivation decreased the yield of WP, grain and straw to 74, 57 and 76% of that in the conventional cultivation, respectively ($P > 0.24$). No differences ($P > 0.05$) in organic matter, neutral detergent fiber and acid detergent fiber content of WP or grain were detected between cultivation systems, but crude protein content was lower ($P < 0.01$) in organic compared with conventional cultivars (6.69 vs. 5.23% for WP, and 12.10 vs. 8.56% for grain). No

differences ($P > 0.05$) between cultivars were detected in chemical composition of straw. Organic and conventionally grown crops did not differ ($P > 0.11$) in their in vitro dry matter digestibility (43.6 vs. 45.2% for WP, 26.3 vs. 24.8% for straw and 79.6 vs. 78.2% for grains). The cultivation method did not affect ($P > 0.26$) either the potential gas production or the average production rate (calculated as mL of gas/h). The results indicate that organic cultivation reduced crop yield and protein content in WP and wheat grains, but no effects were observed on ruminal degradation.

Key Words: organic cultivation, winter wheat, gas production

T135 Comparison of nonlinear functions for describing the growth curve of Nile tilapia *Oreochromis niloticus* var. *chitralada* in a commercial production cycle. D. Rodriguez[1], C. Ariza-Nieto[2], A. Munoz[1], and G. Afanador*[1,2], [1]*Universidad Nacional de Colombia*, *Bogota, Colombia*, [2]*CORPOICA*, *Bogota, Colombia*.

Mathematical models in fish nutrition have proven indispensable in estimating growth and feed requirements. The aim of this study was to make a statistical comparison of the mathematical growth models in Nile tilapia. The data set used for this analysis was taken from a study that evaluated the effects of oregano essential oils (OEO) supplementation in Nile tilapia, *Oreochromis niloticus* (L.) (males) raised form 10 to 550 g of weight. Six nonlinear mathematical functions were compared: Gompertz, Logistic, Richard, Janoschek, Michaelis-Menden, and Bertalanffy which were fitted to the data using the NLIN procedure of SAS. Gauss-Newton method was used through this statistical procedure and the maximum number of iterations to converge was 11. A quantitative approach of statistical analysis was used to evaluate model adequacy and the residual variation for each prediction equation was partitioned into 3 components using means square prediction error (MSPE), analysis for comparing accuracy among models. The Gompertz, Richards and Janoscheck were shown to be the most appropriate models for *Oreochromis niloticus* (4597, 4591 and 4589 MSPE values, respectively). Parameters that allowed comparisons between general rates of body weight change (both absolute and relative) as derived by Gompertz model were: average lifetime absolute growth rate (AGR, 2.395 g/day), average lifetime absolute maturing rate, (AMR, 0.00278) and average lifetime relative growth rate (RGR, 0.0151 g/day).

Key Words: nonlinear functions, Nile tilapia, AGR, AMR, RGR

T136 In vivo measurement of body composition of chickens using quantitative magnetic resonance (QMR). A. D. Mitchell*[1], R. W. Rosebrough[1], G. Taicher[2], and I. Kovner[2], [1]*USDA-ARS*, *Beltsville, MD*, [2]*Echo Medical Systems*, *Houston, TX*.

QMR is a nuclear magnetic resonance based method for measuring the fat, lean and water content of the total body of the live animal. The purpose of this study was to evaluate the use of QMR for measuring the body composition of chickens while comparing QMR results to those obtained by dual x-ray absorptiometry (DXA) and chemical analysis (CA). A total of 144 birds, were scanned live (non-anesthetized) by QMR, killed, and then scanned by DXA. The birds were Ross 708 broiler chickens and ranged in weight from 768 to 2230 g. In addition, 32 of the carcasses were chemically analyzed for total body lipid, water and ash content. For the entire group of birds, the QMR and DXA measurements of total body water and total body lean mass were in good agreement, with no significant difference (1149 ± 202g vs. 1169 ± 183g and 1395 ± 246g vs. 1354 ± 226g, respectively, $P > 0.05$) and highly correlated ($R^2 = 0.96$ and 0.96, respectively). However, the QMR measurement of total body fat was significantly lower ($P < 0.05$) than that measured by DXA (94 ± 44g vs. 190 ± 43g, respectively) and poorly correlated ($R^2 = 0.40$). Compared with CA, QMR underestimated the percentage of total body fat by 37% while DXA overestimated the percentage of fat by 22% (9.7 ± 3.6 by CA vs. 6.1 ± 4.3 by QMR and 11.8 ± 3.0 by DXA, $P < 0.05$). Both QMR and DXA measurements of percentage total body fat were highly correlated with the CA measurement ($R^2 = 0.96$ and 0.82, respectively). Both QMR and DXA estimates of total body water were close to the CA measurement (1153 ± 232g by CA vs. 1199 ± 239g by QMR and 1202 ± 218g by DXA, $P > 0.05$), with R^2 values of 0.81 and 0.82, respectively. In conclusion, the results of this study demonstrate that QMR is a potentially useful method for measuring the body composition of chickens. Major advantages of this method are that no anesthesia is required and no other measurements are needed for the data input or analysis.

Key Words: chickens, body composition, quantitative magnetic resonance

T137 Estimation of direct and maternal heritability of body weights in Iranian native chickens using a multivariate animal model. H. Farhangfar*[1], M. E. Navidizadeh[2], and S. M. Hosseini[1], [1]*Birjand University*, *Birjand, Iran*, [2]*Agricultural Jihad Organisation*, *Mashhad, Iran*.

The main objective of this research was to estimate direct and maternal heritability of body weights in Iranian native chickens. Generally, heritability is a key component for predicting breeding value of animals and few research have been so far undertaken in this respect for native chickens of Iran. To estimate genetic and environmental variance and covariance components for body weight traits, a multivariate animal model was applied. The traits were body weight at ages of 1 (W1) and 56 (W56) days. The data were provided by the breeding center of native chickens located in Khorasan Razavi province of Iran. The total number of records was 18,253 collected over 3 generations from 18,253 male and female chicks representing 315 sires and 2,141 dams. The average W1 and W56 were 33.8 g (SD = 3.27 gr) and 557 g (SD = 95.30 g), respectively. In the multivariate animal model, combined contemporary fixed effect of generation, hatch and sex (GHS), random effects of direct additive genetic, maternal additive genetic and maternal permanent were included. REML estimates of (co)variance components were obtained by DMU package. For W1, direct additive genetic, maternal additive genetic, maternal permanent environment and residual variance components were found to be 1.79, 0.68, 4.64 and 3.16 g^2, respectively. The corresponding figures for W56 were 2383, 823, 685 and 3553 g^2, respectively. Covariance components between direct and maternal additive genetic effects were −0.91 and −1398.8 g for W1 and W56, respectively. Direct heritabilities of W1 and W56 were 0.2 ($P < 0.05$) and 0.39 ($P < 0.05$), respectively. Maternal heritabilities of W1 and W56 were found to be 0.07 and 0.14, respectively. Correlation between direct and maternal additive genetic effects was −0.82 for W1 while it was approximately −1 for W56. The results also indicated that there is a significant additive genetic variation in the Iranian native chickens for W56 suggesting that genetic selection could be successfully practiced.

Key Words: Iranian native chicken, genetic parameters, body weight

T138 Maniçoba hay effects on the gastrointestinal tract of free-range birds. P. E. N. Givisiez*, G. S. G. Bach, J. H. V. Silva, F. G. P. Costa, C. J. B. Oliveira, and R. C. Lima Neto, *Universidade Federal da Paraiba*, *Areia, PB, Brazil*.

This study evaluated the effect of partial substitution of the diet by maniçoba hay (*Manihot pseudoglaziovii*) on gastrointestinal (GIT) morphology of free-range birds at 73 d of age. Eighty-four Paraiso Pedres birds were randomly distributed into 3 treatments and 4 repetitions of 7 birds each. Corn-soybean meal diet was substituted by maniçoba hay at 0, 10 and 20%. At 73 d of age, 2 birds per repetition were slaughtered and liver, gizzard, intestine and its segments were weighed and intestinal and segment lengths were measured. Weight and length were expressed

as percentages of the live weight (%PV). Fragments of duodenum and jejunum were collected from each bird and routinely processed for histological analysis. Villus height and crypt depth were assessed using a image analysis software and the villus:crypt ratio was calculated. Data were submitted to ANOVA in a completely randomized design, with 3 treatments and 8 repetitions for macroscopic parameters and different number of repetitions for microscopic parameters. Means were compared by Tukey's test at 5% probability. There were no significant differences ($P < 0.05$) between treatments for macroscopic results, except for the relative weight of gizzard, which increased in the treatments with maniçoba hay (1.82; 2.42 and 2.46% for 0, 10 and 20%, respectively). In the duodenum, villus height increased ($P < 0.05$) when 10% maniçoba was fed (789.18; 1110.3 and 698.90 μm for 0, 10 and 20%) and crypt depth decreased ($P < 0.05$) with 20% maniçoba (65.07; 68.7 and 44.71 μm for 0, 10 and 20%), but villus: crypt ratio was not affected ($P < 0.05$). No differences were seen in the jejunum. The increase in dietary fiber probably caused more extrusion of epithelial cells. Considering that high energy is necessary for GIT maintenance and that the inclusion of maniçoba hay decreases AME and AMEn, apparently recovery was possible in the 10% treatment, but not in the 20%. Maniçoba hay may be used up to the level of 10% without compromising the epithelium of duodenum and jejunum.

Key Words: free-range birds, intestinal morphology, dietary fiber

T139 Study on probiotic characteristics of three isolates of lactic acid bacteria in in vitro and in vivo condition in broilers. S. Ghyamyipour[1], S. Rahimi*[1], M. A. Karimi Torshizi[1], and N. Mojgani[2], [1]*Tarbiat Modares University*, *Tehran, Tehran, Iran*, [2]*Razi Vaccin and Serum Production Research Institute*, *Karaj, Tehran, Iran*.

The effect of administration of 3 lactic acid bacteria isolates on broiler performance and carcass characteristics were investigated. This study was done in 2 phases. In first phase the microbiological characteristics of these 3 isolates such as tolerance to low pH, growth in presence of bile salts, tolerance to some commercial antibiotics, hydrophobicity, ability to inhibit the growth of some pathogenic bacteria and their ability to release the hydrolase enzyme of bile salt were examined. Data from first phase indicated that the isolated bacteria were identified as lactobacilli. In the second phase, to determine whether probiotics improve broiler growth and carcass characteristics, 3 lactic acid bacterial isolates were added to drinking water. Day old chicks (n = 320) were distributed to 4 experimental groups with 4 replicates with 20 chicks in a completely randomized design. Control group (C) did not receive any probiotic culture in drinking water; groups A, B and D received one of the 3 lactic acid bacterial cultures at a concentration of 10.6 log cfu/mL in drinking water from 9 to 49 d of age. Data were analyzed by Duncan's multiple range test (SAS, 1990). Administration of B culture resulted the greater BW gain compared with the other groups on d 49 ($P < 0.05$). Lactic acid bacteria did not influence the feed intake, weight and length of internal organs and carcass characteristics of chicks and blood factors except spleen weight, jejunum length and total carcass weight.

Key Words: lactic acid bacteria, performance, carcass

T140 Utilization of yeast extract and bacitracin for early intestinal maturation by broiler chicks obtained from breeder hens of different ages. Y. O. Fasina*, R. Thanissery, and S. J. Thomas, *Auburn University*, *Auburn, AL*.

The intestine of the newly hatched chick is immature at hatch and hatchlings from young breeder hens (YHC) typically demonstrate reduced livability compared with those from old breeder hens (OHC). Supplementing yeast extract (YE) into the diet may enhance intestinal development and growth of broiler chicks because, YE contains nucleotides that are essential for cellular functions and are also immunomodulatory. A 14-d experiment was conducted with day-old chicks from young (26–27 week old) and old (58 to 59 week old) breeder hens. Chicks (384) were randomly assigned to 8 dietary treatments. Treatment 1 (YH) consisted of YHC fed corn-soybean meal (SBM) diet without bacitracin methylene disalicylate (BMD) or YE added. Treatment 2 (YHB) consisted of YHC fed corn-SBM basal into which BMD was added at 0.055g/kg. Treatment 3 (YHE) consisted of YHC fed corn-SBM basal into which YE was added at 0.075% level. Treatment 4 (YHED) consisted of YHC fed corn-SBM basal into which YE was added at 0.15% level. Treatments 5 (OH), 6 (OHB), 7 (OHE), and 8 (OHED) consisted of OHC fed diets similar to those given to YHC in treatments 1, 2, 3, and 4, respectively. Intestinal jejunal tissue samples were analyzed for alkaline phosphatase (ALP) activity as an indicator of intestinal maturation on d 4 and 13 of experiment. Results showed that among YHC treatments, intestinal ALP activity was higher in YHB, YHE, and YHED treatments ($P < 0.05$; 1.85 to 2.61 IU/mg protein) compared with YH (1.06 IU/mg protein) on d 4 of experiment. Among OHC treatments, only OHB (2.14 IU/mg protein) had higher ALP activity than OH (0.89 IU/mg protein; $P < 0.05$). By d 13, ALP activity became similar for all treatments ($P > 0.05$). It was concluded that YE supplemented at 0.075% level of the diet performed similarly to BMD in enhancing early intestinal maturation in YHC, but had no effect in OHC.

Key Words: yeast extract, alkaline phosphatase activity, broiler chick intestine

T141 Growth and organogenesis of progeny chicks from dams fed different sources of trace minerals. Q. J. Sun*, S. Y. An, and Y. M. Guo, *State Key Lab of Animal Nutrition, College of Animal Science & Technology, China Agricultural University*, *Beijing, China*.

A study was conducted to evaluate growth and organogenesis of progeny chicks from broiler breeders fed diets supplemented with different sources of trace minerals. A total of 120 Cobb 48 broiler breeder females aged 31 wk were given 3 diets with organic or inorganic trace minerals at equal levels. The control (CON) was the basal diet supplemented with a combination of inorganic minerals ($CuSO_4$, $ZnSO_4$, $MnSO_4$ and Na_2SeO_3 separately, i.e., Cu 8 mg/kg, Zn 50 mg/kg, Mn 60 mg/kg and Se 0.3 mg/kg of diet). The second treatment (ZM) was basal diet supplemented with a combination of inorganic Cu, Mn and Se, and organic Zn from Mintrex-Zn. The third treatment (MIX) was basal diet supplemented with a combination of Mintrex-Cu Zn Mn (Novus Intl., USA) and yeast-selenium from Sel-Plex (Alltech Inc., USA). Diets were formulated based on NRC (1994). Trace minerals in basal diets were Cu 4.6 mg, Mn 30 mg and Zn 47 mg/kg diet based on actual analysis. All diets were iso-energetic, iso-nitrogenous and iso-methionine. After 8 wk, eggs laid during 39wk of age were incubated. Hatched chicks were raised for evaluation of growth performance and development of organs respectively. Broilers were fed with a common commercial ration with inorganic minerals (Cu 8 mg, Zn 50 mg, Mn 60 mg and Se 0.3 mg/kg diet). Results showed that minerals sources in broiler breeder hens diets did not influence the feed intake of their progeny. Supplementation of ZM and MIX in the diet increased body weight (BW) ($P = 0.121$), and decreased feed/gain ($P < 0.05$) of the chicks. No difference was observed in development of heart, however the liver weight (LW) and its relative weight (LW/BW) on d 1 and bursa weight (BAW) on d 11 were increased with ZM and decreased with MIX (LW, $P < 0.05$; LW/BW, $P < 0.10$; BAW, $P = 0.056$). Relative weight of bursa on d 11 was increased when breeders fed ZM ($P < 0.05$). On d 21, chicks fed

inorganic minerals obtained the greatest spleen weight (SW) and its relative weight (RSW) (SW, $P < 0.05$; RSW, $P < 0.10$). In conclusion, organic sources of minerals improved progeny growth performance and affected organogenesis.

Key Words: broiler breeder, progeny, mineral

T142 Effect of dietary probiotic and prebiotic on bone characteristic of Ross broiler chickens. H. Ziaie[1], G. H. Hadarbadi*[1], A. Zeinali[2], M. A. Karimi Torshizi[4], M. Bashtani[3], and H. Farhangfar[3], [1]*Agriculture and Natural Resources Research Center*, *Birjand, South Khorasan, Iran*, [2]*Ferdowsi University*, *Mashhad, Iran*, [3]*Birjand University*, *Birjand, South Khorasan, Iran*, [4]*Tarbiat Moddares University*, *Tehran, Iran*.

Weak bones result in breaking during processing and lower meat grade. Also, weak legs often result in reduced feed intake thus affecting weight gain and feed conversion ratio. Therefore, the objective of the present study was to determine the effect of dietary probiotic and prebiotic on bone characteristic and Breaking Strength of Ross broiler chickens. In this study, 240 day-old male broiler chickens (Ross strain) were allocated to 4 treatments in pens (120 × 100 × 90 cm) with 4 replicates (15 birds / pen) in a block completely randomized design. Experimental diets were fed: T1 = Control diet based corn and soybean meal without supplementation, T2 = Control diet + antibiotic (Virginiamycin) 15 ppm, T3 = Control diet + probiotic (commercial mixture of lactobacillus, Protexin) 150g/ton diet and T4 = Control diet + prebiotic (commercial mixture, Immnuwall) 450g/ton diet).). At the end of the experiment (42 d), 2 birds from each replicate were randomly selected and killed to evaluate the tibia bone characteristic (modulus of elasticity, yield stress and percentage of ash, calcium and phosphorous). Bone breaking strength analysis was conducted using an Instron Materials Tester (Model 4411, Instron Corp., Canton, MA) with Automated Materials Test System software version 8.09. The results of the present study indicated that mechanical parameters, ash percentage, Ca and P contents were significantly improved by the supplementation antibiotic and their alternatives ($P < 0.05$) but, the difference between antibiotic diet and treatments 3 and 4 was not significant ($P > 0.05$). In finally, with the prophylactic use of antibiotic (as growth promoters) in animal feeds probiotic and prebiotic resulted in increase resistance to stress fracture of broiler bones and as a suitable replacement can be proposed.

Key Words: broiler, antibiotic alternative, bone characteristic

T143 Improved hatchability and post-hatch performance in turkey poults receiving iodinated casein in ovo. W. G. Bottje*[1], A. Wolfenden[1], L. Ding[2], M. Morgan[1], N. Pumford[1], R. Wolfenden[1], G. Duncan[3], T. Smith[3], T. Slagel[3], K. Lassiter[1], and B. Hargis[1], [1]*Dept. of Poultry Science, Center of Excellence for Poultry Science, Univ. of Arkansas*, *Fayetteville,* [2]*Dept. of Animal Nutrition, College of Animal Science and Technology, China Agriculture University*, *Beijing, China*, [3]*Cargill Turkey Division*, *Springdale, AR*.

Iodinated casein has been shown to have thyroid hormone-like properties, and thyroid hormone has been shown to improve turkey embryo hatchability. Thus, studies were conducted to investigate the effect of iodinated casein injected in ovo at 25 d of incubation on hatchability, hatch weight, and growth (6 or 7 d post-hatch) in turkey poults. Two experiments were conducted with a commercial turkey hatchery using a commercial egg injection system. In Exp. 1, 3900 turkey eggs (1300 per group) were injected at 25 d of incubation with 200 µL of solution containing either 10 mg/mL of gentamicin (Control) or ones containing 75 µg/mL or 375 µg/mL of iodinated casein (IC75 and IC375, respectively) in a dextrin solution mixture of maltodextrin and potato starch dextrin (~28%). Two hundred poults each from the Control, IC75 and IC375 groups were neck tagged, placed in a commercial turkey house within a single brooder ring, and weighed 7 d later. In Exp. 2, 5200 eggs (2600 per group) were injected with the Control or the IC75 solution. A total of 600 poults (300 per group) were neck-tagged and placed in a single brooder ring in a commercial house and weighed on d 6 post-hatch. Eggs in Exp. 1 and 2 were obtained from hen flocks that were 33 and 5 wk into the laying cycle, respectively. In Exp. 1, the IC75 injection resulted in a 1.8% increase ($P = 0.03$) in hatch weight and numerically higher hatchability and 7 d BW compared with Controls. In Exp. 2, the IC75 treatment resulted in a 2.4% increase in hatchability ($P = 0.01$), a 4.3% increase in hatch weight ($P < 0.001$), and a 1.8% increase in 6 d poult weights ($P < 0.03$) compared with Controls. The results of this study indicate that a solution containing 75 µg/mL iodinated casein in a dextrin solution injected into turkey eggs at 25 d of incubation may be used to improve hatchability and early poult weights in commercial turkey production.

Key Words: poult hatchability, iodinated casein, in ovo injection

T144 Effect of daily lithium chloride (LiCl) administration on bone quality and strength in growing broiler chickens. B. M. Harvey*[1], M. Eschbach[2], E. Ackell[1], S. Kotha[2], M. Darre[1], N. Francis[1], D. J. Adams[3], R. Ramanathan[1], R. Mancini[1], and K. E. Govoni[1], [1]*Department of Animal Science, University of Connecticut*, *Storrs,* [2]*Department of Mechanical Engineering, University of Connecticut*, *Storrs,* [3]*Orthopedic Surgery, University of Connecticut Health Center*, *Farmington*.

Bone fractures and deformities are a serious problem for the broiler industry; therefore, identification of mechanisms to improve bone quality and strength would be beneficial. The wnt/β-catenin pathway plays a critical role in the bone formation process and this pathway can be stimulated by oral LiCl supplementation in mice. We hypothesized that oral supplementation of LiCl would increase bone strength and quality in broiler chickens. 144 broilers were divided into LiCl, control (C) and pair-fed (PF) groups. Beginning at 1 or 3 weeks (wk) of age, chickens were administered LiCl (20 mg/kg BW) or water daily by oral gavage. At 6 wk of age, chickens were killed and blood, bone and muscle samples were collected. A 24h LiCl (20 mg/kg BW) challenge determined that serum LiCl increased within 2h and cleared the system within 24h, thus demonstrating the effectiveness of our oral gavage to deliver LiCl. We did not observe any differences in BW ($P \geq 0.53$) or feed intake ($P \geq 0.19$) between all treatment groups, demonstrating that LiCl treatment did not negatively affect growth in these broilers. To evaluate bone composition, we performed morphometric analysis on the tibiae of C and LiCl groups using microCT imaging. We did not observe a difference in cortical or trabecular bone volume, trabecular thickness, number, or spacing ($P \geq 0.52$). To determine bone strength, we performed 3-point bending on the femora and tibiae of C and LiCl birds from the 1 wk group. We did not measure a difference in bone length or ultimate load ($P \geq 0.60$). However, we did observe a 23% reduction in stiffness ($P = 0.02$) in the femora and 34% reduction in fracture energy ($P = 0.11$) in the tibiae of the LiCl treated birds, thus suggesting reduced bone quality in the LiCl birds. We did not observe any effect of LiCl treatment on pectoralis muscle color or lipid oxidation ($P > 0.05$). In conclusion, LiCl treatment in broilers did not affect growth or meat quality. Surprisingly, we measured a reduction in bone stiffness with LiCl treatment which may be due to the dose of LiCl utilized or a species difference in response to LiCl treatment on bone formation.

Key Words: poultry, bone, broiler

T145 The bi-allelic expression of *delta-like 1 homolog* (*Dlk1*) in avian species. S. Shin* and K. Lee, *The Ohio State University*, *Columbus*.

Delta-like 1 homolog (*Dlk1*) is known as an important gene in the regulation of adipose and muscle differentiation and development. This gene is also known as an imprinted gene usually expressed only from the paternal allele in mammals. To determine the properties of the *Dlk1* genes of the avian species, *Dlk1* genes for chicken, quail and turkey were cloned and characterized for cDNA and amino acid sequences, alternative splicing, and genetic distances from other species. In addition, the structure of genomic DNA containing the cluster of genes including *Dlk1* was investigated in the chicken and compared with the human. The allelic expression pattern of the avian *Dlk1* gene was also determined here. The coding sequences of the quail and turkey *Dlk1* were the same as chicken *Dlk1* in their numbers of nucleotides (1,161 bp) and amino acids (386 a.a.). The similarities in DNA and amino acid sequence were more than 96% among the poultry species. The chicken and turkey *Dlk1* were closer than the quail in the phylogenetic analysis. The domains, such as one signal sequence, 6 *epidermal growth factor* (*EGF*)-like domains and a transmembrane domain were predicted in DLK1. There was no alternative splicing of *Dlk1* transcripts as in the chicken. Like in mammals, *Yy1*, *Wars*, *Wdr25*, *Begain*, *Dlk1*, *Dio3*, and *Ppp2r5c* were found as a syntenic gene cluster in chicken genome. However, *Meg3*, *Rtl1*, and *Meg8* genes located between *Dlk1* and *Dio3* were not found in the cluster of the chicken genome. There were several single nucleotide polymorphisms (SNPs) in the fifth exon of *Dlk1* genes in chickens and quail, and the heterozygous SNPs of *Dlk1* transcripts were observed in the adipose and muscle, indicating the bi-allelic expression of *Dlk1* in the avian species. The data confirmed avian *Dlk1* is not imprinted in poultry and might be regulated in a different manner from mammals.

Key Words: avian Dlk1, genomic imprinting, biallelic expression

T146 Expression of myosin heavy chain isoforms during muscle development in Leghorns and broilers. A. Lee*, Y. Suh, and K. Lee, *The Ohio State University*, *Columbus*.

Myosin heavy chain (MyHC), one of the major components in the contractile machinery of skeletal muscle fibers is found in several isoforms during myogenesis. During chicken development embryonic, neonatal, and adult MyHC isoforms are expressed. Broiler chickens have been selected for fast and large muscle growth while Leghorn chickens have been selected for egg laying capabilities. This has led to an obvious difference in muscle growth and development with broilers being much larger than Leghorns. The objective of this study was to determine if differences in muscle growth and development of Leghorns and broilers are associated with differences in temporal expression of MyHC isoforms in skeletal muscle between the 2 breeds. Pectoralis major muscle was collected from Leghorns and broilers at embryonic d 15, and 17 and d 1, 5, 11, 20, 27, and 33 d post hatch with n = 3 samples per time point and breed. Western blotting using 3 monoclonal antibodies (EB165, 2E9, and AB8) was performed to compare the expression patterns of embryonic/adult, neonatal, and adult isoforms of MyHC, respectively, for all time points in both Leghorn and broiler chickens. Pectoralis major tissue from broiler chickens expressed the adult MyHC isoform as early as d20 whereas the Leghorn chickens began expressing the adult isoform later. Both broiler and Leghorn chickens began expressing the neonatal MyHC isoform on d5 however Leghorn chickens expressed the neonatal isoform much longer than broilers. Leghorn chickens had sustained expression of the neonatal MyHC isoform through d27 whereas in broiler chickens the neonatal isoform was not expressed at d20. The differences in the expression of both adult and neonatal MyHC isoforms in broilers and Leghorns are consistent with the faster maturation and growth of broilers relative to Leghorns. Further study of other MyHC isoforms is needed to determine their association with differences in muscle growth and development of broiler and Leghorn chickens.

Key Words: muscle development, myosin heavy chain, chicken

T147 Growth of internal organs in quail embryo (*Coturnix japonica*) as a function of age. K. L. Arora*, *Fort Valley State University*, *Fort Valley, GA*.

The Japanese quail embryo is a very valuable model for experimental studies in developmental biology, toxicology, virology, teratology, endocrinology and drug testing. Various reports in the literature have focused on embryonic growth, weight, and developmental defects as a function of age. However, it is important to know the progressive changes in the growth of different organs which make up the total organism for complete pathological analysis. Eggs of uniform size and weight (10–11g) were collected, between 3 to 6 p.m., from 56d old birds weighing 130–135g. The birds were housed in cages under 14L: 10D lighting system and fed commercial turkey starter. Eggs were incubated at 37.8°C and 65–70 R.H. At the end of 10, 12, 14, and 16 d of incubation, a group of 15 eggs each were removed from the incubator and opened into Petri-dishes containing lukewarm saline solution. The embryos which were devoid of extra-embryonic tissues and spare yolk, were washed again, blotted with paper towel, organs dissected and removed and weighed individually using analytical balance. Day old chicks were killed with CO_2 and handled in a similar fashion. The following organs were collected: brain, liver, heart, gizzard, proventriculus, lungs, eyes and kidneys. Embryonic mass increased rapidly from 1.44 ± 0.01g at d 10 to 5.38 ± 0.14g at d 16, the time to hatch ($P < 0.01$). By d16, the embryonic mass had reached 91.7%, liver 88.2% heart 98%, kidney 100%, brain 100%, gizzards 89.6%, proventriculus 87.6%, lungs 95.2% and eyes 99.4% of the weight of day-old chick (100%). The embryonic growth accelerated during d10 and 12 and d14 and 16 with the organs growing at different rates ($P < 0.01$). The larger and faster growing organs in order of growth were: eyes, brain, gizzard and liver. The smaller and slower growing organs were ranked similarly in order of growth: proventriculus, heart, lungs and kidneys. The importance of the relationship between the growth of internal organs, age and stage of development will be discussed.

Key Words: Japanese quail, internal organ, embryo

T148 Growth after an innate immune challenge is different between broiler strains. L. Xu*[1], M. deBeer[2], M. Einstein[1], A. Schinckel[1], and T. J. Applegate[1], [1]*Purdue University*, *W. Lafayette, IN,* [2]*Aviagen, Inc.*, *Huntsville, AL*.

The acute phase response (APR) is defined as the early set of innate immune reactions induced by unfamiliar infectious agents or tissue injury. Lipopolysaccharide (LPS)-induced APR is associated with depressed growth and appetite loss. However, the question remains if there is a difference in the recovery after an APR between broiler strains. Therefore, a 40d feeding study was conducted with 2 broiler strains that were challenged between 7 to14 d with LPS. The experiment was designed with 3 treatments per strain (n = 8 cages/treatment; 6 birds/cage) starting at 7 d of age: an unchallenged positive control, LPS-challenged negative control (LPS-NC), and an unchallenged treatment that was pair-fed to LPS-NC. The LPS was injected i.p. Four times at 48-h intervals (1 mg/kg of BW). Body weight was recorded individually at 7, 14, 27, and 40 d of age. The LPS challenge depressed BW gain from 7 to 14 d of age by 10% and 12% for strains 1 and 2,

respectively. However, 67 and 74% of growth depression for strains 1 and 2, respectively, was attributable to factors other than feed intake reduction when compared with the pair-fed treatment. No BW differences between strains were apparent at the end of the challenge period (14 d; $P > 0.05$); whereas Strain 1 was 5.4% heavier (153.9 g) at 40 d of age ($P < 0.0001$). When 7 to 14 d of age BW gain was used as a covariate, average daily gain was affected by treatment within strain 1 but not strain 2. In other words, birds given the LPS treatment for strain 1 demonstrated compensatory growth; whereas those for strain 2 did not. Additionally, the coefficient of variation for 40d BW of strain 1 was 1.3% versus that for strain 2 which was 1.6%. Thus, growth recovery after an APR is different between broiler strains.

Key Words: broiler strain, innate immune response, lipopolysaccharide

T149 Influence of gender and initial body weight uniformity on growth performance and carcass quality of pigs slaughtered at 130 kg BW. L. Cámara*[1], M. P. Serrano[1], D. G. Valencia[2], A. Fuentetaja[3], and G. G. Mateos[1], [1]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [2]*Nutral S.A.*, *Madrid, Spain*, [3]*Copese S.A.*, *segovia, Spain*.

A trial was conducted to study the influence of gender (castrated female, CF vs. castrated male, CM) and initial pen uniformity (BW ± SD, 7.5 ± 0.6 kg vs. 7.5 ± 1.2 kg BW) on performance and carcass quality of crossbreds pigs resulting from Landrace * Duroc × Large White dams mated to Duroc sires pig. Males were castrated at 5 ± 2.0 d of age (2.5 ± 0.57 kg BW) and females at 69 ± 2.6 d of age (22.3 ± 0.83 kg BW). Each treatment was replicated 4 times and the experimental unit was a pen with 30 piglets from 7.5 to 27.3 kg BW and a pen with 14 pigs from 27.1 to 130.4 kg BW for productive traits. For carcass quality traits, 10 carcasses of the same pen constituted the experimental unit. From 7.5 to 27.3 kg BW, CF had lower ADFI ($P < 0.05$) and ADG ($P < 0.001$) and poorer FCR ($P < 0.001$) than CM. Also in this period, uniform pigs tended to be less efficient than less uniform pigs ($P < 0.10$). From 27.1 to 130.4 kg BW, CF tended to eat less feed and to have better FCR than CM but pen uniformity did not affect performance. Castrated females had more ($P < 0.05$) fat thickness at P_2 and tended to have more ($P < 0.10$) fat at *gluteus medius* muscle than CM. Trimmed shoulder yield ($P < 0.001$) and trimmed primal cut yield ($P < 0.01$) were higher for CM than for CF. Gender did not affect carcass, ham, and loin yields or shrink loss. Pen uniformity had little effect on carcass quality; the only effect detected was that uniform pigs tended to have more trimmed primal cut yield than the less uniform pigs. It is concluded that castrated females, had higher carcass fat content than castrated males. Therefore, castrated females are a good alternative to castrated males for the production of pigs destined to the dry-cured industry. On the other hand, the distribution of the pigs to improve pen uniformity does not provide any advantage in growth performance or carcass quality.

Key Words: castration and gender, heavy pig productivity and quality, uniformity

T150 Sow and litter productivity as affected by sow age. L. Cámara[1], M. P. Serrano*[1], D. G. Valencia[2], A. Fuentetaja[3], and G. G. Mateos[1], [1]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [2]*Nutral S.A.*, *Madrid, Spain*, [3]*Copese S.A.*, *Segovia, Spain*.

A total of 180 sows (crossbred of Landrace × Duroc × Large White) was used to study the effect of parity (primiparous, PRI, vs. multiparous in the 3rd and 4th reproductive cycle, MUL) on productive performance and posterior fertility. Each treatment was replicated 5 times and the experimental unit was a room with 16 sows housed individually. Feed and water intake were controlled daily and BW and backfat at P_2 were measured at farrowing and at weaning. Total number of piglets born alive, death, and mummified, and piglet mortality during lactation were recorded per litter. Also, piglet body weight was recorded at birth, and at 3, 14, 21, and at 28 d of age. In addition, the interval weaning to first estrous and the percentage of sows that did not make next farrowing were recorded. Multiparous sows ate more feed (5.64 vs. 4.25 kg/d; $P < 0.001$) and drank more water (28.63 vs. 23.07 l/d; $P < 0.05$) than PRI sows but feed:water ratio was not affected. Body weight change from farrowing to weaning was similar for both groups. Multiparous sows had more piglets born alive (11.4 vs. 10.2; $P < 0.05$) than PRI sows. Piglets from MUL sows were heavier ($P < 0.05$) at birth (1.73 vs. 1.53 kg), 3 (2.14 vs. 1.89 kg; $P < 0.01$), 14 (4.73 vs. 4.26 kg), 21 (6.45 vs. 5.84 kg), and 28 (8.61 vs. 7.58 kg) days of age than piglets from PRI sows. Consequently, from 1 to 28 d of age, piglets from MUL sows had higher ADG than piglets from PRI sows (260 vs. 229 g/d; $P < 0.05$). Mortality of piglets during lactation and of sows between farrowings was not affected by sow parity. The interval weaning to positive gestation was similar for both groups of sows. Sow parity did not affect the number of piglets born alive or death in the following parity. It is concluded that multiparous sows had higher voluntary feed intake and produce more piglets per litter, which are heavier, than primiparous sows.

Key Words: multiparous, primiparous, piglet productivity

T151 Effects of L-arginine supplementation to suckling piglets on plasma metabolites and skeletal muscle properties at weaning. D. Loesel*, S. Goers, and C. Rehfeldt, *Leibniz Institute for Farm Animal Biology (FBN)*, *Dummerstorf, Germany*.

Piglets of low birth weight exhibit a lower total number of skeletal myofibers at birth and throughout life compared with piglets of middle and heavy birth weight, which is associated with impaired (lean) growth, carcass and meat quality at market weight. To investigate, whether L-arginine is effective in stimulating the early postnatal increase in the number of myofibers, piglets of low birth weight (≤1.22 kg) from 5 German Landrace sows received 0.48 g L-arginine-HCl/kg body weight/day (n = 12) or an isonitrogenous amount of L-alanine (control; n = 12) from d 7 to 28 of age. Piglets were weaned and slaughtered at d 28 of age. Supplementation with arginine or alanine increased blood plasma concentrations of arginine and alanine, respectively ($P < 0.001$). Live weight gain, final body weight, and body composition by dissection and chemical analysis were not affected by arginine, except for a reduction in relative liver weight ($P = 0.05$). Plasma concentrations of glucose and free fatty acids remained unchanged, whereas urea concentration tended to be smaller in response to arginine supplementation ($P = 0.12$). The total number of semitendinosus (ST) myofibers was not affected by treatment ($P = 0.80$). Likewise, fiber area and metabolic fiber type composition by red, intermediate, and white fibers were not influenced. Protein and DNA concentrations remained unchanged, whereas total DNA amount tended to be greater in ST muscle of arginine-supplemented piglets ($P = 0.12$). Specific activities of CK ($P < 0.01$) and LDH ($P = 0.05$) increased 1.06-fold and 1.08-fold, respectively, in response to arginine, whereas ICDH activity was unchanged. The results suggest that arginine slightly stimulated muscle differentiation and metabolic maturation, but not muscle protein accretion and myofiber formation. It remains to be investigated whether modifications in the dosage or period of arginine supplementation would be more efficient in affecting skeletal muscle growth and metabolism of suckling piglets.

Key Words: body composition, enzyme, pig

T152 Finishing growth and carcass characteristics following reciprocal embryo transfer between Meishan and White crossbred pigs. J. R. Miles*, J. L. Vallet, B. F. Freking, J. J. Ford, S. D. Shackelford, and T. L. Wheeler, *USDA-ARS, US Meat Animal Research Center*, *Clay Center, NE*.

Crossbreeding studies between Meishan (MS) and contemporary White crossbred (WC) pigs have shown that increased lean, finishing growth of WC pigs is affected by the direct genotype of the piglet. The objective of the current study was to determine the contributions of the piglet and maternal genotypes and their interactions on finishing growth and carcass characteristics following reciprocal embryo transfers between MS and WC gilts. Twenty-five pregnancies were produced in 2 farrowing seasons that represented all piglet and maternal genotype combinations; MS × MS (n = 4 litters), WC × WC (n = 7 litters), MS × WC (n = 7 litters), and WC × MS (n = 7 litters). Starting at d 105 of age, gilts (n = 50) and barrows (n = 40) were weighed and backfat was recorded every 3 weeks. At d 165 of age, pigs were slaughtered and hot carcass weights were recorded. Within 3 d of slaughter, leaf fat was weighed and loin eye color, marbling, and area were determined. All data were analyzed using MIXED model procedures. There were piglet breed effects ($P < 0.01$) for body weight. As a result, average daily gain during grow-finish was greater ($P < 0.001$) in WC pigs. In contrast, average back fat measurements were greater ($P < 0.001$) in MS pigs. At slaughter, a piglet breed effect ($P < 0.001$) was observed in hot carcass weight in favor of WC pigs. Conversely, there was a direct breed effect ($P < 0.05$) of leaf fat weight in favor of MS pigs. No significant genotypic effects were observed for loin eye marbling between the breeds. However, loin eye color was darker ($P < 0.01$) in the MS pig. Furthermore, there was a piglet breed effect ($P < 0.001$) for loin eye area in favor of WC pigs. This study detected no significant interactions between the piglet and maternal genotypes of MS and WC pigs on finishing growth and carcass characteristics, and supports crossbreeding studies illustrating that differences in finishing growth are attributed to the genotype of the piglet.

Key Words: finishing growth, carcass characteristics, pigs

T153 Cytokine gene expression patterns of milk from healthy bovine mammary glands in late and early lactation. D. F. R. Bruno*[1], R. G. S. Bruno[3], P. V. Rossitto[2], J. S. Cullor[2], and J. L. Stott[2], [1]*Texas Veterinary Medical Diagnostic Laboratory*, *Amarillo,*[2]*University of California Davis*, *Davis,* [3]*Texas AgriLife Research and Extension*, *Amarillo*.

Cytokines mediate and regulate the immune system and have been studied as an alternative non-antibiotic therapy to treat and prevent mastitis in dairy cows, mainly in critical times as dry-off and early postpartum. The aim was to compare natural levels of expression of 9 cytokines on late lactation (dry-off) and early lactation (first week postpartum) in milk cells from healthy cow mammary glands. Transcriptional levels of expression of interleukin (IL)2Rα, IL4, IL6, IL8, IL10, IL17, interferon (IFN)γ, inducible nitric oxide synthase (iNOS) and tumor necrosis factor (TNF)α were evaluated in both periods by real time PCR. Milk samples from 10 Holstein cows were collected aseptically from 2 quarters/cow at dry-off and again at first week postpartum. Only quarters with somatic cell count ≤200,000 and absence of bacteria in both time points were considered for this study. Significance was defined as $P < 0.10$. Transcripts from IL2Rα, IL8, IL10, IFNγ, iNOS and TNFα were detected in both periods. IL2Rα and IL6 ($P < 0.10$), and IL8 and IL10 ($P < 0.04$) were upregulated in late lactation in comparison with the levels in early lactation. In late lactation, there was a positive correlation of proinflammatory cytokines IL6 and TNFα with anti-inflammatory cytokine IL10, and chemokine IL8 ($P < 0.10$). However, a negative correlation was observed between the proinflammatory cytokine IL17 with IL6 and IL8 ($P < 0.10$). In early lactation, fewer cytokines were correlated. A positive correlation among IL8 and TNFα and IL2Rα was observed. Similar to late lactation, there was a positive correlation between IL6 and IL10, and between TNFα and IL8, which was also correlated to the regulatory mediator iNOS ($P < 0.10$). In conclusion, cytokine mRNA profiles between late and early lactation showed differences, which can be attributed to dramatic changes the mammary gland is subjected to during these 2 stages of lactation. Positive correlation and upregulation of proinflammatory and anti-inflammatory cytokines account for an efficiency of the mammary gland immune system at late lactation and could be used as markers for health control of the udder.

Key Words: cytokine expression, lactation, RT PCR

T154 Intra- and inter-dairy heifer variation of cellular neutrophil functions. L. E. Hulbert*[1,2], L. R. Schwertner[1], J. A. Carroll[2], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University*, *Lubbock,* [2]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX*.

Immune competence of dairy cattle is difficult to determine as a healthy immune system requires the resolution of pathogen invasion without excessive host-tissue damage. Neutrophil phagocytosis (PG) is important for eliminating pathogens, but PG induces an oxidative burst (OB), which helps destroy the pathogen but also can damage the neutrophil and surrounding tissue. Neutrophil adhesion molecule L-selectin (L) mediates neutrophil rolling in the periphery, allowing for "surveillance" of pathogens, while its counterpart, β-integrin (β), allows for neutrophil anchoring to epithelial cells and migration into tissue from the periphery. The objectives of these studies were to examine inter-heifer variation (Exp.1, n = 36, 13–16 mo. of age) as well as intra-heifer variation (Exp. 2, n = 12, days = 3) of neutrophil functions. Phagocytosis and OB were determined by 2-color flow cytometry using propidium iodide labeled enterotoxigenic *E. coli* and the oxidation of dihydrorhodamine, respectively. Adhesion molecule expressions were also determined using flow cytometry and expressed as the mean fluorescence intensities. In Exp. 1, neutrophil PG and OB were highly correlated ($R^2 = 0.50$), while adhesion molecules L and β were moderately correlated ($R^2 = 0.39$). Inter-heifer coefficients of variation (CV) were low for PG (19.9%) and β (18.5%), but high for OB (51.1%) and L (38.0%). In Exp. 2, there were day effects ($P \leq 0.01$) for PG, OB and β, but not L ($P \geq 0.10$). Neutrophil PG intra-heifer CV was the least among all immune parameters (11.0%) while OB was the most variable at 22.43%. Adhesion intra-heifer CVs were 17.6% for β and 16.1% for L. These data indicate that neutrophil migration into tissue and subsequent phagocytosis of *E. coli* were more similar between Holstein heifers than either the oxidative killing or surveillance potential. Therefore, the OB and L expression are more likely to contribute to individual heifer variation in immune competence.

Key Words: bovine, granulocytes, immunology

T155 Comparison of the proliferative response of CD8 memory T cells from experimentally and naturally infected cattle shows the response to live *Mycobacterium avium* ssp. *paratuberculosis* stronger than the response to Johnin purified protein derivative (JPPD). H. M. Rihan*[1], G. S. Abdellrazeq[2], M. J. Hamilton[3], A. J. Allen[3], K. T. Park[3], and W. C. Davis[3], [1]*Mansoura University*, *Egypt*, [2]*Alexandria University*, *Egypt*, [3]*Washington State University*, *Pullman*.

Johnin purified protein derivative (JPPD) is the antigen most frequently used to study the T-cell response to *Mycobacterium avium* ssp. *paratuberculosis* (MAP). It has been assumed the response to this antigen can be used to characterize the CD4 and CD8 T cell responses to MAP in experimentally and naturally infected animals. Comparison of the response to PPD and live MAP, however, has revealed a clear difference, especially in the CD8 T cell response. Flow cytometric analysis of the proliferative response of PBMC from experimentally infected calves to JPPD and MAP showed the CD8 memory T cell response to JPPD was low during the first 3 mo post infection. In contrast, the response to MAP was strong and similar to the response of CD4 memory T cells. A comparable difference in the response to JPPD and MAP was observed in PBMC from cows at the late stage of infection. The findings show that further investigation of the mechanisms of immunopathogenesis of paratuberculosis must include a comparison of the response to JPPD and live MAP.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, Johnin purified protein derivative, CD8 memory T cell

T156 Tumor necrosis factor-α concentrations from whole blood cultures correlate with isolated peripheral blood mononuclear cell cultures. L. E. Hulbert*[1,2], J. A. Carroll[2], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University*, *Lubbock,* [2]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX*.

Many cellular immune assays are impractical because they require labor-intensive isolation of cells from their natural environment. The objectives of this study were to determine the relationship between cell culture supernatant tumor necrosis factor (TNF)-α from isolated peripheral blood mononuclear cells (PBMC) and whole blood (WB) when stimulated with lipopolysaccharide (LPS from *E. coli* O111:B4; 1 and 10 μg/mL for WB; 0.01 and 1 μg/mL for PBMC). Thirty-six dairy heifers (12–16 mo. age) free from any signs of disease were analyzed in

the study. The PBMCs were isolated using a percoll gradient, washed twice with PBS, counted using a hemacytometer, then resuspended to 2 × 10^6 cells/mL in a cell culture RPMI medium with 1% antibiotics, 10% autologous plasma and 5 ng/mL of recombinant bovine interferon-γ. In the WB assay, 200 μL of whole blood were added to 800 μL of RPMI with 1% antibiotics. Samples were incubated with their respective LPS doses for 24-h before supernatants were collected and analyzed for TNF-α using a commercially available sandwich ELISA. Mean TNF-α concentrations from PBMC and WB were moderately correlated (R^2 = 0.40). There were strong correlations between the low and high doses of LPS within each assay (R^2 = 0.67 and 0.87, for isolated PBMC and WB, respectively). The WB data were not correlated with either the number of leukocytes or the percentages of neutrophils (R^2 = 0.15). Inter-heifer coefficients of variation (CV) for the PBMC and WB data were 39.5% and 57.6%, respectively. In another experiment, using samples from 12 Holstein heifers from 3 consecutive days determined that the intra-heifer CVs for PBMC and WB data were 25.33% and 26.51%, respectively. These data indicate the WB assay may serve as a simple but effective ex vivo assay for evaluating bovine pro-inflammatory cytokine synthesis and secretion potential. Additionally, these data elucidate a large population variation, but if a heifer has a reduced response relative to the population at lower LPS concentrations then she will have a reduced response at a higher LPS concentrations, and vice versa.

Key Words: bovine, innate immunity, immune competence

T157 Effect of a *Bacillus*-based direct-fed microbial on cytokine gene expression in the IEC-6 rat intestinal epithelial cell line. C. A. Wehnes*, K. N. Novak, M. Duersteler, E. Davis, and A. H. Smith, *Danisco USA, Inc.*, *Waukesha, WI*.

Enhanced immune maturation was observed in a previous study where calves were treated with a 3-strain *Bacillus*-based direct-fed microbial (DFM). The objective of this study was to examine the immunomodulatory effects of the combination of bacilli strains in an intestinal epithelial cell line. Treatments were vegetative or sporulated bacilli, applied at 1 × 10^7 cfu per well, compared with untreated rat IEC-6 cells (3 × 10^5 cells per well). Expression of interleukin (IL)-1, IL-6, IL-10, tumor necrosis factor-α (TNF-α), and macrophage-inflammatory protein-2 (MIP-2) was analyzed by quantitative PCR and expressed relative to untreated IEC-6 cells. Sporulated bacilli increased IL-6 and MIP-2 gene expression compared with control cells; whereas, vegetative bacilli increased IL-10 gene expression (Table 1). To determine whether the bacilli would affect inflammation caused by LPS, IEC-6 cells were co-incubated with bacilli and 10 ng LPS per well. LPS increased IL-6, TNF-α, and MIP-2 gene expression compared with control cells (Table 1). Vegetative bacilli reduced ($P \leq 0.05$) elevated TNF-α gene expression caused by LPS 4-fold; whereas, sporulated bacilli did not ($P > 0.05$). These data demonstrate that cytokine gene expression differs depending on whether bacilli are vegetative or sporulated in both the presence and absence of LPS stimulation; furthermore, expression of inflammatory cytokines induced by LPS was reduced by vegetative bacilli, but not by spores.

Table 1. Fold change in gene expression, relative to unstimulated cells, of various cytokines in a rat intestinal cell line (IEC-6) exposed to vegetative or sporulated bacilli with or without lipopolysaccharide (LPS) to stimulate inflammation

Bacilli	None	Spores	Spores	Vegetative	Vegetative
LPS	+	–	+	–	+
IL-1B	1.0	–0.5	3.1	1.9	1.0
IL-6	3.3*	3.4*	5.8*	2.4	2.6
IL-10	2.9	1.7	1.5	5.5*	3.3
TNF-α	25.5*	17.7	35.9*	8.3	7.4
MIP-2	43.1*	42.2*	73.0*	9.7	21.4

*Means are significantly different to untreated control cells ($P \leq 0.05$).

Key Words: probiotic, immunity, DFM

T158 Post-weaning intestinal mucin dynamics is influenced by cereal grain type and commensal microbiota. G. Malik*, M. D. Drew, and A. G. Van Kessel, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

Mechanisms by which diet composition and commensal microbiota influence post-weaning intestinal mucin dynamics were studied using conventional and gnotobiotic pigs in a 2x2 factorial design. Caesarean-section derived germ-free pigs (n = 16) were reared in HEPA-filtered isolator units (4 pigs/unit) and fed sterilized sow colostrum (120 mL/pig) followed by infant formula (2:1; formula: water) ad libitum. Conventional (CON) pigs (n = 32) were vaginally delivered and sow-reared. At 14 d of age all pigs were weaned to diets formulated to meet nutrient requirements using corn or wheat/barley. At 24 d of age, pigs were killed and tissue collected at 75% (cranial to caudal) of small intestinal (SI) length. Contamination of germ-free pigs resulted in monoassociation with *Enterococcus faecium*. Acidic, neutral and total numbers of goblet cells were determined in villi and crypts using stained formalin-fixed tissue cross-sections taken at 75% of SI length. Expression of membrane associated mucin genes Muc 1, Muc 13 and secreted type Muc 2 was also determined. Data were analyzed as a 2x2 ANOVA using GLM procedure (GLM, SPSS software v. 12.0, SPSS Inc., Chicago IL, USA) with main effects of cereal grain (corn vs. wheat/barley) and microbial status (conventional vs. monoassociated) plus interactions as sources of variation. Monoassociation reduced ($P < 0.01$) neutral, acidic and total goblet cells in crypts and neutral goblet cell in villi and mucin gene expression. Monoassociation tended to increase ($P < 0.01$) acidic mucin cells in the villi. Interactive effects were observed only as trends ($P < 0.1$) such that Muc 2 expression was lower only in monoassociated pigs fed wheat-barley. In conclusion, as expected, monoassociation markedly influenced intestinal physiology. Limited effects of cereal grain type were observed.

Key Words: microbiota, mucin, swine

T159 Mannan oligosaccharide (MOS) modulates ileal gene expression in pigs experimentally infected with porcine reproductive and respiratory syndrome virus (PRRSV). T. M. Che*[1], R. W. Johnson[1], K. W. Kelley[1], W. G. Van Alstine[2], K. A. Dawson[3], C. A. Moran[3], and J. E. Pettigrew[1], [1]*University of Illinois*, *Urbana,* [2]*Purdue University*, *West Lafayette, IN,* [3]*Alltech Biotechnology Center*, *Nicholasville, KY*.

The objective of this study was to investigate ileal gene expression in control- or mannan oligosaccharide (MOS) (Bio-Mos)-fed pigs with or without porcine reproductive and respiratory syndrome virus (PRRSV) at d 14 postinfection (PI). Weaned pigs (3 wk old) fed 0% or 0.2% MOS

diets were intranasally inoculated with PRRSV or medium at 5 wk old. Total RNA was extracted from ileal tissue including Peyer's patches. Double-stranded cDNA was amplified, labeled, and further hybridized to the Affymetrix GeneChip Porcine Genome Array consisting of 23,937 probe sets representing 20,201 genes. Microarray data were analyzed in R using packages from the Bioconductor project. The MOS x PRRSV interaction and PRRSV main effect were not significant. Therefore, gene expression data from control-fed pigs and MOS-fed pigs were pooled (4 pigs/dietary treatment) for statistical analysis using the LIMMA package. Dietary MOS affected ($P < 0.05$) the expression of thousands of non-immune probe sets (1151 up and 1571 down). Using a 2-fold change difference and *P*-value cutoff of <0.05, we identified that MOS increased the expression of 134 non-immune genes and reduced the expression of 25 non-immune genes. The greatest mRNA upregulation was observed in many important genes involved in absorption of lipid, glucose, and glutamate, cellular protection from endogenous or external proteolysis, and d-amino acid oxidation. With respect to immune genes, MOS altered ($P < 0.05$) the expression of 23 immune probe sets (16 up and 7 down). Using a 2-fold change difference and P-value cutoff of <0.05, MOS upregulated 8 genes and downregulated 5 genes. The greatest increases were seen in genes encoding antimicrobial peptide, intestinal lymphocyte recruiting chemokine, and complement component 5. In short, PRRSV infection did not affect the ileal gene expression at d 14 PI, but feeding MOS to pigs may be beneficial by enhancing intestinal uptake of nutrients and mucosal defense against enteric infection.

Key Words: ileal gene expression, mannan oligosaccharide, nursery pigs

T160 Differential gene expression in subcutaneous and visceral adipose depots in response to lipopolysaccharide in the Sinclair minipig. S. L. Booker*, C. J. Kojima, J. S. Gouffon, and N. Moustaid-Moussa, *The University of Tennessee*, *Knoxville*.

The goal of this study was to elucidate depot-specific differences in transcriptome response of adipose tissue to a pro-inflammatory challenge. Eight intact male Sinclair minipigs (8 mo of age; 32.3 ± 1.9 kg) were non-surgically cannulated and challenged with 15 μg/kg lipopolysaccharide (LPS; n = 4) or saline (n = 4) delivered IM. Blood was collected every 20 min from −60 to +240 min relative to LPS administration. The following day, pigs received a second IM injection of 5 μg/kg LPS or saline, and were killed 2 h post-injection. Tissues including visceral fat (VF) and subcutaneous fat (SQF) were collected, and RNA was isolated for transcriptome analysis (Affymetrix). Only transcripts for which expression differed between treatments by 2-fold or greater with $P < 0.05$ were noted. In SQF, 541 transcripts were downregulated and 1,117 transcripts were upregulated by LPS relative to saline. Upregulated SQF genes included members of the NFκB inflammation cascade: TLR4 (toll-like receptor 4), TICAM2 (toll-like receptor adaptor molecule 2), TLR9 (toll-like receptor 9), and MIF (macrophage migration inhibitory factor). In VF, only 9 transcripts were downregulated and 7 upregulated by LPS relative to saline. Thrombospondin (THBS1) and adiponectin (ADIPOQ) were upregulated in VF, while in SQF, THBS1 was downregulated and ADIPOQ was not affected by LPS. When transcriptomes from SQF and VF of LPS-treated animals were compared, differentially regulated genes mapped to 3 main pathways: the aryl hydrocarbon receptor (AhR) and transforming growth factor β (TGFβ) signaling pathways (both of which are involved in the inflammatory process), and Type 2 Diabetes (T2D). Genes belonging to the AhR and T2D-related pathways were overall upregulated in VF relative to SQF; genes in the TGFβ pathway were downregulated in VF relative to SQF. These results indicate that both SQF and VF depots are metabolically active but are differentially responsive to an immune challenge. Finally, these data further support the role of visceral adipose in inflammatory processes often associated with metabolic disorders.

Key Words: pig, inflammation, adipose

T161 A comparative analysis of galectin-11 gene expression in ruminants. N. Mikiashvili, M. Worku*, and H. Muktar, *North Carolina Agricultural and Technical State University*, *Greensboro*.

The objective of this study was to assess the expression of galectin-11 in neutrophils isolated from cow and goat blood. Galectin-11 isolated form sheep infected with *Haemonchus contortus* is a member of a family of proteins that consists of β-galactoside binding lectins. Host galectins have been shown to be active participants in the recruitment of cells to sites of inflammation and modulating the effector function of inflammatory cells such as the neutrophil. For example they can serve as negative regulators of lipopolysaccharide (LPS) function, to protect the host from endotoxic shock. The role of galectins in the inflammatory response in ruminants has not been defined. A comparative analysis was conducted to determine expression of galectin-11 in neutrophils and to assess the impact of LPS exposure. Three clinically healthy Holstein Friesian cows and 3 Boer goats pasturing at the North Carolina A&T State University farm were used. Blood was collected from the jugular vein in anticoagulant. Neutrophils were isolated from blood samples by differential centrifugation and hypotonic lysis of red blood cells. Isolated neutrophils in PBS were treated with 10 or 100 ng *E. coli* LPS for 15 or 30 min. Total RNA and DNA isolated using Tri-reagent method. Reverse transcriptase PCR was performed using Oligo (dT) primers. Quantitative one step real time PCR was performed with the intercalating dye SYBR Green. Expression level in target samples was calculated using relative quantification with normalization to a reference gene. Amplified products were run on a 2.5% agarose gel with PCR markers. Primers for GAPDH were used as amplification controls and for calculation with Pfaf method. Neutrophils isolated from cow and goat blood expressed galectin-11. Dose of LPS had an effect on overall transcription in neutrophils as indicated by increased RNA concentration. Control (untreated) and LPS treated samples showed expression of target galectin mRNA transcripts. Our study on ruminant neutrophils may help further understanding of the role of galectins in the inflammatory response following host-pathogen interactions.

Key Words: galectin, neutrophil, ruminant

T162 Analysis of a transient receptor potential channel 3 *(Trpc3)* gene in myotonic goats: A potential model for human cerebellar ataxia. M. M. Corley and J. E. Caviness*, *Virginia State University*, *Petersburg*.

Cerebellar ataxia (CA) is a progressive neurological disorder, manifested by poor coordination of the arms and legs, increased difficulty walking or paralysis, slurred speech, depleted hearing and cold feet. Cerebellar ataxia is caused by the degeneration of Purkinje cells of the cerebellum. More than 50 different inherited forms of CA are known, and evidence suggests common pathological pathways (transcriptional regulation, calcium homeostasis) trigger degeneration of Purkinje cells. Myotonia congenita (MC) is an inherited neuromuscular disorder characterized by the inability of muscles to quickly relax after a voluntary contraction. Mutations in calcium cycling genes have been reported to contribute to the myotonic state. It has been shown that a point mutation in a transient receptor potential channel (Trcp) gene that regulates calcium stores, *Trpc3* causes abnormal Purkinje cell development and CA in moonwalker mice. Although genes in the TRPC family have been linked

to MC, the myotonic goat has not been evaluated as a model for CA, nor has the *Trpc3* gene been isolated in goats. Therefore the objective of this study was to identify and characterize the *Trpc3* gene in the myotonic goat. Total RNA was isolated from whole blood samples and purified. Reverse transcriptase polymerase chain reaction (RT-PCR) was performed using cross species primers designed from the human, bovine, and mouse *Trpc3* gene alignment. The RT-PCR product was visualized via agarose gel electrophoresis. The expected 213 bp RT-PCR product was observed, indicating successful amplification of the goat *Trpc3* cDNA. The RT-PCR product was purified and sequenced. The goat *Trpc3* gene showed 95% and 91% sequence homology to the bovine and human *Trpc3* genes, respectively. Identification and analysis of the myotonic goat *Trpc3* gene will provide insight into the etiology of CA in humans and its relationship to MC.

Key Words: myotonic goat, cerebellar, TRPC3

T163 Simultaneous detection and quantitation of anthelmintic resistance and *Haemonchus contortus* infection in grazing goats. M. M. Corley and A. A. Saeed*, *Virginia State University*, *Petersburg*.

The most prominent factor currently limiting meat goat producers is the blood sucking nematode *Haemonchus contortus*. This gastrointestinal parasite costs the global livestock industry billions of dollars per annum in lost production and drug costs. Resistance to all the major anthelmintic classes is now common worldwide, often leading to failure of treatment and control. Standard methods of gastrointestinal nematode infection (GIN) load are fecal egg counts (FEC), FAMACHA eye color chart score (FAM), and packed cell volume (PCV). Thus far, these detection methods provide the presence of GIN infection, but cannot predict whether the animals will be resistant to the administered anthelmintic after standard method detection. In *Haemonchus contortus*, a single nucleotide polymorphism (SNP) of the β-tubulin gene (TTC to TAC), causing a phenylalanine to tyrosine amino acid substitution, has been shown to be involved in many cases of resistance. This study was conducted to demonstrate simultaneous quantitation of *Haemonchus contortus* load and detection of its resistance to benzimidazole based anthelmintics. Goats exhibiting natural resistance or susceptibility to *Haemonchus contortus* infection were selected based on the standard methods described above. Total RNA and genomic DNA were extracted from stool samples and subjected to both genomic DNA PCR and RT-PCR using primers designed to target the *Haemonchus contortus* β-tubulin 1 gene SNP. Pearson Correlation coefficient analysis showed that there was a negative correlation between FAM and PCV ($P < 0.05$), β-tubulin DNA and a very low positive correlation with FEC ($P < 0.05$). The PCV showed strong negative correlation with FAM ($P < 0.05$), FEC ($P < 0.05$) and β-tubulin DNA ($P < 0.05$). These results demonstrate that the opportunity to detect *Haemonchus contortus* infection by standard methods and at the same time determine whether the animal will be resistant to anthelmintic treatment by DNA detection and quantitation will aid in saving the global livestock industry billions of dollars.

Key Words: *Haemonchus contortus*, anthelmintic resistance, DNA quantitation

Meat Science and Muscle Biology: Fresh Meat Quality of Ruminants, Nonruminants and Poultry

T164 Brazilian commercial cuts yield of crossbred beef bulls slaughtered at different body masses. R. Mello*[1], A. C. de Queiroz[2], F. D. de Resende[3], M. H. de Faria[3], P. V. R. Paulino[2], and G. R. Siqueira[3], [1]*Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [3]*Agência Paulista de Tecnologia dos Agronegócios*, *Colina, SP, Brazil*.

The aim of the present experiment was to study the effects of genetic groups and slaughter end points on commercial meat cuts yield. Thirty-six young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) and 18 F1 Blonde D'Aquitaine × Nellore (1/2 BA 1/2 N) were used. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of shrunk body weight (SBW). A completely randomized experimental design of a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. The pistola from right side of each carcass was dissected into crude and trimmed cuts and trimmed fat for predicted commercial cuts yield. Data were analyzed with SAS software using initial SBW as a covariate. The table below shows the least squares means of dependent variables. The 1/2 BA 1/2 N young bulls had a higher relative yield (% of pistola) of trimmed top sirloin butt than 1/2 RA 1/2 N young bulls. As the slaughter weight increased, the crude loin and top sirloin cap, and trimmed cube roll, strip loin, and top sirloin cap increased; however the trimmed fat from loin and top sirloin butt increased also. Besides, the interaction between GG and SW was significant ($P > 0.05$) for trimmed fat from tenderloin (data not shown), where the 1/2 BA 1/2 N had increase of trimmed as the slaughter weight increased, while the 1/2 RA 1/2 N outcome was virtually unchanged. Thereby, crossbred F1 Blonde D'Aquitaine × Nellore young bulls and heavier animals produced more saleable meat than F1 Red Angus × Nellore and lighter animals.

Table 1. Least squares means

	Genetic Group (GG)		Slaughter Weight (SW)		
	½ RA ½ N	½ BA ½ N	480	520	560
Crude cuts					
Loin	13.5	13.4	12.1^{b}	14.2^{a}	14.0^{a}
Top sirloin cap	2.5	2.5	2.1^{b}	2.7^{a}	2.6^{a}
Trimmed cuts					
Cube roll	3.7	3.6	3.2^{b}	3.5^{b}	4.1^{a}
Strip loin	6.7	6.8	6.2^{b}	7.3^{a}	6.6^{b}
Top sirloin butt	4.7^{B}	4.8^{A}	4.8	4.7	4.7
Top sirloin cap	1.8	1.9	1.6^{b}	2.1^{a}	2.0^{a}
Trimmed fat					
Loin	3.1	3.1	2.6^{b}	3.4^{a}	3.3^{a}
Top sirloin butt	1.4	1.4	1.2^{b}	1.5^{a}	1.5^{a}

Within a row, means followed by different capital and small letters differ ($P < 0.05$), respectively, among GG and SW by Tukey test.

Key Words: boneless cuts, breeds, saleable meat

T165 Brazilian primal cuts yield of crossbreed beef cattle slaughtered at different end points. R. Mello*[1], F. D. de Resende[2], A. C. de Queiroz[3], M. H. de Faria[2], F. Maldonado[2], and G. R. Siqueira[2], [1]*Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Agência Paulista de Tecnologia dos Agronegócios*, *Colina, SP, Brazil*, [3]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

The objective in this trial was to assess the basic cuts yield of finished crossbred feedlot beef bulls and slaughtered at different body masses. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) and 18 F1 Blonde D'Aquitaine × Nellore (1/2 BA 1/2 N) were used. The young bulls were finished on feedlot and slaughtered at 480, 520 and 560 kg of shrunk body weight (SBW). A completely randomized experimental design in a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. Primal cuts were predicted for each carcass using separation (forequarter, thin flank, pistola) on the right side of the carcass. Data were analyzed with SAS software using initial SBW as a covariate. The table below shows the least squares means of Brazilian primal cuts yield. Cuts yield ranged on average from 40.9 to 42.5% of forequarter, 11.2 to 11.9% of thin flank and 45.7 to 47.8% of pistola. There were no effect ($P > 0.05$) of genetic group (GG), slaughter weight (SW) and its interaction (GG × SW) on relative yield (%) of the primal cuts. Thus, finishing of crossbred F1 Blonde D'Aquitaine or Red Angus versus Nellore young bulls on feedlot and slaughter at 480, 520 and 560 kg produced carcasses with the same primal cuts yield.

Table 1. Least squares means

	Genetic Group (GG)		Slaughter Weight (SW)		
	½ RA ½ N	½ BA ½ N	480	520	560
Forequarter, %	41.7	41.1	41.3	40.9	42.0
Thin flank, %	11.7	11.5	11.4	11.6	11.8
Pistola, %	46.6	47.4	47.3	47.5	46.2

Key Words: bone-in cuts, feedlot, young bulls

T166 Portions of high value cuts in carcasses of different beef cattle in the Czech Republic. J. Riha*[1], J. Bezdicek[1], M. Homola[2], E. Vacatko[2], and J. Subrt[3], [1]*Agrovyzkum Rapotin Ltd.*, *Vikyrovice, Czech Republic*, [2]*Research Institute for Cattle Breeding, Ltd.*, *Vikyrovice, Czech Republic*, [3]*Mendel University in Brno*, *Brno, Czech Republic*.

The aim of this study was to assess the effect of breed on highly valued parts of carcasses. The study was carried out with 45 Blonde d'Aquitaine, 40 Piemontese, 48 Hereford and 52 Galloway bulls. After slaughter, the following cuts were evaluated: round, strip loin, tender loin and shoulder blade (boneless). The age of slaughtered animals, and their corresponding BW ranged from 312 to 699 d and 395.2 to 811.9 kg, respectively. Highly valued meat was weighed (in kg) and presented in percent of carcass halfbodies (HC). General regression models (GRM) design with breed as fixed categorical and slaughter age and BW as fixed continuous effects were used for statistical analysis. Coefficients of determination calculated for each model ranged from 0.173 (strip loin) to 0.587 (tender loin). According to the model, round percentage was reduced (*$P < 0.05$; **$P < 0.001$) in the following ascending order: Piemontese (22.82%) > Blonde d'Aquitaine (20.85%) > **Hereford (17.64%) > Galloway (16.85%). For strip loin, tender loin and boneless shoulder blade the order was Blonde d'Aquitaine (4.41%) > Piemontese (4.36%) > Galloway (4.08%) > *Hereford (3.58%); Piemontese (1.83%) > Blonde d'Aquitaine (1.69%) > **Galloway (1.32%) > **Hereford (1.71%) and Piemontese (8.59%) > Blonde d'Aquitaine (8.01%) > *Galloway (7.38%) > **Hereford (6.51%), respectively. The highest percentage of cut with regard to weight and age of bulls was found for Piemontese bulls. From this screening study, it is evident that Piemontese and Blond d'Aquitaine bulls (which however have also more subtle

constitution) have a higher portion of valued cuts than extensively kept ones (Hereford and Galloway) with regard to model correction of weight and age. Selected designed models (e.g., for tender loin) seem to be suitable for prediction of high value cuts portion with usage of the described effects.

Key Words: beef cattle, high value cuts, prediction of cutting parts using GRM

T167 Predicting retail product yield of Nellore bulls using live animal measurements. S. L. Silva*[1,3], R. C. Gomes[1], J. U. Tarouco[2], M. N. Bonin[1], P. R. Leme[1], and J. B. S. Ferraz[1], [1]*Universidade de Sao Paulo (FZEA)*, *Pirassununga, SP, Brazil*, [2]*Universidade Federal do Rio Grande do Sul*, *Porto Alegre, RS, Brazil*, [3]*FAPESP*, *Sao Paulo, SP, Brazil*.

Information regarding retail product yield (RPY) for beef cattle is of great importance for genetic evaluation programs based on carcass merit. Equations using carcass or live animal measurements to predict RPY have been developed mainly based on steers data with little information about its use for young bulls that are mostly used in genetic evaluation programs. Therefore, the aim of this work was to evaluate the accuracy of RPY estimates in young Nellore bulls obtained by using an equation originally developed in our laboratory based on data of Nellore steers. Thirty-eight Nellore young bulls (23 mo old) finished in feedlot (485 ± 37kg of shrunk body weight (SBW) at slaughter) were ultrasound scanned for 12th-rib Longissimus muscle area (ULMA) and backfat thickness (UBFT), and rump fat (URF) determinations, within 3–5 d prior slaughter. The left side of each carcass was deboned into retail cuts according to Brazilian standards, with the excess of fat trimmed to approximately 5 mm. Predicted retail product weight (RPW, kg = –36.28367 + 0.36485*SBW – 0.74324*ULMA; $R^2 = 0.93$; SEP = 7.36) and percentage (RPP, % = 70.38312 – 0.00716*SBW + 0.07257*ULMA – 0.10939*UBFT – 0.15077*URF; $R^2 = 0.34$; SEP = 1.24) were calculated and compared with actual RPW and RPP. The averages of actual and predicted RPW and RPP averaged 196.6kg and 192.4kg, and 71.7% and 70.8%, respectively. Prediction equations underestimated both RPW (bias = –4.2kg) and RPP (bias = –0.91%). Coefficients of determination between predicted and observed RPW and RPP were 0.77 and 0.44, respectively. These results suggest that prediction equations developed from steers can be used with similar accuracy to predict RPY in Nellore bulls. Further studies including a greater number of RPY data in young bulls are necessary to verify the accuracy of these models and their usefulness for use in genetic evaluation programs.

Key Words: beef, ultrasound, zebu

T168 Mixed model analysis of non-linearity between cooking loss and aging time plus other effects. A. Dufek*[1], J. Subrt[2], J. Simeonovova[2], and M. Homola[3], [1]*Research Institute for Cattle Breeding, Ltd.*, *Vikyrovice, Czech Republic*, [2]*Mendel University in Brno*, *Brno, Czech Republic*, [3]*Agriresearch Rapotin Ltd.*, *Vikyrovice, Czech Republic*.

We used the package nlme in the R software for description and statistical analysis of non-linear relationship between cooking loss and aging time. The relationship was described by the asymptotic regression model "cooking loss = Asym+(R0-Asym) exp[-exp(lrc)Time]" with 3 physically meaningful parameters: R0 = the response at slaughter time, lrc = logarithm of the rate constant and Asym = a response that approaches a horizontal asymptote. After the basic model was formed, we put random effects into the model at nested levels: i) subject (animal), ii) subjects within sires and iii) sires within years. Age, fattening system (extensive vs. intensive), length of hind quarter, weight of carcass, ratio between length of fore and hind quarter, weight proportion of the LM in the carcass and status (bulls, steers) were put into the model as fixed effects. We selected the effects to test the hypotheses from the aspects of beef production and anatomy since the LM is of high value as well as important for constitution. The LM was divided into 4 samples and individually vacuum packed. One of the samples was analyzed 48 h post-mortem. The other 3 samples were stored at 2–4°C for 16, 30 and 44 d. Cooking loss was determined by weighing the samples before and directly after cooking in a water bath at 70°C for 1 h. Percentage of cooking loss was calculated. Values of the parameters for the basic model including all animals (n = 46) were R0 = 25.33%, lrc = −2.38, Asym = 34.12%. The random effects analyses showed that only the subject affected the Asym and R0 significantly (tested with AIC). Analyses of fixed effects produced following results: higher values for age resulted in higher Asym ($F = 15.15$, $P = 0.0002$) and R0 ($F = 3.59$, $P = 0.06$). Higher values for length of hind quarter resulted in lower Asym ($F = 5.83$, $P = 0.017$). The Asym of extensively fattened animals was 3.88% higher ($F = 5.05$, $P = 0.026$) and the R0 −1.21% lower than for intensively fattened animals. Steers had −2.57% lower Asym than bulls ($F = 3.99$, $P = 0.047$). The results revealed that fattening system, age and length of animals significantly affect cooking loss in aged beef.

Key Words: mixed, non-linear, beef

T169 Epinephrine-induced MMP expression in muscle cells is uncorrelated with AMPK signaling. M. C. Cha and P. P. Purslow*, *University of Guelph*, *Guelph, Ontario, Canada*.

Acute stress at or around the point of slaughter is known to impact on post-mortem development of pH and subsequent meat quality. One signaling pathway involved in the stress response is AMP-activated protein kinase (AMPK), which regulates energy metabolism in muscle and post-mortem glycolysis. Elevated levels of epinephrine (adrenaline) in the circulation are also known to increase matrix metalloproteinase (MMP) expression in muscle. MMPs are proteases (MMPs) that control the degradation of connective tissue. Post-mortem degradation of intramuscluar connective tissue by MMPs could affect sub sequent meat toughness. Using a cell culture model, we have therefore investigated: (1) whether epinephrine increases the expression of MMPs from muscle cells and fibroblasts isolated from muscle, and (2) any relationship changing MMP expression may have to AMPK signaling. Mouse skeletal fibroblasts (NOR-10) and myoblasts (C2C12) in plate culture with DMEM medium were treated with or without 11 nmol/L or 55nmol/L doses of epinephrine for 2 or 6 hours. The intracellular and secreted expression of MMPs was determined by zymography and AMPK expression was examined by immune blotting. Intracellular MMP-3 expression was increased in muscle cells by both the high and low doses of epinephrine at longer (6 hour) treatment times. Intracellular MMP-2 and MMP-13 expression were also amplified by the lower dose, longer time epinephrine treatment in the myoblasts. AMPK expression was elevated only at the shorter treatment time at both epinephrine dose levels and in both cell lines. At the higher epinephrine dose level only and at short incubation times, fibroblasts also show transient expressions of MMP-2 and −13.

The time-course of MMP expression from muscle cells is not well correlated to the time-course of AMPK activity. Fibroblasts respond only to the higher level of epinephrine and on a much shorter timescale, better correlated to AMPK activity.

Key Words: muscle, proteolysis, collagen

T170 Measurement of purge protein composition as an indicator of beef tenderness. B. C. Bowker*, J. S. Eastridge, and E. W. Paroczay, *USDA-ARS*, *Beltsville, MD*.

The objective of this study is to determine if the protein composition of the purge moisture collected from vacuum-packaged beef can be used as a potential indicator of meat tenderness. Frozen beef striploins (n = 12) were each divided into 3 sections which were thawed, vacuum packaged, and aged at refrigerated temperatures. After 0, 7, and 14 d of aging, purge moisture was collected from the vacuum packages and analyzed for protein content using a biuret assay and protein composition using SDS-PAGE. Steaks were also removed at 0, 7, and 14 d of aging for Warner-Bratzler shear force (WBS) determination. With aging from 0 to 14 d, WBS decreased ($P < 0.0001$) from 5.8 to 3.4 kg shear force. Purge losses at d 7 and 14 were 5.8% and 8.4%, respectively. The amount of purge loss between 0 and 14 d was significantly correlated (r = −0.3707) to the decrease in WBS from d 0 to 14. The protein content of the purge moisture collected after 0, 7, and 14 d was similar, however, the protein composition of the purge changed with aging. SDS-PAGE analysis of collected purge samples demonstrated that 10 protein bands increased ($P < 0.05$) in relative abundance with aging and 4 protein bands decreased ($P < 0.01$) with aging. The relative abundance of 5 protein bands, ranging from 65 to > 250 kDa, were negatively correlated to WBS (r = −0.5072 to −0.6759). The relative abundance of the 45 and 38 kDa protein bands were positively correlated to WBS (r = 0.5700 and 0.6215, respectively). Furthermore, the relative abundance of the 45 kDa protein band measured in the purge moisture collected at d 0 was significantly correlated to WBS at d 14 (r = 0.7692). While these data do not indicate a cause and effect relationship between sarcoplasmic proteins and tenderness, the data suggest that purge protein composition may be an indirect indicator of WBS and that the water-soluble protein fraction of beef muscle may be useful in the development of rapid, non-invasive methodologies for predicting beef tenderness.

Key Words: beef tenderness, purge, protein composition

T171 Effect of oxidative stress on collagen turnover by bovine intramuscular fibroblasts. A. C. Archile*[2,1], S. P. Miller[1], I. B. Mandell[1], M. C. Cha[1], and P. P. Purslow[1], [1]*University of Guelph*, *Ontario, Canada*, [2]*University of Zulia*, *Maracaibo, Venezuela*.

Intramuscular collagen is responsible for the background toughness in cattle. Vitamins E and C may increase collagen turnover, but handling of cattle may reduce vitamin concentrations in muscles, impeding the removal of reactive oxygen species (ROS) and leading to what is known as oxidative stress. Fibroblasts synthesize collagen and regulate its turnover by the production of matrix metalloproteinases (MMPs) responsible for collagen degradation. The aim of this work was to study the effect of oxidative stress on the ability of intramuscular fibroblasts to turnover old collagen and synthesize new collagen. Fibroblasts were isolated from *longissimus dorsi* (LD) and *semitendinosus* (ST) muscles from a yearling animal and grown in DMEM, 10% serum, 5% CO_2. Fibroblasts were treated for 24 h with 1) 0.1 or 0.01 mU/mL xanthine oxidase /500 μ*M* xanthine (X/XO), and 2) 0.5 or 5 μ*M* of hydrogen peroxide (H_2O_2). Control group cells received no treatment. MMP-2 activity secreted into the media was analyzed by gelatin zymography. Total collagen synthesis (TC) in cell lysates was measured using the collagen Sircol assay. Analysis included 2-way ANOVA, Fisher's LSD and Pearson bivariate correlation. There was a different pattern in the response of fibroblasts from the 2 muscles to ROS. Concentrations of 0.01 mU/mL X/XO and 5 μ*M* H_2O_2 induced ($P < 0.05$) the activation of MMP-2 in LD cells, while for ST cells no effect was observed for any treatment. No effect was observed in the inactive Pro-MMP-2 precursor levels for any muscle and treatment. In general, ROS slightly lowered TC, more so in LD-derived cells than in ST cells. No relation ($P > 0.05$) between Pro-MMP-2 and TC was found for cells from either muscle, while for LD cells, MMP-2 activity showed a negative correlation ($P < 0.05$) with respect to TC. Oxidative stress may decrease net collagen turnover in intramuscular fibroblasts and this could lead to decreased collagen solubility in some muscles. Thus, oxidative stress is an environmental/dietary factor that might affect meat quality.

Key Words: oxidative stress, collagen turnover, meat quality

T172 Phenotypic differences in MMP activity between fibroblasts from three beef muscles. A. C. Archile*[2,1], M. C. Cha[1], and P. P. Purslow[1], [1]*University of Guelph*, *Ontario, Canada*, [2]*University of Zulia*, *Maracaibo, Venezuela*.

It has been found that muscles from the same beef carcass may respond differently to the same stimulus. This might cause difficulties when looking for a production system to render meat tender. The aim of this work was to study phenotypic differences in the expression of matrix metalloproteinases (MMP) among intramuscular fibroblasts from 3 beef skeletal muscles. To our knowledge intramuscular fibroblasts from beef animals have not previously been characterized. Fibroblasts were isolated from *longissimus dorsi* (LD), *semitendinosus* (ST) and *sternomandibularis* (SMD) muscles from a yearling animal and grown in DMEM + 10% FCS. All cultures were serially sub-cultured and cell behavior studied from passages 1 to 15. Cell lifespan and doubling times were evaluated for each cell line. After reaching 80% confluence, cells were supplied with fresh DMEM for 24 h. Then, media were collected and analyzed for MMP-2 activity by zymography. Data were analyzed by 2-way ANOVA and Fisher's LSD. At all passages, LD-derived cells had the largest ($P < 0.0001$) doubling time in comparison to SMD and ST; cells from these last 2 muscles also differed significantly ($P < 0.001$). Cultures derived from ST displayed longer ($P < 0.05$) lifespan compared with cells from the other muscles. Cells from ST presented higher ($P < 0.0001$) levels of active MMP-2 in comparison to LD and SDM, which were also different ($P < 0.0001$) from each other. No statistical differences ($P > 0.05$) in pro-MMP-2 expression were found between any cell lines; however, the total expression of this enzyme was higher for ST. These results suggest that fibroblasts from different locations are phenotypically different and so may respond differently to the same growth or nutrition stimulus in vivo, causing differences in accumulation and maturity of collagen, and hence its degree of turnover, which may affect meat tenderness. These findings are of significance when selecting a strategy for improving meat tenderness by manipulation of animal growth, as a strategy applied to the whole animal may work for some muscles but not for others.

Key Words: fibroblast heterogeneity, collagen turnover, matrix metalloproteinases

T173 Myofibril fragmentation index of the longissimus muscle of Senepol and Charolais crossbred bulls. L. del Valle-Mercado*, A. Casas, D. Cianzio, M. Pagan, and G. Ortiz-Colón, *University of Puerto Rico*, *Mayaguez, Puerto Rico, United States*.

The objective of this experiment was to determine whether there was a difference in the Myofibril Fragmentation Index (MFI) of longissimus muscle (LM) samples obtained from Senepol (n = 12) and Charolais (n = 14) crossbred bulls. Calves were weaned at 9 mo (266.5 kg) and then raised under grazing conditions until harvest at 22 mo (499.6 kg). From each bull 2 LM subsamples were cut in 1 cm^2 pieces and homogenized using a Polytron PT1600E homogenizer (30,000 rpm) in cold (4°C)

homogenizing buffer (100 m*M* KCl; 7 m*M* KH_2PO_4; 18 m*M* K_2HPO_4 ; 1 m*M* EDTA; 1 m*M* NaN_3 [pH 7.0]). The Biuret reagent assay was use to determine LM homogenates protein concentrations. All muscle homogenates were diluted to a constant protein concentration of 0.5 mg/mL of homogenization buffer. Subsequently, the absorbance of each LM homogenate was determined at a specified wavelength of 540 nm (Thermo Spectronic Genesys). Absorbance results were multiplied by 200 to determine MFI values. The obtained MFI values were different among crossbreds ($P = 0.012$). Senepol crossbred bulls showed MFI values of 43.89 (SE 4.52) while Charolais crossbred bulls showed MFI values of 30.09 (SE 2.77). Because previous studies have associated higher MFI values with more tender meat, our data suggests that Senepol crossbred bulls might have more tender meat than Charolais crossbred bulls.

Key Words: beef tenderness, MFI, Senepol

T174 Effect of brine enhancement and mechanical tenderization on consumer sensory characteristics of cow semimembranosus steaks. J. M. Popowski*, R. B. Cox, T. J. McNamara, and P. Nelson, *University of Minnesota, Twin Cities*, *St. Paul*.

The purpose of this research was to evaluate the effect of brine enhancement by means of mechanical tenderization on an underutilized cut from the dairy cow carcass. Additionally considered was a comparison of enhanced and tenderized dairy cow beef to traditional fed beef. Beef was evaluated from both dairy cull (CUL) carcasses and fed (FED) beef carcasses. Processing treatments included a control (CON) and a brine enhancement by means of mechanical tenderization (BRN) of the semimembranosus muscle. Beef semimembranosus from both CUL and FED beef carcasses were obtained from the University of Minnesota Meat Laboratory and cut into roasts (60 roasts, 5 per each of 3 replications, approximately 1kg each). FED and CUL roasts were then randomly assigned to CON and BRN treatments. BRN roasts were placed in a commercial meat tumbler with 15% (w/w) brine (water and sodium tripolyphosphate) to create an enhanced roast with a phosphate level of 0.2%. Roasts and brine were tumbled for 30 min. BRN and CON roasts were then individually vacuum packaged and allowed to equilibrate at 4°C for 24 h before being cut into steaks (2.54 cm thick), individually vacuum packed, and frozen (−20°C) until further use. Steaks were thawed at 4°C for 36 h and cooked in an electric oven (180°C) to an internal temperature of 71°C. Each cooked steak was then cut into cubes (1cm –1cm – 1 cm). Sensory evaluation was carried out by an untrained consumer panel. One–hundred–12 consumers rated overall liking, flavor liking, texture liking, off-flavor, juiciness, and toughness of sample from all treatments and replications. BRN scores were higher than CON for overall liking ($P < 0.001$), flavor liking ($P = 0.002$), and texture liking ($P < 0.001$) for CUL steaks, but not FED. BRN scores were lower than CON for juiciness ($P = 0.001$) and off-flavor intensity ($P = 0.01$) in CUL steaks, but not FED. Overall liking ($P < 0.001$) and texture ($P < 0.001$) scores were higher for FED steaks compared with CUL. Results indicate there may be potential to market whole-muscle products from the cow round with mechanical tenderization and enhancement.

Key Words: beef, cull, enhancement

T175 Fatty acid composition including *cis*-9, *trans*-11 CLA of cooked ground lamb. G. Davila-El Rassi*[1], V. Banskalieva[1], and M. Brown[2], [1]*R. M. Kerr Food and Agricultural Products Center, Oklahoma State University*, *Stillwater,* [2]*USDA-ARS, Grazinglands Research Laboratory*, *El Reno, OK*.

Little information is available on effect of cooking on health-promoting fatty acids (FA) such as *cis*-9, *trans*-11 conjugated linoleic acid (CLA) and ω-3 polyunsaturated fatty acids (PUFA). The objective of this study was to examine the impact of broiling per se on the FA composition of ground lamb of 2 different muscles with special emphasis on CLA. Samples were prepared from trimmed, ground steaks of m. *Longissimus lumborum* (LL) and m. *Semimembranosus* (SM) from forage-fed Suffolk × Katahdin lambs. Patties were broiled in a conventional oven, at 205°C, for 6.15 min on each side to internal temperature of 71°C. Raw and cooked patties were subjected to proximate and FA analyses. Data were analyzed by mixed model procedures with linear models including fixed effects of treatment (raw vs. cooked, subunit), muscle type (sub-subunit) and treatment by muscle type. After broiling fat content increased from 2.83 to 4.98% ($P < 0.001$), and from 3.89 to 6.04% ($P < 0.001$), respectively for SM and LL patties, whereas no changes in levels of total saturated, monounsaturated and polyunsaturated FA were observed for either muscle type. No treatment differences were found in percent CLA (0.53–0.58%, raw vs. cooked) or CLA as mg/g fat in SM (6.45–6.72, raw vs. cooked) and in LL (6.2–5.9, raw vs. cooked) patties. However, content of CLA as mg/100 g of cooked lamb increased from 18.1 (raw) to 33.2 ($P < 0.01$) and from 24.05 (raw) to 35.8 ($P < 0.001$), respectively for SM and LL patties. Average over muscles, a trend ($P < 0.1$) for lower proportion of vaccenic acid in cooked (1.64%) vs. raw meat (2.15%) was observed. The ratio ω-6 PUFA/ω-3 PUFA slightly increased from 5.7 (raw) to 6.0 (cooked) ($P < 0.01$) and from 5.8 (raw) to 6.1 (cooked) ($P < 0.01$), respectively for SM and LL patties. Results imply that broiling did not cause thermal degradation of CLA levels and that a serving portion (100g) of cooked lamb provides over 34 mg of CLA. Despite the small changes of ω-6 PUFA/ω-3 PUFA ratio broiling could be considered as a method preserving the nutritional value of lamb.

Key Words: lamb, cooking, fatty acids

T176 Effects of maternal metabolizable protein supplementation during late gestation on ovine fetal muscle calpain and calpastatin activities. J. D. Magolski*[1], W. L. Keller[1], T. M. Jeske[1], C. A. Schwartz[1], L. A. Lekatz[1], J. D. Kirsch[1], C. S. Schauer[2], K. A. Vonnahme[1], and K. R. Maddock-Carlin[1], [1]*North Dakota State University*, *Fargo*, [2]*Hettinger Research Experiment Center*, *Hettinger, ND*.

To investigate the effects of maternal supplementation of MP during late gestation on calpain and calpastatin activities in fetal muscle, multiparous ewes (n = 30) were randomized to receive 75% (LOW), 100% (CON), or 125% (HIGH) of MP requirements from d 100 until d 130 of gestation. On d 130, ewes were slaughtered, and fetuses were necropsied. Longissimus thoracis (LT) and semimembranosus (SM) were collected (20 g) and analyzed for calpastatin activity by casein assay and calpain activity by casein zymograms. μ-Calpain autolysis was evaluated by Western blotting. Ewes carried singletons and twins; however, only singletons were analyzed. Calpastatin activity did not differ ($P \geq 0.21$) among treatments. Casein zymograms showed no treatment differences ($P \geq 0.80$) for μ-calpain or m-calpain activities. Autolysis of μ-calpain in the SM was greater in the HIGH group compared with that in the CON group as indicated by smaller percentage of the ($P = 0.01$) 80 kDa band. Calpastatin activity and specific activity were greater ($P < 0.01$) in the LT (4.02 units/mL ± 0.10; 58.48 units/mg ± 1.51) than in the SM (3.31 units/mL ± 0.10; 47.07 units/mg ± 1.51). Additionally, autolysis was occurring at a greater ($P < 0.01$) extent in the SM than in the LT as indicated by the disappearance of the 80 kDa band (21.72 vs. 27.51 ± 1.84) and the accumulation of the 76 kDa autolysis product (46.27 vs. 39.77 ± 1.66). Therefore, maternal supplementation of MP

during late gestation did not affect calpastatin activities in fetal skeletal muscle, but increased μ-calpain autolysis in HIGH compared with CON may indicate differences in protein accretion. However, there were differences in calpain and calpastatin activities between muscles during late gestation with the LT having greater calpastatin activity and less μ-calpain autolysis, possibly indicating a difference in rate of protein accretion between muscles.

Key Words: fetal muscle, metabolizable protein, calpain

T177 Hyperplastic muscle growth occurs from birth to weaning in pigs. J. M. R. López[1], C. Pardo[2], and G. Bee*[2], [1]*Unidad de nutrición animal, Estación Experimental del Zaidín (CSIC)*, *Granada, Spain*, [2]*Agroscope Liebefeld Posieux, Research station ALP*, *Posieux, Switzerland*.

Pig myogenesis is a biphasic phenomenon with the sequential formation of 2 generations of fibers termed primary (P) and secondary (S) fibers. Currently, it is believed that total number of fibers (TNF) is fixed at birth. However, there are indications that at birth between P and S fibers very-small diameter fibers containing embryonic and fetal myosin heavy chain isoforms exist. They represent a different population of myotubes, designated tertiary myotubes and might contribute to hyperplastic growth after birth. The goal of this study was to establish if TNF remains constant from birth to weaning. For the trial 8 pairs of Swiss Large White female littermates with a similar birth weight (1.41 ± 0.113 kg; $P = 0.82$) were used. One piglet of each pair was sacrificed either at birth or at weaning at d 28 of age (BW: 6.93 ± 0.527 kg). Subsequently, internal organs and the semitendinosus (ST) muscles were collected and weighed. Histological analyses were performed on the ST using the mATPase staining procedure after pre-incubation at pH 10.2. This allowed identifying the muscle cross-sectional area, TNF, number of P and S fibers and the S/P ratio of the dark (STD) and the TNF of the light (STL) portion of the ST. Relative to slaughter weight, the spleen and ST were 90 and 26% heavier ($P < 0.01$), respectively, whereas lungs, liver, heart and kidneys were 17, 16, 30 and 24% lighter ($P < 0.06$) at weaning than at birth. From birth to d 28 of age TNF increased in the STD (151020 vs. 235191; $P < 0.01$) but not in the STL (395497 vs. 405836; $P = 0.83$). The increase resulted from both a greater number of P (4597 vs. 6605; $P < 0.01$) and S fibers (146423 vs. 228586; $P < 0.01$) with no changes in the S/P ratio (32 vs. 35; $P = 0.25$). Overall the TNF of the ST was only numerically greater (546517 vs. 641028; $P = 013$) in weaned than newborn piglets. This preliminary data suggest that the TNF of parts of muscles are not fixed at birth. Further studies needs to determine whether the potential of an increase in TNF can be already observed in the muscles of new born pigs and whether the development of these fibers can be stimulated during postnatal growth.

Key Words: muscle development, semitendinosus, pigs

T178 Relationship between average litter weight and intralitter weight variability on myogenesis in newborn piglets. C. Pardo[1,2], M. Kreuzer[2], and G. Bee*[1], [1]*Agroscope Liebefeld Posieux*, *Posieux, Switzerland*, [2]*ETH Zurich, Institute of Plant, Animal and Agroecosystem Sciences (IPAS)*, *Zurich, Switzerland*.

A high variability in total litter birth weight (BtW) has been reported in common litter sizes (10–15 piglets). Limitations in uterine efficiency may affect the development not only of low BtW piglets but also that of the entire litter. The aim of this study was to elucidate the relationship between average litter BtW and intra-litter variability on semitendinosus (ST) development in newborn piglets and postnatal growth from birth to weaning. From multiparous sows, 7 litters with a high (H: > 1.7 kg) and 7 litters with a low (L: < 1.3 kg) average litter BtW were selected. At farrowing 2 females/litter were sacrificed: from H-sows those with the medium (HM) and lowest (HL) BtW and from the L-sows those with the medium (LM) and highest (LH) BtW. The mATPase staining after pre-incubation at pH 4.3 or 10.2 was used to identify muscle cross-sectional area (CSA), total number of fibers (TNF), number of primary and secondary fibers of the dark and light (STL) portion of the ST. ADG during lactation and BW at weaning of the remaining piglets were determined for each gender. Data were analyzed with PROC MIXED using BtW groups as fixed factor. Three contrasts were established: HM vs. LM and LH, respectively, and HL vs. LH. For H- and L-sows the realized average litter weight/piglet was 1.74 and 1.23 kg (13.3 and 14.8 piglets/litter, respectively). Compared with H-sows, female piglets from L-sows grew slower (236 vs. 293 g/d; $P < 0.01$) and were lighter at weaning (8.54 vs. 10.34 kg; $P < 0.04$). At birth HM-piglets were heavier than LM- and LH-piglets (1.73 vs. 1.27 and 1.57 kg; $P < 0.07$) whereas BtW was similar in HL- and LH-progeny (1.42 vs. 1.57 kg; $P < 0.15$). The STL and by that the ST from HM piglets was larger (CSA: STL = 58 vs. 44 mm^2; ST = 85 vs. 67 mm^2; $P \leq 0.05$) and tended to have more TNF (STL = 380 vs. 308 × 10^3; ST = 540 vs. 467 × 10^3; $P < 0.10$) than LM-piglets. In conclusion, low gestation efficiency resulting in a lower total litter weight not only affects the development of low but also of medium BtW offspring. Interestingly, female but not male progeny from L-sows grew slower during lactation than those from H-sows.

Key Words: birth weight variation, myogenesis, litter weight

T179 Influence of genotype and slaughter weight on carcass and meat quality of Iberian pigs. M. Sánchez*[1], J. Viguera[1], M. I. Gracia[1], J. Peinado[1], A. Robina[2], and J. Ruiz[2], [1]*Imasde Agroalimentaria S.L.*, *Madrid, Spain*, [2]*Universidad de Extremadura*, *Cáceres, Spain*.

A total of 48 pigs (50% castrated males and 50% castrated females) were used to evaluate 2 different genotypes: Duroc1 × Iberian (DR1×IBE) and Duroc2 × Iberian (DR2×IBE) and 2 slaughter weights: 145 and 155 kg BW on carcass traits, composition and color of meat, and fatty acid profile of subcutaneous fat. Data were analyzed as a completely randomized design using PROC GLM of SAS. The model included the terminal sire genotype and slaughter weight as main effects. DR1×IBE pigs showed higher backfat thickness than DR2×IBE pigs (52.7 vs. 46.3 mm; $P < 0.05$). However, no ($P > 0.05$) differences between genotypes were found for carcass, ham, shoulder and loin yields, in the composition or the color of meat and the fatty acid profile of the subcutaneous fat. As expected, pigs slaughtered at 155 kg BW had greater backfat thickness (53.7 vs. 45.3 mm; $P < 0.01$) and carcass yield (81.52 vs. 79.80%; $P < 0.01$), but lower ham and shoulder yields (17.95 vs. 19.16% and 11.64 vs. 12.37%, respectively; $P < 0.01$) than pigs slaughtered at 145 kg BW. Loins from heavier pigs tended to have higher redness value (10.05 vs. 9.26; $P = 0.07$) than lighter pigs, but no differences were observed in lightness and yellowness of loin. Finally, the increase in slaughter weight decreased the level of saturated fatty acids (33.78 vs. 32.14%; $P < 0.01$) and increased that of the monounsaturated fatty acids (54.29 vs. 55.68%; $P < 0.01$) in the subcutaneous fat. Our data indicate that an increase in the slaughter weight of Iberian pigs from 145 to 155 kg BW improved carcass yield and positively altered the fatty acid profile toward a more unsaturated subcutaneous fat.

Key Words: Iberian pig, carcass traits, fatty acid profile

T180 Effect of birth parity and sex on carcass traits and meat quality characteristics in crossbred pigs. G. D. Kim*[1], J. Y. Jeong[2], K. Y. Seo[1], E. Y. Jung[1], H. S. Yang[1], and S. T. Joo[1], [1]*Division of Applied*

Life Science (BK21 Program), Graduate School of Gyeongsang National University, Jinju, Gyeongnam 660-701, Republic of Korea, [2]*Swine Scientic Technique Center, Jinju National University, Jinju 660-758, Republic of Korea*.

The effect of birth parity and sex on carcass traits and meat quality characteristics were studied on crossbred (Landrace × Korean native pig) pigs, with age ranging between 182 and 195 d. 182 males and 158 females of pigs from 3 different birth parities were investigated. The females and third parity pigs grew slower than males and first or second parity pigs. However, there are no significant ($P > 0.05$) differences in carcass weight (kg) among the different sexes and birth parities. Backfat thickness (mm) at 3 points (4th-5th thoracic vertebrae, 11th-12th thoracic vertebrae and vertebrae thoracic-lumber vertebrae) were higher in females (33.8, 29.3, and 27.0mm, respectively) than in males (31.1, 24.8, and 22.6mm, respectively) ($P < 0.01$). The third parity pigs had higher loin eye area (22.10cm2) and lower backfat thickness (30.16mm) at 4th-5th thoracic vertebrae than the others ($P < 0.05$). The males and third parity pigs had higher pH value (5.83) at 24h postmortem ($P < 0.05$). Lightness (L* value) and yellowness (b* value), intramuscular fat content (%), and sarcomere length (Î1/4m) were higher in females than in males, while moisture content (%) was higher in males ($P < 0.05$). Intramuscular fat content (3.41%), redness (a* value, 7.97) and yellowness (b* value, 3.30) were higher in third parity pigs than in the other parities, however, moisture content (73.22%) and drip loss (1.09%) were lower in third parity pigs ($P < 0.05$). The results suggest that females and third parity pigs which exhibited the lowest growth performance, have higher fat content and lower moisture content.

Key Words: birth parity, sex, crossbred pig

T181 Carcass quality of pigs vaccinated against gonadotropin releasing factor compared to surgically castrated males and gilts from two different sire lines. J. I. Morales[1], M. P. Serrano*[2], L. Cámara[2], J. D. Berrocoso[2], J. P. López[1], and G. G. Mateos[1], [1]*Copiso S.A.*, *Soria, Spain*, [2]*Universidad Politécnica de Madrid*, *Madrid, Spain*.

A total of 360 pigs was used to study the influence of gender (immunocastrated males, IM; surgically castrated males, CM; intact females, IF) and terminal sire line (Top York; Tempo) on carcass and meat quality of pigs slaughtered at 125 kg BW. The female line used was Large White × Landrace in all cases. The IM pigs received 2 doses of Improvac (76 and 124 d of age, 7 wk before slaughter). Backfat thickness (BF) was measured the day of slaughter in live pigs, using an ultrasound scanner, and postmortem, using a flexible ruler. Meat samples were taken at m. *Longissimus dorsi* and analyzed by NIR. Treatments were arranged factorially (3 × 2) with 6 replicates (10 pigs/pen) per treatment. The IM pigs had less carcass yield than IF and CM (77.2 vs. 79.1 and 78.7%; $P < 0.001$). Also, IM and IF had less BF than CM ($P < 0.001$) when measured by ultrasound scanner or after slaughter. The correlation coefficient between the in vivo and the postmortem methods was $r = 73\%$ ($P < 0.001$). Fresh (14.8 vs. 14.6 vs. 14.5%) and trimmed (13.2 vs. 13.0 vs. 12.9%) ham yields were higher for IF than for CM with IM being intermediate ($P < 0.05$). Also, IF had higher loin yield than IM and CM ($P < 0.01$). Meat from IM and CM had more intramuscular fat (3.93 and 4.03 vs. 3.52%; $P < 0.01$) than meat from IF. No differences between sire lines were observed for carcass yield, BF or pH_{24}. Crossbreds from Top York presented higher fresh (14.8 vs. 14.5%; $P < 0.05$) and trimmed (13.2 vs. 13.0%; $P < 0.05$) ham yield but lower loin yield ($P < 0.01$) than crossbreds from Tempo. Meat from Tempo crossbreds had more intramuscular fat content than meat from Top York crossbreds (4.01 vs. 3.64%; $P < 0.01$). We conclude that IM and CM present similar values for carcass and meat quality traits. Crossbreds with Top York sire line had better carcass quality but poorer meat quality than crossbreds of Tempo sire line.

Key Words: immunocastration, gender, sire line

T182 The influence of cage housing system and laying hen strain on breast meat quality traits. K. Juurlink*[1], A. McMillan[1], R. Ofori[1], B. Rathgeber[2], and M. Jendral[1], [1]*Nova Scotia Agricultural College*, *Truro, Nova Scotia, Canada*, [2]*Agriculture Agri-Food Canada*, *Truro, Nova Scotia, Canada*.

The influence of cage housing system and laying hen strain on breast meat quality traits was determined for 3 strains of laying hens (Shaver White (SW), Lohmann Lite (LL), Lohmann Brown (LB)) housed in conventional cages, and furnished colony units, and processed under commercial conditions. During the laying period, hens were either housed in conventional battery (CONV) (60 cm × 55 cm) (n = 24 cages per strain; 5 hens per cage) or furnished colony cages (COL) (240 cm × 110 cm) (n = 12; 4 per strain; 40 hens per cage). COL contained a nestbox (60 cm × 55 cm), 3 hardwood, semi-circular perches (240 cm × 5 cm) and a dustbathing facility (60 cm × 20 cm). Hens were slaughtered at 80 weeks and 25 hens per colony cage, and all 5 hens in 9 conventional cages per strain were randomly selected for 17 and 30 min postmortem determination of right breast (pectoralis major) pH and color (lightness (L*), redness (a*) and yellowness), respectively. At 24 h post mortem, left breast (pectoralis major) samples were collected from the same hens to determine shear force values. Data were analyzed using the Mixed model of SAS with significance accepted at $P \leq 0.05$. Breast meat was paler in color in CONV than COL (51.69 vs. 56.72; $P = 0.02$). In Col, LL and LB hens exhibited higher redness values than SH hens (5.99 and 5.12 vs. 2.73; $P = 0.01$). These results suggest that breast meat color may be affected by bird movement in different housing systems, and by genotype.

Key Words: laying hen, furnished cages, meat quality

T183 Effect of ultimate pH on the chemical properties of proteins in turkey breast meat. J. Chan*, D. A. Omana, and M. Betti, *University of Alberta*, *Edmonton, AB, Canada*.

A major challenge facing the turkey industry is the increasing occurrences of pale, soft, exudative (PSE)-like meat. PSE-like meat results in paler color and reduced protein functionality. In contrast, dark, firm, dry (DFD)-like meat results in darker color and shorter shelf life. Hence, the objective of this study was to determine the chemical properties of proteins in turkey breast with different ultimate pH at 24 h postmortem (pH_{24}) so as to improve utilization of these types of meat. Turkey breasts from Hybrid Toms were collected from a local processing plant at 24 h postmortem. Sixteen breasts for each class (pale, normal, dark) were selected based on lightness (L*) values. Further selection of 8 breasts from each class was made based on pH_{24}. Samples were within values: pale (L*>51, pH<5.7), normal (46< L* <51, 5.9< pH <6.0), and dark (L*<46, pH>6.3) and referred to as low, normal, and high pH meat, respectively. Analyses were conducted on fresh minced samples. Data were analyzed using analysis of variance and means were separated using Tukey's HSD. The extent of myosin denaturation was similar as a function of pH_{24} as revealed by Ca^{2+}- ATPase enzyme activity. Total and sarcoplasmic (SP) protein solubility was significantly (P<0.0001) higher in high pH meat. SP protein hydrophobicity (Ho) showed only marginal changes as a function of pH_{24}. However, high pH meat showed significantly (P<0.05) higher myofibrillar protein Ho and reactive sulfhydryl groups compared to low pH meat indicating lesser degree of protein denaturation. The difference in pH_{24} had no significant effect on

total sulfhydryl groups. Protein oxidation was not evident as a function of pH_{24} as shown by carbonyl content. In conclusion, low and normal pH meat showed similar chemical properties whereas high pH meat was found to have higher solubility and hence expected to have better functional properties. Thorough understanding of these properties will assist industry in developing strategies to improve meat quality and protein functionality, thus preventing yield losses.

Key Words: pale, dark, pH, chemical properties, turkey

T184 The effect of turkey breast meat pH on fatty acid profile of polar lipids and susceptibility to oxidation. P. K. Hong*, J. Chan, D. A. Omana, and M. Betti, *University of Alberta*, *Edmonton, AB, Canada*.

High prevalence of PSE-like turkey meat is one of the major challenges for meat processors. However, there are limited studies on the muscle membrane fatty acid content and its oxidative stability in turkey meat with different pH. In this study, fatty acid profile and lipid oxidation level in polar lipid of turkey (Hybrid Tom) breast meat were investigated. Initially, 3 groups (pale, normal & dark) of turkey breasts (16 pieces each) were screened in a local processing plant at 24 h postmortem based on lightness (L*). Eight breasts from each were further selected based on the following criteria: pale (L*>51, pH<5.7), normal (46< L* <51, 5.9< pH <6.0) and dark (L*<46, pH>6.3) and were referred as low (LpH), normal (NpH) and high (HpH) pH meat respectively. All samples were minced and stored at 4°C until use. Total fat was first extracted by the Folch method; polar lipid was separated by silica gel column followed by gas chromatography detection. Lipid oxidation in turkey meat was determined by induced thiobarbituric acid reactive substance (TBARS) values, expressed as nmol malondialdehyde/mg protein (MDA). Data were analyzed using One-way ANOVA test and means were separated by Tukey′s HSD. Results showed that polar lipid from each group differed in the fatty acid composition as they were influenced by meat pH. LpH polar lipid had significantly lower levels of polyunsaturated fatty acids (PUFA) ($P < 0.01$), particularly linoleic acid (C18:2n-6) ($P < 0.001$), total n-3 ($P < 0.05$) and total n-6 fatty acids ($P < 0.05$). For HpH, the highest PUFA level ($P < 0.01$) including total n-3 ($P < 0.05$) and n-6 fatty acids ($P < 0.05$) content were recorded. The TBARS value in LpH meat confirmed that lipid oxidation level was the lowest among the three turkey meat groups (0.17-0.37), followed by HpH (0.24-0.51) and NpH (0.32-0.85). In conclusion, low levels of polyunsaturated fatty acids were found in LpH meat. Our results indicated that different meat pH values are more than a function of short-term antemortem stress.

Key Words: turkey, pH, fatty acid, TBARS, lipid oxidation

T185 Exploring the biochemical basis of dfd in broiler breast and thigh meat. S. Dadgar*[1], H. L. Classen[2], T. G. Crowe[3], and P. J. Shand[1], [1]*Department of Food and Bioproduct Sciences*, [2]*Department of Animal and Poultry Sciences*, [3]*Department of Agricultural and Bioresource Engineering*, *Saskatoon, SK, Canada*.

The effect of acute cold exposure on muscle energy reserve at slaughter and its relation to post-mortem glycolysis and the incidence of dark, firm and dry (DFD) breast and thigh meat was investigated. Male broilers (160) were exposed to temperatures of −9 to −15 (cold-stressed; CS), or +20°C (control) for 3 h before slaughter. Glycolytic potential (GP) and pH of breast and thigh muscles were determined at different times post-mortem from selected birds. Activity of adenosine monophosphate-activated protein kinase (AMPK) in breast meat was assessed at 0 min post-mortem. Color, water binding capacity (WBC) and processing cook yield (PCY) were measured. Data were analyzed using ANOVA option of the GLM procedure of SAS. Classification of breast and thigh meats were based on ultimate pH (pH_u) and lightness (L*): normal breast ($pH_u < 6.1$, L* > 46) and thigh ($pH_u < 6.4$, L* > 44); DFD breast ($pH_u > 6.1$, L* < 46) and thigh ($pH_u > 6.4$, L* < 44). The total AMPK was similar for normal and DFD breast, but phosphorylated AMPK, indicative of its activity, could not be detected. DFD breast meat was darker, higher in pH_u, WBC and PCY ($P < 0.05$ for each), but not ($P > 0.05$) different in initial pH compared with normal meat. DFD thigh meat had higher ($P < 0.05$) initial and ultimate pH, and darker color compared with normal meat. Energy reserve at slaughter (GP) was almost exhausted in DFD (15 μmol/g) compared with normal (76 μmol/g) thigh meat, suggesting lack of substrate availability resulted in DFD thigh meat. However, GP was lower in DFD breast of CS birds (67 μmol/g) compared with DFD meat of control birds (87 μmol/g), which was not significantly ($P < 0.05$) different from normal meat of CS and control birds (92 and 102 μmol/g respectively), indicating that incomplete post-mortem glycolysis may contribute to DFD in breast meat. Thigh and breast meat from CS birds showed a higher incidence of DFD than that of control birds (85 and 42% versus 0 and 20%). GP for breast meat, but not for thigh meat, was time sensitive and showed some fluctuations over time post-mortem. In addition, GP was more highly correlated to changes in meat quality of thigh than breast meat.

Key Words: broilers, meat, energy reserve, DFD, cold

T186 Comparison of four methods that measure hydroxyproline. H. L. Bruce* and A. Chan, *University of Alberta*, *Edmonton, Alberta, Canada*.

Hydroxyproline (HYP) is used to estimate collagen content of meat because it is unique to collagen, a protein associated with toughness. Neuman and Logan (1950)(NL) and Bergman and Loxley (1963)(BL) assays are popular HYP colorimetric methods and the BL assay has been modified by Parekh and Jung (1970)(PJ) and Edwards and O'Brien (1980)(EO) to decrease assay volume. Absorbance variability and stability of the BL, PJ and NL assays were compared in a randomized complete block design blocked by day with assay order randomized and balanced. Assays were performed 9 times using trans-4-HYP (Sigma Chemical Co., Oakville, Ontario) aqueous standards at 2.5, 5, 10, 20 and 40 μg HYP/mL. Absorbance of each standard was assessed 15, 30, 45, 60, 90, 120, 180 and 240 min after an initial 0 min reading using a Jasco V630 spectrometer. EO assay absorbance stability and variability were also compared with those of the BL assay in a second randomized complete block design experiment identical to the first except that each assay was performed 8 times. For each experiment, assay variability was inferred from absorbance standard deviations calculated using PROC UNIVARIATE (SAS Version 9.2, SAS Institute Inc., Cary, North Carolina). Change in color stability was determined using repeated measures within PROC MIXED of the same software ($P < 0.05$). Sources of variations included assay, HYP concentration, time after initial assay reading and their 2- and 3-way interactions. Results showed that assay stability declined with time as HYP concentration increased. All assays except EO were stable for the first 90 min at HYP concentrations less than 10 μg/mL. At 20 μg HYP/mL, absorbance changed at 15, 30, 30 and 120 min for the NL, EO, PJ and BL assays, respectively. At 40 μg HYP/mL, absorbance was stable for 15 min in the BL assay only. The BL assay is most appropriate for high HYP concentration samples or assays with large sample numbers and prolonged measurement times.

Key Words: collagen, meat, hydroxyproline

Nonruminant Nutrition: DDGS

T187 Effect of the inclusion levels of DDGS to the feeds of broilers and glucanase, xylanase and phytase addition to low-energy DDGS-added diets. M. L. Angeles*[1] and S. Gómez[1,2], [1]*INIFAP, Ajuchitlán, Colón, Qro, México*, [2]*FESC-UNAM, Ajuchitlán, Colón, Qro. México*.

Three experiments were carried out to evaluate the growth performance and breast yield of broiler chickens fed diets with increasing levels of DDGS and the additions of different enzymes to compensate the energy reduction in DDGS-added diets. In all the experiments Ross B308 male broilers were individually fed. In Exp. 1, 96 broilers from 21 to 35 d of age were used and assigned to 8 treatments in a factorial combination of 2 diets based either on sorghum (S) or corn (C) and 4 increasing dietary levels of DDGS (0, 5, 10 and 15%). Diets were formulated to meet the nutrient requirements of grower broilers. In Exp. 2, 80 broilers from 35 to 49 d of age were used and assigned to the same treatments used in Experiment 1, but diets were formulated to meet the nutrient requirements of finisher broilers. In Exp. 3, 84 broilers from 32 to 49 d of age were used and assigned to 6 dietary treatments in a factorial combination of 2 cereals: S or C and 3 diets: 1) S or C plus soybean meal (SBM) and 3200 kcal of ME/kg, 2) S or C, SBM, 10% DDGS and 3200 kcal of ME/kg, and 3) S or C, SBM, 10% DDGS but reductions of 100 kcal of ME/kg, 0.12% Ca and 0.12% available P, and added with 200 ppm of phytase (Ronozyme-P [CT]), 175 ppm of glucanase (Ronozyme VP) and 175 ppm of xylanase (Ronozyme WX). In Exp. 1, the feed intake and weight gain were better when 10% DDGS was included in the diet. In Exp. 2, the weight gain, feed conversion and energetic efficiency were improved ($P < 0.01$) at each increment of DDGS in the diet; the best responses were observed for dietary levels of 10 and 15% DDGS. In Exp. 3, there was not any negative effect on the growth performance of broilers fed a low-energy, low-Ca and low-available P diet supplemented with phytase, glucanase and xylanase. In summary, 10% and between 10 and 15% of DDGS can be included in the diet of grower and finisher broilers, respectively, without any negative effect on the growth performance even in low-energy, Ca and P diets added with phytase, glucanase and xylanase enzymes

Key Words: broiler chickens, DDGS, enzymes

T188 High dietary inclusion of dried distillers grains with solubles in broiler rations—Production effects and yields. M. K. Masa'deh* and S. E. Scheideler, *University of Nebraska-Lincoln*, *Lincoln*.

A study was conducted to test the effects of feeding high levels of dried distillers grains with solubles (DDGS) in broiler chicks on body wt, feed intake, feed to gain ratio and parts yield. Ross x Ross broiler chicks were divided into 6 dietary treatments with different inclusion rates of DDGS (0, 10.0, 15.0, 20.0, 25.0 or 30.0%) from day-old to 50 d of age. All diets were formulated to be isocaloric and isonitrogenous and 3 phase-feeding diets were used, starter (0–14 d), grower (14–35 d), and finisher (35–50 d). Birds were assigned to 24 flour pens with total of 15 birds per pen with 4 replicate pens per treatment. Feed intake and body wt were recorded at 14, 35, and 50 d of age. At 53 d of age, 2 birds per pen were selected for whole carcass processing and parts yield. Birds were cut into 8 pieces to determine parts yield (breast, wing, drumstick, and thigh yields). Weight gain and feed intake were significantly different ($P < 0.05$) during the starter period between dietary treatments with the highest wt gain and feed intake for chicks fed 30% DDGS. However, no differences were observed ($P > 0.05$) during grower, finisher or the whole period between dietary treatments for weight gain and feed intake. Feed conversion ratio was not affected ($P > 0.05$) by level of DDGS during all periods. Dressing percentage was similar ($P > 0.05$) between levels of DDGS. Breast yield, wing yield and drumstick yield as percentage of live or carcass weight were not significantly ($P > 0.05$) different between levels of DDGS. Thigh yield as percent of live or carcass weight was different ($P < 0.05$) between levels of DDGS with the highest yield for broilers fed 25% DDGS. In summary, feeding DDGS at higher levels did not negatively affect chick wt, feed intake, feed conversion ratio, wt gain, mortality or dressing percentage compared with a basal diet. Percentage thigh yield was affected by levels of DDGS, while breast yield, wing yield, and drumstick yield were not influenced by DDGS. Feeding DDGS at 30% had an economical benefit with an average of $60/ton compare with basal diet (0% DDGS) when DDGS priced at $146/ton.

Key Words: DDGS, broiler, dressing percentage

T189 Effect of pellet quality on utilization of distillers dried grains with solubles (DDGS) in broiler diets. C. A. Coto*[1], C. Lu[1], Y. Min[1], A. J. Karimi[2], F. Yan[1], and P. W. Waldroup[1], [1]*University of Arkansas*, *Fayetteville,* [2]*University of Kurdistan*, *Kurdistan, Iran*.

DDGS can be used in broiler diets but at high levels a loss in performance is observed with much attributed to reduction in pellet quality. A study was conducted to evaluate different types of pellet binders in diets with addition of 25% DDGS, a level which provides a marginal but detectable reduction in performance. Dietary treatments consisted of a 2 × 4 factorial arrangement with 2 levels of DDGS and 4 levels of binder for a total of 8 treatments. Two basal diets were formulated to contain either 0% or 25% DDGS. The binder applications were as follows: No binder (fed as mash), No binder (fed as pellets), Pel-Stik (fed as pellets) and PellTech (fed as pellets). One-day old birds of a commercial strain were placed in floor pens with 35 birds per pen and 6 replicates per treatment. Pellet quality was determined by quantifying the amount of fines. Birds were weighed and feed consumption determined at d 14, 28 and 41 d. At d 41, 5 birds per pen were processed to determine dressing percentage and parts yield. The inclusion of 25% DDGS in the diet significantly increased the amount of fines in the diet. No significant effect of the binder applied in the diet was found for the amount of fines. The amount of fines in the finisher diet was significantly increased in the following order: No binder (mash) > PellTech > Pel-Stik > No binder (pellets). Birds fed pellets had BW and FCR than those fed mash diets. Birds fed 25% DDGS showed higher BW at d 28 with no difference during the remaining feeding stages. No difference among pellet binders was observed for BW at 41 d. An improved FCR at 28 and 41 d was observed when DDGS was included in the diet. The addition of Pelltech increased FCR at 41 d. A significantly higher mortality rate was observed when birds received diets containing 25% DDGS. The addition of 25% DDGS in the diet significantly reduced the dressing percentage, no other effect from the addition of DDGS was observed for yield. Birds receiving pellet diets regardless of the binder showed a significantly higher yield for breast, leg quarters and wings than birds receiving diets in the mash form.

Key Words: DDGS, broilers, pellets

T190 Effect of distillers dried grains with solubles and an enzyme supplement on performance and egg quality of brown egg layers. A. J. Pescatore*, P. Rossi, A. H. Cantor, J. L. Pierce, T. Ao,

L. M. Macalintal, M. J. Ford, W. D. King, and H. D. Gillespie, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington*.

Effects of diets containing 15 or 23% distillers dried grains with solubles (DDGS) with and without a naturally occurring enzyme complex (Allzyme SSF, Alltech Inc., Nicholasville, KY)was evaluated in brown egg laying hens. Egg production and egg quality was evaluated during 36 wk of production. At 17 wk of age, 420 Hy-Line Brown hens were randomly assigned to 5 treatments with 7 replicate groups of 12 hens each. Treatments consisted of feeding: 1) positive control (corn-soybean meal) formulated to be adequate in all nutrients 2) 15% DDGS, 3) 15% DDGS + enzymes, 4) 23% DDGS, and 5) 23% DDGS + enzymes. Diets containing DDGS had reduced levels of ME (2800 vs. 2877 Kcal/kg), Ca (4.1 vs. 4.2%) and available P (0.17% for 15% DDGS or 0.2% for 23% DDGS vs. 0.29%), compared with the control diet. Six eggs were collected from each replicate every 4 wk to determine egg quality. Feed intake was significantly ($P < 0.05$) decreased by DDGS during wks 5–8 and 17–20. Dietary treatment did not affect feed conversion. Allzyme SSF increased HDP during wks 21–24. Egg weight at wk 20 and yolk weight at wk 20 were decreased by DDGS. Percent yolk was not significantly affected by the addition of DDGS. The diet with 15% DDGS + enzyme increased albumen wt at Week 20. The diet with 23% DDGS + enzyme increased percent shell at wk 36 and shell breaking strength at wks 4, 32 and 36. Haugh unit values were significantly increased by DDGS at wks 16 and 28. Shell weight, percent shell, specific gravity and shell breaking strength were initially lower for DDGS diets at 4 wks of production. By 36 wks the addition of Allzyme SSF to the DDGS diets improved shell weight, percent shell, specific gravity and shell breaking strength. Hens fed 15 or 23% DDGS, +/− enzymes, had lower yolk lightness (L*). Hens fed 23% DDGS had higher yolk redness (a*) and yolk yellowness (b*) values vs. hens fed 15% DDGS or control diet. This study suggests that DDGS could be included to the diet up to 23% without negative effects on feed efficiency and can be used to improve yolk color. Using Allzyme SSF in DDGS diets increase shell quality and albumen weight.

Key Words: DDGS, shell strength, yolk color

T191 Feeding value of DDGS for pigs: Correlating in vitro dry matter digestibility and crude protein digestibility to its nutrient content and color. M. Rudar*, C. F. M. de Lange, I. B. Mandell, C. L. Zhu, and P. McEwen, *University of Guelph*, *Guelph, Ontario, Canada*.

Distillers dried grains with solubles (DDGS), a co-product of ethanol production, may be cost effective for supplying energy and protein in pig diets. However, concerns about the variation in digestible nutrient content of DDGS prevent more widespread use. Techniques to rapidly evaluate the feeding value of DDGS are necessary to properly formulate diets. The study was conducted to determine how the feeding value of DDGS can be estimated via product color, nutrient analysis, and in vitro digestibility assays. Seventy-two DDGS samples were collected from 6 corn-based ethanol plants (12 samples per plant collected over 3 mo) that supply DDGS to Ontario. Each sample was analyzed for dry matter (DM), crude protein (CP), fat, starch, NDF, ADF, acid detergent insoluble nitrogen (ADIN), ash, P, Na, K, Mg, S, and color (before and after grinding to < 1mm particle size) using the CIE, L* a* b* scale. Samples contained (mean ± SD, %): 26.6 ± 1.62 CP, 10.0 ± 0.75 fat, 2.9 ± 1.60 starch, 31.6 ± 2.47 NDF, 2.5 ± 1.13 ADIN, 0.8 ± 0.05 P, and 1.1 ± 0.08 K. Fecal DM and ileal CP digestibility values were determined using in vitro incubations with a series of porcine gastric, enteric, and hindgut enzymes. Step-wise regression analysis was carried out to correlate nutrient content and product color to in vitro DM and CP digestibility values, and to predict DM and CP digestibility. DM digestibility was predicted as $y = -0.43(L^*ground) + 88.03$ ($R^2 = 0.54$, $P < 0.0001$) while inclusion of P, K, starch, and CP improved R^2 to 0.78. CP digestibility was predicted as $y = -0.55(b^*) + 106.22$ ($R^2 = 0.49$, $P < 0.0001$) while inclusion of ADIN, CP, starch, and L* improved R^2 to 0.69. From the analyzed samples, b* was a better predictor of CP digestibility than L*. These models provide a rapid way to estimate the feeding value of DDGS from simple nutrient and color analyses, but relationships with in vivo measurements still need to be determined.

Key Words: DDGS feeding value, pigs, in vitro digestibility

T192 Substitution of sorghum and soybean meal by distillers dried grains with solubles in diets for fattening rabbits. H. Bernal-Barragán*[1,4], Y. Vázquez-Pedroso[2], M. Valdivie-Navarro[2], C. A. Hernández-Martínez[1], M. A. Cerrillo-Soto[3,4], A. S. Juárez-Reyes[3,4], and E. Gutiérrez-Ornelas[1,4], [1]*Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, México*, [2]*Instituto de Ciencia Animal*, *La Habana, Cuba*, [3]*Universidad Juárez del Estado de Durango*, *Durango, Durango, México*, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *Monterrey, Nuevo León, México*.

A trial was conducted to evaluate the partial substitution of sorghum grain and soybean meal by distillers dried grains with solubles (DDGS) in diets for fattening rabbits. Fifty-six 35-d old rabbits (Negro Azteca × Chinchilla) of both genders were allocated in cages, according to a complete randomized design, with 4 treatments (0, 10, 20 and 30% of DDGS in diet) and 7 replicates by treatment. Diets were isonitrogenous (17.4% CP) and isoenergetic (2.80 Mcal DE/kg) and were formulated to meet NRC rabbit requirements. Basal ingredients were alfalfa hay, ground sorghum grain, soybean meal and a commercial vitamin and mineral mix. Feed and water were offered ad libitum. At an age of 96 d viability was 100% and morbidity 0%. There were no differences ($P > 0.05$) among treatments at final weight (1914, 1961, 1853 and 1810 g), average daily gain (21, 22, 20 and 19 g/day), feed intake (93, 93, 92, and 98 g/day) and feed/gain ratios (4.51, 4.32, 4.64, and 5.24) for the 4 treatments, respectively. Carcass yield varied from 46.6 to 49.7% and was not different among treatments ($P > 0.05$). Meat content of carcass was lower ($P < 0.07$) and bone proportion was higher ($P < 0.07$) in rabbits fed 20% DDGS in the diet. Results indicate the possibility to include up to 30% DDGS in diets for fattening rabbits without affecting performance indicators. Effect of DDGS in carcass composition warrants further investigation.

Key Words: rabbits, DDGS, carcass traits

T193 Evaluation of in vitro procedures to measure digestibility of fiber in distillers dried grains with solubles. P. E. Urriola* and H. H. Stein, *University of Illinois*, *Urbana*.

Four experiments were conducted to develop and evaluate an assay for measuring in vitro digestibility of dietary fiber in distillers dried grains with solubles (DDGS). Exp. 1 was conducted to validate the 3-step in vitro digestibility assay (pepsin, pancreatin, viscozyme) in our laboratory. In vitro apparent ileal digestibility (AID) and in vitro apparent total tract (ATTD) digestibility of OM in 4 diets and corn (83.7 and 93.1%) were not different from values analyzed at a reference laboratory (82.4 and 92.4%) indicating that we were able to repeat the assay. Exp. 2 was conducted with the objective of increasing the amount of sample that was used for the in vitro digestibility assay from 0.5 g to 2.0 or 4.0 g. Results of this experiment showed that ATTD of DM was not different among the 3 sample sizes (85.1, 83.7, 83.3% for 0.5, 2.0, and 4.0 g, respectively). Exp. 3 was conducted to measure AID and ATTD of NDF

in DDGS. In vitro AID of NDF was different ($P < 0.01$) among sources of DDGS (21.9 to 40.4%). Values for AID of NDF were greater than expected considering that at this point there were no fiber degrading enzymes added to the samples. The ATTD of NDF (32.5 to 52.2%) was different ($P < 0.01$) among sources of DDGS. These observations suggested that the average concentration of NDF in DDGS (40.2%) in the current experiment may be overestimated. The objective of Exp. 4 was to measure in vitro hindgut fermentation of NDF using purified enzymes or fecal inoculums in 10 sources of DDGS that had in vivo data available. Values for hindgut disappearance of DM and NDF obtained after fecal inoculation (23.0 and 54.3%) were greater ($P < 0.05$) than values obtained using purified enzymes (6.3 and 5.6%), values obtained using fecal inoculums were also closer to values observed in vivo (23.3%). In conclusion, modifications to the 3 step in vitro digestibility assay allowed measuring the in vitro AID and ATTD of DM and NDF in DDGS. Results obtained with the fecal inoculum are closer to in vivo values than values obtained using purified enzymes. Concentration of NDF in DDGS may be overestimated if CP contaminates the NDF residue.

Key Words: in vitro digestibility, DDGS, inoculum

T194 Effects of distillers dried grains with solubles and lactose on fecal *Lactobacillus* biota of nursery pigs. H. Tran*, R. Moreno, J. W. Bundy, E. Hinkle, J. Walter, T. E. Burkey, and P. S. Miller, *University of Nebraska*, *Lincoln*.

An experiment was conducted to evaluate the effects of distillers dried grains with solubles (DDGS), lactose, and their interaction on fecal *Lactobacillus* biota of nursery pigs. Ninety-six pigs (age, 23 d; initial BW, 6.43 kg) were randomly allotted into each of 16 pens by gender, ancestry, and weight (6 pigs/pen; 4 pens/treatment). In phase 1 (wk 1 and 2), pigs were fed 1 of the 4 treatments: 1) control (no DDGS or lactose), 2) 15% DDGS, 3) 20% lactose, or 4) 15% DDGS + 20% lactose. In phase 2 (wk 3 and 4), all pigs were fed a common diet containing 15% DDGS and 10% lactose. Fecal samples were randomly collected from 2 pigs/pen on d 0, 7, 14, and 21. A subsample was taken from 1 pig/pen (4 pigs/treatment) for DNA extraction. *Lactobacillus* specific primers were used for PCR and subsequent denaturing gradient gel electrophoresis (DGGE). Staining intensities of DGGE bands were determined as a proportion of peak surface area of the entire molecular fingerprint of the sample. No interactions of DDGS and lactose on *Lactobacillus* biota were observed; however, tendencies for a main effect of both DDGS and lactose were observed with respect to putative *L. sobrius/amylovorus* on d 7. Pigs fed diet containing DDGS had greater (41.95 vs. 25.36%; $P = 0.06$) staining intensities of *L. sobrius/amylovorus* than pigs not receive DDGS. Similarly, decreased (26.36 vs. 40.95%; $P = 0.09$) staining intensities of *L. sobrius/amylovorus* were observed in pigs fed lactose compared with non-lactose fed pigs. On d 14, a main effect of lactose was observed with respect to putative *L. reuteri* where lactose-fed pigs had greater (54.67 vs. 20.07%; $P = 0.02$) staining intensities of this species compared with pigs not receiving lactose during phase 1. On d 21, DDGS-fed pigs had greater (72.26 vs. 42.02%; $P = 0.05$) staining intensities of *L. reuteri* compared with pigs not receiving DDGS in phase 1. These research findings suggest that feeding lactose and DDGS may affect fecal *Lactobacillus* ssp. in nursery pigs.

Key Words: distiller dried grains with solubles, *Lactobacillus*, lactose

T195 Bone breaking strength of laying chickens fed increasing levels of omega-3 PUFA DHA (22:6) using algae as vehicle of diet enrichment. N. P. Johnston*, C. B. Evans, and R. T. Davidson, *Brigham Young University*, *Provo, UT*.

In recent years a host of health benefits have been associated with the intake of omega-3 fatty acids in general and DHA (22:6 n-3) in particular for both and humans and animals. During a 12-wk feeding trial 60 SCWL pullets were fed omega-3 PUFA-rich diets with increasing levels of docosahexaenoic acid (DHA) 22:6 (n-3) to determine the dietary effects on bone breaking strength (BRS) measured by Young's Modulus (YM). Two of the diets were DHA-free including a corn oil-enriched control and a flaxseed-enriched diet and in the remaining 4 diets a portion of the diet was replaced with increasing levels of algae ranging from 10% to 50%. As a result- dietary DHA ranged from 0 to 0.94% of the diet. The birds were evenly divided by treatment and housed in individual cages in environmentally controlled rooms where they received feed/water ad libitum and a light-dark cycle of 14L:10D. It was hypothesized that with increasing levels of DHA there would be a corresponding increase in bone strength. At the conclusion of the feeding trial the femur, tibia and humerus bones were broken on an Instron 3345 to determine bone strength (YM). Diet improved ($P < 0.05$) the strength of the tibia, femur and humerus (3.08, 2.04, 3.13 N/mm2) at the 50% level and the femur at all added algae levels. In conclusion the 10, 20, and 50% algae-fed birds ($P < 0.05$) had stronger femurs and the 50% ($P < 0.05$) stronger humerus and tibias than the controls; hence, the replacement of flaxseed with DHA-rich algae had a beneficial effect on the bone strength of laying chickens.

Key Words: bone breaking strength, omega-3, algae

Nonruminant Nutrition: Energy

T196 Energy requirement of broiler breeder hens: Egg weight, egg composition and progeny. C. Salas*, R. D. Ekmay, J. England, S. Cerrate, and C. N. Coon, *University of Arkansas*, *Fayetteville*.

Under or overfeeding dietary energy to broiler breeders (BB) can lead to a reduction in hatching egg production. The objective of this study was to evaluate the effects of energy intake (EI) on egg composition, hatchability, fertility and progeny performance. Cobb 500 BB pullets were reared in 3 groups as follows: a control group (SBW), a group 20% heavier (HBW) and a group 20% lighter (LBW). At 21 wks, pullets of each group were moved to cages and fed 1 of 6 diets (each diet had 2860 kcal ME and 20.8-14.3% CP). The EI for each diet was adjusted to provide 330, 360, 390, 420, 450 and 480 kcal ME/hen/d and 24 g of ideal protein/d at peak production. Birds fed 390 kcal ME/d produced 177.1 hatching eggs, 14 and 16.4 more eggs than the BB fed 330 and 480 kcal ME/d, respectively ($P < 0.0001$). The same BBs produce .4g to 1.5g heavier eggs than the other groups ($P < 0.0001$). BBs were inseminated every 5 wks to monitor egg fertility, hatchability and chick weight. At hatch, chicks from LBW hens were always lighter; this translated into BW*EI interactions. The LBW and SBW hens fed 330 and 360 kcal ME/d produced lighter chicks. Chicks from breeders fed 390 to 480 kcal ME/d weighed ≥42g in all hatches. Egg fertility and hatchability were ≥90% and 85%, respectively; for all groups.
Egg composition was determined every 5 wks for each BB group during the production period. In wks 30 and 35 BB fed 480 kcal ME/d produced eggs with the highest % yolk ($P < 0.01$). BB fed 480 kcal ME/d produced eggs with a higher yolk:albumen ratio (0.46 to 0.65)($P < 0.05$), but this had no effect on progeny performance. All progeny from the 50 wk hatch was reared in floor pens until 42d and 5 birds/pen were further processed. There were no differences between the progeny groups in BW gain, feed:gain ratio or processing yields. This study shows that BBs in cages perform well with an EI of 390 kcal ME/d throughout the production period.

Key Words: broiler breeders, energy intake, eggs

T197 Determination of metabolizable energy content of meat and bone meal for broilers using regression method. O. A. Bolarinwa*[1], O. A. Olukosi[1], R. A. Hamzat[2], and O. Adeola[1], [1]*Purdue University*, *West Lafayette, IN,* [2]*South Suburban College*, *Chicago, IL*.

An experiment was conducted to determine the ME content of 2 meat and bone meal (MBM) samples by the regression method. Gross energy of MBM1 and MBM2 were 4.383 and 4.857 kcal/g DM, respectively. The CP, ash, and crude fat contents for MBM1 or MBM2 were 585 or 614, 272 or 218, and 109 or 120 g/kg DM. A standard corn-soybean meal diet with GE and ME of 4.601 and 3.310 kcal/g DM, respectively, and 6 test diets were used for the study. In the standard diet, corn, soybean meal, corn starch and soy oil were used as the sources of energy. In the test diets, each of the 2 MBM samples were added at the rate of 30, 60 or 90 g/kg diet to partly replace corn, soybean meal, corn starch and soy oil such that the ratio of all energy-yielding feedstuffs to one another was the same in all the assay diets. Each of the 7 dietary treatments had 8 replicates with 6 birds per replicate. Birds received a starter diet from d 1 to d 15 post-hatch. Birds with an average BW of 397 g at d 15 post-hatch were assigned to 7 diets in a randomized complete block design. Experimental diets were fed for 7 d and excreta were collected twice daily on d 20 and 21. Average weight gain and feed efficiency were between 391 to 424 g and 700 to 757 g/kg, respectively. The ME content of each MBM sample was determined from the slope of the regression of MBM contribution to apparent ME intake in kilocalories against amount of MBM intake in grams. Metabolizable energy values for meat and bone meal samples derived from the regression analyses were 3.364 and 3.691 kcal/g DM, for MBM1 and MBM2, respectively. It is likely that the difference in energy value is due to greater GE and fat and lower ash in MBM2 compared with MBM1.

Key Words: broiler, meat and bone meal, metabolizable energy

T198 Determination of the chemical composition and true metabolizable energy of high oil poultry by-product meal. M. G. Olyayee*, H. Janmohammadi, A. Taghizadeh, A. Rafat, and S. Ostan, *University of Tabriz*, *Tabriz, Iran.*

Poultry by-product meal (PBPM) is one of the by-products resulting from poultry meat processing and is produced from slaughter wastes of broilers, spent laying hens and breeders. In Iran, the term PBPM refers only to meals which are produced from viscera, feathers, heads and some feet and blood, and are produced by simple low cost technology. The chemical composition of PBPM can vary greatly depending on the raw material source, storage time of raw material before rendering and processing methods. This product is used mostly in poultry diets but there is not enough data of its chemical composition and True Metabolizable Energy (TMEn) content. The present study was conducted to determine the chemical composition and TMEn content of high oil PBPM from Iran. Three composed samples were obtained from local poultry slaughterhouses. The chemical composition of PBPM such as DM, CP, ether extract (EE) and ash content was determined according to AOAC (1990) methods. Gross energy was measured by Parr adiabatic calorimetric bomb and then TMEn was determined by Sibbald precision fed assay. Twenty 4 12-wk-old Ross 308 broiler roosters with similar body weight (2280 ± 80g) were selected. Each sample was replicated 6 times as well as 6 replications for endogenous energy collection. Descriptive statistical responses of all data were obtained by using proc means of SAS (2003). The results showed that this product in comparison with standard tables of nutrient composition has high EE (23.8 ± 1.6%), low ash (6.53 ± 0.8%) and approximately the same CP (57 ± 2.6%) contents. Dry matter was 91.5 ± 0.57. The TMEn values of 3 studied samples were 2798 ± 80, 3518 ± 114.92 and 3220 ± 108.5 kcal/kg. The results showed that TMEn value of high oil PBPM from Iran poultry rendering plants is relatively variable, therefore should be considered by users in poultry diet formulation.

Key Words: TMEn, high oil poultry by-product meal

T199 Metabolizable energy and nutrient digestibility coefficient determination of ingredients with nutritional adjustment. A. G. Bertechini*, V. A. Costa, S. F. Castro, J. C. C. Carvalho, and C. Meneghetti, *Universidade Federal de Lavras*, *Lavras, MG, Brazil*.

Because of the imbalance of the nutrient supplies to the chickens when using the conventional methodology for metabolizable energy and nutrient digestibility coefficients determination, the results cannot be appropriate, for that reason different methods must be developed. In the present study the effect of nutritional adjustment of basal diets after inclusion of the ingredient test (using enzyme) were evaluated. A total of 640 male Cobb 500 broiler chicks from 14 to 21 (n = 400) and 35 to 42 (n = 240) d of age were placed in metabolic cages and assorted into 10 dietary treatment groups with 5 and 3 birds each to first and second phases, respectively. A 5 × 2 factorial treatment scheme, with 5 dietary

adjustments and 2 protease levels (0 and 200 ppm) in a completely randomized design with 8 replicates each was used. The dietary adjustments were: 1) Corn-soybean meal based diet (C-SBM), 2) C-SBM + vitamin + mineral premix, 3) C-SBM 2 + energy, 4) C-SBM 2+ amino acids and 5) C-SBM 2 + energy + amino acids .The variables analyzed were the apparent metabolizable energy (AME) and N corrected (AMEn), the apparent digestibility of crude protein (CPD), dry matter (DMD) and ether extract (EED). The studied ingredient was meat and bone meal (20% of replacement of C-SBM), using total excreta collection (for 3 consecutive days). Results indicated that from 14 to 21 d of age, higher values of AME and AMEn ($P < 0.05$) were observed on treatment 2, followed by treatments 3 and 4. The CPD, DMD and EED were improved ($P < 0.05$) for all treatments where the dietary adjustment was made. Improvements ($P < 0.05$) on AME, AMEn, CPD, DMD and EED with enzyme supplementation was verified. From 35 to 42 d of age highest values ($P < 0,05$) of AME and digestibility coefficients were observed on treatment 5. It is concluded that conventional methodology (without nutritional adjustments) underestimates the nutritional values assigned to meat and bone meal in broiler diets.
Research supported by FAPEMIG, MG.

Key Words: nutrient adjustment, nutrient imbalance, digestibility methodology

T200 True and apparent metabolizable energy values of various wheat screening samples. M. Mazhari and A. Golian*, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

Three trials were conducted to determine the available energy of different wheat screening samples collected from different locations of Khorasan in Iran. In experiment 1, chemical composition and the nitrogen corrected true metabolisable energy (TMEn) were evaluated. A precision-fed rooster assay was used, in which, each wheat screening sample was tube fed to adult roosters, and the excreta were collected for 48 h. In exp. 2 and 3, 5 and 2 wheat screening samples-based diet with or without xylanase and phytase were fed to 16 d old battery reared chicks and total consumption and excreta were measured during 3 next days. The variable nature of wheat screening varieties led to significant differences in mean TMEn values ($P < 0.01$). The TMEn values of samples determined with adult roosters varied by ± 5.03% of the mean value (3097.65 ± 49.32 kcal/kg) and ranged from 2734.90 to 3245.12 kcal/kg. There was a significant correlation ($P < 0.05$) between chemical composition (CP, EE, ash and CF) and TMEn. The best equation for TMEn yielded an R2 = 0.86, with crude fiber being the most efficient compound. The average AMEn values of 5 and 2 samples determined with young broiler chickens were 2968.41 ± 25.70 kcal/kg and 2976.38 ± 8.34 kcal/kg in exp2 and exp3 respectively. Addition of xylanase and phytase to wheat screenings resulted in significant ($P < 0.01$) improvement in AMEn (4.21 and 2.92% respectively).

Key Words: wheat screening, true and apparent metabolisable energy, xylanase and phytase

T201 Effect of various levels of energy and protein on Humoral immune response in broiler chicks. M. Pilevar, A. Golian*, and M. Aami Azghadi, *Ferdowsi University of Mashhad*, *Khorasan Razavi, Iran*.

A complete randomized design experiment with a 4 × 4 factorial arrangement consisted of 4 levels of energy (2900, 3000, 3100 and 3200 kcal/kg) and 4 levels of protein (17, 20, 23 and 26%) was conducted to assess the effect of dietary energy and protein on humoral immune response of chickens. All birds in each replicate were injected intramuscular with SRBC (15% suspension in PBS, 1 mL/chick) at d 15 and 25. Blood samples were collected at d 5 and 10 of injections. The serum from each sample was analyzed for total anti-SRBC antibody as described previously (Cheema et al., 2003). The data were transformed and then analyzed using the GLM procedures of SAS software (v. 9.1). Total anti-SRBC titers were increased in birds fed low energy diet in both postprimary (PPI) and postsecondary injections (PSI), but dietary protein contents did not influence antibody titers of birds. Increasing the level of energy and protein in broiler diets improved growth rate which may cause a negative effect on humoral immune response. Broiler bursa of Fabricius size decreased gradually with increasing dietary energy level, which could affect on immune response. It seems that, there is a negative phenotypic association between immunocompetence and rapid growth in chickens.

Table 1. Effect of various levels of ME and CP on total anti-SRBC titers in postprimary (PPI) and postsecondary (PSI) injections

		Days PPI		Days PSI	
	Level	5	10	5	10
ME	2900	5.304a	2.424	6.450	4.894a
	3000	4.958b	3.060	6.990	4.559ab
	3100	5.048ab	3.555	7.410	4.389b
	3200	5.132ab	3.630	6.780	4.096
CP	17	5.341	2.968	7.000	4.372
	20	5.233	2.887	6.833	4.508

T202 Effect of xylanase supplementation in a pig diet on ileal and postileal energy and fiber fraction digestibility. L. Babinszky*[1], J. Tossenberger[1], D. Ottó[1], and I. Kühn[2], [1]*Kaposvár University*, *Kaposvár, Hungary*, [2]*AB Vista*, *Darmstadt, Germany*.

The trials studied the impact of supplementing high grain/high crude fiber (CF) diets with xylanase (Xyl) on ileal [intake-ileal excretion/intake × 100] and postileal [ileal excretion-fecal excretion/ileal excretion × 100] digestion of GE, NDF, ADF in growing pigs. Each of 4 treatments (Trt) used 5 hybrid barrows (initial live weight 37.3 ± 2.9 kg) in 2 replicates (10 pigs/Trt). Prior to trial pigs were fitted with PVTC-cannulas. Ileal and post-ileal digestibilities (DGY) were determined in same animal using Cr_2O_3 as marker. The wheat, barley, rye, wheat bran, DDGS, soybean hulls based basal diet contained 12.2 MJ MEs, 170.3g CP, 51.1g CF, 223g NDF, 68g ADF, 9.5g LYS, 6.4g M+C / kg. Diets equivalent to 2.6 times maintenance energy requirement (458 KJ MEs/$kg^{0.75}$/d) were fed. TrtI diet had no added Xyl (negative control: NC). Trt2 and 3 diets were supplemented with 8000 BXU/kg and 16000 BXU/kg ECONASE XT (thermostable Xyl from *Trichoderma reesei*). Trt4 was a wheat-barley based positive control diet (PC) with recommended energy level (13.2 MJ MEs). Data were analyzed by ANOVA (SAS, 2004).Trt2 improved ileal DGY over NC from 61.2% to 67.5% (GE), 30.6% to 38.8% (CF), 47.3% to 57.2% (NDF), and 24.0% to 35.3% (ADF); postileal DGY improved from 79.2% to 84.4% (GE), 81.9% to 87.0% (CF), 81.0% to 90.0% (NDF) and 78.0% to 85.5% (ADF) ($P \leq 0.05$). Neither ileal, nor postileal DGY-s increased further in Trt3 ($P \geq 0.05$). DGY-s in Xyl trts

were similar or higher than those in energy balanced Trt4 (PC). Added Xyl also shifted location of energy absorption. While ileal/postileal split of total energy absorption was 74.7% / 25.3% in NC group, Trt2 changed this to 81.2% / 18.8%, supporting that added Xyl improves nutrient DGY in the small intestine. The results show the importance of improved nutrient absorption caused by Xyl supplementation (8000-16000 BXU/kg) to high fiber/NDF grain based diets, if the aim is to provide optimum energy supply for animals.

Key Words: pig, ileal-postileal, digestibility

T203 Influences of four kinds of exogenous enzymes on performance, jejunal digesta viscosity and litter moisture of broilers fed wheat-based diet. H. Shirzadi*, H. Moravej, and M. Shivazad, *University of Tehran*, *Karaj, Tehran, Iran*.

The intention of this work was to determine the effects of 4 enzyme preparations containing xylanase and β-glucanase activities on performance of broiler chicks fed wheat-based diet compare with those that fed corn-based diet without enzyme. Enzyme A provided per kilogram of diet (endo-1,4-β-glucanase activity: min 800 units; endo-1,(4)-β-glucanase activity: min 1800 units; endo-1,4-β-xylanase activity: min 2600 units), enzyme B (endo-1,3(4)-β-glucanase: 100 AGL; endo-1,4-β-xylanase: 1100 visco units), enzyme C (endo-1,4-β-glucanase: 1500 BGU; endo-1,4-β-xylanase: 3600 FXU), enzyme D (1420 units; xylanases: 660 units). Two hundred thirty-four male day-old broiler chicks (Ross 308) were randomly allocated to 6 treatment groups, with 3 replicates and 13 birds per replicate in floor pen. All data was analyzed through the General Linear Model procedure of SAS for a randomized complete block design. The 6 dietary treatments consisted of a 60% corn-based ration without enzyme and 5 other rations containing 60% wheat supplemented with and without enzyme (A, B, C, and D). All parameters were measured at 42d, except viscosity (at 28d). Body weight was not significantly ($P > 0.05$) affected by enzyme addition. Furthermore, feed intake and feed conversion ratio were also not affected by enzyme supplementation ($P > 0.05$), and there were no significant differences between all treatment. In addition, litter moisture was not affected by enzyme, and these results were similar to results of corn-based diet ($P > 0.05$). In addition, the results demonstrated that the viscosity of jejunal contents was not significantly ($P > 0.05$) reduced by enzyme addition, however, this parameter had decreasing trend. The results of current study led to the conclusion that xylanase and β-glucanase activities of these enzymes did not seem to positively affect the xylans and β-glucans content of wheat used in this trial.

Key Words: enzyme, performance, viscosity

T204 Cloning, expression and characterization of a thermostable beta-propeller phytase from *Bacillus licheniformis*. S. J. Fu*[1,3], J. Y. Sun[1], X. Y. Weng[2], L. C. Qian[1], and Z. Q. Shen[4], [1]*Microbiology Division, Institute of Feed Science, College of Animal Science, Zhejiang University*, *Hangzhou Zhejiang, People's Republic of China*, [2]*College of Life Science, Zhejiang University*, *Hangzhou Zhejiang, People's Republic of China*, [3]*Key Laboratory of Preventive Veterinary Medicine and Animal Biotechnology, Binzhou Animal Husbandry and Veterinary Research Institute*, *Binzhou Shandong, People's Republic of China*, [4]*Shandong Lvdu Biological Technology Co., Ltd*, *Binzhou Shandong, People's Republic of China*.

A novel sabler phytase gene (phyC) was cloned from *Bacillus licheniformis*. It was 1146 bp in size and encoded a polypeptide of 381 amino acids. The mature peptide of phyC was successfully expressed in *Pichia pastoris* under the control of AOX1 promoter. The recombinant PhyCm (rePhyCm) was secreted into culture medium. After 96 h of 0.5% methanol induction, the activity of the rePhyCm in the culture supernatant reached the peak, 8.64 U/mg, which was 5.1 times as high as that of the native PhyC (1.7 U/mg). Studies on enzymatic properties showed that the optimum temperature and pH of the rePhyCm were 70°C and 7.5, respectively. The rePhyCm was very stable in a wide pH range of 5.0–9.0 and showed relatively good thermal stability. After incubation at the pH 5.0–9.0, 37°C for 1 h, all the residual activities of the rePhyCm were over 80%. After being exposed to 80°C for 2min in the presence of 1mM CaCl2, the rePhyCm retained 80% of the initial enzyme activity. The rePhyCm exhibited a molecular mass of approximately 42 kDa on SDS-PAGE, indicating that the rePhyC was expressed and efficiently secreted into the growth medium.

Key Words: *Bacillus licheniformis*, phytase, *Pichia pastoris*

T205 Body weight and feed conversion responses in broilers after feeding a lysophospholipid bio-surfactant and β-mannanase based feed enzyme. G. Mathis[1], B. Lumpkins[1], H. Stomp[2], A. Lamptey[2], and A. G. Yersin*[2], [1]*Southern Poultry Research*, *Athens, GA,* [2]*Kemin AgriFoods*, *Des Moines, IA*.

Energy utilization by poultry is dependent on many factors including age of the animal, the amount of lipase and bile salt present in the gut and overall digestibility of the ration components. The use of emulsifiers (lecithin) has been shown to improve nutrient utilization. Studies were conducted to evaluate the effects of a lysophospholipid bio-surfactant and β mannanase based feed enzyme in the diets to improve growth performance in broilers during a 42 d period. Two separate experiments were conducted using a basal corn and soybean meal ration. In study 1, there were 6 treatments based on different fat levels and the presence of the surfactant (454 g/ton inclusion), enzyme (114g/ton inclusion) or both as adjusted on a caloric basis. In study 2, the enzyme was added to all treatments, but the level of fat and surfactant were adjusted based on either a caloric basis or on the feeding phase of the ration (starter, grower or withdrawal phase). Body weight gain, feed conversion and mortality were measured at each dietary feed change in both studies. In study 1, the control (no bio-surfactant, no enzyme) group had a similar ($P < 0.05$) feed conversion and gain response at both 21 and 42 d of age as compared with treatments with either enzyme alone, bio-surfactant alone or the combination. However, the cost per pound of live weight was reduced in the bio-surfactant alone treatment compared with all others. In study 2, the enzyme and bio-surfactant combination group (fed in all phases) had a significantly better ($P < 0.05$) feed conversion and gain response at both 19 (4.9 points, 0.01 kg) and 42 d (3.8 points, 0.073 kg) as compared with all other treatments. The data indicates that both phase of feeding (starter, grower, and withdrawal) as well as the presence of enzyme with a surfactant contribute to overall performance improvements.

Key Words: broilers, bio-surfactant, enzyme

T206 Impact of a new phytase on apparent phosphorus and calcium availability, bone mineralization and performance of broilers. R. Angel*[1], W. Saylor[2], and N. Ward[3], [1]*University of Maryland*, *College Park,* [2]*University of Delaware*, *Newark,* [3]*DSM Nutritional Products*, *Parsippany, NY*.

To determine the impact of adding graded levels of a new phytase (IPA, DSM) to corn-soy starter diets and to compare it with an existing commercial phytase, 9 diets with Celite as marker were fed to 8 replicates of 5 broilers each (Ross 708) from 6 to 20d: Positive Control (PC, 0.45% non-phytate phosphorus (nPP); 0.9% Ca); Moderate and Low nPP (MP and NC, 0.30 and 0.15% nPP, respectively; 0.7% Ca); NC with 250, 500, 1000, 2000, and 4000 FYT IPA /kg; and NC with 1850 Ronozyme P CT (R) (DSM). At 20 d, performance was determined, tibias sampled and

ileal contents removed for apparent Ca and P availability determination. Body weight (20 d) and feed efficiency (FE) were similar ($P > 0.05$) for birds fed the PC, MP, and the NC plus 1000, 2000 and 4000 IPA diets. Broilers fed the NC+R diet had greater BW than those fed the NC diet and similar to those fed the NC+ 200 and 500 IPA. Tibia ash was lowest ($P < 0.01$) in broilers fed the NC diet (38.1%) followed by those fed the NC+R (41.7%) and highest ($P < 0.01$) for broilers fed the PC (50.85%) and NC+4000 IPA (50.45%). There was a quadratic effect ($P < 0.001$; R-squared 0.87) of IPA inclusion on tibia ash. Apparent Ca and nPP retentions were lowest ($P < 0.001$) for broilers fed the PC diet, followed by those fed the NC diet and the NC+R and highest for broilers fed the NC+4000 IPA (51.9 and 42.2; 57.8 and 49.4; 60.7 and 51.7; and 67.9 and 60.1% for Ca and nPP, respectively). IPA inclusion had a quadratic effect ($P < 0.01$) on Ca and nPP apparent availability. In vitro analysis of the pH optima curve of IPA showed it has a higher ($P < 0.001$) P release per unit at all pHs including the 2 to 3.5 pH range compared with phytases from Peniophora l.- and an *E. coli*.

Key Words: broilers, phytase, phosphorus availability

T207 Effects of co-administration of phytase and energy enzymes on broiler performance, tibia strength, bone ash, and processing parameters. J. R. Coppedge*[1], J. Klein[1], A. Jordan[1], K. Jessen[1], S. Pohl[1], B. Brown[2], F. Ruch[2], and J. T. Lee[1], [1]*Texas A&M University*, *College Station,* [2]*Enzyvia LLC*, *Sheridan, IN*.

An experiment was conducted to determine if dietary NSPase inclusion enhances phytase activity during a 40-d growout. The experimental design included 4 non-supplemented diets including an industry control (3090 kcal/kg ME and 0.40 available phosphorus (aP) in the starter diet), a low energy (LE) diet (−132 kcal/kg ME), a low phosphorus (LP) (- 0.10% aP), and a low energy and low phosphorus (LEP) diet (−132 kcal/kg of ME and −0.10% aP). Enzyme supplementation treatments included phytase inclusion of 200 or 250 FTU/kg into the LP diet. In addition, the LEP diet was supplemented with an NSPase enzyme and 200 or 250 FTU/kg phytase. Each of the 8 treatment groups contained 8 replicates of 48 chicks/ replicate. Broilers were fed a starter diet through 14 d of age, a grower diet from 15 - 26 d of age, and a finisher diet through termination of the study on d 40. Following each dietary phase, 3 broilers from each replicate were killed and tibias removed for bone strength and ash determination. On d 40, 10 male broilers from each replicate were processed for determination of carcass and breast yield. Average body weight was reduced ($P < 0.05$) and mortality rates increased ($P < 0.05$) in the LP and LEP diets. Phytase inclusion in the LP diets increased ($P < 0.05$) body weight, reduced mortality, improved feed conversion ratio, and increased bone strength and ash. Phytase inclusion of 250 FTU/kg outperformed the inclusion at 200 FTU/kg in most evaluated parameters regardless of NSPase inclusion. These data confirm that phytase inclusion improves growth performance and bone strength in diets containing inadequate levels of aP, but NSPase inclusion did not enhance phytase activity.

Key Words: broiler, phytase

T208 Effect of CTCZyme β-mannanase on broiler nutrient digestibility in corn-soybean meal diets. F. Mussini*[1], C. A. Coto[1], S. Goodgame[1], C. Lu[1], A. J. Karimi[2], J. Lee[3], and P. W. Waldroup[1], [1]*University of Arkansas*, *Fayetteville,* [2]*University of Kurdistan*, *Kurdistan, Iran*, [3]*CTC Bio Inc.*, *Seoul, Korea*.

The possibility of improving digestibility of nonstarch polysaccharides present in broiler diets by the use of different carbohydrases appears as an opportunity to enhance feed utilization by the birds. In this study, the effect of a β-Mannanase (CTCZyme) on nutrient digestibility in corn-soybean meal diets was investigated. One-day-old chicks received a nutritionally complete corn-soybean meal diet for 19 d. At that time birds were randomly allocated to 4 treatments, each of which had 6 replicates of 5 birds housed in battery brooders with wire floors. Aliquots of the basal diet were supplemented with 4 levels of CTCZyme (CTC Bio Inc., Seoul Korea): 0%, 0.025%, 0.05% (recommended level) and 0.1%. Chromic oxide was used as an indigestible marker. Feed was analyzed for gross energy, Chromium, and amino acid content. After 8 d of acclimation to the test diets, birds were sacrificed and ileal contents collected. Analysis of the ileal contents indicated that digestibility of Lys, Met, Thr, Trp, Arg, Leu, Ile, Cys, and Val were significantly ($P \leq 0.0001$) improved in a linear manner for each increment of CTCZyme inclusion. Lys digestion was increased 4.6% and Met by 3.1% by the highest level of enzyme. Ileal metabolizable energy also increased with each increment of CTCZyme level. These results show that the enzyme improves feed digestibility by making amino acids more available for the bird and increases energy utilization from the feed. These results suggest that lower levels of protein and energy could be used with the same results but further studies are required to estimate potential levels.

Key Words: broilers, mannanase, digestibility

T209 Effect of phytase supplementation on the digestibility of crude protein and amino acids of cowpea (*Vignia unguiculata*) in broilers. E. A. Iyayi*, *University of Ibadan*, *Ibadan, Oyo, Nigeria*.

Cowpea (*Vignia unguiculata*) a tropical legume is being promoted for use in poultry feeding. To determine the digestibility of crude protein (CP) and amino acids (AAs) in the bean, 6 experimental diets were formulated containing 0, 150 or 300 g/ kg of heated cowpea in place of maize starch and 0 or 500 units of phytase enzyme (Natuphos), according to a 3 × 2 factorial arrangement. A total of 288 d old broiler chicks (Ross strain) were distributed into 36 cages on weight basis. Each diet was assigned to 6 cages containing 8 birds each.TiO2 was added as an indigestible marker in the diets. Increase in cowpea level had no significant effect on the amount of dietary CP and AAs digested except for arginine, glutamic acid and phenylalanine which were significantly ($P < 0.05$) reduced. Supplementation with phytase caused a significant ($P < 0.05$) increase in the digestibility of dietary CP and AAs at the terminal ileum. Interaction between cowpea and phytase had no significant effect on CP and AA digestibility in the diets. Digestibility of CP and AAs in cowpea was increased with phytase supplementation. The results showed an increase in the digestibility coefficients. Nevertheless, regression analysis indicated that phytase in this study affected both the CP and AA losses on the basal level and the digestion of CP and AAs from cowpea.

Key Words: phytase, CP and AA digestibility, broilers

T210 Effect of phytase supplementation on the digestibility of phosphorus of cowpea (Vignia unguiculata) in broilers. E. A. Iyayi*, *University of Ibadan*, *Ibadan, Oyo, Nigeria*.

Cowpea (Vignia unguiculata) a tropical legume rich in phytate phosphorus is being promoted for use in poultry feeding. To determine the digestibility of P in the bean and the performance of the birds, 6 experimental diets were formulated containing 0, 150 or 300 g kg-1 of heated cowpea in place of maize starch and 0 or 500 units of phytase enzyme (Natuphos), according to a 3 × 2 factorial arrangement. A total of 288 d old broiler chicks (Ross strain) were distributed into 36 cages on weight basis. Each diet was assigned to 6 cages containing 8 birds each.TiO2 was added as an indigestible marker in the diets. Phytase supplementa-

tion had a significant ($P < 0.05$) improvement on the digestibility of P in the diets and cowpea at the terminal ileum. The digestibility of P in the cowpea increased from 0.55 to 0.67 with phytase supplementation. The level of cowpea and its interaction with phytase had no significant effect on P digestibility and reduction in the loss of P at the basal level. Phytase supplementation caused a significant ($P < 0.05$) increase in feed intake and body weight in the birds but cowpea level or its interaction with phytase had no significant effect on the performance parameters. Results of the study showed that heated cowpea can be included at the rate of 300 g/kg in diets of broilers and that supplementation of such diets with phytase resulted increased P digestibility and better performance in broilers.

Key Words: phytase, phosphorus digestibility, broilers

T211 Effect of Ronozyme ProAct supplementation on growth and meat yield responses of broilers during a forty-two-day production period. W. A. Dozier III*[1], N. E. Ward[2], and S. L. Vieira[3], [1]*Auburn University*, *Auburn, AL*, [2]*DSM Nutritional Products, Inc.*, *Parsippany, NJ*, [3]*Universidade Federal do Rio Grande do Sul*, *Porto Alegre, RS, Brazil*.

Large price differentials between corn and soybean meal have resulted in strategies to reduce diet cost for broilers. A novel protease (Ronozyme ProAct) has been reported to improve amino acid digestibility of feed ingredients. This study examined growth and meat yield responses of broilers provided diets with reduced amino acid density supplemented with or without Ronozyme ProAct. Sixteen hundred Ross × Ross 708 male broilers were randomly distributed into 64 floor pens (25 birds per pen; 0.09 m^2/bird) at 1 d of age and fed 5 dietary treatments until 42 d of age. Dietary treatments consisted of a 1) Positive Control (PC), 2) Negative Control (NC) 4% reduction in amino acid density, 3) Dietary treatment 2 + 200 ppm of Ronozyme ProAct, 4) NC 6% reduction in amino acid density, and 5) Dietary treatment 4 + 200 ppm of Ronozyme ProAct. Dietary amino acid specifications of the PC were considered to be moderate density. Dietary treatments 2 to 5 had amino acid density reduced by 4 or 6% compared with the PC. Primary ingredients consisted of corn, soybean meal, distillers dried grains with solubles (5% inclusion), and meat and bone meal (5% inclusion). Each treatment was represented by 12 replicate pens. BW gain, feed intake, feed conversion, mortality, and processing yields were assessed. Ronozyme ProAct supplementation increased ($P \leq 0.001$) BW gain from 1 to 14 d of age compared with NC with both 4% and 6% amino acid reductions and Ronozyme ProAct inclusion improved ($P \leq 0.02$) 14 d feed conversion with decreasing amino acid density by 4%. Broilers fed the PC diet had advantages ($P \leq 0.05$) in growth performance, carcass weight, and total breast meat weight compared with NC diets. In summary, Ronozyme ProAct supplementation improved growth performance during the starter period.

Key Words: amino acid, broiler, protease

T212 Influences of several enzyme containing β-glucanase and xylanase on meat yield of broilers fed barley-based diet. H. Shirzadi*, H. Moravej, M. Shivazad, and F. Fatehi, *Department of Animal Science, Faculty of Agriculture and Natural Resources, University of Tehran*, *Karaj, Tehran, Iran*.

The goal of this investigation was to compare the effects of 4 enzyme preparations containing β-glucanase and xylanase activities on performance and meat yield of broiler chicks fed barley-based diet with and without enzyme. Enzyme A provided per kilogram of diet (endo-1,4-β-glucanase activity: min 800 units; endo-1,(4)-β-glucanase activity: min 1800 units; endo-1,4-β-xylanase activity: min 2600 units), enzyme B (endo-1,3(4)-β-glucanase: 100 AGL; endo-1,4-β-xylanase: 1100 visco units), enzyme C (endo-1,4-β-glucanase: 1500 BGU; endo-1,4-β-xylanase: 3600 FXU), enzyme D (1420 units; xylanases: 660 units). One hundred ninety-five male day-old broiler chicks (Ross 308) were randomly allocated to 5 treatment groups, with 3 replicates and 13 birds per replicate in floor pen. All data was analyzed through the General Linear Model procedure SAS for a randomized complete block design. The 5 dietary treatments consisted of the barley (60%) supplemented with and without enzyme (A, B, C, and D added on top to diets). All parameters were measured at 42d. Body weight was increased by addition all enzymes ($P < 0.05$), and significant differences were not observed among all enzymes. However, feed intake was not significantly affected by enzyme supplementation. Feed conversion ratio, carcass weight and relative weight of the abdominal fat were significantly improved by addition all enzymes compared with the barley-based diet without enzyme ($P < 0.05$), and no significant differences were found among all enzymes. Carcass yield, relative weight of the breast, legs, liver, and gizzard as percentage of live weight were not affected by enzyme supplementation ($P > 0.05$). The results of current study led to the conclusion that there were similar improvements on performance and meat yield of birds fed diets with enzyme supplementation. Therefore, choice preference of supplementation should be based on its economic value.

Key Words: xylanase, β-glucanase, meat yield

T213 Effect of high levels of phytase for broilers. C. Meneghetti, A. G. Bertechini*, J. A. G. Brito, and S. F. Castro, *Universidade Federal de Lavras*, *Lavras, MG, Brazil*.

Three trials were carried out to evaluate the effects of supplementation of Citrobacter braaki, an *E. coli* derived phytase preparation (Genophos), on the performance, AMEn, retention and excretion of minerals and bone ash of broiler chickens. Broiler performance was evaluated using 3-phase feeding program (1–21 d, 22–35 d and 36–42 d of age). In trial 1, a total of 1456 d-old, male Cobb 500 broiler chicks were placed in 56 litter floored pens in a complete randomized design with 8 replicates/treatment. The treatment diets were: (1) Control (C-SBM based diet and no added phytase); (2) 1,500; (3) 3,000; (4) 4,500; (5) 6,000; (6) 8,000 and (7) 10,000 FTU/kg of supplemented phytase. All treatments with phytase had reduction in ME of 85 kcal/kg, Ca of 0.2% and available P 0.12%. In trial 2, 280 10-d-old male Cobb 500 broiler chicks were allotted in 56 metabolism cages to obtain the apparent digestibility of DM, CP, AMEn, Ca and P retention using the same diet from 1 to 21 d of the trial 1, and the excreta collection from 15 to 17 d of age. For trial 3, 168 28-d-old male Cobb 500 broiler chicks were placed in the same diet from 22 to 35 d of trial 1 and excreta collection between 33 and 35 d of age. Results showed that bird performance was similar of controls when 4,500 FTU/kg or higher of phytase inclusion occurred from 1 to 21 d. From 1 to 35 and 1–42 d, the treatments were comparable to control. A quadratic effect ($P < 0.05$) was observed (10–17 d) for AMEn and Ca retention at maximum values obtained with 7,727 and 5,500 FTU/kg of diet, respectively. A linear ($P < 0.05$) improvement in P retention was observed with increased phytase supplementation. At 32–35 d, a quadratic effect ($P < 0.05$) was observed on Ca retention with maximum values at 5,000 FTU/kg of diet. P retention increased (linear effect) with phytase supplementation ($P < 0.05$). Ash, Ca and P in the tibia (42 d) were not affected by treatments. Phytase supplementation starting at 4,500 FTU/kg improved broiler performance challenged in ME, Ca and P.

Research supported by FAPEMIG, MG.

Key Words: available P, Ca retention, nutrient digestibility

T214 Effect of enzymes in the diet of hens on egg quality. F. G. P. Costa*[1], M. L. Ceccantini[2], C. S. Santos[1], C. C. Goulart[1], C. F. S. Oliveira[1], G. B. V. Lobato[1], J. M. Freire[1], V. P. Rodrigues[1], R. C. Lima[1], I. S. Nobre[1], and R. C. L. Neto[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Adisseo Brazil Animal Nutrition*, *Sao Paulo, SP, Brazil*.

This study aims to demonstrate the technical feasibility and economic use of the set of a 6-phytase, 17 Carbohidrolases and 2 proteases (from the supply Rovabio Max AP) in diets for laying hens. The experiment was divided in 5 periods of 28 d each, which were used 360 hens, distributed in a completely randomized design with 5 treatments and 8 replicates of 9 birds per experimental unit. The treatments consisted of 2 diets without enzyme and 3 with the addition of the enzyme. Diets without enzymes were negative and positive controls. The positive control diet (PC) was formulated to meet the requirements of hens. The negative control diet (NC) was formulated with nutrient reduction (100 kcal / kg and 0.36, 0.014, 0.012, 0.12, and 0.153% in the levels of CP, lysine, methionine + cystine, calcium and phosphorus available, respectively). Diets supplemented with 50 g / ton of Rovabio Max AP were formulated to address different levels of linoleic acid, one with the linoleic acid diet equal to CN, the other with an intermediate value and the last with linoleic acid equal to diet PC. These diets have been reformulated considering the nutritional enzyme formulation. Thus, the three diets supplemented with enzymes have been reformulated to meet the nutritional levels of the control diet, except for linoleic acid.). All diets based on corn and soybeans. The data were subjected to analysis of variance with means tested with Tukey and orthogonal contrasts. The weight and percentage of egg specific gravity and pigmentation of the eggs were influenced (P <0.05) by nutrition and supplementation with enzymes. Enzyme supplementation Rovabio Max AP proves efficient in the availability of nutrients to improve the quality of eggs.

Key Words: additive, linoleic acid, production

T215 Use of enzyme complex on the performance of layer hens. F. G. P. Costa*[1], M. L. Ceccantini[2], C. S. Santos[1], C. C. Goulart[1], C. F. S. Oliveira[1], G. B. V. Lobato[1], and J. M. Freire[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Adisseo Brazil Animal Nutrition*, *Sao Paulo, SP, Brazil*.

This study aims to demonstrate the technical feasibility and economic use of the set of a 6-phytase, 17 Carbohidrolases and 2 proteases (from the supply Rovabio Max AP) in diets for laying hens. The experiment was divided in 5 periods of 28 d each, which were used 360 hens, distributed in a completely randomized design with 5 treatments and 8 replicates of 9 birds per experimental unit. The treatments consisted of 2 diets without enzyme and 3 with the addition of the enzyme. Diets without enzymes were negative and positive controls. The positive control diet (PC) was formulated to meet the requirements of hens. The negative control diet (NC) was formulated with nutrient reduction (100 kcal / kg and 0.36, 0.014, 0.012, 0.12, and 0.153% in the levels of CP, lysine, methionine + cystine, calcium and phosphorus available, respectively). Diets supplemented with 50 g / ton of Rovabio Max AP were formulated to address different levels of linoleic acid, one with the linoleic acid diet equal to CN, the other with an intermediate value and the last with linoleic acid equal to diet PC. These diets have been reformulated considering the nutritional enzyme formulation. Thus, the three diets supplemented with enzymes have been reformulated to meet the nutritional levels of the control diet, except for linoleic acid. The production and feed conversion per dozen eggs were affected (P <0.05) by nutrition and supplementation with enzymes. The enzyme Rovabio Max AP was effective in providing nutrients from food for birds. Despite reductions in nutrient levels are higher than recommended by the manufacturer, the use of carbohidrolase, phytase e protease ensures the same productivity in the control group, confirming the effectiveness of the enzyme complex.

T216 Dietary supplementation with two types of enzyme preparations improves nutrient digestibility in growing pigs. X. Ao*[1], S. M. Hong[1], H. Y. Park[2], K. H. Son[3], B. H. Ku[3], D. H. Shin[3], and I. H. Kim[1], [1]*Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*, [2]*Korea Research Institute of Bioscience and Biotechnology*, *Daejeon, Korea*, [3]*Insect Biotech Co. Ltd.*, *Daejeon, Korea*.

The objective of this experiment was to determine the effects of 2 types of enzyme preparations (single or complex) on fecal digestibility and ileal apparent digestibility (AID) in the hindgut of growing pigs. Three ileal–cannulated growing barrows (28.56 ± 0.58kg) were housed in individual metabolism crates and randomly assigned to 1 of 3 treatments within a 3 × 3 Latin square design. The treatments were as follows: 1) CON (basal diet), 2) P1 (basal diet + 0.1% protease), and 3) P2 (basal diet + 0.1% complex enzyme including protease, xylanase and lipase). The 3 feeding periods consisted of 4 d of acclimation to the diet followed by 5 d of fresh feces samples collection and 6 and 7 d of ileal-digesta collection. Ileal effluents were continuously collected for the same 12–h interval each day. Pigs fed the P1 diet had a higher DM and energy digestibility ($P < 0.05$) than pigs fed the CON and P2 diets, while the N digestibility was greater ($P < 0.05$) in the CON and P1 groups than in the P2 group. The AID of DM and energy was increased ($P < 0.05$) in the P1 and P2 groups when compared with the CON group, with the P1 treatment showing the highest levels. The AID of N digestibility was also greater ($P < 0.05$) for pigs fed the P1 diet than for those fed other diets. Pigs fed the P1 diet had a higher AID of total essential AA and non-essential AA ($P < 0.05$) than those fed the CON and P2 diets. A similar tendency was also observed in individual AA ileal digestibility. In conclusion, these results showed that the single protease addition improved nutrient digestibility.

Key Words: enzyme, nutrient digestibility, growing pigs

T217 Effects of dietary Tylan inclusion level on the growth performance and carcass characteristics of growing–finishing pigs. C. L. Puls*[1], M. Mercedes[1], M. Ellis[1], A. M. Gaines[2], B. A. Peterson[2], B. F. Wolter[2], and M. Kocher[2], [1]*University of Illinois*, *Urbana*, [2]*The Maschhoffs*, *Carlyle, IL*.

This study was carried out to evaluate the effect of including Tylan in the diet of growing-finishing pigs on growth performance and carcass characteristics. The study was carried out from 39.9 ± 1.45 kg to 127.2 ± 1.13 kg BW and compared 2 Tylan inclusion levels (0 vs. 10 g/ton). Diets were formulated to meet or exceed the nutrient requirements proposed by NRC (1998). The study involved 144 barrows housed in pens of 9 with 8 pens per inclusion level. Pigs had ad libitum access to feed and water throughout the study period. At the end of the study period, pigs were sent to a commercial facility for harvest and carcass evaluation. There was no effect ($P > 0.05$) of Tylan inclusion level on overall ADG, ADFI, or G:F ratio. Mortality levels were lower for pigs fed Tylan compared with the control (0.00 vs. 2.82%, respectively); however, this difference was not significant ($P = 0.15$). There was a trend ($P = 0.06$) for carcass yield to be greater for pigs fed Tylan compared with the control (74.9 vs. 74.3%, respectively; SEM 0.42) and this resulted in an improvement ($P < 0.01$) in carcass G:F ratio for pigs fed Tylan (0.26 vs. 0.25 kg:kg, respectively; SEM 0.004). There was no

effect ($P > 0.05$) of Tylan inclusion level on back fat thickness, *Longissimus* muscle depth, or predicted carcass lean content. In conclusion, this study suggests that feeding Tylan (at 10 g/ton) to growing-finishing pigs does not affect live weight growth performance but could reduce mortality, and improve carcass yield and carcass feed efficiency, findings that warrant validation.

Key Words: pigs, growth, Tylan

T218 Effect of a protease enzyme on performance of weanling piglets fed corn-soybean diets with different protein levels. D. Wang[1], X. Piao[1], F. C. Guo[2], H. Cao[2], J. Zhao[2], and R. J. Harrell*[2], [1]*China Agricultural University*, *Beijing, China*, [2]*Novus International Inc.*, *St Charles, MO*.

Application of exogenous enzymes can improve the digestibility of feedstuffs, lower dietary costs, and improve animal performance. The objective of the present study was to examine the benefits of supplementing nursery pig diets with a protease enzyme (NZ) at 2 levels of dietary protein. A total of 190 pigs (8.31 ± 0.63 kg of BW) were allotted by weight and sex to one of 4 treatments in a 2 × 2 factorial arrangement with the factors being high (HP, 20.3% CP) vs. low dietary protein (LP, 18.3% CP) and 0 vs. 500 mg/kg protease (Cibenza DP100, Novus International Inc., St. Charles, MO) for a period of 21 d with 6 replicates (n = 7 or 8 pigs/pen). All the diets were formulated according to an ideal amino acid pattern. CP level did not alter ADFI ($P > 0.83$), ADG ($P > 0.73$), or GF ($P > 0.57$). No differences were observed for the NZ on ADG ($P > 0.20$) or ADFI ($P > 0.22$). The GF was improved by 17% with the addition of NZ (0.623 vs. 0.728 ± 0.016; $P < 0.01$), regardless of dietary CP level. The digestibility of DM, OM, or energy was not affected by dietary CP level ($P > 0.45$). The addition of NZ increased CP digestibility by 3.5% (84.3 vs. 87.2 ± 0.5%, $P < 0.01$), increased DM digestibility by 2.2% (86.1 vs. 88.0 ± 0.4%, $P < 0.01$), and energy by 2.3% (86.5 vs. 88.5 ± 0.4%, $P < 0.01$), regardless of dietary CP level. Blood urea nitrogen levels were higher in pigs fed HP compared with LP (4.0 vs. 2.58 ± 0.21 mmol; $P < 0.01$). The addition of NZ interacted with CP level on BUN levels by increasing BUN in HP, but not in LP dietary CP ($P < 0.02$). These results indicate that the addition of a protease enzyme can improve digestibility of feedstuffs and improve feed efficiency in nursery pigs.

Key Words: swine, nursery, protease

T219 Effects of supplementing different enzymes on performance, nutrient digestibility and blood metabolites in growing pigs. J. K. Jo[1], P. L. Shinde[1], J. S. Kim[1], Y. W. Kim[1], K. H. Kim[1], J. D. Lohakare[1], C. S. Ra[1], J. H. Lee[2], and B. J. Chae*[1], [1]*Kangwon National University*, *Kangwon National University, Chuncheon, Rep. of Korea*, [2]*CTC Bio. Inc.*, *CTC Bio. Inc., Seoul, Rep. of Korea*.

A 28-d growth study was conducted to investigate the effects of mannanase (M), amylase + mannanase (AM), mannanase + protease (MP) and amylase + mannanase + protease (AMP) supplementation on the performance, apparent total tract digestibility (ATTD) of nutrients and blood metabolites in growing pigs. A total of 240 growing pigs (initial BW 55.58 ± 0.85 kg) were randomly allotted to 5 treatments on the basis of BW. Each treatment was comprised of 4 replicates with 12 pigs in each. A corn-soybean meal based diet (control) was supplemented with 0.05% M, AM, MP or AMP as dietary treatments. Pigs fed enzyme supplemented diets had greater ($P < 0.05$) ADG and ATTD of DM than pigs fed control diet. Moreover, pigs fed AMP diet had higher ($P < 0.05$; 949 vs. 918, 933 and 929 g) ADG than pigs fed M, MP and AM diets. Pigs offered AMP and MP diets had better F/G ($P < 0.05$; 2.91 and 2.95 vs. 3.05 g/g) than pigs fed control diet. In addition, pigs fed MP diet gained more ($P < 0.05$; 933 vs. 918 g) when compared with pigs offered M diet. The ATTD of DM was higher ($P < 0.05$; 81.29 vs. 80.50%) in pigs fed AMP diet when compared with pigs fed M diet; while the ATTD of CP was higher ($P < 0.05$; 76.44 vs. 75.24 and 75.21%) in pigs fed AMP diet when compared with pigs fed AM and control diets. Additionally, the blood urea nitrogen concentration was greater ($P < 0.05$; 17.75 vs. 14.15 and 13.50 g/dl) in pigs fed MP diet when compared with pigs fed AM and control diet. These results indicate supplementation of different enzymes in combination (mannanase + protease and amylase + mannanase + protease) to be more efficient in improving the performance and nutrient digestibility in growing pigs.

Key Words: enzymes, performance and nutrient digestibility, growing pigs

T220 Evaluation of the effects of dietary enzyme on growth performance, nutrient digestibility, blood characteristics and ileal digestibility in growing pigs. L. Yan*, H. D. Jang, T. X. Zhou, X. Ao, J. H. Jung, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

Two experiments with growing pigs were conducted to investigate the effects of 2 distinct multi–enzyme preparations on nutrient digestibility, growth performance and blood profiles. In Exp.1, a total of 96 pigs (29.7 ± 0.69 kg) were used in a 42-d performance and digestibility trial using 4 dietary treatments: CON (control diet), E (control+0.10% Endopower), N1 (control+0.10% NSPase) and N2 (control+0.20% NSPase). Endopower is a commercial multi-enzyme preparation that contains α-galactosidase, galactomannase, xylanse and β-glucanase. NSPase primarily contained α-1,6-β-galactosidse, β-1,4-mannanase, and β-1,4-mannosidase. There were 6 replication pens per treatment with 4 pigs per pen. Pigs fed the N1 diet had a higher ADG ($P < 0.05$) and G:F ($P < 0.05$) than those fed the control diet. There were no significant differences in the ADG and G:F among the multi-enzyme treatments ($P > 0.05$). When compared with the control, the apparent digestibility of DM was increased ($P < 0.05$) by E treatment. The N digestibility was improved ($P < 0.05$) in response to multi-enzyme treatments during the experimental period. In addition, BUN was higher ($P < 0.05$) in the E treatment group than in the CON and N1 treatment groups at the end of the experiment, while the level of glucose was improved ($P < 0.05$) by E and N2 treatments. In Exp.2, 4 ileal-cannulated growing barrows (20.17 ± 1.31 kg) were housed in individual metabolism crates and randomly assigned to 1 of 4 treatments (same as Exp.1) within a 4 × 4 Latin square design. Enzyme supplementation improved the majority of apparent ileal AA digestibility ($P < 0.05$). These findings demonstrated that supplementation of the diet of these enzymes could improve the feeding values of growing pigs fed a diet based on corn and soybean meal.

Key Words: enzyme, digestibility, growing pigs

T221 Protease increased in vitro digestibility of various feed ingredients. F. Yan*, P. Disbennett, M. Schulz, M. Vazquez-Anon, N. Odetallah, S. Carter, and D. Dowell, *Novus International Inc.*, *St. Charles, MO*.

A protease (CIBENZA DP100, Novus International Inc.) was evaluated in an in vitro system to evaluate its ability to degrade proteins in a variety of feed ingredients and it was also compared with a commercial protease, denoted as Protease B. Soybean meal, canola meal, cottonseed meal, DDGS, corn, wheat, lupin, poultry meal, meat and bone meal, fish meal, feather meal, and blood meal were tested in the study. Each

test ingredient was solubilized for 4 h at pH 2.4 and protein concentration of 8 mg/ml, buffered to pH 7.5, and then incubated with either DP100 or Protease B for 18 h at 37°C, at an enzyme concentration that it would encounter in the digesta in vivo when it is used at the recommendation dose based on the assumption of water intake being twice of feed intake. For negative control, deionized water was added. After 18 h of incubation, OPA (o-phthaldialdehyde) analysis with UV-vis spectroscopy was performed to measure β ± -amino groups. All tests were performed in quadruplicate. Both DP100 and Protease B demonstrated proteolytic activity for all ingredients tested ($P < 0.0001$) compared with the negative control, which indicated broad substrate specificity of these proteases. Their ability to hydrolyze proteins from different feed ingredients varied where they were most effective in hydrolyzing blood meal proteins and less efficient for corn and feather meal proteins. Cibenza DP100 outperformed Protease B for all ingredients ($P < 0.05$) except for corn. The percent increase in absorbance of DP100 over Protease B was 23.0% for soybean meal, 27.3% for canola meal, 42.0% for cottonseed meal, 59.4% for DDGS, 39.5% for wheat, 51.6% for lupin, 13.4% for poultry meal, 20.9% for meat and bone meal, 12.8% for fish meal, 7.3% for feather meal, and 32.1% for blood meal. These results demonstrated efficacy of CIBENZA DP100 in digesting proteins from various feed ingredients and it can be beneficial in improving protein digestion of animals fed diets containing these ingredients.

Key Words: protease enzyme, in vitro, digestibility

T222 Effects of graded levels of phytase on the apparent and standardized total tract digestibility of phosphorus in corn and corn co-products. F. N Almeida* and H. H. Stein, *University of Illinois*, *Urbana*.

An experiment was conducted to measure the effects of graded levels of microbial phytase on the standardized total tract digestibility (STTD) of P in corn, distillers dried grains with solubles (DDGS), high protein distillers dried grains (HP-DDG), and corn germ. A second objective was to develop regression equations to predict the response of adding phytase to each of these ingredients. Four corn based diets, 4 DDGS based diets, 4 HP-DDG based diets, and 4 corn germ based diets were formulated. The 4 diets with each ingredient contained 0, 500, 1,000, or 1,500 phytase units (FTU) per kg (Optiphos 2000, Enzyvia, Sheridan, IN). A P-free diet was also formulated to measure the basal endogenous losses of P. A total of 102 pigs (initial BW: 18.2 ± 2.1 kg) were individually housed in metabolism cages equipped with a feeder and a nipple drinker and a screen floor that allowed for total collection of feces. Pigs were allotted to the 17 diets in a randomized complete block design with 6 replicates per diet. Supplementation of microbial phytase increased (linear, $P < 0.01$; quadratic, $P < 0.05$) the STTD of P in corn from 40.9 to 67.5, 64.5, and 74.9%, tended to increase (linear, $P = 0.07$) the STTD of P in DDGS from 76.9 to 82.9, 82.5, and 83.0%, increased (linear, $P < 0.01$; quadratic, $P < 0.05$) the STTD of P in HP-DDG from 77.1 to 88.0, 84.1, and 86.9%, and increased (linear and quadratic, $P < 0.01$) the STTD of P in corn germ from 40.7 to 59.0, 64.4, and 63.2% in diets supplemented with 0, 500, 1,000, or 1,500 FTU/kg of phytase, respectively. Regression equations were developed to allow the calculation of the STTD of P with any level of phytase (Optiphos 2000, Enzyvia, Sheridan, IN) for each of the test ingredients. Therefore, results of this experiment allow the prediction of the amount of digestible P in these ingredients containing any level of phytase between 0 and 1,500 FTU.

Key Words: digestibility, phosphorus, phytase

T223 Effects of multi-enzyme on nutrients digestibility and metabolizable energy values of pure corn and wheat diets. G. G. Zhang*, Z. B. Yang, Q. Q. Zhang, W. R. Yang, and S. Z. Jiang, *Shandong Agricultural University*, *Taian, China*.

Objectives of this study were to determine effects of enzyme supplementation in pure corn- and wheat-based diets on energy efficiency and nutrients utilization in poultry. By force-fed true metabolizable energy bioassay (TME Bioassay) method, a metabolic trial was conducted, 90 healthy adult roosters with similar weight were randomly assigned to 10 dietary groups with 3 replicates of 3 roosters for each, 2 of the groups (controls) were not force-fed during experiment for collecting endogenous excreta, other groups were force-fed corn with different levels multi-enzyme (0, 50, 100, and 150 mg/kg of diet), or force-fed wheat with different levels multi-enzyme (0, 50, 100, and 150 mg/kg of diet), respectively. The results showed the use of multi-enzyme preparation in corn enhanced the apparent/true digestibility (AD/TD) of neutral detergent fiber (NDF) ($P < 0.05$), dry matter (DM) ($P < 0.05$), and starch ($P < 0.05$), the apparent metabolizable energy (AME) value and true metabolizable energy (TME) value were increased by 6.76%, and 5.86% respectively. Inclusion of multi-enzyme in wheat improved the AD/TD of NDF($P < 0.05$), DM($P < 0.05$) and starch ($P < 0.05$), AME and TME were enhanced by 9.75%and 8.88% respectively. Nutrients digestibility and metabolizable energy values showed linear or quadric increasing trend, with the amount of multi-enzyme added in corn and wheat. It appears from this study that the nutrients utilization of pure corn or wheat diet could be enhanced by using appropriate multi-enzyme supplement. However, an proper addition is necessary in corn to maximize the nutrients utilization and energy conversion, and higher rates of supplementation did not lead to further increase in nutrients digestibility and ME values.

Key Words: multi-enzyme, digestibility, metabolizable energy

T224 Effect of Rovabio Max on energy and nitrogen utilization in diets high in distillers dried grains with solubles. A. J. Karimi*[2], Y. Min[1], J. H. Park[1], C. A. Coto[1], C. Lu[1], F. Yan[1], and P. W. Waldroup[1], [1]*University of Arkansas*, *Fayetteville,* [2]*University of Kurdistan*, *Kurdistan, Iran*.

The inclusion of DDGS in poultry diets is limited due the reduced content of starch and high levels of Non Starch Polysaccharides (NSP). An improvement on the nutrient availability through the use of exogenous enzymes represents an alternative to increase its utilization. Rovabio Max is a preparation containing xylanases, β-glucanases, pectinases, mannanases, phytase and α-galactosidase. A study was conducted to evaluate the use of Rovabio Max on utilization of diets containing high levels of DDGS. The experimental design consisted of a 2 × 4 factorial arrangement. Two isocaloric (ME = 3020 kcal/kg) basal diets were formulated, one with no DDGS and the second with 30% DDGS of known composition. Chromic oxide was used as an indigestible marker. Aliquots of the 2 basal diets were supplemented with no enzyme or 3 levels of Rovabio: The recommended level (1X), twice (2X) and 4 times (4X) the recommended level. One hundred and 90 2 male chicks of a commercial strain (Cobb 500) were fed a common nutritionally complete diet to 18 d at which time they were placed on the study. Each experimental diet was fed to 4 pen replicates of 6 male chicks in wire floor battery cages. After a 5-d adaptation period, excreta samples were collected and freeze-dried to determine GE, AME and N retention. Birds were weighed and feed consumption determined. The ANOVA considered DDGS level, enzyme, and interaction. No significant ($P > 0.05$) effect of Rovabio, DDGS and their interactions was found on body weight, feed intake, feed conversion and mortality. No effect of the enzyme was found for

GE, N in excreta, N retention, AME and AMEn. No interaction between DDGS and Rovabio was found for nitrogen and energy utilization. The inclusion of 30% DDGS in the diet significantly ($P < 0.05$) increased the GE and N in excreta with no effect on AME and AMEn values. The increased concentration of nutrients in excreta deserves consideration due to environmental implications.

Key Words: DDGS, enzymes, digestibility

T225 Effect feed processing method and enzyme supplementation of wheat- based diets on performance, gastrointestinal and carcass characteristics in broiler chicks. Z. Qobadi and A. Karimi*, *University of Kurdistan, Sanandaj, Kurdistan, Iran*.

This study was carried out to compare the effects of feed processing (pelleted vs. mash) and enzyme supplementation (with and without 0.3g Grindazym GP 15000 /kg of wheat in complete diet) in a wheat-based diet on performance, gastrointestinal and carcass characteristics of broiler chicks to 36 d of age. Ross 308 straight-run broiler chicks (n = 336) were randomly allocated to 4 dietary treatments, each replicated 4 times (21 chicks per pen) in a completely randomized design in a 2 × 2 factorial arrangements. Measurements included body weight (BW), daily gain (DG), feed intake (FI) and feed conversion ratio (FCR) at 20 and 36 d of ages. The relative weights of gastrointestinal organs to body weight were determined at 20 and 36 d of ages. The pH of ileum digesta content was also determined at 20 d of age. The results showed that the broiler chicks fed pelleted diets had significantly improved BW at 36 d of age, DG during 20 to 36 and 0 to 36 d of ages and FI during 0 to 20, 20 to 36 and 0 to 36 d growth period. Feed conversion ratio was significantly increased in pelleted fed treatment during 0–20 and 0 - 36 d growth period. Enzyme supplementation had significantly improved BW at 20 and 36 d of age, DG during 0–20, 20–36 and 0–36 d of ages, FI during 0 to 20 and 0 to 36 d of ages and FCR during 0–36 d of ages. The interaction between feed processing and enzyme supplementation was only significant on FCR during 20–36d. Neither feed processing nor enzyme supplementation had significant effects on ileum digesta pH measurements, carcass and gastrointestinal characteristics, except gizzard relative weight at 36 d of age. In conclusion, the results of this experiment confirmed the beneficial effects of both pelleting and feed enzyme supplementation on broiler chicks' performance.

Key Words: wheat, processing, enzyme

T226 Calcium chloride reduces the negative impact of feeding high potassium and co-product containing diets to finishing pigs. J. Guimaraes*, C. L. Zhu, D. Wey, and C. F. M. de Lange, *University of Guelph*, *Guelph, Ontario, Canada*.

Co-products from the biofuel and human food industries may serve as alternative pig feed ingredients. Previously, we observed a reduction in animal performance when pigs were liquid-fed high potassium (K) diets containing corn steep water (CSW) and whey permeate (WP). This study was conducted to investigate the addition of calcium chloride ($CaCl_2$) to pig diets to reduce the negative impact of feeding high K levels. A total of 192 purebred Yorkshire pigs (average initial BW 45.5 kg; 4 gilts and 4 barrows per pen) were liquid-fed 1 of 6 diets over a 9 week period: (1) CSBM (Corn and soybean meal based diet with added 0.9% potassium carbonate; 0.98% K); (2) CSBM/$CaCl_2$-mEq (CSBM with added 0.84% $CaCl_2$); (3) CSBM/$CaCl_2$ (CSBM diet with added 1.05% $CaCl_2$); (4) Co-prod (22% WP, 6% CSW, 1.28% K); (5) Co-prod/$CaCl_2$-mEq (Co-prod diet with added 0.87% $CaCl_2$); (6) Co-prod/$CaCl_2$ (Co-prod diet with added 0.68% $CaCl_2$). Diets 2 and 5 were formulated to an electrolyte balance of 166 mEq/kg; diets 3 and 6 were designed to maintain a target balance between K and Cl. Data were exposed to analyses of variance using GLM of SAS with treatment as the only source of variation; treatment means were compared using orthogonal contrasts. Diet did not influence feed intake ($P > 0.05$). For CSBM, adding $CaCl_2$ at both levels improved feed to gain (2.36 vs 2.57; $P < 0.01$); such response was not seen for Co-prod ($P > 0.10$). Hot carcass weight and carcass lean yield did not differ among treatments ($P > 0.05$). For Co-prod, adding $CaCl_2$ reduced plasma carbon dioxide levels ($P < 0.01$). Based on quantitative histology observations, the addition of $CaCl_2$ to Co-prod eliminated damage to walls of glomeruli capillaries. Optimal $CaCl_2$ additions to high K diets are still to be confirmed. These results suggest that some of the negative effects of feeding high K co-product containing diets to pigs can be reduced, reducing the reliance on traditional feed ingredients for pigs.

Key Words: pigs, calcium chloride, co-products

T227 Production and characterization of a thermostable beta-propeller phytase from *Bacillus licheniformis*. S. J. Fu*1,3, J. Y. Sun[1], X. Y. Weng[2], L. C. Qian[1], and Z. Q. Shen[4], [1]*Microbiology Division, Institute of Feed Science, College of Animal Science, Zhejiang University*, *Hangzhou Zhejiang, China*, [2]*College of Life Science, Zhejiang University*, *Hangzhou Zhejiang, China*, [3]*Binzhou Animal Husbandry and Veterinary Research Institute*, *Binzhou Shandong, China*, [4]*Shandong Lvdu Biological Technology Co., Ltd*, *Binzhou Shandong, China*.

A novel β-propeller phytase producing thermophilic strain of *Bacillus licheniformis* was isolated from soil. The optimal fermentation parameters for producing phytase by *B. licheniformis* under shake flask culture were determined by single factor test and the results were as follows: 1.0% dextrose used as carbon source, 0.1% $(NH_4)_2SO_4$ as nitrogen source, initially pH7.5, incubation temperature 55°C. After incubation for 36h under these conditions, the activity of neutral phytase reached 0.267 U/mL with specific activity 0.701U/mg. The optimum temperature and pH of the phytase from *B. licheniformis* (PhyC) were 55°C and 7.0, respectively. After treated at 80°C, pH 7.0 for 10 min, the residual activity of PhyC was 57.36%. Over 80% of PhyC activity was retained after treatment by preincubation over a pH range of 6.5–9.0 for 1 h at 25°C. As for substrate specificity, it was very specific for sodium phytate and showed no activity on other phosphate esters. Its activity was greatly inhibited by EDTA and metal ions such as Cd^{2+}, Mn^{2+}, Cu^{2+} and Ba^{2+}.

Key Words: *Bacillus licheniformis*, phytase, characterization

T228 A Lysozyme supplement for piglets: Weaned pigs responses to *Escherichia coli* K88$^+$ (ETEC) oral challenge. E. Kiarie*[1], S. Bhandari[1], D. O. Krause[1], G. Zhang[2], and C. M. Nyachoti[1], [1]*University of Manitoba*, *Winnipeg, MB, Canada*, [2]*Neova Technologies Inc.*, *Abbotsford, BC, Canada*.

Lysozyme is a low-molecular-weight protein with antimicrobial properties. An experiment was conducted to investigate response of piglets receiving Entegard (EG, a water-soluble lysozyme antimicrobial blend) upon oral challenge with ETEC. A total of 36 individually housed weanlings were randomly allotted to 1 of the 4 treatments to give 9 pens per treatment. Treatments were control (C, no additive), antibiotic (AB, in-feed) and EG (EG1 and EG2, in-water). All pigs received a basal diet similar in composition and nutrients (NRC, 1998), except AB pigs which had an added Aureo SP 250. Entegard was delivered in the drinking water: EG1, 0.1% and EG2, 0.2%. Pigs were acclimatized to treatments for a 7-d period to monitor growth performance. On d 8, each pig was bled to obtain serum and gavaged with 6 mL (2×10^9 cfu/ml) of

ETEC. Pigs were monitored for another 7 d to assess severity of diarrhea using a fecal consistency scoring system and growth performance, subsequently all pigs were killed to obtain intestinal tissues and digesta samples. Treatments did not influence ($P > 0.10$) growth performance throughout the study. More ETEC counts were observed on the ileal ($P = 0.001$) and colon ($P = 0.025$) mucosal scrapings of the C pigs than AB and EG1 pigs which in turn showed numerically lower incidences on diarrhea than C. Pigs receiving AB and EG1 had higher small intestine weight and ileal villous height than those receiving C, however, ileal villi height to crypt depth ratio for EG1 (1.56) and EG2 (1.38) was similar to that of AB (1.68) pigs which was in turn higher than that of C (1.34) pigs. Pigs in the EG1 group showed higher ($P < 0.001$) serum tumor necrosis α (TNF-α) and interleukin 6 (IL-6) before ETEC challenge, however, 7-d post-challenge pigs receiving EG2 showed ($P < 0.05$) the least circulating TNF-α and IL-6. Overall, better intestinal growth and development as well as lower ETEC counts on the intestinal mucosal and serum pro-inflammatory cytokines suggest that Entegard can maintain gut health and function in piglets commensurate to antibiotics.

Key Words: lysozyme, piglet performance, gut health and function

T229 Effect of microbial phytase on growth performance, plasma phosphorus concentration and tibia mineralization of broilers according to dietary calcium and phosphorus concentrations. M. P. Letourneau Montminy*[1], N. Meme[2], M. Magnin[3], and A. Narcy[2], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Qc, Canada*, [2]*INRA UR83*, *Nouzilly, France*, [3]*BNA Nutrition Animale*, *Chateau-Gontier, France*.

One hundred ninety-two 4-d-old Ross broilers were used to investigate the effect of microbial phytase according to various dietary non-phytate P (NPP) and Ca concentrations on growth performance, plasma P concentration and bone mineralization. Broilers were fed maize-soybean meal diets from 4 to 21 d of age in a 4 × 2 x 2 factorial arrangement with varying concentrations of Ca (0.5, 0.75, 1.0 and 1.25%), NPP (0.2, 0.3 and 0.4%) and microbial phytase (Natuphos; 0 and 500 FTU/kg). The effect of dietary NPP on ADG, ADFI, feed conversion ratio, plasma P concentration, tibia weight, ash weight and ash concentration was dependent on dietary concentration of Ca (NPP × Ca, $P < 0.001$) and microbial phytase (NPP × Phyt, $P < 0.001$). Thus, the negative impact of decreasing dietary NPP concentration on these variables was more important in high than in low Ca diets. Also, the positive impact of phytase on growth performance, plasma P concentration and tibia mineralization was increased when NPP was decreased. Additionally, the impact of phytase on growth performance, plasma P, tibia weight, ash weight ($P < 0.001$) and tibia ash concentration ($P < 0.05$) is affected by Ca concentration. These results show that broilers are sensitive to P deficiency which decreases growth performance, plasma P concentration and bone mineralization. However, the impact of P deficiency in animal responses is higher when birds are fed high Ca diets. Furthermore, the response of broilers to phytase was affected by dietary Ca and NPP concentrations, increasing phytase effects when Ca was increased or NPP was decreased. Thus, the more severe the P deficiency (high Ca or low NPP), the more the response of birds to phytase for the studied criteria was important. Optimal dietary concentration of NPP should be established according to dietary Ca and phytase addition. It is also worth noting that these results emphasize the needs to normalize dietary conditions in which P equivalency of phytase are determined.

Key Words: calcium, phytase, broilers

T230 Effect of phytase application on the calcium and phosphorus retention and balance of layers in the last third of the laying cycle. J. Tossenberger[1], L. Babinszky*[1], and I. Kühn[2], [1]*Kaposvár University*, *Kaposvár, Hungary*, [2]*AB Vista*, *Darmstadt, Germany*.

Calcium (Ca) and phosphorus (P) retention (RET) and the amount and percentage of Ca and P release via eggs were studied in the last third of the laying cycle (wk 39 of egg production). A corn–soybean meal based diet was fed to 96 Hy-Line Brown hybrid layers (3 layers/cage) distributed over 4 treatments (Trts). Feeds had identical Ca levels (39.3 g/kg); P levels and phytase activities differed. P content of TrtI was 2.0 g/kg non-phytate P (NPP) (positive control: PC). P content of Trt2 was 1.0 g/kg NPP (negative control: NC). Trts3 and 4 had same P content as Trt 2 but also had an added 6-phytase, (FINASE EC, from *Trichoderma reesei*), at 125 PPU/kg (Trt3) and 250 PPU/kg (Trt4). Data were analyzed by ANOVA (SAS, 2004). Ca and P RET was lowest in NC group (Ca: 1686 mg/d, P: 78 mg/d). Adding 125 PPU/kg phytase increased Ca and P RET to the PC group levels ($P \geq 0.05$), i.e. 1888 mg/d and 129 mg/d ($P \leq 0.05$). Ca and P RET increased only numerically in Trt4 ($P \geq 0.05$). While NC birds secreted 84.6% of retained Ca (1420 mg/d) and 84.9% of retained P (66 mg/d) with the egg, these values were 98% (1869 mg/d) and only 67.3% (87 mg/day) for Trt3 birds. In consequence Ca balance dropped from +6.9% (NC) to +0.3% (attributable to increased production of birds), while P balance grew from +3.9% to +12.5% (attributable to relatively low egg P level which offsets increased production) (data not shown). The higher phytase dosage (Trt4) did not lead to further Ca and P output in the egg, their amount and ratio being close to those found in Trt3. The Ca balance of PC birds was at an equilibrium, and their P balance showed a surplus of +6.3%. To conclude, adding the tested 6-phytase to low P (1.0 g NPP/kg) layer diets at a level of 125 PPU/kg already improves the Ca and P RET of layers also in the last third of the laying cycle, beside improving their P balance. This should be considered when choosing the P content of the diets and can be used as a tool to reduce P excretion by layers.

Key Words: layer, phosphorus/calcium, retention/balance

T231 Effect of enzyme preparation on nutrient digestibility, digestive enzyme activities and pancreatic enzyme mRNA expression of hens during late laying period. C. Wen*[1], L. Wang[1], T. Wang[1], Y. Zhou[1], G. Hou[2], and Z. Zhou[2], [1]*Nanjing Agricultural University*, *Nanjing, Jiangsu, China*, [2]*Guangdong VTR Bio-Tech Co., Ltd*, *Zhuhai, Guangdong, China*.

This experiment was conducted to study the effect of enzyme preparation on nutrient digestibility, digestive enzyme activities and pancreatic enzyme mRNA expression of hens during late laying period. Thirty-six 58-wk-old ISA Brown hens were randomly allocated to 2 groups with 6 replicates (3 birds per replicate), and fed corn-soybean meal based diets with or without an enzyme preparation (including phytase, xylanase, cellulase, α-amylase and acid protease) for 4 weeks. The apparent digestibility coefficients of protein, fat and Ca were increased ($P < 0.05$) by enzyme supplementation. The birds fed diets containing enzyme preparation also had a higher ($P < 0.05$) protease activity in jejunal digesta compared with the control group. The pancreatic enzyme activities and their mRNA expression were reduced by enzyme supplementation, but the differences were not significant. The data show that the enzyme preparation is effective in improving nutrient digestibility, but may depress the synthesis of digestive enzymes in pancreas.

Key Words: hen, nutrient digestibility, digestive enzyme activity

T232 Effects of multi-enzyme and *Bacillus subtilis* on sow reproductivity. T. X. Zhou*, J. S. Yoo, H. J. Kim, Q. W. Meng, J. H. Jung, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

The objective of the experiment was to evaluate the effect of multi-enzyme (Endopower: α-galactosidase, β-glucanse, galactoamannanase and xylanase) and *Bacillus subtilis* on sow productivity. A total of 100 sows (Landrace × Yorkshire) were randomly allotted into 4 dietary treatments and each treatment had 25 sows. The experiment was conducted from July to August 2009. Sows were fed experiment diets from 4 d before farrowing to 21 d of weanling. No crossfostering was done. Dietary treatments were as followed: 1) CON (basal diet), 2) E (basal diet + 1 g/kg Endopower), 3) B (basal diet + 0.4 g/kg *Bacillus subtilis*), and 4) EB (basal diet + 1 g/kg Endopower + 0.4 g/kg *Bacillus subtilis*). Differences among treatments were separated by Duncan's multiple range test. Sows fed multi-enzyme and *Bacillus subtilis* had a higher ($P < 0.05$) ADFI than that of sows in CON treatment (4.99 kg/d vs. 4.71 kg/d). The back fat difference of sows fed multi-enzyme and *Bacillus subtilis* was lower ($P < 0.05$) than that of sows in CON treatment (−5.64 mm vs. −3.68 mm). Sows fed multi-enzyme had a higher ($P < 0.05$) litter size than sows fed *Bacillus subtilis* at birth (11.3 vs. 9.6). Sows in E treatment had a greater ($P < 0.05$) number of litters at weanling than sows in B treatment (9.4 vs. 8.1). No difference was observed on litter performance among treatments. Estrus was not affected by dietary treatments. In conclusion, multi-enzyme and *Bacillus subtilis* increased the ADFI of sows and reduced the backfat loss. Besides, multi-enzyme reduced the mortality of piglets.

Key Words: multi-enzyme, Bioplus 2B, sow

T233 EconomasE decreases sterol carrier protein-2 (SCP2) gene expression levels in breast muscle from 6-week-old chickens. K. M. Brennan*, T. Ao, J. L. Pierce, R. F. Power, and K. A. Dawson, *Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech Inc.*, *Nicholasville, KY*.

EconomasE (Alltech Inc.) is a proprietary blend of dietary ingredients designed to enhance antioxidant status. Previous studies have shown that supplemental EconomasE increases serum total antioxidant capacity and decreases breast meat drip loss compared with birds fed a control diet (Ao et al., 2009). Based on these data, breast muscle gene expression profiles were compared from birds fed supplemental vitamin E (VE) and EconomasE. Dietary treatments included 1) corn-soy control diet containing 0.3 ppm Se as selenite, but no VE; 2) Diet 1 plus 50 IU VE / kg; 3) Diet 1 plus 100 IU/kg VE; 4) Diet 1 plus 200 g EconomasE /tonne. Birds were house in pens of 22 birds, with 8 replicate pens per treatment. Seven chicks from each of 4 dietary treatments were randomly selected and killed after 42d on treatment. Total RNA was isolated from frozen breast muscle and gene expression was measured using the Affymetrix microarray system. Gene expression data showed that a potential target, sterol carrier protein 2 (SCP2), decreased with both 50 IU and 100 IU of VE (−1.92-fold and −1.59 fold, respectively) and with EconomasE supplementation (−1.67-fold, $P \leq 0.05$). SCP2 plays an important role in the cellular metabolism of lipids, but SCP2 overexpression leads to increased cellular lipid peroxide damage. The decrease in SCP2 mRNA levels was confirmed using real-time PCR. Relative levels of SCP2 mRNA were significantly decreased with both VE treatments (−1.36-fold and −1.34-fold, respectively) and EconomasE supplementation (−1.42-fold, $P \leq 0.05$). These data show that EconomasE mimics VE in breast muscle, potentially through reducing SCP2 levels and peroxidation of cellular membranes.

Key Words: gene expression, vitamin E, broiler

T234 Effects of different dietary sources of n-3 PUFA on reproductive performance of laying hens. M. Pilevar[1], J. Arshami[1], A. Heravi Moussavi[1], A. Golian*[1], M. R. Basami[1], and A. R. Rezaee[2], [1]*Ferdowsi University of Mashhad*, *Khorasan Razavi, Iran*, [2]*Mashhad University of Medical Sciences*, *Khorasan Razavi, Iran*.

This study was conducted to evaluate the effects of n-3 polyunsaturated fatty acids (PUFAs) on reproductive performance in hy-Line W-36 pullet chicks at the onset of laying period. Two hundred eighty-eight 1-day-old pullet chicks with initial BW of 40.73 g were used in a CRD design to a 2 × 2 factorial arrangement. The main effects were 2 sources of n-3 (flaxseed or fish oil) and 2 levels of n-3 (1.5% and 0.5%) in the diet. The concentration of n-6 PUFA was kept constantly (3% of diet) by soybean oil in all experimental phases. During the 5 experimental phases (starter, grower, developer, pre-developer and pre-peak), feed and water were provided ad libitum. Each dietary treatment (fish1.5, fish0.5, flax1.5 and flax0.5) was assigned to 6 replicate cages with 12 newly hatched pullet chicks per cage. The chicks were raised in cages under optimum environmental conditions until 22 wk as recommended by the Hy-line commercial management guide (2007). On wk 15 of experiment, pullets were transferred to the laying house and individually placed in standard laying cages to determine the day of sexual maturity (first oviposition). All birds were photostimulated at 18 wk of ages. The weight of first egg at sexual maturity and 22 wk egg production were numerically decreased in birds fed diet fish1.5 ($P > 0.05$). However, egg production was affected by the sources ($P = 0.005$) and levels of n-3 ($P = 0.003$) of the diet at 21 wk. At the end of wk 18, no significant differences were observed in the BW and FI between sources and levels of n-3 PUFA ($P > 0.05$). In this study, time of sexual maturity was negatively affected by the sources ($P = 0.029$) and interaction between main effects ($P = 0.03$). Laying hens fed fish oil came into oviposition later, after photostimulation according to this: fish1.5; 20d, fish0.05; 14d, flax1.5; 11d and flax0.5; 14d. Our results show that high levels of fish oil delay the time of first oviposition compared with flaxseed.

Key Words: n-3 PUFA, first oviposition, laying hen

T235 Docosahexaenoic acid does not increase insulin sensitivity in gilts. J. H. Eisemann*, S. Whisnant, and J. Odle, *North Carolina State University*, *Raleigh*.

Dietary fish oil increased insulin sensitivity in several species including miniature pigs. Fish oil is rich in eicosapentaenoic acid (EPA, 20:5, n-3) and docosahexaenoic acid (DHA, 22:6, n-3). The objective was to measure insulin sensitivity in gilts consuming diets containing added DHA. Gilts were fed diets formulated to contain 0% DHA (Control, Cont; n = 5) or 0.54% added DHA provided by DHAgold (Martek Biosciences Corp., Columbia, MD; n = 7). Inclusion of DHAgold also provided 0.23% added docosapentaenoic acid (DPA, 22:5, n-6). Diets were fed for 6 wks before measurement of insulin sensitivity. Body weight at the time of sampling was 110.0 kg (SEM 7.3 kg) for gilts fed Cont and 111.4 kg (SEM = 6.0 kg) for gilts fed DHA. An i.v. glucose tolerance test (IVGTT; 1.25 g glucose/kg BW $^{0.75}$) and an i.v. insulin tolerance test (IVITT; 0.30 IU insulin/kg BW $^{0.75}$) were conducted on successive days. Blood samples were taken from indwelling jugular catheters at 30, 15, and 5 min before and 2.5, 5, 10, 15, 20, 30, 40, 50, 60, 75, and 90 min after infusion to measure concentrations of Gluc and Ins (IVGTT) or Gluc only (IVITT). Basal concentrations of Gluc and Ins did not differ between diets and were 5.06 and 4.82 mM Gluc; and 12.6 and 9.2 uIU/mL Ins for Cont gilts and DHA gilts, respectively. The area under the response curve (AUC) for Gluc response to the Gluc infusion (mM Gluc x 30 min) tended to be greater ($P < 0.07$) in gilts fed DHA (113.9) compared with Cont gilts (94.0). There was a tendency ($P = 0.10$) for greater Gluc half-life (min) in gilts fed DHA (9.96) than gilts fed Cont (8.52). The AUC for Ins response to the Gluc infusion and the AUC for Gluc response to the Ins infusion did not differ for the 2 groups and were 1002 and 1266 (uIU insulin/mL x 30 min) for Cont and DHA gilts, respectively, and 182 and 170 (mM Gluc x 90 min) for Cont and DHA gilts, respectively. Lack of response suggests that fish oil may not increase Ins sensitivity in these pigs, the response observed due to feeding fish oil is due to EPA rather than DHA, or the presence of DPA diminished the response.

Key Words: DHA, fatty acid, insulin sensitivity

T236 Conjugated linoleic acid (CLA) modifies carcass traits and fatty acid composition in finishing pigs fed with high linoleic acid diets. G. Cordero[1,2], B. Isabel[2], J. G. Vicente[2], J. Morales[1], C. Piñeiro*[1], and C. J. López-Bote[2], [1]*PigCHAMP Pro Europa*, *Segovia, Spain*, [2]*Universidad Complutense de Madrid*, *Spain*.

Conjugated linoleic acid (CLA) in swine nutrition has the potential to improve feed efficiency and decrease carcass fat. Moreover, it may also alter fatty acid synthesis and metabolism, thus leading to more saturated fat. Therefore, CLA supplementation in finishing pigs might ameliorate the deleterious effect that a high concentration of polyunsaturated fatty acids (PUFA), particularly linoleic acid (LA), produces on carcass and meat consistency. The objectives of this experiment were to study the effect of a commercial source of CLA (60% of CLA isomers, 30% c9,t11 and 30% t10,c12) supplied with 2 high levels of LA on performance, carcass traits and fatty acid composition of subcutaneous fat. Therefore, there were 4 treatments arranged factorially with 2 CLA dietary contents (0 vs 1%) and 2 LA dietary levels (1.45 vs. 1.17). For the experiment, 40 pigs Large White × (Large White × Landrace) with 129.4 (±4.83) kg live weight were used. Either supplementation with CLA or LA did not affect average daily gain (ADG), average daily feed intake (ADFI) and feed efficiency. Carcass, ham and foreleg weights were recorded, but were not affected by CLA supplementation. The highest level of LA tended ($P = 0.05$) to increase the foreleg weight. No effect of LA was observed on backfat thickness, but a trend ($P = 0.09$) to reduce backfat thickness was shown when pigs received a diet containing CLA. No difference in intramuscular fat content was observed among treatments. A marked effect of CLA administration was observed in most fatty acids, with an increase in the concentration of saturated fatty acids and a decrease in the concentration of total monounsaturated fatty acids, but not effect on PUFA concentration was observed. The highest level of LA increased the concentration of C18:2 n-6, C18:3 n-3, C20:3 n-9 and total PUFA ($P < 0.01$). We conclude that 1% of CLA supplementation enhance fatty acid saturation, which may help to overcome problems of oil and low consistency meat.

Key Words: conjugated linoleic acid, linoleic acid, finishing pigs

T237 Effects of high oil poultry by-product meal in laying hen performance, egg quality, egg components and blood parameters. G. O. Majid*, J. Hossein, T. Akbar, and R. Abass, *University of Tabriz*, *Tabriz, Iran*.

Poultry by-product meal (PBPM) is usually composed of the wastage from poultry meat processing. To examine the effects of high oil PBPM

from Iran on laying hen performance, egg quality, egg components and blood parameters, 160 HyLine W-36 hens at the age of 42 wk housed in laying cages with 4 hens per cage. The trial was conducted using the completely randomized design with 5 experimental diets as treatments and 4 replications for each treatment. Five experimental diets were prepared with inclusion of 0%, 2%, 4%, 6% and 8% PBPM and all diets were isocaloric and isonitrogenous. Egg weight and egg production was recorded daily. Feed intake was recorded every 2 weeks. The egg mass and feed conversion ratio (FCR) was calculated according to the HyLine W-36 2003–2005 commercial management guide. Three eggs from each treatment replicate were randomly collected for measuring egg shape index, Haugh units, shell thickness and egg yolk, shell and albumen weight. Finally for determining blood parameters such as serum glucose, triglyceride, calcium, phosphorous, low-density lipoprotein (LDL) and high-density lipoprotein (HDL), 2 hens from each treatment replicate were randomly selected and were determined by using commercial kits. The results showed that egg weight, egg production, egg mass and feed intake was significantly decreased and FCR was significantly increased by increasing level of PBPM in diets ($P < 0.05$). Egg shape index, shell thickness, albumen weight and all blood parameters were unaffected by different levels of PBPM in diets ($P < 0.05$). Increasing level of PBPM in diets significantly decreased Yolk weight and shell thickness ($P < 0.05$). Results indicated that up to 2% PBPM can be used in laying diets with no negative effects in laying performance and egg quality.

Key Words: laying hen, egg quality, high oil poultry by-product meal

T238 Viability of *Lactobacillus plantarum* in different protective agents and its effects on growth performance and immunity of weaned pigs. J. Wang, H. F. Ji*, R. L. Ge, S. X. Wang, D. Y. Zhang, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences*, *Beijing, China*.

This experiment was conducted to evaluate the effect of different protective agents on the viability of *Lactobacillus plantarum* after freeze-dried and the effects of *Lactobacillus plantarum* on growth performance and immunity of weaned pigs. The strain of *Lactobacillus plantarum* was originally isolated from the gastrointestinal tract of healthy weanling pigs in our laboratory and strains were identified through standard morphological, biochemical, physiological tests, and by 16s rRNA gene sequence analysis by the China Center of Industrial Culture Collection. *Lactobacillus plantarum* were freeze-dried for 24 h in the presence of 10 different combinations of skim milk powder, lactose, soluable starch, ascorbic acid, sodium glutamate, glycerin, L-cysteine, dextrine, and sucrose. The viable count of *Lactobacillus plantarum* reached 1.6×10^{12} cfu/g after freeze-dried under the protective agents of 16% skim milk powder + 2% lactose + 10% dextrin + 0.5% L-cysteine + 1.5% sodium glutamate, showed the highest viability. Sixty-four piglets weaned at 28 d of age (8.13 ± 0.35 kg BW), were divided into 4 groups comprising of control with chlortetracycline at 50 mg/kg, 3 treatments of different *Lactobacillus plantarum* levels (freeze-dried; 0.3%, 0.5%, and 0.7% of diet). The experiment lasted 30 3 d. The results showed that the supplementation of *Lactobacillus plantarum* at 0.3% of diet level had the same effect on average daily gain (ADG) (405 vs. 393 g/d), feed/gain (F/G) (1.95 vs. 1.98), and mortality rate (0% vs. 0%) ($P > 0.05$) compared with chlortetracycline addition. But the 0.5% and 0.7% of diet level showed lower ADG and significant higher F/G and mortality rate compared with control ($P < 0.05$). *Lactobacillus plantarum* supplementation at any level showed significant higher antibody titers against classical swine fever (OD at 630 nm, $P < 0.05$). The present study implies that freeze-dried *Lactobacillus plantarum* at 0.3% of diet may be the most ideal concentration in ensuring growth performance and immunity of weaned pigs compared with chlortetracycline.

Key Words: *Lactobacillus plantarum*, growth performance and immunity, weaned pigs

T239 Effect of dietary delivery controlled antioxidant on the performances of cold stressed broiler. V. Noirot*, *Phodé Laboratories*, *Albi-Terssac, France*.

A product based on the dietary antioxidant curcumin formulated with delivery vehicles designed to control the release in the digestive tract (Phodé Laboratories, France), was tested on 4 groups (0, 50, 500, and 1000 ppm doses in feed) of 6 replicate pens each containing 25 Ross × Ross broiler chickens. Temperature was decreased from 22.5 to 12°C beginning on d 18, to induce an oxidative stress. Birds were individually weighed at 7, 18, 30, and 38 d. Feed conversion was evaluated per pen at each weighing. Serum glutathione peroxidase (GSH-Px) was measured on 2 birds per pen at 37 d of age. Performance data were subjected to the Mixed model procedure of SAS with treatment as fixed, pen as random and time as repeated factors. Chi-squared tests were performed on mortality rates. Mortality rate over the first 30 d tended to be lower ($P = 0.10$) in birds given 50 ppm (0.6%) compared to control birds (1.9%). After 30 d birds receiving 50 ppm were heavier (2,331 kg) than control birds (2,299 kg) ($P < 0.05$). Feed conversion was improved ($P < 0.05$) over the period 0 to 18 d with the levels of 50 and 500 ppm (1.955 and 1.981 respectively) compared to control (2.072) and 1000 ppm (2.009). The GSH-Px levels were increased by 50 ppm (2341 IU/L) compared to the other treatments (1436, 1914, 1371 IU/L for 0, 500, 1000 ppm respectively). The 50 ppm dose reduced mortality associated with cold stress and improved feed conversion and growth before 30 d, but higher doses were not beneficial. The 50 ppm dose may improve birds' antioxidant status.

Key Words: antioxidant, chicken

T240 Effects of feeding oregano essential oil to broilers on ileal digestibility and performance under high altitude conditions. L. Betancourt*[1,3], C. Ariza-Nieto[2], and G. Afanador-Téllez[3], [1]*Universidad de La Salle*, *Bogotá, Colombia*, [2]*CORPOICA*, *Bogotá, Colombia*, [3]*Universidad Nacional de Colombia*, *Bogotá, Colombia*.

It has long been acknowledged that some plant essential oils exhibit diverse functional activities. Oregano essential oil (OEO) has been shown to possess antibacterial activity; however, comparison of ileal digestibility of nutrients due to the supplementation of different varieties of OEO is scarce in the literature. The aim of this study was to test the effect of OEO supplementation on apparent ileal digestibility (AID) of energy, protein and fat of broilers diets. Seven hundred fifty 1-day-old Hybro male broiler chicks were randomly allotted to one of the 6 treatment groups: Control (C), 500 ppm chlortetracycline (AB), 50 ppm of OEO from *O. vulgare* H. ground in Greece (OG) and 3 additional treatments with 200 ppm of OEO from 3 varieties ground in Sabana of Bogota-Colombia (2650 AMSL): *O. vulgare* H. (OH), *O. vulgare* L. (OL) and *O. majorana* (OM). During a 7-d period (14–21 d), the chicken received a diet with 0.5% chromium oxide as an indigestible marker. On the last day, 20 birds per treatment were slaughtered and Ileal digesta samples were collected and stored at −20°C. Dry matter, protein, fat, energy and chromium were analyzed in feed and ileal content and nutrients AID were calculated. AB group showed a higher AID of protein compared with control (83.7% vs. 75.3%, $P < 0.05$), but not significant differences ($P > 0.05$) were observed among the other treatments. Both OM and AB groups showed a higher value of AID for energy and fat compared with control (92.3%, 91.7% vs.84.2%) ($P < 0.05$). Additionally, OM and AB presented the highest body weight at 21d. ($P < 0.05$). These results suggest that the addition of EO from *O. majorana* to broiler diets could enhance their performance.

Key Words: oregano essential oil, protein digestibility, fat digestibility

T241 Utilization of glandless and standard cottonseed meal in broiler diets. C. Salas*, R. D. Ekmay, J. England, S. Cerrate, and C. N. Coon, *University of Arkansas*, *Fayetteville.*

A 42d study was conducted to determine the field performance and processing yield of broilers fed corn-soy diets containing glandless cottonseed meal (GCSM), commercial CSM (CCSM), or only corn/SBM (CSBM). The nutritional value of both CSM samples was determined and utilized to formulate grower (11–21d) and finisher (22–42d) diets. All broilers were fed a starter corn-soy diet from 1 to 10d. The inclusion level of GCSM and CCSM in corn-soy diets was 12.42% based on the gossypol content of the meals to expose the broilers to 200 and 4.1 ppm of free gossypol, respectively. An additional set of all diets was formulated by adding 500 units/kg of phytase and decreasing NPP by

0.10%. The grower and finisher nutrient contents were based on specifications for Cobb 500 and were formulated based on digestible AA. Body weight (BW), feed intake (FI), feed conversion ratio (FCR) and mortality were monitored. At 42d, 5 birds/pen were further processed. The carcass yield was determined and weight of fillet, tenders, wings, leg quarters and rack were expressed as % of chilled weight.
The broilers had significant differences in BW, FI and FCR at 21d ($P < 0.05$). The birds fed the GCSM + phytase diet were the heaviest (946g) followed by the birds fed the CCSM diet (923 g). Broilers fed the CCSM + phytase diet had the poorest BW gain (886 g) and the poorest FCR from 11-21d (1.62) compared to the other treatments ($P = 0.0136$). The FCR, BW and mortality were not significantly different at 42d. The results indicate the protein source did not produce a significant effect on % carcass yield, but had an effect on fillet, tender and leg quarters % yield. The processing data shows significantly higher ($P < 0.01$) % yield for breast meat (≥25%) and tenders (≥5%) for broilers fed the GCSM diets compared to the CSBM diets. Broilers fed CCSM diets produced a higher ($P < 0.01$) % yield of leg quarters (≥31.5%). These results indicate that broilers can be fed standard CSM in broiler grower and finisher diets if free gossypol in total diet does not exceed 200 ppm.

Key Words: broilers, cottonseed meal, performance

T242 TMEn and amino acid digestibility of glandless and commercial cottonseed meal for broilers. C. Salas*, D. R. Ekmay, J. England, S. Cerrate, and C. N. Coon, *University of Arkansas*, *Fayetteville*.

Cottonseed meal (CSM) is an alternative protein source for poultry diets, but CSM use is limited mainly due to the presence of gossypol. Cotton genetic cultivars are presently being developed with a significant lower concentration of gossypol in the seed.
A digestibility study was conducted to determine the TMEn and amino acid (AA) digestibility of a glandless (GCSM) and a commercial (CCSM) cottonseed meal. Thirty male broilers (42d) in individual cages were fasted for a 48 hr period and 30 g of GCSM, CCSM, and dextrose were each precision fed to ten broilers. The dextrose (protein-free) was utilized to estimate endogenous AA losses. Excreta were quantitatively collected after 48 hr and freeze dried for further analysis. The chemical composition, gossypol content, TMEn and digestibility coefficients for AA were obtained for both meals. The crude protein and fat content of the GCSM was higher than the CCSM (48% and 45%, 5.3 and 1.75%, respectively, as is basis). The CCSM had a higher content of total and free gossypol (1.52% and 0.161%, respectively, %DM) when compared to the GCSM (0.02 and .003%, respectively, %DM). The GCSM contained a thousand additional kcal (27% more) of TMEn than the CCSM (3975 vs 2963 kcal/kg, %DM), because the true DM digestibility was 97% compared to 78% for CCSM. The AA content was determined for both meals and was higher for the GCSM when compared to the CCSM, but both had higher contents than the reports in the literature. When compared with the literature, methionine content was 2-fold higher for both GCSM and CCSM; cystine was 74-84% and 84-93% higher for CCSM and GCSM, respectively. The true digestibility coefficients for essential AA ranged from 73.9% for isoleucine to 91.8% for arginine, for CCSM, whereas the digestibility coefficients for GCSM were all higher than 90% for the essential AA.

Key Words: broilers, cottonseed meal, amino acid digestibility

T243 Effects of coated sodium butyrate on the performance and gut morphology of broiler chickens. Y. Zou[1], Z. B. Yang*[1], W. R. Yang[1], S. Z. Jiang[1], G. G. Zhang[1], and R. Yu[2], [1]*Shandong Agricultural University*, *Tai-an, Shandong, China*, [2]*Kangdequan Feed Co., Ltd*, *Hangzhou, Zhejiang, China*.

An experiment was performed to assess the effects of dietary coated sodium butyrate (CSB) on growth performance and morphological aspects of small intestine in broiler chickens at different ages. Three hundred sixty 1-d-old Arbor Acres broilers were randomly distributed into 3 treatments with 3 pens of 40 each and were fed starter rations from d1 to 21 and finisher rations from d22 to 42. Dietary treatment included 1) BD (basal diet), 2) BD+ antibiotics (40 mg/kg bacitracin zinc and 8 mg/kg colistin sulfate), 3) BD+200 mg /kg CSB. Broilers were fed for ab libitum intake and had free access to water. Body weight and feed intake of chicks of each pen were measured weekly for determination of average daily gain (ADG), average daily feed intake (ADFI), and feed conversion rate (FCR). Twelve birds of each treatment were slaughtered at d14 and d35 of the experiment and the intestinal samples were removed to determine gut morphology. All broilers had similar ADFI over the entire experimental period. However, supplementation with 200 mg/kg coated sodium butyrate increased final weight and ADG ($P < 0.05$), but reduced FCR as compared with that of basal and antibiotics diets. Supplementation of CSB increased ($P < 0.05$) villus height of duodunum and jejunum and reduced ($P < 0.05$) the crypt depth at 14-d of age, but did not affect the morphology of ileum. The antibiotics supplementation significantly increased ($P < 0.05$) villus height of jejunum and ileum, but had no effect on villus height of duodunum and on crypt depth of the 3 segments at 14-d of age. Although broilers received butyric acid or antibiotics (zinc bacitracin 40 mg/kg + colistin sulfate 8 mg/kg) as feed additive at 35-d of age had greater villus height and lower crypt depth than the control chicks, the tendency were not significant among the 3 experimental groups ($P > 0.05$). In the current study conducted, the addition of coated sodium butyrate at 200 mg/kg level showed a positive effect on performance and intestinal morphology, and coated sodium butyrate can be a possible substance to replace antibiotics as growth promoters for farm animals.

Key Words: coated sodium butyrate, broiler, performance and gut morphology

T244 Study on the utilization of oregano essentials oils (oeo) by tilapia *Oreochromis niloticus* var. *chitralada* in a commercial production cycle. D. Rodriguez*[1,2], C. Ariza-Nieto[2], A. Munoz[1], and G. Afanador[1,2], [1]*Universidad Nacional de Colombia*, *Bogota, Colombia*, [2]*CORPOICA*, *Bogota, Colombia*.

Carvacrol and thymol are the 2 main active components of oregano essential oil (OEO). The aim of this study was to investigate the effect of different ratios of carvacrol to thymol on growth performance of Nile Tilapia. Five hundred 20 8 10 g tilapia were randomly assigned to one of the 4 treatments groups: C) control group; HT) high thymol (Colombian native oregano); TC) thymol:carvacrol 1:1 ratio (Colombian native oregano+Greek Oregano); and HC) high carvacrol (Greek oregano). Fish were placed in 24 tanks during starter-finish phase and their performance was determined every other week until 550g of body weight. Data were analyzed under a completely randomized design using the GLM procedure of SAS. Specific growth rate (SGR) and daily growth coefficient (DGC) of fish fed HT were higher than those of fish fed both C and TC (1.5929, 1.5187 and 1.5015; 3.186, 3.000 and 2.986, %/day, respectively) ($P < 0.05$). Days to market (550g) of fish fed HT was lower than that of HC (165.7 vs 186.5) ($P < 0.05$), but not significant differences ($P > 0.05$) were noted among other treatments.

It can be concluded that natural Colombian native oregano, can act as a growth promoter when added to nile tilapia feed.

Key Words: Nile tilapia, oregano, carvacrol:thymol

T245 Dietary supplementation effects of oregano essential oils and two sources of fat on the performance of brown laying hens under high altitude conditions. D. Botero[1], F. Silva[1], L. Betancourt*[1,3], C. Ariza-Nieto[2], and G. Afanador-Téllez[3], [1]*Universidad de La Salle*, *Bogotá, Colombia*, [2]*CORPOICA*, *Bogotá, Colombia*, [3]*Universidad Nacional de Colombia*, *Bogotá, Colombia*.

Fish oils have been used to the incorporation of n-3 fatty acids into eggs, but this practice can exert a negative influence on their sensory properties. On the other hand, Oregano Essential Oil (OEO) has been shown to possess anti-oxidant activity. Thus, the aim of this study was to evaluate the effect of OEO carvacrol:thymol ratio and 2 sources of fat on production performance of laying hens and eggs sensory properties. One hundred sixty brown laying hens were randomly assigned to one of 8 treatment combination in a 4 × 2 factorial arrangement. Factors included were, source of fat, fish oil (FO) or palm oil (PO) and carvacrol:thymol ratio supplemented with 200 ppm of OEO; high carvacrol (HC), high thymol (HT), carvacrol:thymol 1:1 ratio (CT) and control (C) without OEO supplementation. Hens were housed in 80 conventional cages (2 per cage) and the study was conducted over a period of 16 weeks. Eggs were collected, numbered and weighed every day. Sensory evaluation was carried out with 40 tasters. When PO was used as a source of fat, the HC improved production egg, mass egg and feed conversion ratio; in contrast, HT and CT decreased egg production and egg mass ($P < 0.05$). The supplementation of OEO HC, HT and CT improved production performance ($P < 0.05$) when the source of fat was FO. HT significantly improved egg taste perception when FO was included in the diet; but HC improved it when PO was included ($P < 0.05$). It can be concluded that OEO can enhance laying hen performance and high thymol ratio has positive effects on flavor when FO is added to diet for functional eggs design.

Key Words: fish oil, n-3 FA, egg taste

T246 Effect of supplementing the diet of sows with a source of yeast-derived proteins during lactation on performances of sows and piglets. P.-A. Plante*[1,2], J.-P. Laforest[2], and C. Farmer[1], [1]*Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre*, *Sherbrooke, QC, Canada*, [2]*Animal Science Dept., Laval University*, *Québec, QC, Canada*.

The impact of supplementing the diet of sows with a source of yeast-derived proteins (NuPro) during lactation on the performances of sows and their piglets was studied. Sixty-five crossbred sows were fed one of 3 levels of yeast proteins (YP) from 0 to 21 d of lactation. Treatments were: control without YP (CTL, n = 22); 30 g of YP per day (Y30, n = 22) and; 60 g of YP per day (Y60, n = 21). Jugular blood samples were obtained from sows on d 2, 7 and 20 of lactation to measure urea concentrations. Milk samples were obtained on d 7 and 20 of lactation for compositional analyses (fat, lactose, dry matter) and quantification of 5`monophosphate nucleotides. Litter size was standardized to 10 ± 1 at 48 h postpartum. Sow BW loss and backfat loss during lactation (from d 2 to 21) were recorded as well as weights of piglets on d 0, 2, 7, 14, 21, 24, 28, 35, 42, 49, and 56. Feed intakes of sows during lactation and of piglets for 5 wk post-weaning were noted. Statistical analyses were performed with PROC MIXED using an ANOVA with one factor (3 levels) according to a completely randomized design. None of the animal performance data differed between treatments ($P > 0.1$). Standard milk composition was also similar across treatments ($P > 0.1$). There were more nucleotides in milk on d 7 than on d 20 of lactation (means ± SD for AMP, CMP, GMP, IMP and UMP were 12.7 ± 2.8, 9.4 ± 2.1, 14.6 ± 2.8, 2.5 ± 0.7 and 281.3 ± 45.1 µmol/100 mL on d 7 and 6.0 ± 1.1, 3.6 ± 0.9, 7.5 ± 1.0, 1.5 ± 0.6 and 138.7 ± 15.4 µmol/100 mL on d 20; $P < 0.001$) but these concentrations were not affected by treatments ($P > 0.1$). On d 2 of lactation, circulating concentrations of urea tended to be greater for Y60 than CTL sows ($P = 0.1$). In conclusion, supplementing the diet of lactating sows with yeast proteins had no beneficial effect on sow and piglet performances.

Thanks to Alltech for financial support.

T247 Microencapsulation of *Lactobacillus plantarum* and its effects on growth performance of weaned pigs. J. Wang, H. F. Ji*, L. J. Lv, S. X. Wang, D. Y. Zhang, and Y. M. Wang, *Institute of Animal Husbandry and Veterinary Medicine, Beijing Academy of Agriculture and Forestry Sciences*, *Beijing, China*.

This experiment was carried out to study the most suitable method and wall material for microencapsulation of the probiotic bacterium *Lactobacillus plantarum* to maintain cell viability during gastric challenge, and the effect of *L. plantarum* microcapsule on growth performance of weaned pigs. Strains of *L. plantarum* were individually encapsulated using different method of extrusion or emulsion. The optimum wall material formula of making microcapsule was studied through the orthogonal experiment. The survival of planktonic cells and encapsulated cells of *L. plantarum* treated with simulated gastric juice were detected. The results showed that extruded microcapsules were larger and more uniformly shaped. The viable count was reached 7.76×10^{10} cfu/g under the wall material formula as 3% alginate, 4% skim milk, 6% milk sugar, and 2% calcium chloride. When planktonic cells and encapsulated cells of *L. plantarum* were subjected to simulated gastric juice challenge at pH 2.1 for 3 h. The survival of *L. plantarum* cells treated with simulated gastric juice was significantly better ($P < 0.05$) when microencapsulated. Thirty-two piglets weaned at 28 d of age (8.11 ± 0.32 kg BW), were divided into 2 groups comprising of control diet with *L. plantarum* (0.5% of diet) and diet with *L. plantarum* microcapsule (0.5% of diet). The experiment lasted 30 d. The results showed that the supplementation of *L. plantarum* microcapsule had higher average daily gain (ADG) (390 vs. 326 g/d; $P < 0.05$) and lower diarrhea rate (3.25 vs. 6.67) and mortality rate (0 vs. 6.25) compared with control. In general, microencapsulation using selected wall material formula by extrusion was found to provide bacteria significantly greater protection ($P < 0.05$) against simulated gastric juice, and had positive effect on growth performance of weaned pigs.

Key Words: *Lactobacillus plantarum*, microencapsulation, weaned pig

T248 Effect of xylo-oligosaccharides on growth performance, enzyme activity and volatile fatty acid production of post-weanling pigs. H. S. Huang[1], S. Zhou[1], Z. B. Yang*[2], W. R. Yang[2], and L. Xiao[3], [1]*Qinghai University*, *Xining, China*, [2]*Shandong Agricultural University*, *Taian, Shandong, China*, [3]*Shandong Longlive Bio-technology Co., Ltd*, *Dezhou, Shandong, China*.

The experiment was conducted to assess the effects of Xylo-oligosaccharides (XOS) on growth performance, volatile fatty acid (VFA) production and intestinal enzyme activity of piglets. A total of 300, 28-d-old post-weanling pigs were randomly assigned to one of 6 dietary

treatments with 5 replicates of 10 piglets each. Treatments included control diet without Xylo-oligosaccharides and test diets supplemented with 40, 60, 80, 100 and 120 mg XOS /kg DM, respectively. Average daily gain (ADG), average daily feed, intake feed (ADFI) and gain ratio (F:G) were measured weekly of each replicate. Diarrhea piglets were recorded 3 times a day to determine diarrhea rate (DR). Five piglets of each treatment were slaughtered at d28 of the experiment and the intestinal contents were removed to determine intestinal VFA (gas chromatography) and digestive enzyme activities (colorimetric method). All pigs had similar ADG and ADFI but XOS diet decreased ($P < 0.05$) DR. However, Supplementation with 40, 60 and 80 mg XOS /kg DM had lower ($P < 0.05$) F:G as compared with that of control. Increasing supplementation of XOS linearly ($P < 0.05$) and quadratically ($P < 0.05$) increased concentrations of acetic acid, propionic acid and butyric acid in the jejunum, ileum and cecum. Lipase activity was quadratically ($P < 0.01$) increased in the duodenum, jejunum and ileum, trypsin activity was linearly ($P < 0.05$) increased in duodenum and jejunum, as well as amylase activity was linearly ($P < 0.05$) increased in the ileum with the increasing supplementation of XOS. In conclusion, supplementation of XOS decreased DR and 40, 60, 80 mg XOS/kg DM reduced F:G. Concentrations of VFA were linearly ($P < 0.05$) and quadratically improved in jejunum, ileum and cecum. Lipase activity and tryptic activity were linearly ($P < 0.05$) and quadratically ($P < 0.05$) increased in duodenum and jejunum and lipase activity and amylase activity were linearly ($P < 0.05$) and quadratically ($P < 0.05$) changed in the ileum with the increasing supplementation of XOS.

Key Words: xylo-oligosaccharides, pigs, volatile fatty acid and enzyme activity

T249 Effect of short-term benzoic acid and chlortetracycline treatment of feed on splanchnic metabolism of valine in growing pigs. N. B. Kristensen*[1], R. G. Engberg[1], B. B. Jensen[1], J. V. Nørgaard[1], H. D. Poulsen[1], H. D. Zacho[2], and N. M. Sloth[3], [1]*Aarhus University*, *Tjele, Denmark*, [2]*Viborg Hospital*, *Viborg, Denmark*, [3]*Danish Agriculture and Food Council*, *Aarhus, Denmark*.

The present study aimed to investigate the effects of short-term feed treatment with benzoic acid (BA) and chlortetracycline (CTC) on portal-drained visceral (PDV) metabolism of arterial [U-13C]Val as well as portal absorption and hepatic uptake of Val in growing pigs fed a low-protein diet. Eight female pigs (70 ± 2 kg BW) fitted with permanent indwelling catheters in the abdominal aorta, v. cava, hepatic portal vein, hepatic vein, and the mesenteric vein were used in the study. Pigs were fed a diet based on wheat (72%), soybean meal (12%), and barley (10%), supplemented with crystalline Lys, Met, Thr, Trp, and Val (0.08%), and containing 14.7% crude protein (as fed). Intake was restricted to 3.6% of BW/d. Pigs were randomly assigned to either control (CON; basal diet) or treatment (TRT; basal diet + 10 g BA and 0.7 g CTC/kg feed). Feed was offered in 3 equal sized meals at 8-h intervals and treatments were applied for 24 h. Blood samples were collected hourly during the last 8 h of the treatment period. Primed continuous infusion of [U-13C] L-Val (0.085 ± 0.005 mmol/h) into the v. cava was initiated 1 h before first sampling. Plasma samples were analyzed for AA by GC/MS and C-13 abundance in Val was determined using GC/C/IRMS. Data were analyzed using the MIXED procedure in SAS by a model including the fixed effects of treatment and block and with pig by block designated as a random effect. The arterial concentration of Val tended ($P = 0.07$) to increase with TRT (0.47 ± 0.02 mmol/L) compared with CON (0.41 ± 0.02 mmol/L). The PDV extraction of arterial Val (4.6 ± 0.4%) did not differ ($P = 0.21$) among treatments. The net portal flux of Val tended ($P = 0.10$) to be less for TRT, but the portal absorption of Val corrected for PDV uptake of arterial Val did not differ ($P = 0.82$) among treatments. The net hepatic and net splanchnic fluxes of Val were not affected by treatment ($P = 0.61$ to $P = 0.94$). Data indicate that upper gut microbial deamination is without quantitative importance to availability of Val in growing pigs fed a low-protein diet added crystalline Val.

Key Words: amino acid, metabolism, pig

T250 Characterization of the gastrointestinal microbiota in neonatal piglets from sows supplemented a *Bacillus*-based direct fed microbial. A. Baker*, E. Davis, and T. Rehberger, *Danisco*, *Waukesha, WI*.

Direct fed microbials (DFMs) supplemented in sow diets may confer health benefits to the host and the piglets by reducing pathogens in the sow and environment. In this study we evaluated the effect of a *Bacillus*-based DFM on the gastrointestinal microbiota of neonatal piglets. A total of 208 sows were divided into 2 treatments: a control diet and the control diet supplemented with a *Bacillus*-based DFM (3.75×10^5 cfu/g feed). Twenty-one piglets sampled from each sow treatment group were killed on d 3 of lactation as well as 15 piglets per treatment on d 10 of lactation. Terminal restriction fragment length polymorphism (T-RFLP) was used to characterize the microbiota in the ileum and colon of the piglets using 3 enzymes (MspI, BstUI, and *Hae*III) to generate terminal restriction fragments (TRFs). The presence and quantity of TRFs were compared between control and DFM pigs and presumptively identified using the Microbial Community Analysis III (MiCA 3) database. There was a greater incidence and quantity of TRFs B423 and H330 (Binary $P = 0.01$, 0.08; Quantitative $P = 0.01$, 0.05 respectively), putatively identified as *Lactobacillus gasseri/johnsonii*, in the ileum of pigs nursing sows supplemented with DFM at d 3. TRF peaks B423 and H330 were also greater (Binary $P = 0.01$, 0.08; Quantitative $P = 0.01$, 0.01 respectively) in the colon of pigs nursing sows supplemented with DFM at d 3. Peaks M495 and B394, putatively identified as *E. coli*, were greater (Binary $P = 0.01$, 0.04; Quantitative $P = 0.01$, 0.01 respectively) in the colon of the control pigs at d 3. At d 10, both presence and quantity of *Lactobacillus* species were greater ($P < 0.05$) in the colon of the DFM treatment. Additionally, there was a tendency for TRFs B227 and H257 (Binary $P = 0.07$, 0.07 respectively), putatively identified as *Clostridium perfringens*, to be present in the ileum of the control pigs at d 10 compared with treated pigs. The results of this study demonstrate the ability of a DFM to influence the gastrointestinal microbiota of a neonatal piglet through supplementation of the DFM to the sow.

Key Words: T-RFLP, swine, direct-fed microbial

T251 Cloning of a porcine trypsinogen gene and over-production of the protein as a feed additive. F. Wang[1], H. Zhao[1], X. J. Xia[1], and X. G. Lei*[1,2], [1]*Int. Ctr. of Future Agriculture for Human Health, Sichuan Agri. Univ.*, *Chengdu, China*, [2]*Cornell University*, *Ithaca, NY*.

Trypsin is a serine protease that plays a key role in the activation cascade of pancreatic digestive enzymes, and may be used to improve feed protein digestion by young animals. To produce a recombinant pancreatic trypsinogen, we used RT-PCR to amplify the full-length cDNA of porcine trypsinogen gene (submitted to GeneBank: FJ969506.1) from the porcine pancreas mRNA and inserted the DNA fragment into the pPICZαA expression vector (Invitrogen, Shanghai, China). The plasmid construct was transformed into *Pichia pastoris* X33 cells, and the transformants were screened by SYBR-green quantitative real-time RT-PCR analysis (ABI 7900HT, Applied Biosystems, Foster City, CA) for high levels of expression. After the transformants were induced by 0.5% methanol for 98 h, the extracellular recombinant trypsinogen contain-

ing a histidine tag in the C terminus was purified using Ni-Sepharose affinity chromatography (GE Healthcare, Piscataway, NJ). The purified protein exhibited a molecular mass of approximately 30 kDa as determined by SDS-PAGE analysis. The successful expression of the recombinant trypsinogen in *P. pastoris* enabled us to further study the enzyme function in animal feed.

Supported by the 863 program (2007AA100602 and 2007AA100601-6) and by the Chang Jiang Scholars Program of the Chinese Ministry of Education (XGL).

T252 Effects of various cereals on nursery pigs: Specific bacteria identified from the gastrointestinal tract. Y. Liu*, M. Rossoni, J. Barnes, and J. E. Pettigrew, *University of Illinois*, *Urbana*.

A study was conducted to evaluate the influence of different cereal grains on the bacterial populations in the gastrointestinal tract of young weaned pigs. A total of 24 pigs (7.71 kg BW) were weaned at 21 d of age and randomly allotted to one of 4 treatments. Each diet contained corn, barley, rolled oats, or rice as the only cereal. Pigs were allowed ad libitum access to feed and water throughout the 14-d experimental period. At the end of the experiment, all pigs were killed to collect mucosal and digesta samples from ileum and distal colon. Denaturing gradient gel electrophoresis (DGGE) was used to assess the microbial population structures. In a few cases, specific bands were present in most pigs fed one treatment, but absent from most pigs fed other treatments. Major bands were excised and sequenced to identify the bacterial species that appear or disappear under different cereal treatments. The results showed that most pigs fed barley lacked significant populations of several species of *Sphingomonas* that were often present in the distal colon digesta and mucosa of pigs fed the other cereals. Most pigs fed rice differed from those fed other cereals in having a significant distal colon mucosal population of a *Corynebacterium* species but lacking a species of *Veillonella*. In conclusion, feeding of different cereals as sources of energy altered microbial diversity in the GI tract, especially with regard to *Sphingomonas* species.

Key Words: cereal, microbial diversity, nursery pigs

T253 Effects of dietary benzoic acid supplementation on net portal absorption and hepatic uptake of amino acids in growing pigs. N. B. Kristensen*[1], H. D. Zacho[2], J. V. Nørgaard[1], and H. D. Poulsen[1], [1]*Aarhus University*, *Tjele, Denmark*, [2]*Viborg Hospital*, *Viborg, Denmark*.

The present study aimed to investigate the effects of adding 1% benzoic acid (BA) to a standard finishing diet for growing pigs on net portal, net hepatic, and net splanchnic fluxes of amino acids (AA). It was hypothesized that BA supplementation would increase the portal absorption of AA, increase hepatic glycine uptake, and decrease splanchnic glycine release. Eight female Duroc × (Danish Landrace × Yorkshire) weighing 63 ± 1 kg at time of sampling and fitted with permanent indwelling catheters in the abdominal aorta, hepatic portal vein, hepatic vein and the mesenteric vein were used in the study. Pigs were fed a diet based on barley and soybean meal with intake restricted to 3.6% of BW/d. Pigs were allocated to 4 sampling blocks and randomly assigned to either control (CON; basal diet) or BA treatment (B; 10 g benzoic acid as top-dress; VevoVitall, DSM Special Products, Rotterdam, The Netherlands) within block. Feed was offered in 3 equal sized meals and blood samples collected hourly for 8 h with first sampling 0.5 h before feeding. Plasma samples were pooled by catheter and pig and analyzed for individual AA by a GC/MS based isotope dilution method following silylation. Data were analyzed using the MIXED procedure in SAS with a model including the fixed effects of treatment and block and with pig by block designated as a random effect. Amino acid fluxes were analyzed as the net flux in grams of AA per kg feed. The net portal flux of Ala and Thr increased ($P < 0.05$) and the net portal flux of His and Lys ($P < 0.10$) tended to increase with B compared with CON. The net hepatic uptake of Gly was not affected by treatment ($P = 0.91$), but the net hepatic uptake of Ser increased ($P = 0.02$) with B compared with CON. The net splanchnic release of Ser tended ($P = 0.08$) to decrease with B compared with CON. No effects of treatment were detected for net splanchnic flux of any AA other than Ser. Impact of benzoic acid supplementation on AA absorption and metabolism warrants further considerations on AA nutrition of pigs supplemented with benzoic acid.

Key Words: pigs, benzoic acid, amino acid metabolism

T254 Effects of dietary Stafac inclusion level on the growth performance and carcass characteristics of growing–finishing pigs. C. L. Puls*[1], M. Mercedes[1], M. Ellis[1], A. M. Gaines[2], B. A. Peterson[2], B. F. Wolter[2], and M. Kocher[2], [1]*University of Illinois*, *Urbana*, [2]*The Maschhoffs*, *Carlyle, IL*.

The effect of dietary Stafac inclusion level on the growth performance and carcass characteristics of growing-finishing pigs was evaluated from 40.0 ± 1.45 kg to 127.8 ± 1.13 kg BW. A randomized complete block design was used with 1 treatment (Stafac inclusion level) and 2 levels (0 and 10 g/ton). Diets were formulated to meet or exceed NRC (1998) recommendations for nutrient requirements. A total of 144 barrows housed in pens of 9 were used with 8 replicates/treatment level. Pigs were weighed at the start and end of the study, and every 2 weeks during the interim period; all feed additions were recorded. At the end of the study, pigs were harvested at a commercial plant and carcass measures were taken. There was no effect ($P > 0.05$) of Stafac inclusion level on live weight growth performance. Mortality levels were 2.8 percentage units lower for pigs fed Stafac compared with controls; however, this difference was not significant ($P > 0.05$). Including Stafac in the diet increased ($P < 0.05$) carcass yield by 0.7 percentage units and, consequently, improved ($P < 0.01$) carcass G:F ratio by 4%. In conclusion, including Stafac in the diet of growing-finishing pigs (at 10 g/ton) did not improve live weight growth performance in this study; however, the potential reduction in mortality levels and increases in carcass yield and carcass feed efficiency are of economic significance and need to be verified.

Key Words: pigs, growth, Stafac

T255 Expression of interleukins, neuropeptides, and growth hormone receptor (GHR) and leptin receptor (LPR) genes in adipose tissue from growing broiler chickens. G. J. Hausman*[1], C. R. Barb[1], B. D. Fairchild[2], A. Hinton[1], and J. A. Cason[1], [1]*USDA-ARS*, *Athens, GA,* [2]*University of Georgia*, *Athens*.

In this study, total RNA was collected from abdominal adipose tissue samples obtained from 10 broiler chickens at 3, 4, 5, and 6 weeks of age and prepared for real time RT-PCR analysis with custom-designed primers and probes. Studies of the gene expression of cytokines and associated genes in chicken adipose tissue were initiated since the discovery of leptin has shown in many animal species that adipose tissue derived factors can dramatically influence growth and physiology. The influence of age on the expression of adipose tissue IL-15, IL-18, neuropeptide Y and GHR and LPR genes and several other cytokines was examined. Between 3 and 6 weeks of age LPR expression decreased ($P < 0.05$) with age while expression of IL-15 and GHR increased significantly ($P < 0.05$). Furthermore, IL-18 and visfatin expression increased ($P < 0.001$) between 4 and 6 weeks of age. Expression of these cytokines was detected for the first time in chicken adipose tissue. Consequently, this is the first demonstration of age related changes in cytokine gene expression in chicken adipose tissue. Gene expression of several cytokines was not detected in chicken adipose tissue including IL-6 and brain derived neurotrophic factor. Future studies are needed to elucidate the role of adipose tissue cytokines in growth and, possibly, disease resistance. Furthermore, these studies provide indirect evidence that the adipose tissue response to leptin and growth hormone change with age.

Key Words: chicken, cytokine, adipose tissue

T256 Apoptosis in different fat depots of cows treated with conjugated linoleic acids (CLA). S. Haeussler*[1], D. Germeroth[1], D. von Soosten[2], S. Dänicke[2], and H. Sauerwein[1], [1]*University of Bonn*, *Bonn, Germany*, [2]*Federal Research Institute of Animal Health*, *Braunschweig, Germany*.

Changes in adipose tissue mass may be associated with a change in adipocyte number and/or a change in adipocyte volume. For development and maintenance of homeostasis, apoptosis plays an important role within organisms. In mice, dietary CLA causes apoptosis of adipocytes (Miner et al. 2001, Obesity Res, 9:129). To investigate whether apoptosis occurs in bovine fat and if apoptosis is influenced by CLA, 25 Holstein heifers were divided in a control (CTR) and a CLA group; from d 1 postpartum (pp) until sample collection, animals from the CLA group were fed with 100 g CLA (containing 10% each of the cis-9,trans-11- and the trans-10,cis-12-CLA isomers) per day. On d 1, 42 and 105 pp, 5 animals of CTR were slaughtered; from CLA, 5 cows each were slaughtered on d 42 and 105. Retroperitoneal (RP) and subcutaneous (SC) fat from the tail head were obtained from all cows. For the detection of DNA fragmentation, deparaffinized sections (10 µm) were stained using the TUNEL method. For positive and negative controls, bovine lymph nodes were treated either with or without DNase after demasking to initiate DNA strand breaks. The apoptotic cell rate (%) was defined as mean number of TUNEL-positive cells/mean number of total cells × 100 and analyzed using the general linear model and Student's *t*-test (SPSS). We determined TUNEL-positive nuclei within bovine adipocytes. The average value for SC and RP fat in CTR animals was 12.7 ± 1.4% and 5.3 ± 1.0%, respectively. The apoptotic rate in SC depot was twice as high compared to the rate of retroperitoneal fat ($P \leq 0.001$), but did not differ with time of lactation. On d 105 pp, the apoptosis rate was increased by more than 1.5-fold in both fat depots of the CLA cows ($P \leq 0.01$) in comparison to the CTR group. Apoptosis may influence the number of adipocytes in bovine adipose tissue. SC fat as main energy store seems to be more affected by mass changes and dietary CLA, thus presumably showing a higher apoptotic rate than the RP depot.

Key Words: adipose tissue, apoptosis, cow

T257 Differences in the mRNA abundance of the adiponectin system and GPR109A in adipose tissue and liver of the F2 cows of Charolais x German Holstein crosses. M. Mielenz*[1], B. Kuhla[2], H. Sauerwein[1], and H. Hammon[2], [1]*University of Bonn*, *Bonn, NRW, Germany*, [2]*FBN Dummerstorf*, *Dummerstorf, MV, Germany*.

Adiponectin, an adipocyte-derived hormone, is described as an insulin sensitizing agent in monogastric mammals. Less information is available about influences on the regulation of the adiponectin system in ruminant species. As well, the relevance of the β-hydroxybutyrate (BHB) sensing receptor *GPR109A* with anti-lypolytic properties is not characterized yet. We herein tested for differences in diverging phenotypes of the F2 offspring from segregated Charolais x German Holstein crosses exhibiting high differences in body fat accretion (FAT (n = 9) vs. LEAN (n = 9)). The animals were slaughtered at 100 d into 2nd lactation. The mRNA abundance of adiponectin (*Adi*) and its receptors *AdiR1* and *AdiR2* as well as of *GPR109A* was analyzed via real-time PCR in 3 different adipose depots and in liver, except for *Adi*. In liver, *AMPK* and phospho-*AMPK* protein were analyzed as well. Data were analyzed using independent samples *t*-test or Mann-Whitney U-test ($P \leq 0.05$). Milk production was much lower ($P \leq 0.05$) in FAT than LEAN cows. There was a trend ($P \leq 0.1$) for a higher *Adi* mRNA content in mesenteric fat of FAT vs. LEAN cows. *AdiR1* mRNA was more abundant in perirenal and mesenteric fat of FAT cows. For *AdiR2* mRNA there was a trend ($P \leq 0.1$) for higher values in subcutaneous fat of FAT cows but lower values were observed in liver. The content of *GPR109A* mRNA was lower in perirenial fat and as a trend in liver of FAT cows compared with LEAN animals. The ratio between phospho-*AMPK* and *AMPK* did not show any difference. In conclusion, the mRNA expression profile of the *Adi* system in adipose tissue of accretion type cows (FAT cows) seems related to increased lipid accumulation. Lower *AdiR2* abundance in liver of FAT cows might be related to specific features of glucose metabolism in this family but its relevance needs further characterization, as there was no activation of *AMPK* observed. Signal transduction by BHB through *GPR109A* in perirenal fat and liver might be of more relevance for secretion type LEAN cows.

Key Words: adiponectin system, GPR109A, cattle

T258 Changes in plasma concentrations of leptin in ewes during pregnancy. J. A. Daniel*[1], A. B. Milam[1], M. E. Gafnea[1], B. K. Whitlock[2], and D. H. Keisler[3], [1]*Berry College*, *Mount Berry, GA*, [2]*University of Tennessee*, *Knoxville,* [3]*University of Missouri*, *Columbia*.

Previous research has demonstrated circulating concentrations of leptin increase in ewes during mid pregnancy then decline in late pregnancy and early lactation. This study was designed to more narrowly define the timing of changes in circulating concentrations of leptin with pregnancy in ewes. Katahdin ewes (n = 19) located at latitude 34.275 and longitude −85.183 (Mount Berry, GA) were utilized. Blood samples were collected weekly via jugular veinpuncture beginning immediately before ram exposure on September 23 and continuing until 4 weeks post-lambing.

Ewes were exposed to a ram fitted with a marking harness for a 63 d breeding season. Breeding marks were recorded daily. Lambing date and number of lambs born was recorded. Week of gestation was calculated by breeding mark. The blood sample collected before breeding was considered wk 0. Plasma concentration of leptin was determined by radioimmunoassay. Data were tested for effects of date of sample, pregnancy status, and date of sample by pregnancy status interaction using procedures for repeated measures (JMP version 7; SAS Institute Inc., Cary, NC). Data were also tested for effects of week of gestation and number of lambs. Pregnancy had an effect on plasma concentrations of leptin ($P = 0.0407$; 6.06 ± 0.19 vs 4.67 ± 0.64 ng/ml in pregnant vs non-pregnant ewes, respectively). There was also an effect of date of sample ($P < 0.0001$) on plasma concentrations of leptin. Week of gestation had an effect of plasma concentrations on leptin ($P < 0.0001$) with ewes having lower plasma concentrations of leptin during wk 12, 13, 16, and 18–21 of gestation as well as 4 weeks after lambing when compared with before breeding. Plasma concentrations of leptin were higher wk 1–12, 14, 15, and 17 of gestation than after lambing, but did not differ from values before lambing. These data confirm a decline in circulating concentrations of leptin in the last third of gestation and continuing into early lactation in ewes.

Key Words: sheep, pregnant, leptin

T259 Nutritional regulation of body condition score at the initiation of the transition period in dairy cows on grazing conditions: hepatic expression of fatty acid metabolism genes. M. Carriquiry*[1], M. L. Adrien[2], V. V. Artegoitia[2], D. Mattiauda[1], and A. Meikle[2], [1]*School of Agronomy, UDELAR*, *Uruguay*, [2]*School of Veterinary Medicine, UDELAR*, *Uruguay*.

Multiparous Holstein cows (n = 10), blocked by body weight and expected calving date, were used to investigate the effect of different body condition score (BCS) at 30 d before calving (−30 d), induced by a differential nutritional management from −100 to −30 d, on hepatic expression of peroxisome proliferator-activated receptors-α (PPARA), carnitine palmitoyl transferase-1 (CPT1A), acyl-CoA dehydrogenase-very long-chain (ACADVL), and acyl-CoA oxidase (ACO) during the transition period. From −100 to −30 d, cows were offered different planes of nutritionwith 7, 14 or 20 kg/day/cow of dry matter (DM) of a long-term pasture to achieve desired BCS −30 d. BCS (scale 1–5) was determined every 15 d, and cows had to gain 0.5 points (HI) or to maintain (LO) BCS at least in 2 subsequent observations to be included in the study. From −30 to 45 d cows were managed together. Liver biopsies were collected at −15, 15, and 45 d and mRNA abundance was determined by real time PCR using hypoxanthine phosphoribosyltransferase (HPRT) as control gene. Means from repeated measure analyses differed when $P < 0.05$. Cows had similar BCS at −100 d (2.9 ± 0.08) and differed after the nutritional treatment (3.4 vs. 2.8 ± 0.08), but groups presented similar BCS at 15 (2.9 vs. 2.7 ± 0.08) and 45 (2.8 vs. 2.7 ± 0.08) d. NEFA concentrations increased around parturition and were greater in LO than HI cows. Expressions of PPAR (2.7 vs. 1.2 ± 0.45), ACADVL (3.0 vs. 0.9 ± 0.5), and ACO (149 vs. 64 ± 28) mRNA were greater for LO than HI cows along the period evaluated. There was an effect of day on CPT1A and ACO mRNA as their abundance was increased (>2-fold) at 15 d, effect that was more evident in LO cows. There was a trend ($P < 0.09$) for an interaction of treatment by day for ACADVL mRNA as its expression was increased at 45 d only in LO cows. Results indicated nutritional plane before the transition period affected regulation of hepatic fatty acid oxidation genes, being these genes upregulated, in agreement with greater NEFA levels, in cows that maintained BCS from −100 to −30 d.

Key Words: mRNA, liver, dry period nutrition

T260 Gluconeogenic enzymes are differentially regulated by fatty acid cocktails in Madin-Darby Bovine Kidney cells. H. M. White*, S. L. Koser, and S. S. Donkin, *Purdue University*, *West Lafayette, IN*.

Increases in serum NEFA levels and changes in serum fatty acid profiles at calving are characteristic of the transition cow. The objective of this study was to examine the effect of 24 h exposure of Madin-Darby Bovine Kidney cells to fatty acid cocktails on expression of pyruvate carboxylase (PC), cytosolic and mitochrondrial phosphoenolpyruvate carboxykinase (PEPCK-C and PEPCK-M), and glucose-6-phosphatase. Cocktails contained C14, C16, C18, C18:1, C18:2, and C18:3 fatty acids and were designed to mimic the fatty acid profile and concentration of cows pre- and post-calving (PPCALV; 0.25 m*M*) and at calving (CALV; 0.5 m*M*). An additional cocktail mimicked the profile of cows with induced fatty liver at calving (IFL; 1 m*M*). Expression of PC mRNA tended to increase ($P < 0.1$) in cells exposed to IFL (6.0 vs. 2.8 ± 1.0 arbitrary units, control vs. IFL, respectively). Expression of PEPCK-C mRNA was increased ($P < 0.05$) in cells exposed to PPCALV compared with all other cells (5.0 vs. 1.2 ± 0.8 arbitrary units, PPCALV vs. control, respectively). Exposure to IFL increased ($P < 0.05$) the ratio of PC to PEPCK-C by 8.4 and 2.4 fold compared with PPCALV and CALV exposure. Exposure of cells to IFL tended to increase ($P < 0.1$) PEPCK-M mRNA (3.0 vs. 1.7 ± 0.5 arbitrary units, IFL vs. control, respectively) and increased ($P < 0.05$) glucose-6-phosphatase mRNA (3.2 vs. 1.5 ± 0.8 arbitrary units, IFL vs. control, respectively). To elucidate effects of fatty acid profile from concentration, cells were exposed to each profile at lower and higher concentrations. Increased concentrations of PPCALV did not increase ($P \geq 0.05$) PEPCK-C mRNA expression as observed at physiological concentrations. Increasing concentration of CALV decreased ($P < 0.05$) expression of PEPCK-C and increased ($P < 0.05$) expression of PEPCK-M mRNA. Fatty acid profile and concentration alters expression of key gluconeogenic enzymes although the magnitude and directionality of the response was not uniform. Regulation of mRNA expression for these enzymes is likely part of the coordinated response in liver during transition to calving.

Key Words: transition cow, Madin-Darby Bovine Kidney cells, fatty acids

T261 The effects of leptin on phosphorylation of mTOR and rpS6 to signal protein synthesis in bovine mammary epithelial cells. E. K. Evans*, J. A. D. R. N. Appuhamy, and M. D. Hanigan, *Department of Dairy Science, Virginia Polytechnic Institute and State University*, *Blacksburg*.

Poor nitrogen utilization efficiency of dairy cows increases the nitrogen excretion into the environment. Efficiency of milk protein synthesis is regulated through cellular signaling pathways which are responsive to hormones, cellular energy status, and cellular amino acid supply. These signals result in phosphorylation of various signaling proteins including mammalian target of rapamycin (mTOR) and ribosomal protein S6 (rpS6) which regulate initiation of protein synthesis and control polypeptide elongation. Thin cows are known to produce less milk than well-conditioned cows. It was hypothesized that this effect could be mediated through leptin actions directly on mammary epithelial cells. The purpose of this experiment was to study the effects of leptin on the phosphorylation status of mTOR and rpS6 in MAC-T cells. Cells were seeded into 6-well plates at a density of 90,000 cells per well, starved in media containing 20% of normal DMEM essential amino acid concentrations and devoid of fetal bovine serum (FBS) for 12 h and subsequently cultured for 2 h in media without or with 160 ng/mL leptin. Each treatment was replicated trice and each replicate consisted of cells in 3 wells. The cells were lysed in the presence of phosphatase and protease inhibitors

and samples were analyzed by Western immunoblotting to determine the phosphorylation status of mTOR(Ser2448) and rpS6 (Ser235/236). The membranes were first probed for the phosphorylated forms of each protein and subsequently probed for the total forms of each. Statistical analysis of immunoblotting results showed no significant difference between the phosphorylation of mTOR in cells treated with or without leptin, but leptin treatment did cause a statistically significant increase in phosphorylation of rpS6 (67%). These results suggest that leptin acts on rpS6 independent of the Ser2448 site on mTOR. Stimulation of rpS6 should stimulate ribosomal biogenesis which would lead to increased protein synthesis, thus the results are supportive of a direct role of leptin on milk protein synthesis.

Key Words: leptin, protein synthesis, signaling proteins

T262 Glucocorticoid regulation of chicken adipose triglyceride lipase in adipose tissue. J. Serr*, S. Shin, Y. Suh, M. Kim, D. Latshaw, and K. Lee, *The Ohio State University, Department of Animal Sciences*, *Columbus*.

The mechanism of adipose tissue lipolysis is one that has not been fully elucidated. Increasing our understanding of this process would allow for increased feed efficiency and reduced fat content, which would lower feeding costs for poultry production. Adipose triglyceride lipase (ATGL) is an adipose-specific enzyme which cleaves at the Sn-1 position of triglycerides, releasing non-esterified fatty acids (NEFA) into the bloodstream. Glucocorticoids have been proven to elevate the level of circulating NEFAs. To determine the regulation of ATGL by glucocorticoid, 30 Ross 308 broilers received a 200 μL intraperitoneal injection of dexamethasone (4 mg/kg). Saline was administered to an additional 12 birds to determine any effect of stress during handling and injection. Another 6 birds received no treatment and were harvested as a control. Dexamethasone-injected birds were harvested at 0.5, 1, 2, 4, and 6 h after treatment; saline-treated birds were collected at 4 and 6 h (6 per time point). Adipose tissue was collected from abdominal and subcutaneous depots. Blood samples were collected via cardiac puncture. Gene and protein expression were analyzed via quantitative real-time PCR (qRT-PCR) and Western blot, respectively. In comparison with the saline-treated group, ATGL mRNA and protein was increased in broilers injected with dexamethasone, demonstrating that any response of ATGL expression to the stress of handling was minimal compared with that of hormone treatment. When dexamethasone response was observed against the untreated group up to 2 h following injection, an increase in ATGL protein was observed as quickly as 0.5 h and increased further at 1 and 2 h, demonstrating an acute response. Additionally, plasma NEFA analysis was done to confirm the release of free fatty acids into the blood. Plasma NEFA increased gradually from 0 to 6 h, and reached statistical significance (Tukey's Test) at 4 h (concurrent with mRNA and protein expression of ATGL). These data show that ATGL expression and activity is positively regulated by glucocorticoid in a time-dependent manner.

Key Words: chicken, lipolysis, glucocorticoid

T263 Bovine acute-phase response following corticotrophin-releasing hormone (CRH) infusion. R. F. Cooke*, A. B. Scarpa, F. M. Nery, F. N. T. Cooke, and D. W. Bohnert, *Oregon State University - EOARC*, *Burns.*

The objective of this study was to evaluate plasma concentrations of cortisol, ACTH, acute-phase proteins, and pro-inflammatory cytokines in beef steers following CRH infusion. Six weaned, halter-trained Angus steers (BW = 163 ± 7.0 kg; age = 203 ± 5.8 d) were fitted with indwelling jugular catheters on d −1 of the study, and assigned to receive intravenously 0.1 μg of bovine CRH/kg of BW on d 0 of the study. Blood samples were collected every hour via jugular catheters from −2 to 8 h, and every 6 h via jugular venipuncture from 12 to 72 h relative to CRH infusion (0 h). Steer rectal temperature was assessed concurrently with each blood collection. Samples collected from −2 to 8 h relative to CRH infusion were analyzed for plasma concentrations of interleukin (IL)-1 and 6, tumor necrosis factor (TNF)-α, interferon (IFN)-γ, cortisol, ACTH, ceruloplasmin and haptoglobin, whereas samples collected from 12 to 72 h were analyzed for plasma concentrations of ceruloplasmin and haptoglobin only. Data were analyzed with the MIXED procedure of SAS. Plasma ACTH and cortisol concentrations peaked ($P \leq 0.02$) 1 h following CRH infusion, and returned to basal levels at 2 and 4 h following infusion ($P > 0.15$), respectively. Body temperature peaked at 2 and 8 h following infusion ($P < 0.01$), and returned to basal levels after 12 h ($P = 0.40$). Contrasted to all other sampling hours, plasma IFN-γ concentrations were greater ($P = 0.03$) at 1 and 5 h, plasma IL-6 concentrations were greater ($P = 0.04$) from 4 to 6 h, plasma IL-1 concentrations tended ($P = 0.12$) to be greater from 6 to 8 h, and plasma TNF-α concentrations were greater ($P = 0.03$) from 5 to 7 h following infusion. Plasma ceruloplasmin and haptoglobin concentrations increased linearly ($P \leq 0.01$), and peaked at 54 and 66 h following CRH infusion, respectively. In conclusion, infusion of CRH at 0.1 μg/kg of BW increased plasma concentrations of ACTH and cortisol, and stimulated the acute-phase response in beef steers.

Key Words: acute-phase response, corticotrophin-releasing hormone, beef cattle

Physiology and Endocrinology: Hormonal Regulation of the Estrous Cycle in Beef Cattle

T264 Effects of 72-h temporary calf removal prior to fixed-time AI on pregnancy rates and subsequent calf performance in suckled beef cows. G. H. L. Marquezini*[1], V. R. G. Mercadante[1], S. L. Bird[2], B. J. Funnell[2], and G. C. Lamb[1], [1]*University of Florida*, *Marianna,* [2]*University of Minnesota, Grand Rapids.*

We determined whether 72 h calf removal (CR) before fixed-time AI (TAI) would increase pregnancy rates or alter subsequent calf performance in suckled, crossbred beef cows. Cows at 2 locations where stratified by days postpartum and parity and randomly assigned to one of 2 treatments: 1) received 100 μg GnRH and a CIDR insert (d −7), followed in 7 d by 25 mg $PGF_{2\alpha}$ and CIDR removal (d 0), followed in 72 h by GnRH and AI (d 3; Control; n = 105). 2) Same as control but calves were removed from their dams for 72 h between d 0 and d 3 (CR; n = 112). Transrectal ultrasonography was used to follow follicle and corpus luteum development on d 0, 3, and 10 and to determine pregnancy status on d 28. Blood samples were collected on d −14, −7, 0, 3, 10, and 28 to determine concentrations of progesterone. Calf weights were determined on d 0, 3, 32, and 140. Pregnancy rates tended ($P = 0.12$) to differ between Control (33.3%) and CR (43.5%). Calf removal did not alter follicle size on d 3, but on d 10 noncycling cows exposed to CR (3.1 ± 0.3 ng/mL) had greater ($P < 0.02$) concentrations of progesterone than Controls (2.0 ± 0.3 ng/mL). On d 10, no difference in concentrations of progesterone were detect for cycling cows. On d 0 calf weights were similar between Control (96.6 ± 2.4 kg) and CR (96.7 ± 2.4 kg) treatments, whereas on d 3 (99.7 ± 2.4 and 94.0 ± 2.3 for Control and CR, respectively), 32 (125.3 ± 2.4 and 119.0 ± 2.3 kg for Control and CR, respectively) and 140 (226.2 ± 2.4 vs. 212.9 ± 2.3 kg for Control and CR, respectively) weights were greater ($P < 0.05$) for Control than CR calves. When calves were classified into age ranges of young (25 to 40 d), medium (41 to 80 d), and old (>80 d) on d 0, young calves lost ($P < 0.001$) more weight as a percentage of body weight during 72 h of calf removal than older calves, whereas medium calves were intermediate. We conclude that calf removal for 72 h tended to increase pregnancy rates, while having negative impacts on subsequent calf performance.

Key Words: calf removal, beef cows, estrous synchronization

T265 Timed AI pregnancy rates in suckled beef cows in response to equine chorionic gonadotropin (eCG). L. D. Wallace[1], S. L. Pulley*[1], K. C. Olson[1], J. R. Jaeger[1], J. W. Bolte[1], S. K. Johnson[1], L. A. Pacheco[1], K. Bischoff[2], T. Loyd[2], G. C. Lamb[2], and J. S. Stevenson[1], [1]*Kansas State University*, *Manhattan,* [2]*University of Florida, Marianna.*

Previously, eCG administered before induced luteolysis stimulated follicle growth and increased progesterone secretion by the corpus luteum (CL) formed after ovulation in cattle. Our objective was to monitor timed AI pregnancy rate (PR) in beef cattle subjected to eCG. Suckled beef cows (n = 513; pure- and crossbred Angus, Simmental, and Hereford) were enrolled in a 7-d CO-Synch + CIDR protocol (100 μg GnRH at CIDR insertion [d –7]; 25 mg PGF2α (PGF) at CIDR removal [d 0]; and 100 μg GnRH at AI 66 h after PGF [d 3]) at 3 locations. Cows were assigned randomly to be controls or receive eCG (200 IU i.m.) at the time of PGF injection and CIDR insert removal. Pregnancy was diagnosed by transrectal ultrasonography at median d 35 and 67 after AI. Serum progesterone concentration (ng/mL) was determined in blood collected on d –17, –7, 0, 3, and at both pregnancy diagnoses (pregnant cows only) to determine cycling status, luteolysis, and potential differences in CL function after AI. Pretreatment cycling status differed ($P < 0.01$) among locations (locations 1 = 76.5%; 2 = 54.3%; and 3 = 27.4%). For cows having elevated (≥1 ng/mL) progesterone at CIDR insert removal, 97.4% had luteolysis, with 17.3% of cows having low (<1 ng/mL) progesterone at insert removal and at timed AI, and 1.2% having increasing progesterone from insert removal to timed AI. Progesterone did not differ on d 35 of pregnancy (6.0 ± 0.3 and 6.4 ± 0.4) or d 67 (6.6 ± 0.4 and 6.4 ± 0.3) for eCG and controls, respectively. Unadjusted PR on d 35 was 42.9 vs. 49.8% for eCG vs. controls, respectively. Herd, cycling status, technician, and treatment influenced PR. Cycling cows were 1.5 times more ($P = 0.046$; 95% CI = 1.01–2.27) likely to conceive than noncycling cows. Control cows were 1.5 times more ($P = 0.036$; CI = 1.03–2.13) likely to conceive than those treated with eCG. Cows in location 3 were 1.8 to 3.5 times more ($P = 0.004$; CI = 1.1–5.6) likely to conceive than cows at other locations. Pregnancy loss to d 67 did not differ between treatments (3.7 vs. 2.3% for eCG vs. controls), respectively. We conclude that eCG treatment did not increase PR under these experimental conditions.

Key Words: timed AI, eCG, beef cattle

T266 Effect of post-insemination GnRH on the pregnancy rate of beef cattle. W. A. Greene* and C. L. Pickworth, *The Ohio State University*, *Wooster*.

The objective of this study was to determine if administering GnRH 7 d after first artificial insemination (AI) would increase pregnancy rates (PR) in beef cattle. Ninety–3 beef cattle were blocked for breed, parity, postpartum interval (PPI), postpartum cyclicity (as determined by estrus detection and ultrasonography), and breeding method (bred based on observed estrus or timed–bred). Blocks were randomly assigned to either receive GnRH or saline. On d 0, all cattle received 100 μg GnRH i.m. and intra–vaginal 1.38 g progesterone inserts (CIDRs). On d 7, CIDRs were removed and cattle received 25 mg $PGF_{2\alpha}$ i.m. Estrus was observed at 0700 and 1900 and AI occurred 11 – 13 h after estrus was observed. If estrus was not observed, cattle were timed AI (TAI) and received 100 μg GnRH i.m. 70 – 72 h after $PGF_{2\alpha}$. On d 7 post–insemination, cattle received either 2 mL GnRH (100 μg) or 2 mL saline i.m. Blood samples were collected for plasma progesterone (P4) analyses 14 d post–insemination. Following the synchronization period, repeat breedings were done until d 75. Pregnancy status was determined by ultrasonography on d 110. The estrus detection rate [EDR] was 61.3%. Cattle bred following an observed estrus had a higher ($P < 0.05$) PR to synchronization than TAI cattle (61.4 vs. 33.3%). GnRH and Saline groups had similar ($P > 0.05$) PR to synchronization (46.8 vs. 54.4%), overall PR (87.2 vs. 97.8%), and mean P4 concentrations (2.6 ± 1.6 vs. 2.1 ± 1.6 ng/ml). Cycling (n = 49) and anestrous cattle had similar ($P > 0.05$) EDR (57.1 vs. 65.9%), PR to synchronization (44.9 vs. 56.8%), and overall PR (91.8 vs. 93.2%). A higher ($P < 0.05$) PR to synchronization was noted for cows with a long PPI (>50 d; n = 42) than cows with a short (≤50 d; n = 29) PPI (61.9 vs. 31.0%). Cycling animals had higher ($P < 0.05$) P4 concentrations than anestrous animals (2.7 ± 1.9 vs. 2.0 ± 1.1). The pregnancy rate of beef cattle was not affected by the post–insemination administration of GnRH.

Key Words: GnRH, post-insemination, progesterone

T267 Reproductive performance of prepubertal *Bos indicus* heifers after progesterone-based treatments. I. Claro Júnior*[1], O. Sá Filho[1], R. Peres[1], F. Aono[1], M. Day[2], and J. L. Vasconcelos[1], [1]*FMVZ-UNESP*, *Botucatu, SP, Brazil*, [2]*Ohio State University*, *Columbus*.

The objective of this study was to evaluate the effects of treatments with exogenous progesterone (P4) on reproductive performance of prepubertal *Bos indicus* heifers. Prepubertal Nelore heifers (n = 935; 24.0 ± 1.13 mo; 298.0 ± 1.89 Kg; body condition score of 3.2 ± 0.26) were randomly assigned to receive, between experimental Days −12 and 0, no treatments (CIDR0; n = 113), an intravaginal insert containing 1.9 g of P4 (CIDR) that had never been previously used (CIDR1; n = 237), or a CIDR insert that had previously been used 3x, with each use occurring for 9 d (CIDR4; n = 239). An additional treatment group consisted in pubertal heifers receiving a 12.5 mg im injection of dinoprost tromethamine on Day 0 (PGF; n = 346) to be used as controls for evaluation of conception rates. On Day 0, heifers were rectally palpated for uterine score evaluation (UtS; 1 to 3 scale), blood samples were taken for analysis of P4 and follicular diameter (FD) was measured. The breeding season (BS) started on Day 1 and consisted of artificial insemination after detection of estrus between Days 1 and 45, and natural service between Days 46 and 90. There were effects of treatment ($P < 0.05$) on serum concentrations of P4 on Day 0 (CIDR0: 0.37 ± 0.16; CIDR1: 2.31 ± 0.11; CIDR4: 1.20 ± 0.11 ng/mL), FD on Day 0 (CIDR0: 9.45 ± 0.24; CIDR1: 9.72 ± 0.17; CIDR4: 11.42 ± 0.16 mm), UtS on Day 0 (CIDR0: 1.49 ± 0.06; CIDR1: 1.88 ± 0.04; CIDR4: 2.24 ± 0.04), estrus detection rates in 7 d (CIDR0: 19.5%; CIDR1: 42.6%; CIDR4: 38.3%) and 45 d of BS (CIDR0: 52.2%; CIDR1: 72.1%; CIDR4: 75.3%), and on pregnancy rates in 7 d (CIDR0: 5.3%; CIDR1: 14.3%; CIDR4: 18.4%), 45 d (CIDR0: 27.4%; CIDR1: 39.2%; CIDR4: 47.7%) and 90 d of BS (CIDR0: 72.6%; CIDR1: 83.5%; CIDR4: 83.7%). Conception rate in 7 d of BS was greater ($P < 0.05$) in heifers from the CIDR4 (46.8%) and PGF (43.8%) than in CIDR0 (27.3%) and CIDR1 (33.7%) treatments. In conclusion, treatments with P4 hastened puberty and improved pregnancy rates at the beginning of BS, and previously used CIDR inserts are preferable for improvement of reproductive performance in prepubertal *Bos indicus* heifers.

Key Words: *Bos indicus* heifers, puberty, progesterone

T268 Comparison of three doses of prostaglandin $F_{2\alpha}$ in a 5-day CIDR-based synchronization protocol in beef cows. T. Robison*, K. Y. Perry, K. G. Carnahan, T. L. Davis, and A. Ahmadzadeh, *University of Idaho*, *Moscow*.

The most common timed artificial insemination (AI) programs used are based on the CO-Synch approach which includes the use of an intravaginal progesterone releasing insert (CIDR) and administration of $PGF_{2\alpha}$ to synchronize the estrous cycle in beef cattle. The objective of the present study was to compare the effect of various doses of $PGF_{2\alpha}$ on estrus and circulating progesterone (P4) concentrations of beef cattle synchronized using a 5 d CIDR protocol. Charolais cows (24 to 94 d postpartum) received a CIDR (d 0) for 5 d. On d 5 after CIDR removal, cows were randomly assigned to receive one of 3 treatments; 1) a single injection of 25 mg $PGF_{2\alpha}$ (control, n = 17), 2) a single injection of 37.5 mg $PGF_{2\alpha}$ (large, n = 17), or 3) 2 injections of 12.5 mg $PGF_{2\alpha}$ 7 h apart (split, n = 17). All cows were fitted with estrus detection aids and observed for behavioral estrus 3 times daily and artificially inseminated (AI) according to the a.m.- p.m. rule. Animals that were not detected in estrus received 100 µg GnRH and timed AI 96 h post-$PGF_{2\alpha}$ injection. Blood was collected on d 0 (before CIDR insertion) and d 7 (56 h post-$PGF_{2\alpha}$ treatment) to measure serum P4 concentrations. At 56 h post-$PGF_{2\alpha}$ treatment, mean P4 concentrations were less than 1ng/ml for all cows. However, P4 concentrations were lower on d 0 ($P < 0.05$) for cows ≤40 d postpartum (dpp) compared with cows that were >40 dpp in all treatments. The interval from $PGF_{2\alpha}$ treatment to estrus was not different among treatments and averaged: control = 67 ± 5.8 h, large = 58 ± 5.7 h, and split = 54 ± 5.6 h. Based on the current study, there was not sufficient evidence to indicate that observed estrus behavior and serum P4 concentrations after treatment with 25 mg $PGF_{2\alpha}$, 37.5 mg $PGF_{2\alpha}$, or 2 injections of 12.5 mg $PGF_{2\alpha}$ 7 h apart was different among treatments.

Key Words: beef cows, progesterone, prostaglandin $F_{2\alpha}$

T269 Pregnancy per AI (P/AI) of dairy cows following presynchronization and splitting the prostaglandin (PGF) injection in the 5d-Cosynch protocol. E. S. Ribeiro*, R. S. Bisinotto, M. Favoreto, L. T. Martins, R. L. A. Cerri, F. T. Silvestre, L. F. Greco, W. W. Thatcher, and J. E. P. Santos, *University of Florida*, *Gainesville*.

Objectives were to compare P/AI of cows subjected to the 5d-Cosynch protocol either presynchronized or with supplemental progesterone (P4), and with a double dose of PGF either as a single or split injections. In experiment 1, 730 grazing cows were randomly assigned to: Presynchronization (G6G; d −8 0.5 mg of cloprostenol, d −6 GnRH) followed by the 5d-Cosynch protocol with 1 mg of cloprostenol as a single (G6G-SI; d 0 GnRH, d 5 PGF, d 8 GnRH + AI) or split into 2 injections (G6G-TI; d 0 GnRH, d 5 and 6 PGF, d 8 GnRH + AI); or no presynchronization but with an intravaginal P4 insert (CIDR) from the GnRH to PGF with 1 mg of cloprostenol as a single (CIDR-SI; d 0 GnRH + CIDR, d 5 remove CIDR and PGF, d 8 GnRH + AI) or split into 2 injections on d 5 and 6 (CIDR-TI). Ovaries were scanned on d 0 and 5 and plasma analyzed for P4 on d 5 and 8. In experiment 2, 655 cows in a confinement system received an injection of 25 mg of dinoprost at 44 and 60 DIM. On d 72 they were assigned to the 5-d Cosynch with 50 mg of dinoprost as a single (d 0 GnRH, d 5 PGF, d 8 GnRH + AI) or split into 2 injections (d 0 GnRH, d 5 and 6 PGF, d 8 GnRH + AI). Pregnancy was determined 35 and 60 d after AI. In experiment 1, presynchronization with G6G increased ($P < 0.001$) the proportion of cows with a CL on d 0 (80.6 vs. 58.8%), ovulation to the first GnRH (64.2 vs. 50.2%), and presence (95.6 vs. 88.4%) and number of CL at PGF (1.79 vs. 1.30). Luteolysis was greater ($P < 0.001$) for the split injection of PGF (95.9 vs. 72.2%), especially in G6G cows (96.2 vs. 61.7%). An interaction ($P = 0.05$) was observed for P/AI. For CIDR cows, method of PGF administration had no effect on P/AI (CIDR-SI = 30.2 vs. CIDR-TI = 34.3%), whereas for G6G cows, splitting the dose into 2 injections improved P/AI (G6G-SI = 28.7 vs. G6G-TI = 45.4%). In experiment 2, splitting the dose of PGF increased ($P < 0.04$) P/AI on d 35 (44.5 vs. 36.4%) and 60 (40.3% vs. 32.6%) after AI. Presynchronization and splitting the dose of cloprostenol or dinoprost into 2 injections increases P/AI in cows subjected to the 5d-Cosynch protocol.

Key Words: dairy cow, luteolysis, timed AI

T270 Luteal function following a normal versus synchronized estrus in beef heifers. M. F. Smith*[1], D. H. Keisler[1], and F. Stormshak[2], [1]*University of Missouri*, *Columbia*, [2]*Oregon State University*, *Corvallis*.

The objective was to characterize changes in plasma concentrations of oxytocin and progesterone in response to a prostaglandin $F_2\alpha$ (PG) injection on d 6 (d 0 = estrus) following a normal or synchronized estrous cycle. Normally cycling Angus heifers were assigned to the following groups: 1) Normal Cycle (Normal = 5 heifers were given PG on d 6 of the cycle immediately following a normal estrous cycle), 2) Synchronized Cycle (Sync = 5 heifers were given PG on d 6 of the cycle immediately following a synchronized cycle; see below), and 3) Synchronized and Ovariectomized (Sync + Ovx = 4 heifers were synchronized then unilaterally ovxed (luteal ovary) on d 4 of the ensu-

ing cycle and given PG on d 6). The experiment was a randomized complete block design with treatment serving as the block. Estrus was synchronized (Sync and Sync + Ovx groups) as follows: GnRH (100 µg, Cystorelin) injection (im) and insertion of a CIDR followed 7d later with injection (im) of PG (500 µg Estrumate) and CIDR removal. On d 6 of the estrous cycle immediately following a normal or synchronized cycle, each heifer received PG (500 µg Estrumate, iv). Jugular blood samples were collected −10, −5, 0 (immediately before PG injection), 5, 10, 15, 20, and 30 min following injection. Plasma was collected and analyzed for oxytocin and progesterone by RIA. Plasma concentrations of oxytocin increased within 5 min of PG injection in the Normal and Sync heifers but not in the Sync + Ovx heifers indicating an ovarian and likely luteal source of oxytocin in the Normal and Sync heifers. Mean plasma concentrations of oxytocin at 30 min after PG injection were lower ($P < 0.01$) in Sync vs. Normal heifers and plasma concentrations of progesterone were also lower ($P < 0.01$) on d 6 (−15 to 30 min) in Sync vs. Normal heifers. In summary, PG-induced secretion of oxytocin from the developing corpus luteum and plasma levels of progesterone were greater on d 6 of an ensuing cycle following a normal compared with a synchronized cycle.

Key Words: prostaglandin, oxytocin, corpus luteum

T271 Evaluation of 5-day versus 7-day CIDR treatment on reproductive outcomes of beef heifers using a modified timed-AI protocol. A. Ahmadzadeh*[1], D. Gunn[2], J. B. Hall[3], and J. B. Glaze Jr.[4], [1]*Univ. of Idaho*, *Moscow*, [2]*Univ. of Idaho*, *Fort Hall*, [3]*Univ. of Idaho R & E*, *Salmon*, [4]*Univ. of Idaho R & E*, *Twin Falls*.

The objective of this experiment was to determine the effect of reducing the duration of CIDR insert exposure, in a CIDR-based timed AI protocol, on pregnancy per AI (P/AI) and pregnancy rates in beef heifers. The experiment was conducted in 4 consecutive years. British cross-bred heifers (yr 1, n = 82; yr 2, n = 70; yr 3, n = 86; yr 4, n = 54) were stratified by BW and age and were assigned randomly to one of 2 treatments: 1) CIDR7 heifers (n = 147) received a CIDR insert for 7 d; and 2) CIDR5 heifers (n = 145) received a CIDR insert for 5 d. Heifers in CIDR7 and CIDR5 were given $PGF_{2\alpha}$ upon CIDR removal followed by GnRH (75 µg) and timed AI 55- 56 h after CIDR removal. Estrual behavior was monitored following CIDR removal. Heifers were inseminated by a single technician. Starting on d 14 after AI, heifers were exposed to fertile bulls for 45 d. Blood samples were collected on the day of CIDR insertion. Pregnancy status was determined by ultrasonography at d 32 to 35 and d 67 to 85 after AI. Data were analyzed by logistic regression and ANOVA. Percentage of heifers detected in estrus was different ($P < 0.05$) between years (69%, 44%, 51%, and 51% for yr 1, 2, 3, and 4, respectively) but not different between treatments. At CIDR insertion, mean serum progesterone (P4) were greater in CIDR7 heifers than CIDR5; however there was no effect of year or year by treatment interaction on P4 concentrations. There was a treatment by year interaction effect on P/AI ($P < 0.05$). For CIDR7 and CIDR5, in yr 1 P/AI was 39% and 65.8% ($P < 0.05$); in yr 2, P/AI was 64.7% and 41% ($P < 0.05$), yr 3 P/AI was 59% and 73.8% ($P = 0.09$) and yr 4 P/AI was 50% and 66% ($P = 0.25$). Overall P/AI tended ($P = 0.09$) to be greater for CIDR5 compared with CIDR7 (62.5% vs. 52%). Final pregnancy rates were unaffected by the treatment protocols or year (92% and 95.5% for CIDR7 and CIDR5, respectively). The P/AI results from this study suggests that reducing the duration of CIDR treatment from 7 to 5 d in a CIDR-based TAI protocol may improve P/AI.

Key Words: estrous synchronization, CIDR insert, beef heifer

T272 Rumen temperature during the estrous cycle of beef cows. B. H. Boehmer*, T. A. Pye, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station*, *Stillwater*.

The objective of this study was to evaluate rumen temperature (RuT) associated with estrus in May to July. Angus cows (n = 46) were administered temperature boluses (SmartStock, LLC) with a bolus gun and estrus was synchronized with $PGF_{2\alpha}$ at 60 to 90 d postpartum. Temperature boluses were programmed to transmit RuT every hour. The onset of estrus was determined by HeatWatch (CowChips, LLC). Progesterone was quantified in plasma collected daily to verify stage of the estrous cycle. Mean RuT for all cows was 38.19 ± 0.01°C and RuT ≤35.3°C, which are associated with water consumption, were excluded from analyses. Progesterone and RuT during estrus were analyzed using the MIXED procedure (SAS). Ambient temperature ranged from 8 to 39°C during the experiment and was not associated with RuT. On the day of estrus, RuT was greater ($P < 0.05$, 38.6 ± 0.1°C) compared with 3 d before (38.2 ± 0.1°C) or 3 d after (38.3 ± 0.1°C) estrus. Rumen temperature was greater ($P < 0.05$, 38.8 ± 0.1°C) during the first 8 h after the onset of estrus compared with the same daily hours the day before (38.2 ± 0.1°C) or after (38.1 ± 0.1°C) onset of estrus. Rumen temperature was recorded hourly and progesterone in plasma was quantified daily in cows (n = 20) during an estrous cycle. Concentrations of progesterone in plasma decreased before the increase in RuT at estrus. On the day of estrus, RuT was greater ($P < 0.05$, 39.0 ± 0.1°C) compared with the other days of the cycle (38.5 ± 0.1°C). These results support our previous report that RuT can be used for the identification of estrus in beef cows.

Key Words: rumen temperature, estrus, beef cows

T273 Effects of feed supplementation and method of weaning on the physiology and performance of beef calves. C. Campistol*[1], H. G. Kattesh[1], J. C. Waller[1], E. L. Rawls[1], G. M. Pighetti[1], and J. A. Carroll[2], [1]*University of Tennessee*, *Knoxville,* [2]*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX*.

A study was conducted to investigate growth performance and physiological measures of stress in pre- and post-weaned beef calves provided a grain supplement and weaned by fenceline or total separation. Angus steer calves (n = 48; 312.2 ± 27.9 kg), housed on pasture with their dams, were blocked by initial BW and assigned randomly on d 0 to be hand-fed a grain supplement (YS; 4.5 kg/head/d) or no supplement (NS) for 7 d. On d 7, calves (12 NS and 12 YS/group) were weaned by fenceline (Group 1) or total separation to a distant pasture (Group 2). On d 14, Group 1 calves were moved to a pasture lot adjoining Group 2. All calves were weighed and bled on d 0, 7, 10, 14, and 21, and provided access to the grain supplement on d 7–21. Blood was analyzed for plasma cortisol (CORT) and interferon-gamma (IFN-γ) concentration, hematocrit (Hct), red blood cell (RBC) and white blood cell (WBC) total count, and neutrophil:lymphocyte ratio (N:L). By d 7, BW increased ($P < 0.001$) and RBC and IFN-γ decreased ($P < 0.001$) in all calves. However, NS exhibited lower ($P < 0.005$) N:L (0.16 vs. 0.27 ± 0.03) and CORT (74.5 vs. 98.4 ± 7.2 nmol/L) compared with YS calves. By d 10, Group 2 steers experienced a reduction ($P < 0.001$) in BW compared with animals in Group 1, which was more pronounced in the NS calves. Measures for RBC, WBC, IFN-γ and N:L increased ($P < 0.01$) in all calves within 3 d following weaning. Compared with NS, both Hct and CORT for YS calves decreased ($P < 0.01$) over this same period. From d 14–21, Hct decreased ($P < 0.01$) and IFN-γ increased ($P < 0.001$). These results suggest that providing a grain supplement

beginning 7 d before weaning may reduce BW loss and temper the animals stress response due to weaning.

Key Words: beef cattle, pre-weaning supplementation, stress

T274 Effect of serum progesterone levels on conception rate in Creole Rodeo multiparous cows and heifers. J. A. Ramirez-Godinez*[1], L. V. Beltran-Prieto[1], J. Dominguez-Viveros[1], A. Flores-Mariñelareña[1], and A. Quezada-Casasola[2], [1]*Universidad Autonoma de Chihuahua*, *Chihuahua, Mexico*, [2]*Universidad Autonoma de Ciudad Juarez*, *Chihuahua, Mexico*.

The aim of the present study was to compare the conception rate (CR) depending on serum progesterone levels (SPL) in Creole Rodeo cows (CC) and heifers (CH) treated with ECP, eCG or hCG, and estradiol benzoate (EB), eCG, and GnRH, respectively, in addition to a CIDR+EB and $PGF_{2\alpha}$ protocol. Thirty-one multiparous CC and 59 CH were randomly assigned to 1 of 3 treatments: CC of T1 (n = 11) received 1 mg of ECP and T2 (n=10) 500 IU of eCG 24 h after CIDR removal, and T3 (n = 10) 2000 IU of hCG 56 h after CIDR removal; CH of T1 (n = 19) received 1.38 mg of EB and T2 (n = 5) same as CC, T3 (n =2 0) 100 μg of GnRH 56 h after CIDR removal. CH not detected in estrus from T2 were reassigned to T4 (n=15), same as T2, but 56 h after CIDR removal 100 μg of GnRH were administered. CC and CH in T1 and T2 were AI 12h after detected in estrus, and in T3 and T4 were fixed-time AI 56h after CIDR removal. Blood samples were collected in CC at days 0, 7, 8, 9, 17, 26 through 32, and in CH at days −7, 0, 2, 4, 6, 8, 10, 12 after CIDR insertion. CR was analyzed using PROC CATMOD of SAS. The variation coefficient of SPL of day 0 and 7 were analyzed with PROC MEANS of SAS. In CC, the CR was higher ($P<0.05$) in T2 (60%) than in T1 (27.27%) and T3 (30%). In CH, CR was similar ($P > 0.1$) being T4 with 46.67% over T1, T2, and T3 (31.58, 40, and 30%, respectively). The variation coefficient of SPL of day 0 and 7 in CC were 82.25% and 82.75%, respectively; for CH was 83.16% at day 0. The SPL were similar between treatments neither in CC nor in CH ($P > 0.1$), and did not have an effect in CR. These results suggest that the use of eCG after CIDR removal might improve the conception rate in multiparous Creole Rodeo cows; in heifers the use of eCG+CIDR+GnRH to induced ovulation, can improve fertility. In addition, the serum progesterone levels at CIDR insertion and at removal did not have an effect in conception rate in multiparous Creole Rodeo cows and heifers.

Key Words: Creole cattle, CIDR, eCG

Physiology and Endocrinology: Male Reproduction, Gamete Cryopreservation and Embryos

T275 Validity of sperm penetration assay in boar fertility testing. S. A. Oh*, Y. J. Park, S. J. Yoon, W. S. Kwon, Y. H. Kim, E. A. Mohamed, Y. A. You, and M. G. Pang, *Department of Animal Science & Technology and BET Research Institute, Chung-Ang University*, *Ansung, Gyeonggi-Do, Korea*.

The prediction of sperm fertility is of paramount importance for breeding animals. Multiple laboratory approaches have been developed for this purpose, but they have yielded equivocal results. The objective of this study was to develop and standardize to a method for predicting fertility in vivo in boars using the in vitro penetration assay. To increase the sensitivity and reduce false-negative results of the assay, each step in the procedure was standardized and quality control was applied. Maximum penetration of hamster zona-free oocytes and immature porcine oocytes was obtained using heparin-treated sperm cells. Hamster zona-free oocytes showed a significantly higher penetration than immature porcine oocytes. To eliminate interassay variability, 2 frozen bull semen samples were applied. All possible variables related to the female were excluded. The SPA (sperm penetration assay using zona-free oocytes) result showed significant correlation with historic average litter size but had no significant correlation with farrowing rates. To determine the normal range for the SPA, lower limits of the sperm fertility index were established as 1.2 for the small litter sizes (<8 piglets) and 2.5 for the large litter sizes (≥10 piglets). The overall accuracy was 93.33% and 93.33% respectively, for the small and large litter sizes. Our laboratory has standardized the procedure for the SPA, resulting in greatly increased sensitivities for small and large litter sizes. The protocol increases the ability to discriminate between good and poor fertility groups and it was highly effective at ranking 30 boars by litter size into large and small litter groups.

Key Words: sperm, fertility, sperm penetration assay

T276 Comprehensive proteomic analysis to defining sperm fertility in bovine. Y. J. Park*, S. A. Oh, W. S. Kwon, S. J. Yoon, Y. H. Kim, E. A. Mohamed, Y. A. You, and M. G. Pang, *Department of Animal Science & Technology and BET Research Institute, Chung-Ang University*, *Ansung, Gyeonggi-Do, Korea*.

The aim of present study was undertaken to determine whether bovine spermatozoa contained protein markers associated with bull fertility, and whether these markers were of value in predicting bull fertility. We undertook differential proteome profiling of spermatozoa from fertile bulls with extreme non-return rates (NRR): a low fertility group (45.10±4.95) and a high fertility group (82.45±6.26). Two-dimensional gel electrophoresis (2-DE) was carried out with triplicate samples of pooled spermatozoa from 3 low and 3 high fertility bulls. Protein expression levels of sperm from low and high fertility were compared using PD-Quest software. The marked difference in spot intensity was arbitrarily set as a >3-fold difference following analysis data from the software manufactures. From the different protein spots expressed in low and high fertility group, only 14 spots showed highly expression in low fertility, conversely, 4 spots were highly expression in high fertility. Six out of 18 spots detected were identified by LC/MS-MS. Metabolism related protein as ATP synthase subunit, protein tyrosin phosphorylation related protein as cytochrome b-c1 complex subunit 2 and sperm motility and cell death pathway related protein as porin were highly expressed in specimen from low fertility group. The other side metabolism related protein as alpha-2-HS glycoprotein, motility related protein as alpha-tubulin and protein oxidation related protein as phospholipid hydroperoxide glutathione peroxide were highly expressed in high fertility group. This study will enable further elucidation of the molecular mechanisms involved in this particular condition and might shed further light on key sperm proteins involved in fertilization. It is also important prerequisite to the development of diagnostic tests for bull fertility.

Key Words: sperm, fertility, proteome

T277 Effects of two egg yolk-free commercial extenders and centrifugation on freezing ability of semen in Mahabadi goat. M. Ansari*[1], A. Towhidi[1], M. Moradi Shahre Babak[1], and M. Bahreini[2], [1]*University of Tehran, Department of Animal Science*, *Karaj, Tehran, Iran*, [2]*Animal Breeding Center of Iran*, *Karaj, Tehran, Iran*.

The objective of this study was to determine the effects of 2 egg yolk-free extenders (Bioxcell and AndroMed) with or without semen centrifugation in 2 × 2 factorial design on quality of frozen-thawed semen in goat. Five mature Mahabadi bucks were selected for semen collection using an artificial vagina. Semen samples were collected, pooled and divided to 4 groups after quality evaluation. The groups consisted of Andromed (AC) or Bioxcell (BC) with centrifuged semen; and Andromed (A) and Bioxcell (B) with whole semen (without centrifugation). Percentage of motility and progressive motility of sperm were evaluated and recovery rate was calculated using post thaw motility divided by before freezing motility. Data was analyzed using proc GLM of SAS. Effect of extender, centrifugation and their interaction was significant ($P \leq 0.05$). Motility and progressive motility percentage of B (50.0% ± 3.5; 36.0% ± 3.6) was significantly higher than BC (28.0% ± 3.5; 17% ± 3.6) and AC (40.0% ± 3.5 ; 26.0% ± 3.6) ($P \leq 0.05$) and tended to be higher than A (45.0% ± 3.5; 26.0 ± 3.6) ($P = 0.07$). Recovery rate percentage in B (71.4 ± 5.0) was significantly higher than BC (40.0% ± 5.0) and AC (57.1% ± 5.0) ($P \leq 0.05$), with no significant difference between B and A (64.3% ± 5.0). It was concluded that extender Bioxcell with whole semen (without centrifugation) was more efficient for cryopreservation of goat semen.

Key Words: sperm cryopreservation, extender, centrifugation

T278 The effect of ethanol supplemented extender on freezing ability of goat semen. M. Ansari*[1], A. Towhidi[1], M. Moradi Shahre Babak[1], and M. Bahreini[2], [1]*University of Tehran, Department of Animal Science*, *Karaj, Tehran, Iran*, [2]*Animal Breeding Center of Iran*, *Karaj, Tehran, Iran*.

Inclusion of fat soluble material to the semen extender or embryo in vitro culture involves their solution into an appropriate solvent such as ethanol. Ethanol might have detrimental effects on sperm characteristics. Thus, the objective of this study was to investigate the effects of adding ethanol to the Bioxcell extender on goat semen freezing ability. Five mature Mahabadi bucks were selected and semen samples were collected using an artificial vagina during 4 weeks. Semen samples were pooled and divided into 2 groups after evaluation for qualitative characteristics. Treatment groups were including 1) basal extender as a control and 2) basal extender+ ethanol (0.05% v/v). Motility, progressive motility were evaluated by standard methods and recovery rate was calculated using post thaw motility divided by before freezing motility. Data was analyzed using Proc GLM of SAS. Motility percentage and recovery rate were

significantly higher in control than those in the treated group (44% ± 1.58, 58.01% ± 0.02 vs. 37% ± 1.58, 50.76% ± 0.02, respectively) ($P \leq 0.05$) but progressive motility percentage was not affected by treatment (33% ± 2.12 vs. 28% ± 2.12, respectively). The result indicated that ethanol had a toxic effect on sperm characteristics.

Key Words: sperm, ethanol, extender

T279 Natural non-synonymous mutations in the ovine leptin gene affect leptin binding affinity and biological activity. S. Reicher*[1,2], A. Gertler[2], E. Seroussi[1], and E. Gootwine[1], [1]*Institute of Animal Science, ARO, The Volcani Center*, *Bet Dagan, Israel*, [2]*The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University of Jerusalem*, *Rehovot, Israel*.

The hormone leptin is involved in diverse biological processes, including regulation of feed intake, body-weight homeostasis and energy balance. Polymorphism in the bovine leptin gene has been found to be associated with variations in carcass fat content and average daily gain, as well as in milk yield, milk somatic cell count and several traits governing reproduction. In the current study, we sequenced genomic DNA and cDNA samples of individuals from 5 divergent sheep breeds and revealed synonymous as well as novel non-synonymous mutations at the third exon of the ovine leptin gene *(oLEP)*. In addition, 2 alternatively spliced *(oLEP)* transcripts were found in the abdominal fat tissue. The biochemical and biological significance of these naturally occurring mutations was examined by generating recombinant oLEP muteins which carried the corresponding mutations. Surface plasmon resonance experiments revealed reduced affinity of all oLEP muteins examined, namely: Q28 deletion, N78S, R84Q, P99Q, V123L and R138Q, to chicken leptin-binding domain (chLBD) relative to the wild-type hormone (0.54, 0.38, 0.36, 0.55, 0.69 and 0.60, respectively). In competitive binding assays between biotinylated oLEP and the leptin muteins, N78S and R84Q exhibited the lowest affinity to both chLBD (0.19 and 0.08, respectively) and human LBD (0.18 and 0.41, respectively) as compared with the wild-type hormone. We then tested the muteins' ability to induce proliferation in Baf-3 cells stably transfected with the long form of the human leptin receptor: significant differences in proliferative activity were only found for N78S (1.8-fold higher) and R138Q (4.2-fold lower) relative to wild-type oLEP. It is speculated that under artificial selection in farm animals, reduced affinity of leptin for its receptor may confer a selective advantage.

Key Words: leptin, polymorphism, ovine

T280 Effect of different aspiration pressure on the number and quality of ovine oocyte. A. Abedini*, H. Kohram, and R. Salehi, *Tehran University*.

This study was designed to characterize the effects of different aspiration pressure (20, 70, 110 mmHg) during oocyte collection on the number and quality of ovine oocytes. Ovine ovaries were collected exactly after slaughter and placed them in a 0.9% NaCl aqueous solution containing penicillin-streptomycin. Cumulus-oocyte complex (COCs) were aspirated almost from 300 ovaries by aspiration pump with a 20-g needle. After aspiration per ovary, with same needle was sucked TCM 199 that supplemented with penicillin-streptomycin. The oocytes were observed under microscope. COCs were categorized to 3 groups: A: denature oocytes, B: oocyte with damaged cumulus, C: qualify oocytes (had more than 3 layers with health cumulus layer). The data of oocytes were investigated separately in each group of oocytes with different aspiration pressure. The total numbers of oocytes and grade A, B, C oocytes per group (20, 70, 110 mmHg) were analyzed by ANOVA. Statistical differences showed that in group with 20 mmHg pressure, the number of oocytes was low but the number of grade C oocytes was more than other groups ($P < 0.05$). In 110 pressure treatment, the total number of oocytes was high but the quality was low. The percentage of grade A and B oocytes in 110 treatment was higher than other groups ($P < 0.05$). This results showed that the high pressure treatment destroyed the cumulus layer and decreased the qualify oocytes. In group with 70 pressure treatment the number and quality of oocytes were in average. The difference between the numbers of oocyte in 110 and 70 mmHg pressure was not significant however, the qualify oocyte was higher in 70 pressure treatment ($P < 0.05$). The results demonstrated that vacuum pressure during ovine oocyte aspiration affects the number and quality of oocytes. High pressure increase the number of oocytes harvested however reduced the qualify oocyte, while low pressure decrease the number of oocyte and increase the quality. To sum up, it seems that the average pressure (70 mmHg) could harvest the qualify oocytes with reasonable numbers.

Key Words: aspiration pressure, number and quality, ovine oocyte

T281 The effect of poly-L-lysine as a new cryoprotectant for ovine oocyte vitrification. N. Li*[1], T. Wuliji[1], A. Qi[1], S. H. Hyon[2], K. Matsumura[2], L. Shi[1], and W. Chen[1], [1]*University of Nevada, Reno*, [2]Kyoto University, Kyoto, Japan.

The objective of this study is to evaluate a polyampholyte, poly-L-lysine (PLL), as a new cryoprotectant for ovine oocytes vitrification. The PLL was experimented as an alternative cryoprotective reagents to the traditional dimethyl sulfoxide (DMSO) protocol. Recently, Matsumura et al. (2009) had demonstrated that PLL effectively protecting L929 stem cells during cryopreservation. Oocytes were screened and collected from fresh ovine tissue, then randomly distributed into 2 developmental stages, namely, germinal vesicle (GV) stage oocytes (immature) and metaphase 2 (M2) stage oocytes (mature). GV stage oocytes vitrification was carried out immediately upon collection, while M2 stage oocytes vitrification was made after 24h in vitro culture for oocyte maturation. Each developmental group was subjected to comparison of 2 different vitrification solutions: (1) PLL based formula (5% PLL for 45s, 10% for 25s) (2) DMSO based formula (10% DMSO, ethylene glycol, and holding medium for 45s, 20% for 25s), Therefore, following 4 groups comparison were conducted: Group I GV stage, vitrification solution (VS) (1); Group II M2 stage, VS (1); Group III GV stage VS (2) and Group IV M2 stage, VS (2). There are 5 replicated batches for each group, and each batch was processed on the same day under the same condition. The normality of developing oocytes was examined under microscope. Normal oocytes showed the characteristics of homogeneous cytoplasm and intact zona pellucida, while abnormal oocytes showed low density of granular cells. Under confocal microscope, the spindle and microtubules of normal oocytes are intact and dispersed within plasma uniformly; the abnormal oocytes displayed a reduced amount of microtubules. The group mean were compared by *t*-test procedure. The preliminary results showed that normal oocyte in group II(82.1) are significantly ($P < 0.05$) higher than that of group IV (58.0), the normal oocytes in group IV are significantly ($P < 0.05$) higher than group III (48.1). However, group I (53.6) and II did not differ. Although encouraging, the advantage of using PLL as an alternative cryoprotectant requires future investigation.

Key Words: poly-L-lysine, ovine oocyte, vitrification

T282 Administration of human chorionic gonadotropin (hCG) to embryo transfer (ET) recipients increased ovulation, progesterone,

and transfer pregnancy rates. L. D. Wallace*[1], C. A. Breiner[2], R. M. Breiner[1], and J. S. Stevenson[1], [1]*Kansas State University*, *Manhattan*, [2]*Cross Country Genetics North Inc.*, *Westmoreland, KS*.

We hypothesized that administration of hCG at ET would induce accessory corpora lutea (CL), increase circulating progesterone concentrations, and reduce early embryonic loss. At 2 locations, mature lactating (94%) and nonlactating (6%) purebred and crossbred Angus, Simmental, and Hereford recipients (n = 471) were assigned alternately to receive i.m. 1,000 IU hCG or 1 mL saline (control) at ET. Fresh or frozen-thawed embryos were transferred on d 5.5 to 8.5 (median = d 7) of the estrous cycle to recipients having a palpable CL (CL grade = 1 or 2). Recipients received a BCS of 1 to 9 at ET. Pregnancy diagnoses occurred by transrectal ultrasonography 28 to 39 d (median = d 36) and reconfirmed 58 to 77 d (median = d 74) post-estrus. At one location (n = 108), ovaries were examined to count the number of CL at pregnancy diagnoses. More ($P < 0.001$) pregnant hCG-treated cows (69.0%) had multiple CL than pregnant controls (0%). Serum progesterone (ng/mL) determined at both pregnancy diagnoses in pregnant cows was greater ($P \leq 0.05$) after hCG treatment than in controls (first: 8.1 ± 0.9 vs. 6.1 ± 0.8; second: 8.8 ± 0.9 vs. 6.6 ± 0.7), respectively. Transfer pregnancy rates (PR) were analyzed using logistic regression. Unadjusted PR at the first diagnosis was 62.0 vs. 55.6% for hCG vs. controls. At the second diagnosis, PR was 59.0 vs. 53.0%, respectively. Factors affecting PR were CL grade ($P = 0.12$), number of previous transfers ($P = 0.03$), and BCS ($P = 0.02$). Odds ratios indicated that greater PR occurred in recipients having a CL grade 1 vs. 2 (63.8 vs. 58.2%), fewer previous transfers 1 vs. > 1 (61.3 vs. 43.1%), and when BCS > 5 vs. ≤ 5 (67.1 vs. 54.0%). An interaction ($P = 0.11$) was detected between treatment and BCS in which hCG tended to improve PR in recipients having BCS ≤ 5 than in controls (60 vs. 48%), whereas no treatment effect occurred in recipients having BCS > 5 (65.5 vs. 68.5%), respectively. We concluded that hCG at ET increased incidence of accessory CL, increased progesterone in pregnant recipients, and tended to increase PR in thinner recipients (BCS ≤ 5).

Key Words: embryo transfer, hCG, pregnancy rates

T283 Effect of addition of cAMP regulators to bovine in vitro oocyte maturation medium. C. Burroughs* and G. Seidel, *Colorado State University*.

In vivo, the LH surge before ovulation stimulates resumption of oocyte meiosis, but in vitro, resumption occurs due to removal of the oocyte from inhibition in follicular fluid. The objective of this experiment was to create an in vitro system with greater resemblance to the in vivo situation to produce greater numbers of bovine blastocysts. The adenylate cyclase activator forskolin (100 μ*M*) and the phosphodiesterase inhibitors caffeine (2 μ*M*) and cilostamide (10 μ*M*), were added to maturation media to increase and maintain cAMP levels. Bovine oocytes were aspirated from abattoir-collected ovaries and immediately placed into medium containing forskolin and caffeine. Oocytes were incubated with different combinations of cAMP regulators during maturation as shown in Table 1 for all 6 replicates. All oocytes were moved to new medium at each time point. Half of the oocytes in each treatment were fertilized at 23 h of incubation and half at 28 h. Cleavage rates were recorded at 2.5 d post-fertilization and blastocyst rates at 7 d post-fertilization. Cleavage rates in treatment D were lower than the control (A) and those in C ($P < 0.05$, Table 1), indicating that prolonged exposure to cilostamide was detrimental to fertilization. There was no effect of time on cleavage rate, and no treatments had higher blastocyst rates per oocyte than the control ($P > 0.1$). Under the conditions used, there were no added benefits to blastocyst production from the treatments studied.

Table 1. Effects of cAMP regulators during in vitro maturation of oocytes

Trt	n	0-2h cult	2-6h cult	6-23/28h cult	Time of fert	Cleav %	Blast %
A	168	No add	No add	No add	23h	83.8±5.8	22.0±4.3

T284 Testicular abnormalities in *Gallus gallus* var. *domesticus* males. J. R. Moyle*, S. M. Whipple, F. D. Clark, and R. K. Bramwell, *University of Arkansas*, *Fayetteville*.

In conducting research on testicular development on *Gallus gallus* var. *domesticus* males it was noticed that several the males had nodules on their testes. Further histological investigation showed that these nodules were composed of seminiferous tubules that were contained within the tunica albuginea of the testicular capsule. The seminiferous tubules within these nodules contained sperm as well as spermatids at various stages of development; however, no direct outlet of the sperm into the testes was identified or observed. These testicular nodules were found in all primary breeder males that were investigated (n = 8 flocks), with occurrences for individual males ranging from 42% to 93%. The flocks that were investigated consisted of commercial breeder flocks, individually caged males, as well as males used in pen trail. Nodules were also found in a pure line of French Mottled Houdan chickens, as well as a random bred broiler breeder line from the 1980s. These nodules occurred only on the left testes in 92% of males, with 1% only on the right, and 7% had nodules on both testes. The number of visible nodules on the testes ranged from 1 to as many as 18, with the size ranging up to 4.5mm. Using histological preparations these testicular abnormalities were detected in males that were 18 weeks of age, and had not been light stimulated. No conclusion about the affect of testicular nodules on fertility was apparent, as all of the flocks investigated had normal or higher fertility. Therefore, at this time the effects of testicular nodules, if any, are unknown.

Key Words: testes, males, broiler breeders

T285 Effects of hypothermic storage of striped bass (*Morone saxatilis*) sperm on intracellular calcium, reactive oxygen species formation, mitochondrial function, motility, and viability. H. D. Guthrie*[1], L. C. Woods III[2], and G. R. Welch[1], [1]*Animal Biosciences and Biotechnology Laboratory, Agricultural Research Service, USDA*, *Beltsville, MD,* [2]*Department of Animal and Avian Sciences, University of Maryland, College Park*.

Experiments were conducted to determine the effect of hypothermic 24 h storage of striped bass sperm cells on viability, intracellular Ca^{2+}[Ca^{2+}]$_i$, mitochondrial membrane potential ($\Delta\psi_m$), and reactive oxygen species (ROS) formation (oxidation of hydroethidine to ethidium) as determined by flow cytometry; motion activation; and ATP concentration as determined by Luciferin-Luciferase bioluminescence assay. Semen was stored for 1 or 24 h at 4°C in an O_2 atmosphere undiluted (raw); or diluted 1:4 (one volume semen with 3 volumes) with T350 (20 mM

TRIS base-NaCl, 350 mOsm/mL, pH = 8) or with seminal plasma (SP) in the presence of various treatments. Viability (% cells excluding propidium iodide) approached 100% after 1 h storage raw or in T350 and SP. After 1 h of storage Fluo-3 fluorescence (marker for $[Ca^{2+}]_i$) was detected in only 3% of sperm cells in raw and T350 or SP extended semen. In contrast to storage for 1 h, after 24 h the incidence Fluo-3 fluorescence intensity was increased in >50% of the viable cells in raw and in T350 or SP extended semen along with increased cell death; the presence of 1 mM EGTA prevented increased Fluo-3 fluorescence and attenuated cell death. Activation of sperm motility was 82% after 1 h in T350 and decreased to 30% after 24 h. However, activation failed in the presence of EGTA at 1 or 24 h. During storage $\Delta\psi_m$ and ATP did not change significantly between 1 and 24 h; however in the presence of EGTA ATP, but not $\Delta\psi_m$ decreased between 1 and 24 h. While ROS formation was induced by menadione treatment, there was no evidence of storage-induced ROS formation in the absence of menadione. The increased intracellular calcium found after 24 h indicates a storage-induced defect in the maintenance of cellular calcium homeostasis which may be detrimental to sperm activation.

Key Words: flow cytometry, Fluo-3, sperm viability

T286 Renin message is up-regulated in spermatogonia and testes of male mice in response to treatment with aflatoxin B1. K. J. Austin*, K. L. Speiser, A. M. Kaiser, R. R. Cockrum, and K. M. Cammack, *University of Wyoming*, *Laramie*.

Aflatoxin B1 (AFB1) has been shown to affect fertility in male mice and numerous livestock species. However, the exact genetic mechanisms associated with the disruption are not known. The objective of these experiments was to examine the genetic response to AFB1 and determine which male reproductive cell types are affected by treatment with AFB1. In previous experiments, male mice ≥4 wks of age were administered 50 µg/ kg BW AFB1 by IP injection daily for 45 d. Testes were collected and stored at −80°C until analysis. Mice were further characterized as being tolerant or intolerant to the effects of AFB1 based on TUNEL staining and the number of pups sired. An Affymetrix array was used to initially test for gene expression differences between tolerant and intolerant males; follow-up gene expression was assessed using real-time RT-PCR. Differences in gene expression were tested for effect of treatment (tolerant versus intolerant; control versus AFB1 treatment) using the GLM procedures of SAS. Messenger RNA for *Renin* was found to be upregulated ($P = 0.05$) in tolerant mice (n = 3) compared with intolerant mice (n = 3) by both microarray and real-time RT-PCR analyses. Further experiments using real time RT-PCR to analyze testicular RNA showed that *Renin* expression increased ($P = 0.02$) 10-fold in AFB1-treated mice (n = 8) compared with control (placebo) treated mice (n = 8). Spermatogonia treated with 0, 5, 10 or 20 µg/ mL AFB1 (n = 6 per treatment) resulted in a 10-fold upregulation of *Renin* mRNA at the 20 µg/ mL level, while Leydig tumor cells treated similarly showed no difference ($P > 0.05$) in mRNA for *Renin* in treated versus control cell cultures. These results demonstrate a genetic response to AFB1 in the testes and spermatogonia through upregulation of *Renin* and may lead to a better understanding of the mechanisms by which AFB1 disrupts fertility in male mice as well as livestock species.

Key Words: aflatoxin, *Renin*, spermatogonia

T287 Testicular development of breeder males reared on an accelerated growth schedule. W. D. Berry*, S. H. Oates, L. M. Stevenson, and J. B. Hess, *Auburn University Department of Poultry Science*, *Auburn, AL*.

Broiler breeders are reared using feed restriction to control body weight and delay sexual maturation. Earlier maturation of breeder males has not been explored with respect to effects on reproductive development. The objective of this study was to determine how rearing on a relatively accelerated growth schedule affects broiler breeder testicular development. In this study, male breeder chicks reared using a conventional feeding/growth schedule (CON) were compared with males reared on a growth schedule accelerated by 6 weeks (ACCEL). The ACCEL males were grown on a linear growth line designed to reach the CON 22-week body weight at 16 weeks. Male broiler breeder chicks in both treatments were started on a standard starter diet and full fed for 3 weeks. ACCEL male chicks were started 5 weeks after CON. The birds were placed in 3 replicates containing 14 chicks per rep at 4 weeks of age. Both treatments were then fed 15% protein grower diet for the remainder of the rearing period. The birds received 8 h light/day during rearing. The birds were transferred to breeder housing at 22 weeks of age (CON) or 17 weeks of age (ACCEL). Light was increased to 12 h/day to stimulate sexual maturation. Birds in both treatments were then fed to maintain the same body weight until termination of the experiment. Body and testes weights were recorded throughout the experiment. Testes samples were formalin fixed, sectioned, and stained for morphology. Testes areas and cell numbers were obtained from photomicrographs using Image J software. Body weights did not differ at photostimulation. Body weight uniformity was the same for the 2 treatments at photostimulation. However, ACCEL birds tended to be less uniform. Testes weight at initial sexual maturity was higher for ACCEL vs. CON (7.87 ± 0.67 vs. 7.16 ± 0.62). Sertoli cell and interstitial cell numbers as a percent of total cell numbers were not different between the treatments. It was concluded that accelerating sexual maturity by 6 weeks does not adversely affect testicular development of breeder males.

Key Words: breeder, testes, seminiferous

T288 Hypoxic conditions during the CAM development (E5-E12) effect on embryo development. S. Druyan*, *Institute of Animal Science, ARO The Volcani Center*, *PO Box 6, Bet Dagan, Israel*.

Hypoxia is a common situation that vertebrate face during fetal life. It plays an essential role in embryo development, inducing vasculogenesis, angiogenesis, hematopoiesis and chondrogenesis. Hypoxic conditions at different time points during embryonic development were found to affect both anatomical and physiological morphogenesis. The literature is unclear about the actual effect of hypoxic conditions on embryo development. Different levels of hypoxia were found to have conflicting effects on development, depending on time point and duration of exposure. It is still unknown whether chronic, alternating or acute hypoxia will induce some degrees of adaptation to hypoxia as a long lasting effect. Fine-tuning (critical period, level and duration) is required. This study was aimed to elucidate the effect of daily exposure to 17% O_2 for 6 or 12 hours during the chorioallantoic membrane (CAM) development on embryogenesis, angiogenesis and hematopoiesis. Data including hatch time, heart rate, oxygen consumption, embryo weight, hematocrit level and hemoglobin concentration were collected from E13 to hatch. Angiogenesis response was measured in the CAM from E6 to E13 by analyzing the blood vessels coverage area. The hypoxic exposure had a mild insignificant effect on embryo weight and relative yolk weight. However, hypoxic exposure was found to affect vascular area that was significantly higher in the 12h embryos compare to control (e.g. 24.7 mm^2 vs. 23.3 mm^2, measured on E12, $P \leq 0.01$). Oxygen consumption was similar for all 3 treatments although it was slightly lower in the 12h embryos. Heart rate was found to be relatively constant while hematocrit and hemoglobin concentration were affected by hypoxia on

several key developmental days (e.g. 41.6%, 41.9% vs. 38.6% for 6h, 12h and control embryos measured on E16, $P \leq 0.01$). These observations indicate that hypoxic exposure during the CAM development may improved its vascular system. Further exploration of this phenomenon may lead to an alternative management scheme to improve the quality of the neonatal chick, which is associated with superior performance during post hatch.

Key Words: hypoxia, embryogenesis, CAM

T289 Rumen fluid inhibits proliferation and stimulates expression of cyclin-dependent kinase inhibitors 1A and 2A in bovine rumen epithelial cells. A. Wang* and H. Jiang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

It has been known for decades that microbial fermentation within the rumen is critical to rumen development and maturation in young ruminants, but the underlying mechanism is largely unknown. In this study, we determined the effect of rumen fluid, which should contain all products from rumen fermentation, on growth of rumen epithelial cells in vitro. Rumen epithelial cells were isolated from newborn Holstein calves using the serial tryptic digestion procedure and were cultured in minimum essential medium supplemented with 10% fetal bovine medium. After 3 d of initial culturing, the cells were treated with 1% or 10% (v/v) rumen fluid from lactating Holstein cows or phosphate buffered saline (PBS). Addition of 10% rumen fluid to the culture medium for 72 h decreased the cell number by 36% ($P < 0.05$, n = 4), while that of 1% rumen fluid had no effect compared with addition of PBS. As revealed by DNA fragmentation analyses, 10% rumen fluid did not induce apoptosis in the cultured rumen epithelial cells (n = 4). Flow cytometric assays showed that 10% rumen fluid inhibited the transition of rumen epithelial cells from the G1 phase to the S phase during the cell cycle ($P < 0.05$, n = 3). Real-time RT-PCR analyses of mRNA for key cell cycle regulators indicated that 10% rumen fluid did not change the expression of cyclin D1, D2, D3, E1, or E2 mRNA or that of cyclin-dependent kinase inhibitor 1B or 2B mRNA ($P > 0.1$, n = 3), but caused nearly 3-fold increase in the expression of cyclin-dependent kinase inhibitors 1A and 2A mRNA in rumen epithelial cells ($P < 0.05$, n = 3). These mRNA data support the possibility that rumen fluid inhibits proliferation of rumen epithelial cells in vitro by increasing the expression of cyclin-dependent kinase inhibitors 1A and 2A. The result that rumen fluid inhibits proliferation of rumen epithelial cells in vitro suggests that the stimulatory effect of rumen fermentation on rumen development in vivo is mediated by indirect mechanisms.

Key Words: cattle, rumen fluid, rumen epithelial cells

T290 Short-term postpartum supplementation on hepatic gene expression in primiparous spring-calved beef cows on grazing conditions. I. Whole rice middlings. A. L. Astessiano*, C. López-Mazz, A. C. Espasandín, P. Soca, R. Pérez-Clariget, and M. Carriquiry, *School of Agronomy, UdelaR*, *Uruguay*.

The aim of this work was to evaluate the effects of short-term supplementation of beef cows on blood glucose and insulin concentrations and hepatic gene expression. The experiment was carried at the Experimental Station Bernardo Rosengurtt (Cerro Largo, 32°35′S, 54°15′W). Primiparous suckled crossbred cows (Hereford/Angus), blocked by calving date and body condition score (BCS) at calving, were at 64 ± 14 d postpartum, randomly assigned to 2 treatments: control (grazing of native pastures, 20 kg DM/animal/d; 8.5% CP, 63%NDF; n = 8; CON) and supplementation (2 kg DM/animal/d of whole rice middlings, 10%CP, 14%NDF, 9%EE; n = 8; SUP) for a 21 d. Glucose and insulin concentrations were measured at −2, 7, and 22 d of initiation of the nutritional treatment. Liver biopsies were collected at the end of the nutrition treatment (d 21). The amount of mRNA for growth hormone receptor (GHR), insulin-like growth factor-I (IGFI), IGF binding proteins-2 (BP2),-3 (BP3), insulin receptor (IR) and hypoxanthine-phosphoribosyltransferase (HPRT, endogenous control) were measured by SYBR Green real time RT-PCR. Means from mixed analyses were considered to differ when $P < 0.05$. Cow body weight and BCS did not differ between treatments. Insulin and glucose concentrations were not affected by nutritional treatment, but there was a trend ($P = 0.08$) for interaction between treatment and sampling day in glucose concentrations as glucose tended to increase from d 7 to 22 only in SUP cows. Expression of HPRT was similar between treatments. There were no differences in hepatic GHR, IGFI, and BP3 mRNA due to nutritional treatment. However, BP2 mRNA and BP2/BP3 mRNA ratio tended ($P < 0.10$) to be less in SUP than CON cows. The GHR mRNA was positively correlated with IGFI (r = 0.62, $P = 0.01$) and BP3 (r = 0.51; $P = 0.05$). Results could indicate that short-term postpartum supplementation with rice middlings could improve metabolic status of spring-calved cows at the initiation of the breeding period.

Key Words: liver, mRNA, somatotropic axis

T291 Short-term postpartum supplementation on hepatic gene expression in primiparous spring-calved beef cows on grazing conditions. 2. *Lotus subbliflorus* cv. Rincon. A. L. Astessiano*[1], R. Perez-Clariget[1], G. Quintans[2], P. Soca[1], and M. Carriquiry[1], [1]*School of Agronomy, UdelaR*, *Uruguay*, [2]*Instituto Nacional de Investigación Agropecuaria*, *Treinta y Tres, Uruguay*.

Primiparous suckled crossbred cows (Hereford/Angus) were used in a randomized block design to evaluate the effect of short-term supplementation on blood glucose and insulin concentrations and hepatic gene expression. The experiment was carried in INIA Treinta y Tres (Uruguay, 33°15′S, 54°28′W). Cows, blocked by calving date and body condition score (BCS) at calving, were at 48 ± 10 d postpartum, randomly assigned to 2 treatments: control (grazing of native pastures, 57 kg DM/ha/d, 12.8%CP, 55.9%NDF; n = 30; CON) and supplementation (123.8 kg DM/ha/d of grazing native pastures improved with *Lotus subbiflorous* cv. Rincon, 13.2%CP, 52.9%NDF; n = 30; SUP) for 23 d. Glucose and insulin concentrations were measured at −2, 12, and 26 d of initiation of the supplementation. Liver biopsies were collected at the end of the nutrition treatment (d 23). The amount of mRNA of growth hormone receptor (GHR), insulin-like growth factor I (IGFI), IGF binding proteins-2 (BP2),-3 (BP3), insulin receptor (IR) and hypoxanthine phosphoribosyltransferase (HPRT, endogenous control) were measured by SYBR Green real time RT-PCR. Means from mixed analyses were considered to differ when $P < 0.05$. Cow body weight (BW) and BCS were increased ($P < 0.05$) in SUP cows after 7 or 21 d of initiated the nutritional treatment, respectively. Calf BW increased at d 21 for SUP cows. Glucose concentrations along the period evaluated did not differ between treatments but insulin concentrations were greater ($P < 0.01$) in CON cows. Expression of HPRT mRNA was similar between treatments. Although GHR, IGFI, and BP2 mRNA were not affected by nutritional treatment, abundance of BP3 mRNA was greater ($P = 0.04$) and IR mRNA tended ($P = 0.07$) to be greater for CON than SUP cows. Short-term supplementation with improved pastures of suckled cows during the early postpartum did not improve hepatic expression of somatotropic axis genes.

Key Words: liver, mRNA, somatotropic axis

T292 Effects of glucose on suckling aggressiveness in newborn Holstein and Brown Swiss calves. M. D. DenBeste* and H. D. Tyler, *Iowa State University*, *Ames*.

To determine potential associations between suckling aggressiveness and glucose concentrations in newborn Brown Swiss (B) and Holstein (H)

calves, glucose concentrations were altered via intramuscular injection of insulin (1 mL) or an oral dose of glucose (25 mg) to 19 calves within 5.35 ± 2.72 min after umbilical cord rupture. Calves born from 19 H cows and heifers (9 carrying B embryos) were assigned to treatment randomly by alternating treatments based on birth order within breed. Initial blood samples were collected from calves within 3.25 ± 1.52 min and glucose and insulin treatments were administered within 5.35 ± 2.72 min after umbilical cord rupture. A second blood sample was obtained 57.85 ± 3.17 min after treatments were administered. Samples were analyzed to determine glucose, non-esterified fatty acids (NEFA), leptin, ghrelin, and glutamate (GLU) concentrations. Glucose, NEFA, leptin, ghrelin, and GLU were analyzed using the General Linear Model procedures of SAS. Calves were fed 2 quarts of colostrum replacer and suckling aggressiveness scores were given 1 – weakly, 2 – moderately, and 3 – aggressively. The FREQ procedure (CHISQ option) was used to determine the frequency of suckling aggressiveness scores within each breed. B calves suckled weakly ($P < 0.05$) when compared with H calves. NEFA, leptin, and ghrelin concentrations did not differ significantly ($P > 0.05$) between breeds, treatments, or suckling aggressiveness scores either at birth or post-treatment. Glucose concentrations only differed significantly ($P < 0.05$) between treatments post-treatment. Prior to treatment, B calves had lower concentrations of GLU ($P < 0.05$) than H calves and calves that subsequently suckled weakly had higher concentrations of GLU ($P < 0.10$) than calves that subsequently suckled more aggressively. Breed differences were still apparent in post-treatment samples. In conclusion, B calves suckled weakly when compared with H calves and altering glucose concentrations at birth had no effect on suckling aggressiveness. However, calves that suckled weakly had higher concentrations of GLU than calves that suckled aggressively.

Key Words: glucose, suckling aggressiveness, newborn calves

T293 Butyrate stimulates the cAMP/protein kinase A signaling pathway. A. Wang*, H. Si, D. Liu, and H. Jiang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Butyrate is one of the major short chain fatty acids formed by microbial fermentation in the gastrointestinal tract. Butyrate is known as not only an important source of energy for ruminants, but also a signaling molecule, as it stimulates rumen development and inhibits growth of various types of cells in vitro. However, the signaling pathway induced by butyrate in cells is unknown. Here, we report that butyrate can activate the cAMP/protein kinase A (PKA) signaling pathway in the human epithelial colorectal adenocarcinoma cell line Caco-2 cells. The Caco-2 cells were cultured in minimum essential medium supplemented with 20% fetal bovine serum and were treated with 0.01, 0.1, 1, or 10 m*M* of butyrate or phosphate buffered saline (PBS) as a control for 30 min (for cAMP, ATP, protein phosphorylation, and PKA, phosphodiesterase, and adenylate cyclase activity assays) or 16 h (for luciferase assay). All experiments were repeated 3 or 4 times. Compared with PBS, 0.1 m*M* or higher concentrations of butyrate increased intracellular cAMP accumulation ($P < 0.05$, n = 4) and PKA activity ($P < 0.01$, n = 3). The same concentrations of butyrate also induced phosphorylation of the cAMP response element (CRE)-binding protein (CREB) ($P < 0.05$, n = 3) without changing its expression, and increased CRE-driven luciferase reporter gene expression ($P < 0.01$, n = 4). Moreover, butyrate at 0.1 m*M* or higher concentrations increased intracellular ATP levels ($P < 0.05$, n = 4), whereas it had no effect on the activity of phosphodiesterase or that of adenylate cyclase. Taken together, these data indicate that butyrate stimulates the cAMP/PKA signaling pathway in Caco-2 cells and that this stimulation may be due to increased ATP accumulation. This result suggests the possibility that butyrate affects rumen development or cell growth through the cAMP/PKA signaling pathway.

Key Words: butyrate, cAMP, protein kinase A

T294 The effect of forage availability on the somatotropic axis in free-ranging alaskan moose (*Alces alces*). A. A. Parillo*[1], J. P. Richmond[1], K. S. White[2], J. Crouse[3], B. W. Dale[4], and S. A. Zinn[1], [1]*University of Connecticut*, *Storrs*, [2]*Alaska Department of Fish and Game*, *Juneau*, [3]*Alaska Department of Fish and Game*, *Soldotna*, [4]*Alaska Department of Fish and Game*, *Palmer*.

To determine if components of the somatotropic axis reflect the availability of forage or nutritional status in adult moose (*Alces alces*), 3 distinct Alaskan populations of free-ranging moose [Gustavus (n = 42), Skwentna (n = 24), and Nelchina (n = 11)] were used. Forage availability, low (Gustavus), medium (med; Nelchina) or high (Skwentna) varied with population. Moose from each population were captured once in fall (October–November; high forage availability) and once the following winter (March; low forage availability). At capture, blood samples were collected via venipuncture to determine if forage availability influenced the somatotropic axis, and rump fat was measured to assess body condition. Concentrations of GH and IGF-1 were quantified by RIA using bovine and human antisera, respectively. Western ligand blots were used to quantify IGFBP-2 and −3. Rump fat was greater in fall than winter (2.4 ± 0.26 vs. 1.1 ± 0.24 cm; $P \leq 0.01$), but was similar across the 3 populations [1.68 ± 0.16 (low), 1.57 ± 0.27 (med) and 2.1 ± 0.18 (high) cm; $P \geq 0.17$]. Concentrations of GH averaged 3.4 ± 1.2 ng/mL and were not different between populations ($P \geq 0.15$) or season ($P \geq 0.12$). Average IGF-1 concentrations were greater ($P \leq 0.03$) in high than low (135.4 ± 17.6 vs 89.8 ± 17.1 ng/mL) forage availability and greater ($P \leq 0.01$) in fall [117 ± 20.01 (low), 138 ± 25.1 (med), and 220 ± 16.4 (high) ng/mL] than in winter [62.5 ± 14.2 (low), 42.2 ± 30.6 (med), and 50.6 ± 18.7 (high) ng/mL]. Conversely, IGFBP-3 was greater ($P \leq 0.01$) in low compared with high (72.1 ± 6.0 vs 43.4 ± 7.4 AU) forage availability, and greater ($P \leq 0.01$) in fall compared with winter (69.2 ± 4.4 vs 34.4 ± 4.6 AU). Similarly, IGFBP-2 was greater ($P \leq 0.01$) in low than high (47.1 ± 3.1 vs 24.4 ± 4.0 AU) forage availability, and was greater ($P \leq 0.01$) in winter than fall (36.9 ± 2.5 vs 32.0 ± 2.9 AU). Serum IGF-1 concentrations increased, whereas IGFBP-2 and IGFBP-3 decreased with greater forage availability. These components of the somatotropic axis may be useful indicators of nutritional status in free-ranging populations of Alaskan moose.

Key Words: somatotropic axis, moose (*Alces alces*), forage availability

T295 Effects of dietary probiotic supplementation and posthatching holding time on intestinal pH and microflora of male broilers. H. Unsal[1], A. G. Onol[1], M. Daskiran[2], O. Cengiz*[1], O. Tatli[1], and O. Sevim[1], [1]*Adnan Menderes University*, *Aydin, Turkey*, [2]*Johnson & Johnson Corporate Science and Technology*, *New Brunswick, NJ*.

A study was conducted to determine the effects of a dietary probiotic, a commonly used feed additive, and posthatching holding time (0, 12, 24, and 36 h post-hatching) on the intestinal pH and microflora of male broiler chicks. A 2 × 4 factorial design was implemented. Eight experimental groups were formed by two levels of dietary probiotic supplementation (Control and Protexin, 0.5 kg/ton) and four levels of posthatching holding time. Four posthatching holding times were 0 (chicks were given feed and water immediately after their arrival), 12, 24, and 36 hours. There were 4 replications for each treatment group and each replication consisted of 20 day-old birds. Chicks were received

from a commercial hatchery and transferred to the Experimental station within 2 hours after feather-sexing procedure. A corn-soybean meal based diet was used in the study. Water and feed were available for ad libitum consumption throughout the study and the experiment lasted 42 days. A significant decrease in day-10 intestinal pH ($P < 0.05$) was noted in groups with dietary probiotic supplementation (6.59 vs. 6.42). Dietary probiotic supplementation also numerically increased the number of colony forming units of lactobacilli at days 10 (7.35 vs. 7.60 cfu) and 21 (6.74 vs. 7.05 cfu) of the study. The number of colony forming units (cfu) of lactobacilli in groups with no feed and water restriction were either numerically or significantly (12 and 36 hour feed and water restriction treatments) higher (7.96 vs. 7.13, 7.28 cfu) than that of the groups with posthatching holding time prior to feeding ($P < 0.01$). Total bacteria count was similar among treatment groups during the experiment. In brief, this study indicated that early exposure to lactobacilli, which is found in either a dietary probiotic supplement or in feed naturally helps broiler chicks to develop a healthier gastrointestinal tract environment and microflora and this microflora may, in turn, inhibit pathogenic microorganisms in broiler gastrointestinal tract.

Key Words: broiler, post-hatching holding time, probiotic

T296 Maintenance energy requirements of gestating beef cows, rumen temperature, and plasma concentration of thyroxine and triiodothyronine. T. A. Pye*, B. H. Boehmer, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station*, *Stillwater*.

Spring calving, Angus cows, (n = 32) were used to determine the effects of maintenance energy requirement (MR) on rumen temperature (RuT), and concentrations of thyroxine (T4) and triiodothyronine (T3) in plasma. Cows (4 to 7 yr of age) with an initial BCS of 4.4 ± 0.1 and BW of 556 ± 5.9 kg were individually fed a complete ration for 17 wk during 4–8 mo of gestation. After 2 wk on a diet calculated to supply MR (Model 1, NRC 1996) the diet was adjusted weekly until constant BW was achieved (regression analyses). BW was maintained for 31 d for 25 cows and the amount of feed consumed was actual MR. Blood samples were collected before and after consumption of feed on 2 d when cows consumed MR. Rumen temperature was recorded hourly, using rumen boluses (Smart Stock, LLC), for 4 consecutive days when cows consumed the MR diet and when cows consumed ad libitum roughage. Cows were classified based on MR as low (>0.5 SD less than mean, LMR), mod (±0.5 SD of the mean, MMR) and high (>0.5 SD greater than mean, HMR). Average MR was 84.04 (SD = 7.13) $Kcal \bullet kg^{-0.75} \bullet day^{-1}$. The difference in MR between the least efficient and the most efficient cow was 32%. Rumen temperature during maintenance and during ad libitum roughage was not influenced by MR. When cows were exposed to warmer temperatures (15°C) plasma T4 was not influenced by MR ($P = 0.92$). When exposed to cooler temperatures (−5°C), LMR cows had greater plasma T4 ($P = 0.003$) compared with HMR. Plasma T3 was not influenced by MR when cows were exposed cooler ambient temperatures ($P = 0.64$). When exposed to warmer temperatures, compared with LMR, HMR cows had greater plasma T3 ($P = 0.007$). During late gestation MR were associated with plasma concentrations of T3 and T4, but RuT was not influenced by MR. Thyroid hormone may be involved in the regulation of MR of beef cows during late gestation. Identification of cows with lower MR and greater efficiency could improve the profitability of beef production.

Key Words: beef cows, maintenance, thyroxine

T297 Effects of cobalt supplementation and vitamin B_{12} injections on energy metabolism of dairy cows. M. S. Akins*[1], S. J. Bertics[1], M. T. Socha[2], and R. D. Shaver[1], [1]*University of Wisconsin*, *Madison*, [2]*Zinpro Corporation*, *Eden Prairie, MN*.

The objective of this study was to determine metabolic responses of primi- and multiparous dairy cows fed different levels and sources (inorganic and organic) of cobalt or given weekly vitamin B_{12} injections. Forty-five primi- and multiparous cows 60 d prepartum were blocked by parity (1 or > 1) and expected calving date, and then randomly assigned to 1 of 5 treatments in a randomized complete block design. The treatments were: no supplemental Co (Control), 25 mg Co from Co carbonate (CoCarb), 25 mg (LcoGH) or 75 mg (HCoGH) Co from Co glucoheptonate, and Control with weekly 10 mg vitamin B_{12} injections. Cows were on trial until 150 DIM. Cobalt (ppm DM) in the lactating diet was 1.0, 1.9, 2.3, and 5.2 for Control and IB12, CoCarb, LCoGH, and HCoGH, respectively. Far-off, close-up, and lactating diets were 13.8, 15.1, and 18.0% CP and 48.8, 40.2, and 32.9% NDF (DM basis), respectively. Intake was not affected ($P > 0.10$) by treatment and was 19.4 ± 0.5 and 23.1 ± 0.8 kg DM/d for primi- and multiparous cows, respectively. Body weight and condition score and calculated energy balance were not affected by treatment ($P > 0.10$). Plasma glucose, non-esterified fatty acids, and β-hydroxybutyrate were not affected by treatment ($P > 0.10$). Effect of sampling day was significant ($P < 0.001$). Glucose decreased from 60 d prepartum (65 ± 1.1 mg/dL) to 30 DIM (55 ± 1.0 mg/dL), and increased at 90 DIM (60 ± 1.0 mg/dL); however, primiparous cows had a larger decrease at 30 DIM and smaller increase thereafter. Non-esterified fatty acids increased from 60 d prepartum (249 ± 39.8 mmol/L) to 1 DIM (724 ± 40.7 mmol/L), then decreased at 30 DIM (398 ± 40.1 mmol/L), with multiparous cows having a larger increase at 1 DIM. Beta-hydroxybutyrate increased from 60 d prepartum (4.2 ± 0.95 mg/dL) to 30 DIM (15.9 ± 0.95 mg/dL). Addition of Co above requirements or vitamin B_{12} supplementation did not improve energy metabolism of dairy cows.

Key Words: cobalt, vitamin B_{12}, dairy cow

T298 The relationship of tissue copper concentrations and genes involved in copper homeostasis in the cow, pig, and goat. H. So, E. Domby*, T. Engle, and H. Han, *Colorado State University*, *Fort Collins*.

Copper (Cu) serves as a cofactor for enzymes involved in a variety of biological functions. Copper transport/distribution within the cell is mediated by the expression of the copper transporter (CTR1), ATPase7A (ATP7A), ATPase7B (ATP7B) which helps Cu trafficking. Copper is also required for activity of lysyl oxidase like 1 (LOXL1) for the production of elastin and collagen in arterial tissue. Liver and pulmonary artery tissues tissue from 5 Angus crossbred steers, 6 Nubian goats, and 6 American Landrace pigs were collected. Liver and pulmonary artery samples were collected at the time of harvest and snap frozen. Liver and pulmonary artery Cu concentrations were determined via flame atomic absorption and gene expression was measured by real time PCR. Data were analyzed using PROC CORR of SAS. Liver Cu concentrations (ppm ± SE) were higher in cows (396.4 ± 109.1) and goats (181.4 ± 37.0) than in pigs (19.2 ± 3.5). All liver Cu concentrations were within normal ranges and considered adequate for each species. Liver Cu concentration was more variable in cows and goats compared with pig liver Cu concentrations. Real Time PCR revealed that goat liver *ATP7A* was positively correlated ($r^2 = 0.920$; $P < 0.003$) to liver Cu concentrations while cow and pig *ATP7A* was not correlated to liver Cu concentration. In the pig, liver *ATP7A* expression was positively correlated to *ATP7B* ($r^2 = 0.662$; $P < 0.049$). Pulmonary artery Cu concentration was highest in cows (14.9 ± 4.7), intermediate in pigs (8.9 ± 3.3), and lowest in goats (3.9 ± 1.1). Goat pulmonary artery Cu concentration was not correlated

to *CTR1* expression, however, *ATP7A* expression was positively correlated with *CTR1* ($r^2 = 0.897$; $P < 0.004$). In cow pulmonary artery, *LOXL1* expression was positively correlated to elastin expression ($r^2 = 0.912$; $P < 0.012$). Pulmonary artery Cu concentration was not correlated to gene expression of Cu homeostatic genes in the pig. This data indicates that genes involved in Cu homeostasis (*CTR1*, *ATP7A*, *ATP7B*, *LOXL1* and *elastin*) are differently regulated in different species. This may contribute to different responses to elevated pulmonary arterial pressure in different species.

Key Words: copper, liver, pulmonary artery

T299 Modification and validation of a bovine TNFα enzyme-linked immunosorbent assay with improved sensitivity. J. K. Farney*, L. K. Mamedova, and B. J. Bradford, *Kansas State University*, *Manhattan*.

Tumor necrosis factor α (TNFα) is an inflammatory cytokine that is involved in immune function and is proposed to play a role in metabolic disorders. Until recently, no bovine-specific antibodies were available for detection of TNFα. While some bovine-specific methods have been published recently, assays used for determining plasma TNFα concentration in bovine disease models often do not offer acceptable precision for measurement of basal concentrations in healthy animals. The objective of this work was to develop an effective, low-cost enzyme-linked immunosorbent assay (ELISA) procedure with improved sensitivity. A protocol developed for use with cell culture supernatant was modified for use with bovine plasma by optimizing antibody concentrations, incubation times and temperatures, and standard diluents. The coating antibody concentration was decreased from 10 μg/mL to 6.8 μg/mL, while the detection antibody concentration remained 2.5 μg/mL. Sample incubation was increased from 1 h at room temperature to an overnight incubation at 4°C, which increased the sensitivity of the assay. Multiple matrices were tested for dilution of standards and were assessed by determining recovery of bovine TNFα spiked into bovine serum and plasma. Standard curve matrices were fetal bovine serum (FBS), dialyzed FBS, lyophilized human serum (rehydrated), and phosphate-buffered saline (PBS) with 4% bovine serum albumin. Recoveries were < 50% when quantified with standards diluted in PBS, FBS, or dialyzed FBS. However, recoveries were acceptable in both bovine serum and plasma (85–120%) when quantified with standards diluted in lyophilized human serum. The modified bovine TNFα ELISA offers a detection range of 2 to 500 pg/mL. This detection limit is at least an order of magnitude lower than previously reported, and will allow for greater precision in determining basal TNFα concentrations in bovine plasma. The improved sensitivity of this ELISA will be critical to assessing current hypotheses concerning the metabolic effects of moderately elevated TNFα concentrations.

Key Words: Tumor necrosis factor alpha, bovine, ELISA

T300 Plasma cortisol, corticosteroid-binding globulin and free cortisol index in pre-and post-weaned pigs supplemented with omega-3 polyunsaturated fatty acid. H. G. Kattesh*, C. J. Kojima, M. P. Roberts, and G. M. Pighetti, *University of Tennessee*, *Knoxville*.

A dietary supplement of omega-3 polyunsaturated fatty acid (PUFA) has been shown to decrease corticosteroid-binding globulin (CBG) response to an LPS challenge in the post-weaned pig, suggesting a reduction in immune system activation and less of a need for the biologically active free form of cortisol. The aim of this study was to examine the effects of PUFA supplementation to lactating sows and their offspring on growth and indicators of stress in the pre- and post-weaned pig. Upon farrowing (d 0), sows received either a standard lactation diet (SC; n = 4) or SC supplemented (1.0% by weight) with a commercial PUFA source (SP) throughout lactation. At 11–14 d of age, pigs within sow-diet treatment group were creep-fed a diet similarly supplemented with or without PUFA. Pigs (n = 6/litter) were weaned at 21–24 d of age into 8 pens in a replicated 2 × 2 factorial design and fed a nursery diet with (PP; 12 SC and 12 SP) or without (PC) PUFA. Pigs were weighed (BW) and bled on d 14, 21 (before weaning), 22 and 28, for determination of plasma cortisol (CORT) and CBG concentrations, free cortisol index (FCI), and neutrophil: lymphocyte ratio (N:L). Pre- and post-weaning BW was not different ($P > 0.10$) among pigs regardless of treatment. On d 21, SP pigs exhibited a lower ($P < 0.01$) CORT (54.8 ± 7.2 vs. 90.0 ± 9.0 nmol/L) and higher ($P < 0.05$) CBG (9.1 ± 0.7 vs. 7.0 ± 0.5 mg/L) compared with SC pigs. The resultant FCI (nmol cortisol/mg CBG) was lower ($P < 0.001$) for the SP pigs. On d 22, CORT, CBG and N:L increased ($P < 0.001$) but returned to pre-weaning levels by d 28. No significant differences were found among the post-weaned treatment groups for any of the stress indicators measured. The results suggest that PUFA supplementation can reduce the amount of circulating free cortisol in the pig before weaning; however, this benefit is negated due to the stress of weaning.

Key Words: pig, PUFA, stress

T301 Characterization of omega-3 PUFA enrichment in laying hens. S. Nain* and R. A. Renema, *University of Alberta*, *Edmonton, AB, Canada*.

This study explored the effects of feeding linolenic acid and the time required to reach a plateau of omega-3 polyunsaturated fatty acid (ω-3 PUFA) concentration in blood plasma and egg yolk in laying hens fed Linpro, an extruded flax product. Additionally, the efficiency of long chain ω-3 fatty acid enzymatic conversion was also investigated. A group of 75, 65 week old Lohman White Leghorn layers divided into 3 groups (25/group) and subjected to either of one diet, Control diet, or low (Moderate) or high omega-3 diet (High) for 18 d. Diets had similar ME and CP concentrations, and contained 0, 7.5% or 15% Linpro, respectively. Baseline values were established for the BW, fatty acid composition in egg yolk and blood plasma before dietary treatment. Data was analyzed with Proc Mixed of SAS and broken stick analysis to determine ω-3 PUFA plateau using the NLIN procedure of SAS. Significance was assessed at the $P < 0.05$ level. The BW of the hens fed Moderate and High diets was reduced compared with Control birds during the study ($P = 0.003$). Dietary treatments did not affect egg production, egg weight, feed intake, or feed conversion. Total ω-3 PUFA in egg yolk achieved plateau of stationary phase at 343.7 mg/egg and 272.0 mg/egg in 6.6 and 5.9 d with High and Moderate diets respectively. In plasma the ω-3 PUFA concentration reached saturation in 7.2 d with 0.93 mg/ml and 0.67 mg/ ml with High and Moderate diets, respectively. Dietary LNA increased yolk LNA and led to increased long-chain ω-3 PUFA while reducing ω-6 PUFA in yolk and blood plasma. Moreover, Moderate and High diets resulted in 64% and 70% increases in yolk DHA, respectively, while in plasma the increase in DHA was only 13% and 8% in these groups, respectively. The calculated desaturase and elongase enzymatic activities for ω-6 PUFA (C20:4/C18:2) were negatively correlated with LNA ($r = -0.59$). Broken stick analysis indicated that High birds reached the target threshold of 300 mg of total ω-3 PUFA/egg in 5d. Individual hen effects on ω-3 PUFA absorption in this project suggest further work to optimizing egg enrichment through dietary strategies would be beneficial for the field of egg enrichment.

Key Words: LinPRO, egg yolk, plasma

T302 Effects of increased milking frequency on productivity of Holstein dairy cows. M. Dehghan-Banadaky*, M. Eslamizad, K. Rezayazdi, M. Moradi-Shahrbabak, and H. Bahrami, *Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran*, *Karaj, Tehran, Iran*.

An experiment was conducted to determine the effects of different milking frequencies on the performance of Holstein cows. 105 multiparous and 15 primiparous Holsteins cows were assigned based on parity at calving to 1 of 3 treatments as follows: 1) milking 6 times per day in whole period (6x) ; 2) milking 6 times per day for 90 d and switching to 3 times subsequently (6x-3x); and 3) 3 times milking per day in whole period (3x). Milk production recorded every day for the first 60 DIM and on 2 consecutive days a week afterward. Cows were weighed after parturition and then weighed and scored for their body condition monthly; milk samples were taken monthly. Data until 150 DIM were statistically analyzed using the repeated measures option in Proc Mixed of SAS with cow as a random effect. Overall milk and fat corrected milk (FCM 3.5%) yield were higher on 6x and 6x-3x cows than 3x cows (41.03, 42.3; 40.11, 40.60 VS 37.97, 38.40 kg/d, respectively). Milk component concentration was not affected by treatment except solids non fat (SNF) that increased in 6x and 6x-3x group ($P < 0.05$). DMI was not different between treatment groups (23.04 and 23.12 vs. 22.45 kg/d for 6x, 6x-3x, and 3x cows respectively). 3x cows began to gain weight sooner than did 6x and 6x-3x cows but there were no significant differences between treatments for body weight change at the end of 150 DIM. These results indicate that increasing milking frequency to 6x, increased milk yield during early lactation, but did not have carryover effect after switching to 3x in 90 DIM. Relative to production and economical aspects, 6x until 90 DIM and then switching to 3x subsequently was preferred to other treatments.

Key Words: milking frequency, milk production, Holstein cows

T303 Effects of increasing milking frequency on blood metabolites of Holstein cows. M. Eslamizad, K. Rezayazdi, M. Dehghan-Banadaky*, H. Kohram, and R. Heydari, *Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran*, *Karaj, Tehran, Iran*.

One hundred five multiparous and 15 primiparous Holsteins cows were assigned based on parity into 3 treatment groups immediately after calving. Treatments were: 1) milking 6 times per day in whole period (6x) ; 2) milking 6 times per day for 90 d and switching to 3 times subsequently (6x-3x); and 3) 3 times milking per day in the entire period (3x). Blood samples were taken from each cow at 15, 30, 60, 90, 120, 150 DIM, 3 h after morning meal for metabolic profiling. Data until 150 DIM were statistically analyzed using the repeated measures option in Proc Mixed of SAS with cow as a random effect. Blood glucose concentration was higher but blood nonesterified fatty acids (NEFA) and β-hydroxybutyric acid (BHBA) concentration were lower in 3x than 6x and 6x-3x cows ($P < 0.05$). Most of the differences were observed 30 initial days of the experimental period, indicating more severe negative energy balance in 6x and 6x-3x than 3x cows in fresh period. Phosphorous, blood urea nitrogen (BUN), triglycerides (TG), total protein, aspartate aminotransferase (AST) concentration were unaffected by treatments (Table 1). Overall, results suggest that metabolic health may be suppressed by increasing milking frequency in fresh cows. In respect to metabolic health aspects, 3x was preferred to other treatments.

Table1. Metabolic profiles of cows had different milking frequency

	Treatments				
Metabolites	6x	6x-3x	3x	SEM	P-value
Glucose (mg/dL)	64.36 a	63.44 a	69.02 b	1.910	0.02

Key Words: milking frequency, Holstein cows, blood metabolites

T304 Effect of temperature-humidity index on test day milk yield of Iranian primiparous Holsteins. H. Farhangfar*[1], A. Arab[1], S. R. Miraee Ashtiani[2], A. Riasi[3], H. Rashid[4], and M. K. Akbari[4], [1]*Birjand University*, *Birjand, Iran*, [2]*Karaj University of Agriculture and Natural Resources*, *Karaj, Iran*, [3]*Esfahan Industrial University*, *Esfahan, Iran*, [4]*Agricultural Jihad Organisation*, *Mashhad, Iran*.

This research aimed to investigate the potential effect of temperature-humidity index (THI) on test day milk yield of Iranian Holsteins. The data were 95,510 moly test day milk records collected from 11,054 first parity Holstein cows calved from 1994 to 2008 in 76 herds of Mashhad, Iran. Milk records were augmented with climate information gathered by local climate stations. The climatic information was daily temperature (maximum, minimum and average) and relative humidity percentage over 2 decades data recording. THI was calculated based upon the formula which was pointed out by Aguilar et al. (J. Dairy Sci. 2009, 92:5702–5711). Response variable was monthly test day milk records for which there was an average 26.92 Kg (SD = 6.91 Kg) in the whole data set. A statistical linear model was used to evaluate the effects of some environmental factors. In the test day model, fixed effects of herd, year and month of milk recording, milking times, along with covariables of Holstein genes (linear), age at test day recording (linear and quadratic), days in milk (linear and quadratic) and THI (linear) were included. The model was fit with Mixed Procedure of SAS program. The results indicated that all environmental independent (categorical and continuous) variables included in the model had statistically significant ($P < 0.01$) influence on test day milk yield. The estimate of partial linear regression coefficient of test day milk yield on THI was found to be 7 gr THI-1 indicating that in average daily milk production increases as THI increases one unit until reaching the turning point in which it decreases due to heat stress. It can be therefore concluded that THI is needed to be taken into account in genetic evaluation of dairy cows as an animal model is applied to predict breeding value of the population under consideration.

Key Words: Iranian Holstein, temperature-humidity index, test day milk yield

T305 Application of mixed linear model to evaluate effects of temperature and relative humidity on lactation milk yield of Iranian primiparous Holsteins. H. Farhangfar*[1], H. Roshan[1], N. Emam Jomeh Kashan[2], and M. H. Fathi Nasri[1], [1]*Birjand University*, *Birjand, Iran*, [2]*Aboureyhan University*, *Tehran, Iran*.

The main aim of this research was to evaluate the effects of temperature and relative humidity on lactation milk yield of Iranian first parity Holstein cows. The data set comprised of 5,323 lactation milk records obtained from 5,323 primiparous Holsteins calved between 1994 and 2007 in 64 herds of Mashhad city, Iran. Total number of sires was 660. In the whole data set, averages of lactation milk yield and age at first calving were 7823 kg and 26.35 Months, respectively. Total lactation milk yield of individual cows was predicted based upon using Gompertz nonlinear function as applied by Fathi Nasri et al. (Journal of Agricultural Science 2008, 146:633–641). A mixed linear model was applied in which fixed effects of herd, year and month of calving, linear covariables of Holstein gene percentage, open days, days in milk, age at first calving (in month), temperature (in Centigrade) and relative humidity (%), and random effect of sire were included. Daily temperature and relative humidity information (obtained from local weather stations) were averaged over the course of the lactation for individual cows. The model was run using Mixed Procedure of SAS software. Results showed that herd, year and month of calving, Holstein gene percentage, age at first calving, days in milk and average temperature had significant ($P <$ 0.01) effects on lactation milk yield. Open days and relative humidity were found to be non-significant factors for lactation milk yield. For all the covariables with significant effect, positive partial regression coefficients were detected. The results indicated that total lactation milk yield increased by 36.65 kg as the average temperature increased by one centigrade. The findings of this research suggest that temperature information could be taken into account for analyzing milk records when a test day model is used.

Key Words: Iranian Holstein, temperature, Gompertz nonlinear function

T306 The association between days in milk, somatic cell counts, milk urea nitrogen, and percentage of milk fat and protein in dairy cows. S. R. Heidari Khormizi*, M. Dehghan Banadaki, and F. Farhang, *University of Tehran*, *Tehran, Karaj, Iran*.

Data concerning to days in milk, SCC, milk urea nitrogen, percentage of milk fat and protein from 5 commercial dairy herds in Iran were collected monthly from 2004 to 2007 to study relationship between them. Days in milk were grouped into 30-d increments with those greater than 420 d grouped into one category. Milk urea nitrogen was grouped by increments of 2 mg/dL with those less than or equal to 6 mg/dL grouped into one category, and equal to or greater than 26 mg/dL as a category. Univariate linear regression models were developed using Proc Mixed in SAS to test the relationship between days in milk (dependent variable) and other variables. The results of this study showed that DIM significantly affected SCC, milk urea nitrogen and percentage of milk fat and protein. In cows, SCC was at its minimum amount between 60 and 90 d after calving and reached maximum between 90 and 120 d of lactation. Significant differences in MUN were observed between herds ($P < 0.0001$), with a significant variability between test dates within herds. Significant effect of parity ($P < 0.0001$) and its interaction with DIM were also found. MUN increased at the beginning of the lactation, reached a maximum between 150 and 180 d postpartum, and then steadily decreased until the end of lactation. Percentage of milk fat and protein increased at >240 d postpartum. The results of this study suggest that days in milk is an important part in demonstrating milk composition changes.

Key Words: days in milk, somatic cell counts, milk urea nitrogen

T307 The association between milk urea nitrogen, milk yield, Somatic Cell Counts and parity in Holstein dairy herds. S. R. Heidari Khormizi*, M. Dehghan Banadaki, S. Hasanlou, and F. Fatehi, *University of Tehran*, *Karaj, Tehran, Iran*.

This study was conducted using data from Dairy Herd Improvement monthly tests to investigate the association between milk urea nitrogen concentration (MUN), milk yield, somatic cell counts, milk fat percentage, milk protein percentage, and order of lactation in 5 commercial dairy herds from Iran. Mean MUN for Holstein cows was 19.78 mg/dl. Mean MUN, categorized by 30-d increments of days in milk (DIM), paralleled changes in milk values and followed a curvilinear shape. Multivariate mixed linear regression (Proc Mixed in SAS) was used to determine the relationship between MUN (dependent variable) and independent variables: milk yield, somatic cell counts, milk fat percentage, milk protein percentage, and order of lactation. The results showed that the highest milk yield (32.65 ± 0.09 kg/d) was associated to higher milk urea nitrogen compare with cows with the lowest daily milk yield. The highest somatic cell counts (970.56×103 cell/ml) was associated to lower milk urea nitrogen compare with cows with the lowest milk urea nitrogen. As the milk protein percentage increased, MUN concentration decreased; Milk fat percentage also decreased so that the higher percentage of milk fat and protein (3.69 ± 0.01 and 3.31 ± 0.003 respectively) were found for cows with lower milk urea nitrogen. For cows, concentration of milk urea nitrogen was different among lactation groups 1, 2, and 3+. Milk urea nitrogen increased as parity decreased. It was concluded that milk urea nitrogen should be evaluated in association with milk yield, somatic cell counts, milk fat, milk protein, and parity.

Key Words: milk urea nitrogen, milk yield, dairy herds

T308 Control of acute postpartum metritis in lactating dairy cows at high risk of developing metritis following dystocia, stillbirth, twinning and/or retained placenta/fetal membranes with ceftiofur crystalline free acid sterile suspension (CCFA-SS). C. McLaughlin*, C. LaGrow, C. Daugherty, E. Stanisiewski, and M. Lucas, *Pfizer Animal Health*, *Kalamazoo, MI*.

Metritis is associated with significant economic loss due to treatment costs, reduced reproductive performance and premature culling. The objective of this multi-location clinical trial was to demonstrate that administration of 6.6 mg/kg BW dose of CCFA-SS once subcutaneously at the base of the ear reduces incidence of acute postpartum metritis compared with control cows. The study was a randomized block design with cows blocked on order-of-entry within herds without regard to parity to either saline treated (CON) or CCFA-SS. Daily observations were performed on d 1 to 14, rectal temperatures were recorded on d 0 to 14 and physical examinations were conducted on d 0–2, 7 ± 1, and 14. Twelve study sites, in CA (4), NY (2), IA (1), MI (2), FL (2) and TX (1) each enrolled at least 40 animals. Of the 494 animals enrolled (247 CON and 247 CCFA-SS), 54 were ineligible for analysis and 17 were removed from the study before d 14 for reasons unrelated to acute postpartum metritis. Cow was the experimental unit and the primary decision variable was incidence rate of metritis, defined during the d 14 physical exam as rectal temperature ≥39.5°C and a vaginal discharge score of 3 (not fetid; thin watery, serous; red, brown vaginal discharge), or a vaginal discharge score of 4 (fetid vaginal discharge), regardless of rectal temperature. Generalized linear mixed models were used. Incidence rate of metritis was lower for cows that received CCFA-SS than for CON (31.6 vs. 48.0%, $P = 0.0182$) with a difference of 16.4%. Mean rectal temperature over the first 6 d of study was lower ($P = 0.0015$) for CCFA-SS compared with CON cows. No detrimental effects attributable to the administration of CCFA-SS were observed. It

was concluded that CCFA-SS is safe and effective for control of acute postpartum metritis in lactating dairy cattle at high risk of developing metritis following dystocia, stillbirth, twinning and/or retained placenta/fetal membranes.

Key Words: metritis, dairy cow, ceftiofur

T309 Evaluation of ceftiofur crystalline free acid sterile suspension (CCFA-SS) administered to dairy cows exhibiting risk factors for acute postpartum metritis. E. Stanisiewski, C. Daugherty*, J. Hallberg, and M. Lucas, *Pfizer Animal Health*, *Kalamazoo, MI*.

The objective was to evaluate incidence of acute postpartum metritis in dairy cows after abnormal calving when given a single dose of CCFA-SS within 24 h following calving (day 0) at 6 commercial dairies. CCFA-SS was administered subcutaneously in the base of the ear. Response was compared with untreated controls (CON) that also exhibited abnormal calving. Abnormal calving was defined as dystocia, twins, retained membranes (≥12 h), stillbirth or any combination thereof. The study was a randomized block design with cows blocked on order of entry within herds without regard to parity to 1 of 2 treatments; CON or CCFA-SS (6.6 mg ceftiofur equivalents/kg). Untreated controls with normal calving (NTX) were included for observational purposes. Cow (122 NTX, 122 CON and 121 CCFA-SS) was the experimental unit. A generalized linear mixed model was used. Daily observations, including rectal temperatures, were performed on days 1 to 21 ± 2 along with physical examinations on Day 0–2, 7 ± 2, 14 ± 2 and 21 ± 2. A random subpopulation (about 50% of abnormal calving/at-risk cows) had samples collected from the uterus by swab on days 3 or 4, 7 ± 2, 14 ± 2 and 21 ± 2 for evaluation of bacteria present. The primary decision variable was incidence rate of metritis, defined as rectal temperature ≥ 39.5°C and fetid vaginal discharge. Cows with associated abnormal calving events that received CCFA-SS had lower ($P \leq 0.038$) incidence rates of metritis than CON at all 3 time points on study, with differences of 13.7 (day 7 ± 2), 16.8 (day 14 ± 2) and 14.9% (day 21 ± 2). Mean rectal temperature was lower ($P = 0.032$) in cattle over the first 6 d of study that received CCFA-SS compared with CON. Within day contrasts showed temperatures were 0.16 to 0.28°C lower ($P < 0.05$) in CCFA-SS cattle on study days 1, 2 and 3 compared with CON. Uterine cultures found *Escherichia coli* in 80% of samples during the first week postpartum. Incidence of acute postpartum metritis was reduced in dairy cows after abnormal calving when given a single dose of CCFA-SS within 24 h following calving.

Key Words: metritis, dairy cow, ceftiofur

T310 Evaluating reproductive outcomes in United States Holstein dairies. L. M. Moeller*[1], N. A. Michael[1], J. C. Dalton[2], and G. C. Lamb[3], [1]*ABS Global, Inc.*, *DeForest, WI*, [2]*University of Idaho*, *Caldwell,* [3]*University of Florida*, *Marianna*.

To assess reproductive management data were analyzed from 85 Holstein dairies in 4 regions of the US. Records of 231,288 cows and 649,495 matings from Region 1 (CA, ID, WA; n = 22 herds), Region 2 (KS, NM, TX; n = 15 herds), Region 3 (IL, MN, SD, WI; n = 35 herds), and Region 4 (IN, MI, NC, NY, OH, PA; n = 13 herds) were evaluated between August 2008 and August 2009. Analyses were conducted with PROC GLM to determine reproductive responses using herd as the experimental unit. Herd size ranged from 258 to 15,866 cows among all herds. Mean herd size was greater ($P < 0.01$) for Region 1 (5,809 ± 522) than Regions 2 (2,569 ± 632), 3 (1,240 ± 414) and 4 (1,704 ± 678). For all inseminations, the overall percentage of cows inseminated after estrus or ovulation synchronization with a fixed-time AI (TAI) protocol was 43.4%, and was greater ($P < 0.01$) for Region 3 (63%) than Regions 4 (46%), 1 (24%), and 2 (18%). The overall percentage of cows receiving an insemination after an observed estrus was 56.4%, and was greater for Region 1 (76%) than Regions 2 (82%), 4 (54%), and 3 (37%). Overall conception rates to first service TAI was 30.5% and was greater ($P < 0.01$) for Region 3 (33.6%) than Regions 1 (28.6%) and 2 (23.9%), whereas Region 4 (30.8%) was intermediate. Similarly, conception rates to cows inseminated after observed estrus was 34.9% and was greater ($P < 0.05$) for Region 3 (37.2%) than Regions 1 (33.6%), 2 (33.1%), and 4 (33.1%). Whole herd 21-d pregnancy rates (17.8%) and AI 21-d pregnancy rates (18.5%) were similar among regions. The mean percentage of cows that became pregnant, relative to the total number of cows eligible to become pregnant in the herd, was 76.9% and did not differ among regions. We conclude that regional differences in reproduction exist in US dairies, specifically in the percentage of cows that are inseminated at TAI and following detection of estrus. In addition, reproduction responses vary among region in terms of multiple measures of fertility, which may be attributed to protocol compliance, heat detection efficiency, and differences in herd size.

Key Words: estrous synchronization, fertility, reproduction

T311 The effect of soy isolate source in milk replacer on growth and health of calves fed milk replacer. R. C. Musser*, B. L. Miller, T. J. Earleywine, and T. E. Johnson, *Land O'Lakes, Inc.*, *Webster City, IA*.

Forty-eight (48) Holstein bull calves with an average initial weight of 44.2 kg were employed in a 42 d trial to evaluate 3 different sources of soy isolate in milk replacer (MR). Calves were allotted to treatment based upon weight and blood gamma globulin status. Calves were fed a 25% protein / 20% fat MR powder to provide 681 g DM feeding rate daily in 2 feedings. Calves were offered one feeding (340 g) per day during the week of weaning. Each MR contained soy isolate protein from one of 3 different sources-A, B and C-and were medicated (0.28 g neomycin:0.14 g oxytetracycline/kg). Soy isolate sources replaced 37.5% of the milk protein. Calf starter (20% CP as-fed) was fed throughout this 42-d trial. The Mixed procedure of SAS was used to analyze data. Source C was inferior ($P < 0.05$) in total weight gain, MR intake, starter intake and feed efficiency when compared with the other soy isolate sources. Soy isolate sources differ in ability to support calf performance.

Table 1. Soy Isolate Source

Item	A	B	C	SE
BW gain, kg	19.0[b]	17.7[b]	6.0[a]	1.239
MR (DM), kg	23.3[b]	22.9[b]	21.1[a]	0.526
Starter (DM), kg	14.9[b]	13.6[b]	8.9[a]	0.447
Feed/Gain	2.12[a]	2.12[a]	5.29[b]	0.372

[a,b] Means within a row differ ($P < 0.05$).

T312 Non-dietary risk factors for lameness and their consequences in dairy cows. I. Guasch[1] and A. Bach*[1,2], [1]*Deparment of Ruminant Production, IRTA*, *Caldes de Montbui, Spain*, [2]*ICREA*, *Barcelona, Spain*.

Forty-three herds (4,366 cows; herd average milk yield 26 ± 2.8 kg/d) located in the Northeast of Spain feeding exactly the same ration were included in a survey aimed at determining non-dietary risk factors for lameness and potential consequences of lameness on herd performance. The survey was conducted within a 2-mo time span and each herd

was visited at least twice. All cows (dry and lactating) were evaluated using a 5-point locomotion scoring system by the same observer for lameness. Management parameters were gathered through a direct interview with the herd manager. Reproductive data were derived from historical records collected for an entire year. Daily milk yield and composition during the 2 mo before and the month that the farm visit took place was collected from the milk processor. Data were analyzed using linear regression analysis. Overall, average lameness (locomotion score ≥4) prevalence was 18 ± 9.0%. No relationship was found between cubicle dimensions and lameness incidence. The frequency of bedding the cubicles (cushioning) was negatively correlated with lameness. Herds that moved cows between pens in groups of several animals had a lower incidence of lameness (14.2 ± 1.97%) than those that moved cows individually (21.6 ± 1.88%). Herds with an average age at first calving (AFC) > 27 mo had a greater lameness prevalence (20.8 ± 2.09%) than those with and AFC <27 mo (14.79 ± 1.71%). Herds producing more than 27 kg/d had a lower lameness incidence (12.9 ± 2.35%) than those producing less than 27 kg/d (20.3 ± 1.64%). Herd milk efficiency (normalized for fat and protein) ranged from 1.03 to 1.52 kg of milk/kg of DMI and tended ($P = 0.06$) to decrease as lameness prevalence increased. Heat detection rate ranged from 26.5% to 72.3%, and decreased as lameness incidence increased. Management aspects such as moving cows in groups, AFC, and frequency of bedding are highly associated with lameness prevalence. Lameness may decrease herd profitability by, among other factors, compromising reproduction through poor heat detection and tending to reduce milk efficiency.

Key Words: lameness, housing, management

T313 Associations between several aspects of heifer development and dairy cow longevity. A. Bach*[1,2], [1]*ICREA*, *Barcelona, Spain*, [2]*Department of Ruminant Production, IRTA*, *Caldes de Montbui, Spain*.

A data set from 8,549 heifers born between 2003 and 2006 including growth rates since birth until first calving, age and BW of insemination, and incidence of diarrhea and respiratory problems (RP) was used to evaluate potential associations between these factors and cow longevity. All heifers were raised in a contract heifer operation (Rancho Las Nieves, Mallen, Spain) and returned to their herds of origin (133 herds in total) before calving. Dates of death were provided by the Subdirección General de Explotaciones y Sistemas de Trazabilidad de los Recursos Agrícolas y Ganaderos from the Ministry of Environment, and Rural and Marine Areas of the Spanish Government. At the time of analysis, 3,138 animals out of the 8,549 considered had died. Age and BW before first calving was 727 ± 41.2 d and 661 ± 43.8 kg, respectively, with an overall ADG between 10 d of life and first calving of 873 ± 117.3 g/d. Average longevity for the 3,138 heifers that had died was 1,395 ± 407 d, with 10.4% of total cullings (or deaths) occurring within the first 50 DIM, and 30.9% of total cullings (or deaths) that did not complete the first lactation. Data were analyzed using a mixed-effects model accounting for the random effect of the farm of origin (and fate), year of calving, and their interaction. The number of RP that heifers experienced was the most significant parameter affecting longevity. Heifers that never incurred an RP had an average longevity of 1,606 ± 126 d, and this number progressively ($P < 0.001$) decreased to 1,511 ± 129 d in those that had experienced 4 or more RP. Heifers that completed the first lactation grew at a greater ($P < 0.05$) rate (875 ± 1.4 g/d) and were bred with a greater ($P < 0.05$) BW (62.9 ± 0.16% of calving BW) than those that never finished it (861 ± 3.85 g/d and 60.9 ± 0.26% of calving BW, respectively). The consideration of these results, especially recurrences of RP and rate of growth, when making decisions on heifer management has the potential to improve overall future herd profitability by increasing cow longevity.

Key Words: longevity, heifer, development

T314 Effects of heat stress and Niashure (NI) supplementation on winter acclimated lactating cattle. S. Rungruang*[1], R. P. Rhoads[1], L. H. Baumgard[1], M. DeVeth[2], J. L. Collier[1], and R. J. Collier[1], [1]*University of Arizona*, *Tucson,* [2]*Balchem Corp, New Hampton, NY*.

A replicated design with 24 multiparous high producing dairy cows (40 ± 1.4 kg/d) was utilized to evaluate a dose range of dietary NI (0, 4, 8, or 12 g/d) in winter acclimated lactating dairy cows on body temperature indices, sweating rate, feed intake, water intake, production parameters and blood niacin concentrations under thermoneutral (TN) and heat stress (HS) conditions. Temperature Humidity Index (THI) values for TN never exceeded 65 while THI values during HS were above 72 (stress threshold) for 12 h/d. The HS environment increased skin, rectal and vaginal temperatures, respiration rate, sweating rate and water intake and decreased feed intake (4 kg/d, $P < 0.01$), milk yield (3.4 kg/d, $P < 0.01$) and milk protein (0.18 g/100 mL, $P < 0.01$). Sweating rate increased during HS (13 g/m^2 h, $P < 0.01$) compared with TN, but this increase was 10-fold lower than reported in summer acclimated cattle. NI supplementation had no effect on sweating rate, dry matter intake, milk yield and composition in either environment. Dietary NI increased blood ($P < 0.07$) and milk ($P < 0.02$) niacin concentrations in a linear manner. Heat stress reduced blood (7.82 vs. 6.63 ug/mL, $P < 0.01$) but not milk niacin concentration. Reduced blood niacin concentration was partially corrected by dietary NI. Dietary NI linearly increased water intake ($P < 0.02$) in both environments but the increase was greater during HS conditions ($P < 0.03$). Dietary NI also increased skin temperature in both environments ($P < 0.01$) from both shaved and unshaved skin in a dose-dependent manner ($P < 0.01$) but the increase was greatest from shaved skin ($P < 0.04$). This suggests skin blood flow was enhanced with increasing NI dose. Results indicate that HS decreased blood niacin concentration in lactating dairy cows and that NI supplementation partially restored blood niacin concentration during HS. Dietary NI increased water intake and skin temperature. There may be seasonal differences in sweating rate responses to HS and NI.

Key Words: niacin, heat stress, cattle

T315 A preliminary investigation of individual variation in N excretion by lactating dairy cows. P. Gregorini*, P. Beukes, A. Romera, C. Clark, and D. Clark, *DairyNZ*, *Hamilton, Waikato, New Zealand*.

Dairy systems are under pressure to reduce their environmental footprint, and N excreted from cows is a primary concern. Three data sets were separately analyzed to explore the animal variability in N excretion, and associations among genetic merit, live weight, DMI and N excretion parameters. This was a preliminary step in evaluating the potential for genetic selection for reduced urinary N (UN) and milk urea N (MUN) concentrations. Data sets consisted of cows fed a) Total mixed ration (TMR), b) Grazing fresh pasture (GR), and c) fresh pasture indoors (IG). Data sets contained 372, 144 and 90 measurements, respectively. Cows in GR and IG were identified by profit-based genetic evaluation in relation to ability to breed efficient replacements (BE) and produce efficiently (PE). Data sets were analyzed using mixed models. Cow variance components were estimated using models that included treatment and period as fixed effects and cow and period within cow as random effects. Associations among the UN, MUN, BE, PE, DMI, and live weight were determined using random coefficient regression for TMR. For GR and IG, pooled within-treatment regression was used. Analyses

indicated a significant ($P < 0.001$) cow variance component for MUN (13 ± 3.9 m*M*/L) in TMR, MUN (7.7 ± 1.8 m*M*/L) and UN (1.2 ± 0.4 g/L) in GR, and UN (7.8 ± 1.0 g/L) in IG, with greater variation between cows than within-cow for each data set. In TMR, UN was positively associated ($P < 0.01$) with live weight and N intake. In GR, UN was negatively associated with PE ($P < 0.05$), but not BE. Live weight was positively associated ($P < 0.01$) with UN. With IG, genetic merit, neither live weight nor DMI was associated with MUN. None of the experiments were designed to study within- and between-cow variation in UN or MUN specifically, so caution must be applied when drawing inferences from these analyses. However, the analyses indicate consistent individual cow variation, suggesting a need for further research to explore the possibility of genetic selection for variation in N excretion.

Key Words: N excretion, dairy cow, genetics

T316 Repeatability coefficients for dry matter intake and efficiency of nitrogen utilization for milk production in lactating Holstein cows challenged with low N diets. N. B. Kristensen*, T. Hvelplund, M. R. Weisbjerg, P. Lund, and P. Løvendahl, *Aarhus University*, *Tjele, Denmark*.

Data from 63 cows fed 4 different diets varying in nitrogen (N) content in a multiple Latin square design with 2 tests, 8 blocks per test, 4 experimental periods of 14 d, and 4 treatments within block were used to estimate repeatability coefficients for dry matter intake, milk production traits, and efficiency of nitrogen utilization for milk production (ENU). Cows were blocked according to parity and days in milk. Diets were composed of corn silage, rolled barley, grass clover silage, and N adjusted by substituting soyhulls and cane molasses for soybean meal (120, 80, 40, and 0 g/kg DM) with a fixed proportion of soyhulls to molasses of 4 to 1. Diets contained 167, 150, 134, and 121 g crude protein/kg DM for the 4 soy levels, respectively. The study included 24, 25, and 14 cows of 1st, 2nd, and +3rd parity and cows were in average (mean ± SD) 160 ± 28, 180 ± 47, and 136 ± 30 d in milk by the first sampling period for the 3 parities, respectively. Repeatability coefficients were estimated in a linear mixed model containing the fixed effects of treatment, treatment × test, and experimental period × test and the random effect of block × test as well as random intercept, linear- and quadratic effects of treatment with subject = the individual cow. Repeatability coefficients were calculated as the variance component estimate for intercept / intercept + residual. The following repeatability estimates were obtained: dry matter intake, 0.77; milk yield, 0.57; energy corrected milk, 0.38; fat yield, 0.55; protein yield, 0.39; ENU, 0.52. Including BW and BW x treatment as fixed effects in the model reduced the estimates for energy corrected milk, 0.18 and protein yield, 0.093, however, the estimate for ENU (0.55) did not decrease, suggesting that ENU is a trait of the individual cow without being a function of its body weight. The estimated high repeatability coefficient for ENU further suggests a possibility for genetic improvement of N efficiency of dairy cows.

Key Words: repeatability coefficients, nitrogen utilization, dairy cows

T317 Metabolic profile and postpartum health in early lactating Holstein cows in southern Brazil. T. A. Frigotto[1], S. O. Juchem[2], R. D. Ollhoff[3], I. R. Barros Filho[1], P. Schmidt[1], and R. Almeida*[1], [1]*Universidade Federal do Paraná*, *Curitiba, PR, Brazil*, [2]*University of California*, *Davis*, [3]*Pontifícia Universidade Católica do Paraná*, *Curitiba, PR, Brazil*.

Objectives of the study were to describe the concentrations of serum metabolites and the occurrence of diseases in a group of parturient cows from commercial dairy herds. Two high-producing dairy herds in the county of Arapoti, Brazil, were monitored from April to July of 2009, resulting in data collection from 105 dairy cows (73 multiparous and 32 primiparous). Blood was withdrawn on d 1, 2, 5, and 10 after calving, and serum analyzed for non-esterified fatty acids (NEFA), β-hydroxybutyrate (BHBA), and calcium (Ca). Continuous data was analyzed as repeated measures, whereas dichotomous data was analyzed with Fisher exact test. The statistical model included the fixed effects of herd, parity, time, and appropriate interactions. Concentration of NEFA in serum decreased ($P < 0.01$) as DIM increased (d1 = 0.73; d5 = 0.62; and d10 = 0.51 mmol/L). Concentrations of NEFA were similar ($P > 0.05$) between herds, but multiparous cows had higher ($P < 0.05$) concentrations of NEFA than primiparous cows (0.71 vs. 0.53 mmol/L). Concentrations of BHBA were highest ($P < 0.05$) at d5 (d1 = 0.45; d5 = 0.59; d10 = 0.43 mmol/L). There was no ($P > 0.05$) difference on BHBA concentrations between first-lactation and mature cows. Concentrations of Ca in serum were similar ($P > 0.05$) between farms (10.5 vs. 10.7 mg/dL) and parity (10.7 vs. 10.6 mg/dL). The incidence of dystocia, displaced abomasum, clinical hypocalcemia, mastitis and subclinical ketosis were similar ($P < 0.05$) between herds and parity. Incidence of retained placenta was higher in primiparous cows from herd A ($P > 0.05$) than herd B (50 vs. 15%), but similar within multiparous cows (28.6 vs. 23.7%). Multiparous cows from herd A had higher incidence of metritis than herd B (28.6 vs. 5.1%; $P = 0.02$). Primiparous cows had higher incidence ($P < 0.01$) of udder edema than multiparous cows (40.6 vs. 11.0%). Milk production was similar between primiparous cows across herds (31 vs. 31 kg/d), but multiparous cows from herd A produced more milk from 14 to 56 DIM (46.5 vs. 39.7 kg/d). Parity and DIM are important sources of variation when monitoring metabolic parameters and evaluating disease incidence of transition cows.

Key Words: NEFA, BHBA, calcium

T318 Factors affecting the bulk tank milk quality collected by a dairy industry of Minas Gerais state, Brazil, from 2002 to 2008. C. A. V. Paiva, A. F. Cunha, M. O. Leite, R. Rodrigues, C. F. A. M. Pena, A. M. Q. Lana, M. Houri Neto, L. M. Fonseca, M. R. Souza, and M. M. O. P. Cerqueira*, *Federal University of Minas Gerais state*, *Belo Horizonte, Minas Gerais, Brazil*.

Objectives were to determine the bulk tank milk quality in compliance with the Brazilian Ministry of Agriculture standards (IN51) and the effect of total bacterial count (TBC) and somatic cell count (SCC) on protein, fat, and solids nonfat solids (SNF) content, as well as on the milk powder yield. A total of 60,243 milk samples were collected on farms in the state of Minas Gerais, Brazil, from 2002 to 2008. The TBC and milk composition and SCC were performed using Bactocount IBC and CombiSystem 2300 (Bentley Instruments Inc.). The results were analyzed by Chi-squared . From 2002 to 2008, the volume of milk (%) in compliance with IN51 increased 11.58% for TBC and 1.4% for protein while it decreased 3.33% for SCC, 2.05% for fat, and 4.07% for SNF. The frequencies of samples (%) in compliance with IN51 regarding TBC, SCC and contents of fat, and NFS were higher ($P < 0.05$) during the dry (72.88, 92.63, 96.27, and 90.65, respectively) than the rainy season (66.55, 90.35, 91.26, and 89.49, respectively). For protein, these frequencies were similar ($P > 0.05$) during the dry (97.72%) and rainy seasons (97.52%). The seasonal variations influenced the bulk tank milk quality. TBC and SCC varied more and had lower means during the dry (5.12 logCFU + 1/mL and 5.41 log SCC + 1/mL, respectively) than the rainy season (5.16 log CFU + 1 and 5.44 log SCC + 1/mL, respectively). Means (%) of fat, protein and SNF were higher during the dry (3.81, 3.30, and 8.82, respectively) than the rainy

season (3.61, 3.26, and 8.79, respectively). Seasonality influenced fat and protein and at the rainy season, SCC and TBC may have decreased the milk solids. Milk powder yield was higher in the dry season due to the highest solids content of milk. However, the total production of kg of solids was lower due to the lower volume of milk collected in that season. Indeed, seasonality influenced all the studied parameters and it may have affected milk powder yield.

T319 Evolution of milk production and premium payment for total bacterial count, somatic cell count, fat and protein contents in a dairy industry of Minas Gerais state, Brazil. C. A. V. Paiva, A. F. Cunha, M. O. Leite, R. Rodrigues, C. F. A. M. Pena, L. M. Fonseca, A. M. Q. Lana, M. Houri Neto, M. R. Souza, and M. M . O. P. Cerqueira*, *Federal University of Minas Gerais state*, *Belo Horizonte, Minas Gerais, Brazil*.

Objectives were to characterize milk quality parameters in the state of Minas Gerais, Brazil, from 2002 to 2008. A total of 60,243 raw bulk tank milk samples were collected and analyzed for total bacterial count (TBC), SCC, fat and protein. Results were tabulated according to year and then related to the volume of milk produced and value paid to the producers according to a system of payment for quality established by the local industry. Descriptive analyses were performed to report results. For all 4 parameters used in the payment for milk quality (TBC, SCC, fat and protein contents), the value paid to the producer increased. However, not all parameters followed the same pattern. TBC and SSC followed distinct trajectories. The volume of milk that received premium payment for TBC increased 27.18% between 2005 and 2008, and the average premium payment for TBC increased 3.15% in the same period. In relation to SCC, the volume of milk that received a premium payment decreased 27.52% between 2005 and 2008, but the premium payment for SCC increased 58.89% in the same period. The average fat content decreased, whereas the protein content increased in the period evaluated. The volume of milk that received premium payment for fat content was reduced 0.92% between 2005 and 2008, but the average premium payment for fat content increased 14.38% in the same period. The volume of milk that received premium payment for protein content increased 61.86% between 2005 and 2008. The average premium payment for protein content increased 69.60% between 2005 and 2008. It is necessary to monitor and to evaluate the parameters used in the payment of milk quality so that it has, in fact, a continuous improvement of the productive processes and the economic index.

Key Words: milk, quality, payment system

T320 Comparison of different methods of rearing management in Holstein dairy calves. F. Niazi, H. Amanlou, E. Qashqayi*, and E. Mahjoubi, *Zanjan University*, *Zanjan, Iran*.

Milk consumption, dry feed intake, body weight (BW) gain and occurrence of diarrhea were studied in male Holstein calves fed milk either through conventional or step-down (STEP) methods. A completely randomized design was used in this study. In conventional method, the calves (n = 9) were fed colostrum and then milk at the rate of 10% of BW for the entire period of 45 d. In STEP method, the calves (n = 9) were given colostrum and then milk for 25 d at the rate of 20% of BW in 2 meals and another calves (n = 9) in 3 meals for 25 d, which was reduced (between d 26 to 30) to 10% of BW for the remaining 15 d. The calves fed through conventional and STEP methods were weaned gradually by milk diluting with water between d 46 and 50. Feed intake and BW of the calves were monitored until 90 d of age. The STEP calves consumed more milk than conventionally fed calves during the pre-STEP (d 1 to 30) and post-STEP (d 31 to 50) periods ($P < 0.01$). Consumption of starter in calves provided milk using conventional method compared with STEP-fed calves was greater during the pre-STEP period and there was no significant difference during the post-STEP and postweaning (d 51 to 90) periods. Body weight gain (8.5, 18.7 and 21.3 kg/30 d, $P < 0.001$, respectively) and feed efficiency (0.37, 0.49 and 0.55, $P < 0.001$, respectively) of calves were greater in those on the STEP method during the pre-STEP period than on the conventional method and were numerically higher during post-STEP and post-weaning. There was no significant difference in occurrence of diarrhea in calves fed milk through conventional method compared with STEP-fed method. Increasing number of milk meals tended to increase body weight gain (65.4 vs. 70.7 kg/90 d, $P < 0.17$). In conclusion, STEP milk feeding may prevent the problems of depressed solid feed intake associated with ad libitum milk feeding and of poor BW gain with conventional milk feeding in dairy calves.

Key Words: weaning, starter, Holstein bull calves

T321 Differences between expanding and non-expanding Wisconsin dairy farms. J. M. Janowski and V. E. Cabrera*, *University of Wisconsin*, *Madison*.

A survey was administered (September 2009 to January 2010) to a sample of 1,000 randomly selected Wisconsin dairy producers to discern differences between those planning to expand and those not planning to expand their operations. A total of 300 dairy producers (30%) across 33 counties in Wisconsin completed the survey. Results indicated 33% of dairy producers planned to expand their dairies in the future. The majority planned to grow their herds from within. Significant differences between dairy producers and their operations were found regarding producer age, producer experience, farm herd size, and land per cow. Low net profit was the top issue hampering growth and modernization for producers planning to expand. Most producers not planning to expand were satisfied with their current operation size and did not feel expansion was necessary. Producers planning to expand cited an increase in net farm income as their most important motivation, while producers not planning to expand wanted to keep the farm at its best size given available labor. Dairy producers planning to expand were interested in receiving more information about financial planning, profitability measures, and financial efficiency. Producers not planning to expand were interested in topics regarding reproduction and financial efficiency. Results provide evidence toward development of risk management and financial management programs tailored for expanding and non-expanding dairy producers.

Table 1. Characteristics of expanding and non-expanding dairy operations

	Planning to expand (n = 78)	SD	Not planning to expand (n = 222)	SD	P-value
Producer age (yr)	47.08	10.70	51.19	10.70	0.01
Producer experience (yr)	25.33	12.99	29.15	12.14	0.04
Farm herd size (#)	247.35	362.97	82.11	117.03	0.00
Farm land per cow (ha/cow)	0.94	1.06	1.73	2.18	0.00

Key Words: expansion, modernization, survey

T322 Effect of heat stress on pregnancy rate of dairy cows using artificial insemination or embryo transfer in commercial dairy farms of central Mexico (Aguascalientes). R. Lozano[1], E. Gonzalez-Padilla[2], C. Vazquez[2], C. F. Arechiga*[3], and J. M. Silva[3], [1]*Instituto Nacional de Investigaciones Forestales, Agricolas y Pecuarias*, *Pabellon, AGS, Mexico*, [2]*Universidad Nacional Autonoma de Mexico*, *Mexico, D.F.*, [3]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico.*

Objective of present study was to evaluate the effect of heat stress on pregnancy rates of Holstein cows using artificial insemination or embryo transfer in commercial dairies from central Mexico (Aguascalientes, Mexico). The study was carried out in 2 commercial dairy herds during 2 seasons of the year: Warm (May 1 to August 17) and Temperate (January 15 to March 27). Cows included in the study were randomly allotted into 2 groups: 1) artificially inseminated (n = 682) and 2) embryo-recipient cows (n = 107). Days in milk (DIM), milk estimated production to 305 d (P305D); and the index temperature-humidity (THI) were recorded during both seasons. Data was evaluated through descriptive statistics. Pregnancy rate was evaluated in recipient cows and analyzed through a first-order multiple logistic regression analysis. DIM of cows in study (86.7 ± 2.8) were similar for both times and reproductive techniques ($P > 0.05$). P305D in recipient cows (9,261.8 ± 192.3) was higher than the observed in cows that were inseminated (8,397.9 ± 84.9; $P < 0.01$). As expected, THI was higher during warm season (76.7 ± 0.3) compared with temperate season (70.3 ± 0.3; $P < 0.05$). Pregnancy rate decreased during the warm season (21.1%) compared with the temperate season (35.9%; $P < 0.01$) for both AI and ET. Pregnancy rates were similar using artificial insemination (32.9%) and embryo transfer (24.9%; $P > 0.05$). Embryo transfer did not improve pregnancy rate over artificial insemination of Holstein cows exposed to heat stress conditions present during the summer in central Mexico (Aguascalientes).

Key Words: heat stress, embryo transfer, pregnancy rate

T323 Calculating field nutrient removal rates to comply with General Order for Existing Milk Cow Dairies from California's Central Valley Regional Water Quality Control Board. J. M. Heguy*, B. M. Karle, P. L. Price, and D. Meyer, *University of California, Davis*.

The Dairy General Order requires dairy operators to document total weight of nutrients removed from fields where manure is applied. A detailed protocol requires sub-sampling (n = 8) from each 16.19 ha, with additional composites made to represent morning and afternoon harvest periods for dry matter (DM). Analysis of forage DM forms the basis for all nutrient removal calculations. A single composite sample for each field is prepared for nutrient analyses. Field observations indicated the detailed sampling protocol was not generally followed at dairies. The objective of this study was to determine if differences exist in calculating DM removal based on various intensities of sub-sample and composite collection. Weights were obtained and samples collected for each truckload (TL) of forage harvested from 3 fields after unloading at the silage pit. Each sample was sealed in a plastic bag and placed on ice. Dry matter was determined for each sub-sample by drying 25–40 g, in triplicate, in a 55°C oven for 24 h, then weighing the dry residual. DM is dry weight divided by wet weight. Actual field DM removal was determined by summing TL × DM for all samples from the field. Field DM removal totals were calculated using 3 composite sampling models (sequence, interval, and period). Sequence values are the average of sample DM within each hour of harvest. Interval values are the average of every 10th sample. Period values represent averages of samples collected in am or pm on each day. Mean ± standard deviation (SD) sequence DM percent ranges were 27.23 ± 1.43 to 29.62 ± 1.64; 21.21 ± 1.45 to 24.57 ± 2.04; and 27.88 ± 1.03 to 31.71 ± 1.81, for Dairy 1, 2 and 3, respectively. Mean ± SD interval DM percent ranges were 27.26 ± 0.90 to 29.06 ± 2.19; 22.49 ± 1.57 to 23.36 ± 1.28; and 29.04 ± 2.40 to 30.65 ± 2.10, for Dairy 1, 2 and 3, respectively. DM percent of am/pm composites were: Dairy 1 (27.74 ± 1.51/29.00 ± 1.62); Dairy 2 (23.72 ± 1.78/22.53 ± 1.39/22.86 ± 1.43); and Dairy 3 (29.71 ± 2.05/31.97 ± 2.18).

Key Words: regulation, sampling, forage

T324 Association of production level and calving season with reproductive function of Holstein cows from an intensive dairy production system of central Mexico (Aguascalientes, Mexico). P. Hernandez-Briano[1], C. F. Arechiga*[1], J. I. Aguilera-Soto[1], M. A. Lopez-Carlos[1], M. Rincon[1], J. M. Silva[1], C. A. Medina-Flores[1], and R. Lozano[2], [1]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico*, [2]*Instituto Nacional de Investigaciones Forestales, Agricolas y Pecuarias*, *Pabellon, Ags, Mexico.*

Objective of present study was to determine factors influencing productive and reproductive function of Holstein cows in an intensive dairy productive system in central Mexico (Aguascalientes, Mexico). Effects of calving season (CS) and milk production level (MPL) on number of services (NS), interval from calving to conception (ICC) and interval from calving to next calving (ICNC) of Holstein cows (n = 363) from January 1st 2008 to March 29th 2009 was evaluated. Data was analyzed by SAS proc GLM as fixed effects of CS, parity (PAR), milk production level (MPL), age of cow and interactions. High-producing Holstein cows (above 20 kg/d; elevated MPL x = 9,644 kg/lactation), required a higher NS (3.4 vs. 2.6), a greater ICC (174.2 vs. 130.9 d), and a greater ICNC (446.9 vs. 401.2 d), compared with low-producing Holstein cows (below 20 kg/d; x = 6,410 kg/lactation). According to CS, it was found that cows calving during cool season of the year and bred during the summer presented a greater NS (3.7 vs. 2.8), a greater ICC (187.2 vs. 140.9 d) and a greater ICNC (467.9 vs. 412.7 d) in comparison to cows calving during the hot season of the year. Probably, due to inseminations carried out during the hot months of the year. Moreover, 2 years-old cows (PAR 1), presented a lower ICC compared with cows with PAR 2 and/or greater ($P < 00.5$). In conclusion, a high MPL, CS and PAR compromised significantly productive and reproductive parameters of Holstein cows from an intensive dairy in Central Mexico (Aguascalientes, Mexico).

Key Words: dairy cow, milk yield, heat stress

T325 Bacterial survival rate in sanitizing teat dips for dairy cows. S. Retz and S. I. Kehoe*, *University of Wisconsin-River Falls*, *River Falls*.

It is common practice to apply a teat dip before and after milking to prevent mammary infections from occurring in dairy cows. Teat dips commonly contain a sanitizer and emollient to reduce bacterial invasion and keep teat skin from drying and cracking. Many dairies use a dip cup which has a container attached where the teat dip is kept to apply pre and post milking. The person milking squeezes the container to fill the cup and then dips the cows. To save teat dip, multiple cows are dipped using the same fluid. Because the fluid contains a sanitizing agent, few people are concerned about bacterial transfer. Therefore, our objective was to determine whether there were any bacteria surviving after dipping multiple cows. One teat dip container and cup were cleaned and filled with 0.1% iodine teat dip. Teat dip was used on 2 cows and then swabbed on a Minnesota Easy Culture System II triplate (Minneapolis, MN). This process was redone a total of 6 times over 4 random days. Results showed a numerically increasing trend ($P < 0.09$) for growth of gram-positive species by sampling time (7.98, 8.69, 19.69, 43.13, 21.41,

and 18.96 cfu). Growth of streptococcus and gram-negative species were not significant however increased numerically (0.39, 0.39, 0.96, 1.25, 1.10, and 1.53 cfu for streptococcus spp. and 0.32, 0.14, 0.61, 1.75, 0.32, and 1.04 cfu for gram-negative spp.). It can be concluded that there is some survival of bacteria as well as further growth. These results indicate that more research is needed to determine other variables such as type of teat dip.

Key Words: teat dip, cows, bacteria

T326 Stage of lactation alters production responses of cows subjected to feed restriction. V. Bjerre-Harpøth, N. C. Friggens, V. M. Thorup, K. L. Ingvartsen, and K. M. Moyes*, *Aarhus University*, *Tjele, Denmark*.

Our objective was to determine the effect of stage of lactation on production responses of cows during feed restriction (FR). Forty-seven healthy Holstein dairy cows in early (E; n = 14; 0–90 DIM), mid (M; n = 15; 91–220 DIM) and late (L; n = 18; 221–355 DIM) lactation were used. Of these, 26 cows were primiparous and 21 cows were multiparous. At the beginning of the study, all cows were fed a standard TMR for ad libitum intake. After 8-d, all cows were FR to provide ~40% of NE_L requirements based on body weight, milk production and composition by supplementing the standard TMR with 60% wheat straw. After 4-d of FR, cows returned to full feed. At each milking, milk yield was recorded and composite milk samples were collected automatically and analyzed for % fat, protein, and lactose and concentration of BHBA and MUN (m*M*). For each cow, the change in each variable was calculated as average [before] – [during] FR. The MIXED procedure of SAS was used to determine the effect of stage of lactation on production responses during FR. Stage of lactation did not affect ($P > 0.05$) changes in fat and MUN but changes in lactose and daily milk yield (kg/d) were greater ($P < 0.05$) in E (0.18 ± 0.02 and 11.6 ± 1.3, respectively) than M (0.08 ± 0.02 and 8.9 ± 1.2, respectively) or L cows (0.13 ± 0.02 and 8.9 ± 1.1, respectively). Changes in protein were greater in both E (0.24 ± 0.03) and M cows (0.28 ± 0.03) than L cows (0.07 ± 0.02). However, greater changes in BHBA (log[m*M*]) were observed in M (0.13 ± 0.06) and L cows (0.06 ± 0.06) than E cows (−0.33 ± 0.06). One week after FR, all cows returned to production levels similar to those observed before FR. Our results show that cows in early lactation respond differently to feed restriction than cows in mid or late lactation. These results provide insight into the homeorhetic mechanisms controlling the partitioning of nutrients of dairy cows during early lactation and should be beneficial for our understanding of how to maintain animal health and productivity throughout the lactation cycle.

Key Words: cow, stage of lactation, feed restriction

T327 The effects of dietary ThermalCare-R (TCR) on body temperature indices, production and metabolism in heat-stressed lactating cows. R. P. Rhoads*[1], M. V. Skrzypek[1], S. S. Block[2], and L. H. Baumgard[3], [1]*University of Arizona*, *Tucson,* [2]*Archer Daniels Midland, Decatur, IL,* [3]*Iowa State University, Ames*.

Multiparous Holstein cows (n = 22; 115 ± 5 DIM, 582 ± 41 kg BW) housed in climate chambers were individually fed a TMR consisting primarily of alfalfa hay and steam flaked corn. Cows were randomly assigned to 1 of 2 treatments: a diet containing TCR(a fermentation material and botanical product for heat stress, n = 11, 45.4 g/d) or control diet (n = 11). Trial length was 21d consisting of a 7d thermal-neutral (TN) period (18°C, 20% humidity) followed by 14d of heat stress (HS; cyclical daily temps ranging from 31.1 to 38.9°C and 20% humidity, maximum heat was at 1300 h). TCR feeding had little or no effect on body temperature indices during TN conditions. During HS and compared with controls, TCR-fed cows tended to have a reduced rectal temperature at 1300 h (40.29 vs. 40.11°C; $P = 0.08$) and a higher shaved rump skin temperature at all time points (37.35 vs. 37.67°C; $P < 0.01$). TCR-fed cows also had an increased respiration rate at all time points during HS (78 vs. 83 BPM; $P < 0.02$). Overall, TCR-fed cows tended to consume less feed (21.9 vs. 22.5 kg/d; $P = 0.06$) but the decrease during HS was not as severe in TCR-fed cows compared with controls (4.8 vs.6.0 kg/d; $P < 0.05$). Cows fed TCR had an overall (independent of environment) increase in milk fat content (3.96 vs. 3.67; $P < 0.01$) and tended to have increased milk protein levels compared with controls (2.78 vs. 2.71; $P = 0.07$). Overall TCR-fed cows produced more milk (0.5 kg/d; $P < 0.05$) and the difference became larger when evaluated on a FCM and ECM basis. During HS, both groups had a similar milk yield reduction (6.1 kg/d). TCR-fed cows had improved feed efficiency (12%; $P < 0.01$) and both groups lost a similar amount of BW (21.5 kg) during HS. During HS, plasma NEFA levels did not change but glucose levels decreased (5%; $P < 0.05$), PUN increased (27%) and TCR-fed cows had overall increased PUN levels (12.7 vs. 11.6 mg/ml; $P < 0.01$). Feeding TCR improved some body temperature indices and production variables in heat-stressed cows.

Key Words: heat stress

T328 Effect of increased omega-3 fatty acids on production and reproduction in high producing lactating cows during cool season and hot season conditions. T. Colburn*[1], K. D. Murphy[1], C. Walhof[2], and A. V. Grove[3], [1]*Virtus Nutrition, LLC*, *Corcoran, CA*, [2]*Valley Veterinarians, Inc.*, *Tulare, CA*, [3]*AG Research, LLC*, *White Sulphur Springs, MT*.

High-producing cow diets contain large quantities of polyunsaturated fatty acids, primarily omega-6 fatty acids. This results in a high omega-6:omega-3 ratio of fatty acids flowing to the small intestine. This elevated ratio may reduce optimal production and reproduction. We hypothesize that increasing dietary omega-3 fatty acids will result in improved production and reproductive parameters in lactating cows during cool season and hot season conditions. Five hundred multiparous Holstein cows were used to evaluate the effect of 2 omega fatty acid nutrition programs on milk yield and conception rates during 2 periods (summer vs. rest of year). Cows were randomly assigned to either control or treatment diets. All cows were supplemented with 113 g omega-6 fatty acid supplement from −21 d prepartum to 21 d postpartum. From 22 to 150 d postpartum, control cows received 225 g calcium salts of long chain fatty acids and cows in the treatment group received 113 g calcium salts of long-chain fatty acids and 113 g of primarily polyunsaturated omega-3 eicosopentanoic (EPA) and docosohexanoic (DHA) calcium salts of fatty acids. Diets were balanced to be isonitrogenous, isolipidic and isocaloric. Peak milk production was greater ($P = 0.02$) in cows in the treatment vs. control groups 51.4 vs. 50.1 kg/d, respectively. Treatment diet tended ($P = 0.06$) to increase conception rate for the 1st insemination during the period covering the entire year, 45.6% for cows consuming the treatment diet and 30.7% for the control cows. Conception rates tended to be associated ($P = 0.07$) with time of year for cows inseminated for the combined 1st and 2nd insemination times, 36.7% during the summer vs 29.4% for the rest of the year. Modifying dietary concentrations of omega-6 and omega-3 fatty acids had positive effects on production and reproduction in lactating cows.

Key Words: dairy cow, calcium salts of fatty acids, omega-3

T329 Effect of thermal stress, cistern size, and milking frequency on plasma mineral concentrations in Holstein dairy cows. R. Ben Younes[1], M. Caccamo*[2], I. Schadt[2], M. Ayadi[3], T. Najar[1], M. Ben M'Rad[1], and G. Caja[4], [1]*Institut National Agronomique de Tunisie*, *Tunisia*, [2]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [3]*Institut Superieur de Biologie appliqué de Médenine*, *Tunisia*, [4]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*.

The study was carried out in 2006, in North Tunisia using 28 Holstein cows (169 ± 16 DIM) producing in average 18.0 ± 5.1 L/cow/d. Cows were classified according to udder cistern size, using a randomized block design, by ultrasonography to large-cisterned (47 cm^2 ± 17; LC) and small-cisterned (23 cm^2 ± 8; SC). The experiment was conducted in 4 times, April 5 (T1), July 18 (T2), August 18 (T3), and September 18 (T4). In each test day temperature and relative humidity data were registered hourly and cows′ blood was sampled from the jugular vein to determine serum concentrates of minerals (P, Fe, Ca, Mg, K, Na, Cl). In T1 and T2, cows were daily milked twice (2X). Immediately after T2, within each group, cows were randomly assigned to 2 levels of milking frequency: 2 times per day (2X) and 3 times per day (3X). To evaluate the effects of period and cistern size, only 2X events were considered. To assess effects of milking frequency, only T3 and T4 were considered. Mean THI values were 62 ± 2, 79 ± 2, 84 ± 2, and 77 ± 1 in T1, T2, T3, and T4, respectively. The concentration of each single mineral was affected by test day ($P < 0.02$), but neither by cistern size nor milking frequency. Minerals concentration least squares means in T1, T2, T3, and T4, respectively, are reported in Table 1. Some minerals, such as Fe, P, Mg, and K, seemed to be lowered through heat stress only after a certain period of exposure to stress. Heat stress should be considered especially for the nutrition of the close-up dry cows group and of cows within 72 h of calving.

Table 1. Least squares means of minerals concentrations

Minerals	T1	T2	T3	T4
P (mg/L)	64.29^{a}	64.75^{ab}	56.50^{bc}	51.89^{c}

T330 Body growth of pregnant Holstein heifers reared on pasture or conventional diet. R. R. Peters*[1], S. W. Fultz[2], J. W. Semler[3], and R. A. Erdman[1], [1]*University of Maryland*, *College Park*, [2]*University of Maryland Extension*, *Frederick*, [3]*University of Maryland Extension*, *Boonsboro*.

Interest in grazing to reduce feed costs and increase profitability has increased in Maryland. To develop internal expertise, grazing work was initiated at our research unit. Study objective was to compare body growth of pregnant Holstein heifers on pasture (P) vs. conventional (C) diets. Between June 10 and Dec. 1, 2009, heifers were alternately assigned to either P or C diets based on date of pregnancy confirmation. One month before predicted parturition date, animals were moved to maternity pens. Both P (n = 16) and C (n = 15) fed heifers were located in adjacent areas. Heifers fed conventional TMR included corn and rye silage, grass hay, and a monensin supplemented grain mix. Pasture reared heifers received no supplemental feed or minerals. Unimproved permanent pasture consisted primarily of endophyte-infected tall fescue. Heifers were rotated daily to a new paddock of approximately 0.1 to 0.3 ha, based on available DM. Measurements included body weight (BW), whither height (WH), hip height (HH), and body condition score (BCS) taken every 2 wk. Data collected for heifers on study for at least 70 d was fitted by quadratic regression to generate growth curves by individual animal. First derivatives of regression equations were used to estimate average growth rates for BW, WH, and HH. Equations of Heinrichs and Hargrove (J. Dairy Sci. 70:653–660, 1987) were used to compare actual growth rates to standard expected growth rates for heifers of this age and breed. Heifers on P had reduced ($P < 0.001$) ADG and BCS while skeletal growth rates (WH, HH) were similar to C. We conclude that P could be used without effect on skeletal development but it did have an impact on BW gain and BCS.

Table 1.

Growth Measure	Pasture	Conventional	SEM	P value
ADG, kg/d	0.42	1.11	0.034	0.001
Expected ADG, kg/d	0.58	0.59	0.025	0.773
WH gain, cm/d	0.041	0.050	0.004	0.376
Expected WH gain, cm/d	0.037	0.036	0.002	0.942
Mean HH gain, cm/d	0.062	0.044	0.001	0.320
BCS	2.87	3.11	0.044	0.001

Key Words: pasture, heifer growth

T331 Postpartum reproduction and NEFA changes during early lactation in Holsteins, Jerseys and their crosses. K. L. Brown*, B. G. Cassell, M. L. McGilliard, M. D. Hanigan, and F. C. Gwazdauskas, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

One hundred sixty-three cows in first and second (n = 111) lactation were sampled to determine if reproduction and NEFA differed between breeds. Thirty-four cows were Holstein-Jerseys (HJ) crosses, 49 were Jersey-Holsteins (JH) crosses, 51 were Holsteins (HH), and 29 were Jerseys (JJ). Blood samples were collected weekly for 10 wk postpartum. Statistical analyses were by MIXED models. Season were cold (November to May) and hot (June to October). Days open were affected by breed and year-season ($P < 0.019$). The days open for HH were 151.1 ± 8.4 d and not different for HJ (133.7 ± 14.1 d), or JJ (127.1 ± 12.6 d), but different from JH (116.5 ± 7.9 d). Services per conception (s/c) were affected by breed ($P < 0.019$). HH had more s/c (2.1 ± 0.1) than JH (1.7 ± 0.1). NEFA were affected by parity ($P < 0.002$), year-season, week, and breed by parity interaction ($P < 0.05$). NEFA were higher in parity 2 (0.50 ± 0.02 mEq/L) than parity 1 (0.43 ± 0.02 mEq/L). NEFA were generally higher in the cold season vs. the hot season, except for yr 3 hot season. NEFA for wk 1 was 0.74 ± 0.02 mEq/L, 0.60 ± 0.02 mEq/L in wk 2, 0.54 ± 0.02 mEq/L in wk 3, 0.50 ± 0.02 mEq/L in wk 4, 0.48 ± 0.02 mEq/L in wk 5, 0.39 ± 0.02 mEq/L in wk 6, 0.36 ± 0.02 mEq/L in wk 7, 0.33 ± 0.02 mEq/L in wk 8, 0.28 ± 0.03 mEq/L in wk 9 and 0.39 ± 0.10 in wk 10. The breed by parity effect showed HH in parity 2 had 0.56 ± 0.03 mEq/L, which was higher than parity 1 (0.44 ± 0.03 mEq/L; $P < 0.0001$). HH parity 2 NEFA was higher ($P < 0.0001$) than HJ parity 1 (0.39 ± 0.03 mEq/L) and JH parity 1 (0.43 ± 0.03 mEq/L; $P < 0.001$) and parity 2 (0.45 ± 0.03 mEq/L). HH parity 2 NEFA was higher than JJ parity 1 (0.45 ± 0.04; $P < 0.02$). HJ parity 1 and 2 were different (0.48 ± 0.03 mEq/L; $P < 0.002$). Even though breed by week interaction was not significant slices analysis revealed differences in wk 1 ($P < 0.03$) and wk 2 ($P < 0.04$). Change in NEFA during the first 2 wk postpartum was most dramatic. Reproductive measures appear more

affected by breed, while week postpartum, season, parity and breed had greater impacts on NEFA.

Key Words: crossbreds, NEFA, reproduction

T332 The effect of feed sorting on intakes of fiber and phosphorus in dairy cows. A. C. Huisman, R. L. Kincaid*, J. J. Michal, K. A. Johnson, and C. T. Gaskins, *Washington State University*, *Pullman*.

This study examined the impact of diet sorting on intake of NDF and P by lactating cows fed one of 2 TMRs that were fed for 10% refusals. Holstein cows (n = 24; 114 DIM) were fed a control TMR (CTMR; 27.3% alfalfa haylage, 25.4% alfalfa hay, 6.4% whole cottonseed, 36.4% concentrate, and 4.5% dried distillers grains and soluble) or a TMR in which 40% of the alfalfa hay DM was replaced by bluegrass straw (BGSTMR). After 3 wk the diets were switched and cows fed for another 3 wk. Fresh diet was delivered 1X/d with frequent pushups. Feed sorting by pen was assessed by comparing particle size distribution of fresh feed and 24 h refusals for 2 consecutive days for each treatment and period. Actual intakes of NDF and P were determined from the nutrient concentration in each particle size fraction for both fresh diet and refusals. Total fecal P excretion was estimated using ADL values. Analysis of data was performed using PROC GLM of SAS and the model included the effects of treatment, period, and treatment by period. Cows sorted ($P < 0.05$) against the long fraction (23 percentage unit increase in refusals) and for the short fraction (53 percentage unit decrease in refusals) for both treatments. Although sorting occurred, the % NDF in the consumed diet did not differ from the formulated diet (34% vs. 33% for formulated and consumed CTMR, and 36% vs. 35% for formulated and consumed BGS TMR, respectively). Similarly, the % P (0.41%) in the consumed diet did not differ from the formulated diet for either treatment. The feces contained 0.69 and 0.67% P and total fecal P excretion was 75 and 76 g/d, respectively, for the 2 treatments. However, comparison of particle size fractions of fresh feed to 24-h refusals does not consider within day variation of nutrient intake. In summary, feed sorting had no effect on daily intakes of NDF and P of cows fed these alfalfa-based diets.

Key Words: sorting, fiber, phosphorus

T333 Effect of Tasco on core body temperature of dairy cows exposed to heat stress. L. B. Pompeu[1], J. E. Williams*[1], D. E. Spiers[1], R. L. Weaber[1], M. R. Ellersieck[1], K. M. Sargent[1], N. P. Feyerabend[1], H. L. Vellios[1], and F. Evans[2], [1]*University of Missouri*, *Columbia*, [2]*Acadian Seaplants*, *Darmouth, Nova Scotia, Canada*.

Previous research in our laboratory revealed Tasco (*Ascophyllum nodosum*) temporarily lowers core body temperature (Tc) in rats and steers fed diets with endophyte-infected tall fescue during heat challenge. The present study determined the impact of Tasco on Tc in dairy cows exposed to elevated ambient temperature (Ta). Holstein cows (n = 32; DIM 107 ± 43; parity 2.7 ± 1.5) were assigned to treatments (trt) using a randomized complete block design, with 8 cows per trt. The study was divided into 3 periods: Period 1 (7 d) was adaptation to the Calan gate system; in Period 2 (28 d) trt were: Control-1 (C-1); Control-2 (C-2); 0.25% Tasco (0.25T); 0.50% Tasco (0.5T); in Period 3 (28 d) C-2 changed to 0.50% Tasco (C-.5T) to evaluate length of feeding Tasco. Each cow had a telemetric temperature transmitter (SmartStock, Pawnee, OK) placed in the reticulum, to record Tc every 20 min. Ta was continuously recorded (Hobo, Onset Computer Corp., Bourne, MA). Daily feed intake and milk production were collected for each cow. For Periods 1, 2 and 3 the average maximum Ta was 29.6, 28.0 and 31.0°C, respectively. In Period 2, no differences ($P > 0.10$) were found between C-1 and C-2 for any parameter, so they were combined for this period (C). Tasco trt had no effect ($P > 0.10$) on milk production, even with occasionally lower ($P < 0.05$) DMI for 0.25T compared with C and 0.5T. In Periods 2 and 3, there was a trend ($P < 0.10$) for a higher Tc for 0.5T compared with other trt. Linear regression of Tc vs Ta showed that, in Period 2, 0.25T had a slower increase in Tc with the rise in Ta during the day compared with C, while in Period 3, both 0.25T and 0.5T had a slower increase in Tc compared with C-1 and C-.5T ($P < 0.05$). In this same study, for Period 3, 0.25T had a slower increase in rump and ear surface temperature than C-1 and C-.5T as Ta increased. These results revealed that 0.25T maintained lower Tc, rump and ear temperature with increasing Ta.

Key Words: Tasco, heat stress, dairy cows

T334 An update of bulk tank milk quality in California. N. Silva-del-Río*[1] and C. Collar[2], [1]*University of California Cooperative Extension*, *Tulare County,* [2]*University of California Cooperative Extension, Kings County.*

Information about bulk tank milk (BTM) quality parameters can be used by dairy producers to compare their milk quality to industry wide benchmarks, and to define achievable goals for their operations. The objective of this study was to describe BTM quality for the California dairy industry. Individual herd information on somatic cell count (SCC), standard plate count (SPC), laboratory pasteurization count (LPC) and coliform count (Coli) from Oct-08 to Sep-09 were provided by a large dairy cooperative in California. All the milk loads shipped by each dairy were sampled weekly (ranging from 1 to 7 loads per week per dairy). Only herds with BTM samples collected throughout the 12 mo period were included in the final data set (n = 537) which comprised a total of 56,455 BTM observations. BTM samples below the regulatory threshold set by the California Department of Food and Agriculture (CDFA) were: 99.4% for SCC (<600,000 cell/mL), 96.5% for SPC (<50,000 CFU), 96.1% for LPC (<750 CFU/mL), and 93.0% for Coli (<750 CFU/mL). BTM quality parameters were described with Proc Univariate of SAS. Season effects (S1 = Jan-Mar, S2 = Apr-Jun, S3 = Jul-Sep, S4 = Oct-Dec) of log-transformed data were evaluated using Proc Mixed of SAS with repeated measurements on herd. Description of BTM quality parameters for the top 25% herds, the bottom 25% herds and the median counts are presented in Table 1. There was a significant effect of season on each of the BTM quality parameters ($P < 0.001$). SCC were lower in S2 than S1-S3-S4. SPC were higher for S1 than S2-S3-S4. However, SPC and Coli were higher in S1-S4 than in S2-S3. Overall, during the study period, California BTM quality was within acceptable parameters.

Table 1. SCC, SPC, LPC and Coli counts in California BTM, top 25% herds, bottom 25% herds and median counts from Oct-08 to Sep-09

	SCC (cell/mL)	SPC (CFU/mL)	LPC (CFU/mL)	Coli (CFU/mL)
25% top herds	<156,698	<2,969	<43	<25
25% bottom herds	>252,679	>5,729	>129	>63
Median	202,208	3,534	74	39

Key Words: bulk tank milk quality, dairy, California

T335 Determination of variation in dairy cows response to heat stress using radiotelemetry. L. B. Pompeu, J. E. Williams, D. E.

Spiers*, R. L. Weaber, and M. R. Ellersieck, *University of Missouri*, *Columbia*.

Summer heat is a major problem for dairy cattle, which have an elevated body heat production. At air temperature (Ta) above thermoneutrality, reduction in feed intake and milk production occur along with increased core body temperature (Tc). However, individual animals vary in response to heat stress, which can provide large variance between groups. To evaluate different levels of animal response to heat stress, a study was performed utilizing 15 Holstein cows, housed in a free-stall barn, during June and July (2008). A telemetric temperature transmitter (SmartStock, Pawnee, OK) was placed in the reticulum of each cow to record Tc. Ta was recorded using Hobo loggers (Onset, Bourne, MA). Feed intake and milk production were collected daily. A period of progressively increasing heat stress (9 d) was chosen to be analyzed (max Ta: 29.7°C, min Ta: 20.7°C). Tc and milk production relationships to Ta were assessed by quadratic and linear regressions, respectively, to separate cows into sensitive (S; n = 5) and non-sensitive (NS; n = 5) groups based on R^2. Five cows showed an intermediate response and were removed from analysis. For the analysis, hours 1000 to 1500 were used to assess the major rise in Tc during the day. A 1-h lag in Tc and 1-d lag for milk production were utilized for better correlation with Ta. Linear regression of Tc vs. Ta showed a difference between regression coefficients and slopes of S ($R^2 = 0.68$; slope = 0.12) and NS ($R^2 = 0.54$; slope = 0.08). Daily max, min, and mean Ta were tested against milk production, with min Ta yielding the best correlation. Milk production also showed a large difference with the linear fit and slope of S ($R^2 = 0.75$; slope = −0.71) being larger than NS ($R^2 = 0.27$; slope = −0.25). The greater slopes of sensitive animals indicate a larger response to Ta compared with non-sensitive animals, indicating variations in responses between animals among the same group of cows. Thus, to evaluate heat strain, it is essential to analyze animals separately by their level of response.

Key Words: heat stress, dairy cow, core temperature

T336 Corn silage management practices on California dairies. N. Silva-del-Río*[1], J. M. Heguy[2], and A. Lago[3], [1]*University of California Cooperative Extension*, *Tulare County,*[2]*University of California Cooperative Extension, Stanislaus and San Joaquin Counties,*[3]*APC Inc., Ankeny, IA.*

The aim of this study was to obtain information on current corn silage feed management practices in California's Central Valley. In summer 2009, a feed management survey was mailed to dairy producers in Tulare, Stanislaus, and San Joaquin; the first, third and seventh largest dairy counties in California, respectively. Producers received an envelope containing an invitation letter to participate in the study, a one-page survey, and a pre-paid return envelope. Response rate was 16.9% (120/710). Herd size ranged from 160 to 6,600 cows (median = 950). Corn silage in California was more frequently stored in piles (85.0%) and on concrete (75.0%), versus bunkers or dirt. Dairies reported top surface spoiled forage: <7.5 cm (25%), 7.5 to <15 cm (53.9%), 15 to <23 cm (15.7%), ≥23 cm (4.9%). Only one producer indicated that silage was not covered. A total of 54.7% (n = 55) of dairies covered silage with oxygen barrier (OB) technology. Top surface spoiled forage was reported to be < 15 cm in 89.3% of silages covered with OB technology and in 64.0% of silages covered with conventional plastic material. Bacterial inoculants of various types were used in 54.0% of corn silages. Most respondents (73.4%) considered that silage faces were maintained smooth, but only 5 producers used face shavers. The entire width of the silage face was removed daily in 41.7% of dairies, and of those, 27% removed less than 15 cm depth per day. Of dairies that did not remove the entire width of the silage face (1/2 face-24.0%, 1/3 face-26.9%, 1/4 face -7.4%), 15.0% advanced less than 15 cm depth per day. Determination of silage dry matter (DM) was conducted at least once a month in 52.3% of dairies. Only 8.3% of dairies determined DM weekly, or more often. Most dairies delegated DM determination to an outside nutrition consultant (86.6%). A total of 25.0% of dairies suspected mycotoxins in 2008. Top surface spoiled forage was discarded by 70.4% of dairies suspecting mycotoxins, and by 55.8% of those that did not suspect mycotoxins. Although dairy owner and manager responses are subjective, results indicate areas where corn silage management can be improved, such as removal rate, surface spoilage, and pile size.

Key Words: corn silage, dairy, survey

T337 Interaction of breed and quantity of milk replacer on the performance of dairy calves. C. J. Cobb* and M. A. Ballou, *Department of Animal and Food Sciences, Texas Tech University*, *Lubbock*.

Objective was to determine the influence of breed and quantity of milk replacer fed on the performance of dairy calves. Forty-two bull calves (n = 20 Holstein and n = 22 Jersey, 2 ± 1 d old) in a 2 × 2 factorial arrangement were observed through 11 weeks of age. Holstein and Jersey calves on the lower plane of nutrition were fed a 20% protein and 20% fat milk replacer at a rate of 454 g / d. Holstein calves on the higher plane of nutrition were fed a 28% protein and 20% fat milk replacer at a rate of 810 and 1,180 g / d for wk 1 and wk 2 – 6, respectively. Jersey calves on the higher plane of nutrition were fed a 28% protein and 25% fat milk replacer at a rate of 568 and 680 g / d for wk 1 and wk 2 – 6, respectively. At wk 7 all milk intakes were reduced to 50% to stimulate starter consumption. Calves were weaned when consuming 900 g/d of starter. There were breed × plane of nutrition × time interactions ($P < 0.01$) for milk refusal, starter intake, and total energy intake. Holstein calves fed the lower plane of nutrition had greater starter intakes from wk 4 through wk 8 than Holsteins fed the higher plane of nutrition. Plane of nutrition did not influence starter intake in Jersey calves. Calves fed the higher planes of nutrition had greater total energy intakes before weaning; however, after reducing milk intakes at wk 7 there was no difference within breed. There was an interaction of plane of nutrition and time ($P < 0.01$) on average daily gain; whereas calves fed the higher planes of nutrition had greater gains from wk 1 to 6, but were not different from the calves fed the lower planes of nutrition from wk 7 to 11. Utilization of energy for body weight gain was greater for calves fed higher planes of nutrition ($P < 0.01$) and Holsteins ($P < 0.02$) from wk 1 to 6; however, from wk 7 to 11 the opposite was observed for plane of nutrition ($P < 0.05$) and breed ($P < 0.01$). These data indicate under the current higher plane of milk feeding schemes both Holstein and Jersey calves performed well; however, the amount of milk replacer fed to Jersey calves may be able to be increased during the pre-weaning period.

Key Words: breed, calf, performance

T338 Evaluation of mannanoligosaccharides route of administration for dairy calves: Performance and rumen development. J. T. Silva[1,2], L. S. Ferreira[1,2], and C. M. M. Bittar*[1,2], [1]*University of Sao Paulo/ESALQ*, *Piracicaba, SP, Brazil*, [2]*CNPq*, *Brasília, DF, Brazil*.

The objective of this study was to evaluate the route of administration of mannanoligosaccharides (MOS) for dairy calves and its effects on performance and plasma parameters indicative of rumen development. Following birth, 24 male Holstein calves were used in a completely randomized design and assigned to the following treatments: 1) Control; 2) MOS (4 g/d Bio-Mos, Alltech Biotech.) via starter feed (MOSF); 3) MOS (4 g/d Bio-Mos, Alltech Biotech.) via milk replacer (MOSR). The animals were housed in individual hutches, with free access to water, and fed 4L/d of milk replacer (18.5% CP, 22.5% fat, 12.5% solids; Nattimilk, Auster Animal Nutrition) until weaning at 6 weeks; calves also received a 23% CP starter feed ad libitum. Fecal scores were evaluated daily. Calves were weighted and growth measurements and blood samples for glucose, urea-N (PUN) and β-hydroxybutyrate (BHBA) were taken weekly until the eighth week of age. There was no significant ($P > 0.05$) effect of treatment or treatment × age interaction for average starter feed intake (737.4; 842.6; 798.6 g DM/d for C, MOSF and MOSM, respectively), weight gain (352.2; 411.3; 409.6 g/d for C, MOSF and MOSM, respectively) or body growth (heart girth: 1.63; 1.74; 1.75 cm/week; hip width: 0.43; 0.4; 0.36 cm/week for C, MOSF and MOSM, respectively). However, there was an age significant effect for all parameters ($P < 0.0001$). Fecal scores were not affected by treatments; animals presented scores considered as diarrhea (>2.0) only during the second week of life. Plasma concentration of glucose (81.4; 82.7; 86.7 mg/dL for C, MOSF and MOSM, respectively), PUN (13.7; 14.6; 14.0 mg/dL for C, MOSF and MOSM, respectively) or BHBA (0.203; 0.177; 0.163 mmol/L for C, MOSF and MOSM, respectively) were also not affected ($P > 0.05$) by treatment or the interaction treatment × age. However, PUN and BHBA concentrations were significant increased with age ($P < 0.05$), suggesting adequate rumen development. For the general and nutritional management imposed, there were no benefits of providing MOS via liquid or solid diet.
Supported by FAPESP.

Key Words: additives, early weaning, fecal score

T339 Impact of solids level of colostrum replacer formulations on immunoglobulin absorption in calves. J. M. Campbell*[1], J. C. Gawthrop[2], A. W. Riad[2], L. E. Russell[1], J. D. Crenshaw[1], and J. Q. Quigley[1], [1]*APC, Inc.*, *Ankeny, IA*, [2]*CalfCare*, *North Manchester, IN*.

The objective was to determine if varying level of solids in a single feeding of colostrum replacer (CR) containing IgG derived from bovine serum fractions affected 24-h serum IgG, serum total protein, and the ability of calves to achieve adequate passive transfer. Forty-eight heifer or bull calves were randomly assigned to 1 of 4 treatments that included receiving a single feeding of CR containing 155 g of IgG reconstituted to 17.4, 20.2, 24.1, or 29.7% solids. Sex was equalized among treatments. All CR were blended, individually packaged, and irradiated before feeding. Colostrum replacers were reconstituted in warm water, mixed using a hand blender, and fed with an esophageal feeder at 1 h of age. Acquisition of passive immunity was assessed by measuring 24-h serum IgG, serum total protein, apparent efficiency of absorption (AEA) of IgG, and the ability to prevent failure of passive transfer (FPT). Data were analyzed as a completely randomized design with BW as a covariate when appropriate. Percentage of calves with FPT was analyzed by chi-squared analysis. Linear contrasts were used to produce linear analysis. As level of solids of the blended CR increased from 17.4 to 29.7%, there was a tendency ($P < 0.10$) for increased 24-h serum IgG, while serum total protein was increased ($P < 0.05$). No treatment differences ($P > 0.10$) were noted in AEA or percent FPT. In conclusion, a range of solids level from 17.4 to 29.7% offered in a single feeding of CR containing 155 g IgG from bovine serum fractions can be fed to calves without impacting AEA or FPT.

Key Words: calves, immunoglobulin, colostrum replacer

T340 Effect of yeast β-glucan and antibiotics on growth and intestinal microflora in early-weaning calves. Y. Zhou, Q. Diao*, Y. Tu, and Q. Yun, *Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

This experiment was conducted to investigate the effect of yeast β-glucan and bacitracin zinc on growth performance and intestinal microflora in rectum of early-weaning calves. Twenty neonatal healthy Holstein male calves were randomly allotted to 4 treatments, each treatment contained 5 replicates with one calf per replicate. All calves were fed with diets supplemented with 0 (Treatment A), 75mg/kg yeast β-glucan (Treatment B and C), 60mg/kg bacitracin zinc (Treatment D). The experiment lasted

for 28 d. On d 21, calves of Treatment A, B and D were challenged orally with *Escherichia coli* (O141:K99). Average daily feed intake (ADFI), average daily gain (ADG) and intestinal tract bacterial communities were determined. Comparing with Treatment A, the ADG of calves in Treatment B increased by 26.17% and 24.93% in the 2 phases before the *Escherichia coli* challenged ($P < 0.05$), the ADG of calves in Treatment B and D increased by 30.38% and 30.81% after the *Escherichia coli* challenged($P < 0.05$).As for the F/G, which in Treatment B and D were significantly lower than that in Treatment A ($P < 0.05$). The amount of *Escherichia coli* in rectum was rapidly increased after the challenge, compared with Treatment A, the amount of *Escherichia coli* in rectum at 12h and 24h in Treatment B and D were significantly decreased ($P < 0.05$), and the amount of Lactobacillus was significantly decreased in the Treatment D ($P < 0.05$). PCR-DGGE of 16S rDNA was used to investigate the similarity index, the band number in Treatment C was significant higher than that in Treatment A and D ($P < 0.05$).The degree of similarities of treatments ranged from 50% to 75%. According to the results, β-glucan could improve the growth of claves and adjust the structure of intestinal microflora, thus using β-glucan in calves feed may decreased the usage of antibiotics.

Key Words: calves, yeast β-glucan, intestinal microflora

T341 Effects of forage quality traits and access to calf starter on selection between forages in milk-fed calves. N. B. Kristensen*, M. R. Weisbjerg, and M. Vestergaard, *Aarhus University*, *Tjele, Denmark*.

The present study aimed to investigate how milk-fed calves selected among 4 different grass-clover forages [1st cut silage (F1), 1st cut hay (F2), 2nd cut silage (F3), and 4th cut silage (F4)] and how access to calf starter affected forage selection. Sixteen Holstein bull calves (20 ± 2 d of age) offered 4.84 kg/d of skim-milk based milk-replacer (12.3% DM) were randomly allocated to no starter (CON) or ad libitum access to a barley-based calf starter (START). Calves were housed in individual pens and offered the 4 forages ad libitum. Calves were harvested at 59 ± 2 d of age. Data on DMI and effect of starter on relative intake of individual forages were analyzed using the MIXED procedure in SAS by a model containing the fixed effects of block, time (day on trial), calf starter treatment, and the interaction between treatment and time. Calf by treatment was designated as a random effect and time considered a repeated measure. Friedman′s test computed using the FREQ procedure was used to evaluate selection between forages. The forages had the following nutrient and fermentation product contents: DM (48 ± 1, 88 ± 1, 41 ± 2, and 47 ± 2%), pH (5.33 ± 0.13, 6.01 ± < 0.01, 4.23 ± 0.01, and 4.34 ± 0.02), DL-lactic acid (17 ± 3, not detectable, 69 ± 2, and 89 ± 3 g/kg DM), and acetic acid (4.6 ± 0.7, 0.7 ± 0.2, 14.6 ± 0.6, and 13.0 ± 0.4 g/kg DM) for F1, F2, F3, and F4, respectively. The intake of the individual forages differed ($P < 0.01$) by source being 57 ± 3, 29 ± 3, 4 ± 1, and 10 ± 2% of total forage intake for F1, F2, F3, and F4, respectively. Only intake of F4 was affected by calf starter (START: 14 ± 2% vs. CON: 6 ± 2%, $P = 0.02$). Forage intake tended ($P = 0.09$) to be lower with START compared with CON, but total daily intake of calf starter + forage did not differ ($P = 0.47$) between treatments (39 d average being 714 and 771 ± 55 g DM/d for CON and START, respectively). Young milk-fed calves showed strong preference for lightly fermented grass-clover silage compared with both hay and more fermented silages, and the preference pattern was unaffected by the access to a barley-based calf starter.

Key Words: milk-fed calf, forage quality, feed intake

T342 Performance of calves fed an all-milk or enzymatically modified plant protein containing milk replacer with and without a specific amino acid profile. F. Soberon*, A. M. Severy, and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

The most nutritionally effective milk replacers (MR) are produced from all milk proteins. Supplementing non-milk protein MR with amino acids (AA) might help overcome some of the performance limitations previously observed with the use of plant proteins. The objectives of this study were to compare the performance of calves fed an all-milk containing MR compared with a MR with 50% of the protein replaced by a proprietary formulation of enzymatically modified plant proteins (EPP) as formulated or with a specific AA profile calculated from body composition and efficiency of use data. Eighty calves (20 per treatment, TRT) were assigned, as they were born, by 24 h of age. Calves were blocked by birth weight and sex and assigned to one of 4 TRT: Control: all milk protein MR (Excelerate milk replacer, Milk Specialties Global (MSG), Carpentersville, IL); TRT 1: Control plus AA supplied by added crystalline AA; TRT 2: EPP containing MR formulated at 28% CP and 15% fat containing proprietary EPP protein (MSG, Carpentersville, IL) representing approx. 50% of the MR protein; TRT 3: EPP containing MR with supplemental AA. All MR were formulated to be isocaloric and isonitrogenous. Significance was declared at $P < 0.05$. Calves were fed only MR to d 28, offered grain from d 29 to 42, and then weaned in a step-down manner over 7 d. Growth and starter intakes were measured until d 70. ADG (kg/d) data are reported in the table. Calves fed the all-milk containing MR had greater ADG up to weaning ($P < 0.05$) whereas post-weaning, increased starter intake in calves fed TRT 2 and 3 negated the growth advantage. Calves fed TRT 1 demonstrated greater hip height by d 49 compared with calves fed TRT 2 and 3 ($P < 0.05$) and the difference remained until d 70. Prior to weaning performance was greater in calves fed milk protein base MR.

Table 1.

TRT	Day 28	Day 49	Day 70
Control, kg/d	0.72[a]	0.74[a]	0.73[a]
TRT 1, kg/d	0.74[a]	0.73[a]	0.71[a]
TRT 2, kg/d	0.63[b]	0.66[b]	0.70[a]
TRT 3, kg/d	0.59[b]	0.63[b]	0.69[a]

Values with different superscripts within column differ $P < 0.05$.

Key Words: amino acids, calves, milk replacer

T343 Measurement of adaptive and innate immune function in calves raised under traditional and accelerated growth regimens. B. A. Hengst*[1], L. M. Nemec[1], R. R. Rastani[2], and T. F. Gressley[1], [1]*University of Delaware*, *Newark*, [2]*Milk Specialties Global Animal Nutrition*, *Carpentersville, IL*.

This study compared conventional and accelerated milk replacer feeding regimens on growth, respiratory and digestive health, vaccination response, and neutrophil mRNA levels. Holstein calves (10 male and 5 female) were randomly assigned to a 10-wk study on d 2 of life. Treatments were control (CON; n = 8) and accelerated (ACC; n = 7) milk replacer feeding programs. CON calves were fed a 20% crude protein (CP)/20% fat milk replacer (Advance Calvita Supreme; Milk Specialties Global, Carpentersville, IL) at 1.25% birth body weight (BW) from wk 1 to 6 and 0.625% birth BW during wk 7. A 28.5% CP/15% fat milk replacer (Advance Excelerate; Milk Specialties Global, Carpentersville, IL) was fed to ACC calves at 1.5% birth BW during wk 1, 2% current BW from wk 2 to 6, and 1% current BW during wk 7. All calves were

given milk replacer twice daily during wk 1 to 6, once daily during wk 7, and were weaned completely during wk 8. Calf starter intake was measured daily through wk 8. BW and wither height were measured weekly. Fecal scores (1 = firm to 4 = liquid) and respiratory scores (1 = normal; 2 = abnormal) were recorded twice daily. Neutrophils were isolated from blood at wk 1, 3, 5 and 8. Quantitative PCR was used to measure neutrophil mRNA levels of 7 functionality genes including the adhesion factor *L-selectin* (CD62L). Adaptive immune function was measured by vaccinating calves against ovalbumin at wk 1, 3 and 5 and measuring anti-ovalbumin IgG production at wk 1, 3, 5 and 8. There was no treatment effect on wither height, respiratory score, or anti-ovalbumin IgG production. BW during wk 4 to 10 was greater for ACC than CON calves ($P < 0.01$). Calf starter intake was greater for CON than ACC calves during wk 4 to 7 ($P < 0.01$), with no difference during wk 8. CON calves had firmer feces than ACC calves (fecal score 1.4 vs. 1.7, $P = 0.02$). Neutrophil *L-selectin* mRNA levels were 51% greater in ACC than CON calves ($P = 0.03$). Feeding calves a 28.5% CP/15% fat milk replacer in an accelerated feeding regimen increased growth and may enhance innate immune function, as indicated by the increased neutrophil mRNA levels of *L-selectin*.

Key Words: dairy calf, immune function, milk replacer

T344 Effects of hay intake on calves fed high volumes of milk. M. A. Khan*[1], D. M. Weary[1], D. M. Veira[2], and M. A. G. von Keyserlingk[1], [1]*University of British Columbia*, *Vancouver, BC, Canada*, [2]*Agriculture and Agri-Food Canada*, *Agassiz BC, Canada*.

Research to date has suggested that access to forage before weaning can limit rumen development in calves fed restricted amount of milk, but no research has addressed the role of forage on calves fed at higher planes of nutrition. This study compared performance and rumen development of calves provided high volumes of milk with and without access to hay. At d 3 of age, individually housed calves were randomly assigned to treatment (either ad libitum access to chopped grass hay or no forage; n=15 calves per treatment, 10 heifers and 5 bulls). All calves were provided ad libitum access to water and starter throughout the study. All calves were offered 8 L/d of milk from a nipple bottle from d 3 to 35, 4 L/d from d 36 to 53 and 2 L/d for the next 3 d before weaning at d 56. Solid feed intake and growth were monitored from d3 to d70. At d 70 males from both treatments were slaughtered and rumen pH and weight of ruminal contents with and without digesta measured. Overall DMI from solid feed did not differ between treatments before weaning. After weaning calves provided hay consumed less starter but more total DM (starter plus hay) than calves that had no access to forage. Over the experimental period (d 4 to 70), calves fed hay gained approximately 6 kg more than did control calves (58.14 ± 1.83 vs. 52.04 ± 2.03 kg, respectively; $P < 0.05$). Hip and wither height, heart girth and body barrel at d 35, 56 and 70 did not differ between treatments. Rumen and reticulum weights with (7.99 ± 0.69 vs.12.77 ± 1.29 kg; $P < 0.05$) and without digesta (1.60 ± 0.09 vs. 1.89 ± 0.05 kg; $P < 0.05$) were heavier in calves fed hay. Mean rumen pH was higher in calves fed hay compared with those fed no forage (5.49 ± 0.08 vs. 5.06 ± 0.04; $P < 0.002$). In conclusion, providing hay before weaning resulted in increased weight gain, rumen weight and rumen pH in calves fed high volumes of milk.

Key Words: solid feed, forage, weaning

T345 Influence of milk replacer feeding program on pre- and post-weaning performance and health of dairy calves. D. Carlson*[1], B. Ziegler[2], D. Schimek[2], M. Raeth-Knight[3], G. Golombeski[3], J. Linn[3], D. Ziegler[4], and H. Chester-Jones[4], [1]*Milk Products LLC*, *Chilton, WI*, [2]*Hubbard Feeds, Inc.*, *Mankato, MN*, [3]*University of Minnesota*, *St. Paul*, [4]*University of Minnesota, Southern Research and Outreach Center*, *Waseca*.

Holstein heifer calves (n = 100, 2–4 d of age) were assigned randomly to 1 of 4 milk replacer (MR) programs to evaluate the effect of MR feeding rate and crude protein (CP) intake on calf performance and health during pre- (d 1–42) and post-weaning (d 43–56) periods. Treatments (TRT) were: 1) 20% CP, 20% fat MR fed at 0.57 kg/d (as-fed powder weight) from d 1–35 and 0.28 kg/d from d 36–42 (CON); 2) 20% CP, 20% fat MR fed at 0.68 kg/d from d 1–14, 0.45 kg/d from d 15–35, and 0.23 kg/d from d 36–42 (TRT 2); 3) 24% CP, 18% fat MR fed at 0.68 kg/d from d 1–14, 20% CP, 20% fat MR fed at 0.45 kg/d from d 15–35 and 0.23 kg/d from d 36–42 (TRT 3), and 4) 28% CP, 16% fat MR fed at 0.68 kg/d from d 1–14, 20% CP, 20% fat MR fed at 0.45 kg/d from d 15–35 and 0.23 kg/d from d 36–42 (TRT 4). Calves were fed MR twice daily from d 1–35, and once daily from d 36–42. Calves were housed in individual calf pens within a naturally ventilated barn with curtain sidewalls, were fed a texturized calf starter (18% CP), and had access to fresh water. Average daily gain (ADG) during d 1–14 was greater ($P < 0.05$) for TRT 2, 3, and 4 versus CON, and TRT 4 had greater ($P < 0.05$) ADG than TRT 2 and 3. For d 15–28, ADG was lower ($P < 0.05$) for TRT 2, 3, and 4 compared with CON. Milk replacer feeding program did not affect ADG from d 29–56, 1–42, or 1–56. Calf starter intake was similar for d 1–14, whereas TRT 4 had greater ($P < 0.05$) starter intake than CON with TRT 2 and 3 being intermediate for d 15–28. For d 29–42, TRT 3 and 4 had greater ($P < 0.05$) starter intake than CON with TRT 2 intermediate. Health parameters did not differ among groups. Under the conditions of this study, increasing MR feeding rate and feeding 28% CP MR resulted in greater ADG from d 1–14, but reducing MR feeding rate and CP intake on d 14 resulted in depressed ADG from d 15–28.

Key Words: calves, milk replacer, feeding rate

T346 The effect of feeding dairy heifers diets with and without supplemental phosphorus for 18 months on growth, reproductive efficiency and lactation performance. D. W. Bjelland*[1], N. M. Esser[1], K. A. Weigel[1], P. C. Hoffman[1], and W. K. Coblentz[2], [1]*University of Wisconsin*, *Madison,* [2]*USDA-ARS Dairy Forage Research Center, Marshfield, WI.*

The phosphorous (P) requirements for dairy heifers (0.20–0.35%) and endogenous levels (0.20–35%) of P in feeds fed to dairy heifers are similar, suggesting that the need for supplemental P in dairy heifer diets may be minimal. Because long-term studies are unavailable, 183 Holstein heifers and 182 backcross Holstein × Jersey heifers were fed diets with (SP = 0.38% of dry matter (DM)) and without (NP = 0.28% of DM) supplemental phosphorus from 4 to 22 mo of age in a replicated pen design. Heifers were evaluated for body weight (BW), external bone/frame growth, dystocia, calf BW, reproductive efficiency, and first lactation performance. Data were analyzed using a mixed model with effects of season of birth, age of dam, pen number as a heifer, sire, sire birth year, and days in milk. No breed × diet interactions were observed. Heifers fed NP had similar average daily gain from 170 to 410 (0.86 vs. 0.83 kg/d) and 410–650 (0.85 vs. 0.86 kg/d) d of age as compared with heifers fed SP. At 22 mo of age, heifers fed NP were wider at the hip but did not differ in BW, hip height, body length, heart girth, cannon bone circumference or pelvic area as compared with heifers fed SP. As heifers, services per conception (1.45 vs. 1.39), age at pregnancy (451 vs. 452 d), and age at first calving (726 vs. 727 d) were not different between heifers fed NP or SP. At parturition, heifers fed NP or SP had similar dystocia scores and calves were similar in BW. Complete first

lactation data (305 d) were available for 333 primiparous cows, and cows fed NP as heifers produced similar milk (8702 vs. 8714 kg), fat (330 vs. 328 kg) and protein (274 vs. 277 kg) as cows fed SP as heifers. Days open (152 vs. 160 d), days in milk at first breeding (76 vs. 76 d), and services per conception (1.82 vs. 1.85) were also similar for primiparous cows fed NP or SP as heifers. Data suggest there was no growth, reproductive or lactation benefit to feeding dairy heifers diets containing 0.38% P as compared with 0.28% P.

Key Words: dairy heifers, phosphorous, lactation performance

T347 The effect of *Megasphaera elsdenii* NCIMB 41125 (Me) on performance of pre-weaned dairy calves. F. M. Hagg*[1], C. M. Muya[2], and P. H. Henning[1], [1]*MS Biotech*, *Centurion, South Africa*, [2]*ARC-Irene*, *Centurion, South Africa*.

Dairy farmers often aim to wean calves as early as possible. They are usually weaned upon reaching a target starter diet intake, so that rapid increase in feed intake becomes an important attribute. Field observations suggest that dosing pre-weaned calves with Me, as a DFM, has a positive effect on their well-being and performance. The objective of this study was to determine if dosing calves with Me could reduce weaning time by increasing the rate at which intake of dry feed increases in pre-weaned calves. Forty pre-weaned Holstein dairy calves entered the trial 14 d after birth, as they became available. The first calf was randomly allocated to one of the 2 treatments and all subsequent calves were alternately allocated to one or the other treatment. Me-treated calves received a single oral dose of Me (50 mL, 10^8 cfu/mL) on d 14. Control calves received no Me but were treated similar in all other respects. Commercial calf starter (18% CP) was fed ad lib while milk supply was restricted. Water was supplied ad lib. Feed, water and milk intake were measured daily while calves were weighed once per week. Calves were weaned upon reaching a DMI of 1.0 kg/d. Four additional calves, 2 each for treatment and control, and handled similar to the others, were slaughtered 72 h after dosing for rumen and colon samples to measure Me using Q-PCR. Me-treated calves had a greater ($P = 0.11$) rate of increase in DMI (37.0 vs. 28.6 g/d) and greater ($P = 0.02$) water intake (3.2 vs. 2.4 kg/d). Milk intake (3.46 and 3.51 kg/d) and ADG (480 and 437 g/d), for Me and control respectively, did not differ ($P = 0.63$ and $P = 0.44$) significantly. Me treatment decreased ($P = 0.21$) the number of days from birth to weaning (40 d vs. 44 d) and Me-treated calves had 67% less mortalities than the untreated calves. Me-treated calves had greater Me levels than controls in both rumen (1.4×10^9 vs. 1.6×10^6 genomes/mL) and colon (1.4×10^7 vs. $<1 \times 10^3$ genomes/mL). These results suggest that dosing calves with *Megasphaera elsdenii* NCIMB 41125 establish the organism in the GIT and may benefit calves through increased DMI and earlier weaning.

Key Words: *Megasphaera elsdenii*, dairy calves, early weaning

T348 Influence of nonmedicated additives as alternatives to antibiotics on calf health, growth, and intestinal development. S. I. Kehoe*[1], D. B. Carlson[2], and E. O. Hardwick[1], [1]*University of Wisconsin-River Falls*, *River Falls,* [2]*Milk Products, Inc., Chilton, WI.*

Many producers use medicated milk replacers to prevent scours in dairy calves, however, a commonly added level of neomycin and oxytetracycline is no longer approved. The objective of this trial was to determine whether a milk replacer with a blend of nonmedicated additives would have similar benefits to a milk replacer with added neomycin and oxytetracycline. Twelve bull calves were purchased from a local farm 3 separate times and were fed one of 3 treatments for a 5 week period. All treatments used a 20% fat, 20% crude protein milk replacer with either no additives (C), a blend of nonmedicated additives (NM; animal plasma, yeast cell wall extracts, inulin, and a direct-fed microbial), or neomycin and oxytetracycline (MED; 400 g/ton of neomycin; 200 g/ton of oxytetracycline). Two calves from each treatment were slaughtered during their second day of scouring and intestinal tissues were collected for morphological analyses. The surviving calves were fed until 3 weeks of age when they were moved to indoor individual pens and grain starter was offered. Weekly growth parameters were recorded and blood was analyzed for blood urea nitrogen (BUN) and glucose concentrations. Results indicate there were no significant differences between treatments for BUN, glucose, and serum protein. Feed intake was also not significant (C 652.4g, NM 759.4g, MED 687.5 g) however, hematocrits were highest for C compared with NM and MED (65.9 vs. 57.5 and 56.3%, respectively; $P < 0.005$). Fecal scores were significantly higher for C than NM and MED (1.9 vs. 1.5 and 1.5, for C, NM and MED, respectively). Intestinal weights and lengths were not significant except for colon weight which was lower for NM than for MED or C ($P < 0.02$). Although not statistically analyzed, fecal results indicate C had the highest density of *E. coli*. Growth parameters were also not significant; however, heart girth was lower in C compared with NM and MED (32.7 vs. 33.1 and 33.5, respectively; $P < 0.005$). These results indicate that nonmedicated additives may have some effect in reducing diarrhea and dehydration, and promoting some growth.

Key Words: calves, milk replacer, health

T349 Pre- and post weaning performance and health of calves fed milk replacers and calf starters with or without yeast supplementation (Nupro) and growth performance from 9 to 25 weeks of age. H. Chester-Jones*[1], J. Tricarico[2], D. Ziegler[1], K. Dawson[2], P. Groenewegen[2], M. Raeth-Knight[3], and G. Golombeski[3], [1]*University of Minnesota Southern Research and Outreach Center*, *Waseca,* [2]*Alltech Inc., Nicholasville, KY,*[3]*University of Minnesota Southern Research and Outreach Center, St. Paul.*

One hundred seven (2- to 4-d-old) individually housed Holstein heifer calves (39.1 ± 0.68kg) were randomly assigned to 1 of 4 treatments to evaluate the effect of supplementing natural yeast (NuPro; NP) in milk replacer (MR) and calf starter (CS) on performance and health pre- (d 1–42) and post-weaning (d 43–56). All calves were fed a 20:20 MR (CP:fat) containing 12.5% solids and an 18% CP starter. Nursery treatments were: 1) 0% NP in calf MR and CS (CON); 2) 5% NP in MR and 0% in CS (NPMR); 3) 0% NP in MR and 2.5% NP in CS (NPCS); and, 4) 5% NP in MR and 2.5% NP in CS (NPMRCS). Milk replacers for all treatments was fed at 0.57 kg/d (as-fed powder weight) twice daily from d 1 to 35 and at 0.28 kg/d 1X daily from d 36 to 42. Calf growth up to 25 wk of age was also monitored in all calves receiving the above nursery treatments when they were housed in group pens (7 calves/pen) and fed a common grower diet from 9 to 25 weeks of age. Pre-weaning ADG tended to be higher ($P = 0.08$) for CON calves than those fed the other treatments. Post weaning gain was lowest for NPMR and NPMRCS calves ($P < 0.05$). Overall 56 d ADG was highest for CON calves ($P < 0.05$). There were no pre- weaning and overall 56 d differences in CS and total DMI. Pre-weaning feed/gain (FG) was higher for NPMR vs. NPMRCS calves ($P = 0.04$). Post weaning FG was lower ($P < 0.05$) for CON and NPMR vs. NPCS calves. There were no differences in pre-weaning scouring days across treatments. There were no effects of nursery feeding programs on calf growth when fed a common diet from 9 to 25 wk of age. Under the conditions of this study supplementing nursery programs with a natural yeast supplement did not enhance individual or group fed heifer calf performance.

Key Words: calf performance, feeds, yeast supplementation

T350 Pre- and post weaning performance and health of calves fed milk replacers and calf starters with or without essential oils. H. Chester-Jones*[1], T. Steiner[2], M. Watkins[3], D. Taylor[3], D. Ziegler[1], M. Raeth-Knight[4], and G. Golombeski[4], [1]*University of Minnesota, Southern Research and Outreach Center*, *Waseca*, [2]*BIOMIN Holding GmbH*, *Herzogenburg, Austria*, [3]*BIOMIN America Inc.*, *San Antonio, TX*, [4]*University of Minnesota*, *St. Paul*.

One-hundred thirty (2- to 4-d-old) individually fed Holstein heifer calves (40 ± 0.73 kg BW) were randomly assigned to 1 of 5 treatments to evaluate the effect of supplementing essential oils (Biomin P.E.P.) in milk replacer (MR) and calf starter (CS) on performance and health pre-(d 1–42) and post-weaning (d 43–56). Treatments were: 1) Medicated MR and a 18% CP (as-fed) texturized calf starter with rumensin (0.033 mg/kg; CON); 2) Non-medicated MR and CS with no additives (NM); 3) Non-medicated MR with PEP (0.88 g/kg) and CS with no additives (NMPEP); 4) Non-medicated MR and CS with PEP (0.41 g/kg; CSPEP); and 5) Non-medicated MR and CS with PEP (MRCSPEP). A 20:20 (CP:fat) milk replacer containing 12.5% solids, was fed at 0.57 kg/d (as-fed powder weight) twice daily from d 1 to 35 and at 0.28 kg/d 1X daily from d 36 to 42. Pre-weaning ADG was higher ($P < 0.05$) for CON and NMPEP calves vs. those fed NM and MRCSPEP. Post weaning ADG was higher ($P < 0.05$) for CSPEP vs. CON and NM calves. Overall ADG was lower ($P = 0.02$) for NM calves vs. NMPEP, CSPEP and MRCSPEP calves. Calves fed NMPEP had higher ($P = 0.04$) overall ADG than MRCSPEP calves. Total calf starter and DMI for NMPEP calves tended to be higher vs. those fed NM ($P < 0.07$) and MRCSPEP ($P < 0.09$). There were no treatment differences in total DMI. Pre-weaning feed/gain (FG) was lowest for CON and NMPEP vs. other treatments. Post weaning FG was similar ($P > 0.05$) across all treatments. There were no treatment differences in scouring days or health costs. In this study, feeding a non-medicated MR with PEP and a CS without additives resulted in similar calf performances compared with a medicated MR and CS with rumensin. There were no benefits of offering non-medicated MR without PEP and CS with PEP or a combination of non-medicated MR and CS with PEP.

Key Words: calf performance, milk replacer, calf starter

T351 Pre- and post weaning performance and health of calves fed texturized calf starters with different levels of monensin and affect on growth from 9 to 25 weeks of age. H. Chester-Jones*[1], B. Ziegler[2], D. Schimek[2], D. Ziegler[1], M. Raeth-Knight[3], G. Golombeski[3], and J. Linn[3], [1]*University of Minnesota Southern Research and Outreach Center*, *Waseca*, [2]*Hubbard Feeds Inc.*, *Mankato, MN*, [3]*University of Minnesota Southern Research and Outreach Center*, *St. Paul*.

One-hundred twenty three (2- to 4-d-old) individually fed Holstein heifer calves (40.3 ± 0.77kg) were randomly assigned to1 of 4 treatments to evaluate pre- (d 1–42) and post weaning (d 43–56) calf performance and health when fed 18% CP (as-fed) texturized calf starters (CS) with varying monensin levels. All calves in the nursery were fed a medicated 20% fat:20% protein milk replacer at 0.284 kg in 1.99 L water (12.5% solids) 2X daily for the first 35 d and 1X daily from d 36 to weaning at 42 d. Calf starters were fed free choice from d 1 and calves had access to fresh water. The formulated CS monensin treatment levels were 1), none; 2), 33 mg/kg; 3), 49.5 mg/kg; and, 4) 66 mg/kg. Monensin level did not affect ($P > 0.05$) pre- and post weaning ADG which averaged 0.69 kg/d for 56 d. Overall starter intake decreased linearly ($P = 0.02$) with increasing dietary monensin. Feed/gain was similar ($P < 0.05$) across CS fed (average 1.9 kg/kg gain). There were no health differences across treatments. Calves were transitioned to grower pens (7 heifers/pen) and performance was monitored from 9 to 25 wk of age. Calves were limit-fed a common 16% CP grain mix containing monensin (42.9 mg/kg d1–84, and 71 mg/kg d 85–112) fed at 2.72 kg for 56 d then 2.27 kg for an additional 56 d with free choice hay. Overall 112 d ADG in the grower period linearly increased ($P = 0.06$) for calves fed increasing monensin levels in the nursery. Under the conditions of this study increasing monensin levels in the CS during the nursery phase did not affect daily gain but starter intake decreased. Calves fed increasing levels of monensin in the nursery tended to show performance compensation when fed a common diet in group pens.

Key Words: calf performance, calf starters, monensin levels

T352 Effect on feed sorting of adding plain or flavored water to a TMR for heifers. A. Mereu[1], A. Puddu[2], I. R. Ipharraguerre*[1], and A. Bach[2,3], [1]*Lucta SA*, *Barcelona, Spain*, [2]*IRTA-Ruminant Production*, *Caldes de Montbui, Spain*, [3]*ICREA*, *Barcelona, Spain*.

The impact on feed sorting of adding plain or flavored water to a TMR was evaluated using 24 Holstein heifers (315 ± 24 kg of BW) in a replicated 3 × 3 Latin square design with 14-d periods. Once daily, heifers were fed individually for ad libitum intake a TMR (16.5% CP, 33.8% NDF) composed of 40% ryegrass hay and 60% concentrate. Treatments resulted from the addition of plain (WET; 55.8% DM) or flavored water (FLAV; 53.7% DM) to the ryegrass hay of a control diet (DRY; 90.2% DM). A flavor combined with a sweetener (Luctarom SFS-R) was mixed with tap water and applied to the hay at 250 g/ton of diet. Dietary particle size distribution was measured with the Penn State Particle Separator determining 4 fractions (long, medium, short and fine) at 0, 6, 12 and 24 h after feeding during the last 2 d of each period. Data were analyzed using a mixed model with animal (period) treated as random variable and treatment, period and their interaction treated as fixed effects. There were no significant differences on DMI. Both ADG and G:F were numerically greater for FLAV (1.41 kg/d and 0.18, respectively) when compared with WET (1.19 kg/d and 0.15, respectively) and DRY (1.34 kg/d and 0.17, respectively). Six hours after feeding, FLAV heifers reduced ($P < 0.05$) the preferential consumption of fine particles (<1.18 mm) compared with DRY and WET. At 24 h post-feeding, heifers in the DRY group consumed proportionally less ($P < 0.05$) long particles (>19 mm) and tended ($P < 0.15$) to consume a larger proportion of fine particles when compared with those receiving the WET and FLAV rations. Findings from this study indicate that plain or flavored water addition to the TMR can contribute to limit the sorting of long particles by heifers. Furthermore, flavor addition can enhance hay palatability and thereby minimize the preferential consumption of fine particles within the first 6 h post-feeding.

Key Words: sorting, palatability, flavor

T353 Effect of including corn distillers dried grains in calf feeds. F. X. Suarez-Mena*[1], A. J. Heinrichs[1], T. M. Hill[2], H. G. Bateman II[2], J. M. Aldrich[2], and R. L. Schlotterbeck[2], [1]*The Pennsylvania State University*, *University Park*, [2]*Nurture Calf Research, Provimi North America*, *Lewisburg, OH*.

A series of 5 trials were conducted to determine the effect of distillers dried grains with solubles (DG) in calf diets. Trial 1 compared 0 and 49% DG in 18% CP starters (as-fed basis) fed to calves initially 2 to 3 d old for 56 d. Digestibility was estimated during d 52 to 56 using chromic oxide. Trial 2 compared 0 and 39% DG in 16% CP growers fed to calves from 8 to 12 wk of age from 28 d. Trial 3 compared 0, 10, and 20% DG in 18% CP starters fed to calves initially 2 to 3 d old for 56 d. Trial 4 compared 0 and 20% DG in 16% CP growers fed to calves from 8 to 12 wk of age from 28 d. As DG increased in all the

experiments, ADF, NDF, and fat increased and calculated metabolizable energy (ME) was similar but not equalized. In Trials 1 and 3, calves (48 calves/trial) housed in individual pens were fed a 26% CP, 17% fat milk replacer powder and weaned at 28 d. Trials 2 and 4 used calves (48 calves per trial) housed in group pens (6 calves/pen) that had been weaned from 28 d before the trials start. Trial 5 (18 calves) had same treatments as Trial 3, with calves killed at 35 d to determine DG effects on rumen development. All trials were completely randomized designs. Calf was the experimental unit (EU) in Trials 1, 3 and 5, and pen was the EU in Trials 2 and 4. In Trial 1, ADG was 6% greater and dry matter digestibility was 10% greater ($P < 0.05$) for calves 0% vs. 49% DG. In Trial 2, ADG (9%), feed efficiency (10%), and hip width change (19%) were greater ($P < 0.05$) for calves 0% vs. 39% DG. In Trial 3, performance measures did not differ among starter treatments. Calf ADG were numerically 4% greater ($P > 0.50$) in calves fed 0% vs. 10 or 20% DG. In Trial 4, ADG (4%), feed efficiency (5%), and hip width change (19%) were greater ($P < 0.05$) for calves fed 0% vs. 20% DG. Thus, these results suggest that high levels of distillers in calf starters and growers reduce calves growth.

Key Words: corn distillers dried grains with solubles, calf digestion, rumen development

T354 Determination of oro-sensorial preferences of protein ingredients in weaned calves. C. Montoro*[1], I. Ipharraguerre[2], and A. Bach[1,3], [1]*Ruminant Production, IRTA*, *Caldes de Montbui, Barcelona, Spain*, [2]*Lucta S.A.*, *Barcelona, Spain*, [3]*ICREA*, *Barcelona, Spain*.

The objective of this study was to determine oro-sensorial preferences among common protein feed ingredients used to manufacture calf starters. A total of 15 assays involving 160 calves were conducted to rank calf oro-sensorial preferences for wheat distillers dried grains (DDG), corn gluten meal (CGM), peas, rapeseed meal (RSM), soybean meal (SBM) and sunflower meal (SFM). To minimize the effect of feed texture, all ingredients were ground at 3 mm. In each assay, 20 naive calves were offered a choice ad libitum of 2 ingredients and feed consumption was monitored every 30 min for 6 h. Each group of calves was used in 2 different assays which were conducted 3 and 5 d after weaning. No calf was presented twice with the same ingredient. Oro-sensorial preferences were calculated as the mean difference in feed consumption every 30 min over a 6-h period. Feed preferences were determined using a mixed-effects model. The most preferred protein ingredients were soybean meal and DDG, whereas CGM was the least preferred. Soybean meal was the most preferred ingredient in all assays and consumption was clearly greater than for the others ingredients (Table 1). On the other hand, CGM was the least preferred ingredient in all assays. Results indicate that SBM and DDG should be the preferred protein sources and CGM should be avoided when formulating starters for calves.

Table 1. Ingredient (Ingr) dry matter intake (DMI) per assay (g/30 min)

Ingr 1	DMI 1	Ingr 2	DMI 2	P-value	Ingr 1	DMI 1	Ingr 2	DMI 2	P-value
DDG	67.77	CGM	11.54	<0.0001	CGM	5.71	PEA	78.02	<0.0001

Key Words: palatability, preferences, intake

T355 Effect of dietary supplementation of exogenous polysaccharide-degrading enzymes on blood metabolites and rumen fermentation and nutrient digestibility for Holstein heifers. C. Y. Guo*, Q. Y. Diao, N. F. Zhang, and Y. Tu, *Chinese Academy of Agricultural Sciences*, *Beijing, China*.

The objective of this job was to investigate the effect of supplementation poly-saccharide-degrading enzymes (EPDE) to TMR diets on their blood metabolites and rumen fermentation and nutrient digestibility for 12 weeks to 24 week Holstein heifers. The treatments were as follows: control (no EPDE), EPDE sprayed onto and mixed with the daily ration (EF, 20.0 g/d). Feed samples were collected once weekly, feed refusals and fecal samples were collected twice weekly. Ruminal fluid was collected from rumen tube. Plasma was collected by centrifugation at 1800xg for 30 min and stored at −20°C until it was analyzed. We chose to measure serum total protein and plasma urea nitrogen (PUN) to evaluate protein metabolism and triglyceride concentrations as indices for fat metabolism. Data were analyzed using the general linear model ANOVA procedures of SAS. The results show that enzyme treatment increased the concentration of soluble reducing sugars ($P < 0.05$) and decreased NDF content ($P < 0.05$) in the treated feed. Compared with control, ruminal fermentation was affected by EF ($P < 0.05$), ruminal VFA patterns were changed. Ruminal carboxymethylcellulase (CMCase) and xylanase activities were not affected by treatment. In a digestion trial, heifers were fed EPDE 20g/heifers per day, and total faces were collected. Compared with control, enzyme treatment increased the apparent digestion of DM ($P < 0.05$), acid detergent fiber ($P < 0.05$). Crude protein in the diet tend to increase numerically. The results of evaluate lipid metabolism and protein metabolism showed that add EPDE to diet have no significant effect on PUN, total albumin, total cholesterol, triglyceride. But numerically, supplement of EPDE decreased total albumin and total cholesterol in plasma and increased the concentrate of blood glucose in plasma. In conclusion, adding EPDE to diets could improve feed nutrition digestibility, especially enhance NDF and ADF digestibility (DM basis), change ruminal fermentation, and have no effects on lipid metabolism and protein metabolism.

Key Words: exogenous enzymes, Holstein heifers, rumen fermentation

T356 Relationships between chewing behavior, digestibility and digesta kinetics parameters in calves fed restricted and ad libitum levels of oat hay. R. S. Dias[1], H. O. Patino[2], S. López[3], E. Prates[2], K. Swanson*[1], and J. France[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Universidade Federal do Rio Grande do Sul*, *Porto Alegre, Rio Grande do Sul, Brazil*, [3]*IGM, CSIC-Universidad de León*, *León, Spain*.

The objective of this study was to elucidate relationships between chewing behavior, digestibility and digesta kinetics parameters in steers fed restricted and ad libitum levels of oat hay. Four male Herefords with an average initial weight of 136 kg were used in an experiment conducted as a Latin square with 4 treatments and 4 periods. Animals were fed 4 levels of oats hay DM (*Avena strigosa* L.) namely: 1.5, 2.0, 2.5% BW/day and ad libitum representing the treatments T1, T2, T3 and T4, respectively. Chewing behavior, digestibility, and digesta kinetics measurements were recorded. Most of the measured parameters were better related to OM intake scaled by metabolic weight. Rumination and eating chewing rate (chews/min/g OM/kg$^{0.75}$) decreased with increased OM intake whereas total chewing and total time spent on each chewing activity increased. Calculated total energy expended by chewing activity was 4.2, 4.4, 5.2 and 5.3%, of ME intake for T1, T2, T3 and T4 respectively. Digestibility of OM, DM, ADF, NDF, hemicellulose and

cellulose decreased with increased OM intake. Retention time (h) was strongly related to OM intake (g/kg$^{0.75}$/day) (r = – 0.85), OM digestibility (r = 0.84) and with ruminating (r = 0.81) and eating chewing rate (r = 0.80) highlighting the relationship between chewing behavior and the digestive process. Fractional outflow rate from the reticulo-rumen and that from the cecum-colon were positively related to total chews, indicating that decrease in particle size facilitates particle flow through the digestive tract. In conclusion, the results of this study show that animals fed a restricted diet altered their chewing behavior when eating and ruminating by increasing chewing rate (chews/min/g OM/BW$^{0.75}$), which was also related to retention time and digestibility.

Key Words: chewing behavior, digestibility, digesta kinetics

T357 Effect of different feeding regimens on growth performance and health of Sahiwal calves during pre-weaning period. S. A. Bhatti*[1], M. F. Ahmed[1], D. McGill[2], M. Sarwar[1], M. Afzal[3], E. Ullah[1], M. A. Khan[4], M. S. Khan[1], R. Bush[5], and H. M. Warriach[2], [1]*University of Agriculture*, *Faisalabad, Pakistan*, [2]*EH Graham Centre (NSW Industry and Investment and Charles Sturt University)*, *Wagga Wagga, Australia*, [3]*Pakistan Agricultural Research Council*, *Islamabad, Pakistan*, [4]*Livestock Production Research Institute*, *Bahadurnagar, Okara, Pakistan*, [5]*University of Sydney*, *Camden, Australia*.

The objective of the study was to examine the growth potential of Sahiwal calves using recommended feeding practices (milk/milk replacer with concentrates and forage) in a clean environment. For this purpose, Sahiwal calves (n = 48; 24 of each sex 3 ± 2 d of age born in January/February 2009) were maintained in raised individual pens until weaning at d 84. Four groups each of 12 animals (6 of each sex) were offered liquid feed as either whole cow′s milk or a commercial milk replacer (MR; reconstituted to specification; Sprayfo) to 10% of their body weight (traditional recommendation in Pakistan) from d 3 ± 2 and solid feed as either a starter ration (SR; prepared at the University CP = 20%, TDN = 72%) plus Berseem hay (H; Egyptian Clover; CP = 21% TDN = 63%) or H only ad libitum from d 7. The milk or MR was withdrawn gradually from d 56 until weaned completely by d 84 but not the solid feed. The data were analyzed using repeated measure analysis by MIXED procedures of SAS. Calves offered milk grew faster than those offered MR (357 ± 8 vs. 162 ± 8; $P < 0.05$) and displayed higher weaning weights (51.6 ± 0.7 vs. 35.2 ± 0.7; $P < 0.05$). Similarly calves offered SR plus H grew faster (311 ± 8 vs. 208 ± 8 g/d; $P < 0.05$) and developed higher weaning weights (48.7 ± 0.7 vs. 38.1 ± 0.7 kg; $P < 0.05$) than those fed H alone. Male calves offered milk plus SR and H showed the highest growth rate and weaning weights (459 ± 16 g/d and 62.9 ± 1.4 kg, respectively). The lowest growth rate and weaning weights were observed in female calves given MR and H only (108 ± 16 g/d and 28.6 ± 1.4 kg, respectively). Calves offered the MR showed a greater incidence of calf scours than those offered the milk (88 vs. 42%, respectively). The feeding of whole milk in combination with starter ration and hay resulted in superior growth rates, higher weaning weights, and healthier calves than the other feeding regimens.

Key Words: calf nutrition, milk replacer

T358 The effect of feeding different dilution levels of milk replacer to calves once or twice daily, with or without yeast culture. M. F. Ortega*, H. M. Rodriguez, and M. Vélez, *Zamorano University*, *El Zamorano, Honduras*.

Conventional feeding in the tropics for calves (2L of milk/milk replacer twice daily) was compared with a lower intake (3L once daily). Effects of live yeast culture (YC; YEA SACC ^{1026}, Alltech, Inc.) addition were investigated when added to these feeding strategies. A study was conducted using 40 male and female newborn calves assigned randomly to a 2 × 2 factorial design to determine the effects on growth in terms of average daily gain (ADG), and initial/final body weight (BW). The treatments consisted of 2 levels of milk replacer: 3 L once a day (3L) or 4 L split in 2 feedings daily (4L). The amount of milk replacer (20% CP and 15%Fat) as such was similar (450 g/d), but diluted in the 3L or 4L treatment with (Y) or without (NY) YC addition. Calves were weaned at 60 d. BW was measured every 30 d until they were 120 d. The statistical analysis of this experiment was performed using the MIXED procedure of SAS. 3L or 4L calves had similar initial body weight (37.37 and 37.42 ± 1.37 kg, respectively; $P = 0.98$), but calves assigned to the Y treatment were significant smaller than NY (34.03 and 40.76 ± 1.37 kg, respectively; $P < 0.01$). Final weights of animals at 120 d followed the same pattern as initial weight. ADG at 60 d of 3L was similar to 4L calves (0.37 and 0.39 ± 0.03 kg/d, respectively, $P = 0.50$), but Y calves had a lower ADG than NY (0.31 vs. 0.44 ± 0.03 kg/d; $P = 0.006$). There were no effects of milk replacer or YC addition on ADG at 120 d (0.44 ± 0.02 kg/d). These results suggests that there is no difference between the diluted levels of milk replacer (3L or 4L) on ADG when grain was offered ad libitum, and that YC-calves had a lower ADG at 60 d but similar ADG after 120 d.

Key Words: calves, milk replacer, yeast culture, average daily gain

T359 Utilization of yeast (*Saccharomyces cerevisiae*) in dairy calf diets. J. A. De Freitas*[1], M. S. Schoten[1], D. R. Fronchetti[1], A. F. Garcez Neto[1], and J. C. De Souza[2], [1]*University Federal of Parana*, *Palotina, Parana, Brazil*, [2]*University Federal of South Mato Grosso*, *Aquidauana, Mato Grosso do Sul, Brazil*.

There are few farms that give priority to calf rearing. Most of farms justify that the economic impact of investments in calf rearing does not provide significant profits. However, feed management practices that can improve animal performance, prevent enteric diseases (diarrhea) and reduce production costs are of great interest. Among the practices used in food nutrition, the inclusion of some substances (additives) in the diet may be responsible for improving digestibility, nutrient absorption and thus in the feed conversion. The aim of this study was to assess the influence of 3 levels of yeast (*Saccharomyces cerevisiae*) in the Holstein calves diet on the weaning weight (W60), weight gain from birth to weaning (WG), average daily gain from 0 to 60 d (ADG), concentrate feed conversion (CFC) and diarrhea incidence (ID). Twenty-one Holstein calves were randomly assigned to 3 treatments consisting of different levels of yeast in the diet (0, 5 and 10 g/animal/day). Immediately after birth, animals were separated from their mothers and transferred to individual pens where they received 5 L of colostrum for 3 d. After that period, the calves received 8 L of colostrum/day divided in 3 meals. The yeast was mixed with the milk of the first meal. From the 2nd week animals had ad libitum access to concentrate feed containing 18% crude protein and 75% TDN. The amount of concentrate ingested was controlled daily. The animals were weighed and had their height measured at birth and every 15 d (0, 15, 30, 45 and 60 d). The data were analyzed by PROC REG of SAS. It was found a quadratic effect of the treatments for WG (kg), ADG (kg) and CFC variables. The equations and their respective coefficient of determination were: WG = 394167 + 3.8178x - 0.3802x^2 ($r^2 = 0.25$), ADG = 0.6567 + 0.0642x - 0.006387x^2 ($r^2 = 0.55$) and CFC = 0.4317 + 0.0482x + 0.0046x^2 ($r^2 = 0.55$). The addition of yeast culture in the calf diet improved feed conversion into increased growth.

Key Words: additives, ruminant nutrition, nutrition efficiency

T360 The effects of feeding fermented soybean meal in calf starter on growth and performance of dairy calves. T. L. Wolfswinkel*[1], H. D. Tyler[1], J. E. Cunnick[1], T. Waugh[2], J. Sewell[2], and A. Chestnut[3], [1]*Iowa State University*, *Ames,* [2]*Nutra-Flo Protein and Biotech Products, Sioux City, IA,* [3]*Vigortone Ag Products, Brookville, OH.*

The use of soybean meal in animal diets is primarily limited to adult animals due to the inefficient digestibility of soy proteins by young animals and the susceptibility of young animals to antinutritional compounds in soybeans that are either not properly processed or undercooked. The objective of this study was to evaluate the suitability of fermented soybean meal for use in dairy calf starter diets in place of soybean meal. The experiment was conducted using 66 dairy bull calves that were randomly assigned to either the control diet, containing soybean meal (SBM) as the primary source of protein in the starter diet, or the treatment diet, containing fermented soybean meal (FSBM) in place of soybean meal as the primary source of protein in the starter diet. Measured parameters included weekly weight gains, total weight gained, attitude, appetite, fecal scores, and immunological parameters that included mitogen proliferation, CD4, CD8, CD45RO, and B-cell counts which were measured by flow cytometry. None of the measured growth and health parameters were significantly different between the calves on the control and treatment diets. Weaning age was older for calves on the fermented soybean meal in comparison to the soybean meal based starter diet ($P = 0.0422$). Immunological data showed no differences in the development and responsiveness of the immune system between groups of calves receiving different treatments. This data suggests that growth and performance of calves fed fermented soybean meal based starter diets are similar to those fed soybean meal based diets.

Key Words: fermented soybean meal, calves, immune system development

T361 In vitro methane production from increasing levels of corn- or wheat-based dried distillers grains with solubles. M. Hünerberg*[1], L. Holtshausen[2], T. A. McAllister[2], K. A. Beauchemin[2], and E. Okine[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Increasing dietary fat levels have shown to depress ruminal methane (CH_4) production, but the reduction may depend upon the dietary forage to concentrate ratio. The objective of this study was to compare in vitro CH_4 production from wheat- or corn-based dried distillers grains with solubles (WDDGS, CDDGS). The WDDGS (4.9% crude fat) and CDDGS (11.5% crude fat) replaced barley silage as substrate at levels of 0, 20, 40, 60 or 100% (DM basis). Each treatment, dried and ground through a 1-mm screen, was incubated (n = 5) in Ankom bags in 125-mL sealed batch culture flasks (0.3 g substrate + 40 mL of anaerobic medium and 10 mL of inoculum). The inoculum was obtained from cows fed a high forage (65% of diet DM) diet. Gas pressures arising from substrate fermentation were measured at 3, 6, 12 and 24 h post inoculation. Pressure values, corrected for gas released from 3 negative controls (no substrate) were used to generate volume estimates. Gas samples collected at the same 4 time points were analyzed for CH_4 concentration. Disappearance of DM and VFA concentration in incubation liquid were measured at 24 h. Production of CH_4 increased linearly (r^2 = 0.98) for CDDGS from 15.2 to 33.3 mL CH_4/g of DM loss at 20 and 100% DDGS, respectively. Production of CH_4 was greater ($P < 0.01$) for WDDGS (averaging 32.6 ± 0.3 mL/g DM loss) than for CDDGS at 20, 40 and 60% of inclusion rates. The percentages of propionate in fluid were greater ($P < 0.01$) for CDDG (22.3, 21.3 and 20.3% of total VFA) than for WDDGS (19.4, 19.4 and 19.5% of total VFA) at 20, 40 and 60% of inclusion. The results suggest: (i) in vitro CH_4 production as per unit of DM loss is lower at lower DDGS inclusion rates (ii) including CDDGS, most likely as response to its higher fat content, produced less CH_4 per unit of DM loss then including WDDG at up to 60% of dietary DM.

Key Words: methane, dried distillers grains with solubles, in vitro

T362 The impact of DDGS on presence of ruminal bacteria, ruminal protozoa and yeast during in vitro fermentation. E. Castillo-Lopez*, J. L. Miner, and P. J. Kononoff, *University of Nebraska-Lincoln*, *Lincoln*.

Changes in ruminal microbial populations is of interest because of their role in feed degradation and metabolizable protein supply to the animal. The objective of this experiment was to evaluate the effect of dried distillers grains and solubles (DDGS) on presence of ruminal bacteria, protozoa and yeast during in vitro fermentation. Treatments were, CONTROL (50% grass hay and 50% rolled-corn), LOW DDGS (33% grass hay, 33% rolled-corn and 33% DDGS) and HIGH DDGS (100% DDGS). Substrates were incubated in rumen inoculum and replicated 3 times. At 0 and 48h fermentation a pellet was isolated from each sample, then bacterial, protozoal and yeast crude protein was estimated by real-time PCR. To do so, microbial markers were designed from the 16S rRNA, 18S rRNA and the second chromosome; for bacteria, protozoa and yeast. Data were analyzed as a 3 × 2 factorial design to test the effects of 3 treatments, 2 time points and interaction between treatment and time. Treatment did not ($P = 0.31$) affect the estimates of bacterial crude protein and averaged 206, 200 and 171 (SEM = 16.08) mg/g DM for the CONTROL, LOW DDGS and HIGH DDGS. However, treatment affected ($P < 0.05$) the estimate of protozoal crude protein and averaged 46, 27 and 6 (SEM = 3.74) mg/g DM for the CONTROL, LOW DDGS and HIGH DDGS. In addition, treatment did not affect ($P = 0.25$) the estimate of yeast crude protein and averaged 0.05, 0.09 and 0.19 (SEM = 0.06) mg/kg DM for the CONTROL, LOW DDGS and HIGH DDGS. Fermentation time did not affect ($P = 0.66$) the estimates of bacterial crude protein and were 197 and 189 (SEM = 12.38) mg/g DM at 0 and 48h. However, time affected ($P < 0.05$) the estimates of protozoal crude protein and were 14 and 39 (SEM = 3.14) mg/g DM at 0 and 48h and the interaction of treatment by time was significant ($P < 0.05$). Furthermore, time did not affect ($P = 0.66$) the estimates of yeast crude protein and were 0.09 and 0.12 (SEM = 0.04) mg/kg DM at 0 and 48h. With real-time PCR, it was possible to estimate the variation of ruminal bacterial, protozoal and yeast crude protein. Level of DDGS may affect the in vitro microbial growth.

Key Words: bacteria, protozoa, real-time PCR, yeast

T363 Effects of low dose of *Saccharomyces cerevisiae* on metabolism by ruminal microbes in dual flow continuous culture fermenters. M. Ruiz-Moreno*[1], M. D. Stern[1], and J. Sullivan[2], [1]*University of Minnesota*, *St Paul,* [2]*Lallemand Animal Nutrition - North America, Milwaukee, WI.*

Effects of *Saccharomyces cerevisiae* (SC) on rumen fermentation were evaluated using a dual flow continuous culture system. Eight fermenters were inoculated with ruminal fluid from a dairy cow in early lactation on d 1 of a 10-d experimental period. Fermenters were provided with 75 g of DM/d of a pelleted diet formulated for a high lactating dairy cow (40 kg milk/d, 3.8% fat, 3.7% protein). Two levels of SC (Levucell, SC20, Lallemand) at 0 or 2 mg/fermenter/day (SC0 and SC2, respectively) were infused twice a day at 0900 and 2100 h to the fermenters in a completely randomized arrangement of treatments. The latter concentration would be equivalent to supplementing 0.5 g/d of SC to a dairy cow. Apparent and true organic matter degradability were not affected ($P > 0.05$) by SC averaging 55.6 vs. 56.0 and 65.5 vs. 64.7% for SC0 and SC2, respectively. Similarly, no differences were obtained ($P > 0.05$) in NDF and ADF digestibility (51.1 vs. 49.4% and 50.3 vs. 48.1% for SC0 and SC2, respectively). Total VFA concentrations were not affected ($P > 0.05$) by treatments (140.2 and 140.8 m*M* for SC0 and SC2, respectively). There was a trend ($P < 0.1$) for a higher branched chain VFA (isobutyrate, isovalerate and 2-methylbutyrate) concentration in SC0 compared with SC2 (2.34 vs. 1.82 m*M*, respectively). The addition of SC resulted in a lower ($P < 0.05$) NH_3-N concentration and NH_3-N flow (6.28 vs. 3.85 mg/100 mL and 0.19 vs. 0.12 g/d for SC0 and SC2, respectively), without affecting ($P > 0.05$) CP degradation and efficiency of microbial protein synthesis (35.7 vs. 29% and 29.1 vs. 25.8 g of N/kg OM truly digested for SC0 and SC2, respectively). Average and minimum pH of fermenters did not differ between treatments ($P > 0.05$) but a trend ($P < 0.1$) for a lower maximum pH was obtained at 5.78 vs. 5.71 for SC0 and SC2, respectively. A low dose of SC may benefit NH_3-N metabolism, without having any negative effects on in vitro rumen fermentation.

T364 Effects of copper and zinc on in vitro ruminal fermentation of total mixed ration using goat inoculum. J. F. Vázquez-Armijo[1], R. Rojo*[1], D. López[1], A. Z. M. Salem[1], and J. M. González-Alvarado[2],

[1]*Universidad Autónoma del Estado de México, Centro Universitario UAEM Temascaltepec*, *Temascaltepec, México, México*, [2]*Universidad Autónoma de Tlaxcala, Facultad de Agrobiología*, *Ixtacuixtla, Tlaxcala, México*.

One in vitro experiment was conducted to examine the effects of supplemental copper (Cu) and zinc (Zn) on ruminal parameters, in vitro dry matter degradability (IVDMD), gas production (GP) and metabolizable energy (ME) (MJ kg^{-1} DM). Total mixed ration was incubated in vitro for 96 h with 4 different supplemental treatments (Control, Cu (860 ppm), Zn (224 ppm), Cu-Zn (860–224 ppm)) provided as mineral premixed. Added Zn increased fraction B (ml g^{-1} DM), but added Zn-Cu treatment decreased fraction B. Supplemental treatments did not alter the initial delay before gas production begins (L) and IVDMD (g^{-1} DM). Added Cu tended to increase the amount of GP (ml g^{-1} DM) at 24, 48 and 96 h (GP_{24}, GP_{48}, and GP_{96}, respectively) of incubation. Cu treatment was the highest value for the fraction the rate of gas production (K) and ME, while Zn was the lowest values. In conclusion, the addition of Cu to in vitro ruminal fermentation was found to increase gas production volume and efficient use of energy.

Table 1. In vitro ruminal fermentation parameters of total mixed ration with different supplemental treatments

Parameters	Control	Zn	Cu	Zn-Cu	SEM	P-value
B	273.57^{bc}	334.90^{a}	288.80^{b}	241.63^{c}	10.78	0.004
K	0.014^{c}	0.008^{d}	0.037^{a}	0.019^{b}	0.003	<0.001
L	0.87	1.32	1.78	0.68	0.19	0.153
GP_{24}	69.35^{c}	58.51^{c}	169.39^{a}	90.72^{b}	13.22	<0.001

T365 Effects of high rates of extruded flaxseed fed to dairy cows on n-3 fatty acids enrichment in milk-fat and the interaction with milk fat content and yield. U. Moallem*[1], M. Zachut[1,2], H. Lehrer[1], L. Livshitz[1], and A. Arieli[2], [1]*Agriculture Research Organization*, *Bet Dagan, Israel*, [2]*Faculty of Agriculture, Hebrew University*, *Rehovot, Israel*.

The objectives were to examine the effects of high rates of dietary extruded flaxseed (EF) containing high proportion of C18:3n-3 on fatty acids (FAs) composition in milk fat, and the interaction with milk fat content and yield. Multiparous Israeli-Holstein dry cows (256 d pregnant) were assigned to 2 treatments: (i) control (n = 22) were fed a dry cow diet and postpartum (PP) lactating cow diet, and (ii) EF (n = 22) supplemented prepartum with 1 kg/d per cow of EF providing 141 g/d of C18:3n-3, and PP to 100 d in milk a diet consisted of 9.2% EF providing on average 382 g/d of C18:3n-3. Milk solids content was determined from 3 consecutive milkings every 2 weeks. Composition of FAs in milk fat was determined in 50 milk samples (24 controls and 26 EF). Milk production was 6.4% higher and fat percentage was 0.4% units lower in the EF group than in the control, with no differences in fat yields. Content and yield of C18:3n-3 in milk fat was 5.1 and 4.6 times higher in the EF group than in controls, respectively. However, the content of C18:3n-3 in milk fat reached a maximum of ≈2% and increasing the dietary supply of C18:3n-3 did not benefit to enrich milk fat. Within group test revealed that the content of C18:3n-3 in milk fat in the EF group was negatively correlated with milk fat percentage (r = –0.91) and yield (r = –0.89). However, no decrease in de novo synthesis of less than 16 carbons FAs was found in the EF group, whereas C16:0 yield were markedly decreased. Moreover, C16:0 yield in the EF cows was negatively correlated with 18:3n-3 content (r = –0.91) and yield (r = –0.65) in milk fat. It appears that the enrichment of 18:3n-3 in milk fat is limited to ≈2%, and it is negatively correlated with milk fat content and yield. It might also be speculated that C18:3n-3 itself suppresses de novo synthesis of C16:0, but not lower chain FAs, which reduced the overall milk fat content in milk.

Key Words: omega-3, milk fat

T366 Effect of grain source and milling process in ethanol production on nutrient contents and in vitro digestibility of ethanol by-product. W. Z. Yang*[1], T. A. McAllister[1], J. J. Mckinnon[2], K. A. Beauchemin[1], and D. Gibb[1], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*Department of Animal and Poultry Science, University of Saskatchewan*, *Saskatoon, SK, Canada*.

Dried distiller grains with solubles (DDGS) can be derived from ethanol fermentation of varying with type of grains (e.g., corn, wheat, or blend of the 2) or milling process (traditional and fractional). Traditional DDGS contain the residual components (bran, protein, germ, and minerals) of the grain after the majority of the starch has been fermented, whereas, fractional DDGS contain no residual bran and germ which are removed before fermentation. The objective of this study was to compare the nutrient content and in vitro digestibility of different DDGS. Sixty DDGS samples varying grain source and milling process were collected from different ethanol plants in Canada and in US. The DDGS samples were determined for the contents of CP, NDF and fat, and were incubated in a batch culture for 0, 4, 8, 14, 24 and 48 h to measure gas production and DM digestion (DMD). The CP content (% DM) was different ($P < 0.01$) with the highest (51.8) for fractional corn DDGS, medium for wheat (37.9) and blend DDGS (35.9), and the lowest for corn DDGS (30.6). The NDF content (% DM) was lower ($P < 0.01$) for fractional DDGS (24.5), but the fat content (% DM) was higher ($P < 0.01$) for corn DDGS (10.1) than for other DDGS (mean ± SD; NDF, 32.0 ± 1.4; fat, 4.3 ± 0.4). DMD linearly ($P < 0.01$) increased with increasing time of batch culture, and no plateau was obtained after 48 h of fermentation. The DMD were lower ($P < 0.01$) for fractional corn DDGS after 24 h (33%) and 48 h (42%) of fermentation than for other DDGS (mean ± SD; 24h, 44 ± 2.1%; 48h, 54 ± 2.8%). The gas production followed the same variation pattern of the DMD. The results indicate that the nutrient contents of DDGS and extent of digestion varied with DDGS source. The information on the type of grain used and milling process before ethanol fermentation is needed to choose DDGS for accurately formulating ruminant diet.

Key Words: distillers grain, nutrient content and digestion, batch culture

T367 In vitro digestion and gas production of two varieties of barley grain sown with different seeding and N fertilization rates in seven sites across Canada. W. Z. Yang*[1], T. A. McAllister[1], M. Oba[2], and D. Gibb[1], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*Department of Agricultural, Food and Nutritional Science, University of Alberta*, *Edmonton, AB, Canada*.

Seeding rate (SR) and N fertilizer application rate (NR) have the potential to alter the starch and protein content of the grain as well as the rate and extent of its digestion. The objective of this study was to determine

whether SR and NR change DM digestion (DMD) and gas production (GP) of barley grain in batch culture. Two malting barley varieties, Copeland and Metcalfe, were seeded at rates of 200 or 400 plants/m^2 with N fertilizer at rates of 0, 30, 60, 90 and 120 kg/ha, respectively, from 7 sites across Canada. Total 560 samples (i.e., 7 sites × 2 varieties × 2 SR × 5 NR × 4 replications) were collected and ground through a 6-mm screen. Fermentability was assessed by measuring in vitro GP and DMD at 0, 4, 8, 12, 18 and 24 h of incubation. The CP content (% DM) of malt barley linearly ($P < 0.01$) increased from 10.3 to 12.2, whereas the starch content (% DM) linearly ($P < 0.01$) decreased from 61.6 to 59.8 with increasing NR. The SR had marginal effect on the contents of CP and starch of barley grains. The DMD after 24 h of batch fermentation ranged on average from 36 to 42% for both varieties and were overall not affected by the SR or NR. There were only one of 7 sites where the SR decreased ($P < 0.01$) DMD of Copeland by 12%, but increased ($P < 0.01$) the DMD of Metcalfe by 17%. The NR linearly ($P < 0.01$) reduced DMD of Copeland from 2 sites and reduced DMD of Metcalfe from one site. There was interaction ($P < 0.01$) between SR and NR on GP: the GP was higher ($P < 0.01$) for 60NR when SR was 200, whereas GP was lower ($P < 0.01$) for 120NR when SR was 400 compared with other NR, respectively. This work demonstrates that the NR changed nutrient content of barley grains and would affect its ruminal degradation rate as shown by the variation of GP.

Key Words: malt barley grain, DM digestion, batch culture

T368 Impact of monensin on rumen microbiota and its stochastic succession. P. Kongmun*[1,2], M. Wanapat[1], and Z. Yu[2], [1]*Department of Animal Science, Khon Kaen University*, *Khon Kaen, Thailand, 40002*, [2]*Department of Animal Science, The Ohio State University*.

This study examined the long-term effects of monensin on rumen microbiota and the effect of monensin on the stochasticity of rumen microbiota using an in vitro model. Rumen fluid samples were collected from 2 Holstein Friesian cows at 6 h post-feeding and constituted into a composite sample as the inoculum. Two sets of cultures (n = 5 each) were incubated at 39°C under anaerobic condition: the monensin cultures contained 5 ppm monensin, while the control cultures contained no monensin. The cultures were transferred every 2 d for 15 d. Samples were collected over the course of the incubation and subjected to analysis for microbiota using both DGGE and sequencing analysis of 16S rRNA genes. The monensin cultures had fewer bands than the control cultures, especially in the high-denaturant area of the DGGE gel that corresponds to bacteria with low GC contact. Principal component analysis (PCA) of the DGGE profiles also showed clear differences between the monensin and the control cultures, with samples collected at d 9 exhibiting the greatest difference. Considerable temporal successions of the microbiota were also evident in both sets of cultures, especially during the initial 9 d of the incubation. Both the DGGE banding patterns and the PCA analysis of the DGGE profiles showed variations among the 5 replicates within the same set of cultures. Because all the cultures were grown in identical test tubes under identical conditions, we attributed these variations among replicates to stochastic succession. It is interesting to note that the early monensin cultures had little stochastic succession among the 5 replicates. A total of 233 random clones were sequenced from individual 16S rRNA gene libraries. At 97% sequence identity level, 46 unique phylotypes were identified that were assigned to genera of *Firmicutes*, *Bacteroidetes*, *Proteobacteria*, and uncultured bacteria. PCA analysis of these phylotypes is concordant with that of the DGGE profiles. The observations in this study may help explain, at least partially, the variations often observed among individual animals fed the same diet.

Key Words: monensin, rumen microbiota, stochasticity

T369 The effect of body condition at calving and supplementation with *Saccharomyces cerevisiae* on energy status and some reproductive parameters in early lactation dairy cows. R. M. Al Ibrahim*, M. A. Crowe, P. Duffy, L. O`Grady, M. E. Beltman, and F. J. Mulligan, *University College Dublin*, *Dublin 4, Ireland*.

The objective was to examine potential benefits of live yeast culture (YS) supplementation on postpartum (PP) energy status and fertility indices of dairy cows managed to have low or high body condition score (BCS, 1 – 5 scale) at calving. Forty Holstein dairy cows were randomly allocated to a 2 × 2 factorial arrangement. Treatments were: BCS at calving (low, L ≤3.5 or high, H ≥3.75; n = 20) and YS supplementation (2.5 g/cow/d for pre-calving and 10 g/cow/d for post-calving × 10^9 CFU of *S. cerevisiae*/g) (supplemented, Y or control, C; n = 20). Daily milk yield was recorded and weekly milk composition, BCS and BW were assessed from calving to wk 10 PP. Estimated energy balance PP was calculated on a weekly basis individually as the difference between the net energy (NE) intake and the sum of NE for maintenance and milk production. Insulin and IGF-I concentrations were determined on d 14 and 7 pre-calving and 1, 5, 15, 25 and 35 PP. Daily ovarian ultrasonography was performed from d 10 PP to monitor the size and development of the first dominant follicle, first ovulatory follicle and days to first ovulation PP. Pre-ovulatory peak of serum estradiol concentration was determined. Data were analyzed using the Mixed procedure in SAS v 9.1, 2004. Cows in H group (over-conditioned) at calving ingested less NE, produced more milk NE output, and consequently had a significantly ($P < 0.05$) exacerbated negative energy balance in comparison with L group (moderately conditioned) during early lactation. Higher ($P < 0.05$) insulin concentrations and a tendency for higher ($P = 0.06$) preovulatory peak estradiol concentrations in L group were detected in the early PP period. Feeding YS had no effect on energy status of lactating dairy cows with high or low BCS at calving, while it improved serum insulin concentration, preovulatory peak of estradiol and the size of first ovulatory follicle in the early PP period. These observed effects of YS supplementation require to be substantiated with further research.

Key Words: dairy cows, yeast culture, energy balance, reproduction

T370 Effect of supplemented diets with sucrose and/or starch on ruminal peptide-N concentration of Holstein steers. M. Danesh Mesgaran*, F. Rezaii, A. R. Heravi Moussavi, and A. Vakili, *Dept. Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran*.

The objective of this study was to determine the effect of diets containing different types of non-fiber carbohydrates [sucrose (Su), starch (St) or equal mixture of Su and St (Su+St)] on ruminal peptide-N concentration of Holstein steers. Four ruminally fistulated steers (body weight = 280 ± 15 kg) were assigned to a 4 × 4 Latin square with 28 d periods. The basal diet contained alfalfa hay, barley grain, soybean meal and sugar beet pulp (400, 290, 190 and 50 g/kg respectively). The non-fiber carbohydrates were added to the basal diet at the rate of 70 g/kg DM. Diets were offered at 2.5 times of the maintenance requirements (7 kg DM/day). Animals were fed twice daily at 08:30 and 16:30. Samples of rumen contents were taken, by suction, at 0.0, 2, 4 and 6 h after the morning feed. Ruminal fluid was prepared for peptide-N analysis using sulfate-tungstate precipitation method. Tungstate acid-precipitate nitrogen was assayed by a standard macro-Kjeldahl procedure. Data were analyzed using mixed procedure of SAS (2003) for repeated measures. Results of the present experiment indicate that peptide-N concentration tended to be lower when steers were fed Su, St and Su+St than BD ($P = 0.09$). Mean Peptide-N concentrations of the sampling times were BD = 2.1, Su = 1.7, St = 1.4 and Su+St = 1.5 mg/dL. Therefore, it might be concluded that the nitrogen metabolism in the rumen is affected by the

type of non-fiber carbohydrates used in the present diets. The effect of sampling time on Peptide-N concentrations was significant ($P < 0.05$). Peptide-N concentrations showed a quadratic significant response to the sampling time ($P < 0.05$). Peptide-N concentrations increased after the morning feeding and declined at 6 h after that. The concentrations of peptide-N at 6 h after the morning feeding (BD = 1.8, Su = 1.4, St = 1.2 and Su+St = 1.3 mg/dL) was less than those of before feeding (BD = 1.9, Su = 1.6, St = 1.3 and Su+St = 1.4 mg/dL).

Key Words: rumen, peptide-N, carbohydrates

T371 Effect of diets supplemented by sucrose and/or starch on in vivo ruminal *Ruminococcus flavefaciens* populations of Holstein steers determined by real time-PCR. M. Danesh Mesgaran*, F. Rezaii, A. R. Moussavi Heravi, M. Nassiri, and A. Vakili, *Dept. Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran*.

The objective of the present work was to investigate the effect of diets containing different types of non-fiber carbohydrates on *Ruminococcus flavefaciens* populations in the rumen fluid of Holstein steers determined by real-time polymerase chain reaction (RT-PCR). Four ruminally fistulated Holstein steers (body weight = 280 ± 15 kg) were assigned to a 4x4 Latin square with 28 d of each period. Basal diet (BD) was formulated to contain of alfalfa hay, barley grain, soybean meal and sugar beet pulp (400, 290, 190 and 50 g/ kg DM, respectively). Sucrose (Su), starch (St) or a 1:1 mixture of Su and St (Su+St) was added to the basal (70 g/ kg DM). Diets were offered as 2.5 times of maintenance requirements (7 kg DM/d) at 0830 and 1630 h. Rumen fluid samples were collected before and 4 h after the morning feeding at the last day of each period. Samples were analyzed for *Ruminococcus flavefaciens* quantitation using RT-PCR. The DNA extraction was performed from the samples using the QIAamp DNA stool mini kit (Qiagen Ltd, Crawley, West Sussex, UK). *Ruminococcus flavefaciens* rDNA concentrations were measured by RT-PCR relative to the total bacteria amplification (ΔΔCt). The 16s rRNA gene-targeted primer sets used in the present study were forward: CGAACGGAGATAATTTGAGTTTACTTAGG and reverse: CGGTCTCTGTATGTTATGAGGTATTACC. Cycling conditions were 95°C for 5 min, 40 cycles of 95°C for 15 s, 60°C for 15 s and 72°C for 30 s. Data were expressed relative to the quantification of the total bacterial population, and analyzed using mixed procedure of SAS (2003) and means were compared by the Tukey test at $P < 0.05$. Present results indicate that the supplementation of the basal diet with Su+St tended to decrease ($P = 0.07$) the relative population of *Ruminococcus flavefaciens* in the rumen samples taken before the morning feeding (95×10^{-5} vs. 279×10^{-5}). The adding of Su to the basal diet increased the population of *Ruminococcus flavefaciens* (8689×10^{-5}) compared with BD ($P = 0.06$; 279×10^{-5}) and Su+St ($P = 0.05$; 307×10^{-5}) in the rumen samples of 4 h after the morning feeding.

Key Words: rumen, carbohydrates, *Ruminococcus*

T372 Exogenous proteolytic enzyme increases degradation of dried distillers grains with solubles during in vitro ruminal fermentation. J. M. Vera, J.-S. Eun*, D. R. ZoBell, and A. J. Young, *Utah State University*, *Logan*.

We performed a series of in vitro batch culture experiments to assess if an exogenous proteolytic enzyme (EPE) would improve degradation of dried distillers grains with solubles (DDGS) and beef growing and finishing TMR diets containing DDGS. A commercial enzyme product (Protex 6L, Genencor Division of Danisco, Rochester, NY) having only a protease activity was investigated in this study. In all experiments, strained ruminal fluid was obtained from 2 cannulated beef cows. In experiment 1, the EPE was added to the DDGS at 0, 0.7, 1.4, and 2.1 mg/g DM in a filter bag, and they were incubated for 24 h in gas-tight culture vials (125-mL capacity) with ruminal fluid. The EPE addition resulted in quadratic responses on degradability of DM, NDF, and ADF, and its optimum dose rate was found at 1.4 mg/g DM. In experiment 2, efficacy of the EPE added at 1.4 mg/g DM to DDGS was assessed for 96 h using the Daisy II in vitro fermentation system (Ankom Corp., Macedon, NY). Degradability of NDF and ADF increased starting at 18 h of incubation. In experiment 3, efficacy of the EPE was further investigated using beef growing and finishing TMR diets containing 20% DDGS on a DM basis. Experimental procedures were the same as those used in experiment 2. Addition of the EPE tended to increase ($P = 0.07$) NDF degradability of growing and finishing diets at 12 h of incubation, but the effect of EPE on fiber degradation of beef diets was minor at the later hours of incubation. Total VFA production did not differ due to EPE addition in beef diets. Adding EPE in DDGS as a single substrate resulted in a sizable increase in DM and fiber degradability, but its effects were reduced when added in beef growing and finishing diets containing approximately 20% DDGS. It is recommended that the EPE be further evaluated in a beef steer growth study using diets containing relatively high DDGS inclusion rates.

Key Words: exogenous proteolytic enzyme, dried distillers grains with solubles, in vitro fermentation

T373 Effects of eugenol addition on milk fatty acid composition of dairy cows fed high- or low-concentrate diets. C. Benchaar*[1], W. Z. Yang[2], H. V. Petit[1], and P. Y. Chouinard[3], [1]*Agriculture and Agri-Food Canada*, *Dairy and Swine R&D Centre, Sherbrooke, QC, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethridge Research Centre, AB, Canada*, [3]*Université*, *Département des Sciences Animales, Québec, QC, Canada*.

Four primiparous lactating cows (BW = 568 kg; DIM = 67) were used in a 4 × 4 Latin square design (28-d periods) with a 2 × 2 factorial arrangement of treatments to determine the effects of eugenol (EUG) addition (0 vs. 50 mg/kg of DMI) and concentrate proportion of the diet (high-concentrate: HC vs. low-concentrate: LC; 65 vs. 35%, DM basis) on milk fatty acid (FA) composition. Diets contained 17.2% CP and were formulated to be isocaloric ($NE_L = 1.65$ Mcal/kg DM) using a commercial source of calcium salts of long-chain FA (Megalac) in LC diets. Analyses of FA were performed on pooled samples collected from 4 consecutive milkings (d 22 to 23). Data were analyzed as a 2 × 2 factorial using the MIXED procedure of SAS (SAS Inst., Inc., Cary, NC). Significance was declared at $P \leq 0.05$ and tendency at $0.05 < P \leq 0.10$. No interaction concentrate level × EUG was observed for any of the FA measured. Milk FA profile was not changed by EUG supplementation. Proportions (g/100 g of total FA) of C16:0 (28.2 vs. 24.5%) and *cis*-9 C18:1 (19.4 vs. 16.1%) were higher while the proportion of *cis*-9, *cis*-12 C18:2 (2.04 vs. 2.69%) was lower in milk fat of cows fed LC diets than in that of cows fed HC diets. Milk fat concentrations of *trans*-10 C18:1 (0.34 vs. 0.30%), *trans*-11 C18:1 (1.06 vs. 0.96%; $P = 0.08$), and *cis*-9, *trans*-11 C18:2 (CLA; 0.53 vs. 0.44%) increased in cows fed LC diets as compared with cows fed HC diets, but the ratio *trans*-11 C18:1 to *trans*-10 C18:1 was not significantly affected by concentrate proportion. These results suggest that under the experimental conditions of this study, neither the addition of EUG (50 mg/kg of DMI) nor the increase in dietary concentrate proportion of the diet modified the pathway of biohydrogenation of FA in the rumen.

Key Words: essential oil/eugenol, concentrate proportion, milk fatty acid

T374 Effects of sugar beet pulp substituted for ground corn on the performance and health of Chinese Holstein dairy cows. M. Wang, J. Y. Zhang, J. Q. Wang*, D. P. Bu, L. Y. Zhou, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Sixty multiparous Holstein cows (60 ± 22 DIM, 31.2 ± 6.2 kg of milk/d) were used to study the effect of sugar beet pulp (SBP) substituted for ground corn on performance, nutritional status as measured using blood metabolites and health. Cows were randomly divided into 2 pens and within each pen where 3 groups (control, 20SBP or 40SBP) and each group comprised of 10 cows (n = 10). The cows were fed a diet containing either ground corn (control) or SBP (20% or 40% of the ground corn replaced with SBP on the basis of corn DM, 20SBP and 40SBP) as the main energy source. Cows were fed 3 times daily in a tie-stall barn. Feed intake was recorded daily. Cows were milked 3 times daily. Blood samples were collected monthly via venous puncture from coccygeal vein 2 h after morning feeding. Data were analyzed statistically by using PROC MIXED of SAS. The results showed that dry matter intake (21.45, 21.58 and 21.56 kg/d), milk production (28.52, 28.45 and 27.89 kg/d), energy corrected milk (ECM, 28.50, 28.76, 28.33 kg/d) were not effected by increasing SBP substitution ($P > 0.05$). The milk protein (2.95, 2.98, 3.04%), milk fat (3.55, 3.65, 3.66%), milk lactose (4.73, 4.78, 4.79%), total solids (TS,12.18,12.33,12.43%), and solid non-fat (SNF, 8.53, 8.58, 8.66%) showed no significant differences among 3 treatments. In blood metabolite, the concentrations of blood urea nitrogen (BUN, 23.39, 19.76, 20.94 mg/dl) and glucose (52.34, 44.2, 44.66 mg/dl) decreased when cows fed SBP in the diets ($P < 0.01$). Nonesterified fatty acid (NEFA) and β-hydroxybutyrate (BHBA) concentrations were not significantly different among treatments. Manure score was lower (2.97, 2.85, 2.89, respectively) for 20SBP than for the other treatments ($P < 0.05$). However, no significant differences existed among 3 treatments on somatic cell counts (SCC), body condition score (BCS), locomotion score, and average body weight ($P > 0.05$). The results indicate that supplemented dried sugar beet pulp is equal to corn as an energy source for lactating dairy cows when fed at the replacing 20 and 40% of corn the DM.

Key Words: sugar beet pulp, ground corn, performance

T375 Garlic botanical reduces methane production in rumen fluid determined in vitro. S. Cavini[1], D. Bravo[2], S. Calsamiglia[1], G. F. Schroeder*[3], M. Rodriguez[1], and A. Ferret[1], [1]*Universitat Autonoma de Barcelona*, *Spain*, [2]*Pancosma*, *Geneva, Switzerland*, [3]*Cargill Innovation Campus*, *Elk River, MN*.

The intent of this study was to evaluate the effect of increasing doses of a particular garlic extract standardized in propyl propyl thiosulfonate (PPT) on rumen fermentation pattern and methane production in vitro. The effect of PPT on in vitro microbial fermentation using ruminal fluid from a dairy cow was determined using the gas production technique. Thirty milliliters of a 1:4 ruminal fluid-to-buffer solution were introduced into glass polypropylene tubes supplied with 0.5 g of DM of a 60:40 forage:concentrate diet and incubated for 72 h at 39°C. Gas production was measured and samples were collected for VFA, ammonia, and methane (CH_4) concentrations. Treatments were control (CON), 20, 40, 80, 120 and 160 mg/L of PPT (abbreviated PPT20 to PPT160) and 500 mg/L of Monensin (MON) as positive control. Each treatment was tested in duplicate and in 2 replicated periods. Results were analyzed with PROC MIXED and PROC REG of SAS. The PPT linearly decreased total VFA ($Y = -0.084X + 86.20$, R^2=0.76) with PPT160 producing more VFA (69.7 m*M*) than MON (57.9 m*M*). The PPT quadratically depressed the molar proportion of acetate ($Y = -0.0002X^2 + 0.012X + 77.2$, $R^2 = 0.96$). Inversely, PPT quadratically increased the molar proportion of propionate ($Y = 0.0001X^2 - 0.006X + 13.1$, $R^2 = 0.97$) with PPT160 producing still less propionate than MON (14.6 vs. 18.4 mol/100 mol). Increasing doses of PPT quadratically decreased CH_4 production ($Y=-0.0006X^2 + 0.042X + 14.61$, $R^2 = 0.97$) with PPT160 producing 6.01 μL/L (compared with CON = 14.3 and MON = 1.8 μL/L). Furthermore, in order to take into consideration the parallel reduction in CH_4 and VFA, the ratio CH_4/VFA was also analyzed, resulting in decrease by PPT dose ($Y = -7.10^{-6}X^2 = 5.10^{-4}X + 0.174$, $R^2 = 0.94$) with PPT160 being associated with a 50.3% decrease. The present results indicated that a garlic extract standardized in thiosulfonates exhibited promising effect on reduction of CH_4 production in vitro. An in vitro dose between 120 and 160 mg/L may be optimal.

Key Words: methane, garlic, in vitro

T376 In vitro methane production by ruminal microorganisms is affected by the diet of donor animals. M. L. Tejido[1,2], M. J. Ranilla*[1,2], C. Saro[1,2], and M. D. Carro[1,2], [1]*Dpto. Producción Animal, Universidad de León*, *24071, León, Spain*, [2]*Instituto de Ganadería de Montaña (CSIC-ULE), Finca Marzanas s/n*, *24346 Grulleros, León, Spain*.

Six rumen-fistulated sheep were fed 4 diets in a partially replicated 4 × 4 Latin square design to investigate the effects of forage to concentrate ratio (F:C) and type of forage (FOR) in the diet on in vitro methane production. The diets consisted on either 70:30 (HF) or 30:70 (HC) F:C ratio, and either alfalfa hay (A) or grass hay (G) as FOR. In each period, ruminal fluid from each sheep was used to inoculate batch cultures containing the same 4 diets as substrate. Cultures were incubated at 39°C for 24 h. There were no F:C x FOR interactions ($P > 0.05$) for any measured variable. Methane and total volatile fatty acids (VFA) production was 17.5 and 10.0% times greater ($P < 0.05$) with HC-inoculum compared with HF-inoculum. Changing the F:C in the diet of sheep did not affect ($P > 0.05$) propionate production for any substrate, but production of butyrate was augmented ($P < 0.01$) as F:C increased. Methane:VFA ratio and apparent dry matter digestibility were not affected ($P > 0.05$) by F:C in the diet of sheep. For all substrates, inoculum from sheep fed A diets promoted greater ($P < 0.05$) production of methane and total and individual VFA, as well as greater ($P < 0.01$) acetate:propionate ratios and apparent dry matter digestibility compared with inoculum from sheep fed G diets. Methane:VFA ratio was greater ($P < 0.05$) with A-inoculum compared with G-inoculum for HC substrates, but no effect of FOR was observed for HF substrates.
There were clear differences in methane production among inocula from different sheep, which persisted across diets and substrates. Methane emission estimated from VFA production was about 21% greater ($P < 0.001$) than that directly measured, but both values were significantly related ($r = 0.612$; $P < 0.001$; $n = 128$). The results indicate that methane production in vitro is affected by both F:C ratio and type of forage in the diet of donors, and these variables should be taken into account when conducting in vitro experiments.

Key Words: methane, forage:concentrate ratio, forage

T377 Hydrogen sulfide release by ruminal microbes maintained in batch culture. M. Ruiz-Moreno*[1], E. Seitz[1], J. Garrett[2], and M. D. Stern[1], [1]*University of Minnesota*, *St. Paul,* [2]*Quali Tech Inc., Chaska, MN.*

Hydrogen sulfide (H_2S) release in the rumen depends upon ruminal pH, sulfur availability and its interaction with other minerals. An in vitro rumen fluid incubation was conducted using 2 sources of sulfur and 2 sources of Zn, Cu and Mn in a 2 × 2 factorial arrangement of treatments during 2 consecutive 24-h periods. A synthetic diet consisting of 36% cellulose, 32% starch, 19% CP, 5% fat and 2.4% sugar provided substrate for microbial metabolism. Sulfur was added as $NaSO_4$ or sulfur-bound lignosulfonate to a final concentration of 0.75% of DM. Copper, Zn and Mn were added as $CuSO_4$, $ZnSO_4$ and $MnSO_4$ or as protected Cu, Zn and Mn (SQM protected minerals, Quali Tech Inc.) to a final concentration of 16, 56 and 71 ppm of DM, respectively. Rumen fluid was obtained from a ruminal cannulated lactating dairy cow and mixed with McDougall's artificial saliva to a 1:4 ratio. Treatments were assigned in 6 replicates to 120-mL serum bottles containing 40 mL of the inoculum mix and 0.5 g dietary DM. Serum bottles were flushed with N_2, crimp sealed and incubated during 24 h at 39.1°C. At the end of incubations, gas volume was measured, H_2S in the headspace of bottles was analyzed and final pH of incubations was recorded. Results were analyzed as a 2 × 2 factorial design. An interaction between lignosulfonate and mineral source was detected. Addition of SQM minerals and lignosulfonate resulted in lower pH ($P < 0.05$) than that without lignosulfonate (5.87 vs. 5.95, respectively), while absence of SQM minerals resulted in intermediate pH of incubations despite lignosulfonate (5.90 ± 0.04). Addition of lignosulfonate without SQM minerals decreased total gas production ($P < 0.001$) compared with the other treatments (173.1 vs. 175.9 mL/g OM). Lignosulfonate resulted in a lower ($P < 0.001$) production of H_2S (416.2 vs. 475 µg/g OM). In contrast, addition of SQM minerals increased ($P < 0.001$) production of H_2S (469.5 vs. 421.5 µg/g OM). Results indicate that source of trace mineral can influence the dynamics of rumen fermentation.

Key Words: rumen, hydrogen sulfide, in vitro

T378 Comparison of bacterial diversity in the rumen of sheep and in Rusitec fermenters as assessed by ARISA–PCR. M. J. Ranilla*[1,2], M. L. Tejido[1,2], C. Saro[1,2], and M. D. Carro[1,2], [1]*Dpto. Producción Animal, Universidad de León*, *24071, León, Spain*, [2]*Instituto de Ganadería de Montaña (CSIC-ULE), Finca Marzanas s/n*, *24346 Grulleros, León, Spain*.

This study was designed to compare the effects of 4 diets on bacterial communities in bacterial pellets (BP) isolated from the solid (SAB) and liquid phase (LAB) of the rumen of sheep with those observed in Rusitec fermenters. The 4 experimental diets had forage:concentrate ratios (F:C) of 70:30 (HF) or 30:70 (HC) and alfalfa hay or grass hay as forage (FOR). SAB and LAB were isolated from each sheep (4 per diet) and fermenter (n = 4) immediately before feeding, and bacterial diversity was analyzed by ARISA-PCR of the 16S ribosomal DNA. A total of 170 peaks were detected in the ARISA electropherograms across the full set of 64 BP. The number of peaks (NP) in BP from sheep ranged from 42 to 82 for LAB, and from 31 to 81 for SAB (168 peaks in total). In fermenters, NP ranged from 53 to 79 for LAB, and from 21 to 69 for SAB (162 peaks in total). No effect of F:C ($P > 0.05$) on NP or Shannon index (SI) was observed on LAB in any system. F:C did not affect SAB profile in fermenters, but NP and SI were greater ($P < 0.05$) in SAB from sheep fed HF diets compared with those from HC-sheep. Feeding grass hay diets promoted greater ($P < 0.01$) SAB diversity in both systems compared with alfalfa hay diets. FOR did not ($P > 0.05$) affect LAB profile in sheep, but grass hay-fed fermenters had greater ($P < 0.01$) LAB diversity compared with fermenters fed alfalfa hay diets. The results indicate that bacterial diversity was more markedly affected by FOR than by F:C. There was a positive relationship (P = 0.001) between the NP in LAB and that in SAB in Rusitec, but no relationship ($P = 0.72$) was found in sheep; this would indicate that dietary effects on bacterial diversity were similar in LAB and SAB in fermenters, but contrasting in sheep. When all samples were analyzed together by clustering analysis, 2 distinct clusters were observed for in vivo and in vitro BP, which suggests a different structure of the bacterial communities in sheep and fermenters.

Key Words: rumen, fermenters, bacterial diversity

T379 Effect of supplemented diet by sucrose or starch on fungi populations in rumen fluid as determined by real-time polymerase chain reaction in Holstein steers. A. Vakili*, M. Danesh Mesgaran, H. Jahani Aziz-abadi, F. Rezaii, and S. Ghovvati, *Dept. of Animal Science, Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of this work was to investigate the effect of diets containing different type of non-fiber carbohydrates (sucrose or starch) on fungi populations in rumen fluid as determined by real-time polymerase chain reaction. Four Holstein steers (BW = 280; SD = 15 kg) were assigned to a 4 × 4 Latin square with 21-d periods. A basal diet was formulated to be contained of alfalfa hay, barley grain, soybean meal and sugar beet pulp (400, 290, 190 and 50 g/ kg, respectively). Starch (St) or sucrose (Su) or a 1:1 mixture of starch and sucrose (St+Su) was added to the basal diet at the rate of 70g/kg DM. Diets were offered as 2–2.5 times of maintenance requirements (7 kg DM/d). Rumen fluid samples were collected before and 4 h after the morning feeding. DNA was extracted from the samples using the QIAamp DNA stool mini kit (Qiagen Ltd, Crawley, West Sussex, UK) following the manufacturer′s instructions. Fungi rDNA concentrations were measured by real time PCR relative to total bacteria amplification (ΔΔCt). The 16s rRNA gene-targeted primer sets used in the present study were forward: GAGGAAGTAAAAGTCGTAACAAGGTTTC and reverse: CAAATTCACAAAGGGTAGGATGATT. Cycling conditions were 95°C for 5 min, 40 cycles of 95°C for 15s, 60°C for 15s and 72°C for 30s; fluorescence readings were taken after each extension step, and a final melting analysis was obtained by heating at 0.1°C/s increment from 60 to 95°C, with fluorescence collection at 0.2°C at intervals. Data are expressed relative to quantification of the total bacterial population. Data were analyzed using mixed procedure of SAS (2003). Statistical model was: $Y_{ijk} = \mu + T_i + C_j + P_k + \varepsilon_{ijk}$, where Y_{ijk} is dependent variable, μ is the overall mean, T_i is treatment effect, C_j is cow effect, P_k is period effect, and ε_{ijk} is error. The results of this experiment showed that different type of non-fiber carbohydrates didn't have any effect on fungi populations before or 4 h after the morning feeding[St = 52 and 44,Su = 48 and 45, St+Su = 47 and 42, SEM = 5 and 3 ($10 \times ^{-7}$) fungi relative to total bacteria, respectively].

Key Words: fungi, real-time PCR, rumen

T380 Sodium acetate/acetic acid as a buffer solution to simulate an acidic in vitro rumen environment. R. C. Araujo*[1], A. V. Pires[1], and A. L. Abdalla[2], [1]*ESALQ, Universidade de São Paulo*, *Piracicaba, SP, Brazil*, [2]*CENA, Universidade de São Paulo*, *Piracicaba, SP, Brazil*.

Incubation media based on $NaHCO_3$ and NH_4HCO_3 as buffers have a pH close to 6.8. A low-pH medium would provide a more realistic in vitro rumen simulation of animals fed feedlot diets. Treatments were: CTL6.8 – Theodorou's medium with a pH of 6.8 based on $NaHCO_3$ (7.28 g/L of medium) and NH_4HCO_3 (0.83 g/L of medium) as buffers; CTL5.8 – control acidified with 72% sulfuric acid to achieve a pH of 5.8; NaAc – Theodorou′s medium with Na acetate (56.6 g/L of medium) and glacial acetic acid (2.08 mL/L of medium) as buffers to achieve a pH of 5.8. In each flask (160 mL), 0.5 g of an 80:20 concentrate:forage diet

(91.4% DM) was incubated with 50 mL of medium and 25 mL of rumen fluid at 39°C for 16h. A randomized complete block design was used with n = 8 for gas production and n = 4 for all other variables. Two inocula (3 animals each; mean pH = 5.61 ± 0.11) from lambs adapted to the above diet were used as a source of variation. Data were analyzed by PROC Mixed of SAS with differences declared when $P < 0.05$. The pH variation after 0, 4, 8, 12, and 16h of incubation was: CTL6.8 – 6.77, 6.57, 6.45, 6.39, 6.31; CTL5.8 – 5.82, 5.51, 5.38, 5.34, 5.31; NaAc – 5.68, 5.65, 5.61, 5.59, 5.57, respectively. Mean pH was lowest for CTL5.8 (5.47), followed by NaAc (5.62) and CTL6.8 (6.50). CTL6.8 showed the greatest values for gas production (151.1 mL), CH_4 production (13.3 mL), and truly degraded DM (TDDM; 70.7%). Gas production (86.9 vs. 80.2 mL), CH_4 production (4.2 vs. 2.1 mL), and TDDM (51.4 vs. 49.6%) were similar between CTL5.8 and NaAc, respectively. It was not possible to determine C_2 concentration for NaAc. Total SCFA (94.0 vs. 61.4 m*M*) and C_2 (50.5 vs. 21.4 m*M*) concentrations as well as C_2 to C_3 ratio (2.20 vs. 0.95) were greater for CTL6.8 than CTL5.8. Concentration of C_3 was the greatest for CTL6.8 (23.8 m*M*), intermediary for CTL5.8 (22.7 m*M*), and the lowest for NaAc (19.4 m*M*). In spite of less pH variation, Na acetate/acetic acid solution as buffer interfered in C_2 determination and showed similar results in comparison with an acidified $NaHCO_3/NH_4HCO_3$-based medium.

Key Words: buffer, medium, pH

T381 Milk selenium content and performance of cows supplemented with selenized yeast. L. Q. Melo[1], L. L. Bitencourt[1], S. Siécola Júnior[1], G. S. Dias Júnior[1], N. M. Lopes[1], V. A. Silveira[1], I. R. Rios[1], R. A. N. Pereira[2], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras*, *Lavras, Brazil*, [2]*Empresa de Pesquisa Agropecuária de Minas Gerais*, *Lavras, Brazil*.

This study evaluated the effect of replacing sodium selenite (45.1% of Se) with selenized yeast (Selemax, Biorigin, Brazil. 2245 ppm of Se). Twenty-eight Holsteins were fed a Se supplement free diet for a 60-d standardization period (0.08 ppm of Se in the diet), before being paired blocked and assigned to a treatment for 105 d: Orally given gelatin capsules containing 2.1 g of Selemax (4.64 mg of Se) or 0.011 g of Selenite (4.88 mg of Se) daily. Milk yield and DMI were measured daily, and milk composition on days −1 and 0, 15 to 17, 36 to 38, 57 to 59, and 99 to 101. Milk Se content was determined on d 0, 4, 8, 16, 37 and 57. Total collection of feces and urine was performed on d 39 to 41 for Se balance. Blood samples were obtained on d 0, 43 and 106 to determine Se content and glutathione peroxidase activity. Data were analyzed as repeated measures over time with Mixed of SAS. The model contained the effects of covariate (measure of the same variable at the end of the standardization period), block, treatment, time, and time by treatment interaction. Cow within treatment tested the treatment effect. Daily milk yield was 26.7 kg for Selemax and 26.9 kg for Selenite ($P = 0.84$), milk SCC (× 1,000 cells) was 354 and 352, respectively ($P = 0.99$), and no difference in milk solids or DMI were detected ($P > 0.22$). Selemax increased milk Se content from 8 to 32.3 μg/kg ($P < 0.01$), observed after 4 d of supplementation and throughout data sampling. Plasma Se content was 91.4 and 77.3 μg/L ($P = 0.14$) for Selemax and Selenite, respectively. Glutathione peroxidase activity was greater for Selenite on d 43 and for Selemax on d 106 ($P = 0.05$ for the interaction). There was no difference in Se excreted in urine and feces or retained ($P > 0.46$). Selenized yeast increased milk Se content shortly after starting the supplementation.

Key Words: selenium, yeast, glutathione peroxidase

T382 Effect of direct-fed microbial (DFM) products on rumen bacterial communities in Holstein cows at 2 and 6 weeks postcalving. E. A. Galbraith*[1], A. H. Smith[1], K. J. Mertz[1], Z. Wu[2], and J. D. Ferguson[2], [1]*Danisco*, *Waukesha, WI*, [2]*University of Pennsylvania School of Veterinary Medicine*, *Kennett Square*.

Increase in performance was measured in a study to determine the efficacy of 3 DFM treatments in dairy production. Treatment with a *Propionibacterium* DFM 2 weeks prepartum followed by a *Lactobacillus* DFM through 22 weeks postpartum or *Bacillus pumilus* 8G-134 at either 5×10^9 or 1×10^{10} CFU/head/day both pre- and postpartum resulted in improved milk volume (*B. pumilus* 8G-134) and milk fat (all DFM treatments). This study investigated if these DFM treatments were also associated with changes in ruminal microbial populations at 2 and 6 weeks postcalving. At 8 h postfeeding, cows were restrained and rumen fluid collected via stomach tube. The microbial community of rumen fluid samples was monitored by terminal restriction fragment length polymorphism (T-RFLP) analysis of amplified 16S rDNA genes. Peak profiles from all samples using 3 restriction enzymes were between 70% and 93% similar. All samples tended to have several major peaks and the taxonomic identities of species responsible for these peaks were determined by searching 16S databases. Major peaks present in most samples included common rumen species of *Prevotella*, *Bacteroides*, *Butyrvibrio fibrisolvens*, *Selenomonas ruminantium*, and *Clostridium clostridioforme* and *coccoides*. Analysis of dendrograms indicated no overall clustering by treatment, sampling date, or lactation, but MANOVA analysis did pinpoint several minor TRF peaks which were significantly associated ($P < 0.1$) with treatments. On a CFU per gram basis, the level of DFM treatments fed in this trial would constitute less than 0.1% of the total rumen bacterial population, therefore below the threshold of detection of microbial ecology techniques such as T-RFLP. However, even at low concentrations, the DFM treatments affected performance and bacterial populations, suggesting an impact on bacteria that may be part of a rarer biosphere in the rumen. Examination of rumen bacterial communities may help elucidate the mode of action of these direct-fed microbials.

Key Words: dairy cows, rumen bacteria, direct-fed microbial

T383 Effects of a rumen protected B vitamin complex supplemented to multiparous Holstein cows on milk production and reproductive performance. S. O. Juchem*[1,2], P. H. Robinson[1], and E. Evans[3], [1]*University of California*, *Davis*, [2]*California State University*, *Fresno*, [3]*Technical Advisory Services*, *Bowmanville, ON, Canada*.

Increase in milk yield of dairy cows through supplementation with B vitamins was reported, but the impact on reproductive performance of dairy cows in unknown. Objectives were to evaluate the effect of supplementation with a complex of rumen protected B vitamins (RPBV) that contained biotin, pantothenic acid, folic acid, cyanocobalamin, and pyridoxine to early lactating multiparous cows on milk yield, milk composition and reproductive performance during the first 170 d of lactation. Multiparous Holstein cows (n = 1243) that calved between November of 2007 and April of 2008 were assigned to 2 treatments as cows moved from fresh to one of the 4 early lactation pens: control diet (CT); and B vitamin diet (BV), supplementation with 3.6 g/cow/d of RPBV. Early lactation diets were identical for CT and BV treatments, except for the RPBV supplement fed in the first TMR load to the 2 treatment pens. Cows were artificially inseminated upon estrous detection every morning, and pregnancy diagnosis was performed by per rectum palpation at 42 ± 3 d after breeding. Yields of milk and milk composition were measured monthly. Body condition (BC) was scored from a subgroup of 170 cows at 40 and 100 DIM. A total of 949 cows provided data for statistical analysis, 448 CT and 501 BV cows. Cows were moved to treatment pens at 22.3 DIM. Loss of BC was similar ($P = 0.11$) for CT

(−0.055) and BV (−0.034) cows during early lactation, as well as group DMI, 25.4 and 25.0 kg/d, respectively. Milk yield was similar ($P = 0.18$) for BV and CT during the first 170 d of lactation, 44.9 vs. 44.4 kg/d, respectively. Milk fat content was reduced by feeding RPBV (3.29 vs. 3.38%; $P < 0.01$), but milk fat yield was not affected (1464 vs. 1485 g/d; $P > 0.15$). Day at first service was not different ($P = 0.44$) for BV and CT cows (67.9 vs. 67.2 d), but BV cows had higher ($P < 0.05$) first service conception rate than CT cows (40.8 vs. 35.8%). In summary, supplementation with a RPBV complex improved first service conception rate, whereas milk yield was not affected.

Key Words: biotin, folic acid, cyanocobalamin

T384 Effect of feeding live yeast on performance of Holstein cows during summer. R. S. Marsola*, M. Favoreto, F. T. Silvestre, J. H. Shin, A. T. Adesogan, C. R. Staples, and J. E. P. Santos, *University of Florida*, *Gainesville*.

Objectives were to evaluate the effect of amount of dietary live yeast (LY) intake on performance of cows under heat stress. Holstein cows, 27 multiparous and 33 primiparous, were blocked by parity and milk yield in the first 20 DIM and randomly assigned to receive 0 g/d LY, 0.5 g/d LY (20 billion cells/g, *Saccharomyces cerevisiae* strain CNCM I-1077, Levucell SC20, Lallemand Animal Nutrition, Milwaukee, WI), or 1 g/d LY in the diet from 30 to 107 DIM. Cows were milked twice daily and DM intake and milk yield were measured daily. Milk components were measured once weekly. Cows were weighed weekly. Blood was sampled weekly and analyzed for concentrations of NEFA. Cows were fed chromic oxide in the last 2 wk of the study for calculation of total tract digestibility of nutrients. Ruminal fluid was collected once by rumenocentisis 6 h after feeding for measurement of pH. During the study period, the mean daily temperature was 26.8 C and humidity was 83.2%, and the temperature and humidity index ranged from 73 to 81. Data were analyzed by the GLIMMIX procedure of SAS and linear and quadratic orthogonal contracsts were used. Rectal temperature was not affected by LY and averaged 38.9 ± 0.04°C. Feeding LY did not influence DMI, yields of milk, 3.5% FCM, energy-corrected milk (ECM), and milk fat. Feeding LY caused a linear increase in feed efficiency (ECM/DMI) and milk true protein yield, and had a quadratic effect on OM digestibility, but tended to decrease calculated energy balance. Mean rumen pH increased, and proportion of cows with low pH (<5.8) decreased linearly with LY. Feeding 1 g/d of LY increased efficiency of feed conversion into ECM, yield of true protein, and rumen pH, and reduced the risk of sub-acute rumen acidosis.

Table 1.

	g/d				P	
	0	0.5	1	SEM	Linear	Quadratic
DM intake, kg/d	20.9	20.3	20.3	0.4	0.25	0.61

T385 Population dynamics of protozoa in dairy cows fed with Rumensin200 and tallow during dry and lactating stages. H. Castillo, A. Castillo*, D. Dominguez, G. Villalobos, M. Arana, and J. A. Ortega, *Universidad Autonoma de Chihuahua*, *Chihuahua, Chihuahua, Mexico*.

Addition of Rumensin200 and tallow in TMR for dairy cows on protozoan populations was explored in dry and early-lactating cows. Ionophores have been used in ruminants to decrease acidosis and to mitigate gaseous emissions in dairy operations, by inhibiting growth of microorganisms such as protozoa. Also, tallow as an energy alternative in TMR has shown changes in fiber digestibility and gases production, mainly due to the interaction of its unsaturated component with rumen microorganisms. For this experiment, 4 ruminally fistulated Holstein cows were fed rations based on a 90:10 (dry) and 40:60 (lactating) forage to concentrate ratios. Four treatments were randomly assigned in a 4 × 4 Latin Square experimental design as follows: TMR (T1), TMR + 2/3.3 g Rumensin 200(dry/lactating), (T2), TMR + 3,2% DM tallow (T3) and TMR + 2/3,3 g Rumensin 200+ 3,2% DM tallow (T4). Samples of ruminal content were taken at 0, 1, 2, 4, 8, 12, 18 and 24 h after feeding, filtered, preserved with an equal volume of 5% formalin and frozen. Thawed samples were treated with brilliant green and glycerol for direct protozoa count on a Neubauer chamber under a microscope at 40X. Oxidation-reduction potential (ORP) and pH were recorded *in rumen* during the same sampling times. Total number of protozoa at 24 h after feeding did not differ ($P > 0.001$) among treatments in lactating cows, whereas the addition of Rumensin200 to TMR for dry cows caused a significant decrease ($P > 0.001$) in population size (5.0^5 vs. 1.06^5, respectively). Also, protozoa were less diverse in lactating compared with dry cows; while the *Diplodiniae* species were dominant (98%) in lactating cows with any treatment, dry cows fed T3 exhibited a more diverse community formed by 68% *Diplodiniae* and 29% *Entodinium*. Monitoring of pH did not show significant differences ($P > 0.001$) among treatments in both dry and lactating stages, while ORP values suggested a more reduced environment (−241 to –310 mV) in lactating than in dry cows (−234 to –294 mV). This experiment showed changes in protozoan community composition led by modification of the rumen environment.

Key Words: Rumensin, tallow, protozoa

T386 Construction and analysis of metagenomic fosmid library from rumen microflora of Chinese Holstein dairy cow. D. Li, J. Q. Wang*, K. L. Liu, D. P. Bu, and W. Feng, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

The vast majority of rumen microbial diversity has been inaccessible by culture dependent methods. Recent progress in molecular microbial ecology has reveled that traditional culturing methods fail to represent the scope of microbial diversity in rumen, since only less than 11% of viable microorganisms are recovered by culturing techniques. To investigate the full extent of microbial diversity and compare genomic studies among ruminant microflora species by metagenomic method, a fosmid library was constructed with genomic DNA isolated directly from rumen content. Preparation of ruminant genomic DNA for library construction was extracted by LMP agarose gel plug. Extracted ruminant genomic DNA was digested with *Hin*dIII. Purified DNA of 36–48 kb length was recovered by pulsed field electrophoresis and ligated with pcc2FOS vector and transformed into *E. coli* EPI300. The fosmid genomic library of rumen microbe was successfully constructed with the capacity of 1050 Mb in which the insert fragment size was about 35 kb, and about 30000 clones. Excluding the 2% of empty clones, the

coverage of this library is 93% genome equivalents. This fosmid library offers a new tool for gene screening and cloning, and for comparative genomic studies among ruminant microflora species.

Key Words: metagenomics, fosmid library, rumen microflora

T387 Effects of *Saccharomyces cerevisiae* and *Aspergillus niger* (fermentation soluble meal extracted) on productivity of Holstein cows in early lactation. R. Heydari, M. Dehghan-Banadaky*, K. Rezayazdi, and A. Zali, *Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran*, *Karaj, Tehran, Iran*.

The objective of this study was to investigate the effects of feeding *Saccharomyces cerevisiae* (SC) and *Aspergillus niger* fermentation solubles meal extracted (AN) to early lactation cows. Twenty-four Holstein lactating cows (8 primiparous and 16 multiparous; 24 ± 7 DIM) were assigned to 1 of 4 dietary treatments as follows: 1) SC (Biosaf SC47)10 g/d/cow; 2) AN (Bospro) 30 g/d/cow; 3) SC 10 g/d/cow and AN 30 g/d/cow; 4) control (no additive). Cows were fed the same total mixed ration (19.5% alfalfa hay, 19.5% corn silage, 7.1% beet pulp and 53.9% concentrate on dry matter basis) and additives were top-dressed during experimental period (75 d). Milk production and DM intake were recorded daily and milk samples were collected weekly from all cows for measurement of somatic cell count (SCC) and milk composition. Blood samples were taken from each cow on the last day of experiment, 3 h after morning meal for metabolic profiling. Data (except blood data) were statistically analyzed using the repeated measures option in Proc Mixed of SAS. DMI was similar between treatments (21.44, 20.41, 21.83 and 21.54 kg/d, respectively). Cows fed SC (treatment 1 and 3) produced more milk than other groups, but fat corrected milk (FCM4%) was not significantly affected by treatments ($P > 0.05$). Milk protein percent significantly increased in cows fed SC as well as milk protein yield. However, other milk composition percentage and SCC were similar for all treatments. Changes in body weight and body condition score (BCS) were not influenced by treatments. Blood metabolites includes: glucose, nonesterified fatty acids, urea nitrogen, triglycerides and phosphorous were unaffected by treatments. These results indicate that supplementation of SC can improve milk production and milk composition, but AN did not affect productivity.

Key Words: *Saccharomyces cerevisiae*, *Aspergillus niger*, milk production

T388 Diversity of nitrogen-fixing bacteria in Holstein dairy cow rumen. S. Zhao, J. Wang*, D. Bu, L. Zhou, and C. Zhang, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

The rumen has a suitable environment for N_2-fixation, because of N_2 presence and the presents of some nitrogen fixing bacteria. The gene *nif*H encodes the dinitrogenase reductase, an enzyme for N_2 fixation, is conserved and used to analyze the phylogenetic diversity of the nitrogen-fixing microorganisms. To reveal the diversity of nitrogen-fixing microorganisms in dairy cow rumen, the *nif*H clone library was constructed. Rumen total DNA was extracted based on the method of freezing/thawing and N-lauroyl sarcosine/proteinase K lysis. Polymerase chain reaction was used to amplify the *nif*H genes from rumen total DNA. PCR products were purified and ligated to pMD19-T vector. *Nif*H gene clones got by transforming ligation product into *E.coli* JM109 were sequenced. The sequences were analyzed by Blast on GenBank and phylogenetic tree was built by Mega 4.0. In results, a total of 64 *nif*H gene clones were obtained. Most of the *nif*H genes belonged to *Fermicute* with the percent of 85.93%, and some belonged to *Archaea*, *α-Proteobacteria*, *Chlorobi* with the percent of 7.81%, 4.70%, 0.56%, respectively. The *nif*H phylogenetic tree also revealed that there was a remarkable diversity of nitrogenase genes in the rumen. The study provided first evidence for the diversity of nitrogen-fixing bacteria from dairy rumen.

Key Words: nitrogen-fixing bacteria, *nif*H, rumen

T389 Dietary cation-anion difference: Effects on fluid metabolites and health status of transition cows in Karst area. W. X. Wu*, *College of Animal Science, Guizhou University*, *Guiyang, China*.

There has little information of dietary cation-anion difference (DCAD, mmol/kg DM) on the performance of dairy cows in Karst area, especially in southwest, China. This study is conducted to evaluate the effects of DCAD on the fluid metabolites, health status, and subsequent lactation performance of transition cows in Karst area. Thirty pregnant, nonlactating Holstein multiparous cows were randomly assigned to 3 blocks of 10 cows based on their age (4 yr), body weight (600 kg), and expected calving date (21 d). Animals were fed 1 of 3 DCAD diets: control (+81), treatment 1 (+20), and treatment 2 (−32), respectively. Anionic salts were included to reduce DCAD. Feeding of reduced DCAD resulted in lower urinary pH than control ($P < 0.05$). Plasma Ca and Cl levels in treatment 2 was higher over those in control ($P < 0.05$). There were no significant difference in plasma glucose and urea nitrogen; Na, K, and P concentrations for 3 dietary treatments ($P > 0.05$). Anionic salts supplementation reduced the cases of hypocalcemia (3:1:1) and retained placenta (4:2:1). Dry matter intake, milk yield and contents of protein, fat, and lactose were unaffected by DCAD modulation ($P > 0.05$). These results suggested that negative DCAD is beneficial for transition cows in Karst area. Further study is necessary to investigate the effect of DCAD on the reproductive performance.

Key Words: dietary cation-anion difference, Karst area, transition cows

T390 Effects of subacute ruminal acidosis challenges on lipopolysaccharide endotoxin (LPS) in the rumen, cecum, and feces of dairy cows. S. Li, A. Kroeker, E. Khafipour, J. C. Rodriguez, D. O. Krause, and J. C. Plaizier*, *Department of Animal Science, University of Manitoba*, *Winnipeg, MB, Canada*.

Feeding high grain diets to cows can cause subacute ruminal acidosis (SARA) and increase the amount of dietary starch that is digested in the large intestine. Grain-induced SARA can increase free lipopolysaccharide endotoxins (LPS) in the rumen, due to increased lysis of gram-negative bacteria. Increased starch in the large intestine may also reduce the pH of the digesta, and increase LPS in the large intestine and in the feces. This could explain symptoms of SARA, as it may be easier for LPS to translocate into the blood in the large intestine than in the rumen. SARA can also be induced by feeding forage pellets. This does not increase the content of starch in the diet. Hence, the effects of this form of SARA on the large intestine may differ from that of grain-induced SARA. To test this, a study was conducted with non-lactating dairy cows with cannulas in the rumen and in the cecum. A Latin square with 3 4-wk periods was used. In wk 1–3 cows received a control diet containing 70% of forage (DM basis) and 30% mixed concentrates. In wk 4 cows received either the control diet, a high grain diet for a grain pellet-induced SARA challenge (GPI_SARA, 38% wheat-barley pellets, 32% mixed concentrates, and 30% of forages), or a diet that contained alfalfa pellets for an alfalfa-pellet induced SARA challenge (API_SARA, 45% of mixed concentrates, 32% of alfalfa pellets, and 23% of other forages). During this week, rumen pH was monitored continuously in all cows.

Rumen fluid, digesta from the cecum, and feces were sampled immediately before feed delivery and at 6 h after feed delivery. All samples were analyzed for LPS. The pH of cecum samples were determined. Both SARA challenges resulted in depressions of rumen pH that were representative of SARA, and decreased the pH of digesta in the cecum, but not as much as the rumen pH. GPI_SARA greatly increased LPS in the rumen, cecum, and feces. API_SARA increased LPS in the rumen, but not in the cecum and in the feces. Results confirm our hypothesis that grain-induced SARA, but not SARA induced by feeding pelleted forages, increases LPS in the large intestine and in the feces.

Table 1. Rumen and cecum pH and LPS in the rumen, cecum and feces

	Control	API_SARA	GPI_SARA	SEM	P-value
Average rumen pH	6.30[a]	5.99[b]	5.98[b]	0.04	<0.01
Time < rumen pH 6, min/d	332[b]	770[a]	744[a]	57	<0.01
Time < rumen pH 5.6, min/d	56[b]	255[a]	299[a]	30.7	<0.01
Cecum pH	7.07[a]	6.86[b]	6.79[b]	0.06	<0.01
Rumen LPS, EU/mL	8,333[b]	18,425[b]	124,566[a]	8,738	<0.01
Cecum LPS, EU/mL	18,289[b]	15,631[b]	128,410[a]	20,379	<0.01
Feces LPS, EU/mL	13,909[b]	18,998[b]	101.555[a]	16,355	<0.01

T391 Supplementing *Megasphaera elsdenii* modulates diurnal rumen fermentation profile in dairy cows. Q. Zebeli[1], S. Iqbal[1], A. Mazzolari[1], S. M. Dunn[1], W. Z. Yang[2], and B. N. Ametaj*[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Megasphaera elsdenii is a direct-fed microbial possessing lactate-utilizing properties. We hypothesized that its supplementation might modulate the fermentation profile in the rumen of dairy cows. This study sought to evaluate the effects of supplementing *M. elsdenii* on diurnal volatile fatty acids (VFA) concentration and profile in the rumen fluid of mid-lactation dairy cows. Eight rumen-cannulated Holstein cows were used in a paired 2 × 2 crossover design with 2 21-d periods. All cows were offered a total mixed ration containing (dry matter basis) 32% rolled barley grain, 15% alfalfa hay, 40% barley silage, and 13% protein-, and vitamin-mineral supplement. A culture of 35 mL of *M. elsdenii* ATCC 25940TM, containing 10^7 - 10^9 CFU/mL, was inoculated daily via rumen fistula to each cow pertaining to the treatment group (TRT), whereas control cows (CTR) were inoculated with 35 mL of carrier only. Rumen samples were collected on d 21, shortly before the morning feeding at 0800 and every 2 h up to 2000, and VFA were analyzed by GC. ANOVA was conducted with MIXED procedure of SAS accounting for repeated measures. Data showed that treatment did not affect the concentration of total VFA (128 vs. 125 m*M*; $P > 0.05$), but lowered the molar proportion of acetate (61.3 vs. 59.9% of total VFA; $P < 0.01$) and isobutyrate (1.9 vs. 1.7%; $P < 0.01$). On the other hand, the TRT cows had greater proportions of butyrate (12.7 vs. 14.4%; $P < 0.01$) and valerate (1.9 vs. 2.3%; $P < 0.01$) than the CTR cows. There was an hour by treatment interaction for acetate to propionate ratio ($P = 0.03$) and the proportion of propionate in the rumen fluid ($P = 0.05$). Rumen caproate and isovalerate were not affected by treatment ($P > 0.05$). In conclusion, data of this study indicated that supplementation of *M. elsdenii* modulated the fermentation in the rumen of dairy cows shifting its profile from acetate to the production of butyrate and valerate.

Key Words: dairy cow, fermentation profile, *Megasphaera elsdenii*

T392 Effects of supplementing *Megasphaera elsdenii* on preprandial rumen fermentation profile in dairy cows. Q. Zebeli[1], S. Iqbal[1], A. Mazzolari[1], S. M. Dunn[1], W. Z. Yang[2], and B. N. Ametaj*[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Ingestion of large amounts of cereal grains leads to rapid accumulation of volatile fatty acids (VFA) and lactate in the rumen fluid and major changes in their profile. *Megasphaera elsdenii*, a rumen obligate anaerobe, has lactate-utilizing properties and the potential to modulate rumen fermentation profile by converting lactate into VFA. This study sought to evaluate the effects of supplementing *M. elsdenii* on VFA concentration and profile in the rumen fluid in mid-lactation dairy cows. Eight rumen-cannulated Holstein cows were used in a paired 2 × 2 crossover design with 2 21-d periods (first 11 d used for adaptation). All cows were offered a total mixed ration containing (dry matter basis) 32% rolled barley grain, 15% alfalfa hay, 40% barley silage, and 13% protein-, and vitamin-mineral supplement. A culture of 35 mL of *M. elsdenii* ATCC 25940TM, containing 10^7 - 10^9 cfu/mL, was inoculated daily via rumen fistula to each cow pertaining to the treatment group (TRT), whereas control cows (CTR) were inoculated with 35 mL of carrier only. Preprandial rumen samples were collected shortly before morning feeding on d 12, 14, 16, 18, and 21, and VFA were analyzed by GC. ANOVA was conducted with MIXED procedure of SAS accounting for repeated measures. Data showed that treatment did not affect the concentration of total VFA in the rumen fluid ($P > 0.05$), but tended to increase the molar proportion of propionate (19.9 vs. 21.0% of total VFA; $P = 0.09$), and lower the acetate to propionate ratio (3.32 vs. 3.09; $P = 0.07$). The TRT cows also had lower concentration of valerate (2.4 vs. 1.8 m*M*; $P = 0.04$) and isovalerate (2.7 vs. 2.2 m*M*; $P < 0.01$) than their CTR counterparts. Other VFA such as acetate, butyrate, isobutyrate, and caproate were not affected by the treatment ($P > 0.05$). In conclusion, results of this study indicated that supplementation of *M. elsdenii* slightly modulated the preprandial fermentation profile in dairy cows.

Key Words: dairy cow, fermentation profile, *Megasphaera elsdenii*

T393 Diagnosis of subacute ruminal acidosis (SARA) using the Optium Xceed Diabetes Monitoring System. S. Li[1], A. Kroeker[1], D. O'Gorman[2], D. O. Krause[1], J. C. Rodriguez[1], and J. C. Plaizier*[1], [1]*Department of Animal Science, University of Manitoba*, *Winnipeg, MB, Canada*, [2]*Marigot Ltd.*, *Carrigaline, Co. Cork, Ireland*.

The current diagnosis of subacute ruminal acidosis (SARA) relies on measuring the pH of rumen fluid samples, which are difficult to collect and may not be representative. Studies have reported that monitoring of blood glucose may aid in the diagnosis of SARA. However, SARA caused by feeding high grain diets and SARA caused by feeding diets with insufficient physically effective fiber, e.g., a diet containing alfalfa pellets, can affect blood glucose differently. This may affect the accuracy of this measurement for the diagnosis of SARA. The Optium Xceed Diabetes Monitoring System for glucose measurement was tested for the diagnosis of SARA. The study included 6 rumen cannulated nonlactating dairy cows in a 3 × 3 Latin square with 4 wk periods. In wk 1–3 cows received a control diet (70% forage and 30% mixed concentrates (DM basis)) . In wk 4, cows received either the control diet, a high grain diet for a grain pellet-induced SARA challenge (GPI_SARA, 38% wheat-barley pellets, 32% other mixed concentrate, and 30% forages), or a diet that contained alfalfa pellets for an alfalfa-pellet induced SARA challenge (API_SARA, 45% mixed concentrate, 32% alfalfa pellets, and 23% other forages). During wk 4, rumen pH was monitored in all cows, and blood was sampled immediately before feed delivery and at 6 h after feed delivery. Glucose in whole blood was measured using

the Optium Xceed Diabetes Monitoring System, which can be used on farm. The average daily rumen pHs were 6.30, 5.99, and 5.98, for control, API_SARA, and GPI_SARA, respectively. The durations of the rumen pH below 5.6 were 56.4, 225.2 and 298.7 min/d for control, API_SARA, and GPI_SARA, respectively. This shows that both forms of SARA resulted in similar depressions of rumen pH and that SARA was induced. Blood glucose was higher during GPI_SARA than during control (4.47 vs. 4.25 mmol/L,), but blood glucose did not differ between the API_SARA and control. This shows that the Optium Xceed Diabetes Monitoring System can aid in the diagnosis of grain induced SARA, but that additional tests may be needed for the diagnosis of SARA caused by diets with insufficient physical effective fiber.

Key Words: SARA, diagnosis, blood

T394 Simplified procedure for quantifying ruminal microbe populations using real-time PCR. C. R. Mullins*, L. K. Mamedova, and B. J. Bradford, *Kansas State University*, *Manhattan*.

A variety of molecular techniques exist to quantify ruminal microbiota; however, sample processing requirements for most techniques are complex and time consuming. The objective of this work was to use real-time PCR to quantify relative abundance of 10 microbial populations while simplifying the sample preparation process. Our trial utilized ruminal contents from 8 ruminally cannulated Holstein cows used in a 4 × 4 Latin square experiment that examined the effect of varying wet corn gluten feed inclusion rate (0–36% DM). Rumen samples were collected every 9 h over a 3-d period so that 8 samples were taken from each cow each period, representing every 3 h of a 24-h period, thus accounting for diurnal variation. Digesta and rumen fluid were collected as one sample to capture the free-floating and particle adherent microbes in similar proportions as found in the rumen. Samples were collected from 5 locations throughout the rumen, mixed, and a representative subsample (200 g) was collected and frozen at −20°C. Prior to processing, samples were thawed at room temperature until they became pliant, then composited by cow period. Each composited sample was diluted with distilled, deionized water at a 1:1 ratio and homogenized. A subsample was then obtained from the homogenized mixture and used for microbial DNA isolation using a commercial kit (Zymo Research Fecal DNA kit). Quantitative real-time PCR was used to determine relative abundance of bacterial populations using previously validated primers specific for genes encoding 16S ribosomal RNA. Efficiencies were calculated to determine population abundance relative to the total bacterial population. Dietary treatments had few effects, but diets that decreased ruminal pH tended to decrease the *Butyrovibrio fibrosolvens* population ($P = 0.09$).The relative population densities for most species quantified were within the range reported previously; for example, the *Prevotella* genera and *Fibrobacter succinogenes* accounted for 39.9% and 1.0% of the ruminal bacteria, respectively. This procedure offers a simpler and quicker means to quantify relative abundance of rumen microbial populations.

Key Words: rumen, real-time PCR, DNA extraction

T395 Effects of forage-to-concentrate ratio and rumen fermentation characteristics on apparent ruminal synthesis of niacin and vitamin B6 in lactating dairy cows. M. Seck*[1,3], J. A. Voelker Linton[2], M. S. Allen[2], P. Y. Chouinard[3], and C. L. Girard[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Quebec, Canada*, [2]*Department of Animal Science, Michigan State University*, *East Lansing,* [3]*Departement de sciences animales, Universite Laval*, *Quebec, Quebec, Canada*.

Effects of forage-to-concentrate ratio and rumen fermentation characteristics on apparent ruminal synthesis and post-ruminal supply of niacin (B3) and vitamin B6 were evaluated in an experiment using 14 ruminally and duodenally cannulated Holstein cows. The experiment was a crossover design with 2 15-d treatment periods and a preliminary period in which dry matter intake (pDMI) of a diet intermediate in composition between the treatments was determined. Treatments were diets containing low-forage (LF; 44.8% forage, 32.8% starch, 24.4% NDF) or high-forage (HF; 64.1% forage, 22.5% starch, 30.7% NDF) concentrations. No interactions between treatment and pDMI were observed ($P \geq 0.2$). LF decreased B3 intake (1035 vs. 1135 ± 16 mg/d; $P \leq 0.01$) but increased apparent ruminal synthesis (2831 vs. 1885 ± 250 mg/d; $P \leq 0.01$) and duodenal flow (3866 vs. 3020 ± 255 mg/d; $P \leq 0.01$) of B3 compared with HF. Although B6 intake was not influenced (91 vs. 89 ± 1; $P > 0.1$) by treatments, LF decreased apparent ruminal degradation (−3 vs. −20 ± 3 mg/d; $P \leq 0.01$) and increased B6 duodenal flow (88 vs. 68 ± 4 mg/d; $P \leq 0.01$) compared with HF. B3 flow tended to be correlated positively to B3 intake (r = 0.36, $P = 0.06$) while B6 flow was correlated positively to B6 intake (r = 0.73, $P < 0.01$). Ruminal synthesis and duodenal flow of B3 and B6 were correlated negatively to mean ruminal pH (r = −0.45, $P < 0.02$ for all) and correlated positively to true ruminally degraded starch (kg/d; r = 0.42, $P < 0.03$ for all). Ruminal synthesis and duodenal flow of B3 and duodenal flow of B6 were correlated positively to microbial N flow (g/d, r = 0.51, $P < 0.01$ for all). Niacin and vitamin B6 supply to dairy cows is increased with greater dietary starch concentration and starch digestion in the rumen.

Key Words: dairy cow, niacin, pyridoxine

T396 The effect of high inclusion of monensin on lactation performance in dairy cows. L. R. Behling*[1], K. Perfield[2], R. Martin[1], R. Greenfield[1], and S. Onetti[1], [1]*Vita Plus Corporation*, *Madison, WI*, [2]*Elanco Animal Health*, *Greenfield, IN*.

Three free-stall herds were used to conduct on-farm trials to determine if a high inclusion of monensin (MON) in the lactating cow TMR would affect milk fat production. Each herd provided 2 pens each of cows at similar DIM, parity and age. Herds were fed typical Midwestern diets, composed of alfalfa haylage and corn silage. Diets were formulated for 17.3% CP, 25.6% starch and 22.2% NDF from forage, DM basis. The trials were conducted during winter (Dec and Jan) and summer (Jul and Aug) in 2009 to evaluate potential interactions between season and MON inclusion. All cows were fed MON at an inclusion of 11.4 g/ton DM before the start of the trial. At the beginning of the trial, MON was removed from the diets in the control pens, and increased to 15.3 g/ton in the treatment pens, based on formulated DMI of 23.7 kg/d. After 2 weeks, treatment pens were increased to 19.1 g MON/ton. After 4 weeks at 19.1 g/ton, milk samples were collected from the milk line for each pen and pen milk weights were recorded. Data were analyzed using MIXED models of SAS. The model included fixed effects of treatment, season and their interaction. Herd was the specified term for the random statement. There were no season x treatment interactions on milk production and components. Inclusion of MON had no effect on milk yield, milk fat % or milk fat and protein yield. Milk protein % was significantly decreased by MON inclusion and MUN was significantly lower in the winter. In summary, inclusion of MON at 19.1 g/ton did not affect milk fat production.

Table 1. Milk production of dairy cows after 4 weeks of supplementation with 19.1 g MON/ton DM

	Winter		Summer	
	g MON/ton DM			
Variable	0	19.1	0	19.1
Milk, kg	36.3	37.1	34.5	36.1

T397 Effects of a microbial fermentation product on milk production and blood metabolites on commercial dairies in eastern Canada. A. M. Gehman*[1], J. D. Johnston[2], and J. M. Tricarico[1], [1]*Alltech*, *Brookings, SD,* [2]*Ritchie Feed and Seed, Ottawa, Ontario, Canada.*

Three dairy farms located in Ontario and Quebec, Canada, were utilized to determine effects of feeding a microbial fermentation product (MFP; CP = 47% DM; soluble CP = 40% CP) on milk production, components, and blood metabolites of lactating dairy cattle. The study was conducted as a crossover design with 2 21-d periods. Experimental rations were: 1) control, 0 g/d MFP; or 2) MFP, 600 g/d MFP. Diets were isonitrogenous and isoenergetic. The MFP ration was formulated to provide 600 g/head/d MFP (2.1% ration DM) by replacing a portion of plant-based protein. Each farm was assigned to one of 2 treatment sequences: control followed by MFP or MFP followed by control. Milk production and feed intake were recorded for the last 2 d of each period, and blood samples were taken from 15 randomly selected cows on each farm during the last week of each period. Average DIM for cows that were blood sampled was 200 for control and 147 for MFP. Milk was analyzed for fat and protein, and blood was analyzed for non-esterified fatty acids (NEFA), β-hydroxybutyric acid (BHBA), and blood urea nitrogen (BUN). Energy-corrected milk tended to be greater ($P = 0.09$) for MFP than control (36.1 vs. 33.3 ± 0.8 kg/d), while dry matter intake was not different, ave: 24.0 ± 0.5 kg/d. Milk fat content was and yield tended to be higher ($P = 0.03$ and 0.09) for MFP than control (3.96 vs. 3.86 ± 0.05% and 1.34 vs. 1.22 ± 0.03 kg/d). Milk protein content was not different between treatments, ave: 3.34 ± 0.06%, but yield was greater ($P = 0.04$) for MFP than control (1.13 vs. 1.05 ± 0.02 kg/d). While BHBA and NEFA were not different between treatments, ave: 0.68 ± 0.03 and 0.17 ± 0.04 mmol/L respectively, BUN was greater ($P = 0.02$) for MFP than control (4.95 vs. 4.53 ± 0.04 mmol/L). Including MFP in a ration at 600 g/d increased energy-corrected milk by 2.8 kg/d and both milk fat and protein yield by 0.12 kg/d, while not affecting dry matter intake. Blood metabolites BHBA and NEFA were not affected by MFP, suggesting the increase in production and components was not due to mobilization of body reserves.

Key Words: dairy cow, microbial fermentation product, milk

T398 Effect of *Megasphaera elsdenii* NCIMB 41125 (Me) on production of lactating dairy cows. P. H. Henning*[1], L. J. Erasmus[2], C. H. Horn[3], and H. H. Meissner[1], [1]*MS Biotech*, *Centurion, South Africa*, [2]*University of Pretoria*, *Pretoria, South Africa*, [3]*Biotherapeutics*, *Centurion, South Africa*.

High concentrate intake in fresh cows pose an acidosis risk. *M. elsdenii* (Me) is a key ruminal lactic acid utilizer, but its numbers may be low in early lactation. Me was isolated from rumens of cattle adapted to high concentrate diets. The objective of this study was to evaluate use of Me as direct fed microbial (DFM) for dairy cows. Sixty multiparous Holstein cows were blocked according to previous milk production and BW, and randomly assigned to 4 treatments in a 2x2 factorial design. Treatments were + or - Me and low (L) or high (H) concentrate diet. The +Me cows were orally dosed with Me (10^{11} cfu once on each of d 1, 10 and 20 postpartum). The -Me cows received a placebo. Diets L and H, respectively, contained (g/kg DM) ground corn (354, 482), alfalfa hay (319, 196), *Eragrostis curvula* hay (79, 79), non-fiber carbohydrate (NFC) (448, 504) and neutral detergent fiber) NDF (282, 238). DM intake and milk yield (daily), milk composition (weekly) and BW and BCS (monthly) were measured for the first 80 d of lactation. Data were analyzed as a completely randomized block design (Genstat 5). Contrasts (+ vs. –Me for all cows, L cows and H cows, respectively) were used to determine significance of treatment effects. Since higher-producing cows may be more prone to acidosis results were also analyzed using only the 10 highest-producing cows in each treatment group. With all cows included, dosing with Me resulted in greater milk production ($P = 0.10$) (35.1 vs. 33.1 kg/d), higher mean BW ($P = 0.02$) (640 vs. 610 kg) and better BCS ($P = 0.06$) (2.63 vs. 2.38), while milk fat % was increased ($P = 0.03$) (3.14 vs. 3.07) for L cows. With only highest-producing cows included, dosing with Me increased milk production for the H group ($P = 0.06$) (39.3 vs. 35.9), without a significant increase in DM intake, and increased (both $P = 0.02$) BW (644 vs. 597) and BCS (2.71 vs. 2.26). Milk fat was again increased ($P = 0.06$) (3.56 vs. 3.21) for the L cows. Results suggest that dosing with *Megasphaera elsdenii* NCIMB 41125 may improve milk production, milk fat, body weight and body condition score, with greater benefit likely for higher-producing cows on higher concentrate diets.

Key Words: *M. elsdenii*, acidosis, dairy cows

T399 Effect of soluble yeast protein extract and dietary fermentable carbohydrate on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech*, *Nicholasville, KY*.

Effects of addition of soluble yeast protein extract (SYPE) to diets differing in fermentable carbohydrate (fCHO) content were investigated in single-flow rumen-simulating fermenter cultures. Twelve cultures were used in a 2 × 2 factorial design with 4 dietary treatments and 3 replications per treatment. Daily feed amounts provided to cultures were 24.1, 24.76, 24.34, and 25 g for low fCHO, low fCHO + SYPE, hi fCHO, and hi fCHO + SYPE treatments, respectively, with twice daily feeding for 6 d. SYPE was included at 2.64% of diet to raise dietary CP to 17.5 from 16.6% (DM basis). Fermentation samples were collected from cultures before morning feeding during the last 3 d of experiment. Composite effluent samples from each fermenter were used for DM and NDF disappearance and volatile fatty acid (VFA) analyses. Nitrogen flow measures were estimated by using purine to N ratios for effluent and bacteria. Data were analyzed for effects of treatment using GLM procedure of SAS and fCHO and SYPE effects determined by orthogonal contrasts. Culture pH and ammonia concentration before morning feeding were higher in cultures fed low fCHO diets ($P < 0.05$) and ammonia concentration higher in cultures fed SYPE ($P < 0.05$). Cultures fed lower fCHO diets had greater molar proportion of acetate, lower molar proportion of butyrate ($P < 0.0001$), and lower total VFA concentration ($P < 0.01$). Digestion of true DM was greater when cultures received higher fCHO diets ($P < 0.05$). Bacterial N yield was not affected by fCHO or

SYPE ($P > 0.10$) but an interaction between fCHO and SYPE was noted with an increase in bacterial N yield with SYPE addition to hi fCHO diets of 9.6% ($P < 0.05$). Efficiency of bacterial N production based on fCHO provided was greater in lower fCHO cultures ($P < 0.001$). The effects of soluble yeast protein extract addition were dependent upon dietary fermentable carbohydrate with positive responses in bacterial yield on higher fCHO diets.

Key Words: soluble yeast protein extract, fermentable carbohydrate, ruminal metabolism

T400 Effect of soluble yeast protein extract and culture feed rate on fermentation, digestion, and N flow in rumen-simulating fermenters. G. A. Harrison*, M. D. Meyer, and K. A. Dawson, *Alltech*, *Nicholasville, KY*.

Effects of soluble yeast protein extract (SYPE) and culture feed rate (FR) were investigated in single-flow rumen-simulating fermenter cultures. Twelve cultures were used in a 2 × 2 factorial design with 4 dietary treatments and 3 replications per treatment. Dietary treatments were low FR SBM, low FR SYPE, hi FR SBM, and hi FR SYPE with twice daily feeding for 6 d. Culture daily feed rates (as fed) were 20 and 30 g for low and high FR, respectively, and SYPE was included at 2.64% (DM basis) and primarily replaced soybean meal. Fermentation samples were collected from cultures before morning feeding during the last 3 d of experiment. Composite effluent samples from each fermenter were used for DM and NDF disappearance and volatile fatty acid (VFA) analyses. Nitrogen flow measures were estimated by using purine to N ratios for effluent and bacteria. Data were analyzed for effects of treatment using GLM procedure of SAS with FR and SYPE effects determined by orthogonal contrasts. Culture pH before morning feeding was lower in hi FR cultures ($P < 0.0001$). Mean ammonia concentration before morning feeding was not affected by treatment ($P > 0.10$). Volatile fatty acid pattern was altered by feed rate with molar proportions of acetate and isoacids being lower ($P < 0.05$) and molar proportion of butyrate higher with increased feed rate ($P < 0.001$). Cultures fed more feed had increased total VFA concentration ($P < 0.0001$). Digestion of true DM and NDF were not affected by treatment ($P > 0.10$). When feed rate was increased, increases were noted in measured g of RDP and bacterial N yield ($P < 0.01$). No differences were detected in fermentation, digestion, and N flow due to SYPE ($P > 0.10$). A numerical increase in bacterial N yield was observed when SYPE replaced SBM in the higher FR cultures (10.2%) but not in the lower FR cultures (interaction; $P > 0.10$). Culture feed rate influences fermentation pattern N flow in rumen-simulating fermenters.

Key Words: soluble yeast protein extract, culture feed rate, ruminal metabolism

T401 Effect of essential oils on rumen fermentation, milk production, and feeding behavior in lactating dairy cows. L. R. Tager* and K. M. Krause, *West Virginia University*, *Morgantown*.

Eight ruminally cannulated lactating Holstein dairy cows were used in a Latin rectangle design to assess the effects of 2 commercial essential oil (EO) products on rumen fermentation, milk production, and feeding behavior. Cows were fed a TMR with a 42:58 forage:concentrate ratio (DM basis). Treatments included addition of: 0.5 g/d XT 6965 (CEL; 85 mg cinnamaldehyde and 140 mg eugenol), 10 g/d XT 6965 (CEH; 1700 mg cinnamaldehyde and 2800 mg eugenol), 0.25 g/d XT 6933 (CAP; capsicum), or no oil (CON). Cows were fed ad-libitum twice daily for 21 d per period. Total VFA, individual VFA, acetate:propionate ratio, and ammonia production were not affected by EO ($P > 0.05$). Mean rumen pH as well as bouts, total h, mean bout length, total area, and mean bout area under pH 5.6 did not differ among treatments ($P > 0.05$). Total tract digestibility of OM, DM, NDF, ADF, CP, and NSC were not affected by EO ($P > 0.05$). In situ DM disappearance was not affected by EO ($P > 0.05$). However, OM disappearance tended to decrease compared with CON ($P = 0.08$; 60.3% vs. 57.6%) with CEH. Compared with CON, NDF disappearance ($P = 0.05$; 41.5% vs. 37.6%) and ADF disappearance ($P = 0.04$; 44.5% vs. 38.8%) decreased with addition of CEH. DMI, number of meals/d, h eating/d, mean meal length, rumination events/d, h ruminating/d and mean rumination length were not affected by EO ($P > 0.05$). However, length of the first meal after feeding decreased with addition of CEH (47.2 min) and CAP (49.4 min) compared with CON (65.4 min; $P = 0.01$). Milk yield and composition did not differ. CEL had no effect on rumen fermentation, milk production, or feeding behavior. CAP shortened length of the first meal without changing rumen fermentation or production, making it a possible additive for altering feeding behavior. CEH negatively affected rumen fermentation and altered feeding behavior, suggesting that a dose of 10 g/d is not beneficial to lactating dairy cows.

Key Words: essential oil, dairy nutrition, rumen fermentation

T402 Rumen-protected choline affects methionine methyl group metabolism in lactating dairy cows. S. L. A. Benoit, B. J. Bequette, and R. A. Erdman*, *University of Maryland*, *College Park*.

Methionine (Met) is a precursor for protein synthesis and the primary donor of labile methyl groups. We hypothesized that milk production responses to rumen protected choline (RPC) relate to choline sparing Met as a methyl donor. The objectives of this study were to determine the bio-availability of RPC and whether Met methyl group flux is reduced when dairy cows are fed RPC. Four multiparous Holstein cows in mid lactation were fed a nutritionally complete basal diet except for Met that was limited to 1.49% of metabolizable protein. Treatments included the basal diet or the basal diet plus 15g/d RPC as choline chloride (Reashure, Balchem Corp., New Hampton, NY) in single reversal design with 2 wk periods. Metabolic fates of Met were measured by continuous i.v. infusion of [1-^{13}C] and [methyl-^{13}C] Met, and [trimethyl-C^2H_3] choline for 12 h on d 14 of each period. Milk was collected at 3 h intervals and blood taken over the last 6 h. Supplementation with RPC did not affect total milk yield or milk fat and protein yields which averaged 39 kg/d, 1634 g/d and 1110 g/d, respectively. Based on plasma [1-^{13}C] Met and [methyl-^{13}C] Met enrichments, total Met flux, irreversible loss, and remethylation were not affected by treatment, averaging 15.2, 11.5, and 4.2 mmol/h, suggesting that 24% of Met was remethylated. In contrast, using plasma [1-^{13}C] homocysteine as the true intracellular precursor, total Met flux, irreversible loss, and remethylation rates (mmol/h) were 80.1, 67.6 ($P = 0.04$); 38.3, 33.5; and 41.8, 34.1 ($P = 0.07$), for control and RPC, respectively. Differences in plasma vs. casein [methyl-$^2H_3$] Met labeling, which arises from [trimethyl-C^2H_3] choline, suggested that ~40% of Met in the mammary gland underwent transmethylation with choline serving as the methyl donor. Finally, based on treatment differences in Met methyl flux, the bio-availability of RPC approximated to 72%. These results illustrate the central role of Met and choline in methyl metabolism and the importance of methyl group transactions in the high producing dairy cow.

Key Words: methionine, methyl metabolism, dairy cows

T403 Cloning and identification of novel hydrolase genes from a metagenomic library of dairy cow rumen microflora and characterization of the expressed cellulases. X. Gong*, M. Qi, R. J. Forster, T.

A. McAllister, and R. M. Teather, *Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada*.

A 6,000-clone metagenomic bacterial artificial chromosome (BAC) library was constructed from microbial flora DNA extracted from the rumen contents of a grass hay-fed dairy cow and activity-based screening was employed to explore the functional hydrolase genes. Ninety-four independent clones specifying distinct hydrolytic activities (51 esterases, 18 xylanases and 25 cellulases) were identified. Subcloning and sequence analysis of a subset of these hydrolase-positive clones identified 10 endoglucanase genes. Amino acid sequences of 5 of these genes indicated less than 55% homology among them, while similarity to the cellulases in the National Center for Biotechnology Information (NCBI) databases averaged 70%. Glycoside hydrolase families 5, 8 and 9 were represented by 6, one, and 3 of the 10 endoglucanases, respectively. Subcloning and sequence analysis of a subset of the esterase-positive clones identified 10 esterase genes. These shared less than 33% homology, with an average similarity of 53% to esterases in the databases, as assessed by predicted amino acid sequence. Preliminary characterization of the encoded cellulases was carried out using crude extracts of each of the subclones. Zymogram analysis using carboxymethylcellulose as a substrate showed a single positive band for each sample, confirming that only one functional cellulase gene was present in each subclone. Optimal pH for these cellulases ranged from 6.5 to 7.0 and their optimal temperatures were 40°C to 50°C. All the endoglucanases could hydrolyze a wide range of β-1,3-, and β-1,4-linked polysaccharides with varying activities. The present work revealed an increased diversity of functional cellulases and esterases in the rumen.

Key Words: esterase, ruminal microorganisms, BAC library

T404 Development of a diet inoculate with two substrates by submerged solid fermentation. D. Díaz-Plascencia*[1], C. Rodríguez-Muela[1], F. Salvador[1], J. Jiménez[1], H. Rubio[2], S. Mena[3], and A. Elías[4], [1]*Universidad Autónoma de Chihuahua*, *Chihuahua, México*, [2]*Instituto Nacional de Investigaciones Agrícolas Forestales y Pecuarias*, *Chihuahua, México*, [3]*Universidad de Guadalajara*, *Jalisco, México*, [4]*Instituro de Ciencia Animal*, *La Habana, Cuba*.

To evaluate 2 substrates (apple byproduct (AB) and sugar cane molasses (CM)) in the preparation of an inoculate with yeasts for ruminant rations, 2 yeasts strains (YS) were used by submerged solid fermentation (YS A, commercial yeast of the *Saccharomyces cerevisiae* and YS D, *Kluyveromyces lactis*, obtained by apple pomace fermentation) under aerobic conditions in a liquid medium. Treatments used were Tr1: 200 mL of AB + 1 g of YS. Tr2: 132 mL of AB + 34 g of CM + 1 g of YS. Tr3: 66 mL of AB + 66 g of CM + 1 g of YS. Tr4: 100 g of CM + 1 g of YS. All treatments were employed for growth of both YS. Treatments were added with 1.2% of urea, 0.2% of ammonium sulfate, 0.5% of mineral supplement. Fermentation was carried out in flasks of 1,000 mL with distilled water. Five replicates by Tr and different sampling times (0, 12, 24, 48 and 96 h) were used. Variables evaluated were: pH, temperature, soluble carbohydrates, yeast count, ammonia and lactic acid. Data were analyzed as a randomized 4 × 2 factorial design in a split-plot experiment. Results showed different ($P < 0.01$) pH behavior among the substrates. Temperature had an increase ($P < 0.01$) from 0 h to 12 h in all treatments. Ammonia was different ($P < 0.01$) among treatments and among YS. Lactic acid showed effect ($P < 0.01$) among treatments and among YS. Soluble carbohydrates were different ($P < 0.01$) among treatments, YS and sampling time. Yeast count of YS D was higher ($P < 0.01$) in Tr4 with value of $2.8 \times 10^9 \pm 0.05$ cell.mL^{-1} at 48 h, versus YS A count of $9.6 \times 10^8 \pm 0.05$ cell.mL^{-1} in Tr4 at the 96 h. It can be concluded that the use of sugar cane molasses, increases the growth of yeast, especially *K. lactis*, during the preparation of a diet inoculated by submerged solid fermentation.

Key Words: yeasts, fermentation, apple byproduct

T405 Glycerol can replace corn grain in diets for transition dairy cows. E. R. Carvalho*, N. S. Schmelz, H. White, and S. S. Donkin, *Purdue University*, *West Lafayette, IN*.

Expansion of the biofuels industry has increased the availability of glycerol as an alternative feed for dairy cows. The objective of this study was to determine the effects of glycerol on feed intake, milk production, rumen VFA, and metabolic parameters in transition dairy cows. Twenty-six multiparous Holstein cows were paired by expected calving date and fed diets containing either high moisture corn or glycerol from −28 through +56 d relative to calving. Glycerol was included at 11.5 and 10.8% of the ration DM for the pre- and postpartum diets, respectively. Prepartum feed intake was not changed ($P \geq 0.05$) by glycerol feeding (14.6 vs. 14.9 kg/d, glycerol vs. control) nor did postpartum feed intake differ ($P \geq 0.05$; 20.7 vs. 19.8 kg/d, glycerol vs. control). Overall milk yield did not differ ($P \geq 0.05$; 37 vs. 35.8 kg/d, glycerol vs. control), but there was a tendency ($P \leq 0.15$) for a treatment × week of lactation effect that was greater for glycerol. There were no effects of glycerol on milk composition, milk urea nitrogen, somatic cells, and energy balance ($P \geq 0.05$). During the prepartum period, blood glucose was reduced ($P \leq 0.05$; 53.4 vs. 59.1 mg/dL, glycerol vs. control) and β-hydroxybutyrate was increased ($P \leq 0.05$; 0.82 vs. 0.58 mmol/L, glycerol vs. control) in cows fed glycerol. Concentrations of blood nonesterified fatty acids did not differ between the treatment groups ($P \geq 0.05$), and there was no response ($P \geq 0.05$) to glycerol for blood metabolites during the postpartum period. Total rumen VFA (mmol/L) did not differ ($P \geq 0.05$; 85.9 vs. 82.3, glycerol vs. control), but percentage of rumen propionate (28.6 vs. 22.7%, glycerol vs. control) and butyrate (15.3 vs. 11.5%, glycerol vs. control) were greater ($P \leq 0.05$) for cows fed glycerol at the expense of acetate (51.5 vs. 61.4%, glycerol vs. control). These data indicate that glycerol is a suitable replacement for corn grain in diets for transition dairy cows and suggest that glycerin, a biofuels coproduct, is compatible with transition cow health and productivity.

Key Words: biofuels, glycerol, transition cows

T406 Evaluation of performance of lactating dairy cows supplemented with branched chain volatile fatty acids (Nutricattle). E. R. Val Neto*[1], R. P. Lana[1,2], H. N. Val[3], M. I. Leão[1], and A. B. Mâncio[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*CNPq*, *Brasília, DF, Brazil*, [3]*Faculdades Associadas de Uberaba (FAZU)*, *Uberaba, MG, Brazil*.

Tropical pasture is the main source of cattle feed, but in the dry season it is deficient in protein, which is essential for microbial growth. The search for technology to increase animal performance may be a feasible alternative to reduce costs with dairy cattle nutrition. This work aimed to compare the performance and the efficiency of lactating cows on pasture, supplemented with concentrate containing 16% crude protein (CP) on dry matter basis using cottonseed meal with 38% CP as protein source, with or without a feed additive containing branched chain volatile fatty acids (Nutricattle). Twenty-four lactating Holstein × Gir crossbred cows were evaluated (average body weight = 436.5 kg, days in milk = 119, body condition score = 2.75, and average milk yield = 7.55 L/day). Animals were offered 1.0 kg/animal/day of concentrate in 2 milking times. In the first week, cows were fed the same diet. After the adaptation period, each lot was randomly assigned to feed the concentrate with or without 24 g of additive/cow/day. Data were analyzed in a randomized blocks design, including milk production and body condition score as covariates, using F test. Although there was a reduction in supplement intake in the fourth week, average milk yield of the additive treatment (8.3 L) was higher ($P = 0.01$) than the average milk yield of the control (7.3 L). There was no difference in the final body condition score between treatments ($P = 0.48$), but the additive increased 0.5 units during the experimental period. In relation to milk quality, no difference was observed in milk fat ($P = 0.21$) and cryoscopy ($P = 0.71$) between treatments. Therefore, although pastures usually have good quality during the rainy season, according to this result, the inclusion of Nutricattle additive was nutritionally efficient, increasing milk production by 12%.

Key Words: cattle, nutrition, volatile fatty acids

T407 Intake and apparent nutrient digestibility in dairy cows fed with different levels of sunflower cake in the ration. E. S. Pereira*[1], P. G. Pimentel[1], M. R. G. F. Costa[1], J. G. L. Regadas Filho[2], and J. E. L. Sousa[1], [1]*Universidade Federal do Ceará*, *Fortaleza, Ceará, Brasil*, [2]*Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brasil*.

The aim of this study was to evaluate the intake and apparent nutrient digestibility of dairy cows fed rations containing increasing levels of sunflower cake (SC). The SC has an average 164.29 g/kgDM of crude protein (CP) and 116.28 g/kgDM of ether extract (EE). Eight multiparous Holstein × Zebu cows, between 50 and 74 d in milk and 20 ± 2 kg milk/day were allocated in a 4 × 4 double Latin square design. Sunflower cake was fed in the concentrate at the levels of 0; 7; 14 and 21% and Tifton hay was used as main forage in a 60:40 forage to concentrate ratio. The PROC GLM of SAS was used for the statistical analysis. Periods were 16 d long; the first 10 d of each period were for dietary adaptation, with weight and samples of diets, refusals and feces taken during d 11 to 16 of each period to determine the consumption and apparent digestibility of dry matter (DM) and nutrients. Meals were offered to allow 10% refusals according to the calculated ration consumed on the previous day. The internal marker indigestible acid detergent fiber was used to estimate the fecal DM excretion. The ether extract content of the experimental rations was, respectively, 27.14; 29.79; 31.15 and 35.41g/kgDM, to the levels 0; 7; 14 and 21% of SC inclusion. Dry matter intake of the rations was not affected by the treatments (14.06 kg/day, 2.75% of live weight and 130.89 g/kg of unit metabolic body weight). The intake of the rations without SC and at the level of 21% varied of 0.39 to 1.09 and 9.18 to 10.88 g/day, respectively, for EE and total digestive nutrients, showing linear increase ($P = 0.001$). The apparent digestibility of DM and neutral detergent fiber increased linearly with the addition of the byproduct (69.96 to 72.43 and 59.85 to 64.13%, respectively), while the digestibility of CP and EE showed quadratic behavior ($P < 0.05$). Sunflower cake can be recommended as a potential alternative for feeding dairy cows at the maximum level of inclusion of 21% in the concentrate.

Key Words: byproducts, lipids, ruminants

T408 Milk production and composition from cows with different levels of sunflower cake in the ration. E. S. Pereira*[1], P. G. Pimentel[1], M. R. G. F. Costa[1], J. G. L. Regadas Filho[2], and J. E. L. Sousa[1], [1]*Universidade Federal do Ceará*, *Fortaleza, Ceará, Brasil*, [2]*Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brasil*.

The objective of this research was to evaluate the milk production and composition of dairy cows fed diets containing increasing levels of sunflower cake. The sunflower cake has an average 164.29 g/kgDM of crude protein and 116.28 g/kgDM of ether extract. Eight multiparous Holstein x Zebu cows, between 50 and 74 d in milk and 20 ± 2 kg milk/day were allocated in a 4 × 4 double Latin Square Design. Sunflower cake was fed in the concentrate at the levels of 0; 7; 14 and 21% and Tifton hay was used as main forage in a 60:40 forage to concentrate ratio. The PROC GLM of SAS was used for the statistical analysis. The milk production increased linearly with the addition of the byproduct (18.88 to 19.29 kg/day), while 4% fat-corrected milk yield showed linear decrease (18.28 to 17.05 kg/day, $P < 0.05$). The milk fat and protein content decreased linearly with greater proportions of sunflower cake in the ration (3.79 to 3.23 and 3.28 to 3.17%, respectively). The lactose content was not affected by increasing levels of sunflower cake in the ration, but the N-ureic in milk decreased linearly. The palmitic acid (C16:0) decreased linearly with the addition levels of the byproduct, although for the other saturated fatty acids, as well as to the monounsaturated and polyunsaturated fatty acids were not observed significant differences ($P > 0.05$). Sunflower cake can be recommended as a potential alternative for feeding dairy cows at the maximum level of inclusion of 21% in the concentrate.

Key Words: byproducts, lipids, ruminants

T409 Supplemental metabolizable lysine delivered with Megamine-L improves productive performance of lactating cows. E. Block*[1], E. Evans[2], and N. Clark[3], [1]*Church and Dwight Co., Inc.*, *Princeton, NJ,* [2]*Evans Technical Consulting Services, Bowmanville, ON, Canada,* [3]*Atlantic Dairy and Forage Institute, Fredericton Junction, NB, Canada.*

Sixteen cows were fed one of 4 diets in a 4 × 4 Latin square treatment arrangement designed to evaluate the delivery of intestinally available lysine in a new product, Megamine-L (MEG-L; 16% lysine). The control diet was formulated using CPM Dairy v3.0 for 35 kg of milk with 3.8% fat and 3.1% protein and contained methionine at 2.4% of the metabolizable protein (MP) and lysine at 6.1% of the MP using corn

and clover silages, corn and barley grain, soybean meal, urea, Megalac, and Smartamine-M. Excess metabolizable protein and energy were at zero in the final formulation. MEG-L was substituted for Megalac in the 3 treatment diets at 50, 100 and 150 g/cow/day. Results are shown in the table. Supplementing MEG-L in all diets resulted significant ($P < 0.05$) increases in production performance with the 100g/d feeding rate being closest to ideal lysine supplied. Using actual productive performance data and DMI for each cow in CPM Dairy resulted in an average metabolizable lysine estimate for MEG-L of 46%.

Table 1. Production responses of dairy cows fed 3 levels of Megamine-L (MEG-L)

	g/d MEG-L				
	Control (0)	50	100	150	P≥F
Milk, kg/d	31.1[a]	34.1[b]	35.4[c]	34.8[b]	0.047
3.5 FCM, kg/d	34.2[a]	37.5[b]	40.3[c]	39.1[c]	0.035
ECM, kg/d	31.2[a]	34.1[b]	35.4[c]	34.8[c]	0.041
DMI,kg/d	22.2	21.8	21.6	22.4	0.786
Fat Yield, kg/d	1.28[a]	1.40[b]	1.54[c]	1.48[bc]	0.040
Protein Yield, kg/d	973[a]	1.15[b]	1.18[b]	1.16[b]	0.038

Estimated metabolizable Lys from MEG-L, % of lysine	0	47.2	50.0	43.6	

[abc]Values with different superscripts differ ($P \leq 0.05$).

Key Words: metabolizable lysine, lactating cow, milk production

T410 A model to compare effects of supplemental fat sources on performance and dry matter intake in dairy cows: Effects of fat inclusion level. E. Block*[1] and E. Evans[2], [1]*Church and Dwight Co., Inc.*, *Princeton, NJ,* [2]*Evans Technical Consulting Services, Bowmanville, ON, Canada.*

Experiments conducted to evaluate the addition of fat to diets for dairy cows have involved a range in the amounts supplied. This study was conducted to assess production and dry matter intake responses to different sources of fat (calcium salts, prilled fatty acids, tallow, and vegetable oil) compared with control diets (no added fat) as influenced by level of dietary fat inclusion (normal levels, defined as lower dietary fat than milk fat output vs. excessive levels, defined as higher dietary fat than milk fat output). Data obtained from full peer reviewed manuscripts published since 1990 were used for model development if diets were considered typical (protein from 15 to 22%; NDF from 27 to 44%). Data were analyzed using a GLM procedure accounting for experiment and fat source. Treatment values were compared as differences from control. A Tukey's test was conducted to determine pairwise differences between treatments and control. Milk yield (MY), fat yield (FY), energy corrected milk (ECM), and ECM/DMI were improved ($P < 0.05$), protein yield (PY) was unchanged and DMI was reduced when fat was included in the normal range in diets. The model showed that the improvements in MY, FY and ECM caused by fat inclusion in the normal range were associated with studies involving calcium salts primarily with little effects of prills, tallow, and vegetable oils while tallow was primarily responsible for the decline in DMI when comparing fat additions to control diets. When dietary fat was excessive, there were no changes in MY, FY, PY or ECM compared with control diets. In diets containing excessive fat, NE intake increased, but DMI decreased relative to the controls.

Key Words: dietary fat, dairy cow, production performance

T411 A model to compare the effects of fat sources upon performance and dry matter intake in dairy cows: Effects of trial duration. E. Block*[1] and E. Evans[2], [1]*Church & Dwight Co., Inc.*, *Princeton, NJ,* [2]*Evans Technical Consulting Services, Bowmanville, ON, Canada.*

Fat contributes to energy balance as well as milk output, and there can be carryover effects in shorter term (ST, <28 d) changeover trials and Latin square trials that would lead to erroneous conclusions relative to long-term (LT) blocked feeding trials. This study was conducted to model responses to supplemental fat sources (calcium salts, prilled fatty acids, tallow, and vegetable oil) as determined from ST and LT trials. Data obtained from full manuscripts published since 1990 were used for model development if diets were typical (protein from 15 to 22%; NDF from 27 to 44%). Data were analyzed using a GLM procedure accounting for experiment and fat source. Treatment values were compared as differences from control. A Tukey's test was conducted to determine pairwise differences between treatments and control. In the ST model, milk yield (MY), fat yield (FY), energy corrected milk (ECM) and ECM/DMI increased ($P < 0.05$) with fat supplements relative to control. The increases in MY and ECM/DMI were associated with studies involving calcium salts only. Protein yield (PY) was not affected ($P > 0.05$). DMI and calculated NEI declined ($P < 0.05$) in ST with added fat and this was primarily associated with the feeding of tallow. In the LT model there were no trials using prilled fatty acids that fit the criteria for inclusion. In this LT model MY, ECM, NE balance, and ECM/DMI were improved with fat, with no effects of fat on FY or PY. The increase in NE balance was associated with vegetable oil while the improvement in ECM/DMI was associated with calcium salts. DMI did not change with added fat in the LT trials ($P > 0.05$). The magnitude of effects of feeding fat was much greater in LT than in ST trials.

Key Words: dietary fat, dairy cow, production performance

T412 Hourly effective rumen degradation ratio in wheat DDGS, Corn DDGS and Blend DDGS from bio-ethanol plants: Effect of bio-ethanol plant and DDGS type. W. G. Nuez-Ortín* and P. Yu, *Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objectives of this study were to compare different types of DDGS and different bio-ethanol plants on hourly effective rumen degradation ratio (ED), determined based on the model published by Sinclair et al. in 1993. The corn DDGS, wheat DDGS and blend DDGS (70% wheat: 30% corn), and wheat and corn samples with 3 to 5 different batches were obtained. The data was analyzed using a mixed procedure of SAS with a CRD model. In dairy cows, the optimum ratio between the effective extent of degradability of N and OM to achieve maximum microbial synthesis and minimize N loss is 25 g N per kg OM truly digested in rumen. The results showed that (1) wheat exhibited higher than optimal ED ratio at all incubation times except at 2 h, ranging from 23 to 991 g N/kg OM, while corn showed less than optimal ratio during the entire incubation, ranging from 0 to 24 g N/kg OM. (2) Comparing with DDGS, the hourly ED ratios of N/OM for wheat were higher ($P < 0.05$) than those for DDGS samples at 0, 12 and 24 h, however, the ratios for corn were lower ($P < 0.05$) at all incubation times. (3) Comparing among the 3 types of DDGS, wheat DDGS had the highest ($P < 0.05$) ratios (26–103 g N/kg OM), while ratios for blend DDGS (29–89 g N/kg OM) were numerically higher ($P > 0.05$) than those for corn DDGS (14–56 g N/kg OM). The hourly ED ratios of N/OM tended to rise with increasing incubation time for wheat DDGS and blend DDGS; however, they remained constant for corn DDGS. This reflects a higher difference in the hourly effective degradation of N at later stages for blend DDGS

and wheat DDGS than for corn DDGS rather than differences in the hourly effective degradability of OM. (4) The bio-ethanol plant effect was significant at the beginning and end of incubations. The hourly ED ratios of N/OM for wheat DDGS from SK-Plant 1 was greater at 0 h (42 vs. 16 g N/kg OM) but lesser at 12 h (80 vs. 88 g N/ kg OM) and 24 h (85 vs. 114 g N/kg OM). The results shown here indicate that DDGS samples exhibited more than optimal rumen degradation ratio.

Key Words: hourly effective rumen degradation ratio, bioethanol co-products, dried distillers grains with solubles

T413 Production response of Holstein lactating cows to roasted or electron beam irradiated whole soybean. A. Akbarian[1], G. Ghorbani[1], M. Khorvash[1], P. Showrang[3], M. Dehghan-Banadaky*[2], and M. Jafari[1], [1]*Isfahan University of Technology*, *Isfahan, Iran*, [2]*University of Tehran*, *Karaj, Tehran, Iran*, [3]*Nuclear Science and Technology Research Institute, Atomic Energy Organization of Iran*, *Tehran, Iran*.

Nine lactating Holstein cows (130 ± 15 DIM, 39 ± 2 kg/d milk yield) were used in a duplicated 3 × 3 Latin square design experiment with 3 21 d periods. Cows were fed with rations with 60% concentrate and 40% forage. Treatments consisted of untreated, roasted and electron beam irradiation (63 kGy) formulated to meet energy and protein requirements recommended by the NRC (2001). The amount of feed and orts offered were measured daily for individual cows to calculate dry matter and crude protein intake. Cows were milked 3 times daily. The data were analyzed with Proc Mixed of SAS. The statistical model included fixed effects of treatment, square and their interaction. The effects of period and cow within the square were random. Dry matter and crude protein intake were not significantly different among treatments ($P > 0.05$, Table 1). Milk production and energy corrected milk of cows fed ration containing roasted whole soybean tended to increase ($P > 0.05$). Fat, protein and lactose contents of milk were not differ ($P > 0.05$) among treatments. There was a significant effect on milk efficiency of cows fed different diets ($P < 0.05$). Results showed that feeding roasted whole soybean improved milk production efficiency of cows.

Table 1. Production performance for Holstein cows fed diets contained untreated, roasted or irradiated whole soybean

	Diets			
Items	Untreated	Roasted soybeans	Irradiated whole soybean	SEM
DMI (kg/day)	26.7	24.9	27.1	0.63
CP Intake (kg/day)	4.5	4.4	4.5	0.2
Milk yield (kg/day)	38.1	39.4	38.6	0.99
ECM (kg/day)	41.5	41.9	42.5	1.01
Milk efficiency (milk yield/DMI)	1.4[b]	1.6[a]	1.4[b]	0.04
Fat %	4.1	4.1	4.2	0.07

[a,b] Means with different letters differ ($P < 0.05$).

Key Words: whole soybean, roasted, electron beam irradiated

T414 The relationship between nitrogen use efficiency and N isotopic fractionation in dairy cows using milk samples collected in the morning or afternoon. L. Cheng*[1], R. Dewhurst[2], J. Larkin[2], F. Buckley[3], C. Thackaberry[3], and G. Edwards[1], [1]*Lincoln University*, *Christchurch, Canterbury, New Zealand*, [2]*Teagasc*, *Dunsany, Co. Meath, Ireland*, [3]*Teagasc*, *Fermoy, Co. Cork, Ireland*.

This study investigated the potential to use fractionation of N isotopes among milk fractions to assess NUE. Nine Holstein-Friesian cows grazing on ryegrass and white clover mixture pasture only were used in this study. All cows were milked twice daily, one morning and afternoon milk samples from each cow were collected for analysis. Milk samples were defatted by centrifugation and protein was precipitated using acetone (4 acetone: 1 milk (vol/vol)). Whole milk, protein pellet (PP) and the supernatant (NPN) were freeze-dried and analyzed for ^{15}N (delta-^{15}N units; per ml). The ^{15}N in milk fractions, between am and pm samples, and the relationship between N isotope fractionation and milk urea N (MUN; mg/dL) were compared using one-way ANOVA (ANOVA) with cow as experimental block and linear regression. The mean ^{15}N in PP (7.05; SD = 0.248) was significantly ($P < 0.001$) higher than in whole milk (6.81; SD = 0.265), while ^{15}N in NPN was significantly ($P < 0.001$) lower (1.61; SD = 0.448). The correlation between am and pm values was weaker for MUN ($P < 0.05$) than for ^{15}N in milk fractions ($P < 0.001$). ^{15}N in NPN was lower for am samples (1.41 vs. 1.91; SED = 0.172; $P < 0.05$), while MUN tended to be higher (17.5 vs. 16.1; SED = 0.77; $P = 0.07$). There was a positive linear relationship ($y = 2.58x + 12.51$; $r^2 = 0.35$; $P = 0.05$) between MUN (y) and ^{15}N in average NPN (x), but this differed between am and pm samples. This may be related to differences in N isotopic discrimination between urea derived from excess N in the rumen or tissues, or differences in the other components of milk NPN. In conclusion, there were consistent differences between cows in the ^{15}N content of milk and milk fractions, though further work is needed to elucidate the effects of different pathways on N isotopic discrimination.

Key Words: stable nitrogen isotopes, milk urea nitrogen, discrimination

T415 Effect of replacing blood meal with rumen-protected amino acids on milk production and composition in lactating dairy cows. G. E. Aines*[1], G. F. Schroeder[2], M. Messman[2], and M. J. de Veth[1], [1]*Balchem Corporation*, *New Hampton, NY*, [2]*Cargill Animal Nutrition, Innovation Campus*, *Elk River, MN*.

A study was conducted to determine the effects on milk production and composition when lysine (Lys) and histidine (His) supplied by porcine blood meal were replaced by lipid-encapsulated rumen-protected forms (Balchem Corporation) of these 2 amino acids. Forty-four Holstein cows (mean 102 DIM) were used in a randomized block design. Treatments were: 1) Positive Control (PC) = diet which contained blood meal (0.4% of DM) and was balanced to meet metabolizable Lys and His, 2) Negative Control (NC) = similar to PC but removing blood meal, meeting a minimum of 80% of the metabolizable Lys and His requirements, 3) NC+His = NC diet supplemented with rumen-protected His to provide the same total level of His supply as the PC, and 4) NC+His+Lys = similar to NC+His but supplemented with rumen-protected Lys to provide the same levels of the 2 amino acids as the PC. NC and PC diets contained 17.0 and 17.8% CP, respectively. His and Lys were top dressed twice daily. DMI and milk yield were recorded daily and averaged by week. Milk composition was analyzed on the last day of each week. Data was analyzed using the PROC Mixed procedure of SAS with repeated measures and pretreatment milk yield was used as a covariate. Cows on NC treatment produced less milk (40.4 kg) compared with PC (42.5 kg, $P < 0.05$). NC+His had similar milk yield (39.9 kg) compared with NC, however, NC+His+Lys increased milk yield (42.6 kg) compared with NC and NC+His indicating that Lys was first limiting or co-limiting with His. PC and NC+His+Lys milk production were not different.

Milk components, DMI and feed efficiency were not different among treatments. MUN (mg/dl) was significantly ($P < 0.01$) lower for NC, NC+His and NC+His+Lys (11.8, 12.2 and 11.5, respectively) compared with PC (16.7), indicating that protein was used more efficiently in the lower protein diets. The results suggest that replacing the essential amino acids Lys and His that are supplied from porcine blood meal with equal levels from rumen-protected sources can maintain milk yield despite lower CP levels.

Key Words: blood meal, histidine, lysine

T416 Fatty acid composition of milk from Holstein cows fed diet supplemented with fish oil and canola oil from transition period to early lactation. T. S. Vafa, A. Heravi Moussavi*, A. A. Naserian, M. Danesh Mesgaran, and R. Valizadeh, *Ferdowsi University of Mashhad, Excellence Center for Animal Science, Faculty of Agriculture, Mashhad, Khorasan Razavi, Iran*.

The objective of this study was to examine the effects of feeding fish oil and canola oil from transition period to early lactation on milk fatty acid composition. Experimental diets were supplemented with either 0% oil (Control, n = 9), or 2% oil (supplemented, 1% canola oil-1%fish oil, n = 9), and fed 2 times a day from day −21 to 50 related to calving. Cows were blocked by parity, previous 305–2x milk production and expected calving time. Milk samples of first, third and sixth week of lactation were collected for fatty acids analysis using gas chromatography. All milk fatty acid results were expressed as g/100g of total fatty acids. The data repeated in time were analyzed by using a mixed model for a completely randomized design with repeated measures. Significance was declared at $P < 0.05$. As revealed in table1, total short (SCFA; C4:0- C8:0) and medium (MCFA; C10:0- C16:0) fatty acids decreased and total poly unsaturated fatty acids (PUFA) increased in supplemented diet. The proportion of C16:0, C16:1 and C18:0 decreased in supplemented diet. The proportion of trans (t) 10, cis (c) 12–18:2, c9, t11–18:2, c9, c12–18:2, t9, t11–18:2, t-18:1, eicosapentanoic acid (EPA) and docosahexaenoic acid (DHA) increased in supplemented diets, but the proportion of c11–18:1 and c9–18:1 were similar between diets. The results of this study demonstrate that feeding a combination of fish oil and canola oil had significant effect on milk fatty acids composition.

Table 1. Effects of pre- and post calving feeding of fish oil and canola oil on milk fatty acids composition (g/ 100 g FA)

T417 Partial replacement of soybean meal by encapsulated urea in commercial dairy herds. V. A. Silveira[1], N. M. Lopes[1], R. C. Oliveira[1], B. Gonzales[1], A. V. Siqueira[1], L. P. P. Bier[2], M. S. Zoni[3], W. Giardini[4], R. Almeida*[2], and M. N. Pereira[1], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil*, [2]*Universidade Federal do Paraná, Curitiba, PR, Brazil*, [3]*Milkonsult, Castro, PR, Brazil*, [4]*Alltech do Brasil, Brazil*.

Two on-farm trials were conducted to evaluate the partial replacement of soybean meal by encapsulated urea (OptigenII, Alltech do Brasil, Brazil). From a control treatment, 1 kg of soybean meal was replaced by 160 g of Optigen plus 2.5 kg of corn silage in trial 1 or 150 g of Optigen plus 0.85 kg of ground corn in trial 2. Researchers were responsible for manually mixing the treatments in proportion to the offered TMR and performing data collection in each farm. Trial 1 started with 68 Holsteins (243 DIM) paired blocked based on parity and yield and allocated to a treatment for 21 d, after a 5-d standardization period. Trial 2 started with 120 cows (291 DIM), also paired blocked and allocated to a sequence of 2 treatments in a crossover design with 21-d periods. Seven cows were lost in trial 1 and 23 were lost in trial 2. Response variables were measured on d 17 to 21 of treatment allocation, during which feed offered and orts were sampled daily. Data for trial 1 was analyzed with the GLM of SAS with a model containing the effects of covariate (measure of the same variable at the end of the standardization period), block and treatment. Data from trial 2 used a model containing the effects of cow, period, and treatment. Orts as a percentage of the offered diet fresh matter was 4.7 and 5.3% for trial 1 and 2.7 and 2.3% for trial 2, for Control and Optigen treatments, respectively. The DM, CP and NDF content of the offered diets and orts were similar across treatments, as well as cow′s body weight and body condition score. Milk yield was 38.4 kg for Control and 38.9 kg for Optigen in trial 1 ($P = 0.62$), and 27.0 kg and 27.2 kg in trial 2 ($P = 0.64$), respectively. No difference in milk solids secretion was detected ($P > 0.44$). Optigen increased MUN from 16.3 to 17.3 mg/dL in trial 1 ($P < 0.01$), but did elicit such a response in trial 2 ($P = 0.14$). Optigen tended to increase the group ratio of milk to feed in trial 2 ($P = 0.08$). Replacing soybean meal by Optigen did not induce lower performance, although increased MUN was observed when Optigen combined with corn silage replaced soybean meal.

Key Words: non-protein nitrogen, slow-release urea, Optigen

T418 The effect of feeding a prototype of ruminally protected lysine (RPL) on production performance and plasma amino acid profile of early lactation dairy cattle. J. E. Nocek[1], M. Miura[2], and I. Shinzato*[2], [1]*Spruce Haven Farm and Research Center, Auburn, NY*, [2]*Ajinomoto Co., Inc., Tokyo, Japan*.

Thirty-six lactating Holstein cows were used to examine the effects of ruminally protected lysine (RPL) supplementation and dosage on production performance and plasma amino acid profile of high-producing dairy cows. Multiparous cows were balanced across treatments based on their 4 week of lactation average milk production as follows: Control, 75, 150, 225 g/d of RPL. These treatments were designed to deliver 0, 4.5, 9.0 and 13.5 g/cow/d of supplemental intestinally available lysine, respectively. Cows started the experimental period on the fifth week post-calving and remained on treatment for 4 weeks. Prior to treatment administration, all cows received the control diet, which contained 75% of forage from corn silage, for one week. Control diet was fed to all cows throughout the experimental period, however, in addition, cows received 500 g/d of corn meal premix top dressed once daily to deliver 0, 75, 150 or 225 g/d of RPL. Dry matter intake was the highest for cows receiving 225g RPL compared with Control or 150g RPL. As a percentage of body weight, DMI remained higher for cows receiving 225g RPL

compared with 75g RPL. Mean milk yield was higher ($P < 0.05$) for cows receiving 75g RPL than Control (43.4 vs. 40.2 kg), with 150g and 225g RPL not being different than either. Fat percentage was higher ($P < 0.05$) for 150g and 225g RPL compared with 75g (3.83 vs. 3.35%, respectively), with control not being different. However, fat percentage for 75g RPL increased with time on treatment. Fat yield reflected this same numeric tendency ($P = 0.08$). Protein percentage was higher for control compared with 75g RPL with 150g and 225g not being different from either. Protein yield, lactose, MUN and SCC were not affected by RPL treatment. There were no significant ($P > 0.10$) or notable effects of RPL level on plasma AA concentration. These results demonstrated lysine is limiting in high corn silage diets for milk production.

Key Words: ruminally protected lysine, milk production, plasma amino acids

T419 Effect of HMBi supplementation on splanchnic methionine metabolism in postpartum transition cows. M. Larsen*, K. F. Dalbach, B. M. L. Raun, and N. B. Kristensen, *Faculty of Agricultural Sciences, Aarhus University*, *Tjele, Denmark*.

Eight second lactation Holstein cows implanted with permanent indwelling catheters in major splanchnic blood vessels were used to study the effect of dietary supplementation with the methionine hydroxyl analog (2-hydroxy-4-methylthio butanoic acid isopropyl ester; HMBi; Adisseo, France) on splanchnic methionine (Met) metabolism. At calving, cows were assigned to 1 of 4 diets in a 2 × 2 factorial design with one factor being HMBi supplement (2.6 g/kg dry matter) compared with no supplement (CTRL). The second factor was source of alcohol (ethanol vs. propanol). Diets were fed ad libitum in equally sized meals at 8 h intervals. Eight hourly sets of arterial, portal vein, and hepatic vein samples were obtained at −15 ± 5 d prepartum as well as 4, 15, and 29 d in milk (DIM). Met was analyzed in pooled plasma by GC-MS. The statistical model included both factors, DIM and possible interactions, where DIM was considered as a repeated measure. No interactions were observed between factors studied. Postpartum, milk yield and dry matter intake were unaffected by HMBi supplementation ($P \geq 0.32$) and averaged 34 ± 1 and 18 ± 1 kg/d, respectively. Casein content in milk tended to decrease at a lower rate with HMBi compared with CTRL as lactation progressed (interaction, $P = 0.06$). Milk fat content tended ($P = 0.07$) to be greater with HMBi. The change in arterial Met concentration from prepartum to 4 DIM differed ($P < 0.01$) between HMBi (from 20 to 23 μM) and CTRL (from 21 to 17 μM). Postpartum, arterial Met concentrations tended ($P = 0.09$) to remain greater with HMBi. The net portal and net splanchnic releases of Met were unaffected ($P \geq 0.50$) by HMBi and averaged 7.7 ± 0.3 and 5.3 ± 0.3 mmol/h, respectively. The net hepatic removal of Met tended ($P = 0.08$) to be greater with HMBi as compared with CTRL (2.7 and 2.0 ± 0.3 mmol/h, respectively). In conclusion, dietary HMBi supplementation to postpartum transition cows prevented a decrease in plasma Met in the first week postpartum without requiring time for adaptation to HMBi feeding. The greater hepatic removal of Met with HMBi indicates that Met was supplied in excess relative to other amino acids.

Key Words: transition, methionine, metabolism

T420 The effect of abomasal infusion of histidine and proline on milk composition and amino acid utilization in high producing lactating dairy cows. M. W. Hofherr*, D. A. Ross, and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

Histidine has been shown to be a limiting amino acid in grass fed lactating dairy cows and to alter fat secretion under certain conditions. A significant increase in milk protein output and a reduction in arginine uptake by the mammary gland were observed when proline was infused into the duodenum of 2 cows. The objective of this experiment was to determine the effects of abomasal infusion of histidine and proline on lactation performance in cows fed more conventional diets and to measure amino acid utilization by the mammary gland. Four rumen-fistulated Holstein cows (52 ± 19 DIM) with indwelling intercostal arterial catheters were used in a 4 × 4 Latin square experiment. Experimental treatments were continuous abomasal infusion of water (control), His (10g/d), Pro (20 g/d), and His (10 g/d) + Pro (20 g/d), with 7-d treatment periods. Cows were fed a TMR (14.4% CP, 2.3 Mcal/kg ME) once per day for ad libitum intake and refusals were measured and analyzed. The CNCPS v6.1 was used to formulate a diet to exceed the metabolizable energy requirement, provide 95% of the predicted metabolizable protein requirement, and supply adequate amounts of all essential amino acids, except Arg. Fat corrected milk yields were not affected by treatment (51.8 kg/d, TRT C; 50.6 kg/d, TRT H; 49.0 kg/d TRT H^+P; 52.4 kg/d TRT P), however abomasal infusion of Pro decreased feed intake and improved feed efficiency by 0.17 kg 3.5% FCM per kg dry matter ($P < 0.05$). Pro infusion increased lactose percentage ($P < 0.05$) but not yield. The lactose response suggests that longer infusions might have resulted in increased milk yield. A similar effect for lactose and feed efficiency was observed for the H^+P treatment. In this experiment abomasal infusion of His resulted in no performance difference or change in efficiency. Our results indicate that postruminal supplementation of Pro might increase milk fat production and feed efficiency in high producing dairy cows.

Key Words: amino acids, feed efficiency, infusion

T421 Response of dairy cows to the supplementation of fatty acids from calcium salts of soybean oil or heated soybeans. G. S. Dias Júnior[1], N. M. Lopes[1], L. L. Bitencourt[1], V. A. Silveira[1], G. G. S. Salvati[1], N. N. Morais Júnior[4], E. O. S. Saliba[3], R. A. N. Pereira[2], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras*, *Lavras, Brazil*, [2]*Empresa de Pesquisa Agropecuária de Minas Gerais*, *Lavras, Brazil*, [3]*Universidade Federal de Minas Gerais*, *Belo Horizonte, Brazil*, [4]*Instituto Federal de Educação Ciência e Tecnologia do Espirito Santo*, *Colatina, Brazil*.

This study evaluated the effect of supplementing corn silage based diets with fatty acids from calcium salts of soybean oil (Megalac E, Química Geral do Nordeste SA, Nova Ponte, Brazil) or from cracked whole roasted soybeans (Alfa Nutrisoja, Cooperalfa, Chapecó, Brazil). The content of Megalac was 1.4% of diet DM and the content of heated soybeans was 5.4. The dietary EE content was 4.3% of DM for Control and 6.0 for the fat supplemented diets. Diets contained 42.3% of DM from corn silage, 14.2% from high moisture corn, and 0.9% from bicarbonate. The dietary content of soybean meal and citrus pulp were 22.1 and 18.6 for Control, 18.4 and 16.9 for Soybean, and 22.5 and 16.8 for Megalac; diets CP content were 16.3, 16.7, and 16.6, respectively. Twenty-four Holsteins (638 kg, 216 DIM) received a sequence of the treatments in 8 concurrently run 3 × 3 Latin Squares, with 28-d periods, and 21 d of adaptation. Daily milk yield was 31.7 kg for Control, 32.7 for Soybean, and 31.8 for Megalac ($P = 0.43$). Megalac reduced daily DMI from 21.4 to 20.5 kg compared with Control ($P = 0.05$). There was a trend for decreased time of the first daily meal with Megalac ($P = 0.07$). Milk to feed ratio was 1.56 for Megalac and 1.48 for Control ($P = 0.07$). Megalac decreased milk fat content from 3.11 to 2.64% and daily fat yield from 0.986 to 0.828 kg ($P < 0.01$), resulting in lowered daily milk energy secretion ($P = 0.04$). Soybean had no effect on milk solids ($P > 0.33$). Rumen protozoa count was decreased by both fat supplements ($P < 0.01$), no difference was detected in MUN ($P = 0.92$)

or the daily excretion of allatoin in urine ($P = 0.54$). Supplementation of corn silage based diets with fatty acids from calcium salts of soybean oil decreased milk fat secretion and diet intake, and tended to increase feed efficiency, while the same fat content from whole roasted soybeans did not induce a similar response.

Key Words: calcium soap, fat, soybean oil

T422 Variability of estimated protected proteins of feather meals. J. A. Davidson*, K. B. Cunningham, H. C. Puch, and B. L. Miller, *LongView Animal Nutrition Center, Land O'Lakes Purina Feed, Gray Summit, MO*.

The objective was to evaluate the quality of sources of feather meal in regard to ruminal undegraded protein and available protein. Nine feather meal samples along with control samples of SurePro (non-enzymatically browned soybean meal) and SBM were evaluated utilizing in sacco techniques. Samples prepared in 51-μm polyester bags were exposed for 12 h within a ruminally-cannulated steer fed a forage:concentrate diet of 60:40 at DMI of 3.5% of BW. Additional subsets of bags were utilized to determine a 0-h protein disappearance and protein disappearance after digestion with pepsin (0.1 *N* HCl) for an additional 12 h. The RUP value was calculated as percent remaining after 12-h exposure in rumen and available protein (AP) was the difference between % protein disappearance at 12-h exposure in rumen and 12-h pepsin digestion. The mean ± SE estimated RUP for the feather meals, SurePro, and SBM were 78 ± 1.9%, 81 ± 0.6%, and 40%, respectively. The mean ± SE AP for the feather meals, SurePro, and SBM were 25 ± 3.9%, 70 ± 0.9%, and 38%, respectively. In comparison, the NRC 2001 estimates of RUP as % CP for feather meals were 62 to 65% with a RUP digestibility of 65 to 70%; 69 to 79% RUP with 93% digestibility for SurePro; and 31 to 43% RUP with 93% digestibility for SBM. Thus, the NRC 2001 described the AP of feather meal, SurePro, and SBM as 40 to 46%, 64 to 73%, and 29 to 40%, respectively. Based on our measurements, the AP of feather meal is 15% lower than those of NRC 2001, whereas SurePro and SBM were within the reported range. In conclusion, this data set demonstrates the need to continually monitor and evaluate protected protein sources. In sacco methods along with pepsin digestion are tools to characterize the consistency and quality of RUP and AP from multiple sources. Feather meal as a source of RUP for lactating cow diets does not consistently have high digestibility and is a poor alternative to other feed ingredients.

Key Words: protected protein, feather meal, in sacco methods

T423 Milk fat responses to dietary short and medium chain fatty acids in lactating dairy cows. D. Vyas*, B. B. Teter, and R. A. Erdman, *University of Maryland, College Park*.

During diet induced milk fat depression, the short- and medium-chain fatty acids (SMCFA), synthesized de novo in the mammary gland, are reduced to a much greater extent than the long-chain fatty acids (LCFA) originating from the diet. Our hypothesis was that SMCFA limit milk fat synthesis even under conditions when milk fat is not depressed. Our objective was to test the potential limitation of SMCFA on milk fat synthesis via dietary supplementation. Sixteen lactating Holstein cows (86 ± 41 DIM) randomly assigned in groups of 4 per pen and fed corn silage based TMR were supplemented with 1 of 4 dietary fat supplements (600g/d) in a 4 × 4 Latin square design with 21-d experimental periods. Treatments consisted of fat supplements containing mixtures of calcium salts of LCFA (Megalac; M) and a SMCFA mixture (S) (C8:0- 3.3%, C10:0- 7.6%, C12:0- 9.85%, C14:0- 32.12% and C16:0- 47.11%) that contained 0, 200, 400, and 600 g/d S substituted for M (S0, S200, S400, and S600, respectively). No significant changes were observed with dry matter intake, milk yield, and fat corrected milk (FCM), whereas milk fat concentration was increased ($P = 0.008$) by 0.17, 0.25, and 0.33 percentage units for the respective S treatments. Fat yield peaked with S200 and milk protein content and yield were reduced at the higher S levels due to a trend toward reduced milk yield in the S600 treatment. In conclusion, SMCFA supplementation increased milk fat content in a linear fashion but the trend toward reduced feed intake and milk production at the highest level of supplementation might have masked the effects of SMCFA on total milk fat synthesis.

Table 1. Production responses to increasing SMCFA

SMCFA, g/d	0	200	400	600	SEM	P-value

T424 Effect of feeding varied levels of crude protein and absorbable methionine on milk yield in lactating dairy cows. G. A. Broderick*[1], R. A. Patton[2], W. Heimbeck[3], and C. Parys[3], [1]*U.S. Dairy Forage Research Center, Madison, WI*, [2]*Nittany Dairy Nutrition, Inc., Mifflinburg, PA*, [3]*Evonik Degussa GmbH, Hanau, Germany*.

Supplementing with limiting AA should allow less CP to be fed; reducing dietary CP will decrease urinary N and ameliorate the environmental impact of dairying. Rumen-protected Met (RPM) fed as Mepron to provide 9 g/d of absorbable Met allowed similar milk yield at 15.8% CP as at 17.1% CP without RPM (Broderick et al., J. Dairy Sci. 92:2719, 2009). A lactation trial was conducted to assess response to RPM at different CP levels. TMR were prepared from alfalfa and corn silages, dry and high moisture corn, and solvent and expeller soybean meals. Diets were formulated to 28% NDF and 12, 14, 16 or 18% CP (DM basis); at each level of CP, RPM provided 0, 4.5, 9.0 and 13.5 g/d of absorbable Met, assuming 25 kg/d of DMI and 0.6 g absorbed Met/g of Mepron (total = 16 diets). Sixty-four cows were blocked by DIM into 16 squares and randomly assigned to balanced 4 × 4 Latin squares. The 4 levels of RPM were fed at each CP level for 4, 4-wk periods. Data from the last 2-wk of each period were analyzed for linearity of response to dietary CP and RPM using the Mixed model of SAS; LS means are reported. Analysis of TMR extracts with the Met-nitroprusside reaction confirmed that RPM was fed in desired amounts but CP was higher than formulated. Dietary CP increased DMI, BW gain and yield of milk, 3.5% FCM, fat and protein but did not affect milk/DMI. Production was not increased when diets contained 15.8% or more CP. Although the NRC model indicated that diets had Lys/Met ratios ranging from 3.3 to 3.7, and observed milk yield was more than MP-allowable milk on 12.9 and 15.8% CP, more absorbable Met had no effect on production in this trial.

Key Words: methionine, rumen-protection, milk yield

T425 Methionine supplementation to diets varying in rumen undegradable soy protein. N. N. Morais Júnior[3], V. A. Silveira[1], N. M. Lopes[1], G. S. Dias Júnior[1], G. Pessoa Júnior[1], G. G. S. Salvati[1], C. O. Faria[5], R. A. N. Pereira[2], N. D. Luchini[4], and M. N. Pereira*[1], [1]*Universidade Federal de Lavras*, *Lavras, Brazil*, [2]*Empresa de Pesquisa Agropecuária de Minas Gerais*, *Lavras, Brazil*, [3]*Instituto Federal de Educação Ciência e Tecnologia do Espirito Santo*, *Colatina, Brazil*, [4]*Adisseo*, *Alpharetta, GA*, [5]*Better Nature Research*, *Ijaci, Brazil*.

Methionine (Met) is one of the 2 amino acids (AA) that limits milk production. The objective of this study was to evaluate the effect of supplementing a source of Met to 2 diets with different rumen undegradable protein content. Twenty Holsteins were allocated to 5 4x4 Latin Squares in a 2 × 2 factorial arrangement of treatments. Each period lasted 21 d of which the last 7 were for data collection. Treatments consisted of feeding a diet composed of 38.5% corn silage, 7.8% tifton hay, 24.2% corn, 5.0% soybean meal, 8.3% citrus pulp, and 13% of raw or roasted soybeans (Alfa Nutrisoja, Cooperalfa). The Met supplement (isopropyl ester of 2-hydroxy-4-(methylthio) butanoic acid. MetaSmart, Adisseo) was orally given twice a day to the allocated cows. Diet CP content was 15.8% and EE was 6%. No significant results were observed for the interaction of amino acid and soybean main effects ($P > 0.15$). Roasted soybeans increased milk yield from 34.7 to 37.7 kg, protein yield from 1.003 to 1.078 kg, and fat yield from 1.060 to 1.162 ($P < 0.01$). The milk to feed ratio was 1.49 for raw and 1.59 for roasted soybeans ($P < 0.01$). MetaSmart induced non-statistically detectable increases in milk yield from 36.0 to 36.4 kg ($P = 0.46$), protein from 1.032 to 1.049 kg ($P = 0.29$), and fat from 1.101 to 1.120 kg ($P = 0.45$). Daily DMI was 24.0 kg for cows on MetaSmart and 23.4 for controls ($P = 0.13$). The milk urea nitrogen was 13.1 mg/dL for raw and 12.5 for roasted soybeans ($P = 0.04$). There were no detectable treatment effects on total tract digestibility ($P > 0.62$) and plasma glucose ($P > 0.76$). MetaSmart decreased the daily excretion of urinary allatoin and the ratio of allantoin to digestible OM intake ($P = 0.02$). Plasma urea nitrogen (PUN) content of 10 samples obtained over a 24-h period was analyzed as repeated measures over time with Mixed of SAS. Raw soybeans increased PUN from 14.3 to 15.4 mg/dL ($P < 0.01$), while MetaSmart decreased it from 15.1 to 14.6 ($P = 0.05$). For these soybean based diets, the response to increased flow of dietary AA in the metabolizable protein was larger than the response to Met, suggesting than other amino acids may have been more limiting to milk production.

Key Words: amino acid, methionine, protein

T426 Effects of level of rumen degradable protein and corn distillers grains in corn silage-based diets on milk production and ruminal fermentation in lactating dairy cows. G. I. Zanton* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

Two of the potential obstacles precluding inclusion of higher levels of dry distillers grains with solubles (DDGS) in corn-based, dairy cow diets are the low levels of rumen degradable protein (RDP) and the fatty acid content and composition of DDGS. Therefore, the objective of this experiment was to evaluate the production and rumen responses to dietary alterations in the level of RDP and DDGS for dairy cows fed a high corn silage diet. The experimental design was a replicated, 4 × 4 Latin square with 21 d periods: 14 d of adaptation and 7 d of sampling; 16 uncannulated cows and 4 rumen cannulated cows were blocked and assigned randomly to treatment sequences. Rations (basal ingredients: 47% corn silage, 3% long grass hay, 12% finely ground corn, 4% extruded soybean meal, 7.5% canola meal; mean composition: 17.4% CP, 36% NDF, 36% NFC, 1.69 Mcal NE_L/kg) were provided as total mixed rations and were formulated to be high or low RDP, with or without DDGS replacing soybean-based concentrates: high RDP, no DDGS (HDRP0); low RDP, no DDGS (LRDP0); low RDP, 10% DDGS; and low RDP, 20% DDGS. Contrasts of interest were HRDP0 vs. LRDP0 and linear and quadratic effects of level of DDGS; differences were declared at $P < 0.05$. Body weight (696 kg) and dry matter intake (26.6 kg/d) were not affected by treatment ($P > 0.50$). Rumen ammonia concentration was greater for HRDP0 than LRDP0 ($P < 0.01$), but was unaffected by level of DDGS inclusion. Mean and minimum rumen pH and time < pH 5.5 was not different between diets ($P > 0.25$). Milk production tended to be lower for cows fed HRDP0 than LRDP0 ($P < 0.06$) and tended to be linearly reduced as DDGS inclusion increased ($P < 0.07$). Milk protein yield tended to be greater for cows fed LRDP0 than HRDP0 ($P < 0.07$), but was unaffected by DDGS level. Milk fat production, concentration, and fat corrected milk were linearly reduced by increasing levels of DDGS ($P < 0.01$).

Key Words: dry distillers grains with solubles, rumen degradable protein, corn silage

T427 Effect of quebracho-chestnut tannin extracts at two dietary crude protein levels on performance and rumen fermentation of dairy cows. M. J. Aguerre*[1], M. A. Wattiaux[1], M. C. Capozzolo[1], P. Lencioni[2], and C. Cabral[2], [1]*University of Wisconsin-Madison*, *Madison*, [2]*Silvateam, Indunor S. A*, *Argentina*.

The objective of this study was to determine the effects of a dietary tannin mix on lactating cow performance and rumen fermentation, and whether any responses were affected by dietary CP. Eight ruminally cannulated and 16 noncannulated multiparous Holstein cows (669 ± 55 kg BW; 89 ± 36 DIM) were randomly assigned to a diet of 15.5 or 16.8% CP (%DM) and to 1 of 4 levels of tannins in three 4 × 4 Latin squares within each level of dietary CP. Rice hull was removed from 50:50 forage to concentrate ratio (%DM) total mixed rations as a tannin extract mixture from Quebracho and Chestnut trees was included at 0 (control), 0.45, 0.90 and 1.8% of dietary DM. There was no interaction between dietary CP and tannin supplementation. Reducing dietary CP had no effect on measurements, except for reducing milk urea N (MUN; 18.8 vs. 15.6mg/dL, $P < 0.05$) and ruminal NH_3-N (11.0 vs. 9.3 mg/dL, $P < 0.05$). Overall, milk yield (40.4 kg/d), 3.5%FCM (40.3 kg/d), milk

fat and lactose content and yield, and ruminal pH were not affected by tannin. The *P*-values for a linear increase in BW gain (0.46 kg/d), a linear increase in feed efficiency (1.68 kg milk/kg of DMI) and a linear decrease in DMI (24.4 kg/d) with incremental levels of tannin extracts in the diet were 0.11, 0.15 and 0.07, respectively. Relative to control (2.87%), milk true protein content increased to 2.91% ($P < 0.05$), did not change (2.86%) and decreased to 2.83% ($P < 0.05$) when tannin was 0.45, 0.90 and 1.8% of dietary DM respectively. Also, relative to control (1.14 kg/d), milk protein yield did not change with inclusion of tannin, but it was higher ($P < 0.05$) at the 0.45 than the 0.9 or 1.8% inclusion level (1.16, 1.12 and 1.11 kg/d, respectively). Relative to other treatments, the 1.8% tannin in the diet lowered MUN (13.8 vs. 12.9 mg/dL, $P < 0.05$) and rumen NH_3-N (10.6 vs. 8.1 mg/dL, $P < 0.05$). Results indicate that regardless of dietary CP, 0.45% tannin extract in the diet had a small positive effect on milk protein content independently of a reduction in ruminal protein degradation, which was observed along with a reduction in MUN, only at the 1.8% level of inclusion.

Key Words: tannin, performance, protein

T428 Effect of quebracho-chestnut tannin extracts at two dietary crude protein levels on nitrogen partitioning in lactating dairy cows. M. J. Aguerre*[1], M. A. Wattiaux[1], M. C. Capozzolo[1], P. Lencioni[2], and C. Cabral[2], [1]*University of Wisconsin-Madison, Madison*, [2]*Silvateam, Indunor S. A.*, *Argentina*.

Our objective was to determine the effects of a dietary tannin mix on nitrogen (N) partitioning and whether responses were affected by the level of dietary CP. Eight multiparous Holstein cows (708 ± 41 kg of BW; 125 ± 41 DIM) were randomly assigned to a diet of 15.5 or 16.8% CP (%DM) and to one of 4 levels of tannin in a 4 × 4 Latin squares within each level of dietary CP. Rice hull was removed from 50:50 forage to concentrate ratio (%DM) total mixed rations as a tannin extract mixture from Quebracho and Chestnut trees was included at 0 (control), 0.45, 0.90, and 1.8% of dietary DM. Nitrogen mass balance was conducted by a 3-d total fecal and urine collection. There was no CP by tannin interaction for any of the measured variables. Reducing dietary CP had no effect on DMI (24 kg/d), N intake (613 g/d), milk N (172 g/d) and N efficiency (milk protein N/N intake; 0.28) but increased fecal N (214 vs. 257 g/d, $P = 0.07$) and decreased (all Ps < 0.05) urinary N (232 vs. 167 g/d), urinary urea N (164 vs. 99 g/d) and apparent N digestibility (65.4 vs. 57.2%). Although manure N (fecal N + urinary N; 435 g/d) remained unaltered, lowering dietary CP from 16.8 to 15.5% resulted in a 40% reduction in urinary to fecal N ratio (1.10 vs. 0.66; $P < 0.05$). Tannin did not affect N intake, milk N, or N efficiency, however, it increased fecal N relative to control (214 vs. 243 g/d; $P < 0.05$) with no differences among inclusion levels. In addition, urine N was lower when tannin inclusion rate was 1.8% of dietary DM compared with 0, 0.45 and 0.9% inclusion rates (211 vs. 177 g/d; $P < 0.05$). Inclusion of tannin in the diet did not alter manure N, but it lowered the urinary N to fecal N ratio. Relative to control, urinary N to fecal N ratio was decreased by 18% in the 2 intermediate tannin inclusion rates (1.05 vs. 0.87, respectively; $P < 0.05$), the latter value being further reduced ($P < 0.05$) to 0.72 at the 1.8% inclusion rate (a 31% reduction compared with control). Results indicated that reducing dietary CP and inclusion of tannin extract in the diet had additive effects on altering urinary to fecal N ratio.

Key Words: tannin, nitrogen, manure

T429 Digestibility of amino acids in rumen undegraded corn silage determined by the modified three-step procedure. S. M. Fredin*[1], S. E. Boucher[2], D. Sapienza[3], N. L. Whitehouse[1], and C. G. Schwab[1], [1]*University of New Hampshire, Durham*, [2]*William H. Miner Agricultural Research Institute, Chazy, NY*, [3]*Sapienza Analytica, LLC, Slater, IA*.

Five corn silage (CS) hybrids were utilized in an evaluation of the modified 3-step procedure (mTSP) to estimate intestinal (ID) and total tract digestibility (TTD) of crude protein (CP) and AA. Samples were ground to 2-mm and ruminally incubated in situ for 16 and 24 h in 2 lactating cows averaging (mean ± SD) 43 ± 8 d in milk fed a 58% forage, 42% concentrate ration. Two time points were chosen to evaluate differences in ID due to ruminal incubation time using the MIXED procedure of SAS. After ruminal incubation, rumen undegraded CS was incubated for 1 h in a pepsin-HCl solution and for 24 h in a pancreatin solution. Estimates of ruminal degradability, ID, and TTD of CP and AA were calculated. In vivo estimates of ruminal degradability, ID, and TTD of CP and AA were previously determined for the same CS samples using the mobile bag technique (MBT). Coefficients of determination between in vivo and mTSP data were calculated using the REG procedure of SAS. With the mTSP, average ruminal degradability of CP and total AA for all CS samples (incubated for either 16 or 24 h; n = 10) was 74.0 ± 5.85 and 78.9 ± 3.91%, respectively. Estimates of ruminal degradability of CP and total AA were 13.3 and 9.5% greater for the mTSP compared with ruminal degradability estimates from the MBT evaluation. No difference was observed ($P > 0.05$) for in vitro estimates of ID of CP and AA ruminally incubated for 16 or 24 h. Intestinal digestibility of CP and total AA measured with the mTSP for all rumen undegraded CS samples were 10.6 ± 5.15 and 36.9 ± 8.13%, respectively. Estimates of ID obtained using the mTSP and the MBT were not correlated (R2 = 0.07 for CP and R2 = 0.23 for total AA). The mTSP tended to under-predict intestinal digestibility of CP and total AA by 16 and 13%, respectively. Correlations between the 2 methods were improved for TTD of CP (R2 = 0.92), total AA (R2 = 0.82), and essential AA (averaged R2 = 0.72). The mTSP may not be an acceptable in vitro method to determine ID of AA in rumen undegraded CS, but, it may be suitable to determine TTD of AA.

Key Words: corn silage, amino acid digestibility, modified three-step procedure

T430 Evaluation of sampling protocols to estimate ruminal microbial protein production using urinary excretion of purine derivatives. S. E. Boucher*, H. M. Dann, P. K. Krawczel, H. M. Gauthier, J. D. Darrah, and R. J. Grant, *William H. Miner Agricultural Research Institute, Chazy, NY*.

Urinary excretion of purine derivatives (PD) is a technique commonly used to estimate ruminal microbial protein production. However, urine sampling protocols for this technique reported in the literature vary. The objective of this experiment was to evaluate 2 urine sampling protocols to estimate ruminal microbial protein production in lactating cows. Sampling protocols (SP) were employed on cows concurrently enrolled in a 4 × 4 Latin square trial with 21-d periods designed to evaluate the effects of a feed additive and dietary rumen undegraded protein content on ruminal microbial protein production. Urine samples were collected: 1) 4 h post-feeding (1630) on d 18 and 19 of each period and analyzed separately (SP1) or 2) at 0200 and 1630 on d 18, 19, and 20 of each period and composited by cow by period for analysis (SP2). At each time point a minimum of 40 mL of urine was collected. Aliquots of samples were analyzed for allantoin, uric acid, and creatinine concentrations. In cattle, allantoin and uric acid are the primary PD excreted in urine, and creatinine is used as a marker for urine volume. Daily excretion of urinary PD and microbial N production calculated by each protocol were analyzed using the MIXED procedure of SAS to determine least

squares means (LSM), standard errors, and the variance components associated with each sampling method. The LSM of microbial N for the 4 dietary treatments estimated from SP1 and SP2 were 544, 558, 508, and 553 (SE = 19), and 476, 465, 445, and 476 g/d (SE = 18), respectively. The residual variance as a proportion of total variance for SP1 and SP2 was 28 and 37%, respectively. The residual variance is the proportion of the variance associated with day-to-day variation and measurement errors within cows. Based on differences in LSM and variance components with the 2 sampling protocols, standardization of urine sampling protocols when utilizing urinary excretion of PD to estimate microbial protein production in ruminants is needed.

Key Words: microbial protein production, urinary purine derivatives, sampling protocols

T431 Determining the difference in the supply of metabolizable methionine to dairy cows fed four methionine supplements using concentrations of selenium in milk. J. E. Plank*, W. P. Weiss, and N. R. St-Pierre, *The Ohio State University*, *Columbus*.

Accurately quantifying the amount of metabolizable methionine (Met) supplied by Met supplements can be economically beneficial to dairy producers. A previously developed method to estimate the supply of metabolizable Met, based on changes in the concentration of Se in milk when Met sources are fed, was used to compare metabolizable Met supplied from 4 Met supplements: DL-Met, Smartamine, 2-hydroxy-4-(methylthio)-butanoic acid (HMB) and the isopropyl ester of HMB (HMBi). Twenty Holstein cows were fed a diet containing 32% corn silage, 17% corn, 14% legume hay, 13% distillers grains and 13% wheat middlings as a percent of dietary dry matter (DM), as well as 0.3 mg of Se from Se-yeast/kg of dietary DM. Then, in a truncated Latin square experiment (2 blocks, 2 14 d periods), a methionine or control supplement was added to their diet. Methionine supplements were mixed with soyhulls and were fed twice daily as a 500g/day topdressing to provide 18g of Met/day, while control cows were fed 500g/day of soyhulls. Cows were allowed 11 d for adjustment followed by milk sampling on d 12–14 of each period. The specific activity (SA) of milk (the ratio of Se concentration to milk N concentration) was calculated for each treatment. Supplementing Met reduced the SA of milk for cows treated with HMBi (11.0 μg Se/mg N) and Smartamine (11.1 μg Se/mg N) relative to control (12.1 μg Se/mg N, $P < 0.05$), but SA of milk from other treatments did not differ from control. The SA in milk from treatment cows was divided by SA in milk from control cows to determine the change in supply of metabolizable Met. The digestible met flow for control cows, calculated using the Dairy NRC model, was 44 g/day. The calculated flow of metabolizable Met for cows supplemented with DL-Met, Smartamine, HMB and HMBi was 44.4, 48.3, 45.7 and 45.2 g/day respectively. DM intake was different only for cows supplemented with HMBi (21.1 kg/day vs. 19.7 kg/day for control, $P < 0.01$) and the data were adjusted accordingly. The average milk production was 30.3 kg/day and was not affected by the treatments.

Key Words: methionine, milk protein, selenium

T432 The relationship between milk urea nitrogen concentrations, diet, and milk production on Northeast dairy farms. K. M. Kouri*, *Poulin Grain*, *Newport, VT*.

Previous research has shown that concentrations of milk urea nitrogen (MUN) can be measured to monitor the efficiency of dietary protein utilization, and to decrease costs associated with feeding excess protein. The objective of this study was to determine the relationship between MUN concentrations, time of year, milk production, and diet on Northeast dairy farms. Data from 18 dairy farms (approximately 9300 cows) in Vermont and New York were collected and analyzed to identify associations with and possible predictors of MUN concentrations. Monthly milk production and composition for each farm was collected by local milk cooperatives. A subset of 8 farms was used to determine the relationship between MUN concentrations and nutritional measures. Across all farms, MUN levels averaged 11.3 ± 1.2 mg/dl and milk production was 33.8 ± 2.6 kg/d. Concentrations of MUN were affected by time of year ($P < 0.01$), being highest in the summer and lowest in the late winter. There was a positive relationship between MUN and milk yield ($r = 0.70$; $P < 0.08$), and a negative relationship between MUN and both fat ($r = -0.50$; $P < 0.03$) and protein ($r = -0.70$; $P < 0.002$) percentages. In contrast, there was a positive relationship between MUN and percent other solids ($r = 0.80$; $P < 0.04$). There was a modest negative relationship between MUN and forage:concentrate ratio ($r = -0.50$; $P < 0.17$). Somatic cell count, crude protein, rumen degradable protein, rumen undegradable protein, and soluble protein were not correlated with MUN levels in milk ($P > 0.05$). In conclusion, MUN concentrations changed throughout the year and this should be considered when making nutritional management decisions based on MUN. In addition, the positive relationship between MUN and milk production performance of farms in the current study indicates that dietary protein was not being fed in excess.

Key Words: milk urea nitrogen, Northeast dairy farm, production

T433 A critique of dose-response plots that relate changes in content and yield of milk protein to predicted concentrations of lysine in metabolizable protein by the NRC (2001), CPM-Dairy (v.3.0.10), and AMTS.Cattle (v.2.1.31) models. N. Whitehouse*[1], C. Schwab[1], D. Luchini[2], and B. Sloan[2], [1]*University of New Hampshire*, *Durham,* [2]*Adisseo, Atlanta, GA.*

The objective of this study was to critique the Lys dose-response plots for the NRC, CPM and AMTS models (Whitehouse et al., 2009) with an expanded database. To help ensure that Met was not limiting production responses to supplemental Lys, regression analysis for NRC was limited to data where Met was greater than 2.16% of MP; the Met constraint used previously was 2.07%. The resulting data set for NRC contained 59 observations; the data sets for CPM and AMTS contained 48 and 37 observations, respectively. Observations were less for CPM and AMTS because the models, particularly AMTS, predicted lower concentrations of Lys in MP for the high corn-based basal diets without Lys supplementation than NRC. This created ranges of Lys in MP for more studies than with NRC where the highest predicted concentration of Lys in MP did not overlap with the ranges of Lys in MP for the rest of the studies. This precluded being able to identify a fixed reference concentration of Lys in MP that was intermediate to the lowest and highest values in as many of the Lys studies; a fixed reference concentration is needed to calculate the production responses (plus and minus values) for the y-axis of the dose-response plots. The resulting breakpoint estimates for the required concentrations of Lys in MP for maximal content and yield of milk protein were 6.89 and 6.95% for NRC, 7.23 and 7.36% for CPM, and 6.84 and 6.74% for AMTS. Using this expanded database pinpointed that diets rich in corn protein have very low predicted concentrations of Lys in MP when evaluated through AMTS and CPM, due primarily to the low Lys concentrations in RUP as estimated by the insoluble protein method. This not only precluded the use of certain data, but had consequences on the slopes (0.141 vs. 0.128 vs. 0.105) for NRC, CPM and AMTS and the breakpoints determined. It is suggested that an assessment be undertaken of what database is used for AA profiles of ingredients before updating present formulation guidelines.

Key Words: lactating cows, lysine, methionine

T434 Fatty acid supplementation to periparturient dairy cows fed diets containing low basal concentrations of fatty acids. L. F. Greco*, M. Garcia, M. G. Favoretto, R. S. Marsola, L. T. Martins, R. S. Bisinotto, E. S. Ribeiro, F. S. Lima, W. W. Thatcher, C. R. Staples, and J. E. P. Santos, *University of Florida*, *Gainesville*.

Objectives were to evaluate the impacts of supplementing diets containing low amounts of long chain fatty acids (FA, < 1.8%) with either mostly saturated free FA (SFA) or with Ca salts enriched with polyunsaturated FA (PUFA, 27% C18:2n6 and 3.5% C18:3n3 of the total FA) on performance of Holstein cows. Prepartum cows were allocated randomly to 1 of 3 dietary treatments from 60 d before expected calving date until 90 d postpartum. Supplementation with FA (% dietary DM) consisted of 0% (CTL, n = 26), 1.7% SFA (n = 25), and 1.7% as Ca salts of PUFA (EFA, n = 25). The DMI was recorded daily from 30 d pre- to 90 d postpartum. Body weight and BCS were measured at 60 and 30 d prepartum, at calving and then weekly postpartum. Milk production was measured daily and composition was evaluated weekly. Blood samples were collected weekly before calving and then thrice weekly postpartum for 40 d. Prepartum DMI was lower for cows fed EFA (11.3, 11.4 and 10.2 kg/d, respectively for CTL, SFA and EFA). Feeding EFA reduced postpartum DMI in multiparous but not in primiparous cows. Milk and protein yields were greater for primiparous cows fed EFA, however, fat yield did not differ. Postpartum BW, BW change, and BCS were not different among treatments. Feed efficiency was better and mean concentrations of plasma BHBA were greater for multiparous cows receiving supplemental EFA. Mean concentrations of plasma NEFA were lower for primiparous cows not fed supplemental fat. Cows supplemented with EFA had improved efficiency of converting feed into milk, and increased concentrations of BHBA despite similar BW and BW changes.

Table 1.

	CTL		SFA		EFA		P[1]		
	P[2]	M[3]	P	M	P	M	TRT* Parity	Fat	FA

Key Words: dairy cow, fatty acids, linoleic acid

T435 Intake, digestibility and productive performance of dairy cows fed with sunflower meal. A. S. de Oliveira*[1], J. M. S. Campos[2], E. P. Viana[2], D. S. Caixeta[2], S. C. Valadares Filho[2], A. M. F. Santiago[2], J. P. do Carmo[2], A. C. S. Souza[2], G. H. Soares[2], J. P. Giordani[2], and L. F. do Lago[2], [1]*Universidade Federal de Mato Grosso*, *Sinop, MT, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

Twelve multiparous Holstein cows (128 ± 38 DIM and 627 ± 48 kg BW) were distributed in three 4 × 4 Latin squares by DIM, with 4 periods of 21 d (7 d of mensurations) to evaluate the effect of sunflower meal (SFM; 37.5% of CP) in diet (0, 7, 14 and 21% of DM) on intake, total tract apparent digestibility and productive performance. Diets TMR were isonitrogen (16.2% of CP), containing 55% of corn silage (DM basis). The SFM replaced mixture (37.5% of CP) containing 53.57% of soybean meal and 47.37% of wheat middlings. Fecal samples were directly collected once daily at 1600, 1400, 1200, 1000 e 800 h, of 15 to 19 d of each period. Indigestible ADF (after 264 h of ruminal incubation) was used to estimate fecal output. Milk samples were collected on 18 and 19 d of each period at am and pm milking. Data were analyzed using model mixed (PROC MIXED, SAS Inst. Inc., Cary, NC). Was applied Williams test to comparison of means for quantitative data. The SFM inclusion increased RDP (10.6, 10.7, 10.9 and 11.1% of DM), NDF (39.9, 40.8, 4. and 42.6), lignin sulfuric acid (2.3, 2.5, 2.8 and 3.1% of DM) and indigestible ADF (8.6, 9.6, 10.6 and 11.6 of DM) of diets. DM (21.6 kg/d), CP (3.75 kg/d) and NFC (7.8 kg/d) intakes were not affected by SFM ($P > 0.05$), but NDF intake (7.9, 7.9, 8.0 and 8.6 kg/d) was greater ($P < 0.05$) to 21% of SFM. DM digestibility (65.1, 64.1, 64.3 amd 62.1%), total carbohydrate digestibility (60.9, 59.2, 59.2 and 57.2%) and TDN (63.8, 62.7, 62.7 and 60.5%) of diets were not affected ($P > 0.05$) until 14% of SFM, but were reduced ($P < 0.05$) with 21% of SFM. Milk yield (29.8, 28.8, 28.7 and 27.4 kg/d) and milk lactose yield (1.32, 1.28, 1.30 and 1.23 kg/d) were not reduced ($P > 0.05$) until 14% of SFM, but were reduced ($P < 0.05$) with 21% of SFM. Milk crude protein (3.22, 3.18, 3.09 and 3.11%) was reduced ($P < 0.05$) from 7% of SFM. Milk efficiency (1.33 kg of milk/ kg of DM intake), milk fat (3.61%), milk lactose (4.47%) and milk solids non-fat (8.63%) were not affected ($P > 0.05$) by SFM. The SFM can be included in up to 14% in DM diets for dairy cows with production of 30 kg/d without affecting intake, digestibility and productive performance.

Key Words: milk

T436 Metabolism of nitrogen compounds in dairy cows fed with sunflower meal. A. S. Oliveira*[1], J. M. S. Campos[2], D. S. Caixeta[2], E. P. Viana[2], S. C. Valadares Filho[2], L. F. do Lago[2], A. M. F. Santiago[2], J. P. Giordani[2], G. H. Soares[2], J. P. do Carmo[2], and A. C. S. Souza[2], [1]*Universidade Federal de Mato Grosso*, *Sinop, MT, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

Twelve multiparous Holstein cows (28.7 ± 4 kg/day of yield milk, 128 ± 38 DIM and 627 ± 48 kg BW) were distributed in three 4 × 4 Latin squares by DIM, with 4 periods of 21 d to evaluate the effect of sunflower meal (SFM; 37.5% of CP) in diet (0, 7, 14 and 21% of DM) on metabolism of nitrogen compounds (N) and efficiency of N utilization for milk production. Diets TMR were isonitrogen (16.2% of CP), containing 55% of corn silage (DM basis). The SFM replaced mixture (37.5% of CP) containing 53.57% of soybean meal and 47.37% of wheat middlings. Milk samples were collected on 18 and 19 d of each period at am and pm milking. Spot urine samples were obtained approximately 0, 3 and 6 h postfeeding on 17 d of each period. Urine volume was estimated using creatinine concentration as a marker and assuming creatinine excretion of 24.05 mg/kg of BW/d. Data were analyzed using model mixed (PROC MIXED, SAS Inst. Inc., Cary, NC). Was applied Williams test to comparison of means for quantitative data. The SFM inclusion increased RDP (10.6, 10.7, 10.9 and 11.1% of DM). Rumen microbial crude protein synthesis (MPS, estimated by the derivatives in purine urinary excretion and secretion of milk; 2.10, 2.01, 2.03 and 1.77 kg/d) was not affected ($P > 0.05$) until 14% of SFM, but was reduced ($P < 0.05$) with 21% of SFM. The g of MPS/kg TDN intake (152.6) was not affected ($P > 0.05$) by SFM, but the efficiency of RDP intake used for MPS (0.90, 0.88, 0.88, 0.73 kg de MPS/kg of RDP intake) was reduced ($P < 0.05$) with 21% of SFM. Milk urea-N (17.60 mg/dL), blood urea-N (17.80 mg/dL), urinary N-urea (195.7 g/d), urinary N (240 g/d; 40% of N intake), feces N (185.2 g/d; 30.9% of N intake) and balance N (32.6

g/d; 5.5% of N intake) were not affected ($P > 0.05$) by SFM. However, because of lower efficiency RDP intake for MPS, the milk N/intake N (24.9, 24.2, 23.5 and 22.0%) was reduced ($P < 0.05$) from 14% of SBM. The SFM can be included in up to 7% in DM diets of dairy cows without affecting metabolism of nitrogen compounds (N) and efficiency of N utilization for milk production.

Key Words: blood urea-N, microbial crude protein synthesis, n efficiency

T437 A critique of dose-response plots that relate changes in content and yield of milk protein to predicted concentrations of methionine in metabolizable protein by the NRC (2001), CPM-Dairy (v.3.0.10), and AMTS.Cattle (v.2.1.31) Models. N. Whitehouse*[1], C. Schwab[1], D. Luchini[2], and B. Sloan[2], [1]*University of New Hampshire*, *Durham,* [2]*Adisseo, Atlanta, GA.*

The objective of this study was to critique the Met dose-response plots for the NRC, CPM and AMTS models (Whitehouse et al., 2009) with an expanded database. To help ensure that Lys was not limiting production responses to supplemental Met, regression analysis for NRC was limited to data where Lys was greater than 6.45% of metabolizable protein (MP); the Lys constraint used previously was 6.16%. The resulting data set for NRC and CPM contained 91 observations; the data set for AMTS contained 82 observations. Observations were less for AMTS because the model predicted lower concentrations of Met in MP than CPM for several of the basal diets without Met supplementation. This created ranges of Met in MP where the highest predicted concentrations of Met in MP in some studies did not overlap with the lowest concentrations of Met in MP for the rest of the studies. This precluded being able to identify a fixed reference concentration of Met in MP that was intermediate to the lowest and highest values in all studies; a requisite for calculating the production responses (plus and minus values) for the y-axis of the dose-response plots. The resulting breakpoint estimates for the required concentrations of Met in MP for maximal content and yield of milk protein were 2.23 and 2.38% for NRC and 2.40 and 2.44% for CPM. These compare favorably to the respective breakpoint estimates of 2.23 and 2.38 for NRC and 2.40 and 2.44 for CPM by Whitehouse et al. (2009). For AMTS, the relationship between changes in content and yield of milk protein to predicted concentrations of Met in MP was linear, a result of the more restricted database and differences between AMTS and CPM in predicted concentrations of Met in MP. It is suggested that an assessment be undertaken of what database is used for AA profiles of ingredients before updating present formulation guidelines for Met in MP for the models evaluated

Key Words: lactating cows, methionine, lysine

T438 In situ ruminal degradability of crambe, sunflower and soybean grains, and its by-products. R. H. de Tonissi e Buschinelli de Goes*, K. A. de Souza, R. A. Patussi, K. A. G. Nogueira, D. de Faria Pereira, T. da Cunha Cornélio, K. C. da Silva Brabes, and E. R. de Oliveira, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

The ruminal degradation of dry matter (DM) and crude protein (CP) of crambe (*C. abyssinica*), sunflower, soybean grains and its by-products (crushed seeds), were evaluated by the in situ technique, using 3 rumen fistulated sheeps. The feeds were grounded though a 2mm screen and incubated directly in rumen for 72, 48, 24, 12, 6, 3, and 0 h. Potential degradation, were adjusted by a no linear regression by Gauss-Newton's method, PD = A+B*(1-exp-ct), being A = soluble fraction, B = potentially degradable fraction, c = degradation rate of the fraction B, and t = time of incubation. Effective degradability (ED = a+(b*c)/(c+k)), where k = passage rate of 5%/h. DM and CP for crambe, sunflower and soybean was 93.5, 93.6, 89.4% and 27, 22.3, 50.3%; for its by-products was 70, 87.4, 90.5%, and 52.8, 30.3, 46.8%. The Crambe soluble fraction (23.5%) and potentially degradable fraction (74.1%), provided more ED (75.4%) for DM. Crambe crushed, showed lower degradability (60.4%) and soluble fraction (20.1%) and higher rate of degradation (14.7%). The soybean and sunflower had the lowest effective degradability (47.6 and 39.7%), possibly related to low soluble fraction (4.8 and 11.7%), while its by-products had the highest ED (75.6 and 84.5%), with soluble fraction of 23.2 and 22.9%, and potentially degradable fractions of 70.3 and 73.7%. For the CP, the crushed soybean presented a higher effective degradability and potentially degradable fraction (70.9 and 89,1%), while the grain presented 38.7 and 55.6%. The sunflower, crambe and its by-products presents ED and potentially degradable fraction of 30.7, 44.0, 45.0, and 35.5% and 41.3, 38.1, 34.6, 22.0%. The soluble fractions were 8.7, 9.8, 18.3, 7.7, 13.7, and 19.3, for soybean, sunflower, crambe and its by-products. The low degradation presented by crambe and sunflower by-products can be associated with the processing of grain for oil extraction, and undegradable fraction (58.7 and 51.7%). The grains of crambe, sunflower and soybean and its by-products had a medium degradability for the dry matter and low degradability for crude protein, except soybean by-product, that showed high degradability.

Key Words: nylon bags, chemical composition, oil seeds

T439 Effects of supplemented high linoleic or linolenic oil in the diet on lipid metabolism by rumen microbes in sheep. S. H. Choi*[1], G. W. Jin[2], H. G. Lee[3], C. W. Choi[4], S. S. Chang[4], S. B. Smith[1], and M. K. Song[2], [1]*Department of Animal Science, Texas A&M University*, *College Station,* [2]*Department of Animal Science, ChungBuk National University, Cheong Ju, Chungbuk, Korea,* [3]*Department of Animal Science, Pusan National University, Miryang, Gyongnam, Korea,* [4]*National Institute of Animal Science, RDA, Suwon, Gyunggi, Korea.*

A metabolic trial with 3 ruminally cannulated sheep (60 ± 6 kg) was conducted in a 3 × 3 Latin square design to investigate the effects of high linoleic (18:2 *n*-6; soybean oil) or α-linolenic oil (18:3 *n*-3, perilla oil) on the ruminal fermentation, formation of conjugated linoleic acid (CLA) in the rumen and apparent digestibilities of nutrients. Sheep were fed 1.3 kg of diet (DM basis) consisting of 60% concentrate and 40% chopped alfalfa hay. Oils were supplemented to concentrate at 5% level of the total diet (DM basis). Rumen pH was not influenced by the oil supplementation. But ammonia-N concentration significantly decrease ($P = 0.05$) by the feeding the oil supplemented diets. Molar proportion of each VFA in rumen fluid and whole tract digestibilities of DM, CP, EE, NDF and OM were not affected by oil supplementation. The compositions of *trans*-10, *cis*-12 CLA (from 0.56% to 1.43%) in the rumen fluid were slightly higher than that of *cis*-9, *trans*-11 CLA (from 0.27% to 1.47%). Oil supplementation resulted in decreased plasma oleic acid (18:1 *n*-9) proportion ($P < 0.03$) but increased linoleic acid proportion ($P < 0.04$) at 1 h before feeding. At 1 h post-feeding, oil supplementation resulted in a decreased stearic acid (18:0) proportion ($P < 0.02$) but increased palmitoleic acid (16:1*n*-7) proportion ($P < 0.01$) in plasma. The proportions of *cis*-9, *trans*-11 CLA in plasma was slightly (from 0.18% to 0.62% ; $P = 0.37$) increased with oil supplementation at 1 h post-feeding.

Key Words: conjugated linoleic acid, plant oil, sheep

T440 Effects of increasing amounts of high-linolenic perilla fatty acid infused into the duodenum on blood lipids metabolism and

their susceptibility to peroxidation in dairy cows. Q. S. Liu[1,2], J. Q. Wang*[1], D. P. Bu[1], E. Khas[1], G. Yang[1], L. Y. Zhou[1], P. Sun[1], and K. L. Liu[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*College of Animal Science and Technology, Yangzhou University*, *Yangzhou, China*.

Our objective was to determine the effects of increasing amounts of high-linolenic perilla fatty acid (HLPFA) emulsion (82.4% *cis-9*, *cis-12*, *cis-15* 18:3; 14.7% *cis-9*, *cis-12* 18:2; 2.8% *cis-9* 18:1 and 0.1% other fatty acids) infused into the duodenum of dairy cows on blood lipids metabolism and the susceptibility of blood to oxidation. Four primiparous Chinese Holstein cows (BW = 476 ± 6 kg, DIM = 100 ± 2 d) fitted with duodenal cannulas were administered 2 treatments in a crossover design. Treatments were homogenized aqueous mixtures of HLPFA emulsion (0, 100, 200, 300, 400 g/d) or control containing only the emulsifying ingredients. The control infusate consisted of 15 g/d of xanthan gum, 5 g/d sodium alginate, and 25 g/d of Tween 80 in 10 L of purified water. Each period lasted 5 wk, during period 1, 2 cows received each amount of HLPFA for 1 wk each, and the other 2 cows received only the carrier infusate. In period 2, the procedures were repeated, so that the other 2 cows received the HLPFA doses in sequentially increasing amounts and the cows that previously received HLPFA received the control infusate. Blood collection was made during the last day of each infusion amount. Data were analyzed statistically by using PROC MIXED of SAS. The concentration of high density lipoprotein cholesterol and total cholesterol were increased quadratically ($P = 0.0036$, 0.0013 respectively). The concentration of α-linolenic acid in blood increased linearly as infusion increased ($P = 0.0001$). The activity of total superoxide dismutase tended to decrease linearly ($P = 0.18$), and the total antioxidant capacity also tended to decrease quadratically ($P = 0.23$), but the thiobarbituric acid reactive substances tended to increase linearly ($P = 0.066$), and the content of vitamin E in serum tended to increase quadratically ($P = 0.096$) as the infusion increased. Infusion with increasing amounts of HLPFA into the duodenum altered the composition and distribution of blood lipids, but decreased the oxidative stability of the blood in dairy cows.

Key Words: high-linolenic perilla fatty acid, blood lipid, oxidation stability

T441 Effects of feeding ruminally protected lysine, with or without isoleucine, valine and histidine, to lactating dairy cows on productive performance and plasma amino acid profiles. P. H. Robinson[1], S. Juchem[1], N. Swanepoel*[2], and E. Evans[3], [1]*UC Davis*, *Davis, CA,* [2]*Meadow Feeds, Roodepoort, South Africa,* [3]*Essi Evans Technical Advisory Services, Bowmanville, ON, Canada.*

The literature on post-ruminal Lys supplementation to diets of lactating dairy cows shows small negative responses to supplemental intestinally absorbable Lys (IAL), and our recent survey of California dairy rations identified other amino acids (AA) that could become co-limiting if supplies of IAL were met. Objectives were to estimate the rumen escape of a ruminally protected (RP) Lys (RPL) product, and an RPL also containing Ile, Val and His (RPAA), to determine effects of their feeding on performance and plasma AA profiles of lactating dairy cows. Three pens of ~310 multiparous early lactation cows were used in a 3 × 3 Latin square design with 28-d experimental periods in which the basal total mixed ration (TMR) was the same for all groups except for the RP products that were added to the treatment pens at a level designed to deliver an equal amount of IAL to both groups. However rumen stability was slightly higher for the RPL vs. the RPAA, and RPL was calculated to deliver ~13.2 g/cow/d of IAL and the RPAA calculated to deliver ~10.6, 5.4, 2.2 and 1.6 g/cow/d of IAL, Ile, His and Val respectively. Only milk protein % was increased with RPL. Replacement of RPL with RPAA increased milk and milk lactose yields, while milk protein and energy outputs tended to increase. Plasma levels of both non-essential and essential AA, including Lys, were not impacted by feeding RPL or RPAA. Overall, feeding RPL alone caused generally reduced productive performance, which could be interpreted to suggest that Lys was not supplied in sufficient quantity or that it was not required. Addition of Ile, His and Val to the RPL increased performance overall, which supports an overall hypothesis that Lys alone resulted in an imbalance and/or deficiency of Ile, His and/or Val which was alleviated by their supplementation. Overall treatment differences, regardless of statistical significance, were small and of limited practical importance. Nevertheless, feeding a complex of RPAA was beneficial beyond supplementation of RP Lys alone.

Key Words: amino acids, imbalance, body condition

T442 Effect of extruded cotton seed and canola seed on the composition of unsaturated fatty acids in plasma, erythrocytes and liver of Mehraban male lambs. A. Akbarian[1], A. Golian*[1], A. Tahmasbi[1], M. H. Ghafari[1], and M. Mirzaee[2], [1]*Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*, [2]*Isfahan University of Technology*, *Isfahan, Iran*.

An experiment was conducted to study the effects of supplementary extruded cotton seed (ECOS) or canola seed (ECAS) on the composition of unsaturated fatty acids in plasma, erythrocytes and liver of Mehraban male lambs. The treatments included: (1) control (C); (2) diet C+6% ECAS, (3) diet C+6% ECOS, (4) diet C+12% ECAS, (5) diet C+12% ECOS, (6) diet C+6% ECAS+6% ECOS, (7) diet C+12% ECAS +6% ECOS, (8) diet C+6% ECAS +12% ECOS, (9) diet C+12% ECAS+12% ECOS, (10) diet C+18% ECAS+18% ECOS. A completely randomized design experiment was applied to feed the 10 dietary treatments to 60 individually pen housed lambs, to have 6 lambs per diet. The average weight of 5–6 mo lambs at the commence of study was 34.3 ± 2.12 kg. The experiment lasted for 90 d. The amount of oleic acid, linoleic acid and linolenic acid in plasma and oleic acid, and linolenic acid in erythrocytes lipids were higher in lambs fed diet contained either or a combination of supplemental extruded oil seeds compared with those fed control diet. The supplementation of 6% or 12% ECAS significantly increased linoleic acid in liver lipids compared with those fed diet containing ECOS. There was a linear ($P < 0.001$) correlation between the levels of dietary ECAS or ECOS with linoleic and linolenic acids content of liver.

Key Words: lamb, extruded cotton and canola seeds, fatty acids

T443 Effects of roasted and electron beam irradiation on ruminal and intestinal disappearance of whole soybean. A. Akbarian[1], M. Khorvash[1], G. Ghorbani[1], M. Dehghan-Banadaky*[2], P. Shawrang[3], and E. Ghasemi[1], [1]*Isfahan University of technology, Department of Animal Sci.*, *Isfahan, Iran*, [2]*University of Tehran, Department of Animal Sci.*, *Karaj, Tehran, Iran*, [3]*Nuclear Science and Technology Research Institute, Atomic Energy Organization of Iran*, *Tehran, Iran*.

The aim of this study was to evaluate the effects of roasting and electron bean irradiation on in situ ruminal and intestinal dry matter and crude protein degradability of whole soybean. Whole soybeans were roasted in a commercial roaster in 145°C for approximately 30 min. The TT200 Rhodotron accelerator was used for irradiation of whole soybean at dose of 63 kGy. Three rumen and duodenum fistulated non-lactating Holstein cows (620 ± 25 kg) were used for in situ study. Rumen degradability of

dry matter and crude protein were determined using the nylon bag technique and mobile nylon bag technique used for intestinal disappearance. Bags were incubated in the rumen for 2, 4, 8, 12, 24 and 48 h and bags washed without incubation in the rumen for 0 h. Rumen degradation (p) was estimated by the curves were fitted using the nonlinear procedure (PROC NLIN) of SAS, which yielded the equation parameters a, b, and c, each of which is defined as: $P = a + b\ (1\text{-}e^{-ct})$. The soluble fraction (a) and effective degradation (ED, K = 0.05 h-1) decreased and insoluble potentially degradable fraction (b) increased in roasted soybeans (Table 1) but irradiation increased fraction of a and ED and decreased the b fraction of DM and CP ($P < 0.05$). Roasting increased but e-beam irradiation decreased intestinal digestibility of DM and CP. Base on present results, roasting could improve ED and intestinal disappearance of soybean seed but e-beam in 63 kGy could not improve aggregation of soybean protein to increase by pass protein.

Table 1. Rumen degradability and intestinal digestibility of untreated, roasted and irradiated whole soybean

Parameters	Treatments			SEM
	Untreated	Roasted soybeans	Irradiated soybeans	
DM				
a	28.6[b]	20.9[c]	33.9[a]	2.05
b	71.3[b]	79[a]	64.9[c]	3.01
c(h-1)	8.1[b]	4.9[b]	12.9[a]	0.02
Effective degradability	69.5[b]	64.1[b]	80.04[a]	2.3
CP

T444 Meta-analysis for the prediction of net portal absorption (NPA) of amino acid-N (AAN) and ammonia (NH_3) in ruminants. C. Côrtes*[1], R. Martineau[1], D. Sauvant[2], D. R. Ouellet[1], J. Vernet[3], I. Ortigues-Marty[3], and H. Lapierre[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Quebec, Canada*, [2]*AgroParisTech*, *Paris, France*, [3]*URH INRA*, *Theix, France*.

To improve the efficiency of N utilization in ruminants, the objective of this meta-analysis was to predict NPA of AAN and NH_3 from feed intake and composition. Composition of feed ingredients was estimated from INRA (1988) tables, except for N and NDF when reported. Selection of publications (FLORA, Vernet and Ortigues-Marty, 2006) was done on availability of NPA-AAN or NH_3, N intake (NI), BW, and feeding treatments. The final database included 68 publications, 90 experiments (sheep n = 44, cattle: beef and dairy breeds n = 29, dairy: lactating cows n = 17) for a total of 216 treatments: NI, NPA of AA-N and NH_3 averaged (SD): 0.48 (0.20), 0.21 (0.13) and 0.19 (0.12) g N/d per kg BW. In addition to NI, dietary interfering factors (IF) were tested on sub-groups with a sufficient variation of the IF: NDF, CP, ruminally (R) digestible starch (RdS), R-degradable protein (RDP), R-undegradable protein (RUP), R-fermented organic matter (RfOM), and RfOM minus RDP (RfOM-RDP) as %DM; RUP and RDP, as %CP; RdSi (g/d per kg BW), RDP:RfOM, RDP:RfOM-RDP and RdS:RfOM. Seven and 5 IF had a significant slope with the within-experiment residues of the model $Y = \alpha + \alpha i + \beta Ni + \varepsilon$, on NPA of AAN and NH_3, respectively. Each of the IF with an effect on the residues was included to generate a model: $Y = \alpha + \alpha i + \beta Ni + \gamma X + \zeta X^2 + \varepsilon$. Looking for a common IF, RDP:RfOM was selected as the best IF: NPA-AAN = -0.001^{NS} (0.02) + 0.59***(0.05) × NI - 0.60***(0.16) × RDP:RfOM, RMSE = 0.0373, R^2adj = 88.4%, with a species effect** on the intercept: Δ = 0.05, 0, −0.05 for sheep, cattle and dairy cows; NPA-NH_3 = −0.09*(0.04) + 0.15**(0.06) × NI + 2.05***(0.48) × RDP:RfOM - 3.77***(1.08) × RDP:$RfOM^2$, RMSE = 0.0309, R^2adj = 92.3%, species × NI interaction*: Δ = −0.13, 0.09, 0.04 for sheep, cattle and dairy cows. The ratio RDP:RfOM combining the availability of N and energy in the rumen and estimated from dietary characteristics is, in addition to NI, a useful predictor of NPA of AAN and NH_3.

Key Words: amino acid, ammonia, ruminants

T445 Effect of tannins in pistachio by-product and urea infusion into the rumen on rumen fermentation and blood metabolites in Iranian Balochi sheep. H. Gholizadeh, A. A. Naserian*, R. Valizadeh, and A. M. Tahmasebi, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of this study was to determine the effects of tannins in pistachio by-product (PB) on ammonia concentrations in rumen, abomasum and blood metabolites in Iranian Balochi sheep. Three rams with ruminal cannulas and T cannulas in the abomasums were used in a 3 × 3 change over design experiment. Rams were maintained in individual metabolism crates (1.3 m × 0.5 m) which access to water at all times. Treatments were including 3 levels of PB (T1 = 0, T2 = 20 and T3 = 40% of DM). Urea was continuously infused into the rumen via peristaltic pump (1 mL/ min). Daily intake was determined. Abomasum samples were taken simultaneously from all rams twice daily during a period of 4 successive days as follows: d 1, 0900 and 1500 h; d 2, 1000 and 1600 h; d 3, 1100 and 1700 h and d 4, 1200 and 2000 h. Ruminal samples were obtained from each ram on d 3 of the 5-d collection period before the morning meal and 1, 2, 3, 4, 6 and 8 h after feeding. Blood samples were collected from each rams at the end of experiment via jugular vein 2 h after morning feeding. Dry matter intake (DMI) decreased for sheep fed PB (0.75, 0.74 and 0.64 kg, respectively). This reduction was significant for T3 and no differences were observed between T1 and T2. The addition of PB in the diet reduced ammonia concentration in the rumen. In contrast, ammonia concentration in the abomasum increased (25.01, 26.09 and 31.90 mg/dL, respectively). Treatment effects on blood urea nitrogen (BUN) did not differ ($P > 0.05$), but tended to be greater for sheep fed the PB (14.66, 16.33 and 17.66 mg/dl, respectively). Blood glucose, triglyceride and cholesterol decreased for sheep fed T3 compared with control (57 vs. 64; 8 vs. 13 and 26 vs. 40 mg/dL, respectively) It was concluded that feeding PB at high levels (40% of DM) led to decreased DMI, glucose, cholesterol and triglyceride compared with control, but the addition of 20% had no affect.

Key Words: pistachio by-product, urea, Balochi sheep

T446 The protection of nano-encapsulated conjugated linoleic acid (CLA) from biohydrogenation by rumen bacteria. S. D. Cho*[1], H. G. Park[1], H. G. Ji[2], E. G. Kweon[3], and Y. J. Kim[1], [1]*Department of Food and Biotechnology, Korea University*, *Chungnam, Korea*, [2]*Pharmachem*, *Samjung-dong, Ohjung-gu, Bucheon-city, Kyounggi-do, Korea*, [3]*Hanwoo Experimental Station, National Livestock Research Institute*, *Gangwon, Korea*.

Conjugated linoleic acid (CLA) occurs mainly in dairy products because it is produced as an intermediate in the ruminal biohydrogenation process of linoleic acid, a characteristic biochemical process carried out by some rumen bacteria. Thus, dietary sources of CLA are not well protected from

biohydrogenation. In this study, nano-encapsulated CLA; nanosome complex with lecithin was tested as one of the ways to protect CLA from ruminal biohydrogenation. CLA was emulsified with saturated lecithin, capric-capric triglyceride, glycerin, and cholesterol ester using microfludizer. Free form of CLA (CLA-FFA), and triglyceride form of CLA (CLA-TG) were coated with nanosome about the size 100 nm in diameter. To test the protection effect, rumen bacteria were cultured in rumen fluid media in 500 mL continuous culture fermenter. Fresh media was supplied at 25 mL/h with 2% fat substrates with 4 different forms (CLA-FA, CLA-TG, CLA-FFA nanosome, and CLA-TG nanosome). The change in fatty acid profiles by rumen bacteria was monitored during the 48 h incubation. Gas chromatography was used to analyze fatty acid profiles in each group. In all tested groups, the biohydrogenations of CLA were observed during incubation. In CLA-TG and CLA-FFA nanosome groups, the protection effects were not significant compared with CLA-FFA group. In CLA-FFA group, most of CLA was hydrogenated to vaccenic acid (C18:1) or stearic acid. However, in CLA-TG nanosome group, the degree of conversion to vaccenic acid from CLA was the lowest in all tested groups ($P < 0.05$). These results showed that nanoemulsification is one of the ways to protect natural form of unsaturated fatty acids from the ruminal biohydrogenation and to increase the accumulation level of CLA in the tissue of ruminants.

Key Words: conjugated linoleic acid, rumen bacteria, biohydrogenation

T447 Study on the effect of flaxseed and vitamin E supplementation on rumen biohydrogenation by Rumen Simulation Technique (RUSITEC). H. Sultana*[1], M. L. He[1], M. E. R. Dugan[2], and T. A. McAllister[1], [1]*Agriculture and Agri-Food Research Centre*, *Lethbridge, AB, Canada*, [2]*Agriculture and Agri-Food Research Centre*, *Lacombe, AB, Canada*.

Supplementation with omega-3 fatty acid (FA)-rich flaxseed, is used to increase poly-unsaturated fatty acids (PUFA) in meat and milk. High levels of vitamin E (VE) are often included in such diets to reduce oxidation of PUFA in ruminant products. In this study, the RUSITEC was used to assess the effects of flaxseed and/or VE on rumen fermentation, DM disappearance, methane emission and FA profile. Inoculum was obtained from 3 ruminally cannulated non-lactating Holstein cows fed a 75:20:5 diet of barley grain:barley silage:mineral supplement. Fermenters were fed a barley silage (2 g DM) / barley- grain concentrate (8 g DM) diet daily. The experiment was a 2 × 2 factorial with ground flaxseed replacing concentrate at 0 or 15% of DM, along with VE at 0 or 100 IU/kg DM. Volume of effluent, pH and total gas were determined daily at feeding. After 8 d of adaptation, 48-h DM disappearance from silage and concentrate were determined on d 9, 10, 11, 15, 16, and 17. Methane in gas samples and FA accumulations in 24-h effluent were analyzed on d 12, 13, 14, 18, 19, and 20. Disappearance of DM from concentrate was unaffected ($P = 0.93$) by VE, but tended to be lower ($P = 0.07$) with flaxseed. There was no significant difference in total gas or methane production among treatments. As a percent of total FA, inclusion of flaxseed increased levels of saturated ($P = 0.03$), including C18:0 ($P = 0.001$) and decreased ($P = 0.03$) levels of PUFA. Inclusion of flaxseed tended to increase percentage of C18:1 t11 ($P = 0.08$) and the ratio of C18:1 t11/t10 FA ($P = 0.08$). Inclusion of VE did not appear to influence biohydrogenation or the fatty acid profile in effluent. In conclusion, this study indicates that alteration in FA profile arises from the inclusion of flaxseed in the diet with VE having no measurable influence.

Key Words: rumen fermentation, flaxseed, fatty acid

T448 Partial replacement of common bean by-products (*Phaseolus vulgaris*) with soybean meal impacts on feed intake and apparent digestibility in growing lambs. H. P. Mejia[1], A. Z. M. Salem*[1,2], E. J. D. Coronado[1], J. L. Tinoco[1], and F. Avilés[1], [1]*Universidad Autónoma del Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [2]*University of Alexandria*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Four total mixed rations (TMRs) were prepared with supplementary protein supplied by soybean meal (TMR1) being replaced by protein from either 50 (TMR2), 75 (TMR3) or 100% (TMR4) of the common bean by-products (*Phaseolus vulgaris*) as the only sources of protein. Six Pelibuey male lambs (29 ± 10kg BW) were allocated into each of the dietary treatments in a random complete design of 4 TMRs × 6 repetitions (animals) and were fed ad libitum. Nutrients and energy composition as well as daily DM intake (DMI) and in vivo apparent digestibility of the treatments were determined. The CP, and energy contents (i.e., NEm, NEg) content of the all TMRs were approximately 13.5%, 1.72 and 1.1 Mcal/kg DM, respectively, while CF was 21% in TMR1 and TMR2 and was approximately 18% in TMR3 and TMR4. No significant differences were observed among the 4 treatments in DMI with a tendency to increase in TMR1 (1.15 kg DM, $P = 0.590$) than others treatments. Digestibility of DM (DMD, $P = 0.838$) and CP (CPD, $P = 0.872$) also had tendency to improve from TMR1 to TMR4 (73, 74, 74 and 76% for the DMD, and 76, 76, 77 and 78% for the CPD, and for the 4 treatments, respectively. Digestibility of CF was not affected by the replacement of *P. vulgaris* with soybean meal in TMR and all TMRs were approximately the same (72%, $P = 0.872$). In conclusion, *P. vulgaris* could be used in a partial substitution of the soybean meal and it could be used as an alternative source of protein in Pelibuey lambs diets.

Key Words: *Phaseolus vulgaris*, digestibility, lambs

T449 The effect of partial replacement of soybean meal by *Phaseolus vulgaris* byproducts on growth performance in Pelibuey growing lambs fed finishing diets. H. P. Mejia[1], A. Z. M. Salem*1,2, J. L. Tinoco[1], R. S. Robollar[1], E. J. D. Coronado[1], and F. Avilés[1], [1]*Universidad Autónoma del Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [2]*University of Alexandria*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Twenty-four Pelibuey male lambs ((29 ± 10 kg BW) were used to evaluate the effect of replacing soybean meal with common bean by-products (PV- *Phaseolus vulgaris*) as the only sources of protein, on average daily gain (ADG), feed conversion (FC) and economic efficiency (EE). Lambs were fed finishing diets and assigned randomly to one of 4 dietary treatments. Treatment diets were prepared with supplementary protein supplied by soybean meal (CON, n = 6), being replaced by protein from either 50 (PV50, n = 6), 75 (PV75, n = 6) or 100% (PV100, n = 6) of the common bean by-products (*P. vulgaris*). Crud protein and energy contents (i.e., NEm, NEg) were approximately similar, while crude fiber was higher in CON and PV50 compared with PV75 or PV100. No differences ($P = 0.590$) were noticed in feed intake, final weight, total gain, and ADG among all treatment diets. FC ratio was numerically ($P = 0.940$) increased in PV50 lambs, than the CON or PV75 and PV100 diets. Cost of one kg gain (i.e., EE) was also numerically decreased in PV75 and PV100 lambs when compared with CON or PV50 groups. These data indicate that feeding fattening Pelibuey growing lambs diets containing 100% of CP diet from the *P. vulgaris* did not affect feed intake or growth performance parameters that could also supported to reduce the production costs in fattening sheep.

Key Words: Pelibuey lambs, *Phaseolus vulgaris*, growth performance

T450 Effect of supplemental grower / finisher ration protein level on growth rate, chevon production and cost of gain of crossbred meat goats grazing Joy Chicory pasture. M. Lema*, S. Murray, and B. Barlow, *Tennessee State University*, *Nashville*.

Chicory (*Chicorum intybus*) is becoming popular as a warm-season forage for ruminant livestock in the United States. A study was conducted with weaned crossbred meat goats to elucidate how growing / finishing meat goats grazing Joy chicory pasture respond to supplementation with varying levels of dietary protein. Thirty 6 weaned crossbred kids (26 ± 3 kg) were blocked by body weight and genotype and divided into 3 treatment groups. Each treatment group was replicated in 2 0.4 ha Joy chicory and native grass paddocks with 6 kids per paddock and supplemented with isocaloric grower / finisher ration containing 11, 16 or 21% crude protein for 56 d. The data generated from the study was subjected to Analysis of Variance for randomized complete block design. Grower / finisher ration intake (1.13, 1.31 and 1.31 kg / day) and cost (0.41, 0.51 and 0.51 dollars / day) for the 11, 16 and 21% protein supplemented groups, respectively) were not affected by protein content of the diet. Total live weight gain (7.7 kg) and average daily gain (145.0 g) for the16% protein level were significantly higher ($P < 0.05$) than for the 11% (2.7 kg and 52.0 g, respectively) and 21% (6.0 kg and 113.0 g, respectively) protein levels. Feed cost per kg gain was significantly lower ($P < 0.05$) for the 16% protein level than for the 11 and 21% protein levels (3.5 versus 7.8 and 4.5 dollars / day, respectively). Boneless retail cut from the leg, loin, shoulder and rack followed similar trend as weight gain, being significantly higher ($P < 0.05$)for the 16% protein level than for the 11 and 21% while the 21% level was higher than the 11%. Back fat thickness and fat cover over the carcass tended to increase ($P < 0.05$) with protein level in the diet. It is concluded that optimum performance and return from meat goats grazing Joy Chicory is obtained when they are supplemented with 16% protein in the diet as compared with lower (11%) and higher (21%) levels.

Key Words: meat goat, chicory, protein level

T451 Effects of breed and slaughter endpoint on feed intake, growth performance, and carcass traits of purebred Boer and Kiko goat kids. S. Solaiman*[1], B. R. Min[1], N. Gurung[1], J. Behrends[2], E. Taha[1], and C. Hill[1], [1]*Tuskegee University*, *Tuskegee, AL,* [2]*Mississippi State University, Mississippi State.*

The objectives of this experiment were to determine the effects of 2 different breeds (Boer vs. Kiko) and 4 slaughter endpoints (SEP; d 0, 35, 63 and 88) on DMI, ADG and carcass traits of male goat kids (n = 6). Forty-eight purebred (BW = 23.9 ± 1.50 kg) kids were used in a completely randomized design experiment with a 2 × 4 factorial arrangement of treatments. Goats were stratified by BW within breed and randomly assign to 4 SEP. Kids were born between March 15 and April 7, and were represented by at least 3 sires within each breed. They were housed indoors in individual pens, had ad libitum access to water and mineral blocks, and were fed concentrate: hay (80:20%, respectively) diet once a day. At designated time, goats were transported to the Meat Science Lab., MSU, MS and were slaughtered. Performance and carcass data were analyzed using PROC MIXED of SAS. There were no interactions between breeds and SEP. Both breeds had similar DMI; however, the Kiko goats consumed more hay ($P < 0.01$) and Boer goats consumed more concentrate ($P < 0.01$). There was no different in initial BW for 2 breeds, but final BW ($P < 0.03$), ADG ($P < 0.001$), and G:F ($P < 0.001$) were higher for Boer breed. Boer goats tended to have higher HCW ($P = 0.08$) and cold carcass weights (CCW; $P = 0.08$) only on d 88. No differences were observed in transportation shrink, carcass shrink, dressing percentage, 12th rib fat thickness, and LM area between 2 breeds. Muscle and fat weights were higher for Boer breed ($P < 0.01$) at d 0, but only fat was higher ($P < 0.01$) on d 88. Although bone, muscle, and fat as a % of CCW remained relatively the same ($P > 0.10$) for both breeds up to the 3rd SEP, ratio of fat increased in Boers ($P < 0.002$) and muscle ratio increased ($P < 0.01$) in Kikos by d 88. Breed or SEP did not affect the muscle/bone and muscle/fat ratios. Breed type and SEP had no effect on meat color. We concluded that Boer goats had higher ADG and attained higher BW at earlier age, with higher grain input. However, Kiko goats had more muscle and less fat at the later SEP (d 88) with less grain input.

Key Words: breed, goats, slaughter endpoint

T452 Effects of feeding varying levels of peanut skins on fatty acid profile of growing Kiko crossbred intact male goats. N. K. Gurung*[1], A. R. Stone[1], S. G. Solaiman[1], D. L. Rankins Jr.[2], K. R. Willian[1], and W. H. McElhenney[1], [1]*Tuskegee University*, *Tuskegee, AL*, [2]*Auburn University*, *Auburn, AL*.

The objectives of this experiment were to evaluate the effects of feeding different levels of peanut skins (PS) containing diets on fatty acid profile in the longissimus muscle (LM), the mesenteric adipose (MA) depot, and the s.c. adipose (SA) depot of meat goats. Twenty 4 Kiko crossbred intact male goats (18.2 ± 1.41 kg initial BW and 3 to 4 mo of age) were randomly assigned to one of the 4 experimental diets containing 47.3% bermudagrass hay plus 52.7% concentrate mix. Diets contained 0, 10, 20, and 30% of PS on as fed basis. Feed offered and refusals were collected daily. After 92 d, goats were harvested and carcass characteristics were measured. Samples of LM, MA and SA tissues were analyzed for fatty acid profile. Data on carcass quality and fatty acid composition of LM, MA and SA were analyzed as a completely randomized design. Dressing percent, chilled carcass weight and LM area decreased linearly ($P < 0.05$) with increasing level of PS. We were able to detect 18 fatty acids in LM and MS, and 13 in SA. No changes ($P > 0.10$) were detected in the fatty acid composition (on percentage basis) across treatments with the exception of C18:0, stearic acid, which increased linearly in LM ($P = 0.05$), MS ($P = 0.06$) and SC ($P = 0.06$) with increasing level of PS. Total saturated fatty acid percentage increased linearly ($P = 0.05$) in LM fat only. Total C18:1, oleic acid, decreased linearly ($P < 0.05$) in LM fat but a quadratic trend ($P < 0.05$) was observed for MA and SA. Monounsaturated fatty acids decreased linearly ($P < 0.05$) as the level of PS increased in LM fat but was not different among MS and SA fat samples. Polyunsaturated fatty acids were not different ($P > 0.05$) among treatments for all fat samples. It was concluded that the fatty acid composition of carcass can be altered with the addition of PS in the diets.

Key Words: goats, fatty acid profile, peanut skins

T453 Effect of cull-chickpeas on carcass characteristics and commercial cuts of feedlot hair sheep. F. G. Rios*[1,4], H. Bernal-Barragán[2,4], M. A. Cerrillo-Soto[3,4], A. Estrada-Angulo[1,4], E. Gutiérrez-Ornelas[2,4], A. S. Juárez-Reyes[3,4], J. F. Obregon[1,4], and J. J. Portillo-Loera[1,4], [1]*FMVZ-Universidad Autónoma de Sinaloa*, *Culiacán, Sinaloa, México*, [2]*FA-Universidad Autónoma de Nuevo León*, *Monterrey, Nuevo León, Mexico*, [3]*FMVZ-Universidad Juárez del Estado de Durango*, *Dur-*

ango, Durango, México, [4]*Red Internacional de Nutrición y Alimentación en Rumiantes*, *Culiacán, Sinaloa, México*.

A study was carried out to determine the effect of cull-chickpeas (CCH) on carcass characteristics and their commercial cuts from Katahdin × Pelibuey lambs. Forty animals (36.1 ± 2.9 kg initial BW) were fed 5 dietary treatments based on substitution of diet cracked corn grain and soybean meal for 0, 15, 30, 45, or 60% of CCH. Animals were allotted in pens (2/pen) and randomly grouped to 4 blocks of 10 animals. At the end of a feeding trial of 84 d, the lambs were humanly slaughtered at a weight of 50.3 ± 4.2 kg. The left half of the carcass was used for carcass evaluation and dissection according to commercial standards. The fat depth was measured at the level the 12th rib. Single cuts such as neck, rack, breast, shoulder, foreshank, loin, leg, and flank were also classified. Data were analyzed according to a completely randomized block design using the GLM procedure; means comparisons were performed using Duncan's test. Orthogonal polynomial contrasts were used to determine lineal effect of treatments. Hot carcass weight (29.1 ± 2.36 kg), dressing carcass (57.8 ± 2.58%), rib eye area (15.9 ± 2.21 cm^2), and backfat thickness (3.0 ± 1.15 mm) were similar ($P > 0.05$) among treatments. Empty body weight was higher ($P < 0.05$) in lambs receiving 30% of CCH (48.5 kg), and lowest in those fed 0% (46.4 kg). Kidney, pelvic and heart fat was modified by the effect of the treatments where a lineal pattern ($P < 0.01$) was observed. Yields of loin (8.5 ± 0.84%), shoulder (19.4 ± 1.94%), rack (11.4 ± 0.85%), and foreshank (11.4 ± 1.28%), were similar ($P > 0.05$) among treatments. Breast (7.9%) was similar between lambs receiving 15 and 45% CCH, and higher ($P < 0.05$) than the other treatments (7.3%). Leg (28.6%) was lower ($P < 0.05$) in lambs receiving 60% CCH. Flank (8.2%) was higher ($P < 0.05$) in lambs fed 45% CCH. It is concluded that CCH can be included up to 45% in the diet of hair lambs. Nonetheless, as the inclusion level of CCH is favored, enhanced fat deposition results, while leg yield is reduced.

Key Words: hair sheep, cull-chickpeas, carcass characteristics

T454 Effects of intraduodenally infused soybean small peptides and amino acids on absorption of peptides in the small intestine of dairy goats. L. Wang[1,2], S. Li*[1], Z. Cao[1], and H. Liu[1], [1]*China Agricultural University*, *Beijing, China*, [2]*Ningxia University*, *Yinchuan, China*.

The object of the study was to investigate the effects of intraduodenally infused soybean small peptides (SSP) and AA on absorption of peptides in the small intestine and the net fluxes of mesentetic-drained viscera (MDV) and portal-drained viscera (PDV). Four dairy goats (BW = 38.38 ± 3.09kg), fitted with permanent cannulas at the proximal duodenum and fitted with indwelling catheters in carotid artery, proximal and distal mesenteric vein and portal vein were used in a crossover treatment design. The treatments were intraduodenal infusion of 60 g/d SSP (SSP group) or AA (AA group) providing the same daily quantities of individual free AA as SSP group . The results showed that the mesenteric, portal venous and arterial plasma concentration of PAA in SSP group were higher than in the AA group, but only the concentration of peptide serine, valine, isoleucine and arginine were significant higher than in the AA group ($P < 0.05$). The MDV net fluxes of PAA in SSP group were significant higher than in the AA group ($P < 0.05$). The PDV net fluxes of PAA in the SSP group were higher than in the AA group, but there was no significant difference between the SSP group and the AA group ($P < 0.05$). The mesenteric, portal venous and arterial plasma concentrations and the MDV and PDV net fluxes of total FAA in AA group were significant higher than in the SSP group ($P < 0.05$). The concentration of plasma glucose, insulin, glucagon and growth hormone were higher in SSP group than in the AA group, the concentration of PUN and IGF-1 in SSP group were lower than in the AA group, however, there was no significant difference between SSP group and AA group ($P > 0.05$).

Key Words: small peptide, amino acid, dairy goat

T455 Effects of graded intraduodenal soybean small peptide infusion on absorption of small peptides in the small intestine of dairy goats. L. Wang[1,2], S. Li*[1], Z. Cao[1], and H. Liu[1], [1]*China Agricultural University*, *Beijing, China*, [2]*Ningxia University*, *Yinchuan, China*.

The objective of the study was to investigate the effects of graded intraduodenal soybean small peptide (SSP) infusion on absorption of small peptides in the small intestine and the net fluxes of mesentetic-drained viscera (MDV) and portal-drained viscera (PDV). Seven dairy goats (body weight 37.88 ± 3.03kg) were used to a 4 × 4 Latin square design, fitted with permanent cannulas at the proximal duodenum and implanted with indwelling catheters in carotid artery, proximal and distal mesenteric vein and portal vein. Four infused SSP levels, i.e., 0 g/d (0.9% normal saline, 700 mL/d), 60 g/d, 120 g/d and180 g/d, were used. Infusions were conducted continuously using a peristaltic pump. Each infusion period lasted for 12 d. On the last day, Para-aminohippuric acid (PAH) was infused into the mammary vein catheter. After 1 h of infusing PAH, blood samples were collected from the carotid artery and mammary vein at 1 h intervals into centrifuge tubes containing heparin-saline. The results showed that with the increase of SSP infusion level, the mesenteric, portal venous and arterial plasma concentration and the net fluxes of MDV, PDV of peptide amino acids (PAA) were all raised significantly. The total PAA net flux of MDV in group infused with 180 g/d was higher than that group infused with 60 g/d. The absorption rate of total PAA in small intestine was decreased with the increase of quantities of SSP infusion into duodenum, the values were 28.43%, 22.23% and 17.43% respectively. The PDV net fluxes of total FAA were all lower than the MDV net fluxes of total FAA in 4 groups. The concentrations of plasma urea nitrogen were significantly increased with increasing the quantities of SSP infusion, but the concentrations of plasma glucose, insulin, growth hormone, glucagon and IGF-1 had not been affected by infusing SSP.

Key Words: dairy goats, soybean small peptide

T456 Effects of shearing on energy use by growing Angora goats. R. Puchala*[1], A. Helal[1,2], A. L. Goetsch[1], and T. Sahlu[1], [1]*American Institute for Goat Research, Langston University*, *Langston, OK,* [2]*Animal and Poultry Nutrition Department, Desert Research Center, El Matareya, Cairo, Egypt.*

Eight Angora wethers (initial BW 19.0 ± 1.14 kg) and 8 doelings (initial BW 16.3 ± 1.15 kg), approximately 17 mo of age, were used to assess effects of shearing on energy expenditure (EE) and heart rate (HR). Animals were fed a pelleted diet at 1100 h to achieve 12.5 g/d tissue gain and 7.5 g/d mohair fiber growth. Animals were placed in an indirect, open-circuit respiration calorimetry system in 4-animal sets (2 wethers and 2 doelings) for gas exchange measurement 1 d before (d 0) and for 3 d after shearing (d 1, 2, 3). Temperature and relative humidity were controlled at 20°C and 50%, respectively. Shearing was at 0900 h. To avoid effects of feeding on HR and EE, data collected during the daytime (0800 to 1900 h) were omitted. Energy expenditure was greater ($P < 0.05$) after than before shearing (3.48, 4.30, 4.01, and 3.82 MJ/d on d 0, 1, 2, and 3, respectively; SEM = 0.142). Similarly, HR (92.6, 104.8 97.5, and 100.0 beats/min; SEM = 3.02) and EE relative to metabolic size (405, 503, 468, and 448 kJ/kg $BW^{0.75}$ on d 0, 1, 2, and 3, respectively; SEM = 10.8) were affected ($P < 0.05$) by shearing. The ratio of EE to HR was similar among days after shearing (4.45,

4.87, 4.87, and 4.52 kJ/kg body weight$^{0.75}$ per heart beat on d 0, 1, 2, and 3, respectively; SEM = 0.151). A decline ($P < 0.05$) in respiratory quotient after shearing (1.049, 1.034, 1.016, and 1.015 on d 0, 1, 2, and 3, respectively; SEM = 0.0079) suggests increased body fat catabolism. Regression analysis indicated that more than 4 d would be required for EE and HR to return to pre-shearing levels. In conclusion, even with non-stressful environmental conditions, shearing Angora goats increases energy consumption.

Key Words: goats, shearing, energy

T457 Optimum duration of performance testing growing Boer bucks for growth rate, feed intake, and feed efficiency. W. Hu*[1], T. A. Gipson[1], S. P. Hart[1], L. J. Dawson[1,2], A. L. Goetsch[1], and T. Sahlu[1], [1]*American Institute for Goat Research, Langston University*, *Langston, OK,* [2]*College of Veterinary Medicine, Oklahoma State University, Stillwater.*

Central performance testing of meat goats has increased in popularity recently, but minimum test length has not been ascertained. This study was conducted to determine the minimum length of time required for accurate evaluation of growing Boer bucks for ADG, DMI, and feed efficiency as assessed by ADG:DMI and residual feed intake. Data were collected from 425 bucks in Langston University tests from 2000 to 2009. Bucks averaged 111 ± 25 d of age and 27 ± 8 kg BW at the beginning of the test, consumed a pelletized 50% concentrate diet ad libitum, and were weighed weekly. Daily feed intake was determined with Calan feeding gates (American Calan, Inc., Northwood, NH) and automated feeding units (MK3 FIRE, Osborne Industries Inc., Osborne, KS). Weekly data of 4 performance traits were analyzed using the MIXED procedure of SAS with a repeated-measures model. The first-order ante dependence [ANTE(1)] structure type was selected as the appropriate covariance structure based on goodness-of-fit criteria. Residual variance relative to that at 84 d (%) was 338, 272, 223, 188, 153, 129, 119, and 108% for ADG, 167, 159, 149, 141, 130, 119, 112, and 106% for DMI, 427, 305, 223, 164, 135, 123, 112, and 105% for ADG:DMI, and 156, 138, 131, 118, 107, 103, 102, and 102% for residual feed intake at 28, 35, 42, 49, 56, 63, 70, and 77 d, respectively. Grafted polynomial break-points determined by nonlinear regression indicated that residual variance had stabilized at 63, 63, and 57 d for ADG, ADG:feed intake, and residual feed intake, respectively. A break-point for DMI was not estimable, although the correlation between DMI at 63 and 84 d was 0.99 ($P < 0.01$) compared with r of 0.95, 0.96, and 0.97 ($P < 0.01$) for ADG, ADG:DMI, and residual feed intake, respectively. In conclusion, under these conditions the duration of Boer buck performance tests could be decreased from 84 to 63 d with little loss in accuracy.

Key Words: goats, performance testing

T458 Feeding behavior of intact yearling hair sheep and meat goat males pen-fed in single- and mixed-species groups. S. Wildeus* and R. A. Stein, *Virginia State University*, *Petersburg*.

Group size and social hierarchy influence animal performance, and here we evaluated interactions of yearling rams and bucks housed indoors in 3 × 2.5 m pens with a single feeding station. Animals were fed chopped grass hay mixed with corn and soybean (~14% CP). In Exp. 1, 2 males were allocated to 15 pens either as single- or mixed-species groups (5 replications/grouping; 15 rams and 15 bucks total). In Exp. 2, 2 or 4 males were assigned to 16 pens, either as sheep-only, or an equal number of rams and bucks (4 replications/grouping; 36 rams and 12 bucks total). In both experiments animals were fed for 17 d. Immediately after feed was placed into each pen, behavior was recorded for 10 min (position changes at feeder, duration of first meal, and incidence of fighting). Observations were made for 3 consecutive days at the beginning, middle and end of each experiment. Data were analyzed for the effect of pen composition and time of trial in Exp. 1, and pen composition, stocking rate and time of trial in Exp. 2. In Exp. 1 initial time at the feeding station was shorter ($P < 0.01$), and number of fights and position changes at feeder more frequent ($P < 0.01$) in sheep-only pens (142 ± 32 s, 6.0 ± 0.8 and 14.3 ± 2.4, respectively) than goat-only (381 ± 41 s, 0.3 ± 0.09 and 1.8 ± 0.1, respectively) and mixed pens (380 ± 41 s, 0.1 ± 0.04 and 2.0 ± 0.2, respectively). Number of fights and position changes increased ($P < 0.01$) from the start to the end of the trial in sheep-only pens (6.6 to 23.1 and 3.6 to 6.1, respectively), but not in goat-only and mixed pens. In mixed pens, goats initiated feeding more frequently than sheep (81.8 vs. 18.2%, $P < 0.01$). In Exp. 2 observations on feeding time, fighting and position changes for sheep-only and mixed pens were similar to Exp. 1. However, fighting and position changes increased in sheep-only, but not mixed pens as stocking rate increased from 2 to 4 animals (stocking rate by pen composition interaction: $P < 0.05$). Data suggest that bucks were more dominant than rams, activity levels were lower in pens with bucks, and that increasing stocking rate differentially affected behavior in the 2 species.

Key Words: behavior, goats, sheep

T459 Feeding glucogenic precursors to dairy goats carrying twins around kidding. S. Cavini[1], M. Rodriguez-Prado[1], S. Calsamiglia*[1], A. Foskolos[1], and M. A. Gomez[2], [1]*Universitat Autonoma de Barcelona*, *Bellaterra, Spain*, [2]*NUTEGA*, *Madrid, Spain*.

Ketosis is the result of an unbalance between energy supply and requirements. Dairy goats carrying twins are highly susceptible to gestational ketosis. Monopropylene glycol is a glucogenic precursor that has been successfully used to prevent ketosis. The objective of this study was to compare monopropylene glycol with other glucose precursors to prevent ketosis. Twenty-two pregnant Murciano-Granadina goats carrying twins were assigned to 4 different treatments in a randomized complete block design, where group was the experimental unit: monopropylene glycol (MG: 36.9 g/goat/d, 65% purity) considered as positive control; glycerol (GLY: 60.0 g/goat/d, 40% purity); monopropylene glycol plus B vitamins (MGB: 44.3 g/goat/d, 54% purity); glycerol plus monopropylene glycol plus B vitamins plus oligoelements (GMGB: 56.4 g/goat/d, 33 and 9.5% purity, respectively). Goats were controlled from 25 before 30 d after kidding. Goats were group fed, were received an ad libitum forage diet and were individually supplemented with 400 and 800 g of concentrate before and after kidding, respectively. Intake was recorded daily, milk production and composition determined weekly, body weight and condition score were recorded −15, 0, 15 and 30 d around kidding, and blood samples were taken on days −15, −7, −3, −1, 0, 1, 3, 5, 7, 15 and 30 around kidding to measure insulin, glucose, non-esterified fatty acids, triglycerides and β-hydroxybutyrate. Results were analyzed using the PROC MIXED procedure of SAS and differences declared at $P < 0.05$. No differences were found in body weigh and condition score. Intake of DM increased ($P < 0.04$) in GLY compared with MG (1.36 vs. 1.43 ± 0.02 kg/d) with no effects on milk production (1.93 ± 0.18 L/d). Milk fat and protein tended ($P < 0.10$) to be higher in GLY (5.69 vs. 4.83 ± 0.24% and 4.15 vs. 3.55 ± 0.16%, respectively) compared with MG. There were no differences in blood metabolites among treatments. Glycerol may be a good alternative to propylene glycol in dairy goats around kidding.

Key Words: glycerol, glycol, goats

T460 Evaluation of milk serum amyloid A 3 (M–SAA3) protein as a potential mammary health indicator in goats. A. Domènech*[1], A. Gómez–Martín[2], C. De la Fe[2], J. C. Corrales[2], and A. Serrano[1], [1]*Ruminant Production, IRTA*, *Barcelona, Spain*, [2]*Department of Animal Health, University of Murcia*, *Murcia, Spain*.

The objective of this study was to investigate the potential of M–SAA3 protein as a mammary health indicator in caprine milk. For this purpose, a preliminary study of quantification of SAA3 in half milk samples from healthy (n = 26) and clinical mastitic (n = 28) Murciano-Granadina goats was conducted. Clinical mastitis milk samples were characterized in accordance with bacterial isolation in blood and McConkey agar, Gram staining and catalase and oxidase tests. Gram + and catalase + samples were further characterized with a *Staphylococcus aureus* agglutination test. Milk samples from healthy goats were verified by negative bacterial culture and somatic cell count. Results from bacterial identification in mastitic milk samples reported 75% of Gram + infections (90.5% *Staphylococcus* spp. and 9.5% *Streptococcus* spp.). 71.5% of the Gram – milk infected samples were oxidase + (no enterobacteriae) and *Escherichia coli* was identified in the rest of them (28.5%). Milk levels of SAA3 were measured using a commercial ELISA kit (Mast ID SAA3 kit, Tridelta, Ireland). Milk levels of SAA3 from healthy and mastitic goats were log-transformed and compared using an ANOVA. Results indicated no significant differences ($P = 0.22$) in milk SAA3 levels in samples obtained from mastitic (35.05 ± 0.30μg/mL) or healthy goats (20.36 ± 0.32μg/mL). However, the CV of SAA3 milk contents was numerically greater in mastitic milk (59%) than in milk from healthy goats (26%). Results indicate that M–SAA3 might not be an accurate indicator of clinical mastitis in goat milk but do not exclude the potential of exploring M-SAA3 levels in samples of caprine subclinical mastitis. Further studies with a greater number of samples are being conducted.

Key Words: SAA3, caprine, mastitis

T461 Milk fat synthesis is progressively reduced in dairy goats fed increasing levels of an unprotected conjugated linoleic acid (U-CLA) supplement. D. Fernandes[1], J. Souza[1], M. Baldin[1], R. Dresch[1], E. C. Sandri[1], J. H. Bruschi[2], F. C. F. Lopes[2], M. A. S. Gama[2], and D. E. Oliveira*[1], [1]*Santa Catarina State University*, *Chapecó, Brazil*, [2]*National Dairy Cattle Research Center*, *Juiz de Fora, Minas Gerais, Brazil*.

This objective was to evaluate the dose-response effect of dietary U-CLA on milk fat synthesis in dairy goats. Eight Toggenburg goats (4 primiparous and 4 multiparous; 120 to 150 DIM) received 4 levels of U-CLA in a 4 × 4 Latin square (LS) design. The treatments were: 1) Control: 45 g/d of calcium salts of soybean oil (CSSO); 2) CLA15: 30 g/d of CSSO plus 15 g/d of U-CLA; 3) CLA30: 15 g/d of CSSO plus 30 g/d of U-CLA and 4) CLA45: 45 g/d of U-CLA. Each experimental period lasted 12 d, separated by 6 d washout intervals. The U-CLA contained 29% of trans-10 cis-12 CLA; therefore, it was delivered about 0, 4.5, 9.0 and 13.5 g/d of trans-10 cis-12 CLA for control, CLA15, CLA30 and CLA45, respectively. Lipid supplements were mixed into the concentrate (1.0 kg/goat/d) and fed twice a day after milking. Corn silage was fed ad libitum and orts were recorded daily to calculate forage intake. Milk production was recorded daily and milk samples were collected in the last 3 d of each period (d 10, 11 and 12). Body condition score was recorded on the 1st and 12th day of each period. Data were subjected to ANOVA and the statistical model included animal, period, LS, animal within LS, treatment and interaction LS x treatment as sources of variation. There was no interaction LS x treatment for any variable, showing that responses to U-CLA doses did not differ between primiparous and multiparous. Milk fat content and yield were linearly reduced ($P < 0.0001$) in response to increased U-CLA dose (2.90, 2.40, 1.94 and 1.72%; SE = 0.08 and 67.8, 57.7, 46.9 and 40.3 g/d; SE = 2.72, respectively). However, the increase in U-CLA dose had no effect on milk yield (2.32, 2.37, 2.41 and 2.35 kg/d; SE = 0.08), milk protein content (2.76, 2.78, 2.75 and 2.79%; SE = 0.03), milk protein yield (63.7, 65.5, 65.5 and 65.5 g/d; SE = 1.95), forage intake (2.21, 2.25, 2.15 and 2.19, SE = 0.09) and BCS (2.75, 2.75, 2.72, 2.78; SE = 0.07).

Key Words: goat, conjugated linoleic acid, milk

T462 Requirements of magnesium, potassium and sodium for maintenance and growth of Boer crossbred kids. M. H. M. R. Fernandes[1], K. T. Resende[1], L. O. Tedeschi[2], J. S. Fernandes Jr.[1], and I. A. M. A. Teixeira*[1], [1]*Universidade Estadual Paulista/UNESP and INCT-CA members*, *Jaboticabal, SP 14870, Brazil*, [2]*Texas A&M University*, *College Station*

The requirements of magnesium (Mg), potassium (K) and sodium (Na) of goats have been assumed to be identical to those for cattle and sheep (3.5, 50, 15 mg/kg of BW, respectively). The objective of this study was to determine the requirements of Mg, K, and Na for maintenance and growth of 34 intact male crossbred kids (3/4Boer 1/4Saanen), varying BW from 20 to 35 kg. The comparative slaughter technique with 3 slaughter periods was used to determine the mineral requirements. A baseline (BL) group was comprised of 7 randomly selected kids, averaging 20 kg BW. The intermediate slaughter group was fed ad libitum and consisted of 6 randomly selected kids that were slaughtered when they reached 27.5 kg BW. The remaining kids (n = 21) were allocated randomly on d 0 to 3 levels of DMI (treatments were ad libitum or restricted to 70 or 40% of the ad libitum intake) within 7 slaughter groups. A slaughter group contained 1 kid from each treatment, and kids were slaughtered when the kid fed ad libitum reached 35 kg BW. Body components were weighed, ground, mixed, and subsampled for chemical analysis. Initial body composition was determined using equations developed from the composition of the BL kids. The diet DM consisted of 47% corn hay and 53% concentrate (0.95% Ca, 0.52% P, 0.19% Mg, 0.62% K, 0.22% Na). A digestion trial with 15 kids at 3 levels of intake was concurrently conducted to determine the apparent absorption coefficient and endogenous fecal and urinary losses. During the trial, all kids (n = 34) were fed once daily (0800) in individual pens with free access to water. The requirements of Mg, K, and Na for maintenance were 7.8 ± 7.0 mg/kg BW, 39.7 ± 0.38 mg/kg BW and 10.4 ± 0.35 mg/kg BW, respectively. The net Mg, K and Na requirements for growth ranged from 0.29 to 0.31 g/kg empty weight gain (EWG), 1.18 to 1.05 g/kg EWG and 0.67 to 0.62 g/kg EWG for 20 and 35 kg BW, respectively. These results indicated that Mg, K, and Na requirements for Boer crossbred, a meat type breed, are less than those recommended for cattle and sheep. Further studies are required to confirm these findings for growing goats.

Key Words: Boer, minerals, net requirement

T463 Calcium and phosphorous requirements for maintenance and growth of Boer crossbred kids. M. H. M. R. Fernandes[1], K. T. Resende[1], L. O. Tedeschi[2], J. S. Fernandes Jr.[1], and I. A. M. A. Teixeira*[1], [1]*Universidade Estadual Paulista/UNESP and INCT-CA members*, *Jaboticabal, SP 14870, Brazil*, [2]*Texas A&M University*, *College Station*.

Calcium (Ca) and phosphorous (P) play an important role in several metabolic functions. The net requirements of Ca and P for goat dairy breeds are 2 and 1.4 g/d (BW of 30 kg). The objective of this study was to determine Ca and P requirements for maintenance and growth of 34 intact male crossbred kids (3/4Boer 1/4Saanen) varying BW from 20

to 35 kg. The comparative slaughter technique with 3 slaughter periods was used to determine the mineral requirements. A baseline (BL) group was comprised of 7 randomly selected kids, averaging 20 kg BW. The intermediate slaughter group was fed ad libitum and consisted of 6 randomly selected kids that were slaughtered when they reached 27.5 kg BW. The remaining kids (n = 21) were allocated randomly on d 0 to 3 levels of DMI (treatments were ad libitum or restricted to 70 or 40% of the ad libitum intake). These kids were pair-fed in 7 slaughter groups. A slaughter group contained 1 kid from each treatment, and kids were slaughtered when the ad libitum treatment kid reached 35 kg BW. Body components were weighed, ground, mixed, and subsampled for chemical analysis. Initial body composition was determined using equations developed from the composition of the BL kids. The diet DM consisted of 47% corn hay and 53% concentrate (0.95% Ca, 0.52% P). A completely randomized design digestion trial was conducted in parallel with the comparative slaughter trial and used 15 kids at 3 levels of intake to determine apparent absorption coefficient and endogenous fecal and urinary losses. During the trial, all kids (n = 34) were fed once daily (0800) in individual pens with free access to water located in a masonry shed and protected from rain and wind. The Ca and P requirements for maintenance were 16.1 ± 29.1 mg/kg BW and 31.6 ± 14.3 mg/kg BW, respectively. The net Ca and P requirements for growth ranged from 6.7 to 7.0 g/kg empty weight gain (EWG) and 5.3 to 5.4 g/kg EWG for 20 and 35 kg BW, respectively. These findings suggested that net Ca and P requirements for growth of Boer crossbred, a meat type breed, might be lower than those requirements published for dairy goats.

Key Words: Boer, minerals, net requirement

T464 Blood mineral concentration of adult goats in a subtropical region of southern Mexico during the rainy and dry season. R. Rojo*, A. Z. M. Salem, F. Jiménez, S. Rebollar, J. L. Tinoco, B. Albarrán, J. F. Vázquez, D. Cardoso, J. Hernández, and F. González, *Centro Universitario UAEM-Temascaltepec*, *Temascaltepec, Estado de México, México*.

The aim of work was to evaluate the effects of season (rainy: RS; and dry: DS) and sample location of 3 different places (Rio Topilar: RT; El Devanador: ED; y San Pedro Limon: SPL) at the province of Tlatlaya in Mexico State on mineral status of blood plasma in crossbred adult goats (LW 35 ± 1.5 kg) during transition period under the semiarid rangeland of southern Mexico. Representative samples of 7 adult Creole goats were taken from each production unit (7 animals × 3 production unit) within each season (dry and rainy). Mineral concentrations (Ca, P, K, Mg, Na, Zn and Cu) in plasma were assayed using the Atomic absorption. Data were analyzed using one way ANOVA test; significant differences between means were tested by Tukey. Higher Ca and P concentrations were observed during the DS than RS ($P < 0.01$), with a lowest value in SPL during the DS. No significant differences ($P > 0.05$) were observed between seasons or production units in concentration of Mg, while Na concentration was affected by the production unit (P 0.05), and the highest values were during the DS. Lowest Zn concentration was observed during the DS in SPL (0.18 mg/dL), while Cu concentration was significantly ($P < 0.01$) increased during the same season than in RS (0.07 to 0.10 mg/dL, respectively). Generally, the concentration of K, Zn and P in goat plasma was above the recommended levels by NRC (2007), while the concentration of Ca, Mg, Na and Cu were below. Adult Creole goats during transition period under the semiarid rangeland of southern Mexico had a deficiency in some blood minerals such as K, Zn and P, and this maybe due to their native grazing behavior on browse shrubs and 3 foliages in the province of Tlatlaya in México State.

Key Words: adult goats, blood serum, mineral concentration

T465 Effect of copper and zinc on in vitro ruminal fermentation of total mixed ration in goats. J. F. Vazquez[1], R. Rojo*[1], D. Lopez[1], A. Z. M. Salem[1], J. M. Gonzalez[2], D. Colín[1], and J. L. Tinoco[1], [1]*Centro Universitario UAEM-Temascaltepec*, *Temascaltepec, Estado de México, Mexico*, [2]*Facultad de Agrobiología, Universidad Auténoma de Tlaxcala*, *Ixtacuixtla, Tlaxcala, México*.

One in vitro experiment was conducted with the objective of evaluate the effect of copper and zinc addition on some parameters of ruminal fermentation of total mixed ration (TMR) (14% CP, 25.6% NDF and 18.3% ADF) using ruminal inoculum of goats. The TMR was incubated during 96 h with 4 different supplementary treatments: Control, Cu (860 ppm), Zn (224 ppm), Cu-Zn (860–224 ppm) provided as mineral premixed at 3 per cent of TMR. One g of TMR with each treatment was incubated in serum botles with 90 mL nutritive solution and 10 mL ruminal fluid from goats. In vitro gas production (ml g^{-1} DM) after 24 (GP_{24}), 48 (GP_{48}) and 96 h (GP_{96}) of incubation, dry matter degradability (IVDMD: g/kg DM) were determined while *b* (asymptotic gas production (ml g^{-1} DM)), *k* (rate of gas production (/h)), lag phase (lag) and metabolizable energy (ME: MJ kg^{-1} DM) were estimated. Data were analyzed using the general lineal model (GLM) procedure in SAS in a complete random design and differences among means by Tukey test. Addition of Zn increased fraction B, but addition of Zn-Cu decreased this fraction. Treatments did not affect the fraction lag and IVDMD. Cu addition tended to increase the volume of GP at 24, 48 and 96 h of incubation. Cu treatment had the highest value for the fraction K and ME, while Zn appeared to have the lowest values. Addition of Cu in the diet improved gas production volume and fermentation efficiency in goats.

Table 1. In vitro ruminal fermentation parameters of total mixed ration with four different supplemental treatments

Parameters	Control	Zn	Cu	Zn-Cu	SEM	P <

T466 Nutritional supplementation does not improve the sexual response of goats managed in northern Mexico. F. G. Véliz*[1], C. A. Meza-Herrera[2], M. A. De Santiago-Miramontes[1], R. Rodríguez-Martínez[1], and M. Mellado[3], [1]*Universidad Autónoma Agraria Antonio Narro*, *Torreón, Coahuila, Mexico*, [2]*Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas*, *Bermejillo, Durango, México*, [3]*Universidad Autónoma Agraria Antonio Narro*, *Buenavista, Saltillo, Coahuila*.

The objective was to determine if nutritional supplementation of native goats under an extensive management system in northern Mexico improves pregnancy rate in goats. Native multiparous goats (n = 79), were divided in 2 homogenous groups with respect to BW and body

condition. Both experimental groups grazed (11:00 to 17:00 h) rangeland and crop residues fields. Five days before and 20 d after breeding, the supplemented group (SS, n = 37) received a supplemental ration to provide 75% of its energy and protein maintenance requirements. The control group (CC; n = 24) received no supplementation during the experimental period. In March 20th, experimental groups were exposed to 4 male bucks, which were induced to an intense sexual activity by means of a photoperiodic treatment of 2.5 mo. Data were analyzed by means of Chi-squared test. More than 90% of goats in both experimental groups showed sexual behavior during the experimental period. In fact, during the first 6 d, 91% (38/42) of the CC-group exhibited estrual activity, while the SS-group exhibited corresponding values of 95% (35/37). The observed pregnancy and ovulatory rates were 1.26 and 64% and 1.15 and 75% in the CC and SS groups, respectively. Our results suggest that native multiparous goats under extensive-range production systems in Northern Mexico, receiving or not nutritional supplementation before or after breeding season, had similar productive and reproductive outcomes.

Key Words: nutritional supplementation, goat reproduction, male effect

T467 Seasonal reproductive activity of Nubian, Alpine and Criollo female goats exposed to natural photoperiod in a semiarid region of central-north Mexico. M. T. Rivera[1], M. O. Diaz-Gomez[1], M. Rincon[1], F. J. Escobar[1], C. F. Arechiga[2], H. G. Gamez[3], J. Urrutia*[3], and H. Vera-Avila[3], [1]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico*, [2]*Universidad Autonoma de San Luis Potosi*, *San Luis Potosi, Mexico*, [3]*Instituto Nacional de Investigaciones Forestales, Agricolas y Pecuarias*, *San Luis Potosi, Mexico.*

Female goats in a temperate climate have showed a seasonal reproduction influenced by photoperiod and great differences have been observed among breeds: Alpine goats have showed a much shorter reproductive season than Nubian goats. It is not clear whether this behavior will persist under tropical conditions, where photoperiod variations are less accentuated. In this study, variation of reproductive activity of Nubian, Alpine and Criollo goats was examined in the semiarid region of central-north Mexico (San Luis Potosi State; 22° N latitude). The study was conducted at the UASLP-Goat Unit under natural photoperiod and temperate conditions during a whole year (from April to April). Female goats, Alpine, Nubian and Criollo (n = 8 of each breed), were included in the study and exposed to presence of 2 Alpine bucks kept in a separate barn, but close enough to detect their visual, olfactory and audible signals. Progesterone concentrations indicate that all goats showed a great variation in reproductive activity throughout the year, showing ovulatory cycles between September and February. Nubian goats showed a shorter breeding season (113.8 d), than Alpine (132.1 d) and Criollo goats (138.5 d; (P = 0.12). A slight variation on live body weight ($P > 0.05$) throughout the study allowed to assume that BW did not affect reproductive activity. Results indicate that Nubian, Alpine and Criollo goats kept at 22° N present a wide seasonal variation in ovulatory activity, which was not influenced by breed, despite the fact that these breeds have shown great differences in length of their reproductive season at higher latitudes. Alpine goats showed a higher number of ovulatory cycles than Criollo and Nubian goats (51 vs. 45 vs. 40; respectively). Induction of long ovulatory cycles (≥26 d) was greater for Criollo goats than Nubian or Alpine goats (25.5 vs. 10 vs. 2%; respectively). These results demonstrate that the main influence that photoperiod exerts on seasonal reproductive activity of female goats persist under tropical photoperiodic conditions.

Key Words: goats, seasonal reproduction, photoperiod

T468 Conditions to test electric fence modifications of cattle barb wire fence for goat containment. A. L. Goetsch*, G. D. Detweiler, R. Puchala, T. Sahlu, and T. A. Gipson, *American Institute for Goat Research, Langston University*, *Langston, OK*.

Two 6 × 6 Latin squares, each with 24 yearling meat goat doelings previously exposed to electric fence, were conducted to identify appropriate conditions to test electric fence modifications of cattle barb wire fence for goat containment. After overnight fasting, groups of 4 doelings were placed in 2.4 × 2.4 m pens without forage. Pens had 3 metal panel sides and 1 side with 5 strands of barb wire 31, 56, 81, 107, and 132 cm from the ground adjacent to a pasture with forage and browse. Intervals between the 6 periods of 2–3 d and 1 wk were assigned to the 2 squares. The 6 treatments in each square were 4 strands 15, 28, 43, and 58 cm from the ground at low voltage of 4–4.5 kV (4S-LV); 2 strands at 15 and 43 cm and high voltage of 8.5–9 kV (2S-HV); 2 strands at 15.2 and 43.2 cm and low voltage (2S-LV); 1 strand at low height of 15 cm and low voltage (1S-LH-LV); 1 strand at 43 cm and low voltage (1S-HH-LV); and 1 strand at 23 cm and high voltage (1S-MH-HV). Means were separated by least significant difference with a protected F-test. The percentage of doelings exiting after 2 (during continuous visual observation) and 6 h was similar between intervals (6.3 and 4.2% at 2 h (SE = 2.49) and 9.7 and 6.3% at 6 h (SE = 2.33)) for long and short intervals, respectively). Doelings receiving a first shock in 2 h did not differ between intervals (16.7 and 19.4% for long and short intervals, respectively; SE = 3.20). The percentage of doelings exiting at 2 and 6 h was not affected by fencing treatment ($P > 0.05$). Period of the squares affected ($P < 0.05$) the percentage of doelings shocked in 2 h (62.5, 29.2, 6.3, 6.3, 0, and 4.2%; SE = 4.92) and exiting pens after 2 (20.8, 8.3, 2.1, 0, 0, and 0%; SE = 3.24) and 6 h (27.1, 10.4, 6.3, 4.2, 0, and 0% for 4S-LV, 2S-HV, 2S-LV, 1S-LH-LV, 1S-HH-LV, and 1S-MH-HV, respectively; SE = 3.44). Low pen exit, particularly in latter periods, suggests desirability of more thorough prior training to electric fence. Memory of previous exposure to electric fence appeared substantial, implying need to evaluate longer intervals. The overnight fasting period may not have created an adequate impetus to test electric fence for pen exit.

Key Words: goats, fence, pasture containment

T469 Accuracy of calculated distances between consecutive fixes of GPS collars worn by goats. T. A. Gipson*, G. D. Detweiler, and A. L. Goetsch, *American Institute for Goat Research, Langston University*, *Langston, OK*.

Small ruminants have been fitted with GPS collars to estimate distance traveled in grazing studies; however, accuracy has not been assessed. To do so, a mobile stand was developed to hold 21 Lotek 3300 GPS collars (Lotek Wireless, Newmarket, Ontario, Canada) and was moved a prescribed distance between fixes on 4 azimuthally different courses (NE at 45°, S at 180°, W at 270°, and NW at 315°). Fixes were scheduled at 5-min intervals. Distances traveled on a course were 0, 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 m. Distances were replicated 3 times for each course and the order of the distances was randomized within each replicate. Two courses were run per day and each course was paired with every other course, for a total of 6 different dates. Fixes were downloaded and distances between fixes were calculated using spherical geometry. The BIAS was estimated as distance calculated from collars minus true distance and was analyzed using a repeated measures design (PROC MIXED; SAS). Dependent fixed effects included true distance (0 to 100 m), course (NE, NW, S, W), and the 2-way interactions. Collars and dates were considered random effects. There was no effect ($P > 0.10$) of course on BIAS. For true distance, BIAS was greatest for 0 m (7.6 m ± 0.36) and least for 60 m (0.5 m). Other estimates of BIAS were

intermediate at 10 (2.9 m), 20 (1.6 m), 30 (0.9 m), 40 (1.7 m), 50 (1.4 m), 70 (0.6 m), 80 (0.8 m), 90 (1.2 m), and 100 m (1.3 m). There were linear and quadratic ($P < 0.01$) effects on BIAS when all distances were analyzed. However, if 0 and 10 m distances were eliminated, the linear effect disappeared ($P > 0.10$) but the quadratic remained ($P < 0.05$). The ability of GPS collars to differentiate between when an animal is stationary or moving only a short distance between fixes appears very limited; however, if an animal is moving more than 20 m between GPS fixes, collar estimates are within 1.6 m of actual distance traveled.

Key Words: goats, GPS, distance

T470 Use of biometric measurements to estimate fetal mass in dairy goats. C. J. Härter*, I. A. M. Teixeira, L. D. Lima, H. G. O. Silva, A. R. Rivera, and K. T. Resende, *Universidade Estadual Paulista*, *Jaboticabal, SP, Brasil*.

An understanding of fetal mass is important to check for normal fetal growth. Moreover, it can be helpful for estimating nutritional requirements of pregnant females. The aim of this study was to estimate fetal mass based on biometric measurements. Data were obtained from 39 dairy female goats with an average BW = 50.59 ± 7.71, and body condition scored as 2.58 ± 0.59. After the pregnancy confirmation, female goats were distributed to treatments according to a 2 × 2 × 3 factorial design as follows: 2 breeds (Oberhasli and Saanen), 2 types of pregnancy (single and twin) and 3 gestational ages (80, 110 and 140 d). Multiple linear regression was used to analyze the data using SAS PROC MIXED. At pre-established pregnancy ages goats were slaughtered and the mammary gland and reproductive tract were removed and separated from the cervix, and the uterus, fetus, placenta, and placental fluid were dissected. After fetal removal, weights, body length in centimeters (BL), height at withers, height at rump, chest width, rump width, rump length, hearth girth (HG) and abdominal girth were recorded for fetuses. The slaughter procedures followed the recommendations of the ethics committee for animal experimentation. The biometric measurements highly correlated with fetal mass ($P < 0.001$) which allowed the creation of predictive equations for fetal mass. The best equations were generated using body length ($Y = -549.4 \pm 520.4 + 22.14 \pm 50.25\ BL + 3.296 \pm 1.12\ BL^2$ ($R^2 = 0.89$); and hearth girth ($Y = 103.0 \pm 305.2 - 54.18 \pm 30.31\ HG + 5.175 \pm 0.696\ HG^2$ ($R^2 = 0.94$), whereas Y = fetal mass (g). Fetal mass can be precisely estimated based on fetus biometry showing an interesting perspective of pregnancy management as biometric measurements can be further determined using ultrasound, similar to what has been demonstrated in humans.
Fapesp (2009/10125–0).

Key Words: biometry, fetal weight

T471 The relationship of real-time ultrasound body composition measurements, body weight and hip height with body condition score in mature Boer crossbred does. A. M. Duff*, J. A. Carter, C. A. Hughes, K. N. Gates, C. S. Ellason, W. S. Stewart, and F. R. B. Ribeiro, *Texas A&M University-Commerce*, *Commerce*.

The purpose of this study was to determine the relationship between real-time ultrasound (RTU) measurements of body composition, BW, and hip height (HH), with body condition score (BCS) in mature Boer crossbred does (n = 27). BCS was assessed visually using a 1 to 5 scale. The body composition traits measured by RTU were 12–13th rib *longissimus lumborum* muscle area (uLMA, mean = 9.08 cm^2), 12–13th rib fat thickness (uBF, mean = 0.27 cm), and ultrasound rump fat thickness (uRUMP, mean = 0.24 cm). Ultrasound measurements were taken using an Aloka 500 with a 12 cm 3.5 MHz transducer, and each animal′s hair was clipped to no longer than 0.64 cm, and vegetable oil was used as a coupling agent to enhance image quality. Data were analyzed using the Proc CORR and Proc REG procedures of SAS. BW was correlated ($P < 0.05$) to HH, uBF, uLMA and uRUMP (0.55, 0.44, 0.67, and 0.58, respectively). BCS was correlated ($P < 0.05$) to uBF, uLMA and uRUMP (0.83, 0.77, and 0.92, respectively), and HH was not correlated ($P > 0.05$) to any of the RTU traits measured. Linear regression to predict BCS was developed using a stepwise selection. The first variable to enter the model was uRUMP which accounted for 84% of the variation and HH entered next in the model, accounting for an additional 6% of the variation, with the full model accounting for 90% of the variation in BCS. Body condition scoring done before breeding is very important to ensure that animals have enough body reserves to go through gestation and lactation. Since uBF was not a good predictor of BCS evaluators should give more emphasis in palpation of the rump area rather than the back of the animal when evaluating goats for BCS in order for a better assessment of total body fat reserves. Results of this study suggest that BCS can be accurately predicted from uRUMP and HH.

Key Words: ultrasound, body composition, goat

T472 Relationship between participation in youth equine organizations and collegiate equine activities. M. Nicodemus*, *Mississippi State University*, *Mississippi State*.

Despite current economic uncertainties, youth equine organizations are flourishing. While University budgets cuts threaten elimination of equine programs due to relatively low enrollment, a potential rise in enrollment would justify program continuation. To determine whether a background in youth equine activities influences participation in collegiate equine activities, students enrolled in equine courses (n = 95) at Mississippi State University were asked to fill out a researcher-developed, 10-item survey instrument with questions focusing on youth and collegiate activities. Effect of youth equine activities on percentage of those students involved in equine collegiate activities was tested using a one-way ANOVA ($P < 0.05$). Less than half (30%) of surveyed students had participated in youth equine organizations with 4-H (40%) ranking the highest for those individuals. The majority (82%) of those with a youth background planned on a career in the equine industry with only 58% for those with no background. As for equine extra-curricular activities, 36% of those with a youth background were active compared with only 13% of those with no background. The majority (89%) of those with a youth background planned on taking another equine course with the other 11% unable to take another course due to graduation, while 39% of those with no youth background were not planning to take another equine course with the majority of those students (22%) not graduating. Even though those with a youth background had a strong equine handling foundation before college, 79% had taken or were currently taking a course with a hands-on laboratory. Overall, a youth equine background was found to influence the involvement in collegiate equine activities as although these students were the minority their involvement in collegiate equine activities (riding teams, judging teams, clubs, hands-on riding laboratory courses, hands-on non-riding courses, non-hands-on laboratory courses, and enrollment in multiple equine courses) was greater than those without ($P < 0.05$) suggesting the growth currently seen in youth equine organizations will result in a growth of students active in future collegiate equine activities.

Key Words: youth equine organizations, collegiate equine activities

T473 Free web applications for educational purposes. P. A. Curtis* and M. O. Kloepper, *Auburn University*, *Auburn, AL*.

Using free web applications costs you—nothing! This session will focus on free applications that the presenters use in face-to-face and distance education classes, encourage you to invest a little bit of time to learn about them and discover how they might be used for your educational purposes. Only free applications will be showcased. Discussion will be encouraged among attendees to suggest and share novel ways the various applications might be used.

T474 Applications of functional anatomy in farm animals using collaborative learning. H. G. Kattesh*, M. H. Sims, R. B. Reed, and F. M. Hopkins, *University of Tennessee*, *Knoxville*.

A multimedia program dedicated to the teaching of fundamental principles of functional anatomy in farm animals using a problem-oriented approach was produced and developed for web course distribution in promoting collaboration among students and faculty at other colleges and universities. Students are presented a series of lessons containing text, graphics, animation, and audio and video that involve the anatomy and physiology of the respiratory system in farm animals. Mastery level of the lessons is assessed using 20 randomly selected multiple-choice questions from the 10 lesson chapters. Three case studies of respiratory system abnormalities in animals of agricultural significance were documented. Expert prompts, including history and details pertinent to each case, are provided in video and text formats to aid the student in documenting initial observations. Upon successful completion of the lesson material, the student is permitted to enter conclusions about the nature of the abnormality. This information, along with the student's notes and quiz responses, is stored on the Blackboard Web site for subsequent review by the instructor. At the end of the program the expert will give a synopsis of the case. We have received favorable comments from our undergraduate, graduate and professional students regarding the program′s quality, format, and innovative nature. Using a designated Web site, syllabi from participating universities that offer a comparable course in farm animal anatomy and physiology will be solicited and published to facilitate interaction among the students and their instructors. Each instructor will facilitate discussion forums and web forms will be used to collect data on the learning process. Participation in this collaborative learning community should improve problem-solving skills of students as they practice applying physiologic concepts to their own observations and, at the same time, form partnerships with other undergraduate agricultural students to better utilize limited resources.

Key Words: collaborative learning, functional anatomy, respiratory system

T475 Measuring the impact of varied instructional approaches in an introductory animal science course. B. G. Bolt* and K. D. Layfield, *Clemson University*, *Clemson, SC*.

The objective of this study was to measure the impact of various teaching formats on a student's likelihood of correctly answering a knowledge-based question and to also assess any relationships between knowledge acquisition and self-perceived levels of engagement. Data were collected on students in the AVS 150, introductory animal science class (n = 155) at a southeastern university during the fall of 2008. Ten to 15 min of class time were allocated to use of one of 3 teaching formats. The 3 teaching formats were labeled as traditional lecture, technology-enhanced or Web-enhanced. At the conclusion of allocated time, students were posed a knowledge question, germane to the presented material and they were also asked to respond with a perceived level of engagement in classroom activities. The responses were collected via a 5-point Likert-type scale (1 = completely disaffected to 5 = completely engaged) using the i-Clicker audience response system. There was a significant difference ($P < 0.05$) in students reported level of engagement in traditional lecture (M = 3.41), Web-enhanced (M = 3.52) and technology-enhanced (M = 3.70). No significant relationships were identified between a student's level of engagement and the likelihood of answering a knowledge question correctly. This finding suggests that although students indicate a preference for how material is delivered, this preference did not impact academic performance.

Key Words: student engagement, teaching methods, undergraduate education

SYMPOSIA AND ORAL PRESENTATIONS

Animal Behavior and Well-Being: Sow Housing, Management, and Stress

409 Productivity and well being of pregnant sows in loose housing is affected by floor space allowance and dietary fiber content. A. R. Hanson*[1], A. E. DeDecker[2], J. L. Salak-Johnson[2], P. M. Walker[1], and J. P. Holt[1], [1]*Illinois State University*, *Normal,* [2]*University of Illinois*, *Urbana*.

As government mandates and public perceptions encourage the adoption of group housing, appropriate management strategies must be evaluated to determine their effect on sow well being and performance. To evaluate the effects of floor space allowance (FSA) and dietary fiber, a 10 mo study was conducted involving 6 trials (n = 40 sows/trial). Pregnant, mixed parity sows were housed 10 per pen with either 2.32m^2 (B) or 1.67m^2 (S) of FSA per sow. Sows were floor fed either a traditional corn-soy based control (C) or higher fiber diet (F). Sows were evaluated for BCS, BW and 10th rib backfat (BF) at d34 (start of trial), d65, and d90 of gestation. Sows were weighed and BCS at d110 of gestation (end of trial), and were scored for lesions at d34 of gestation (before mixing sows), every 2nd day for 2 weeks, and at d65, d76, d90, d110 of gestation to assess skin injury. Farrowing data were collected for each litter, including total birth and weaning weight, piglet mortality, number of pigs born, born alive, born dead and weaned. Data were analyzed by GLM procedures or mixed models, using repeated measures analysis when appropriate to measure effects across gestation days (GD). Sows were assigned to 1 of 3 parity groups (PG) for gilts entering parity 1 (G), sows entering parities 2–3 (M), and sows entering parity 4 or higher (H), respectively. There were significant PG by diet interactions for BCS change, weight gain, and ADG. Gilts lost more BF over gestation compared with other PG ($P < 0.05$). Sows in B pens tended to have higher ADG/period than those in S pens ($P = 0.09$). The HF sows had higher ADG/period than the other diet by PG classifications ($P < 0.05$). The FSA by GD interaction was significant, with S sows accruing lesions of higher severity compared with B sows at d36 ($P = 0.002$) and d76 of gestation ($P = 0.07$). Litter birth weight, and litter live birth weight were greater for higher parity sows ($P < 0.05$).These results indicate that a diet high in fiber can be fed to sows without detrimentally impacting performance, and that FSA may affect lesion severity.

Key Words: sow group housing, fiber, floor space allowance

410 Effects of fiber and floor space allowance on group kept dry sow well-being. A. E. DeDecker*[1], A. R. Hanson[2], P. M. Walker[2], and J. L. Salak-Johnson[1], [1]*University of Illinois*, *Urbana,* [2]*Illinois State University*, *Normal*.

Alternative housing systems for gestating sows is one of the most controversial welfare issues facing the swine industry, thus it is imperative that before implementing new systems that various components of group housing systems be fully evaluated. Therefore, the objective of this study was to evaluate the effects of dietary fiber (source of energy) and floor space allowance on immune and endocrine status, and behavior of sows during gestation. On d34 of gestation, 160 multiparous (parities 1–6) large white crossbred sows were randomly allotted to a dietary treatment (control or high-fiber supplemented diet) and a floor space allowance of either 1.7m^2/sow or 2.3m^2/sow. Group size was kept constant at 10 sows per pen. On d 34 and 90 of gestation both sow immune and endocrine statuses (n = 40 sows/treatment) were measured and for a 24h period between gestation d 75 and 105 sow behavior (n = 10 sows/treatment) was continuously observed using EZViewLog by Geovision. Data were analyzed using Proc MIXED with repeated measures and Chi-squared analysis (SAS). Both diet and days of gestation had an effect on sow immune status; with neutrophil phagocytosis and plasma cortisol being greater ($P < 0.05$) for sows fed a control diet when compared with sows fed a high-fiber diet. Whereas, concanavalin-A induced lymphocyte proliferation was greater ($P < 0.05$) for sows fed high-fiber compared with sows fed a control diet. On d90 of gestation, lymphocyte proliferation was greater ($P < 0.01$) for sows fed a high-fiber diet than for sows fed a control diet. Sow behavior was also affected by diet; with sows fed the high-fiber diet being engaged in more ($P < 0.001$) agonistic encounters than sows fed a control diet. Durations of oral-nasal-facial (ONF), standing, and eating behaviors were all greater ($P < 0.05$) for sows fed the control diet compared with sows fed the high-fiber diet. Moreover, sow behavior was affected by floor space allowance; sows kept at 1.7m^2/sow performed more ($P < 0.05$) ONF, standing, and eating behaviors than did sows kept at 2.3m^2/sow. These results indicate that fiber and floor space allowance can influence sow physiology and behavior which may ultimately impact sow well-being.

Key Words: fiber, well-being

411 Effect of alternative individual and group housing on dry sow performance and physiology. A. E. DeDecker*[1], A. R. Hanson[2], P. M. Walker[2], and J. L. Salak-Johnson[1], [1]*University of Illinois*, *Urbana,* [2]*Illinois State University*, *Normal*.

Sow housing is one of the most controversial issues facing the swine industry, but before implementing alternative systems, we must fully understand the impact that various housing types have on the well-being of gestating sows. Therefore the objectives of this study were to evaluate the effects of individual standard and turn-around stalls on sow performance and physiology during gestation (Exp.1), and to determine the effects of keeping sows in one of the 2 types of stall for first 30d of gestation and then moving sows to group-pens for the rest of gestation (Exp.2). Forty multiparous crossbred sows were allocated, based on body weight and parity, to a standard stall (STS; n = 10) or a turn-around stall (TAS; n = 10) for all of gestation (Exp.1); or a standard stall (STS-G; n = 10) or turn-around stall (TAS-G; n = 10) for 30 d of gestation and then moved to group-pens of 10 sows/pen, at floor space allowance of 2.32m^2/sow (floor fed; Exp. 2). On d 30 and 90 of gestation sow immune and endocrine statuses were measured. Performance measures and lesion scores (scale 1–7) were also assessed throughout gestation. Data were analyzed using Proc MIXED with repeated measures (SAS) and experimental unit was the sow. Fixed effects included parity, day of gestation, treatment and interactions. In Exp. 1, stall-type influenced sow performance and immune status; with lesion scores being greater ($P < 0.05$) among sows kept in TAS than sows kept in STS. Sows kept in STS had greater ($P < 0.05$) body condition score (BCS) than those

sows kept in TAS. Mitogen-induced lymphocyte proliferation was greater ($P < 0.05$) for sows kept in TAS than for sows kept in STS. In Exp. 2, Treatment influenced both performance and immune status of sows; BCS, back fat, and lesion scores all tended to be greater ($P < 0.10$) for sows kept in TAS-G than for sows kept in STS-G. Neutrophil phagocytosis and count, and total WBC count were all greater ($P < 0.05$) for sows kept in STS-G than for sows in TAS-G. In conclusion, these data indicate that type of individual stall throughout gestation and before group-pens can affect performance and immune status of the sow, thus affecting sow well-being.

Key Words: group, stall

412 Effect of alternative accommodations on sow behavior during gestation. A. M. Visconti*[1], A. E. DeDecker[1], A. R. Hanson[2], P. M. Walker[2], and J. L. Salak-Johnson[1], [1]*University of Illinois*, *Urbana*, [2]*Illinois State University*, *Normal*.

Currently there is a lack of scientifically-sound data to establish welfare-friendly guidelines on how to effectively manage gestating sows. Thus, to improve sow well-being, we must understand the impact that various housing systems have on the behavioral aspects of gestating sows. The objectives of this study were to determine the impact that keeping sows in either a standard or turn-around stall throughout gestation has on sow behavior (Exp. 1), and to evaluate the effects of keeping sows in either a standard or turn-around stall for first 30d of gestation and then moving sows to group-pens for remainder of gestation has on sow behavior (Exp.2). Post-mating, 30 multiparous white crossbred sows were randomly allotted to 2 treatments (TRT) either a standard traditional stall (STS; n = 5/TRT) or a turn-around stall (TAS; n = 5/TRT) for entire gestational period (Exp.1), or to a standard stall (STS-G; n = 10/TRT) or turn-around stall (TAS-G; n = 10/TRT) for 30 d and then moved to group-pen until d107 of gestation (Exp.2). Sow behavior was observed continuously from 0800 to 0900 h, 1200 to 1300 h, and 1600 to 1700 h on d6, 30, and 90 of gestation for Exp. 1 and on d30, 45, 65 and 90 for Exp. 2. Data were analyzed using Proc MIXED with repeated measures and Chi-squared (SAS). In Exp. 1, stall type and day of gestation affected behaviors. On d90, duration of standing and eating was greater ($P < 0.01$) for sows in TAS than for sows kept in STS. Duration of eating was greater ($P < 0.05$) for sows kept in STS on d30 than for sows in TAS. In Exp. 2, treatment and day of gestation both affected sow behavior. Duration of ONF was greater ($P < 0.05$) for sows kept in TAS-G compared with sows kept in STS-G. Frequency of aggression was greater ($P < 0.01$) for sows kept in TAS-G than sows in STS-G. Duration of lying on d45 and 90 was greater ($P < 0.05$) for sows kept in TAS-G compared with sows kept in STS-G. These data indicate that individual stall design throughout gestation and type of stall before group-housing can influence sow behavior; therefore further assessment of alternative accommodations is needed before implementation of alternative systems.

Key Words: behavior, sow

413 Effects of alternative housing systems on the well-being of gestating sows. A. E. DeDecker* and J. L. Salak-Johnson, *University of Illinois*, *Urbana*.

Housing systems for gestating sows is one of the most controversial welfare issues facing the swine industry. New systems are being implemented without scientifically evaluating the impact these alternative accommodations may have on sow well-being. The objectives were to evaluate the effects of 3 housing systems on sow physiology, performance, productivity and behavior. On d30 of gestation 36 multiparous sows were allocated to a standard crate (CRATE; control), a width adjustable crate (FLEX), or free access stall-pen (FREE). Immune and endocrine status, body condition and lesion scores, body weight, and back-fat depth were measured at weaning (d 0), various time points throughout gestation, and again at d110. Behavior was observed for 24h on d29, 30, 66, and 87 of gestation for block 1. Data were analyzed using Proc MIXED with repeated measures (SAS). Sows in the FREE system had greater ($P < 0.01$) body condition and lesion scores, body weight, and back fat depth than sows in either FLEX or CRATE systems. Sows in FLEX had greater litter size ($P < 0.10$) and piglet mortality rate ($P < 0.05$) than did sows in CRATE; while sows in FLEX had piglets with greater ($P < 0.01$) wean weight and rate of gain than did sows kept in either FREE or CRATE systems. Sows in FREE had less ($P < 0.05$) banded neutrophils than did sows in either FLEX or CRATE. On d31 (24 h later), all sows had greater ($P < 0.05$) lymphocyte and neutrophil counts, neutrophil chemotaxis, and concanavalin A- and lipopolysaccharide-induced lymphocyte proliferative responses than any other day of gestation. Sows kept in CRATE engaged in more oral-nasal-facial (ONF) behaviors than sows kept in other systems ($P < 0.05$). Sows in CRATE stood more ($P < 0.05$) than sows in all other treatments. Also, as day of gestation increased ($P < 0.05$), duration of ONF, sham-chewing, eating, and drinking behaviors all increased. These data indicate that alternative housing accommodations can affect immune status, physiology, performance, productivity and behavior of pregnant sows throughout gestation. Moreover, these data support the hypothesis that modifications of specific housing components within existing housing systems can affect sow well-being.

Key Words: behavior, immune

414 The effect of a repeated prenatal stressor and low-dose Ketamine on the anxiety and social behavior of pigs. B. L. Davis*[1] and M. A. Sutherland[2], [1]*Texas Tech University*, *Lubbock,* [2]*Ruakura Research Centre, AgResearch*, *Hamilton, New Zealand*.

The fetal programming hypothesis states that exposure to elevated glucocorticoid concentrations in utero can alter offspring development. Animals exposed to stress prenatally have been shown to display increased anxiety-like behavior coupled with a reduced ability to cope with stress. The objective of this research was to determine if exposure to stress prenatally would affect the social and anxiety-like behavior of pigs and whether an anxiolytic drug (Ketamine) would reverse these behavioral changes. Sows were allocated to one of 2 treatments; 1) Sows were given an injection of adrenocorticotropic hormone (ACTH; 100 IU i.m.) 3 times a wk during the last 5 wk of gestation (ACTH; n = 10), and 2) Sows were control handled (HAN; n = 10). At 6 mo of age, the female offspring from the ACTH (PNS; n = 20) and HAN (CON; n = 20) sows were tested for 10 min in an open-field test (OFT) to measure anxiety and for 30 min in a social test (ST) to measure social interactions. The ST involved observing the interactions between 2 pigs; the experimental pig and a naïve non-experimental pig. Pigs were tested in each behavioral test twice; 1 wk apart. Two h before testing, pigs were given either Ketamine (KET; 0.5mg/kg, i.m.) or saline (SAL) at the same dose. Videos from behavior tests were analyzed using Observer 7.0. Data were analyzed using the MIXED procedure of SAS. At 6 mo of age, PNS pigs tended ($P = 0.075$) to weigh less than CON pigs. In the OFT, PNS pigs spent more ($P < 0.05$) time in the middle squares and pigs given KET spent less ($P < 0.05$) time displaying escape behaviors compared with SAL pigs. In the ST, PNS pigs given KET tended to spend less time ($P = 0.065$) fighting and more time ($P < 0.05$) performing non-aggressive social touching than CON pigs given KET. In conclusion, exposure to elevated glucocorticoid concentrations in utero may affect

offspring growth and anxiety-like behaviors. Furthermore, low-dose KET appeared to have anxiolytic effects on pig behavior, especially among prenatally stressed pigs.

Key Words: stress, pigs, anxiety

415 Heart rate variability—A tool to differentiate positive and negative affective states in pigs? R. Poletto*[1], R. M. Marchant-Forde[1], J. N. Marchant-Forde[1], J. L. Rault[1,2], D. F. Hogan[3], and D. C. Lay Jr.[1], [1]*USDA-ARS-Livestock Behavior Research Unit*, *West Lafayette, IN,* [2]*Department of Animal Sciences, Purdue University*, *West Lafayette, IN,* [3]*Veterinary Clinical Sciences, Purdue University*, *West Lafayette, IN*.

Neurophysiological processes, such as autonomic nervous system activity, that mediate behavioral and physiological reactivity to an environment have largely been ignored in farm animal research. Heart rate variability (HRV) analysis is a clinical diagnostic tool used to assess affective states (stressful and pleasant) in humans, but its application is limited in farm animals. This experiment aimed to determine if HRV may be used to differentiate affective states in swine. Ten 4-mo-old barrows and gilts underwent surgery to place an intracardiac ECG lead attached to a biotelemetry device; pigs had a 3-wk recovery period before data collection. A negative state was induced by restraining pigs for 1 h in metabolism crates located in the same room, while a positive state was induced by allowing pigs′ access to the hallway for 10 min. Behavior and ECG data were recorded. For data analyses, a 512–beat section of HR inter-beat intervals was selected per pig while behaviorally inactive during restraint; or while performing a combination of play- and exploratory-like behaviors in the hallway. Data were analyzed using time and frequency domain analysis followed by a factorial analysis of test × sex with mixed models and Tukey's post hoc test. Average HR was lower for restraint than the hallway test (121.7 vs. 162.4 ± 4.4 bpm; $P < 0.01$), while RMSSD, index of vagal cardiac control, was higher for restraint than for hallway test (11.0 vs. 7.0 ± 1.0 msec; $P < 0.05$). Gilts had higher low frequency (LF) power than barrows (65.1 vs. 43.9 ± 4.0 msec^2/Hz; $P < 0.01$). High frequency (HF) power was lower in hallway than in restraint (4.2 vs. 14.1 ± 1.9 msec^2/Hz; $P < 0.01$). Sympathovagal balance (LF/HF) was higher during hallway test compared with restraint ($P < 0.01$). Gilts showed primarily sympathetic modulation of HR; while over both sexes, restraint resulted in greater parasympathetic control of cardiac function. Results indicate that HRV can be used to distinguish different degrees of activity/states in pigs. Further research will assist to identify distinct autonomic response patterns to different well-being states in farm animals.

Key Words: swine, heart rate variability, behavior

416 A combination of head/heart electric stunning is more effective than the head-only method in pigs. K. D. Vogel*[1], G. Badtram[2,3], J. R. Claus[3], T Grandin[1], S. Turpin[3], R. E. Weyker[3], and E. Voogd[4], [1]*Department of Animal Sciences, Colorado State University*, *Fort Collins,* [2]*Wisconsin Department of Agriculture, Trade, and Consumer Protection, Division of Food Safety*, *Madison,* [3]*Department of Animal Sciences, University of Wisconsin-Madison*, *Madison,* [4]*Voogd Consulting, Inc.*, *West Chicago, IL*.

Head-only electrical stunning is a reversible procedure that is effective for approximately 15 s. Shackle to bleed time in small slaughter facilities may exceed 30 s, primarily due to slow hoist speed. A 2-stage stunning method was proposed where head-only stunning for 3 s was followed by application of the same stunning apparatus to the cardiac region of the animal for 3 s while lying in lateral recumbency (head/heart). A paired-comparison study was performed on 89 pigs in a small Wisconsin slaughter facility to compare the head-only method applied for 6 s to the head/heart method. The study objective was to evaluate signs of return to sensibility, shackle to bleed time, blood lactate concentration, muscle pH, drip loss, and fresh meat color to validate the head/heart electrical stunning method for small slaughter plants. Incidence of corneal reflex was not different ($P > 0.05$) between head/heart (93.8%) and head only (85%) stunning. Nose twitching was more common ($P < 0.05$) in head only (26.5%) than head/heart (5%) stunning. The head/heart method eliminated rhythmic breathing, natural blinking, eye tracking to a moving object, and righting reflex, which were all observed in head-only stunned pigs. Blood lactate was not different ($P > 0.05$) between stunning methods (head only: 8.8 ± 0.7 mmol/L, head/heart: 7.8 ± 0.7 mmol/L). Shackle to bleed time did not differ ($P > 0.05$) between stunning methods (head only: 32 ± 1 s, head/heart: 33 ± 1 s). Mean time to loss of detectable heartbeat with the head-only method was 121 ± 5 s. No detectable heartbeat was observed with the head/heart method. Longissimus thoracis pH, color, and drip loss were not different ($P > 0.05$) between stunning methods. Farm of origin effects were observed in blood lactate, meat color, and drip loss. Farm effects can be generated by differences in genetics and management, which were not investigated in this study. This study determined that the head/heart electrical stunning method reduces the incidence of signs of return to sensibility without significant effect on meat quality, speed of plant operation, and blood lactate concentration.

Key Words: swine, stunning, welfare

417 Effects of pen size on the stress response of market weight pigs during loading and unloading. L. M. Gesing*[1], A. K. Johnson[1], K. J. Stalder[1], J. T. Selsby[1], M. Faga[2], A. Whiley[2], S. Abrams[2], H. Hill[2], R. Bailey[3], and M. J. Ritter[4], [1]*Iowa State University*, *Ames,* [2]*Iowa Select Farms*, *Iowa Falls,* [3]*JBS Swift and Co.*, *Marshalltown, IA,* [4]*Elanco Animal Health*, *Greenfield, IN*.

The objective of this trial was to determine the effects of pen size on the stress response and transport losses in market weight pigs. Twenty-six loads (~174 pigs/load) of pigs (n = 4522) were used in a complete randomized block design. Three commercial grow-finish sites were used over July and August. Each site had 2 rooms with both treatments represented in each room. The small pen (SP) treatment had 36 pigs/pen (0.59 m^2·pig^{-1}). The large pen (LP) treatment had 324 pigs/pen (0.59 m^2·pig^{-1}). To achieve large pens, 8 consecutive swing gates were kept open. During loading, all swing gates were closed in LP pens. Pigs from both treatments were sorted from pen mates at the time of loading, moved in groups of 4–6 using sort boards and electric prods if necessary, and loaded onto straight deck trailers. Treatments were randomly assigned to a deck, pigs were provided with ~0.42 m^2·pig^{-1}, and transported ~1 h to a commercial harvest facility. During loading and unloading, the number of pigs displaying open mouth breathing (OMB), skin discoloration (SD) and muscle tremors (MT) were recorded. At the plant, dead and non-ambulatory pigs (fatigued and injured) were recorded during unloading and total losses were defined as the sum of dead and non-ambulatory pigs. Data were analyzed using Proc Glimmix of SAS. MT at loading and injured and DOA at plant could not be run and will be presented descriptively. SP had lower incidences of OMB ($P = 0.0015$) and SD ($P = 0.0120$) during loading than LP. At loading MT was 0.04% SP vs. 0% LP. At the plant, LP had a lower incidence of SD ($P < 0.0001$) than SP; however, there were no ($P > 0.05$) differences between treatments for OMB, MT, fatigued, total non-ambulatory, or total losses. Incidence of injured pigs was 0% SP vs. 0.04% LP and there were no DOAs. In summary, pen size did not impact the incidence of transport losses.

Key Words: pen size, pig, transport loss

418 Effects of vehicle design on blood stress indicators and meat quality in pigs of three genotypes for two different travel distances. A. Vanelli Weschenfelder*[1,2], S. Torrey[3], N. Devillers[2], L. Saucier[1], and L. Faucitano[2], [1]*Université Laval*, *Sainte-Foy, Québec, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lennoxville, Québec, Canada*, [3]*University of Guelph*, *Guelph, ON, Canada*.

This study aimed at evaluating the effects of vehicle design on stress response and meat quality traits of 3 different pig genotypes; namely Piétrain HALNn (A), Piétrain HALNN (B) and Duroc crossbreds (control; C). A total of 360 pigs (120 pigs/genotype) were transported either for a short or long distance (45 min and 7h, respectively) over a 6 weeks period. The vehicles were a 3-decked Pot-Belly (PB) trailer equipped with 2 internal ramps and a 3-decked Flat-Deck (FD) trailer equipped with moving decks and no internal ramps. For each group, blood samples were collected at exsanguination from a sub-sample of 144 pigs (4 pigs/genotype/vehicle/week) for the analysis of lactate and creatine phospho-kinase (CPK) concentrations, while meat quality was assessed in the Longissimus dorsi (LD) and Semimembranosus (SM) muscles of all 360 pigs (10 pigs/genotype/vehicle/week). Data were analyzed using the mixed model procedure of SAS. In the short distance journeys, CPK levels were higher ($P = 0.021$) in A pigs transported on the PB trailer compared with those transported on the FD trailer. Pigs transported on the PB trailer had higher ($P = 0.02$) pHu values in the SM muscle than those transported on the FD trailer. Yet, in the short distance study group, A pigs had lower ($P = 0.008$) pHu and higher ($P < 0.001$) drip loss in the LD muscle compared with B and C pigs. Concurrently, the LD muscle of A and B pigs was paler (higher L* value; $P = 0.002$) than that of C pigs. A pigs also had higher L* and drip loss values ($P = 0.04$ and $P < 0.001$, respectively) in the SM muscle. In the long distance transportation, no effect of vehicle type was found on blood stress indicators ($P > 0.05$). Nonetheless, A and B pigs had higher lactate ($P = 0.003$) and CPK levels ($P < 0.001$) than C pigs. Regarding meat quality parameters, differences between genotypes were similar to those found in the short distance travel study. Overall, the use of PB trailer for short distance transportation and of HALn carrier pigs are not recommended from an animal welfare and meat quality improvement perspective.

Key Words: transport, pigs, stress

419 Effects of pasture versus stall housing on cortisol and DHEA concentrations in young Quarter Horses. S. M. Garey*, T. H. Friend, L. R. Berghman, A. L. Adams, and C. L. Terrill, *Texas A&M University*, *College Station*.

Adaptation of horses to long-term stall housing has not been thoroughly investigated. The objective of this study was to determine if cortisol or dehydroepiandrosterone (DHEA) differed among groups of young horses when housed in individual stalls versus in a group on pasture. Eighteen 2- to 3-yr-old Quarter Horses were randomly assigned to either stall or pasture housing for 21 d. The 3.05 × 3.05 m stalls had solid concrete side and rear walls with a small ventilation window, while the front allowed horses to view the alley of the barn. The stalled horses were allowed 15 min of exercise 3 d per week. The 9 pasture horses were on a novel 0.2 km^2 pasture. All horses were fed concentrate 2 times per day, pastured horses had coastal grass, and stalled horses had coastal hay. After 21 d, all horses were combined on pasture and observed for 7 d. Jugular blood samples were drawn at 24 h and 0.5 h before treatment, then every 12 h for 3 d, every 24 h for 5 d, and every 48 h for the final 13 d. On d 22, blood samples were collected at 0.5 h before combining the horses, 12 h and 24 h post-combination, then every 24 h for the remaining 6 d. Plasma was analyzed by ELISA to determine cortisol and DHEA concentrations. A mixed model repeated measures ANOVA with unstructured covariance determined treatment and time of sampling effects. Overall, stalled horses had significantly higher cortisol concentrations (5.11 ng/mL) than pastured horses (3.62 ng/mL, $P < 0.0001$), although no significant differences were observed in DHEA ($P = 0.08$). No significant differences were observed in cortisol concentrations between treatment groups during the pre-treatment sample periods ($P = 0.29$), however, average cortisol concentration of stalled horses during the treatment period (4.73 ± 1.08 ng/mL) was significantly higher ($P < 0.0001$) than pastured horses (3.23 ± 1.08 ng/mL). In conclusion, differences between the treatment groups were initially slight, and became more exaggerated over the treatment period. These results suggest that isolation in an individual stall over an extended period of time causes changes in cortisol that merit further investigation.

Key Words: housing, stall, cortisol

420 Use of infrared thermography to measure inflammation associated with castration and anti-inflammatory drugs. L. A. González*[1], K. S. Schwartzkopf-Genswein[2], E. Fierheller[3], E. Janzen[3], N. Caulkett[3], and T. A. McAllister[2], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*, [3]*University of Calgary*, *Calgary, Alberta, Canada*.

Angus bulls (n = 48; initial BW 301 ± 3 kg) were randomly assigned to 1 of 6 treatments according to a 3 × 2 factorial design to study the effect of castration method and pain medication on eye (ET) and scrotal area temperature (ST). Castration (Cast) treatments consisted of sham (C), band (B), and surgical (S) castration. Pain medication (Med) treatments consisted of either lactated ringer solutions (NM) or pain mitigation drugs (M). Drugs used were 2% lidocaine with epinephrine injected at 10 mL into each testicle plus 10 mL subcutaneously at the scrotal base, and a subcutaneous injection of flunixin meglumine (2.2 mg/kg BW) in the neck of calves. Maximum ET and ST were measured with an infrared camera on day −1, 0, 2, 5, 7, 14, 21, and 35 relative to castrations. Data were analyzed with a mixed-effects regression model considering the fixed effects of covariate (d −1), Cast, Med, and Day as repeated measure, the random effect of Pen, and all possible interactions. Maximum temperature of the scrotal area was affected by Cast ($P < 0.001$), Cast × Med ($P < 0.05$), and Cast × Day ($P < 0.001$). S calves had greater temperature than C and B at d 2, 5, and 7 after castration ($P < 0.05$). In contrast, B had greater temperature than S and C at d 21 and 28, and greater than C at d 14 and 35 ($P < 0.05$). MB calves had lower ($P < 0.05$) ST compared with NMB but this was not the case in S and C ($P > 0.10$), values being 36.0, 35.3, 35.2, 35.5, 34.2, and 34.7 ± 0.32°C for BNM, BM, SNM, SM, CNM, and SM, respectively. Cast and Med did not significantly influence ET ($P > 0.10$). Based on ST, S produces inflammation during the first week whereas B produced inflammation during wk 3 and 4 after castration. However, neither Cast nor Med resulted in systemic inflammation because no differences in ET were observed. The medication protocol used in the present study reduced local inflammation in band castration only.

Key Words: bull inflammation, castration method, pain medication

421 Influence of cattle temperament on stress hormones and IgG concentrations in Angus-cross calves. R. C. Vann*[1], N. C. Burdick[2], J. G. Lyons[2], T. H. Welsh, Jr.[2], and R. D. Randel[3], [1]*MAFES-Brown Loam Research Station*, *Raymond, MS,* [2]*Texas AgriLife Research*, *College Station,* [3]*Texas AgriLife Research*, *Overton*.

The objective of this study was to determine the influence of temperament on concentrations of cortisol, epinephrine, norepinephrine, and

IgG in Angus-cross calves. Calves from 2005 and 2006 were selected based on temperament score measured 28 d before weaning and at weaning. Based on temperament score the 10 calm, 10 intermediate and 10 temperamental calves from each sex (steers and heifers in 2005, bulls and heifers in 2006) were selected from each calf crop (n = 120). Blood was collected 28 d before weaning, weaning, 28 and 56 d post-weaning to determine serum cortisol and IgG, and plasma epinephrine (EPI) and norepinephrine (NE) concentrations. Data were analyzed using the MIXED procedure of SAS specific for repeated measures. Sources of variation included temperament, sex, day and year. Concentrations of EPI and NE were greater in 2005 than 2006 ($P = 0.004$). Cortisol concentrations were lower in calm (25.9 ± 0.9 ng/mL, $P < 0.001$) compared with intermediate or temperamental calves (35.5 ± 0.7 and 32.7 ± 0.9 ng/mL, respectively). Heifers had greater ($P < 0.001$) cortisol concentrations (37.2 ± 0.7 mg/mL) with steers being intermediate (34.2 ± 1.2 ng/mL) and bulls having lower concentrations (22.7 ± 1.3 ng/mL). Calm had lower ($P < 0.001$) EPI concentrations (389 ± 65 pg/mL) than intermediate (613 ± 64 pg/mL) and temperamental calves (788 ± 64 pg/mL). Concentrations of EPI declined over the 4 collection times ($P < 0.002$). Temperamental had greater concentrations ($P < 0.001$) of NE (754 ± 53 pg/mL) and NE did not differ between calm and intermediate calves (461 ± 53 and 470 ± 53 pg/mL, respectively). Concentrations of NE differed ($P = 0.012$) over the 4 collection times and were not influenced by sex. Concentrations of IgG were influenced by the following interactions: temperament × sex ($P < 0.002$) and sex × day ($P < 0.02$). In summary, there appears to be a relationship between temperament and concentrations of stress hormones. In addition, sex influenced concentrations of cortisol and EPI whereas, both temperament and sex influenced IgG.

Key Words: cattle, temperament, stress hormones

Animal Health Symposium: Accounting for Diseased Animals in Research Trials (Outliers, Treatments, Interactions)/ Disease Induction by Treatment?

422 Factors influencing onset of disease and subsequent effects on feedlot performance. R. M. Enns*[1], R. L. Weaber[2], H. Van Campen[1], and G. H. Loneragan[3], [1]*Colorado State University*, *Fort Collins*, [2]*University of Missouri*, *Columbia*, [3]*West Texas A&M University*, *Canyon*.

Prevention and treatment of disease in the dairy and beef industries increases production costs for producers. For researchers, disease symptoms often lead to the removal of animals from study outcomes. Removal of these animals from research trials may bias study results if susceptibility to disease is genetically related to outcomes of interest. Failing to correct performance records for factors that induce phenotypic variation can downwardly bias heritability estimates and diminish the power to detect quantitative trait loci. A more complete understanding of factors influencing onset of infectious disease, including genetic contributors, and the resulting influence of these diseases on subsequent animal performance and recovery time lag is warranted. Due to the variable nature of incidence of disease, estimation and quantification of factors contributing to disease susceptibility is often clouded by issues associated with specificity, sensitivity, and exposure to pathogens. Bovine respiratory disease (BRD) represents the largest proportion of disease incidence in feedlot cattle and results from the interactions of stress level, immunological status and response, and the presence of infectious organisms. Stress and immunological response have been reported to have heritable components. Feedlot personnel rely on animals exhibiting clinical signs of BRD for diagnosis and initiation of treatment. Yet, when lung lesion scores are collected at harvest and combined with treatment records a substantial portion of untreated animals have lung lesions while a noteworthy portion of calves treated do not exhibit lung damage. Taken alone, diagnosis and treatment of BRD is related to lower feedlot ADG, carcass weight, and quality. These effects seem to be dependent upon timing of treatment relative to slaughter with effects on recovered animals diminishing with longer periods on feed. A more complete understanding of the environmental and genetic factors contributing to the occurrence of BRD could lead to a reduction in disease frequency and better methodologies for predicting and accounting for impacts on animal performance in research studies.

Key Words: cattle, bovine respiratory disease, health

423 Reporting standards for randomized controlled trials in cattle: Improving the quality of research. I. A. Gardner*[1], A. M. O'Connor[2], J. M. Sargeant[3], J. S. Dickson[4], and M. E. Torrence[5], [1]*University of California, Davis,* [2]*Iowa State University*, *Ames,* [3]*University of Guelph*, *Guelph, Ontario, Canada*, [4]*Iowa State University*, *Ames,* [5]*USDA-ARS*, *Beltsville, MD*.

Design, analysis and reporting of randomized, controlled trials with production, health, and food safety outcomes in livestock presents unique challenges that may not be adequately addressed in published trial reports or in the CONSORT statement (Consolidated Standards of Reporting Trials of 22 items, available www.consort-statement.org). A consensus meeting of 24 experts (biostatisticians, epidemiologists, food safety researchers, and livestock production specialists) resulted in development of an extension of the CONSORT statement. The new statement is called REFLECT (www.reflect-statement.org/statement/). Thirteen items on the CONSORT checklist were modified as well as the inclusion of one additional item: item 1 (title and abstract), item 3 (participants), item 4 (interventions), item 5 (objectives), item 7 (sample size), item 8 (randomization sequence allocation), item 9 (allocation concealment), item 10 (randomization implementation), item 11 (blinding/masking), item 12 (statistical methods), item 13 (participant flow), item 15 (recruitment), and item 20 (interpretation). The additional item proposed was a new sub-item for item 4 (challenge trials). The consensus group also proposed terminology to describe study subjects to make the language more consistent with common usage in livestock production. Implications of these new standards for trials in dairy herd health and production medicine will be discussed with a focus on statistical methods to account for censored and missing observations and cluster designs.

Key Words: randomized controlled trials, statistical methods, censoring

424 Accounting for diseased animals in research trials. G. D. Snowder*, *National Center for Foreign Animal and Zoonotic Disease Defense*, *College Station, TX*.

Unfortunately, livestock on research trials frequently experience pathogenic or metabolic diseases. Sick or deceased research animals often present a dilemma for investigators by influencing the statistical power and/or conclusions of the study. A decision tree approach is recommended for determining appropriate handling of data from such animals. When the treatment effect is associated with the disease, the disease effect should be included in the statistical analyzes. When the disease is not associated with the treatment then it must be determined whether the animal is a statistical outlier which may be adjusted for or an anomaly that could be discarded. There are several different statistical approaches to adjusting data sets to account for outliers, but the interpretation of adjusted data can be difficult to comprehend. The most critical factor in accounting for diseased animals is the number of experimental units (animals) in a treatment or block. In trials with large numbers of experimental units ($n > 30$) per treatment, data from a few sick or deceased animals are frequently deleted. This approach is justified when statistical tests indicate large differences between treatment means and/or measures of variation for the healthy animals. When these statistical differences are small, one may consider inclusion of data from sick or diseased animals that have been properly adjusted or accounted for. When the number of experimental units per treatment is small, the decision to delete sick or deceased animals becomes critical. Depending on the response variable(s) measured, covariate analysis or sub-treatment group analysis may be considered. A decision tree approach with options for statistical methods will be presented for various scenarios to handle data from sick or deceased animals in research trials.

Key Words: statistics, sick, outliers

ARPAS-Ruminant Nutrition Joint Symposium: Nutrition Models–Where Are We Going in the Next Decade?

425 The role of models in animal nutrition: Research and field applications. J. A. Metcalf* and N. S. Ferguson, *Nutreco Canada Inc*, *Guelph, Ontario, Canada*.

Mechanistic mathematical models are essential to the interpretation of data from scientific experimentation, since they can be used to explain and predict outcomes. The more inclusive the theory behind the model, the more accurately the outcome can be explained or predicted, while at the same time being at risk of error due to inadequacy in the theoretical framework or scientific understanding. Nevertheless a sound biological model offers a powerful tool which requires that the parameters used to design and/or drive the model be fully understood by the user. Modeling and experimental design can be used together in research models, with the model used to identify areas where further investigation is required, while the experimental results can be used either to validate or further develop the model. There are many models used in practical animal nutrition, usually relating to diet formulation, predicting growth and the interaction of nutritional parameters with genetics and environment. Successful field models are those which have a sound mechanistic basis, allowing the incorporation of new technologies, such as rumen active feed additives or digestibility analyses. These technologies must be rigorously tested so that the impact on the model is predictable under field conditions, and training for the users requires that they understand the limitations of the model. Applied models which incorporate financial impacts, such as carcass grading or milk composition, as well as the cost of the nutrition, are essential for better decision making on farm. One extension of this is the ability to generate multiple solutions by allowing nutritional inputs to vary, in order to demonstrate to the producer the cost of changing objectives on milk production or growth. A frequent failing of applied models is at the user interface. Focusing on the ease of use by providing adequate default settings and a logical approach to diet formulation or evaluation can increase the usefulness of a model, and is an area which is undervalued.

Key Words: mechanistic modeling, nutritional models, diet formulation

426 Nitrogen recycling and rumen degradable protein requirements: Quantitative updates to describe microbial requirements, sources, and applications in ration formulation. M. E. Van Amburgh*, E. B. Recktenwald, D. A. Ross, R. J. Higgs, T. R. Overton, and L. E. Chase, *Cornell University*, *Ithaca, NY*.

Estimating the requirements for ruminal nitrogen (N) is a function of microbial demands driven by the availability of rumen fermentable carbohydrates for microbial growth. To improve overall efficiency of use and to reduce the environmental impact of N from cattle, we need to refine our estimates of ruminal N demand and supply to minimize urinary N excretion. The ruminant is an obligate recycler of N designed to conserve N in times of limitations in an effort to maintain an optimal microbial population. The objective of this abstract is to present a quantitative description of the demand and supply of ruminal N for a field application model. Recent work has indicated that recycled N to meet ruminal demands are greater and more constant than previously considered, are a function of intake N and are supplied as ammonia N and peptide N. Further, the current characterization of soluble protein into non-protein N and true protein has under-estimated the peptide content of the soluble protein fraction of feeds, particularly of forages, which has confounded not only estimations of rumen available N, but also metabolizable protein supply. Urea N synthesis is directly related to N intake and review of our work and the literature shows the conversion of intake N into urea N generally ranges from 50 to 70%. The proportion of N intake that reenters the gastrointestinal tract (GIT) as urea-N in the dairy cow is on average 30–45%. Microbial capture of the recycled N is of greatest interest and what impacts efficiency of use. Other sources of rumen available N are endogenous N and microbial turnover. Measurements of endogenous N flows through the rumen range from 5 to 15% of the total N supply, contribute to the rumen available N supply as peptides, are taken up by the microbes and constitute up to 15% of the microbial protein supply, which is comparable to the amount of bacterial N coming from recycled urea N. In addition, the use of N by protozoa and the interaction of protozoa with the bacterial pool will also be discussed.

Key Words: recycled N, RDP, modeling

427 Tackling the variable efficiencies in post-absorptive amino acid utilization. M. D. Hanigan*[1] and E. C. Titgemeyer[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Kansas State University*, *Manhattan*.

Productive performance of all animals including ruminants is nutrient dependent. While excess energy can be stored in times of excess, the ability to store amino acids (AA) is extremely limited. Thus, performance declines when AA supplies are limiting and excess AA are degraded when supply exceeds demand. Matching AA supply and tissue needs thus requires an accurate representation of the efficiency with which absorbed AA are utilized. The current NRC ruminant models assume that conversion of absorbed AA to product is high and constant when supply is at or below requirements. However, there is significant evidence that efficiency of conversion is moderate and variable. The assumption of constant efficiency is predicated on the concept of a single limiting nutrient. That paradigm dictates that productive output will increase in a linear manner in response to a nutrient until another nutrient becomes limiting or genetic potential is reached at which point productive responses will abruptly cease. In this scenario, the metabolic machinery remains constant and substrate supply dictates the rate of production. However, emerging work on the regulation of protein synthesis within the cell clearly supports the role of both AA and energy status as regulators of protein synthesis and AA extraction from blood resulting in continuously variable metabolic efficiency and demand. Further these data are not supportive of the single limiting nutrient approach. We have begun to build models representing both the substrate and regulatory effects of AA, energy yielding substrates, and hormones at the tissue level. These lower level models must be aggregated across tissues and consolidated into a postabsorptive system that is capable of predicting efficiencies for at least the essential AA over a range of conditions. Such a system should allow diet formulation to achieve animal N efficiencies of 40% or greater which will dramatically reduce N loss to the environment and may reduce feed costs.

Key Words: amino acid, requirement model, ruminant

428 VFA production and absorption: Modeling the impacts on energy availability. A. Bannink*[1], J. France[2], J. L. Ellis[2], and J. Dijkstra[3], [1]*Animal Sciences Group, Wageningen UR*, *Lelystad, the Netherlands*, [2]*Centre for Nutrition Modelling, University of Guelph*, *Guelph, Ontario, Canada*, [3]*Wageningen University*, *Wageningen, the Netherlands*.

Current feed evaluation systems aim to match supply and requirement for various nutrients. These systems are largely empirically based and fail to address the underlying mechanisms causing variation in feed digestion and nutrient absorption. Modeling exercises were undertaken to evaluate these mechanisms with a distinct representation of rumen, small intestine and large intestine functioning. Volatile fatty acids (VFA) are the main source of metabolizable energy and propionic acid the main glucose precursor. Their accurate estimation is a prerequisite to understanding variation in ruminant performance. Published VFA prediction methods differ in approach, type of information used, and level of detail represented. Substrate fermented (or bypassing rumen fermentation) is estimated from rates of outflow and degradation. The type of rumen VFA produced is mostly associated with the type of substrate fermented or some general dietary characteristics. But, details of rumen fermentation processes or intraluminal conditions are rarely taken into account. Also, the concepts used and presumptions made in rumen modeling efforts may restrict the possibilities to apply these representations of VFA production. The large intestine delivers a minor fraction of total VFA production (on average some 10%) but variation in hindgut fermentation is large and should be taken into account to obtain accurate estimates of the total tract VFA production. The absorption of VFA depends on the amount of VFA produced as well as on intraluminal conditions and rumen wall characteristics. Intraluminal state and VFA absorption rate are mutually dependent, rumen epithelia strongly adapt to intraluminal conditions, and intraluminal state affects rumen fermentation as the source of VFA. This means that for an understanding of the contribution of enteric fermentation to feed digestion and energy absorbed as VFA, these aspects need to be considered simultaneously.

Key Words: digestibility, VFA, modeling

429 Predicting dry matter intake responses: Modeling the influence of cattle management. R. J. Grant*[1], T. P. Tylutki[2], and P. D. Krawczel[1], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*AMTS LLC*, *Cortland, NY*.

Prediction of dry matter intake (DMI) may be improved by combining measures of the animal physical and social environment with traditional inputs such as body weight, milk production, stage of lactation, or dietary energy density. Rudimentary attempts have been made to adjust DMI predictions directly and indirectly based on environmental factors such as temperature, humidity, wind speed, degree of muddiness, hair coat, and distance walked. In the next decade, nutritional models will increasingly incorporate inputs such as stocking density, grouping strategy, and parity effects that characterize key components of the social environment and influence the animal response to diet. For instance, research shows that short-term daily DMI is unaffected by pen stocking density of stalls and feed manger, but feeding rate within a meal may be increased by up to 25%. Consequently, dynamic models will be required to accurately predict the impact of varying stocking densities on feeding, rumen conditions, and performance. Commingling primi- and multiparous cows often reduces the daily DMI of the younger, subordinate animals and also affects feeding rate and meal patterns. An input for parity will be useful in static and dynamic nutritional models. Time budget analysis of eating and resting times will ensure that adequate time is available for predicted daily DMI. Inputs related to the feeding environment such as feeding frequency and feed availability also affect DMI. The feeding environment specifically determines achievable DMI, in contrast to predicted DMI, and future models must accurately capture the key inputs and how these environmental factors influence feeding behavior and DMI. Currently, research that evaluates the effects of the social and physical environment on behavioral responses as well as DMI is limited, but it will be needed to improve nutritional models over the next decade. The Cornell Net Carbohydrate Protein System model (version 6.1) will be used to illustrate what may be implemented now and in the future to better predict DMI with a specific focus on dairy cattle.

Key Words: dry matter intake, nutrition models, social and physical environment

430 Application of a crossbred model reveals additional genetic variation in reproduction traits of commercial females. S. Bloemhof*[1,2], E. F. Knol[1], A. Kause[2], and I. Misztal[3], [1]*IPG, Institute for Pig Genetics B.V.*, *Beuningen, the Netherlands*, [2]*Animal Breeding and Genomics Centre, Wageningen University*, *Wageningen, the Netherlands*, [3]*Department of Animal and Dairy Science, University of Georgia*, *Athens*.

The objective of our study was to estimate genetic parameters for litter size and farrowing rate in a data set of 2 pure lines and the corresponding crossbreds. Data were obtained from the TOPIGS database and included 91,461 cycle records from 23,432 sows on 33 farms in Spain and Portugal collected from 2003 to 2008. Sows originated from two lines, namely Yorkshire (D) and Large White (I), and from their crosses (DI). Traits studied were litter size (1 to 29) and farrowing rate (0 or 1). Litter size was analyzed using a linear animal model and farrowing rate was analyzed using a threshold model. Both models included fixed effects of parity and number of inseminations, and random effects of herd-year-month, service sire, permanent environment, and the additive animal effect. Within-line and crossbred variance components were estimated via Gibbs sampling. Within-line heritability estimates for litter size were 0.05±0.01 for line D, 0.11±0.01 for line I, and 0.08±0.02 for line DI. Heritability estimates for litter size, obtained from the crossbred model, were 0.06±0.01 for line D, 0.11±0.01 for line I, and 0.14±0.03 for line DI. Genetic correlations for litter size were 0.81±0.15 between line D and line DI, and 0.85±0.06 between line I and line DI. Within line heritability estimates for farrowing rate were 0.06±0.01 for line D, 0.07±0.01 for line I, and 0.02±0.01 for line DI. Heritability estimates for farrowing rate, obtained from the crossbred model, were 0.07±0.01 for line D, 0.07±0.01 for line I, and 0.10±0.04 for line DI. Genetic correlations for farrowing rate were 0.57±0.57 between line D and line DI, and 0.50±0.25 between line I and line DI.
Estimates for genetic variation in litter size almost doubled (0.76 to 1.36) and for farrowing rate more than quadrupled (0.02 to 0.12) when pure line data were added to the crossbred dataset. Genetic correlations between pure line and crossbred data were (considerably) less than unity. These results indicate that pig breeders are advised to introduce crossbred data in their routine evaluations to increase genetic progress at commercial level.

Key Words: pig breeding, crossbred model, reproduction

431 Genetics-nutrition interactions influencing wool spinning fineness in Australian crossbred sheep. A. E. O. Malau-Aduli* and B. Holman, *School of Agricultural Science/TIAR, University of Tasmania*, *Hobart, Tasmania 7001, Australia*.

Our objective in this study was to investigate the interactions between sire genetics, supplement and gender on spinning fineness (SF) in crossbred sheep either grazing or supplemented with dietary protein. Correlations between SF and other wool traits were also investigated. We utilized 5 sires (Texel, Coopworth, White Suffolk, East-Friesian and Dorset) and mated them with 500 Merino ewes at a ratio of 1:100 in individual paddocks. Five hundred of the F1 progeny were raised on rye grass until weaning at 12 weeks of age. Forty of the weaners with initial BW range of 23–31kg (average of 27 ± 3.2 kg) were subjected to a supplementary feeding trial that lasted for 6 weeks. They were randomly assigned to 4 treatment groups in a 5 × 2 × 2 × 2 factorial experimental design representing 5 sire breeds, 2 supplementary feeds (canola and lupins), 2 feeding levels (1 and 2% BW) and 2 sexes (ewes and wethers). SF of the wool was commercially measured at the Australian Wool Testing Authority. The data were statistically analyzed in SAS using MIXED models procedures with sire fitted as a random effect, while sire breed, supplement, level of supplementation and gender and their interactions were fitted as fixed effects. We found highly significant interactions between sire breed × level of feeding ($P < 0.0043$) and sire breed × gender ($P < 0.019$) on SF that ranged from 22.7 ± 0.16 microns in White Suffolk-sired progeny to 25.1 ± 0.21 in East-Friesian crosses. Coopworth-sired sheep supplemented with either canola or lupins at 1%BW recorded the highest spinning fineness. There were significant correlations between SF and wool fiber diameter (0.93), CV of fiber diameter (−0.40), wool curvature (−0.12) and wool yield (0.10). We concluded that the significant interactions between sire genetics and nutrition would impact on choices sheep farmers make in selecting sires and supplementary feeding levels to achieve desirable spinning fineness in their crossbreds. The correlations between spinning fineness and other wool traits should be taken into account when designing breeding programmes.

Key Words: spinning fineness, wool, sheep

432 Effects of index selection and sire breed on crossbred lamb growth and finishing. G. C. Márquez*[1], W. Haresign[2], M. H. Davies[3], R. Roehe[4], L. Bünger[4], G. Simm[4], and R. M. Lewis1,4, [1]*Virginia Polytechnic Institite and State University*, *Blacksburg,* [2]*Aberystwyth University*, *Wales, UK*, [3]*ADAS Rosemaund*, *Preston Wynne, England, UK*, [4]*Scottish Agricultural College*, *Edinburgh, Scotland, UK*.

A lean growth index (LGI) was developed in the UK for terminal sire sheep to increase carcass lean weight keeping fat constant. High and low LGI rams were progeny tested to evaluate the effectiveness of the LGI in improving growth and carcass of their crossbred progeny reared commercially. From 1999 to 2002, Charollais (CH), Suffolk (SF) and Texel (TX) rams were selected for high or low LGI score, differing 5 SD on average. Across years, 15 high and 15 low LGI sires from each breed (90 total) were mated to 4,800 crossbred ewes at 3 farms in the UK. Most rams were used for 2 mating seasons, with some rotated among farms to create genetic links. Live weight of 6,515 lambs was recorded at birth (BWT), 5 weeks (5WK), 10 weeks (10WK), and finishing (FWT) at approximately 11% subcutaneous fat. Data were analyzed with a mixed model in SAS to investigate effects of sire index and breed on body weight and finish age (FAGE). Fixed effects were sire index and breed, their interaction, sex, dam breed, dam age, birth-rearing rank, farm and year, and their interaction. Covariates were d within lambing season for BWT, age for 5WK and 10WK, and subcutaneous fat percentage for FAGE and FWT. Rearing dam and residual were fitted as random effects. Lambs from high vs. low LGI sires were 0.07 ± 0.017, 0.3 ± 0.06, 0.4 ± 0.08, and 1.1 ± 0.1 kg heavier at BWT, 5WK, 10WK, and FWT, respectively. The SF sired lambs were heavier at BWT, 10WK and FWT ($P < 0.05$), while SF and TX lambs were heavier than CH lambs at 5WK ($P < 0.01$). High and low LGI sires did not differ for FAGE ($P > 0.1$), and TX sired lambs finished faster ($P < 0.01$). Birth-rearing rank influenced FAGE ($P < 0.01$): single born and reared lambs finished at 119 ± 1.9 d, multiple born, single reared at 154 d ± 2.1 d, and multiple born and reared at 189 ± 1.1 d. Multiple born and reared lambs from high LGI sires required 2.5 ± 1.2 more d to finish, with breed differences persisting. Selection of sires on LGI produced lambs that were heavier at all ages, and at finish. Irrespective of sire LGI, lambs reared

as singles took the same time to finish but offspring of high LGI lambs sires reared as multiples finished significantly later.

Key Words: sheep, selection index

433 Inclusion of the inbreeding coefficient into models for genetic evaluation of dairy cattle. C. A. García-Munguía, A. Ruíz-Flores*, R. Núñez-Domínguez, R. Ramírez-Vlaverde, and R. López-Ordaz, *Universidad Autónoma Chapingo*, *Chapingo, México, México*.

The objective was to evaluate the effect of the inclusion of the inbreeding coefficient (F) into the models to predict breeding values (BV) of Jersey (J) and Brown Swiss (BS) Mexican dairy cattle. In J the conventional model that included the fixed effect of herd-year-season, and the random genetic additive, permanent environmental, and residual effects; was compared with an alternative model that additionally included F. In BS the models also included the linear covariable of upgrading level, and the linear and quadratic covariables of age of cow at calving. The traits analyzed in J were milk (MY), fat and protein yields per lactation, and the percentages of fat and protein (%P) in milk. In BS only MY was studied. The analyses were done using an animal model and the MTDFREML program. The pedigrees for J and BS included 21,026 and 101,861 animals. Several criteria to compare the results from the alternative models were used. The effect of the inclusion of F into the models depended on the criterion of comparison and the trait. The most notorious change was for the BV for %P in J; the BV for the other traits remained essentially the same with the 2 models in both breeds. The percentage of coincidence among the top 100 sires evaluated with the 2 models ranged from 90 to 98% for all traits. The regression coefficients of BV and their accuracies from the conventional model on the BV and their accuracies from the alternative model ranged from 0.96 to 1.10, and from 1.00 to 1.01, respectively. For the 2 alternative models, the variance components and h^2 estimates were essentially the same. The results suggest that inclusion of F into the models to evaluate genetically Jersey and Brown Swiss Mexican dairy cattle is not necessary.

Key Words: inbreeding coefficient, genetic evaluation, Brown Swiss

434 Jersey-sired and Montbeliarde-sired crossbred heifers compared to pure Holstein heifers for survival and fertility from birth to first parturition. A. R. Hazel*, L. B. Hansen, B. J. Heins, A. J. Seykora, D. G. Johnson, and J. G. Linn, *University of Minnesota*, *St. Paul*.

Jersey x Holstein crossbred (JH) heifers (n = 91) were compared with pure Holstein (HO) heifers (n = 87). Also, Montbeliarde × Holstein crossbred (MH) heifers (n = 66) and Montbeliarde/(Jersey x Holstein) crossbred ((MJH) heifers (n = 101) were compared with HO heifers (n = 188) for survival to 90d, 365d, and to first parturition; days to first service; first service conception rate; interval from first to last service; number of services; age at conception; and gestation interval to first calving. The heifers were born at 2 research facilities of the University of Minnesota, and JH and HO contemporary heifers were born from September 2001 to June 2003, and MH, MJH and contemporary HO heifers were born from September 2003 to May 2008. JH heifers were mated to Montbeliarde AI sires, MH heifers were mated to Jersey AI sires, and MJH and HO heifers were mated to HO AI sires. Independent variables for all traits included breed group. Also, 2-breed versus 3-breed crossbreds nested within breed group was an independent variable for the MO crossbreds. Additionally, effects of location and year of birth were considered. JH and HO heifers did not differ significantly for survival to 90d, 365d, or to first parturition. MH (94.2%) and MJH (94.2%) were similar to HO (91.3%) heifers for survival to 90d. For survival to 365d and to parturition, MH and MJH were similar to HO heifers. Age at first breeding tended ($P < 0.07$) to be less for JH (437d) compared with HO (445d) heifers. MJH (429d) were significantly ($P < 0.05$) younger at first breeding than HO (440d) heifers. For first service conception rate, MH (63.5%) were significantly higher than HOL (48.4%) heifers. Age at conception was significantly ($P < 0.05$) less for JH (462d) than HO (484) heifers. MJH were significantly ($P < 0.01$) younger at conception than HO heifers (457 d versus 480 d). The MH heifers, carrying Jersey-sired calves, and the MJH heifers, carrying HO-sired calves, had longer ($P < 0.01$) gestation length than pure HO heifers (280 d versus 278 d, respectively).

Key Words: crossbreeding, survival, Montbeliarde

435 Productivity over five lactations of Normande, Montbeliarde, and Scandinavian Red crossbreds compared to pure Holsteins in commercial dairies in California. B. J. Heins* and L. B. Hansen, *University of Minnesota*, *Saint Paul*.

Normande (NM) × Holstein (HO) crossbreds (n = 245), Montbeliarde (MO) × HO crossbreds (n = 494), and Scandinavian Red (SR) × HO crossbred (n = 328) cows were compared with pure HO (n = 380) cows for 305-d milk, fat, and protein production and SCS during their first 5 lactations. Cows were housed in 7 commercial dairies in California and calved from June 2002 to January 2009. All HO sires and HO maternal grandsires of all cows were required to have a code assigned by the National Association of Animal Breeders to assure they were sired by AI bulls. The SR was a mixture of Swedish Red and Norwegian Red. Best Prediction was used to calculate actual production (milk, fat, and protein) for 305-d lactations. Adjustment was made for age at calving and milking frequency, and records less than 305 d were projected to 305 d. Independent variables for statistical analysis were the fixed effects of parity, herd-year-season (4-mo seasons within the 7 herds) nested within parity, the genetic level of HO maternal grandsire (linear), genetic group, parity nested within genetic group, and cow within genetic group, which was a random effect. During first lactation, the SR × HO (637 kg) cows were not significantly different from the pure HO (646 kg) cows for fat plus protein production; however, the NM × HO (597kg) cows and the MO × HO (623 kg) cows had significantly ($P < 0.05$) lower fat plus protein production than pure HO cows. Pure HO cows were significantly ($P < 0.05$) higher for fat plus protein than all crossbred cows during second and third lactation. Pure HO (808 kg) cows had significantly ($P < 0.05$) greater fat plus protein than NM × HO (723 kg) and SR × HO (774 kg) cows during fourth lactation. The MO × HO and SR × HO cows were not significantly different from pure HO cows for fat plus protein production during fifth lactation. Pure HO cows and all crossbred cows were not significantly different for SCS for first to fourth lactation, however, during fifth lactation the NM × HO (3.70), MO × HO (3.46), and SR × HO (3.74) cows had significantly ($P < 0.05$) less SCS than pure HO (4.14) cows.

Key Words: crossbreeding, heterosis, production

436 Death rates, survival rates to 5th lactation, and profitability of Normande, Montbeliarde, and Scandinavian Red crossbreds compared to pure Holsteins. B. J. Heins* and L. B. Hansen, *University of Minnesota*, *Saint Paul*.

Normande (NM) × Holstein (HO) crossbreds (n = 251), Montbeliarde (MO) × HO crossbreds (n = 503), and Scandinavian Red (SR) × HO crossbred (n = 321) cows were compared with pure HO (n = 416) cows for death rate and survival to calving a second, third, fourth, and fifth time. Cows were housed in 6 commercial dairies in California and

calved from June 2002 to January 2009. All HO sires and HO maternal grandsires of cows were required to have a code assigned by the National Association of Animal Breeders to assure they were sired by AI bulls. The SR was a mixture of Swedish Red and Norwegian Red. All cows had the opportunity to calve at least 3 times. Four cows (2 HO and 2 SR) did not have the opportunity to calve a fourth time, and 71 cows (10 HO, 4 NM × HO, 33 MO × HO, and 24 SR × HO) cows did not have the opportunity to calve a fifth time. A chi-squared test was conducted for all traits. Ten of 1,075 crossbred cows (0.9%) died before first observation for milk recording, however, 15 of 416 pure HO (3.6%) died before first observation for milk recording. Pure HO (5.3%) cows had significantly ($P < 0.05$) higher death rate on farm than NM × HO (1.2%) cows, MO × HO (2.0%) cows, and SR × HO (1.6%) cows during the first 305-d of first lactation. All crossbred groups had ($P < 0.01$) significantly more cows calving a second, third, fourth, and fifth time than pure HO cows. For pure HO cows, 77% calved a second time; 59% calved a third time, 35% calved a 4 time, and 18% calved a fifth time. Percentage of cows calving a second, third, fourth, and fifth time for NM × HO (88%, 70%, 51%, 28%) cows, MO × HO (88%, 70%, 52%, 32%) cows, and SR × HO (86%, 69%, 50%, 28%) cows were significantly higher than pure HO cows in all cases.

Key Words: crossbreeding, heterosis, reproduction

437 Production, reproduction, health and growth traits in backcross Holstein x Jersey and their Holstein contemporaries. D. W. Bjelland*, N. M. Esser, K. A. Weigel, and P. C. Hoffman, *University of Wisconsin*, *Madison.*

A total of 172 purebred Holsteins and 177 backcross Holstein x Jersey dairy cattle were compared for production, reproduction, health, and growth traits. These animals were born between 2003 and 2006 and were housed in the University of Wisconsin - Madison experimental herd. All animals had Holstein dams, which had been mated to either Holstein sires to produce purebred Holsteins or Jersey × Holstein crossbred sires to produce the backcross animals. Traits were analyzed using a linear mixed model with effects of season of birth, age of dam, pen number as a heifer, sire, birth year of sire, and days in milk. Holsteins had significantly ($P < 0.05$) greater 305-d milk yield (9230 vs. 8311 kg), 305-d mature equivalent milk yield (10836 vs. 9632 kg), peak daily milk yield (35 vs. 32 kg), total milk yield (8913 vs. 7682 kg), and total protein yield (284 vs. 267 kg) compared with the crossbreds. Days open (152 vs. 162 d), services per conception as a heifer (1.43 vs. 1.40) or first parity cow (1.70 vs. 2.03) did not differ, but the proportion of first parity births with calving ease score ≥3 was significantly less in Holsteins than in crossbreds (11 vs. 32%). Health traits included incidence of scours and respiratory problems as a heifer and incidence of mastitis, feet problems and injury during first lactation. Holsteins had a significantly higher incidence of injury (39 vs. 22%) and scours (30 vs. 23%) and a lower incidence of respiratory problems (5 vs. 18%). Holsteins were significantly heavier (630 vs. 559kg), with greater hip height (145 vs. 139 cm), body length (167 vs. 163 cm), heart girth (205 vs. 198 cm), and hip width (55 vs. 53 cm) at 22 mo of age. Results of this study suggest that backcross Holstein × Jersey have decreased production but fail to demonstrate an advantage in health and reproduction when compared with purebred Holsteins.

Key Words: crossbreeding, backcross, Jersey

438 Multibreed genomic evaluation of dairy cattle. K. M. Olson*[1] and P. M. VanRaden[2], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

Multibreed models are currently used in traditional USDA dairy cattle genetic evaluations of yield and health traits, but within-breed models are used in genomic evaluations. Multibreed genomic models were developed and tested using all 19,686 genotyped bulls included in the official August 2009 USDA genomic evaluation. The data were divided into training and validation sets. The training data set were comprised of bulls that were proven (had daughter information) as of November 2004 and totaled 5,331, 1,361, and 506 Holstein, Jersey, and Brown Swiss, respectively. The validation data set had 2,477 Holstein, 410 Jersey, and 182 Brown Swiss bulls that were unproven (no daughter information) in November 2004 and proven by August 2009. A common set of 43,385 single nucleotide polymorphisms (SNP) were used for all breeds. Three methods of multibreed evaluation were investigated. Method 1 estimated SNP effects separately within-breed and was tested by multiple regressions to predict daughter deviations of bulls of another breed. Method 2 estimated a common set of SNP effects from combined genotypes and phenotypes of all breeds. Method 3 solved for correlated SNP effects within each breed estimated jointly using a multitrait model. Multiple regressions were used to test across-breed genomic predicted transmitting ability (GPTA) with within-breed GPTA and parent average (PA). A few effects were significant with method 1, mostly for Jerseys and Holsteins, but estimates were small compared with within-breed GPTA and PA. Across-breed GPTA from method 2 were significant for certain traits in some breeds; correlations between within-breed GPTA and across-breed GPTA ranged between 0.91 and 0.93. Results from method 3 were significant and adjusted coefficient of determinations for protein yield (the only trait tested for method 3) were highest of all methods for all breeds. However, compared with the current within-breed genomic model, method 3 increased the adjusted coefficient of determination by only 0.0097, 0.0042, and 0.0017 for Brown Swiss, Jerseys, and Holsteins, respectively.

Key Words: dairy cattle, genomic evaluation, multibreed

Food Safety: Poultry Aspects

439 Hide and pen floor contamination and transmission of *Escherichia coli* O157:H7 among feedlot steers. K. Stanford*[1], T. P. Stephens[1], and T. A. McAllister[2], [1]*Alberta Agriculture and Rural Development*, *Lethbridge, Alberta Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta Canada*.

Super-shedders, cattle shedding at least 10^4 colony forming units (CFU) of *E. coli* O157:H7, elevate risks of contaminating the food chain and maintaining the organism in cattle populations. As detecting super-shedders in cattle populations is laborious and time-consuming, a study was conducted to evaluate the role of hide and pen-floor contamination by model super shedders (MSS) in transmission of *E. coli* O157:H7 to penned cattle. Steers (n = 48) negative for *E. coli* O157:H7 for 3 wks were allocated to 6 pens, with 2 replicate pens per treatment. Treatment A consisted of 3000 g of feces inoculated with 10^6 CFU spread in artificial fecal pats on the pen floor for d 0 through 4 and 14 through 18 of the study. For treatment B, 100 g of the feces was spread on the perineum of 1 MSS per pen and the remaining feces spread on the pen floor similar to treatment A. Treatment C differed from B in that 50 g of feces was spread on the perineum and 50 g on the brisket of the MSS. Fecal samples, perineal swabs (500 cm^2 area of the rump), freshly voided fecal pats and manila rope samples were collected during the 56 d experimental period. More positive rope samples were found in treatments B and C as compared with A ($P < 0.05$) and steers within treatments B and C were 1.3 times more likely ($P < 0.05$) to shed *E. coli* O157:H7 in their feces than steers in treatment A. Even though loads of *E. coli* O157:H7 were similar in pens, results indicate a heightened importance of hide as compared with pen floor contamination for transmission of this organism to cattle. As cattle within treatments B and C were persistently colonized with *E. coli* O157:H7, this model would be suitable for future studies investigating mitigation of *E. coli* O157:H7 transmission by super-shedders.

Key Words: *Escherichia coli* O157:H7, feedlot cattle, super-shedder

440 Feed supplementation with caprylic acid reduces *Campylobacter* colonization in market aged broiler chickens without altering cecal microbial populations. I. Reyes-Herrera*[1], F. Solis de los Santos[1], M. Hume[2], K. Venkitanarayanan[3], A. M. Donoghue[4], I. Hanning[1], M. F. Slavik[1], V. F. Aguiar[1], J. H. Metcalf[1], P. J. Blore[1], and D. J. Donoghue[1], [1]*Dept. Poultry Science, University of Arkansas,*, *Fayetteville,* [2]*Food and Feed Safety Research Unit, Southern Plains Agricultural Research Center, USDA-ARS*, *College Station, TX,* [3]*Dept. Animal Science, University of Connecticut*, *Storrs,*[4]*Poultry Production and Product Safety Research Unit, USDA-ARS*, *Fayetteville, AR*.

Campylobacter is a leading cause of food-borne illness in the United States and epidemiological evidence indicates that poultry products are a significant source of human infections. Caprylic acid is an 8-carbon medium chain fatty acid which has been reported by our laboratories to reduce *Campylobacter* colonization in chickens. The mechanism of action of caprylic acid, however, has not yet been determined but may be due to changes in the intestinal microflora. To evaluate this possibility, cecal microbial populations were evaluated using denaturing gradient gel electrophoresis (DGGE) in market age broiler chickens fed caprylic acid. In the first trial (n = 40 per trial) chicks were assigned to 4 treatment groups (n = 10 birds per treatment group): Positive controls (*Campylobacter*, no caprylic acid) with or without a 12 h feed withdrawal before slaughter; 0.7% caprylic acid supplemented in feed for the last 3 d of the trial with or without a 12 h feed withdrawal before slaughter. Treatments were similar for Trial 2, except caprylic acid was supplemented for the last 7 d of the trial. On d 14 of age, chicks were orally challenged with *C. jejuni* and on d 42, ceca were collected for DGGE and *Campylobacter* analysis. Caprylic acid supplemented for 3 or 7 d at 0.7% reduced *Campylobacter* compared with the positive controls (approx. Three log reduction), except for the 7 d treatment with a 12 h feed withdrawal period. DGGE profiles of the cecal content showed that caprylic acid had little, if any, effect on the cecal microbial community. The results of this study indicate that caprylic acid′s ability to reduce *Campylobacter* does not appear to be due to changes in cecal microflora.

Key Words: *Campylobacter*, caprylic acid, DGGE

441 Evaluating the prevalence and distribution of *Campylobacter* in newly constructed broiler houses. K. N. Eberle*[1], J. L. Purswell[2], J. D. Davis[1], C. D. McDaniel[1], and A. S. Kiess[1], [1]*Mississippi State University*, *Mississippi State,* [2]*USDA-ARS Poultry Research Unit*, *Mississippi State*.

In 2009, the USDA Food Safety and Inspection Service announced the development of new pathogen reduction performance standards for *Salmonella* and *Campylobacter* both on-farm and in the processing plant. The objective of this study was to evaluate the prevalence and distribution of *Campylobacter* in 3 newly constructed broiler houses for the first 4 flocks placed to determine the necessity for on-farm regulation. Litter and fecal samples were collected from each house at 0, 28, and 48 d of production. Samples were serially diluted and spread onto Campy Cefex agar plates. Two 40-mL water samples were collected each production day and filtered through a 0.45 µm membrane before being placed onto a Campy Cefex agar plate. All plates were purged with a microaerophilic gas and incubated for 36 h at 42°C. Individual plates were screened for characteristic *Campylobacter* colonies and suspect colonies were confirmed using a latex agglutination kit. An additional 50 g of litter was collected from the evaporative cooling inlets, middle, and tunnel ventilation fans to determine litter moisture and pH. Inside and outside temperature and humidity were collected using a weather station. Out of 2300 litter, 900 fecal, and 45 water samples, only 5, 6 and 1 of the collected samples respectively were confirmed *Campylobacter* positive. Litter moisture was different depending on location: the middle contained a higher moisture level (37%) than the evaporative cooling inlets (33%) and tunnel ventilation fans (34%) ($P < 0.05$). Litter pH was not different for day, location or flock. Temperature and humidity averaged 26.8°C and 69.3% inside and 27.6°C and 60.6% outside. In conclusion the newly constructed houses did not show a high prevalence of *Campylobacter*. Litter moisture and humidity were at levels conducive for *Campylobacter* growth. The high litter pH and low temperatures, along with other on-farm management strategies, may have suppressed the ability of *Campylobacter* to colonize the litter.

Key Words: *Campylobacter*, litter, broiler house

442 Colonization of marker and field strains of *Salmonella* Enteritidis and Typhimurium in antibiotic pretreated and non-pretreated laying hens. J. F. Hannah*[1], J. L. Wilson[1], N. A. Cox[2], L. J. Richardson[2], J. A. Cason[2], and R. J. Buhr[2], [1]*University of Georgia, Department of Poultry Science*, *Athens*, [2]*USDA, ARS, Richard Russell Research Center*, *Athens, GA*.

A study was conducted to evaluate the effects of a vancomycin (VNC) pretreatment on the ability of marker (nalidixic acid-resistant) *S*. Enteritidis (SE^M), field *S*. Enteritidis (SE^F), or marker *S*. Typhimurium (ST^M) to colonize within the intestinal and reproductive tracts and translocate to other internal tissues of laying hens. In each of 3 trials, caged hens (76, 26, and 33 wk-of-age) were divided into 6 groups designated to receive SE^M, SE^F, or ST^M, and half pretreated with VNC (n = 12). VNC treated hens received 0.5 mL for 5 d to inhibit gram-positive bacteria. On d 6, all hens were challenged orally, intravaginally and intracolonally with *Salmonella* and placed into separate floor pens on new wood shavings. Two wk post-inoculation, all hens were killed and samples aseptically collected from the ceca, spleen, liver/gallbladder (LGB), upper (URT) and lower (LRT) reproductive tracts, and ovarian follicles, and cultured for *Salmonella*. Results for the 3 hen ages were combined, and Chi-squared and Fisher's exact test were used to identify significant differences ($P < 0.05$) in colonization. Among tissues sampled, there were no significant differences in SE^M, SE^F, and ST^M colonization between VNC pretreated and non-pretreated hens. For the ceca, spleen, and LGB samples, SE^F (83, 100, and 100%) and ST^M (100, 73, and 91%) colonization was significantly greater than SE^M (8, 0, and 8%) colonization in non-pretreated hens. For VNC pretreated hens, SE^F (92, 92, and 83%) and ST^M (100, 75, and 83%) colonization among ceca, spleen, and LGB samples was significantly greater than SE^M (36, 0, and 0%) colonization. Overall colonization of *Salmonella* in the LRT samples was relatively low, ranging from 8 to 42% and SE^F and ST^M were isolated from 8 and 18% URT samples, respectively. Only SE^F (8–17%) was isolated from the ovarian follicles. In conclusion, the VNC pretreatment had no significant effect on the level of colonization of SE^M, SE^F, or ST^M in the tissues evaluated, and these results may provide further understanding of *Salmonella* ecology within laying hens.

Key Words: *Salmonella* colonization, vancomycin, laying hens

443 Evaluation of *Campylobacter* challenge route (in ovo vs. crop) and feed additives to reduce cecal *Campylobacter* in broilers. T. A. Scott*, J. E. de Oliveira, and E. Hangoor, *Provimi Feed Solutions*, *Sint-Stevens-Woluwe, Belgium*.

The objective was to compare challenge route to establish *Campylobacter* in the ceca of broilers and then the efficacy of additives to reduce this reservoir of contamination. Twelve treatment groups (8 cages of 7 male Ross 308 broilers) were evaluated, representing 2 challenge routes (in ovo E17d; gavage to the crop at 3d post hatch) and 6 additives (None, Antibiotic, Adhesion, Probiotic, MCFA and Organic acid). Based on preliminary experiments the optimum in ovo dose of *Campylobacter jejuni* was determined to provide cecal colonization; one half of the chicks were thus infected and then randomized in respective cages separated from other cages by solid plastic sheets 30cm in height. The remaining cages were housed with chicks from the same egg source, but hatched in a commercial hatchery to avoid cross contamination. All chicks were given ad libitum access to feed (6 diets) and water. A basal mash diet, formulated to meet or exceed the NRC broiler requirements was divided into 6 groups and remixed with appropriate feed additive, the chicks were maintained on diets to 18d of age. At 3 d, a excreta (collected on paper for 4 h) sample from each cage was used to establish presence of *Campylobacter*; all cages from in ovo chicks, except those fed an antibiotic were 100% positive; only 3 of the 48 non challenged cages were positive demonstrating low cross contamination. Body weight (18d) was significantly impacted by challenge route (3d Crop > in ovo) and additive (Antibiotic > MCFA = Organic Acid = None = Adhesion > Probiotic), and reflected similar differences in feed intake and FCR. At 11 and 18 d of age 4 broilers/cage (32 / treatment) were monitored for presence of *Campylobacter* by cloacal swab and cecal content swab, respectively. There were no significant differences in number of contaminated birds due to challenge route, although this was numerically higher for in ovo treated birds. Only the Antibiotic diet caused a significant reduction in *Campylobacter* at 11 and 18d of age, the None treated diet was numerically the highest, but not different from Organic Acid = Adhesive = Probiotic = MCFA.

Key Words: *Campylobacter*, in ovo challenge, broilers

444 The efficacy of the natural plant extracts, thymol and carvacrol, against *Campylobacter* colonization in broiler chickens. K. Arsi*[1], J. H. Metcalf[1], I. Reyes-Herrera[1], A. M. Donoghue[2], K. Venkitanarayanan[3], P. J. Blore[1], A. C. Fanatico[1], and D. J. Donoghue[1], [1]*Dept. Poultry Science, University of Arkansas*, *Fayetteville,* [2]*Poultry Production and Product Safety Research Unit, USDA-ARS*, *Fayetteville, AR,*[3]*Dept. Animal Science, University of Connecticut*, *Storrs*.

Campylobacter is one of the most common causes of foodborne bacterial gastroenteritis in the US. Case control studies have demonstrated that consumption or handling of raw or under-cooked poultry products can be directly linked to human campylobacteriosis. Incidence of *Campylobacter* in broiler flocks can range from 70 to 100%, thus a reduction of this pathogen in poultry would greatly reduce the incidence of human disease. Unfortunately, most treatments fail to produce consistent reductions in *Campylobacter* colonization in chickens. Natural plant extracts, such as thymol and carvacrol, have been tested against pathogens like *Salmonella, E. coli, Shigella, Listeria* but their ability to reduce *Campylobacter* in chickens has not been reported. The objective of this study was to determine the efficacy of different concentrations and combinations of thymol and carvacrol in feed to reduce *C. jejuni* in broilers. To evaluate in vivo efficacy, day of hatch birds were feed 0% (controls) or 0.0625, 0.125, 0.25, 0.5, 1.0 or 2.0% thymol or carvacrol or combinations of both (n = 10 chicks/dose). Birds were orally challenged with 5 different *C. jejuni* strains at d 3 and at d 10, cecal samples were collected for *Campylobacter* enumeration. Four different trials were conducted. Data were analyzed by ANOVA using the GLM procedure of SAS and a probability of $P < 0.05$ was required for statistical significance. Significant reductions of *C. jejuni* were observed with 0.25% or 2% thymol, and for 1% or 2% carvacrol. A 2-log reduction was observed with the combination of 0.5% thymol and 0.5% carvacrol. However, treatments did not always produce consistent reduction in *C. jejuni* between trials. These results justify the potential application of these compounds to control *Campylobacter* in chickens, but additional experiments are required to determine the most consistently effective concentrations and combinations of these plant extracts.

Key Words: *Campylobacter*, natural plant extracts, carvacrol/thymol

445 Probability of identifying different *Salmonella* serotypes in poultry samples. J. A. Cason*, N. A. Cox, R. J. Buhr, D. V. Bourassa, and L. J. Richardson, *Russell Research Center, USDA/ARS*, *Athens, GA*.

Recent work has called attention to the unequal competitive abilities of different *Salmonella* serotypes in standard broth culture and plating media. Such serotypes include Enteritidis and Typhimurium that are specifically targeted in some regulatory and certification programs because they cause a large proportion of human salmonellosis. Common lab methods recommend selecting 3 to 5 colonies per plate, but surveys show that many laboratories pick and identify only 1 probable *Salmonella* colony from poultry samples. To explore the implications of *Salmonella* serotypes surviving and growing at different rates during culture and

isolation, spreadsheet formulas were used to calculate binomial and multinomial probabilities of picking serotypes present at various ratios on plates, assuming that 100% of picked colonies are *Salmonella*. When 2 serotypes are present in equal numbers, 6 colonies must be picked to have a 95% probability of finding both serotypes. To identify 3 serotypes under the same conditions, 11 colonies must be picked. If a serotype is outnumbered 10 to 1 by another serotype on a plate, a ratio that has been reported in the scientific literature, 32 colonies must be picked to have a 95% probability of finding the minority serotype. Relatively small survival and growth rate differences can produce large changes in the likelihood of picking a colony of a particular serotype even when that serotype was present in the original sample in equal numbers, so picking one colony per plate can give a distorted picture of what serotypes are in samples. Given the labor and expense of isolating and serotyping suspect *Salmonella* colonies, methods are needed for culturing specific serotypes of interest.

Key Words: *Salmonella*, serotypes, colonies

446 The effect of electrostatic polarization ultraviolet light filters on *Enterobacteriaceae*, and *Salmonella* spp. bacteria in a broiler processing plant hang room. J. C. Butler*, P. A. Curtis, C. R. Kerth, D. E. Conner, and L. K. Kerth, *Auburn University*, *Auburn, AL*.

Poultry processing hang rooms are one of the dirtiest areas of a processing plant. To determine the bioaerosols in the hang room of a particular processing plant, 3 electrostatic polarization light filters utilizing UV light were mounted on 3 different walls of the hang room. Over a period of 24 sampling days, the filters were turned on or off and air and settle plate samples were taken of the air in the room to test for Glucose- and Lactose-fermenting *Enterobacteriaceae*, and *Salmonella spp.* Relative humidity, temperature and wind speed were also taken inside and outside the hang room and number of workers in the room and number of fans on were also noted. Samples were taken every 0, 3, 6, or 9 h into the processing shift. *Enterobacteriaceae*, (Lactose and Glucose) levels were not affected ($P > 0.05$) by filter position. *Salmonella* was low in counts sampled for at all positions, but were not different from one another when comparing position location within the bacteria. The filters had no impact on airborne *Enterobacteriaceae*, (Lactose) during sampling hours 0, 3, and 9 ($P > 0.05$). Results showed a significant decrease for both *Enterobacteriaceae*, bacteria at the 9h sampling period. These results may be indicative of a shift change occurring in between the 6 and 9h where new workers were introduced to the environment. *Salmonella* positive counts were not significantly different regardless of filter use or hour. In general, all of the bacterial counts were low, only reaching approximately 2 logs at their highest. The environmental factors accounted for did not attribute to a large amount of variation for any bacteria sampled. Although, position of the filters were highly correlated for both *Enterobacteriaceae*, types.

Key Words: poultry, bioaerosols, *Enterobacteriaceae*

447 Role of lauric acid-potassium hydroxide concentration on bacterial contamination of spray washed broiler carcasses. A. Hinton Jr.*, J. Cason, R. Buhr, and K. Liljebjelke, *Russell Research Center*, *Athens, GA*.

A series of experiments were conducted to examine reductions in bacterial contamination of broiler carcasses washed in a spray cabinet with various concentrations of lauric acid (LA)-potassium hydroxide (KOH) solutions. Fifty eviscerated carcasses and 5 ceca were obtained from the processing line of a commercial poultry processing facility. An inoculated cecal paste was prepared by mixing 5 g of cecal contents with 0.3 mL of a bacterial suspension containing 10^8 cfu/mL each of antibiotic resistant strains of *Escherichia coli*, *Salmonella* Typhimurium, and *Campylobacter coli*. A 0.1 g portion of the inoculated cecal paste was applied to the skin of each carcass and allowed to dry for 15 min. Inoculated carcasses were then divided into 5 groups of 10 carcasses each, and groups were spray washed with water, 0.25% LA-0.125% KOH, 0.5% LA-0.25% KOH, 1% LA-0.5% KOH, or 2% LA-1% KOH at 80 psi (552 kPA) for 15 s. Washed carcasses were rinsed for 15 s with sterile, deionized water to remove excess LA-KOH before whole carcass rinses were performed for 2 min in 200 mL of sterile phosphate buffered saline. Total plate count bacteria (TPC) and antibiotic resistant *E. coli*, *Salmonella* Typhimurium, and *C. coli* in the rinsates were enumerated, and the pH of the rinsates was measured. Findings indicated that significantly fewer TPC bacteria, *E. coli*, and *Salmonella* Typhimurium were recovered from carcasses washed with 2% LA-1% KOH than from carcasses washed in water. Furthermore, significantly fewer *C. coli* were recovered from carcasses washed in 1% LA-0.5% KOH than from carcasses washed in water, and no *C. coli* were recovered from carcasses washed in 2% LA-1% KOH. The pH of rinsates from carcasses washed in water, LA-0.125% KOH, 0.5% LA-0.25% KOH, 1% LA-0.5% KOH, or 2% LA-1% KOH was 7.27, 7.41, 7.57, 8.00, and 9.94, respectively. Findings indicate that the concentration of LA-KOH plays an important role in the ability of this antibacterial surfactant to reduce bacterial contamination of broiler carcass.

Key Words: lauric acid, potassium hydroxide, spray washing

448 Antimicrobial effect of sodium metasilicate on *Salmonella enterica* serovar Typhimurium and psychrotrophs in ready to cook, skin-on chicken breast meat stored at 4 ± 1°C. C. S. Sharma*, S. K. Williams, and G. E. Rodrick, *University of Florida*, *Gainesville*.

The objectives of this study were to determine the antimicrobial effects of sodium metasilicate (SMS) against *Salmonella* Typhimurium and psychrotrophic organisms in fresh ready to cook skin-on chicken breasts, and to ascertain the effects of the treatments on pH. The chicken breasts were inoculated with *S.* Typhimurium (ATCC 14028), treated with 0% SMS and no inoculum (negative control), 0% SMS and inoculum (positive control), 1% and 2% SMS (w/w), packaged and stored at 4 ± 1°C. All samples were analyzed in duplicate after 0, 1, 3, 5 and 7 d of storage for recovery of *S.* Typhimurium, psychrotrophic organisms and pH measurements. The whole experiment was repeated 3 times. Treating the breast meat with 1% and 2% SMS resulted in low ($P < 0.05$) *Salmonella* counts when compared with the positive control. Chicken breasts treated with 1% and 2% SMS resulted in 1.1 to 1.4 and 2.5 to 4.1 log cfu/g reductions of *S.* Typhimurium, respectively, as compared with positive controls. Psychrotrophic counts for breast meat treated with 2% SMS were lower ($P < 0.05$) than the control samples on all sampling days except d 0. The pH values were higher ($P < 0.05$) for all SMS treatments when compared with the negative and positive controls. This study revealed that SMS could function to control the pathogen *S.* Typhimurium, and extend the shelf life of poultry by retarding the growth of psychrotrophic bacteria, which are the primary spoilage organisms in fresh poultry.

Key Words: sodium metasilicate, *Salmonella*, psychrotrophs

449 Antimicrobial effect of sodium metasilicate marinade on *Salmonella enterica* serovar Typhimurium and psychrotrophs in ready to cook skinless and boneless chicken breast meat stored at 4 ± 1°C. C. S. Sharma*, S. K. Williams, and G. E. Rodrick, *University of Florida*, *Gainesville*.

The objectives of this study were to determine the antimicrobial effects of sodium metasilicate (SMS) marinades against *Salmonella* Typhimurium and psychrotrophic organisms in fresh marinated ready to cook skinless and boneless chicken breast meat, and to ascertain the effects of the treatments on pH. The chicken breasts were inoculated with *S.* Typhimurium (ATCC 14028), marinated in solutions containing either 0% SMS and no inoculum (negative control), 0% SMS and inoculum (positive control), 1% or 2% SMS, packaged and stored at 4 ± 1°C. All samples were analyzed in duplicate after 0, 1, 3, 5 and 7 d of storage for recovery of *S.* Typhimurium, psychrotrophic organisms and pH measurements. Chicken breasts marinated with 1% and 2% SMS had lower ($P < 0.05$) *Salmonella* counts when compared with the positive control at 3 d storage and through 7 d. Chicken breasts treated with 1% and 2% SMS resulted in 0.83 to 0.91 and 1.04 to 1.16 log cfu/g reductions of *S.* Typhimurium, respectively, after 3 d through 7 d of storage as compared with positive controls. The psychrotrophic counts were similar ($P > 0.05$) for all treatments. The pH values for 1% and 2% SMS treatments were higher ($P < 0.05$) when compared with the controls. This study revealed that SMS could function to control the pathogen *S.* Typhimurium, but had no effect on reducing the spoilage microflora when it was used in the marinade.

Key Words: sodium metasilicate, *Salmonella*, psychrotrophs

450 Aviplus treatment improves growth efficiency in broilers and swine but does not affect intestinal populations of experimentally inoculated *Salmonella*. T. R. Callaway*[1], E. Grilli[2], T. S. Edrington[1], N. Krueger[1], R. Anderson[1], D. W. Pitta[3], W. E. Pinchak[3], and A. Piva[2], [1]*USDA/ARS, Food and Feed Safety Research Unit*, *College Station, TX,* [2]*University of Bologna*, *Bologna, Italy*,[3]*Texas A&M University Agrilife Research Station*, *Vernon*.

Organic acids improve growth efficiency in food animals, and can impact the microbial ecology of the gastrointestinal tract. Thus it has been suggested that they could be used to reduce foodborne pathogenic bacterial populations before animals enter the food chain. This study was undertaken to determine the effect of a commercial microencapsulated organic acid product on populations of experimentally inoculated Salmonella populations in swine and broilers. Broiler chicks (n = 192 in 2 replications; 1 d of age) were artificially inoculated with 10^6 CFU S. Typhimurium and randomly assigned to 0g, 0.2 kg, 2 kg, or 10 kg Aviplus/1000 kg feed diets. Feed consumption and weights were measured daily for 7 d. Salmonella populations were analyzed upon sacrifice but no differences in cecal Salmonella populations were found. Aviplus treatment at 0.2 kg/1000 kg feed increased ($P < 0.05$) pen weight, average body weight and average daily gain across the study. Aviplus inclusion at 0.2, 2, and 10 kg/1000 kg feed reduced ($P < 0.05$) feed to gain ratios as well. In another study, newly weaned pigs (7 d of age; n = 24) were blocked by sex and were randomly assigned to either 0g, 3 kg, or 30 kg Aviplus /1000 kg feed diets and fed for 14 d and were weighed and feed intake was measured daily. Pigs were artificially inoculated with 10^7 CFU S. Typhimurium and fecal samples were collected daily for 5 d until sacrifice. Intestinal contents from the rectum, cecum and ileum were collected, as well as ileocecal lymph nodes. No differences in Salmonella populations were found in any compartment, though rectal populations were reduced in swine fed 30 kg Aviplus/1000 kg feed. Feed efficiency (feed to gain) in pigs were increased ($P < 0.05$) by 3 kg Aviplus/1000 kg feed treatment, and ADG and BW was increased by 30 kg Aviplus/1000 kg feed treatment. Collectively, our results indicate that while Aviplus does not affect artificially inoculated Salmonella populations in vivo in these short-term studies, Aviplus treatment increased the feed efficiency of broiler chicks and newly weaned swine.

Key Words: food safety, organic acids

451 Aviplus treatment reduces *E. coli* and *Salmonella* populations in pure and mixed ruminal culture fermentations. T. R. Callaway*[1], E. Grilli[2], and A. Piva[2], [1]*USDA/ARS, Food and Feed Safety Research Unit*, *College Station, TX,* [2]*University of Bologna*, *Bologna, Italy*.

Foodborne pathogenic bacteria can live in the intestinal tract of cattle, swine and poultry and can be transmitted to humans through the food supply or indirectly through animal/fecal contact. Organic acid products have been used as non-antibiotic modifiers of the gastrointestinal fermentation of food animals to improve animal health and performance. However, the impact of these organic acid products on foodborne pathogens remains unknown. Therefore, this study was designed to examine the effects of a commercial organic acid product on populations of the foodborne pathogens, *Escherichia coli* O157:H7 and Salmonella Typhimurium. Pure cultures (2×10^3 CFU/mL) of each pathogen were added to tubes that contained water-solubilized Aviplus added at of 0, 0.1, 0.5, 1, 2, 5, and 10% (w/v; n = 4). Water-solubilized Aviplus reduced ($P < 0.05$) the growth rate and final populations of *E. coli* O157:H7 and S. Typhimurium in pure culture at concentrations greater than 2% w/v. In further in vitro studies, *E. coli* O157:H7 and S. Typhimurium were added to mixed ruminal bacterial fermentations collected from cattle fed a pasture-based diet. The in vitro fermentations contained water-solubilized Aviplus at concentrations of 0, 1, 2, 5, and 10% (w/v; n = 2) and were incubated for 24 h. Aviplus addition reduced ($P < 0.05$) final populations of *E. coli* O157:H7 and S. Typhimurium in the ruminal fluid at concentrations >5% w/v. The A:P ratios from the in vitro ruminal fermentations were reduced ($P < 0.05$) by solubilized Aviplus treatment and total VFA production was not affected, but methane and ammonia concentrations were decreased. Organic acid products, such as Aviplus, can alter the intestinal microbial ecology and enhance animal productivity and health. Under in vitro conditions, solubilized Aviplus can be used to reduce populations of pathogenic bacteria. Intervention strategies to reduce foodborne pathogens that can improve animal performance have the advantage of a food safety intervention that pays for itself financially.

Key Words: food safety, *Salmonella*, organic acids

452 Lamb and cow performance when fed corn silage that has reduced ferulate cross linking. H. G. Jung*[1,3], D. R. Mertens[2], and R. L. Phillips[3], [1]*USDA-ARS*, *St. Paul, MN,* [2]*USDA-ARS*, *Madison, WI,* [3]*University of Minnesota*, *St. Paul*.

Ferulate-mediated lignin/hemicellulose cross linking in grasses reduces in vitro NDF digestibility (IVNDFD). Impact of ferulate cross linking on animal performance was examined in lamb digestibility and dairy cow performance trials using the seedling ferulate ester (*sfe*) corn mutant that reduces cross linking and improves IVNDFD. Digestibility of control (W23) and 2 near-isogenic *sfe* (M04–4 and M04–21) silages was determined with lambs fed ad lib and restricted. Each silage was fed to 4 lambs as the sole ingredient. The same silages were fed to lactating cows in 37% corn silage diets formulated for 29% diet NDF and 70% of NDF from corn silage. A 28-d lactation trial was conducted with 14 cows per diet. Feed intake and milk production were determined. Both trials were analyzed as a randomized complete block using PROC MIXED. Orthogonal contrasts were used to compare W23 to *sfe* lines combined and M04–21 only. The *sfe* silages had fewer ferulate cross links than W23 (0.96, 0.86, and 0.81% of NDF in W23, M04–4, and M04–21, respectively), but the *sfe* mutants had higher NDF and ADL, and lower starch concentrations than W23. The IVNDFD of MO4–21 silage after 24-, 48-, and 96-h was greater than W23, while M04–4 IVNDFD was only greater after 24 h. Lamb ad lib silage intake was greater ($P < 0.05$) for W23 than *sfe* lines combined, but M04–21 did not differ from W23. Digestibility of DM was greater ($P < 0.05$) for W23 than *sfe* at ad lib but not restricted intake, whereas silages did not differ for NDF or starch digestibility at either intake. Lambs were less selective against NDF when fed *sfe* silages ad lib ($P < 0.05$) or restricted ($P < 0.10$). Intake (21.8, 23.4, and 23.3 kg/d for W23, M04–4, and M04–21, respectively) and milk production (38.9, 39.3, and 41.6 kg/d for W23, M04–4, and M04–21, respectively) were greater ($P < 0.01$) for cows fed the *sfe* containing diets. Diet refusals indicated cows selected less against NDF in the *sfe* diets than for W23 diets. The data suggest reduced ferulate cross linking in corn silage had a small positive impact on ruminant performance.

Key Words: ferulate, corn silage, NDF

453 Impact of brown midrib trait and seeding rate on chemical composition and in vitro gas production of pearl millet silage. F. Hassanat*[1], A. Mustafa[2], P. Seguin[3], and R. Berthiaume[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*Department of Animal Science, McGill University*, *Montreal, QC, Canada*, [3]*Department of Plant Science, McGill University*, *Montreal, QC, Canada*.

The impact of brown midrib trait and seeding rate on chemical composition, and in vitro gas production of millet (*Pennisetum glaucum*) silage was investigated in a 2 × 3 completely randomized factorial block design. Regular (RM, variety CFPM101) and brown midrib (BM, variety CFPBMR) millet were seeded at rates of 5, 10, and 15 kg ha^{-1}. Forages were harvested at vegetative stage (pre boot, 2m average height, 8 fully developed leaves) and ensiled in mini-silos for 28 d. Chemical composition of silages was determined as well as in vitro gas production profiles using 24 h incubation in Ankom^{RF} gas production monitoring system. Michaelis-Menten model was used to estimate gas production parameters. Chemical composition of solid and liquid incubation residues was used for degradability calculations. Results showed that both millet cultivars produced well preserved silage with an average pH of 4.2 and 120 g kg^{-1} lactic acid. Brown midrib millet silage contained 5.3% less neutral detergent fiber (NDF), and 32% less acid detergent lignin ($P < 0.05$) than RM. Treatments had no effect on crude protein content, which averaged 130 g kg^{-1}. Asymptotic gas production was similar between the 2 millet types, while degradation rate was 40% higher ($P < 0.05$) for BM than RM. Thus, brown midrib trait reduced ($P < 0.05$) time to degrade 50% and 75% of the silage substrate by 2 and 6 h, respectively. In vitro true dry matter degradability and NDF degradability were 3 and 5% higher ($P < 0.05$) for BM than RM silage. Acetic, propionic and butyric acid concentrations in the liquid residue were all higher ($P < 0.05$) for BM than RM. Microbial protein production efficiency per g substrate was 9% higher ($P < 0.05$) for BM than RM. This is supported by post incubation medium ammonia concentration, which was higher ($P < 0.05$) for RM than BM silage. Seeding rate had no impact on chemical composition or in vitro gas production parameters of millet silage. Quality of BM silage was superior to that of RM silage by providing more substrate for microbial growth and more volatile fatty acids for energy production.

Key Words: millet, brown midrib, in vitro gas production

454 Exogenous fibrolytic enzyme or anhydrous ammonia effects on digestion kinetics of steers fed bermudagrass harvested at two regrowth intervals. J. J. Romero*, A. T. Adesogan, M. A. Zarate, O. C M. Queiroz, J. H. Han, J. H. Shin, C. R. Staples, and W. F. Brown, *University of Florida*, *Gainesville*.

The objectives were to compare effects of fibrolytic enzyme (ENZ, Biocellulase A20) and anhydrous ammonia (AMN, 4% of DM) treatment of 5 and 13-wk regrowths of bermudagrass hay on digestion kinetics in steers. Six individually housed, ruminally-cannulated Brangus steers (BW 216 ± 6 kg) were used in an experiment with a 6 × 6 Latin square design with a 3 (additives) x 2 (regrowth intervals, RI) factorial arrangement. Steers were fed hay in ad libitum amounts supplemented with 2 kg of sugar cane molasses and 0.8 kg of distillers grains daily. In each period, after 14 d of adaptation, ruminal liquid volume, dilution rate, VFA, NH_3-N, and pH were quantified and in situ ruminal DM degradation was measured in triplicate in steers fed the incubated hay. The 5-wk hay had a longer ($P < 0.001$) in situ lag time (2.8 vs. 1.5 h) and contained less ($P < 0.05$) soluble (12.7 vs. 13.6%) and indigestible (40.9 vs. 43.5%) fractions and more ($P < 0.001$) potentially digestible fraction (46.4 vs. 42.9%) than the 13-wk hay. Proportion (mol / 100 mol) of ruminal acetate was greater ($P = 0.002$; 58.3 vs. 56.5) and butyrate was lower ($P = 0.001$; 16.1 vs. 17.8) for steers fed the 5-wk vs. 13-wk hay. Ammoniation increased ($P < 0.05$) concentrations of total VFA (155 vs. 144 mM) and ruminal NH_3-N (15.1 vs. 11.4 mg/dl) and the potentially digestible fraction (50.3 vs. 42.7%) and decreased ($P < 0.05$) the molar proportion of propionate (17.9 vs. 19.1 mol / 100mol) and the indigestible fraction (34.6 vs. 45.3%). Ammoniation also increased the degradation rate of the 13 wk hay (7.4 vs. 5.6% / h; AMN × RI interaction, $P = 0.04$). Enzyme treatment did not affect any of these measurements. Ruminal fluid volume, dilution rate and turnover time were unaffected by additives or RI. Ammoniation improved the digestion kinetics of the hays but enzyme application did not.

Key Words: forage, enzyme, ammonia

455 Effect of chopping or cubing on apparent digestibility of hay when fed to steers. R. Willcutt*[1], B. J. Rude[1], and J. Davis[2], [1]*Animal & Dairy Sciences, Mississippi State University*, *Starkville,* [2]*Agricultural & Biological Engineering, Mississippi State University*, *Starkville*.

Resurged interest in pelleting (cubes) grass has been a result of the push to decrease reliance upon fossil fuels, thereby the cubes can be co-fired in coal furnaces to generate energy production. As such, these cubes may have a dual function that will allow grass producers to determine optimum marketing of cubes based upon economic incentive for either energy production or animal feed. The objective of this study was to evaluate the apparent digestibility of chopped or chopped and cubed hay and its value as a feedstuff for ruminants. Angus (n = 6), Hereford (n = 3), and Charolais (n = 3; total n = 12; 226 ± 19.3 kg) steers were stratified by breed and then randomly assigned into 3 treatment groups: 1) long stem hay; 2) chopped (approx. Fifteen cm) hay; and 3) chopped and then cubed hay. Steers were adapted to their respective diets for14 d, after which they were placed in metabolism crates for 10 d and allowed ad-libitum access to diets and water. The first 3 of the 10 d were used for adaptation to the crates followed by 7 d of data collection. All data was analyzed using the GLM procedures in SAS. There was no difference ($P > 0.05$) for DM intake of the steers consuming the 3 diets (between 4.0 and 4.3 kg/d; 1.8 and 1.9%BW/d). Apparent digestibility of DM (between 61 and 71%, SEM = 3.3), organic matter (between 63 and 73%, SEM = 7.9), NDF (between 63 and 72%, SEM = 3.3), ADF (between 60 and 70%, SEM = 3.9), hemicellulose (between 66 and 75%, SEM = 2.8), and energy (63 and 71%, SEM = 3.2) were not different ($P > 0.05$) among the 3 diets. However, steers consuming long stem hay digested more ($P = 0.0302$) CP (65%, SEM = 5.6) than those consuming chopped hay (39%, SEM = 5.6) with those consuming cubed hay had an intermediate value (51%, SEM = 5.6). Additionally, Steers fed long stem and chopped hay (68 and 63%, respectively, SEM = 3.8) digested more ($P = 0.0071$) fat than those fed cubed hay (47%, SEM = 3.8). For hay producers that are interested in cubing hay for the fuel market, it appears that when prices for cubes used as fuel are reduced, selling cubed hay as a feed may be a viable alternative.

Key Words: cubed hay, digestibility, beef cattle

456 Effect of cutting time and conditioning method on cattle preference for trefoil–grass hay. R. Berthiaume*[1], A. F. Brito[2], and C. Lafreniere[1], [1]*Agriculture & Agri-Food Canada*, *Sherbrooke, QC, Canada*, [2]*University of New Hampshire*, *Durham.*

Ruminants prefer forages cut in the afternoon. However, PM–cut could increase losses due to rainfall, prolonged wilting time, leaching and respiration. Maceration, an intensive mechanical conditioning applied to herbage, can enhance field drying, reduce wilting time and improve animal performance. We hypothesized that maceration would have different effects when applied to forages cut in PM vs. AM. A trefoil-grass field was divided in 4. Half was cut at 18:00(PM) with a mower conditioner. Fifty percent of the PM cut herbage was macerated after 12 h and left to wilt. The other half of the field was cut at 06:00 (AM) the next morning with 50% of the AM cut herbage macerated after 4 h and left to wilt. The 4 hays were field dried, baled at the same time, and chopped before their use. Two preference trials were conducted with the same 6 growing steers. The first trial was conducted in October 2008 whereas the second was conducted in February 2009. During adaptation, hays were offered alone as meals. In the experimental phase, every possible pair of hays (n = 6) was randomly presented for a meal to each of the 6 steers over 6 consecutive days. Dry matter intake was measured after 2, 4, 8, and 24 h. Data were analyzed by multidimensional scaling and by ANOVA with a model including hay and animal effects. During the first trial steers showed a preference for PM over AM-cut hay at every time points ($P = 0.006$). Steers ingested 222, 177, 133 and 38% more DM ($P \leq 0.0001$) from PM than AM-cut hay after 2, 4, 8 and 24 h. In the second trial steers showed no preference for PM over AM-cut hay ($P = 0.51$). Nevertheless, DMI was 57, 60 and 51% higher ($P \leq 0.007$) for PM over AM-cut hay after 2, 4 and 8 h. DMI after 24h was not affected by cutting time. In both trials, there was no effect of maceration and no interaction between cutting time and maceration. Maceration had no effect on the preference of cattle for trefoil–grass hay whether it was cut in the PM or AM.

Key Words: feeding preferences, dry matter intake, conditioning

457 Acceptability of teff hay by horses. S. McCown*, M. Brummer, J. Earing, S. Hayes, and L. Lawrence, *University of Kentucky*, *Lexington*.

Teff hay *(Eragrostis tef)* is a summer annual forage that has recently been introduced to the equine industry in the United States. Teff hay has been fed to horses in parts of the US; however, its relative acceptability compared with other hays has not been reported. Therefore, a study was conducted to evaluate the acceptability of 2 different teff hays when compared with midmaturity alfalfa (A) or timothy (TIM) hay. Two teff varieties were used: Horse Candi (HCT) and Tiffany (TT). The HCT was planted June 8, 2009, and harvested August 16, 2009, in the late heading stage. The TT was planted June 2, 2008, and harvested on July 11, 2008, in the early heading stage. The acceptability of both types of teff was compared with A in experiment 1 (E1) and to TIM in experiment 2 (E2) using 2-choice preference tests. Each experiment used 4 mature mares that had been previously acclimated to individual 3 × 15 m partially covered pens. Mares were offered a different combination of 2 hays each day, so each mare received all combinations in the experiment. The 2 hays were offered in side-by-side hay nets in the pens for 2, 1 h periods on 3 consecutive days. In the first period, 4 kg of each hay was offered to the mares. After an hour, the hay nets were taken away for 1 h. The mares were then offered new hay nets for 1 h with the same hay combination, but with the right-left positions reversed. Hay nets were weighed to determine intake of each hay. In E1, mares consumed more A than HCT (1.66 kg A vs 0.24 kg HCT; $P < 0.05$; SE = 0.25), more A than TT (1.74 kg A vs 0.16 kg TT; $P < 0.05$; SE = 0.25), and more TT than HCT (1.08 kg TT vs 0.24 kg HCT; $P < 0.05$; SE = 0.25). In E2, mares consumed more TIM than HCT (1.54 kg TIM vs 0.12 kg HCT; $P < 0.05$; SE = 0.16), more TIM than TT (1.04 TIM vs 0.66 kg TT; $P < 0.05$; SE = 0.16), and more TT than HCT (0.65 kg of TT vs 0.33 kg HCT; $P < 0.05$; SE = 0.16). When given a choice, mares chose A and TIM over either variety of teff. The mares did discriminate between the 2 teff hays. The reason for the difference in preference between TT and HCT has yet to be determined.

Key Words: preference, horse, hay

458 Nutritive value of North American grasses during establishment. A. E. Lee*[1,4], J. P. Muir[3], B. D. Lambert[1,3], J. L. Reilley[2], and T. R. Whitney[4], [1]*Tarleton State Univ.*, *Stephenville, TX*, [2]*Kika de La Garza PMC*, *Kingsville, TX*, [3]*TX AgriLife Research*, *Stephenville*, [4]*TX AgriLife Research*, *San Angelo*.

Non-native grass species currently used by ranchers can become invasive. To promote the use of native warm-season grasses as forage, more nutritive information is needed. In the spring of 2007 (establishment year), seeds from 3 native grasses [plains bristlegrass (*Setaria vulpiseta* Scribn. and Merr., PBG); multiflower false rhodesgrass (*Chloris pluriflora* Fourn., MFR); and pink pappusgrass (*Pappophorum bicolor* Fourn., PPG)] were collected in south Texas. Plants were then grown in a greenhouse and transplanted into plots (n = 1 to 2/species) within block (n = 4) located in Stephenville, TX, with either no fertilizer or a single spring application of N (67 kg/ha) and P (127 kg/ha) fertil-

izer. During July to November (2007) and April to November (2008), monthly clippings were taken to evaluate effects of fertilization on forage N, NDF, and ADF and in vitro organic matter digestibility (IVOMD) using fistulated steers and goats. During both years, a species × treatment × month interaction ($P < 0.10$) was observed for N. During year 1, N in PBG increased ($P = 0.04$) in September due to fertilization, but average species N increased ($P = 0.02$) due to fertilization in July and September. During year 2, N in PBG increased in July, but unexpectedly decreased in October ($P < 0.04$) due to fertilization. No species × month interaction ($P = 0.19$) was observed for NDF during year 1, but was observed ($P < 0.001$) during year 2. A species × month interaction ($P < 0.001$) was observed for ADF during both years. An animal × species x month interaction ($P < 0.001$) was observed for IVOMD for both years. The IVOMD determined using rumen fluid from goats was greater ($P < 0.02$) for all species during July, October, and November of year 1 and greater ($P < 0.05$) for MFR and PPB during April and May of year 2. Differences in nutrient characteristics and digestibility need to be considered when utilizing these grass species.

Key Words: fiber, native grasses, digestibility

459 Effects of different manure sources and urea on chemical composition of three tropical pasture grasses. O. M. Arigbede*[1,2], U. Y. Anele[1,2], K.-H. Südekum[2], J. A. Olanite[1], A. O. Oni[1], P. A. Dele[1], and J. O. Bolaji[1], [1]*University of Agriculture*, *Abeokuta, Nigeria*, [2]*University of Bonn*, *Bonn, Germany*.

A study was carried out to investigate the effects of different fertilizer types on chemical composition of 3 tropical grasses. The grasses were established in the small ruminant paddocks on the teaching and research farm, University of Agriculture, Abeokuta, Nigeria. The grasses were cut at 10 cm above ground level and sampled 4 weeks before the commencement of the trial and subsequently on monthly basis. A 4 × 3 factorial design was adopted with 4 treatments (control - no manure, urea - 150 kg/ha, caged layers droppings - 250 kg/ha, compost manure - 350 kg/ha) and 3 grass species (*Panicum maximum* (local), *P. maximum* (Ntchisi), and *Pennisetum purpureum*) with 3 field replicates. About 1 kg of each grass species from every plot were cut at 10 cm above ground level, weighed, and oven-dried at 65°C to a constant weight. The plots were maintained weed-free through manual weeding. Manure application generally improved ($P < 0.05$) the chemical composition of the grasses when compared with the urea fertilized and unfertilized ones. Differences ($P < 0.05$) existed between the major nutrient contents with the grasses fertilised with caged layer droppings recording the highest CP concentration (161, 168, and 150 g/kg DM) and the lowest NDF (ash-free) concentration (388, 363, and 448 g/kg DM) for *P. maximum* (local), *P. maximum* (Ntchisi), and *P. purpureum*, respectively. The nutrient contents of the 3 grasses did not differ ($P > 0.05$) between grasses fertilized with caged layer droppings or compost manure. There was also no difference ($P > 0.05$) in the ash content of grasses from the 4 treatments. The use of organic manure proved more effective in enhancing the chemical composition of tropical pasture grasses when compared with those under urea fertilization. Therefore, based on this study organic manure is recommended as a tool for organic ruminant livestock production grazing systems.

Key Words: tropical grass, chemical composition, fertilizer

460 In vitro ruminal fermentation characteristics of anthocyanidin accumulating Lc-alfalfa. A. Jonker*[1,2], M. Gruber[2], Y. Wang[3], and P. Yu[1], [1]*Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Saskatoon Research Centre, Agriculture and Agri-Food Canada*, *Saskatoon, SK, Canada*, [3]*Lethbridge Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Transformed Lc-progeny were previously found to have a decrease initial rate of N and DM degradation but did not survive winter conditions in western Canada. Therefore, the objective of this study was to determine the effect of winter hardy Lc-progeny expressing different phenotypes on in vitro fermentation characteristics. To develop winter hardy Lc-progeny, 3 non-winter hardy transgenic T0 Lc-alfalfa populations 88–19, 88–09 and 88–01 were crossed with 3 winter hardy alfalfa varieties Rangelander, Rambler and Beaver, respectively and harvested at a vegetative pre-bud stage. The Lc-plants were subsequently phenotyped into 3 groups per population in the field based on colors, green (Gr), light purple-green (LP) and purple-green(PG), Ground (1 mm) freeze-dried samples were compared in quad duplicate for their ruminal fermentation characteristics with their non-transgenic (NT) parents using a in vitro gas production technique. The results were analyzed in a completely randomized design with repeated measurement in Proc Mixed of SAS. Anthocyanidin concentration was 0, 103.9, 108.4 and 282.5 µg/g DM in NT, Lc-Gr, Lc-LP and Lc-PG alfalfa, respectively. The NT-alfalfa had the highest ($P < 0.05$) and Lc-Gr alfalfa the lowest ($P < 0.05$) cumulative gas production after 48 h. Average gas production per h, fractional degradation rate (K_d) and half time to maximum gas production were all higher ($P < 0.05$) in NT-alfalfa compared with the 3 Lc-alfalfa phenotypes. At 48-h incubation, concentration of methane in total gas was lower ($P < 0.05$) and concentration of propionic acid was higher ($P < 0.05$) in Lc-LP alfalfa compared with NT-alfalfa, whereas production of total volatile fatty acids (VFA) was similar between Lc-LP and NT-alfalfa. It was also observed that branch chain VFA concentration was higher ($P < 0.05$) and NH3 concentration lower ($P < 0.05$) for the 3 Lc-phenotypes compared with NT-alfalfa after 48-h incubation. In conclusion, all 3 Lc-alfalfa phenotypes accumulated anthocyanidin and fermentation profiles differed between the 3 phenotypes and between non-transgenic alfalfa and Lc-alfalfa.

Key Words: anthocyanidin-accumulating alfalfa, in vitro ruminal fermentation, methane

461 Revisiting heat damaged-protein and ruminal degradation kinetics in heated hays. W. K. Coblentz*[1], P. C. Hoffman[2], and N. P. Martin[3], [1]*US Dairy Forage Research Center*, *Marshfield, WI*, [2]*University of Wisconsin*, *Madison,* [3]*US Dairy Forage Research Center*, *Madison, WI.*

Previous studies utilizing conventional (45-kg) hay bales have shown that acid-detergent insoluble CP (ADICP), ruminal CP degradation rate (K_d), and rumen degradable protein (RDP) are related to various measures of spontaneous heating in simple linear relationships that frequently exhibit relatively high r^2 statistics. However, large-round bales often attain much greater maximum internal bale temperatures (MAX) during storage than conventional 45-kg bales, and these greater temperatures may persist for longer durations of time. Our objective was to use regression techniques to relate ADICP, K_d, and RDP to spontaneous heating within large-round bales of mixed alfalfa-orchardgrass hay, and then to compare these responses to the simple linear relationships observed commonly within conventional 45-kg bale packages. Changes in concentrations of ADICP (poststorage – prestorage; ΔADICP) during storage increased with heating degree days >30°C (HDD), and were best explained with a nonlinear model [$Y = 14.9 – (15.7*(e^{-0.0000019*x*x})$); $R^2 = 0.934$]. A similar quartic response ($Y = -0.000053x^4 + 0.012x^3 – 1.00x^2 + 35.7x - 470.9$; $R^2 = 0.975$) was observed for the regression of ΔADICP on MAX. Changes in K_d during storage (ΔK_d) were best explained with

cubic models for regressions on both HDD ($R^2 = 0.939$) and MAX ($R^2 = 0.876$), and these changes represented an approximate 50% rate reduction in severely heated hays relative to prestorage controls. Within ranges of heating most commonly encountered under field conditions, changes in RDP during storage (ΔRDP) declined in mostly linear relationships with HDD or MAX. However, when severely heated hays also were considered, the relationships became cubic ($Y = -0.0000000079x^3 + 0.000028x^2 - 0.027x + 1.1$; $R^2 = 0.802$) for HDD and quadratic ($Y = 0.025x^2 - 3.04x + 86.5$; $R^2 = 0.734$) for MAX. Generally, responses for ADICP, K_d, and RDP in large-round bales were consistent with the linear nature observed previously within conventional 45-kg bales at low-to-modest increments of heating, but exhibited more complex relationships when heating became more extreme.

Key Words: spontaneous heating, ADICP, ruminal kinetics

462 Effects of spontaneous heating on estimates of energy from alfalfa-orchardgrass hays stored in large-round bales. W. K. Coblentz*[1] and P. C. Hoffman[2], [1]*US Dairy Forage Research Center*, *Marshfield, WI*, [2]*University of Wisconsin*, *Madison*.

Using the summative approach to estimate total digestible nutrients (TDN), truly digestible fiber can be estimated from inputs of: i) protein-corrected NDF and acid-detergent lignin (LIG-METHOD); or ii) protein-corrected NDF and 48-h neutral detergent fiber digestibility (NDFD-METHOD). Our objectives were to assess the relationship between TDN and spontaneous heating, and to describe any differences that may result specifically from the 2 methods of estimating truly digestible fiber. During 2006 and 2007, mixed alfalfa (*Medicago sativa* L.)-orchardgrass (*Dactylis glomerata* L.) hays were obtained from 3 harvests at the same 8.2-ha research site. Following storage of the hays, both options for estimating truly digestible fiber (LIG-METHOD or NDFD-METHOD) were then used via the summative approach to estimate the total concentrations of TDN (TDN-LIG or TDN-NDFD, respectively). Estimates of both TDN-LIG and TDN-NDFD were related to heating degree days >30°C accumulated during storage by various regression techniques. Changes (poststorage – prestorage) in TDN-LIG that occurred during storage (ΔTDN-LIG) were best fitted with a nonlinear decay model in which the independent variable was squared [$Y = (11.7 * e^{-0.0000033*x*x)} - 11.6$; $R^2 = 0.928$]. For changes in TDN-NDFD (ΔTDN-NDFD), a quadratic regression model provided the best fit ($Y = 0.0000027x^2 - 0.010x + 0.4$; $R^2 = 0.861$). Generally, ΔTDN-LIG was 2.0 to 4.0 percentage units lower (more negative) than ΔTDN-NDFD when heating degree days >30°C exceeded 500. For regressions on maximum internal bale temperature, both ΔTDN-LIG ($Y = -0.38x + 16.3$; $r^2 = 0.954$) and ΔTDN-NDFD ($Y = -0.25x + 10.2$; $r^2 = 0.848$) were best fitted by linear models with heterogeneous ($P < 0.001$) slopes and intercepts. In general, TDN-NDFD was greater in heated hays than TDN-LIG, largely because the relationship between NDFD and spontaneous heating was poor. In contrast, TDN-LIG declined more rapidly with spontaneous heating, largely because the LIG-METHOD for estimating truly digestible fiber was sensitive to changes in concentrations of both protein-corrected NDF and acid-detergent lignin.

Key Words: alfalfa hay, spontaneous heating, TDN

Immunology and Pathology Symposium: Immunity, Nutrition, Genomics, and Gut Microbiota

463 Direct fed microbial supplementation alters hosts' immune response and repartitions energy to the immune system. M. D. Koci* and W. J. Croom, *North Carolina State University*, *Raleigh*.

Direct fed microbials (DFMs) are used in animals and humans as dietary supplements to improve health. In recent years, increased scrutiny by the Food and Drug Administration, regarding the use of subtherapeutic levels of antibiotics in food animal production has stimulated new interest in DFMs. Currently, our understanding of the mechanism(s) of action of DFMS and the factors that influence their effects on health and performance is limited. This is due to our incomplete understanding of how the gut microflora and the hosts' tissues communicate; the effects of DFMs on host animal metabolism; our limited understanding of the dynamics regulating the microbial ecosystem in the gut, and our inability to culture and/or identify the majority of the organisms living in the host′s intestine. In spite of these challenges, contemporary studies, using different host species, demonstrate DFMs can, and do, augment health. Although the extent of biological activity varies among different model consortia, there appear to be common mechanisms. These include the prevention of colonization of pathogenic and opportunistic organisms, enhancement of nutrient digestion and absorption, and increased immune function. Research in our laboratory suggests DFMs can mediate changes in host tissue energy partitioning which may help facilitate enhanced immune response. Collectively, published studies underscore both the complexity of the DFM/host interaction, and the need for a greater understanding of how intestinal physiology and immunity are interrelated.

Key Words: direct fed microbials, immunity, animal health

464 Role of antibiotics on gut microbiota and incidence of gangrenous dermatitis in commercial broilers. G. Ritter*[1], G. Siragusa[2], S. Dunham[2], and A. Neumann[2], [1]*Mountaire Farms Inc.*, *Millsboro, DE,* [2]*Danisco*, *Waukesha, WI*.

Gangrenous dermatitis (GD) is a bacterial translocation disease of commercial broilers and turkeys caused by *Clostridium perfringens* (CP) and *Clostridium septicum* (CS). In affected birds, CP/CS that are part of the normal gut flora of poultry escape from the gut and invade target tissues of skin, liver and joints producing rapid toxicosis and death. The incidence of GD in a 1.5M birds per week commercial broiler complex was tracked for 5 years. Increased incidence of GD during the study period was positively correlated to feeding programs containing ionophore coccidiostats (polyether antibiotics) included in grower feed diets fed to broilers from 19 to 28 d of age. A gastrointestinal (GIT) microbiota field study was conducted on 6 GD endemic commercial broiler farms. Four farms were fed a diet including ionophore grower feed (correlated with high incidence of clinical GD) and 2 farms were fed grower feed without ionophores that is not associated with clinical expression of GD. GIT bacterial communities in birds on each farm were characterized using molecular techniques of 16S cloning/sequencing and terminal restriction fragment length polymorphism (T-RFLP) from pooled gut samples collected from 6 presumably healthy birds at 16, 24, 25 and 41 d of age. Results of 16S cloning/sequencing revealed that birds fed ionophores in grower feed had the most *Clostridiaceae* and least *Lactobacillaceae* in their GITs while birds not fed ionophores had the least *Clostridiaceae*. T-RFLP results showed differences in bacterial community profiles and individual T-RFLP peaks between treatment groups. These observed differences may be important to GD disease development and clinical expression.

Key Words: gangrenous dermatitis, antibiotics, commercial broilers

465 Antibiotics disrupt the microbiota-host-pathogen interaction. B. Willing*, *University of British Columbia*, *Vancouver, BC Canada*.

The mucosal immune system is essential for protecting the host from a steady barrage of bacterial, fungal, and viral pathogens that it encounters. However, proper functioning of the mucosal immune system requires continual stimulation by a resident gastrointestinal microbiota. When a healthy microbiota is absent as a consequence of antibiotic therapy or other disturbances, the mucosal immune system fails to control pathogens allowing the host to become sick. Each bacterium affects the immune system in a different way, therefore the effects of an antibiotic regimen on the mucosal immune system are dependent upon which bacteria the antibiotic targets. Understanding the changes in mucosal immunity and how they relate to deviations in gut bacteria will be important in the development of strategies to bolster the mucosal immune system and promote intestinal health.

Key Words: antibiotics, microbiota, host-pathogen

466 Nutrigenomics: Understanding how nutrients influence host innate immunity and modulate host-pathogen interaction. H. Lillehoj*[1], S.-H. Lee[1], D.-K. Kim[1], and D. Bravo[2], [1]*Beltsville Agricultural Research Center, USDA-Agricultural Research Service*, *Beltsville, MD,* [2]*Pancosma S.A.*, *Grand Saconnex, Geneva, Switzerland*.

With anticipated human population growth to 9.5 billion in 2050 (2.5 people every second), we need more efficient and safe animal production system to meet the demands for high-protein meat products. In 2006, the European Union banned antibiotics growth promoters in animal feed due to increasing concerns with the drug uses and resistances for human antibiotics. This new constraints for animal and pharmaceutical industry was the driving force for a new thrust in research to find alternative non-drug dependant strategies for growth promoting and disease control for farm animals. Recently, there has been increasing interest and research activities on the nutrition-based strategy to enhance host immunity, especially using plant-derived products in clinical medicine. However, there is very limited information on the use of phytonutrients in veterinary medicine and knowledge on the nutrient-host gene interaction in poultry is scarce. To best utilize the available information in nutrition, immunity and gut microbiota for developing alternative disease control strategies against poultry diseases, we are applying new technology in nutrigenomics to develop dietary immunomodulation strategy as an alternative to antibiotics in poultry disease control.

Key Words: nutrigenomics, host-pathogen, poultry

Lactation Biology 1

467 The effect of milk accumulation on gene expression in bovine mammary gland. E. H. Wall*[1], J. P. Bond[2], and T. B. McFadden[1], [1]*Department of Animal Science, University of Vermont*, *Burlington,* [2]*Vermont Genetics Network Bioinformatics Core, University of Vermont*, *Burlington*.

We hypothesized that accumulation of milk would influence gene expression in the mammary gland of lactating dairy cows. To test this hypothesis, we enrolled 4 multiparous Holstein cows (150 ± 10 DIM) in a half-udder milk stasis experiment. On d 1 of the experiment, right udder halves were milked at 0430 h and 1430 h. On d 2 of the experiment, right udder halves were milked at 0430 h and mammary biopsies were obtained from both udder halves immediately thereafter. At the time of biopsy, it had been 24 h since left udder halves had last been milked. Using Affymetrix GeneChip Bovine Genome Arrays, we identified 32 genes that were differentially expressed between left (full) and right (empty) udder halves (fold change >1.5; $P < 0.05$). Four of the genes were downregulated in response to milk stasis, whereas 28 were upregulated. Differentially expressed genes were associated with extracellular matrix remodeling, tight junction formation, regulation of blood flow, and apoptosis. In addition, 4 of the differentially expressed genes had been previously identified as candidates for local regulation of milk production in dairy cows. Expression of 2 of these candidates, early growth response-1 (EGR-1) and thrombospondin-1 (THBS-1), was validated using real-time quantitative RT-PCR. Consistent with microarray results, both genes were upregulated in response to 24-h of milk stasis ($P < 0.03$). Immunofluorescence was used to localize expression of EGR-1 protein, which was restricted to epithelia and was uniformly distributed. We conclude that accumulation of milk alters gene expression in the bovine mammary gland. In particular, EGR-1 and THBS-1 have emerged as strong candidates for local regulation of milk production in dairy cows.

Key Words: gene expression, mammary gland, milk stasis

468 Expression of ER stress pathways genes in bovine mammary tissue during the lactation cycle. G. Invernizzi*[1,2], M. Bionaz[1], G. Savoini[2], and J. Loor[1], [1]*University of Illinois*, *Urbana-Champaign,* [2]*University of Milan*, *Milan, Italy*.

Endoplasmic reticulum (ER) has a crucial role in cellular metabolism. Recent studies uncovered a tight relationship between ER stress pathways and lipogenic transcription factors. Mammary gland is subject to extreme metabolic loads at the onset of lactation. Recently, it was discovered that X-box binding protein 1 (XBP1) and eukaryotic translation initiation factor 2-α kinase 3 (PERK) play critical roles in regulating the expression of lipogenic transcription factors such as PPARγ and SREBF1. Furthermore, evidence from non-ruminant cell systems has shown that $p58^{IPK}$ ((DnaJ (Hsp40) homolog, subfamily C, member 3 (DNAJC3)) interacts with PERK to inhibit its eIF2α kinase activity. The latter is induced during the unfolded protein response (UPR) by an ER stress response element in its promoter region. Quantitative real-time RT-PCR of $p58^{IPK}$, PERK and XBP1 in mammary biopsy tissue (n = 5 at each time) was performed at −15, 1, 15, 60 and 240 d relative to parturition. Expression of $p58^{IPK}$ showed peaks ($P < 0.05$) at d 15 and 240 after calving with the highest expression at d 240 (2-fold vs. −15 d). Expression of PERK was similar to $p58^{IPK}$ at d 15 and was significantly increased (1.5-fold) at d 240. A possible unfolded protein response accompanying the sharp increase in milk production after calving (d 15) as well as apoptosis at late lactation (240 d) can partly explain the responses of PERK and $p58^{IPK}$. Preliminary results suggest that the mammary gland experiences ER stress at different stages of the lactation cycle. Further studies could explain better the role of XBP1 in regulation of the ER stress pathways through splicing mechanisms rather than mRNA expression.

Key Words: ER stress, lactation cycle, bovine mammary tissue

469 Effect of dexamethasone and age at induction on milk yields of heifers induced into lactation. A. L. Magliaro-Macrina*[1], A. C. W. Kauf[1], D. A. Pape-Zambito[1], and R. S. Kensinger[2], [1]*The Pennsylvania State University*, *University Park*, [2]*Oklahoma State University*, *Stillwater*.

The objectives of the present study were to determine if age or dexamethasone administration on d 1 and 2 of milking would affect milk production in heifers induced into lactation using estradiol and progesterone. Nonpregnant Holstein heifers at 14 (n = 20; 354 ± 38 kg BW) and 18 mo of age (n = 20; 456 ± 30 kg BW) were randomly assigned to dexamethasone (DEX) or control (CON) treatment groups in a 2 × 2 factorial arrangement with age and DEX as the 2 factors. Heifers were induced into lactation with daily subcutaneous injections of estradiol–17B and progesterone (75 and 250 μg/kg BW/d, respectively) on treatment d 1 to 7. They also received bST every 14 d beginning on treatment d 1. Milking began on treatment d 18 (= d 1 of lactation). DEX (10 mg) was administered on d 1 and 2 following the a.m. milking. CON heifers did not receive DEX. Milk yield from d 2 to 15 of lactation of heifers receiving DEX (7.8 kg/d) was greater ($P < 0.05$), than that of CON heifers (6.0 kg/d) but was similar thereafter until 200 DIM (17.9 kg/d). Milk production to d 11 was similar for 14 and 18 mo old heifers, but milk yield was greater for 18 (19.1 kg/d) than for 14 mo animals (16.7 kg/d) through 200 DIM ($P < 0.01$). Milk fat percent was greater over d 1 to 21 of lactation in DEX (4.48) vs. CON heifers (3.49, $P < 0.01$); milk lactose percent was higher ($P < 0.05$) in DEX (4.40) than CON (4.15) through d 21 of lactation. Day 1 to 7 mean IgG concentration and mass were greater ($P < 0.05$) for 18 (48.1 mg/ml; 41.8 g mass) vs. 14 mo (32.3 mg/ml; 30.0 g mass) old heifers. DEX treatment did not affect IgG content. There were no DEX × age interactions. Administration of DEX to heifers induced into lactation increased d 2 to 15 milk production compared with heifers that did not receive DEX, but not after 15 DIM. DEX appeared to stimulate mammary cell differentiation but did not change the rate of decline of milk IgG concentrations. Higher milk yield and IgG content in 18-mo-old heifers might be due to greater mammary epithelium and/or increased body mass.

Key Words: induced lactation, dexamethasone, dairy heifers

470 Effect of intramammary infusions of fluoxetine (FLX) and 5-hydroxytryptophan (5-HTP) on milk secretion rate and composition in lactating Holstein cows at dry-off. R. J. Collier*1,3, J. L. Collier[1], L. L. Hernandez[2], and N. D. Horseman2,3, [1]*University of Arizona*, *Tucson,* [2]*University of Cincinnati*, *Cincinnati, OH,* [3]*Amelgo*, *Covington, KY*.

Serotonin (5-HT), produced in mammary epithelial cells negatively feeds back on milk secretion via 5-HT receptors in mammary tissue. We hypothesized that increasing 5-HT concentration in milk via inhibiting its reuptake, (FLX) or by increasing the precursor for 5-HT synthesis, 5-HTP would accelerate milk yield at dry-off. Multiparous Holstein cows (45) milked 3x daily and producing at least 20 kg/d were randomly

assigned to once a day milking and one of 3 intramammary treatments (15 cows each) for 3 d. Each infusion was followed by prophylactic antibiotic (Today) on d1 and 2 and Quartermaster and Orbeseal on d 3. The control group (C) received the carrier (sterile H20 and oil at 9:1) The FLX group received 5 mg of FLX and carrier. The 5-HTP group received 5 mg of 5-HTP and carrier. Milk yield and composition samples were obtained daily. Blood samples were obtained by tail venipuncture on d 2 to 4. Rate of milk yield decline was greater for FLX and 5-HTP groups (9.5 and 10.0 kg) compared with C (7.5 kg) on d-1 following initiation of treatments ($P < 0.01$) and did not differ after. Milk lactose, protein and fat % were unaffected by treatment but milk Na:K ratio was increased to 2.8 in FLX treated animals d-2 post-infusion compared with 1.44 in C and 1.78 in 5-HTP treated animals ($P < 0.01$). Plasma lactose was increased 2-fold in FLX treated animals on d-1 post-infusion compared with C and 5-HTP animals ($P < 0.001$). Udder surface temperatures declined as milk yield declined in all animals ($P < 0.001$) and was lower in FLX treated animals than C and 5-HTP treated animals ($P < 0.003$). Rectal temperatures were also reduced in FLX treated animals ($P < 0.03$). We conclude that decrease in milk secretion during the first 24 h after reduction in milking rate from 3x to 1x was accelerated in FLX treated animals. Increase in the milk Na:K ratio and plasma lactose in the FLX groups suggest these treatments altered tight junction function post-dryoff.

Key Words: serotonin, lactation inhibition, dry-off

471 Acute fluoxetine administration accelerates mouse mammary gland involution. L. L. Hernandez*[1], R. J. Collier[2,3], and N. D. Horseman[1,3], [1]*University of Cincinnati*, *Cincinnati, OH,* [2]*University of Arizona*, *Tucson,* [3]*Amelgo*, *Covington, KY*.

Serotonin (5-HT) acts via autocrine-paracrine mechanisms on mammary epithelial cells in a variety of species. In human and bovine mammary epithelial cells, inhibition of the 5-HT reuptake transporter (SERT) with selective 5-HT reuptake inhibitors (SSRIs) exhibit disruption of tight junctions and decreased milk protein mRNA expression. SSRIs act to increase the cellular exposure to 5-HT by preventing reuptake of 5-HT by the cell and eventual degradation. This experiment set out to determine the in vivo effects of fluoxetine (FLX) treatment on lactation in mice. We utilized 7 ICR mice, approximately at 8–10 d of lactation and treated with either a single i.p. injection of sterile saline (CTRL; n = 3) or 40 mg/kg body weight FLX (n = 4). At the time of injection, the number 1, 3, 5 and 7 glands were sealed and the number 2, 4, 6 and 8 glands were left open. Mothers were then returned to their pups for 24 h. After 24 h, lactating dams were sacrificed and the number 1–8 glands were collected from all mothers. Mammary glands were stored in 4% paraformaldehyde overnight, and paraffin embedded and processed for hematoxylin and eosin staining at the Cincinnati Children's Hospital Pathology Research Core. Representative photographs were taken of each gland from each animal and analyzed for alveolar area and number of epithelial cells shed into the alveolar lumen using NIH ImageJ software. The alveolar area and number of epithelial cells shed of 6 alveoli per mammary gland were used for the analysis. Alveolar area was increased in FLX sealed glands relative to CTRL sealed glands ($P = 0.0028$) and in FLX open glands relative to CTRL open glands ($P = 0.04$). The number of epithelial cells shed into the luminal space was increased in FLX sealed glands compared with CTRL sealed glands ($P = 0.0166$) and FLX open glands compared with CTRL open glands ($P = 0.0395$). Results indicate that mammary gland involution was accelerated by systemic FLX treatment in both open and sealed glands compared with CTRL injections.

472 Effects of early ovariectomy on caprine mammary gland parenchyma during prepuberty. L. Finot[1,2], Y. Yart[1,2], and F. Dessauge*[1,2], [1]*INRA UMR 1080 Dairy Production*, *35590, Saint Gilles, France*, [2]*Agrocampus UMR 1080 Dairy Production*, *35000, Rennes, France*.

In ruminants, ovarian hormones (estradiol and progesterone) are absolutely essential for normal mammary development. From birth to puberty, the mammary parenchyma undergoes rapid growth characterized by cell proliferation and expansion of a ductal network into the surrounding fat pad. The objectives of this study were to increase the understanding of biological mechanisms underlying mammary growth and to investigate the role of ovary secretions during early prepubertal caprine mammogenesis. Alpine young goats were ovariectomized (OVX; n = 9) or sham operated (SHAM; n = 9) at 3 periods before puberty (P1 = 1 mo, P2 = 2 mo and P3 = 3 mo after birth). Goats were harvested at 9 mo of age to remove the mammary gland. Ovariectomy did not influence mammary gland weight at any experimental period. Histological observations revealed that adipose tissue was widely represented compared with secretory tissue (parenchyma) in OVX goats. Morphological analysis of mammary tissues indicated that parenchymal structures of OVX goats were negatively affected by ovariectomy with limited lobules and undeveloped ducts. Ovariectomy at P1 and P2 reduced estrogen receptor α at both the transcriptional (P1 = −85% and P2 = −90%) and translational (P1 = −65% and P2 = −70%) levels. In P1 and P2 periods, ovariectomy strongly affected cell-cell adhesion molecules and extracellular matrix protease activities. Lower expression of E-Cadherin (P1 = −78%; P2 = −76%), Pan-Cadherin (P1 = −60%; P2 = −43%) and P-Cadherin (P1 = −86%; P2 = −75%) was accompanied by a decrease of α and β catenins. In addition, the metalloproteinase MMP2 activity was significantly reduced in ovariectomized animals (P1 = −13% and P2 = −8%). No effects were observed with ovariectomy at 3 mo (P3). In conclusion, ovariectomy at 2 mo of age was the most critical for parenchymal development. These findings suggest that ovary secretions are required to initiate mammary epithelial cell proliferation in prepubertal goats.

Key Words: caprine mammary gland, ovariectomy, estrogen

473 Role of miR–15a in the mammary gland and mammary epithelial cells of dairy cows. H. M. Li, C. M. Wang, and Q. Z. Li*, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

MicroRNAs (miRNAs) are a class of small non-coding RNAs consisting of 18–25 nucleotides. They regulate the expression of target genes at the post-transcriptional level by degradation or translational inhibition of the complementary mRNA target sequences. The role of miRNA in mammary gland development and lactation is relatively unknown. In this study, qRT-PCR was used to detect the expression of miR-15a and its target gene growth hormone receptor (GHR) in virgin, pregnancy, lactation and involution physiological stages in the mammary gland of Holstein dairy cows, and 3 cows were sampled at each physiological stage. The results revealed that miR-15a and GHR followed the same expression pattern across different physiological states. The expression of miR-15a and GHR was only increased significantly in the sixth month of pregnancy. In the other developmental periods, the expression of miR-15a and GHR was low. To determine the relationship between miR–

15a and GHR, bovine miR-15a was transfected into bovine mammary epithelial cells (BMEC, a cell culture line established by our laboratory). Experiments were replicated 3 times. After miR-15a was overexpressed by transfection, the extent of the miR-15a were 8.4-fold relative to the endogenous miR-15a and the expression of GHR mRNA and protein decreased ($P < 0.01$ and $P > 0.05$, respectively). Flow cytometry showed that over-expression of miR-15a inhibited the proliferation of mammary epithelial cells ($P < 0.01$). In conclusion, these results revealed that miR-15a inhibited the proliferation of mammary epithelial cells as well as the expression of GHR mRNA and protein level. Therefore, this miRNA may play an important role in mammary gland physiology.

Key Words: miR-15a, GHR, mammary epithelial cell

474 Expression of let–7g in development, lactation and involution of the murine mammary gland. Y. Li, L. Tian, C. M. Wang, and Q. Z. Li*, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

Micro RNAs (miRNAs) play important roles in the development, lactation and involution of the mammary gland. To identify key miRNAs implicated in mammary gland physiology, healthy female kunming mice in different mammary cycle stages were used (12 time points: virgin 28d, virgin 35d, virgin 49d, pregnancy 2d, pregnancy 9d, pregnancy 13d, lactation 2d, lactation 9d, lactation 13d, involution 2d, involution 5d, involution 10d;and 6 mice were used for each time point). The fourth pairs of abdominal mammary gland tissues were prepared under sterile condition and used for microarray (miRCURY LNA Arrays) and qRT-PCR analysis. Total RNA isolated from mammary gland tissues collected across 12 time points was covalently labeled with Hy3, respectively, and hybridized to the array. The microarray contained 4 replicate subarrays. The data analysis used Genepix Pro 6.0, and GeneSpring 7.2 was used for further data analysis. qRT-PCR was used to confirm the microarray results. Finally, the data were analyzed with SPSS by ANOVA. Expression levels of let-7g changed with the mammary cycle. Microarray and qRT-PCR produced similar results for the expression of let-7g, which exhibited significant changes during the mammary cycle. The microarray showed that let-7g was down-regulated in glands collected during pregnancy compared with virgin and involuting glands ($P < 0.05$). qRT-PCR showed that the expression of let-7g was lower in pregnancy ($P < 0.01$), and was relatively higher in virgin, lactating and involuting glands. To identify genomic targets of let-7g, an algorithm named miRanda and Pic Tar was used. The results showed that let-7g target genes were important transcription factors, such as Myc, Map3k1, Map4k3, and Stat3, which play significant roles in the mammary gland. In conclusion, let-7g was identified as a potential regulator of murine mammary gland development, lactation and involution.

Key Words: mammary gland, miRNAs, let-7g

475 Effect of heat stress during the dry period on mammary gland development of dairy cattle. S. Tao*, J. W. Bubolz, B. C. do Amaral, M. J. Hayen, S. E. Johnson, and G. E. Dahl, *University of Florida*, *Gainesville*.

Heat stress during the dry period affects immune status, alters hepatic metabolism and decreases milk production in the subsequent lactation. However, cellular mechanisms involved in the mammary response are unclear. Our objective was to evaluate the effects of heat stress during the dry period on mammary gland development of multiparous cows. Cows were dried off 46 d before expected calving and assigned to 2 treatments, heat stress (HT, n = 15) or cooling (CL, n = 14). Average THI during treatment was 76.6 for all cows, but CL cows had sprinklers and fans that came on when ambient temperatures reached 21.1 0C, whereas HT cows were in the same barn without fans or sprinklers. Rectal temperature (RT) was measured twice daily (0730 and 1430 h) and respiration rates (RR) recorded at 1500 h on a Mon-Wed-Fri schedule from dry-off to calving. After parturition, all cows were housed in a free-stall barn with sprinklers and fans. Milk yield was recorded daily to 147 DIM. Mammary biopsies were taken at dry-off, −20, +2 and +20 d relative to calving from a subset of cows (HT, n = 7, CL, n = 7) and infiltrated with paraffin. Numbers of Ki67 immunopositive epithelial and stromal cells were measured in 4-μm mammary tissue sections from each animal. Total cell numbers were measured following hematoxylin histology and percent proliferation was calculated as Ki67+/ total × 100. Compared with HT cows, CL cows had lower morning and afternoon RT (38.6 vs. 38.8 0C, 39.0 vs. 39.40C, $P < 0.01$, respectively) and lower RR (46 vs. 78 breaths/min, $P < 0.01$). Relative to HT cows, CL cows produced more milk (36.5 vs. 31.6 kg/d, $P < 0.06$). Compared with HT, CL cows had a higher percentage of proliferative epithelial cells at −20 d relative to calving (3.3 vs. 1.3%, $P < 0.05$), but there was no difference in labeled stromal cells ($P > 0.1$). We conclude that heat stress abatement during dry period improves milk production in the subsequent lactation possibly by increasing mammary epithelial cell proliferation during the dry period.

Key Words: heat stress, mammary gland, epithelial cell

476 Characterization of bovine glucose transporter 1 kinetics and substrate specificities in *Xenopus laevis* oocytes. P. A. Bentley[1], Y. Misra[1], A. D. Morielli[2], and F.-Q. Zhao*[1], [1]*Lactation and Mammary Gland Biology Group, Department of Animal Science, University of Vermont*, *Burlington,* [2]*Department of Pharmacology, College of Medicine, University of Vermont*, *Burlington*.

Glucose is essential for milk production as it serves as both a substrate for lactose synthesis and as an energy source. Glucose uptake in the bovine mammary gland therefore plays a key role in milk synthesis. Facilitative glucose transporters (GLUTs) mediate glucose uptake in the mammary gland. GLUT1 is the major facilitative glucose transporter expressed in the bovine gland and has been shown to localize to the basolateral membrane of mammary epithelial cells. GLUT1 is therefore thought to play an important role in glucose uptake during lactation. The objective of this study was to determine the kinetic properties of bovine GLUT1 transport using the *Xenopus* oocyte model. Bovine GLUT1 was expressed in *Xenopus* oocytes by microinjection of in vitro transcribed cRNA and was found to be localized to the plasma membrane, which resulted in increased glucose uptake. This bGLUT1-mediated glucose uptake was dramatically inhibited by specific facilitative glucose transport inhibitors, cytochalasin B and phloretin. Kinetic analysis of bovine GLUT1 was conducted under zero-trans conditions using radio-labeled 2-deoxy-D-glucose and the principles of Michaelis-Menten kinetics. Bovine GLUT1 exhibited a Km of 7.69 ± 1.7 m*M* for 2-deoxy-D-glucose. Transport by bovine GLUT1 was inhibited by mannose and galactose, but not fructose, indicating that bovine GLUT1 may also be able to transport mannose and galactose. Our data provide insight into potential functional properties of GLUT1 in transporting glucose across mammary epithelial cells for milk synthesis.

Meat Science and Muscle Biology: How Does Pre- and Postnatal Muscle Development Affect Meat Composition, Quality and Value?

477 Coordinating myogenesis and angiogenesis: a novel role for the satellite cell in skeletal muscle growth. R. P. Rhoads*, K. L. Flann, and R. E. Allen, *University of Arizona*, *Tucson*.

The cellular basis for postnatal muscle growth and hypertrophy has been realized over the past several decades. Skeletal muscle is extremely responsive to environmental and physiological cues by modifying growth and functional characteristics in accordance with the demands placed on it. This ability extends to instances of injury or trauma, where skeletal muscle exhibits the capacity to regenerate despite being largely composed of post-mitotic, multi-nucleated fibers. The plasticity of skeletal muscle results, in large part, from a population of resident stem-like cells, often referred to as satellite cells. When needed, satellite cells proceed through a terminal differentiation program culminating in fusion competency to participate in myogenic activities. The importance of satellite cell activity to skeletal muscle growth and hypertrophy is underscored when events leading to disruptions in myonuclear accumulation occur during critical growth or repair phases leading to muscle growth deficits that cannot be overcome. Although traditionally viewed exclusively in a myogenic role, new efforts have revealed novel roles, based on spatial, temporal and functional characteristics, ascribed to the satellite cell during muscle growth and repair. For example, the satellite cell location within the skeletal muscle niche and ability to produce numerous growth factors suggest communication between myogenic and angiogenic cell types exist. Recent experiments provide evidence that activated satellite cells initiate a potent pro-angiogenic program that may participate in vascularization of skeletal muscle. Coordination of myogenesis and angiogenesis may therefore be accomplished through the secretion of soluble factors by activated satellite cells.

Key Words: skeletal muscle, satellite cell, angiogenesis

478 The energy metabolism impacts that come along with muscle fiber type and its effect on postmortem metabolism. T. M. Scheffler, J. M. Scheffler, S. Park, A. L. Grant, and D. E. Gerrard*, *Department of Animal and Poultry Sciences, Virginia Tech*, *Blacksburg*.

The meat industry has reduced the variation in product quality through modifications in animal handling protocols and implemented procedures that mask some negative quality attributes. Even so, however, carcasses with poor meat quality remain an inefficiency in the food production chain. Understanding meat quality development, therefore, is of utmost concern to the animal industry. Meat quality development is largely impacted by the rate and extent of postmortem metabolism. Recall muscle consists of a heterogeneous population of muscle cells, which collectively dictate the overall biochemical and contractile nature of muscle. The relationship between these interdependent muscle characteristics is difficult to separate given their intimate function within muscle fibers. Yet, depending on the physiological status of the animal, muscle has the ability to modify its functional characteristics to accommodate a myriad of cues. We have studied this "plastic" nature of muscle to address how muscle fiber type-specific characteristics affect muscle growth and meat quality development. We have utilized repartitioning agents, transgenic mice, and natural mutations to manipulate muscle to better understand underlying mechanisms controlling growth, adaptation, and metabolism. The capacity for lean growth may be determined by muscle fiber type composition, yet various pathways are responsible for this response. Indeed, integration of various signals, such as nutrient availability, energy status, hormones, is necessary to match precisely supply and demand. Moreover, the response to these cues is different in various fiber types and during different phases of growth. AMP activated protein kinase (AMPK) may be key in integrating these cues; it modulates multiple energy production and consumption pathways, and regulates protein turnover. Understanding these mechanisms that contribute to regulation of muscle hypertrophy and contractile and metabolic phenotype are important for optimizing the quantity and quality of meat.

Key Words: meat, muscle, energy

479 How growth and body composition can affect the quality of poultry meat? C. Berri*, E. Le Bihan-Duval, and M. J. Duclos, *INRA, UR083 Recherches Avicoles*, *Nouzilly, France*.

Although poultry products are diverse, the general trend is for portioned and further processed products to increase their market share. In this context, technological quality of poultry meat is an important aspect. In poultry, the processing ability of meat is highly related to the acidification process occurring in muscle post-mortem. This later is mainly determined by the amount of resting glycogen in the muscle at death and by the stress susceptibility of the bird before slaughter. Several studies highlighted the great impact of growth rate and body composition on these parameters in chicken. Indeed, selection for greater body weight or muscle development has induced histological and biochemical modifications of the muscle tissue. More precisely, in fast-growing broiler lines, as fiber size increased muscle glycogen reserve at death decreased and as a consequence breast meat exhibited higher ultimate pH, darker color and reduced drip loss. It has also been observed that lean chickens showed a comparatively lower level of glycogen stores than fat chickens, with again positive consequences on ultimate pH, color and water holding capacity of breast meat. Even though the genetic determinism of meat quality traits as well as the possibility to modulate them by nutrition have been established, the molecular mechanisms involved in chicken meat quality variations are still poorly described. Recently, several genomic programs allowed identifying QTL regions as well as genes and molecular pathways controlling muscle post-mortem metabolism and meat quality. These approaches constitute a promising way to better control and improve chicken breast meat properties. It would allow developing useful breeding tools, such as molecular markers, to select birds with expected meat properties, and help optimizing rearing practices, via the study of gene regulation.

Key Words: poultry meat, growth, genomics

480 ASAS Early Career Award Presentation: Prenatal muscle development affects beef composition and quality. M. Du*, *Department of Animal Science, University of Wyoming*, *Laramie*.

The quality of beef is determined by its marbling and tenderness. Marbling (intramuscular fat) is associated with the number and size of adipocytes. While the size of adipocytes can be increased during the fattening stage, the number of intramuscular adipocytes is largely determined during the late fetal and early postnatal stages. Adipogenesis inside skeletal muscle which forms intramuscular adipocytes are the sites for marbling fat accumulation. On the other hand, connective tissue which is synthesized by fibroblasts contributes to the background toughness of beef. Pre-natal skeletal muscle development involves myogenesis, adipogenesis and fibrogenesis, all of which are mainly derived

from mesenchymal stem cells (MSC). Switching the commitment of MSC from myogenesis to adipogenesis will increase intramuscular adipocytes, but to fibrogenesis will promote intramuscular collagen accumulation. Maternal nutrition and physiological status such as inflammation affects the differentiation of MSC to myogenesis, adipogenesis and fibrogenesis, which could permanently alter the amount of intramuscular fat and connective tissue in offspring skeletal muscle and thus the quality of beef

481 Effect of *Origanium vulgare* on ruminal fermentation, nutrient utilization, and production in dairy cows. J. A. Tekippe*[1], A. N. Hristov[1], K. S. Heyler[1], T. W. Cassidy[1], V. D. Zheljazkov[2], and G. A. Varga[1], [1]*Pennsylvania State University*, *University Park,* [2]*Mississippi State University, NMREC*, *Verona*.

A lactating cow trial was conducted to study the effects of dietary addition of oregano (*Origanium vulgare* L.; 0, control vs. 500 g/d, OV) on ruminal fermentation, total tract digestibility, manure emissions, N losses, milk taste, and dairy cow performance. Eight primiparious and multiparious Holstein cows (80 ± 30 DIM; 6 of the cows were ruminally cannulated) were used in a switch over design with 2, 21-d periods. Cows were fed once daily. The OV material was top-dressed to the TMR. Intake of DM averaged 26 ± 0.83 kg/d and did not differ between treatments. Apparent total tract digestibly of DM, OM, NDF, ADF, crude protein, and total nonstructural carbohydrates did not differ between treatments. Rumen pH and concentration of total and individual VFA, acetate:propionate ratio, and total free amino acids concentration were also not affected by treatment. Ruminal ammonia concentration was increased by OV compared with the control (5.3 vs. 4.3 mmol/L; $P < 0.001$). Blood urea N and glucose concentrations were not affected by treatment. Average milk yield, milk fat, protein, and lactose concentrations, MUN, and SCC were unaffected by diet. Milk sensory parameters were also not affected by treatment. Fat-corrected (3.5%) milk yield and 3.5% FCM feed efficiency were increased ($P = 0.03$ and <0.001) for OV compared with the control (42.2 vs. 40.7 kg/d and 1.63 vs. 1.53 kg/kg, respectively). Ruminal microbial N flow, urinary and fecal N losses, and manure ammonia, methane, and carbon dioxide emissions were similar between treatments. Under the current experimental conditions, supplementation of dairy cow diet with 500 g/d of *Origanium vulgare* did not affect ruminal fermentation, nutrient digestibility, and manure gas emissions. However, there is a potential for increased FCM and feed efficiency of FCM.

Key Words: *Origanium vulgare*, rumen fermentation, milk production

482 Effect of prostaglandin $F_{2\alpha}$ on growth of *Staphylococcus aureus* associated with bovine mastitis. C. A. Autran*[1], A. Ahmadzadeh[1], B. Shafii[1], M. A. McGuire[1], and J. C. Dalton[2], [1]*University of Idaho*, *Moscow,*[2]*University of Idaho*, *Caldwell R & E, ID*.

Some fatty acids inhibit the growth of mastitis-causing *Staphylococcus aureus*. The objective of this study was to determine the bacteriostatic and bactericidal effects of prostaglandin$F_{2\alpha}$ ($PGF_{2\alpha}$) on *S. aureus*. Tryptic soy broths were inoculated (1:100) with an *S. aureus* (Novel) overnight culture and subsequently treated with 0, 0.3, 0.6, 1.2 and 2.4 mg/mL of $PGF_{2\alpha}$ (dinoprost tromethamine). Cultures were incubated for 24 h at 37°C (with shaking at 250 rpm), and sampled at 0 h and every 3 h thereafter to determine growth, as measured by optical density at 600 nm (OD) and colony forming units (log CFU). Data were analyzed by ANOVA repeated measures using mixed procedures. Mean OD and log CFU values were not different between treatments at 0 h. There was an effect ($P < 0.05$) of treatment and treatment by time interaction on mean OD and log CFU. Overall mean OD values for $PGF_{2\alpha}$ treatments were different ($P < 0.05$) from control and decreased with increasing concentrations of $PGF_{2\alpha}$ in a dose dependent manner. Initial OD for treatments and control averaged 0.15 ± 0.11 at 0h, and the control reached 22.6 ± 0.27 at 24 h. In contrast, the 0.3, 0.6, 1.2 and 2.4 mg/mL treatments reached OD values of 15.6, 8.1, 5.47, and 1.1 ± 0.27, respectively at 24 h post-treatment. All $PGF_{2\alpha}$ treatments also differed ($P < 0.05$) in mean log CFU compared with control. Initial log CFU for treatments and control averaged 8.12 ± 0.02 at 0 h, and the control reached 10.5 ± 0.04 at 24 h. The 0.3, 0.6, 1.2 and 2.4 mg/mL treatments reached 9.4, 9.0, 8.1, and 1.8 ± 0.04 log CFU, respectively at 24 h post-treatment. The mean log CFU, over a 24 h period of time, for 0.3mg/mL and 0.6mg/mL were not different from each other. However, mean log CFU for 1.2mg/mL and 2.4mg/mL were different ($P < 0.05$) when compared with each other and also compared with 0.3mg/mL and 0.6mg/mL treatments. These results provide evidence for the first time, that $PGF_{2\alpha}$ has both bacteriostatic and bactericidal effects on the growth of in vitro.

Key Words: *S. aureus*, prostaglandin$F_{2\alpha}$, mastitis

483 Effects of partial replacement of corn grain with high fiber byproducts in calf starter on growth and ruminal pH in dairy calves during weaning transition. A. H. Laarman* and M. Oba, *University of Alberta*, *Edmonton, Alberta, Canada*.

This study evaluated the effects of partially replacing corn grain with high fiber byproducts in calf starter on growth and rumen pH in dairy calves during the weaning transition. Forty-two 2 wk old Holstein bull calves were blocked by BW and experiment start date, and offered one of 3 texturized calf starters. Control starter (CON) contained dry ground corn at 19% of dietary dry matter (DM) in the pellet. For a beet pulp starter (BP) and a triticale dried distillers' grains with solubles (DDGS) starter (DG), dry ground corn was replaced by beet pulp and triticale DDGS at 10% dietary DM. All calf starters contained steam flaked corn and steam rolled barley grain at 19 and 10% of dietary DM, and were formulated to contain 21.5% CP. Calf starter was provided ad libitum up to 2500 g/d. Calves were fed milk replacer (26% CP, 18% fat) at 1200 g/d until wk 5, and 900 g/d and 600 g/d for wk 6 and 7, respectively. Starting wk 8, when calves were completely weaned, hay was provided ad libitum. When a calf consumed at least 2450 g for 3 consecutive days, a small ruminant rumen pH-measuring device (20.6 mm diameter, 138 mm length, 245 g mass) was inserted orally to measure rumen pH continuously for 4 d. Statistical analysis was conducted using mixed procedure of SAS with fixed effects of block and treatment. Average daily gain (1.01 ± 0.02 kg/d) was unaffected by treatment. While mean rumen pH (5.78 ± 0.07) and acidosis duration (857.7 ± 38.7 min/d), time rumen pH was less than 5.8, were not affected by treatment, calves fed DG had more severe acidosis, indicated by a greater area under pH 5.8, than calves fed CON or BP (487.8 ± 57.8 vs 366.4 ± 57.8 and 325.1 ± 52.5 min × pH/d, respectively; $P < 0.05$). Mean rumen pH was positively correlated to hay intake ($r = 0.416$; $P < 0.05$) but not water intake, indicating that hay intake may play an important role in rumen pH regulation during the weaning transition in dairy calves. In conclusion, partially replacing corn grain with high fiber byproducts does not ameliorate, but may exacerbate, rumen acidosis during the weaning transition.

Key Words: rumen pH, calf starter, weaning transition

484 Effect of a pre-synchronization injection of prostaglandin $F_{2\alpha}$ during the voluntary waiting period on dairy cattle. K. D. Baldock*[1], M. E. Wilson[2], and D. L. Smith[1], [1]*Eastern New Mexico University*, *Portales,* [2]*West Virginia University*, *Morgantown*.

It is a common practice on United States dairies to use a prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) injection, during the voluntary waiting period to improve reproductive management. It has been hypothesized that $PGF_{2\alpha}$ will accelerate uterine involution which may decrease the number of days open, while improving first service conception rates. Our hypothesis is that $PGF_{2\alpha}$ given during the voluntary waiting period will improve the reproductive performance of the lactating dairy cow. The objective of this experiment was to administer $PGF_{2\alpha}$ to lactating Holstein dairy cattle during the voluntary waiting period and analyze the effects on first service conception rates, number of days open, services per conception, and days to first service. Lactating, Holstein dairy cows (n = 753) milked 3x per day, were randomly assigned either to the control group (n = 374; no injection of $PGF_{2\alpha}$ between d 30 and 36 postpartum) or treatment group (n = 379; injection of $PGF_{2\alpha}$ between d 30 and 36 postpartum). There were no significant differences ($P > 0.28$) between the treatment and control groups in first service conception rates, number of days open, services per conception and days to first service. Some earlier research suggested a benefit to a pre-synchronization injection of $PGF_{2\alpha}$. However, other researchers reported no benefit. In all cases, low animal numbers may have contributed to inconclusive results. Based on these findings in a large sample group, the common practice of $PGF_{2\alpha}$ administered during the voluntary waiting period of dairy cattle is not a beneficial reproductive management tool.

Key Words: dairy cow, prostaglandin $F_{2\alpha}$, volunteer waiting period

485 Effects of feeding brown midrib corn silage and dried distillers grains with solubles on performance of lactating dairy cows. H. A. Ramirez Ramirez*[1], P. J. Kononoff[1], and K. Nestor[2], [1]*University of Nebraska-Lincoln*, [2]*Dow AgroSciences LLC*, *Wooster, OH*.

Thirty-six Holstein cows (4 fitted with a rumen cannula), averaging 111 ± 35 DIM and 664 ± 76.5 kg BW were used in a replicated 4 × 4 Latin square. The objective was to investigate the effects of 2 corn hybrids, brown midrib (*bm3*) and conventional (DP) corn silages, and the inclusion of dried distillers grains and solubles (DDGS) on milk production and digestibility. In each 28 d period cows were assigned to one of 4 treatments that differed by corn silage hybrid and inclusion rate of DDGS; DP corn silage plus 0% DDGS (CON); *bm3* corn silage plus 0% DDGS (BMR); DP corn silage plus 30% DDGS (CONDG); and *bm3* corn silage plus 30% DDGS (BMRDG). Dry matter intake was affected by hybrid and DDGS ($P < 0.01$); and it was higher for cows consuming diets with *bm3* (25.8 and 24.4 ± 0.47 kg for *bm3* and DP), likewise for cows consuming DDGS (24.3 and 25.9 ± 0.47 kg/d for 0 and 30%). Hybrid and DDGS had an effect ($P < 0.01$) on total tract digestibility of NDF (NDFD). Compared with DP hybrid, NDFD was higher for *bm3* (32.5 vs. 38.1 ± 1.79%). In diets containing DDGS, NDFD was 37.8 and 42.2 ± 1.79% for CONDG and BMRDG. There was an interaction ($P < 0.01$) for total concentration of volatile fatty acids (VFA) and rumen pH as the highly digestible treatment BMRDG resulted in the highest concentration of VFA and the lowest pH. Milk yield was not affected by hybrid nor DDGS ($P > 0.05$) and averaged 30.6 ± 1.09 kg/d. Compared with DP, milk protein yield (MPY) was greater ($P < 0.01$) for *bm3* (0.97 vs. 0.93 ± 0.029 kg/d), similarly MPY was greater ($P < 0.01$) for diets containing DDGS (0.98 vs. 0.92 ± 0.029 kg/d). There was a hybrid by DDGS interaction ($P = 0.02$) for milk fat yield (MFY) resulting in 1.03, 1.08, 0.84 and 0.78 ± 0.045 kg/d for CON, BMR, CONDG and BMRDG. Fat corrected milk (FCM) was only affected by DDGS ($P < 0.01$) and averaged 30.0 and 26.4 ± 1.0kg/d for 0% and 30% inclusions; there was a trend ($P = 0.13$) to increase FCM when cows were fed *bm3* without DDGS. These results indicate that *bm3* corn silage and DDGS increase DMI, NDFD and MPY; however high inclusion of corn silage with 30% DDGS reduces FCM.

Key Words: corn silage, DDGS, nutrient digestibility

486 Effects of equine chorionic gonadotropin administration during the synchronization protocol on luteal volume, progesterone concentration and embryo survival in embryo recipient lactating Holstein cows. A. G. Kenyon*[1], G. Lopes Jr.[1], L. G. D. Mendonca[2], J. R. Lima[1], R. G. S. Bruno[1], and R. C. Chebel[1,2], [1]*Veterinary Medicine Teaching and Research Center, University of California Davis*, *Tulare,* [2]*Department of Veterinary Population Medicine, University of Minnesota*, *Saint Paul*.

Objectives were to determine the effects of treating embryo recipient lactating dairy cows with equine chorionic gonadotropin (eCG) during the synchronization protocol on luteal volume, progesterone concentration (P4) and pregnancy per embryo (P/ET). Cows not inseminated received the Presynch-Ovsynch (d −35 PGF, d −28 CIDR, d −21 PGF and CIDR removal, d −9 GnRH, d −2 PGF, d 0 GnRH) and cows inseminated started the resynchronization protocol (d −16 GnRH, d −9 GnRH, d −2 PGF, d 0 GnRH) 24 d after AI. Cows were randomly assigned to receive (eCG, n = 139) or not receive (control, n = 152) 800 IU of eCG on d −7. Blood was sampled on d −9, −2, 0, 7, and 14 and ovaries were examined by ultrasound on d −9, −2, and 7. Cows bearing a corpus luteum (CL) on d 7 received embryo transfer (ET). Pregnancy was diagnosed at 23 and 60 d after ET. Cows treated with eCG had more ($P = 0.03$) follicles >10 mm on d −2 than control cows (2.3 ± 0.1 vs. 1.9 ± 0.1) and there was ($P = 0.04$) an interaction between treatment and parity because eCG primiparous cows had more follicles >10 mm in diameter on d −2 than control primiparous cows (2.5 ± 0.1 vs. 1.7 ± 0.1), but there was no difference between multiparous cows (2.1 ± 0.1). Proportion of cows with estrous cycle synchronized from d −9 to d 0 was smaller ($P = 0.05$) for eCG treatment (61.0 vs. 71.7%) and fewer ($P = 0.03$) eCG cows received ET (79.1 vs. 87.5%). Among cows receiving ET, proportion with multiple CL on d 7 was not ($P = 0.35$) affected by treatment. Among cows receiving ET, eCG treatment increased ($P < 0.01$) total CL volume on d 7 (8.4 ± 0.4 vs. 6.6 ± 0.4 cm3) and tended ($P = 0.12$) to increase P4 between d 7 and 14 (4.1 ± 0.2 vs. 3.7 ± 0.2 ng/mL). Interaction between treatment and parity tended ($P = 0.07$) to affect P/ET at 60 d because eCG increased P/ET in multiparous cows (30.3 vs. 21.3%) and reduced P/ET in eCG primiparous (16.3 vs. 27.5%). Treatment with eCG reduced proportion of cows eligible to receive ET and only increased P/ET of multiparous cows.

Key Words: embryo transfer, equine chorionic gonadotropin, lactating Holstein cow

487 Adjusting milk replacer intake during heat stress and non-heat stress as a means of improving dairy calf performance. T. M. Chavez*, T. A. Wickersham, and G. A. Holub, *Texas A&M University*, *College Station*.

We evaluated the effects of varying planes of nutrition and heat stress on dairy calf performance. Holstein bull calves < 4 d of age were randomly assigned to 1 of 6 treatments arranged as a 2 × 3 factorial. The factorial consisted of 2 locations: inside (INS) or outside (OUT) and 3 feeding strategies: increasing amounts of milk replacer from 1.1% BW to 1.5% BW (INC), constant at 1.1% BW (CON), or decreasing from 1.6% BW to 1.2% BW (DEC). Provision of milk replacer was increased by 0.1% of BW weekly for INC and decreased by 0.1% of BW for DEC. Prior to initiating milk replacer treatments on d 9 all calves received 1.1% milk replacer per day. The BW used to determine the amount of

milk replacer fed was determined twice weekly. Calves had ad libitum access to commercial starter feed and water. Starter intake, water intake, and fecal score (1 to 4) were recorded daily. Respiration rates and rectal temperatures were collected twice daily at 0600h and 1800h. Temperatures averaged 23.0 ± 4.6 and 30.8 ± 8.5°C for INS and OUT, respectively; correspondingly, THI averaged 66.3 and 79.7 for INS and OUT, respectively. Over the 42 d study ADG was higher ($P < 0.01$) for INS calves compared with OUT (0.77 vs. 0.62 kg/d); however, no significant differences among feeding strategies were observed. Calves INS consumed more starter than those OUT (1.71 vs. 1.31 kg/d; $P < 0.01$). OUT calves had greater water intake than INS (3983 vs. 2228mL/d; $P < 0.01$). INS had greater AM rectal temperatures (101.74 vs. 101.52; $P < 0.01$) while OUT exhibited greater PM rectal temperatures (102.10 vs. 101.86; $P < 0.01$). Respiration rates for OUT were greater ($P < 0.01$) in the AM and PM than INS (35.78 vs. 33.27 and 46.82 vs. 34.65, AM and PM, respectively). Alternate milk replacer feeding strategies were not effective in ameliorating the negative effects of heat stress nor did feeding strategy impact calf performance in animals subject to a more favorable environment.

Key Words: heat stress, dairy calves, milk replacer

488 Comparison of postpartum health, uterine involution, and resumption of ovarian cycles of Holstein and crossbred dairy cows. L. G. D. Mendonca*, C. C. Abade, E. M. da Silva, and R. C. Chebel, *Department of Veterinary Population Medicine*, *Saint Paul, MN*.

Objectives were to evaluate whether Holstein (HO) and Montbeliarde sired crossbred dairy cows (MS) differ in regards to postpartum health, uterine involution, and resumption of ovarian cycles. Cows (HO = 46 and MS = 43) were enrolled in the study 45 d before expected calving date. Cows were examined daily from 0 to 14 DIM for diagnosis of pyrexia (>39.5°C), retained fetal membranes (RFM), puerperal metritis, ketosis, and displacement of the abomasum (DA). At 24 DIM cows were examined by vaginoscopy for diagnosis of clinical endometritis. Starting at 14 DIM cows were examined by ultrasound every third day until 42 DIM and volume of the previous gravid and non-gravid uterine horns were recorded as well as number and size of corpora lutea (CL) and follicles class II (5-9 mm) and class III (>9 mm). At 42 DIM cytology of the uterus was performed for diagnosis of sub-clinical endometritis. Incidences of RFM (HO = 6.5, MS = 7.0%; P = 0.89), metritis (HO = 13, MS = 4.7%; P = 0.12), DA (HO = 2.2, MS = 0%; P = 0.95) were not different between by breed, but HO cows tended (P = 0.07) to be more likely to have pyrexia (HO = 54.4, MS = 34.9%) and were (P = 0.03) more likely to have at least one of the diseases described above (HO = 56.5, MS = 34.9%). MS cows were (P = 0.01) less likely to have endometritis (HO = 47.8, MS = 22%), consequently MS cows tended (P = 0.07) to have smaller uterine discharge score (HO = 1.7±0.2, MS = 1.1 ± 0.3). There were no (P = 0.97) differences in incidence of sub-clinical endometritis (HO = 14.3, MS = 10%). Breed was not associated with volume of gravid (P = 0.70) and non-gravid (P = 0.27) uterine horns from 14 to 42 DIM. Although HO cows had (P = 0.01) more follicles class III from 14 to 42 DIM (1.6 ± 0.1 vs. 1.2 ± 0.1), MS cows tended (P = 0.07) to be more likely to ovulate by 42 DIM (75.6 vs. 90.2%). Holstein cows were at higher risk for puerperal disorders and tended to be less likely to ovulate by 42 DIM.

Key Words: postpartum health, Holstein, crossbred

Nonruminant Nutrition: Amino Acids 2

489 Impact of sulfur amino acid intake and immune system stimulation on pathways of sulfur amino acid metabolism at transcriptional level in growing pigs. A. Rakhshandeh*[1], A. Holliss[2], N. A. Karrow[1], and C. F. M. de Lange[1], [1]*University of Guelph, Department of Animal and Poultry Science*, [2]*University of Guelph, Advance Analysis Centre*, *Guelph, Ontario, Canada*.

Sulfur amino acid intake (SAA) and immune system stimulation (ISS) alter post-translational metabolism of SAA. In this study we investigated the impact of SAA intake and ISS on expression of key regulatory genes that control the pathways of SAA metabolism in different tissues of pigs. Restricted-fed barrows (BW 21.5 kg) were allotted to one of 2 levels of SAA intake (1.1 and 3.2, g/d) and injected with either saline (n = 8) or increasing amounts of *Escherichia coli* lipopolysaccharide (n = 16) every 48 h for 7 d. Pigs were then killed for the collection of liver, spleen and ileum tissues for total RNA extraction. Tissue and an internal standard (KANr) RNA were then reverse transcribed. Expression was simultaneously determined by multiplex PCR amplification of cDNA from tissues, the housekeeping gene (β-2-microglobulin) and the internal standard in the presence of their corresponding florescent labeled primers. The interactive effect (ISS × SAA) resulted in upregulation of adenosylhomocysteinase (AHCY) at higher level of SAA intake in liver of ISS pigs ($P < 0.01$). No interactive effect on other studied genes was observed. Increased SAA intake upregulated cysteine dioxygenase (CDO1), 3-mercaptopyruvate sulfurtransferase (MST) and cysteine sulfinic acid decarboxylase (CSAD) in liver ($P < 0.05$). Expression of CDO1, MST and cystathionine β-synthase (CBS) in liver was upregulated by ISS. However, ISS downregulated methionine adenosyltransferase 2 (MAT2) in liver ($P < 0.05$). Expression of methionine synthase (MTR) and cystathionine γ-lyase (CTH) was not affected by the treatments. Results of gene expression in spleen and ileum are forthcoming. This study suggests that the SAA metabolism pathways are changed at transcriptional level by ISS and SAA intake.

Key Words: sulfur amino acids, immune system stimulation, gene expression, multiplex PCR

490 The effect of feeding heavy and medium weight nursery pigs increased levels of amino acids on pig performance. J. L. Pietig* and C. E. Hostetler, *South Dakota State University*, *Brookings*

A study was conducted to determine the effect of feeding increased levels of amino acids to nursery pigs, which were heavy and medium weight at weaning. A total of 144 (n = 144) crossbred, mixed sex pigs (21.7 d of age) was used in the study. A 3 phase feeding program was used to mimic industry practice. Treatments consisted of nursery diets with increased levels of lysine, methionine, threonine and tryptophan. The control diet was designed to meet industry standards (IS; n = 36). Dietary concentrations of the aforementioned amino acids were increased above the control diet by 10% (+10; n = 36), 20% (+20; n = 36), and 30% (+30; n = 36) using synthetic amino acids. Pigs were blocked by body weight (Heavy; 7.87 kg BW and Medium; 5.88 kg BW) at weaning. Pigs were weighed at trial initiation and at each diet change; average daily feed disappearance (ADFD) was determined for each phase. All pigs were bled on d 4, 11, and 28 after initiation of the trial for determination of plasma urea nitrogen (PUN) levels. In phase 1 there was a significant effect of treatment on ADG (0.177 vs. 0.156, 0.150, 0.144 Kg; +10 vs. IS, +30, +20 respectively; $P < 0.05$) and feed to gain efficiency (F:G; 1.31 vs. 1.19, 1.18, 1.11; +20, +30, IS, +10 respectively; $P < 0.05$). In period 2 there was an effect of treatment on ADFD (0.367 vs. 0.412, 0.418, 0.448 Kg; +30, +20, +10, +IS respectively; $P < 0.05$) and PUN levels (13.23 vs. 8.55, 8.28, 7.741; IS, +20, +30, +10 respectively; $P < 0.05$). Also, PUN levels were affected by weight (10.83 vs. 8.07; Heavy vs. Medium respectively; $P < 0.05$). In phase 3 there was no significant effect of treatment on performance or PUN levels. Over the entire trial, there was a significant effect of treatment on F:G (1.38 vs. 1.42, 1.43, 1.464; +10, +30, +20, IS; respectively; $P < 0.05$) and PUN was effected by weight (12.707 vs. 10.328; heavy vs. medium; $P < 0.05$). These results indicate that there may be benefit to feeding higher levels of amino acids to nursery pigs and that medium weight pigs may benefit from increased amino acid levels compared with heavy weight pigs.

Key Words: swine, nutrition, amino acids

491 Amino acid digestibility in heated soybean meal fed to growing pigs. J. C. González*[1,2], B. G. Kim[2], A. Lemme[3], and H. H. Stein[2], [1]*National University of Colombia*, *Bogota, Condinamarca, Colombia*, [2]*University of Illinois*, *Urbana,* [3]*Evonik Degussa GmbH*, *Rodenbacher Chaussee, Hanau, Germany*.

Excessive heat treatment during processing may lead to destruction of AA and the formation of biologically unavailable AA-carbohydrate complexes (i.e., Maillard formation). The objective of the present experiment was to determine the effects of heat treatment of soybean meal (SBM) on standardized ileal digestibility (SID) of AA by growing pigs. Ten growing barrows (average initial BW: 25.3 ± 2.04 kg) were individually fitted with a T-cannula in the distal ileum and used in the experiment. Pigs were allotted to a replicated 5 × 5 balanced Latin square design with 5 diets and 5 periods. Four sources of SBM were prepared by 1) no heat treatment, 2) autoclaving at 125°C for 15 min, 3) autoclaving at 125°C for 30 min, or 4) oven drying at 125°C for 30 min. Four diets contained each of the 4 SBM sources as the sole source of AA. A N-free diet was used to estimate basal endogenous losses of AA. The SID of CP and all AA in SBM linearly decreased as the time of autoclaving increased from 0 to 30 min ($P < 0.01$; Table 1). Oven drying at 125°C for 30 min only tended to reduce the SID of CP and AA in this study. It is concluded that heat treatment in the form of autoclaving at 125°C impairs the digestibility of AA in SBM.

Table 1. Standardized ileal digestibility of CP and AA in soybean meal that has either not been heated, autoclaved (AC) or oven-dried (OD)[1]

	Soybean meal					
Item	Not heated	AC at 125°C for 15 min	AC at 125°C for 30 min	OD at 125°C for 30 min	SEM	P-value
CP, %	93.1[a]	88.8[a]	84.0[b]	91.4[a]	1.48	< 0.01
Lys, %	93.0[a]	89.3[b]	84.2[c]	91.3[ab]	1.21	< 0.01
Met, %	93.2[a]	91.1[a]	88.3[b]	92.4[a]	0.91	< 0.01
Thr, %	89.2[a]	87.1[ab]	83.5[b]	86.1[ab]	1.45	< 0.01
Trp, %	90.9[a]	88.0[ab]	83.8[b]	88.4[a]	1.37	< 0.01

[1]Each least squares means represents 10 observations.

Key Words: amino acid, digestibility, soybean meal

492 Effects of balanced protein level on growth performance and carcass composition of growing-finishing pigs. N. W. Shelton[1], R. D. Goodband[1], M. D. Tokach[1], S. S. Dritz[1], J. L. Nelssen[1], J. M. DeR-

ouchey[1], M. S. Redshaw[2], and J. K. Htoo*[2], [1]*Kansas State University, Manhattan,* [2]*Evonik Degussa GmbH, Hanau, Germany*.

A total of 1,003 barrows and gilts (PIC 337; initial BW of 51.5 kg) were used in a 88-d study to determine the effects of varied levels of balanced protein (BP) on growth performance and carcass characteristics. Balanced protein refers to balancing dietary AA according to the ideal protein ratio at least for the first 4 limiting AA. In a completely randomized design, 3 corn and soybean meal-based experimental diets were tested over 2 phases, including a growing phase (d 0–28; 51–79 kg BW) and a finishing phase (d 29–88; 79–130 kg BW) using 6 replicate gilt and 7 replicate barrow pens per treatment. Dietary treatments included a low BP diet which met the NRC (1998) requirements, a diet which met Evonik Degussa (ED) recommendations, and a diet which was formulated to be 10% above the ED recommendations. Diets were formulated to contain identical net energy content. No gender × BP interactions were observed ($P > 0.30$) for any of the growth performance and carcass responses. During the growing phase, G:F improved ($P = 0.001$) and ADG tended to increase ($P = 0.07$) as the BP level increased in the diet. The greatest improvements were achieved with the highest BP level containing 0.89% standardized ileal digestible Lys. Gilts had improved ($P < 0.001$) G:F from d 0 to 28 compared with barrows. During the finishing phase, BP levels did not affect ($P > 0.05$) growth performance which may have been confounded by a relatively long duration (60 d) of the finishing phase. Over the entire 88-d period, ADG and G:F improved ($P < 0.02$) as the dietary BP levels increased. Gilts had lower ADFI and improved G:F ($P < 0.01$) than barrows during the entire period. Carcass characteristics (yield, backfat depth, loin depth, lean percentage) and income over feed cost were not affected by feeding varied levels of BP. These results suggest that today′s pigs with high lean potential respond to a higher BP than current recommendations.

Key Words: balanced protein, lysine, pig

493 Effect of tryptophan level on growth performance in 10- to 50-kg pigs. D. Renaudeau*[1], M. Giorgi[1], C. Anais[1], and Y. Primot[2], [1]*Institut National de la Recherche Agronomique, UR143, Petit-Bourg, French West Indies, France*, [2]*Ajinomoto Eurolysine, Paris, France*.

The effect of dietary tryptophan (Trp) content and pig density were tested between 10 to 50 kg BW on a total of 80 Large White pigs (40 females and 40 barrows) as a complete randomized block design in a 2 × 2 factorial arrangement (2 replicates/treatment). Pigs were randomly assigned to one of 4 treatments in 8 similar pens (3 × 2 m) of 8 or 12 animals (0.75 or 0.50 pig/m^2). In each pen, females and barrows were equally mixed. Dietary treatments consisted of 2 diets with different standard ileal digestible (SID) Trp content (0.19 or 0.25%), where the SID lysine content (1.06%), energy level (10.2 MJ NE/kg) and ideal AA patterns (Lys, Thr, Met, Ile, Val) were kept constant. Data were subjected to an ANOVA including the effect of diet, pig density, replicate, sex, block and interactions (GLM procedure of SAS). There were no interaction between dietary Trp content and pig density ($P > 0.05$). The average daily feed intake (ADFI) was not influenced by pig density between 10 and 25 kg (827 g/d on average; $P > 0.05$). Between 25 and 50 kg, ADFI was reduced when pig density increased from 8 to 12 pig/pen (1600 vs. 1357 g/d; $P < 0.05$) which resulted in a non-significant reduction of the average daily gain (ADG) (715 to 646 g/d; $P = 0.07$). Between 10 to 25 kg, ADFI and ADG were significantly higher in high Trp diet (863 vs. 790 g/d and 500 vs. 454 g/d; $P < 0.05$). Feed conversion ratio (FCR) was not influenced by diet and averaged 1.7 kg/kg. Between 25 to 50 kg, ADG, ADFI and FCR were not affected by diet and averaged 681 g/d, 1480 g/d and 2.3 kg/kg, respectively. The lack of effect of high dietary Trp content from 25 to 50 kg could be explained by the fact that dietary lysine content was not limiting for growth for this BW range after 25 kg. For the whole experiment period, ADFI remained unaffected by diet ($P > 0.05$) and ADG tended to be higher in pigs fed high Trp diet (601 vs. 557 g/d; $P = 0.06$). These results suggested that a SID Trp content higher than 0.19 g/100 g or 0.18 g/100 g SID lysine is necessary to maximize growth performance in pigs especially between 10 to 25 kg BW.

Key Words: pig, amino acids, tryptophan

494 Estimation of optimum tryptophan to lysine ratio in wheat-barley or corn-soybean meal based diets for 15- to 35-kg pigs. J. K. Htoo*[1], M. Naatjes[2], K. H. Tölle[3], and A. Susenbeth[2], [1]*Evonik Degussa GmbH, Hanau, Germany*, [2]*Christian-Albrechts University, Kiel, Germany*, [3]*Training and Research Center Futterkamp, Bliekendorf, Germany*.

A 28-d dose-response assay was conducted with 880 mixed-sex pigs (Pietrain × dbNaima; initial BW of 14.4 kg) with 5 pen replicates per treatment to determine the optimum dietary standardized ileal digestible (SID) Trp:Lys ratio for 15 to 35 kg pigs fed corn-soybean meal (SBM) or wheat-barley based diets. Two Trp-deficient basal diets, based on wheat-barley or corn-SBM, were formulated, using analyzed ingredient AA contents and published SID AA values to meet requirements of AA other than Trp and Lys. The Lys level (1.05% SID Lys) was marginally limiting in all diets, which corresponds to 91% of requirement (1.15% SID Lys) recommended for the pigs used in the study. L-Trp was added to both basal diets at the expense of wheat or corn to create 7 SID Trp:Lys ratios (13.3, 14.8, 16.3, 17.8, 19.3, 20.8 and 22.3%), and a Lys-adequate diet (diet 8, equivalent to diet 7 with added L-Lys-HCl to contain 1.15% SID Lys) was also formulated as a control for both diet types. The SID Trp:Lys ratios (based on analyzed AA content) were 13.1, 14.2, 15.3, 16.4, 17.5, 18.6 and 19.7% in diets 1 to 7 of wheat-barley based diets, and 14.3, 15.4, 16.5, 17.6, 18.7, 19.8 and 20.9% in diets 1 to 7 of corn-soybean meal based diets, respectively. The ADG and FCR of pigs were improved ($P < 0.05$) with increasing Trp:Lys ratio for both wheat-barley and corn-SBM based diets. Feed intake was increased by graded level of Trp:Lys ratio in both wheat-barley ($P < 0.05$) and corn-SBM based diets ($P < 0.10$). The estimated SID Trp:Lys ratios to optimize ADG were > 19.7 and 15.9% in wheat-barley based diets, and > 20.9 and 17.8% in corn-SBM based diets based on the exponential (at 95% of plateau) and broken-line regression, respectively. The SID Trp:Lys ratios to optimize FCR were > 19.7 and 17.0% for wheat-barley based diets, and > 20.9 and 19.9% for corn-SBM based diets by using the respective exponential and broken-line models.

Key Words: lysine, ratio, tryptophan

495 Effect of lysine level and curve feeding on the performance and carcass characteristics of grow-finish pigs. K. L. Herkelman*[1], S. Kelley[2], S. Bailey[1], and E. Engle[3], [1]*Wenger's Feed Mill, Inc., Rheems, PA,* [2]*Country View Family Farms, Lancaster, PA*, [3]*Hatfield Quality Meats, Hatfield, PA*.

An experiment was conducted to evaluate the effect of lysine level and curve feeding on the performance and carcass characteristics of grow-finish pigs. Crossbred pigs (n = 1,012; initial BW: 28.4 kg) were blocked by BW and gender and allotted to 4 treatments with 10 replicate pens/treatment and 25 or 26 pigs/pen. Treatments were arranged in a 2 × 2 factorial design with 2 levels of lysine (Control or Control + 0.1% dietary lysine in each phase) and 2 types of feeding systems (Feed Budget or Curve Feeding). The Control treatment consisted of diets containing 1.21, 1.10, 1.00, 0.86, and 0.78% dietary lysine fed in 5 phases. Pigs fed

using a feed budget were fed 23, 34, 46, 57 and 16 kg/pig for phases 1 to 5, respectively. Pigs fed on the feed curve started each phase at the lysine level of pigs fed on the feed budget. Lysine level was decreased every 5 lb of feed disappearance/pig using a FeedPro feeding system by blending diets containing 1.31 and 0.78% lysine. All pigs were fed a Paylean (6.75 g/ton) diet from the end of phase 5 to market weight. Pigs were allowed ad libitum access to feed and water. Pigs were marketed by pen at an average slaughter weight of 129.4 kg and carcass AutoFom data was collected. No lysine level × feeding system interactions were observed for any parameter. An increase in dietary lysine improved ($P < 0.05$) growth rate (1.01 vs. 0.99 kg/day) and feed disappearance (2.40 vs. 2.36 kg/day) of pigs compared with pigs fed the Control. Efficiency of feed utilization was similar ($P > 0.10$) between pigs fed the Control and diets with increased lysine levels (2.38 kg feed/kg gain). Curve feeding improved ($P < 0.02$) the growth rate (1.01 vs. 0.99 kg/day) and efficiency of feed utilization (2.37 vs. 2.40 kg feed:kg gain) of pigs compared with pigs fed by feed budget. Carcass characteristic were not influenced ($P > 0.10$) by lysine level or feeding system. In conclusion, increasing dietary lysine increased feed disappearance and improved the growth rate of grow-finish pigs. Diets fed on a feed curve improved the growth rate and efficiency of feed utilization of pigs compared with using a feed budget.

Key Words: lysine, pigs, curve feeding

496 Effects of ileal sample collection strategies on ileal digestibility of CP and the concentration of chromium in ileal digesta. B. G. Kim*[1,2] and H. H. Stein[1], [1]*University of Illinois*, *Urbana*, [2]*Konkuk University*, *Seoul, Korea*.

An experiment was conducted to measure the effect of ileal sample collection time on the concentration and digestibility of CP by growing pigs. Eight barrows with an initial BW of 34.6 kg (SD = 2.1) were individually fitted with a T-cannula in the distal ileum and randomly allotted to a replicated 4 × 4 Latin square design with 4 diets and 4 periods per square. Three diets contained corn, soybean meal, or distillers dried grains with solubles as the sole source of CP. An N-free diet was also prepared. All diets contained 0.5% chromic oxide as an indigestible marker. Equal meals were provided at 0800 and 2000. Ileal digesta samples were collected in 2-h intervals from 0800 to 2000 during the last 3 d of each 7-d period. The concentrations of Cr (1.22, 1.39, 1.65, 1.61, 1.39, and 1.20%; SEM = 0.06) and CP (16.3, 19.0, 23.6, 22.1, 19.4, and 17.1%; SEM = 0.7) in ileal samples collected in each of the 6 2-h periods exhibited a quadratic effect ($P < 0.001$) that increased and then decreased in pigs fed the 3 CP-containing diets. However, apparent ileal digestibility of CP (62.2, 59.5, 59.2, 60.7, 61.7, and 59.6; SEM = 2.2) was unaffected ($P = 0.745$) by collection time, and the values were comparable to the 12-h digestibility (61.6%) calculated using the Cr and CP concentrations of 12-h collection periods. The endogenous loss of CP tended to decrease (27.4, 25.7, 29.5, 26.0, 22.3, 21.4 g/kg DMI; SEM = 4.5; $P = 0.099$) with collection time. Standardized ileal digestibility values of CP linearly decreased (81.0, 77.1, 79.4, 78.5, 76.9, and 74.3%; SEM = 2.2; $P = 0.008$), but values for the third and fourth 2-h periods were comparable to the 12-h standardized ileal digestibility (78.7%). In conclusion, diurnal variation of Cr and CP concentration were observed, but the digestibility of CP was largely unaffected by collection time. We suggest that 2 to 4 h of ileal sample collection from 4 h after feeding may provide samples that allow for calculation of a representative CP digestibility.

Key Words: diurnal variation, ileal digestibility, pigs

497 Ileal amino acids digestibility of raw and heat-processed pea protein concentrates in broilers. M. Frikha[1], D. G. Valencia*[2], M. P. Serrano[1], H. M. Safaa[3], R. Lázaro[1], and G. G. Mateos[1], [1]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [2]*Nutral S.A.*, *Madrid, Spain*, [3]*Faculty of Agriculture, Cairo University*, *12613 Giza, Egypt*.

A trial was conducted to determine the apparent (AID) and standardized (SID) ileal digestibility of the AA of 2 different batches of pea protein concentrate (PPC) either raw or heat processed (HP, autoclaving at 108°C for 8 min at 0.6 bars) as compared with soy protein concentrate (SPC) in 21-d-old broilers. Each of the 5 treatments was replicated 6 times (6 cages with 6 chicks per replicate). The 2 PPC and the SPC batches contained 45.6, 44.6, and 52.4% CP, 3.48, 3.29, and 2.69% total Lys, and 9.4, 9.1, and 0.2 mg/g trypsin inhibitor activity (TIA), respectively. The diets were based on corn starch and sucrose and the ingredient tested was the only source of CP (20%). In addition, a N-free diet was used in 6 extra replicates to estimate the basal ileal endogenous losses. Chicks were fed their respective experimental diets ad libitum in mash form from 18 to 21 d of age. Chicks fed the HP PPC had higher ($P < 0.001$) AID of CP (87.61, 82.19, and 83.43%) and of most of indispensable AA (i.e, 92.14, 88.80, and 84.69% for Lys) than chicks fed the raw PPC with chicks fed the SPC being in general intermediate. The SID of most of indispensible AA was similar for the SPC and the HP PPC and higher for both ($P < 0.05$) than for the raw PPC. An interaction between type and HP of the PPC was observed; the beneficial effects of HP on AA digestibility were more pronounced in one of the 2 PPC samples studied ($P < 0.05$). The different response observed for the 2 PPC types with HP, was consistent with the higher reduction in TIA in one of the samples (9.4 to 2.8 mg/g vs. 9.1 to 5.8 mg/g, respectively). It is concluded that HP of PPC improves the ileal digestibility of CP and of the AA. Also, HP PPC had higher ileal digestibility of most AA than PPC. Thus, HP PPC is a good alternative to SPC in poultry diets.

Key Words: pea protein concentrate, heat processing, ileal amino acid digestibility broilers

498 Identification of lysine transport systems affiliated with differences in chick gain when fed a lysine limiting diet. M. A. Raymond* and B. D. Humphrey, *California Polytechnic State University*, *San Luis Obispo*.

Lysine (Lys) is the first or second limiting amino acid for growth in poultry feed, yet the mechanisms controlling Lys utilization within tissues are not well understood. Lys transporters facilitate the import and export of Lys within tissues. The objective of this study was to use a Lys limiting growth model to better understand the role of Lys transporters in Lys utilization within the pectoralis, liver, and duodenal mucosa. Male broiler chicks (3 d of age) were weighed, randomly assigned to pens and provided a Lys adequate (LA: 1.3% Lys) or Lys deficient diet (LD: 0.66% Lys). On d 14, chicks were sorted based upon d 3 to 14 gain. Chicks consuming the LD diet with the highest gain were designated as high gain (HG; n = 10) and chicks with the lowest gain were designated as low gain (LG; n = 10). LA chicks with average gain served as the control (C; n = 5). HG, LG and C chicks were housed in individual pens for 3 d. On a BW basis, HG chicks had 134% higher gain and 64% higher breast yield compared with LG chicks ($P < 0.05$) despite similar lysine intake ($P > 0.05$). Pectoralis, liver and duodenal mucosal scrapings were collected on d 17 for measurement of Lys transporter mRNA by real-time qPCR. Overall, HG and LG chicks had higher tissue Lys transporter mRNA abundance compared with C chicks. In the pectoralis, LG chicks had 1.6-fold higher CAT3 and 1.4-fold higher y^+LAT1 mRNA abundance compared with HG chicks ($P < 0.05$). In the liver, CAT3 mRNA abundance was 1.7-fold higher in LG chicks compared

with C chicks ($P < 0.05$). In duodenal mucosa, LG chicks had 1.45-fold higher y^+LAT2 mRNA abundance compared with HG chicks ($P < 0.05$). The difference in gain between LG and HG chicks was associated with increased mRNA abundance of LYS transporters within the pectoralis (CAT3, y^+LAT1), liver (CAT-3) and duodenum (CAT3, y^+LAT2). These data indicate that the respective tissue transporters may play an important role in the utilization of dietary Lys.

Key Words: lysine, transport, pectoralis

499 Valine and isoleucine as potential limiting amino acids in broiler diets based on corn, soybean meal, and meat and bone meal. L. Mejia*[1], W. A. Dozier III[2], R. E. Loar II[1], M. T. Kidd[3], P. B. Tillman[4], and A. Corzo[1], [1]*Mississippi State University*, *MS*, [2]*Auburn University*, *Auburn, AL*, [3]*University of Arkansas*, *Fayetteville, AR*, [4]*Ajinomoto Heartland LLC*, *Chicago, IL*.

A randomized complete block design study, using area of the house as a blocking factor, was designed to evaluate Ile and Val as potential fourth and fifth limiting amino acids in diets based on corn, soybean meal, and meat and bone meal. Eleven hundred and 52 Ross × Ross TP16 male broilers were randomly placed across 96 floor pens (12 birds/pen). Common diets were fed to all broilers from 0 to 28 d of age and formulated to satisfy all nutrient recommendations. An experimental diet was provided to the broilers from 28 to 42 d of age, served as negative control (NC), and was formulated to satisfy all nutrient recommendations with the exception of Ile and Val (0.57% dig Ile and 0.66% dig Val). The NC diet was supplemented with L-Ile and L-Val at either 0.05 or 0.10%, alone or in combination. A diet formulated to digestible Val and Ile of 0.76 and 0.67%, respectively, mimicking commercial practice served as a positive control (PC). Body weight gain was depressed ($P < 0.01$) with the NC, but was recovered to a weight similar to birds that were fed the PC when Val was added to the test-diet either alone or in combination with Ile. Feed conversion was improved ($P < 0.001$) when L-Val and L-Ile were simultaneously supplemented to the NC. Carcass weight and yield were unaffected ($P > 0.05$) by the dietary treatments. Abdominal fat percentage was reduced ($P < 0.05$) with the combined supplementation of L-Val and L-Ile to the NC. Breast meat yield seemed to be more responsive ($P < 0.01$) to L-Ile supplementation than L-Val. Results from this study suggest that Val needs may be more sensitive for live performance while breast meat yield was maximized with L-Ile supplementation. However, it seems that under these experimental circumstances, a combination of L-Val and L-Ile is required for optimum growth and meat yield of broilers.

Key Words: broiler, isoleucine, valine

500 Effect of different sorghum varieties on early chick growth. C. M. Rude*[1], M. A. Barrios[1], R. Rierson[1], S. Bean[2], and R. S. Beyer[1], [1]*Kansas State University*, *Manhattan,* [2]*ARS, USDA, Grain Marketing and Product Research Center*, *Manhattan, KS*.

Although corn is the predominant cereal grain used in commercial broiler rations in the US, price advantages sometimes allow the use of sorghum in least cost rations. Similar to corn and wheat, sorghum hybrids exist for human versus animal feed. Besides costs, geographical limitations, environmental impacts, grain yields and availability of sorghum by products could allow some of these products to be used in poultry rations. An experiment was designed to test the effect of grain sorghum varieties on broiler chick growth. Broiler starter rations were formulated to NRC recommendations, using sorghum as the cereal grain. Chicks were fed one of 4 different white sorghums: Macia, straight run sorghum grown almost exclusively in Africa; F 1000, popular commercial hybrid for food; Sp3303 new food hybrid; and MMR 315–10, relatively new food hybrid grown extensively in Russia. All sorghums were grown on the same farm in western Kansas. Diets were fed to 21 d of age, with feed and BW recorded on d 0 and 21, with FC calculated from this data. Each treatment had 8 replications, with 6 birds per pen housed in Petersime battery cages. Feed and water were provided ab libitum. Differences were observed between sorghums in BWG and FC ($P < 0.05$). Sorghum hybrid F1000 had the lowest BWG with 484 g, followed by Macia at 532 g. Highest BWG of 765 g was observed with the MMR 315–10 hybrid and which was statistically similar to Sp3303 with a BWG of 747 g. Two sorghums were statistically similar, F1000 and Macia, had lower feed consumption than the other 2 sorghums, Sp3303 and R315–10, who were also statistically similar. Feed conversion was 0.744, 0.752, 0.767, and 0.783 for the Macia, F1000, Sp3303 and MMR 315–10 varieties, respectively. Differences in growth are attributed to differences in the sorghums characteristics. Hybrid F1000 is widely used in the food industry for its high dough viscosity, an attribute that could reduce broiler performance. Macia is grown for its drought hardiness and disease resistance. These results indicate that caution is required when using varieties of sorghum that have been developed for other markets than animal feeding.

Key Words: sorghum, broiler, hybrid

501 Dietary hydrolyzed yeast extract enhances early innate immune function in broiler chicks. J. L. Saunders-Blades*, K. L. Nadeau, and D. R. Korver, *University of Alberta*, *Edmonton, Canada*.

The effects of dietary yeast on growth and immune function of broiler chicks were studied. A bioethanol process derived yeast product was fed as either intact (I) or hydrolyzed by a 1–3 β-glucanase (H), at 4 levels (250, 500, 1000 or 2000 g/t) plus a control diet (C) with no yeast for a total of 9 diets (n = 6 pens/treatment). BW and feed intake were measured for the starter (0 to 10 d) and grower (11 to 28 d) periods. Whole blood was obtained weekly from 10 chicks/treatment to make in vitro assessments on the number of cells able to engulf at least one *Escherichia coli* (% phagocytosis), average number of *E. coli*/cell (phagocytic capacity), and *E.coli* bactericidal capacity. There were no diet effects on broiler production traits during the starter period. During the grower phase, lower feed intake among birds fed 500 or 2000 g/t of H ($P < 0.05$) resulted in a marginally lower BW gain ($P = 0.056$) and overall BW ($P = 0.058$); feed efficiency was not affected. At 2 wk, cells from H birds had a greater % phagocytosis (11–13% increase) and phagocytic capacity (15–31% increase) than those in the I group ($P < 0.05$). There was no difference in % phagocytosis between the cells from birds in any H groups with the C treatment, however cells from birds in the H2000 group had a 13% greater phagocytic capacity than the C treatment. At 3 wk, H2000 resulted in a 10% lower % phagocytosis than the C chicks and all levels of I (from 5 to 15%; $P < 0.05$). At 4 wk, cells from I2000 and H250 birds had a greater % phagocytosis than those from C birds (14 and 17% increase, respectively; $P < 0.05$). Diet did not affect bactericidal capability at any age. Both the I and H yeast increased early innate immune function in broilers relative to C. The H yeast (>500g/t) was most effective at increasing innate immunity at 2 wk, as the broilers aged (>3wk) the difference between the I and H was less pronounced. This may be a function of changes in the development of the immune system and the components present in the different treatments to activate it as the bird ages.

Key Words: broiler, hydrolyzed yeast, innate immune function

502 Influence of pea hulls inclusion in the diet on digestive traits and nutrient retention in broilers. E. Jiménez-Moreno*[1], J. M. González-Alvarado[2], S. Chamorro[3], C. Centeno[3], R. Lázaro[1], and G. G. Mateos[1], [1]*Universidad Politecnica de Madrid*, *Madrid, Spain*, [2]*Universidad de Tlaxcala*, *México*, [3]*Consejo Superior de Investigaciones Científicas*, *Madrid, Spain*.

The effects of inclusion of pea hulls (PH; 47% neutral detergent fiber and 9% starch) in the diet on the digestive traits and total tract apparent of retention (TTAR) of nutrients were studied in broilers from 1 to 21 d of age. A control diet based on cooked rice, soy protein concentrate, and fish meal that contained 3,260 kcal AME_n/kg, and 1.25% digestible Lys was diluted with 0, 2.5, 5.0, and 7.5% PH (1.6, 2.6, 3.5, and 4.5% CF, respectively). Each treatment was replicated 6 times (a cage with 12 chicks). Digestive traits and nutrient retention were recorded at 7, 14, and 21 d of age, and jejunal histology was measured at 14 d of age. The relative weight (% BW) of proventriculus ($P \leq 0.01$), gizzard ($P \leq 0.001$), and ceca ($P \leq 0.05$) increased as the level of PH in the diet increased. Digesta content of the gizzard was increased ($P \leq 0.001$) and gizzard pH was reduced ($P \leq 0.001$) with 2.5% PH. No further changes were observed with 5% and 7.5% inclusion. Crypt depth decreased linearly ($P \leq 0.05$) with PH inclusion. However, villus height and villus height:crypt depth ratio were not affected. The TTAR of soluble ash and N increased with up to 5% PH inclusion ($P \leq 0.001$). Also, TTAR of DM and OM, as well as the AME_n of the diet ($P \leq 0.001$) were improved with 2.5% PH inclusion; however, a further increase to 5% reduced TTAR of these nutrients. We conclude that an increase in dietary PH increases proventriculus, gizzard, and ceca weight in broilers from 1 to 21 d of age. Also, the inclusion of 2.5% PH increases digesta content and reduces the pH of the gizzard. The inclusion of up to 5.0% PH in the diet (3.5% CF) improves N retention but reduces the AMEn of the diets. A further increase to 7.5% PH (4.5% CF in the diet) impairs digestibility of all nutrients studied. The optimal requirement of CF in diets for young chicks might be between 2.6% and 3.5%.

Key Words: pea hulls, nutrient digestibility, broiler

503 Dietary camelina meal for broiler chickens: 2. Thigh meat fatty acid profile and sensory evaluation. P. H. Patterson*[1], R. M. Hulet[1], T. L. Cravener[1], A. Y. Pekel[2], and J. E. Hayes[1], [1]*The Pennsylvania State University*, *University Park*, [2]*Istanbul University*, *Turkey*.

Camelina is an oilseed plant from the Brassicaceae family. It has recently been grown for biodiesel production with the meal utilized as a dietary protein supplement with a residual complement of omega-3 fatty acids. An experiment was conducted to examine the effect of dietary camelina meal (CM) supplementation on broiler live performance and meat quality. A total of 864 Ross x Cobb-500 straight run chicks were allocated to control (Con), 5% or 10% CM diet treatments with 8 pens per treatment from 1 to 35d. The CM utilized in this study contained 33.6% CP, 15.0% fat and 4.22% total omega-3 fatty acids. At the conclusion of the study, the birds were processed, cut up and meat frozen for further fatty acid analysis and sensory evaluation. Frozen thigh samples were thawed, skin was removed and then de-boned. The meat (270–280g portions) was placed in vacuum pouches, sealed under vacuum and held at 3.3C overnight before sensory evaluation. The meat was cooked sous-vide at 73.8C in a water bath for 50m. Cooked and cut meat (15–20g) was placed in insulated bowls and presented to 59 participants in a 2 triangle test sensory evaluation. Each participant received 6 bowls, 3 for test 1 and 3 for test 2. Two samples in each test were the same and participants were asked to choose the different sample. Dietary treatments significantly influenced thigh meat fatty acid profiles. Feeding the 10% CM diet increased thigh meat 18:3, 20:3, 20:5 (EPA), 22:5 (DPA), 22:6 (DHA) and total omega-3 fatty acids compared with meat from the Con and 5% CM fed birds which were not significantly different. Thigh muscle linoleic (18:3), EPA and DHA levels were increased 180, 100, and 128% by the 10% CM treatment respectively above the Con samples. Sensory evaluation showed participants were not able to distinguish between the Con and 5% CM thigh samples, yet 36 of 59 where able to identify the different sample when presented the Con and 10% CM meat ($P <$ 0.05). However, it should be noted that discrimination does not imply a preference by consumers and further acceptability trials would be required for preference determination.

Key Words: *Camelina sativa*, sensory evaluation, omega-3 fatty acids

504 Effect of feeding Mexican sunflower leaf *(Tithonia diversifolia*, Hemsley A Gray) on performance of broiler chicks. A. H. Ekeocha*[1], A. A. Mako[2], T. J. Williams[3], and A. Aderiye[1], [1]*Department of Animal Science University of Ibadan*, *Ibadan, Oyo State, Nigeria*, [2]*Department of Agricultural Production and Management Sciences, Tai Solarin University of Education*, *Ijagun Ijebu-Ode, Ogun State, Nigeria*, [3]*Department of Animal Physiology, University of Agriculture*, *Abeokuta, Ogun State, Nigeria.*

One hundred and fifty (150) day old Abor Acre broiler chicks were randomly allocated to 5 experimental diets of 30 birds each. The first diet was the standard (basal) starter and finisher diet and served as control. The other rations contained 2.5%, 5.0%, 7.5% and 10.0% Mexican sunflower leaf (MSL) respectively as graded replacement (w/w) for maize and Soya meal. The study investigated the performance and hematological responses of the birds to the diets. Mexican sunflower leaf meal supplementation did not improve performance characteristics over basal diets and significantly ($P < 0.05$) retarded feed intake, growth rate, feed conversion except for its inclusion at 5.0%, while hematological parameters were significantly ($P > 0.05$) enhanced except for eosinophil and lymphocytes concentration. Mexican sunflower leaf is therefore a promising feed ingredient that could be cheaply incorporated into poultry rations at 5.0% level when convectional feeds are inadequate.

Key Words: lesser known sunflower, feed intake, daily weight gain

505 Effect of feeding Mexican sunflower leaf *(Tithonia diversifolia*, Hemsley A Gray) on carcass characteristics of broilers. A. H. Ekeocha*[1], O. A. Adu[2], K. D Afolabi[1], and E. J Ubah[3], [1]*Department of Animal Science, University of Ibadan, Ibadan, Oyo State, Nigeria*, [2]*Department of Animal Production and Health, Federal University of Technology, Akure, Nigeria*, [3]*Department of Animal Science, Wageningen University, Wageningen, Netherlands*.

A study was conducted for 8 weeks to investigate the effect of feeding Mexican Sunflower Leaf *Tithonia diversifolia* on carcass characteristics of broilers. One hundred and fifty white day-old Abor Acre broiler chicks were used. The broiler chicks were randomly assigned to 5 treatments A, B, C, D and E. Treatment A served as control while birds in treatments B, C, D and E received Mexican Sunflower Leaf (MSL) at 2.5, 5.0, 7.5, and 10.0% respectively. Feeds and water were provided ad-libitum and the routine vaccination / medication followed the standard procedures. The results shows a significant ($P > 0.05$) decrease in all the parameters measured for carcass characteristics (shank, gizzard, head, crop, thigh, drumstick, wings, breast, back, neck, abdominal fat, spleen, heart, lung, liver, intestine and proventriculus) except for the neck weight where birds on treatment B (2.50 MSL) obtained the highest neck weight (182.31g) and the spleen with highest weight (3.60g) obtained in treatment C (5.0 MSL). The carcass quality were also significantly decreased ($P > 0.05$) except for the neck and spleen weights. The result of this study shows that inclusion of MSL at 2.5, 5.0, 7.5, and 10.0% has almost no effect on both the carcass characteristics and carcass quality of the broilers under study.

Key Words: sunflower, carcass characteristics, *Tithonia diversifolia*

506 A 42-day floor pen evaluation of broiler chickens fed standard energy and low energy diets supplemented with a blend of carvacrol, cinnamaldehyde and capsicum oleoresin with or without bacitracin. M. Sims*[1], D. Bravo[2], and A. Vikari[2], [1]*Virginia Diversified Research Corporation*, *Harrisonburg, VA*, [2]*Pancosma*, *Geneva, Switzerland*.

A 42-d, 30 bird/pen, 6 treatment, 8 rep. (48 pens) broiler study was conducted to compare the performance, carcass/breast yield, breast moisture loss and Salmonella shedding of broiler chickens fed standard (S) or low (L) ME feeds with either a blend of carvacrol, cinnamaldehyde and capsicum oleoresin (XT, Xtract 6930) 125 ppm in starter feeds, 100 ppm in grower feeds (S/XT, L/XT) or BMD 50 ppm (S/B, L/B) or a combination of BMD 25 ppm + XT 100 ppm (S/B+XT, L/B+XT). Pen and feed weights collected at 21d and 42d, Salmonella shedding at 20d and 41d and carcass/breast yield at 43d. Each paired treatments means were analyzed by use of a 2-tailed distribution basic *t*-test model with equal variances assumed and $P = 5\%$. At 21d, BW of S/XT (2.02 kg) and S/B+XT (2.01 kg) were higher than L/XT (1.92 kg), with other groups intermediate. The 42d BW of the S/XT group (2.34 kg) was greater than each of the Low ME groups (mean = 2.24 kg) and not different from S/B (2.31 kg). FCR at 42d was lower for S/XT (1.69) than for the S/B (1.79), L/B (1.77), or L/XT group (1.75). The 0-42 day mortality with culls removed of S/XT (2.5%) was lower than L/B+XT (5.4%). Salmonella shedding at 41d was lower for S/B+XT (0%) than S/B (16.7%), S/XT (12.5%), L/XT (12.5%) and L/B (25.0%). Carcass yields were not different by pens, males, or females. Pen breast yield of S/B group (33.7%) was greater than S/XT (32.6%) and S/B+XT groups (32.0%). Pen breast moisture loss of S/XT was lower (6.9%) than all other groups (mean = 9.6%) with S/B (10.0%) and L/BMD (10.4%) being the highest. Breast yields after moisture loss means were similar for S/XT and S/B (30.3%). These data show that broilers fed diets supplemented with XT have final BW, FCR, carcass

yield, breast yield, feed cost/bird and returns on investment similar to broilers fed standard diets supplemented with BMD 50 ppm.

Key Words: essential oils, broiler, carcass yield

507 Effects of mung bean waste inclusion on mash diet characteristic, growth performance and nutrient digestibility in pigs. P. Rungcharoen*, N. Amornthewaphat, Y. Ruangpanit, S. Rattanatabtimthong, and S. Attamangkune, *Kasetsart University*, *Bangkok, Thailand*.

Three experiments were conducted to evaluate the apparent metabolizable energy of mung bean waste in pigs and effects of mung bean waste inclusion in pig diets on growth performance and nutrient digestibility. In Exp 1, 2 consecutive trials were performed in starter (BW of 20 kg) and grower pigs (BW of 50 kg) in the determination of the apparent metabolizable energy of mung bean waste. Twenty 4 crossbred barrows (Large white × Duroc × Landrace) were enrolled in each trail (one pig in each cage; 12 metabolic cages per treatment). Treatments were corn soybean basal diet and 20% mung bean waste substituted basal diet. The apparent metabolizable energy of mung bean waste for a starter pig and a grower pig were 2,132.3 ± 137.83 and 2,557.1 ± 50.39 kcal/kg. In Exp 2, 2 trials were conducted in nursery phase (5 to 9 wk) and starter to finisher phase (11 to 24 wk) in a growth assay. A total of 192 pigs in each trial was allotted to a randomized completely block design (8 pigs per pen; 6 pens per treatment with 3 pens of gilts and 3 pens of barrows). Sex was a block factor. Treatments were mung bean waste inclusion of 0%, 2.5%, 5% and 7.5% in the experimental mash diets. Mung bean waste inclusion linearly decreased bulk density for all diets ($P \leq 0.001$) of both trials. There was no difference in growth performance of pigs in nursery phase and starter to grower phase. For finisher phase, however, there was decreased ADG from 712g to 597g in pigs fed mung bean waste diets ($P \leq 0.05$). In Exp 3, 24 barrows (BW of 7.5 kg) were used in the determination of nutrient digestibility (one pig in each cage; 6 metabolic cages per treatment). Treatments used were the same as in Exp. 2. Mung bean waste inclusion in the diet did not affect the digestibility of protein, fat and fiber. In conclusion, incorporation of 7.5% mung bean waste in the nursery to grower pig diets did not showed negative responses to growth performance and nutrient digestibility. However, low bulk density of mung bean waste mash diet needed to be concerned.

Key Words: pig, mung bean waste, growth performance

508 Short-term feeding of genetically modified Bt maize (MON810) to weanling pigs: Effects on gut microbiota, intestinal morphology and immune status. M. C. Walsh*[1], S. G. Buzoianu[1,3], G. E. Gardiner[3], M. C. Rea[2], R. P. Ross[2], and P. G. Lawlor[1], [1]*Teagasc, Pig Production Development Unit, Moorepark Research Centre*, *Fermoy, Co. Cork, Ireland*, [2]*Teagasc, Moorepark Food Research Centre*, *Fermoy, Co. Cork, Ireland*, [3]*Waterford Institute of Technology*, *Waterford, Ireland*.

The objective of this study was to identify any effects short-term (31 d) feeding of genetically modified (GM) Bt (MON810) maize may have on gut microbiota, intestinal morphology and immune status of weanling pigs. Male pigs (n = 32) were weaned at ~28 d of age, blocked by weight and ancestry and randomly assigned to 1 of 2 treatments; non-GM isogenic maize or transgenic MON810 maize. Fecal samples were collected for microbiological analysis on d −1 and 30. Ileal and cecal digesta and small intestinal tissue were sampled at slaughter (d 31) for microbiological and histological analysis, respectively. Cytokine production from stimulated peripheral blood mononuclear cells (PBMCs) was measured on d 0 and 29. All data were analyzed as a randomized complete block design using the GLM procedures of SAS. Feeding GM maize had no observed effect on fecal *Lactobacillus* or total culturable anaerobe counts or ileal and cecal counts of *Lactobacillus*, *Enterobacteriaceae* or total anaerobes. Fecal *Enterobacteriaceae* counts in GM maize-fed pigs tended to be reduced on d 30 ($P = 0.10$) compared with control pigs. Feeding GM maize had no effect on duodenal, jejunal, ileal villus height or crypt depth. However, non-GM fed pigs tended ($P = 0.10$) to have more goblet cells/μm of duodenal villus compared with GM fed pigs. Phorbol myristate acetate stimulated PBMCs isolated from pigs fed GM maize tended ($P = 0.10$) to produce less IL-12 than control PBMCs on d 30. There was no effect of treatment on IL-10, IL-6, IL-4, TNFα or IFNγ production from resting or stimulated PBMCs. In conclusion, short-term feeding of GM maize to weanling pigs has demonstrated no observed adverse effects on intestinal morphology or systemic immunity while it was associated with a reduction in potential pathogens in the feces.

Key Words: pigs, MON810 maize, microbiota

509 Effects of dietary oat hulls and sugar beet pulp on productive performance and nutrient digestibility of broilers from 1 to 42 d of age. J. M. Gonzalez-Alvarado[1], E. Jiménez-Moreno[2], F. D. Royón[2], R. Lázaro[2], and G. G. Mateos*[2], [1]*Universidad de Tlaxcala*, *México*, [2]*Universidad Politecnica de Madrid*, *Madrid, Spain*.

The effects of the inclusion of additional fiber in the diet on growth performance and digestive traits were studied in broilers from 1 to 42 d of age. The control diet was based on rice and contained 3,120 kcal AMEn/kg, 1.12% digestible Lys, and 1.5% crude fiber content. The 2 experimental diets included 3% of either oat hulls (OH) or sugar beet pulp (SBP). Growth performance was measured from 1 to 42 d, total-tract apparent retention (TTAR) of nutrients were determined at 32 d, and the relative weight (RW; g/kg BW) of the GIT and the gizzard was measured at 42 d of age. Cumulatively, broilers fed OH had higher ($P \leq 0.001$) ADG and better ($P \leq 0.01$) FCR than broilers fed SBP or the control diet. From 1 to 10 d of age, OH inclusion improved ($P \leq 0.01$) ADG (19.5 vs. 16.8 g/d) and FCR (1.215 vs. 1.333) as compared with the control diet. Also, SBP improved FCR in this period but the effects disappeared with age. In fact, from 25 to 42 d of age, SBP inclusion reduced ($P \leq 0.05$) feed intake with respect to the control diet and feed intake ($P \leq 0.05$) and BWG ($P \leq 0.001$) with respect to the OH diet. The RW of the GIT was higher ($P \leq 0.05$) with the SBP than with the control diet with the OH diet being intermediate. Also, the RW of the gizzard increased ($P \leq 0.001$) with fiber inclusion and the effects were more pronounced ($P \leq 0.05$) with OH than with SBP. Fiber inclusion increased ($P \leq 0.01$) TTAR of all nutrients and AMEn of the diet. The improvement in TTAR observed for DM was more pronounced ($P \leq 0.01$) for OH than for SBP. We conclude that OH inclusion improves growth performance at all ages in broilers fed low fiber diets. Also, SBP inclusion improves growth performance from 1 to 10 d of age but not thereafter. The TTAR of nutrients are improved by fiber inclusion and the benefits are more pronounced with OH than with SBP.

Key Words: fiber sources, digestive organ size, broiler performance

510 Influence of origin on nutritional and quality parameters of soybean meal. G. G. Mateos*[1], M. P. Serrano[1], S. Sueiro[2], M. González[2], M. Hermida[2], P. G. Rebollar[1], and R. Lázaro[1], [1]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [2]*Laboratorio de Mouriscade*, *Pontevedra, Spain*.

Soybean meal (SBM) is the main source of protein in non-ruminant diets. Most published tables of ingredient composition for feed formulation

differentiate 2 types of SBM based on its CP content (regular with 44% CP and high protein with 47 to 48% CP) and do not have into consideration the origin or processing method of the beans. However, available information indicates that processing and origin of the beans might have an effect on the nutritional value of SBM. The present research (n = 345) was conducted to determine the influence of origin (USA; Brazil, BRA; Argentine, ARG) on protein quality and nutrient value of SBM. On DM bases, USA meals (n = 139) had more CP (53.8 vs. 52.8 vs. 51.5%; $P < 0.001$) and less NDF (8.8 vs. 10.7 vs. 12.0%; $P < 0.001$) than ARG (n = 121) and BRA meals (n = 85). Sucrose and stachyose content was higher for USA than for BRA with ARG meals being intermediate (8.1 vs. 6.7 vs. 7.5% and 6.4 vs. 5.3 vs. 5.5%, respectively; $P < 0.001$). The USA meals had more phosphorus (0.79 vs. 0.68 vs. 0.74%; $P < 0.001$) than the BRA meals with ARG meals being intermediate. Also, BRA meals had more Fe (189 vs. 128 and 133 mg/kg; $P < 0.001$) but less K (2.3 vs. 2.6 and 2.5%; $P < 0.001$) than ARG and USA SBM. The USA meals had higher KOH solubility (87.6 vs. 82.3 and 84.3%; $P < 0.001$), protein dispersibility index (19.8 vs. 17.1 and 15.5%; $P < 0.001$), and trypsin inhibitor activity (3.9 vs. 3.0 and 3.0 mg/g; $P < 0.001$) than the ARG or BRA meals. The amino acid profile (% CP) varied with the source of SBM. The content of Lys (6.15 and 6.09 vs. 5.96%; $P < 0.001$), Met + Cys (2.86 and 2.86 vs. 2.75%; $P < 0.001$), Thr (3.91 and 3.92 vs. 3.83%; $P < 0.001$), and of 5 key amino acids (Lys, Met + Cys, Thr, Trp; $P < 0.01$) were higher for USA and ARG than for BRA SBM. It is concluded that the nutrient composition and protein quality parameters favor the utilization of USA meal over the South American meals in poultry diets.

Key Words: soybean meal survey, protein quality, nutritional value

511 Lactose in diet influences the degradation of mixed linked β(1-3;1-4)-D-glucan in the small intestine of pigs. K. E. Bach Knudsen*, *Aarhus University, Faculty of Agricultural Sciences*, *Department of Animal Health and Bioscience, Tjele, Denmark*.

The objective of the current study was to investigate if lactose in diet would influence the degradation of mixed linked β(1–3;1–4)-D-glucan (β-glucan) in the small intestine. B-glucan is an important cell wall (dietary fiber, DF) component of the endosperm of barley and oats. The digestibility of β-glucan in the small intestine from both cereals is among the highest of all DF components, but in one particular study with oat-based diets it was significantly lower than what was found in other studies. In this study whey protein containing lactose was used as protein supplement. Lactose is slowly digestible in the small intestine. To investigate if lactose could be causative for the lower digestibility of β-glucan in the study with whey protein, it was decided to quantify the content of lactose in the diets and to analyze for lactose in digesta samples from the small intestine (the small intestine was divided in 3 by length equal segments: SI1, SI2, SI3) and ileal digesta along with parameters for organic acids (lactic acids and short-chain fatty acids). Diets containing lactose were based on oat goats, oat flour, and oat bran (lactose 1.2–3.8% of DM), whereas the reference diets were based on rolled oats, rolled oats and oat bran, wheat flour with added oat bran and wheat flour with added β-glucan (lactose 0–0.1% of DM). Lactose was identified in digesta up to SI2, but disappeared in digesta from SI3 and the ileum. There was no difference in the digestibility of β-glucan among diets up to SI3, whereas the digestibility in ileum was significantly higher in diets without lactose compared with diets containing lactose. With all diets, β-glucan was virtually completely digested in the cecum. No difference was found in the concentration of organic acids between diets either in SI3, ileum or cecum. In conclusion slowly digestible lactose was the most likely cause of the reduced digestibility of β-glucan in oat diets containing lactose.

Key Words: β-glucan, digestion, pigs

512 Effects of dietary calcium formate inclusion on broiler growth performance, bone ash, and tibia breaking strength. S. Pohl*, D. Caldwell, J. Lee, J. Coppedge, K. Stringfellow, S. Dunn-Horrocks, K. Jessen, and M. Farnell, *Texas A&M University*, *College Station*.

Calcium formate (CaFo; Rovelan–Lanxess Corporation, Germany) is a commonly used source of calcium in poultry and swine feed in the EU. Due to increased cost, US interest in alternate feedstuffs has grown. The objective of this study was to evaluate CaFo in broiler diets as an alternate calcium source during a 49d pen trial. A total of 2,160 male Cobb 500 broilers were randomized and placed in 40 floor pens with 50% used litter and 50% fresh pine shavings. Four experimental groups (0.0, 0.5, 1.0, and 1.5% CaFo) were evaluated with 10 replicate pens per treatment. Bulk pen weights were determined at the conclusion of each feeding phase (d15, 28, 42, and 49). Additionally, at d15, 28, and 42, one bird was removed from each pen and tibia removed for determination of bone strength and ash. At termination (d49) an additional 3 birds were removed from each pen for tibia sampling. Parameters evaluated for each phase included average BW, FCR, bone strength, bone ash content, and mortality. With regard to BW, significant differences ($P \leq 0.05$) were seen at d15 with 1.0% CaFo showing decreased BW. At d28 the 0.5% CaFo diet showed increased BW with respect to the 1.0 and 1.5% CaFo diets. At d42 and 49 all diets yielded statistically equivalent BW. For the duration of the trial, no differences were observed with regard to FCR among diets. No significant differences were seen among treatment groups with regard to mortality, tibia weight, or bone ash percentage. With respect to tibia breaking strength, a significant increase in breaking force was observed in the 1.0% CaFo treatment group in comparison to the control and 1.5% CaFo groups. These data suggest that CaFo may be used as a calcium alternative in broiler diets and may potentially increase bone strength in larger broilers when included at the appropriate concentration.

Key Words: broiler, calcium formate, bone ash

513 Broiler breeder age and dietary Cu, Zn and Mn source affect chick bone development at hatch. C. A. Torres* and D. R. Korver, *University of Alberta*, *Edmonton, AB Canada*.

Organic sources of dietary trace minerals (OTM) can have higher bioavailability than inorganic sources (ITM). OTM in the hen's diet might positively impact bone development in the embryo as Cu, Zn and Mn are involved in bone development. We investigated the effects of maternal dietary Cu, Zn and Mn source and level on chick bone traits at hatch from early (EEP; 33 wk), mid (MEP; 46 wk) and late (LEP; 60 wk) hen age. Broiler breeders (n = 18/diet), were housed in individual cages, and fed a basal ration low in Cu, Zn and Mn. Trace minerals were added as: 1) Control: ITM; mineral sulfates at industrial levels (100 ppm Zn, 120 Mn, 10 Cu); 2) OTM: Zn, Mn and Cu chelated by 2-hydroxy-4-(methylthio) butanoic acid (HMTBA) at NRC (1994) levels (50 ppm Zn, 60 Mn, 10 Cu); 3) OTM+ITM: Trt 1 plus an additional 40 ppm Zn, 40 Mn and 20 Cu as OTM; 4) High ITM: Trt 1 plus 40 ppm Zn, 40 Mn and 20 Cu as ITM. Weekly egg production, and chick bone weight, thickness and length data were analyzed using repeated measures analysis (PROC MIXED). Total and settable eggs, egg weight and hatchability were analyzed as a 1-way ANOVA (PROC MIXED). Significance was set at $P \leq 0.05$. Total and settable egg production, egg weight and hatchability to 60 wk of hen age were not affected by diet. Femur weight (with chick weight as a covariate) decreased 12% from EEP to LEP. At EEP, chicks from the OTM hens had femurs and tibias that were thicker than chicks from Control (both by 5%) and High ITM (both by 6%) hens. At MEP, chicks from the OTM and High ITM hens had thicker femurs (by 4 and 7%, respectively) than chicks from the OTM+ITM group; none of the treatment chicks were different from the Control chicks. At LEP there was no diet effect on femur and tibia thickness. Dietary TM affected chick bone thickness at early and mid hatches even though bone development appeared to decrease with hen age. Despite a lower level of supplemental TM, tibia development at hatch was increased in the OTM group relative to all other treatments at EEP; OTM resulted in greater femur development relative to the ITM and High ITM at EEP, and relative to OTM + ITM at MEP.

Key Words: broiler breeder age, organic trace mineral, chick bone development

514 Use of the broiler (*Gallus gallus*) as an in vivo screening tool for Fe bioavailability in maize-based diets. E. Tako*[1], M. Lung'aho[1], L. V. Kochian[2], O. A. Hoekenga[2], and R. P. Glahn[2], [1]*Cornell University*, *Ithaca, NY,* [2]*Robert W. Holley Center for Agriculture and Health*, *Ithaca, NY*.

Iron biofortification of staple food crops such as maize (*Zea mays*), is a strategy that alleviates Fe deficiency. By using in vitro cell culture model, 2 maize varieties were developed for high and low Fe bioavailability. In vitro observations should be tested in animals before human efficacy studies. Therefore, the maize varieties were tested for Fe bioavailability by using the broiler chicken as a model. Diets were made with 75% w/w maize of either the low (Low) or high (High) Fe bioavailability maize; Fe content did not differ between varieties (both 24 µg/g). In vitro analysis showed lower cellular ferritin formation (ie. Fe uptake, $P \leq 0.05$) in cells exposed to the Low (20 ng/mg) vs. High (37 ng/mg) diets. One-week-old broiler chicks (n = 6) were fed the maize based diets for 4 weeks. Hemoglobin (Hb), body weight, feed consumption, liver ferritin and gene expression were measured. Duodenal DMT1, Dcytb and ferroportin were higher ($P < 0.05$) in the Low group vs. the High group, indicating a response to lower dietary Fe availability. Hb concentrations, hemoglobin maintenance efficiency, Hb-Fe and liver ferritin were higher in the High group vs. the Low group ($P \leq 0.05$), indicating greater Fe absorption from the High diet and improved Fe status. We conclude that the in vivo results support the in vitro observations, i.e., the High variety contains more bioavailable Fe than the Low and that maize shows promise for Fe biofortification. In addition, the results indicate that, the broiler model can serve as an intermediate screening tool for Fe bioavailability before human efficacy trials.

Key Words: broiler, bioavailability, maize

515 Relationship between expression of sodium-dependent phosphate transporter type II-b gene and phosphorus utilization in broilers. O. A. Olukosi*, S. A. Adedokun, K. M. Ajuwon, and O. Adeola, *Purdue University*, *West Lafayette, IN*.

Broiler chicks at 21 d old were used to study the relationship between the level of expression of sodium-dependent phosphate transporter type IIb gene (NaPi-IIb) in 3 sections of the small intestine (duodenum, jejunum or ileum) and P utilization. Birds were allocated at 1-d old to 4 treatments in a randomized complete block design, each treatment had 7 replicate cages with 8 birds per replicate cage. Corn-soybean meal diets formulated to meet all nutrients requirements except for P were fed throughout the study. The ratio of Ca to total P was kept constant in all

diets. Non-phytate P levels in the diets were 2.5, 3.5, 4.5 and 5.5 g/kg. Twenty-eight birds, one bird from each cage, with weight closest to the average weight of the cage, were killed at d 21. Mucosa scraping was collected from the duodenum, jejunum and ileum of the selected birds and the expression level of NaPi-IIb relative to GAPDH was determined by RT-PCR. Ileal digesta was collected on d 21 from the remaining birds in the cage. Expression level of NaPi-IIb was negatively correlated with P level and total P intake but positively correlated with P digestibility ($P < 0.05$) at the jejunum. Correlation of expression level of NaPi-IIb at duodenum and ileum were mostly opposite to that at jejunum. Expression level of NaPi-IIb was similar in duodenum and jejunum but lowest ($P < 0.05$) at the ileum. Dietary P level had no influence on NaPi-IIb expression at any section of the small intestine. Ileal P digestibility was not affected by P supply but both total and digestible P intake were increased ($P < 0.01$) with increasing level of P in the diets. The data indicate that all the sections of the small intestine contribute to prececal P disappearance but duodenum and jejunum contribute the most. In addition, the data indicate that manipulation of NaPi-IIb expression level especially at the jejunum will strongly influence P utilization and excretion in broilers.

Key Words: broilers, phosphate transporter, small intestine

516 Effects of HMTBA chelated zinc, manganese and copper on performance, mineral status and immunity of broilers. Y. Ruangpanit*, S. Attamangkune, S. Rattanatubtimthong, and C. Khomkamon, *Kasetsart University*, *Nakhon-Pathom, Thailand*.

Two studies were conducted to investigate the effects of HMTBA chelated Zn, Mn and Cu on performance, mineral status and immunity of broilers. In Exp. 1, the effects of HMTBA Zn, Mn and Cu on performance and mineral status of broiler were evaluated. Two thousand, day-old, Ross 308 were divided into 2 dietary treatments including, 1) Corn-soy basal diet containing inorganic Zn, Mn and Cu at the recommended levels of the Thai standards (ITM) and 2) Corn-soy basal diet containing HMTBA Zn, Mn and Cu (Mintrex) at 25% of the inorganic levels used in ITM diet (CTM). Both diets were calculated to be isonitrogenous and isocaloric and were offered in pellet form. Each treatment consisted of 20 replications with 50 broilers per replication (25 males and 25 females). All birds were raised in environmental controlled house for 42 d. At the end of the experiment, carcass trail was evaluated. Liver and bone were collected for mineral analysis. Birds received CTM diet had significantly lower feed intake during 1–17 and18–35 d, and lower body weight gain during 1-17 d ($P < 0.05$). However, no significant difference in overall broiler performance and carcass trait were observed. The Zn, Mn and Cu concentrations in serum at d 20 were similar, but serum Zn and Cu concentrations of birds fed CTM diet were lower at d 42 ($P < 0.05$). Liver Zn, Mn and Cu concentrations and Zn and Cu concentrations in bone were not significant different. However, birds received CTM diet had lower bone Mn concentrations ($P < 0.05$). In Exp. 2, the effects of HMTBA Zn, Mn and Cu on immunity, oxidative stress status and mineral excretion were evaluated. One hundred and twenty, 12 d old, male Ross 308 were assigned into 2 dietary treatments as in Exp. 1. Each treatment consisted of 6 replications with 10 birds per replication. All birds were raised in metabolic cages. Birds fed CTM diet had higher secondary IgG responses against 7% SRBC antigen ($P < 0.05$). Both ITM and CTM birds had similar serum MDA concentration. Expectedly, broiler fed CTM diet had lower Zn, Mn and Cu excretion ($P < 0.05$). From this study, it can be concluded that chelated trace minerals have higher bioavailability and lower levels can be fed in the diet.

Key Words: broiler, organic mineral, mineral excretion

517 Effect of organic zinc supplementation on growth performance and carcass quality of broilers. H. M. Salim*, H. R. Lee, C. Jo, S. K. Lee, and B. D. Lee, *Chungnam National University*, *Yuseong, Daejeon, South Korea*.

The effect of supplementing diets with organic zinc on growth performance and carcass quality of female broiler chickens was investigated. A total of 3,200 1-d-old female broiler chicks were randomly assigned to 4 floor pens, 800 birds per pen, with 4 replicates (200 birds/replicate). A corn-wheat-soybean meal basal diet (Control) was formulated, and 20 ppm organic zinc (20 OZ), 40 ppm organic zinc (40 OZ), and 80 ppm organic zinc (80 OZ) were added to the basal diet to form 4 dietary treatments. During the 5-wk experimental period, feed and water were provided ad libitum. Body weight, feed intake, feed conversion and mortality were measured. At the end of the feeding trial, 2 birds per replicate pen were selected according to average body weight, slaughtered, defeathered and carcass evaluation was performed. For histology analysis, about 1 cm2 of skin samples from the thigh and back region of each bird were collected, embedded, sectioned, stained, and thickness of skin layers were examined under light microscope. Results showed no significant difference between the treatments in growth performance. A significant increase ($P < 0.05$) of thigh skin epidermis and dermis thickness were shown in the organic zinc supplementation groups; however, no effect of the zinc on the thickness of back skin epidermis and dermis was found. Collagen content in breast and thigh muscles was not influenced by organic zinc supplementation but a significant increase of collagen content was found in the back and thigh skin ($P < 0.05$). This increase of collagen content was significantly higher in the back and thigh skin of OZ 80 compare with OZ 20. Shear force of back skin and muscles was not significantly influenced by the dietary supplementation of zinc. Water holding capacity in breast muscle increased significantly ($P < 0.05$) when birds were fed OZ 40 and OZ 80; however, organic zinc supplementation had no adverse effect on over all consumer acceptability of broiler meat. It has been concluded that dietary organic zinc does not affect growth performance of broilers but increases collagen content in skin, thereby improving carcass quality of broilers.

Key Words: organic zinc, skin quality, broilers

518 Effect of dietary copper source and level on GI copper levels and ileal *E. coli* survival in broiler chicks. K. C. Klasing* and A. Naziripour, *University of California*, *Davis*.

Pentahydrate copper sulfate (CS) and tribasic copper chloride (TBCC) are the primary Cu sources fed at high levels to improve the health and growth of animals. TBCC is less soluble in water than CS but is more bioavailable so our goal was to examine their biological properties along the GI tract. These 2 Cu sources were fed at 150 ppm to 6 pens per trt of 3 broiler chicks per pen from d 3 to 14 of age. Intestinal luminal content was collected to determine total Cu, water extractable Cu, Cu that could be extracted using the strong complexing agent, ethylenebis-hydroxyphenylglycine (EHPG), and Cu that could not be extracted (presumed to be unavailable for nutritional and microbicidal purposes). Bacteriostatic activity to *E. coli* spiked into ileal intestinal contents was greater for TBCC than for CS ($P < 0.05$). Total Cu in luminal contents was not affected by Cu source. CS increased duodenal luminal soluble Cu and epithelial metallothionein more than TBCC ($P < 0.05$), indicating that it was taken up by epithelial cells at a greater rate in the upper small intestine, but this effect did not occur in the lower intestines. TBCC resulted in more EHGP-extractable Cu in all regions of the intestines ($P < 0.05$) and less unremovable Cu ($P = 0.05$), which may be related to its greater bioavailability and anti-coli activity.

Key Words: copper, intestines, broilers

519 Effects of dietary iron and age on cellular copper metabolism in liver of weanling pigs. R. S. Fry*, J. W. Spears, S. L. Hansen, H. C. Liu, and M. S. Ashwell, *North Carolina State University*, *Raleigh*.

Thirty-six weanling, male pigs were used in a 2 × 3 design to determine the effect of dietary iron (Fe) and age on hepatic cellular copper (Cu) metabolism. Pigs received diets containing 97 mg/kg Fe (control) or 797 mg/kg Fe (H-Fe) for either 21, 42, or 63 d. On each of these d 6 pigs per treatment were harvested and liver and bile were collected for Cu analysis and mRNA analysis of hepatic Cu transporters and chaperones. On the day before harvest jugular blood was obtained for plasma Cu and ceruloplasmin (Cp). Liver Cu was not affected by diet, but was affected by age. Pigs harvested on d 21 had higher ($P < 0.01$) liver Cu than pigs harvested on d 42 and 63. Plasma Cu and Cp were not affected by diet but both increased ($P < 0.01$) with age. Bile Cu was affected by a treatment × day interaction ($P < 0.05$). On d 21, bile Cu tended to be higher ($P < 0.10$) in H-Fe vs. control pigs, but did not differ on d 42. However, by d 63, bile Cu tended to be lower ($P < 0.10$) in H-Fe vs. control pigs. Messenger RNA of Ctr1, Atox1, and Atp7b were affected ($P < 0.05$) by a treatment × day interaction, and Cp mRNA tended ($P < 0.10$) to be affected by a treatment × day interaction. On d 21 and 63, Ctr1 was not affected by diet, but on d 42 mRNA of this Cu-importer was lower ($P < 0.01$) in H-Fe vs. control pigs. On d 21, Atox1, a chaperone that delivers Cu to the Cu-exporter, Atp7b, was markedly higher ($P < 0.01$) in H-Fe vs. control pigs, but did not differ on d 42 and 63. On d 21, Atp7b tended ($P < 0.10$) to be higher in H-Fe vs. control pigs. By d 42, Atp7b was lower ($P < 0.01$) in H-Fe vs. control pigs and was numerically ($P = 0.11$) lower in H-Fe pigs on d 63. On d 21 and 42, Cp, a Cu-dependent ferroxidase, was not affected by diet, but by d 63 it was lower ($P < 0.05$) in H-Fe vs. control pigs. In conclusion, age did not affect mRNA of Cu transporters and chaperones. However, high dietary Fe affected bile Cu and Cu transporters and chaperones involved in the secretory pathway of Cu metabolism. These data provide a better understanding of how Fe antagonistically affects Cu metabolism.

Key Words: pigs, copper, iron

520 Effect of level and source of dietary copper on copper metabolism in the small intestine of weanling pigs. R. S. Fry*, M. S. Ashwell, W. L. Flowers, K. R. Stewart, and J. W. Spears, *North Carolina State University*, *Raleigh*.

Thirty weanling pigs were used to determine the effect of level and source of dietary copper (Cu) on performance and Cu metabolism in the duodenum, proximal jejunum, and ileum. Dietary treatments consisted of 1) control (no added Cu), 2) 225 mg supplemental Cu/kg from Cu sulfate ($CuSO_4$) or 3) 225 mg supplemental Cu/kg from tribasic Cu chloride (TBCC). Feeding regimen consisted of 3 phase diets. Phase 1 diets were fed from d 0 to 6, phase 2 diets were fed from d 7 to 21, and phase 3 diets were fed for the remainder of the study. Prior to harvest on d 35 and 36, pigs were fasted for 8 h then re-fed for 8 h. Digesta and mucosal scrapings were collected from each section of the intestine for determination of soluble Cu and mucosal Cu concentrations. Digesta pH was obtained upon collection. During phase 1, TBCC pigs had higher ($P < 0.05$) average daily gain and gain:feed than $CuSO_4$ and control pigs. However, overall performance for the 35 d study was not affected by Cu level or source. Digesta pH increased ($P < 0.01$) as digesta descended down the small intestine, but did not differ by Cu level or source. Soluble Cu in the digesta and mucosal Cu in duodenum, proximal jejunum, and ileum were higher ($P < 0.05$) in Cu supplemented vs. control pigs. In the duodenum, soluble Cu in digesta tended ($P < 0.10$) to be lower while mucosal Cu was lower ($P < 0.05$) in TBCC vs. $CuSO_4$ pigs (104.3 vs. 130.3 mg/kg Cu). Soluble Cu in digesta from proximal jejunum and ileum was not different between Cu sources. However, pigs fed TBCC had higher ($P < 0.01$) Cu concentrations in mucosa of the proximal jejunum than $CuSO_4$ fed pigs (44.7 vs. 22.1 mg/kg Cu). In the ileum, mucosal Cu tended ($P < 0.10$) to be higher in TBCC vs. $CuSO_4$ pigs. In conclusion, pigs supplemented with Cu had much higher concentrations of soluble Cu in the digesta and intestinal mucosa than control pigs. Furthermore, Cu source affected Cu uptake differently throughout the small intestine. Markedly lower water solubility of TBCC compared with $CuSO_4$ may explain these differences.

Key Words: pigs, copper, metabolism

521 Dietary calcium and phosphorous and organic and inorganic trace minerals on nursery pig growth performance. J. S. Jolliff* and D. C. Mahan, *The Ohio State University*, *Columbus*.

Dietary Ca and P levels were evaluated for their effect on trace mineral usage as measured by postweaning growth performance and plasma minerals. Two levels of Ca and P (Ca:P) and 5 trace mineral (TM) treatments (2 × 5 factorial) were analyzed as an RCB over 6 blocks with 240 total nursery pigs (6.43 kg BW) for 35 d. The 2 Ca:P levels were 0.80% Ca and 0.65% P (Low) and 1.10% Ca and 0.91% P (High). Of the 5 TM treatments, 4 comprised a 2 × 2 factorial between 2 TM sources (organic or inorganic) and 2 TM levels. The first TM level (1x) provided 15 ppm Cu, 15 ppm Fe, 10 ppm Mn, and 140 pp Zn while the second level (2x) provided twice the amount of TM of the first level. The fifth TM treatment was no TM supplemented to the diet, i.e., all minerals were considered indigenous (basal). Pigs were weighed and feed disappearance recorded once per week postweaning. On d 35, all pigs were bled and hemoglobin, hematocrit, and plasma minerals were analyzed. TM treatment affected pig BW ($P < 0.05$) from d 21 onwards with the Basal TM treatment resulting in lighter weight pigs. Furthermore, pigs fed the Basal TM treatment had lower ($P < 0.05$) ADG, ADFI, and G:F by 21 d postweaning. Inorganic TM resulted in greater ADFI for the entire 35 d trial. There were Ca:P x TM interactions ($P < 0.05$) for BW, ADG, ADFI, and G:F in the later half of the nursery period. TM treatment affected ($P < 0.05$) pig hemoglobin with Basal having the lowest concentrations, inorganic TM having greater concentrations than organic, and the 2x TM level having greater concentrations than the 1x level. Pig hematocrit showed a similar pattern to hemoglobin, although TM level had no effect ($P > 0.05$). Low Ca:P resulted in greater ($P < 0.05$) plasma P and Zn than High Ca:P. Pigs in the Basal treatment had lower ($P < 0.05$) plasma P, Fe, and Zn than pigs receiving supplemental TM. There were no Ca:P interactions for any blood constituents. In summary, pigs fed inorganic TM had greater feed intake, hemoglobin concentrations, and hematocrit while High Ca:P reduced plasma P and Zn.

Key Words: pig, calcium, minerals

522 Effect of organic and inorganic trace mineral source and preslaughter deletion on tissue mineral content of pigs. Y. L. Ma*, M. D. Lindemann, G. L. Cromwell, and G. Rentfrow, *University of Kentucky*, *Lexington*.

Crossbred pigs weaned at 21 ± 3 d (n = 144; BW = 7.4 kg) were used to assess an organic form (ORG) of several trace minerals to standard inorganic forms (IN) on tissue mineral content when those minerals were deleted for various times preslaughter. Pigs were allotted to 24 pens (6 pigs/pen) based on gender and BW and fed a diet containing either IN ($CuSO_4 \cdot 5H_2O$, ZnO, $FeSO_4 \cdot H_2O$, MnO) or ORG (Bioplexes; Alltech Inc., Nicholasville KY) trace minerals (Cu, Zn, Fe, Mn) at the NRC (1998) requirement for each of 5 dietary phases of BW (equivalent to

14, 14, 42, 28, 42–d periods). Two pigs were removed from each pen at the end of phase 4 (BW = 82.6 kg), and at the end of phase 5 (BW = 126.6 kg) for the collection of tissue samples. After phase 4, 3 pens from each treatment were switched to a common diet without trace mineral supplementation in 2–wk intervals. This resulted in 4 groups within the IN and ORG source in which supplementation was deleted for 0, 2, 4, and 6 wk preslaughter. All data are reported on an mg/kg tissue DM basis. At the end of phase 4, ORG Mn content was greater ($P < 0.03$) in heart (0.77 vs. 0.68), liver (9.46 vs. 8.30), and longissimus dorsi (LD; 0.30 vs. 0.23). ORG Cu was greater ($P < 0.03$) in LD (2.12 vs. 1.89). ORG Fe was greater ($P < 0.03$) in LD (21.8 vs. 19.4) but lower in liver (466.1 vs. 564.4). Zn source did not affect tissue content. At the end of phase 5, increased length of deletion period (from 0 to 6 wk) resulted in a decrease (linear and quadratic, $P < 0.01$) in liver Zn (ORG – 209.2 to 118.8; IN – 183.8 to 124.8) and an increase (linear, $P < 0.01$) in heart Mn (ORG – 0.76 to 1.12; IN – 0.64 to 1.03) and liver Mn (ORG – 8.21 to 12.68; IN – 7.27 to 13.23). The only mineral source by deletion period interaction ($P < 0.04$) was in LD Zn where increasing deletion was associated with less Zn in IN–fed pigs (63.9, 55.7, 56.8, and 49.8) but not in ORG–fed pigs (56.4, 59.5, 56.7, and 62.0). The results demonstrate differential effects of mineral deletion on tissue mineral content depending on both mineral assessed and source of the mineral.

Key Words: trace minerals, pigs

523 The "immunocrit," a simple measure of passive transfer, is a useful predictor of nursing ability and preweaning mortality of piglets. J. L. Vallet*, J. R. Miles, L. A. Rempel, and L. A. Kuehn, *USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

Initiation of lactation and newborn piglet nursing ability are 2 factors that can influence preweaning mortality. We have developed the "immunocrit" that can assess both lactation initiation and neonatal piglet nursing ability based on the transfer of immunoglobulin G (IgG) from the sow to the piglet. To perform an immunocrit, 50 μL serum was mixed with 50 μL 40% ammonium sulfate, the mixture was loaded into a hematocrit capillary tube and centrifuged for 5 min. The result was the ratio of the mm precipitate to mm solution in the tube. To test the immunocrit, the smallest piglet in 205 litters was sacrificed, blood was collected and full and emptied stomachs were weighed to obtain the weight of stomach contents. Blood was analyzed for IgG by precipitation of serum samples with protein A-Sepharose followed by SDS-PAGE. Densitometry of the heavy chain of IgG was used to quantify IgG. To test use in cattle, blood samples from 96 calves were obtained 24 h after birth and IgG was measured (Bovine IgG radial immunodiffusion kit; VMRD, Inc.). Piglet and calf blood samples were also analyzed by immunocrit. For piglets, the correlation between densitometry and immunocrit values was 0.83. For calves, the correlation between kit IgG and immunocrit values was 0.90. Piglet immunocrit values were also correlated ($r = 0.44$; $P < 0.01$) with stomach contents at 24 h, indicating that immunocrits could be used to screen for piglet nursing ability. To assess the influence of immunocrit values on piglet preweaning survival, immunocrits were performed on every piglet in 48 1st and 68 2nd parity litters and survival to weaning was recorded. Preweaning survival was independently associated ($P < 0.01$) with birth weight of the piglet and immunocrit values. Second parity sows had greater litter average immunocrit values compared with 1st parity sows (0.133 ± 0.003 and 0.123 ± 0.004, respectively; $P < 0.05$). These results indicate that the immunocrit is a useful tool to monitor colostrum intake in piglets and calves.

Key Words: colostrum, immunoglobulin, lactation

524 Influence of temperament on stress hormone and IgG concentrations in Brahman calves. N. C. Burdick*[1], D. A. Neuendorff[2], R. C. Vann[3], J. G. Lyons[1], T. H. Welsh Jr.[1], and R. D. Randel[2], [1]*Texas AgriLife Research*, *College Station,* [2]*Texas AgriLife Research*, *Overton,* [3]*MAFES, Mississippi State University*, *Raymond*.

This study was designed to determine the influence of temperament on cortisol, epinephrine (EPI), norepinephrine (NE), and IgG concentrations in Brahman calves. Calves from crops in 2006 and 2007 were selected based on temperament score measured 28 d before and at weaning. Based on temperament score the 10 calm, intermediate, and temperamental calves from each sex (bulls and heifers) were selected from each calf crop (n = 120). Blood was collected 28 d before weaning, at weaning, and 28 and 56 d post-weaning to determine serum cortisol and IgG, and plasma EPI and NE concentrations. Data were analyzed using the MIXED procedure of SAS specific for repeated measures. Sources of variation included temperament, sex, day, and year. Cortisol ($P < 0.01$) was, and EPI tended ($P = 0.08$) to be, greater in 2006 than 2007. Cortisol was affected by temperament with calm calves having lower cortisol (14.4 ± 0.7 ng/mL; $P < 0.01$) than intermediate (18.6 ± 0.7 ng/mL) and temperamental (30.8 ± 0.7 ng/mL) calves. Heifers had greater cortisol than bulls ($P < 0.01$; 22.9 ± 0.6 and 19.6 ± 0.6 ng/mL, respectively). Cortisol increased from d0 (18.5 ± 0.8 ng/mL) through d+56 ($P < 0.01$; 25.2 ± 0.8 ng/mL). Calm calves had lower EPI (149 ± 18 pg/mL) than intermediate (203 ± 18 pg/mL) and temperamental calves ($P < 0.01$; 381 ± 18 pg/mL). Heifers had greater EPI ($P < 0.01$; 278 ± 14 pg/mL) than bulls (212 ± 15 pg/mL). Concentrations of EPI decreased from d-28 (326 ± 20 pg/mL) through d+56 ($P < 0.01$; 169 ± 22 pg/mL). Calm calves had lower concentrations of NE than intermediate and temperamental calves ($P < 0.04$; 510 ± 72, 732 ± 74, and 719 ± 72 pg/mL, respectively). Concentrations of NE changed over time ($P = 0.01$) and were not affected by sex ($P = 0.98$). Concentrations of IgG were not affected by temperament ($P = 0.43$) or time ($P = 0.22$) but tended to be affected by sex with heifers (26.7 ± 2.2 mg/mL) having greater IgG than bulls (21.6 ± 2.2 mg/mL; $P = 0.11$). In summary, temperamental calves have greater stress hormone concentrations. Additionally, cortisol, EPI, and IgG concentrations can vary depending on sex of the calf.

Key Words: cattle, temperament, stress

525 Effect of cytochrome P450 and aldo-keto reductase inhibitors on progesterone decay in primary bovine hepatic cell cultures. C. O. Lemley* and M. E. Wilson, *West Virginia University*, *Morgantown*.

Progesterone is required for maintenance of pregnancy and peripheral concentrations of progesterone are affected by both production and inactivation. Hepatic cytochrome P450 (CYP) and aldo-keto reductases (AKR) play a pivotal role in the first step of steroid inactivation. The current objectives were to discern the proportional involvement of hepatic progesterone catabolic enzymes on progesterone decay using specific enzyme inhibitors. Liver biopsies were taken from 6 lactating dairy cows and dissociated using a non-perfusion technique. Confluent wells (n = 12/treatment) were preincubated for 4 h with enzyme inhibitor and then challenged with progesterone for one hour. Cell viability was unaffected ($P > 0.50$) by inhibitor treatment and averaged 84 ± 1%. In control wells 50% of the progesterone had been inactivated after a one hour challenge with 5 ng/ml progesterone. Preincubation with curcumin (CYP and AKR inhibitor), ticlopidine (CYP2C inhibitor) or naproxen (AKR inhibitor) caused the greatest reduction ($P < 0.001$) in progesterone decay compared with controls and averaged 77, 39 or 37%, respectively. Hydroxylation of 4-nitrophenol to 4-nitrocatechol in intact cells was inhibited by 65% ($P < 0.001$) after treatment with curcumin or ticlopidine. However, phase II glucuronidation of phenol red or 4-nitrocatechol in intact cells was inhibited ($P < 0.01$) by treatment with curcumin, dicumarol or naproxen, showing a lack of specificity in phase I enzyme inhibition (CYP and AKR). The contribution of CYP2C and CYP3A enzymes to progesterone decay in bovine hepatic cell cultures appeared to be 40 and 15%, respectively. Depending on the inhibitor used it would appear that the AKR enzymes contributed 40% to the observed progesterone decay; however, a portion of this loss may be due to glucuronosyltransferase (phase II enzyme) inhibition. A greater understanding of these steroid biotransformation pathways in the dairy cow could help researchers modify the bioavailability of progesterone.

Key Words: cytochrome P450, aldo-keto reductase, progesterone decay

526 Residual feed intake selection and its effects upon pre- and postpartum changes in NEFA concentrations and body weight and condition in Brahman females. A. K. Poovey*[1,2], A. N. Loyd[1,2], A. W. Lewis[1], D. A. Neuendorff[1], S. L. Morgan[1,2], L. C. Caldwell[2],

T. D. A. Forbes[3], T. H. Welsh Jr.[2], and R. D. Randel[1], [1]*Texas AgriLife Research*, *Overton,* [2]*Texas AgriLife Research*, *College Station,* [3]*Texas AgriLife Research*, *Uvalde*.

Residual feed intake (RFI) is one method to identify efficient animals based upon the relationship of predicted to actual individual feed intake. Nonesterified fatty acid (NEFA) concentrations are the products of catabolism of triglycerides and are negatively correlated with energy balance and body weight in females. The objective of this study was to examine the relationship among RFI status with pre- and postpartum NEFA concentrations in beef females. Based upon prior post-weaning RFI evaluations, Brahman females (n = 93) were classified as having either a negative RFI (efficient) or a positive RFI (inefficient). Body condition score (BCS), body weight (BW), and serum samples were collected at weekly intervals beginning 5 wk before and continuing through 5 wk after calving. Pre-calving, NEFA concentrations did not differ between low and high RFI groups ($P > 0.3$). There was an interaction between NEFA concentrations and prepartum time period ($P = 0.02$). However, during this time, RFI ($P = 0.8961$) and age group ($P = 0.11$) did not affect change in BW although there tended to be differences in BW between 2 year old (YO) heifers and cows 4 years and older ($P = 0.05$). Similarly, change in BCS was not affected by RFI ($P = 0.88$); however, age group tended to differ ($P = 0.06$). Specifically, 2 YO cows lost more BCS than 3 YO ($P = 0.02$) and 3 YO tended to lose more BCS than cows 4+ YO ($P = 0.07$). Postpartum NEFA concentrations changed over time ($P = 0.02$) and were affected by sampling week ($P = 0.02$). Neither age nor RFI influenced changes in BW ($P = 0.75$; $P = 0.98$, respectively) or BCS ($P = 0.29$; $P = 0.79$, respectively). Circulating concentration of NEFA in pre- and postpartum females was not related to RFI previously evaluated when the females were heifers. Changes in BW and BCS did not differ due to previous evaluation for RFI as heifers during the same peri-partum periods. Age of cow was the only factor found to be related to serum NEFA concentrations or changes in BW and BCS.

Key Words: feed efficiency, nonesterified fatty acids, peri-partum cows

527 Ruminal degradability and intestinal release of different vitamin A formulations. D. P. Preveraud* and P. A. Geraert, *Adisseo France SAS*, *Antony, France*.

The most convenient way to provide vitamin A (VA) to ruminants is to include it with concentrate mixtures. Feed industry usually formulates a VA ester emulsified into a gelatin beadlet to ensure good stability and biological availability. The aim of this study was to evaluate the rumen degradability and intestinal release of different VA formulations, including the double emulsion (Microvit A1000 Supra, Adisseo), by using a Mobile Nylon Bag (MNB) methodology. Two dairy cows equipped with ruminal and duodenal cannulas were used in a 2-period crossover experimental design. The 9 tested formulations were incubated in the rumen in nylon bags (6 replicates) for 6, 10 or 18h and residues from these bags were then incubated in a pepsin HCl solution (38.5°C, pH 2) for 2.5h to simulate abomasal digestion, and finally inserted through the duodenal cannula to be recovered from feces after 24h. Nylon bags were then analyzed for their VA content and results were expressed as a percentage of residual VA compared with initial content of non-incubated product (see table). Microscopic photographs were also taken to follow the degradation of the different formulations. The overall results of this experiment indicated that these VA sources could be divided into 3 groups according to their rumen stability and in relation with their formulation: stable (double emulsion, Microvit), intermediate (products A, B, C, G and H) and sensitive (products D, E and F). Despite a low (14%) but significant loss of the double emulsion formulation after 18h incubation in rumen, 81% of the initial amount finally reaches the intestine where VA is totally released. Among the sources of vitamin A being studied, the double emulsion formulation seems to be more bioavailable to cattle. This should be confirmed later on by a greater tissue concentration of VA.

Table 1. VA residues[1] at each step of the MNB technique (% of initial content)

	6-h rumen	10-h rumen	18-h rumen	abomasum	feces

528 Poisson analysis of number of services per conception for Iranian Holstein cows. H. Farhangfar*[1] and F. Bahri[2], [1]*Birjand University*, *Birjand, Iran*,

[2]*Ferdowsi University of Mashhad*, *Mashhad, Iran*.

To evaluate the effects of some environmental factors on the number of services per conception (NSC) in Iranian Holstein cows, a total of 38,074 records obtained from 10,726 cows at different parities (1985–2009) was utilized. All records were collected from a very large dairy herd comprising of 2 separate units. The units were different from each other from dairy farm management point of view. Average number of services per conception was 2.29 in the whole data set. A generalized statistical linear model was applied to analyze NSC. Poisson distribution was assumed for NSC and a log link function was applied for the response variable. In the model, fixed effects of period of years (in 3 levels), month of insemination, technician, parity and unit were included. Based upon the year of insemination, 3 year periods were defined as follows: 1985–1990, 1991–2000 and 2001–2009. The statistical model was run with the use of GLMMIX procedure add in program implemented in SAS software. The results indicated that year period and unit were the only significant factors that influenced NSC ($P < 0.01$). Least squares means of NSC (in original scales) were 2.1776, 2.2807 and 2.2805 for year periods of 1985–1990, 1991–2000 and 2001–2009, respectively. The least squares means of NSC (in original scales) of farms units were obtained to be 2.1707 and 2.3234 for units 1 and 2, respectively revealing slightly different reproductive efficiency between 2 units of the dairy herd. Among different parities, the largest and lowest NSC least squares means were found for parity 7 and 10, respectively. However, no significant differences were revealed among the parities. From the results of this research it could be concluded that the reproductive efficiency of Iranian Holstein cows has been deteriorating over the past decades suggesting that a sophisticated genetic selection program

should be considered for improving the traits associated with reproduction performance.

Key Words: Iranian Holstein, Poisson analysis, reproduction performance

529 Effects of continuous infusion of tumor necrosis factor-alpha (TNFα) into adipose tissue on glucose and fatty acid metabolism in lactating dairy cattle. C. A. Martel*[1], L. K. Mamedova[1], E. J. Minton[1], M. L. Jones[2], J. A. Carroll[3], and B. J. Bradford[1], [1]*Department of Animal Sciences and Industry*, *Kansas State University*, *Manhattan*, [2]*Veterinary Medical Teaching Hospital, Kansas State University*, *Manhattan*, [3]*Livestock Issues Research Unit, ARS-USDA*, *Lubbock, TX*.

Late-lactation Holstein cows (n = 9/treatment) were used to evaluate effects of TNFα administration on glucose and fatty acid (FA) metabolism. Cows were blocked by feed intake and milk yield and randomly assigned within block to 1 of 3 treatments: control, TNFα, and pair-fed control. Treatments (4 mL saline or 14 μg/kg TNFα in 4 mL saline) were infused continuously over 7 d via 2 osmotic pumps in the adipose layer in the tailhead region. Plasma, milk samples, milk yield, and DMI data were collected daily. On d 7, pumps were removed and liver and contralateral tailhead adipose samples were collected. Results were modeled with fixed effect of treatment and random effect of block; *P* values >0.10 were considered non-significant. TNFα did not alter adipose or liver TNFα mRNA abundance, plasma TNFα, IL-4, IL-6, or interferon-γ concentrations, DMI, or rectal temperature. Milk fat and lactose concentrations decreased with TNFα ($P < 0.05$), but milk yield was unchanged and treatments did not alter the proportion of short vs. long-chain FA in milk on d 7. Treatments did not alter plasma NEFA concentration, liver triglyceride content, or adipose mRNA abundance for hormone-sensitive lipase or perilipin. Plasma glucose turnover rate, as measured by disappearance of U-^{13}C-glucose bolus, was not altered by treatment, nor was liver mRNA abundance for phosphoenolpyruvate carboxykinase or pyruvate carboxylase. However, TNFα tended to decrease adipose TNFα mRNA abundance ($P = 0.09$) and increase liver IL-10 mRNA abundance ($P = 0.05$) compared with controls. This TNFα delivery protocol may have allowed for an adaptive anti-inflammatory response to suppress systemic inflammation, which may account for the lack of metabolic responses, in contrast with previous responses to daily subcutaneous TNFα injections.

Key Words: dairy, TNFα, gluconeogenesis

530 Reproductive rate of semi-free ranging Bison (*Bison bison*) at the National Bison Range. M. J. Borgreen*[1,2], T. J. Roffe[2], E. M. Berry[1], R. B. McCosh[1], and J. G. Berardinelli[1], [1]*Montana State University*, *Bozeman,* [2]*US Fish and Wildlife Service*, *Bozeman, MT*.

Recruitment of calves at the National Bison Range (NBR) near Moiese, Montana, has dropped from the historic average of 87 to 33 calves per 100 breeding-age cows in 2008. The purpose of monitoring the NBR bison pregnancy rate (PR) and calf recruitment is to determine where in the reproductive cycle NBR female bison fail to recruit calves. The reproductive cycle was divided into 3 stages: conception to early embryonic development; maintenance of pregnancy during the second and third trimesters; and, calving to recruitment. In 2008, transrectal ultrasonography was used to determine PR in cows (ages 4 to 12 yr) in October; 28 of 41 cows (68%) were pregnant. Pregnant cows were painted with a unique bleach number. Fecal samples were collected in Oct., Jan., Mar. and Apr. until the bleach number was illegible. Fecal samples were analyzed for progesterone (P4). Pregnancy rates estimated by fecal P4 concentration decreased ($P < 0.01$) from 100% (n = 28) in Oct. to 53% (n = 15) in Apr. The percentage lost continuously decreased throughout the second stage, with the largest percent decrease between first and second trimester (17%). Of the original 28 pregnant cows the PR in April was 53%; a reduction of 47%. This closely matched calf recruitment of the herd at the 2009 roundup (71 calves for 126 cows; 56%): indicating that the accuracy for estimating pregnancy using fecal P4 was 94.7%. In 2009, PR was determined by ultrasonography of 89 cows, including 38 of the 41 cows from 2008. Pregnancy rate for 2009 was 63%, which was similar to PR in 2008 (68%). Radio collars were secured to 27 pregnant and 10 non-pregnant cows. These animals will be monitored throughout the rest of the reproductive cycle to determine calf production using fecal P4 assay. Fecal P4 assays appear to give an accurate estimate of PR in semi-free ranging bison. In conclusion, it appears that the decrease in calf recruitment at the NBR can be, at least in part, due to fetal losses during gestation.

Key Words: bison, fecal progesterone, pregnancy rate

Physiology and Endocrinology: Sperm-Oviduct Interactions in Livestock and Poultry

531 Evidence that oviduct secretions influence sperm function: a retrospective view for livestock. G. J. Killian*, *The Pennsylvania State University*, *University Park*.

The mammalian oviduct has long been recognized as an organ essential to the success of reproduction. Bovine, ovine, porcine and equine animal models have offered clear advantages for oviduct study related to gamete physiology, fertilization and early embryo development. Livestock species are amenable to surgical alteration of the reproductive tract, estrous cycle manipulation, gamete cryopreservation, artificial insemination as well as in vitro fertilization and embryo production. Although most reproductive technology developed for livestock was intended to benefit production animal agriculture, these techniques are a treasure trove of tools for researchers to better understand how the oviduct influences gamete function. Oviduct secretions obtained from in vitro tissue cultures or via indwelling oviduct catheters have been used for analyses to define the protein, lipid, carbohydrate, enzyme and electrolyte compositions of the secretions during the estrous cycle or in response to hormone treatment. Oviduct secretions or components purified there from have also been used in in vitro assays to assess their ability to bind to sperm and/or influence on sperm viability, motility, sperm capacitation, the acrosome reaction, sperm-egg binding, egg penetration as well as subsequent embryo development. Compelling data have emerged which show that the composition of secretions differs during the estrous cycle and that their composition differs whether they originate from the ampullar or isthmic regions of the oviduct. These differences in composition are functionally relevant and associated with different responses by sperm. Evidence suggests that oviduct -specific glycoproteins, glycosaminoglycans, carbohydrates, norepinepherine, catecholamines, heat-shock protein and osteopontin are components of the oviductal milieu which have the capacity to modulate sperm function. Continued research on the livestock oviduct will likely unravel the role that specific oviduct secretions have in modulating sperm function and how these modifications ultimately affect fertilization and embryo development.

Key Words: sperm, oviduct, secretions

532 Role of the oviduct in maintaining sustained fertility in hens. M. R. Bakst*[1] and J. P. Brillard[2], [1]*ARS, USDA*, *Beltsville, MD*, [2]*INRA*, *Tours, France*.

In poultry, sperm transferred by natural mating or artificial insemination (AI) into the distal end of the vagina immediately begin their ascent to the utero-vaginal junction (UVJ) located at the anterior end of the vagina. During their transport there is an intense sperm selection process that may reduce the number of sperm initially transferred by as much as 99.5%. Those "select" sperm reaching the UVJ enter the thousands of tubular invaginations of the vagina's surface epithelium located in the UVJ mucosa, collectively referred to as the sperm-storage tubules (SST). Sperm residing in the SST lumen are capable of surviving for several weeks while retaining their fertilizing capacity. Resident sperm are released gradually from the SSTs while the hen is in egg production, ascend to the site of fertilization, and interact with the next ovulated ovum. In this manner, given the absence of an estrus to synchronize ovulation with copulation, poultry, and birds in general, are assured a population of sperm at the site of fertilization during a daily succession of ovulated ova. Over the past decade several new and diverse observations have been published addressing the microanatomy of the UVJ and SST, and the cellular and molecular mechanisms orchestrating oviductal sperm selection and storage. These include: the SST numbers in different poultry species and lines of high and low fertility; roles of the immune system and possibly neuroendocrine-like cells in the vagina in sperm selection and storage; the roles of aquaporins and a fluid exchange mechanisms contributing sperm release from the SSTs; and, gene expression of the SST epithelial cells with or without resident sperm. The objective of this presentation is to integrate these observations into a comprehensive understanding of the cellular and molecular events influencing the fate of sperm in the hen's oviduct, particularly in the area of oviductal sperm selection and storage.

Key Words: poultry, reproduction, oviduct

533 Effect of sperm mobility phenotype on fertility, sperm competition, and in vivo sperm storage in the domestic fowl. D. P. Froman*, *Oregon State University*, *Corvallis.*

Sperm mobility is a quantitative trait. Phenotype is determined by the extent to which sperm move against resistance at body temperature. This ability is measured in vitro by sperm penetration of 6% (wt/vol) Accudenz from an overlaid sperm suspension. The study of sperm mobility has provided: 1) an estimate of heritability, 2) an explanation for phenotypic variation based upon properties of individual motile sperm, 3) a plausible model that explains why a portion of sperm ejaculated by any given male are immobile in addition to why this proportion varies among males, and 4) loci of interest within the fowl genome. The distinction between sperm motility and mobility is critical. Whereas all mobile sperm are motile, not all motile sperm are mobile; for a motile cell must have a velocity >30 μm per second to be mobile in vitro. This distinction is biologically significant because sperm mobility phenotype predicts male fertility when hens are inseminated with a fixed number of viable sperm. Immobile sperm contain dysfunctional mitochondria, and the time course for mitochondrial failure begins before ejaculation. Percentages of affected sperm appear to range between 10 and nearly 100%. This variation is attributed to a genetic predisposition that puts sperm cells at risk as they pass through the deferent ducts of the testis. Sperm mobility is heritable ($h^2 = 0.30$), and phenotype is influenced by a maternal additive genetic effect, attributed to the Z chromosome based upon genome-wide SNPlotype analysis. To date, experiments have been reductionist in nature. Nonetheless, synthesis of experimental outcomes has afforded 4 new insights. These include: 1) how fitness varies among normal, fertile males within a population, 2) a likely mechanism enabling in vivo sperm storage, 3) a quantitative, gene-based definition of semen quality, and 4) a new approach to semen preservation based upon bioenergetic theory. In essence, sperm are self-propelled DNA delivery vehicles. This presentation will explain how the self-propulsive nature of sperm varies among males and how such variation affects male fitness.

Key Words: domestic fowl, fertility, sperm

534 Bovine oviduct-sperm interactions preceding fertilization. S. S. Suarez*, *Cornell University*, *Ithaca, NY*.

The bovine oviduct is not a simple conduit for sperm. The epithelium and luminal fluids of the oviduct affect the physiological state of sperm and movement of sperm into and through the oviduct. There is evidence that the oviduct is open to sperm for only a limited time after insemina-

tion; furthermore, sperm may require certain cell surface proteins to gain access. After entering the oviduct, bull sperm bind to the oviductal epithelium using 3 proteins in the BSP family (PDC109 or BSPA1/A2, BSPA3, and BSP30K), which are the major secreted proteins of the seminal vesicles. The BSP proteins coat the heads of sperm when they come into contact with vesicular secretions at ejaculation. Putative oviductal receptors for the BSP proteins are 4 proteins in the annexin family (ANXA1,2,4,5). Sperm binding to oviductal epithelium results in the development of a storage reservoir of sperm in the lower oviduct. There is evidence that binding prolongs the fertility of sperm; that is, when sperm coated with BSP proteins are incubated with apical plasma membranes of oviductal epithelium, their motile lives are extended. Release of sperm is likely a gradual process, with sperm breaking loose and then reattaching several times. The gradual release of sperm would reduce the numbers that arrive at the oocyte at any one time, thereby preventing polyspermy, and would also prolong the arrival of sperm in the upper oviduct to ensure that fertilization takes place. Capacitation may play a role in sperm release, because the process involves shedding of BSP protein and reduces bull sperm binding to oviductal epithelium. Capacitation of bull sperm is enhanced in vitro by heparin and heparin-like glycosaminoglycans have been detected in bovine oviduct fluid. Considering the role of heparin in capacitation, it is interesting that both BSP and annexin proteins bind heparin. Differential shedding of the BSP proteins and their differing affinities for the 4 annexin proteins may result in a gradual and directed release of sperm toward the site of fertilization.

Key Words: sperm, oviduct, seminal vesicles

535 In vivo imaging of in situ motility of fresh and liquid-stored ram spermatozoa in the ewe genital tract. X. Druart*[1], J. Cognié[1], G. Baril[1], F. Clément[2], J.-L. Dacheux[1], and J.-L. Gatti[1], [1]*UMR 6175 INRA, CNRS-Université de Tours-Haras Nationaux*, *Nouzilly, France*, [2]*INRIA Paris-Rocquencourt*, *Le Chesnay Cedex, France*.

The fertility of ram semen after cervical insemination is substantially reduced by 24 h of storage in liquid form. The effects of liquid storage on the transit of ram spermatozoa in the ewe genital tract was investigated using a new procedure allowing direct observation of the spermatozoa in the genital tract. Ejaculated ram spermatozoa were fluorescently labeled and used to inseminate ewes in estrus either cervically through the vagina or laparoscopically into the base of the uterine horns. Four hours after insemination, the spermatozoa were directly observed in situ using fibered confocal fluorescence microscopy. The high resolution video images obtained with this technique allowed determination of the distribution of spermatozoa and individual motility in the lumen of the ewe's genital tract. The results showed a gradient of increasing concentration of spermatozoa from the base of the uterus to the UTJ 4 h after intrauterine insemination into the base of the horns. The in vitro storage of spermatozoa in liquid form decreased their migration through the cervix and reduced the proportion of motile spermatozoa and their straight line velocity at the UTJ and their transit into the oviduct.

536 Comparison of timed AI pregnancy rates in Santa Gertrudis (SG) and SG crossbred heifers following the 7-d or 5-d CO-Synch+CIDR protocol. R. L. Stanko*[1,3], K. D. Arnold[1], J. R. Ramirez[2], S. Moore[2], and R. Silguero[2], [1]*Texas A&M University-Kingsville*, *Kingsville,* [2]*King Ranch, Inc.*, *Kingsville, TX,* [3]*Texas AgriLife Research*, *Beeville*.

Our objective was to evaluate the effectiveness of CO-Synch + CIDR protocols and timed AI (TAI) in beef heifers typical to the gulf coast states. Heifers (n = 239) of 2 breed types were used: Santa Gertrudis (SG, n = 145) and SG x Red Angus, F1 (SGX, n = 94). Heifers (n = 6, 2.5%) were removed from data set due to lost CIDR or absence at TAI or pregnancy determination. Age was determined from recorded birth date, and BCS and BW was recorded at CIDR insertion. All heifers were administered GnRH (100 µg, i.m.) and either a new (n = 121) or an autoclaved, once-used (n = 118) CIDR insert (1.38 g progesterone) at random on d 0. CIDR inserts were removed and prostaglandin F2α (PG, 25 mg, i.m.) was administered on d 7 (n = 160) with TAI performed 55 to 58 h after PG or CIDR inserts were removed and PG administered twice on d 5 (n = 73) with TAI at 72 to 75 h after PG. All heifers were administered GnRH (100 mg, i.m.) following TAI. Pregnancy was diagnosed by transrectal ultrasonography at 34, 35 or 36 d after TAI. Heifer age, BW, BCS, and TAI pregnancy rate (PR) was 372.0 ± 2.0 d, 331.0 ± 3.1 kg, 5.6 ± 0.04, and 43.8%, respectively. Chi-squared analysis was used to determine differences in PR. Overall, PR was greater ($P < 0.01$) in SGX (51/92, 55.4%) than in SG (51/141, 36.2%) heifers. Similar ($P > 0.1$) PR was observed between heifers receiving the once-used or new CIDR (56/115, 48.7% vs. 46/118, 39%), and between heifers on the 7-d or 5-d CIDR insert (68/160, 42.5% vs. 34/73, 46.6%). SG heifers receiving the 7-d CO-Synch + CIDR protocol had lower ($P < 0.01$) pregnancy rate (30/91, 33.0%) than SGX (38/69, 55.0%) receiving the same protocol. However, SG and SGX heifers receiving the 5-d CO-Synch + CIDR protocol had similar ($P > 0.1$) PR (21/50, 42.0% vs. 13/23, 56.5%, respectively). Heifers with less than 1/4 Brahman influence had acceptable PR with the CO-Synch + CIDR protocol, regardless of duration or CIDR type. The 5-d CO-Synch + CIDR protocol may prove to be an acceptable TAI protocol for SG heifers. Other synchronization of estrus and ovulation protocols are needed to enhance success rate of TAI in cattle adapted to the gulf coast region.

Key Words: heifer, CIDR, synchronization

537 Neither temperament or residual feed intake affect sexual maturity in Brahman heifers. A. N. Loyd*[1], D. A. Neuendorff[1], A. W. Lewis[1], T. D. A. Forbes[2], and R. D. Randel[1], [1]*Texas AgriLife Research*, *Overton*, [2]*Texas AgriLife Research*, *Uvalde*.

Selection of calm and feed efficient cattle based on temperament and residual feed intake (RFI), respectively may improve the overall profitability of beef cattle operations. While studies have investigated the relationships of temperament and RFI with growth parameters, only limited data are available concerning reproductive traits. The objective of this study was to evaluate the effects of temperament and RFI on sexual maturity of Brahman heifers. Brahman heifers born in 2005 (n = 48) and 2006 (n = 54) were evaluated at weaning for temperament using pen score (PS) and exit velocity (EV). Temperament score was calculated for each heifer as the average of PS and EV. Heifers (n = 38 in 2005; n = 41 in 2006) were fed a balanced ration at 2.5% BW twice daily at 0800 and 1600 h in Calan gates. Residual feed intake was calculated from weekly feed intake and BW data collected for 70 d. Following the feeding trial, heifers were allowed to graze coastal bermudagrass pasture and were exposed to a mature Brahman bull for natural breeding. Age at calving was recorded and age at sexual maturity was defined as 292 d before calving. Weight at sexual maturity was determined from BW and ADG data collected every 28 d. For statistical analysis, heifers were categorized as calm, intermediate or temperamental based on ± 0.5 standard deviation (SD) of both the mean EV and mean temperament score. RFI sign was used to categorize heifers as efficient (negative RFI) or inefficient (positive RFI). Heifers were also classified as efficient,

intermediate or inefficient based on ± 0.5 SD of the mean RFI. Using EV, temperament score, RFI sign, and RFI category as class variables, age and weight at sexual maturity were analyzed by PROC GLM. No differences ($P > 0.05$) were detected among these parameters comparing all temperament and RFI classifications. These data suggest that selection for RFI or temperament should not affect age or weight at sexual maturity in Brahman heifers.

Key Words: heifer, residual feed intake, temperament

538 Evaluation of a reproducible model for necrotic enteritis in broilers and analysis of NetB toxin profiles of different field isolates of *Clostridium perfringens*. S Shivaramaiah*[1], J. R. Barta[2], S. L. Layton[1], M. J. Morgan[1], R. E. Wolfenden[1], B. M. Hargis[1], and G Téllez[1], [1]*University of Arkansas*, *Fayetteville,* [2]*University of Guelph*, *Guelph, ON, Canada*.

Necrotic enteritis (NE) caused by Type A strains of *Clostridium perfringens* (CP) is an economically important disease in commercial poultry production. *Eimeria* infection is considered an absolute prerequisite to cause NE by disrupting intestinal integrity. Several reproducible NE models have used either immunosuppression or dietary modifications as common predisposing factors in conjunction with *Eimeria* infection. Preliminary data from our studies indicated that *Salmonella* infection early in the age followed by *Eimeria* and CP challenge accentuated NE-associated morbidity and mortality. In 2 replicate experiments, day-of-hatch chicks (n = 25/trt) were randomly assigned as Negative control (G1), *Eimeria* + CP (G2) or *Salmonella* + *Eimeria* + CP (G3). Challenge organisms included wild type *Salmonella typhimurium* (ST; ~2 × 10^8 cfu/chick) at day-of-hatch, sporulated oocysts of *E. maxima* (4 × 10^4/chick), at either D18 or D21, and 2 field strains of CP (1 × 10^8 cfu/chick), at either D22–23 or D25–26. Body weight (BW) was recorded before *Eimeria* challenge and at termination (D25 or D28) to determine weight gain. In addition, total mortality and lesion scores were evaluated. BW and lesion score data were analyzed using JMP7 while mortality was analyzed using the chi-squared test of independence. In both experiments, chicks in G3 suffered reduced ($P < 0.05$) weight gain as compared with either G1 or G2. In addition, total mortality and lesion scores were higher ($P < 0.05$) in G3 as compared with G2. Toxin profiling for challenge strains were evaluated to check for the presence of NetB, a toxin which is apparently obligatory for disease. Future studies are directed toward confirmation of the obligatory role of NetB in the pathogenesis of NE and the potential of NetB negative isolates to cause NE. The ability of selected probiotics to ameliorate NE is also currently under investigation.

Key Words: *Salmonella*, necrotic enteritis, NetB

539 Effects of a microbial litter amendment on litter quality and broiler performance. M. J. Hinkle*[1], S. M. Gottselig[1], J. L. McReynolds[2], J. T. Lee[1], and C. D. Coufal[1], [1]*Texas A&M University*, *College Station*, [2]*USDA-ARS*, *College Station, Texas*.

The reuse of litter in broiler production can lead to litter pathogen buildup and high levels of ammonia in broiler housing, thus resulting in poor broiler performance. This study evaluated the effects of a commercially available microbial culture litter amendment product on litter characteristics, ammonia production and broiler performance. Eight pens approximately 3 × 3 m each were used to rear broilers to 49 d of age at a density of 743 cm^2 (0.8 ft^2) per bird. Four pens were treated with the amendment according to the manufacturer's specification, and the remaining 4 pens served as untreated controls. Litter that had been used for 14 flocks was obtained from a commercial broiler farm and placed into the pens at an average depth of 11 cm. Feed consumption and mortality were recorded for each pen throughout the experiment. Ammonia production was measured by placing an enclosed chamber over the litter and sampling the headspace after 20 min with a Drager CMS unit. Ammonia measurements were taken one week before chick placement, at the time of chick placement, and once per week for the remainder of the grow-out. Litter samples were collected at the same time and location as ammonia measurement. On d 49, all caked litter was removed from each pen, weighed and sampled. Litter and cake samples were analyzed for total aerobic and anaerobic microbial counts. Paw scores were also recorded on d 49 for all birds using a 3-point scale (0, 1 or 2). Data were subjected to ANOVA using the GLM procedure with means deemed significantly different at $P < 0.05$. Percent mortality was significantly lower for treated pens (2.1%) than control (3.65%), but no statistical differences were observed for any other parameters measured. Average ending BW, feed:gain, paw score and cake weight per pen were 3.24 kg, 1.74, 0.75 and 128 kg for control pens and 3.19 kg, 1.70, 0.69 and 104 kg for treated pens, respectively. Average chamber ammonia concentrations decreased from 193 ppm at chick placement to 70 ppm at d 21, then increased to 131 ppm on d 49. Based on this experiment, the microbial amendment had a positive effect on broiler performance.

Key Words: broiler, litter, amendment

540 Bacterial content following simulated rainfall on poultry waste. J. H. Metcalf*[1], P. A. Moore Jr.[2], A. M. Donoghue[2], I. Reyes-Herrera[1], K. Arsi[1], P. J. Blore[1], and D. J. Donoghue[1], [1]*Poultry Science Department, University of Arkansas*, *Fayetteville,* [2]*Poultry Production and Product Safety Research Unit, USDA-ARS*, *Fayetteville, AR*.

To evaluate potential bacterial runoff from poultry litter, litter was applied to test plots and exposed to simulated rainfall. The experiment consisted of 21 small (100 sq. ft) plots which were subjected to simulated rainfall after litter was applied to the plots. Water runoff samples were tested for *Salmonella* and *Campylobacter*, 2 bacterial pathogens associated with poultry. Each trial consisted of 7 treatments; 1) controls (no litter) or the equivalent of 2) one ton/acre of normal litter, 3) 2 ton/acre of normal litter, 4) 4 ton/acre of normal litter, 5) 2 ton/acre of alum-treated litter, 6) 2 ton/acre deep stacked litter, and 7) 2 ton/acre composted litter. Rainfall was applied at the rate of 5 cm/h until the first runoff was observed from each plot (mean 37 min) and then continued for an additional 30 min. Rainfall was applied at one, 8 and 15 d after litter application and the trials were replicated 3 times. Data were analyzed by ANOVA using the GLM procedure of SAS and a probability of $P < 0.05$ was required for statistical significance. No *Campylobacter* was isolated from any of the runoff samples, and most samples tested negative for *Salmonella* as well. While most samples were negative, *Salmonella* was recovered from some plots, including the untreated control plots (no litter). Because *Salmonella* was recovered from untreated controls, the *Salmonella* detected may originate from sources other than the applied litter (e.g., wild birds, rodents, deer).

Key Words: Water runoff, *Salmonella*, *Campylobacter*

541 Effect of a low sulfur diet on air emissions, nutrient excretion, and performance of laying hens. W. Wu-Haan*[1], W. Powers[1], R. Angel[2], D. Karcher[1], and T. Applegate[3], [1]*Michigan State University*, *East Lansing,* [2]*University of Maryland*, *College Park,* [3]*Purdue University*, *West Lafayette, IN.*

The objectives of the current study were to evaluate the effect of feeding commercial diet (C), reduced S (RedS) diet, and a low S (LowS) diet on air emissions, nutrient excretion, and performance of Hy-line W36 laying hens from 47 to 50 wk of age (4 environmental rooms/diet; 56 hens/room). The C, RedS, and LowS diets were formulated to contain 0.19%, 0.11%, and no supplemental DL-Met. Methionine intake of 274.7, 361.6, or 406.7 mg/hen/d resulted in increasing egg weights

of 61.1, 63.9, and 65.1 g ($P < 0.01$) for the LowS, RedS and C diets. Analyzed S contents (2,602; 2,540; and 2,460 ppm) corresponded to S intakes of 244.6, 236.6, and 217.0 mg/bird/d in hens fed C, RedS and LowS diets ($P < 0.01$). Egg production (89%) and BW change (18.4 g) were unaffected by diet ($P > 0.05$) over the study period. A decrease in daily H2S emission was observed ($P < 0.01$) as S content in the diet decreased. Daily H2S emissions from hens fed C, RedS, and LowS diets were 0.83, 0.62, and 0.44 mg/bird ($P < 0.01$). Overall, hens fed LowS diet decreased daily H2S emissions by 46.4% (mg/kg BW basis), 45.6% (mg/kg FI basis), 46.7% (mg/g egg mass basis), 22.9% (mg/kg excreta DM basis) and 44.1% (mg/g S intake basis), respectively ($P < 0.01$) compared with hens fed the C diet. Emission factors that resulted from feeding the RedS diet were intermediate to those for the C and the LowS diets. No significant diet effects on daily emissions of SO2 (0.35 mg/kg BW), NH3 (480 mg/kg BW), NO2 (3.0 mg/kg BW), CH4 (32.4 mg/kg BW), non-CH4 (4.6 mg/kg BW), CO2 (48.8 g/kg BW), and O2 utilization (−122 g/kg BW) were observed during the trial period. In addition, total DM excretion (20.8 g/bird/d) was unaffected by diet. However, S excretion decreased ($P < 0.01$) from hens fed LowS diet (98.6 mg/bird/d) and RedS diet (105.3 mg/bird/d) compared with those fed the C diet (137.6 mg/bird/d). The results of this study demonstrate that feeding less DL-Met has great potential to reduce H2S emissions and S excretion from laying hens and reducing DL-Met up to 40% had no negative impact on hen performance; however, completely eliminating DL-Met supplementation resulted in less cumulative egg mass.

Key Words: air emission, egg, sulfur

542 Comparison of nutrient balance and performance of laying hens, housed in either enriched or conventional cage systems, over an entire production. M. Neijat*[1], J. D. House[1], W. Guenter[1], and E. Kebreab[2], [1]*University of Manitoba*, *Winnipeg, Canada*, [2]*University of California*, *Davis*.

The move to alternative cage designs for laying hens has the potential to lead to differences in hen behaviors, with a resultant effect on manure characteristics and estimates of nutrient flow. To this end, an experiment was conducted to assess nitrogen (N), calcium (Ca) and phosphorus (P) balances, manure weight and composition, and indices of performance of laying hens housed under 2 distinct caging systems. A total of 4,836 commercial Shaver White hens were caged in either enriched (EC) or conventional (CC) (average floor space per hen of 642.6 and 468.4 cm^2 respectively) under a semi-controlled environment. Enriched cages provided hens with a curtained nesting area, scratch pad and perches. All birds were fed the same standard layer diet for 11 periods in 4 week intervals. Data, expressed on a hen basis, were analyzed as repeated measures using the MIXED model procedure of SAS. Egg production, feed conversion ratio, body weight, egg weight and egg mass were not significantly different between the 2 systems. Lower feed intake ($P < 0.01$) (92.5 vs. 95.0 g/d DM basis) and manure output ($P < 0.01$) (79.8 vs. 91.3 g/d as is basis and 27.0 vs. 28.1 g/d DM basis) were observed in birds housed in EC compared with CC. Manure DM% were 31.0 and 34.1 for CC and EC respectively. Overall mean Ca and P excretions in manure were significantly ($P < 0.01$) lower in EC birds (2.11 ± 0.04 and 0.619 ± 0.005 g/d respectively) than their counterparts in CC (2.29 and 0.643 g/d respectively). There were no significant differences in the amount of manure N excreted by birds in both cage systems (1.94 and 1.96 ± 0.02 g/d for EC and CC respectively). Taking into account the increasing intensity of poultry production, welfare and environmental concerns, enriched caging systems may help in reducing Ca and P excretions, and the total weight of manure.

Key Words: caging, manure, nutrient excretion

543 Effects of the removable chicken house on the growth performance of broilers and indoor environment parameters. A. G. Chen*, Z. Wang, X. M. Wang, Q. H. Hong, and C. M. Yang, *Zhejiang University*, *Hangzhou, China*.

A total of 880 one-day-old Ling-nan broilers were selected to study the effects of the removable chicken house on the growth performance and indoor environment parameters. All broilers were raised in the removable house during 0–21d period and then were randomly divided equally into 2 groups, each with 4 replications, and respectively raised in the removable chicken house (the trial) and in the general fixed one (the control) from 22d to 70d. Both groups of chickens received the same diets include a starter for 0–21d, a grower for 22–49d and a finisher for 50–70d period, respectively. The growth performance of broilers was determined every period and the indoor environment parameters, average temperature (AT), average relative humidity (ARH) were measured daily and average ammonia concentration (NH_3) was detected at 0800, 1400 and 2000 h every other day. During the entire test period, the average daily gain (ADG) in the trial group was 28.05 ± 7.04g and was 0.75% ($P > 0.05$) higher than that in the control, and the feed to gain ratio (F/G) 3.10 ± 0.82 was 0.96% ($P > 0.05$) lower than that of the control, respectively. The survive rate of the trial group was 94.38%, a little higher than the control′s (93.75%). The incidence of diseases in the removable group was 5.00 ± 0.68% and in the fixed group was 8.25 ± 1.71%. When the average outdoor temperature was 6.12°C, AT, ARH and NH_3 in the removable chicken house were 11.22°C, 64.67% and 2.98ppm, respectively, while in the general fixed one, the data were 9.96°C, 67.60% and 2.70ppm, respectively. The results showed that there were similar indoor environment parameters and growth performance of broilers in 2 types of chicken houses, but the removable chicken house resulted in lowered incidence of diseases.

Key Words: removable chicken house, fixed chicken house, environment parameters

544 Effect of DDGS and mineral sources on air emissions from laying hens. W. Li*[1], W. Powers[1], D. Karcher[1], R. Angel[2], and T. J. Applegate[3], [1]*Michigan State University*, *East Lansing*, [2]*University of Maryland*, *College Park*, [3]*Purdue University*, *West Lafayette, IN*.

The objectives of the current study were to evaluate the dietary effects of distillers dried grains with solubles (DDGS) and the sources of mineral supplement on air emissions from Hy-line W-36 hens from 50 to 53 wk of age (3 environmental rooms/diet; 56 hens/room). Diets were arranged in a 2 × 2 factorial design. Factors were dietary concentration of DDGS (0 or 20% of diet dry matter) and source of minerals (common inorganic sources; In or organic mineral sources from Pancosma, Geneva, Switzerland; Org). Analyzed diets contained 18.31% CP, 0.68% P and 4.20 Ca. Analyzed S content was 0.25%, 0.26%, 0.30% and 0.31% for the 0In, 0Org, 20In and 20Org diets. Concentration and airflow of ammonia (NH_3), hydrogen sulfide (H_2S), nitrous oxide (N_2O), methane (CH_4) and non-methane total hydrocarbons (NMTHC) were measured in exhaust air from each room. Egg weight (65.12g) and egg production (88%) were not affected by diet ($P > 0.05$). Feed intake in hens fed the 0Org (106.88 g/d/hen) was greater than for hens fed any of the other treatments (104.29, 104.93 and 103.92 g/d/hen in 0In, 20In and 20Org). Feeding DDGS decreased mass of NH3 emitted daily (592 vs. 512 mg/hen/d for 0% and 20% DDGS) and the following emission factors: mg/kg BW (by 16%), mg/g N consumed (by 17%), mg/g egg (by 14%). No mineral source effects were observed for NH_3 emission variables. Feeding DDGS increased daily CH_4 emissions by 13 to 15% (39.3 vs. 45.4 mg/hen/d; and 0.70 vs. 0.82 mg/g egg/d; $P < 0.05$). Daily H_2S emitted (0.78 mg/hen/d), N_2O emitted (58.6 mg/hen/d), non-methane total

hydrocarbon (24.4 mg/hen/d) ($P > 0.05$) were not changed as a result of diet fed. Mass of excreta (27.3 vs. 31.5 kg DM) and mass of N excreted (1.25 vs. 1.52 kg N) from 56 hens over a 3-wk period were increased as a result of feeding DDGS. Diet inclusion of DDGS or organic trace minerals did not change short-term performance of laying hens. Feeding 20% DDGS reduced NH_3 emissions, increased CH_4 emissions and had no effect on emissions of other gases. Substitution of inorganic trace mineral sources with organic sources did not alter air emissions.

Key Words: laying hen, DDGS, organic trace mineral

545 Effect of amino acid formulation and supplementation on nutrient mass balance and air emissions from turkeys. Z. Liu[1], W. Powers*[1], D. Karcher[1], R. Angel[2], and T. J. Applegate[3], [1]*Michigan State University*, *East Lansing*, [2]*University of Maryland*, *College Park*, [3]*Purdue University*, *West Lafayette, IN*.

Nutrient mass balance and air emissions were determined for turkeys fed 4 diets in a 2 × 2 factorial design to determine the effects of diets with 100 or 110% of NRC (1994) recommended amino acid (AA) formulation and diets containing 2 (Lys and Met) or 3 (Lys, Met, and Thr) supplemental AA. Hybrid tom turkeys were raised and monitored in 12 rooms (3 reps/diet; 20 toms/room at hatch culled to 16 toms/room at 4 wk then 12 toms/room at 8 wk of age). All feed and litter entering and leaving the rooms were quantified and analyzed for nutrient content. Air emissions were measured throughout the 20-wk study. Data were analyzed statistically by ANOVA using the MIXED model procedure of SAS. The 100% NRC diets contained less N compared with the 110% NRC (2.64% vs. 2.73% during wk 16 to 20). Diets containing 3 vs. 2 supplemental AA had less N content (2.61% vs. 2.76% during wk 16 to 20). Cumulative feed intake (55.67 kg/tom) and BW (19.85 kg/tom) were not affected by diet. Feeding 3 supplemental AA resulted in lower N content in excretion (3.21% vs. 3.50%, $P < 0.05$) as compared with feeding 2 supplemental AA and an interaction between the main effects was observed ($P < 0.05$). The 100% NRC diets resulted in lower emission rates of NH_3 (1.52 vs. 1.77 g/tom-d), non-methane hydrocarbon (0.10 vs. 0.12 g/tom-d) and H_2S (3.78 vs. 4.69 mg/tom-d) compared with the 110% NRC diets ($P < 0.05$). Feeding 3 supplemental AA resulted in lower NH_3 emission rates (1.23 vs. 1.68 g/tom-d, $P < 0.05$) as compared with feeding 2 supplemental AA and a significant interaction was observed ($P < 0.05$). The 100% NRC diets reduced cumulative NH_3 emission by 14% compared with the 110% NRC (187 vs. 218 gN/tom, $P < 0.05$). The 3 supplemental AA diets reduced cumulative NH_3 emission by 23% compared with the 2 supplemental AA (176 vs. 230 gN/tom, $P < 0.05$). Total N emission averaged 217 gN/tom. Across all 4 diets, N partitioning, as a percentage of inputs, averaged 32%, 58%, 12%, and −2% for retention, excretion, air emission, and unaccounted losses respectively. The results demonstrated the potential of reducing nutrient excretion and air emissions from turkeys through diet modification of AA, and illustrated fate of N, P and S in a turkey production system.

Key Words: diets, retention, excretion

546 Magnitude and variability of distillers grains greenhouse gas credits in the corn-ethanol-livestock life cycle. V. R. Bremer*, A. J. Liska, H. S. Yang, T. J. Klopfenstein, G. E. Erickson, D. T. Walters, and K. G. Cassman, *University of Nebraska*, *Lincoln*.

Feeding distillers grains (DGS) to livestock is an important part of the greenhouse gas (GHG) mitigation benefit due to ethanol production. Three scenarios were used to evaluate the magnitude and variability of DGS GHG emissions credit and GHG balance of ethanol relative to gasoline in the corn-ethanol-livestock life cycle with the Biofuel Energy Systems Simulator (BESS; www.bess.unl.edu). The BESS model accounts for GHG emissions associated with corn production for ethanol and livestock feed, ethanol plant operation based on type of DGS produced, corn, urea, and soybean meal displaced when DGS is added to livestock diets, differences in feedlot cattle enteric fermentation, and feedlot fuel use change due to DGS feeding. Scenario 1evaluated feeding Nebraska wet, modified, or dry DGS to feedlot steers, Scenario 2 evaluated feeding Midwest dry DGS to beef, dairy, or swine, and Scenario 3 evaluated Iowa, Nebraska, and Texas corn-ethanol-livestock production systems by types of DGS fed to different livestock classes. The DGS GHG emissions credit from the analyzed scenarios varied by more than 2-fold, from 11.5 to 28.3 g CO2e per MJ of ethanol produced, depending on the fraction of DGS used without drying, the proportion of DGS used to feed feedlot cattle vs. dairy or swine, and the location of corn production. Quadratic improvements in DMI ($P = 0.01$), ADG ($P < 0.01$), and G:F ($P = 0.09$) of feedlot cattle fed increasing levels of wet DGS are an important part of maximizing DGS GHG credits. Regional variability in GHG intensity of crop production and future livestock feeding trends will determine the magnitude of DGS GHG offset against GHG emissions elsewhere in the corn-ethanol-livestock life cycle. The DGS GHG credit represents a 19 to 38% offset of total corn-ethanol-livestock life cycle positive emissions and a 41 to 60% reduction in GHG emissions of ethanol motor fuel relative to gasoline. The DGS GHG credit was optimized when wet DGS was fed to beef cattle.

Key Words: distillers grains, environment, greenhouse gases

547 Methane production, fermentation patterns and protozoa numbers In Vitro as related to sources of rumen fluid from different cattle feeding systems and animal waste substrate digestion. C. L. Ross*, M. A. Froetschel, S. Buaphan, S. Chinnasamy, and K. C. Das, *The University of Georgia*, *Athens*.

Rumen fluid, collected by stomach tube, from beef cattle grazing pasture, lactating dairy cattle fed a total mixed ration, and beef cattle fed a feedlot ration were used to determine the influence of different rumen microbial inoculations on In Vitro methane production and fermentation of animal wastes, in a 3x3 factorial designed experiment. Broiler litter, dairy and swine manure were used as substrates. A modified Tilley and Terry procedure was used and fermentation gas was collected in sampling bags with septum valves. Dry matter and gross energy digestion and volatile fatty acids and ammonia production and protozoa counts were measured using standard techniques after 24 h incubations. All parameters were corrected with measurements from rumen fluid blank incubations without substrate. The source of rumen fluid did not affect the volume of methane produced ($P > 0.3$), but the volume of methane produced in vitro tended to increase by 75% with broiler litter as a substrate ($P < 0.08$). Ammonia production increased with rumen fluid from dairy and feedlot compared with grazing cattle, several fold especially with broiler litter as substrate (rumen fluid by substrate interaction $P < 0.02$). Total VFA produced were 40 to 90% higher with broiler litter and swine manure as compared with dairy manure ($P < 0.01$) and IVDMD was almost 2 fold greater with broiler litter as compared with the other wastes as substrate ($P < 0.01$). The moles of methane produced per digestible energy fermented was 2-fold greater with rumen fluid from feedlot cattle ($P < 0.08$) but there was no difference in efficiency of methane produced as related to type of animal waste used as substrate. The methane produced per energy fermented was positively correlated to protozoa counts ($r = 0.58$, $P < 0.03$) and negatively correlated to VFA production ($r = 0.70$, $P < 0.01$). Mixed cultures of rumen fluid especially from feedlot cattle, have potential to enhance animal waste remediation and methane generation for bio-fuel production.

Key Words: animal waste, bio-fuel production, methane

548 Trace mineral metabolism in ruminants. T. E. Engle*, *Colorado State University*, *Fort Collins*.

Trace minerals have long been identified as essential dietary components for domestic livestock species. Included in the category of essential trace minerals (or microminerals) are chromium, cobalt, copper, iodine, iron, manganese, molybdenum, nickel, selenium, and zinc. Numerous biochemical reactions require trace minerals for proper function. It has been well documented that deficiencies of various trace minerals can result in metabolic diseases. The interactions between trace minerals and metabolic processes are extremely complex. Trace minerals have been identified as essential components for carbohydrate, lipid, protein, and vitamin metabolism, and have been shown to be involved in hormone production, immunity, and cellular homeostasis. Past and current research would suggest that copper (Cu) is involved in lipid metabolism in ruminants. Copper supplemented at physiological concentrations to beef cattle has been reported to be involved in cholesterol metabolism, ruminal biohydrogenation, catecholamine production, and lipid metabolism of subcutaneous adipose tissue. Additional impacts of Cu on lipid metabolism and homeostatic mechanisms related to Cu metabolism are currently being investigated. Recently, we have reported that genes involved in bovine liver Cu homeostasis, ATP7A, ATP7B and Cox17, are correlated with CTR1 gene expression in the bovine liver, similar to those reported for non-ruminants. Despite the apparent involvement of certain trace minerals in animal production and disease resistance, deficiencies of trace minerals have not always increased the susceptibility of domesticated livestock species to natural or experimentally induced infections or decreased performance. There are many factors that could affect an animal's response to trace mineral supplementation such as the duration, concentration, and source of trace mineral supplementation, physiological status of an animal (i.e., pregnant vs. non pregnant), the absence or presence of dietary antagonists, environmental factors, and the influence of stress on trace mineral metabolism.

Key Words: trace mineral, beef cattle, copper

549 Effects of copper supplementation on performance and carcass characteristics of cattle fed diets containing 60% DDGS. T. L. Felix* and S. C. Loerch, *The Ohio State University*, *Wooster*.

Dried distillers grains with solubles (DDGS) are an excellent source of energy and protein for feedlot cattle and their dietary inclusion may improve performance and reduce cost of gain. Because of the high S levels, DDGS have not typically made up the majority of the diet even when it would be economically advantageous to do so. Dietary S above 0.4% may reduce cattle performance and increase incidence of polioencephalomalacia. Copper binds with S in the rumen to form insoluble copper sulfides. The hypothesis was that including Cu in high DDGS diets would bind S, thereby reducing potential toxic effects and improving animal performance. The objective of this research was to determine effects of 3 supplemental Cu levels on performance and carcass characteristics of cattle fed diets containing 60% DDGS (S = 0.46%). Angus-cross yearling steers and heifers (n = 87; initial BW = 238 ± 36 kg) were blocked by sex and allocated to 12 pens. Treatments were: 1) 60% DDGS with 0 ppm Cu supplementation, 2) 60% DDGS with 100 ppm Cu supplementation, 3) 60% DDGS with 200 ppm Cu supplementation. The remainder of the diet was grass hay (10%) and a vitamin-mineral supplement (15%). Diets were offered ad-libitum throughout the finishing phase (168 d). Three randomly selected cattle from each pen (n = 36) were slaughtered on d 168. Carcass data and liver samples were collected. Copper supplementation did not affect ADG ($P > 0.35$). However, cattle that were supplemented with Cu had numerically lower DMI than those not supplemented, resulting in improved feed efficiency ($P = 0.03$) in cattle supplemented with Cu (G:F = 0.167, 0.177, and 0.177 for 0, 100, and 200 ppm Cu, respectively). There were no treatment effects ($P > 0.05$) on measured carcass characteristics. Cattle supplemented with 100 and 200 ppm Cu had higher liver Cu concentrations ($P < 0.0001$; mean = 708.24 and 933.32 ug/g, respectively) than cattle that were not supplemented with Cu (mean = 86.29 ug/g). These data suggest that cattle consuming diets with S above the maximum tolerable limit may be supplemented with Cu to improve Cu absorption and feed efficiency. Effects on S absorption are being pursued.

Key Words: DDGS, feedlot cattle, copper

550 Vitamin A restriction does not improve marbling in Holstein bulls at the same extent as in Holstein steers. S. Marti*[1], C. Realini[2], A. Bach[3,1], and M. Devant[1], [1]*Department of Ruminant Production, IRTA*, *Barcelona, Spain*, [2]*Carcass Quality Subprogram, IRTA*, *Girona, Spain*, [3]*ICREA*, *Barcelona, Spain*.

The aim of the current study was to evaluate if a temporal vitamin A restriction could increase marbling and thus could be an alternative method to castration in Holstein bulls to improve fattening. Forty-seven Holstein calves, 24 steers and 23 bulls (initial BW = 252 ± 3.5 kg and age = 187 ± 7.5 d), were randomly allocated to 4 treatments. Treatments followed a 2x2 factorial design with gender (bulls vs steers) and vitamin A level (restricted at 1.3 × 1,000 IU/kg, VAR, vs control at 4.6 × 1,000 IU/kg, CTR). Animals were fed concentrate and straw ad libitum. Feed consumption and BW were recorded every 28 d. Animals were slaughtered at 331 ± 7.3 d of life. The LM was removed from each carcass from the 7th to the 13th rib and pH, LM area, instrumental color, i.m. fat content, instrumental tenderness, oxidative and color stability, and purchase decisions were evaluated. Data were analyzed using a mixed-effects model with repeated measures that included initial BW, level of vitamin A, gender, time (month or aging), and the interactions between these factors, as fixed effects, and animal as a random effect. Steers had a lesser ($P < 0.01$) final BW, ADG, and HCW compared with bulls. The i.m. fat was lesser ($P < 0.01$) in bulls (2.8 ± 0.30%) than in steers (4.2 ± 0.30%), and greater ($P = 0.05$) in VAR (3.9 ± 0.31%) than in CTR (3.0 ± 0.31%) animals. Vitamin A restriction increased i.m. fat from 2.7 to 2.9% (7%) in bulls and from 3.4 to 4.9% (44%) in steers. Vitamin A did not affect tenderness, but oxidative stability tended ($P = 0.09$) to be greater in meat from VAR than from CTR at 21 d of aging. Purchase decision scores were greater ($P = 0.05$) in VAR (3.35 ± 0.07) than in CTR meat (3.16 ± 0.07). Vitamin A restriction does not affect animal performance, improves meat oxidative stability, and increases i.m. fat; however vitamin A restriction does not achieve the marbling levels obtained with castration in Holstein bulls.

Key Words: beef, marbling, vitamin A

551 Effect of added sulfur on in vitro fermentative activity of ruminal contents from steers fed corn-based diet. S. Uwituze*, L. C. Hollis, and J. S. Drouillard, *Kansas State University*, *Manhattan*

We previously reported that elevated sulfur (S) levels in finishing diets containing dried distiller′s grains with solubles (DDGS) decreased DMI and ADG of cattle, but were associated with increased diet digestibility

in vivo. An in vitro titration study was conducted to investigate effects of added sulfur (S) on IVDMD, VFA profiles, and NH_3 production from different substrates by mixed ruminal organisms. The study was a randomized complete block design with a 2 × 7 factorial treatment arrangement. Factor 1 consisted of substrate (a 94:4.5:1.5 mixture of ground corn, soybean meal, and urea [GC-SBM] or a 69.4:30.6 mixture of ground corn and DDGS [GC-DDGS]), and factor 2 consisted of the level of added S (0; 0.1; 0.2; 0.3; 0.4; 0.5; or 0.6% of substrate, DM basis) using sodium sulfate as the S source. Basal S levels were 0.18 and 0.28% of DM for GC-SBM and GC-DDGS, respectively. Isonitrogenous substrates (0.5 g DM) with varying levels of S were combined with a 2:1 mixture of McDougall′s buffer and strained ruminal fluid from a single donor animal (fed 40% alfalfa and dry-rolled corn) and incubated in triplicate for 24 h at 39C. The study was repeated for 3 d. Concentrations of VFA, NH_3, and IVDMD were analyzed using Proc Mixed of SAS with fixed effects of substrate, S, and substrate × S, and random effects of day, day × substrate, day × S, and day × substrate × S. Concentrations of NH_3, total VFA, individual VFA, A:P ratio, and IVDMD were unaffected by S ($P > 0.05$) or by the S × substrate interaction ($P > 0.05$). Cultures with GC-DDGS yielded lower concentrations of NH_3, propionate, butyrate, and valerate, and had lower IVDMD than GC-SBM cultures ($P < 0.05$). Substrates yielded marked differences in fermentative end products, but elevated sulfur did not alter in vitro fermentation of these substrates by mixed ruminal microorganisms. These data suggest that previous in vivo changes in digestibility associated with high sulfur are likely attributable to host factors, such as feed intake level.

Key Words: sulfur, distillers grains, fermentation

552 Dietary sulfur negatively affects gain and mineral status in beef steers. E. L. Richter*, M. E. Drewnoski, and S. L. Hansen, *Iowa State University*, *Ames*.

Crossbred yearling steers (n = 96; 321 ± 29 kg BW) were used in a trial to examine the effects of feeding a high sulfur (S) distillers grains (DDGS) supplement to steers on pasture before moving into the feedlot. Steers were blocked by weight and were supplemented with either a low S DDGS (0.3% S; LS; n = 48) or LS DDGS plus 0.3% S from sodium sulfate (high S; HS; n = 48). During the 35 d backgrounding period steers were supplemented daily at 1% BW and were stripgrazed weekly on 2 ha smooth bromegrass pastures (4 pastures per treatment; n = 12 steers per pasture). Mean daily supplement intake was 3.6 kg DM per head for both treatments. Daily S intake was greater ($P < 0.01$) for HS steers compared with LS steers (23.7 and 14.2 g S, respectively). Forage mass offered and grazing residual mass did not differ among treatments ($P = 0.6$ and 0.4, respectively). In vitro dry matter digestibility was not different between treatments ($P = 0.9$). Blood samples were collected on d 0 and 35 for plasma mineral analysis. On d 35 HS steers exhibited lower ($P = 0.05$) plasma magnesium (Mg) concentrations (18.4 mg/L) compared with LS steers (19.3 mg/L). Average daily gains for the 35 d period were not different ($P = 0.5$) due to treatment. On d 35 steers were moved into feedlot pens and housed in groups of 4 by treatment. Half of the steers remained on their original S treatment and half were switched to the opposite treatment, resulting in 4 treatments in total (LS-LS, LS-HS, HS-LS, HS-HS; n = 24 per treatment). Steer weights were collected on d 89 of the finishing period (d 124 of the study). HS steers tended ($P = 0.06$) to have lower ADG compared with steers receiving the LS diet during the finishing period (1.4 and 1.6 kg, respectively). In summary, plasma Mg was lower in HS steers and high dietary S negatively impacted gain during the finishing period, but did not affect steer gains while on pasture. Microbial population analysis of rumen fluid samples collected during the backgrounding and finishing periods may clarify these differences.

Key Words: cattle, magnesium, sulfur

553 Inclusion of molybdenum and copper with high distiller's grain diets as a strategy to mitigate hydrogen sulfide emissions. L. D. Cross*, S. R. Rust, and W. J. Powers, *Michigan State University*, *East Lansing*.

A rising concern with feeding high levels of distiller's grain with solubles (DGS) is its high sulfur content and the effects it might have on hydrogen sulfide emissions from gas produced in the rumen and/or from emissions from excreted feces. A study was conducted with 12 Holstein steers housed in individual environment-controlled rooms to monitor gas production of ammonia, hydrogen sulfide, and methane. Steers (3 treatments, 4 steers/treatment) were assigned to either a control diet (Trt1): 81% high moisture corn (HMC), 10% corn silage, 4% mineral supplement, and 5% soybean meal; 40% DGS diet (Trt2): 40% DGS, 46% HMC, 10% corn silage, and 4% mineral supplement; or Trt3 which was comprised of Trt2 with an added mineral supplement of 6 ppm molybdenum (Mo) and 60 ppm copper (Cu). The Cu-Mo mineral supplement served as a potential strategy to mitigate hydrogen sulfide emissions. Gaseous emissions were monitored for 4 weeks and fecal bags were placed on steers the last 6 d to determine what effects separating urine and feces would have on air emissions. Results demonstrated that 40% DGS diets increased ammonia emission (5.44 g/d vs. 11.73 g/d for the control diet compared with the DGS diets ($P = 0.01$) and hydrogen sulfide (16.41 mg/d vs. 183.45 mg/d for the control diet compared with the DGS diets ($P = 0.03$). The use of 6 ppm Mo and 60 ppm Cu did not reduce hydrogen sulfide emissions when 40% DGS diets were fed. No diet effect was observed for methane emissions (25.04 g/d). Separating feces from urine reduced ammonia and hydrogen sulfide emissions from exhausted room air. Most hydrogen sulfide (>99%) and ammonia (88.2%) emissions were from the manure and not eructated by the animal. Most methane emissions were due to eructation (>99%). Dietary addition of Cu and Mo did not mitigate hydrogen sulfide emissions.

Key Words: DGS, hydrogen sulfide, molybdenum and copper

554 The effect of supplemental molybdenum and copper on the concentrations of hydrogen sulfide in the rumen gas cap and copper in the liver of yearling steers consuming high sulfate water. R. K. Peterson*[1], J. J. Wagner[1], T. E. Engle[1], and T. C. Bryant[2], [1]*Colorado State University*, *Fort Collins,* [2]*JBS Five Rivers Cattle Feeding*, *Greeley, CO*.

Seventy-two crossbred yearling steers (323 kg) were utilized in an experiment to evaluate the effect of supplemental molybdenum (Mo) and copper (Cu) on the concentrations of hydrogen sulfide (HS) in the rumen gas cap and Cu in the liver of feedyard steers. Four dietary treatments were utilized: control - 90 mg/kg Cu from copper carbonate; organic Cu - 45 mg/kg Cu from copper proteinate and 45 mg/kg Cu from copper carbonate (OCu); molybdenum - 90 mg/kg Cu from copper carbonate and 100 mg/kg Mo from sodium molybdate (M); and molybdenum plus organic Cu - 90 mg/kg Cu from copper carbonate, 45 mg/kg Cu from copper proteinate, and 100 mg/kg Mo from sodium molybdate (MCu). The average HS concentration in the rumen gas cap was reduced ($P < 0.05$) from 1200 ± 78 to 951 ± 94 mg/L for steers fed MCu as compared with control. The number of steers with HS concentrations of 500 mg/L and greater was reduced ($P < 0.01$) from 76.5% for control to 53.1% for the MCu treatment. The number of steers with HS concentrations of 1000 mg/L and greater was reduced ($P < 0.01$)

from 50.6% for control to 30.2% for MCu. A 19.6 fold increase ($P < 0.0001$) in fecal Mo and a 13.5% increase ($P < 0.10$) in fecal sulfur were observed for MCu steers as compared with control. From May 6 through June 17, liver Cu concentration, on a dry weight basis, increased ($P < 0.06$) for control steers from 373 to 472 mg/kg but declined ($P < 0.05$) for M steers from 401 to 276 mg/kg. Average daily gain appeared higher ($P < 0.06$) for MCu steers as compared with other treatments. These data indicate that the concentration of HS in the rumen gas cap can be reduced without adversely affecting performance by feeding supplemental Mo; however, it is not known whether reductions in HS of this magnitude are physiologically important in reducing the incidence of polioencephalomalacia.

Key Words: molybdenum, copper, hydrogen sulfide

555 Effects of supplemental manganese on ruminal pH and hydrogen sulfide concentration in beef steers fed high-sulfur diets containing distillers grains plus solubles. J. M. Kelzer*[1], T. D. Maddock[2], M. Ruiz-Moreno[1], A. DiCostanzo[1], G. I. Crawford[3], and G. C. Lamb[2], [1]*University of Minnesota*, *St. Paul*, [2]*North Florida Research and Education Center, University of Florida Extension Regional Center*, *Marianna*, [3]*Extension Regional Office, University of Minnesota*, *Hutchinson*.

Effects of including 1000 ppm manganese (Mn; supplied as manganese oxide) in high dietary sulfur (S) feedlot diets containing distillers grains plus solubles on ruminal pH and hydrogen sulfide (H_2S) concentration were examined. Seven ruminally cannulated beef steers (437 ± 61 kg initial BW) were assigned randomly to treatments in a switchback design (2, 14-d periods). Treatments included a base finishing diet (65% rolled corn, 21% dried distillers grains plus solubles, 8% bahia hay, 15% CP, 1.31 Mcal NEg/kg DM, 0.46% S) containing either 0 ppm Mn (CON) or 1000 ppm Mn (MNO). Wireless sensors programmed to record pH every 5 min were inserted into the rumen on d 10. Steers were allowed access to treatments from 0730 to 1630 daily. Rumen gas samples were collected at −1, 1, 2, 3, 4, and 6 h post-feeding on d 11–12 and analyzed for H_2S concentration. Daily DMI was similar ($P = 0.61$) across treatments (8.61 vs. 8.91 ± 0.53 kg/d for MNO and CON, respectively). Ruminal pH was higher ($P = 0.02$) at 1 h before feeding with MNO (6.29) vs. CON (6.01). However, no pH differences were observed ($P > 0.17$) between treatments at other time points (5.90 vs. 5.77, 5.81 vs. 5.66, 5.74 vs. 5.62, 5.70 vs. 5.62, and 5.62 vs. 5.61 ± 0.08 for MNO vs. CON at 1, 2, 3, 4, and 6 h post-feeding, respectively). Ruminal H_2S concentration was similar ($P = 0.24$) between treatments at all time points (0.35 vs. 0.36, 1.55 vs. 1.76, 2.42 vs. 3.16, 2.77 vs. 3.74, 3.59 vs. 3.63, and 3.98 vs. 4.18 ± 0.31 µg/mL for MNO vs. CON at −1, 1, 2, 3, 4, and 6 h post-feeding, respectively). Cumulative ruminal H_2S concentration tended to be lower ($P = 0.09$) with MNO compared with CON (6.47 vs. 7.74 ± 0.53 µg/mL). Results suggest including 1000 ppm Mn in high S finishing diets may initially maintain higher ruminal pH to reduce cumulative ruminal hydrogen sulfide gas concentration in feedlot cattle.

Key Words: feedlot cattle, hydrogen sulfide, manganese oxide

556 Effects of supplemental manganese on performance and stress responses in beef cattle fed low- and high-sulfur finishing diets containing distillers grains plus solubles. J. M. Kelzer*[1], T. D. Maddock[2], T. N. Holt[3], A. DiCostanzo[1], G. I. Crawford[4], and G. C. Lamb[2], [1]*University of Minnesota*, *St. Paul*, [2]*North Florida Research and Education Center, University of Florida Extension Regional Center*, *Marianna*, [3]*Colorado State University*, *Fort Collins*, [4]*Extension Regional Office, University of Minnesota*, *Hutchinson*.

To investigate the effects of including 400 ppm manganese (Mn) in low- and high-sulfur (S) finishing diets on performance, pulmonary arterial pressure (PAP), and plasma acute phase protein (APP) response, 40 crossbred beef cattle (274 ± 51 kg initial BW; 27 steers, 13 heifers) were assigned in a 2 × 2 factorial design. Treatments were fed for 56-d and included base diets containing either 0.25 (LS) or 0.43% dietary S (HS) and 0 (NOMN) or 400 ppm Mn (MN). Base diets contained 65% rolled corn, 15.5% dried distillers grains plus solubles, 10.5% soy hulls, 14.4% CP, and 1.40 Mcal NEg/kg DM. To achieve targeted levels of S and Mn, calcium sulfate and Mn oxide were added. Plasma blood samples and PAP were collected on all cattle on d 0, 7, 14, 28, and 56. On d 22, 4 randomly selected steers from each treatment were subjected to a stress challenge by subcutaneous injection of 2 mL of *Mannheimia hemolytica* (One-Shot, Pfizer, Inc.). Blood samples were collected at −1, 0, 1, 2, 3, 4, 5, 6, 10, and 22-h post-challenge to determine APP response. There was a tendency ($P = 0.08$) for a MN*S interaction for DMI. Supplemental MN reduced ($P < 0.01$) DMI in HS diets (6.46 vs. 7.10 kg/d) but not in LS diets ($P = 0.62$). Compared with LS, HS diets decreased ($P < 0.01$) ADG (0.95 vs. 1.40 kg) and reduced ($P < 0.01$) G:F (0.138 vs. 0.176). Supplemental MN tended to reduce ($P = 0.07$) PAP (32.0 vs. 33.7 mmHg), but S had no effect ($P = 0.63$). Haptoglobin was similar ($P > 0.10$) among treatments and averaged 6.6 mg Hbβ/100 mL. Ceruloplasmin (CER) was increased ($P < 0.01$) with LS vs. HS diets (15.0 vs. 10.3 mg/dL). A MN × S interaction occurred ($P = 0.01$) for CER area under curve (AUC) in steers subjected to the stress challenge. Steers fed MN-HS had lower ($P < 0.01$) CER AUC than NOMN-HS. Low-S treatments were similar ($P = 0.50$) for CER AUC, and both were higher ($P < 0.01$) than either HS treatment. Supplemental Mn tended to decrease PAP and in HS diets, reduced DMI and CER AUC following a stress challenge, while high-S concentration in finishing diets reduced performance and CER levels in cattle.

Key Words: beef cattle, manganese, sulfur

557 Effects of sulfur content of wet or dry distillers grains in beef cattle finishing diets on intake, ruminal pH, and hydrogen sulfide. J. O. Sarturi*, G. E. Erickson, T. J. Klopfenstein, J. T. Vasconcelos, K. Rolfe, and M. G. Dib, *University of Nebraska*, *Lincoln*

A metabolism study was conducted to evaluate dietary sulfur (S) in beef cattle finishing diets formulated with wet and dry distillers grains with solubles (DGS) containing low (0.82%) and high (1.16%) S concentration. Six steers with rumen cannulas (BW = 381 ± 31kg) were assigned to 1 of 5 treatments in an unbalanced Latin square design (6 steers and 5 diets) and fed for 5, 14 d periods. Steers were fed once daily ad libitum. Treatments were arranged as a 2x2+1 factorial with factors being moisture (wet or dry DGS included at 40% of diet DM), S concentration (high or low), and a diet containing wet DGS from high S provided at 32% of diet DM to match the low S wet DGS. All diets contained 15% corn silage, 5% supplement, and a blend (60:40) of high-moisture and dry-rolled corn. Intake and pH (wireless pH probes) were collected on the last 7 d of each period. Ruminal gas samples were collected 8h post feeding on the last 3d of each period, and H2S analyzed. Chromium oxide (7.5g) was added into the rumen twice a day, every day, and spot fecal samples were collected twice daily on the last 5 d of each period for DM digestibility (DMD). Data were analyzed using the GLIMMIX procedures of SAS. No interaction ($P > 0.16$) was observed between moisture and S for DMI, DMD, or H2S. Steers fed dry DGS had greater DMI ($P < 0.01$) than steers fed wet DGS (10.6 vs. 9.1 kg/d). Likewise, steers fed low S DGS consumed more ($P < 0.01$) than steers fed high S

DGS (10.4 vs. 9.3kg/d). Greater ($P = 0.06$) H2S was observed for wet DGS (9.33 vs. 2.87 µmol/L gas, SEM = 2.80) compared with dry DGS. High S DGS tended ($P = 0.13$) to increase H2S compared with low S DGS. An interaction between moisture and S was observed for average pH ($P < 0.01$). Steers fed high S wet and low S dry DGS had greater ($P < 0.01$) average pH compared with low S wet and high S dry DGS, but these differences were subtle. Greater ($P < 0.01$) DMI and H2S were observed when low S DGS at 40% was fed compared with high S at 32% inclusion (10.0 vs 8.8 kg/d; 1.87 vs. 7.09 µmol/L gas). Sulfur of DGS impacts DMI and ruminal H2S production and wet DGS may be more prone to conversion of S to H2S in the rumen.

Key Words: byproduct, metabolism, sulfur

558 Days on feed and dietary sulfur content affect rumen hydrogen sulfide concentrations in feedlot steers. M. E. Drewnoski*, E. L. Richter, and S. L. Hansen, *Iowa State University*, *Ames*.

For feedlot cattle on high sulfur (S) diets, low rumen pH during the transition period may cause more sulfide in the rumen to be in the gaseous form of hydrogen sulfide (H_2S), increasing the risk of S induced polioencephalomalacia (PEM). To investigate the effects of transition diet on rumen H_2S concentrations, 96 yearling steers were blocked by weight (321 ± 29 kg) and assigned to receive either a low S (LS) distiller's grains (DDGS) or LS plus 0.3% S (high S; HS) supplement while grazing bromegrass pastures for 35 d. Concentrations of H_2S did not differ on d 35 due to treatment (trt; $P = 0.9$). Steers were then moved into the feedlot (4 steers per pen) and received ad libitum hay plus 1% BW DDGS for 10 d, followed by 3 7 d step-up diets. When steers were moved into the feedlot, half of the steers remained on their original S trt and half were switched to the opposite trt. Previous S diet did not affect DM intake or H_2S concentrations ($P > 0.1$) during the feedlot period, therefore only dietary feedlot trt means are presented. Intake (DM) did not differ among trt ($P = 0.5$). One steer per pen was sampled for rumen H_2S concentrations on the last d of each transition diet, and on d 25 of the finishing period. Concentrations of H_2S did not differ due to dietary S trt until corn composed 28% or more of the diet. Interestingly, daily S intakes within trt did not differ between TMR3 and TMR4 ($P > 0.4$), yet H_2S levels for both trt were greater on TMR4 vs. TMR3 ($P < 0.01$), suggesting that extra-dietary factors such as rumen microbial population shifts may be occurring during this time.

Table 1. Diet, S intake and rumen gas H_2S concentrations

	d on	% of diet DM			S intake, g/d		Rumen gas H_2S, mg/L	
Diet	diet	Hay	DDGS	Corn	LS	HS	LS	HS
Hay + DDGS	10	57	43	0	29.0d	41.1c	1400bc	1733b
TMR 1	7	47	40	13	17.3fg	43.0c	605cd	1283bc
TMR 2	7	32	40	28	18.1f	45.4b	280d	1091bc
TMR 3	7	17	40	43	19.4ef	50.8a	644cd	1849b
TMR 4	25	10	40	50	20.4e	51.8a	1316b	4964a

[a-g]Means lacking common letters differ ($P < 0.05$).

559 Selenium fed in inorganic and organic forms differentially and commonly alters liver gene expression profile of growing beef heifers. S. F. Liao*[1], K. R. Brown[1], A. J. Stromberg[2], W. R. Burris[1], J. A. Boling[1], and J. C. Matthews[1], [1]*Department of Animal & Food Sciences*, *University of Kentucky*, *Lexington,* [2]*Department of Statistics*, *University of Kentucky*, *Lexington*.

To determine if source of dietary selenium (Se) supplements differentially affects liver gene expression profile of beef cattle, after 75 d-feeding without Se supplementation, 30 Angus heifers (age 336 ± 6 d, BW 393 ± 9 kg) were randomly assigned to 3 dietary treatments (n = 10) and individually fed 7.8 to 8.2 kg/d of a corn and cottonseed hull-based diet to achieve an ADG of 0.5 kg/d. For each animal, the basal diet supplied 0.4 mg Se/d, whereas the mineral premixes provided no additional Se (Control), 3 mg inorganic Se/d as sodium selenite (ISe treatment), or 3 mg organic Se/d as Sel-Plex (Alltech; OSe treatment). After 105 or 106 d on the treatments, liver samples were collected by aspiration biopsy and total RNA extracted. The mRNA from 6 randomly-selected animals/treatment were individually subjected to microarray analysis (Affymetrix Bovine GeneChip). Raw microarray data were corrected and normalized with gcRMA-Medianpolish algorithms, and then statistically analyzed with 1-way ANOVA and means separation contrasts (Partek Genomics Suite software). ISe treatment altered ($P \leq 0.01$) 56 gene transcripts (30 upregulated, 26 downregulated), whereas OSe treatment altered ($P \leq 0.01$) 53 gene transcripts (31 upregulated, 22 downregulated). Bioinformatics analysis (Ingenuity Pathways Analysis) of these gene transcripts found that the affected genes were associated with nutrient metabolism (e.g., GCLM, CANT1); cellular growth, proliferation, and immune response (e.g., KNG1, CL-43, TLN1); cell communication or signaling (e.g., IGF2, IGFBP3); and tissue/organ development and function (e.g., BHLHB2, KLF10, KLF11). We conclude that source of supplemental Se affected liver gene expression: 26 genes were solely affected by ISe treatment, 23 solely affected by OSe treatment, and 30 commonly affected by both ISe and OSe treatments.

Key Words: cattle, liver, dietary selenium supplementation, nutrient-gene interaction

560 Meta analysis of dairy cow responses to dietary forage NDF. D. Sauvant*[1] and D. R. Mertens[2], [1]*Agroparistech-INRA*, *Paris, France*, [2]*US Dairy Forage Center*, *Madison, WI.*

Dietary forage NDF (fNDF) offers the potential of combining fiber and its particle size influences in a common index. For this reason, it may be more precise than dietary NDF or proportion of concentrate to predict dairy cow responses. To evaluate this hypothesis a database was compiled from 116 published experiments (n = 289 treatments) where dietary NDF or concentrate varied. Forages were long or coarsely chopped. Dietary NDF averaged 34.4 ± 8.2% of DM while fNDF was 26.2 ± 10.2% (from 11.0 to 59.6). Meta analyses with GLM allowed to focuse on within experiment regressions. Chewing index (CI; 38.2 ± 11.8 min chewing/kg DM Intake) was linearly related to fNDF (CI = 19.8 + 0.70 fNDF, n = 195, nexp = 80, rmse = 2.9). Mastication time also increased with fNDF, but obtained a plateau of 865 min/d at fNDF around 52%. Dry matter intake (20.4 ± 3.5 kg/d) was related negatively and curvilinearly to fNDF (= 22.6 - 0.003 fNDF2, rmse = 1.1), and milk yield (28.3 ± 7.1 kg/d) presented a similar shape (= 22.6 - 0.005 fNDF2, rmse = 1.4). Opposite responses were observed for milk percentages of fat (= 2.5 + 0.07 fNDF - 0.00008 fNDF2, rmse = 0.17) and protein (= 3.3 + 0.001 fNDF - 0.00001 fNDF2, rmse = 0.08). Ruminal pH was positively related to fNDF (= 5.62 + 0.023 fNDF - 0.00014 fNDF2, n = 145, nexp = 56, rmse = 0.08). Acetate/propionate ratio increased with fNDF (= 1.05 + 0.10 fNDF - 0.001 fNDF2, n = 163, nexp = 66, rmse = 0.24). Values of pH = 6.1 and A/*P* = 3.0 corresponded to fNDF = 24%. An increase in fNDF significantly increased the rumen liquid load (RLL = 73 ± 11.1 kg, = 53.6 + 1.14 fNDF - 0.014 fNDF2, n = 76, nexp = 32, rmse = 5.0) and rumen liquid outflow rate. In contrast, fNDF decreased the organic matter digestibility (= 74.1 - 0.139 fNDF, n = 186, nexp = 73, rmse = 2.3) and the energy balance became negative when fNDF > 31.5%. In conclusion, most predictions were curvilinear and fairly accurate. As a measure of fill effect, the minimization of fNDF enhances the milk performance, however when fNDF is < 20–25% DM the risk of acidosis increases.

Key Words: forage NDF, dairy cow, meta analysis

561 Effect of forage type on passage rate estimated from rumen evacuation studies. S. J. Krizsan*[1], S. Ahvenjärvi[2], and P. Huhtanen[1], [1]*Department of Agricultural Research for Northern Sweden, Swedish University of Agricultural Sciences*, *Umeå, Sweden*, [2]*MTT-Agrifood Research Finland, Animal Production Research*, *Jokioinen, Finland*.

A meta-analysis of studies using the flux/compartmental pool method with indigestible NDF (iNDF) as internal marker was conducted to study the effect of forage type on particle passage rate (k_p) in cattle. Data were comprised of 172 treatment means from 49 studies conducted in Europe and in the USA. A total of 145 diets were fed to dairy cows and 27 to growing cattle. Prerequisite for inclusion of an experiment was that DMI, intake of NDF (NDFI), proportion of concentrate (CProp) in the diets, live weight (LW), and diet chemical composition (concentrations of CP, NDF, NFC and iNDF) were determined or could be estimated. Mixed model regression analysis including a random study effect was used to generate prediction equations of k_p. Initially 13 different forage types were classified, but when not different ($P > 0.10$) from grass silage the groups were pooled. The best fit model when forage type was not included was: k_p (%) = 1.19 + 0.0879 × NDFI (g/kg LW) + 0.792 × CProp (on NDF basis) + 1.21 × iNDF/NDF (RMSE = 0.231%, Akaike's information criterion = 199 and $R^2 = 0.66$). The best general equation correcting for the effect of forage type was: k_p (%) = 1.54 + 0.0866 × NDFI (g/kg LW) (RMSE = 0.207% and $R^2 = 0.80$). The effect on k_p of fresh grass (FG), mixes of alfalfa and corn silage(AS/CS) and dry or ensiled alfalfa as sole forage component (AH/AS) were estimated by adjusting the intercept in the general equation accounting for forage. The adjustment factor on the intercept for FG, AS/CS and AH/AS were −0.914, +0.831 and +0.237, respectively. The results from this meta-analysis suggested that consistency of ruminal digesta is affected by intrinsic forage characteristics that influence particle passage rate. Further, including an effect of forage type on k_p could not be explained by any of the chemical composition parameters of the diets.

Key Words: cattle, forage type, passage rate

562 Abrupt changes in forage dry matter of one to three days affect intake and milk yield in early lactation dairy cows. J. Boyd* and D. R. Mertens, *US Dairy Forage Research Center*, *Madison, WI.*

Our objective was to determine the effects of 1, 2, and 3 d changes in forage dry matter on lactating cow performance and yield. Forty-four Holstein cows (22 primiparous and 22 multiparous) averaging 65 DIM, 43.3 kg/d of milk, and 574 kg body weight were used in study conducted from October through December 2009. Within each parity, cows were assigned to 1 of 11 blocks based on production and days in lactation and one cow of each parity-block was randomly assigned to 1 of 2 groups. Study design was replicated 2 × 2 Latin squares for each set 1, 2, or 3 d treatments. Each period consisted of a 3d pre-treatment, 1 to 3d treatment, and a 3d post-treatment phase. Diets contained about 18% alfalfa and 36% corn silage (DM basis) and were control (Ctrl) with no water added and treatment (Trt) with water added to decrease forage DM by 8%-units, which mimicked rainfall events on a bunker silo and feeding an imprecise ration based on as-fed ratios of ingredients. Ctrl ration was adjusted daily to maintain DM ratios of ingredients during the study. Milk yield was recorded daily and component samples were taken 2x daily. Forages, TMR, and refusals were sampled daily and concentrates sampled 2x weekly. Chemical composition (DM, CP, NDF) of samples were determined by NIR. Data was analyzed using Proc MIXED of SAS with cow within parity-block as a random variable. On day1, DMI was reduced 2.4 ($P < 0.0001$), 1.2 ($P = 0.0001$), and 0.8 kg ($P = 0.003$), for the 1, 2, and 3d treatments, respectively, but DMI recovered during the following 1 to 3 d even during Trt phases. Although daily milk decreased slightly on day1 of each Trt, the decrease was largest on day2: −1.4 ($P = 0.02$), −2.6 ($P = 0.002$) and −1.9 kg ($P = 0.006$), for the 1, 2, and 3d treatments, respectively. Smaller reductions in daily milk occurred on the remaining days of Trt and for 4% fat-corrected milk. We conclude that abrupt changes in forage DM cause economically significant reductions in daily milk yield, but the duration of the change does not worsen the losses if adequate ration amounts are provided.

Key Words: dry matter changes, precision feeding, milk yield

563 Effects of corn silage harvested with or without ears on rumen fermentation and milk performance of dairy cows. M. Boivin*, R. Gervais, and P. Y. Chouinard, *Université Laval*, *Québec, QC, Canada*.

The objective of this study was to evaluate the effects of grain fraction in corn silage (CS) on rumen fermentation and milk performance of dairy cows. To reach this objective corn ears were manually removed from half of the plants in the same field. Whole CS and earless CS were

harvested the day after. Eight multiparous (4 rumen fistulated) Holstein cows (84 ± 31 DIM) were fed TMR in a double 4x4 Latin square design with 21-d periods. Treatments were WCS: 23% whole CS (DM basis), RCS: reconstituted CS with 12.4% earless CS and 10.6% high moisture corn, ECS: 23% earless CS, and GS: 23% grass silage. All TMR contained alfalfa silage, grass hay, ground corn, soybean meal, corn gluten meal, soy hulls, and corn oil. Contrasts were made to compare WCS vs. RCS, WCS vs. ECS, and ECS vs. GS. Statistical difference was declared at $P < 0.05$, and tendency at $0.05 \leq P \leq 0.10$. DMI did not differ between WCS and RCS or between ECS and GS, but was higher for WCS compared with ECS (27.5 vs. 25.2 kg/d). Milk yield was higher with WCS than ECS and RCS (42.8, 39.0 and 39.5 kg/d, respectively), and tended to be higher with GS (40.7 kg/d) than ECS. Milk fat content and yield were unaffected by treatments. Milk protein content of ECS was lower than WCS (2.94 vs. 3.04%) and tended to be lower than GS (2.99%). Milk protein contents of WCS and RCS were similar. Milk protein yield was higher for WCS than RCS and ECS, and was lower for ECS than GS (1.30, 1.20, 1.14, 1.21 kg/d, respectively). Rumen pH recorded at 0, 1, 2, 4 and 6 h post feeding decreased linearly with time, but was not affected by treatments. Mean rumen NH3-N concentrations recorded at the same sampling times were lower with GS than ECS (10.8 vs. 12.6 mg/dl). Mean proportions of acetate were lower and those of propionate were higher for WCS than for ECS (59.9 vs. 61.9% and 22.1 vs. 19.8%, respectively). Acetate to propionate ratio was greater with ECS compared with WCS (3.14 vs. 2.74). Under the condition of this experiment removing the grain fraction from CS reduced milk production and modified ruminal fermentation without affecting milk fat content and yield.

Key Words: corn silage, corn stalklage, forage-to-concentrate ratio

564 Comparison of alfalfa and orchardgrass hay as replacements for grain in lactating dairy cow diets. M. L. Raeth-Knight*[1], H. G. Jung[1,2], P. R. Peterson[1], N. B. Litherland[1], and J. G. Linn[1], [1]*University of Minnesota*, *St. Paul*, [2]*USDA-Agricultural Research Service*, *St. Paul, MN*.

A study was conducted to compare lactating dairy cow performance when alfalfa (40% NDF) or orchardgrass (60% NDF) hay replaced corn grain in a corn silage-based total mixed ration. Fifty cows were blocked by sire breed, ranked by DIM and randomly assigned to 1 of 10 treatments. Treatments were 5 dietary inclusion levels of either alfalfa (15, 20, 25, 30 and 35% of diet DM) or orchardgrass (10, 15, 20, 25 and 30% of diet DM). Across treatments, cows averaged 86 DIM at study initiation, and cows remained on their respective treatments for 8 wk. Feed intake, feed refusals, and milk production were recorded daily, and milk composition was determined weekly. During wk 4 and 8, fecal grab samples were collected to determine in vivo diet digestibility; and eating, ruminating and resting time were recorded every 15 min for 24 h. Within alfalfa and orchardgrass treatments, 3.5% FCM yield decreased with increasing hay inclusion level (r2 = 0.59). The rate of decline was similar between hay species with cows averaging 44.6 and 37.3 kg 3.5% FCM/d at the lowest and highest hay inclusion levels, respectively, across hay species. When milk production was regressed on diet NDF concentration, within hay species, 3.5% FCM yield declined at a faster rate for the alfalfa as dietary NDF concentration increased. Range in diet NDF was 29.5 to 35.6% NDF and 29.9 to 39.8% NDF for alfalfa and orchardgrass, respectively. With each percentage unit increase in dietary NDF concentration, 3.5% FCM yield decreased 1.22 kg/d and 0.46 kg/d for alfalfa and orchardgrass, respectively. There was no difference in milk fat (3.8%) or true protein (3.0%) among treatments. Rate of in vitro NDF digestibility (IVNDFD) was similar (4.6 vs. 5.2%/h), while extent of IVNDFD was greater (79% vs. 56%) for orchardgrass compared with alfalfa hay. In this study, these alfalfa and orchardgrass hays supported similar levels of milk production when they replaced corn grain in the diet.

Key Words: dairy nutrition, alfalfa, orchardgrass

565 The effect of feed sorting on NDF, starch, and particle intake. D. D. Maulfair*, G. I. Zanton, and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

Ration sorting occurs when cattle selectively consume certain parts of their ration, generally sorting for finer particles and against longer particles. Sorting is thought to have negative impacts on cow health and production. The objective of this experiment was to study the effects of varying TMR particle size on sorting behavior of lactating dairy cows and to evaluate effects on chewing behavior, milk yield and components, and rumen fermentation. Eight multiparous, Holstein cows (90 ± 32 d in milk; 4 rumen cannulated) were randomly assigned to replicated 4 × 4 Latin squares. Cows were fed diets that varied in chop length of dry grass hay. Diet forages and their percentage of diet DM were: corn silage (29.4), haylage (17.6), and grass hay (11.8). The geometric mean lengths (X_{gm}) of diets fed were: 4.46, 5.10, 5.32, and 5.84 mm for the short (S), medium (M), long (L), and extra long (XL) TMR respectively. Consumed X_{gm} for diets after 24 h was 4.44, 4.90, 4.82, and 5.10 mm for the S, M, L, and XL diets respectively. Differences between X_{gm} at time of feeding and after 24 h increased with increasing TMR particle size. In addition, refusal NDF concentration increased by 10.8 and 1.4%, while refusal starch concentrations decreased by 6.4% and increased by 1.5% throughout the day for the longest and shortest diets respectively. However, when NDF and starch intake were calculated after 24 h, mean NDF intakes varied by only 2.3 kg and there were no differences in starch intake. No differences were found in rumen VFA and NH_3 and mean rumen pH only varied by 0.13. Milk production and components were also similar between diets. Despite large changes in particle size distribution and NDF and starch concentrations of refusals due to sorting, there were no negative effects on rumen fermentation or milk production and components found in this study. Therefore, it is important to calculate the actual consumption of diet components to determine if sorting is a problem, because diet refusals represent only a small percentage of total diet intakes.

Key Words: chewing, particle size, sorting

566 Effects of varying inclusion rates of prairie hay and wet corn gluten feed on productivity of dairy cows. D. J. Rezac*[1], K. N. Grigsby[2], and B. J. Bradford[1], [1]*Kansas State University*, *Manhattan,*[2]*Cargill Incorporated*, *Blair, NE*.

Productivity of lactating dairy cows fed diets with wet corn gluten feed (Sweet Bran, Cargill Inc.; WGCF) as the primary energy substrate and prairie hay as the primary source of physically effective NDF (peNDF) was assessed versus a control diet. Forty-eight Holstein cows, 100–250 d in milk, were randomly assigned to 1 of 6 pens and pens were randomly assigned to treatment sequence in a replicated 3x3 Latin square. Treatments were a control ration with 18% alfalfa, 18% corn silage, 33% WCGF, and 15% forage NDF (CON); a diet with 20% prairie hay, 46% WCGF, and 13% forage NDF (PH20); and a diet with 14% prairie hay, 56% WCGF, and 9% forage NDF (PH14). However, midway through period 2, PH14 was discontinued due to numerous cases of diarrhea among cows on that treatment. Data from period 2 for PH14 pens was discarded and the pens which had been assigned to PH14 for period 3 were randomly assigned to the other treatments. Data were analyzed

with mixed models using random effects of period and pen and fixed effect of treatment. Dry matter intake was not altered by treatment. Least squares means milk yields were 36.2, 34.6, and 35.6 kg/d for CON, PH20 and PH14, respectively; milk yield was significantly greater for CON than PH20 ($P = 0.03$). Milk fat concentration was lowest for PH14 ($P < 0.01$), with means of 3.47, 3.40, and 2.82% for CON, PH20, and PH14, respectively. Fat yield was significantly greater for CON compared with PH14 ($P < 0.01$) but was not different from PH20. Milk urea nitrogen was the greatest for PH20 and least for CON ($P < 0.01$) with PH14 being intermediate, consistent with differences in dietary protein. Efficiencies, expressed as energy corrected milk divided by DMI, were 1.45, 1.40, and1.30 for CON, PH20, and PH14, respectively, and were not significantly different. These data suggest that PH14 did not provide adequate peNDF to support normal rumen function in midlactation dairy cows; however, PH20 offered a feasible diet for use on dairies where high-NDF grass hay and WCGF are available.

Key Words: non-forage fiber, physically effective fiber, wet corn gluten feed

567 Fiber digestion kinetics in muskoxen. E. M. Ungerfeld*[2], R. J. Forster[2], P. B. Barboza[1], M. B. Leigh[1], and C. Glover[1], [1]*University of Alaska Fairbanks*, *Fairbanks,* [2]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*.

The objective of this study was to examine fiber digestion in the muskox rumen as a potential source of enzymes and microbes for biofuel production from fibrous biomass. We measured the kinetics of ruminal digestion in situ for triticale straw (low quality diet) and brome hay (medium quality diet) in a 2-period crossover design (n = 4). Each period consisted of 3 weeks adaptation to diets, after which pairs of polyester bags containing triticale straw or brome hay ground through 1mm mesh were placed in the rumen for 24 to 120 h. Negative exponential regressions were fitted to calculate fractional rate and extent of digestion of cellulose (defined as ADF – lignin), hemicellulose (NDF – ADF) and lignin for each animal-diet-substrate combination. Responses were initially modeled as functions of animal (random), period (random), diet, substrate, animal × substrate (random), period × substrate (random) and diet × substrate. Interactions were not significant for any response variable and were dropped from models. Cellulose digestion rate of both substrates was greater ($P = 0.004$) in animals fed straw than in those fed hay, indicating dietary induction of cellulotyic activity. Cellulose digestion rate was similar between substrates ($P = 0.69$) even though more cellulose was digested from hay than from straw ($P < 0.001$). Diet did not affect the rate ($P = 0.86$) or extent ($P = 0.24$) of hemicellulose digestion from either substrate. Hemicellulose digestion rate was greater ($P = 0.033$) in straw than in hay substrate, but its extent of digestion was greater ($P = 0.001$) in hay. Small values for lignin digestion at 120 h were greater for hay as substrate ($P < 0.001$) and for straw as a diet ($P = 0.012$). Results suggest that, for the substrate processing used, cellulose digestion rate, but not extent, was limited by microbial enzymatic activity, whereas hemicellulose digestion rate and extent was limited by surface available for microbial colonization and digestion. Muskoxen consuming low quality forages may induce cellulolysis and could be a potential source of useful fibrolytic microbes and enzymes.

Key Words: muskox, rumen, digestion

568 Nutrient utilization of different levels of dietary fiber in dairy heifers limit-fed high and low concentrate diets. G. J. Lascano* and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

The objective of this experiment was to assess the optimal levels of dietary fiber (DF) incorporated in high concentrate (HC) and low concentrate (LC) diets for limit-fed dairy heifers. Eight Holstein heifers (335.6 ± 7.41 kg BW) were randomly assigned to 2 levels of concentrate: HC (20% forage) and LC (80% forage) and to a forage type sequence (0% of forage as corn stover (CT), 100% corn silage (CS); 20% CT, 80% CS; 40% CT, 60% CS; 60% CT, 40% CS) within forage level administered according to a split-plot, 4 × 4 Latin square design (21-d periods). All diets provided similar intakes of ME and allowed 800 g/d of ADG. DF (NDF and ADF) and non fiber carbohydrates composition were allowed to vary with the dietary ingredients. HC-fed heifers had higher apparent total tract (TD) digestibility of dry matter (DM; 72.6 vs.64.9 ± 0.52%; $P \leq 0.01$) than LC. Increasing DF level by increasing the amount of CT in the diet resulted in a linear decrease of DMTD (73.3, 71.5, 66.2 and 63.9 ± 0.51%, respectively; $P \leq 0.01$). Organic matter TD followed the same pattern as DMTD. LC diets had higher NDF ($P \leq 0.01$) and tended to have lower ADF TD than HC diets ($P = 0.06$). As level of DF increased, NDF and ADF TD had a cubic response with 20% CT diets having the highest values. HC diets decreased fecal output on DM and wet-bases, and DF had a decreasing linear effect on these parameters ($P \leq 0.01$). Urine volume excretion tended to be higher for HC-fed heifers (16.2 vs. 7.7 ± 2.51 kg/d; $P = 0.06$) and increasing level of DF tended to decrease urine output ($P = 0.10$). Total purine derivatives did not differ between treatments or CT level, but uric acid tended to be higher in HC-fed heifers ($P = 0.06$), and tended to decrease linearly ($P = 0.10$) when levels of DF increased. We conclude that CT decreased DM, and OM TD linearly while NDF, and ADF TD were maximized when 20% CT was added to HC and LC diets; HC diets were more digestible and generated less fecal output, but total manure was not different between HC or LC diets.

Key Words: high concentrate diet, fiber, limit-feeding, dairy heifer

569 Dietary starch level and dose response of *Saccharomyces cerevisiae* for limit fed-dairy heifers. G. J. Lascano*[1], J. M. Tricarico[2], and A. J. Heinrichs[1], [1]*The Pennsylvania State University*, *University Park*, [2]*Alltech Inc.*, *Nicholasville, KY*.

The objective of this experiment was to determine the effects of 2 levels of dietary starch and the dose at which the effects of *Saccharomyces cerevisiae* (Yea-Sacc[1026], Alltech Inc.; YC) are maximized based on nutrient total tract digestibility (AD), rumen fermentation, microbial protein synthesis, and N utilization of limit-fed dairy heifers. A split plot design with starch level as the whole plot and YC dose as sub-plot was administered in a 4 period (21 d) 4 × 4 Latin square. Eight Holstein heifers (432.49 ± 6.81 kg BW) were allocated to 2 starch treatments (30% starch: HS; 15% starch: LS) and to a sequence of YC doses (0, 10, 30, and 50 g/d). DM ($P = 0.98$) and NDF ($P = 0.28$) AD were not different between HS and LS; however, HS decreased ADF and increased hemicellulose AD (48.5 vs 44.9 ± 1.38 and 45.0 vs. 56.4 ± 3.20% respectively). YC dose increased DM AD quadratically (68.6, 68.8, 71.3, and 69.8 ± 0.47%; $P < 0.01$). NDF, ADF, and hemicellulose AD increased or tended to increase quadratically with increasing YC dose ($P = 0.03$, 0.06, 0.10 respectively). No significant effects were noted on fecal or urine output. Mean ruminal pH was higher for LS treatment (6.18 vs. 6.05 ± 0.06), and there was a trend ($P = 0.09$) for YC dose and starch interaction. The highest pH for LS and HS diet were at 0 and 50 g/d respectively. Total volatile fatty acid concentration was not different among YC doses or starch level. Concentrations of propionate, isobutyrate and iso-valerate were higher for HS than LS. Isovalerate was reduced linearly with increasing addition of YC and acetate: propionate responded quadratically to YC addition with 10 g/d having the lowest

value. Estimated microbial N outflow was not different among starch treatments or YC doses. We conclude that starch level did not affect DM AD, but influenced ADF and hemicellulose AD. YC dose had a greater effect on DM, NDF, ADF, and hemicellulose AD when added at 30 g/d. Fermentation parameters were not different among dietary treatments, but rumen pH was higher for LS diets.

Key Words: yeast culture, starch, limit-feeding, dairy heifer

570 Effects of limit-feeding on the feeding behavior of dairy heifers. B. L. Kitts*, B. W. McBride, I. J. H. Duncan, and T. J. DeVries, *Department of Animal and Poultry Science, University of Guelph, Kemptville Campus*, *Kemptville, Ontario, Canada*.

Limit-feeding replacement dairy heifers has been shown to control growth, while reducing feed costs and increasing efficiency; however, it also poses behavioral concerns. The objective of this study was to determine if these concerns are mitigated by providing straw alongside a limit-fed ration. Twenty-four Holstein dairy heifers (187 ± 11.3 d of age, 231.1 ± 12.0 kg), divided in groups of 4, were exposed to each of 3 treatments in a replicated Latin square design with 28-d periods. The treatment rations were: 1) TMR, 2) TMR with straw (2kg/d/heifer) offered as a choice (TMR-C) and 3) TMR with straw (2kg/d/heifer) mixed in (TMR-M). The TMR was fed at a restricted level (2.02% of BW) and contained (DM basis) 19.0% haylage, 21% corn silage, 45% high moisture corn, and 15% protein supplement. Feeding behavior was recorded for the last 14 d of each period. Standing time was recorded for the last 7 d of each period. Rumination behavior was recorded twice weekly in the last 14 d of each period. BW was recorded weekly and group DMI was recorded daily. Data were averaged per treatment per group, and analyzed in a GLMM with treatment, period and square as fixed effects and group within square as a random effect. DMI was lowest for the TMR treatment compared with the treatments with straw (5.7 vs 7.3kg/d; SE = 0.02, $P < 0.001$). Heifer ADG tended to be lower on the TMR-M compared with the TMR and TMR-C treatments (0.78 vs 0.94kg/d; SE = 0.04, $P = 0.1$). Feed efficiency (DMI/ADG) improved (SE = 0.01, $P < 0.001$) on the TMR (6.3) compared with TMR-C (7.8) and TMR-M (9.9). Daily feeding time differed (SE = 6.6; $P < 0.001$) between TMR (76.1 min/d), TMR-C (206.9 min/d), and TMR-M (279.2min/d). Inactive standing time differed between treatments (SE = 6.4; $P < 0.001$); with TMR being the highest compared with TMR-C and TMR-M (556.4 vs 409.9 vs 340.1 min/d). There tended to be fewer heifers ruminating on the TMR compared with TMR-M (14 vs 21.9%; SE = 2.0; $P = 0.1$). The results suggest that provision of straw as a choice, alongside a limit-fed ration, will allow heifer growth rates to be targeted, as well provide a suitable foraging source that heifers can use to satisfy their natural feeding behavior patterns.

Key Words: limit-feeding, dairy heifer, feeding behavior

571 Evaluation of potential carry over effects associated with limit feeding gravid Holstein heifers. K. A. Kruse*, N. M. Esser, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison*.

To evaluate potential carry over effects associated with limit feeding dairy heifers 96 Holstein heifers (400 ± 6 kg, 15.2 ± 0.1 mo) including 9 heifers with ruminal cannula were fed one of 3 dietary treatments for 180 ± 8 d in a randomized replicated pen design. Treatment diets included a control diet (C100) and 2 limit fed (LF) diets. The LF diets were formulated to provide similar nutrient intakes to C100. One LF diet (L85) was fed at 85% of C100 intake, and the other contained an ionophore (I; 325 mg/hd/d of Lasalocid) and was fed at 80% of C100 intake (L80+I). Heifers were evaluated for growth, rumen digesta volume, nutrient excretion and lactation performance. Data were analyzed using SAS proc mixed procedure with the replication of pen being the experimental unit. The LF heifers consumed less DM, NDF, and had greater ADG (0.96, 0.89 vs 0.81 kg/d), and lower feed:gain ratios (9.1, 9.3 vs. 13.0 kg/kg) as compared with heifers fed C100. No differences in rumen pH, NH_3-N, or VFA concentrations were observed between C100 or LF heifers. Limit fed heifers tended to excrete less DM (3.9, 3.2 vs 4.3 kg/d), whereas N and P excretion values were not different. Apparent N retention was improved in LF over C100 heifers (84.1, 96.8 vs. 77.1 g/d). Limit feeding did not alter rumen digesta volume, weight or density ($P > 0.05$). No differences were observed for dystocia index (≤1.0), calf BW (40.6 kg), or 7 d postpartum BW (566 kg) between LF and C100 fed heifers. After parturition, all heifers were fed a common high fiber diet. Lactation BW (551 kg), DMI (19.9 kg/d), and feed efficiency (1.6 kg/kg milk) were similar between treatments at 45 or 90 DIM. Milk yield (33.2 kg/d), milk fat (3.70%) and milk protein (2.90%) also were similar. At 45 DIM, rumen digesta volume was greater (99.1 vs. 66.1 L) for cows fed L85 as compared with cows fed L80 + I as heifers, but this effect was not observed at 90 DIM. Rumen digesta volume, lactation DMI, and milk yield of LF gravid Holstein heifers for 180 d did not result in negative carryover affects.

Key Words: limit feeding, heifers, ionophore

Small Ruminant Symposium: Going, going, gone! How Curtailment of Livestock Grazing on Federal Lands Could Alter the US Sheep Industry

572 How curtailment of livestock grazing on public lands could alter the US Sheep Industry. J. B. Taylor*, *USDA, Agricultural Research Service*, *Dubois, ID*.

This symposium will demonstrate how the potential curtailment of livestock grazing on federal lands will alter the US sheep industry, and what policies, perceptions, and biases are being used to challenge the use of federal lands for agricultural production. Five speakers will demonstrate the influence of land management policies and other related legislation, judicial decisions, and nonlitigation activities on availability of federal lands for sheep grazing, and detail the potential economic impact on the US sheep industry if livestock grazing is prohibited on federal lands in the future. The overall goal of the symposium is to challenge attendees to consider where to best place their information dissemination and research efforts in light of current policies, judicial decisions, and events that threaten the continued availability of federal lands for livestock production.

Key Words: public lands, sheep, symposium

573 The future of livestock grazing on federal lands: Opportunities for change. J. Kaiser*, *USDA, Forest Service*, *Washington, DC*.

The regulatory, environmental, social, and judicial aspects of grazing livestock on federal lands are duplicative, complicated, and litigious. Environmental laws and policies are enacted with good intentions, but often take a short-term approach to save a species without consideration of long-term effects, which may result in the demise of that same species. The threat of disease transmission from domestic to wild species has alarmed the public and various land-management agencies. A consequential reaction to this threat has been to completely separate domestic and wild species. For example, management decisions were instituted that resulted in removal of domestic sheep from federal lands that wild sheep inhabit. Although seemingly prudent for the short-term, such action fails to address long-term management needs and simultaneously threatens the vitality of sheep enterprises dependent upon federal lands. Land management policies and resulting actions must be based on sound science and a ″balance of harms″ approach, which takes the long-term view. The challenge is to override perceptions and deliver credible information that forms sound policy and drives workable solutions. To successfully develop sound policies, one should consider relevant regulatory, environmental, social, and judicial aspects of federal-land grazing; understand ″balance of harms″ approach for managing federal lands; and be aware of perceptions that drive policy related to separation of domestic and wild species using the same federal lands. Ultimately, policy should enable management that sustains healthy federal lands that provide habitat for thriving and diverse populations of wildlife and forage for productive sheep enterprises.

Key Words: policy, public lands, sheep

574 The future of livestock grazing on federal lands: Real and perceived threats. W. G. Myers*, *Holland & Hart LLP*, *Boise, ID*.

Various special interest groups want to nudge federal lands out of reach of livestock producers. In the 11 western Public Land States, federal lands that are administered by the US Department of Agriculture, Forest Service and the Department of Interior, Bureau of Land Management are an important and sustainable source of forage for many sheep enterprises. Preservation, conservation, and antiagriculture groups that are opposed to the use of federal lands for agricultural purposes have initiated species- and process-based litigation and other tactics to advocate removal of sheep grazing from public lands. For example, litigation that relates to Federal Land Policy and Management Act, Endangered Species Act, National Environmental Policy Act, and National Forest Management Act has been initiated to limit or restrict grazing access to federal lands. Furthermore, a variety of nonlegal tactics have been employed that result in unbearable fiscal, management, or labor burdens for sheep owners using federal lands. These antigrazing actions have resulted in closure of some federal lands to sheep grazing and(or) producers forfeiting grazing leases. Ultimately, closure of federal lands to sheep grazing may set precedents for removal of all livestock grazing, including beef cattle, on federal lands.

Key Words: grazing, litigation, public lands

575 Economic considerations of sheep grazing on federal and public lands. N. R. Rimbey*[1] and L. A. Torell[2], [1]*University of Idaho*, *Caldwell,* [2]*New Mexico State University*, *Las Cruces*.

Dependency of the western livestock industry on federal lands varies widely. Federal lands administered by the US Department of Agriculture, Forest Service and the Department of Interior, Bureau of Land Management contribute significant portions of the annual forage base for sheep and cattle in the western United States. These lands also provide critical habitat for wildlife and recreational opportunities to the public. Conflicts over the use and management of federal lands have greatly influenced development of grazing regulations and policies, which significantly impact the availability of federal lands for grazing. Relatively low grazing fee levels contribute to the image that federal-land grazing is heavily subsidized. These real and perceived subsidies have led to the development of asset values of federal grazing permits and of livestock enterprises that hold these permits. Therefore, administration of grazing regulations and policies that affect the availability of federal grazing permits directly influence the overall worth and viability of many western sheep enterprises. The focus of this presentation will be to discuss historic legal and regulatory basis for managing federal land grazing resources, methods for estimating grazing-use dependency, how the federal grazing fee formula is derived from federal and private grazing costs, the role that grazing permit value plays in the grazing fee debate, and policy-based alternatives related to the future of federal land grazing management.

Key Words: grazing permit, public lands, sheep

576 Impact of reduced federal and public land grazing on viability of the US sheep industry. D. P. Anderson*, *Texas A&M University*, *College Station*.

The sustained viability of the US sheep industry is linked to grazing on federal lands. As of January 1, 2010, the 11 western Public Land States contained 46 percent of the US mature ewe flock. Many of those sheep spend some portion of their lives on federal lands, which are mainly administered by the US Department of Agriculture, Forest Service and the Department of Interior, Bureau of Land Management. Loss of access to federal lands for grazing purposes would have a negative impact that is beyond the sheep enterprises that are dependent upon these lands. For example, factors that further aggravate the long-term decline in US lamb

inventory could be enough to reduce the US sheep industry to levels below a critical mass for industry infrastructure, e.g., meat packers and wool warehouses, to survive. In addition to lambs from the western Public Lands States, many meat packers also process a significant number of lambs and goats from non-public land states (e.g., Texas, the largest sheep producing state) to maintain a critical volume that is essential to keeping the plant operational. This presentation examines the economic impact of the loss of federal land grazing on the US sheep industry. Components of the US sheep industry that will be discussed are regional flock inventory in the US, lamb packing capacity, seasonal lamb production affecting packing capacity, regional wool production and quality effects, regional lamb prices, and import levels.

Key Words: economic viability, public land, sheep industry

577 So what? What is a scientist supposed to do? G. S. Lewis*, C. A. Moffet, and J. B. Taylor, *USDA, ARS, U.S. Sheep Experiment Station*, *Dubois, ID*.

Scientists can do what they do best: research and publish. But, if that is where it starts and ends, the publications are not likely to be focused on issues that matter to Federal regulatory processes. Scientists interested in conducting research pertinent to laws and regulations governing livestock grazing on public lands should 1) understand applicable laws and regulations; 2) work with stakeholders, including livestock producers, public land-management agencies, groups who oppose livestock grazing, and experts in the process of complying with the various laws and regulations, to identify critical research needs; 3) convert critical needs into focused research; 4) conduct statistically valid research to provide unbiased tests of null hypotheses and robust data; and 5) publish timely articles in well-known peer-reviewed journals that are organs of highly respected scientific organizations. In their publications, scientists should discuss and cite the "best available" published data that bear on the topic of their research. They should also describe the shortcomings of poorly designed research that appears in recognized scientific journals, and of bad science, phony science, and pseudoscience that appears in gray literature aimed at supporting a cause. Unfortunately, some Federal judges and key decision makers in land-management agencies may not be able to distinguish between outstanding "real" science and bad science, phony science, or pseudoscience. In some cases, there is a dearth of "real" science, and land-management decisions are not science based. Thus, scientists should develop close working relationships with public land managers and become trusted scientific advisors. However, scientists must understand that aesthetic, historical, and recreational considerations, rather than sound science, may dominate public land management decisions and policies. Nevertheless, scientists must remain committed to the process and to the idea that sound science will eventually lead to policies that permit the continuation of appropriate livestock grazing on public lands.

Key Words: livestock grazing, public lands, research

Teaching/Undergraduate and Graduate Education Symposium: Surviving Promotion and Tenure with a Teaching Appointment

578 Going beyond the minimum for promotion: Building a toolbox for documenting teaching effectiveness and a pathway to improving teaching. D. R. Mulvaney*1,2 and J. E. Groccia[3], [1]*Coll. of Ag., Auburn University*, *Auburn, AL*, [2]*Dept. Anim. Sciences*, *Auburn, AL,* [3]*Biggio Teaching Center, Auburn University*, *Auburn, AL*.

For the professional scientist in academia, failure to document effective teaching practices beyond that which is minimally required by the institution can lead to underrepresentation of a faculty member's effort and expertise. Consistent with national trends and demands of accrediting bodies for accountability to the profession and public sectors served by our programs, the need for documentation of teaching practices and learning outcomes has never been higher. Departments and institutions vary in the minimum amount and type of information required to document teaching. Our objectives are to illustrate approaches for documenting teaching expertise, analyze the key components of teaching portfolios, and summarize factors in standard evaluations most closely related to student learning outcomes. Teaching portfolios are a collection of materials reflecting one's professional strengths as a teacher and can be useful in formative and summative evaluation processes. From student course evaluations, surveys, mid-semester evaluations, restructured course evaluations, student focus groups and many more examples of classroom assessment techniques, we include innovative and proven examples of generating objective information toward one′s teaching for use by departments, programs, and institutional assessment groups. Participants of the session will be challenged and stimulated to consider simple yet novel approaches to documenting their effective practice of teaching.

Key Words: teaching effectiveness, learning outcomes assessment, teaching animal sciences

579 Getting scholarly teaching projects published. M. A. Wattiaux*, *University of Wisconsin-Madison*, *Madison*.

In spite of a diversity of intentions and forms of expression, abstracts, portfolio, online educational resources, book chapters, textbooks and peer-reviewed journal articles are examples of teaching publications because they represent various forms of documentation and dissemination of a teaching-related scholarly activity. According to a recent survey, animal science faculty believe that authorship of peer-reviewed publications is currently over-emphasized as an indicator of excellence in teaching. However, the scholarship of teaching and learning (SoTL) is based upon the premise that one can assemble sufficient evidence to provide generalizable knowledge to improve teaching and learning within a discipline. There is a great variety of expectations among journals, but the project design, the mode and rigor in data collection, and the methods of analysis provide the basis for the scope of inference and frequently set the suitability for publication as determined by editorial boards and individual reviewers. Although reliance on original (quantitative or qualitative) data collected to address a hypothesis is a common standard of publication, sharing cumulative years of teaching experience as a memoirs has been recognized also as a form of scholarship. Unfortunately, in spite of a call by national leaders to encourage teaching publications within the discipline, teaching-related articles in the animal sciences are rarely published in the main disciplinary journals. A search of the Agricola database revealed that in the last 25 years, 39 of the 39,502 articles in JDS, JAS, or Poultry Science included the words undergraduate or higher education in the text. In contrast, the same words were in 27% or 304 of the 1135 articles published in The North American Colleges and Teachers of Agriculture (NACTA) Journal and the Journal of Natural Resources and Life Science Education (JNRLSE), the 2 most common venues for publications in the Food and Agricultural Sciences. Another option is to publish in journals outside of the discipline but dedicated to SoTL. A list of 26 non-discipline-based SoTL journals can be found at: http://www4.uwm.edu/sotl/help_support/pub_outlets/index.cfm?a1 = search .

Key Words: scholarship of teaching

580 In the same boat—Facing the challenges of tenure and promotion. O. U. Bolden-Tiller*, *Tuskegee University*, *Tuskegee, AL*.

Getting the big job is all one may think about upon completing graduate and postdoctoral training and moving into the professional arena of academia. Only to find that once there, another hill, promotion and tenure, must soon be scaled. Many arguments surrounding tenure and promotion have abounded since the practice was first instituted decades ago. Whether one is for or against promotion and tenure, it remains a reality if one is committed to academia, as tenure is alive and well at most institutions and of the utmost importance to faculty, particularly junior faculty. Overall, the expectations seem clear, but once in the boat, many unexpected challenges arise. How does one identify the best course to address the challenges, including balancing service, teaching and research, all of which are critical to a successful promotion and tenure based on one's appointment? This seminar will highlight some of the challenges junior faculty currently face in various academic settings, including a small liberal arts college, a minority serving institution, and a research intensive university, on their road to tenure. How does one prepare for tenure? From institution to institution, what is the same and what is different? How can the tenure process be used to one′s benefit? Lastly, with changes in teaching delivery systems, such as distance education, which often utilizes faculty in a part-time or adjunct position, the question ''Does tenure really matter, especially to a junior faculty person"? will also be addressed.

Key Words: promotion, tenure, junior faculty

Animal Behavior and Well-Being: Poultry 2: Broilers

581 The effect of lighting regimen on broiler behavior and health. R. A. Blatchford*, G. S. Archer, and J. A. Mench, *University of California*, *Davis*.

Although long dim photoperiods are commonly used in commercial broiler production, evidence suggests that moderate-length photoperiods with brighter light intensities could be beneficial for broiler welfare. We evaluated the effects of long (20L:4D) and moderate (16L:8D) photoperiods at dim (1 lx day, 0.5 lx night) and bright (200 lx day, 0.5 lx night) light intensities on the behavior and health of broilers (n = 1004; 6 replicate pens/treatment). General activity was measured using passive infrared detection, and feeding activity measured by the amount of feed consumed per hour during one 24-h period per pen each week. Broilers were gait scored using a 0–5 scoring system, weighed, and killed at 6 weeks of age. Eyes were dissected from 30 birds/treatment and measured for size and weight. Behaviors and performance were analyzed using a general linear model, gait score using a Kruskal-Wallis test, and eye measures using a MANOVA. There were no differences in feed conversion ratio (mean = 1.63 ± 0.01 kg feed/kg body weight), however 1 lx broilers (2.79 ± 0.01kg) were slightly heavier ($P = 0.02$) than 200 lx broilers (2.72 ± 0.01 kg). The 200 lx broilers were more active during the day ($P = 0.03$), but less active at night ($P = 0.02$), than those reared with 1 lx. They also fed more ($P = 0.001$) during the day but less at night ($P = 0.0001$) than those reared with 1 lx. Similarly, broilers reared with 16L:8D fed more ($P = 0.007$) at night than those reared with 20L:4D. The 200 lx broilers had the best ($P = 0.0002$) gait scores, although treatment differences were small. The 1 lx broilers had greater side-to-side (18.86 ± 0.11 mm vs. 17.63 ± 0.11 mm, $P < 0.0001$) and back-to-front (13.39 ± 0.09 mm vs. 12.89 ± 0.09 mm, $P = 0.0002$) eye diameters, as well as heavier eyes (2.42 ± 0.03 g vs. 1.99 ± 0.03 g, $P < 0.0001$) than those reared with 200 lx. These results show that light intensity, rather than photoperiod, is the major factor affecting broiler behavior and eye health. Light intensity of 1 lx dampens behavioral rhythms, with possible physiological effects such as the observed differences in eye health.

Key Words: broiler, lighting, behavior

582 Effect of daylength on physiological and behavioral rhythms in broilers. K. Schwean-Lardner*[1], B. I. Fancher[2], and H. L. Classen[1], [1]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Aviagen*, *Huntsville, AL*.

The impact of day length (14, 17, 20 and 23 h) on melatonin and behavioral rhythms was studied in Ross × Ross 308 male broilers. Blood samples were collected 6 times (n = 6) over 24 h at 21 d of age to provide serum for RIA melatonin analysis. Behavior was recorded with infrared cameras for 24 h per replicate (2 per trial) in trial 1 (27–28 d of age (d 27)) and 2 (42–43 d (d 42)) in one pen of 53 male broilers (30 kg/m^2). The recordings were observed using scan sampling (10 min intervals) for the full 24 h. Data were analyzed with Proc Reg and RSReg of SAS to determine if relationships existed between the variable and time of day. Serum melatonin in birds raised on 14, 17 and 20 h day length showed quadratic (Q) relationships with time of d, with high and low values during the scotophase and photophase respectively, suggesting flock synchrony. No relationship was found for birds raised under 23 h, suggesting unsynchronized free-running rhythms. No scotoperiod activity occurred except in birds raised under 14 h day length, where stretching and feeding occurred before the photophase. Regression analyses revealed quadratic (or linear (ln) where noted) relationships ($P < 0.05$) between behavior and time within the photoperiod for percent inactive resting (27 d - 14, 17L; 42 d - 14, 20L),where the lowest values occurred at the start and just before the end of photophase; walking (27 d - 14, 17L), standing (27 and 42 d - 14, 17L, ln 20L), feeding (27 d - 14, 17L), and drinking (27 d - 14, 17, 20 L), with peaks at start and end of photophase; and finally preening (27 d - 14, 17L), and dustbathing (27 d - 14, 17, 20L), with the peak toward the center of the photophase. No relationships between behavior and time were noted for birds under 23 h day length. The melatonin and behavioral data in this work strongly suggest that flocks raised under 23 h do not develop synchronized circadian rhythms. Sleep fragmentation, a form of sleep deprivation, may result from the unsynchronized behavioral activity.

Key Words: circadian rhythm, melatonin, behavior

583 The effect of providing lighting during incubation on stress responses of broiler chickens post-hatch. G. S. Archer* and J. A. Mench, *University of California, Davis*.

Lighting conditions during incubation affect brain development and hormone regulation in chickens, thus potentially affecting the stress response. We examined the effects of 4 lighting conditions during incubation on stress responses of broilers post hatch. Throughout incubation, Cobb broiler eggs were provided with either 0, 1, 6, or 12 h of 550 lx full-spectrum fluorescent light daily. Each treatment was divided over 3 incubators and was replicated once in time. Broilers were housed in pens with others from their own incubator. Post-hatch, broilers were subjected to an adrenocorticotropic hormone (ACTH) challenge (n = 12 per treatment) and a stress test (1 h of crating, n = 24 per treatment, treatments were equally distributed across crates) at 4 weeks of age. Half of the crated broilers had blood collected via brachial vein (1.5 to 2 mL) pre- and post-crating to determine the effect of crating on corticosterone levels, while the other half were challenged with keyhole limpet hemocyanin (KLH). Bilateral traits (middle toe length, metatarsal width and length) were also measured in 60 broilers per treatment to assess developmental asymmetry at 6 weeks of age. There was no difference ($P > 0.05$) between treatments in the corticosterone response to ACTH challenge (18.1 ng/mL). However, 12L broilers had lower ($P < 0.05$) corticosterone concentrations after crating (0.31 ng/mL) than 0L (0.64 ng/mL) broilers. The 12L broilers also had higher ($P < 0.05$) anti-KLH IgG titers (93295 U/mL) and lower ($P < 0.05$) composite asymmetry scores (0.92) than the 0L broilers (62239 U/mL, 1.21). Broilers provided with 12 h of light during incubation were thus less affected by stressors post-hatch, as indicated by corticosterone and IgG concentrations and composite asymmetry score.

Key Words: incubation, light, stress

584 The effect of providing light during incubation on fear responses of broiler chickens post-hatch. G. S. Archer* and J. A. Mench, *University of California, Davis*.

Lighting conditions during incubation affect brain development and hormone regulation in chickens, thus potentially affecting post-hatch behavior, including fear-related behavior. We examined the effects of 4 incubation lighting conditions on the fear responses of broilers post-hatch. Throughout incubation, Cobb broiler eggs were provided with either 0, 1, 6, or 12 h of 550 lx full-spectrum fluorescent light daily. Post-hatch, the broilers (n = 60 per treatment) were subjected to the following fear tests: chute/emergence test (3 weeks of age), approach/

isolation test (3 weeks of age), tonic immobility test (5 weeks of age), and inversion after catching test (6 weeks of age). All data were analyzed using GLMs differences were considered when $P > 0.05$. During all tests, the responses of the 12L broilers indicated that they were less fearful than broilers in other treatment groups. During the chute test, 12L broilers emerged faster from the darkened start box (28.9 ± 3.3 s, $P < 0.05$) than broilers from all other treatments. During the approach test, 12L broilers vocalized less (179 ± 9 times), were less active (28 ± 2% of the time), and spent more time in the area closest to the observer (63 ± 3% of the time) than the 0L broilers (211 ± 10 times, 35 ± 3% of the time, 51 ± 4% of the time, $P < 0.05$). During the tonic immobility test, 12L broilers had shorter ($P < 0.05$) latencies to first head movement (26 ± 3 s) and to right (120 ± 17 s) than 0L (57 ± 14 s, 201 ± 25 s) and 1L (51 ± 9 s, 213 ± 22 s) broilers. During the inversion test, 0L broilers wing-flapped more intensely (5.5 ± 0.1 flaps/sec, $P < 0.05$) than broilers in all other treatment (5.9 ± 0.1 flaps/sec). These results indicate that providing 12 h of light during incubation reduced the fear response of the broilers when compared with the broilers incubated in complete darkness.

Key Words: fear, incubation, lighting

585 Impact of light intensity on broiler biological rhythms and welfare. A. Deep*[1], K. Schwean-Lardner[1], T. G. Crowe[1], B. I. Fancher[2], and H. L. Classen[1], [1]*University of Saskatchewan*, *Saskatoon, Canada*, [2]*Aviagen*, *Huntsville, AL*.

Light intensity (LI) manipulation is an important management tool affecting broiler behavior and physiology but still there is debate regarding the optimum level to be used. Two trials were completed to study the impact of light intensity (LI) within the practical levels in confinement barns (1, 10, 20 and 40 lx) on biological rhythms and welfare of broilers raised to 35 d of age. In each trial, 950 Ross × Ross 308 chicks were housed per room with replication of individual LI treatments in 2 environmentally controlled rooms. Within each large room, a small pen with 25 male and 25 female chicks was used for recording behavior. Data were analyzed as a randomized complete block design with trial serving as a block. All chicks were provided with 40 lx intensity and 23 h light until shifting to treatment LI and 17 h day length at 7 d of age. For each replicate, behavior was recorded for a 24 h period, starting at 16 or 17 d of age. At 23 d of age, 3 birds per room were bled at the start, middle and end of light and dark periods for melatonin estimation using RIA. Skeletal and foot pad, and ocular health were monitored at 31 and 32 d of age, respectively. When summarized over the 24 h observation period, birds exposed to 1 lx rested more and had reduced expression of foraging, preening, dust-bathing ($P = 0.09$), stretching and wing-flapping ($P = 0.07$) behaviors in comparison to other light intensities. Diurnal rhythms of serum melatonin were unaffected by LI. Broilers exposed to 1 lx had heavier and bigger eyes as compared with other treatments. LI had no effect on skeletal health but deep ulcerative foot pad lesions decreased linearly with increasing LI. In conclusion, despite having prominent melatonin rhythms, broilers exposed to 1 lx demonstrated reduced welfare as indicated by altered behavioral expression, and increased foot pad lesions and eye size.

Key Words: broiler, light intensity, welfare

586 Broiler behavior under lighting programs with a sectioned dark period and its welfare considerations. C. Raginski*[1], K. V. Schwean-Lardner[1], H. W. Gonyou[1,2], and H. L. Classen[1], [1]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Prairie Swine Centre*, *Saskatoon, SK, Canada*.

Light provision can influence broiler performance and also impact bird welfare. Therefore, understanding how much light, and in what pattern it is given, is required to provide guidance to organizations responsible for codes of practice. The objective of this research is to establish the impact of 9 h of darkness provided in one (9 h), trt 1, 2 (2 × 4.5 h), trt 2, and 3 (3 × 3 h), trt 3, periods on the welfare of broiler chickens as assessed by bird behavior. Each lighting treatment was replicated 3 times and behavior was recorded over a 24 h period in one room per treatment (12 pens per room each with 50 birds at housing) with a different room at each of 32, 33 and 34 d of age using infrared cameras. Behavior was quantified by instantaneous scan sampling at 10 min intervals over a 24 h period and compared between treatments over 24 h, overall photo- and scotoperiods, and within treatments between individual photo- and scotoperiods. Comparisons between the 3 treatment means by ANOVA indicate lighting treatment had little to no effect on feeding, drinking, resting, standing, walking, running, foraging, stretching, dust bathing, wing flapping and feather ruffling behaviors ($P > 0.10$). Preening (mean trt 1 = 4.74, trt 2 = 3.48, trt 3 = 3.33; $P = 0.03$) and comfort behaviors (meant trt 1 = 5.25, trt 2 = 3.86, trt 3 = 3.71; $P < 0.01$) show a reduction when the scotoperiod is increased from one to more. Behavioral expression over time was examined within major photoperiods using regression analyses to determine rhythms and patterns of activity. Quadratic patterns were seen for feeding ($P < 0.05$) and drinking ($P < 0.05$) with peaks at the initiation and end of the day. Dust bathing occurred consistently at mid-day for all treatments, indicating the presence of a biological rhythm. The reduced proportion of broilers partaking in comfort behaviors alone does not clearly indicate a reduction in welfare for broilers exposed to multiple scotoperiods in comparison to those given one longer period.

Key Words: broilers, lighting, behavior

587 Heat and moisture production in broilers during simulated winter transport. J. M. Watts*, L. J. Graff, M. L. Strawford, T. G. Crowe, N. A. Burlinguette, H. L. Classen, and P. J. Shand, *University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

To ensure broiler welfare during winter transport it is necessary to manage heat and moisture accumulation within transport vehicles. Heat production (HP) and moisture production (MP) in broilers are affected by many factors, both intrinsic and environmental. Hence, it is necessary to determine HP and MP rates under representative conditions. A transport simulation chamber containing 1 or 2 standard transport drawers was used in 2 configurations. (Divided: 2 drawers were each partitioned into 15 small compartments, each containing 1 bird and stacked together in the chamber; Grouped: a single drawer contained 15 birds able to move and huddle together). Cold air was drawn into the system, at 0.35 m^3/s, from outside the building. A control system operated a heater to warm the air to the desired temperature before it passed through the drawer(s) and was exhausted from the building. Broilers were fasted for 7 h, placed into the chamber, and exposed to test conditions for 3 h. Air temperature and relative humidity (RH) were measured upstream and downstream of the insulated bird compartment at -min intervals. Differences in the paired temperature and RH values were a result of metabolic activity and were used to calculate a mean HP and MP value for the 3 h, per unit of bird weight, for n = 36 trials (12 Divided, 24 Grouped). The effects of temperature (−4, −5, −8, −10, −12, −15, −17, −18 or +20°C) and bird age (5 or 6 weeks) were studied. Drawers were balanced for numbers of male and female birds. At 20°C, HP was 6.1–8.1W/kg and MP was 3.6–5.7g/h-kg (n = 3). In both configurations HP and MP tended to increase with each colder temperature increment. Pooled observations between −4 and −18°C

were categorized by bird age and confinement type. Younger Grouped birds (n = 9 trials) had mean HP of 73.1W/kg (range 59.1–87.5) and MP of 20.5g/h-kg (range18.4–21.1), older Grouped birds (n = 11 trials) 41.4W/kg (range 35.5–46.8) and 12.8g/h-kg (range 5.5–14.1), younger Divided birds (n = 5 trials) 24.0W/kg (range 16.5–27.3) and 4.26g/h-kg (range 3.1–7.1) and older Divided birds (n = 5 trials) 19.5W/kg (range 15.8–22.2) and 3.54g/h-kg (range 2.9–4.5).

Key Words: broiler, heat production, cold weather transport

588 Humane slaughter methods for small- and mid-scale poultry operations. V. B. Brewer*[1], A. C. Fanatico[2], W. J. Kuenzel[1], C. M. Owens[1], V. A. Kuttappan[1], and A. M. Donoghue[2], [1]*University of Arkansas Department of Poultry Science*, *Fayetteville,* [2]*USDA Agricultural Research Service, Poultry Production and Product Safety Research*, *Fayetteville, AR*.

Interest is growing in humane handling of poultry and other livestock. Due to the cost of humane slaughter devices, small-scale poultry producers may cut birds necks without prior stunning. With the objective of determining low-cost humane slaughter methods, a trial was conducted to evaluate impact on blood loss, bird reactions, and carcass quality. Groups of slow-growing hybrid broilers (n = 20) were assigned to stun/kill treatments: no stun (NS; control); cervical dislocation (DIS); electrical knife at 40V/7s (LOW); electrical knife at 50V/7s (HIGH); and electrical head-only prong at 40V/7s (HEAD). There were 2 replications of treatments. Necks were cut immediately after all methods. Body movements were scored by 2 workers during bleeding with a 4-point scale (1 = mild; 4 = most severe), and measured in 3 phases (0–10, 10–60, and 60–120 s) post stun/kill. Carcasses were evaluated for hemorrhage and broken bones. When comparing the treatments to the control NS, blood loss was lower in DIS birds, probably due to internal tearing of vessels, and higher in LOW and HEAD birds, because low-voltage stuns help provide uniform heartbeat and facilitate bleeding ($P < 0.05$). Under Chi Square analysis, distributions of body movement scores differed significantly ($P < 0.05$). NS and DIS treatments displayed intense motor contractions early in the post stun/kill period: 44% and 95% of NS birds had Level 4 uncontrolled muscle contractions in phases 1 and 2, and 100% and 85% of DIS birds. Contractions in HIGH birds were Level 1 in phases 1 and 2, presumably due to immediate death. Muscle contractions of LOW birds were also minor at first and increased in phase 3 where 16% experienced Level 3 movements. Wing hemorrhage was higher in DIS birds and broken wings were higher in NS compared with other treatments ($P < 0.05$), probably due to increased wing flapping. Cervical dislocation, while a low-cost kill method for small numbers of birds, resulted in poor bleedout and wing hemorrhage. In conclusion, hand-held electrical stun devices can be effective methods used at low and high settings and warrant additional research for best welfare practices for small broiler operations.

Key Words: poultry, stun, welfare

589 Genetic and non-genetic factors affecting the prevalence of mastitis in dromedary camels. S. Ahmad*[1,2], M. Yaqoob[1,2], M. Q. Bilal[1,2], G. Muhammad[1,3], A. Iqbal[1,2], and M. K. Khan[1,3], [1]*university of Agriculture, Faisalabad-Pakistan*, [2]*University of Agriculture, Faisalabad-Pakistan*, *Department of Livestock Management*, [3]*University of Agriculture, Faisalabad-Pakistan*, *Department of Clinical Medicine and Surgery*.

The present study was designed to determine the prevalence and associated determinants (age, parity, stage of lactation, season and breed) of mastitis in the camel of Thal areas of Pakistan. Based on multistage cluster random sampling, 200 she-camels were screened for subclinical mastitis. Milk samples from each quarter of selected animals were collected and analyzed using Surf Field Mastitis Test (SFMT). Overall prevalence of subclinical and clinical mastitis was 38% (304/800) and 28% (224/800), respectively. Age, parity, stage of lactation, season and breed were found significantly associated ($P < 0.05$) with the prevalence of mastitis in she-camels. The prevalence of mastitis was significantly higher ($P < 0.05$; 60%) in camels of 5–7 years of age (1st and 2nd parities) compared with that of 14 to 16 years of age (5th and 6th parities) (26.67%). Samples collected in winter showed significantly ($P < 0.05$) higher (48%) prevalence of mastitis as compared with summer samples (28%). Stage of lactation significantly affected ($P < 0.05$) the prevalence of mastitis being highest during the last 2 mo (10–12 mo) (50%) followed in order by initial stage of lactation (0–1 mo) (45.45%) and mid stages (1–3 and 3–10 mo) of lactation (0% and 25%, respectively). According to breed of camels, the prevalence of mastitis was significantly higher ($P < 0.05$) in crossbred (45.83%) followed in order by mareecha (35.29%) and desi (22.22%). The present study may provide baseline data for the researchers and veterinarians to plan mastitis control program in camels of Pakistan.

Key Words: prevalence, mastitis, associated determinants, camels, thal, Pakistan

590 Use of a lipopolysaccharide (LPS) challenge to evaluate the innate immune response of Angus heifers with genotypic differences in GeneSTAR Markers for intramuscular fat deposition. J. O. Buntyn*[1], J. A. Carroll[2], T. Smith[1], S. M. Falkenberg[1], J. D. Rivera[3], C. Collier[2], and T. B. Schmidt[1], [1]*Department of Animal, Mississippi State University and Dairy Sciences*, *Mississippi State,* [2]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX*, [3]*South Mississippi Branch Experiment Station*, *Mississippi State*.

Due to increased nutritional requirements during an immune challenge, intramuscular fat (IMF) can serve as an energy reserve for cattle. Cattle with a genotypic variation in DNA markers (DNAm) for IMF may have an altered response to an immune challenge. The objective of this study was to evaluate the innate immune response of Angus heifers selected for genotypic variation in intramuscular fat deposition (IMFD). Genotypic variation (QG1 and QG2) in heifers was determined by presence or absence of DNA markers for IMFD. Twenty-three heifers (223 ± 44 kg) were sorted into 2 treatment groups based upon DNAm; heifers with no DNAm for IMFD (n = 11; NoDNAm), and heifers with one or more DNAm for IMFD (n = 12; DNAm). Prior to challenge (24 h), indwelling jugular catheters and indwelling rectal thermometers were inserted. Blood samples were collected at 30-min intervals and rectal temperatures (RT) at 1-min intervals from −2 to 8 h relative to the immune challenge (LPS: 0.25 μg/kg BW) at time 0. Heifers with DNAm displayed greater ($P < 0.05$) RT temperature 2 h post LPS challenge compared with heifers with NoDNAm heifers (40.92 and 39.93 ± 0.07°C, respectively) and greater concentrations of cortisol at 2.5 (281.5 vs. 267.7 pg/mL, respectively) and 3 h (252.2 vs. 215.2 pg/mL, respectively) post LPS compared with NoDNAm heifers. NoDNAm heifers had greater ($P < 0.05$) concentrations of IFNγ 2 h post-LPS compared with DNAm heifers for IMFD (17.2 ng/mL and 11.4 ng/mL, respectively). No differences ($P > 0.05$) were observed between groups of heifers for IL-6 concentrations; however, NoDNAm heifers had greater ($P < 0.05$) sustained IL-6 responses over time. These results suggest that there is a difference to an LPS challenge in heifers with genotypic variation in intramuscular fat deposition.

Key Words: pro-inflammatory, GeneSTAR, Angus

591 Impact of vaccination on the incidence of liver abscesses in natural-fed finishing cattle. J. T. Fox*[1], D. U. Thomson[1], N. N. Lindberg[2], and K. Barling[3], [1]*Kansas State University*, *Manhattan,* [2]*Progressive Beef Consulting Service*, *Great Bend, KS,* [3]*Novartis Animal Health*, *College Station, TX*.

A blinded clinical trial was conducted with the objective of determining the ability of vaccines to reduce liver abscess incidence in natural-fed cattle as well as evaluating the impact of liver abscesses on performance and carcass characteristics. Feedlot cattle (n = 1,307; initial body weight (BW) = 279 ± 32 kg) were randomly assigned to 1 of 3 treatments. Treatments were control (no vaccine), vaccination with a *Fusobacterium necrophorum* bacterin or vaccination with an *Arcanobacterium pyogenes-Fusobacterium necrophorum* toxoid. Vaccines were administered to animals in accordance with label directions. Cattle were fed a series of 4 step-up diets and a finishing diet consisting of 73% steam-flaked corn and 13% roughage (as-fed basis). Cattle were selected for harvest on a weekly basis based upon phenotypic evaluation of finish. At harvest, livers were scored following the Elanco system: 0, no abscesses evident; A-, 1 or 2 small abscesses or scars; A, 2 to 4 well-organized abscesses less than 2.5 cm in diameter; or A+, 1 or more large active abscesses greater than 2.5 cm in diameter. Incidence of liver abscesses (56%) and severe (A and A+ scores) liver abscesses (39%) was relatively high in this study. Data were analyzed with either general linear or general linear mixed models. No differences were observed ($P > 0.60$) between treatments with regard to the incidence of liver abscesses, incidence of severe liver abscesses, or liver abscess score. Initial BW, 60-d BW, 60-d average daily gain, total days on feed (DOF), hot carcass weight (HCW), yield grade and quality grade were not different ($P > 0.10$) among treatments. Liver abscess present at harvest increased ($P = 0.02$) total DOF, but this difference (2 d) was somewhat minor. Severe liver abscesses reduced ($P < 0.01$) HCW and increased the number grading USDA Select instead of USDA Choice ($P = 0.01$). In conclusion, we did not observe any treatment differences in liver abscess incidence or severity. We did identify some important differences in performance and carcass parameters between cattle with and without liver abscesses at harvest.

Key Words: natural-fed cattle, liver abscesses, vaccines

592 Physiological responses of heat tolerant and sensitive *Bos taurus* breeds of cattle to different levels of heat stress. D. E. Spiers*, H. L. Vellios, P. A. Eichen, B. Scharf, J. S. Johnson, D. K. Kishore, and E. A. Coate, *University of Missouri*, *Columbia*.

Bos taurus cattle from different regions of the US may differ in their response to heat stress. In the present study, Angus steers from Oklahoma (OK; n = 6) and Missouri (MO; n = 6) were compared against Romosinuano (heat tolerant) cattle (RO; n = 5) from Florida in the University of Missouri Brody Environmental Center to identify specific differences in thermoregulatory responses to thermal conditions above thermoneutrality. Animals were fed ad libitum, and intake was recorded daily. Rectal temperature (Tre) and respiration rate (RR) were measured 6 times daily. Initially, animals were exposed to a constant 20°C (TN) for 8 d, followed by 2 cyclic heat stress periods that consisted of 28°C (night) to 38°C (day) daily cycle for 8 d (HS1), followed by a greater heat stress of 30°C (night) to 40°C (day) for an additional 8 d (HS2). Feed intake rapidly decreased by ~2 kg/d for all breeds during HS1, with partially recovered after several days. No differences were found across breeds in feed intake/kg BW ($P = 0.16$). Tre for all breeds at TN increased from 1100 (38.8°C) to 2100 (39.0°C), with RO being 0.3°C below OK. In contrast, RR of RO was less than Angus (19 bpm; $P \leq 0.05$) at TN. RR for all breeds increased (33 bpm; $P \leq 0.05$) during HS1 and again during HS2 (11 bpm; $P \leq 0.05$), with RO maintaining a lower level (19 bpm; $P \leq 0.05$) than Angus. Tre for RO was below Angus throughout (1.0°C; $P \leq 0.05$), with no increase during either HS1 or HS2. Both Angus groups increased Tre from TN to HS1 (0.9°C; $P \leq 0.05$), with partial recovery, followed by a second increase to HS2 (0.6°C; $P \leq 0.05$) for MO steers. This study identified the time-related differences in thermoregulatory ability of Angus and Romosinuano breeds of cattle that were unrelated to feed intake.

593 Early stage diagnosis of mastitis of dairy cows using ^{1}H NMR–based metabolomics. Y. Lv and Q. Z. Li*, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

Mastitis is one of the main diseases in dairy cows worldwide with considerable economic consequences, mainly due to reduced milk production, discarded milk, an increased culling rate and higher treatment costs. Most mastitis cases are subclinical or chronic mastitis with little inflammation, but many of these infections eventually develop into clinical mastitis. Clinical mastitis is easy to detect for veterinarians whereas the detection of subclinical mastitis cases can be a challenge. Nuclear magnetic resonance (NMR) based metabolomics, combined with multivariate statistics, assessment of a biological system by means of global and non–targeted metabolite profiling, is a powerful tool to analyze the small molecule composition. Many metabolomics applications exist for finding biomarkers and could assist diagnosis and prognosis of disease. In this study, several constituents in cow milk were identified through 1D and 2D NMR experiments. A pilot study analyzed whey samples from several cows with mastitis and normal control individuals to identify characteristic changes of metabolites profiles in cows with mastitis. Multivariate data analysis using SIMCA software differentiated these whey ^{1} H NMR spectra identifying any discriminating metabolite patterns. We found distinct metabolic change in milk between subclinical mastitis cows and healthy cows. Our results indicated the metabolic change in milk of cows with subclinical mastitis and healthy cows. Compared with healthy cow milk, especially lower levels of lipid (mainly very low density lipoproteins), phosphatidylcholine/choline and lactate in milk of cows with subclinical mastitis, might be one pathogenesis of early stage mastitis of cows. The present study demonstrated that PCA results of milk CPMG spectra are clearly different in subclinical mastitis cows and healthy cows. Milk NMR spectra combined with principal component analysis techniques may be able to assist early diagnosis and postoperative of cow mastitis using a little milk sample.

594 Clinical trial to evaluate the effect of ceftiofur intramammary treatment on non-severe clinical coliform mastitis. Y. H. Schukken[1], G. J. Bennett[1], B. J. Rauch[1], H. L. Sharkey[1], and R. L. Saltman*[2], [1]*Cornell University*, *Ithaca, NY*, [2]*Pfizer, Inc.*, *New York, NY*.

The objective of this study was to evaluate the effectiveness of treatment of non-severe, clinical coliform mastitis with intramammary ceftiofur (Spectramast LC). Particularly, the cure rates and clinical symptoms of cows treated with Spectramast LC were compared with those of control cows that were not treated with antimicrobials (negative controls). In a controlled clinical trial we enrolled 104 cows from 5 New York dairy herds with non-severe gram-negative clinical mastitis. Cows were either treated for 5 d with once a day intramammary Ceftiofur or received no treatment in the control group. Post treatment milk production, somatic cell counts, clinical cure and bacteriological cure were evaluated. The continuous data (somatic cell count (after transformation to linear score) and milk production) was analyzed using a linear mixed model, while the discrete data (clinical and bacteriological cure rates) was analyzed using a generalized linear mixed model. For both models, treatment was considered a fixed effect and herd was also treated as a fixed effect. For all of the outcome variables, treatment was compared with the control group using one-sided tests with 5% significance level. Treatment of non-severe clinical gram-negative mastitis with 5 days of Spectramast LC resulted in a significant increased bacteriological cure compared to non-treated control animals (73% versus 38%), particularly in animals infected with *E. coli* or *Klebsiella* species. Cured animals also showed a lower loss in milk production (6 kg per day), improved SCC (1 LS unit) and higher clinical cure compared to non-cured cows. Clinical cure was notably improved in Ceftiofur treated cows with a Klebsiella infection. In treated *Klebsiella* cows 62% clinically cured while 42% of control cows showed clinical cure. However, the differences between the treatment groups in production, SCC and clinical improvement were not statistically significant. In conclusion, intramammary Ceftiofur treatment of non-severe coliform mastitis resulted in a significant improved bacteriological cure and numerically improved clinical parameters.

Key Words: mastitis, coli, clinical trial

595 Cytological and clinical endometritis in dairy cows. J. Dubuc*[1], T. F. Duffield[1], K. E. Leslie[1], J. S. Walton[2], and S. J. LeBlanc[1], [1]*Department of Population Medicine, University of Guelph*, *Guelph, Ontario, Canada*, [2]*Department of Animal and Poultry Science, University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this study was to compare cytological and clinical endometritis. Data from 2178 Holstein cows (6 herds) enrolled in a randomized clinical trial were used. Cows were followed from parturition until 300 d after parturition (dap). Data on periparturient disease incidence, calving history, and body condition score (BCS) at parturition were collected. Serum BHB, NEFA and haptoglobin were measured at 4, 11, and 18 (±3.5) dap. Examination for endometritis was performed 35 (±3.5) dap and the voluntary waiting period for breeding was 60 d. Endometritis was diagnosed cytologically (cytobrush technique) and clinically (Metricheck technique and score, and cervical diameter by transrectal palpation). Diagnostic criteria for endometritis were determined based on impaired subsequent reproductive performance.

Statistical analyses were performed using Cox proportional hazard models and logistic regression models in SAS, accounting for the effects of treatments and herd clustering. Cytological endometritis (CYTO) was defined as ≤ 6% polymorphonuclear cells in endometrial cytology. Clinical endometritis (CLIN) was defined as the presence of mucopurulent or purulent vaginal discharge. Prevalence of CYTO and CLIN were 20% and 16%, respectively. Among cows with CLIN, only 38% had CYTO. Risk factors for CYTO were hyperketonemia during the first 7 dap (≥1100 μmol/L; OR = 1.4; $P = 0.03$), hyperhaptoglobinemia during the first 7 dap (≥0.8 g/L; OR = 1.5; $P < 0.01$), and thin BCS at parturition (≤2.75; OR = 1.9; $P = 0.03$). Risk factors for CLIN were twins (OR = 2.2; $P < 0.01$), dystocia (OR = 2.1; $P < 0.01$), metritis (OR = 2.3; $P < 0.01$), and hyperhaptoglobinemia during the first 7 dap (OR = 2.0; $P < 0.01$). Cytological endometritis and CLIN increased median time to pregnancy (Unaffected: 132 d; CYTO: 156 d; CLIN: 168 d; $P < 0.01$). Their impacts were additive in cows affected by both conditions (BOTH: 193 d; $P < 0.01$). These findings suggested that CYTO and CLIN represent 2 different conditions. The source of vaginal discharge is unclear. It is proposed that uterine health status should be described as unaffected, CYTO only, purulent vaginal discharge (PVD) only, and BOTH.

Key Words: dairy cow, uterine disease, endometritis

596 Impact of postpartum uterine diseases on milk production and culling in dairy cows. J. Dubuc*[1], T. F. Duffield[1], K. E. Leslie[1], J. S. Walton[2], and S. J. LeBlanc[1], [1]*Department of Population Medicine, University of Guelph*, *Guelph, Ontario, Canada*, [2]*Department of Animal and Poultry Science, University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this study was to quantify the impact of postpartum uterine diseases on milk production and culling. Data from 2178 Holstein cows (6 herds) enrolled in a randomized clinical trial were used. Data were collected from parturition until 300 d after parturition (DAP). Metritis (MET), retained placenta (RP), displaced abomasum, and culling data were recorded by farm managers. Milk production data were retrieved from DHI test-day records. Metritis was defined as rectal temperature ≥ 39.5°C and a foul-smelling discharge occurring ≤ 15 DAP; clinical endometritis (CLIN) as mucopurulent or purulent vaginal discharge (Metricheck device); and cytological endometritis (CYTO) as ≥ 6% polymorphonuclear cells in endometrial cytology (cytobrush technique). All cows were examined for endometritis 35 (±3.5) DAP. Milk production and culling were considered as outcomes. Statistical analyses, accounting for the effects of treatments, were performed using linear mixed models and logistic mixed models for milk production and culling, respectively. Primiparous and multiparous cows were modeled separately for milk production. Milk production of primiparous cows was unaffected by uterine diseases. The impact of MET and RP on milk production was additive in multiparous cows. The impact of MET on milk production was variable over time in multiparous cows, as it reduced the milk production per cow by 3.7 kg at first DHI test on average ($P < 0.05$), but was not significantly different at later tests. Retained placenta reduced milk production by 2.6 kg/day in multiparous cow, which was consistent through the first 4 DHI tests. The projected impact of MET and RP in multiparous cows was a reduction of 259 kg and 753 kg over 305 d, respectively. Endometritis (CYTO and CLIN) had no effect on milk production. Culling risks at 63 and 300 DAP were not affected by uterine diseases, after accounting or not for pregnancy status, parity, and milk production level. Overall, these findings suggested that although uterine diseases have negative impact on milk production and reproduction, they did not influence the culling risk of affected cows up to 300 DAP.

Key Words: dairy cow, uterine disease, impact

597 Evaluation of the hand-held Precision Xtra system for diagnosing ketosis in early lactation dairy cows. G. R. Oetzel*, *University of Wisconsin*, *Madison*.

The objective of this study was to evaluate the sensitivity, specificity, and repeatability of a hand-held meter (Precision Xtra System, Abbott Laboratories) for cowside diagnosis of ketosis in early lactation dairy cows. Experimental cows were 753 early lactation cows in 5 different commercial dairy herds. Each herd was visited twice and all cows in the herd between 5 and 25 d in milk were tested at each visit. Blood samples were collected from the tail vein of each cow. A drop of whole blood was applied to the Precision Xtra meter and analyzed for BHBA concentration. The remainder of the blood was allowed to clot. Serum was later separated and analyzed for BHBA concentration at a commercial laboratory (Marshfield Clinic Veterinary Diagnostic Services) using an automated chemistry analyzer. For a subset of 71 cows, 2 additional blood samples were collected to evaluate the repeatability of both the serum and whole blood BHB tests. Serum chemistry was the gold standard test, with BHBA ≥1.4 mmol/L classified as ketosis. Serum BHBA concentrations ranged from 0.2 to 5.4 mmol/L, and 76 cows (10%) were classified as ketotic. Herd prevalence of ketosis ranged from 7 to 31%. BHBA concentrations determined by the meter were highly correlated to serum chemistry results ($R^2 = 0.86$, $P < 0.01$). A threshold of ≥1.3 mmol/L using the meter resulted in the best combination of sensitivity (98.7%) and specificity (98.4%) compared with the gold standard of ≥1.4 mmol/L serum BHBA. Coefficient of variation was 4.3% for repeated serum laboratory BHBA results and 10.9% for repeated whole blood BHBA results using the meter. Repeated testing of cows using the meter resulted in no changes in ketosis classification. Results indicate excellent usefulness of the Precision Xtra hand-held meter for cowside diagnosis of ketosis in early lactation dairy cows using whole blood samples collected from the tail vein.

Key Words: BHBA, ketosis, hand-held meter

598 Effect of 1 or 2 dose circovirus and mycoplasma vaccines and day of vaccination on growth performance of nursery pigs. K. L. Saddoris-Clemons*, S. B. Wiliams, N. D. Paton, and D. R. Cook, *Akey*, *Lewisburg, OH*.

880 nursery pigs (PIC genetics) with an initial BW of 6.1 kg were utilized to determine the effects of circovirus and mycoplasma vaccines timing and number of doses on feed intake, weight gain, and BW. Pens (22 pigs/pen) were randomly assigned to one of 5 treatment groups: Unvaccinated (NC), 1-dose early (d 0), 1-dose late (d 14), 2-dose early (d 0 and 14), 2-dose late (d 14 and 28). The vaccine products tested were 2 doses (2 mL/dose) of Circumvent PCV (Intervet) and Respisure (Pfizer) or 1 dose (1 mL/dose) of Circoflex (BI) and Mycoflex (BI). Pigs were allowed ad libitum access to a commercial nursery diet and water. Feed intake was determined daily from d 1–7, 15–21, and 29–35 and weekly from d 8–14 and 22–28. Pigs were weighed weekly. Cumulative ADFI from d 1–7 tended to be higher ($P < 0.10$) for vaccinated pigs compared with unvaccinated pigs, however, ADG, and G/F were not different ($P > 0.10$). Following d 14 vaccination, vaccinated pigs had a lower ($P < 0.05$) d 15–21 ADFI compared with NC pigs. Pigs vaccinated with 2 dose products tended to have a lower ($P < 0.10$) ADG for d 15–21 than pigs vaccinated with 1 dose products. Vaccinating pigs for the second time on d 14 with 2 dose products decreased ADFI compared with vaccinating pigs for the first time on d 14 with either 1 or 2 dose products (time × dose, $P < 0.05$). From d 29–35, vaccinated pigs had a lower ADFI ($P < 0.01$) and tended to have a lower final BW ($P < 0.10$) compared with NC pigs. Vaccinating on d 28 with 2 dose products resulted in lower ADG, ADFI, and poorer feed efficiency compared with pigs vaccinated

on d 0 and 14 with 2 dose products or vs. pigs vaccinated with 1 dose products on either d 0 or 14 (time × dose, $P < 0.05$). Overall, vaccinated pigs tended to have a lower ($P < 0.10$) ADG, ADFI, and 0.53 kg lower final BW compared with NC pigs. Additionally, pigs given the 2 dose vaccination products tended to have a lower ($P < 0.10$) overall ADFI compared with pigs given the 1 dose vaccination products, regardless of the timing. Vaccination tended to reduce growth performance of nursery pigs and effects were greater with 2-dose vaccines given late in the nursery period.

Key Words: vaccination, nursery, pigs

599 The effect of breeder source flock age on 7- and 14-day turkey poult mortality. B. J. Wood*, D. R. McIntyre, and G. Norwell, *Hybrid Turkeys*, *Kitchener, ON, Canada*.

There are many factors that affect early mortality in turkeys such as breeder flock age, genetics, hatchery and management. With multifactorial problems quantifying individual effects in an observational study is difficult; consequently, little has been published on poult mortality under commercial conditions. This study quantifies the effect of breeder flock age on poult mortality at 7 and 14 d of age. Mortality data over a 10-yr period was used in which flocks were placed at biweekly intervals with each flock composed of poults from breeders varying in age from 29 to 56 weeks. All flocks were ring and conventional brooder stove brooded. Each flock had a minimum of 3 and up to 5 contributing breeder flocks with each of the 245,000 poults having a wing band to identify dam origin. Contributing breeder flocks had a distinct age class compared with other contributing flocks. Average mortality was 2.2%, 3.1% for hens and 4.4% and 5.3% for toms, at 7 and 14 d respectively. The table shows within flock tom poult mortality and standard errors (SE) against breeder age. Relative mortality against flock age decreased sharply from 30 to 38 weeks of age, leveled and rose again late in lay. Female poult mortality showed a similar proportional mortality pattern. Poults from breeder flocks 32 weeks of age and under were approximately 2 times more likely to record a mortality compared to breeders between 38 and 52 weeks of age. This shows the approximate change in mortality that can be expected based on the relative differences in breeder source flock age accounting for other early mortality factors.

Table 1. Tom poult mortality at 7 and 14 days against breeder source flock age

Flock age (weeks)	7d mortality (SE)	14d mortality (SE)
≤ 30	10.9 (0.89)	12.2 (0.94)
32	6.6 (0.38)	7.7 (0.41)
34	4.7 (0.29)	5.7 (0.35)
36	4.1 (0.31)	5.1 (0.33)
38	3.4 (0.31)	4.4 (0.33)
40	3.4 (0.32)	4.2 (0.35)
42	3.4 (0.40)	4.2 (0.42)
44	4.2 (0.60)	5.0 (0.61)
46	3.7 (0.66)	4.6 (0.67)
48	3.8 (0.61)	4.4 (0.65)
50	3.2 (0.48)	3.6 (0.49)
52	2.6 (0.60)	3.1 (0.64)
≥ 54	5.2 (1.88)	5.5 (1.88)

SE = standard error.

Key Words: early mortality, liveability, turkeys

600 Development of an inflammation model for use in the commercial duck. P. Cotter*[1], T. Applegate[2], R. Murdoch[3], K. Daugherty[3], and M. Turk[3], [1]*Cotter Laboratory*, *Arlington, MA,* [2]*Purdue University*, *West Lafayette, IN,* [3]*Maple Leaf Farms*, *Milford, IN*.

The response to injection with *E. coli* LPS was tested as a means to assess the effects of inflammation on performance of young commercial ducks. Inflammation was measured by temperature changes, feed consumption, and body weight. Natural antibody titer and complement activity were used as immunity measures. It was determined by a preliminary trial that of 3 doses (n = 4 per dose) of LPS, 0.1, 1, and 5 mg/kg BW only the high dose (5 mg/Kg) resulted in fever (+ 1 C increase in cloacal temperature). A second trial using 6 ducks at each of 4 injection treatments: none, non-pyrogenic saline, 5 mg LPS, and *Riemerella anatipestifer* bacterin (RAB) given on day of age 21 and 23 was conducted. Pre-injection measurements obtained at d 18 compared with post injection measurements through d 25 indicated that both LPS and RAB were associated with reduced feed intake ($P = 0.008$), reduced BW gain: 0.73Kg (LPS) 0.86Kg (RAB) 0.95Kg (no inj.) 1Kg (saline)($P = 0.06$); but only LPS caused fever ($P = 0.001$). Immunity was measured by comparing natural (anti-rabbit erythrocyte) agglutinins and lysins. Four parameters: HA1, HA2 (agglutination), L100, L50 (lysis) assessed agglutination and complement activity in serum at d 25. As C′ activity was anticipated to be an important component of the inflammatory response serum diluents were (PBS) supplemented with Ca, Mg, or both. HA1 (IgM type) agglutination (log 2 titer) was not affected by injection treatments but HA2 (IgG type) agglutination was lower in LPS (7.0) and saline (7.7) (vs. 8.4 no injection, and 9.7 RAB injection treatments) when assessed with Ca or Mg supplemented PBS ($P < 0.02$) but not when assessed with un-supplemented PBS. More C′ activity was detected using diluents supplemented with both Ca and Mg than with either alone. Ca supplemented lysis of rabbit cells (L50) was lowered by RAB injection more than by LPS ($P < 0.002$). This duck inflammation model appears useful and might have application in testing the effectiveness of dietary products designed to modulate immunity in this species.

Key Words: ducks, inflammation, LPS

601 Comparison of water-based foam and inert gas mass emergency depopulation methods of turkeys. M. K. Rankin*, E. R. Benson, R. L. Alphin, D. P. Hougentogler, and P. Mohankumar, *University of Delaware*, *Newark*.

Current control strategies for avian influenza (AI) and other highly contagious poultry diseases include surveillance, quarantine, depopulation, disposal, and decontamination. Selection of the best method of emergency mass depopulation needs to maximize human health and safety while minimizing disease spread and animal welfare concerns. The method used must be compatible with species, age, housing type, and disposal options. Research has shown differences in gassing and foam depopulation procedures when comparing time to and consistency of time to brain death. Unconsciousness precedes terminal convulsions. The objective of this study was to compare the time to death and other physiological markers for water based foam and CO_2 gas depopulation methods. An experiment was conducted individually comparing the use of water based foam and CO_2 gas for depopulation of turkeys. The time to death of the birds was evaluated using electroencephalogram (EEG), electrocardiogram (ECG) and motion cessation. Each bird was instrumented with a surgically implanted EEG transmitter and an external accelerometer and ECG pads. Eighteen turkeys, aged 14–26 weeks, were individually depopulated per treatment. The EEG results showed that foam caused more rapid brain death (mean of 190 s (foam) versus

a mean of 242 s (CO_2 gas)) and the differences were statistically significant. Although ECG results showed that foam caused more rapid cardiac suppression (200 s (foam) versus 220 s (CO_2 gas)), the differences were not statistically significant. Onset of terminal convulsions occurred at similar times (166 s (foam) and (174 s (CO_2 gas)) for both treatments. Additional analysis of brain activity before and during treatment was also conducted. The use of water based foam depopulation results in more rapid brain death than available gassing procedures, reducing the time that the bird is conscious and aware during depopulation.

Key Words: foam, depopulation, EEG

ASAS-ADSA Cell Biology Symposium: Receptors and Signaling

602 The GnRHR: GPCR trafficking in health and disease. P. M. Conn*[1,2] and J. A. Janovick[1,2], [1]*Oregon Health and Science University*, *Portland,* [2]*Oregon National Primate Research Center*, *Beaverton*.

The GnRH receptor (GnRHR) is a heptahelical G protein coupled receptor (GPCR) found in gonadotrope cell plasma membrane. GnRHR mutants from patients with hypogonadotropic hypogonadism are frequently misfolded and mislocalized proteins, retained in the ER by the cell's quality control system (QCS). The vast majority of these mutants (16 of the 19 point mutations reported from patients) can be restored to function by peptidomimetic antagonists, acting as pharmacological chaperones or "pharmacoperones." Pharmacoperones are a newly appreciated class of drugs, made up of small, target-specific molecules that diffuse into cells and serve as folding templates to cause otherwise misfolded proteins to fold in a manner that is acceptable to the QCS. Accordingly, these drugs rescue misfolded proteins, restore them to the correct location in the cell and allow normal function.It has become obvious that many protein mutants retain or regain their fundamental properties as ion channels, enzymes or receptors when re-routed correctly and so, the use of pharmacoperones has general application. Among the diseases caused by misfolding (which may benefit from this approach) include cystic fibrosis, hypogonadotropic hypogonadism, nephrogenic diabetes insipidus, retinitis pigmentosa, hypercholesterolemia, cataracts, neurodegenerative diseases (Huntington's, Alzheimer's and Parkinson's), cancers and digestive disorders. It is fair to say that virtually every person will be affected by protein folding diseases during his or her lifetime, either directly or due to the illness of a loved one. This presentation will provide an overview of the GnRHR, emphasizing its role as a model for protein folding and mutant rescue. Among the topics that appear to have general application are the interaction and molecular mechanism of action of pharmacoperones, the "dominant negative" effect, whereby oligomerizing GnRHR (WT and mutants) cause the retention of WT-mutant hetero-aggregates because the oligomer is recognized as misfolded and the mechanism by which the cells protects itself against constitutively active mutants.

Key Words: g-protein coupled receptors, protein trafficking, pharmacoperone

603 Function and regulation of the toll-like receptor family. G. M. Barton*, *University of California, Berkeley*.

The toll-like receptors (TLRs) are a family of innate immune receptors that have evolved to recognize conserved features of microbes. These receptors link the recognition of invading microbes to induction of innate and adaptive immune. Accordingly, TLRs have been implicated in immunity to many pathogens. Inappropriate activation of these receptors can also lead to autoinflammatory or autoimmune disorders. Our group has been studying the regulatory pathways responsible for maintaining the balance between immunity and tolerance. In this presentation I will provide an overview of TLRs and will highlight our recent work on the regulation of these receptors in immunity and autoimmunity.

Key Words: toll-like receptors, innate immunity, autoimmunity

604 Insulin signaling is a modulator of muscle growth. T. A. Davis*, A. Suryawan, R. A. Orellana, and M. L. Fiorotto, *USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

The growth rate of skeletal muscle during the neonatal period is higher than at any other stage of postnatal development and is driven by an elevated rate of protein synthesis. The high rate of muscle protein synthesis in neonatal mammals is in part due to a marked stimulation of protein synthesis after feeding. This response to feeding is, in part, due to an enhanced sensitivity to the postprandial rise in insulin. The effect of insulin on protein synthesis is most pronounced in skeletal muscle. The decline with age in the response of muscle protein synthesis to insulin parallels the developmental decline in the rate of muscle protein synthesis. The high rate of protein synthesis in neonatal muscle is in part due to an enhanced activation of the insulin signaling pathway. Thus, the postprandial rise in insulin activates in muscle the insulin receptor, insulin receptor substrate 1/2, phosphatidylinositol 3-kinase, phosphoinositide-dependent kinase 1, protein kinase B, mammalian target of rapamycin, ribosomal protein S6 kinase-1, eukaryotic initiation factor (eIF) 4E-binding protein 1, and eIF4E associated with eIF4G and these responses decrease with development. The reduced activation of negative regulators of insulin signaling also contributes to the high rate of neonatal muscle protein synthesis. These include protein tyrosine phosphatase 1B, phosphatase and tensin homolog deleted on chromosome 10, protein phosphatase 2A, tuberous sclerosis 2, and proline-rich Akt/PKB substrate 40 kDa. These studies demonstrate that the high rate of protein synthesis and rapid gain in skeletal muscle mass in neonatal pigs are in part modulated by changes in the activation of components in the insulin signaling pathway.

Key Words: muscle, protein synthesis, insulin

605 Imaging the organization and trafficking of lipolytic proteins in adipocytes. J. G. Granneman*, *Wayne State University School of Medicine*, *Detroit, MI*.

Growing evidence indicates that hormone-stimulated lipolysis involves protein kinase A (PKA)-regulated protein trafficking at the surface of lipid droplets and that perilipin A (Plin), a lipid droplet scaffold protein, plays an essential role. We investigated mechanisms whereby Plin regulates hormone stimulated lipolysis with a panel of fluorescently-tagged proteins and novel protein-protein interaction assays that allow monitoring of dynamic interactions in live cells. Our data show that Plin regulates lipolysis by direct and indirect means. First, Plin directly regulates HSL activity by providing a docking site for phosphorylated HSL to bind and gain access to triglyceride substrate. Second, Plin indirectly regulates the activity of adipose triglyceride lipase (Atgl) by controlling the availability of its coactivator, Abhd5, in a manner that requires Plin phosphorylation. Our results demonstrate that Plin binds Abhd5 in the basal state which greatly inhibits Abhd5/Atgl interactions and reduces basal lipolysis. PKA activation leads to rapid release of Abhd5 from Plin. We identify the PKA phosphorylation sites on Plin that are necessary both for releasing Abhd5 from Plin and promoting its interaction with Atgl. Finally, we show that the PKA-dependent interaction of Abhd5 and Atgl occurs mainly on lipid droplets containing Plin.

Key Words: lipolysis, perilipin, adipocytes

Bioethics Symposium: Should Animal Welfare be Law or Market Driven?

606 Bioethics symposium introduction: Should animal welfare be law or market driven? C. C. Croney*, *The Ohio State University*, *Columbus*.

In recent years, concern about the welfare of food producing animals has provided the impetus for greater regulation of US animal production practices and policies. Annual polls conducted within the United States indicate strong and consistent public support for such regulation. Intensive confinement of animals, relief of animal pain, humane handling of animals and timely and appropriate euthanasia remain high on the list of concerns articulated by consumers, animal activists, scientists and other key stakeholders. Consequently, the rate of passage of state legislation of farm animal production has escalated. Concurrently, most food retailers have adopted some form of animal welfare assurance scheme and audit program to meet consumer expectations relative to animal welfare. Despite these efforts, frequent undercover exposés depicting treatment of farm animals that is socially unacceptable or questionable, and occasionally, clearly abusive suggest some need for greater regulation. However, hastily regulating farm animal welfare may have unforeseen consequences, including negative implications for animal producers, food prices, concerned citizens and the animals themselves, and these should also be considered. All of this suggests the need for thoughtful debate about whether protection of farm animal welfare in the US should be legislated, voluntarily regulated by the animal industries, or driven simply by market demands.

Key Words: ethics, regulation, animal production

607 Should we legislate farm animal welfare? J. C. Swanson*, *Michigan State University*, *East Lansing*.

In the last 5 years successful state citizen initiatives and legislation has created a patchwork of farm animal welfare regulation across the United States. Consequently, some states have responded with defensive measures such as creating state livestock care boards or advisory councils charged with promulgating standards for the care of livestock and poultry within the state. Although recent citizen initiatives and state bills begin with similar themes, during the legislative process deals are struck and the enacted laws often differ. Implementation periods, minimum space requirements, and noncompliance penalties are negotiated areas that create subtle yet important differences. Similar issues could erupt between state livestock care boards. As more states opt to regulate, it will eventually force a discussion about the federal regulation of farm animal care. This presentation will explore whether farm animal welfare ought to be legislated.

Key Words: animal welfare, legislation, regulation

608 Impact of slaughter bans on horse welfare. D. L. Gies*, *Animal Assistance Foundation*, *Denver, CO*.

This session will provide attendees with an historical perspective of horse slaughter in the United States and the effects of slaughterhouse closures on horse welfare from both a scientific and non-scientific perspective. It will provide up-to-date information on the status and detail of the competing horse slaughter legislation and will discuss the ongoing efforts of the horse community to measure horse welfare. Many animal and horse welfare organizations have raised concerns for years about the slaughter of horses for human consumption. Specifically, groups stated that the horse slaughter process was inhumane, that horses should not be processed for human consumption and that horses should not be slaughtered in the U.S. for export. In 2007, the three equine slaughter plants operating in the U.S., located in Illinois and Texas, closed following state legislation that banned the slaughter of horses for human consumption. In their final year of operation, these plants processed 102,260 horses. Since 2007, questions have been raised about whether the closure of the slaughter plants has in fact improved horse welfare. In 2009, there were an estimated 170,000 unwanted horses. Approximately 100,000 of these horses were exported to Mexico or Canada for slaughter in plants not regulated by USDA inspectors.
Currently there is no federal legislation banning domestic horse slaughter for human consumption. However, USDA inspectors are prohibited from inspecting horse meat slaughtered in U.S. plants for human consumption, effectively barring horse slaughter plants from operating. As a result, a national debate regarding horse slaughter continues. The proposed Prevention of Equine Cruelty Act seeks to ban horse slaughter in the U.S. and the export of horses for slaughter. A competing bill, the proposed Humane and Optimal Restoration and Sustainability of Equines Act (HORSE), seeks to reopen slaughter plants within the U.S. by removing the regulatory roadblocks to USDA inspection of horse meat.

Key Words: horse, slaughter, welfare

609 Should animal welfare be law or market based? B. Rollin*, *Colorado State University*, *Fort Collins*.

Between 1976 and 1985, a group of people at Colorado State University engaged the task of writing federal animal welfare legislation for research animals. Between us we had over 50 years of experience in animal research. We were particularly concerned about the lack of knowledge of analgesia and pain control in research. Not only was there virtually no use of pain management in invasive research protocols, there was not even literature on the subject. Yet the knowledge existed in the research community that the failure to control pain and distress skewed key variables being studied. In other words, pain control should have been a matter of rational self-interest, assuring that one's results in experimentation were as accurate as they could be. Even self-interest could not override widespread ideological agnosticism about animal pain and consciousness rife in the scientific community, nor could it override ignoring ethical questions occasion by animal research. When we did successfully legislate pain control for research animals in 1985, both knowledge and use of analgesia in research proliferated. From a total absence of papers on pain control in animals in 1982, there now exists an estimated 10,000 such papers. In other words, legislation was essential to incorporating into animal research what should have been ethically presuppositional to its activities. If self-interest did not lead researchers to control pain, it is clear that market options would have done so. Fulfilling one's ethical obligation attendant upon using animals for human benefit should not be a matter of choice of the sort that market options provide. The animal agricultural industry knows full well that the public often chooses the cheaper product even when expressing a commitment to animal welfare or environment friendly products. This does not prove the weakness of these commitments, it rather shows what ancient Stoic philosophers call akrasia, or weakness of the will. That is why repeated polls have demonstrated that fully 75% wish to see farm animal welfare encoded in legislation. Honoring basic moral obligations should not be left to market choices, but should be presuppositional to such choices.

Key Words: pain, research animal law, market

610 Should euthanasia and pain management be mandatory? Veterinary viewpoint. G. C. Golab*, *American Veterinary Medical Association*, *Schaumburg, IL*.

The AVMA believes animal pain and suffering are clinically important conditions adversely affecting quality of life, and encourages veterinarians to make every attempt to prevent and alleviate pain in animals. Because animals vary considerably in their response to stimuli, preventive and therapeutic strategies for managing pain must be tailored to individuals. Pain management protocols must be flexible and allow professional judgment in their application.
Considerations in managing pain include species, type/breed, age, procedure performed, extent of tissue trauma, behaviors, degree of pain, health status, and availability of techniques and pharmaceuticals. Pharmacologic and nonpharmacologic approaches should be considered. Pharmacologic approaches include appropriate selection and use of sedatives/tranquilizers, anesthetics, and analgesics. Consideration should be given to multimodal approaches, as these may improve analgesia, allow reductions in dose of drugs, and minimize adverse effects. Nonpharmacologic approaches include nutritional support, good husbandry practices, and positive owner interactions. It may not be possible (or desirable) to completely avoid or eliminate pain in animals. In such cases, veterinarians should pursue strategies that improve an animal's ability to cope with pain, allow the animal to engage in as many normal activities as possible (e.g., eating, sleeping, ambulating, socializing with conspecifics and/or people), and avoid suffering. When suffering cannot be avoided, and resolution of the condition leading to suffering is unlikely, euthanasia should be considered. Delaying euthanasia, when euthanasia is the appropriate choice, is unacceptable in terms of risks to animal well being and human ethical responsibilities. Euthanasia is the act of inducing humane death. Veterinarians have a responsibility to ensure that if an animal′s life is taken, it is done with the greatest degree of respect and with an emphasis on making its death as pain- and distress-free as possible. Euthanasia techniques should result in rapid loss of consciousness, followed by cardiac or respiratory arrest and the ultimate loss of brain function.

Key Words: pain management, euthanasia

611 Consumer preferences for market and regulatory responses to farm animal welfare concerns. F. B. Norwood* and J. L. Lusk, *Oklahoma State University*, *Stillwater*.

Consumers can pursue changes in how farm animals are raised by purchasing products differentiated by the level of animal welfare provided, or by seeking regulations forcing farmers to adopt certain production practices. The desirability of market or regulatory responses depends on the extent to which animal welfare is considered a private or public good. The greater extent to which people care about the animals producing other peoples' food, the more animal welfare resembles a public instead of a private good. Consumer experiments were conducted to measure the private and public good component of livestock welfare. Over 300 individuals from 3 cities were educated about the farm animal welfare issue, and were presented with 4 different systems for producing pork and eggs. These individuals then submitted bids in a real auction to measure the extent to which they will pay premiums for animal-friendly pork and eggs. The auctions were specifically designed to measure welfare concerns for the animals producing their personal food and the animals producing other peoples' food. The results suggest that approximately one-third of Americans do not value welfare improvements, many consumers posses a relatively high value on the private good component of animal welfare, but that the public good component for the average American is small. The results suggest markets may address animal welfare concerns better than regulations.

Key Words: consumer experiments, consumer preferences, farm animal welfare

612 Utility of genomic relationship matrix to identify genotyping errors. R. Simeone*[1], I. Misztal[1], and I. Aguilar[1,2], [1]*University of Georgia*, *Athens*, [2]*INIA*, *Las Brujas, Uruguay*.

The purpose of this study was to use the genomic relationship matrix (G) as an indicator of genotyping or other analysis problems in a single-step genomic evaluation procedure. Data was obtained from Cobb-Vantress and consisted of body weights for 183,784 broiler chickens over 3 generations with pedigrees on 186,222 animals. Of these animals 3,284 were genotyped for 57,636 SNP. Loci with no variation or minor allele frequency <0.02 were removed from the data, leaving 48,006 loci for analysis. Construction of G used current allele frequencies. Theoretically, the mean of the diagonal elements in both relationship matrices should be the same. The mean of the diagonal elements of G was 1.03 ± 0.16, however, the distribution of these elements showed 3 peaks: 3,195 in the range from 0.54 to 1.19, 88 in the range from 1.73 to 2.09, and one with a value of 3.12. Animals with a diagonal element >1.2 were assumed to have abnormal genotypes. Genetic predictions were computed by a single-step procedure (SSP) that combined phenotypic, pedigree and genomic information. This procedure was applied with all genotypes or with abnormal genotypes removed and with all phenotypes or only with phenotypes of genotyped animals. Accuracies were computed by dividing the predictive ability by the square root of heritability. Removing genotypes causing abnormal diagonals increased the accuracy from 0.648 to 0.657 when all phenotypes were used and from 0.584 to 0.586 when only phenotypes of genotyped animals were used. The difference between predictions obtained with and without the abnormal genotypes was distributed close to normal but with longer tails. Analysis of diagonals in G may serve as a diagnostic tool to identify erroneous genotypes. Very large diagonals suggest an analysis problem; explanations may be presence of animals of another breed, allele frequency shifts or a genotyping error. Removing suspected genotypes is likely to improve accuracy of genetic evaluation, especially for animals with suspected genotypes or their progenies.

Key Words: genomic relationship, genotyping error, single-step procedure

613 Genetic evaluation including phenotypic, full pedigree, and genomic information: An application in broiler chickens. C. Y. Chen*[1], I. Misztal[1], I. Aguilar[1,2], S. Tsuruta[1], T. H. E. Meuwissen[3], S. E. Aggrey[4], and W. M. Muir[5], [1]*Department of Animal and Dairy Science, University of Georgia*, *Athens,* [2]*Instituto Nacional de Investigación Agropecuaria*, *Las Brujas 90200, Uruguay*, [3]*Department of Animal and Aquacultural Sciences, Norwegian University of Life Sciences*, *NO-1432 As, Norway*, [4]*Department of Poultry Science, University of Georgia*, *Athens,* [5]*Department of Animal Science, Purdue University*, *West Lafayette, IN*.

A complete phenotypic data set (FULL) consisted of 183,784 and 164,246 broilers for 2 lines across 3 generations. Genotyped subset (SUB) consisted of 3,284 and 3,098 broilers in lines 1 and 2 with 57,636 SNP available. Traits were body weight at 6 weeks (BW), ultrasound (US), and binary leg defect score (LEG). Some records were missing for US. Heritability with FULL were 0.17–0.20 for BW, 0.30–0.35 for US, and 0.09–0.11 for LEG. Genetic evaluation was performed by regular BLUP, by a single-step procedure (SSP) that combined relationships based on pedigree and the SNP data, and by Bayes A procedure. While BLUP and SSP could use the complete data set, Bayes A could use only the genotyped subset. Genotyped animals in generation 3 were treated as validation population. The average accuracies of the validation population with BLUP for BW, US, and LEG were 0.46, 0.30, and < 0 with SUB and 0.51, 0.34, and 0.28 with FULL. With SSP, those accuracies were 0.60, 0.34, and 0.06 with SUB and 0.61, 0.40, and 0.37 with FULL, respectively. Accuracies with BayesA were similar to SSP with SUB. Accuracies in lines 1 and 2 were similar for US but different for BW and LEG. For traits with high heritability, the accuracy of the evaluation using the genomic information and only records of genotyped animals may be higher than that using the complete data and BLUP. The opposite is likely for traits with lower heritability, many missing records, or undergoing pre-selection. An optimal genomic evaluation would be multi-trait and would involve all traits and records on which the selection is based.

Key Words: chicken, genetic evaluation, genomic prediction

614 Scaling the genomic relationship matrix for single-step evaluation using phenotypic, pedigree and genomic information. S. Forni*[1,2], I. Aguilar[3,2], I. Misztal[2], and N. Deeb[1], [1]*PIC/Genus Plc*, *Hendersonville, TN,* [2]*University of Georgia*, *Athens,* [3]*INIA*, *Las Brujas, Uruguay*.

Data included litter sizes for 338,346 PIC sows, of which 1,919 had genotypes using the porcine 60k SNP chip. Genotypes were also available for 70 sires. Analyses involved a complete data set or a subset of genotyped animals and their parents (n = 5,090). A genomic relationship matrix was constructed using equal (G05) or observed gene frequencies (GOB). Additional relationship matrices were the pedigree-based relationship matrix (A) and a combined pedigree-genomic matrix (H). For genotyped animals, the mean of diagonal elements in A (G05, GOB) was 1.00 (1.25, 0.94). The mean of off-diagonal elements was 0.03 (0.59, 0.00). A normalized matrix (GN) was obtained by multiplying GOB by a constant to achieve an average diagonal of 1. Using A and the complete data set, the estimate of the additive variance was 1.26(±0.03). With H that included G05, GOB or GN the additive variance estimates were 1.28(±0.03), 1.28(±0.03) and 1.27(±0.03), respectively. Using A and the subset of the data, the estimate of the additive variance was 2.28(±0.52). With H that included G05, GOB or GN the additive variance estimates were 3.43(±0.56), 2.42(±0.39) and 2.25(±0.36), respectively. Accuracies for the complete data set were estimated by inversion. The average accuracy for genotyped animals using A, G05, GOB and GN were 0.23, 0.38, 0.31, and 0.30, respectively. When the genomic relationship matrix has a different scale than the pedigree-based matrix, the estimates of the additive variance may be biased especially for small data sets. Also, estimates of the accuracies of evaluation obtained by inversion may be inflated. One solution to normalize the genomic relationship matrix is by using realized gene frequencies and scaling this matrix to obtain an average diagonal close to 1.

615 Accuracies of direct genomic breeding values estimated in dairy cattle with a principal component approach. N. P. P. Macciotta*[1], M. A. Pintus[1], R. Steri[1], C. Pieramati[2], E. L. Nicolazzi[3], E. Santus[4], D. Vicario[5], J. T. van Kaam[6], A. Nardone[7], A. Valentini[7], and P. Ajmone-Marsan[3], [1]*Università di Sassari*, *Sassari, Italia*, [2]*Università di Perugia*, *Perugia, Italia*, [3]*Università di Piacenza*, *Piacenza, Italia*, [4]*ANARB*, *Bussolengo, Italia*, [5]*ANAPRI*, *Udine, Italia*, [6]*ANAFI*, *Cremona, Italia*, [7]*Università della Tuscia*, *Viterbo, Italia*.

A severe risk of overfitting due to the huge asymmetry between number of markers and phenotypes usually represents the main constraint for the implementation of genomic selection in livestock species. In the present work, the number of predictors for calculating direct genomic breeding values (DGV) is reduced by using principal component (PC) analysis. Sires of 3 dairy cattle breeds farmed in Italy were genotyped with the 54K Illumina beadchip: 863 Holstein (H), 749 Brown (B), and 479 Simmental (S). SNPs retained after edits were 40,658, 37,254, and 40,179 and the number of PC extracted 2,564, 2,257, and 2,476 for H, B, and S respectively. Effect of PC on polygenic EBV was estimated in the reference population with a BLUP model. Traits considered were milk yield, protein percentage, udder score and economic index. To create reference and validation population, bulls were tagged either by birth year or randomly. Accuracies were calculated as correlation between DGV and polygenic EBV in validation bulls. High DGV accuracies are obtained with reference animals selected at random (Table 1). When older animals are used to predict younger bulls, DGV accuracy drops dramatically for milk yield, especially for B and H, while it remains almost unchanged for udder score, protein percentage in B and milk yield in S.

Table 1.

	Random			By Year		
Trait	Holstein	Brown	Simmental	Holstein	Brown	Simmental
Milk yield	0.62	0.82	0.72	0.21	0.18	0.46
Protein percentage	0.52	0.58	0.32	0.37	0.54	0.36
Udder score	0.63	0.64	0.58	0.61	0.52	0.46
Economic index	0.67	0.84	0.64	0.44	0.33	0.28

Key Words: genomic selection, principal components, dairy cattle

616 Choice of parameters for single-step genomic evaluation for type. I. Misztal*[1], I. Aguilar[1,2], A. Legarra[3], and T. J. Lawlor[4], [1]*University of Georgia, Athens,* [2]*INIA, Las Brujas, Uruguay*, [3]*INRA, Toulouse, France*, [4]*Holstein Association, Brattleboro, VT.*

In a single step procedure, the pedigree-based matrix A is replaced by a matrix H that blends pedigree and genomic relationships. The inverse of matrix H involves an expression $G^{-1} - A_{22}^{-1}$, where G is a genomic relationship matrix and A_{22} is a pedigree relationship matrix for genotyped animals. Two modifications to that expression: $(\alpha\, G + \beta\, A_{22})^{-1} - A_{22}^{-1}$ and $\tau\,(0.95\, G + 0.05\, A_{22}^{-1} - \omega\, A_{22}^{-1}$ were investigated with regard to accuracy and scale of genomic predictions. While the first is equivalent to assuming a genomic and polygenic effect for genotyped animals, the second is equivalent to assuming a double prior for the additive effect. Data included final scores recorded from 1955 to 2009 for 6.2 million Holsteins, pedigrees for 10.5 million animals, and SNP50 genotypes for 6,508 bulls. Analyses used a repeatability animal model. Comparisons involved R^2 and regression coefficients (REG) based on 2004 predictions of young bulls and their 2009 daughter deviations. REG below 1.0 indicate inflation of genomic predictions. The initial expression yielded $R^2 = 0.41$ and REG = 0.75. With the first modification, varying α from 0.6 to 1.2 decreased R^2 less than 0.01 and decreased REG from 0.81 to 0.71. Increasing β from 0 to 0.6 decreased the R^2 and REG by 0.02 or less. With the second modification, varying τ from 0.6 to 1.5 increased R^2 by about 0.02 and increased REG by 0.02 ($\omega = 0$) to 0.15 ($\omega = 1.0$). Decreasing ω from 1.0 to 0 decreased the R^2 by 0.03 and increased REG from 0.2 ($\tau = 1$) to 0.3 ($\tau = 0$). Parameters $\tau = 1.5$ and $\omega = 0.4$ yielded $R^2 = 0.40$ and REG = 1.0. While the scale of G (parameters α and τ) has a small effect on R^2 and REG, matrix G as used here is about 50% too large. The scale of A_{22}^{-1} (parameter ω), which is associated with parental index based on genotyped bulls, has a large impact on inflation of genomic predictions.

Key Words: genomic relationships, single-step evaluation, inflation

617 Improved reliability approximation for genomic evaluations in the United States. G. R. Wiggans* and P. M. VanRaden, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

For genomic evaluations, the time required to calculate the inverse of the coefficient matrix for the mixed-model equations increases cubically as the number of genotyped animals increases, and an approximation became necessary for estimating US evaluation reliabilities. The original approximation method used the same contribution to reliability from genomics for all animals. That method was improved by using a weighted sum of the genomic relationships of an animal with predictor animals (ΣG_W), which allowed for individual animal differences. Because calculation time for the genomic relationship matrix only increases quadratically and is routinely available, the sum of relationships of an animal with predictor animals can be obtained. Those relationships were weighted by reliability of the traditional evaluation after removing the contribution to reliability from parent average by first converting both reliabilities to daughter equivalents (DE). Reliabilities from August 2009, the last genomic evaluation for which the coefficient matrix was inverted, were decomposed to extract the genomic contribution in terms of DE calculated with an error-to-sire variance ratio of 14. Of 28,047 genotyped Holsteins, 8,353 bulls and 3,559 cows had genomic evaluations and 16,135 animals did not. Regression of DE on ΣG_W was calculated for those 3 groups. Goodness of fit was assessed by plotting predicted values against mean DE for ΣG_W groups, where groups were by 10. A straight line through the origin provided a good fit except for low ΣG_W. A floor of 30 DE was adopted to improve evaluation accuracy for animals with low ΣG_W. The slope was 0.0584 for evaluated bulls, 0.0557 for evaluated cows, and 0.0506 for animals without evaluations. The higher slope for bulls resulted in a higher reliability for the same ΣG_W. The improved approximation method increased accuracy of genomic reliabilities, particularly when comparing animals with different countries of origin and bulls with only genomic evaluations with progeny-test bulls.

Key Words: reliability, genomic evaluation, genomic relationships

618 Cow adjustments for genomic predictions of Holstein and Jersey bulls. G. R. Wiggans, T. A. Cooper*, and P. M. VanRaden, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

Genomic evaluations are calculated by using values that have been deregressed from traditional PTAs estimating single nucleotide polymorphism (SNP) effects. Previous research indicates that including cow genomic data to calculate SNP effects does not increase reliabilities of genomic evaluations of yield traits. Upward bias in traditional PTA of genotyped cows may be the reason for this. The direct genomic value (DGV) is the sum of an animal's SNP effects. It should be consistent with traditional PTA and is for bulls. For cows, however, the traditional PTA is higher. To make the cow PTA more like those of the bulls for the yield traits (milk, fat and protein), mean and variance adjustments were calculated. Evaluations were stratified by reliability so cow PTA could be adjusted to be similar to bulls with the same reliability. The variance adjustment was the SD of deregressed Mendelian sampling within reliability group for bulls divided by the value for cows. The mean adjustment is the difference between bull and cow evaluations

after variance adjustment. Deregressed Mendelian sampling values were adjusted, and then the deregression was reversed to obtain the corrected PTA. To determine gains in reliabilities, predictions were made for bulls with current evaluations that did not have evaluations in August 2006. The predicted values were compared with the bull's actual evaluation from January 2010. For Holstein bulls, predictions using cows' adjusted data were 2.5, 2.8 and 2.1 points higher than those from data without adjustment for milk, fat and protein respectively. Jersey bulls also benefit from cow adjustments with an increase in gains in reliability over parent average of 3.9 points for milk, 5.6 points for fat and 3.5 points for protein. Brown Swiss adjustments could not be evaluated due to low numbers of genotyped cows. Genomic evaluations for Holsteins and Jerseys will be more accurate by better using the information from cows.

Key Words: genomics, prediction, evaluation

619 Investigating bull dam bias in national genetic evaluations. F. Canavesi* and R. Finocchiaro, *Associazione Nazionale Allevatori Frisona Italiana*, *Cremona, Italy*.

Parent averages (PA) are used in combination with direct genomic values to predict genomic breeding values (GEBV). Studies conducted in Germany (2009) showed that classic PA making use of sire and dam EBV deviates from expected contribution to the EBV of sons. This is due to overestimation of bull dams for production traits if compared with a trait like somatic cell score where selection and commercial interests play a minor role. The objective of this study was to investigate the relationship between PAs and realized EBVs in the Italian genetic evaluation system for progeny test bulls. A total of around 800 EBV of bulls born between 2001 and 2003 were used to analyze the relationship between their EBV in January 2010 and their PA in 2004 for production, conformation and somatic cells traits. Regression coefficients of sire and dam, EBV used to predict realized 2010 EBV were examined. Results show that both production and conformation traits deviates from expected values while somatic cell count are close to expected contribution of 0.50 for both EBVs of sire and dam respectively. In agreement with the German study the use of male pedigree information resulted in values close to expected and therefore would be the preferred choice in the prediction of GEBV.

Key Words: parent average, future predictions, bulldam bias

620 Gains in reliability from combining subsets of 500, 5,000, 50,000 or 500,000 genetic markers. P. M. VanRaden and M. E. Tooker*, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

More genetic markers can increase both reliability and cost of genomic selection. Fewer markers can be used to trace chromosome segments within a population once identified by high-density haplotyping. Combinations of marker densities can improve reliability at lower cost. As of January 2010, 33,414 North American Holsteins had been genotyped for 50,000 genetic markers. Genotypes for 500,000 markers were simulated using pedigree data for this same population. Linkage was introduced among base alleles to make correlations among simulated genotypes similar to actual. Reduced subsets were examined using every 10th, 100th, or 1000th marker. In marker regression models, polygenic variance was 70, 30, 10, and 0% of genetic variance with 500, 5,000, 50,000 and 500,000 markers, respectively. Respective reliabilities obtained as squared correlations of estimated and true breeding values averaged across 5 replicates were 39.4, 70.2, 82.6, and 84.0% for 14,061 young bull predictions. At highest density, one processor required 2.5 d to complete 150 iterations for the 5 replicates. A mixed-density data set had 500,000 markers genotyped for 3,515 young bulls and 3,883 bulls with > 90% reliability and 50,000 markers genotyped for the remaining 26,016 animals. This data set had 70% missing genotypes; however, after imputing from haplotypes, only 4% of genotypes were missing, and average reliability was 83.1%. Two other mixed-density data sets had 50,000 markers for cows and progeny-tested bulls but only 5,000 or 500 markers for young animals. Reliabilities averaged 79.6% for young animals if 5,000 markers were genotyped and the other 45,000 imputed. At 500-marker density, inheritance probability was computed for each marker instead of simply assigning either parental haplotype; reliabilities averaged 70.3% when young animals were genotyped for 500 markers and both parents were genotyped for 50,000. Very high marker density can increase reliability slightly (1.4%), whereas low marker density allows breeders to apply cost-effective genomic selection to many more animals.

Key Words: reliability, marker density, genomic evaluation

621 Accuracy of direct genomic values derived from imputed single nucleotide polymorphism genotypes in Jersey cattle. K. A. Weigel*[1], G. de los Campos[1], A. I. Vazquez[1], G. J. M. Rosa[1], D. Gianola[1], and C. P. Van Tassell[2], [1]*University of Wisconsin*, *Madison,* [2]*USDA-ARS*, *Beltsville, MD*.

The objective of the present study was to evaluate the predictive ability of direct genomic values for economically important dairy traits when genotypes at some single nucleotide polymorphism (SNP) loci were imputed, rather than measured directly. Genotypic data consisted of 42,552 SNP genotypes for each of 1,762 Jersey sires. Phenotypic data consisted of predicted transmitting abilities (PTA) for milk yield, protein percentage, and daughter pregnancy rate from May 2006 for 1,446 sires in the training set and from April 2009 for 316 sires in the testing set. The SNP effects were estimated using the Bayesian least absolute selection and shrinkage operator (LASSO) with data of sires in the training set, and direct genomic values (DGV) for sires in the testing set were computed by multiplying these estimates by corresponding genotype dosages for sires in the testing set. The average correlation across traits between DGV (before progeny testing) and PTA (after progeny testing) for sires in the testing set was 70.6% when all 42,552 SNP genotypes were used. When genotypes for 93.1, 96.6, 98.3, or 99.1% of loci were masked and subsequently imputed, mean correlations between DGV and PTA were 68.5, 64.8, 54.8, or 43.5%, respectively. When genotypes were also masked and imputed for a random 50% of sires in the training set, mean correlations between DGV and PTA were 65.7, 63.2, 53.9, or 49.5%, respectively. Results of this study indicate that a low density chip comprised of 3,000 equally spaced SNPs can provide approximately 95% of the predictive ability observed with the BovineSNP50 Beadchip (Illumina, Inc., San Diego, CA), but if fewer than 1,500 SNP are genotyped the accuracy of DGV may be limited by errors in the imputed genotypes of selection candidates.

Key Words: genomics, imputation, Jersey

622 Filling in missing genotypes using haplotypes. P. M. VanRaden*[1], J. R. O'Connell[2], G. R. Wiggans[1], and K. A. Weigel[3], [1]*Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD,* [2]*University of Maryland School of Medicine*, *Baltimore,* [3]*University of Wisconsin*, *Madison*.

Unknown genotypes can be made known (imputed) from observed genotypes at the same or nearby loci of relatives using pedigree haplotyping, or from matching allele patterns (regardless of pedigree) using population haplotyping. Fortran program findhap.f90 was designed to

combine population and pedigree haplotyping. Each chromosome was divided into segments of about 100 markers each. Each genotype was matched to the list of currently known haplotypes sorted from most to least frequent for efficiency. If a match was found (no conflicting homozygote), any remaining unknown alleles in the found haplotype were imputed from homozygous genotypes. The individual's second haplotype was obtained by subtracting its first from its genotype, and the second was checked against remaining haplotypes. If no match was found, the new genotype (or haplotype) was added to the list. After completing population haplotyping, pedigrees were examined to resolve conflicts between parent and progeny haplotypes, locate crossovers that created new haplotypes, and impute haplotypes of nongenotyped ancestors from their genotyped descendants. One processor took 2 h to find haplotypes for 43,385 actual markers of 33,414 Holsteins. For the same population, time increased only to 2.5 h with 500,000 simulated markers but with 500 markers per segment. Computing time increased much less than linearly because most haplotypes were excluded as not matching after just the first few markers. Genotype storage required 13 GB for 500,000 markers, but haplotype storage required only 2.5 GB. Shared haplotypes were stored just once, and only index numbers were stored for individuals instead of full haplotypes. Paternal alleles were determined correctly for 95% of heterozygous markers, and linkage was determined correctly for 98% of adjacent pairs of heterozygous markers in simulated data. Population haplotyping correctly filled 95% of missing high density marker genotypes. Pedigree haplotyping can fill missing genotypes efficiently for nongenotyped ancestors or progeny with lower marker density.

Key Words: haplotyping, marker density, imputation

623 Use of haplotypes to predict selection limits and Mendelian sampling. J. B. Cole*, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

Limits to selection and Mendelian sampling terms can be calculated using haplotypes, which are sums of individual additive effects on a chromosome. Haplotypes were imputed for 43,385 actual markers of 3,765 Jerseys using the Fortran program findhap.f90, which combines population and pedigree haplotyping methods. Longer chromosomes had more distinct haplotypes, ranging from 7,287 for *Bos taurus* autosome 1 (BTA) to 2,460 for the X chromosome. This is expected because longer chromosomes undergo recombination more often than shorter ones. Mendelian sampling (MS) variances were calculated for genotyped animals as the sum of squared haplotype differences for each chromosome in the genome. The distribution of MS variances had a heavy right tail (skewness = 0.276), with a mean of 49,290 ± 13,981. Genotypes for each chromosome were constructed from pairwise combinations among the top 5% of haplotypes based on the sum of marker effects for lifetime net merit (NM) for each chromosome. Correlations among raw and adjusted values in the top group ranged from 0.897 on BTA12 to 0.998 on the X chromosome. Selection of the best unadjusted haplotypes for each chromosome results in an animal with an EBV of +$5,243 for NM. Adjusting for inbreeding resulted in a slightly lower EBV of +$4,496. Haplotype values were adjusted to account for changes in homozygosity by adding or subtracting 6% of an additive genetic standard deviation per 1% decrease or increase in homozygosity. The top Jersey bull, ALL LYNNS RESTORE VERNON-ET (29JE03647), had an EBV NM of +$1,180 in the January 2010 evaluation. For 11 chromosomes (BTA 4, 9, 13, 15, 20, 21, 22, 25, 26, 28, and X) the best genotype after adjusting for inbreeding consisted of 2 copies of the same haplotype. Differences between the best and poorest haplotypes ranged from a maximum of $65 for BTA1 to a minimum of $12 for BTAX. Selecting animals rather than chromosomes may result in slower progress, but limits may be the same because most chromosomes will become homozygous with either strategy. Selection on functions of MS could be used to change variances in later generations.

Key Words: genetic gain, haplotyping, mendelian sampling

Dairy Foods Symposium: Towards a Mechanistic Understanding of Probiotic Function in Man and Animals

624 Application of "omic" tools to understanding probiotic action. T. R. Klaenhammer*[1,2], [1]*North Carolina State University*, *Raleigh,* [2]*Southeast Dairy Foods Research Center*, *Raleigh, NC*.

Lactic acid bacteria are associated with various plant and animal niches and play a key role in the production of fermented dairy foods and beverages, with some species also exerting probiotic properties. As generally recognized as safe (GRAS) organisms, they have been orally ingested safely by humans over the centuries, often at levels exceeding 100 million per gram of food. Genome sequencing of ~30 LAB and probiotic species has revealed a path of evolution toward specialized habitats that are nutritionally rich. Comparative genomic analyses of lactobacilli occupying either food/dairy systems, or the intestinal tract (probiotic species), have identified both conserved and unique gene sets important for food/dairy fermentations, but recently have also identified key genes likely involved in functional roles that impact health. Functional genomic analyses using "omic" technologies have identified systems responsible for acid and bile tolerance, prebiotic utilization and revealed several cell surface proteins and structures on probiotic microbes that interact with host epithelial and immunomodulatory cells. Among these are lipoteichoic acids, surface layer proteins, and mucus binding proteins. Alteration of the cell surface display of such structures can dramatically alter dendritic cell binding and cytokine signaling and promote inflammatory or anti-inflammatory responses. Employing genomic tools for gene cloning, expression, and inactivation, the field is uniquely positioned to investigate mechanisms through which probiotic microbes interact with the intestinal mucosa, compete with pathogens and impact health.

Key Words: probiotic, lactic acid bacteria, genomics

625 The gastrointestinal microbiome and probiotics: Effects on intestinal physiology and mucosal inflammation. J. Versalovic*, *Baylor College of Medicine*, *Houston, TX*.

The human gastrointestinal microbiome is composed of many bacterial species that may affect signaling pathways in intestinal epithelial cells, stem cell compartments and mucosal immune cells. Differences in microbial composition may affect the intestinal mucosa in terms of effects on cell proliferation, apoptosis, antibody and cytokine production, and cell migration. Direct effects by microbial and probiotics-derived signals on specific mammalian cell signaling pathways may explain mechanisms of mucosal immunity. The gut microbiome may affect the biology of innate and adaptive immune responses in the gut mucosa. Specific components of the microbiome may have net anti-inflammatory or pro-inflammatory effects, and the relative balance of microbes may result in different patterns of mucosal inflammation. Differences in patterns of inflammation and immune responses to the gut microbiome and probiotics may determine, in part, differences in the risk of immune-mediated disorders and infections of the gastrointestinal tract.

626 An evolutionary link between bifidobacterial probiotics and milk. D. Mills*, *University of California*, *Davis*.

Bifidobacteria are commonly used as probiotics in dairy foods. Select bifidobacterial species are also early colonizers of the breast-fed infant colon, however the mechanism for this enrichment is unclear. We have previously shown that *Bifidobacterium longum* ssp. *infantis* is a prototypical bifidobacterial species that can readily utilize human milk oligosaccharides as a sole carbon source. Mass spectrometry-based glycoprofiling has revealed that numerous *B. infantis* strains preferentially consume small mass oligosaccharides, abundant in both human and bovine milks. Genome sequencing showed that *B. infantis* possesses a bias toward genes required to utilize mammalian-derived carbohydrates. Many of these genomic features encode enzymes that are active on milk oligosaccharides including a novel 40-kb region dedicated to oligosaccharide utilization. Biochemical and molecular characterization of the encoded glycosidases and transport proteins have further resolved the mechanism by which *B. infantis* selectively imports and catabolizes milk oligosaccharides. Expression studies indicate that many of these key functions are only induced during growth on milk oligosaccharides and not expressed during growth on other prebiotics. In addition, key cell surface oligosaccharide binding proteins in *B. infantis* bind both milk oligosaccharides and epithelial cell surface glycans. Moreover, growth on milk oligosaccharides results in significant increases in binding of *B. infantis* to intestinal cells in vitro. Additional sequencing of numerous *B. infantis* genomes has confirmed that these features are common among the *infantis* subspecies and likely constitute a competitive colonization strategy employed by these unique bifidobacteria. Through detailed characterization of the molecular mechanisms responsible for bifidobacterial enrichment in the gastrointestinal tract of breast fed infants, these studies provide a conceptual framework for enhancement of probiotic persistence and host-interaction through delivery in animal milks.

Key Words: probiotics, milk oligosaccharides, bifidobacteria

627 Assessing and maintaining probiotics in food. T. Hornbaek*, *Chr. Hansen A/S*, *Hoersholm, Denmark*.

Dairy products, and specifically yogurt-like products, form the largest segment by far in the market for probiotic foods. Dairy products are excellent vehicles for delivering useful probiotic bacteria such as Bifidobacteria and introducing them into the gastrointestinal tract. Increased consumer awareness of the health benefits of probiotics has led to numerous new probiotic product launches both in the market for fermented milk products as well as other food categories. In the development of new probiotic food products, there are several factors to consider including: 1) the documentation of the probiotic strain; 2) the ability to produce the probiotic strain in large scale; and 3) successful application in the food product. This presentation will focus on the last aspect: how to obtain successful probiotic food applications. Challenges with respect to sensory impact and survival of probiotics in different food applications will be discussed. Recent work will be presented to illustrate various ways of increasing probiotic cell counts and stability in dairy as well as non-dairy applications. Ways to circumvent the lack of important nutrients and the potential negative effect of different processing conditions will be discussed, also in relation to the use of adjunct cultures.

Without having bio-markers related to probiotic effects, the best way to ensure the probiotic properties of a food product is by measuring probiotic cell counts throughout shelf life. Our newest findings will be presented on the correlation between traditional plate counting methods and novel probiotic cell count methods such as qPCR and flow cytometry. Furthermore, a dynamic, multi-compartmental model system will be presented which provides the ability to estimate survival rates of probiotics delivered in different food vehicles on their way through the stomach and small intestine.

Key Words: probiotic, food, survival

628 Translating the science into efficacy claims on probiotic or prebiotic products in the US market. M. E. Sanders*, *Dairy & Food Culture Technologies*, *Centennial, CO*.

The US marketplace is home to an increasing number of food products labeled "probiotic" or "prebiotic." Although the scientific definitions of these terms are clear, they lack legal definition in the US. Responsible companies seek scientific substantiation for claims. Translating science into product claims starts with conducting research on endpoints that are compatible with the category of product. A product claiming to cure, treat, mitigate or prevent disease is a drug, not a food. Claims stating the effect of the product on the normal structure or function of the human body (structure/function claim), or on reducing the risk of a diet-related, chronic disease (health claim) are allowed for food. However, many studies comprising the body of research on probiotics and prebiotics would be considered drug studies by the FDA, and therefore would not be suitable as primary substantiation for a structure/function claim. Endpoints such as prevention of allergy, reducing the incidence of intestinal or respiratory infections among healthy children or managing symptoms of irritable bowel syndrome are seen by the FDA as drug uses. Securing public funding to conduct such research might trigger a request to file an Investigational New Drug Application with the FDA. Such a process – especially for a study recruiting healthy subjects - seems like an unnecessary burden for researchers with no intention to market a drug. Endpoints such as modulation of immune system function and alteration of colonizing microbiota fall under the structure/function claim rubric, but the consumer benefit from such endpoints is not always obvious. The arena of crafting "truthful and not misleading" product claims that accurately reflect scientific substantiation is a challenge. In addition to compliance with regulatory statutes, claims are scrutinized by other audiences, such as: consumers, healthcare professionals, media professionals, consumer watchdog organizations, advertising watchdog organizations (e.g., the National Advertising Division of the Better Business Bureau), and litigious elements in society.

Key Words: probiotic, prebiotic, claims

629 Strategic application of direct-fed microbials to livestock for growth efficiency and production. E. Davis* and T. Rehberger, *Dansico*, *Waukesha, WI.*

The establishment of the commensal microbiota in the gastrointestinal tract of the neonate is the impetus for the development of a functional immune system, with ramifications on metabolic functions related to subsequent growth in later production stages. The administration of probiotics, termed direct-fed microbials (DFM) when delivered to livestock, affords an opportunity to dictate a portion of the microbial consortia and thereby exert a positive influence on production efficiency and health. With the use of culture-independent molecular techniques, microbial diversity in the intestinal tract of neonatal pigs has been assessed and members of the intestinal microbial population identified that were positively correlated to specific immune cell phenotypes and growth performance traits. The administration of a *Bacillus*-based DFM to sows enhanced specific *Lactobacillus* populations in piglets at 3 and 10 d of age compared with pigs born to unsupplemented sows, with differences also observed in nutrient composition and immune cell phenotypes within colostrum, piglet growth, and immune cell populations in the gastrointestinal tracts of piglets. Although early delivery of a DFM may be ideal to influence early microbial colonization, administration of microorganisms in later production stages can still elicit improvements in production efficiency. Administration of *Propionibacterium* strain P169 to dairy cows during late gestation and early lactation altered ruminal metabolism toward increased propionate, resulting in increased milk production without increasing DMI. Host-microbial interactions during early post-natal development and in later production stages indicate that strategic applications of DFM to livestock can positively impact growth efficiency and production.

Key Words: probiotics, swine, cattle

Forages and Pastures: Environmental Impact of Forage-Based Livestock Production Systems

630 Compatibility of beef cattle management with multiple use values on western rangelands. T. DelCurto* and P. Kennedy, *Eastern Oregon Agricultural Research Center, Union Station, Oregon State University*, *Union*.

Beef cattle production in the western United States is dependent on systematic approaches that maintain the biological diversity of native rangelands. In addition, the continued use of these rangelands may depend on our ability to demonstrate that domestic livestock production can be compatible with multiple uses that not only include native vegetation/wildlife diversity, but also focus on water quality, fisheries, and recreation/esthetic values. The purpose of this paper is to quantify research that has evaluated the impact of beef cattle grazing on big game habitat, riparian areas critical to fish habitat, vegetation diversity, logging/grazing interactions, and, although information is limited, insect and bird diversity/abundance. Over 20 years of research will be summarized in respect to the interaction of beef cattle grazing and deer/elk big game herds in the Blue Mountains of Oregon. This research represents decades of collaborative research between the USDA FS Starkey Experimental Forest and Range and Oregon State University. In addition, research focused on the management of beef cattle relative to riparian areas that provide habitat to threatened and endanger fish will be discussed. Finally, a new generation of research will be discussed that uses a food web approach to enumerate the impact of beef cattle grazing on soils, vegetation, insects that feed on the vegetation, insects that prey on other insects, and ground nesting birds that need the vegetation for cover as well as use insects for their primary food sources. This type of research is difficult and often necessitates the need to develop multi-disciplinary and, in some cases, multi-agency teams. However, this type of research approach may be critical to addressing public concerns about the long-term sustainability of beef cattle production on western rangelands.

Key Words: beef cattle, rangelands, multiple use

631 Livestock grazing and endangered species habitat. G. S. Lewis*, C. A. Moffet, and J. B. Taylor, *USDA, ARS, U.S. Sheep Experiment Station*, *Dubois, ID*.

Livestock grazing can improve wildlife habitat, including critical habitat for species listed as endangered. However, that assertion presumes that appropriate and unbiased data have been used to define critical habitat; an appropriate recovery plan has been approved with clear and firm objectives that can be used to develop grazing strategies for habitat conservation; and legal challenges do not result in significant and frequent changes in the recovery plan. The Endangered Species Act (ESA) of 1973 defines endangered species as one that is "in danger of extinction throughout all or a significant portion of its range, and a threatened species as one that is "likely to become an endangered species within the foreseeable future." The ESA and amendments "provide a means whereby the ecosystems upon which endangered species and threatened species depend may be conserved, provide a program for the conservation of such endangered species and threatened species, and take such steps as may be appropriate to achieve the purposes of the treaties and conventions set forth" in the ESA, including "esthetic, ecological, educational, historical, recreational, and scientific value." Also, the ESA describes the process of listing species, determining critical habitat, developing a recovery plan, and delisting species. Nearly 1,900 species have been listed and <50 species have been delisted under the ESA. Even though strategic livestock grazing can benefit wildlife habitat, the scope and vagaries of the ESA and Federal judicial process, combined with institutional opinions of "antiagriculture" groups that livestock grazing is always detrimental, prevents scientists from conducting the well-designed research needed to develop site-specific livestock grazing plans for conserving endangered species habitat. Our presentation will include discussions of these issues and suggestions for how scientists can provide robust data for developing livestock grazing plans that will conserve endangered species habitat.

Key Words: Endangered Species Act, livestock grazing

632 Economic and environmental issues associated with confinement and pasture-based dairy systems. D. A. Clark*[1], S. F. Ledgard[2], P. Gregorini[1], and C. A. Rotz[3], [1]*DairyNZ*, *Hamilton, Waikato, New Zealand*, [2]*AgResearch*, *Hamilton, Waikato, New Zealand*, [3]*USDA-Agricultural Research Service*, *University Park, PA*.

Milk is produced in a continuum of dairy systems from full confinement to full pasture grazing. Climate, available feeds, and milk price: feed cost ratio influence the preferred system. All dairy systems have an environmental impact and inputs to maximize profit may lead to pollution levels unacceptable to society. There is vigorous debate concerning the trade-off between dairy farm profit and air and water quality impacts. Reasoned debate requires good information on the key production, economic and environmental parameters associated with different dairy systems and an agreement on the boundaries of each system. We provide a summary of literature on experiments and modeling of confinement and pasture-based dairy systems as a framework for future analysis and debate. There are few published experimental comparisons of confinement and pasture-based systems that account for both production and environmental parameters, so we make extensive use of modeling studies (e.g., life cycle assessment, Integrated Farm System Model, DairyNZ Whole Farm Model and OVERSEER). Where possible we use experimental data to evaluate model predictions. We compare a subset of possible dairy systems for both economic and environmental performance and identify areas of high sensitivity to factors such as input costs or environmental pollutants. Strengths and weaknesses of different systems are identified and we highlight opportunities for economic and environmental improvements by both component technologies and system redesign. Stored feed systems need to reduce their production costs and environmental footprint. Pasture-based systems need to reach the energy intake levels associated with TMR, and reduce the nitrate and N_2O losses associated with urine patches in grazed pasture. Dairy systems research must ensure that advances in animal and plant breeding lead to simultaneous economic and environmental benefits.

Key Words: dairy production systems, confinement feeding, grazing

633 Forages and livestock production with declining water resources and a changing agricultural industry. V. G. Allen*, C. P. Brown, R. L. Kellison, P. N. Johnson, and C. J. Zilverburg, *Texas Tech University, Lubbock*.

Agriculture is undergoing radical change driven by continued global population growth, a fossil fuel-based energy system, unstable economics and policies, depletion of natural resources, environmental concerns, and dependence on irrigation. Agriculture is the biggest single user of water, largely for irrigated crop production, and demands continue to

escalate. Urban expansion and conversion of prime agricultural land to non-agricultural uses force crop production into more marginal environments resulting in increased resource inputs to ensure production. Such inputs frequently include water for irrigation at non-sustainable rates of use. The semi-arid Texas High Plains is one of the most intensive agricultural areas in the US and is a model for factors driving change. Agriculture conservatively accounts for over 40% of the regional economy but depends heavily on water for irrigation from the Ogallala aquifer. Recharge is negligible, and water demand is expected to exceed supply within the next 10 to 20 years. About 30% of the cotton (*Gossypium hirsutum* L.) and 25% of the cattle on feed in the US are located here primarily in monoculture systems. Recently, the dairy industry and an emerging renewable fuel industry have entered this region placing increased demands on soil and water resources and influencing cropping decisions. Impending water depletion, evolving water policies and laws, and volatile commodity and input prices are contributing to destabilizing agriculture. A 10-year replicated comparison of an integrated crop/forage/beef stocker steer system and a monoculture cotton system demonstrated ($P < 0.05$) that the integrated system required about 25% less irrigation water, 40% less nitrogen fertilizer, improved soil organic carbon and microbial activity, reduced erosion, and was as profitable as the cotton monoculture. Monitoring of 27 producer systems in the Texas High Plains continues to demonstrate water conservation and economic opportunities through integrating forages and livestock into cropping systems but long-term field-scale systems research is essential. Lessons learned here have global significance.

Key Words: water, grazing systems, integrated systems

634 Pasture management strategies to minimize the impacts of grazing on water quality of surface water resources. J. R. Russell*[1], D. A. Bear[1], K. A. Schwarte[1], and M. M. Haan[2], [1]*Iowa State University*, *Ames,* [2]*Michigan State University*, *Hickory Corners*.

Sediment, nutrient, and pathogen loading of pasture streams result from stream bank erosion, direct manure deposition, and\or transport in precipitation runoff. Risks of loading streams with these pollutants may be increased by biotic and abiotic factors that encourage congregation of cattle near streams. Congregation of cattle near pasture streams may be discouraged by management practices that control the temporal\spatial distribution of grazing cattle. Restricting stream access of beef cows either to stabilized crossings in continuously stocked pastures or to riparian paddocks grazed to a minimum sward height of 10 cm in rotationally stocked pastures reduced the proportion of time that cattle spent in and within 33.5 m of the pasture streams by 81% in comparison to continuous stocking with unrestricted stream access. Providing off-stream water or shade may alter the temporal\spatial distribution of cattle in pastures, but efficacy of management practices to alter the distribution of grazing cattle is dependent on pasture size and shape and climatic conditions. The proportion of time that cattle spent in and within 30.5 m of a stream (streamside zone) in pastures with different areas was more highly related to the proportion of pasture area in the streamside zone than pasture shade distribution or botanical composition. In pastures with comparable areas, the proportion of time that cattle spent in the streamside zone was highly related to the proportion of total pasture shade in the streamside zone in the spring and fall, but not in the summer. Stream bank erosion and total coliform concentrations in stream water were not affected by stocking density or grazing management. Reducing pasture stocking density or restricting stream access to stabilized crossings or riparian paddocks limit the risk of sediment, nutrient, and pathogen loading of streams by reducing the proportion of bare and\or manure-covered ground and precipitation runoff in streamside zones.

Key Words: grazing, water quality, beef cattle

635 Evaluation of the NCAPG I442M locus, a major gene for bovine prenatal growth, for effects on postnatal development compared to a disruptive mutation in the myostatin encoding gene GDF8. C. Kuehn*, P. Widmann, R. Pfuhl, and R. Weikard, *Leibniz Institute for Farm Animal Biology (FBN)*, *Dummerstorf, Germany*.

Recently, we identified the I442M mutation in the bovine non-structural maintenance of chromosomes condensin I complex, subunit G (NCAPG) gene affecting bovine prenatal growth in an F2 resource population. Due to consistent application of embryo transfer during generation of the resource population, the direct genetic background of divergent postnatal growth dissected from putatively persistent maternal allelic effects could be addressed. In addition to the NCAPG I442M locus, also the disrupting mutation Q204X of the growth differentiation factor 8 (GDF8) segregated in our resource population. Thus, the effects of both loci could be evaluated on an identical genetic background. For our study, male calves were fed a milk replacer/hay/concentrate diet until d 121 followed by a semi ad libitum feed ration of concentrates and chaffed hay. Body weight was recorded monthly until 18 mo of age. All P0, F1 and F2 individuals were genotyped for NCAPG I442M and GDF8 Q204X. Association analyses were performed with a single locus and a 2 locus model fitting a fixed effect of the year of birth, an additive genetic SNP effect and an infinitesimal polygenic animal effect. The NCAPG 442M allele that had been associated with increased birth weight, showed a significant effect ($P = 0.0001$) increasing body weight at 18 mo of age. The locus explained 9.3% of the variance in the model. The effect of the loss-of-function allele GDF8 204X on body weight was also significant ($P = 0.006$). The difference between alleles amounted to 25.4 kg (std. err. 6.34 kg) for NCAPG I442M and 30.0 kg (std. err 12.5 kg) for GDF8 Q204X, respectively. For the 2-locus model, effects of essentially the same magnitude were obtained. In conclusion, both, the NCAPG I442M locus and the GDF8 Q204X locus, exhibit significant, independent effects on postnatal growth.

Key Words: postnatal growth, cattle, NCAPG

636 Maternal nutrition differentially influenced gene expression responsible for fetal bovine adipocyte development. T. D. Jennings*, K. R. Underwood, A. E. Wertz-Lutz, and A. D. Weaver, *South Dakota State University*, *Brookings*.

Maternal nutrition during mid-late gestation influences adipose development in the fetus of various species, however bovine research is limited. The objective of this experiment was to determine the effects of maternal nutrition on the expression of genes in bovine fetal tissues. Genes of interest were selected because each has been demonstrated previously to influence body composition. Twenty-two Angus cross-bred heifers (BW = 527.73 ± 8.3 kg) were assigned randomly to 3 dietary treatments. Maternal dietary treatments were formulated and intake was controlled to provide 150% (HIGH; n = 7), 100% (INT; n = 7), and 80% (LOW; n = 8) of maintenance energy requirements for growing pregnant heifers. Heifers received dietary treatment from d 85 to d 180 of gestation, at which time fetuses were removed via cesarean section and muscle, subcutaneous fat, and liver samples were collected. At trial initiation, dam BW was similar among treatment groups. Final BW was lowest for the LOW dams ($P < 0.05$), however final BW for INT and HIGH were similar. Ribfat thickness increased in the HIGH treatment group compared with LOW and INT dams ($P < 0.05$). Thus, dam growth was influenced by diet during the treatment period, however dietary treatment did not influence fetal weight, crown rump length, or liver weight. Preadipocyte factor-1 showed increased expression in fetal LM ($P < 0.05$) of HIGH fetuses as compared with INT and LOW. Peroxisome proliferator-activated receptor gamma and C/EBPα did not differ as a result of dietary treatment. However, LOW fetuses showed increased C/EBPβ expression as compared with INT ($P < 0.05$). Collectively these results suggest that fetal growth characteristics are not affected by maternal nutritional manipulation during mid-gestation in beef cows. However, differences in expression of fetal genes regulating adipose tissue growth and development could lead to differences in composition of growth and warrants further investigation.

Key Words: adipose tissue, beef cattle, fetal programming

637 Lipid accumulation and fibrosis in skeletal muscle of offspring born to obese dams. X. Yan*[1], Y. Huang[1], M. J. Zhu[1], N. M. Long[1], A. B. Uthlaut[1], R. J. McCormick[1], S. P. Ford[1], P. W. Nathanielsz[2], and M. Du[1], [1]*Department of Animal Science, University of Wyoming*, *Laramie,* [2]*University of Texas Health Science Center*, *San Antonio*.

Enhancing adipogenesis in muscle increases intramuscular adipocytes, while increasing fibrogenesis would affect meat tenderness. The objective was to evaluate the effects of maternal obesity on the intramuscular fat and collagen content of offspring muscle. Multiparous ewes (Rambouillet/Columbia cross) were fed a control diet (100% energy requirement, Con, n = 8) or an obesogenic diet (150% energy requirement, OB, n = 9) from 2-mo before pregnancy to parturition. Then, offspring lambs were fed commercial feeds to 22 mo old. The Longissimus dorsi (LD) muscle (2g) was biopsied at the left 12th rib for histochemical examination, mRNA and protein expression analyses and collagen content assessment. Mean ± standard errors of means are reported. No difference was observed in maternal body weight (68.3 ± 2.9 kg vs. 71.6 ± 3.2 in Con and OB) or body condition score (4.9 ± 0.4 in Con and 5.0 ± 0.3 in OB) before dietary treatments. Following 2 mo treatment (before mating), both maternal body weight (73.1 ± 4.0 vs.108.8 ± 3.1 in Con and OB, $P < 0.05$) and maternal body condition score (4.9 ± 0.3 vs. 8.6 ± 0.2, $P < 0.05$) were higher on OB compared with Con diet. More intramuscular adipocytes were observed in OB offspring muscle compared with Con muscle; the mRNA expression of peroxisome proliferator-activated receptor (PPAR) γ, an adipocyte marker, was 33.6 ± 15.6% higher ($P < 0.05$) in OB, and the protein content was 51.1 ± 5.1% greater ($P < 0.05$), consistent with the 32.1 ± 9.8% higher intramuscular triglyceride content in OB compared with Con muscle ($P < 0.05$). The mRNA and protein contents of fatty acid transport protein 1 (FATP1) were increased in OB group by 61.8 ± 24.8% and 40.8 ± 9.3% ($P < 0.05$) respectively. We also detected 39.4 ± 8.8% higher mRNA expression for fatty acid translocase (FAT)/CD36 ($P < 0.05$). In addition, 50.6 ± 15.3% higher collagen content was detected in OB compared with Con offspring muscle ($P < 0.05$). In conclusion, maternal obesity increases intramuscular fat and collagen contents in offspring muscle, which results in changes of skeletal muscle composition and might affect the quality of resulting meat.

Key Words: maternal obesity, collagen, muscle

638 Enhanced transforming growth factor β (TGF-β) signaling and fibrogenesis in ovine fetal skeletal muscle of obese dams at late gestation. Y. Huang*[1], X. Yan[1], M. J. Zhu[1], R. J. McCormick[1], S. P. Ford[1], P. W. Nathanielsz[2], and M. Du[1], [1]*Department of Animal Science, University of Wyoming*, *Laramie,* [2]*University of Texas Health Science Center*, *San Antonio*.

Maternal obesity is increasing at an alarming rate. The objective was to evaluate the effect of maternal obesity on fibrogenesis in fetal skeletal muscle at late gestation when ovine fetal muscle matures. Non-pregnant ewes were assigned to a control diet (Con, fed 100% of NRC nutrient recommendations, n = 6) or obesogenic diet (OB) fed 150% of NRC recommendations, n = 6) from 60 d before conception, and fetal semitendenosus (St) muscle was sampled at 135 d of gestation (term 148 d). The total concentration and the area of collagen in the cross-sections of muscle increased by 27.0 ± 6.0% ($P < 0.05$) and 105.1 ± 5.9% ($P = 0.05$) in OB compared with Con group. The expression of precursor TGF-β was 177.3 ± 47.6% higher ($P < 0.05$) in OB fetal muscle. The concentration of phospho-p38 was 74.7 ± 23.6% higher ($P < 0.05$) in OB group. An increase of 327.9 ± 168.0% ($P < 0.05$) and 188.9 ± 82.1% ($P < 0.05$) respectively for the mRNA expression of Smad7 and fibronectin was observed in OB compared with Con samples. In addition, enzymes involved in collagen synthesis, including lysyl oxidase, lysyl hydroxylase 2b and prolyl 4-hydroxylase α1 were increased by 350.2% ± 90.0% ($P < 0.05$), 236. Five ± 25.2% ($P < 0.05$) and 82.0 ± 36.2% ($P = 0.05$) respectively in OB muscle. In conclusion, maternal obesity enhanced fibrogenesis in fetal muscle at late gestation which was associated with upregulation of TGF-β/p38 signaling pathway. Because muscle fibrosis is a hallmark of aging, enhanced fibrogenesis at such an early stage of development is expected to negatively affect the properties of offspring muscle.

Key Words: collagen, TGF, muscle

639 Up-regulation of nutrient transporters in the placenta of nutrient restricted pregnant ewes. Y. Ma*[1], M. J. Zhu[1], P. W. Nathanielsz[2], and S. P. Ford[1], [1]*Center for the Study of Fetal Programming, Univ. of Wyoming*, *Laramie,* [2]*Center for Pregnancy and Newborn Research, Univ. of Texas Health Sciences Center*, *San Antonio*.

In sheep, maternal:fetal exchange occurs in placentomes, comprised of uterine caruncular and placental cotyledonary (COT) tissues. Glucose transporters (GLUT) and fatty acids transporters (FATP) in COT deliver glucose and long chain fatty acids (LCFA) to the fetal compartment. We have reported that fetuses from ewes fed to 50% NRC recommendations from 28 to 78 d of gestation (dGA; nutrient restricted, NR) weighed ~30% less than fetuses gestated by control ewes (C, 100% of NRC) at 78dGA. In contrast, NR fetuses exhibited a marked increase of LCFA storage in their lung, liver and muscle. When NR ewes were re-alimented to a C diet from 78dGA, their fetuses exhibited weights similar to C fetuses by 135dGA. COT tissue collected on 78 and 135 dGA was used to investigate GLUT and FATP systems via Realtime PCR and Western blot. Ewes assigned to C (n = 5) and NR (n = 6) groups were necropsied on 78dGA, while 6 C and 7 NR-realimented ewes were fed the C diet from 78 to 135dGA before necropsy. At 78dGA, COT GLUT1 mRNA and protein levels were greater ($P < 0.05$) in NR than C ewes. Similarly, COT FATP4 mRNA and protein levels were greater ($P < 0.05$ and $P = 0.06$, respectively), and CD36 mRNA and Protein levels tended to be greater ($P = 0.06$) in NR versus C ewes. At135dGA, COT FATP4 mRNA and protein levels tended to remain elevated ($P = 0.06$ and $P = 0.09$, respectively) in NR-realimented versus C ewes. CD36 and GLUT3 protein levels also tended to remain elevated ($P = 0.08$ and $P < 0.05$, respectively) in NR-realimented versus C ewes on 135dGA. The increased COT GLUT and FATP expression in NR versus C ewes at 78dGA is consistent with increased placental efforts to increase maternal nutrient transfer to the fetus. The continued elevation in COT GLUT3, FATP4 and CD36 expression after realimentation of NR ewes, would facilitate delivery of the increased blood levels of maternal nutrient to the fetus, accelerating its growth, and possibly causing metabolic problems in postnatal life.

Key Words: maternal nutrient restriction, placental nutrient transport, sheep

640 Effect of grouping calves post-weaning according to pre-grouping feed intake on animal performance. C. M. Matuk*[1], M. Chahine[1], A. Bach[2,3], B. Ozer[1], M. E. de Haro Martí[3], J. B. Glaze Jr.[1], T. Fife[1], and M. Nelson[1], [1]*University of Idaho*, *Twin Falls*, [2]*IRTA*, *Caldes de Montbui, Spain*, [3]*ICREA*, *Barcelona, Spain*, [4]*University of Idaho*, *Gooding*.

The effect of grouping calves post-weaning according to pre-grouping feed intake on animal performance was evaluated using 752 replacement Holstein calves raised on a large operation in southern Idaho. In 4 different periods, individual feed intake was recorded 4 times a week during the last 3 wk that calves were individually hutched (56 d of age). Calves were classified as ′high eaters′ (highest feeding level quartile) and ′low eaters′ (lowest feeding level quartile). When leaving the individual hutches in each period, calves formed 6 groups: 20 animals randomly chosen without considering their level of feed intake (Control), 20 calves within the highest quartile of feed intake during the 3 wk prior leaving the hutches (HH), 20 within the lowest quartile (LL), 5 calves from the lowest and 15 from highest feeding level (LHH), 15 calves from the lowest and 5 from highest feeding level (LLH), and 10 calves from the highest and 10 from lowest feeding level (HL). Thus, out of 752 initially-tracked heifers, 480 heifers were chosen to form the 20 groups (6 groups per period) that were studied. Pen feed intake was recorded during the first 4 wk after grouping. After grouping, calves received a TMR composed of 95% starter and 5% alfalfa. Final weight was recorded at the end of the 12 wk of study. Pen was the experimental unit. Data were analyzed using a mixed-effects model with repeated measures accounting for the random effect of period and pen and the fixed effects of treatment, intake level class, time of measurements, and their 2-way interaction. Average DMI after grouping was greatest ($P < 0.05$) in HH (2.24 kg/d) and HHL (2.15 kg/d) followed by HL (2.07 kg/d), Control (2.06 kg/d), LLH (1.92 kg/d) and LL (1.77 kg/d). Similarly, ADG was greatest ($P < 0.05$) in HH (694 g/d) and HHL (658 g/d) than in HL (584 g/d), LLH (571 g/d), Control (546 g/d), and LL (531 g/d). The coefficient of variation of final BW (at 84 d of age) was lowest ($P < 0.05$) for HH (9.3%) and LL (11.7%), followed by Control (12.9%), LLH (15.8%), HHL (13.5%), and HL (17%). Grouping calves according to pre-weaning intake improves overall animal performance and diminishes variation.

Key Words: calves, heifers, intake

641 Evaluation of serum protein-based arrival formula and serum protein (Gammulin) on growth, morbidity, and mortality of stressed dairy calves. A. Pineda*[1], J. K. Drackley[1], and J. M. Campbell[2], [1]*University of Illinois*, *Urbana,* [2]*APC, Inc.*, *Ankeny, IA*.

Appropriate nutrition is a crucial factor to decrease morbidity and mortality of pre-weaning dairy calves. Several nutritional additives are available that may help to achieve this goal; however, their effectiveness is uncertain. The objective of this study was to evaluate a serum protein-based arrival formula (AF) and use of a commercial serum protein supplement (G; Gammulin, APC Inc.) in milk replacer for stressed (transport, cold) male calves on performance, morbidity, and mortality. Ninety-three male Holstein calves were stratified by arrival BW and plasma protein, and then randomly assigned to 1 of 4 treatment groups: Treatment A = AF, milk replacer without G (n = 22); Treatment B =

control electrolyte, milk replacer without G (n = 25); Treatment C = AF, milk replacer with G (n = 22); and Treatment D = control electrolyte, milk replacer with G (n = 24). At arrival, calves were fed either AF or a control electrolyte solution. At the next feeding, all calves received either a commercial calf milk replacer (20% CP, and 20% fat; no G supplementation) or the same milk replacer supplemented with G (50 g/d during the first 14 d only). Feed offered and refused was recorded daily. Calf health was assessed by daily assignment of scour and respiratory scores. Body weight, withers height, body length, heart girth, hip height, and hip width were measured weekly. Calves remained in the experiment until d 56. Data were analyzed using the MIXED procedure of SAS (v. 9.2). Results indicated that, during the first 2 wk of dietary treatment, calves fed AF had significantly greater hearth girth ($P = 0.05$) and body length ($P = 0.03$), while G supplementation resulted in greater BW ($P = 0.05$). In addition, a significant ($P = 0.03$) interaction of G × week was observed for ADG. Mortality was greater ($P = 0.007$) for calves that did not receive G. Addition of a serum protein product improved early growth and decreased mortality in transported male calves.

Key Words: calves, serum protein, Gammulin

642 The effect of maternal exercise on gestating gilts on neonatal piglet organ weight. E. K. Harris*, K. A. Vonnahme, J. D. Kirsch, J. D. Magolski, T. L. Neville, and E. P. Berg, *North Dakota State University*, *Fargo*.

To determine the effects of maternal exercise of gestating gilts on fetal piglet development and growth, Yorkshire gilts (n = 8), bred to a common boar, were placed in individual gestation stalls at d 30 of gestation. Treatments were assigned and initiated at d 40 of gestation. Exercise gilts (EX) were housed in individual gestation stalls but were individually exercised 3 times per week for 30 min until d 105 of gestation. Control gilts (CON) remained in gestation stalls for the duration of gestation. All farrowings were attended. Within 12 h of completion of farrowing, the lightest (LWT) and heaviest (HWT) male and female from each litter, excluding piglets <800 g, were selected for necropsy. Adrenal glands, brain, digesta, heart, kidneys, intestines, liver, lung, pancreas, spleen, stomach, gonads, semimembranosus (SM) and semitendinosus (ST) were dissected and weighed. Organ weights (g) and organ weight/live BW (g/g) were analyzed by PROC MIXED. Live weight of necropsied piglets was greater in offspring from EX gilts ($P = 0.03$; 1282.06 and 1698.70 ± 125.40 g). Piglets from EX gilts had larger adrenal glands (g) ($P < 0.01$), kidneys (g) ($P < 0.01$), liver (g) ($P < 0.01$), and stomach (g) ($P < 0.01$) than CON gilts. Piglets from EX gilts had a tendency ($P < 0.10$) to have more digesta (g), heavier hearts (g), intestines (g), spleen (g), and SM (g/g). The brain and pancreas were the only organs not affected by treatment. Treatment by weight interaction occurred in liver (g/g) ($P = 0.05$), ovaries (g) ($P = 0.02$), and uterus (g/g) ($P < 0.01$). Light weight EX offspring had larger liver (g/g) ($P < 0.001$) compared with LWT CON offspring but were not different compared with HWT CON and EX treatments. LWT CON livers were also smaller than HWT EX ($P = 0.01$) but not different than HWT CON livers. Ovaries (g) were lightest in gilts from LWT CON gilts compared with all other treatment groups ($P < 0.05$). Light weight CON offspring had heavier uteri (g/g) compared with all other treatment groups ($P < 0.05$). Maternal activity during mid to late gestation influenced the developmental composition of the neonate.

Key Words: neonatal offspring, organ weights, pigs

643 Changes in gene expression during pituitary morphogenesis and organogenesis in embryonic chicks. M. Proszkowiec-Weglarz*, S. E. Higgins, and T. E. Porter, *University of Maryland, Department of Animal and Avian Sciences*, *College Park*.

The anterior pituitary gland (AP) plays an important role in the regulation of many physiological processes in vertebrates. Formation of Rathke's pouch (RP), the precursor of the AP, involves invagination of the oral ectoderm (OE) and a multi-step process regulated by cell interactions, signaling pathways and transcription factors. In contrast to mammals, the molecular mechanisms underlying development of the AP in birds are poorly understood. Thus, the aim of this study was to evaluate tissue-specific gene expression patterns in the developing chicken AP. OE/RP and the adjacent neuroectoderm (NE) were collected by laser capture microdissection from 60 paraffin-embedded chicken embryos at 12-h intervals from embryonic day (e) 2.5 to e7 (n = 3 replicates). After RNA isolation and amplification, quantitative real-time PCR was performed to determine RP- and NE-specific gene expression. RP was formed by invagination of OE around e2.5, and by e6-e6.5 RP lost its connection with the oral cavity and proliferated to form the AP. Among genes involved in early pituitary organogenesis, *Pitx1*, *Pitx2* and *Hesx1* showed high expression at e2.5 in RP that decreased during development ($P < 0.05$). Expression of pituitary cell lineage specification and differentiation genes (*Pit1* and *Tbx19*) increased gradually, reaching the highest level by e7 and e6.5 in RP, respectively ($P < 0.05$). *Alpha-GSU*, encoding a common glycoprotein subunit of gonadotropins and thyrotropin, showed increasing mRNA expression from e4 ($P < 0.05$). *BMP4*, *BMP2*, *Wnt5a*, *Isl1* and *Noggin* were expressed in both RP and NE, while *Nkx2.1* showed NE-specific expression during AP formation. Taken together, we present a gene expression profile of the developing AP in the chicken. Our results will be helpful in better understanding the functional development of this gland, which is critical for controlling animal growth, reproduction, metabolism, and stress responses.

Key Words: Rathke's pouch and neuroectoderm, pituitary development, chicken embryo

644 Effects of in ovo feeding of carbohydrates and arginine on the energy metabolism, protein status and perinatal growth in Pekin ducks. M. Tangara*, W. Chen, F. R. Huang, and P. Jian, *Laboratory of Animal Molecular Nutrition, Department of Animal Nutrition and Feed Science, Huazhong Agricultural University*, *Wuhan, Hubei, P. R. China*.

The objective of the present study was to determine the effects of in ovo feeding of exogenous nutrients on the glycogen reserves, protein status and early growth of Pekin ducks. To this end, based on randomized completely block design, 750 fertile eggs were divided into following 5 groups of 150 eggs: 1) Uninjected; 2) 0.35% sodium chloride (NaCl); 3) 2.5% sucrose + 3% maltose (CHO); 4) 0.22% arginine (Arg); and 5) 2.5% sucrose + 3% maltose + 0.22% arginine (CHO+Arg). At 23 d of incubation, 1.2 mL of each solution was injected into amniotic fluid of each group using a 22-gauge needle. Ten eggs/ducklings per treatment were sampled at 25 d of incubation, hatch, 3 and 7d of age to determine liver and muscle glycogen, glucose-6-phosphatase (G6P) activity and different protein expression including S6K1 (S6 kinase1), phosphorylated S6K1 and phosphorylated adenosine monophosphate-activated protein kinase (AMPK) using iodine reduction test, colorimetric oxidase test and Western blot, respectively. Maximal hatchability was found in the group ($P < 0.05$) fed with CHO+Arg (94%) followed in order by Arg (90%), CHO (89%), uninjected control (85%) and NaCl (80%). All the ovo fed ducklings improved BW at hatch, 3, 7, 14, 21, 28 and 35 d of age related to uninjected ($P < 0.05$). Arg and CHO+Arg had significantly enhanced the liver glycogen by 188% and 249%, respectively at hatch ($P < 0.01$) compared with that of uninjected group.

CHO and CHO+Arg significantly increased muscle glycogen level ($P < 0.01$) by 22% and 42%, respectively at 25 d of incubation over the uninjected group. CHO and Arg had significantly decreased ($P < 0.01$) G6P by 41% and 30%, respectively at 25 d of incubation, whereas NaCl and CHO+Arg increased G6P by 30% and 20%, respectively at hatch in comparison with the uninjected group ($P < 0.01$). At 25 d of incubation, hatch, 3 and 7d posthatch, greater values of S6K1 and S6 phosphorylation were observed in duck embryos and neonates fed with Arg and CHO+Arg. The activation of AMPK was also detected in the group fed with Arg and CHO+Arg. The present results indicated that in ovo feeding CHO and Arg may improve glycogen storage and muscle protein deposition in ducks

Key Words: in ovo feeding, energy, protein, metabolism, growth, ducks

645 The effect of induced moisture loss on embryonic development of pekin ducks. C. Noonan* and M. S. Lilburn, *Ohio State University/OARDC*, *Wooster*.

Moisture loss in commercial Pekin duck eggs during incubation is often variable and accelerated moisture loss may contribute to excessive hatchling dehydration and adversely effect later developing systems such as the intestine. Two experiments were conducted to determine the effect of induced moisture loss on embryonic development. In both experiments, commercial duck eggs were individually weighed at set. At 12 d, all eggs were reweighed and randomly allocated to one of 4 treatments consisting of 0, 1, 2, or 3 holes (Experiment 1; n = 40 per treatment) or 0, 1 or 2 holes (Experiment 2; n = 120 per treatment). The holes (<1 mm) were drilled above the air sac. All eggs were reweighed at approximately 2-d intervals. All data was analyzed by ANOVA using the PROC Mixed program (SAS Inc.) and least squares means were separated using LSD. In Experiment 1, there were no differences in initial egg wt or moisture loss (4.67%; $P > 0.05$) at 12 d. On D 14 and all sample days thereafter, there were incremental increases in moisture loss with each additional hole ($P < 0.01$). At D 19, the range was 7.35% (0-hole) to 20.86% (3-hole) and the experiment was terminated. In Experiment 2, the range was from 5.32% (0-hole) to 7.34% (2-hole) on D 14 ($P < 0.01$) and 8.03% (0-hole) to 15.15% (2-hole) on D 19. On Day 20, a sample of embryos from each treatment (n = 25) was broken out for embryo weight determination. Wet embryo weight was heavier ($P < 0.01$) in the 1-hole treatment (36.7 g) compared with the 0-hole (33.9 g) and 2- hole (31.8 g) treatments. The same pattern was observed for dry embryo weight. There was a progressive decrease in hatch weight ($P < 0.05$) as moisture loss increased (0-hole, 55.3 g; 1-hole, 53.6 g; 2-hole, 52.3 g) but no effects on intestinal measures (villus height; crypt depth). In conclusion, major differences in moisture loss during incubation in Pekin duck embryos have only a small effect on body weight or physiological status at hatch.

Key Words: Pekin, embryo, incubation

646 Bone development of three breed crosses of broilers is affected by incubation profiles. E. O. Oviedo-Rondón*, M. J. Wineland, C. M. Ashwell, and P. R. Ferket, *North Carolina State University*, *Raleigh*.

Genetics, maternal nutrition, and incubation conditions affect bone development in broilers. One experiment was conducted to observe epigenetic effects of 2 incubation temperature profiles on bone development in 3 groups of broilers (A, B, C) differing in genetic background and maternal nutrition. Group A was the final cross of this strain; and B and C were the progeny of the male line either feed restricted or with no feed restriction. The first incubation profile followed standard (SS) temperatures to maintain eggshell temperature (EST) at 37.5°C. The second profile (LH) was similar to what one observes when eggs are in a multi-stage incubation system, the first 7 d EST was maintained at 36.5°C EST, during the second 7 d at 37.5°C EST and the remaining days at 39°C EST. At hatch, a random sample of 8 chicks per treatment were collected, weighed, sacrificed, and residual yolk determined. Both legs were dissected and shank and femur weights, lengths, and thickness were obtained. Relative asymmetry and weight relative to BW without yolk (%) of each leg section were calculated, and bone density estimated as g/mm. A total of 288 chicks were randomly placed in 48 battery cages and raised until 21 d. Bones were collected again at 14 and 21 d and similar parameters evaluated. Data were analyzed as a 2x3 factorial design considering incubation profiles and genetic strain as main factors. No consistent interactions were observed. Chickens from C group were heavier than B chickens only at hatch. The B group had the shortest bones and the lowest femur density. The C group was heavier at 14 d, but no other effects of epigenetics were observed. The LH profile reduced yolk absorption, and weight, length, width and density of all bones at hatch. Similar effects of incubation were observed at 14 and 21 d of age. The LH profile caused shorter bones, with lower density, and higher asymmetry independently of the genetic group. These results indicated that incubation profiles may have more importance on bone development than the genetic background, and the epigenetic effects of parental feed restriction were only observed at hatch.

Key Words: bone development, incubation, epigenetics

647 Effect of in ovo selenium injection on chick embryo viability and tissue selenium levels. L. M. Macalintal*, A. H. Cantor, A. J. Pescatore, M. J. Ford, H. D. Gillespie, J. L. Pierce, K. A. Dawson, and R. F. Power, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington*.

The effect of injecting graded levels of selenium (Se) as selenomethionine (SeMet) or sodium selenite (Na_2SeO_3) into the yolk of incubating eggs on embryo viability and liver Se levels was studied. Fertile eggs were obtained from white shell laying hens (Hy-Line W-36) that were fed a low Se corn-soybean meal diet. On Day 10 of incubation, eggs were candled to ensure embryo viability. The shell surface was disinfected with alcohol and a small hole was drilled over the air cell. The yolk of each of 30 eggs per treatment was then injected with 0.1 mL of a phosphate buffered saline solution providing 0, 2.5, 5, 10 or 20 µg Se as either SeMet or Na_2SeO_3. In a control group of eggs holes were drilled in the shell, but no injection was administered. The holes were sealed with glue and eggs were returned to the incubator. On Day 20 of incubation, eggs were candled to determine viability. Viable embryos were then killed to obtain tissue samples. Liver samples were analyzed for Se using fluorometric analysis following digestion in nitric and perchloric acids. Embryo viability values for the non-injected eggs and eggs injected with buffer without Se were 100% and 94%, respectively. Viability values for eggs injected with 2.5, 5, 10 and 20 µg Se as SeMet were 97, 94, 90 and 83%, respectively, while the respective values for eggs treated with Na_2SeO_3 were 87, 94, 74 and 87%. Injecting graded doses of Se resulted in linear increases ($P < 0.001$) in liver Se. However, the regression coefficient for Na_2SeO_3 was greater than that for SeMet (0.059 vs. 0.014). The results indicate that in ovo injection of Se as SeMet or Na_2SeO_3 at levels up to 20 µg does not have a detrimental effect on embryo viability. The effects of the SeMet and Na_2SeO_3 on liver Se concentrations suggests that the compounds are metabolized differently by the chick embryo.

Key Words: in ovo injection, selenium, embryo viability

648 Testosterone exposure alters embryonic bursal gene expression in chicken lines selected for differential antibody response. R. L. Taylor, Jr.*[1], T. Burks[1], C. Timmerman[2], P. B. Siegel[3], and C. M. Ashwell[2], [1]*University of New Hampshire*, *Durham,* [2]*North Carolina State University*, *Raleigh,* [3]*Virginia Tech*, *Blacksburg*.

Chicken B cells mature in the bursa of Fabricius (BF) microenvironment producing antibody diversity through their V-gene repertoire. Testosterone propionate (TP) exposure on d 3 of incubation severely impairs BF development, elevates IgM, lowers IgG and causes bursal epithelial cell proliferation. From a common founder population, White Leghorn lines selected for high (HAS) or low (LAS) antibody produced 5 d after a 0.25% SRBC suspension (0.1 mL) injected intravenously, have a several fold difference in anti-SRBC antibody titer. Eggs from the 34th selected generation were dipped in a 2% TP ethanol solution or ethanol alone for treatment and control groups, respectively. We examined gene expression in bursal tissue collected from 4 embryos of each line and treatment (HAS, HAS TP, LAS, LAS TP) at 15, 18, and 21 d of incubation. Tissue samples were held in RNALater at −80 C until RNA was extracted followed by reverse transcription to cDNA. Individual cDNA samples, labeled indirectly with Cy3 or Cy5 fluorescent dyes, were hybridized including a dye swap to a 320 gene focused microarray. Each gene, represented by a 70-mer oligonucleotide, was spotted 12 times in a single array enhancing sensitivity to detect sample group differences. Fluorescent intensity data were transformed via log2, normalized by weighted regression, and analyzed by a mixed-model ANOVA. Pathway, process and networks were evaluated using the Metacore database. Growth hormone (GH), growth hormone receptor (GHR), thyroid hormone receptor α, and hemoglobin rho expression was higher in Line LAS controls than Line HAS controls. TP treatment in Line LAS elevated GH and GHR genes as well as interleukin(IL)-1 whereas Line HAS TP embryos had higher fibroblast growth factor 1 and endothelin receptor expression. Network analysis identified biomarkers associated with pathways for immune response IL-1, immune response NK2g, and developmental growth hormone signaling. Real-time PCR confirmed gene expression differences found on the microarray.

Key Words: immune response, microarray, bursa of Fabricius

649 Limiting dilution studies to detect avian influenza viruses from questionable allantoic fluid samples. T. V. Dormitorio* and J. J. Giambrone, *Auburn University*, *Auburn, AL*.

Detection of avian influenza viruses (AIV) from wild birds can be complicated when there is the presence of other hemagglutinating agents, including some avian adenoviruses, mycoplasma, Newcastle disease virus (NDV), and other paramyxoviruses (APMV). Moreover, dual isolations of influenza virus and APMVs are not unusual. Limiting dilution studies were conducted using fecal swab samples collected from wild birds, which were determined to be AIV positive by real-time RT-PCR (rRT-PCR), but had high crossing point (Cp) values (>32). The NVSL failed to isolate AIV from 2 of these samples, but instead they reported the presence of APMV-1 and APMV-4. Results showed that AIV positive samples, with high Cp, had either AIV, APMV, or both. The effect of egg passage on AIV detection by rRT-PCR had lowered Cp, indicating that there was an increase in the detectable virus. When there was a mixed infection, several dilutions and passages were needed to separate the viruses. Moreover, the presence of APMVs may have interfered with AIV detection, and thereby produced false positive AIV rRT-PCR results.

Key Words: avian influenza virus, avian paramyxovirus, real-time RTPCR

650 Development and characterization of mouse monoclonal antibodies reactive with chicken CD80. S.-H. Lee*[1], H. Lillehoj[1], M.-S. Park[1], K.-W. Lee[1], C. Baldwin[2], D. Tompkins[2], B. Wagner[3], U. Babu[4], and E. Del Cacho[5], [1]*Animal and Natural Resources Institute, ARS-USDA*, *Beltsville, MD,* [2]*University of Massachusetts*, *Amherst,* [3]*Cornell University*, *Ithaca, NY,* [4]*Food and Drug Administration*, *Laurel, MD,* [5]*University of Zaragoza*, *Zaragoza, Spain*.

The CD80 (B7.1) is a molecule found on monocytes providing a signal necessary for T cell activation and interferon-γ production. The characteristics of this molecule have been studied in human, swine, ovine, feline, and canine. However, information about CD80 and its antibodies (Abs) in chicken has not been reported. To develop immune reagents for chicken CD80 (chCD80), we have immunized mice with recombinant chCD80, and hybridomas producing monoclonal Abs against chCD80 were produced. Recombinant chCD80/IgG4 fusion protein was expressed in mammalian cells and chCD80 was purified and used to immunize mice. In this study, 158 hybridomas were screened and 3 mAbs with high binding specificity against chCD80-transfected cells were selected by flow cytometric analysis. Western blot showed a 80 kDa protein against chCD80. Monoclonal Abs to chCD80 showed staining of chicken macrophage cell line (HD11), bursa, and spleen. Taken together, mouse monoclonal antibodies specific for chicken CD80 have been developed and these immune reagents will be useful tools to analyze CD80 activity during infections and to do basic and applied research for poultry.

This project was funded by USDA-CSREES proposal 2005–01812 and carried out as part of the US Veterinary Immune Reagent Network, http://www.umass.edu/vetimm.

Key Words: chickens, CD80, monoclonal antibody

651 Suppressive properties of chicken CD25$^+$ cells during lipopolysaccharide injection. R. Shanmugasundaram[1,2] and R. K. Selvaraj*[1,2], [1]*Ohio Agricultural Research and Development Center*, *Wooster,* [2]*The Ohio State University*, *Wooster*.

Suppressive properties of splenic chicken CD25$^+$ cells were evaluated during in vivo lipopolysaccharide (LPS) injection. One-week-old chickens were injected with 0 or 100 μg of LPS/kg body weight. Spleen CD4+8–25+ cell percentage increased from 8% to 24% at 4 d post-LPS injection. Spleen CD4+8–25+ cell percentage decreased to 11% at 5 d post-LPS challenge, but remained greater than the 0 μg LPS control group until 12 d post-LPS injection. Suppressive properties of CD25$^+$ cells were determined by naïve cell proliferation suppression assay. At CD25$^+$:T responder cell ratio of 1:1, CD4+8–25+ cells collected at 5 and 12 d after 100μg LPS injection were suppressive while CD4+8–25+ cells collected at 2 d after 100 μg LPS injection were not suppressive. CD4+8–25+ cells collected at 5d after LPS injection had a greater suppressive potential in the 100 μg LPS group than CD4+8–25+ cells from the 0μg LPS group. At 5 d post LPS injection, CD4+8–25+ cells from 100 μg LPS injection were suppressive at CD25$^+$:T responder ratio of 0.25:1, while those from 0 μg LPS injection were suppressive only at Treg:T responder ratio of 1:1, but not at 0.25:1. It could be concluded that in vivo LPS treatment alters the suppressive properties of chicken CD25$^+$ cells.

Key Words: T regulatory, suppression, LPS

652 Expression profile of cytokines in cecal tonsils of broiler chicks challenged with *Clostridium perfringens*. Y. O. Fasina*[1], H. S. Lillehoj[2], M. S. Park[2], and D. E. Conner[1], [1]*Auburn University*, *Auburn, AL*, [2]*USDA-ARS-ANRI-APDL*, *Beltsville, MD*.

Necrotic enteritis is an economically important enteric disease of poultry that is caused by *Clostridium perfringens* (CP). Understanding the role of cytokines in modulating intestinal innate immune response to CP will facilitate the design of effective non-antibiotic control measures such as vaccines. An experiment was conducted to determine the effect of CP infection on the expression of selected T helper type 1 (Th1 - inflammation-inducing) and T helper type 2 (Th2 - antibody-inducing) cytokines in the cecal tonsils of broiler chicks. Chicks (400) obtained from a commercial hatchery were randomly assigned to 4 treatments. Treatment 1 (CX) consisted of chicks fed unmedicated corn-soybean meal (SBM) diet. Treatment 2 (MX) consisted of chicks fed corn-SBM basal into which bacitracin methylene disalicylate antibiotic was added at 0.055g/kg. Treatments 3 (PCX) and 4 (PMX) consisted of chicks fed diets similar to those given to CX and MX, respectively, and were additionally challenged with 3.5 mL of CP inoculum (10^8 CFU/mL) on d 14, 15, and 16 of experiment. At 1 and 7 d post-challenge, intestinal CP levels were estimated. Cecal tonsils were also collected and subjected to quantitative reverse transcriptase-polymerase chain reaction (qRT-PCR) to determine the expression levels of cytokine genes. From results, PCX and PCM (3.04 to 3.68 $\log_{10}$ CFU/mL) had higher CP levels ($P < 0.05$) compared with control CX and MX (1.12 to 1.70 $\log_{10}$ CFU/mL), thus confirming an established infection in PCX and PCM chicks. RT-PCR results showed upregulation of genes of several Th1/proinflammatory cytokines (interleukin [IL]-1β, IL-12, and lipopolysaccharide-induced TNF-associated factor], and to a lesser extent Th2 cytokines such as IL-13 in PCX and PCM ($P < 0.05$), compared with control CX and MX. There was no difference in anti-inflammatory IL-10 among treatments. It was concluded that cytokine response to CP infection in the cecal tonsil is more of a Th1 type which promotes cell-mediated immunity.

Key Words: *Clostridium perfringens*, cytokines, broiler chickens

653 Gel spray as a viable method to apply a coccidia vaccine to chickens. G. F. Mathis*[1], E. H. Lee[2], T. Cosstick[2], and B. Lumpkins[1], [1]*Southern Poultry Research, Inc.*, *Athens, GA,* [2]*Vetech Laboratories, Inc.*, *Guelph, Ontario, Canada*.

On day of hatch, chicks are routinely administered uniformly low doses of live coccidia oocysts to aid in the development of immunity against coccidiosis. Two studies were conducted to examine the novel approach of using a spray gel to orally deliver the oocysts to the chicks through mutual preening. In both studies, chicks were vaccinated with Immucox, a coccidia vaccine. In study 1, on d 21 chicks were individually weighed and challenged with field isolates of *Eimeria* (*E. acervulina* (EA), *E. maxima* (EM), *E. tenella* (ET), or *E. necatrix* (EN)). Individual bird weights and coccidia lesion scores were recorded on d 26 (6 d post challenge). EA, EM, ET, and EN lesion scores were significantly lower (greater than 1.5 score reduction for each species) and weight gain during the challenge period was significantly better than non-vaccinated challenged and equal to the non-vaccinated, non-challenged controls. Study 2 examined performance of non-vaccinated non-challenged, non-vaccinated challenged and Gel sprayed challenged. To represent a natural coccidiosis challenge, on d 28 all birds in the challenge groups were orally dosed with a mixture of EA, EM, and ET. Feed conversion and weight gain were determined on d 21 and at market weight (d 42). On d 21, weight gain was not significantly different among treatments. There was significantly higher feed conversion in the gel spray treatment birds than the non-vaccinated treatment birds. On d 42, gel spray treatment birds had significantly better feed conversion (1.859) and average live weight (1.985 kg) than non-vaccinated challenged (1.954 and 1.857 kg, respectively). However, the gel sprayed birds had significantly lower performance than the non-vaccinated non-challenged birds. Efficacy of the gel spray vaccination was indicated by the reduction in lesion scores and improvements in performance when compared with those of the non-vaccinated challenged control.

Key Words: coccidia, vaccine, chicken

654 A mixture of capsicum and turmeric oleoresins improve performance of vaccinated broilers challenged or not with coccidiosis. V. Brito*[1], C. Moynat[2], A. Casarin[3], M. Forat[3], and D. Bravo[2], [1]*Euronutec*, *Querétaro, Mexico*, [2]*Pancosma*, *Geneva, Switzerland*, [3]*Instituto Internacional de Investigacion Animal*, *Mexico*.

Capsicum (CA) and turmeric (TU) positively impact innate immunity. Their combination should improve performance of birds. Vaccines induce acquired immunity and are efficient in case of challenge. So combining CA, TU and vaccination should improve performance of birds infected by *Eimeria*. The objective was to evaluate the effect of a mixture of CA and TU oleoresins (PF = Proflora/XT 6986) on performance of vaccinated broilers challenged with coccidiosis, and non-challenged non-vaccinated birds. One-day-old broilers were allotted to the following treatments (48 birds × 10 cages/treatment), doses in ppm, with Bacitracin (BA), Nicarbazin (NI), Salinomycin (SA). T1b and T1a acted as positive controls either challenged or not (T1a = 125 NI + 55 BA from d1 to 28, 125 NI + 55 BA from d29 to 52; T1b = T1a + challenge to Eimeria spp. at d14). T2a tested the effect of PF on non vaccinated and non challenged birds (T2a = 50 PF from d1 to 42, 100 PF from d42 to 52). T2b tested the effect of PF on vaccinated and challenged birds (T2b = T2a + coccidiosis vaccine at d1 and challenge to *Eimeria* sp. at d14). BW, BWG and FCR were recorded. Data were analyzed using GLM procedure of SAS. Pre-challenge, T2a and T2b performed better ($P < 0.01$) than T1a and T1b for BWG (+8.2%), FCR (−5.5%) and BW at d14 (+6.9%), showing the positive effect of stimulating innate immunity on performance. T2a and T2b had similar ($P > 0.1$) BWG, FCR and BW, confirming that vaccination was not affecting performance without challenge. After d14, T2a and T2b exhibited same BWG, FCR and final BW ($P > 0.7$), as well as T1a and T1b ($P > 0.5$). This demonstrated that PF with vaccination can maintain the performance of challenged birds at the same level as non challenged birds. Finally, BW in T2a and T2b was 3.7% higher than in T1a and T1b ($P < 0.03$), suggesting that using PF during the whole growing period improved final BW of birds.

Key Words: essential oils, coccidiosis, vaccination

655 Cinnamaldehyde and a blend of capsicum and turmeric oleoresins improve performance of vaccinated broilers subject to coccidiosis. C. Moynat*[1], V. Brito[2], A. Casarin[3], M. Forat[3], and D. Bravo[1], [1]*Pancosma*, *Geneva, Switzerland*, [2]*Euronutec*, *Queretaro, Mexico*, [3]*Instituto Internacional de Investigacion Animal*, *Mexico*.

Cinnamaldehyde (CI), capsicum (CA) and turmeric (TU) positively impact innate immunity. The combination of these 3 products should positively affect immunity and improve performance of birds infected by *Eimeria*. The objective was to evaluate the effect of a mixture of CA and TU oleoresins (PF1 = Proflora / XT 6986) and a product with CI (PF2 = Proflora Plus / XT 6987) on performance of vaccinated broilers challenged with coccidiosis. Broilers vaccinated against coccidiosis at d 1 were allotted to 5 treatments and challenged at d 14 with *Eimeria* sp. (40 birds * 12 cages/treatment). The treatments were set as follow,

doses expressed in ppm, with Bacitracin (BA), Nicarbazin (NI), Salinomycin (SA): T1 = un-supplemented. For starter diet (d 1 to 14): T2 = 55 BA; T3 = 100 PF1; T4 = 100 PF1 + 10 PF2; T5 = 10 PF2. For grower diet (d 15 to 42): T2 = 55 BA + 50 NI + 30 SA; T3 = 100 PF1 + 50 NI + 30 SA; T4 = 100 PF1 + 5 PF2 + 30 SA; T5 = 100 PF1 + 10 PF2 + 30 SA. For finisher diet (d 43 to 52): T2 = 55 BA + 50 NI + 30 SA; T3 = 100 PF1 + 50 NI + 30 SA; T4 = 100 PF1 + 2.5 PF2 + 30 SA; T5 = 100 PF1 + 5 PF2 + 30 SA. BW, BWG and FCR were recorded. Data were analyzed using GLM procedure of SAS. Pre-challenge, there was no difference between treatments in BW, BWG, FCR ($P > 0.1$). Post-challenge, FCR of T1 was deteriorated (+4.3%, $P < 0.01$) showing the positive impact of supplementations on vaccinated birds subject to coccidiosis. No difference between supplementations was observed for FCR ($P > 0.1$). Final BW of T1 was lower ($P < 0.01$) than T2 (−4.2%), T3 (−4.8%) and T4 (−16.4%), and tended to be lower than T5 ($P = 0.08$). A higher inclusion of PF2 post-challenge is not beneficial for the supplementation program. These results show that a mixture of CA and TU oleoresins alone or combined with adequate doses of CI can be used with vaccination to maintain broiler performance.

Key Words: essential oils, cocciodiosis, vaccination

656 Ileal and cecal microbial populations and coccidia infection in broilers given probiotics and essential oil blends. M. E. Hume*[1], E. O. Oviedo-Rondón[2], N. A. Barbosa[2,3], N. K. Sakomura[3], M. C. Jenkins[4], and S. E. Dowd[5], [1]*USDA, ARS, FFSRU*, *College Station, TX*, [2]*Department of Poultry Science, North Carolina State University*, *Raleigh*, [3]*Universidade Estadual Paulista*, *UNESP-Jaboticabal, Brazil*, [4]*Animal Parasitic Diseases Laboratory, USDA, ARS*, *Beltsville, MD*, [5]*Research and Testing Laboratories, Medical Biofilm Research Institute*, *Lubbock, TX*.

A protective digestive microflora helps prevent and reduce broiler infection and colonization by enteropathogens. Some feed additives (FA) promote healthy and protective microbial populations (MP) and could be used as alternatives to antibiotic growth promoters. In the current experiment, broilers fed corn-soybean meal diets with inclusion of 5% DDGS and supplemented with essential oil (EO) blends and probiotics were infected with mixed *Eimeria* spp. to determine effects of these FA and *Eimeria* infection on ileal and cecal MP. The 8 treatments (Trt) included 4 controls: Uninfected-Unmedicated (UU), Unmedicated-Infected (UI), BMD+Coban as positive control (PC), and ionophore (Coban) as negative control (NC). The 4 Trt included FA: 2 probiotics, BC30, and Calsporin; and 2 EO, Crina POULTRY Plus (CPP) and Crina PoultryAF (CPF). Day-old male Ross broilers were raised to 14 d and inoculated at 15 d with *E. acervulina*, *E. maxima*, and *E. tenella*. Ileal and cecal samples were collected at 14 and 22 d (7 d post-infection). Digesta DNA was PCR-amplified at the 16S rDNA V3 region and analyzed by denaturing gradient gel electrophoresis (DGGE) to generate % similarity coefficients (%SC) on band pattern dendrograms. Coccidia infection, probiotic, and EO changed MP from those seen in UU ilea. Treatment with CPF greatly altered cecal MP. UU ilea MP had about 60%SC to those in other treatment groups. While CPF cecal MP at pre-challenge had 77.7%SC with other groups, there was a decreased to 54%SC at post-challenge. There were expected changes in pre- and post-challenge ileal and cecal MP, respectively, with CPF having the greatest treatment effect on digestive MP.

Key Words: coccidia, probiotic, essential oil

657 Effect of microbial-nutrition interaction on chicken immune system after the early administration of probiotic with organic acids in young chicks. J. C. Rodriguez-Lecompte*[1], J. Brady[1], G. Camelo-Jaimes[2], S. Sharif[3], G. Crow[1], G. O. Ramirez-Yañez[1], W. Guenter[1], and J. D. House[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*ADYZYME*, *Bogota, Cundinamarca, Colombia*, [3]*University of Guelph*, *Guelph, Ontario, Canada*.

The present study was conducted to characterize the effect of *Lactobacillus acidophilus*, *Streptococcus faecium*, and *Saccharomyces cerevisiae* and organic acids (e.g., sorbic acid and citric acid) on intestinal morphology, immunological parameters, and nutritional associated-genes. One-day old chicks were randomly allocated to one of 3 treatments: treatment 1 (T1) consisting of chicks not receiving either probiotic or organic acids; chicks in treatment 2 (T2) orally received probiotics and organic acids for 7 consecutive d; and treatment 3 (T3) chicks receiving probiotics and organic acids for 14 consecutive d. The study lasted 21 d. On d 11 and 21 (4 and 7 d after finishing T2 and T3 respectively), intestinal sections from duodenum (distal), jejunum (proximal to Meckel's diverticulum), ileum (proximal to ileo-cecal junction), and cecal tonsils were collected and analyzed by histology, reverse transcriptase-polymerase chain reaction (RT-PCR), and quantitative RT-PCR. T2 and T3 decreased ($P < 0.05$) villous height and width, crypt depth in the jejunum area during the first 7 d. At d 21, T3 affected increasing crypt depth and the number of goblet cells/mm2 in the jejunum and ileum area ($P < 0.05$). Regardless of the treatment at d 0, 11 and 21, there was only avian β-defensin (AvBD)3 mRNA expression in the crop, proventriculus, duodenum, jejunum, ileum, cecal tonsil and bursa; however, cathelicidin B1 was present in the bursa in all treatments after d 7. Interestingly, AvAng4 was not affected either by treatment or time. In the ileum area, only mRNA levels of interleukin (IL)-10 and IL-12 were affected by T2 and T3 at d 22 ($P < 0.05$). In cecal tonsils, IL-6 and IL-12 were affected by T2 and T3 at d 11 ($P < 0.05$); however, there was a significant downregulation of IL-12 and upregulation of interferon-γ at d 22 ($P < 0.05$). GHR and GHSR mRNA expression was detected in all the groups at d 11 and d 22. In conclusion, probiotic and organic acid effects on chick's intestine include triggering sensor molecules of the innate immune system, which may produce antimicrobial proteins and peptides.

Key Words: probiotic, defensin, cytokines

658 Probiotic, prebiotic and yeast supplementation in broiler diets from 1 to 42 days of age: 2. Immune response and slaughter traits. H. M. Safaa*[1], S. A. Riad[1], F. R. Mohamed[1], S. S. Siam[2], and H. A. El-Minshawy[3], [1]*Animal Production Department, Faculty of Agriculture, Cairo University*, *Giza 12613, Giza, Egypt*, [2]*Breeding Department, Animal Production Research Institute*, *Dokki, Giza, Egypt*, [3]*Ministry of Agriculture*, *Dokki, Giza, Egypt*.

A total of 630 Arbor Acres broiler chicks at one-day old was used to study the effect of probiotic, prebiotic and/or yeast supplementation on the immune response and slaughter traits. Chicks were divided randomly into 6 treatments and housed at deep litter in an open house system. The 6 treatments, each replicated 3 times (35 chicks/replicate), were as follows: T1 (control; chicks fed corn-soy basal diet), and the other treatments diets were supplemented with 1g probiotic/kg diet as *Lactobacillus acidophilus* (T2), 1g yeast/kg diet as *Saccharomyces cerevisiae* ($5x10^{12}$ CFU/g; T3), 1g prebiotic/kg diet as mannan-oligosaccharide (T4), 1g probiotic+1g prebiotic/kg diet (T5), or 1g yeast+1g prebiotic/kg diet (T6). Basal diet contained 23.1% CP and 3,103 kcal AME/kg for the starter diet (0–21 d) and 20.0% CP and 3,207 kcal AME/kg for the finisher diet (21–42 d). Results indicated that, all biological additives increased the total count of white blood cells, the antibody titer against sheep red blood cells and the relative weights of immune organs (bursa, spleen and thymus) at 42 d. However, heterophils/lymphocytes ratio was

not affected by any treatment. In addition, carcass, giblets and edible relative weights at 42 d of age were improved by using the biological feed additives. For all traits, the best values were obtained in T6 followed by T5. It could be recommended from this study to supplement the biological additives to broiler diet from 0 to 42 d of age as mentioned above because it improves the broiler immunity and slaughter traits.

Key Words: probiotic, prebiotic, yeast, broiler immune response, slaughter traits

659 Forage concentration and dried distillers grains with solubles in diets for lactating dairy cows. S. D. Ranathunga*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University*, *Brookings*.

The objective of this study was to investigate the effects of concentrations of forages and dried distillers grains with solubles (DDGS) on production of lactating dairy cows. Twelve Holstein cows were assigned randomly to replicated 4 × 4 Latin squares in a 2 × 2 factorial arrangement of treatments. Diets were formulated containing low forage (LF; 41% of diet DM) or high forage (HF; 60% of diet DM) and DDGS at 0 or 18% of diet DM. Forage consisted of 80% corn silage and 20% alfalfa hay (DM basis). Ground corn and soybean feeds were partially replaced by DDGS from 0% DDGS diets to formulate 18% DDGS diets. Average DMI was not affected by diets (Table 1). Milk yield was greater when cows were fed LF compared with HF regardless of the addition of DDGS (43.3 vs. 41.5 kg/d). Milk fat concentration (3.03 vs. 3.38%) were lesser for cows fed LF compared with HF, whereas protein concentration (3.11 vs. 2.98%) and yield (1.34 vs. 1.24 kg/d) were greater for cows fed LF compared with HF. Yields of fat, total solids (TS), and 4% fat-corrected milk (FCM) were not affected by diets. Cows fed HF had greater feed efficiency FCM/DMI) compared with cows fed LF (1.50 vs. 1.43). Overall, there were no interactions of forage and DDGS for any of the measures. Results suggest that the concentration of forage in diets influences the performance of cows, but not the addition of DDGS. Consequently, partially replacing starch from ground corn and protein from soybean feeds with DDGS at either 41 or 60% of forage in the diet did not affect the production of lactating dairy cows.

Table 1.

	Low forage		High forage			
Item	0DDGS	18DDGS	0DDGS	18DDGS	SE	Pa
DMI, kg/d	25.6	26.1	25.1	25.1	0.56	NS
Milk, kg/d	42.8	43.7	41.7	41.2	1.31	F
Fat, %	3.07	2.99	3.42	3.34	0.25	F
Protein, %	3.09	3.13	3.00	2.96	0.05	F
Fat, kg/d	1.30	1.30	1.43	1.37	0.08	NS
Protein, kg/d	1.32	1.36	1.25	1.22	0.04	F
TS, kg/d	5.17	5.26	5.12	4.96	0.15	NS
4% FCM, kg/d	36.6	37.0	38.1	37.0	1.32	NS
FCM/DMI	1.43	1.42	1.52	1.48	0.04	F

F = Forage effect ($P < 0.05$); NS = No significant effect of forage, DDGS levels, and forage*DDGS interaction.

Key Words: distillers grains, starch, forage

660 In vitro effects of *Escherichia coli* lipopolysaccharide on the function and gene expression of neutrophils isolated from the blood of dairy cows. X. S. Revelo* and M. R. Waldron, *University of Missouri*, *Columbia*.

The objective of this study was to investigate the effects of *Escherichia coli* lipopolysaccharide (LPS) on the function and gene expression of bovine neutrophils (PMNL). PMNL from midlactation cows (161 ± 15 d postpartum; n = 7) were incubated with 0, 1, 25 and 50 μg/mL of LPS for 120 min and the generation of reactive oxygen species (ROS), PMNL extracellular traps (NETs), chemotaxis and killing of *Staphylococcus aureus* were determined. Incubation with 25 μg/mL of LPS increased intracellular ROS by 79% in non-mitogen-stimulated PMNL whereas 50 μg/mL of LPS enhanced intracellular ROS in non-stimulated and stimulated PMNL by 184 and 145%, respectively. Non-stimulated PMNL incubated with 25 and 50 μg/mL of LPS both had a 105% increase in NETs. LPS had no effect on subsequent PMNL chemotaxis or killing of *S. aureus*. To examine the effect of LPS on the expression of genes involved in PMNL function, mRNA was purified from PMNL isolated from midlactation (143 ± 5.6 d postpartum; n = 5) and early lactation cows (7 ± 0 d postpartum; n = 5), after a 120-min incubation with 0 or 50 μg/mL of LPS. Amounts of interleukin-8 (IL-8), tumor necrosis-α (TNF-α), bactericidal/permeability-increasing protein (BPI), myeloperoxidase (MPO), superoxide dismutase (SOD), cytosolic NADPH oxidase (p67-phox), flavocytochrome *b* (p22-phox), histone H2A.1 (H2A.1) and histone H2B-like (H2B) mRNA were determined by real-time quantitative reverse transcription PCR. LPS increased IL-8, TNF-α and SOD mRNA expression in PMNL isolated from all cows (7.9, 21.5 and 2.1 fold change relative to β-actin, respectively) whereas only PMNL collected from midlactation cows had higher p67-phox and flavocytochrome mRNA expression when incubated with LPS (2.10 and 2.06 fold change relative to β-actin, respectively). LPS had no effect on MPO, H2A.1 and H2B mRNA levels. These results suggest that LPS primes the neutrophils toward enhanced immunity by increasing the generation of ROS and expression of NETs along with elevated expression of genes encoding inflammatory mediators and enzymes involved in the production of ROS.

Key Words: neutrophils, lipopolysaccharide, reactive oxygen species

661 Expression analysis of genes of sialic acid metabolism in transition and late lactation Holstein cows using microarrays and RNA sequencing. S. Wickramasinghe*, S. Hua, G. Rincon, A. Islas-Trejo, C. B. Lebrilla, and J. F. Medrano, *University of California, Davis*.

Recent studies on sialylated milk oligosaccharides demonstrated beneficial effects to the suckling neonate. However, the concentrations of sialylated oligosaccharides are low in cow milk and it is important to identify a genetic strategy to optimize the content of sialylated oligosaccharides because cow milk based formula is the first choice as a substitute for human breast milk. The objective of this project was to identify and characterize the genes involved in sialic acid (Sia) metabolic pathways in milk in transition and late lactation cows. Expression analysis of genes in Sia metabolism was conducted by microarrays and RNA-sequencing (RNaseq) in milk cell samples collected from Holstein cows. Gene expression results from microarrays and RNaseq were in good agreement. However, RNaseq offered a larger dynamic range and provided a detailed characterization of genes by identifying alternative splice forms and abundant single nucleotide polymorphisms. Twenty genes in Sia metabolic pathway had low or medium levels of expression in milk and were categorized as genes involved in Sia synthesis, conjugation, transport and breakdown. Eighteen genes showed increased levels of expression in late lactation. ST8SIA1 which regulates synthesis of GD3, the most abundant ganglioside in early lactation showed a higher expression in transition milk, and ST35Gal5 that regulates synthesis of GM3, a prominent ganglioside in late lactation, had high expression in late lactation milk. Among the genes in conjugation, α-2,3-sialyltransferases showed higher levels of expression at the 2 stages of lactation than α-2,6-sialyltransferases, that is characteristically more active in human milk. Sialidases and Sia transporters showed a higher activity in late lactation milk indicating an increase in synthesis and breakdown of sialylconjugates in late lactation. These findings agree with published research on bovine milk oligosaccharide profiles and

variation in type and amount of sialylconjugates, and provide a detailed characterization of the expression of genes determining oligosaccharide content in cow′ milk.

Key Words: milk, sialic acid, gene expression

662 Incidence and risk factors of bovine respiratory disease in dairy heifer calves in Ontario and Minnesota. C. Windeyer*[1], S. J. LeBlanc[1], K. D. Lissemore[1], D. C. Hodgins[1], S. M. Godden[2], and K. E. Leslie[1], [1]*University of Guelph*, *Guelph, ON, Canada*, [2]*University of Minnesota*, *St Paul*.

Bovine respiratory disease (BRD) during calfhood has substantial impacts on the growth, survival and profitability of replacement heifers. One objective of this study was to evaluate risk factors for BRD in dairy heifers until 4 mo of age. A total of 2882 heifer calves from 15 herds in Ontario and 4 herds in Minnesota were examined at 1–7, 15–21, 35–42, and 84–112 d of age. Height, weight and body temperature were measured and health scores assigned using a standardized system. Serum total protein was assessed to evaluate passive transfer, with values less 5.2 g/dL considered failure of passive transfer (FPT). Farm personnel maintained birth, treatment and death records. Mortality was 2.9% overall (4.4% in Ontario and 1.5% in Minnesota) with herd mortality risk ranging from 0 to 9.5%. FPT occurred in 11.3% of calves, but varied by farm (0 to 53.5%). In Ontario, 19.1% of calves had FPT compared with 4.1% of calves from the herds in Minnesota. Overall, 19.4% of calves were treated for BRD (range: 0 to 36.7%). Mean age at first diagnosis was 33 d. Similar proportions of calves were treated for BRD in Ontario (21.9%) and Minnesota (17.1%). Significant risk factors as determined by a generalized linear mixed model for BRD were FPT, season of birth and assistance at calving, controlling for clustering by farm. Calves with FPT had 1.9 times (CI: 1.4–2.7) the odds of BRD compared with calves with successful passive transfer. Odds ratios of BRD for calves born in winter versus fall and summer, and spring versus summer were 2.1 (CI: 1.2–3.5), 2.7 (CI: 1.7–4.2), 2.1 (CI: 1.5–3.0), respectively. Assistance at calving increased a calf's odds of BRD 1.6 times (CI: 1.0–2.7). FPT, season of birth and assistance at calving significantly affect the odds of BRD. The age of onset of BRD may be earlier than traditionally expected. The variation by farm in FPT, incidence of BRD and mortality warrants further investigation.

Key Words: calf, respiratory disease, passive transfer

663 Effect of antibiotic treatment at post-weaning movement and BRD on growth at multiple time points in commercial dairy calves. A. L. Stanton*[1], S. J. LeBlanc[1], D. Kelton[1], S. T. Millman[2], J. Wormuth[3], and K. E. Leslie[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Iowa State University*, *Ames,* [3]*CY Heifer Farm*, *Elba, NY*.

Bovine respiratory disease (BRD) is common following weaning and movement of calves from individual to group housing. The objective was to evaluate the effects of single injection of tulathromycin administered at post-weaning grouping of calves, and the effect of BRD in the 60 d following grouping on the growth of dairy calves at multiple time points. The study was conducted at a custom heifer raising facility in New York State. 1,367 weaned dairy calves were randomly assigned to receive either tulathromycin (TUL) or oxytetracycline (TET), once at the time of first movement to group housing. The incidence of BRD was 8% and 13% in the TUL and TET groups. A total of 248 heifers were identified and treated for BRD in the 60 d following movement. Post-weaning BRD events were recorded by trained barn staff. Weights and heights were measured at strategic points throughout the growing period based on movement through the facility. On average, calves were 56 d of age at enrollment and were re-weighed at 98, 180, 271 and 381 d of age. The effect of BRD and experimental treatment on the ADG of calves that were retained in the herd (n = 1,271) was evaluated between each time period using a mixed model, controlling for source farm and enrollment cohort. Between 56 and 98 days of age, TUL calves had an ADG of 0.90 ± 0.02 kg/day compared to TET calves with an ADG of 0.82 ± 0.02 kg/day ($P < 0.001$). After 98 days of age, there was no difference in ADG. However, the initial advantage in ADG resulted in TUL calves weighing 3.7 kg more than TET calves at 180 days ($P < 0.05$). Calves with BRD in the 60 days following enrollment gained 0.15 ± 0.02, 0.06 ± 0.01 and 0.03 ± 0.01 kg/day less than non-BRD calves between 56 and 98, 98 and 180, and 180 and 270 days of age, respectively. BRD did not have a significant effect on ADG after 270 days of age. At 381days of age BRD calves weighed 18kg less than non-BRD calves ($P < 0.001$).
In this population of calves, who remained in the herd for over a year, BRD in the 60 days following first movement to group housing continued to affect the ADG until 9 months of age.

Key Words: respiratory disease, dairy heifers, tulathromycin

664 Effects of glucose and essential amino acids on phosphorylation of signaling proteins for protein synthesis in bovine mammary epithelial cells. J. A. D. R. N. Appuhamy*[1], J. Escobar[2], and M. D. Hanigan[1], [1]*Department of Dairy Science, Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University*, *Blacksburg*.

Protein synthesis responds to nutrient signals such as amino acids and energy supply which involve AMP-activated protein kinase (AMPK), tuberous sclerosis complex 2 (TSC2), mammalian target of rapamycine (mTOR), ribosomal protein S6 (rpS6), and eukaryotic elongation factor 2 (eEF2). Increasing phosphorylation (PhS) of AMPK, TSC2, and eEF2 impair protein synthesis while increasing PhS of mTOR and rpS6 stimulate it. Our objective was to investigate the individual and interactive effects of essential amino acids (EAA) and glucose on PhS of AMPK, TSC2, eEF2, mTOR and rpS6 in MAC-T cells. Cells were deprived of serum, EAA, and glucose overnight and then incubated in complete or EAA-deprived DMEM/F12 with and without glucose (3.51 g/L) in a 2 × 2 factorial design for 1 h. Cell lysates were subjected to Western immunoblotting with antibodies against total and phosphorylated mTOR (Ser2448), rpS6 (Ser235/236), eEF2 (Thr56), AMPK (Thr172), and TSC2 (Thr1462). The PhS of each signaling protein was determined as a ratio of the phosphorylated to total forms. Glucose and EAA deprivations increased ($P < 0.10$) PhS of TSC2 (47 and 85%) and AMPK (29 and 28%), and reduced ($P < 0.01$) PhS of rpS6 (31 and 58%). Deprivation of EAA alone reduced ($P = 0.02$) PhS of mTOR by 31% and increased ($P = 0.01$) PhS of eEF2 by 20%. Interactive effects between glucose and EAA for PhS of AMPK, TSC2, and eEF2 were significant ($P < 0.06$) but that for mTOR and rpS6 were non-significant ($P > 0.51$). Glucose and EAA availability appear to synergistically modulate PhS of AMPK, TSC2 and eEF2. Regulation of rpS6 by EAA appears to be mediated by mTOR (Ser2448), but regulation by glucose occurred through an alternative mechanism in MAC-T cells. The effects of EAA on mTOR and rpS6 and the effects of glucose on rpS6 are supportive of independent effects of energy and EAA on protein synthesis.

Key Words: energy, amino acid, cellular signal

665 Prevention of *Mycobacterium avium* ssp. *paratuberculosis* (MAP) infection in Balb/c mice by feeding probiotic *Lactobacillus acidophilus* NP-51. M. A. Osman*[1], J. R. Stabel[2], J. M. Hostetter[3], D. S Nettleton[4], and D. C. Beitz1,5, [1]*Department of Animal Science, Iowa State University*, *Ames,* [2]*US Department of Agriculture, ARS, National Animal Disease Center*, *Ames, IA,* [3]*Department of Veterinary Pathology, Iowa State University*, *Ames,* [4]*Department of Statistics, Iowa State University*, *Ames,* [5]*Department of Biochemistry, Biophysics, and Molecular Biology, Iowa State University*, *Ames*.

The objective of this study was to examine effects of feeding *Lactobacillus acidophilus* strain NP51 to mice challenged with *Mycobacterium avium* ssp. *paratuberculosis* (MAP), the causative agent of Johne's disease. We hypothesized that feeding NP51 would increase Th-1 responses and decrease progression of MAP infection in mice. Thus, Balb/c mice were randomized to treatment groups in a factorial design including mice either fed heat-killed or viable NP51and challenged with either heat-killed or viable MAP. Mice were fed 1×10^6 CFU of either heat-killed or viable NP51·mice^{-1}·day^{-1} along with normal mouse chow until the end of the study. On d 45, mice were challenged with 1×10^8 CFU of heat-killed or viable MAP injected intraperitoneally. Ten mice from each group were killed on d 45, 90, 135, and 180. At each sampling period, tissues were excised from mice and cultured for MAP. Splenocytes were cultured in vitro with either MAP antigen or concanavalin A and examined for proliferation of T cells subpopulations. Overall, feeding NP51 to mice (either heat-killed or viable) significantly increased the frequency of CD8+ cytotoxic T cells in spleens of mice infected with viable MAP. Most importantly, MAP burden was decreased in the mesenteric lymph nodes, livers, and spleens of mice fed the NP51 compared with the MAP-infected controls on d 135. These results suggest that feeding NP51 modifies the immune responses and prevents progression of MAP infection in Balb/c in mice.

Supported in part by the Nutrition Physiology Corp.

Key Words: MAP, Johne's disease, *Lactobacillus acidophilus*

666 Effects of varying DCAD and Na:K on production, rumen and urine parameters in lactating dairy cows. K. E. Cowles* and M. R. Murphy, *University of Illinois*, *Urbana*.

Six multiparous Holstein cows, fitted with rumen cannulas, averaging 122 ± 31 d in milk were randomly assigned to 6 treatments allocated in an equiradial (pentagonal) second-order response surface design with a center point to examine the effects of dietary cation-anion difference (DCAD) and Na:K on lactating dairy cows. Replication of treatments within a 6 × 6 Latin square minimized the potential effects of outliers and allowed a surface covering a 3 × 3 matrix of DCAD and Na:K combinations to be examined. Ranges in DCAD and Na:K were chosen to be equally spaced on logarithmic scales; tripling each time from 0.25 for the former, and 1.5-fold each time from 25 mEq/100 g DM for the latter. The response surface was centered on a molar Na:K of 0.75 (0.60% Na and 1.37% K in DM) and a DCAD of 37.5 mEq/100 g of DM. The other 5 treatments were: 1.63, 50.0 (Na:K, DCAD); 0.46, 53.8; 0.25, 35.2; 0.63, 25.1; and 2.00, 31.2. Percentages of Na and K in DM of the TMR for vertices of the pentagon were calculated as 1.05, 1.10; 0.56, 2.08; 0.27, 1.84; 0.44, 1.17; and 0.84, 0.72. Diets were based on corn silage and corn-based grain mix. The Na:K ratios were varied with $NaHCO_3$ and K_2CO_3. Periods were 14 d. Daily feed intake of each cow was recorded during each period; samples of feed and orts were collected daily. Milk production was measured daily; samples were collected weekly and analyzed for components. Rumen and urine samples were collected and analyzed for pH on the last 3 d of each period. The MIXED procedure of SAS was used for ANOVA. There were no response surface effects of treatment on milk production and components, and DMI ($P < 0.05$). A linear relationship ($r^2 = 0.15$, $P < 0.022$) between mean rumen pH and mean urine was found. A quadratic effect of Na:K ($P < 0.01$) and interaction of DCAD ($P < 0.003$) indicated that urine pH was maximal (8.24 or above) at high DCAD and low Na:K. Linear ($P < 0.05$) and quadratic effects ($P < 0.05$) of DCAD on rumen pH were indicated. In conclusion, relationships exist among rumen pH and urine pH. Urine pH was maximized when diets had high DCAD and low Na:K. Rumen pH responded quadratically to DCAD.

Key Words: DCAD, rumen pH, urine pH

667 Increased AME and growth performance in broiler chicks fed a high DDGS diet supplemented with a mixture of NSPase. H. B. Lee*, K. L. Price, M. D. Utt, and J. Escobar, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

High-fiber content of distillers dried grains with soluble (DDGS) is partially responsible for its low ME, which may be increased with dietary inclusion of non-starch polysaccharidase (NSPase). Broiler chicks (7-d-old, 6 chicks/pen, 6–7 pens/diet) were randomly allotted to 4 treatments with free access to feed and water. Corn and DDGS (20%) diets were supplemented or not with a proprietary mixture of NSPase. DDGS diets were formulated to be deficient only in ME (90% of corn diets). In wk 2, average weekly weight gain (AWG), gain:feed, and apparent ME (AME) of the chicks receiving corn diets were higher ($P < 0.001$) than DDGS diets. DDGS+NSPase increased ($P < 0.08$) AME by 9.4% but had no effect on AWG. In wk 3, AWG and gain:feed were higher ($P < 0.001$) in chicks receiving corn diets compared with DDGS diets. NSPase inclusion improved ($P < 0.04$) AWG in both corn (312 vs. 338 g) and DDGS (262 vs. 283 g) diets. DDGS+NSPase increased ($P < 0.007$) AME by 11.7%, which made this diet comparable in energy to both corn diets. However, AWG of chicks fed DDGS+NSPase was lower ($P < 0.005$) than chicks eating the corn diets, regardless of NSPase inclusion. The main effect of NSPase inclusion during the 2-wk assay was an increase in standardized ileal digestibility (SID) of all amino acids ($P < 0.003$). Overall energy restriction reduced SID of Pro, Leu, Phe, and Ala ($P < 0.05$). Regardless of diet, age increased ($P < 0.05$) amino acid SID except for Ser, His, Thr, Val, and Ala. Results indicate the ability of a mixture of NSPase to increase AME of ME-deficient diets containing 20% DDGS. Further, a lag in AWG response at equal AME suggests a metabolic adaptation in birds to the use the reducing sugars freed by NSPase for growth.

Key Words: non-starch polysaccharidase, apparent metabolizabe energy, amino acid standardized ileal digestibility

668 Effects of heat treating soybean meal and DDGS on ileal amino acid digestibility in broilers. A. Helmbrecht*[1], H. Kluth[2], A. Lemme[1], M. S. Redshaw[1], and M. Rodehutscord[3], [1]*Evonik Degussa GmbH*, *Hanau, Germany*, [2]*University Halle-Wittenberg*, *Halle-Wittenberg, Germany*, [3]*University Hohenheim*, *Stuttgart, Germany*.

The objective was to study effects of extreme feed conditioning on ileal amino acid (AA) digestibility of protein sources in broilers. Soybean meal (SBM) and corn DDGS were subjected to heat (135°C) in combination with steam in an autoclave system for 20 or 40 min. Each of the untreated and treated ingredients was included at 0, 10 or 20% into a basal diet at the expense of corn starch. Ileal AA digestibility both of SBM and of DDGS were finally calculated by linear regression analysis resulting in digestibility coefficients which are independent of endogenous losses. Ileal AA digestibility was studied in 2 experiments utilizing 3-week-old broilers and using TiO_2 as the indigestible marker. Each dietary treatment was allocated to 6 pens of 10 birds each. Feeds and water were offered for ad libitum intake for 5 d. For SBM, the 20-min heat treatment caused a significant reduction in digestibility of all AA, and the 40-min treatment caused a further significant reduction in digestibility for 6 out of 17 AA studied ($P < 0.001$). Mean digestibility of Arg, His, Ile, Leu, Lys, Met, Phe, Thr, Trp and Val wa reduced from 82% (control) to 68% (20 min) and 62% (40 min). For DDGS the treatment effects were not as great as for SBM. However, the mean digestibility of the aforementioned AA was 85% (control), 80% (20 min) and 79% (40 min). The effect of 20-min treatment of DDGS was significant for 11 out of 17 AA studied ($P < 0.001$). It was concluded that extreme conditions in feed conditioning will reduce AA digestibility greatly. The magnitude of the effect depends on the origin of the protein in the diet.

Key Words: amino acid digestibility, broiler, heat treatment

669 High dietary inclusion of dried distillers grains with solubles in broiler chick rations in combination with AllzymeSSF enzyme—Effects on yield and endogenous enzyme levels. M. K. Masa'deh*[1], C. A. Fassbinder-Orth[2], and S. E. Scheideler[1], [1]*University of Nebraska-Lincoln*, *Lincoln,* [2]*Creighton University*, *Omaha, NE*.

A study was conducted to test the effects of feeding high levels of dried distillers grains with solubles (DDGS) in combination with AllzymeSSF enzyme on production parameters and endogenous enzyme activity in broiler chicks. 480 d-old broiler chicks were divided into 8 diets (15 chicks per pen) with 4 replicate pens from day-old to 43 d. Chicks were fed 4 DDGS levels (0, 10.0, 20.0, or 30.0%) and 2 levels of the enzyme AllzymeSSF (0, or 0.02%) having activities of phytase, protease, pentosanase, pectinase, cellulase, beta-glucanase, and amylase in 4 × 2 factorial design. All diets were formulated to be isocaloric and isonitrogenous with the enzyme treatments replacing 75 kcal/kg ME, 0.1% Ca, and 0.1 P. All diets were fed a phase-feeding program, starter (0–15 d), grower (15–30 d), and finisher (30–43 d). At 43 d, 2 birds per pen were selected for yield %, parts yields and enzyme activities of amylase, maltase, aminopeptidase, trypsin and chymotrypsin from intestinal and pancreatic tissues. The dietary enzyme by DDGS interaction was not different ($P > 0.05$) for production parameters, mortality, yield % and tissue enzyme activities. Percent carcass yield ($P > 0.05$) was no different between treatments. Parts yield were not affected ($P > 0.05$) by dietary treatments except for breast yield as a % of carcass wt ($P < 0.05$) with the highest yield for broiler fed 10% DDGS. Endogenous enzyme activity levels in the intestine and pancreas were not different ($P > 0.05$) between DDGS levels. However, AllzymeSSF enzyme increased endogenous amylase activity ($P < 0.1$) in the enzyme treatments compared with non-enzyme treatment. In summary, feeding DDGS at higher levels, up to 30% in combination with AllzymeSSF enzyme, did not negatively affect production parameters or % yield compared with the basal diet. Exogenous enzyme supplementation appears to positively influence endogenous enzyme activity. Feeding DDGS at 30% had an economical benefit on average of $60/ton compare with the basal diet (0% DDGS). In addition, feeding the AllzymeSSF enzyme has an economical benefit of $14/ton.

Key Words: DDGS, AllzymeSSF, amylase

670 Effect of exogenous enzyme supplementation on performance and carcass characteristics of broilers fed distillers dried grains with solubles (DDGS). B. Jung*[1], A. B. Batal[1], and R. Mitchell[2], [1]*University of Georgia*, *Athens,* [2]*Perdue Farms, Inc.*, *Salisbury, MD*.

An experiment was conducted to determine the effect of supplementing with exogenous enzymes on performance, gastrointestinal tract weights and carcass characteristics of broilers fed diets containing distillers dried grains with soluble (DDGS). In a 3 × 2 factorial design 1,920 one-day-old male Heritage broilers were randomly assigned to the 6 dietary treatments; Corn-soybean meal (SBM), Corn-SBM + Hemicell, Corn-SBM + Avizyme 1510, 12% DDGS, 12% DDGS+ Hemicell, and 12% DDGS+

Avizyme 1510. Eight replicate pens containing 40 chicks were fed each experimental diet from 0 to 50 d of age. The diets were formulated to be isocaloric and isonitrogenous and to meet the bird′s digestible amino acid requirements. Performance was evaluated at 14, 21, 36 and 50 d of age, gastrointestinal tract weights were measured at 21 and 50 d of age, and carcass characteristics were measured at 51 d of age. From 0 to 36 d of age the inclusion of 12% DDGS in the diets decreased ($P < 0.05$) BW gain and feed efficiency (gain: feed). The supplementation of enzymes (Hemicell and Avyzime) to the corn-SBM and 12% DDGS diets increased ($P < 0.05$) BW gain and feed efficiency. The birds fed the diets with DDGS had significant heavier ($P < 0.05$) relative proventriculus and small intestinal weights, but the supplementation with enzymes did not affect the relative gastrointestinal tract weights at 21 d of age. There was no interaction between DDGS and enzymes on performance and gastrointestinal tract weights. The carcass data are being conducted. Careful consideration should be given when 12% DDGS is fed to broilers due to negative effects on performance and the addition of enzymes to the DDGS diets may overcome this negative effect.

Key Words: distillers dried grains with solubles (DDGS), broilers, performance

671 Effects of varying levels of DDGS on broiler growth and intestinal content characteristics at 28 days post-hatch. R. E. Loar II*, J. R. Donaldson, and A. Corzo, *Mississippi State University*, *MS*.

A study comprised as a factorial arrangement of treatments consisted of a starter (0 vs. 8%) and grower (0, 7.5, 15, 22.5, 30%) feed phases with various DDGS inclusion levels that served as the factors evaluated. 1,350 Ross × Ross 708 male chicks were placed in floor pens (15 birds/pen) and randomly assigned to a starter phase diet from placement until 14 d of age, and subsequently a grower phase diet (14–28 d). Birds were collectively weighed at d 0, 14 and 28 d. Feed consumption and mortality were monitored throughout the study. At the conclusion of the grower phase, the cecal contents from one randomly selected bird were analyzed for *Clostridium perfringens* and *Escherichia coli* growth through both selective media and real-time PCR. Two additional birds were randomly selected from each pen, their liver weights determined, and their ileal contents measured for viscosity. Our results indicated that DDGS levels had no effects during the starter phase. Birds exhibited a linear decrease in BW gain ($P < 0.0001$) and liver relative weight ($P < 0.0004$) as dietary DDGS were increased in the grower phase. Feed conversion and mortality were unaffected by DDGS grower phase level. A DDGS starter × grower phase interaction ($P < 0.05$) was observed for feed consumption during the grower phase, where birds that consumed no DDGS during the starter phase exhibited a decrease in feed consumption at 22.5 and 30%, while birds that received 8% DDGS during the starter phase were unaffected by DDGS during the grower phase. Broilers were unaffected by DDGS grower phase levels for ileal viscosity, and cecal *C. perfringens* and *E. coli* concentrations. Results from this study suggest that young broilers remain susceptible to high levels of DDGS inclusion during the 14 to 28 d feeding period.

Key Words: DDGS, broiler, PCR

672 Effect of distillers dried grains with solubles and enzyme supplementation on production performance and egg quality of laying hens through 36 weeks of egg production. P. Rossi*, A. J. Pescatore, A. H. Cantor, J. L. Pierce, T. Ao, L. M. Macalintal, M. J. Ford, W. D. King, and H. D. Gillespie, *Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington*

The effects of diets containing 15 or 23% distillers dried grains with solubles (DDGS) with and without a naturally occurring enzyme complex (Allzyme SSF, Alltech Inc., Nicholasville, KY) on performance and egg quality of laying hens was evaluated during 36 weeks of production. At 17 weeks of age, 420 Hy-Line W-36 hens were randomly assigned to 5 treatments with 7 replicate groups of 12 hens each. Treatments consisted of feeding the following diets: 1) positive control (corn-soybean meal), 2) 15% DDGS, 3) 15% DDGS + enzymes, 4) 23% DDGS, and 5) 23% DDGS + enzymes. Diets containing DDGS had reduced levels of ME (2800 vs. 2877 Kcal/kg), Ca (4.1 vs. 4.2%) and available P (0.17% for 15% DDGS or 0.2% for 23% DDGS vs. 0.29%), compared with the control diet. Six eggs were randomly collected from each replicate every 4 weeks to determine egg quality. Feed intake was significantly ($P < 0.05$) decreased by DDGS during wk 9–12, 17–20 and 25–28. During the 36 weeks of production Allzyme SSF reduced feed intake by 2.6 g/hen/d. Hen-day production was lower for DDGS + enzymes during wk 29–32. There was no effect of treatments on feed efficiency. Egg weight at wk 8, 12, 16 and 20 and shell weight at wk 12 were decreased by 23% DDGS. The diet with 15% DDGS + enzymes increased yolk weight at wk 12 and 16 and % yolk at wk 16. Albumen weight was significantly increased by 15% DDGS at wk 8 and 16. Hens fed 15 or 23% DDGS +/− enzymes, had lower yolk lightness (L*) vs. hens fed the control diet. Hens fed 23% DDGS had higher yolk redness (a*) and yellowness (b*) values vs. hens fed 15% DDGS or the control diet, indicating a darker yolk color. The current study suggests that DDGS can be included in the diet up to 23% with minimal effects on performance and egg quality and can be used to improve yolk color. Using Allzyme SSF in DDGS diets with lower nutrient density can reduce feed intake. Feeding diets with 15% DDGS plus Allzyme SSF increased yolk weight and percent yolk.

Key Words: DDGS, yolk color, egg quality

673 Effects of high concentrations of distillers dried grains with solubles on long-term laying hen performance. J. Green*, D. U. Ahn, and M. E. Persia, *Iowa State University*, *Ames*.

A 28-week study was conducted with 240 Hy-Line W-36 laying hens to investigate the effects of long-term feeding of high concentrations of corn distillers dried grain with solubles (DDGS) on hen performance (egg production, feed intake). The experimental treatments consisted of 10 replicate groups of 6 hens housed in 2 hens per cage in 3 consecutive cages. The 4 dietary treatments consisted of increasing percentage of DDGS (0, 17%, 35%, and 50%) formulated into a corn-soybean meal (SBM) based diet. The DDGS were obtained from a local ethanol plant and all diets were formulated to be isocaloric and to meet or exceed industry based nutrient requirements. Crude protein content of the diets was allowed to increase with increasing dietary concentrations of DDGS. Hens were secured from a local commercial facility at 72 weeks of age after having gone through a molt period. Hens were started on 12 h of light with a half-hour increase weekly until hens reached 16 h of light daily. Hens were fed corn-SBM diets for 2 weeks before being stair-stepped up to 50% DDGS diets after a 2-week adjustment period to higher DDGS diets. Egg production and mortality data were collected and recorded daily, feed intake and egg production were analyzed weekly, while body weight gain was determined monthly. After 24 of 28 weeks on the 0, 17, 35 and 50% DDGS diets, total egg production was 89.2, 84.0, 86.8 and 63.5%, respectively. Feed intake for this period mirrored egg production at 104.1, 101.7, 105.4, and 91.6 g of feed intake per hen per day for the 0, 17, 35 and 50% DDGS diets, respectively. The reduction in feed intake and egg production with the 50% DDGS diet is most likely due to a methionine deficiency. Longer

term laying hen performance is possible with diets formulated to contain higher concentrations of dietary DDGS, but care must be taken to ensure adequate amino acid utilization when including this highly variable feed ingredient into laying hen diets.

Key Words: laying hen, DDGS, egg production

674 Effects of high concentrations of dried distillers grains with solubles on intestinal structure and nutrient and endotoxin transport of laying hens. K Gudenkauf*, M Jeffrey, N. K Gabler, D. U Ahn, and M. E Persia, *Iowa State University*, *Ames*.

The objective of this research is to determine the effects of high concentrations of dried distillers grains with soluble (DDGS) on nutrient and endotoxin transport of laying hens. Second-cycle laying hens were fed corn-soybean meal based diets containing either 0 or 50% DDGS for one month. Both diets were formulated to meet minimum total amino acid requirements regardless of crude protein content and equal energy concentrations. Eight hens per dietary treatment were sacrificed and intestinal tissue samples were collected from the duodenum loop (duodenum) and the midpoint between Meckel's diverticulum and the ilio-cecal junction (ileum). Fresh segments of ileum were collected and mounted in modified Ussing chambers to measure mucosal to serosal glucose, glutamine, phosphate, lysine, and methionine (met) transport rates. The changes in electro-physiology for each tissue were calculated after each nutrient challenge. Furthermore, permeability and tight junction integrity were also assessed by measuring the transepithelial electrical resistance (TEER). Statistical analysis was carried out using ANOVA. In general, nutrient transport was unaltered by diet although met transport rate tended to be increased by the 50% DDGS diet (P = 0.10), likely due to met deficiency in the 50% DDGS diet. No differences were noted in TEER. Lastly, ileal and colon samples were also mounted in modified Ussing chambers and mucosal to serosal endotoxin transport rates were determined using fluorescein isothiocyanate labeled lipopolysaccharide. The diet did not alter ileum endotoxin transport, but the 50% DDGS diets resulted in a significant decrease in colon endotoxin transport ($P \leq 0.05$). These data may indicate that the increased fiber in the DDGS diet is stimulating colon health resulting in decreased endotoxin transport.

Key Words: DDGS, laying hen, endotoxin transport

675 Effects of extruding DDGS at high and low temperatures on nutritional value of diets for nursery pigs. S. M. Williams*, J. D. Hancock, S. Issa, C. B. Paulk, and T. L. Gugle, *Kansas State University*, *Manhattan*.

A total of 224 nursery pigs (112 barrows and 112 gilts with an average initial BW of 8.4 kg) were used in a 21-d experiment to determine the effects of extrusion processing on the nutritional value of DDGS. The pigs were weaned, blocked by weight, and allotted by sex and ancestry with 7 pigs/pen and 8 pens/treatment. All pigs were fed a common diet for 11 d post weaning and the experimental treatments for the next 21 d. Treatments were a corn-soybean meal-based control and 3 diets formulated with 30% DDGS. For the DDGS treatments, the DDGS were not extruded, extruded with the barrel configured for processing cereal grain (to generate less shear and temperature rise), and extruded with the barrel configured for processing soybeans (to generate more shear and temperature rise). Orthogonal contrasts were used to separate treatment means with comparisons of: 1) the control vs. DDGS treatments; 2) untreated DDGS vs. extruded DDGS; and 3) low shear vs. high shear extrusion of the DDGS. For d 0 to 21, ADG and ADFI were greater for pigs fed the corn-soy control compared with pigs fed the DDGS treatments ($P < 0.02$). Extruding the DDGS did not affect ADG or G:F ($P > 0.11$) and there were no differences in growth performance among pigs fed the DDGS extruded with low- vs. high shear ($P > 0.2$). Overall, ADG was 526, 507, 472, and 493 g/d, ADFI was 784, 741, 682, and 707 g/d, and G:F was 671, 684, 692, and 697 g/kg. Our results indicate that feeding nursery pigs diets with 30% DDGS decreased ADG and ADFI with no affect on G:F. Extruding the DDGS did not ameliorate this loss in performance in nursery pigs.

Key Words: nursery pigs, DDGS, extrusion

676 Belly firmness and bacon quality from finishing pigs fed DDGS with various withdrawal times and with added tallow. M. C. Ulery*[1], G. L. Cromwell[1], G. Rentfrow[1], M. D. Lindemann[1], and M. J. Azain[2], [1]*University of Kentucky*, *Lexington,* [2]*University of Georgia*, *Athens*.

An experiment involving 168 pigs (6 reps of 3 or 5 pigs/pen) was conducted to evaluate belly firmness and bacon quality of pigs fed a high level of DDGS followed by varying withdrawal periods before slaughter, and to see if adding a more saturated fat (tallow) to diets containing DDGS would alter belly firmness and bacon quality. Treatments (Trt) were (1) a corn-soy diet or (2) a diet with 45% DDGS fed to term (121 kg) or removed during the final 2, 4, or 6 wk (Trt 3, 4, 5). Trt 6 and 7 were the same as 1 and 2 except 5% tallow was added. Belly flex measures (Abstr. 159, Midwest Section ASAS, 2010) indicated that bellies were softer in pigs fed DDGS, but firmness increased linearly ($P < 0.01$) with increased withdrawal time; tallow addition did not improve firmness. Backfat (inner and outer) and belly fat were analyzed for FA. PUFA (mean of the 3 fat depots) increased when DDGS was fed ($P < 0.01$), and the changes were moderated (linear, $P < 0.01$) with DDGS withdrawal time (Trt 1–5: 12.6, 24.9, 21.6, 18.8, 17.0% of total FA). Iodine values (IV) followed similar trends (62.0, 78.2, 74.1, 69.7, 67.7). Tallow addition had little effect on PUFA (Trt 6–7: 13.4, 23.3%) and IV (66.5, 78.7), particularly in pigs fed DDGS. Bellies from 3 reps were pumped with brine, smoked, and sliced (9 slices/2.54 cm) at a commercial plant. Bacon slices (10/slab) were scored for shatter; fried and scored for distortion, cook loss, and shrink; and evaluated by an 8-member trained sensory panel. DDGS inclusion did not affect bacon yield but it improved shatter scores ($P < 0.01$). Greater distortion, cooking loss, and shrink ($P < 0.05$) occurred in fried bacon from pigs fed DDGS with withdrawal time having no effect. Tenderness and flavor of bacon was not affected by DDGS. Tallow did not consistent affect any of the measures. The results indicate that withdrawal of a high level of DDGS from the finishing diet for 6 wk partially restores belly firmness, but addition of a harder fat does not overcome softer bellies. Except for an improvement in shatter scores and increased cooking loss, most of the other traits and eating quality of bacon were not affected by DDGS.

Key Words: pig, DDGS, bacon

677 Effects of co-products inclusion on growth performance and carcass characteristics of grower-finisher pigs. R. Jha*[1], J. K. Htoo[2], M. G. Young[3], E. Beltranena[1,4], and R. T. Zijlstra[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Evonik Degussa GmbH*, *Hanau, Germany*, [3]*Gowans Feed Consulting*, *Wainwright, AB, Canada*, [4]*Alberta Agriculture and Rural Development*, *Edmonton, AB, Canada*.

Using co-products (Co-P) while balancing on the basis of NE and standardized ileal digestible (SID) AA provides opportunities to reduce pig feed costs. In a completely randomized design, effects of increasing (from 2.0 to 12.5, 25.0, 37.5 and 50.0%) levels of Co-P (identical ratio of co-extruded flaxseed and field pea, canola meal, wheat/corn

DDGS (1.5:1.0:2.5) on growth performance, carcass quality, and feed cost indices were evaluated. Diet 6 supplemented SID AA 10% above the 37.5% Co-P diet to overcome potential ADFI reductions. In total, 1056 pigs (initial BW 29.5 kg) were fed 1 of 6 isocaloric and iso-lysinic dietary regimens in 4 phases (2.40, 2.35, 2.30, and 2.30 Mcal NE/kg and 3.96, 3.62, 3.22, and 2.83 g SID Lys/Mcal NE for d 0 to 19, d 20 to 38, d 39 to 56, and d 57 to 97, respectively) with 22 pigs per pens and 8 pen replicates per regimen. After slaughter at constant BW (118 to 120 kg), carcasses were characterized for all pigs. During the entire 97 d, increasing Co-P did not affect ADFI (2.90 kg), ADG, (1.01 kg) and G:F (0.35). For d 0 to 56, feeding 50% Co-P diet but not at or below 37.5% Co-P inclusions, reduced ($P < 0.05$) ADG and ADFI, however, G:F was not affected. Increasing dietary Co-P levels decreased ($P < 0.05$) dressing percentage and loin depth, but carcass weight was not affected. Increasing Co-P from 2 to 50% decreased ($P < 0.01$) feed cost/unit BW gain by 7%. Supplementing extra 10% SID AA to 37.5% Co-P did not affect performance, increased ($P < 0.01$) carcass lean, but decreased ($P < 0.01$) dressing percentage and backfat compared with 37.5% Co-P diet, indicating that dietary AA supply did not limit BW gain. In conclusion, using feed formulation to balance for identical NE and SID AA content, Co-P can be included up to 50% in grower-finisher pig diets to reduce feed costs without affecting growth performance.

Key Words: carcass quality, co-products, pig

678 Effects of dietary crude protein and inclusion of co-products on growth performance and carcass characteristics of grower-finisher pigs. R. T. Zijlstra*[1], R. Jha[1], M. G. Young[2], J. F. Patience[3], E. Beltranena[1,4], and J. K. Htoo[5], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Gowans Feed Consulting*, *Wainwright, AB, Canada*, [3]*Iowa State University*, *Ames,* [4]*Alberta Agriculture and Rural Development*, *Edmonton, AB, Canada*, [5]*Evonik Degussa GmbH*, *Hanau, Germany*.

The use of supplemental AA and co-products (Co-P) provide opportunities to reduce feed costs. Co-extruded flax-field pea Co-P may also enhance pork ω-3 fatty acid content, especially α-linolenic acid, and thereby add pork value attributes. In a 2 × 3 factorial arrangement, effects of 2 levels of dietary CP (N-CP: normal, without restriction) and reduced CP (R-CP: 3%-unit reduction in CP plus supplemental AA), and 3 levels of Co-P (low, without Co-P; medium, 30% Co-P; and high, 40 to 50% Co-P) on growth, carcass, and feed cost indices were explored. In total, 1056 pigs (initial BW 35.4 kg) were fed 1 of 6 isocaloric (2.40 Mcal NE/kg) and iso-lysinic (SID Lys:NE (g/Mcal); 4.00, d 0 to 25; 3.63, d 26 to 50; 3.25, d 51 to 71; 2.92, d 72 until end) diet regimens, in pens of 22 pigs for 8 pens per regimen. At slaughter (118 kg BW), the carcass was characterized for all pigs and jowl fat was sampled on 2 pigs per pen. Overall (d 0 to 86), increasing Co-P decreased ($P < 0.001$) ADFI and consequently ADG, and BW at d 86, but did not alter G:F. Decreasing CP did not affect ADG, ADFI, and G:F. Increasing dietary Co-P at the highest level increased ($P < 0.001$) jowl α-linolenic acid by 82%, decreased ($P < 0.001$) carcass weight and backfat, and reduced ($P < 0.001$) feed cost/unit BW gain by 15%. Decreasing CP did not affect jowl α-linolenic acid content, loin depth, and feed costs, but increased ($P < 0.01$) backfat content. In conclusion, increasing dietary Co-P above 30% may reduce growth performance of pigs via reduced ADFI, but will drastically reduce feed costs while enhancing carcass ω-3 fatty acid profile.

Key Words: co-product, omega-3 fatty acid, pig

679 Effects of dbcAMP on the proliferation, differentiation and adipogenesis-related genes of porcine adipocytes. L. Wang*[1,2], Z. Y. Jiang[1], Y. C. Lin[1], X. Y. Ma[1], and X. G. Lei[2], [1]*Institute of Animal Science, Guangdong Academy of Agricultural Sciences*, *Guangzhou, Guangdong, China*, [2]*Department of Animal Science, Cornell University*, *Ithaca, NY*.

We investigated the roles of dbcAMP (N^6, 2′-O-dibutyryl adenosine 3′, 5′ cyclic monophosphate) on adipogenesis of porcine adipocytes. Adipocytes were derived from freshly dissected back subcutaneous fat of 7-d Duroc × (Large White × Landrace) crossbred pig and incubated for 1d to 6d in DMEM/F12 media containing 10% fetal bovine serum and dbcAMP (0, 0.001, 0.01, 0.1, 1, 10, 100 and 1000 μmol/L). The proliferation and differentiation of adipocytes were measured by the MTT assay and Oil Red O staining, respectively. The mRNA expression of peroxisome proliferator-activated receptor γ_2 (PPARγ_2), adipocyte fatty acid binding protein (A-FABP) and CCAAT/enhancer binding protein α (C/EBPα) were measured by semiquantitative RT-PCR using β-actin as an internal standard. All data were analyzed by ANOVA using the GLM procedure of SAS 8.2. Supplementation with dbcAMP inhibited porcine preadipocytes proliferation in a dose-dependent manner with significance ($P < 0.05$) reached at 1000 μmol/L. The differentiation of porcine preadipocytes changed quadratically with increasing concentration of dbcAMP, and minimal differentiation at 0.1 or 1 μmol/L ($P < 0.05$). PPARγ_2 and A-FABP mRNA expression were decreased significantly ($P < 0.05$) by supplementation with 1000 μmol/L dbcAMP, while C/EBPα mRNA expression was unchanged. Above-mentioned results indicated dbcAMP supplementation in porcine preadipocytes inhibited proliferation and differentiation.

Key Words: dbcAMP, adipocytes, adipogenesis

680 DbcAMP increased lean percentage and protein deposition in finishing pigs. Z. Y. Jiang, L. Wang*, Y. C. Lin, C. T. Zheng, and X. Y. Ma, *Institute of Animal Science, Guangdong Academy of Agricultural Sciences*, *Guangzhou, Guangdong, China*.

This study was conducted to investigate the effects of dbcAMP (N^6, 2′-O-dibutyryl adenosine 3′, 5′ cyclic monophosphate) on growth performance and muscle growth in finishing pigs. Seventy-two Duroc × (Landrace × Large White) barrows (57.3 ± 0.6 kg) were randomly allotted to 3 treatments with 6 replicate pens (4 pigs per pen). The pigs were fed corn-soybean diets containing 0 (control), 10 and 20 mg/kg dbcAMP (purity, 98%), respectively, and allowed ad libitum access to feed and water, until the final slaughter weight of approximately 90 kg. Lean percentage was calculated by dissecting lean, fat and bone. Cryostat sections were stained with hematoxylin and eosin to determine fiber diameter and density of longissimus dorsi muscle (LDM). The concentration of cAMP (3′, 5′-cyclic adenosine monophosphate) and activities of cAMP dependent protein kinase A, adenylate cyclase (AC) in LDM were measured by ELISA. The mRNA expression of myogenic determinative factor (MyoD), myostatin, α-actin and myosin heavy chain (MHC) were measured by semiquantitative RT-PCR using β-actin as an internal standard. All data were analyzed by ANOVA using the GLM procedure of SAS 8.2. The ADG were 808, 836 and 832 g/d separately, but there were no significant differences among treatments ($P > 0.05$). Lean percentage in pigs fed 10 mg/kg dbcAMP was 5.64% greater ($P < 0.05$). No difference in fat percentage, bone weight percentage and in fiber density of LDM were detected ($P > 0.05$) among treatments. Compared with the control, fiber diameter of LDM tended to increase 8.61 ~26.17% ($P = 0.06$). Supplementation with 10 mg/kg dbcAMP elevated significantly AC activity, and MyoD, α-actin, MHC mRNA expression in LDM ($P < 0.05$). These results indicated that supplementation with dbcAMP in the diet could promote muscle growth and increase protein deposition in finishing pigs.

Key Words: dbcAMP, protein deposition, finishing pigs

681 The impact of dietary long chain fatty acids on bone and cartilage in swine. C. I. O'Connor-Robison*[1], J. D. Spencer[2], and M. W. Orth[1], [1]*Michigan State University*, *East Lansing,* [2]*JBS United, Inc.*, *Sheridan, IN*.

Dietary long chain polyunsaturated fatty acids (LCPUFA) including arachidonic acid (AA), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) can regulate the production of certain inflammatory mediators. The objective of this study was to characterize the effects of dietary LCPUFA on cartilage fatty acids and bone density and morphology. Sows and gilts were fed either control corn/soybean meal based diets, or the control diet supplemented with 1.0% protected LCPUFA from Fertilium (JBS United, Sheridan, IN). Sows had completed an average of 5.5 parities while gilts reached an average BW of 111 kg at time of slaughter. The cartilage was biopsied from the right and left humeral-ulnar joints of 14 sows (7/trt) and 16 gilts (8/trt) within 30 h of slaughter for fatty acid analysis. The right fused radius/ulna was saved for analysis via computerized topography (CT). Cartilage was pulverized in a freezer mill then fatty acids were extracted, methylated, and analyzed by GLC. Bones were cleaned and then analyzed with CT where 1 cm slices were acquired through the distal radius, central radius, and proximal ulna. Cortical width and density were measured and trabecular density was measured at the distal radius. Sows fed LCPUFA had increased DHA ($P < 0.01$), decreased C20:1 ($P < 0.01$), and an overall decrease in the omega-6 to omega-3 ratio ($P < 0.05$) in cartilage. Gilts fed LCPUFA had increased EPA ($P < 0.10$), DHA ($P < 0.01$), C22:1 ($P < 0.01$), and C22:5 ($P < 0.10$) in cartilage. CT scans of the radius/ulna from gilts revealed no differences for cortical width and bone density. Sows fed LCPUFA had greater cortical width of the proximal ulna ($P < 0.05$) and decreased cortical width of the distal radius ($P < 0.05$). Although the LCPUFA diet did increase omega-3 incorporation into chondrocytes the biological significance is unclear since concentrations of AA were at least 9-fold higher than EPA or DHA. Also, bone density was not affected by a LCPUFA enriched diet. Changes in cortical width were interesting but cannot be explained at this time. Thus, if omega-3 fatty acids can mitigate inflammation in joints, the benefit would likely be the result of systemic changes in inflammatory mediators.

Key Words: swine, omega-3, cartilage

682 Cannabinoid receptor type 1 (CB1) antagonist, SR141716 suppresses hepatic carnitine palmitoyltransferase 1 (CPT1) gene expression in rat. T. Wu*, Z. Yuan, and Y. Wang, *Institution of Feed Science*, *Hangzhou, Zhejiang province, China*.

SR141716 is the antagonist of cannabinoid receptor type 1 (CB1). The study was conducted to investigate the effects of SR141716 on body weight gain, hepatic fat deposit and carnitine palmitoyltransferase 1 (CPT1) expression in obese Sprague-Dawley (SD) rats induced by high fat diet (HFD). Twenty-four SD rats were randomly allocated to 3 groups: the normal diet (ND) as control group, the high fat diet (HFD) and SR141716 treated HFD-diet (SFD) animals as experimental

groups. Plasma was collected immediately for following plasma indexes determination. Liver samples were flash frozen in liquid nitrogen and stored at –80°C until use for following experiments. Compared with the ND group, HFD significantly increased the body weight gain (ND: 158.5 ± 4.14g, HFD: 173.8 ± 2.58g, $P \leq 0.05$), total viscera fat pad (ND: 2.38 ± 0.14 g/100g BW, HFD: 2.52 ± 0.11 g/100g BW, $P \leq 0.05$) and hepatic triglyceride (TG) (ND: 5.74 ± 0.58 mg/100g tissue, HFD: 10.71 ± 1.05 mg/100g tissue, $P \leq 0.05$) in rats, while SR141716 significantly suppressed these effects (154.6 ± 5.96g; 2.04 ± 0.10g/100g BW; 7.76 ± 0.52mg/100g tissue, $P \leq 0.05$). Furthermore, hepatic CPT1 mRNA level was significant decreased by HFD (24.78%, $P \leq 0.05$). Hepatic CPT1 and PPARgamma mRNA level were significantly suppressed by SR141716 accompanied with a decrease in expression of CB1 mRNA (19.52%, $P \leq 0.05$). The results indicated that SR141716 can significantly suppress the excess hepatic adipose deposit induced by HFD in rats. During this process, the pivotal role of CB1 in hepatic fat deposit may be due to modulation of CPT1 expression through PPARgamma. However, the accurate mechanism remains to be elucidated in the future.

Key Words: SR141716, Hepatic fat deposition, CPT1

683 Is the effect of dietary energy levels on feed intake of broiler chickens affected by bird age? M. Cho*[1], R. L. Payne[2], and H. L. Classen[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Evonik-Degussa Corporation*, *Kennesaw, GA*.

It is historically known that chickens are able to adjust their feed intake according to the dietary energy content. However, broiler chickens may not be able to adjust their feed intake due to intense genetic selection and/or limited gut capacity at a young age. Hence, 2 experiments were conducted to clarify the relationship between dietary energy level and feed intake in broiler chickens and how it is affected by bird age. Trial 1 was conducted to determine the AME of Western Canadian feedstuffs using 5 and 21 d old broilers. Differences were found between 5 and 21 d old chickens for AMEn of some ingredients and therefore the determined values were used to formulate diets for trial 2 using age appropriate values. Trial 2 was conducted to investigate the effect of age on the feed intake response of broiler fed diets with a range in dietary energy content (2700, 2833, 2966 and 3100 kcal/kg). Diets in this energy range were fed for the entire experiment (SGF), for the grower and finisher periods (GF) or only in the finisher period. (F). Starter, grower and finisher diets were fed from 0 to10, 11 to 25 and 26 to 35 d, respectively. Amino acid levels in diets met or exceeded the primary breeder recommended values. Overall, birds did not adjust their feed intake based on the energy level of the diet. Switching from 3100 kcal/kg diets to lower energy had no impact on feed intake when started at the grower phase. A similar switch at the finisher phase caused a temporary (25 to 30 d) decrease in feed intake and consequently growth rate. Growth rate of birds fed the 2700 kcal/kg diet was lower than other treatments. The data suggest that modern broilers do not or cannot change feed intake in response to dietary energy when dietary amino acid requirements are met and this response is relatively consistent through-out the broiler growth period.

Key Words: nutrient density, poultry nutrition, AME

684 Estimation of net energy values of feedstuffs by simulation of biochemical reactions in broiler chicks. S. Cerrate* and C. Coon, *University of Arkansas*, *Fayetteville*.

A computer program is proposed which simulates energy metabolism in the growing broiler chicken for the estimation of net energy (NE) values of feedstuffs. This approach is based on a quasi-steady-state system which measures reactants and products in major metabolic pathways for carbohydrates, protein and fats. The input variables were digestible carbohydrates, amino acids and fatty acids and the output variables were 1) estimated net energy needs for maintenance and 2) net energy for tissue gain. Adenosine triphosphate was used to quantify the energy from chemical reactions obtained from oxidative metabolism of nutrients and then utilized for maintenance and gain by anabolic reactions. Simulations of a basal diet and 10 experimental diets (basal + feedstuff), were formulated to estimate their NE values. For each diet an estimation of NE value was simulated and then calculated for each feedstuff. The simulated NE values for each feed ingredient were compared with determined NE values of feedstuffs reported by past studies. A high correlation was observed between simulated and determined NE values for feed ingredients. The data indicates that the proposal model can be used to predict net energy values of feed ingredients.

Key Words: broiler, net energy, biochemical reactions

685 Energy determination of corn co-products fed to broiler chicks from fifteen to twenty-four days of age and use of composition analysis to predict AME_n. S. J. Rochell*[1], B. J. Kerr[2], and W. A. Dozier, III[1], [1]*Auburn University*, *Auburn, AL*, [2]*USDA-ARS Agroecosystems Research Unit*, *Ames, IA*.

Fifteen co-products collected from various wet and dry milling plants were fed to broiler chicks to determine AME_n and to generate an equation to predict AME_n based upon each ingredient′s chemical composition. Co-products included: DDGS (6), high protein dried distillers grain (HP-DDG) (2), dehydrated corn germ (2), corn germ meal, corn bran, corn gluten meal, corn gluten feed, and dehulled degermed corn. A control diet was fed containing corn, soybean meal, dextrose (15%), dicalcium phosphate, limestone, salt, vitamins, and trace minerals. Test diets were formulated by mixing the control diet with 15% of a co-product at the expense of dextrose. Nineteen hundred and 20 Ross × Ross 708 chicks (10 per pen; 5 males and 5 females) were randomly assigned to 15 dietary treatments (12 replicate pens). Broilers were fed experimental diets from 15 to 22 d of age followed by a 48 h total excreta collection period. Ingredients were analyzed for GE, CP, DM, crude fat, crude fiber, ash, total dietary fiber, NDF, and ADF, and hemicellulose was determined by difference. Gross energy was determined on the feed and excreta to calculate AME_n for each ingredient. The corn-soybean meal portion of the basal diet averaged 3,037 kcal AME_n/kg DM, with dextrose having an assumed value of 3,640 kcal/kg DM. For the 6 samples of DDGS, AME_n ranged from 2,146 to 3,098 kcal/ kg DM, averaging 2,676 kcal/ kg DM. The AME_n values for dehydrated corn germ, corn germ meal, HP-DDG, corn gluten meal, corn gluten feed, corn bran, and dehulled, degermed corn were 3,308, 1,991, 2,820, 3,182, 1,746, 3,030, and 3,442 kcal/kg DM, respectively. Stepwise regression resulted in the equation: AME_n, kcal/kg DM = 3,517 + (46.02 × % crude fat, DM basis) – (82.47 × % ash, DM basis) – (33.27 × % hemicellulose, DM basis) ($R^2 = 0.89$; SEM = 191; $P \leq 0.01$). These results determined that wide variability exists among corn co-products produced from dry and wet milling plants, and that the best predictors of AME_n are crude fat, ash, and hemicellulose.

Key Words: corn co-products, metabolizable energy, chicks

686 Apparent metabolizable energy (AME_n) content and standardized ileal amino acids digestibility of wheat, wheat-corn and corn distillers dried grains with solubles (DDGS) for broilers. A.

Rogiewicz*, B. A. Slominski, W. Jia, C. M. Nyachoti, and K. M. Wittenberg, *University of Manitoba*, *Winnipeg, MB, Canada*.

In Exp. 1, the apparent metabolizable energy (AME_n) contents of 2 samples of wheat distillers dried grains with solubles (DDGS), 3 samples of wheat-corn DDGS, and 3 samples of corn DDGS were determined. A total of 225 broiler chickens were assigned to 9 dietary treatments, each consisting of 5 pens of 5 birds each, and were fed a basal starter diet or the basal diet plus 30% of DDGS from 14 to 19 d of age. All diets contained titanium dioxide (0.3%) as an indigestible marker. On average and in comparison with corn DDGS, wheat DDGS had lower AME_n content (2,872 vs. 3,177 kcal/kg DM) which is a reflection of its lower fat (4.5 vs. 10.7% DM) and carbohydrate (7.1 vs. 10.5% DM), including residual starch (1.6 vs. 6.6% DM), contents. The wheat-corn DDGS samples had intermediate values for AME_n contents which averaged 2,975 kcal/kg DM. As blending of wheat and corn is a common practice in bio-ethanol production in western Canada, a prediction equation for energy availability was developed and demonstrated a strong relationship between the amount of wheat and corn grain used and the AME_n content ($R^2 = 0.95$). The AME_n values corresponded well with the TME_n values, which averaged 3,160 for wheat DDGS, 3,238 for wheat-corn DDGS, and 3,488 kcal/kg DM for corn DDGS. In Exp. 2, the standardized ileal digestibility (SID) of amino acids (AA) was determined for 2 wheat DDGS, 6 wheat-corn DDGS and 4 corn DDGS samples. A nitrogen-free diet was used to determine endogenous AA losses. The SID values averaged 59.0, 59.6 and 62.7% for Lys; 82.7, 79.8 and 82.7% for Arg, and 70.6, 64.4 and 68.3% for Thr, respectively, for wheat, wheat-corn and corn DDGS ($P > 0.05$). The SID for Met was lower ($P < 0.05$) in wheat-corn DDGS (73.3%) compared with wheat DDGS (81.2%) or corn DDGS (81.3%). Overall, there was no conclusive relationship between the SID of amino acids and the type of DDGS used.

Key Words: DDGS, AME_n, amino acid digestibility

687 Use of the precision-fed rooster TME assay and chick AME assay to quantify the energy value of Nutridense corn. T. Loeffler*, D. A. Neves, and A. B. Batal, *University of Georgia*, *Athens*.

To determine the energy value of Nutridense corn, 2 precision-fed rooster TME assays and 2 conventional chick AME digestibility trials were conducted. The TME and AME values were compared within each experiment for both the Nutridense corn and the control corn, and the same experimental design was used for each study. The rooster assays were traditional precision-fed rooster assays in which 10 birds per diet were fasted for 24 h, crop intubated with 35 g of the test diet containing 92.25% control corn or 92.25% Nutridense corn, and excreta was then collected for 48 h. For the chick studies, 288 one-day-old Cobb 500 by product male broiler chicks were placed in Petersime battery brooders with raised wire floors. There were 12 replications of 12 chicks per replication assigned to the 2 corn diets. Chicks were fed a standard corn-soybean meal starter diet until 13 d of age, and on d 14, the chicks were allowed ad libitum access to the corn diet. Excreta were collected on d 17, dried, weighed, ground and analyzed for gross energy and crude protein. The determined AME values were 3.1% higher in study 1 (3096 vs. 3003 kcal/kg) and 2.3% higher in study 2 (2974 vs. 2907 kcal/kg) for the Nutridense as compared with the control corn. The determined TME values were also higher for the Nutridense corn as compared with the control corn; 2.2% increase (3463 vs. 3390 kcal/kg) and 1.2% increase (3446 vs. 3404 kcal/kg) for study 1 and 2, respectively. There was a larger difference in the ME values between the rooster TME and chick AME for study 1 than for study 2, but the Nutridense always had a higher ME than the control corn. Although the results for energy digestibility are not in agreement between the chicks and roosters in these studies, analysis of the data indicates that Nutridense corn has higher metabolizable energy than the control corn.

Key Words: Nutridense, corn, ME

688 Evaluation of energy digestibility among and within feedstuffs for swine using an in vitro digestibility technique. L. F. Wang*[1], P. R. Regmi[1], N. S. Ferguson[2], A. Pharazyn[2], and R. T. Zijlstra[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Nutreco Canada*, *Guelph, ON, Canada*.

The DE content of feedstuffs varies; thus, rapid and accurate evaluation of apparent total tract digestibility (ATTD) of energy is required for accurate swine feed formulation. Previously, a 3-step in vitro energy digestibility technique using pepsin, pancreatin and Viscozyme predicted ATTD of energy accurately among single samples of 8 feedstuffs ($R^2 = 0.97$). Within feedstuff variability was predicted well for grains and poorly for canola meal and corn DDGS. The objective was to expand the feedstuff matrix to multiple samples of corn, pulse crops, soybean meal and wheat; and to compare the accuracy of predicting ATTD of energy between in vitro digestibility and data from proximate analyses (fiber, ether extract, CP). The ATTD of energy was determined for 60 samples of 7 feedstuffs using 148 grower pigs with the indicator method. For multiple samples per feedstuff, in vitro energy digestibility was the best single predictor ($R^2 = 0.71$) compared with proximate analyses ($R^2 = 0.63$). Prediction accuracy of the in vitro technique was similar to using proximate analyses ($R^2 = 0.71$ vs. 0.75; SE of prediction [SEP] = 5.5 vs. 5.0; respectively). The prediction residuals from both methods were highly correlated (r = 0.88); the SEP for in vitro was highest for corn (5.1), then pulse (4.0), soybean meal (4.2), and lowest for wheat (1.3). Among feedstuffs, combining in vitro digestibility and proximate data reduced the error (SEP = 4.6). However, within feedstuff, the SEP of in vitro digestibility data was higher than for multiple chemical data (corn, 2.8 vs. 0.9; pulse crops, 2.6 vs. 1.7; soybean meal, 2.3 vs. 0.6; wheat, 1.4 vs. 0.1). In conclusion, in vitro energy digestibility and proximate analyses resulted in similar prediction accuracy for the ATTD of energy among feedstuffs. In contrast to grains, other feedstuffs revealed difficulty in achieving an accurate prediction of ATTD of energy within feedstuff using current procedure of in vitro energy digestibility.

Key Words: energy digestibility, in vitro, pig

689 The ontogeny of intestinal carbohydrate digestive, absorptive and nutrient sensing proteins in pigs. M. Al-Rammahi*[1], A. Moran[1], D. Batchelor[1], P. Sangild[2], C. Ionescu[3], D. Bravo[3], and S. Shirazi-Beechey[1], [1]*University of Liverpool*, *Liverpool, UK*, [2]*University of Copenhagen*, *Frederiksberg, Denmark*, [3]*Pancosma*, *Geneva, Switzerland*.

In the small intestine, dietary carbohydrate is hydrolysed ultimately by intestinal brush border membrane hydrolases, sucrase, lactase and maltase, to glucose, galactose and fructose. Glucose and galactose are transported across the luminal membrane of enterocytes by the Na^+/glucose cotransporter 1, SGLT1, which is upregulated by luminal sugars via the sweet taste receptor, T1R2/T1R3, expressed in enteroendocrine cells. Na^+-independent transporters, facilitate transport of fructose across the luminal membrane (GLUT5) and all 3 monosaccharides across the basolateral membrane (GLUT2). Aim: To determine the developmental profile of these key carbohydrate digestive-related gut functions in pigs before and after birth. Methods: Intestinal tissues were removed from pre-term (fetal age 105 d, n = 4), full-term (115 d, n = 4), suckling (15 d, n = 4) and weaned (28 d, n = 8) piglets following

euthanasia under ethical approval. Results: By immunohistochemistry, we showed presence of SGLT1 (on enterocytes luminal membrane), GLUT2 (on enterocytes basolateral membrane) and the glucose sensor (in enteroendocrine cells) both before and after birth; GLUT5 protein was only present after weaning. By functional assays and qPCR, we demonstrated highest expression of SGLT1 in weaned animals (on 60% carbohydrate diet). The expression level of SGLT1 was weaned > suckling > term > pre-term. A similar pattern of expression was observed for sucrase and maltase, while the developmental profile of lactase expression showed maximal levels in suckling animals. The presence of carbohydrate digestive/absorptive and nutrient sensing proteins in the intestine during pre-natal life indicates that a pre- programming of intestinal functions occurs before birth to prepare the gut for its post-natal functional demands. A better understanding of both ′hard wired′ and diet- induced functions of the gut in early life allows the design of rational and innovative approaches to formulate feed and feed additives to ensure the health and well-being of the young animal.

Key Words: gut development, sugar transporters, disaccharidases

690 Quality characteristics and fatty acid composition of eggs from hens fed *Camelina sativa* (camelina meal). R Kakani*[1], A Haq[1], J Fowler[1], E Murphy[2,3], T Rosenberger[3], M Berhow[4], and C. A. Bailey[1], [1]*Texas A&M University*, *College Station,* [2]*University of North Dakota*, *Grand Forks,* [3]*Agragen, LLC*, *Cincinnati, OH*, [4]*National Center for Agricultural Utilization Research, USDA*, *Peoria, IL*.

Camelina sativa or false flax is an oilseed producing plant rich in essential omega-3-fatty acids. Camelina meal is the by-product of oil extraction, and has a crude protein content (40%) similar to that of rapeseed meal. Camelina meal is a rich source of essential n-3 and n-6 fatty acids that can be incorporated in laying hen diets to enrich eggs with n-3 fatty acids. In this study, the effects of feeding camelina meal to commercial laying hens on egg production, egg quality characteristics and fatty acid composition of eggs was determined. Twenty-nine-week old Lohmann White Leghorn hens were randomly allocated to 3 dietary treatments (n = 25 per treatment) and data collected over a 12 week production period. All the treatment groups were fed a corn soy based experimental diets containing 0% (CON), 5% (CAM5) and 10% (CAM10) extruded camelina meal. Feed and water were offered ad libitum. There were no significant differences in % hen day egg production among the treatment groups. Egg weight was significantly lower in CAM5 (58 ± 4 g) relative to CON (60 ± 4 g), whereas no significant difference was detected between CAM10 (60 ± 5 g) and control. Egg shell strength (Instron) was significantly higher in CAM5 (5.0 ± 1.1 kg) and CAM10 (4.7 ± 1.1 kg) than in CON (4.5 ± 1.0 kg). Total cholesterol content in the yolk was unchanged between groups. Total egg n-3 fatty acid content was nearly doubled in CAM5 (117 ± 24 mg/yolk) and tripled in CAM10 (161 ± 20 mg/yolk) when compared with CON (60 ± 8 mg/yolk). The n-6 to n-3 ratio was significantly different between groups, 12.4 ± 0.8 (CON), 6.0 ± 0.2 (CAM5), and 4.3 ± 0.1 (CAM10). There were no detectable glucosinolates in the eggs of CAM5 and CAM10 treatment groups. Significant accretion of n-3 fatty acids was observed in the yolk of hens fed 5% and 10% camelina meal. These results indicate that camelina meal is a viable dietary source of n-3 fatty acids for poultry and its inclusion results in eggs enriched with n-3 fatty acids, including a 2.5-fold increase in DHA.

Key Words: camelina meal, egg quality characteristics, n-3 fatty acids

Nonruminant Nutrition Symposium: Models for Disease × Nutrition Evaluation and the Impact of Nutrition on Health, Disease, and/or Recovery

691 Possible nutritional interventions to improve intestinal health. J. Escobar*, M. A. Ponder, K. L. Price, and H. B. Lee, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

In sick animals, the anorectic response is part of a series of complex but coordinated physiological and behavioral adaptations to recover from a disease episode. Thus, it is not surprising that animals appear to have a physiological preference for using endogenous nutrients over dietary supply, particularly during acute immune activation. Because survival and recovery have utmost nutritional priority, sick animals usually exhibit reduced growth performance, and nutritionists commonly rely on non-productive outcomes to determine the benefits of nutritional interventions. The effect supplementing diets with several nutrients and feed additives on intestinal health have been evaluated in various animal models using a wide variety of single immunological challenges. Our laboratory is currently using both *Salmonella*- and lipopolysaccharide-challenged pigs to determine how immune activation alters nutrient utilization as well as the contribution of prebiotic supplementation on intestinal health and recovery from an enteric infection. Results from our studies indicate increased amino acid catabolism during acute experimental sepsis and impaired amino acid digestibility during a bacterial infection of the gastrointestinal tract. Further, inclusion of a yeast-derived prebiotic in the diet of Salmonella-challenged pigs appears to improve fecal beneficial bacteria and intestinal morphology, which were associated with an enhanced growth performance during the recovery phase. The appropriateness of the animal model and the immune challenge, however, must be carefully considered when making intestinal health inferences of nutrients and supplements to be implemented in commercial animal production systems, which are usually affected by diseases of complex etiology.

Key Words: disease, intestine, amino acids

692 Challenge models to study foodborne pathogen transmission and test intervention strategies. P. Ebner*, *Purdue University*, *West Lafayette, IN*.

Foodborne illnesses are continually associated with the consumption of contaminated animal products (among other foods). As most of the more notable bacterial foodborne pathogens have reservoirs in at least one livestock species (e.g., *Campylobacter* in poultry, *Salmonella* in pork, *E. coli* O157:H7 in beef cattle), preharvest or on-farm intervention strategies aim to improve food safety by decreasing the amount and types of pathogens that animals bring with them into the processing facility. Various challenge models have been used in assessing the efficacy of these different strategies. Foodborne pathogen infection models present some special challenges as the organisms are, in many cases, among the normal microbiota of the animal. In addition, many of these organisms are seemingly ubiquitous within livestock facilities and are regularly isolated from the general environment. Such epidemiological factors should be taken into account when assessing the value of a certain infection model. Nutrition and management factors must also be taken under consideration with foodborne pathogen challenge models to varying degrees depending upon the organism. We have experimented with different models to study *Salmonella* infections in livestock. A major focus of our laboratory currently is the development of different methods to limit *Salmonella* infections associated with transport and lairage due to contaminated post-farm environments (e.g., contaminated trailers, crates or holding pens). Once a treatment has proven effective using a basic challenge such as co-inoculation, we usually progress to more complex models. As an example, we have simulated contaminated trailers or holding pens by inoculating small groups of seeder animals and then introducing unrelated treated and non-treated animals to the contaminated pen. These models, also used by other groups with *Salmonella* and other foodborne pathogens, attempt to more closely mimic the quantities and routes of exposure that the animal might encounter under a production setting in effort to better understand on-farm transmission and effectively reduce pre-processing pathogen loads in food animals.

Key Words: foodborne pathogens, *Salmonella*

693 Nutritional modulation of the gastrointestinal barrier and its role in gut health and disease. A. J. Moeser*, *North Carolina State University*, *Raleigh*.

Enteric disease is a major cause of mortality and production inefficiencies in swine. Environmental factors such as stress and nutrition have a profound influence on gut health and can triggers the onset of enteric disease but the mechanisms are poorly understood. Our studies have focused on elucidating how production stressors and nutritional factors influence the intestinal barrier, a critical line of defense against pathogens and antigens residing in the intestinal lumen. We have shown that stressors associated with current weaning practices have a deleterious impact on intestinal barrier function measured by increased intestinal permeability and mucosal inflammation. Furthermore, it was shown that weaning age is an important factor in determining the severity and duration of weaning-induced intestinal barrier dysfunction as incrementally increasing weaning age from 16 to 23 d of age led to graded improvements in post-weaning mucosal barrier function. Mechanisms underlying this weaning event were shown to be mediated through peripheral stress signaling pathways and innate immune cell dysfunction. Recent experiments with weaned pigs showed that early weaning exacerbated clinical disease and intestinal injury in response to an *E. coli* challenge. Furthermore, it was shown that increasing weaning age from 18 to 20 d of age ameliorated enteric disease *E. coli* challenged pigs. Given the important role of the intestinal barrier in gut health, we have begun studies investigating nutritional factors that can regulate the intestinal barrier. Beneficial results were shown with supplemental plasma protein into post-weaning diets specifically ameliorating a portion of the barrier dysfunction and intestinal inflammation and diarrhea that is associated with early weaning. In summary, the integrity of intestinal mucosal barrier is critical to pig health and can be influenced by production stress and nutrition. Identifying strategies to enhance intestinal barrier health in the pigs will be important to promote optimal pig health, performance, and well-being.

Key Words: intestine, stress, weaning

694 Is immunomodulation good? K. C. Klasing*, *University of California*, *Davis*.

Nutrients, pharmacological agents, and immunogens are often administered to animals for the purpose of immunomodulation, which is defined as shifting the immune systems response to pathogens or other triggers. The underlying principle is that the immune system can be improved by an informed intervention. Implicit in the idea of immunomodulation is that an animals immune system is mal-regulated or mal-designed as the result of improper genetics or environment and we know how to fix

it. Several examples of immunomodulation from the nutrition literature indicate that immunomodulation is situation dependent: improving disease resistance against some pathogens while impairing it against others. An understanding of the polarized response of the immune system in context of the optimal protective immune response helps explain this dichotomy. Pathogens often subvert the immune system to marshal a vigorous, yet counterproductive response. Modulation of the immune system in a more protective direction helps. However, this same immunomodulation may impair the protective response to other pathogens with different pathogenicity mechanisms. Thus, the value of immunomodulation appears to be context specific. When a single pathogen is dominant in a production system and the type of protective immune response is clearly understood, an immunomodulator that is known to shift the immune system in the protective direction is good for that pathogen; but not necessarily for others.

Key Words: nutrition, immunity, modulation

695 Functional characterization of folic acid transport in the intestine of the laying hen. G. B. Tactacan*, W. Guenter, and J. D. House, *University of Manitoba*, *Winnipeg, Manitoba, Canada*.

The deposition of dietary supplemented folic acid (FA) into the chicken egg is likely regulated by its absorption in the intestine. Therefore, factors affecting the intestinal transport of FA in the laying hen may influence the level of egg folate concentrations. To this end, a series of experiments using intestinal everted sacs were conducted to characterize the different aspects of the intestinal FA absorption process in laying hens. Effects of naturally occurring folate derivatives (5-methyl and 10-formyltetrahydrofolate) on FA absorption were also investigated. Folic acid absorption was measured based on the rate of uptake of ^{3}H-labeled FA in the everted sac from various segments of the small and large intestines. Folic acid concentration, incubation length, and pH condition were set to optimum before the performance of the uptake experiments. The distribution profile of FA transport along the intestine was highest in the upper half of the small intestine. Maximum uptake rate (nmol•100 g tissue^{-1}•min^{-1}) was observed in the jejunum (22.3 ± 2.0) and duodenum (20.6 ± 1.9) and decreased significantly ($P < 0.001$) in the ileum (15.3 ± 1.1) and cecum (9.3 ± 0.9). Transport characteristic of FA in the jejunum demonstrated a pattern of saturation, exhibiting decreased uptake rate with increased FA concentration. Transport increased proportionately ($P < 0.002$) between 0.0001 and 0.1 μM FA but showed a trend toward saturation in excess of 0.1 μM FA. Folic acid uptake in the jejunum showed greater transport at lower pH, exhibiting highest uptake at pH 5.5–6.0 but decreased ($P < 0.009$) at higher pH (7.5). Presence of 5-methyl and 10-formyltetrahydrofolate impeded FA uptake, reducing intestinal FA absorption by 21.9 and 14.9%, respectively, when added at concentrations ranging from 0 to 100 μM. Overall, these data indicated the presence of a FA transport system in the entire intestine of the laying hen. Uptake of FA in the cecum raises the likelihood of absorption of bacterial-derived folate.

Key Words: folic acid, everted sac, laying hen

696 Effect of choline, folacin and vitamin B_{12} on egg components and egg phospholipid composition in laying hens. P. Krishnan* and S. E. Scheideler, *University of Nebraska Lincoln*, *Lincoln*.

Choline, folacin and vitamin B_{12} are essential nutrients for all animals and a required dietary supplement for poultry. This study was designed to determine the effect of added choline, folacin and vitamin B_{12} to a corn-soy diet on egg production, egg quality and egg yolk phospholipid composition. A corn-soy basal diet was formulated with 2 levels supplemental choline (500 and 1000 ppm) 2 levels supplemental folacin (2 and 4 ppm) and 2 levels supplemental vitamin B_{12} (0.01 and 0.02 ppm) in a 2 × 2 × 2 factorial arrangement along with a control (no supplementation) group. The 9 experimental diets were arranged in a randomized complete block design with 6 replicate cages and 4 birds per cage for a total of 54 cages and fed for 6 wks. Percentage egg production, daily feed intake and body wt gain did not show any significant difference between experimental treatments as well as with the control. There was a significant ($P < 0.05$) effect of folacin on yolk wt with the wt. increasing at 2 ppm of folacin supplementation. Yolk wt also showed a significant ($P < 0.05$) 3 way interaction between choline, folacin and vitamin B_{12}. There was a significant difference in yolk wt between experimental treatments with the highest yolk wt being observed with choline, folacin and vitamin B_{12} at 1000, 2 and 0.01 ppm respectively. Albumen wt. showed a significant difference ($P < 0.05$) with choline and folacin supplementation with the values being higher at 1000 ppm of choline and 4 ppm of folacin. Phosphatidylcholine (PC) showed a significant increase ($P < 0.0001$) with added levels of choline, folacin or vitamin B_{12} with subsequent reduction in phosphatidylethanolamine (PE). The average value of PC (mg/g of egg yolk) at 500 and 1000 ppm of choline was 152.61 and 164.53 mg respectively. Similarly, the average values for PC at 2 and 4 ppm of folic acid and 0.01 and 0.02 ppm of vitamin B_{12} were 153.06, 164.07, 155.68 and 161.46 mg respectively. Results indicate that choline, folacin and vitamin B_{12} positively affect yolk wt. and egg yolk phospholipid composition in laying hens.

Key Words: choline, folacin, vitamin B_{12}

697 Effects of canthaxanthin and 25-hydroxycholecalciferol on reproductive aspects of roosters. A. P. Rosa*[1], P. Ferreira[1], A. Scher[1], R. P. Ribeiro[1], G. Farina[1], and J. O. B. Sorbara[2], [1]*Universidade Federal de Santa Maria - Animal Science Department - Poultry Laboratory*, *Santa Maria, RS, Brazil*, [2]*DSM Nutritional Products*, *São Paulo, SP, Brazil*.

Avian spermatozoa are characterized by high concentrations of fatty acids within their phospholipids and are susceptible to lipid peroxidation considered a problem in poultry reproduction. Antioxidant system is based on interactions of various antioxidants and the carotenoids are an essential part of that system. Among the carotenoids, canthaxanthin is characterized by its relatively high antioxidant activity. 25-OH-D3 (25-hydroxycholecalciferol) is an intermediary between the vitamin D3 and the active form of this vitamin. The aim of the present study was to evaluate the effects on the reproductive performance and seminal characteristics of roosters, fed diets with ROVIMIX MaxiChick (6 ppm Cantaxantina + 69 μg/kg of diet 25-OH-D3). This experiment was conducted at the Poultry Laboratory of Animal Science Dept. at The Federal University of Santa Maria-Brazil. Forty White Plymouth Rock roosters from 40 to 59 weeks of age were used. The males were submitted to T1 = control diet or T2 = control diet + MaxiChick. A completely randomized design was used with 2 treatments with 20 repetitions (one male each). The experimental phase was divided into 5 periods of 28 d. The parameters evaluated were: body weight and feed intake, motility, vigor score, sperm concentration and morphological anomalies. The data were transformed to adjustment the normality and then they were subjected to ANOVA. The differences between treatments were compared by Duncan test at 10% significance level. The addition of ROVIMIX MaxiChick in the diet improved the sperm concentration from 4.40 to 5.91*10^{8}/ml ($P = 0.0001$), motility improved from 91.40 to 92.80 ($P = 0.0071$) and sperm vigor score from 4.38 to 4.57 ($P = 0.0296$) and contributed to reduce the morphological anomalies from 21.90 to 16.70% in the semen ($P = 0.0001$).

Key Words: vitamin, D3, reproduction

698 Supplementation of canthaxanthin and 25-OH-D_3 to broiler breeders diet on broiler chick hatchery parameters and egg yolk TBARS. A. P. Rosa*[1], A. Scher[1], L. Boemo[1], T. N. N. Vieira[1], J. A. G. Ferreira Jr.[1], and J. O. B. Sorbara[2], [1]*Universidade Federal de Santa Maria - Animal Science Department - Poultry Laboratory*, *Santa Maria, RS, Brazil*, [2]*DSM Nutritional Products*, *São Paulo, SP, Brazil*.

The objective of this study was to determine the effect of the supplementation of Rovimix MaxiChick to broiler breeders diet on hatchery parameters and the antioxidant potential. The experiment was carried

out at The Federal University of Santa Maria, Brazil. Twenty incubations were carried out with eggs from 360 females Cobb 500 with 45 weeks of age. The experimental design was in a CRD with 2 treatments, control and Control + Rovimix MaxiChick (6ppm canthaxanthin + 69mcg/kg of diet 25-OH-D3) and 6 replicates of 30 females and 3 males each. The eggs were incubated following standard incubation procedures, and at 21 d the hatchability parameters were assessed. To evaluate the antioxidant potential of Rovimix MaxiChick, eggs were stored at 0, 4, 8 and 12 d. After storage period the yolk was collected for TBARS analysis. During incubation yolks or viteline sacs of embryos were collected at 0, 7, 14 and 18 d of incubation for TBARS analysis. When MaxiChick were supplemented, Hatchability improved from 83.03% to 87.35% ($P < 0.0001$); Hatchability of fertile eggs improved from 91.30 to 93.97 ($P < 0.0001$); Fertility improved from 90.94% to 92.95% ($P = 0.0017$); Total Embryo Mortality during incubation reduced from 5.46% to 3.46% ($P = 0.0002$). TBARS (MDA mg1 protein) of egg yolks during different storage time reduced from 13.53 to 10.82 ($P = 0.0355$); from 20.87 to 15.04 ($P < 0.0001$); from 20.73 to 12.96 ($P < 0.0001$); and from 28.97 to 20.90 ($P < 0.0001$) at 0, 4, 8 and 12 d of storage, respectively. TBARS (MDA mg1 protein) of egg yolks during different incubation time reduced from 21.14 to 12.12 ($P < 0.0001$) at 0 d of incubation and from 16.69 to 14.67 ($P < 0.0001$) at 7 d of incubation. At 14 and 18 d of incubation no statistical response were detected. The supplementation of Rovimix MaxiChick in the broiler breeders diet improved all hatchability parameters evaluated in this trial. An antioxidant effect was observed in eggs from birds fed with MaxiChick.

Key Words: antioxidant, breeder, 25-hydroxycholecalciferol

699 Sparing vitamin E effects of a synthetic antioxidant blend in broilers. J. Zhao*, M. Vazquez-Anon, R. J. Harrell, J. D. Richards, F. Yan, T. Wineman, and S. Carter, *Novus International Inc.*

A total of 720 ROSS 308 female broilers were used to determine vitamin E sparing effects of a synthetic antioxidant blend (AOX, Novus International Inc., St Louis, MO). The trial was a 4 × 2 factorial design with 4 levels of vitamin E (5, 15, 30, and 60 IU/kg) with or without antioxidant (AOX at 0.025%). Birds were randomized into 8 treatments with 9 replicates per treatment and 10 birds per pen. Oxidized soybean oil was added in all diets to provide peroxide value of 6mEq/kg in the final diet. Without AOX, quadratic vitamin E response was observed on weight gain ($P = 0.04$) and feed intake ($P = 0.07$) with the maximum response between 15 and 30 IU/kg. AOX tended to improve feed efficiency regardless of dietary vitamin E levels ($P = 0.07$). A significant 2-way interaction of dietary vitamin E and AOX was observed on body weight and weight gain ($P = 0.05$) in that AOX improved gain at the low vitamin E but not at high vitamin E diets (interaction, $P = 0.05$). Weight gain for the 21 d growth period was 699 and 791 g at 5 IU/kg, 783 and 773 g at 15 IU/kg, 788 and 777 g at 30 IU/kg, 775 and 762 g at 60 IU/kg dietary vitamin E without and with AOX, respectively. Similar to weight gain, birds fed AOX ate more feed and had better feed efficiency at 5 IU/kg dietary vitamin E compared with birds fed non-AOX diet (by contrast, $P < 0.05$) but the benefits were not observed at high vitamin E diets. Plasma and liver vitamin E were linearly increased with increased dietary vitamin E ($P < 0.05$) regardless of AOX. In addition, plasma and liver vitamin E concentration increased with AOX addition regardless of dietary vitamin E levels ($P < 0.05$). Liver vitamin E were 8.7 and 11.1 ug/g at 5 IU/kg, 18.1 and 21.4 ug/g at 15 IU/kg, 27.8 and 36.2 ug/g at 30 IU/kg, and 51.1 and 59.4 ug/g at 60 IU/kg vitamin E without or with AOX. In summary, AOX spared vitamin E based on performance and tissue vitamin E concentration, and can be used to spare dietary vitamin E as an antioxidant in broiler diets.

Key Words: antioxidant, vitamin E, broiler

700 Effect of percentage pellet fines and house-walking schedule on broiler growth performance. W. J. Pacheco*, R. D. Malheiros, C. R. Stark, P. R. Ferket, and J. Brake, *North Carolina State University*.

Feed accounts for around 65–75% of total broiler production costs. Pelleted feed has been shown to reduce feed wastage and improve growth as it encourages broilers to eat feed faster. The objective of the study was to evaluate the effect of quantity of pellet fines and house-walking schedule on broiler growth performance. The experiment was a 2 × 2 factorial of pellets fines (0% or 50% fines) and house-walking (1 or 3 times daily). A total of 1,024 male 1-d-old broiler chicks were randomly assigned to 2 different blocks and 2 treatments with 8 replicate pens per treatment in each block and 32 birds per pen. The starter diet was fed in crumbled form to 21 d while the grower and finisher diets were in pelleted form. The 0% fines diet was created by screening the pellets and the 50% fines diet was created by re-combining the screened pellets with the fines. Body weight (BW) and feed consumption were determined at 21, 42, and 49 d of age and feed/gain ratio (FCR) was calculated. The fines in the 0% and 50% treatment grower diets was found to be 20% and 62%, respectively, while the finisher diets contained 3% and 54%, respectively. No pellet fines by walking treatment interaction effects were observed. The 50% fines treatment decreased 42 d BW (2,848 g vs. 2,998 g, $P < 0.0001$) and increased 1–42 d FCR (1.74 vs. 1.70, $P < 0.05$) relative to 0% fines. The 50% fines treatment continued to adversely effect 49 d BW (3,637 g vs. 3,774 g, $P < 0.0001$) but not on 1–49 d FCR (1.84 vs. 1.82). House walking 3 times daily decreased BW at 42 d (2,891 g vs. 2,954 g, $P < 0.005$) without affecting FCR. There were no walking treatment effects observed at 49 d. This experiment demonstrated the adverse effects of fines in pelleted feed on growth performance of broilers, regardless of whether they were encouraged to get up by walking the pens more frequently. Indeed, entering the pens 3 times per day may have disturbed eating and resting behavior before 42 d.

Key Words: broilers, feed fines, growth performance

701 The effects of feeder-trough space and gap setting on growth performance of finishing pigs. A. J. Myers*, R. D. Goodband, M. D. Tokach, S. S. Dritz, J. R. Bergstrom, J. M. DeRouchey, and J. L. Nelssen, *Kansas State University*, *Manhattan*.

A total of 288 pigs (initial BW 41.3 kg) were used in a 91-d study to evaluate the effects of feeder trough space (4.45 vs. 8.9 cm/pig) and minimum feeder gap opening of 1.3 cm (narrow), vs. 2.5 cm (wide) on finisher pig performance. Our hypothesis was that at minimal feeder trough space (4.45 cm/pig), feeders should be set at a wide gap opening to not limit feed intake and ADG. The feeders were adjusted to the minimum gap setting but the agitation plate could be moved upwards to a maximum gap opening of 1.9 or 3.2 cm, respectively. The treatments were arranged in a 2 × 2 factorial with 6 replications per treatment. All pens had the same feeder with 2 35.6 wide by 11.4 cm deep feeder holes. Feeder trough space was adjusted by having pens of either 8 to 16 pigs per pen. Gating was adjusted giving each pig 0.74 m2 of floor space. Pigs had ad libitum access to feed and water. A corn-SBM based diet containing 20% DDGS was fed in 4 phases to all treatments. Pen weights and feed disappearance were measured every 2 wk. Overall (d 0 to 91) there were no trough space × feeder adjustment interactions observed ($P > 0.10$). However, there was a tendency ($P = 0.08$) for increased ADG as feeder trough space increased from 4.45 to 8.9 cm/pig. Pigs fed with the wide feeder gap setting had increased ($P < 0.01$) feed disappearance and decreased ($P < 0.01$) G:F compared with pigs with the narrow feeder gap setting. These results suggest that regardless of feeder trough space, pigs with the wide feeder adjustment appeared to waste more feed as evidenced by the poorer G:F.

Table 1. Effects of feeder gap setting and feeder space on finisher pig performance, (d 0 to 91)

	4.45 cm trough space		8.9 cm trough space		P-value	
Item	Narrow	Wide	Narrow	Wide	Space	Adjustment
ADG, kg	0.99	1.01	1.02	1.03	0.08	0.33
ADFI, kg	2.99	3.16	3.04	3.24	0.18	<0.01
G:F	0.33	0.32	0.34	0.32	0.90	<0.01

Key Words: finishing pigs, feeder gap, feeder space

702 Modeling the response of growing turkeys to nutrition: from experimental to commercial data. V. Rivera-Torres*[1,2], P. Ferket[3], and D. Sauvant[4], [1]*Techna*, *Couëron, France*, [2]*AgroParisTech*, *Paris, France*, [3]*North Carolina State University*, *Raleigh,* [4]*INRA-AgroParisTech*, *Paris, France*.

A mechanistic model was previously built to describe growth profiles of turkeys in a controlled environment. The model was further developed to be used as a predictor of turkey growth performance in commercial conditions. The model used protein and lipid turnover rates in carcass, viscera and feathers to define the expression of the growth potential in a specific environment. Feed intake depended on the limiting amino acid requirement, or on net energy utilization when no nutrient was limiting. Nutrient ingestion was assumed as glucose, amino acid and fatty acid equivalents, driven by homeostatic regulations to maintain a constant plasma concentration. Nutrient oxidation was expressed as the formation of acetyl coenzyme A. Data from calorimetry measurements and slaughter analyses were used to calibrate the model using performance of male and female turkeys fed standard diets. Protein and lipid deposition were calibrated with the turnover rates, whereas nutrient oxidation was calibrated on CO_2 production. The homeostatic response to different energy and amino acid levels was calibrated using literature data. Finally, protein and lipid deposition in carcass were adapted to the body weight (BW) and feed efficiency observed in commercial facilities, while variability between flocks was supposed to be due to feed intake differences. Based on the calibration on calorimetry measurements, females had a lower protein turnover in viscera ($P < 0.01$), and a greater lipid turnover than males ($P < 0.01$). A 3% increase in dietary nutrient density tended to result in increased feed efficiency ($P = 0.08$), mostly because of increased protein deposition in viscera ($P = 0.05$). The variability in final BW and feed efficiency of commercial turkey flocks at 18 wk of age was due to a variation from 95 to 105% of average feed intake. The calibration on experimental data enabled the model to be used as a predictor of nutritional responses of turkey populations grown in commercial conditions.

Key Words: turkey, model, growth

703 Maximum profit feed formulation: 3. Interaction between energy content and temperature. S Cerrate* and P. W. Waldroup, *University of Arkansas*, *Fayetteville*.

Nutritional models for comparison of 2 environmental conditions on responses to dietary energy using data from literature were evaluated to formulate broiler diets by maximum profit feed formulation with real or simulated prices of corn and soybean meal. These diets were formulated based on corn and soybean meal (C-SBM) diets and others with wheat and cottonseed meal (+W-CM) as alternatives sources. Average body weight gain or feed intake slopes at normal temperature were significantly higher than those at heat stress. The rate of gain per calorie was 2 times higher at normal compared with heat stress and the rate of feed intake per calorie was half time higher at normal than did at heat stress. At real or simulated prices, the economic energy content in most cases was reduced by heat stress compared with those at normal temperature. For real prices the energy reductions from normal temperature to heat stress were from 3.254 to 3.015 kcal/g for diets based on C-SBM or from 3.2 to 2.961 kcal/g for diets based on +W-CM. These economic energy reductions were around 7% from real prices, up to 10% from simulated corn prices and up to 9% from simulated SBM prices. The inclusion of +W-CM reduced the economic energy content and increased the profitability compared with those based on C-SBM diets. These data indicate that broiler diets fed during heat stress should be formulated with reduced economic energy content due to decreased rate of gain or feed intake per calorie compared with those at normal temperature.

Key Words: temperature, economic energy content, profit

Physiology and Endocrinology: Neuroendocrinology and Hormone Receptors

704 Chicken Pit-1 isoforms: Expression, nuclear localization, and involvement in growth hormone promoter activation. M. Mukherjee* and T. E. Porter, *University of Maryland*, *College Park*.

A POU-Homeodomain transcription factor, Pit-1, is expressed in lactotrophs, thyrotrophs and somatotrophs of the anterior pituitary gland. Pit-1 regulates expression of Prolactin, thyroid-stimulating hormone and growth hormone (GH). Multiple isoforms of Pit-1, differing from each other primarily in the N-terminal transactivation domain, have been reported. In chickens, 4 Pit-1 mRNA isoforms have been reported, Pit-1α, Pit-1β1, Pit-1β2 and Pit-1γ, but functional assays of these isoforms have not been completed. This study aimed at characterizing each isoform in its ability to translocate to the nucleus and regulate the chicken GH gene. We hypothesized that the isoforms will differ in their ability to translocate to the nucleus and/or regulate the GH gene, due to the presence of different transactivation domains. Expression of all isoforms from recombinant expression plasmids in HEK-293 cells was confirmed by Western blotting using antiserum against rat Pit-1. Pit-1α and Pit-1β2 were found to activate the GH promoter, while Pit-1γ had no effect. Interestingly, the level of expression of Pit-1γ was considerably lower than the other isoforms. Nuclear localization of the isoforms was tested in HEK-293 cells using immunofluorescence localization of expressed proteins. All isoforms except Pit-1γ showed efficient nuclear localization. To eliminate the possibility that lower expression of Pit-1γ was due to translational inefficiency, N-terminal HA- and c-myc-tagged proteins were expressed in HEK-293 cells. All tagged isoforms, except Pit-1γ were detected using antibodies directed against the tag, indicating that reduced expression of Pit-1γ was not due to inefficient translation. A remaining possible explanation for the reduced Pit-1γ levels observed is proteolytic degradation of an unstable Pit-1γ, a hypothesis that we will test empirically using inhibitors of protein degradation pathways. Future work will focus on elucidating potential physical interactions between the isoforms and their ability to interact with other transcriptional co-activators involved in regulation of Pit-1 regulated genes.

Key Words: transcription factor, anterior pituitary, growth hormone

705 Ras-dva is a novel Pit-1 and glucocorticoid regulated gene in the developing avian pituitary gland. L. E. Ellestad* and T. E. Porter, *Department of Animal and Avian Sciences and Molecular and Cell Biology Program, University of Maryland*, *College Park*.

Corticosterone (CORT) initiates growth hormone (GH) and prolactin (PRL) expression during embryogenesis. Microarray screens identified Ras-dva as a glucocorticoid-induced gene that may play a role in regulating GH and PRL expression. The objective of this study was to characterize tissue-specific and glucocorticoid regulation of Ras-dva expression in the developing chick embryo. Pituitary Ras-dva mRNA increased from embryonic day (e) 10 to a maximum just before hatch, then decreased post-hatch ($P < 0.05$; n = 3). Ras-dva mRNA was highly enriched in the pituitary relative to other tissues ($P < 0.05$; n = 3). CORT increased Ras-dva mRNA in mid- and late-stage embryonic pituitary cells, both in the presence and absence of a protein synthesis inhibitor ($P < 0.05$; n = 3), suggesting it may be a direct target of the glucocorticoid receptor (GR). We identified 5 putative Pit-1 binding sites (−0.35, −2.2, −2.5, −3.2, and −3.4kb) and 2 putative GR binding sites (−2.1 and −4kb) within the 5′-flanking region of the chicken Ras-dva gene that may be responsible for pituitary specificity and glucocorticoid regulation. E11 pituitary cells were transfected with reporter constructs containing 2kb (pGL3–2kb) and 4kb (pGL3–4kb) of the 5′-flanking region and cultured in the presence or absence of CORT (n = 3). Under basal conditions, pGL3–2kb was activated 40-fold over an empty reporter vector ($P < 0.05$), indicating that the most proximal Pit-1 site may be responsible for basal promoter activity in embryonic pituitary cells. Mutagenesis of this site in pGL3–2kb substantially reduced basal promoter activity ($P < 0.05$), confirming that this Pit-1 site is necessary for full activation of the promoter. CORT treatment had no effect on pGL3–2kb activity, but increased activity of pGL3–4kb 5-fold ($P < 0.05$). Surprisingly, mutagenesis of the potential GR binding sites did not affect CORT induction, indicating that neither putative GR binding site is necessary for CORT stimulation. In conclusion, Ras-dva is a novel glucocorticoid-regulated gene in the developing pituitary that is expressed in cells of the Pit-1 lineage, including GH- and PRL-producing cells.

Key Words: growth hormone, prolactin, corticosterone

706 Hypothalamic galanin-like peptide and kisspeptin may regulate the hypothalamo-pituitary-gonadal axis in the Mallard duck (*Anas platyrhyncos*). G. S. Fraley*, *Hope College*, *Holland, MI*.

The Mallard duck is a seasonal breeder and an excellent model for studying the neural mechanisms that regulate the activation of the hypothalamo-pituitary-gonadal axis (HPG). Recently, 2 neuropeptides have stood out as important modulators of the mammalian HPG, namely kisspeptin (KP) and galanin-like peptide (GALP). The goals of these studies were to determine (a) if KP and GALP regulate the avian HPG, (b) if KP and GALP are expressed in the mallard brain, and (c) if KP and/or GALP are co-localized with aromatase in the avian brain. Central administration of both KP and GALP significantly (ANOVA; $P < 0.01$) increased plasma luteinizing hormone, an effect blocked by pretreatment with the GnRH antagonist, acyline. Kisspeptin and aromatase immunoreactive (ir) cell bodies were observed in the medial preoptic nucleus (POM) and in fibers throughout the anseriforme brain. Virtually all POM kisspeptin-ir soma also expressed aromatase, suggesting that autocrine mechanisms may predominate in the interaction between steroid provision and kisspeptin expression. No colocalization was observed between kisspeptin-ir and GnRH-ir, although the respective fibers were in dense close proximity throughout the tuberoinfundibular area. GALP cell bodies were observed in the tuberoinfundibular nucleus and GALP-ir fibers were observed in close proximity to both GnRH- and KP-ir cell bodies and fibers. Taken together, these data suggest that estradiol synthesized by aromatase- and kisspeptin co-expressing POM neurons may regulate the HPG via an effect on GnRH secretion. Furthermore, as is observed in mammals GALP is anatomically positioned to regulate the HPG via interactions with both GnRH and KP. These observations suggest a conservation of HPG regulation in birds and mammals.

Key Words: luteinizing hormone, KiSS1

707 Gene expression profiling of dopamine-melatonin neurons in the avian premammillary nucleus. S. Kosonsiriluk*, S. W. Kang, L. J. Mauro, J. R. Garbe, S. C. Fahrenkrug, and M. E. El Halawani, *University of Minnesota*, *St. Paul*.

Dopamine-melatonin (DA-MEL) neurons of the hypothalamic premammillary nucleus (PMM) are proposed as a site for photoperiodic time measurement regulating reproductive seasonality in birds. Gene expression profiles of PMM DA-MEL neurons from photosensitive long day

(LD; n = 4 pools with 6 birds/pool) and short day (SD; n = 4 pools with 6 birds/pool) turkey hens were determined at circadian time 14 (CT14). The chicken 20.7k long oligo microarrays purchased from the University of Arizona were validated and used for this study. After hybridization and image acquisition, fluorescence intensities were extracted and graded using BlueFuse software (BlueGnome Ltd., Cambridge, United Kingdom). Microarray data was processed and normalized using JMP Genomics (SAS Institute Inc., Cary, NC). Expressed probes were identified as those whose median signal intensity was brighter than the 99th percentile of negative control expression values. Significance of gene expression was determined by ANOVA. P-values were adjusted for a false discovery rate controlled P-value threshold of 0.05. The results from expression arrays confirmed expression of clock genes in PMM DA-MEL neurons. The upregulation of *Per3*, *Cry2* and *Bmal1* was observed in SD birds (CT14, dark phase). In contrast, *Cry1*, *Per2*, *Bmal2* and *Clock* were upregulated in LD birds (CT14, light phase). In addition, expression of photopigment molecules was observed in PMM DA-MEL neurons including rhodopsin, panopsin and melanopsin. Upregulation of the rhodopsin gene was also observed in LD birds, as compared with SD birds, along with the genes encoding rod cGMP-specific phosphodiesterase 6B (PDE6B) and retinal pigment epithelium-specific protein (RPE65). This interesting expression shift following photostimulation implies possible light perception. The expression of photopigments, signaling molecules, and clock genes in PMM DA-MEL neurons provides additional support for this hypothalamic region as a site of photoreception and photoperiodic time measurement.

708 Septal and hypothalamic structures activated following sexual and agonistic encounters in male broiler breeders. W. J. Kuenzel*, J. Xie, and A. Jurkevich, *University of Arkansas*, *Fayetteville*.

Induction of Fos protein, an indicator of neuronal activation, was utilized to identify groups of neurons activated by either sexual or aggressive interactions in roosters. Experimental groups included handled controls, non-contact interaction with a female (M-FN), or contact interaction with a taxidermy female (M-FT), a live female (M-FC) or a live male (M-M). Eight brain areas were examined and 6 will be discussed. Results showed that the medial portion of the bed nucleus of stria terminalis, subnucleus 2 (BSTM2) was activated solely by appetitive sexual behavior (M-FN). Consummatory sexual behavior (M-FT and M-FC) resulted in significantly higher Fos protein counts in the medial preoptic nucleus (POM), lateral septum (SL), paraventricular nucleus (PVN),ventral lateral thalamic area (VLT) and bed nucleus of the pallial commissure (NCPa). Aggressive behavior (M-M) resulted in activation of the POM, SL, PVN, VLT and NCPa. It is seen that 5 neural structures were activated for both sexual and aggressive behavior suggesting that the same neural structures are utilized for functionally distinct behaviors. The most pronounced increase in Fos counts due to agonistic behavior was seen in the PVN and dual immunocytochemical studies showed that induced Fos protein occurred in magnocellular arginine vasotocin (AVT) neurons. Since magnocellular AVT neurons project directly to the posterior pituitary, it suggests that the stress response depends upon peripheral release of AVT independent of the established peptide release into the median eminence and portal system for activating ACTH secretion from the anterior pituitary. In summary, results demonstrate that use of Fos protein is effective for elucidating differential sets of neurons involved in specific behaviors of chickens.

709 Various social behaviors induce differential activation of aromatase neurons in the brain of male broilers. J. Xie*, W. J. Kuenzel, and A. Jurkevich, *University of Arkansas*, *Fayetteville*.

Several steroid-sensitive nuclei in the brain form a network regulating various social behaviors. The medial preoptic area (POM) and the medial portion of bed nucleus of stria terminalis (BSTM) are important components of this network. Our previous study demonstrated that the POM is activated following male sexual behavior and intermale conflict. The subnucleus 2 of BSTM (BSTM2) was specifically activated by appetitive sexual behavior. The objective of this study was to investigate the activation of aromatase-immunoreactive (ARO-ir) neurons in the POM and BSTM using dual immunolabeling for ARO and immediate early gene product, Fos. Males were subjected to a 20-min non-contact interaction with a female (M-FN), or contact interaction with a female (M-FC) or another male (M-M). Handling (HC) and open-field (OF) groups were used as controls. In the POM, intermale interactions decreased the total number of ARO-ir cells, while M-FN had more ARO+Fos-ir neurons than other groups. The lateral portion of POM had more ARO+Fos-ir cells than the medial portion. In the BSTM1, M-FN had a higher percentage of ARO+Fos-ir cells than HC and M-M groups. In the BSTM2, social interactions resulted in a decrease of ARO-ir cells with lowest number of ir cells in the M-FC group. M-FN had significantly more ARO+Fos-ir cells than any other treatment group. In the lateral POM, ARO+Fos-ir cells positively correlated with the frequency of waltzing toward a female (courtship), while waltzing toward a male (agonistic display) negatively correlated with ARO-ir cell counts in the medial POM. In the BSTM1 and 2, positive correlations were found between ARO+Fos colocalization and waltzing toward a female, while chasing and waltzing frequency in intermale interactions negatively correlated with ARO-ir cell counts in the BSTM1 and 2, respectively. The findings suggest that activation of different ARO-ir cell groups may underlay the roles of POM and BSTM in distinct behaviors.

710 Fos protein induction in vasotocinergic neurons of male broilers following different social contexts. A. Jurkevich*, J. Xie, and W. J. Kuenzel, *University of Arkansas*, *Fayetteville*.

Vasotocin (VT) in avian species and its mammalian counterpart vasopressin are important peptidergic regulators of social behavior. The medial portion of the bed nucleus of stria terminalis (BSTM) of chickens contains parvocellular neurons producing VT in a sex dimorphic pattern with males having abundant VT cells and projections and females virtually devoid of VT in this location. In males, these cells also express galanin, corticotropin-releasing hormone and estradiol-producing enzyme aromatase suggesting important roles of this relatively small neural system in neuroendocrine regulation. The aim of this study was to reveal vasotocinergic neurons activated in roosters following different social encounters using Fos protein as an indicator of metabolic stimulation. Individual roosters were placed in an observation pen where they were provided with restricted or unrestricted access to a female (groups M-FN and M-FC), unrestricted access to a male (group M-M) or were exposed

to an empty pen (open field control, OF). After completion of tests, neurons immunolabeled for VT and Fos were quantified in 2 portions of the BSTM. In the dorsolateral subnucleus of the BSTM (BSTM1), male-female or male-male interactions did not change the total number of VT cells or percentage of VT cells co-expressing Fos. In the ventromedial subnucleus of the BSTM (BSTM2), there was a significant increase ($P < 0.05$) in percentage of VT cells co-expressing Fos in males that had non-contact interactions with females (group M-FN, 49.2 ± 4.8) as compared with control males exposed to an empty pen (group OF, 29.4 ± 7.1). Same-sex interactions resulted in lower percentage of VT and Fos co-expressing cells in BSTM2 than opposite-sex interactions ($P < 0.05$). The findings demonstrate that vasotocinergic neurons in BSTM2 of males are preferentially activated following opposite-sex interactions and confirm our previous observations regarding a key role of BSTM2 in control of male sexual behavior in roosters.

711 Effects of RFamide-related peptide-3 (RFRP-3) on secretion of LH in ovariectomized prepubertal gilts. N. L. Heidorn[1], C. R. Barb[2], C. J. Rogers[1], G. J. Hausman[2], and C. A. Lents*[1], [1]*University of Georgia*, *Athens,* [2]*USDA-ARS Richard B. Russell Agriculture Research Center, Athens, GA*.

Pulses of LH are suppressed before puberty in the gilt. RFRP-3 is proposed to be a hypophysiotropic hormone in mammals. A series of experiments (EXP) were conducted to test the hypothesis that RFRP-3 inhibits LH release in ovariectomized (OVX) prepubertal gilts. All gilts were OVX at least 2 weeks before being fitted with indwelling jugular catheters for the collection of serial blood samples. In EXP I, blood samples were collected every 15 min for 6 h. Commencing at 120 min after the start of sampling, all gilts (n = 3) received a loading dose of 1 mg of RFRP-3 followed by repeated injections of 40 μg of RFRP-3 every 5 min for 2 h resulting in a total infusion of 2 mg of RFRP-3. All injections were administered by hand in 2 mL of 0.9% saline. Area under the curve (AUC) was determined in each of 3 periods; 1 h before treatment (period 1), the first h of treatment (period 2), and the second h of treatment (period 3). In EXP II, blood samples were collected every 15 min for 8 h. Commencing at 240 min after the start of sampling, animals received intracerebroventricular (i.c.v.) injections of 10, 50, or 100 μg of RFRP-3 in 0.9% saline (n = 6/group). Control animals received 0.9% saline alone (n = 7). AUC was determined for each of 2 periods (4 h before and 4 h after i.c.v. treatment). Mean LH (1.33 ± 0.13 ng/mL), number of LH pulses (2.0), or pulse amplitude (1.32 ± 0.25 ng/mL) was not different during the 2-h treatment period when compared with 2 h pre- or the 2 h post-treatment. However, there was a tendency ($P = 0.09$) for total LH release, as indicated by AUC, to be reduced in period 3 compared with periods 1 or 2. In EXP II, central administration of 10 μg of RFRP-3 yielded an apparent suppression in area under the curve (59.4 ± 20.91% of the pre-i.c.v. value), but this did not reach significance ($P = 0.27$). We conclude that RFRP-3 does not act to inhibit the pulsatile release of LH in prepubertal gilts.

712 The effects of fluoxetine on lactation and lamb growth in sheep. P. L. Black*[1], R. A. Halalsheh[1], L. M. Lankford[1], M. M. Marricle[1], M. M. Christiansen[1], M. M. Scroppo[1], L. L. Hernandez[2], and T. T. Ross[1], [1]*New Mexico State University*, *Las Cruces*, [2]*University of Cincinnati*, *Cincinnati, OH*.

Fluoxetine (a selective serotonin reuptake inhibitor; FLX) has been shown to cause a delay in the onset of lactogenesis stage II when taken during pregnancy and/or lactation. A study was conducted to evaluate if ewes would be an appropriate model to determine the effects of FLX on milk production. Twenty-nine ewes (85 ± 12 kg; body condition score 2.6 ± 0.3) in late gestation were used in this study. Ewes allotted to treatments were stratified by fetal numbers and breeding date. Ewes were orally dosed daily with an empty capsule for controls or a capsule containing 40 mg of FLX. Dosing began on about d 121 of gestation and continued until lambing. Ewes were dosed every morning at 0700 h. Following parturition and before nursing, milk and blood samples were collected from each ewe and her lamb(s). The first milk yield was measured 8 h after birth and subsequent milkings were conducted at 1500 and 1800 h every other day for 9 d. Milk letdown was induced by a 1 mL intravenous injection of oxytocin, 1 min before milking. Milk yields were measured over a 3 h period when lamb(s) were removed. We observed a treatment by parity interaction, as ewes with multiple lambs treated with FLX had greater ($P = 0.01$) milk yields than treated or control ewes giving birth to single lambs and control ewes giving birth to multiple lambs. Lambs were weighed at birth (d 0) and following the milk yield study (d 9). We observed no differences ($P > 0.05$) in either birth weight or d 9 weights. Lamb gain over the 9 d milking period was similar among treated and control ewes ($P > 0.05$). No interactions were observed between parity and treatment in lamb weights or gain. Fluoxetine treatment during late pregnancy resulted in greater milk production in ewes giving birth to multiple lambs. However, FLX had no effect on lamb weights or lamb weight gain.

Key Words: fluoxetine, lactation, sheep

714 Cloning and characterization of chicken galanin and galanin receptors. J. C. W. Ho*[1], Y Wang[2], and F. C. Leung[1], [1]*The University of Hong Kong*, *Hong Kong, HKSAR, China*, [2]*Sichuan University*, *Chengdu, Sichuan, China*.

Galanin is a neuropeptide of 29 to 30 amino acids, widely distributed in the mammalian nervous systems and peripheral tissues. It exerts multiple physiological functions including modulation of cognitive functions and hormones release through the interaction with at least 3 known G protein-coupled receptors (GalR1, 2 and 3), which have only been identified in mammals. In the present study, 4 transcript variants of galanin prepropeptide precursor (cGAL), 3 galanin receptors (cGalR1, 2 and 3) and 2 additional receptors with considerable homology to cGalR1 and cGalR2, thus herein designated cGalR1-L and cGalR2-L, were cloned from chicken whole brain and intestine tissue respectively. Four variant cDNAs for chicken galanin prepropeptide, resulted from alternative splicing, encode precursor peptides of 88, 117, 141 and 150 amino acids respectively, while the 5 cloned receptors are ranged from 357 to 405 amino acids in lengths, sharing considerable amino acid sequence identities (50% to 86%) to their mammalian homologs. Using reverse transcription-polymerase chain reaction (RT-PCR), cGAL and its receptors were found to be widely distributed in the 12 adult chicken tissues and different regions of oviduct examined, with particularly high abundances in brain, small intestine, ovary and pituitary, except for cGalR3 in which its expression was restricted to ovary. Using different luciferase reporter systems, we also demonstrated that chicken galanin peptide was capable of altering luciferase activities, in dose-depending manners, in Chinese hamster ovary (CHO) cells expressing each cloned receptor, thus suggesting the differential functional couplings of each receptor to various classes of G proteins. The characterization of chicken galanin receptors would provide a better understanding to the physiological functions of galanin in avian species.

Key Words: chicken, galanin, galanin receptor

715 Influence of dairy herd longevity and productivity on lifetime N use efficiency. J. M. Moorby*, *Institute of Biological, Environmental and Rural Sciences*, *Aberystwyth, UK*.

Excretion of excess dietary N from dairy cows contributes to environmental pollution, with ammonia, nitrate, and nitrous oxide being the major pollutants. Apparent efficiency of feed N use for milk protein production is typically about 25%, depending on diet. However, there are long periods when a dairy cow is not productive (during heifer growth and when dry) which reduce lifetime apparent N use efficiency (NUE) because the animal excretes N with little useful output at these times. This situation is exacerbated as cow longevity decreases, and the ratio of non-productive to productive periods of life increases. A simple modeling exercise was carried out to investigate the effect of dairy cow productivity and longevity on lifetime NUE of a dairy herd yielding an assumed fixed quantity of milk. Opportunistic losses in milk production caused by disease and infertility were included to take into account the number of extra animals required for target herd milk yield. N losses during growth (including heifer mortality), pregnancy, and culling were included. With an assumed baseline NUE largely determined by nutrition (e.g., 25%) herd longevity of milking cows with a mean lactation yield of 7,500 kg resulted in lifetime NUEs of 11.8, 18.6, 21.0, 22.1 and 22.7% for lactations 1 to 5 respectively. The response was well described (R^2 = 0.99) by a general saturation curve model (Morgan-Mercer-Flodin). For a fixed herd milk yield, increased individual animal productivity resulted in better lifetime NUE because of fewer cows in the herd (e.g., 19.7, 21.0, 21.8% for 5,000, 7,500, and 10,000 kg cows completing 3 lactations). This equates to less N excretion per kg milk produced by higher yielding cows. However, this assumes rates of disease incidence and longevity are unaffected by productivity, which may not be achieved in practice. In conclusion, for herds with very high replacement rates, overall lifetime NUE is significantly affected by animal longevity. For animals surviving for about 3 lactations or more the major factor determining lifetime NUE efficiency is nutrition, and the unproductive periods of the cow's life have a relatively minor influence.

Key Words: dairy cows, longevity, N use efficiency

716 Optimal dry period length and management to maximize production and health. D. E. Santschi*[1], C. L. Girard[2], R. I. Cue[3], D. Pellerin[4], and D. M. Lefebvre[1], [1]*Valacta*, *Ste-Anne-de-Bellevue, Qc, Canada*, [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, Qc, Canada*, [3]*McGill University*, *Ste-Anne-de-Bellevue, Qc, Canada*, [4]*Université Laval*, *Québec, Qc, Canada*.

The objective of this study was to determine optimal dry period (DP) length to maximize milk production and facilitate transition according to management (MGMT) used. Data were obtained from a previous study comparing effects of short (SDP; 35d dry; pre-calving ration only) and conventional DP (CDP; 60 d dry; dry-off ration until d-21 and 21d of pre-calving ration). The current data set included information on 964 cows managed with either 21d (CDP) or 35d (SDP) of pre-calving ration. Optimal DP length was determined within each MGMT group. Fixed effects of the model were DP, parity, block, herd and DP*Parity in Proc GLIMMIX (disorder incidences) or Proc MIXED (other variables). For both MGMT groups, previous lactation ECM yield was not different among DP length groups ($P \geq 0.18$). Within the CDP MGMT strategy, DP ≤ 42d tended to lower incidence of ketosis but to increase incidence of retained placenta (RP) compared with the other DP lengths ($P \leq 0.09$). However, DP length did not affect average ECM yield in the following lactation ($P = 0.62$). Within the SDP MGMT strategy, DP ≤ 28d decreased incidence of ketosis ($P = 0.01$), but increased incidence of RP ($P = 0.01$). DP ≤ 28d also decreased average ECM yield compared with DP ≥ 29d ($P = 0.01$). No effect was observed on dystocia, displaced abomasum, metritis and milk fever in either MGMT group. DPxParity was not significant. Results suggest a minimal DP of 29d is required to maximize milk yield and facilitate transition when a MGMT of 35d of pre-calving ration is used. Further analyses on reproduction and total lactation milk and component yields are required to formulate adequate recommendations.

717 Effect of dietary phosphorus amount on milk production of dairy cows in China. Z. Liu[1], C. Wang*[1], J. X. Liu[1], D. M. Wang[1], and Z. Wu[2], [1]*Institute of Dairy Science, Zhejiang University*, *Hangzhou, 310029, P. R. China*, [2]*University of Pennsylvania, School of Veterinary Medicine*, *Kennett Square*.

The effect of reducing dietary phosphorus (P) on milk production of dairy cows in China was determined using 45 multiparous Holsteins over a full lactation period. Animals were blocked into 15 groups according to milk production of previous lactation and parity, and allocated to treatments randomly within each group. Diets contained 0.37, 0.47, or 0.57% P (DM basis), based on NRC guidelines, the level recommended by the Chinese feeding standard, and the amount currently fed by most producers, respectively. Milk yield was recorded and milk composition analyzed monthly. Blood samples were collected on d −6, −3, 0, 3, 6 relative to calving and then monthly throughout the experiment. Feces and urine were analyzed in wk 12, 24, and 36. All data were analyzed using the MIXED procedure of SAS software system with cow as the repeated subject using the covariance type AR (1). The model included phosphorus level, time, and interaction of phosphorus level × time. Neither DMI nor milk yield was affected by dietary P content (see Table 1). Milk fat was slightly higher for 0.37% P than for the other 2 dietary P concentrations. Serum P did not reflect dietary P amount, and there was no influence of dietary P on serum Ca concentration. Fecal P excretion was reduced by 25% when 0.37% P was fed compared with 0.57% P. Urinary P reached a maximum concentration for all groups during peak lactation. Reducing dietary P from 0.57 to 0.37% did not negatively affect milk production, while P excretion was significantly decreased.

Table 1. Milk performance and serum Ca and P pre- and post-partum influenced by dietary P amount in dairy cows

	Dietary P, %				
	0.37	0.47	0.57	SEM	P
Milk yield, kg/d	21.5	20.7	22.0	1.00	0.63

Key Words: dietary phosphorus amount, milk production, phosphorus excretion

718 Voluntary use of showers: Effects on behavior and physiology of dairy cattle in summer. A. L. Legrand[1,3], K. E. Schütz[2], and C. B. Tucker*[1], [1]*Department of Animal Science, University of California, Davis,* [2]*AgResearch Ltd, Hamilton, New Zealand,* [3]*Division of Animal Health & Welfare, University of Edinburgh, Roslin, UK*.

Water is often used to cool dairy cows in summer. There is limited evidence that cattle find water cooling aversive and may avoid wetting parts of the body, such as the head. Our objective was to understand whether dairy cattle will voluntarily use water located away from other resources, such as feed and lying areas, and if usage affects behavioral and physiological indicators of heat stress. Twenty-four dairy cows were used, half of which had access to a cow shower that consisted of a pressure-sensitive platform fitted with 2 shower heads; water flowed when the cow stepped on the platform. Internal body temperature and behavior were recorded 24h/d for 5d during summer, and respiration rate and skin temperature were recorded during the day. Cattle spent 3.0 ± 2.1h/d in the shower, and there was considerable variability between animals (0 to 5.8h/d). Cows preferentially used the shower during the daytime, with 89 ± 12% of use between 10:00–19:00h. Shower use increased with warmer weather by 0.3h for every 1°C increase in air temperature. Respiration rate and skin temperature did not differ between treatments (*t*-test; 53 ± 3.7 vs. 61 ± 4.3 breaths/min and 35.0 ± 0.3 vs. 35.4 ± 0.4°C in shower and control, respectively, $P \geq 0.16$). In contrast, cows provided with a shower had lower (*t*-test; 0.2 ± 0.1°C) body temperature than control cows in the evening ($P \leq 0.05$); peak body temperature occurred at this time. Weather affected cattle time budgets and physiological responses in both treatments, as assessed with regression. Cows spent less time lying when heat load index (HLI; a composite measure of air temperature, humidity, wind speed and solar radiation) increased ($P < 0.01$), but the total time spent lying, standing, and feeding did not differ between treatments (*t*-test; $P > 0.32$). Cows also had higher respiration rate, and skin and body temperature as HLI increased ($P < 0.01$), regardless of treatment. These data suggest that most cattle will make considerable use of water cooling in summer, and, as expected, this alleviated some of the effects of heat load in summer. There is, however, considerable individual variation in use of water and further work is required to understand the implications of these differences in a production setting.

Key Words: heat stress, behavior, physiology

719 The influence of technological and biological factors on productivity in dairy farms. A. H. Herlin*[1] and K. Bäckman[2], [1]*Dept. Rural Buildings, Swedish University of Agricultural Sciences, Alnarp, Sweden,* [2]*Estate Office, Swedish University of Agricultural Sciences, Uppsala, Sweden*.

There are many strategic decisions for the milk producer. The Swedish milk producers, as well as many others, have increased herd sizes and have increased use of technologies which mainly improve precision and/or are labor saving. The aim of this investigation was to explore how different biological or technological factors influence productivity in dairy farms. Eight dairy farms in southern Sweden were selected as they participated in economic extension service. Detailed economic results from book-keeping were used in the analysis together with data from milk recording scheme and data from enquiries. Different milking systems were also considered for the selection of farms. On farms, technical level were registered as milking systems and number of milking units, milking frequency, number of free-stalls and type of feeding systems. Biological factors as production level, calving age, calving interval, replacement rate and causes for replacement and health on herd level and calf mortality. Data was compiled in Excel and regression coefficients determined in Minitab. Herd sizes were 97 to 550 cows with an average of 266. Average milk production was 9775 kg (SD. 1640). Increasing herd size was associated, but not significantly, with lower production. Herds with herring bone or parallel milking systems had production of about 10 500 kg milk while the herds with robotic and carousel milking had a production of about 8500 kg. Milking frequency influenced only slightly production (R^2 24%; $P = 0.218$). Occupancy rate (cows per free-stalls) showed a positive relationship in milk per cow (R^2 40%; $P = 0.091$). Increasing herd size reduced working hours per cow ($P = 0.049$), but reduction was most evident below 260 cows per herd. Higher milk revenue minus feed costs was correlated with higher production levels. The complexity of milk production on the farm level makes it also difficult to fully acquire reliable empirical data for analysis in how different factors influence profitability. However, our data show that within the herd sizes investigated, work hours per cow and year is less likely to go below 26 h in herds larger than 260 cows but further studies have to confirm that.

Key Words: profitability, milk production

720 Management-driven heterogeneity in the relationship between milk production and reproductive performance of dairy cows. N. M. Bello*, J. P. Steibel, R. J. Erskine, and R. J. Tempelman, *Michigan State University, East Lansing*.

Although research on the relationship between milk production and reproduction of dairy cows has been extensive, many studies are conflicting. Much work is characterized by a common under-appreciation of the relative importance of the within-herd (cow-level) component versus the between-herd (herd-level) component of this relationship, and how these may depend upon herd management. We recently developed and validated a bivariate hierarchical Bayesian approach to model multifactorial sources of heterogeneity for these 2 components of variances and covariances. The objective of this study was to apply this methodology to evaluate various herd management factors as sources of potential heterogeneity on variances of and covariance between milk production and reproductive performance of Michigan dairy cows. Data consisted of 124,079 lactation records from 541 Michigan dairy farms. The means, variances, and covariances between cumulative milk yield at 305 DIM (305MILK) and calving interval (CI) were modeled as a function of management practices; significant herd management factors influencing the relationship between the 2 traits were selected using the Deviance Information Criterion. The production-reproduction relationship at the herd level was generally favorable with average herd CI estimated to

decrease 0.13 ± 0.06 d for every 100 kg increase in herd 305MILK. However, for within-herd relationships, higher producing cows had poorer reproductive performance (0.50 ± 0.03 d longer CI per 100 kg increase in 305MILK) than lower producing herdmates. This unfavorable relationship was, nevertheless, alleviated by ~12% in herds with a high level (>50% cows) of bST supplementation. Significant random herd-specific sources of heterogeneity in the magnitude of the cow-level production-reproduction relationship suggest further investigation of additional management practices. Understanding the conditions under which milk yield and fertility express different associations is critical to help guide management decisions to optimize dairy cow and herd performance at its dual production-reproduction core.

Key Words: dairy cow, production-reproduction relationship, management

721 Milking frequency and milk production in pasture-based lactating dairy cows. A. G. Rius*, J. K. Kay, C. V. C. Phyn, S. R. Morgan, and J. R. Roche, *DairyNZ*, *Hamilton, New Zealand*.

The objective of this study was to test the effect of modified milking frequency (MF) during early lactation on milk production in grazing dairy cattle. Multiparous Holstein-Friesian cows (n = 150) were randomly assigned to one of 5 treatments at parturition: milked once daily (1X) for 21 d (1X21), milked 1X for 42 d (1X42), milked twice daily (2X), milked thrice daily (3X) for 21 d (3X21), and milked 3X for 42 d (3X42). All cows were milked 2X post treatment until wk 24 in lactation. Animals were offered a generous allowance of fresh pasture and supplemented with 4 kg DM/d of concentrate during the first 16 wk in milk and 2 kg DM/d for 8 wk thereafter. Effects of MF, duration of MF, and interactions during treatment and post treatment periods were tested using mixed models (GenStat 12.1). During the treatment period, a MF x duration interaction was detected for milk, protein, and fat yields. Relative to 3X21, 3X42 failed to increase milk production further. However, 1X42 had lower ($P < 0.05$) milk (2.4 kg/d), protein (0.10 kg/d), and fat (0.12 kg/d) yields compared with 1X21 during the treatment period. Relative to 2X, 3X cows produced more milk (1.5 kg/d; $P < 0.05$), however, protein and fat yields were not different during or after the treatment period. There was no MF x duration interaction post treatment. An adverse effect in production occurred for 1X in the post treatment period; however, 3X cows failed to sustain increased production compared with 2X. Relative to 2X, 1X cows had lower yields of fat (0.1 kg/d; $P < 0.01$) and protein (0.05 kg/d; $P < 0.05$) post treatment. Body weights were reduced in 2X cows compared with 1X during the treatment (476 vs. 484 kg; $P < 0.05$) and post treatment periods (500 vs. 512 kg/d; $P < 0.01$). In summary, 1X for the first 21 or 42 DIM impaired milk production and the losses continued for the remainder of the lactation. Relative to 2X, 3X in early lactation did not improve milk production beyond the period of increased milking frequency.

Key Words: milking frequency, duration, milk production

722 Water use and effectiveness of a low pressure mister system for cooling lactating dairy cows during chronic heat stress. J. K. Bernard*[1], D. R. Bray[2], N. A. Mullis[1], and C. P. Rowe[1], [1]*University of Georgia*, *Tifton,* [2]*University of Florida*, *Gainesville*.

A replicated switchback design trial was conducted during June and July, 2009 to determine the effectiveness of a low pressure mister system for providing supplemental evaporative cooling compared with a high pressure mister system. Both mister systems were mounted to the face of 91.4 cm high speed fans spaced every 18.3 m over the feed alley and free stalls in a 4-row free stall barn. The low pressure mister system (Arato Dairy Cooling System, Aratowerk GmbH & Co. KG, Germany) operated at an average line pressure of 3.4 bar (50 psi) whereas the high pressure system operated at an average line pressure of 12.4 bar (180 psi). The fans were set to operate when the ambient temperature inside the barn exceeded 22.2 C (72 F) and the mister systems operated anytime the fans were on and the relative humidity was less than 85%. Conditions within the free stall barn were continuously monitored using a Hobo ProRH/Temp data logger. Each replicate of the trial consisted of 3 wk and there were 2 replicates. For each replicate, the body temperature of 10 lactating Holstein cows each in 2 groups was continuously recorded every 5 min for 3 d using a water probe placed in the vagina each wk. Water usage for each system was measured during the second replicate using inline water meters. Environmental conditions inside the free stall barn were characteristic of chronic heat stress in that the temperature-humidity index was greater than 72 throughout the trial. The body temperature of the cows cooled with the low pressure and high pressure systems were similar ($P = 0.69$) and averaged 38.794 and 38.789 C (101.83 and 101.82 F), respectively. No differences ($P = 0.58$) were observed in respiration rates of cows which averaged 61.0 and 62.5 breaths per min for low pressure and high pressure systems, respectively. The low pressure mister system used 43% less water per day than the high pressure system. Results of this trial indicate that a low pressure mister system that uses less water can be used to provide supplemental cooling of lactating dairy cows housed in a free stall barn during chronic heat stress conditions.

Key Words: heat stress, evaporative cooling, dairy cows

723 A point-in-time comparison of the environmental impact of Jersey vs. Holstein milk production. J. L. Capper*[1] and R. A. Cady[2], [1]*Department of Animal Sciences, Washington State University*, *Pullman,* [2]*Elanco Animal Health*, *Greenfield, IN*.

This study investigated the environmental impact of producing 500,000 MT of cheddar cheese using either Jersey or Holstein cow populations. The model used current DRMS DairyMetrics population data for milk yield and composition (Jersey: 20.9 kg/d, 4.8% fat, 3.7% protein; Holstein: 29.1 kg/d, 3.8% fat, 3.1% protein), age at first calving, calving interval, and culling rate. Each population contained lactating and dry cows, bulls and herd replacements for which rations were formulated according to NRC at breed-appropriate bodyweights. Resource inputs included feedstuffs, water, land, fertilizers and fossil fuels. Waste outputs included manure and greenhouse gas emissions. Cheese yield (kg) was calculated according to Van Slyke (1949). Increased daily milk yield in Holstein cows reduced the population size required to produce 500,000 MT of cheese by 8.5%. The potential magnitude of the difference in population size was mitigated by the earlier age at first calving and shorter calving interval of Jersey cows, which reduced replacement heifer and dry cow numbers respectively. Despite the increase in total animal numbers, decreased bodyweight of individual Jersey animals reduced the total body mass of the Jersey population. In consequence, maintenance energy was reduced by 21%, water use by 27% and cropland use by 23% per unit of cheese. Fossil fuel use was reduced by 21% per unit of cheese made using milk from the Jersey population. Methane and nitrous oxide emissions associated with cheese produced by the Jersey population were reduced by 18% and 7.1% respectively. The carbon footprint (total CO_2-equivalents) was reduced by 18% per unit of cheese in Jerseys compared with Holsteins. Results demonstrate that reductions in environmental impact conferred by the 'dilution of maintenance' effect are not simply mandated by changes in milk pro-

duction, but are also markedly affected by the interplay between animal bodyweight and nutrient density of milk.

Key Words: environmental impact, carbon footprint, dilution of maintenance

724 Bio-economic value of extended lactations in Italian Holstein farms. A. S. Atzori*, R. Steri, C Dimauro, A. Cannas, and G. Pulina, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Sardinia, Italy*.

The extension of lactations over the standard 305 DIM might be suitable due to the low feeding cost in late lactation and the negative effect of pregnancy on milk yield. About 50% of the > 1,000,000 heads of Italian Holstein cows (about 9000 kg of milk/y per cow) became pregnant after 143 DIM and had a mean calving interval (CI) > 450 d. Farmers usually try to inseminate the cows as early as possible to achieve a short CI to maximize daily milk yield. Unfortunately, higher milk yields tend to reduce cow fertility in early lactation due to genetic and management constraints, reducing the economic benefit of the farm plan. A bio-economic model was developed in Excel to assess possible advantages of extended lactations. The model accounted for feeding, reproductive, milking, culling and replacement costs, based on data from farm surveys or Italian literature if needed. Total feeding costs, expressed as cost of total energy requirements at each lactation stage, were calculated per energy unit (€/Mcal) and decreased from early lactation to dry (<120, 120–250, > 250 DIM and dry). Income came from the selling of milk and live animals. The model assumed a fixed number of lactations per productive life, which increases proportionally to CI. The annual gain per cow when first insemination was delayed, voluntarily or not, from 85 to 285 DIM was calculated. To quantify the effect of pregnancy on milk yield, the estimates of Genizi et al. (1992) were used. The model showed that: 1) the annual gain per cow increased by 6.7% as lactation length increased voluntarily from 305 to 385 DIM and then decreased due to higher culling and cost of Mcal in short lactations; 2) the annual cow gain was reduced, due to infertility costs, by 2.9% and 5.6% for lactation of 385 and 505 DIM, respectively, in relation to voluntarily delayed insemination. The application of this model indicated the need for testing it in a wide range of dairy farms taking into account the milk yield level, to ascertain the effect of peak of lactation on economic results.

Key Words: extended lactation, economic value, model

725 Physiological and nutritional changes of dairy goats for maintaining milk yield during extreme heat stress conditions at late lactation. S. Hamzaoui, A. A. K. Salama*, G. Caja, E. Albanell, C. Flores, and X. Such, *Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*.

Eight Murciano-Granadina dairy goats (43.5 ± 2.6 kg BW; 194 ± 3 DIM) kept in metabolic cages were allocated in 2 balanced groups and randomly assigned to 2 climatic treatments according to a crossover design (35 d periods). Treatments were (temperature, °C; humidity, %; THI, Thorn heat index):1) thermal neutral (TN, 15 to 20°C and 35 to 45%; THI = 59 to 64), and 2) heat stress (HS, 12 h/d at 37°C and 40%, and 12 h/d at 30.5°C and 40%, THI = 85 and 77, respectively). Goats were fed daily 0.8 kg concentrate, 0.65 kg alfalfa pellets, and dehydrated fescue ad libitum. Concentrate was adjusted daily to maintain constant the forage:concentrate ratio. Feed and water intake, milk yield, and rectal temperature and respiration rate at 8, 12 and 17 h were recorded daily. Milk and blood samples were collected weekly. Blood samples for acid-base balance indicators (d 25), as well as feces and urine for digestibility and N balance (d 31 to 35) were also collected in each period. Rectal temperature (38.7 vs. 39.2°C), respiration rate (34 vs. 82 per min), water intake (5.5 vs 11.1 L/d) and evaporation (1.1 vs. 3.3 L/d), were greater in HS ($P < 0.001$) than in TN, while feed intake (2.0 vs. 1.6 kg/d) was lower ($P < 0.001$). Blood NEFA (37 vs.12 mmol/L) and haptoglobin (0.134 vs. 0.105 ng/mL) were greater ($P < 0.05$) in HS than TN only at d 7. Despite the lower feed intake of HS goats, milk yield (1.23 L/d) did not vary, but milk of HS goats contained less ($P < 0.05$) protein (3.36 vs. 3.84%) and casein (2.84 vs. 3.21%) than TN goats. Panting decreased blood CO_2 (21.9 vs. 25.7 mmol/L; $P < 0.01$) in HS goats, but they maintained blood pH at a similar value to TN goats by lowering HCO_3^- (20.9 vs. 24.6 mmol/L; $P < 0.01$) and increasing Cl^- (109 vs. 107; $P < 0.05$) in blood. Digestibility of DM, OM, and ADF tended ($P < 0.15$) to be greater in HS goats, which partially compensated for the reduction in feed intake. In conclusion, late lactating dairy goats were able to adapt to severe heat stress conditions maintaining milk yield but with reduced milk protein content.

Key Words: heat stress, dairy goat, nutrition

726 Impact of evaporative pads and cross ventilation on core body temperature and resting time of lactating cows. J. F. Smith[1], B. J. Bradford*[1], J. P. Harner[1], K. Ito[2], M. vonKeyserlingk[2], C. R. Mullins[1], J. C. Potts[1], and M. W. Overton[3], [1]*Kansas State University*, *Manhattan*, [2]*University of British Columbia*, *Vancouver, Canada*, [3]*University of Georgia*, *Athens*.

A trial was conducted to determine the impact of evaporative pads (EP) on core body temperature (CBT), time spent lying and number of lying bouts of Holstein cows housed in cross ventilated freestall facilities. Two facilities were used; 1 with EP and 1 without evaporative pads (NP). Each facility had 4 pens, 1 baffle/pen and a nominal width of 122 m. Cows (n = 143) were fit with data loggers (HOBO Pendent G) to determine resting activity and 87 cows were fit with data loggers (HOBO U12) attached to blank CIDRs to determine CBT every 5 min. Ambient conditions were collected every 15 min on both sites. Individual cow CBT and activity data (9 d/cow) were analyzed to determine the amount of time CBT was above 38.9 and 39.2°C, time spent lying, and lying bouts/d. These variables were analyzed using pen as the experimental unit, with cow and day as random effects. Parity, reproductive status, and days in milk were tested as covariates in each model but removed if they did not contribute significantly to the prediction equation. Average maximum temperatures were 25°C. Lying times and lying bouts were similar for both treatments; means for lying time and bouts were 666 min/d and 12.0/d for EP and 654 min/d and 12.9/d for NP. CBT was above 38.9°C for 566.3 and 704.5 min/d for EP and NP, respectively ($P = 0.06$), and above 39.2°C per day for 321 and 378 min/d for EP and NP ($P = 0.06$). Despite the cool ambient conditions, cows in NP tended to have CBT above 38.9°C for 2.3 more h/d and CBT above 39.2°C for 1.0 more h/d. These trends were evident even though the stocking density of the freestalls in EP was higher than NP (123.4% vs. 113.1%). These results indicate that CBT tends to be reduced even under relatively mild ambient conditions when EP are used in cross ventilated facilities.

Ruminant Nutrition: Beef: Proteins and Carbohydrates

727 Evaluation of triticale dried distillers grain as a barley silage substitute in feedlot finishing diets. K. T. Wierenga*[1], T. A. McAllister[2], D. J. Gibb[2], A. V. Chaves[2], E. K. Okine[1], K. A. Beauchemin[2], and M. Oba[1], [1]*University of Alberta*, *Edmonton, AB, Canada*, [2]*Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

The objective of this study was to assess the value of triticale dried distillers grains with solubles (DDGS) as a substitute for barley silage in a dry-rolled barley (DRB) grain-based feedlot finishing diet. The trial used 144 intact (478 ± 84 kg) and 16 rumen cannulated (494 ± 50 kg) crossbred yearling steers arranged in a complete randomized design and a replicated 4 × 4 Latin square design, respectively. Steers were housed in 16 pens; 8 pens with 10 intact steers / pen, and 8 pens equipped with the GrowSafe system housing 8 intact and 2 rumen cannulated steers / pen. Steers were fed one of 4 diets (DM basis): 1) 85% DRB and 10% barley silage (CON); 2) 65% DRB, 20% triticale DDGS, and 10% barley silage (D-10S), 3) 65% DRB, 25% triticale DDGS, and 5% barley silage (D-5S), and 4) 65% DRB, 30% triticale DDGS (D-0S). Ruminal pH was measured with indwelling electrodes over 4 7-d periods. Steers fed D-10S had less variation in mean ruminal pH ($P = 0.008$) and DMI ($P = 0.009$), and tended to have higher DMI ($P = 0.08$), but similar ADG and gain:feed ratio (G:F) as compared with those fed CON. In addition, steers fed D-10S tended to have increased back fat ($P = 0.10$), and lower dressing percentage ($P = 0.06$), rib eye area ($P = 0.10$) and meat yield ($P = 0.06$) compared with those fed CON. Severity and number of abscessed livers was higher ($P = 0.006$) in steers fed D-10S as compared with CON. Replacing barley silage with triticale DDGS linearly decreased mean ruminal pH ($P = 0.006$), while duration ($P = 0.006$ and $P = 0.01$) and area ($P = 0.02$ and $P = 0.05$) below pH 5.5 and 5.2 linearly increased, and tended to linearly decrease DMI ($P = 0.10$) and increase ($P = 0.06$) G:F. Although mean ruminal pH decreased as triticale DDGS replaced barley silage, the trend for improved growth performance suggests that lower ruminal pH did not affect animal performance; however a dietary additive for liver abscess control is advised.

Key Words: triticale DDGS, finishing diet, cattle

728 Examination of rumen bacterial community changes in feedlot cattle. R. M. Beliveau*[1,2], W. Z. Yang[2], R. J. Forster[2], J. J. McKinnon[1], and T. A McAllister[2], [1]*Department of Animal and Poultry Science, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Agriculture and Agri-Food Canada Research Center*, *Lethbridge, Alberta, Canada*.

A feeding trial was conducted to determine the effects of 2 finishing rations on rumen fermentation conditions and the diversity of rumen bacterial populations. Eight animals used in a concurrent replicated 4 × 4 Latin square feeding trial were sub-sampled over 4–21 d periods. The 2 diets representing extremes in forage to concentrate ratio were a typical finishing ration (85% barley, 10% silage, 0% DDGS) and an atypical ration containing no forage (60% barley, 0% silage, 35% DDGS). Rumen digesta was collected one hour before- and 3 h post-feeding on d 14 of each period. Samples were divided into liquid and solid fractions and bacterial DNA was extracted. Continuous in-dwelling pH measurements were averaged over 5 d (d11 – d16). PCR-DGGE profiles were created using universal bacterial 16S rDNA primers and analyzed using Dice coefficients to obtain percent similarity between branch clusters using UPGMA in BioNumerics software. Cluster analysis showed high levels of similarity (90.6%) between pre and post-feeding samples, however there was low similarity (≤40%) in banding profiles within each of the dietary treatments. Dendrogram representation of the cluster analysis showed no divergence between the 2 treatments based on the banding patterns of each sample. Diversity profiles of the liquid and solid fractions of digesta also showed a low level of similarity (37.0%), however clustering within liquid and within solid samples was visible. Daily range in ruminal pH, pH at time of sampling or nadir did not appear to alter bacterial diversity as determined by cluster analysis. These results indicate that the detectable bacterial community structure in the rumen is highly diverse and influenced by a variety of environmental and host factors. Animals fed high concentrate feedlot rations maintain similar bacterial profiles despite a wide divergence in forage to concentrate ratio.

Key Words: DGGE, rumen microbial diversity, pH

729 Longitudinal gene network and pathway analysis in skeletal muscle from early-weaned Angus steers fed high-starch or low-starch diets during the growing phase. S. J. Moisa*, D. E. Graugnard, L. L. Berger, D. B. Faulkner, S. L. Rodriguez-Zas, R. E. Everts, H. A. Lewin, and J. J. Loor, *Department of Animal Sciences, University of Illinois*, *Urbana*.

Metabolic regulation in complex organisms relies partly on transcriptional control of gene networks as a long-term mechanism affecting the level of expression of several key enzymes. Objectives were to evaluate temporal gene expression profiles in longissimus lumborum (LL) of early-weaned (155 ± 10 d age at weaning) Angus steers (n = 7/diet) fed a high-starch (HiS, NEG = 5.98 MJ/kg diet dry matter) or low-starch (LoS, NE_G = 4.97 MJ/kg) diet for 120 d, at which point all steers were switched to a common feedlot diet until slaughter. LL biopsies for transcript profiling and blood for metabolite analyses were collected at 0, 56, 112, and 224 d of feeding. A 13,257 bovine oligonucleotide (70-mers) array was used for transcript profiling. Functional analysis was performed by means of Ingenuity Pathways Analysis and DAVID. Analysis of variance using a false discovery rate <0.01 revealed ca. 5,000 differentially expressed genes (DEG) due to time alone. During the growing phase, the most striking differences occurred at 60 vs. 0 d when a total of 1,471 DEG were observed. The number of DEG due to time, however, was 3,702 at 224 vs. 0 d. Within the 1,471 DEG, the functional analysis revealed >45 enriched canonical pathways (e.g., acute phase response signaling, fatty acid metabolism, ERK/MAPK signaling). However, initial analysis based on expression pattern (i.e., up- or downregulation) of the genes within pathways indicated that the putative function of most of those was inhibited. Fewer canonical pathways were enriched within DEG at 224 vs. 0 d. These included oxidative phosphorylation, mitochondrial dysfunction, and LPS/IL-1 Mediated Inhibition of RXR Function. Expression patterns of genes within these pathways revealed an overall activation. Results revealed marked adaptations in networks and pathways during rapid growth of skeletal muscle.

Key Words: systems biology, transcriptomics, energy

730 Carbohydrate-responsive element binding protein (MLXIPL) and PPARγ gene network expression in longissimus lumborum of early-weaned and normal-weaned Angus steers fed a high-starch diet during the growing phase. S. J. Moisa*, D. W. Shike, D. B. Faulkner, and J. J. Loor, *University of Illinois*, *Urbana*.

Our previous work indicated precocious upregulation of adipogenic gene networks in longissimus lumborum (LL) of early-weaned Angus steers

fed a high- vs. low-starch diet during the growing phase (Graugnard et al., 2009; Br. J. Nutr. Dec. 21 [E-pub ahead of print]). Further, data provided evidence of metabolic imprinting effects of high-starch on the transcription factors sterol regulatory element-binding transcription factor 1 (SREBF1) and carbohydrate responsive element binding protein (MLX interacting protein-like, MLXIPL), both of which had greater expression in the early-weaned/high-starch-fed group after 120 d of feeding a common finishing diet. To examine the effect of weaning age on transcriptional networks associated with adipogenesis due to high-starch, 7 early-weaned (EW, 163 ± 17 d old) and 7 normal-weaned (NW, 213 ± 17 d old) calves were used and managed to receive a corn-based creep supplement (NW) or a high-starch diet (EW). For the ~100 d treatment period, EW calves remained in the feedlot and NW calves nursed their dams while on pasture. NW calves were weaned ca. 230 d postpartum and joined the early-weaned calves at the feedlot at which point both groups were fed a common finishing diet until slaughter. LL biopsies were collected at 0 (early weaning), 25, 50, 100 (normal weaning), mid-way through finishing, and 1 wk before slaughter for transcript profiling using quantitative PCR. Preliminary results from the treatment period showed that expression of both PPARG and MLXIPL was greater (ca. 2.5- and 3-fold, $P < 0.05$) in NW vs. EW steers at the start of the study. However, EW steers had gradual increases (diet × time $P < 0.05$) in both PPARG and MLXIPL such that at the end of the treatment period their expression averaged 3.4- and 5-fold relative to start of treatments. During that time-frame, expression of both genes averaged 1.3-fold of the expression at the start of treatments in NW steers. Results indicated a marked pro-adipogenic response of high-starch feeding at an early age.

Key Words: adipogenesis, nutrition, transcriptomics

731 Effects of fructose-based block supplement on ruminal concentration of lactate and growth of lactate-utilizing bacteria in forage-fed cattle. K. A. Miller*, G. L. Parsons, M. J. Quinn, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

Acidosis is common among cattle as they are transitioned from forages to concentrates due to accumulation of lactate and other organic acids. This study was conducted to determine if supplementation with a fructose-based supplement could stimulate ruminal production of lactic acid and subsequent growth of lactate-utilizing bacteria in forage-fed cattle. A mixture of fructose corn syrup and vegetable oil (4%, DM basis) was dehydrated in a steam-jacketed kettle (121°C), subjected to a vacuum, discharged into containers, and cooled to form a hardened, amorphous mass. Ruminally fistulated heifers (n = 12) were blocked by BW (535 ± 54 kg), placed into individual pens, and randomized to CONTROL (no block) or BLOCK (fructose block fed at 0.9 kg/d) treatments. Heifers had ad libitum access to prairie hay and salt for 10 d, after which supplement was offered to cattle in the BLOCK treatment for 3 d by dosing directly into the rumen via the fistula at 0700 h. Ruminal digesta was sampled after 1 and 3 d of supplementation every 30 min for 8 h post-feeding to determine effects on ruminal pH, lactate, and VFA. Anaerobic cultures containing lactic acid as substrate were inoculated with strained ruminal fluid, and turbidity changes were monitored for 24 h as an indicator of capacity for lactate utilization. Ruminal pH was lower ($P < 0.01$) for the first 3 h after administration of the block. Ruminal concentrations of lactate (3.38 m*M* versus 0.66 m*M*) and butyrate (6.6 versus 4.0 m*M*) were greater for BLOCK heifers compared with CONTROLS ($P < 0.01$). Incubation of ruminal contents in lactate media revealed greater ($P < 0.05$) capacity for lactate utilization in BLOCK heifers. Feeding fructose-based blocks increased ruminal lactate production and subsequent growth of lactate-utilizing bacteria. These data provide a foundation for further investigations into possible application of fructose-based supplements to prevent acidosis when cattle are transitioned from forages to concentrate-based diets.

Key Words: fructose, lactic acid, acidosis

732 Effects of corn steep liquor in low-moisture blocks processed under vacuum or at atmospheric pressure on performance of growing heifers fed forage-based diets. K. A. Miller*, G. L. Parsons, L. K. Thompson, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

A study was conducted to evaluate a novel process for manufacturing low moisture supplement blocks containing corn steep liquor (CSL) and effects on growing heifer performance. Crossbred heifers (n = 359; BW 236 ± 8.9 kg) were utilized in a randomized complete block design. Heifers were fed a basal diet containing (DM basis) 44% corn silage, 29% corn stalks, and 27% alfalfa hay, along with no supplement (CON), blocks containing 15% CSL processed at atmospheric pressure and high temperatures (HT-15), blocks processed under vacuum at low temperatures (LT-15), or blocks containing 40% CSL and processed under vacuum at low temperatures (LT-40). Heifers were fed their respective treatments 84 d, then fed a common diet 14 d to minimize differences in gut fill. Supplementing LT-15 or LT-40 blocks increased ADG over non-supplemented CON and HT-15 supplemented heifers ($P < 0.05$), but ADG were similar between the CON and HT-15 groups ($P > 0.8$), as well as for LT-15 and LT-40 treatments ($P > 0.6$). Forage DMI was similar among treatments ($P > 0.1$). Daily consumption of block supplements was greater for heifers fed LT-15 and LT-40 compared with those fed HT-15 ($P < 0.01$), but daily intakes of LT-15 and LT-40 blocks were not different ($P > 0.2$). Total intake (block intake + forage intake) was greater for heifers fed LT-15 and LT-40 blocks than non-supplemented heifers ($P < 0.05$). Total intakes of heifers fed HT-15 were intermediate and not different from CON or other block treatments ($P > 0.2$). Feed efficiency was not different among treatments ($P > 0.2$). Supplementing blocks containing CSL processed at low temperatures improves performance over non-supplemented heifers. However, when processed at high temperatures and at atmospheric pressure, adding CSL to low-moisture blocks yields no discernable benefit to cattle fed forage-based diets. This study reveals limitations in using heat sensitive ingredients in block supplements.

Key Words: low-moisture blocks, vacuum processing, condensed corn fermented extractives

733 Relationship between eating pattern and performance of Holstein bulls and steers fed high-concentrate rations using a computerized concentrate feeder. M. Devant*[1], S. Marti[1], and A. Bach[2,1], [1]*Department of Ruminant Production, IRTA*, *Barcelona, Spain*, [2]*ICREA*, *Barcelona, Spain*.

A total of 132 animals (initial BW = 220 ± ± 22 kg and age = 172 ± 0.4 d) were used to study the relationship between feeding pattern and performance. Animals were randomly allocated in 6 pens with 2 pens for each treatment: 44 intact bulls, 44 steers castrated at 3 mo of age (CAS3), and 44 bulls castrated at 8 mo of age during the study (CAS8). The study finished at 285 d of life. Each pen had one computerized concentrate feeder (GEA WestfaliaSurge, Germany), one straw feeder, and one drinker. Concentrate and straw were offered ad libitum. Animals were weighed every 14 d and concentrate eating pattern (daily mean, CV, minimum and maximum) was averaged for each 14-d period. The relationships between each eating pattern parameter and ADG or concentrate efficiency were evaluated by regression analyses using a fit model procedure of JMP with animal as random effect. Overall, average

BW was 305 ± 58.3 kg, ADG 1.4 ± 0.53 g/d, feed efficiency 22 ± 9.1%, daily intake 6.3 ± 1.01 kg/d (21 ± 0.5% CV), daily feeder visits 6.3 ± 1.29 /d (28 ± 1.0% CV), meal size 1.1 ± 0.25 kg (63 ± 1.3% CV), meal duration 10.2 ± 2.20 min (59 ± 1.2% CV), inter-meal time 244.8 ± 55.38 min (59 ± 0.7% CV), and eating rate 112 ± 16.9 g/ min (32 ± 2.1% CV). In bulls, as CV of daily intake increased ($P < 0.001$, r = −0.40) ADG decreased. In addition, in bulls as maximum daily intake increased ($P < 0.001$, r = −0.34) efficiency decreased. In steers CAS8 as CV of daily intake increased ($P < 0.001$, r = −0.36) ADG decreased. In steers CAS3 as mean daily intake and maximum daily intake increased ($P < 0.001$, −0.53 and −0.55, respectively) efficiency decreased. In addition, in CAS3 steers as mean and minimum eating rate increased ($P < 0.001$; r = −0.47 and r = −0.37, respectively) concentrate efficiency decreased. Also in steers CAS3 as mean and maximum meal size increased ($P < 0.001$; r = −0.33 and −0.33, respectively) efficiency decreased. Bulls and steers have different relationships between feeding pattern parameters and performance.

Key Words: beef, monitoring, eating pattern

734 Effect of supplemental protein source during the winter on pre- and postpartum glucose metabolism. F. W. Harrelson*[1], S. L. Ivey[1], S. H. Cox[1], R. L. Dunlap II[1], J. T. Mulliniks[1], B. H. Carter[1], C. A. Löest[1], and M. K. Petersen[2], [1]*New Mexico State University*, *Las Cruces,* [2]*USDA-ARS Fort Keogh Livestock and Range Research Laboratory*, *Miles City, MT*.

Circulating serum glucose concentrations as well as glucose utilization have been shown to be affected by forage quality. Supplemental protein provided to grazing range cows while consuming low quality forage may improve glucose metabolism. The objective of our study was to determine the effects of winter protein supplement strategy on serum glucose half-life, insulin response, as well as identify the effects of previous gestational protein supplementation on mid lactation milk yield. The study was conducted 2 consecutive calving seasons utilizing 5-yr old Angus and Angus crossbred cows (n = 8/trt each yr, 530 kg average BW). Cows were supplemented until calving with 1) a control 36% CP (35% UIP of CP) cottonseed meal based cube (CON), hand-fed at 454 g/d delivered 3d/wk ($16/45.4 kg), or 2) a self-fed 50:50 loose mineral and fishmeal 33% CP (60% UIP of CP) small supplement (SSP), formulated for a targeted consumption of 113g/d ($52/45.4 kg). After calving, cows were supplemented similarly (CON at 908 g/d offered 3 d/wk). Supplemental protein source affected ($P = 0.03$) glucose half-life, whereby the SSP cows had a lower half-life compared with CON (62 and 85 min respectively). Supplement also influenced insulin area under the curve (AUC; $P < 0.01$) with CON having a larger area compared with the SSP treatment (95.18 ± 4.9 and 75.02 ± 4.8 respectively). Prepartum glucose AUC ($P = 0.10$) and insulin half-life ($P = 0.75$) were unaffected by supplement treatment. Milk yield or components was not affected ($P > 0.05$) by supplement; however year showed a significant ($P < 0.05$) effect on these parameters. Milk yield was decreased from 7531 g ± 299 in yr 1 to 4328 g ± 293 in yr 2, possibly due to lower forage quality (~3% CP vs. ~8% CP in yr 1). These results suggest that supplemental undegradable intake protein, during times of low quality forage, may improve glucose clearance.

Key Words: beef cattle, glucose, supplementation

735 Ruminal and rectal temperatures during acidosis challenge in beef cattle. J. L. Wahrmund*, J. R. Ronchesel, C. R. Krehbiel, and C. J. Richards, *Oklahoma State University, Department of Animal Science*, *Stillwater*.

An experiment was conducted to determine the effects of ruminal acidosis challenge on ruminal temperature of beef steers. Twelve ruminally cannulated steers with ruminal temperature monitoring devices which recorded current temperature every 2 min were fed a 63% concentrate diet at 1.6% BW and randomly assigned to one of 3 challenge treatments: no dietary change (CON), half of diet replaced with cracked corn (HALF), or all of diet replaced with cracked corn (CORN). Acidosis challenge was initiated by ruminally dosing steers with their daily allotment of challenge treatment diets. Ruminal pH and rectal temperatures were recorded every 3 h for 72 h. All steers were offered CON diets at 24 and 48 h after challenge. Effects of treatment, day, hours since challenge/feeding, and all interactions were determined using the MIXED procedure of SAS. Relationships between ruminal and rectal temperatures and pH were measured using the CORR procedure of SAS. Ruminal pH showed a treatment × d effect, as pH of CORN steers was lower ($P < 0.05$) than CON and HALF steers by 0.44 units on d 1, 0.67 units on d 2, and 0.34 units on d 3. Treatment did not affect ($P > 0.05$) rectal temperatures. There was a treatment × hours since feeding effect for temperature change since initial ruminal temperature ($P < 0.05$). At time of feeding 24 and 48 h post-challenge, ruminal temperatures of CON and CORN steers were 0.04°C less than initial temperature, while those of HALF steers were 0.21°C greater ($P < 0.05$) than initial temperature. CORN and HALF steers exhibited a 0.21°C greater ($P < 0.05$) increase in ruminal temperature than CON steers 9 h after feeding. Rectal temperatures were correlated ($P < 0.05$) with ruminal temperatures for all treatments. Ruminal and rectal temperatures were negatively correlated ($P < 0.05$) with pH in HALF and CORN steers, but not in CON steers ($P > 0.05$). A 1.44 unit decrease since initial pH in CORN steers was correlated ($P < 0.05$) with a 0.14°C increase since initial ruminal temperature, but changes in these measurements were not correlated ($P > 0.05$) in HALF or CON steers. Decreasing pH associated with acidosis results in a rise in ruminal temperature.

Key Words: beef cattle, acidosis, body temperature

736 The influence of dietary protein regimens on crude protein and dry matter apparent digestibility in steers fed a steam-flaked corn based diet. E. C. Westover*[1], J. J. Wagner[1], T. E. Engle[1], T. C. Bryant[2], S. L. Archibeque[1], and J. Ham[1], [1]*Colorado State University*, *Fort Collins,* [2]*JBS Five Rivers Cattle Feeding*, *Greeley, CO*.

Four hundred crossbreed steers (330 kg ± 0.8 initial BW) were used to investigate the effects of dietary protein regimens on dry matter (DM) and crude protein (CP) digestibility, using acid insoluble ash (AIA) as an indigestible indicator substance. Cattle were randomly assigned to the following treatments that were applied to a 91% concentrate (steam-flaked corn based) diet: 1) High CP (HCP; 13.5% CP), 2) Oscillating CP (OCP; 11.62% CP diet fed Wednesday, Thursday, and Sunday and the HCP diet fed Monday, Tuesday, Friday, and Saturday), 3) Intermediate CP (ICP; 12.56% CP), and 4) Low CP (LCP; 11.62% CP). Urea was used to modify dietary CP concentrations. At the initiation of the experiment, steers were implanted with controlled release implant containing 200 mg trenbolone acetate and 40 mg estradiol. Steers were weighed every 28 d throughout the experiment and fecal grab samples were obtained over 2 d (d73 or d74; from 12 of pens per treatment) and frozen immediately. Weekly feed samples were collected, frozen, and then composited monthly. Feed and fecal samples were analyzed for DM, N (conversion factor = 6.25), and acid insoluble ash. Treatment tended ($P < 0.06$) to be a significant source of variation for CP digestibility. Steers receiving HCP diet had similar CP digestibility relative to steers receiving OCP and ICP diets. However, steers receiving the LCP diet had higher ($P < 0.04$) CP digestibility when compared with steers fed

HCP. Treatment was a significant ($P < 0.001$) source of variation for DM digestibility. Dry matter digestibility tended ($P < 0.06$) to be higher in OCP fed steers and was higher ($P < 0.001$) in LCP steers compared with HCP fed steers. Acid insoluble ash has been documented to be an accurate prediction of digestibility of DM and CP; however digestibility can be overestimated due to low AIA content in feed and feces samples. These data indicated that DM and CP digestibility can be influenced by dietary CP concentration.

Key Words: protein, digestibility, acid insoluble ash

737 Effects of rumen-protected methionine on performance and health of growing feedlot heifers. M. R. McDaniel*, D. A. Walker, K. M. Taylor, and C. A. Loest, *New Mexico State University*, *Las Cruces*.

Methionine is a limiting AA in growing cattle fed diets low in rumen undegradable protein. An experiment at the Clayton Livestock Research Center (Clayton, NM) evaluated the effects of supplementing rumen-protected Met (RPMET; METHIOPLUS, Kemin AgriFoods, Des Moines, IA) on performance and health of 718 Angus-cross heifers (average BW = 265 ± 27.8 kg). Heifers were randomly assigned to 4 treatments in 36 pens (9 pens/treatment), and were fed once daily diets that consisted of 77% Sweet Bran (Cargill Inc., Minneapolis, MN), 19.8% wheat silage, 0.24% urea, 2.95% supplement, and treatments (DM basis). Treatments were daily supplementation with 0, 7.5, 15.0, and 22.5 g of RPMET per head (estimated to supply 0, 4, 8, and 12 g/d of metabolizable DL-Met, respectively) that was mixed with the diet for a treatment group of cattle before feeding. Feed bunks were managed to maintain ad libitum intake. Performance and health were monitored for 56 d. Increasing RPMET from 0 to 12 g/d in the diets of heifers increased DMI (quadratic; $P = 0.02$), ADG (linear; $P = 0.02$), and G:F (linear; $P = 0.04$; Table 1). Supplying RPMET did not affect mortality ($P = 0.38$) and morbidity ($P = 0.19$). Supplementing a wet corn-gluten feed-based diet with RPMET improves performance of heifers during the growing phase.

We acknowledge R. Musser of Kemin AgriFoods for supplying METHIOPLUS and Cargill for supplying Sweet Bran.

Table 1. Effects of METHIOPLUS supplementation for 56 days on performance of growing feedlot heifers

	METHIOPLUS, g/d					P-value		
Item	0	7.5	15.0	22.5	SEM	Linear	Quadratic	0 vs suppl
DMI, kg/d	7.7	7.8	7.9	7.7	0.11	0.59	0.02	0.09
ADG, kg/d	1.48	1.55	1.57	1.55	0.045	0.02	0.06	<0.01
G:F	0.192	0.198	0.199	0.200	0.0027	0.04	0.47	0.04

738 Influence of feeding increasing levels of dry or modified wet corn distillers grains plus solubles in whole corn grain-based finishing diets on pancreatic mass, and α–amylase and trypsin activity in feedlot cattle. H. Salim*[1], K. M. Wood[1], P. L. McEwen[2], I. B. Mandell[1], S. P. Miller[1], and K. C. Swanson[1], [1]*University of Guelph*, *Guelph, Ontario, Canada*, [2]*Ridgetown Campus*, *Guelph, Ontario, Canada*.

One hundred and fourteen cross-bred steer calves and 17 heifers (BW = 357.2 ± 5.8 kg) were used in a completely randomized block design (2 × 3 factorial arrangement of treatments plus a control) to determine the effect of inclusion level and form of distillers grains plus solubles (DGS) on pancreatic mass, and α-amylase and trypsin activity using whole corn grain-based finishing diets. The DGS were fed at 0 (control), 16.7, 33.3, and 50% of ration DM using dry (DDGS) or modified wet (50% DM; MWDGS) product. Data were analyzed using GLM of SAS; treatment means were compared using contrast statements (control vs. other treatments, DDGS vs. MWDGS, inclusion levels of DGS (linear, quadratic), and interactions between form and linear and quadratic inclusion levels). There were no effects ($P > 0.10$) of dietary treatment on pancreatic weight (g and g/kg BW), however pancreatic protein concentration (mg/g) was greater ($P = 0.10$) in cattle receiving DGS vs. control. Pancreatic concentration of α–amylase activity (U/g) increased ($P = 0.09$) in cattle receiving DGS vs. control. Pancreatic concentration of trypsin activity (U/g) increased linearly ($P = 0.02$) with increasing inclusion of DGS. A form by quadratic effect of inclusion level interaction ($P = 0.02$) was observed for pancreatic trypsin activity (U/g) because pancreatic trypsin activity (U/g) decreased as DDGS increased from 16.7 to 33.3% of diet DM and then increased as DDGS increased from 33.3 to 50%, while pancreatic trypsin activity (U/g) increased linearly with increasing inclusion of MWDGS. These data indicate that pancreatic concentration of α–amylase and trypsin activity may be influenced by the form and inclusion level of DGS in whole corn grain-based finishing diets.

Key Words: beef cattle, pancreas, distillers grains

739 Effects of lauric and myristic acids on ruminal fermentation, production, and milk fatty acid composition in lactating dairy cows. A. N. Hristov*[1], C. Lee[1], T. Cassidy[1], M. Long[1], K. Heyler[1], and B. Corl[2], [1]*Pennsylvania State University*, *University Park,* [2]*Virginia Tech*, *Blacksburg*.

The objective of this experiment was to investigate the effects of lauric and myristic acids on ruminal fermentation, production, and milk fatty acid (FA) profile in lactating dairy cows. The experiment was conducted as a replicated 3 × 3 Latin square. Six ruminally-cannulated cows (95 ± 26.4 DIM), were subjected to the following treatments: 240 g/cow/d of each, stearic (SA, control), lauric (LA), or myristic (MA) acids. The basal diet contained (DM basis) 15.2% CP and 33.9% NDF. Experimental periods were 28 d and cows were refaunated between periods. LA reduced ($P < 0.001$) protozoal counts in the rumen by 96% (no effect of MA), acetate, total VFA, and ammonia concentrations, and microbial N outflow from the rumen (by 32%; $P = 0.002$), compared with SA. Ruminal methane production was not affected by treatment. DMI was severely depressed ($P < 0.001$) by LA (18.6) compared with SA (26.7) and MA (24.7 kg/d), which decreased ($P = 0.017$) milk yield (35.8 and 43.6 kg/d, LA and SA, respectively). Feed efficiency, however, was the highest ($P = 0.008$) for LA (1.91), followed by MA (1.81), and SA (1.63 kg/kg). Milk fat content was also severely depressed ($P = 0.021$) by LA (2.59) compared with SA (3.42%). Treatment had no effect on milk protein content. Milk N efficiency was greater ($P = 0.022$) for LA (34.9) than SA (30.6%). Concentration of milk FA < C16 was 20% lower ($P = 0.011$) for LA than MA. Concentration of C12:0 was more than doubled ($P < 0.001$) by LA and C14:0 was increased by MA (by 45%; $P < 0.001$), compared with SA. LA resulted in lower ($P = 0.027$) C16, but greater ($P = 0.014$) long-chain FA, compared with SA and MA. Concentrations of trans C18:1 and *cis*-9, *trans*-11 CLA were doubled ($P < 0.01$) by LA compared with SA and MA. In conclusion, LA had profound effects on ruminal fermentation, mediated through inhibited microbial populations, and decreased DMI, milk yield, and milk fat content. Both LA and MA modified significantly milk FA profile.

Key Words: lauric acid, myristic acid, dairy cow

740 Time course of recovery from diet induced milk fat depression in dairy cows. D. E. Rico* and K. J. Harvatine, *The Pennsylvania State University*, *University Park*.

Nine ruminally cannulated cows were randomly assigned to treatment sequence in a Latin Square designed for analysis of recovery from diet-induced milk fat depression (dMFD). A control diet with 32% NDF was fed during the Control and Recovery periods. A low fiber and high oil diet containing 27% NDF and 3.0% soybean oil was fed during the diet-induced MFD period (dMFD). Treatment periods were 21 d in length. Milk yield and DMI were measured daily. Milk samples were taken every other day and milk was analyzed for fat and true protein. Data was analyzed using the repeated measures statement of Proc Mixed (SAS Institute); the model included period, sequence, and cow nested in sequence as random effects, and treatment, day on diet and the interaction of treatment and day on diet as fixed effects. Day was the repeated variable and the heterogeneous autoregressive covariance structure was used. Denominator degrees of freedom were adjusted by the Kenward Rogers method. DMI progressively decreased when cows were switched to dMFD and was significantly different from control after d 6 ($P < 0.05$). Intake recovered after d 15 of the recovery period. Milk yield was not affected by treatment and averaged 32.5 ± 2.1 kg. Milk fat percent and yield decreased progressively from d 1 when fed the MFD diet and were significant by d 3 ($P < 0.05$) and 7, respectively ($P < 0.05$). After switched to the recovery diet, milk fat concentration and yield progressively increased from d 1 and were the same as control on d 19 and 11, respectively. Milk protein percent increased progressively when cows were on the MFD diet and was significantly different from control after d 11 ($P < 0.001$ from d 11 to 21), reaching a plateau on d 13. Milk protein percent was 6% higher on average for dMFD vs. control cows between d 11 and 21. Milk protein yield was not affected by treatment. Our data shows that recovery from diet induced milk fat depression occurs progressively with a very short lag when dietary NDF and polyunsaturated fatty acid concentration are corrected.

Key Words: milk fat depression, dairy cows

741 Meta-analysis to calculate volatile fatty acid production in the rumen of cattle. D. Sauvant*[1] and P. Noziere[2], [1]*AGROPARISTECH-INRA MoSAR*, *Paris, France,* [2]*INRA-URH*, *63122 St Genes Champanelle, France.*

The estimation of the production of volatile fatty acids (VFA) in the rumen remains a limit for diet evaluation and formulation. To progress on this topic, a meta-analysis of published data where apparently digestible organic matter in the rumen (ADOMr) and VFA profiles were documented was performed. A database was compiled from 237(nexp) experiments (599 treatments, tr), 59% being conducted on lactating cows. Most were focused on the effects of dietary protein (32%), starch (23%), NDF (18%), or particle size (11%). There were large variations of dry matter intake (2.7 ± 0.8%LW), dietary NDF (37.4 ± 12.0%DM) or concentrate (CO, 46.8 ± 22.8%DM). The OM digestibility in the whole tract (OMDt), and intake of ADOMr were 70.3 ± 6.7% and 10.6 ± 3.7 g/kgLW, respectively. The ADOMr represented 61.6 ± 15.4% of OM digested in the whole tract. The molar percentages were 62.9 ± 5.7 for acetate, 21.4 ± 5.0 for propionate, 11.7 ± 2.0 for butyrate, and 3.8 ± 1.6 for minor VFA. ADOMr being considered as the OM recovered as VFA and gas, it was interpreted as C flows, assuming 37 and 45 mmol of C per g of carbohydrate and protein, respectively. Production of VFA was calculated from C flows and VFA profiles assuming 0.33, 0.0, 0.33, 0.15 mol of C as gas per mol of C as acetate, propionate, butyrate and minor VFA, respectively. The calculated production of VFA was 121.2 ± 42.7 mmol/kgLW, i.e. 7.1 ± 1.8 mmol/g OM digested in the whole tract. The % of C as VFA in C from ADOMr was 74.2 ± 1.5. This ratio increased with the % CO (73.0 + 0.02%CO, R2 = 0.82, RMSE = 0.8, nexp=43). For 513 of the tr, the true DOMr (TDOMr) was also measured, and the ratio VFA/TDOMr was 8.3 ± 1.2 mmol/g TDOMr. This is close to the value obtained by other approaches. Thus, Noziere et al. (2010, Animal, in press) obtained a ratio of 8.0 ± 0.6 with a database of VFA production measured in vivo with labeled VFA. In conclusion, it is possible to interpret experimental data on ADOMr and VFA profile to calculate realistic values of production of VFA from ADOMr.

Key Words: volatile fatty acid, rumen, meta-analysis

742 Forage physically effective fiber source alters ruminal pH and site of digestion. M. B. Hall*, *U.S. Dairy Forage Research Center, USDA-ARS*, *Madison, WI.*

The study objective was to evaluate the effects of physically effective fiber source (peNDF) and starch sources with different rates of fermentation (ST). Thirty-two lactating Holstein cows (8 cannulated) were

used in an incomplete Latin square design with 3 21-d periods. Dietary treatments were inclusion of chopped wheat straw (WS) or ensiled corn stover (ES) to provide 10% of diet DM as NDF, and inclusion of dry ground corn (DC) or high moisture shelled corn (HC) as the starch sources. Diets were formulated to contained similar concentrations of starch, N, and NDF. DMI was not affected by treatment. Time per day spent ruminating did not differ by diet, but time spent eating tended to be greater for cows with DC than for HC. At 2 h post-feeding, ruminal digesta DM% was greater with WS than ES. Rumen digesta DM kg did not differ by treatment. Ruminal digesta liquid kg tended to be greater with DC than HC on ES diets, but HC was greater than DC on WS diets. Ruminal pH was lower with WS than ES. In contrast, fecal pH was lower with ES than with WS. Neither pH was affected by ST. Lower ruminal pH and higher fecal pH with WS suggests that WS retained more feed to be digested in the rumen, whereas the reverse response with ES suggests that this peNDF source allowed more fermentable carbohydrate to pass from the rumen to ferment in the hindgut. Forage peNDF source may affect passage of carbohydrate.

Table 1. Effects of physically effective fiber (peNDF) and starch (ST) sources

	Diets					P-values		
	ESHC	ESDC	WSHC	WSDC	SED	peNDF	ST	Int.

743 Evaluation of 2-hydroxy-4-(methylthio) butanoic acid isopropyl ester (HMBi) and methionine (Met) supplementation on digestibility and efficiency of bacterial growth in continuous culture. C. M. Fowler[1], S. K. R. Karnati[1], B. J. Bequette[2], Z. Yu[1], and J. L. Firkins*[1], [1]*The Ohio State University*, *Columbus*, [2]*University of Maryland*, *College Park*.

Assuming that HMBi metabolism is slower than dl-Met in the rumen, we hypothesized that HMBi would provide a more continual supply of Met for direct incorporation into protein or for methyl donating reactions or else spare common intermediates for bacterial synthesis of other AA. Four 50% concentrate:50% crushed alfalfa pellet diets were fed to 4 dual flow fermenters every 8 h (100 g/d). Diets were moderately limited in RDP (7.8% of DM) and CP (14.2%) to ensure that preformed AA would limit bacterial growth. The 4 treatments were 1) control (no infusion), 2) dl-Met (0.097% of DM) or isomolar 3) HMBi or 4) a 50:50 mix of HMBi and dl-Met, which were pulse-dosed 3 times daily with the feedings. On d 9, C-13 labeled HMBi or dl-Met replaced a portion of the unlabeled doses for 6 continuous infusions (over 2 d) to analyze isotopic plateau and elimination kinetics. N-15 was dosed 3 d before and during sampling, and enrichment measured in effluent, bacterial, and ammonia N. Neither NDF nor ADF digestibility were affected, but hemicellulose (NDF-ADF) digestibility and total VFA production were linearly decreased ($P < 0.05$) as HMBi replaced Met. Although flow and efficiency of bacterial N production were not affected, ammonia N concentration and flow linearly decreased ($P < 0.08$) and, conversely, peptide concentration linearly increased ($P < 0.05$) as HMBi replaced Met. Correspondingly, the bacterial N derived from ammonia increased ($P < 0.05$) with increasing HMBi. Preformed Met was transferred extensively into bacterial Met (25% for Met and 48% for the dl-Met/HMBi mix). The HMBi washout from the fermenters [kp/(kd+kp)] averaged 62%, although there likely would be significant absorption from the rumen. HMBi that did not pass out of the fermenters was readily converted to Met, which accumulated in the free Met pool, with only 5% transfer into bacterial Met. Future research is evaluating if HMBi is converted to d-Met, which would accumulate if mixed bacterial cultures lack sufficient racemase activity.

Key Words: HMBi, methionine, bacterial protein synthesis

744 Ruminal degradability of forages and diets in lactating dairy cows fed a hemicellulose extract. K. J. Herrick*[1], M. Abdullah[2], A. R. Hippen[1], D. S. Schingoethe[1], K. F. Kalscheur[1], and R. S. Patton[3], [1]*South Dakota State University*, *Brookings*, [2]*University of Veterinary and Animal Sciences*, *Lahore, Pakistan*, [3]*Temple Inland, Inc.*

Inclusion of hemicellulose extract in cattle diets has shown potential for improving fiber digestibility and production efficiency. The objective of this research was to evaluate production and in situ digestibility effects of a hemicellulose extract (Temple Inland Inc.) on mid-lactation cows. Twelve multiparous Holstein cows (142 ± 44 DIM, 685 ± 19 kg BW) including 4 with ruminal fistula were used in a 2 × 2 Latin square with 21-d periods. Cows were fed a control diet containing 55% forage (DM basis, 2/3 corn silage and 1/3 alfalfa hay) or a similar diet where 1.0% of the diet DM forage was replaced with the extract. Dry matter intake averaged 27.1 and 26.9 kg/d for the control and treatment, respectively, and was not affected by treatment. The percentage of protein (3.40 vs. 3.29) in milk was less ($P = 0.03$) and the percentage of fat (3.91 vs. 3.80) tended ($P = 0.06$) to be less for cows fed the treatment diet. Because of numerically greater milk production (38.8 vs. 39.2 kg) for cows fed the treatment diet, there were no differences in component yields other than lactose (1.86 vs. 1.94 kg/d) which tended to be greater ($P = 0.08$) for cows fed the treatment. For in situ determinations, Dacron bags containing corn silage, alfalfa hay, and either the control or treatment TMR were incubated in triplicate in the rumens of the cannulated cows at 0, 3, 6, 9, 12, 24, and 48 h on d 18 of each period. Each TMR was incubated only in cows assigned to the corresponding diet. For corn silage, the rate of disappearance (K_d) of NDF (1.7 vs. 4.3) and ADF (1.8 vs. 4.7%/h) increased ($P < 0.05$) for cows fed the treatment diet. For alfalfa hay, the disappearance of fraction A of DM, NDF, and ADF decreased and fraction B of DM and NDF increased with treatment ($P < 0.05$). The K_d for DM (8.0 vs. 11.0), NDF (6.3 vs. 10.3), and ADF (5.5 vs. 9.2) increased greatly for the alfalfa hay in rumens of treated cows ($P < 0.05$). Results demonstrated that supplementing diets of lactating dairy cows with a hemicellulose extract had a beneficial effect on fiber degradation characteristics and provide opportunities for improving animal performance.

Key Words: hemicellulose extract

745 Effect of replacing canola meal with wheat-based dried distillers grains with solubles on ruminal fermentation, microbial nitrogen supply and milk production in dairy cows. G. E. Chibisa*, D. A. Christensen, and T. Mutsvangwa, *University of Saskatchewan*, *Saskatoon, Canada*.

The objective was to determine the effect of replacing canola meal (CM) with wheat–based dried distillers grains with solubles (WDDGS) on ruminal fermentation characteristics, microbial N supply, and animal

performance. Eight lactating dairy cows were used in a replicated 4 × 4 Latin square design with 28-d periods (20 d of dietary adaptation and 8 d of measurements). Four cows in one Latin square were ruminally cannulated for measurement of ruminal fermentation characteristics and total tract nutrient digestion. Cows were fed either a standard barley silage–based TMR containing CM as the major protein supplement (control) or rations formulated to contain 10, 15 and 20% WDDGS (DM basis). Wheat-based DDGS replaced CM. Inclusion of WDDGS linearly increased DMI ($P < 0.01$; 29.5, 31.2, 30.2 and 31.9 kg/d for 0, 10, 15 and 20% WDDGS diets, respectively; n = 8). Ruminal VFA concentrations were unaffected, except that the inclusion of 20% WDDGS resulted in a decrease ($P < 0.01$) and a tendency ($P = 0.09$) for a decrease in molar concentrations of isobutyrate and total VFA, respectively. There were no differences ($P > 0.05$) among treatments for ruminal pH and ammonia concentrations, and apparent total tract nutrient digestibilities. Urinary excretion of purine derivatives (PD) was not different ($P = 0.20$) among diets; consequently, microbial N supply, estimated using urinary PD excretion, was not affected ($P = 0.19$). The addition of WDDGS in place of CM resulted in a quadratic change ($P < 0.01$) in milk yield (42.8, 42.2, 43.6 and 40.5 kg/d for 0, 10, 15 and 20% WDDGS diets, respectively; n = 8). There were no differences ($P > 0.05$) among treatments for concentrations and yields of milk fat, protein, and lactose. These data indicate that WDDGS can substitute for CM in dairy cow diets without a negative impact on ruminal fermentation characteristics, microbial N supply and animal performance.

Key Words: wheat-based DDGS, nutrient supply, milk production

746 Shifts in fermentation and intermediates of biohydrogenation induced by potassium supplementation into continuous cultures of mixed ruminal microorganisms. T. C. Jenkins*[1], E. Block[2], and J. H. Harrison[3], [1]*Clemson University*, *Clemson, SC,* [2]*Arm and Hammer Animal Nutrition*, *Princeton, NJ,* [3]*Washington State University*, *Puyallup*.

Recent studies have reported increased fat percentages in milk of lactating dairy cattle when diets were supplemented with potassium carbonate. Because milk fat yield has been associated with ruminal production of certain conjugated linoleic acid (CLA) isomers, this study was conducted to determine if increasing K exposure to ruminal microorganisms alters biohydrogenation and CLA production. Five dual-flow continuous fermenters were fed 60 g/d of a 1:1 forage (10% alfalfa hay and 90% corn silage) to concentrate mix in 2 equal portions at 0800 and 1600 h for 10-d periods (n = 4). Three of the 5 fermenters were injected just before each feeding with a 10% (w/w) stock potassium carbonate solution to provide the equivalent of 0.6 (K1), 1.2 (K2), and 1.8 (K3) g K/d. One of the remaining fermenters received no injection (K0) and the last fermenter (pHCON) was injected with adequate NaOH stock solution (10%, w/w) to match the pH observed for the K3 treatment. pH and acetate/propionate in fermenters increased ($P \leq 0.05$) linearly for K0 to K3. pH was the same but acetate/propionate was lower ($P \leq 0.05$) for pHCON compared with K3. Losses of oleic, linoleic, and linolenic acids averaged 216, 872, and 125 mg/d, respectively and were not affected by treatment. Stearic acid production changed ($P = 0.14$) from K0 to K3 (397, 449, 562, and 316 mg/d), but K3 and pHCON (206 mg/d) did not differ. Production of *trans*-10 C18:1 declined ($P \leq 0.05$) and *trans*-11 C18:1 increased ($P \leq 0.05$) linearly from K0 to K3, but pHCON and K3 were the same for both C18:1 isomers. The *cis*-9, *trans*-11 and *trans*-9, *trans*-11 isomers increased ($P \leq 0.05$) linearly from K0 to K3, but K3 and pHCON did not differ. There was a numerical decrease in production of *trans*-10, *cis*-12 from K0 to K3 (11.4, 11.5, 7.9, and 8.5 mg/d), but its production remained high (13.2 mg/d) for pHCON. The results show that increasing K in the diet has effects on shifting fermentation and biohydrogenation pathways, which can only partially be explained by elevation of pH.

Key Words: potassium, biohydrogenation, rumen

747 Methane production, fermentation patterns and protozoa numbers In Vitro as related to source of rumen fluid and feed as substrate from different cattle feeding systems. M. A. Froetschel*, C. L. Ross, S. Buaphan, S. Chinnasamy, and K. C. Das, *The University of Georgia*, *Athens*.

Rumen fluid, collected by stomach tube, and samples of diet of beef cattle grazing pasture, lactating dairy cattle fed a total mixed ration, and beef cattle fed a feedlot ration were used to determine the influence of substrate and rumen microbial population on In Vitro methane production and fermentation in a 3x3 factorial designed experiment. A modified Tilley and Terry, procedure was used and fermentation gas was collected in sampling bags with septum valves. Dry matter and gross energy digestion and volatile fatty acids and ammonia production and protozoa counts were measured using standard techniques after 24 h incubations. All parameters were corrected with measurements from rumen fluid blank incubations without substrate. Rumen fluid from feedlot and dairy cattle produced 32.8% more methane volume ($P < 0.01$). Dairy and feedlot substrate produced 60% to 116% more methane volume than grazing substrate ($P < 0.01$). Although rumen fluid source from dairy and feedlot cattle increased moles of methane per digestible energy fermented by 70.5% as compare with that from grazing cattle ($P < 0.05$), methane production per energy fermented was not influenced by substrate. Methane production efficiency was positively related to VFA production ($r = 0.98$, $P < 0.01$) and the molar percentages of propionate and butyrate but negatively related to the molar percentage of acetate ($r = 0.92$, $P < 0.02$). Protozoa counts in rumen fluid from feedlot and dairy cattle were several-fold higher than that from grazing cattle but numbers decreased dramatically in vitro after 24 h. These results imply that the methane production is more related to the level of energy fed than the pattern of rumen fermentation.

Key Words: rumen fermentation, methane, digestible energy

748 Time course of changes in ruminal chemistry and bacterial community composition following exchange of ruminal contents between lactating Holstein cows. P. J. Weimer*[1,2], D. M. Stevenson[1], H. C. Mantovani[3], and S. Man[2], [1]*USDA-ARS*, *Madison, WI,* [2]*University of Wisconsin*, *Madison,* [3]*Universidade Federale de Viçosa*, *Viçosa, MG, Brazil*.

The purpose of this study was to examine the stability and host specificity of a cow's ruminal bacterial community following massive challenge with the ruminal microflora from another cow. In each of 2 experiments, one pair of cows was selected on the basis of differences in ruminal bacterial community composition (BCC), determined by automated ribosomal intergenic spacer analysis, a culture-independent "community fingerprinting" technique. Each pair of cows was then subjected to a one-time exchange of > 95% of ruminal contents without changing the composition of a corn silage/alfalfa haylage-based TMR. In experiment 1, the 2 cows differed ($P < 0.01$) in pre-feed ruminal pH (mean = 6.88 vs. 6.14) and pre-feed total VFA concentration (mean = 57 vs. 77 m*M*), averaged over 3 d. Following exchange of ruminal contents, ruminal pH and total VFA concentration in both cows returned to their pre-exchange values within 24 h. Ruminal BCC also returned to its original profile, but this change required 14 d for one cow and 61 d for the other cow. In experiment 2, the 2 other cows differed ($P < 0.01$) in pre-feed

ruminal pH (mean = 6.69 vs. 6.20) and total VFA concentration (mean = 101 vs. 136 m*M*). Following exchange of ruminal contents, the first cow returned to its pre-exchange pH and VFA values within 24 h; the second cow's rumen rapidly stabilized to a higher pre-feed pH (mean = 6.47) and lower pre-feed VFA concentration (mean = 120 m*M*) that was retained over the 62 d test period. Both cows reached somewhat different BCCs than before the exchange. However, the BCC of both cows remained distinct and were ultimately more similar to that of the pre-exchange BCC than of the donor animal BCC. The data indicate that the host animal can quickly re-establish its characteristic ruminal pH and VFA concentration despite dramatic perturbation of its ruminal microbial community, and that ruminal BCC displays substantial host specificity that can re-establish itself when challenged with a microbial community optimally adapted to ruminal conditions of a different host animal.

Key Words: rumen, ruminal bacterial community

749 Acute phase protein response during acute bovine ruminal acidosis. A. M. Danscher*[1], M. B. Thoefner[1], P. M. H. Heegaard[2], C. T. Ekstroem[1], P. H. Andersen[1], and S. Jacobsen[1], [1]*University of Copenhagen*, *Denmark*, [2]*Technical University of Denmark*, *Copenhagen, Denmark*.

The aim was to describe the acute phase protein response during acute oligofructose-induced ruminal acidosis. Two experiments involved oral oligofructose (OF) overload (17g/kg BW) to non pregnant Danish Holstein heifers. Trial 1 included 12 heifers (8 fed grass hay and 4 barley silage) sampling was done in a 3 d control period before overload (baseline) and 9 d after overload. Trial 2 included OF overload in 10 heifers and 6 control heifers receiving tap water. Blood samples (6–48 h intervals) were analyzed for serum amyloid A (SAA), haptoglobin and fibrinogen. Heifers receiving OF generally developed a profound ruminal and systemic acidosis. In Trial 1, SAA concentrations exceeded baseline on all time points from 6 to 216 h ($P < 0.001$). Heifers fed hay had higher SAA levels (max. 290 ± 151 mg/L) than heifers fed silage (max. 225 ± 137 mg/L, $P < 0.001$). In Trial 2, SAA concentrations in OF heifers were higher than controls on all time points from 6 to 72 h (max. 325 ± 149 mg/L, $P < 0.05$). In Trial 1, haptoglobin concentrations in hay fed heifers exceeded baseline on all time points from 36 to 168 h (max. 3449 ± 1702 mg/L, $P < 0.05$). Heifers fed silage had lower haptoglobin concentrations than heifers fed hay at 60, 72 and 120 h (max. 1802 ± 950 mg/L, $P < 0.05$). In Trial 2, haptoglobin concentrations in OF heifers were higher than controls on all time points from 18 to 72 h (max. 4226 ± 924 mg/L, $P < 0.001$). In Trial 2, fibrinogen concentrations in OF heifers were higher than control heifers at all time points from 36 to 72 h (max. 12.2 ± 3.3 g/L, $P < 0.01$).
Acute ruminal acidosis caused by OF overload resulted in a distinct acute phase protein response in dairy heifers. The magnitude of the response was dependent on the feeding of the animals before overload. This difference might be due to specific adaptation of the ruminal flora and mucosa to the carbohydrate substrate supplied in the feed. Although the acute phase response is nonspecific, measurement of acute phase proteins may be used to monitor the inflammatory reaction occurring in bovine ruminal and systemic acidosis.

Key Words: ruminal acidosis, acute phase proteins, oligofructose overload

750 Redox potential measurement: A new way to explore ruminal metabolism. C. Julien*[1], J. P. Marden[2], R. Moncoulon[1], and C. Bayourthe[1], [1]*Université de Toulouse, INRA, UMR 1289 INRA/INPT/ENVT TANDEM*, *31326 Toulouse, France*, [2]*Lesaffre Feed Additives*, *59520 Marquette-Lez-Lille, France*.

Microbial metabolism is thermodynamically driven by numerous biochemical reactions that can be assessed either by free energy (ΔG) calculation or redox potential (E_h) measurement. Recent studies reported that positive E_h values recorded in a buffered sterile rumen fluid, i.e., deprived of any living organism, revealed oxidative conditions (+270 mV). On the contrary, in vivo E_h values ranged generally between –220 and –110 mV which confirmed that ruminal reducing conditions directly originated from microbial activity. Furthermore, considering that the evolution of pH with time around meal reveals ruminal metabolism, the simultaneous E_h evolution seemed to reflect the varying energetic transfers involved. Therefore, ruminal metabolism could be associated to a redox equilibrium also expressed by means of Clark's exponent (rH) which combines both E_h and pH measurements. Several experiments revealed that E_h and rH equilibrium varied with diet composition in lactating dairy cows. For example, ruminal E_h and rH were significantly different in cows receiving a corn silage-based diet complemented with different degradable protein sources: –166 mV and 6.36 for soybean meal and –147 mV and 7.48 for tanned soybean meal, respectively. To go a step further, live yeast used as ruminant feed additive proved to be a potent modulator of E_h and rH equilibrium in rumen. Recent studies showed that live yeast significantly improved ruminal reducing power in dairy cows fed a high concentrate diet: –115 mV and 8.05 for the control diet and –149 mV and 7.31 for the yeast diet. Even if ruminal E_h is not easy to assess in field conditions, it proved to be an endogenous parameter as meaningful as ruminal pH or fermentative profiles, allowing a different focus on rumen metabolism. It should be considered as a precious and interesting tool for future investigations in ruminant feeding.

Key Words: ruminal redox potential, metabolism, microflora

Small Ruminant: Sheep and Goat Production 2

751 Live and carcass leg characteristics in terminally sired lambs. M. R. Mousel*[1], T. D. Leeds[2], D. R. Notter[3], H. N. Zerby[4], S. J. Moeller[4], and G. S. Lewis[1], [1]*USDA, ARS, U.S. Sheep Experiment Station*, *Dubois, ID,* [2]*USDA, ARS, National Center for Cool and Cold Water Aquaculture*, *Leetown, WV,* [3]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [4]*The Ohio State University*, *Columbus*.

Live and carcass leg characteristics of F_1 wether lambs were investigated to determine whether there were terminal-sire breed differences. Over a 3-yr period, Columbia, MARCIII, Suffolk, and Texel rams were mated with mature Rambouillet ewes to produce the lambs (n = 521). Lambs were finished in a feedlot to a mean BW of 61.9 kg (SD = 9.5 kg) and harvested at comparable ages. Before transport to slaughter, width of hind legs was measured at the widest point of the hind legs above the twist and BW was recorded for all lambs. For each carcass, weight and leg width were measured and a subjective leg score was assigned. Carcasses were fabricated into subprimal cuts, which were weighted. Live leg width (LLW), carcass leg width (CLW), leg score (LS), bone-in leg weight (BIL), and boneless leg weight (BLL) were described using mixed models that included fixed effects of breed of sire (breed), year of birth (YR), age of dam (ADAM), and type of rearing (TR) to weaning (i.e., single or as twins) and random effects of sire and maternal grandsire. The ADAM was not significant in any model, but YR and TR affected ($P < 0.01$) LLW, CLW, BIL, and BLL. The TR, but not YR, affected ($P < 0.01$) LS. Leg widths, scores, and weights were greater for single-reared than for twin-reared lambs. Breed affected ($P < 0.01$) LLW, CLW, and LS. Texel-sired lambs had the greatest leg widths, and MARCIII-sired lambs had the least. Texel-sired lambs had the greatest LS, and Columbia-sired lambs had the least. The BIL and BLL differed with breed ($P < 0.01$). Suffolk-sired lambs had the heaviest weights and MARCIII-sired lambs had the lightest. Even though breed of terminal sire affected F_1 lamb live and carcass leg traits, breeds that excelled for progeny leg shape differed from those that excelled for progeny leg weights. With this information, producers could select a terminal sire breed that would fit their production system to improve market lamb leg shape or weights.

Key Words: lamb, leg traits, terminal sire

752 The relationship of real-time ultrasound body composition measurements, body weight and hip height with body condition score in mature Suffolk x Hampshire ewes. J. A. Carter*, C. A. Hughes, K. N. Gates, and F. R. B. Ribeiro, *Texas A&M University-Commerce*, *Commerce*.

The objective of this study was to determine the relationship between real-time ultrasound (RTU) measurements of body composition, BW, and hip height (HH), with body condition score (BCS) in mature Suffolk × Hampshire ewes (n = 48). BCS was assessed visually using a 1 to 5 scale. The body composition traits measured by RTU were 12–13th rib *longissimus lumborum* muscle area (uLMA, mean = 11.75 cm^2), 12–13th rib fat thickness (uBF, mean = 0.28 cm), and ultrasound rump fat thickness (uRUMP, mean = 0.24 cm). Ultrasound measurements were taken using an Aloka 500 with a 12 cm 3.5 MHz transducer, each animal′s wool was clipped to no longer than 0.64 cm, and vegetable oil was used as a coupling agent to enhance image quality. Data were analyzed using the Proc CORR and Proc REG procedures of SAS. BW was correlated ($P < 0.05$) with BCS and HH (−0.33 and 0.60, respectively). BCS was correlated ($P < 0.05$) with HH, uLMA and uRUMP (−0.33, 0.32, and 0.46, respectively) and HH was not correlated with any of the RTU traits measured. Linear regression to predict BCS was developed using a stepwise selection. The first variable added in the model was uRUMP accounting for 21% of the variation. HH entered next in the model, accounting for an additional 6% of the variation. The full model included BW, uLMA and uRUMP and accounted for 35% of the variation in BCS. When evaluating sheep for BCS, evaluators should palpate the rump area to get a better assessment of total body fat of sheep. These results show that RTU and BW can be used to predict BCS in ewes. However, more research needs to be done to ensure the accuracy of the model.

Key Words: ultrasound, body composition, sheep

753 Redberry juniper as a roughage source in lamb finishing rations: wool and carcass characteristics, meat fatty acid profiles, and sensory panel traits. T. R. Whitney* and C. J. Lupton, *Texas AgriLife Research*, *San Angelo*.

This study was used to determine if dry redberry juiper leaves can replace cottonseed hulls in lamb finishing rations without negatively affecting wool and carcass characteristics and meat fatty acid profiles of Rambouillet ram lambs (n = 24, initial BW = 28.6 ± 4.9 kg). In a study with 2 feeding periods (Period 1 = 65% concentrate ration, 28 d; 5-d transition; Period 2 = 85% concentrate ration, 49 d), lambs were individually fed ad libitum diets containing cottonseed hulls (control; CSH), half of the cottonseed hulls replaced by dry juniper leaves (CSHJ), or all the cottonseed hulls replaced by dry juniper leaves (JUN). Lambs were completely shorn on d −1 and 83 and wool characteristics were evaluated. Lambs fed CSH, CSHJ, and JUN grew the same amount of wool when measured as greasy fleece ($P > 0.18$), clean fleece ($P > 0.45$; 0.85, 0.88, 0.81 kg ± 0.06), and clean wool production per unit of BW ($P > 0.54$;15.2, 15.8, 16.0 g/kg of BW ± 1.0). Average fiber diameter measured on mid-side samples quadratically decreased ($P = 0.04$; 20.6, 20.8, and, 19.7 μm ± 0.28) as percentage of juniper increased in the diet. On d 86, 6 lambs per treatment were randomly selected, humanely slaughtered and evaluated for carcass characteristics and meat fatty acid profiles and sensory panel traits of the LM. Carcass characteristics were not affected ($P > 0.16$) by diet, but myristic, palmitic, palmitoleic, CLA (18:2 cis-9,trans-11; 0.59, 0.64, and 0.81% ± 0.08), and arachidic fatty acids increased ($P < 0.09$) as percentage of juniper increased in the diet. Sensory panel traits were similar ($P > 0.36$) among lambs, except for off-flavor linearly increasing ($P = 0.02$) as percentage of juniper increased in the diet. Results suggest that replacing cottonseed hulls with dry juniper leaves can reduce fiber diameter and negatively affect meat flavor, but can increase CLA.

Key Words: carcass characteristics, juniper, wool

754 Evaluating roughage level in lamb finishing diets containing 40% distillers dried grains: Carcass characteristics, meat fatty acid profiles, and sensory panel traits. T. R. Whitney*, M. G. Williamson, and J. K. Mceachern, *Texas AgriLife Research Center*, *San Angelo*.

Cottonseed hulls are a common roughage source used in lamb finishing diets, especially in Texas, because of their high concentrations of NDF and ADF. Cottonseed hulls also contain condensed tannins, which can reduce rumen solubility and degradability of protein. Effects of increasing concentrations of cottonseed hulls in diets containing high concentrations of DDG on carcass characteristics, meat fatty acid profiles, and sensory panel traits are unknown. Rambouillet wether

lambs (n = 33 ± 2.3 kg) were individually fed ad libitum pelleted diets for 100 d containing 40% distillers dried grains and other ingredients, with 10% (CSH10), 20% (CSH20), or 30% (CSH30) cottonseed hulls replacing an increasing amount of ground milo. On d 100, 8 randomly selected wethers per treatment were humanely slaughtered and evaluated. Quadratic trends ($P < 0.07$) were observed for hot carcass weight (27.7, 29.3, and 27.4 kg ± 1.56) and body wall thickness (1.5, 1.8, and 1.4 cm ± 0.04) as percentage of cottonseed hulls increased in the diet. The LM area was similar ($P > 0.59$) among lambs. Quadratic trends ($P < 0.05$) were also observed for oleic acid, CLA *cis*-9,trans-11 isomer (0.19, 0.26, and 0.27% ± 0.01), CLA isomers other than *cis*-9,trans-11 (0.13, 0.13, 0.12% ± 0.01), myristic acid, palmitoleic acid, arachidic acid, and arachidonic acid as percentage of cottonseed hulls increased in the diet. The *cis*-vaccenic acid linearly decreased ($P = 0.04$) as percentage of cottonseed hulls increased in the diet. Sensory panel traits were similar ($P > 0.13$) among lambs except for initial juiciness and sustained tenderness linearly decreasing ($P < 0.05$) as percentage of cottonseed hulls increased in the diet. Results suggest that increasing percentage of cottonseed hulls in lamb finishing diets affects some carcass characteristics, meat fatty acids, and sensory traits and can increase meat CLA concentrations.

Key Words: roughage level, distillers dried grains, carcass characteristics

755 Accuracy of the FAMACHA system for estimating degree of *Haemonchus contortus* induced anemia in Hampshire, Polypay and percentage White Dorper ewes. D. K. Aaron*, M. M. Simpson, D. G. Ely, E. Fink, B. T. Burden, M. E. Hoar, and J. Farris, *University of Kentucky*, *Lexington*.

The FAMACHA system is designed to provide sheep producers with tools for on-farm detection and treatment of *Haemonchus contortus* infection. The objective of this study was to evaluate accuracy of the FAMACHA system for categorizing ewes on the basis of severity of anemia as measured by packed cell volume (PCV). A total of 1,507 records was collected on Hampshire (H; n = 414), Polypay (PP; n = 385) and percentage White Dorper (WD; n = 708) ewes from 2005 through 2009. Eyelid scores based on color of the ocular conjunctiva (1 = red, healthy to 5 = white, anemic) were assigned by the same trained technician using the FAMACHA card. Blood samples were collected and PCV were determined using a digital microhematocrit reader. Percentages of eyelid score values in each category (from 1 to 5) were 19, 38, 31, 10 and 2%, respectively. PCV decreased linearly as eyelid scores increased; however, the magnitude of change (percentage of red cells per unit change in eyelid score) was dependent upon breed (H: −2.26 ± 0.28, PP: −4.06 ± 0.22, WD: −3.69 ± 0.18; $P < 0.01$). Similarly, strength of the linear association between PCV and eyelid score varied among breeds (H: −0.388, PP: −0.671, WD: −0.610; $P < 0.01$ as per Chi-squared test of homogeneity). Across breeds, measured PCV were higher than expected within each eyelid score. Percentages of PCV exceeding the expected upper limit of the eyelid score category (from 1 to 5) were 93, 80, 92, 91 and 78% ($P < 0.01$). Few PCV were below the expected lower limits in any eyelid score category. These data confirm the FAMACHA system will allow detection of anemic animals. However, if ewes with eyelid scores of 3, 4 and 5 are considered anemic, many non-anemic ewes will be treated for parasite infection. Also, the association between eyelid score and PCV may be influenced by face color.

Key Words: anemia, *Haemonchus contortus*, sheep

756 Using FAMACHA and alternative dewormers to manage gastrointestinal nematodes in a dairy goat herd. S. P. Hart*[1] and L. J. Dawson[2,1], [1]*E (Kika) de la Garza American Institute for Goat Research, Langston University*, *Langston, OK,* [2]*Oklahoma State University CVM*, *Stillwater*.

Gastrointestinal nematodes (GIN) are the greatest health problem in goat production. FAMACHA eye color scores have been developed for selective treatment of animals to reduce the rate of development of anthelmintic resistance. Alternative anthelmintics generally are only moderately effective (40–60% fecal egg count reduction; FECR) which may not be adequate for use with FAMACHA. The purpose of this study was to test the use of alternative anthelmintics in a FAMACHA program. Lactating Alpine dairy goats (n = 91) were FAMACHA scored at 2 wk intervals from June 10 to October 15. Does with FAMACHA scores of 4 were administered one of 3 alternative anthelmintics and those with FAMACHA score of 5 were treated with levamisole HCl at 12 mg/kg BW (L). Fecal samples were taken for fecal egg counts (FEC) and blood samples were taken for packed cell volume (PCV) and serum total protein (TP). The 3 alternative anthelmintics were: 1) 2.0 g of copper oxide wires in a gelatin capsule (W), 2) 2.0 mL of a 4% solution of copper sulfate per 4.5 kg of BW as an oral drench (S), and 3) 4.0 g of cayenne pepper in a gelatin capsule (P). At least 3 animals in each period that had FAMACHA score of 3 were used as controls. FECR was low and not significantly different ($P > 0.10$)among anthelmintics (35, 52, 3, 1, and −11% for L, W, P, S, and C, respectively). FAMACHA score was improved ($P < 0.05$; except for treatment P) by administering an anthelmintic (−0.48, −0.41, −0.16, −0.37, and +0.67, for L, W, P, S, and C, respectively). TP was improved ($P < 0.01$) by administering an anthelmintic (0.45, 0.10, 0.08, 1.20, and −0.96 for L, W, P, S and C respectively). PCV was improved ($P < 0.05$) by administering an anthelmintic (−1.2, 1.0, 0.3, 1.6, and −2.4% for L, W, P, S and C, respectively. Most anthelmintics improved physiological values above the control, but W appeared superior to other alternative anthelmintics and comparable to L and would be the alternative anthelmintic of choice to use with a FAMACHA program.

Key Words: anthelmintic, alternative dewormer, gastrointestinal nematodes

757 Effects of garlic supplementation on nematode parasite infection in grazing goats. Z. Wang*, A. L. Goetsch, G. D. Detweiler, S. P. Hart, and T. Sahlu, *American Institute for Goat Research, Langston University*, *Langston, OK*.

Effects of garlic supplementation on internal parasitism and performance of lactating meat goat does grazing grass/forb pastures in the summer were determined. Forty multiparous Boer does (2 to 5 yr of age) naturally infected with nematode parasites, mainly *Haemonchus contortus*, were used in the 84-d experiment. Litter size was 1 or 2, with kids 1 to 4 mo of age when the experiment began. Five does with their kids grazed each of the 8 0.4-ha pastures. Treatments were control and garlic, with 4 pastures per treatment. Control does received 80 g/d of a mixture of 25% molasses and 75% ground corn. Does on the garlic treatment received the same supplement plus 20 g/d of garlic powder. A loose mineral-vitamin supplement was available free-choice. Means were separated by LSD. Initial mean fecal egg count (FEC; number per gram) of does was 448 (range of 0 to 1,450) and 500 (range of 0 to 2,450) for control and garlic, respectively (SEM = 119; $P > 0.05$). On d 42, doe FEC was less ($P < 0.06$) for garlic vs. control (2,837 and 6,105, respectively; SEM = 927). Does with high FEC and appreciable BW loss were treated with Levasole on d 42. Thereafter, FEC of the garlic treatment remained steady and tended to be lower compared

with the control (1,739, 1,689, and 1,303 for garlic and 1,532, 2,340, and 1,967 for control at d 56, 70, and 84, respectively; SEM = 280, 517, and 340, respectively). Doe BW was similar between treatments ($P > 0.05$). These data suggest that garlic supplementation of lactating meat goats grazing grass/forb pastures in the summer can lessen level of nematode parasitism.

Key Words: garlic, goats, internal parasitism

758 Efficacy of ginger and pumpkin seeds in controlling internal parasites in meat goat kids. D. J. O'Brien[1], M. C. Gooden[2], J. C. Warren*[1], E. K. Crook[1], J. E. Miller[3], N. C. Whitley[4], and J. M. Burke[5], [1]*Delaware State University*, *Dover,* [2]*University of Maryland Eastern Shore*, *Princess Anne,* [3]*Louisiana State University*, *Baton Rouge,* [4]*North Carolina A&T State University*, *Greensboro,* [5]*USDA, ARS, Dale Bumpers Small Farms Research Center*, *Booneville, AR*.

Twenty-two naturally infected Boer crossbred kids (mixed sex), averaging 144.4 ± 1.1 d of age and 17.6 ± 0.6 kg were used to determine the effect of 2 possible natural dewormers on BW, packed cell volume (PCV) and fecal egg counts (FEC). Goats were randomly assigned to treatments of water (CON; n = 7), 170 g pumpkin seed drench/34.0 kg BW (PUM; n = 10) or 3 g ginger/kg BW (GIN; n = 5). Treatments were administered orally to individually penned animals every other day starting at d 0 and ending on d 40. All treatment groups received a 15% CP meat goat feed daily fed at approximately 3% of their BW daily and BW and blood and fecal samples were collected weekly throughout the study period. Blood PCV were measured using microhematocrit tube centrifugation and FEC were determined using the Modified McMaster's technique (reported as eggs per gram; epg) with a sensitivity of 50 epg. Data for FEC were log-transformed for analysis but actual means ± SEM are reported. Goat BW were influenced by day, increasing over time such that d 42 BW (20.1 ± 0.6 kg) were greater ($P < 0.01$) than d 0 BW (17.6 ± 0.6 kg). Goats in the CON group had greater ($P < 0.05$) FEC than both the PUM and GIN groups (4,683 ± 483 epg, 3,409 ± 404 epg, and 2096 ± 572 epg, respectively). Goat FEC were also influenced by day with d 0 (6194 ± 750 egg) and d 7 (3749 ± 750 epg) FEC greater ($P < 0.01$) than d 35 (661 ± 750 epg) and d 42 (1308 ± 750 epg). Treatment influenced PCV with PCV for GIN (31.4 ± 1.2%) treated animals being greater than that of both CON (25.2 ± 1.0%) and PUM (27.4 ± 0.9%) treated animals. In conclusion, under the conditions of this study, additional research using ginger and pumpkin seeds are needed to further evaluate the efficacy of these natural dewormers in controlling internal parasites in goats.

Key Words: parasite, pumpkin, ginger

759 Casein glycomacropeptide (CGMP) in the diet of early weaned piglets reduces the *Escherichia coli* attachment to the intestinal mucosa and increases lactobacillar numbers in digesta. R. G. Hermes*, F. Molist, J. F. Pérez, A. G. de Segura, M. Ywazaki, and S. M. Martín-Orúe, *Universitat Autonoma de Barcelona*, *Barcelona, Spain*.

Adherence of bacteria to the intestinal mucosa is considered a prerequisite step for the colonization of pathogens. In this study we evaluated if CGMP in the diet can reduce the attachment of *E. coli* to the intestinal mucosa of oral challenged animals by enterotoxigenic *E. coli* (ETEC) K88. The experiment included 72 piglets (24 ± 3 d old) with an average BW of 6.9 ± 0.46 kg, divided into 4 treatments according to a 2 × 2 factorial design (2 diets including or not 1.5% of CGMP; ETEC challenged or not). Four days after a single 2-mL oral dose (10 CFU/ml) of the ETEC, 24 animals were killed and ileal (digesta and tissue) and colonic samples (digesta) were collected. Enterobacteria and lactobacilli were quantified in digesta by real time PCR (using SYBR green dye). Attachment of *E. coli* to ileal mucosa was monitored by FISH (fluorescent in situ hybridization) staining technique using EC1531 oligonucleotide probe, specific for *E. coli* and labeled with cyanine 3). The data were analyzed using the GLM procedure of SAS (1999), with factorial ANOVA design ($P = 0.05$). The ETEC challenge produced a mild diarrhea with increases in enterobacteria in ileal (9.2 vs. 8.4 log of 16S rDNA copies/g, $P = 0.033$) and colonic digesta (11.2 vs. 10.2 log of 16S rDNA copies/g, $P = 0.004$), and *E. coli* attachment to the ileum mucosa (34.6 vs. 8.6% of villi with bacteria adhered, $P = 0.031$). The inclusion of CGMP did not produced significant changes in the animal performance. However, it increased the lactobacilli in the colonic digesta (11.7 vs. 10.9 log of 16S rDNA copies/g, $P = 0.007$) and reduced the ileal enterobacteria, especially in the challenged animals (8.3 vs. 10.1 log of 16S rDNA copies/g, P interaction = 0.006). The CGMP most relevant result was observed on the reduction of *E. coli* adhered to the ileal mucosa (10.9 vs. 32.4% of villi with bacteria adhered, $P = 0.034$), although it was not observed significant interaction. Our results suggest that the inclusion of 1.5% of CGMP in piglet diets modify the intestinal microbial populations and impair the *E. coli* attachment to the intestinal mucosa after an ETEC oral challenge.

Key Words: casein glycomacropeptide, *Escherichia coli*, piglet

760 Early- vs. late-gestation dietary lysine requirement of young sows. R. S. Samuel*[1], S. Moehn[1], P. B. Pencharz[1,2], and R. O. Ball[1,2], [1]*Department of AFNS, University of Alberta*, *Edmonton, Alberta, Canada*, [2]*Research Institute, Hospital for Sick Children*, *Toronto, Ontario, Canada*.

Pregnant sows are traditionally fed a single dietary formulation during the entirety of gestation. The optimal feeding strategy should account for changing dietary requirements due to the linearly increasing growth rate of fetuses during the last third of gestation and the development of the mammary gland close to parturition. Young, rapidly growing sows might be expected to have greater requirements than older, slower growing sows. The objective of this study was to determine the lysine requirement of a population of 2nd and 3rd parity sows in early- (d 24 – 45) and late- (d 86 – 110) gestation. Pregnant Hypor Hybrid (Hypor Inc.) sows (n = 7; 185.7 ± 9.6 kg BW) were adapted to individual intakes of a semi-synthetic diet containing 14.0 MJ ME/kg. Each sow received 6 different test diets, in random order. These ranged from 60 – 150% and from 60 – 185% of the requirement suggested by NRC (1998) in early- and late-gestation, respectively. These were equivalent to dietary lysine intakes of 7.5 – 19.3 g/d in early- and 8.1 – 23.7 g/d in late-gestation. Oxidation of the indicator amino acid L-[1-^{13}C]-phenylalanine (Phe) during a primed-constant oral infusion was measured. The average number of piglets born alive was 13.7 ± 1.9, but ranged from 4 to 20. The average piglet birth weight was 1.5 ± 0.1 kg. Sows gained 600 g/d from breeding and weighed 258.8 ± 8.3 kg before farrowing. Breakpoint analysis of Phe oxidation indicated that the lysine requirement of 2nd parity sows was 13.1 g/d and 18.7 g/d in early- and late-gestation, respectively. For 3rd parity sows, the dietary lysine requirement was 8.2 g/d and 13.0 g/d for early- and late-gestation, respectively. The dietary requirements for lysine in early- and late-gestation were greater than previously reported by NRC (1998). Growing evidence indicates that phase feeding of sows would be economically advantageous by reducing feed costs and maximizing lifetime productivity.

Key Words: sow, gestation, lysine

761 A wheat bran extract shows a high attachment to K88 *Escherichia coli in vitro*. F. Molist, R. G. Hermes*, J. F. Pérez, and S. M. Martín-Orúe, *Universitat Autonoma de Barcelona*, *Barcelona, Spain*.

The aim of this study was to elucidate in vitro the ability of wheat bran (WB) and other fiber sources to bind K88 *E. coli* as a likely blocking mechanism of its attachment to the intestinal mucosa. The in vitro adhesion test was done in polystyrene 96-well plates using WB, rice hulls, soybean hulls, cereal straw, sugar beet pulp, pea hulls and oat hulls as possible blocking agents and 2 *E. coli* strains (K88 and non-fimbriated), isolated from the feces of post-weaning piglets. The fiber sources were diluted in phosphate buffer (PBS, 4%, w/v), sonicated 3 times and centrifuged. The supernatant was introduced in the plate and incubated at 4°C overnight. After that, the plate was washed with sterile PBS and the non-specific adhesion sites blocked with 1% BSA. The test of adhesion started when *E. coli* strains were inoculated at a concentration of 10^8 CFU/mL and allowed to adhere during 30-min at room temperature. Finally the plate was washed with sterile PBS to remove the non-attached bacteria and Luria Broth media was added to promote the growth of the attached bacteria. Plates were incubated at 37°C/10 h in a spectrophotometer where the optical density (OD, 650 nm) was recorded every 10 min. All OD data were processed using the PROC NLIN of SAS. The parameters thus obtained were used to calculate $t_{OD = 0.05}$ (delay time (h) for the cultures to reach an OD of 0.05 at 650nm). Analysis of variance of the $_{OD = 0.05}$ values was done using the PROC GLM of SAS. Results showed that the non-fimbriated *E. coli* adhered less to the fiber substrates compared with the K88 (3.14 vs. 2.72h, $P = 0.001$) which indicates that the presence of fimbria (F4) play an important role in the interaction bacteria-fiber substrate. Regarding the fiber sources, more bacteria bind to the WB (0.94 and 2.73 h for K88 and non-fimbriated, respectively, $P = 0.001$) compared with the other fiber sources (average 2.97 and 3.20 h). Our results suggest that WB could act as an anti-adhesive ingredient against pathogenic *E. coli* and improve the animal health in the post-weaning period.

Key Words: wheat bran, *E. coli*, adhesion

762 Effect of a softer surface in the farrowing crate on feed intake of lactating sows. A. Da Silva*, S. S. Anil, J. Deen, and S. K. Baidoo, *University of Minnesota*, *Saint Paul*.

Lameness in swine herds is both an economic and welfare concern. The pain associated with lameness may decrease lactation feed intake. An

important cause for lameness has been suggested to be claw lesions. Claw lesions in pigs are the result of the interaction between claw and the floor surface. However, the effect of floor type on lameness and its effects on feed intake of sows are poorly understood. The present study aimed to explore the effect of providing rubber mats in farrowing crates as a measure to minimize the adverse effects of lameness on feed intake of lactating sows. This study involved 70 lame and 70 non-lame gestating sows (gestation stall n = 63 and group pens with ESF n = 77) identified based on their ability to bear weight on all limbs without favoring any particular limb, on d 109 of gestation when they were moved from the gestation housing systems to farrowing rooms. Equal numbers of sows were randomly allocated to farrowing crates with cast iron total slatted floor or to crates with rubber mats on the cast iron total slatted floor in the posterior half. Sows in farrowing crates were hand-fed twice daily weighed amount of feed which was recorded. Feed consumed was assumed to be equal to that fed if the feeder was empty. Orts were weighed on weaning day to estimate feed intake during the lactation period. The frequency of the number of lactation days was calculated for all sows using daily feed intake (d 2 to 14 of lactation) category of 0 to 5 lbs (2.27 kg). The feed intake of lame and non-lame sows with and without rubber mats were compared using separate models for each category, controlling for the effect of housing system (Proc Genmod, SAS v 9.2). The number of days sows consumed less than 5 lbs (2.27 kg) was 42% higher in lame sows and 30% lower in stall housed sows ($P < 0.05$ for both). Rubber mat was not found to be associated with feed intake in this study.

Key Words: lameness, sow, feed intake

763 Effect of P.G. 600 on estrous cycles in gilts. M. J. Estienne* and R. J. Crawford, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

A combination of eCG (400 IU) and hCG (200 IU) (P.G. 600, Intervet/Schering-Plough Animal Health, De Soto, KS) is labeled for stimulating first estrus in prepubertal gilts. Variation exists among farms, however, in the estrual response. Perhaps at least some of the variation is due to inadvertent treatment of gilts that are already cycling. The objective was to determine the effect of i.m. P.G. 600 on estrous cycle length. Prepubertal gilts (110 kg BW and 175 d of age) were checked for estrus in the presence of a boar daily throughout the experiment. Gilts in Treatment (TRT) 1 (n = 16) received P.G. 600 at the onset of boar exposure. Gilts in TRT 2 – 5 (n = 16/TRT) were allowed to express a natural first estrus and were then treated with P.G. 600 as follows: TRT 2, at d 6 ; TRT 3, at d 12 ; and TRT 4, at d 18 of the cycle. Gilts in TRT 5 received no P.G. 600. More ($P < 0.05$) gilts in TRT 1 (43.8%) were in estrus by d 7 of the experiment compared with gilts in TRT 2 – 5 (20.3%), and for gilts in estrus by d 7, the interval from the start of the study was lesser ($P < 0.01$) for TRT 1 compared with TRT 2 – 5 (4.7 ± 0.3 vs. 6.1 ± 0.3 d). Gilts displaying estrus during the entire experiment (97.5%) was not affected by treatment ($P = 0.28$). Gilts that displayed a normal estrous cycle (17 – 24 d) was greater ($P < 0.05$) for TRT 4 (100%) and 5 (100%) compared with TRT 1 (73.3%) and 3 (60%), with TRT 2 having a value (87.5%) that was not different from the other groups. Abnormal cycle lengths were 37.0 ± 9.4 d for TRT 1, 23.7 ± 13.2 d for TRT 2, and 32.5 ± 7.6 for TRT 3 ($P < 0.75$). The percentages of gilts that expressed a first estrus but then were anestrus for the remainder of the experiment was 6.7 for each of TRT 1 and 3, and 0 for TRT 2, 4 and 5 ($P < 0.23$). Although mechanisms responsible for these effects must be further scrutinized, the results demonstrate to swine producers the need to correctly classify replacement gilts as prepubertal or cycling before administering P.G. 600.

Key Words: P.G. 600, estrous cycle, gilts

764 Analysis of the association between lameness and claw lesions in stall-housed gestating sows. A. Da Silva*, S. S. Anil, J. Deen, and S. K. Baidoo, *University of Minnesota*, *Saint Paul*.

Lameness in sows has both economic and welfare implications. Severe claw lesions can cause lameness in pigs. Not all claw lesions may lead to lameness in pigs. Housing conditions and management practices may be associated with the development of claw lesions. An evaluation of the association between claw lesions and lameness would provide strategies to minimize the incidence of such lesions and reduce removal of sows for lameness. The objective of this study was to analyze the association of lameness with different types of claw lesions in sows. Claws of 63 stall-housed sows (parities 1 to 8) in a breeding herd at the University of Minnesota, Southern Research and Outreach Center, Waseca, MN were individually examined for lesions on d 110 of gestation when sows were in the farrowing crates, before farrowing. Lesions included erosions, cracks, and overgrowths. Areas in the claw were categorized as side wall, heel including overgrown heel, sole, heel-sole junction, white line and overgrown dew claw and toe. Lesions were scored on a scale of 0 (no lesion) to 3 (severe lesion). The total score for each claw area was obtained by adding the scores for that area in the lateral and medial claws of front and hind limbs. The level of lameness in these sows was assessed when they were moved to the farrowing crates, based on their ability to bear weight on all 4 limbs without favoring any particular limb. A multivariate logistic regression analysis was performed (Proc Logistic, SAS v 9.2) to assess the association of lesion scores of different claw areas with lameness (lame vs. non-lame). Lesions on the heel and the white line were associated with lameness. Total heel lesion score was negatively associated with lameness (odds ratio 0.65, $P < 0.05$). For every unit increase in total white line lesion score, the likelihood of lameness increased by 31% ($P < 0.05$). The likelihood of lameness increased with an increase in the severity of lesions in other claw areas as well, though the associations were not statistically significant.

Key Words: claw lesions, lameness, gestation stall

765 Design of porcine lactoferricin-based antimicrobial peptides with improved activity. F. F. Han*, Y. F. Liu, Y. G. Xie, Y. H. Gao, and Y. Z. Wang, *Feed Science Institute of Zhejiang University*, *Hangzhou, Zhejiang, China*.

Structure-function relationships in antimicrobial peptides have been extensively investigated to obtain improved analogs. In the present study, a series of synthetic derivatives of porcine lactoferricins were prepared with an aim to understand the structural basis of activity as well as improve its activity. We found that the 20-residue porcine lactoferricin (LP20) and its derivatives LF2A, LF-1, LF-3 displayed antimicrobial activity against *Escherichia coli*, *Staphylococcus epidermidis*, *Salmonella choleraesuis*, and *Salmonella typhimurium*. The minimal inhibitory concentrations of LP20 ranged from 64 to 128Î1/4g/mL; LF2A, LF-1 and LF-3 were 2–8 times more effective than LP20. The studies demonstrate that replacing the Cys with Ala not only increased the activities against gram-negative bacteria but also decreased hemolytic activity. Replacing the Ile with Trp both increased the antimicrobial and hemolytic activity at 4, 32, 64, 128, and 256 Î1/4g/mL ($P < 0.05$). The cytotoxic potential of LP20 analogs were quantified by colorimetric WST-1 and LDH assays in PBMC. LF2A, LF-1 and LF-3 increased cell proliferation and viability in a dose dependent Fashion. Compared with LP20, 25–200 Î1/4g/mL LF-1 improved the cell proliferation significantly ($P < 0.05$), while 400 Î1/4g/mL LF-1 decreased the cell proliferation ($P < 0.05$). Both 200Î1/4g/mL and 400Î1/4g/mL LF-1 induced an increase ($P < 0.05$) in LDH release from PBMC whereas 25–50Î1/4g/mL decreased the LDH release ($P < 0.05$). Moreover, LF-1, LF-3 able to disrupt the

cytoplasmic membranes at relatively low concentrations. In contrast, LP20 and LF2A had more-modest antibacterial activities, a lesser ability to depolarize the cytoplasmic membrane.

Key Words: porcine lactoferricin, antimicrobial peptide, cytotoxic activity

ADSA Production Division Symposium: Dairy Products and Human Health: The Facts

766 Dairy products and human health: The facts. D. I. Givens*, *University of Reading, Reading, Berkshire, United Kingdom*.

Increasing obesity and an aging population increase substantially the risk of chronic disease and its associated cost. Diet is a modifier of risk and since milk and its products are staple components of most Western diets providing key nutrients, it is very important to understand whether these foods also increase or decrease the risk of chronic disease. This paper will assess the current evidence available. A recent meta-analysis (Elwood et al., 2008) showed the relative risk of stroke and/or heart disease in subjects with high milk or dairy consumption was 0.84 (95% CI 0.76, 0.93) and 0.79 (0.75, 0.82) respectively, relative to the risk in those with low consumption. Four studies reported incident diabetes as an outcome, and the relative risk in the subjects with the highest intake of milk or diary foods was 0.92 (0.86, 0.97). The World Cancer Research Fund (2007) report confirmed that increased milk consumption will probably decrease the risk of colorectal cancer. Some studies have shown a positive association between increased milk consumption and prostate cancer but the increased risk is small and not consistent across studies. It should however not be ignored. Set against the proportion of total deaths attributable to the life-threatening diseases in the EU i.e. vascular disease, diabetes and cancer, the available data provide evidence of an overall survival advantage from the consumption of milk although the situation with other dairy foods is much less clear and needs urgent clarification. For milk in particular there appears to be an enormous mismatch between both the advice given on milk/dairy foods items by various authorities and public perceptions of harm from the consumption of milk and dairy products, and the evidence from long-term prospective cohort studies. These foods do however supply a sizeable proportion of dietary saturated fatty acids in many countries but simply reducing milk consumption to reduce saturated fatty acid intake is not likely to produce benefits overall though the production of dairy products with reduced saturated fatty acid contents is likely to be helpful.

Key Words: milk, health, epidemiology

POSTER PRESENTATIONS

Animal Health: Probiotics and Diet

W1 Improved health status of newborn calves from dairy cows treated intravaginally with probiotic bacteria. Q. Zebeli*, S. Iqbal, S. M. Dunn, and B. N. Ametaj, *University of Alberta*, *Edmonton, AB, Canada*.

Improving cow's reproductive health during the transition period might be beneficial for the health status of newborn calves. We recently developed an intravaginal probiotic treatment to prevent uterine infections in dairy cows. This study sought to evaluate the effects of probiotic treatment of dairy cows on selected plasma variables and the incidence of diarrhea in newborn calves. Nineteen dairy calves coming from control (CTR; n = 10) or cows administered intravaginally with a probiotic culture (PRO; n = 9) at −2 and −1 wk prepartum as well as at +1, +2, +3, and +4 wk postpartum were used in this study. A total of 10^{10} to 10^{12} cfu of a probiotic culture consisting of *Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138 was dissolved in 1 mL reconstituted skimm milk. Calves were supplied with 4 kg colostrum/d up to 3 d after birth, and blood samples were collected from the jugular vein on d 3 and 10. The incidence of diarrhea was monitored daily in all calves up to 2 wk. Blood data were submitted to repeated measures ANOVA, whereas the incidence of diarrhea was analyzed by chi-squared test with SAS. Significance and tendency levels were considered at $P < 0.10$ and $P < 0.15$, respectively. Data indicated that PRO calves showed greater concentration of glucose (89.4 vs. 101.5, ± 4.6 mg/dL), but lower lactate (5.7 vs. 4.3, ± 0.5 mmol/L) in the plasma ($P < 0.10$). Also, concentrations of haptoglobin (444 vs. 347, ± 60.1 μg/mL) and β-hydroxy-butyrate (125 vs. 107, ± 6.9 μmol/L) in the plasma tended to be lower in the PRO calves ($P = 0.11$). There was no effect of treatment on calf's body weight at birth, plasma non-esterified fatty acids, and cholesterol ($P > 0.15$). Frequency tables revealed that 6 out of 10 calves (60%) pertaining to the CTR group were affected by diarrhea, whereas the PRO calves showed lower ($P = 0.09$) incidence of diarrhea (2 from 9; 22.2%). In summary, results suggested that intravaginal treatment of the pregnant cows with probiotics during the transition period enhanced the metabolic health status of newborn dairy calves.

Key Words: probiotics, dairy calf, plasma metabolites

W2 Infusion of commensal bacteria intravaginally improved overall health status of transition dairy cows. Q. Zebeli*, S. Iqbal, S. M. Dunn, and B. N. Ametaj, *University of Alberta*, *Edmonton, AB, Canada*.

Transition period is associated with high incidence of metabolic and infectious diseases in dairy cows. Because commensal lactobacilli exert immune-stimulating properties, we hypothesized that intravaginal administration might promote health status of the transition dairy cows. This study sought to evaluate the effects of intravaginal administration of commensal lactobacilli on the incidence of metabolic diseases in transition dairy cows. Eighty Holstein cows were blocked by parity and incidence of disease in the previous lactation, and randomly allocated to 1 of the 2 different treatment groups. Forty cows (incl. 12 primiparous cows) were administered intravaginally with 10^{10} to 10^{12} cfu bacterial culture (*Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138) dissolved in 1 mL reconstituted skim milk (TRT). The control cows (CON) received 1 mL of reconstituted skim milk only. Infusion was carried out by an insemination pipette at −2 and −1 wk prepartum and at +1, +2, +3, and +4 wk postpartum. Urine and vaginal pH were measured before the culture administration. Cows were monitored daily for incidence of disease, starting from −2 wk up to +8 wk postpartum. Data were analyzed statistically by chi-squared test with SAS. Results showed that TRT cows had lower incidence of lameness (56.1 vs. 34.2%; $P = 0.04$) and susceptibility from more than one disease such as metritis, pyometra, and mastitis (27.5 vs. 15.9%; $P < 0.01$). Treatment tended to lower the number of medications (7.3 vs. 4.5 medications/cow; $P = 0.09$) throughout the experiment in multiparous cows. Also, multiparous TRT cows showed greater urine pH (7.9 vs. 8.2; $P = 0.03$). Vaginal pH was affected only by day of sampling being the lowest at −3 d before parturition ($P = 0.02$). Data showed that 51.9% of multiparous CON cows had a strong (>25%) day-to-day variation of feed intake, whereas this variable was 21.4% in the TRT cows ($P = 0.02$). In conclusion, results indicated that intravaginal treatment of the pregnant cows with commensal lactobacilli improved health status of transition dairy cows.

Key Words: dairy cow, metabolic disorder, intravaginal lactobacilli

W3 Intravaginal administration of commensal lactobacilli modulated plasma metabolites and innate immunity in periparturient dairy cows. S. Iqbal, Q. Zebeli, S. M. Dunn, and B. N. Ametaj*, *University of Alberta*, *Edmonton, AB, Canada*.

Dairy cows experience a high incidence of uterine infections after parturition which initiates major changes in metabolism and activation of an acute phase response. The objective of this study was to test the effects of an intravaginal infusion of a mixture of lactobacilli around parturition on selected plasma metabolites and innate immunity in transition dairy cows. Eighty pregnant Holstein heifers and dairy cows were randomly assigned to one of the following treatments: 1) intravaginal administration of 1 mL of carrier alone (reconstituted skim milk) for the control cows, or 2) intravaginal administration of 10^{10}-10^{12} cfu of probiotic bacteria dissolved in 1 mL of reconstituted skim milk. The probiotic preparation contained a mixture of *Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138 isolated from the vaginal tracts of healthy cows. Probiotics were applied intravaginally with a sterile syringe and insemination pipette once during wk −2, −1, +1, +2, +3, and +4 relative to parturition. Blood samples were collected from 15 cows per group (5 heifers and 10 cows) to be analyzed for β-hydroxybutyrate (BHBA), non-esterified fatty acids (NEFA), glucose, lactate, and haptoglobin (Hp). Results showed lower concentrations of BHBA (647 vs. 846 μmol/L; $P < 0.05$) and greater plasma NEFA (266 vs. 136 μEq/L; $P < 0.01$) in primiparous cows of treatment group. These cows also showed an interaction between treatment and wk of sampling for NEFA which were higher on wk +1, +2, and +4 ($P < 0.05$), and tended to be greater on wk +6 ($P = 0.11$). Also, an

interaction between treatment and time of measurement for cholesterol in multiparous cows ($P = 0.13$) was obtained. Interestingly, the overall analysis showed an interaction between treatment and wk of measurement for plasma Hp which was lower in the treatment group on wk −1 ($P = 0.05$) and tended to be lower on wk +2 ($P = 0.07$). In summary, intravaginal administration of lactobacilli modulated plasma metabolites and improved innate immunity in periparturient dairy cows.

Key Words: dairy cow, intravaginal probiotics, plasma metabolites

W4 Intravaginal treatment with probiotics decreased the incidence of subclinical mastitis in dairy cows. S. Iqbal, Q. Zebeli, S. M. Dunn, and B. N. Ametaj*, *University of Alberta*, *Edmonton, AB, Canada*.

The decrease in milk production and high culling rate associated with mastitis are major concerns of the dairy industry. The aim of this study was to evaluate the effect of an intravaginal administration of a probiotic preparation around parturition to prevent development of subclinical mastitis in dairy cows. Eighty pregnant Holstein cows were randomly assigned to one of the 2 treatment groups: 1) intravaginal administration of 1 mL of carrier alone (reconstituted skim milk) for control cows, or 2) intravaginal administration of 1 mL of reconstituted skim milk containing 10^{10} to 10^{12} cfu of probiotic bacteria. The probiotic preparation contained a mixture of *Lactobacillus sakei* FUA 3089, *P. acidilactici* FUA 3140, and *Pediococcus acidilactici* FUA 3138 isolated from the vaginal tracts of healthy cows. Probiotic bacteria were applied intravaginally with a syringe and a sterile insemination pipette once during wk −2, −1 and +1, +2, +3, and +4 around calving. Milk samples were collected from 15 cows (5 heifers and 10 cows) per group to be analyzed for different milk variables. Results of the overall ANOVA showed that treatment lowered SCC (85,000 vs. 236,000 cells/mL; $P = 0.02$); whereas, there was a tendency for higher protein yield (1.06 vs. 0.91 kg; $P < 0.10$), as well as lactose content (4.37 vs. 4.30%; $P = 0.12$), and yield (1.59 vs. 1.35 kg; $P < 0.10$). Data also indicated higher milk lactose yield (1.74 vs. 1.39 kg; $P = 0.04$) in multiparous cows treated with probiotics. The latter cows showed tendencies for lower SCC (73,000 vs. 235,000 cells/mL; $P < 0.10$), fat content (4.24 vs. 4.82%; $P < 0.10$), fat to protein ratio (1.48 vs. 1.69; $P < 0.10$) and solid non fats (1.48 vs. 1.69 kg; $P < 0.10$), but higher for protein yield (1.14 vs. 0.93 kg; $P < 0.10$) and lactose content (4.37 vs. 4.26%; $P = 0.10$). Data also demonstrated that the total solids tended to be higher (13.4 vs. 12.6%; $P = 0.15$) in primiparous cows. In conclusion, intravaginal probiotic administration lowered the risk of sub-clinical mastitis and modulated several milk components in postpartal dairy cows.

Key Words: dairy cow, probiotics, somatic cell counts

W5 Improved feed intake and milk production in transition dairy cows treated intravaginally with probiotic bacteria. S. Iqbal, Q. Zebeli, S. M. Dunn, and B. N. Ametaj*, *University of Alberta*, *Edmonton, AB, Canada*.

The transition period is critical for the health and productivity of dairy cows due to major changes in the dietary composition and physiological state. The aim of this study was to investigate the effects of an intravaginal administration of a mixture of lactobacilli around parturition on health status and milk production of dairy cows. Eighty pregnant Holstein primiparous and multiparous dairy cows were assigned, 2 wk before the expected day of calving, to one of the following groups receiving either 1) intravaginal administration of 1 mL of carrier alone (controls), or 2) intravaginal administration of 1 mL of reconstituted skim milk containing 10^{10} to 10^{12} cfu of probiotic bacteria. The probiotic preparation was a mixture of *Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138 prepared with commensal bacteria isolated from the vaginal tracts of healthy cows. Probiotic bacteria were applied intravaginally with a sterile syringe and insemination pipette once during wk −2, −1,+1, +2, +3, and +4 around calving. Rectal temperatures were taken during +2 wk before and +3 wk after calving, whereas milk production and feed intake were collected starting from +2 wk before until +8 wk after calving. Multiparous cows tended to have greater feed intake (32 vs. 28 kg/d; $P = 0.08$) associated with higher milk production (37 vs. 34 kg/d; $P < 0.01$). The cumulative analysis of milk data demonstrated a trend for higher milk production in the treatment group ($P = 0.14$). The overall analysis also showed a trend for feed intake to be greater (32 vs. 28 kg/d; $P = 0.10$) in treated cows. Interestingly, treatment did not influence feed intake or milk production in primiparous cows ($P > 0.05$). Treatment also had no effect on body condition score ($P > 0.05$). Results showed an interaction between treatment and day of measurement for rectal temperature in multiparous cows during wk +2 ($P = 0.02$). In summary, intravaginal administration of commensal Lactobacilli improved feed intake and milk production in postpartal multiparous dairy cows.

Key Words: dairy cow, intravaginal probiotics, milk production

W6 Effect of medicinal plants on immune system of broilers. A. Naghizadeh, S. Rahimi*, S. Askari Rankouhi, K. Gharib Naseri, M. Lotfi, and M. Rezaei, *Tarbiat Modares University*, *Tehran, Tehran, Iran*.

This study was carried out to investigate the effects of dietary administration of some medicinal plants to improve immune responses efficiency in broilers. Total of 180 d-old broilers (Arbor Acres Plus) were randomly distributed in 6 dietary treatments as follow: control; 4 groups of medicinal plants (dried powder of peppermint; thyme; basil and garlic at 1.5%); and one group fed diets containing antibiotic (15 ppm). Each treatment was replicated 3 times. Blood samples were collected from 3 birds at random from each group on d 25 and 46 of the experiment for evaluation of immune responses, including humoral immune response to sheep red blood cells (SRBC) and Newcastle disease vaccine (ND) and cellular immune response to phytohemagglutinin (PHA). Results showed that supplementation of broilers diets with garlic and peppermint increased humoral immune response significantly (4.33 ± 0.07 and 3.99 ± 0.03 for garlic and peppermint groups vs. 2.33 ± 0.11, 2.66 ± 0.08, 3.00 ± 0.13 and 3.33 ± 0.06 for control, antibiotic, basil and thyme treatments respectively) ($P < 0.05$). There were no significant differences among the treatments on cellular immune response. Also there were no significant differences in Newcastle disease antibody titer (HI) except garlic treatment ($P > 0.05$). Results indicated that use of medicinal plants as dry powder, had no significant effects on humoral immune responses, except for garlic and peppermint. However, garlic supplementation to broiler diets caused significantly higher HI titers against Newcastle disease at 46d compared with 25d.

Key Words: medicinal plants, immune system, broilers

W7 In vitro effects of plant and mushroom extracts on immunological function of chicken lymphocytes and macrophages. S.-H. Lee*[1], H. Lillehoj[1], Y.-H. Hong[1], S.-I. Jang[1], E. Lillehoj[2], and D. Bravo[3], [1]*Animal and Natural Resources Institute, Agricultural Research Service, USDA*, *Beltsville, MD,* [2]*Department of Pediatrics, School of Medicine, University of Maryland*, *Baltimore,* [3]*Pancosma S.A.*, *Grand Saconnex, Geneva, Switzerland*.

The present study was conducted to examine the effects of 4 different plant extracts from milk thistle (*Silybum marianum*), turmeric (*Curcuma*

longa), reishi (*Ganoderma lucidum*) and shiitake mushroom (*Lentinus edodes*) on innate immunity and tumor cells. The innate immunity was measured by splenocyte proliferation, NO production by an established avian macrophage cell line, HD11, and the inhibitory effect on a chicken B-cell tumor cell line, RP9. Cytokine transcript levels (IFN-α, IL-1β, IL-6, IL-12, IL-15, IL-18, TNFSF15) in the HD11 treated with turmeric or shiitake mushroom were also measured by real time RT-PCR. In vitro culture of splenocytes treated with milk thistle, turmeric, or combined extract of shiitake plus reishi induced significantly higher cell proliferation compared with the control ($P < 0.01$). Stimulation of macrophages with milk thistle or combined extract of shiitake plus reishi ($P < 0.001$), but not turmeric, resulted in robust NO production. All extracts inhibited the growth of RP9 cells at the dose ranges of 6 to 100 μg/mL ($P < 0.001$). Finally, the levels of IL-1β, IL-6, IL-12, IL-18, and TNFSF15 mRNAs were enhanced in HD11 that were treated with turmeric or shiitake mushroom compared with the untreated control ($P < 0.01$). These results show that plant extracts used in this study activate innate immune system and are cytotoxic against an avian tumor.

Key Words: innate immunity, phytonutrients

W8 Yeast autolysate combined with probiotic strains: Investigation of health effects in vitro and ex vivo. A. Ganner*[1], S. Masching[2], N. Reisinger[1], G. Schatzmayr[1], and T. Applegate[3], [1]*BIOMIN Research Center*, *Tulln, Austria*, [2]*BIOMIN Holding GmbH*, *Herzogenburg, Austria*, [3]*Purdue University*, *West Lafayette, IN*.

Yeast derivates have been proposed to improve animal health by preventing infectious diseases, by modulating the immune system and by controlling pathogenic bacteria. Probiotics have been described as being capable of protecting the intestinal mucosa by being antagonistic to undesirable microorganisms. The study was conducted to evaluate a product, consisting of yeast autolysate, lactobacilli, *Enterococcus* sp., *Pediococcus* sp. and bidifobacteria, on jejunal structure, apoptotic enterocytes, blood profile and health status of broilers. To exclude weakening effect of live probiotic components, the yeast autolysate was examined in vitro for its capacity to bind *Lactobacillus* sp., *Enterococcus* sp. and *Bifidobacterium* sp. with a microplate assay by measuring the OD as growth parameter of adhering bacteria. In a 35 d study, 300 broilers were distributed into 2 groups: control and trial group (0.1% autolysate + probiotic mix of 10^8 CFU/kg feed). On d 35, parts of distal jejunum were collected from 8 birds per group. Villi length and goblet cells were examined by Schiff and hematoxylin staining. Apoptotic enterocytes were examined with DeadEnd TUNEL. Blood samples were analyzed by flow cytometry. No binding was detected between autolysate and selected probiotics. A clear positive influence could be observed by the test product on weight d 14 and daily weight gain (DWG) 1–14 ($P = 0.0001$); slight improvement weight d 35 and DWG 1- 35 ($P = 0.08$). The goblet cell number was also increased by test diet with 126/villus (control 98/villus, $P = 0.1$). Villus height, crypt and apoptotic cells were not affected. Heterophils ($P = 0.08$) and lymphocytes ($P = 0.004$) were enhanced in the trial group. Our results indicate that the product consisting of yeast autolysate and probiotics is able to improve gut health, to modulate immune cells and to enhance bird performance.

Key Words: autolysate, probiotic, jejunum, performance

W9 Effects of a feed additive on neutrophil expression of immunomodulatory genes and production performance in periparturient dairy cows. R. D. Schramm, S. L. Shields*, D. L. Sevier, M. A. McGuire, and P. Rezamand, *University of Idaho*, *Moscow*.

The objectives of this study were to determine the effects of a feed additive, OmniGen-AF, on 1) neutrophil expression of immunomodulatory genes including interleukin-8 receptor (IL-8r), L-selectin (L-SEL), and interleukin converting enzyme (ICE), and 2) production performance and milk composition during the early postpartum period in dairy cows. Holstein cows were blocked by parity and randomly assigned to one of 2 treatments: OmniGen-fed (n = 11) and control-fed (n = 11). All cows received a standard dry ration before calving and were switched to a lactation ration after parturition either supplemented with OmniGen-AF (220 g/d of an inert additive containing 56 g OmniGen-AF) or received the same ration with inert additive but without OmniGen-AF. Cows were individually fed using Calan gates, and feed intake and milk yield were determined daily. Blood samples were obtained on d 28 and 7 before expected calving date and on d 9, 19, and 28 postpartum. Blood neutrophils were isolated and analyzed for mRNA expression of IL-8r, L-SEL, and ICE by rt-PCR. Populations of white blood cells were determined by flow cytometry in a subset of samples (n = 3/treatment), and milk composition was determined by a certified DHI laboratory. Data were analyzed by SAS in the mixed model procedure. No significant treatment effect was detected on feed intake, milk yield, or milk composition. Populations of leukocytes, granulocytes, T-cells and B-cells were also not different ($P > 0.05$) between treatments. Neither SCC nor neutrophil expression of immunoregulatory genes tested differed significantly between treatments. However, mRNA expression of IL-8r decreased as parturition approached, and increased beyond the initial level during the postpartum period ($P = 0.008$). Downregulation of IL-8r in the present study may explain, in part, the immunosuppression evidenced in periparturient dairy cows. Further studies are needed to clarify the specific roles of OmniGen-AF on mammary gland health in dairy cows.

Key Words: dairy cow, neutrophil, OmniGen-AF

W10 Potential of *Metharrizium anisopliae* as biological mean to control *Boophilus microplus* in tropical dairy farms. E. Maldonado-Siman*[1], P. Martinez-Hernandez[1], E. Galindo-Velasco[2], M. Alonso-Diaz[3], and R. Rodriguez-DeLara[1], [1]*Animal Science Department, University of Chapingo*, *Texcoco, Mexico, Mexico*, [2]*University of Colima*, *Tecoman, Colima, Mexico*, [3]*Autonomous National University of Mexico*, *Martinez de la Torre, Veracruz, Mexico*.

Biological control of tick (*Boophilus microplus*) infestations in tropical dairy farms can be a feasible alternative to chemical control. The aim of the study was to determine the tick load on dairy cows sprayed with *Metharrizium anisopliae* (entomopathogenic fungus) in the summer. Field work was carried out in a certified organic dairy farm in Veracruz, Mexico. Two treatments were evaluated: spraying cows with *M. anisopliae* strain Ma34 at a concentration of 1×10^8 conidia/ml every other week and no-spraying (control). Control cows were sprayed with water every time treated cows were sprayed. A completely random experimental design with 21 replicates was used. The experimental unit was a cow. Experiment lasted 16 weeks (May to August). All cows had the same management except at the spraying time. Ticks were counted every week; the first count was just before the first spraying. Treatments were compared every week. All cows showed a same initial tick load (50 ticks/cow). Afterward, in 10 out of the 15 weeks, cows sprayed with the fungus showed from 34 to 78% lower ($P < 0.05$) tick load than control cows, the largest difference in tick load was found in the last 2 weeks of the experiment. It was concluded that *M. anisopliae* represents a potential biological control of ticks.

Key Words: biological control, ticks, tropical dairy

W11 Effects of Globigen egg protein on calf health and performance. D. Wood*, R. Blome, and J. Sowinski, *Animix*, *Juneau, WI*.

Study objective was to evaluate effect on calf health and performance of supplementation of Globigen egg antibody preparation (AB). Auction sourced Holstein bull calves (n = 150; ~1 wk of age) were shipped to the facility and randomly placed in individual raised, slatted stalls. Calves were assigned to receive 1) calf milk replacer (CMR, 22% C.P. 20% fat) n = 75, or 2) same formula +AB at 1 g/calf/fdg wk 1, 2 g/calf/fdg wk 2 and 1 g/fdg wk 3, total AB 56 g/calf, n = 75. No differences were noted in individual serum total protein ($P \leq 0.22$). Total 21 kg CMR was fed over 42 d starting at 362 g/calf/day stepping up to 682 g/calf d 16. Calves in every-other-stall in the barn received AB. Manufacturer detected anticipated presence rotavirus and coronavirus titer in AB fed. Both formulas contained plasma (5%), mannanoligosaccharides and chlortetracycline. Neomycin was administered in both formulas d 1–14. Starter grain (18% CP) was introduced d 14 at 113 g/calf, increased to 227 g/d d 21 and to 454 g/day d 34. Orts were not measured. There was no effect on gain during any period of the study. Data was analyzed using F-test for variances and student *t*-test comparing 2 means. Five fecal samples from scouring calves in both groups were analyzed for presence of rotavirus and coronavirus using real-time PCR assays. Strong positive was detected in 5/5 and 4/5 fecal samples for coronavirus and rotavirus respectively in both groups. Number of calves treated during peak scours (wk 2) was 33% and 37% for control and AB respectively. Total number of calves treated was 56% and 59% for control and AB respectively ($P \leq 0.74$). Total number of treatments week one were reduced 33% in AB ($P \leq 0.62$). Avg med $/calf was $2.53 control and $2.01 AB and AB cost $9+/calf. Both mortalities were not disease related. In conclusion, under conditions of this study AB had no effect on gain or morbidity despite presence of target pathogens and incidence of FPT exceeding 50%. Calves receiving AB may have been continually re-infected from neighboring calf not receiving AB, due to every-other-calf study design.

Table 1. Calf Performance

	Control	AB	P-value
Initial Wt, kg	46.4	46.5	≤0.87
21 d ADG, g	244	231	≤0.43
21–42 d ADG, g	685	675	≤0.69
42 d ADG, g	465	453	≤0.50
Mortality	2	0	

Key Words: calf, egg, antibody

W12 The effect of three commercial herbal extracts on broilers performance. Z. Teymourizadeh, S. Rahimi*, and M. A. Karimi Torshizi, *Tarbiat Modares University*, *Tehran, Tehran, Iran*.

An experiment was conducted to evaluate the effects of 3 herbal extracts and virginiamycin on performance, immune system, blood factors and intestinal selected bacterial populations in broiler chickens. A total of 4 hundred and 80 1-d old male broiler chicks were assigned to the basal diet (control); or basal diet supplemented with 15 ppm virginiamycin; 0.1% extracts of thyme (*Thymus vulgaris*), coneflower (*Echinacea purpurea*), garlic (*Allium sativum*); or a blend of extracts with the same dose(s). Broilers in the virginiamycin and coneflower treatment groups had the highest and lowest BW (2595g ± 56.20 vs. 2269g ± 48.2) and WG (2550.60g ± 45.7 vs. 2225g ± 36.4), respectively ($P < 0.05$). Lowest and highest FCR related to virginiamycin (1.71 ± 0.08, $P < 0.05$) and coneflower (1.86 ± 0.09, $P < 0.05$) respectively. There were no differences in carcass characteristics and fat pad, but small intestinal weight differed among treatments. Animals supplemented with virginiamycin had the lowest average small intestinal weight (2.29 ± 1.2), and control animals had the highest (2.84 ± 1.4) ($P < 0.05$). Relative weight of bursa Fabricius to body weight in the garlic group showed a significant increase compared with other groups, but relative weight of spleen to body weight was unaffected by treatments. Cutaneous basophil hypersensitivity response (to phytohemagglutinin injection) and antibody response to sheep red blood cells (SRBC) was higher in coneflower group ($P < 0.05$). Garlic (*Allium sativum*) significantly reduced the serum levels of cholesterol, LDL, and triglyceride and significantly increased the level of HDL. *E. coli* in ileo-cecal digesta of birds in the blend group was significantly lower compared with control group. However, there was no difference in *E. coli* counts between blend group and other treatment groups (this excludes the basal diet). Lactic acid bacterial counts were higher in the thyme group compared with the other groups except coneflower ($P < 0.05$).

Key Words: thyme, coneflower, garlic

W13 Omega-3 fatty acid enrichment of chicken meat by using fish oil. H. Saleh[1], S. Rahimi*[1], M. A. Karimi Torshizi[1], and A. Rahimi[2], [1]*Tarbiat Modares University*, *Tehran, Tehran, Iran*, [2]*Islamic Azad University*, *Tehran, Tehran, Iran*.

A 42-d study was conducted to evaluate the influence of fish oil inclusion on performance parameters, serum lipid content, antibody responses to sheep red blood cells (SRBC) antigen and meat fatty acid composition in broilers. Two hundred and sixteen 1-d-old broiler chicks from a commercial hybrid (Cobb 500) were randomly allocated to 4 groups comprising of 0.0, 1.5, 3.0 and 6% fish oil, according to a completely randomized design (CRD). The differences among the groups were significant regarding the performance, so that low level of fish oil (1.5%) were led to the higher feed intake and improvement of feed efficiency in comparison to control group ($P < 0.01$). The result of omega-3 fatty acid evaluation indicated significant differences among groups ($P < 0.01$) and the birds in 6% fish oil fed group had the highest level of n-3 fatty acid in meat. N-6/n-3 ratio of polyunsaturated fatty acids was lower in fish oil fed groups compared with the control group ($P < 0.01$). Broilers fed diets rich in omega-3 fatty acid had higher levels of anti-SRBC titer and lower levels of serum cholesterol and triglyceride than those fed control diet ($P < 0.05$). In conclusion, administration of 3% fish oil in broilers diet can improve the performance and immune response in these birds.

Key Words: performance, immune response, broiler meat

W14 Comparison the effect of commercial probiotics on performance and morphology of small intestine in broiler chicks. M. Soleimani[1], S. Rahimi*[1], M. A. Karimi Torshizi[1], and F. Niknafs[2], [1]*Tarbiat Modares University*, *Tehran, Tehran, Iran*, [2]*Zarbal Breeding Company*, *Amol, Mazandaran, Iran*.

Objective of this study was to compare the effects of different probiotics on performance and intestinal mucosa of broiler chickens. In this trial 480 d-old male broilers (Ross 308) were assigned as a completely randomized design to 6 experimental groups with 4 replicates with 20 birds per replicate as follows: control group (no feed additive in feed or water); 4 commercial probiotics and a lab-made probiotic. Body weight gain was significantly affected by monostrain, multispecies and yeast in finisher periods ($P < 0.05$). Multustrain, and lab-made probiotics significantly reduced FCR in starter period ($P < 0.05$). In all probiotic fed groups zigzag pattern of villi in ileum was more than control in d

21 of age ($P < 0.05$). In yeast, lab- made and monostrain groups ileum, villus length ($P < 0.01$) and apparent villus surface area were more than control and other probiotic groups ($P < 0.01$).The highest number of rows were observed in control group and the lowest number was in lab-made, and yeast group in duodenum in 35 d of age ($P < 0.05$). Crypt depth in jejunum was more in monostrain group in duodenum in 35 d of age. Tongue shaped villi in multispecies, lab-made, multistrain, yeast and monostrain groups were more than control group in 49 d of age. Leaf shaped villi in multispecies, multistrain, lab-made; yeast and monostrain groups were less than control group in d 49 ($P < 0.05$). Regardless of sampling age and site, lab-made group had the highest percent of tongue shaped villi and the lowest percent of leaf shaped villi ($P < 0.05$). Mortality rate, fecal moisture, blood hemoglobin concentration, serum cholesterol, relative weight of digestive organs, relative length of duodenum, jejunum, ileum, percent of convolute, bridge and finger shaped villi, villi length to crypt depth ratio, villi number per view field were not influenced by probiotics ($P > 0.05$).

Key Words: broiler, probiotic, performance

W15 Subjective assessment versus objective measurement of FAMACHA and hematocrits in sheep and goats fed herbs and ivermectin as dewormers under natural grazing conditions. H. A. Swartz*[1], C. Clifford-Rathert[1], A. N. Stewart[1], D. K. Sommerer[1], F. P. Wulff[1], K. Schmidt[1], and M. R. Ellersieck[2], [1]*Lincoln University*, *Jefferson City, MO*, [2]*University of Missouri*, *Columbia*.

Paramount in sheep and goats in hot summer months are internal parasite losses. The objective of this study was to determine the validity of applying a color chart, FAMACHA, (FAM) a subjective measurement (S) to hematocrits (HEM), an objective measurement (O) looking at the effects of *Haemonchus contortus*, that kills many sheep and goats from anemia. This trial compared ivermectin, a commercial dewormer, commercial herbs, herbal plants fed and a control groups receiving no treatment. Fecal egg counts (FEC) were measured in each collection period. The study was conducted in May, June, July, August, September and October 2009 with collection every 4 weeks. There were 4 treatment groups: 1) control, 2) ivermectin, 3) greenhouse *Artemisia absinthium* and (4) a commercial herbal dewormer. The control groups received no treatment, the ivermectin groups were treated monthly and the herbal groups were fed the herbs weekly. The McMaster FEC was used over the 6 mo period. The FAM subjective assessment ranged from 1 to 5 examining the ocular conjunctiva eyelid. The score of 1) bright red, 2) less red, 3) pink, 4) pale pink and 5) white indicating high to low HEM. Measurement of FAM, HEM and FEC were collected in Dorset (D) (n = 39), Katahdin (K) (n = 40) and Boer (B), (n = 41) divided into the 4 groups. Correlations coefficients over the 6 mo period used the Pearson correlation in statistics for S and O: 1) FAM-1 vs. HEM-1, r = −0.33 ($P \leq 0.01$), FAM-2 vs. HEM-2, r = −0.224 ($P \leq 0.01$), FAM-3 vs. HEM-3, R = .-.33 ($P \leq 0.0003$), FAM-4 vs. HEM-4, r = −0.36 ($P \leq 0.0001$), FAM −5 vs. HEM-5 r = . < 0.37 ($P \leq 0.0001$), FAM-6 vs. HEM-6, r = −0.53 ($P \leq 0.0001$). These results were analyzed using the Pearson correlation coefficient. The McMaster FEC showed differences within breeds and months using the SAS Proc MIXED statistical procedure on the FEM, HEM and FEC. All treatments differed within breeds and months from May to October and were highly significant at the $P \leq 0.000$l. In this study, herbs and ivermectin were effective in controlling internal parasites in K, D and B.

Key Words: FAMACHA, hematocrits, sheep and goats

W16 Effects of short-term tocopherol (T) feeding on nitric oxide production and protein nitration following endotoxin (LPS) challenge in beef calves. S. Kahl*[1], T. Elsasser[1], J. Shaffer[1], C. Li[1], K. Lebold[2], M. Traber[2], and S. Block[3], [1]*USDA, Agricultural Research Service*, *Beltsville, MD*, [2]*Oregon State University*, *Corvallis,* [3]*Archer Daniels Midland (ADM), Inc.*, *Decatur, IL*.

Posttranslational protein tyrosine nitration (pTN) contributes to functional tissue damage during pro-inflammatory stress. With regard to chemical reactivity, α-T has a greater antioxidant potential while γ-T has greater ability to inactivate reactive oxynitrogen species potentially involved in pTN formation. Our objective was to determine the effects of 5-d feeding of supplemental α-T (*A*, Novatol 1490, ADM; T content (%): α = 98.2, γ < 1) or γ-T (*G*, Decanox MTS-90 G, ADM; T content (%): α = 10, γ = 69) on the generation of key biomarkers of pTN during pro-inflammatory episodes initiated with LPS (0.25 μg/kg BW, i.v., *E. coli* 055:B5). Beef calves (n = 21; 211 ± 6 kg) were group penned in equal numbers across 3 test diet assignments: control (*C*, no supplement), *A*, or *G*. A growth diet was fed daily in all pens at 90% mean group ad libitum intake and top-dressed with a premix containing the treatments (daily intake/calf: Novatol = 1.25 g; Decanox = 3.85 g). Blood samples were obtained at 0, 7, and 24 h, and liver biopsy samples at −24 and 24 h relative to LPS injection. At LPS challenge, liver [γ-T] was: $G > C$ or A ($P < 0.01$) while [α-T] was: $A > G > C$ ($P < 0.01$). In all calves mean plasma concentrations of xanthine oxidase (XO, a superoxide anion producer, $P < 0.05$) and nitrate+nitrite (NO_x, an estimate of NO production, $P < 0.01$) increased after LPS. For XO no differences were observed between treatments but the increase in NO_x was attenuated in both *A* (45.7%) and *G* (46.3%) as compared with *C* ($P < 0.05$). The generation of pTN (measured by quantitative immunohistochemical localization of nitrotyrosine pixel density) 24 h after LPS was lower in *A* (24.4%) and *G* (27.4%) than in *C* ($P < 0.01$). Results indicate that a 5-d feeding of vitamin E isoforms differentially affects the generation of mediators of pTN but both significantly decrease overall pTN.

Key Words: cattle, endotoxin, vitamin E

W17 Interactive effects of active *Saccharomyces cerevisiae* and its cell wall material on intestinal microbial ecology during the receiving period of stressed beef cattle. C. T. Collier[1], J. A. Carroll*[1], J. R. Corley[2], A. G. Estefan[2], D. N. Finck[3], and B. J. Johnson[3], [1]*ARS-USDA*, *Lubbock, TX,* [2]*Lesaffre Feed Additives*, *Milwaukee, WI,* [3]*Texas Tech University*, *Lubbock*.

The effects of active *Saccharomyces cerevisiae* (SC) addition and/or its cell wall (CW) on hindgut microbial ecology were evaluated in receiving beef cattle (203+1.45 kg). Cattle were assigned to 1 of 4 treatment groups; with SC (n = 5); with CW (n = 4); with SC and CW (n = 6) and without (control; n = 5). The cattle were fitted with indwelling jugular catheters after 38d on feed. At 39d, *E. coli*-derived lipopolysaccharide (0.25 μg/kg BW) was administered via jugular catheter. After 24h, fecal samples were collected from the rectal probes inserted ~27 cm. Nucleic acids were isolated from the fecal samples then PCR amplified using 16S-V3-specific primers. Denaturant gradient gel electrophoresis was used to separate the resultant unique bacterial amplicons. Band numbers (bacterial species) were counted and banding patterns analyzed via Sorenson's pairwise similarity coefficients (C(S)); an index measuring common bacterial species between samples. Band numbers (23.5+1.3 vs. 29.6+0.8, respectively) and band intensity were greatest ($P < 0.05$) in SC-treated cattle when compared with CW-treated cattle suggesting a more species- and numerically-dense microbial profile. Intra-treatment band number variations were greatest ($P < 0.05$) in control (+3.6 bands) and SC/CW-treated (+5.5 bands) cattle when compared with

SC- (+1.6 bands) and CW-treated (+2.5 bands) cattle. Intra-treatment C(S) values were high, ranging between SC/CW (68.3+1.2) and SC (75.6+0.8). Inter-treatment C(S) comparison values were lower ($P < 0.05$) than intra-group values. Cumulatively, the C(S) values indicate homogenous microbial profiles within treatments that were unique from each other treatment. These results suggest that potential performance and immunological modulation of SC- and CW-treated cattle may partially be the result of modifying the intestinal microbial ecology. As the dynamic nature of the hindgut microbiota is typically resistant to protracted treatment-induced alterations, the sustained altered microbial profile observed here indicates that supplementation may select for a beneficial persistent microbiota.

Key Words: cattle, 16S-V3, ecology

W18 Effects of ochratoxin A on performance of broilers and the efficacy of a mycotoxin detoxifying product. U. Hofstetter*[1], R. Borutova[1], V. Starkl[1], I. Rodrigues[1], and C. W. Kang[2], [1]*Biomin Holding GmbH*, *Herzogenburg, Austria*, [2]*Animal Resources Research Center, College of Animal Bioscience and Technology, Konkuk University*, *Seoul, Korea*.

Aim of the study was to investigate the effects of various levels of ochratoxin A (OTA) on broilers and to evaluate the effect of a mycotoxin deactivator. 200 d-old male broiler chicken were divided into 20 groups and fed 5 different diets for 5 weeks. Group 1: control (OTA free); group 2: 1mg/kg OTA; group 3: 1mg/kg OTA with 0.2% mycotoxin deactivator ; group 4: 2mg/kg OTA; group 5: 2mg/kg OTA with 0.2% mycotoxin deactivator. The statistic method used was General Linear Model (SAS, 2002) for dispersion analysis and when there were statistically significant differences Duncan's multiple range test was used. As dietary OTA increased, feed intake and weight gain significantly ($P < 0.05$) decreased. The relative weights of liver and kidneys and the activities of glutamic-oxaloacetic transaminase and glutamic-pyruvic transaminase in the groups fed diets containing OTA alone were significantly higher ($P < 0.05$) compared with the control group. The level of total serum cholesterol was significantly reduced ($P < 0.05$) by feeding OTA contaminated diets. As dietary OTA increased, the levels of OTA in liver and kidney tissue were significantly increased ($P < 0.05$). The presence of a mycotoxin deactivating product in contaminated diets significantly decreased ($P < 0.05$) the OTA accumulation in organs. Moreover the fecal excretion of OTA and the metabolite OTα were significantly increased ($P < 0.05$) by feeding the mycotoxin deactivator. This increase of fecal excretion of OTA was attributed to the bentonite which is one component of the feed additive whereas the increase of fecal excretion of OTα was attributed to the yeast strain *T. mycotoxinivorans*, which is able to biotransform OTA into this non-toxic metabolite. In conclusion, these results indicated the harmful effects of dietary OTA on broiler performance. Adversary changes of physiological responses were observed in broilers. Feeding a mycotoxin deactivating feed additive ameliorated the OTA organ accumulation and OTA-induced performance reduction. Moreover levels of OTA in liver and kidney were found to be a better biomarker of intoxication than OTA in blood.

Key Words: ochratoxin A, broilers

W19 Effects of short-term tocopherol (T) feeding on structure-localized protein tyrosine nitration (pTN) patterns of mitochondrial ATPase following endotoxin (LPS) challenge in beef calves. T. Elsasser*[1], S. Kahl[1], J. Shaffer[1], R. Castellano-Perez[1], C. Li[1], and S. Block[2], [1]*USDA, Agricultural Research Service*, *Beltsville, MD*, [2]*Archer Daniels Midland (ADM), Inc.*, *Decatur, IL*.

Mitochondrial ATPase/Complex-V (MCV) is an electron transport chain (ETC) component needed for ATP synthesis. The ETC, exquisitely sensitive to proinflammatory mediators (PIM), generates oxynitrogen reactants leading to pTN formation as mitochondrial membrane leakage occurs. Immunohistochemical localization (IHC-L) of pTN (a biomarker of pTN damage to proteins) in liver following LPS suggests that pTN responses to PIM are not uniform across liver structures. Furthermore, because of their respective oxynitrogen reactivities, α-T and γ-T may differentially affect pTN formation in cells. Our objective was to determine the effects of 5-d feeding of supplemental α-T (*A*, Novatol 1490, ADM; T content (%): α = 98.2, γ < 1) or γ-T (*G*, Decanox MTS-90 G, ADM; T content (%): α = 10, γ = 69) on the nitration of MCV in central venous (CV), portal triad (PT), and hepatocyte/paranchymal (HP) areas of the liver after LPS challenge (0.25 μg/kg BW, i.v.). Beef calves (n = 21; 211 ± 6 kg) were penned and fed in equal numbers one of 3 test diets: control (*C*, no supplement), *A* (Novatol = 1.25 g/calf/d), or *G* (Decanox = 3.85 g/calf/d). Liver biopsy samples were obtained at −24 and +24 h relative to LPS injection. The MCV was measured by quantitative IHC-L and MCV nitration analyzed by proximity ligation assay (PLA, Olink Biosciences, Sweden). After LPS, MCV staining increased 4-, 3.4-, and 2-fold (vs. pre-LPS) in *C*, *A*, and *G*, respectively ($P < 0.05$, effect of T). By structure, MCV intensities (pixels/cell) were: HP < PT < CV ($P < 0.05$). With CV as the target structure, PLA demonstrated a 5-fold increase ($P < 0.05$) in colocalized pTN signals associated with MCV after LPS with decreasing ($P < 0.05$) nitration of MCV in samples where $G < A < C$. The data are consistent with MCV as a target for nitration after LPS and a protective effect of T against this nitration.

Key Words: endotoxin, mitochondria, vitamin E

W20 Reserpine-induced changes of the small intestinal histology and the expression of genes relative to mucosal immunity in rat. X. Zhu*[1], K. Guo[2], F. Liu[2,3], J. Yu[2], A. Lu[2], N. Zhang[1], G. Cheng[2,3], P. Yin[1], N. Wang[2], and J. Xu[1], [1]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine, China Agricultural University*, *Beijing, China*, [2]*Department of Animal Science and Technology, Beijing University of Agriculture*, *Beijing, China*, [3]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*.

Clinical and experimental evidence indicates that damage to the intestinal surface structure can significantly impair intestinal epithelial integrity, as well as the stability of the mucosal immune system. The aim of this study was to investigate the changes of the small intestinal surface structure and the gene expression profile caused by reserpine treatment. Rats were randomly divided into two groups: the control groups (C) and the reserpine treated group (Res), 6 rats each group. The control rats and the Res rats were administered with Salt solution 0.9% and reserpine subcutaneously 0.5 mg/kg respectively for 7 days. At the end of the experimental period, the duodenum, jejunum and ileum were sampled for morphology structure examination and microarray analyses. Structural changes of the mucosa in Res included atrophy of villi and reduction in crypt size, indicating significant injury to the small intestinal mucosa. DNA microarrays were employed to examine the gene expression profile in the jejunum of Res versus C. According to the GeneSpring GX 10.0 analysis, twelve genes (Log2Ratio < −1.0) related to mucosal immunity were down-regulated and confirmed by real-time PCR. Genetic network of toll-like receptor 2 (Tlr2), toll-like receptor 4 (Tlr4), complement component 3 (C3), myxovirus (influenza virus) resistance 1 (Mx1) and myxovirus (influenza virus) resistance 2 (Mx2) was performed by GeneSpring GX 10.0 software. Results showed that genes associated with TLR2, TLR4 by a variety of mechanisms. The

lower levels of TLR2 protein in the jejunum of Res were in concert with previous findings that the mRNA levels of TLR2 were significantly lower in the Res. Immunohistochemistry results suggested that most TLR2 deposited from the epithelial cells of the rats jejunum brush border and submucosa. Rats treated with reserpine can induce down-regulation in gene expression relative to the innate mucosal immunity of the small intestine, as well as the TLR2 protein expression.

Key Words: reserpine, gene expression, small intestinal mucosa

W21 Gastrointestinal motility and gastrointestinal hormones VIP and GAS expression in reserpine-induced FGID rats. G. Jingyi[1], Z. Xiaoyu[1], C. Fei[1], C. Guilin[2,3], L. Fenghua[2,3], and X. Jianqin*[1], [1]*China Agricultural University China Agricultural University*, *Beijing, China*, [2]*Beijing University of Agriculture*, *Beijing, China*, [3]*CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*.

The purpose of this study was to investigate effects of reserpine-induced rat functional gastrointestinal disorders (FGID) on the gastrointestinal motility, gastrointestinal hormones VIP and GAS expression. The rats were randomly assigned to 2 groups: Reserpine-treated group (RG) and Control group (CG), 12 rats each group. RG was intraperitoneally injected with reserpine 0.5 mL/kg; and CG with normal saline 0.5 mL/kg, once daily for 7 consecutive days separately. Six rats were chosen randomly from each group. Gastric emptying rate and intestinal propulsive ratio were detected by administration trophism semisolid. Collect serum and detect for the Amylase (AMS) and Lipase (LPS) activities were determined by kit manuals. Total RNA was isolated from stomach and small intestine using Trizol reagent. RT-PCR detected VIP and GAS mRNA expression. VIP and GAS protein contents were assayed by ELISA with according to the kit instructions. The surplus 6 rats of each group were determined gastric myoelectrical activity with Pclab-UE Systems. The statistic analysis were performed using ANOVA of SPSS 12.0. The results showed: compared with the control groups, serum amylase activity had significantly decreased ($P < 0.05$), while the lipase activity obviously increased ($P < 0.05$); gastric emptying rate was highly significantly lower ($P < 0.01$), and the intestinal propulsion ratio had improvement significantly ($P < 0.01$); both of the frequencies and amplitudes of gastric electrical ware had decreased obviously ($P < 0.05$). VIP mRNA expression in the reserpine-treated groups was significantly lower in the duodenum and jejunum ($P < 0.05$). GAS mRNA expression had improvement significantly in the stomach and ileum, and obviously decreased in the duodenum and jejunum ($P < 0.01$). VIP sharply decreased and GAS increased significant degree in the stomach ($P < 0.05$). The conclusion is, enzyme activities of serum and gastrointestinal motility were disordered as reserpine induced rat FGID. The stomach is a sensitive part of GI hormones VIP and GAS. The abnormal expression of GAS is one of the important factors.

Key Words: reserpine, gastrointestinal motility, GI hormones

W22 Effects of medicinal plants on broilers performance, organs weight, small intestine morphology and GIT microflora. A. Niknam, S. Rahimi*, J. Azimi, M. Hoseinzadeh, M. Moradi Nejad, and K. Seifi, *Tarbiat Modares University*, *Tehran, Iran*.

The objective of this study was to compare the effects of medicinal plants on some broilers characteristics. A total of 420, d-old male broilers (Arbor Acres) were randomly allocated into 7 groups with 5 replicates in a completely randomized design. The treatments were control, dry peppermint (*Mentha piperita*) (15kg/ton), thyme (*Thymus vulgaris*) (15kg/ton), basil (*Ocimum basilicum*) (15kg/ton) or garlic (*Allium sativum*) (15kg/ton), Virginiamycin (150g/ton) and Primalac (1kg/ton). On 42 d of experiment 15 birds from each group were sacrificed. The garlic increased ($P < 0.05$) body weight (BW) and feed conversion ratio (FCR) during d 0 to 28. There were no significant differences between groups in BW and FCR from d 28 to 42, total FCR and relative weights of gizzard, liver, neck and back muscle. However, the relative weight of the breast muscle and thigh were increased for peppermint and garlic-fed broilers, respectively ($P < 0.05$). Birds in the thyme and basil groups had highest villus height (VH) in duodenum and ileum, respectively ($P < 0.05$). Also, peppermint diet significantly increased duodenal absolute and relative length, and ileal villus width (VW), crypt depth and relative weight ($P < 0.05$). The only change found in the jejunum was an increase in the VW in birds given Primalac. Villus height to crypt depth ratio only increased at the ileum for virginiamycin-fed broilers ($P < 0.05$). Crop contents of garlic and peppermint treatments had highest and lowest number of lactobacillus (5.88 vs. 3.68 Log10 cfu/g), respectively ($P < 0.05$). There was no significant difference in coliforms number in crop, while highest number of total aerobic bacteria observed for control treatment (5.69 Log10 cfu/g), respectively ($P < 0.05$). Supplementation of diet with garlic increased number of lactobacillus in ileum (8.76 Log10 cfu/g) compare with other groups ($P < 0.05$), and Primalac increased both coliforms and total aerobic bacteria in ileum higher than other treatments ($P < 0.05$). In present study, effectiveness of medicinal plants in broiler performance demonstrates their use a potential alternative for antibiotic as growth promoters.

Key Words: medicinal plants, broiler performance, GIT microflora

W23 Identification of small heat shock proteins in the bovine genome. S. Schepis and M. Worku*, *North Carolina Agricultural & Technical State University*, *Greensboro*.

Protein-damaging stresses, including heat shock, cold, altered pH and oxygen deprivation induce the expression of a subgroup of molecular chaperones, called heat shock proteins (Hsp), which consist of several protein families designated by their molecular weight, such as the Hsp90, Hsp70, Hsp60, and the small Hsp (sHsp) families. Small heat shock proteins (sHsp) with a molecular mass of 15–30 kDa are ubiquitous and conserved. This large family of proteins is present within the prokaryotic and eukaryotic cell as large oligomeric complexes, ranging in size from 200 to 800 kDa. Unlike the high molecular weight Hsp, which are involved in protein folding in vivo, under normal conditions, sHsp play an important role in protecting organism from stress. The sHsp share an evolutionarily conserved sequence of 80–100 amino acids, located in the C-terminal region, and called "alpha-crystallin domain." Ten active genes for sHsp have been identified in the human genome. This project focused on 10 α-crystallin related Hsps belonging to the sHsp molecular chaperone family: HspB1- HspB10. It is anticipated that the recently completed annotated sequence of the cattle genome will lead to identification of genes for disease resistance and higher quality meat. The purpose of this project was to determine if genes coding for human sHsp are found in the bovine genome, and if so, how highly the sequences were conserved across the 2 species. The NCBI search engine, BLAST, and CLUSTALW on Biology Workbench were used. Homologs of 10 α-crystallin human small heat shock protein (sHsp) molecular chaperone family (HspB1- HspB10) were found within the bovine genome and single nucleotide differences identified in silico. The sequence for human sHspB9 expressed exclusively in the testis and cancerous tissue did not identify related sequences in the bovine.

Key Words: heat shock protein, bovine, human

W24 Use of partial least-square regression to predict SNP when some animals are genotyped with low density marker panels. C. Dimauro*, G. Gaspa, R. Steri, S. Sorbolini, E. Pintus, and N. P. P. Macciotta, *University of Sassari*, *Sassari, Italy*.

Genome wide selection exploits information from dense marker platforms (usually 50K-60K) to predict genomic breeding values (GEBV) for livestock. However, costs of analysis are expensive for high density marker (HDM) platforms, allowing the genotyping of only a few thousand animals. A decrease in costs could be reached by using low density marker (LDM) chips, but, in this case, a unavoidable reduction in GEBV accuracy is expected. An alternative could be the use of both reference (REF) and prediction (PRED) populations of animals genotyped with HDM and LDM chips, respectively. Missing genotypes in the PRED population could be reconstructed using a suitable mathematical model which exploits information from REF population. In this work the partial least square regression (PLSR) is used at this purpose. A data set, generated for the XII QTLs-MAS workshop, which simulated a genome with 6 chromosomes and 6,000 equally spaced biallelic SNP for 5,865 animals, was used. It was split into 2 data sets, the REF with 4,665 animals and 6,000 SNP and the PRED with 1,200 individuals and 3,000 SNP. The PLSR, applied separately for each chromosome, was used to predict the 3,000 missing SNP in the PRED population. Different scenarios of missing SNP sampling in PRED and decreasing size of REF population were tested. Goodness of prediction was evaluated by calculating correlations between actual and predicted data. Best results were obtained when unknown SNP were chosen evenly spaced along the chromosome and all 5,865 individuals in the REF population were used. In this case, the mean correlation between actual and predicted data was 97%. As the size of REF population decreased to 2,000 individuals, the mean correlation reached a value of 94%. Therefore, if an adequately large REF population is used, the PLSR technique is able to predict with high accuracy the missing SNP in other animals genotyped with a LDM platform. This research was funded by FAR 2008.

Key Words: PLSR, SNP

W25 Multiple trait genetic evaluation of linear type traits using genomic and phenotypic information in US Holsteins. S. Tsuruta*[1], I. Aguilar[1,2], I. Misztal[1], A. Legarra[3], and T. J. Lawlor[4], [1]*University of Georgia*, *Athens*, [2]*INIA*, *Las Brujas, Uruguay*, [3]*INRA*, *Castanet-Tolosan, France*, [4]*Holstein Association USA Inc.*, *Brattleboro, VT*.

Genetic evaluation was conducted for linear type traits using combined genomic and phenotypic data in US Holsteins. Single nucleotide polymorphism (SNP) markers from the Illumina BovineSNP50 genotyping Beadchip, consisting of 38,416 SNP on 30 chromosomes, were used available for 6,931 bulls. A unified approach proposed by Aguilar et al. (2010) was used to estimate genomic evaluations with single trait (ST) and multiple trait (MT) models. Three analyses of 5 linear type traits (stature, strength, body depth, dairy form, and rump angle with heritabilities 0.45, 0.27, 0.34, 0.30, and 0.34) were conducted, utilizing 8,865,120 records in 2009 and 7,715,925 records in 2004. The EBV were calculated using 2009 and 2004 data sets with phenotypes (traditional genetic evaluation) and a 2004 data set with phenotypes and genotypes (unified approach). Coefficients of determination (R^2) and regressions on 2004 genomic EBV were calculated for 1,307 young bulls with at least 50 daughters in 2009 using daughter deviations from 2009 MT traditional evaluations. The EBV for 2004 traditional evaluation were parent average (PA). The R^2 from regressing daughter deviations on ST PA, MT PA, ST genomic, and MT genomic predictions were 0.34, 0.34, 0.54, and 0.54, respectively, for stature. Corresponding R^2 for strength were 0.25, 0.29, 0.40, and 0.44, respectively. In general, R^2 for ST and MT genomic models were 13-19% and 14-18% higher, respectively, than those of PA (28-42%). The regressions with MT were slightly (0.01-0.02) higher than those with ST, indicating less bias. The genomic evaluation by MT is more accurate for selected traits than by ST. The improvement in accuracy from ST to MT in genomic predictions follows a similar improvement in PA. Preliminary results show that, with a small modification in the unified approach, bias can be essentially eliminated at the cost of a small reduction in R^2.

Key Words: genomic selection, linear type traits, US Holsteins

W26 Genotype by environment interaction: Effects of nutritional management on production traits. M. W. Dekleva*[1], C. D. Dechow[1], J. M. Daubert[1], S. Bauck[2], J. W. Blum[3], and G. A. Varga[1], [1]*The Pennsylvania State University*, *State College*, [2]*IGENITY Livestock Production Business Unit*, *Duluth, Georgia*, [3]*University of Bern*, *Switzerland*.

The objective of this study was to determine the effect of nutritional management factors on the level of genetic expression for milk, fat, and protein yield. Intakes of dry matter, crude protein and net energy of lactation (NE_L) in addition to 305 d yield were available for 970 cows from 11 tie-stall herds in Pennsylvania. All herds were visited monthly

to measure 24-h intake. Feed samples were collected on each visit and analyzed for dry matter percentage, crude protein percentage and NE_L (MCal/kg) content. Sire PTA for yield was available for all 970 cows, while 881 cows were genotyped and received an Igenity Profile Score (IS) for milk, fat, and protein where 1 corresponds to the lowest, and 10 corresponds to the highest genetic potential for yield. Multiple regression models were fit for 305 d milk, fat and protein yield. Fixed effects were herd averages for kg of dry matter refusals (DMR), ration crude protein percentage (CP), NE_L and the interactions of these herd averages with PTA or IS, herd-year-season, and lactation. Permanent environment was included as a random effect. For daughters of bulls that differed in PTA for milk by 500 kg, there was a 151.5 kg difference in milk yield at the tenth percentile for DMR compared with a 584.8 kg difference for cows at the ninetieth. A difference of 25 kg for sire PTA fat corresponded to a difference of 17.9 kg of fat yield for herds in the tenth percentile for CP and 51.5 kg for herds in the ninetieth. A change of one unit in Igenity Score corresponded to a difference of 1.87 kg of fat yield for cows at the tenth percentile for NE_L., compared with a 6.91 kg difference for cows at the ninetieth percentile. The results indicate that response to selection was reduced in herds that did not provide cows with adequate intakes of dry matter, crude protein and NE_L.

Key Words: genotype, environment, production

W27 Evaluation of the effect of inbreeding on age at first calving in Holstein cattle. J. Bezdicek* and J. Riha, *Agrovyzkum Rapotin s.r.o.*, *Rapotin, Czech Republic*.

The objective of this study was to examine the effect of inbreeding depression on age at first calving (d) in Holstein cows. The databases included cows (173,000) that calved in the years 1995–2006 at farms in the Czech Republic. Inbred cows were matched with their outbred contemporaries (n = 811) based on sire, farm of first calving, year and period of calving (±2 mo), and dam's breeding value for milk production (±5%). Inbred cows and their matched outbred contemporaries were subsequently divided according to inbreeding coefficients of the inbred cows (F_x = 1.25%; F_x = 12.5%; F_x = 25%, and other). The data were analyzed with StatSoft Inc. Statistica 8 using descriptive statistics and paired *t*-tests. The GLM procedure of SAS Inc. was used to analyze the effects of inbreeding depression. Age at first calving increased when the level of inbreeding increased. Within the observed groups (F_x = 1.25%; F_x = 12.5%; F_x = 25.0% and all animals), the average age at first calving for inbred cows (for their outbred contemporaries) was 820 (818); 835 (822); 844 (822) and 832 (820) d. In the groups F_x = 25% and other, differencies between inbred and outbred cows were highly significant ($P < 0.001$). There was also greater variability for groups of inbred cows (s_x = 83.2 d) compared with groups of outbred contemporaries (s_x = 63.4 d). Inbred cows also had significantly ($P < 0.01$) lower breeding values for milk (20.8 kg) than in outbred contemporaries (63.6 kg). Overall, this study confirmed an increase in age at first calving in inbred cows compared with their outbred cohorts.

Key Words: age at first calving, inbreeding, Holstein

W28 Age at first calving in Holstein cattle in the United States. J. Cole and D. Null*, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

Heifer rearing costs account for 15 to 20% of the total expense of milk production, and the decline in fertility of US Holsteins is well documented. Earlier age at first calving (AFC) may improve profitability and fertility. Records for 400,000 U.S Holstein cows born on or after January 1, 1997 were selected by random sampling of herd codes and used to estimate (co)variance components and breeding values. Phenotypic AFC averaged 788 ± 89 d, and ranged from 540 to 1095 d. The model included random animal and residual effects, and a fixed herd-year-season (HYS) of birth effect. Herd-year-season of birth was included to avoid confounding between sires and period-of-birth, and groups were required to include at least 10 observations. The 4 seasons were defined as: December to February, March to May, June to August, and September to November. Heritability averaged 0.027 ± 0.003 across the 6 data sets, which is lower than some literature estimates, and consistent with earlier, unpublished studies on US Holsteins. Predicted transmitting abilities for AFC of active bulls ranged from −13 to +14 d, and averaged −1.9 ± 3.6. Correlations were calculated among sire PTA for bulls with reliabilities of lifetime net merit (NM$) of at least 90%. Age at first calving had favorable (negative) correlations with milk (−0.22), fat (−0.18), and protein yield (−0.23), SCS (−0.05), productive life (−0.01), NM;(−0.18), heifer conception rate (HCR; −0.18), and persistency of milk (−0.12), fat (−0.13), and SCS (−0.02). Unfavorable (positive) correlations were found with cow conception rate (0.04) and protein persistency (0.04). Daughter pregnancy rate (DPR) was uncorrelated with AFC (0.001; $P > 0.05$). Excessive AFC has a negative effect on yield and lifetime profitability, which is reflected in these correlations. Genetic trend was estimated by regression of sire PTA for AFC on birth year, and was slightly negative, decreasing by −0.09 d per year ($P < 0.01$). Routine genetic evaluation of AFC is desirable because it provides dairy producers with an additional tool for managing reproduction in their herds.

Key Words: age at first calving, fertility, genetic evaluation

W29 Relationship of reason for lactation termination with genetic merit of Holsteins in the United States. H. D. Norman, J. R. Wright, and S. M. Hubbard*, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.

Reasons that producers report to 4 dairy records processing centers for why individual cows exit the herd (lactation termination codes) were examined for 6.2 million US Holsteins with lactation records that ended in 2007 and 2008 to determine their relationship to genetic merit. The most frequent termination reasons were lactation ended normally and cow stayed in the herd (68%), cow died (5%), and cow was sold for low production (4%), reproductive problems (4%), or mastitis (4%) or for dairy purposes (3%); 9% of lactations had no reason specified. For cows with normally ended lactations, mean predicted transmitting ability (PTA) and standard deviations (SD) were 135 ± 271 kg for milk, 5 ± 10 kg for fat, 4 ± 8 kg for protein, 2.95 ± 0.38 for somatic cell score (SCS), 0.8 ± 1.4 mo for productive life (PL), 0.1 ± 0.9% for daughter pregnancy rate (DPR), and net merit (NM) was $115 ± 132; corresponding means and SD for parent averages (PA) were 117 ± 219 kg milk, 4 ± 8 kg fat, 4 ± 6 kg protein, 2.95 ± 0.37 SCS, 0.6 ± 1.3 mo PL, 0.1 ± 0.9% DPR, and $98 ± 111 NM. Mean PTA and PA for all yield traits and PL as well as NM generally were lower for cows that did not end their lactations normally; lowest means were 18 kg for PTA milk, 1 kg for PTA fat, 1 kg for PTA protein, 0.2 mo for PTA PL, $37 for NM, 74 kg PA milk, 3 kg PA fat, 2 kg PA protein, 0.3 mo for PA PL, and $62 for NM for cows sold for low production and –0.2% for PTA DPR and –0.1% for PA DPR for cows sold for reproductive problems. Cows that aborted had the highest mean PTA for all yield traits (159 kg for milk, 5 kg for fat, and 5 kg for protein) and PA milk (125 kg). For SCS, PTA and PA were highest for cows with normally ended lactations and lowest (2.80 for PTA SCS and 2.81 for PA SCS) for cows that died; cows sold because of mastitis had mean PTA SCS of 2.91 and mean PA SCS of 2.90. Across termination categories, SD were similar for each

trait except SCS. In general, cows with lactations that ended normally were genetically superior for all traits except SCS.

Key Words: lactation termination, genetic merit, Holstein

W30 Comparison of Holstein service-sire fertility for heifer and cow breedings with conventional and sexed semen. H. D. Norman*, J. L. Hutchison, and P. M. VanRaden, *Animal Improvement Programs Laboratory, ARS, USDA*, *Beltsville, MD*.
