Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $708 for print. For institutions in all other countries (prices include airspeed delivery): $798 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $50 for paper copy in US, and additional $75 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: To advertise a position announcement in the News and Announcements section of the journal, please use the FASS Job Resource Center (http://www.fass.org/job.asp); e-mail jrc@assochq.org if you have questions.

For display advertising orders and inquiries please contact Danny Wang at 212.633.3158 or by e-mail at d.wang@elsevier.com. For non-recruitment classified advertising orders and inquiries please contact John Marmero at 212.633.3657 or by e-mail at j.marmero@elsevier.com. Both representatives are located at Elsevier Inc., 360 Park Avenue South, New York, NY 10010. Fax number is 212.633.3820.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact journals@assochq.org.

Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail jeremyh@assochq.org; fax 217.378.4083.

Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.462.1935; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Poultry Science® (ISSN 0032-5791) is the official publication of the Poultry Science Association, Inc., and is published 12 times per year (monthly) for the purpose of advancing the scientific study of poultry. Periodicals postage paid at Champaign, IL, and at additional mailing offices. POSTMASTER: Send address changes to the Poultry Science Association, Inc., 2441 Village Green Place, Champaign, IL 61822.

Manuscripts for publication Editorial requirements for the submission of manuscripts appear on the inside back cover of this journal. Complete instructions are posted online (http://ps.fass.org/misc/ifora.dtl). Authors will be charged $100 (professional members) or $170 (nonmembers) per printed page or fraction thereof to partially cover the costs of publication of *Poultry Science*.

Subscription rate $500 electronic only or $575 (electronic + print) annually in advance for US, outside the US $500 (electronic only) or $607 (electronic + print); single copies are $50. The PSA membership fee for individuals is $120 and includes an electronic-only version of the journal; $80 additional for a paper copy. All inquiries about membership and subscriptions should be sent to the Poultry Science Association, Inc. business office.

Claims for copies lost in the mail or defective copies must be received within 60 days (120 days international) of the date of issue to ensure free replacement. Claims are to be made to the Poultry Science Association, Inc., 2441 Village Green Place, Champaign, IL 61822.

Application for membership in the American Society of Animal Science is invited from persons with interest in animal science and livestock production. In 2010, annual dues including access to the electronic version of the *Journal of Animal Science* are $135 in U.S.A., Canada, and Mexico and in other countries. For those in the U.S.A., Canada, or Mexico who wish to receive a paper copy of the journal, the additional fee is $75; for those in other countries, the additional fee is $100. Student Affiliate Membership is granted to those who are certified by a professional member as a regularly enrolled college student who does not hold a full-time position at the time of application for, or annual renewal of, membership. Graduate student memberships ($20 annually) and undergraduate student memberships (free) include access to the electronic version of the *Journal of Animal Science*. Postdoctoral fellows' membership dues are $65. An Institutional subscription ($500 annually) entitles an institution internet access to *e-JAS* within appropriate IP addresses. For an additional $75 fee institutions within the US, Canada, and Mexico will receive a paper copy of the journal (an additional $100 fee for all other countries). For corporate subscriptions, please contact the ASAS office for pricing. Individual sustaining membership, $375 per year. Applications for membership with remittance should be mailed to the ASAS Business Office.

Late-Breaking Original Research

LB1 Identifying new biomarkers in liver for monitoring physiological imbalance and the response to feed restriction for cows during early lactation. K. L. Ingvartsen, E. Bendixen, M. C. Codrea, and K. M. Moyes*, *Aarhus University*, *Tjele, Denmark*.

The aim of this study was to identify new biomarkers in liver for monitoring physiological imbalance and to examine the different coping strategies used during feed restriction (FR) between cows in physiological imbalance and cows metabolically "normal" during early lactation. Twenty-two cows (22–55 DIM) were fed a standard TMR for ad libitum intake. After 5-d, all cows were FR to provide ~40% of NE_L requirements based on body weight, milk production and composition by supplementing the standard TMR with 60% wheat straw. After 4-d of FR, cows returned to full feed. Liver biopsies were collected −1 and 3 d relative to FR. Prior to FR, an index of degree of imbalance was calculated for all cows based on plasma fatty acid, ketone, and glucose concentration. A subset of 6 cows classified as having either the greatest (n = 3) or least (n = 3) degree of imbalance were used for iTRAQ-based quantitative profiling in liver using LC/MS/MS. Prior to FR, 8 proteins were differentially expressed ($P \leq 0.05$) due to physiological imbalance. Proteins upregulated (6) were involved in amino acid metabolism, gluconeogenesis, and β-oxidation of fatty acids. Feed restriction resulted in 20 proteins differentially expressed between cows in physiological imbalance and cows metabolically ′normal′. Upregulated proteins (8) were involved in β-oxidation of fatty acids and gluconeogenesis whereas downregulated proteins (12) were involved in antioxidant defense and glycine metabolism. This study is the first to identify new biomarkers in liver based on a physiological imbalance index and provide a better understanding of the differences in coping strategies used during FR for cows in physiological imbalance. Screening for relevant markers in more accessible samples (i.e., blood and milk) will help farmers identify cows at risk. Results provide new avenues for future management strategies relating to maintaining animal health and productivity during early lactation.

Key Words: physiological imbalance, cow, proteomics

LB2 A novel nonsense mutation of the *DMP1* gene is responsible for inherited rickets in Corriedale sheep. X. Zhao[1], K. E. Dittmer[2], S. Onteru[1], H. T. Blair[2], K. G. Thompson[2], M. F. Rothschild[1], and D. J. Garrick*[1,2], [1]*Iowa State University*, *Ames,* [2]*Massey University*, *Palmerston North, New Zealand*.

Inherited rickets of Corriedale sheep is a recently discovered skeletal disease of unknown prevalence characterized by decreased growth rate, thoracic lordosis and angular limb deformities. Previous outcross and backcross studies suggest it is a simple autosomal recessively inherited disorder. A genome-wide association study was conducted using the Illumina OvineSNP50 BeadChip on 17 sheep diagnosed as affected and an additional 3 known carriers descended from 1 carrier ram. Genomic regions showing association were scrutinized for possible candidate genes that were sequenced for causal polymorphisms concordant with disease status. A homozygous region of 199 consecutive single-nucleotide polymorphism (SNP) loci was identified in all the affected sheep, covering a region of 10 Mbp on ovine chromosome 6. Among 91 candidate genes in this region, exon 6 of the dentin matrix protein 1 (*DMP1*) gene was sequenced using DNA from the 3 carriers to reveal 10 novel SNPs including a nonsense mutation 253T/C. This T/C transition introduced a stop codon (R145X) that could truncate C-terminal amino acids. Genotyping by PCR-RFLP (restriction fragment length polymorphism) for this mutation showed that, all 17 affected sheep were "TT" genotypes and the 27 phenotypically normal sheep were either "CT" or "CC." This locus is not in complete linkage disequilibrium with the other 9 SNPs that can all be ruled out as candidates. Previous research has shown that mutations in *DMP1*gene are responsible for autosomal recessive hypophosphatemic rickets in humans. *Dmp1*_knockout mice also exhibit rickets phenotypes. We believe the *DMP1*_exon6_235T/C mutation to be responsible for the inherited rickets found in Corriedale sheep. A simple diagnostic test can be designed to identify carriers with the defective "T" alleles. Affected sheep could be used as animal models for this form of human rickets, and for further investigation of the role of DMP1 in phosphate homeostasis.

Key Words: rickets, DMP1, genome wide association

LB3 Association of polymorphisms in GPAT4 and SLC27A6 genes with bovine milk fat percentage and fatty acid composition. R. A. Nafikov*[1], J. P. Schoonmaker[2], K. T. Korn[2], K. Noack[1], D. J. Garrick[1], K. J. Koehler[1], J. Minick-Bormann[3], J. M. Reecy[1], D. E. Spurlock[1], and D. C. Beitz[1], [1]*Iowa State University*, *Ames,* [2]*Purdue University*, *West Lafayette, IN,* [3]*Kansas State University*, *Manhattan*.

The purpose of our study was to discover genetic polymorphisms to select animals producing milk with healthier fatty acid composition. The glycerol-3-phosphate acyltransferase-4 (GPAT4) and solute carrier family 27, isoform A6 (SLC27A6) involved in milk triacylglycerol biosynthesis and fatty acid transport into the mammary epithelial cells were candidate genes. We hypothesized that polymorphisms in GPAT4 and SLC27A6 will affect selectivity of fatty acid acylation onto glycerol-3-phosphate and of fatty acid uptake into the mammary epithelial cells, leading to variations in milk fatty acid composition. To test this hypothesis, milk samples were collected monthly over a 305-d lactation from 500 cows and analyzed for fatty acid composition by gas chromatography. After discovering single nucleotide polymorphisms (SNPs) in the genes of interest and genotyping animals for those SNPs, intragenic haplotypes were reconstructed and tested for associations with milk fat percentage and fatty acid composition by linear mixed models. Results showed that the haplotype effect of GPAT4 was associated significantly with concentrations of capric (10:0), lauric (12:0), palmitic (16:0), and oleic (18:1c9) acids, saturated fatty acids (SFA), unsaturated fatty acids (UFA), monounsaturated fatty acids (MUFA), polyunsaturated fatty acids (PUFA), and SFA/UFA. The haplotype effect of SLC27A6 was associated significantly with percentage of milk fat, concentrations of capric, lauric, myristic (14:0), and palmitic acids, SFA, UFA, MUFA, and SFA/UFA. The size of effects for some of the traits was numerically the same or greater than allelic effects of well known diacylglycerol

acyltransferase-1 (DGAT1) A232K mutation. Results of our study provide opportunity for selection for cows with healthier milk.

Key Words: milk fat percentage, milk fatty acid composition, SNP

LB4 Renneting properties of milk containing high molecular weight oat β-glucan. N. Sharafbafi*[1], S. M. Tosh[2], M. Alexander[1], and M. Corredig[1], [1]*Department of Food Science, University of Guelph, Guelph, Ontario, Canada*, [2]*Agriculture and Agri-Food Canada, Guelph Food Research Center, Guelph, Ontario, Canada*.

The effect of concentration and molecular structure of high molecular weight oat β–Glucan (BG) on renneting properties of concentrated skim milk gels were investigated. Incorporation of BG (0.15, 0.3, 0.6, and 0.9% w/w in permeate) into twice-concentrated skim milk resulted in bulk phase separation of gelling systems as shown by reduction in turbidity parameter (1/l*) and diffusion coefficient using diffusing wave spectroscopy (DWS). However, by controlling the kinetics of gelation and phase separation (using shear in renneted milk before BG addition), it was possible to create casein networks with entrapped BG. $CaCl_2$ was added to reduce time of gelation (TG), and increase textural properties, where high concentrations of BG (≥0.6%) resulted in weakening of protein gel network. The effects of shear and the presence of $CaCl_2$ on microstructure and rheological behavior of the renneted gels containing BG were monitored using DWS combined with small deformation rheology. In addition, BG distribution in the rennet gel network was observed by differential staining technique (Calcofluor and Rhodamine B, for BG and protein, respectively) using confocal laser scanning microscopy. The results showed that the onset of protein interactions, illustrated by the turbidity parameter, and the aggregation point, measured by the diffusion coefficient, were strongly affected by increase in BG concentration. BG-containing gels exhibited a significantly lower elastic modulus (G′) compared with their control counterparts ($P \leq 0.05$). Increase in BG concentration delayed the TG, and reduced gel firmness due to the non-interacting nature of the BG polymer. In contrast, the addition of $CaCl_2$ reduced the TG and produced a firmer gel in both control and BG added samples. BG addition could improve the texture and nutritional value of calorie-reduced cheeses, whose hard texture has traditionally been a barrier to their production.

Key Words: β-glucan, concentrated milk, renneting

LB5 Genome-wide association of a novel porcine stress-syndrome and isoflurane sensitivity to dystrophin. D. J. Nonneman*, T. M. Brown-Brandl, S. A. Jones, and G. A. Rohrer, *USDA, ARS, US Meat Animal Research Center, Clay Center, NE*.

Losses of slaughter-weight pigs due to transport stress are an economic concern to pork producers. Historically, the HAL-1843 mutation in the ryanodine receptor 1 gene was considered responsible for most of the losses; however, DNA testing has effectively eliminated this mutation from commercial herds. We identified 2 sibling barrows in the USMARC swine herd that died after transport to a research location at 8 weeks of age. The original mating was repeated along with sire-daughter matings to produce additional offspring. Pigs were challenged with isoflurane anesthesia (3% for 3 min) at 8 weeks. Heart rate and ECG were monitored during anesthesia and blood was collected one week before challenge and immediately after isoflurane administration. Four males from the original sire-dam mating and 2 males from a sire-daughter mating died after one minute of anesthesia. Animals from 6 other litters were identified as having a stress response, sometimes resulting in death, during regular processing and weighing. Their littermates were also challenged with isoflurane. Affected animals tended to have elevated plasma creatine phosphokinase (CPK) levels and cardiac arrhythmias, as determined by ECG. Pedigrees containing 58 pigs including 14 affected animals were genotyped with the Illumina Porcine 60K SNP Beadchip and 2 chromosomal regions were significantly associated with the syndrome at the genome-wide level. One is on SSC14 at position 82.7 to 88.9 Mbp, and the other is on SSCX at 25.1 to 27.7 Mbp over the dystrophin gene. In addition to muscular dystrophies, mutations in human dystrophin can cause dilated cardiomyopathy, rhabdomyolysis, and a malignant hyperthermia-like reaction in response to inhaled anesthesia, which supports this locus as a cause for the observed phenotypes in pigs. The identification of the causative mutation in these families will allow investigation of the prevalence of this disease in commercial populations.

Key Words: swine, stress, genotyping

LB6 Duration of maternal undernutrition differentially alters fetal development and metabolism in twin sheep pregnancies. M. Field*, R. Anthony, T. Engle, S. Archibeque, and H. Han, *Colorado State University, Fort Collins*.

Maternal undernutrition is known to impact fetal development and predispose the offspring to the metabolic syndrome later in life. We examined the impact of maternal undernutrition during early- to mid-gestation or from early gestation until near term on twin sheep pregnancies. Multiparous whiteface ewes (n = 19) were randomly assigned to one of 3 treatments beginning on 28 d of gestational age (dGA). Ewes were either fed 100% (Control; n = 7), or 50% of nutrient requirements from 28 to 78 dGA and readjusted to 100% beginning at 79 dGA (50-100; n = 5) or 50% of requirements from 28 to 110 dGA, followed by a 5% increase at 5 d intervals until 135 dGA (50-50; n = 7). Body weight of the Control (4.3 kg) fetuses were intermediate between the 50-50 (4.1 kg) and 50-100 (4.6 kg; $P < 0.05$). Organ weights differed between 50-50 and 50-100 fetuses ($P < 0.05$). Uterine artery glucose concentrations did not differ ($P = 0.35$), but 50-100 dams (98.8 mg/dL) were numerically higher than Control (76.6 mg/dL) and 50-50 (81.2 mg/dL) dams. The uterine artery:umbilical vein glucose gradient was numerically higher in 50-100 (50-100 = 65.5 mg/dL; Control = 52.3mg/dL; 50-50 = 53.2 mg/dL). The same trend was noted in umbilical vein glucose (50-100 = 34.4mg/dL; Control = 27.7 mg/dL; 50-50 = 25.7 mg/dL; $P = 0.23$). Interestingly, the umbilical vein:artery glucose gradient was less ($P < 0.05$) in 50-50 (4.68 mg/dL) fetuses compared with Control (6.84 mg/dL) and 50-100 (7.02mg/dL) fetuses. A similar trend was seen with umbilical vein:artery differences in O_2 content (50-100 = 4.43 m*M*; Control = 5.02 m*M*; 50-50 = 3.41 m*M*; $P = 0.10$). In conclusion, lower glucose and O_2 content gradients in 50-50 fetuses suggest lower metabolic rates resulting from long-term maternal diet restriction, while mid gestation realimentation may program maternal and placental glucose metabolism, providing for accelerated fetal growth.
Supported by USDA-NIFA-NRI grant 2009-35206-05273.

Key Words: undernutrition, pregnancy, sheep

LB7 Bovine mammary stem cells: Transcriptome profiling and the stem cell niche. R. K. Choudhary*[1], R. W. Li[2], C. M. Evock-Clover[2], and A. V. Capuco[2,1], [1]*Department of Animal and Avian Sciences, University of Maryland, College Park,* [2]*Bovine Functional Genomics Laboratory, USDA-ARS, Beltsville, MD*.

Identification and transcriptome analysis of mammary stem cells (MaSC) are important steps toward understanding the molecular basis of mammary epithelial growth, homeostasis and tissue repair. Our objective was to evaluate the molecular profiles of 4 categories of cells within

the bovine mammary epithelium, 2 subpopulations of putative stem cells and 2 subpopulations of control cells, with the goal of localizing and characterizing MaSC in situ. Putative MaSC were identified based upon their ability to retain the thymidine analog, bromodeoxyuridine (BrdU), for an extended period. Five Holstein calves were injected with BrdU, tissue was harvested 45 d later and label retaining epithelial cells (LREC) were identified in mammary cryosections by immunostaining. Using laser microdissection, LREC from basal (LRECb) and embedded (LRECe) layers of mammary epithelium were isolated along with adjacent control epithelial cells (EC). Cells (6–13) in each category per heifer were lysed, cDNA synthesized, amplified and labeled for microarray hybridization. Data analysis revealed 592 differentially expressed genes ($P \leq 0.05$; ≥2-fold change) between LRECb and basal EC, and 110 genes between LRECe and their embedded EC. Of these, 387 genes with enriched expression in LRECb were involved in cell growth and proliferation, cell cycle, and post-translational modifications. Low expression of estrogen receptor-β and high expression of aldehyde dehydrogenase 3B1 in LRECb were consistent with stem cell character. We found high expression of *NR5A2* (pluripotency transcription factor) and no expression of *XIST* (X-chromosome inactivation factor) in LRECb. Comparison between LRECb and LRECe showed downregulation of cell survival and proliferation factors (*IGF2, HSPB6, LAMC1*), nestin (stem cell marker), epigenetic modifiers (*JRID2, METTL33, SMARCC2*), and upregulation of apoptotic genes (*SFRS5, THAP3*) and *XIST* in LRECe. We conclude that BrdU label retention identifies stem and progenitor cells, wherein MaSC (LRECb) are located in the basal region of the mammary epithelium and committed progenitor cells (LRECe) are localized in more apical layers.

Key Words: mammary stem cell, progenitor, microarray

LB8 First metagenomic analysis of the rumen microbiome of dairy cows with subacute ruminal acidosis and identification of specific *Escherichia coli* virulence factors. E. Khafipour*[1], A. C. Little[1], N. C. Berard[1], P. C. Aikman[2], S. Li[1], S. E. Dowd[3], J. C. Plaizier[1], and D. O. Krause[1], [1]*University of Manitoba*, *Winnipeg, MB, Canada*, [2]*University of Reading*, *Earley Gate, Reading, United Kingdom*, [3]*Medical Biofilm Research Institute*, *Lubbock, TX*.

Subacute ruminal acidosis (SARA) is a metabolic disease in high-producing dairy cattle characterized by low rumen pH, reduced feed intake, lower milk fat, and systemic inflammation. We reproduced similar low rumen pH conditions of SARA with an alfalfa-pellet or a high-grain diet, but only the high-grain fed animals showed symptoms of SARA other than rumen pH depression. To further investigate rumen dynamics rumen DNA samples were subjected to next generation high-throughput pyrosequencing of 16S rRNA. A total of 81,416 sequences were generated of which 39,599 were unique. Sequences were converted to categorical data using a standard taxonomy by comparing the sequences to 16S rRNA databases. A negative binomial distribution was fitted to the data and analyzed using generalized linear mixed-model methodology (GLIMMIX) of SAS for categorical data. A total of 16 phyla were represented in the data set, with *Bacteroidetes*, *Firmicutes*, and *Proteobacteria* forming the most dominant phyla. Loss of *Bacteroidetes* was associated ($P < 0.05$) with grain-induced SARA suggesting that members of this phyla (*Prevotella* and *Bacteroides*) have a protective role in the rumen. Gram-negative *Proteobacteria* were associated ($P < 0.05$) with grain-induced SARA. To further evaluate the role of *Proteobacteria* we isolated *Escherichia coli* from rumen samples and performed PCR analysis on 25 *E. coli* virulence factors. *E. coli* were at least 3-logs ($P < 0.05$) higher in grain-induced SARA and curli fibers were highly associated ($P < 0.01$) with *E. coli* from grain induced, but not alfalfa pellet induced SARA. Curli fibers were first identified in *E. coli* isolated from bovine mastitis and attack tight junctions between cells potentially increasing permeability of the rumen epithelium to antigens. This is the most comprehensive metagenomic study of the rumen and the first in which specific virulence factors have been identified that potentially explain the etiology of SARA.

Key Words: subacute ruminal acidosis, rumen microbiome, *Escherichia coli*

Triennial Growth Symposium: Dietary Regulation of Growth and Development

1 Vitamin D mediated phosphate homeostasis—Implications for skeleton growth and mineralization. T. D. Crenshaw,* *University of Wisconsin*, *Madison.*

Foundational roles of vitamin D (D) in skeletal growth involve interrelationships between Ca, PTH, and conversion of D to the active hormone, 1α, 25-$(OH)_2$ D_3. Until the past decade relatively little research focused on these interrelationships and P homeostasis. A focus on Ca was driven, in part, by the limiting amount of Ca and abundance of P in human diets. Most ingredients used in monogastric animal diets are limiting in Ca and P. Ca and P have been typically supplied in excess of requirements from inorganic sources with minor incentives to improve nutrient efficiency. Constraints on amounts of supplemental P are driven by ingredient costs and environmental concerns. Thus P, not Ca, is typically more limiting in monogastric diets. The introduction of phytase supplements has only exasperated the need to understand P homeostasis. In the past 5 yr, discovery of novel pathways for P homeostasis offer opportunities to improve P efficiency without compromising skeletal growth and animal well-being. The objective of this review is to summarize interrelations of dietary P, D and the role of fibroblast growth factor 23 (FGF23) in P homeostasis. FGF23 directly affects P homeostasis via action on a renal Na-P transport protein and renal 1 α-hydroxylase activity. FGF23 is produced primarily in osteocytes which allow localized osteocyte regulation of osteoblast-mediated bone formation and regulation of systemic renal P excretion relative to needs for bone mineralization. In transgenic mice, overexpression of FGF23 led to hypophosphatemia and urinary P wasting. In contrast FGF23 knockout mice displayed hyperphosphatemia and renal P conservation. Current studies in our lab have shown that deletion of D supplements in diets fed to sows during gestation and lactation compromised ($P < 0.05$) skeletal bone mineral content in offspring at 13 wk of age and decreased the age at which pigs displayed kyphosis. These responses appear to be mediated by the efficiency of dietary P use. In summary, development of dietary inputs to balance both Ca and P homeostasis are needed to improve skeletal growth and nutrient efficiency.

Key Words: FGF23, kyphosis, Na-P transport

2 Effects of polymeric carbohydrates on growth and development. K. E. Bach Knudsen,* *Aarhus University, Faculty of Agricultural Sciences*, *Department of Animal Health and Bioscience, Tjele, Denmark.*

The main objective of the presentation is to provide insight into the role of polymeric carbohydrates in growth and development of pigs. Polymeric carbohydrates—starch and non-starch polysaccharides (NSP)—quantitatively represent the largest portion of the diets for pigs and are therefore the largest energy contributor. The 2 types of polysaccharides, however, have different fates and functions in the gastrointestinal tract and lead to different metabolites upon digestion. Pancreatic and mucosal enzymes in the small intestine break down the majority of starch, while NSP primarily are degraded by the microflora in the large intestine. Starch degradation leads to the release of glucose which is absorbed by an active absorption process that triggers the release of insulin from the pancreas, whereas the fermentation of NSP to short-chain fatty acids (SCFA: acetate, propionate and butyrate) occurs at a slower and more constant rate and with SCFA being absorbed by passive diffusion. Type and levels of polymeric carbohydrates influence growth and development through different mechanisms; first, the proportion of starch to NSP plays an important role for the content of available energy (digestible, metabolized and net energy); available energy relative to protein is crucial for performance and carcass quality; second, the proportion of starch to NSP will influence rate and type of metabolites (glucose vs. SCFA) deriving from carbohydrate assimilation, and finally, type of starch (types A, B, and C) and soluble NSP will influence the release of insulin, the hormone that facilitate nutrient uptake by tissues, organs and cells, and thus play a critical and essential role in protein synthesis and muscle growth as well as lipid synthesis and adipose tissue growth. In conclusion, polymeric carbohydrates influences growth and development through events in the gut and direct and indirect effects of different metabolites deriving from carbohydrate assimilation.

Key Words: polymeric carbohydrates, pigs, growth

3 Effect of feed additives on cattle growth and development. R. A. Zinn*[1], P. Garces-Yepez[2], and J. Salinas-Chavira[3],[1]*University of California*, *Davis,* [2]*UNAM*, *Mexico City, DF, Mexico*, [3]*UAT*, *Ciudad Victoria, Tam., Mexico*.

Feed additives are of themselves largely non-nutritive materials that are included in diet formulations to enhance health and growth performance. This presentation will focus on use of additives intended to enhance growth performance of feedlot cattle. They include: alkalizers (e.g., sodium bicarbonate, potassium carbonate, calcium carbonate, magnesium hydroxide), ionophores (e.g., laidlomycin, lasalocid, monensin, salinomycin), non-ionophore "mycin's" (e.g., bambermycins, virginiamycin), subtherapeutic antibiotics (e.g., chlortetracycline, tylosin), probiotics (e.g., *Lactobacillus*, *Bifidobacterium*, *Saccharomyces*), essential oils (e.g., cinnamonaldehyde, eugenol, limonene, terpinen, thymol, vanillin), enzymes (e.g., amylase, xylanase, cellulase), hormones (e.g., melengestrol acetate), and β-agonists (ractopamine, zilpaterol). This presentation will provide a brief overview of various additive classes, including possible modes of action, and practical measures of efficacy (growth performance and digestive function).

Key Words: additive, cattle, growth

4 Host targeted antibody strategies for preventing growth depression due to microbial colonization. M. E. Cook*[1,2] and S. M. Huebner[2], [1]*University of Wisconsin, Department of Animal Sciences*, *Madison,* [2]*University of Wisconsin, Department of Nutritional Sciences*, *Madison.*

The growth rate and feed efficiency of chicks and pigs colonized with commensal bacteria is only 80 to 90% of germ-free housed animals. Reduced growth of conventionally housed animals, when compared with germ-free animals, is the result of inflammatory processes. New information on the signaling pathways of inflammatory processes has provided scientists with new targets to improve animal growth and feed efficiency. It has become evident that inflammation can be regulated at the intestinal lumen/mucosa interface. Secretory phospholipase A2 (sPLA2) has emerged as a host target worthy of study. sPLA2 is secreted into the lumen of the gastrointestinal tract (GIT) during systemic inflammation. Following sPLA2 release, GIT permeability is increased, and sPLA2 action on phospholipids permit intracellular signal transduction for inflammatory mediator production (e.g., eicosanoids and cytokines). In addition, sPLA2 lipid products, such as lysophosphatidylcholine, can signal natural killer T cell (NKTC) cytokine production via the CD1d molecule on antigen presenting cells. Egg antibodies specific to host sPLA2 decreased lipopolysacchride-induced PGE2 and tumor necrosis factor release in macrophages and reduced cytokine production by NKTC. Egg anti-sPLA2 was tested in chick growth trials and found to improve growth and feed efficiency approximately 5%. Feeding anti-sPLA2 to pigs, calves, fish species resulted in improved growth. Studies were also conducted in animals with bacteria and protozoan challenges, and anti-SPLA2 was found to be protective in some diseased states or to have no beneficial or adverse effect on animal health. The anti-sPLA2 example suggests that inflammatory products and pathways are useful host targets for improving animal growth. Orally delivered antibodies, such as egg antibody, may serve as useful tools for discovering key mechanisms for increasing the efficiency for production of animal products.

Key Words: growth, inflammation, egg antibody

5 Neural regulation of feed intake: Modification by hormones, fasting and disease. J. L. Sartin*[1], B. K. Whitlock[2], and J. A. Daniel[3], [1]*Auburn University*, *Auburn, AL,* [2]*University of Tennessee*, *Knoxville,* [3]*Berry College*, *Mt. Berry, GA.*

Appetite is a complex process that results from the integration of multiple signals at the hypothalamus. The hypothalamus receives hormonal signals such as insulin, leptin and ghrelin to nutrient molecules such as glucose, free fatty acids, amino acids and volatile fatty acids. This effect is processed by a specific sequence of neurotransmitters beginning with the arcuate nucleus and orexigenic cells containing neuropeptide Y or agouti-related protein and anorexigenic cells containing proopiomelanocortin (POMC, yielding the neurotransmitter α-melanocyte stimulating hormone) or cells expressing cocaine amphetamine related transcript. These so called first order neurons end on second order orexigenic neurons containing either melanin concentrating hormone or orexin. The activity of these neuronal pathways are altered externally by nutritional alterations such as fasting or severe catabolic circumstances such as disease. In addition, there are other pathways from within the brain that may interact to dictate feed consumption patterns in farm animals. This review will begin with the central hypothalamic pathways and then discuss the ways in which hormones and metabolites may alter the process to impact on feed intake.

Key Words: appetite, leptin, NPY

6 Leucine acts as a nutrient signal to stimulate protein synthesis. T. A. Davis,* A. Suryawan, R. A. Orellana, and M. L. Fiorotto, *USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine.*

The postprandial rise in amino acids and insulin independently stimulates protein synthesis in skeletal muscle of piglets. Leucine is an important mediator of the response to amino acids. We have shown that the postprandial rise in leucine, but not isoleucine or valine, acutely stimulates muscle protein synthesis in piglets. Leucine increases muscle protein synthesis by modulating the activation of signaling components of translation initiation. Thus, leucine increases the phosphorylation of mammalian target of rapamycin (mTOR), 70-kDa ribosomal protein S6 kinase, eukaryotic initiation factor (eIF)4E-binding protein-1, and eIF4G, decreases the phosphorylation of eIF2 α, and increases the association of eIF4E with eIF4G. However, leucine does not affect the canonical upstream activators of mTOR, i.e., protein kinase B, AMP-activated protein kinase, and tuberous sclerosis complex 1/2, or the translation elongation regulator, eukaryotic elongation factor 2. The acute leucine-induced stimulation of muscle protein synthesis is not maintained for prolonged periods, despite continued activation of the mTOR signaling pathway, because circulating essential amino acids fall as they are utilized as substrates for protein synthesis. However, if circulating amino acids levels are maintained, the leucine-induced stimulation of muscle protein synthesis can be maintained for prolonged periods. The activation of the mTOR signaling pathway by leucine does not appear to be affected by the circulating levels of other amino acids. Supplementation of low protein diets with leucine stimulates protein synthesis in muscle and most visceral tissues to a rate similar to that achieved by feeding high protein diets and this stimulation involves activation of the mTOR downstream effectors. Together, these studies indicate that leucine acts as a nutrient signal to stimulate translation initiation but whether this translates into a sustained increase in protein synthesis depends on the sustained availability of dietary amino acids.

Key Words: muscle, protein synthesis, amino acids

7 Important roles for L-glutamine in swine nutrition and growth. G. Wu,* F. W. Bazer, G. A. Johnson, R. C. Burghardt, D. A. Knabe, T. E. Spencer, X. L. Li, and J. J. Wang,*Texas A&M University*, *College Station.*

L-Glutamine (Gln) has traditionally not been considered as a nutrient needed in diets for livestock species or even mentioned in animal nutrition textbooks. This is due to previous technical difficulties in the analysis of Gln (free and protein-bound) and the unsubstantiated assumption that animals can synthesize sufficient amounts of Gln to meet their needs. Consequently, the current 10th version of NRC (1998) does not recommend dietary Gln requirements for growing, gestating or lactating swine. This lack of knowledge about Gln nutrition has contributed to suboptimal efficiency of global pig production. Because of recent advances in analytical methods and biochemical research, Gln is now known to be an abundant amino acid in physiological fluids (e.g., milk and fetal fluids) and proteins (both plant and animal), as well as a major fuel for rapidly dividing cells (including enterocytes and lymphocytes) and a key regulator of gene expression. Additionally, Gln participates in cell signaling via the mammalian target of rapamycin pathway, AMP-activated protein kinase, extracellular signal-related kinase, Jun kinase, mitogen-activated protein kinase, and nitric oxide. Exquisite integration of these regulatory networks has profound effects on cell proliferation, differentiation, metabolism, homeostasis, survival, and function. As a result of translating basic research into practice, dietary supplementation with 1% Gln maintains gut health and prevents intestinal dysfunction in low-birth-weight piglets and early-weaned piglets, while increasing their growth performance and survival. Also, supplementing 0.6% Gln to a corn- and soybean meal-based diet between d 30 and 114 of gestation ameliorates fetal growth retardation in gilts. Furthermore, adding 1% Gln to a conventional diet enhances milk production by lactating sows. Thus, adequate amounts of Gln in diets are necessary to support maximum growth, development and production performance of swine.

Key Words: growth, physiology, requirement

8 Feedlot performance and carcass quality of conventionally raised lambs implanted with zeranol versus naturally raised lambs. S. R. Eckerman*[1,2], G. P. Lardy[1], M. M. Thompson[2], B. W. Neville[1], M. L. Van Emon[1,2], P. T. Berg[1], and C. S. Schauer[2], [1]*North Dakota State University, Department of Animal Sciences*, *Fargo,* [2]*Hettinger Research Extension Center*, *Hettinger, ND*.

Our objectives were to compare feedlot performance and carcass quality of conventional and naturally raised lambs. Two-hundred 88 crossbred lambs (34 ± 0.1 kg) were assigned randomly to one of 12 pens (6 pens/treatment) and fed a finishing ration for 112 d. Treatments were conventional (CONV) or naturally raised (NAT). Naturally raised lambs were fed 80% corn and 20% commercial supplement ad libitum (DM basis; 87.9% TDN and 15.8% CP) with decoquinate included. The NR lambs were not treated with antibiotics nor given growth promoting implants. Conventional lambs were fed a similar ration, with decoquinate, chlortetracycline and lasalocid included in the ration and were implanted with 36 mg zeranol on d 28 and treated with antibiotics as necessary, primarily for treatment of prolapse. Lambs were weighed and feed refusals collected every 28 d. Lambs were harvested on d 117 and carcass data collected 24 h post chill. Data were analyzed using the mixed procedures of SAS. Repeated measures was used to analyze period effects for ADG, DMI, and G:F. Treatment x period interactions were observed for ADG, DMI, and G:F ($P < 0.01$). From d 29 to 56, CONV lambs had increased ADG, DMI, and G:F ($P \leq 0.01$) compared with NAT lambs. However, ADG, DMI, and G:F were not different between treatments ($P \geq 0.06$) for d 0 to 112. Naturally raised lambs had greater rib eye area ($P = 0.03$), decreased body wall thickness ($P = 0.05$), and a greater percentage boneless, closely trimmed retail cuts ($P = 0.05$). More CONV lambs prolapsed rectally or vaginally ($P = 0.001$; 8.3 vs 0%) which increased mortality ($P = 0.01$; 2.8 vs 0%). Lambs managed utilizing antibiotics, implants, and ionophores may have increased growth performance compared with lambs raised naturally, but may have diminished carcass quality and are more susceptible to prolapse and mortality.

Key Words: lamb, zeranol, naturally raised

9 Effects of rumen protected arginine supplementation on ewe serum amino acid concentration, circulating progesterone, and ovarian blood flow. C. S. Saevre*[1,2], J. S. Caton[1], J. S. Luther[3], A. M. Meyer[1], D. V. Dhuyvetter[4], R. Musser[5], J. D. Kirsch[1], M. Kapphahn[1], D. A. Redmer[1], and C. S. Schauer[2],[1]*Department of Animal Sciences, North Dakota State University*, *Fargo,* [2]*Hettinger Research Extension Center, North Dakota State University*, *Hettinger,*[3]*University of Wisconsin River Falls*, *River Falls*,[4]*Ridley Block Operations*, *Mankato, MN,* [5]*SODA Feed Ingredients, LLC*, *Mankato, MN*.

Objectives were to determine if rumen-protected arginine supplemented to ewes on d 8 to 13 of the estrous cycle affected serum amino acid concentration, ovarian blood flow, and circulating progesterone. Nineteen multiparous Dorset ewes (63.8 ± 1.1 kg initial BW) were individually housed and randomly allocated to 1 of 4 rumen-protected arginine treatments: 0 (CON, n = 5), 90 (90 ARG, n = 4), 180 (180 ARG, n = 5), or 360 mg/kg BW supplemental arginine (360 ARG, n = 5). Following estrous synchronization, ewes were individually fed rumen-protected arginine blended into 150 g ground corn, which was immediately followed with 650 g of a pelleted diet (2.40 Mcal ME/kg and 12.9% CP, DM basis) on d 8 to 13 of the estrous cycle. Jugular blood samples were taken for amino acid and progesterone analysis. On d 12, color Doppler ultrasonography was used to determine ovarian hemodynamics. Ewes fed 360 ARG had greater serum arginine concentration than CON, 90 ARG, and 180 ARG on d 11 (175.5 vs. 153.2, 132.3, and 145.4 ± 8.6 nmol/mL, respectively; $P = 0.01$) and d 12 (166.4 vs. 142.7, 121.7, and 128.2 ± 7.4 nmol/mL, respectively; $P = 0.002$). On d 11, arginine as a percent of total amino acid concentration was increased in 360 ARG compared with CON and 90 ARG (7.16 vs. 6.19, 5.70 ± 0.34 nmol/mL, respectively; $P = 0.04$). Total essential amino acid concentration was elevated in 360 ARG compared with 90 ARG and 180 ARG ($P = 0.08$) on d 12. Arginine supplementation increased peak systolic velocity in the corpus luteum for 360 ARG and 90 ARG compared with CON (30.53 and 32.59 vs. 22.63 ± 2.48 cm/s, respectively; $P < 0.07$). Flow time (milliseconds) in the ovarian hilus and corpus luteum was increased in 360 ARG compared with all other treatments ($P \leq 0.02$ and $P \leq 0.06$, respectively). Supplemental rumen-protected arginine had no effect on serum concentration of progesterone ($P > 0.50$). Results indicate that rumen-protected arginine supplemented to ewes at the rate of 360 mg/kg BW may increase circulating serum arginine concentration, in addition to increasing ovarian blood flow.

Key Words: arginine, ovarian hemodynamics, sheep

10 Effect of wet distillers grains with solubles on rumen bacterial community profiles in individually fed cattle. L. N. Tracey*[1], J. Browne-Silva[1], C. H. Ponce[2], J. B. Osterstock[3], J. C. MacDonald[2,3], M. Brown[2,3], and S. L. Lodge-Ivey[1],[1]*New Mexico State University*, *Las Cruces,* [2]*West Texas A&M*, *Canyon,* [3]*Texas AgriLife Research*, *Amarillo.*

Despite the growing use of wet distillers grains with solubles (WDGS) in the US, very few data are available that describe potential rumen fermentation and microbial ecology alterations that may occur by feeding higher concentrations of WDGS. The objective of this experiment was to evaluate the effects of WDGS on ruminal bacterial communities. Twenty-three steers that had been acclimated to steam-flaked corn finishing ration (average BW = 340 ± 29.6 kg) were randomized and assigned to one of 3 treatment groups. Cattle were individually fed via calan gates once per day. Treatments were replacement of steam-flaked corn with 0, 30, or 60% WDGS (DM basis; n = 7, 8, and 8, respectively). Ruminal fluid was collected once per wk for 5 wk via esophageal tubing before feeding. Samples were frozen and stored at −20°C for further analysis. Ruminal fluid community DNA and 16S rDNA was amplified and analyzed by denaturing gradient gel electrophoresis (DGGE). Clustering of DGGE banding patterns was normalized to an external standard and compared based on binary and numerical coefficients of Dice and Pearson, respectively. Binary banding patterns for all samples were 59.8% similar and total number of bands per sample was not influenced by treatment ($P = 0.96$). Analysis of treatment dendrograms for binary banding pattern revealed a decrease in similarity from 30 to 60% WDGS, with 0% being intermediate (68.5, 71.2, and 59.2 ± 7.09% for 0, 30, and 60% WDGS, respectively). Banding pattern similarity decreased during the duration of the experiment (73.4, 80.4, 72.8, 60.0, and 61.9 ± 8.65% for wk 1–5, respectively). Construction of dendrograms based on band intensity resulted in a dramatic reduction (19.2 ± 12.32%) of similarity across treatments. These results indicate feeding high levels of WDGS does not decrease the richness of the bacterial population but shifts in individual bacterial community members do occur.

Key Words: wet distillers grains with solubles, cattle, bacteria

11 Forage selection preferences by multiparous and primiparous beef cows grazing native tallgrass range during winter. N. A. Sproul,* L. W. Murray, J. R. Jaeger, D. A. Blasi, L. N. Edwards, G. J. Eckerle, L. A. Pacheco, and K. C. Olson, *Kansas State University*, *Manhattan.*

Our objective was to evaluate diet selection preferences of 18 experienced multiparous and 20 naive primiparous beef cows (9 and 2 yr old, respectively) grazing dormant, native tallgrass pastures during winter. The study was analyzed as a 4-period, 8-pasture (average size = 28 ha) Latin rectangle. Predominant pasture forage species were *Andropogon geradii* and *Schizachyrium scoparium*, which were grouped together for analysis (BL); *Bouteloua curtipendula* (SO); *Bouteloua gracillis*, (BG); *Panicum virgatum* (SG); *Sorghastrum nutans* (IG); *Amorpha canescensi* (LP); *Symphyotrichum ericoides* (HA); *Liatris punctata* (DG); and *Dalea purpurea* (PP). Animals were grouped randomly by parity status (n = 4 or 5) and grazed 1 of 4 assigned pastures during 4 consecutive 48-h periods. Fecal samples were collected from each animal at the end of each period. Range-plant fragments in fecal samples were quantified using a modified microhistological technique; plant fragment prevalence in fecal material was assumed to be equivalent to diet composition on a DM basis. Primiparous cows selected more forbs and fewer grasses (main effect of parity; $P = 0.09$) than multiparous cows. Multiparous cows ate more ($P = 0.07$) BL and less DG ($P = 0.05$) than primiparous cows. Consumption of all forbs, PP, LP, and DG by both classes of cows declined ($P \leq 0.04$) over time, while consumption of all grasses, BL, and BG increased over time ($P \leq 0.02$), possibly indicating that forb availability diminished over time. Occasional differences in consumption of IG, SG, SO, and HA between primiparous and multiparous cows occurred; however, differences were inconsistent (parity × period effect; $P \leq 0.02$) over time. Differences in diet selection patterns between multiparous and primiparous cows during a short-term winter grazing period could be indicative of differences in long-term foraging strategies. We interpreted these data to suggest that foraging strategies associated with cow stayability may be related to selection preferences during periods of poor forage quality.

Key Words: botanical composition, beef cows, grazing

12 Dry matter intake is repeatable over parities and residual feed intake is negatively correlated with dry matter digestibility in gestating cows. T. J. McDonald,* B. M. Nichols, M. M. Harbac, T. M. Norvell, and J. A. Paterson, *Montana State University*, *Bozeman*.

Feed costs account for approximately two-thirds of total cash inputs for cow/calf producers. Selecting cows that consume less DM, but maintain production, would lower breakeven costs. The objectives of these 2 experiments were to determine repeatability of DMI over parities, calculate residual feed intake (RFI), and examine the relationships between RFI and diet DM digestibility. Nichols et al. (2010, these proceedings) previously determined individual DMI for 120 gestating, primiparous heifers in 2008. Twenty-four of these heifers that had the highest and lowest DMI were selected for this 2009 experiment. Cows (3-yr-old, BW = 593 ± 50 kg, second trimester gestation) were fed a diet composed of 74% grass hay and 26% grain-based supplement (104% of MP requirement) to determine the correlation of DMI per $BW^{.75}$ between 2008 and 2009 when cows were in a similar gestational state. Diets were limit fed at 12.7 kg DM•cow^{-1}•d^{-1} using a GrowSafe system. Cows were adapted to the diet for 10 d, followed by a 70-d trial to determine individual feed intakes and weight gain. Residual feed intake was calculated as the residual from the linear regression of DMI on $BW^{.75}$ and ADG. Dry matter intake per $BW^{.75}$ was highly correlated (r = 0.71, $P < 0.01$) between first and second parities. Residual feed intake ranged from 4.46 kg/d to −4.58 kg/d. Immediately following Exp. 1, cows were fed for an additional 5 d for collection of feces (Exp. 2). Grab samples were collected daily at 0600 and 1800, and indigestible ADF was used to estimate DM digestibility. Residual feed intake was negatively correlated with DM digestibility (r = −0.51, $P = 0.03$, range = 62.6% to 74.2%) but had no relationship with digestible DMI ($P = 0.32$). Results showed that DM intakes were repeatable over parities, and as RFI increased, DM digestibility of a forage-based diet decreased.

Key Words: residual feed intake, gestation, digestibility

13 The relative importance of weaning management and vaccination history on performance by ranch-direct beef calves during weaning and receiving. M. J. Macek*[1], J. W. Iliff[1], K. C. Olson[1], J. R. Jaeger[2], T. B. Schmidt[3], D. U. Thomson[1], and L. A. Pacheco[1], [1]*Kansas State University*, *Manhattan,* [2]*Western Kansas Agricultural Research Center*, *Hays,* [3]*Missisippi State University*, *Starkville.*

Angus × Hereford calves (n = 437; average initial BW = 208 ± 25 kg) were stratified by BW, sex, and age and assigned randomly to 1 of 3 treatments that corresponded to length of time between weaning and shipping to a feedlot: 45, 15 or 0 d. Within each weaning period length, calves were assigned randomly to 1 of 2 bovine respiratory disease (BRD)-vaccination treatments: vaccinated 14 d before weaning and again at weaning (PRE) or vaccinated on the d of arrival at the feedlot and again 14 d later (POST). On a common shipping date, calves were transported 3 h to an auction market and held for 12 h. Calves were then transported 1 h to a feedlot. Calves were fed the same diets ad libitum throughout the study. Incidence of undifferentiated fever 15 d after weaning was greater ($P < 0.01$) for calves weaned 45 d before shipping than for calves weaned 15 d before shipping; however, ADG before shipping was greater ($P < 0.01$) for calves weaned 45 d than those weaned 15 d. Incidence of undifferentiated fever and ADG before shipping were similar ($P > 0.66$) between PRE and POST. Average DMI before shipping by 45-d calves was less ($P < 0.01$) than that by 15-d calves. Also, DMI by PRE calves was less ($P = 0.03$) than that by POST calves. Incidence of undifferentiated fever during receiving was similar ($P \geq 0.73$) between weaning and vaccination treatments. Calf ADG during receiving tended to be greater ($P < 0.07$) for 45- and 15-d calves than for 0-d calves. Receiving DMI increased ($P < 0.01$) as number of d between weaning and shipping increased. Conversely, the timing of vaccination did not affect ($P \geq 0.51$) ADG or DMI during receiving. Growth efficiency was similar ($P \geq 0.36$) among weaning and vaccination treatments. Weaning more than 15 d before shipping did not improve health or growth of cattle that were moved from their ranch of origin to a feedlot within 16 h and were not commingled with market-sourced cattle. Pre-shipment BRD vaccination may not change health or performance of ranch-direct cattle relative to BRD vaccination deferred until feedlot arrival.

Key Words: health, preconditioning, weaning

14 Effects of sun-curing and harvest maturity on concentration and protein-binding capacity of condensed tannins in sericea lespedeza (*Lespedeza cuneata*). G. J. Eckerle*[1], K. C. Olson[1], J. R. Jaeger[2], J. L. Davidson[3], T. K. Kraft[1], and L. A. Pacheco[1], [1]*Kansas State University*, *Manhattan,* [2]*Western Kansas Agricultural Research Center*, *Hays,* [3]*Greenwood County Extension*, *Eureka, KS.*

A study was conducted to evaluate the effects of sun-curing and harvest maturity on concentrations of condensed tannins (CT) and protein-precipitable phenolics (PPP) in sericea lespedeza (SL). Samples of SL (n = 200 plants/sample) were collected from a single native tallgrass pasture at 1 to 4-wk intervals from June 24 to October 11 that corresponded to

single-stem, branched-stem, budding, flowering, and senescent stages of plant phenology. Samples were divided randomly into 2 equal portions that were either dried via sun-curing or were frozen immediately after harvest and later freeze-dried. Total phenolics were extracted from dried, ground SL samples using a modified methanol-extraction technique and were analyzed for CT and PPP. Concentrations of CT in sun-cured SL were less (main effect of treatment, $P < 0.01$) than that in fresh SL. Concentration of CT in SL responded cubically ($P < 0.01$) over time; CT was least during June and October and peaked from late July to mid September. Peak CT concentration corresponded to the budding and flowering stages of the SL life cycle. Concentrations of PPP in SL also changed over time but the magnitude of the effect was influenced by treatment (treatment × period, $P < 0.01$). Concentrations of PPP in sun-cured SL responded cubically ($P < 0.01$) as the growing season advanced; PPP was least during June and October and peaked during July and August. In contrast, PPP in fresh SL increased quadratically ($P < 0.01$) over time, indicating that significant concentrations of PPP remained in SL late into the growing season. Concentration of CT and PPP in SL decreased dramatically during drying and storage. These data may explain why sharp avoidance of SL by grazing livestock is not generally observed when SL is fed in the form of sun-cured hay. Understanding how drying and plant growth stage influence tannins in SL could lead to more effective research models for the study of SL intake by ruminants.

Key Words: condensed tannin, noxious weed, sericea lespedeza

15 Effects of gestational dietary metabolizable protein level and dry matter intake on subsequent production traits in primiparous heifers. B. M. Nichols*[1], T. J. McDonald[1], M. M. Harbac[1], A. J. Roberts[2], and J. A. Paterson[1], [1]*Department of Animal and Range Sciences, Montana State University*, *Bozeman,* [2]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory*, *Miles City, MT.*

The objective of this experiment was to determine if feeding 2 levels of dietary metabolizable protein (102% vs. 119% of NRC requirements) and biological variation in feed intake during the second and third trimesters of gestation influenced subsequent production traits in primiparous heifers. Two-yr-old Angus and Simmental x Angus heifers (n = 120, initial BW = 448 ± 36 kg) had individual DMI determined using a GrowSafe feeding system. Dietary treatments were based on approximately 85% grass hay and 15% supplement. Supplements contained whole soybeans plus corn (102% MP) or dried distillers grains plus soybean meal (119% MP) and each supplement was assigned to 2 pens. Heifers were randomly assigned to one of 3 periods (P; 40 heifers/P) followed by random assignment to one of 4 pens (10 heifers/pen). Diets were fed at approximately 10.3 kg DM•heifer^{-1}•d^{-1}. After 35 d of intake measurement, heifers were placed into adjacent pens and fed their diets for an additional 50 (P1 and 2) or 82 d (P3). The next 40 heifers (P2) were placed in the facility and DMI was again determined over 35 d. Upon completion of the feeding trial, heifers were returned to the ranch, managed as a single group, and production data were measured. Level of dietary MP had no effect ($P > 0.17$) on calf birth weight, adjusted 205 d weight, ADG, age at weaning, cow BW at calving, proportion of cows cycling at bull turnout, or proportion of cows which conceived. Dry matter intake per unit of BW$^{0.75}$ (range = 0.057 - 0.187 kg/kg) did not affect ($P > 0.17$) any of the variables measured. Under the conditions of this study, feeding MP in excess of NRC recommendations during mid- to late-gestation did not enhance subsequent heifer productivity. Heifers that consumed less DM/kg BW$^{0.75}$ produced similarly to heifers that consumed more DM/kg BW$^{0.75}$.

Key Words: metabolizable protein, dry matter intake

16 Sampling bias when estimating adipocyte cellularity. G. D. Cruz*[1], J. A. Oliveira[2], T. R. Famula[1], and J. G. Fadel[1], [1]*University of California*, *Davis,* [2]*Universidade Federal de Goiás*, *Goiânia, Goiás, Brazil*.

The objective of this study is to determine if a random adipose sample would represent the overall cellularity mean within the *Longissimus dorsi* at the 12th rib. Marbling is a major factor in the determination of beef quality grades and is evaluated by appraisal of the *Longissimus dorsi* at the 12–13th rib interface in the United States. Thus, a goal is to increase marbling without negatively affecting carcass characteristics. A common measurement of the development and distribution of adipocytes is through cellularity, which involves measurements of size and number of adipocytes. Current estimates rely on one sample obtained from the muscle. To evaluate sampling bias, one muscle (2.54cm thick) was divided horizontally into halves of 1.22cm and each half was vertically divided in approximately 10 strips of various lengths for a total of 20 strips. These 20 strips were placed next to each other and 10 were selected by choosing every other one. These strips were evenly divided horizontally into a total of 89 samples. Twenty-five milligrams of marbling fat were dissected from each sample and osmium tetroxide technique was applied to estimate adipocyte cellularity. A random number generator was used to choose 5 samples to represent the muscle. The mean diameters of the samples were 72.4, 90.7, 77.0, 93.4, and 94.2 µm and the overall mean diameter was 81.6 µm. The mean number of cells for each sample was 2.73, 6.36, 1.38, 5.41, and 1.40 cells/g × 10^{-5} and the overall mean number was 2.59 cells/g × 10^{-5}. The mean diameter of each of the 5 samples was different ($P < 0.01$) from the overall mean. Also, 3 of the 5 samples were different (($P < 0.01$) from the overall mean number of cells. In conclusion, sampling bias is the major source of variation when estimating adipocyte size and number. A sampling technique should be developed to reduce sampling bias and increase the precision when estimating adipocyte cellularity. Currently our laboratory is developing such technique.

Key Words: adipocyte cellularity, sampling bias, beef cattle

17 Effect of forage energy intake and supplementation on marbling deposition in growing beef cattle. E. D. Sharman,* P. A. Lancaster, G. G. Hilton, C. R. Krehbiel, and G. W. Horn, *Oklahoma Agricultural Experiment Station*, *Stillwater*.

Glucose is the primary carbon source for fatty acid synthesis in intramuscular fat, whereas, acetate is primarily utilized by subcutaneous fat. Our objective was to examine the effect of forage energy intake and type of fermentation on marbling deposition by stocker cattle grazing dormant native range (DNR) or winter wheat pasture (WP). Angus steer calves (n = 68; 258 ± 29 kg) were used in a completely randomized design comparing 4 winter grazing treatments: (1) control, 1.02 kg•hd^{-1}•d^{-1} of a 40% CP supplement to meet their DIP requirement while grazing DNR; (2) control plus corn-based supplement at 1% BW while grazing DNR; (3) WP at a high stocking rate (3.2 steers/ha) to achieve a low rate of BW gain; and (4) WP at a low stocking rate (2.2 steers/ha) to achieve a high rate of BW gain. Supplements were fed individually 5 d/wk during the 138-d winter grazing phase. Following winter grazing, 3 steers per treatment were randomly selected for intermediate harvest. The remaining wheat pasture steers were transitioned to the finishing phase, while the DNR treatments remained on summer pasture for 115 d before finishing. Steers were fed to a predicted backfat end point of 1.27 cm. During winter grazing, ADG was 0.19, 0.52, 0.68, and 1.37 ± 0.03 kg/d ($P < 0.01$) for treatments 1–4, respectively. Steers that grazed WP had heavier HCW and larger REA ($P < 0.01$) at intermediate harvest than steers supplemented on DNR. Backfat was 0.03, 0.10, 0.17, and

0.85 ± 0.07 cm ($P < 0.01$) and marbling scores were 180, 217, 280, and 340 ± 11.67 ($P < 0.01$) for treatments 1–4, respectively. At harvest after finishing, treatment 3 had a thicker backfat and smaller REA resulting in higher YG ($P < 0.02$) compared with the other treatments. There were no differences in final marbling scores (423, 428, 427, and 425 ± 14.92; $P = 0.99$, respectively). These data indicate that growing programs differing in forage energy intake and type of fermentation can influence marbling deposition at the end of winter grazing; however, final marbling scores may not be affected when cattle are fed to a common fat end point.

Key Words: growing beef cattle, forage energy intake, marbling deposition

18 Grazing patterns of Angus, Brangus and Brahman cows in the Chihuahuan Desert. M. L. Russell,* D. W. Bailey, M. G. Thomas, B. K. Witmore, and C. C. Bailey, *New Mexico State University*, *Las Cruces.*

In extensive pastures, forage utilization may decrease due to limited water sources. However, adapted breeds of cattle may facilitate an improvement in grazing distribution by utilizing distant portions of extensive pastures. A 2-yr study was conducted to evaluate grazing distribution and quality of diet for Angus, Brangus and Brahman cows in the Chihuahuan Desert during 3 seasons (winter, early summer and late summer) using 3 pastures varying in terrain. Cows were tracked with GPS technologies every 10 min for 10- to 14-d periods in each pasture (3 periods per season). Pooled data from 7 cows of each breed were evaluated in 2008 utilizing a Latin square design with breed as the treatment and period and pasture as blocking factors (n = 9). Breeds were kept together during 2009 and evaluated for 10 to 14 d in each of 3 pastures during each season using breed and pasture as fixed effects. When cows were rotated among pastures, fecal samples were collected and analyzed using near infrared spectroscopy (NIRS) to estimate diet quality. In 2008, CP content of diets was similar ($P > 0.31$) among breeds during all seasons. Brahman cows regularly traveled greater distances per day than Angus or Brangus cows during early and late summer seasons in 2008 and 2009 ($P < 0.05$). Brahman cows traveled 12.4 ± 0.6 km/d while Angus and Brangus traveled 7.2 ± 0.6 and 8.3 ± 0.6 km/d, respectively, during late summer 2009. In contrast, average distance from water was similar ($P > 0.59$) among breeds during both 2008 and 2009, which suggests that distribution patters were similar. Diurnal movement patterns sometimes differed among breeds. In late summer 2009, Brahman cows (1.81 ± 0.11) made more ($P = 0.03$) trips to water each day than Angus (1.15 ± 0.11) or Brangus (1.36 ± 0.11); however, during the winter and early summer in 2008 and 2009, trips to water each day were similar ($P > 0.48$) among breeds. Spatial movement patterns of Brahmans appeared to differ from Angus and Brangus, however, no clear advantage in grazing distribution was observed for any breed.

Key Words: breed, distribution, telemetry

19 Arginine supplementation does not alter nitrogen metabolism of beef steers during a lipopolysaccharide challenge. B. H. Carter*[1], C. A. Löest[1], G. G. Gilliam[1], B. C. Graham[1], J. A. Carroll[2], C. T. Collier[2], and D. M. Hallford[1], [1]*New Mexico State University*, *Las Cruces,* [2]*USDA ARS*, *Lubbock, TX.*

Demand for Arg is reported to increase during immune challenges. This study evaluated effects of lipopolysaccharide (LPS) and abomasal Arg infusion on N metabolism and immune response of 20 ruminally cannulated steers (369 ± 46 kg BW) in a randomized block design. Each block consisted of a 14-d adaptation, 1-d blood collection, and 5-d fecal and urine collection. Steers were fed a diet (12.9% CP, 0.99 Mcal/kg NEg) at 1.5% BW. Treatments (2 × 2 factorial) were AA solutions with no Arg (-ARG) or 10 g/d Arg (+ARG), and sterile saline with no LPS (-LPS) or 1 µg LPS (+LPS; *E. coli* 055:B5) per kg BW. The AA solutions were abomasally infused (720 mL/d) from d 7 to 20; LPS solutions (100 mL) were intravenously infused (1 mL/min) on d 15. Rectal temperature (RT) and blood samples were collected 0, 2, 4, 8, 12, and 24 h after LPS infusion on d 15. No LPS × Arg × h or LPS × Arg interactions occurred ($P > 0.24$). Cortisol, IL-6, and RT were greater (LPS × h, $P < 0.01$) for +LPS vs -LPS at 2, 4 (peak), 8 and 12 h (cortisol, IL-6). Tumor necrosis factor-α was greater at 2 h, and haptoglobin was greater at 24 h in +LPS vs -LPS steers (LPS × h, $P < 0.01$). Plasma Ala was greater (LPS × h, $P = 0.04$) for +LPS vs -LPS at 2, 12, and 24 h. Plasma Met, Leu, Val, Gln, and Orn of +LPS vs -LPS steers were greater (Met, Leu) or not different (Val, Gln, Orn) at 0 h, not different at 2 and 4 h, lower at 8 (all) and 12 h (Met, Val, Gln, Orn), and either not different (Met, Val, Orn) or greater (Leu, Gln) at 24 h (LPS × h, $P < 0.01$). Plasma Thr, Ser, Asp, Asn, and Glu were lower (LPS × h, $P \leq 0.02$) for +LPS vs -LPS at 2 (Asn), 4, 8, 12, and 24 h (Thr, Ser, Asp, Glu). Plasma Ile and Pro were lower (LPS × h, $P < 0.01$) for +LPS vs -LPS at 4, 8, and 12 h (Ile). Plasma Lys, Tyr, and Trp were lower ($P < 0.05$) for +LPS vs -LPS, and plasma Ala, Pro, and Orn were greater ($P < 0.05$) for +ARG vs -ARG. The +LPS vs -LPS steers tended to have greater ($P = 0.13$) urinary N excretion and lower ($P = 0.11$) N retention, and steers infused with Arg had greater ($P < 0.01$) digested N and tended to have greater ($P = 0.15$) N retention. Abomasal infusion of Arg does not alter the effects of LPS on N metabolism.

Key Words: arginine, lipopolysaccharide, steer

20 Calcium and phosphorus metabolism in finishing steers supplemented with vitamin D_3. J. S. Schutz*[1], M. R. Genho[2], J. A. Scanga[3], K. E. Belk[1], G. C. Smith[1], and T. E. Engle[1], [1]*Colorado State University*, *Fort Collins,* [2]*Ascendant Partners, Inc.*, *Greenwood Village, CO,* [3]*Elanco Animal Health*, *Greenfield, IN.*

Twelve Angus steers (435kg ± 5.01) were used to determine the effect of high dietary vitamin D_3 (Vit D_3) on Ca and P metabolism in feedlot cattle. Steers were randomly assigned to one of 2 treatments: 1) 0.5×10^6 IU of Vit D_3•hd^{-1}•d^{-1} (0.5 Vit D_3) or 2) 5.0×10^6 IU of Vit D_3•hd^{-1}•d^{-1} (5.0 Vit D_3) for 8 consecutive days. Steers were maintained on a basal ration for 7 d, followed by 8 d of Vit D_3 supplementation and then 5 d of basal ration. Vitamin D_3 was administered via a premix carrier immediately before feeding the basal diet to assure complete consumption of Vit D_3. Individual daily DMI, 24-h urine volume and fecal excretion were recorded and sub-sampled daily for subsequent Ca and P apparent absorption and retention determination. Jugular blood samples were obtained before initiation of Vit D_3 supplementation, at the end of Vit D_3 supplementation, and 5 d following Vit D_3 supplementation. Vitamin D_3 supplementation increased ($P < 0.05$) serum concentrations of 25-OH_2-Vit D_3 in both treatments. Steers supplemented with 5.0 Vit D_3 had greater ($P < 0.05$) serum concentrations of 25-OH_2-Vit D_3 than 0.5 Vit D_3 supplemented steers. Serum Ca concentrations were higher in steers supplemented with 5.0 Vit D_3 compared with 0.5 Vit D_3 supplemented steers. Relative to baseline measurements for each treatment, apparent absorption and retention of Ca were reduced ($P < 0.05$) in steers supplemented with 5.0 Vit D_3 but not altered in steers supplemented with 0.5 Vit D_3. Apparent absorption and retention of dietary P were similar for both treatments. Daily urine excretion increased ($P < 0.05$) from the pre-supplementation period to the end of the Vit D_3 supplementation period and remained greater ($P < 0.05$) throughout the subsequent 5 d non-Vit D_3 supplementation period relative to baseline excretion volumes in

5.0 Vit D_3 supplemented steers. Supplementation of feedlot steers with 5.0 million IU of Vit D_3•hd^{-1}•d^{-1} increased serum Ca concentrations, decreased Ca absorption, and decreased retention of Ca.

Key Words: vitamin D, calcium, phosphorus

21 Genetic and environmental influences on distribution patterns of beef cattle grazing foothill rangeland. D. W. Bailey[1], S. Marta*[1], D. Jensen[2], D. L. Boss[2], and M. G. Thomas[1], [1]*New Mexico State University*, *Las Cruces,* [2]*Montana State University*, *Havre.*

A study was conducted in foothill rangelands of northern Montana to determine the relative effects of genotype and environment (or early learning) on grazing distribution. Based on 5 years of observations, 5 of 180 Hereford and Tarentaise crossed cows that used the highest and steepest terrain (hill climbers) and 5 cows that used the most gentle terrain near water (bottom dwellers) were used as donors for embryo transfer. A single AI sire was used in these matings. Crossbred recipient cows were classified as hill climbers (HC) and bottom dwellers (BD) based on 4 years of observation from a separate herd of 98 cows. This resulted in 2x2 factorial study with donor and recipient as the 2 factors and HC and BD as the 2 levels within each factor. A total of 28 of these cows were observed in late summer of 2009 when they were mature (4 to 6 years of age). Horseback riders recorded positions of cows during the early morning when they were gazing for 10 d during the 6 weeks cows were in the 336 ha study pasture. Elevation in the pasture ranged from 1184 to 1398 m and the average slope was 34%. Horizontal distance to water, elevation, and slope of the recorded positions of each cow were averaged together resulting in one value for each trait for each cow. Donor (genotype), recipient (environment) and the donor*recipient interaction were used as fixed effects in the statistical analyses. Distance from water and slope use were not affected by donors, recipients or the donor*recipient interaction ($P > 0.20$). Daughters of HC donors (1314 ± 7 m) used higher elevations ($P = 0.04$) than those from BD (1290 ± 8 m), and cows raised by HC recipients (1315 ± 7 m) also used higher elevations ($P = 0.04$) than cows from BD recipients (1290 ± 8 m). Cattle use of higher elevations in foothill rangeland appears to be influenced to at least some degree by both genetic (donor dam -daughter relationships) and environmental factors such as early learning (recipient dam - daughter relationships).

Key Words: genotype, early learning, behavior

22 *Propionibacterium acidipropionici* P169 and glucogenic precursors to improve rumen parameters associated with low quality forage. P. H. Sanchez,* L. Tracey, J. Browne-Silva, and S. L. Lodge-Ivey, *New Mexico State University*, *Las Cruces.*

Cattle grazing dormant western rangelands tend to have a high ruminal acetate to propionate ratio (A:P) and may have low tissue clearance of acetate. Two studies were conducted to evaluate the effects of *P. acidipropionici*, P169 (P169) on VFA production, forage digestibility, and rumen bacterial ecology. In Exp. 1, in vitro effect of P169 on IVDMD and VFA production was evaluated in a 2 × 2 factorial arrangement of treatments. Factors were substrate (dormant warm-season grass extrusa or 50:50 Sudan:corn, DM basis) and P169 (with or without). In Exp. 2, 12 2-yr old, pregnant Brangus heifers (BW = 416 ± 85 kg) were assigned to 1 of 3 treatment (n = 4). All cattle were fed a basal ration consisting Old World Blue stem hay at 1.5% BW 10 d before initiation of treatment and for the duration of the experiment. Treatments were 1) protein supplement (36% CP, 35% UIP of CP, DM basis, fed at 454 g/hd per d; CON), 2) CON plus P169 (6×10^{10} cfu/hd, twice per d; P169), 3) calcium-propionate supplement fed at 454 g/hd per d (36% CP, 53% UIP of CP + 80 g calcium propionate; PROP). Ruminal fluid was collected and analyzed for VFA, ammonia, pH and community DNA was extracted for denaturing gradient gel electrophoresis (DGGE). Glucogenic potential of treatment was evaluated with an acetate tolerance test on d 49. In Exp. 1, IVDMD, total VFA, acetate, propionate, and A:P increased ($P < 0$ 0.001) in both extrusa and 50:50 with P169 addition. In Exp. 2, the only effect of P169 on rumen parameters was a 4.3% increase in propionate ($P < 0.02$) over CON. Calcium-propionate supplement increased propionate and decreased A:P by 7.8% and 5.9% respectively ($P < 0.004$) over CON. Similarity of bacterial populations between treatments was evaluated with construction of a DGGE dendrogram using the Dice coefficient and samples were 73.9 ± 6.38% similar. Acetate half-life did not differ by treatment ($P = 0.49$). These data indicate that addition of propionate-producing bacteria to low quality forage diets could be as beneficial as supplementing with a propionic salt.

Key Words: cattle, propionate, *Propionibacterium acidipropionici*

23 Effects of supplemental docosahexaenoic acid to ewes on lamb production, immunocompetence, serum metabolites, and thermogenesis. J. I. Keithly,* R. W. Kott, J. G. Berardinelli, S. Moreaux, and P. G. Hatfield, *Montana State University*, *Bozeman*.

Eighty twin-bearing Targhee ewes (ages 2 to 5 yr; 68.5 ± 3 kg) were stratified by age and assigned randomly to 1 of 2 supplemental treatments to determine the effects of feeding algae containing docosahexaenoic acid (DHA) to ewes during late gestation and early lactation on lamb growth (from birth to 38 d), passive immunity (anti-Parainfluenza Type 3 titers), serum metabolites, and thermogenesis. Treatment supplements were formulated to be isocaloric and isonitrogenous, and when fed at the rate of 0.9 kg daily with a 10% CP and 58.1% TDN hay met the CP and TDN requirements of a 70-kg twin-bearing ewe during late gestation. Supplement treatments were: 1) 12 g/ewe daily of DHA Gold (Advanced Bionutrition Corporation, Columbia, MD), in the form of algal biomass (ALGAE), and 2) no DHA (CONTROL). Diets were individually fed (40 ewes/treatment) daily during the last 30 d of gestation and pen fed (6 pens/treatment, and 6 or 7 ewes/pen) during the first 38 d of lactation. One hour after lambing, twin-born lambs were weighed, bled via jugular puncture, and placed in a 0°C dry cold chamber for 30 min. Lamb rectal temperature was recorded every 1 min. After cold exposure, lambs were removed from the cold chamber, bled via jugular puncture, and returned to their dam. Lambs were weighed and bled via jugular puncture on the final day of the trial (38 d of age ± 7 d). Lamb sera were assayed for glucose, NEFA, cortisol, and anti-Parainfluenza Type 3 (PI_3) titers. There was a treatment by time interaction ($P < 0.01$) for lamb rectal temperature. Lambs born to ALGAE ewes had higher ($P = 0.09$) rectal temperatures at 0 min compared with CONTROL lambs, but rectal temperature did not differ ($P \geq 0.11$) at any other time during cold exposure. Glucose, cortisol, NEFA, anti-PI_3 titers, and birth weights did not differ between treatments. Lamb 38-d BW was greater ($P = 0.03$) in lambs born to CONTROL ewes than in lambs born to ALGAE ewes. Supplementation of DHA during late gestation and early lactation did not appear to benefit lamb production, or factors that may impact production.

Key Words: docosahexaenoic acid, lamb production, thermogenesis

24 Sustainability implications of feedlot management practices. K. L. Cooprider,* F. M. Mitloehner, and A. L. Van Eenennaam, *University of California*, *Davis*.

There is an increased consumer demand for animal products that have been raised sustainably. This term has many definitions, but generally

refers to some balance of environmental, social, and economic goals. The use of biotechnologies that increase units of output (e.g., pounds of meat) with the same or fewer inputs should be included in sustainability assessments. The objective of this project was to quantify the inputs (days on feed, kg feed fed and refused, ADG, health treatments) and outputs (carcass measurements, greenhouse gas emissions) associated with 2 feedlot cattle management regimens: Never Ever 3 (NE3) and conventional cattle (CON). The former treatment group received no feed additives or implants, whereas the latter were implanted with Synovex Choice (Fort Dodge) on d 1 and d 70, and were additionally fed Elanco's Rumensin (330 mg/head/day), Tylan (90 mg/head/day), and for the 29 d before shipping Optaflexx β-agonist (254 mg/head/day). Angus-cross steers were stratified by BW (n = 104; 337 kg ± 17) and randomly assigned to 4 pens per treatment group. Amount of feed fed per pen and refusals were recorded daily. Animals were shipped on a constant average pen weight basis (Target 590 kg; actual 596 kg ± 32 BW). The CON cattle had higher ADG (1.81 vs. 1.35 kg, $P < 0.01$), and were on feed fewer days (146 vs. 188 d, $P < 0.01$) than NE3. No significant differences were observed in HCW or dressing percentage between groups ($P > 0.05$), however CON carcasses had larger ribeyes (87 vs. 80 cm^2, $P < 0.01$), lower USDA marbling score (5.4 vs. 6.2, $P < 0.01$), backfat thickness (1.64 vs. 1.84 cm, $P < 0.05$) and yield grade (3.38 vs. 3.95, $P < 0.01$) as compared with NE3. Overall, CON cattle consumed 393 kg less feed in the feedlot (1250 vs. 1643 kg, $P < 0.05$). Although additives resulted in additional costs in CON steers, cost of feed per kg of gain was significantly lower ($1.12 vs. $1.35/kg, $P < 0.05$) relative to NE3. The use of implants and feed additives reduced feed inputs and production resources required to produce a fixed amount of output, with resultant environmental and economic sustainability advantages.

Key Words: feedlot, sustainability, biotechnology

25 Effect of ram exposure on temporal patterns of progesterone and metabolic hormones concentrations in 18-mo-old virgin Targhee ewes during the transition into the breeding season. R. B. McCosh*[1], E. M. Berry[1], M. E. Wehrman[1], R. R. Redden[1], R. W. Kott[1], D. Hallford[2], and J. G. Berardinelli[1], [1]*Montana State University*, *Bozeman,* [2]*New Mexico State University*, *Las Cruces.*

The objective was to determine if ram exposure during the transition into the breeding season altered progesterone (P4), cortisol, triiodothyronine (T3), thyroxine (T4), T3:T4 ratios, prolactin (PRL) or IGF-1 concentrations in 18-mo-old Targhee ewes. Anestrous ewes were stratified by residual feed intake (RFI) score (efficient; n = 12); middle; n = 12; inefficient; n = 12) and assigned randomly to be exposed to rams (RE; n = 18) or wethers (NE; n = 18). Ewes within exposure type were assigned to one of 2 pens (1 male/9 ewes/pen); with 33 m separation between RE and NE pens. Blood samples were collected from each ewe by jugular venipuncture every other day for 20 d, beginning on the first d of exposure. Samples were assayed for P4, cortisol, T3, T4, PRL, and IGF-1. Resumption of luteal activity began earlier ($P < 0.05$) in RE than in NE ewes. There were no differences in patterns of cortisol, T3 or IGF-1 concentrations, or T3:T4 ratios between RE and NE ewes or among ewes with efficient, middle, or inefficient RFI scores. There was a treatment by day interaction ($P < 0.05$) for T4 and PRL concentrations. Concentrations of T4 in RE ewes decreased less rapidly and over a longer interval before increasing by the end of the sampling period than those in NE ewes. Concentrations of PRL were greater in RE than in NE ewes 4 d after exposure but decreased over the next 12 d; whereas, PRL decreased in NE ewes during the first 6 d then increased over the next 14 d. There was an exposure type by RFI score interaction ($P < 0.05$) for BW change. Change in BW did not differ among NE and RE ewes with medium or inefficient RFI scores. However, RE ewe with efficient RFI scores showed a greater increase in BW over the 20-d experiment than NE ewes with efficient RFI scores. Exposing 18-mo-old ewes to rams accelerated resumption of luteal activity and altered T4 and PRL concentrations during the transition into the breeding season. Furthermore, the ram effect appears to alter BW change in ewes with efficient RFI scores differently than in ewes of lower RFI scores.

Key Words: ram biostimulation, seasonal anestrus, metabolic hormones

26 Conjugated linoleic acid decreases prostaglandin synthesis in bovine luteal cells. K. C. P. May,* G. Bobe, C. J. Mueller, and M. J. Cannon, *Oregon State University*, *Corvallis*.

Feeding conjugated linoleic acids (CLA) improves reproductive performance in dairy cows; however, the molecular mechanisms by which CLA improves reproduction are not well understood. Therefore, we evaluated whether the CLA isomers, *trans*-10, *cis*-12 CLA and *cis*-9, *trans*-11 CLA altered synthesis of steroidogenic hormones in bovine luteal cells by measuring concentrations of progesterone, PGE_2, and $PGF_{2\alpha}$ in conditioned medium and expression of genes involved in their synthesis. Confluent luteal cells from each of 4 cows were cultured in 0 μM (control) or 0.1 μM solutions of *trans*-10, *cis*-12 CLA and *cis*-9, *trans*-11 CLA in varying ratios (1:0, 0:1, 1:1, 2:1, 1:2, 5:1, 1:5, 9:1, or 1:9) for 48 h in the presence and absence of 1 μM of the adenylate cyclase activator forskolin. Independent of CLA isomer and ratio, CLA decreased, compared with control, hormone concentrations of prostaglandin $F_{2\alpha}$ (62.6 ± 10.5 vs. 50.4 ± 9.9 pg/mL; $P = 0.003$) and, in the absence of forskolin, prostaglandin E_2 (61.2 ± 11.3 vs. 36.1 ± 10.1 pg/mL; $P < 0.001$) in cultured luteal cells, while no effect was observed for progesterone ($P = 0.94$). Compared with control, CLA decreased relative levels of COX-2 mRNA, a rate limiting enzyme in prostaglandin synthesis, by 1.7 fold ($P < 0.001$) and 3 β-hydroxysteroid dehydrogenase mRNA, a rate limiting enzyme in progesterone synthesis, by 1.4 fold ($P = 0.008$). Relative levels of PGE synthase and PGE_2 9-keto-reductase mRNA, both involved in prostaglandin synthesis, and steroid acute regulatory protein and cytochrome P450 side chain cleavage mRNA, both involved in progesterone synthesis, were not significantly altered by CLA. In conclusion, a potential mechanism by which *trans*-10, *cis*-12 CLA and *cis*-9, *trans*-11 CLA may improve reproductive performance in dairy cows, is by suppressing $PGF_{2\alpha}$ synthesis in luteal cells through attenuating COX-2 gene expression.

Key Words: cattle, corpus luteum, progesterone

27 Camelina meal and crude glycerin as feed supplements for developing replacement beef heifers. P. Moriel,* B. I. Cappellozza, V. Nayigihugu, K. M. Cammack, and B. W. Hess, *University of Wyoming*, *Laramie*.

Two hundred and 4 (n = 99, yr 1; n = 105, yr 2) Angus × Gelbvieh rotationally crossbred heifers were used in a 2-yr randomized complete block designed (RCBD) experiment to determine the effect of feeding camelina biodiesel co-products (meal and crude glycerin) on serum concentrations of thyroid hormones and glucose, as well as on growth and reproductive performance. Heifers were stratified by BW (297 ± 5.8 kg) and randomly allocated to a pen that received bromegrass hay plus 1 of 3 supplements (12.6% CP): control (50% ground corn and 50% soybean meal, as-fed); camelina meal (mechanically extracted); glycerin (50% soybean meal, 33% ground corn, 15% crude glycerin, 2% corn gluten meal; as-fed) for a 60-d period. Preprandial blood samples

were collected via the jugular at d 0, 30 and 60 of the experimental feeding period. On d 60, heifers were synchronized for estrus using a 2-shot PGF2α protocol; any heifer exhibiting estrus was bred via AI 12 h after standing heat. Heifers not exhibiting estrus were given GnRH and bred by AI on d 74. Data were analyzed as a RCBD using the MIXED procedure of SAS with pen as a random effect for BW and reproduction traits; serum parameters were analyzed as repeated measures. Dietary treatment × sampling period interactions were not detected ($P = 0.17$ to 0.87). Dietary treatment did not affect serum T_4 ($P = 0.96$), glucose ($P = 0.59$) or BW at d 30 or 60 ($P \geq 0.40$), but increased ($P = 0.05$) T_3 in heifers fed camelina meal. Additionally, dietary treatment did not affect the percentage of heifers detected in estrus before timed AI ($P = 0.82$), first service conception rates of those heifers detected in estrus ($P = 0.87$), conception rates to timed AI ($P = 0.19$), or overall first conception rates ($P = 0.65$). Heifers fed camelina co-products maintained growth and reproductive performance comparable to heifers fed the control supplement. Therefore, camelina co-products can replace conventional corn-soybean meal supplements.

Key Words: beef heifers, supplementation, biodiesel co-products

28 Use of a portable near infrared spectrophotometer to predict nutrient composition of feces from Holstein cattle fed high-concentrate diets. J. D. Allen,* D. R. Tolleson, L. W. Hall, C. D. Burrows, G. Xie, and G. C. Duff, *University of Arizona*, *Tucson*.

Our objective was to evaluate the application of a chute-side near infrared spectrophotometer (NIRS) analysis to predict nutrient composition of feces from Holstein cattle. Growing Holstein cattle (42 steers and 2 freemartin heifers; average initial BW = 220 kg) were fed either 86 or 90% steam-flaked corn-based concentrate diets (3 pens/diet with 7 to 8 animals/pen). Fecal samples were collected in plastic bags and scanned within 2 h after collection using an ASD Field Spec NIRS unit (Boulder, CO). Spectra were collected under ambient conditions using a contact probe. Samples were then dried at 60°C, ground in a Wiley mill to pass a 1 mm screen and analyzed for DM, CP, NDF and ADF. Calibrations were developed using samples collected on d 0 and 28 with log 1/R spectra in the 1,100 to 2,400 nm range. Partial least squares (PLS) regression in SAS was used to develop calibrations. Cross validation was employed to determine the number of PLS factors to use. Simple regression was used to evaluate the relationship between observed and predicted constituent values. Although regression values were moderate for predicting CP ($R^2 = 0.88$) and fair for DM ($R^2 = 0.68$) and NDF ($R^2 = 0.62$), prediction regression values for ADF were statistically significant ($P < 0.01$) but not predictive ($R^2 = 0.34$). Our data indicate that while our calibrations were variably successful, validations were mostly unsuccessful ($R^2 < 0.4$). Lack of validation success is most likely due to small sample number and limited range of values. However, this project has illustrated a relationship between NIR spectra and the observed laboratory values for these constituents, and that the use of a portable NIRS on-site may improve the nutritional management of a commercial feedlot.

Key Words: NIRS, Holstein, nutrient composition

29 Effects of implant type and protein source on growth performance of steers grazing summer pasture. C. P. McMurphy,* E. D. Sharman, D. A. Cox, G. W. Horn, and D. L. Lalman, *Oklahoma State University*, *Stillwater*.

Implants consistently increase performance 10 to 15% in grazing cattle and supplemental protein is necessary in late summer when forage is maturing and rumen ammonia-N is first limiting. Therefore, a split-plot design was used to investigate the effects of implant type and protein source on performance of steers grazing summer pasture. Crossbred steers (n = 392; BW = 212 ± 24 kg) were ranked by weight and randomly assigned to 1 of 15 pastures and then randomly allotted to implant treatment, within pasture. Supplement treatments were control (no supplement), dried distillers grains with solubles (DDGS; 33% CP), and cottonseed meal (CSM; 33% CP). Implant treatments were control (no implant), Ralgro and Component TE-G. The grazing season was 126 d with supplementation beginning in late July. Steers were group fed, within pasture, each wk on Monday, Wednesday and Friday at a rate of 0.95 kg•steer^{-1}•feeding^{-1}. Data were analyzed using PROC MIXED procedure of SAS where supplement treatment served as the whole-plot and implant treatment served as the sub-plot. Orthogonal contrasts were used to determine the effects of supplementation, supplement type, implantation and implant type. Protein supplementation increased ($P < 0.05$) BW and ADG by 12 and 0.16 kg, respectively. Compared with CSM, DDGS improved ($P < 0.05$) ADG by 0.05 kg resulting in improved supplement efficiency (2.39 vs. 3.49 kg of supplement per kg of additional ADG for DDGS and CSM, respectively). Implantation increased final BW ($P = 0.02$) and improved ADG 8.1% ($P < 0.05$) during the first ~95 d, but implant type had no influence on rate of BW gain during this period. During the final ~31 d of the grazing season there was no difference in ADG for Ralgro and non-implanted steers, while Component TE-G increased ($P < 0.05$) ADG by 0.08 kg. Steer performance was enhanced when supplemental CSM was replaced by DDGS. Furthermore, Component TE-G implants enhanced weight gain further into the grazing season than Ralgro.

Key Words: implants, supplementation, grazing steers

30 The effect of morbidity on feedlot performance and carcass quality in feedlot steers. K. J. Austin*[1], J. L. Seabrook[1], T. E. Engle[1], R. K. Peel[1], C. M. McAllister[1], B. W. Brigham[1], R. M. Enns[1], R. L. Weaber[2], H. Van Campen[1], G. H. Loneran[3], J. L. Salak-Johnson[4], and C. C. L. Chase[5], [1]*Colorado State University*, *Fort Collins,* [2]*University of Missouri*, *Columbia*, [3]*West Texas A & M University*, *Canyon*, [4]*University of Illinois*, *Urbana*, [5]*South Dakota State University*, *Brookings*.

The objective of this project was to examine the effects of morbidity in feedlot cattle on animal performance, carcass quality, and subsequent carcass value. Performance and morbidity data were collected over a 2 year period (year 1 n = 1551; year 2 n = 1319). Steers were randomly assigned to 9-head pens and fed a commercial feedlot ration for 230 ± 5 d (year 1 and year 2) with an average entry weight of 224 kg or 219 kg for year one or 2, respectively. Body weight and ultrasound measurements of ribeye area (REA), intramuscular fat (IMF) and backfat (BF) were collected at 6day intervals between d0 and d180. Animal performance data in conjunction with yield and quality grade measurements at the time of slaughter were analyzed to determine impacts on performance resulting from feedlot morbidity. Morbidity was defined as behavioral and/or physical abnormalities observed during daily rounds (between 0700 and 0900), severe enough to warrant pharmaceutical treatment and/or isolation pens from designated treatment pens. For year one, morbidity was a source of variation for ultrasound BF and REA measurements ($P < 0.01$, $P = 0.02$, respectively), and resulted in lower final live body weight ($P = 0.01$). For year 2, morbidity was a source of variation for final live body weight and hot carcass weight (HCW) ($P < 0.01$), and calculated yield grade was marginally lower in morbid steers ($P = 0.08$). Feedlot morbidity was a factor in reducing the performance and ultimate carcass yield from the steers in this experiment.

Key Words: carcass characteristics, feedlot performance, morbidity

31 Changes in hepatic gene expression in steers administered high-S water with or without supplemental Mo. K. L. Kessler*[1], K. C. Olson[2], C. L. Wright[2], K. J. Austin[1], and K. M. Cammack[1], [1]*University of Wyoming*, *Laramie*, [2]*South Dakota State University*, *Brookings*.

High-S water is associated with reduced performance, poor health, and an increased incidence of polioencephalomalacia (PEM) in ruminant livestock. Changes in expression of immune function and inflammatory response genes have been shown in steers administered high-S water. Our objective was to determine changes in hepatic gene expression in steers administered low-S water or high-S water with or without supplemental Mo. Yearling steers (n = 96) were randomly assigned to a low-S water (LS; 375 mg SO_4/L), high-S water (HS; 2,218 mg SO_4/L), or high-S water plus Mo (HSMO; 2,218 mg SO_4/L; 100 mg Mo/kg DM) treatment for 56 d. Body weights were recorded on d −1, 29, and 57, and liver biopsies were conducted on d 57. Feed intake (as-fed basis) was lower in HSMO steers than HS ($P = 0.018$) and LS ($P = 0.002$) steers. Also, ADG was lower ($P < 0.001$) in HSMO steers than LS and HS steers, with HS steers being intermediate. For real-time RT-PCR analysis, RNA was extracted from liver tissues of 8 randomly selected steers within each treatment. Genes selected for analysis included *Reg1*, *TGFβ1*, *INHβA*, *Iβ2*, *TG2*, and *APP*, all of which were affected by high-S water in a previous study. Relative expression values were tested for treatment differences using the GLM procedure of SAS. Expression of *TG2* tended to be greater in HS steers than LS ($P = 0.08$) and HSMO ($P = 0.06$) steers. However, *TG2* expression was not different between LS and HSMO steers, indicating that Mo prevented the change in *TG2* expression induced by high-S water. Expression of *APP* was lower in HSMO steers than both LS ($P < 0.001$) and HS ($P = 0.04$) steers. No differences in *APP* expression were detected between LS and HS steers, indicating that the downregulation of *APP* in the HSMO steers was due to the Mo treatment, not the high-S water. No other changes in gene expression were observed. Results from this study indicate that hepatic gene expression is altered in response to high-S water and possibly Mo treatment. Further work is needed to determine other genes and metabolic pathways affected by high-S water consumption in ruminant livestock.

Key Words: gene expression, sulfate water, beef cattle

Symposium: National Extension Workshop: The Impact of Major Food Policy Shifts on the US Food Supply and its Producers: Animal Welfare Issues

32 Washington Update. R. D. Reynnells,* *USDA/NIFA/PAS*, *Washington, DC*.

The 2010 Extension Special Recognition Award is presented to Greg Martin, The Pennsylvania State University. Greg has been an integral part of the planning for the Poultry Science Association (PSA) National Extension Workshop, member and Chair of the PSA Extension Committee and made significant other contributions to extension programming. On October 1, 2009 the National Institute of Food and Agriculture replaced the Cooperative State Research, Education and Extension Service. Multi-state research committees are creating innovative programs: the NCCC209 (Agricultural Bioethics) and NC1029 (Applied Animal Behavior and Welfare) collaborated on a USDA educational grant. A 5 year portfolio review for Plant and Animal Systems was completed in 2009, but otherwise are conducted internally each year. Areas of primary responsibility are: (Knowledge Area (KA) 306, Environmental Stress in Animals; KA308, Improved Animal Products (Before Harvest); KA315, Animal Welfare). The 2009 Southern Region (Quadrennial) Poultry Extension Workshop, was held in Raleigh, NC, (contact Ken Anderson, NC). Edgar Oviedo (NC) is the coordinator of the 2010 National Poultry Waste Management Symposium. The 2009 Future Trends in Animal Agriculture symposium provided a balanced discussion on what animal production and processing would and should look like in 2030, and other animal welfare (AW) issues. The Council for Agricultural Science and Technology scheduled their Food Animal Agriculture Symposium for June, 2010. The annual Animal Welfare Assessment Contest is open to undergraduate, graduate and veterinary students at Land Grant and other universities, and was held at Michigan State University. The contest focuses on AW and animal behavior areas, and emphasizes the importance of collaboration between disciplines and commodities to address AW and related issues. Bioethics (ethics as applied to biological systems) is an important component of discussions of AW and animal rights concepts and issues. Bioethics discussions help us understand value-driven perspectives of members of society, and proposed mandated restrictions regarding animal use.

Key Words: special recognition award, animal welfare, bioethics

33 The impact of major food policy shifts on the US food supply and its producers: Animal welfare issues. J. Reynolds,* *University of California*, *Davis*.

Major governmental policy shifts that have impacted the welfare of farm animals in the US have included changes in farm subsidy programs, milk price supports, subsidizing ethanol production and increasing environmental regulations. These have had effect on the consolidation of farm production and subsequent changes in animal housing and management. In the US many policies are determined by the private sector, not the government. This has been the case with farm welfare issues. Because our society prefers industries to set standards or regulations the trend in the US has been for retailers of food products to work to develop welfare standards tolerated by consumers. Examples using the housing of poultry and sows and cattle tail docking and dehorning will be discussed to illustrate the effects of governmental policy driving consolidation and production efficiency and the attempts by retailers to counteract the dissonance in animal welfare experienced by animals and consumers.

34 Animal agricultural conflict as competing worldviews. W. Jamison,* *Cornerstone Public Relations, LLC*, *Tequesta, FL*.

Animal Agriculture in industrialized nations has become the locus of intense conflict regarding the proper role and treatment of animals. Most analysis of the related animal welfare issues involves physiological, behavioral, or economic research focused on confinement systems and their impacts on the animal. Nonetheless, all of these analytic constructs are socially derived in that the larger social and political context defines what constitutes acceptable research and valid questions. However, this paper argues that animal welfare can be better understood as a social conflict between the competing worldviews regarding animals and their roles in human life. Consumptive-instrumentalist worldviews accept that animals and animal products will be slaughtered and consumed for human benefit; hence animal welfare becomes a function of that reality. Aesthetic-instrumentalist worldviews conversely understand the role of animals as companions or in other aesthetic roles for human benefit, hence animals are protected from consumptive uses. These 2 views are irreconcilable in that consumptive-instrumentalism results in animal death, while the goal of aesthetic-instrumentalism is the perpetuation of animals for human benefit.

35 Update on the *Guide for the Care and Use of Agricultural Animals in Research and Teaching*. J. J. McGlone*[1] and J. Swanson[2], [1]*Texas Tech University*, *Lubbock*, [2]*Michigan State University*, *East Lansing*.

In January 2010, the third edition of the Ag Guide was published. The first edition was in 1988 and the first revision was in 1999. The third edition of the Ag Guide had 62 authors with expertise in each common species of farm animal and from each major discipline of the animal sciences. In addition, the authors represented the diversity of the FASS membership and Veterinarians and Agricultural Engineers. This updated Ag Guide is different in some meaningful ways. Previous editions used the title of agricultural animals in agricultural teaching and research. The title was changed by deleting the second use of the word agricultural. The authors concluded that this Guide applies to care of agricultural animals in any type of research and teaching (biomedical or agricultural). Two new chapters were added: farm animal handling and transport, and environmental enrichment. The husbandry and animal health chapters were reorganized and expanded. Information on biosecurity and genetically engineered animals was added. The scientific literature was updated in each species chapter. The veal chapter was deleted and information in calf husbandry was added to the beef and dairy chapters. The revised Ag Guide suggests that all animal uses be understood and managed by the institution, including field studies on commercial farms. The revised Ag Guide will be a useful resource to people that conduct and oversee research and teaching using agricultural animals.

Key Words: animal care, animal welfare, animal research

36 Update on horse slaughter. K. Martinson*[1] and T. Lenz[2], [1]*University of Minnesota*, *St. Paul,* [2]*Pfizer Animal Health*, *Louisburg, KS.*

Slaughter is the humane ending of an animal's life under federal regulation when the carcass is processed for food. Legislation surrounding horse slaughter began in 2001 when a bill prohibiting the transport of horses to slaughter was introduced. This bill was never taken up by the House. In 2003 and 2004, The American Horse Slaughter Prevention Act

(HR 857) was introduced to prohibit the slaughter of horses for human consumption. A similar bill was introduced in the Senate (S 2352). Both limited the methods available for euthanasia of horses, including penetrating captive bolt, the method used at processing plants. Neither bill moved out of committee. The Horse Slaughter Prohibition Bill (HR 503) was introduced in the House in 2005 and aimed to prohibit the sale or transportation of horses to slaughter for human consumption. A similar bill was introduced in the Senate (S 1915). In 2006, HR 503 passed the House, but was not taken up by the Senate. In 2007, HR 503 was reintroduced along with a new Senate bill (S 311). Both bills aimed to end slaughter of the US horse for human consumption and prohibited export to other countries. Neither bill has moved forward. In 2007, a 1949 TX law that prohibited the slaughter of horses was discovered and enforced. That same year, IL bill HB 1711 was passed and banned slaughter of horses for human consumption in IL. Both bills closed the remaining horse processing plants in the US. In 2008, The Prevention of Equine Cruelty Act (HR 6598) was introduced and aimed to impose a fine or prison term for possessing, shipping, or transporting horses or horse parts for human consumption. The bill was reintroduced in 2009 (HR 503) but has not been taken up by the House. In 2009, the Senate ordered an investigation into the impact that banning US horse slaughter has had on horse welfare and farm income. The study should be released by March 2010. Some states have also introduced horse slaughter bills. A consequence of banning equine processing has been an increase in unwanted horses. In MN, the number of horses involved in humane cases increased 411% between 2003 and 2008. This issue is likely to influence development and content of future equine Extension programs across the US.

Key Words: horse, slaughter, legislation

POSTER PRESENTATIONS

Animal Behavior and Well-Being: Livestock

M1 Rubber flooring impact on health of dairy cows. S. D. Eicher*[1], D. C. Lay Jr.[1], J. D. Arthington[2], and M. M. Schutz[3], [1]*USDA-ARS*, *West Lafayette, IN,* [2]*University of Florida*, *Ona,* [3]*Purdue University*, *West Lafayette, IN*.

Rubber flooring in dairies has become popular because of perceived cow comfort. The objective of this longitudinal study was to evaluate locomotion, stress, and immunity over the first 180d of each of the 1st and 2nd lactations of cows assigned to free-stall housing with either rubber (RUB) or concrete (CON) at the feed-alley of their housing. Cows entered the experiment at d −60 before 1st (n = 30) lactation and were observed over 2 lactations. Between lactations cows remained in a straw bedded-pack dry-cow pen. Locomotion scores and blood samples were obtained at approximately −60, −30, 0, +7 and weekly through d +189 relative to calving throughout 2 lactations. Data were analyzed as a completely randomized design with repeated measures. Chi Square analysis was used to evaluate hoof pathologies. Cortisol responses were only affected by d ($P = 0.05$). White blood cell (WBC) counts increased for CON cows compared with RUB cows after d 63 through 182. WBC counts returned to similar counts of RUB cows over the dry period, but quickly became greater than those of CON cows after parturition (9.0, 9.5, and 7.8, and 11.0, 8.8, and 13.0×10^6 cells/mL for RUB and CON cows at d 142, parturition, and d 142 of 2nd lactation; treatment by d interaction, $P < 0.01$). Neutrophil counts only tended to be affected by d ($P = 0.10$) and a weak trend ($P = 0.13$) for a treatment by d interaction was detected. Lymphocyte counts followed the pattern of WBC counts, but only had a trend ($P = 0.08$) for a treatment by d effect (4.9, 5.1, and 5.3, and 6.8, 5.1, and 8.4×10^6 cells/mL for RUB and CON cows at d 142, parturition, and d 142 of 2nd lactation; treatment by d interaction, $P < 0.01$). Monocytes counts were not affected by treatment or time ($P > 0.10$). Haptoglobin (treatment by d interaction, $P = 0.15$) and ceruloplasmin (week effect, $P = 0.08$) were not affected by treatment. Hoof pathology was different by number of treatments that were required (RUB = 2.1 and CON = 1.4; $P = 0.03$). Lame and sound classifications were not different between treatments ($P = 0.13$). These data show that flooring affected cow hoof and leg health and altered immune cell counts, which may indicate an underlying chronic inflammation.

Key Words: innate immunity, rubber flooring, stress

M2 Rubber flooring impact on production and herdlife of dairy cows. M. M. Schutz*[1] and S. D. Eicher[2], [1]*Purdue University*, *West Lafayette, IN,* [2]*USDA- ARS*, *West Lafayette, IN*.

Use of rubber flooring in dairies has become popular because of perceived cow comfort. The overall objective of this longitudinal study was to evaluate production, reproduction, and retention of first and second lactations of cows assigned to either rubber (RUB) or concrete (CON) flooring at the feed alley. Feeding system included headlocks; and cows were fed once daily, with feed pushed up 5 times daily. Grooved concrete cow alleys provided access to 2 rows of free stalls in each pen. Cows entered the experiment at d −60 before 1st (n = 13 for CON and n = 17 for RUB) lactation and were observed over 2 lactations. Between lactations cows remained in a straw bedded-pack dry-cow pen. Production and health data were recorded throughout both lactations. Date left was recorded for each cow or considered to be 4 years after first calving for cows still in the herd. Milk, fat, and protein; somatic cell scores (SCS); and numbers of days open and inseminations were analyzed as linear models using Proc Mixed of SAS. Explanatory variables in models included fixed effects of treatment, age and year-season of calving, and number of days open. Days from calving to exiting the herd were analyzed separately by parity. RUB increased mature equivalent (ME) fat (488 vs 432 kg), ME protein (364 vs 326 kg), and protein % (2.99 vs 2.81%) and persistency of the milk lactation curve (114 vs 106%) ($P < 0.04$) and tended to increase fat % (4.02 vs 3.70%) ($P < 0.10$) in first parity. However, for second parity, CON increased ME fat (524 vs 432 kg) ($P < 0.04$) and tended to increase fat % (3.95 vs 3.49%) ($P < 0.08$). Treatment did not affect days of herd life from first calving, but those cows calving a second time tended to remain in the herd more days after second calving on CON (660 vs 368 d) ($P < 0.08$). Treatment by parity interactions were confirmed in repeated records analyses. These data indicate that flooring can influence production and herd life. Rubber flooring for cow comfort may not be justified solely in terms of yields and herd life.

Key Words: housing, production, rubber flooring

M3 Motivation to walk affects speed but not gait score in dairy cattle. A. K. Barrientos*, M. A. G. von Keyserlingk, and D. M. Weary, *University of British Columbia*, *Vancouver, Canada*.

Gait scoring systems have been developed as a tool to improve early detection and treatment of lameness; however, a variety of confounding factors including motivation to walk to toward an attractive resource (such as fresh feed) may affect the way cows walk. Our aim was to vary motivation to walk (by providing a food reward) testing the prediction that increased motivation will a) increase walking speed and b) reduce gait score (i.e., make lame cows appear sound). Eleven cows, scored for presence and severity of hoof lesions and balanced for lameness, were trained to walk individually down a 16 m test alley. Cows received 4 training sessions per day; during each session cows were randomly assigned to either receive a food reward (from a feed bin visible from the end of the alley) or not. After 5 d of training cows were tested using the same procedure. Walking speed (m/s) was recorded electronically using light sensors. Gait was scored using a 1-to-5 numerical rating system (NRS; 1 = sound, 5 = severely lame) and a continuous 100-unit visual analog scale (VAS) of 6 gait attributes (back arch, head bob, tracking-up, joint flexion, asymmetric steps, and reluctance to bear weight). Cows walked faster when they were given a reward than when they were not rewarded (1.22 ± 0.02 m/s vs. 1.01 ± 0.02 m/s, $P < 0.001$). This increase in walking speed tended to be lower for cows with sole ulcers, interdigital hyperplasia or both than for cows without these conditions (0.16 ± 0.04 m/s vs. 0.28 ± 0.05 m/s, $P = 0.08$). Provision of a reward had no effect on NRS (3.26 ± 0.04 vs. 3.34 ± 0.04, $P = 0.20$). However, the food reward affected certain gait characteristics; cows had greater back arch (54 ± 1 vs. 50 ± 1, $P = 0.01$), but better tracking up (44 ± 3

vs. 53 ± 3, $P = 0.05$), when provided a food reward. These results show that motivation to walk affects walking speed and gait attributes likely affected by speed (back arch and tracking up), but that overall gait score remains consistent.

Key Words: lameness, locomotion, reliability

M4 Resting patterns of dairy cows and housing characteristics. A. Bach*[1,2] and I. Guasch[1], [1]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain*, [2]*ICREA, Barcelona, Spain*.

One hundred and 41 lactating Holstein cows (milk yield = 37.1 ± 7.6 kg/d, DIM = 136 ± 67 d) wearing a pedometer able to record daily number of lying bouts and lying time were monitored for a period of 6 mo to evaluate whether resting behavior was affected by the characteristics of different pens within a farm. Cows were distributed in 8 different pens holding an average of 67 ± 14 cows with about 25% of the cows in each pen wearing a pedometer. All cows received the same ration and were milked 3 times daily. Average ratios of stalls and feedbunk per cow were 1.0 ± 0.22 and 1.12 ± 0.17, respectively. Average distance from the neck rail to end the of the stall was 186 ± 12.2 cm, and the diagonal from the top of the neck rail to rear of the stall was 226 ± 7.3 cm. Stall design was not confounded with DIM, as several pens with different stall designs had the same number of DIM. Resting activities were averaged within pen, and a weighted regression analysis (including the proportion of animals wearing a pedometer in each pen as a weighting variable) with DIM as a covariate was used to determine associations between different housing parameters and lying time across pens. Average resting time was 11.4 ± 0.98 h/d distributed in 15.5 ± 2.2 bouts/d. Lying time tended ($P < 0.10$) to be positively correlated with DIM. The numbers of stalls and feed bunk spaces per cow were positively correlated (r = 0.98 and 0.74, respectively) with resting time. The distance between the neck rail and the end of the stall and the diagonal from the top of the neck rail to the end of the stall were also positively correlated (r = 0.69 and 0.72, respectively) with lying time. Stall curb height was negatively correlated (r = −0.87) with lying. Cows lying on stalls with 25 cm or lower curb heights (50% of the pens) rested for 12.3 ± 0.67 h/d and those on stalls with curb heights above 25 cm rested 10.3 ± 0.33 h/d. Providing sufficient number of stalls and feedbunk space should improve lying time. In addition, when designing stalls, an attempt should be made to minimizing curb height and maximizing the diagonal between the end the top of the neck rail and the rear end of the cubicle.

Key Words: behavior, lying, housing

M5 Short-term overcrowding did not affect the feed intake, hygiene, or stress response of Holstein dairy cows. **P. D. Krawczel*[1,2], L. B. Klaiber[1], R. E. Butzler[1], L. M. Klaiber[1], M. P. Carter[1], H. M. Dann[1], C. S. Mooney[1], and R. J. Grant[1], [1]***William H. Miner Agricultural Research Institute***, *Chazy, NY*, [2]***The University of Vermont, Department of Animal Science***, *Burlington*.**

Access to feeding and resting resources is critical to the welfare of dairy cows. The objective of this study was to determine whether housing Holstein dairy cows at stocking densities of 100 (1 cow per stall and headlock), 113, 131, and 142% would affect the well-being (assessed from dry matter intake (DMI), fecal cortisol metabolites and udder and leg hygiene). Multiparous cows (n = 96) and primiparous cows (n = 40) were assigned to 1 of 4 pens (34 cows per pen) in a 4-row freestall barn. Pens were balanced for parity, milk production, days in milk, and somatic cell count. Treatments were imposed for 14 d using a 4 × 4 Latin square design. DMI was assessed at the pen-level over the final 3 d of each period. Fecal cortisol metabolites were measured from samples collected from the focal cows (n = 12) in each pen on d 13 and d 14 of each period. Udder and leg hygiene was assessed using a scale of 1-to-4 on the focal cows, who were groomed on d 1 of each period and scored on d 14. Data were analyzed using MIXED procedure of SAS. DMI (26.4 ± 0.6 kg/d) was unaffected by treatment ($P > 0.10$). Cortisol metabolites (3.2 ± 0.2 ng/g; $P = 0.21$) and udder hygiene score (1.8 ± 0.1; $P = 0.99$) did not differ among treatments. Leg hygiene scores differed between 131 (2.5 ± 0.2) and 142% (2.8 ± 0.2; $P = 0.03$). The mean score when housed at 100 and 113% (2.6 ± 0.2) indicated this observed difference was not biologically meaningful. Overall, the results suggest that well-being, as defined within this experiment, was not affected by short-term overcrowding. However, further research is needed to determine if the same responses are observed over longer durations.

Key Words: dairy cow, overcrowding, well-being

M6 Greater feed bin stocking density increases the social aggression of postpartum dairy cows. P. D. Krawczel*[1,2], D. M. Weary[3], R. J. Grant[1], and M. A. G. von Keyserlingk[3], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*The University of Vermont, Department of Animal Science*, *Burlington,* [3]*Animal Welfare Program, University of British Columbia*, *Vancouver, BC, Canada*.

Beyond dry matter intake, feed bunk management practices that affect feeding-related behaviors may influence the welfare of postpartum dairy cows. The objective of this study was to determine the effects of feed bin stocking densities of 100% (1:1, bin:cow), 133% (1: 1.33), 150% (1:1.5), and 200% (1:2) on the feeding and social behavior of dairy cows during the 3 wk after parturition. Two groups of multiparous, Holstein cows (n = 24) with no clinical illness were housed sequentially in a pen containing 36 freestalls (freestall stocking density was 67%) and 18 feed bins. The pen was managed as a dynamic group to keep stocking density constant. Daily visits to the feed bin were recorded by an electronic feeding system. Meals and total meal time (defined as time feeding from bin plus time of within meal intervals) were calculated from the bimodal distribution of the frequency of the intervals between visits to the feed bins. Social behavior was defined as the number of successful displacements from the feed bin. Displacements were recorded for 3 h following 6 consecutive deliveries of a total mix ration during wk 2 of each cow's lactation. Data were analyzed as a randomized design using the mixed procedure of SAS. The model included week as the repeated measure for feeding behavior. Feed bin visits decreased after wk 1 ($P < 0.001$) and a treatment by week interaction was evident ($P = 0.03$). Meals decreased (from 8.4 ± 0.2 to 7.5 ± 0.2 per day; $P < 0.001$) and total meal time increased (from 3.8 ± 0.1 to 4.9 ± 0.1 h/d; $P < 0.001$) from wk 1 to wk 3, but were not affected by treatment ($P > 0.80$) or treatment by day interaction ($P > 0.10$). At 200%, cows initiated more displacements ($P < 0.03$) and were involved in a greater total number of interactions ($P \leq 0.05$) than the other treatments, but were only displaced more ($P = 0.04$) than the 100% cows. These results are consistent with earlier work on transition cows showing increased aggressive interactions with overcrowding. Future work should consider the role of freestall overcrowding or clinical illness on the response to feed bunk competition.

Key Words: dairy cow, behavior, competition

M7 Lying and standing behavior on farms using deep-bedded versus mattress freestalls. K. Ito*, M. A. G. von Keyserlingk, and D. M. Weary, *University of British Columbia*, *Vancouver, BC, Canada*.

Freestall dairy herds using mattresses experience a higher prevalence of lameness than do herds using deep-bedded stalls. This difference may be due to reduced comfort of mattresses as a lying surface, but the effects of mattresses on lying and standing behaviors are not well understood. The aim of this study was to compare lying and standing behavior on commercial farms using mattresses with minimal bedding (MAT; n = 17) versus those using deep-bedded stalls with sand or sawdust bedding (DB; n = 12). We have previously reported lameness prevalence for these 29 freestall herds: 10.3% severe lameness (score ≥4 on a 5-point gait scoring system) on MAT farms versus 4.6% on DB farms. Using electronic data loggers attached to the hind leg, lying behavior of 48 ± 2 focal cows/farm were recorded at 1-min intervals for 5 d, from which mean lying time (h/d) and the SD of lying time (h/d) among cows within farm were calculated. Numbers of cows that were standing fully inside stall, perching with only 2 feet inside stall, lying down in stall, and feeding were counted on each farm during one farm visit 2 h before afternoon milking. Stall Standing Index (SSI) was calculated as the percentage of cows in the pen not feeding that are standing or perching in the freestall. Effect of stall base on each behavioral variable was tested using a *t*-test. Lying time averaged 11.0 ± 0.7 (mean ± SD) h/d, and did not differ with stall base ($P = 0.5$). However, the variation (SD) in lying time was greater on MAT farms compared with DB farms (2.1 ± 0.07 h/d vs. 1.8 ± 0.08 h/d, respectively, $P = 0.005$). SSI at the time of assessment was 21.6 ± 1.9% on MAT farms compared with 12.0 ± 1.2% on DB farms ($P < 0.001$). In summary, farms using mattresses have more variable lying times, and cows on these farms spend more time standing and perching in the freestall.

Key Words: lameness, cow comfort, stall design

M8 Limit-feeding dairy heifers: Effects of feed bunk space and provision of a low nutritive feedstuff. K. Stevenson, B. L. Kitts, A. M. Greter, and T. J. DeVries*, *Dept. Animal and Poultry Science, University of Guelph, Kemptville Campus*, *Kemptville, ON, Canada*.

The objective of this study was to examine the effects of feed bunk space and provision of a low nutritive feedstuff on the behavior of limit-fed dairy heifers. Twelve Holstein dairy heifers (391.1 ± 44.8 d of age; 415.4 ± 47.2 kg), divided in groups of 3, were exposed to each of 3 treatments in a Latin square design with 7-d periods. The treatments were: 1) 0.68m of feed bunk space/heifer (TMR-0.68), 2) 0.34m of feed bunk space/heifer (TMR-0.34), and 3) 0.34m of feed bunk space/heifer with straw (up to 2kg/animal/d) provided (TMR-S). All heifers were fed a TMR at a restricted level (1.9% of BW), which contained (DM basis) 19.9% haylage, 20.1% corn silage, 49.6% high moisture corn, and 10.4% protein supplement. Group DMI was recorded daily. Feeding behavior and displacements from the feed bunk were recorded for the last 4 d of each period. Data were analyzed in a general linear mixed model. Heifers consumed more DM on the TMR-S treatment provided compared with the TMR-0.68 and TMR-0.34 treatments (9.4 vs 7.8kg/d; SE = 0.07, $P = 0.001$). Feeding time was also longer on the TMR-S treatment (147.7 min/d) compared with the TMR-0.68 and TMR-0.34 treatments (64.5 min/d; SE = 5.5; $P = 0.005$). Within the TMR-S treatment, feeding time on straw was 80.4 min/d, thus the rate of consumption of only the TMR was similar across all treatments. During the first 90 min following feed delivery, when all TMR consumption occurred, very little time (4.0 ± 1.6 min) was spent consuming straw on the TMR-S treatment. During that 90-min time period, the frequency of displacements from the feed bunk was similar (SE = 2.4; $P = 0.5$) between the TMR-0.68 (13.0), TMR-0.34 (13.2), and TMR-S (15.1) treatments. For the TMR-S treatment, heifers displaced each other 8.7 times per day during the rest of the day while consuming straw. As result, there was more competition at the feed bunk on the TMR-S treatment over the course of the day as compared with the other treatments (23.8 vs. 13.1; SE = 2.9; $P = 0.05$). The results suggest that neither increased feed bunk space, nor provision of a low nutritive feedstuff, will reduce competition for, or slow consumption rates of, a limit-fed TMR.

Key Words: limit-feeding, dairy heifer, feed bunk space

M9 Effect of feed type exposure on diet selection behavior of dairy calves. E. K. Miller-Cushon* and T. J. DeVries, *Dept. of Animal and Poultry Science, University of Guelph, Kemptville Campus*, *Kemptville, ON, Canada*.

Dairy cattle exhibit characteristic feeding behavior patterns which may be influenced by early experiences. The objective of this study was to determine how early exposure to different feed types affects diet selection behavior (sorting) of dairy calves once fed a mixed ration. Eight Holstein bull calves were randomly assigned at birth to a feed exposure treatment: 1) concentrate (CONC) or 2) hay (HAY), offered ad libitum. All calves received 8L/d of milk, incrementally reduced after 4 weeks to enable weaning by the end of wk 7. After milk weaning, all calves were fed a mixed ration containing 60% concentrate and 40% chopped hay (as is basis) for 9 weeks. Intake was recorded and calves were weighed 3x/week. Daily samples of fresh feed and orts from each calf were taken biweekly to determine dry matter intake (DMI), and duplicate samples were taken on wk 8, 12, and 16 for particle size analysis. The separator had 3 screens (19, 8, and 1.18mm), producing long, medium, short, and fine particle fractions. Sorting of each fraction was calculated as actual intake as a percentage of predicted intake. Sorting values >100% indicate sorting for, while values <100% indicate sorting against. Data were analyzed using a repeated measures mixed model. CONC calves tended to have higher DMI than HAY both pre-weaning (0.49 vs. 0.16kg/d; SE = 0.12; $P = 0.09$) and post-weaning (3.3 vs. 2.6 kg/d; SE = 0.21; $P = 0.06$). Pre-weaning weights were similar ($P = 0.4$) but CONC calves had higher weights post-weaning (118.1 vs. 104.6 kg; SE = 4.0; $P = 0.05$). Initially after weaning, calves sorted for familiar feed; CONC calves sorted for short particles (126.4 ± 4.6%; $P < 0.01$), which were mainly concentrate, while HAY did not (94.2 ± 8.5%; $P = 0.3$). HAY calves tended to sort for long particles (113.4 ± 10.6%; $P = 0.08$), which were solely hay, while CONC calves sorted against them (56.4 ± 12.6%; $P < 0.01$). By wk 12, sorting was similar between treatments ($P > 0.15$), with both CONC and HAY calves sorting ($P < 0.01$) for short (117.4 ± 3.0, 120.5 ± 2.7%) and against long particles (62.4 ± 6.8, 54.4 ± 4.9%). The results indicated that feed familiarity affected initial diet selection post-weaning, but did not have any lasting effect.

Key Words: feed selection, dairy calves

M10 Lying time and animal activity after surgical castration of Holstein bulls recorded with pedometers. S. Marti*[1], M. Devant[1], and A. Bach[1,2], [1]*Department of Ruminant Production, IRTA*, *Barcelona, Spain*, [2]*ICREA*, *Barcelona, Spain*.

The aim of this study was to evaluate the effect of surgical castration on lying time and animal activity. A pedometer was placed in the left hind leg of 86 animals (27 bulls, 29 steers castrated at 3 mo of age, and 30 bulls castrated at 8 mo of age during the study) randomly chosen from a total of 132 animals (initial age = 232 ± 4.4 d). Animals were allocated in 6 pens (2 pens for each treatment). The study started 5 d before bulls were surgically castrated and finished 10 d after. Each pen had one

computerized concentrate feeder (GEA SurgeWestfalia, Germany), one straw feeder, and one drinker. Animals received concentrate and straw *ad libitum*. Daily lying time and average number of steps per hour were automatically recorded using a pedometer (E.N.G.S. Systems, Almagor, Israel). The statistical model included gender, day and their 2-way interaction, as fixed effects, and pen as a random effect. An interaction ($P < 0.05$) was observed between treatment and day in lying time. From castration day until 5 d later, surgically castrated bulls spent a lesser amount of time lying (10.1 ± 1.88 h) than bulls and steers (12.7 ± 0.65 h and 13.2 ± 0.89 h, respectively). Steers activity (48 ± 5.0 steps/h) was 54% lesser ($P < 0.01$) than that of bulls (106 ± 5.0 steps/h). Activity was also affected ($P < 0.001$) by an interaction between treatment and day. Bulls castrated at 8 mo of age showed a reduced activity above the first 3 d after castration (69 ± 5.5 steps/h) being lesser than that of bulls (109 ± 22.7 steps/h) but greater than that of steers castrated at 3 mo of age (43 ± 6.2 steps/h). Lying time is reduced during the 5 d following surgical castration. Bulls are more active (steps/h) than steers, and activity of steers decreases immediately after castration and for at least 10 d after castration remains lesser than that of bulls.

Key Words: beef, behavior, pedometers

M11 Dairy cattle welfare assessment in 25 farms in southern Brazil. G. B. Bond*[1], A. Ostrensky[2], R. Almeida[1], and C. F. M. Molento[1], [1]*Universidade Federal do Paraná*, *Curitiba, PR, Brazil*, [2]*Pontifícia Universidade Católica do Paraná*, *Curitiba, PR, Brazil*.

The objective of this study was to assess the main welfare indicators for lactating cows in 25 dairy farms in southern Brazil. The participating farms used confined or semi-confined systems, and had a median of 164 (min. 78, max. 480) lactating Holstein cows with a mean daily production of 28.5 ± 4.1 kg/cow. The visits occurred during the morning or afternoon milking, when a sample of 20% of the lactating cows was selected for locomotion scoring for locomotion scoring (0-good, 1-imperfect, 2-impaired, 3-severely impaired). After milking, other sample of 20% of the lactating cows was selected at the free stall. The animals were then observed for claw overgrowth (0 = normal, 1 = mildly overgrown, 2 = severely overgrown), hock lesions (0 = healthy, 1 = hair loss, 2 = abrasion), hock swelling (0 = healthy, 1 = mildly swollen, 2 = severely swollen) and hygiene score (1 = clean, 2 = slight manure splashes, 3 = demarcated plaques of manure, 4 = confluent plaques of manure). The data was analyzed through descriptive statistics using the FREQ procedure of SAS. Most animals (47.7%, min. 0, max. 63.9%) had imperfect locomotion and 7.6% (min. 0, max. 20%) presented the most severe degree. Some of them (6.1%, min. 0, max. 30%) had overgrown claws, and hock lesions were observed in 41.7% (min. 15%, max. 65.4%) of the cows; 7.2% (min. 0, max. 34,8%) of the animals had severely swollen hocks. Regarding the hygiene score, 10.7% (min.0, max. 52.9%) had excessively dirty sides (scores 3 and 4), 40.9% (min. 0, max. 81%) had excessively dirty hind limbs and 19.3% (min. 0, max. 50%) of the cows showed excessively dirty udders. The welfare indicators recognized internationally can also be used in Brazilian intensive dairy farms. The animals studied face important animal welfare issues, and preventive measures should be taken to avoid them. Further studies are needed investigating the causes of the specified problems to improve animal welfare assessment.

Key Words: cows, lameness, incidence

M12 Correlations between production traits and dairy cattle welfare indicators in 19 farms in southern Brazil. G. B. Bond*[1], A. Ostrensky[2], R. Almeida[1], and C. F. M. Molento[1], [1]*Universidade Federal do Paraná*, *Curitiba, PR, Brazil*, [2]*Pontifícia Universidade Católica do Paraná*, *Curitiba, PR, Brazil*.

The objective of this study was to analyze the correlation between animal welfare and production indicators for lactating cows in 19 dairy farms in southern Brazil, during the winter of 2009. The studied farms used confined or semi-confined systems, and had a median of 211 (max. 480, min. 80) lactating Holstein cows with a mean daily production of 33.6 ± 10.4 kg/cow. The visits occurred during the morning or afternoon milking. A sample of 50 lactating cows per herd was selected, according to their position in the milking parlor, for locomotion scoring (0-good, 1-imperfect, 2-impaired, 3-severely impaired). After milking, another sample of 50 lactating cows was selected at the free stall. The animals were then scored for claw overgrowth (0–normal, 1–mildly overgrown, 2-severely overgrown), hock lesions (0–healthy, 1–hair loss, 2-abrasion), hock swelling (0–healthy, 1–mildly swollen, 2-severely swollen) and hygiene score (1–clean, 2-slight manure splashes, 3-demarcated plaques of manure, 4-confluent plaques of manure). The correlations were analyzed through Kendall Tau-b correlations in SAS (the CORR procedure). The correlations show that low BCS was associated to overgrown claws and to higher milk yield (−0.153, $P < 0.01$ and −0.186, $P < 0.01$). Also, later lactation was associated to higher BCS (0.184, $P < 0.01$). Severe hock lesions were associated to swollen hocks (0.402, $P < 0.01$). The cow hygiene indicators for 3 separate body parts are highly correlated. The correlations between cow dirtiness (side, hind limb and udder) and milk production were positive (0.132, 0.164 and 0.136, respectively, $P < 0.01$). Later lactation was associated to less milk yield (−0.308, $P < 0.01$) and to cleaner sides and hind limbs (−0.123 with sides, −0.124 with hind limbs, $P < 0.01$). There was no clear association between lameness and milk production. Higher locomotion scores were associated to more lactations in lifetime (0.229, $P < 0.01$). The correlations between animal welfare indicators and productive traits were generally low, but many are statistically significant. Other studies are needed, correlating indicators such as lameness and cow hygiene.

Key Words: dairy cows, milk yield, lameness

M13 Effect of food restriction on the behavior of penned goats kids. D. Oliveira, I. A. M. A. Teixeira*, S. F. Souza, M. J. R. Paranhos da Costa, K. T. Resende, A. G. Pascoa, O. Boaventura Neto, and T. F. V. Bompadre, *Universidade Estadual Paulista/UNESP*, *Jaboticabal, SP 14884900, Brazil*.

The aim of this study was to evaluate the behavior and welfare of preweaned goat kids submitted to feed restriction. To adjust the period of observation, a preliminary trial was carried out to evaluate the circadian rhythm of 3 male Saanen kids. Direct way (video cameras) observations were conducted to evaluate the frequency and length of the behaviors. Data were analyzed using Rayleigh's Test of Uniformity (Oriana software). Based on the analyses of the circadian rhythm trial, 6 h of observation were defined per day: 10 a.m., 11 a.m., 12 a.m., 1 p.m., 3 p.m., and 4 p.m. Once established the hours for behavioral evaluation, 27 35 d-old goat kids (males, females, castrates) were subjected to 3 nutritional levels: without restriction (ad libitum), intermediate restriction (25%) and severe restriction (50%). The individual feed intake was daily recorded and the behavior observations were determined considering 11 categories (feeder, water drinker and pen interaction; reaction to human; active and passive social interaction; standing; lying; movement; bipedal and self-grooming). The evaluations were based on the frequency and length of the behaviors, totalizing 702 h

of observation. Data were analyzed as a 3x3x3 factorial arrangement (period of observation x nutritional level x sex) using PROC MIXED. DMI was lower than what is commonly reported for kids at similar age (8 g/day of DM), and there were not significant differences between nutritional levels ($P = 0.47$) and sex ($P = 0.27$). Kids subjected to severe feed restriction were less reactive to human and showed less reaction to external stimuli, staying in standing position for longer periods ($F = 3.71$; $P = 0.04$). Kids in this treatment also showed apathy and depression, indicating impaired welfare. All animals presented stereotypes. However, females were more sensitive to restrictive conditions, biting pen bars more often and for longer periods than other animals. This study showed that feed restriction affected animal welfare, which calls attention to the consequences in adopting such technique.

Key Words: behavior stereotype, chronobiology, dairy goat

M14 Effect of metabolizable energy levels on the feeding behavior of Santa Inês sheep. R. M. Fontenele*, E. S. Pereira, P. G. Pimentel, M. S. de Souza Carneiro, A. B. Selaive Villarroel, and J. G. L. R. Filho, *Federal University Ceará*, *Fortaleza, Ceará, Brazil*.

The objective of this study was to evaluate the feeding behavior of Santa Inês sheep fed different levels of energy (2.08, 2.28, 2.47 and 2.69 Mcal/kg DM) in diets. Twenty lambs, average weight of 13 kg ± 0.56 kg and age 50 d, confined in individual pens with concrete floor and provided with feeders and drinkers. The animals were weighed, identified and treated for ecto and endoparasites, then distributed in 4 experimental treatments with different levels of metabolizable energy (2.08, 2.28, 2.47 and 2.69 Mcal/kg DM) in a randomized block design with 5 replications. The roughage used was the Tifton 85 hay. Since the experimental variables were subjected to ANOVA and regression using the Statistical Analysis System and Genetic - SAEG. Feeding time, expressed in h/day, decreased linearly ($P = 0.02$) with the increase in energy levels of experimental diets (5.83, 5.87, 4.85 and 4.77 min/day, levels 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively). With regard to leisure time, there was a linear increase ($P = 0.03$), recording the values of 5.10, 5.65, 6.14 and 6.50 min/day, to levels 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively. However, rumination, feeding efficiency (g DM/h and g NDF/h), and rumination efficiency (g NDF/h), were not affected ($P > 0.05$) by levels of energy in diets. However, the efficiency of rumination (g DM/h), decreased linearly ($P = 0.007$) with increasing energy levels in diets, recording values of 5.10, 5.65, 6.14 and 6.50 h/day, for the levels of 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively. It was observed that the total mastication time (min/day), too, was influenced ($P = 0.02$) the energy levels of the experimental diets, with linear effect, with values of 15.56, 14.63, 13, 78 and 13.08 min/day, for the levels 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively. As for variables such as frequency of regurgitation, frequency of mastication, frequency of mastication and regurgitation of mastication time per regurgitation were not affected ($P > 0.05$) by levels of energy in the diets.

Key Words: lamb, roughage:concentrate ratio, ruminants

M15 Evaluation of feed behavior traits in beef heifers using a GrowSafe intake measurement system. E. Mendes*, G. Cartens, and L. Tedeschi, *Texas A&M University*, *College Station*.

The objective of this study was to evaluate the use of an electronic feed intake system to quantify feeding behavior traits in beef heifers. Feed intake and feeding behavior data were recorded in 32 heifers (initial BW = 285 kg) fed a high grain diet (3.1 Mcal ME/kg DM) for 81 d while confined to a pen equipped with 4 GrowSafe 4000E feedbunks (2-s read rate). Time-lapse video was used to record observations of individual bunk visits for 10 heifers over 3 consecutive d. Bunk visit frequency (BVF) and duration (BVD) were computed using software (DAQ4000E ver. 9.22) at parameter settings (PS) of 30, 60, 100, 150 and 300 s, which defines maximum duration between transponder hits for a new event (default = 300 s). Meal frequency (MF) and duration (MD) were computed from BV data using a meal criteria as 5 min. Daily BVF and BVD data were split into 4 6-h periods for statistical comparison with observed video data using r^2, mean square error of prediction (MSEP), mean bias (MB), accuracy (Cb), and corrected Akaike's Information Criterion (AIC). Observed BVF and BVD (mean ± SD) were 12.8 ± 9.1 events and 18.0 ± 12.1 min/6-h period. As PS increased from 30 to 300 s, BVF decreased (16.6, 12.7, 11.9, 11.6 and 11.4 events/6-h, respectively) and BVD increased (13.4, 16.0, 17.0, 17.7 and 18.3 min, respectively). Statistical analyses revealed that PS of 60 and 100 s generated predicted BVF data most similar to observed data (0.91 and 0.88, 0.1 and 0.2, 0.01 and 0.13, 1.0 and 0.9, and −218 and −192 for r^2, MSEP, MB, Cb, and AIC, respectively), while PS of 100 and 150 s generated predicted BVD data that were most similar to observed data (0.91 and 0.91, 0.2 and 0.2, 0.13 and 0.01, 1.0 and 1.0, and −203 and −201 for r^2, MSEP, MB, Cb, and AIC, respectively). Meal frequency and duration computed from BV data was minimally affected by PS. These results suggest that BVF and BVD computed with a PS of 100 s most accurately predicted observed feeding behavior traits, which were on average 94 and 95% of observed BVF and BVD, respectively.

Key Words: feeding behavior, intake

M16 Feeding behavior and ruminal acidosis in beef cattle offered a total mixed ration or dietary components separately. D. Moya*[1], A. Mazzenga[2], L. Holtshausen[3], G. Cozzi[2], L. González[4], S. Calsamiglia[1], D. Gibb[3], T. McAllister[3], K. Beauchemin[3], and K. Schwartzkopf-Genswein[3], [1]*UAB*, *Barcelona, Spain*, [2]*UP*, *Padova, Italy*, [3]*Agriculture Canada*, *Lethbridge, Canada*, [4]*U of Manitoba*, *Winnipeg, Canada*.

Eighty continental crossbred beef heifers (414.9 ± 37.9 kg BW), including 16 ruminally cannulated, were used in a 52-d experiment conducted as a complete randomized block design, to asses if, when allowed to select their own diet, heifers would choose a proportion of ingredients that prevents drops in ruminal pH and improves the rumen environment. Treatments were: TMR (85% barley-grain, 10% corn silage); free-choice diet (FCD) (BGCS) of barley-grain (BG) and corn silage (CS); FCD (BGDG) of BG and wheat distillers grain (DG); and FCD (CSDG) of CS and DG. Animals were housed in groups of 10 in 8 pens equipped for automatic recording of feeding events 24 h/d, allowing for the calculation of individual feeding behavior. Cannulated heifers were fitted with an indwelling pH probe to record ruminal pH every 60s. Data were summarized as mean pH, and area under the curve (AUC) with pH lower than 5.8. Ruminal samples were taken from cannulated animals 2 h post-feeding on d 4 and 42, for determination of VFA. Data were analyzed with a mixed model which included treatment, time and their interactions as fixed effects and pen as a random factor. Heifers fed TMR had lower ($P < 0.05$) meal length, time, and size than those fed FCD. Cattle fed BGCS and BGDG increased ($P < 0.05$) the proportion of BG intake over the trial up to 80 and 70%, respectively, by increasing ($P < 0.05$) eating rate and maintaining ($P > 0.10$) feeding duration of BG, and increasing ($P < 0.05$) eating rate but decreasing ($P < 0.05$) feeding duration of either CS or DG. Even with these changes, ruminal pH and VFA profile was not different ($P > 0.10$) over the trial or compared with TMR. Cattle fed CSDG ($P > 0.10$) maintained DG intake at 60% over the trial, and had greater ($P < 0.05$) mean ruminal pH, AUC, and acetate to propionate ratio than those fed other treatments. Finishing feedlot cattle fed FCD including BG as an option consume

similar ingredients and have intake and ruminal fermentation profiles similar to those fed TMR.

Key Words: beef cattle, acidosis, feeding behavior

M17 Association between facial hair whorl and temperament in noncastrated male cattle *Bos taurus* and *Bos indicus*. R. Rivas*[1,2], A. Schmidek[2], E. N. Andrade[3,2], F. D. Resende[2], G. R. Siqueira[2], M. H. Faria[2], and R. O. Roça[3], [1]*Centro Universitário da Fundação Educacional de Barretos - UNIFEB*, *Barretos, SP, Brazil*, [2]*Agência Paulista de Tecnologia do Agronegócio - APTA*, *Colina, SP,Brazil*, [3]*Universidade Estadual Paulista Júlio de Mesquita Filho - UNESP*, *Botucatu, SP, Brazil*.

Studies have associated cattle temperament with the presence and location of facial hair whorls in these animals. The objective of this work was to investigate the relationship between facial hair whorl and temperament during weighing crate. Seventy-three noncastrated males were used (*Bos taurus* and *Bos indicus* – Angus and Nelore), aged between 20 to 22 mo. The animals were classified into 4 categories according to the location and presence of hair whorl: above the eye, at eye level, below the eye or absent upon entry into a handling crush. All animals were submitted to the same type of housing and handling. The first weighing crate was done 21 d after at the beginning of feedlot. Later, they were done every 21 d, always after a 12 h fasting period. Temperament was evaluated during weighing crate, according to the tension shown in the first 5 s after closing the gates to the scale. The animals were classified as relaxed or tense, based on the speed of movements and muscle tone. Response variables of hair whorl and temperament were evaluated through Spearman correlation in SAS. There was no significant association between facial hair whorl and temperament ($P \geq 0.05$). Most animals (90.4%) were classified as tense during evaluations. The absence of whorl was observed in 57.1% of relaxed animals and 43.9% of tense animals did not show hair whorls. Hair whorl at eye level was observed in 42.9% of relaxed animals and 31.8% of tense animals. There were no relaxed animals among those with hair whorls above and below the eye. The location of facial hair whorls did not prove to be an applicable tool in the identification of temperament in noncastrated male cattle (*Bos taurus* and *Bos indicus*).

Key Words: bovine, Nelore and Angus, temperament

M18 Comparison of adrenal responsiveness to corticotropin-releasing hormone (CRH) in Angus and Brahman steers of divergent temperament. K. O. Curley Jr.*[1,2], J. A. Carroll[3], R. C. Vann[4], R. D. Randel[1], and T. H. Welsh Jr.[1], [1]*Texas AgriLife Research*, *College Station,* [2]*Texas AgriLife Research*, *Overton,* [3]*USDA ARS*, *Lubbock, TX,* [4]*MAFES*, *Raymond, MS*.

The objective of this study was to compare adrenal activity after pituitary stimulation with exogenous CRH, in cattle of differing temperament and breedtype. Using a combination of exit velocity, the rate at which cattle exit a squeeze chute and traverse a fixed distance (1.83 m), and pen score, a subjective assessment of cattle's behavior toward a handler, we identified the 10 calmest (C) and 10 most temperamental (T) weaned calves from a Brahman (B) and an Angus (A) herd. Blood samples were collected via indwelling jugular cannula for a period of 6 h pre- and 6 h post- administration of CRH (0.1 μg/kg BW). Sampling intervals were 15 min throughout the 12 h except for the initial 30 min of the post-challenge period when the sampling intervals were 5 min. Serum cortisol concentrations were determined by RIA. MIXED model repeated measures ANOVA was conducted for a factorial analysis of (1) time and breed, within temperament, or (2) time and temperament, within breed, effects on hormone concentrations throughout the duration of blood sampling. Additionally, the GLM was utilized for ANOVA of adrenal response parameters. During the initial 3 h of sampling an effect ($P < 0.01$) of breed was present in only the calm animals, as the A steers maintained higher cortisol concentrations than the B steers. Baseline cortisol concentrations were affected ($P < 0.01$) by both breed (A = 16.7 ± 2.7; B = 9.7 ± 1.2 ng/ml) and temperament (t = 18.2 ± 2.5; C = 8.7 ± 1.3 ng/ml); no breed by temperament interaction was present. During the post-challenge sampling period there was a time by temperament interaction ($P < 0.005$) observed within each breed. Only a breed effect ($P < 0.005$) on peak stimulated-cortisol concentrations (A = 35.1 ± 1.7; B = 28 ± 1.3 ng/ml) was observed. However, only temperament influenced ($P < 0.01$) the amplitude of the cortisol response (C = 22.3 ± 2.1; t = 14.1 ± 2.0 ng/ml). Thus, cattle characterized as temperamental exhibit an endophenotype of a higher basal secretion of cortisol coupled with a blunted adrenal response to exogenous CRH. The genetic bases of variation in endophenotype and temperament warrant investigation in cattle.

Key Words: adrenal, cortisol, temperament

M19 Evaluation of temperament on pregnancy rate in beef embryo recipient cows. S. S. Jennings*[1], K. J. Stutts[1], C. R. Looney[2], and T. H. Welsh Jr.[3], [1]*Sam Houston State University*, *Huntsville, TX*, [2]*OvaGenix, Inc.*, *Bryan, TX*, [3]*Texas AgriLife Research*, *College Station*.

The objective of this study was to determine if temperament had an effect on pregnancy rate (PR) of recipient females to embryo transfer (ET). Multiparous cows (n = 57) of various breed compositions were used as recipient females. Donor and recipient females were synchronized using a vaginal insert containing progesterone in combination with estradiol 17β and prostaglandin $F_2\alpha$. Embryos were non-surgically collected 7 d after insemination and transferred to recipients the same day as fresh embryos, or were frozen-thawed embryos preserved in ethylene glycol. At the time of ET, cows were assigned a temperament score of 1 to 5 (1 = docile and 5 = aggressive) based on the cow's behavior while being confined in the chute. Following transfer of the embryo, 10 mL of blood was collected via coccygeal venipuncture to determine serum cortisol concentration to assess each cow's stress response to handling at the time of ET. Serum concentration of cortisol was quantified by RIA. Pregnancy exams were conducted using transrectal ultrasonography at least 21 d post transfer to determine PR. Cortisol data were analyzed using one-way ANOVA and PR was analyzed by chi-squared analysis using the frequency procedure. Pearson correlation coefficients were used to determine the relationship between PR and cortisol concentration. There was no effect of temperament score ($P = 0.36$) on PR to ET and no relationship between PR and serum cortisol concentration (r = 0.18). Recipients that were assigned temperament scores of 4 or 5 had a higher mean serum cortisol concentration (31.1 ng/mL) than recipients assigned scores of 1 to 3 (22.9 ng/mL) but this difference was not significant. Results of this study indicate that temperament of recipient females does not have a significant effect on PR to ET nor is there a correlation between PR and stress response of the recipient at the time of ET as indicated by serum cortisol concentration immediately following ET.

Key Words: temperament, recipient females, embryo transfer

M20 Ingestive behavior and physiological parameters of crossbreed heifers under different feeding schedules. R. A. S. Pessoa*[1], F. M. Silva[1], M. A. Ferreira[1], M. Azevedo[1], L. H. S. Gomes[1], E. C. Silva[1], J. G. R. Cunha[1], A. S. S. Filho[2], D. C. Santos[2], and J. C. V. Oliveira[2], [1]*Universidade Federal Rural de Pernambuco*, *Recife, Pernambuco, Brasil*, [2]*Instituto Agronômico de Pernambuco*, *Recife, Pernambuco, Brasil*.

The objective was to evaluate the physiology variables and ingestive behavior in heifers under different feeding schedules. The maximal and minimal temperatures in the period ranged from 25.8 to 31.4°C and 21.3 to 23°C, respectively. Five crossbreed housed heifers were used, with average live weight of 250 kg and age of 24 mo, in a 5 × 5 Latin square design. Each experimental period lasted 15 d, 10 d being for the adaptation of the animals to the diet and 5 d for data collecting. The animals were fed a TMR twice daily, and the diet was composed of 70% forage (41% of cactus pear and 29% bermudagrass hay) and 30% concentrate (14% soybean meal, 13.5% of corn meal and 1.5% mineral mixture) twice a day. The first meal was provided at 7:00 for all animals. The treatments consisted by different feeding schedules of the second meal (12:00; 14:00; 16:00; 18:00 or 20:00 h). The physiology variables were record 2 h before and 2 h later of the second meal (treatment). The ingestive behavior was record in a period of 24 h, in intervals of 10 min. The data were submitted to ANOVA using the SAS. The different feeding schedules affect the respiratory frequency and the rectal temperature after the meal, which decreased with the hours (61.0 to 40.8 movements/minute and 39.0 to 38.5°C for respiratory frequency and rectal temperature, respectively). The ingestive behavior was not affected by the treatments, with average of 822, 396 and 222 min/day for total time resting, total time ruminating and total time feeding, respectively. Overall, different times of feeding changed respiratory frequency and rectal temperature, whereas it did not affect the ingestive behavior of the crossbreed heifers.

Key Words: heifers, meal, feed management

M21 Influence of exercise on feedlot performance and carcass characteristics in steers. B. J. Howell*[1], J. R. Brethour[2], and T. Noffsinger[3], [1]*Fort Hays State University*, *Hays, KS*, [2]*Agricultural Research Center, Kansas State University*, *Hays,* [3]*Production Animal Consultants*, *Benkelman, NE*.

Cattle in feed yards are not commonly exercised beyond the confines of their pen, with the exception of possibly one or 2 re-implant events. The objective of this experiment was to investigate the effect of regular exercise on animal performance and carcass characteristics. Angus crossbred steers (n = 189) were stratified by initial body weight and ultrasonically measured carcass characteristics, and assigned randomly to 2 treatment groups (control vs. exercise) with 3 replications per treatment (n = 31 hd/replication). The exercise treatment protocol consisted of daily exercise for 5 d upon arrival, followed by alternate day exercise for the next 10 d, and then exercise 2 times/week for the remainder of the feeding period. The total feeding period was 124 d for replication 1, and 166 d for replications 2 and 3. Cattle in exercise treatment pens were allowed to exit their pen into a feed alley of an area approximately 67 × 13 m for 15 min and were then returned to their pen. The control animals were not removed from their pens with the exception of ultrasonic measurement of longissimus muscle characteristics. No differences ($P > 0.05$) were observed between treatments for average daily gain, dressing percentage, backfat, calculated yield grade, marbling, proportion grading Choice, or kidney, pelvic and heart fat. Under the conditions of our study, this exercise treatment strategy did not affect feedlot average daily gain or carcass characteristics.

Key Words: exercise, beef cattle, feedlot

M22 Lack of magnetic orientation of beef cattle. M. Erikson*, E. Leduc, R. Prince, and G. Gallagher, *Berry College*, *Mount Berry, GA*.

Recently published research suggests cattle and deer orient themselves toward the magnetic poles when grazing or at rest. However, this study was based on evaluation of satellite images with stringent criterion for data inclusion. We hypothesize that if orientation of cattle was not random, it could be due to environmental influences. Therefore, the objective of this study was to determine if pastured cattle exhibited orientation preferences and if that orientation could be attributed to environmental factors. Photographs of beef cattle (n = 585) on the Berry College campus pastures, were taken twice per week from Jan 20, 2009 – Feb 21, 2009, during the day between 0700h – 1100h (n = 283) by digital camera and at night between 2000h – 2200h (n = 279) using a FLIR thermal camera. Compass readings were obtained for each photograph using visible landmarks as points of reference to verify orientation of each photograph. Temperature, wind speed, and humidity were also recorded for all photographic events. Cattle orientation was determined by placing a transparent 360° grid, divided into 8 sectors on each image. Each sector was comprised of a 45° region bisecting respective primary directions of N (Sector 1), E (Sector 3), S (Sector 5) and W (Sector 7). Remaining sectors represented NE (Sector 2), SE (Sector 4), SW (Sector 6) and NW (Sector 8). Orientation of each animal was assigned to a sector based on the direction of the head relative to the longitudinal direction of the body. Chi-squared analyses were conducted under the assumption that animal orientation within each sector would be similar (12.5%) among the 8 sectors. Results indicated a larger ($P < 0.05$) than expected (21.0%) orientation in Sector 2 (NE) and less than expected (6.6%; $P < 0.05$) in Sector 1 (N). No differences ($P > 0.05$) were found in orientation among the other sectors. These results suggest little evidence to support the concept of North – South cattle orientation as a result of the earth magnetic field or local environmental conditions.

Key Words: magnetic poles, cattle orientation

M23 Effect of cattle liner microclimate on core body temperature and shrink in market-weight heifers transported during summer months. M. Bryan*[1,2], K. Schwartzkopf-Genswein[1], T. Crowe[2], L. González[3], and J. Kastelic[1], [1]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*, [2]*University of Saskatchewan*, *Saskatoon, Saskatchewan*, *Canada*, [3]*University of Manitoba*, *Winnipeg, Manitoba, Canada*.

Market weight heifers (n = 452; BW 619 ± 22 kg) were transported in one of 5 compartments within a cattle liner on 10 journeys (940 km) during summer months to study the effect of trailer microclimate during transit (T) and stationary (S) periods on core body temperature (baseline–journey temperature; ΔCBT) and live weight loss (loading weight–unloading weight; LWL) in market weight heifers. Microclimate measurements included temperature (Temp; °C) and temperature humidity index (THI). The trailer ceiling (TC) of all 5 compartments was fitted with a total of 45 temperature/humidity data loggers. A single data logger was also placed intravaginally in a subset of 10 heifers/liner to obtain core body temperature 2 d before transport (baseline), as well as during the entire journey until the time of off–loading. The same heifers also had a data logger affixed to their ear tag (ET) to determine the temperature at animal level. Data was analyzed with a mixed model considering the fixed effects of cattle liner, compartment and day as repeated measure, as well as the random effect of compartment x day and all possible interactions. Temp was greater during S than T (23.35 and 20.32 ± 0.44; $P < 0.0001$) and also greater for ET than TC (23.20 and 20.48 ± 0.43;$P < 0.0001$). ΔCBT was greater during S than T ($P < 0.0001$) with values of 0.36 and 0.19 ± 0.06°C, respectively. Trailer

THI did not have an impact on ΔCBT ($P > 0.10$). However, a significant positive relationship ($P < 0.03$) was observed between THI and LWL. There were no differences ($P > 0.02$) in LWL among compartments. Trailer microclimate is variable according to location (animal level vs ceiling) within a compartment and whether the truck is in transit or is stationary and can negatively impact animals during summer transport. The impact may be more severe on journeys that have long stationary periods.

Key Words: cattle, transport, microclimate

M24 Natural resistance-associated macrophage protein (Nramp1) and goat health. Y. Ahmed, M. Worku*, H. Mukhtar, and R. Noble, *North Carolina Agricultural and Technical State University*, *Greensboro*.

The objective of this study was to determine how Nramp1 expression may be associated with disease states in the goat. Natural resistance-associated macrophage protein (Nramp1) is expressed exclusively in professional phagocytes. Expression of Nramp1 affects host innate immunity to intracellular bacteria because of its ability to transport divalent cations in late endosome/lysosomes. Studying the association of the NRAMP1 gene and innate immune response to pathogens may aid in understanding and enhancement of goat genetic resistance to pathogens. Clinically healthy Boer, Spanish and Spanish-Boer cross goats (n = 60) from the NC A&T Small ruminant unit were used. Fecal samples were evaluated for levels of *Haemonchus* and *Coccidia* using McMaster slides. Blood samples were evaluated for packed cell volume and white blood cells Differential count. The FAMACHA score body condition score, body weight, body temperature, and age were recorded. Genomic DNA was extracted from blood (n = 12 goats)on FTA cards according to the manufacturer's protocol. RNA was extracted using the ZR Whole-Blood Total RNA Kit. RNA samples were reverse-transcribed and the cDNA was obtained using the Ambion-Retroscript as per the manufacturer protocol. Specific primers for Nramp1 and GAPDH as loading control were used for RT PCR. Data were analyzed using SAS ANOVA and an independent sample *t*-test. Nramp1 was expressed with variability among animals. Identification of Nramp1 in genomic DNA was not affected by breed. However, Nramp1 expression was significantly increased with increased fecal coccidia egg counts ($P < 0.05$) but was not affected by fecal *Haemonchus* egg counts ($P = 0.0677$).

Key Words: NRAMP-1, goat, pathogen

M25 Identification of serum biomarkers in poultry with leg problems. K. S. Rasaputra*[1,2], R. Liyanage[1], J. O. Lay Jr.[1], and N. C. Rath[2], [1]*University of Arkansas*, *Fayetteville,* [2]*Agricultural Research Service/ USDA*, *Fayetteville, AR*.

Disease induced changes in tissue metabolism is often reflected in the blood; therefore, serum chemistry is conventionally used for diagnosis of health problems. Being the structural and functional basis of tissues, changes in the serum protein profiles are of considerable interest as biomarkers. Tibial dyschondroplasia (TD), caused by the failure of growth plate to form bone results in lameness causing significant economic loss to the poultry industry. Serum markers could identify poultry susceptible to these problems aiding in better genetic selection. Thus, the objective of our study was to identify serum protein differences in normal and diseased birds for use as biomarkers. Similar to other applications involving serum, identification of serum protein biomarkers is hindered because of few high abundant proteins. We used combinatorial peptide ligand library based "Proteominer" beads to enrich low abundant proteins and study their differential expressions in serum. Serum was collected from 6 wk-old chickens with and without leg problems and processed through the proteominer column to deplete the high abundant and enrich the low abundant proteins. Equal amounts of proteins from both groups were subjected to 2D gel electrophoresis. The Coomassie blue stained protein spots in the gels were analyzed using Melanie software to identify differentially expressed proteins in both groups. The protein spots were subjected to in gel trypsin digestion followed by MALDI peptide mass fingerprinting for protein identification. The results showed that proteominer resulted in enrichment of several new protein spots and depletion of some of the high abundant proteins. The Coomassie stained gel showed 50 protein spots of which 21 spots were identified. Melanie analysis showed 4 differentially regulated proteins in the diseased condition. Two spots corresponding to immunoglobulin G (IgG) were upregulated while the other 2 protein spots were down-regulated. It is not known whether the pathogenesis of TD is related to immunity; however, our results show that the IgG levels are upregulated suggesting the role of immunity in TD.

Key Words: tibial dyschondroplasia, serum, proteomics

M26 The detection of bovine respiratory disease in low risk cattle using infrared thermography. A. L. Schaefer*[1], N. J. Cook[2], C. Bench[3], J. Colyn[1], B. Chabot[1], T. Liu[1], P. Lepage[1], D. Froehlich[2], L. Holt-Klimek[1], S. Marchand[1], J. Basarab[2], and E. Okine[3], [1]*Agriculture and Agri-Food Canada, Lacombe Research Centre, Lacombe, Alberta*, [2]*Alberta Agriculture, Lacombe Alberta*, [3]*Department of AFNS, University of Alberta, Edmonton, Alberta*.

Bovine respiratory disease (BRD) causes significant harm to the cattle industry. Clinical methods can identify BRD once the symptoms are advanced. However, identifying symptoms earlier in low risk cattle is more challenging yet important to avoid missing false negatives. The objective of the present study was to examine whether infrared thermography (IRT) of the eye could identify BRD in low risk calves more effectively than conventional methods. Sixty 5 crossbred calves averaging 220 kg were used. The calves were from Agriculture and Agri-Food Canada (AAFC) herds. The calves were weaned and transported approximately 1h to an auction and held over night. The animals were transported back to an AAFC feedlot facility, offloaded, weighed, blood sampled, examined for rectal temperature (RT) and placed into a feedlot pen with free access to cereal silage and water. Daily clinical scores were conducted by pen checkers and an automated, RFID triggered IRT camera (FLIR S60) was mounted at the water station to record eye temperatures. All calves were again monitored 2 weeks later. Hematology analysis included white blood cell counts (WBC) and neutrophil/lymphocyte ratios (N/L). A true positive animal (TP) for BRD needed to display 2 or more of; RT > °104 C, WBC >11 or <7 X 1000 /μL, Clinical Score values (CS) > 3 or N/L ratios >0.8 or <0.1 . No calves were identified by clinical pen checking as in need of treatment. However, hematology, CS and RT identified 11 of the 65 calves as TP with 7 of these TP at both blood sampling dates. Values for TP calves for RT, CS, WBC and N/L ratios were 103.6 ± 0.74 (SD), 4.5 ± 1.1, 11.16 ± 2.65 and 0.13 ± 0.7 respectively while for calves displaying true negative values (TN) at both sample periods were 102.1 ± 0.5, 2.11 ± 1.02, 8.97 ± 1.15 and 0.21 ± 0.1 ($P < 0.01$). Of interest was the observation that the average IRT value for the TP calves was higher throughout the 2 week period (35.44 ± 0.58 C) compared with the TN calves (34.7 ± 0.57 C, $P < 0.01$). Data from this study suggests that the use of non invasively collected eye IRT data may be useful in early identifying calves displaying BRD.

Key Words: bovine respiratory disease, infrared thermography, cattle

M27 Feeding *Lactobacillus* spp. and *Bacillus* spp. does not improve growth or survival of channel catfish experimentally challenged with *Edwardsiella ictaluri*. B. C. Peterson*[1], M. L. Wood[1], N. J. Booth[1], M. Morgan[2], N. Pumford[2], G. Tellez[2], and B. M. Hargis[2], [1]*USDA/ARS, Stoneville, MS,* [2]*University of Arkansas, Fayetteville*.

A major problem in the channel catfish industry has been high disease loss to enteric septicemia of catfish, caused by the bacterium *Edwardsiella ictaluri*. Feeding probiotics may prove beneficial in improving disease resistance. The first study examined the effects of a *Lactobacillus* probiotic (FloraMax-B11; Ivesco, LLC, Springdale, AR) (poultry origin) on growth and resistance to *E. ictaluri*. Two hundred catfish (23.5 ± 0.3 g) were assigned to 2 treatments with 5 replicates each: 1.) Control (36% CP diet) and 2.) FloraMax-B11 (11 *Lactobacillus* spp., sprayed on feed at 10^6 cfu/g of diet). The fish were fed for 6 wks and then experimentally challenged with *E. ictaluri*. The second study examined the effects of 3 spores of *Bacillus* spp. on growth and disease resistance. *Bacillus subtilis*-1 (environmental sample) and *B. subtilis* -2 (catfish origin) were previously shown to have antibacterial in vitro activity against *Escherichia coli* and *E. ictaluri*. *Bacillus pumilus* of catfish origin, which did not show in vitro antibacterial activity, was also tested in this study. Five hundred catfish (11.2 ± 0.1 g) were assigned to 4 treatments with 5 replicates each: 1) Control (36% CP diet); 2) BS-1 (*B. subtillis* at 10^7 cfu/g of diet); 3) BS-2 (*B. subtilis* at 10^7 cfu/g of diet); and 4) BP (*B. pumilus* at 10^6 cfu/g of diet). Fish were fed for 9 wks and challenged with *E. ictaluri*. Data were subjected to ANOVA with tank as the experimental unit. Addition of *Lactobacillus* spp. and *Bacillus* spp. to the diet of catfish had no effect on weight gain, FE, or survival after challenge with *E. ictaluri* ($P > 0.10$). The results of these studies suggest that neither the *Lactobacillus* based probiotic nor any of the 3 spore base probiotic candidates improved growth performance or resistance against *E. ictaluri* . Identifying other catfish specific bacteria and understanding how they may manipulate the microflora of the GI tract will be key in determining whether probiotics have a benefit in improving catfish aquaculture.

Key Words: probiotics, disease, catfish

M28 Effects of intravenous *Escherichia coli* (*E. coli*) dose on the pathophysiological response of colostrum-fed Jersey calves. M. A. Ballou*[1], J. W. Dailey[2], L. E. Hulbert1,2, C. J. Cobb[1], and J. A. Carroll[2], [1]*Texas Tech University, Department of Animal Science, Lubbock,* [2]*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX*.

Objective was to determine the effects of *E. coli* dose on the pathophysiological response of dairy calves following an intravenous challenge. Eighteen 3-wk-old colostrum-fed Jersey calves were completely randomized to 1 of 6 doses of *E. coli*. The challenge doses included 0, 10^5, 10^6, 10^7, 10^8, and 10^9 colony-forming units (CFU) given as a bolus in 5 mL of sterile isotonic saline. Peripheral blood samples were collected at 0, 2, 4, 8, 12, 24, and 48h relative to the challenge for blood metabolite, total white blood cell count and differential analyses. Rectal temperatures were collected via indwelling rectal probes at 1-min intervals, and hourly averages calculated from 2d before the challenge till 2d after the challenge. All calves survived the 48h observation period following the challenge. The attitude of calves given 10^8 and 10^9 CFU was altered ($P < 0.01$) beginning 0.5h after the challenge and returned to that of the control calves by 8 and 48h for calves challenged with 10^8 and 10^9 CFU, respectively. There were treatment x time interactions ($P < 0.01$) on total white blood cell counts and plasma glucose concentrations. Calves administered 10^8 and 10^9 CFU had leucopenia and neutropenia beginning 2h after the challenge and returning to counts similar to the control calves within 24h. Additionally, those calves were hypoglycemic from 4 to 12h after the challenge with the degree of hypoglycemia inversely related to the dose of the *E. coli*. There were treatment x time interactions ($P < 0.01$) on rectal temperatures following the challenge. All calves challenged with *E. coli* developed a febrile response, but the intensity and duration of the response were dependent on the challenge dose. These data indicate that calves intravenously challenged with 10^8 and 10^9 CFU of an *E. coli* showed immediate clinical and biochemical signs indicative of septicemia. However, calves administered 10^7 or less of the *E. coli* had febrile responses, but did not develop septicemia.

Key Words: calf, *E. coli*, septicemia

M29 *Eimeria tenella* oocyst output in cecal or fecal material following challenge in restrict-fed broilers. A. Jordan*[1], D. Caldwell[1], J. Klein[1], J. Coppedge[1], S. Pohl[1], K. Jessen[1], S. Fitz-Coy[2], and J. Lee[1], [1]*Texas A&M University, College Station*, [2]*Intervet/Schering-Plough Animal Health, Summit, NJ*.

The current experiment was conducted to compare *Eimeria tenella* oocyst shedding in fecal or cecal contents in restrict-fed broilers following experimental challenge in brooder batteries. Ninety-six Cobb 500 by-product males were placed in battery pens with 8 chicks per pen. On d 14, restrict feeding was initiated and chicks were challenged with one of 3 challenge levels (1,000, 5,000, and 20,000 oocysts). Total 24 h collections of cecal and fecal material were obtained separately beginning on d 4 post-challenge through d 10 post-challenge for oocysts per gram and total output determination. Six days post-challenge, 4 broilers from each pen were removed and subjected to necropsy for lesion assessment. Data was subjected to a one-way ANOVA using the GLM procedure. Means were deemed significantly different at $P < 0.05$ and means were separated using Duncan's Multiple Range Test. Body weight gain was not affected due to challenge level throughout the experimental period. Increases ($P < 0.05$) in both gross and microscopic lesion development were observed with each increase in challenge level. Oocyst output peaked on d 8 post-challenge. Oocyst concentration was higher ($P < 0.05$) in cecal droppings as compared with fecal material throughout peak shedding. However, total output of *Eimeria tenella* oocysts was similar ($P > 0.05$) in fecal and cecal material. These data indicate that total oocyst output during an experimental challenge are similar in fecal and cecal material, however concentrations are significantly lower in fecal material compared with cecal material when compared on a output per gram basis.

Key Words: *Eimeria*, broiler, oocyst shedding

M30 Effect of aqueous iodine supplementation on growth and dental condition of newly weaned piglets. A. L. Tucker* and R. M. Friendship, *University of Guelph, Guelph, Ontario, Canada*.

Weaning is a stressful event and many pigs experience poor growth in their first weeks in the nursery. The use of antibiotics to improve growth and health has come under increasing scrutiny and alternative means of reducing bacterial load are desirable. Iodine, a broad-spectrum antiseptic, shows potential as a therapeutic agent because it has low potential for resistance and is inexpensive. It is also used to prevent oral disease, a condition that can develop in nursery age piglets. Recently, premolar eruption and the presence of poor oral conditions have been shown to affect weight gain in weaned piglets. The aim of this study was to examine the efficacy of an aqueous iodine supplement for improving piglet weight gain and oral condition. Across 3 trials, 624 piglets on a commercial farrow-wean farm were examined. An iodine-based sanitizer containing 1.75% titratable iodine was added to the water supply to a final concentration of 1 ppm. Water was supplied to via nipple drinkers

with testing confirming mean concentrations of 0.96, 0.68 and 0.91 ppm in trials 1, 2 and 3. Piglets were weighed and given oral exams within 24 h of weaning and again 3 and 6 wks later. Deciduous teeth were recorded as being erupted (vs not erupted) if any portion of the tooth crown penetrated the gingiva. Dental staining and caries (cavities) on incisors, gingivitis around any teeth and oral lesions on the gingiva, tongue, cheeks or throat were recorded. A repeated measures ANOVA (SAS Proc MIXED) was used to examine how iodine supplementation influenced growth and oral condition. Overall, the presence of staining and caries on the primary incisors increased between weaning and wk 3 ($P < 0.05$), while the incidence of both oral lesions and gingivitis increased between wks 3 and 6 ($P < 0.05$). There were no significant treatment differences in piglet growth or oral condition during the period that iodine was supplemented ($P > 0.05$). These results indicate that deleterious oral conditions do develop and increase throughout the weaning period, but, at 1 ppm, an aqueous iodine supplement does not provide an advantage for weight gain or oral condition in nursery piglets.

Key Words: growth, dentition, swine

M31 Interaction of breed and quantity of milk replacer on innate immune competence of dairy calves. M. A. Ballou* and C. J. Cobb, *Department of Animal and Food Sciences, Texas Tech University*, *Lubbock*.

Objective was to determine the influence of breed and quantity of milk replacer fed on the immune competence of dairy calves. Forty 2 bull calves (n = 20 Holstein and n = 22 Jersey, 2 ± 1 d old) were studied in a 2 × 2 factorial arrangement. Holstein and Jersey calves on the lower plane of nutrition (LPN) were fed 454 g /d of a 20/20 milk replacer. Holstein calves on the higher plan of nutrition (HPN) were fed 810 and 1,180 g / d of a 28/20 milk replacer for wk 1 and wk 2 – 6, respectively. Jersey calves on the HPN were fed 568 and 680 g / d of a 28/25 milk replacer for wk 1 and wk 2 – 6, respectively. On d 4, 42, and 77 peripheral blood was collected for ex vivo immunological analyses, and on d 7 all calves were challenged subcutaneously with LPS (4 μg/kgBW) and clinical and biochemical responses evaluated at 0, 1, 2, 3, 4, 5, 6, 9, 12, 24, and 72 h. There was a breed x plane of nutrition interaction ($P < 0.04$) on serum glucose concentrations following the LPS challenge; whereas Holsteins on the HPN had higher glucose concentrations than the other treatments. There were no breed or plane of nutrition interactions with time following the LPS challenge. Isolated mononuclear cells from Holstein calves when stimulated ex vivo with LPS on d 42 and 77 synthesized more tumor necrosis factor-α than cells from Jersey calves (2149 and 1527 pg/mL ± 149.9; $P < 0.01$). There were breed x day ($P < 0.05$) and plane of nutrition x day ($P < 0.07$) interactions on the intensity of the oxidative burst produced in response to a pathogenic *E. coli*; whereas Jersey calves fed LPN had a reduced intensity on d 77 when compared with the other treatments. Additionally, on d 77 Jerseys fed LPN had a reduced ($P < 0.04$) whole blood killing capacity when incubated with the *E. coli* for 60 min. When whole blood was incubated with the *E. coli* for 10 min, Jersey calves consistently had reduced ($P < 0.03$) killing capacities over the entire study period. These data indicate that Jersey calves had lower measures of many innate immune variables and HPN may improve aspects of the innate immune competence in a breed and immune variable specific manner.

Key Words: breed, calf, immune

M32 Effects of neomycin and oxytetracycline (N/T) fed at treatment rate for 14 days in calf milk replacer (CMR) on calf performance and health. D. Shields*[1], R. Blome[2], D. Wood[2], and J. Sowinski[2], [1]*Merrick's, Inc.*, *Middleton, WI*, [2]*Animix*, *Juneau, WI*.

New government regulations for the treatment of bacterial scours levels of the new combination (1:1) for neomycin/oxytetracycline of 10mg/lb BW for 14 d are now in effect. There is minimal calf data for feeding this new level. The objective of this study was to evaluate calf health and performance under the new federal guidelines. Auction sourced Holstein bull calves (n = 48, 3–5 d old) were stratified by weight into 2 treatment groups (24 calves/trt). Calves were weighed 1×/wk during the 8 wk trial. Calves were housed in individual hutches and fed 284 g reconstituted CMR (20% C.P., 20% fat, all milk protein) via individual nipple bottles at 0600 and 1700 h. Trt 1 received the treatment rate for bacterial scours for 14 d, and trt 2 received a non-medicated control formula. Water and a commercial textured calf starter (18% CP, 2.5% fat, Decoquinate) was offered daily for ad libitum consumption. Orts were collected and weighed daily and no hay fed. Straw-bedded hutches held a consistent nesting score ≥ 3. Subjective fecal scores (FS) were recorded 1×/d using 1–4 scale with 1 being normal and 4 severe scours. FS ≥ 3 were given electrolyte therapy. Weaning occurred at 42 d if starter intake (SI) was ≥ 454 g for 3 d and non-weaned calves were reduced to 1×/d CMR to promote SI. During the first 3 wks, ADG tended ($P \leq 0.09$) to improve with N/T (0.40 vs. 0.34 kg/d) and total SI was higher (3.7 vs. 2.1 kg). From wk 3– 6 opposite trends were observed as ADG tended ($P \leq 0.09$) to be higher for control calves (0.81 vs. 0.89 kg/d) and F/E was improved 11.7% ($P \leq 0.02$) at 0.58 vs. 0.65. Overall in the 56 d study no differences noted in growth, SI or F/E. However, N/T reduced calves that scoured 38% ($P \leq 0.06$), calves that required health treatments 36% ($P \leq 0.07$) and treatment d 28.6% ($P \leq 0.07$). Under conditions of this study N/T reduced incidence of scours, treatment days of calves treated and improved early SI but did not affect ADG, total SI or FS.

Key Words: calf, medication

M33 The effect of adding the organic complex of zinc, copper, manganese and cobalt on hoof health and performance in feedlot cattle. G. R. Noori[1], H. Amanlou[1], D. Zahmatkesh[1], E. Mahjoubi*[1], and Y. Mokhtabad[2], [1]*Zanjan University*, *Zanjan, Iran*, [2]*Azad University*, *Mazandaran, Iran*.

It has been shown that Zn, Mn, Cu and Co are essential for protein synthesis, vitamin metabolism, connective tissue synthesis and immune system function. There is, however, little evidence in finishing cattle. A study was conducted to investigate the effects of micro-mineral organic complex on lameness occurrence and performance in Holstein bull calves. Ninety-three Holstein bull calves (250.21 ± 4.21) were used in a completely randomized design. Calves were group fed a similar basal diet during 42 d experimental period. Used treatments included 1) control treatment without feed additive, and 2) experimental diet that calves consumed 7 g/d micro-mineral complex (Availa 4, an amino acid mineral complex available from ZinPro Corporation, Eden Prairie, MN), that supplied 360 mg Zn, 200 mg Mn, 125 mg Cu and 12 mg Co. Results showed that the effect of experimental diet on dry matter intake was significant (7.02 vs. 7.22 kg/d, $P < 0.001$) but feed conversion ratio was not significant (7.36 vs. 7.23, $P < 0.21$). A tendency was detected for average daily gain (0.96 vs. 1.04 kg/d, $P < 0.11$) and weight gain during the trial (40.3 vs. 43.6 kg, $P < 0.11$). The consumption of micro-mineral organic complex influenced plasma concentration of globulin (2.96 vs. 3.98 g/dL, $P < 0.03$) and albumin (3.26 vs. 2.44 g/dL, $P < 0.002$) significantly. The prevalence of lameness was higher in control group than organic complex supplemented treatment (23% vs. 11%; odds ratio

= 2.5). Generally, our results show that feeding micro-mineral organic complex can have an efficient role in reducing lameness occurrence and increasing profitability in feedlot farms.

Key Words: lameness, trace mineral, Holstein bull calves

M34 The effect of early feeding on blood factors, immune system, digestive tract and intestinal morphology of broiler chicks. M. Asgari[1], S. Rahimi*[1], M. Kiaei[2], and M. A. Karimi Torshizi[1], [1]*Tarbiat Modares University*, *Tehran, Iran*, [2]*University of Tehran*, *Tehran, Iran*.

In this study 560 male broiler chicks (ROSS 308) were used to study the effect of early feeding on blood factors, immune system, digestive tract and intestinal morphology. Birds were divided into 5 treatments with 4 replicates (112 chicks per treatment) as follows: 1. Control group (were fed starter diet 48 h after hatch); 2. Vitagel group (received 5g per bird jelly feed for the first 48 h after hatch and then starter diet); 3. Chick-mix group (were administered with starter diet); 4.Wet feed (with10% moisture for first 48 h after hatch and then starter diet); 5. Saline (1mL sterile saline were injected via subcutaneous in neck of each bird in this group after hatch and they were fed starter diet 48 h later). Body weight, feed intake, feed conversion, weight of liver, Proventriculus, gizzard, small intestine, bursa of Fabricius, spleen, pancreas, yolk sac, digestive tract, and length of small intestine were measured for all groups. Newcastle disease (NDV) and SRBC antibody titer, glucose, triglyceride, and cholesterol of serum were determined. The number of villi, length and width of villi, depth of crypt and percentage of different villi (leaf, tongue, bridge and finger shape) in small intestine were measured for all groups. At end of the experiment (40 d), weight of different parts of carcass and productive index were measured. The production index, GUT weight, intestine length, villi height and crypt depth were higher in early fed groups compared with other groups ($P < 0.05$). There were no significant differences in BW, FCR, and antibody titer against NDV and SRBC between different treatments. Serum glucose, relative weight of liver, proventriculus, pancreas, intestine, bursa of Fabricius, spleen, length of small intestine were higher in early fed groups ($P < 0.05$). In conclusion, early feeding of broiler chicks can be recommended to have better performance and immune response in these birds.

Key Words: broiler chicks, early feeding, blood factors

M35 Evaluation of effect of sodium bicarbonate as a top-dress on preventing laminitis and performance in feedlot cattle. G. R. Noori[1], H. Amanlou[1], D. Zahmatkesh[1], E. Mahjoubi*[1], and Y. Mokhtabad[2], [1]*Zanjan University*, *Zanjan, Iran*, [2]*Azad University*, *Mazandaran, Iran*.

Sodium bicarbonate is known as a pH modulator in cattle. Acidosis and, subsequently, laminitis are common in feedlot cattle. The effect of sodium bicarbonate as a top-dress has not been investigated. Therefore, our objective was to investigate the effects of sodium bicarbonate on laminitis occurrence and performance. One hundred Holstein bull calves (251.75 ± 5.75) were used in a completely randomized design. Calves were group fed a similar basal diet during 42 d experimental period. Used treatments included 1) control treatment without feed additive, and 2) experimental diet that calves consumed 50 g/d sodium bicarbonate as a top-dress. Results showed that the effect of experimental diet on dry matter intake (7.02 vs. 7.36 kg/d, $P < 0.001$), average weight gain through trial (40.3 vs. 46.6 kg, $P < 0.03$) and feed conversion ratio (7.36 vs. 6.53, $P < 0.02$) were significant. A tendency was detected for average daily gain (0.96 vs. 1.11 kg/d, $P < 0.07$). Compared with control group, occurrence of laminitis in experimental group was less (22% vs. 9%; odds ratio = 2.6). Generally, results showed that feeding of sodium bicarbonate as a top-dress can have an efficient role in reducing laminitis occurrence and increasing profitability in feedlot farms.

Key Words: laminitis, feedlot, sodium bicarbonate

M36 Expression of members of the wingless gene family in goats. M. Worku*, H. Mukhtar, and N. Mikiashvili, *North Carolina Agricultural and Technical State University*, *Greensboro*.

The objectives of this study were to identify members of the wingless (Wnt) signaling pathway (Wnt gene family) in the goat genome and to evaluate expression of genes involved in Wnt signaling in blood. The Wnt gene family encodes secreted members of the wingless family of signaling molecules that control cell fate, specification, proliferation, polarity, and movement in animal development and diseases. Wnt gene expression impacts production traits in farm animals as well as meat quality and is reported to be crucial for myogenesis and adipogenesis. Blood was collected from meat (4 Boer) and milk (4 Alpine) goats on FTA elute cards (Whatman Inc.) for DNA isolation. For RNA isolation PAXgene Blood RNA tubes were used. Genomic DNA was extracted from the FTA card according to the manufacturer's protocol. RNA was extracted using the ZR Whole-Blood Total RNA Kit. RNA samples were reverse-transcribed and the cDNA was obtained using the Ambion-Retroscript as per the manufacturer protocol. Specific primers for Wnt1, Frizzeled and secreted frizzeled were used for PCR amplification. Amplified products were run on a 1% agarose gel with PCR markers. Gels were stained with ethidium bromide and visualized using a Gel documentation system. GAPDH was used as loading control and primers in the absence of DNA were used as negative controls. Variability was observed among animals in detection of Wnt-1 in genomic DNA. Genes were detected in blood. Wnt-1 and Frizzeled genes were expressed in goats. Differential gene expression and animal to animal variability were observed. Both Wnt and Frizzeled family genes appear to be conserved in goats. This simple method for detection of Wnt-1 gene expression in goat blood will aid in the deciphering of the underlying mechanisms involved in animal development and disease impacting production traits in farm animals.

Key Words: goat, Wnt family, gene expression

M37 Dynamic changes in physiological responses to heat stress in cattle of different geographic origins. P. A. Eichen*, H. L. Vellios, B. S. Scharf, J. S. Johnson, D. K. Kishore, E. A. Coate, and D. E. Spiers, *University of Missouri*, *Columbia*.

Response to heat stress may differ in *Bos taurus* cattle originating in different US regions. Hourly measurements at specific heat stress levels may enable further understanding of these regional differences. Angus steers from Oklahoma (OK; n = 6) and Missouri (MO; n = 6) were compared with heat-tolerant Romosinuano steers (RO; n = 5) from Florida in the University of Missouri Brody Environmental Center. Initially, the 3 groups were exposed to air temperature (Ta) treatments that included a constant thermoneutral temperature (TN) of 20°C for 8 d, followed by a daily heat cycle (HS1) of 28 to 38°C for 8 d, and a greater heat cycle (HS2) of 30 to 40°C for 8 d. Twenty-four hour measurements were made after stabilization at each temperature. Hourly measurements included rectal temperature (Tr), respiration rate (RR), and skin temperatures averaged at trunk and peripheral sites. Linear regression was used to determine animal and ambient relationships, with ANOVA for group differences. There was no difference in Tr between groups at TN, but Tr was lower in RO compared with Angus during HS1 and HS2 ($\alpha = 0.05$). Relationships between Tr and Ta were similar for MO and OK during

HS1 and HS2. However, there was no relationship between Tr and Ta for RO during HS1 and HS2. RO had lower RR during TN and HS1 ($\alpha = 0.05$), but were not different from Angus during HS2 to suggest an adaptive response. Interestingly, relationships between RR and Ta for RO were equal to Angus during HS1 and HS2, indicating no group difference in the RR relationship. Skin temperatures at trunk or peripheral sites were affected by hour of day during all 3 temperature treatments ($P < 0.03 - 0.0001$). There was also an hour x group effect on trunk temperature during all 3 periods ($P < 0.05$), with no effect on peripheral sites. Geographic origin of Angus did not affect the heat stress response. Romosinuano steers exhibited characteristic heat tolerance, but showed some temporal shifts in response to prolonged heat exposure.

Key Words: heat stress, cattle, diurnal

M38 Patterns of heat response and adaptation on summer pasture: A comparison of heat sensitive (Angus) and tolerant (Romosinuano) cattle. J. S. Johnson*, B. Scharf, R. L. Weaber, P. A. Eichen, and D. E. Spiers, *University of Missouri*, *Columbia.*

Heat stress in *Bos taurus* cattle is a problem that affects many regions of the world. Numerous studies have focused on heat stress in feedlots or environmental chambers; but few have looked at undisturbed cattle on pasture. The present study followed 2 cattle breeds throughout a mid-Missouri summer to determine thermoregulatory responses to fluctuating summer air temperature (Ta). Breeds included 22 Angus grouped into 10 Missouri Angus (468 ± 11 kg BW) and 12 Oklahoma Angus (490 ± 9 kg BW). These were compared with 11 heat tolerant Romosinuano (RO; 352 ± 6 kg BW) steers from Florida. Animals were monitored on 16 d from June 8 through August 9 of 2009 on endophyte free tall fescue at the University of Missouri South Farm. For analysis, the data was divided into 2 periods that consisted of the first 11 d (Period 1; 9 d; Ta range = 19.8–34.3°C) and the last 27 d (Period 2; 7 d; Ta range = 15.5–33.4°C). Periods were determined by comparing respiration rate (RR) to Ta. Periods 1 and 2 were the times at which RR response to Ta was significantly different at ($P < 0.05$). RR was measured (counting 1 min flank movement) at 0800 and 1500 h, and ruminal temperature (Trum) was monitored hourly as an indication of core body temperature using a telemetric temperature transmitter (SmartStock, Pawnee, OK). Relationships between RR, Trum, and Ta were determined using linear regression for both breeds and groups within breeds. RR and Trum showed no significant differences between Angus groups ($P = 0.05$), however breed differences were found between Angus and RO ($P < 0.05$) steers. Slopes of RR to Ta from Periods 1 to 2 decreased from 2.55 to 1.13 bpm/°C and 2.27 to 0.49 bpm/°C for Angus and RO, respectively. Slopes of Trum to Ta also decreased from Periods 1 to 2 from 0.12 to 0.01°C /°C and 0.02 to 0.01°C /°C for Angus and RO, respectively. Correlations of Trum to Ta in Period 2 were insignificant ($P > 0.05$). Although Romosinuano have a lower respiration rate and ruminal temperature than Angus, they share a similar pattern of adaptation from early to late summer periods.

Key Words: cattle, heat stress, adaptation

M39 Taguchi approach for anti-heat stress prescription compatibility in mice spleen lymphocytes in vitro. X. Zhu*[1], G. Cheng[2,3], F. Liu[2,3], J. Yu[2], Y. Wang[1], T. Yu[2], J. Xu[1], and M. Wang[1], [1]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine, China Agricultural University, Beijing, China*, [2]*Department of Animal Science and Technology, Beijing University of Agriculture*, *Beijing, China*, [3]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*.

The study was to evaluate the possible immune function of Agastache rugosa, Atractylodes lancea, Cortex Phellodendri, and Gypsum Fibrosum on spleen lymphocytes under heat stress. The Taguchi Design, which allows rapid and high efficiency to select the best conditions for the composition, was used to investigate the compatibility of the herbs. The extracts from herbs in various dilutions were added to previously cultured cells with final concentrations of 10, 50, 100, 200 μg/mL to give a total volume of 100 μL/well. Then lymphocytes exposed with extracts were incubated at 37°C for 24 h, heated at 42°C for 2 h and recovered to 37°C for 22 h. As a heat shock group (HS), lymphocytes (with ConA, 10 μg/mL or LPS, 2.5 μg/mL) were treated at 37°C for 24 h, heated at 42°C for 2 h and recovered to 37°C for 22 h. As a control, lymphocytes (with ConA, 10 μg/mL or LPS, 2.5 μg/mL) were treated at 37°C for 48 h. Lymphocyte proliferation was evaluated by MTT assay. The optical density (OD, 570nm) of HS was significantly lower than the control group ($P < 0.05$). Under heat stress the OD of higher concentrations of Agastache rugosa (200 μg/ml and 100 μg/ml), Atractylodes lancea (200 μg/ml and 100 μg/ml), Cortex Phellodendri (100 μg/ml and 50 μg/ml) and Gypsum Fibrosum (200 μg/ml and 100 μg/ml) caused a significant increase on ConA/LPS-induced proliferation of lymphocytes than HS ($P < 0.05$). The Taguchi results demonstrated that Agastache rugosa (200 μg/ml), Atractylodes lancea (200 μg/ml), Cortex Phellodendri (100 μg/ml) and Gypsum Fibrosum (100 μg/ml) were the optimal conditions for the composition of herbs. The validation experiment results confirmed that our composition in optimum extraction conditions has enhancing effects on ConA or LPS-induced lymphocytes under heat stress. The 4 herbal extracts may recover from the immunosuppression induced by heat stress. Taguchi optimization approach is a suitable method for optimization of the composition of herbs.

Key Words: heat stress, spleen lymphocytes, taguchi approach

M40 Effect of heat stress on the rat small intestine: A morphological and gene expression study. A. Lu*[1], G. Cheng[1,2], W. Luan[1], B. Zhou[1], F. Liu[1,2], and J. Xu[3], [1]*Department of Animal Science and Technology, Beijing University of Agriculture, Beijing*, *China*, [2]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, PR China*, [3]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine, China Agricultural University, Beijing, PR China.*

The aim of the current study was to investigate changes in morphology and gene expression in the rat small intestine in response to heat stress. Forty-eight male SD rats (200 ± 20 g) were randomly divided into control or heat-stressed groups. Rats in control group housed with the environment of 25°C, while rats in heat-stressed group were subjected to 40°C for 5 h each day for 10 successive days. Rats were sacrificed on 1st, 3rd, 6th, and 10th day after heat treatment and sections of the small intestine epithelial tissue were excised for morphological examination and microarray analyses. During the microarray examination, each group contain 3 chips, 3 rats' cRNA were pooled and hybridized to each chip. The rat rectal and body surface temperature and serum cortisol levels were all significantly increased after heat treatment ($P < 0.01$). The duodenum and jejunum were significant damaged after 3

d of treatment, and the damage was recovered gradually as time went on. Microarray analysis found 289 genes upregulated (log 2ratio > 1, $P < 0.01$) and 133 genes downregulated (log2ratio < −1, $P < 0.01$) in response to heat stress. Subsequent bioinformatic analysis (including gene ontology and KEGG pathway analysis) revealed the genes altered in response to heat stress mainly related to apical part of cell, oxidation reduction, response to stress, tetrapyrrole binding, rhythmic process, oxidoreductase activity, oxygen binding, transcription factor activity. The pathway mainly involve in Antigen processing and presentation, MAPK signaling pathway, Circadian rhythm-mammal, "Glycine, serine and threonine metabolism" and Retinol metabolism. Heat stress caused significant damage to the rat small intestine and altered gene expression in the rat jejunum. The results of the bioinformatic analysis from the present study will be beneficial to further investigate the mechanisms involved in heat stress-induced damage in the rat small intestine.

Key Words: heat stress, morphology, microarray

M41 Study of immune expression profile of heat stress-induced rat using gene microarray. A. Lu*[1], G. Cheng[1,2], W. Luan[1], J. Yu[1], B. Zhou[1], F. Liu[1,2], and J. Xu[3], [1]*Department of Animal Science and Technology, Beijing University of Agriculture*, *Beijing, China*, [2]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*, [3]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine*, *Beijing, China*.

The aim of the current study was to investigate the changes in morphology of intestine mucosa and gene expression of mucosal immune in the rat small intestine in response to heat stress. Forty-eight male SD rats (200 ± 20 g) were randomly divided into control or heat-stressed groups. Rats in the control group were housed with the environment of 25°C and 60% humidity daily for 10days; while heat-stressed group were housed under control group conditions, but exposed to 40°C and 60% humidity for 5h each day for 10 consecutive days. Rats were sacrificed on 1st, 3rd, 6th, and 10th day after heat treatment. Hematoxylin and eosin (HE) and periodic acid-Schiff (PAS) staining method was used to observe the Morphology changes and the numbers of immune cells. The gene expression profile was analyzed using Agilent microarray. Quantitative RT-PCR (qRT-PCR) was carried out for interesting genes that upregulated and downregulated more than 2 times to validate the reliability of microarray analysis. Structural changes of the mucosa included atrophy of some villi and a reduction in the size of crypts. In contrast to control group, the numbers of lymphocyte and chalice cell were both significantly decreased ($P < 0.01$). There were approximately 3152 expressed genes ($P < 0.01$) among total 41012 genes set in the microarray plate, and 56 immune related genes including 14 upregulated and 42 downregulated genes ($P < 0.01$). Some genes were assayed by qRT-PCR and demonstrated the same alteration tendency as in microarray analysis. Subsequent bioinformatic analysis (including gene ontology and KEGG pathway analysis) revealed the immune genes altered in response to heat stress were related to Positive regulation of immune system process, regulation of immune system, immune system development, leukocyte activation and migration, and genes involved in signal transduction. Heat stress caused significant effect to the rat small intestine mucosa and altered immune related gene expression in the rat jejunum.

Key Words: heat stress, immune, microarray

M42 Study of the mechanism of heat stress-induced IEC-6 cell apoptosis. W. Luan[1], K. Guo[1], G. Cheng[1,2], J. Yu[1], F. Liu*[1,2], and J. Xu[3], [1]*Department of Animal Science and Technology, Beijing University of Agriculture*, *Beijing, China*, [2]*Beijing Key Laboratory of TCVM, CAU-BUA TCVM Teaching & Research Team*, *Beijing, China*, [3]*TCVM Laboratory, CAU-BUA TCVM Teaching & Research Team, College of Veterinary Medicine, China Agricultural University*, *Beijing, China*.

The aim of the study was to study the effects of heat stress on apoptotic of IEC-6 in rat. The IEC-6 cell were divided into control group and heat stress group, both cultured for 4 h with the condition of 37°C and 42°C respectively. The morphological changes of IEC-6 was observed by acridine orange (AO) fluorescence staining; reverse transcription-polymerase chain reaction (RT-PCR) was used to determine the mRNA expression of apoptosis-related gene, such as caspase-3, caspase-8, caspase-9, bax and bcl-2; the early and late apoptotic rate of the 2 groups was detected by flow cytometry; the activity of terminal execute enzyme caspase-3 was detected by the UV spectrophotometry. In contrast to control group, the apoptotic cells were stained by AO and showed densely green yellow or fragment in heat stress group. The percentage of early and late apoptotic cells in heat stress group was significantly higher than that of control group ($P < 0.05$). After heat stress, mRNA expression level of the bax, caspase-3, caspase-9 were significantly increased ($P < 0.01$), mRNA expression level of the bcl-2 was significantly decreased ($P < 0.01$); and activation of Caspase-3 was significantly enhanced ($P < 0.01$). In conclusion, our results revealed that heat stress could trigger IEC-6 cell apoptosis via the mitochondrial pathway of apoptosis, depending upon the activation of caspase-9.

Key Words: IEC-6 apoptosis, mitochondrion, bax, bcl-2, caspase-3, caspase-9

M43 Coagulase-negative staphylococci mastitis management. T. E. Quirk*, L. K. Fox, J. L. Capper, D. D. Hancock, and J. R. Wenz, *Washington State University*, *Pullman*.

Coagulase-negative staphylococci (CNS) are the most common pathogens associated with intramammary infections (IMI) in dairy cows. We hypothesize that post-milking teat disinfection, teat dip, would reduce the microbial colonization of the streak canal and thus reduce the prevalence of IMI caused by CNS species. The efficacy of iodine post-milking teat dip was tested against CNS colonization of the streak canal, and incidence of IMI was measured. Using an udder-half model, 43 Holstein cows at the Washington State University Dairy were enrolled in the trial; teat dip was only applied after milking to one udder-half. Streak canal swab solutions and mammary quarter milk samples were taken in duplicate once a week for 16 weeks for microbial culture. A CNS IMI was identified when 2 of 3 consecutive duplicate quarter milk samples were identified with the same CNS species containing > 120 cfu/ml. The isolates were speciated using PCR-RFLP and gel electrophoresis. Colonization of the streak canal and IMI by CNS were assessed. Twenty-five CNS IMI were diagnosed; prevalence of IMI in control quarters and treated quarters were 8.1% and 19.7%, respectively. Isolation of CNS in milk was less likely in treated than control quarters (Odds Ratio = 0.704, $P = 0.0113$, 95% CI = 0.536–0.925). The majority of CNS IMI was by *Staphylococcus chromogenes* (44%) and appeared to be linked to streak canal colonization. Conversely, the second most prevalent cause of CNS IMI was by *Staphylococcus xylosus* (36%), but did not appear to be linked to colonization of the streak canal. In conclusion, post-milking teat dip was efficacious for reducing IMI caused by CNS, but CNS IMI was not necessarily linked to streak canal colonization.

Key Words: coagulase-negative staphylococci, mastitis, teat dip

M44 Morphometric evaluation of udders in Gir cows and the prevalence of subclinical mastitis. M. A. F. Porcionato[1], M. V. Santos*[1], C. B. M. Reis[1], M. M. Stradiotto[2], C. S. Cortinhas[1], and W. V.B Soares[3], [1]*Department of Nutrition and Animal Production, FMVZ/USP, Pirassununga, Brazil*, [2]*Department of Basic Science, FZEA/USP, Pirassununga, Brazil*, [3]*Institute of Zootecny, IZ/APTA, Mococa, Brazil*.

This trial aimed to evaluate the relation between morphological teats characteristics of Gir cows evaluated by ultrasound and the prevalence of subclinical mastitis. Eighty lactating Gir cows with 90 to 200 d of the 2nd or 3rd lactation were grouped according with their milk flow: fast or slow and milked twice a day with mechanical milker. The teats characteristics were measured by ultrasound and external morphometrical measurements. Somatic cell count (SCC) was determined by the fluoro-opto-electronic method (Somacount 300, Bentley Instrument Inc., Chaska, MN, USA). Samples were considered positive for subclinical mastitis with SCC > 200,000 cells/mL and the pathogens identified in microbiological culture. Data were analyzed using GLM procedure (SAS, version 8.2) and differences were considered significant at $P < 0.05$. Ultrasonography images showed higher ($P < 0.05$) teat channel in slow flow (25.68 mm) than in fast flow (22.31 mm) groups. No significant correlation ($P > 0.05$) was observed between Log(SCC) and morphological teats characteristics. The infrared thermography technique was used to the evaluate udder temperature variation in cows with subclinical mastitis, but no differences ($P > 0.05$) were observed for type of microorganism or Log(SCC). The channel length and the distance for the teat to floor had influence on the prevalence of subclinical mastitis, as well as the mastitis-causing pathogens in Gir cows.

Key Words: mastitis, morphology, thermography

M45 Comparison of 16S rRNA gene sequencing and aerobic culture results performed on milk samples from cows with clinical mastitis. J. R. Wenz*, T. E. Besser, and L. K. Fox, *Washington State University*, *Pullman*

The hypothesis tested in this study was that 16S rRNA gene sequencing (16S) performed on DNA from quarter milk samples of cows with clinical mastitis (CM) would identify the same bacteria found by aerobic milk culture. To test this hypothesis duplicate milk samples were collected from cows with CM. Aerobic milk culture was performed on 100 μL of milk for presumptive bacterial identification and cfu/ml determination. Cows with the same milk culture result on duplicate milk samples (n = 31) were included. Common mastitis pathogens were cultured from 24 samples and 7 were bacteriologically negative (BN). DNA was harvested from each 2 mL milk sample and quantitated. A variable region of the small ribosomal subunit gene was amplified using PCR primers complementary to flanking regions shared among eubacteria and cloned. Sequences of 12 clones from each sample were determined and GenBank searches used to identify bacterial species with the most similar sequences (>99% identity). For 18 of 24 (75%) of the samples, 16S results agreed with culture results. These samples all had >250 cfu/mL (median 13,650; range 290 to > 30,000 cfu/mL) bacteria on culture and >40ng/mL of DNA (median 444; range 45.4 to 1730 ng/mL). In contrast, the remaining 6 samples had lower bacterial counts (median 40 cfu/mL; range 10 to 520) and lower DNA yields (median 44 ng/mL; range 0.70 to 756). In 4/6 samples where culture and 16S results differed, culture identified low numbers of coagulase negative staphylococci and no consistent clone was revealed by 16S. Similarly, BN samples had low DNA yields and no consistent clone identification (and no clone consistent with common mastitis pathogens) was revealed by 16S. The results of this study suggest 16S and culture results are consistent when bacterial numbers are ≥ 300 cfu/mL. Furthermore, these results do not support the hypothesis that BN milk samples result from infection with unculturable bacterial agents.

Key Words: 16S r RNA gene sequence, clinical mastitis, aerobic culture

M46 Hyphenated mass spectrometry investigations applied to the characterization of organic chelates. A. Yiannikouris*[1], C. Connolly[2], R. Power[1], and R. Lobinski[3], [1]*Alltech Inc.*, *Nicholasville, KY,* [2]*Alltech Ireland*, *Dunboyne, County Meath, Ireland*, [3]*CNRS UMR 5254*, *Pau, France*.

This work focused on the development of a method to screen for the presence of metal-complexes in organic chelates using hyphenated techniques of inductively coupled plasma-mass spectrometry (ICP-MS). Identification and characterization of metal-peptide interactions was achieved using hyphenated techniques of mass spectrometry (ESI-MS). The ICP-MS detection in HPLC formed the basis of the methods developed because of its sensitivity regardless of the matrix, which allowed the optimization of the analyte purification before ESI-MS/MS. Analyses indicate that using size-exclusion chromatography (SEC) 5 peaks were characterized for the organic mineral. Chromatogram intensity was a linear function of the total area under the curve indicating the reproducibility of extraction (R2 = 0.999 and RSD ≤3.25%). Application to batch-to-batch reproducibility on 6 samples injected in triplicate showed that the morphology of the Cu elution pattern was identical and reproducible with significant overlapping of the chromatograms ($P \leq 0.05$). Coefficient of variation of the area under the curves ranked between 0.007 and 0.012. SEC ICP-MS detection is thus a valid technique to monitor the molecular mass distribution of metal-binding molecules to assess product quality and the unique fingerprinting per proteinate investigated, with a detection limit below 1 μg/g. This procedure offers a novel application to the detection of the complexes in premixes and feed samples. The fine characterization of the metal-peptides complexes formed through parallel ICP MS and ESI MS/MS detection enabled the identification of the ones stable enough to survive the ionization process. The precursor proteins were identified by means of the ExPASy Proteomics Server of the Swiss Institute of bioinformatics data on soybean genome. In silico molecular modeling using a force-field adapted to the protein and ligand interactions studies (CVFF) clarified the coordination of the amino acids surrounding the mineral by the evaluation of a potential energy according to environmental settings.

Key Words: organic minerals, chelates, speciation

M47 Methods to predict true disease prevalence in beef cattle. C. M. McAllister*[1], B. W. Brigham[1], R. K. Peel[1], H. Van Campen[1], G. H. Loneragan[2], R. L. Weaber[3], J. L. Salak-Johnson[4], and C. C. L. Chase[5], [1]*Colorado State University*, *Fort Collins*, [2]*West Texas A&M University*, *Canyon*, [3]*University of Missouri*, *Columbia*, [4]*University of Illinois*, *Urbana*, [5]*South Dakota State University*, *Brookings*.

Inherent complications arise during the evaluation of disease data for the genetic improvement of disease susceptibility and immune response including the imperfect diagnosis of infection, time of infection, severity of disease challenge, level of disease challenge of clinically normal individuals, and variation in prevalence across years. The objective of this study was to identify alternative methods for classifying diseased versus healthy individuals to improve the accuracy of which bovine respiratory disease (BRD) prevalence (Pr) is estimated. Data for this study included feedlot treatment records (TR), lung lesion scores (LS), early (eADG) (80 d.) and overall average daily gain (ADG) on 2,434 crossbred steers. Disease prevalence was 24.9 and 58.6% for TR and

LS, respectively. Cluster analysis was performed to group animals with similar performance based on TR, mean lung score (MLS), and eADG or ADG to estimate prevalence. A k-means method was implemented in R which utilizes an Euclidean distance matrix to form cluster groups. Principal components (PC) of the individual cluster components were used to determine the point variation explained by TR, LS, and clustered groups. Cluster 1 (C1) grouped animals on TR, MLS, and ADG. The Pr for C1 was 39.2%, recategorizing 725 animals between TRT and C1 and 477 animals between LS and C1. The first 2 PC were able to explain 72.94% of the point variation associated with TR, LS, and C1. Cluster 2 (C2) was formed by replacing ADG with eADG. The Pr of C2 was estimated to be 58.6%, recategorizing 1,202 animals between TR and C2, and no animals between LS and C2. The first 2 PC from the C2 analysis were able to explain 74.8% of the point variation of TRT, LS, BRD, and C2. The amount of point variation explained by the first 2 PC suggest that eADG is more accurate than ADG in predicting true BRD prevalence. The increased predictive power of eADG can be attributed to the majority of animals being diagnosed with BRD occurring early in the feeding period. Comparison of categorical groups indicates that LS is most sufficient at estimating true BRD prevalence during the postweaning phase.

Key Words: beef cattle, bovine respiratory disease, health

M48 A research model for inducing leg problems in broilers. R. F. Wideman*[1], F. Khajali[2], K. R. Hamal[1], A. F. Wideman[1], and H. Lester[1], [1]*University of Arkansas Division of Agriculture*, *Fayetteville,* [2]*Shahrekord University, Faculty of Agriculture*, *Shahrekord, Iran*.

Leg problems increasingly affect fast growing broiler chickens worldwide. Studies investigating practical methods for reducing lameness have been hampered by the sporadic onset and variable incidence of leg problems within experimental flocks. Our objective was to develop a model for inducing a reliably high incidence of lameness in fast growing broilers. To accomplish this we constructed wire floors to create sporadic unstable footing in broiler pens. Rectangular frameworks were constructed from 5 cm x 5 cm lumber. Each frame was 3.05 m long and 1.52 m wide, with 5 cm x 5 cm cross members added for support. Hardware cloth (1.3 cm x 2.54 cm mesh) was fastened to the frame and cross-members. Ten pens (3.05 m x 3.05 m) were set up with floor litter only and 10 pens were set up with half litter and half wire-frame floors. Initially the wire frame was placed flat on the pen floor. Tube feeders were positioned on one side of the pen and the nipples were positioned above the wire frame on the opposite side of the pen. When the chicks reached 2 weeks of age the wire floor was elevated to a 20% slope (Experiment 1) or a 30% slope (Experiment 2), forcing the chicks to walk up and down the sloping wire to drink. Chicks were placed at densities of 50 or 100 per pen in Experiments 1 and 2, respectively. Cumulative incidences of lameness were compared for 2 to 8 wk old broilers using a z-test, with significance declared at $P \leq 0.05$. The incidence of lameness induced in Experiment 1 by the 20% sloping wire floor (6.8%; 34/500 birds) did not differ from the spontaneous occurrence of lameness on litter alone (5.8%; 29/500 birds). The incidence of lameness induced in Experiment 2 by the 30% sloping wire floor (26.7%; 111/416 birds) was significantly higher ($P = 0.01$) than the spontaneous occurrence of lameness on litter alone (10.7%; 43/400 birds). Sloping wire floors can be used to reliably induce reasonably high incidences of lameness, thereby permitting future assessments of practical strategies for reducing leg problems during broiler production.

Key Words: lameness, model, broilers

M49 Microbial diversity in the ileal and cecal contents of broilers using pyrosequencing. S. J. Eom*[1], H. J. Kim[1], C. J. Cha[2], and G. B. Kim[1], [1]*Department of Animal Science and Technology, Chung-Ang University*, *Anseong 456-756, South Korea*, [2]*Department of Biotechnology (BK21 Program), Chung-Ang University*, *Anseong 456-756, South Korea*.

The microbiota in the gastrointestinal (GI) tract of animal plays a pivotal role in the animal′s overall health. However, there is a scarcity of information on the microbial diversity in the gut of livestock animals including broilers and layer hens. Recent developments in microbial ecology have utilized rapid sequencing technologies such as pyrosequencing to investigate the microbial diversity of the human and animal gut. The present study was designed to evaluate differences in the ileal and cecal microbial communities of adult broilers (5 wks old, n = 6) using a bacterial barcoded pyrosequencing strategy. The V1-V3 region of the 16S rRNA gene was amplified by PCR using bar-coded universal primers of 27F and 518R. The amplicons were combined in a single region of the picotiter plate such that approximately 5,000 sequences were obtained from each animal. Taxonomic assignment was performed using the EzTaxon database (http://www.eztaxon.org) and the quantitative analyses was carried out based on the number of sequence reads of each bacterial taxon. Lactobacilli were found to be predominant in the upper gastrointestinal tract and the most abundant *Lactobacillus* species in the ileum were *L. salivarius, L. crispatus*, and *L. aviarius*. Another 12 *Lactobacillus* species were also detected at different levels. In addition, *Enterococcus cecorum* were also abundant in the ileum of adult broilers. In the ceca, the microbial community was highly diverse and *Lactobacillus* species were not found. Clostridia were the most abundant, representing 79% of the total reads. The most common genus detected in the ceca was *Clostridium* and other genera found in the ceca were *Dorea, Alistipes, Bacteriodes*, and *Roseburia*. Pyrosequencing used in this study was proven to be a useful tool for the evaluation of the microbial diversity in the GI tract. Further studies using this tool should be done to better understand the normal microbiome associated with efficient productivity, as well as the impact of changes made in the diet including probiotics supplementation for hens or broilers.

Key Words: broilers, microbiota, pyrosequencing

M50 Use of infrared thermography to monitor risk factors in newborn piglets. J. Morales[1], A. Manso[1], M. Aparicio[1,2], and C. Pineiro*[1], [1]*PigCHAMP Pro Europa*, *Segovia, Spain*, [2]*Centro de Experimentación y Formación en Porcino*, *Segovia, Spain*.

Hypothermia is one of the most important factors affecting perinatal mortality. In this study, infrared thermography was used as a new tool to determine hypothermia and its evolution in newborn piglets. Thermography might provide high advantages in swine clinical practice, revealing lesions and risk factors that would remain hidden with other diagnostic systems. Twenty-two piglets from 2 different litters entered the study at birth time. In each litter, half of the piglets were immediately dried with an absorbent material (cut paper). The other half was not manipulated at birth. Skin temperature on the back was recorded from each piglet at birth and every 10 min time during 1.5 h using a thermographic camera (Fluke Ti45). Piglets were weighed at birth and at 2, 4 and 9 d of life. Data were analyzed using the MIXED procedure of SAS (v 9.00). The statistical model for the temperature analysis included the fixed effects of treatment (control vs drying), time (10 min intervals) and their interaction and the block effect of litter within treatment. Drying piglets immediately after birth increased the skin temperature in the first 90 min of life (39.3°C vs 37.8°C in dried and control piglets, respectively; $P < 0.05$). Evolution of the skin temperature was also different

between treatment (P treatment x time = 0.0001). Initial temperature was 39.3 ± 0.79°C and was kept almost constant in the dried-piglets in the 90 min-interval, while in the control group immediately decreased after birth and then increased progressively until 90 min after farrowing, when skin temperature did not differ between groups (P = 0.27). Body weight evolution did not differ between treatments (2.71 kg at 9 d of life). Drying piglets immediately after birth was effective to keep the body temperature, confirming it as a good management practice to prevent perinatal hypothermia. Infrared thermography demonstrated enough accuracy to be considered as a new tool to complement other diagnostic tools.

Key Words: infrared thermography, newborn piglet, hypothermia

M51 Relationship between lying patterns, feeding management, and incidence of intramammary infection in dairy cows milked in an automated system. T. J. DeVries*[1], K. E. Leslie[2], H. W. Barkema[3], J. Rodenburg[4], and G. Seguin[5], [1]*University of Guelph, Kemptville Campus*, *Kemptville, ON, Canada*, [2]*University of Guelph*, *Guelph, ON, Canada*, [3]*University of Calgary*, *Calgary, AB, Canada*, [4]*DairyLogix Consulting*, *Woodstock, ON, Canada*, [5]*Dairy Farmers of Ontario*, *Casselman, ON, Canada*.

The objectives of this study were to investigate whether feed manipulation affects post-milking standing time in cows milked in an automated milking system (AMS) and to determine if this time relates to the incidence of coagulase-negative staphylococci (CNS) intramammary infection (IMI). Over a 4-mo period, 111 lactating Holstein dairy cows, kept in a sand-bedded freestall barn with 2 pens, each with a free traffic AMS, were monitored. Feed was delivered once daily, and pushed up 2–3 times per day. Quarter milk samples were collected for bacteriological culture from each cow, once every 4 wks. A new IMI was defined as a positive culture sample following a negative culture. For 7 d before each of the last 3 milk samplings, lying behavior, and times of milking and feed manipulation (feed delivery and push up) were recorded. A logistic regression model was used to assess the relationship between post-milking standing time and occurrence of a new CNS IMI. Feed manipulation around the time cows were milked (1 h before 2 h after) resulted in the longest post-milking standing times (86.9 ± 4.3 min; P < 0.001). The shortest post-milking standing times (50.9 ± 4.6 min) were seen in those cows that were milked >4 h before feed manipulation. Over the study period, 58 new CNS IMI were detected, resulting in a herd incidence rate of 0.94 CNS IMI/quarter-year at risk. A non-linear relationship between post-milking standing time and CNS IMI incidence was found (P < 0.04). Compared with those cows that lie down <120 min after milking, those cows that lie down for the first time 120–150 min after milking had lower risk (OR = 0.26, 95% CI = 0.04, 1.98), while those cows that lie down for the first time >150 min after milking had higher risk (OR = 2.70, 95% CI = 1.08, 6.78) of a new CNS IMI. These results suggest that despite being able to manage post-milking standing time of cows milked in an AMS by providing fresh feed, as well as by pushing up feed, frequently throughout the day, the use of such a feeding management strategy in AMS will not necessarily prevent new CNS IMI.

Key Words: intramammary infection, automated milking, lying behavior

M52 Proteomics analysis of plasma and milk protein between healthy dairy cows and *Staphylococcus aureus* infected-subclinical cows. Y. X. Yang*, G. L. Cheng, H. L. Zhao, X. C. Jiang, and S. Chen, *Anhui Academy of Agricultural sciences*, *Hefei Anhui, China*.

Mastitis caused by *Staphylococcus aureus* that are most often the contagious type remains the largest problem on dairy farms. The purpose of our study was to investigate the dynamic changes of plasma and milk protein from healthy and *S. aureus* infected cows. Plasma and milk was collected from dairy cows on d 8 ± 2 and d 50 ± 2 with following diagnosis of acute subclinical mastitis (n = 6) and negative control cows (n = 10) according to the bacteriological culture of milk from all 4 quarters and somatic cell count. Plasma and milk proteins were separated by 2-dimensional electrophoresis; differentially expressed proteins were analyzed by PDQuest 8.0 software, and identified by HPLC equipped with ion trap mass spectrometer. Expression of haptoglobin was abruptly upregulated on d 8 ± 2, and similarly on d 50 ± 2, while α 1 acid glycoprotein was upregulated on d 50 ± 2 in plasma of cows subclinically infected with *S. aureus* mastitis. Expression of albumin and β-casein variant was increased on d 8 ± 2 and continuously on d 50 ± 2 in milk protein of *S. aureus* infected cows, in addition, albumin and β-casein fragments were more variation on d 50 ± 2 than control milk and on d 8 ± 2 in milk protein. The results indicated that expression abundance of plasma and milk proteins were altered and participated in the principal effects of the inflammatory response during dairy cows infected with *S. aureus* subclinical mastitis. Moreover, milk proteins from *S. aureus* infected cows had much larger variation as time goes on. The findings may be useful to provide evidence for treatment the *S. aureus* subclinical mastitis in the early stage of infection to minimize production losses.

Research was supported by the Natural Science Fund of Anhui Province (090411024).

Key Words: dairy cow, *Staphylococcus aureus* mastitis, proteome

M53 Developmental changes in plasma proteins during the transition period in dairy cows. Y. X. Yang[1,2], S. S. Li[1], J. Q. Wang*[1], D. P. Bu[1], L. Y. Zhang[1], and L. Y. Zhou[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Institute of Animal Science and Veterinary Medicine, Anhui Academy of Agricultural Sciences*, *Hefei, China*.

Plasma proteins undergo programmed changes in response to parturition-induced immunosuppression during the transition period. In this study blood samples were collected at 21 d before calving, 1 d and 21 d after calving from healthy Chinese Holstein heifers (n = 6) considered free of mastitis, milk fever, and endometriosis based on the somatic cell count and clinical diagnosis. Developmental changes of plasma were examined using integrated proteomic approaches consisting of minor abundance protein enrichment by ProteoMiner, protein separation by 2-dimensional gel electrophoresis, and protein identification by HPLC equipped with ion trap mass spectrometer. Of the 4 proteins identified, expression of serum amyloid A isoform was altered at parturition, while apolipoprotein E and clusterin were upregulated in minor abundance plasma on d 1 and d 21 after calving compared with d 21 before calving. In addition, IgG, which exerts antimicrobial function, was downregulated on d 1 after calving when compared with other time points during the transition period. Quantitative determination of IgG in plasma was performed using a sandwich ELISA method. Levels of plasma IgG on d 1 after calving were 2.04 ± 0.64 mg/mL, slightly less than IgG concentrations of 2.56 ± 0.87 mg/mL and 3.45 ± 0.96 on d 21 before and after calving, respectively. The IgG concentrations detected

by ELISA were not in complete agreement with the 2-dimensional gel electrophoresis and mass spectrometer expression data. This discrepancy possibly related to IgG polymorphisms. These results may be useful in guiding future studies to investigate mechanisms of the plasma protein secretion during the transition period and to elucidate immune system response at the protein level.

Key Words: periparturient, dairy cow, plasma proteome

M54 Effects of single and combined *Mycoplasma gallisepticums* vaccination on blood electrolytes and acid–base balance in commercial egg-laying hens. H. A. Olanrewaju*, S. D. Collier, and S. L. Branton, *USDA–ARS*, *Starkville, MS*.

Previous study on F-strain *Mycoplasma gallisepticum* (FMG) inoculated layers from our laboratory showed a significant increase in arterial partial pressure of oxygen (pO_2), which is generally associated with an oxygen-dependent improvement in tissue oxygenation to improve the layer chicken's ability to withstand the harmful effects of stressors on their performance and well–being. The aim of this study was to determine whether Bacterin (killed vaccine) and TS-11 (Live vaccine) treatment combination could enhance the arterial (pO_2) levels in layer chickens. The experiment was conducted in 2 trials and arranged in a completely randomized experimental design with 4 treatments. The treatments consisted of Control (MG-Clean), Bacterin, TS-11, and Bacterin + TS-11 combined. In each of the 2 trials, 160 1-day-old *Mycoplasma gallisepticum* (MG) free pullets were raised to 10 week of age (WOA) and were transported to a poultry disease isolation facility. Sixteen isolation units were divided in 4 treatments and each of the 4 treatments had 4 replications with 10 birds/unit (40 birds/treatment). Venous blood samples were collected at the termination of the study. TS-11 vaccinated chickens had significantly ($P \leq 0.05$) higher blood (pO_2) and significantly ($P \leq 0.05$) lower partial pressure of CO_2 (pCO_2) when compared with control and combined MG vaccinated groups. However, no significant differences were observed between Bacterin and TS-11 treatment groups. Hematocrit and blood concentrations of hemoglobin were not statistically affected among treatments, but were slightly higher in TS-11 treatment group. There was a significant ($P \leq 0.05$) effect on blood concentrations of Na^+, Ca^{2+}, and anion, but no significant effect on glucose, cholesterone, triglyceride, and osmolality. These data suggest that inoculation of layers with TS-11 was more effective in elevating (pO_2), than inoculation with Bacterin or TS-11 + Bacterin combined.

Key Words: *Mycoplasma gallisepticum*, vaccine, acid–base balance

M55 Continuously growing chicken liver cell lines for the vaccine production against poultry viruses. J. Y. Lee* and B.-W. Kong, *University of Arkansas*, *Fayetteville*.

A continuously growing, immortal cell line can serve as a stable substrate to produce a cell culture based viral vaccine. The objective of this study is to develop an immortal chicken cell line that can efficiently propagate avian infectious viruses, such as infectious laryngotracheitis virus (ILTV), which causes acute upper respiratory disease in chickens. Primary chicken embryo liver (CEL) cells, which were permissive to ILTV, were transfected with various ectopic expression constructs and/or small interfering RNAs (siRNAs) for cell cycle regulatory genes. As results, 3 immortal chicken embryonic liver (CELi) cell lines were established. The CELi-si-p53 was transfected with the expression construct for siRNA against p53, the CELi-Vector was transfected with the expression vector control, and CELi-im was immortalized spontaneously without transfection. All 3 CELi lines are permissive to ILTV, but the titers produced were low levels (~10 plaque forming units/ml). To further characterize epigenetic states for CELi cells, alterations of mRNA expression for cell cycle regulatory genes were determined at passages of 30, 50, 70, and 90 for all 3 CELi cell lines by quantitative reverse transcription PCR. Throughout all passages in 3 CELi cell lines, the mRNA expression of both p53, (function for cell cycle arrest) and its transcriptional target gene, p21WAF1, were down-regulated showing 10 to 20% expression levels compared with those in primary CEL counterpart. The mRNA expression of E2F1 (function for cell cycle progression), was increased 5.3 - 7.1 fold in all 3 CELi cell lines compared with primary CEL cell counterpart. These results are correlated with mRNA expressions shown in previously established immortal chicken embryo fibroblast cell lines, that efficiently propagate Marek's disease virus (MDV). Though newly established CELi cell lines produced only low ILTV titers, those can be utilized for cell culture based vaccine production against other avian viruses, such as MDV or avian metapneumovirus.

This work was supported by US Poultry and Egg Association.

Key Words: immortal chicken liver cell lines, cell cycle regulation, virus propagation

M56 Effect of rabbit sacculus rotundus antimicrobial peptides on serum antibody titers of AIV and NDV in chicken. R. P. She*[1], K. Z. Wang[2], W. M. Ma[1], Y. Ding[1], and J. Tang[1], [1]*College of Veterinary Medicine, China Agricultural University*, *Beijing,100193,China*, [2]*Research Center of Laboratory Animal*, *Jinan, 250002, Shandong, China*.

Multicellular organisms express numerous antimicrobial peptides (AMP), which have received increased attention over the past decade; over 400 AMP have been identified to date in insects, plants, and animals. AMP have the capacity to kill or inactivate a particular spectrum of bacteria, fungi, and some enveloped viruses in vitro. Our previous research demonstrated that Rabbits Sacculus Rotundus (RSRP) AMP have been shown to improve the structure of intestine and promote intestinal mucosal immunity during the chicken growth period. The purpose of this study was to evaluate the effect of RSRP on serum antibody titers against Avian Influenza virus (AIV) and Newcastle disease (NDV) in chickens and to investigate the potential use of AMP in modulation of the immune response for animal health. Ninety one-day-old healthy Xinza chicks were randomly divided into 2 groups: 40 chickens in the control group, and 50 chickens in the experimental group and control group. AMP from RSRP was injected (I.M.) at doses of 0.1, 0.2, 0.3, 0.4, 0.5, 0.5, 0.5 mg, at the ages of 7, 14, 21, 28, 35, 42, and 49d. Chickens in control groups were given the same doses of sterile saline, respectively. Blood was drawn from chickens at the ages of 7, 14, 21, 28, 35, 42, and 56d, and serum separated. The hemagglutination inhibition titers of NDV and AIV serum antibody were detected in the serum samples of 10 chickens, which were selected randomly from each group. Results: The results were as follows, serum antibody titers of NDV and AIV in the chickens of experimental group were significantly higher than that of the control group ($P < 0.01$) at ages of 21, 28, 35, 42 and 56d. The present observation investigated that AMP of the RSRP could enhance significantly the serum antibody titers of ND live vaccine and AI inactivate vaccine.

Key Words: antibacterial peptide, Newcastle disease, avian influenza, serum antibody titers

M57 Results from the US National Johne's Disease Demonstration Herd Project: Most important areas from the Johne's risk assessment. C. Fossler* and J. Lombard, *USDA:APHIS:VS*, *Fort Collins, CO*.

The National Johne's Demonstration Herd Project (NJDDHP) in the United States was initiated to evaluate the long-term feasibility and effectiveness of management-related practices designed to control Johne's disease on dairy and beef cattle operations. The NJDDHP began in 2003 and includes 62 dairy herds and 20 beef herds in 17 states. All herds began with culture-confirmed Mycobacterium avium subspecies paratuberculosis (MAP) on the operation, and all herd owners agreed to make efforts to control Johne's disease on the operation. Risk assessments, management plans, and testing of herds were completed on an annual basis. Results to date indicate that, for both beef and dairy herds, prevalence of *Mycobacterium avium* subspecies *paratuberculosis* (MAP) in the third, fourth, and fifth years of participation was significantly lower than prevalence during the first year of participation. An analysis using Poisson regression was undertaken to identify areas from the risk assessment most important with regard to MAP prevalence. Among the main areas from the risk assessment (which included calving area, preweaned heifers, postweaned heifers, bred heifers, cows and bulls, and additions/replacements), preliminary results indicate that for dairy and beef herds, the calving and preweaned heifer areas appeared to be most important with regard to risk of cattle being MAP-positive. Specific factors related to the calving and preweaned heifer areas will be further assessed to identify practices associated with a greater risk for cattle to be MAP-positive. For dairy herds, preliminary results indicate that making sure udders and legs of cows in the calving area are clean, using individual animal calving areas (or allowing fewer animals in the calving area), and preventing Johne's disease clinical or suspect animals from entering the calving area were most important with regard to control of Johne's disease on dairy operations.

Key Words: Johne's, control, demonstration herds

M58 Evaluation of the next-generation Parachek ELISA for high-throughput detection of Johne's disease in milk and serum samples. P. Schacher[1], A. Zurfluh[1], D. Zwald[1], T. Byrem[2], and A. J. Raeber*[1], [1]*Prionics AG*, *Schlieren, Switzerland*, [2]*AntelBioSystems Inc*, *Lansing, MI*.

Frequent testing of milk samples for antibodies to *Mycobacterium avium* ssp. *paratuberculosis* (MAP) by ELISA has become an important tool in managing control of Johne's disease in dairy cattle operations. Originally developed for serum samples, Parachek ELISA (also marketed as AntelBio Johne's Milk ELISA) has been validated with bovine milk samples for which it received approval from the USDA in 2006 and is currently marketed in the US by AntelBio. In the last 10 years, Parachek, also known as the AntelBio Johne's Milk ELISA, has been used successfully on more than 750,000 samples within the laboratory network of the Dairy Herd Improvement Association (DHIA). To simplify the use and increase throughput, we have further improved Parachek to make it more user-friendly and allow full automation. The performance of the improved Parachek2 was evaluated on a set of 368 bovine milk samples of which 16 were fecal culture positive, 351 were fecal culture negative or derived from free herds and from 1 sample no culture result was available. Fecal culture for *M. paratuberculosis* was performed by the TREK ESP para-JEM Culture System II. Parachek2 has a sensitivity of 56% (95% CI of 32% - 81%) and a specificity of 98% (95% CI of 92% - 100%). A comparison of the improved Parachek 2 with the currently used Parachek2 showed an almost perfect agreement with a Cohen′s kappa value of 0.93. To enhance throughput Parachek2 was automated on a Beckman Coulter Biomek FXP. The Laboratory Automation Workstation was equipped with a 96-well plate washer and a plate reader which allows for a throughput of up to 16 plates in one working day (8.5 h) starting from serum or milk samples. Comparison of the fully automated system with manual processing showed almost perfect agreement with a kappa value of 0.96. These results demonstrate that Parachek2 can be easily run on an automated system with the same excellent performance as with manual processing of the samples using the Parachek and thus enabling laboratories to save time and freeing staff for other work.

Key Words: Johne's disease, ELISA, milk

M59 Analysis of the immune response to a major membrane protein of *Mycobacterium avium* ssp. *paratuberculosis* in experimentally and naturally infected cattle. G. S. Abdellrazeq*[1], H. M. Rihan[2], M. J. Hamilton[3], A. J. Allen[3], K. T. Park[3], J. P. Bannantine[4], J. R. Stabel[4], and W. C. Davis[3], [1]*Faculty of Vet Med, Alexandria Univ*, *Edfina, Rosetta-line, Behera Province, Alexandria University, Egypt,* [2]*Faculty of Vet Med, Mansoura Univ*, *El Mansoura, Egypt,* [3]*Wash State Univ*, *Pullman*, [4]*USDA-ARS National Animal Disease Center*, *Ames IA*.

The 35 kDa major membrane protein (MMP) of *Mycobacterium avium* ssp. *paratuberculosis* was studied to determine the potential of using MMP to develop a subunit vaccine. A flow cytometric (FC) assay was developed to conduct the study. Comparison of the immune responses to MMP, purified protein derivative (PPD) and soluble antigen (SAg) in experimentally (n = 5) infected calves revealed the CD4 response was stronger than the CD8 response to MMP at 3 mo ($P < 0.05$). No significant differences were observed in the CD4 response to MMP compared with PPD and SAg. A significant difference was observed between CD8 response to MMP compared with PPD and SAg ($P < 0.05$). At 12 mo the CD4 response to MMP was still stronger than the CD8 response. The CD4 response to PPD and SAg was significantly stronger than the response to MMP ($P < 0.05$). No significant difference was observed in the CD8 response to MMP compared with PPD and SAg. The CD4 and CD8 response to MMP, PPD, and SAg was significantly higher in naturally infected cows compared with the response in experimentally infected calves, at the preclinical (n = 3) and clinical (n = 5) stage of disease ($P < 0.05$). The findings show the cell-mediated immune response to MMP develops slowly, as detected by FC, and is not diminished at any stage of infection. These findings indicate that MMP does not elicit a protective immune response in its native form. A strategy is needed to modify MMP so that it elicits a strong early response, essential for blocking the capacity of Map to dysregulate the immune response and cause disease.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, MMP, immune response

M60 Flow cytometric and in-house ELISA methods of milk testing for Johne's disease diagnosis. A. Wadhwa*[1], J. P. Bannantine[2], B. A. Elliot[1], M. C. Scott[1], and S. Eda[1], [1]*University of Tennessee, Knoxville*, [2]*United States Department of Agriculture*, *Ames, IA*.

Use of enzyme-linked immunosorbent assay (ELISA) in dairy herds is recommended as a Johne's disease (JD) control measure; however, current ELISA tests suffer low sensitivity. The long-term goal of this project is to develop a sensitive ELISA method of testing milk samples for JD diagnosis. By using a flow cytometric method (FCM), we demonstrated previously that *Mycobacterium avium* ssp. *paratuberculosis* (MAP)-infected cattle produced serum antibodies against surface antigens of MAP. Also, an in-house ELISA test developed using surface antigens of MAP showed a higher level of sensitivity in detecting MAP infections than that of current ELISA tests. The objective of this study is to demonstrate a "proof-of-concept" that surface antigens of MAP can be used for detection of anti-MAP antibodies in milk as well as serum samples. FCM-Intact MAP bacilli were incubated with 48 bovine serum and milk samples and subsequently with fluorescein-labeled anti-bovine IgG secondary antibody. Antibody binding to the surface of MAP was detected by using a flow cytometer. In-house ELISA-Surface antigens of MAP were extracted by a brief treatment of the bacteria with 80% ethanol, coated on a microtiter plate, and reacted with bovine milk samples. Antibody binding to the immobilized MAP surface antigens was detected in an ELISA format by using a horseradish peroxidase–labeled secondary antibody and its substrate. The following conditions were optimized: concentrations of antigen, milk, and secondary antibody for better differentiation of milk samples obtained from JD-positive and JD-negative herds and 6 different mycobacteria were tested as absorbent of cross reactive antibodies. In FCM, a high level of correlation (r^2 = 0.79) between antibody binding levels of serum and milk was observed. In the optimized in-house ELISA test, 9 out of 10 JD-positive milk samples showed positive antibody reactions. These results suggest that MAP-infected cattle produce milk antibodies against surface antigens of MAP. Further study may reveal whether a sensitive ELISA test can be developed based on the surface antigens of MAP.

Key Words: *Mycobacterium paratuberculosis*, antigen, diagnosis

M61 Induction of B cell responses upon experimental infection of neonatal calves with *Mycobacterium avium* ssp. *paratuberculosis*. J. R. Stabel*[1], J. P. Bannantine[1], S. Eda[2], and S. Robbe-Austerman[3], [1]*USDA-ARS-NADC*, *Ames, IA,* [2]*University of Tennessee*, *Knoxville,* [3]*USDA-APHIS-NVSL*, *Ames, IA*.

Animal models are useful for studying host responses to infection and aid in the development of diagnostic tools and vaccines. The current study was designed to compare the effects of different methods of experimental infection: Oral (*Mycobacterium avium* ssp. *parauberculosis* (MAP) strain K-10; Oral/DXM (pretreatment with dexamethasone before oral inoculation with strain K-10); IP (intraperitoneal inoculation with strain K-10); and Oral/M (oral inoculation with mucosal scrapings from a clinical cow) in neonatal calves. The objective of this study was to determine if infection with MAP over 12-mo period would invoke changes in the percentages of total B cells in the peripheral blood mononuclear cell population and in subpopulations of B cells as determined by CD5, CD25, and CD45RO markers. Over the course of the study, the percentage of total B cells in nonstimulated and antigen-stimulated cell cultures increased ($P < 0.01$) for orally and intraperitoneally infected calves, with the highest percentages noted at 3 and 6 mo post-infection. Oral infection of calves with a clinical strain of MAP (Oral/M) resulted in increased ($P < 0.05$) percentages of $CD5^{dim}$ and $CD5^{bright}$ B cells, regardless of in vitro stimulation, by 9 and 12 mo post-infection. Experimental infection by all methods resulted in increased ($P < 0.05$) expression of CD25+B cells and CD45RO+ B cells early in the study but the most significant results were observed at 12 mo for calves pre-treated with dexamethasone before oral inoculation with strain K-10 (Oral/DXM) and Oral/M calves. Immunoblot analyses demonstrated the greatest reactivity to a whole-cell sonicate of MAP in sera from IP calves and the lowest was observed in calves orally inoculated with strain K-10. Further evidence of strong MAP-specific antibody responses in the IP calves was demonstrated using the EvELISA method. In summary, the method of experimental inoculation with MAP did affect the induction of B cell subpopulations and the appearance of MAP-specific antibody during the 12-mo study period.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, cattle, B cells

M62 Deletion of *relA* attenuates in vivo survival of *Mycobacterium avium* ssp. *paratuberculosis*. K. T. Park*[1], A. J. Allen[2], M. J. Hamilton[1], A. Grimm[1], H. M. Rihan[3], G. S. Abdellrazeq[4], and W. C. Davis[1], [1]*Department of Veterinary Microbiology and Pathology, Washington State University*, *Pullman,* [2]*Department of Veterinary Clinical Sciences, Washington State University*, *Pullman,* [3]*Department of Bacteriology, Mycology and Immunology, Mansoura University*, *Egypt*, [4]*Department of Microbiology, Alexandria University*, *Egypt*.

Extensive effort is underway to develop a mutant *Mycobacterium avium* ssp. *paratuberculosis* that can be used as a vaccine to control paratuberculosis in cattle. Studies in mice have shown that deletion of *relA* in *M. tuberculosis* attenuates survival in vivo. Mice infected with the *relA* mutant survived longer with a reduction in bacterial burden and pathology. The objective of the present study was to test the hypothesis that deletion of *relA* also attenuates survival of *Map in vitro* and in vivo. To test the hypothesis we generated a deletion mutant (*relA*) in the K10 strain of *Map*, tagged with the green fluorescent protein gene (*gfp*) and infected calves (n = 5). Wild type K10-*gfp* was used as a control (n = 3). Analysis in an in vitro assay revealed deletion of *relA* reduced survival in monocyte derived macrophages compared with survival of wild type K10 at 6 d post infection (12.5% ± 6.3 SD vs. 29.4% ± 3.6 SD) ($P < 0.05$ by Kruskal-Wallis test). Analysis in vivo using a calf cannulated ileum model showed that deletion attenuated survival without altering the immune response to *Map* 3 mo PI. At necropsy, 9 different tissue sites were processed for *Map* culture. No bacteria were detected in any tissue sample (n = 45) from calves infected with the mutant at 3 mo PI. In contrast, bacteria were detected in 13 of 27 tissue sites obtained from calves infected with wild type K10 (all 3 animals had at least 4 positive tissues) ($P < 0.05$ by chi-squared test). The findings show that further studies are warranted to determine if a *relA* deletion mutant can be used as a vaccine.

Key Words: live vaccine, paratuberculosis

M63 Microfluidic system for serodiagnosis of Johne's disease. S. Eda*[1], A. Wadhwa[1], J. P. Bannantine[2], M. C. Scott[1], R. W. Shaw[3], and R. S. Foote[3], [1]*University of Tennessee, Knoxville*, [2]*United States Department of Agriculture*, *Ames, IA,* [3]*Oak Ridge National Laboratory*, *Oak Ridge, TN.*

Microfluidics (Lab-on-a-chip) technology has been used in various analytical processes, including electrophoresis, single-cell analysis, biochemical assays, and immune assays. The technology offers opportunities for the development of point-of-care diagnostic devices for various infectious diseases. Diagnosis of Johne's disease (JD) is currently conducted in diagnostic laboratories, creating dairy farmers costly expenses

for veterinary service, sample handling, and shipping. An automated point-of-care diagnostic device for JD would reduce diagnosis-related costs and also may improve the accuracy of testing because it would require a minimum of examiner intervention. The long-term goal of this project is to develop a point-of-care serological diagnostic device for JD. For this report, we tested serum antibodies against *Mycobacterium avium* ssp. *paratuberculosis*, the causative agent of JD, using a microfluidic system. In this project, magnetic micro-beads were used as the solid phase for antibody binding reactions. Magnetic micro-beads were treated with ethanol-extracted antigens of *M. paratuberculosis*, serum sample, and then a fluorescently labeled secondary antibody. Antibody binding was subsequently detected by using a flow cytometer. Assay conditions were optimized for higher analytical sensitivity and specificity of the bead-based flow cytometric test. Using the optimized conditions, we then tested JD-negative and JD-positive serum samples in a microfluidic system. Using a well-classified set of 155 serum samples, diagnostic sensitivity and specificity of the flow cytometric test were estimated to be 60.0% and 98.0%, respectively. Five serum samples were tested using a microfluidic system we designed and the results were compared with those of the flow cytometric test on the same set of samples. As a result, a high level of correlation (linear regression, $r^2 = 0.994$) between the results of flow cytometric and microfluidic tests was observed. Our data demonstrated a 'proof-of-the-concept' that JD can be diagnosed by employing a test based on microfluidics technology.

Key Words: paratuberculosis, diagnosis, microfluidics

M64 Evaluation of *Mycobacterium avium* ssp. *paratuberculosis* strains and a locus associated with tissue infection. H. L. Neibergs*[1], Y. Schukken[2], R. H. Whitlock[3], A. Pradhan[2], J. M. Smith[4], and E. Hovingh[5], [1]*Washington State University*, *Pullman*, [2]*Cornell University*, *Ithaca, NY*, [3]*University of Pennsylvania*, *Kennett Square*, [4]*Unversity of Vermont*, *Burlington*, [5]*Pennsylvania State University*, *University Park*.

Mycobacterium avium ssp. *paratuberculosis* (*Map*) strains vary by the presence of multiple copies of fatty acid metabolism genes which are thought to increase the virulence of the mycobacterium and potentially increase the incidence of Johne's disease. We previously identified a locus on chromosome 3 (*ss86341066*) that showed that animals with an A allele were 3 times less likely to be tissue infected with *Map* than those with a C allele (Settles et al. 2009, Animal Genetics, 40, 655–662). The objective of this study was to determine if there was an interaction between *Map* strains and the genotypes of hosts with *Map*-infected tissue. *Map* strain types were identified by multilocus short sequence repeat analysis from ileo-cecal lymph nodes, ileo-cecal valve, or ileum and fecal samples from19 Holstein cows representing 3 herds. *Map* strain types coded as 2, 3, 4, 6, 9, 11 and 12 were identified in 10, 1, 4, 4, 1, 1, and 1 sample, respectively. Three animals had 2 different strains isolated from their tissue and feces (2 animals-type 2 and 4; 1 animal-type 3 and 6). *Map* strains 3, 4, 6, 9, 11 and 12 were combined into one group for analysis due to the small number of observations. A Fishers exact test compared the *ss86341066* allele frequencies with the *Map* strain that infected each animal. For animals infected with *Map* strain types 3, 4, 6, 9, 11 and 12 the frequency of the minor protective allele (A) was 0.0 and the frequency was 1.0 for the major allele (C). For animals with *Map* strain type 2, the frequency of the minor allele (A) was 0.25 and the frequency was 0.75 for the major allele (C). The frequency of the *ss86341066* alleles differed ($P < 0.05$) between animals with *Map* strain type 2 and *Map* strains type 3, 4, 6, 9, 11 and 12. These data suggest that *Map* strain type 2 may be more virulent in the Holstein animals tested than *Map* strain types 3, 4, 6, 9, 11 and 12 and that there is an interaction between *Map* strains and *ss86341066* associated with tissue infection. Further studies with larger sample sizes will be needed to confirm and further characterize this interaction.

Key Words: Johne's, strains, locus

M65 Genome sequence of a *Mycobacterium avium* subspecies *paratuberculosis* isolate from a patient with Crohn's Disease. L. Li*[1], A. Amonsin[2], S. Sreevatsan[3], and V. Kapur[1], [1]*Penn State University*, *University Park,* [2]*Chulalongkorn University*, *Bangkok, Thailand*, [3]*University of Minnesota*, *St. Paul.*

Mycobacterium avium subspecies *paratuberculosis* (Map) has been associated with human Crohn's disease, a chronic inflammatory bowel disease. To identify polymorphic sequences with potential relevance to host specificity and evolution, an isolate recovered from a Crohn's disease patient, MAP4 has been sequenced. Second-generation sequencing approaches were used to generate a total of 88.5 million base pairs of finished sequence, representing an 18-fold coverage of the genome. Currently, the genome has been assembled into ~60 contiguous pieces accounting for ~98% of the K10 genome. Whole-genome comparison of MAP4 with K10 revealed a lack of major large-sequence polymorphisms. A total 171 single-nucleotide polymorphisms (SNPs) were identified, with 152 in coding regions, which is ~6-fold lower than SNPs found in genome comparison of 2 Mycobacterium tuberculosis strains. Two-thirds of the SNPs in coding regions were non-synonymous and were primarily found in genes encoding metabolic pathways, cell envelope, and virulence genes involved in invading mammalian cells. Fifty-eight synonymous SNPs were identified and the pattern of synonymous nucleotide substitution between 2 genomes at 4,350 putatively orthologous loci showed a synonymous substitution rate of 3.7×10^{-5}, suggesting a relatively recent divergence between MAP4 and K10. Many of the SNPs identified in MAP4 were verified in 10 isolates from human and cattle and the results indicate that these were not specific in isolates from human hosts. Overall, the comparison of 2 genome sequences confirmed restricted allelic variation in Map, and clearly showed the considerable similarity in sequences between Map isolates recovered from cattle and humans.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, genome sequence, single-nucleotide polymorphism

M66 Impact of vaccination against Johne's disease on lactation performance of dairy cows: Milk production, reproduction and overall culling. J. R. Lima*[1], E. Patton[2], B. Knust[1], J. Bohn[3], and S. J. Wells[1], [1]*University of Minnesota*, *St. Paul*, [2]*Wisconsin Department of Agriculture*, *Madison*, [3]*Veterinary Clinic*, *Amery, WI*.

Our objective was to evaluate the impact of vaccination against Johne's disease on lactation performance measured by milk production, reproductive outcomes and overall culling rate. Three dairy herds in the state of Wisconsin previously identified with *Mycobacterium avium* ssp. *paratuberculosis* (MAP) infection, by a combination of diagnostic tests (serum ELISA and TREK fecal culture) and presence of clinical disease were enrolled in this study. Within each herd, heifer calves at birth were systematically allocated to a vaccination or control group, until 2 cohorts of 50 animals or 10% of the adult cow herd was formed, establishing an overall sample size across herds of 307 animals (vaccinated = 162 vs. control = 145). Vaccination was performed up to 35 d of age. From each of the study cows a fecal sample was collected at first freshening, at 90 d of pregnancy in the first lactation, at 90 d of pregnancy for all following lactations and at time of culling to assess MAP infection. Milk production, reproductive performance and culling

data, from the year 2005 until 2009, were obtained from the dairy herd records and fecal culture results were collected from the laboratory. Animals were classified positive for MAP if the TREK fecal culture score was ≥ 1. Mixed modeling was used to analyze differences in total milk production per lactation between the 2 groups. Logistic regression was used to evaluate conception at first breeding and Cox regression was used to estimate days in milk (DIM) to conception and days from birth until culling. Vaccination against Johne's disease had no effect on total milk production across lactations, conception at first breeding and DIM to conception. Time to test positive for Johne's disease was statistically significantly longer among vaccinates but no difference was observed in overall culling rate between groups. In this study, vaccination against Johne's disease had no improvement on overall lactation performance.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, Johne's disease, lactation performance

M67 Effect of Tri-Lution (T), a synbiotic, on milk production and shedding of *Mycobacterium avium* ssp. *paratuberculosis* (MAP) in a commercial dairy herd. D. M. Albin*, C. Jones-Anding, D. P. Casper, D. A. Spangler, and G. A. Ayangbile, *Agri-King, Inc.*, *Fulton, IL*.

The effects of feeding T (synbiotic) in a dairy herd with Johne's disease on milk production and shedding of MAP (causative agent of Johne's) was evaluated for 10 mos. Thirty-six lactating Holsteins on a commercial dairy farm were divided into 2 groups, T (n = 19) and control (C, n = 17), based on days in milk and fecal shedding of MAP. Tri-Lution was added to a corn silage, haylage, and high-moisture corn diet. Tri-Lution was included at 56.7 g/cow/d for 22 weeks, and then 113.4 g until the end. Milk production and composition data were obtained monthly via Dairy Herd Improvement Association sampling. Fecal samples were collected every other week. Samples were used to assess MAP shedding via polymerase chain reaction. Fat-corrected milk (3.5%, FCM) production was increased for cows fed 56.7 g T within 5 mos compared with cows fed C (33.2 ± 4.3 vs 26.8 ± 2.4 kg/d for T and C, respectively). Cows fed 113.4 g T within 3 mos (8 mos total) had greater FCM production than cows fed C (33.0 ± 3.9 and 25.1 ± 4.5 kg/d). In addition, when cows were fed 56.7 g T, the decline in milk production was slower than C (−0.6 vs −1.2 kg FCM/cow/mo) and less linear (r^2 = 0.56 for T, 0.81 for C). For cows fed T, milk shedding of MAP was reduced by 39%, and incidence of shedding (number of positive samples) was reduced 16%, with 56.7 g T vs C. When cows were fed 113.4 g T, following 56.7, MAP shedding in milk was further reduced 9%, while incidence was further reduced 1%. For cows fed 56.7 g/d T fecal shedding of MAP was reduced by 18%, while incidence was reduced 5%. With 113.4 g T, fecal shedding was further reduced 3%, while incidence was further reduced 8% vs C. Relative standard error of shedding data ranged from 8.7 to 30%. Tri-Lution improved milk production, and reduced milk and fecal shedding of MAP (Johne's), over a 10-mo period. Tri-Lution can be a beneficial management practice on commercial dairy farms with Johne's disease.

Key Words: synbiotic, Johne's disease, milk production

M68 Survivability of *Mycobacterium avium* subsp paratuberculosis in grass silage after fermentation and exposure to low pH and high organic acids. S. A. Flis*[1], K. L. Cook[2], and C. S. Ballard[3], [1]*Bourdeau Bros.*, *Middlebury, VT*, [2]*USDA–ARS*, *Bowling Green, KY*, [3]*W. H. Miner Agricultural Research Institute*, *Chazy, NY*.

Mycobacterium avium ssp. *paratuberculosis* (Map) is a pathogen of concern in dairy production due to its ability to withstand harsh conditions and cause new infections. Infection is a result of ingesting Map from contaminated feed, water, or manure. The study objective was to evaluate the ability of Map to survive low pH and high organic acid concentrations encountered as part of ensiling. Three experiments were conducted to evaluate survivability and the ability to differentiate live and dead bacteria. Study 1 evaluated survivability in grass silage fermented in vacuum bags. Forage was inoculated with live Map, dead Map, or no Map (control) and incubated for 25, 50, 75, or 100d. Fermented forage averaged 4.7 ± 0.11 pH, 8.3 ± 2.1 lactic acid (% DM), 3.5 ± 0.9 acetic acid (% DM), and 0.05 ± 0.03 propionic acid (% DM). Study 2 evaluated survivability in buffered citric acid solutions of pH 4, 5, 6, and 7. Live Map bacteria were added to solutions and bacterial concentrations were measured at 0, 5, 15, 20, 30, and 35 d. Study 3 evaluated survivability in exudates from control silage in study 1. Exudates were filter sterilized to eliminate background population interference and pure live Map was exposed to exudates for 0, 5, 10, 15, 20, 25, or 30 d. Study 1 found no changes in concentration of Map regardless of number of fermentation days or viability/presence of MAP inoculated. After exposure to citric acid in study 2, samples were analyzed for Map concentration by PCR (total bacteria) and propidium monoazide (PMA; live bacteria). Study 2 found that live MAP concentration decreased as pH decreased and exposure time increased with a 2-fold log reduction for pH 4 at 37d. In study 3, no change in Map concentration was found when bacteria were exposed to exudates. These results indicate that while Map is sensitive to low pH, this only occurs with concentrations of acid higher than experienced with proper forage fermentation. Map present in manure and applied to forage grasses may survive ensilaging process and silage may therefore be a potential route of infection.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, silage, quantitative PCR

M69 A membrane associated serine protease of *Mycobacterium avium* subspecies *paratuberculosis* plays a role in resistance to phagosomal acid stress. A. Kugadas*[1], H. K. Janagama[1], E. A. Lamont[1], and S. Sreevatsan[1,2], [1]*Department of Veterinary Population Medicine, University of Minnesota*, *Saint Paul*, [2]*Department of Veterinary Biomedical Sciences, University of Minnesota*, *Saint Paul*.

Pathogenic mycobacteria successfully survive in the acidic micro-environment of the phagosome. We hypothesize that *Mycobacterium avium* ssp. *paratuberculosis* (MAP) expresses a membrane associated serine protease encoded by MAP0403, in response to phagosomal acidification and is vital for the intracellular survival. Expression of serine protease by MAP K-10 was studied at 10, 30, and 120-min. post infection of bovine monocyte derived macrophages treated with or without bafilomycin to block phagosomal acidification. MAP serine protease was significantly upregulated exclusively in the acidified phagosomes. Highest level of MAP0403 expression coincided with the timing of peak phagosome acidification in the macrophages. Inasmuch as *Mycobacterium smegmatis mc^2 155* cannot resist and persist in the acidified phagosome, we cloned the open reading frame of MAP0403 via a pSM417 vector into *M. smegmatis mc^2 155*. Compared with controls, *M. smegmatis mc^2 155* transformants carrying the MAP serine protease show a temporal survival advantage during the in vitro acid stress for 30 and 120min. Our studies suggest that MAP serine protease is critical in resisting the phagosomal acid stress by MAP. Further establishment of this mechanism will lead to better understanding of a proximal step in the pathogenesis of mycobacterial infections to establish an intracellular niche.

M70 Quantifying Johne's disease infectivity in Indiana dairy herds. C. C. Wu*, T. L. Lin, A. Storm, C. A. Alinovi, and M. P. Ward, *Purdue University*, *West Lafayette, IN*.

Analysis of fecal culture and ELISA serology for Johne's disease (JD) was conducted on 5 dairy herds to quantify infectivity of JD from 2004 to 2009. Various positive management practices and risk assessment have been employed in these herds. Spearman′s coefficient was calculated for the relationship between fecal shedding level and ELISA score. In a large open Holstein herd (900 milking) prevalence of JD by semiquantitative fecal culture was 36.1% in 2004, 18.5% in 2005, and 18.7% in 2006. In a small closed herd (50 milking) none of the tested cows were positive for JD by fecal culture in 2004. This herd did have one cow that was fecal culture positive in 2005 (0.9%), though all cows were negative for JD when tested in 2006. Two small open herds were studied. In one herd (80 milking) 19% of cows were positive for JD by fecal culture in 2004, 9.4% in 2005, and only 3.3% of cows were positive in 2006. The herd prevalence for JD went up to 24.6% in 2007 with new unvaccinated cows added to the herd, but reduced to 4.2% in 2008. In the other small herd (60 milking), 4.2% of the cows were positive for JD by fecal culture in 2005, 4.5% in 2006, and all tested animals were negative for JD in 2007 (0.0%). The fifth herd is a medium-sized (300 milking) open dairy herd where 10% of cows were fecal positive for JD in 2003 and herd prevalence had risen to 31.7% when tested in 2005. In subsequent years, the herd prevalence of JD decreased to 14.8% in 2006 and 9.8% in 2007. Vaccination against JD was practiced in all herds except the small closed herd (50 milking). Between 2003 and 2007, mean ELISA values increased in herds practicing vaccination with little change in the non-vaccinated herds. In conclusion, ELISA testing alone cannot be used to identify positive and shedding animals for culling program. ELISA is best used to screen the status of JD in herd and fecal culture remains the most accurate ante-mortem method to identify animals that are mycobacterial shedders.

Key Words: Johne's disease, infectivity, culture

M71 Preliminary observation of an indigenous Johne's disease vaccine study in infected cattle herd in India. S. V. Singh*, A. Srivastva, B. Singh, A. Kumar, and A. V. Singh, and P. K. Singh, *Central Institute for Research on Goats*, *Makhdoom, Farah, Mathura (UP), India*.

Ineffective control strategies of Johne's disease (JD) by 'test and cull' method, banned on culling of cows due to social issue, high presence of Mycobacterium avium ssp. paratuberculosis (MAP) in livestock, humans and in environment, difficulties in early diagnosis etc. were major challenges to successful JD control program in India. An indigenous JD vaccine has been developed using a native MAP strain of 'Indian Bison type' of goat origin and found very effective in preventing and also curing of JD in goats and sheep. In present study the status of MAP infection and the efficacy of indigenous vaccine for the control of JD in a naturally infected cattle herd (based on preliminary data) were described. Fecal, blood and serum samples from 135 cows (100 adult and 35 calves), showing moderate to advanced symptoms of JD were processed for assessing the status of MAP infection before vaccination by microscopy, PCR and ELISA test, respectively. A total of 60 and 31.85% cows were positive by ELISA and blood PCR. Positive samples by PCR were further genotyped as MAP Bison type by IS 1311 PCR-REA. Out of 32 calves and 51 adult cows, 65.6 and 84.3% were positive in microscopy of fecal smear, respectively. Necropsy of few died cows showed advanced gross lesions of JD. All the cows were vaccinated, sampled (20%) and monitored for improvement in physical condition, reduction in MAP shedding, morbidity, mortality and immune response. Sample results and other data recorded before and 2 mo post vaccination showed reduction in number of MAP shedder/positive cows as well as shedding level, reduced morbidity and mortality despite of extreme winter condition, accelerated sero-conversion, checked diarrhea, increased appetite, no untoward reaction etc. were recorded. Conclusively, developed indigenous vaccine may perform equally (as in previous study on goat and sheep) in controlling the clinical cases of JD in cattle.

Key Words: indigenous vaccine, Johne's disease, *Mycobacterium avium* ssp. *paratuberculosis*

M72 Association of a single nucleotide polymorphism of calpain 1 gene with meat tenderness of the yak. X. J. Wu[1], L. Yang[1], H. L. Wang[1], L. P. Zhang[1], J. H. Wang[1], M. A. Brown*[2], and J. P. Wu[1], [1]*Gansu Agricultural University*, *Lanzhou, Gansu, China*, [2]*USDA-ARS, Grazinglands Research Laboratory*, *El Reno, OK*.

The association of a single nucleotide polymorphism (SNP) of calpain 1 (CAPN1) gene with shear force of 2.54 cm steaks from *M. longissimus dorsi* from Gannan yaks (*Bos grunniens*, n = 181) was studied. The experimental design was a repeated measures with the main unit in a completely randomized design with a factorial arrangement of treatments (age at harvest x SNP) and the repeated subunit was aging days. Individual animal was used as the experimental unit. Yaks were harvested at 2, 3, and 4 yr of age (n = 51, 59, and 71, respectively), and samples of each yak carcass were aged at 4°C for 0, 1, 3, 7, 14 or 21d. Shear force for each sample was determined at each of 6 postmortem aging times using Warner-Bratzler shear force methodology. Fragments of the yak CAPN1 gene including exon 9 and intron 9 were amplified and subjected to single strand conformation polymorphism analysis. A SNP was found within intron 9 of the CAPN1 gene G5837A, and there were 2 genotypes of GG and GA identified, respectively. The genotypic frequency of GG was 82.87% compared with 17.13% for GA. Statistical analysis was done using SAS PROC MIXED. Interaction of SNP × age at harvest × aging days was demonstrated ($P < 0.10$) for shear force. In 2-yr-old yak, genotype GG had lesser shear force than that of GA at the aging times of 0, 3, and 7 d (0.78, 0.92, and 0.65 kg, respectively; $P < 0.05$); however, in 3-yr- and 4-yr-old yak, genotype GG had lesser shear force than GA at aging time of 14 d (0.71 and 0.58 kg, respectively; $P < 0.05$). Genotype had little effect ($P > 0.05$) on shear force for 3- and 4-yr-old yaks averaged over aging time. In 2-yr-old yak, genotype GG had 0.57 kg lesser shear force than yaks with genotype GA ($P < 0.05$) averaged over aging time. Therefore, results from this research suggest that the CAPN1 SNP affected shear force of *M. longissimus dorsi* but the effect differed depending on age of yak and aging time of the meat.

Key Words: yak, calpain, genotype

M73 The effects of single nucleotide polymorphisms of calpastatin gene on meat tenderness of the yak. J. H. Wang[1], J. P. Wu*[1], H. L. Wan[1], L. Yang[1], X. J. Wu[1], M. A. Brown[2], and L. P. Zhang[1], [1]*Gansu Agricultural University*, *Lanzhou, Gansu, China*, [2]*USDA-ARS, Grazinglands Research Laboratory*, *El Reno, OK*.

The association of single nucleotide polymorphisms (SNPs) of calpastatin (CAST) gene with shear force of 2.54 cm steaks from *M. longissimus dorsi* from Gannan yaks (*Bos grunniens*, n = 181) was studied. Yaks were harvested at 2, 3, and 4 yr of age (n = 51, 59, and 71, respectively), and samples of each yak carcass were aged at 4°C for 0, 1, 3, 7, 14 or 21d. Shear force for each sample was determined at each of the 6 postmortem aging-day using Warner-Bratzler shear force methodology. Fragments of the yak CAST gene including exon 3 were amplified and subjected to single strand conformation polymorphism analysis. Two linkage SNPs were found within exon 3 of the CAST gene: G40455A and G40463A, and there were 2 genotypes of GG/AA and GA/GA demonstrated respectively. The genotypic frequency of GG/AA was 72.93% compared with 27.07% for GA/GA. Statistical analysis was done using SAS PROC MIXED. Interaction of genotype × age at harvest × aging time was demonstrated ($P < 0.05$) for shear force. In 2-yr-old yak, GG/AA had lesser shear force than GA/GA at the aging times of 1 and 7 d (1.15 and 0.57 kg, respectively; $P < 0.05$); 4-yr-old yak GG/AA had lesser shear force than GA/GA at aging times of 7 and 14 d (0.64 and 0.49 kg, respectively; $P < 0.05$). Genotype had little effect ($P > 0.05$) on shear force in 2-yr- and 3-yr-old yak averaged over aging time. In 4-yr-old yak, GG/AA had 0.40 kg lesser shear force than GA/GA ($P < 0.05$) averaged over aging time. Therefore, it was concluded that the CAST SNPs affect ($P < 0.10$) shear force of *M. longissimus dorsi* depending on age of yak and aging time of the meat. Further study should focus on the ontogeny of CAST gene mRNA expression.

Key Words: yak, calpastatin, tenderness

M74 Estimation of inbreeding and effective population size of fullblood Wagyu cattle registered with the American Wagyu Association. H. L. Neibergs*[1], R. Zanella[1], J. F. Taylor[2], C. T. Gaskins[1], J. J. Reeves[1], and J. M. de Avila[1], [1]*Washington State University*, *Pullman*, [2]*University of Missouri*, *Columbia*.

The founders of the American Wagyu herds were imported from Japan during a period when inbreeding was high and the effective population size of the Japanese Wagyu was low. The effective population size represents the number of breeding animals in an ideal population where each male and female has an equal chance of contributing to the next generation. The objectives of this research were to estimate the inbreeding and effective population size of the Wagyu breed using pedigree information from 2504 fullblood animals registered with the American Wagyu Association and from genotypes of 50 fullblood Wagyu animals representing 8 prominent sire lines. The Illumina BovineSNP50 BeadArray was used to genotype the Wagyu samples. Excess homozygosity was used to estimate inbreeding by genotype using PLINK (Purcell et al. 2007) while inbreeding based on pedigree was estimated with FSpeed Pro (http://www.tenset.co.uk/fspeed/fspeed.html). The effective population size was estimated for the period of 1990 to 2007 as described by Nomura et al. (2001) where the annual rate of inbreeding ($\Delta F_{ST,y}$) was used to estimate the annual effective population size (N_e). The estimated level of inbreeding for American Wagyu based on pedigrees was 5.8% which reflects that inbreeding is underestimated for foundation animals with shallow pedigrees. The estimated inbreeding based on pedigrees and genotypes in the 8 sire lines are shown in Table 1. The effective population size averaged 8.8 between 1990 and 2007, with a low of 1.5 in 1991 and a high of 16 in 2007. Wagyu in America are the result of a small number of cattle imported from Japan between 1976 and 1999 and additional importations in the near future are not expected. Strategies to increase genetic diversity and limit inbreeding should be considered to maintain this unique breed of cattle.

Table 1. The percent inbreeding for each of 8 sires based on their 5 generation pedigree and genotypes from the SNP50 BeadArray

Sires	%Inbreeding: Pedigree	%Inbreeding: Genotype
TF Itomichi 1/2	0	25
Kitaguni Junior	0	18.4
TF Kikuhana	18.7	39.1
Kitateruyasudoi	9.4	27.3

Sanjirou	12.9	33.1
Takazakura	12.5	31.2
JVP Fukutsuru 068	9.4	21.9

Key Words: Wagyu, inbreeding, population

M75 Genetic network update for economically important traits in a Wagyu x Limousin reference population. Z. Jiang*[1], J. J. Michal[1], T. F. Daniels[1], J. Chen[1], Z. X. Pan[1], T. Kunej[1], M. D. Garcia[2], C. T. Gaskins[1], J. R. Busboom[1], L. J. Alexander[3], R. W. Wright Jr.[1], and M. D. MacNeil[3], [1]*Washington State University*, *Pullman,* [2]*Louisiana State University*, *Baton Rouge,* [3]*USDA-ARS, Fort Keogh Livestock and Range Research Laboratory*, *Miles City, MT*.

In the present study, 84 genes representing 6 different biological pathways were investigated for their associations with 5 carcass, 6 eating quality and 8 fatty acid composition traits in a Wagyu × Limousin reference population, including 6 F1 bulls, 113 F1 dams, and 246 F2 progeny. A total of 157 mutations, mainly single nucleotide polymorphisms were genotyped using a Sequenom assay, but only 135 tagged mutations were selected by the HAPLOVIEW analysis for the association study. Single marker-trait association runs revealed 153 significant associations ($P < 0.05$), which were then placed into 3 groups of quantitative trait modes (QTMs) with additive, dominant and overdominant effects if a marker had 3 genotypes with at least 9 animals for each group of genotypes. All significant markers and their QTMs associated with each of these 19 traits were involved in a linear regression model analysis, which confirmed single-gene associations for 4 traits, but revealed 2-gene networks for 9 traits and 3-gene networks for 4 traits. Such genetic networks involving both genotypes and QTMs resulted in high correlations between predicted and actual values of performance, thus providing evidence that the classical Mendelian principles of inheritance can be applied in understanding the genetic complexity of complex phenotypes. Our present study also indicated that carcass, eating quality and fatty acid composition traits rarely share genetic networks. Therefore, marker-assisted selection for improvement of one category of these traits would not interfere with improvement of another.

Key Words: quantitative traits, genetic networks, beef cattle

M76 Genetic trends for image analysis traits in Japanese Black cattle. Y. Nakahashi*, S. Ido, and K. Kuchida, *Obihiro University of A & VM*, *Obihiro-shi, Hokkaido, Japan*.

Intramuscular fat has been a concern in genetic improvement of Japanese Black cattle. Beef Marbling Standard (BMS) has been used as an indicator of the amount of marbling. However, there are factors other than marbling that are known to affect BMS, such as the coarseness or fineness of marbling flecks. In the present study, we investigated genetic trends and the relationships between traits related to BMS. A total of 10,556 of Japanese Black cattle that were shipped to a meat processing plant in Hokkaido, Japan, were used in the study. High quality digital images were collected and analyzed to calculate the marbling percent (MP) and coarseness index of marbling (CIM). The AIREMLF90 program was used for estimation of genetic parameters. Genetic trends were calculated as the average of standardized breeding values (BV) of the dams by birth year for every trait. Regression coefficients (β) were used to compare the genetic trends. The estimated heritabilities of BMS, MP, and CIM were 0.63 ± 0.04, 0.74 ± 0.04, and 0.51 ± 0.04, respectively. The genetic correlation coefficients of BMS with MP and CIM were 0.58 and 0.96, respectively. The trend in average BMS BV was flat from 1937 to 1970 ($\beta = -0.01$), increasing from 1970 to 1990 ($\beta = 0.04$), and accelerating after 1990 ($\beta = 0.18$). Similarly, the genetic trends for MP and CIM also increased. These results indicated that the genetic improvement of BMS is occurring, but at the same time genetic merit for the undesirable trait of marbling coarseness is also increasing. To achieve improvement of BMS without increasing coarseness of marbling, it is suggested to utilize image analysis in genetic evaluation, as this technology can indicate detailed characteristics of marbling.

Key Words: genetic trend, image analysis, Japanese Black cattle

M77 Multivariate analyses of weight traits fitting reduced rank and factor analytic models in Nellore cattle. A. A. Boligon*[1], A. B. Bignardi[1], M. E. Z. Mercadante[2], and L. G. Albuquerque[1], [1]*FCAV/UNESP*, *Jaboticabal, São Paulo, Brazil*, [2]*Instituto de Zootecnia*, *Sertãozinho, São Paulo, Brazil*.

A total of 61.528 records from 12,246 animals from the Nellore Cattle Breeding Program were used to estimate genetic parameters using multivariate analysis (MV). Reduced rank analyses fitting the first m = 2, 3, 4 and 5 genetic principal components (RR) and analyses that fitted a factor analytic structure considering m = 2, 3, 4 and 5 factors (FA), were carried out. The traits evaluated were: birth weight (BW), weaning weight (WW), weight at 365 (W365) and 550 d of age (W550), and weight at 2, 3, 4, 5 and 6 year of age (W2Y, W3Y, W4Y, W5Y and W6Y, respectively). Genetic additive direct effects and residual effects were considered as random. For BW and WW, the genetic maternal and maternal permanent environment effects were included as random effect. Contemporary group (farm, sex, year, and month of birth) was included as a fixed effect. Linear and quadratic effects of animal age at recording (except BW), and dam age at calving (for BW, WW, W365 and W550) were included as covariables. The residual, genetic maternal and permanent environment covariance matrix was assumed to have full rank throughout. Models were compared by Akaike's Information Criterion (AIC) and Schwarz's Bayesian Information Criterion (BIC). The model containing the largest number of parameters - MV (96 parameters) showed the worst fit. For models with the factor number equal to the principal component number, the value of log L was very similar. In general, the results indicate that RR models with 3 principal components (RR-PC3) are sufficient to model the genetic covariance structure among the weight traits. The 3 principal components explained more than 90% of the genetic variation. Genetic correlation estimates between weights traits ranged from 0.42 to 0.96. Results from RR-PC3 agreed closely with estimates from MV analyses and literature results. The RR estimation decreased computational requirements relative to MV analyses.

Key Words: growth traits, genetic parameters, principal component analysis

M78 Genetic parameters for weight traits from birth to 630 days of age in Guzera cattle by random regression models. I. S. Silva*[1], I. U. Packer[2], L. O. C. Silva[3], C. M. R. Melo[4], and R. A. A. Torres Junior[3], [1]*University of Brasília - UnB*, *Brasília /DF, Brazil*, [2]*University of São Paulo - USP/ESALQ*, *Piracicaba/SP, Brazil*, [3]*Embrapa Gado de Corte*, *Campo Grande/MS, Brazil*, [4]*Federal University of Santa Catarina - UFSC*, *Florianópolis/SC, Brazil.*

A total of 60,782 body weight records belonging to Guzera breed from birth to 630 d of age were analyzed to estimate the variance components and the genetic parameters by random regression models and the REML methodology. Ten regression models were analyzed with contemporary group as fixed effect and age of dam as a covariate. Covariance functions of different order were analyzed for direct additive genetic random (kA), animal permanent environmental (kC), maternal permanent environmental (kQ) and residual effects with homogeneous (r1) and heterogeneous variance structures, with 5 (r5) or 10 (r10) residual variance classes. Models were compared by the Likelihood Ratio Test, the Akaike Information Criterion (AIC) and the Schwarz's Bayesian Information Criterion (BIC). The variance estimates in the analyses by the regression models were relatively similar. AIC values showed that the adjustment of the model with order of covariance functions of 6 for kA, kC, kQ (Reg666) and r10, was superior in relation to the other models. BIC values showed that the most parsimonious model

had order of covariance functions of 6 for kA, 5 for kC and 3 for kQ (Reg653), and r10, was optimal among the models with 10 residual variance classes. The heritability estimates for weights at birth (WB), 205 (W205), 365 (W365) and 550 (W550) days of age were 0.13, 0.43, 0.46, 0.48 for the model Reg666-r10, and 0.13, 0.46, 0.54, 0.56, for the model Reg653–10. The phenotypic, genetic, animal and maternal permanent environmental correlations were all positive and were similar for all models. Considering the most parsimonious model, Reg653 and r10, the genetic correlations between WB/W205, WB/W365, WB/W550, W205/W365, W205/W550 and W365/W550 were 0.40, 0.40, 0.42, 0.68, 0.74 and 0.81, respectively. Models with variance homogeneity were inadequate. It was observed that division of the residual variance into 10 distinct classes was the most suitable model for describing variation in the weights studied herein.

Key Words: beef cattle, variance components, random regression

M79 Principal component analysis of traits contributing to genetic evaluation of Brahman bulls in Brazil. J. C. Souza*[1], L. O. C. Silva[2], A. Gondo[2], P. B. Ferraz Filho[3], J. A. Freitas[4], C. H. M. Malhado[5,7], R. L. Weaber[6], and W. L. Lamberson[6], [1]*Mato Grosso do Sul Federal University - UFMS*, *Aquidauana, MS, Brazil*, [2]*Empresa Brasileira de Pesquisa Agropecuaria - EMBRAPA*, *Campo Grande, MS, Brazil*, [3]*Mato Grosso do Sul Federal University - UFMS*, *Tres Lagoas, MS, Brazil*, [4]*Parana Federal University - UFPR*, *Palotina, PR, Brazil*, [5]*UESB*, *Jequie, BA, Brazil*, [6]*Animal Sciences, MU - USA*, *Columbia, MO,* [7]*Scholarship of CNPq*, *Brazilia, DF - Brazil*.

The objective of this study was to evaluate the contribution of each trait contributing to genetic evaluation of Brahman sires. The data were from the 2006 summary of Brahman bulls published by EMBRAPA/CNPGC. Estimates of EPD were obtained using a multiple trait animal model including: weight to maternal phase – 120 d (PM); weight total maternal phase (TMMP); weaning weight (WW); total maternal weaning weight (TMW); yearling weight (YW); pre-weaning gain (GNW) (g/day); total maternal pre-weaning gain (TMPG); post-weaning gain (YGP); age (days) at first calving (IPP); interval between the 1st and 2nd calving (I2P); interval and other calving (IOP); scrotal circumference measurements (SC); and genetic qualification index (IQG = 10% * PM + 15% * WW + 20%*TMW + 30% * YW + 10% * IPP + 10% * I2P + 5% * SC)) of 542 bulls. The characteristics were evaluated by using the PRINCOMP procedure of SAS. The eigenvalues and proportions of the first 5 principal components were 6.72, 0.52; 1.78, 0.14; 1.49, 011; 1.18, 0.09; 0.61, 0.05, respectively; the first eigenvalue totaled 0.52; first 2 0.65; the first 3 0.77, the first 4 0.86, and a total of 5 0.91. The estimated contribution of the first principal component for each trait was WW (0.3757); IQG (0.3749); YGP (0.3724), YW (0.3573); TMW (0.3569); TMPG (0.3526); TMMP (0.3161); YGP (0.2316), SC (0.1515), IOP (0.1347), IPP (0.0527), PM (−0.0060); and I2P (−0.0528). The traits that most contributed were weaning weight, genetic qualification index and post-weaning gain. The traits which contributed least were weight to maternal phase and interval between 1st and 2nd calving. The largest genetic correlations were between weaning weight and post-weaning gain (0.96); yearling weight (0.97); and IQG (0.9556).

Key Words: gain, principal components, Zebu

M80 Allelic frequencies of polymorphisms associated with feed efficiency in Aberdeen Angus cattle in Uruguay. A. I. Trujillo, P. Grignola, I. Pandulli, P. Nicolini, A. Casal, A. Espasandin, F. Peñagaricano, and M. Carriquiry*, *Universidad de la Republica*, *Montevideo, Montevideo, Uruguay*.

We are interested in selecting cattle with improved feed efficiency by searching for residual feed intake (RFI) candidate genes. In confinement systems, neuropeptide Y (NPY), leptin (LEP) and insulin growth factor-1 (IGF-1) have shown association with feed efficiency. Since frequencies of single nucleotide polymorphisms (SNP) of NPY, LEP and IGF-1 are unknown in beef cattle population in Uruguay, our objective was to study the distribution of these SNP in the Aberdeen Angus breed. This is a first step in evaluating the associations of these SNP with RFI and investigating their use as molecular markers for assisted selection in pasture-based system. A totally of 130 genetically unrelated calves from 5 Aberdeen Angus herds (the major contributors to the national genetic pool) were sampled. DNA was extracted from fresh blood using the "salting out" procedure. High resolution melting (HRM) of PCR small amplicons in presence of SYBR Green dye was used to genotype. An A/G SNP located in intron 2 of the NPY gene, a C/T SNP located in exon 2 of the LEP gene and a C/T SNP located in the promoter region of IGF-1 gene, were the markers genotyped. The allelic frequencies of SNP were 0.76 and 0.24 (A and G) for NPY, 0.46 and 0.54 (C and T) for LEP, and 0.61 and 0.39 (C and T) for IGF-1. The SNP frequencies distributions were similar across different herds ($P \geq 0.05$, Chi-squared test). This data shows that the frequency of "favorable" alleles is lower than the "unfavorable" alleles in Aberdeen Angus cattle in Uruguay. These results support our proposal that it is possible to improve feed efficiency by using marker-assisted selection in the context of a national program.

Key Words: SNP NPY LEP IGF-1, feed efficiency, Aberdeen Angus breed

M81 Techniques for sifting inconsistent data points from repeatedly weighed beef cattle. S. E. Speidel*, C. M. McAllister, D. H. Crews Jr., and R. M. Enns, *Colorado State University*, *Fort Collins*.

Prior to their inclusion in genetic evaluations, phenotypic records are typically sifted following Beef Improvement Federation guidelines to exclude erroneous data points. Random regression techniques allow the use of data points regardless of age at measurement. Given the range of ages typically seen in field data sets, it can be challenging to identify problematic observations. The objective of this study was to compare data sifting procedures that can be implemented on a large scale for the purpose of identifying individual data points inconsistent within an individual animal's growth curve. The data set consisted of 1372 animals with an average of 10.98 weight observations per animal ranging from 0 to 519 d of age. Three methods were used to identify inconsistent data within a given animal. First individual animals with R^2 values less than 0.90 for the linear regression of weight on age were examined. Second, residuals from this regression were compared with residuals on all animals, to identify observations with residuals greater than 4, 5, and 6 standard deviations (SD) from 0. Finally, each weight was compared with the overall variability of weight within age window across years, to identify those greater than 4, 5, and 6 SD from the mean. This last method was the least robust of all 3 failing to identify any erroneous data points. The R^2 method was not sensitive enough in this data set given that only 5 animals possessed an R^2 less than 0.90, although one individual animal was identified with a data point not consistent with his remaining values. The most sensitive method compared each individual residual value to the overall residual variability. Here, a total of 10, 2

and 0 animals were identified with residuals greater than 4, 5, and 6 SD from the mean, respectively. For this data set, the inclusion of birth and weaning weights along with the test weights gave better predictions of average daily gain by more precisely estimating the intercept for each regression line. Since the R^2 values were so high the residual method easily found those observations inconsistent with the remaining records on the individuals.

Key Words: beef cattle, data sifting, longitudinal data

M82 Use of principal component approach to predict direct genomic breeding values for meat traits in Italian Simmental Bulls. M. A. Pintus[1], G. Gaspa[1], N. P. P. Macciotta*[1], P. Carnier[2], E. L. Nicolazzi[3], C. Dimauro[1], D. Vicario[4], P. Ajmone-Marsan[3], A. Nardone[5], and A. Valentini[5], [1]*Università di Sassari*, *Sassari, Italia*, [2]*Università di Padova*, *Padova, Italia*, [3]*Università di Piacenza*, *Piacenza Italia*, [4]*ANAPRI*, *Udine, Italia*, [5]*Università della Tuscia*, *Viterbo, Italia*.

In the current study, principal component (PC) analysis was used to reduce the number of predictors in the estimation of direct genomic breeding values (DGV) for meat traits in a sample of 457 Italian Simmental bulls. SNP marker genotypes were determined with the 54K Illumina beadchip. After edits, 40,179 SNPs were retained. PC extraction was carried out separately for each chromosome and 2,466 new variables able to explain 70% of total variance were obtained. Bulls were divided into reference and validation population. Three scenarios of the ratio reference/validation were tested: 70:30, 80:20, 90:10. Effect of PC scores on polygenic EBVs was estimated in the reference population with a BLUP model. Traits analyzed were daily live weight gain, size score, muscularity score, feet and legs score, beef index (economic index), calving ease direct effect, and cow muscularity. Accuracy was calculated as correlation between DGV and polygenic EBV in the validation bulls. Muscularity, feet and legs, and the beef index show the highest accuracies (Table 1), calving ease the lowest. In general, accuracies are slightly higher (Table 1) when reference animals are selected at random and the best scenario is 90:10.

Table 1. Accuracy of GEBV for 7 meat traits

	Scenarios					
	Sorted by birth year			Random		
Trait	70:30	80:20	90:10	70:30	80:20	90:10
Daily live weight gain	0.38	0.35	0.53	0.47	0.37	0.63
Size score	0.44	0.47	0.54	0.49	0.47	0.47
Muscularity score	0.71	0.67	0.80	0.71	0.70	0.79
Feet and leg score	0.72	0.74	0.85	0.76	0.77	0.83
Beef index	0.63	0.57	0.74	0.63	0.60	0.77
Calving ease direct effect	0.23	0.23	0.24	0.34	0.26	0.29
Cow muscularity	0.80	0.85	0.83	0.82	0.84	0.82

Key Words: principal component analysis, genomic selection, meat trait

M83 Genetic analysis of visual score data with different distributions and genetic parameters using linear and nonlinear models. F. Barichello*[1], M. M. Alencar[2], and R. A. A. Torres Júnior[3], [1]*Unesp*, *Jaboticabal, SP, Brazil*, [2]*Embrapa Southeast Livestock*, *São Carlos, SP, Brazil*, [3]*Embrapa Beef Cattle*, *Campo Grande, MS, Brazil*.

The aim of this study was to evaluate the effect of the way (Y) of assigning discrete visual scores (VS, 6 levels) for the values of a continuous underlying scale (USC) on the estimated breeding values (BV) for 2 heritability values (h^2: 0.25 and 0.49) and 2 magnitudes of contemporary group variance (CG: 0.25 and 1.00). Three different models (M) (linear, threshold, and linear with transformed data) were used for the analysis. Herds with 40 sires and 1,200 dams, mated at random, were simulated for 20 years. Direct and maternal BV, maternal permanent environmental, CG, and age of dam effects were generated and combined with an independent error term to form the phenotype in the USC. The USC were assigned, as a function of CG, according to normal relative (Y_1) and normal fixed (Y_2) distributions. The BVs were estimated using the GIBBS2F90 and THRGIBBS1F90 programs with previously estimated variance components. The procedure was repeated 10 times for each combination. Correlations (R) between estimated and true BV were obtained for each animal class (sires, dams and offspring). Significant effects of Y on R for all animal classes were found. The Y_1 distribution presented better estimates than Y_2 distribution for all animal classes (sires: 0.92 vs 0.91; dams: 0.61 vs 0.60; offspring: 0.69 vs 0.68). For dams and offspring, significant effect of h^2 on R was found, where high level of h^2 provided greater correlation between true and estimated BV (dams: 0.67 vs 0.55; offspring: 0.74 vs 0.63). For sires, significant effects of h^2 x CG interaction on R were found (at $h^2 = 0.49$ no differences were found between levels of CG, but at $h^2 = 0.25$ greater R values were found with a low level of CG). M had no effect on R. The results indicate slightly better performance of the Y_1 way of assigning VS to US values, and all M yielded consistent results for VS evaluation.

Key Words: breeding value, threshold model, transformed data

M84 Multibreed genetic evaluation of calving ease and birth weight using a threshold-linear model in Gelbvieh cattle. S. Tsuruta*, A. H. Nelson, J. K. Bertrand, and I. Misztal, *University of Georgia*, *Athens*.

Multibreed genetic evaluation (MBE) was implemented for calving ease (CE) and birth weight (BW) using a threshold-linear model applied to data from the American Gelbvieh Association. Data included 138,072 CE records (3 categories) and 941,811 BW records from 1972 to 2008. The pedigree file contained 1,204,867 animals. Heterosis priors of CE were not available from the literature, so they were constructed by making them proportional (0.02) to the BW priors. Priors of unknown parent group within breeds (breed effects) for CE were also constructed in proportion to those for BW. Priors of external BW and CE EPD for Angus sires in the Gelbvieh data set were provided by the American Angus Association. The computer program used a preconditioned conjugate gradient and iteration on data method. The MBE converged when priors for heterosis and breed effects were used without considering prior external EPD information; however, analyses did not converge when the external EPD priors were included. Correlations between EPD with and without heterosis and breed effect priors were 0.95 and 0.99 for CE and BW, respectively. Correlations of the Angus sire EPD computed in the Gelbvieh MBE with the external EPD of the same Angus sires were 0.23 and 0.33 for CE and BW, respectively, indicating that the external EPD for Angus sires were not good priors in the Gelbvieh data. When low accuracies were assumed for the external Angus EPD for CE and BW, the program converged. This indicates that CE provided from an Angus sire mated to a Gelbvieh female may not be representative of the Angus sire's performance based on external EPD, which were the result of mating Angus sires to Angus dams. This result may suggest that the external EPD priors for BW only should be used in the MBE because informative external EPD priors may not be available for CE.

Key Words: multibreed evaluation, calving ease, threshold-linear model

M85 Comparison of a feed efficiency measure for steer progeny produced from divergently mated sires and dams phenotyped for residual feed intake. N. O. Minton*, R. L. Weaber, R. L. Kallenbach, and M. S. Kerley, *University of Missouri*, *Columbia*.

Objectives of this research were to determine feed efficiency of progeny produced from mating RFI phenotyped sires and dams and the effect of test duration (0 to 70 d, 0 to 120 d, and 70 to 120 d) on RFI values of calves. We hypothesized that parent RFI would influence progeny feed efficiency. We further hypothesized that an increase in test duration for RFI is necessary to accommodate for pre-test effects that could alter RFI values of calves. Simmental crossbred heifers (n = 12 RFI- and n = 12 RFI+) were mated with RFI- (n = 2) and RFI+ (n = 2) bulls. Sire was used as an independent variable to measure the effect of sire on progeny performance. Three dam groups were formed by assigning one SD greater than (INEFF) and one SD less than (EFF) average (AVG) RFI. Steer progeny were placed on feed post weaning where intake and BW were measured over 120 d. Intake and weight data were used to calculate ADG, intake, FCR and RFI. Progeny performance differed among sire groups. Progeny from RFI- sires were more efficient than progeny from RFI+ sires on test durations 0 to 70 d (−0.50 v −0.06; $P < 0.12$) and 0 to 120 d (−0.51 v −0.05; $P < 0.15$). Unexpectedly, one RFI+ sire's progeny performed similar to progeny of 2 RFI- sires. Progeny from INEFF dams had greater RFI's (0.5 v −0.63; $P < 0.03$) from 0 to 70 d and from 0 to 120 d (0.55 v −0.72; $P < 0.03$) than progeny of EFF dams. Progeny RFI values were not significantly different from 70 to 120 d between sire and dam groups. Correlations for RFI were high between test durations of 0 to 70 d and 0 to 120 d (0.87) and 0 to 120 d and 70 to 120 d (0.88). Correlations were low for RFI between 0 to 70 d and 70 to 120 d (0.54). We concluded selecting against the lower third of INEFF dams within a population will improve progeny feed efficiency. Furthermore, extending the test duration is required for progeny that are not acclimated to the test facility or ration before intake collection.

Key Words: residual feed intake, feed efficiency, beef

M86 The relationship of bovine respiratory disease and carcass ultrasound measures. B. W. Brigham*[1], C. M. McAllister[1], R. K. Peel[1], H. Van Campen[2], R. L. Weaber[3], G. H. Loneragan[4], J. L. Salak-Johnson[5], C. C. L. Chase[6], E. J. Pollak[7], and R. M. Enns[1], [1]*Department of Animal Science, Colorado State University*, *Fort Collins,* [2]*Department of Microbiology, Immunology and Pathology, Colorado State University*, *Fort Collins,* [3]*Department of Animal Science, University of Missouri*, *Columbia,* [4]*Department of Agricultural Sciences, West Texas A&M University*, *Canyon,* [5]*Department of Animal Sciences, University of Illinois*, *Urbana,* [6]*Department of Biology and Microbiology, South Dakota State University*, *Brookings,* [7]*Department of Animal Science, Cornell University*, *Ithaca, NY*, [8]*Department of Agricultural Sciences, West Texas A&M University*.

Bovine respiratory disease (BRD) has been identified as an economically relevant trait which lacks selection tools to reduce post-weaning incidence. The lack of sufficient field morbidity data has been a major obstruction to development of tools for genetic improvement. The objective of this study was to investigate the genetic associations among real time carcass ultrasound (US) measures and probability of treatment for BRD. Phenotypes of 2,870 crossbred steers were collected over 2 years (1,551 yr 1; 1,319 yr 2). The US measurements were collected at 3 times during the feeding period; receiving (0d), processing 2 (80d) and processing 3 (150d). US measurements included ribeye area (UREA, cm^2), backfat thickness (UFAT, cm) and percent intramuscular fat (UIMF, %). Morbidity data were collected over the entire 240d feeding period and classified as a binary observation, 1 for treated and 0 for non-treated, respectively. Data included 796 morbidity records; 2,848 first; 2,682 s; and 2,444 third US measurements with a sire pedigree (n = 3,255). (Co)Variance components were estimated for each individual processing period using a multivariate sire model and average information REML procedures to obtain estimates of heritability and genetic correlations. Model fixed effects included contemporary group for all traits and processing weight as a linear covariate for US traits. Contemporary groups were comprised of year, ranch of origin and feedlot pen. An additional factor of US date was added to the definition for each respective processing period. Heritability estimates of morbidity, UREA, UFAT and UIMF at first, second and third processing were 0.15, 0.10, 0.06, 0.20; 0.16, 0.11, 0.09, 0.12; and 0.15, 0.14, 0.11, 0.06 respectively. Morbidity had a negative genetic correlation with all US measurements. The genetic correlations with the greatest magnitude were between morbidity and UREA, UFAT, and UIMF taken at receiving of −0.15, −0.58, and −0.11 respectively. These results imply those individuals with smaller ribeye area and less backfat upon arrival to the feedlot have the highest probability of suffering from a BRD incidence.

Key Words: beef cattle, health, carcass ultrasound

M87 Performance and live-ultrasound traits of beef cattle breeds associated with DNA commercial markers. F. Loya-Olguín*[1], M. Encinias[2], R. E. Kirksey[2], L. Lauriault[2], and L. Avendaño-Reyes[1], [1]*Universidad Autonoma d Baja California*, *Ejido Nuevo Leon, Valle de Mexicali, Baja California, Mexico*, [2]*New Mexico State University*, *Las Cruces*.

The commercially available DNA markers, such as GeneSTAR Markers, provide prediction of phenotypic performance of tested animals. The objective of the present study was to evaluate performance and live-ultrasound traits of 4 beef cattle breeds using commercial DNA markers. Seventy 2 bulls from breeds Angus (n = 30), Charolais (n = 20), Hereford (n = 8), and Maine-Anjou (n = 15) were utilized. Initial BW for Angus, Charolais, Hereford, Maine-Anjou were 326.31, 360.66, 306.94, and 330.48 kg, respectively. The performance test lasted 112 d. All bulls were live-ultrasound for rumpfat (RF), ribfat (RBF), rib-eye (RE), and intramuscular fat (IMF). Also, were recorded average daily gain (ADG), weight per day of age (WDA); and genetic progeny difference on feed efficiency (GPDFE), tenderness (GPDT) and quality grade (GPDQG). The Charolais bulls had higher average number of stars, RE, WDA and GPDFE (11.32 ± 0.41, 14.73 ± 0.28 cm2, 1.50 ± 0.03 kg, - 3.44 ± 0.11 kg, respectively) than ($P < 0.05$) Angus, Maine-Anjou and Hereford bulls. Average of stars, RE and WDA of Angus and Maine-Anjou (10.30 ± 0.35, 13.37 ± 0.24 cm2, 1.42 ± 0.02 kg and 10.13 ± 0.47, 13.25 ± 0.32 cm2, 1.39 ± 0.03 kg, respectively) bulls were similar. Meanwhile, Angus bulls had higher ($P < 0.05$) RF, RBF, IMF, ADG, and GPDT (0.36 ± 0.01 cm, 0.28 ± 0.009 cm, 4.56 ± 0.12%, 1.97 ± 0.03 kg, and −1.42 ± 0.08 kg, respectively) than the Charolais, Maine-Anjou and Hereford bulls. The use of ultrasound technology in live animals and commercial markers data can be useful tools to select a potential genetically superior breed, and within the breed, can sort and predict a potential bull.

Key Words: molecular value predictions, rib-eye area, Charolais

M88 No evidence for association between leptin polymorphism C.73 C>T and bovine viral diarrhea virus (BVDV) vaccine response. X. Fang*[1], L. A. Hoff[1], J. A. Walker[1], K. C. Olson[1], G. A. Perry[1], J. X. Wu[1], C. Maltecca[2], and M. G. Gonda[1], [1]*South Dakota State University*, *Brookings*, [2]*North Carolina State University*, *Raleigh*.

We have previously reported that sire affected humoral Bovine Viral Diarrhea Virus (BVDV) vaccine response in beef calves, suggesting that genetics may contribute to BVDV vaccine variation. In this study, we hypothesized that a single nucleotide polymorphism (SNP) within the leptin gene (LEP C.73 C > T) may be associated with BVDV vaccine response. To test this hypothesis, humoral BVDV vaccine response was measured in 209 Angus and Angus-cross calves. Calves were born between February and May 2009 at the South Dakota State University Antelope, Cottonwood and Cow-calf research herds. All individuals were vaccinated with Bovi-Shield GOLD-10 or −5, which includes modified-live BVDV strains type 1 and 2 (Pfizer, Inc., Exton, PA). Blood samples were collected at time of vaccination (d = 0) and post-vaccination (d = 21). Samples collected on d 0 were used to measure maternal BVDV antibody and to test for persistently infected (PI) BVDV calves, while samples collected on d 21 were used to measure humoral BVDV response to the vaccine. Real-time RT-PCR for BVDV on RNA isolated from plasma samples (Qiagen, Valencia, CA) revealed that none of the calves were PI with BVDV. A BVDV antibody ELISA (Idexx, Inc., Westbrook, ME) was used to measure total BVDV-specific antibody present on d 0 and 21. Antibody concentrations were converted to sample-to-positive (S/P) ratios, and maternal antibody S/P ratios (d = 0) were subtracted from d = 21 S/P ratios to calculate vaccine response. A PCR-RFLP assay was used to genotype the leptin polymorphism. To investigate a possible effect of the leptin polymorphism on BVDV vaccine response, an ANOVA model including effects of leptin genotype, month of birth, gender, and herd was fitted. Herd was significantly associated with vaccine response ($P < 0.05$) and gender approached significance ($P < 0.10$). Leptin genotype and month of birth were not significantly associated with BVDV vaccine response. Our results suggest that selection on the leptin genotype to improve beef cattle carcass quality will not have a pleiotropic effect on BVDV vaccine response.

Key Words: BVDV, leptin, vaccine response

M89 A genotype combination approach using μ-calpain as a candidate gene for growth, carcass, and meat quality in bulls of Senepol and Charolais inheritance. P. Rivera*, J. Bosques, A. Casas, D. Cianzio, and M. Pagan, *University of Puerto Rico at Mayaguez*, *Mayaguez, PR*.

A cytosine/guanine transversion in the μ-calpain regulatory subunit (CAPN1–316) and cytosine/ thymine transition in catalytic subunit (CAPN1–4751) were organized as combined genotypes to investigate its potential associations with growth, carcass, and meat quality traits. Senepol, Charolais, and Senepol × Charolais bulls grown under grazing conditions were genotyped (n = 94) for each individual single nucleotide polymorphisms and organized in a total of 9 combinations (CC/CC, CC/TT, CC/CT, GG/CC, GG/TT, GG/CT, CG/CC, CG/TT, and CG/CT). For growth traits, a subset of 36 animals were used for the correspondent statistical analyses using the more representative CG/CT (n = 16), GG/CT (n = 10), and GG/TT (n = 10) bulls. CAPN1 was associated with heavier body weights: at birth, 205 d, 240 d, and daily weight gain at 205 and 240 d. At birth, animals with the GG/CT combination were heavier ($P < 0.05$) than those with CG/CT. However, CG/CT bulls were heavier ($P < 0.05$) at 205 d, and gain at both 205 and 240 d than the GG/TT. Moreover, at 240 d, CG/CT animals were heavier than GG/CT and GG/TT, and at slaughter CG/CT weighed more ($P < 0.05$) than GG/CT only. For carcass and meat quality traits (CG/CT, n = 9; GG/CT, n = 6; GG/TT, n = 5), CG/CT bulls presented greater tenderness ($P < 0.05$) at 0 d (24 h aging period) than GG/CT, as determined by sensory evaluation of the loin. After 14 d of aging, beef from CG/CT was classified as moderately tender while GG/CT improved from moderately tough to slightly tender (hedonic scale; 1 = extremely tough/8 = extremely tender). In addition, in that same period, differences in sensory tenderness between CG/CT and GG/TT (less tender) were significant ($P < 0.01$). However, the longissimus dorsi and bicep femoris muscle weights were lower ($P < 0.05$) in the double heterozygous. The results of this study suggest that the double heterozygous for CAPN1 (316 = CG, 4751 = CT) presented more desirable growth, carcass, and meat quality traits. Therefore, the usefulness of these markers seems to be beyond its exclusive association with meat tenderness.

Key Words: CAPN1, growth, heterozygous

M90 An insertion/deletion polymorphism at the bovine Calpastatin locus is associated with economically important traits. N. Vega*[1], D. Velez[1], A. Casas[1], D. Cianzio[1], C. W. Ernst[2], and M. Pagan[1], [1]*University of Puerto Rico*, *Mayaguez, PR*, [2]*Michigan State University*, *East Lansing*.

A total of 126 bulls (50% to purebred Senepol and Charolais) were genotyped for a cytosine insertion/deletion identified at intron 2 of the bovine Calpastatin locus to determine its segregation and potential associations with growth and meat quality traits. Overall, the frequency of the allele labeled as A (cytosine deletion) was higher (0.84) than the B (cytosine insertion) allele (0.16). In bulls of Senepol descent, allele frequencies were 0.90A/0.10B, whereas in those with Charolais blood, frequencies were 0.68A/0.32B. Genotypic frequencies were 0.82AA, 0.17AB, 0.01BB and 0.45AA, 0.47AB, 0.08BB for Senepol and Charolais bulls, respectively. Because the BB genotype was only observed in one Senepol bull and 3 Charolais bulls, it was excluded for corresponding statistical analyses (n = 55 for growth; n = 24 for meat quality traits). At birth, AB genotype bulls were heavier than AA bulls ($P < 0.05$). However, the AA bulls presented higher body weights and weight gain at 205 and 240 d ($P < 0.05$). After a 24 h aging period, lower Warner Bratzler shear force (WBS) was found in AA bulls (4.48 kg) than AB bulls (6.05 kg) in the longissimus dorsi muscle for a difference between genotypes of 1.57 kg ($P < 0.01$). The difference in WBS after 14 d of aging was 0.60 kg (AA = 3.13 kg, AB = 3.73 kg; $P > 0.05$). These results indicate that the Senepol breed has a higher AA genotype frequency than the Charolais breed, and may imply a tendency for Senepol animals to gain weight efficiently and produce tender beef. Therefore, this study suggests that this calpastatin polymorphism might be useful in animal selection due to its significant relationship with important beef traits.

Key Words: Calpastatin, Senepol, polymorphism

M91 Partial characterization of bovine complement receptor-2 (CR2) in Angus cattle. S. A. Olenich*, X. Fang, L. A. Hoff, J. A. Walker, K. C. Olson, G. A. Perry, and M. G. Gonda, *South Dakota State University*, *Brookings*.

Complement receptor-2 (CR2, or CD21), found on T-helper cells, assists in antigen recognition of B cells by reducing the threshold for antigen receptor stimulation. Antigen receptor stimulation is important for developing an effective vaccine response; therefore, CR2 is a candidate gene that could be associated with vaccine response in

cattle. Thus, our objective was to characterize genetic variation in CR2 among beef cattle using a DNA-pooling sequencing approach. Blood samples were collected from 300 Angus and Angus-cross calves from 3 research herds in South Dakota: the SDSU Cow-Calf Unit, Cottonwood Research Station, and Antelope Research Station. The DNA was extracted from white blood cells by phenol and chloroform extraction. Pools of equal amounts of DNA (n = 50) were formed (6 pools total) and CR2 exon sequences were amplified using pooled DNA. Forward and reverse primers were designed in CR2 introns to ensure that the entire exon coding region would be amplified. Amplicons were sequenced in both the forward and reverse direction with the same primers used for amplification. Polymorphisms were identified by visually inspecting sequence traces. To date, we have characterized exons 1–4 and partial intron sequences flanking these exons. We have putatively identified a SNP in intron 1 (CR2 c.58+36 *t* > G) and an SSR within intron 2 (CR2 c.181–34T[12_13]). We have not found any polymorphisms within exons 1–4. This study reports the identification of 2 novel, putative intronic CR2 polymorphisms in Angus influenced beef cattle. The polymorphisms discovered in this study will be used to test for association between CR2 polymorphisms and vaccine response in cattle.

Key Words: CR2, CD21, polymorphisms

M92 Evaluation of insertion/deletion and single nucleotide polymorphisms identified at the bovine insulin like growth factor binding protein-2 locus. D. Velez*[1], C. W. Ernst[2], and M. Pagan[1], [1]*University of Puerto Rico at Mayaguez*, *Mayaguez, Puerto Rico, Puerto Rico*, [2]*Michigan State University*, *East Lansing*.

A total of 54 bulls of Senepol and Charolais inheritance were genotyped for 9 single nucleotide polymorphisms (SNPs) previously identified in a 1,180 bp sequence tagged site of the insulin-like growth factor binding protein-2 (IGFBP-2) gene locus (GenBank Accession Number: BV680048). These SNPs have been identified as C/G (nt 162), G/A (nt 254), G/C (nt 259, 822) C/T (nt 345, 433, 448), A/G (nt 719), and T/C (nt 1109) substitutions. In addition, an insertion/deletion polymorphism creates an alternative allele that lacks the base at position 443 and has a GG insertion between bases 449 and 450. Additional genotyping was performed for a recently identified SNP located at position 245 (A/T) and a trinucleotide insertion/deletion (TGT) at nt 1103–1105. The presence of C at nt 443 was linked to the insertion of TGT at nt 1103 in these animals. The majority of animals genotyped exhibited deletions at both nt 443 and nt 1103–1105 (frequency 0.78), which were in linkage disequilibrium with homozygous SNP genotypes at nt 448 (TT/0.77), 433 (CC/0.85), 345 (TT/0.61), 259 (CC/0.83), 254 (AA/0.77), 245 (AA/0.62) and 162 (GG/0.73). A limited number of animals were heterozygous for the insertion/deletions (frequency 0.17 and 0.13 for nt 443 and nt 1103–1105, respectively). For these animals, because of different allele lengths, genotypes for SNP's at nt 822 and 719 could not be determined. Most of the IGFBP2 polymorphisms were segregating at very low frequencies in the purebred Senepol, purebred Charolais and crossbred Charolais animals. With the exception of SNPs at nt 245 (AT frequency 0.54) and 345 (CT frequency 0.62), most markers were also not segregating in the Senepol crossbred cattle. The SNPs at these 2 positions were associated with ribeye area (AA > AT for nt 245; TT > CT for nt 345; $P < 0.05$). Therefore, further evaluation of these IGFBP2 polymorphisms and polymorphism combinations in additional animals is needed.

Key Words: IGFBP-2, SNP, bovine

M93 Residue of melamine and cyanuric acid in milk and tissues of dairy cows fed with different doses of melamine. J. S. Shen, J. Q. Wang*, H. Y. Wei, D. P. Bu, P. Sun, G. C. Luan, and Z. F. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

Melamine (MEL) may be degraded into cyanuric acid (CYA) and some other analogs by rumen microorganism. This study was conducted to investigate the residue of MEL and CYA in milk and tissues of dairy cows fed with different doses of MEL. Forty mid-lactation dairy cows (157 ± 43 DIM, 20.8 ± 1.4 kg of milk/d) were divided into 4 groups (n = 10/group) in a completely randomized design. The cows of the 4 groups were dosed with MEL (purity ≥99.5%) at 0 (Control), 300 (TRT 1), 500 (TRT 2) and 1000 (TRT 3) mg/d per cow, respectively. The whole trial lasted for 18 d (12 d feeding period, followed by 6 d clearance period). Milk samples were collected at d 1, 2, 3, 4, 8, 12, 13, 14, 15 and 18. On d 13, 3 cows of TRT 2 and TRT 3 were chosen randomly to slaughter, and tissue samples (kidney, liver, mammary, bladder, gluteus medius and longissimus dorsi) were collected. Milk and tissue samples were analyzed for MEL and CYA simultaneously by liquid chromatography tandem mass spectrometry (LS-MS/MS). Minor MEL was detected in concentrated feed background (6.23 ± 1.26 mg/kg), however, no CYA was detected. In MEL treated groups, milk MEL concentration increased quickly and reached a stable concentration at d 4, 8 and 12 after the first administration of MEL. Milk MEL concentration of treated groups in steady-state condition (0.18, 0.27 and 0.50 mg/L for TRT1, TRT2, TRT3, respectively) was significantly affected by MEL feeding dose ($P < 0.05$), with a linearly relationship between MEL intake and milk MEL concentration ($R^2 = 0.91$). No CYA was detected in milk of all groups. MEL residue in tissues of TRT 4 was about 2-fold higher than TRT 3, with the highest concentration in the kidney. The difference of CYA residue in tissues of TRT 4 and TRT 3 was not very obvious. Liver, kidney and bladder has higher CYA residue than other tissue. The CYA may come from the degradation of MEL in rumen.

Key Words: melamine, cyanuric acid, dairy cow

M94 Factors affecting microbiological and physicochemical characteristics of milk produced in dairies located in central Mexico (Altos de Jalisco). A. S. Aguilar, M. A. Lopez-Carlos, C. F. Arechiga*, J. I. Aguilera, F. Mendez-Llorente, H. Rodriguez, M. Rincon, and C. Diaz-Mora, *University of Zacatecas*, *Zacatecas, Mexico*.

Factors affecting physicochemical and microbiological characteristics of milk from 54 dairies located in 2 regions of central Mexico were evaluated. Effects of region, month, season, farm sanitary conditions; farm size and water hardness were evaluated. Variables measured were: protein, lactose, total solids (TS), non-fat solids (NFS), reductase, temperature, acidity, cryoscopy, and density; and the microbiological characteristics: CFU and SCC. Data was analyzed by SAS (proc- mixed). Fat, protein and lactose decreased in January and February. Northeast region scored higher values of milk quality compared with West region. Moreover, microbiological and physicochemical characteristics showed a quadratic trend with farm sanitary conditions. Whereas, physicochemical conditions showed a linear trend for volume, fat, protein, and lactose. A quadratic effect was observed for SCC in herds over 101 cows. Herd size showed a positive linear trend for milk volume, protein, TS, NFS and cryoscopy. Water hardness influenced microbiological characteristics, resulting in higher CFU and SCC by using medium-hard water compared with soft-water (196×10^6 vs. 126×10^6 for CFU and 748×10^6 vs. 631×10^6 SCC, respectively). Furthermore, soft-water hardness significantly affected fat, lactose TS, and NFS in milk. Finally, season of the year affected SCC (summer: 877×10^6 vs. autumn: 709×10^6; $P > 0.05$), and had no effect on CFU. In conclusion, factors evaluated confirmed the need to improved sanitary conditions and to monitor water hardness. It became evident the need to implement preventive medicine programs and stricter health controls for milking during periods with elevated incidence of subclinical mastitis especially in big herds.

Key Words: milk, microbiologic, physicochemical

M95 Determination of Cd and Pb content on tissues of beef cattle raised in a tropical pasture based system in Brazil. J. R. Lima*[1], M. B. M. Teixeira[2], J. L. B. Silva[2], E. F. Silva[2], R. G. Reis[2], L. R. D. A. Neto[1], H. M. Queiroz[2], and L. G. Nussio[1], [1]*University of São Paulo/ESALQ*, *Piracicaba, Brazil*, [2]*Ministry of Agriculture, Livestock and Food Supply*, *Campinas, São Paulo, Brazil*.

To satisfy the requirements of the international market it is necessary to monitor several quality traits in meat products such as heavy metals. The purpose of this study was to determine Cd and Pb in liver and Pb in kidney tissues of 27 beef steers pasture raised in a tropical grazing system to compare the accumulation of Cd and Pb at the same tissue and Pb in 2 different tissues. The animals were fed at *Brachiaria brizantha* (palisade grass) pastures stocked under a rotational grazing system for 8 mo receiving energy and mineral supplementation sources. They were allocated in 3 treatments with 3 replications up to the finishing period which was taken at feedlot in a random block design. The supplements supplied on pasture were: 1) mineral supplementation (MS) *ad libitum*; 2) MS + ground corn (0.3% of BW); 3) MS + ground corn (0.6% of BW). There was no intentional contamination with Cd and Pb of animal feed, soil or water to provide a positive control and the analyzed heavy metals were checked for all of them. Livers and kidneys samples were taken at slaughter and immediately frozen. The analysis method utilized was previously validated according to Commission Decision 2002/657/EC and Regulation 2007/333/EC and accredited, in accordance with ISO/IEC 17025/2005. Duplicates samples of about 10 g of each tissue were weighted and twice burned at 500°C in a muffle furnace and ashes were washed with HNO_3. The concentration was determined with a graphite furnace atomic absorption spectrometry (GF AAS) technique with quantification limits for Cd and Pb of 22µg/kg and 75µg/kg, respectively. Mean levels for Cd and Pb content in all samples of the liver and Pb in the kidney were bellow acceptable levels (Cd - 500µg/kg and Pb - 500µg/kg on wet basis) established by European Community (Regulation 2006/1881/EC) and bellow the quantification limits too. The lack of contamination of beef livers and kidneys with Cd and Pb suggests the meat from a typical grazing system in Brazil is considered safe based on the European Community regulations.

M96 Effects of iodine intake and teat dipping practices on milk iodine concentrations. S. I. Borucki Castro*[1], R. Berthiaume[1], A. Fouquet[2], A. Robichaud[2], F. Beraldin[2], and P. Lacasse[1], [1]*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada*, *Sherbrooke, Québec.*, [2]*Food Directorate, Health Products and Food Branch, Health Canada*, *Montréal, Québec.*

A study was conducted to determine the effects of different iodine levels in lactating cow diets and different post dip practices on the concentration of milk iodine. Sixty 3 cows in mid-lactation were assigned to a 3 × 3 factorial with: 0.25, 0.5 and 1.0 mg dietary iodine / kg DM and 3 different post dip managements: chlorhexidine with dip cup, 1% iodine dip cup and 1% iodine spray, for a total of 9 treatments. During the 13-d pre-experimental and the 17-d experimental period, non-iodized sanitizers were used in premilking management or flushing of the milking units. At the end of the pre-experimental period, where all cows were fed 0.5 mg iodine/ kg DM and chlorhexidine was used as post dip, the levels of milk iodine averaged 299.5 (±11.55) µg/kg and no relationship was found with lactation number, days of lactation or milk production. Dietary iodine and milking management both affected milk iodine concentrations ($P < 0.001$). Although teat dipping with 1% iodine had no effect on milk iodine concentration, the same solution applied by spraying greatly increased milk iodine levels ($P < 0.05$). The results from this study confirm that iodine should not be overfed to preserve the safety of milk. Spraying iodine-based teat dipping solutions result in large increases of milk iodine contents and should be avoided.

Table 1. Least square means (LSM) of milk iodine concentrations at the end of 17-d treatment (µg/kg)

	Post milking management		(SEM=42.6)	
Dietary iodine (mg/kg DM; SEM 42.5)	Chlorhexidine - dip	1% Iodine - dip	1% Iodine - spray	Diet (SEM = 24.3)[1]
Low (0.28)	143	201	593	312_a
Recommended (0.53)	261	289	700	417_b
High (0.99)	325	386	665	459_b
Post dip (SEM=24.3)[2]	243_a	292_a	653_b

M97 Iodine concentrations in feeds in farms with contrasting levels of iodine in milk. S. I. Borucki Castro*[1], P. Lacasse[1], A. Fouquet[2], A. Robichaud[2], F. Beraldin[2], and R. Berthiaume[1], [1]*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada*, *Sherbrooke, Québec, Canada,* [2]*Food Directorate. Health Products and Food Branch, Health Canada*, *Montréal, Québec, Canada.*

In a previous study, iodine concentration of bulk-tank milk in Canada (n = 501 farms) was found to vary considerably and appeared to be influenced by feeding practices. A subset of 200 participating farms was used to determine the relationship between milk iodine concentrations and concentration of this mineral in different feeds and diets of lactating dairy cows. The 30 farms with the lowest (Low) and the 30 farms with the highest (High) levels of iodine in milk were selected. Each of them completed a questionnaire providing information about the feeding management and samples of all feed ingredients, water and bulk tank milk were collected. The iodine offered on each of the farms was estimated using the amount recommended by the software Ration′L and the iodine concentration in the feed sampled and analyzed using inductively coupled plasma mass spectrometry. Milk iodine concentrations averaged 146 (±13.9) µg/kg (Low) and 487 (±44.6) µg/kg (High). Dietary concentrations of iodine offered daily were 33% lower ($P < 0.01$) for the group Low compared with the group High, 1.20 (±0.099) vs. 1.81 (±0.195) mg/ kg DM, respectively. A linear relationship ($P < 0.01$) was found between dietary iodine concentration and milk iodine levels: (y) Milk iodine (µg/kg) = 145 (±66.9) + 113 (±39.4) x (dietary iodine concentration, mg/kg DM). However, the low R^2 (0.15) indicates that other factors such as milking management and the presence of goitrogens, must have affected the concentrations of iodine in milk. Forages supplied approximately 17% of iodine requirements in the average lactating cow diet. Therefore, variation in the iodine content of forages are unlikely to cause iodine overfeeding. Conversely, 27% of mineral mix samples presented iodine concentrations above 100,000 µg/kg DM (and up to 322,000 µg/kg DM). More than 80% of the farms tested fed higher iodine levels than dietary iodine recommendations (0.50 mg iodine/kg DM; NRC, 2001). Our results suggest that iodine supplements should be used with caution in lactating cow diets.

Key Words: iodine, milk iodine, feed ingredients

M98 European Union principles for the risk assessment of feed additives. M. Anguita*, J. Galobart, and C. Roncancio-Peña, *European Food Safety Authority*, *Parma I43121, Italy*.

In the European Union (EU), all feed additives before being placed on the market undergo an authorization procedure as established in the Regulation (EC) No 1831/2003. In this procedure the European Food Safety Authority (EFSA), and in particular the Panel on additives and products or substances used in animal feed (FEEDAP), is the responsible of assessing the safety and the efficacy of the additive. Feed additives are substances, microorganisms or preparations, other than feed material and premixtures, which are intentionally added to feed or water to perform one or more of the following functions: favorably affect the characteristics of feed or animal products, favorably affect the color of ornamental fish and birds, satisfy the nutritional needs of animals, favorably affect the environmental consequences of animal production, favorably affect animal production, performance or welfare or have a coccidiostatic or histomonostatic effect. To be authorized, feed additives should be safe, and therefore should not have (i) an adverse effect on the animal health, human health or the environment, and (ii) should not be presented in a manner which may mislead the user; the additives should also be efficacious. Any person seeking the authorization of an additive should submit an application to the European Commission and a technical dossier to EFSA. The dossier should be compiled following Commission Regulation (EC) No 429/2008 and the guidance documents that EFSA has prepared to help the applicants. The data provided in the technical dossier should allow a complete assessment of (i) the identity of the additive, (ii) the safety for the target animals, for the consumers of food products derived from animals fed diets containing the additive, for those persons handling the additive and for the environment and (iii) the efficacy of the additive, according to the claim made. The scientific assessment carried out by the FEEDAP Panel finishes with the adoption of a scientific opinion which will be the basis for the Commission to grant or deny the authorization of the product for its use in the EU market.

Key Words: additives, assessment, European Union

M99 Development an on-farm technique using lactic acid bacteria as a biomarker to detect of toxins in milk. M. H. Hathurusinghe*[1], A. AbuGhazaleh[2], M. R. Reddy[1], S. A. Ibrahim[1], M. Tajkarimi[1], and D. Song[1], [1]*North Carolina Agricultural and Technical State University*, *Greensboro, NC*, [2]*Southern Illinois University*, *Carbondale*.

Because many dairy farms lack adequate biosecurity there is a risk of intentional contamination of milk with harmful chemicals. Such contamination has potential health risk to the human consumers as well as major economic losses to the country. Most of the existing methods to detect toxins are expensive and time consuming. Thus, there is an urgent need for developing simple on-farm techniques that can detect toxins in raw milk. The objective of this study was to determine the effect of brodifacoum, bromadiolon, strychnine, and sodium cyanide on the growth of selected strains of lactic acid bacteria (LAB) and to test the potential of LAB as a biomarker for early detection of toxins in milk. Three strains of bifidobacteria, one strain of *Lactobacillus rhamnosus* GG and a commercially available yogurt culture were used to detect their sensitivity to selected toxins. Toxins at different concentrations were added into separate tubes containing different strains of bacteria. Samples were incubated at 37°C for 24 h. Milk samples without toxins were used as the control. The turbidity of the sample was recorded at 3, 9 and 24 h intervals. Results showed that *B. longum* was not sensitive to the tested toxins. *B. adolescentis* and *B. breve* were sensitive to the toxins and the inhibition was observed after 24 h. The yogurt culture and *L. rhamnosus* GG were the most sensitive to all the toxins at levels of 1µg/ml and 2µg/ml respectively, except for sodium cyanide which was 0.1µg/ml for both yogurt culture and *L. rhamnosus* GG after 3 h of incubation. These findings suggest that a highly sensitive, environmentally safe, fast and accurate test kit could be developed using selected LAB as a universal biomarker.

Key Words: toxin, lactic acid bacteria, biomarker

M100 Food safety in developing countries using no technology: The Wagashi study case. F. La Terra[1], G. Belvedere[1], M. Manenti[1], C. Pediliggieri[1], S. Mirabella[1], J. C. Codjia[2], S. Doko[3], and G. Licitra*[1,4], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*University of Abomey-Calavi*, *Benin*, [3]*University of Parakou*, *Benin*, [4]*DACPA, Catania University*, *Catania, Italy*.

The Wagashi cheese, produced in Benin from Peuhl communities, is a cheese that has a homogeneous structure and can be found usually in round shaped 300 to 800 g pieces. To produce Wagashi cheese, milk coagulation occurs at temperatures higher than 70°C. This allows a first thermic treatment of milk extremely important when production hygiene conditions cannot be controlled. Fresh milk is first heated at 60°C for 5 min. After, a vegetal coagulant extracted from the latex of *Calotropis procera* leaves is added and temperature is raised and maintained at 95°C for 3 to 5 min until curd separates from whey. The latex of *Calotropis procera* is used to produce the Wagashi cheese with very low proteolytic activity that allows boiling the cheese over and over again, every 2 d, for about 20–30 d since it has been produced. This simple practice makes the cheese safe. Alternatively, cheese can be sun-dried to extend shelf life. The aim of this study was to assess variations of chemical, biochemical, and microbiological properties of Wagashi cheese, to evaluate the food security conditions. Production conditions and processes were reproduced and monitored in a laboratory trial. Eleven 500-g cheeses were produced using cow raw milk. Cheeses were sampled after cheese making process and, after 24h and 48h, before and after boiling for 10, 20, and 40 min. Cheese samples were analyzed for pH, soluble proteins (TCA 12%), soluble proteins pH 4.6, fat, total nitrogen, urea PAGE, total bacteria count (TBC), total and fecal coliform count, and *S. aureus* count. After 24h, 10-min boiling were sufficient to reduce TBC in the center of the cheese from 3.5×10^3 to 10^2 cfu/g. After 48h, 10-min boiling reduced TBC from 1.10×10^6 to 6.30×10^4 cfu/g, whereas 20 min were necessary to reduce TBC to 10^1 cfu/g. The proteolytic profiles of Wagashi cheese obtained before and after boiling treatment were in overlapping, confirming the low proteolytic activity. The results showed how the temperature during cheese making is an important factor for the microbiological food safety and in addition the re-boiling process for 20 min each 48h guarantee its shelf-life for several days.

Key Words: food safety, proteolysis, Wagashi cheese

M101 Stress-induced adaptive tolerance response influences virulence in *Campylobacter jejuni*. G. S. Kumar*, I. Hanning, Y. Ma, and M. Slavik, *University of Arkansas*, *Fayetteville*.

Campylobacter jejuni, the major cause of human gastroenteritis, is a fragile bacterium requiring special conditions in the laboratory for its growth. In nature, however, this organism is able to survive in very diverse and hostile environments and produce disease in humans. The mechanisms that the organism has evolved for its survival in stressful conditions are not fully understood. To determine the effect of acid stress on *C. jejuni*, 4 different strains of *C. jejuni* were exposed to an acid pH of 5.5 and then re-challenged with a pH of 4.5. Acid-adapted cells were found to have higher viability to survive further acid stress, but adaptation and survival were time-dependent. The effects of starvation stress also were studied. Expression of virulence gene *cadF* was upregulated by starvation stress, while virulence genes *cdtB* and *ciaB* were downregulated. Adhesion and invasion are thought to be important factors for the colonization of *C. jejuni* in the intestinal tract of host. In vitro studies with INT 407 tissue culture model (mammalian intestinal cells) were conducted with different times of exposure to acid (2h and 3h), to determine the effects of stress on adhesion and invasion of *C. jejuni*. All the tissue culture experiments were performed in replicates of 3. Results indicated that acid-adapted bacteria had increased adhesion and invasiveness, but varied with the strains and the time of exposure to the acid. Exposure of acid-adapted *C. jejuni* to further stress of starvation for 24 h did not have any significant difference in the adhesion and invasion abilities as compared with cells exposed to starvation stress only. These results indicate that *C.jejuni* surviving stress may be more resistant to further stress such as passage through the human gastrointestinal tract and that stress may be a significant factor in inducing some virulence genes.

Key Words: *C. jejuni*, stress, acid-adapted

M102 *Salmonella* Enteritidis challenge in chicks of different genotypes. P. E. N. Givisiez*[1], E. G. Santos[1], F. G. P. Costa[1], J. H. V. Silva[1], and A. Berchieri Jr.[2], [1]*Universidade Federal da Paraiba*, *Areia, PB, Brazil*, [2]*Universidade Estadual Paulista*, *Jaboticabal, SP, Brazil*.

Alternative poultry production is a promising business for small farmers, who should choose breeds based on robustness, consumer concerns and health issues. This study evaluated the resistance of Cobb and Naked Neck birds fed 2 threonine levels and challenged with *Salmonella* Enteritidis at 2 d of age. Twenty Cobb chicks (CC) and 20 naked neck chicks (NN) were distributed into a completely randomized design according to a 2 × 2 factorial (2 genotypes and 2 threonine levels) and 8 repetitions. Antibiotic-free corn-soybean diets with 0.821 and 0.917% digestible threonine were used. The birds were inoculated with *Salmonella* Enteritidis $^{Nal++}$ (1.2×10^8 CFU.mL^{-1}) and killed at 10 d of age for performance evaluation and bacterial counts (CFU.g^{-1}), which were

transformed into Log10. Data were subjected to ANOVA and means were compared using Tukey's multiple comparison test ($P < 0.05$). There was no interaction between genotype and threonine level ($P > 0.05$). Lower *Salmonella* counts ($P > 0.01$) were seen for NN compared with CC (1.37 vs 6.91). Furthermore, 94% of CC (15/16) and 25% (4/16) of NN were positive for salmonella counts. Body weight and weight gain were higher ($P < 0.01$) for CC (250.13 vs 120.19 g and 206 vs 77.75 g, respectively). Although threonine has been suggested to help diminishing enteric pathogen infection, higher threonine levels had no effect on salmonella counts or performance. The results corroborate the need of *Salmonella* control during the first week of rearing, since birds contaminated during this period may be infected until slaughter and there is potential risk for consumers. NN was best fitted for alternative production, considering the higher resistance to infection by *Salmonella* and slower growth rate. In conclusion, naked neck chicks were more resistant to *Salmonella* Enteritidis than Cobb independent of threonine dietary levels.

Key Words: alternative poultry, salmonellosis, nutrition

M103 Effect of feeding distillers dried grains to lactating cows on farms in the southern dairy region of Chile. R. Shaver*[1], R. Ehrenfeld[2], M. Olivares[2], J. Cuellar[3], and F. Inostroza[1], [1]*University of Wisconsin*, *Madison,* [2]*Cooprinsem*, *Osorno, Chile*, [3]*US Grains Council*, *Bogota, Columbia*.

A field trial was conducted on 5 farms to determine the effect of feeding distillers dried grains (DDGS) on milk production in the southern dairy region of Chile. The trial was repeated on each farm during winter (July and August; primarily silage-based rations) and spring (November and December; pasture-based rations). Only for one farm could the treatments be applied concurrently by feeding different isonitrogenous concentrate mixes to randomly assigned cows in the milking parlor with data analyzed as a randomized complete block design. Milk yield tended ($P < 0.07$) to be greater for cows fed DDGS (2.0 kg/cow per d) by 1.9 kg/d in winter and 1.8 kg/d in spring. In winter, milk protein yield was ($P < 0.02$) greater for cows fed DDGS by 73 g/d. Milk fat content was ($P < 0.01$) lower for cows fed DDGS by 0.26%-units in the spring, however, milk fat yield was unaffected by treatment. The 4 farms that could not apply the treatments concurrently were randomly assigned to either a control to DDGS or a DDGS to control isonitrogenous concentrate treatment sequence in a crossover design with monthly feeding periods during the winter and spring. Data were analyzed as a crossover design with farm as the experimental unit. Milk yield was ($P < 0.05$) greater for farms fed DDGS (2.5 kg/cow per d) by 0.9 kg/d in winter. We conclude that DDGS was an effective dairy concentrate ingredient in the southern dairy region of Chile.

Key Words: pasture, dairy cows, distillers grains

M104 Yield and quality of grasses and legumes for dairy cattle feeding. E. E. Corea Guillén*[1], J. M. Flores Tensos[1], F. M. Salinas Munguia[1], E. A. Crespin Payés[1], and J. A. Elizondo-Salazar[2], [1]*Departamento de Zootecnia, Facultad de Ciencias Agronómicas, Universidad de El Salvador, El Salvador,* [2]*Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, Costa Rica.*

Forages used in a cut-and-carry system are a very important feed resource for dairy cattle in El Salvador and many areas of Central America. However, forages are extremely variable in terms of yield and quality and they are usually low in CP content. Planting legumes mixed with grasses is a management practice to take advantage of their unique ability to bind atmospheric N and to improve the quality of the forage when harvested. This study was conducted to determine yield and quality of 2 forages, 2 legumes and a 1:1 sward mixture between them. Two varieties of Sorghum (*Sorghum bicolor* var. CENTA S-2 and *Sorghum bicolor* var. RCV) and the legumes Canavalia (*Canavalia ensiformis*) and Vigna (*Vigna sinensis*) were used in the study. Forages were established in 12 × 12-m plots with 3 replications in a randomized block design. Seeding rate was 250000, 250000, 50000, and 75000 plants/ha for S-2, RCV, Canavalia and Vigna, respectively. They were planted in different days so that they would be harvested at maturity age (75, 70, 80, and 60 d for S-2, RCV, Canavalia and Vigna, respectively). Samples were taken at maturity age to estimate yield and for determination of DM yield, DM, CP, NDF, and ADF concentration. Variables were analyzed using GLM procedure of SAS 9.1. Separation of means was done using the Duncan's multiple comparison procedure. There were differences ($P < 0.01$) between treatments for all variables studied. Grasses produced more available DM (kg/ha) than legumes. Legumes had higher CP content than grasses as expected. The findings of the study corroborate that grasses (S-2 and RCV) produced more biomass than legumes and that a mixture of both is a way to improve the yield of the legume alone and the quality of the grass alone.

Table 1. Yield and quality of grasses and legumes

M105 Quality of ensiled grasses and legumes for dairy cattle feeding. E. E. Corea Guillén*[1], J. M. Flores Tensos[1], F. M. Salinas Munguia[1], E. A. Crespin Payés[1], and J. A. Elizondo-Salazar[2], [1]*Departamento de Zootecnia. Facultad de Ciencias Agronómicas*, *Universidad de El Salvador, El Salvador*, [2]*Estación Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias*, *Universidad de Costa Rica, Costa Rica*.

Silage is an excellent way to preserve forages at the optimum stage of growth for use during a time when it is unavailable. This is very important in all Central American countries in which there is a very marked dry season. However, it is well known that nutritional quality of grasses is not high and studies have demonstrated the superiority of grass-legume silages in comparison with grass silages. There is also a growing interest in organic and low-input production systems. A study was conducted to assess the nutritional value and quality of microsilages prepared from different combinations of grasses and legumes. A completely randomized design was used with 2 varieties of Sorghum (*Sorghum bicolor* var. CENTA S-2 and *Sorghum bicolor* var. RCV) and 2 legumes Canavalia (*Canavalia ensiformis*) and Vigna (*Vigna sinensis*). Forages were harvested at maturity age (75, 70, 80, and 60 d for S-2, RCV, Canavalia and Vigna, respectively). Seven kg of fresh-chopped forages in the proportions of 100:0, 70:30, and 50:50% w/w for grass and legume respectively, were placed in plastic bags in triplicate. Air was extracted by compacting the forage mass and bags were tightly sealed. Microsilages were open after a 21 d period and a sample was taken to determine pH, and for DM, CP, NDF, and ADF concentration. Variables were analyzed using GLM procedure of SAS 9.1. Separation of means was done using the Duncan's multiple comparison procedure. There were significant differences ($P < 0.01$) for the variables studied among the different mixtures. pH was among accepted values. Dry matter content was highest when grasses were ensiled alone. CP values were higher when a 50:50 proportion was used. Differences in the chemical composition of these silages reflect variations in the proportion of each forage type.

M106 Chewing and ruminating with various forage qualities in non-lactating dairy cows. M. Fustini*[1], A. Palmonari[1], A. J. Heinrichs[2], and A. Formigoni[1], [1]*Università di Bologna*, *Bologna, Italy*, [2]*Department of Dairy and Animal Science*, *The Pennsylvania State University, University Park*.

In Parmigiano Reggiano cheese area use of silages is not allowed. Thus, hay is the sole source of fiber in these diets. Forage quality strongly affects eating behavior, in particular if hay is represented by alfalfa. This study investigated typical dry forage diets used in the Parmigiano Reggiano area. Six multiparous, non-lactating Holstein cows were used in a replicated 3 × 3 Latin square to evaluate 3 different cuts of alfalfa hay fed as the sole forage source. First diet contained a first cut forage, while a second cut (poorly digestible) and a fifth cut (highly digestible) were used in the second and third diet. Eating and ruminating behavior were studied to investigate forage properties related to chewing activity. Digestibility was evaluated in vitro using the Tilley and Terry technique. Statistical analysis was conducted using PROC MIXED of SAS. No differences were found in eating time (average value 220.5, 261.7, 235.5 min/d for 1st, 2nd and 3rd diet respectively, $P > 0.05$); however, ruminating time per kilogram of physically effective neutral detergent fiber was greater when cows were fed first cut alfalfa than second or fifth cut (average value 136.1, 111.2, 107.1 min/d for 1st, 2nd and 3rd diet respectively, $P < 0.05$), despite not different digestibility and diet particle size of first and third diet (% dNDF 24h average values 50.44, 48.38 for 1st and 3rd diet respectively, $P > 0.05$). In summary, this study found no differences in eating time for the 3 hays fed. Ruminating time was not related to overall nutrient composition or digestibility of the hay, but varied by cutting with first cutting hay promoting more rumination.

Key Words: eating behavior, ruminating, forage quality

M107 The effect of management on corn silage quality. L. O. Abdelhadi*[1], C. A. Malaspina[2], W. R. Barneix[2], P. A. Saravia[2], and C. de Elia[3], [1]*Est. El Encuentro, Research & Extension in Ruminant Nutrition*, *Cnel. Brandsen, Bs.As., Argentina*, [2]*CACF*, *Argentina*, [3]*Alltech Biotechnology*, *Argentina*.

When formulating diets, corn silage quality is usually evaluated from samples taken before feedout and exposure to air, underestimating the losses related to exposure, extraction, mixing and feeding. A completely randomized design with a 3x2 factorial arrangement of treatments was used to evaluate the effects of silo type and sample location on CS nutrient composition in 12 commercial dairy and beef farms. Corn silage was manufactured in either bunker (n = 6) or bag (n = 6) silos, was inoculated with 5g/ton of Sil-All and sealed with plastic for 45d before feed out. The feed out rate was 0.2 to 0.3m twice daily for all bags and bunkers. Composite samples for analysis were collected from 3 locations: Depth = sample taken at 1m depth from the exposed face; Face = sample taken from the surface of the exposed face; and Feed bunk (FB) = sample taken from the FB after exposure to air for 3 to 4 h. Samples from the center of the silo were collected using a forage sampler at 0.5, 1.0 and 1.5 m from the floor. Sub samples were hand-mixed, divided into equal quarters, with 2 opposite quarters selected to obtain the composite sample including the fines. Samples were analyzed for DM, OM, NDF, WSC, CP, Starch, pH and in vitro DM digestibility (IVDMD). Although no effects of sampling location were detected for most variables, IVDMD tended ($P = 0.07$) to be reduced from Depth to FB, independently of silo type. This reduction seemed to be associated with a higher pH ($P = 0.09$) from depth to FB. These results suggest that CS extraction and distribution negatively affect the nutritional quality and this change should be considered for a more accurate diet formulation.

Table 1. Corn silage quality by sampling site or type of silo

	Sampling site (n=12)				Type of silo (n=18)		
Variable	Depth	Face	FB	SE	Bunker	Bag	SE

M108 Whole-plant corn quality parameters for ensiled and unensiled samples: Effects of hybrid and length of fermentation. C. M. Fish*[1,2], R. D. Shaver[1], D. C. Weakley[2], J. G. Lauer[1], and T. E. Piper[2], [1]*University of Wisconsin*, *Madison,* [2]*Land O' Lakes Inc.*, *Shoreview, MN*.

Most corn hybrid trials use unensiled samples for laboratory analysis of forage quality parameters. The purpose of this study was to determine the effect of ensiling on ranking hybrids for silage quality. Twenty-nine corn hybrids of differing genetic backgrounds from early, mid, and late relative maturity groups were planted in replicated field test plots using a randomized complete block design at Lancaster, Plymouth and West Salem, WI. During harvest at 30–35% whole-plant DM content, 3 400-g samples were obtained from each field test plot; one sample was immediately refrigerated (0 d fermentation) for no more than 48 h before drying and 2 were ensiled in 25 cm by 33 cm vacuum-sealed bags stored at room temperature at the Land O'Lakes warehouse in Vincent, IA for 30 d or 120 d fermentation times. Refrigerated and ensiled samples were dried in a forced-air oven at 43–46°C for 48 h, ground on a Wiley mill to pass a 6mm screen, and analyzed using the Perten Diode Array 7200 NIR Analyzer. Parameters analyzed were starch, NDF, ivNDFD (30 h; % of NDF), and an index of in vitro starch digestibility (GPN).

Quality data were used to calculate milk per ton (MPT; kg per US ton; MILK2006). Data were analyzed using Proc Mixed in SAS with fixed effects of fermentation, hybrid and their interaction, and random effects of location, replication, and location interactions. Maturity trial averages and P-values for quality parameters are presented in the Table. Hybrid differences were detected for most parameters. There was a significant effect of fermentation on NDF, ivNDFD, GPN and MPT. However, interactions between hybrid and fermentation were not detected. Unensiled sample data may be used in quality evaluation trials for ranking corn silage hybrids, but fermentation influences silage quality parameter results.

Table 1. Maturity trial averages and P values for main effects and interaction

	NDF%	ivNDFD%	Starch%	GPN	MPT, kg/ton
Early Trial Avg	39.5	45.6	35.9	8.13	1502

M109 Fermentation characteristics of corn-lablab bean silage mixtures. F. E. Contreras-Govea*[1], M. A. Marsalis[2], S. V. Angadi[3], G. R. Smith[4], and L. M. Lauriault[5], [1]*New Mexico State University, Plant and Environmental Sciences Department*, *Artesia,* [2]*New Mexico State University, Extension Plant Sciences Department*, *Clovis,* [3]*New Mexico State University, Plant and Environmental Sciences Department*, *Clovis,* [4]*Texas AgriLife Research, Texas A&M University System*, *Overton,* [5]*New Mexico State University, Plant and Environmental Sciences Department*, *Tucumcari.*

The objective of this study was to assess the fermentation characteristics of corn (*Zea mays* L.) when in mixture with different proportions of lablab bean (*Lablab purpureus* (L.) Sweet) for silage. Corn and lablab bean cv Rio Verde were grown in separate fields at 2 locations in 2009. Corn was harvested between 1/3 and 1/2 milk line and lablab between 5% and 15% bloom. Corn and lablab bean were chopped to a theoretical length of 25-mm. Chopped samples of both crops were hand mixed on per cent fresh weight basis to obtain 6 corn-lablab composite mixtures, 1) 100–0, 2) 90–10, 3) 75–25, 4) 50–50, 5) 25–75, and 6) 0–100. Mixtures were ensiled in 1-L glass jars at a density of 500-g of fresh material per jar. Four replications per treatment were included at each location. Mini-silos were fermented for 60 d at room temperature (25°C). At opening 250-g of fresh silage was vacuum sealed in plastic bags, frozen, for later analysis of fiber and fermentation characteristics. Data analysis was conducted as a randomized complete design for each location. Crude protein ($P < 0.01$) increased from 8.0% to 20.0% as the proportion of lablab bean increased in the mixture at both locations. At Location 1 NDF ($P < 0.003$) decreased and at Location 2 ($P < 0.01$) increased as lablab increased in mixture. At location 2, 48 h in vitro DM digestibility decreased from 87.3% to 81.3% as lablab increased in mixture, with no differences at the Location 1 ($P > 0.634$). Silage pH ($P < 0.0001$) and lactic acid concentration ($P < 0.01$) increased as well as the proportion of lablab increased in the mixture at both locations. Mixing lablab bean with corn for silage can potentially reduce protein supplementation requirements in dairy cow rations.

Key Words: corn, lablab bean, silage fermentation

M110 Fermentation characteristics of forage sorghum-lablab bean silage mixtures. F. E. Contreras-Govea*[1], M. A. Marsalis[2], S. V. Angadi[3], G. R. Smith[4], and L. M. Lauriault[5], [1]*New Mexico State University, Plant and Environmental Sciences Department*, *Artesia,* [2]*New Mexico State University, Extension Plant Sciences Department*, *Clovis,* [3]*New Mexico State University, Plant and Environmental Sciences Department*, *Clovis,* [4]*Texas AgriLife Research, Texas A&M University System*, *Overton,* [5]*New Mexico State University, Plant and Environmental Sciences Department*, *Tucumcari.*

The objective of this study was to assess the fermentation characteristics of forage sorghum (FS) [*Sorghum bicolor* (L.) Moench] for silage when in mixture with different proportions of lablab bean (*Lablab purpureus* (L.) Sweet) cv Rio Verde. Forage sorghum and lablab were grown in separate fields at 2 locations in 2009. Forage sorghum was harvested between soft and late dough stage of the kernel and lablab bean between 5% and 15% bloom. Forage sorghum and lablab were chopped to a theoretical length of 25 mm. Chopped crops were hand mixed on per cent fresh weight to obtain 6 FS-lablab composite mixtures, 1) 100–0, 2) 90–10, 3) 75–25, 4) 50–50, 5) 25–75, and 6) 0–100. Mixtures were ensiled in 1-L glass jars at a density of 500-g of fresh material per jar. Four replications per treatment were included at each location. Mini-silos were fermented for 60 d at room temperature (25°C). At opening, 250-g of fresh silage was vacuum sealed in plastic bags, and frozen for later analysis of fiber and fermentation characteristics. Data analysis was conducted as a randomized complete design for each location. Over both locations CP ($P < 0.0001$) and IVTD ($P < 0.01$) increased from 9.0% to 20.6% and from 79% to 85% respectively, as the proportion of lablab bean increased in the mixture. However, ADF ($P < 0.0001$) also increased with the addition of lablab bean in the mixture. Lactic ($P < 0.0001$) and Acetic ($P < 0.0001$) acids, and pH ($P < 0.0001$) also increased with the addition of lablab in the mixture. Mixing lablab bean with FS for silage can potentially reduce protein supplementation in rations for dairy or beef cattle and improves digestibility of the silage.

Key Words: forage sorghum, lablab bean, silage fermentation

M111 Growing degree-days as corn silage harvest indicator. J. S. Oliveira*[1], E. J. D. de Almeida[2], F. C. F. Lopes[1], and E. C. M. de Lanes[3], [1]*Embrapa Gado de Leite*, *Juiz de Fora, MG, Brazil*, [2]*Universidade Federal de Juiz de Fora*, *Juiz de Fora, MG, Brazil*, [3]*Centro de Ensino Superior de Juiz de Fora*, *Juiz de Fora, MG, Brazil*.

Dry matter content (DM%) at harvesting is important to have high quality corn silage. Ideal DM% ranges from 31 to 35 for bunker silos. Methods used by farmers to estimate DM% of corn crop are laborious or not reliable. This research studied the relation between growing degree-days (GDD) and DM% in different corn hybrids and its use as a tool to predict DM% in a corn crop. The field work was done at National Dairy Center Research, EMBRAPA, Coronel Pacheco, MG, Brazil. Six hybrids were planted in 4 dates (12/15/2004, 01/14/2005, 10/26/2005, 11/24/2005) using a casual block design and 3 replications. The experimental unit was a line 20 m long with 90 plants. After the eightieth day, 5 plants were sequentially harvested every 3 d from each line for dry matter content determination (DM%). Starting at seedling, maximum and minimum daily temperatures were recorded and used to calculate GDD using the formula GDD = [(Tmax - Tmin) / 2] - TB,

where TB is the base temperature, considered 8 for that region. Pairs of DM% and GDD originated a linear regression equation to estimate the required GDD for plants of each experimental unit reach 33% dry matter (GDD33). From the 72 equations, only 5 presented *P* value higher than 0.01 for parameter b. The GDD33 of only one of the 6 hybrids was affected ($P < 0.05$) by planting date. Also, GDD33 average was different ($P < 0.05$) between hybrids. Considering 80% precision, the error when using GDD33 to estimate 33% of DM varied from ± 2 (one hybrid) to ± 3 (5 hybrids) DM% units. Because DM content for ensiling must be in a range and not a fixed value, GDD seems to be a reliable tool to predict the proper time for corn silage harvest. This information should be included by seed companies when recommending a corn hybrid for silage.

Key Words: growing degree units, dry matter, hybrids

M112 Production and quality of alfalfa harvested at different stages of maturity. R. Copado[1], C. Arzola*[1], J. A. Payan[2], J. Salinas[3], O. Ruiz[1], C. Rodriguez-Muela[1], E. Rodriguez[1], J. A. Ortega[1], and O. Serna[2], [1]*Universidad Autonoma de Chihuahua*, *Chihuahua, Chih., Mexico*, [2]*INIFAP*, *Chihuahua, Chih., Mexico*, [3]*Universidad Autonoma de Tamaulipas*, *Cd. Victoria, Tams., Mexico*.

To evaluate the effect of maturity upon the nutritional quality of 2 varieties of alfalfa ("Cuff-101" and "Excellent multileaf") harvested on 2 seasons (summer and fall), the production (kg/ha) and quality of forage was characterized. There were determined the leaf/stem ratio of biomass and its content of dry matter, crude protein, neutral detergent fiber, acid detergent fiber and lignin over a range of maturity following an initial phenologic stage characterized by an average stem length of about 0.3 m, (but not visible buds, flowers, or seedpods) within the 2 seasons. Within each season, plots were clipped initially (d 0) and then additional sampling dates were scheduled at 5-d intervals for the next 20 d, resulting in a total of 5 clipping dates (0, 5, 10, 15, and 20 d). Data were analyzed as a split-plot experiment, the plots arranged factorially in a randomized complete block design, being the alfalfa varieties and season the main effects, and maturity the subplot term. Season influenced both production and forage quality, so during the fall the production of dry matter was lower ($P < 0.01$). On d 20 in summer a yield of 5.8 ton MS/ha was registered and in fall only 4.9 ton MS/ha, without differences among varieties ($P > 0.05$). Dry matter crude protein (CP) content of leaves in fall in growing stage was 35.0% on d 0, whereas stem's was 25.3% and whole plant was 31.8%. In summer, CP was 32.7% in leaves, 22.6% in stems and 29.3% in the whole plant. On the 20 d (flowering stage) of fall the leaves had 25.4% CP, stems 20.2% and whole plant 23.7%, compared with 23.5%, 19.1% y 21.6% CP in summer, respectively. Contents of FDN and FDA diminished ($P < 0.01$) in fall, due to a dilution effect or an observed diminution of fiber for a rapid accumulation of biomass. In summer, the accumulation of biomass on both varieties was larger than 4 ton/ha of DM. It was concluded that the best quality of forage is obtained during fall regardless of variety, but yield is lower. With the advancement of maturity, nutritional quality of alfalfa diminished, whereas production increased.

Key Words: alfalfa, stage of maturity, nutritional quality

M113 Gas production profiles of two varieties of alfalfa harvested on different stages of maturity. O. Serna-Beltran[1,2], C. Arzola*[1], E. Santellano-Estrada[1], J. A. Payan-Garcia[2], A. Corral-Luna3,1, O. Ruiz[1], C. Rodriguez-Muela[1], and J. Salinas[4], [1]*Universidad Autonoma de Chihuahua*, *Chihuahua, Mexico*, [2]*Instituto Nacional de Investigaciones Forestales, Agricolas y Pecuarias*, *Delicias, Chihuahua, Mexico*, [3]*Department of Animal Sciences-University of Illinois at Urbana-Champaign*, *Illinois*, [4]*Universidad Autonoma de Tamaulipas*, *Reynosa, Tams. Mexico*.

Alfalfa (*Medicago sativa*) dry matter is readily fermented in the rumen. Even though this phenomenon has been extensively studied in relation to the effects of the conservation method, there are not many studies regarding the effect of maturity upon the rumen degradability of alfalfa hay. The objective of this study was to assess the effect of maturity, expressed as time of harvest over a range of sampling periods (0, 5, 10, 15, and 20 d following Stage 2, (when stem length was > 0.40 m, but no buds, flowers, or seedpods were visible) of 2 varieties ("Excellent 9HQ and "Excelent multifoliar 9HQ ML," AgriBioTech) on 4 seasons (spring, early and late summer, and fall). An exclosure was sub-divided on 5 stripes on each of 8 locations of Delicias, Chih., Mexico, and sampled within 5 d intervals after an initial cut. Data were analyzed with a sub-plot design, with variety and period as main effects and day of cutting as sub-plot term. Statistical analysis used the GLM procedure of SAS. Gas production data were adjusted with the monophasic model of Groot, using proc NLIN of SAS. Linear, quadratic, cubic and quartic effects tests were performed for forage composition traits and gas production kinetics parameters within each maturity stage. There were not differences among varieties ($P > 0.05$) in the content of crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF) and acid detergent lignin (ADL). As maturity advanced, CP decreased linearly ($P < 0.001$), yet NDF, ADF, and ADL increased ($P < 0.001$) linearly. Maturity had also a strong effect upon the ruminal degradability of alfalfa as assessed with gas production profiles. A significant linear tendency ($P < 0.01$) was found for both A (gas production asymptote) and B (time after incubation at which half of the asymptotic amount of gas has been formed) parameters increasing as maturity advanced. Parameter C (a constant determining the sharpness of the switching characteristic of the profile) declined, showing linear ($P < 0.01$) effects.

Key Words: alfalfa, degradability, maturity

M114 Can different ME estimation methods give different values for tanniferous forages? H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Reza Yazdi[1], [1]*Department of Animal Science, University of Tehran*, *Karaj, Tehran, I.R. Iran*, [2]*Department of Animal Science, University of Urmia*, *Urmia, West Azerbaijan, I.R. Iran*.

Condensed tannins (CT) are antinutritional factors, reduced nutrient digestibility by binding them and probably can disrupt digestibility estimation methods. To determine any possible effects, experiments carried out with different methods for estimating metabolizable energy of sainfoin. Forages were taken from farms in Isfahan and representative dry samples were analyzed for DM, OM and CT. For gas production test, 2 mm sieved samples, were used in Triplicates and 2 separated runs. Rumen fluid was obtained from 2 maintenance level fed, rumen fistulated Taleshi cows. 24h gas production data were used for calculation of ME content by follow equations: 1) $ME = 2.2 + 0.1357GP_{24} + 0.0057CP + 0.0002859CP^2$, 2) $ME = 2.2 + 0.136GP_{24} + 0.057CP + 0.0029CF^2$ & 3)%OMD = $14.88 + 0.8893GP_{24} + 0.0448CP + 0.0651$ash. For in vitro digestion trial, samples milled through a 1 mm sieve. Two separated runs, each in triplicates and 3 jars as blank, applied. ME estimated using ME = 0.0157 × DOMD. Also, an in vivo digestibility trial (17 d, with7

d for fecal collection) was done using 3 ruminally fistulated Holstein cows. Forages were fed as sole diet at 10% above maintenance energy requirements. Total fecal collection and marker assay including AIA and Cr_2O_3 (5 gr infused from ruminal fistula, d 8 to 14) were done for determining OM digestibility. Data were analyzed by GLM procedure of SAS 9.1 with CRD design and Duncan test ($P \leq 0.05$). CT content was 21.3 g/kg DM. Estimated ME from in vitro digestion trial was 10.11 and mean estimations from gas production and in vivo trial was 7.19 and 8.75 MJ kg^{-1} DM. No significant differences were exist between different ME estimates of gas production or between in vivo methods. Also, OM digestibility in in vitro was higher than values determined by in vivo and gas production profiles. Higher OM digestibility values for filtration based methods can be explained by rapid passing of phenols throughout filter paper that take part in digestible fraction. It seems that in vitro digestibility trial overestimate OM digestibility of tanniferous forages and cannot be used efficaciously and precisely for estimation of ME in high tannin forages.

Key Words: sainfoin, tannin, ME

M115 Ruminal degradability of nutrients in Sainfoin, a tanniferous legume forage. H. Khalilvandi-Behroozyar*[1,2], K. Reza Yazdi[1], and M. Dehghan-Banadaki[1], [1]*Department of animal Science, University of Tehran*, *Karaj, Tehran, I. R. Iran*, [2]*Department of animal Science, University of Urmia*, *Urmia, West Azerbaijan, I.R. Iran*.

Sainfoin (*Onobrychis viciifolia* Scop.), a nonbloating member of the Fabaceae family. Information regarding nutritive value of sainfoin is scarce, that limit its use in balanced rations. This experiment was done using second cut, mid bloom forage samples taken from farms in Isfahan, Iran for determining degradability of sainfoin nutrients. Representative samples obtained from at least 30 bales. An In situ experiment designed for evaluating sainfoin hay for DM, OM, CP, NDF and NDF_{OM} degradability, by 3 ruminally fistulated Holstein cows (multiparous, 680 ± 20kg of BW), fed 2 equal meals (0800 and 1800) of a balanced ration with CNCPS V5 for 10% above maintenance requirements with forage:concentrate ratio of 60:40.Samples were ground to pass 2 mm screen size (Wiley mill) and then sieved to remove particles less than 50µ. Five gram samples were weighed into nylon bags (10 × 20 cm) with 50µ pore size, to create sample size: surface area of 12.5 mg/cm^2. Duplicate samples were incubated for 4, 8, 12, 24, 48, 72 and 96h in ventral rumen, just before morning meal. After incubation, bags were removed and rinsed with cold tap water, until the rinsed water remained clear. To obtain the 0 h values triplicates were rinsed by 39°C water for 20 min. bags were dried at 60°C for 48 h in a forced air oven and then weighed. Aliquots were used for ash, CP, NDF and NDFom determination. Degradation profiles were calculated by the nonlinear model. The effective degradability (ED) in the rumen with digesta passage rate of 0.05 h^{-1} was calculated using NEWAY computer package. Total tannin and Condensed tannin contents were 38.5 and 21.3 g/kg DM. Low CP degradability can be explained by formation of tannin-protein complexes that are not available for microbial degradation. Tannins extracted from sainfoin can inhibit proteolysis by rumen major proteolitic bacteria. Lower cell wall degradability can be explained by formation of unbearable tannin complexes with plant cell wall that can recovered as ADL (during digestion) and preventing microbial attachment, condensed tannins can prevent microbial cellulase activity and deactivation of β endoglucanases.

Table 1. In situ degradation parameters of sainfoin (g/g)

	a	b	c(h^{-1})	ED
DM	0.334±0	0.363±0.01	0.07±0.02	0.540±0.02
OM	0.316±0	0.387±0.01	0.09±0.02	0.548±0.02
CP	0.171±0	0.459±0.05	0.04±0.01	0.379±0.02
NDF	0.014±0	0.518±0.01	0.05±0.01	0.271±0.03
NDF_{OM}	0.042±0	0.505±0.02	0.05±0.01	0.265±0.02

Key Words: sainfoin, tannin, degradability

M116 A survey of molds and yeasts in Canadian corn silage. H. V. L. N. Swamy*, A. M. A. Heeg, and A. B. Rae, *Alltech Canada*, *Guelph, ON, Canada*.

Penicillium mycotoxins from silage have been implicated in various disorders in ruminant animals, especially dairy cows. Commercial facilities to analyze silage *Penicillium* mycotoxins, except PR toxin, are currently not available in North America. Mold count and identification in silage have been used to indirectly assess the potential toxicity of *Penicillium* mycotoxins. Such information, however, is not available for Canadian silage. A survey, therefore, was conducted in the summer of 2008 wherein 34 corn silage bunks in Ontario were sampled for mold and yeast counts. Samples with mold count exceeding 1000 col/gm were further subjected to mold identification. All the samples were analyzed at Dairyland Laboratories, Inc., WI, USA. The samples were frozen immediately after collection and were shifted to USA in dry ice. The average mold count was 65,000 col/gm and the average yeast count was 3.2 million col/g. Twenty 4 samples were above 1000 col/gm and they were subsequently subjected to mold identification. *Penicillium* mold represented 50% of mold spectrum while *Mucor* and *Fusarium* were at 15 and 14%, respectively. *Penicillium* mold was the dominant species among all in contrast to the conventional thinking. Given the temperate climate in Canada, *Fusarium* molds were thought to be the primary molds in Canadian feedstuffs. This survey for the first time indicated that Canadian silages should be tested for *Penicillium* molds and/or mycotoxins along with *Fusarium* mycotoxins to assess the total animal toxicity.

Key Words: silage, *Penicillium*, mycotoxins

M117 A survey of mold count and identification in Pennsylvanian dairy feed ingredients. H. V. L. N. Swamy*[1], J. M. Lawrence[2], and N. J. Adams[2], [1]*Alltech Canada*, *Guelph, ON, Canada*, [2]*Alltech California*, *Fresno, CA*.

Penicillium mycotoxins from silage have been implicated in various disorders in ruminant animals, especially dairy cows. Commercial facilities to analyze silage *Penicillium* mycotoxins, except PR toxin, are currently not available in North America. Mold count and identification in feed ingredients have been used to indirectly assess the potential toxicity of *Penicillium* mycotoxins. Such information, however, is not published specific to Pennsylvania region in USA. A survey, therefore, was conducted in 2009 wherein 278 feed ingredients, collected from commercial dairy farms in PA, were sampled for mold and yeast counts. Samples with mold count exceeding 1000 col/gm were further subjected to mold identification. The major ingredients tested included corn silage (n = 107), haylage (n = 45), high moisture corn (n = 40), TMR (n = 30) and hay (n = 8). All the samples were analyzed at Dairyland Laboratories, Inc., WI, USA. The samples were frozen immediately after collection and were shifted to lab in dry ice. The samples with mold count more

than 1000 col/gm were considered positive and this was amounted to 74.5%. Among these 39.6, 40.6, 11.1, and 8.7% samples had mold counts between 1001 and 10,000, 10,001 and 100,000, 100,001 and 1 million, and more than 1 million col/gm, respectively. Mold count more than 10,000 col/gm has potential to cause production losses and this was amounted to 60.4% of positive samples. Mold identification revealed that *Penicillium* mold represented 62.3% of mold spectrum while *Mucor*, *Aspergillus*, *Fusarium* and *Cladosporium* were at 46.4, 7.7, 7.7 and 6.3%, respectively. It is important to note that mold identification percentages need not have to add up to 100% as some samples can be contaminated with more than one mold type. *Penicillium* mold was the dominant species among all in contrast to the conventional thinking. Given the temperate climate in Pennsylvania, *Fusarium* molds were thought to be the primary molds in dairy feedstuffs. This survey indicated that silages should be tested for *Penicillium* molds and/or mycotoxins along with *Fusarium* mycotoxins to assess the total animal toxicity.

Key Words: silage, *Penicillium*, mycotoxins

M118 Summer annuals for fall grazing in the high elevation Intermountain West. J. B. Hall*, B. R. Johnson, R. H. Stokes, and R. Ambrosek, *University of Idaho*, *Moscow*.

The objective of this study was to compare summer annuals for fall and winter grazing on irrigated pastures in the Intermountain West. The cool desert areas of this region have short growing seasons (≤120 d) with high daytime temperatures and cool nights resulting in sufficent growing degree days, but impaired production on cool season forages during late summer. Five species were planted in Carmen, ID (45°17′N, 113°53′W; 1155 m elevation) in 0.10 ha plots with 3 plot replicates per species. Four species were planted in yr 1 and 2: CORN (*Zea mays*), sorghum x sudangrass (*Sorghum* spp; SUDEX), TEFF (*Eragrostis tef*), and GERMAN foxtail (*Setaria italica*). PEARL millet (*Pennisetum glaucum*) planted in yr 1 was replaced by PROSO millet (*Panicum miliaceum*) in yr 2. All species except TEFF were planted no-till from June 25 to July 2. TEFF was planted after minimum tillage. Three 1/1000 ha yield samples were taken from each plot. Pooled samples for each species were analyzed for CP, ADF, NDF, Ca and P. TEFF was sampled at 50 d post planting (haying) with all species sampled after killing frost (September 8 and 16, yr 1 and 2, respectively). Heifers grazed the plots during November and December, and animal grazing days were recorded. Yield data were analyzed by ANOVA with means compared using a *t*-test. Data for each yr were analyzed separately. Species affected DM yield ($P = 0.10$ yr 1; $P < 0.02$ yr 2). Yields (DM; Mg ha^{-1}) were not different ($P = 0.22$) for CORN (5.5 ± 1.6, 10.7 ± 1.0), GERMAN (5.4 ± 0.4, 5.8 ± 1.0), and SUDEX (7.0 ± 0.7, 7.1 ± 1.8) in yr 1 and 2, respectively, and TEFF (6.1 ± 0.2; yr 1 only). In yr 1, yields of SUDEX and TEFF exceeded ($P < 0.01$) PEARL (3.9 ± 1.2 Mg ha^{-1}). CORN yields were greater ($P < 0.01$) than GERMAN or PROSO (3.9 ± 1.6 Mg ha^{-1}) in yr 2. Nutrient content of all forages exceeded NRC requirements for cows in mid-gestation. TEFF, PROSO, and PEARL produced fewer ($P = 0.10$) animal grazing days than the other species. In conclusion, CORN, SUDEX, and GERMAN produce acceptable fall and winter grazing for the Intermountain West.

Key Words: cattle, grazing, fall

M119 Biological parameters by spring and fall-calving cows grazing with full access, limited access, or no access to endophyte-infected tall fescue–2 year summary. J. Caldwell*[1], K. Coffey[1], M. Looper[2], D. Kreider[1], E. Kegley[1], J. Jennings[3], C. West[1], D. Hubbell III[1], J. Tucker[1], A. Young[1], T. Hess[1], M. Popp[1], M. Savin[1], D. Philipp[1], C. Rosenkrans Jr.[1], [1]*University of Arkansas*, *Fayetteville,* [2]*USDA-ARS*, *Booneville, AR,* [3]*University of Arkansas Cooperative Extension Service*, *Little Rock*.

Cattle consuming *Neotyphodium coenophialum*-infected tall fescue (E+) may have altered physiological responses. Replacing E+ with non-toxic endophyte-infected fescue (NE+) may help this problem, but acceptance of NE+ by producers has been slow. Our objective was to determine the extent limited access to NE+ will alter biological parameters by spring (S) and fall-calving (F) cows grazing E+ or NE+ at different percentages of the total pasture area. Crossbred cows (n = 178) were stratified by BW and age within calving season and allocated randomly within calving season to 1 of 14 groups representing 5 treatments: 1) F on 100% E+ (F100; n = 3); 2) S on 100% E+ (S100; n = 3); 3) F on 75% E+ and 25% NE+ (F75; n = 3); 4) S on 75% E+ and 25% NE+ (S75; n = 3); and 5) S on 100% NE+ (NE100; n = 2). Cow serum K, Cu, NEFA, and prolactin (PRL) concentrations at breeding, and serum Na and PRL concentrations at the end of breeding were greater ($P < 0.05$) for S vs. F. Serum Ca, Mg, and Fe concentrations at breeding and serum Fe, Zn, Cu, and NEFA concentrations at the end of breeding were greater ($P < 0.05$) for F vs. S. Serum P and PRL concentrations at breeding were greater ($P < 0.05$) for S75 and F75 vs. S100 and F100; serum NEFA concentrations at the end of breeding were greater ($P < 0.05$) for S100 and F100 vs. S75 and F75. At breeding, serum NEFA concentrations were lower ($P < 0.05$) for NE100 vs. S75, and serum PRL concentrations at the end of breeding were greater ($P < 0.05$) for NE100 vs. S75. Calf serum Zn concentrations at weaning were greater ($P < 0.05$) for F vs. S, but serum Fe and Cu concentrations at weaning were greater ($P < 0.05$) for S vs. F. Serum Fe concentrations at weaning were also greater ($P < 0.05$) for S75 and F75 vs. S100 and F100. Therefore, calving season may alter biological parameters for cows grazing E+ during critical stages of production. Limited access to NE+ may improve cow PRL concentrations at breeding, and may affect calf serum Zn concentrations at weaning.

Key Words: cow, fescue

M120 Immune function responses by spring and fall-born calves weaned from wild-type or non-toxic endophyte-infected tall fescue. M. A. Ata*[1], K. P. Coffey[1], J. D. Caldwell[1], E. B. Kegley[1], M. L. Looper[2], A. N. Young[1], D. Philipp[1], C. P. West[1], G. F. Erf[1], D. S. Hubbell III[1], and C. F. Rosenkrans Jr.[1], [1]*University of Arkansas*, *Fayetteville,* [2]*USDA-ARS*, *Booneville, AR*.

Cattle grazing *Neotyphodium coenophialum* infected tall fescue (E+) may have reduced immune function. Recently, non-toxic endophyte-infected fescues (NE+) were shown to enhance cattle performance. A 3-years study (2007–2009) was conducted using Gelbvieh x Angus calves (558 ± 9.2 lb, n = 500) to determine how limited access to NE+ affects immune function in calves weaned from E+ pastures. Prior to weaning, groups of spring (S) and fall-born calves (F) grazed E+ continuously (S100 and F100, respectively), or E+ for much of the year, but grazed NE+ for 1 mo. before weaning (S75 and F75, respectively). Groups of spring-born calves also grazed NE+ continuously (NE100). Blood samples were collected at weaning for all 3 years and analyzed for whole blood cell counts (K/µl). Starting in 2008, calves (1 fall and 2 spring groups, n = 266) were injected at weaning with 200 µ g of phyto-hemagglutinin (PHA) in the caudal fold underneath the tail head. Blood samples were collected for serum prolactin (PRL) analysis. Skinfold thickness was measured before injection (0 h) and at 6, 12, 24, 48 h after injection. Statistical analyses performed by using PROC MIXED procedure of SAS. Concentrations of neutrophils, hemoglobin, and hematocrit were greater ($P < 0.05$), while concentrations of eosinophils and basophils were lower ($P < 0.05$) for F vs. S. lymphocytes Concentrations were greater ($P < 0.05$), and that of red blood cells were lower ($P < 0.05$) for NE100 vs. S75. Concentrations of total white blood cells and neutrophils were greater ($P < 0.05$) for S75 and F75 vs.S100 and F100. Within spring-born calves, skinfold thickness was greater ($P < 0.05$) for NE100 vs. S75 at 0h, and 6, 12, and 24 h after injection with PHA. Serum PRL concentrations were greater ($P < 0.05$) for S75 vs. S100 at 24 h post-weaning. Within fall-born calves, serum PRL concentrations were greater ($P < 0.05$) for F75 vs. F100 at weaning. Therefore, allow-

ing calves limited access to NE+ before weaning may enhance certain aspects of immune function.

Key Words: fescue, immunity, calves

M121 Antagonism of 5-hydroxytryptamine$_{2A}$ receptor results in decreased contractile response of bovine lateral saphenous vein to tall fescue alkaloids. J. L. Klotz*[1], J. R. Strickland[1], L. P. Bush[2], B. H. Kirch[1], K. R. Brown[1], and G. E. Aiken[1], [1]*USDA-ARS, FAPRU, Lexington, KY*, [2]*University of Kentucky*, *Lexington*.

Pharmacologic profiling of 5-hydroxytryptamine (5HT) receptors of bovine lateral saphenous vein has shown that cattle grazing endophyte-infected (*Neotyphodium coenophialum*) tall fescue (*Lolium arundinaceum*) have altered responses to ergovaline (ERV), 5HT, $5HT_{2A}$ and $5HT_7$ agonists. To determine if 5HT receptor binding of tall fescue alkaloids is affected by grazing endophyte-free (EF), wild type (WT), or novel endophyte-infected (NE) tall fescue, contractile responses of lateral saphenous veins biopsied from cattle grazing these different fescue-endophyte combinations were evaluated in presence or absence of antagonists for $5HT_{2A}$ (ketanserin; KET) or $5HT_7$ (SB-269970; SB). Biopsies were conducted over 2 years on 35 mixed breed steers (361.5 ± 6.3 kg) grazing KY31 (WT; n = 12), EF (n = 12), MAXQ (NE AR542; n = 6) or KYFA9301 (NE AR584; n = 5) pasture treatments (3 ha) between 84 and 98 d (Yr 1) or 108–124 d (Yr 2). Segments (2–3 cm) of vein were surgically biopsied, sliced into 2–3 mm cross-sections, and suspended in a myograph chamber containing 5 mL of oxygenated Krebs-Henseleit buffer (95% O_2/5% CO_2; pH = 7.4; 37°C). Veins were exposed to increasing concentrations of 5HT, ERV, and ERV+1 × 10^{-5} M KET, or +1 × 10^{-6} M SB in Yr 1. In Yr 2, ergotamine (ERT) and ergocornine (ERO) were evaluated in presence or absence of 10^{-5} M KET. Data were normalized to a reference addition of 1x10^{-4} M norepinephrine and analyzed as a CRD factorial with steer as experimental unit. In Yr 1, contractile response to 5HT and ERV were lowest in WT KY31 pastures ($P < 0.05$) and the presence of KET greatly reduced the response to ERV in all pastures ($P < 0.05$). The presence of SB did not alter contractile response to ERV. In Yr 2, there was no difference in response to ERO or ERT across pastures, but KET again reduced the contractile response ($P < 0.05$). The $5HT_{2A}$ receptor is involved in alkaloid-induced vascular contraction and alkaloid binding may be affected by exposure to different endophyte-fescue combinations.

Key Words: alkaloid, bovine, 5-hydroxytryptamine

M122 Tall fescue alkaloids cause vasoconstriction in equine medial palmar artery and vein. J. L. Klotz*[1] and K. J. McDowell[2], [1]*USDA-ARS, FAPRU*, *Lexington, KY*, [2]*University of Kentucky*, *Lexington*.

Mares grazing endophyte-infected (*Neotyphodium coenophialum*) tall fescue (*Lolium arundinaceum*) typically exhibit reproductive dysfunction rather than peripheral vasoconstriction as a primary sign of the fescue toxicosis syndrome. Recent work using Doppler ultrasonography demonstrated that consumption of endophyte-infected tall fescue seed causes measurable vasoconstriction in the medial palmar artery (PA). The objective of this study was to evaluate contractile responses of medial palmar artery and vein (PV) to increasing concentrations of tall fescue alkaloids. Medial PA and PV were collected immediately following euthanasia from 18 horses of mixed breed, age and gender along the third metacarpal proximal to the fetlock joint from both forelimbs. Vessels were separated, cleaned of excess connective and adipose tissue, divided into 2–3 mm cross-sections and suspended in a multimyograph chamber with continuously oxygenated Krebs-Henseleit buffer (95%O_2/5%CO_2; pH = 7.4; 37°C). Following a 90-min equilibration and recovery from a 1x10^{-4} M NE reference addition, additions of ergotamine (ERT), ergonovine (ERN), ergocryptine (ERP), ergocristine (ERS), ergocornine (ERO), lysergic acid (LSA), norepinephrine (NE) and 5-hydroxytryptamine (5HT) occurred every 15 or 20 min for PV and PA, respectively. Data were normalized as a % contractile response induced by the 10^{-4} M NE addition and analyzed as a completely randomized design with significance set at $P = 0.05$. Response between PA and PV for alkaloid or biogenic amine did not differ. All alkaloids produced a contractile response, except neither PA nor PV responded to LSA. Both NE and 5HT had a 2-fold greater ($P < 0.05$) maximal response than all alkaloids in both PA and PV, ERN had the greatest PV response ($P < 0.05$), and ERN and ERO had greatest PA maximal responses ($P < 0.05$). Although horses do not outwardly appear to be affected by peripheral vasoconstriction as observed in cattle, these data indicate that tall fescue alkaloids are vasoactive and suggest that potential exists for peripheral vascular effects of tall fescue alkaloids in horses.

Key Words: alkaloids, equine, vasoconstriction

M123 Comparison of management strategies commonly used to lessen or alleviate the symptoms of fescue toxicosis in cattle using meta-analysis. J. Hawley*, J. D. Caldwell, E. B. Kegley, and K. P. Coffey, *University of Arkansas*, *Fayetteville*.

Cattle consuming toxic endophyte-infected fescue (E+) may develop fescue toxicosis, causing production losses exceeding $600 million annually. Currently, there is no cure for fescue toxicosis; however, management strategies that are primarily designed to limit the amount of toxin ingested by the animal are available to producers. This review of data compared cattle performance effects (ADG and DMI) of management strategies used to lessen or alleviate the symptoms of fescue toxicosis. Management strategies evaluated were novel endophytes (NE), diet supplementation, interseeding, and other inventive remedies. For inclusion in the analysis, studies (n = 38) were conducted in the United States from 1985 to present, reported randomization to treatment and untreated control groups, used cattle, were sourced from peer-reviewed journals, and reported sufficient information to calculate correlation coefficients (r). Dot plots were used to examine the data for trends toward a uniform effect of management strategy on cattle performance. Management strategies displaying a uniform response on the dot plot compared with negative controls were analyzed using mixed models. Examination of dot plots for NE, diet supplementation, and other inventive remedies revealed performance advantages for treated cattle relative to cattle in negative control groups. An insufficient number of studies met the inclusion criteria to conduct meta-analyses comparing interseeding with negative controls. Studies comparing NE to E+ indicated a large (r and 95% confidence interval [CI] = 0.63 [0.52, 0.75], $P < 0.05$) effect on cattle performance. Studies comparing diet supplementation to no diet supplementation indicated a medium (r and 95% CI = 0.35 [0.24, 0.46], $P < 0.05$) effect on cattle performance. Similarly, studies comparing other inventive remedies to no other inventive remedies indicated a medium (r and 95% CI = 0.35 [0.24, 0.46], $P < 0.05$) effect on cattle performance. The data discussed herein illustrate that the negative effects of fescue toxicosis on cattle performance may be mitigated by altering management strategies.

Key Words: cattle, fescue toxicosis, meta-analysis

M124 Yield potential of eastern gamagrass in central Wisconsin. W. K. Coblentz*[1], W. E. Jokela[1], M. G. Bertram[2], and P. C. Hoffman[2], [1]*US Dairy Forage Research Center*, *Marshfield, WI*, [2]*University of Wisconsin*, *Madison*.

Recently, perennial warm-season grasses have received considerable interest, largely through bioenergy initiatives, but their suitability for limiting caloric intake by ruminants has not been explored. Our objective was to assess the yield potential of eastern gamagrass [*Tripsacum dactyloides* (L.) L.] for potential incorporation into dairy-heifer diets offered throughout the north-central US. Replicated plots of 'Pete' eastern gamagrass were arranged in a split-plot design, where 9 harvest systems (wholeplots) and 4 N fertilization regimens (subplots) were evaluated over a 3-yr period. Harvest systems included one-time cuts on 1 June, 15 June, 1 July, 15 July, 1 August, and 15 August, plus 3 2-cut systems with harvests spaced at 45-d intervals (1 June/15 July, 15 June/1 August, and 1 July/15 August). Nitrogen fertilization was applied as ammonium nitrate (34–0-0) at rates of 0, 67, 134, or 202 kg N/ha annually. For 1-cut harvest systems, yields of DM increased across harvest dates, reaching numerical maximums of 7192, 9764, and 7554 kg/ha by mid-August of 2007, 2008, and 2009, respectively. During each year, there was a strong linear ($P < 0.001$) effect of harvest date; however, higher-ordered effects varied within year. Relatively large yield increases (≥1812 kg/ha) between 1 and 15 August during 2008 and 2009 suggested that improved yields could be achieved by delaying 1-cut harvests beyond 15 August. Yields of DM from 2-cut harvest systems were not competitive with 1-cut harvest systems timed in mid-August. Nitrogen fertilization rate affected ($P < 0.001$) yields of DM, but did not interact with other treatment effects ($P \geq 0.082$). Overall, yields of DM increased with N fertilization, exhibiting both linear ($P < 0.001$) and quadratic ($P = 0.027$) effects, but efficiencies were reduced at greater application rates. Current recommendations for eastern gamagrass generally adopt a conservative philosophy concerning growth-reserve status; therefore, delaying a 1-cut harvest closer to first-frost may improve yields, but also could negatively affect persistence. This approach for further increasing yields of DM might be viable, but it needs to be evaluated critically.

Key Words: eastern gamagrass, N fertilization, DM yield

M125 Nutritive value of pearl millet hay as affected by moisture concentration and bale sampling depth. J. Kanani*, D. Philipp, K. P. Coffey, A. N. Young, R. Rhein, and J. D. Caldwell, *University of Arkansas*, *Fayetteville*.

A study was conducted to evaluate the effects of moisture (15, 21, and 28% DM) and sampling depth (0.2, 0.4, and 0.6 m) on chemical composition and in situ disappearance of pearl millet [*Pennisetum glaucum* (L.) R. Br.] hay stored for 71 d. Seven ha of pearl millet were divided into 3 blocks and 3 subplots to assign moisture treatments of which 3 round bales (1.2 × 1.5 m) were obtained and stored (n = 27). Heating degree days (HDD) were calculated as summation of the daily internal bale temperature above 35°C. Duplicate sample bags for in situ (10 × 20 cm) analysis were incubated in 6 ruminally cannulated cows (BW = 585 ± 37.8 kg) for 0, 6, 12, 18, 24, 36, 48, 72, 96, and 120 h. Data for bale temperature and forage chemical composition were analyzed as a randomized complete block design using Proc Mixed procedures of SAS and tested for moisture, depth, and their interactions. Residual DM weight for each in situ sampling time was fit to a non-linear statistical model using PROC NLIN of SAS to determine DM degradation kinetics. Increasing bale moisture led to increased bale temperature (140.4, 365.3, and 840.8 HDD; $P < 0.01$). Crude protein concentration was not affected ($P > 0.1$) by moisture or sampling depth, but increasing moisture tended ($P = 0.07$) to affect NDF, OM, and ADF negatively. Increasing moisture increased ($P < 0.05$) NDIN (40.8, 47.5, and 49.8% of total N), ADIN (7.0, 9.5, 22.8% of total N), and ADL (3.0, 2.9, and 6.0% DM); however, hemicellulose decreased ($P < 0.05$) with increasing moisture (31, 31, and 25% DM). Increasing bale moisture also reduced the rate of DM disappearance (K_d; 0.047, 0.043, 0.036 h^{-1}; $P = 0.03$). Sampling depth did not affect ($P > 0.1$) any of the digestion variables, but the immediately degradable fraction (A), potentially degradable fraction (B), and effective disappearance were affected ($P < 0.05$) by a moisture × sampling depth interaction. Storing pearl millet at high moisture concentrations appeared to result in heat damage and reduced forage quality and digestibility.

Key Words: pearl millet, moisture and sampling depth, nutritive value

M126 Characterization of plant cuticular wax markers in native grazing pastures of southwest Virginia. A. E. Tanner*[1], S. R. Blevins[1], E. Green[2], R. W. Mayes[2], and R. M. Lewis[1], [1]*Virginia Tech*, *Blacksburg,* [2]*The Macaulay Land Use Research Institute*, *Aberdeen, Scotland, UK*.

Plants contain cuticular wax compounds in varied concentrations, and can be used to estimate intake and diet composition of grazing animals. Native plant species available to pasture-raised beef cattle were evaluated during the production season on a southwest Virginia farm. Our objectives were to: i) determine forage heterogeneity; ii) quantify *n*-alkane and long chain alcohol (LCOH) concentrations; and iii) investigate changes over time. Six 0.73 ha paddocks were selected randomly and sampled bi-monthly (April to September 2009). A 0.5m x 0.5m quadrat was thrown in random directions within each paddock. Plants within quadrats were harvested and separated according to species. Milled oven-dried (85°C) samples were heated with ethanolic KOH (90°C, 16h), extracted into heptane and separated into *n*-alkane and LCOH fractions before being quantified by GC. Patterns of *n*-alkane and LCOH concentrations were analyzed for 3 plant categories: grass, legume, and weed, with ANOVA. Plant species, carbon chain length, their interaction, and sampling period were fitted as fixed effects. Plant *n*-alkane C29 and C31 concentrations were higher in May (294 ± 8 mg/kg DM; $P < 0.001$) then declined to 1/3 that amount. Plants differed in C27, C29, C31 and C33 concentration ($P < 0.001$), although orchardgrass and dandelion were difficult to differentiate. *N*-alkane patterns were not specific to a plant category. Orchardgrass had extremely high concentrations of 1-C26-OH from July onward (18447 to 19670 mg/kg DM), 10 times that of other plants, inflating variance. There was no change in LCOH over time ($P = 0.09$) for other species. Plants differed in 1-C26-OH, 1-C28-OH, and 1-C30-OH concentrations ($P < 0.001$), but LCOH patterns were not specific to a plant category. Plant total LCOH concentration was more consistent than *n*-alkane concentration (CV 17.9% and 69.9%, respectively), suggesting greater utility to delineate plant species. Plant heterogeneity limits the usefulness of grouping plants by category. Combined *n*-alkane and LCOH data delineates plants. Plant patterns remain fairly static over time, which will be important for investigating foraging patterns in cattle.

Key Words: cuticular wax, *n*-alkane, LCOH

M127 Statistical variation in predicting dry matter intake of Brahman bulls using the n-alkane technique. A. D. Aguiar*[1,4], L. O. Tedeschi[1], F. M. Rouquette[2], T. D. A. Forbes[3], C. M. Hensarling[3], and R. D. Randel[2], [1]*Texas A&M University*, *College Station,* [2]*Texas AgriLife Research*, *Overton,* [3]*Texas AgriLife Research*, *Uvalde,* [4]*University of Florida*, *Gainesville*.

The objectives of this study were to determine the variation structure within and across days when determining DMI using C_{32} alkane as an external marker, to determine the optimum fecal collection periods, and to compare C_{31} and C_{33} as plant markers in estimating DMI. Brahman bulls (n = 16) stratified by previous residual feed intake (RFI) rankings were placed in 4 groups. Each group had 2 high (inefficient) and 2 low (efficient) RFI bulls. Groups were randomly assigned to 4 Coastal bermudagrass [*Cynodon dactylon* (L.) Pers.] pastures and stocked at moderate to low grazing pressure. Corn gluten was marked with C_{32} n-alkane and bulls were individually fed 400 g twice daily to estimate DMI. There were 3 periods (P1, P2, P3) of collection from mid-July to late-Aug; each period was divided into 2 sub-periods in which fecal samples were collected 4 times a day for 5 d (0700, 1100, 1500, and 1900 h). Gas chromatography was used to determine n-alkanes. A double repeated measure design in a completely randomized block design was used. During P1 and P2, the prediction of DMI using C_{33} had a better fit (smaller $-2 \times$ Log) than C_{31} either with or without adjustments for forage C_{32}. The variation in DMI decreased when adjustments for forage C_{32} were not used. The variances of DMI were similar using C_{31} across days, but the correlations between days were low, suggesting that several days of collection were needed to accurately predict DMI. Correlations between times of fecal collection were medium to high for all periods and varied from 0.65 to 0.97 for C_{31} and from 0.26 to 0.96 for C_{33}. When all periods were analyzed together, estimates of DMI using either C_{31} or C_{33} had low correlations between days of collection. In addition, the adjustment for forage C_{32} did not improve the variance and (co)variance matrix. In conclusion, C_{33}/C_{32} had the lowest variation in predicting DMI and at least 5 d of continuous fecal collection were needed to decrease the variability of DMI. The optimum times for fecal collection were 0700 and 1500 h and it was important to adjust for forage C_{32} concentration to predict DMI of Brahman bulls grazing Coastal bermudagrass.

Key Words: cattle, correlation, grazing

M128 A comparison of anatomical and compositional differences of residual feed intake (RFI)-indexed Brahman bulls under grazing conditions. T. D. A. Forbes*[1], F. M. Rouquette[2], L. O. Tedeschi[3], R. D. Randel[2], and F. R. B. Ribeiro[4], [1]*Texas AgriLife Research*, *Uvalde,* [2]*Texas AgriLife Research*, *Overton,* [3]*Texas A&M University*, *College Station,* [4]*Texas A&M University-Commerce*, *Commerce*.

This study compared gastrointestinal tract (GIT) measures, carcass composition, and ADG of Brahman bulls grazing Coastal bermudagrass at 2 stocking rates (SR) for 60 d. Prior to the grazing trial, bulls were fed a high roughage diet for 70 d, stratified as efficient (LRFI) or inefficient (HRFI), and randomly assigned to high (HSR) or low (LSR) SR pastures. Shrunk BW (SBW) was recorded after animals fasted for 18 h before harvest. Carcass was weighed; KPH and internal organs were separated; the GIT was dissected and emptied; small and large intestine lengths were recorded, and internal fat (excluding KPH) was separated from the GIT; all components were then weighed. After a 48 h chill, the 9–11th rib section (RIB) was removed from the left carcass. Lean, fat, and bone were physically separated. Fat and lean tissues were analyzed for moisture and fat. Independent variables were expressed as amount and percent of SBW. Data were analyzed using a split-plot design in a 2×2 factorial arrangement with pastures within SR as random factors. There was no effect of RFI ($P = 0.74$) or SR ($P = 0.74$) on initial BW. Low RFI bulls had heavier SBW ($P = 0.04$) and HCW ($P = 0.01$) (393 and 217 kg, respectively) than HRFI bulls (381 and 203 kg, respectively). There was no effect of RFI ($P = 0.09$) on ADG (0.66 and 0.50 kg/d for LRFI and HRFI, respectively). There was a tendency ($P = 0.08$) for an interaction between RFI and SR for fat thickness (FT). Low RFI bulls at LSR had less FT compared with LRFI bulls at HSR (1.7 vs 2.94 mm). There was an interaction between RFI and SR ($P = 0.02$) on the lipid content of the RIB which was greater (17.9%) in LRFI bulls at HSR. Low SR bulls had greater ($P = 0.03$) liver % BW than HSR bulls while HRFI tended to have greater ($P = 0.07$) liver % BW than LRFI bulls. Low RFI bulls had lighter ($P = 0.02$) small intestine % BW and more ($P = 0.06$) internal fat % BW than HRFI bulls. These initial results suggest that efficient bulls tend to gain more and may deposit more fat when forage availability does not limit DMI, but when forage is limited there may be no influence of RFI on carcass composition.

Key Words: cattle, efficiency, carcass

M129 *Cenchrus ciliaris* in a silvopastoral system with *Prosopis juliflora*. T. Clavero* and R. Razz, *Centro de Transferencia de Tecnologia en Pastos y Forrajes. Universidad del Zulia.*, *Maracaibo, Estado Zulia, Venezuela*.

Buffelgrass (*Cenchrus ciliaris*) planted under and outside the canopies of mesquite (*Prosopis juliflora*) in Venezuela's semi- arid region were evaluated to determine dry matter production, forage quality, and soil chemical characteristics. Harvested buffelgrass was analyzed for dry matter yield (DM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), and lignin. Transects extending from the tree trunk to open grass areas were established and soil samples (0–15 cm) and buffelgrass cv. Biloela (standing live biomass in one square meters plots) samples were taken at 5 sites (0, 20, 80, 150, 200% of the average canopy radius) during growing season. A randomized block design was used with 5 replications. The results showed that DM decreased as shading increased ($P \leq 0.05$). The DM production was about 21% lower in the understory areas. The shaded plants exhibited a trend for larger, thinner, wider leaves and developed larger leaf area ($P \leq 0.05$). Tree canopies had a positive effect on CP content on buffelgrass ($P \leq 0.05$). Overall, soil moisture content was greater ($P \leq 0.05$) under mesquite, and leaf blade increased, which is highly correlated to CP (r = 0.87) . Grass samples showed no significant differences ($P \geq 0.05$) in NDF, ADF, and lignin under mesquite compare with open pasture. Greater levels of soil C, N, P, Ca, Mg and K were found under the canopies of mesquite ($P \leq 0.05$), with differences of 0.64% C, 0.46% N, 2.40 ppm P, 2.10 ppm Ca, 1.27 mEq/100 g Mg and 0.57 mEq/100 g K. Soil analyses showed no significant differences ($P \geq 0.05$) in Na and Mn under mesquite compared with open grassland. Results suggest that mesquite has a lot of potential for use in a silvopastoral system with buffelgrass. Fodder availability of buffelgrass was lower under the trees; however, canopies had a positive effect on nutritional value and improved soil chemical conditions.

Key Words: *Prosopis juliflora*, *Cenchrus ciliaris*, silvopastoral

M130 Quantifying terpenes in rumen fluid, serum, and plasma from sheep. R. E. Estell*[1], S. A. Utsumi[2], and A. F. Cibils[3], [1]*USDA, ARS, Jornada Experimental Range*, *Las Cruces, NM,* [2]*Michigan State University, Kellogg Biological Station*, *Hickory Corners,* [3]*New Mexico State University*, *Las Cruces*.

Determining the fate of terpenes consumed by browsing ruminants require methods to quantify their presence in blood and rumen fluid. Our objective was to modify an existing procedure for plasma terpenes to quantify 25 structurally diverse mono- and sesquiterpenes in serum, plasma, and rumen fluid from sheep. The terpenes examined were tricyclene, α-pinene, camphene, sabinene, β-pinene, myrcene, 2-carene, 3-carene, α-terpinene, *p*-cymene, limonene, 1,8-cineole, *cis*-β-ocimene, γ-terpinene, *cis*-sabinene hydrate, terpinolene, linalool, camphor, borneol, terpin-4-ol, α-terpineol, longifolene, β-caryophyllene, α-humulene, and caryophyllene oxide. Terpenes were extracted with SPE columns and quantified using gas chromatography (n = 8 per terpene/fluid combination). Data were analyzed with the MIXED procedure of SAS with fluid as the independent factor, and means were separated by LSD in the event of a significant *F* test (α = 0.05). Recovery estimates were 100 ± 5% for 14, 7, and 4 terpenes from serum, plasma, and rumen fluid, respectively. Recovery from plasma and serum differed for 12 terpenes ($P < 0.05$), although typically differences were <10%. Recovery from rumen fluid differed ($P < 0.05$) from both serum and plasma for 16 compounds (lower in each case except linalool). Recovery did not differ ($P > 0.05$) among the 3 matrices for only 2 compounds (*p*-cymene and terpinolene). Greater recovery was generally observed for oxygenated terpenes than hydrocarbon compounds, particularly for monoterpenes. This procedure is applicable to a wide array of terpenes in fluids from sheep, but differential recoveries among terpenes and fluids require that estimated concentrations of each analyte be corrected for recovery using that specific compound in the same matrix collected under the same set of experimental conditions, and that caution be exercised in generalizing responses among different compounds with this procedure.

Key Words: terpene, serum, rumen fluid

M131 The effect of supplementing corn by-products or mesquite twigs on daily gain of Creole x Zebu young steers: A simulation model. J. M. Tapia-González*[1], A. Tewolde-Medhin[2], W. E. Grant[3], J. C. Martinez-González[2], H. Diaz-Solís[4], A. Moreno-Valdéz[5], O. D. Montañez-Valdez[1], J. A. Martínez-Ibarra[1], and G. Rocha-Chavez[1], [1]*CUSUR, U de G*, *Ciudad Guzman, Jalisco, Mexico*, [2]*Unidad Académica Multidisciplinaria Agronomía y Ciencias. UAT*, *Cd. Victoria, Tamaulipas, México*, [3]*Wildlife and Fisheries Sciences, Texas A&M University*, *College Station,* [4]*Área de Recursos Naturales, UAAAN*, *Saltillo Coahuila, México*, [5]*Área de Recursos Naturales, Instituto Tecnológico de Ciudad Victoria*, *Cd. Victoria, Tamaulipas, México*.

The Software STELLA II Version 5 was used for predicting a potential beef cattle daily gain scenario out of a conceptual mathematical model. Type of feed (hay or hay + supplement) was used to examine the effect on daily gain of Creole-Zebu steers. The model was created using real data coming out of several types of production systems totaling up to 30,000 cases. A total of 20 repetitions during 48 mo were represented in the model to predict daily gain of 8-weeks old steers up to 48 mo of age. The growing sector of steers was evaluated under the effect of supplementing several types of ingredients included in 4 experimental groups: (1) hay only, (2) hay + silage, (3) hay + nutritional blocks and (4) hay + mesquite twigs. Two types of corn were used for groups 2 and 3 (local creole maize or hybrid) and 2 types of crops were considered (raised either with or without cultural management practices). Blocks are made of chopped dry corn plant (including grain and straw), molasses and minerals pressed together to form a brick. Mesquite twigs include small branches and leaves of *Prosopis farcta* and *Celtis spinosa*. ANOVA was used to compare means and significance was set to $P < 0.05$. Higher gains were observed in steers supplemented with something more than hay because they had 14 to 21% of crude protein (CP) whereas hay had only 4.4 to 14% of CP with 30% digestibility. The highest gain was observed in group 4 probably because *Celtis spinosa* may have up to 21% CP and digestibility of 46% while nutritional blocks only have 14% CP and silage 14.6% of CP. There was no effect of corn type or rising method on total gain of steers (Table 1). Since all these parameters (coming exclusively out of the simulation model) are similar to those obtained in the field by several researches, we can conclude that simulation models are useful for predicting beef production scenarios.

Table 1. Total gain of 48-month steers with several types of feed regimen

Treatment	Cycles[1]	Total gain of steers (kg, mean ± SE)
Hay only	20	144.91 ± 16.92[c]
Hay + corn silage	20	182.30 ± 17.71[b]
Hay + corn blocks	20	179.29 ± 35.95[b]
Hay + mesquite twigs	20	224.80 ± 9.60[a]

[1]All values evaluated for each treatment representing a cycle of 48 months totalizing 80 years of evaluation.
[a–c]Different letters in the same column differs significantly ($P < 0.05$).

Key Words: mesquite, daily gain, steers

M132 Effects of dietary beta-glucan on the T helper cytokine balance in the intestine of broiler chicks. C. M. Cox*[1], L. H. Stuard[1], S. Kim[1], A. P. McElroy[1], M. Bedford[2], and R. A. Dalloul[1], [1]*Virginia Tech*, *Blacksburg*, [2]*AB Vista Feed Ingredients*, *Marlborough, UK*.

Immunomodulators like β-glucans have attracted considerable attention as potential alternatives to the prophylactic use of antibiotics. Despite increasing research, little is known about their regulatory influence on immune function in poultry. Two studies were conducted to evaluate the effects of a yeast-derived β-glucan (Auxoferm YGT) on gene expression of T helper cytokines in the intestine. Day old chicks were fed a diet containing 0, 0.02, or 0.1% β-glucan. For the first study, small intestinal sections were collected on d 7 and d 14 to evaluate gene expression by quantitative real-time PCR. On d 7, interleukin (IL)-18 expression was upregulated in the jejunum but decreased on d 14 in the duodenum of the 0.02% β-glucan birds. Expression of IL-18 also decreased on d14 in the ileum of both β-glucan groups when compared with control. On d 7, IL-4 expression was downregulated in both β-glucan treated groups in the duodenum and in the 0.1% treated group in the jejunum and ileum. In contrast, IL-4 was upregulated in the duodenum of treated birds and in the ileum of 0.1% fed birds on d 14. Similarly, IL-13 was downregulated in all intestinal sections of 0.1% β-glucan fed birds on d 7. The second study included a mixed *Eimeria* infection on d 8 and samples were collected on d 10, 14, and 21 post-hatch. Despite the fact that no significant differences were seen among treatment groups, IL-18 expression was consistently upregulated in the *Eimeria* challenged birds due to β-glucan exposure. IL-4 expression was downregulated in the non-challenged birds fed the 0.1% β-glucan diet. Mucin-1 expression was significantly decreased due to 0.1% β-glucan supplementation. On d 14, mucin-2 expression was decreased due to the *Eimeria* infection in the 0.1% β-glucan fed birds. Though not significant, there was a tendency for birds fed 0.1% β-glucan to express lower levels of IL-13 than the control birds. Taken together, the data provided from these trials strongly suggest that β-glucans downregulate T helper type 2 cytokines and thus favor a T helper type 1 cell response.

Key Words: β-glucan, poultry, cytokines

M133 Effect of capsicum and turmeric oleoresins with betaine on the performance of broilers challenged with coccidiosis. V. Brito[1], C. Moynat*[2], A. Casarin[3], M. Forat[3], and D. Bravo[1], [1]*Euronutec*, *Queretaro, Mexico*, [2]*Pancosma*, *Geneva, Switzerland*, [3]*Instituto Internacional de Investigacion Animal*, *Mexico*.

During coccidiosis, vaccination acquired immunity is insufficient to keep broiler performance. Studies showed that betaine (BE), capsicum (CA) and turmeric (TU) positively impact innate immunity. The combination of these 3 products should positively affect immunity and therefore improve performance of birds infected with coccidiosis. The objective was to evaluate the efficiency of a mixture of CA and TU oleoresins (PF = Proflora / XT 6986) combined with 2 levels of BE on performance of vaccinated broilers challenged with coccidiosis. Day-old broilers were allotted to 4 treatments and challenged with *Eimeria* spp. at d 14 (48 birds * 10 cages/treatment). The treatments were set as follow, doses in ppm, with bacitracin (BA), Nicarbazin (NI), salinomycin (SA), nitrofuran (NO). Starter Diet (d 1 to 14): T1 = 55 BA + 125 NI; T2 = 50 PF; T3 = 50 PF; T4 = 50 PF. Grower diet (d 15 to 42): T1 = 55 BA + 65 SA + 50 NO; T2 = 50 PF; T3 = 50 PF + 500 BE; T4 = 50 PF + 1000 BE. Finisher (d 43 to 52): T1 = 55 BA + 65 SA + 50 NO; T2 = 100 PF; T3 = 100 PF + 500 BE; T4 = 100 PF + 1000 BE. All birds except in T1 were vaccinated against coccidiosis at d 1. BW, BWG, FCR were recorded. Data were analyzed using GLM procedure of SAS. Before the challenge, there was no difference between treatments in FCR ($P = 0.23$). After the challenge, FCR of T1 was lower than T4 (−3.4%, $P = 0.02$) and tended to be lower than T2 (−2.6%, $P = 0.08$). FCR was similar between T1 and T3 (2.50 kg/kg, $P = 0.93$). No difference between treatments was observed in terms of BWG ($P = 0.65$) and final BW ($P = 0.68$). In spite of different modes of action, anticoccidials or vaccine combined to PF and BE lead to similar performance. These results show that a mixture of capsicum and turmeric oleoresins with 500 ppm of BE can be used associated to vaccination to maintain broiler performance in case of coccidiosis infection.

Key Words: essential oils, betaine, coccidiosis

M134 Excess dietary amino acids reduce splenic pro-inflammatory cytokine mRNA abundance and increase anti-inflammatory cytokine mRNA abundance during an acute phase response. A. Diaz[1], N. Hamel[1], K. Martorana[1], R. Angel[2], and B. D. Humphrey*[1], [1]*California Polytechnic State University*, *San Luis Obispo,* [2]*University of Maryland*, *College Park*.

The objective of this experiment was to determine the effect of dietary amino acid levels on the catabolic response to infection. Catabolic responses to infection are coordinated through the pleiotropic effects of cytokines, thus mRNA abundance of interleukin (IL)-1β, IL-6, IL-18, IL-4, IL-13 and transforming growth factor (TGF)-β4 were quantified in the spleen. Male Cobb 500 hatchlings were raised in pens (n = 15/pen) for 14 d and were fed a diet that met NRC requirements. On d 14, birds were fed 1 of 2 diets (n = 20/diet) that contained adequate (A) or excess (E) amino acid levels. The E diet contained excess Phe (+0.43%), Trp (+0.14%), Thr (+0.30%) and Arg (+0.35%). On d 21, half of the pens per dietary treatment (n = 10) were either not injected or injected with 1 mg/kg BW of *E. coli* lipopolysaccharide (LPS). The spleen from one bird per pen was collected at 3, 12, 24, 48, 96 and 168 h post-injection for measurement of cytokine mRNA abundance using quantitative real-time PCR. IL-4 and IL-13 mRNA were not detected at any time point. At 3 h, LPS-injected chicks fed the E diet had 2.6-fold higher TGF-β4 mRNA abundance compared with LPS-injected chicks fed the A diet ($P < 0.05$). At 12 and 168 h, LPS-injected chicks fed the A diet had 2-fold and 7.8-fold higher IL-1β mRNA abundance compared with LPS-injected chicks fed the E diet, respectively ($P < 0.05$). At 24 h, LPS-injected chicks fed the E diet had 3-fold higher IL-18 mRNA abundance compared with LPS-injected chicks fed A diet ($P < 0.05$). At 168 h, LPS-injected chicks fed the A diet had 12.6-fold higher IL-6 mRNA compared with LPS-injected chicks fed the E diet ($P < 0.05$). Taken together, the changes in cytokine profiles in response to LPS-injected birds fed the E diet indicate that feeding specific amino acids in excess of their growth requirement may mitigate the catabolic response to LPS-injection.

Key Words: amino acid, cytokine, inflammation

M135 Effects of repeated intravenous lipopolysaccharide injection on hematological characteristics of chicken blood. O. T. Bowen, R. F. Wideman, R. L. Dienglewicz, and G. F. Erf*, *Department of Poultry Science, Division of Agriculture, University of Arkansas*, *Fayetteville*.

Lipopolysaccharide (LPS) is a cell-wall component of gram-negative bacteria and an important pathogen-associated molecular pattern

recognized by pattern-recognition receptors of innate immunity. LPS stimulates monocytes/macrophages via Toll-like receptor-4 to produce vasoactive factors including nitric oxide, a potent vasodilator. In previous in vivo studies we established that in chickens, intravenously (i.v.) administered LPS induced a transient pulmonary hypertensive response within 1 h, increased plasma nitric oxide (NO) reaching peak levels by 6 h, and resulted in greatly reduced monocyte levels in blood samples collected 1 h post-LPS injection. Examination of the effects of a repeat i.v. injection of LPS revealed a lack of response of the pulmonary vasculature to a second LPS injection that lasted 5 d post-primary LPS injection. The objective of this study was to examine in vivo effects of a second i.v. LPS injection on cells in the systemic circulation using the 6 h peak in plasma NO levels and the 1 h drop in monocytes as end-point measurements of in vivo LPS effects. The second i.v. LPS injection was administered at 1 (24 h), 2, 3, 4, 5, 6, or 7 d post-initial LPS injection. Additionally, LPS-specific antibody titers in the plasma were also monitored post-primary LPS injection. While the drop in monocyte concentrations at 1 h and the increase in plasma NO at 6 h were observed with all second LPS administrations, the LPS-stimulated rise in plasma NO levels was, however, attenuated when LPS was injected at 5- or 6-d post-initial LPS injection. This attenuation in the increase in plasma NO following a second LPS administration at 5- and 6-d post-primary LPS injection may be explained by the presence of LPS-specific antibodies which reached peak plasma levels 4- to 6-d post-primary LPS injection. Hence, it appears that unlike the pulmonary vasculature, cells in the systemic circulation continue to be responsive to LPS stimulation administered 24 h to 7 d post-primary LPS injection.

This research was funded by an Arkansas Experiment Station Animal Health grant.

Key Words: lipopolysaccharide, nitric oxide, chicken leukocytes

M136 Effects of dietary conjugated linoleic acid on macrophage functions in broilers immunosuppressed with cyclophosphamide. D. Liu*, F. Y. Long, Y. M. Guo, Z. Wang, and J. M. Yuan, *China Agriculture University*, *Beijing, China*.

This study was carried out to investigate the effects of conjugated linoleic acid (CLA) on macrophage functions in broilers immunosuppressed with cyclophosphamide (CY). The experiment was designed as a 3 × 2 factorial arrangement, i.e., 3 CLA levels (0, 1.0% and 2.0%) in the diet and with or without CY injection as an immunosuppressive challenge. Two hundred and 16 1-d-old male Arbor Acres broiler chickens were randomly allocated into 6 treatments with 6 replicates. CLA was the mixture of 2 CLA isomers (c9,t11-CLA:t10,c12-CLA = 20:80). CY was injected into the femoral muscle of broilers at a dose of 80 mg/kg of body weight for 3 consecutive days (14, 15 and 16). On d 21, the peritoneal exudate macrophages from 12 broilers per treatment were collected for in vitro culture. Phagocytic rate and phagocytic index of macrophages were detected through ingesting sheep red blood cells. The levels of nitric oxide (NO) and the cytokine interleukin (IL)-1 in the culture supernatants of macrophages were assayed by Griess reagent and bioassay method, respectively. Statistical analysis of all data was performed by 2-way ANOVA with SPSS. Individual treatment means were compared using Duncan′s multiple comparison when the significant ($P < 0.05$) interaction between the main effects was observed. The results showed that the immunosuppressive challenge with CY significantly decreased the phagocytic rate and index of macrophages ($P < 0.05$), and the addition of 2% CLA significantly increased the phagocytic rate and index of macrophages ($P < 0.05$). There was a significant interaction between CLA levels and immunosuppressive challenge on the secretion of NO and IL-1 of macrophages ($P < 0.05$). But 1% dietary CLA had no influence on phagocytic functions and the secretion of NO and cytokines of macrophages. These results suggest that the dietary supplementation of 2% CLA alleviates the suppressive effects of CY on macrophage phagocytic functions and has the effects of bidirectional regulation on the secretion of NO and IL-1 of macrophages in broilers.

Key Words: conjugated linoleic acid, macrophage function, broilers

M137 Broiler breeder feeding programs and trace minerals on cytokine gene expression response in progeny. N. M. Leandro[1,2], R. Ali[1], M. Koci[1], V. Moraes[1], M. J. Wineland[1], J. Brake[1], and E. O. Oviedo-Rondón*[1,3], [1]*North Carolina State University*, *Raleigh,* [2]*Universidade Federal de Goiás*, *Goiania, GO, Brasil*, [3]*Universidade Estadual Paulista, UNESP*, *Jaboticabal, SP, Brasil*.

This study examined how feed allocation programs during breeder pullet rearing and dietary trace mineral (TM) sources during lay could affect the immune response of broiler progeny. Cobb 500 breeders were fed according to 2 feed allocation programs, either sigmoid late fast (LF) or sigmoid late slow (LS) until peak of production. From 56 to 62 wk of age, breeders were fed corn-soybean diets with 5% DDGS with either inorganic TM or an organic source (Mintrex P) to replace 30% of Cu, Zn, and Mn. Total dietary levels of the TM evaluated were 25, 125, and 125 ppm, respectively. Fertile eggs were collected for 4 d, incubated, and placed in pedigree bags at 19 d of incubation. Thirty 6 chicks/treatment were identified with neck tags to track hen effects, and placed in 2 isolation rooms, each with 6 floor pens. Three broilers per treatment were placed in each pen for 12 broilers per pen total. All broilers were fed the same diet. At 7 d of age, La Sota Newcastle disease virus (NDV) vaccine was applied by ocular route in one room only. Whole blood cells were collected at 4 d after vaccination to assay for cytokine (interleukin (IL)-2, IL-4, and interferon-γ) gene expression and serum was collected at 14 d post vaccination to assay for humoral response to NDV. Data were analyzed as a 2 × 2 × 2 factorial design considering breeder feeding programs, TM sources in breeder diet, and broiler vaccination as main factors. Broiler vaccination increased gene expression of all cytokines evaluated. Broiler progeny from breeders fed diets with 30% organic TM increased IL-4 expression after NDV vaccination, while vaccination did not cause significant upregulation of this gene in broiler progeny when breeders were fed 100% inorganic. Expression of IL-2 was found to be increased following vaccination in broilers from LF breeders fed diets with 30% organic TM. However, there was no significant change in IL-2 expression post vaccination in broilers from LS breeders fed the same diet. It was concluded that breeder feeding programs during rearing and dietary TM source during egg production influences the type and magnitude of cytokine expression in broiler progeny.

Key Words: breeder effects, trace minerals, cytokines

M138 Copy number variants in two genetically distinct chicken lines. X. Li*[1], W. Chou[1], S. J. Lamont[2], R. Croomjmas[3], and H. Zhou[1], [1]*Texas A&M University*, *College Station,* [2]*Iowa State University*, *Ames,* [3]*Wageningen University*, *PO Box 338, 6700 AH, Wageningen, the Netherlands*.

Genomic copy number variation (CNV) is another important source of genetic variation besides single nucleotide polymorphisms and microsatellites. In humans, CNVs are associated with Mendelian disease and complex traits. The high-throughput array has provided a powerful tool to discover copy number variation at the genome level. Two genetically distinct highly inbred chicken lines (Fayoumi and Leghorn G-B1) were used in this study. Previous study has shown that Fayoumi is resistant,

while Leghorn is susceptible, to avian influenza virus (AIV) infection. The Agilent 244K chicken CGH array was utilized to identify the potential CNVs associated with host response to pathogen. Six biological replicates from each line, in total, 12 biological replicates, were used. Red Jungle fowl was used as a reference to normalize the microarray data. There were 241 and 269 CNVs identified in Fayoumi and Leghorn, respectively, of which 116 and 119 were located in known chicken QTLs based on chicken QTLdb database. The CNVs identified in this study have also generated strong candidate CNVs potentially associated with host response to AIV infection in chickens.

Key Words: copy number variation, host response, avian influenza virus

M139 Phage display selection and characterization of a single-chain antibody (scFv) against chicken CD40. D. Abi-Ghanem*[1], C-H. Chen[1], L. Njongmeta[1], J. Bray[1], W. Mwangi[1], S. D. Waghela[1], J. L. McReynolds[2], and L. R. Berghman[1], [1]*Texas A&M University*, *College Station*, [2]*U.S. Department of Agriculture, Agricultural Research Service*, *College Station, TX*.

CD40, an integral membrane glycoprotein of the tumor necrosis factor-receptor super family, is mainly expressed on antigen-presenting cells (APCs), including B-cells, macrophages, and dendritic cells. The interaction between CD40 and its ligand CD154 (CD40L) mediates specific $CD4^+$ T-cell help to APCs in response to T-cell dependent antigens, and provides crucial signals for antigen-specific T-cell priming and expansion, as well as heightened antibody production and immunoglobulin class switching in B-cells. In contrast to the extensive characterization of mammalian CD40 by use of agonistic anti-CD40 monoclonal antibodies, which can mimic $CD4^+$ T-cell help to APCs, investigation of chicken CD40 (cCD40) has been limited. In this study, we describe the production of a dimeric single-chain antibody fragment (scFv) against cCD40. An immune antibody library against cCD40 was constructed by phage display. Following 3 rounds of panning against cCD40, specific, likely high-affinity antibodies were obtained. Soluble anti-cCD40 scFv (~35 KDa) was purified by nickel affinity chromatography and characterized by immunoblotting. This scFv recognized cCD40 in ELISA, and agglutinated chicken DT40 B-cells in vitro. We are currently investigating the biological activities of this scFv, particularly the induction of nitric oxide synthesis in chicken HD11 macrophages and proliferative stimulation of serum-starved chicken DT40 B-cells. These activities will evaluate the extent to which the anti-cCD40 scFv can mimic the effects of CD40L, providing the signals needed to induce activation of chicken APCs in vitro. Such an agonistic anti-cCD40 scFv may therefore constitute a powerful tool to study the role of CD40 in the chicken immune system.

Key Words: chicken CD40, single-chain antibody fragment, co-stimulation

M140 Functional characterization of the avian macrophage migration inhibitory factor (MIF). S. Kim*[1], K. B. Miska[2], M. C. Jenkins[2], R. H. Fetterer[2], C. M. Cox[1], L. H. Stuard[1], and R. A. Dalloul[1], [1]*Animal & Poultry Sciences, Virginia Tech*, *Blacksburg,* [2]*Animal Parasitic Diseases Laboratory, ARS, USDA*, *Beltsville, MD*.

Macrophage migration inhibitory factor (MIF) is recognized as a soluble factor produced by sensitized T lymphocytes and inhibits the random migration of macrophages. Recent research shows a more prominent role of MIF as a multi-functional cytokine mediating both innate and adaptive immune responses. This study describes the cloning and functional characterization of avian MIF in an effort to better understand its function and potential in poultry health applications. The full-length avian MIF gene was amplified from stimulated chicken lymphocytes and cloned into a prokaryotic expression vector. The confirmed 115 amino acid sequence of avian MIF has 71% identity with human and murine MIF. The bacterially expressed avian recombinant MIF (rChMIF) was purified, the endotoxins removed, and a 4 h-chemotactic assay performed using a 48-well chemotaxis chamber. Diff-Quick staining results showed sharply decreased migration of macrophages in the presence of 10 ng/ml rChMIF. Further, the expression of various cytokines was measured in peripheral blood mononuclear cells (PBMCs) or splenocytes using quantitative real-time PCR (qRT-PCR). Isolated PBMCs or splenocytes were cultured in the presence or absence of rChMIF, with or without lipopolysaccharide (LPS) or Concanavalin A (Con A) for 6 or 12 h. qRT-PCR analysis revealed that rChMIF alone did not induce transcription of interleukin (IL)-1β or induced-nitric oxide synthase (iNOS). However, the presence of rChMIF enhanced levels of IL-1β and iNOS during PBMCs stimulation with LPS. Similarly, there was no effect of rChMIF alone on splenocytes; however, the Con A-stimulated lymphocytes showed enhanced interferon (IFN)-γ and IL-2 transcripts in the presence of rChMIF. Interestingly, addition of rChMIF to the stimulated PBMCs, in the presence of lymphocytes, showed anti-inflammatory function of rChMIF. To our knowledge, this study represents the first report for the functional characterization of avian MIF, which inhibits migration of macrophages similarly to mammalian MIF, and it also mediates inflammatory responses during antigenic stimulations.

Key Words: MIF, avian immunity, real-time PCR

M141 US Veterinary Immune Reagent Network. H. Lillehoj*[1], S.-H. Lee[1], D.-K. Kim[1], M.-S. Park[1], D. Tompkins[2], C. Baldwin[2], J. LaBresh[3], and B. Wagner[4], [1]*USDA-ARS*, *Beltsville, MD,* [2]*University of Massachusetts*, *Amherst,* [3]*Kingfisher Biotech*, *St. Paul, MN,* [4]*Cornell University*, *Ithaca, NY*.

To advance veterinary immunology and animal disease research, a CSREES-funded NRI consortium grant (#2005–01812) was established in 2005 to develop immunological reagents specific for poultry, ruminants, swine, equine and aquaculture species (http://www.umass.edu/vetimm). Immunological reagents to be developed through this grant include monoclonal antibodies (mAb) and polyclonal antibodies that identify the major leukocyte subpopulations (T and B lymphocytes, NK cells, neutrophils, macrophages, and dendritic cells) for many animal species including fish. In addition, recombinant cytokines and chemokines as well as antibodies to them and to their receptors, will be developed and these immune reagents will be valuable in research to understand the major components of immune system which are involved in inflammation, innate and adaptive immunity. These immunological reagents will be used to (1) evaluate changes associated with diseases and vaccination, and (2) manipulate various lymphocyte subpopulations to evaluate their roles in protective immunity as well as in immunopathology. In this report, progress in poultry immune reagent development will be discussed.

This project is funded by USDA-CSREES proposal 2005-01812 and was carried out as part of the US Veterinary Immune Reagent Network. For commercially available immune reagents from this consortium, go to http://kingfisherbiotech.com

M142 Expression of the development gene CAMK2G in the virgin mammary gland of the dairy goat. L. N. Wang, C. Li, Q. Z. Li*, and C. Y. Yuan, *Key Laboratory of Dairy Science of Education Ministry, Northeast Agricultural University*, *Harbin, China*.

Identification of the key genes related to mammary gland development in the dairy goat is important for optimizing milk production. In this research, after comparing the expression of ESTs in 7 Long-SAGE libraries corresponding to different stages of development (early virgin, late virgin, early pregnancy, late pregnancy, middle lactation, early involution and late involution) and sequence alignment with BLAST in the sheep library, we found the gene CAMK2G to be an important gene that affected the development of the mammary gland in virgin dairy goats. mRNA was extracted from healthy virgin mammary glands of dairy goat, and then amplified by RACE (rapid amplification of cDNA ends). We synthesized the 3′- and 5′-RACE-fragments by using the CAMK2G's EST from the virgin mammary gland long-SAGE library as the gene-specific primer, then cloned and sequenced RACE fragments to obtain the full-length gene. The anticipated length of the 3′cDNA of gene CAMK2G was about 500 bp, and 5′cDNA was about 1500 bp. Comparing the homology with the sheep EST library provided by NCBI GenBank confirmed that the cloned gene was CAMK2G. We next performed an RNAi (RNA interference) experiment. The synthesized siRNA was based on the full-length of the gene CAMK2G and transfected into cells that were subcultured from primary epithelial cells of the virgin mammary gland. After the detection of cell viability analyzer and flow cytometry, both the proliferation and the activity of mammary epithelial cells were inhibited ($P < 0.05$). Real-time PCR showed that the expression of CAMK2G was lower after RNAi ($P < 0.01$). Addition, Western blotting showed that the expression of β-casein was decreased ($P < 0.05$). The experiments above were repeated 3 times. Thus, the gene CAMK2G may be important in mammary gland development of the virgin goat.

This work was supported by the National High Technology Research and Development Program of China (Grant No. 2006AA10Z1A4).

Key Words: dairy goat, mammary gland development, CAMK2G

M143 Effects of thyroxine, glucagon and insulin on mRNA levels of heat shock proteins in bovine mammary epithelial cells under heat stress in vitro. R. L. Cui[1], J. Q. Wang*[1], H. Y. Wei[1], D. P. Bu[1], H. Hu[1,2], and L. Y. Zhou[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences*, *Beijing, China*, [2]*Faculty of Animal Science & Technology, Gansu Agriculture University*, *Lanzhou, China*.

The objective of this study was to establish the effects of thyroxine (T4), glucagon and insulin on the mRNA levels of heat shock proteins (HSPs) in bovine mammary epithelial cells under heat stress in vitro. The mammary epithelial cells were cultured in DMEM/F12 media containing 10% fetal bovine serum (FBS) at 38°C until they reached 80% confluence. T4 (0, 0.01, 0.1, 0.5, 1 and 2 μmol/L), glucagon (0, 0.01, 0.1, 0.5, 1 and 2 μmol/L) and insulin (0, 0.005, 0.01, 0.1, 0.5 and 1 μmol/L) were separately added into the media then cells were exposed at 42°C for 12 h as a heat stress model and 38°C for 12 h as the control. Levels of HSP mRNA were detected by RT-qPCR. Each treatment had 3 replicates in this experiment, and one-way ANOVA of SAS was used to analyze the experimental data. The results indicated that (1) At 38°C, HSP90 did not significantly change with insulin (0.005, 0.01, 0.1, 0.5 and 1 μmol/L) and T4 (0.01, 0.1, 0.5 and 1 μmol/L) ($P > 0.05$); HSP70 increased markedly with 0.005 and 1 μmol/L insulin ($P < 0.05$), and did not change markedly with 0.01, 0.1 and 0.5 μmol/L insulin ($P > 0.05$); However, other treatments all significantly decreased the mRNA levels of HSP27, 70, 90 and heat shock factor-1 (HSF-1) ($P < 0.05$). (2) The mRNA levels of HSP27, 70, 90 & HSF-1 were all significantly lower after cells were cultured with different concentrations of T4, glucagon and insulin separately at 42°C for 12 h ($P < 0.01$). In conclusion, T4, glucagon and insulin could inhibit mRNA levels of HSPs in mammary epithelial cells under heat stress.

Key Words: bovine mammary gland epithelial cells, heat shock proteins, FQ-PCR

M144 Immunodetection of the secreted forms of osteopontin in bovine milk. N. Bissonnette[1,3], C. Thibault[1], and G. Robitaille*[2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre*, *Sherbrooke, Qc, Canada*, [2]*Agriculture and Agri-Food Canada, Food Research and Development Centre*, *Saint-Hyacinthe, Qc, Canada*, [3]*Université de Sherbrooke*, *Sherbrooke, Qc, Canada*.

Osteopontin (OPN), a phosphoglycoprotein, presents in human a complex pattern of gene expression (splicing variants) which is tissue and physiological state-dependent. The concentration reaches 1 g/L and varies during lactation. Bovine OPN is secreted in lower but substantial amounts (10 mg/L) in bovine milk. The aim of this study was to monitor bovine OPN and to identify the different isoforms in milk. Four human and one mouse commercial anti-OPN targeting different portions of the human OPN were tested on bovine OPN. In addition, 2 antisera were raised against synthetic peptides designed from the NCBI refseq bovine sequence and one was raised against the protein that was purified from milk by HPLC; the purification method allows the isolation of a significant amount of pure protein. Purified and commercial bovine OPN were characterized by silver coloration and ECL Western blot analysis. The signature of both sources was identical as detected by silver coloration. One of the 3 human anti-OPN, which targeted the N-terminal part of the protein, profiled 2 bovine OPN isoforms at 65 and 40 kDa, whereas 3 human anti-OPN failed to detect purified OPN. The bovine anti-OPN (synthetic peptide) and the anti-mouse-OPN, which are highly specific to the C-terminal part of the protein, detected only the 65 kDa isoform. The bovine antisera (purified OPN from milk) recognized both forms and other forms in milk. Preliminary ELISA assays allowed a specific detection of bovine OPN. Using these antibody preparations it is possible to determine the abundance of each of these isoforms in milk. In conclusion, analysis of the bovine OPN reveals the presence of 2 isoforms. The immunodetection of the respective isoforms will allow to determine their relative abundance during lactation and to speculate on their local bioactivity.

Key Words: osteopontin, bovine, milk

M145 Differentiated immortalized porcine mammary epithelial cells grown on polysulfone hollow fiber provide a potential cell culture system for expression of recombinant proteins. T. C. Kuan*[1], Y. L. Sun[2], C. Y. Yen[1], and C. S. Lin[1], [1]*Department of Biological Science and Technology, National Chiao Tung University*, *Hsinchu, Taiwan*, [2]*Division of Biotechnology, Animal Technology Institute Taiwan*, *Miaoli, Taiwan*.

Spontaneously immortalized porcine mammary epithelial cells (PMEC) isolated from the mammary gland of lactating sows can express milk

proteins following differentiation into mammary gland-like structures (gland ducts, lateral buds, and alveoli). Hollow fiber bioreactors have been used for large-scale mammalian cell culture to produce monoclonal antibodies or recombinant proteins. The hollow fibers provide a culture system with a high surface to volume ratio. The system allows extremely efficient exchange of nutrients and waste products across the fiber wall. Therefore, we attempted to culture PMEC transformed with recombinant DNA in these hollow fiber bioreactors to produce recombinant proteins. In the present study, we investigated the optimum conditions for culturing the PMEC onto polysulfone hollow fibers (PHF). The results showed that the seeded PMEC could attach, grow and form monolayers on the surface of PHF. The PMEC could differentiate into mammary gland-like structures when the cells were grown on PHF coated with Matrigel. The regulatory region of the milk gene, α lactalbumin, was inserted upstream of luciferase cDNA to generate a recombinant DNA, pAL-luc. The pAL-luc was transformed into PMEC and used to test the potential for recombinant protein production by PMEC cultured on PHF. Luciferase activity expressed from the PMEC grown on the PHF coated with 2.5 mg/ml and 5 mg/ml Matrigel were increased by 2.7-fold and 7.0-fold compared with that of the cells grown on the PHF without Matrigel (n = 3). Moreover, prolactin supplementation enhanced the luciferase expression. In this established PHF-cell culture approach, the PMEC could be continuously cultured for one week and potentially express recombinant protein. In conclusion, we have provided a potential PHF-cell culture approach in which PMEC can differentiate and express recombinant protein.

Key Words: mammary epithelial cells, polysulfone hollow fiber, recombinant protein

M146 Effects of nutrient restriction on mammary cell activity and hormonal statement in lactating dairy cows. F. Dessauge*[1,2], V. Lollivier[1,2], E. Cutullic[1,2], J. Portanguen[1,2], C. Disenhaus[1,2], S. Barbey[3], B. Ponchon[1,2], and M. Boutinaud[1,2], [1]*INRA UMR 1080 Dairy Production*, *35590, Saint Gilles, France*, [2]*Agrocampus UMR 1080 Dairy Production*, *35000, Rennes, France*, [3]*INRA UE 326 Domaine Experimental du Pin au Haras*, *61310, Le Pin au Haras, France*.

Feed restriction results in milk yield (MY) decrease. However the consequences on mammary activity and the involvement of prolactin (PRL) in the lower mammary synthesis are not known. The aim of the study was to investigate the effects of nutrient restriction on mammary epithelial cell activity in lactating dairy cows. We used 15 Holstein × Normande crossbred dairy cows, divided into 2 groups submitted to 2 feeding levels. From calving to wk 11 postpartum, the cows were fed a total mixed ration composed either of 55% maize silage, 15% dehydrated alfalfa and 30% concentrate (Basal diet-group as control, n = 7) or of 60% grass silage and 40% hay (Restricted diet-group, n = 8). Cows were milked twice daily. MY and composition were measured. Blood samples were harvested at wk 11 postpartum for the determination of PRL concentration. After 11 weeks of lactation, cows were slaughtered and mammary glands were removed and weighted. Expression of proteins involved in secretory activity was evaluated on mammary tissue by real-time qPCR and immunohistochemical staining was performed. Restricted diet-group cows had lower 11-week average daily MY (20.5 kg/d vs. 35.5, $P < 0.001$) and lower milk protein and lactose content from calving to slaughter than Basal diet-group cows. The size of the mammary acini were lower (−41%, $P < 0.01$) in the Restricted diet-group. Nutrient restriction decreased kappa-casein ($P < 0.01$) and α-lactalbumin ($P < 0.01$) mRNA levels in the mammary gland. The decrease in mean PRL concentration was not significant (−27%, $P = 0.15$) in Restricted diet-group compared with Basal diet-group. In conclusion, nutrient restriction resulted in a lower MY in lactating dairy cows. This was partly due to a modulation of mammary epithelial cells activity regulated at mRNA level.

Key Words: nutrient restriction, mammary epithelial cell, prolactin

M147 Effects of incremental sunflower seed supplementation on milk composition and mammary expression of genes regulating fatty acid uptake and lipogenesis. J. W. Møller, T. Bjørn, P. K. Theil, M. T. Sørensen, and K. Sejrsen*, *Faculty of Agricultural Science, Aarhus University*, *Tjele, Denmark*.

Dietary supplementation with unsaturated fatty acids is a well-established strategy for enhancing milk fat content of unsaturated fatty acids. The objective was to examine the effects of increased sunflower seed supplementation (SFS) on milk fat composition and mammary expression of genes regulating fatty acid uptake and lipogenesis. Twenty 4 lactating Holstein Friesian cows (186 ± 20 DIM; 25.3 ± 2.5 kg/d) were randomly assigned to 4 groups and fed a control diet or diets supplemented with 5%, 10%, or 15% sunflower seeds (% of DM) for a 5 week experimental period. DM intake and milk yield was reduced in cows fed 10% and 15% SFS when compared with control, whereas 5% SFS did not differ from control. All levels of SFS tended to increase milk fat content ($P = 0.08$). SFS decreased content of C4–14 ($P = 0,008$) and C16 fatty acids ($P = 0.014$). Content of ≥ C18 fatty acids was increased ($P = 0.015$). SFS increased the level of unsaturated fatty acids ($P < 0.001$) when compared with control and increased in a linear manner ($P < 0.001$) the content of rumenic acid (C18:2 c9t11) from 0.3% to 0,9%. Gene expression was analyzed by RT-PCR on RNA from mammary biopsies using the ΔΔCT method. SFS (5–15%) reduced mRNA abundance of SREBP-1 ($P = 0.034$), SCAP ($P = 0.0075$), FASN ($P = 0.035$), FADS1 ($P = 0.006$), and SCD ($P = 0.046$). mRNA abundance of ACC tended to be reduced ($P = 0.06$). SFS did not affect expression of the lipid uptake and transport genes LPL ($P = 0.189$), FABP3 ($P = 0.862$), and FAT ($P = 0.403$). In conclusion, our results show that dietary supplementation with high levels of unsaturated fatty acids in form of sunflower seeds leads to increased milk fat content in spite of decreased de novo milk fat synthesis as substantiated by a reduction in lipogenic genes. Furthermore, the expression of genes regulating fatty acid uptake and transport were unaffected although the amount of dietary fat present in milk was increased.

Key Words: dietary supplementation, mammary gene expression, conjugated linoleic acid

M148 Principal component analysis of milk fatty acid composition and the relationships between stearoyl CoA desaturase genotype and conjugated linoleic acid production in dairy cattle. J. Thomson*, L. Clark, M. Oba, and S. Moore, *University of Alberta*, *Edmonton, AB, Canada*.

The objectives of this study were to assess the relationships between individual milk fatty acids and conjugated linoleic acid (CLA) concentration in bovine milk fat and to assess the relationship between a single nucleotide polymorphism in the stearoyl CoA desaturase gene and CLA production using principal component analysis (PCA). 215 cows from an Alberta commercial dairy farm were genotyped and milk samples were collected for milk fatty acid analysis. Forty-three variables including milk production parameters, individual fatty acid concentrations, and indices of desaturation were analyzed. The first 3 principal components explained 47.61% of the total variance (PC 1, 24.13%; PC 2, 13.95%; and PC 3, 9.53%). The first PC had high loadings for most of the short chain fatty acids, the second PC had high loadings for the yield

measurements, and the third PC had high loadings for long chain fatty acids. Thus, the majority of the variables were described by 3 principal components. There was a positive correlation among the short chain or de novo synthesized fatty acids (C4-C16) ($P < 0.05$), and a negative correlation between the de novo synthesized fatty acids and the long chain fatty acids which primarily come from peripheral circulation (C18 and C20 isomers) ($P < 0.05$). CLA concentration had a positive correlation with C18:1 t6–8, C18:1 t9, C18:1 t10, C18:1 t12, C18:1 t13–14 and 18:1 t11 ($P < 0.05$). CLA was negatively correlated with C18:1 c9 ($P < 0.05$). A high positive correlation between the concentration of C12:0 with CLA yield (coefficient of 0.85, $P < 0.0001$) was observed. The CLA desaturation index (CLA /18:1t11 + CLA) was positively correlated to C8:0, C10:0, C12:0, C14:0, C14:1, and C16. This relationship may warrant further research. Genotype did not explain a significant amount of the variation in these data. This suggests that fatty acid origin (de novo synthesized fatty acids vs. fatty acids from circulation) had a much bigger impact than genotype on fatty acid variation in milk.

Key Words: stearoyl CoA desaturase, milk fatty acids

M149 Improved lactation persistence and altered milk composition in growth hormone-treated mice is not linked to dramatic changes in mammary mitochondrial biogenesis or the degree of mTOR or AMP kinase phosphorylation. W. Olea*[1], A. Parlow[2], R. Collier[3], and D. Hadsell[1], [1]*Baylor College of Medicine*, *Houston, TX*, [2]*Harbor-UCLA Medical Center*, *Torrance, CA*, [3]*University of Arizona*, *Tucson*.

Previous work in our lab has shown that mice treated with growth hormone (GH) under both ad-libitum (AL) and reduced (4X) nursing frequency can support greater litter gain during prolonged lactation. However, the mechanism of this response is not well understood. Our hypothesis was that GH treatment would increase milk production or alter milk composition through effects on signaling pathways regulating protein synthesis or mitochondrial biogenesis. To test this hypothesis we compared milk concentrations of fat, protein, and lactose, mammary mitochondrial (mt) DNA copy number, and the phosphorylation of mammalian target of rapamycin (mTOR) and AMP kinase (AMPK) in mammary tissue from lactating mice treated (n = 6/treatment) with either saline (SAL) or recombinant murine GH (18 mg/kg/day) under conditions of either AL or 4X nursing frequency during prolonged lactation. GH treatment increased (main effect, $P < 0.05$) milk triglyceride (172.47 ± 25.42, 321.50 ± 33.33, 185.27 ± 51.75, and 271.45 ± 52.07 mM for AL-SAL, AL-GH, 4X-SAL, and 4X-GH, respectively), and protein concentrations (93.68 ± 7.02, 109.63 ± 9.84, 81.68 ± 6.32, 106.64 ± 9.78 mg/mL for AL-SAL, AL-GH, 4X-SAL,4X-GH, respectively). Mitochondrial DNA copy number, measured as the ratio of cytochrome-B to β-Actin by real time qPCR, was not significantly impacted by nursing frequency or GH treatment. Immunofluorescent staining for Phospho-mTOR and phospho-AMPK were also not significantly affected by nursing frequency or GH treatment. Staining for total mTOR, however, was higher in GH treated animals than SAL (main effect, $P < 0.01$). These results support the conclusion that although GH treatment increases milk production and alters milk composition during prolonged lactation in mice, this response is not mediated through dramatic alterations in the phosphorylation of mTOR or AMPK or through affects on mitochondrial biogenesis.

Key Words: growth hormone, persistence, mitochondria

M150 Beef quality of bovines supplemented with vitamin E. G. Aranda-Osorio*[1], H. Barragan-Gonzalez[1], M. Huerta-Bravo[1], O. Hernandez-Mendo[2], E. Maldonado-Siman[1], and J. C. Garcia-Ortiz[1], [1]*Universidad Autonoma Chapingo*, *Chapingo, Mexico*, [2]*Colegio de Posgraduados*, *Montecillos, Mexico*.

The aim of this study was to establish the feeding duration and dietary level of vitamin E offered to young bulls which does not affect performance but positively improve shelf-life of beef. Three experiments were carried out: E1) 1,000 IU vitamin E/animal per d fed during 37, 49, and 63 d; E2) 2,000 IU vitamin E/animal per d fed for 77 d and E3) 3,000 IU vitamin E/animal per d fed for 55 d. In E1, E2 and E3 a total of 36 (12, 549 ± 22.44; 12, 510.42 ± 27.48; and 12, 480.25 ± 19.99 kg), 24 (396.21 ± 24.39), and 24 (432.50 ± 23.81 kg) crossbred (*Bos taurus* × *Bos indicus*) young bulls were used, respectively. Average daily weight gain (ADG), dressing percentage (DP) as well as pH, water retention capacity (WRC), L* and chroma values and hue angle (hue°) of the rib eye (obtained between the 12th and 13th rib) were determined. Data were analyzed as a randomized block (E1) and completely randomized (E2 and E3) design using PROC GLM of SAS. Neither ADG nor DP were negatively affected ($P \leq 0.05$) by the feeding duration or the dietary vitamin E level (E1, E2 or E3). Differences ($P \leq 0.05$) in pH, L*, chroma and hue° in beef until d 63 (E1) of supplementation were observed in animals offered vitamin E. There were no ($P \geq 0.05$) differences in beef quality traits on d 1 post-mortem, but differences ($P \leq 0.05$) were found on d 8 and 16 post-mortem (E2), when the beef color was more stable. In E3 the beef quality traits were similar to those found in E2, suggesting that supplementing 3,000 IU of vitamin E/animal per day during 55 d had a similar effect than supplementing 2,000 IU vitamin E/animal per d during 77 d. In conclusion, it is feasible to supplement 1,000, 2,000, or 3,000 IU of vitamin E/animal per d without compromising the finishing performance. However, the vitamin E supplement has to be offered for at least 45 d before the slaughter to improve beef quality.

Key Words: beef cattle, vitamin E, meat traits

M151 Effect of vitamin E supplementation on the finishing of beef cattle. G. Aranda-Osorio*[1], P. De la Cruz-Honorato[1], R. Hernadez-Arrieta[1], O. Hernandez-Mendo[2], and J. C. Garcia-Ortiz[1], [1]*Universidad Autonoma Chapingo*, *Chapingo, Mexico*, [2]*Colegio de Posgraduados*, *Montecillos, Mexico*.

The objective of this study was to evaluate the effect of vitamin E supplementation on performance (dry matter intake (DMI), average daily gain (ADG), feed conversion (FC), feed efficiency (FE), backfat depth (BFD), trimming fat (TF), hot carcass yield (HCY), and profitability of finishing young bulls. Two experiments were carried out. In experiment 1 (E1), 36 young bulls (*Bos taurus* × *Bos indicus*) were assigned to 3 BW blocks (549.50 ± 22.44, 510.42 ± 27.48 and 480.25 ± 19.99 kg) and offered 1000 IU vitamin E /head per d for 37, 49 or 63 d during the finishing period. To each BW block 12 animals were assigned (6 with and 6 without vitamin E supplementation). Each bull was the experimental unit, with 6 replicates per treatment. In experiment 2 (E2) 24 young bulls (*Bos taurus* × *Bos indicus*) with an ILW of 396.21 ± 24.39 were used. Half of them were offered 2000 IU vitamin E/head per d during 77 d. They were vaccinated against *Clostridium*, dewormed, vitamined, implanted and individually penned (2 × 2 m). The diet was based on corn (42.2%), bakery waste (24.6%), barley straw (22.9%), soybean meal (7.93%), minerals (2%), and $CaCO_3$ (0.4%), with 13.1% crude protein, 1.79 Mcal ENm, 1.16 Mcal ENg and 11.6% crude fiber. The animals were slaughtered the d after they finished their fattening period. Data were analyzed as a randomized block (E1) and completely randomized (E2) design using PROC GLM of SAS. In E 1, vitamin E supplementation for 37 d enhanced ($P \leq 0.05$) DMI, ADG, FC, FE, BFD, and TF but decreased ($P \leq 0.05$) HYC. However, vitamin E supplementation for 49 or 63 d enhanced ($P \leq 0.05$) DMI but affected ($P \leq 0.05$) ADG, FC, FE, BFD, and HCY. In E 2, 2000 IU vitamin E supplementation improved ($P \leq 0.05$) feedlot performance but decreased ($P \leq 0.05$) FC. However, due to the high costs of dietary vitamin E profitability was reduced. It is concluded that vitamin E supplementation in the finishing period of young bulls did not negatively affect animal performance and therefore can be used to improve beef quality.

Key Words: young bulls, vitamin E, performance

M152 Influence of different forms of lipid supplements on physical characteristics of heifers' meat fed on feedlot system. M. C. A. Santana*[1], T. T. Berchielli[1], R. A. Reis[1], G. T. Pereira[1], and R. C. Canesin[1], [1]*São Paulo State University*, *Jaboticabal, São Paulo, Brazil*, [2]*Bellman Animal Nutrition Mineral Supplements*, *Jaboticabal, São Paulo, Brazil*.

Physical quality of meat products can be influenced by the feed offered to the animal. The evaluation of beef quality indicators is important because it is able of determining the product which will be offered to the consumer. The focus areas in this experiment are colors (a, b, L), shear force (WBSF), water-holding capacity (WHC), pH and cooking loss percentage (CLoss) in meat from heifers fed under different lipid supplements in feedlot system. The experiment design was completely random, using 3 supplements. The supplements came from soya lipid-based supplements, offered in different forms (soybean grain, soybean oil and protected fat - Megalac-E), 60:40 concentrate:corn silage. The treatments were compared by analyzing variables using the GLM procedure (SAS 9.1, SAS Institute, Inc., Cary, NC). Mean values were compared using the Tukey test at a significance level of 0.05. Using a colorimeter, the color of the longissimus muscle (LM) at the 12th and 13th rib interface in the L*a*b* color space (CIE system) was determined. A time span of 30 min was awaited before color analysis. The WBSF was obtained from steaks previously thawed and roasted using an insert thermometer until 70°C was obtained. Later, the samples were cut into cubes; the data collected was achieved using a Warner-Bratzler shear machine. The muscle pH measurements were taken from the interior of the LM at 24 h and 48h postmortem using a portable pH meter. The water holding capacity was obtained by determining the difference of the sample weights under 10 kg of pressure for 5 min. The cooking loss value was determined according to the reduced percentage rate before and after the meat was cooked. The results of this research suggest that the physical indicators of meat quality were not influenced by the supplements, offered in different forms (soybean grain, soybean oil and protected fat - Megalac-E).

Table 1. Means for the colors a, b and L, meat pH, water-holding capacity (WHC), and percentage cooking loss (CLoss) and shear force (WBSF) of heifer's meat from feedlot.

	Soybean grain	Soybean oil	Protected fat	Mean	CV (%)
WBSF (kgf/cm^3)	6.5	8.2	7.9	7.6	21.7^{NS}
WHC (%)	73.8	71.8	71.2	72.2	6.6^{NS}
CLoss (%)	34.7	33.7	32.7	33.6	5.1^{NS}
Color L (%)	35.0	34.0	34.7	34.5	7.4^{NS}
Color A (%)	16.6	16.7	16.4	16.5	13.5^{NS}
Color B (%)	3,5	3.5	3.6	3.6	33.6^{NS}
pH (48 h)	6.1	6.1	6.2	6.1	3.2^{NS}
pH (24 h)	5.6	5.6	5.7	5.6	2.2^{NS}

NS = nonsignificant.

Key Words: soybean grain, soybean oil, protected fat

M153 Effect of maternal nutritional status on muscle development and carcass characteristics in heifer progeny. L. V. Nicodemus*, K. R. Underwood, J. F. Tong, P. L. Price, B. W. Hess, S. I. Paisley, W. J. Means, R. J. McCormick, and M. Du, *Department of Animal Science, University of Wyoming*, *Laramie*.

In the Western United States, cow herds commonly experience nutrient deficiency due to frequent drought conditions. Mid to late gestation is an important time for skeletal muscle and adipose tissue development. The objective of this study was to evaluate the effects of maternal nutrient deficiency during mid gestation on the growth performance and carcass traits of heifer progeny. Thirty-two heifers, born to crossbred cows from 2 years were evaluated for the effects of dietary treatments from d 45 through d 180 of gestation on muscle development, meat quality, and carcass characteristics. At d 45 of gestation cows were randomly allotted to 1 of 3 dietary treatments consisting of individually fed native grass hay plus a soybean meal-based supplement: control (C, 100% NRC requirements), nutrient restricted (NR, 70% NRC requirements), and nutrient restricted plus ruminally undegradable protein supplementation (NRP, 70% NRC requirements with essential amino acids supplemented to the control level), and that 11 C, 7 NR and 14 NRP offspring heifers were produced from the herd. Following weaning, heifers from all treatments were back-grounded, and then place in the feedlot where they received a high concentrate diet until slaughter. Carcass characteristics were measured at 48 h postmortem. Steaks were removed 14 d postmortem for Warner-Bratzler Shear Force and proximate analysis. The 12th rib fat thickness of C heifers was less ($P \leq 0.05$) than that of NR. The Semitendinosus muscle weight was reduced in NR compared with C carcasses ($P \leq 0.05$). There was no difference in LM area, percent KPH fat, or marbling scores between treatments. Data show that a low plane maternal nutrition during early to mid-gestation increased fatness and reduced muscling of heifer progeny, and protein supplementation had no major impact on carcass composition of offspring heifers.

Key Words: maternal nutrition, beef, fetal development

M154 Nutrient restriction during early prenatal growth and carcass characteristics of beef steers. T. A. Pye*, B. H. Boehmer, R. P. Wettemann, and G. W. Horn, *Oklahoma Agricultural Experiment Station*, *Stillwater*.

To evaluate the effect of prenatal nutritional restriction on carcass characteristics, Angus heifers (15 mo of age) were AI, and after 32 ± 1 d, pregnancy was determined. Heifers were stratified by BW and BCS and allotted to low (L, 55% of NRC requirements) or moderate nutritional (M, > 100% NRC requirements) treatment groups. After 86 d of treatment (128 d of gestation), heifers were managed in a single pasture and received a common diet (>100% of NRC requirements). Bulls were castrated at birth, weaned at 230 d, and maintained as a group before and after weaning. At 14 (rep 1) or 18 mo (rep 2) of age, L (n = 13) and M (n = 10) steers were fed a high-energy finishing diet and gained 2.1 ± 0.2 kg/d to a BW of 592 ± 7 (rep 1) or 631 ± 6 kg (rep 2). Steers were harvested at 1.3 ± 0.2 cm backfat. Data were analyzed using PROC GLM procedures of SAS. There was no treatment × rep effects ($P > 0.32$). At onset of treatment, BW ($P = 0.37$) and BCS ($P = 0.30$) were similar for L and M heifers. During early gestation M heifers gained 68 ± 7 kg and L heifers lost 54 ± 8 kg ($P < 0.001$). After treatment, M heifers had greater BCS (5.5 ± 0.1) compared with L heifers (4.3 ± 1; $P < 0.001$). Hot carcass weight ($P < 0.001$), dressing percentage ($P < 0.001$), REA ($P < 0.02$), marbling ($P < 0.001$) and KPH fat ($P < 0.001$) were influenced by replication but not by prenatal nutritional treatment ($P > 0.15$). Neither treatment nor replication influenced yield grade or fat thickness at the 12th rib. Major nutritional restriction of young bovine dams during 32 to 118 d of gestation, that resulted in 1.2 BCS units difference, did not influence carcass characteristics of steer progeny at normal harvest weights.

Key Words: beef cattle, carcass characteristics, prenatal programming

M155 Residual feed intake in three-cross beef heifers: color and chemical composition of *Longissumus dorsi* muscle. S. F. Reis[1], P. V. R. Paulino*[1], S. R. Medeiros[2], S. C. Valadares Filho[1], G. L. D. Feijó[2], R. A. A. Torres Júnior[2], R. O. Cristaldo[2], R. A. Silva[2], D. A. Fausto[3], and J. Cavali[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*EMBRAPA Gado de Corte*, *Campo Grande, MS, Brazil*, [3]*Universidade de São Paulo*, *Piracicaba, SP, Brazil*.

Residual feed intake (RFI), as an index for feed efficiency selection, is promising because it is independent of growth traits of the animal. However, studies have shown that efficient animals (low RFI) tend to produce beef with less intramuscular fat (IMF). This trial aimed to evaluate the color and chemical composition of *Longissumus dorsi* (LD) muscle of 31 3-cross beef heifers. The same diet (ME = 2.73 Mcal/kg DM, CP = 11.90% DM) was fed during 84 d. The experiment was conducted according to a completely randomized design. The animals were classified in 3 groups according to their RFI value (high, medium or low). The RFI was calculated as the difference between an animal's actual and predicted feed intake – Predicted DMI = −3.82593 + 0.15438 × MBW + 1.09531 × ADG. At the end of the trial all animals were slaughtered. After 18 h of chilling, color (L*, a *, b *) of the LD was evaluated, according to CIELAB system. A sample of the LD was collected to assess the chemical composition. Data were analyzed using the PROC GLM of SAS and the effects of treatments were considered significant at $P < 0.05$. Chemical composition and color of the LD was similar ($P > 0.05$) among RFI groups. The mean chemical composition of the LD obtained was 4.28% fat; 18.3% CP and 77.42% moisture. The mean L*, a* and b* values were 40.47, 24.74 and 16.13, respectively. The L* and a* values were greater than those commonly reported for

beef (35.00 – 38.00 and 18 – 22, respectively). The b* value found in this study (16.13) was greater than the values reported for cattle under feedlot conditions (3.00 to 5.00). The yellow intensity is related to the amount and color of IMF in the meat. Thus, one can hypothesize that it might have been influenced by the high proportion of IMF (4.28%) found in this study as well as to a greater carotene incorporation, once the animals were raised on pasture for approximately 2 years before being placed in a feedlot. We conclude that efficient animals (low RFI) produce beef with color attributes and chemical composition similar to that produced by less efficient animals (high RFI).

Key Words: feedlot, feed efficiency, meat color

M156 Residual feed intake in three-cross beef heifers: Sensorial traits of *Longissimus dorsi* muscle. S. F. Reis[1], P. V. R. Paulino*[1], R. A. Silva[3], S. R. Medeiros[2], S. C. Valadares Filho[1], G. L. D. Feijó[2], R. A. A. Torres Júnior[2], F. A. Curci[2], and M. A. Rezende[2], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*EMBRAPA Gado de Corte*, *Campo Grande, MS, Brazil*, [3]*Universidade Federal do Mato Grosso do Sul*, *Campo Grande, MS, Brazil*.

Studies have indicated that animals selected for residual feed intake (RFI) may produce lean carcasses which can result in changes in sensory traits of meat. This trial aimed to evaluate sensorial traits (flavor, texture and juiciness) of *Longissumus dorsi* (LD) muscle of 31 3 cross beef heifers. A same diet (ME = 2.73 Mcal/kg DM, CP = 11.90% DM) with roughage:concentrate ratio of 40:60 was fed during 84 d. The experiment was conducted under a completely randomized design. The animals were classified in 3 groups according to its RFI value (high, medium or low). RFI was calculated as the difference between an animal′s actual and predicted feed intake – Predicted DMI = −3.82593 + 0.15438 × MBW + 1.09531 × ADG. At the end of the trial all animals were slaughtered and the carcasses chilled for about 18 h. After chilling, a sample was removed from LD muscle to evaluate sensorial traits and shear force (SF). The sensorial panel was composed by trained individuals (regular consumers of beef, up to 3 times / week). The sensory panel scores were attributed for each sample, following a scale ranging from 1 (low meat quality) to 9 (high meat quality). Data were analyzed using the GLM procedure of SAS. No differences ($P > 0.05$) between classes of efficiency for the sensorial traits and SF of LD muscle were detected. Sensory panel score means for flavor, texture and juiciness were 5.6; 6.1 and 5.4. As all traits were analyzed by a subjective method (sensory panel), only very contrasting results would be detected as different. In this study, animals with low RFI produced meat tenderness similar to those from other classes of efficiency. The mean value of SF was 5.3 kg, which was above those usually reported to crossbred animals (about 4.0 kg) and it may be accounted to the fact that the heifers had 25% of zebu breeds in their composition. The hypothesis that animals with better RFI produce tougher and less desirable meat was not proven in this study, thus RFI is as an interesting tool to select animals in breeding programs.

Key Words: feed efficiency, feedlot, tenderness

M157 Ageing process influence on fatty acids relations in yearling bulls fed different sources of omega-3 and omega-6. A. A. M. Sampaio[1], T. M. Pivaro[1], E. A. Oliveira*[1], W. Henrique[2], B. L. Rosa[1], and A. R. M. Fernandes[3], [1]*FCAV/Unesp*, *Jaboticabal, SP, Brazil*, [2]*APTA*, *São José do Rio Preto, SP, Brazil*, [3]*UFGD*, *Dourados, MS, Brazil*.

The aim of this study was to investigate the effects of oil supplemented diets on the fatty acids levels of bovine *Longissimus thoracis* muscle aged for different days. Thirty-five yearling Nellore bulls were kept in feedlot during 96 d during which 5 dietary fat sources were tested: control (without oil), soybean oil, soybean oil rumen-protected, linseed oil and linseed oil rumen-protected. Sugarcane was the exclusive roughage source for all diets. Sections of loin meat (2.5 cm of thickness) were removed from each left half-carcass, vacuum packed and submitted to aging for 7, 14 and 21 d, followed by lyophilization, lipid extraction and methylation. Fatty acid methyl esters were analyzed using gas chromatography. All data were subjected to ANOVA and Student's *t*-test. The interaction treatment × aging period was not significant in this experiment. There were no ($P > 0.05$) differences for variables related to total amount of saturated and unsaturated fatty acids, neither for the saturated/unsaturated fatty acids ratio when comparing aging periods and *in natura* meat. Aged meat monounsaturated fatty acids values (46.66, 46.76 and 47.23%), monounsaturated:saturated ratio (1.04; 1.03; 1.04) and omega-6:omega-3 ratio (3.85; 3.76 and 3.99) for 7, 14, and 21 d, respectively, were lower ($P < 0.05$) when compared with non-aged meat (48.29%, 1.08, 4.12). However, the amount of polyunsaturated fatty acids was higher ($P < 0.05$) in aged (8.62, 7.89 and 7.44%, respectively) than in non-aged meat (6.18%). Aged meat values for omega-3 (1.24, 1.70 and 1.57%), omega-6 (6.14, 5.56 and 5.23%) and polyunsaturated:saturated ratio (0.19; 0.17 and 0.16) were also higher ($P < 0.05$) than in non-aged meat (1.44%, 4.88% and 0.13, respectively). Independently of the oil source, oil supplementation improves the fatty acid composition of meat aged for 7 and 14 d.

Key Words: fatty acids ratio, saturated fatty acids, unsaturated fatty acids

M158 Feeding flaxseed to beef cows increases concentrations of omega-3 fatty acids and linolenic acid biohydrogenation intermediates in subcutaneous fat. M. L. He[1,3], T. A. McAllister*[1], J. P. Kastelic[1], Y.-H. Chung[1], K. A. Beauchemin[1], P. S. Mir[1], J. L. Aalhus[2], M. E. R. Dugan[2], and N. Aldai[2], [1]*Lethbridge Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*, [2]*Lacombe Research Centre, Agriculture and Agri-Food Canada*, *Lacombe, AB, Canada*, [3]*University of Saskatchewan, Saskatoon*, *Saskatoon, SK, Canada*.

This study was conducted to investigate changes in fat deposition and fatty acid profiles in beef cows fed hay or silage based diets, with or without flaxseed supplementation. Crossbred cull beef cows (64, > 30 mo of age, 620 ± 5 kg) were removed from grassland pastures, randomly assigned to 16 pens and given ad libitum access to 50:50 (wt:wt, DM basis) forage:concentrate diets containing 0 or 15% ground flaxseed (DM basis, 5.2% added fat). The diets were: hay control, HC; hay+flaxseed, HF; silage control, SC; silage+flaxseed, SF. Flaxseed improved ($P < 0.01$) feed conversion ratio and tended to increase body weight gain ($P = 0.10$) and back fat thickness ($P = 0.07$), as assessed by ultrasonography. Compared with hay, silage increased ($P < 0.01$) feed intake, body weight gain, fat thickness ($P = 0.07$) and improved ($P < 0.01$) feed conversion. Subcutaneous fat contained 0.65% omega-3 fatty acids (wt:wt) at arrival, which reached concentrations of 0.69, 0.81, and 0.93% in HF cows, and 0.65, 0.77, and 0.90% in SF cows, after 6 wk, 12 wk, and at slaughter, respectively. In contrast, at these same sampling points, omega-3 fatty acids had decreased in HC and SC cows, to 0.50, 0.47, and 0.43%, and to 0.39, 0.36, and 0.33%, respectively. Flaxseed also improved ($P < 0.01$) wt:wt of conjugated linoleic acids in plasma and fat and resulted in an accumulation of non-conjugated, non-methylene interrupted dienes in fat. This was more pronounced ($P < 0.01$) in cows fed with hay- than with silage-based diet. In summary, a 15% flax supplement in hay- or silage-based diets fed to cows coming off fall pastures increased omega-3 fatty acid concentrations,

which was accompanied by increased concentrations of linolenic acid biohydrogenation intermediates.

Key Words: cull beef cow, flaxseed, omega-3 fatty acids

M159 Effect of finishing system on subcutaneous fat melting point and fatty acid composition. S. K. Duckett*[1], J. P. S. Neel[2], W. S. Swecker[3], J. P. Fontenot[3], and W. Clapham[2], [1]*Clemson University*, *Clemson, SC,* [2]*USDA-ARS*, *Beaver, WV,* [3]*Virginia Tech University*, *Blacksburg*.

Angus-cross steers (n = 69) were used to determine the effect of finishing system on subcutaneous fat melting point and fatty acid composition. Three finishing systems were evaluated: 1) mixed pasture for 134 d [MP], 2) mixed pasture for 93 d and alfalfa for 41 d [AL], or 3) concentrate finishing for 134 d [CONC], in a 2-yr study. Subcutaneous fat samples at the 12th rib were obtained at 24 h postmortem. Melting point was determined using the OptiMelt Automated Melting Point System. Total saturated fatty acid (SFA) and omega-3 fatty acid contents were greater ($P < 0.05$) for AL and MP than CONC. Monounsaturated fatty acid and omega-6 polyunsaturated fatty acid contents were greater ($P < 0.05$) for CONC than AL and MP. The ratio of omega-6 to omega-3 fatty acids was higher for CONC (8.81) than forages (1.64), regardless of forage species grazed. Average temperature for onset point, start of melting point where liquid first appears, was higher ($P < 0.05$) for MP and AL than CONC. Average temperature for clear point, melting point where fat is completely liquid, was higher ($P < 0.05$) for MP and AL than CONC. Melting point was highly, positively correlated with SFA (r = 0.73) and highly, negatively correlated with MUFA (r = −0.78) and omega-6 (r = - 0.60). Prediction equations for s.c. fat melting point included MUFA and SFA contents, and explained 83% or 93% of the variation for AL and MP, respectively. Prediction equations for s.c. fat melting point included omega-3, omega-6 and SFA, and explained 57% of the variation for CONC. Finishing system altered subcutaneous fat composition and melting point. Finishing on forages (MP and AL) increased SFA by 17% and decreased MUFA by 24%, which translated to a higher subcutaneous fat melting point (42.35 vs. 38.64 C).

Key Words: beef, forages, fatty acids

M160 Effects of supplemental dietary lipid sources on fatty acids compositions of *Longissimus* muscle in yearling bulls. E. A. Oliveira*[1], A. A. M. Sampaio[1], W. Henrique[2], B. L. Rosa[1], T. M. Pivaro[1], and A. R. M. Fernandes[3], [1]*FCAV/Unesp*, *Jaboticabal, SP, Brazil*, [2]*APTA*, *São José do Rio Preto, SP, Brazil*, [3]*UFGD*, *Dourados, MS, Brazil*.

The aim of this study was to improve fatty acids composition of bovine *Longissimus* muscle by adding different sources of fat in the diet of Nellore yearling bulls. Thirty-five animals, averaging 18 mo of age (402.69 ± 14.90Kg), were housed during 96 d in individual pens at Jaboticabal Campus of São Paulo State University. Five different diets were tested: control (without oil), soybean oil (3.8% of diet), rumen-protected soybean oil (4.5% of diet), linseed oil (3.8% of diet) and rumen-protected linseed oil (4.5% of diet). All diets included sugarcane as exclusive roughage source. The experiment was a randomized block design with 7 blocks and 5 replications and means were compared by orthogonal contrasts. After 24 h of carcass cooling process, *Longissimus thoracis* (<b < LT) muscle sections were removed at the 12–13th rib level and submitted to lyophilization, lipid extraction and methylation. Samples were analyzed by gas chromatography. The LT of animals fed the oil-supplemented diets had higher ($P < 0.05$) levels of conjugated linoleic (CLA) (0.72% vs 0.35%) and linolenic acid (LLA) (0.66% vs. 0.32%) and lower levels ($P < 0.05$) of saturated fatty acid. Among oil-supplemented diets, there was no ($P > 0.05$) difference for CLA when comparing soybean and linseed oil (0.77% and 0.67%, respectively). However, the LT of animals fed linseed oil had higher ($P < 0.05$) levels of LLA (1.21% vs. 0.44%). There was no ($P > 0.05$) difference between control and other diets concerning saturated and unsaturated fatty acids concentrations. Omega6:omega3 ratio was lower ($P < 0.05$) and closer to ideal for linseed oil when compared with the other diets (2.36 vs. 3.77, respectively). Soybean or linseed oils supplementation to feedlot cattle provides better fatty acids composition and improve their relationship, leading to a healthier and more balanced meat, independently of being protected or not.

Key Words: beef, fatty acids, health

M161 Fatty acid profile of intramuscular fat of young bulls grazing tropical pasture and supplemented with different strategies. J. Cavali[1], P. V. R. Paulino*[1], I. M. Oliveira[1], M. M. C. Silva[1], H. J. Fernandes[2], R. Mezzomo[1], J. F. H. Rodrigues[1], É. E. L. Valente[1], S. F. Reis[1], and L. A. M. Gomide[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*Universidade Estadual do Mato Grosso do Sul*, *Aquidauana, MS, Brazil*.

Grass fed beef gathers desirable nutritional characteristics that are valuable to the final consumer. The objective of this study was to evaluate the fatty acid profile of intramuscular fat (IMF) of young bulls grazing *Brachiaria decumbens* pastures and supplemented with different strategies. Fifty 2 Nellore young bulls were used, being distributed, in a completely randomized design, into 4 treatments (13 replicates): control, when the animals had free access only to mineral mixture throughout the experiment; and 3 protein supplementation strategies, when the animals were creep-fed with supplements containing 10, 20 and 30% CP, respectively. After weaning the creep-fed animals received isonitrogenous supplements designed to supply 0.50 and 0.66 g of CP/day during growing and finishing, respectively. After 580 d, the animals were slaughtered and a sample of the *Longissimus dorsi* was taken at the level of the last rib and the fatty acid profile of the IMF was determined by gas chromatography. IMF of bulls of the control group (pasture + mineral mixture) had greater ($P < 0.10$) contents of palmitic (C16:0), oleic (C18:1), linoleic (C18:3) and eicosapentaenoic acid (EPA), more monounsaturated fatty acids (MUFA) and lower estearic acid (C18:0) when compared with the other groups, but did not differ ($P > 0.10$) from the supplemented counterparts regarding total saturated fatty acids (SFA) content. Protein supplementation improved ($P < 0.10$) the amount of polyunsaturated fatty acids (PUFA) and n-6/n-3 ratio of the IMF of the animals, when compared with the control group. However, the MUFA and EPA content of the IMF of the supplemented animals were lower ($P < 0.10$) than the values observed in the animals that received only mineral mixture. Different strategies of protein supplementation of young bulls grazing tropical pastures can modify the fatty acid profile of intramuscular fat and thus be used as a tool to produce beef that meets specific niche markets.

Key Words: beef cattle, pasture, protein supplementation

M162 How do n-3 fatty acids affect human perception of ground beef? T. Jiang*, J. R. Busboom, M. L. Nelson, and R. Mengarelli, *Washington State University*, *Pullman*.

Our objective was to determine the impact of increasing levels of Eicosapentaenoic acid (EPA; C20:5n-3) and Docosahexaenoic acid (DHA; C22:6n-3) on beef palatability. Two commercial supplements of EPA and DHA (GNC DHA 250 with DHA: EPA = 2.5:1 and GNC Triple Strength Fish Oil with EPA: DHA = 2.6:1) were added to patties

(176.2 ± 3.76 g) made from 85% lean ground beef with different levels (0, 0.3, 0.4, 0.5, 0.6, 0.7, and 1% as-is). Olive oil was added so that a total of 1% lipids were added to all treatments. A control treatment was prepared with no fatty acid supplement or olive oil. Patties were aged for 72 h at 3°C, frozen at –20°C and vacuum packaged. A 9-member trained sensory panel was conducted to evaluate beef aroma, off-aroma, beef flavor, off-flavor, tenderness, juiciness, and overall acceptability of ground beef on a 10-cm unstructured line scale labeled at each end. Six tasting sessions were conducted with 6 patties served in each session. Patties were assigned across the sessions in a randomized complete block design, with the first 3 sessions as block 1 and the next 3 as block 2. Control and 0% supplement (1% olive oil) patties were served in each session. Results indicated that increasing levels of DHA did not impact ground beef palatability. Similarly, increasing levels of EPA had no impacts on most sensory attributes. However, off-aroma and off-flavor scores vs. EPA levels fit a non-linear plateau model ($P < 0.0001$). The slopes (β_1) of the models for off-aroma and off-flavor were 4.4 ± 0.62 and 9.0 ± 0.95, respectively. The maximum scores (D) were 1.9 ± 0.35 and 4.2 ± 0.53 for off-aroma and off-flavor, respectively. In conclusion, n-3 long chain polyunsaturated fatty acid EPA had a greater negative impact on ground beef palatability than DHA. Furthermore, the panelists seemed to be more sensitive to EPA in off-flavor perception than off-aroma.

Key Words: EPA, DHA, ground beef palatability

M163 Geometrical isomers of octadecenoic, octadecadienoic and octadecatrienoic acids from subcutaneous fat of British or Continental versus Nellore crossbred cattle slaughtered at different end points. R. Mello*[1], A. C. de Queiroz[2], F. D. de Resende[3], D. P. D. Lanna[4], M. H. de Faria[3], and E. da Costa Eifert[4], [1]*Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [3]*Agência Paulista de Tecnologia dos Agronegócios*, *Colina, SP, Brazil*, [4]*Universidade de São Paulo – Escola Superior de Agricultura 'Luiz de Queiroz'*, *Piracicaba, SP, Brazil*.

The study was carried out to evaluate the effect of genetic group (GG) and slaughter weight on C18:1, C18:2 and C18:3 fatty acids isomers in subcutaneous fat sampled at the 13th rib. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) at 447.7 ± 5.8 kg of shrunk body weight (SBW) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) at 444.3 ± 6.5 kg of SBW were used. The animals were in compensatory growth. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of SBW. A completely randomized experimental design in a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. Data were analyzed with SAS software using initial SBW as a covariate. The backfat thickness increased ($P < 0.05$) as slaughter weight rised, being 2.1, 2.7 and 4.4 mm, respectively, for animals slaughtered at 480, 520 and 560 kg. The 1/2 RA 1/2 N young bulls had a higher ($P < 0.05$) *cis*-12 C18:1, *cis*-9,12 C18:2, and *cis*-9,12,15 C18:3 levels than 1/2 BA 1/2 N young bulls. As the slaughter weight rised the *cis*-15, *trans*-9, *trans*-11, and *trans*-12 C18:1 levels decreased ($P < 0.05$); while *cis*-11 C18:1 level increased. The *trans*-11 *cis*-15 C18:2, *cis*-9 *trans*-11 C18:2 (CLA), and *cis*-6,9,12 C18:3 levels also decreased ($P < 0.05$) as the slaughter weight increased. The interaction between GG and SW was significant ($P > 0.05$) for *cis*-9, *cis*-13 and *trans*-16 C18:1 levels. The 1/2 RA 1/2 N young bulls slaughtered at 520 kg had lower *cis*-9 and *cis*-13 C18:1 levels and the 1/2 RA 1/2 N slaughtered at 560 kg had lower *trans*-16 C18:1 level than others. Thus, crossbred F1 Red Angus × Nellore young bulls had higher *cis*-9,12,15 C18:3 ($\alpha = n$-3) level in the subcutaneous fat (0.41) than F1 Blonde D′Aquitaine × Nellore young bulls (0.37). Animals slaughtered at lighter weights had higher *cis*-9 *trans*-11 C18:2 (CLA, 0.50) and *cis*-6,9,12 C18:3 ($\gamma = n$-6, 0.13) levels in the subcutaneous fat than animals slaughtered at heavier weights (0.32 and 0.10 respectively).

Key Words: conjugated linoleic acid, fatty acids, *trans* stereoisomer

M164 Fatty acid profiles of subcutaneous adipose tissue from cross young bulls produced by different genetic groups sires and slaughtered with distinct weights. R. Mello*[1], A. C. de Queiroz[2], F. Dutra de Resende[3], D. P. D. Lanna[4], M. H. de Faria[3], and E. da Costa Eifert[4], [1]*Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [3]*Agência Paulista de Tecnologia dos Agronegócios*, *Colina, SP, Brazil*, [4]*Universidade de São Paulo – Escola Superior de Agricultura 'Luiz de Queiroz'*, *Piracicaba, SP, Brazil*.

In the present study the aim was to investigate fatty acid profiles of subcutaneous adipose tissue from *Longissimus dorsi* muscle at 13th rib of crossbred bulls at different body masses. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) at 447.7 ± 5.8 kg of shrunk body weight (SBW) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) at 444.3 ± 6.5 kg of SBW were used. The animals were in compensatory growth. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of SBW. A completely randomized experimental design in a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. Data were analyzed with SAS software using initial SBW as a covariate. The table below shows the least squares means of dependent variables. The backfat thickness increased ($P < 0.05$) as slaughter weight raised, being 2.1, 2.7 and 4.4 mm, respectively, for animals slaughtered at 480, 520 and 560 kg. The 1/2 RA 1/2 N young bulls had a higher ($P < 0.05$) content of long-chain fatty acids, polyunsaturated fatty acids and *n*-6 than 1/2 BA 1/2 N young bulls. On the other hand, the 1/2 BA 1/2 N young bulls had a higher ($P < 0.05$) content of medium-chain fatty acids than 1/2 RA 1/2 N young bulls. As the slaughter weight raised the content of odd-chain fatty acids decreased ($P < 0.05$); whereas the animals slaughtered at 520 kg had a smaller ($P < 0.05$) content of *n*-3. The interaction between genetic group (GG) and slaughter weight (SW) was significant ($P > 0.05$) for saturated fatty acids and monounsaturated fatty acids (data not shown). The 1/2 BA 1/2 N young bulls slaughtered at 520 kg had smaller content of saturated fatty acids, while 1/2 RA 1/2 N young bulls slaughtered at 520 kg had smaller content of monounsaturated fatty acids than others. Thereby, crossbred F1 Red Angus × Nellore young bulls and lighter animals had better fatty acid profiles in the subcutaneous fat than F1 Blonde D′Aquitaine × Nellore young bulls and heavier animals.

Table 1. Least squares means

	Genetic Group		Slaughter Weight		
Fatty acids	½ RA ½ N	½ BA ½ N	480	520	560
Short-chain	0.1	0.1	0.1	0.1	0.1
Medium-chain	41.0^{B}	43.4^{A}	42.7	42.9	41.0
Long-chain	56.4^{A}	54.0^{B}	54.4	54.6	56.6
Very long-chain	0.1	0.1	0.1	0.1	0.1
Odd-chain	2.3	2.4	2.7^{a}	2.2^{b}	2.2^{b}
Saturated	49.2	49.3	50.0	49.1	48.6
Monounsaturated	47.3	47.7	46.9	47.6	48.1
Polyunsaturated	3.4^{A}	3.0^{B}	3.1	3.3	3.3
n-3	0.8	0.7	0.8^{a}	0.7^{b}	0.8^{a}
n-6	3.0^{A}	2.5^{B}	2.5	2.8	2.8

Within a row, means followed by different capital and small letters differ ($P < 0.05$), respectively, among GG and SW by Tukey test.

Key Words: beef cattle, feedlot, *Longissimus dorsi*

M165 Meat quality of Nellore heifers finished at pasture, in tropical conditions, supplemented with crushed sunflower. S. L. N. Cerilo*, R. H. de Tonissi e Buschinelli de Goes, H. L. Lima, A. R. M. Fernandes, K. A. de Souza, D. de Faria Pereira, K. C. da Silva Brabes, and A. F. Marquez, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

Meat quality traits of Nellore Heifers finished on pasture of *Brachiaria humidicola* and fed crushed sunflower, in partial substitution of soybean meal, were evaluated. Twenty animals, slaughtered at a 378.5 kg BW were used. The supplements contained 20% CP and was composed of corn, soybean meal and minerals. The soybean meal was replaced by crushed sunflower in the proportions of 0, 20, 40 and 60% and its lipid content was 2.5, 4.7, 7.0 and 9.2%, respectively. The supplement was offered at 0.8% BW/animal per d, which corresponded to 3.31, 3.35, 3.28 and 3.25 kg of supplement/d. The experimental design was completely randomized and mean values were compared using the Tukey's test at $P < 0.05$. After slaughter the carcasses were cooled for 20 h. Subsequently, from the left carcass at the 12nd to 13rd rib level, a 2.5 cm thick LM sample was removed and pH, L*a*b*-values, water holding capacity, cooking loss, and shear force were determined. There was no ($P > 0.05$) effect of replacing soybean meal by crushed sunflower for pH, L*, a* and b* values, water holding capacity, cooking loss and shear force. The mean values were for pH = 5.59, L* = 37.48, a* = 18.42, b* = 10.01, water holding capacity = 65.86%, cooking loss = 31.94% and shear force = 7.70 kg/cm^2. Partial substitution of soybean meal by crushed sunflower does not alter the qualitative characteristics of meat from Nellore heifers finished on pasture under tropical conditions.

Key Words: shear force, luminosity, pH

M166 *Longissimus dorsi* muscle fiber profile in young bulls grazing tropical pasture and supplemented with different strategies. J. Cavali*[1], P. V. R. Paulino[1], I. Lage[2], C. A. Neves[1], M. V. Santos[1], M. F. Paulino[1], R. Justino[3], J. F. H. Rodrigues[4], and D. Melo[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*Universidade Federal dos Vales do Jequitinhonha e Mucuri*, *Diamantina, MG, Brazil*, [3]*JBS Friboi*, *Barretos, SP, Brazil*, [4]*Universidade Estadual Paulista*, *Jaboticabal, SP, Brazil*.

The objective of this study was to evaluate the muscle fiber profile of young bulls grazing *Brachiaria decumbens* pastures and supplemented with different strategies. Fifty 2 Nellore young bulls were used, being distributed, in a completely randomized design, into 4 treatments (13 replicates): control, when the animals had free access only to mineral mixture throughout the experiment; and 3 protein supplementation strategies (T1, T2 and T3), when the animals were creep-fed with supplements containing 10, 20 and 30% crude protein (CP), respectively. After weaning the creep-fed animals received isonitrogenous supplements designed to supply 0.50 and 0.66 g of CP/day during the growing and finishing phases, respectively. The supplements used during growing and finishing contained different urea levels: 0; 4.0; 8.0 and 0; 3.0; 6.0% for T1, T2 and T3 respectively. After 580 d, the animals were slaughtered and a sample of LD muscle was taken at the last rib, frozen at −80°C. Later on histological cuts were obtained to assess the muscle fiber profile. T2 and T3 supplementation strategy elicited an increase ($P < 0.10$) in the frequency of IIB muscle fiber (61.00 and 59.80%) when compared with control and T1 treatments (54.00 and 56.15%). Probably, a modulation of intermediate muscle fibers (type IIA) into glycolitic fibers (IIB) occurred, as the increase in the proportion of IIB muscle fiber observed in T1 and T2 treatments was accompanied by a decrease ($P < 0.10$) in the frequency of IIA muscle fibers (31.17a; 31.03a; 27.57b and 25.32% for control, T1, T2 and T3 treatments, respectively). The frequency of type I muscle fiber was equal ($P > 0.10$) among treatments (19.50%). Probably, the protein supplementation strategies T2 and T3 might have provided a higher energy intake by the animals, leading to muscle modulation into more glycolitic fibers. The change observed in muscle fiber metabolism due to the different protein supplementation strategies can alter important beef quality attributes. However, it still has to be investigated in beef cattle grazing tropical pastures.

Key Words: muscle fiber, protein supplementation, tropical grass

M167 Effect of concentrate- vs. forage-based finishing diet on carcass traits, beef palatability, and color stability of longissimus muscle from Angus heifers. A. J. Garmyn*, D. L. VanOverbeke, R. G. Mateescu, and G. G. Hilton, *Oklahoma State University*, *Stillwater*.

The objective of the study was to determine the effect of finishing diet on carcass traits, beef palatability, and color stability of longissimus from Angus heifers. Half-siblings were obtained from a herd involved in selection for increased intramuscular fat, ribeye area, and retail product, and decreased back fat and alternatively assigned to a forage- or concentrate-based finishing diet. Longissimus muscle samples (n = 155) were obtained and fabricated into steaks for trained sensory panel, Warner-Bratzler Shear force (WBS), thiobarbituric acid reactive substances (TBARS), and simulated retail display. ANOVA was conducted through the MIXED procedure of SAS using harvest age as a covariate. Carcasses from heifers finished on concentrate had greater adjusted fat thickness (1.86 vs. 0.87 cm), higher percentage KPH (2.14 vs. 1.35%), higher numerical yield grades (3.38 vs. 2.25), and higher marbling scores (modest 90 vs. traces 70; $P < 0.05$) than forage-finished heifers. There was no difference in longissimus muscle area between diets ($P > 0.05$). Steaks from concentrate-fed heifers had lower WBS values (3.67 vs. 5.05 kg), higher tenderness ratings, higher beef flavor intensity, lower grassy/cowy flavor intensity, and higher painty/fishy flavor intensity than steaks from forage-fed heifers ($P < 0.05$). There was no difference ($P > 0.05$) between diets for initial or sustained juiciness and livery/metallic flavor intensity. Initial TBARS were higher ($P < 0.05$) in steaks from concentrate-fed heifers when compared with grass-fed heifers, but TBARS were not different ($P > 0.05$) between diets following 7 d in retail display. Diet did not have an effect on instrumental or subjective color, except L* values (0 = black and 100 = white) were higher (38.36 vs. 32.25; $P < 0.05$) for steaks from concentrate-fed heifers than from forage-fed heifers. This study points to several disadvantages of forage-based finishing diets in relation to beef palatability, especially tenderness and beef flavor.

Key Words: beef palatability, color stability, diet

M168 Does creep feed and backgrounding energy source affect lifetime growth performance and carcass characteristics of nursing calves pastured on annual ryegrass? M. S. Gadberry*[1], P. A. Beck[2], B. Barham[1], W. Whitworth[3], and J. Apple[4], [1]*University of Arkansas*, *Little Rock*, [2]*University of Arkansas*, *Hope*, [3]*University of Arkansas*, *Monticello*, [4]*University of Arkansas*, *Fayetteville*.

Angus sired, fall born steer (n = 36) and heifer (n = 24) calves (BW = 153 kg) with their dams were randomly assigned to 1 of 3 creep feeding treatment pastures (2 pastures/treatment) 93 d before weaning. Annual ryegrass (*Lolium multiflorum*) pastures were stocked at 2.47

cow/calf pair per ha. Treatments included no creep (NC), soybean hull (SC) based creep, or corn (CC) based creep offered at 1% BW (as-fed). After weaning, calves were allocated to 1 of 12 backgrounding pens receiving either a soybean hull or corn based diet for 63 d. Following the backgrounding phase, calves were fed a common finishing diet for 133 d. Pasture and pen were considered the experimental units. Post-weaning data were analyzed as a split-plot with pre-weaning treatments as the whole plot and backgrounding treatments and pre-weaning by backgrounding interaction as the subplot. Creep feed did not affect ADG pre-weaning ($P = 0.41$). Pre-weaning ADG averaged 1.3, 1.4, and 1.4 kg/d for NC, SC, and CC, respectively. Backgrounding BW gain was not affected by pre-weaning diet ($P = 0.14$), backgrounding diet ($P = 0.38$), or their interaction ($P = 0.54$). Backgrounding ADG averaged 1.2 kg/d among treatments. Over the 133 d finishing period, calves averaged 1.8 kg/d BW gain which was not affected by pre-weaning diet ($P = 0.88$), backgrounding diet ($P = 0.52$), or their interaction ($P = 0.86$). Calves were harvested with an average back fat thickness of 1.6 cm. Hot carcass weight (339 kg), back fat thickness, calculated yield grade (3.6), and percentage USDA Choice (56.4%) were not significantly affected by pre-weaning diet, backgrounding diet, or their interaction. These results suggest that neither creep feed nor source of energy in creep or backgrounding diets affect lifetime performance when calves are developed on a high plain of nutrition beginning pre-weaning.

Key Words: creep feed, backgrounding, carcass characteristics

M169 Does creep feed and backgrounding energy source affect lifetime growth performance and carcass characteristics of nursing calves pastured on improved warm-season grasses? B. Barham*[1], P. A. Beck[2], M. S. Gadberry[1], W. Whitworth[3], and J. Apple[4], [1]*University of Arkansas*, *Little Rock*, [2]*University of Arkansas*, *Hope*, [3]*University of Arkansas*, *Monticello*, [4]*University of Arkansas*, *Fayetteville*.

Angus sired, spring born steer (n = 78) and heifer (n = 42) calves (BW = 141 kg) with their dams were randomly assigned to 1 of 3 creep feeding treatment pastures (2 pastures/treatment) 90 d before weaning. Mixed warm-season, grass pastures were stocked at 2.47 cow/calf pair per ha. Treatments included no creep (NC), soybean hull (SC) based creep, or corn (CC) based creep offered at 1% BW, as-fed basis. After weaning, calves were allocated to 1 of 12 backgrounding pens receiving either a soybean hull or corn based diet for 45 d. Following the backgrounding phase, calves were fed a common finishing diet for either 147 or 183 d. Pasture and pen were considered the experimental units. Post-weaning data were analyzed as a split-plot with pre-weaning treatments as the whole plot and backgrounding treatment and pre-weaning by backgrounding interaction as the subplot. Creep fed calves gained 0.3 kg/d more than NC calves ($P = 0.002$); however, there was no difference between SC and CC ($P = 0.28$). Creep feed conversion averaged 5.2 kg feed per kg additional BW gain. Average daily gain during the backgrounding phase was not affected by creep diet ($P = 0.45$), backgrounding diet ($P = 0.93$), or their interaction ($P = 0.46$). At feedlot entry, creep fed calves continued to weigh more than NC calves ($P = 0.03$); however, by the conclusion of the finishing phase, there were no significant treatment effects on finished BW. Calves were finished at an average back fat thickness of 1.4 cm after an average 173 d finishing period. Hot carcass weight (319 kg), days on feed, back fat thickness, calculated yield grade (3.7), and percentage USDA Choice (73.6%) were not significantly affected by pre-weaning diet, backgrounding diet, or their interaction. These results suggest that improvements in BW gain may occur with calves offered creep feed during summer months; however, the benefit of additional BW may diminish by the end of feedlot finishing. In addition, creep feeding showed no beneficial effect on carcass characteristics.

Key Words: creep feed, backgrounding, carcass characteristics

M170 Genetic group and slaughter weight influence on meat quality of feedlot cattle. R. Mello*[1], F. D. de Resende[2], A. C. de Queiroz[3], M. H. de Faria[2], R. A. Possenti[2], and G. F. Alleoni[2], [1]*Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Agência Paulista de Tecnologia dos Agronegócios*, *Colina, SP, Brazil*, [3]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*.

The purpose of this study was to investigate the genetic group and slaughter weight influence on meat quality of the cattle. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) were used. The young bulls were finished in a feedlot and slaughtered at 480, 520 and 560 kg of shrunk body weight (SBW). A completely randomized experimental design of a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. The animals were slaughtered in a commercial slaughter-house. Data were analyzed with SAS software using initial SBW as a covariate. The table below shows the least squares means of pH at 24 h after slaughter in the *Longissimus dorsi* muscle (LM), tenderness (WBSF) and cooking loss in the LM at 12th rib, and chemical composition (humidity, ash, crude protein, crude fat) in the LM at 13th rib. There was no effect ($P > 0.05$) of genetic group (GG) and the interaction between GG and slaughter weight (SW) was not significant ($P > 0.05$) for all measured traits. The tenderness, cooking loss, and chemical composition (humidity, ash, crude protein, crude fat) of meat were similar for all treatments. On the other hand, as the slaughter weight raised the pH 24 h increased ($P < 0.05$). Therefore, finishing of crossbred F1 Blonde D′Aquitaine or Red Angus versus Nellore young bulls on feedlot and slaughtered at 480, 520 and 560 kg produced meat with similar and suitable quality.

Table 1. Least squares means

	Genetic Group (GG)		Slaughter Weight (SW)		
	½ RA ½ N	½ BA ½ N	480	520	560
pH 24 hours	5.8	5.8	5.7^{c}	5.8^{b}	5.9^{a}
Shear (WBSF), kgf/cm ^{2}	4.41	4.72	4.88	4.47	4.35
Cooking loss, %	26.0	24.3	23.3	25.0	27.2
Humidity, %	75.3	74.5	75.4	75.1	74.1
Ashes, %	1.0	1.0	0.9	1.0	1.0
Crude protein, %	19.5	20.0	19.2	20.0	20.1
Crude fat, %	4.3	4.5	4.4	3.9	4.8

Within a row, means followed by different capital and small letters differ (P<0.05), respectively, among GG and SW by Tukey test.

Key Words: chemical composition, *Longissimus dorsi*, young bulls

M171 Animal health effects on carcass quality. T. M. Jeske*, R. J. Maddock, and K. R. Carlin, *North Dakota State University*, *Fargo*.

The objective of this study was to investigate the effects of medical treatment and lung condemnations on carcass quality of feedlot cattle. Steers and heifers (n = 1974) were individually identified in one of 3 cooperating feedlots, and all health issues and treatments were noted. When cattle reached market weight, they were slaughtered at one location and USDA yield and quality grade was obtained for all carcasses. In addition, complete carcass traits were recorded from 276 head. Data were

analyzed using ANOVA to compare between carcasses with or without condemned lungs, and to compare between treated and untreated. Difference in grading percentages were evaluated using chi-squared. Lung condemnations were noted for 1297 carcasses at slaughter, of which 109 lungs (8.4%) were condemned for some defect related to the heart, lung or trachea. USDA Quality grades of cattle with condemned lungs were 0% Prime, 69.7% Choice, 27.5% Select and 2.7% as No Rolls. Complete carcass data on 38 of the carcasses with condemned lungs found an average ribeye area of 80 cm^2 (SD = 3.4) marbling score of 459 (Sm59) (SD = 28), fat thickness of 1.26 cm (SD = 0.12). Cattle with lungs not condemned (n = 1185) had a USDA Quality grade breakdown with 1% Prime, 68% Choice, 28% Select and 2.1% as No Rolls. Average carcass data for carcasses without lung condemnations was a ribeye area of 83 cm^2 (SD = 4.1) marbling score of 437 (Sm37) (SD = 41) and a fat thickness of 1.17 cm (SD = 0.16). No significant differences in carcass traits were noted between carcasses with or without condemned lungs. Cattle treated at the feedyard consisted of 84 out of 1974 head or 4.25%. USDA Quality grades for treated cattle were 0% Prime, 56% Choice, 37% Select and 7% as No Roll, and an average USDA Yield grade of 2.54. Comparatively, overall carcass data was 1.1% Prime, 67.3% Choice, 29.5% Select, 2% as No Rolls, and average USDA Yield grade was 2.51. A strong trend ($P = 0.08$) was found for treated cattle to have inferior USDA quality grading percentages. These data indicate that health status may be related to USDA Quality grade of steer and heifers.

Key Words: beef, health, carcass quality

M172 Effect of garlic and onion on the thiobarbituric acid reactive substances (TBARS), volatile compounds and sensory evaluations of irradiated cooked ground beef. H. S. Yang*, G. D. Kim, K. Y. Seo, E. Y. Jung, and S. T. Joo, *Division of Applied Life Science (BK21 Program), Graduate School of Gyeongsang National University, Jinju, Gyeongnam 660-701, Republic of Korea.*

The effects of adding garlic and onion on the lipid oxidation, volatile compounds, and sensory evaluations of irradiated ground beef patties were investigated during storage. Beef rounds were ground, added with none (control), 0.1% garlic or 0.5% onion, packaged in oxygen permeable bags, irradiated at 0 or 2.5 kGy, and cooked to an internal temperature of 75Â°C. Data was analyzed by the procedures of generalized linear model (GLM) of SAS (2000). SNK (Student-Newman-Keuls) multiple-range test was used to compare the mean values of treatments. Differences in sensory values were compared using the Tukey's honestly significant differences. Irradiated ground beef had significantly higher TBARS values than nonirradiated ones regardless control and garlic treatment at 3 d. However, at d 5, the TBARS values of irradiated ground beef with 0.5% onion (0.78) sample was lower than nonirradiated control (1.04 mg malonaldehyde/kg meat) ($P < 0.05$). Addition of garlic greatly increased the amounts of all sulfur compounds. In control beef, carbon disulfide was not detected, but methanethiol, dimethyl disulfide, and dimethyl trisulfide were newly produced after irradiation. During storage, the amounts of all S-compounds in ground beef decreased rapidly, and carbon disulfide, 2-propen-1-thiol, 3,3-thiobis-1-propene, methyl 2-propenyl disulfide, dimethyl trisulfide and di-2-propenyl disulfide were not detected from the irradiated ground beef with 0.5% onion treatment after 3 d storage and no S-compounds were found in both onion alone and control ground beef after 5 d storage. Although, addition of garlic produced large amounts of S-compounds, the intensity of irradiation aroma and flavor in irradiated cooked ground beef with garlic or onion was similar to that of the nonirradiated control ($P > 0.05$). Therefore, addition of 0.5% onion or 0.1% garlic is recommended to mask or prevent off-odor in irradiated ground beef.

Key Words: irradiated, ground beef, garlic and onion

Graduate Student Poster Competition: National ADSA Dairy Foods Poster

M173 Angiostatin-like peptides in milk: Potential development for dairy products capable of cancer prevention. E. Stefanutti* and R. Jiménez-Flores, *California Polytechnic State University*, *San Luis Obispo*.

Angiogenesis, the development of new blood vessels from pre-existing vascularization, represents one of cancer's hallmarks. Blood supply is essential for a tumor to progress toward a malignant condition since this allows the delivery of nutrients and oxygen necessary to support cancerous cells' growth as well as entrance into the circulation causing metastasis to arise. Study on angiogenesis inhibitors has shown promising results on animal models. Blocking cancerous cells' blood access resulted in a reduction on primary tumor size and number of metastatic colonies. One of the peptides that showed interesting results on this study was angiostatin, the internal fragment of the fibrinolytic enzyme plasminogen in blood. It is well known that bovine plasminogen gets transferred into milk during lactation. The objective of this research was to investigate enzymes capable of releasing the antiangiogenic peptide from bovine plasminogen and compare the anticancer activity of the fragment with that of human angiostatin. We tested enzymes such as *Lactobacillus* (*L. casei*, *L. reuteri*, *L. acidophilus*) and *Bacillus* (*B. subtilis*, *B. cereus*, *B. coagulans*) originated proteases, *Bacillus polymyxa* metalloprotease dispase as well as elastase. Techniques such as SDS-PAGE, column chromatography, MALDI-TOF, and Western blot were utilized. After hydrolysis, results from electrophoresis showed bands in the molecular range of 37 kDa, which were confirmed through sequence analysis to belong to the kringle 1–4 region of plasminogen. Test for anticancer activity on melanoma and colon malignant cells, demonstrated a reduced proliferation of cancerous cells for samples treated with angiostatin and plasminogen; interestingly highest inhibition was obtained for treatments from bovine sources. We believe that these results represent a starting point for future development of novel dairy products capable of cancer prevention.

Key Words: plasminogen, angiostatin, proteases

M174 The effect of different inulin types on the formation of rennet-induced gels. A. Foo*, A. R. Hill, and M. Corredig, *University of Guelph*, *Guelph, Ontario, Canada*.

The objective of this research was to determine the effect of the prebiotic fiber inulin on rennet induced gelation of skim milk, and to determine the potential for utilization of inulin in rennet cheese applications. Four chicory inulin types (CLR, ST, XL, and HPX) with different degree of polymerization (DP) were studied. Inulin was added to untreated milk at concentration up to 3% (w/v) and the rennet-induced gelation was followed using dynamic oscillatory rheology and confocal microscopy. Experiments were performed in triplicates and differences were determined statistically using 2-way ANOVA and Tukey ($P < 0.05$). Gelation time, gel stiffness and strain at break changed depending on type and concentration of inulin. XL, and HPX (high DP molecules) significantly increased gelation time at 2 and 3% compared with the control sample. All inulin-fortified gels were stiffer and were less brittle than control milk gels. Rennet-induced gels containing 0.02% FITC were observed after 3h incubation at 30°C with confocal laser scanning microscope, and results showed that type and concentration of inulin affected the gel structure formation. Low DP inulins (CLR and ST) produced similar structures as control, while high DP inulins (XL and HPX) produced more branched structures. The degree of branching seemed to increase with concentration. Syneresis was tested after gel formation at 3h. CLR and ST fortified gels had almost identical syneresis rates as control, while XL and HPX fortified gels showed slower syneresis rates, especially at 3% inulin concentration. A modified HPLC method using an evaporative light scattering detector was used to analyze the amount of inulin present in the whey. Majority of CLR and ST (~90 ± 2–4%) were loss into the whey, while XL and HPX retained ~50 ± 2–4% in gels. The results indicated that high DP inulins were more retained in the gel than low DP inulins, but they also affected the gelling properties of caseins and network formation.

Key Words: inulin, rennet curd, rheological properties

M175 Impact of temperature and fat content on bleaching of liquid whey. M. A. D. Listiyani*[1], R. E. Campbell[1], R. E. Miracle[1], D. M. Barbano[2], and M. A. Drake[1], [1]*North Carolina State University*, *Raleigh,* [2]*Cornell University*, *Ithaca, NY*.

The use of whey protein as an ingredient in foods and beverages is increasing, and thus demands for colorless and mild tasting whey protein are also rising. Bleaching is commonly applied to fluid colored cheese whey to decrease color, and different temperatures and bleach concentrations are applied. The objectives of this study were to compare the effects of hot and cold bleaching and the point of bleaching (before and after fat separation) on bleaching efficacy and volatile components of liquid Cheddar whey. Liquid colored Cheddar whey was produced in triplicate and pasteurized. Part of the whey was collected (no separation, NSE) and the rest was subjected to fat separation (FSE). NSE and FSE whey were then subdivided and bleaching treatments (benzoyl peroxide (BPO) 50 or 100 mg/kg and hydrogen peroxide (HP) 250 or 500 mg/kg) at 68C for 30 min or 4C for 16 h were applied. Control NSE and FSE with no added bleach were also subjected to each time temperature combination. Volatile compounds from wheys were evaluated by gas chromatography mass spectrometry (GCMS) and norbixin (annatto) was extracted and quantified to compare bleaching efficacy. Proximate analysis, including total solids, protein, and fat content were also conducted. Liquid whey subjected to hot bleaching at both concentrations of HP or 100 mg/kg BPO had significantly higher lipid oxidation products (aldehydes) compared with unbleached wheys, 50 mg/kg BPO hot-bleached whey, or cold-bleached wheys. Fat separation had no impact on the relative abundance of volatile lipid oxidation products ($P > 0.05$). Wheys bleached with BPO had lower norbixin recovery compared with wheys bleached with HP ($P < 0.05$). HP bleaching efficacy was decreased at 4C compared with 68C ($P < 0.05$), BPO bleaching efficacy was not impacted by temperature ($P > 0.05$). These results suggest that fat separation has no impact on bleaching efficacy or lipid oxidation and that hot bleaching may result in increased lipid oxidation in fluid whey.

Key Words: whey, bleach, flavor

M176 Bleaching liquid Cheddar whey using ultraviolet radiation. E. J. Kang* and M. A. Drake, *North Carolina State University*, *Raleigh*.

Two of the desirable attributes of whey protein (WP) are a neutral color and bland flavor. The residual annatto colorant from Cheddar cheese production, therefore, has to be removed by bleaching. Currently, in the United States, hydrogen peroxide and benzoyl peroxide are the only bleaching agents approved to bleach colored whey. Recent studies have demonstrated that peroxide bleaching can negatively impact WP flavor.

Alternative bleaching methods may be valuable to the dairy industry. The objective of this study was to investigate the efficacy of UV radiation on bleaching of liquid Cheddar whey. Fluid colored Cheddar whey was manufactured on duplicate occasions. Following pasteurization and fat separation, whey was subjected to UV radiation for 30, 60, 90 or 120 min or cooled with no bleaching (control). The UV reactor consisted of a stainless steel feed tank (4 L), peristaltic pump, and a UV reactor. A 385 mm length low pressure mercury lamp was enclosed in a 24 mm diameter glass tube inside the stainless steel UV reactor. This UV reactor had a 151 mL working volume. Liquid whey circulated through the UV reactor, back into the feed tank and then re-circulated while the feed tank was held at 60°C. Wheys were then subjected to norbixin extraction and quantitation to measure bleaching efficacy. Control Cheddar whey with no UV treatment had 4.12 ppm of norbixin. Whey exposed to UV radiation for 30, 60, 90 or 120 min had 0.65ppm, 0.39ppm, 0.52ppm, and 0.37ppm norbixin, respectively. Norbixin decreased ($P < 0.05$) compared with control whey when exposed to UV light for 30 min; but increasing time up to 2 h did not increase the bleaching effect ($P > 0.05$). Overall norbixin concentration in fluid whey was reduced 84~91% when treated with UV radiation. UV radiation may be an alternative to peroxide bleaching of fluid whey.

Key Words: UV radiation, liquid whey, bleach

M177 Development and analysis of a dairy-based nutrient dense gel food rich in milk bioactives. M. Cleveland* and R. Jiménez-Flores, *California Polytechnic State University*, *San Luis Obispo.*

Milk products are a rich source of nutrients and bioactive compounds beneficial to human health. Some of these include immunoglobulins, phospholipids, casein and whey proteins and peptides, and components of the milk fat globule membrane (MFGM). These products although originally in milk, can be found in higher concentrations in other products, such as colostrum, buttermilk, and whey protein powders. Addition of ingredients such as probiotics add additional value and are apt to be easily incorporated into a dairy system due to their natural residence in milk. The application of dairy ingredients in product development has great potential to create a strong nutrition delivery system with benefits beyond those of fluid milk. Exploitation of dairy ingredients in this way is economical and promotes use of products that still have untapped potential in the marketplace. Development of dairy-based ready-to-eat foods is an excellent way to provide a rich source of the aforementioned milk bioactives. These products would serve as a compact, convenient source of energy and specialized nutrition. The health benefits include immune system development and function, stimulation of gastrointestinal function, and probiotic activity. We have created and biochemically analyzed a dairy-based high nutrient density gel food. It has a pleasing sensory profile, provides significant whey protein, and due to its ingredient profile is an excellent source of milk bioactives. The protein quality and quantity were designed to promote satiety and healthy muscle mass. We have analyzed the gel for immunoglobulin concentration (ELISA), phospholipid content (HPLC method), probiotic survival and binding preference to phospholipids, and basic macronutrient content (FTIR). The results of these assessments show a significantly higher level of milk bioactivity in the gel than in an equivalent gram quantity of fluid milk. From our studies, we conclude that we have created a highly valuable, convenient dairy-based nutrition delivery system with potentially great health benefits. Future work includes design of large-scale manufacture and studies of bioactivity in cell culture.

Key Words: milk bioactives, nutrition, dairy foods

M178 Identification of bioactive peptides derived from fermentation of organic milk. S. R. Pritchard*, M. Phillips, and K. Kailasapathy, *University of Western Sydney*, *East Richmond, New South Wales, Australia*.

The aim was to identify peptides isolated from bacterial fermentations of organic milk that may have antimicrobial, antihypertensive and antioxidant properties. Organic milk was fermented in duplicate with *Lactobacillus acidophilus* LAFTI L10, *Lactobacillus casei* 2603, *Lactobacillus rhamnosus* 2625 (2, 6 and 9 d) and *Lactobacillus helveticus* (10% v/v) (2, 4 and 6 h). The pH was adjusted to 4.6 and soluble and insoluble peptide fractions were extracted by centrifugation followed by filtration. The extracts were screened for the presence of antimicrobial, antihypertensive and antioxidant activity. All analysis was carried out in triplicate. Antioxidant activity was measured by the inhibition of the free radical 1, 1-diphenyl-2-picrylhydrazyl (DPPH). The soluble fractions had the greatest inhibition of DPPH compared with the insoluble fractions. The peptides extract that inhibited DPPH the greatest were derived from organic milk fermented by *L. rhamnosus* for 6 d (42.83% ± 1.26 standard deviation (SD)), followed by the peptide extracts derived from milk fermented by *L. helveticus* for 2 h (34% ± 3.45) and *L. helveticus* for 4 h (32% ± 0.45). Antimicrobial peptides were determined by inhibition of 3 bacteria namely *Escherichia coli* ATCC 8739, *Bacillus cereus* ATCC 11778 and *Staphylococcus aureus* ATCC 6538. Overall, *E. coli* was inhibited the greatest by soluble peptide fractions including the peptide extracts derived from organic milk fermented by *L. acidophilus* for 9 d (108.38% ± 8.85 SD), with *L. rhamnosus* for 6 d (101.13% ± 1.95) and with *L. casei* for 9 d (90.04% ± 3.52). Antihypertensive activity was determined by the inhibition of the angiotensin-converting enzyme (ACE) using RP-HPLC to detect the amount of hippuric acid produced. Overall, the soluble fractions had the lowest IC50 values. The peptide extract derived from organic milk fermented for 9 d by *L. casei* had the lowest IC50 value (0.124mg/ml ± 0.008 SD). This research has shown that peptide extracts derived from fermented organic milk have antimicrobial, antihypertensive and antioxidant properties.

Key Words: bioactive peptide, milk, fermentation

M179 Increasing stringiness of low fat mozzarella cheese using polysaccharides. E. N. Oberg*[1], K. M. Larsen[1], D. A. Irish[1], M. M. Motawee[2,1], and D. J. McMahon[1], [1]*Western Dairy Center, Utah State University*, *Logan*, [2]*National Organization for Drug Control and Research*, *Cairo, Egypt*.

Removing fat from mozzarella cheese decreases fiber formation because protein strands fuse together during stretching and extruding. This study examined the ability of polysaccharides to act as fat mimetics and aid in fiber formation in manufacture of string cheese. Low fat mozzarella cheese curd made from 273 kg of 0.7%-fat milk was salted at a rate of 10 g/kg then divided into 2.7-kg batches that were hand-stretched in 5% (wt/wt) hot brine (80°C) and formed into a homogeneous mass. The hot cheese was hand mixed with a hot (80°C) polysaccharide slurry and then placed into a small piston-driven extruder and cheese forced through a 16-mm die to form the string cheese and cut manually into about 15-cm lengths. Cheeses were analyzed for fat, salt, pH, and moisture. After 1 wk of storage at 4°C, extent of stringiness was measured by pulling apart the cheese longitudinally, visually observing and photographing size and appearance of individual strings of cheese, and measuring their length. In one trial, 3 starches (waxy corn, waxy rice, and instant tapioca starches) were tested using 8% (wt/vol) slurries at a ratio 7% (wt/wt) of stretched curd. Waxy rice and waxy corn starches did not mix well with hot cheese and in a second trial, xanthan gum and guar gum slurries were added at a ratio of 2% (wt/wt), and polydextrose and instant

tapioca starch added at 7%. In the control low fat cheese there was no apparent fiber formation and the cheese was homogeneous in texture. All cheeses made with added polysaccharides had substantial fiber formation and were more similar to regular commercial string cheese. Low fat cheese with added xanthan gum had the most pronounced fiber formation with the longest strings (i.e., the full length of the cheese stick) and best string separation. Adding polydextrose produced cheese with the least string formation and was only slightly better than the control. Overall, extent of stringiness was greatest immediately after extrusion and tended to decrease during storage with string diameter increasing and string length decreasing.

Key Words: mozzarella, string cheese, low fat

M180 Enrichment of low fat Cheddar cheese with dietary fiber. R. Wadhwani*, D. J. McMahon, and D. A. Irish, *Utah State University*, *Logan*.

Dietary fiber intake of 20 to 35 g/d is recommended for lowering coronary heart disease, cancer, and other health benefits such as satiety and improved digestion. However, the average American daily intake is only 12 to 18 g/d. Fiber intake can be increased by enriching more foods and this study examines the feasibility of enriching low fat Cheddar cheese (6% fat) with dietary fibers and their effect on cheese organoleptic acceptability. Low fat Cheddar was made and stored for 15 d, then comminuted to 1.5 mm particle size. Then, inulin, pectin, polydextrose, or resistant starch were mixed into 1.82 kg batches of comminuted cheese at 50 g/kg with or without addition of 50 g/kg of water. The comminuted batches were then repressed individually in cheese molds, vacuum packaged and stored at 4°C. All cheese samples were analyzed at 90 d for composition and fiber was calculated by difference. Texture profile analysis was performed at 90 and 180 d of storage. Sensory flavor analysis was performed at 180 d with a full fat Cheddar cheese comparison. Chewiness was evaluated by counting the number of bites before swallowing cheese. No liquid expulsion from repressed cheese mixed with fiber was observed which resulted in 100% retention of fiber in cheese except for polydextrose which experienced liquid expulsion of < 0.5%. When added with water, cheese mixed with inulin or pectin resulted in better knitting and uniform mixing of cheese particulates which was confirmed by increased cohesiveness from 0.48 to 0.65 for inulin with water and 0.50 for pectin with water. Hardness for inulin (46.41N) and pectin (55.87N) cheeses were significantly lower than non-repressed control cheeses (80.94N) and chewiness was also significantly reduced from 44.18N to 12.45N. Polydextrose and resistant starch cheese were poor in appeal and lacked smooth texture. Chewdown method showed that full fat cheese and comminuted cheeses required 12 bites before swallow whereas non-comminuted cheese control was reported 24 bites by trained panel which is clearly double the number. This study indicated a feasibility to enrich comminuted low fat cheese with fiber contributing to better texture and no impact on overall flavor.

Key Words: fiber, Cheddar, texture

M181 Development of a rapid method for determination of lactose in process cheese using blood glucose meter. A. C. Biswas*, J. Amamcharla, and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University*, *Brookings*.

The lactose content can influence the functional and textural attributes of process cheese (PC). Hence, the development of a rapid and accurate method for determination of lactose in PC will be beneficial to the industry. Previously, a blood glucose meter method (BGMM) was developed for the determination of lactose in model solutions and raw milk. The current objective was to modify the BGMM for the determination of lactose in PC. The previous method was modified by utilizing a phosphate buffer to dilute the sample and used a new generation of glucose meter for analysis. For sample preparation, 1 g of PC was added to 20 g of 0.01 M phosphate buffer (pH 7.4) and mixed vigorously at 60°C. Five milliliters of the mixture was transferred to a test tube, and 0.01 mL of β-galactosidase was added. The solution was incubated at 40°C for 10 min to hydrolyze the lactose into glucose and galactose, and then analyzed for glucose in duplicate using the ReliOn Confirm glucose meter and its compatible test strips. To evaluate the variation between different test strip lots, 4 lots of test strips were utilized. For all 4 lots of test strips an individual calibration curve was developed using PC with known lactose concentrations between 3.2 and 8.2%. A universal calibration curve was also computed by pooling the data from all 4 lots of test strips. A sample of the original dilution of PC and buffer was also analyzed for lactose using an HPLC based method. The new rapid method was validated using 10 PC. The slopes and intercepts of individual calibration curves ranged from 1.23 to 1.37 and from −105 to −60, respectively. The slope and intercept of the universal curve were 1.32 and 88, respectively. The mean absolute bias was found to be between 0.11 – 0.32% for individual calibration and 0.15 – 0.24% for the universal calibration curve. The observed moderately high bias could be caused by variability in the test strip lots and intrinsic components of PC. Overall the novel rapid method is promising. However, modifications in sample preparation and calibration need to be developed to improve the method.

Key Words: lactose, glucose meter, process cheese

M182 Monitoring changes in the non-casein nitrogen fraction of raw milk during storage using casein/fat standardizer (CFS). P. Salunke*, J. Amamcharla, and L. E. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

Prolonged storage at refrigerated temperatures causes changes in the nitrogen distribution of raw and pasteurized milk. An increase in the non-casein nitrogen (NCN) fraction during storage is the result of psychrotrophic microorganisms and proteolytic enzymes. This phenomenon has direct implications on both cheese yield and quality. The Casein-Fat-Standardizer (CFS; Tetra Pak CPS, MN and Metron Instruments, OH) is being used as an on-line tool for standardizing the casein and fat of cheese milk. CFS uses a patented Brewster analysis method of laser light scattering to measure the casein and fat in the cheese milk. The objective of this study was to determine if the CFS can be used to follow the increase in the NCN fraction of cheese milk during refrigerated storage. Four raw milk samples (1 L) were collected immediately after milking. Each of the 4 samples was divided into 6 sub-samples and stored at 4°C. On each experimental day (for 6 consecutive days), one of the 6 sub-samples was withdrawn and tempered to 40°C. The sample was analyzed for fat, total protein (TP) and NCN in triplicate using the respective standard methods. The sample was also analyzed using the CFS to measure the casein and fat. It was found that there was no significant ($P > 0.05$) effect of storage time on the TP and fat of raw milk as analyzed by the standard methods. However, the NCN fraction of milks significantly ($P < 0.05$) increased during the storage period leading to a significant ($P > 0.05$) decrease in casein content after 2 d of storage. Similarly, the casein content analyzed by the CFS also showed significant ($P > 0.05$) differences after 3 d of refrigerated storage. The fat content measured in CFS also showed a significant ($P > 0.05$) decrease from d 0 to d 1, but showed no significant ($P < 0.05$) difference between the remaining storage period. Paired *t*-test comparison between the standard methods and CFS measured fat and casein showed

no significant differences for casein ($P = 0.76$) and fat ($P = 0.72$). These results indicate that the CFS instrument is capable of monitoring changes in the NCN content of milk during refrigerated storage.

Key Words: NCN, raw milk storage, CFS

M183 Impact of xylitol on the functional properties of low fat process cheese. A Kommineni*, J Amamcharla, and L. E. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University.*

Process cheese is a dairy food made by blending natural cheese, salt, emulsifying salts and other dairy and non dairy ingredients, and heating with continuous agitation to produce a homogeneous product. Due to increased health concerns the demand for low fat products has increased. Fat is a critical component of process cheese and plays an important role in its functional characteristics. Reducing or lowering the fat content of process cheese results in poor functional properties. The objective of the current study was to evaluate the effect of xylitol on the functional properties of low fat PC. Three different low fat PC formulations were made with 0%, 2% and 4% xylitol. All PC formulations contained 5% fat and 55% moisture and each treatment was manufactured in triplicate. Rheological characteristics including elastic modulus (G′), Viscous modulus (G″) and Temperature at Tanδ = 1 were determined using Dynamic Stress rheometry (DSR). The DSR was carried out at 1.5Hz frequency and 400 Pa stress levels using a temperature sweep from 200C to 900C. The hardness of the samples was also determined with texture profile analysis (TPA). Compositional analysis indicated that all treatments had a similar fat, protein, and moisture content. The elastic (G′) and viscous (G″) modulus results obtained with DSR decreased with increasing xylitol addition. The meltability index temperature was not significantly ($P > 0.05$) different between all treatments. TPA analysis demonstrated that xylitol addition significantly ($P < 0.05$) decreased the hardness of low fat process cheese. Based on the results obtained with DSR and TPA this study has demonstrated that xylitol addition improves the functional properties of low fat PC.

Key Words: process cheese, low fat, xylitol

M184 Application of salt whey in process cheese food made from young Cheddar cheese containing exopolysaccharides. O. Janevski*, A. N. Hassan, and L. Metzger, *South Dakota State University*, *Brookings*.

The objective of this study was to utilize salt whey in making process cheese food (PCF) from young (3-week-old) Cheddar cheese. To maximize the level of salt whey in process cheese, low salt (0.6%) Cheddar cheese was utilized. Since salt reduction causes undesirable physicochemical changes during extended cheese ripening, young Cheddar cheese was used in making process cheese. An exopolysaccharides (EPS) producing culture (JFR) was used to reduce rigidity and improve meltability of young Cheddar cheese. A non-EPS-producing culture (DVS) was applied in making the control cheese. To obtain similar composition in the EPS-positive and negative Cheddar cheeses, the making protocol was modified in the later cheese to increase its moisture level. The composition of Cheddar cheese was determined and used to formulate the corresponding PCF (JFR-PCF and DVS-PCF). Three-week-old Cheddar cheese containing 41.4% moisture, 31% fat, and 21.2% protein, was shredded, and stored frozen until used for PCF manufacture. No differences in pH and level of water-soluble nitrogen were seen between the EPS-positive and negative Cheddar cheeses. The utilization of low salt Cheddar cheese allowed up to 13% of salt whey containing 9.1% salt to be used in process cheese making. The preblend was mixed in the Rapid Visco Analyzer (RVA) at 1000 rpm, heated at 95°C for 3 min, and process cheese was transferred into copper cylinders, sealed and kept at 4°C. Process cheese contained 43.28% moisture, 23.7% fat, 18.9% protein, and 2.1% salt. No difference in composition was seen between the JFR-PCF and DVS-PCF ($P > 0.05$).The texture profile analysis showed that JFR-PCF was softer, and less gummy and chewy ($P \leq 0.05$) than DVS-PCF. The end apparent viscosity and meltability in JFR-PCF were higher ($P \leq 0.05$) than those in DVS-PCF, whereas the emulsification time was shorter ($P \leq 0.05$) in the former cheese. In conclusion, process cheese, containing up to 13% salt whey, with improved textural and melting properties could be made from young EPS-positive Cheddar cheese.

Key Words: process cheese, salt whey, exopolysaccharides producing cultures

M185 Prediction of water activity of natural cheese using a model cheese system. J. Grummer* and T. C. Schoenfuss, *University of Minnesota*, *St. Paul*.

The ability to predict the water activity of natural cheese in modified formulas is critical in developing products such as reduced or low sodium cheese. In published attempts to develop reduced sodium cheese, replacement salts have been added at levels too low to create the equivalent microbial and enzymatic stability of full sodium controls. The objective of this study was to develop a model system that could be used to measure Aw directly to verify samples formulated using predictive equations. Flour, butter and water were blended at levels that represented typical solids, fat, and water levels in Cheddar cheese. Predictive equations were used to calculate the levels of the various salt replacers needed to achieve the same water activity as samples with 600 mg sodium/100g. Sodium chloride and salt replacers (potassium chloride, modified potassium chloride (Nu-tek Products, Minnetonka, MN), magnesium chloride hexahydrate, and calcium chloride dehydrate) were added to the model blends to produce cheese with less than 300 mg sodium/100g of cheese. The measured water activities did not match the predicted values in some cases. This could have been due to differences in purity and moisture levels between the salts or the solubility of the salts at the percent moisture tested. The discrepancy demonstrated the benefit of using this model system for direct testing of water activity in a model system before producing batches of cheese.

Key Words: water activity, prediction, cheese

M186 Optimization of a CO_2 injection method for increasing the permeate flux in cold microfiltration of skim milk. T. J. Tan*, A. Sauer, and C. I. Moraru, *Cornell University, Ithaca, NY.*

Cold microfiltration (MF) was proven effective for microbial removal from skim milk. One of the challenges associated with MF is the low permeate flux, caused by fouling. To address this, a CO_2 injection technique capable to counteract membrane fouling was developed and optimized. The experimental MF unit consisted of a feed tank connected to a variable-speed centrifugal pump, a tubular heat exchanger and a tubular ceramic membrane of Tami design, placed inside a stainless steel housing. The membrane had a nominal pore size of 1.4 µm and total membrane area of 0.35 m^2. Three portable CO_2 injection ports were attached to the membrane housing. The combinations tested included: no CO_2 injection (control), 1 port, and 3 ports. Four combinations of CO_2 injection frequencies and durations were tested: no injection (control), 60s frequency with 2s duration (60s/2s), 60s frequency with 1s duration (60s/1s), and 120s frequency with 1s duration (120s/1s). The MF experiments were performed at a temperature of 6°C, a cross-flow velocity of 7 m/s and a transmembrane pressure of 83 kPa. A data acquisition

port was used to collect the temperature, pressure and permeate weight data; the latter was then used to calculate the permeate flux. In all runs, permeate flux showed an initial rapid decrease followed by a long and gradual decline. A series of 45min experiments were first performed. At similar water flux values of the membrane (1500 ± 50 L/m^{2}h), the combination of 3 ports with 120s/1s produced the highest flux (46.09 L/m^{2}h at 45min) followed by 3 ports with 60s/1s (41.32 L/m^{2}h) and 3 ports with 60s/2s (39.41 L/m^{2}h). Three hour experiments were then conducted: without injection (control), and with optimal CO_2 injection (3 ports, 120s/1s). After 3 h, the flux for the control was 26.36 ± 3.38 L/m^{2}h, while for the optimized CO_2 injection experiment, a flux of 33.65 ± 3.68 L/m^{2}h was obtained. In addition, a smaller drop in flux was observed for the CO_2 injection experiment (23% after 3h) as compared with the control (31.5% after 3h). The developed method is effective and can be used to increase the flux in microfiltration applications.

Key Words: microfiltration, fouling, CO_2 injection

M187 Polysaccharide addition to lowfat Cheddar cheese to improve texture. R. Kumar* and T. C. Schoenfuss, *University of Minnesota*, *St. Paul.*

Fat plays a role in cheese texture by acting as a plasticizer and inhibiting cross-linking between protein chains. Reductions in fat to produce lowfat cheese (less than 3 g fat/50 g cheese) results in texture defects. The objective of this study was to improve the texture of lowfat cheese by incorporating a polysaccharide gel as a filler to disrupt protein cross-links. Polysaccharides examined were alginate, xanthan, pectin, carageenan (Danisco USA Inc., New Century, KS) and Novagel RCN 15 (FMC Biopolymer, Philadelphia, PA). The level of polysaccharide needed to produce a soft gel was mixed with whey protein concentrate (Avonlac 180, Glanbia Nutritionals, Monroe, WI) on a high shear mixer. The gel (calculated at 10% of the pressed cheese if all was retained) was homogenized (Niro panda, GEA, Hudson, WI) at 160 bar with all the cream and a portion of the skim milk. It was then blended with the remaining skim. Control lowfat cheese was made with homogenized cream without polysaccharides. The cheesemaking procedure used a stirred curd method with pre-acidification to pH 6.2, and a final curd pH of 5.7 at salting. Curds were pressed in 0.7 kg Wilson-style hoops overnight. Cheeses were evaluated at 2 mo of age by sensory and texture profile analysis. Untrained panelists were instructed to place cheese samples (treatments and controls presented blindly) spatially on a 61 × 61 cm sheet of paper based on differences they perceived in texture and flavor. The distance of each sample from a full-fat sample was measured in cm. Novagel and pectin treatments were placed significantly closer ($P < 0.05$) to the full fat cheese than low fat control. Samples measured on a TA.XT-Plus Texture Analyzer (Texture Technologies, Scarsdale, NY) showed pectin and carageenan samples were significantly lower in percent energy recovered ($P < 0.05$) than lowfat control. Moistures of the lowfat samples were not significantly different, (52 to 54%). It was concluded that pectin, carageenan and Novagel had a positive effect on cheese texture using this method.

Key Words: lowfat, Cheddar, polysaccharides

M188 Effect of concentration and temperature on the rheological properties of 95% serum protein (SP) reduced micellar casein concentrates (MCC). A. Sauer*, C. Beliciu, and C. I. Moraru, *Cornell University*, *Ithaca, NY*.

The use of casein preparations obtained by membrane separation is receiving increasing interest from the dairy industry, as well as other industries. Currently, there is a lack of knowledge regarding the flow behavior of these protein concentrates under various processing conditions such as temperature and shear. This work focused on evaluating the rheological properties of micellar casein and on understanding how they are affected by concentration, temperature and shear. MCC with 95% SP reduced were obtained from skim milk by microfiltration followed by spray drying. MCC preparations of concentrations ranging from 5% to 12.5% were obtained by dispersing the MCC powders in deionized water, under vigorous stirring. Large amplitude and small amplitude rheological analyses were performed to evaluate the viscosity and flow behavior, as well as the network structure of these protein preparations. Steady shear experiments at temperature ranging from 0C to 80C were performed using an ARES strain controlled rheometer (TA Instruments). The viscosity vs. shear rate curves were used to evaluate the effect of shear on viscosity, and apparent viscosity at a shear rate of 100s-1 was used to make direct comparison between various concentrations and temperature conditions. All protein preparations displayed a shear thinning behavior, which was more pronounced as casein concentration increased. The apparent viscosity of MCC increased exponentially with casein concentration and decreased with temperature. The dependency of apparent viscosity on temperature followed an Arrhenius relationship. The activation energy for viscous flow (Ea) in the Arrhenius relationship increased with concentration. Ea values of 21280 kJ/mol, 26730 kJ/mol and 40167 kJ/mol were obtained for MCC concentrations of 5%, 7.5% and 10%, respectively. The relationships developed will allow the prediction of rheological properties under desired temperature and concentration conditions, which will provide the dairy and food industry with critical rheological data necessary for developing applications of micellar casein preparations.

Key Words: micellar casein, rheology, viscosity

M189 Formation of bacterial biofilms on spiral wound reverse osmosis whey concentration membranes and its influence on retentate quality. M. Avadhanula*, A. C. Biswas, S. Anand, and A. Hassan, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University*, *Brookings*.

Fouling is a major operational hurdle in the membrane processing of whey. In addition to the deposition of organic matter, bacterial biofilm formation on membranes may play a role in their reduced performance. The present investigation was conducted to study the formation of bacterial biofilms on spiral wound, reverse osmosis (RO) whey concentration membranes using the standards plate counting technique. Membrane cartridges from a commercial whey RO system were drawn at intervals of 2 mo up to a total duration of 12 mo to evaluate the effect of membrane aging on biofilm formation. Swab samples were taken from 1x1cm^2 membrane pieces drawn randomly from each cartridge. Counts of different bacterial groups were monitored in the feed, retentate and on the surface of membranes using selective media. The results confirmed the presence of multispecies bacterial biofilms on the whey RO membranes. Considerable variations were noticed in the distribution pattern of bacterial constituents in biofilms as the membranes aged. The average colony forming units (cfu/cm^2) for mesophiles, coliforms, lactic acid bacteria, staphylococci, and β-hemolytic colonies were 1.16, Nil, 0.78, 0.72, and 1.26 on the 2 mo old membrane, 4.11, 3.15, 4.05, 1.4, and 3.0 on the 6 mo old membrane, and 3.86, 2.38, 4.04, 1.91 and 2.86 on the 12 mo old membrane, respectively. The average log count (cfu/ml) in the feed whey was 5.44, which increased to 7.67 at the end of a 24 h cycle. In comparison to that, the average retentate count (cfu/ml) increased from log 5.30 to log 7.93. The higher increase in the retentate counts than that in the feed may be due to contamination from the membrane biofilms. This study provides a qualitative analysis of bacterial constituents of the

biofilm consortia obtained from whey concentration membranes from active industrial processes and its influence on retentate quality.

Key Words: whey retentate, reverse osmosis membrane, multispecies biofilm

M190 Thermal aggregation of whey proteins in the presence of buttermilk. M. Saffon*[1], M. Britten[2], and Y. Pouliot[1], [1]*STELA Dairy Research Center, Institute of Nutraceuticals and Functional Food (INAF), Université Laval*, *Québec, QC, Canada*, [2]*Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada*, *St-Hyacinthe, Québec, Canada*.

Reincorporating heat-denatured whey proteins in cheese milk is widely used in the cheese industry. The use of buttermilk is however limited because it increases cheese moisture. It was hypothesized that a co-denaturation process involving a mixture of whey and buttermilk proteins increases the use of buttermilk in cheesemaking. In preliminary experiments, mixed dispersions were prepared from powdered concentrates acidified to pH: 4.6; 5.4 and 6.2 using HCl 1N and heated at 2 temperatures (80°C and 90°C). From these trials, heating the mixed dispersions to 90°C and pH 4.6 showed the best results and this condition was chosen to test different ratios of whey to buttermilk protein. Cheese whey and buttermilk were concentrated by ultrafiltration up to 9.5% (w/v) protein content. Mixtures were heated to 90°C for 25min (including come-up time). After cooling, samples were homogenized 5 times at 9500 psi. Aggregated material was separated by centrifugation at 15000g for 20 min. Protein aggregation was calculated from protein content in the supernatant and water holding capacity (WHC) was determined on the pellet. Heat denaturation was also applied to protein mixtures containing thiol blocker (N-ethylmaleimide) to understand the impact of disulfide bonds on the formation of aggregates. All the heating experiments were repeated 3 times, statistical analysis of the data was performed using ANOVA and the results were considered significantly when $P < 0.05$. Increasing temperature significantly increased protein aggregation from 58% to 75% when heating temperature was raised from 80°C to 90°C. Decreasing heating pH significantly decrease WHC. Minimum WHC being observed at pH 4.6. Increasing the fraction of buttermilk protein in the mixture increased significantly protein aggregation and reduced WHC up to a ratio of 25:75 (78% and 1.80 g water/g protein. The use of NEM significantly increased protein aggregation by 6.2% and decreased WHC by 0.73 g water/g protein. Overall, our results show that increasing buttermilk fraction resulted in higher protein aggregation and lower WHC and suggest that disulfide bonds are formed in the early stages of aggregation.

Key Words: cheese whey, buttermilk, aggregation

Graduate Student Poster Competition: National ADSA Production MS Poster

M191 Assessment of tannin-free and tanniniferous legumes in lactating dairy diets using continuous culture. C. M. Williams*[1], C. M. Dschaak[1], J.-S. Eun[1], J. W. MacAdam[2], and A. J. Young[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University*, *Logan*, [2]*Department of Plants, Soils, and Climate, Utah State University*, *Logan*.

Dual-flow continuous culture fermentors (700 mL) were used to determine the effects of feeding tannin-free (alfalfa and cicer milkvetch) and tanniniferous (birdsfoot trefoils and sainfoin) legumes in lactating dairy diets on in vitro methane production and ruminal fermentation characteristics by mixed ruminal microbiota. We hypothesized that methane and ammonia-N production would be reduced when alfalfa hay was replaced by cicer milkvetch and tanniniferous legumes as main forages in TMR diets. Fermentors were inoculated with filtered ruminal contents and allowed to adapt to experimental diets for 6 d, followed by 3 d of sample collection. All dietary treatments were formulated for lactating dairy cows in early lactation. Five TMR diets were evaluated, each containing a different forage source as hay: 1) alfalfa (ALF) as a control, 2) cicer milkvetch (CMV), 3) Norcen birdsfoot trefoil (NBFT), 4) Oberhaunstadter birdsfoot trefoil (OBFT), and 5) sainfoin (SF). The experiment was conducted as a 5 × 5 Latin square design, and all data were analyzed using the MIXED procedure of SAS. Culture pH was not influenced when replacing ALF with CMV, NBFT, and OBFT, but increased when feeding SF ($P < 0.01$). Ammonia-N concentration was reduced when feeding CMV and SF ($P < 0.01$), but was not affected when replacing ALF with NBFT and OBFT. Total VFA production and acetate molar proportion were not influenced by treatments. However, molar proportion of propionate increased by feeding CMV, NBFT, and OBFT ($P < 0.01$). Acetate to propionate ratio decreased in cultures offered CMV and OBFT, but increased by SF when compared with ALF ($P < 0.01$). Methane production, as measured in headspace gas, decreased when replacing ALF with all other treatments ($P = 0.01$). The decrease of in vitro methane production when feeding cicer milkvetch, birdsfoot trefoils, and sainfoin may make these forages suitable for mitigating enteric methane emissions by lactating dairy cows, and maintaining potential productive performance.

Key Words: tanniniferous legumes, continuous culture, methane

M192 Post treatment outcomes of clinical mastitis on commercial dairy farms. C. Pinzón-Sánchez*, C. Hulland, and P. L. Ruegg, *University of Wisconsin*, *Madison*.

The objective was to characterize 60 d outcomes after treatment of mild (abnormal milk) and moderate (abnormal milk and abnormal udder) cases of clinical mastitis (CM) occurring on WI farms (n = 4). Duplicate milk samples were collected for microbiological analysis at onset of CM (PRE) and 20 d later (POST). Cows were treated with an intramammary product containing 125mg ceftiofur. Bacteriological cure (BCURE) was defined as absence of pathogens in POST sample, whether or not a causative pathogen was isolated in PRE sample. Recurrence (RECUR) was defined when CM occurred after the milk withholding period. Permanence (PERM) was defined as cows remaining in the herd. Somatic Cell Cure (SCCURE) was defined as SCC at first test after CM below 200,000 cells/ml. Effects of farm, DIM, parity, severity, PRE outcome, BCURE, previous milk yield, previous SCC, previous occurrence of CM and treatment duration were assessed using Chi-squared analysis and logistic regression. Distribution of cases was: *E. coli* (14), *Klebsiella sp.* (11), *Enterobacter sp.* (8), *Serratia sp.* (7), other gram neg. (3), *Strep sp.* (25), CNS (4); *Staph. aureus* (1); *Staph. ag* (1), other gram-positives (9), and culture negative (60). The first case of CM was 8 times more likely to result in BCURE compared with cases preceded by CM ($P < 0.001$). Cases that were culture positive were 3–5 times less likely to experience BCURE as compared with cases that were culture negative ($P = 0.05$). Occurrence of a previous case of CM, parity, and DIM were associated with the probability of RECUR ($P < 0.04$). Older cows and cows in earlier lactation were more likely to RECUR. The odds of RECUR were 5 times greater for the first case of CM as compared with second or greater cases. Greater milk yield ($P < 0.001$) was the most important predictor for PERM. Farm, severity, milk yield and BCURE were associated with probability of SCCURE. SCCURE was more likely to occur when cows presented mild symptoms of CM (Odds ratio = 20) as compared with cows with moderate symptoms and cases that resulted in BCURE were 29 times more likely to result in SCCURE.

Key Words: mastitis, dairy, treatment

M193 Assessment of prior grazing experiences on adaption to pasture and performance of dairy heifers. F. Lopes*[1], D. K Combs[1], P. C. Hoffman[1], N. M Esser[1], and W. Coblentz[2,1], [1]*University of Wisconsin*, *Madison,* [2]*USDA/ARS, US- Department of Agriculture/Agricultural Research Service*, *Marshfield, WI*.

The objective of this study was to evaluate how previous grazing experience affects animal behavior on pasture. Animal behavior was monitored in 32 Holstein (n = 21) and Holstein-Jersey (n = 11) yearlings. Two heifer groups (n = 8 per group) had been exposed to pasture from August through October 2008, while the other 2 groups had been continuously housed in a bedding pack barn since weaning. All 4 groups were housed in the same bedding pack barn from November 2008 until the start of the experiment. In June 2009, heifers were assigned to one of 4 Italian ryegrass pastures. The experimental unit was paddock and the experimental design was a randomized complete block. Each group was allocated approximately 50kg pasture DM/head initially. Animal activity was assessed by visual observation. The same person recorded the activity of each heifer every 15 min from 0700h to1600h during the first 5 d of the study. Heifer's activities were categorized as: walking, drinking water, grazing, lying down or standing but not grazing. Behavior of heifers that grazed in 2008 initially differed from those with no previous grazing experience. During the first day, heifers with grazing experience spent more time grazing than heifers that had no prior grazing experience (57 vs. 43% of the time, $P < 0.05$). By the fourth day no difference between treatments group was observed. After the first week, behavior was monitored every 2 weeks through August 2009 (7 periods, 2 consecutive days per period). After the initial week on pasture, both groups spent approximately 60 percent of the time grazing (60 vs. 59% of the time, $P > 0.05$). At the end of the grazing season animal body weight was not different between experienced and inexperienced animals (451 vs. 442 kg, $P > 0.05$). The data suggests that prior grazing experience initially affected animal behavior on pasture. Time spent grazing increased for both experienced and inexperienced heifers over the first few days of the grazing period. Both groups of heifers adapted to the pastures within one week and there was no evidence that grazing behavior or weight gain were affected after the first week of pasture adaptation.

Key Words: grazing, heifers, behavior

M194 Seasonal variation of nutrients and in vitro dry matter degradability of forage hay. L. Shi*, N. Li, T. Shenkoru, W. Yang, S. McConahey, and T. Wuliji, *University of Nevada*, *Reno*.

Nutrient composition and digestibility change from season to season. It is advantageous to determine which month of the growing season is most nutritious for the forage hay production. The objective of this study is to determine the seasonal variation in the feed composition and in vitro dry matter degradability of forage hay harvested from the irrigated pastures. The forage hay samples were collected at 3 intervals during the growing seasons from the irrigated grazing pastures, namely for interval I, II and III respectively at the end of June, August and October on the Rafter 7 Ranch, Yerington, Nevada. Organic matter (OM), ash, neutral detergent fiber (NDF), acid detergent fiber (ADF) and crude protein (CP) were estimated. The in vitro dry matter degradability (IVDMD) was determined by incubating dried ground samples in tubes with cattle rumen fluid (Tilley and Terry, 1963). The OM and CP of interval I were higher than II and III; Ash, NDF and ADF were increased from June (I) to October (III), except NDF was lower in II than I and III. But ADF was remained the same for both I and II sampling intervals. The IVDMD was significantly ($P < 0.05$) higher for interval I than II and III. The IVDMD of interval II was lower ($P < 0.05$) than III. Data of feed composition were analyzed for mean and standard errors whereas data of IVDMD were analyzed for ANOVA and t Tests (LSD) procedures of SAS. The results showed that forage hay nutrients and IVDMD estimates are highest at June interval, which is also more suitable to produce a high quality forage hay production from grazing pastures.

Table 1. Nutrient composition (mean±SE) and IVDMD (%) of forage hay from Rafter 7 Ranch, Yerington

Interval	OM%	ASH%	NDF%	ADF%	CP%	IVDMD%
I	89.2±0.01	10.8±0.01	52.3±0.19	33.7±0.44	15.7±0.14	66.3[c]
II	86.9±0.02	13.2±0.02	48.8±0.19	33.1±0.05	14.5±0.04	51.2[a]
III	83.6±0.01	16.4±0.01	58.4±0.33	40.1±0.38	12.2±0.03	53.6[b]

[abc]Mean with a different superscript differs significantly at $P < 0.05$ in column.

Key Words: degradability, in vitro, forage hay

M195 Performance of Holstein heifers supplemented with probiotics. J. Graves*[1], S. Hill[1], E. Suever[1], B. Rude[1], J. Brett[2], and Y. Vizzier-Thaxton[3], [1]*Department of Animal and Dairy Science, Mississippi State University*, *Mississippi State*, [2]*College of Veterinary Medicine, Mississippi State University*, *Mississippi State*, [3]*Department of Poultry Science, Mississippi State University*, *Mississippi State*.

Sixty (n = 12) Holstein heifers were used to evaluate growth and health when supplemented with coccidiostat, mannanoligosaccharide (MOS) or β-glucan in milk replacer. Calves were randomly assigned to one of 5 treatments at birth: CX (1 g/d Deccox), MOS (10 g/d MOS), β-g (0.5 g/d β-glucan), CX + MOS (1 g/d Deccox + 10 g/d MOS) and MOS + β-g (10 g/d MOS + 0.5 g/d β-glucan). Heifers received 3.8L milk replacer (22% CP, 20% Fat) once daily until 6 wks of age, but remained on trial for 56d. Calves were fed a non-medicated starter (18% CP) at 0.9 kg/d and increased by 0.9 kg/d when orts = 0. Orts were collected and weighed daily and pooled by week within treatment. Calves had ad lib access to clean water. At birth, calves were fed colostrum via esophageal tube, weighed, and measured. Fecal and respiratory scores were recorded daily; body measurements, blood and fecal samples were collected weekly. Fecal samples analyzed for coccidia bi-weekly after 21 d; at 2, 4, and 8 wks fecal samples were analyzed for E. *coli*. Blood samples were analyzed for CBC w/differential. There were no significant differences in DMI ($P < 0.93$), FE ($P < 0.95$), ADG ($P < 0.79$) or blood analysis ($P > 0.10$) among treatment groups. Given similar diets fed, no changes in growth or intake were expected. No differences in fecal or respiratory scores, CBC, or other health measures indicated that supplementation with MOS, β-g, or a combination supported immune function similarly to CX. Fecal shedding of E. *coli* was not different across treatments ($P < 0.23$), however, orthogonal contrasts showed greater E. *coli* from MOS + β-g (80.4×10^4 CFU/µl feces) compared with β-g (23.2×10^4 CFU/µl feces; $P < 0.04$). There was also a trend for calves fed MOS to shed more E. *coli* compared with the calves fed β-g (70.3 vs. 23.2×10^4 CFU/µl feces, respectively, $P < 0.06$). E. *coli* shedding decreased over time (114.6, 49.4 and 5.0×10^4 CFU/µl feces at wk 2, 4 and 8, respectively; $P < 0.01$).

Key Words: probiotics, growth, Holstein heifers

M196 Effects of condensed tannins supplementation on ruminal fermentation and lactational performance of dairy cows when fed high or low forage diet. C. M. Dschaak*, C. M. Williams, M. S. Holt, J.-S. Eun, and A. J. Young, *Department of Animal, Dairy, and Veterinary Sciences, Utah State University*, *Logan*.

A lactating dairy trial was conducted to determine the influence of water-soluble Quebracho extract containing approximately 75% condensed tannins (CT; DM basis) with 99% solubility (Chemtan Company Inc., Exeter, NH) on intake, digestibility, ruminal fermentation, and lactational performance of dairy cows. The cows were fed high forage (HF) or low forage (LF) diet with forage to concentrate ratio of 59:41 and 41:59 on DM basis, respectively. Eight lactating Holstein cows (DIM = 62 ± 8.8) were used, and 4 cows were surgically fitted with ruminal cannulas. The design of the experiment was a double 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments, and each period lasted 21 d (14 d of treatment adaptation and 7 d of data collection). Four dietary treatments were tested: HF without CT (HF−CT), HF with CT (HF+CT), LF without CT (LF–CT), and LF with CT (LF+CT). The Quebracho extract was added to the HF+CT and the LF+CT diets at a rate of 3% of dietary DM. Data were analyzed using the MIXED procedure of SAS. Supplementing CT on HF diet decreased DM intake, but not on LF diet. Digestibilities of DM and nutrients were not affected by CT supplementation on HF and LF diets. Milk yield was not influence by CT supplementation, but milk true protein decreased by supplementing CT in HF diet. Milk urea N concentration decreased with CT supplementation regardless of diet type, whereas efficiency of N use for milk N production was not affected by CT supplementation. Supplementing CT decreased total VFA production in HF and LF diets. Molar proportions of acetate ($P = 0.07$) and butyrate ($P = 0.06$) tended to increase by CT supplementation. Acetate to propionate ratio decreased with CT supplementation in HF diet, while conversely increasing the ratio in LF diet with CT supplementation. Ruminal ammonia-N concentration did not differ across treatments. Supplementing Quebracho extract in lactating dairy diets can improve dietary use of N as indicated by lower milk urea N, therefore N excretion can be reduced.

Key Words: condensed tannins, lactating dairy cows, milk urea nitrogen

M197 Relationships between prepartum energy intake and reproductive parameters in Holstein cows. F. C. Cardoso*, M. R. Murphy, and J. K. Drackley, *University of Illinois*, *Urbana*.

A meta-analysis was conducted to determine the effect of prepartum energy intake on days to first artificial insemination (DTFAI), days to conception (DTC), and number of artificial inseminations per conception (NAIC). The database was developed from 6 different experiments completed in our group from 1993 to 2006. Net energy lactation (NE_L) values in the diets varied from 1.21 Mcal/kg to 1.73 Mcal/kg DM. A total of 304 cows (281 multiparous and 23 primiparous) were included in the analyses. Prepartum dry matter intake (DMI) was recorded daily in all experiments. The NE_L intake ($NE_L I$) was calculated from the cow's respective dietary NE_L and average prepartum DMI. Full models were reduced by removing terms that did not contribute significantly to the model. Such terms included body condition score at calving ($P = 0.81$), season of the year at first artificial insemination ($P = 0.40$), and parity ($P = 0.62$). The DTFAI (n = 258) was lower for cows with higher $NE_L I$ ($P = 0.057$) and was not influenced ($P = 0.39$) by postpartal health problems (DISE). In this analysis, DTC (n = 212) was not influenced by $NE_L I$ ($P = 0.66$) or DISE ($P = 0.20$). Similarly, NAIC (n = 212) was not influenced by $NE_L I$ ($P = 0.50$) or DISE ($P = 0.45$). Inferences related to DTC and NAIC should be reevaluated when these results can be incorporated with those of similar experiments, to increase sample size. Based on the variances of DTFAI, DTC and NAIC in these experiments, the suggested number of cows needed to detect a 10% difference in these variables at a 95% confidence level are 88, 257, and 294, respectively. In conclusion, prepartum NE_L intake affected DTFAI.

Key Words: transition cow, energy intake, reproduction

M198 Effectiveness of an herbal remedy compared to control or traditional therapy in dry off treatments. K. A. E. Mullen*, K. L. Anderson, and S. P. Washburn, *North Carolina State University*, *Raleigh*.

Dry cow therapy, administered at the end of lactation, is aimed at eliminating current and preventing future intramammary bacterial infections. Dry cow therapy conventionally uses antibiotics. Certified organic dairies are restricted from antibiotic use and thus must use an alternative or no dry cow therapy. The current study used 150 Holstein, Jersey, and crossbred cattle to compare an herbal treatment (Phyto-Mast) to conventional (Quartermaster and Orbeseal) or no dry cow therapy. Each treatment (conventional, Phyto-Mast, or none) was balanced by breed, age, and due date and included 40 cows and 10 heifers. Milk weights and somatic cell scores (SCS) from the first test date in the first month postpartum were compared among treatment groups; no significant difference was observed between treatments. SCS average from the previous lactation was also recorded. Mean milk production was 22.7 ± 1.2 kg for conventional cows (CC), 14.7 ± 1.9 kg for conventional heifers (CH), 21.1 ± 1.0 kg for no treatment cows (NC), 14.5 ± 1.1 kg for no treatment heifers (NH), 22.9 ± 1.1 kg for Phyto-Mast cows (PC) and 17.1 ± 1.43 kg for Phyto-Mast heifers (PH). Milk production at the first test day postpartum was similar among multiparous cows, but the first-calf heifers in the Phyto-Mast group tended to have higher milk production at the first test than heifers in other groups. SCS were 1.89 ± 0.23 for CC, 3.33 ± 0.83 for CH, 2.15 ± 0.38 for NC, 3.73 ± 0.37 for NH, 2.17 ± 0.32 for PC, and 3.73 ± 0.85 for PH. SCS averages from the previous lactation were 3.74 ± 2.9 for CC, 3.63 ± 2.93 for NC, and 2.94 ± 2.72 for PC. Differences from previous lactation SCS for cows were not significant and remained similar across treatment groups at the start of the subsequent lactation. Also, SCS among first lactation heifers did not differ in early lactation but tended to be higher than for older cows. Neither lack of treatment nor the use of an herbal treatment differed from a conventional dry treatment for milk production or SCS at the start of lactation. More information on specific mastitic organisms in cows of various treatment groups is needed before definitive conclusions can be made.

Key Words: dry cow therapy, mastitis, organic dairy

M199 Serum pregnancy-associated glycoprotein (PAG) and progesterone concentrations after induction of pregnancy loss at day 39 of gestation in lactating dairy cows. J. O. Giordano*[1], J. N. Guenther[1], G. Lopes Jr.[1], M. F. McGrath[2], and P. M. Fricke[1], [1]*University of Wisconsin*, *Madison*, [2]*Monsanto Agricultural Company*, *St. Louis, MO*.

Pregnancy status was evaluated in lactating crossbred (75% Holstein, 25% Jersey) dairy cows (n = 29) by ultrasonography 39 d after TAI, and pregnant cows were randomly assigned to one of 3 treatments: 1)

control cows (CON, n = 10) received an injection of saline (5 mL, i.m.); 2) PGF cows (PGF, n = 10) received an injection of $PGF_{2\alpha}$ (25 mg, i.m.); and 3) infusion cows (INF, n = 9) received an intrauterine infusion of 120 mL hypertonic saline (25%, v/v) into the uterine horn containing the embryo. Blood samples were collected every 12 h for 6.5 d after treatment and daily from 6.5 to 10 d after treatment to assess serum PAG and progesterone (P4) concentrations. Uterine contents were evaluated using ultrasonography every 12 h to determine embryo presence and viability. All embryos from CON cows remained viable based on embryonic heart beat throughout the experiment. Time from treatment to cessation of embryonic heart beat was greater ($P < 0.001$) for PGF than for INF cows (36.0 ± 1.3 vs. 0.3 ± 1.4 h, respectively), and time from treatment to conceptus expulsion was greater ($P < 0.001$) for INF than for PGF cows (7.1 ± 0.8 vs. 1.9 ± 0.7 d, respectively). There was a treatment by day interaction ($P < 0.001$) for serum P4 concentrations in which P4 concentrations were greater for CON and INF than for PGF cows (8.7 ± 0.6, 8.1 ± 0.6, and 0.9 ± 0.6 ng/ml, respectively). Beginning 12 h after treatment, PGF cows had lower P4 concentrations than CON and INF cows. There was a treatment by day interaction ($P < 0.001$) for serum PAG concentrations in which mean PAG was greater for CON (3.5 ± 0.3 ng/ml) than for PGF (1.4 ± 0.3 ng/ml) and INF (1.4 ± 0.3 ng/ml) cows. Serum PAG concentrations differed among CON cows and PGF and INF cows beginning 60 h after treatment. We conclude that although timing of conceptus expulsion occurred 5.2 d later for INF than for PGF cows, serum PAG concentrations for INF and PGF cows decreased at a similar rate from the onset of treatment

Key Words: PAG, pregnancy loss, embryo

M200 Prepartum 2,4-thiazolidinedione alters gene expression of peroxisome proliferator-activated receptor gamma and leptin in the adipose tissue of dairy cows. K. M. Schoenberg*, K. L. Perfield, S. L. Giesy, Y. R. Boisclair, and T. R. Overton, *Cornell University*, *Ithaca, NY*.

Thiazolidinediones (TZD) are potent ligands for peroxisome proliferator-activated gamma (PPARγ). Administration of TZD has been shown to alter lipid metabolism and energy status in transition dairy cows. The objective of this experiment was to determine the effect of prepartum TZD administration on mRNA expression of PPARγ, leptin, fatty acid synthase (FAS), and lipoprotein lipase (LPL) in adipose tissue. Holstein cows entering second or greater lactation were administered 0 (n = 6), 2.0 (n = 5), or 4.0 (n = 4) mg TZD/kg BW by intrajugular infusion once daily from 21 d before expected parturition until parturition. Adipose tissue was collected on d −7 before expected parturition. After 14 d of TZD administration, PPARγ expression was increased ($P = 0.01$) by 24% (2.0 mg TZD/kg BW) and 10% (4.0 mg TZD/kg BW) over control cows. Increased expression of PPARγ is a marker of improved energy status and is consistent with previous data from this study on improved insulin sensitivity, decreased plasma non-esterified fatty acids, and decreased liver triglycerides with TZD administration. Leptin expression was decreased (−34%) in cows administered the 2.0 mg dose, but increased (+7%) in cows administered the 4.0 mg dose ($P = 0.07$); also corresponding with previous data. There were no significant changes in expression of LPL or FAS. It is likely that these results are confounded by changes in body condition scores and variation in time relative to actual calving dates. However, these results offer additional evidence that TZD treatment alters leptin expression. These data indicate that TZD administration increases PPARγ expression in transition dairy cattle. Further investigation is required to characterize the metabolic changes produced by TZD treatment in transition dairy cattle.

Key Words: transition cow, thiazolidinedione, leptin

M201 Effects of cobalt supplementation and vitamin B_{12} injections on energy metabolism of dairy cows. M. S. Akins*[1], S. J. Bertics[1], M. T. Socha[2], and R. D. Shaver[1], [1]*University of Wisconsin*, *Madison*, [2]*Zinpro Corporation*, *Eden Prairie, MN*.

The objective of this study was to determine metabolic responses of primi- and multiparous dairy cows fed different levels and sources (inorganic and organic) of cobalt or given weekly vitamin B_{12} injections. Forty-five primi- and multiparous cows 60 d prepartum were blocked by parity (1 or > 1) and expected calving date, and then randomly assigned to 1 of 5 treatments in a randomized complete block design. The treatments were: no supplemental Co (Control), 25 mg Co from Co carbonate (CoCarb), 25 mg (LcoGH) or 75 mg (HCoGH) Co from Co glucoheptonate, and Control with weekly 10 mg vitamin B_{12} injections. Cows were on trial until 150 DIM. Cobalt (ppm DM) in the lactating diet was 1.0, 1.9, 2.3, and 5.2 for Control and IB12, CoCarb, LCoGH, and HCoGH, respectively. Far-off, close-up, and lactating diets were 13.8, 15.1, and 18.0% CP and 48.8, 40.2, and 32.9% NDF (DM basis), respectively. Intake was not affected ($P > 0.10$) by treatment and was 19.4 ± 0.5 and 23.1 ± 0.8 kg DM/d for primi- and multiparous cows, respectively. Body weight and condition score and calculated energy balance were not affected by treatment ($P > 0.10$). Plasma glucose, non-esterified fatty acids, and β-hydroxybutyrate were not affected by treatment ($P > 0.10$). Effect of sampling day was significant ($P < 0.001$). Glucose decreased from 60 d prepartum (65 ± 1.1 mg/dL) to 30 DIM (55 ± 1.0 mg/dL), and increased at 90 DIM (60 ± 1.0 mg/dL); however, primiparous cows had a larger decrease at 30 DIM and smaller increase thereafter. Non-esterified fatty acids increased from 60 d prepartum (249 ± 39.8 mmol/L) to 1 DIM (724 ± 40.7 mmol/L), then decreased at 30 DIM (398 ± 40.1 mmol/L), with multiparous cows having a larger increase at 1 DIM. Beta-hydroxybutyrate increased from 60 d prepartum (4.2 ± 0.95 mg/dL) to 30 DIM (15.9 ± 0.95 mg/dL). Addition of Co above requirements or vitamin B_{12} did not improve energy metabolism of dairy cows, because vitamin B_{12} status was likely adequate.

Key Words: cobalt, vitamin B_{12}, dairy cow

M202 Genetic analysis of type traits in the Holstein population of Iran. M. R. Bakhtiarizadeh*, M. M. Shahr Babak, and A. Pakdel, *Tehran University, Karaj, Tehran, Iran.*

The objective of this study was to estimate the genetic parameters for 13 linear type traits, in Holstein population of Iran. Type traits records generated for first lactation Holstein dairy cows from 1991 to 2007 over 220 herds, 13 type traits were analyzed: stature (ST), body depth (BD), rump width (RW), chest width (CW), udder depth (UD), fore udder attachment (FU), udder width (UW), udder height (UH), fore teat placement (FTP), rear teat placement (RTP), suspensory ligament (SL), foot angle (FA) and rear leg, side view (RLS). For the analysis of type traits, herd, year and season of calving, age at Classification, age at calving, effect of classifier and days in milk effects were included in the model. The genetic parameters were estimated by ASREML software. Heritabilities ranged from 0.03 to 0.29. The largest value was for ST, the smallest for FA. The largest positive correlations were between ST

and CW (0.83), FTP and RTP (0.64), FU and UD (0.61). The largest negative correlations were between RLS and FA (−0.56), RLS and UD (−0.48), RLS and SL (−0.46). The genetic parameters estimate for type traits was consistent with other studies in different populations. The phenotypic correlations tended to be weaker than their corresponding genetic correlations although the signs of the correlations were generally the same. ST, BD, RW and CW seem to be strongly genetically correlated in the positive direction. Larger cows (taller, deeper cows with more rump width) tended to have stronger SL and more UH. Within the udder traits, FTP, RTP and SL were positively genetically correlated. The highest genetic correlation was between FU and UD. The highest negative genetic correlations were between UW and UH. Cows with shallow udders possess tighter FU. Animals with genetically stronger, shallower udders with superior udder support tended to have more sickled rear legs. A strong negative genetic correlation existed between FA and RLS indicating that cows with a steep FA tended to have straighter rear legs. The results from this study indicate that considerable genetic variation existed for some type traits within this sample in the Holstein population of Iran.

Key Words: genetic parameters, type traits, genetic correlation

M203 Effects of porcine relaxin on motility characteristics of boar sperm as assessed by computer-assisted sperm analysis (CASA). J. C. Rodriguez-Munoz*, J. M. Feugang, M. Crenshaw, S. T. Willard, and P. L. Ryan, *Mississippi State University, Mississippi State.*

Relaxin is a small peptide found in both female and male reproductive tissue. Relaxin is detected in the seminal plasma of various mammals, but its effect on sperm motility is still unclear. Here, we evaluated the role of porcine relaxin (pRLX) on the motility characteristics of boar spermatozoa during storage (~21°C) using a CASA system (IVOS, Hamilton Thorne, Beverly, MA). Diluted semen from several boars was centrifuged and Nidacon products (Mölndal, Sweden) were used to purify spermatozoa. Motile sperm were selected through a discontinuous percoll gradient, washed twice, counted and diluted with BoviExtend to a final concentration of $75x10^6$ sperm/ml. Samples were incubated for 60 min at 37°C with 0, 25, 50 or 100 ng/ml pRLX. Three µl of each treatment group were loaded into 4-chamber Leja slides for CASA analysis. Experiments were conducted on 3 consecutive days using the same batch of semen. Four independent replicates were used and pRLX effects assessed in triplicate for each treatment. All data were analyzed using ANOVA-2 or −3. The threshold of significance was $P < 0.05$. The ANOVA-3 analysis showed that pRLX and storage time affected the proportion of motile, progressive, and rapid spermatozoa ($P < 0.05$). Similar effects were observed on the amplitude of lateral head displacement (ALH), straightness (STR) and linearity (LIN) ($P < 0.05$). Using ANOVA-2, we found no significant effect of pRLX on proportion of motile cells on d 1 and d 3, but a significant increase on d 2 ($P < 0.05$). The presence of 100 ng/ml pRLX increased the proportion of progressive and rapid spermatozoa on all days, while the ALH was decreased on d 2 and d 3 ($P < 0.05$). There was no effect on beat cross frequency (BCF) at all times ($P > 0.05$). Moreover, 100 ng/ml pRLX significantly increased the STR on all days, while 50 and 100 ng/ml enhanced the LIN on d 2 and d 3 ($P < 0.05$). Overall, our study indicates a beneficial effect of relaxin on motility of boar spermatozoa during storage, in particular the proportion of progressive and rapid spermatozoa. Relaxin positively affects STR, LIN, and ALH which are indices of rapid sperm movement.

Key Words: boar, sperm motility, relaxin

M204 Response surface model for broiler chickens performance fed diets varying in digestible protein and amino acids. H. Ahmadi and A. Golian*, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

Response surface methodology (RSM) and 5-level-4-factor central composite design (CCD) were used to evaluate the response of broilers (BWG and FCR) to dietary digestible protein (dP), lysine (dLys), methionine+cysteine (dTSAA), and threonine (dThr). Eighty 4 cages of 5 birds each were assigned to feed diets contained 5 levels of dP (18, 19, 20, 21 and 22%), dLys (1.06, 1.12, 1.18, 1.24 and 1.30%), dTSAA (0.81 to 0.86, 0.91, 0.96 and 1.01%), and dThr (0.66, 0.71, 0.76, 0.81 and 0.86%) from 11 to 17 d of age. Diets were prepared using corn, soybean meal (45.2% CP), and corn gluten meal (48.6% CP). Protein and amino acid analyses were performed for these ingredients. All diets were formulated to have 3050 kcal/kg. The experimental results of CCD were fitted with the second-order polynomial equation. A ridge analysis was utilized to compute the optimum response for maximizing BWG and minimizing FCR. The fitted second-order polynomial equations for BWG and FCR are produced as follows: BWG (g/bird/d) = 1222.2 −76.7 dP −2.4 dP^2 −1468.0 dLys −260.0 $dLys^2$ +675.2 dTSAA −522.0 $dTSAA^2$+ 404.0 dThr −793.5 $dThr^2$ +77.6 dP*dLys +41.6 dP*dTSAA +51.5 dP*dThr +145.8 dLys*dTSAA +556.5 dLys*dThr −958.3 dTSAA*dThr; R^2 = 0.70; Root MS error = 4.97. FCR = −124.3 +12.8 dP +0.2 dP^2 +70.8 dLys +44.7 $dLys^2$ −86.5 dTSAA +60.8 $dTSAA^2$ −18.6 dThr +64.3 $dThr^2$ −9.7 dP*dLys −4.5 dP*dTSAA −4.0 dP*dThr +34.3 dLys*dTSAA −24.8 dLys*dThr +34.3 dTSAA*dThr; R^2 = 0.71; Root MS error = 0.53. The ridge max analysis on BWG and ridge min analysis on FCR models revealed that the maximum BWG may be obtained with dP 18.5%, dLys 1.10, dTSAA 0.89, and dThr 0.73 and minimum FCR may be obtained with dP 19.44%, dLys 1.18, dTSAA 0.90, and dThr 0.75. At the optimum point, the predicted BWG and FCR were 40.2 g/bird/d and 1.09, respectively. The combination of CCD and RSM techniques consider simultaneously all investigating factors and their possible interactions. Thus, it appears that the platform may be used to describe relationship between dietary concentration of nutrients and broiler performance to achieve optimal target.

Key Words: response surface model, digestible protein and amino acid, broiler chicken

M205 Partitioning of lysine stable isotopes in broiler breeders during the transition into sexual maturity. R. D. Ekmay*, C. Salas, J. England, and C. N. Coon, *University of Arkansas*, *Fayetteville*.

A study was conducted to determine how lysine is partitioned during the transition into sexual maturity in broiler breeder hens. At 21 wk, 15 Cobb 500 hens were individually housed and fed a 100g meal. Twelve of these hens were, in addition, administered a 15mg oral dose of ^{15}N-lysine daily beginning at wk 22; 3 hens did not receive any ^{15}N-lysine to serve as controls. At first egg, administration of ^{15}N-lysine ceased and a daily 15mg oral dose of ^{13}C-lysine began. When the second egg was laid, 6 hens (Group 1) were slaughtered and the left *Pectoralis major* was excised and snap frozen in liquid nitrogen. The egg contents were also frozen. The remaining 6 hens (Group 2) were slaughtered after the third egg and sampled as described. Molar percent excess (MPE) was determined in the egg and breast samples by GC-MS. The 159 and 160 *m/z* fragments were utilized for determination of ^{13}C enrichment. The 130 and 131 *m/z* fragments were utilized for determination of ^{15}N enrichment. MPE was calculated using the Rosenblatt (1992) approach. Statements of significance are based on testing at $P < 0.05$. No differences in breast weight or the number of days of enrichment between groups were determined. The ^{13}C-lysine enrichment in breast muscle was not significantly higher than in control hens, however ^{15}N-lysine enrichment was higher in groups 1 and 2 compared with the control. The ^{15}N-lysine enrichment of the egg increased significantly by the 3rd egg (Group 2). The ^{13}C-lysine enrichment of the egg did not differ from the control eggs. In summary, skeletal tissue appears to play an increasingly important role in supplying amino acids for egg formation during hen maturation.

Key Words: broiler breeders, amino acids, nutrient partitioning

M206 Varying levels of dietary methionine inclusion on the hematology and serum biochemistry of broilers. G. O. Adeyemo* and A. D. Ologhobo, *University of Ibadan*, *Ibadan, Oyo, Nigeria*.

The influences on hematology and serum biochemistry of graded levels of methionine inclusion in the diets of broilers were researched. One hundred and fifty broiler chicks were divided into 5 treatments consisting of 6 replicates of 5 chicks each. The chicks were kept in floor pens. The study lasted for 56 d at the teaching and research farm of the university of Ibadan Nigeria. No significant differences ($P > 0.05$) were observed in the packed cell volumes (PCV), red blood cells (RBC) and white blood cells (WBC) values of broilers fed the different levels of methionine inclusion, at the finisher phase, but at starter phase significant differences ($P < 0.05$) were observed, with the WBC values increasing as the inclusion rate of methionine increased. Total protein value of 4.80 g/dl and 4.48 g/dl were obtained for treatments 4 and 5 respectively which were not significantly ($P > 0.05$) different from each other. There were wide variations in the glucose concentration of the birds. The highest glucose concentration was observed from birds on diet 2 (220.90 g/dl) while the least was observed for birds fed the control diet though significant differences ($P < 0.05$) were observed, it did not follow a particular order.

Key Words: broilers, methionine, serum biochemistry

M207 Separate response to lysine and methionine in broiler starter diets. C. Lu*[1], C. A. Coto[1], A. Karimi[2], J. H. Park[1], Y. Min[1], and P. W. Waldroup[1], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Kurdistan*, *Kurdistan, Iran*.

A study was conducted to evaluate the separate response to Lysine (Lys) and to Methionine (Met) in diets on live performance of young broiler chickens from 0 to 18 d of age. Corn and soybean meal of known protein and moisture content were used to formulate basal diets to provide 0.90 to 1.40% digestible Lys in increments of 0.10%. The mean of suggested amino acid ratios to Lys suggested by literature values was used in formulation according to the ideal protein concept. All amino acids other than Met and TSAA were calculated to meet or exceed the expected ratio to Lys. Diets were calculated to be isocaloric with 3086 kcal/kg ME and were supplemented with inorganic trace mineral premix to avoid any source of Met from this premix. Experimental diets were prepared by addition of variable amounts of MHA (84% of Met) and cornstarch to the Lys basal diets to provide increments of 0.04% up to 0.28% supplemental Met activity for each level of digestible Lys, with a 6 × 8 factorial arrangement of 6 levels of Lys and 8 levels of supplemental Met resulting in a total of 48 treatments. Each of the 48 experimental diets was fed to 6 replicate pens of 6 male chicks (Cobb

500). Body weights by pen were obtained at 1 and 18 d of age with feed consumption determined during the test period. The ANOVA considered levels of Lys and Met and their interaction. There was significant ($P < 0.05$) effect of the dietary Lys level on feed intake, body weight gain and feed conversion ratio, with optimal level close to 1.2% of digestible Lys for both body weight gain and feed conversion ratio. There was no significant ($P < 0.05$) effect of the added Met level on feed intake, body weight and feed conversion ratio, indicating that the Met level in the basal diet of this study might be sufficient to support body weight and feed conversion ratio. No significant interactions were observed between Lys and Met for these 3 parameters. Results of this study suggest that the response to variation in Lys is a response to itself but not to Met in broiler starter diets.

Key Words: broilers, lysine, methionine

M208 Effect of crude protein and essential:nonessential amino acids ratio on nitrogen balance in broiler. C. C. Goulart[1], F. G. P. Costa*[1], E. T. Nogueira[2], M. Kutschenko[2], H. S. Rostagno[3], C. F. S. Oliveira[1], R. C. L. Neto[1], and V. P. Rodrigues[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Ajinomoto Animal Nutrition*, *Sao Paulo, SP, Brazil*, [3]*Federal University of Viçosa*, *MG, Brazil*.

This study aimed to evaluate the effect of crude protein (CP) and for essential amino acids:nonessential amino acids (EAA:NEAA) diet on nitrogen balance in broiler chickens from 18 to 21 d. A total of 480 Cobb broiler chicks, males, distributed in a completely randomized design with 4 treatments and 6 replicates of 20 birds. Was formulated a diet with 18% CP supplemented with lysine, methionine, threonine, arginine, valine, isoleucine, glycine and tryptophan, to meet the requirements of amino acids (AA) digestible. After the formulation, there was the delivery of EAA in total AA (TAA). Added to the total amount of EAA was calculated and compared with the level of dietary protein, considering this value as AAT. Were considered EAA: lysine, methionine + cystine, threonine, arginine, valine, tryptophan, isoleucine, leucine, phenylalanine, histidine and glycine. The other treatments were formed from glutamate supplementation to achieve levels of 19, 20 and 21% CP. Starch, oil and gravel were used in animal feed to make them isocaloric. Relations EAA:NEAA diets with 18, 19, 20 and 21% CP were 55:45, 52:48, 49:51 and 47:53, respectively. In the period of 18 to 21 d were collecting excreta and feed intake was measured for the determination of consumption, excretion and retention of N. It was observed linear increase in the consumption and excretion of N with increasing levels of dietary CP. No significant levels of CP level on N retention by the birds, however, the retention efficiency of N responded quadratically with increasing CP, being higher in the diet with 19% CP ($y = -403.77 + 49.414x - 1.3025x^2$; $r^2 = 0.98$). Diet with 19% CP and EAA:NEAA ratio of 52:48 is recommended in diets for broilers from 8 to 21 d.

Key Words: ideal protein, N excretion, N retention

M209 True ileal amino acid digestibility and protein utilization in broilers fed various levels of canola meal and phytase. C. Kong* and O. Adeola, *Purdue University*, *West Lafayette, IN*.

A total of 384 broiler chicks were used in a 14-d trial to examine the effect of levels of canola meal (CM, 387.5 g/kg CP) and microbial phytase on ileal amino acid (AA) digestibility and protein utilization of broilers. Experimental treatments consisted of 2 factors including phytase at 2 levels (0 or 1500 FTU/kg) and CM at 3 levels (125, 250, or 375 g/kg). The birds received standard starter diet from d 1 to 7 and the assay diet from d 8 to 22. On d 8, birds were allocated to 6 dietary treatments in a randomized complete block design and excreta were collected from d 12 to 14 and 19 to 21 and on d 22, ileal digesta were collected. Regressions of CM-associated digestible AA intake against AA intake without or with phytase were used for determination of true ileal AA digestibility of CM. There was a significant phytase effect ($P < 0.05$) for true ileal digestibility of all indispensable AA except for histidine. On d 15 and 22, there was a linear increase ($P < 0.05$) in N retention as CM increased from 0 to 375 g/kg, whereas there was a linear decrease ($P < 0.05$) in P retention, regardless of phytase addition. Weight gain (WG), feed intake, protein gain (PG), and protein intake (PI) linearly increased ($P < 0.01$) with increasing CM level regardless of phytase supplementation and experimental period. There were phytase effects ($P < 0.05$) on WG and protein efficiency ratio (PER) on d 15, whereas there were phytase effects ($P < 0.05$) on WG and PG on d 22.On d 15, there was a linear increase ($P < 0.01$) in net protein utilization (NPU) of the diets with phytase, whereas on d 22, there was a linear increase ($P < 0.05$) in NPU regardless of phytase supplementation. In conclusion, the result of this study indicated that phytase supplementation improves the true ileal digestibility of indispensable AA and WG, whereas PER was only improved on d 15 by addition of phytase.

Key Words: phytase, true ileal digestibility, protein utilization

M210 Separate response to lysine and methionine in broiler grower diets. C. Lu*[1], C. A. Coto[1], A. Karimi[2], J. H. Park[1], Y. Min[1], and P. W. Waldroup[1], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Kurdistan*, *Kurdistan, Iran*.

A study was conducted to evaluate the separate response to Lysine (Lys) and to Methionine (Met) in diets on live performance of young broiler chickens during the grower period of 14–35 d. Corn and soybean meal were used to formulate basal diets to provide 0.80 to 1.30% digestible Lys in increments of 0.10%. The mean of suggested amino acid ratios to Lys suggested by literature values was used in formulation according to the ideal protein concept. All amino acids other than Met and TSAA were calculated to meet or exceed the expected ratio to Lys. Experimental diets were prepared by addition of variable amounts of MHA (84% of Met) and cornstarch to the Lys basal diets to provide increments of 0.03% up to 0.21% supplemental Met activity for each level of digestible Lys. Two consecutive trials using the same experimental diets were conducted with identical design. Each of the 48 test diets was fed to 2 replicate pens of each trial at 14 d. Body weights by pen were obtained at 14, 28 and 35 d of age with feed consumption determined during the test period. During the period of 14 to 28 d, there were significant effects of the dietary Lys and added Met levels on BWG and FCR, with optimal digestible Lys level ≥0.90% for BWG and ≥ 1.30% for FCR. The optimal level of added Met during this period is ≥0.09% (total Met ≥ 0.33) and ≥ 0.12% (total Met ≥ 0.43) for BWG and FCR, respectively. During the period of 28 to 35 d, there were significant effects of the dietary Lys and added Met levels on BWG and FCR, with optimal digestible Lys level ≥1.00% for BWG and ≥ 1.30% for FCR. The optimal level of added Met during this period is ≥ 0.18% for both BWG (total Met ≥ 0.38) and FCR (total Met ≥ 0.49). No significant interactions between Lys and Met were observed based on BWG and FCR during each of the 2 periods. Results of this study suggest that the response to variation in Lys is a response to itself but not to Met in broiler grower diets.

Key Words: broilers, lysine, methionine

M211 Digestible arginine:lysine ratios for broilers during the starter and finisher periods. A. Campos[1], E. T. Nogueira[2], L. F. Albino[1], and H. S. Rostagno*[1], [1]*Federal University of Viçosa*, *Viçosa, MG, Brazil*, [2]*Ajinomoto of Brazil/Ajinomoto Animal Nutrition*, *Sao Paulo, SP, Brazil*.

The ideal protein concept requires all amino acids to be present in exact levels to provide for maintenance and protein deposition. Arginine (Arg) is an essential amino acid for poultry and also related to immune functions. Little information has been reported on digestible Argl:Lys ratios for starter and finisher broilers. Two experiments were carried out to evaluate digestible Arg:Lys ratios for male Cobb 500 broilers in 2 periods: 7 – 21 (starter) and 28 – 40 (finisher) days of age. A total of 1000 starter and 800 finisher broilers were distributed in a completely randomized experimental design with 5 digestible Arg:Lys ratios and 8 replicates of 25 and 20 birds per experimental unit (pen) in the starter and finisher period, respectively. Diets were formulated to meet or exceed the nutritional requirements in both periods, except for digestible Lys (1.08% and 0.98% for the starter and finisher periods, respectively). Digestible Arg:Lys ratios of 95 (1,026% dig Arg), 100, 105, 110, and 115% were used in the starter period, whereas ratios of 91 (0.892% dig Arg), 98, 105, 112, and 119% were used in the finisher period. Statistical analysis using different models (quadratic, 95% of the quadratic peak, broken line and quadratic and plateau) were applied to the performance data. In the starter period, weight gain and feed conversion presented a quadratic response ($P < 0.05$) to Arg:Lys ratios, as described by the equations $Y = -1530.57 + 39.174\ Arg - 0.1742\ Arg^2$ ($R^2 = 0.96$) and $Y = 5.047 - 0.0649\ Arg + 0.00029\ Arg^2$ ($R^2 = 0.98$), respectively. In the finisher period, there was a quadratic effect ($P < 0.05$) on weight gain ($Y = -926.96 + 38.09\ Arg - 0.172\ Arg^2$; $R^2 = 0.94$) and feed conversion ($Y = 4.323 - 0.0468\ Arg + 0.000205\ Arg^2$; $R^2 = 0.95$). These results suggest that a dietary Arg:Lys ratio of 108% is adequate for optimal performance of broiler chickens during the starter and finisher periods.

Key Words: arginine, lysine, performance

M212 Effect of a mono component protease on true amino acid digestibility of a corn and soybean meal diet for chicks. R. K. G. Messias[1], L. F. T. Albino[1], J. O. B. Sorbara[2], and H. S. Rostagno*[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*DSM Nutritional Products*, *São Paulo, SP, Brazil*.

Today the utilization of feed additives that improve performance and reduce the impact of pollution generated by intensive broiler chicken production is a concern of every poultry nutritionist. A digestibility trial was conducted to determine the effect of a mono component protease on true ileal amino acid digestibility (TAAD) of a corn and soybean meal diet. The trial was conducted with 168 male chickens placed on 28 wire cages from 12 to 22 d of age, in a complete randomized experimental design with 4 treatments (a corn soy diet and a protein free diet with and without protease supplementation) with 6 replicates of 7 birds each. The mono component protease used was RONOZYME ProAct with 75000 Prot Units/g product (dose of 200 ppm). Acid insoluble ash (Celite) was added to all diets as inert marker. Feed and water were provided ad libitum. At 22 d of age all birds were sacrificed and ileum content collected. Digesta samples were freeze-dried at −40°C for 72 h. The protease improved ($P < 0.05$) TAAD by 4%, 2%, 6%, 11%, 11%, 10%, 6%, 6%, 1%. 5%, 17%, 9%, 6%, 6% and 9% for Lys, Met, M+C, Thr, Val, His, Arg, Ile, Phe, Gly+Ser, Asp, Glu, Ala, Pro and Tyr, respectively. The essential TAAD of the corn soybean basal diet was increased on average 6% by the enzyme supplementation.

Key Words: enzyme, broiler, digestibility

M213 Performance of white commercial layers fed with different of threonine: lysine ratio. F. G. P. Costa*[1], M. R. Lima[1], E. T. Nogueira[2], L. Sá[2], J. H. V. Silva[1], H. S. Rostagno[3], C. C. Goulart[1], R. B. Souza[1], S. A. N. Morais[1], and G. S. Lima[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Ajinomoto Animal Nutrition*, *Sao Paulo, SP, Brazil*, [3]*Federal University of Viçosa*, *MG, Brazil*.

The reduction of the crude protein levels of the diets of the commercial layers causes damages to the productive performance, therefore it can make with that other amino acids if become considerably with limits of performance, as the threonine and the tryptophan, for example, thus compelling a supplementation with industrial sources of these amino acids. On the basis of this, this study intended to evaluate the nutritional requirements in digestible threonine for white layer in initial phase of production, being used itself diets with different relations threonine digestible: digestible lysine on the basis of the parameters of productive performance of white commercial layers. A total of 288 chickens with 29 weeks, distributed in delineation randomized, with 6 treatments, 6 repetitions, with 8 birds for experimental unit. The diets had consisted of a basal diet, where the evaluated levels had been 0.446, 0.486, 0.526, 0.565, 0.605 and 0.645% of digestible threonine, generating the threonine digestible: digestible lysine ratios 56, 61, 66, 71, 76 and 81%. With a quadratic behavior, the egg production improved until relation 76%, in accordance with the regression ($\hat{Y} = -0.0112x^2 + 1.6896x + 30.352$; $r^2 = 95$), the maximum point, that is, the best digestible threonine: digestible lysine was 75.43%. For the egg weight (EW), egg mass (EM) and egg mass conversion (EMC), the behavior was similar to the one of the egg production, where its regressions (EW: $\hat{Y} = -0.006x^2 + 0.8728x + 33.256$; $r^2 = 86$; EM: $\hat{Y} = -0.0149x^2 + 2.1964x - 19.562$; $r^2 = 80$; EMC: $\hat{Y} = 0.0005x^2 - 0.0728x + 4.5332$; $r^2 = 96$), had esteem the best relations in 72.73, 73.70 and 72.80%, respectively. These results corroborate with research that evidences the importance of the threonine in the metabolism of the chickens and that its daily necessities of this amino acid had grown with passing of the years and this, conclude that the excellent digestible threonine: digestible lysine ratio for white commercial layers in initial phase of production is of 75%.

Key Words: amino acid, ideal protein, performance

M214 Digestible valine:lysine and isoleucine:lysine ratios for brown egg laying hens. G. Lelis[1], E. T. Nogueira[2], L. F. Albino[1], and H. Rostagno*[1], [1]*Federal University of Viçosa*, *Viçosa, MG, Brazil*, [2]*Ajinomoto of Brazil/ Ajinomoto Animal Nutrition*, *São Paulo, SP, Brazil*.

When formulating minimum cost diets for laying hens it is essential to supply enough valine (Val) and isoleucine (Iso) to allow the hens to express their maximum genetic potential. Val or Iso deficiency may decrease the efficiency of the utilization of methionine + cystine and lysine (Lys), which are the first and second limiting amino acids in layer diets. Two experiments were carried out simultaneously to evaluate 3 digestible Val:Lys and Iso:Lys ratios for brown egg laying hens. In each trial a total of 180 Dekalb Brown layers (25– to 37–wk–old) were evaluated during 3 periods of 28 d with 3 treatments and 10 replicates of 6 birds per experimental unit. The following digestible Val:Lys ratios were tested: 84 (0.554% dig Val), 90 and 96%. The Iso:Lys ratios evaluated were 67 (0.442%), 75 and 83%. To prevent excess, digestible Lys level (0,660%) was calculated to supply 93% of the Brazilian Tables (Rostagno et al., 2005) recommendation. A positive control treatment (60 layers; 0.706% dig Lys; 0.633% dig Val and 0.548% dig Iso) was included to show that Lys was the second limiting amino acid in both experiments. Layers fed the positive control diet presented the best performance when compared with those fed the Val:Lys and Iso:Lys diets. During the period of 25 to 37 weeks, there was a linear response

to the dietary Val:Lys ratios as to egg production ($P < 0.002$) (%/bird/day Y = 31.445 + 62.135 Val; $R^2 = 0.99$) and egg mass ($P < 0.001$) (g egg/bird/day Y = 12.056 + 41.562 Val, $R^2 = 0.93$). Laying hens fed diets containing different Iso:Lys ratios presented quadratic response ($P < 0,05$) for the following parameters: egg production (%/bird/day) and egg mass (g egg/bird/day). Based on the evaluated parameters, the digestible Val:Lys and Iso:Lys ratios recommended for brown egg laying hens are 96% and 79%, respectively.

Key Words: valine, isoleucine, brown egg hens

M215 Influence of diet formulation technique on requirements of sulfur amino acids and lysine to brown egg laying hens. J. H. V. Da Silva*[1,2], P. B. Lacerda[1], D. V. Gonçalves Vieira[2], C. T. Silva[2], J. J. Filho[1], M. L. G. Ribeiro[1], J. M. B. De Souza[1], J. A. De Araújo[1], E. L. Da Silva[1], and F. G. Perazzo Costa[2], [1]*CCHSA-Universidade Federal da Paraíba*, *Bananeiras, Paraíba, Brazil*, [2]*CCA-Universidade Federal da Paraíba*, *Areia, Paraíba, Brazil*.

Three trials were carried out to evaluate the influence of 2 techniques of diet formulation on the requirements of amino acids and the relationship Met+Cys: Lys utilizing brown egg laying hens as biologic model. The first technique consisted of simultaneous supplementation of a reference diet (RD) deficient in Met+Cys and Lys with industrials sources of these amino acids, maintaining a constant relationship between these amino acids in 0,85 and the second technique consisted of RD deficient in one amino acid. Each trial was developed in a completely randomized design and involved 180 birds with 18 weeks of age and initial live weight of 1.64 kg. In trial one a RD deficient in Met+Cys and Lys was supplemented to provide levels of these amino acids of 0.55 and 0.64%; 0.62 and 0.72%; 0.69 and 0.81%; 0.76 and 0.88%; and 0.83 and 0.96%. In trial 2 the RD deficient only in Met+Cys was supplemented to provide 0.55; 0.62; 0.69; 0.76 and 0.83% Met+Cys, and in trial 3, the RD deficient only in Lys was supplemented to provide 0.64; 0.68; 0.72; 0.76; 0.80; 0.84 and 0.88 of Lys. All trials were divided into 6 periods of 28 d. In trial one the requirements of Met+Cys were 0.67% and Lys 0.79%. In trial 2 the requirement of Met+Cys was 0.65% and in trial 3 Lys was 0.76%. According the results Met+Cys and Lys requirements increased when the relationships between amino acids was maintained at 0.85. However, the relationship Met+Cys: Lys remained unchanged considering the estimates values from trials 2 and 3. These results suggest that the technique of formulating diets influences the amino acid requirements of birds but not the Met+Cys: Lys relationship.

Key Words: egg production, experimental method, nutritional interrelation

M216 Amino acid digestibility in corn, soybean meal, field peas, and corn co-products fed to weanling pigs. G. I. Petersen* and H. H. Stein, *University of Illinois*, *Urbana*.

Several alternative feedstuffs are available for use in weanling pig diets, but the standardized ileal digestibility (SID) of AA in most ingredients have not been measured in weanling pigs. The objective of the present experiment, therefore, was to measure the SID of AA in corn, soybean meal, corn gluten meal, high protein distillers dried grains, and field peas fed to weanling pigs. Twelve weanling barrows (initial BW: 10.3 ± 0.9 kg) were prepared with a cannula in the distal ileum and randomly allotted to a replicated 6 × 6 Latin square design with 6 diets and 6 periods in each square. Five diets were formulated using corn, soybean meal, corn gluten meal, high protein distillers dried grains, or field peas as the sole source of protein and AA. An N-free diet that was used to calculate basal endogenous losses of AA and protein was also formulated. Chromic oxide was included in all diets as an indigestible marker. All pigs were fed each diet for 7 d and ileal digesta were collected during the last 2 d of each period. Samples were lyophilized and analyzed for CP and AA and the SID of all AA were calculated according to standardized procedures (Table 1). It is concluded that the SID of all AA in corn gluten meal is similar to that in soybean meal, but high protein distillers dried grains have SID values for AA that are less than in both corn and soybean meal.

Table 1. Standardized ileal digestibility of AA in corn, soybean meal, corn gluten meal, high protein distillers dried grains, and field peas

	Corn	Soybean meal	Corn gluten meal	High protein distillers dried grains	Field peas
Ile	81.6^{b}	87.0^{ab}	88.2^{a}	72.0^{c}	82.2^{b}
Lys	75.9^{b}	86.6^{a}	84.5^{ab}	56.0^{c}	85.1^{a}
Met	86.4^{a}	88.2^{a}	90.4^{a}	80.9^{b}	79.7^{b}
Thr	75.7^{b}	83.7^{ab}	86.5^{a}	64.9^{c}	79.0^{ab}
Trp	85.0^{ab}	88.1^{a}	88.9^{a}	75.6^{c}	78.9^{bc}
Val	81.4^{b}	86.3^{ab}	88.0^{a}	70.8^{c}	81.2^{b}

^{abc}Means lacking common superscript in same row are different ($P < 0.05$).

Key Words: corn co-products, pigs, standardized ileal amino acid digestibility

M217 Pyrolic infusion of arginine increases portal vein blood flow in growing pigs. S. W. Kim*[1], M. I. Perret-Gentil[2], M. W. Hart[3], and R. D. Mateo[4], [1]*North Carolina State University*, *Raleigh*, [2]*The University of Texas at San Antonio*, [3]*Georgia State University*, *Atlanta*, [4]*Texas Tech University*, *Lubbock*.

This study was conducted to test if dietary arginine would affect portal vein blood flow (PVBF) in growing pigs. Two pigs (26.3 ± 0.6 kg BW), surgically fitted with catheters into the carotid artery (CA), portal vein (PV), mesenteric vein (MV), and pyloric region of the stomach (PL), were allotted to 2 × 2 Latin square design with 2 treatments: Injection of arginine-HCl (ARG); and injection of L-alanine (CON) through the PL catheter and with 2 periods (72-h intervals). Alanine was used as a non-specific nitrogen source in CON matching the contribution of nitrogen from arginine in ARG. Each period was composed of 48-h feeding (0.09 kg x $BW^{0.75}$), 19.5-h fasting, and 4.5-h infusion. A corn-soybean meal based diet with 18.2% CP and 3.35 Mcal ME/kg but without supplemental arginine was fed to pigs for 48 h before fasting. Para-aminohippuric acid (PAH) was infused (3.2 mg/min) into MV for a 4.5 h period. L-arginine-HCl (19 g) and L-alanine (32 g) was mixed with 100 mL distilled water and injected into the lumen of PL catheter 60 min after beginning the PAH infusion period. Blood samples (3 mL) were collected simultaneously from CA and PV catheters at −60, −30, 0, 15, 30, 45, 60, 90, 120, 150, and 210 min relative to injection to measure PAH concentration in the plasma. The PVBF rate (L/min) was calculated by PAH infusion rate (mg/min) / ($[PAH]_{PV}$–$[PAH]_{CA}$) (mg/L). Blood flow before the injection was averaged 1.85 ± 0.23 L/min. After injection, average increase in PVBF of ARG (1.66) tended to be greater ($P = 0.09$) than PVBF of CON (−0.14) during the entire 210 min. Increase in PVBF of ARG was greater ($P < 0.05$) than PVBF of CON at 60 (6.05 vs. −0.20) and 90 (3.40 vs. −0.77) min after the injection. Increase in PVBF occurred ($P < 0.05$) at 60 min and maintained until 90 min after injection of arginine whereas injection of alanine did not increase PVBF during the 210 min period. This study suggests that

one time dose of arginine can have a short-term increase in PVBF in growing pigs.

Key Words: arginine, blood flow, pigs

M218 Apparent and standardized ileal digestibilities of amino acids for pigs fed corn-soybean meal-based diets at varying crude protein levels. H. Zhai* and L. Adeola, *Purdue University*, *West Lafayette, IN*.

A study was conducted to determine the effect of CP level on apparent (AID) and standardized ileal digestibility (SID) of AA. Six pigs (initial BW 47.1 ± 0.97 kg) fitted with T-cannula at distal ileum were fed 6 diets for 6 periods in a 6 × 6 Latin square design. The 6 diets consisted of a nitrogen-free diet and 5 corn-soybean meal-based diets that contained 5 CP levels at 6.8, 10.5, 14.1, 17.7, and 21.4%. Each period consisted of a 5 d of adjustment period and 2 of ileal digesta collection for 10 h on each of d 6 and d 7. The ratio of corn:soybean meal was fixed at 3 to 2 by weight and cornstarch was added to dilute the CP concentration. Chromic oxide was included at 0.5% as an indigestible marker. The results showed basal endogenous loss ranged from 65 mg/kg DMI for Met to 3,104 mg/kg DMI for Pro. Proline and Gly (1,053 mg/kg DMI) were the 2 most abundant endogenous AA in endogenous flow and together accounted for approximately 43% of the total endogenous AA flow. The AID were 80.9 to 84.7%, 85.1 to 87.4%, 72.9 to 79.5%, and 86.5 to 87.9% for Lys, Met, Thr, and Trp individually with corresponding SID being 86.6 to 88.6%, 87.5 to 90.3%, 82.7 to 86.8%, and 90.2 to 93.6% as dietary CP increased from 6.8 to 21.4%. There were linear increases in AID of N, Arg, Ile,Val, Thr, Gly and Tyr ($P < 0.05$) as CP increased and linear decreases in SID of Leu, Trp, Asp, Cys, and Glu ($P < 0.05$). Both linear and quadratic effects were observed in AID and SID for Pro ($P < 0.05$). In conclusion, the protein levels in corn-soybean meal diets evaluated in the current study affected SID of the indispensable AA Leu, Phe, and Thr and the dispensable AA Gly, Pro, and Tyr.

Key Words: amino acid, apparent ileal digestibility, standardized ileal digestibility

M219 Influence of total lysine level provided during the finishing period on carcass, meat and fat characteristics of heavy barrows and gilts. M. A. Latorre*[1], J. A. Rodríguez-Sánchez[2], M. Blanco[2], M. A. Sanz[2], and M. Joy[2], [1]*Universidad de Zaragoza*, *Spain*, [2]*CITA de Aragón*, *Zaragoza, Spain*.

A total of 120 Duroc × (Landrace × Large White) pigs were used to study the influence of gender and lysine content during the finishing period on carcass, meat and fat characteristics. The experimental diets were based on corn, barley, wheat, and soybean meal diets, contained 2,280 Kcal NE/kg and 13.5% CP and were provided from 100 to 130 kg BW. There were 6 treatments with 2 genders (barrows and gilts) and 3 total lysine levels (0.70, 0.65 and 0.60%). Each treatment was replicated 4 times and the experimental unit was the pen constituted by 5 pigs allocated together. No significant interaction between gender and dietary treatment was detected. Carcasses from barrows had similar ($P > 0.05$) carcass yield but were ($P < 0.001$) heavier and fatter at the level of *gluteus medius* muscle (GM) than carcasses from gilts. The total weight of trimmed lean cuts (shoulder+ham+loin+sirloin) were heavier ($P < 0.01$) in barrows than in gilts but the yield was similar ($P > 0.05$). Meat from barrows had higher ($P < 0.05$) intramuscular fat content but lower ($P < 0.05$) protein content than meat from gilts. Subcutaneous fat from barrows had higher ($P < 0.05$) content in saturated fatty acids and lower ($P < 0.01$) in unsaturated fatty acids than that from gilts. The reduction in total lysine content in diet did not modify ($P > 0.05$) the weight and yield of carcass and main lean cuts but fat thickness at the GM muscle tended to increase ($P < 0.10$). Meat characteristics were not affected by dietary treatment but saturated fatty acids tended ($P < 0.10$) to increase and monounsaturated fatty acids tended ($P < 0.10$) to reduce as lysine content reduced. It is concluded that any effect of dietary treatment was independent of gender. The effect of reducing total lysine content provided during the finishing diet on carcass, meat and fat quality of pigs were scarce. However, a decrease of lysine levels from 0.70 to 0.60% could be interesting in the case of pigs intended for dry-cured products when a minimum carcass fat thickness is a criterion to choose the carcasses.

Key Words: lysine, carcass and meat quality, pigs

M220 Comparison of amino acid digestibility of corn, corn distillers dried grains with solubles (DDGS), meat and bone meal (MBM), and poultry-by-product meal (PBPM) determined with the precision-fed cecectomized rooster assay and the standardized ileal amino acid digestibility chick assay. E. J. Kim*[1], P. L. Utterback[1], T. J. Applegate[2], and C. M. Parsons[1], [1]*University of Illinois at Urbana-Champaign*, *Urbana,* [2]*Purdue University*, *West Lafayette, IN*.

The objective of this study was to evaluate and compare the standardized amino acid digestibility (SAAD) of several feedstuffs using 2 commonly accepted methods; the precision-fed cecectomized rooster assay (PFR) and the standardized ileal amino acid chick assay (SID). To carry out these objectives, 17 different feedstuffs were obtained. These samples included 6 corn, 6 corn distillers dried grains with or without solubles (DDGS/DDG), 2 meat and bone meal (MBM) and a poultry-by-product meal. The SAAD varied among the feed ingredients and among samples of the same ingredient. For corn, there were generally no differences in SAAD between the 2 bio-assay methods. When differences did occur, there was no consistent pattern among the individual amino acids due to bio-assay methods. The SAAD was not different between the 2 methods for the 4 DDGS samples; however, the PFR did yield greater SAAD for a high protein DDG and a conventionally processed DDGS. The PFR yielded greater SAAD values than the SID for several amino acids in one MBM and the poultry-by-product meal, but it yielded lower SAAD values for the other MBM. Overall, there were no consistent differences between methods for SAAD values.

Key Words: amino acid digestibility methods, roosters, chicks

M221 Feeding a diet containing specific excess amino acids minimizes the reduction in performance and carcass traits associated with an inflammatory response. A. Diaz[1], M. Raymond[1], R. Angel[2], and B. D. Humphrey*[1], [1]*California Polytechnic State University*, *San Luis Obispo,* [2]*University of Maryland*, *College Park.*

The objective of this experiment was to determine the effect of feeding specific amino acids in excess of their growth requirement on performance and carcass traits during an inflammatory response. Male Cobb 500 hatchlings were raised in pens (n = 15 chicks/pen) for 14 d and were fed a diet that met NRC requirements. On d 14, birds were fed 1 of 2 diets (n = 20/diet) that contained either adequate (A) or excess (E) amino acid levels. A and E diets were similar, except the E diet contained excess Phe (+0.43%), Trp (+0.14%), Thr (+0.30%) and Arg (+0.35%). On d 21 (0 h), half of the pens per dietary treatment (n = 10) were not injected or injected with 1 mg/kg BW of *E. coli* lipopolysaccharide (LPS). At 0, 3, 6, 9, 12, 15, 18, 21, 24, 48, 72, 96, 120, 144 and 168 h pen and feeder weights were measured and one bird per pen was sampled for determination of organ and carcass traits. LPS-injected chicks fed the E diet consumed 6.3% more feed from 0 to 168 h compared with chicks fed

the A diet ($P < 0.05$). LPS-injected chicks fed the E diet had 28% higher gain from 0 to 168 h compared with LPS-injected chicks fed the A diet ($P < 0.05$). LPS-injected chicks fed the E diet had lower feed conversion from 0 to 164 h compared with A chicks ($P < 0.05$). LPS-injected chicks fed the E diet had 7.4% higher body weights at 168 h compared with LPS-injected chicks fed the A diet ($P < 0.05$). Relative visceral weight was 12.2% higher in LPS-injected chicks fed the E diet compared with LPS-injected chicks fed the A diet ($P < 0.05$). At 168 h, absolute and relative pectoralis weight were higher in LPS-injected chicks fed the E diet compared with LPS-injected chicks fed the A diet ($P < 0.05$). These data indicate that feeding specific amino acids in excess of the growth requirement may help to mitigate the reductions in performance and carcass traits associated with an inflammatory response.

Key Words: amino acid, inflammation, pectoralis

M222 Amino acid digestibility of various feedstuffs of plant and animal origin using three different methods. E. J. Kim*, C. M. Jacobs, P. L. Utterback, and C. M. Parsons, *University of Illinois at Urbana-Champaign*, *Urbana*.

The objective of this study was to determine and compare amino acid (AA) digestibility of 3 distillers dried grains with soluble (DDGS), a corn gluten meal (CGM), canola meal, and a fish meal samples using the precision-fed cecectomized rooster assay (PFR), the standardized ileal assay (SID), and a newly developed precision-fed chick assay (PFC). For the PFR, after a 24 h feed withdrawal period, cecectomized roosters were precision-fed approximately 30 g of feed sample and excreta were collected for 48 h post-feeding. For the SID, 16 d-old broiler chicks were fed a semi-purified diet containing the feed samples from 17 to 21 d, with ileal digesta collected at 21 d. For the PFC, after a period overnight feed withdrawal, 22 d-old chicks were precision-fed 10 g of sample mixed with chromic oxide and ileal digesta were collected at 4 h post-feeding. Digestibility coefficients were standardized using a nitrogen-free diet (NFD) for the SID and PFC and using fasted roosters for the PFR. When 3 DDGS samples were evaluated, the PFR produced higher digestibilities than the PFC for all 3 DDGS samples for most of the amino acids. When comparing the PFR and the SID, the PFR yielded higher values than the SID for one DDGS, whereas there was no significant difference between the 2 methods for the other 2 DDGS samples. For the CGM, the PFR yielded significantly higher amino acid digestibilities than the SID and PFC for the majority of the amino acids. For canola meal, the PFR generally yielded greater amino acid digestibilities than the PFC with the SID yielding intermediary values. Differences did occur among methods for amino acid digestibility in fish meal; however, these differences were not consistent among methods or amino acids. The results of this study indicated there were differences among standardized amino acid digestibility values for the PFR, SID, and PFC in some instances but that the differences were not consistent among methods.

Key Words: amino acid digestibility methods, ileal digestibility, roosters and chicks

M223 Effect of the use of L-valine and metabolizable energy levels of diet on nitrogen intake, retention and apparent excretion in broilers. F. G. P. Costa*[1], C. C. Goulart[1], E. T. Nogueira[2], M. Kutschenko[2], J. H. V. Silva[1], V. P. Rodrigues[1], G. B. V. Lobato[1], and R. C. L. Neto[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Ajinomoto Animal Nutrition*, *Sao Paulo, SP, Brazil*.

The experiment was conducted at the Agrarian Sciences Center of UFPB, Brazil. The aim was to evaluate the effect of the use of L-valine (VAL) and metabolizable energy (ME) levels of diet on nitrogen (N) intake, retention and apparent excretion in broilers from 1 to 42 d. Seven hundred and 20 male broiler chicks were distributed in completely randomized design, in factorial scheme 2 × 3 (without or with VAL × 3 ME levels). To the treatments 1, 2 and 3, only L-lysine, DL-methionine and L-threonine were added, which allowed CP to attend digestible amino acids ratio, and the ME varied −50, 0 and +50 kcal/kg, respectively, according to the requirements for each stage of creation. In treatments 4, 5 and 6 was also added VAL, resulting in a CP reduction, and ME was similar to that in the previous treatments. N retention was determined by the difference in body N content of the birds at 42 d (2 birds per pen, ground whole, with feathers) and an additional group with 15 chicks 1 d old, used to determine the initial N content. The apparent N excretion was determined by the difference between N intake (N content of diet x feed intake) and N retention. The N retention was always higher in birds fed diet with VAL (79.6 vs 75.2 g/bird). Assessing the levels of ME within each diet, it was found that for birds fed diets without VAL, the diet with −50 kcal/kg reduced N retention. However, when the VAL was used the greater N retention was observed with the highest ME level. The apparent N excretion was lower with the diet with VAL, for any ME levels evaluated (46.3 vs. 56.7 g/bird). For the VAL-free diet, the lowest N excretion was observed at the intermediate ME level and for the diet with VAL, the lowest N excretion was observed with the diet with +50 kcal. It is concluded that the use of VAL and increase of 50 kcal of ME/kg in diet improves N retention and reduces N excretion to the environment.

Key Words: amino acids, body protein, ideal protein

M224 Effect of the use of L-valine and metabolizable energy levels of diet on body composition of broilers. F. G. P. Costa*[1], C. C. Goulart[1], E. T. Nogueira[2], M. Kutschenko[2], J. H. V. Silva[1], V. P. Rodrigues[1], and R. C. L. Neto[1], [1]*Federal University of Paraiba*, *Areia, PB, Brazil*, [2]*Ajinomoto Animal Nutrition*, *Sao Paulo, SP, Brazil*.

The experiment was conducted at the Agrarian Sciences Center of UFPB, Brazil. The aim was to evaluate the effect of the use of L-valine (VAL) and metabolizable energy (ME) levels of diet on body composition of broilers at 42 d old. Seven hundred and 20 male broiler chicks were distributed in completely randomized design, in factorial scheme 2 × 3 (without or with VAL × 3 ME levels). To the treatments 1, 2 and 3, only L-Lysine, DL-Methionine and L-Threonine were added, which allowed CP to attend digestible amino acids ratio, and the ME varied −50, 0 and +50 kcal/kg, respectively, according to the requirements for each stage of creation. In treatments 4, 5 and 6 was also added VAL, resulting in a CP reduction, and ME was similar to that in the previous treatments. At 42 d 2 birds per pen were selected, killed by cervical dislocation after fasting for 24 h and ground whole (with feathers) to body composition analysis. There was an interaction between the use of VAL and ME levels for percentages of protein (%CP), fat (%EE) and water body, while the percentage of ash was not influenced by treatments (expressed in % as-fed). In diets without VAL the largest body %CP (17.1%) was found with the intermediate ME level and lower %CP (15.9%) with the lowest ME level. At the lowest ME level the body %CP was higher in birds fed diets with VAL in relation to those fed diets without VAL (17.5 vs. 15.9%), with no differences between the higher ME levels. This shows that in birds fed diets with VAL, the lowest level of CP and consequent reduction of excess amino acids to be excreted, resulting in less need of ME that diets without VAL. At the intermediate ME level, body %EE was higher when using a diet with VAL (12.8 vs. 10.3%). Using diets without VAL the lowest %EE (10.3%) was observed in intermediate ME level. It is concluded that

VAL can be used in diets with a reduction of 50 kcal in ME without harming the body composition of broiler chickens.

Key Words: body fat, body protein, ideal protein

M225 Different protein and conjugated linolenic acid levels on broilers diets. T. Previero[1], C. J. C. Castillo[2], N. B. Petroli[1], R. Albuquerque[3], C. S. S. Araujo*[4], and L. F. Araujo[1], [1]*Universtiy of Sao Paulo*, *Pirassununga, SP, Brazil*, [2]*University of Sao Paulo*, *Piracicaba, SP, Brazil*, [3]*University of Sao Paulo*, *Sao Paulo, SP, Brazil*, [4]*Poultry Nutritionist*, *Pirassununga, SP, Brazil*.

The objective of this research was to study the effects of the conjugated linoleic acid, known as CLA, associated with reduction of crude protein (CP) level in broiler diets. An experiment was conducted from 21 to 41 d, using 1440 male broilers Ross, with the same weight initial, which were allocated according to a completely randomized design, with factorial model 3x3, corresponding in 3 CLA inclusions levels (0%, 0,5% and 1,0%) and 3 CP levels (19%,17%,15%). Data were statistically evaluated by GLM. Weight gain reduction and increased feed conversion were only related to decrease of CP level. Carcass and breast meat yields decreased due to the reduction of CP addition in diets ($P < 0.05$). The interaction between CLA and CP factors modified liver size, and both elevated the abdominal fat ($P < 0.05$). In relation to parameters analyzed in breast samples, the pH elevated proportionally to CP inclusion, the redness and yellowness were modified by CP or CLA addition and interaction of both were detected to luminosity parameter ($P < 0.05$). About fatty acid composition, the addition of CP only elevated the stearic acid and CLA inclusion improved the saturated fatty acid levels and reduced the monounsaturated fatty acid levels ($P < 0.05$). An improvement on incorporation of CLA isomers was verified due to more inclusion of this product in 19% or 17% CP diets ($P < 0.05$). In the case of 15% CP diets, the incorporation of CLA isomers had a maxim limit. Reduction on CP can affect negatively and CLA can improve carcass parameters and carcass quality, respectively.

Key Words: carcass quality, fatty acids, performance

M226 Effect of dietary arginine, glutamine, and tryptophan on growth performance, gut morphology, and meat quality of broilers. S. J. Park*[1], C. Z. Alvarado[1], and S. W. Kim[2], [1]*Texas Tech University*, *Lubbock*, [2]*North Carolina State University*, *Raleigh*.

This study was conducted to evaluate the supplemental effects of Arg, Gln, and Trp on growth performance, gut morphology, metabolic response, and meat quality of broilers. Newly hatched birds were allotted to 4 dietary treatments (6 replicates per treatment and 6 birds per cage): C (Control); A (a diet with 0.5% L-Arg); G (a diet with 0.5% L-Gln); and T (a diet with 0.5% L-Trp). Corn and soybean meals were the major ingredients in the diets. All diets were isonitrogenous using L-Ala and isocaloric using corn oil. Birds were fed the diets for 6 wk based on a 3 phase feeding program (2 wk each). Body weight and feed intake were measured at the end of each phase. On d 11, 2 birds from each pen were killed to measure gut morphology and serum immunoglobulins (Ig). At 6 wk of age, 2 birds from each pen were killed to measure carcass characteristics. On d 11, serum IgA and IgG were not different among treatments. Heights of villus in jejunum of birds in C (65.9 μm), A (69.8 μm), and G (64.4 μm) were greater ($P < 0.05$) than birds in T (59.3 μm). Depths of crypts did not differ among treatments. At the end of wk 6, birds in A (2.55 kg), G (2.40 kg), and T (2.53 kg) were heavier ($P < 0.05$) than birds in C (2.14 kg). Feed intake and feed:gain ratio did not differ among treatments. Hot carcass weights of birds in A (1.89 kg), G (1.75 kg), and T (1.88 kg) were greater ($P < 0.05$) than birds in C (1.56 kg). Cold carcass weights of birds in A (1.97 kg) and T (1.98 kg) were greater ($P < 0.05$) than birds in C (1.64 kg). Weights of breast meat and thigh meat of birds in A (451 and 296 g, respectively), G (427 and 267 g), and T (451 and 277 g) were greater ($P < 0.05$) than birds in C (361 and 263 g). The pH of breast meat of birds in T (6.43) was higher ($P < 0.05$) than birds in C (5.94), G (6.02), and T (5.97). Collectively, dietary supplementation of L-Arg, L-Trp, and L-Gln at 0.5% improves growth and carcass gain of birds when fed for 6 wk period.

Key Words: amino acids, broilers, growth

M227 Dietary supplementation of L-glutamine and L-glutamate or sodium butyrate during early growth of female broilers. Y. Avellaneda*[1], J. Hernandez[1], C. Ariza-Nieto[2], and G. Afanador[1,2], [1]*Universidad Nacional de Colombia*, *Bogota, Colombia*, [2]*CORPOICA*, *Bogota, Colombia*.

This study determined the effects of dietary supplementation of a commercial mixture of L-glutamine and L-glutamate (GlnGlu) and sodium butyrate (SB) for female broiler on nutrients digestibility, intestinal morphometry and performance. Three hundred twenty-five 1-d COBB females broiler were randomly allocated to one of the 5 treatments: 0, 0.5, 1.0, 1.5% of GlnGlu and 0.07% of BS. In every treatment there were 5 replicate pens. Body weight and feed intake were record at 1, 8, 15 and 25 d of age. Three broilers from each treatment were randomly selected and sacrificed on d 8, 15 and 25 d. Intestinal tissues were collected at the middle part of duodenum, jejunum and ileum to measure crypt depth, villus height and width. During a 4-d balance period (21–24 d), the chicken received a diet with 0.5% chromium oxide and excreta were collected twice a day. Protein digestibility and apparent metabolize energy (AME) value were calculated. Data were analyzed as a completely randomized design. Dietary protein digestibility was higher ($P < 0.05$) in birds fed 1.5% of GlnGlu (64.2%) compared with control group (58.3%). AME was 3170 Kcal/Kg and 3161 Kcal/Kg for broilers fed with 1.0 and 1.5% Gln+Glu, respectively. These values were higher compared with the control group (2979 Kcal/Kg, $P < 0.05$). Digestibility of organic matter was directly related to EMA values. At d 25, broilers fed 1.5% of GlnGlu showed a villi of the duodenum larger compared with the control group (1347 vs 1080 um) and supplemented with GlnGlu (1127 and 1116 um, 0.5 and 1.0% of GlnGlu, respectively) ($P < 0.05$). Female broilers fed 1.5% of GlnGlu showed a higher body weight gain compared with both control and BS groups (36, 34.0 g and 32.3 g/d, respectively). BS group presented the lowest feed intake (42.4 g/d) compared with the other treatments (49.7 g/d, on average) ($P < 0.05$). Feed conversion ratio of BS and 1.5% GlnGlu groups were significantly lower compared with the control and 0.5% GlnGlu ($P < 0.05$). It can be concluded that the supplementation with biomolecules as L-glutamine and L-glutamate showed positive effects on female broiler performance.

Key Words: L-glutamine, L-glutamate, sodium butyrate, female broiler

M228 Evaluation of the fixed crude protein conversion factor (6.25) versus ingredient-specific conversion factors. N. Sriperm*[1], G. M. Pesti[1], and P. B. Tillman[2], [1]*University of Georgia*, *Athens,* [2]*Ajinomoto Heartland LLC*, *Chicago, IL*.

This study examines the validity of the historical nitrogen to crude protein conversion factor of 6.25 based upon assay values of commonly used feed ingredients, analyzed during 2009. A calculated protein level

for an ingredient should provide an indication of the amino acid content of that ingredient. Since laboratory methods for determining nitrogen content report both nitrogen from ammonia (NH_3) and from non-amino acid sources (nucleic acids, etc.), the determined crude protein value is typically over-estimated, relative to the nitrogen strictly from amino acids, the true protein. Amino acid values were collected from the Ajinomoto Heartland LLC laboratory analysis database. Ingredients evaluated included ground corn, soybean meal (dehulled, solvent extracted), corn distillers dried grains with solubles, poultry by-product meal and meat & bone meal. Data for ammonia (NH_3) and 18 individual amino acids were included in the determination of ingredient specific conversion factors. Using the nitrogen content for NH_3 and of each amino acid, along with the analyzed content of NH_3 and each amino acid within each ingredient, the average nitrogen content of each ingredient was calculated. Using these values, ingredient specific conversion factors: K_A, K_P and K (average of K_A and K_P) were determined as outlined by Mosse′ (1990). It should be noted that the determined ingredient specific conversion factors were not equal to the standard 6.25% factor. Plant protein sources had higher conversion factors than animal based protein sources. An ingredient specific true protein conversion factor is proposed as being more applicable than a standard fixed factor, especially when the determined true protein content is based upon nitrogen from amino acid analysis.

Table 1. Ingredient-specific nitrogen to crude protein conversion factors

Ingredient	n	K_A	K_P	K
Ground corn	75	5.65	5.02	5.33
Soybean meal	230	5.64	5.13	5.38
Corn DDGS	188	5.74	4.98	5.36
Poultry by-product meal	45	5.45	4.81	5.13
Meat and bone meal	156	5.37	4.77	5.07

Key Words: crude protein, amino acid, corn soybean meal

M229 Effect of dietary probiotic and prebiotic on ileal nutrient digestibility of Ross broiler chickens. H. Ziaie*[1], A. Zeinali[2], M. Bashtani[3], M. A. Karimi Torshizi[4], G. H. Hadarbadi[1], H. Farhangfar[3], and A. Nasr Abad[1], [1]*Agriculture and Natural Resources Research Center*, *Birjand, South Khorasan, Iran*, [2]*Ferdowsi University*, *Mashhad, Iran*, [3]*Birjand University*, *Birjand, Khorasan, Iran*, [4]*Tarbiat Moddares university*, *Tehran, Iran*.

An experiment was conducted using 240 one-day old male Ross broiler chickens to evaluate the effect of dietary probiotic and prebiotic on ileal nutrient digestibility of Ross broiler chickens. Chicks were allocated to a randomized complete block design with 4 replicate pens (15 birds per pen). The experimental treatments were: T1 = control, T2 = control + 15 ppm of Virginiamycin, T3 = control + 100 mg probiotic (Protexin) per kg diet and T4 = control diet + 100 mg prebiotic (Immnuwall) per kg diet. At age 21 and 42 d, ileal digestibility of nutrients was measured by Titanium oxide marker. Data was statistically analyzed using the GLM models of SAS. Duncan's multiple range test was used for pair-wise comparisons of treatment means. The results showed that supplemental diets significantly ($P < 0.05$) improved bioavailability of energy and ileal digestibility of protein. At 21 d of age, broiler fed with treatments 3 and 4 had lower bioavailability of energy and ileal digestibility of protein as compared with treatment 2, but their differences were not significant at 42 d of age. The experimental diets had no effect on ileal digestibility of fat. In conclusion, using probiotic and prebiotic in broiler diets could improve nutrient digestibility indicating that these compounds may be an alternative to antibiotics.

Key Words: broiler, antibiotic alternative, nutrient digestibility

M230 Tryptophan, niacin and insulin metabolism in weaned pigs? J. J. Matte*[1], Y. Primot[2], and N. LeFloc'h[3], [1]*Agriculture & Agri-Food Canada*, *Dairy & Swine R & D Centre, Sherbrooke, QC, Canada*, [2]*Ajinomoto-Eurolysine SAS*, *Paris, France*, [3]*Institut National de la Recherche Agronomique (INRA)*, *UMR-SENAH, St-Gilles, France*.

The present experiment aimed to better define the role of an active metabolite of tryptophan (Try) oxidation, niacin (vitamin B_3), on post-meal insulin response in weanling piglets. A group of 24 weaned piglets were distributed, at 4 wks of age, in 4 factorial dietary treatments: 2 additions of Try, 0 (-Try) vs. 0.10% (+Try) for Try/Lys ratios of 0.16 vs. 0.23, respectively, and 2 additions of dietary niacin, 15 mg/kg (LB_3) vs. LB_3 + 45 mg/kg (HB_3). Animals were fed ad libitum up to 10 wks of age and were trained to restricted feeding (1 kg/d) in one morning meal during one wk. At 11 wk of age, repeated blood samples were collected during 6 h following initiation of the meal (0.5 kg) to determine profiles of plasma C-peptide, insulin, glucose, Try, kynurenin (Kyn), an intermediate metabolite of Try oxidation and nicotinamide (Nam), an indicator of niacin status. There was no treatment effect on either the peak or the area under the curve of C-peptide or glucose after the meal ($P > 0.12$). However, for insulin, the postprandial peak was lower in +Try piglets especially within LB_3 piglets (Try effect and interaction Try*niacin, $P < 0.05$); values were 1.3, 1.0, 0.7 and 1.0 nM (SE: 0.1) in -Try LB_3, -Try HB_3, +Try LB_3 and +Try HB_3, respectively. The molar ratio insulin:C-peptide during the 0–90 postprandial period was lower ($P < 0.02$) in +Try vs -Try piglets (0.47 vs 0.57, SE:0.03). The post-meal plasma Try (96.2 vs. 72.3 μM, SE:0.1) and Kyn (1.7 vs. 1.3 μM, SE:0.1) were higher ($P < 0.01$) in +Try vs -Try piglets. Post-meal plasma Nam was higher in +Try vs -Try ($P < 0.01$) and in HB_3 vs LB_3 piglets ($P < 0.01$) with overall values of 1.0, 2.7, 2.7 and 4.0 μM (SE: 0.4) in -Try LB_3, -Try HB_3, +Try LB_3 and +Try HB_3, respectively. The present results on C-peptide, insulin and molar ratio insulin:C-peptide suggest that the Try action is exerted mainly on insulin clearance (catabolism and/or cellular uptake in target tissues) rather than on insulin secretion in piglets. However, the postprandial responses of the different plasma metabolites to dietary treatments suggest that the Try effect on insulinemia in piglets is unlikely modulated by either Nam or Kyn homeostasis after a meal.

Key Words: tryptophan, insulin, piglets

M231 Effect of glutamine and temperature on performance of broiler chickens. S. Cerrate*, R. Ekmay, C. Salas, and C. Coon, *University of Arkansas*, *Fayetteville*.

The effect of glutamine and 2 ambient temperatures were evaluated during the finisher period of broiler chickens, from 36 to 50 d of age. A corn-soy control and a corn-soy-glutamine diet (1% inclusion) were fed to broilers housed in one of 2 ambient temperatures: 21 ± 1°C (normal temperature) and 30 ± 0.6°C (heat stress). Data were analyzed as a 2 × 2 factorial design. Ten male birds housed individually were placed for each treatment. Broilers housed at 21°C showed greater BW gain and feed intake than did birds housed in 30°C. There were interactions between dietary treatments and temperature on BW gain ($P = 0.018$) and feed conversion ($P = 0.006$). Birds housed at 21°C showed similar BW gain, feed intake and feed conversion between the control and glutamine diets, whereas broilers fed the glutamine diet housed at 30°C had greater BW gain and a more efficient feed conversion than did birds fed the control diet. These data indicate that glutamine inclusion may be beneficial during heat stress.

Key Words: broiler, glutamine, housing temperature

M232 Effect of dietary protein content on cecal microbial ecosystem and mortality of young rabbits. S. Chamorro[1], R. Carabaño[2], J. García[2], I. Badiola[3], G. G. Mateos*[2], and C. de Blas[2], [1]*Instituto del Frío-ICTAN, CSIC*, *Madrid, Spain*, [2]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [3]*CReSA (UAB-IRTA)*, *Bellaterra, Spain*.

The aim of this work was to study the effect of dietary CP content on cecal microbial ecosystem and mortality of young rabbits weaned at 25 d. Two (HP and LP) isoenergetic (3,200 kcal DE/kg DM) diets differing in the CP content (175 and 159 g/kg DM, respectively), were formulated. Rabbits (240/treatment) weaned at 25 d were fed experimental diets during 10 d, and mortality incidence from 25 to 35 d was recorded. At 35 d-old, 30 5 rabbits per treatment were slaughtered and cecal contents were taken to characterize the microbial population by restriction fragment length polymorphism (RFLP). The biodiversity degree (BD) defined as the number of fragments obtained by RFLP, and frequency of detection (FD) defined as the percentage of animals that had a fragment compatible with the presence of a certain bacteria, were recorded. Data were analyzed as a completely randomized design using type of diet as main effect. Mean comparisons of mortality and FD were made using a chi-squared test. A decrease of dietary CP content tended to reduce the mortality rate from 15 to 10% ($P = 0.09$). Animals fed LP diets showed a lower BD than those fed HP diets (1,905 vs. 2,561, $P = 0.04$). A reduction of dietary CP content led to a lower FD of several potential pathogens as *Helicobacter* spp. (from 80.0 to 57.1%, $P = 0.04$) and *Leptospira* spp. (from 77.1 to 57.1%, $P = 0.07$), and the FD of other intestinal bacteria as *Escherichia* spp. (from 45.7 to 20.0%, $P = 0.02$), and *Butyrivibrio fibrisolvens* (from 57.1 to 22.9%, $P = 0.003$). In conclusion, a reduction in dietary CP from 175 to 159 g/kg DM reduced the mortality rate, the biodiversity degree, the presence of several potential harmful bacteria at cecum, and should be contemplated as a strategy to increase the intestinal health in young rabbits.

Key Words: dietary protein, intestinal microbiota, rabbits

M233 Effect of lysine and leucine levels in wheat-based diets on the expression of two cationic amino acid-transporter proteins in growing pigs. M. A. Barrera, A. Morales*, M. Cervantes, A. B. Araiza, E. Avelar, and D. González, *ICA, Universidad Autónoma de Baja California, Mexicali.*

Dietary amino acid (AA) content may affect the AA absorption. Lysine is the first limiting AA in wheat for pigs, and leucine is recognized as an activator of mTOR, the protein synthesis regulator in muscle cells. An experiment was conducted to determine if adding lysine and leucine, above the NRC (1998) requirement level, to wheat-based diets affects the expression of b0,+ and CAT1 mRNA in 2 muscles (longissimus-LM and semitendinosus-SM), jejunum (J), and liver (L). Twenty crossbred pigs (Landrace-Ham-Duroc; BW of 16.4 ± 1.7 kg) were used. Treatments (T) were: T1, basal wheat-based diet fortified with crystalline lysine, threonine, and methionine; T2, basal plus 0.35% lysine; T3, basal plus 0.15% leucine; and T4, basal plus 0.35% lysine and 0.15% leucine. All diets were added with vitamins and trace minerals. At the end of a 28-d trial, 16 pigs were sacrificed and samples from LM, SM, L, and J were collected to analyze the expression of b0,+ and CAT1 mRNA. The effects of lysine, leucine, and their interaction were tested. Also, 3 contrasts were constructed to analyze the effect of the single or combined AA addition. The relative expression results (arbitrary units: ratios of b0,+ or CAT1 mRNA molecules:18S rRNA molecules) were: for b0,+; J, 1.84, 2.48, 0.43, 0.12; LM, 1.23, 3.71, 1.89, 1.50; SM, 0.80, 0.45, 0.81, 0.42; L, 1.41, 0.95, 4.26, 0.49; for CAT1; J, 0.10, 0.18, 0.13, 0.21; LM, 0.69, 1.38, 0.68, 1.08; SM, 0.33, 0.10, 0.54, 0.38; L, 0.92, 19.1, 0.36, 3.12, for T1 to T4, respectively. Leucine decreased b0,+ expression in J and LM ($P < 0.05$). Because of lysine addition the expression of b0,+ in LM increased ($P < 0.05$), but in SM decreased and tended to decrease in L ($P < 0.10$). Leucine increased but lysine decreased CAT1 expression in SM; in L there was an opposite response ($P < 0.05$). These data indicate that dietary AA levels affect the expression of their transporter proteins, and their effects are variable, depending on the AA and the animal tissue studied.

Key Words: swine, amino acids, transporters

M234 Effect of high lysine and leucine levels in wheat-based diets on performance and muscle expression of myosin mRNA in growing pigs. M. A. Barrera[1], M. Cervantes*[1], A. Morales[1], A. Araiza[1], D. Cervantes[1], V. Méndez[1], and H. Bernal[1], [1]*ICA, Universidad Autónoma de Baja California*, *Mexicali, BC, México*, [2]*Universidad Autónoma de Nuevo León*, *Monterrey, NL, México*.

Lysine is the first limiting amino acid (AA) in wheat-based diets for pigs; leucine is recognized as an activator of mTOR, which regulates protein synthesis in muscle cells. An experiment was conducted to evaluate the effect of adding lysine and leucine, above the NRC (1998) requirement levels, to wheat-based diets on the performance of growing pigs and the expression of myosin mRNA in the longissimus (LM) and semitendinosus (SM) muscles. Twenty crossbred pigs (Landrace-Ham-Duroc; BW of 16.4 ± 1.7 kg) were used in a Randomized Complete Block design. Treatments (T) were: T1, basal wheat-based diet fortified with crystalline lysine, threonine, and methionine; T2, basal plus 0.35% lysine; T3, basal plus 0.15% leucine; and T4, basal plus 0.35% lysine and 0.15% leucine. All diets were added with vitamins and trace minerals. At the end of the 28-d trial, 16 pigs were sacrificed and samples from LM and SM were collected to analyze the expression of myosin mRNA. The effects of lysine, leucine and their interaction were tested. Also, 3 contrasts were constructed to analyze the effect of the single or combined AA addition. The pig performance results were: weight gain, 0.607, 0.560, 0.492, 0.573 kg/d; feed intake, 1.24, 1.18, 1.11, 1.20 kg/d; feed conversion, 2.05, 2.14, 2.27, 2.11, for T1 to T4, respectively. There was a lysine x leucine interaction for weight gain and feed conversion ($P < 0.05$). Adding leucine alone decreased weight gain and depressed feed conversion ($P < 0.05$). Lysine addition to the leucine added diet tended to restore the daily gain ($P < 0.10$) and feed conversion ($P < 0.05$). The results of myosin mRNA relative expression (arbitrary units: ratios of myosin mRNA molecules:18S rRNA molecules) were: LM, 3.6, 3.3, 1.7, 0.12; SM, 1.46, 1.46, 0.59, 1.15, for T1 to T4, respectively. Leucine alone decreased myosin mRNA in both muscles ($P < 0.01$) and, combined with lysine, leucine further reduced myosin mRNA in LM ($P < 0.01$). These data indicate that excess of leucine negatively affects the expression of myosin mRNA, which was associated with a growth depression in pigs.

Key Words: swine, myosin, amino acids

M235 The effect of different animal and vegetable protein sources on the feed intake and weight gain of piglets. D. Solà-Oriol[1], J. Figueroa[1], E. Borda*[2], C. Chetrit[2], and J. F. Pérez[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Spain*, [2]*Bioiberica*, *Palafolls, Spain*.

Porcine Digestible Peptides (PDP; Palbio 50RD) is a highly digestible and economic protein source for weanling diets. The aim of the present work was to study the effect of PDP (52.8%CP) in the diet as compared with Peruvian fish meal (FM; 68.5%CP), spray dried animal plasma (SDAP; 75.0%CP), potato protein (PP; 79.5%CP) and soybean protein concentrate (SBP; 56.0%CP) on the early performance of weaned piglets. A total of 1540 26-d-old piglets (mixed sexes) were used in 4

consecutive trials conducted in the same commercial facility. Animals were distributed into 20 pens (18–20 piglets/ pen) according to the initial BW. Experimental treatments were formulated to meet or exceed piglet requirements with the same energy, protein, Lys, Met+Cys, Thr and Trp content. Control diet was formulated to contain 5% of PDP; and Test diet was obtained by replacing PDP by celite plus either FM (3.82%), SDAP (3.52%), PP (3.32%) or SBP (4.72%) according to their protein content. Feed was offered ad libitum in mash form. Individual animal weight and feed disappearance were recorded at 0, 7 and 14d post-weaning (PW) to calculate the average daily feed intake (ADFI) and average daily gain (ADG). Feed intake was not different ($P > 0.10$) between PDP, FM, SDAP or PP, but tended to be higher for PDP than SBP from 7 to 14d PW (324.8 vs 297.9 g/d; $P = 0.066$). The ADG of piglets fed on PDP tended to be higher ($P < 0.10$) than those fed FM or PP from 0 to 7d post-weaning, and was higher than those fed FM and SBP from 7 to 14d post-weaning (160.6 vs 128.0 g/d; and 200.0 vs 183.0 g/d; $P < 0.01$). However, no differences were observed on body weight at 14 d PW ($P > 0.10$). Lower feed conversion ratio (FCR) was observed for PDP compared with FM from 7 to 14d PW (1.714 vs 2.044; $P < 0.05$) but, higher compared with SDAP for the same period (2.272 vs 1.909; $P < 0.05$). Moreover, better FCR was also observed for PDP than FM during the entire starter phase (0 to 14dPW). Compared with the common protein sources, PDP may be considered as suitable source of protein for piglet diets improving the economic balance of the post-weaning phase.

Key Words: porcine digestible peptides, protein sources, piglets

M236 Aflatoxins and productive performance of two broiler breeder genotypes. A. Scher*[1], A. P. Rosa[1], J. M. Santurio[2], A. Londero[1], T. N. N. Vieira[1], and J. A. G. Ferreira Jr.[1], [1]*Poultry Laboratory – Universidade Federal de Santa Maria*, *RS, Brazil*, [2]*Lapemi– Universidade Federal de Santa Maria*, *RS, Brazil*.

The objective of this study was to determine the effect of aflatoxins (AFL) exposure on productive aspects of 2 broiler breeder genotypes. The experiment was carried out at The Federal University of Santa Maria – Brazil. 660 broiler breeder females and 60 males were submitted to intoxication with AFL (AFB1:86%, AFB2: 8.5%, AFG1:3.8%, AFG2: 1.7%) from the 24th to 64th week. From 65th to 68th week, all birds were fed with AFL free diets to evaluate residual effects. The estimated parameters were egg production and egg weight. The experimental design was in a CRD in factorial arrangement with 3 levels of AFL (0.0, 0.50 and 1.0 mg/kg diet) and 2 breeders' strains (A and B), totaling 6 treatments with 5 replicate pens of 22 females and 2 males each. The laying rate was depreciated by the addition AFL in the diet. The addition of 1.0mg AFL/kg of diet was more harmful than 0.5mg AFL/kg, indicating a dose dependent effect. Breeders fed diets containing 0.0; 0.5 and 1.0mg AFL/ kg had average laying rates of 63.93; 61.54 and 58.53% respectively ($P \leq 0.0001$) during the intoxication period. It was observed that strain B breeders had a laying rate of 61.72%, and strain A laying rate that was 60.94% ($P = 0.0018$). There was interaction among the levels of AFL and the strains ($P = 0.0779$). Birds of genotype B, when subjected to 0.5 and 1.0mg AFL/ kg diet, showed eggs productions 3.03 and 8.73% lower than not intoxicated. In strain A, the reduction in egg production was 4.45 and 8.16% when the birds were intoxicated with 0.5 and 1.0mg AFL/kg diet, respectively. There was no recovery in the laying rate of birds intoxicated after withdrawal of the AFL. The eggs weight was not influenced by levels of AFL; however, strain A breeders produced the heaviest eggs during the study period. The productive performance of broiler breeders was depressed by AFL. Strain A breeders were more susceptible to 0.5 mg AFL/kg diet than those of strain B.

Key Words: egg production, breeders, strains

M237 Progeny of broiler breeders from two genotypes intoxicated with aflatoxins. A. Scher*[1], A. P. Rosa[1], J. M. Santurio[2], A. Londero[1], G. Farina[1], and J. A. G. Ferreira Jr.[1], [1]*Poultry Science Lab – Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*, [2]*Lapemi– Universidade Federal de Santa Maria*, *Santa Maria, RS, Brazil*.

The objective of this study was to evaluate the performance of the progenies of 2 broiler breeder genotypes intoxicated with aflatoxins (AFL). This study was carried out at Poultry Laboratory at The Federal University of Santa Maria – Brazil. Were performed 3 experiments, from 1 to 21 d, each using 600 chicks. In the first (Experiment 1), were used chicks from eggs produced by hens with 32 wk of age, the second and third evaluations were carried out with chicks produced by breeders with 48 (Exp.2) and 64 wk of age (Exp.3), respectively. The progenies were housed in batteries, located in an environment controlled room. For each experiment was used a CRD factorial arrangement 3x2 (0.0, 0.5 and 1.0mg of AFL/kg in breeders diets and 2 genotypes: A and B), totalizing 6 treatments with 10 repetitions of 10 males each. The feed and water were provided ad libitum. In the Experiment 1, hens fed diets containing AFL produced chicks with lower body weight (BW) ($P \leq 0.0001$). The addition of 0, 0.5 and 1.0mg AFL/kg resulted in chicks with 41.83g, 41.48 and 41.09g of BW, respectively. In Experiments 2 and 3, only the addition of 1.0mg/kg AFL in breeders diets depressed chicks' BW ($P = 0.0704$ and $P = 0.0341$). In all experiments, chicks produced by breeders submitted to diets containing 1mg AFL/kg had lower body weight at 21 d. Progeny from genotype A breeders had higher BW, at 1 and 21d, than genotype B progeny. Studying the interaction among the AFL levels and the genotypes, it was observed that genotype B breeder's exposure to AFL did not affect the progeny's initial weight, however, in genotype A, there was a decreased progeny initial weight from breeders exposed to AFL. The addition of 1 mg AFL/kg in broiler breeder's diets resulted in negative effect on the progenies weights.

Key Words: progeny, breeders, strains

M238 The effects of the dietary supplementation with essential oils from selected species of the Lamiaceae family on the performance of growing broilers chickens. L. Roldan*[1], C. Ariza-Nieto[2], G. Diaz[1], and G. Afanador[1,2], [1]*Universidad Nacional de Colombia*, *Bogota, Colombia*, [2]*CORPOICA*, *Bogota, Colombia*.

The effects of essential oils (EO) obtained from 3 Lamiaceae plants (*Thymus vulgaris*, *Rosmarinus officinalis* and *Ocimum basilicum*) on the performance of growing broilers were investigated. A total of 210 one-day-old Ross male broiler chicks were placed in 30 brooder cages and were randomly assigned to the 5 experimental groups: 1) control; 2) growth promoter antibiotic, 500 ppm Bacitracin; 3) 600 ppm of thyme EO; 4) 600 ppm of rosemary EO, and 5) 600 ppm of basil EO. Throughout the experimental period of 21 d, body weight gain and feed intake were recorded at 7, 14, and 21 d of age, and feed conversion ratios were calculated. Data were analyzed as repeated measures under a completely randomized design using the MIXED procedure of SAS (Ver. 9.0, SAS Institute, Cary, NC).The statistical model included the fixed effects of EO supplementation, age and the interaction. Random intercepts and slopes were included to account for within pen effect. A likelihood ratio test (LRT) was used to test which variance/covariance (compound symmetry, unstructured) structure fit better to the data using the residual maximum likelihood (REML) algorithm. Additionally, LRT was performed using the maximum likelihood (ML) estimating method to eliminate nonsignificant factors from the model. The final model was run using REML. Least squares means adjusted by Tukey method were used to compare means. Body weight gain and feed consumption were not significantly affected ($P > 0.05$) by EO supplementation. The supplementation of dietary basil EO resulted in a significantly ($P < 0.05$) lower feed conversion ratio (1.18) compared with the other groups; growth promoter antibiotic (1.26), control (1.25), rosemary EO (1.24) and thyme EO (1.28). This parameter indicated that basil EO exerted a growth promoter effect in broiler chickens.

Key Words: essential oils, Lamiaceae, broilers

M239 Effect of crude glycerin on the performance of female broilers chickens at high altitude. C. Ariza-Nieto*[1], Y. Avellaneda[1], and G. Afanador[1,2], [1]*CORPOICA*, *Bogota, Colombia*, [2]*Universidad Nacional de Colombia*, *Bogota, Colombia*.

This study evaluated the use of crude glycerin, a co-product of biodiesel production, in a feeding program for female broilers chickens maintained at high altitude. Six hundred forty 24-d-old Ross female broilers were randomly assigned to 1 of 4 glycerin levels (0, 3, 6, and 9% of the diet). The birds were placed in 16 pens during growth-finishing phase and their performance was determined every other week until slaughter. Data were analyzed under a completely randomized design as repeated measures on time using the MIXED procedure of SAS (Ver. 9.0, SAS Institute, Cary, NC, USA). The shadow price of crude glycerin was established using linear programming. Glycerin levels did not affect feed intake (average during the 18 d period female broilers was 135.6 ± 16.6 g/bird). Body weight gain was lower ($P = 0.0799$) in female broilers chickens fed 9% glycerin (64.9 g), compared those receiving 3% (68.3 g) or 6% (69.4 g), respectively. The level of inclusion of glycerin showed a quadratic effect ($P = 0.0177$), an inclusion level of 4.2% of crude glycerin maximizes body weight gain. Feed conversion of birds fed glycerin at 3% and 6% of inclusion were significantly lower ($P < 0.05$) compared with the control and 9% group. This ratio showed a quadratic effect and 3.88% of crude glycerin was the optimum. No significant effects on mortality were shown due to the inclusion of crude glycerin. Diets containing up to 4% of crude glycerin maximizes performance of female broilers at high altitude during growing-finishing phase.

Key Words: glycerin, female broilers, high altitude

M240 Vitamin E, herbs and spices in broilers diets: Evaluation of oxidative stability of pre-cooked meat balls. A. M. C. Racanicci*[1], J. F. M. Menten[2], and M. Nascente[1], [1]*University of Brasília (UnB)*, *Brasília, DF, Brazil*, [2]*University of São Paulo (ESALQ)*, *Piracicaba, SP, Brazil*.

The dietary utilization of natural antioxidants has been reported to improve oxidative stability of chicken meat and meat products. The objective of this study was to evaluate the dietary supplementation of resin oils from previously selected herbs and spices on oxidative stability of stored pre-cooked meat. Resin oil from 6 herbs (H: rosemary, thyme, oregano, sage, bay, and basil) and 3 spices (S: cinnamon, clove, and ginger) were microencapsulated (20% of resin oil) and fed to 80 male one-day-old Cobb chicks raised in 20 cages, randomly assigned to 8 treatments with 2 replications of 5 birds. Experimental treatments were CONT (basal diet with tocopherol from premix and feed ingredients); VITE (basal diet + 200 mg α-tocopheryl acetate/kg); H500 (basal diet + 100 mg of herbs/kg); H250 (basal diet + 50 mg of herbs/kg); S500 (basal diet + 100 mg of spices/kg); S250 (basal diet + 50 mg of spices/kg); HS500 (basal diet + 100 mg of herbs and spices/kg) and HS250 (basal diet + 50 mg of herbs and spices/kg). At 41 d of age, 5 birds of each treatment were slaughtered and breast meat collected, minced, pooled, and mixed to 0.1% of salt to produce meat balls (±30g). After vacuum-packaging, the balls were cooked, re-packed and stored in a cold and dark room for up to 8 d. TBARS were determined in duplicate in 3 samples per treatment on d 0, 1, 3, 6 and 8 to assess the degree of lipid oxidation during chilled storage. The supplementation of α-tocopherol (VITE) protected meat balls against lipid oxidation as shown by statistically lower ($P < 0.0001$) TBARS values at d 8 (30.3 μmol MDA/kg of meat) compared with all treatments (CONT 56.7, H500 70.0, S500 56.3, HS500 65.0, H250 61.1, S250 62.7 and HS250 71.4 μmol MDA/kg of meat). However, the supplementation of natural antioxidants (H, S or HS) showed an unpredicted prooxidant effect demonstrated by the increase ($P < 0.0001$) in TBARS values compared with CONT for both concentrations, except S500.

Key Words: natural antioxidants, tocopherol, TBARS

M241 Effect of technical grade glycerin on the performance of brown laying hens at high altitude. Y. Avellaneda*[1], D. Cifuentes[1], G Afanador[1,2], and C. Ariza-Nieto[1], [1]*CORPOICA*, *Bogota, Colombia*, [2]*Universidad Nacional de Colombia*, *Bogota, Colombia*.

Biodiesel production processes generate about 10% glycerin by volume as a waste co-product. In recent years production has increased exponentially, which have led to a reduction of its price, making this co-product an opportunity to reduce production costs of feed in the poultry industry. The aim of this study was to evaluate the use of technical grade glycerin (99.5% purity) in brown layer hens at high altitude. Eighty 24-wk-old Babcock Brown laying hens were randomly assigned to one of the 4 glycerin levels (0, 2.5, 5.0, and 7.5%). Hens were placed in 40 cages during 20 weeks and their performance was record every other week and during the study, they were fed ad libitum with a feed meal (2800 kcal AMEn/ kg, 19% CP, 0.86% digestible lysine, 4.0% Ca and 0.42%

P available) and drinking water was also available ad libitum. Data were analyzed under a completely randomized design as repeated measures on time using the MIXED procedure of SAS (Ver. 9.0, SAS Institute, Cary, NC). Feed intake, egg production, egg mass, feed conversion per dozen and feed conversion on an egg mass were not affected ($P > 0.05$) due to the inclusion of technical grade glycerin. On average feed intake, egg production, egg weight, feed conversion per dozen, and feed conversion on an egg mass basis were 111.5 g/d, 93.2%, 58.9 g, 2.4, and 1.5, respectively. In terms of quality of the eggs, the albumen height was not affected due to the inclusion of glycerin (6.21 ± 1.08 mm), but the eggs of hens 2.5% group showed a thicker eggshell compared with the 5 and 7.5% ($P < 0.05$). Pale-yolks were observed in eggs from hens fed 5.0 or 7.5% glycerin compared with the control. It is concluded that technical grade glycerin in diets for brown laying hens up to 7.5% did not affect productive performance, but egg quality related to the color of the yolk can adversely be affected when the inclusion level of glycerin increases from 5.0 to 7.5%.

Key Words: technical glycerin, performance, laying hen

M242 Effects of Korean herb supplementation (*Paeniae radix*, *Angelicae gigantis radix*, *Cnidium rhizome*, and *Polygoni multiflori radix*) on growth performance, nutrient digestibility, blood characteristics, meat quality and fatty acid content of meat of growing pigs. Q. W. Meng*, J. S. Yoo, H. J. Kim, J. P. Wang, J. H. Jung, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to investigate the effects of Korean herb mixture supplementation (*Paeniae radix*, *Angelicae gigantis radix*, *Cnidium rhizome*, and *Polygoni multiflori radix*) on growth performance, nutrient digestibility, meat quality and fatty acid content of meat produced by growing pigs. A total of 64 pigs (40.19 ± 1.42kg) were evaluated over 84 d. Dietary treatments included: 1) CON (basal diet), 2) KH (basal diet + 1% Korean herb mixture), 3) HKH (basal diet + 1% Korean herb mixture with heat treatment), and 4) HKHE (HKH + 0.2% β-mannanase). Each treatment consisted of 4 replicates with 4 pigs per pen in a randomized complete block design. The highest ADG, digestibility of dry matter (DM), nitrogen (N) and energy ($P < 0.05$) was observed in the HKHE group during wk 0–6. A decreased DM, N and energy digestibility were observed in the KH group when compared with other groups during wk 0–6. Moreover, dietary HKHE resulted in a higher HDL-cholesterol ($P < 0.05$) and lower LDL-cholesterol than the CON treatment at the end of the experiment. The meat pH was highest in the HKHE group and lowest in the KH group ($P < 0.05$). Pigs fed the KH diet showed the lowest marbling ($P < 0.05$) among treatments. The drip loss on the fifth day was higher ($P < 0.05$) in the CON group than the KH group. Of the fatty acids, the saturated fatty acid (SFA) levels were higher in the CON group ($P < 0.05$) than in the HKHE group. Polyunsaturated fatty acid (PUFA) was shown to be higher in the HKHE group ($P < 0.05$) than in the CON group. In conclusion, supplementation of the diet with Korean herb mixture improved growth performance, nutrient digestibility and meat quality.

Key Words: Korean herb mixture, meat quality, growing pigs

M243 Effects of dietary bamboo vinegar supplementation on growth performance, blood characteristics, meat quality, fatty acid content and fecal malodor emission in finishing pigs. Q. W. Meng*, J. H. Lee, H. D. Jang, T. X. Zhou, L. Yan, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Choenan, Choongnam, Korea*.

A 42 d trail with 60 [(Landrace × Yorkshire) × Duroc] pigs (79.66 ± 1.42 kg) was conducted to investigate the effects of bamboo vinegar (Bio-BV) supplementation in diets on growth performance, blood characteristics, meat quality, fatty acid and fecal malodor emission in finishing pigs. Pigs were randomly allotted to 1 of 3 dietary treatments in a randomized complete block design according to their sex and body weight (BW) (5 replicates with 4 pigs per pen). The experimental treatments included: 1) CON (basal diet), 2) BV1 (CON + 0.1% Bio–BV), and 3) BV2 (CON + 0.2% Bio-BV). BV1 and BV2 supplementation had higher ADG ($P < 0.05$) than CON group during 0–3 weeks as well as the overall period. Pigs fed diets with BV2 increased pH and sensory score (firmness) ($P < 0.05$) compared with the other groups. Moreover, the BV2 treatment improved sensory color and a* value ($P < 0.05$) compared with the control group. L* value was significantly improved ($P < 0.05$) when pig received control diet compared with BV2 treatment. In term of fatty acid, the total SFA level and stearic acid (C18:0) were improved ($P < 0.05$) in BV groups compared with CON group. Bio-BV supplementation decreased the total UFA and UFA/SFA ratio ($P < 0.05$) when compared with those fed CON diet. Pigs fed Bio-BV supplementation improved ($P < 0.05$) linoleic acid (C18:2n–6) concentration compared with CON. In fecal malodor emission, NH_3 emission was significantly reduced ($P < 0.05$) in BV2 group compared with CON and BV1 groups on the first and 5th day. On 10th day, CON treatment showed greater NH_3 emission ($P < 0.05$) than BV1 treatment. BV1 group had higher ($P < 0.05$) NH3 emission than BV2 group. Pigs fed control diet had higher ($P < 0.05$) H_2S and total mercaptan concentration than those fed BV2 diet. In conclusion, Bio-BV supplementation can exhibit beneficial effects on growth performance and meat quality, and concomitantly decreases NH_3, H_2S and Total mercaptan emission. Besides, Bio-BV administration increased certain unsaturated fatty acids while decreasing some saturated fatty acids.

Key Words: bamboo vinegar, meat quality, finishing pigs

M244 The effects of caper (*Capparis ovata* Desf.) on some hematological parameters and organs of Lohmann roosters. O. Yildiz-Gulay*[1], M. S. Gulay[1], A. Balic[2], and A. Ata[1], [1]*Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*, [2]*Sakarya Toyota Hospital*, *Sakarya, Turkey*.

Caper (*Capparis* genus in the Capparaceae family) is a plant found in tropical/subtropical areas. Caper is consumed widely in most Mediterranean countries and can be consumed for long time periods. However, no detailed study has been performed concerning consumption of capers. Thus, the purpose of this study was to determine the effects of caper (*Capparis ovata* Desf.) on blood parameters, body weight (BW) changes, and organs of Lohmann roosters. Twenty-four week-old roosters were randomly assigned to control (C) and caper treatment (TR) groups (8 per group) and fed a standard diet (14% crude protein and 3000 kcal/kg metabolizable energy). Roosters in C received 10 mL of tap water, whereas roosters in TR received 1 g of caper per 1 kg of BW suspended in 10 mL of tap water. Experiment was lasted for 39 d and treatments were given by oral gavages. Roosters were weighed at the end of caper treatments and blood was taken from the vena brachialis. Organ weights were recorded after sacrifice. No negative effect of caper treatment was observed on hemoglobin (C = 15.6 ± 0.58 vs. TR = 15.2 ± 0.35 g/dL), hematocrit (C = 38.3 ± 1.13 vs. TR = 37.1 ± 1.21%), plasma protein (C = 5.3 ± 0.21 vs. TR = 5.6 ± 0.39 g/dL), red blood cell count (C = 2.97 ± 0.14 vs. TR = 3.18 ± 0.11 × 10^6/μL), white blood cell count (C = 27.1 ± 0.98 vs. TR = 25.6 ± 0.89 × 10^3/μL), BW (C = 2070.6 ± 35.8 vs. TR = 2022.8 ± 56.4 g), liver weight (C = 25.8 ± 0.88 vs. TR = 26.5 ± 1.63 g), kidney weight (C = 5.12 ± 0.24 vs TR = 5.14 ±

0.24 g), testis weight (C = 10.4 ± 1.33 vs TR = 10.9 ± 1.08g), pancreas weight (C = 3.83 ± 0.13 vs. TR = 3.91 ± 0.21 g) or heart weight (C = 9.65 ± 0.60 vs. TR = 9.45 ± 0.52 g). In addition, no apparent changes in liver, kidney, testis, pancreas and heart were detected by gross post mortem and histopathological examination to suggest toxic effects of oral use of caper for 39 d. Interestingly, Caper treatment increased the thrombocyte levels in treated roosters (C = 0.244 ± 0.26 vs TR = 0.377 ± 0.21× 10^5/μL; $P < 0.01$). In conclusion, the results suggest no toxic effect of capers in roosters. Moreover, high thrombocyte count due to caper treatment should be evaluated further for use in diseases causing low thrombocyte counts.

Key Words: rooster, hematological parameters, histopathology

M245 Safety evaluation of Event 5307 transgenic corn in broiler chickens. A. Sauvé[2] and J. T. Brake*[1], [1]*North Carolina State University, Department of Poultry Science, Scott Hall*, *Raleigh,* [2]*Syngenta Biotechnology, RTP*, *Raleigh, NC*.

A 49-d feeding study evaluated whether broiler diets prepared with Event 5307 transgenic maize (corn) had an effect on broiler livability, BW, feed conversion ratio (FCR), feed consumption, or carcass yield when compared with diets prepared with either non-transgenic, near-isogenic control corn or commercially available control corn (NC2007). The 5307 corn contained eCry3.1Ab and phosphomannose isomerase (PMI) transgenic proteins. The eCry3.1Ab protein is a chimera of modified Cry3A and Cry1Ab proteins and has insecticidal activity against certain corn rootworm species. The PMI protein acts as a selectable marker enabling the selection of positive transformants. Broiler males had a 49-d BW of 3,543 g while females weighed 2,898 g. Overall livability was 98%. Final 49-d BW, adjusted FCR, feed consumption, and livability of the 5307 transgenic, non-transgenic, and NC2007 groups did not differ. There were no statistically significant differences other than during the grower diet period, when the 5307 transgenic group had a lower FCR compared with the NC2007 group, with the non-transgenic group being intermediate. This difference was small in magnitude, resolved by the finisher diet period and was not considered adverse. There were no differences in carcass yield between groups on a gross BW basis. When compared on a percentage BW basis, the thighs of males in the non-transgenic group weighed more than those in the 5307 transgenic and NC2007 groups and the thighs and Pectoralis minor of females in the non-transgenic and NC2007 groups weighed more than those in the 5307 transgenic group. However, due to the lack of differences in other carcass parts these were considered incidental. Diets prepared with 5307 transgenic corn supported rapid broiler growth and excellent FCR without a significant impact on overall carcass yield. The results clearly indicate that the transgenic corn had no deleterious effects on bird health in this study.

Key Words: transgenic corn, transgenic maize, 6307 corn

M246 Effect of garlic extract (Garlicon) on piglet productive performance in the nursery period. J. Morales[1], R. López[2], P. Coscojuela[2], and C. Piñeiro*[1], [1]*PigCHAMP Pro Europa*, *Segovia, Spain*, [2]*Prebia Feed Extracts*, *Toledo, Spain*.

Intensive research has focused on the potential of phytogenic feed additives to replace antibiotics in piglet diets, mainly based on their potential to promote a beneficial gut microflora which protects the host against pathogens and helps to alleviate periods of stress. In vitro, the antimicrobial effect of some plant extracts, as in the case of garlic, is as consistent as the effect of antibiotics. However, their effect in vivo is not consistent compared with antibiotics. The aim of this study was to assess the effect of a plant extract based on garlic (GAR) in weaned piglets. Three different dietary doses of GAR were assessed (50, 100, and 150 ppm) in a 3-wk period, and compared with a negative control group and with a positive control group supplemented with gentamycin (20 ppm). For the experiment, 280 piglets were used (10.3 ± 1.81 kg BW) and allotted in 40 pens (8 per treatment). Average daily gain (ADG), feed intake (FI) and feed efficiency were controlled in the starter phase (42 to 70 d of age). A linear and quadratic effects were observed with GAR supplementation and groups supplemented with 50 and 100 ppm of GAR showed higher average daily gain (ADG) and final BW than the negative control and 150 ppm groups (532, 592, 592, 559 g/d ADG; $P < 0.01$ in control, 50, 100 and 150 ppm groups, respectively). Feed intake tended to be higher in GAR groups than in the control group ($P < 0.10$), while feed efficiency did not differ among groups. In comparison with gentamycin, productive performance was not different in the GAR supplemented piglets, being numerically higher performance in 50- and 100-ppm GAR than in gentamycin-supplemented piglets. No differences were found in feed efficiency between antibiotic and GAR groups. We conclude that GAR supplementation improved ADG, FI and, consequently, final BW in the nursery period, especially supplemented at 50- and 100-ppm. Furthermore, productive performance obtained by the GAR supplementation was as consistent as the one obtained by the dietary gentamycin.

Key Words: plant extracts, phytogenic additives, pigs

M247 Effect of different levels of substitution of maniçoba hay on the performance of free-range birds in the semi-arid region. P. E. N. Givisiez*[1], M. A. S. F. Campos[2], C. C. Goulart[1], F. G. P. Costa[1], and J. H. V. Silva[1], [1]*Universidade Federal da Paraiba*, *Areia, PB, Brazil*, [2]*Universidade Federal do Rio Grande do Norte*, *Natal, RN, Brazil*.

Local resources should be evaluated as potential ingredients to be used in poultry feeding in alternative or organic systems. This study evaluated the effect of partial substitution of conventional corn-soybean meal diet by maniçoba hay (*Manihot pseudoglaziovii*) on the performance and cut yields of free-range birds in the semi-arid region of Brazil. Eighty-four Paraiso Pedres birds were randomly distributed into 3 treatments and 4 repetitions of 7 birds (4 males and 3 females). Diets for the growing (30 to 42 d) and final (43 to 73 d) phases were partially substituted by 0, 10 and 20% of maniçoba hay. Body weight (BW), weight gain (WG) and feed:gain ratio (F:G) were determined for each phase. Two birds per repetition were killed at 73 d to determine carcass weight, absolute (g) and relative weight (%) of cuts and abdominal fat. Data were submitted to ANOVA in a completely randomized design, with 3 treatments and 4 repetitions for performance parameters and 8 repetitions for carcass and cuts analyses. Means were compared by Tukey's test at 5% probability. BW, FI and WG were not affected by the use of maniçoba hay until 42 d. Conversely, weight gain (42 to 73 and 30 to 73 d), body weight at 73 d and FC were negatively affected by increasing maniçoba levels, probably as a result of higher crude fiber levels in the diet and lower AME and AMEn. Carcass, breast and drumstick weights (g) were decreased ($P < 0.05$) by increasing levels of maniçoba, as well as breast yield (%). Therefore, maniçoba hay should not be used if cuts are to be commercialized. On the other hand, the majority of free-range birds are commercialized as live birds or whole carcasses, and levels up to 10% would not impair gain. In conclusion, maniçoba hay may be used up to 10% for free-range birds reared in the semi-arid region without affecting profit.

Key Words: dietary fiber, free-range birds, performance

M248 Performance of broilers fed mash or pellet diets containing whole or ground pearl millet. T. R. Torres[1], M. C. M. M. Ludke*[1], J. V. Ludke[2], C. B. V. RAbello[1], M. A. M. Faria[1], E. M. S. R. Andrade[1], E. J. O. Souza[1], and M. R. Lima[1], [1]*Universidade Federal Rural de Pernambuco*, *Recife, Pernambuco, Brasil*, [2]*Embrapa Suínos e Aves*, *Concordia, Santa Catarina, Brasil*.

The effect of whole or ground millet grain inclusion at level of 20% into mash or pellet diets on performance of male broilers reared during 21 d was evaluated. The trial was established in 2 nutritional phases: from 1 to 7 and 8 to 21 d of age. A randomized block design in a factorial 3 × 2 with 3 diets (without millet -CSBM, with whole -WMG or ground millet grain -GMG) and 2 physical forms (mash, m, or pellet, p) were established containing 5 replicates per treatment and 10 birds per experimental unit. Parameters evaluated were feed intake, weight gain -WG, feed to gain ratio -F:G and feed efficiency (energetic - FE and proteic - EP) in both phases and during entire trial. Broilers fed mash diets had higher feed consumption than those fed pellet diets: 153 g x 144 g in period 1 to 7 d ($P < 0.05$, CV = 4.46%), 986 g x 944 g in period 8 to 21 d ($P < 0.05$, CV = 3.57%), 1170 g x 1117 g in total period ($P < 0.05$, CV = 3.18%). Feed to gain ratios were better for pellet diets than for mash diets: 1.24 × 1.33 in period 8 to 21 d ($P < 0.05$, CV = 2.62) and 1.27 × 1.18 in total period ($P < 0.05$, CV = 2.13). The proteic efficiency was higher for pellet diets than for mash diets in period 8 to 21 d: 3.82 × 3.57 g/g ($P < 0.05$, CV = 2.64%). In Table 1 were presented the mean values of parameters whose interactions between factors were significant ($P < 0.05$). Pearl millet may be used either in whole grain or ground when fed in pellet diets.

Table 1. Mean values of the evaluated parameters with significant interaction between physical form of diets and diet type

From 1 to 7 days	Physical form	WMG	GMG	CSBM
F:G g/g	mash	1.07^{a}	1.03^{a}	1.03^{a}
	pellet	0.94^{b}	0.98^{b}	0.94^{b}
WG, g	mash	141.5^{b}	151.1	147.8
	pellet	154.5^{a}	148.9	150.8
EE, g/g	mash	0.314^{b}	0.322^{b}	0.323^{b}
	pellet	0.356^{a}	0.340^{a}	0.359^{a}
PE, g/g	mash	4.24^{b}	4.40^{b}	4.40^{b}
	pellet	4.80^{AB,a}	4.62^{B,a}	4.86^{A,a}

^{a,b}Different lowercase letters within a column were different ($P < 0.05$).

^{A,B}Different uppercase letters within a row were different ($P < 0.05$).

Key Words: diet physical form, feed efficiency, poultry

M249 Using marine algae *Chlorella vulgaris* as a prebiotic alternative on broiler chicks. M. Rezvani*, M. Zaghari, M. Shivazad, and H. Moravej, *University of Tehran*, *Karaj, Tehran, Iran*.

To evaluate the effects of chlorella on broiler chick performance, an experiment was conducted by using 80 Ross 308 male broiler chicks. The experiment was accomplished in completely randomized design including 5 treatments with 4 replication and 4 mail chicks in each. The basal diet based on corn-soybean meal and without any additives was formulated. A graded level of chlorella (0.07, 0.14, and 0.21%) was added to basal diet to formulating diets 2, 3 and 4 respectively. To comparing the effects of chlorella with commercial prebiotics an extra diet (diet 5) was formulate by adding a commercial prebiotic to the basal diet. Data was analyzed by using GLM procedure of SAS software means were compared by Duncan multiple range test. Results showed that there were no significant differences in weight gain between the treatments in all ages. While the chlorella treatments in compare with the control treatment had numeral increasing in this trait. Feed conversion ratio significantly decreased by adding the chlorella and commercial prebiotic to the basal diet at 42 d of age ($P < 0.05$). Evaluation of ceca content showed an increasing in lactobacillus population and improving the ratio of lactobacillus to coliform population by increasing the chlorella in the basal diet. The results of this experiment indicated that chlorella have prebiotic properties and even have better performance in some quality to compare the commercial prebiotics.

Key Words: broiler, chlorella, prebiotic

M250 Effects of mung bean waste on pelleting characteristics, growth performance, nutrient digestibility and carcass quality in broilers. N. Amornthewaphat*, P. Rungcharoen, Y. Ruangpanit, S. Rattanatabtimthong, and S. Attamangkune, *Kasetsart University*, *Bangkok, Thailand*.

Series of experiments were conducted to determine the apparent metabolizable energy of mung bean waste in broilers and effects of mung bean waste inclusion in broiler diets on growth performance and nutrient digestibility. In Exp. 1, 120 male broilers (28-d of age; 10 chicks per metabolic cage; 6 cages per treatment) were randomly fed 2 experimental diets consisting of corn soybean basal diet and 20% mung bean waste substituted basal diet. The apparent metabolizable energy of mung bean waste for broilers was 1,844.71 ± 130.71 kcal/kg. In Exp. 2, a total of 1,200 broilers were used in a 42-d growth assay with 3 phase-feeding programs (50 chicks per pen; 6 pens per treatment). Treatments were mung bean waste inclusion of 0%, 5%, 10% and 15% in the experimental pelleted diets and arranged in a randomized completely block design. Sex was a block factor. Increasing mung bean waste resulted in increased palm oil inclusion in the diets. These resulted in linearly decreased pelleting energy consumption and pellet durability index ($P \leq 0.001$). Increasing mung bean waste in the diets decreased ($P \leq 0.05$) body weight gain of starter chicks from 612 to 583 g and linearly suppressed ($P \leq 0.001$) feed conversion from 2.25 to 2.35. There was no difference in growth performance for a grower and a finisher period. For the carcass quality, decreased abdominal fat ($P \leq 0.001$) and increased gizzard weight ($P \leq 0.05$) were observed in chicks fed mung bean waste diets. In Exp. 3, 96 male broilers were used in a 10-d total excreta collection assay (6 broilers per metabolic cage; 4 cages per treatment). Treatments used were the same as in Exp. 2. There was linear decrease ($P \leq 0.05$) dry matter from 80.07 to 77.41% and fiber utilization from 26.83 to 13.59% with increasing mung bean waste. In conclusion, the recommendation of mung bean waste inclusion in the broiler diets should less than 5% to achieve optimum growth performance and nutrient digestibility of broilers.

Key Words: mung bean waste, broilers, growth performance

M251 Effects of dietary grape seed polyphenols on plasma lipid and mineral contents, and intestinal microflora in broiler chicks. A. Viveros*[1], S. Chamorro[2], A. Brenes[2], C. Romero[3], I. Arija[1], and C. Centeno[2], [1]*Facultad de Veterinaria, UCM, Madrid, Spain*, [2]*Instituto del Frio-ICTAN, CSIC, Madrid, Spain*, [3]*Escuela Tecnica Superior de Ingenieros Agronomos, UPM, Madrid, Spain*.

Grapes contain a large array of phenolic compounds which have been showed to have hypolipidemic and anti-microbial effects as well as to act as antioxidant by scavenging reactive oxygen species (ROS) and chelating metal ions which promote the generation of ROS. An experiment was conducted to study the effect of the inclusion of grape seed extract (GSE) and vitamin E in broiler chicks diets on performance,

plasma lipid and mineral contents, and ileal and cecal microflora at 21 d of age. Experimental diets were as follows: 1) Control wheat-soybean diet (WS); 2) WS + vitamin E (200 mg/kg); 3) WS + 50 mg/kg tetracycline; 4, 5, 6 and 7) WS + 0.025, 0.25, 2.5 and 5.0 g/kg GSE, respectively. Each treatment was randomly assigned to 7 pen replicates (5 birds each). Performance was not affected by dietary treatments except in the case of birds fed the highest GSE diet which showed a decrease of body weight. The inclusion of graded concentrations of GSE in the chicken diets lowered the concentration of plasma cholesterol and LDL-cholesterol and increased the content of plasma triglycerides and HDL-cholesterol in a dose-dependent manner. Plasma VLDL-cholesterol was not affected by dietary treatment. Compared with the vitamin E diet, the GSE diet increased the concentration of plasma triglycerides and reduced the contents of plasma HDL and LDL-cholesterol. Regarding plasma mineral contents, the addition of increasing concentrations of GSE in the chicken diets reduced the concentrations of copper, iron and zinc compared with those fed the control and vitamin E diets. In the ileal content, birds fed the lowest concentration of GSE had a lower population of *E. coli* than in any other treatment group. Compared with the control diet, the GSE diet reduced the populations of *E. coli* and coliformes in the cecal digesta. In conclusion, dietary GSE reduced the iron and copper status of broiler chick which could play an important role in the antioxidant processes. GSE has showed to have hypocholesterolemic effect and caused a decrease in the populations of *E. coli* in the intestinal microflora.

Key Words: chicks, grape polyphenols, blood parameters and intestinal microflora.

M252 Comparison of dietary supplementation of cumin essential oil and prebiotic on humoral immune response, blood metabolites and performance of broiler chickens. M. Aami-Azghadi, A. Golian*, H. Kermanshahi, and M. Sedghi, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

Five hundred day-old male Ross broiler chicks were divided into 50 groups of 10 birds each and randomly assigned to 10 dietary treatments with 5 replicates each. Two corn-soybean meal-based diets were first provided to meet 100% and 95% of recommended digestible amino acids (RDAA) for starter (1–14 d), grower (15–35 d) and/or finisher (36–49 d) periods. Each starter diet was subdivided into 5 parts and supplemented with 0 and 2 g/kg Fermacto and 0.2, 0.4 and 0.8 g/kg cumin essential oil (CEO). The grower diets contained half of the same supplementation in the starter diets and each of the un-supplemented finisher diet was fed to the corresponding birds. The performance parameters were determined during all periods and carcass yields and relative organ weights measured on d 28 and 49. The blood metabolites, cell differentiation and total anti-SRBC, IgG and IgM titers measured on d 26 in birds fed 100% RDAA diets. The CEO and Fermacto did not have a significant effect ($P > 0.05$) on performance in the starter and finisher periods but higher BWG was observed in birds fed diet with the lowest level of CEO in the grower period. Birds fed diet with 100% RDAA and Fermacto had higher feed: gain ratio in the growing period compared with those fed diet of similar AA and 0.2 g/kg of CEO. A 5% decrease in the RDAA had no adverse effect ($P > 0.05$) on the overall FI and BWG, but FCR was increased ($P > 0.05$). Carcass yields and cuts were not influenced ($P > 0.05$) by CEO, Fermacto or DAA levels. There was not a significant difference ($P > 0.05$) in total anti SRBC, IgG and IgM titers The inclusion of Fermacto or various levels of CEO in diets did not affect ($P > 0.05$) serum metabolite (mg/dL) at d 28, although triglyceride and VLDL concentrations was lower ($P < 0.05$) in chicks fed starter diet contained 0.4 g/kg CEO.

Key Words: cumin essential oil, humoral immune response, chickens performance

M253 Effect of ginger root and ginger oil on antioxidant status and meat quality of broilers. G. F. Zhang[1], Z. B. Yang*[1], Y. Wang[2], W. R. Yang[1], and S. Z. Jiang[1], [1]*Shandong Agricultural University*, *Tai-an, Shandong, China*, [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre*, *Lethbridge, AB, Canada T1J 4B1*.

A total of 720 broilers were used to investigate the effects of ginger root and ginger oil on antioxidant status and meat quality of broilers. The birds were randomly distributed into 6 treatments with 3 pens of 40 each. Dietary treatment included 1) BD(basal diet), 2) BD+ antibiotics (40 mg/kg bacitracin zinc and 8 mg/kg colistin sulfate), 3) BD+5 g/kg ginger root, 4) BD+10 g/kg ginger powder, 5)BD+20 g/kg ginger powder, 6) BD+100 mg/kg ginger oil (essential oil from ginger). Broilers were fed starter rations from d1 to 21 and finisher rations from d22 to 42. Blood and liver samples were obtained to determine the antioxidant status. Breast muscle samples were collected to determine meat quality of broilers. Supplementation of ginger powder or ginger oil all increased ($P < 0.05$) the activities of total superoxide dismutase (TSOD), glutathione peroxidase (GSH-Px), as well as total antioxidant capability (TAOC), and decreased ($P < 0.05$) the MDA content in serum of chickens compared with the control group at 21 and 42 d of age. Broilers addition of 10 or 20 g/kg of ginger had higher ($P < 0.05$) serum TSOD (145.37, 141.73 vs. 129.10 U/mL at 42d) and GSH-Px activities and lower MDA content (6.25, 6.17 vs. 8.86 nmol/mL at 21d) than the antibiotics group. In liver, addition of ginger significantly elevated ($P < 0.05$) TSOD (21d) and GSH-Px (21d) activities and improved the TAOC (21d and 42d) in contrast to the control. Significant increases ($P < 0.05$) of Hunter a* values and decreases ($P < 0.05$) of drip loss and water loss rate of breast muscle were observed in broilers supplemented with ginger powder and ginger oil in contrast to the control or the antibiotics group. There was no effect on pH value. It was concluded that diets supplemented with ginger could improve meat quality by increasing the antioxidant status of broilers. Ginger powder and ginger oil can be used as a potential additive substituted for antibiotics.

Key Words: ginger, broilers, antioxidant status

M254 Utilization of Mexican sunflower (*Tithonia diversifolia*, Hemsley A gray) leaf meal on the average production cost and returns of broiler chicks. A. H. Ekeocha*[1], A. Akinfemi[1], O. A. Adu[1], and O. A. Adebiyi[1], [1]*Department of Animal Science University of Ibadan*, *Ibadan, Oyo State, Nigeria*, [2]*Faculty of Agriculture P.M.B.135, Nasarawa State University*, *Shabu - Lafia Campus, Nasarawa State, Nigeria*, [3]*Department of Animal Production and Health, Federal University of Technology*, *Akure, Ondo State, Nigeria*, [4]*Department of Animal Science, University of Ibadan*, *Ibadan, Oyo State, Nigeria*.

One hundred and fifty, white, day old Arbor Acre broiler chicks were used in evaluating the utilization of Mexican sunflower meal on the economics of broiler chicks. The broiler chicks were randomly assigned to 5 treatments A, B, C, D, and E. Treatment A served as the control and treatments B, C, D, and E received Mexican sunflower leaf meal at 2.5, 5.0, 7.5, and 10.0% levels replacing maize and soymeal respectively. Feed and water were provided ad-libitum and routine vaccinations and medications administered. Performance characteristics measured were feed intake and net profit. The results of the experiment showed that there were significant differences ($P < 0.05$) in the live weight and feed intake. However, birds on treatment A performed best by attaining a live weight of 2610.30 g in 8 weeks with feed intake of 4,680.56g per bird.

The same birds yielded the highest net profit of N182.42 or $1.586 per bird on dressed weight unlike a deficit of N63.29 or $0.55 per bird on birds in treatment E (10% MSLM) and N306.75 or $2.667 per bird on live weight and a profit of N18.74 or $0.163 per bird in treatment E (10%MSLM). Birds in treatments B(2.5% MSLM), C (5.0% MSLM) and D(7.5% MSLM) have appreciable level of profits which suggest that in the absence of conventional feed stuff, nonconventional feeds such as MSLM at 2.5% to 7.5% can be optimized in the diets of broilers.

Key Words: lesser known sunflower, production cost, broiler chicks

M255 Dietary supplementation of medicinal plants and organic acid on serum lipid profile in Ross broilers. H. Ziaie*[1], A. Zeinali[2], G. H. Hadarbadi[1], M. A. Karimi Torshizi[4], M. Bashtani[3], and H. Farhangfar[3], [1]*Agriculture and Natural Resources Research Center*, *Birjand, South Khorasan, Iran*, [2]*Ferdowsi University*, *Mashhad, Iran*, [3]*Birjand University*, *Birjand, Khorasan, Iran*, [4]*Tarbiat Moddares University*, *Tehran, Iran*.

This study evaluated the supplementation of medicinal plants and organic acid on the serum lipid profile in a feeding program for broilers maintained at commercial condition. Two hundred and 40 1-d old Ross male broiler chicks were placed in 16 cages under a completely randomized design. Cages were randomly assigned to 4 treatments: 1) control diet based corn and soybean meal without supplementation; 2) control + antibiotic, 150 ppm of Virginiamycin; 3) control + 450 mg medicinal plants Digestrom /kg diet; and T4) control diet + 400 mg organic acid Formycine /kg diet). At d 28 and 42 of the experiment, 4 birds from each replicate were randomly selected and blood samples taken from the wing vein into syringes. The blood samples were then centrifuged at 2,000 × *g* for 10 min and the serums were transported into aseptically treated vials then at 20°C for further analysis. Serum samples were analyzed for determining the total cholesterol, triglyceride, HDL cholesterol, and LDL cholesterol by enzymatic diagnostic kit (Sigma kit). Experimental units were treated under T3, which was found to have the lowest cholesterol, triglyceride, and LDL cholesterol concentrations. This treatment also resulted in an increased HDL/LDL ratio compared with T1 and T2. Supplementation diets with medicinal plants and organic acid had no significant effect on HDL cholesterol. In addition, treatment 4 reduced serum total cholesterol and LDL cholesterol concentrations in broilers during 42 d. Generally, the results indicated that the medicinal plants and organic acid as an alternative antibiotic have a hypolipidemic effect in broilers.

Key Words: hypolipidemic, probiotic, prebiotic

M256 Changes of internal egg quality during cold storage when hens fed diets containing cottonseed meal treated with sodium bentonite. A. Gilani, H. Kermanshahi, A. Golian*, and A. Tahmasbi, *Ferdowsi University of Mashhad*, *Mashhad, Iran.*

This experiment was designed to determine interactive effects between dietary sodium bentonite (SB) containing ferric oxide and free gossypol (FG) on internal egg quality during cold storage. In a 3 × 3 factorial arrangement in a CRD with 9 dietary treatments in 4 replicates consisting of 3 levels of SB (0, 1, and 2%) and 3 levels of CSM (0, 10, and 20%) were tested. Nine mash diets were fed to 288 commercial Hy-Line W-36 hens from 51 to 62 wk of age after 1 wk of acclimatization. Each experimental unit consisted of 2 cages with 4 birds per cage. The 4 eggs were randomly chosen in each experimental unit from the eggs laid during the 4 consecutive days at every 28-d period (total 3 periods) and then were stored at 4°C for 1, 2, 3, and 4 wk to enhance yolk discoloration, respectively. After storage, eggs were individually opened, and the degree of yolk discoloration was scored based on egg yolk scoring protocol. After determination of albumen spread, the yolk was separated from the albumen and the pH of yolk and albumen was measured. Data were analyzed using the GLM procedure of SAS 9.1. Tukey's Studentized Range (HSD) test was used to compare means ($P < 0.05$).Yolk score significantly ($P < 0.01$) increased with increasing of CSM and significantly ($P < 0.01$) diminished with increasing of SB in the diet during cold storage. There was no significant effect of dietary treatments on spread of albumen, but albumen quality gradually decreased during 4 weeks. Generally, pH of yolk and albumen increased after cold storage. There was no significant effect of dietary treatments on pH of yolk or albumen. Egg discoloration in the current research was limited to that associated with gossypol. No eggs were observed to have developed pink albumen. In this study, cloudy white was sometimes observed after cold storage in all treatments. The yolks of eggs laid by hens consuming CSM became rubbery, viscous, and pasty in appearance after cold storage. Under the conditions of this experiment, SB in the diet was useful for reduction of yolk discoloration.

Key Words: cottonseed meal, sodium bentonite, internal egg quality

M257 Sensory characteristics of table eggs from laying hens fed diets containing hemp oil or hemp seed. E. Goldberg*, D. Ryland, N. Gakhar, J. D. House, and M. Aliani, *University of Manitoba*, *Winnipeg, MB, Canada*.

Hemp seed contains approximately 30% oil, and this oil is rich in α-linolenic acid (17% of total fatty acids). As such, hemp seed and its' oil can be used in poultry diet formulations to produce eggs enriched with these essential fatty acids. Ideally, enriched eggs should maintain the characteristic sensory attributes of non-enriched eggs to remain acceptable to consumers. The concern with omega-3 eggs in the past has been the potentially deleterious effects on sensory attributes including off-flavor and off-odor, and altered texture. The current study was designed to assess the sensory attributes of eggs procured from hens consuming diets containing hemp seed products. Forty-eight individually caged Bovan hens received 1 of 6 isonitrogenous and isoenergetic diets containing 0, 4, 8, 12% hemp oil or 10, 20% hemp seed for a 12 week period. Trained panelists (n = 8) evaluated 6 aroma and 7 flavor attributes of cooked eggs. Attributes that were measured included "egg," "salty," "sour," "milky," "creamy" and "buttery," with "sweet" as the additional flavor attribute. No significant differences in aroma or flavor ($P > 0.05$) were found between eggs from different dietary treatments. For yolk color, L*, a* and b* values (mean ± SD) for control (0%) eggs were 61.0 ± 0.3, 1.0 ± 0.1, and 43.2 ± 0.4, respectively. Addition of either hemp seed or hemp oil led to significant ($P < 0.05$) reductions in L*, and significant ($P < 0.05$) increases in a* and b*, with the largest changes observed in the 20% hemp seed treatment (L* = 58.7 ± 0.1; a* = 5.3 ± 0.1; b* = 60.0 ± 0.3). The results provide evidence that hemp oil or seed use in poultry diet formulations leads to increased yolk color intensity, but does not have adverse effects on flavor and aroma profiles of the cooked eggs.

Key Words: sensory, egg, hemp

M258 Effect of guar meal as a source of protein on laying hens performance. P. Soleimani, A. Golian*, H. Kermanshahi, and M. Sedghi, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

An experiment was conducted to evaluate guar meal (GM) as a source of protein on laying (58 weeks of age) performance and egg quality. Two hundred 20 8 laying hens (58 weeks of age) were fed diets containing

0, 3, 6 and 9% guar meal with/without β-mannanase (Hemicell) for 12 weeks. A complete block randomized design with 4 × 2 factorial arrangement were used to have 8 diets of each fed to 4 replicate hens of 9 each. Daily egg production and weekly egg weight and feed consumption were recorded. Three eggs from each replicate were used to measured egg components each other week. Hen-day egg production was significantly decreased when hens fed diets contained 6 and 9% GM in first week and only 9% GM at second week of experiment as compared with 0 and 3% GM fed birds. Whereas hen-day egg production was not influenced when hens fed up to 9% GM after third week. Egg mass was significantly lower when hens fed 9% GM during the experimental periods compared with control and 3% GM fed birds (46.8 vs. 50.8 or 52.4, respectively). Feed conversion ratio (FCR) in 3 initial weeks of experiment was significantly higher in 9% GM fed birds. Feeding of GM did not affect specific gravity, percentage wet albumen and wet yolk based on percentage of whole egg weight and shell weight and thickness. Feed consumption, hen-day egg production, egg mass, FCR and egg quality were not affected by Supplementation of β-mannanase during the experimental periods. The results of this study showed that 6% GM may be added to the diet of laying hens with no adverse effects on performance.

Key Words: guar meal, egg production, laying hen

M259 Effect of dietary supplementation of licorice extract on egg quality and performance of hens. M. Sedghi, A. Golian*, and P. Soleimani, *Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

The objective of this study was to determine the effects of various levels of dietary licorice extract on egg production, egg weight, specific gravity, feed conversion ratio, egg shell quality and egg yolk color. One hundred 20 8 laying hens (58 weeks age) were divided to 4 groups with 4 replicates (8 hens each) in a complete block randomized design. Data were analyzed using ANOVA and means were separated using Tukey's HSD ($P < 0.05$). The experimental diets were supplemented with 0, 2, 4 or 6 g/kg of diets licorice extract. Daily egg production, weekly egg weight and feed consumption were recorded. Three eggs in each replicate were used to measured egg components each other week. Daily egg production in hens fed diet supplemented with 4 g/kg of licorice extract numerically increased ($P = 0.06$) when compared with the control diet in the entire experiment. Hens fed diet 4 g/kg licorice extract had significantly increased ($P < 0.05$) shell thickness compared with those fed diets supplemented with 6 g/kg (389 vs. 374 mm). Percentage of abdominal fat pad was significantly decreased ($P < 0.05$) in birds fed diet containing 6 g/kg licorice extract compared with control diet (0.83 vs. 1.49%). Performance parameters (feed consumption, feed conversion ratio), egg parameters (egg weight, dry shell weight, egg-specific gravity, percentage of wet albumen and wet yolk based on percentage of whole egg weight) and organ weights were not influenced ($P > 0.05$) by licorice supplementation. It seems that licorice extract at the level of 4 g/kg may have positive effects on egg production, shell quality and decreases abdominal fat pad at 6 g/kg level.

Key Words: licorice extract, egg production, laying hen

M260 Effects of fermented garlic powder supplementation on production performance, egg quality and blood characteristics of laying hens. J. S. Yoo*, H. J. Kim, J. P. Wang, X. Ao, J. H. Jung, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

The effects of fermented garlic powder on the production performance, egg quality and blood characteristics of laying hens were studied in a 35–d experiment. A total of 240 (ISA brown) 41-wk-old layers were allocated into the following 4 treatments: 1) CON (basal diet), 2) G1 (CON + 0.005% fermented garlic powder), 3) G2 (CON + 0.01% fermented garlic powder), and 4) G3 (CON + 0.02% fermented garlic powder). There were no differences ($P > 0.05$) in the egg production, egg weight, eggshell breaking strength and eggshell thickness among groups throughout the entire experimental period. However, the yolk height increased significantly ($P < 0.05$) in response to the addition of fermented garlic powder during the 5th week. Additionally, the yolk color was greater ($P < 0.05$) in the CON and G3 groups than in the G1 and G2 groups during the 5th week. The Haugh unit value was higher ($P < 0.05$) in groups that received the fermented garlic powder treatments during the 5th week than in the CON group. None of the treatments had a significant effect on the total protein, albumin, and IgG levels in blood throughout the experimental period ($P > 0.05$). There was a significant ($P < 0.05$) reduction in the serum cholesterol concentration when the dietary level of fermented garlic powder was increased from 0.005 to 0.02%. Overall, this study demonstrated that the addition of fermented garlic powder to the diets of laying hens reduced the serum cholesterol concentration without any adverse effects on production performance. In conclusion, dietary fermented garlic powder supplementation improved yolk height and Haugh unit, and reduced serum cholesterol concentration laying hens.

Key Words: fermented garlic powder, egg quality, laying hens

M261 Effects of marine algae (*Spirulina platensis*) on egg yolk color and laying hens performance. N. Zahroojian, H. Moravej*, and M. Shivazd, *University of Tehran*, *Karaj, Tehran, Iran*.

Egg yolk color has always been regarded as an important egg quality characteristic. There are some synthetic pigments for produce an aesthetically pleasing yolk color of egg, but consumers often prefer eggs that were enriched by natural materials. It seems that the algae as a natural pigment can be useful for produce an aesthetically pleasing yolk color. Therefore, in this experiment, a total of 128 Hy-line W36 hens, 63 weeks of age were used. Hens were put at random into 4 treatment groups (4 replicates and 32 hens per treatment). The hens were fed 4 diets; 3 diets with different levels of spirulina (1.5%, 2% and 2.5%) and one control group based on wheat and soybean meal that received no spirulina in the ration. Egg production, feed conversion ratio, feed intake, egg weight and yolk color were compared with control group. Egg yolk color was measured by the BASF *Ovo-color* fan. Our Results indicated that egg production, feed conversion ratio, feed intake and egg weight did not show any changes with the spirulina addition ($P < 0.05$), while a significant increase in egg yolk color was observed in the treatments that received the spirulina comparing to control diet ($P < 0.0001$). Yolk color scores of control group and different levels of spirulina (1.5, 2, and 2.5%) were 1.5, 10.5, 11.4, and 11.6 in BASF color fan, respectively. There were no significant differences between the treatments with 2% and 2.5% of spirulina, so we can suggest using 2% spirulina in the egg industry to produce an aesthetically pleasing yolk color.

Table 1. Effect of treatments on egg production, feed conversion ratio, feed intake, egg weight and yolk color

Spirulina level (%)	Egg production, n	Feed conversion ratio	Feed intake	Egg weight	Yolk color
0 (control group)	74.168[a]	1.562[a]	100.275[a]	63.923[a]	1.55[c]
1.5	78.333[a]	1.550[a]	97.803[a]	63.198[a]	10.55[b]

M262 Use of salvage pet food in diets of weaned pigs. J. P. Holt and S. J. Gasca*, *Illinois State University*, *Normal*.

The United States pet food industry produced over 8 million tonnes of pet food in 2008 and continues to grow. A by-product of this industry, salvage pet food (SPF), is often available to swine producers. Two experiments were conducted to determine the effects of adding SPF as an alternative ingredient in weaned pig diets. SPF, an expired, extruded dog food product, was ground and added to conventional weaned pig diets at 0 (CON), 10, 25, or 40%, substituting corn and soybean meal. SPF had the following nutrient composition: 22.7% CP, 3.7% CF, 8.9% crude fat, and 7.2% ash. Two dietary phases were mixed. Barrows (n = 24) were placed into metabolism crates and fed phase 2 experimental diets for 10 d, with 3 d of total feces collection. Feed and fecal samples were analyzed for GE using bomb calorimetry and nitrogen using the combustion method. For a growth assay, 348 pigs, blocked by weight and sex, were placed into 48 nursery pens. Pigs were fed a common pre-starter for 4 d followed by their respective experimental diets for 28 d (14 d per phase). Pig weight and feed disappearance were measured weekly and used to calculate ADG, ADFI, and G:F. Blood samples were collected weekly, from one pig per pen, for analysis of blood urea nitrogen (BUN). Diets containing 40% SPF were found to have a greater energy density than anticipated. However, GE intake of pigs was not different ($P > 0.05$) between treatments during the metabolism trial. There was no effect ($P > 0.05$) of SPF inclusion on energy and nitrogen digestibility of pigs fed experimental diets. Analysis of growth data revealed that pigs fed diets containing 25 and 40% SPF had an increased ($P < 0.05$) G:F compared with pigs fed the CON diet. Pigs fed diets containing 40% SPF tended ($P = 0.07$) to have increased BUN in comparison to pigs fed either 0 or 10% SPF. Results of these experiments show that SPF is a quality ingredient for use in weaned pig diets; when included at high levels, pigs displayed a greater efficiency of feed utilization.

Key Words: pet food, swine

M263 Effect of meat powder supplementation on growth performance, nutrient digestibility and blood characteristics of growing pigs. S. M. Hong*, J. H. Lee, J. P. Wang, Q. W. Meng, B. W. Yang, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

A total of 48 [(Duroc × Yorkshire) × Landrace] pigs (25.67 ± 1.13 kg) were used in a 42–day trail to investigate the effects of dietary meat powder on growth performance, nutrient digestibility and blood characteristic in growing pigs. Pigs were allotted into 3 dietary treatments in a randomized complete block design according to sex and initial BW. Dietary treatments included: 1) CON [basal diet], 2) M2 [basal diet + 0.2% meat powder] and 3) M4 [basal diet + 0.4% meat powder]. Each treatment had 8 replicates with 2 pigs per pen. Pigs were housed in an environmental controlled, slatted-floor facility in 24 adjacent pens (1.80 × 1.80 m2) and were allowed ad libitum access to feed and water through a self-feeder and nipple waterer throughout the experimental period. In the current study, dietary meat powder did not affect the growth performance (ADG, ADFI and G/F ratio). Nutrient digestibility (DM, N and energy) were not affect by the inclusion of the meat powder, although a numerically increase was observed on the N digestibility in the M2 treatment compared with the CON treatment. In addition, pig fed the dietary meat powder diets had a decreased (Linear $P = 0.006$) BUN concentration in serum with the increasing meat powder level, which suggested that the meat powder could exert positive to the protein utilization. However, no effect was observed on the creatinine concentration among the treatments. In conclusion, dietary meat powder could improve the protein utilization and have a tendency to increase the nutrients digestibility.

Key Words: meat powder, growth performance, growing pigs

M264 Effects of fermented garlic powder on growth performance and blood profiles of weanling pigs. J. P. Wang*, J. H. Lee, H. J. Kim, L. Yan, S. M. Hong, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

The overall objective of this study was to evaluate the growth performance and blood profile responses of pigs fed diets supplemented with fermented garlic powder. Garlic (*Allium sativum*) has several beneficial effects for either human or animals having antimicrobial, antioxidant, as well as antihypertensive properties. The growth performance and blood profile responses of 144 weanling pigs (5.5 ± 0.4 kg) fed dietary supplementation of fermented garlic powder were evaluated in a 5-wk trial. Pigs were randomly allocated to the following 4 dietary treatments: CON (basal diet) and CON with fermented garlic powder added at 0.05% (G0.05), 0.10% (G0.1) or 0.20% (G0.2). There were 6 replications with 6 pigs per pen. Throughout the experimental period, no effect on G:F was observed ($P > 0.05$). However, during wk 1–3, the ADFI was higher ($P < 0.05$) in the G0.05 group than the other treatment groups. In addition, the ADG was improved during wk 3–5 ($P < 0.05$) in response to fermented garlic powder treatments, while only the ADFI in the G0.05 group was increased ($P < 0.05$). Overall (0–5 wk), G0.05 treatment increased the ADG by 10% and the ADFI by 12% ($P < 0.05$) when compared with the CON group. Furthermore, the IgG, RBC and lymphocyte levels were greater ($P < 0.05$) in the G0.1 and G0.2 treatment groups at the end of the trial. In conclusion, the addition of fermented garlic powder improved the ADG in weanling pigs and partially benefited the immunity.

Key Words: fermented garlic powder, growth performance, weanling pigs

M265 Evaluation of algae meal from *Nannochloropsis oculata* as a protein source for non-ruminant animals. B. A. Howe*[1], I. N. Roman-Muniz[1], B. D. Willson[2], and S. L. Archibeque[1], [1]*Colorado State University, Department of Animal Sciences*, *Fort Collins*, [2]*Colorado State University, Department of Mechanical Engineering*, *Fort Collins*.

A study was developed to explore the safety and potential use of algae meal that remained after the oil was extracted from the algae species

Nannochloropsis oculata for biodiesel production. This algae meal was included at 10% (DM basis) to a test diet that was isocaloric and isonitrogenous to the control diet (as analyzed by proximate analysis). Twenty-four adolescent male Sprague-Dawley rats were used (n = 12/treatment). The rats were fed ad-libitum for 36 d and body weights were recorded every 7 d. Blood was drawn via a lateral venous tail puncture, and analyzed for metabolites on d 0, and 21 of the study. A nutrient balance trial was conducted from d 21 through d 28, measuring all food and water consumed, as well as all feces and urine produced. On d 36 of the study, the rats were killed, blood was collected via a heart puncture, at the same time the organ weights were recorded, and tissue samples for histology were taken of the kidneys, liver and spleen. The ADF (11.08 vs. 7.51 g/d) and NDF (25.10 vs. 21.14 g/d) intake of rats fed the algae meal diet was greater ($P < 0.01$) than those fed the control diet. Subsequently, apparent DM and CP digestibility was slightly lower ($P < 0.03$) in the algae fed rats then the controls There were no apparent differences ($P > 0.10$) in final body weight, or CP balance. There were no differences in blood glucose ($P = 0.15$), base excess ($P = 0.79$) or BUN ($P = 0.69$). Additionally, there were no apparent differences ($P > 0.10$) in histology of the kidneys, livers or spleens of rats fed either the control or diet with algae meal. These data indicate that the algae meal of *N. oculata* may be a safe alternative protein source for non-ruminant animals, yet the digestibility may be limited by the increased fiber content of the algae meal.

Key Words: algae, biodiesel, digestibility

M266 The effect of supplementation with ginger on dietary oxidation stability. X. Zhao and Z. B. Yang*, *Shandong Agricultural University*, *Tai-an, Shandong, PRC*.

The experiment was conducted to evaluate the effect of supplementation with ginger on dietary oxidation stability. Treatments included control diet without ginger supplementation and test diets supplemented with 5, 10, 15, 20 g/kg of ginger. All of the diets were placed in plastic air-tight envelope that were distributed randomly in a 20°C oven for 60-d experimental period. Lipid was extracted from samples at 10-d intervals using the method of Soxhlet extraction (<45°C). The peroxide value (PV) was determined on the extracted oil using the AOCS method Cd 8–53 (Walker, 1989). The anisidine value (AV) was measured using the official IUPAC method (Paquot, 1979). Supplementation with ginger in poultry diets caused a greater ($P < 0.05$) increase in PV than the control diet during the first 30 d. But after that time, the PV showed no difference ($P > 0.05$) until last except the 0, 5g/kg of ginger supplementation diets were lower ($P < 0.05$) at Day 60. In contrast to the PV, the control diet caused the fastest ($P < 0.05$) rate of oxidation, whereas the 20 g/kg of ginger supplementation diet showed the lowest ($P < 0.05$) rate of oxidation during the first 30 d and then no significant differences ($P > 0.05$) in AV between the control and the test diets. Further analysis showed that AV of all the diets were linearly ($P < 0.05$) and tended ($P < 0.05$) to quadratically increased. In conclusion, AV and PV of the diets were strongly affected by time. Supplementation with ginger in poultry diets can decrease AV but increase PV. As all know, both PV and AV are important characteristic of the edible oils quality and appears as an indicator of the lipid oxidation and oil properties deterioration. PV measures the first products, hydroperoxides and peroxides, which are transient and decompose to aldehydes and ketones, whereas AV measures these secondary oxidation products. Through above analysis, ginger supplementation in poultry diets may effective to restrain the conversion of first oxidation products to secondary ones.

Key Words: ginger, poultry diets, oxidation stability

M267 Effects of dietary wild ginseng adventitious root meal on egg quality, egg production, and fatty acid content of yolk in egg produced by laying hens. H. J. Kim*, J. S. Yoo, J. P. Wang, Q. W. Meng, B. W. Yang, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of dietary wild ginseng adventitious root meal on the egg quality, egg production and fatty acid content of yolks in egg produced by laying hens. A total of 240 ISA Brown laying hens 55 wk of age were used in this 5–wk feeding trial. Dietary treatments included 1) CON (basal diet), 2) WGR1 (basal diet + 1% wild–ginseng adventitious root meal), and 3) WGR2 (basal diet + 2% wild–ginseng adventitious root meal). The laying hens were allotted into 3 dietary treatments with 40 replicate pens and 2 laying hens per pen in a completely randomized design. Evaluation of the egg quality revealed that the egg shell thickness, egg yolk color, egg yolk height and Haugh unit had no significant different among treatment groups ($P > 0.05$). Egg production was also significantly increased in the WGR1 and WGR2 groups when compared with the CON group ($P < 0.05$). The fatty acid content of yolk, palmitic acid, stearic acid, saturated fatty acid content and the saturated fatty acid/unsaturated fatty acid ratio were significantly lower in the WGR1 and WGR2 groups when compared with the CON group ($P < 0.05$). The linoleic acid, eicosenoic acid and unsaturated fatty acid content in the WGR group was higher than in the CON group ($P < 0.05$). In conclusion, the addition of wild-ginseng adventitious root meal improved egg quality, egg production and fatty acid content of yolk.

Key Words: wild ginseng, egg quality, laying hens

M268 Effect of a mixture of turmeric and capsicum oleoresins and of a garlic botanical on broiler chickens performance and intestinal histology. D. Bravo*[1], T. G. Petrolli[2], L. F. T. Albino[2], and H. S. Rostagno[2], [1]*Pancosma*, *Geneva, Switzerland*, [2]*Federal University of Viçosa, Department of Animal Science*, *Viçosa, Brazil*.

Our objective was to evaluate the effect of a mixture of turmeric and capsicum oleoresins (PF, Proflora) and of a garlic botanical (GB) on the performances and small intestine villus height and crypt depth of broiler chickens fed a corn soybean meal diet. One day-old male broiler chicks were distributed in a completely randomized block design with 6 treatments, 8 rep. and 20 birds per rep. (floor pen) in the starter (1–21d) and grower/finisher (21–40d) phases. T1 was the nonsupplemented control (positive control, PC, 3000 kcal/kg ME, 1.263% Lys, 0.574% Met). T2 (negative control, NC) was T1 with reduction of 75 kcal ME/kg and 2% AAs. T3 was T2 + 100 ppm of XT. T4 was T2 + 75 ppm of GB. T5 was T2 + 150 ppm of GB. Birds and feed were weighted at d1, 21 and 40. At d21, 1 bird of each rep. was sacrificed and a portion of jejunum was collected to determine villus height (VH), crypt depth (CD) and villus/crypt ratio (VC). The data were subjected to one-way ANOVA. Treatments effect was tested by the Newman Keul's Test ($P < 0.05$). From d 1 to 21, BWG and G:F were decreased by NC (−7.9%, −5.3%), improved by either XT (+5.3%, +3.6%), or 75 and 150 ppm of GB (BWG = +6.5%, +8.8%; G:*F* = +3.5%, +4.1%) and similar between T3, T4, T5 and PC. From d1 to 40, BWG and G:F were depressed by NC (−4.2%, −2.3%), improved by XT (+1.9%, +1.1%, $P > 0.05$) and by 150 ppm of GB (+5.3%, +3.4%). The NC diet decreased VH (−2.9%) and increased CD (+3.0%, $P > 0.05$). When compared with NC, birds fed XT improved VH (+19.5%) and reduced CD (−5.8%, $P > 0.05$), which was a 20.8% improvement of VC ratio. GB improved VH (−12.2% for 150 ppm, $P > 0.05$) and decreased CD (+8.9% for 75 ppm, $P > 0.05$). The results indicated that broilers on the NC diet had poorer performance and intestinal histology than those fed the PC diets (T1) and the NC plus

additives (T3, T4, T5). XT, and GB improved chicks BWG, G:F and intestinal histology to values similar to those fed the PC diets.

Key Words: essential oils, gut health, broilers

M269 Effects of dietary medicinal plants (Artemisia, Acanthopanax, and garlic) on productive parameters in pigs. J. H. Jung*[1], H. D. Jang[1], T. X. Zhou[1], S. H. Oh[2], R. C. Noble[2], and I. H. Kim[1], [1]*Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*, [2]*Department of Animal SCience, North Carolina A&T State University*, *Greensboro, North Carolin, United States*.

This study was conducted to determine the effect of supplemental medicinal plants (Artemisia, Acanthopanx and garlic) on productive parameters in pigs. In experiment 1, Three days before parturition, a total 90 multiparous (4.5 ± 0.3) sows were used in a 21–d performance assay. Sows fed treatments included 1) CON (basal diet; Control), 2) BM1 (CON + 0.1% medicinal plants) and 3) BM2 (CON + 0.2% medicinal plants). We detected the initial, final body weight, backfat and estrus interval of sows. Litter's average of birth and weanling weight and average dairy gain were checked. Backfat thickness difference from farrowing to weaning was significantly increase ($P < 0.05$) in CON treatment compared with medicinal plants treatments. The piglets weigh gain was higher ($P < 0.05$) in the medicinal plants treatments than in control. In experiment 2, a total of 60 finishing pigs [(Landrace × Yorkshire) × Duroc, 65.21 ± 1.04 kg average initial body weight] were used in a 56–d performance assay to determine the effects of supplemental medicinal plants (Artemisia, Acanthopanx, and garlic) on growth performance and carcass characteristics in finishing pigs. Finishing pigs fed treatments included 1) CON (basal diet), 2) BM1 (CON + 0.1% medicinal plants) and 3) BM2 (CON + 0.2% medicinal plants). During 4~8weeks and overall period, ADG was higher ($P < 0.05$) in the medicinal plants treatments than in control. CON treatment was higher pH of loin after 24 h of storage and cooking loss than BM1 treatment ($P < 0.05$). Water holding capacity and Drip loss after 1 d of storage were affected by the dietary BM treatments ($P < 0.05$). In conclusion, the results obtained from this feeding trial suggest that the medicinal plants mixture supplementation in diets for finishing pigs improved ADG, water holding capacity, cooking loss and sow decreased backfat loss and litter weight gain improved.

Key Words: medicinal plants, sow, finishing pigs

M270 Effects of cassava on production performance and relative organ weight in Korean native broilers. J. H. Lee*, H. D. Jang, J. P. Wang, T. X. Zhou, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of cassava for energy source on the performance and relative organ weight in Korean native broilers. A total of 528 broilers were allocated into the following 4 treatments: 1) CON (basal diet), 2) C5 (5% of cassava diet), 3) C10 (10% of cassava diet), and 4) C20 (20% of cassava diet). The broilers were allotted into 4 dietary treatments with 6 replicate pens and 22 chicks per pen in a completely randomized design and studied in a 9-wk experiment. During 9 wk, weight gain and feed intake was not affected by treatments ($P > 0.05$), however, feed/gain ratio was higher in C10 and C20 treatments compared with C5 treatment ($P < 0.05$). In liver, abdominal fat, leg and carcass percentage were not difference was observed. However, in breast meat percentage was higher in CON compared with C10 treatment ($P > 0.05$). In conclusion, this study demonstrated that the cassava for energy source in Korean native broilers can be used at up to 20% without negative effect on performance.

Key Words: cassava, relative organ weight, Korean native broilers

M271 Effects of cassava on production performance and egg quality in laying hens. J. H. Lee*, H. J. Kim, J. P. Wang, T. X. Zhou, and I. H. Kim, *Department of Animal Resource and Science, Dankook University*, *Cheonan, Choongnam, Korea*.

This study was conducted to evaluate the effects of cassava for energy source on the production performance and egg quality in laying hens. A total of 240 (ISA brown) 47 week old layers were allocated into the following 4 treatments: 1) CON (basal diet), 2) C5 (5% of cassava diet), 3) C10 (10% of cassava diet), 4) C20 (20% of cassava diet), and 5) C30 (30% of cassava diet). The laying hens were allotted into 5 dietary treatments with 24 replicate pens and 2 laying hens per pen in a completely randomized design and studied in a 35-d experiment. Egg production was significantly decreased in the C30 treatment when compared with other treatments ($P < 0.05$). Evaluation of the egg quality revealed that the egg weight, eggshell thickness, eggshell breaking strength, egg yolk height and Haugh unit was not affect by treatments ($P > 0.05$). However, in egg yolk color, C20 and C30 treatments were dramatically decreased from 2nd and 1st week ($P < 0.05$). In conclusion, this study demonstrated that the cassava for energy source in laying hens can be used at up to 20% without negative effects on performance, however consider pigment for yolk color.

Key Words: cassava, egg quality, laying hens

M272 Inclusion of shrimp heads meal (*Litopenaeus* spp.) and red crab meal (*Pleuroncodes planipes*) in rations for laying hens, and its effect on the egg physical and sensorial quality, at different time and temperature of storage. E. M. Carranco*[1], L. Sangines[1], E. Morales[2], E. Avila[3], B. Fuente[3], R. Ramirez[3], S. Carrillo[1], C. Calvo[1], and F. Perez-Gil[1], [1]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran*, *Mexico, D.F., Mexico*, [2]*Universidad Autonoma Metropolitana*, *Mexico, D.F., Mexico*, [3]*Universidad Nacional Autonoma de Mexico*, *Mexico, D.F., Mexico*.

The aim of this study was to determine if the inclusion of shrimp heads meal (SM) and red crab meal (RCM) in laying hen diets has an effect on the egg physical and sensory characteristics when is stored at 4°C and 20°C during 15 and 30 d. One hundred thirty-five laying hens were distributed in 3 treatments: Control diet, SM (20%), and RCM (4%). At the end of the trial, 250 eggs were taken: 50 fresh eggs were analyzed, 100 eggs were stored at 4°C and 20°C/15 d and another 100 at 4°C and 20°C/30 d. Egg physical quality and pH were measured, while the egg flavor and yolk color where evaluated, too. The results were analyzed using a 3 × 3 × 2 factorial design; the comparison among means was done with the multiple range test of Duncan ($P < 0.05$). There were no statistical differences ($P > 0.05$) in productive parameters, weight of shell and sensory evaluation. It was found that egg weight decreased at longest time and lowest temperature ($P < 0.05$). The albumen height and Haugh Units increased in old treatments in egg at 0 d at SM and RCM at 20°C, but decreased when eggs were stored at 4° and 20°C during 15 and 30 d. The yolk color decreased with SM and RCM at 15 and 30 d (20°C). Eggshell thickness presented the great loss at 30 d/4°C ($P < 0.05$). The pH was increased as the time was longer by itself. It was concluded the inclusion of SM and RCM in laying hen diets did not affect both productive variables and the sensory characteristics in eggs at 0 and 15 d (4° and 20°C) but the physical quality and pH were affected.

Key Words: egg quality, shrimp heads meal, red crab meal

M273 The effect of medicinal plants and plant extracted oils on broiler duodenum morphology and immunological profile. L. Stef*[1], G. Dumitrescu[1], D. Drinceanu[1], D. Stef[1], D. Mot[1], C. Julean[1], R. Tetileanu[1], and N. Corcionivoschi[2], [1]*Banat's University of Agricultural Sciences and Veterinary Medicine, Department of Animal Science*, *Timisoara, Romania*, [2]*University College Dublin*, *Ireland*.

It was previously reported that essential oils from aromatic plants have antimicrobial activity against many bacterial pathogens. We have conducted an in vivo experiment to study the effect of some aromatic plants and in particular to investigate the effect of oils extracted from these plants at the immune level and duodenal morphology. During the experiment 90 broiler chicken were divided in 3 experimental groups: control group (C), group 1 (G1) and group 2 (G2). Broilers from group G1 had received feed with 0.05% incorporated oils extracted from savory (*Satureja hortenis*), mint (*Mentha piperita*) and sea-buckthorn (*Hippophae rhamnoides*). Group G2 received a premix of plants (savory, mint, and sea-buckthorn) during daily feeding. The control group (C) received normal feed with no supplements. The amount of lysozyme detected at group G1 was doubled (28.55 μg/cm^3; $P < 0.05$) comparing G2 (13.2 μg/cm^3; $P < 0.01$) and the control (11.42 μg/cm^3; $P < 0.005$). The incorporation of extracted oils in food determine a powerful stimulation of intestinal mucous membrane, manifested by development of intestinal villi, the hypertrophy of villi, hyperplasic hypertrophy of capillary network and the stimulation of leukocytes infiltrate. The muscular hypertrophic processes and of leukocytes infiltrates are visible in the endomysium and perimysium of the muscular tunic. The microscopical images taken from the duodenum sections were sampled from the G2 group suggest the stimulation of angiogenesis ($P < 0.05$). The processes are however of smaller intensity comparative with experimental lot G1 ($P < 0.001$). This work shows that essential oils extracted from plants improve the immune response and also are able to determine changes of the duodenal mucosa with beneficial effects for the animal.

Key Words: medicinal plants, plant oils, broiler nutrition

M274 Effects of dietary polyphenol-rich grape products on gut morphology and intestinal microflora in broiler chicks. A. Viveros*[1], S. Chamorro[2], M. Pizarro[1], W. Siqueira[3], C. Centeno[2], I. Arija[1], and A. Brenes[2], [1]*Facultad de Veterinaria, UCM*, *Madrid, Spain*, [2]*Instituto del FRIO-ICTAN, CSIC*, *Madrid, Spain*, [3]*Faculdade de Veterinaria, Universidade Estadual do CEARA*, *Fortaleza, Brasil*.

Grapes have high amounts of phenolic compounds which can modulate the gut activity as well as to modify the structure and function of the gastro-intestinal tract. An experiment was conducted to study the effect of the inclusion of grape pomace concentrate (GPC) and grape seed extract (GSE) in broiler chick diets on performance, intestinal morphology (jejunum), and ileal and cecal microflora at 21 d of age. Dietary treatments included an antibiotic-free diet (CTL-), a positive control (CTL+, 50 mg/kg of avoparcin), and an antibiotic-free diet containing GPC (60 g/kg) or GSE (7.2 g/kg). Each treatment was randomly assigned to 5 pen replicates (5 birds each). Jejunum histology was examined to determine the villi height, crypt depth, villi-height-to-crypt depth ratio, and muscularis layer thickness. Ileal and cecal contents were assayed for *Escherichia coli*, lactobacilli, enterococci, and *Clostridium perfringens*. Performance was not affected by dietary treatments except in the case of birds fed GSE diet which showed a decrease of weight gain. CTL- fed birds had longer villi and deeper crypt depth than birds in any other treatment group. The best villi height: crypt depth ratio corresponding to birds fed GPC diet and the worst to those fed CTL- diet. Muscularis layer thickness was not affected by dietary treatment except in the case of CTL- group which was reduced. In the ileal content, birds fed CTL- and GSE diets had the highest population of lactobacilli. Compared with the CTL- diet, the CTL+, GPC and GPS diets increased the populations of enterococci and decreased the counts of *C. perfringens* in the ileal content. There were no differences in the ileal population of *E. coli* among all dietary treatments. In the cecal digesta, birds fed GPC and GSE diets had a higher population of *E. coli*, lactobacilli, enterococci, and *C. perfringens* than in any other treatment group. Based on the results of the present study, it can be stated that dietary polyphenol-rich grape products modify the intestinal microflora and gut morphology in broiler chicks.

Key Words: chicks, grape pholyphenols, gut morphology and intestinal microflora

M275 Effects of hemp oil on the expression of FADS1, FADS2, and ELOVL5 in laying hens. M. Jing*, N. Gakhar, E. Goldberg, and J. D. House, *University of Manitoba*, *Winnipeg, Canada*.

Hemp seed and oil products are rich and balanced sources of omega-3 and omega-6 polyunsaturated fatty acids (PUFAs). Hemp contains about 17% α-linolenic acid (ALA) and 56% linoleic acid (LA), which are precursors for omega-3 and omega-6 PUFAs, respectively. In conjunction with studies designed to evaluate the transfer efficiency of dietary ALA to table eggs, the present study investigated the effects of dietary hemp oil (HO) inclusion on 3 principal biosynthetic genes involved in PUFA metabolism: FADS1 (Δ5 desaturase), FADS2 (Δ6 desaturase), and ELOVL5 (elongation of very long chain fatty acids protein 5). Bovan White laying hens (n = 8 per diet) received wheat-barley-soy-based diets containing 12% supplemental oil as either corn oil (CO; 0% HO), blend of 33:67 (4% HO) or 67:33 HO:CO (8% HO), or HO (12% HO), with a gradual decrease in the LA:ALA ratio as HO inclusion increased. The hens were fed over a period of 12 weeks. All the diets were formulated with equal protein and energy. Liver tissue was freshly harvested at the end of the experiment and used for RNA isolation. The mRNA expression profile of the 3 genes was assessed by semiquantitative real-time PCR. Results revealed that the mRNA levels of FADS1 were significantly reduced by 39.48% ($P < 0.05$) in hens fed the diet containing 12% of HO, and FADS2 mRNA was decreased by 45.18% and 51.32% ($P < 0.05$) in hens fed the diet containing 8% and 12% of HO in comparison with the basal diet, respectively. However, the expression of ELOVL5 was unaffected ($P > 0.05$) by the treatment of HO. Overall, this study demonstrates that 2 desaturase genes including FADS1 and FADS2 are downregulated by the supplementation of hemp oil in laying hen diets, and these changes may be related to the ratio of the prevailing dietary fatty acids.

Key Words: hemp oil, gene expression, laying hens

M276 Dietary supplementation effects of oregano essential oils on intestinal digest microbial community in broilers under high altitude conditions. L. Betancourt*[1,2], V. Phandanouvong[3], F. Rodriguez[3], C. Ariza-Nieto[3], M. Hume[4], D. Nisbet[4], and G. Afanador-Téllez[2], [1]*Universidad de La Salle*, *Bogotá, Colombia*, [2]*Universidad Nacional de Colombia*, *Bogotá, Colombia*, [3]*CORPOICA*, *Bogotá, Colombia*, [4]*USDA, ARS, FFSRU, College Station*, *TX*.

Microbiota impact broiler health and production. Essential oils have been shown to play a significant role in the modulation of gut microflora and the colonization of pathogenic bacteria. The aim of this study was to test the effect of oregano essential oils (OEO) on the microbial community on broiler chickens reared at high altitude. Seven hundred and fifty 1-d-old Hybro male broiler chicks, maintained at high altitude, were placed in 30 brooder cages under a completely randomized design. Six treatments

were evaluated: 200 ppm of OEO from 3 varieties produced and ground in Sabana of Bogota-Colombia 1) *O. vulgare* H. (OH); 2) *O. vulgare* L. (OL) and 3) *O. majorana* (OM); 4) 50 ppm of EO from O. vulgare H. ground in Greece (OG); 5) 500 ppm Chlortetracycline (AB) and 6) control (C). Template DNA was isolated from pooled duodenal, ileal, and cecal contents of 5 chickens in each group, respectively, and analyzed by denaturing gradient gel electrophoresis (DGGE). Dendrogram analysis of amplicon profiles from duodenum, ileum and cecal bacterial DNA revealed 2 main groups, OEO-treated chicks and non-treated control chicks at 14 and 35d. The highest similarity coefficient (CS), CS > 90%, was observed for OM and AB in jejunum (21d), ileum (3 and 21d), cecal (3, 7 and 21d) and colon (7 and 21d). OM and AB presented the highest body weight at 21d. Comparison of bacterial DNA profiles from different gut compartments revealed diverse bacterial populations between duodenum, jejunum and ileum compared with cecal and colon. The results suggest that digestive microbial populations of these broilers from the Sabana of Bogotá (2650 AMSL) can be altered by addition of OEO in the diet. *O. majorana* essential oil was associated with increased body weight gain. A possible association was observed between the bacterial DNA profile of the intestine and body weight of broilers.

Key Words: DGGE, DNA bacterial, gut

Physiology and Endocrinology: Nutritional Effects on Reproduction and Development

M277 Effects of body weight loss on serum progesterone concentrations of non-lactating dairy cows. R. Rodrigues*[1], C. Trevisanuto[1], T. Leiva[1], M. Barbosa[1], R. Cooke[2], and J. Luiz Vasconcelos[1], [1]*FMVZ - UNESP*, *Botucatu, SP, Brazil*, [2]*Oregon State University*, *Burns*.

The objective of this study was to evaluate serum concentrations of nonesterified fatty acids (NEFA), cortisol, insulin, and progesterone (P4) of dairy cows maintaining or mobilizing body weight (BW). Eleven non-lactating, non-pregnant, and ovariectomized Gir × Holstein cows were stratified by BW and body condition score (BCS), and randomly assigned to one of 2 treatments on d −7 of the study: 1) BW loss (6 cows; LOSS) and 2) BW maintenance (5 cows; MAINT). Treatments were achieved through a grazing schedule utilizing 3 different pastures (A, B, and C). From d −7 to d 1 of the study, all cows were maintained in pasture A (adequate forage availability; 12 kg of dry matter/cow daily). From d 2 to d 30, LOSS cows were maintained in pasture B (minimal forage availability; less than 1.0 kg of dry matter/cow daily), whereas MAINT cows were maintained in pasture C (adequate forage availability; 12 kg of dry matter/cow daily). From d 3 to d 30 of the study, cows from both treatments were re-grouped daily into pasture A from 0600 to 1200 h to allow LOSS cows to consume, on average, 4.5 kg/d of forage dry matter. From d −66 to d 3 of the study, all cows were inserted with CIDR to promote P4 uptake by adipose tissues, which was replaced every 14 d and removed on d 3. Cow BW and BCS were assessed on d 0 and 30. Blood samples were collected daily, from d 0 to d 30, at 0600 and 1200 h. Changes in BW and BCS were greater in LOSS cows compared with MAINT cows (−0.95 vs. −0.07 kg of BW/d, SEM = 0.216; −0.30 vs. 0.00 of BCS change, SEM = 0.092). Within samples collected at 0600 h, serum NEFA concentrations were greater in LOSS cows compared with MAINT. Similarly, serum P4 concentrations were typically greater in LOSS cows compared with MAINT. Serum cortisol concentrations were also greater for LOSS compared with MAINT cows, but only on d 6, 28, and 29 of the study. In conclusion, data from this study indicates that BW loss increases circulating concentrations of P4 in non-lactating ovariectomized dairy cows, and this outcome can be mainly attributed to fat mobilization and consequent release of P4 stored in adipose tissues.

Key Words: adipose tissues, progesterone, weight loss

M278 Effects of maternal metabolizable protein supplementation in late gestation on uterine and umbilical blood flows in sheep. L. E. Camacho*[1], L. A. Lekatz[1], M. L. VanEnom[2], C. S. Schauer[2], K. R. Maddock Carlin[1], and K. A. Vonnahme[1], [1]*Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University*, *Fargo,* [2]*Hettinger Research Extension Center, North Dakota State University*, *Hettinger*.

To examine effects of maternal MP supplementation in late gestation on uterine and umbilical blood flows, multiparous ewes (n = 11) were assigned to receive either 75% (LOW, n = 4), 100% (CON, n = 4), or 125% (HIGH, n = 3) of MP requirements from d 100 until d 130. At surgery on d 130, uterine blood flow was measured by Transonic Doppler flow probes and umbilical blood flow was measured using color-Doppler US. Throughout surgery, maternal blood pressure was monitored. After determination of blood flow, fetal and placental tissue were collected and weighed. Data were analyzed with PROC GLM and means separated with LSMeans. Data were considered significant if ($P < 0.05$. Fetuses from HIGH ewes were heavier ($P \leq 0.04$) than fetuses from LOW ewes with fetuses from CON ewes being intermediate. Total placental wt was not different ($P = 0.41$) among treatments. Uterine blood flow had a tendency ($P = 0.07$) to be greater in the LOW group compare with HIGH (818.0 vs. 447.3 ± 105.3 mL/min) with CON being intermediate. Uterine blood flow per fetus wt was increased ($P < 0.02$) in LOW ewes compare with CON and HIGH (0.42 vs. 0.22 and 0.12 ± 0.07 mL/min/g). Umbilical blood flow per fetus wt was not affected ($P = 0.14$; 0.20, 0.14, and 0.08 ± 0.04 mL/min/g for LOW, CON, and HIGH, respectively) by MP supplementation. Maternal blood pressure did not differ ($P = 0.19$) among groups. However, unprotected LSD means (used only in blood pressure analysis) showed that LOW ewes had increased ($P \leq 0.01$; 150.5 ± 13.5 mmHg) blood pressure compared with HIGH (113.6 ± 11.0 mmHg) and CON (124.8 ± 11.0 mmHg). Factors influencing uteroplacental blood flow appear to be associated with maternal MP intake and have yet to be determined.

Key Words: metabolizable protein, umbilical blood flow, uterine blood flow

M279 Effects of maternal protein supply on offspring somatotropic axis: Serum IGF-binding proteins-2 and -3 in pigs at weaning and market weight. A. Ooster*[1], U. Müller[1], H. Sauerwein[1], I. Lang[2], M. Peters[2], C. Rehfeldt[2], and C. C. Metges[2], [1]*University of Bonn*, *Bonn, Germany*, [2]*Leibniz Institute for Farm Animal Biology*, *Dummerstorf, Germany*.

Fetal growth is reflected in size at birth possibly associated with postnatal metabolic function and health. The GH/IGF axis is affected by intrauterine growth retardation and might be permanently readjusted. We aimed to characterize the plasma concentrations of IGF binding proteins (IGFBP) 2 and 3 in offspring of gilts fed with diets differing in protein content. Isoenergetic diets with low, adequate or high CP contents (6, 12 or 30%) were fed to a total of 40 gilts throughout pregnancy. At birth the piglets were cross fostered to nursing sows fed a 12% CP gestation diet and then a standard lactation diet. From weaning (d 28) to slaughter (d 185) offspring received standard fattening diets. Serum collected at d 28 and 185 from 144 piglets was assessed for IGFBP using a non-radioactive Western ligand blotting protocol optimized to yield quantitative data. The chemiluminescence signals were densitometrically evaluated and the bands corresponding to IGFBP-2 and -3 were compared. Maternal feeding group, sex, litter size and weight at birth classes and the respective interactions were considered fixed. Values were compared by t-test at d 28 and 185. At d 28 and 185, IGFBP-3 was not affected by either factor tested. For IGFBP-2, there were trends for feeding group and birth weight differences ($P = 0.093$ and 0.057, respectively) on d 28, without any interactions. Piglets from sows fed 6% CP had less IGFBP-2 than those from the 12% diet ($P = 0.037$). At d 185, IGFBP-2 was not affected by either factor tested. IGFBP-3 increased ($P < 0.05$) from d 28 to 185 in all groups, whereas IGFBP-2 was decreased ($P < 0.05$) solely in pigs from sows fed at 12% but remained unchanged in offspring from sows fed at 6 or 30% protein. Carry-over effects of maternal feeding during gestation on offspring IGFBP-2 resulting in divergent concentrations at weaning and in altered patterns of age-related changes are thus indicated.

Key Words: somatotropic axis, IGFBP, pig

M280 The impact of maternal obesity on offspring hypothalamic-pituitary-adrenal axis response to stress. N. M Long*[1], A. B. Uthlaut[1], P. W. Nathanielsz[2], and S. P. Ford[1], [1]*Center for the Study of Fetal Programming, Animal Science Department*, *University of Wyoming, Laramie,* [2]*Center for Pregnancy and Newborn Research, Department of Obstetrics and Gynecology*, *University of Texas Health Sciences Center, San Antonio*.

Multiparous Ramboullet × Columbia crossbred ewes were fed either 100% of NRC recommendations (Control, C) or 150% of NRC (Obese, OB) from d 60 d before mating until lambing. Lambs born to these dams (10 OB, 5 wethers, 5 ewes: and 8 C, 3 wethers and 5 ewes) were maintained as a group before and after weaning and fed a similar diet until 19 mo of age when they received jugular catheters and were subjected to a corticotrophin releasing hormone (CRH)/arginine vasopressin (AVP) challenge, an ACTH challenge, and an isolation stress test, on separate occasions. ACTH and cortisol responses to the isolation stress test and CRH/AVP challenge and cortisol responses to ACTH challenge were determined. Cortisol was quantified via RIA and ACTH was quantified using an Immulite 1000. Hormone data were analyzed using repeated measures analysis utilizing the MIXED procedure of SAS. Offspring from OB mothers tended ($P = 0.06$) to have a greater ACTH response after an intravenous CRH/AVP injection than offspring from C mothers (1234 ± 143 vs. 817 ± 157 pg/mL, respectively). The cortisol response of offspring to a CRH/AVP or ACTH challenge was not influenced by maternal nutrition ($P < 0.46$), and averaged 4.77 ± 0.2 and 1.94 ± 0.01 µg/dL. The ACTH response following the isolation stress test was also similar ($P = 0.82$) for OB and C offspring (147 ± 20 pg/ml). Cortisol response during the isolation stress test was also similar between C and OB offspring ($P = 0.64$, 5.25 ± 0.3 µg/dl).These findings suggest that maternal obesity before and during gestation does not affect stress responses by the offspring, but has an impact on hypothalamo-pituitary-adrenal sensitivity. The lack of differences in cortisol release under the influence of difference concentrations of ACTH during the CRH/AVP challenge could indicate adrenal dysfunction in OB offspring.

Key Words: maternal obesity, offspring, stress response

M281 Effects of two-stage and total vs. fenceline weaning on the physiology and performance of beef calves. C. Campistol*[1], H. G. Kattesh[1], J. C. Waller[1], E. L. Rawls[1], J. D. Arthington[2], T. E. Engle[3], and J. A. Carroll[4], [1]*University of Tennessee*, *Knoxville,* [2]*University of Florida - IFAS, Range Cattle Research and Education Center*, *Ona,* [3]*Colorado State University*, *Fort Collins,* [4]*Livestock Issues Research Unit, USDA-ARS*, *Lubbock, TX.*

Calves weaned using a 2-stage method, where nursing is prevented between cow-calf pairs before separation (Stage 1), experience less weaning stress after separation (Stage 2) based on behavior and growth measures. The aim of this study was to document changes in various physiological measures of stress in calves weaned using the 2-stage with total separation or temporary fenceline contact. Steer calves (n = 48; 314.1 ± 20.5 kg), housed on pasture with their dams, were blocked by initial BW and assigned randomly during Stage 1 to be fitted with a nose-flap weaning device (YD) or no device (ND) for 7 d preweaning. During Stage 2, calves (12 YD and 12 ND/group) were weaned by fenceline (Group 1) or total separation to a distant pasture (Group 2). After 7 d, Group 1 calves were moved to a pasture lot adjoining Group 2. Calves were weighed and bled on d −7, 0, 3, 7 (d of weaning), 10, 14, 21, and 42, and injected with ovalbumin on d 0. Blood was analyzed for total cortisol, IgG to ovalbumin, interferon-gamma (IFN-γ), haptoglobin (HAP), ceruloplasmin (CER), hematocrit (Hct), and neutrophil:lymphocyte ratio (N:L). Weight gain was similar ($P = 0.74$) among steers regardless of Stage 1 treatment. The YD calves had higher ($P < 0.05$) Hct than ND calves during Stage 1. Weight gain was greater ($P < 0.01$) in Group 1 versus Group 2 on d 14–42. Ovalbumin-specific IgG increased ($P < 0.01$) in all calves by d 10 unrelated to Stage. Both HAP and CER increased ($P < 0.01$) by d 3 in response to ovalbumin. Between d 7 and 10, CER, IFN-γ, and N:L increased ($P < 0.05$) in ND but not YD calves. In conclusion, 2-stage weaning may improve calf well-being when fenceline separation is employed.

Key Words: beef cattle, two-stage weaning, stress

M282 Effects of dietary n-3 fatty acids on timing of estrus onset and LH surge in synchronized estrous cycles of dairy cows. M. Zachut*[1,2], H. Lehrer[1], A. Arieli[2], L. Livshitz[1], and U. Moallem[1], [1]*Agriculture Research Organization*, *Bet Dagan, Israel*, [2]*Faculty of Agriculture, Hebrew University*, *Rehovot, Israel*.

In a previous study conducted in our lab we observed a delay in behavioral-estrus manifestation in cows fed flaxseed, which contained a high proportion of 18:3n-3. The objectives were to examine the effect of dietary extruded flaxseed (EF) on the interval between $PGF_{2\alpha}$ injection and LH surge in synchronized estrous cycles. Multiparous Israeli-Holstein dry cows (256 d pregnant) were assigned to 2 treatments (i) control (n = 22) were fed a dry cow diet and postpartum (PP) lactating cow diet, which consisted of 5.8% ether extracts and (ii) EF (n = 22) supplemented prepartum with 1 kg/d per cow of EF providing 141 g/d of 18:3n-3, and PP to 100 d in milk (DIM) a diet consisted of 9.2% EF providing on average 382 g/d of 18:3n-3. At 40 DIM ovaries were monitored by ultrasound to ensure normal cyclicity. Cows received a GnRH analog injection at d 0, and 7 d later were monitored by ultrasound for corpus luteum (CL) presence. Cows that had CL were injected with $PGF_{2\alpha}$ (d 7) followed 2 d later (d 9) by GnRH injection. Seven d later (d 16) cows were injected with $PGF_{2\alpha}$ to stimulate luteolysis and 5-d period of intensive follow-up was conducted. Cows were observed continuously (24 h a day) for onset of behavioral-estrus signs and thereafter blood samples were taken every 3 h during 24 h for LH detection. A total of 38 successful estrous cycles (16 controls and 22 EF) were obtained in 2 sessions. Interval from $PGF_{2\alpha}$ injection to behavioral-estrus onset was not significantly different (57.3 and 59.4 h for control and EF, respectively). LH peak in the controls occurred on average 5.8 h after estrus-onset, as compared with 7.6 h in the EF ($P < 0.03$). Interval from $PGF_{2\alpha}$ injection to LH peak tended to be longer in the EF than in controls (67.0 and 62.1 h, respectively; $P < 0.07$). These results imply that dietary n-3 fatty acids may delay timing of LH peak, perhaps due to changes in the secretion of prostaglandins E_2 that are involved in ovulation control.

Key Words: omega-3, LH surge

M283 The effects of ancient Mediterranean aphrodisiac capari (*Capparis ovata* Desf.) on some reproductive parameters of Lohmann roosters. A. Ata, M. S. Gulay*, and O. Yildiz-Gulay, *Mehmet Akif Ersoy University, Faculty of Veterinary Medicine*, *Burdur, Turkey*.

The focus of this research was to determine the effects of dietary supplementation of capari on some spermatological parameters in Lohmann roosters. Twenty-four week old roosters were randomly assigned to control and capari treatment groups (8 per group) and fed a standard diet. Roosters in control group received 10 mL of tap water, whereas roosters in treatment group received 1 g/kg of caper in 10cc tap water daily by oral gavages for 39 d (3 spermatogenesis duration). Semen was collected from each rooster by abdominal massages weekly and sperm analyses were performed on individual semen samples collected

39 d after introduction to capari. There were no difference between control and caper treated roosters on semen volume (44.3 ± 13.4 vs. 62.8 ± 11.3 μL), semen pH (8.24 ± 0.11 vs. 8.25 ± 0.14), percent morphologically normal sperm (89.2 ± 3.0 vs. 92.3 ± 2.7%), percent live spermatozoa by eosin-nigrosine staining mixture (87.4 ± 1.3 vs. 88.3 ± 1.3%), respectively. On the other hand, daily caper treatment increased the progressive motility (85.0 ± 0.84 vs. 87.6 ± 0.70%, $P < 0.04$) and sperm concentration (3.78 ± 0.59 vs. 5.45 ± 0.41 × 10^9 mL, $P < 0.04$). The results indicated that there is a merit to use dietary supplementation of capari to improve spermatological performance of roosters.

Key Words: caper, rooster, spermatological parameters

M284 Blood urea nitrogen and nonesterified fatty acid concentrations in the umbilical blood of fetal pigs at day 90 and 110 of gestation. T. A. Wilmoth*, C. O. Lemley, and M. E. Wilson, *West Virginia University*, *Morgantown*.

Speculation as to why fetal size variation occurs has led to the investigation of placental efficiency and function. Unequal nutrient delivery and usage by the fetus can be a result of fetal or placental inefficiency. Measuring the metabolites of nutrient degradation such as blood urea nitrogen (BUN) and nonesterified fatty acids (NEFA) may give insight to placental and fetal usage of these nutrients. The objective of this study was to determine the concentrations of BUN and NEFA in arterial and venous umbilical blood of fetuses at d 90 and 110 of gestation. Gilts (n = 13) were randomly assigned to be ovariohysterectomized on d 90 or 110 of gestation at the time of breeding. Arterial and venous umbilical blood samples were collected for the determination of BUN and NEFA. Tissue sections were fixed in paraffin for the determination of placental and endometrial vascular densities. Placental efficiency (fetal weight divided by placental weight) was determined for each fetus. Means and correlation coefficients were determined using the correlation procedure of SAS. On d 90 of gestation, arterial BUN concentrations were 198.7 mg/mL, while venous BUN concentrations were 212.2 mg/mL. Arterial and venous NEFA concentrations were 0.24 mg/mL. A trend for a negative correlation between placental efficiency and the arterial venous difference (A-V) in BUN existed ($r = -0.34$, $P < 0.1$). On d 110, arterial and venous BUN were 242.6 mg/mL and 128.6 mg/mL, respectively. Arterial NEFA was 0.23 mg/mL and venous NEFA was 0.18 mg/mL. A positive correlation between endometrial vascular density and placental efficiency existed ($r = 0.28$, $P < 0.05$). A negative correlation existed between placental vascular density and the A-V difference in BUN ($r = -0.35$, $P < 0.05$). The change in metabolites being delivered to and returning from the placenta changes between d 90 and 110 of gestation suggesting that there is an increased amino acid catabolism by the fetus at d 110 of gestation and a greater removal of urea from fetal circulation at d 110.

Key Words: placental efficiency, blood urea nitrogen, nonesterified fatty acids

M285 Effect of dry period lengths on follicular dynamics in early lactation Holstein cows. A. Soleimani*[1,2], A. Heravi Moussavi[2], M. Danesh[2], G. Golian[2], and S. Safa[2], [1]*Islamic Azad University-Kashmar Branch*, *Kashmar, Khorasan Razavi, Iran*, [2]*Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

The study was designed to test the effects of dry period lengths on follicular dynamics parameters during the subsequent lactation in Holstein cows. Cows (n = 42) were randomly assigned in 1 of 3 treatments: 1) traditional 60 d dry period (DP) (n = 14), 2) 35 d DP (n = 15) and 3) 20 d DP. Holstein cows were blocked in pairs based on their previous 305 d milk, parity, and expected calving dates. All cows were fed by routine ration of farm (total mixed diet) twice a day and had at all time free access to water. To monitor follicular parameters, ultrasound measurements of follicular activity were made on alternate days from d 10 to 35 postpartum to determine the characteristics and fate of the 1st follicular wave. The data were analyzed using the General Linear Model (GLM) for a completely randomized design. Number of follicles (≥5 mm in diameter) on d 10 and 14 postpartum were similar among the groups. Length of dry period had no effect on days postpartum to first ovulation ($P = 0.91$; 24.69 ± 2.2, 24.07 ± 2.2, and 23.27 ± 2.4 d, respectively), number of days until detection of a follicle ≥10 mm in diameter ($P = 0.42$; 11.53 ± 1.0, 11.64 ± 0.9, and 13.23 ± 1.0 d, respectively), diameter of the largest follicle at first ultrasound ($P = 0.92$; 10.8 ± 0.91, 10.46 ± 0.8, and 13.11 ± 0.9 mm, respectively), and also days open ($P = 0.88$; 170.25 ± 25.8, 159.10 ± 28.3, and 178.72 ± 27.0 d, respectively). Diameter of the first dominant follicle ($P < 0.05$; 18.76 ± 1.1, 19.80 ± 1.1, and 14.46 ± 1.1 mm, respectively) and diameter of the dominant follicle on d 14 ($P < 0.05$; 13.65 ± 0.8, 12.96 ± 0.7, and 9.95 ± 0.8 mm, respectively) were different among the groups. Results from this experiment demonstrated that dry period length had no apparent effect on most follicular dynamics parameters and days open during the subsequent lactation. Meanwhile, a short dry period reduced the diameter of dominant follicle.

Key Words: dairy cows, dry period, follicular dynamic

M286 The application of TARGET bovine CL progesterone test kit for early pregnancy diagnosis in ewes. W. Chen*, T. Wuliji, H. Wang, N. Li, and A. Qi, *Animal Biotechnology, University of Nevada-Reno*, *Reno*.

The objective of the experiment was to identify the applicability of TARGET Bovine CL progesterone test kit (TARGET) for early pregnancy diagnosis in ewes. TARGET is a commercial test kit to identify pregnant cows from non-pregnant cows in field. When the blood or milk sample progesterone level is high, the test kit shows a white color and the cow is diagnosed as pregnant, and the dark blue color indicates non-pregnant, whereas the light blue or faint blue indicates that there is no definite diagnosis, so a second test is required. Three other methods were applied to verify the accuracy of TARGET. They are ELISA analysis of the blood progesterone level, ultrasound scanning for the pregnancy diagnosis, and the lambing record. 82 ewes were assigned in a spring breeding flock, of which 52 ewes with the TARGET test, while 30 ewes were assigned with non-TARGET test group. Blood samples were collected from ewes on 20d of post-breeding and the serum samples were used for the TARGET test and the ELISA analysis. Sample color grade readings were assigned to the standard color grade chart provided by TARGET. Ultrasound scanning diagnosis was conducted on 50d of post-breeding. TARGET color grade readings, ELISA analysis, ultrasound scanning results, and lambing records were analyzed by the CORR procedure of SAS program. The correlation coefficients between ELISA analysis and Ultrasound scanning diagnosis was the highest as 0.89 ($P < 0.001$) when the serum progesterone level was 2ng/ml or higher. Therefore, this level is defined as the threshold for the status of pregnancy. Six possible color grades recombination within 4 color grades were evaluated. The correlation analysis was conducted with the results obtained from all 4 procedures. The combination of the color indicator with the TARGET kit standard chart showed the highest correlation ($P < 0.01$) with ELISA progesterone level, ultrasound scanning diagnosis, and lambing record which are 0.85, 0.89, and 0.62, respectively (Table 1). Therefore, the bovine TARGET test kit is applicable to the early pregnancy diagnosis in ewes with a high degree of accuracy.

Table 1. Correlation coefficients of TARGET kit color grade assignments for pregnancy diagnosis with three other pregnancy diagnostic methods

Groups	Pregnant	Unassigned	Non-Pregnant	ELISA	Ultrasound	Lambing Record
A	1	2,3	4	0.85**	0.89**	0.62**
B	1,2	3	4	0.75**	0.81**	0.56**
C	1,2,3	–	4	0.56**	0.64**	0.44**

M287 Endocrine events during the periestrus period and the effect of various PMSG on estrus synchronization in shall ewes. T. Saberifar, H. Kohram*, and E. Dirandeh, *University of Tehran*, *Karaj, Tehran, Iran*.

The aim of the present study was to investigate the endocrinology of periestrus period and the days after until estrus in ewes (n = 40) synchronized out of breeding season and diagnosing the related pregnancies after laparoscopic insemination comparing to different doses of PMSG that was used. Animals treated for 12 d with CIDR followed by administration with different doses (0, 450, 550, 650, 750, 850 IU) of PMSG after CIDR withdrawal. Number of ewes in each group was 7 except for control group that was 5. 48 h after CIDR removal, ewes were inseminated by frozen semen using laparoscopy method. Blood samples were collected once daily from the jugular vein into heparinized tubes beginning at day CIDR removal until the day of estrus. Plasma was harvested and stored at −20°C until progesterone or estradiol assay. Concentrations of progesterone (Progesterone RIA, Biosource, Belgium) and estradiol (estradiol RIA, Biosource, Belgium) were determined. Pregnancies were diagnosed using ultrasonography at d 30 following insemination in ewes. Progesterone levels did not differ between groups during periestrus period. Estradiol levels also did not differ between groups during the days CIDR removal and one day later. However, estradiol levels in the control group comparing to groups 550 and 850 was significantly lower and higher (control: 12.14 pg/mL, 550:19.91 pg/mL, 850:8.98 pg/mL) at estrus, respectively. Pregnancy diagnosing showed that, the number of nonpregnant ewes was lower in group 550 and higher in group 850 comparing to control group (control:3, 550:0, 850:4). The result of this study demonstrated that 550 IU PMSG would be the best dose to increase the plasma estradiol at the onset of estrus and also for synchronizing Shall ewes out of breeding season and have the best lambing rate in this breed.

Key Words: periestrus period, PMSG, shall ewes

M288 Reproductive endocrine profile in ewes with different thickness of dorsal fat added with bypass fat. R. Nieto[1], T. Sánchez[1], O. Mejía[2], L. Olivares[3], J. Peralta[4], J. Cordero[1], P. Molina[1], M. Cárdenas[5], E. García*[6], and N. Cedillo[4], [1]*Colegio de Postgraduados*, *Montecillo, Edo. de México*, [2]*CEIEPO, FMVZ. UNAM*, *Tres Marías México*, [3]*Universidad Autónoma del Edo. de México*, *Edo. de México*, [4]*Universidad Autónoma del Edo. de Hidalgo*, *Tulancingo, México*, [5]*INNSZ*, *Mexico City, México*, [6]*CUCSur, Universidad de Guadalajara*, *Autlán, Jalisco, México*.

To determine the effect of bypass fat in serum concentrations of luteinizing hormone (LH), estradiol (E2), progesterone (P4) and insulin (INS) during 7d before removal of intravaginal sponges in Dorset ewes, ewes (n = 59) were classified by thickness of dorsal fat by ultrasonography with a 7.5-MHz transducer. Ewes with low (LDF, 2mm) and high (HDF, 4mm) thickness dorsal fat were subdivided in groups: Low thickness without (LDF0, n = 14) and with (LDF1, n = 14) the addition of 150 g of bypass fat; High thickness without (HDF0, n = 15) and with (HDF1, n = 16) the addition of 150 g of bypass fat, respectively. Estrous cycles were synchronized with sponges of flugesterone acetate (FGA, 20 mg), for 12 d, 10 d after insertion 15 mg of prostaglandins (PGF2α) were injected. LH was analyzed by PROC GLM and means by Tukey; P4, E2 and INS by PROC MIXED and mean values by least squares means (SAS). There were no differences ($P \geq 0.05$) by addition of fat, in onset, duration, and LH preovulatory peak, however, amplitude of LH preovulatory peak was different among treatments ($P \leq 0.05$). P4 concentration was higher in ewes without addition of fat compared with the added group ($P \leq 0.05$, 2.74 ± 0.2 vs. 2.58 ± 0.2 ng mL^{-1}). E2 and INS concentrations increased in ewes with HDF compared with LDF group ($P \leq 0.05$, 15.4 ± 11.8 pg mL^{-1}; 0.37 ± 0.02 ng mL^{-1} vs. 5.1 ± 11.8 pg mL^{-1}, 0.25 ± 0.02 ng mL^{-1}, respectively). It is concluded that the addition of bypass fat did not alter onset and duration of LH preovulatory peak, but decreased P4 concentration probably due to an early secretion of PGF2α, nevertheless, E2 and INS concentrations increased in ewes with HDF, which is attributed to an improved metabolic, nutritional and body animal status.

Key Words: ultrasonography, hormones, synchronized estrus.

M289 Effects of human chorionic gonadotropin on serum progesterone concentrations, embryonic survival and lambing rates in ewes. L. M. Lankford*[1], D. T. Yates[2], R. A. Halalsheh[1], P. L. Black[1], D. M. Hallford[1], and T. T. Ross[1], [1]*New Mexico State University*, *Las Cruces,* [2]*University of Arizona*, *Tucson*.

This study was conducted to determine if multiple injections of human chorionic gonadotropin (hCG) will increase circulating concentrations of progesterone (P4) in sheep following mating and prolong elevated levels through the period of fetal attachment. Fifty-nine nulliparous, primiparous, and multiparous Suffolk ewes (avg BW = 79.7 ± 2.5 kg) received an intravaginal P4-containing insert (CIDR, 0.3 g P4) for 12 d and were mated with fertile rams on the second estrus after CIDR removal. Ewes were randomly assigned to one of 2 treatments. The treated group received 200 IU (0.4mL) of hCG im and controls received 0.4 mL saline im on d 4, 7, and 10, after onset of estrus (d 0; mating). Blood samples were taken via jugular venipuncture beginning on d 0 and on alternate days until d 35. Serum P4 concentrations were similar ($P > 0.10$) between treatment groups through d 5. However, beginning on d 7, ewes treated with hCG had greater ($P < 0.01$) serum P4 concentration than controls, and P4 remained higher ($P < 0.05$) throughout the sampling period (d 35). Of ewes receiving hCG, 68% had 4 or more total CL present compared with 33% for controls ($P < 0.05$; determined by laparoscopy on d 25). Fetal numbers were determined via flank ultrasound on d 60 and 85% of hCG-treated ewes had multiple fetuses compared with 62% of controls ($P < 0.10$). In addition, 82% of hCG-treated ewes gave birth to 2 or more lambs compared with 63% of control ewes ($P = 0.17$). In conclusion, hCG administration on d 4, 7, and 10 after mating resulted in elevated serum P4 concentrations from d 7 through d 35, with more ewes carrying multiple fetuses.

Key Words: hCG, progesterone, lamb crop

M290 Administration of genistein does not alter anterior pituitary concentrations of LH and IGF-I in ovariectomized gilts. C. Paulson*, A. Taylor, and J. Clapper, *South Dakota State University*, *Brookings*.

Previously we have shown that administration of genistein to barrows increases anterior pituitary (AP) concentrations of IGF-I and LH and increased expression of AP IGF receptor. However, whether similar changes occur in ovariectomized gilts remains to be determined. Therefore, the objective of this experiment was to determine if short-term administration of genistein alters serum and anterior pituitary (AP) concentrations of LH and IGF-I and expression of AP GnRH receptors and LHβ subunit. Sixteen cross bred gilts of similar weight (95.5 kg)

were ovariectomized and assigned to either control (C; n = 8) or genistein (G; n = 8) groups. G pigs received 8oo mg of genistein in DMSO while C pigs received an equal volume of DMSO i.m. on d 0, 1, 2, and 3. Blood samples were obtained by jugular venipuncture on d 0, 1, 2, and 3. Pigs were slaughtered on d 4 when blood and AP were collected. Serum and AP concentrations of LH and IGF-I were determined in duplicate by RIA. Relative expression of GnRH receptor and LHβ subunit were determined by real time RT-PCR, and fold changes analyzed using the REST software. Differences in serum and AP concentrations of LH and IGF-I were determined using the Proc Mixed procedure of SAS. Serum concentrations of LH were not different ($P > 0.05$) in G pigs compared with C pigs on d 0, 1, 2, 3 and 4. Serum concentrations of IGF-I were not different ($P > 0.05$) between C and G pigs on d 0 through d 4. AP concentrations of LH and IGF-I did not differ ($P > 0.05$) between C and G pigs. Relative expression of LHβ subunit and GnRH receptor did not differ ($P > 0.05$) between C and G pigs. These preliminary data suggest that short-term administration of genistein does not increase serum and AP concentrations of LH or IGF-I, or expression of GnRH receptors and LHβ subunit in the ovariectomized gilt.

Key Words: genistein, IGF, pigs

M291 Changes in plasma concentrations of growth hormone and luteinizing hormone in ewes following central and peripheral treatment with kisspeptin. B. K. Whitlock*[1], J. A. Daniel[2], B. P. Steele[3], and J. L. Sartin[3,4], [1]*Department of Large Animal Clinical Sciences, College of Veterinary Medicine, The University of Tennessee*, *Knoxville,* [2]*Department of Animal Science, Berry College*, *Mt. Berry, GA,* [3]*Department of Anatomy, Physiology and Pharmacology, College of Veterianry Medicine, Auburn University*, *Auburn, AL*, [4]*Agricultural Experiment Station, Auburn University*, *Auburn, AL*.

Kisspeptin (KP), a neuroendocrine regulator of gonadotropin releasing hormone, has been hypothesized as an integrator of nutrition and hormones critical to metabolism and regulation of reproduction. Recent evidence suggests growth hormone (GH) secretion may be influenced by KP. The objective of this study was to determine if the GH stimulatory effect of KP is due to actions on the hypothalamus or anterior pituitary gland in ewes. Adult ovariectomized ewes (n = 8) were fitted with intracerebroventricular (ICV) cannula to facilitate central administration of experimental treatments. Ewes received one of 8 treatments [4 intravenously (IV) and 4 ICV]. Peripheral treatments [0 (Veh), 100, 200, or 1000 pmol/kg body weight (BW) KP-10 (human KP 45–54; 4389-v, Peptide Institute, Inc., Osaka, Japan) in saline] were administered as a bolus via jugular cannula and ICV treatments [Veh, 50, 100, or 200 pmol/kg BW KP-10] were administered via the ICV cannula. Blood samples were collected from a jugular cannula at −15, 0, 10, 20, 30, 45, 60, and 75 min relative to treatments. Experiments were repeated until all ewes received each treatment. Plasma GH and luteinizing hormone (LH) concentrations were determined by radioimmunoassay. Effects of treatment on plasma concentrations of LH and GH were tested using procedures for repeated measures (SAS Institute Inc., Cary, NC). The 200 and 1000 pmol/kg IV KP-10 increased ($P < 0.05$) plasma concentrations of LH. However, there was no effect of IV KP-10 on plasma GH. Conversely, 100 and 200 pmol/kg KP-10 administered ICV increased ($P < 0.05$) plasma GH concentrations. Maximum GH responses occurred 30 min following ICV KP-10 injection and were greater ($P < 0.05$) than both Veh and the 50 pg/ml KP-10 ICV. In addition to activating the gonadotropic axis, KP can activate the somatotropic axis in ruminants and present data support a central site of action.

Key Words: sheep, kisspeptin, growth hormone

M292 Temporal changes during the periparturient period on metabolic and endocrine parameters of spring-calving beef cows in grazing conditions. A. L. Astessiano*[1], R. Pérez-Clariget[1], G. Quintans[2], P. Soca[1], and M. Carriquiry[1], [1]*School of Agronomy, UdelaR*, *Uruguay*, [2]*Instituto Nacional de Investigación Agroprcuaria*, *Treinta y Tres, Uruguay*.

Primiparous crossbred cows (Hereford/Angus, n = 20), classifiedby BCS at calving (scale 1-8), were used in a randomizedblock design, to study temporal changes on metabolic andendocrine parameters during the peripartum in grazingconditions. Cows grazed together a native pasture paddock (60 ha) with an average forage mass available of 453 kg DM/ha (13.2% CP, 24.4% ADF). Means from repeated measure analyses were considered to differ when $P<0.05$. Cow BCS throughout the period evaluated was greater for BCS >3.75 than BCS ≤3.5 calved cows. Concentrations of NEFA were affected ($P < 0.01$) by day postpartum (DPP) as NEFA were elevated at −45 DPP, peaked at −7 DPP and were reduced thereafter for all cows. However, NEFA levels were less from −45 to −15 DPP but greater at −7 DPP for BCS >3.75 than BCS ≤3.5 calved cows, while no differences between groups were observed during the postpartum. Glucose, urea, and total protein concentrations were affected ($P < 0.01$) by DPP and there was an interaction ($P < 0.03$) between BCS at calving and DPP for urea and total protein levels. Glucose concentrations tended ($P = 0.07$) to decrease from −7to 30 DPP while urea concentrations were elevated at −45DPP, peaked at −7 DPP and decreased thereafter. However, changes in urea were steep around parturition for BCS >3.75 but not for BCS ≤3.5 calved cows. Total protein concentrations were elevated during the last month of gestation, decreased at parturition and remained reduced until 45 DPP. Cows with BCS >3.75 at calving had greater total protein at −15 DPP but less around parturition than cows with BCS ≤3.5. There were no differences in circulatinginsulin levels along the period evaluated, however, insulinwas less for BCS >3.75 than BCS ≤3.5 calved cows dueto a drastic increase of insulin levels after 15 DPP in the lastones. Metabolic and endocrine parameters reflected the negative energy balance during the prepartum of cows grazing native pastures in winter.

Key Words: peripartum, metabolites, cattle

M293 Metabolic measurements in the sow and relationship to post-weaning reproductive performance. L. A. Rempel*, J. L. Vallet, and D. J. Nonneman, *USDA, ARS, USMARC*, *Clay Center, NE*.

Extreme weight (wt) loss during lactation is an indicator ofcatabolism in exchange for maintaining metabolic output andcan have adverse effects on reproductive parameters. Creatine is a nonprotein nitrogen that acts as a phosphagen and aids in tissue repair. Creatine may be indicative of a sow's ability to support offspring as well as the postpartum uterus. Our objective was to establish creatine and body condition measurements at periods of physiological changes due to parturition and lactation in the sow and how these components related to post-weaning (pw) reproductive performance. First and 2nd parity sows were bled and weighed at d110 gestation (d110), d1 post-farrowing (d1PF), and at weaning(wn) Plasma was assayed for creatine. Loin eye area (LEA)and 10th rib backfat (bft) were measured by ultrasound atd110, wn, and following pw estrus (pwE). Weaning to estrus interval (WEI), pwE within 14d, and subsequent ovulation rate (OR) were recorded. Day 110 bft and change in bft from wn to pwE was negatively associated (-ASSOC; $P<0.05$) with pwE in 1st parity sows. Creatine at d110 tended ($P<0.10$) to be -ASSOC with pwE in 1st parity sows as well. Body wt change in 2nd parity sows from d110 to d1PF and d1PF to wn tended ($P < 0.10$) to be positively associated (+ASSOC) with pwE, and change in body wt from d110 to wn was +ASSOC ($P < 0.05$) with pwE. Creatine at wn

and change in creatine from d1PF to wn were -ASSOC ($P < 0.05$) with pwE in 2nd parity sows only. 1st parity WEI was -ASSOC ($P < 0.05$) with d1PF creatine and +ASSOC ($P < 0.05$) with change in creatine from d1PF to wn. OR was +ASSOC ($P < 0.05$) with LEA at wn of 1st parity sows whereas OR in 2nd parity sows was +ASSOC ($P < 0.05$) with wn wt. Creatine at wn in 1st parity sows was -ASSOC (P<0.05) to both wn wt and LEA at wn. Backfat in 1st parity sows was associated with pwE whereas creatine at wn in 2nd parity sows was coupled with pwE. First parity WEI was related to creatine at d1PF, which may reflect stress events associated with parturition. These data suggest that body wt, bft, LEA, and creatine contribute to the complex trait of pw reproduction but may respond differently dependent upon female maturity.

Key Words: swine, reproduction, metabolism

M294 Lipoic acid decreases progesterone clearance rates in ovariectomized ewes. R. S. Mottet*[1], C. O. Lemley[2], E. L. Berg[1], E. P. Berg[1], and K. A. Vonnahme[1], [1]*North Dakota State University*, *Fargo,* [2]*West Virginia University*, *Morgantown*.

Lipoic acid is a naturally occurring compound that has been shown to modulate insulin sensitivity when supplemented to the diet. Elevated blood insulin concentrations have been shown to decrease progesterone catabolism in several species by modulating expression and/or activity of cytochrome P450 2C (CYP2C) or 3A (CYP3A). We hypothesized that lipoic acid would decrease progesterone catabolism by the liver. The objective was to determine how supplementation of lipoic acid impacted progesterone clearance rate in ovariectomized ewes. Eight ovariectomized ewes were fed an alfalfa-grass ration at 95% of ad libitum for the duration of the experiment. Ewes were randomly assigned to lipoic acid treatment [an empty bolus administered by gavage (n = 4; CON), or lipoic acid supplemented at 32 mg/kg BW administered by gavage (n = 4; LA)]. Progesterone was administered via CIDR devices on d 5 to all ewes. Daily blood samples were collected from d 5 to 10. On d 10, liver biopsies were obtained from each ewe to determine CYP2C and CYP3A activity. On d 11, serial blood samples were collected after CIDR removal to determine progesterone clearance from the blood stream. Ewes treated with LA had decreased ($P < 0.03$) serum progesterone clearance compared with CON ewes; however, no difference ($P > 0.20$) in hepatic enzyme activity was found. We conclude that while lipoic acid decreases progesterone clearance in the blood, it does so without affecting hepatic CYP2C or CYP3A enzyme activity; therefore, the mechanism of action is yet to be elucidated.

Key Words: lipoic acid, progesterone, liver

M295 Zearalenone increases reproductive tract development, but not skeletal muscle signaling in prepubertal gilts. W. T. Oliver*[1], J. R. Miles[1], D. E. Diaz[2], J. J. Dibner[2], G. E. Rottinghaus[3], and R. J. Harrell[2], [1]*USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE,* [2]*Novus International, Inc.*, *St. Charles, MO,* [3]*Veterinary Medical Diagnostic Laboratory, University of Missouri, Columbia*.

Zearalenone (zea) is a potent mycotoxin that has estrogenic properties. In vitro results indicate that zea metabolites are capable of downregulating proteins associated with protein synthesis (mammalian target of rapamycin, mTOR) and cellular proliferation (extracellular signal-regulated kinase, ERK) in muscle. The objectives were to determine the effect of zea consumption by prepubertal gilts on: 1) growth performance, 2) reproductive tract development, and 3) skeletal muscle mTOR and ERK activation. Gilts were weaned at 21 d of age and allowed to adjust for 1 wk on a commercial diet. After 1 wk (d 0), gilts were randomly assigned to consume a commercial basal diet (C, n = 9) or C + 1.5 mg/kg zea (n = 10) for 4 wk, at which time gilts were killed, urine collected, and tissue collected and frozen. Zearalenone, α-zearalenol, and β-zearalenol were detected at levels of less than 4 μg/kg in urine of C gilts, but were increased (292 ± 76, 113 ± 20, and 15 ± 3 μg/kg, respectively) in pigs consuming zearalenone ($P < 0.01$). No differences were observed in ADG, ADFI, or G:F between treatments ($P > 0.28$). Reproductive tract size was increased 1.5-fold (20.9 ± 4.3 vs. 50.6 ± 3.8 g) in zea gilts ($P < 0.01$). Uterine endometrial gland development was increased 50% in gilts consuming zea ($P < 0.01$). In uterus, estrogen receptor (ER)-α mRNA and protein were unchanged ($P > 0.28$), but gilts consuming zea had 2- and 3-fold higher abundance of ER-β mRNA and protein, respectively, compared with the C group ($P < 0.01$). No differences were observed in mTOR and ERK protein phosphorylation or total abundance in skeletal muscle ($P > 0.36$). The consumption of zea had no effect on growth performance or skeletal muscle signaling in prepubertal gilts, but zea increased reproductive tract size and glandular development, possibly due to altering the expression of ER-β.

Key Words: swine, uterus, zearalenone

M296 Quantitative bioluminescence imaging of porcine antral follicles in vitro. S. Jung* and S. T. Willard, *Mississippi State University*, *Mississippi State*.

Determining the relationships between optimal imaging time, plasmid DNA dose and luciferase expression for quantitative bioluminescence imaging is critical to the development of new biophotonic paradigms. In this study, we analyzed the time course of luminescence emitted from transfected porcine whole follicle units. We used cationic lipid transfection with increasing doses of plasmid DNA (pGL4) encoding a luciferase reporter gene. Follicles between 5.5 to 6 mm in diameter were dissected from the ovaries. DNA–lipid complexes were formed at a DNA (μg):lipid (μL) ratio of 2:5 in PBS, by adding FuGene 6 diluted in PBS to 0 μg, 1 μg, 2 μg or 3 μg of pGL4 and introduced into each follicle unit by injection using a microinjector. A total of n = 48 follicles were randomly allocated in 4 groups (negative control, 1 μg, 2 μg and 3 μg groups) and cultured at 39°C under 45% O_2; 50% N_2; 5% CO_2 for 20 h. The luminescence from each follicle unit was detected using an IVIS 100 imaging system after 300 μg of luciferin was injected. An imaging series of 30-s exposures were collected up to 10 min. The signal intensity was reported as mean ± SEM of photon counts (PC; n = 12 per group), and the experiment was repeated 6 times. Data were analyzed by repeated measures ANOVA. The means of the negative control group at individual peak time points served as a background signal and subtracted from means of 1 μg, 2 μg, and 3 μg groups. The signal intensity reached a peak at 1.5 min ($1.08 \times 10^6 \pm 0.47 \times 10^6$ PC) in the 3 μg group, and at 1 min in both 1 μg ($2.45 \times 10^5 \pm 0.88 \times 10^5$ PC) and 2 μg ($4.60 \times 10^5 \pm 1.62 \times 10^5$ PC) groups after the injection and declined gradually afterward. The luciferase expression level of follicles in the 3 μg group tended to be greater than the 1 μg group ($P = 0.09$), but did not differ from the 2 μg group ($P = 0.18$). Overall, a higher level of luciferase expression was observed in follicles transfected with 3 μg of pGL4, with an optimal time for quantification at 1.5 min after luciferin injection. These data are the first to demonstrate luciferase detection and quantification, indicative of transcription, within whole antral follicle cultures in vitro.

Key Words: bioluminescence imaging, antral follicle, in vitro culture

M297 Feed restriction and pre-synchronization on progesterone concentration and LH peak in ewes on a synchronization program. P. Molina[1], T. Sánchez[1], M. E. Ortega[1], L. Olivares[2], O.

Mejía[3], M. Cárdenas[4], E. García*[5], J. Cordero[1], J. Peralta[6], and R. Nieto[1], [1]*Programa de Ganadería, Colegio de Postgraduados*, *Texcoco, México*, [2]*UAEM*, *Edo. México*, [3]*CEIEPO, UNAM*, *Tres Marías, México*, [4]*INNSZ*, *Mexico City*, [5]*CUCSUR*, *Autlán, Jalisco, México*, [6]*ICAP, UAEH*, *Hidalgo, México*.

To evaluate the effect of pre-synchronization and feed restriction in progesterone concentration and characterization of onset, duration and amplitude of LH peak, 69 Dorset ewes were randomly assigned to 4 treatments: Treatment 1 n = 18 (T1): Ewes received 1 kg of commercial supplement (16% protein) for 30 d and were synchronized with FGA sponges (40 mg) for 12 d; Treatment 2 n = 17 (T2) ewes received the same diet as T1, but they were synchronized with 2 doses of $PGF_{2\alpha}$, 16 and 8 d before sponges; Treatment 3 n = 17 (T3) ewes were feed restricted and received 1 kg of oat hay during 30 d, and synchronization regimen as T1; and Treatment 4 n = 17 (T4) received the same diet as T3 and the synchronization regimen as T2. Estrus was determined when ewes allowed the ram for mount after sponge removal. All groups showed 100% of estrus. Progesterone concentrations were greater in pre-synchronized groups ($P \leq 0.05$) compared with non pre-synchronized. Feed regimen affected onset of LH peak ($P \leq 0.05$), with a faster increase on groups with commercial supplement (T1 y T2), compared with groups feed with oat hay (T3 y T4). For synchronization program no differences were observed ($P \geq 0.05$). Duration and amplitude of LH were not affected ($P \geq 0.05$) for type of feed, synchronization program neither interaction between effects. Under the present experimental conditions, it is concluded that nutrition influenced onset of pre-ovulatory LH peak, while greater P4 concentration was observed in ewes pre-synchronized during the luteal phase, as a result of corpus luteum secretion.

Key Words: $PGF_{2\alpha}$, ewes, flugesterone acetate

M298 Progesterone and insulin concentration on ewes with different body condition fed bypass fat in a superovulatory program. P. Molina[1], T. Sánchez[1], M. E. Ortega[1], L. Olivares[2], O. Mejía[3], M. Cárdenas[4], E. García*[5], J. Cordero[1], J. Peralta[6], and R. Nieto[1], [1]*Programa de Ganadería, Colegio de Postgraduados*, *Texcoco, México*, [2]*UAEM*, *Edo. México*, [3]*CEIEPO, UNAM*, *Tres Marías, México*, [4]*INNSZ*, *México City*, [5]*CUCSUR UADG*, *Autlán Jal., México*, [6]*ICAP UAEH*, *Hidalgo, México*.

Dorset ewes in body condition score of 3 (1–5 scale) wererandomly assigned to two treatments: In T1 (n=26) eweswere fed with commercial supplement and in T2 (n=21)ewes were fed with oat hay to reduce the body condition ofthese ewes and both groups received this diet for a month. Then six ewes of each group were superovulated (donors) and the rest remained as recipient ewes. At the beginning of the superovulation treatment dorsal fat was 2.5 and 1.97 mm and body weight was 69 and 65 kg, for T1 and T2, respectively. During the first 8 days of synchronization and superovulation treatment both groups received 100 g of protected fat and same diet as T1, synchronization for donors and receptors was performed by sponges of flugesterone acetate (FGA, 40 mg) during 12 days. Recipient ewes received 200 IU of eCG 12 h before sponge removal. Donor ewes were superovulated with decreasing doses of FSHp for 4 d and embryos were obtained and transferred 7 d later. At synchronized estrus ewes of T1 and T2 weighed 72 and 69 kg ($P > 0.05$) and dorsal fat measures were 3.5 and 3.29 mm ($P > 0.05$) respectively. All ewes from T1 (100%) responded to superovulation, while in T2 only 67% responded. Progesterone and insulin secretion were greater ($P < 0.05$) in ewes of the T1 group, compared to those of the T2 group. There were differences in number of corpora lutea present (9.5 vs. 14.7) for T1 and T2 groups, respectively, and also in rate of recovered embryos (93 vs. 71%). There were no differences in gestation rate ($P > 0.05$), with 35 and 31.5% for T1 and T2 groups, respectively. Based on the present experimental conditions, it is concluded that previous undernutrition affects ovulatory rate, and serum concentrations of progesterone and insulin but not pregnancy rate.

Key Words: FSH, embryos, Dorset ewes

Physiology and Endocrinology: Reproductive Management

M299 Effect of prepartum somatotropin on milk production, metabolism and reproduction in primiparous Holstein dairy cows. A. Schneider*, E. Schwegler, P. Montagner, L. T. Hax, M. M. Antunes, E. Schmitt, F. A. B. Del Pino, I. Bianchi, and M. N. Corrêa, *Federal University of Pelotas*, *Pelotas, RS, Brazil*.

The aim of this work was to evaluate the effect of prepartum somatotropin (bST) injection on metabolic adaptation and resumption of ovulatory cycles in primiparous dairy cows. For this study 31 primiparous Holstein cows in a commercial dairy herd were used. The cows had a mean body weight (BW) of 568.8 ± 47.8 kg and 3.4 ± 0.4 of body condition score (BCS) at the beginning of the experiment. Cows in the bST group (n = 15) received subcutaneous injections of bST (500 mg, Boostin) at −32.2 ± 6.9 d and −18.9 ± 6.9 d, and, if pertinent, at −4.7 ± 7.1 d from calving date. Control cows (n = 16) did not receive any treatment and were managed in the same conditions of treated cows. Blood samples were collected weekly from −35 d to 45 d after calving for glucose, non-esterified fatty acids (NEFA), insulin-like growth factor I (IGF-I) and progesterone assays. Postpartum cows were milked twice daily and production was recorded. A cow was considered ovulated when blood progesterone exceeded 1 ng/mL after calving. Data was compared between groups by ANOVA for repeated measures. Ovulatory status was compared among groups by the Chi-squared test. A value of $P < 0.05$ was considered significant. The positive effect of prepartum bST on milk production and resumption of ovulation could be related to the better adaptation, as seen by the reduced postpartum BCS loss, and, also to the exposure of mammary and reproductive tissues to higher IGF-I concentrations. In conclusion, prepartum somatotropin injection reduced BCS loss, percentage of anovulatory cows, and improved milk production during the first 45 DIM.

Table 1. Variables analyzed for control and prepartum somatotropin treated (bST) groups

	Treatment			P
Variables	Control	bST	SEM	Treat
Prepartum				
BW, kg	568.7	559.7	6.4	0.32
BCS	3.1	3.2	0.0	0.36
Glucose, mmol/L	3.1	3.0	0.1	0.85
NEFA, mmol/L	0.9	1.0	0.0	0.004
IGF-I, ng/mL	84.1	127.8	7.3	<0.0001
Postpartum				
BW, kg	532.9	524.7	4.7	0.22
BCS	2.6	2.8	0.0	<.0001
Glucose, mmol/L	3.2	3.2	0.1	0.49
NEFA, mmol/L	0.9	0.9	0.0	0.28
Milk production, kg/day	22.6	25.3	0.5	<0.0001
Anovulatory at 45 DIM, %	62.5	20.0	-	0.016

Key Words: dairy cows, prepartum bST, postpartum ovulation

M300 Effect of dietary energy on ovarian development and fertility in postpuberal beef heifers. S. E. Echternkamp*, R. A. Cushman, and C. L. Ferrell, *USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE*.

Beef producers are advised to develop replacement heifers to 65% of mature BW, but reports indicate this BW could be reduced to lower input costs. To determine whether lower dietary intake impedes ovarian development and fertility in purebred or crossbred heifers, Angus (n = 60) and MARC II (1/4 Angus, 1/4 Hereford, 1/4 Gelbvieh, and 1/4 Simmental; n = 60) heifers were fed either a high (HE) or low (LE) energy diet for 180 d postweaning to achieve 65 vs. 53% of mature BW at first breeding. At 14 mo of age, heifers were housed with fertile bulls for 47 d. Estrus was monitored for 21 d, and 12 h after estrus, ovaries were ultrasounded in one-half of the heifers to measure ovarian length and height, preovulatory follicle diam., and total number of antral follicles (AFC); corpus luteum (CL) diam. and blood progesterone were measured 7 to 14 d after estrus. Data were analyzed by SAS PROC GLM or GLIMMIX with diet and genetic line as independent variables; 2-way interactions were not significant. Initial BW (282.8 kg) did not differ but, at breeding, HE heifers were heavier (429.4 vs. 344.8 ± 7.1 kg) and fatter (6.9 vs. 5.0 ± 0.1 BCS) than LE heifers ($P < 0.01$); experimental ADG was 0.81 vs. 0.35 ± 0.02 kg/d ($P < 0.01$). Puberty occurred in 93.3% of heifers prebreeding. Size of preovulatory follicle (13.7 ± 0.2 mm), ovary (length = 24.2 ± 0.3 mm; height = 13.3 ± 0.2 mm), CL (19.4 ± 0.5 mm), and AFC (23.4 ± 1.3) did not differ between HE and LE, but follicle diam. (14.3 vs. 13.1 ± 0.3 mm; $P < 0.01$) and ovarian length (25.1 vs. 23.1 ± 0.7 mm; $P = 0.05$) were greater for MARC II vs. Angus heifers. Ovarian size was correlated with AFC (r = 0.64; $P < 0.01$). Plasma progesterone was greater for HE vs. LE heifers (5.3 vs. 4.3 ± 0.3 ng/mL; $P < 0.05$), but CL diam. (19.4 ± 0.5 mm) was not affected by diet or line. Pregnancy rate did not differ between diets but tended ($P = 0.07$) to be greater for MARC II vs. Angus (80 vs. 65%). Developing yearling beef heifers to 53% of mature BW did not impede ovarian development or heifer pregnancy rate.

Key Words: beef heifers, diet, fertility

M301 The pH decreases in the vaginal portion of the cervix in mares near ovulation. J. J. Parrish*, *University of Wisconsin*, *Madison*.

The objective was to determine if vaginal pH in mares varies during the estrous cycle and could be a predictor of time to breed. In this study, wireless transmitting boluses were obtained from Kahne Limited, New Zealand, that were capable of measuring pH, temperature and pressure. Boluses of 15 × 3 cm, were originally designed for remote rumen measurements but modified in our lab for limited time use in mares. The boluses were sterilized in Nolvasan followed by rinsing in distilled water and calibration with pH standards. The mare's vulva was disinfected with 3 washes of detergent as done for artificial insemination. The bolus was inserted with a lubricated gloved hand into the vagina. The tip of the bolus was inserted deep into the anterior vagina and into the folds of the vaginal portion of the cervix. This location was chosen as air entering the vagina produced unstable pH readings when the bolus was left in just the anterior vagina. Pressure measurements demonstrated the vagina was 10 mbar below ambient pressure and influx of air occurred at unpredictable times. The pH was recorded at 5 s intervals and the average pH determined over a mean ± SEM of 4.1 ± 0.3 min (225 measurements) per mare. Data was obtained on 3 mares on days −7, −2, −1 and 0 relative to ovulation as detected via ultrasonography. Mares exhibited estrus on days −2, −1 and 0. The mean ± sem pH across mares was 7.02

± 0.01, 6.95 ± 0.02, 6.88 ± 0.02, and 6.75 ± 0.07 for days −7, −2, −1 and 0 respectively. Using Dunnett's procedure, days −7 and −2 had greater pH values than d 0 ($P < 0.05$) but d 0 was not different from day −1 ($P > 0.05$). Temperature measured along with pH did not vary over stage of cycle ($P > 0.05$). If left in the vagina overnight, the boluses were ejected at 12 – 24 h and often damaged. Vaginal pressure changes were detected when an estrus mare was brought into contact with a stallion. The experiment demonstrated that the pH of the vaginal portion of the cervix in mare's is neutral in diestrus and decreases near the time of ovulation and thus could be a suitable marker of the time to breed. The boluses were the generous donation of Kahne Limited.

Key Words: vaginal pH, estrous cycle, ovulation

M302 Main endocrine-metabolic differences between 1st and 2nd lactation of the dairy cows around calving. G. Bertoni*, R. Lombardelli, F. Piccioli-Cappelli, and E. Trevisi, *Istituto di Zootecnica, Universitá Cattolica S. Cuore*, *Piacenza, Italy*.

Dairy cows yield less milk in the 1st lactation in comparison to the following one and this seems to be mainly due to mammary gland development, although other factors can be involved (e.g., level of DMI, digestive tract development, different experience of stress). With the aim to better clarify the influence of metabolic-endocrine changes on differences in milk yield between 1st (L1) and 2nd (L2) lactation, 8 healthy Italian Frisian cows reared under very similar conditions (housing, diet, climate), were checked in their first 2 lactations. Cows were individually fed with corn silage, chopped alfalfa and grass hays distributed every 12 h, and concentrate, fed in 2 (dry period) or 8 (lactating period) meals at regular intervals. Cows have been daily checked for milk yield, DMI, and fortnightly for BW and BCS. Blood samples were weekly withdrawn, before the morning meal, from −28 to 120 DIM to determine metabolites and hormones. During 1st month of lactation, L2 showed higher milk yield (40.0 vs. 30.8 kg/d), DMI (20.5 vs. 17.9 kg/d) and lower BCS (2.36 vs. 2.49 score). The negative energy balance was more accentuated in L2 as suggested by the lower glucose for 3 weeks (3.43 vs. 3.78 mmol/L; $P < 0.01$) and higher BHBA (0.64 vs. 0.89 mmol/L; $P < 0.05$), despite NEFA were similar. Hormones with an apparent relationship with lactation start were bST and glucagon (increased) and IGF-I, insulin and perhaps triiodothyronine (T3) (reduced); nevertheless, in the periparturient period very small differences has been observed, according to parity, for bST, glucagon and T3. Otherwise, the average values (end pregnancy - first two months of lactation) were lower in L2 for insulin (5.9 vs. 7.6 mcU/mL; $P < 0.01$) and IGF-I (47 vs. 63 ng/mL; $P < 0.01$). These last differences suggest that the more negative energy balance of L2, due to higher milk yield, is the main cause of lower glucose and, consequently, of lower insulin and IGF-1. This explanation seems confirmed by the good correlation between glucose recovery and that of insulin and IGF-1 in the 1st month of lactation. To conclude, higher milk yield in the 2nd lactation does not seem to be affected by hormonal changes, but it indirectly causes a reduction of insulin and IGF-1.

Key Words: milk yield, parity, hormone

M303 Effect of thermal preconditioning during the prebreeder period on breeder turkey hens' reproductive performance. S. W. Kang*, S. Kosonsiriluk, S. J. Welch, and M. E. El Halawani, *University of Minnesota*, *St. Paul*.

Breeder turkey hens photostimulated in the month of May are highly susceptible to a sudden increase in environmental temperature which has a detrimental effect on egg production. The objective of this study was to investigate the effects of thermal preconditioning before photostimulation on enhancing egg production during the summer months. Hens were reared under the photoperiod 14L/8D daily with day length reduced to 6L/18D from 17 to 30wk. At 30wk, hens were photostimulated (15L/9D). In experiment 1: Hens were subjected to temperature treatments at 20 wks of age (6hrs/day). Treatments included: 1) Control, no temperature treatment. 2) 10 wks: subjected to 75°F, increasing by 5°F every 2 wks. 3) 5 wks: same as treatment (2) excepting each temperature cycle was only for one wk. 4) 3 wks: treatment started at 27 wk, starting at 85°F, increasing by 5°F for the next 2 wks. In experiment 2: Treatments included: 1) Control, same as experiment 1. 2) 3wks: subjected to 85°F at 27 wk, increasing by 5°F every wk. 3) 2 wks: subjected to 90°F at 28 wk, increasing by 5°F at 29 wk. 4) 1 wk: subjected to 95°F at 29 wk. Peak egg production was comparable among all treatment groups between wk 1–4 of photostimulation. In experiment 1, average egg production was highest in the 3 wks preconditioning group (4.16 eggs/hen/wk) during the 27 wks production period. Lowest average egg production was that of hens receiving 10 wks of preconditioning (3.43 eggs/hen/wk). Control group was 3.86 eggs/hen/wk. In experiment 2, average egg production of the 1 wk preconditioning group (3.96 eggs/hen/wk) was 37.5% higher than that of control (2.88 eggs/hen/wk). There was no significant difference among treatment groups (1, 2, and 3 wks). The results clearly indicate that thermal preconditioning can be beneficial or detrimental to egg production of hens photostimulated in the month of May depending on the preconditioning temperature schedule and age of hens at the time of treatment initiation.
Supported by Minnesota Turkey Growers Association, Willmar Poultry Co., and Minnesota Agricultural Experiment Station.

Key Words: turkey reproductive performance, heat stress, thermal preconditioning

M304 In vitro investigation of anti-*Escherichia coli* O157:H7 effects of free fatty acids under acidic conditions. J. Yang*[1,2], X. Hou[1], P. S. Mir[2], and T. A. McAllister[2], [1]*Inner Mongolia Agricultural University*, *Hohhot, P. R. China*, [2]*Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada*.

Preventing acid-tolerant *Escherichia coli* O157:H7 from colonizing the lower gut of cattle could reduce fecal shedding of this zoonotic pathogen. This study aimed to test the antimicrobial effects of fatty acids (FA) against *E. coli* O157:H7 at acidic pH. From 4 strains of *E. coli* O157:H7 (E32511, E318N, H4420N and R508N) screened for acid tolerance, strain H4420N was selected for further study of the influence of pH on bactericidal activities of 6 FA (capric, lauric, palmitic, oleic, linoleic, and linolenic). Strain H4420N was cultured at pH 2.5, 4.3 and 7 for 6 h at 37°C in the presence (20 m*M*) of selected FA in Luria-Bertani broth containing 4% (v/v) Tween 80. Triplicate cultures were prepared for each FA × pH combination, and the entire experiment was repeated. Bacterial numbers were $\log_{10}$ transformed for statistical analysis. Differences were identified using the Least Squares Means of GLM (SAS Institute, Cary, NC). None of the FA exhibited bactericidal activity at pH 7.0. At pH 4.3, capric acid (C10:0) caused a 5 $\log_{10}$ reduction in cfu/mL and both lauric and linoleic acids reduced ($P < 0.001$) viability of H4420N. None of the other FA showed bactericidal activity at pH 4.3. At pH 2.5, oleic (C18:1) and linolenic acids (C18:3) had modest effects on the H4420N viability, whereas capric (C10:0), lauric (C12:0) and linoleic acids (18:2) resulted in ≥ 5 $\log_{10}$ reductions in cfu/mL. Capric and lauric acids were examined further at pH 2.5 at concentrations ranging from 0.15 to 20 m*M*. After 10 min of exposure, 5 $\log_{10}$ cfu/mL reductions were achieved by lauric acid at 2.5 m*M* and by capric acid at 0.31 m*M*. Acid stress increased the sensitivity of *E. coli* O157:H7 to FA, particularly capric, lauric and linoleic acids. Thus, the ability of this pathogen to survive passage to the lower gut may be reduced if these fatty acids are included in diets for cattle.

Key Words: fatty acids, pH, *E. coli* O157:H7

M305 A more specific and sensitive detection method for avian influenza H5N1 using antibodies against N1 subtype and red blood cell amplification in an impedance biosensor. J. Lum*[1], R. Wang[1], D. Abi-Ghanem[2], B. Hargis[1], L. Berghman[2], S. Tung[1], and Y. Li[1], [1]*University of Arkansas*, *Fayetteville,* [2]*Texas A&M University*, *College Station*.

Avian influenza (AI) H5N1 was first discovered in the 1990s and since then has become a likely source of a global pandemic and economic loss. Current specific detection methods are time consuming, expensive, and require special training or facilities. A rapid, sensitive, and specific screening method is needed for in-field or bedside testing of AI virus to implement quarantines and medications. An impedance biosensor has been developed to meet this need, but it is not ready to detect AI H5N1 subtype at very low concentrations. Therefore, the objective of this study was to improve the specificity and sensitivity of this impedance biosensor for rapid screening of AI H5N1 using secondary antibody against N1 subtype and red blood cell (RBC) amplification. Three major components of the developed biosensor are immunomagnetic nanoparticles for separation of AI virus, a microfluidic chip for sample control, and an interdigitated microelectrode for impedance measurement. In this study, polyclonal antibody against N1 subtype was immobilized on the surface of the microelectrode to generate more specific impedance signal, and red blood cells were mixed with the sample to amplify impedance value. The impedance of the nanoparticle-virus-RBC complex was measured and compared with the negative control. The change in impedance could be correlated with the concentration of AI H5N1 virus. Using polyclonal anti-N1 along with red blood cell amplification, the impedance biosensor was capable of detecting AI H5N1 at levels down to 100 EID50/ml in less than 3 h. Red blood cell amplification caused a significant increase ($P < 0.001$) in impedance change as compared with antibody immobilization alone.

Key Words: avian influenza, biosensor, rapid detection

M306 Survival of *Escherichia coli* O157:H7 incubated with corn- or wheat-based dried distillers' grains with solubles in ruminal or fecal inoculum. H. E. Yang[1,2], W. Z. Yang[1], J. J. McKinnon[2], T. W. Alexander[1], Y. L. Li[1], and T. A. McAllister*[1], [1]*Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada*, [2]*University of Saskatchewan*, *Saskatoon, SK, Canada*.

Including corn-based dried distillers grains with solubles (DDGS) in feedlot diets may increase fecal shedding of *E. coli* O157:H7 by cattle. In western Canada, wheat-based DDGS is also available to finishing cattle. This study investigated whether corn- or wheat-based DDGS (CDDGS, WDDGS) replacing 0, 20 or 40% of barley grain in substrate for in vitro batch culture affected survival of *E. coli* O157:H7 in ruminal content- or feces-based inoculum. Donors for ruminal and fecal inoculum were 2 ruminally cannulated non-lactating Holstein cows fed diets containing both corn- and wheat-based DDGS, in equal proportions, to ensure that microbial populations associated with digesta from both forms of DDGS were present in the digestive tract. Triplicate incubation vials (200 mg substrate + 20 mL ruminal or fecal inoculum) were prepared for time points 0, 4, 12 and 24 h and each of 5 substrates (ground barley grain replaced with 0, 20 or 40% CDDGS or WDDGS). After inoculation with a 4-strain (E318N, E32511, R508N, and H4420N) mixture of *E. coli* O157:H7 (total 10^8 cfu/mL), vials were sealed and incubated at 39°C. Neither type nor level of DDGS affected fermentation or survival of *E. coli* O157:H7 in ruminal contents. In fecal inoculum, however, a time × DDGS interaction ($P = 0.05$) was observed. At 4 and 12 h of incubation, numbers of *E. coli* O157:H7 in feces were similar across treatments, but at 24 h, they were greater in 40% WDDGS and 40% CDDGS than in other treatments. Additionally, *E. coli* O157:H7 concentrations at 24 h were greater in fecal incubations with CDDGS than with WDDGS. Differences in numbers of *E. coli* O157:H7 were not attributable to changes in pH or VFA concentrations. These results suggest that inclusion of high levels of either corn- or wheat-based DDGS in feedlot diets for cattle may encourage the persistence of *E. coli* O157:H7 in feces.

Key Words: *E. coli* O157:H7, distillers grains, ruminal contents

M307 The effect of fungus myceliated grain supplementation in different feeding phases on coccidiosis and production performance of broilers. W. L. Willis, O. S. Iskhuemhen, S. L. Hurley, D. Wall*, R. C. Minor, and E. I. Ohimain, *North Carolina Agricultural and Technical State University*, *Greensboro*.

A 49 d experiment was conducted to evaluate fungus myceliated grain (FMG) supplemental inclusion levels in different feed phases on coccidiosis and production performance in broiler chickens. This study utilized 294 straight-run broiler chicks that were randomly weighed and distributed into 7 treatment (trt) groups with 3 replications of 14 chicks each on recycled litter as follows: 1) Control- no myceliated grain, 2) Starter

feed-FMG 5%, 3) Grower feed-FMG 5%, 4) Starter/grower/finisher feeds-FMG 5%, 5) Starter feed-FMG 10%, 6) Grower feed-FMG 10% and 7) Starter/grower/finisher feeds-FMG 10%. Assessment data were taken on male/female BW, fecal *Eimeria sp.* egg count, bursa and spleen wts, and mortality. BW of males and females broilers was significantly depressed in trt 5 when compared with the control 2.00 vs. 2.52 kg males and 1.83 vs. 2.10 kg females. Treatments 1 and 2 had the highest growth of *Eimeria sp.* with the other trts had varying levels of reduced counts. Trts 6 and 7 had the lowest counts though not significantly different from trts 3, 4 and 5 ($P > 0.05$), but significantly ($P < 0.05$) different from trts 1 and 2. Male relative bursa wts were highest in trt 4 (0.021) vs the control (0.017), while trt 6 had the lowest (0.013) vs the control (0.017). Average feed consumed did not differ greatly among trts. The results from this study reflect a positive response of fungus myceliated grain fed at the 10% inclusion level throughout the entire feeding phases for anticoccidial control and production performance.

Key Words: broilers, fungus myceliated grain, coccidiosis

M308 Tibial dyschondroplasia in four crosses of male commercial broilers and its relationship to gait score. P. Y. Hester*[1], P. N. Talaty[1], and M. N. Katanbaf[2], [1]*Purdue University*, *W. Lafayette, IN*, [2]*Cobb-Vantress, Inc.*, *Monticello, KY*.

The objective of the following study was to determine the incidence of tibial dyschondroplasia (TD) among 4 crosses (crosses A, B, C, and D) of male meat-type commercial broilers and its relationship to gait score at 6 wk of age. At 38 and 39 d of age, 360 birds were evaluated individually for gait score. Three male chickens/pen with good walking ability (gait score of 0 or 1) and 3 male chickens/pen with poorer walking ability (gait score of 3) were killed and individual BW determined at 6 wk of age. Both drumsticks were retrieved and the distal and proximal tibia were scored for TD lesion (0 = no lesion; 1 = mild lesion; 2 = moderate lesion; and 3 = severe lesion). Data were analyzed via ANOVA using the mixed model procedure of SAS. Very few birds showed TD lesions. The TD scores were similar among crosses even though gait scores differed among genotypes with cross C having better gait scores than crosses A and B but did not differ from cross D. The TD lesion scores did not differ between male broilers with a gait score of 0 or 1 (mean TD lesion score of 0.03 ± 0.03) as compared with those with a poorer walking ability and a gait score of 3 (mean TD lesion score of 0.08 ± 0.03). The proximal end of the right and left tibia had similar TD lesion scores. The TD lesions scores were higher for the right proximal tibia when compared with the distal ends of the right and left tibia. These results suggest the poorer walking ability of male broilers in this study was not due to TD lesions.

Key Words: tibial dyschondroplasia, male broiler, gait score

M309 Impact of egg storage on blastodermal cell viability and embryonic metabolism in broiler breeders. J. A. Hamidu*[1], Z. Uddin[1], G. M. Fasenko[2], and D. R. Barreda[1], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*University of New Mexico*, *Albuquerque*.

The objective of the current study was to investigate the impact of short-term (4 d) and long-term (14 d) egg storage on blastodermal cell viability and embryonic metabolism. Two separated experiments were conducted using Ross 308 broiler strains after egg storage (4 d vs. 14 d) at 18°C and 80% RH. Study–1 involved separation of individual blastoderms into individual cells. The cells were pooled together in each treatment and stained with Annexin V-FITC and propidium iodide. A flow cytometer (BD FACScan) was used to analyze the cell suspensions and separated into percentages of live cells (Annexin V–/PI–), early apoptotic cells (Annexin V+/PI–), necrotic cells (Annexin V–/PI+) and late apoptotic/necrotic cells (Annexin V+/PI+). In study–2, eggs from each treatment were placed in metabolic chambers inside an incubator. Measurements of O_2 consumption and CO_2 production were used to calculate embryonic heat production. Daily dry embryo weights (4 to 21 d of incubation) were measured and used to determine heat production/g embryo weight. All data were analyzed by the proc mixed model procedure of SAS ($P \leq 0.05$). The PDIFF procedure in SAS was applied to separate LSmeans between storage treatments. The percentage of live cells decreased significantly as egg storage duration increased (4 d = 81.17 ± 2.13% vs. 14 d = 68.18 ± 2.15%). The percentage of early apoptotic cells increased in 14 d (17.88 ± 1.87%) vs. 4 d (4.32 ± 1.89%). While daily embryo weight and heat production decreased with egg storage, the heat production/g embryo weight increased. Though embryos from 14 d stored eggs were metabolizing at a higher rate than 4 d storage group, they had reduced embryonic metabolism. The study indicates that reduction in blastodermal cell numbers following egg storage for 14 d is primarily due to events of apoptosis. Examining genes that induce apoptosis in broiler breeders could be used to slow down the events of apoptosis and increase cell viability, improve embryonic metabolism and embryo survival during incubation.

Key Words: egg storage, viable and apoptotic cells, embryonic metabolism

M310 Influence of hen's age and phenotypic correlation between external and internal traits of eggs. O. T. F. Abanikannda* and A. O. Leigh, *Lagos State University*, *Ojo - Lagos, Nigeria*.

Table egg remains the cheapest source of animal protein, however competing demands for nutrients by the hen for its maintenance and production at different stages of lay impact on the quantity and quality of eggs produced. This study investigates the influence of hen's age on quality of egg's external and internal traits. A total of 300 eggs derived from Harco Black layers from 5 ordinal groups based on age [A (22–32), B (33–43), C (44–54), D (55–65) and E (66–76) weeks] consisting of 60 eggs from each group were sampled and measured. Data were analyzed using JMP (7.0.1) statistical software for basic descriptives, correlation, regression and ANOVA. The overall mean ± SE for egg weight (EGGWT), egg length (EGGLT), egg width (EGGWD), shape index (SHPINDX), vertical circumference (VTCIRC) and horizontal circumference (HTCIRC) are 55.65 ± 0.28 g, 56.09 ± 0.15 mm, 42.40 ± 0.08 mm, 75.69 ± 0.19%, 15.67 ± 0.03 cm and 13.41 ± 0.03 cm, respectively. The effect of hen's age was highly significant ($P < 0.01$) on all external traits, and accounted for 0.26, 0.22, 0.16, 0.07, 0.27, and 0.33, respectively, of the total variation. Age Group A consistently had the least mean values for all external traits except shape index, while group D recorded the highest. The internal traits exhibited similar trend as the external traits across different age groups, with overall mean values of 15.66 ± 0.12g, 33.53 ± 0.21g, 6.46 ± 0.04g, 28.15 ± 0.17%, 60.93 ± 0.22%, 11.64 ± 0.06%, 46.56 ± 0.41% and 0.36 ± 0.01mm respectively for yolk weight (YLKWT), albumen weight (ALBWT), shell weight (SHLLWT), yolk ratio (YLKRAT), albumen ratio (ALBRAT), shell ratio (SHLRAT), yolk:albumen ratio (YKALBRT) and shell thickness (SHLLTKN). Largest correlation was recorded between Albumen weight and all external traits ($P < 0.05$) except for shape index which was low and not significant. Yolk ratio, albumen ratio and yolk:albumen ratio had very low correlation against all external traits and were not significant ($P > 0.05$). The study revealed that hen's age significantly ($P < 0.05$) affect both external and internal traits of eggs and that some of the internal traits had moderate to high correlation with most of the external traits studied.

Table 1. Phenotypic correlations between external and internal traits of egg

M311 Effects of heat stress on egg production and quality in two strains of layers. L. A. Mack*[1], J. N. Felver-Gant[1], R. L. Dennis[2], and H. W. Cheng[2], [1]*Purdue University*, *West Lafayette, IN*, [2]*LBRU, USDA-ARS*, *West Lafayette, IN*.

Heat stress is a problem for both egg production and bird well-being. Given a stressor, genetic differences can alter the type and degree of birds' responses and their adaptation. This study examined heat stress responses of 2 strains of White Leghorns: DeKalb XL (DXL), an individually-selected, commercial strain and a strain of kind, gentle birds (KGB) genetically-selected on high group productivity and survivability. Ninety 28wk-old birds (48 DXL, 42 KGB) were randomly paired, housed by strain, and assigned to hot (H) or control (C) treatments for 14 d (mean: H = 32.6°C, C = 24.3°C). Birds' egg production (egg number, EN; egg weight, EW; shell thickness, ST; and percentage of broken eggs, PB), behavior, and physical variables (BW; ovary weight, OW; number of mature follicles, FN; and crop feed weight, CF) were measured. Data were analyzed in SAS using the mixed models procedures. Compared with C birds, EN, EW, and ST were lower in H birds across both strains ($P < 0.05$). In H birds but not in C birds, both EN and EW increased over time while ST decreased. The PB tended to be greatest in the H-DXL, intermediate in the C birds, and lowest in the H-KGB birds, but a significant difference was found between H-DXL and H-KGB only ($P < 0.5$). Behaviorally, comparing treatments, H birds spent more time drinking and resting, and less time sitting ($P < 0.05$) than C birds. Comparing strains, DXL birds rested more on d 1 ($P < 0.05$) and tended to drink more on d 13 than KGB birds ($P < 0.1$). C-KGB birds ate more frequently than C-DXL birds on d 6 and 11 ($P < 0.05$) but no strain difference was evident in responding to heat stress ($P > 0.05$). H-KGB birds tended to have lower CF than C-KGB birds at both wk 1 and 2, while H-DXL birds tended to have higher CF than C-DXL birds at wk 1 only ($P < 0.1$). Body weight, d 14 OW and FN were all reduced in the H birds compared with relative controls ($P < 0.05$). Although heat stress reduced production variables in both strains of birds, genetic background shaped both the nature and intensity of the response.

Key Words: heat stress, egg quality, behavior

M312 Effect of litter type and wetness on foot pad dermatitis in broiler chickens. O. Cengiz*[1], J. B. Hess[2], and S. F. Bilgili[2], [1]*Adnan Menderes University*, *Aydin, Turkey*, [2]*Auburn University*, *Auburn, AL*.

An experiment was conducted to determine if wetting fresh or used litter for a short period of time during the latter part of the grow-out could influence the incidence and severity of foot pad dermatitis (FPD) in broiler chickens with and without existing lesions. A total of 2 hundred male broiler chickens with and without existing FPD lesions were selected from a 52-d old (Ross 708) flock and reared to 67 d of age in a design consisting of 2 × 2 arrangement of litter type (fresh or used) and added moisture (with or without added water). Broilers (8 treatments; 5 birds per pen; 40 pens total) were reared in floor pens (3 × 4 ft) prepared with used or fresh pine shavings bedding (8 cm deep). One half of the pens were wetted with a gallon of water daily for 5 d starting on Day 52. Litter samples were collected, pooled and analyzed for moisture at 56 and 67 d of age. FPD incidence and severity were assessed at the end of the study by using a 3-point scale. A common withdrawal feed and water were freely available; lighting was continuous throughout the study. Data were analyzed as a factorial design by the GLM procedure of SAS, Inc. Moisture level was higher with used than fresh litter on Day 56 ($P < 0.05$) but not on Day 67 of the trial. Wetting increased the moisture level from an average of 24 to 54% on Day 56. Litter moisture remained high in fresh wetted pens, but was equalized between the two litter types by Day 67. Placing the birds with FPD lesions on fresh bedding significantly reduced the incidence at 67 days of age (78 and 50% for used and fresh litter, respectively). Similarly, FPD severity was also reduced from 42 to 14% with fresh, as compared to used litter. Wetting treatment did not affect FPD incidence, but reduced mild ($P < 0.06$) and severe ($P < 0.07$) lesions at 67 days of age. Neither litter type nor litter wetting influenced FPD incidence or severity in adult birds without existing FPD lesions. These findings indicate that FPD may be occurring early in the grow-out and that improvements in litter quality can reverse the severity of lesions in market age broilers. In addition, in older broiler chickens, exposure to wet litter conditions for short periods prior to marketing is not sufficient to induce FPD.

Key Words: broiler, foot pad dermatitis, litter moisture

M313 Eggshell quality of Japanese quail (*Coturnix japonica*) after long-term selection for egg production. M. M. Fathi*[1], A. E. El-Dlebshany[2], and M. Bahie El-Deen[2], [1]*Al-Qassim University*, *Buridah, Al-Qassim, Saudi Arabia*, [2]*Alexandria University*, *El-Shatby, Alex., Egypt*.

An experiment was conducted to evaluate egg quality and ultrastuctural measurements of eggshell using scanning electron microscopy (SEM) in 2 lines (selected and control) of Japanese quails. Selection program was applied over 22 consecutive generations for higher egg production and lower broken egg percentage. The results revealed that the females of selected line significantly ($P < 0.01$) produced higher egg mass compared with that of control line. Also, selection procedure resulted in significantly improvement in feed conversion ratio. The eggshell of selected line had a higher breaking strength compared with that of control line, although there was no difference between them in shell thickness. Significantly higher wet ($P < 0.01$) and dry ($P < 0.05$) eggshell percentages were found in selected line. In general, the eggshells of selected line had a lower total score (good) of ultrastructural evaluation compared with control line. According to scanning electron microscopy data, the incidence of certain structural variants is more common in eggshell of control line suggesting poor shell strength. Alignment appearance was more prevalent in control eggshells compared with selected ones, suggesting lower resistance to breakage. Late fusion and large interstitial spaces of palisade layer indicating decrease resistance to fracture were observed in control eggshells. It could be concluded that long-term selection for egg production over 22 generations improved mammillary layer measurements and in turn breaking strength.

Key Words: Japanese quail, ultrastructural measurements, eggshell quality

M314 Effects of ambient temperature on body weight, cloacal temperature and blood traits in Pekin ducks. J. F. Huang*[1], C. H. Su[1], C. C. Lin[2], J. H. Lin[1], and S. R. Lee[1], [1]*Ilan Branch, Livestock Research Institute*, *Ilan, Taiwan*, [2]*National Ilan University*, *Ilan, Taiwan*.

This study aimed to investigate the effects of ambient temperature on body weight, cloacal temperature, and blood traits in Pekin ducks. A total of 36 Pekin ducks at 10–11 weeks of age were randomly assigned into 3 temperature groups: (1) 25 ± 1°C (LT), (2) 30 ± 1°C (MT), and (3) 35 ± 1°C (HT) and raised in an individual cage in a climate chamber. The relative humidity was 80–85% for all groups. This study lasted for 3 weeks. Body weight, feed intake, cloacal temperature and blood traits were determined once a week. The data was analyzed by the General Linear Model procedure of the Statistical Analysis System. The most dramatic decrease in body weight was observed in the HT group, followed by MT and then LT groups. Although there was a trend

of lower feed intake in the MT and HT groups, no significant differences among treatments were observed. After one week of treatment, significant differences in cloacal temperature were observed between the LT and HT groups. However, this significance disappeared after 2 weeks of treatment, probably due to adaptation of ducks to high ambient temperature. The cloacal temperatures in the MT and HT groups after 2 week of treatment were lower compared with those measured after one week of treatment. The blood traits showed that levels of calcium, sodium, magnesium, chloride ions, glucose, and total cholesterol were decreased in the MT and HT groups after one week of treatment, but were increased thereafter. However, the levels of the blood traits were relatively stable in the LT group throughout this study. The high ambient temperature caused the most remarkable decrease in body weight and blood traits and the most remarkable increase in cloacal temperature in the first week.

Key Words: ambient temperature, blood trait, Pekin duck

M315 The study on correlation between the liver enzyme activity and dioxin contents in the eggs of laying Brown Tsaiya ducks. C. C. Lin*[1], T. H. Ueng[2], Y. H. Lin[1], J. F. Huang[3], and S. R. Lee[3], [1]*National Ilan University*, *Ilan, Taiwan*, [2]*National Taiwan University*, *Taipei, Taiwan*, [3]*Ilan Branch, Livestock Research Institute*, *Ilan, Taiwan*.

The objective of this study was to study the correlation between the liver enzyme activity and dioxin contents in the eggs of laying Brown Tsaiya ducks. One hundred Brown Tsaiya ducks (119 d old) were raised in the Hsiangsi township (dioxin- contaminated area) and Wuchieh township (not dioxin-contaminated area), respectively. In each township, 50 ducks were raised on the ground and 50 ducks were raised in the cage. This study lasted for 7 mo. In each month, we collected duck liver microsomes to detect 7-ethoxy resorufin O-deethylase (EROD), 7-pentoxyresorufin O-dealkylase (PROD), and 7-ethoxycoumarin O-deethylase (ECOD) activity and also collected the egg samples for analysis and calculation of dioxin toxic equivalency (TEQ_{DF}) by high-resolution gas chromatography/mass spectrometry (HRGC/HRMS). Then, the correlation coefficient was calculated between liver enzyme activity and HRGC/HRMS results. An average correlation coefficient of 0.95 was observed between duck liver EROD and duck egg dioxin TEQ_{DF}. In contrast, a very low correlation coefficient was observed between liver PROD or ECOD activity and dioxin TEQ_{DF} in duck eggs. Furthermore, we used real-time PCR to determine CYP1A4 mRNA expression in duck liver. It showed the highest value of CYP1A4 expression was observed in the liver of ducks raised on the ground of dioxin-contaminated area compared with those in other treatments. The high correlation coefficient between liver EROD activity and dioxin TEQ_{DF} in duck eggs suggests that EROD is a valuable bio-marker of dioxin contamination in Brown Tsaiya ducks.

Key Words: Brown Tsaiya duck, dioxin, EROD

M316 Safety of industrial hemp as feed ingredient in the diets of laying hens and its impact on their performance. N. Gakhar*, E. Goldberg, and J. D. House, *University of Manitoba*, *Winnipeg, MB, Canada*.

Despite the utility of industrial hemp (*Cannabis sativa* L.) as a source of fiber and seed, its cultivation in N. America in the past was deemed illegal, due to concerns over the presence of the psychoactive compound tetrahydrocannabinol (THC) in the plant components. Regulatory changes undertaken by the Canadian government in 1998 permitted the use of cannabis cultivars containing lower concentrations (<0.3%) of THC. These changes present an opportunity to exploit the immense untapped potential of industrial hemp. Keeping this in perspective, a total of sixteen 19-wk-old individually housed Bovan White laying hens were fed one of the 2 diets containing 10 and 20% of hemp seed (HS). Concurrently, a total of twenty-four 19-wk-old individually housed Bovan White laying hens were fed one of the 3 diets containing 4, 8 and 12% of hemp oil (HO). Eight birds fed wheat, soy and corn oil based diets served as control. The diets were fed over a period of 12 weeks. All the diets were formulated to be isonitrogenous and isoenergetic. Daily egg weights, egg production, average daily feed intake (ADFI), feed efficiency (FE) and weekly body weights were recorded for the entire 12 weeks. Shell thickness and Haugh units (HU) were recorded from the eggs collected in wk 4, 8 and 12. Data were subjected to statistical analysis using Proc Mixed procedure of SAS. Daily egg weights (55.13 vs. 51.49 ± 1.2 g), FE (1.74 vs. 1.88 ± 0.04) and body weights (1.47 vs. 1.43 ± 0.02 kg) were higher ($P < 0.05$) for the birds fed 20% HS in comparison to the control. ADFI was lower ($P < 0.05$) in all HO treatments as compared with the control. Hen day egg production (91.12 vs. 96.84 ± 0.07%) and HU (83.8 vs. 86.8 ± 1.53 HU) were lower ($P < 0.05$) in 4% HO group whereas HU increased ($P < 0.05$) in 8% HO group as compared with the control. FE was higher ($P < 0.05$) in 12% HO group (1.70 vs. 1.85 ± 0.04) as compared with the control. In conclusion, this study allays concerns over the safety of feeding industrial hemp to the laying hens and demonstrates the positive impact of feeding HS on their performance.

Key Words: laying hens, hemp seed, hemp oil

M317 Duckweed as a feed ingredient in laying hen diet and its effect on egg production and composition. K. E. Anderson*, Z. Lowman, A. Stomp, and J. Chang, *North Carolina State University*, *Raleigh*.

Duckweed is a native North Carolina aquatic plant that can be used for bio-fuels (ethanol) and animal feeds. Researchers at North Carolina State University have worked for a decade and have developed a system to produce high-protein duckweed biomass utilizing the nutrient-rich effluent from anaerobic digestion of swine wastewater. This aspect of the project was to evaluate data generated in a feeding trial utilizing the duckweed biomass as a protein source in laying hen feed. First, the nutrient and energy composition of the Duckweed grown in these conditions was determined, and found to contain 29.05% CP, 25.08% C Fiber, and 695 kcal/kg AMEn based on a feeding trial with marker. Then a completely randomized design study to evaluate the impact of duckweed on the performance of a commercial layer egg production and feed conversion was conducted. Two layer diets were formulated to be iso-nitrogenous (18.1% crude protein) and Iso-caloric (2930 kcal/kg). The Control (C) no Duckweed and Duckweed (D), using the analysis to formulate the diet containing 12.6% duckweed. The study, utilized 60, 76 wk old Hy-Line, W-36 hens that were individually caged such that 30 hens received the C diet and the remaining 30 hens received the D diet. During the 12 wk study performance criteria were monitored daily and each week USDA grades, Haugh unit, shell strength, vitelline membrane strength, and yolk color data was collected on 1 d production. The data was analyzed using the Proc T-Test procedure, with significant differences of ($P < 0.05$) determined by *t*-test. On wk 3, 7, and 11 whole 6 egg pooled samples were collected and sent in for nutrient composition laboratory analysis. Diet had no impact on the hen-day production. There was a significant increase ($P < 0.05$) in the percent grade B eggs in the hens fed the D by 2% over the C hens. Surprisingly, there was no difference in the nutrient composition of the eggs except for omega-3 fatty acids concentration which were 0.06% higher ($P < 0.0001$) than in the C hens. The results indicate that duckweed can be fed at a 12.6%

inclusion rate and not impact the performance of laying hens and may be a means of enhancing omega-3 fatty acid concentration in eggs.

Key Words: laying hen, duckweed, egg nutrient composition

M318 Blood lipid concentration and performance parameters of broiler was fed by tomato pomace and turmeric powder under heat stress condition. S. J. Hosseini-Vashan[1,2], A. Golian*[1], A. Yaghobfar[2], H. Lotfolahian[2], and P. Esmaeilinasab[3], [1]*Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, IR Iran*, [2]*Animal Science Research Institute*, *Karaj, Tehran, IR Iran*, [3]*Birjand University*, *Birjand, Khorasan Jonobi, IR Iran*.

The effects of including tomato pomace and turmeric powder in dietary broiler chickens, on performance and lipid concentration were evaluated. 440 one-day old Arian broiler were randomly allotted into 20 pens which were assigned to 5 dietary treatments containing 0 (control), 3 or 5% tomato pomace, or 0.4 or 0.8% turmeric powder. Each dietary treatment was replicated 4 times with 22 broilers per pen. Feed and water were offered ad libitum. The ambient temperature was increased from 22 to 32°C for 5 h (10–15 h) on study d 28 to 42 (simulating diurnal temperature during heat stress). Relative humidity ranged from 50% to 65%. On study d 42, one bird from each replicate was randomly selected, slaughtered and blood samples taken from the jugular vein. Data were pooled and analyzed using the general linear model of SAS, and means were separated by Tukey test when $P < 0.05$. Dietary treatments did not influence ($P > 0.05$) body weight gain and feed intake. Feed conversion (intake/gain) was not affected by dietary treatments until d 28, after which it decreased ($P < 0.05$) in birds fed diets with a high content of tomato pomace and turmeric powder. Total cholesterol and triglyceride content of serum did not differ ($P > 0.05$) among dietary treatments. Birds fed diets with high contents of tomato pomace had higher ($P < 0.05$) concentration of HDL cholesterol in serum and no differences were found among birds fed the control diet and diets containing turmeric powder. The lowest serum LDL cholesterol was observed when birds were fed the diet containing 5% tomato pomace. It is concluded that supplementation of 5% tomato pomace and 0.8% of turmeric powder could alleviate the effects of heat stress on feed conversion and they could modulate the serum concentration of LDL and HDL cholesterol.

Key Words: tomato pomace, turmeric powder, heat stress

M319 Reduction of *Clostridium perfringens* colonization in turkey poults by feeding Primalac. S. Rahimi[1], J. L. Grimes*[2], S. Kathariou[2], and R. Siletzky[2], [1]*Tarbiat Modares University*, *Tehran, Islamic Republic of Iran*, [2]*North Carolina State University*, *Raleigh*.

Clostridium perfringens (CP) is recognized as an enteric pathogen in humans, domestic animals, and livestock. This organism is associated with necrotic enteritis, gangrenous dermatitis, clostridial dermatitis (turkeys) and gizzard erosion in poultry. This study was conducted to evaluate the effectiveness of a direct-fed microbial (DFM), Primalac (PM), as a preventative or mitigator of intestinal colonization by *C. perfringens* in turkey poults. One hundred and 20 8 d-old Large White Turkey poults were randomly divided into 4 treatments with 4 replicates (8 birds/pen) consisting of 1) basal diet (C); 2) basal diet supplemented with PM (1.5 kg/ton); 3) basal diet with poults gavaged with *C. perfringens* (C+CP); 4) basal diet supplemented with PM and poults gavaged with *C. perfringens* (PM+CP). Feed and distilled water were provided ad libitum throughout the trial. On d 3 and 7, each bird in CP groups were gavaged with 1 mL of *C. perfringens* (10^8cfu/mL). On d 21, 2 birds per pen were killed. Spleen and bursa of Fabricius (BF) were collected and weighed. On d 21, cecal contents were used for C. perfringens enumeration. Feed consumption (FC), BW and feed conversion ratio (FCR) were calculated weekly and cumulatively. Data were analyzed using GLM of SAS ($P < 0.05$). The *C. perfringens* in ceca were C – 5.88^{bc}, C+CP – 7.26^{a}, PM – 5.35^{c}, PM+CP – $6.19^{b} \pm 0.36$ $\log_{10}$ cfu/g. No differences were observed for BW, FC, FCR, organ weights, or relative organ weights. Further studies are needed to fully ascertain the potential of using DFM (Primalac) to reduce the colonization of *C. perfringens* in the gastrointestinal tract of turkey poults.

Key Words: *Clostridium perfringens*, direct fed microbial, turkey

M320 Influence of *Bacillus subtilis* PB6 (CloSTAT) on the performance of Hyline W-98 layers from 68 to 102 weeks of age. M. Elliot[1], R. Myers[2], A. Lamptey[2], and A. G. Yersin*[2], [1]*A&E Nutrition Services, LLC*, *Lititz, PA,* [2]*Kemin AgriFoods*, *Des Moines, IA*.

The microbial population of the gastrointestinal tract is influenced by several factors, including pH, substrate availability, toxins, antibodies, and other bacteria. Birds possess an unstable microbial ecosystem and poorly digested nutrients and anti-nutritional factors can lead to undesirable microbial growth, often resulting in a negative impact on performance. Periods of stress can cause a shift in the microbial profile from positive to negative. Products, such as CloSTAT Dry Direct-Fed Microbial, a DFM based on a patented *Bacillus subtilis* PB6 organism, assist in maintaining intestinal microbial balance. A study was conducted at a commercial laying operation to evaluate the effect of CloSTAT on the performance of Hyline W-98 layers from 68 to 102 weeks of age. One house, utilizing a split feeding system, was utilized in the study. This arrangement allowed one group of 136,000 hens to be fed the control diet and another group of 136,000 hens to receive the DFM treatment under similar housing conditions. CloSTAT was added at 1 lb/ton (0.5 kg/tonne) to normal second cycle diets 2–3 weeks before induction of the molt and fed for an additional 34 weeks. Egg production, egg weight, body weight, feed intake and mortality were measured weekly. Egg production and mortality tended to be improved in the CloSTAT group throughout the trial, resulting in an increase of 1.9 eggs per hen-housed and 0.57 lb (0.25 kg) of egg per hen-housed and a 1.5% reduction in mortality in the CloSTAT group. Feed intake and body weight were slightly elevated in the CloSTAT group through approximately 83 weeks of age, after which there was no discernible difference between treatment groups. The results of this trial suggest that the use of CloSTAT will result in improved production, improved hen-housed eggs and decreased mortality in second cycle Hyline W-98 layers.

Key Words: *Bacillus subtilis*, layers, egg yield

M321 Do dietary protein:energy ratios modify growth and frame size of young broiler breeder females? E. Mba*, R. A. Renema, A. Pishnamazi, and M. J. Zuidhof, *University of Alberta*, *Edmonton, AB, Canada*.

Feeding practices to minimize muscling of broiler breeder pullets could improve maternal support for early egg production and long-term maintenance of lay. A total of 1,140 Ross 708 broiler breeder females were divided into 30 pens (38/pen) and fed a common starter ration until 3 wk of age, when experimental diets began. Pens were randomly assigned to a high energy (HE), standard energy (STD) or low energy (LE) treatment and a low protein (LP) or high protein (HP) treatment in a 3 × 2 factorial with 3 energy (2,600 kcal, 2,800 kcal and 2,950 kcal) and 2 crude protein levels (14% and 16%). Pen BW was determined 2×/wk to allow feed allocation changes to maintain a common BW target. Individual BW was recorded every 2 wk from 3 wk of age and frame size parameters

(shank length, keel length, and thoracic width) measured every 4 wk. Results were assessed with the proc MIXED procedure of SAS, with significance assessed at the $P < 0.05$ level. Feed intake varied widely to achieve BW targets, ranging from 47.9 (HP-HE) to 54.2 g/bird/day (LP-LE) by 9 wk of age. Differences in feeding level did not impact growth as measured by shank or keel length. On average, LE birds ate 9% more feed than HE or STD birds (P=0.002). Hence, the HE ration provided no growth benefit to the birds compared to the STD diet. Birds fed the LP diet consumed approximately 10% more feed than HP birds to maintain a similar rate of BW gain ($P = 0.001$). Increased diet density had the potential to improve BW uniformity. The higher density HP/HE feed resulted in a BW CV of 13.7 compared to 15.1 for birds fed the lower density LP-LE diet. Impact of diets that elevated ME intake at the expense of CP were of interest. The HE-LP diet resulted in the highest overall ME intake/g feed (0.43/g) while providing average feed volume and measures of BW CV. However, when total intake of CP or ME per g of BW gain was measured, there were no differences among treatments. In this phase of growth, the degree of feed restriction limits lipid deposition, which may be masking the impact of unbalanced CP or ME intake.

Key Words: broiler breeders, CP, ME

M322 Population densities impact on feed intake and growth performance in Japanese quail. D. Cardoso-Jiménez[1], A. Z. M. Salem*[1,2], R. Rojo[1], S. R. Rebollar[1], and A. Perez-Cháves[1], [1]*Universidad Autónoma del Estadode México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, México*, [2]*University of Alexandria*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Two-hundred seventy-six Japanese quail (*Coturnix cournix japónica*) of 17 d of age were used to investigate the impact of population densities on quail feed intake and growth performance. A complete random design of 3 population densities (80 (PD80), 100 (PD100), and 120 (PD120) birds/m^2) of 4 repetitions were used during 17 d of the experiment in floor housing system of 4 pens for each population densities type. Dry matter intake (DMI), average daily gain (ADG), Feed conversion (FC) and mortality were evaluated. DMI was improved ($P < 0.05$) at PD120 than PD100 or PD80 (380, 313 and 310g DM/bird, respectively). No significant differences were observed among treatments in ADG, whereas the FC was significantly ($P < 0.05$) improved at PD80 compared with PD100 and PD120 (3.7, 4, 5.6, respectively). A similar mortality of 1% was observed at the 3 experimental treatments. Population densities may be a very important factor that could affect on quails growth performance. Data suggested that, population sizes at 80 birds/m2 was better than the other densities used

Key Words: Japanese quail, population density, growth performance

M323 Effects of dietary energy and broiler breeder hen energetic efficiency on egg production and fertility. T. G. V. Moraes*, M. J. Zuidhof, A. Pishnamazi, and R. A. Renema, *University of Alberta*, *Edmonton, Alberta, Canada*.

The effects of dietary energy and broiler breeder hen efficiency on production traits and duration of fertility were examined. At 21 wk, 192 Ross 708 pullets were individually caged in 1 of 6 environment chambers, and photostimulated at 23 wk. Birds were fed either a high energy (HE; 2900 kcal/kg) or low energy (LE; 2700 kcal/kg) diet. At 41 wk of age, individual energetic efficiency was determined through calculation of residual MEm (RMEm), which was the difference between observed and predicted maintenance requirements relative to ME intake. The highest and lowest efficiency hens (n = 32/group) were inseminated on 2 consecutive days. Eggs were collected for 21 d to measure duration of fertility. Results were analyzed with the MIXED procedure of SAS. Efficient hens were 266 g heavier than inefficient hens (P<0.0001), which did not affect egg size. Though egg numbers were similar, efficient hens produced 1.52 g/d more egg mass than inefficient hens ($P = 0.025$). At dissection (46 wk of age), inefficient hens had less breast muscle (19.8%) than efficient hens (20.8%), but neither % fatpad nor fertility were affected by hen efficiency. Egg weight in the LE treatment was 0.9 g more than HE eggs ($P = 0.056$), likely a result of 0.91 g/d higher CP intake with LE feed ($P = 0.13$). Duration of fertility of hens on the LE diet was 12.8 d compared to 11.8 d in HE treatment ($P = 0.034$). Hatch of fertile was similar among all treatment groups (mean=92.7 ± 1.5%). Breast muscle was larger in LE hens (20.7%) vs. HE hens (19.9%) and fatpad was 0.41% lower ($P = 0.0004$). These results suggest that the higher ME:CP ratio may reduce fertility due to lower CP intake.

Key Words: broiler breeder efficiency, metabolizable energy, fertility

M324 Growth performance of Pearl Grey guinea fowl subjected to varying floor densities from hatch to fourteen weeks of age. S. Nahashon*, J. Tyus, and D. Wright, *Tennessee State University*, *Nashville*.

Little is known of the required floor density for optimum performance of the Pearl Grey guinea fowl. The objective of this study was to assess the effect of varying floor densities on growth performance of the Pearl Grey guinea fowl. In 3 replicates, 786 1-d-old French guinea keets were weighed individually and randomly assigned to floor pens covered with pine wood shavings at 80, 69, 60 and 53 birds/pen, equivalent to densities of 18, 15.6, 13.6, and 12 birds/m^2, respectively. Birds in these floor densities were allowed feeder space of 2.3, 2.7, 3.1, and 3.5 cm/bird, respectively, and water space of 1.2, 1.4, 1.6, and 1.8 cm/bird, respectively. All birds received 23 h and 12 h lighting regimen at 0–8 and 9–14 weeks of age (WOA) and were fed diets comprising 3,000 and 3,100 kcal of ME/kg of diet at 0–5 and 6–8 WOA, respectively, and 24% CP. The birds were fed diets comprising 3,100 kcal ME/kg of diet and 18% CP at 9–14 WOA. Feed and water were provided for ad libitum consumption. Body weight and feed consumption (FC) were measured weekly. Overall body weight gains (BWG) were higher ($P < 0.05$) and feed conversion ratios (FCR) were significantly lower in birds reared on floor density of 18 birds/m2 when compared with birds on floor densities of 12, 13.6 and 15.6 birds/m^2 at 0–8 WOA. However at 9–14 WOA, birds in floor densities of 12 birds/m2 exhibited higher BWG and feed consumption and significantly lower FCR ($P < 0.05$) than those reared on 13.6, 15.6 and 18 birds/m2. Therefore, pearl gray guinea fowl seem to exhibit superior performance when reared at floor densities of 18 birds/m^2 at 0–8 WOA and 12 birds/m2 at 9–14 WOA.

Key Words: Pearl Grey guinea fowl, floor density, growth performance

M325 Feedlot performance and carcass traits of hairsheep lambs treated with a β-adrenergic agonist during summer. J. V. Velázquez-Morales, F. D. Álvarez-Valenzuela, N. G. Torrentera-Olivera, J. Rodríguez-García, U. Macías-Cruz, A. Correa-Calderón, and L. Avendaño-Reyes*, *Instituto de Ciencias Agricolas, Universidad Autonoma de Baja California*, *Ejido Nuevo Leon, Valle de Mexicali, Baja California, Mexico*.

The objective of this study was to determine the effect of feeding the β-agonist zilpaterol hydrochloride to female lambs on growth traits and carcass characteristics during hot ambient temperatures. Twenty female lambs from hairsheep crossbreeds with an average initial BW of 32.2 ± 0.58 kg were used in a 33 d feeding study. The lambs were blocked by initial BW and assigned individually to 20 pens in a closed calf rearing unit provided with fans during summer. Data were analyzed under a completely randomized block design. Treatments were: 1) Control (C: no β-agonist in the diet), comprising a formulation of wheat grain, molasses, alfalfa hay, soybean meal, wheat straw, and a mineral supplement; and 2) a treated group supplemented (as fed basis) with 10 mg of zilpaterol hydrochloride (ZH; Zilmax, Intervet, Mexico City, Mexico) per head per day. The ZH feed additive was mixed into 100 gr of wheat grain and was offered daily in the morning before offering the finishing diet. Climatic conditions during the study revealed a severe heat stress conditions, with an average ITH of 88.2 units during the study. Lambs fed ZH had similar ($P > 0.05$) feedlot performance (daily weight gain, final weight, fed intake, feed conversion, and gain:feed ratio) than control lambs. The β-agonist increased hot and chilled carcass weights, with carcasses from ZH lambs being 13% and 12% heavier ($P < 0.01$) than carcasses from C lambs respectively. Dressing percentage was higher in ZH lambs (53.8%; $P < 0.01$) than in C lambs (46%). The rib-eye area was larger ($P < 0.05$) in ZH lambs (18.9 cm2) than in C lambs (15.5 cm2), as well as carcass conformation (7.0 vs 6.0 units for ZH and C lambs, respectively). There was no difference ($P > 0.05$) in carcass length, fat thickness, kidney, pelvic and heart fat, and shear force between ZH and C lambs. Hide and head weights, as well as weight of several internal organs (heart, lungs, liver, kidneys, small intestine, and rumen, omasum and abomasum) did not differ between treatments ($P > 0.05$). Even though the severe hot ambient conditions observed during the study, some carcass traits were improved in hairsheep female lambs supplemented with zilpaterol hydrochloride.

Key Words: female lambs, zilpaterol hydrochloride, heat stress

M326 Genetic factors affecting survival rate and litter size of Pelibuey ewes under two times of weaning in northwestern Mexico. U. Macías-Cruz[1], F. D. Alvarez-Valenzuela[1], A. Correa-Calderón[1], L. Molina-Ramírez[2], and L. Avendaño-Reyes*[1], [1]*Instituto de Ciencias Agrícolas, Universidad Autónoma de Baja California*, *Ejido Nuevo León, Valle de Mexicali, Baja Cañifornia, México*, [2]*Centro de Bachillerato Tecnológico Agropecuario No. 41*, *Poblado Benito Juárez, Valle de Mexicali, Baja California, México*.

The aim of this study was to evaluate the effect of sire breed, type of birth and lambing year on some traits of Pelibuey ewe productivity in 2 times of weaning. As part of a hairsheep crossbreeding program between Pelibuey (Pb) ewes and Dorper (Dr), Katahdin (Ka) and Pb rams, data from 250 ewes lambed during 2003 and 2008 were used to characterize Pb ewe productivity with breeds specialized in mutton production. Response variables were litter size, and survival rate at 0 (lambing), 30, 60 and/or 90 d post-lambing per ewe lambed. Weaning time at 60 d occurred from 2003 to 2005, and weaning time at 90 d from 2005 to 2008. The information was divided based on weaning time, 60 or 90 d. Two models based on a factorial design, which included fixed effects of lambing year, type of birth (1, 2, or > 3) sire breed (3) and double interactions among them were performed. For 60 d weaning time, sire breed did not influence ($P > 0.05$) litter size or survival rate at lambing; but at 30 and 60 d post-lambing, survival rate was greater ($P < 0.01$) in litter of ewes mated by Ka sires (0.96 ± 0.05 and 0.95 ± 0.05) than those mated by Pb sires (0.78 ± 0.05 and 0.68 ± 0.06). Ewes with multiple lambing ($P < 0.05$) had higher litter size (3.20 ± 0.06, 2.44 ± 0.12 and 2.18 ± 0.14 lambs/ewe lambed at 0, 30 and 60 d, respectively) but lower survival rate (0.78 ± 0.05 and 0.70 ± 0.05 at 30 and 60 d, respectively) than those ewes with single or twin lambing during all pre-weaning period. For 90 d weaning time, there was higher ($P < 0.05$) litter size at 30, 60 and 90 d in ewes with multiple lambing and mated by Dr or Ka sires than all other ewes. At 30, 60 and 90 d, ewes with multiple lambing had the lowest ($P < 0.05$) survival rate than those of single or twin lambing. Survival rates at weaning time (60 and 90 d) were affected ($P < 0.05$) by lambing year in both models. Collectively, these results suggest that survival rate and litter size of Pb ewes could be improved through crossbreeding schemes including Dr or Ka. Type of lambing had a marked influence on survival rate and litter size.

Key Words: hair sheep, ewe lambed, weaning

M327 Artificial insemination in reindeer using frozen-thawed semen. M. P. Shipka*[1], J. E. Rowell[1], and S. Bychawski[2], [1]*University of Alaska Fairbanks*, *Fairbanks,* [2]*Optimum Genetics*, *Regina, Saskatchewan, Canada*.

Traditional practices of extensive reindeer ranching on the Seward Peninsula, Alaska, are being modified to accommodate a rapidly changing environment. Holding reindeer in large enclosures during vulnerable times of the year (breeding and calving season) is a practice being tried by some herders. Enclosing reindeer, even temporarily, requires the adoption of management strategies more typical of traditional agriculture. However, such strategies need to be modified to cope with the extreme logistics imposed by an arctic environment. Artificial insemination has been proposed as an alternative to maintaining rutting bulls in enclosures. Our objective was to evaluate the practicality of using AI in the Alaska reindeer industry. Semen was collected from a 15 mo-old reindeer bull in Saskatchewan, Canada, processed to a final dilution of 3.5×10^7 sperm per 0.5cc straw, frozen and shipped to Alaska. Sperm motility was 70% (fresh) and 45% (thawed) with 68% normal sperm. We applied a white-tailed deer AI protocol to 8 nulliparous, 2.5 yr-old captive reindeer at the UAF Agricultural and Forestry Experiment Station. The female reindeer were synchronized with CIDR-b, modified to fit the smaller reindeer vagina, using a 2 CIDR, 14 d schedule. At removal of the second CIDR, the females received 200 IU PMSG I.M. (either PG 600, n = 4; or PMSG, Sigma Chemicals, n = 4). At the time of breeding, one female's vagina was too small to accommodate the speculum and she was dropped from the study. The remaining 7 females exhibited signs of estrus (copious, clear mucus) at insemination. Intracervical insemination took place 55 h after CIDR removal. PSPB assay of serum collected 11 wks post-insemination indicated 1 pregnant female, 1 female possibly undergoing pregnancy loss and 5 open females. Options for increasing pregnancy rate within the context of the logistics imposed by an arctic reindeer industry require further research.

Key Words: reindeer, artificial insemination

M328 Constant long artificial days increase milk production in Alpine goats in northern Mexico. R. Rodríguez-Martínez*[1], C. A. Meza-Herrera[2], M. A. De Santiago-Miramontes[1], M. Mellado[3], and F. G. Véliz[1], [1]*Universidad Autónoma Agraria Antonio Narro*, *Torreón, Coahuila, Mexico*, [2]*Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas*, *Bermejillo, Durango, México*, [3]*Universidad Autónoma Agraria Antonio Narro*, *Buenavista, Saltillo, Coahuila*.

The aim of this study was to determine if the use of an artificial long-day photoperiod scheme during winter and spring improves milk production in Alpine goat raised in Northern Mexico. Alpine multiparous goats (n = 40) were randomly assigned to one of 2 experimental groups: Control Group (CG; n = 21), exposed to naturals photoperiod variations of the region during the whole experimental period (10 h and 19 min in the winter solstice), and the Experimental Group (EG; n = 19), subject, from December 28th to may 12th, to a constant long day photic treatment (16 h light/8 h dark). Both groups were fed 300 g concentrate/animal/day, and alfalfa hay ad libitum. From the beginning of the trial (d 0 = 13 ± 0.6 postpartum days) up to d 14 (weaning of kids). Milk yield was daily recorded and data were analyzed by means of 2 factors ANOVA (time and treatment) followed by Student's *t*-test, to find differences between experimental groups. Milk yield did not differ ($P > 0.05$) between groups. However, from 28 d to 112 d, 20% increase of milk yield was observed in the EG-group (3.3 ± 0.1 vs. 2.6 ± 0.04 L/day/animal EG vs. CG; $P < 0.02$). These results show that, during winter and at the beginning of spring, exposure to a long day artificial photoperiod scheme induced an increase in milk production in Alpine goats raised in northern Mexico. Further studies are required to evaluate the effect of a long-day photoperiodic scheme upon milk production during the prepartum period as well as how this photoperiodic treatment could affect the hormonal reproductive status in goats.

Key Words: milk yield, milk composition, photoperiod

M329 Blood selenium levels in mule deer in eastern Washington. E. López-Pérez*[1], L. A Shipley[2], and W. Myers[3], [1]*Universidad Autónoma Chapingo*, *México*, [2]*Washington State University, Pullman,* [3]*Washington Department of Fish and Wildlife*.

Mule deer have been declining in the western United States over the last few decades, including eastern and north-central Washington. Because eastern Washington is naturally deficient in selenium (Se), Se deficiencies can affect the productivity of ungulates, and little is known about the natural concentration of Se in mule deer, we examined the range and spatial distribution of the concentration Se in mule deer across eastern Washington. We captured 115 female mule deer by net-gunning from a helicopter in 2002–2003 in 7 study areas ranging from shrub-steppe to montane coniferous forests. We collected 10 mL of whole blood from each animal by jugular venipuncture, and determined the concentration of Se in the blood using neutron activation. Individual blood Se concentration varied over 4 orders of magnitude, ranging from 0.000084 to 0.497 ppm. Study area means varied from a low of 0.04 ± 0.02 in 2 shrub steppe habitats to a high of 0.090 ± 0.02 and 0.125 ± 0.01 in 2 montane habitats ($F = 2.47$, $P < 0.01$, Table 1). Surprisingly, patterns of blood Se did not correspond with soil Se values, which are lower in the more northern and western montane habitats. These values are low when compared with livestock standards of >0.1 ppm which may indicate a potential for Se deficiency. On the other hand, mule deer, may have a lower Se requirement than do livestock and are adapted for soil and plant conditions in northeastern Washington.

Table 1. Blood selenium levels (ppm) in mule deer does from north central eastern Washington

Study areas	Habitat	Spring n	Spring blood Se content (ppm)	Winter n	Winter blood Se content (ppm)
Chelan	Montane forest	22	0.062±0.012	18	0.124±0.012
Flagstaff	Montane forest			5	0.076±0.028
Okanogan	Montane forest	5	0.094±0.023	4	0.088±0.025
Vulcan	Montane forest	9	0.060±0.006	7	0.060±0.012
Cofee pot	Shrub-steppe			12	0.048±0.015
Revere	Shrub-steppe			13	0.061±0.010
Colville	Shrub-steppe	6	0.047±0.021	17	0.060±0.012

Key Words: deer, selenium, blood

M330 Breeding performance of rams in two Wyoming producer flocks. B. M. Alexander*[1], N. Cockett[2], T. L. Hadfield[2], and G. E. Moss[1], [1]*University of Wyoming*, *Laramie,* [2]*Utah State University*, *Logan*.

Poor mating behavior results in increased ram costs, extended lambing seasons, and decreased genetic progress from sires with desired production traits. Producers recognize the importance of ram libido; however, time, labor, and facility constraints generally limit its routine evaluation. Although approximately 23% of all rams were predicted to exhibit poor-mating behaviors, breeding performance of individual rams in multi-sire flocks typical of Wyoming range operations has not been determined. Therefore, goals of the current experiment were to determine the incidence of low- and high sexually performing rams and numbers of lambs sired by each ram in 2 representative range flocks. All rams successfully passed breeding soundness evaluations conducted before the onset of the breeding season. Blood samples were collected from all rams, and approximately one-third of the lambs and their dams for paternal genotyping using microsatellite markers. Assuming each ram had equal opportunity to mate with ewes in estrus, number of lambs expected to be sired by each ram was established by calculating 99% confidence intervals for the mean in each flock. In flock one, sires (n = 24) for 290 lambs (80% of lamb samples) were successfully identified. Of those rams, 7 (29%) sired less than, 11(46%) equal to, and 6 (25%) sired more lambs than predicted (siring 6.9, 47.6, and 45.5% of the sampled lambs, respectively) based on the 99% confidence interval. In the second flock, sires (n = 13) for 170 lambs (85% of lamb samples) were successfully identified. Similar to flock one, 3 (23%) rams sired less than, 7 (54%) equal to, and 3 (23%) sired more lambs than predicted siring 8.2, 54.4, and 39.4% of the sampled lambs, respectively. These data emphasize the importance of identifying and eliminating poor-sexually performing rams to reduce sire costs. In addition, the identification and use of high-sexually performing rams with desired genetic traits is a requisite to the timely incorporation of those traits into a flock.

M331 Breaking resistance of lamb ears according to ear tag insertion position and sheep breed. G. Caja*[1], H. Xuriguera[2], M. A. Rojas-Olivares[1], S. González-Martín[2], A. A. K. Salama[1], S. Carné[1], and J. J. Ghirardi[1], [1]*Universitat Autònoma de Barcelona*, *Bellaterra, Barcelona, Spain*, [2]*Universitat de Barcelona*, *Barcelona, Spain*.

A total of 167 lamb ears tagged with official plastic ear tags were obtained after harvesting in a commercial slaughterhouse and used to study the resistance to breakage when submitted to tensile forces

under laboratory conditions. Ears were washed (cold and warm water) and classified according to breed (Lacaune, n = 26; Manchega, n = 45; Ripollesa, n = 60; other, n = 36), side (left, right), ear tag insertion position (distal, central, proximal) and preservation method (fresh, 1-7 d in a refrigerator, 2 to 4 wk in a freezer). Breaking force was measured by submitting the ears to a tensile test using a computer-controlled universal testing machine (PCM Mecmesin, Horsham, UK). Ears were locked to a fixed clamp at the insertion base and ear tags fixed to a mobile clamp to be tested by pulling the ear tag at a constant displacement rate (500 mm/min) until the ears broke. On average, ears measured 107 ± 1 mm long and 51 ± 0.4 mm wide, have ear tags adequately inserted (12% distal, 40% central and 24% proximal) and broke longitudinally at 191 ± 5 N (9.8 N = 1 kgf). No ear tags broke or opened during the test. Ear breaking force varied quadratically ($R^2 = 0.999$, $P < 0.001$) according to ear tag insertion position (distal, 93 ± 6; central, 188 ± 5; proximal, 251 ± 8 N) and by breed (Lacaune, 205 ± 11; Manchega, 193 ± 8; Ripollesa, 233 ± 8; other, 107 ± 6 N), but did not vary according to side or short-term preservation method ($P > 0.05$). Freezing reduced the force to break the ears ($P < 0.01$). In conclusion, ear tag position was a key factor for ear breakage. New ear tag design, taking into account ear resistance may improve sheep welfare and ear tag retention rate for long-term identification.

Key Words: identification, eartag, sheep

M332 Animal weight gain in a pastured hog production system. S. Pietrosemoli*[1,2], J. C. Guevara[2], J. Cardona[3], W. Maradiaga[3], A. Lobo[3], and J. T. Green[4,2], [1]*Animal Science Dept., North Carolina State University*, *Raleigh,* [2]*Alternative Swine Research and Extension Project*, *Raleigh, NC,* [3]*Universidad Nacional de Agricultura*, *Catacamas, Olancho, Honduras.*, [4]*Crop Science Dept., North Carolina State University*, *Raleigh.*

At the Center for Environmental Farming Systems (CEFS) located in Goldsboro NC, 60 crossbred (Yorkshire, Landrace, Hamsphire and Duroc) commercial hogs (35.7 ± 2.1 kg and 125.7 ± 2.3 kg initial and final live weight, respectively) were used in a 98-d trial (May–August 2009) to evaluate the effect of stocking rate (SR; 37, 74, 111, and 148 heads/ha) and sexual condition (SC; castrated male [CM] or female [F]) on average daily weight gain (ADG). Animals were managed under a continuous grazing system on bermudagrass (*Cynodon dactylon*) plots sized to match the SR, and had ad libitum access to a concentrate feed (16% CP). The average pig concentrate intake (ACI) was estimated for each plot. Five hogs were allotted to each one of 12 plots, but data from only 4 (2 CM and 2 F) animals were included in the statistical analysis. The experimental design was a randomized complete block, with 4 × 2 factorial arrangement of treatments and 3 field replicates. ANCOVA was performed using the PROC GLM procedure of SAS, v. 9.1 with initial live weight as a covariate. Differences were observed for ADG between replicates ($P = 0.0009$); SR ($P = 0.0566$) and SC ($P < 0.0001$). Animals in the lowest SR (37 heads/ha) had the lowest ADG (0.85 kg) whereas the other treatments were similar (0.94, 0.96 and 0.90 kg ADG, respectively, for 74, 111 and 148 heads/ha). ADG of CM was 17.9% higher than of F (0.99 vs 0.84 kg, respectively). ACI differed between replicates ($P = 0.0027$) and SR ($P = 0.0182$). The lowest intake was recorded for pigs in the lowest SR (37 heads/ha, 2.90 kg/head/d) compared with the other SR (2.96; 2.96; 2.94 kg/head/d, for 74, 111 and 148 heads/ha, respectively). Results indicated that performance of pasture-finishing pigs was influenced by SR and SC.

Key Words: outdoor swine, bermudagrass, weight gain

M333 Analysis of the effect of complexed trace minerals on the prevalence of lameness and severity of claw lesions in stall-housed sows. S. S. Anil*[1], L. Anil[2], J. Deen[1], S. K. Baidoo[2], M. E. Wilson[3], and C. Rapp[4], [1]*Veterinary Population Medicine, University of Minnesota*, *St Paul,* [2]*Southern Research and Outreach Center, University of Minnesota*, *Waseca,* [3]*Zinpro Corporation*, *Eden Prairie, MN*, [4]*Zinpro Performance Minerals*, *Boxmeer, the Netherlands*.

When considering the development of claw lesions, mineral nutrition is an important factor to examine. Trace minerals such as Cu, Zn and Mn are reported to be critical in the keratinization process. Both the quantity and form (organic or inorganic) determine the bioavailability of the trace minerals. The objective of the present study involving 229 sows was to evaluate the effect of supplementing complexed trace minerals on the prevalence of lameness and lesions in different claw areas (side wall, heel, including overgrown heel, sole, heel-sole junction, white line, and overgrown dew claw and toe) of stall-housed gestating sows. The sows were randomly allocated to 2 groups and fed either a control diet (ITM, inorganic sulfate minerals, n = 113; Zn–125 ppm, Mn–40 ppm and Cu–15 ppm) or a diet containing complexed trace minerals (CTM, n = 116) as a partial substitution of inorganic minerals Zn-50 ppm, Mn–20 ppm and Cu–10 ppm) fed at isolevels of total trace mineral supplementation. The lesions in different claw areas of these sows were scored by a trained person in one or 2 consecutive parities at mid-gestation. The total score for each claw area was obtained by adding the scores for that area in different claws. The sows were assessed for lameness while they were moved for lesion scoring. The scores for lesions in different claw areas among the sows fed ITM or CTM were compared using Kruskal-Wallis Test. The proportions of lame sows among the groups were compared using 2-sample proportion test. The results indicated that total claw lesion score and total lateral claw lesion score were lower ($P \leq 0.05$ for both) in the sows fed CTM. The total score for horizontal side wall cracks was higher ($P \leq 0.05$) for the sows fed CTM. The proportion of lame sows was lower ($P \leq 0.05$) in the sows fed CTM (34.5% vs. 51.0%). The results show a protective effect of complexed trace mineral supplementation on claw lesions and lameness in stall-housed sows.

Key Words: claw lesions, lameness, trace mineral supplementation

M334 Comparison of the production performance of group-housed sows receiving complexed trace minerals. S. S. Anil*[1], L. Anil[2], J. Deen[1], S. K. Baidoo[2], M. E. Wilson[3], and T. L. Ward[3], [1]*Veterinary Population Medicine, University of Minnesota*, *St Paul,* [2]*Southern Research and Outreach Center, University of Minnesota*, *Waseca,* [3]*Zinpro Corporation*, *Eden Prairie, MN*.

Trace minerals are important to maintain the high production performance of the modern sow. The bioavailability of trace minerals depends on both the quantity and form (organic or inorganic). The objective of the present study, involving 386 sows housed in group pens with electronic sow feeders was to compare the production performance of sows fed diets containing complexed trace minerals (CTM) with sows fed diets containing trace minerals in inorganic form (ITM). The CTM diet contained trace minerals as a partial substitution of inorganic minerals (Zn, 50 ppm, Mn, 20 ppm and Cu, 10 ppm) fed at isolevels of total trace mineral supplementation. The ITM diet contained inorganic sulfate minerals, Zn 125 ppm, Mn, 40 ppm and Cu, 15 ppm). The sows were allocated randomly to CTM (n = 197) and ITM (n = 189) diet groups. 1056 parity records (ITM, n = 527; CTM, n = 529) of these sows pertaining to 1, 2, 3 or 4 farrowings were obtained during the study period. Information on farrowing and weaning performances and lactation feed intake were collected from the PigCHAMP database of the research unit and sow cards, and compared using 2 sample *t*-test (SAS v. 9.1). Results indicated differences ($P < 0.05$ for all) between the sows fed ITM and CTM in terms of still born (1.3 in ITM vs. 1.1 in CTM), average piglet weight at weaning (14.0 in ITM vs. 14.3 lbs in CTM) and weight of the sow at weaning (543.4 in ITM vs. 531.6 lbs in CTM). The groups did not differ ($P > 0.05$) in terms of piglets born alive, mummies, average birth weight of pigs and average lactation feed intake.

Key Words: complexed trace minerals, production performance, sows

M335 Risk factors associated with frequency of abortion in swine farms. N. M. Rainho[1], M. Aparicio[1], M. A. de Andrés[1], J. Morales[1], R. Pallás[2], V. Rodríguez-Estévez[3], and C. Piñeiro*[1], [1]*PigCHAMP Pro Europa*, *Segovia, Spain*, [2]*Kubus, SA*, *Madrid, Spain*, [3]*Universidad de Córdoba*, *Spain*.

Current swine production is linked to a proper analysis and monitoring of results. Literature has described references for most of the reproductive factors, but interactions between them have not been studied in depth.

The objectives of the present study were to investigate the relationship between the relative frequency of abortion (percentage; AP) and number of parity (NP), weaning to first mating interval (WSI), number of services (NS), and day of week for service (DW). More than 870,000 mating records through 4 years (2005–2008) corresponding to about 80,000 sows in 161 farms from Spain, Portugal and Italy registered with PigCHAMP software were used. Each factor was categorized in different groups: NP in 1, 2, 3–6 and ≥ 7 parities; NS in first-serviced (FS), first re-serviced (FRS) and second-reserviced (SRS); WSI in ≤ 3, 4–7, 8–11 and ≥ 12 d; and DW in weekday and weekend. Data were analyzed using the MIXED procedure of SAS (v 9.00). Mean value of AP was 0.78 ± 0.03%. Among NP, mean AP in parities 1 and ≥ 7 was higher than those in parities 2 and 3–6 ($P < 0.001$), showing a quadratic effect that explains the higher risks in both gilts and old sows. A lineal effect was found for WSI, when AP in WSI ≤ 7 was lower than those of WSI ≥ 8 ($P < 0.001$). AP also depended on DW, and it was higher for matings during the weekend ($P < 0.001$). Finally mean AP for NS increased with the number of estrus repetition, showing 0.45, 2.87, 4.26% for FS, FRS, SRS respectively ($P < 0.001$). Some interactions between the main factors studied were found, being the most interesting one between WSI and DW: sows with ≤ 3 WSI showed no differences between DW; sows with normal WSI (4–7 d) showed a higher risk during weekends (0.63 vs 1.29%; $P < 0.001$); AP in later mated sows served 8–11 d post weaning was lower in matings during weekend (1.24 vs 0.75%; $P < 0.001$). These results add more information about the relative information of some classical factors as NP, NS or WSI, and show a new factor as it is DW.

Key Words: abortion risk factors, swine, abortion

M336 Analysis of the effect of high ambient temperature on growing pigs performance: A meta-analysis approach. D. Renaudeau* and J. L. Gourdine, *Institut National de la Recherche Agronomique, UR143*, *Petit-Bourg, French West Indies*.

The high ambient temperature has been recognized as the most important climatic factor influencing pig performance during summer heat waves in temperate climate and all the year in tropical climate. However, results from experiments dealing with the effects of high temperature on pig performance are remarkably variable. In the present work, a meta-analysis was carried out to analyze the results from different studies designed to evaluate the effect of elevated temperature on average daily feed intake (ADFI) and average daily gain (ADG) in growing finishing pigs. Data were extracted from 86 and 80 trials for ADFI and ADG, respectively, from studies published in scientific journals in PubMed, Science direct and proceedings of scientific meetings updated trough December 2009. Data on ADFI and ADG were analyzed with a linear mixed model that included the linear and the quadratic effects of temperature (T) and pig body weight (BW), the interaction between T and BW as covariates. The trial has been included as block random variable. The effects of housing conditions (n = 2; individual vs. group) and the year of publication of the trial (n = 3; 1970–1989, 1990–1999, and 2000–2009) were tested on the intercept and the linear slope of T. Results showed that high T had a curvilinear effect of ADFI and ADG and that this effect was highlighted in heavier pigs. Whatever the temperature level, the ADFI was lower when pigs were group-housed. The intercept and the slope for T were significantly affected by the year of the study publication. The effect of elevated T was greater in earlier works suggesting that modern genotypes could be more sensitive to heat stress than low growth potential pigs. In conclusion, results of this meta-analysis confirm that a large between-study variability exits for the effects of high T on pigs' performance. A part of this variability is explained by changes in pig BW and to a lesser extent by the year of the study publication.

Key Words: pig, heat stress, performance

M337 Weight gain of Duroc pigs managed in a Sudangrass (*Sorghum bicolor*) pasture. S. Pietrosemoli*[1,2], J. C. Guevara[2], A. Lobo[3], J. Cardona[3], W. Maradiaga[3], and J. T. Green[4,2], [1]*Animal Science Department, North Carolina State University*, *Raleigh,* [2]*Alternative Swine Research and Extension Project*, *Raleigh, NC,* [3]*Universidad Nacional de Agricultura*, *Catacamas, Olancho, Honduras.*, [4]*Crop Science Department, North Carolina State University*, *Raleigh.*

To reduce potential upload of soil nutrients in pastured swine systems and improve their spatial distribution, producers have the possibility to implement strategic movements of equipment. Therefore, the impact of either stationary (S) or mobile (M) shade and drinking structures on average daily weight gain (ADG) were investigated with female (F) or castrated male (CM) pigs. Mobile structures were moved on a weekly basis. Seventy-two Duroc pigs (31.9 ± 0.76 and 96.9 ± 1.69 kg initial and final live weight, respectively) were used in summer 2009 at the Center for Environmental Farming System (CEFS) in Goldsboro, NC. Twelve pigs were randomly assigned to each of 6 sudangrass paddocks (0.16 ha, 74 head/ha) and were managed under a continuous grazing system during 12 weeks. Pigs had ad libitum access to a concentrate feed (16% CP) and water. Individual pig concentrate intake (CI) was estimated from paddock average. Data from only 8 pigs (4 F and 4 CM) per paddock were included in the statistical analysis. The experimental design was a randomized complete block with a 2 × 2 factorial arrangement of treatments (S or M; F or CM) and 3 field replicates. ANOVA was performed using PROC GLM of SAS v 9.1. Initial weight (IW) was used as a covariate for ADG . Weekly movements of structures influenced CI ($P = 0.0572$) (2.37 vs 2.25 kg/head/d for S and M, respectively). Sexual condition ($P < 0.0001$) and IW affected ADG (0.71 vs 0.84 kg/day for F and CM, respectively). According to the results of this study, weekly movements of shade and drinking structures did not affect pig average daily weight gain.

Key Words: outdoor pigs, sudangrass, weight gain

M338 Heat challenge effect on peripheral blood mononuclear cells viability: comparison of a tropical and a temperate pig breed. J. C. Bambou, R. Grondin, J. L. Gourdine, and D. Renaudeau*, *Institut National de la Recherche Agronomique, UR143*, *Petit Bourg, French West Indies, France*.

Evidence was found that local Caribbean pigs (Creole) are better adapted to seasonal climatic changes of tropical climate than exotic breeds imported from Europe. We evaluated the effect of heat challenge on peripheral mononuclear blood cells (PBMC) isolated from Creole (CR) and Large White (LW) pigs, on cell viability, concanavalin A– induced proliferation and heat shock proteins (HSPs) mRNA expression. PBMC from Creole (CR) and LW growing pigs of 7 to 12 weeks of age were isolated, cultured for 9 h at 37°C, and thereafter subjected to one of the 3 trials. In trial 1, cells from 18 CR and 18 LW pigs were exposed to 42°C or 45°C for 2, 4, 6 and 9 h and cell viability was monitored using the trypan blue method. In trial 2, we evaluated mitogen–induced proliferation of PBMC from 5 CR and 5 LW pigs after for 2 and 9 h heat exposure at 45°C followed by 24 h-stimulation at 37°C with concanavalin A. The aim of trial 3 was to measure induction of HSP70.2 and HSP90 mRNA expression in PBMC from 5 CR and 5 LW pigs after a heat challenge at 45°C for 3, 6 and 9 h. Viability was affected by breed and temperature ($P < 0.01$) but no effect of breed × temperature or breed × exposure

time interactions was observed. The decrease in viability caused by heat challenge was greater for LW than for CR pigs. For mitogen-stimulated PBMC, incubation at 45°C reduced lymphoblastogenesis ($P < 0.001$). However, this reduction was not influenced by breed ($P > 0.05$). When compared with PBMC cultured at 37°C, the mRNA expression of HSP70.2 and HSP90 increased at 45°C. After 9 h exposure at 45°C, PBMC from CR pigs showed a decreased expression of HSP90 mRNA when compared with the LW pigs. In contrast, the temperature × breed interaction was not significant for HSP70 mRNA expression. In conclusion, breed differences in resistance to heat challenge at the whole organism scale is also reflected at the cellular level. Neither HSP70.2 nor HSP90 mRNA expression level could explain this effect.

Key Words: pig, breed, heat stress

M339 Manipulation of rumen fermentation and ecology of swamp buffalo by coconut oil and garlic powder supplementation. P Kongmun*[1,2], M Wanapat[1], and Z Yu[2], [1]*Khon Kaen University*, *Khon Kaen, Thailand, 40002*, [2]*The Ohio State University*.

This experiment was conducted to investigate the effect of coconut oil (CO) and garlic powder supplementation on digestibility of nutrients, ruminal fermentation, ecology, microorganisms and methanogen diversity. Four, 3-year old, rumen fistulated swamp buffalo bulls were randomly assigned in a 4 × 4 Latin square design to receive 4 dietary treatments; 7% CO, 7% CO with 50 g/d of garlic powder, 7% CO with 100 g/d of garlic powder and non-supplemented (control). During the experiment, concentrate was offered at 0.5% of BW while rice straw was given on ad libitum basis. It was found that supplementation of 7% CO had significantly influenced on total DM intake, OM, NDF and ADF digestibilities while supplementation of 7% CO with garlic powder (50 and 100 g/d) were not significantly different when compared with the control. Blood urea nitrogen was significantly higher in supplemented groups. Total VFA concentration, proportion of C2 and C2:C3 ratio was reduced by supplementation. Proportion of C3 was increased ($P < 0.05$) when supplemented with 7% CO and 7% CO with 100 g/d of garlic powder. Methane production was dramatically reduced ($P = 0.005$) in supplemented treatments and was 10% reduced in 7% CO supplementation. Amylolytic and proteolytic bacteria were increased ($P = 0.007$ and $P = 0.024$) while protozoal population by decreased 68 – 75% ($P < 0.01$) by supplementation. Total bacterial population was increased by supplementation while total fungi and total methanogens were not significantly different among treatments. Percentage of cellulolytic bacterial population was not different among treatments. However, dietary supplementations were reduced ($P < 0.001$) percentage of F. succinogenes population. However, methanogen diversity was not changed using PCR-DGGE as technique. Based on this study, supplementation with 7% CO plus 100 g/d of garlic powder could be efficiently utilized in the rumen and thus, could provide good fermentation end-products and improve rumen ecology for the host swamp buffaloes particularly in reducing 9% methane gas production without changing nutrient digestibilities.

Key Words: garlic powder, coconut oil, swamp buffalo

M340 Adding whole hops to high concentrate diets enhances *in vitro* ruminal fermentation. N. Narvaez*, Y. Wang, Z. Xu, and T. McAllister, *Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

To assess the potential of hops (*Humulus lupulus*) as an alternative to antimicrobials for improving ruminant production, whole hops (pelleted and ground) were included in batch culture in vitro ruminal incubations (500 mg substrate + 40 mL inoculum) of barley grain (Exp 1) and barley grain:barley silage-finishing diet (Exp 2). Hops were included at 0, 50, 100, 200 and 400 μg/mL in Exp. 1; in Exp. 2, at 0, 200, 400, 800, and 1600 μg/mL, with and without polyethylene glycol (PEG; 250 μg/mL). PEG was included to selectively deactivate condensed tannins (CT). In Exp. 1, ^{15}N-labeled $(NH_4)_2SO_4$ was used to measure microbial protein (MP) synthesis. Gas production and methane concentration were measured at 3, 6, 12, and 24 h in both Exps. Concentrations of VFA and ammonia (NH_3-N), starch disappearance and MP synthesis were determined at 3, 6, 12, and 24 h in Exp 1. Total VFA, NH_3-N and apparent DM disappearance (DMD) were analyzed after 48 h in Exp. 2. Adding PEG did not alter the in vitro rumen fermentation suggesting that hop CT were not responsible for altering microbial activity. With hops inclusion, gas production from barley grain was linearly increased ($P = 0.029$) but from finishing diet, it was linearly ($P < 0.001$) decreased. Apparent dry matter disappearance (DMD) from finishing diet and starch disappearance from barley grain increased linearly ($P < 0.001$) with increasing hops content. Hops linearly increased ($P < 0.001$) VFA production from the finishing diet but with barley grain, VFA were decreased by hops only at 100 μg/mL. The acetate:propionate ratio was decreased quadratically ($P < 0.001$; minimum at 800–1600 μg/mL) by hops added to finishing diet, but A:P was unaffected by hops during incubation with barley. Methane production from both diets was quadratically reduced ($P < 0.01$) by hops. These results suggest that including hops in high-grain diets for ruminants may have potential to improve feed efficiency, possibly by reducing enteric methane emissions.

Key Words: barley grain, ruminal methane, β-acids

M341 Effects of hops on in vitro ruminal fermentation of high forage diets. N. Narvaez*, Y. Wang, Z. Xu, and T. McAllister, *Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Hops (*Humulus lupulus)* exert selective antimicrobial effects against gram-positive bacteria and may have potential as an alternative to antimicrobials for growth promotion in livestock. The effects of whole hops on ruminal fermentation of mixed forage (MF; Exp 1) or a barley silage:barley grain-based backgrounding diet (BD; Exp 2) were assessed during 48 h incubations (n = 4). Hop pellets (var. Tea Maker) were included in cultures (500 mg substrate + 40 mL inoculum) at 0, 50, 100, 200 and 400 μg/mL in Exp. 1 and at 0, 200, 400, 800 and 1600 μg/mL in Exp. 2. In Exp. 1, microbial protein (MP) synthesis was determined using $^{15}(NH_4)_2SO_4$, enabling true DM disappearance (TDMD) to be estimated. In Exp. 2, vials were prepared with and without polyethylene glycol (PEG) to bind condensed tannins (CT) and indirectly assess their effects on ruminal fermentation. Lack of any effect of PEG on fermentation suggested that CT in hops do not influence ruminal fermentation. Including hops linearly decreased ($P < 0.001$) gas production from MF and BD. Whereas true DMD from MF was linearly increased ($P < 0.001$) by hops, apparent DMD from BD was linearly decreased ($P < 0.001$). In Exp. 1, a quadratic ($P < 0.001$) response of MP synthesis to hops was observed. With BD, total VFA content was linearly reduced ($P < 0.001$) by hops, but with MF, the response was quadratic ($P = 0.002$). The acetate:propionate ratio was linearly increased ($P < 0.001$) with MF but quadratically decreased ($P < 0.001$) with BD. Hops quadratically reduced ($P < 0.05$) methane emissions from MF and BD. Hops have the potential to decrease methane production and may improve fermentation efficiency in ruminants consuming forage-based diets.

Key Words: hops, methane, β-acid

M342 Microencapsulation strategies to protect plant extracts against heat process of manufacture diets. P. W. Cardozo*[1], D. Ribera[1], A. Viso[1], H. Mengel[2], and M. Coenen[3], [1]*Research and Development Department, Carotech Technologies S.A*, *Tarragona, Spain*, [2]*KoVet, Coordination Staff for Veterinary Clinical Studies, Faculty of Veterinary Medicine, University of Leipzig*, *Leipzig, Germany*, [3]*Institute Animal Nutrition, Nutrition Diseases and Dietetics, Faculty of Veterinary Medicine, University of Leipzig*, *Leipzig, Germany*.

The purpose of this study was to evaluate the thermo-stability of standard combination of cinnamaldehyde and garlic oil in a protection capsule

(WEC) versus without encapsulation (WOEC) and the possible consequences after pellet process. Raw materials were provided by Carotenoid Technologie S.A. (Carotech, Tarragona Spain). Treatments were mixed at the rate of 5 g/ kg of a typical dairy concentrate diet, and were pelleted for 2 min at 80°C. Samples of both groups were taken before and after the pelleting process and the recovery of active ingredients was analyzed by HPLC technique. As expected, before pelleting, the recovery concentration of active ingredients in both treatments was similar ($P > 0.05$; average of 2.15 mg cinnamaldehyde/ g of feed, and average of 0.35 mg garlic oil/ g of feed). However, pelleting process (2 min at 80°C) affected the stability of active ingredients of WOEC recovering only 79.93% of cinnamaldehyde and 69.70% of garlic oil ($P < 0.05$), respectively. In the case of the encapsulated product, both cinnamaldehyde (98.65%) and garlic oil (95.78%) were not affected by pellet process ($P > 0.05$). The results of this trial showed that the stability was significantly higher in WEC than WOEC. The potential contribution of this study is focused on the technology used in this trial that allowed incorporating 100% of active ingredients with a percentage of active compounds recovered of approximately 98% after pelleting process. Further studies are necessary to determine the effectiveness of these active ingredients encapsulated on in vivo rumen microbial fermentation and animal performance.

Key Words: plant extracts, encapsulation system, pellet process

M343 Encapsulated combination of cinnamaldehyde and garlic oil as rumen modifiers in early-lactating dairy cows. X. Guozhong[1], X. Junxin[1], P. W. Cardozo*[2], and D. Yingying[2], [1]*Institute of Shanghai Dairy Science*, *Shanghai, China*, [2]*Research and Development Department*, *Tarragona, Spain*.

Two hundred lactating cows (DIM <60 d) were used in a completely block design (15 d of adaptation and 60 d for sampling period) to evaluate the effects of encapsulated combination of 129 mg/cow/d of cinnamaldehyde and 21mg/animal/d of garlic oil (Next Enhance 300; NE 300). Results obtained during the first 15 d were considered as covariant in the model. Milk yield was recorded every 15 d. Milk samples were taken at 15, 30 and 60 d to determine milk protein, fat percentage as well as milk urea nitrogen (MUN) and somatic cell count (SCC). Differences were declared at $P < 0.05$. Animals fed NE 300 increased ($P < 0.05$) milk production (over 1.7 kg/d) compared with control (37.38 kg/d vs. 35.73 kg/d). There was no overall effect ($P > 0.05$) of feeding NE 300 in milk fat (average 3.32%) and protein (average 2.95%) contents compared with control. However, cows fed with NE 300 showed an important reduction ($P < 0.05$) in milk urea nitrogen (14.7 mg/ dL) and SCC (168 × 1000)/mL) compared with control (15.5 mg/dL, and 337 × 1000)/mL, respectively). This study shows that the inclusion of an encapsulated combination of cinnamaldehyde and garlic oils (Next Enhance 300) in the early-lactating dairy diet has potential to influence milk production and milk composition, especially reducing MUN when fed to dairy cows in early lactation. Further studies are necessary to confirm that this encapsulated combination can be as useful as modifiers of rumen fermentation lactating dairy cows.

Key Words: dairy cows, cinnamaldehyde, garlic oil

M344 Effect of chestnut tannins on rumen activity of dairy sheep grazing on pasture. A. Nudda*[1], G. Battacone[1], R. Boe[1], R. Rubattu[1], A. H. D. Francesconi[1], M. Decandia[2], and G. Pulina[1], [1]*Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*, [2]*Agricultural Research Agency of Sardinia - AGRIS Sardegna*, *Sassari, Italy*.

A 4-wk trial was conducted to investigate the effect of pasture supplementation with a concentrate (300 g/d; 87.1% DM; 29.4% NDF, 16.9% ADF, 17.6% CP, on a DM basis) containing 3 levels of commercial chestnut hydrolyzable tannin (0, 6 and 12%, on a DM basis; T0, T6, T12, respectively) on rumen activity of dairy ewes. Thirty-six 2- to 4-yr-old Sarda ewes (12 per experimental group), in mid lactation (90–120 DIM) and grazing on pasture of 70% *Medicago polymorpha* (27.5% DM; 44.3% NDF, 29.5% ADF, 18.3% CP, on a DM basis) and 30% of *Lolium rigidum* (39.6% DM; 58.3% NDF, 31.2% ADF, 9.4% CP, on a DM basis) were used. Rumen fluid samples were collected with a stomach tube 3 times (every 10 d) during the experimental period from 5 animals/group. Concentrate intake was measured daily. The pH, VFA (acetic, propionic and butyric acids), ammonia N (NH3-N) and the fatty acid profile of the rumen samples were determined. Data were analyzed by ANOVA including tannin level, sampling and their interaction. Concentrate intake of T6 and T12 were, respectively 10% and 25% lower than that of T0. Rumen pH was higher in T6 than in T0, being intermediate in T12. The T6 group contained the lowest content of acetic acid and the highest of butyric acid. Tannins also influenced the percentages of C18:2 n6 and C18:3 n3, which were lower in the control group, even if its C18:2 n6 content did not differ significantly from T6. The NH3-N tended to be reduced by the inclusion of tannin in the diet. These results suggest that the lack of effect of tannins on rumen activity in T12 was probably related to its lower intake of concentrate.

Research supported by the Ministero dell'Istruzione dell'Università e della Ricerca (Project PRIN 2008).

Key Words: dairy sheep, rumen activity, tannin

M345 Effect of the inclusion of treated apple waste on in vitro ruminal fermentation of alfalfa hay. Y. Castillo-Castillo[1], O. Ruiz-Barrera*[2], C. Arzola-Alvarez[2], C. Rodriguez-Muela[2], A. Elias-Iglesias[3], C. Angulo-Montoya[2], O. La O-Leon[3], and J. A. Ortega[2], [1]*Universidad Autónoma de Ciudad Juárez.*, *Nuevo Casas Grandes, Chih, México*, [2]*Universidad Autónoma de Chihuahua.*, *Chihuahua, Chih, México*, [3]*Instituto de Ciencia Animal.*, *La Habana, Cuba.*

Feed produced by solid-state fermentation (SSF) has been satisfactorily added to ruminant fibrous diets due to an improvement on the ruminal fermentation patterns, including dry matter digestibility. The objective of this work was to evaluate the effect of the addition of fermented apple waste (FAW) on ruminal pH, ammonia nitrogen ($N\text{-}NH_3$), volatile fatty acids concentration (VFA), in vitro dry matter digestibility (IVDMD), lactic acid content (LA), and microorganisms counting (yeast, total bacteria and protozoa) of good quality alfalfa hay incubated in an in vitro ruminal ecosystem. Four levels of FAW inclusions were evaluated (0, 0.25, 0.50 and 0.75 g DM replacing 1.5 g DM of alfalfa hay and incubated at several times of fermentation (0, 4, 8, 12 and 24 h.) using a completely at random experimental design with repeated measures in time. Results showed that yeast concentration in the ruminal ecosystem was greater in the treatments with FAW addition up to the 12 h of incubation (2.4×10^6, 1.7×10^6 and 3.2×10^6 CFU/mL $\log^{10}$) in relation to the control (1.2×10^6 CFU/mL $\log^{10}$) and 0.75 g FAW addition exhibited the greatest concentration ($P < 0.0001$). LA content also increased at 12 h of incubation in response to the addition of FAW ($P < 0.001$) (13.86, 16.84 and 14.57 µg/ml, respectively) in relation to the control (10.61 µg/ mL). However, other measured variables as ruminal pH, $N\text{-}NH_3$, VFA, IVDMD total bacteria and protozoa counting remained unaffected by the treatments. According to these results, we concluded that substitution of alfalfa hay by FAW incubated in an in vitro ruminal ecosystem during 24 h only modified positively the population of viable yeast and

AL content, with no effect on other fermentative and microbiological parameters of the ruminal environment.

Key Words: fermentation, apple, ruminants

M346 Effects of hops on rumen fermentation, growth, carcass traits and shedding of *Escherichia coli* by feedlot cattle. Y. Wang*[1], A. V. Chaves[1,2], F. L. Rigby[3], M. L. He[1], and T. A. McAllister[1], [1]*Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada*, [2]*The University of Sydney*, *Sydney, NSW, Australia*, [3]*Yakima*, *WA (deceased)*.

Hops (*Humulus lupulus*) have antimicrobial properties, which may have potential in livestock production. Experiments were conducted to evaluate the effects of hops on ruminal fermentation, fecal shedding of *Escherichia coli* and the growth of feedlot cattle. Sixty individually penned British × Charolais steers were randomly assigned to treatment for a 160-d feeding trial (55 d growing + 105 d transition/finishing) using barley grain:barley silage-based diets (n = 15). Hop cone pellets were added to the growing diet at levels of 0, 119, 238 and 476 mg/kg DM and to the finishing diet at 0, 238, 476 and 952 mg/kg DM. Fecal samples were collected every 28 d to assess the effects of hops on fecal shedding of *E. coli*. Feed deliveries were recorded daily and feed refusals were weighed weekly. The steers were weighed every 28 d and warm carcass weight, longissimus muscle area, marbling score and saleable meat yield were recorded at slaughter for each steer. Including hops in the diet did not affect ($P \geq 0.05$) growth (DMI, ADG or feed conversion efficiency) or carcass characteristics of steers, nor fecal shedding of *E. coli*. During both the growing and finishing periods, however, ADG was 6% improved ($P = 0.11$) with the highest levels of hops compared with the controls. In corresponding 24-h batch culture incubations of the 8 diets (n = 6), hops inclusion with the growing diet increased ($P \geq 0.001$) DM disappearance (IVDMD), gas production, and VFA accumulation, with linear increases ($P \geq 0.001$) of IVDMD and total VFA. The proportion of propionate in VFA was increased ($P < 0.001$) and acetate proportion and acetate:propionate ratio were decreased ($P < 0.001$). With the finishing diet, a linear increase ($P = 0.002$) in gas production was observed. However, these in vitro improvements were not reflected in improved growth or efficiency of feedlot cattle. Inclusion of higher levels of hops in the diet may be favorable for ruminant production.

Key Words: growth performance, rumen fermentation, *Humulus lupulus*

M347 Effect of phlorotannins from brown seaweed on ruminal bacteria. Y. Wang*, L. J. Yanke, Z. Xu, and T. A. McAllister, *Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada*.

Brown seaweed has been used as feed additive to mitigate *E. coli* O157:H7 in feedlot cattle, but its impact on rumen bacteria is not clear. The effects of phlorotannins (PT) isolated from the brown seaweed, *Ascophyllum nodosum*, on ruminal bacteria were investigated in pure culture studies. *Prevotella bryantii*, *Ruminobacter amylophilus*, *Selenomonas ruminantium* and *Streptococcus bovis* were cultured through 10 serial 24-h transfers in ruminal fluid medium containing 0 or 50 μg PT/mL. The 4 strains, each non-exposed or pre-exposed to PT, were then inoculated into media containing 0, 75, 150 or 300 μg PT/mL and 24-h growth curves were determined (n = 6). The ruminal cellulolytic bacteria (CB) *Ruminococcus flavefaciens*, *Fibrobacter succinogenes* and *Ruminococcus albus* were also pre-cultured through 10 serial 72-h transfers in ruminal fluid medium containing 0 or 12.5 μg PT/mL and then, for 72 h, on Whatman no. 54 filter paper as a sole carbohydrate source in medium containing 0, 25, 50 or 75 μg PT/mL for the determination of filter paper digestion (n = 4). The effects of PT on growth of non-cellulolytic bacteria (NCB) were species-dependent, and were also affected by their having been pre-exposed to PT or not. At 24 h of incubation, growth of all 4 NCB was inhibited ($P < 0.01$) by as little as 75 μg PT/mL irrespective of their having been pre-exposed. Pre-exposed *P. bryantii* exhibited greater ($P < 0.01$) growth at 24 h in 75 μg PT/mL medium than did its non-exposed counterpart. At PT concentration of 75 μg PT/mL, *Sel. ruminantium* and *P. bryantii* exhibited more growth ($P < 0.01$) between 16 and 24 h of incubation than did *Str. bovis* or *Rb. amylophilus*. Phlorotannins inhibited digestion of filter paper by all 3 CB, but *F. succinogenes* was less ($P < 0.05$) sensitive to PT than were *Rc. flavefaciens* or *Rc. albus*. Pre-exposure to PT did not affect filter paper digestion by the 3 CB. Phlorotannins from *A. nodosum* inhibit both NCB and CB, but CB exhibit greater sensitivity than NCB. Thus, PT could negatively affect fiber digestion if brown seaweed is fed to ruminants.

Key Words: phlorotannins, ruminal bacteria, pure culture

M348 Additives (sodium monensin, salinomycin, and virginiamycin) for Nellore bulls feedlot fed high concentrate finishing rations. C. Sitta*, F. A. P. Santos, G. B. Mourão, A. M. Pedroso, R. Carareto, J. R. R. Dórea, T. G. Neri, and D. A. Rodrigues, *University of Sao Paulo*, *Piracicaba, SP, Brazil*.

The aim of the present study was to compare the effect of different additives on the performance of Nellore bulls fed high concentrate rations. One hundred and 30 4 Nellore bulls with initial weight of 330 kg were tested in a 102 d finishing trial, of which 21 d comprised adaptation to the high concentrate diet. Animals were grouped according to initial live weight and allotted to 24 pens. The final diet contained 12% tifton hay, 78.1% finely ground corn, 6% sugar cane molasses, 1.4% urea, 2.5% mineral and vitamin premix and respective additives. Treatments consisted in: 1) Control (without additives); 2) Sodium monensin 30ppm; 3) Sodium monensin 20ppm + Virginiamycin 15ppm; 4) Sodium monensin 30ppm + Virginiamycin 15ppm; 5) Virginiamycin 17ppm; 6) Virginiamycin 15ppm + Salinomycin 13ppm. Data were analyzed with Proc. Mixed from SAS (1999), version 9.2 for Windows, and the pens were used as experimental units. Dry matter intake and daily weight gain were not affected by treatments ($P > 0.05$). Feed conversion (DMI/ADG) was lower for the treatments containing monensin (M20 + V15; M30 + V15) and salinomycin (S13 + V15), both in combination with virginiamycin. Diet net energy for gain was higher for the treatments with monensin, monensin with virginiamycin, virginiamycin and salinomycin with virginiamycin ($P < 0,05$). The combination of monensin 30 ppm and virginiamycin 15 ppm resulted in an increase in the energy density of the rations in comparison with the other treatments (Table 1).

Table 1. Dry matter intake (DMI), average daily gain (ADG), feed conversion (DMI/ADG) and net energy (NE) of finishing Nellore bulls fed different additives

	Control	M 30	M20 + V15	M30 + V15	V 17	S13 + V15	P-value

M349 In vitro effect of peppermint (*Mentha piperita*) essential oil and non-fiber carbohydrates on gas production parameters of alfalfa hay. M. Danesh Mesgaran*[1], E. Jani[2], A. Vakili[1], A. Solaimany[2], and H. Jahani-Azizabadi[1], [1]*Dept. Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran*, [2]*Islamic Azad University*, *Kashmar, Iran*.

The aim of this study was to evaluate the effect of peppermint essential oil (PE) and non-fiber carbohydrates (NFC) including sucrose (SUC) and starch (STA) on gas production parameters of alfalfa hay (AH). Treatments were AH, AH plus PE (40 and 80 µl/g DM), AH supplemented with SUC or STA at 60 and 90 mg/g DM plus PE (0.0, 40 and 80 µl/g DM). Approximately 0.3 g of each sample (n = 4) was placed into a 100 mL glass syringe containing 40 mL of buffered rumen fluid (buffer to rumen fluid was 2:1). Rumen fluid was obtained from 2 rumen cannulated sheep (body weight = 45.5 ± 2 kg) before the morning feeding and strained through 4 layers of cheesecloth. Animals were fed 1.5 kg DM alfalfa hay and 0.4 kg DM concentrate (165 g CP/ kg DM) per head/ day. Syringes were incubated at 39°C and the volume of gas produced were recorded at 2, 4, 8, 12, 24, 36, 48, 72 and 96 h. Data were fitted to an exponential equation of $P = b\ (1\text{-}e^{-ct})$, where b is the volume of gas produced, c is the fractional rate constant of gas production (/h), t is the incubation time (h) and P is the volume of gas produced at time t. The gas production parameters of the supplemented samples were compared with AH as control using Dunnett's test at $P < 0.05$. The parameters for AH were b = 72 mL and c = 0.07/h. Supplementation of AH with PE reduced the volume of gas produced, however, peppermint essential oil caused to reduce ($P < 0.05$) the volume of gas produced from the samples of AH supplemented with the NFC sources. The rate constant of gas produced (c) from AH was significantly ($P < 0.05$) increased by the adding of the NFC and PE (except PE as 80 µL/g DM, which had no significant effect on c). The fractional rate constant was significantly increased when PE as 40 µL/g DM was added to the AH supplemented with the SUC and STA (0.13 and 0.10, respectively). However, at 80 µL/g DM of PE, c was significantly decreased ($P < 0.05$) for those treatments (0.06 and 0.05, respectively). It was concluded that PE at the both applied rates had a potential to alter the fermentability of AH and AH supplemented with the NFC sources.

Key Words: essential oil, gas production, peppermint

M350 Effect of fennel (*Foeniculume vulgare*) essential oil on in vitro gas production parameters of alfalfa hay supplemented with sucrose or starch. M. Danesh Mesgaran*[1], E. Jani[2], A. Vakili[1], H. Jahani-Azizabadi[1], and A. Solaimany[2], [1]*Dept. Animal Science, Ferdowsi University of Mashhad, Mashhad, Iran*, [2]*Islamic Azad University*, *Kashmar, Iran*.

The aim of the present study was to evaluate the effect of fennel essential oil (FE) on gas production parameters of alfalfa hay (AH) and AH supplemented with sucrose (SUC) or starch (STA). Treatments were AH, AH plus FE (40 and 80 µL/g DM), AH supplemented with SUC or STA at 60 and 90 mg/g DM plus FE (0.0, 40 and 80 µL/g DM). Approximately 0.3 g of each sample were placed in a 100 mL glass syringe containing 40 mL of buffered rumen fluid as 2: 1 (n = 4). Rumen fluid was obtained from 2 rumen canullated sheep (body weight = 45.5 ± 2 kg) before the morning feeding and immediately strained through 4 layers of cheesecloth. Animals were fed 1.5 kg DM alfalfa hay and 0.4 kg DM concentrate (165 g CP/ kg DM) per head per day. Syringes were incubated at 39°C and the volume of gas produced were recorded at 2, 4, 8, 12, 24, 36, 48, 72 and 96 h. Statistical analysis was conducted using SAS (1999) procedure. The gas production data were fitted to an exponential equation of $P = b(1\text{-}e^{-ct})$, where b is the volume of gas produced, c is the fractional rate constant of gas production (/h), t is the incubation time (h) and P is the volume of gas produced at time t. The gas production parameters of the supplemented samples were compared with AH as control using Dunnett's test at $P < 0.05$. Supplementation of AH with FE, at both rates applied, reduced the volume of gas produced ($P < 0.05$; 72, 52 and 54 mL/0.3 g DM, respectively), but increased the fractional rate constant of gas production ($P < 0.05$; 0.07, 0.12 and 0.10, respectively). In addition, FE particularly as 40 µL/g DM, reduced ($P < 0.05$) the volume of gas produced from the AH samples supplemented with both SUC and STA. The rate constant of gas produced (c) from AH supplemented with SUC and STA at both levels (0.09 and 0.08/h, respectively) was increased ($P < 0.05$) by the adding of FE as 40 and 80 µL/g DM (0.13 and 0.09/h, respectively). It might be concluded that FE, as 40 or 80 µL/g, caused an alteration in the fermentation potential of AH alone or supplemented with the NFC sources used.

Key Words: essential oil, gas production, fennel

M351 Effect of individual and mixed natural tree extracts on in vitro ruminal fermentation profiles in sheep. F. S. Jiménez-Peralta[1], A. Z. M. Salem*1,4, H. Ammar[2], M. Ronquio[3], and P. B. Albarrán[1], [1]*Autónoma del Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [2]*Ecole Supérieure d'Agriculture de Mograne*, *Zaghouan, 1121 Mograne, Tunisia*, [3]*Universidad Autónoma del Estado de México*, *Facultad de veterinaria, Toluca, Mexico*, [4]*Alexandria University*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Extracts of 2 tree leaves species [*Salix babilónica* (SB) and *Leucaena leucocephala* (LL)] and their mixture (SBLL, 1:1, v/v) rich in secondary metabolites (ESM, 10 g DM/80 mL of solvent), were in vitro evaluated on ruminal fermentation pattern in 4 levels of 0, 0.6, 1.2, and 1.8 mL extract/g DM of TMR (50:50 forage:concentrate diet). Animals used for the extraction of rumen liquid (RL) for the in vitro incubations were allocated into 2 experimental groups (8 animals/group): control (CG) and treated (TG) group. Animals of CG were fed daily on TMR, while those of TG were fed on the same TMR and drenched a daily oral dose of SBLL (30mL/animal) for 60 d. Concentrations of secondary metabolites (SM) in terms of total phenolics (TP), saponins (SAP) and aqueous fraction (AF, lectins, polypeptides and starch) were examined in each tree extract and gas production was recorded at different incubation times (2, 4, 6, 8, 10, 12, 24, 48 and 72 h) of TMR with different extracts levels. Short chain fatty acids (SCFA), in vitro organic matter degradability (IVD) and metabolizable energy (ME)) were estimated. As compared with SB, extracts of LL had higher TP, SAP and AF (i.e., 24, 14 and 116 versus 15, 6 and 74 g/kg DM, respectively). For both animal groups, increasing the extracts dose until 1.8mL/g DM improved ($P < 0.05$) the ruminal fermentation activities of TMR with increasing the extracts dose until 1.8mL/g DM in ether TG or CG, probably due to a higher extracts -soluble sugars. However, higher fermentation activities were observed in SB than LL and SBLL extracts. Ruminal fermentative activities of TMR were reduced by more than 50% in TG versus to CG during all the incubation times, except the first 2 h. In conclusion, administration of SBLL during 60 d to animals did not enhance the ruminal fermentation activities of TMR in sheep. Individual extracts-rich in secondary metabolites at 1.8mL/g DM, in particular SB extracts, had the most potential on ruminal microorganism's activities and may serve as an alternate to antibiotics and ionophores as a growth promoter of weaned lambs.

Key Words: extracts, secondary metabolites, in vitro fermentation, sheep

M352 Medium-term orally administration of extracts impacts on in vitro rumen fermentative activity of some tree leaves in sheep. A. Z. M. Salem*[1,4], F. S. Jiménez-Peralta[1], H. Ammar[2], R. R. Rojo[1], L. M. Camacho[3], and D. Cardoso-Jiménez[1], [1]*Universidad Autónoma del Estado de México, Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [2]*Ecole Supérieure d'Agriculture de Mograne*, *Zaghouan, 1121 Mograne, Tunisia*, [3]*Universidad Autónoma de Guerrero*, *Facultad de veterinaria, México*, [4]*University of Alexandria*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Four tree leaves species (i.e., *Celtis pallid*, *Ficus trigonata*, *Fraxinus excelsior* and *Prunus domestica*) collected during the dry season were used to explore medium-term effects of *Salix babilónica* and *Leucaena leucocephala* extract (SBLL, 1:1 v/v) rich in secondary compounds (ESC, 10g dry leaves/80 mL of solvent) on fermentative activity in the rumen of sheep. Sixteen crossbreed male (Katahdin × Pelibuey) sheep were fed on a TMR (18%CP) and used as a source of rumen liquor. Eight animals were fed the TMR with a daily oral dose of 30mL/animals/d of SBLL for 60 d and used as the treated group (TG), whereas the other sheep were not received extract and always fed the same TMR and used as the control group (CG). The objective was to investigate if adaptation to ESC at the rumen level may develop in response to regular consumption of secondary compounds (SC), resulting in an enhanced ability to digest tree leaves. Gas production was recorded at 2, 4, 6, 8, 10, 12, 24, 48 and 72 h after incubation of leaves samples. Differences in the fermentative activity (short chain fatty acids (SCFA), in vitro organic matter degradability (IVD) and metabolizable energy (ME)) were examined in batch cultures inoculated with rumen fluid obtained on d 60 from both groups of sheep. Gas production and other fermentative parameters (i.e., SCFA, IVD and ME) of the 4 leaves species were reduced by more than 50% in TG versus CG during the all incubation times, except the first 2 h. The magnitude of this effect may be due to direct negative impact of SC in the orally dose on ruminal microorganisms activities or the indirect impacts of SC on saliva production composition. Highest fermentation activities ($P < 0.05$) were in *P. domestica* while the lowest values ($P < 0.05$) were in *F. excelsior*. This effect may be due to the different SC concentrations as well as ADF and NDF composition in leaves samples. In conclusion, administrations of SBLL to animals do not enhance the ruminal fermentation activities and gas production kinetics of tree leaves species. *P. domestica* demonstrated a higher ruminal digestion than other tree species.

Key Words: extracts, in vitro fermentation, sheep

M353 Effect of cumin essential oil on in vitro gas production parameters of alfalfa hay, barley grain and sugar beet pulp. M. Sadjadian, M. Danesh*, A. R. Vakili, H. Jahani, and J. Amini, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of the present study was to evaluate the effect of cumin essential oil (CEO) on in vitro gas production parameters of alfalfa hay (AH), barley grain (BG) or sugar beet pulp (BP). Samples of AH, BG, and BP were provided as untreated or treated with CEO (400 mL/g DM). In vitro incubations were carried out using 0.3 g of each sample (4 replicates) which was placed in a 100 mL glass syringe containing 40 mL buffered rumen fluid (ratio of buffer to rumen fluid was 2:1). Rumen fluid was obtained from 2 ruminally cannulated sheep (body weight = 45.5 ± 2 kg), before the morning feeding, and immediately strained through 4 layers of cheesecloth. Animals were fed 1.5 kg DM alfalfa hay and 0.4 kg DM concentrate (165 g CP/ kg DM) per head per day. Syringes were then incubated at 38.6°C and the volume of gas produced was determined at 2, 4, 8, 12, 24, 36, 48, 72 and 96 h after the incubation. The gas production data were fitted using an exponential equation of $P = b \times (1–e^{-ct})$, where b is the volume of gas produced, c is the fractional rate constant of gas production (/h), t is the incubation time (h) and P is the volume of gas produced at time t. Statistical analysis was conducted using SAS (1999) software. Results demonstrated that the gas production parameters of the feed samples (Table 1) were significantly different ($P < 0.05$). In addition, results of the present study indicate that the gas production parameters of the feed samples were significantly altered when CEO was included in the medium. Cumin essential oil caused a significant ($P < 0.05$) decrease of c parameter of BG and BP. While, when cumin was added to the AH and BP samples, the b parameter was decreased (Table 1).

Table 1. Gas production parameters of alfalfa hay, barley grain and sugar beet pulp as untreated or treated with cumin essential oil as 400 mL/g DM

	Treatments						
Gas production parameters	AH	BG	BP	AH+CEO	BG+CEO	BP+CEO	SEM
b (ml/0.3 g)	49.6^{d}	98.7^{b}	84.0^{c}	20.4^{f}	105.6^{a}	44.9^{e}	2.34
c (/h)	0.06^{b}	0.04^{c}	0.09^{a}	0.06^{b}	0.02^{d}	0.06^{b}	0.004

M354 Influence of two browse extracts-rich secondary compounds and their mixture on lamb feed intake and growth performance. A. Z. M. Salem*1,4, H. P. Mejia[1], H. Ammar[2], M. Ronquio[3], J. L. Tinoco[1], R. Rojo[1], and A. M. Garcia[1], [1]*Universidad Autónoma del Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [2]*Ecole Supérieure d'Agriculture de Mograne*, *Zaghouan, 1121 Mograne, Tunisia*, [3]*Universidad Autónoma del Estado de México*, *Departmento de Nutricion Animal, Facultad de Veterinaria, Toluca, Mexico*, [4]*University of Alexandria*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Thirty-two crossbreed male (Katahdin × Pelibuey) lambs (3–4 mo old, average LW 24 ± 0.3kg) were used to study effects of daily oral administration of the extracts-rich secondary compounds (ESC, 10g dry leaves/80 mL of solvent) of either 2 browse species namely *Salix babilónica* (SB) and *Leucaena leucocephala* (LL) or their mixtures (SBLL) during 60 d lamb feed intake and growth performance. Lambs were randomly assigned into 4 groups (8 animals per group) in a factorial design: received no ESC (Control –CTR), and the other 3 groups were submitted to a treatment with ESC (30mL) of either SB, LL or SBLL (1:1 v/v) during the experimental period. Feed intake (FE) was recorded daily while the body weight of lambs was recorded every 20 d among the experimental period: 20 (P1), 40 (P2), and 60 d (P3). Animals of different groups were fed ad libitum on a total mixed ration (18% CP) that was formulated to meet all nutrient requirements for finishing lambs. Oral administration of ESC improved average daily gain (ADG), feed conversion (FC) and economic efficiency (EE) during all the experimental periods, without changing in FE. A gradually improvement in growth performance (ADG and FC) of ESC treated lambs was observed from P1 to P3, versus CTR lambs. Generally, growth performance of SB and LL lambs was better ($P < 0.05$) than SBLL lambs. The cost of one kg DG (i.e., EE) was reduced ($P < 0.05$) by 20.2, 13.3 and 12.88% with ESC administration of SB, LL and SBLL, respectively. This effect may be due to an adaptation of ruminal microorganisms to plant secondary compounds in extracts. Results of our present study revealed that daily administration of ESC, particularly of SB, improved lamb performance rather than LL or SBLL.

Key Words: extracts and secondary compounds, growth performance and feed intake, lambs

M355 Effect of polyclonal antibody preparation on ruminal microbial diversity population in cattle fed three different energetic sources. W. Otero[1], C. Marino*[2], M. Stradiotto[4], C. Barreto[3], V. Pellizari[3], M. Arrigoni[2], and P. Rodrigues[1], [1]*University of Sao Paulo, FMVZ*, *Pirassununga, Brazil*, [2]*University of Sao Paulo State, FMVZ*, *Botucatu, Brazil*, [3]*University of Sao Paulo, ICB II*, *Sao Paulo, Brazil*, [4]*University of Sao Paulo, FZEA*, *Pirassununga, Brazil*.

Nine ruminally fistulated cows were used to test an avian-derived polyclonal antibody preparation (PAP) against specific ruminal bacteria *Streptococcus bovis*, *Fusobacterium necrophorum*, *Clostridium aminophilum*, *Peptostreptococcus anacrobius* and *Clostridium sticklandii*. The experimental design was a 3 × 3 Latin square replicated 3 times with a factorial arrangement of treatments 3 × 3 regarding 2 rumen modifiers, monensin (MON) and PAP plus control group and 3 energy sources. The energetic sources utilized were dry-grounded corn grain (CG), high moisture corn silage (HMCS) and citrus pulp (CiPu). The ruminal content was collected in the d 21 of each trial at 4 h after feeding for the analysis of microbial ruminal diversity by the denaturing gradient gel electrophoresis. Data were submitted to variance analysis by GLM procedure, which separated the effects of interaction between feed additive and energy source, effect of feed additive, effect of energy source as well as effects of period and animal inside the square. Mean effects were separated by Duncan test. Differences were declared at $P < 0.05$. It was observed energetic source effect ($P = 0.0470$) for number of bands amplified in DGGE for *Archaea* community. Animals receiving CiPu demonstrated an increase of 1.56 band (52%) compared with animals receiving CG. Those fed HMCS did not differ between the other 2 groups. For the total sum of bands amplified in DGGE, energetic source effect was observed. The group fed HMCS had more amplified bands than the group fed CG. The group fed CiPu did not differ from the other 2 groups. In general lines, in the present experiment, it was not possible to assign that there was a pattern in the structures of amplification by *Bacteria* and *Archaea* communities of the ruminal content of animals treated with 2 different rumen modifiers or 3 distinct energetic sources.

Table 1. Number of amplified bands obtained by DGGE for *Bacteria*, *Archaea* and sum of *Bacteria* and *Archaea* communities obtained with treatments composed by different energetic sources

	Energy sources					
Variable	CG	HMCS	CiPu	Mean	SEM	Prob.
Bacteria	5.94	9.11	5.94	7.00	0.6400	0.1106

M356 Effect of polyclonal antibody preparation on ruminal protozoa population in cattle fed three different energetic sources. W. Otero[1], C. Marino*[2], M. Stradiotto[4], C. Barreto[3], V. Pellizari[3], M. Arrigoni[2], and P. Rodrigues[1], [1]*University of Sao Paulo, FMVZ*, *Pirassununga, Brazil*, [2]*University of Sao Paulo State, FMVZ*, *Botucatu, Brazil*, [3]*University of Sao Paulo, ICB*, *Sao Paulo, Brazil*, [4]*University of Sao Paulo, FZEA*, *Pirassununga, Brazil*.

Nine ruminally fistulated cows were used to test an avian-derived polyclonal antibody preparation against specific ruminal bacteria *Streptococcus bovis*, *Fusobacterium necrophorum*, *Clostridium aminophilum*, *Peptostreptococcus anacrobius* and *Clostridium sticklandii*. The experimental design was a 3 × 3 Latin square replicated 3 times with a factorial arrangement of treatments 3 × 3 regarding 2 feed additives (monensin and PAP) plus control group and 3 energy sources. The energy sources utilized were dry-grounded corn grain (CG), high moisture corn silage (HMCS) and citrus pulp (CiPu). Sample collection for quantitative protozoa analysis were performed at 19 d of each period at 0 and 4 h after morning meal collected my manual scanning of rumen floor. Data were submitted to variance analysis by GLM procedure, which separated the effects of interaction between feed additive and energy source, effect of feed additive, effect of energy source as well as effects of period and animal inside the square. Mean effects were separated by Duncan test. Differences were declared at $P < 0.05$. Relative counting of *Entodinium* was influenced by the type of energy source at 0 h ($P = 0.0091$) and 4 h ($P = 0.0026$). Animals treated with CG and HMCS showed higher values of these protozoa when compared with animals receiving CiPu but do not differ between them. It was observed feed additive effect for *Isotricha* ($P = 0.1008$) at 4 h. The group treated with PAP showed great values for relative counting compared with CON. The MON group did not differ from the others 2. Also, it was observed energy source effect for *Isotricha* at 0 h ($P = 0.0008$) and 4 h ($P = 0.0001$), where the animals fed CiPu showed greater relative counting than animals fed HMCG and CG that did not differ between them. The utilization of PAP and the addition of CiPu resulted in an increase of total and relative counting of Isotricha which indicate an effect on ruminal microbial population.

Table 1. Absolute ($\times 10^3$/mL) and relative (%) counting of protozoa obtained with the treatments composed by different feed additives and energy sources

	Feed Additive			Energy source

M357 Effects of ethanol extracts of two specific mixtures of herbs and spices on in vitro rumen microbial fermentation. N. Narvaez*[1], Y. Wang[1], T. A. McAllister[1], and C. Benchaar[2], [1]*Agriculture and Agri-Food Canada*, *Lethbridge Research Centre, Alberta*, [2]*Agriculture and Agri-Food Canada*, *Dairy and Swine R&D Centre, Sherbrooke, Quebec*.

Two in vitro batch culture experiments were conducted to assess the effects of ethanol extracts of 2 different combinations of herbs and spices (ApexRuminant and ApexCalf; Nutri-Ad, Elgin, IL) on rumen microbial fermentation. The treatments were control (no additive), monensin (10 µg/mL), ethanol extract of ApexRuminant (ARe, Exp. 1) and ethanol extract of ApexCalf (ACe, Exp. 2) both supplied at 125, 250, 500, 1000 and 2000 µg/mL. Production of total gas (GP), volatile fatty acids (VFA) concentration, microbial protein (MN), and true dry matter disappear-

ance (TDMD) were determined after 24 h of incubation. Data were analyzed as a completely randomized design and polynomial contrasts were used to determine linear and quadratic dose-effects. Significance was declared at $P \leq 0.05$. In both experiments, monensin increased propionate proportion but decreased GP, TDMD, MN synthesis, total VFA production (mmol/g DM), molar proportions of acetate, butyrate, and branched-chain VFA (BCVFA), and the acetate:propionate ratio (A:P). Addition of ARe at levels up to 500 μg/mL and ACe up to 1000 μg/mL did no cause substantial modifications of rumen fermentation, whereas at higher doses it resulted in different effects that in most cases inhibited rumen fermentation. These effects were dose-dependent and entailed both linear and quadratic trends. When supplied at 1000 or 2000 μg/mL, ARe reduced GP, TDMD, and total VFA production, but increased butyrate and BCVFA proportions, whereas at 2000 μg/mL, ARe supply increased MN and A:P ratio. Addition of ACe at 2000 μg/mL reduced GP, TDMD, but increased MN without altering VFA production or A:P ratio. Results from this study suggest that the active compounds of Apex mixtures are ethanol soluble and exhibited antimicrobial activity at high doses with greater inhibitory effects exerted by ARe compared with ACe on ruminal microbial fermentation.

Key Words: plant extract, rumen fermentation, ethanol extract

M358 Assessment of the effects of two herbs and spices mixtures and their ethanol extracts on in vitro rumen microbial fermentation. N. Narvaez*[1], Y. Wang[1], T. A. McAllister[1], and C. Benchaar[2], [1]*Agriculture and Agri-Food Canada*, *Lethbridge Research Centre, AB,Canada,* [2]*Agriculture and Agri-Food Canada*, *Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.*

An in vitro batch culture experiment was conducted to determine the effects of 2 specific mixtures of herbs and spices (ApexRuminant: AR and ApexCalf: AC; Nutri-Ad, Elgin, IL) and their ethanol extracts (ARe; ACe) on rumen microbial fermentation. Treatments were control (no additive), monensin (10 μg/mL), AR, AC, ARe or ACe, supplied at 250, 500, 1000 and 2000 μg/mL. Production of total gas, volatile fatty acid (VFA) and ammonia N (NH_3-N) concentrations, and apparent dry matter disappearance (ADMD) were determined after 48 h of incubation. Data were analyzed as a completely randomized design and according to a 2 × 2 × 4 factorial to determine the effects of the type of product and the method of extraction. Polynomial contrasts were also used to determine linear and quadratic dose-effects. Significance was declared at $P \leq 0.05$. Compared with the control, monensin reduced ADMD, NH_3-N concentration, total VFA production (mmol/g DM), and acetate:propionate (A:P) ratio. Addition of AR and ARe linearly reduced gas production, ADMD, VFA but linearly increased the A:P ratio. Addition of AC and ACe did not alter gas production, but linearly reduced ADMD and VFA production. The A:P ratio from ACe linearly increased but a quadratic response was observed with AC, being lowest at 500 μg/mL. Compared with AC and ACe, the addition of AR and ARe resulted in lower ADMD, NH_3-N concentration, VFA production, but higher A:P ratio. Addition of AR and AC had higher NH_3-N concentration, but lower ADMD and A:P ratio than ARe and ACe. Considering the type of product (ApexRuminant vs. ApexCalf) and preparation method (no extraction vs. ethanol extraction), ApexRuminant and ethanol extracts (ARe and ACe) exerted greater effects on rumen fermentation than ApexCalf and no extraction. These effects became statistically significant at the supplementation levels of 1000 and 2000 μg/mL.

Key Words: plant extract, ethanol extraction, in vitro rumen fermentation

M359 Use of pine sawdust (*Pinnus patula*) as a fiber source in lamb finishing rations. E. C. Guerra-Medina[1], O. D. Montañez-Valdez*[2], M. A. Cobos-Peralta[3], and M. Pérez-Sato[4], [1]*Centro Universitario de la Costa Sur de la Universidad de Guadalajara*, *Autlán, Jalisco, México*, [2]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [3]*Colegio de Postgraduados*, *Montecillo, Texcoco, México*, [4]*Benemérita Universidad Autónoma de Puebla*, *Puebla, Puebla, México*.

Rations for sheep include 5 to 40% of fibrous sources that can be used as cereal straws, alternate sources of oak (*Quercus ilex*) or pine (*Pinnus patula*) sawdust have been used; however its effectiveness has not been researched in depth. With the objective of using an alternative source of fiber in diets for sheep in feedlots, 2 treatments were assessed for 4 periods of 14 d each. There were 2 treatments, one with 30% pine sawdust (SD) and another with 30% corn straw (CS). The variables evaluated were average daily gain (ADG), dry matter intake (DMI), ruminal pH, concentration of volatile fatty acids, and concentration of ammonia. A Completely Randomized Design was used and the data were analyzed using the procedure of repeated measurements. The ADG (246.07 g d^{-1}), concentration of propionic acid (27.3 mol/100 mol), and the average ruminal pH (6.28) was higher ($P < 0.05$) in the SD treatment, while the average concentration ammonia was higher ($P \leq 0.05$) in the CS treatment (33.6 m*M*). There no were differences in DMI ($P \leq 0.05$) between treatments. The results indicate the possibility of using until 30% of pine sawdust as a source of fiber in diets for sheep in feedlots.

Key Words: fiber substitute, average gain, ruminal fermentation

M360 Effect of an inoculum and additive on in situ nutrients digestibility of sugar cane silage. J. A. Reyes-Gutiérrez[1,2], O. D. Montañez-Valdez*[1], R. Rodríguez-Macías[2], M. A. Ruiz-López[2], E. Salcedo-Pérez[2], and M. R. Rodriguez-Ramirez[3], [1]*Centro Universitario del Sur de la Universidad de Guadalajara*, *Ciudad Guzmán, Jalisco, México*, [2]*Centro Universitario de Ciencias Biológicas y Agropecuarias de la Universidad de Guadalajara*, *Las Agujas, Jalisco, México*, [3]*Instituto Nacional de Investigaciones Agricolas y Pecuarias*, *Tecomán, Colima, México*.

The objective of this study was to evaluate the effect of adding an inoculum and an additive handmade in sugar cane silage (SCS) on the in situ digestibility of DM, OM and ruminal pH. Four Holstein cows fitted with rumen cannula (BW 650 ± 50 kg) were randomly assigned to a 3 × 3 Latin square and they were housed in individual pens. Each period was 15 d, 10 for adaptation to experimental diets and 5 to collect samples. The treatments were: T1) sugar cane silage; T2) sugar cane silage with 1% inoculum and 1% additive; T3) sugar cane silage with 3% inoculum and 1% additive. The inoculum consists of 10.0% molasses, 1.0% of yogurt, 5.0% chicken manure, urea 0.5% and 83.0% water and the additive was formulated with 1.0% urea, 0.1% ammonium sulfate and 0.25% phosphorus. There were differences ($P \leq 0.05$) among treatments on the in situ digestibility of DM and OM and ruminal pH (Table 1).The ruminal pH was higher in T1 (7.15) and T2 (6.91) and lower in T3 (6.52). T3 showed higher percentages of DM and OM compared with T2 and control, these results could be explained because the inoculums improve predigestion of nutrients from the sugar cane during the ensiling process. The use of an inoculums and additive on cane sugar silage changes the ruminal pH and disappearance of DM and OM

Table 1. Coefficients of digestibility in situ of DM and OM of experimental materials (%)

M361 The effects of cinnamaldehyde and garlic extract on feed intake and nutrient digestibility by lambs. T. M. Norvell*, B. M. Nichols, T. J. McDonald, M. M. Harbac, and J. A. Paterson, *Department of Animal and Range Sciences, Montana State University*, *Bozeman*.

Three lamb experiments were conducted to evaluate the effects of a commercially available feed additive containing cinnamaldehyde and garlic (CG) on DM intake, DM, NDF and N digestibilities. Experiment one was a 3 × 3 Latin square to determine individual DMI. Twenty-one ewe lambs were randomly assigned to 3 treatments (7 ewes/treatment) in a GrowSafe facility which measures individual feed intake. Diets consisted of 85% ground grass hay and 15% supplement. Dietary treatments were control (no CG), 70 ppm CG, and 140 ppm CG. For each period, individual DMI was measured for 10-d with no adaptation to diets. Average DMI was similar ($P = 0.82$) for the 3 treatments (average = 2.3 kg/d). For Exp. 2, 24 wether lambs were placed in individual metabolism crates and randomly assigned to treatments to measure nutrient digestibility. Wethers were again fed increasing levels of CG. Diets consisted of 77% ground grass hay and 23% supplement. Treatments compared were control (no CG) and diets with 20, 40, or 80-ppm dietary CG. Wethers were fed diets at 3.3% of BW for 10-d of adaptation followed by 6-d fecal collection. The CG did not change DM ($P = 0.99$), NDF ($P = 0.90$) or N digestibilities ($P = 0.82$). Experiment 3 was designed as a 2 × 2 factorial arrangement of treatments using 24 wethers housed in individual metabolism crates. Main effects evaluated were 85% roughage (grass hay) vs. 85% concentrate (corn), and 0 vs. 80 ppm dietary CG. Wethers were offered diets at 2.7% of BW for 18-d of diet adaptation followed by 5-d of feces collection. There were no CG × forage level interactions and CG did not change DM ($P = 0.69$), NDF ($P = 0.33$), or N digestibilities ($P = 0.46$). Average DMI was greater ($P < 0.05$) for the 85% forage diets compared with 85% concentrate diets. Results indicate that at the levels offered, CG did not negatively affect DMI and had no affect on nutrient digestibility.

Key Words: cinnamaldehyde, garlic, feed intake

M362 Interaction of rumen pH, cinnamaldehyde and eugenol mixture and capsicum oleoresin on in vitro fermentation pattern and methane production. D. Bravo[1], S. Calsamiglia*[2], N. D. Pyatt[3], and P. H. Doane[3], [1]*Pancosma*, *Geneva, Switzerland*, [2]*Universitat Autonoma de Barcelona*, *Spain*, [3]*ADM Research*, *Decatur, IL*.

A 2 × 3 factorial arrangement of treatments was used to investigate the interaction between 2 sources of rumen inocula and inclusion of plant extracts on in vitro rumen fermentation and methane. Plant extracts were control (no extract) a mixture of eugenol and cinnamaldehyde (CIE, XT 6965, Pancosma,250 mg/L) or an oleoresin of capsicum (CAP, XT 6933, Pancosma, 250 mg/L). Rumen inocula was obtained from either dairy cows (50:50 forage:concentrate diet, pH 7.0) or beef cattle (10:90 forage:concentrate diet, pH 5.0). Each treatment was tested in triplicate and repeated in 2 periods. Fifty milliliters of a 1:1 ruminal fluid-to-buffer solution were introduced into polypropylene tubes supplied with 0.5 g of DM of DDGS and incubated for 24 h at 39°C. Samples were collected for ammonia N, VFA concentrations and methane analysis. Results were analyzed using SAS, and significant differences declared at $P < 0.05$. The beef-type fermentation resulted in lower total VFA (155.3 mM, −16%), acetate (45.4 mol/100mol, −25%) and butyrate (6.8 mol/100mol, −29%) proportions, reduced acetate to propionate ratio (1.26, −53%), ammonia-N (16.0 mg N/dL, −15%) and methane (18.7 µL/L, −48%) concentrations, and higher propionate proportion (36 mol/100mol, +61%). Using beef inocula, inclusion of CIE increased total VFA (+12%) and the proportion of propionate (+24%), and decreased methane (−18%) concentration. When dairy rumen inocula was used, CIE increased propionate proportion (+25%) and decreased acetate proportion (−8%), the acetate to propionate ratio (−25%), and methane production (−38%). For both inocula environments, CAP had little effect, agreeing with earlier research where the main effect for CAP being reported for DMI and feeding behavior. These results indicated that the mixture CIE reduced methane production in vitro, and that the effect was larger in a dairy-type environment without addition of CAP, compared with the beef-type environment.

Key Words: essential oils, methane, in vitro

M363 Influence of condensed tannin supplementation on intake, ruminal and total digestibility, rate of digestion, and urinary excretion of urea and total nitrogen of beef steers fed high concentrate diet. R. Mezzomo*[1], P. V. R. Paulino[1], S. C. Valadares Filho[1], J. P. I. S. Monnerat[1], G. S. Viana[1], M. G. Machado[1], J. C. M. Lima[1], T. S. Martins[1], P. Lencioni[2], and D. Grandini[3], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*Silva Team*, *Buenos Aires, Argentina*, [3]*Nutron*, *Itapira, SP, Brazil*.

This trial was conducted to evaluate the effect of condensed tannin (TN) associated or not with a true protein source on intake, ruminal and total digestibility, ruminal digestion rate and urinary nitrogen excretion in beef steers fed high concentrate diet (87% of DM). Four crossbred steers (407 kg BW) fitted with rumen cannula were assigned to a 4x4 latin square design, arranged in a 2x2 factorial arrangement. Steers were fed a basal diet based on cracked corn, whole cottonseed, sugar-cane bagasse, mineral mixture and one out of 4 supplements: soybean meal with condensed tannin (SMT); soybean meal without condensed tannin (SM); condensed tannin without soybean meal (TN) and a treatment without both soybean meal and condensed tannin (BS). Quebracho extract were used as tannin source, included to provide 4 g of tannin/100 g of diet DM and all diets were formulated to be isonitrogenous. Intake of DM and nutrients was not affected ($P > 0.10$) by TN supplementation. However, there was an effect ($P < 0.10$) of TN supplementation on ether extract digestibility. A smaller ($P < 0.10$) excretion of urinary urea nitrogen (71.94 vs. 53.62 g) and total nitrogen (86.43 vs. 74.07 g) was observed in the animals supplemented with TN. Serum urea nitrogen concentration did not differ ($P > 0.10$) among treatments. There was an interaction ($P < 0.10$) between condensed tannin and soybean mean on ruminal digestibility and digestion rate of crude protein (CP).

When soybean meal was provided in the diet TN caused a reduction on CP ruminal digestibility from 46.92 to 33.46%, leading to a smaller digestion rate of CP. No differences in DM passage rate were observed ($P > 0.10$) among treatments. Urinary urea nitrogen and total nitrogen excretions were higher in the animals supplemented with soybean meal. The use of condensed tannin as an additive in cattle fed high concentrate diet using soybean meal as true protein source decreases the digestion rate and ruminal degradability of crude protein without affecting feed intake.

Key Words: feedlot, protein, RUP

M364 Effect of Copaiba (*Copaifera* sp.) oils on in vitro rumen fermentation of coastcross hay. R. C. Araujo*[1], A. V. Pires[1], A. L. Abdalla[2], M. R. S. R. Peçanha[2], and A. S. Morsy[2], [1]*ESALQ, Universidade de São Paulo*, *Piracicaba, SP, Brazil*, [2]*CENA, Universidade de São Paulo*, *Piracicaba, SP, Brazil*.

Copaiba oils have antimicrobial properties and are obtained from the trunk of *Copaifera* sp. trees. A randomized complete block design was used to determine the effects of *C. reticulata*, *C. multijuga*, and *C. langsdorfii* oils on rumen fermentation of coastcross (*Cynodon* sp.) hay by using an in vitro gas production (GP) system. Treatments were control (CTL), pure monensin at 3 µM (MON), and 75 or 150 µL of *C. reticulata*, *C. multijuga*, or *C. langsdorfii* oil. In each flask (160 mL), 0.5 g of hay (91.3% DM) was incubated with 50 mL of medium and 25 mL of rumen fluid at 39°C for 24h. Replicates were n = 6 for GP and n = 3 for all other variables. Two inocula (from 3 lambs each) were used as source of variation. PROC Mixed of SAS was used and differences declared when $P < 0.05$. By GC/MS analysis, major secondary compounds in oils were *C. reticulata* – trans-caryophyllene (50.2%) and α-humulene (8.1%); *C. multijuga* – trans-caryophyllene (21.9%), α-trans-bergamotene (11.4%), and β-bisabolene (9.1%); *C. langsdorfii* – trans-caryophyllene (56.5%) and α-humulene (9.4%). MON decreased GP (117.5 vs. 103.7 mL), CH_4 production (13.0 vs. 9.8 mL), CH_4 to gas ratio (0.1100 vs. 0.0943), and truly degraded dry matter (TDDM; 57.4 vs. 50.9%) when compared with CTL. MON did not affect total SCFA and C_2 concentrations, but increased C_3 concentration (12.3 vs. 14.0 mM) and decreased C_4 concentration (8.6 vs. 7.5 mM) when contrasted with CTL. All Copaiba oils at 150 µL had lower GP than CTL. However, TDDM was reduced by all Copaiba oils in both doses. The CH_4 production and CH_4 to gas ratio did not differ between *Copaifera* sp. oils and CTL. Total SCFA, C_2, and C_3 concentrations, as well as C_2 to C_3 ratio were also not influenced by *Copaifera* sp. oils. The only exception was *C. reticulata* oil at 75 µL, which showed a greater C_3 concentration than CTL (12.3 vs.13.0 mM). All treatments showed similar results for ammonia concentration. Results indicate that *Copaifera* sp. oils decreased in vitro DM degradability with minimal effects on fermentation profile of coastcross hay.

Key Words: methane, plant extracts, plant secondary compounds

M365 Effects of garlic oil on methane production, microbial growth and diet fermentation in Rusitec fermenters. M. D. Carro*[1,2], M. L. Tejido[1,2], C. Saro[1,2], and M. J. Ranilla[1,2], [1]*Dept. Producción Animal, Universidad de León*, *24071 León, Spain*, [2]*Instituto de Ganadería de Montaña (CSIC-ULE)*, *Finca Marzanas, 24346 Grulleros, León, Spain*.

Garlic oil (GAR) has been shown to reduce methane production in the rumen, but little is known about its effects on ruminal microbial growth. Two 15-d incubation runs were conducted with 4 Rusitec fermenters to investigate the effects of GAR on ruminal microbial growth and fermentation of a 50:50 alfalfa hay:concentrate diet. Each fermenter received daily 30 g of diet DM. In each run, 2 fermenters received daily 100 mg of GAR dissolved in 0.7 mL of ethanol (180 mg of GAR / L of fermenter content) and 2 received 0.7 mL of ethanol (control). After 11 d of GAR treatment, the main fermentation parameters were determined during 3 consecutive days. Microbial growth was determined on d 15 using 15N as a microbial marker.

No effect of GAR ($P > 0.05$) was observed on dry matter degradability (61.9 vs. 62.3% for control and GAR, respectively), neutral detergent fiber degradability (44.6 vs. 45.9%) and daily production of total volatile fatty acids (VFA; 100 vs. 103 mmol) and ammonia-N (210 vs. 221 mg). The GAR increased the molar proportion of propionate ($P = 0.02$; 17.5 vs. 14.9%), decreased butyrate proportion ($P < 0.001$; 14.6 vs. 17.2%), and tended to decrease the proportion of acetate ($P = 0.07$; 53.6 vs. 54.5%). Fermenters receiving GAR showed greater ($P < 0.001$) proportions of isobutyrate, valerate and caproate compared with controls. Daily production of methane was reduced ($P < 0.001$) by 10.8% by GAR, resulting in lower ($P = 0.002$) methane/VFA ratios in GAR treated fermenters compared with controls. Microbial growth tended to be greater ($P = 0.09$) in fermenters receiving GAR (247 vs. 237 mg of microbial N/d), but its efficiency was similar in all fermenters ($P = 0.12$; 25.5 vs. 23.0 mg of microbial N / g organic matter apparently fermented). Supplementation of GAR to fermenters was an effective means to reduce methane production without negatively affecting microbial growth, diets degradability or VFA production.

Key Words: garlic oil, methane, Rusitec fermenters

M366 Effect of Copaiba (*Copaifera* sp.) oils on in vitro rumen fermentation of a high-concentrate diet. R. C. Araujo*[1], A. V. Pires[1], A. L. Abdalla[2], L. A. Castilho[2], and R. C. Lucas[2], [1]*ESALQ, Universidade de São Paulo*, *Piracicaba, SP, Brazil*, [2]*CENA, Universidade de São Paulo*, *Piracicaba, SP, Brazil*.

Copaibas (*Copaifera* sp.) are Brazilian trees whose oil extracted from the trunk shows antimicrobial properties. A randomized complete block design was used to determine the effects of *C. reticulata*, *C. multijuga*, and *C. langsdorfii* oils on rumen fermentation of an 80:20 concentrate:forage diet by using an in vitro gas production (GP) system. Treatments were: control (CTL), pure monensin at 3 µ*M* (MON), and 75 or 150 µL of *C. reticulata* (RET75 and RET150), *C. multijuga* (MLT75 and MLT150), or *C. langsdorfii* (LNG75 and LNG150) oil. In each flask (160 mL), 0.5 g of diet (91.4% DM) was incubated with 50 mL of medium and 25 mL of rumen fluid at 39°C for 16 h. Replicates were n = 6 for GP and n = 3 for all other variables. Two inocula from lambs (n = 3 each) adapted to the incubated diet were used as source of variation. The PROC Mixed of SAS was used with differences declared when $P < 0.05$. By GC/MS analysis, major secondary compounds in oils were RET – trans-caryophyllene (50.2%) and α-humulene (8.1%); MLT – trans-caryophyllene (21.9%), α-trans-bergamotene (11.4%), and β-bisabolene (9.1%); LNG – trans-caryophyllene (56.5%) and α-humulene (9.4%). Compared with CTL, MON decreased GP (160.3 vs. 147.5 mL) and CH_4 production (16.3 vs. 13.8 mL) as well as truly degraded dry matter (TDDM; 81.5 vs. 77.9%). MON did not affect total SCFA and C_2 concentrations, but increased C_3 concentration (17.9 vs. 21.3 m*M*) and decreased C_2 to C_3 ratio (2.67 vs. 2.21) when compared with CTL. MLT75 (164.8 mL), LNG75 (167.7 mL), and LNG150 (165.5 mL) had greater GP than CTL (160.3 mL). No effects were observed for all oils on CH_4 production, CH_4 to gas ratio, and TDDM. Compared with CTL, LNG150 showed greater total SCFA (89.9 vs. 98.7 m*M*) and

C_2 (48.0 vs. 53.9 m*M*) concentrations. RET75, RET150, and LNG150 showed greater C_3 concentration (19.1, 19.3, 18.9 m*M*, respectively) when contrasted with CTL (17.9 m*M*). All oils did not affect C_2 to C_3 ratio. Copaiba oils affected rumen fermentation of a high-concentrate diet without effects on methanogenesis. *C. langsdorfii* oil at 150 µL showed the most positive effects by increasing total SCFA concentration.

Key Words: methane, plant extracts, plant secondary compounds

M367 Effects of supplemental poultry fat on calves grazing bermudagrass pasture. J. G. Powell*, T. J. Wistuba, and E. B. Kegley, *University of Arkansas*, *Fayetteville*.

Bermudagrass is a warm season perennial found throughout the southeastern US If fertilized, bermudagrass can contain adequate crude protein for growing cattle, but energy is often limiting for maximal growth rates. Supplementing grain will increase energy intake; although at high rates of supplementation grain can cause decreased forage intake. The objective of this experiment was to evaluate the effect of adding poultry fat to a grain supplement on growth performance of calves grazing bermudagrass; the supplemental fat could make a more energy dense, beneficial, supplement or alternatively the added fat could impair rumen fiber digestion and thus reduce forage intake. Sixty calves (228 ± 3.2 kg, 30 heifers and 30 steers) were obtained from a single source. Calves were stratified by sex and weight and assigned randomly to 6 2.4-ha pastures. Pastures were assigned randomly to receive 1 of 2 treatments. The 2 treatments were corn-soybean meal supplements with 0 or 5% poultry fat. Supplements were formulated to be isonitrogenous (17% CP, DM basis). Calves were offered 1.1 kg/d of the appropriate supplement for the 140-d trial. Calves were weighed and forage availability in the pastures was measured at 28-d intervals. Cattle growth and forage availability were analyzed using the mixed procedures of SAS with pen as the experimental unit. Pregnancy data were analyzed using the GENMOD procedures of SAS with heifer as the experimental unit. Supplemental poultry fat did not affect final BW (337 vs. 336 kg, $P = 0.76$) or ADG ($P = 0.86$). No differences were detected in available forage due to dietary treatment (treatment × day interaction, $P = 0.43$). After the trial, heifers were kept as a single group, fed a common diet, and bred. There was no effect of supplemental fat during the growing phase on the number of heifers that became pregnant (53 vs. 43%, $P = 0.72$). Adding 5% poultry fat to the grain supplement fed to growing cattle grazing bermudagrass had no impact on growth.

Key Words: growing cattle, poultry fat, bermudagrass

M368 Studying the effect of different direct fed microbials on rumen fermentation in vitro. D. Barrau, M. Quintino Cintora, and N. D. Walker*, *Lallemand Animal Nutrition*, *Montreal, QC, Canada*.

Direct-fed microbials (DFMs) are commonly used in the beef feedlot industry to improve host health and productivity. The aim was to study the effect on rumen fermentation of a live yeast DFM Levucell SC (LSC), and 2 bacterial DFM products; one containing *L. buchneri* (MLB); the other a mixture of *L. buchneri* and *L. acidophilus*, (MLB+LA) with incubations which had no added DFM. Rumen contents were removed before feeding from 3 steers fed a finishing diet (70% high moisture corn, 15% DDGs, 10% alfalfa hay) and pooled. Strained contents (SRF) were mixed with anaerobic buffer (1:1) and used to set up triplicate batch incubations containing either glucose, corn starch or ground corn, +/− the test DFMs. Bacterial DFMs were added at a final cfu/ml of 1 × $10e^{05}$, yeast at 1 × $10e^{06}$. At 0, 3, 6, 9 and 24 h, gas production and pH were measured and samples removed for VFA and lactate analysis. To determine the effect of the 3 DFMs on fiber digestion, the %DM and %NDF disappearance of samples of wet (WDG) and dry Distillers grains (DDG) (+/− solubles), wet corn gluten (CG), alfalfa hay (AH) and the mixed ration (MR) the animals were fed, was measured using the Daisy fermentor. Incubation jars, including a control (no addition) were set up by mixing SRF with anaerobic buffer (1:4). Each DFM was added to a jar along with filter bags containing a known amount of each substrate. Triplicate bags were removed at 0, 3, 6, 12 and 24h and analyzed for fiber content. All incubations were repeated on 2 different days. Compared with control, all 3 DFMs reduced the accumulation of lactate from corn starch at 9 and 24h ($P < 0.008$) and significantly reduced lactate accumulation from ground corn at 6 h ($P < 0.05$). No effect of the DFMs on gas production or pH was seen. The effects on fiber digestion were DFM, substrate and time dependent. MLB significantly increased %NDFd of DDGs at 6 and 12h and MR at 3 and 24h ($P < 0.05$). LSC increased %DMd and %NDFd of CG by 24 h ($P < 0.05$). All 3 DFMs increased %NDFd of WDGS ($P < 0.05$) in the later part of the incubation. No significant effect was observed on the other substrates tested. To conclude, DFMs may help reduce lactate accumulation and improve fiber digestion.

Key Words: DFM

M369 Effect of a commercial microbial inoculant (Promote) on corn silage and animal performance. C. J. Fruge*, F. M. LeMieux, W. A. Storer, and T. H. Shields, *McNeese State University*, *Lake Charles, LA*.

An experiment was conducted to evaluate the efficacy of a commercial microbial inoculant (Promote) for corn silage and the subsequent effect on heifer performance. The 3 experimental treatments were: 1) no inoculant (control), 2) inoculant (100,000 CFU per gram of corn silage), and 3) inoculant (50,000 CFU per gram of corn silage). Promote was applied to corn silage as a liquid suspension during the ensiling process in horizontal poly bags. Silage samples were collected at d 0, 7, 14, 21, and 61 relative to ensiling. Samples were analyzed (Analab, Fulton, IL) for chemical composition for each treatment. Levels of lactic acid increased while pH decreased in both treatments of inoculated silage. A growth study with developing heifers, (n = 225) average initial wt 261 kg, was initiated at d 135 post ensiling. After a 14 d acclimation to feeding, heifers were randomly allotted (n = 75) to receive one of the 3 treatments as the forage component of their diet. Heifers were weighed on d −14, 0, 21, 55, and 86 to obtain ADG. Heifers consuming diets treated with Promote had increased ($P < 0.01$) ADG during the first month. Subsequently, heifers receiving the untreated silage excelled. Overall ADG between heifers receiving treatments 1 and 2 became similar ($P > 0.1$) by d 86 and were greater than ($P < 0.01$) heifers receiving treatment 3.

Key Words: silage, inoculant, heifer

M370 Effects of Fibrozyme on in vitro ruminal digestion and fermentation of a corn and wet distillers-based finishing beef diet with and without monensin. J. M. Tricarico, M. A. Witt, and J. S. Jennings*, *Alltech, Inc.*, *Brookings, SD*.

Two in vitro ruminal fermentation experiments were conducted to analyze the effects of a fibrolytic enzyme (Fibrozyme, Alltech Inc.) dose on digestibility of a corn and wet distillers-based finishing diet with or without monensin. Diets were a conventional finishing diet containing monensin at 50 µg/g of substrate (CONV) or a natural finishing diet with no monensin (NAT). The diet substrate (0.5g) was weighed in an Ankom bag and placed in a sealed 200 mL glass bottle. Bottles were flushed with

CO_2 and 100 mL of a 20% rumen fluid 80% buffer solution was added to begin the 72 h incubation period. Rumen fluid was collected from a single Holstein cow, receiving a common dairy TMR. During Exp. 1, the CONV and NAT diets with and without Fibrozyme at 0, 0.6, and 1.2 mg/mL of inoculum were compared. Fibrozyme was then applied to the NAT diet at 0, 0.6, 1.2, and 1.8 mg/mL of inoculum in Exp. 2. Enzyme by diet interactions occurred ($P < 0.05$) for true DM (TDMD) and NDF digestibility (NDFD) in Exp. 1. Fibrozyme increased TDMD (87.4, 88.7, and 89.1%) and NDFD (26.1, 33.7, and 36.1%) linearly ($P < 0.05$) in the CONV diet but only the highest dose increased TDMD (86.0 vs. 87.0%) and NDFD (30.3 vs. 35.4%) in the NAT diet. After elevating the dose further in the NAT diet (Exp. 2), the increases in TDMD (86.0 vs. 89.0 and 89.1%) and NDFD (25.8 vs. 41.8 and 42.3%) were similar for 1.2 and 1.8 mg/mL of supplemental Fibrozyme inclusion. In addition, 1.8 mg/mL of supplemental Fibrozyme increased ($P < 0.05$) final culture pH (6.51 vs. 6.56) and reduced butyrate molar proportions (0.183 vs. 0.173). Fibrozyme inclusion also tended ($P = 0.06$) to increase the fractional rate of degradation linearly (0.065, 0.073, 0.077, and 0.079 h-1). These results are consistent with our hypothesis that Fibrozyme will increase digestibility in finishing feedlot diets with a lower effective dose of Fibrozyme in the presence of monensin.

Key Words: fibrolytic enzyme, digestibility, finishing diet

M371 Influence of condensed tannin supplementation on protein efficiency, microbial protein yield, nitrogen balance and ruminal fermentation characteristics in beef steers fed high concentrate diet. R. Mezzomo*[1], P. V. R. Paulino[1], M. S. Duarte[1], L. S. Moura[1], L. H. P. Silva[1], E. San Vito[1], L. D. A. Rufino[1], C. Cabral[2], D. Grandini[3], and S. C. Valadares Filho[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*Silva Team*, *Buenos Aires, Argentina*, [3]*Nutron*, *Itapira, SP, Brazil*.

This trial was conducted to evaluate the effects of condensed tannin (TN) associated or not with a true protein source on protein efficiency, microbial protein yield, nitrogen balance and ruminal fermentation characteristics (RFC) in beef steers fed high concentrate diet (87% of DM). Four crossbred steers (407 kg BW) fitted with rumen cannula were assigned to a 4x4 latin square design, arranged in a 2x2 factorial arrangement. Steers were fed a basal diet based on cracked corn, whole cottonseed, sugar-cane bagasse, mineral mixture and one out of 4 supplements: soybean meal with condensed tannin; soybean meal without condensed tannin; condensed tannin without soybean meal and a treatment without both soybean meal and condensed tannin. Quebracho extract were used as tannin source, included to provide 4 g of TN/100 g of diet DM and the diets were formulated to be isonitrogenous. The nitrogen balance indicated that the use of TN improved the efficiency of nitrogen utilization ($P < 0.10$), however, no differences were observed when soybean meal was added to the diet ($P > 0.10$). There was an interaction ($P < 0.10$) between condensed tannin and soybean mean supplementation on the flux of rumen undegradable protein (RUP), metabolizable protein (MP) and on the ratio MP:CP. In the presence of soybean meal the addition of TN increased the flux of RUP (302.24 to 416.02 g/d), MP (540.23 to 671.03 g/d) and improved the ratio MP:CP (58.69 to 46.54). Microbial protein yield and microbial efficiency did not differ among treatments ($P > 0.10$). There was no effect of TN supplementation ($P > 0.10$) on ruminal pH, VFA and ammonia (N-NH3) concentration. N-NH3 increased and ruminal pH decreased with the inclusion of soybean meal ($P < 0.10$) in the diet. The utilization of condensed tannin as an additive in cattle fed high concentrate diet using soybean meal as true protein source implies in positive effects on efficiency of N utilization, increasing the flux of metabolizable protein.

Key Words: Quebracho extract, feedlot, RUP

M372 Effects of supplementing an exogenous proteolytic enzyme on growth performance in growing beef steers. J. M. Vera[1], C. T. Noviandi*[1], Arief[2], J.-S. Eun[1], and D. R. ZoBell[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University*, *Logan,* [2]*Faculty of Animal Science, Andalas University*, *Padang, West Sumatra, Indonesia*.

An exogenous proteolytic enzyme (EPE) has been previously found to increase in vitro NDF degradability of dried distillers grains with solubles (DDGS). To further investigate the effects of EPE, 48 Angus crossbred growing beef steers (292 ± 25.2 kg BW) were used to assess the growth performance when fed a DDGS-based TMR diet without or with an EPE supplementation in a completely randomized design. The growing TMR diet consisted of 13.6% alfalfa hay, 50.3% corn silage, 30.7% DDGS, and 5.4% feedlot supplement (DM basis). The EPE contained 38,622 U/g protease activity with negligible fibrolytic activities. The EPE was diluted with water and added at a rate of 0.52 g/kg DM TMR as it was mixing for the group of EPE treatment. Four animals were placed in each pen, and 6 pens allocated to each treatment. All steers were adapted to the TMR diet for a 2-week period before start of the trial. Feed was offered for ad libitum consumption once daily at 0800 h with free access to water. Feed intake was measured weekly, and individual BW of steers was recorded on 2 consecutive days at the beginning of trial and wk 4 and 8. The experiment lasted 56 d, and data were analyzed using the MIXED procedure of SAS. There were no significant differences ($P > 0.10$) for final BW (398 vs. 401 kg), BW gain (107 vs. 108 kg), and ADG (1.90 vs. 1.93 kg/d) between control and EPE treatment, respectively. Furthermore, EPE supplementation did not affect DM intake (10.5 vs. 10.0 kg/d) and gain to feed ratio (0.191 vs. 0.199). Therefore, supplementation of an EPE product at the dose rate used in this study did not alter growth performance of growing beef steers fed a DDGS-based TMR diet.

Key Words: exogenous proteolytic enzyme, growing beef steers, growth performance

M373 Effects of zinc and chlortetracycline supplements on growth performance, blood metabolites, carcass characteristics, and claw health in young Holstein bulls. H. Fagari-Nobijari[1], H. Amanlou[1], M. Dehghan-Banadaky*[2], and M. H. Shahir[1], [1]*University of Zanjan*, *Zanjan, Iran*, [2]*University of Tehran*, *Karaj, Tehran, Iran*.

This study conducted to evaluate the effects of supplementing finishing diet with zinc and/or chlortetracycline on growth performance and claw health of calves. Holstein bulls (n = 212; initial BW = 375.5 ± 18.4 kg) were randomly allocated to one of 4 treatments in a completely randomized design as a 2 × 2 factorial experiment for 56 d. Dietary treatments include: 1) the basal diet (control); 2) basal diet plus 150 mg of Zn/kg of DM as ZnSO4; 3) basal diet plus chlortetracycline (200 mg/animal/d; CTC); and 4) basal diet plus 150 mg of Zn/kg of DM + CTC (200 mg/animal/d). Animals received fresh total mixed ration for ad libitum. DMI was measured daily. BWs were recorded and blood samples were collected on d 0, 28, and 56. Liver samples were taken on d 56. Ultrasound measurements of backfat thickness (UFAT), rump fat thickness (URPFAT), and longissimus muscle area (ULMA) were made on d 56. All claws of animals were examined every 2 weeks to identify claw lesions. Data were statistically analyzed using the repeated measures option in Proc Mixed of SAS. Zn supplement decreased ADG, G:F, and apparent DM digestibility ($P < 0.01$); however, DMI was not influenced. Dietary CTC improved G:F on d 28 to 56 and decreased DM digestibility, but it did not affect ADG and DMI. Dietary CTC increased plasma total protein and urea nitrogen. Zinc supplementation decreased ULMA. The supplementation of CTC decreased UFAT and URPFAT.

Serum concentration of Zn, Cu, plasma total protein, albumin, alkaline phosphatase, and Zn concentration of liver were affected by the interaction of CTC × Zn. The prevalence of lameness was 14.15% with the highest odds ratio (OR) for lameness in control and Zn supplemented groups (OR = 7.2, 2.53, respectively). In summary, CTC supplementation did not improve ADG and G:F in bulls, however it affected carcass characteristics and improved claw health. Supplemental Zn decreased ADG and G:F and did not decrease lameness.

Key Words: zinc, chlortetracycline, young bulls

M374 The use of copper and chlortetracycline supplements for improving of growth performance, carcass characteristics and claw health in young Holstein bulls. H. Fagari-Nobijari[1], H. Amanlou[1], M. Dehghan-Banadaky*[2], and A. Shabani[3], [1]*University of Zanjan*, *Zanjan, Iran*, [2]*University of Tehran*, *Karaj, Tehran, Iran*, [3]*Tabriz Islamic Azad University*, *Tabriz, Iran*.

Two hundred 12 young Holstein bulls (initial body weight = 375.4 ± 17.1 Kg) were allotted to one of 4 treatments in a completely randomized design as a 2 × 2 factorial experiment for 56 d. treatments include: 1) the basal diet (control); 2) basal diet plus 30 mg of Cu/kg of DM as CuSO4; 3) basal diet plus chlortetracycline (200 mg/animal/d; CTC); and 4) basal diet plus 30 mg of Cu/kg of DM + CTC (200 mg/animal/d). Animals received a fresh total mix ration for ad libitum. DMI was measured daily. The body weights were recorded and jugular blood samples were collected on d 0, 28 and 56. Ultrasound measurements of backfat thickness (UFAT), rump fat thickness (URPFAT), and longissimus muscle area (ULMA) were made on d 56. All claws of young bulls examined every 2 weeks for identifying claw lesions. Data were statistically analyzed using the repeated measures option in Proc Mixed of SAS. Copper supplementation with or without CTC improved average daily gain, gain:feed and it might also influenced carcass characteristics ($P < 0.05$). Serum cholesterol decreased with Cu supplementation. Serum urea nitrogen tended to decrease by CTC supplementation ($P < 0.1$) and serum Ca tended to increase by supplemental of Cu ($P < 0.1$). Cu supplementation decreased UFAT and UPRFAT; however, it increased ULMA. Interaction of Cu × CTC affected UPRFAT ($P > 0.03$); also, UFAT tended to decrease by interaction of Cu × CTC ($P < 0.1$). Supplemental CTC had no effect on ultrasound carcass characteristics. Hip height was similar between treatments. The prevalence of lameness and skin and interdigital space disorders (ID) were high in Cu supplemented bulls compared with CTC group (OR = 2.97 and 1.94, respectively). The prevalence of white line disorders, heel erosion, and sole disorders statistically were not significant. In summary, supplemental Cu may improve carcass characteristics and growth performance of finishing bulls, but it may not prevent lameness. However, lameness decreased when Cu supplementation was used with CTC.

Key Words: copper, chlortetracycline, young bulls

M375 Chlortetracycline supplementation affected carcass characteristics and claw health in young Holstein bulls. H. Fagari-Nobijari[1], M. Dehghan-Banadaky*[2], S. H. Hosseini-Sabeghi[3], H. Amanlou[1], and A. Shabani[4], [1]*University of Zanjan*, *Zanjan, Iran*, [2]*University of Tehran*, *Karaj, Tehran, Iran*, [3]*Ghaemshahr Islamic Azad University*, *Ghaemshahr, Iran*, [4]*Tabriz Islamic Azad University*, *Tabriz, Iran*.

One hundred and 6 young Holstein bulls (initial BW = 376 ± 19.5 kg) were randomly allocated to 2 treatments in a completely randomized design for 56d. Treatment groups received 1) the basal diet with no supplemental chlortetracycline (control) and 2) basal diet plus chlortetracycline (100 mg/animal/d; CTC). Animals received fresh total mix ration for ad libitum allowing 10% orts. Group dry matter intake was measured daily. The Body Weights were recorded and Jugular blood samples were collected on d 0, 28 and 56. Ultrasound measurements of backfat thickness (UFAT), rump fat thickness (URPFAT), and longissimus muscle area (ULMA) were made on d 56. All claws of animals examined every 2 weeks for identifying claw lesions. Chlortetracycline supplementation tended to decrease average daily gain (ADG) ($P = 0.2$) but gain:feed (G:F) did not differ ($P = 0.48$). Also, URPFAT was not affected by treatments ($P = 0.2$). However, CTC tended to decrease UFAT ($P = 0.07$). Statically, young bulls supplemented with CTC did not increase ULMA vs. unsupplemented animals ($P = 0.3$). Supplemental CTC improved serum concentrations of Cu ($P = 0.04$) and Zn ($P = 0.004$) and also, decreased cholesterol ($P = 0.05$) than control. There was no difference between treatments on concentration of plasma IGF-I ($P = 0.4$). The prevalence of lameness was 19.81%. Lameness was most frequently observed in the control group (OR = 4.08). The prevalence of skin and interdigital space disorders (ID) was the greatest cause of lameness in the present study (52.38% of whole lameness) and was higher in control than the other group (OR = 5.17; 42.85% of whole lameness). Statistically, the prevalence of sole disorders (SD), white line disorders (WD), and heel erosion (HE) were not different ($P = 0.56$, 0.33, and 0.56, respectively). In summary, supplemental CTC may decrease growth performance in finishing bulls, however, it may successfully prevent lameness and may alter fat metabolism.

Key Words: chlortetracycline, claw health, young bulls

M376 Effect of chestnut tannins supplement on milk production traits of dairy sheep on pasture. A. Nudda*[1], G. Battacone[1], A. Fenu[1], M. Decandia[2], M. Sitzia[2], M. Acciaro[2], and G. Pulina[1], [1]*Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*, [2]*Agricultural Research Agency of Sardinia - AGRIS Sardegna*, *Sassari, Italy*.

The use of tannins in grazing ruminants reduces OM digestibility in the rumen and increases protein escape. This is particularly desirable when animals graze on grass with a high content of soluble protein, because tannins can reduce the production of ammonia in the rumen and increase the protein available for intestinal digestion. The present study aimed to investigate the milk productive response of dairy ewes, grazing on pasture composed by 70% of *Medicago polymorpha* (27.5% dry matter, DM; 44.3% NDF, 29.5% ADF, 18.3% CP, on a DM basis) and 30% of *Lolium rigidum* (39.6% DM; 58.3% NDF, 31.2% ADF, 9.4% CP, on a DM basis), to the supplementation of concentrate (300 g/d; 87.1% DM; 29.4% NDF, 16.9% ADF, 17.6% CP, on a DM basis) containing 3 levels of commercial chestnut hydrolyzable tannin (0, 6 and 12%, on a DM basis; T0, T6 and T12, respectively). Thirty-six 2- to 4-yr-old Sarda ewes (12 per experimental group), in mid lactation (90–120 DIM), and grazing on pasture were used in this one-month trial. Daily milk production was recorded and daily milk samples were collected for analysis of fat, protein, lactose, SCC and urea. Data were analyzed by ANOVA including tannin level and sampling as fixed factors and their interaction. Tannin level did not influence milk yield and milk fat and protein concentration. Lactose was higher in T12 than in T0, being T6 intermediate. The urea content was not modified by the addition of tannin to the diet. The SCC was lowered by the inclusion of tannin in the diet. These results showed that the dose of tannins used did not modify the productive performance of dairy sheep on pasture.
Research supported by the Ministero dell′Istruzione dell′Università e della Ricerca (Project PRIN 2008).

Key Words: dairy sheep, tannins, milk

M377 The estimation of rumen fungi growth on maize stubble treated with steam and sodium hydroxide by using of quantitative competitive polymerase chain reaction. M. Chaji* and T. Mohammadabadi, *Department of Animal Science, Ramin (Khuzestan) Agricultural and Natural Resources University*, *Ahwaz (Molassani), Khuzestan, Iran*.

This experiment was conducted to evaluate the effect sodium hydroxide (NaOH) and steam on growth of rumen anaerobic fungi on maize stubble (MS) using quantitative competitive polymerase chain reaction (QC-PCR) assay. Rumen fungi were isolated from pre-incubated wheat straw in the rumen of fistulated sheep and then grown by Joblin (1981) method. These isolates were used (1:9) as a source of fungi inoculums in serum bottles containing fungi culture medium, 1 g maize stubble (as untreated or treated with 45 g/ kg DM NaOH, steam at 130°C and 120 min, and or $NaOH^+$steam; UMS, T1MS, T2MS and T3MS, respectively) and 1 mL antibiotic solution at 39°C (3 times sub culturing). Total genomic DNA was isolated from pure culture samples using guanidine thiocyanate-silica gel method. A universal PCR primer pair GAF (F): 5′-GAG GAA GTA AAA GTC GTT AAC AAG GTT TG-3′ and GAF (R): 5′-GAA ATT CAC AAA GGG TAG GAT GAT TT-3′ was used to amplify a specific region of 18S rDNA from rumen anaerobic fungi. Standard control DNA was constructed to use in the QC-PCR and was shown to amplify under the same reaction condition and the same amplification efficiency as the target DNA. The relative intensities of PCR products that were used to compare fungal biomass, was quantified by Image J 1.29x and the data was analyzed using the GLM procedure of SAS for a completely randomized design. The result showed that growth of rumen anaerobic fungi in the medium containing MS treated with NaOH and steam (+0.24, +0.19, respectively) was greater than untreated MS (−0.61) and the highest fungi growth was for medium containing MS treated with $NaOH^+$steam (+0.63) ($P < 0.05$). Therefore it is appears that rumen anaerobic fungi growth and in vitro maize stubble degradation increased by NaOH and steam treatments.

Key Words: maize stubble, rumen fungi, steam

M378 The in vitro fermentation of sesame straw processed with alkali by rumen isolated bacteria. T. Mohammadabadi* and M. Chaji, *Department of Animal Science, Ramin (Khuzestan) Agriculture and Natural Resources University*, *Ahwaz (Molassani), Khuzestan, Iran*.

The aim of this study was to determine rumen bacteria fibrolytic activity by using disappearance of DM and NDF in rumen isolated bacteria culture containing sesame straw (SS) as untreated and or treated with sodium hydroxide (NaOH). The experimental samples were including; untreated SS and SS treated with 30, 40 and 50 g/kg DM NaOH; USS, N1SS, N2SS and N3SS, respectively. Rumen fluid collected from 4 fistulated sheep, centrifuged (1000 rpm, 10 min), and supernatant was used to grow bacteria in medium containing fungicides (benomyle: 500 ppm/mL medium and metalaxyle: 10 mg/ml medium) under anaerobic conditions at 39°C for 24 h. These isolates were then used as a source of inoculum for culturing bacteria in a serum bottle containing 45 mL of culture medium and 1 g of experimental sample under anaerobic conditions (using 3 times subculture) for 12, 24, 48, 72 and 96 h. The residual substrates of each bottle were then filtered and used to determine disappearance of DM and NDF. Data of DM and NDF disappearance were analyzed as a completely randomized design using the general linear model procedure of SAS (1990). The result showed disappearance of DM after 96 h incubation by rumen isolated bacteria will be 67.3, 78.3, 86.3 and 92.1 g/100 g for untreated SS and treated with 30, 40 and 50 g/k g DM NaOH, respectively ($P < 0.05$). The highest increase of NDF disappearance after 96 h incubation was for SS treated with 50 g/kg DM NaOH (452.3 mg/g DM) that fallowed by SS treated with 40 and 30 g/kg DM NaOH (420.2 and 383.3 mg/g DM, respectively) ($P < 0.05$). Therefore, it appears that the growth and fibrolytic activity of rumen isolated bacteria on sesame straw is influenced by sodium hydroxide content.

Key Words: sesame straw, sodium hydroxide, rumen bacteria

M379 Synergism between cellulolytic and non-cellulolytic rumen bacteria on different fibrous substrates: Study in semi-defined cultures. J. Chiquette* and K. Lauzon, *Agriculture Canada*, *Sherbrooke, Quebec, Canada*.

The objective was to investigate the occurrence of synergistic fibrolysis when cellulolytic bacteria are cocultured with non-cellulolytics in a semi-defined medium in vitro. Cellulolytic bacteria were *Fibrobacter succinogenes* GC5 and *Ruminococcus flavefaciens* NJ and the non-cellulolytics were *Prevotella bryantii* 25A and *Prevotella ruminicola* 19189. Timothy hay and alfalfa hay were used as substrates to measure NDF disappearance with time (3 and 7 d). Each bacterial population was quantified by real-time PCR when in monoculture or when cocultured on the different substrates. Cellulolytic bacteria were grown at 37°C

for 72 h in basal medium containing 1% (w/v) Avicel (NJ) or 0.3% cellulose filter paper (GC5). Non-cellulolytic bacteria were grown in basal medium containing 0.5% (w/v) cellobiose as a sole carbon source until the end of the log phase (12h). The OD-adjusted inocula were added in monocultures (0.2 mL) or in cocultures (0.2 mL each for cellulolytics and non-cellulolytics) to tubes containing 10 mL of basal medium with 100 mg of each substrate. After 7 d of incubation, a greater disappearance of timothy NDF was observed when *R. flavefaciens* was cocultured with *P. ruminicola* (18.2%) or *P. bryantii* (18.1%) compared with the monoculture of *R. flavefaciens* (16.4%) ($P \leq 0.05$). Similarly, when *F. succinogenes* was cocultured on timothy hay with *P. ruminicola*, NDF disappearance was greater (26.9%) compared with the monoculture of *F. succinogenes* (24.3%) ($P \leq 0.05$). *P. ruminicola* was in greater number when cocultured with NJ or GC5 on timothy hay ($P \leq 0.05$). *P. bryantii* tended to be in greater number ($P \leq 0.15$) when cocultured with *R. flavefaciens*. There was no synergistic fibrolysis between the 2 bacterial groups on alfalfa hay. These results demonstrated that synergistic fibrolysis was substrate dependent and was accompanied by increased populations of the non-cellulolytic bacteria.

Key Words: synergism, fibrolysis, rumen

M380 Effects of chemical treatments on in situ ruminal degradation of canola straw in Holstein cows. M. Ghiasvand, M. Dehghan-Banadaky*, and K. Rezayazdi, *Department of Animal Sci., Campus of Agriculture, University of Tehran*, *Karaj, Tehran, Iran*.

This study was conducted to evaluate the effects of different chemical treatments on canola straw including: T1 urea (3% of DM); T2 urea and molasses (urea 3% and molasses 2% of DM); T3 ammonium hydroxide (3% of DM); T4 sodium hydroxide (5% of DM); T5 sodium hydroxide and hydrogen peroxide (NaOH 5% and H2O2 2% of DM); and T6 water (2.5 L/ Kg DM). All treatments received 2.5 L water/ kg DM of canola straw. Chopped straw treated in double plastic bags at room temperature for 21 d then samples of each treatment collected and used for in situ nylon bags procedure. Three nonlactating, ruminally cannulated Holstein cows were used for the in situ experiment. Samples incubated in rumen for 0, 3, 6, 12, 24, 48, 72 and 96 h. Bags residual analyzed for dry matter (DM) and neutral detergent fiber (NDF) to calculate ruminal disappearance of nutrients. Data were fitted to the nonlinear regression equation: $D(t) = a + b(1 - e^{-ct})$ where D is percentage disappearance of DM or NDF at time t, a the soluble fraction and b the less rapidly degradable fraction which disappears at the constant fractional rate c per time t. Fraction of a for DM and NDF in T4,5 were greater than other treatments. Ruminal degradation rate (c) of DM and NDF were significantly faster in treated compared with untreated straw, but T4 and 5 increased degradation rates and degradability compared to other treatments. Although T4 and T5 had similar actions, T4 is prefer because of less chemical material usage and cost.

Key Words: canola straw, chemical treatments, ruminal degradation

M381 Effect of rice bran extracts on fermentation, protein, dry matter and organic matter digestibility in rumen in vitro. D. Srichana*[1] and S. Kondo[2], [1]*Department of Agricultural Technology, Faculty of Science & Technology, Thammasat University*, *Pathumtani, Thailand*, [2]*Faculty of Medicne, Thammasat University*, *Pathumtani, Thailand*.

Rice bran consists of γ-oryzanol which has ferulic acid, a phenolic compound as a component. Phenolic compounds have been known to change rumen fermentation. Hence this study was conducted to investigate the effect of rice bran extracts on rumen fermentation end products and protein, dry matter and organic digestibility in batch culture. The experiment was performed at 39°C for 24 h. Culture flasks containing 3 g of dairy cow diet were added with 120 mL mixture of rumen fluid and buffer (1:3). The extraction of Sangyot rice bran (SYE) and Hom Mali rice bran (MLE) using 95% ethanol had been carried out. Seven treatments of the 2 extracts were prepared at concentrations of 0.05, 0.5, 5 mg/ml and the control (without the extract). They were subsequently arranged in CRD and added to the culture flasks in triplicate. The results showed that ammonia concentration was decreased ($P < 0.05$) by SYE 5 mg/ml (6.23 m*M*) and it was increased ($P < 0.05$) by MLE 5 mg/L (11.54 m*M*) when compared with the control (9.38 m*M*). The obtained results were parallel with the results of protein digestibility which was decreased ($P < 0.05$) by SYE 5 mg/mL (39.89%) and increased ($P < 0.05$) by MLE 5 mg/mL (49.11%) when compared with the control (48.04%). Dry matter and organic matter digestibility was decreased ($P < 0.05$) by SYE 5 mg/mL (51.95 and 50.23%, respectively) when compared with the control (61.11 and 60.33%, respectively). The rest and the control were not significantly different ($P > 0.05$). The highest OD was MLE 5 mg/mL (2.77) followed by the OD of SYE 5 mg/mL (2.56). Both were higher ($P < 0.05$) than the OD of the control (2.27). The lowest concentrations of acetic acid and propionic acid (49.99 and 24.12 m*M*, respectively) were detected when treated with SYE 5 mg/mL. Butyric acid concentrations of all the treatments were not significantly different ($P > 0.05$) ranging from 10.62 to 14.09 m*M*. In conclusion, SYE 5 mg/ml decreased the digestibility of protein, dry matter and organic matter whereas MLE 5 mg/L enhances the highest growth of rumen microbes. None of the extracts were able to increase propionic acid concentration in batch culture.

Key Words: rice bran extract, rumen, batch culture

M382 The effect of sewage irrigation on mineral composition and in vitro digestibility of forage sorghum. E. Yosef*[1], J. Miron[1], E. Zukermann[2], M. Nikbachat[1], and D. Ben-Ghedalia[1], [1]*ARO Israel*, *Bet-Dagan Israel*, [2]*Extension Service-Ministry of Agriculture*, *Bet-Dagan, Israel*.

Sorghum is common summer forage cultivated in Israel, and due to lack of summer rainfalls it needs irrigation. Use of sewage water irrigation increased in Israel due to regional droughts and the necessity to eliminate the excess urban waste water. The purpose of this study was to evaluate the effect of secondary-treated sewage water irrigation on the composition and in vitro digestibility of forage sorghum strain FS5 grown for summer and sequential autumn harvests. The irrigation treatments were sewage (S) vs. flood (F) water at a level of 1890 m^3 /ha during summer growth and a level of 2400 m^3/ha during sequential autumn growth. Each treatment consisted of 5 replicate plots and sampled by manual harvesting at the soft dough stage of maturity. The conductivity of S and F water was 1.41 and 0.81 ds/m, respectively. The plant morphology, crop yields and NDF content were not affected by type of water irrigation; however, yields and plant protein content were significantly lower in autumn cut than in summer cut for both treatments. The S treatment had no significant effect on DM digestibility in vitro of both harvests (62.9% vs. 61.5% for 1st cut and 60.7% vs. 59.1% for 2nd cut). The NDF content of autumn cut was higher and dry matter and NDF digestibility lower as compared with summer plants. However, in summer harvest, S treatment decreased significantly NDF digestibility as compared with F treatment (43.1% vs. 47.4%). Despite higher mineral concentrations in S water as compared with F water: Na (x 5.4), S (x 2.6), K (x 14), P (x 473), Al (x 5.6), B (x 2.4), Mn (x 24.3), Cu (x 31.9), the mineral content of sorghum plants from both treatments was similar. In autumn cut plants, B and Na contents were by 98% and 109% higher

than in summer cut. In summer plants the nitrate contents were 4 fold higher than in the autumn plants. In this study the minerals content of secondary-treated sewage water were below the critical level that might damage sorghum quality.

Key Words: sorghum forage, digestibility, minerals

M383 Kinetics of degradation assessment and prediction of the fraction of indigestible neutral detergent fiber by-products. J. G. L. Regadas Filho[1], E. S. Pereira*[2], P. G. Pimentel[2], T. S. OLiveira[1], M. R. G. F. Costa[2], and I. S. G. Maia[2], [1]*Universidade Federal de Viçosa*, *MG, Brazil*, [2]*Universidade Federal do Ceará*, *Fortaleza, Brazil*.

The experiment was conducted to estimate the kinetics parameters of ruminal degradation of neutral detergent fiber (NDF) of by-products of cashew (*Anacardium occidentale*; pulp and cashew nut), passion fruit (*Passiflora edulis*), melon (*Cucumis melo*), pineapple (*Ananas comosus* L. Merr), west indian cherry (*Malpighia emarginata*), grape (*Vitis vinifera* L.), annatto (*Bixa orellana* L.) and coconut (*Cocos nucifera*) submitted to the gravimetric technique of nylon bag, and evaluate the prediction equation of indigestible fraction of neutral detergent fiber (iNDF) adopted by the Cornell Net Carbohydrate and Protein System (CNCPS). The feed samples were ground, placed in nylon bags with dimensions of 7 × 14 cm and porosity of 50 micron and incubated in duplicate in the rumen of a heifer, at 0, 3, 6, 9, 12, 16, 24, 36, 48, 72, 96 and 144 h. The incubation residues were evaluated for NDF content and interpreted by a non-linear logistic model. The evaluation process of predicting the indigestible fraction of NDF was carried out through adjustment models of linear regression between values predicted and observed values. There was wide variation in the degradation parameters of NDF from by-products. The rate of degradation of NDF ranged from 0.0267 h^{-1} and 0.0318 h^{-1} for grape and pulp cashew to 0.0884 h^{-1} and 0.0971 h^{-1} for passion fruit and west Indian cherry, respectively. The potentially digestible fraction of NDF (pdNDF) ranged from 4.17 and 14.13% for the melon and grape to 81.91 and 90.67% for cashew nut and coconut respectively. The equation used by CNCPS was able to predict the iNDF of the by-products, however, due to the high value of the mean square prediction error (291.40), such estimative shown inaccurate, being preferred the estimation by biological means.

Key Words: CNCPS, feeds, validation

M384 Plant bioactive screening of vegetation browsed/grazed by goats on Mexican semiarid rangelands. H. M. Cuchillo*[1], D. C. Puga[1], O. A. Navarro[2], and F. R. Perez-Gil[1], [1]*Departamento de Nutrición Animal, INCMNSZ*, *Mexico, Distrito Federal, México*, [2]*Facultad de Química, UNAM*, *Mexico, Distrito Federal, México*.

It is well recognized that plants consumed by ruminants, to cope their nutritional needs, contain a wide range of non-nutrient phytochemicals. Many plant bioactive metabolites are linked to antinutritive properties; however some of them are recognized as beneficial compounds which their significance remain unclear. Thus, we evaluated antioxidant activity (AA), total polyphenols (TP), flavonoids (FV) and hydroxycinnamic acids (HA) of plants browsed/grazed by goats during summer 2008. Direct observation of 2 core animals throughout grazing/browsing time during 3 d was done. Vegetation recollection was performed simulating the goats bites. The assessment included *Aristida adscensionis, Bouteloua curtipendula, B. repens, Chloris virgata, Leptochloa dubia, Lippia queretarensis, Pennisetum ciliare, Rhynchelytrum roseum, Urochloa fasciculata, Acacia farnesiana, A. schaffneri, Mimosa biuncifera, Prosopis laevigata, Celtis pallida, Jatropha dioica, Psilactis brevilingulata, Verbasina serrata, Zalazania augusta, Opuntia affasiacantha, O. amyctaea, O. hytiacantha, O. imbricata. O. robusta, O. streptacanta*, and *O. tomentosa*. Consecutive methanolic extractions in triplicate were realized whether from whole plants, steams, leafs, cladodes, fruits, flowers or a mixture of them. A screening of AA was completed with TLC method against $DPPH^+$ whereas TP was made with Folin-Ciocalteu reagent. FV and HA were determined by HPLC. Results showed that all the extracts displayed AA, though the pronounced effects have a positive relation with TP content. TP, HA and FV were found in higher means on fruits and flowers while the lowest were achieved by stems, cladodes and leaves. TP ranged from 0.077 for *O. hyatacanta* cladodes to 38.20 g of gallic acid/100g for *A. farnesiana* fruits. Besides, fruits of *P. laevigata* reported the top value of caffeic acid while *B. repens* achieved the greatest cinnamic acid mean. Epigallocatequin accounted the highest concentrations in *O. hytiacantha* prickly pears. Further investigations to clarify the possible implications of plant bioactives on animal husbandry and productivity are necessary.

Key Words: grazing, antioxidant activity, plant bioactives

M385 The effects of high pressure steam treatment on some chemical and physical characteristics of sugarcane pith. M. Chaji*[1], A. A. Naserian[2], R. Valizadeh[2], and T. Mohammadabadi[1], [1]*Ramin Agricultural and Natural Resources University*, *Ahwaz, Khuzestan, Iran*, [2]*Ferdowsi University of Mashhad*, *Mashhad, Khorasan Razavi, Iran*.

The nutritional characteristics of the steam treated sugarcane pith were determined by physico-chemical properties. High-pressure steam-treated sugarcane pith was prepared at 19 bar for 3 min (70% moisture) in a Monel pressure vessel (Emamkhomeini Co., Khuzestan-Iran). Functional specific gravity (FSG) was measured by pycnometeric method; a hydration solution prepared from rumen liquor was used. Water holding capacity (WHC) of feedstuffs was measured using filtration method; the samples were filtered through Whatman No. 1 filter paper. The wet sample was weighed after letting water decant for 10 min. WHC was the quantity of water retained by the sample and expressed as mg/ml sample dry matter. A 100 mL glass graduated cylinder was filled with sample and swirled for 15 s., bulk density (BD) was equal to the weight of sample (mg) over the volume occupied (ml). Steam treatment resulted in a significant decrease in NDF, 77 vs. 55%; hemicellulose to cellulose ratio, 0.54 vs. 0.10, and increase degradation of hemicellulose. Using the steam pressure improved the physical properties of sugarcane pith by increasing the BD, 0.20 vs. 0.31 mg/ml and FSG, 0.3 vs. 0.57 g/ml and decreasing WHC, 2.5 vs. 2.1 mL/g. Steam-pressure treatment may improve the nutritional value of sugarcane by-product for ruminants, and also the physical properties might explain some behaviors of the feedstuffs in rumen which are not recognizable by the chemical approach.

Key Words: functional specific gravity, water holding capacity, bulk density

M386 Effects of chemical treatment on the digestibility of corn stover in diets with modified distillers grains with solubles. J. L. Anderson*[1], J. R. Russell[1], D. D. Loy[1], N. A. Pyatt[2], M. J. Cecava[2], and P. H. Doane[2], [1]*Iowa State University*, *Ames*, [2]*Archer Daniels Midland*, *Decatur, IL*.

Two sheep metabolism trials were conducted to investigate the effects of chemical treatment on the DM digestibility of corn stover in diets with modified distillers grains with solubles (MDGS). Chopped corn stover was either untreated (C) or treated with anhydrous ammonia at 3% (NH3) or calcium oxide at 5% (CaO; DM basis) at either a low (27%; LM) or high (36%; HM) moisture concentration and ensiled in 115-l barrels for 6 mo at ambient conditions. Post-ensiling, each stover was

ground through a 2.54-cm screen. In Exp 1, wether lambs (42 kg) were used in a 6 × 6 Latin-square design to evaluate stover silages at 30% (DM basis) in diets with 65% MDGS and 5% of a corn-based supplement. In Exp 2, wether lambs (43 kg) were used in a 7 × 7 Latin-square design to evaluate the effects of stover inclusion level in MDGS diets. The control consisted of 10% corn silage (CS), 40% MDGS, and 50% of a corn-based supplement (DM basis). Treatments consisted of the HM-C or HM-CaO stover silages fed at 10, 20, and 35% of diet DM with the balance of the diet as MDGS (40, 50, and 60%) and a corn-based supplement (50, 30, and 5%) of the DM. Both trials had a 10-d adjustment phase when all diets were limit-fed at 1.5x maintenance for the least digestible diet and a 5-d collection phase when amounts fed were adjusted for orts collected during the adjustment period. Apparent DM digestion (g/d and %; $P < 0.05$) for LM-C, HM-C, LM-NH3, HM-NH3, LM-CaO, and HM-CaO diets were 473, 67.5; 478, 66.1; 572, 70.1; 551, 71.5; 548, 72.3; and 595, 74.3, respectively. In Exp 2, apparent DM digestion (g/d and %; $P < 0.05$) were 760, 83.1; 686, 80.9; 629, 78.4; 593, 74.5; 682, 78.5; 461, 64.1; and 544, 69.1 for the CS, 10% HM-C, 10% HM-CaO, 20% HM-C, 20% HM-CaO, 35% HM-C, and 35% HM-CaO diets, respectively. Treatment with 5% CaO at a high moisture concentration is more effective than anhydrous 3% NH3 in the improvement of corn stover digestibility.

Key Words: corn stover, alkali treatment, digestibility

M387 Partial replacement of corn silage and alfalfa silage with Italian ryegrass silage in diets of high producing dairy cows. J. T. Woolever* and D. K. Combs, *University of Wisconsin-Madison*.

Two experiments were conducted to evaluate milk yield and milk composition when high quality Italian ryegrass silage was used as a source of digestible fiber and digestible energy in rations of high producing dairy cows. In experiment I, 6 pens of 8 animals were randomly assigned to a control diet (n = 3) or a treatment diet (n = 3) in a 6-week crossover design (3 weeks/treatment). In experiment II, 10 pens of 8 animals were assigned to the same control diet (n = 5) or the same treatment diet (n = 5) in a randomized complete block design. In both experiments, control diet consisted of alfalfa silage (25% of diet DM), corn silage (25% of diet DM), high moisture corn (30% of diet DM) and concentrate. Treatment diet included alfalfa silage (16% of diet DM), corn silage (17% of diet DM), ryegrass silage (18% of diet DM), high moisture corn (30% of diet DM) and concentrate. Diets were formulated to be iso-nitrogenous and iso-caloric, but the treatment diet contained less nonfiber carbohydrate (NFC) (46.5% vs. 48.5%) and more NDF (26.9% vs. 24.8%) as a % of DM. Milk yield and milk components were collected over the course of both experiments. In experiment I, cumulative milk yield was unaffected by diet (7,196 kg control vs. 7,003 kg treatment, $P > 0.40$). Pens of cows consuming the ryegrass diet had higher milk fat levels in experiment I (3.75% vs. 3.60%, $P < 0.05$). Cumulative 4% fat corrected milk yield was similar for control and treatment groups (7,321 kg vs. 7,301 kg). Other milk components did not statistically differ between periods or diets. Cumulative milk yield was similar between treatment groups during experiment II (118,842 kg vs. 118,724 kg, $P > 0.98$). Milk composition and 4% fat corrected milk yield did not differ due to treatment in experiment II. Rations including ryegrass silage can produce similar levels of milk and fat corrected milk compared with more traditional high NFC diets containing high levels of corn and alfalfa silages. Including grass in dairy rations appears to be a feasible method to reduce the NFC level of early lactation diets and increase levels of dietary fiber.

Key Words: Italian ryegrass, grass silage, NDF digestibility, NDFD

M388 Effect of a live yeast, *Saccharomyces cerevisiae* I-1077 on in situ ruminal degradation of alfalfa hay and fiber-associated microbes. F. Chaucheyras Durand[1,2], A. Ameilbonne[1,2], N. D. Walker*[1], P. Mosoni[2], and E. Forano[2], [1]*Lallemand Animal Nutrition*, *Blagnac, France*, [2]*INRA*, *Saint-Genes Champanelle, France*.

In ruminants the digestion of plant material is performed by a complex symbiotic relationship of rumen microbiota. However, the chemical composition and the physical structure of the plant material limit the efficacy of degradation. Also, fibrolytic microbial activities may be depressed under certain dietary conditions, as with ruminal acidosis. Our aim was to investigate effects of a live yeast, *S. cerevisiae* I-1077, on in situ ruminal degradation of alfalfa hay under non-acidotic conditions. We also measured the population levels of bacteria and fungi associated to feed particles by qPCR. Three rumen cannulated cows were fed with grass silage and meadow hay. A first period of 4 weeks without yeast (-SC) was followed by a second 4 week-period (+SC) during which the cows received daily 10^{10} cfu of *S. cerevisiae* I-1077. Nylon bags containing 5g of chopped alfalfa hay were incubated in the rumen for 2, 6, 12 and 24 h. Bags were removed from the rumen, washed, dried and residual NDF determined. *F. succinogenes, B. fibrisolvens* and anaerobic fungi were quantified by PCR. The live yeast induced a significant increase in alfalfa DMd and NDFd (Table 1). The rate of degradation was particularly stimulated. The early colonisation of alfalfa particles by anaerobic fungi appeared to be improved; the populations of *B. fibrisolvens* were greatly promoted whatever the incubation time of the bags, whereas *F. succinogenes* populations, which were dominant, were not influenced by yeast supplementation. In conclusion, the daily distribution of *S. cerevisiae* I-1077 significantly improves alfalfa hay degradation in the rumen and affects feed particle associated microbial populations.

Table 1. Effects of *S. cerevisiae* I-1077 on alfalfa hay degradation and particle associated microorganisms

M389 Evaluating the effect of an active dry yeast on fiber digestion in vitro and *in situ*. N. D. Walker* and M. E. Quintino Cintora, *Lallemand Animal Nutrition*, *Montreal, QC, Canada*.

The aim was to measure the effect of adding live yeast CNCM I-1077 (LSC) on fiber digestion kinetics by rumen microorganisms in vitro and in situ. For the in vitro studies, rumen contents were removed from 3 fistulated lactating dairy cows fed 50% forage:50% concentrate, DM basis, pooled and strained (SRF). SRF was mixed with anaerobic buffer (1:4) and added to 4 jars (2 control, 2 treatment) containing filter bags with a known weight of substrate and incubated in a Daisy fermentor. LSC was added at 1×10^6cfu/mL incubation. Substrates tested were corn silage (CS), wheat silage (WS), alfalfa silage (AS), grass silage

(GS), alfalfa hay (AH), hay (H) and straw (S). Bags (3) were removed at 0,3,6,12 and 24h and analyzed for %NDFd. Incubations were repeated on 2 different days. In vitro data showed that yeast supplementation significantly increased %NDFd for CS ($P < 0.01$), WS ($P < 0.05$), AS ($P < 0.05$), GS ($P < 0.05$) and AH ($P < 0.05$). At 12h, %NDFd was significantly increased for S ($P < 0.05$), however no significant effect was observed on H. In a second part of the study, nylon bags containing the same samples of CS, WS, AS, AH and H, were placed in the rumen of the donor animals and incubated for 0, 3, 6, 12, 24, 48 and 96h and analyzed for %DM and %NDF losses. At the same time, rumen contents were removed from each animal and used to set up corresponding Daisy fermentors. Due to limitations with the number of fermentor jars, only CS, WS and AS were tested. Animals were then fed LSC (1×10^{10}cfu/day) for 14 d before the measurements were repeated. Applying Mertens and Loften NDF kinetics model to the in situ data demonstrated that LSC significantly ($P < 0.05$) reduced the lag time for all except AS. The extent of fermentable NDF was increased ($P < 0.05$) for all except WS. The fractional rate was increased for AH ($P < 0.05$), WS ($P < 0.01$) and AS ($P < 0.01$) with LSC supplementation, with the rate being doubled for WS and AS. No correlation existed between the in vitro and in situ results at 24 h, however if LSC had increased the rate in vitro it also increased it in situ. All the data shows that supplementation with LSC can have a positive effect on fiber digestion both in vitro and in situ.

Key Words: yeast, fiber

M390 Influence of Rumensin200 and tallow on the rumen parameters and fiber digestion of dairy cows. H. Castillo, M. Rivas*, D. Dominguez, L. Durán, M. Arana, G. Villalobos, and J. A. Ortega, *Universidad Autonoma de Chihuahua*, *Chihuahua, Chihuahua, Mexico*.

The modification of rumen physical-chemical parameters such as pH and oxidation-reduction potential (ORP) by addition of Rumensin200 and tallow to the TMR of dry and lactating cows was investigated. For this experiment, 4 ruminally fistulated Holstein cows were fed rations based on a 90:10 (dry) and 40:60 (lactating) forage to concentrate ratios. Four treatments were randomly assigned in a 4 × 4 Latin square experimental design as follows: TMR (T1), TMR + 2/3.3 g Rumensin 200(dry/lactating), (T2), TMR + 3,2% DM tallow (T3) and TMR + 2/3.3 g Rumensin 200+ 3.3% DM tallow (T4). The cows were fed ad libitum (0800 and 1500 h) in individual stalls and milked twice daily (0400 and 1300 h). Each of 4 experimental periods had 12 d of conditioning, followed by sampling on d 13 and 15. Samples of ruminal content were taken at 0, 1, 2, 4, 8, 12, 18 and 24 h after morning feeding for DM and NDF digestibility evaluation with standard protocols. Oxidation-reduction potential and pH were measured in rumen with a multiparameter electrode. Statistic analysis of data was done using PROC mixed in SAS. Ruminal pH fluctuated considerably during day and showed a quadratic trend for all treatments ($P < 0.05$), producing wide value ranges as follows: T1 = 6.22–7.02, T2 = 6.27–7.02, T3 = 6.22–6.93, and T4 = 6.03–6.95. However, there were not significant differences among treatments and between dry and lactating stages ($P > 0.05$). The oxidation-reduction potential changed significantly between physiological stages and over time ($P < 0.05$), while exhibiting little variation among treatments. Dry matter digestibility and NDF were not different among treatments ($P > 0.05$). This experiment suggested that the addition of Rumensin200 and tallow lowered the ORP to more negative values and showed a significant difference of this parameter between dry and lactating stages.

Key Words: Rumensin, ORP, pH

M391 Nutrient demand interacts with orchardgrass maturity to affect dry matter intake and yields of milk and milk fat. K. L. Kammes* and M. S. Allen, *Michigan State University*, *East Lansing*.

The effect of dry matter intake in the preliminary period (pDMI) on responses to diets containing orchardgrass silage harvested at 2 maturities were evaluated. Fifteen ruminally cannulated Holstein cows were used in a crossover design experiment with a 14-d preliminary period and 2 18-d treatment periods. During the preliminary period, pDMI of individual cows ranged from 22.9 to 33.4 kg/d and 3.5% fat-corrected milk yield ranged from 30.8 to 58.3 kg/d. Treatments were diets containing orchardgrass silage harvested from one field at either 44.9% (EARLY) or 54.4% NDF (LATE) as the sole forage. Both diets contained 22% forage NDF and 27% total NDF. Main effects of maturity and their interaction with pDMI were tested by ANOVA. There was no main effect of treatment for DMI, however, DMI response to grass maturity tended to depend on pDMI ($P = 0.11$). While cows with high pDMI consumed more EARLY compared with LATE, the reverse was observed for cows with low pDMI. Intakes of organic matter (OM), starch, NDF, and nitrogen were greater for LATE compared with EARLY ($P < 0.05$). LATE increased yields of milk, milk protein, lactose, and solids not fat compared with EARLY. Interactions were detected between grass maturity and pDMI for fat-corrected milk and milk fat yield and concentration with a greater benefit for EARLY compared with LATE as pDMI increased. Rumen pool of indigestible NDF (iNDF) was greater for LATE compared with EARLY (3.63 vs. 2.53 kg, $P < 0.001$), which resulted in greater rumen pools of DM, OM, and NDF. Greater rumen pool size of iNDF for LATE was because of greater iNDF fraction of the forage NDF and a longer ruminal turnover time ($P < 0.05$) compared with EARLY. Rates of passage and digestion of potentially digestible NDF were similar for both treatments ($P > 0.10$). Dry matter intake was likely increasingly limited by rumen fill for LATE compared with EARLY as nutrient demand increased. Greater starch intake for LATE compared with EARLY is consistent with greater yield of milk and decreased yield of milk fat.

Key Words: grass maturity, intake, milk production

M392 High total nonstructural carbohydrates timothy enhanced performance of mid-lactation dairy cows. A. F. Brito*[1], G. F. Tremblay[3], A. Bertrand[3], Y. Castonguay[3], G. Bélanger[3], R. Michaud[3], and R. Berthiaume[4], [1]*University of New Hampshire*, *Durham*, [2]*Université Laval*, *Québec, QC, Canada*, [3]*Agriculture and Agri-Food Canada*, *Québec, QC, Canada*, [4]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*.

We have previously reported that alfalfa cut at sundown [high total nonstructural carbohydrates (TNC)] and harvested as baleage increased milk yield and microbial protein synthesis in late-lactation cows fed only forage. The current study examines the effects of feeding a timothy-based high-TNC TMR on performance of mid-lactation cows. Diets contained (% of DM): 1) 40% PM-cut timothy baleage and 25% PM-cut timothy silage (High-TNC diet) or 2) 40% AM-cut timothy baleage and 25% AM-cut timothy silage (Low-TNC diet). Both TMR contained a common concentrate (35% on DM basis). The High- and Low-TNC TMR contained respectively (% of DM): 16.8 vs. 16.9 CP, 43.3 vs. 44.1 NDF, and 14.2 vs. 13.3 TNC. Six multiparous (MC) and 10 primiparous cows (PC) averaging 135 DIM were blocked by DIM, milk yield, and parity and randomly assigned to treatments in a crossover design. No signicant diet (TNC) x parity interaction was observed. DMI ($P = 0.02$) and yields of milk fat ($P = 0.01$), milk protein ($P = 0.04$), and milk lactose ($P = 0.05$) were all higher in cows fed the High- vs. the Low-TNC diet. Compared with the Low-TNC diet, the High-TNC diet

increased both milk yield ($P = 0.07$) and 4% FCM ($P = 0.03$). Overall, the high-TNC diet enhanced performance of mid-lactation cows fed 35% of dietary concentrate.

Table 1. Performance of cows fed High- vs. Low-TNC diets

	PC			MC			P	
Item	High-TNC	Low-TNC	SED	High-TNC	Low-TNC	SED	TNC	Parity

M393 Modification of the Penn State Particle Separator with 3.18- or 4.76-mm perforated steel sieves to measure physically effective fiber. K. W. Cotanch*, J. D. Darrah, C. S. Ballard, and R. J. Grant, *William H. Miner Agricultural Research Institute*, *Chazy, NY*.

The Penn State Particle Separator (PSPS) 3-sieve system was modified in attempts to better predict physical effectiveness factor (pef) of total mixed rations (TMR), corn silage, and haycrop silage with as-is samples on-farm. The PSPS 1.18-mm wire mesh sieve was replaced with either 3.18-mm (40% open area) or 4.76-mm (32% open area) perforated steel sieve. These sieves are identical to those used in the Z-Box system. Samples were sieved according to standard PSPS protocol using 19-mm, 8-mm, and either the 3.18-mm or 4.76-mm sieve. Samples were sieved in 3 replicates by 2 technicians. Samples were: 25 TMR varying in dry matter, forage-to-concentrate ratio, and forage type (dry hay or silage), 12 corn silages, and 12 haycrop silages. Physical effective factor of as-is sample determined with modified PSPS was compared with pef determined with the standard method of dry vertical sieving with RoTap (proportion of DM ≥1.18 mm). Within forage type, mean bias of pef determined using RoTap and PSPS sieve was calculated. The PSPS sieve with the smallest mean bias (expressed as units of pef) and narrowest 95% confidence interval encompassing zero was deemed to most accurately assess pef. Use of 3.18-mm perforated steel sieve in the PSPS reliably predicts pef of as-is corn silage samples, while the 4.76-mm sieve accurately predicts pef of haycrop silage. The 3.18-mm sieve is slightly more accurate than the 4.76-mm sieve at predicting pef of TMR samples. Modification of the PSPS with perforated steel sieves accurately predicts pef of as-is samples.

Table 1. Mean bias and confidence interval of pef determined using RoTap and PSPS sieve

Forage type	n	Sieve (mm)	Mean bias ± SD	Upper 95% CI	Lower 95% CI
Corn silage	12	3.18	0.020 ± 0.012	0.028	0.013
		4.76	–0.045± 0.020	–0.032	–0.058
Haycrop silage	12	3.18	0.138 ± 0.061	0.176	0.099
		4.76	–0.004 ± 0.082	0.048	–0.056
TMR	25	3.18	0.042 ± 0.076	0.073	0.011
		4.76	–0.047 ± 0.065	–0.020	–0.074

Key Words: Penn State Particle Separator, physical effective factor

M394 Effect of the level of forage and monensin on *trans*-18:1 isomers and CLA in milk. R. Mohammed*[1], J. J. Kennelly[1], and J. K. G. Kramer[2], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*Guelph Food Research Centre*, *Guelph, Ontario, Canada*.

Milk fat *cis*9, *trans(t)*11-conjugated linoleic acid (CLA) is well known for its anti-cancer effects in animal models. This study reports the effect of the level of forage (F), monensin (M) and its interaction (F×M) on t-18:1 isomers and CLA in milk. Forty Holstein cows in mid-lactation were assigned to 4 diets in a 2 × 2 factorial arrangement of treatments. Treatments were 2 levels of forage (60% or high forage, HF and 40% or low forage, LF) and 2 levels of monensin per kg DM (0 ppm or M- and 16 ppm or M+). All diets were supplemented with sunflower seed (3.6% DM). Milk samples were collected at the end of 2nd and 4th week during treatment and again at the end of 2nd and 4th week after monensin-withdrawal. During treatment, milk *t*10–18:1 (% total FAME) was 0.70^{b}, 0.79^{b}, 0.71^{b}, and 1.2^{a}, for HFM+, HFM-, LFM+ and LFM- respectively (SEM = 0.09; *P*-values for F = 0.03, M =< 0.01 and F×M = 0.04). Milk *t*11–18:1 content was 1.2, 1.3, 1.2 and 1.7 for HFM+, HFM-, LFM+ and LFM- respectively (SEM = 0.13; P-values for F = 0.07, M = 0.02 and F×M = 0.08) and CLA content was 0.61, 0.77, 0.70 and 0.98 for HFM+, HFM-, LFM+ and LFM-, respectively (SEM = 0.06; *P*-values for F = 0.02, M <0.01 and F×M = 0.34) during treatment. After monensin withdrawal, the main effects and interaction for milk t10–18:1 was not different. Milk *t*11–18:1 content was 0.94, 1.1, 1.2 and 1.3 for HFM+, HFM-, LFM+ and LFM- respectively (SEM = 0.09; *P*-values for F = 0.02, M = 0.14 and F×M = 0.85) and CLA content was 0.50, 0.64, 0.63 and 0.67 for HFM+, HFM-, LFM+ and LFM-, respectively (SEM = 0.04; *P*-values for F = 0.05, M = 0.02 and F×M = 0.15) after monensin-withdrawal. Conclusions: This study demonstrates the role of low forage diet in enhancing milk CLA and *t*11–18:1. Monensin supplementation at 16 ppm did not favor greater *t*11–18:1 and CLA. However, its presence reduced the shift to *t*10–18:1, particularly for the LF diet. Monensin effects on milk fat *t*10- and *t*11–18:1 did not persistent in the monensin-withdrawal period.

Key Words: forage level, monensin, CLA

M395 Comparison between the Penn State Particle Separator and the Z-Box to estimate the peNDF content of dairy cow rations. A. S. Atzori*, P. Carta, and A. Cannas, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Sardinia, Italy*.

Optimal particle size distribution in TMR requires field monitoring. Two field sieving devices to assess physical effective NDF content (peNDF) of dairy cattle rations, the Penn State Particle Separator (PSPS), made by 3 sieves, and the Z-Box (ZB), made by 1 sieve, were compared with a reference method. Samples from 2 different diets for lactating cows (34.1 ± 1 and 39.1 ± 1% of NDF on DM basis for rations 1 and 2, respectively) were collected from the beginning, middle and end of feeding alleys. The ration peNDF (25.3 ± 1 and 28.1 ± 1% of DM) was determined by dry sieving the diets with the laboratory reference method of Mertens (1997). Rations peNDF were hence obtained by sieving the as fed diets using the PSPS (1.5 L sample) and the ZB (0.25 L sample) following the indications of the producers. TMR distribution homogeneity was evaluated measuring the differences in peNDF in the 3 points of the feeding alley. Results were compared with a monofactorial ANOVA. The PSPS and ZB differed in peNDF estimations within diet ($P < 0.01$). The PSPS estimates of peNDF (27.4 ± 1 and 33.6 ± 1% of DM, for rations 1 and 2, respectively) were higher than the laboratory values, but the differences were significant ($P < 0.05$) only for ration 2, the most fibrous. The ZB estimates of peNDF (20.6 ± 1 and 24.6 ± 1% of DM for ration 1 and 2, respectively) were only numerically ($P >$

0.1) lower than the laboratory values. For both devices, increasing the quantity of sieved sample (1.0, 2.0, 3.0 L for PSPS; 0.15, 0.35, 0.45 L for ZB) resulted in increased peNDF concentration. Regarding TMR distribution homogeneity, both PSPS and ZB were able to detect the small differences in peNDF content (<8%) that occurred within feeding alley. The PSPS was also able to detect, due to the use of 3 sieves, large differences (>50%) in homogeneity within feeding alley for large particles (>8 and 19 mm). In conclusion, the 2 field sieving methods tested gave different values of peNDF compared with the reference method. Their accuracy was also affected by dietary NDF concentration.

Key Words: peNDF, PSPS, Z-Box

M396 Effects of methionine analogues on rumen fibrolytic activities and fibrolytic microorganisms. E. Devillard*[1], C. Martin[2], D. Morgavi[2], E. Forano[2], and P. Mosoni[2], [1]*Adisseo SAS*, *03600 Commentry, France*, [2]*INRA de Theix*, *63122 St Genes Champanelle, France*.

Milk performance can be improved by balancing rations with methionine (Met) analogs, HMB and HMBi [2-hydroxy-4-(methylthio)-butanoic acid and its isopropyl ester, respectively]. It has been suggested that all the HMB and part of the HMBi act in the rumen through improving organic matter digestibility and fiber degradation, partially explaining improvements in milk performance. The aim of the present study was to investigate the effects of HMB and HMBi on rumen activities and rumen microbial populations, with a special emphasis on fibrolytic activities and fibrolytic microorganisms. Six rumen-cannulated Holstein cows fed a wheat/hay (50/50) diet were used in 3 × 3 Latin square design with 2 animals per block. Treatments were supplementation or not with HMB or HMBi (14 g equivalent Met per day). Each period of treatment consisted in 3-week adaptation followed by 8 weeks of experimentation. Under our experimental conditions, supplementation with HMB and HMBi had no effect on rumen carboxymethylcellulase and xylanase activities, in sacco degradability of maize grain and maize silage, ammonia and total volatile fatty acid concentrations. However, a decrease in acetate/propionate ratio was observed with both Met analogs ($P < 0.05$) due to a numerical increase in propionate concentration. The concentrations of total protozoa (counted by microscopy), total bacteria and 2 fibrolytic bacteria *Fibrobacter succinogenes* and *Ruminococcus albus* (quantified by qPCR), were not affected by the supplementations. Conversely, the concentration of the fibrolytic bacterium *Ruminococcus flavefaciens* increased by 1.7 fold in the presence of both Met analogs ($P = 0.03$). In addition, *R. flavefaciens* was also found to better colonize maize silage and maize grain with HMBi (2 fold, $P = 0.01$). In conclusion, both Met analogs stimulate *R. flavefaciens* population but only HMBi increases *R. flavefaciens* attachment to feeds. The modes of action of the 2 sources of Met on fibrolytic populations still require further investigation.

Key Words: rumen, methionine, fibrolytic microorganisms

M397 Effect of soybean hulls levels on ruminal parameters of dairy cows grazing elephant grass. J. C. Martinez*[1,3], T. V. Voltolini[4], A. V. Pirez[2], and F. A. P. Santos[2], [1]*São Paulo State University*, *Jaboticabal, São Paulo, Brazil*, [2]*São Paulo University*, *Piracicaba, São Paulo, Brazil*, [3]*University of California*, *Davis,* [4]*Embapa Semi-árido*, *Petrolina, Pernambuco, Brazil*.

The trial evaluated soybean hulls (SH) inclusion on concentrate supplements offered to lactating cows grazing Elephant Grass during the rainy season. Trial was conducted at Animal Sciences Department, USP/ESALQ, Piracicaba/SP-Brazil. Twelve multiparous Holstein (509 kg LW, 90 DIM at trial beginning) were used on a replicated 4 × 4 Latin Square design. Data were analyzed by MANOVA and GLM procedures of SAS (2002). Animals were kept on a 4.6ha pasture area divided in 25 0.2ha paddocks fertilized with 80 kg N ha/month. All concentrates had 19% crude protein (CP) and were soybean and ground corn based. SH substituted 20, 50 and 75% of corn on experimental treatments. The microbial N was analyzed by HPLC, and VFA by photometry. Treatments did not affect ruminal VFA (123.5 m*M*), ammonia (26.9 mg/dL) concentrations, ruminal pH (6.33), and microbial N flux (183.0 g N/day) (Table 1). Results indicate that SH can be utilized as a replacement for corn on lactating cows rations with no effects on rumen fermentation parameters.

Table 1. Ruminal parameters of dairy cows supplied with different levels of soybean hulls

	Treatments					
	Corn	25%SH	50%SH	75%SH	Mean	Pr(t)
C2, mM/mL	71.6	76.4	69	71.2	71.3	.87
C3, mM/mL	37.2	31.8	27.4	31.7	32	0.09
C4, mM/mL	16	15.8	13.4	13.8	14.8	0.32
Iso-C4, mM/mL	1.23	1.33	1.26	1.09	1.23	0.08
C5, mM/mL	1.7	1.62	1.47	1.57	1.59	0.24
Total VFA, mM/mL	130.6	126.7	115.1	121.6	123.5	0.42
NH3, mg/dL	28.5	25.2	27.1	26.7	27	0.12

M398 Effects of crude protein levels in the supplementation of dairy cows grazing elephant grass on milk yield and composition. M. A. C. Danes*, F. A. P. Santos, L. J. Chagas, J. R. R. Dorea, and A. M. Pedroso, *University of Sao Paulo*, *Piracicaba, Brazil*.

The experiment was conducted to evaluate the effects of crude protein (CP) levels in grazing dairy cow rations on milk yield and composition. Thirty-one Holstein and crossbred (Holstein × Jersey) cows averaging 120 d in milk (DIM) were fed 3 levels of crude protein in the concentrate supplement for 72 d. Cows were blocked by breed, parity, DIM and milk yield into 11 incomplete groups of 3 cows and randomly assigned to dietary treatments. Concentrates contained fine ground corn, minerals, vitamins and 3 CP levels (8.7, 13.4 and 18.1% DM) were achieved by replacing corn with soybean meal. Grazing management was intensive, with high levels of nitrogen fertilizer and high stocking rate. Cows were allotted to a new paddock every day, after the afternoon milking, and received the concentrate individually twice a day before each milking, at a 1 kg concentrate/3 kg milk ratio. Milk yield was registered weekly, and milk, concentrates and pasture samples were taken weekly. The data were analyzed as an incomplete randomized blocks design. The average crude protein content of the Elephant grass was 18,5% DM. Increasing the CP level of the concentrate had no effect on milk yield, which was 19.5, 19.4 and 19.1 kg/d for 8.7, 13.4 and 18.1% CP concentrate respectively. There was no difference in protein, fat, and casein content of milk among treatments. Milk fat, protein and casein content average values were 3.5%, 3.3% and 2.6%, respectively. Milk urea nitrogen (MUN) increased linearly ($P < 0.01$) from 8.4 to 10.3 and 13.1 mg/dL as the CP level of the supplement increased from 8.7 to 13.4 and 18.1%. Under the conditions of this study, yields of milk and milk protein were not increased by feeding protein supplement for dairy cows grazing highly

fertilized tropical grasses. The linear increase in MUN resulted from an excessive nitrogen (RDP) supply in the diet.

Key Words: grazing dairy cows, protein supplementation, tropical pasture

M399 Effect of soybean hulls levels on performance of dairy cows grazing elephant grass. J. C. Martinez*[1,3], T. V. Voltolini[4], and F. A. P. Santos[2], [1]*São Paulo State University*, *Jaboticabal, São Paulo, Brazil*, [2]*São Paulo State University*, *Piracicaba, São Paulo, Brazil*, [3]*University of California*, *Davis,* [4]*Embrapa Semi-árido*, *Petrolina, Pernambuco, Brazil*.

The trial evaluated soybean hulls (SH) inclusion on concentrate supplements offered to lactating cows grazing Elephant grass during the rainy season. Trial was conducted at Animal Sciences Department, USP/ESALQ, Piracicaba/SP-Brazil. Twelve multiparous Holstein (509kg LW, 90 DIM at trial beginning) were used on a replicated 4 × 4 Latin Square design. Data were analyzed by GLM procedures of SAS (2002). Animals were kept on a 4.6-ha pasture area divided in 25 0,2ha paddocks fertilized with 80 kg N ha/month. All concentrates had 19% crude protein (CP) and were soybean and ground corn based. SH substituted 20, 50 and 75% of corn on experimental treatments. Cows received concentrate according to milk production on a 1:3 basis, fixed at trial beginning, twice daily after each milking. No differences were observed among treatments ($P > 0.05$) for milk production. Treatments did not affect milk fat, protein, lactose, total solids and urea concentrations ($P > 0.05$) (Table 1). As complement, the live weight (LW) (516 kg), body condition score (BCS) (2.2), plasma urea (31.8 mg/dL) and nonesterified fatty acids (NEFA) (358.2 mEq/L) concentrations were not affected by treatments ($P > 0.05$). Results indicate that SH can be utilized as a replacement for corn on lactating cows rations with no effects on milk production and composition, LBW and blood composition.

Table 1. Milk yield and composition of dairy cows feed with different levels of soybean hulls

	Treatments					
	Corn	25%SH	50%SH	75%SH	Mean	Pr>(t)

M400 Evaluation of starch digestibility and physico-chemical properties of Monsanto corn hybrids. D. Ngonyamo-Majee*[1], P. Feng[2], J. Hinen[1], G. Hartnell[1], B. Kutzner[1], M. Brandt[1], and M. Stephens[1], [1]*Monsanto Company*, *St. Louis, MO,* [2]*Monsanto Company*, *Ankeny, IA*.

The negative correlation between corn vitreousness vs. starch availability and milk production potential has been widely reported in US and Europe. Two studies were conducted in 2006 and 2007 to determine the variability of Monsanto corn germplasm on kernel physico-chemical properties and their influence on ruminal starch degradability (RSTARCHD). Samples (30 hybrids in 2006 and 44 hybrids in 2007) for both studies were sourced from various Monsanto locations where the particular hybrid background is recommended. The decision to cover diverse germplasm background and different locations ensured we develop a more robust near infrared reflectance (NIR) calibration. The hybrids were all harvested at R6 stage (black layer). The samples were split into 2 sets. One set was used for whole kernel analyses; vitreousness (visual procedure), 1000-kernel weight, density (water displacement procedure) and NIT predictions of starch and protein. The other set was ground through a 6 mm Wiley grinder and processed for determination of in vitro ruminal starch degradability using the Daisy II procedure. Results from these studies showed wide genetic variability on RSTARCHD and physico-chemical traits. Negative correlations were observed between RSTARCHD and kernel protein ($r = -0.79$), density ($r = -0.30$), and vitreousness ($r = -0.42$). A positive correlation was observed with extractable starch ($r = 0.76$). The data generated NIR calibration with RSTARCHD ranging from 50.3 to 66.3% (mean 56.6 ± 3.33%). The calibration statistics were within acceptable range ($R^2 = 0.83$; standard error of calibration = 1.36 and standard error of cross validation = 1.67). We are continuing to expand the calibration with more diverse germplasm and locations.

Key Words: corn starch, rumen degradability, vitreousness

M401 Growth performance of Bluchi female lambs fed by diets containing different levels of date palm leaves. R. Valizade, A. Salahi*, and M. Mahmodi, [1]*Ferdowsi University*, *Mashhad, Iran*.

The objective of present study was to evaluate the effect of diets containing date palm leaves (DPL) fed to Baluchi female lambs in a completely randomize design on growth performance. The study was carried out with 24 female Iranian Baluchi lambs of 4–5 mo of age and average body weight (BW) of 20.48 ± 4.9 kg, and lambs were allocated to 4 dietary treatments in a feedlot condition. All lambs were given a TMR composed of 39% forage (Alfalfa hay (15%), and wheat straw or DPL) and 61% concentrate (corn grain 45%, soybean meal 15%, limestone 0.4%, premix 0.4%, and salt 0.2%). The dietary treatment were 1) wheat straw (24%), 2) wheat straw (16%), DPL (8%), 3) wheat straw (8%), DPL (16%), 4) DPL (24%). The experiment was conducted for 76 d and data were analyzed using the PROC MIXED procedure (repeated measurement) of SAS (version 9.1; SAS Institute Inc., Cary, NC). Average daily feed intake by the lambs in different treatment were 857, 918, 986, and 1035 g/d, respectively. The difference between all means was significant ($P < 0.05$). Lambs fed by 1 dietary treatment were lower average daily body weight gain (g/day) than other groups. Average daily gains of lambs on dietary treatments of 1, 2, 3 and 4 were 106,143, 156, and 165 g/d, respectively. The best feed conversion ratio was also recorded for the lambs on diet containing 24% DPL (6.16 kg feed consumed per kg of weight gain). The obtained data at Feed intake on metabolic weight (69.3, 69.1, 75.6 and 74.5 g/kg W0.75) differed significantly. Ruminal pH (6.64, 6.55, 6.56 and 6.53); ruminal NH3 (13.12, 12.4, 11.12 and 10.38 mg/100mL); blood urea nitrogen (19.27, 20.74, 20.36 and 20.09 mg/dl); blood glucose (71.62, 60.31, 67.2 and 62.6 mg/dl) were into the normal ranges. It was concluded that inclusion of DPL can be beneficial mainly for smallholder farmers during periods of low rainfall and forage scarcity.

Key Words: date palm leaves, Bluchi female lambs, growth performance

M402 Effect of date palm leaves substitution with wheat straw on health and rumen parameter of Saanen dairy goats. A. Salahi*, R. Valizade, A. Naserian, and A. Tahmasbi, *Ferdowsi University*, *Mashhad, Iran*.

This experiment was conducted to determine the effect of date palm leaves (DPL) feeding on the blood parameter of Saanen dairy goat. Nine lactating dairy goats were randomly assigned to treatment in a 3 × 3 Latin squares design. All goats were given a TMR composed of 40% forage and 60% concentrate (corn grain 26%, cotton seed meal 15%, sugar beet pulp 15.5, wheat bran 2%, limestone 0.5%, premix 0.5%, salt 0.5%). The dietary treatment were 1) alfalfa hay (20%), wheat straw (20%) 2) alfalfa hay (20%), DPL (20%) and 3) alfalfa hay (20%), treated (4% urea) and ensiled DPL (20% DM basis). The experiment lasted for 63 d (3 periods of 21 d which 15 d for diet adaptation and last 7 d for data collection). Goats were individually fed twice daily at 07:00 and 15:00. Data were analyzed using General Linear Models procedure of SAS 9.1 for ANOVA to evaluate difference among experimental groups, mean compared with Duncan test. Average dry matter intake by the goats in different treatment were 2055, 2055, and 1794 g/d, respectively. The difference between there means was significant ($P < 0.05$). Ruminal pH (6.43, 6.41, 6.24); ruminal NH3 (23.8, 22.9, 19.00 mg/100 mL); blood urea nitrogen (20.2, 20.2, 18.9 mg/dL); blood glucose (39.1, 38.5, 40.1 mg/dL); blood Cholesterol (79.7, 79.7, 79.1 mg/dL) were into the normal ranges. Although no differences were detected between these figures, the obtained data on blood triglyceride (6.9, 12.2, 9.9 mg/dL) differed significantly. The studied parameters in this experiment support inclusion of DPL into the diets for dairy goats in a dry area with poor vegetation and rainfall.

Key Words: date palm leaves, Saanen dairy goat, blood parameter

M403 Milk production and composition of Saanen dairy goat fed by ration containing date palm leaves. A. Salahi*, R. Valizade, A. Naserian, and A. Tahmasbi, *Ferdowsi University*, *Mashhad, Iran*.

Date palm leaves (DPL) is one of the most abundant agricultural by-products in south of Iran were fed to 9 Saanen dairy goat in a 3 × 3 Latin square design. All goats were given a TMR composed of 40% forage and 60% concentrate (corn grain 26%, cotton seed meal 15%, sugar beet pulp 15.5, wheat bran 2%, limestone 0.5%, premix 0.5%, salt 0.5%).The dietary treatment were 1) alfalfa hay (20%), wheat straw (20%) 2) alfalfa hay (20%), DPL (20%) and 3) alfalfa hay (20%), treated (4% urea) and ensiled DPL (20% DM basis). The experiment lasted for 63 d (3 periods of 21 d which 15 d for diet adaptation and last 7 d for data collection). Data were analyzed using General Linear Models procedure of SAS 9.1 for ANOVA to evaluate difference among experimental groups, mean compared with Duncan test. Average dry matter intake by the goats in different treatment were 2055, 2055, and 1794 g/d, respectively. The difference between the means was significant ($P < 0.05$). Average milk production by the goats in different treatments were 1375, 1389 and 1381 g/d, respectively. The difference among there means as well as other milk constituents (fat, protein, and lactose) was not significant. Although no differences were detected between these figures, the obtained data on BUN (11, 11, 15.5 mg/dL) differed significantly. Total solid of the milk produced by goats in different treatments were 10.34, 10.63, and 10.8%, respectively. Total cell counts of the milk samples were 241, 314, and 537cell per mL, respectively. The difference among there means also was not significant. It was concluded that DPL can be fed to such animals without any adverse effects.

Key Words: date palm leaves, Saanen dairy goat, milk parameter

M404 Effects of an alfalfa feeding strategy in the first week postpartum on feed intake and ketogenic status in transition cows. M. Larsen* and N. B. Kristensen, *Faculty of Agricultural Science, Aarhus University*, *Tjele, Denmark*.

Feeding additional forage fiber to fresh cows is believed to secure good rumen function. Thirteen multiparous Holstein cows were used in a randomized block design to study the effects of an alfalfa feeding strategy to postpartum transition dairy cows on dry matter intake (DMI) and ketogenic status. At calving, cows were randomly assigned to 1 of 2 ad libitum fed total mixed diets: a control lactation diet (CTRL) or an alfalfa haylage lactation diet (ALFA) for the first week postpartum. From wk 2 to 4 postpartum, all cows were fed CTRL. The CTRL was composed of (dry matter basis) 35% corn silage, 25% grass-clover silage, 20% rolled barley and 20% concentrate mix. The ALFA diet was composed of 50% CTRL diet and 50% alfalfa haylage. Forage NDF was 19.1% in CTRL and 30.1% in ALFA. Blood was sampled at 14 d prepartum and at 4, 15, and 29 d in milk (DIM). The statistical model included block, treatment, DIM and treatment × DIM, where DIM within cow was considered as a repeated measure. In the first week postpartum, DMI was unaffected by treatment ($P = 0.41$) and averaged 10.5 and 11.5 ± 0.8 kg/d with ALFA and CTRL, respectively. A carry over effect of ALFA was observed during wk 2 to 4 postpartum, where DMI was lower ($P < 0.01$) for cows previously fed AFLA as compared with CTRL (14.4 and 16.4 ± 0.4 kg/d, respectively). The orts percent was higher ($P < 0.01$) with ALFA in the first week postpartum, but did not differ ($P = 0.40$) in wk 2 to 4 postpartum. Milk yield was unaffected by treatment ($P = 0.30$). Blood plasma glucose concentration decreased more ($P = 0.04$) from prepartum to 4 DIM with AFLA as compared with CTRL. Concomitantly, plasma concentrations of acetoactetate+acetone and β-OH-butyrate as well as their ratio tended to increase more ($P = 0.06$ to $P = 0.11$) from prepartum to 4 DIM with AFLA as compared with CTRL. In conclusion, the tested alfalfa haylage feeding strategy did not induce greater DMI in postpartum transition cows. The results showed that high forage feeding strategies for fresh cows increase the risk for hyperketonemia.

Key Words: transition, feed intake, forage fiber

M405 Milk production efficiency improves with addition of an exogenous fibrolytic enzyme to a total mixed ration. L. Holtshausen*[1], Y.-H. Chung[1], H. Gerardo-Cuervo[2], M. Oba[2], and K. A. Beauchemin[1], [1]*Agriculture and Agri-Food Canada*, *Lethbridge, Alberta, Canada*, [2]*University of Alberta*, *Edmonton, Canada*.

Ruminant response to feed enzymes remains variable despite it being well researched in the last couple of decades. This study aimed to determine whether addition of Econase RDE (AB Enzymes, Germany) to a TMR improves productivity of early-lactation dairy cows. Sixty Holstein dairy cows (46 ± 10 DIM) were blocked by parity and randomly assigned to one of 3 treatments for a 10-wk period: 1) Control diet (CTL; no enzyme), 2) Low enzyme (LE; CTL with 0.5 mL Econase RDE/kg TMR DM) and 3) High enzyme (HE; CTL with 1.0 mL Econase RDE/kg TMR DM). Endoglucanase and xylanase activity for Econase RDE was 722 and 2604 nmol/mg enzyme product, respectively. The CTL diet had 21% alfalfa silage, 21% barley silage, 11% alfalfa hay and 47% concentrate (DM basis). Twenty-four hour in situ DM, NDF and ADF degradation of alfalfa and barley silage, with and without enzyme, were determined using 6 cannulated cows. Cows on the CTL diet had a higher DMI ($P < 0.01$) than cows on the HE diet and tended ($P = 0.09$) to have a higher DMI than cows on the LE diet. Fat corrected milk yield and milk composition did not differ. Cows on the HE diet had a greater FCM production efficiency than CTL cows ($P < 0.01$), with that of LE

cows being intermediate and not different from CTL cows ($P = 0.31$). Enzyme addition did not improve in situ DM or NDF degradation of alfalfa or barley silage, but there was a tendency ($P = 0.10$) for greater ADF degradation of alfalfa silage. Greater FCM production efficiency with dietary addition of exogenous fibrolytic enzymes might in part be a result of greater ADF degradation of some feedstuffs, particularly alfalfa.

Table 1. Performance of early-lactation dairy cows and in situ degradation of feedstuffs with the addition of an exogenous fibrolytic enzyme

M406 Effect of different sources of pectin feedstuffs on chewing activities in early lactating Holstein cows. M. Kordi*, A. Naserian, R. Valizade, and A. Tahmasbi, *Ferdowsi University*, *Mashhad, Iran*,

Eight primiparous early lactating Holstein cows (60 ± 23 d postpartum, weighing 530 ± 60 kg) were assigned into a duplicated 4 × 4 Latin square design for evaluation of different pectin feedstuffs on intake and chewing activities of lactating dairy cows with 4 3-wk periods. Cows were allocated into 4 diets whit 1)10% barley grain, 2)10% sugar beet pulp, 3)10% wheat bran and 4) 10% dried citrus pulp . Each experimental period was 21 d including 14 d adaptation period and 7 d collecting samples. Chewing behavior observations were visually recorded every 5 min for 24 h. The time spent for each animal observation was not more than 5 s. Eating, ruminating, and total chewing times were determined and expressed as minutes per day. Time (expressed in minutes) expended in each activity was calculated by the number of observations recorded multiplied by 5. Total chewing time was considered as the sum of eating and ruminating times. Eating, ruminating, and total chewing times were also expressed as minutes per kg of DM and NDF intakes. Chewing activities data are shown in Table 1).There were no differences ($P > 0.05$) in the daily intake of DM (kg/d). Eating behavior as minutes per Kg of DMI were not affected by treatments ($P > 0.05$) but there were significant differences in eating behavior as minutes per kg of NDFI ($P < 0.05$). Similarly there were significant differences on ruminating and total chewing activities between treatment diets ($P < 0.05$). These data suggest that, the addition of sources of pectin feedstuffs at 10% levels (dry matter basis) of the dairy cow ration instead of cereal grain; will decrease the cost of milk production without any negative effect on chewing activities.

M407 Effect of different sources of pectin feedstuffs on blood metabolites in early lactating Holstein cows. M. Kordi*, A. Naserian, R. Valizade, and A. Tahmasbi, *Ferdowsi University*, *Mashhad, Iran*.

This experiment was conducted to determine the effect of different sources of pectin feedstuffs on blood metabolites in early lactating Holstein cows. Eight primiparous early lactating Holstein cows (60 ± 23 d postpartum, weighing 530 ± 60 kg) were assigned into a duplicated 4 × 4 Latin square design with 4 3-wk periods. Cows were allocated into 4 diets whit 1)10% barley grain, 2)10% sugar beet pulp, 3)10% wheat bran and 4) 10% dried citrus pulp . Each experimental period was 21 d including 14 d adaptation period and 7 d collecting samples. Blood samples were collected from the jugular vein 2h after the morning feeding. Blood serum was collected after centrifuged at 1,500 × *g* for 20 min, frozen at – 40°C, and later analyzed for glucose, urea N, cholesterol, triglyceride, alkaline phosphate and albumin. Blood metabolites data and DMI are shown in Table 1.There were no differences ($P > 0.05$) on daily intake of DM (kg/d) (Table 1). Similarly, no treatments effects were observed blood metabolites (Table 1). These data suggest that, the addition of sources of pectin feedstuffs at 10% levels (dry matter basis) of the dairy cow ration instead of cereal grain; will decrease the cost of milk production without any negative effect on DMI and blood metabolites.

M408 Effects of forage family (alfalfa vs. orchardgrass) on apparent ruminal synthesis of niacin and vitamin B6 in lactating dairy cows. M. Seck*[1,3], J. A. Voelker Linton[2], M. S. Allen[2], P. Y. Chouinard[3], and C. L. Girard[1], [1]*Agriculture and Agri-Food Canada*, *Sherbrooke, Quebec, Canada*, [2]*Department of Animal Science, Michigan State University*, *East Lansing,* [3]*Departement de sciences animales, Universite Laval*, *Quebec, Quebec, Canada*.

Effects of forage family on apparent ruminal synthesis and post-ruminal supply of niacin (B3) and vitamin B6 were evaluated using 8 ruminally and duodenally cannulated lactating Holstein cows. The experiment was a crossover design with 2 15-d treatment periods and a preliminary period in which dry matter intake (pDMI) of a diet intermediate in composition between the treatment diets was measured. Treatment diets were formulated to contain 23% forage NDF and contained as sole forage, alfalfa (AL, 43% NDF) or orchardgrass (OG, 48% NDF) silages. Intakes of B3 and B6 were greater ($P \leq 0.01$) for AL than OG (B3: 2337 vs. 847 ± 87 mg/d; B6: 75 vs. 55 ± 4 mg/d) but AL decreased ($P \leq 0.03$) duodenal flows of B3 and B6 compared with OG (B3: 1702 vs. 2508 ± 175 mg/d; B6: 46 vs. 82 ± 11 mg/d for B6). Ruminal synthesis of B3 and B6 was greater ($P \leq 0.01$) for OG compared with AL (B3: 1661 vs. −635 ± 139; B6: 27 vs. −28 ± 9 mg/d). Intakes of B3 and B6 increased with pDMI for AL but not for OG (pDMI × T, $P \leq 0.01$) but duodenal flow of B3 tended to increase with pDMI to a greater extent for OG than for AL (pDMI × T, $P = 0.09$). With increasing pDMI, B3 degradation in the rumen increased for AL but synthesis increased for OG (pDMI × T, $P \leq 0.01$). No interactions between pDMI and treatments were observed for B6 duodenal flow or ruminal synthesis ($P > 0.6$). B3 intake was correlated negatively with ruminal synthesis ($r = -0.9$, $P < 0.01$) and flow ($r = -0.52$, $P = 0.04$) while B6 intake and synthesis were correlated negatively ($r = -0.48$, $P = 0.06$). Mean ruminal pH was correlated negatively with ruminal synthesis ($r = -0.76$, $P \leq 0.01$) and flow ($r = -0.68$, $P \leq 0.01$) of B3 (not B6). Microbial nitrogen flow (g/d) was correlated positively with ruminal synthesis ($r = 0.48$, $P = 0.06$) and flow ($r = 0.6$, $P \leq 0.01$) of B6 (not B3). Forages from different families (alfalfa vs. orchardgrass) altered ruminal fermentation which affected ruminal synthesis and supply of vitamins B3 and B6 to dairy cows.

Key Words: dairy cow, niacin, pyridoxine

M409 Effect of the volatile fraction from silage and forage:concentrate ratio on ruminal degradation of fresh chopped or ensiled sugarcane. J. L. P. Daniel*[1], L. G. Nussio[1], R. C. Amaral[1], S. G. Toledo Filho[1], J. R. Lima[1], E. Cabezas[1], and O. C. M. Queiroz[2], [1]*University of São Paulo, "Luiz de Queiroz" College of Agriculture*, *Piracicaba, SP, Brazil*, [2]*University of Florida*, *Gainesville*.

The objective of this study was to determine whether volatile fermentation end products from silage and forage:concentrate ratio affect the in situ ruminal degradation of fresh chopped or ensiled sugarcane. We hypothesized that ethanol present in the volatile fraction from silage could increase ruminal degradation, and high-concentrate diet could decrease it. Sugarcane was mechanically harvested at 21.5 degrees brix and ensiled in 200 L plastic buckets (experimental silos) without adding any additive. Samples obtained before and after 90 d of storage, were dried at 60oC in a forced air oven, ground at 5 mm, and used to prepare Dacron bags, in triplicate, keeping the ratio 10–20 mg of sample per cm2 of the bag. Six Nelore beef steers were randomly assigned in a replicated 3 × 3 Latin square design with 14-d periods. Steers were fed ad libitum once daily at 0800 h. Dietary treatments were balanced to be isonitrogen content: 75D – 75% sugarcane silage without volatile fraction (dried at 60oC and re-hydrated) and 25% concentrate, 75W – 75% wet sugarcane silage and 25% concentrate, and 40W – 40% wet sugarcane silage and 60% concentrate (DM basis). On d 11 of each period, at feeding time, all bags were positioned into the ventral sac of the rumen during 24 h. Rumen pH was measured each 2 h during 24 h on d 13. Dry matter degradation (DEG24) was determined as the difference between sample and residue weights. Fresh and ensiled sugarcane were compared. DEG24 of fresh sugarcane (55%) was higher ($P < 0.01$) than that of ensiled sugarcane (39%). It was not detected effect ($P = 0.13$) on DEG24 across dietary treatments (averages: 75D = 48%, 75W = 47%, 40W = 45% of DM). Rumen pH was lower ($P < 0.01$) for the high-concentrate diet (75D: 6.65, 75W: 6.71, 40W: 6.33), however, all diets kept favorable rumen environment for digestion. The volatile fraction present in sugarcane silage did not improve the ruminal degradation of DM.

Key Words: volatile organic compounds, ethanol, rumen pH

M410 Performance of lactating crossbreed cows on tropical pasture fed by supplements with soybean meal and Optigen or urea. D. C. Abreu*[1], R. P. Lana[1], A. S. Oliveira[1], F. A. Barbosa[2], F. L. Andrade[1], P. T. Silva[1], and F. A. C. Neto[3], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brasil*, [2]*Universidade de Brasília*, *Brasília, DF, Brasil*, [3]*Colorado State University*, *Fort Collins*.

Sources of nonprotien nitrogen (NPN) are attractive because of their low cost relative to vegetable proteins. Urea is the most commonly used NPN source but is rapidly hydrolysed to ammonia within the rumen and may therefore be used inefficiently by the rumen microbes. This study investigated the performance and nutrient utilization response of crossbreed lactating dairy cows to the substitution of soybeans by 2 sources of non-protein nitrogen. Twenty one crossbreed Holstein-Zebu cows (second or third parity; BW = 499 ± 60,63 kg; DIM = 167 d) grazing *Brachiaria decumbes* pastures were distributed in a 3 × 7 incomplete Latin squares design. Three periods, with 21 d each (samples collected on last 7 d of with period). Within herd, cows were fed by pasture source (ad libitum) and concentrated supplement isonitrogenous with 24% of crude protein, on DM basis (Table 1). The control diet contained a conventional N source (soybean meal; SBM) and others NPN as urea and Optigen. Daily milk production was condensed to weekly averages. Data was analyzed by repeated measures using PROC-MIXED of SAS. There was no effect ($P > 0.05$) of difference source of protein (SBM vs. NPN); interaction of source of NPN and level of NPN; source of NPN (urea vs. Optigen) and level of NPN. For crossbreed Holstein-Zebu cows on tropical pasture, the urea or Optigen can be supplemented and add until 6% of DM of concentrated, without difference in the performance of lactating crossbreed cows.

Table 1. Composition of ingredients of supplement (%, DM basis)

	Source of NPN						
Ingredients, %	control diet	Urea, %			Optigen, %		
		2	4	6	2	4	6
Corn grain	58.50	69.00	79.50	90.00	69.00	79.50	90.00

Key Words: nonprotein nitrogen, Optigen, crossbreed dairy cows

M411 Modeling degradation characteristics and nutrient availability of anthocyanidin accumulating Lc-Alfalfa and alfalfa selected for a low initial rate of degradation in dairy cows. A. Jonker*[1,2], M. Gruber[2], Y. Wang[3], and P. Yu[1], [1]*Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan*, *Saskatoon, SK, Canada*, [2]*Saskatoon Research Centre, Agriculture and Agri-Food Canada*, *Saskatoon, SK, Canada*, [3]*Lethbridge Research Centre, Agriculture and Agri-Food Canada*, *Lethbridge, AB, Canada*.

Protein efficiency of dairy cattle eating alfalfa might be improved by introducing a gene that stimulates the accumulation of anthocyanidin in alfalfa forage. The objective of this study was to determine nutrient availability in the rumen and small intestine of newly developed anthocyanidin accumulating Lc-alfalfa populations by a modeling approach. Three winter hardy alfalfa varieties Rangelander, Rambler and Beaver were crossed with 3 transgenic T0 Lc-alfalfa populations 88–19, 88–09 and 88–01, respectively. The 3 phenotypic purple Lc-progeny used in this study were compared with AC Grazeland (selected for a low initial rate of degradation; LIRD). Alfalfa samples were collected at a vegetative pre-bud stage during the growing season of 2008 (AAFC, Saskatoon, SK, Canada). Data from wet chemical analysis and an in situ trail was used as input for the Dutch 2007 DVE/OEB protein system and VEM energy system to determine nutrient availability from tested alfalfa populations for dairy cows. The results were analyzed in a CRD using the contrast statement in Proc Mixed of SAS. The Lc-alfalfa populations had an average anthocyanidin concentration of 163.4 µg/g DM. The Lc-alfalfa had a lower ($P < 0.05$) undegradable NDF fraction and tendency for a higher ($P < 0.10$) rumen degradable CP and rumen degradable CHO and rumen degraded protein balance compared with LIRD-alfalfa. Total intestinal digestible protein (70.0 vs. 61.9 g/kg DM) tended to be higher ($P < 0.10$) and net energy for lactation was higher ($P < 0.05$; 1.50 vs. 1.42 Mcal/kg) in Lc-alfalfa compared with LIRD-alfalfa. In conclusion, Lc-alfalfa accumulated anthocyanidin and had a higher nutrient availability for the animal for milk production than LIRD-alfalfa.

Key Words: anthocyanidin-accumulating alfalfa, protein and energy models, dairy cattle

M412 Influence of reconstituted and silage sorghum grain on site and extent digestion in finishing cattle. U. A. González[1,3], M. González[1], A. Plascencia[2], and L. Corona*[3], [1]*Universidad Autónoma del Estado de México*, *Toluca, Estado de México,México*, [2]*Universidad Autónoma de Baja California*, *Mexicali, BC, México*, [3]*Universidad Nacional Autónoma de México*, *Cd. Universitaria, DF, México*.

Five calves (average BW: 190 ± 30 kg) with cannulas in the rumen and proximal duodenum were used in a 5 × 5 Latin square design to evaluate the influence of reconstituted and ensiling sorghum grain on nutrient digestion with the following treatments: 1) DCC (dry cracked corn); 2) RCS (reconstituted cracked sorghum); 3) DWS (dried whole sorghum); 4) RWS (reconstituted whole sorghum); and 5) DCS (dry cracked sorghum). The diets contained 73% of grain (% DM). Ruminal digestion of OM was greater ($P < 0.01$) for DWS and RWS (60 ± 1%) compared with others treatments. The higher ($P < 0.005$) ruminal starch digestion was for DWS and RWS (64 and 65% respectively), while N digestion was greater ($P < 0.0004$) for RWS (48%) compared with RCS (40%). Post-ruminal digestion of OM was higher ($P < 0.0001$) for RCS (71%) and starch digestion was greater ($P < 0.05$) for RCS (82%) compared with the other treatments. Total tract digestion of OM was greater ($P < 0.05$) for RCS and RWS (87 and 83%) compared with DCC, RWS and RCS (78 ± 1%); total starch digestion was greater ($P < 0.05$) for RCS (93%) respect to DCC, RWS and DCS (87 ± 1%), and lower for DWS (83%). The ruminal pH was higher ($P < 0.0453$) for DWS compared with RCE and RWS. DCC had the lowest ($P < 0.0084$) ruminal proportion of acetic acid respect to RCS and DCS. Propionic acid production was higher ($P < 0.0235$) for DCC on RCS and DCS. Butyric acid production showed the lowest proportion ($P < 0.021$) for DWS respect RCS and RWS. The ratio acetate: propionate was lower ($P < 0.0085$) for DCC respect the rest of the treatments. The energy values calculated by replacement for RCS, DWS, RWS and DCS corresponded to 4.58, 3.77, 4.14 and 3.71 ED Mcal/kg, respectively. We concluded that the method of processing before restore cracked (RCS) and reconstituted sorghum (RWS) improve their nutritional value due to increase post-ruminal digestion of starch and N.

Key Words: cattle, digestion, reconstituted sorghum

M413 Effect of germinated and ensiling sorghum grain on digestion and ruminal fermentation by feedlot cattle. F. Rodríguez[1], S. E. Buntinx[1], M. E. Ortega[2], and L. Corona*[1], [1]*Universidad Nacional Autónoma de México*, *Cd. Universitaria, DF,México*, [2]*Colegio de Posgraduados*, *Montecillo, Edo. de México, México*.

Five steers (average BW: 400 kg) with cannulas in the rumen and proximal duodenum were used in a 5 × 5 Latin square design to evaluate the influence of sorghum grain germinated and ensiling on nutrient digestion and ruminal fermentation . Treatments consisted of a basal finished diet containing 73% sorghum grain(% DM basis) as: 1) DCS (dry cracked sorghum-0h reconstituted); 2) RWS (reconstituted whole sorghum-24h); 3) GS2 (germinated sorghum 2d-48h); 4) GS4 (germinated sorghum 4d-96h); and 5) GS6 (germinated sorghum 6d-144h). The grain germinated and ensiling was reconstituted to 30% moisture, germinated for 2, 4, 6 d and ensiling for 21d. Post-ruminal digestion of OM was lower (5%,$P < 0.01$) for GS2 than for GS6 and for starch was higher (29.5%$P < 0.10$) for germinated treatments respect to DCS. Geminated tended to increase (linear effect, $P < 0.10$) post-ruminal starch digestion. Total tract digestion was higher for SG6 respect to SG2 for OM (7.22% $P < 0.05$), starch (3.76, $P < 0.10$) and nitrogen (4.06%, $P < 0.05$). DE Mcal/kg was higher ($P < 0.05$) for SG6 (3.72) than for SG2 (3.50). The ruminal pH was lower ($P < 0.10$) for DCS (6.24) respect to GS2, GS4 and GS6 (6.6, 6.5, 6.4 respectively). Germinated treatments increased ($P < 0.1$) molar proportion of acetate (6.73%) and decreased ($P < 0.05$) molar proportion of butyrate. Germinated tended to increase (linear effect, $P < 0.10$) molar proportion of acetate. Germinated increased post-ruminal starch digestion and SG6 had the higher total tract digestion for OM, starch, N and DE value.

M414 Performance of beef heifers finished at pasture in tropical conditions and supplemented with sunflower crushed seeds, in dry season. S. L. N. Cerilo*, R. H. de Tonissi e Buschinelli de Goes, H. L. Lima, K. A. de Souza, A. F. Marquez, T. da Cunha Cornélio, K. A. Guimarães Nogueira, D. de Faria Pereira, E. R. de Oliveira, and A. M. de Araújo Gabriel, *Universidade Federal da Grande Dourados*, *Dourados, MS, Brasil*.

To evaluate the partial substitution of soybean meal for sunflower crushed seeds in the performance of Nellore Heifers, at pastures of *B. humidicula* during the dry season, we used 24 animals, with initial body weight (BW) of 310 kg, with body condition score (BC) of 2.25, divided into paddocks of 3000 m^2, in a completely randomized design. Supplements evaluated were supplied collectively at 0.8% BW/animal/day consisting of corn, soybean meal and mineral, with 20% CP; the soybean

meal was replaced in the proportions of 0, 20, 40, and 60% for sunflower crushed seeds. The estimated ether extract of the supplements were 2.5, 4.7, 7.0, 9.2%, respectively. The animals were weighed every 21 d and monitored for BC (1–5). The average daily gain of animals showed a quadratic response (ADG = 0.2416+0.012x-0.0002x^2, r^2 = 0.99), and the replacement levels of 20 and 40% showed higher daily gains, 0.411 and 0.440 kg/day, while the levels of 0 and 60% had average of 0.242 and 0.320 kg/day. The inclusion of sunflower crushed seeds improved daily gain ($P < 0.10$) (average of 0.390 kg/day), this corresponds to an increase by 60% compared with supplementation with only corn and soybean meal. The efficiency of the use of concentrates (kg gain/kg of supplement) was greater for supplements containing sunflower crushed seeds, 12.26, 13.42 and 9.87% for the replacement levels of 20, 40 and 60% of soybean meal; the supplement without sunflower crushed seeds was efficient to 7.31%, these values can be related to the inclusion of sunflower crushed seeds into the concentrate, changing the energy density. The animal's BC improved with the sunflower crushed seeds, where the animals supplemented had the best initial (2.2, 2.5 and 2.2) and final (4.0, 4.0 and 3.7) body condition, for substitution levels of 20, 40 and 60%. The animals supplemented with corn and soybean, were initial and final body conditions of 2.1 and 3.6. Partial substitution of soybean meal with sunflower crushed seeds improves daily gain and body condition of animals on finishing systems on pasture.

Key Words: supplement, concentrated efficiency, daily gain

M415 Ingestive behavior of grazing Nellore steers supplemented with increased levels of energetic concentrate. J. R. R. Dorea, F. A. P. Santos, A. L. Marra, L. R. D. Agostinho Neto, D. C. Balestrin, M. A. C. Danes*, V. N. Gouvea, and A. M. Pedroso, *University of Sao Paulo*, *Piracicaba, Brazil*.

The objective of this trial was to evaluate the ingestive behavior of grazing Nellore steers receiving increased levels of energetic concentrate during rainy season. Eight rumen canulated Nellore steers averaging 380 kg of initial body weight, were randomly assigned to 1 of 2 complete 4x4 Latin squares. Each of the 4 experimental periods lasted 18 d, with 17 d for adaptation and 1 d for data collection. The grass pasture was *Brachiaria brizantha*, cv. Marandu. Pastures were rotationally grazed using a height-based management, on which 25 cm was the entrance height into the paddocks, that were left when a 15 cm post grazing residue was reach. The treatments were 3 levels of energetic supplementation (0.3, 0.6 and 0.9% BW, DM basis), based on fine ground corn and monensin (20 ppm/animal/d), plus a control treatment, with no supplementation. The concentrate was individually fed once daily, in the morning, and the animals had free access to a mineral premix. Ingestive behavior was determined by visual observation of individual animals, during 24 h, 5 min intervals, totaling 288 observations. Parameters evaluated were grazing, rumination and resting periods. The data was tested with *t*-test at 5% probability. There was a linear decrease ($P < 0.05$) in grazing time as the level of the supplementation increased. There was no difference among treatments for ruminating and resting periods. The energetic supplementation of animals grazing a high quality pasture can increase even more the substitution effect, what can result in decreased grazing time.

Table 1. Ingestive behavior of beef steers under increased level of energetic supplementation during rainy season

	Levels of concentrate (%BW)				P-value	Contrast		SEM[1]

M416 The effect of rumen protozoa of water buffalo and cow on fiber digestion in vitro. S. Jabbari*, M. Eslami, M. Chaji, T. Mohammadabadi, and M. Bojarpour, *Department of Animal Science, Ramin (Khuzestan) Agriculture and Natural Resources University*, *Ahwaz (Molassani), Khuzestan, Iran*.

The objective of this study was to compare the in vitro digestibility of wheat straw by rumen protozoal populations of water buffalo and Holstein cows. There is no information about the fibrolytic activity of rumen protozoa of water buffalo of Khuzestan in Iran. In vitro digestibility of dry matter (DM) and neutral detergent fiber (NDF) was measured by procedure of Tilley and Terry (1963). Rumen fluid was obtained from 2 buffalo and cows, which fed 30:70 concentrate: forage (corn grain, barley grain and wheat bran: sugarcane silage, corn silage, alfalfa hay and wheat straw). To preparing rumen protozoa, rumen fluid was added to antibiotic solution (streptomycin sulfate, penicillin G and chloramphenicol, 0.1 mg/ml each) and fungicides (benomyle: 500 ppm/ml medium and metalaxyle: 10 mg/ml medium), then was mixed with McDougall buffer in a ratio 1:4. After gasifying with CO2, tubes were incubated at 39°C. After 48 h the fermentation, 6 mL of HCl solution (20%) and 5 mL pepsin solution were added and the incubated for 48 h simulating post-ruminal degradation. After incubation, the residual substrates of each tube were filtered and used to determine disappearance of DM and NDF. Data of DM and NDF disappearance were analyzed as a completely randomized design using the general linear model procedure of SAS. The results of this experiment indicated that the DM digestibility of wheat straw by rumen protozoal population of buffalo was higher than that by rumen protozoa population of cows (25.2 and 21.13 g/100 g, respectively) ($P < 0.05$). Neutral detergent fiber digestibility of wheat straw was 16.7 and 10.3 g/100 g for protozoal population of buffalo and cows, respectively ($P < 0.05$). The DM and NDF digestibility by rumen protozoa from buffalo was 1.19 and 1.62 folds of the rumen protozoa from cows, respectively. Therefore, rumen protozoa of Khuzestan water buffalo have higher fiber breakdown compared with cows under the same diet.

Key Words: fiber digestion, buffalo, rumen protozoa

M417 The degradation of alfalfa treated with enzyme and or sodium hydroxide by rumen anaerobic fungi. T. Mohammadabadi* and M. Chaji, *Department of Animal Science, Ramin (Khuzestan) Agriculture and Natural Resources University*, *Ahwaz (Molassani), Khuzestan, Iran*.

This experiment was conducted to investigate the effect of rumen fungi on degradation of alfalfa treated with enzyme (30 g/kg DM) or sodium hydroxide (45 g/ kg DM) by using disappearance of dry matter (DM) and neutral detergent fiber (NDF) and chitin content in pure culture of

rumen anaerobic fungi for 12 d. Treatments were: untreated alfalfa and treated with sodium hydroxide (NaOH) (45 g/ kg DM), enzyme (30 g/kg DM) and or NaOH +enzyme. Rumen fluid was collected from 2 fistulated Holstein steers and centrifuged (1000 rpm, 10 min), then supernatant was used to grow fungi in medium containing antibiotic solution (streptomycin sulfate, penicillin G and chloramphenicol, 0.1 mg/ml each) under anaerobic conditions at 39°C for 24 h, by Joblin (1981) method. These isolates were used (1:9), as a source of inoculum for culturing fungi in a serum bottle containing 45 mL of culture medium and 1g of experimental sample under anaerobic conditions (using 3 times subculture) for 12, 24, 48, 72 and 96 h. The residual substrates of each bottle were then filtered and used to determine the DM and NDF concentrations. The chitin content of each medium was determined as described by Chen and Johnson (1983). The result showed disappearance of dry matter after 12 d incubation by rumen fungi will be 43.2, 58.3, 60.3 and 63.3 g/100 g DM for untreated alfalfa and treated with NaOH, enzyme and or $NaOH^{+}$enzyme, respectively. Sodium hydroxide and enzyme caused to increase disappearance of NDF and chitin content, and the highest increase was for medium containing alfalfa treated with $NaOH^{+}$enzyme (168.6 mg/g DM and 5.96 g/kg DM, respectively) ($P < 0.05$). Therfore, it appears that the degradation of alfalfa by rumen fungi is influenced by NaOH and enzyme treatments.

Key Words: rumen fungi, sodium hydroxide, enzyme

M418 Exchanging tropical fiber sources on intake and ingestive behavior of feedlot rations in beef cattle. R. S. Goulart*, V. P. Santos, G. B. Muraro, J. L. P. Daniel, R. C. Amaral, S. G. Toledo Filho, E. H. Cabezas, L. G. Nussio, and A. V. Pires, *University of São Paulo–ESALQ*, *Piracicaba, SP, Brazil*.

Forage and nonforage tropical fiber sources were evaluated in a 5 × 5 Latin square trial using Nelore steers within five 19-d periods (10-d adaptation followed by 9-d data collection). The 5 diets were composed of fiber sources: 20% NDF from corn silage (CS) (50.2% NDF); and 4 diets containing 10% NDF from corn silage added with 10% NDF from each of the following sources: sugarcane (SC) (46.8% NDF), sugarcane bagasse (SCB) (81.0% NDF), soybean hulls (SH) (75.1% NDF) and high oil – cottonseed meal (HOCM) (49.2% NDF). Steers were fed once daily in the morning and allowed ad libitum access to feed in tie stall pen. Data from the Latin squares were analyzed using Mixed procedures of SAS. Greater DM intake (9.26 kg/d) was observed for the diet which contained 20% NDF as CS ($P < 0.05$) compared with diets containing SC (8.85 kg/d) or SCB (6.86 kg/d). No differences in DM intake was observed between HOCM diets (9.62 kg/d) and CS diets. However, steers fed SH diet (8.44 kg/d) consumed less ($P < 0.05$) than CS. Steers fed SC or SCB diets showed greater capacity ($P < 0.01$) in stimulating rumination (50.0 and 62.3 min/kg DM, respectively) when compared with CS (42.5 min/kg DM), SH (26.7 min/kg MD) or HOCM diets (38.9 min/kg DM) for the same inclusion of NDF (% DM). This variation in feeding behavior affected the amount of acid produced in rumen fermentation of each treatment. Greater pH ruminal was observed for SC (6.21) and SCB (6.30) ($P < 0.01$) compared with CS (6.08) and SH (6.04). Thus, dietary NDF concentration alone from tropical roughage sources were not correlated to ruminal pH. Even though, it might provide a useful tool for exchanging roughages in diets, these results suggested that this fraction should not be considered exclusively as a predictor for estimate DM intake and ingestive behavior. Further studies involving physical and chemical traits from tropical roughage sources are on the way.

Key Words: roughage source, dry matter intake, Nelore steers

M419 Effect of levels of fiber and corn grain processing in diets for finishing Zebu cattle. R. Carareto*, F. A. P. Santos, G. B. Mourão, A. M. Pedroso, C. Sitta, W. Angolini, and B. Correa, *University of Sao Paulo*, *Piracicaba, São Paulo, Brazil*.

The objective of this trial was to compare 3 levels of grass hay and 2 types of corn grain processing in high concentrate diets for finishing feedlot cattle. Ninety-two Nellore bulls with an average initial SBW of 400 kg were used in a 63-d feeding trial after a 21 d period for adaptation to high concentrate diets. Animals were blocked by SBW and randomly allotted to 16 pens. Experimental diets were isonitrogenous and contained (%DM) 10% to 0% hay, 53.6 to 63.6% corn grain, 35% wet corn gluten feed, 1.4% of mineral mix with monensin.
Treatments were: 1) fine ground corn and 10% hay, 2) fine ground corn and 5% hay, 3) fine ground corn and 0% hay, 4) cracked corn and 0% hay. Data were analyzed based on a randomized complete blocks design, with pens as the experimental units, using the Proc. Mixed of SAS (1999) version 9.2 for Windows. Dry matter intake (DMI) and ADG were lower for treatments without hay ($P < 0.05$) (Table 1). Feed efficiency (DMI/ADG) was not affect by treatments ($P > 0.05$) (Table 1). Although the DMI and ADG were lower, the finishing Nellore bulls performance was not affected by treatments.

Table 1. Dry matter intake (DMI), average daily gain (ADG) and feed efficiency (DMI/ADG) of finishing Nelore bulls fed 4 different diets

Variables	T1	T2	T3	T4	Standard Error	Pr>F
ADG (kg /day)	1.55	1.51	1.30	1.36	0.0800	0.032
DMI (kg DM/day)	10.32	10.26	8,79	9.00	0.3729	0.0002
DMI/ADG	6.65	6.80	6.75	6.67	0.2365	0.9827

M420 Influence of daily ingestion of alfalfa treated with quebracho tannins on in vitro fermentative activity of some browse species. H. Ammar[1,2], S. López[2], A. Z. M. Salem*[3,4], and J. S. González[2], [1]*Ecole Supérieure d'Agriculture de Mograne*, *Dept. Production Agricole, 1121-Zaghouan, Tunisia*, [2]*Instituto de Ganadería de Montaña (CSIC-Universidad de León)*, *24346 León, Spain*, [3]*Universidad Autónoma del Estado de México*, *Centro Universitario UAEM-Temascaltepec, Estado de México, C.P. 51300, México*, [4]*Alexandria University*, *Department of Animal Production, Faculty of Agriculture (El-Shatby), Egypt*.

Leaves from 4 shrub species (*Erica australis*, *Cistus laurifolius*, *Quercus pyrenaica*, and *Rosa canina*) collected from the mountain of Leon (northwestern Spain) were used to test the medium-term effects of the intake of quebracho condensed tannins on the fermentative activity in the rumen of sheep. Leaves from all shrubs were sampled at 3 different maturity stages (spring, summer and autumn). Eight Merino rumen cannulated sheep fed chopped alfalfa hay were used. Four sheep were given alfalfa hay treated with 50 g quebracho/kg DM for 60 d (group Q), whereas the other animals were always given untreated alfalfa hay and used as the control group (C). Differences in the fermentative activity were examined in vitro in batch cultures inoculated with rumen fluid obtained on d 60 from both groups of sheep. In vitro dry matter digestibility (IVD) and gas production kinetics from leaves and flowers of all shrub species were determined. Except for the flowers of *C. laurifolius*, IVD was higher ($P < 0.05$) when rumen fluid from Q sheep was used. Likewise, a significant effect of inoculum source on the dry matter disappearance after 144 h of incubation was observed for the flowers of *E. australis*. For the same substrate, the inoculation with rumen fluid from Q sheep resulted in a higher gas production at 24 h and faster fractional

gas production rates. The differences were generally statistically significant ($P < 0.05$) in most comparisons and the magnitude of this effect was greater when material with higher tannin contents was incubated (leaves of *E. australis* and *C. laurifolius*). In conclusion, rumen fluid from sheep fed a diet supplemented with condensed tannins showed a higher fermentative activity to degrade tannin-rich browse. This could be due to the appearance and proliferation of tannin-tolerant bacterial species or to the induction of changes in the existing bacteria to enhance their tolerance to these phenolic compounds.

Key Words: shrub, in vitro digestibility and gas production, sheep

M421 Productive characteristics and chemical composition of elephant grass (*Pennisetum purpureum Schum,* cv. Mineiro) submitted to chemical and organic fertilization. T. S. Oliveira*[1], J. C. Pereira[1], R. A. M. Vieira[4], J. G. L. Regadas Filho[1], and E. F. Aguiar[2], [1]*Universidade Federal de Viçosa*, *Viçosa, Minas Gerais, Brazil*, [2]*Universidade Federal do Vale do Jequitinhonha e Mucuri*, *Diamantina, Minas Gerais, Brazil*, [3]*Universidade Estadual de Montes Claros*, *Janaúba, Minas Gerais, Brazil*, [4]*Universidade Estadual do Norte Fluminense Darcy Ribeiro*, *Campo dos Goytacazes, Rio de Janeiro, Brazil*.

The objectives of this work were to study the effect of chemical (CF) and organic (OF) fertilization on the forage DM production and chemical composition characteristics of elephant grass and to estimate the total net energy for lactation (NEL) and the total digestible nutrients (TDN). Two elephant grass stocking piles were formed and 2 fertilization systems were used. The plant was evaluated in relation to height, age, DM ha-1 production (DMP), DM content and leave: stem ratio. Except for the age, the other values were analyzed in relation to the plant height. Based on the plant age, DM ha day-1 production and growth rate (GR) were calculated. As for elephant grass nutritive values (chopped forage), the experiment was carried out in a completely block (6 periods) randomized design and 3 replicates per forage (CF and OF) per block. Data of CP, NDF, ash, Ca, P, Mg and K were evaluated by F test, at 5% of probability. Based on the NDF contents, the NEL and TDN of the elephant grass from the 2 fertilization systems were estimated. The best plant performance at field was for the elephant grass submitted to organic fertilization, which was higher in water content, growth rate and forage DM ha day-1 production. Also in the nutritive value aspect, the elephant grass submitted to OF showed higher chemical composition values, which were indicatives of better nutritional quality. In this forage, higher contents of CP (17.26%), ash (26%) and P (36.88%) and smaller of NDF (3.96%) were observed in relation to the elephant grass submitted to CF. In the conversion of NPK fertilizer in forage DM, the elephant grass submitted to OF was 41.38% smaller than elephant grass submitted to CF. The elephant grass cultivated under organic fertilization was harvest with higher frequency and with better nutritional quality.

Key Words: elephant grass, chemical fertilization, organic fertilization

M422 Effects of condensed tannins supplementation in a lactating dairy TMR diet on ruminal fermentation in continuous culture, maintained at high and low pH. C. M. Dschaak*, C. M. Williams, J.-S. Eun, and A. J. Young, *Department of Animal, Dairy, and Veterinary Sciences, Utah State University*, *Logan*.

We investigated whether supplementing a water-soluble Quebracho extract would be beneficial to improve the rumen ecosystem by examining effects of ruminal pH on ruminal fermentation. The Quebracho extract contained approximately 75% condensed tannins (CT; Chemtan Company Inc., Exeter, NH), and the CT was supplemented to a barley-based high concentrate, lactating diet at 6% of dietary DM. A dual-flow continuous culture system consisting of 4 fermentors was used in a 4 × 4 Latin square with dietary treatment arranged as 2 × 2 factorial (high and low pH vs. without CT and with CT). High ruminal pH (HpH) was maintained with normal artificial saliva, while low ruminal pH (LpH) was achieved by diluting 60% of the normal artificial saliva with water. The ruminal pH averaged 6.2 and 5.9 to the HpH and the LpH, respectively. The diet used consisted of 33% alfalfa hay, 7% corn silage, 40% rolled barley grain, and 20% concentrate mixture. The 4 treatments were: 1) TMR with HpH and without CT; 2) TMR with HpH and with CT; 3) TMR with LpH and without CT; and 4) TMR with LpH and with CT. Filtered ruminal contents were allowed 5 d of adaptation to the treatments followed by 3 d of data collection. Culture pH decreased with CT supplementation in the HpH, however pH was not affected in the LpH. Methane production increased ($P < 0.01$) in the HpH, but decreased in the LpH due to CT supplementation. Ammonia-N concentration ($P < 0.01$) decreased with CT supplementation regardless of type of ruminal pH. Total VFA increased ($P = 0.02$) with CT supplementation in the HpH, but was not affected in the LpH. Molar proportion of acetate increased ($P = 0.02$) in the HpH, whereas CT supplementation did not affect acetate proportion in the LpH. Propionate proportion was not affected by CT supplementation in the HpH and the LpH. The supplementation of CT in the HpH resulted in positive impacts on microbial production, as was seen in increased VFA and decreased ammonia-N. However, CT supplementation in the LpH had no benefit on ruminal fermentation.

Key Words: condensed tannins, continuous culture, ruminal pH

M423 Milk fatty acid composition of grazing dairy cows supplemented with soy and fish oils. G. M. Martínez[1], G. A. Gagliostro*[2], D. A. Garciarena[1], V. I. Cejas[3], M. A. Rodríguez[3], R.A Castañeda[3], and M Balán[4], [1]*INTA EEA Salta*, *Salta, Argentina*, [2]*INTA EEA Balcarce*, *Balcarce. Buenos Aires, Argentina*, [3]*INTI Lácteos*, *San Martín, Buenos Aires, Argentina*, [4]*Prodeo SRL*, *Chivilcoy, Buenos Aires, Argentina*.

The effect of feeding soy oil (SO, 55.5% C18:2) or a residue of SO extraction (SOR, 61% oil, 55.9% C18:2) combined or not with fish oil (FO, 9.89% EPA, C20:5 n3 and 20.64% DHA, C22:6 n3) on milk fatty acid (FA) profile was studied on 32 grazing dairy cows (115 ± 28 DIM) in a 2x2 factorial arrangement. Oils were mixed with corn silage (CS) immediately before feeding. Treatments (DM basis) were: SO = 72.63% CS, 2.79% urea and 24.58% SO; SO-FO = 68.42% CS, 2.63% urea, 5.79% FO and 23.16% SO; SOR = 62.95% CS, 2.42% urea and 34.63% SOR and SOR-FO = 59.77% CS, 2.30% urea, 5.06% FO and 32,87% SOR. Concentrate (7.3 kg/cow/d) and pasture (8.4 kg/cow/d) were also consumed. Milk samples were obtained before (basal) and then once a week after oils feeding during 35 d. A factorial arrangement with repeated measures over time adjusted by covariable was used. Factor A compared SO vs SOR and factor B examined the effect of FO. Comparisons between basal and final milk FA were tested by the Student t-Test for paired observations. Concentration of C4:0, C6:0 and C8:0 resulted higher in SOR treatments. C14:0 (g/100g FA) was lower ($P < 0.03$) in SO (9.15) compared with SOR (10.17). Compared with basal (12.52 g/100g FA) SO-FO showed the most important reduction in C14:0 (−3.55 g/100g FA). The atherogenicity index of milk (2.29 to 2.59) was reduced (1.43) without differences between treatments. Basal concentrations of 10t C18:1 (0.28 to 0.31 g/100g FA) were increased particularly with SO (4.55 g/ 100 g FA) instead of SOR (3.9 g/ 100 g FA). SO-FO showed the highest 10t C18:1 concentration (5.27 g/100g FA). Increase of 11t C18:1 (VA) over basal (2.56 g/100g FA) resulted higher in SO-FO (+3g/100g FA) followed by SOR-FO (2.91 and +2.84), SO (2.78 and +1.36) and SOR (2.54 and +1.06 g/100g FA). Concentrations

(g/100g FA) of 9c, 11t CLA averaged 3.23 (SO-FO), 2.95 (SOR-FO), 2.43 (SO) and 2.19 (SOR) resulting higher ($P = 0.01$) in FO treatments FO (3.14 vs 2.31) without interaction between FO and sources of supplementary C18:2. After supplementation, the CLA/11t C18:1 ratio decreased in all treatments. The SOR may successfully replace SO to modulate milk FA composition.

Key Words: soy oil residue, fish oil, conjugated linoleic acid

M424 Does the in situ ruminal degradation of feeds vary with the finishing ration fed to beef cattle? Y. L. Li*[1,2] and W. Z. Yang[1], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*Feed Research Institute, Chinese Academy of Agricultural Sciences*, *Beijing, China*.

An in situ study was conducted to determine degradation of feeds in the rumen of beef cattle fed finishing diets that varied with the amounts of silage, barley grain and wheat DDGS. This study was part of the measurements in a metabolic study. Eight ruminally fistulated Angus heifers were assigned in a replicated 4 × 4 Latin square design with 4 diets that consisted of barley silage, barley concentrate, and wheat DDGS in ratios of 15:85:0, 10:65:25, 5:65:30 and 0:65:35, respectively, for control, low, med and high DDGS. Five grams of the barley silage (chopped), barley grain (temper-rolled) and wheat DDGS (as fed) fed to the cattle were incubated in situ in the rumen of 8 heifers for 0, 2, 4, 6, 12, 24 and 48 h in the first 2 periods of the study. The model $y = a+b(1-e^{-ct})$ was fitted to determine degradation kinetics of DM, NDF and CP, where y is nutrient degraded, a is soluble fraction, b is slowly degradable fraction, c is degradation rate constant, t is incubation time. Effective degradability (ED) was determined by $ED = a+[bc/(c+k)]$, where k = 0.06/h. For barley silage, soluble fraction of DM decreased quadratically ($P = 0.01$). The slowly degradable fraction of DM tended to linearly ($P = 0.06$) decrease, and that of CP quadratically ($P = 0.05$) decreased with increasing amount of DDGS in the diets. For barley grain, the kinetic parameters of DM, NDF and CP were generally not affected by the diets except for the ED of NDF which was greater ($P = 0.01$) for med DG (48%) than for the other 3 diets. Finally, for wheat DDGS, the degradation kinetics and ED of DM, NDF and CP were overall not affected. The results suggest that the effects of finishing diet fed to cattle on in situ ruminal degradation kinetics vary with type of feed and nutrient measured; in situ ruminal degradation of wheat DDGS was the least affected by the diets fed to cattle among 3 feeds evaluated.

Key Words: In situ ruminal degradation, wheat DDGS, beef cattle

M425 Performance of grazing dairy cows supplemented with soy and fish oils. G. M. Martínez[1], G. A. Gagliostro*[2], and D. A. Garciarena[2], [1]*INTA EEA Salta*, *Salta, Argentina*, [2]*INTA EEA Balcarce*, *Balcarce, Buenos Aires, Argentina*.

Feeding soy oil (SO) or a residue of oil extraction (SOR) combined or not with fish oil (FO) may be an inexpensive way to increase vaccenic and conjugated linoleic acids in milk. Production responses of dairy cows fed SO (55.5% C18:2), SOR (61% oil; 55.9% C18:2) and FO were examined on 32 grazing dairy cows (115 ± 28 DIM) in a DCA with a 2x2 factorial arrangement over a 35 d period. Oils were mixed to corn silage (CS) defining 4 treatments: SO = 72.63% CS, 2.79% urea and 24.58% SO; SO-FO = 68.42% CS, 2.63% urea, 5.79% FO and 23.16% SO; SOR = 62.95% CS, 2.42% urea and 34.63% SOR and SOR-FO = 59.77% CS, 2.30% urea, 5.06% FO and 32,87% SOR. Concentrate (7.3 kg) and pasture (8.4 kg) were also consumed. Results were analyzed as a factorial arrangement with repeated measures adjusted by covariable. Factor A compared SO vs SOR and factor B examined the effect of including FO. Within treatments, comparisons between pre- and final records were performed using the Student t-Test for pairwise observations. Intake of ration (kg DM/cow/d) was lower ($P < 0.01$) in SO-FO (2.14) and SOR-FO (2.30) compared with SO (2.66) and SOR (2.78). Pre-trial milk yield, milk fat and milk protein contents averaged 26.6 kg/v/d, 35.7 and 34.4 g/kg, respectively. After 35 of oil supplementation milk yield (SO-FO:-3,18, SO:-2.90, SOR-FO:-1.97 and SOR:-1,62 kg/cow/d) and milk fat content (SOR: −9.9, SOR-FO: −9.1, SO-FO: −9 and SO: −6,9 g/kg) decreased ($P < 0.01$), but milk protein content remained unaffected. FCM was also depressed. Milk yield (kg/cow/d) resulted higher ($P < 0.002$) in SOR treatments (23.9) compared with that including SO (22.9). Milk fat content (AxB, $P < 0.10$) was higher ($P < 0.05$) in SO (29.1g/kg) compared with SO-FO (26.1), SOR (26) and SOR-FO (2.61). FCM resulted higher ($P < 0.03$) for treatments without FO (19.75 vs 19.0 kg/cow/d). Yield of FCM (AxB, 0.07) was depressed by SO-FO (18.5 kg/cow/d) compared with SO (19.9), SOR (19.6) and SOR-FO (19.5). Milk fat secretion (g/cow/d) resulted higher in SO (698) compared with SO-FO (631) and SOR (622) without differences between SO and SOR-FO (640). A lower depression of milk yield and milk fat content was observed feeding the SOR supplement.

Key Words: soy oil, milk yield, milk composition

M426 Effect of production system on metabolic and endocrine responses of grass fed cows. L. D. Kaufmann[1], A. Münger[1], H. A. van Dorland[2], R. M. Bruckmaier[2], and F. Dohme*[1], [1]*Agroscope Liebefeld-Posieux, Research Station ALP*, *Posieux, Switzerland*, [2]*University of Bern Vetsuisse Faculty, Veterinary Physiology*, *Bern, Switzerland*.

We previously reported that energy expenditure was higher in dairy cows on pasture compared with those offered the same grass in a free-stall barn. Aiming to better understand these differences, the metabolic and endocrine profile and feed intake of the dairy cows fed grass of the same quality either on pasture (P) or in the barn (B) were investigated. Fourteen dairy cows (milk yield: 44 ± 2.7 kg/d) were randomly assigned to a crossover study. The 2 experimental periods lasted 2 wk each and consisted of an adaptation and a data collection period of 1 wk each. The P cows grazed on pasture whereas B cows had ad libitum access to grass from the same paddock, fed in a free-stall barn. All cows were supplemented with a cereal-based concentrate to meet their predicted nutrient requirements. Concentrate was offered in the barn at 0630 and 1630 h using weighing troughs. Grass intake and nutrient digestibility were estimated by the double alkane technique. Milk metabolites were analyzed and BW was recorded daily during the collection periods. On each day of the collection period, blood was taken at 0530 h from one cow of each treatment group. Samples were centrifuged and stored at −20°C until further analysis. As expected, grass quality was similar in both treatment groups (CP, 179 g/kg DM; NDF, 407 g/kg DM). Daily grass (15.6 kg DM) and concentrate intake (6.4 kg DM) did not differ ($P > 0.05$) and therefore no differences ($P > 0.05$) were observed in total DM, OM and NDF intake between treatments. Digestibility of OM (81.6%) and NDF (78.9%) were similar ($P > 0.05$) in both experimental groups. Milk acetone concentration (1.13 mg/kg) was unaffected ($P > 0.05$) while milk urea level tended ($P = 0.06$) to be lower in P cows (186 mg/kg) compared with B cows (208 mg/kg). Neither blood metabolites (albumin, BHBA, cholesterol, glucose, NEFA, total protein, triglycerides, and urea) nor IGF-1, T3, and T4 differed ($P > 0.05$) between treatments. In conclusion, the analyzed blood traits as well as the nutrient intake do not help explaining the observed differences in energy expenditure of grazing cows compared with cows fed the same grass in the barn.

Key Words: dairy cows, metabolic and endocrine profile, pasture

M427 Production of dairy cows fed varying levels of total mixed ration and pasture. A. Quilaguy-Ayure, G. A. Gagliostro*, D. A. Garciarena, L. Antonacci, and C. A. Cangiano, *INTA EEA Balcarce*, *Balcarce, Buenos Aires, Argentina*.

Nine dairy cows were offered combinations of total mixed ration (TMR) and pasture (P) in a triplicated 3 × 3 Latin square design with 3 partial mixed rations (PMR) targeted at (1) 75% TMR and 25% P, (2) 50% TMR and 50% P and (3) 25% TMR and 75% P. All cows were also fed the TMR-100% diet. TMR was composed (DM) by corn silage (36%), concentrate (49%), soybean meal (6.5%), soybean grain (6.5%) and feather meal (2%). Data were analyzed by a model that included treatment, square and period as fixed effects and cow within square as random effect. Differences between the TMR-100 and the other treatments were stated using the t-Test for paired observations. The actual proportions of TMR and P were (1) 79:21, (2) 58:42 and (3) 33:67. TMR intake (kg DM/cow/d) was 20.32, 13.44 and 7.06 for (1), (2) and (3) treatments, respectively ($P < 0.01$). Reducing the proportion of TMR increased ($P < 0.01$) pasture consumption (5.27, 9.77 and 14.49 kg DM/cow/d) and reduced ($P < 0.01$) total DM intake (25.59, 23.21 and 21.55 kg/cow/d for 1, 2 and 3, respectively). Total DM intake (kg/cow/d) for TMR-100 was higher (28.23, $P < 0.03$) compared with PMR treatments. Total DM intake (% of BW) was similar between TMR-100 (4.42%) and PMR-79 (4.26%), but higher ($P < 0.01$) to PMR-58 (3.82%) and PMR-33 (3.06%). Yields (kg/cow/d) of milk (31.2) or 4%FCM (26.8) did not differ between PMR. Milk production (kg/cow/d) in TMR-100 (32.1) was higher ($P < 0.01$) than PMR-58 (30.7) and 4%FCM did not differ between TRM and PMR treatments. Milk fat content (g/kg) was similar between TMR-100 (28.5) and TMR-79% (29.6) but lower ($P < 0.02$) to TMR-58% (31.3) and TMR-33% (32). Milk protein content (g/kg) resulted higher ($P < 0.02$) in TMR-100% (33.7) compared with TMR-79% (33.2). Milk fat secretion (0.954 kg/cow/d) did not differ. Milk protein yield (kg/cow/d) was similar between PMR diets (1.03) but lower ($P < 0.04$) to TMR-100% (1.07) for TMR-58 and TMR-33. Feed efficiency (kg milk/kg DM) had a tendency ($P < 0.08$) to increase from 1.13 to 1.42 with increased pasture levels in PMR diets. For cows producing between 32 to 30 kg of milk, decreasing the pasture TMR ratio in the diet did not show a clear production benefit.

Key Words: intake, pasture, partial mixed ration

M428 Effect of different pectin rich by products on feed intake, milk production and composition and ruminal pH of lactating dairy cows. M. Kordi*, A. Naserian, R. Valizade, and A. Tahmasbi, *Ferdowsi University*, *Mashhad, Iran*.

Eight primiparous early lactating Holstein cows (60 ± 23 d postpartum, weighing 530 ± 60 kg) were assigned into a duplicated 4 × 4 Latin square design for evaluated of different pectin rich by products on feed intake, milk production and composition and ruminal pH of lactating dairy cows with 4 3-wk periods. Cows were allocated into 4 diets whit 1)10% barley grain, 2)10% sugar beet pulp, 3)10% wheat bran and 4) 10% dried citrus pulp . Each experimental period was 21 d including 14 d adaptation period and 7 d collecting samples. Milk yield recorded daily and milk samples were taken from each milking times during the last 3 d of each period. Milk samples were subjected to analysis for CP, lactose, fat and SNF. The dry matter intake (DMI), NDFI, milk yield and composition and ruminal pH are presented in the Table 1. There were no differences ($P > 0.05$) in the daily intake of DM (kg/d), and milk yield and composition, among treatments (Table 1). Similarly, there were no significant differences in ruminal pH among treatment diets ($P > 0/05$). The NDF intake was significantly different among treatments ($P < 0.05$). These data suggest that, the addition of sources of pectin feed stuffs at 10% levels (dry matter basis) of the dairy cow ration instead of cereal grain; will decrease the cost of milk production without any negative effect on dairy cows performance.

Table 1. Dry matter intake, NDF intake, milk production and composition, and ruminal pH of dairy cows

	Treatment				
Item	T1	T2	T3	T4	SEM
DMI (kg /day)	19.34	19.63	19.74	18.69	0.122
NDF intake(kg/d)	6.05b	6.61a	6.63 a	5.8 8 b	0.110

M429 Modification of the Z-Box system for assessing particle distribution of forages and total mixed rations. K. W. Cotanch*[1], C. S. Ballard[1], J. W. Darrah[1], L. M. Klaiber[1], R. J. Grant[1], and K. Yagi[2], [1]*W. H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*Zen-Noh National Federation of Agricultural Co-operative Associations*, *Tokyo, Japan*.

The Z-Box has been proven to be an accurate on-farm tool for determining the physical effectiveness factor (pef) of silage-based TMR, corn silage, and haycrop silage. It would be advantageous to consultants and dairy producers to modify the Z-Box to measure particle distributions in addition to pef. The objective of this studywas to select perforated steel screens for the Z-Box to provide particle size distributions similar to the Penn State Particle Separator. Twenty-five kg samples of corn silage (CS, n = 12), haycrop silage (HCS, n = 12), and total mixed ration (TMR, n = 41) were sub-sampled and processed using the Penn State Particle Separator (PSPS) and Z-Box following the accepted methodology for both systems. Three replications of each sample were processed by 3 technicians. For the Z-Box, samples were processed sequentially working from the smallest to largest screen (3.18, 4.76, 6.35, 12.70, and 15.88-mm) following the standard Z-Box vertical-shaking method.. The Z-Box method for assessing particle distribution was evaluated for accuracy within forage type by calculating the mean bias of particle distributions determined using PSPS and various Z-Box screens. The Z-Box screen with the narrowest 95% confidence interval (CI) encompassing zero most accurately assessed particle distribution. For TMR and HCS, 4.76- and 12.70-mm screens with the Z-Box resulted in the closest agreement with the PSPS method. For CS, the 4.76- and 15.88-mm screens assessed particle distribution most accurately.

Table 1. Mean bias of particles screened using PSPS and corresponding Z-Box sieves for forages and TMR

Sample	Z-Box Sieve < (mm)	PS Screen < (mm)	Mean bias ± SD	Upper 95% CI	Lower 95% CI
CS	3.18	8	–12.92± 3.0	–11.01	–14.83
	4.76	8	–4.31± 2.26	–2.88	–5.75
	6.35	8	6.28± 1.80	7.42	5.13
	12.7	19	–11.92± 5.09	–8.69	–15.16
	15.88	19	0.66± 1.10	1.36	–0.04
HCS	3.18	8	–21.49± 6.19	–17.56	–25.42
	4.76	8	–6.04± 5.45	–2.58	–9.50
	6.35	8	11.76± 4.69	14.74	8.78
	12.7	19	0.29± 1.85	1.46	–0.88
TMR	3.18	8	–13.03± 3.11	–12.05	–14.01
	4.76	8	0.20± 3.06	1.17	–0.76
	12.7	19	–0.38± 4.53	1.05	–1.81

M430 Zinc and heat treatments reduce ruminal protein degradation of grass leaf protein. K. L. Kammes*, B. D. Bals, B. E. Dale, and M. S. Allen, *Michigan State University*, *East Lansing*.

Leaf protein (LP) produced as a coproduct of cellulosic ethanol production can be utilized by ruminants. Effects of grass maturity, chemical and heat treatment, and conservation method on ruminal protein degradation of LP extracted from orchardgrass (OG) were evaluated. Two maturities of OG were harvested from the same field in 2008 with crude protein (CP) concentrations of 17% (immature) and 13% (mature). Grasses (fresh, stored, or wilted) were chopped and protein rich juice was extracted with a screw press. The juice was chemically treated with concentrated hydrochloric acid (HCl, pH 3.3) with or without zinc (Zn, 2.085 g zinc chloride per liter) and treated with heat (100 or 140°C for 1 h) or without (21°C; control) followed by centrifugation to harvest precipitated LP. Crude protein concentrations of LP approximately doubled that of the original grass to 34.4 and 25.8% for immature and mature, respectively for all chemical and heat treatment combinations. In vitro protein degradation of LP was evaluated using enzymes extracted from rumens of lactating dairy cows. The HCl+Zn, 140°C treatment decreased CP degradation the greatest extent compared with HCl, control for fresh OG LP (4 vs. 20% degraded in 12 h). An interaction ($P < 0.10$) between maturity and Zn was observed with Zn decreasing CP degradation of immature OG more than mature OG after 4 h incubation. The HCl+Zn treatment decreased CP degradation more than HCl alone (3.0 vs. 9.9% after 4 h and 5.5 vs. 13.8% after 12 h; $P < 0.05$). Heat also decreased CP degradation with temperatures of 100 and 140°C resulting in similar degradation, which were lower than control (4.0 vs. 11.3 after 4 h and 7.3 vs. 14.4% after 12 h; $P < 0.05$). There was an effect of conservation method on HCl+Zn, 140°C treated OG LP with similar degradability for stored (7.7%) and wilted (9.8%), which were higher than fresh (1.7%; $P < 0.01$). Leaf protein from fresh OG treated with zinc and heat resulted in decreased ruminal CP degradation.

Key Words: leaf protein, protein degradation, bypass protein

M431 Prediction of residual feed intake in beef heifers by infrared thermography. J. J. Colyn*[1], A. L. Schaefer[1], J. A. Basarab[2], E. K. Okine[3], T. Liu[1], K. L. Robertson[2], and S. L. Scott[4], [1]*Agriculture and Agrifood Canada, Lacombe Research Centre*, *Lacombe, AB, Canada*, [2]*Alberta Agriculture*, *Lacombe, AB, Canada*, [3]*Department AFNS, University of Alberta*, *Edmonton, AB, Canada*, [4]*Agriculture and Agrifood Canada*, *Brandon, MB, Canada*.

The cow herd is estimated to require 65–75% of the total energy required for beef production. Measurements of residual feed intake (RFI) to improve feed efficiency in beef breeding programs have mainly focused on replacement bulls but potential for improvements exist in replacement heifer selection. A limitation to the widespread use of measuring RFI is the cost and complexity of collecting individual daily feed intake. An alternative method to predicting RFI, which has shown utility in mature cows, growing bulls, and steers, is to measure radiated energy losses by infrared thermography (IRT). The purpose of the present study was to investigate the potential of IRT as a predictor of RFI in growing replacement heifers. Sixty-one crossbred beef heifers were fed a balanced conventional barley silage ration. At Day 0, 94, and 113 a sequence of IRT images of the head were collected with a FLIR S60 camera. Average IRT temperature of the cheek region (CHK) was calculated for each date. Actual feed intake (FI), as measured by the Growsafe feeding system was regressed against average daily gain, metabolic mid-point weight and final ultrasound backfat to obtain expected feed intake (EFI). RFI was the difference between FI and EFI, and values ranged from −1.55 to 2.19 kg d-1 as-fed (avg = 0.0; sd = 0.777). Heifers were then classified into low, medium, or high RFI groups based on ± 0.5 of the standard deviation around the RFI mean. Using CHK for each date in a repeated measure analysis, heifers with a low RFI value (n = 17; avg = −0.915 kg d-1; sd = 0.316) or a medium RFI value (n = 27; avg = −0.003 kg d-1; sd = 0.214) displayed a CHK temperature of 19.98°C (se = 0.230) and 20.33°C (se = 0.184) respectively and were significantly different ($P <$ 0.01) from heifers with a high RFI value (n = 17; avg = 0.919 kg d-1; sd = 0.552) which displayed a CHK temperature of 21.31°C (se = 0.230). Data from this study suggest measurements of IRT may have utility as a rapid screening tool to predict growth efficiency in heifers.

Key Words: feed efficiency, cattle, infrared

M432 Predicting ME and metabolizable protein (MP) balances of Santa Gertrudis cows under grazing conditions using a nutrition model. A. D. Aguiar*[1,4], L. O. Tedeschi[1], K. McCuistion[2], D. S. DeLaney[3], and S. Moore[3], [1]*Texas A&M University*, *College Station,* [2]*Texas A&M University-Kingsville*, *Kingsville,* [3]*King Ranch*, *Kingsville, TX,* [4]*University of Florida*, *Gainesville*.

Predictions of Santa Gertrudis cow requirements of ME and MP (g/d) grazing pastures containing Kleberg bluestem (*Dichanthium annulatum*) and Coastal bermudagrass [*Cynodon dactylon* (L.) Pers] were performed using the Large Ruminant Nutrition System (LRNS). Simulations were performed using measured clime, forage, and animal data; and concentrate DMI. Forage DMI was predicted by the LRNS. Three reproductive cycles were evaluated: P1 (05/06 – 04/07), P2 (05/07 – 04/08), and P3 (05/08 – 04/09). The fractional fermentation rate (kd) of monthly forage NDF was determined using in vitro gas production technique. TDN values were estimated as 0.98 × (100 - NDF - CP - EE - ASH) + Digestible CP + 2.25 × (EE - 1) + (NDF - NDIN) × (kd/(kd + kp) + IDNDF) – 7 in which EE is ether extract, NDIN is N in the NDF, IDNDF is indigestible NDF, and kp is fractional passage rate. When kp was assumed to be 4%/h, predicted values had the greatest accuracy (Cb = 0.82), the least mean bias (−2.19%), but the least precision (r^2 = 0.59) compared with a published theoretical equation. The predicted TDN varied from 48.5 to 59 (P1), 46.6 to 61.5 (P2), and 46 to 59.6% (P3). The predicted DMI by the LRNS was 1.75, 1.99, and 1.86% BW for P1, P2, and P3; respectively, contrasting with literature data of 2.6% BW. When the LRNS predicted DMI was used, ME and MP balances were negative for most months of the year. When 2.6% of BW was used, the ME and MP balances were negative only for May and Jun for P1; Apr (ME) and Apr to Jun (MP) for P2; while cows in P3 had predicted positive ME and MP balances for Jul, Aug, and Sep. The results of 2.6% BW to predict DMI were more consistent with the observed BW and BCS changes during these periods (ADG = 0.16 kg/d), suggesting that cows had an overall positive MP and ME balances and likely used the surplus of nutrients for growth and to increase BCS. The LRNS underpredicted forage DMI given the predicted forage TDN. The use of empirical equations to predict DMI of grazing beef cows may not be acceptable in designing supplementation strategies. More integrated and mechanistic nutrition models are needed to predict DMI.

Key Words: cattle, requirements, supply

M433 Estimating rumen microbial crude protein in vitro using purine analysis or real-time PCR. E. Castillo-Lopez*, P. J. Kononoff, and J. L. Miner, *University of Nebraska-Lincoln*, *Lincoln*.

In ruminants, microbial crude protein (MCP) contributes to metabolizable protein. Estimation of MCP has traditionally been based on purine analysis, but it may be confounded by purines not originating from microbial DNA, therefore, a more direct approach is needed. The objectives of this experiment were to compare real-time PCR and purine analysis on estimates of MCP and to evaluate the impact of fermentation time, and lastly to evaluate the impact of dried distillers grains and solubles (DDGS) when replacing hay and corn. For each treatment, 1 g of substrate was incubated in 100 mL of rumen inoculum and replicated 3 times. A 3X2X2 factorial design experiment was used to determine the impact of 3 fermentation substrates at 2 times estimated with 2 methods on MCP. Treatments were as follows, CONTROL (50% grass hay and 50% rolled-corn), LOW DDGS (33% grass hay, 33% rolled-corn and 33% DDGS) and HIGH DDGS (100% DDGS.). At each time point a pellet was isolated and bacterial, protozoal and yeast crude protein was estimated using real-time PCR and purine analysis. To do so, microbial markers (primers and probe) were designed from the 16S rRNA, 18S rRNA and the second chromosome; for bacteria, protozoa and yeast (*Saccharomyces cerevisiae*), respectively. Estimates of MCP were different ($P < 0.05$) and were 221 and 246 (SEM = 6.55) mg/g DM according to the real-time PCR assay and that based on purine analysis. Fermentation substrate affected ($P < 0.05$) yield of MCP which was 263, 243 and 195 (SEM = 7.77) mg/g DM for CONTROL, LOW DDGS, and HIGH DDGS respectively. Fermentation time did not ($P = 0.25$) affect yield of MCP which was 229 and 239 (SEM = 6.34) mg/g of DM at 0 and 48h fermentation respectively. There was no method by diet interaction (P = 0.44). Inclusion, the real-time PCR estimates of MCP differed from those obtained with the purine analysis and it may be a feasible approach for the estimation of MCP. In addition, increasing level of DDGS may affect the in vitro synthesis of MCP.

Key Words: DDGS, microbial crude protein, purine analysis, real-time PCR

M434 An in vitro gas production technique to evaluate the effect of microwave irradiation on fermentation potential of cottonseed hulls using medium of ruminal fungal isolation. A. Faramarzi Garmroodi, M. Danesh Mesgaran*, H. Jahani-Azizabadi, A. R. Vakili, A. Tahmasbi, and A. R. Heravi Moussavi, *Dept. of Animal Science (Excellence Center for Animal Science), Ferdowsi University of Mashhad*, *Mashhad, Iran*.

Gas production parameters of microwave irradiated cottonseed hulls (CH) were assessed using gas production procedure of medium containing ruminal fungal isolation. Cottonseed hulls were hydrated by distilled water as 25 g/kg DM, then, irradiated (microwave, 900 W) for 4, 6 and 8 min (mic4, mic6 and mic8, respectively). Approximately, 0.3 g of each sample was placed in a 100 mL glass syringes (n = 4), then, incubated into 40 mL of buffered protozoa and bacteria free rumen fluid (ratio of buffer to rumen fluid was 2:1) for 2, 4, 6, 8, 12, 24, 48, 72 and 96 h. Rumen fluid was obtained from 3 sheep (body weight, 49.5 ± 2.5 kg) fitted by rumen fistulae, before the morning feeding, and strained through 4 layers of cheesecloth. The animals were fed 1 kg/d DM of alfalfa hay and 0.3 kg/d DM of concentrate (165 g CP/kg DM). Rumen fluid was centrifuged (10 min, 3000 rpm) and a solution of penicillin and streptomycin was added to protozoa free supernatant to remove the bacterial population. Data of gas produced over the incubations were applied to an exponential equation of $P = b(1\text{-}e)^{-ct}$ where (b) is the amount of produced gas from the fermentable fraction, (c) is the fractional constant rate and (t) is time. Data were analyzed using the GLM procedure of SAS 9.1 and the means were compared by the Tukey test ($P < 0.05$). The amount of gas produced from the fermentable fraction (b ± SEM) was 3.7 ± 2.82, 3.9 ± 2.17 and 4.4 ± 2.98 for mic4, mic6 and mic8, respectively. The fractional constant rate parameters (c ± SEM) were 0.01 ± 0.011, 0.01 ± 0.011 and 0.01 ± 0.018 for mic4, mic6 and mic8, respectively. Present data indicate that the physical procedure used has not any benefit on fermentation potential of CH while a medium of isolated ruminal fungal was used.

Key Words: cottonseed hulls, gas production, microwave irradiation

M435 The effect of microwave irradiation on gas production parameters of cottonseed hulls using medium containing ruminal bacterial isolation. A. Faramarzi Garmroodi, M. Danesh Mesgaran*, H. Jahani-Azizabadi, A. R. Vakili, A. Tahmasbi, and A. R. Heravi Moussavi, *Dept. of Animal Science (Excellence Center for Animal Science), Ferdowsi University of Mashhad*, *Mashhad, Iran.*

Gas production parameters of microwave irradiated cottonseed hulls (CH) were assessed using gas production procedure of medium containing ruminal bacterial isolation. Cottonseed hulls were hydrated by distilled water as 25 g/kg DM, then, irradiated (microwave, 900 W) for 4, 6 and 8 min (mic4, mic6 and mic8, respectively). Approximately 0.3 g of each sample was placed in a 100 mL glass syringes (n = 4), then incubated into 40 mL of buffered protozoa and fungi free rumen fluid (ratio of buffer to rumen fluid was 2:1) for 2, 4, 6, 8, 12, 24, 48, 72 and 96 h. Rumen fluid was obtained from 3 sheep (body weight, 49.5 ± 2.5 kg) fitted by rumen fistulae, before the morning feeding, and strained through 4 layers of cheesecloth. The animals were fed 1 kg/d DM of alfalfa hay and 0.3 kg/d DM of concentrate (165 g CP/kg DM). Rumen fluid was centrifuged (10 min, 3000 rpm) and a solution of cycloheximide was added to protozoa free supernatant to remove the fungal population. Data of gas produced over the incubations were applied to an exponential equation of $P = b(1\text{-}e)^{-ct}$ where (b) is the amount of gas produced from the fermentable fraction, (c) is the fractional constant rate and (t) is time. Data were analyzed using the GLM procedure of SAS 9.1 and the means were compared by the Tukey test ($P < 0.05$). The amount of gas produced from the fermentable fraction (b ± SEM) was 48.1 ± 3.8, 43.3 ± 3.56 and 42.6 ± 2.5 for mic4, mic6 and mic8, respectively. The fractional constant rate parameters (c ± SEM) were 0.01 ± 0.001, 0.01 ± 0.002 and 0.01 ± 0.001 for mic4, mic6 and mic8, respectively. Data of the present study demonstrate that there is not a positive response for enhancing the CH fermentability by ruminal bacteria when microwave irradiation was applied.

Key Words: cottonseed hulls, gas production, microwave irradiation

M436 The influence of extrusion of low-glucosinolate full-fat rapeseed and whole pea on site and extent of protein digestion in dairy cows. C. Bayourthe* and F. Enjalbert, *UMR 1289 INRA/INPT/ENVT TANDEM*, *31326 Castanet-Tolosan, France*.

The objectives of the study were to develop suitable treated blends for protection of low-glucosinolate rapeseed (canola) proteins from rumen degradation and to determine the protein quality after rumen exposure. Full-fat canola seeds (CS) were mixed either with canola meal (CM) or with canola meal plus whole pea seeds (PS). The effect of extrusion at 130 and 150°C on in situ crude protein (CP) degradability of raw and treated blends was measured by the nylon bag technique using 3 fistulated non-lactating Holstein cows. Ruminal degradation rate of CP was estimated as percent nitrogen degradation (DgN) from polyester bags incubated in rumen for 2, 4, 8, 16, 24 and 48 h. Data were fitted to the nonlinear regression equation: $DgN(t) = a + b(1 - e^{-ct})$ where DgN is percentage disappearance of N at time t, a the soluble fraction and b the less rapidly degradable fraction which disappears at the constant fractional rate c per time t. Heating the blends at 130 and 150°C decreased the effective degradability of crude protein (EDCP) when compared with the raw blend: 37.3 and 33.6 respectively vs 57.2% for CM/CS blend; 53.8 and 42.4 respectively vs 62.5% for the CM/CS/PS blend. Total CP disappearing in the digestive tract was estimated by incubating bags in the rumen for 16h, followed by a pepsin bath for 2h and then introduced into the duodenum for subsequently recovery in feces. For the CM/CS blend, amounts of rumen undegraded dietary CP digested in the intestine were increased from 32.7 (raw blend) to 49.3% at 130°C and 53.6% at 150°C. Similarly, for the CM/CS/PS blend, corresponding values were 27.9 for the raw blend to 38.2 and 53.3% respectively for 130 and 150°C heat treatments. The results showed that PS was the most effective carrier of rapeseed during extrusion. The tested blends and the treatments applied appeared to be a viable and consistent method of increasing the ruminally undegradable protein fraction

Key Words: extrusion, canola, ruminal degradation

M437 In situ ruminal degradability of dry matter and crude protein of soybean meal treated with formaldehyde and extrusion. A. A. Naserian* and H. Gholizadeh, *Ferdowsi University of Mashhad*, *Mashhad, Iran*.

The objective of this study was to determine effect of formaldehyde and extrusion on in situ ruminal degradability of DM and CP of soybeans. Treatments include; untreated soybean meal (USM) treated with formaldehyde (TF) and extruded soybean (ES). The treated soybean meal was sprayed with 2.5 (w/v) formaldehyde at the rate of 0.2 l/kg. Extrusion was conducted on ground soybeans (EXP 160 KW). Extrusion temperature and residence time averaged 1550 C and 25 s respectively. Four ruminally fistulated steers (400 ± 20 kg, body weight) were used. Steers were fed 5.2 kg of alfalfa hay, 1.3 kg of corn silage and 2.6 kg of concentrate. Bags (12 × 19 cm, pore size of 48 µm) containing 5 g DM of each sample was incubated in the rumen (4 replicates per each animal) for 0.0, 2, 4, 8, 16, 24, 48, and 72 h. After removal of the bags

from the rumen, they were washed using cold water and dried in a forced air oven (60 0C, 48 h), weighed to determination DM disappearance, and CP of the samples determined. Data was fitted to exponential model to calculate degradation parameters of CP and DM (Orskove et al.,1980). TF had the lowest in situ quickly degradable (a) fraction (27%, $P < 0.05$). No difference in (a) fraction of DM was observed between ES and USM (42 and 38% respectively, $P > 0.05$). In situ (a) fraction of CP was highest for USM (27%, $P < 0.05$) and had no difference between ES and FT (7 and 11% respectively, $P > 0.05$). Slowly degradable (b) fraction of DM did differ between treatments ($P < 0.05$). USM had the highest (b) fraction (63%) and did not differ between TF and ES (34 and 27% respectively, $P > 0.05$). Slowly degradable (b) fractions of CP had no difference between ES and USM (78 and 72% respectively, $P > 0.05$), were higher than TF (34%). Rate of degradation (c) of DM and CP were significant ($P < 0.05$). TF had a lower (c) fraction of DM and CP (3 and 1% respectively) compared with USM (9 and 9%) and ES (12 and 4%) compared with USM. It was concluded that TF decreased (a) and (b) fraction of DM and CP relative to USM. But, ES led to decreased (a) and increased (b) fraction.

Key Words: soybean, extrusion, formaldehyde

M438 Disappearance of total carotenoids in the rumen and intestine of steers measured using a mobile nylon bag technique. R. G. Cruz-Monterrosa*[1], I. Guerrero-Legarreta[1], and E. Ramirez-Bribiesca[2], [1]*Universidad Autonoma Metropolitana*, *D.F., Mexico*, [2]*Colegio de Postgraduados*, *Texococo Mexico*.

There are few studies on the disappearance of total carotenoids in tropical forages. However, it could be a contributing factor in the wide variation in bio-availability of carotenoids of natural forages. The disappearance of dry matter (DM) and total carotenoids were measured in 4 Holstein steers (312 kg) using a mobile nylon bag technique. In situ effects and differences between forage in rumen and intestine, and total tract disappearance of DM, and total carotenoids were analyzed using the GLM procedure of SAS with Tukey multiple range test used for the comparison of means. A higher ($P < 0.05$) proportion of the dry matter and total carotenoids in the *Cynodon* spp. disappeared drastically in the rumen during the first 12 h, and after were stabilized from 24 to 72 h. A similar trend ($P < 0.05$) was evident in the disappearance of the total carotenoids in the *Cynodon* spp. Correlation value within *Cynodon* spp. between the disappearance of DM and total carotenoids in the rumen was 0.997 ($P < 0.001$). 53% of the carotenoids in the *Cynodon* spp. disappeared from the duodenal bags in the lower digestive tract when it was not incubated in the rumen. Bags with longer incubation in the rumen contain less carotenoids and therefore the efficiency of disappearance in the small intestine decreased ($P < 0.05$). In the total disappearance of carotenoids content in digestive tract was half when the grass sample was not incubated into the rumen; subsequently, the disappearance of total carotenoids in the small intestine increased in forage samples with significant differences between ruminal hours post incubation ($P < 0.05$). These results show that apparent availability in the total digestive tract was higher to 0.70 of intake. The concentration of total carotenoids in *Cynodon* spp. was 627 mg/kg DM. It is concluded that degradability of total carotenoids contained in *Cynodon* spp. is high and not all absorbed as carotenoids. Thus, the yellow color of beef fat is caused by accumulation of carotenoids in the fat depots.

Key Words: carotenoids, *Cynodon* spp., cattle

M439 The relationship between intestinal digestibility of crude protein and dry matters and the protein fractions with ruminant feedstuffs. R. Zhou, J. Q. Wang*, F. M. Pan, D. P. Bu, H. Y. Wei, and L. Y. Zhou, *State Key Laboratory*, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China*.

The study was to find out the relationship between the degradation and the digestibility and the contents of each protein fractions of 11 feeds common used in China. Chemical contents were determined according to the methods provided by CNCPS Version 5.0. The mobile nylon bag technique was used to investigate the apparent small intestinal digestibility of crude protein (CP) and dry matters (DM).Three dairy cows fitted with permanent ruminal cannulas and T-type duodenal cannulas were used to investigate intestinal digestibility of CP and DM by mobile nylon bag technique in soybean meal (SBM), cottonseed meal (CSM), rapeseed meal (RSM), peanut meal (PM), flaxseed meal (FSM), linseed meal (LSM), distillers dried grains (DDGS), expanded soybean (ES), corn grain (CG), brewer's grains (BG), alfalfa hay (AH), chinese wildrye (CW) and whole corn silage (WCS). The content of undegraded DM after 16 h incubation was affected by the NDF and PB3 fractions ($r^2 = 0.9088$). The content of ruminal undegraded protein (RUP) have a high relationship with contents of the NDF and PA fractions ($r^2 = 0.6227$). The absorbed DM in intestine increased while the feeds have more NDF. The protein content absorbed in the intestine can be mainly predicted by the NDF and PC content ($r^2 = 0.7344$). In our result, we can see that the intestinal absorbed DM and CP have a high relationship with the content of each protein fractions.

Key Words: protein fractions, intestinal digestibility, ruminants

M441 Enzymatic activity of microorganisms attached to solid residues of *Festulolium*, fermentation variables and in vitro kinetics of gas production. I. Almaraz-Buendía[1], S. S. González-Muñoz*[1], O. Loera[2], L. A. Miranda-Romero[3], M. A. Cobos-Peralta[1], M. Meneses-Mayo[1], B. Alarcón-Zúñiga[3], and R. Bárcena-Gama[1], [1]*Colegio de Postgraduados*, *Montecillo, Edo. de México, México*, [2]*Universidad Autóoma Metropolitana–Iztapalapa*, *México D.F., México*, [3]*Universidad Autónoma Chapingo*, *Chapingo, Edo. de México, México*.

The objective of the present study was to determine the effect of *Festulolium*, harvested either at 28 (T1) or 35 d, on enzymatic activities from microorganism attached to this fermented substrate [IU/g DM; at 39°C and pH 6.8: after 1 h for carboxymethycellulases (CMCases) and after 30 min for xylanases], in addition to VFA, N-NH3 and in vitro DM disappearance (IVDMD). Samples of enzymatic extract (EE) were obtained at 12, 16, 24 and 48 h of fermentation. Xylanolytic activity was determined at substrate concentration ranges ensuring linear release of reducing sugars (R2 = 0.99 for up to 60 min). Maximal gas volume (Vmax), lag phase (L) and fractional rate (S) were calculated with a logistic model and PROC NLIN (SAS). The experimental design was incomplete randomized blocks with a split-plot arrangement and data was analyzed using PROC MIXED (SAS). Enzymatic activity and N-NH3 were similar among treatments ($P \geq 0.05$). The highest CMCase activity ($P \leq 0.05$) was obtained at 12 (T1:8.19, T2:7.75 IU/g DM) and 16 h (T1:7.75, T2:7.65 IU/g DM) of fermentation, whereas maximal xylanolytic levels ($P \leq 0.05$) were observed after 16 (T1:51.09, T2:46.68 IU/g DM) and 24 h (T1:51.23, T2:46.15 IU/g DM). The highest concentration ($P \leq 0.05$) of acetic (30.05 vs 42.92 mM/L), propionic (9.69 vs 12.3 mM/L) and butyric acids (8.03 vs 12.04 mM/L) were detected ($P \leq 0.05$) in T2 after 48 h of fermentation. Both maximal ($P \leq 0.05$) IVDMD and Vmax were also observed in T2, whereas L and S were highest ($P \leq 0.05$) in T1. According to these results, in vitro CMCases and xylanases from microorganism attached to *Festulolium*, harvested either at 28 or 35 d, remain unchanged; however IVDMD and gas

production kinetics did show an effect as a function of harvesting date of *Festulolium*.

Key Words: *Festulolium*, enzymatic activity, microbial attachment

M442 Use of in vitro starch and neutral detergent fiber degradation rates to predict carbohydrate availability. M. A. Brooks*, N. F. Johnson, R. M. Harvey, and M. S. Kerley, *University of Missouri*, *Columbia*.

The purpose of this in vitro experiment was to compare degradation rates (K_d) of ruminally degradable starch and neutral detergent fiber (NDF) of various feedstuffs, then use these data to predict carbohydrate (CHO) release. The feedstuffs, ground corn (GC), corn bran (CB), corn starch (CS), dried distiller's grains (DDG), soy hulls (SH), and ground alfalfa (AL), were fermented in rumen inoculum. Carbohydrate degradation was determined at 0, 4, 8, 12, 16, 24, 36, and 48 h for each feed. Undigested feed was separated via differential centrifugation (1,000 × g, 15 min) and dried at 55°C. Samples were analyzed for total starch and NDF. The time point at which degradation reached extent (no further starch or NDF was degraded) was set to 100%. Carbohydrate mass at each time point was calculated as proportion of starch or NDF remaining. Data were analyzed using proportion of potential degradation as the dependent variable with flask as the experimental unit to determine homogeneity of slope with the means adjusted to time as a covariate. Pair-wise comparisons for similarity were then done of each feed using a significance level of $P > 0.01$. Slope of the data was indicative of degradation rate over time. All R^2 values were >0.80, and since these data were evaluated as proportions and were corrected for extent of degradation, all intercepts values were similar to 1.0. The starch K_d values for AL, CB, CS, DDG, GC, and SH were 5.01, 6.08, 4.80, 5.51, 2.31, and 4.14% h^{-1}, respectively. Analysis showed GC had a slower K_d ($P < 0.01$) than all other feeds, which were not different from each other ($P > 0.01$). The NDF K_d values for AL, CB, CS, DDG, GC, and SH were 2.18, 2.24, 2.16, 2.18, 2.44, and 2.31% h^{-1}, respectively. Analysis showed no differences in NDF K_d ($P > 0.01$). Digestion of CHO in the rumen occurred at similar rates independent of feedstuff. Similarity of starch and NDF K_d across feeds, when adjusted for passage rate, makes possible prediction of CHO digestibility in the rumen by ruminal microbes and prediction of microbial growth and efficiency potential.

Key Words: starch, NDF, ruminant

M443 Effect of lysozyme-adapted *Lactobacillus acidophilus* on fermentation in an artificial rumen system (Rusitec). M. L. He[1,3], T. A. McAllister*[1], and L. M. Rode[2], [1]*Agriculture and Agri-Food Canada, Research Centre*, *Lethbridge, AB, Canada*, [2]*AB Sage Biosciences Inc.*, *Edmonton, AB, Canada*, [3]*University of Saskatchewan*, *Saskatoon, SK, Canada*.

Direct-fed microbials are increasingly being used as an alternative to subtherapeutic antibiotics in dairy and beef production because of their potential to enhance animal performance without promoting the emergence of antibiotic-resistant bacteria. Lysozyme is an enzyme that hydrolyzes the 1,4-β-linkages between N-acetylmuramic acid and N-acetyl-D-glucosamine residues in the peptidoglycan of gram-positive bacteria. The cell wall of lysozyme-adapted bacteria may exhibit increased rigidity and thereby contribute to their perseverance in highly competitive environments such as the rumen ecosystem. The Rumen Simulation Technique (Rusitec) was used to evaluate the effect of a lysozyme-adapted (L- BT1386) or a non-adapted strain (BT1386) of *Lactobacillus acidophilus*, as well as strain La 14, on ruminal fermentation. Ruminal fluid for the Rusitec was collected from 3 Holstein cows fed a 90% concentrate:10% silage diet. Sixteen fermenters (920 mL capacity; dilution rate 0.029/h) were provided fresh substrate daily (8 g steam-rolled barley grain + 2 g silage; DM basis). Four fermenters per treatment were inoculated with 5×10^{10} cfu/d of the specified strain or with buffer only. Compared with non-inoculants, L-BT1386 increased ($P = 0.04$) gas production (mL/d) and BT1386 increased ($P = 0.02$) VFA and ammonia production. Methane emissions (mL/d) were numerically greater ($P = 0.09$) in inoculated fermenters than in non-inoculants, as were disappearances (at 48 h) of DM, ADF, NDF and N from barley grain and silage ($P = 0.20$ to 0.66). Protozoal numbers were similar among treatments ($P = 0.21$) but decreased ($P < 0.05$) over time (d 9 to 18). Measured fermentation parameters did not differ between L-BT1386 and BT1386. Studies using strain-specific molecular probes are underway to determine if exposure to lysozyme increased the numbers and persistence of BT1386 within the Rusitec.

Key Words: direct fed microbials, rumen fermentation, rumen simulation technique

M444 Development of a PCR assay for the detection of *Zymomonas mobilis* in distillers grains. M. A. Rasmussen* and F. H. Benahmed, *U.S. Food and Drug Administration, Center for Veterinary Medicine, Office of Research*, *Laurel, MD*.

The objective of this project was to develop a PCR assay for the detection of *Zymomonas mobilis* (Zm) in distillers grains (DG). This bacterium can produce ethanol at rates and concentrations exceeding those of yeast. This has made Zm, an attractive alternative or supplement to *Saccharomyces cervisiae* for ethanol production. Naturally occurring Zm can only ferment glucose, fructose and sucrose and as a result there has been an ongoing effort to modify the microbe to broaden its substrate range. However, the use of Zm as a primary fermentative microorganism may alter the nutritional content of DG and the extent of its use for ethanol production is currently unknown. Therefore, we developed an assay for DG that can be used to determine if Zm is being used for ethanol production. PCR is a useful and sensitive technique that can detect the bacterium even if nonviable or nonculturable. Reference strains of Zm were obtained from the ARS culture collection in Peoria, IL and were cultivated in YP media under oxygen limiting conditions. Overnight cultures were serially diluted into buffer supplemented with Tween 20. Zm cells were harvested and tested directly by PCR. Primer sequences specific for Zm targeted a 900 bp rRNA overlapping region of the 16s gene Z16p3 and the 23s gene Z23p5. For tests in the relevant matrix, the assay was tested on DG samples inoculated with serial dilutions of Zm cells. A single PCR band was visualized in all Zm strains investigated and no band was observed in the negative control DG matrix. Additionally, plate culture was used for assay optimization and confirmation. The limit of detection for the PCR assay was determined to be 10 cfu/ml of the DG wash/suspension buffer or 100 cfu/g of DG. Current activities are directed at optimizing the assay for use with DG field samples to determine if Zm is present. In conclusion, this assay can be used to test for Zm and is more rapid and sensitive than traditional culture methods.

Key Words: distillers grains, *Zymomonas*, bioethanol

M445 Intake prediction using *n*-alkanes in beef cattle fed a mixture of switchgrass and alfalfa hay. S. J. Chavez*, C. Baum-Lane, E. Leonard, J. Burns, and G. B. Huntington, *North Carolina State University*, *Raleigh*.

The objectives of the study were to use *n*-alkanes to predict intake in beef cattle fed mixed forage and to predict intake of forage constituents based

on forage alkane concentrations. In May and June 2009, 11 Angus-cross steers and 1 heifer (BW = 283 ± 25 kg) were housed under a roof on expanded metal flooring with access to 6 feeding stations. Cattle were fed 1 kg of a soyhull and corn supplement once daily at one feeding station that was sprayed with dotriacontane (C32) and hexatriacontane (C36). Cattle consumed approximately 300 mg each of C32 and C36. Cattle were offered a switchgrass:alfalfa (3:1 as fed) mixed hay at 0.6% BW at each feed station. Hay was ground in a hammer mill to minimize sorting. Periods consisted of one week adaptation followed by 14 d of feeding supplement with added alkanes. Fecal grab samples were collected between 0800 and 1000 during the last 5 d. Fecal samples were stored frozen and oven-dried to constant weight at 60°C. Hay and fecal samples were saponified, alkanes were extracted with heptane, and samples analyzed by gas chromatography for alkane concentrations. One steer was removed from data analysis due to inconsistent eating and rear leg inflammation and another was removed for highly variable fecal ratios of hentriacontane (C31) and C32. Tetratriacontane (C34) was used as an internal standard for saponification and extraction with recoveries ranging from 80 to 90%. When feed and fecal ratios of C31 and C32 were used in prediction equations, predicted daily DMI (5.96 ± 0.70 kg) was not different ($P < 0.35$) from measured intake (5.51 ± 0.68 kg). Using simultaneous equations and concentrations of nonacosane (C29) and C31 in the hays, the predicted ratio of switchgrass:alfalfa (3.09:1) was similar to the actual ratio. Using C36, predicted digestibility was 58.7 ± 2.2% for the switchgrass and alfalfa hay. Alkanes can be used to predict intake in cattle fed a mixed forage diet and also predict the proportion of each forage consumed.

Key Words: cattle, alkane, intake

M446 A comparison of methods to evaluate in vitro intestinal digestibility. D. A. Ross*, M. M. McCullouch, and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

Various assays are used to evaluate the intestinal digestibility of dry matter (DM) and nitrogen (N) in ruminant feeds (Casamiglia and Stern, 1995; Gargallo et al. 2006). The objective of this study was to evaluate in vitro (IV) intestinal digestibility of DM and N of 7 feeds (fishmeal, corn silage, alfalfa silage, 2 soy products and 2 DDG) following in situ (IS) or ruminal IV procedures. We wanted to determine if ruminal IV or IS exposure or length of exposure altered the IV intestinal digestibility and further, if the pore size of the incubation bag affected variation of the assay. Samples (0.5g) were placed in 3 pore size (15, 25 or 50 µm) bags (5 × 5 cm) and incubated for 12-h or 24-h ruminal digestion either IS or IV (Daisyincubator, Ankom, Macedon, NY) followed by IV intestinal digestion (modified Gargallo et al. 2006). Empty bags were incubated for correction. Data were analyzed as a factorial design using GLM in SAS and Tukey's method to separate means. Incubation time in the rumen or rumen fluid affected digestibility, but there was no difference in IV intestinal digestibility based on ruminal exposure time (Table 1). Digestibility of DM and N_DM were significantly lower in the 25 µm pore bags; however no differences among bag pore sizes were detected for IV intestinal digestion parameters. The effect of bag pore size for ruminal IV or IS digestion was not linear, due to characteristics of the bag material and will be discussed.

M447 The role of ADIN in determining nutrient availability in new co-products from bio-ethanol processing. W. G. Nuez-Ortín* and P. Yu, *Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan*, *Saskatoon, SK, Canada*.

The objectives of this study were to investigate the role of acid detergent insoluble nitrogen (ADIN) in determining the nutrient availability in the new co-products of bio-ethanol processing and the relationship between ADIN content and nutrient utilization of the bioethanol co-products in ruminants. The corn DDGS, wheat DDGS and blend DDGS (70% wheat: 30% corn), and wheat and corn samples with 3 to 5 different batches were obtained during 2007–2008. The results showed that compared with the grains, DDGS contained higher ($P < 0.05$) acid detergent insoluble crude protein (ADICP) level from 1.2 to 7.6%CP vs. 0 to 0.1% crude protein (CP) in the grains. However, all ADICP levels were lower than 13% of total CP across DDGS samples, revealing no effects ($P > 0.05$) on protein ruminal digestion with a correlation between ADICP and rumen-degradable protein (RDP): R = −0.08, $P = 0.74$. However, the difference in the ADICP content was reflected in largely numerical differences in the intestinal digestibility of rumen-undegradable protein (RUP) in vitro, which ultimately affected ($P < 0.05$) the intestinal availability of RUP (ARUP) as well as the predicted total post-ruminal protein supply and availability (the correlation between ADICP and metabolizable protein (MP): R = −0.74, $P < 0.05$). This suggests a higher sensitivity to low ADICP levels in the rumen than that in the small intestine in the DDGS samples.

Key Words: nutrient utilization and availability, bio-ethanol co-products, ADIN

M448 A comparison of models used to estimate kinetics of in vitro degradation of alfalfa hay dry matter. C. A. Old*[1] and D. A. Sapienza[2], [1]*California Chapter of the American Registry of Professional Animal Scientists*, *LeGrand, CA,* [2]*Sapienza Analytica, LLC*, *Des Moines, IA*.

To determine more accurately alfalfa hay quality California ARPAS undertook a project to estimate metabolizable energy, rate, site and extent of degradability of selected chemical and proximate entities and use these as part of a set of prediction equations in near infrared (NIR) spectrophotometry. This study had in vivo, in vitro and in silico components based on 150 samples of alfalfa hay collected during the

2008 growing season in California. The diversity of samples can be seen from the range of crude protein and acid detergent fiber content, the former was 13 percentage points and the latter 30 percentage points. Samples for in vitro analysis were ground through a 6-mm screen and incubated from 1 to 120 h. Losses of N were calculated from 16-h amino acid losses and averaged 63%. Disappearance of individual amino acids ranged from a low of 57% (Leu) to a high of 75% (Pro). Variation in losses among samples was less than variation among amino acids. Dry matter losses, at 120 h, averaged 80.2%. Kinetics of in vitro dry matter degradation were estimated using a heterogeneous, stochastic model assuming a gamma distribution of rates (HS): $C_t = D(1+\beta[t-\tau])^{-\alpha}+I$, a single exponential deterministic model (SE): $C_t = C_0e^{-kt}$ and a biexponential deterministic model (BE):$C_t = C_{01}e^{-k1t}+ C_{02}e^{-k2t}$. C_t is the residue at time t, D is the degradable fraction, β and α are shape parameters of a gamma distribution, τ is lag time, I is the undegradable fraction,C_{0n} is compartment n at time 0 and k_n is the rate constant for compartment n. Average residual sum of squares for models HS, SE and BE were 0.012, 4.29 and 0.160, respectively. As a result of this study, kinetics of alfalfa hay degradation will be described in the NIR model using a heterogeneous, stochastic model.

Key Words: alfalfa hay quality, kinetic models, amino acids

M449 Application of near infrared spectroscopy to estimate composition of NuPro. G. A. Harrison*, M. D. Meyer, E. C. Taylor, and K. A. Dawson, *Alltech*, *Nicholasville, KY*.

The properties of near infrared spectroscopy (NIR) make this technology attractive in quality assurance programs. Provided reliable reference methods are utilized to determine component concentrations in calibration samples, NIR can potentially replace routine wet chemistry. The objective of this project was to determine the feasibility of using NIR to estimate the composition of NuPro (an extract of a select yeast strain containing a combination of amino acids, peptides, nucleotides, inositol, and glutamic acid) in the Alltech Quality Assurance Program. From an initial 239 NuPro samples, 100 calibration samples and 20 test samples were randomly selected with equal representation from each of 2 manufacturing sites. Samples were scanned in triplicate using a Bruker MPA FT-NIR Spectrometer (Bruker Optics, Inc., Billerica, MA). For each component, 3 calibration models were developed using cross validation and various spectral preprocessing methods. Multiple criteria were utilized to determine the best fit model including coefficient of determination (R2), root mean square error of cross validation (RMSECV), and residual prediction deviation (RPD). Additionally, NIR-predicted values of test samples were compared with values measured by reference methods. Bias and percentage of samples with predicted values within 5 and 10% of measured were calculated. A 2-tailed paired *t*-test was used as the final criterion. The best fit DM model had an R^2 of 84.6, RMSECV of 0.479, and RDP of 2.55 with 100% of samples were within 5%. The best fit N model had an R^2 of 93.0, RMSECV of 0.072, and RDP of 3.77 with 100% of samples within 5%. For total nucleotides, the best fit model had an R^2 of 86.6, RMSECV of 0.603, and RDP of 2.73 with 60 and 80% of samples within 5 and 10%, respectively. Statistical analyses by paired *t*-test found no difference between measured and predicted values for DM, N, C, H or total nucleotides ($P > 0.10$). For quality assurance purposes, composition of NuPro can be estimated through the use of NIR models.

Key Words: near infrared spectroscopy, quality assurance

M450 Ability of NIR to predict crude fat, fatty acids and unsaturated fatty acids in total mixed ration fed to dairy cattle. S. Weaver*[1], R. Ward[1], and R. A. Patton[2], [1]*Cumberland Valley Analytical Services*, *Maugansville, MD*, [2]*Nittany Dairy Nutrition*, *Mifflinburg, PA*.

It is known that formation of CLA due to consumption of high levels of linoelic and linolenic acids may have a negative effect on milk fat production depending on the rumen environment. Determination of the amounts and types of fatty acids (FA) in total mixed rations (TMR) would allow nutritionists to better control these elements. At present determination of fat and FA percent as well as individual fatty acid amounts is expensive and time consuming. We postulated that NIR has the potential to rapidly and inexpensively predict the amount of fat, percentage of FA, and the FA composition of this fat in TMR. A data set of 89 individual TMR samples were analyzed for crude fat by the AOAC method for feeds (2003.05). Fatty acids were analyzed as methyl esters on a Restek 30 m capillary column (90% biscyanopropyl / 10% phenylcyanopropyl polysiloxane) using a Perkin Elmer Autosystems GC with a flame ionization detector using the method of Sukhija and Palmquist (1988. J. Agric. Food Chem. 36:1202–1206). Comparisons of observed versus NIR predicted values were by the MSPE method described by Bibby and Toutenburg (1977). NIR predicted crude fat values were close to values for chemically defined fat (observed mean = 4.68, predicted mean = 4.74, RMSPE = 0.45 with 96% random error). The prediction of total FA was even more precise (observed mean = 3.63, predicted mean = 3.63, RMSPE = 0.2 with 99% random error). However, predictions of individual unsaturated fatty acids, although reasonable for mean values, displayed considerable regression bias. This suggests that further research may yield better NIR prediction equations for individual fatty acids.

Key Words: fatty acids, TMR, NIR

M451 Evaluation of models to predict passage rate in cattle. S. J. Krizsan*[1], S. Ahvenjärvi[2], and P. Huhtanen[1], [1]*Department of Agricultural Research for Northern Sweden, Swedish University of Agricultural Sciences*, *Umeå, Sweden*, [2]*MTT-Agrifood Research Finland, Animal Production Research*, *Jokioinen, Finland*.

The passage rate (k_p) prediction equations in the National Research Council (2001) and the Cornell Net Carbohydrate and Protein System (CNCPS) were evaluated with compiled data of rumen evacuation studies. Data were comprised of 172 treatment means from 49 studies conducted in Europe and in the USA. A total of 145 diets were fed to dairy cows and 27 to growing cattle. The primary objectives of the trials included in the database were to study dietary effects on digestion and passage kinetics of fiber fractions. The concentration of indigestible NDF (iNDF) was determined by long-term ruminal incubations or in vitro incubations in rumen fluid. National Research Council (NRC) and CNCPS give separate k_p prediction equations for concentrate and forage feed. Therefore, an aggregated k_p was calculated according to: k_p (%) = 100 × Flux of indigestible component into the compartment (kg/h) / Rumen pool of indigestible component (kg). Preferably intake of iNDF of forage and concentrate (n = 165), else intake of NDF from forages and concentrates (n = 7) were used to calculate the aggregated k_p. Rumen pool sizes of iNDF and NDF were defined separately for concentrate and forage feed and total pool size was estimated from the sum. Mixed model regression analysis including a random study effect was used to investigate the relationships between NRC and CNCPS predictions and observed k_p of iNDF. Prediction equations were evaluated by regressing residual values on the predicted values. Relationships between predicted and observed k_p were $y = 0.53(\pm0.187) + 0.41(\pm0.0373)x$ and $y = 0.58(\pm0.162) + 0.46(\pm0.0377)x$ for the NRC and CNCPS models, respectively. Residual analysis of the NRC and CNCPS models resulted

in both significant ($P < 0.001$) mean biases of −2.40 and −1.70% and linear biases of −0.59 and −0.53, respectively. This evaluation suggested that both the NRC and CNCPS models grossly overestimated ruminal particulate matter k_p.

Key Words: cattle, evaluation, passage rate

M452 Net portal absorption of energy nutrients in ruminants: Assessment of prediction models. C Loncke*[1], P Nozière[1], G Kraft[1], I Savary-Auzeloux[1], J Vernet[1], H Lapierre[2], D Sauvant[3], and I Ortigues-Marty[1], [1]*INRA, UR 1213*, *Theix, France*, [2]*Agriculture and Agri-Food Canada*, *Sherbrooke, QC, Canada*, [3]*INRA-AgroParisTech, UMR 791*, *Paris, France*.

In ruminant nutrition, the evolution of feed evaluation systems toward nutrient-based systems is an important challenge. Net portal appearance (NPA) of total VFA, acetate (C2), propionate (C3), butyrate (C4), glucose, β-hydroxybutyrate (BHBA), and lactate can be estimated with response equations based on ration intake and composition characterized according to INRA Feed Tables for Ruminants and derived from meta-analyses on the FLORA database. The present objective was to evaluate the models using the results of a recent study, conducted on 6 growing lambs, catheterized at the portal level. The lambs were fed 3 diets made of 30% hay and 70% of 1 of 3 concentrates, according to a Latin Square design. The control diet (C) was designed to offer a balanced and adequate supply of protein and ME for growing lambs according to INRA allowances. Low nitrogen (LN) and energy (LE) diets presented a 23% and 20% deficit in protein and ME supply respectively compared with the C diet. To evaluate the prediction ability of the models, observed (Y) and predicted NPA (X) was compared using a GLM model including a within-animal effect. The slopes obtained were equal to 0.88 ± 0.13, 0.78 ± 0.21, 1.06 ± 0.22, 0.88 ± 0.22, 0.80 ± 0.25, 1.30 ± 0.50, respectively for total VFA, C2, C3, C4, BHBA and lactate NPA and proved not different from 1. Moreover the intercepts of all models were not different from 0 ($P > 0.2$). The slope (12.4 ± 2.4) of the relation between observed and predicted values of glucose NPA showed a lower adjustment probably due to larger uncertainties on the ruminal starch degradability required for the prediction. In most cases the best prediction was observed for the C diet probably because diet compositions of LN and LE were not fully included in the meta-design range of validity used to establish the models. In conclusion, this work suggested that the energy nutrients NPA could be predicted with a good accuracy.

Financial support from INZO and LIMAGRAIN is acknowledged.

Key Words: meta-analyses, energy nutrients, ruminants

Small Ruminant: Sheep Production 1

M453 Milk yield and composition from dairy ewes fed two sources of lipid supplements associated or not with conjugated linoleic acid (CLA). M. Baldin[1], R. Dresch[1], J. Souza[1], E. C. Sandri[1], F. Batistel[1], E. Ticiani[1], A. Panzera[1], L. O. Tedeschi[3], M. A. S. Gama[2], D. Fernandes[1], and D. E. Oliveira*[1], [1]*Santa Catarina State University*, *Chapecó, Brazil*, [2]*National Dairy Catlle Research Center*, *Juiz de Fora, MG, Brazil*, [3]*Texas A&M University*, *College Station*.

It is known that rumen-protected lipid (RPL) supplements or CLA may affect milk fat content in dairy ewes, but their combination has not been fully investigated. The objective of this study was to evaluate the effects of 2 sources of RPL with or without CLA supplement (29% t-10 c-12 and 29% c-9 t-11 isomers) on milk yield and milk composition of dairy ewes. Thirty-six East Friesian ewes (50 to 70 DIM) were used in a 2 × 2 factorial design and received the following treatments: 1) 30 g of calcium salts of long chain fatty acids from soybean oil (LCFAS); 2) 27 g of calcium salts of long chain fatty acids from palm oil (LCFAP); 3) 30 g of LCFAS plus 20 g of CLA; and 4) 27 g of LCFAP plus 20 g of CLA. The lipid supplements were isocaloric. CLA, LCFAS, and LCFAP were added into a corn-based concentrate (1.0 kg/d, as-fed) and individually fed twice daily after morning and afternoon milkings. Ewes were grazing *Panicum maximum* Jacq. cv. Aruana pasture during the experimental period (53 d) of which 5 d were used for adaptation, 40 d for data collection, and 8 d for residual effects. Data were analyzed in a repeated measure design, including RPL, CLA, d, and their interactions as sources of variation. Milk yield was unaffected by CLA (1.17 kg/d; $P = 0.64$) and RPL (1.15 kg/d; $P = 0.95$). There was an interaction between CLA and RPL ($P = 0.02$) for milk fat content. For ewes receiving CLA, milk fat content was similar ($P = 0.49$) between LCFAP and LCFAS (4.31 vs. 4.18%, respectively). However, when CLA was not fed, milk fat content was greater ($P = 0.004$) for ewes receiving LCFAP compared with those receiving LCFAS (6.27 vs. 5.52%, respectively). LCFAP increased ($P = 0.02$) milk protein content compared with LCFAS (4.96 vs. 4.77%, respectively). Even though RPL and CLA did not impact milk yield, the source of RPL may affect milk fat composition when CLA is not provided to lactating dairy ewes.

Key Words: cojugated linoleic acid, lactating dairy ewes, milk composition

M454 New management technique in early lactation can improve profitability in dairy sheep farms. S. P. G. Rassu, C. Carzedda, A. Mazzette, C. Dimauro, A. Mazza, and G. Pulina*, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*.

The effect of 2 management techniques on farm profitability of dairy Sarda ewes was tested. During the suckling period, i.e., the first month of lactation, 22 Sarda ewes (2–4 year old) were used. Eleven ewes (SL group) were separated from their lambs, starting from 5 d after birth, from 0800 to 1600 h, fed on pasture and milked one time per day before to be rejoined with their lambs. The other 11 ewes (NSL group) were fed on pasture, never separated from the lambs, and milked at the same time of SL group. Lambs of SL group were also supplemented with a commercial feed (0.40 €/kg) to compensate for less available milk. All lambs were slaughtered at 25 d of age. Milk yield of ewes, and body weight of lambs were recorded during the sucking period. Moreover, milk yield, fat and protein contents of ewes were measured during the month after lamb slaughtering. Data were analyzed by a GLM model, using management (SL and NSL), date of the measurement sampling and their interaction as fixed factors. Milk yield was higher in SL compared with NSL group both during suckling period (g/d 645 ± 38 vs 83 ± 38; $P = 0.000$) and during first month after lambs slaughtering (g/d 1494 ± 31 vs 1334 ± 33; $P = 0.001$). Body weight at slaughter (SL kg 11.4 ± 0.2 vs NSL kg 11.1 ± 0.2; $P = 0.563$) and daily growth of lambs (SL g/d 267 ± 9 vs NSL g/d 263 ± 9; $P = 0.703$) were not different between experimental groups as well as milk fat (SL 5.46% ± 0.09 vs NSL 5.67% ± 0.09; $P = 0.087$) and milk protein content (SL 5.12% ± 0.05 vs NSL 5.06% ± 0.05; $P = 0.323$). Therefore, profitability of SL group was higher than NSL group, in particular during suckling period. Indeed, return of the SL group is equal to 0.393 €/head/d (gain from milk = production 0.645 g/head/d × 0.650 €/kg of milk) minus 0.026 €/lamb/d cost of feeding lambs (pellet feed consumed 65 g/head/d × 0.40 €/kg of pellet) that is equal to about 8.0 €/head in 25 d of suckling. Return of the NSL group is equal to 0.054 €/head/d (no cost for lambs feeding and little gain from milk) that is equal to about 1.0 €/head on the same period.

Key Words: sheep, milk, lamb

M455 Assessment of milk yield and milk composition in ewes fed diets with canola, sunflower or castor oil. M. O. Maia*, I. Susin, A. V. Pires, E. M. Ferreira, R. S. Gentil, C. Q. Mendes, D. B. Galvani, and A. L. M. Selegato, *University of São Paulo/ESALQ*, *Piracicaba, SP, Brazil*.

The inclusion of fat sources in ruminant diets is an alternative to achieve nutritional requirements, especially in early lactation. Additionally, vegetable oils can modify milk fatty acid profile. Forty-four Santa Inês ewes (66.6 ± 4.9 kg BW and 14 ± 3 d in milk) were penned individually and used in a complete randomized block design to determine the effects of adding canola, sunflower or castor oil on DMI, milk production, and milk composition. Ewes were fed a basal diet (14.7 ± 0.1% CP, DM basis) containing 50% concentrate and 50% coastcross hay. The 4 treatments included control (0% oil, CONT), canola oil (3%, CAN), sunflower oil (3%, SUN) or castor oil (3%, CAS). Ewes were fed the diets from the wk 2 to 8 of lactation. Milk production was determined every 7 d during the experiment. Ewes were separated from lambs, oxytocin (10 IU) was infused i.v. to stimulate milk letdown, and ewes were mechanically milked. After 3 h, the procedure was repeated and milk production was recorded and a sample collected for milk composition analysis. Ewes were weighed for 3 consecutive days at the start and end of the experiment. Data were analyzed using SAS PROC Mixed procedure and means compared by Tukey Test. Dry matter intake was greater ($P \leq 0.01$) for ewes fed CONT diet (2.48 kg), whereas, no effect was observed on DMI among diets with oil inclusion (2.06, 2.18, and 2.09 ± 0.03 for CAN, SUN, and CAS, respectively). Milk production, milk protein and milk lactose were not different ($P \geq 0.05$) among diets. However, milk fat (7.9, 8.2, 7.7, and 9.3 ± 0.12% for CONT, CAN, SUN, and CAS, respectively) and total solids (18.6, 18.7, 18.6, and 20.0 ± 0.12% for CONT, CAN, SUN, and CAS, respectively) concentrations were greater ($P \leq 0.001$) for ewes fed the diet containing castor oil. There was no difference on BW change among treatments. In conclusion, the addition of oil regardless of source decreased DMI, but no effect on milk production was observed. Milk fat was increased with the inclusion of castor oil in lactation diets.

Key Words: lipids, oil source, Santa Inês

M456 Effect of different vegetable oils fed to lactating ewes on milk and cheese fatty acid profile. R. Bodas[1], P. Gómez-Cortés[2], A. R.

Mantecón[1], M. Juarez[2], M. A. De la Fuente[2], and T. Manso*[3], [1]*Instituto de Ganaderia de Montaña (CSIC-ULE)*, *León, Spain*, [2]*Instituto del Frío (CSIC)*, *Madrid, Spain*, [3]*E.T.S. Ingenierías Agrarias (Universidad de Valladolid)*, *Palencia, Spain*.

The aim of this study was to evaluate the effects of different vegetables oils fed to lactating ewes on milk and cheese fatty acid (FA) profile. After lambing, 48 Churra ewes were fed 2.1 kg of 40:60 (as-fed basis) lucerne:concentrate total mixed ration (TMR) daily and were milked twice a day. Ewes were assigned to 1 of 4 groups, which received 3% (as-fed basis) of the corresponding oil added daily to the TMR: hydrogenated palm oil (Con), olive oil (Oli), soybean oil (Soy) or linseed oil (Lin). On d 55 of lactation, 3 cheeses per treatment were made from the milk and samples of milk and cheeses were collected for FA analyses. The data were subjected to ANOVA according to a 2 (milk and cheese) by 4 (oils) factorial design using the MIXED procedure of SAS. Regardless the type of oil added to the diet, milk and cheese FA profiles were not different ($P > 0.10$). Cheese and milk samples from Con treatment had the greatest saturated FA (SFA) contents, but the least long chain FA (LCFA, > 18C), vaccenic (VA), and rumenic (RA) acid contents ($P < 0.001$). Milk and cheese from Soy treatment had the least SFA ($P < 0.001$), but the greatest VA, RA and linoleic acid contents and n6/n3 ratio ($P < 0.001$). Lin and Soy ewes produced milk and cheese with the greatest amount of polyunsaturated FA ($P < 0.001$). Olive oil supplementation increased oleic acid and decreased linoleic acid content ($P < 0.001$), whereas Lin gave raise to the greatest linolenic acid content and the least n6/n3 ratio ($P < 0.001$). From the results observed, it can be concluded that supplementing the diet of lactating ewes with oils is a suitable way of modulating naturally the FA profile of their milk and cheese.

Key Words: cheese, fatty acids, sheep

M457 Milk performance of ewes fed fish oil and soybean oil. E. M. Ferreira*, A. V. Pires, I. Susin, C. Q. Mendes, S. Gilaverte, R. S. Gentil, M. O. Maia, D. B. Galvani, and R. C. M. Meneghini, *University of São Paulo/ESALQ*, *Piracicaba, SP, Brazil*.

Dietary fish oil in combination with linoleic or linolenic fatty acid source consistently increases milk vaccenic and conjugated linoleic fatty acid concentrations. However, inclusion of fish oil in the diet can decrease DMI and milk production. Fifty Santa Inês ewes (64.9 ± 5.9 kg BW and 18 ± 2 d in milk) were used in a complete randomized block design and assigned to individual pens to determine the effects of replacing soybean oil with fish oil on lactation performance. The control diet (CONT) contained 29% forage (sugarcane bagasse) and 71% concentrate on a DM basis. In the remaining 4 treatments, fish oil replaced soybean oil (4% on DM basis) at 0, 0.25, 0.50, and 0.75%. Ewes were fed the diets from wk 2 to 8 of lactation. Milk production was measure every 7 d during the trial. Ewes were separated from lambs, oxytocin (10 IU) was infused i.v. to stimulate milk letdown, and ewes were mechanically milked. After 3 h, the procedure was repeated and milk production was recorded and a sample collected for milk composition analysis. Preplanned contrasts were supplemental fat (soybean oil or fish oil) versus no fat and linear, and quadratic contrast of fish oil inclusion. Dry matter intake (2.34, 2.12, 2.13, 2.07, and 2.11 ± 0.02 kg/d for CONT, 0FO, 0.25FO, 0.50FO and 0.75FO, respectively) was greater ($P < 0.01$) for ewes fed the CONT diet vs. fat inclusion, whereas, no effect ($P > 0.05$) was observed on DMI with fish oil inclusion. A linear increase ($P < 0.01$) for milk production (184.1, 190.2, 207.2, and 220.9 ± 4.5 g/3 h for 0FO, 0.25FO, 0.50FO and 0.75FO, respectively) was shown with fish oil inclusion. Milk fat concentration was similar ($P < 0.05$) for all diets. Milk protein (4.8, 4.7, 4.5, and 4.5 ± 0.04% for 0FO, 0.25FO, 0.50FO and 0.75FO, respectively) and total solids (18.0, 17.5, 17.4, and 17.3 ± 0.01% for 0FO, 0.25FO, 0.50FO and 0.75FO, respectively) concentrations decreased ($P < 0.01$) linearly with fish oil addition. Milk lactose (4.6, 4.8, 4.8, 4.8, and 4.8 ± 0.02% for CONT, 0FO, 0.25FO, 0.50FO and 0.75FO, respectively) concentration was greater ($P < 0.05$) for ewes fed the fat-supplemented diets vs. the control. In conclusion, replacing 4% soybean oil with fish oil up to 0.75% of the diet improved milk production without detrimental effect on DMI.

Key Words: milk production, sheep, fish oil

M458 Evaluation of inbreeding depression effect on birth weight of Baluchi sheep breed of Iran. G. Motaghinia*[1], H. Farhangfar[1], M. Bashtani[1], A. Shadparvar[2], H. Saraee[1], H. Janati[3], and J. Modarresi[4], [1]*Birjand University*, *Birjand, Iran*, [2]*Guilan University*, *Rasht, Iran*, [3]*Baluchi Sheep Breeding Station*, *Mashhad, Iran*, [4]*Agricultural Jihad Organisation*, *Birjand, Iran*.

The main objective of this research was to estimate the effect of inbreeding on birth weight of Baluchi sheep breed of Iran. A total of 13,007 birth weight records was utilized. The data were collected from 13,007 lambs (born from 1984 to 2006) in Baluchi sheep breeding station, northeast region of Iran. The lambs were born between December and April. Birth weight average was 4.27 kg. Inbreeding coefficient was calculated for individual lambs using pedigree software. In the data set, minimum and maximum of the inbreeding coefficient were 0 and 0.321, respectively. Dependent variable was birth weight and the data were analyzed by a Mixed Linear Model applied in SAS software. In the model, fixed main effects of herd, year and month of birth, lamb sex, birth type, as well as 2-way interactions between herd and month of birth, sex and birth type, year and sex, year and birth type, month and sex, month and birth type, herd and birth type, and between herd and lamb sex were included. Dam age and coefficient of inbreeding were also included in the model as covariables. The results indicated that dam age (linear and quadratic terms), year and month of birth, sex and birth type of lamb, interactions between year and birth type, sex and birth type and herd and birth type had significant influences on birth weight ($P < 0.05$). Regression coefficient of birth weight on inbreeding was found to be −343 g but it was not statistically significant.

Key Words: Baluchi sheep, birth weight, inbreeding

M459 Cubicle use and maternal bonding in sheep: tests of an alternative lambing management strategy. N. L. Pettifor* and M. L. Thonney, *Cornell University*, *Ithaca, NY*.

Many farm flocks are intensively managed while lambing in barns, where ewes are often kept in high-density areas and moved with their lambs to claiming pens shortly after lambing. Other methods may improve the process of maternal bonding and use less labor. One alternative to traditional lambing management uses "cubicles," open 2.4 × 1.5 m pens in which ewes may choose to isolate themselves at lambing time. As ewes on pasture will naturally seek isolation at lambing, it is expected that more ewes would choose to lamb in the privacy of a cubicle. Additionally, time spent on the birth site may increase the strength of a ewe's bond with her lambs because lambing in a cubicle avoids the disruption of being moved from a lambing area to a claiming pen. To test the cubicle concept, 43 Dorset, Finnsheep, and Dorset × Finnsheep ewes were lambed in a cubicle system. Ewes were regularly added to the lambing area to maintain a stocking density of 1.9 to 2.3 m^2 per ewe and were video-recorded 24 h per day for the duration of the lambing season. An additional 110 ewes were managed traditionally, using claiming pens. After the end of the lambing period, ewes from the traditional system were compared with 2 groups of ewes from the

cubicle system: one set that did use cubicles and another set that did not. Two behavioral tests of maternal bonding, also video-recorded, were used to compare these groups: a 2-choice discrimination task and a modified maternal behavior score (MMBS, 1 to 5) test. Ewes did not preferentially lamb in cubicles: 23.3% of recorded ewes were located in cubicles when they lambed; 29.6% of the total lambing area consisted of cubicle space. MMBS scores were not statistically different between cubicle-using and non-using experimental ewes (4.33 and 4.05 ± 0.47, respectively), but were higher ($P = 0.26$) than the value of 3.15 ± 0.47 for the traditionally managed group. The cubicle approach appeared to result in easier sheep movement and reduced shepherding, and may have improved maternal behavior.

Key Words: behavior, maternal, sheep

M460 Selective genotyping using genome-wide association studies (GWAS) that are associated with fiber diameter in Merino sheep. M. Goher*, W. Rauw, D. Thin, and L. Gomez-Raya, *University of Nevada Reno*, *Reno*.

The objective of this study was to investigate methods and statistical power for mapping quantitative trait loci (QTL) using selective genotyping and Illumina's 50K BeadChip. A large unrelated population is recorded for a phenotypic trait. Animals with extreme phenotypes are used for genotyping with Illumina's arrays and QTL are mapped by linkage disequilibrium (LD). We carried out computer simulations to compute statistical power using this approach after varying QTL allele frequency, proportion selected in the extremes, and population size. For example, power for a population of 1,000 animals after genotyping the top and bottom 5% (QTL effect of 0.5 phenotypic standard deviations, α of 0.01 and allele frequency of 0.1) and assuming maximum LD, was 0.95. The method was tested in a Merino flock with 979 ewes in which fiber diameter (FD) was recorded. Illumina 50K BeadChip was used for simultaneous genotyping of 54,000 SNPs in selected animals. Three different approaches were used to rank and to use selective genotyping of animals: 1) extreme phenotype for FD, 2) extreme estimated breeding value for FD, and 3) extreme phenotypes within the year class with the highest number of animals. Statistical tests were carried out comparing the number of copies for each of the 2 alleles at each SNP in the 2 extreme phenotypes (top and bottom 5%). No genome-wide significant results were obtained when using extreme phenotypes for FD. Analyses using extreme estimated breeding values and extreme phenotypes from the largest year class are currently in progress.

Key Words: GWAS, statistical power, selective genetyping

M461 An alternative wool harvesting system for wool sheep flocks. T. Wuliji*[1], T. Watts[2], A. Qi[1], and T. Filbin[3], [1]*University of Nevada*, *Reno,* [2]*Heiniger Australia Pty*, *Perth, Western Australia, Australia*, [3]*Rafter 7 Ranch*, *Yerington, NV*.

The objective of this investigation is to evaluate the efficacy of a biological wool harvesting system-Bioclip as an alternative to mechanical shearing of the wool sheep flocks in the US, which mostly farmed for meat and wool dual production. Bioclip reagent was developed for a biological wool harvesting in Merino breed or its derived sheep in Australia. Twenty-two 10-mo-old ewes were selected for Bioclip shearing comparison experiment. Ewes were weighed and stratified by BW and breed, and divided into a control (conventional shearing, n = 10) and Bioclip treatment group (n = 12). Treatment group animals were each given 2.5 mL Bioclip injection formula (7.5 mg/ml epidermal growth factor (EGF) subcutaneously on the inguinal bare skin area, and subsequently put fleece retention net on them. Animals were fed alfalfa hay for 4 wk under a semi-sheltered pen until fleece removal at 28 d later. Post treatment wool re-growth was monitored and compared for the control and bio clipped groups. After 5 wk re-growth, wool fiber length (mm) and weight (mg/cm^2) collected from the mid side skin patch area was measured, analyzed and compared for differences. Data were analyzed for one-way ANOVA and mean values compared using *t*-tests. Bioclip injection resulted a simultaneous and complete shedding of fleeces in all treated animals. There was no difference in post treatment BW, weight gain, fiber diameter and wool re-growth rate between control and Bioclip treatment. However, fleece staple length and re-growth fiber length measured significantly ($P < 0.01$) longer for Bioclip harvested wool than conventional shorn sheep. The results suggest that Bioclip can improve wool clip quality, animal welfare, and farm labor intensity. Therefore, Bioclip may be used as an alternative biological wool harvesting system to the traditional mechanical shearing procedure for wool sheep flocks.

Key Words: biological wool harvest, epidermal growth factor, Merino sheep

M462 Comparison of two instruments for measuring fiber characteristics of wool. F. A. Pfeiffer*, C. J. Lupton, and D. F. Waldron, *Texas AgriLife Research*, *San Angelo*.

An experiment was designed to compare an on-farm OFDA2000 instrument with a lab instrument, the OFDA 100 (BSC Electronics, Ardross, W. Australia). The OFDA 100 measures average fiber diameter (AFD) and variability (SDFD and CVFD) of animal fiber snippets (2-mm lengths) and was approved for use in standard methods. Cleaned, conditioned (21°C and 65% RH) snippets are measured between 2 glass slides. Average fiber curvature (AFC), variability (SDFC and CVFC), and comfort factor (CF, % fibers <30 µm) are also estimated. The OFDA2000 measures greasy fiber staples with corrections being made for non-standard atmospheric conditions, grease, and other contaminants on the raw fiber. A retrofitted add-on permits the OFDA2000 to measure cleaned snippets mounted on glass slides. Two sets of greasy wool staples (n_1 = 108, AFD = 22.8 ± 1.5 µm, n_2 = 107, AFD = 25.7 ± 2.1 µm) shorn from rapidly growing yearling Rambouillet rams were first measured on the OFDA 2000. Snippets were then guillotined from the base of each staple, cleaned, conditioned, and spread onto a glass slide. Each slide was measured on the OFDA 100 and then on the OFDA2000. Data were analyzed using the paired *t*-test, and CORR procedures of SAS. Results for the finer set only are presented in Table 1. Average snippet AFD was not different between instruments ($P = 0.11$) though it was for the coaser set (Δ AFD = 0.11 µm, SED = 0.02 µm, $P < 0.01$). All other measured traits were different ($P < 0.01$). Thus, some caution is required when comparing results from the 2 instruments.

Table 1. Means and r values for wool characteristics measured with 2 instruments

Item	1, 100, snippet	2, 2000, staple	3, 2000, snippet	r, 1 vs 2	r, 1 vs 3	r, 2 vs 3

M463 Comparison of Rambouillet sheep with Australian Merino F1 crosses. C. J. Lupton*[1], F. A. Pfeiffer[1], W. S. Ramsey[2], M. W. Salisbury[3], D. F. Waldron[1], J. W. Walker[1], and T. D. Willingham[1], [1]*Texas AgriLfe Research*, *San Angelo,* [2]*Texas A&M University*, *College Station,* [3]*Angelo State University*, *San Angelo, TX.*

The objective of this study is to estimate the differences in wool production and value between Rambouillet (R) and R × Australian Merino (M) crosses. Semen from the desired type of M sires (n = 5 in 2007, 3 in 2008) was located and purchased. The M sires had similar mature BW but greater fleece weight and finer wool than R rams. R ewes (n = 407, 3–5 yr of age, BW = 61.5 ± 6.9 kg, average fiber diameter [AFD] = 21.3 ± 2.1 μm) were bred to the M rams via laparoscopic artificial insemination in June 2007 and October 2008. Contemporary R lambs were produced naturally by exposing R ewes (n = 235) to R rams (n = 4 in 2007 and 2008). Lambs born in 2008 and 2009 were weighed at 5 mo of age. Fleece weights (greasy and clean, GFW and CFW) and fiber characteristics were determined on yearling fleeces. Data were analyzed using the MIXED procedure of SAS. The model included fixed effects of genotype and sex and a random effect of sire within genotype. BW at 5 mo of age (27.1 kg) for lambs born in 2008 and 2009 was not different between genotypes. Least squares means of yearling fleece weights and fiber characteristics for lambs born in 2008 are presented in Table 1. Fleece weights and average staple length (ASL) did not differ between genotypes. The M × R yearlings produced higher yielding and finer (more valuable) wool with less crimp (lower average fiber curvature, AFC) than R sheep. Female yearlings produced coarser wool than males.

Table 1. Fleece and fiber characteristics of yearling sheep

	Genotype			Sex		
Dependent variable	M × R (n = 47)	R (n = 44)	P	Female (n = 45)	Male (n = 46)	P
GFW, kg	4.3	4.1	0.543	4.1	4.2	0.509
CY, %	60.8[a]	56.3[b]	0.005	57.9	59.1	0.119
CFW, kg	2.6	2.3	0.119	2.4	2.5	0.239
AFD, μm	17.8[b]	18.7[a]	0.015	18.6[a]	17.9[b]	0.012
ASL, mm	12.0	11.4	0.429	12.0	11.4	0.077
AFC, deg/mm	87.2[b]	95.5[a]	0.019	90.7	92.0	0.519

[a,b]Within a row and within genotype or sex, means with a different superscript letter differ ($P < 0.05$).

Key Words: Merino, Rambouillet, wool

M464 Effects of substituting distillers dried grains for cottonseed meal and milo on wool and carcass characteristics in lamb finishing diets. T. R. Whitney*, A. E. Lee, M. G. Williamson, C. D. Swening, and R. L. Noland, *Texas AgriLife Research Center*, *San Angelo*.

Distillers dried grains (DDG) should continue being an economical feed if the market remains saturated. Cottonseed meal and sorghum grain are common feed sources for lamb finishing diets, especially in Texas, but the sheep industry's interest in using greater concentrations of DDG has increased. Limited research exists evaluating carcass characteristics of lambs fed diets containing greater than 50% DDG. Rambouillet wether lambs (n = 42, initial BW = 28.8 ± 3.3 kg) were individually fed ad libitum diets containing DDG that replaced 0% (0DDG), 25% (25DDG), 50% (50DDG), or 75% (75DDG) of the CSM and milo for 72 d in a completely randomized design. On d 72, 35 randomly-selected wethers were humanely slaughtered and evaluated for carcass characteristics. Quadratic trends ($P < 0.05$) were observed for hot carcass weight (22.0, 23.2, 24.6, and 22.5 kg ± 0.7) and 12th-rib back fat thickness (0.5, 0.5, 0.6, 0.4 cm ± 0.06) as percentage of DDG increased in the diet, and backfat thickness was greater ($P = 0.04$) for lambs fed 0DDG than 75DDG. The LM area was similar ($P > 0.14$; 14.4, 14.8, 15.6, 14.5 cm^2 ± 0.54) among lambs. Quadratic trends ($P < 0.07$) were also observed for body wall thickness (1.4, 1.7, 1.7, 1.4 cm ± 0.8) and leg circumference (30.35, 30.96, 31.61, 30.70 cm ± 0.4). Results suggest that carcass characteristics are affected by increasing percentage of DDG in lamb diets; the quadratic trends were unexpected.

Key Words: carcass characteristics, distillers dried grains, lambs

M465 Nutrient intake in Santa Inês sheep fed different levels of metabolizable energy in the ration. R. M. Fontenele*, E. S. Pereira, P. G. Pimentel, M. S. de Souza Carneiro, A. B. S. Villarroel, and J. G. L. Regadas Filho, *Federal University Ceará*, *Fortaleza, Ceará, Brazil*.

The objective of this study was to evaluate the nutrient intake of Santa Inês sheep fed different levels of metabolizable energy (2.08, 2.28, 2.47 and 2.69 Mcal/kg DM) in diets. Twenty lambs, average weight of 13 kg and age 50 d, were distributed in randomized block design with 5 replications. The roughage used was the Tifton 85 hay. Since the experimental variables were subjected to ANOVA and regression using the Statistical Analysis System and Genetic - SAEG. Was found among the energy levels on the dry matter intake, g/day ($P = 0.002$) (695.02, 914.17, 1030.16 and 1287.06, to 2.08, 2.28, 2,47, and 2.69 Mcal/kg DM, respectively) and g/$kg^{0,75}$ ($P = 0.02$) (80.54, 93.27, 98.70 and 107.02, to 2, 08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively). For the dry matter intake, in %BW, there was no influence ($P > 0.05$) of energy levels in diets. Intake in g/day of organic matter ($P = 0.002$) (713.50, 946.88, 1071.10 and 1349.90 to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively), crude protein ($P = 0.001$) (107.58, 172.19, 205.81 and 253.64 to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively), ether extract ($P = 0.0001$) (11.80, 21.49, 34.96 and 40.28 to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively), non-fibrous carbohydrates ($P = 0.00001$) (148.69, 243.35, 360.52 and 511.00 to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively) and total digestible nutrients ($P = 0.001$) (695.02, 914.17, 1030.16 and 1287.06, to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively), performed equal to the intake of dry matter. There was also increased intake of total carbohydrates ($P = 0.01$), despite the decrease of this nutrient as increased energy levels in diets (538.38, 671.18, 803.37 and 873.01 to 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively). Observed influence of the energy levels on the use of neutral detergent fiber, in %BW ($P = 0.0004$) (44.40, 45.27, 40.27 and 33.77 for 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively) and g/$kg^{0.75}$ ($P = 0.009$) (44.40, 45.27, 40.27, and 33.77 for 2.08, 2.28, 2.47 and 2.69 Mcal/kg DM, respectively). The daily intake of acid detergent fiber were not affected ($P > 0.05$) by the dietary energy.

Key Words: lambs, performance, ruminants

M466 Body composition and net energy requirements for growth of Santa Inês lambs. J. G. L. Regadas Filho[2], E. S. Pereira[1], P. V. R. Paulino*[2], A. B. S. Villarroel[1], P. G. Pimentel[1], R. M. Fontenele[1], and I. S. G. Maia[1], [1]*Universidade Federal do Ceará*, *Fortaleza, Brazil*, [2]*Universidade Federal de Viçosa*, *MG, Brazil*.

This study was conducted to determine the body composition and energy requirements for maintenance and growth of Santa Inês lambs. Twenty-four non-castrated males, 50 d old and with 13.00 ± 0.56 kg of initial body weight were used. Four animals were slaughtered at the beginning of the trial, as a reference group, to estimate the initial empty body weight (EBW) and body composition. The remaining ani-

mals were assigned in a randomized block design with 5 replicates per block and 4 diets, with increasing metabolizable energy contents (2.08; 2.28; 2.47 and 2.69 Mcal/kg of DM). The animals were slaughtered at 28.00 ± 0.97 kg of BW. The logarithm of heat production (HP) was regressed against metabolizable energy intake (MEI) and the net energy requirements for maintenance (kcal/kg $EBW^{0.75}$/d) were estimated by extrapolation, when MEI was set to be zero. Regression equations of the logarithm of body fat and body energy on the logarithm of EBW were adjusted. The derivatives of these equations allowed the estimation of the fat content of empty body weight gain (EBWG) and the net energy requirement for EBWG, respectively. The net energy requirement for maintenance obtained was 50.72 ± 1.20 kcal/kg $EBW^{0.75}$/d. The energy and fat contents of the EBW of the animals increased from 1.91 and 85.18 to 2.78 Mcal/kg and 221.23 g/kg of EBW, respectively, as the BW increased from 15 to 30 kg. Similarly, the composition of the EBWG consisted of more fat and energy as the animals became heavier. The net energy requirements for EBWG increased from 2.94 to 4.28 Mcal/kg of EBWG for body weights of 15 and 30 kg, respectively. The net energy requirement for maintenance of Santa Inês lambs is lower than values commonly recommended by the main evaluation systems of food and nutritional requirements of sheep.

Key Words: empty body weight, maintenance, tropical sheep

M467 Body composition and net protein requirements for Santa Inês lambs. J. G. L. Regadas Filho[2], E. S. Pereira[1], P. V. R. Paulino*[2], A. B. S. Villarroel[1], P. G. Pimentel[1], R. M. Fontenele[1], M. R. G. F. Costa[1], and M. S. Duarte[2], [1]*Universidade Federal do Ceará*, *Fortaleza, Brazil*, [2]*Universidade Federal de Viçosa*, *MG, Brazil*.

This study was conducted to determine the body composition and protein requirements for maintenance and growth of Santa Inês lambs. Twenty-four non-castrated males, 50 d old and with 13.00 ± 0.56 kg of initial body weight were used. Four animals were slaughtered at the beginning of the trial, as a reference group, to estimate the initial empty body weight (EBW) and body composition. The remaining animals were assigned in a randomized block design with 5 replicates per block and 4 diets, with increasing metabolizable energy contents (2.08; 2.28; 2.47 and 2.69 Mcal/kg of DM) and crude protein (CP) (12.74; 14.36, 15.97 and 17.65% CP of DM). The animals were slaughtered at 28.00 ± 0.97 kg of BW. A regression equation of nitrogen intake (g/kg $BW^{0.75}$/d) on nitrogen retention (g/kg $BW^{0.75}$/d) was adjusted. When N intake was set to be zero, the negative intercept of regression equation was considered as the endogenous N losses, which represents the maintenance requirements. A regression equation of the logarithm of body protein content on the logarithm of EBW was adjusted. The derivative of this equation enabled the estimation of the net protein requirements for gain of empty body weight (EBWG). Endogenous nitrogen loss was estimated to be 277 ± 0.05 mg/kg $BW^{0.75}$/d, which corresponds to the net protein requirement for maintenance of 1.73 ± 0.31 g/kg $BW^{0.75}$/d. Protein content of EBW decreased from 157.83 to 144.33 g/kg of EBW as the animals BW increased from 15 to 30 kg, respectively. The protein deposited in the EBWG decreased from 137.47 to 125.71 g/kg as the animals BW increased from 15 to 30 kg, respectively. Endogenous nitrogen loss and protein requirement for maintenance of Santa Inês lambs are lower than the values commonly cited by the main systems of feed evaluation and nutrient requirements of sheep.

Key Words: empty body gain, requirements, tropical sheep

M468 Effects of dietary copper level on serum cholesterol and nonesterified fatty acids in lambs. S. Hasanlou*, A. Zali, M. Ganjkhanlou, and M. Dehghan, *Tehran University, Tehran, Iran.*

An experiment was conducted to determine the effect of dietary Cu on serum cholesterol and NEFA in lambs. Twenty-four castrated male Lori-Bakhtiary lambs (3 to 4 mo of age; average BW = 26 ± 0.5kg) were used in this experiment. Lambs were housed in individual pens and were assigned randomly to one of 3 treatments. Treatments consisted of 1) control (no additional supplement), 2) lambs received 5 mg Cu/d, and 3) lambs received 10 mg Cu/d. Treatments were gavaged daily (esophagus gun) before AM feeding. Blood samples were collected from the jugular vein by venipuncture. Serum NEFA concentrations were not affected by the supplementations (0.15, 0.15, and 0.21mmol/L). Total cholesterol of serum had tendency to be lower in groups received 5 mg Cu/d relative to the other supplemented groups ($P = 0.06$). Animals received 5 mg Cu/d had significantly ($P = 0.01$) higher serum HDL-cholesterol compared with others. Whereas serum LDL-cholesterol concentrations was similar between supplemented groups (19.43, 19.39, and 17.34 mg/dL respectively). The Cu concentrations of serum were higher in lambs received 10 mg Cu/d compared with the other supplemented lambs ($P < 0.001$). Based on the current results, Cu supplementations had beneficial effect on reduction of serum cholesterol in lambs.

Key Words: copper, cholesterol, lambs

M469 Effects of dietary copper level on growth, performance, and carcass characteristics in lambs. S. Hasanlou*, A. Zali, M. Ganjkhanlou, and M. Dehghan-Banadaki, *Tehran University, Tehran, Iran.*

An experiment was conducted to determine the effect of dietary Cu on growth, performance, and carcass characteristics in lambs. Twenty-four castrated male Lori-Bakhtiary lambs (3 to 4 mo of age; average BW = 26 ± 0.5kg) were used in this experiment. The lambs were housed in individual pens and were assigned randomly to 1 of 3 treatments. Treatments consisted of 1) control (no additional supplement), 2) lambs received 5 mg Cu/d, and 3) lambs received 10 mg Cu/d. Treatments were gavaged daily (esophagus gun) before AM feeding. Daily feed intake and orts were recorded daily. Body weight was measured at the start and the end of experimental period. Least squares means of feed intake was similar for Supplemented and control lambs (1.13, 1.13, and 1.14 kg/d respectively). Lower daily gain observed for lambs received 10 mg Cu/d compared with control and those were fed 5 mg Cu/d ($P < 0.05$). Gain:feed were affected by Cu level, so that lambs received 10 mg Cu/d had the lowest level. Dressing percentage was not affected by supplementations (45.54, 43.54, and 46.95% respectively). Lambs received 10 mg Cu/d had lower back fat versus others ($P < 0.05$). Based on the current results, Cu supplementations had no beneficial effect on the performance characteristics of lambs.

Key Words: copper, lambs, carcass

M470 Effect of zilpaterol and ractopamine feeding program on growth performance and carcass characteristics of finishing lambs. M. A. Lopez-Carlos*[1,2], R. G. Ramirez[2], J. I. Aguilera-Soto[1], C. F. Arechiga[1], F. Mendez-Llorente[1], H. Rodriguez[1], and M. Rincon[1], [1]*Universidad Autonoma de Zacatecas*, *Zacatecas, Mexico*, [2]*Universidad Autonoma de Nuevo Leon*, *Nuevo Leon, Mexico.*

The objective of this trial was to determine the response on growth and carcass traits when ractopamine (RAC) and zilpaterol (ZIL) were administered at 3 feeding programs (constant, increasing and decreasing concentration) in the diet of finishing lambs for the last 27 d before

harvest. Eighty-four lambs (30 ± 1.6 kg) were used in a split-plot design with 7 treatments, 3 blocks (grouped by weight) and 3 periods (9, 18 and 27 d; subplots). Treatments were: Control, RAC and ZIL constant (RC and ZC) (0.20 and 0.70 mg/kg BW respectively, main plot), RAC increasing (RI) (0.35, 0.70 and 1.05 mg/kg BW), ZIL increasing (ZI) (0.10, 0.20 and 0.30 mg/kg BW), RAC decreasing (RD) (1.05, 0.70 and 0.35 mg/kg BW), and ZIL decreasing (ZD) (0.30, 0.20 and 0.10 mg/kg BW). Adjustments for RAC and ZIL concentration were made at beginning of each evaluation period. Basal diet was 18% CP and 3 Mcal/kg of ME. The data analysis was performed using the GLM procedure of SAS. Differences between treatments were established by Duncan's test. Total gain (GT), average daily gain (ADG), dry matter intake (DMI), feed:gain (F:G), hot and cold carcass weights (HCW and CCW), meat and fat color (MC and FC), fat thickness (FT), carcass classification (CC) and longissimus muscle area (LM), were determined. During the first period there was a decrease ($P < 0.01$) for DMI, ADG and feed efficiency (FE) for lambs that consumed ractopamine and zilpaterol respect to Control. However, in subsequent periods, growth variables were higher ($P < 0.05$) for ZIL and RAC regardless of dosing schedule. Hot carcass weight (HCW), CCW, CC and LM were higher for RI, ZI, RC and ZC. MC, FC and FT were improved ($P < 0.05$) with RAC and ZIL administration independently of dosing schedule. In conclusion, increasing concentration of dietary RAC and ZIL to finishing lambs prolongs the growth response on time, while constant and increasing dietary RAC and ZIL improve carcass characteristics.

Key Words: sheep, zilpaterol, ractopamine

M471 Use of zeranol and reimplantation on performance of finishing hair lambs. D. Domínguez, G. Amaya*, G. Villalobos, H. Castillo, J. A. Ortega, and L. Carlos, *Universidad Autónoma de Chihuahua*, *Chihuahua, Chihuahua, México*.

Use of zeranol has improved daily gain and gain efficiency of lambs, leading to a higher profitability in sheep industry. This study evaluated the effect of using different zeranol levels and its reimplantation on dry matter intake, body weight, average daily gain and gain efficiency of finishing hair lambs. Thirty-two weaned intact male lambs (21.2 ± 1.58 kg and 60 d old) crosses of Dorper × Pelibuey and Kathadin × Pelibuey were blocked by initial body weight and randomly assigned to 4 treatments (n = 10, 5 pens and 2 lambs per pen): Z0 (control); Z12 (12 mg of zeranol, Ralgro), Z24 (24 mg of zeranol in a single application), and Z12–12 (12 mg of zeranol given twice). Lambs were implanted 12 d before starting the experiment, and animals of Z12–12 were reimplanted 28 d after starting the study. Lambs were fed ad libitum a 80:20 concentrate:forage diet (% DM) containing 2.7 Mcal ME/kg DM and 18.2% CP. Dry matter intake (DMI) was determined daily, while body weight, average daily gain (ADG) and gain efficiency (GE) were recorded every 14 d during the 56 d trial. Data were analyzed as a complete random design with repeated mesarurements on time, using the PROC MIXED. Implanted animals had similar DMI vs. non implanted (1.42 vs. 1.47 kg). Final body weight of implanted animals was not improved vs. non implanted (40.0 vs. 36.9 kg), and was similar among implanted treatments. The ADG of implanted lambs was 12.4% higher vs. non implanted (0.326 vs. 0.290 kg/d; $P < 0.05$), and it was 6.2% enhanced in lambs of Z24 compared with lambs of Z12 (0.340 vs. 0.320 kg/d; $P < 0.05$), and was similar between Z24 and Z12–12 treatments. Implanted lambs had 17% higher GE (4.4 vs. 5.3; $P < 0.05$), and it was 8.7% superior in Z24 vs. Z12 (4.2 vs. 4.6), and was similar between Z24 and Z12–12 treatments. Implanting finishing lambs with 24 mg of zeranol in a single dosis showed the best animal performance.

Key Words: implants, finishing lambs, zeranol

M472 Fatty acid profile and lipid oxidation of meat from Sarda lambs managed in different feeding systems. S. P. G. Rassu, C. Carzedda, R. Boe, M. G. Manca, and A. Nudda*, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*.

Fatty acid composition and the lipid oxidation of raw meat were evaluated in suckling lambs managed in 2 different feeding systems. Twenty-two Sarda male lambs were divided into 2 feeding system groups: 11 lambs (SL group), after 5th day of age, were confined in a fold and every day separated from their dams from 8.00 a.m. to 4.00 p.m. and then rejoined after ewes milking. These lambs were also fed with a suitable pellet feed ad libitum to compensate smaller available milk. Remainine 11 lambs (NSL group) were never separated from their dams and herded to pasture with them and confined in a fold during the night. At d 25 of age, the 5 heavier lambs of each group were slaughtered. Mean BW and ADG for NSL and SL group were, respectively: 4.70 and 6.08 kg at birth ($P = 0.012$), 11.2 and 13.4 kg at slaughter ($P = 0.000$) and 270 and 287 g/d ($P = 0.382$). After 24 h of refrigeration at 4°C, the lumbar region was dissected from each right half-carcass and used for analysis. Fatty acid profile was determined by gas-cromatography while lipid oxidation was measured by the Thio-Barbituric Acid Reactive Substances (TBARS) method. Data were analyzed with a one-way ANOVA using group as the main effect. Lipid oxidation was not significantly influenced by group but was higher in NSL group than SL group (0.42 vs 0.34 mg MDA/kg of meat). The content in fat and protein were not significantly affected by feeding system (Table 1). Fatty acid composition was not significantly influenced by group (Table 1).

Table 1. Composition of raw meat from suckling lambs raised with 2 different feeding system

	Group	
	NLS	SL
Protein	20.32	20.42
Fat	1.98	2.31

M473 Deciding whether light lambs should be weaned or left with the dam until slaughter age. M. Terré[1], A. Nudda[2], and A. Bach*[3,1], [1]*Institut de Recerca i Tecnologia Agroalimentàries*, *Barcelona, Spain*, [2]*University of Sassari*, *Sassari, Italy*, [3]*Institució Catalana de Recerca i Estudis Avançats*, *Barcelona, Spain*.

The objective was to compare the performance and meat quality of 2 different lamb rearing systems: weaning lambs at 7 wk of age and then either feeding concentrate and forage or rearing lambs with their mother until sacrifice. A total of 22 lambs from 17 ewes were assigned to weaning (W) treatment and 20 lambs from 16 ewes to unweaning (U) treatment. Lambs in U treatment were kept with their mother and fed a concentrate ad libitum. Lambs in W treatment were weaned at 7 wk of age and fed concentrate and straw ad libitum. Lambs were weighed weekly until sacrifice. Carcasses were weighed after slaughter. After sacrifice (48 h), Longissimus dorsi (LD) was sampled from 8 male

lambs per treatment to determine color, texture, fat content and fatty acid (FA) composition. Data were analyzed using a fixed effects model with pen as the experimental unit. Lambs in the U treatment tended ($P = 0.09$) to weigh more than W lambs 4 wk after weaning (19.7 vs 18.3 ± 0.06 kg BW, respectively). Lambs in U treatment were 13 d younger ($P < 0.001$) at slaughter than the W lambs. Dressing percentage was greater ($P < 0.05$) in U than in W lambs (44.9 vs 42.0 ± 1.23%, respectively). Colorimetric parameters of LD indicated that L and a values were similar in both treatments, whereas b values were greater ($P < 0.05$) in W than in U lambs (12.9 vs 12.3 ± 0.16, respectively). There were no differences in texture measurements (WBSF) and total fat in LD. The LD from U lambs had a greater ($P < 0.05$) percentage of 16, 18:3 n-3 FA and a lower ($P < 0.05$) percentage of 17, 17:1 FA than LD from W lambs. However, the ratio n-6/n-3 was lower ($P < 0.01$) in U than in W lambs (6.47 vs 9.19 ± 0.527, respectively). Rearing lambs with the ewe until sacrifice reduces days to slaughter and improves FA composition of LD.

Key Words: light lamb, weaning, meat quality

M474 Lamb finalization allowing free-choice intake of roughage and concentrate. P. Martinez-Hernandez*, C. Sanchez-DelReal, E. Cortes-Diaz, E. Maldonado-Siman, and R. Lazo-Soto, *Animal Science Department, University of Chapingo*, *Texcoco, Mexico, Mexico*.

The objective of this study was to determine performance and feeding behavior of lambs offered roughage and concentrate as either a mixed diet or split feeds free-choice. Three treatments were evaluated: mixed diet, or concentrate offered once (C1) or twice (C2) a day with roughage provided for ad libitum intake. Mixed diet was 78:22 concentrate:roughage, concentrate was: 78.53% milo; 10.26% soybean meal; 10.18% meat meal poultry; and, 1.03% mineralized salt (estimated ME 2.87Mcal/kg). Roughage sourece was ground (1.8 cm screen) corn stover. Experimental design was a completely random with 3 replicates; experimental unit was a pen with 2 lambs. Feeding trial lasted 32 d. Rambouillet lambs with initial weight of 37.7 ± 3.1 kg and less than one year old were used. Feed offered was adjusted daily to provide 15% above the day-before intake. Intake was calculated daily by weighing feed offered and rejected. Mixed diet, corn stover and concentrate of C1 and half of C2 were given at 7:00 h, the other half of C2 at 18:00 h. Mixed diet and C1 showed the highest and lowest ($P < 0.05$) of both daily total and concentrate intakes, respectively. Average daily gain, final weight, feed conversion and total time-spent-eating were not different ($P > 0.05$) among treatments. At the beginning, daily time spent eating concentrate in C1 lambs was up to 53% higher ($P < 0.5$) than in C2 lambs, but toward to the end of the trial there was no difference ($P > 0.05$); C1 lambs decreased 38% in time eating concentrate. Daily rumination time was 38% lower ($P < 0.05$) in C1 lambs than the rest of the lambs. Incidence of lambs off-feed was 3 times higher ($P < 0.05$) in C1 than in the other 2 treatments. It was concluded that controlled offering of concentrate could allow for feeding roughage and concentrate as split feeds.

Key Words: mixed diets, feeding system, lamb performance

37 Biohydrogenation intermediates of ^{13}C-labeled docosahexanoic acid in ruminal batch cultures. C. M. Klein* and T. C. Jenkins, *Clemson University*, *Clemson, SC*.

There are no reported pathways of docosahexanoic (DHA) biohydrogenation; however, DHA is metabolized by ruminal microorganisms. In this study a 0.5mg pulse dose of uniformly 13C labeled DHA in ethanol was injected at 0h as a metabolic tracer. This study did not examine every fatty acid metabolite, but rather identified several saturated and trans-18:1 fatty acid metabolites and set a foundation for future work. Ruminal microorganisms collected from a lactating Holstein cow were incubated in 10 mL batch cultures for 0, 6, 24 and 48 h. Treatment groups were 0.5% 13C DHA and 0.5% DHA. Duplicate cultures were methylated and then separated on a 100-m CP-Sil 88 column. Abundances of the quasimolecular (M) and M+n ions were determined by mass spectroscopy in chemical ionization mode. Enrichment was calculated as {M+n/[M+(M+n)]} × 100 in labeled minus unlabeled cultures and tested for their difference from zero by *t*-test ($P < 0.01$). DHA decreased from 0.207mg to 0.041mg between 0 and 48h and had an enrichment of 98.1%. Oleic, linoleic, and linolenic acids decreased 0.431, 0.962 and 0.081mg in the same time period. Stearic acid increased 1.37mg and trans-18:1 monenes increased 0.415 mg. Palmitic, eicosanoic, and docosanoic acids increased 0.196, 0.008 and 0.005 mg respectively. Palmitic, stearic, all trans-18:1, eicosanoic, and docosanoic acids were examined for enrichment. Docosanoic acid was highly enriched at 24h and 48h to 20.2% and 16.3% (SE = 0.466; $P < 0.01$). Neither eicosanoic acid, nor any trans-18:1 monenes were enriched at any time ($P < 0.05$). Low levels of enrichment (<0.1%; $P < 0.01$) were found in palmitic and stearic acids. This study clearly identifies docosanoic acid as an intermediate of DHA biohydrogenation. It also identifies that, in this system, eicosanoic acid and trans-18:1 fatty acids were not intermediates. Stearic acid had minor enrichments, but DHA only made up 3.13% of total fat or 10.3% of metabolized unsaturated fat.

Key Words: docosahexanoic acid, biohydrogenation

38 Cows genetically more susceptible to mastitis have altered neutrophil migration patterns. A. A. Elliott*, S. Minkin, J. Biggerstaff, J. Dunlap, and G. M. Pighetti, *University of Tennessee*.

The largest loss in profit for dairy farmers occurs with mastitis, an inflammation of the mammary gland. Our prior research identified a marker in the CXCR1 gene associated with mastitis and decreased neutrophil migration in vitro. Because neutrophil migration is critical for eliminating most infections, our ongoing research seeks to identify the specific mechanisms causing impaired migration. The first study evaluated actin polymerization, one of the first steps in neutrophil migration, in cows with different CXCR1+777 genotypes. Neutrophils from cows with GG (n = 11) and CC (n = 11) genotypes were isolated and stimulated with zymosan activated sera (ZAS). Cells were fixed and stained for F-actin and subsequently evaluated for F-actin content, distribution, and cell morphology. Neutrophils of the CC cows had significantly lower average F-actin polymerization than the GG cows ($P = 0.05$). Because F-actin polymerization drives neutrophil movement, lower amounts could partly explain reduced migration. In contrast, cell morphology and F-actin distribution was similar between genotypes. Our second study focused on directed migration of neutrophils toward interleukin-8 (IL8). The migration of neutrophils from GG (n = 4) and CC (n = 4) genotypes was captured under a microscope and velocity, acceleration, distance of the path, distance from origin, largest X distance and largest Y distance were analyzed for each individual cell. Cells from GG genotype traveled further and more directly compared with CC genotype cells. Our findings suggest lower F-actin polymerization in combination with a lower ability to directly and efficiently move toward the site of infection could impair neutrophil response to infection in cows with the CC genetic background and may contribute to increased mastitis susceptibility.

Key Words: mastitis, chemotaxis, neutrophil

39 Effects of different levels of cottonseed hulls on rumen development and growth in dairy calves. R. M. Doescher*, C. C. Williams, C. F. Hutchison, B. F. Jenny, and A. H. Dolejsiova, *LSU AgCenter*, *Baton Rouge*.

A study was conducted to determine the effects of varying levels of cottonseed hulls on growth and metabolic indications of rumen development of dairy calves. Sixty-four Holstein calves (Heifers, n = 40; Bulls, n = 24) were randomly assigned to one of 4 dietary treatments which included calf starters containing no cottonseed hulls (control; C), 10% cottonseed hulls (10% CSH), 15% cottonseed hulls (15% CSH), or 20% cottonseed hulls (20% CSH). Calves were fed their respective treatments beginning on d 8 until d 56 of age. Body weights were measured at birth and biweekly thereafter until d 56 of age. Wither and hip heights were measured beginning on d 14 and biweekly thereafter until d 56 of age. Feed intake and fecal scores were recorded twice daily through d 56. On d 14, 28, 42, and 56, rumen fluid was collected for analysis of pH, volatile fatty acids (VFA), and ammonia (NH3), and blood was collected for analysis of plasma urea nitrogen (PUN) and β–hydroxybutyrate (BHBA). There was no treatment effect ($P > 0.1$) on average daily starter intake, fecal scores, body weight, wither height, and hip height. Calves consuming CSH had higher ($P < 0.05$) rumen pH than C. Rumen pH also decreased ($P < 0.01$) as calves aged. There was no treatment effect ($P > 0.1$) on rumen acetate, propionate, butyrate, and total VFA concentrations. There was a trend for a treatment by week interaction ($P < 0.1$) and a treatment effect ($P < 0.1$) on NH3 production, with calves consuming 10% CSH having higher concentrations. There was no significant treatment effect ($P > 0.1$) on BHBA, but a main effect of sex ($P < 0.05$) was observed in which males had higher BHBA concentrations. There was no significant treatment effect ($P > 0.1$) on PUN concentrations, but a main effect of sex ($P < 0.05$) was observed with females having greater concentrations. Overall, incorporating cottonseed hulls into a calf starter showed no significant effect on growth and rumen development in Holstein dairy calves.

Key Words: cottonseed hulls, dairy calves, rumen development

40 Effects of herbs and essential oils on in vitro batch culture ruminal fermentation. J. A. Tekippe*[1], A. N. Hristov[1], K. S. Heyler[1], V. D. Zheljazkov[2], J. Ferreira[3], and G. A. Varga[1], [1]*Pennsylvania State University*, *University Park,* [2]*Mississippi State University, NMREC*, *Verona,* [3]*USDA-ARS*, *Beaver, WV*.

Medicinal herbs and essential oils were evaluated in a batch culture in vitro screening experiment as potential anti-methanogenic additives for ruminant diets. A total of 88 essential oils and 14 herbs were tested. Rumen inoculum enriched with particle-associated microorganisms was collected from a lactating dairy cow, 2 h before feeding. Incubation was conducted in serum bottles containing 1 g of a feed mixture (0.7 g alfalfa hay, 0.2 g corn starch, and 0.1 g solvent-extracted soybean meal), 1 mL of essential oils (10, 50, and 100 mg/L, final medium concentration), 19 mL of McDougall's buffer with 5 g/L glucose and 2.5 g/L acid-hydrolyzed casein, and 20 mL of ruminal inoculum. Bottles were then flushed with CO2 and incubated at 39°C for 6 h. Corresponding 50 mL tubes were incubated for 24 h for NDF degradability analysis. Herbs were tested using the same procedure, except a portion of the alfalfa hay was replaced with 12.5, 50, 100, and 200 mg of plant material (air-dry basis), and NDF was tested using the DAISY apparatus. Blanks and monensin (5 mg/L, final medium concentration) were also incubated. At the end of the incubations, total gas and methane production, VFA and ammonia concentration, and NDF degradability were measured. Treatment by application level interactions were not significant for any of the essential oil treatments. Two of the essential oils increased acetate production, 12 increased propionate production, 10 increased butyrate production, 3 reduced methane production (by 20 to 30%), and 2 decreased ammonia production. With the herbs, 1 increased acetate production, 2 increased propionate production, 1 decreased methane production (by 30%), and 1 decreased ammonia production. Eight of the herbs increased NDF degradability at various inclusion levels. Overall, these results indicated that some essential oils and medicinal herbs may have a significant effect on ruminal fermentation in vivo.

Key Words: essential oil, medicinal herb, rumen fermentation

42 Use of environmental protection best management practices by Maryland horse farm operators. N. M. Fiorellino*, K. M. Wilson, and A. O. Burk, *University of Maryland*, *College Park*.

A survey study was conducted to identify use of environmental protection best management practices (BMPs) by horse farm operators in Maryland (MD). A 35-question survey was mailed to 1,000 MD horse farm operators using a multiple wave mailing strategy. Data were collected from February to March 2009. Survey response rate was 43.9%, with responses received from 91.3% of counties. Respondents housed 16.8 ± 1.6 horses on 11.6 ± 1.6 ha of turnout with a mean stocking density of 0.81 ± 0.04 ha horse^{-1}. Primary use of horse farms was recreational (32.8%), boarding (30.7%), and breeding (14.7%). On a scale from 1 (low) to 5 (high), respondents reported they had the least knowledge of farm cost-share programs (2.0 ± 0.06), grass and weed identification (2.8 ± 0.05), and soil conservation plans (3.0 ± 0.05) and the most knowledge of recommended stocking density (3.6 ± 0.06), rotational grazing (3.6 ± 0.05), and manure management (3.5 ± 0.05). Most respondents assessed their pasture vegetative cover at >70% (78.5%); however, respondents operating a farm with a high stocking density (<0.4 ha horse^{-1}) reported lower rates. The majority of respondents used a recommended stocking density of ≥0.61 ha horse^{-1} (53.9%). Only 15.4% of respondents did not maintain a proper vegetative buffer between horses and water sources. However, 71.4% of respondents stored their manure on an impermeable or permeable surface uncovered, 30.7% allowed horses unlimited access to surface water, 39.4% did not utilize sacrifice lots to rest pastures, and more than half (55.4%) of respondents reported soil erosion in their pastures. Soil erosion was noted less by respondents operating a farm for recreation and those with a low stocking density (>0.81 ha horse^{-1}). Only 3 of 10 recommended BMPs were being used correctly by the majority (≥51%) of respondents, with proper manure storage, use of sacrifice lots, and rotational grazing being used by the lowest percentage of respondents. BMPs with low adoption rates should be the focus of future education programs for horse farm operators in MD to minimize environmental impact to the Chesapeake Bay Watershed.

Key Words: best management practices, horse, survey

43 Sources of variation and importance of the quantification of the in vitro NDF digestibility for estimating rates of NDF digestion. E. Raffrenato* and M. E. Van Amburgh, *Cornell University*, *Ithaca, NY*.

Accurate and precise estimations of intrinsic NDF digestibility and digestion kinetic parameters have been shown to be important for the evaluation of forages. Methods for measuring NDFD are more variable than those for NDF and there is no standard method. Within laboratories, the standard deviation (SD) of repeatability for single determinations of NDFD is 1.5 to 2 times that of the NDF assay. The SD of reproducibility among laboratories for single in vitro determination is 3 to 5 times that of NDF and can greatly impact the calculations for rate of digestion. Recently a method has been proposed to standardize the inoculum (Goeser et al., 2009) and although the CV of multiple runs was reduced, the method appeared to result in lower NDFD values. Our objective was to evaluate the sources of and reduce the variability of both NDF and NDFD assays. Several hundred forages were analyzed for aNDFom (Mertens, 2002), ADL (Van Soest et al., 1991) and NDFD using Goering and Van Soest buffer in 125 mL Erlenmeyer flasks under CO_2 using inoculum from multiple lactating cows within 20 min of collection and filtered in crucibles. One of the factors impacting the outcome of NDF, ADL and NDFD was the loss of soluble materials through the Gooch crucible. The use of glass filters (Whatman, 934-AH, 1.5 µm) improved recoveries from 0 and 4% ($P < 0.05$) and 0 and 8% ($P < 0.05$) for NDF and NDFD, respectively, and reduced the CV below 2% for intra-run and below 3% for inter-runs, among all forages. In vitro (240 h) and in situ (360 h) NDF recovery was improved up to 15% with the use of the filter and through the use of bags with porosity of 15 µm, respectively. Further, the use of the filter increased ($P < 0.05$) recovery of ADL from 3 to 36%. In conclusion improved recovery and inoculum handling allowed better estimations of NDF, NDFD, ADL and indigestible NDF and result in a more precise and accurate estimations of the rate of digestion (Van Amburgh et al., 2004). This data will serve to provide recommendations for the standardization of the NDFD procedure.

Key Words: NDF, NDFD, ADL

44 Effect of capsicum oil on feeding behavior and milk production in lactating dairy cattle. L. R. Tager* and K. M. Krause, *West Virginia University*, *Morgantown.*

A preliminary study was conducted to study the effect of capsicum oil on feeding behavior and milk production in lactating dairy cows. Twenty lactating dairy cows (16 Holstein and 4 Ayrshire) were used in a crossover design using the Growsafe monitoring system (Growsafe

Systems Ltd., Airdrie, AB, Canada). After balancing for milk yield and DIM, 10 cows were randomly assigned to each of 2 pens (5 Growsafe bins/pen). Cows were fed a TMR with a 54:46 forage:concentrate ratio (DM basis) ad-libitum twice daily. Experimental treatments included: 2 g/cow/d capsicum oil (CAP; XT 6933; Pancosma S.A., France) or no oil (CON). Data was collected until 20 d of sound data were accumulated for each experimental period. There was no difference in DMI (23.05 kg/d vs. 23.17 kg/d; $P = 0.91$), number of meals/d (12 vs. 12; $P = 0.34$), total h spent eating/d (3.22 h vs. 3.16 h; $P = 0.89$), mean meal length (17.24 min vs. 17.23; $P = 0.96$), length of first meal after feeding (43.3 min vs. 46.2 min; $P = 0.21$), or feeding rate (7.49 kg/h vs. 7.78 kg/h; $P = 0.80$) between CAP and CON. Milk yield did not differ between CAP and CON (27.6 kg/d vs. 28.1 kg/d; $P = 0.72$). Based on this preliminary study, feeding CAP at 2 g/cow/d does not change feeding behavior or milk production. To add more experimental units and confirm the results of the preliminary study, this project is currently being replicated.

Key Words: capsicum, feeding behavior

45 Digestive fate of free ferulic acid in lactating dairy cows. M. A. Soberon*, D. J. R. Cherney, and D. A. Ross, *Cornell University*, *Ithaca, NY*.

Ferulic acid (FA), a phenolic compound with antioxidant and anti-cancer activities, naturally occurs in plants as one of the building blocks of lignin. Many veins of research have been devoted to releasing FA from the lignin complex to improve digestibility of plants fed to livestock. Thus, it is of interest to study the fate of a given dosage of FA in the dairy cow to determine the likelihood of its transfer from ingested feed to milk when available in free form. Six mid to late lactation Holstein cows at the Cornell Research Farm were given 14 d adaptation to diet and stall. Ad libitum access to a total mixed ration based on haylage and corn silage (31.1% NDF, 5.52 mg/g FA) was provided during the study. A cross over design was used so that each cow alternated weekly between Treatment (Trt) and Control. On d 1, jugular cannulas and urine catheters were placed in all cows. On d 2, Trt cows received a single dosage of 150 g pure FA powder via their fistula (n = 4) or a balling gun for nonfistulated cows (n = 2). Plasma, urine, feces, feed, orts, milk and rumen fluid were sampled intensively for the next 36 h. On d 8, the cows crossed over and the experiment was repeated. All samples were analyzed for FA concentration. FA administration did not have an effect on DMI ($P = 0.593$), milk yield ($P = 0.501$), milk fat yield ($P = 0.457$), milk protein yield ($P = 0.959$), SCC ($P = 0.495$), NDF content of orts ($P = 0.462$) or NDF content of feces ($P = 0.393$). The level of FA in the feces did not change as a result of Trt ($P = 0.399$). As expected, [FA] increased dramatically upon FA dosage and decreased over time until returning to basal levels in rumen fluid (detectable until 4.25 h post-dosage), plasma (detectable until 5.5 h post-dosage), and urine (detectable until 23 h post-dosage). Baseline values for FA in urine and rumen fluid were variable among cows and had an effect on [FA] in Trt cows. FA was detected in the milking following FA dosage (6.5 h post-dosage) at significantly higher concentrations in Trt cows. From this study, it is observed that orally ingested FA can be transported into the milk and that the physiological transfer of FA occurs from rumen to urine within 1 h and milk within 6.5 h.

Key Words: ferulic acid, cow

46 The effect of form of trace mineral supplementation on lactation, neutrophil function, and vaccination response in Holstein cows. L. M. Nemec*[1], J. D. Richards[2], C. Atwell[2], D. E. Diaz[2], and T. F. Gressley[1], [1]*University of Delaware*, *Newark*, [2]*Novus International Inc.*, *St. Charles, MO*.

The aim of this study was to compare inorganic versus chelated forms of supplemental Cu, Mn, and Zn on production, neutrophil activity, antibody titer, and plasma and milk mineral concentrations. Holstein cows (n = 25) averaging 63 d in milk were assigned to a 12-week completely randomized design study in 2 groups. Diets were supplemented at 100% of NRC requirements either by inorganic trace minerals (ITM) in sulfate and oxide forms, or by chelated trace minerals (Mintrex; Zn, Cu and Mn as Mintrex Zn [$Zn(HMTBa)_2$]; Mintrex Cu [$Cu(HMTBa)_2$]; Mintrex Mn [$Mn(HMTBa)_2$]; Novus International Inc., St. Charles, MO). Intake and milk production were recorded daily. Milk composition was measured weekly, and milk Cu, Mn, and Zn was determined at wk 0 and 8. Blood Cu and Zn concentrations and neutrophil activity were measured at wk 0, 4, 8, and 12. Neutrophil activity was measured by in vitro assays of phagocytosis, reactive oxygen species (ROS) production, and chemotaxis. A rabies vaccination was administered at wk 8, and vaccine titer response at wk 12 was measured by both Rapid Fluorescent Focus Inhibition Test (RFFIT) and ELISA. Wet chemistry analysis of the total mixed rations indicated dietary Cu was 17 and 24 ppm, Mn was 40 and 62 ppm, and Zn was 84 and 138 ppm for the ITM and Mintrex diets, respectively. There was no effect of treatment on milk production (42 kg/d), milk composition, plasma minerals, neutrophil ROS production, or neutrophil chemotaxis. Dry matter intake tended to be lower for Mintrex than ITM cows (24.1 vs. 25.3 kg/d, $P = 0.06$). Milk Cu concentration was greater for Mintrex than ITM cows (76 vs 57 ï g/L, $P < 0.01$). Neutrophil phagocytosis tended to increase for the Mintrex treatment ($P = 0.09$). Rabies antibody titer was approximately 2.5 fold higher for Mintrex than ITM cows, regardless of assay ($P = 0.08$ for RFFIT; $P = 0.009$ for ELISA). In summary, the Mintrex treatment increased bioavailability as indicated by increased milk Cu and enhanced both innate and adaptive immune responses as indicated by increased neutrophil phagocytosis and vaccine titer response, respectively.

Key Words: trace minerals, neutrophils, parity

47 The effects of length of storage on the composition and nutritive value of corn silage. M. C. Der Bedrosian*[1], L. Kung Jr.[1], and K. E. Nestor Jr.[2], [1]*University of Delaware*, *Newark,* [2]*Mycogen Seeds*, *Indianapolis, IN*.

The objective of this study was to evaluate the effect of length of storage on the composition and nutritive value of corn silage. The primary treatments were a brown midrib (BMR) and a non-BMR silage hybrid (nBMR) harvested at a normal DM (32%) and a high DM (41%). Forages were vacuumed and heat-sealed in quintuplet storage bags and ensiled for various periods of time between 0 to 360 d before analyses. Nutrient analysis, fermentation end products and in vitro NDF (NDF-D; 30 h) and starch digestion (starch-D; 7 h) techniques were used to evaluate the samples. Over both maturities and time of ensiling, compared with nBMR, BMR silage was lower ($P < 0.01$) in lignin, CP and ADF but higher in starch content. The NDF content of silages was not affected by treatment. Of the fermentation end products, the concentration of acetic acid increased substantially with length of storage for all treatments specifically increasing as much as 140% between d 45 to d 365 for normal DM BMR silage. The NDF-D was greater overall all times for BMR (68% DMB) than nBMR (52%) but there was an interaction ($P < 0.01$) between hybrid and maturity. Increasing maturity did not affect NDF-D of nBMR but it decreased for BMR by approximately 5

percentage units. Fiber digestion did not change substantially between 45 and 365 d regardless of hybrid or DM content. Starch digestibility was highest ($P < 0.01$) in normal DM nBMR samples at d 0 (about 80%) and lower (65 to 68%) for other treatments. This was most likely due to the fact that normal DM nBMR had a low starch content (21%) compared with other treatments (31 ± 3%). Starch-D increased ($P < 0.01$) about 6 to 8 percentage units for nBMR silages but increased ($P < 0.01$) approximately 15 percentage units for BMR silages over the ensiling period. Relative to the 2 corn silage hybrids used in this study, the results show that time of ensiling does not affect NDF-D but it results in marked increases in starch digestion. The NDF-D of BMR but not the nBMR hybrid was affected by harvesting at a higher DM. Allowing corn silage to ensile for prolonged periods of time can improve its nutritive value.

Key Words: Silage, BMR

48 Effect of forage particle length on rumen fermentation and chewing activity of late lactating and dry dairy cows. F. X. Suarez-Mena*, G. I. Zanton, and A. J. Heinrichs, *The Pennsylvania State University*, *University Park*.

The objective of this study was to determine forage particle size effects on chewing activity, rumen pH, and rumen fill in dairy cattle fed rations with similar physically effective NDF but different mean particle length. Two experiments were conducted to determine chewing behavior, rumen pH, and rumen fill. Treatments consisted of 3 diets differing only in forage length (geometric mean length, mm): hay (5.40, 8.96 and 77.90, for short (S), medium (M) and long (L) diets, respectively) for Experiment 1 (E1), and straw (10.16 S, 24.68 M and 80.37 L) for Experiment 2 (E2). Hay or straw comprised the sole source of forage (50% for E1 and 75% for E2). Both experiments used 3 rumen cannulated, non-pregnant Holstein dairy cows, late lactating in E1 and dry in E2, with 3 × 3 Latin square designs. Chewing behavior was visually monitored for 48 h at 2-min intervals. In E1, DMI (18.3 ± 2.1 kg/d), pH (6.4 ± 0.1), time spent eating (280 ± 22.5 min/d), time spent ruminating (487 ± 17 min/d), and total time spent chewing (767 ± 34 min/d) were not different, while min/kg of DMI and min/kg of NDF intake tended to increase linearly ($P < 0.1$) as forage length increased. Rumen digesta volume (L; 113.3 S, 117.8 M, and 114.4 L ± 17.1) had a quadratic response ($P < 0.05$) and rumen digesta weight tended to respond quadratically ($P < 0.1$); however, differences were numerically small. In E2, DMI (8.3 ± 1.3 kg/d), pH (6.7 ± 0.1), time spent eating (236 ± 23.5 min/d), time spent ruminating (468 ± 45.2 min/d), total time spent chewing (704 ± 67.7min/d) and min/kg NDF intake were not different, while min/kg of DMI had a trend for a quadratic effect ($P < 0.1$). Rumen digesta volume (111 ± 18.8 L) and weight (103 ± 17.4 kg) were not different. Changes in rumen characteristics and chewing in cows in late lactation and dry cows were not detected or were small when the particle size of the forage was changed.

Key Words: particle size, chewing, rumen pH

Alpharma Beef Cattle Nutrition Symposium: "Parameterizing" Health and Performance Expectations of Feedlot Cattle

49 Practical relationships between morbidity and growth performance. V. R. Bremer[1], G. E. Erickson*[1], T. J. Klopfenstein[1], D. R. Smith[1], K. J. Hanford[1], R. E. Peterson[2], L. O. Burciaga-Robles[2], D. B. Faulkner[3], and C. R. Krehbiel[4], [1]*University of Nebraska*, *Lincoln*, [2]*Feedlot Health Management Services*, *Okotoks, Alberta, Canada*, [3]*University of Illinois*, *Urbana*, [4]*Oklahoma State University*, *Stillwater*.

Six trials suggested that bovine respiratory disease (BRD) depresses ADG and carcass finish. These studies did not account for DMI or G:F. Therefore, 5 new data sets were evaluated. Data (n = 978 lots; 276,116 cattle) from 2 Alberta, Canada feedlots with 0 to 70% BRD (CAN) were used to evaluate impact of BRD on performance. A subset (n = 33,074 cattle) had carcass data. A trial (OSU) was conducted with 193 heifers fed (6 heifers/pen) based on 0, 1, 2, 3, or 3+ BRD treatments during receiving, with incidence of 58%. Individual performance of 900 growing and 987 finishing cattle (UNL; 16 and 19% BRD treatment, respectively) were classified by time of BRD treatment at receiving, < 31 d on trial, > 30 d on trial, or no treatment. A third data set of 1,940 individual finishing cattle with 10% BRD treatment (UofI) were analyzed by time of BRD treatment. The CAN pen level closeout data indicate quadratic decreases ($P = 0.03$) in DMI and ADG and a trend for linear ($P = 0.08$) improvement in G:F as % of pen treated for BRD increased. The CAN carcass data indicates quadratic decreases ($P < 0.01$) in HCW, marbling score, and LM area, and a linear decrease ($P < 0.01$) in fat thickness as number of BRD treatments increased. In the OSU trial, feeding heifers based on BRD incidence at receiving indicates ADG linearly increased ($P = 0.01$), DMI was unchanged, and G:F increased as number of BRD treatments increased. Heifers treated 3 or more times required more d to reach a common end point. Growing cattle (UNL) treated > 30 d on trial had decreased ADG and G:F ($P < 0.01$) relative to cattle treated earlier or not at all. Finishing cattle (UNL) treated > 30 d on trial had similar DMI, ADG, and G:F ($P > 0.16$) as cattle treated earlier or not at all. The UofI cattle treated for BRD > 30 d on trial had decreased ($P < 0.01$) DMI and ADG and similar ($P = 0.51$) G:F as other BRD classes and required more d to reach a common end point. Cattle requiring treatment before 30 d on feed have similar performance to healthy cohorts; however, cattle requiring treatment after 30 d on feed may require increased d to reach a similar endpoint as healthy cohorts due to lower DMI and ADG, but G:F is unaffected.

Key Words: bovine respiratory disease, feed efficiency, growth

50 Predictability of feedlot cattle growth performance. M. L. Galyean*, N. DiLorenzo, J. P. McMeniman, and P. J. Defoor, *Texas Tech University*, *Lubbock*.

Predicting performance is vital to management and marketing decisions in commercial feedlots. Agreement between performance predicted from net energy equations or empirical regression relationships and actual performance is generally high, suggesting that factors affecting feedlot performance are fairly well documented. The challenge for feedlot managers is to predict performance with limited information at the start of the feeding period. Sex and initial BW are typically known with greatest certainty when cattle start on feed. Information on background and breeding is potentially important but less reliable. Relationships between initial BW, sex, and performance were evaluated using 3,363 pen records collected over 4 yr from 3 commercial feedlots in the Texas Panhandle. Mixed-model regression was used to account for random effects of feedlot × season × year and fixed effects of initial BW (range = 227 to 451 kg), sex (steer or heifer), and initial BW × sex ($P < 0.10$ for all variables evaluated). As expected, initial BW was positively related to DMI. With intercept and slope adjustments for sex, the R^2 was 0.72 for regression of DMI (adjusted for random effects) on initial BW. Similarly, with adjustments for random effects, regression on initial BW with sex adjustments accounted for 46, 82, and 81% of the variation in ADG, final shrunk BW, and HCW, respectively. Initial BW was negatively related to G:F ($R^2 = 0.22$). Analysis of a university data set (200 pens of steers; initial BW = 300 to 450 kg) indicated that adding ADG from d 0 to 70 of the feeding period increased R^2 for predicting HCW. Similarly, including early DMI data increased R^2 and decreased prediction error for DMI, indicating that updating predictions with interim performance data should prove beneficial. Adding data on previous health issues might improve predictions but is difficult to apply to pen settings. Environmental effects (e.g., severe heat or cold stress) can greatly affect performance and thereby decrease predictability. Overall, results suggest that initial BW has considerable value in predicting growth performance by feedlot cattle.

Key Words: feedlot cattle, initial body weight, predicted performance

51 Applying detection controls in assessing variance in feedlot cattle performance. R. A. Zinn*, *University of California*, *Davis*

ADG and DMI of feedlot cattle are predictable functions of gender, quality score (QS; values range from 1 to 3, increasing inversely with frame size), shrunk initial weight (SIW, kg), average shrunk live weight (SLW, kg), and dietary NEm and NEg (Mcal/kg):

MFWsteer, kg = 509.6 + 0.4697 SIW - 46.54 QS,
MFWheifer, kg = 551.5 - 0.2482 SIW + 0.00119 SIW^2 - 39.84 QS,
ADGsteer, kg = 1.628 + 0.00287 SIW −0.00000107 SIW^2 − 0.461 QS,
ADGheifer, kg = 1.265 + 0.00432 SIW - 0.00000425 SIW^2 − 0.410 QS,
DMIsteer, kg = $(0.0606*((SLW*478/MFW)^{0.75})*ADG^{0.905})/NEg) + (0.077LW^{0.75}/NEm)$,
DMIheifer, kg = $(0.0618*((SLW*478/MFW)^{0.75})*ADG^{0.905})/NEg)+(0.077LW^{0.75}/NEm)$.

Variance in observed vs expected feedlot cattle performance occurs for many reasons, including: inaccurate measures of dietary DM percentage; estimation of dietary NE; unbalanced rations; improper feed mixing; inadequate grain processing; negative associative effects of dietary ingredients (i.e., too much fat); poor weighing conditions; 3) errors in recording live weight and DMI; transferences of cattle from one lot to another; failure to implant, or improper implanting technique; pen location and/ or orientation; inadequate pen, shade, manger, or drinker allocation; poor pen conditions; environmental extremes; poor health; etc. In this presentation, numerous examples using actual feedlot closeout data will be provided to illustrate how performance expectations (standards of performance) are used in fine-tuning feedlot management decisions.

Key Words: feedlot, cattle, performance

Animal Behavior and Well-Being: Animal Welfare Assurance: Science and Application

52 Resource-based versus animal-based criteria in on-farm evaluation of welfare. A. Butterworth*, *University of Bristol, Clinical Veterinary Science*, *Langford, N Somerset, UK*.

Existing farm assurance schemes tend to assess welfare by examination of the provision of housing or resources (Resource Based Measures, RBM), rather than looking at the animals themselves (Animal Based Measures, ABM). Research scientists have for some time suggested that ABMs could provide valid indicators of animal welfare, since welfare is a characteristic of the individual animal, not just of the system in which animals are farmed. The sorts of questions which are being asked are Are the animals properly fed and supplied with water? Are the animals properly housed? Are the animals healthy? Can the animals express a range of behaviors and emotional states? To implement effective use of animal-based assessment methods on farm, it is necessary to adopt the following steps. Step 1, Measure (ABMs and RBMs) → Step 2, Analyze risk factors → Step 3, Inform (producer, purchaser) → Step 4, Support management decisions to create improvements in welfare. Once measures have been carried out on a farm, it may be possible to create a range of 'scores'. The individual measures can be combined to give aggregate scores which can be presented to the producer and the consumer. This requires the attribution of weighted values to the measures, to assess the impact of each measure with respect to animal welfare. In the Welfare Quality project, an Integrated European Research initiative carried out under Framework 6, ABM based assessment systems have been created for Pigs, Cattle and Poultry. There remain many questions regarding practical application of ABMs', - who will carry the cost, can the measures be made in a repeatable and reliable way within the timescale of an routine assessment, how would they work in relation to changing seasons, can a single farm-based score provide useful information, and can ABMs fit into existing assessment frameworks?

Key Words: farm assessment, animal based measures, outcome based measures

53 Developing animal welfare standards: Translating experimental studies to the farm. J. Rushen*[1], E. Vasseur[2], and A. M. de Passillé[1], [1]*Agriculture and Agri-Food Canada*, *Agassiz, BC, Canada*, [2]*University of British Columbia*, *Vancouver, BC, Canada*.

Considerable research has successfully developed measures of animal welfare and tested the effect of housing and management variables on welfare within controlled laboratory settings. However, there are challenges in extending this research onto farms. We illustrate some of these challenges and offer some solutions by referring to recent developments in welfare standards for dairy cattle. On-farm assessment of animal welfare requires using measures that can be taken by personnel with limited scientific training, in conditions that vary greatly among farms, usually in a short period of time, and often with little technical support. There is a risk that measures are chosen on the basis of feasibility rather than validity. Although the global assessment of animal welfare requires us to examine all aspects of animal welfare, these difficulties in taking measures have resulted in an over-emphasis on health based measures. Automated measures of behavior hold promise as a way of addressing some of this imbalance. Stakeholders prefer that animal welfare standards be science-based, but ensuring that such standards acknowledge the scientific uncertainty is also challenging. Balanced input from all scientific disciplines dealing with animal welfare is needed and the process of obtaining scientific input must be transparent and unbiased. Compliance with animal welfare standards requires buy-in from all stakeholders. The process used in developing the recent Canadian standards for the welfare of dairy cattle illustrates some methods for achieving this.

Key Words: animal welfare, dairy cattle

54 Integration of science, regulation and training in animal welfare auditing programs. J. C. Swanson*, *Michigan State University*, *East Lansing*.

Corporate social responsibility policies are employed by food retailers to publically convey an internal commitment to address an important consumer issue like farm animal welfare. Private sector social responsibility policies, coupled with increasing public scrutiny and calls for regulatory oversight of farm animal care practices, have led the US livestock and poultry industries to create voluntary guidelines and on-farm animal welfare assurance and audit programs. Third party audits, an audit in which the auditor has no conflict of interest with the farm he or she is auditing, are becoming a condition of doing business with the food retail sector. In addition, recent state legislative actions have created requirements for government oversight of standards of farm animal care that have been socially negotiated. Together, these social responsibility and legislative mandates create a need for highly trained farm animal welfare auditors. The objective of this paper is to examine the challenge of successfully integrating science and diverse regulatory mandates into an effective animal welfare auditing program.

Key Words: science, animal welfare, audits

Animal Health-Johne's Disease (JDIP): Basic Biology/Immunology/ Vaccine Development

55 A novel approach to evaluate the cost-benefit of use of Johne's disease vaccine while considering effects on the bovine tuberculosis eradication program. F. J. Zagmutt*[1], L. A. Espejo[2], H Groenendaal[1], J. R. Lima[2], E. Patton[3], I. A. Gardner[4], and S. Wells[2], [1]*Vose Consulting*, *Boulder, CO*, [2]*College of Veterinary Medicine, U. of Minnesota*, *St. Paul,* [3]*Division of Animal Health, Wisconsin DATCP*, *Madison, WI*, [4]*School of Veterinary Medicine, U. of California Davis*, *Davis*.

Johne's disease (JD) vaccination has the potential to reduce losses for individual herds. However, the effectiveness of widespread adoption of JD vaccination on JD control, and the effects of cross-reactivity (CR) between *M. avium* ssp. *paratuberculosis* (MAP) and *M. bovis* on the control and eradication of each disease is unknown. The objective of this study was to assess the cost-benefit of Johne's Disease (JD) vaccination on MAP infected dairy herds, and its effect on the bovine tuberculosis (bTB) eradication program in the USA. The results of 12,957 parallel fecal culture (HEY media) and serum ELISA (IDEXX) from 8 dairy herds enrolled in the MN JD Demonstration Herd Program over 9 years, and 970 fecal culture from 3 JD-vaccinated dairy herds enrolled in the WI JD Demonstration Herd Program for 4 years were used to build a model for the within-herd spread of JD and estimate its parameters. The uncertainty in the parameters was linked to the progression of the disease in each animal based on tests results. Herd and test parameters estimated with a latent-class Bayesian analysis were used to calculate the confidence in the disease status of each animal in time, and then the status of animals in each iteration was grouped to calculate spread parameters dynamically. The parameters were used to simulate disease spread in vaccinated and non-vaccinated herds. The model predictions using different scenarios of vaccine efficacy and disease spread were used in an economic break-even analysis. As bTB animal prevalence in the US may change in time, the threshold of bTB prevalence that would make JD vaccination not economic was calculated for each scenario. Even in scenarios with very high bTB prevalence (1% and higher) and a 10% relative drop in Sp of CFT in vaccinated herds, vaccination provided financial benefits (NPV > 0). However, while vaccination reduced herd-level JD losses at the producer level, the majority of the costs of CR due to JD vaccination are borne by the government. This economic threshold was highly sensitive to the reduction of JD losses resulting from vaccination.

56 Stochastic simulations of a multi-group compartmental model for Johne's disease on US dairy herds with test-based culling intervention. Z. Lu*, Y. H. Schukken, R. L. Smith, and Y. T. Gröhn, *Cornell University, Ithaca, NY.*

The objective of this study was to evaluate the effectiveness of test-based culling intervention and its impact on fadeout of Johne's disease in dairy herds using a stochastic modeling approach. Infection elimination may be an important goal of control programs; only in stochastic infection models can true infection elimination be observed, as fadeout. To investigate the stochastic dynamics of Mycobacterium avium ssp. paratuberculosis (MAP) infection in US dairy herds with test-based culling intervention, we developed a continuous time Markov chain model with both horizontal and vertical transmission. The stochastic model predicted fadeout and within-herd prevalence to have a large variance. Although test-based culling generally decreased prevalence over time, it took longer than would be desired by producers to eliminate an endemic MAP infection from a herd. Uncertainty analysis showed that, either using annual fecal culture tests and culling only high shedding animals or culling of both low and high shedders while delaying culling of low shedders for 12 mo, MAP infection persisted in many herds beyond 20 years. Using a semi-annual whole-herd fecal culture test and culling of both low and high shedders, with a 6-mo delay in culling of low shedders, MAP infection in many herds would be extinct within 20 years. Sensitivity analysis of the cumulative density function of fadeout suggested that combining test-based culling and reduction of transmission rates, through decreased contact between susceptible calves and shedding animals, may be more effective than either control strategy alone in eliminating endemic MAP infection. We also examined the effects of other factors, such as herd size, heifer replacement, and adult cow infection on the probability of fadeout.

Key Words: Johne's disease, test-and-cull, stochastic modeling

57 Unrestricted transmission of highly pathogenic Indian Bison type of *Mycobacterium avium* ssp. *paratuberculosis* in India. S. V. Singh*, B. Singh, A. Tiwari, A. Kumar, P. K. Singh, and A. V. Singh, *Central Institute for Research on Goats*, *Makhdoom, Farah, Mathura (UP), India, 281 122*.

The aim of present study was to determine the status of MAP infection and its genotype in free ranging wild species, primate, soil, river water, milk and humans to understand the disease transmission for future evaluation of regional and national JD control programs and improvement in diagnostics and vaccine designing. A total of 74 fecal samples from wildlife species [Monkeys (Primate)-25, Hog Deer-20, Wild bison-7, Chinkara deer-16, Blue bull-6], 39 stool samples from humans (with/ without inflammatory bowel disease; IBD), 51 soil samples (from grazing land), 8 water samples from different Yamuna river bank, were collected from North India and screened for the presence of MAP and further its genotyping by IS1311 PCR-REA. In 74 fecal samples from wild animals 50% and 46.9% were positive by microscopy and PCR [40.0, 20.0, 42.8, 100.0 and 66.6% (by microscopy) and 4.0, 15.0, 57.1, 75.0, and 66.7% (by PCR) Monkeys, Hog deer, Wild Bison, Chinkara deer and Blue bull, respectively). Of the 51 soil samples, 52.9 and 29.4% were positive for MAP by microscopy and PCR, respectively. In 8 samples from Yamuna river 12.5 and 37.5% sample were positive by microscopy and PCR. Out of 39 stool samples from humans 28.21 and 20.51% samples were positive in microscopy and PCR. There was significant high occurrence of MAP in samples collected from persons suffering from IBD. All the PCR positive samples in present study were showed restriction profile of 'MAP Bison type' by IS 1311 PCR-REA. High presence of MAP of same genotype i.e. Bison type in different free ranging wild animal species, primate, human, soil and river water indicated host unrestricted and high rate of transmission among different animals species, serious risk to human health and active biohazard for environment.

58 *Mycobacterium avium* subspecies *paratuberculosis* produces endospores. E. A. Lamont*[1], J. P. Bannantine[4], A. Armién[1], D. S. Ariyakumar[3], and S. Sreevatsan[1,2], [1]*Veterinary Population Medicine,*

University of Minnesota, *Saint Paul*, [2]*Deptartment of Biomedical Sciences, University of Minnesota*, *Saint Paul*, [3]*Veterinary Diagnostic Lab, University of Minnesota*, *Saint Paul*, [4]*National Animal Disease Center, USDA-Agricultural Research Service*, *Ames, IA*.

Achievement of latency represents pathogenic mycobacteria's ultimate stratagem for survival, yet it remains one of the least understood and ill-defined aspects of its lifecycle. Two debated viewpoints concerning latency are that 1) bacilli are in a non-replicating state of chronic persistence (dormancy) and 2) replicating bacilli periodically escape from the granuloma and enter adjacent vessels to infect new sites. We hypothesize and show that MAP is capable of spore production in one year old MB7H9 cultures and AK-sporulation media. Experiments were conducted in triplicate. All MAP endospore samples, including germinated spores, were positive for IS900. All cultures were determined to be free of contamination by absence of growth on BHI plates. In addition to spore visualization, we have identified several mycobacterial candidate genes corresponding to those in the sporulation pathway of several *Bacillus* and *Streptomyces* species. Research investigating Bacillus spp. pathogenicity indicates that the stringent response regulated by carD is essential to robust spore production. Quantitative real-time PCR (Qt-RT-PCR) analysis of dormant MAP cultures show a 15-fold upregulation of carD compared with log-phase controls. MAP cells primed by carD may utilize sporulation as an alternate survival tactic to combat a hostile host environment to achieve latency. The hypothesized critical roles of carD and sporulation in latent infection is expected to aid in novel mitigation strategies to combat MAP infection, which may have far reaching benefits to other mycobacterial infections, including M. tuberculosis.

59 Transcriptional analysis of MAP genes contributing to invasion and persistence in ileal mucosa of cattle. S. Khare*[1], K. Drake[2], and L. G. Adams[1], [1]*Department of Veterinary Pathobiology, Texas A&M University*, *College Station*, [2]*Seralogix Inc.*, *Austin, TX*.

Mycobacterium avium ssp. *paratuberculosis* (MAP) initiate the disease process by invading and passing through the intestinal epithelium. This triggering mechanism is generally very rapid and may lead to a persistent infection. MAP undergoes a complex extracellular and intracellular environment. However, little is known about the bacterium-host interactions that occur at these stages. We hypothesize that MAP meets the challenges of hostile changing environments of ileum as soon as it comes into the contact of the host. We have used the MAP isolated from ligated ileal loop model to test our hypothesis. The objective of the current study was to determine the temporal changes in the MAP gene expression during the early invasion in the ileum. Tissue-associated MAP RNA from MAP infected bovine ligated ileal loop were enriched using "Prokaryote Enrichment kit" that selectively removes the Eukaryotic RNA. This enriched prokaryotic RNA is amplified using MAP-genome derived primers during in vitro transcription. Genomic DNA from in vitro grown MAP was labeled with Cy5 and used as the reference RNA. Enriched and amplified tissue-associated MAP was labeled with Cy3. The Cy5 labeled g-DNA and Cy3 labeled tissue-associated cDNA were co-hybridized on the MAP microarray (obtained from JDIP core facility). After hybridization arrays were washed and dried by centrifugation and were immediately scanned. We will describe in detail the groups of interrelated genes that as a whole represent the activation (perturbation) of pathways or GO biological processes over the time-course of these experiments (1h, 2h, 4h, 8h, 12h). This approach ranks groups of genes/proteins across all time points instead of individual genes in a single time point, to determine differences between experimental conditions. Using this approach, we have identified several mechanistic genes that play key regulatory role during invasion and persistence of MAP in the ileum.

Key Words: Johne's disease

60 The transcriptome of *Mycobacterium avium* subspecies *paratuberculosis* during infection. C.-W. Wei and A. M. Talaat*, *University of Wisconsin-Madison*, *Madison*.

Mycobacterium avium ssp. *paratuberculosis* (M. ap) causes an enteric infection in cattle, with a great impact on the dairy industry in the United States and worldwide. Before contracting a new host, M. ap are known to survive the harsh intracellular microenvironments, especially those inside activated macrophages. To improve our understanding of the pathogenesis of M. ap and help in a better control strategy against Johne's disease, we profiled the transcriptional responses of M. ap mutant or wild type following exposure to variable stress conditions including macrophage microenvironments. Mycobacterial cultures were exposed to heat shock, nitric oxide or H2O2 treatments. Other aliquots were used for infecting J774 cell lines at the 10 MOI (Bacteria: Macrophage). Following each stress, mycobacterial RNA samples were extracted using a Trizol-based protocol. Using DNA microarray analysis, Bayesian statistics revealed the presence of 123 genes that were significantly regulated when in vitro samples were compared with samples collected from M. ap isolated from 2 h post infection of macrophages. This group of genes includes sigH (a global gene regulator) and aceA that were shown before to play a role during infection. Further analysis identified additional 67 genes that were regulated when IFN-γ treated cells were compared with naïve cells before infection including genes involved in iron metabolism (e.g., fdxA). Currently, analysis is underway to generate specific gene mutants to examine their role in M. ap virulence using the mouse model of paratuberculosis. Overall, our analysis indicated a significant change in mycobacterial gene expression once they encounter the macrophage microenvironment. Additionally, the activity status of macrophages seems to play a role in directing the mycobacterial transcriptome to a specific stress-responsive profile.

61 The response of auxotrophic MAP leuD mutant under environment stresses. J.-W. Chen*, J. Scaria, S. Chandra, and Y. F. Chang, *Cornell University*, *Ithaca, NY*.

Mycobacterium avium ssp. *paratuberculosis* (MAP) causes Johne's disease in ruminants. In M. tuberculosis, deletion of leuD gene results in severely attenuated phenotype. To explore the possibility of using leuD mutant strain of MAP as a vaccine candidate for Johne's disease, and to understand the mechanism of attenuation of MAP leuD deletion, a phage-mediated allelic exchange method was used to construct a leuD mutant strain in MAP K10 strain. The leuD deletion was confirmed by both PCR and DNA sequencing. In the absence of leucine supplementation, the growth of leuD mutant is completely inhibited in 7H9 medium. With supplementation of leucine the growth of mutant is restored but grows at a slower rate than that of wild type. To analyze the mechanism of leuD attenuation, mutant and wild type were subjected different environmental stress and following Agilent protocols. Three ug of RNA from mutant and wild types were competitively hybridized against a whole genome Agilent expression array of MAP. Array results were analyzed using Genespring GX 7.3. Arrays were log-transformed and subjected to lowess normalization and fold change analysis of mutant vs. wildtype was performed. Expression levels changes 1.5 fold or more were considered significant. The results of array studies demonstrate that leuD plays an important role in the MAP metabolism and that

there are more than 500 genes that belong to different pathways that are modulated in different stress conditions. These genes are distributed across Cluster of Orthologous Gene (COG) categories. The major COG categories include energy production and conversion, lipid transport and metabolism, inorganic transport, secondary metabolite production and cell membrane biogenesis. These results indicate that deletion of leuD in MAP results in global changes in lipid transport, cell secretion apparatus and changes in cell membrane biochemistry. Mice studies showed that inoculation of 107 cells of leuD mutant can provide partial protection of mice when challenged after 16 weeks with wild type.

Key Words: Johne's disease, LeuD mutant, microarray

62 A gene specific to *Mycobacterium avium* ssp. *paratuberculosis*, but only at the transcription-translation level. J. P. Bannantine*[1], R. E. Briggs[1], E. A. Lamont[2], J. R. Stabel[1], and S. Sreevatsan[2], [1]*National Animal Disease Center*, *Ames, Iowa,* [2]*University of Minnesota*, *St. Paul*.

There is no known antibody that detects *M. avium* ssp. *paratuberculosis* and does not cross react with other *M. avium* subspecies. In the present study, a monoclonal antibody was identified from mice immunized with a cell membrane fraction of *M. avium* ssp. *paratuberculosis* strain K-10. This antibody detected a protein in *M. avium* ssp. *paratuberculosis* whole cell extracts, but did not bind to any of the 20 non-paratuberculosis subspecies strains tested in immunoblot assays. The antibody was further tested with 15 strains of *M. avium* ssp. *paratuberculosis* and showed variable expression levels of the target binding protein in select strains. This target binding protein was identified by screening a *M. avium* ssp. paratuberculosis-lambda phage genomic expression library with the monoclonal antibody. The identity of the protein was encoded by a gene that was not annotated in the *M. avium* ssp. *paratuberculosis* K-10 genome sequence and showed no similarity to other proteins in sequence databases. Furthermore, this gene has extensive overlap with an annotated gene on the opposite strand. The epitope detected by the mAb was precisely mapped to 7 amino acids and served as an anchor point in studies that identified the start and stop locations for this unique gene. Similarity searches reveal that the DNA sequence is present in other MAC complex species. However, expression analysis shows that only *M. avium* ssp. *paratuberculosis* makes a transcript and expresses the protein in macrophages as well as when cultured in Middlebrooks 7H9. The protein is not a strong antigen, but it is detected in the context of Johne's disease. These findings have new implications for comparative genomics and gene regulation differences among mycobacteria.

Key Words: protein, antibody, Johne's disease

63 Binding affinity of *Mycobacterium avium* ssp. *paratuberculosis* 85 complex to 40 kDa domain of fibronectin. C. J. Kuo*[1], J. Bannantine[2], V. Kapur[3], and Y. F. Chang[1], [1]*Cornell University*, *Ithaca, NY*, [2]*NADC*, *Ames, Iowa*, [3]*Pennsylvania State University*, *University Park*.

Antigen 85 complex proteins (Ag85), consisting of members 85A, 85B and 85C, have been shown to be the important secreted antigens and are retained in the cell wall of Mycobacterium avium ssp. paratuberculosis (MAP). Ag85 binds specifically to a host extracellular matrix protein, fibronectin (Fn), which consists of N-terminal domain (NTD), gelatin-binding domain (GBD), cell-binding domain (CBD), and 40kDa domain. Fibronectin-binding proteins are important virulence factors of MAP and Ag85 may contribute to the adherence, invasion, and dissemination of organisms in host tissue. However, the critical residues of Fn involved in Ag85 binding are still unknown. Our objective of this study is to identify the Fn binding domain(s) to antigen 85 complexes. In this study, we constructed and overexpressed antigen 85A of MAP in *E. coli*. Four domains of Fn were tested for Ag85-Fn interaction by using native gel electrophoresis and ELISA. Except the 40 kDa domain (including 12, 13, 14, and v region), no significant binding was observed for other Fn domains. Subsequently, the synthesized peptides based on the binding sequence of Fn were subjected to a competition binding assay. Our data shows that these peptides can partially abolish the interaction between MAP and host cells. This is the first report to identify the Fn binding domain in Ag85.

Key Words: fibronectin, Johne's disease, adhesin

64 *MAP* induces calcium-dependent phagosome acidification to enlist IL-1β processing and macrophage recruitment. E. A. Lamont*[1], S. M. O'Grady[3], T. Eckstein[4], and S. Sreevatsan[1,2], [1]*Veterinary Population Medicine, University of Minnesota*, *Saint Paul*, [2]*Department of Veterinary Biomedical Sciences, University of Minnesota*, *Saint Paul*, [3]*Department of Animal Sciences, University of Minnesota*, *Saint Paul*, [4]*Department of Microbiology, Immunology and Pathology, Colorado State University*, *Fort Collins*.

Processing of *MAP* by the host epithelium involves a dynamic innate immune response initiated by *MAP*-epithelial cell cross-talk, which may also be further augmented by interactions between host pathways and/or cell types (epithelial-macrophage). We show that *MAP* induces phagosome acidification within MacT cells as early as 10 min., resulting in upregulation of IL-1β at transcript and protein levels. Previous studies report that IL-1β is a potent macrophage chemoattractant. We hypothesized that *MAP* harnesses host responses to recruit macrophages to the site of infection to ensure its survival and dissemination. These initial host-pathogen interactions may dictate a form of cooperative self-destruction in which the host is deceived into reacting to the benefit of *MAP*; thereby, setting the tone for the ensuing infection. We investigated macrophage recruitment in response to *MAP* using a MacT-bovine macrophage coculture system. All time points were conducted in triplicate. Within 10 min of *MAP* infection, macrophages were recruited to the apical side of Mac-T cells ($P < 0.05$, ANOVA). Inhibiting phagosome acidification with bafilomycin treatment abrogated this response ($P < 0.05$, ANOVA). Since IL-1β cleavage and subsequent release to the epithelial milieu is dependent upon calcium influx, we next sought to define the role of calcium oscillations in phagosome acidification and macrophage recruitment. Pre-treatment of Mac-T cells with BAPTA-AM, an established intracellular calcium chelator, abolishes phagosome acidification and IL-1β processing to its active form. Thus, *MAP* guidance of phagosome-acidification enlists IL-1β processing in a calcium dependent manner to efficiently transverse the epithelium and into its niche—the macrophage.

65 Macrophages infected with *Mycobacterium avium* subspecies *paratuberculosis* are highly resistant to apoptosis, while uninfected culture mates are highly apoptotic. E. Kabara* and P. M. Coussens, *Michigan State University*, *East Lansing*.

Mycobacterial infections have long been implicated in altering the apoptosis status of infected macrophages. Previous research has linked more virulent mycobacteria to an increase in macrophage apoptosis. However, this research often does not take into account that most macrophage culture infections with mycobacteria are mix of infected and uninfected cells, with the infected macrophages comprising less then 50% of the total cell population. More recent studies specifically looking at the differences between infected and uninfected macrophages in a culture

show that most of the infected macrophages are highly resistant to cell death while the uninfected macrophages are more likely to undergo apoptosis. While most of this evidence has arisen from research with Mycobacterium tuberculosis, a large scale microarray project recently performed by our group implicated infection with Mycobacterium avium subspecies paratuberculosis (MAP), the causative agent of Johne's disease in cattle and possibly Crohn's disease in humans, as changing the apoptotic potential of cultures. We hypothesize that MAP-infection prevents apoptosis in infected macrophages while upregulating apoptosis in uninfected macrophages in the same culture to prevent proper immune function while increasing bacterial survival. To study the true apoptotic status of MAP-infected and MAP-uninfected macrophages in the same culture, fluorescent dye was used to label the bacteria before infection and cells were examined individually using flow cytometry. After using the Annexin V/ 7-AAD apoptosis stains, we clearly show that MAP-infected macrophages are much less likely to undergo apoptosis, while uninfected macrophages in the same culture are highly apoptotic. We further demonstrated that MAP-infected macrophages are much more likely to undergo necrosis when stimulated with hydrogen peroxide, TNFa, and FASL. Conversely, uninfected macrophages in a MAP-infected culture are much more likely to undergo apoptosis than control macrophages unexposed to MAP after stimulation with these same agents.

Key Words: *Mycobacterium*, paratuberculosis, apoptosis

66 Genetic correlations of gross feed efficiency with yield, body weight, body condition score, and energy balance in dairy cattle. C. D. Dechow*[1], J. Vallimont[1], M. D. Dekleva[1], J. M. Daubert[1], and J. W. Blüm[2,1], [1]*Pennsylvania State University*, *University Park*, [2]*Unversity of Bern*, *Switzerland*.

The objective of this study was to estimate genetic correlations of gross feed efficiency with 305 d fat corrected milk yield (FCM), 305 d protein yield, body weight (BW), body condition score (BCS), BCS change (BCSCH) from 5 to 30 d in milk (DIM), and cumulative energy balance (CEB) from 5 to 30 DIM. Intake, BW and BCS were recorded once per month for 6 consecutive months on 11 Pennsylvania tie-stall dairy farms. Feed samples were taken at each visit to determine net energy of lactation intake (NEI) and crude protein intake (CPI). Random regression models were used to analyze 35,390, 3999, 2195 and 4998 test day records of yield, intake, BW and BCS, respectively. Daily phenotypic FCM, protein yield, BW, BCS, NELI and CPI were derived from the random regression model solutions. Daily records were used to obtain 305 d totals (FCM, protein yield, NELI, and CPI), 305 d averages (BW and BCS), and BCSCH. Daily energy balance was derived from daily FCM, BW and BCS observations and summed from 5 to 30 DIM to obtain CEB. Net energy efficiency (NEE) was defined as FCM/NEI, whereas protein efficiency (PE) was defined as protein yield/CPI. The traits were analyzed with multiple-trait animal models that included fixed effects of lactation and herd-year-season of calving; random effects included animal, permanent environment, and error. NEE was genetically (0.92) and phenotypically (0.81) correlated with higher FCM. Likewise, genetic and phenotypic correlation estimates between PE and protein yield were strong at 0.96 and 0.80, respectively. BCS and BW were negatively correlated with NEE and PE (genetic correlation range = −0.42 to −0.54). Genetic correlation estimates of CEB with NEE and PE (−0.51 and −0.52, respectively) and of BCSCH with NEE and PE (0.64 and 0.73, respectively) were unfavorable. Genetic variation exists for feed efficiency, but measures of efficiency not unfavorably correlated with energy balance should be considered.

Key Words: feed efficiency, energy balance, genetic correlation

67 Genetic characterization of feed intake and utilization in performance tested beef bulls. D. H. Crews Jr.*[1], C. T. Pendley[1], G. E. Carstens[2], and E. D. M. Mendes[2], [1]*Colorado State University*, *Fort Collins,* [2]*Texas A&M University*, *College Station*.

Feed intake, growth, and pedigree data from the Midland Bull Test database were used to estimate parameters required for genetic evaluation of feed utilization traits. Length of the feeding period was 70 d, and test ADG was estimated as the slope of the regression of BW on test d. Records on DMI, ADG, and estimated mid-test BW raised to the power of 0.75 (MBW) from bulls (n = 2,346) and heifers (n = 221) representing 11 breeds (1,819 Angus) were included in a multiple trait animal model to estimate variance components using average information REML. The model for all traits included the fixed effects of contemporary group (n = 99) and a linear covariate for age at the start of test, and random animal genetic effects (n = 10,327). Heritability estimates for DMI, ADG, and MBW were 0.45 ± 0.09, 0.35 ± 0.07, and 0.54 ± 0.09, respectively, and genetic correlation estimates (SE <0.13) among the traits were positive, ranging from 0.38 to 0.60. Phenotypic residual feed intake (RFI) was defined as the difference between DMI and expected DMI from regression on ADG and MBW. A 4 trait model including phenotypic RFI failed to converge because of the linear dependence with DMI, ADG, and MBW. Breeding values for genetic RFI were then estimated as the difference between EBV for DMI and expected DMI derived using genetic regression. Genetic RFI has the property of independence from EBV for ADG and MBW whereas traditional EBV for phenotypic RFI could have genetic correlations with ADG and MBW. Genetic RFI EBV ranged from −0.54 to 0.56 kg/d (SD = 0.08). Phenotypic or genetic RFI contain no more information than DMI, ADG, and MBW phenotypes or EBV, respectively. Therefore, genetic evaluation of RFI is equivalent to evaluation of a function of the component traits.

Key Words: beef cattle, feed intake, genetic evaluation

68 Analysis of published genetic parameter estimates for feed utilization traits in beef cattle. C. T. Pendley*, R. M. Enns, and D. H. Crews Jr., *Colorado State University*, *Fort Collins.*

Increasing profitability of beef production through the reduction of inputs has been documented by an increasing number of published genetic parameter estimates for feed intake and utilization traits. The inclusion of input traits in genetic improvement programs requires knowledge of parameters for those traits, but an understanding of these parameters, especially for feed intake, is limited due to the cost of recording individual feed intake on cattle and reports are scarce. Fourteen sets of estimates involving more than 34,000 cattle and published between 1995 and 2010 were included in a meta-analysis of genetic parameters for feed intake and related traits. Papers were required to include individual feed intake, and computed SE for heritability and genetic correlation estimates. A generalized least squares approach was used to compute weighted mean heritability and genetic correlation estimates, as well as their weighted SE, where weights were a function of inverse SE. Weighted heritability estimates for feed conversion ratio (FCR), residual feed intake (RFI), ADG, metabolic body weight (MBW) and DMI were 0.28 ± 0.08, 0.38 ± 0.08, 0.32 ± 0.08, 0.39 ± 0.08, and 0.41 ± 0.07, respectively. Weighted genetic correlations of FCR with RFI, ADG, MBW, and DMI were 0.60 ± 0.11, −0.31 ± 0.14, 0.03 ± 0.15, and 0.35 ± 0.12, respectively. Weighted genetic correlations of RFI with ADG, MBW were near zero, but were 0.38 ± 0.09 with DMI. The phenotypic correlation of RFI with ADG and MBW are forced to zero by definition. The weighted genetic correlation of ADG with MBW was 0.45 ± 0.13. These weighted heritability and genetic correlation estimates may be more useful in the design of genetic improvement programs than relying on estimates from individual studies with low numbers of feed intake observations.

Key Words: feed intake, genetic parameters, meta-analysis

69 Heritability and genetic correlations of residual feed intake between Angus and Simmental bulls and resulting steer relatives. W. C. Rutherford*, L. A. Kriese-Anderson, and G. S. Hecht, *Auburn University*, *Auburn, AL*.

Objectives of this research are to observe breed differences for feed intake (FI) and trait differences of low, medium and high residual feed intake (RFI) bulls and steers, estimate h^2 in central tested bulls and steers and compare RFI in bulls and steers. Individual FI was measured on 1433 Angus, Simmental and composite Simmental-Angus bulls at the Auburn University Beef Evaluation Center (AUBEC) from 1977 to 2007. Bulls were consigned by producers and housed at the AUBEC a minimum of 70 d. Bulls were measured for weight and height biweekly or monthly depending on year. SC and ultrasound measurements for carcass traits

were taken at yearling age (330 to 400 d). FI and carcass trait data from 760 Angus and Simmental-composite steers were acquired courtesy of the American Simmental Association Carcass Merit Project. RFI was determined by regressing metabolic mid-weight and ADG on intake by year of test for bulls and by contemporary group (cg) for steers. High percentage Angus bulls consumed more DM per day, had higher FCR and RFI than purebred Angus, 50% Angus: 50% Simmental (50:50), high percentage Simmental and Simmental bulls. Angus steers consumed more DM per day had higher FCR and RFI than high percentage Angus and 50:50 steers. Heritability was estimated for RFI using a bivariate model and MTDFREML in bulls (0.42 ± 0.05) and in steers (0.20 ± 0.05). Fixed effects for bulls included year and breed percentage. Fixed effects for steers included cg and breed percentage. Covariates of final age, final wt or final frame score were used. Genetic correlations between steer and bull RFI ranged from −0.18 to 0.33 depending on covariate. Bulls and steers classified as low RFI consumed less DM per day and had more favorable FCR than medium and high RFI animals. Results indicate RFI is a moderately heritable trait and improvements for FI and FCR should be achievable when selection is made using RFI. However, selection of bulls based on their RFI in an attempt to sire more efficient steers may not be practical as the genetic relationships between steer RFI and bull RFI were variable and moderate.

Key Words: residual feed intake, heritability, genetic correlations

70 A region on BTA6 is associated with feed intake and gain in beef cattle. A. K. Sexten*[1,2], L. A. Kuehn[1], T. P. L. Smith[1], H. C. Freetly[1], W. M. Snelling[1], and A. K. Lindholm-Perry[1], [1]*USDA, ARS, U.S. Meat Animal Research Center*, *Clay Center, NE,* [2]*Oklahoma State University*, *Stillwater*.

Genetic selection for animals that require less feed while still achieving acceptable levels of production could result in substantial cost savings for cattle producers. The purpose of this study was to identify DNA markers with predictive merit for differences among cattle in feed intake and BW gain. Crossbred steers (n = 1,195) were fed a high-corn diet for 140 d and ADFI, residual feed intake (RFI), and ADG were measured. Steers were genotyped with the Illumina Bovine SNP50 BeadChip. An association analysis of these SNP on each trait was performed using MTDFREML, from which 14 SNP clustered in a 1.7Mb region at BTA6: 37.4 to 39.1 were identified as having significant association ($P \leq 0.009$) with one or more of the 3 traits. All statistical models included fixed effects of year and location; covariates of age, heterosis, and breed percentage; and a random polygenic effect. To develop markers with the maximum ability to discriminate favorable alleles and potentially identify the functional variation, 44 additional SNP, not present on the BeadChip, were identified in and around potential candidate genes in this chromosomal region. These new SNP were genotyped on the same animals and the statistical analysis program Mendel was used to test for association with feed intake and gain. Four markers located in a 90Kb region on BTA6 were significant for both ADFI and ADG. After correction for multiple testing, all markers remained significant for ADG ($P \leq 0.02$) and 2 markers were significant for ADFI ($P \leq 0.01$). These markers are located in a bovine gene that is homologous to a human gene that has been associated with skeletal frame size, thus providing a potential link between the observed bovine variation and growth-related traits of ADFI and ADG. Genetic markers predictive for feed intake and growth in this population of cattle may be useful for the identification and selection of animals that are more efficient, although potential impact of marker-assisted selection on all production traits will need to be assessed.

Key Words: beef cattle, genomics, feed efficiency

71 A neural network approach for association between a low-density whole genome SNP marker panel and residual feed intake and dry matter intake. H. Wang*[1], X. Liu[1], B. Woodward[2], S. Bauck[2], and R. Rekaya[1], [1]*University of Georgia*, *Athens,* [2]*Merial Limited*, *Duluth, GA*.

The predictive ability of a low-density SNP panel derived from the Illumina Bovine SNP50 and developed for marbling, backfat thickness, hot carcass weight, ribeye area, yearling weight, and heifer pregnancy rate was evaluated for residual feed intake (RFI) and dry matter intake (DMI). Data consisted of the genotypes of 1,032 Angus animals and their corresponding EPDs computed from actual individual weight and intake data. Missing genotypes were replaced with the most likely genotype. Linear regression (LR) and neural network (NN) approaches were implemented and compared. For LR, a cross validation procedure was adopted where the data was randomly divided into 5 groups with equal size. In each one of the 5 replicates, 80% of the data was used for training and the remaining 20% for validation. For the NN approach, randomly 2/3 and 1/3 of the data were used for training and validation, respectively. The process was replicated 5 times. A NN is an artificial system of massively interconnected neurons. The network architectures and the learning algorithm define the manner in which the neurons are related and structured. In this study, a feed-forward NN with one hidden layer was used. The parameters of the NN such as the number of neurons in the hidden layer, and learning rate were set heuristically. For RFI, the correlation between the observed and predicted breeding values for the validation data was 0.22 and 0.28 for the LR and NN, respectively. The correlation was 0.23 and 0.36 for DMI using LR and NN, respectively. These results indicate that, although the low-density SNP panel was developed for other traits, it still has some ability to predict RFI and DMI. The lower correlations observed for RFI could be due in part to the uncertainty on the trait of RFI compared with DMI that tends to be more accurately measured. The superiority of the NN approach could be due to its ability to intrinsically accommodate the non-linear relationship between variables.

Key Words: SNP, whole genome, feed efficiency

72 Effects of divergent selection for serum insulin-like growth factor-I concentration on mature weight and growth curves in Angus cattle. Q. Qin* and M. E. Davis, *The Ohio State University*, *Columbus*.

The purpose of this study was to investigate the effect of divergent selection for serum insulin-like growth factor-I (IGF-I) concentration on mature weight estimated using growth curve functions in Angus cattle. Multiple serum IGF-I measurements (d 28, d 42, d 56 of the 140-d postweaning period) from a total of 2,514 animals and weight records from birth to at least 3 yr of age from a total of 172 animals were collected from an ongoing divergent selection experiment involving IGF-I that was initiated in 1989. Four growth curve functions (Brody, Logistic, Gompertz, Von Bertalanffy) were used to estimate the parameters for mature weight (A) and maturing rate (k) using the NLIN procedure in SAS (SAS Inst. Inc., Cary, NC). The heritability estimates for serum IGF-I at different ages and growth curve parameters from each function were estimated using a multiple-trait, derivative-free, REML program. Genetic, environmental, and phenotypic correlations between IGF-I and growth curve parameters were also obtained. The direct heritability (h_d^2) estimates for serum IGF-I at d 28, 42, and 56 were 0.42, 0.42, and 0.33, respectively. The h_d^2 estimates for A from the 4 growth functions ranged from 0.72 to 1.00, whereas h_d^2 estimates for k ranged from 0.01 to 0.21. The genetic correlations between A and k within each growth curve function ranged from −0.57 to −0.49. The genetic correlations

between IGF-I (d 28, 42, and 56) and A within each growth curve function ranged from −0.46 to −0.01. Although serum IGF-I was negatively correlated with mature weight genetically, the phenotypic correlation between these 2 traits was moderate (0.47 to 0.59) due to a highly positive environmental correlation (1.00). The shapes of growth curves from the 4 functions were almost identical, as were the growth curves for the high and low IGF-I selection lines.

Key Words: Angus cattle, growth curve, insulin-like growth factor

73 Bayesian estimation of a genetic covariance matrix with different degrees of belief via a Generalized Inverted Wishart distribution. R. J. C. Cantet*, *Facultad de Agronomía, Universidad de Buenos Aires - CONICET*, *Buenos Aires, CABA, Argentina*.

When taking a Bayesian approach for estimating a genetic covariance matrix, animal breeders use an Inverted Wishart (IW) prior density. The advantage of this formulation is that the posterior distribution is in conjugate form, so that the sampling is from an updated IW. Also, the degrees of belief are the same for all genetic parameters, i.e., any (co)variance component is assumed to have the same amount of prior information. However, there are situations where this assumption does not hold. Take for example a model with grand-maternal effects. There is more prior information and information on the data for the additive direct variance than for the additive maternal variance and this, in turn, has more information than the additive grand-maternal variance. The objective of this research was to develop an algorithm for estimating a genetic covariance matrix with different degrees of belief for the (co) variance components. The method employs the Bartlett decomposition of a matrix to produce a conditional covariance matrix from the generalized inverted Wishart distribution (GIW). As a result, the algorithm consists of successive samplings from inverted chi-squared (or IW) densities for the additive variances, and from normals (or multivariate normals) for the additive covariances. It should be mentioned that the genetic parameters have to be ordered within the covariance matrix so that their degrees of belief decrease when going from the first row (or column) to the last. The algorithm was employed on a beef cattle data set, and the model fitted included additive direct, maternal and grand-maternal effects. The classic algorithm using the IW to sample from the conditional posterior of the additive covariance matrix was also fitted to the data. Convergence was faster for the GIW methods than for the IW, as samples of the (co)variance components were less dependent. In conclusion, the GIW algorithm allowed the use of different degrees of belief for the dispersion parameters and converged faster to the stationary distribution.

Key Words: generalized inverted Wishart, Bayesian estimation, additive covariance matrix

74 A simulation approach for analyzing genomic data using a package of specific FORTRAN 90 functions. P. Faux*[1,2] and N. Gengler[1,3], [1]*University of Liège - Gembloux Agro-Bio Tech*, *Gembloux, Belgium*, [2]*National Research Fund*, *Luxembourg, Luxembourg*, [3]*National Fund for Scientific Research*, *Brussels, Belgium*.

A panel of FORTRAN 90 functions was developed to simulate the distribution of bi-allelic (e.g., SNP) genetic markers along a defined genome and the distribution of their alleles in a given population. The simulation program used 3 parameters, those related to the species studied (number of autosomes, average length of autosomes, average number of crossovers by chromosome), the number of markers and those related to the studied population (pedigree). The simulation proceeds in 3 steps: a) random choice of marker positions and allelic frequencies for the minor allele of each marker (range: 0.05 to 0.475), b) simulation of genotypes of the ancestors in the pedigree based on randomly chosen allelic frequencies and c) planned mating of the ancestors according to the pedigree and according to the average crossover rate as a genetic recombination parameter. The simulation returns a fully-genotyped population. This method is flexible because it can be applied to a wide range of cases (not restricted to a single species) and the FORTRAN functions can be extended and used to simulate phenotypes. It is also realistic, because it performs mating plans and selection of animals based on real pedigrees. Development of this simulation panel was the first step in research around advanced methods to compute and invert genomic relationship matrices.

Key Words: genomic prediction, SNP simulation

ASAS-EAAP Global Issues Symposium: Contemporary and Emerging Issues and International Animal Agriculture Joint Symposium: Global Livestock Production to 2050: Challenges and Opportunities

75 Perspectives for livestock production in developing countries – changes in production systems needed to meet projected demand. R. D. Sainz*[1], G. B. Martha, Jr.[2,3], and L. G. Barioni[4], [1]*University of California*, *Davis*, [2]*Embrapa Cerrados/Embrapa Strategic Studies and Training*, *Brasília-DF, Brazil*, [3]*Fellow, National Research Council*, *Brazil*, [4]*Embrapa Agricultural Informatics*, *Campinas-SP, Brazil*.

According to the medium growth projections of the United Nations, the human population should reach 9.15 billion by 2050, an increase of 33% over the 6.91 billion today. This increase will take place largely in developing countries. Additionally, developing countries are projected to experience a steady increase in per capita income, so that demand for food should increase by close to 70%, and for animal products by perhaps 100%. This scenario raises concerns about use of scarce resources, mainly land and water, as well as other environmental, social and economic impacts. Moreover, these changes will be concentrated in developing regions, and the technological advances in tropical agriculture required to achieve a sustainable path toward food security over the next decades must take all of these factors into account. In particular, opportunities for expanding agricultural frontiers are limited. Clearly, a 100% increase in meat and milk production on the same or only slightly greater crop and pasture land areas will require substantial improvements in productivity. This paper qualitatively and quantitatively describes several technologies and production systems that show promise toward meeting the expected demand. These include genetically improved crops, pastures and animals, integrated crop-livestock-forestry systems, increased animal feeding (particularly with crop and industrial by-products), improved pasture management, and alternative production systems (such as improved aquaculture systems). Development and implementation of these technologies and systems will require major investments by the private and public sectors. A revitalization of agricultural R&D investments to sustain productivity growth over the long run and a comprehensive program of technology transfer are needed if economic, social and environmental objectives are to be met.

76 A European perspective on the challenges for livestock farming to achieve a sustainable contribution to food security and a reduced impact on the environment. P. Herpin*[1], R. Duijghuisen[2], J. Oldham[3], P. Vriesekoop[2], and J. Williams[1], [1]*INRA*, *France*, [2]*Wageningen UR*, *the Netherlands*, [3]*Scottish Agricultural College*, *Scotland*.

World population forecasts are 9.2 billion by 2050. The daily intake of animal products will continue to rise as economies develop. Over 56% of people in the European Union live in rural areas where the livestock sector underpins community cohesion and employment. Its farm gate production value was 152 billion € in 2008, but its contribution to the European economy is greater as it supplies other sectors that generate considerable added value. Sustaining and even expanding the animal-farming sector to meet the demands for food, to reduce the rural exodus, is a priority. The European challenge is complex because we must not only increase efficiency and effectiveness to face very strong global competition but also accommodate major demands for a positive environmental impact, improved animal health and welfare and adapt to possible future changes in the Common Agricultural Policy. Climate change may also alter production capacity differentially across Europe, accelerate the emergence of new animal diseases and menace animal and human health. Both adaptation and mitigation strategies will recognize these challenges and opportunities. Past research reinforced the sector's competitiveness. But we need a 'vision for tomorrow' to face these new grand challenges that will re-design more sustainable, integrated, resource efficient and environmentally acceptable production systems. This will take new knowledge from research, with efficient innovation, implementation, and shifts in stakeholder behavior e.g., exploiting new genomic tools for novel multi-trait selection of robust and healthy animals. Renewed attention to the exploitation of feed resources, to improving reproductive efficiency, to more integrated approaches to disease control and animal welfare, and to generating animal products beneficial to human health is also needed. This research agenda needs to address local issues in a global context, embracing all disciplines and stakeholders. Research teams must question past practices, use open thinking to encompass these new dimensions, dialog with other disciplines and network in a constructive manner with society at large.

77 Sustainability of livestock production globally. H. Steinfeld*, *UN Food and Agriculture Organization*, *Rome, Italy*.

The livestock sector is contributing to the globally increasing pressure on ecosystems and natural resources: land, water and biodiversity. At the same time, the sector is increasingly facing natural resource constraints and growing competition for resources. Awareness is also increasing of the interactions between livestock and climate change, with the livestock sector both contributing to it and suffering from its impacts. Conversely, it is also being recognized that the sector can play a key role in mitigating climate change through improved technologies. Governments and institutions need to develop and enact appropriate policies that focus on and account for livestock-environment interactions. Continued growth in livestock production will otherwise exert enormous pressures on the health of ecosystem, biodiversity, land and forest resources, and water quality, and will contribute substantially to global warming. A key policy focus should be on correcting market distortions and policy failures that encourage environmental degradation, such as subsidies that directly or indirectly promote overgrazing, land degradation, deforestation, over-use of water, or greenhouse gas emissions. Market-based policies should cause producers to internalize the costs of environmental damages caused by livestock production. Environmental damage associated with open-access common-property resources can be addressed by clarifying property rights and promoting mechanisms for cooperation. The promotion of technologies that improve land and feed efficiency can mitigate the negative effects of livestock production on biodiversity, ecosystems, and global warming. Technologies that increase livestock efficiency include improved genetics, improved grazing land management, improved herd health management, and silvopastoralism. Payments for environmental services can be an effective means to promote better environmental outcomes. The livestock sector has an enormous potential to contribute to climate change mitigation. Realizing the potential will require new and extensive initiatives at national and international levels, including the promotion of research and development on new mitigation technologies; and effective and enhanced means for financing.

Extension Education 1

78 Multi-state Beef Reproduction Task Force provides science based recommendations for the application of reproductive technologies. S. K. Johnson*[1], R. N. Funston[2], J. B. Hall[3], D. J. Kesler[4], J. W. Lauderdale[5], G. C. Lamb[6], D. J. Patterson[7], G. A. Perry[8], and D. R. Strohbehn[9], [1]*Kansas State University*, [2]*University of Nebraska*, [3]*University of Idaho*, [4]*University of Illinois*, [5]*Michigan State University*, [6]*University of Florida*, [7]*University of Missouri*, [8]*South Dakota State University*, [9]*Iowa State University*.

Beef extension personnel met in 2000 to determine how best to communicate to beef producers the latest information related to reproductive technologies. Research on estrous cycle control in cattle had expanded to more precise methods that included treatment with progestins, manipulation of follicular waves, and control of the lifespan of the corpus luteum. The rapid development of new protocols to synchronize estrus and ovulation and their associated acronyms created confusion. The Beef Reproductive Task Force was formed to coordinate efforts to identify effective breeding management protocols and to provide leadership for education. Based on research data and field experience, a short list of recommend protocols for synchronization of estrus and ovulation was developed in cooperation with representatives from semen providers, veterinarians and the animal health industry. These protocols are presented uniformly in sire catalogs from all major semen providers. Protocol updates occur annually to incorporate appropriate research findings. In cooperation with the Iowa Beef Center, the Estrus Synch Planner software program now reflects the same recommendations. Since 2002 the Beef Reproduction Task Force has hosted 9 educational workshops in key cow-calf states representing 66% of US beef cows; targeted were producers, AI technicians, veterinarians, allied industry and academia. A national media sponsor has provided online coverage of the last 2 meetings. At the most recent conference, 77% of attendees indicated that information received at the conference would probably or definitely increase the profitability of their operation. When asked what changes they would make in how they applied reproductive technologies, 55% provided a response with 15% responding more use of fixed-timed AI, 13% more use of AI and/or synchronization, and 40% would change something about how they applied the technology such as specific protocols or management changes.

Key Words: estrous synchronization, fixed-timed AI, beef cattle

79 Fundamentals of beef reproduction and management: Focus on estrus synchronization. A new web-based curriculum. D. J. Patterson*[1], R. D. Geisert[1], D. C. Busch[2], N. R. Leitman[3], S. E. Poock[1], J. L. Parcell[1], and M. F. Smith[1], [1]*University of Missouri*, *Columbia,* [2]*KABA Select Sires, Inc.*, *Louisville, KY,* [3]*Boehringer Ingelheim Vetmedica Inc.*, *St. Joseph, MO*.

Reproduction is the major factor impacting profitability in a cow-calf operation. The largest cause of reproductive loss in beef herds is that cows fail to become pregnant during the breeding season. Heifers and cows fail to become pregnant because they do not show estrus or fail to conceive after showing estrus. Estrus synchronization protocols have been developed that increase the proportion of females that conceive early in the breeding season and facilitate the use of AI. Estrus synchronization and AI create the opportunity to add value to a beef cattle enterprise through use of high accuracy sires and enhanced reproductive management. A new web-based curriculum is available for beef producers, animal science instructors, veterinarians, allied industry and students entitled Fundamentals of Beef Reproduction and Management: Focus on Estrus Synchronization. The curriculum includes 3 courses with the following topics. Course 1 provides an overview of physiological principles that underlie estrus synchronization, and a review of commercially available estrus synchronization products. Course 2 reviews estrus synchronization protocols recommended for beef heifers and cows. Course 3 reviews management considerations for implementing an estrus synchronization program and a description of the impact of estrus synchronization on reproductive management. Each module includes assessment questions to evaluate the student's comprehension of the information. The focus of this Extension education program draws on the fundamental basis upon which extension and the Land Grant System were founded: The use and application of what we know to create knowledge. This curriculum will enable participants to effectively implement reproductive strategies into practice. The curriculum is available through the University of Missouri Division of Animal Sciences Web site at http://animalsciences.missouri.edu/, and the NCBA Cattle Learning Center.

This project was supported by National Research Initiative Competitive Grant no. 2005-55203-15750 and 2007-55618-18238 from the USDA Cooperative State Research, Education, and Extension Service.

80 Transferring reproductive technologies to the field: Fixed-time AI and high accuracy sires. D. J. Patterson*, D. A. Mallory, J. L. Parcell, S. E. Poock, and M. F. Smith, *University of Missouri*.

USDA-NRI integrated projects require a combination of research, education and extension and are expected to generate new knowledge, coincident with the application of existing knowledge. Project themes are required to be outcome oriented, stakeholder driven and problem focused. Our goal has been to foster the adoption of reproductive technologies focused on expanded use of fixed-time artificial insemination, and coincident with progress in the development of new and more effective methods to synchronize estrus and ovulation in beef cattle. Missouri's Show-Me-Select Replacement Heifer Program provides the infrastructure for effective implementation of new reproductive technologies and economic feedback regarding their use. By-products of adoption of reproductive technologies in beef cattle include enhanced genetic merit of heifers and steers, and improvements in whole herd reproductive management. Beef producers interested in implementing or expanding an AI program are encouraged to identify high accuracy sires for use in their AI programs. The Missouri Show-Me-Select Replacement Heifer Program recently created a Tier 2 classification that distinguishes heifers from high accuracy sires. Economic data collected from the program will be used to value heifers based on genetic merit, and economic indexes for heifers will be determined from steer mates based on feedlot performance and carcass merit. Organized on farm demonstrations facilitated the transfer of technology related to fixed-time AI to 73 herds in Missouri involving 7028 cows. In addition, the Division of Animal Science's Miller Internship in Reproductive Management has provided internship opportunities for 140 students that involved breeding programs in 12 states and over 175,000 cows and heifers. These efforts have lead to the successful integration of research, education and extension programming and are collectively impacting reproductive management in Missouri's beef herds.

This project was supported by National Research Initiative Competitive Grant no. 2005-55203-15750 and 2007-55618-18238 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: technology transfer, beef, AI

81 Evaluation of attitudes, knowledge gained and anticipated behaviors of extension clientele completing food defense training conducted regionally in Missouri. R. L. Weaber*, C. L. Lorenzen, M. K. Hendrickson, A. D. Clarke, M. C. Shannon, R. M. Torres, and K. L. Savage-Clarke, *University of Missouri*, *Columbia*.

Food defense is the prevention of intentional contamination at any point during the food production/processing chain. To increase awareness of food defense government directives and industry initiatives among food producers and processers, a work book curriculum was developed and a series of half-day workshops were conducted in 5 regions of Missouri. In addition to providing basic information about the importance of food defense as a mechanism to help ensure the safety and security of the US food supply, the workshop included training on risk assessment, countermeasure development, construction and implementation of a food defense and a response plan. Workshop participants (n = 81) were surveyed to evaluate the quality of the curriculum, pre- and post-training attitudes, knowledge gain and anticipated behaviors. Participants included livestock producers (15%), crop producers (4%), food processors (22%), producers targeting production to local food systems (35%), and others (25%) that included animal nutritionists, and inspectors/regulatory personnel. Two-thirds of respondents (n = 59) indicated their operation employed only family members or less than 6 individuals. Seven percent of operations had > 100 employees. Prior to the workshops, 22% of respondents (n = 63) were not familiar with the term ′food defense′ while 42% had either written or were familiar with the basics of a food defense plan. 83% of respondents (n = 74) indicated the information was valuable to their operation. A 6-point Likert scale was used to evaluate knowledge gain. More than 90% of participants indicated with scores of 4 or higher (4 = somewhat agree, 5 = agree, 6 = strongly agree) that they could assess risks, describe basic steps, develop a food defense and response plan. Perimeter security was most often cited (19%) as a vulnerability followed by limiting access to internal areas/processes (14%). Following the workshop and development of their own food defense plan, 42% of the participants had an increased awareness of food defense and 50% planned to either implement or maintain their plan.

Key Words: food defense, curriculum, extension

82 Documenting a 60-year trend in improved efficiency for the United States swine industry. M. S. Carlson*, J. A. Lory, R. E. Massey, B. Young, J. Zulovich, S. Edwards, R. Plain, and T. J. Safranski, *University of Missouri*, *Columbia*.

Swine production practices have evolved significantly over the past 60 years. In the mid 1940s, all phases of swine production typically occurred outside on dirt lots and pasture; by 2006, 94% of US commercial production had been moved into buildings. The objective of this project was to use statistical data from state and federal agricultural agencies and a literature review to assess the impact of these changes on the cost of production, herd health, feed efficiency and environmental efficiency for grow-finish pigs. Since 1945, the quantity of pork produced in the United States more than doubled from less than 10 to more than 23 billion pounds annually. Cost of production ($/cwt) has decreased with decreased feed costs more than compensating for increased housing and energy costs. Pig mortality decreased and some parasites such as lungworm (*Metastrongylus* spp.) and kidneyworm (*Stephanurus dentatus*), that once infected 55–95% of pigs, are now rarely seen. Daily gain (kg/d) and feed efficiency (gain to feed) improved from 0.7 to 0.89 and 3.8 to 2.6, respectively, over the past 60 years. Improved animal efficiency combined with increased crop production per hectare increased the pork produced per hectare by more than 200% over the period. Through better diet formulation, feed preparation, genetic selection and management, phosphorus excreted by pigs fed to recommended levels decreased over 50% per kg of pork produced. In summary, current production methods have increased production while reducing the land required for pork production.

Key Words: production efficiency, swine industry, herd health

84 A survey of the economic, environmental, public policy and production issues facing animal agriculture in Louisiana. T. A. Lavergne*, S. M. DeRouen, and G. M. Hay, *LSU AgCenter*.

Beef, dairy, and poultry producers/growers, personnel in allied industries, state agencies, and LSU AgCenter, as well as other leaders in these industries were surveyed on various issues affecting animal agriculture in Louisiana to determine their opinions on these issues. Respondents were asked to rate 10 items within 4 categories of issues: economic, environmental, public policy, and production issues. The items were rated from 5 (extremely important) to 1 (not important). Of the 230 respondents, 85 worked in the beef industry, 71 worked in the dairy industry, and 74 worked in the poultry industry. For economic issues, the overall average ratings ranged from 4.2 to 4.3 for all groups surveyed. “Rising input costs” received the highest rating for economic issues. For environmental issues, average ratings ranged from 3.3 to 4.0 for all groups surveyed. “Public perception of the environmental effects of animal agriculture” received the highest rating for environmental issues. For public policy issues, the overall average ratings ranged from 3.0 to 4.0 for all groups surveyed. “Consumer confidence in food and animal product safety” received the highest rating for public policy issues. For production issues, the overall average ratings ranged from 3.7 to 4.0 for all groups surveyed. “Improving production efficiency” received the highest rating for production issues. Respondents rated most items as moderately, substantially, or extremely important. Economic issues received the most substantially important and higher ratings. The responses indicate that economic, environmental, public policy, and production issues are important to these respondents involved in Louisiana’s animal industries.

Key Words: animal agriculture, environmental issues, economic issues

85 The value of poultry litter to crop producers in South Georgia. C. S. Dunkley* and D. L. Cunningham, *University Of Georgia*.

A survey was conducted to assess the value of poultry litter to crop producers in South Georgia. Respondents were asked 23 questions pertaining to poultry litter use and their farming operations. The questions included; the amount of litter they applied each year, the cost of poultry litter, the cost of inorganic fertilizer, the amount of land they applied litter and inorganic fertilizer to and the length of time they have been using poultry litter. Of the 165 respondents 75.49% of them grew row crops, specifically peanuts, pecans, cotton and corn. The remaining respondents grew forage crops and vegetable crops. When asked whether or not they used poultry litter, a total 50.3% of the respondents stated that they used poultry litter while 49.7% of them did not use it. Of the total respondents who used poultry litter 75.64% of them used poultry litter and inorganic fertilizers as nutrient sources while 24.26% of them used only litter as their nutrient source. When asked about the amount of soil amendment they added each year, about a half of the respondents applied up to 500 lbs of inorganic fertilizer per acre while about 93% of the respondents who used litter applied 2 tons per acre. The amount of money the growers paid per ton for litter ranged from $10 to $55 compared with $500 to $1200 per ton for inorganic fertilizer. Approximately

11% of litter users traveled over 100 miles to obtain the litter compared with 0.78% of inorganic fertilizer users who had to travel a similar distance. More inorganic fertilizer users (14.63%) applied more than once per year when compared with litter users (5.08%). The responses from this survey indicates that crop producers in South Georgia have found poultry litter to be of substantial value for their operations and will travel far distances to acquire the product.

Key Words: poultry, litter use, litter value

86 Testing foam depopulation equipment in the field. D. P. Hougentogler*, E. R. Benson, R. L. Alphin, and C. A. Kinney, *University of Delaware*, *Newark*.

Foam depopulation is currently one of the available options for mass emergency depopulation of floor reared poultry. Conditions including water, foam concentrate, and equipment can change the quality of the foam. Foam quality impacts depopulation efficacy. A method for evaluating foam quality in the field was developed and tested. Foam expansion rate, flowability, and drawdown time are key characteristics to making good foam. These can be evaluated using 2 simple tests. To test foam expansion in the field, a known amount of water and container of known size to generate foam into is required. Expansion rate will vary depending on the foam generation equipment used, but should follow USDA and AVMA standards for foam depopulation. Draw down time and flowability can be tested using flow over time. The field test developed to evaluate foam using a funnel and graduated cylinder measures the amount of foam flow over a given time period. This method uses a 1 L funnel with a 6.3 mm (1/4 inch) outlet, a stopper, and a 2 to 3 L graduated cylinder. Once the funnel is filled, unplug the stopper and measure the time it takes for 99% of the foam to pass through the discharge hole. A range of good flowability would allow 0.3 L to 0.9 L of foam to flow within 60 and 120 s. Foam flowability was used to develop a simple go-no go graphic that can be used in the field to evaluate foam quality. The impact of water quality was also tested using this procedure. While testing salt, hard, and brackish water, with this method it showed that they did not inhibit the production of good quality foam.

Key Words: foam, mass emergency depopulation, poultry

87 Assessing the potential economic value of an automated temperature monitoring system using stochastic simulation. J. M. Bewley*[1,2] and M. M. Schutz[2], [1]*University of Kentucky*, *Lexington,* [2]*Purdue University*, *West Lafayette, IN*.

Numerous automated temperature monitoring systems (ATMS) are marketed to dairy producers. However, the economic benefits of ATMS have not been studied. The primary objective of this research was to identify factors that influence the profitability of investment in an ATMS. An expert opinion survey was conducted to provide estimates of potential improvements arising from adoption of this technology. Experts ranked benefits of ATMS as follows: ability to monitor heat stress, mastitis detection, estrus detection, metritis detection, pneumonia and respiratory disease detection, improved animal well-being and pregnancy detection. A stochastic simulation model of a dairy farm was utilized to perform a Net Present Value (NPV) analysis. This model was developed to evaluate investments in Precision Dairy Farming technologies and was constructed to embody the biological and economic complexities of a dairy farm system within a partial budgeting framework. The @Risk add-in (Palisade Corp., Ithaca, NY) for Microsoft Excel was utilized to account for the stochastic nature of key variables by Monte Carlo simulation. The model comprised a series of modules, which synergistically provide the required inputs for profitability analysis. Benefits of ATMS were estimated by assessing the impact of its use on estrus, mastitis, metritis, and respiratory disease detection rates. In addition, the expert opinion survey results were used to calculate the associated reductions in the negative effects of disease for mastitis, metritis, and respiratory disease. Using model assumptions, the mean NPV of investing in this ATMS was $404,333 ± 208, 474 ranging from -$217,892 to $737,335. The NPV was greater than 0 in 930 of 1000 iterations. Stochastic price variables having the most influence on NPV were milk price, corn price, slaughter cow price, soybean price, and replacement cow price. More importantly, the percentage of estrus events identified using the technology had a considerable impact on investment profitability. Investment in an ATMS may be profitable, but results will be herd-specific.

Key Words: temperature monitoring, investment analysis, precision dairy farming

83 Missouri Goat Camp: Collaborative effort to enhance successful goat production projects by Missouri youth. E. L. Walker*[1], B. Fay[2], H. Swartz[3], and C. Clifford-Rathert[3], [1]*Missouri State University*, *Springfield,* [2]*Univesity of Missouri*, *Greenfield,* [3]*Lincoln University*, *Jefferson City, MO.*

Goat production continues to be the fastest growing segment of Missouri livestock production, and is becoming popular for Missouri 4-H and FFA members. Meat goat participants in Missouri 4-H has increased from 457 in 2007 to 748 in 2008. Current numbers show a total of 1171 members involved in 4-H goat projects. Budget cuts are being proposed for post-secondary education which would severely limit educational programs for youth and adults. As a way to off-set costs and enhance development of goat production, goat camps (GC) have been designed and established jointly by Missouri State University (MSU), University of Missouri Extension/4-H (UME), and Lincoln University (LU). Currently camps are held in Jefferson City at the LU Carver Farm and Springfield at the Darr Agricultural Center. Topics covered include ethics, showmanship skills, selection of goats, quality control, marketing, diseases, parasite management, and reproduction. Promoting more youth-oriented programs like these will ensure quality producers will abound in future years. All topics and instruction culminates with 4-H and FFA youth receiving certification for goat quality assurance, at the same time the adults are also being educated as an added benefit. Participants of the most recent joint camp, the 2010 GC-Springfield, were surveyed resulting in 119 respondents. The camp lasted approximately 6 h with breaks and lunch provided by the organizers. The structure consisted of 7 instructional, 25 min round robin sessions. Survey respondents included 71 youth and 48 adults. Speakers were rated at an overall mean of 1.05 ± 0.18 (1 = educator seemed prepared, 2 = somewhat prepared, 3 = not prepared) and a 2.78 ± 0.61 regarding length of activities (1 = too short, 2 = too long, 3 = just right) and all respondents reported they would recommend the clinic to others. In 2009, 189 participants attended 2 camps hosted by LU consisting of both youth and adults. As more people become interested in goat production and budgets decline, it will become necessary for more joint extension and service activities to occur between major educational entities.

Key Words: goat, youth, Missouri

Food Safety Symposium: Potential Impact of Reduced Antibiotic Use and the Roles of Prebiotics, Probiotics, and Other Alternatives in Antibiotic-Free Broiler Production

89 Probiotics and direct-fed microbials: Practical applications and real-world needs. J. T. Barton*, *The Poultry Federation Lab*.

It seems likely that antibiotic treatments of food animals will end, despite the strong support of antibiotic use by agricultural advocates as well as scientific evidence that the use of antibiotics in food animals is not the major cause of pathogen resistance in the human population. If the post-antibiotic farm comes to pass, farmers will still depend on veterinarians and scientists to deliver effective therapies that relieve animal suffering and protect against financial losses. Probiotics, direct-fed microbials, and perhaps other types of beneficial bacteria appear to be the most likely successors to the functional role of antibiotics in meat and poultry farming. The perception of farmers regarding beneficial bacterial applications in food animal husbandry has evolved from skepticism to curiosity to guarded acknowledgment of positive attributes. These views have changed due, in part, to publications in scientific journals and well as hands-on experience applying beneficial bacterial products. It is certain that the natural diminution of ineffective, yogurt-sourced *Lactobacillus* sp. and the development of species-targeted probiotics and direct-fed microbials have caused a major shift in the use of beneficial bacteria in food animal farming. Future advancement in beneficial bacteria application will depend upon increased knowledge of their mechanism(s) of action as well a continued discovery of novel microbial species for development.

Key Words: probiotic, direct-fed microbial, beneficial bacteria

90 Probiotics: Current limitations and future potential in commercial poultry. B. M. Hargis*[1], G. Tellez[1], R. E. Wolfenden[1], S. Shivaramaiah[1], A. D. Wolfenden[1], S. E. Higgins[2], and T. E. Porter[2], [1]*University of Arkansas*, *Fayetteville*, [2]*University of Maryland*, *College Park*.

During the last 2 decades, we and many colleagues have worked toward development of commercially applicable probiotics (DFM) that could consistently replace or ameliorate removal of antibiotic growth promoters from poultry rations. There have been many educational failures along with some striking successes during this odyssey. In several published manuscripts, we have shown that a highly selected group of compatible lactic acid bacteria could reduce enteric *Salmonella* in laboratory and commercial field studies, improve performance in large broiler and turkey field trials, effectively treat idiopathic diarrhea in commercial turkeys, and prevent necrotic enteritis in challenge studies. The effects of treating *Salmonella*-infected broilers is observed very quickly, between 12 and 24 h, leaving the conventional explanation for mechanism of action, that of competitive exclusion, in doubt. Very recently we have observed very rapid changes in host gene expression through microarray analysis that could explain the rapidity of these observations suggesting that elicitation of a host innate immune response may be partially responsible for the beneficial action of this probiotic. Because lactic acid bacteria are not stable or thermotolerant, we have also worked toward selection of effective spore-forming *Bacillus*-based probiotics using intense in vitro selection criteria, and ultimately, in vivo testing. During this more recent experience, we have concluded that in vitro biological activity of *Bacillus* is not highly predictive of isolates with potential to improve performance or to reduce necrotic enteritis or *Salmonella* infections in vivo. Interestingly, a select subset of *Bacillus* isolates appear to be capable of complete spore-to-spore life cycle completion within the chicken gut, which may be important for selection. Our studies indicate that for effective administration of useful spore-formers in feed, very high concentrations of spores are required (~1×10^6 cfu/g finished feed). Therefore, selection of highly efficient thermotolerant spore-formers is necessary for cost-effective development of feed-additive probiotics (DFM).

Key Words: *Bacillus*, DFM, probiotic

1087 Alternatives to antibiotic treatment for necrotic enteritis. C. L. Hofacre*[1], M. Lee[1], and G. Mathis[2], [1]*The University of Georgia*, *Athens*, [2]*Southern Poultry Research*, *Athens, GA*.

Necrotic enteritis (NE) is the reason poultry producers use growth promoting antibiotics. Our research has shown that it is the subclinical form of NE that affects the birds' small intestines to result in the reduced growth rate and poorer feed efficiency that is seen when antibiotics are not used. The disease-causing agent is the obligate anaerobic bacteria *Clostridium perfringens* and more specifically a strain that produces an exotoxin. These are ubiquitous bacteria; therefore, just presence of *C. perfringens* in the birds' intestines is not enough to cause disease either clinical or subclinical in most cases. There must also be a change in the bacterial normal flora of especially the small intestine to allow the *C. perfringens* to grow and elaborate the toxin. In the past, we have used antibiotics to keep the flora in balance and the *C. perfringens* in check. One of the major causes for shifts in the normal intestinal flora is coccidian infection of the duodenum, jejunum and ileum. When the birds' intestine responds by producing mucus, this provides the mucolytic bacteria, *C. perfringens*, a ready nutrient source which results in rapid growth and elaboration of the toxin(s). This results in further intestinal damage and production of additional mucus and a cycle begins that would be prevented by antibiotics. The presence of the ubiquitous bacteria *C. perfringens* in the birds' intestines does not necessarily mean N.E. will occur. As long as the normal flora of the small intestine stays in balance, the *C. perfringens* level will stay low; however if the intestinal epithelium becomes damaged or the birds experience an extreme level of stress, *C. perfringens* can grow rapidly and produce its toxin resulting in most often slower growth, lower body weights and poorer utilization of feed. In the extreme form of N.E., we see necrosis of the intestinal epithelium and death. Managing the normal intestinal flora of the bird can be a highly effective method of preventing both clinical and subclinical necrotic enteritis.

Key Words: necrotic enteritis, antibiotics

88 Historical perspective: Prebiotics, probiotics, and other alternatives to antibiotics. M. E. Hume*, *USDA, ARS, Food and Feed Safety Research Unit*, *College Station, TX*.

European Union food animal producers have moved away from the use of selected antibiotic growth promoters. Some poultry producers in the United States have opted to reduce or remove antibiotic growth promoters from their production schedules. Additionally, there is increasing public sentiment in the US toward the complete removal in this country of antibiotic growth promoters from poultry and other food animal production. The symposium will examine a history of prebiotic,

probiotic, and other antibiotic alternatives; current needs and expectations of antibiotic replacements; current limitations of probiotic and future potential; current experiences with antibiotic-free poultry production; and bacteriocins as potential replacements for antibiotic growth promoters. The concept of a prebiotic was launched in 1995 by Glenn Gibson and Marcel Roberfroid. An updated definition of a prebiotic was proposed in 2007 by Marcel Roberfroid as "a selectively fermented ingredient that allows specific changes, both in the composition and/or activity in the gastrointestinal microflora, that confers benefits upon the host well-being and health." The notion of a probiotic began at the end of the nineteenth and early twentieth century with the observations of Eli Metchnikoff, who put forth the idea that aging was affected by certain putrefying toxins created by microbes in the large intestine. He went on to state that villagers in eastern Europe who consumed milk fermented by lactic-acid bacteria characteristically lived long lives. A probiotic as redefined in 1989 by Roy Fuller is "A live microbial feed supplement which beneficially affects the host animal by improving its intestinal microbial balance." Fuller stressed the need for the probiotic organism to be viable. Both concepts recognize the importance of developing, supporting, supplementing, and maintaining a healthy digestive microflora. The 2 concepts have been the focus of considerable research and cover a range of materials and formulations in the livestock and human arenas.

Key Words: prebiotic, probiotic, antibiotic growth promoter

92 Effects of microclimate and pasture characteristics on temporal/spatial distribution of beef cows in Midwestern pastures. D. A. Bear*, J. R. Russell, and D. G. Morrical, *Iowa State University*, *Ames, IA*.

Pastures located on southern Iowa cow/calf farms, from 8 to 125 ha in size, were used to evaluate the effects of microclimate, shade, botanical composition, and other pasture characteristics influencing the temporal/spatial distribution of cattle within and outside streamside zones of pastures. Cows were Angus and Angus-cross on 4 of the farms, and Mexican Corriente on the remaining farm. During spring, summer, and fall of 2007–2009, 2 to 3 cows on each farm were fitted with Global Positioning Systems (GPS) collars and used to record location within a pasture at 10 min intervals for periods of 5 to 14 d. One hundred 39 data sets were obtained throughout the 2007–2009 grazing seasons. Data loggers recorded microclimate variables at 10 min intervals. Water sources and fence lines were referenced on a geospatial map and used to establish zones within the pastures; in the stream or pond (water source), closer or further than 30.5 m (Uplands) from the water source. Farm and seasonal effects on cow distribution in pastures were analyzed using the GLM procedure of SAS using years as replicates. LOGISTIC procedure of SAS tested microclimate variables effects on the probability of cattle being in or within 30.5 m of the water. Mean proportions of observations when cattle were in the water source differed ($P < 0.0001$) between seasons. Mean proportion of cattle observations within the streamside zone (defined as being in the water source or within 30.5 m of the water source) differed ($P < 0.0001$) between farms. The proportion of time cattle were within the streamside zone increased with decreasing pasture size ($r^2 = 0.40, 0.55, 0.59$) and increasing the proportion of streamside zone within a pasture ($r^2 = 0.40, 0.64, 0.39$) for the spring, summer, and fall seasons, respectively. Proc LOGISTIC determined the probability of cattle located in the streamside zone increased with increasing ambient temperatures. Implementation of grazing management practices for the protection of pasture streams will likely be most effective on small and/or narrow pastures in which cattle have less opportunity to locate in upland locations.

Key Words: GPS, distribution, water quality

93 Preference for diverse pastures by sheep in response to intraruminal administrations of tannins, saponins, and alkaloids. J. J. Villalba*[1], F. D. Provenza[1], A. K. Clemensen[1], R. Larsen[2], and J. Juhnke[1], [1]*Utah State University*, *Logan,* [2]*University of California*, *Templeton*.

Plant secondary compounds (PSC) are increasingly recognized as important in animal health, welfare and nutrition. We explored how sheep modify their foraging behavior in pastures with different PSC when challenged with a single PSC. Six pairs of lambs received intraruminal administration of a PSC (Treatment) in 3 successive periods (1- Condensed tannins, 2-Saponins, or 3-Ergotamine) of 5 d each. Six other pairs of lambs received just the vehicle (Control). The design was a split-plot with pairs of lambs nested within group (Treatment, Control). Day and period were the repeated measures. Pairs of lambs were allowed to graze a choice of 1) *Lotus corniculatus* (birdsfoot trefoil - BFT), 2) *Medicago sativa* (alfalfa - AA), 3) *Festuca arundinacea* (endophyte-infected tall fescue - TF) with high concentration of tannins, saponins, and alkaloids, respectively, and 4) *Dactylis glomerata* (orchardgrass - OG). Lambs were observed at 1 min. intervals and their behavior recorded (scans). Control lambs manifested a strong preference for AA (75–85% of all scans; $P < 0.0001$) throughout all testing periods. In contrast, lambs treated with tannins had more scans than Controls on BFT ($P = 0.002$) and TF ($P = 0.004$). Lambs that received saponins had more scans than Controls on TF ($P = 0.01$), and animals treated with ergotamine had more scans than Controls on BFT ($P = 0.03$). Lambs showed the lowest proportion of scans on AA after treatment with saponin ($P \leq 0.09$) and on TF after infusions of ergotamine ($P \leq 0.009$). Lambs infused with PSC thus utilized forage species more evenly than did Controls, and they avoided plants (AA, TF) containing PSC (saponin, ergotamine) that matched those delivered into their rumens. Treatment lambs also diluted the effects of the PSC by increasing preference for OG, and selectively increased preference for certain PSC-containing forages such as TF and BFT. Animals offered a diversity of plants with multiple PSC may minimize the negative impacts of PSC in their bodies through changes in their foraging behavior.

Key Words: forage diversity, foraging, plant secondary compounds

94 Grazing behavior of cattle and sheep grazing alone or together on grass swards differing in plant species diversity. H. M. Cuchillo* and J. Isselstein, *Georg-August University of Goettingen, Institute of Grassland Science*, *Goettingen. Germany.*

Grassland composition and animal species may modify the grazing efficiency and ingestive behavior of pasture. However, precise knowledge on potential interactions between sward diversity and mixed grazing is not available. Thus, a trial was conducted to evaluate the main (grazing, walking, and ruminating) and secondary (bites per minute, steps per minute, and bites per step) animal behavior patterns of cattle and sheep grazing alone or together on grass swards differing in botanical composition. The study was conducted in Lower Saxony/Germany from May to September 2009. Three blocks (A, B and C) individually arranged into 6 treatments were employed; i.e., low diversity/cattle, low diversity/sheep; low-diversity/cattle-sheep; high diversity/cattle, high diversity/sheep and high diversity/cattle-sheep. Botanical composition of either mixed grass-legume-forb (14 species per $9m^2$) or grass dominated swards (7 species) was manipulated by the use of herbicides. The stocking density was 3000 kg of animal weight per plot. Animals were moved to the next block when the compressed sward height decreased from 12 to 6.5 cm. The main behavior patterns of 3 core animals within each paddock were recorded 7 times by conducting scan sampling every 10 min from 0600 to 2200 h. Secondary patterns were obtained from 15 measurements per core animal and observation day. Results were analyzed with a Completely Random Variance Analysis in a 2 × 2 factorial arrangement using the Proc Mixed of SAS. Results show that cattle on high diversity swards spent more time grazing, have the lowest time for ruminating and the lowest mean of bites per minute ($P < 0.05$). Co-grazing increased the rumination time of cattle regardless of sward composition ($P < 0.05$). Interestingly, there were no significant differences on main and secondary behavior patterns of sheep, neither due to the type of grazing nor the sward composition ($P > 0.05$). Complementary studies of vegetation consumption preferences joined with ruminal physiology assessments should be done to evaluate the benefits and limitations pasturing on rich or poor diversity swards.

Key Words: grassland, mix-grazing, botanical composition

95 Evaluation of dairy heifer performance and pasture composition when co-grazing heifers and goats. T. S. Dennis*, L. J. Unruh-Snyder, M. K. Neary, J. E. Tower, and T. D. Nennich, *Purdue University*, *West Lafayette, IN*.

Alternative feeding strategies that reduce costs and maintain animal performance improve the sustainability of livestock operations. The objective of this study was to evaluate the effects of co-grazing heifers and goats supplemented with co-product feeds on heifer performance, pasture composition, and DM yield. Forty-eight Holstein heifers (BW = 147.4 kg, BCS = 2.9) were randomly assigned to one of 12 paddocks and allocated to a 2 × 2 factorial design with 2 co-product supplements (dried distillers grains (DDGS) or soybean hulls (SBH)) and 2 grazing strategies (heifers with goats (HG) or heifers without goats (HO)). Heifers were intensively grazed on tall fescue/white clover pastures and supplemented at 0.9% of BW. Body weights were measured biweekly. Wither heights (WH), hip heights (HH), and BCS (1 to 5 scale) were measured and blood samples were collected for plasma urea nitrogen (PUN) analysis monthly. Pasture intakes were estimated 2 times/wk. Pasture composition, DM yield, and nutrient analysis were determined monthly. Heifer data were analyzed by paddock as repeated records using PROC MIXED of SAS. Heifers fed DDGS tended to gain more weight ($P = 0.1$) and had greater changes in HH and WH ($P = 0.02$ and $P = 0.03$, respectively). The percent of weeds in the pasture tended to decrease ($P = 0.06$) for HG. Pasture DM yields for HO and HG did not differ between treatments ($P > 0.1$). Heifer growth and feed efficiency improved when heifers were supplemented with DDGS. Co-grazing heifers with goats did not affect heifer performance ($P > 0.1$).

Table 1. Effects of supplementation type (SUPP) and grazing strategy (GS) over all time periods on intake, growth, feed efficiency, and plasma urea nitrogen in dairy heifers

	DDGS	DDGS	SBH	SBH		P-value

Key Words: dairy heifer, co-grazing, goats

96 Effects of aluminum from water-treatment-residual applications to pastures on mineral status of cattle and forage mineral concentrations. R. K. Madison, L. R. McDowell** G. A. O′Connor, N. S. Wilkinson, P. A. Davis, A. T. Adesogan, T. L. Felix, and M. Brennan, *University of Florida*, *Gainesville*.

Extensive efforts have been focused on finding ways to reduce soluble P in manure-impacted soils. Aluminum binds to P and application of Al could be one potential solution to the problem. Two experiments (145 and 148d) using Holstein steers were conducted to determine the pasture application of water treatment residuals (Al-WTR) on mineral status (primarily P) and performance of grazing cattle. Experiments (1995 and 1996) began June 1st with cattle initially weighing 306 and 169 kg, respectively, on d 0. The experiments were a completely randomized design with treatments replicated 3 times. Four treatments were with and without Al-WTR and with and without P-free mineral supplement. Total pasture application of Al-WTR over 2 years was 75.8 t dry weight/ha. Steers were allotted (3/pasture) to one of 12 0.81 ha bahiagrass (*Paspalum notatum*) pastures. Body weights, blood samples and liver biopsies were taken at d 0, d 84 and 148. Plasma was analyzed for Al, Ca, Cu, Mg, P and Zn; liver for Al, Cu and P and bone for Al, Ca, P and Mg. A second objective was to evaluate the effects of the applied Al-WTR on mineral concentrations of the bahiagrass pastures. Forage samples were taken on d 0 and every 28 d thereafter for 5 mo. The Al-WTR had little or no effect ($P > 0.5$) on weight gains and mineral tissue concentrations. Forage mineral concentrations were generally unaffected by treatment but were affected ($P < 0.05$) by collection dates. Forage P contractions ranged from 0.12 to 0.22%. Most forage samples were deficient in Na (<0.06%), Cu (<10ppm), Se (<0.1ppm) and Co (0 < 0.1ppm) and at various collections deficient in Ca (<0.35%), P (<0.18%), Fe (<50ppm) and Zn (<30ppm). In conclusion, Al-WTR applications had little effect on animal status of P or any other mineral analyzed. Likewise, Al-WTR had little effect on forage mineral concentrations. Applications of Al-WTR are effective in reducing P contamination without affecting forage or cattle mineral status.

Key Words: cattle, forages, water treatment residuals

97 Effect of maturity and nitrogen fertilization on bahiagrass production and nutritive value. N. M. Kenney*, J. E. Sawyer, R. O. Dittmar III, and T. A. Wickersham, *Texas A&M University*, *College Station*.

Bahiagrass (*Paspalum notatum*), a forage resource in the southern United States, often has lower forage quality than cool-season grasses and legumes, but may require fewer nutrient inputs than other available forage options. Our objectives were to determine the effects of N fertilization and maturity on nutritive value, in situ OM digestibility, and yield of bahiagrass. Treatments were arranged as a 4 × 4 factorial with 4 levels of N fertilization (0, 45, 90, and 135 kg N per ha) and 4 maturities (3, 5, 7, and 9 wk after N fertilization). An established stand of bahiagrass was divided into 3 blocks with all treatments contained in each block. In situ determinations were made with 3 steers fed Bermudagrass hay and samples were incubated for 0, 2, 6, 12, 24, 48, and 72 h. Increasing provision of N tended ($P = 0.06$) to quadratically increase in DM yield (3354, 4386, 4876, and 5182 kg DM per ha for 0, 45, 90, and 135 kg N, respectively). Similarly, advancing maturity increased DM yield quadratically ($P < 0.01$; 3206, 4580, 4894, and 5119 kg DM per ha for 3, 5, 7, and 9 wk, respectively). A maturity by N interaction ($P = 0.02$) was observed for CP concentration. Increasing N resulted in more rapid declines in CP with advancing maturity. At 3 wk CP was 8.0% for 0 N and 11.6% for 135 N. In contrast, at 9 wk the CP was 5.0% for 0 N and 6.6% for 135 N. In situ OM digestibilities were determined on samples from wk 5, 7, and 9. A maturity by N interaction ($P = 0.03$) was observed for the rapidly degraded (A) fraction of OM. At 5 wk maturity the A fraction decreased with increasing N fertilization, whereas at 9 wk maturity the A fraction increased with increasing N fertilization. The B fraction was linearly reduced ($P < 0.01$) and the C fraction was linearly increased ($P < 0.01$) with advancing maturity. At a fixed passage rate of 3% per h, the calculated extend of OM degradation was 58.6, 54.9, and 53.4% for maturities 5, 7, and 9, respectively (linear, $P < 0.01$). Overall, additional fertility increased bahiagrass CP content, despite more rapid declines with advancing maturity, and maturity was the primary driver of bahiagrass degradability.

Key Words: bahiagrass, in situ, maturity

98 Effect of mineral supplementation on the performance by stocker cattle grazing winter-wheat pasture. S. A. Gunter*[1] and G. F. Combs[2], [1]*USDA-ARS, Southern Plains Range Research Station*,

Woodward, OK, [2]*USDA-ARS, Grand Forks Human Nutrition Research Center*, *Grand Forks, ND*.

To evaluate the efficacy of mineral supplementing stocker cattle grazing wheat pasture, 2 experiments were conducted. In Exp 1, 72 steer and heifer calves (BW = 228 ± 11.4 kg) were randomly assigned to 12, 4.9-ha pastures on November 12 at 1.2 animals/ha (4 pastures), and February 5 at 2.5 animals/ha (8 pastures) for 84-d. In Exp 2, 38 steers (BW = 248 ± 4.8 kg) were randomly assigned to 12, 2.5-ha wheat pastures on February 24 for 84 d at 1.3 steers/ha. In Exp 2, pastures were planted with conventional tillage or a no-till drill. In Exp 1 and 2, half the pastures received a free-choice mineral mixture (Wheat Pasture Pro; Land O Lakes Purina Feed, LLC; St. Paul, MN; Ca, 16% and P, 4%) provided in ground-type mineral feeders (Exp 1: completely random design; Exp 2: 2 × 2 factorial); feeders were weighed weekly to determine intake. All pastures were drilled the first of September 2008 (67 kg of seed/ha) and were fertilized with 50 kg of urea-N/ha. Standing herbage DM was determined in pastures when cattle were weighed every 28-d by clipping wheat to the ground along 122 cm of drill row at 10 transects. Data were analyzed by AOV with treatment as the fixed effect and pasture as the random effect. In Exp 1, cattle offered the minerals had a 45% faster ADG ($P < 0.01$; 0.75 kg) than cattle not offered minerals (0.52 kg); hence, the supplemented cattle weighed 8% more ($P < 0.01$; 308 kg) after grazing than non-supplemented cattle (289 kg). In Exp 2, supplementation did not interact ($P \geq 0.44$) with tillage. Also, steers offered the mineral had a 30% faster ADG ($P = 0.03$; 1.12 kg) than steers not offered minerals (0.86 kg) and the supplemented cattle weighed 6% more ($P = 0.03$; 341 kg) after grazing than non-supplemented cattle (320 kg). In both experiments, daily standing herbage DM averaged 1,536 kg/animal and never differed ($P \geq 0.13$) between treatments. Mineral intakes averaged 73 (Exp 1) and 168 (Exp 2) g/d, resulting in cost of supplement to kilogram of added BW gain conversions of $0.26 and $0.57 assuming a mineral cost of $0.88/kg. Overall, there was an improvement in ADG and the supplement to added BW gain conversion seemed profitable.

Key Words: cattle, grazing, wheat pasture

99 Effect of corn hybrid on the amount of residue available for grazing relative to grain yield. J. A. Musgrave*, L. A. Stalker, T. J. Klopfenstein, M. C. Stockton, and K. H. Jenkins, *University of Nebraska*, *Lincoln*.

Utilization of corn crop residue by cattle to extend grazing can have positive economic impacts. Cattle primarily consume the leaf and husk portions of the corn residue. Amount of residue available to grazing cattle may be influenced by corn hybrid. Ten corn hybrids were evaluated to determine differences in corn grain yield and crop residue dry matter. Ten hybrids that best represented a wide range of production traits were selected from a total of 40 hybrids grown in a test plot located near Paxton, Nebraska. The following hybrids were evaluated: Pioneer P0541XR, P1173HR, P1395XR, Dekalb 59–35, 61–04, NK N68B–GT, N74C–3000GT, Croplan Genetic 5757 VT3, Golden Harvest 8211 3000GT, and Midwest Genetics 76482R. Each sample consisted of the complete above ground portion of the corn plant and was collected randomly. Each sample was sorted into the following parts: stems, leaves (including leaf sheath), husks, cobs, and corn grain. Plant parts were dried in a forced air oven at 60°C to determine dry matter yield. Data were analyzed as a completely randomized design. There was no difference in corn grain yield among hybrids (13,240 kg/ha ± 788, DMB; $P = 0.23$). Differences were present between hybrids in amount of stems ($P < 0.001$), leaves ($P = 0.05$), husks ($P = 0.01$), and cobs ($P < 0.001$). Considering these differences, it is not surprising that total residue production (sum of stems, leaves, husks and cobs) was different ($P = 0.02$) among hybrids. However, differences also existed in the ratio of corn grain to total residue production ($P < 0.001$) and corn grain to leaf and husk ($P < 0.001$), indicating potential differences in plant efficiency. Corn hybrids differ in the amount of residue produced independent of the amount of grain. Since corn hybrids differ in the amount of residue they produce, possible differences in amount of residue available for cattle to graze, also differs. Using these differences, economic estimates of the ranking identify potential value differences.

Key Words: corn stalks, corn residue, grazing

100 Replacing synthetic N with clovers or alfalfa in bermudagrass pastures for growing calves. P. Beck*[1], D. Hubbell[1], T. Hess[1], K. Haas[2], and J. Jennings[1], [1]*University of Arkansas*, *Fayetteville,* [2]*Haas Hay & Cattle Co.*, *Gurley, AL*.

The objective of this research was to determine the impact of alfalfa or clover additions to common bermudagrass (*Cynodon dactylon* [L.] Pers.) pastures on performance of growing calves and pasture carrying capacity compared with commercial N fertilizer. In October 2008, 0.81 ha bermudagrass pastures were interseeded with 1) a mixture of 13 kg/ha red clover (*Trifolium pretense*, cv. Morningstar, Cal/West Seeds, Woodland, CA) and 3.3 kg/ha ladino white clover (*Trifolium repens*, cv. Regal Graze, Cal/West Seeds, n = 4) or 2) 28 kg/ha alfalfa (*Medicago sativa*, cv. PGI 459, Producers Choice, Woodland, CA, n = 4). The following summer 12 bermudagrass pastures received 0, 56, or 112 kg N/ha as ammonium nitrate. Beef steers (BW = 278 ± 13.6 kg) grazed pastures from 29 May to 9 September in a put and take experiment. Data were analyzed as a completely randomized design with 4 pastures/treatment using the mixed procedure of SAS. A single df contrast was used to determine the linear N fertilization rate effect, and predicted differences separated the effects of alfalfa and clover. Stand counts of alfalfa pastures decreased from 34 ± 10.6% in May to 15 ± 12.7% in October, but remained relatively unchanged in clover pastures 43 ± 12.8% in May and 38 ± 5.2% in October. Daily gains and BW tended ($P = 0.08$) to increase linearly with increasing N rate. Gains and BW of steers from alfalfa pastures did not differ ($P \geq 0.91$) from 56 kg N rate. Gains and BW of clover steers was greater ($P \leq 0.02$) than alfalfa and 56 kg N rate, but did not differ ($P = 0.11$) from 112 kg N rate. Grazing-d/ha and gain/ha increased linearly ($P = 0.01$) with increasing N rate. Grazing-d/ha of alfalfa and clover did not differ ($P \geq 0.31$) from 56 or 112 kg N/ha rates. Pastures containing clover produced more ($P = 0.02$) gain/ha than 56 kg N rate and tended ($P = 0.10$) to produce more BW gain/ha than 112 kg N rate. Gain/ha for alfalfa did not differ ($P = 0.95$) from 56 kg N rate. Clovers produce equivalent BW gains and animal grazing days to 112 kg/ha N, but stands of alfalfa were not dense enough throughout the grazing season to maintain animal performance above that of 56 kg/ha N.

Key Words: alfalfa, clover, bermudagrass

101 Effects of winter swath grazing barley and millet on background and feedlot performance and rumen metabolism of beef calves. R. Kumar*[1], H. A. Lardner[1,2], and J. J. McKinnon[1], [1]*University of Saskatchewan*, *Saskatoon, Canada*, [2]*Western Beef Development Centre*, *Humboldt, Saskatchewan, Canada*.

A 2-year winter grazing and feedlot finishing trial (Exp1) and subsequent metabolic study (Exp2) were conducted to evaluate the effects of swath grazing forage barley *(Hordeum vulgare* cv. Ranger) and foxtail millet *(Setaria italica* cv. Golden German) compared with grass-legume hay fed in drylot on beef calf performance and rumen degradation kinetics.

In Exp1, 120 spring born Angus calves (60 steers, 60 heifers) were fall weaned, stratified by weight, allocated into 20-head groups then assigned randomly to 1 of 3 replicated (n = 2) backgrounding (BG) systems.. Data were analyzed using Proc Mixed with year as a block. Systems were (i) field swath graze barley (BR); (ii) field swath graze millet (ML); and (iii) bunk fed ground hay drylot (DL). Field calves were limit grazed in 8 ha paddocks for 3 d grazing period using electric fencing for 96 d each year, with all groups receiving additional pelleted supplement at 0.62% BW. Calves were weighed at start, every 21 d and end of background period. Following BG period, calves were placed in feedlot, separated by sex and BG treatment and fed a similar finishing ration and harvested once a targeted endpoint of 12 mm backfat was reached. Forage samples collected every 21 d were analyzed for DM, CP and digestible energy (DE). Forage dry matter analyses was greatest ($P = 0.03$) for barley swath (DE = 2.6 Mcal/kg) and lowest ($P = 0.03$) for grass-legume hay (DE = 2.2 Mcal/kg). Calf background ADG was greatest ($P = 0.002$) for BR compared with ML or DL, while feedlot ADG was not different ($P = 0.32$) for all calves. In situ degradability (Exp2) of barley DM and CP was greater ($P = 0.0001$) compared with millet or hay, while millet had greater ($P = 0.0001$) NDF degradability. These findings indicate that swath grazing barley or foxtail millet with beef calves resulted in similar or improved performance compared with a traditional dry-lot pen system.

Key Words: barley, millet, swath grazing

Graduate Student Symposium: Transitions: Preparing for Your Future

102 Surviving the transition from thesis to published manuscript: An editor′s perspective of the review process. J. L. Sartin*, *Auburn University*.

This talk will be oriented to the graduate student with a focus on how the editorial process works behind the scenes. This will range from how reviewers are selected to how decisions are made about whether to publish or reject a manuscript. Common problems cited by reviewers will be listed as well as a discussion of how to respond to the reviewers comments. The end of the session will be a discussion of the options for what to do in the event a paper is not published.

Key Words: journal, review, author

103 Taking the reins: Transitioning from PhD student to associate professor. K. A. Vonnahme*, *Department of Animal Sciences*, *Fargo, ND*.

Congratulations! You are ready to begin your own research program! How can you guarantee your success in getting tenure? The journey toward tenure begins before you accept any job offer. Make sure you start in the right place. Do your homework: Do the values of the institution match your values? What are your future colleagues like? How will your research interests fit in with those that will surround you? After you decide on a place, PLAN. Tenure is just 6 short years away, and you need to have a written game plan that you share with your lab and your significant other. Here are 6 tidbits that aided my way to obtaining tenure. 1) Surround yourself with good people. Ask the right questions as you interview graduate students, post-docs, and technicians. Taking more time before the hire makes the time after you get the job more pleasant. 2) Motivate those around you. Motivation is different for everyone, but people will work hard if you show that you care and appreciate their efforts. Remember that their successes are your successes, too. 3) Find a mentor. A formal mentor may be given to you at hiring, but seek out others whose programs are already successful. They will share their successes and headaches. Listen. 4) Begin your promotion and tenure document the day you begin. This is a tedious task that is a necessary evil—embrace it early. 5) Manage your time. Keep one calendar for both your professional and personal appointments. This leads to greater efficiency. Make use of small pieces of time. 6) Having it all. Make sure you choose your partner wisely. You will take your job home with you quite often, and having the support and understanding of someone at home makes life so much easier. Remember that your PhD program has trained you in many areas that will guarantee success in a tenure track position: excellence in your field of study, how to interact with various types of people, the ability to gather and analyze data, the ability to organize your studies and your time, the confidence to act on intuition, integrity, and resilience. Continue to hone these skills as you transition to an associate professor.

Key Words: career, promotion and tenure, success

104 Animal scientists of the future – Embrace change, challenges and opportunities. M. E. Benson*, *Washington State University*, *Pullman.*

Academia and the animal sciences are in a dynamic era and those who embrace change and see and create new opportunities are those who will be successful. Academic success will continue to require all of the technical skills and competencies that have always existed in a chosen discipline or mission. Changes in funding sources, clientele demographics and the increasing role society will play in influencing research and education priorities and activities will require nimble people capable of responding to and anticipating challenges. Five attributes that can help a new faculty or staff member to be successful include: an ability to thrive in a changing environment, enjoying and valuing interdisciplinary opportunities and relationships, the willingness and ability to be entrepreneurial, the willingness and ability to communicate science and its implications, and the ability to be an innovator. With change also comes the need for individuals to work collectively to accomplish new tasks, teach new courses, respond to emerging issues and extend knowledge to the public. The reality is that new skills and techniques will be required to address tomorrow′s increasingly complex questions. Those who are willing to acquire new skills that can contribute new expertise and who are willing and able to lead interdisciplinary research teams will be those best positioned to achieve external funding success. A skilled innovator will find ways to turn challenges into opportunities and capitalize on those opportunities. Looking for and finding ways to do the *impossible* are characteristics tomorrow′s elite animal scientists will possess. We must capitalize on change and those who can will find exciting and rewarding times ahead.

Key Words: success, innovation, academia

Growth and Development: Regulatory Mechanisms in Growth and Development

105 The effect of feeding frequency on circulating thyroid hormones in turkey chicken. A. Towhidi*, A. Yahyabeig, and E. Dirandeh, *University of Tehran*, *Karaj, Tehran, Iran*.

A strategy that improves growth efficiency is to reduce basal metabolic rate, providing additional energy for growth. Thyroid hormones enhance metabolism and lipolysis. Previous studies have shown that increase of feeding frequency could change blood hormonal profile affecting metabolism and growth in some animals. The objective of this study was to investigate the effect of increased feeding frequency on thyroid hormones status in turkey. Twenty turkey chickens were randomly assigned to 2 groups. In control group, turkey chickens were fed ad libitum, whereas birds in treatment group fed every 4 h and blood samples were collected at 4 intervals. Data were analyzed with Proc Mixed of SAS. Overall mean plasma concentration of triiodothyronine in treated group was higher than control (4.05 ± 0.34 vs. 2.59 ± 0.30 ng/mL, $P = 0.0001$). Mean plasma concentration of thyroxin in treated group was higher than control (47.50 ± 1.6 vs. 24.08 ± 1.7 µg/dL, $P = 0.0001$). It was concluded that increasing feeding frequency failed to decrease thyroid hormones level. As a result, this kind of feeding management may not be efficient to improve growth performance in turkey chicken.

Key Words: turkey, thyroid hormones, feeding frequency

106 The role of syndecan-4 cytoplasmic domain in turkey skeletal muscle growth and development. Y. Song*[1], D. C. McFarland[2], and S. G. Velleman[1], [1]*Ohio Agricultural Research and Development Center, The Ohio State University*, *Wooster,* [2]*Department of Animal and Range Sciences, South Dakota State University*, *Brookings*.

Skeletal muscle formation is a complex process involving the interactions between cells and their extracellular matrix. Syndecan-4 is a cell membrane heparan sulfate proteoglycan that passes signals from the extracellular matrix into the cell. Syndecan-4 core protein is composed of an extracellular domain, a transmembrane domain, and a cytoplasmic domain. The cytoplasmic domain is important in regulating signal transduction into the cell and the formation of focal adhesion complexes which is critical for cell survival. In the current study, the role of the syndecan-4 cytoplasmic domain in muscle cell proliferation, differentiation, fibroblast growth factor 2 (FGF2) responsiveness, and apoptosis was explored. Turkey wild type syndecan-4 (S4) and syndecan-4 without the cytoplasmic domain (S4C) were cloned into the pCMS-EGFP vector and then subcloned into the pcDNA3.1/V5-His TOPO TA expression vector. Wild type syndecan-4, S4C, and the pCMS-EGFP empty vector were transfected into turkey skeletal muscle satellite cells. After transfection, cell proliferation, differentiation, and FGF2 responsiveness were measured. Wild type syndecan-4 and S4C subcloned into the pcDNA3.1/V5-His TOPO TA expression vector were used to test cell apoptosis by a CaspACE assay using CaspACE FITC-VAD-FMK in situ marker which fluorescently labels apoptotic cells. The pcDNA3.1/V5-His TOPO TA expression vector was used because it does not express green fluorescence protein as the pCMS-EGFP vector which will interfere with the CaspACE assay. Results showed that the overexpression of S4C decreased cell proliferation ($P < 0.05$) but did not change cell differentiation, or responsiveness to FGF2 during proliferation and differentiation compared with the cells transfected with S4. The cells transfected with S4C had more apoptotic cells compared with those transfected with S4. These results suggest that syndecan-4 plays a critical role during cell proliferation, and the syndecan-4 cytoplasmic domain regulates cell proliferation and survival in an FGF2-independent manner.

Key Words: turkey, muscle satellite cell, growth and development

107 Comparative phylogenetic analysis of gut microbiota of broilers fed with and without antibiotics. P. Singh*[1], A. Karimi[2], P. W. Waldroup[1], and Y. M. Kwon[1], [1]*University of Arkansas*, *Fayetteville,* [2]*University of Kurdistan*, *Sanadaj, Kurdistan, Iran*.

Antibiotics growth promoters (AGP) have been used for growth promotion of chickens in poultry industry since 1950. Recently, concerns have been raised to the use of AGP in livestock due to development of antibiotic resistance in bacteria. The objective of our study is to investigate the effect of AGP in cecal microbiota of broiler chickens. Two groups (n = 30) of chickens were fed corn-soybean meal diets with (ANT) and without supplementation of Penicillin (CON) at the concentration of 55 mg/kg. At 18 d of age, ANT group had significantly ($P < 0.05$) higher mean body weight than CON group (668.6 vs. 570.0 g). Cecal samples of 5 randomly selected birds were pooled from each group and used for genomic DNA isolation and PCR amplification of 16S rRNA gene. 454 pyrosequencing of the amplicons resulted in 7,881 and 11,214 sequence reads for CON and ANT groups, respectively. BLAST and phylogenetic analysis using MEGAN-3 indicate that AGP supplementation in ANT group resulted in elevated proportion of phylum Firmicutes from 16.67% to 17.47% and a decreased proportion of phylum Bacteriodetes from 15.71% to 0.14% as compared with CON group. Recent studies conducted in humans, pigs and mice have shown a similar shift in gut microbiota in obese individuals as compared with lean ones, indicating that this shift could be responsible for increase in energy harvest and body weight. The results of this study suggest that the growth promoting effect of AGP supplementation in broilers may be mediated by a similar microbial process. Hence, new and alternative methods for promoting the growth of the birds need to be sought for that may alter gut microflora in a similar pattern.

Key Words: antibiotics growth promoter, 16S rRNA gene, cecal microbiota

108 Impact of feeding raw materials on intestinal viscosity and performance of broilers. F. Nuyens[1], I. Somers[1], S. Van De Craen[1], W. Röser[1], C. Chudaske[2], and S. Van Dyck*[1], [1]*Kemin AgriFoods Europe*, *Herentals, Belgium*, [2]*Südzucker AG Mannheim/Ochsenfurt*, *Ochsenfurt, Germany*.

Alternative cereals and cereal by-products can be used to reduce the costs of poultry diets. However, the application of these new raw materials may call for an evaluation of their effect on gut viscosity. This paper evaluates the changes that appear in fiber analysis and in vitro viscosity for diets including 10% of wheat-based distillers dried grains with solubles (DDGS). It is the objective of this paper to assess the impact of feed viscosity changes on broiler performance and intestinal viscosity. Furthermore, the beneficial effect of feed enzymes will be demonstrated. A broiler growth trial was performed with 200 birds divided over 4 treatments (see Table 1) in a randomized block design. On d 21 of the trial, 9 broilers were sacrificed per treatment and viscosity of jejunum and ileum contents was measured (Dusel et al., 1997). The use of feed enzyme in the diet had significant effects ($P < 0.05$) on the intestinal viscosity (Table 1). By use of the feed enzyme in the diets that included

DDGS, the intestinal viscosity was decreased by 40% in the jejunum and 24% in the ileum. The results show that the fiber content in DDGS is much greater than in regular wheat. The DDGS did not induce a greater viscosity than regular wheat. The bioethanol production process might have reduced part of the soluble, long-chain arabinoxylan fibers that are responsible for the viscosity effect. The low viscosity values of both wheat and DDGS after treatment with a feed enzyme indicate the potential to control intestinal viscosity when wheat or DDGS are used in the feed formulation. The treatment with highest intestinal viscosity showed poorest daily gain and feed conversion ratio (FCR), while the group with lowest intestinal viscosity showed the best zootechnical performance (Table 1, $P < 0.05$).

Table 1. Intestinal viscosities and FCR for broilers fed a regular wheat diet and a modified wheat diet with 10% DDGS. The Feed Enzyme was supplemented at a dosage of 500 g/tonne.

Treatment	Jejunum	Ileum	FCR
Control	3.73^{a}	5.28^{ab}	1.83^{ab}
Control + DDGS	4.67^{b}	6.50^{b}	1.89^{b}
Control + Feed Enzyme	2.60^{c}	4.14^{a}	1.75^{a}
Control + DDGS + Feed Enzyme	2.81^{c}	4.95^{a}	1.85^{b}
SEM	0.048	0.018	0.001
p-value	0.0001	0.0039	0.0006

Means in same column with different superscripts are significantly different ($P < 0.05$).

Key Words: DDGS, Feed enzyme, intestinal viscosity

109 Ontogenic changes in the activation of translation initiation factors post feeding are not seen in adolescent Thoroughbred mares. A. L. Wagner*, J. C. Gould, R. B. Ennis, and K. L. Urschel, *University of Kentucky*, *Lexington.*

Following consumption of a protein meal, signaling proteins associated with the mTOR pathway are activated, triggering muscle protein synthesis due to increases in both insulin and amino acid (AA) concentrations. In neonates, the activation of the mTOR pathway decreases with age resulting in lower skeletal muscle protein synthesis. The slower growth seen during the adolescent age has not been studied with regards to mTOR-related signaling in any species. The purpose of this study was to determine the effects of an 18h feed witholding period, either with (postprandial; PP) or without (post-absorptive; PA) the re-feeding of a protein meal ($t = 0$ min), on the activation of translation initiation factors in gluteal muscle of yearling, 2y old, and mature Thoroughbred mares (n = 18). Blood samples were taken during the experimental protocol to measure plasma AA via HPLC. A gluteal muscle biopsy was taken after the last blood sample ($t = 90$ min) to measure the phosphorylation (P) of Akt at Ser^{473} and Thr^{308}, 4EBP1 at Thr$^{37/46}$, rpS6 at Ser$^{235/236;240/244}$, and p70 S6 Kinase at Thr^{389} using Western blotting. For all horses, indispensible plasma AA were ~25- 110% higher in the PP versus PA period ($P < 0.01$). There was a significant increase in Akt P-Ser^{473} ($P < 0.01$), 4EBP1 P-Thr$^{37/46}$ ($P < 0.01$), rpS6 P-Ser$^{235/236}$ ($P < 0.01$), rpS6 P-Ser$^{240/244}$ ($P < 0.01$), and p70 S6 Kinase P-Thr^{389} ($P < 0.01$), and a trend for higher AktP-Thr^{308} ($P = 0.10$) in the PP versus PA state. There was an interaction of age and treatment on the P of 4EBP1 ($P = 0.05$), and a trend for an interaction for the P of p70 S6 Kinase ($P = 0.08$). Age did not have an effect on the P of any protein ($P > 0.05$), although there was a trend for an age effect on AktP-Thr^{308} ($P = 0.10$). Consumption of a high protein meal, appeared to activate proteins associated with the mTOR pathway in adolescent and mature horses. However, growth of adolescent horses did not have a greater effect on the P of the proteins in the mTOR pathway compared with mature horses. More research is necessary to determine whether an effect of age is present in the rapidly growing equid neonate.

Key Words: mTOR pathway, growth, protein synthesis

110 Productive performance of pigs vaccinated against gonadotropin releasing factor compared to surgically castrated males and gilts from two different sire lines. J. I. Morales[1], M. P. Serrano*[2], L. Cámara[2], C. H. Zúñiga[2], J. P. López[1], and G. G. Mateos[2], [1]*Copiso S.A.*, *Soria, Spain*, [2]*Universidad Politécnica de Madrid*, *Madrid, Spain*.

A total of 360 pigs was used to study the influence of gender (immunocastrated males, IM; surgically castrated males, CM; intact females, IF) and terminal sire line (Top York; Tempo) on productive performance of pigs slaughtered at 125 kg BW. The female line used was Large White × Landrace in all cases. Improvac (Pfizer, Madrid, Spain) was used for active immunization against GnRH. The IM pigs received a first dose of Improvac at 76 d of age (16 d on trial) and a second dose at 124 d of age (64 d on trial; 7 wk before slaughter). There were 6 treatments (6 replicates of 10 pigs each) arranged factorially (3 × 2) with 3 genders and 2 terminal sire lines. From 60 to 76 d of age (IM were still entire males), IF and IM had lower ADG than CM (729 and 749 vs. 792 g/d; $P < 0.001$) but no differences were observed for feed intake. From 76 (injection of the first dose of the immune vaccine) to 124 d of age, IM had lower ($P < 0.001$) ADFI and ADG than CM with IF being intermediate. However, from 124 (injection of the second dose of the immune vaccine) to 172 d of age, IM recovered and in fact, they had better ($P < 0.001$) ADG and FCR than IF and CM. For the entire experimental period, IF and IM ate less feed than CM (2.43 and 2.43 vs. 2.59 kg/d; $P < 0.001$) whereas IM and CM had higher ADG than IF (952 and 945 vs. 913 g/d; $P < 0.01$). Also, IM had better FCR than CM with IF being intermediate (2.55 vs. 2.66 vs. 2.74 g/g; $P < 0.001$). From 60 to 172 d of age, crossbreds from Tempo sires had better ADG than crossbreds from Top York sires (952 vs. 922 g/d; $P < 0.001$) but no differences were observed for ADFI or FCR. We conclude that IM have better ADG and are more efficient than CM. Consequently, based on growth performance data, IM are a good alternative to CM for the production of 125 kg BW pigs. Also, the Tempo sire line is a good alternative to the Top York sire line for the production of heavy pigs.

Key Words: immunocastration and gender, sire line, pig performance

111 Effects of nutrient balance and implant status on IGF-1 and PUN concentrations of feedlot calves. T. Lee*, L. K. Mamedova, S. Guillossou, B. J. Bradford, C. D. Reinhardt, and D. U. Thomson, *Kansas State University*, *Manhattan*.

To simulate nutritional conditions in highly stressed feedlot calves with low nutrient intake, 16 predominantly English-breed calves (BW = 293.3 ± 5.41 kg) were used in a 2 × 2 factorial experiment to evaluate the main and interactive effects of poor vs. adequate nutrient intake and implant status on growth and PUN and serum IGF-1 concentrations. All calves were individually fed a common, pelleted, complete diet (15.3% CP; 1.44 Mcal NE_m /kg DM). After a 28-d period of adaptation to the Calan gates and the diet, 4 calves each were randomly assigned to receive either (1) implant + 2× maintenance energy intake; (2) implant + 1× maintenance energy intake; (3) no implant + 2× maintenance energy intake; or (4) no implant + 1× maintenance energy intake. Dietary NE_m content was estimated using dietary ingredient concentrations and NRC (1984) nutrient values. Animal NE_m requirement was determined based on d0 BW and NRC (1984) requirement tables; 1× maintenance calves

were fed to meet their NE_m requirement; 2× maintenance calves were fed twice their NE_m requirement; intake was subsequently adjusted based on d14 BW. Implanted calves were implanted (Revalor-XS; 40 mg estradiol-17β + 200 mg trenbolone acetate) on d0; all calves were weighed and processed through the chute on d0 and fed for 28 d. Blood samples were drawn on d0, d14, and d28 for analysis of serum IGF-1 (analyzed using ELISA) and plasma urea nitrogen (colorimetric assay). Data were analyzed as a repeated measures design using the MIXED procedure of SAS (v. 9.1). Diet affected ($P < 0.05$) ADG (1.65 vs. 0.04 kg/d for 2× vs. 1×), and d28 PUN (6.21 vs. 5.35 mM/L for 2× vs. 1×) but there was no effect of implant or any interaction between diet and implant on weight gain, PUN, or IGF-1 concentrations. These data suggest that nutrient restriction does not alter IGF-1 response or subsequent cellular nutrient uptake response due to implants.

Key Words: diet, feedlot, implant

112 Growth hormone and insulin-like growth factor I have different effects on bovine myoblasts and myotubes in culture. X. Ge* and H. Jiang, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Growth hormone (GH) and insulin-like growth factor I (IGF-I) are 2 major regulators of skeletal muscle growth in animals. The objective of this work was to compare the effects of GH and IGF-I on proliferation and fusion of primary bovine myoblasts, and their effects on protein synthesis and degradation in cultured bovine myotubes. Myoblasts were isolated from extensor carpi radialis of adult cattle by Pronase digestion and were allowed to proliferate or induced to form myotubes in culture. Recombinant bovine GH at the concentrations of 10 ng/mL and 100 ng/mL did not affect myoblast proliferation and fusion. However, both concentrations of GH increased protein accumulation by 15% compared with no-GH control ($P < 0.01$) without changing protein degradation. Although IGF-I at concentrations of 50 ng/mL and 500 ng/mL had no effect on myoblast fusion, IGF-I at concentration of 500 ng/mL increased myoblast proliferation by 20%, compared with no-IGF-I control ($P < 0.05$). Both concentrations of IGF-I increased protein accumulation in bovine myotubes by more than 75% ($P < 0.01$) and decreased protein degradation by 30% ($P < 0.05$), compared with no-IGF-I control. These data indicate that GH and IGF-I have largely different effects on proliferation and fusion of bovine myoblasts and on protein synthesis and degradation in bovine myotubes. These results suggest that GH and IGF-I might stimulate skeletal muscle growth in cattle through different mechanisms.

Key Words: GH, IGF-I, muscle

113 Trenbolone regulates myogenic differentiation via inducing androgen receptors and β-catenin interaction in muscle derived stem cells of cattle. J. X. Zhao*, J. Hu, M. J. Zhu, W. J. Means, and M. Du, *Department of Animal Science, University of Wyoming*, *Laramie*.

Anabolic steroid hormones have been widely used in the beef cattle industry for more than 50 years. Trenbolone is a synthetic analog of anabolic steroid hormone which can promotes both skeletal muscle and bone growth; however the underlying mechanisms remain obscure. Because canonical Wingless and Int (Wnt)/β-catenin signaling is known to promote myogenesis, we hypothesized that trenbolone regulates myogenesis through promoting the interaction of androgen receptor with β-catenin, increasing the transcription of β-catenin targeted genes. Muscle derived stem cells were prepared from male fetal skeletal muscle of cattle at mid-gestation, and treated with or without trenbolone (10 n*M*) in a myogenic medium consisting of DMEM plus 2% horse serum. Results showed that trenbolone treatment increases the protein contents of MyoD (0.72 ± 0.18 vs. 1.45 ± 0.19 arbitrary units, $P < 0.05$), myosin heavy chain (0.22 ± 0.03 vs. 0.38 ± 0.02 arbitrary units, $P < 0.05$), and androgen receptor (0.92 ± 0.04 vs. 1.18 ± 0.03 arbitrary units, $P < 0.05$) compared with the control group. The myogenic effect of trenbolone was blocked by cyproterone acetate, a specific inhibitor of androgen receptor, showing that the myogenic effect of trenbolone is mediated by androgen receptor. Immunoprecipitation showed that androgen receptor and β-catenin formed a complex; addition of trenbolone increased interaction between androgen receptor and β-catenin. Both cytoplasmic and nuclear β-catenin levels were increased following trenbolone treatment. The enhanced translocation of β-catenin to the nuclei following trenbolone treatment was correlated with higher β-catenin/T-cell transcription factor 1 (TCF) mediated transcriptional activity compared with that of control group (11.7 ± 1.6 vs. 6.9 ± 0.9 relative luciferase activity, $P < 0.05$). In conclusion, these data provide evidence that trenbolone promotes the interaction between androgen receptor and β-catenin, which promotes the expression of β-catenin targeted genes and myogenesis in the muscle derived stem cells of cattle.

Key Words: catenin, beef, androgen

114 Increasing days on the finishing diet equalizes carcass grade distributions of zilpaterol-HCl fed heifers. B. C. Bernhard*[1], R. S. Swingle[2], T. E. Lawrence[3], W. T. Nichols[4], D. A. Yates[4], J. P. Hutcheson[4], M. N. Streeter[4], J. C. Brooks[1], M. F. Miller[1], B. J. Johnson[1], and R. J. Rathmann[1], [1]*Texas Tech University*, *Lubbock*, [2]*Cactus Research Ltd.*, *Amarillo, Texas*, [3]*West Texas A&M University*, *Canyon*, [4]*Intervet Schering Plough Animal Health*, *DeSoto, Kansas*.

British × Continental heifers (n = 3,382; 307 kg) were serially slaughtered to determine if increasing days on the finishing diet (DOF) mitigates negative consequences of zilpaterol-HCl (ZH) on quality grade and tenderness. A 2 × 3 factorial arrangement of treatments in a completely randomized block design (36 pens; 6 pens/treatment) was used. Zilpaterol-HCl (8.33 mg/kg DM) was fed 0 and 20–22 d before slaughter plus a 3–5 d withdrawal to heifers spending 127, 148, and 167 DOF. Feedlot and carcass performance data was collected in addition to Warner-Bratzler shear force (WBSF) of strip loin steaks aged for 7, 14, and 21 d. No ZH × DOF interactions were detected ($P > 0.05$). Feeding ZH increased ADG, G:F, carcass ADG, carcass G:F, carcass ADG:live ADG, HCW, dressing percent, LM area and WBSF at 7, 14, and 21 d; decreased 12th-rib fat, YG ($P < 0.01$) and KPH ($P = 0.05$); and tended to decrease marbling score ($P = 0.10$). Feeding ZH decreased empty body fat percentage (EBF) and increased 28% EBF adjusted final BW ($P < 0.01$). Analysis of interactive means indicated that the ZH × 148 DOF group had a similar percentage of USDA Prime, Premium Choice, Low Choice and YG 1, 2, 3, 4, and 5 carcasses ($P > 0.10$); an increased percentage of total Choice ($P = 0.02$); and decreased percentage of Select ($P = 0.03$) and Standard ($P = 0.05$) compared with the Control × 127 DOF group. The ZH × 148 DOF group was tougher than the Control × 127 DOF group, but more tender than the ZH × 127 DOF group ($P < 0.01$) at 21 d. As a result of ZH shifting body composition, an additional number of DOF equalizes carcass grade distributions, but ZH mediated advantages in feedlot and carcass weight gain are sustained.

Key Words: zilpaterol-HCl, beef heifers, serial slaughter

115 Mitochondrial complex I protein is correlated to residual feed intake in beef cattle. M. H. Ramos* and M. S. Kerley, *University of Missouri*, *Columbia*.

Crossbred beef steers (310kg, n = 48) were fed over a 100 d period where daily feed intake and weight gain were measured. Diet fed to steers consisted of corn (62.5%), soyhulls (15%), distillers grain (10%), glycerol (10%) and mineral/vitamin supplements (2.5%). Dry matter intake and body weight was measured daily using Growsafe feed intake system. Intake was regressed on average metabolic body weight (MBW) and average daily gain (ADG) and resultant coefficients used to calculate predicted feed intake. Difference between actual and predicted intake was residual feed intake (RFI). Efficient animals (- RFI) had lower actual intake than predicted while inefficient animals (+ RFI) had higher actual intake than predicted. Blood was collected via jugular vein puncture and mitochondria isolated from lymphocytes. Mitochondria were processed to measure complex I quantity (CI), complex I enzyme activity (CIE) and pyruvate dehydrogenase quantity (PDH, as a mitochondria marker). Efficient animals had higher (P = 0.006) CI compared with average and inefficient animals (68.4, 39.2 and 28.5, respectively). Correlation between RFI and CI was −0.37 (P = 0.03) We concluded that efficient animals had higher CI. These results agree with previous research showing that efficiency is correlated to differences among animals in mitochondrial protein concentration.

Key Words: RFI, efficiency, mitochondria

116 Bone tissue-specific over-expression of growth differentiation factor 11 propeptide transgene causes homeotic transformation of the seventh cervical vertebra into a thoracic vertebra in mice. Z. Li*, M. Kawassumi, B. Zhao, S. Moisyadi, and J. Yang, *University of Hawaii at Manoa*, *Honolulu*.

Skeletal formation is highly dependent upon sequential switching on and off specific gene activities that control cellular events. Growth differentiation factor 11 (GDF11), also known as bone morphogenetic protein 11 (BMP11), is one of the significant genes that control skeletal formation and development. Complete deficiency of GDF11 function by gene targeting caused abnormal patterning of the anterior/posterior axial skeleton. However, all the GDF11-deficient mice died at birth because of serious kidney defect. To obtain live animals with disrupted GDF11 function, we developed a novel strategy to block the function of GDF11 through its propeptide. Using the intracytoplasmic sperm injection (ICSI) technique in combination with piggyBac transposon-mediated gene transfer, we produced viable transgenic mice overexpressing GDF11 propeptide under the control of a bone tissue-specific promoter, 2.3kb alpha1 type 1 collagen promoter. The transgenic mice exhibited skeletal abnormalities that appeared to represent homeotic transformation of the seventh cervical vertebra into a thoracic vertebra. The GDF11 propeptide transgene was detected as early as at 12.5 dpc in embryonic skeleton. Over 80% of the transgenic mice from a line expressing high level of transgene showed ectopic ribs on the seventh cervical vertebra. The transgene caused expression shifts of Hoxa-4 and 5 genes from their normal prevertebra locations in embryos. These results strongly suggest that the GDF11 function in the transgenic mice is suppressed in bone tissue. The transgenic mice with overexpressed GDF11 propeptide are useful animal models for investigating the role of GDF11 in skeletal formation and bone metabolism during late embryonic and postnatal growth.

Key Words: GDF11 propeptide, cervical rib, Hox gene

117 Soaking hay in water to reduce soluble carbohydrate concentrations prior to horse feeding. K Martinson*[1], C Sheaffer[1], and H Jung[1,2], [1]*University of Minnesota*, *St. Paul,* [2]*USDA-ARS*, *St. Paul, MN*.

Administering high concentrations of fructan to horses has resulted in laminitis. Cool season grasses accumulate fructan, which is estimated as the difference between water soluble carbohydrates (WSC; sucrose, fructose, glucose, fructans) and ethanol soluble carbohydrates (ESC; sucrose, fructose, glucose). Reducing fructan content in hay is critical for susceptible horses. The objective was to determine loss of WSC, ESC, and fructan from different hay types soaked in warm or cold tap water for various lengths of time. Five hays were evaluated; early bud (AB) and full flower (AF) alfalfa, mixed alfalfa orchardgrass (AO), and vegetative (VO) and mature (MO) orchardgrass. Soaking treatments included cold (22°C) and warm (39°C) water for 15, 30, and 60 min; cold tap water for 12 h; and a non-soaked control. One ′flake′ from each of 6 bales was randomly assigned to treatments. Hays were weighed, placed in mesh bags, and submerged in 25 L of fresh tap water. After soaking, flakes were drained for 30 min before drying at 60°C for 72 h. Each flake was ground and sent to a forage testing laboratory for WSC and ESC analysis. Data was analyzed using Proc Mix in SAS. Hays contained 81, 73, 114, 134, 129 g/kg WSC; 57, 48, 88, 68, and 66 g/kg ESC; and 24, 25, 27, 66 and 63 g/kg fructans (AB, AF, AO, VO, and MO, respectively). However, alfalfa does not contain fructan and AB and AF results probably reflect WSC extracted pectin. Soaking reduced WSC, ESC and fructan content in all hays ($P < 0.001$), except AO fructan. Except AB WSC and AO fructan, 15 min cold water soaking resulted in the least reduction of WSC, ESC, and fructan ($P < 0.001$), while the 12 h cold soak had the greatest reductions ($P < 0.001$). Soaking AF, AO, MO, and VO in warm water for 60 min had greater reductions in WSC compared with 60 min in cold water ($P < 0.001$). Reductions in MO fructan content were greater after soaking in warm vs. cold water for 60 min ($P < 0.001$). Forage type, soaking length, and water temperature all affected reductions in WSC, ESC, and fructan. Hay soaking is a viable method to reduce WSC, ESC, and fructan in hays.

Key Words: WSC, ESC, fructan, horse, hay soaking

118 Fasting length and hay type on metabolic parameters in the horse. A. M. Bruce* and E. L. Wagner, *Auburn University*, *Auburn, AL*.

Several metabolic disorders in the horse have been associated with postprandial fluctuations of insulin and glucose in response to the composition of feedstuffs consumed. Many studies have been conducted on altering grain form, type or feeding method to minimize the glycemic response to a meal; however there is a lack of research focusing on hay feeding protocols. The objectives of this study were 1) to examine changes in blood glucose and insulin in response to different fasting intervals and 2) to compare the effects of warm season and cool season hays on those same blood parameters. Six mature geldings were utilized in a 2 × 3 factorial design experiment. The horses were fed either bermudagrass hay (warm season) or fescue hay (cool season) during each of the fasting treatments. The 3 fasting periods consisted of a no fast where the horses would be offered ad libitum hay throughout the night, a short fast where the animals would receive hay until 2200 h with hay re-introduced at 0600 h, and a long fast where the animals would be offered hay until 2200 h and not offered any hay until the 0700 h morning feeding. All horses received concentrate and additional hay at 0700 h. Following a 6 d treatment adaptation, horses were fitted with an indwelling jugular catheter to facilitate a 7 h serial blood draw in conjunction with the morning feeding. Area under the curve (AUC) was calculated by the trapezoidal method for blood insulin and blood glucose concentrations. Insulin and glucose AUC were compared using the GLM procedure of SAS. No significant differences ($P < 0.05$) in AUC for blood glucose or insulin concentrations were seen between warm season and cool season hay. Fasting length did not alter blood glucose or insulin AUC concentrations. Fasting length and hay type do not significantly alter the blood insulin and glucose values in the horse; allowing the horse owner to use the method that is most convenient.

Key Words: horse, fasting length, hay type

119 Effects of endophyte-infested fescue seed consumption on post exercise recovery of horses in humid climates. J. A. Ford*, G. W. Webb, S. P. Webb, H. M. Hurshman, E. L. Walker, and B. Onyango, *Missouri State University*, *Springfield*.

The objective of this study was to determine the effect of endophyte consumption on horses subject to a standardized exercise test (SET) in humid conditions. Nine quarter horses (422–568 kg) were assigned into 2 groups of 5 and 4 to equalized skill level. During the first of 2 28 d periods, the groups were randomly assigned to E+ (endophyte-infested seed) or E- treatments (endophyte-free KY-31 seed) and exposed to the opposite treatment during the second 28 d, which followed immediately after the first. Horses were fed alfalfa hay, commercial sweet feed and either E+ or E- ground fescue seed. A molasses-water solution was used to mix the seed with the grain and encourage intake. Diets contained 12% seed, resulting in 459 ppb ergovaline for the E+ diet. Three days a week horses were subjected to a 25 min conditioning program: walk, trot, lope, stops, turns, and suppling exercises. Two days a week horses were trained on a mechanical cow for 5 min (20–25 turns) except on d 14, 28, 42, and 56 when they were ridden on the SET. The SET consisted of 40 turns in 4 min and was designed to raise the horse's heart rate (HR) beyond the anaerobic threshold (~150 bpm). During the SET, humidity averaged 80.3% and temperature averaged 27.3°C. Parameters measured on SET days were HR, respiration rate (RR), rectal temperature (RTemp), and blood lactate (Lac). Data were analyzed by ANOVA with treatment considered a fixed effect and all other effects considered random. Post SET values for Lac confirmed the horses were performing anaerobic work. Treatment had no effect on Lac, RTemp or HR at any time measured. There was a horse effect ($P \leq 0.05$) on post SET RR, HR, and Lac but not RTemp. There was no horse x treatment interaction for these variables. RR did not vary by treatment at rest or 1 min post SET. During the periods when horses consumed E+ seed, RR were higher at 5 and 10 min post SET ($P \leq 0.005$). There was no period effect, period x treatment or period x horse interaction. Horses that consumed E+ versus E- seed maintained higher respiration rates after a SET in which they were subjected to anaerobic work in humid conditions.

Key Words: horse, fescue, exercise

120 Digestibility of oats in horses using the substitution approach. A. D. Woodward*[1], A. Willyard[1], A. Buckley[1], J. Liesman[1], C. F. M. de Lange[2], and N. L. Trottier[1], [1]*Michigan State University*, *East Lansing*, [2]*University of Guelph*, *Ontario, Canada*.

Limited published information regarding apparent whole tract N digestibility of oats fed as a single protein source is available in horses due to the dietary obligate requirement for forages. The objective of the study was to estimate the apparent whole tract N digestibility of oats using the substitution approach. Six mature Arabian geldings (450 kg) were allocated to 6 diets over 6 time periods in a 6 × 6 Latin square design. Diets were composed of varying ratios of timothy grass hay and oats fed at 1.6% BW (DM basis), i.e., 1.6:0, 1.45:0.15, 1.3:0.3, 1.15:0.45, 1:0.6, and 0.85:0.75. Diets were formulated and fed to provide equal amounts of CP per kg BW (DM basis); percentage dietary CP contribution from hay and oats were 100:0, 91:9, 83:17, 74:26, 66:34, and 55:45, respectively. Each period consisted of 11-d adaptation to the diet followed by collection of all feces and urine every 8 h over 3 d. Feed, fecal and urine samples were analyzed for N. Apparent whole tract N digestibility was regressed against the contribution level of CP from oats to the total diet, i.e., 0, 9, 17, 26, 34, and 45%. As the level of oats inclusion and contribution of CP from oats increased, apparent whole tract N digestibility tended to increase ($P = 0.08$). The relationship was defined as y = 0.15 (±0.05)x + 51.90 (±1.45) ($R^2 = 0.72$, $P < 0.001$), where y is the intercept and represents the apparent N digestibility of timothy grass hay and x represents the level of CP contribution from oats to the diets. The apparent N digestibility of oats, estimated with x = 100, was 67%, and timothy grass hay, with x = 0, was 52%. In conclusion, apparent whole tract N digestibility of oats is 67%. The oats N digestibility value estimated using the substitution approach will allow the formulation of equine diets on a digestible protein basis to more efficiently meet protein requirements of horses receiving oats in addition to forages.

Key Words: horse, oat nitrogen digestibility, substitution approach

121 Effect of dietary energy manipulation on mares and their foals: Performance and hormones of mares in late gestation. K. N. Winsco*[1], J. A. Coverdale[1], and C. J. Hammer[2,3], [1]*Department of Animal Science, Texas A&M University*, *College Station,* [2]*Department of Animal Sciences, North Dakota State University*, *Fargo,* [3]*Center for Nutrition and Pregnancy*, *Fargo, ND*.

To investigate the effect of dietary DE manipulation on performance and reproductive hormones of mares in the last third of pregnancy, 30 Quarter Horse mares (538 to 695 kg of BW and 4 to 19 yrs of age) were blocked by expected foaling date. All mares were allowed ad libitum access to coastal bermudagrass pasture and randomly assigned within block to one of 2 dietary treatments: pasture (P) or pasture + concentrate (PC; concentrate fed at 0.75% BW on an as-fed basis). Treatments began 110 d before expected foaling date and terminated at parturition. Blood samples were collected every 14 d until parturition and analyzed for progesterone (P4), estradiol (E2), and cortisol (CORT) concentrations. Mare performance parameters (BW, BCS, and rump fat (RF)) were also recorded every 14 d. Data were analyzed using the PROC MIXED procedure of SAS. There was no influence of dietary treatment on mare BW. However, RF and BCS decreased ($P \leq 0.01$) in mares fed P compared with PC. There was no effect of dietary treatment on P4, E2, or CORT concentrations ($P \geq 0.10$). Regardless of diet, plasma P4 concentrations increased steadily over time ($P < 0.01$) from d 70 to d 112 (2.26 to 8.61 mg/ml). There was a tendency for a treatment by time interaction ($P < 0.10$) with plasma P4 concentrations rising sharply in PC mares beginning at d 70 and being greater ($P < 0.05$) than P mares at d 84. Serum CORT was also influenced by time ($P < 0.01$) with concentrations rising sharply before parturition. In addition, there was a treatment by time interaction ($P < 0.05$) with P mares having a rapid decline in plasma CORT until d 42. Serum E2 concentrations decreased sharply over time ($P < 0.01$) from d 42 to d 70 (311.23 to 223.98 pg/ml). In addition, there was a treatment by time interaction ($P < 0.05$) with PC mares having lower ($P < 0.05$) E2 concentrations than P mares at d 56 and 70. In summary, these data indicate that dietary DE manipulation of mares in late gestation influenced BCS and rump fat values, but not mare BW. Furthermore, dietary manipulation of DE altered mare hormonal response before parturition.

Key Words: mares, energy, pregnancy

122 Evaluation of the capacity for maternal transfer and foal synthesis of long-chain polyunsaturated fatty acids. L. K. Warren*, J. Kivipelto, and E. Gettinger, *University of Florida*, *Gainesville*.

Long-chain polyunsaturated fatty acids (LCPUFA), particularly 20:4ω6 and 22:6ω3, are necessary for normal neural development and are important regulators of cell function. Equine diets typically lack LCPUFA, thus foals presumably acquire LCPUFA via placental transfer, milk or through bioconversion of 18:2ω6 and 18:3ω3 precursors. Eighteen Thoroughbred (n = 11) and Quarter horse (n = 7) mares and foals were used to assess the capacity for maternal transfer and foal synthesis of LCPUFA. Mares were offered Coastal bermudagrass hay *ad libitum* and individually fed 1.5% BW/d of concentrate (16.7% CP, 3.8% fat, 10.2% ADF). Fatty acid (FA) composition of colostrum and umbilical cord plasma collected at foaling and milk, plasma and red blood cells (RBC) collected from mares and foals at 5 and 50 d of age was determined. Capacity for LCPUFA bioconversion was estimated as the ratio of 20:3ω6/18:2ω6 (Δ5-desaturase activity) and 20:4ω6/20:3ω6 (Δ6-desaturase) in plasma. Data were evaluated using the mixed procedure of SAS (v. 9.2). Mare diets were devoid of LCPUFA. LCPUFA were not detected in colostrum, but were present as <1 g/100 g FA in milk. Cord plasma was higher ($P < 0.01$) in LCPUFA, and lower ($P < 0.01$) in18:2ω6, total ω6, 18:3ω3, and total ω3 than foal and mare plasma at d 5 and 50. Foal plasma and RBC were higher ($P < 0.01$) in LCPUFA, total ω3 and 18:3ω3, and lower ($P < 0.01$) in total ω6 and 18:2ω6 than mare plasma and RBC at d 5 and 50. Foal and mare plasma were higher in Δ5-desaturase activity ($P < 0.01$) and lower in Δ6-desaturase ($P < 0.01$) than cord plasma. Higher LCPUFA in cord plasma indicates capacity for synthesis by the mare and selective placental transfer to the foal. Higher LCPUFA in foal plasma compared with mare plasma likely reflects mobilization of FA deposited in utero, intake from milk, and synthesis of LCPUFA from precursors consumed in milk. Greater Δ5-desaturase activity in foal compared with cord plasma indicates capacity for 20:4ω6 and 20:5ω3 synthesis by the foal. However, low Δ6-desaturase activity in foal plasma suggests fetal stores of LCPUFA are critical to support pre- and postnatal development of neural tissues.

Key Words: DHA, essential fatty acids, horse

123 Profiling the change in fecal microbial populations of mares and foals over time. J. E. Earing*[1], A. C. Durig[1], G. L. Gellin[2], M. D. Flythe[2], and L. M. Lawrence[1], [1]*University of Kentucky*, *Lexington*, [2]*USDA-ARS*, *Lexington, KY*.

The gastrointestinal tract of the mature horse contains a complex community of microorganisms, many of which aid in digestion. Little information is available concerning the establishment of these microbial populations in young horses. The limited research that has been conducted has utilized culture-dependant methods, but culture-independent methods have revealed that cultivation underestimates species diversity. Polymerase chain reaction-denaturing gradient gel electrophoresis (PCR-DGGE) is a molecular technique that can be used to evaluate diversity in microbial communities. The objective of this study was to compare the microbial profiles of the feces of mares and foals using

PCR-DGGE in an attempt to describe bacterial colonization in the equine gut. The hypothesis was that foals would be born sterile, and would be indistinguishable from mares by 12 wk of age. Nine mare/foal pairs were used for the study. Fecal samples were collected from each mare and foal as the foal matured; samples were subjected to PCR-DGGE. Comparisons between mares and foals were made using UPGMA cluster analysis and reported as percent similarity. The mean similarity between mares and their foals was 11% on the day of parturition (d 0; n = 2), 51% on d 1 (n = 4), 52% on d 4 (n = 3), 67% at wk 2 (n = 4), 71% at wk 6 (n = 5), and 70% at wk 12 (n = 5). These results indicate that most of the colonization events occurred within the first few days of the foal's life, which is consistent with a study utilizing culture-based techniques. By wk 2, the mean similarity between mares and foals was numerically higher than the mean similarity among mares (61%), suggesting that by 2 wk of age the bacterial species found in the foal's gut are similar to those found in the mature horse. While PCR-DGGE can be used to examine the diversity of bacteria present in the gut, it does not estimate the relative abundance of the bacterial populations. Also, the presence of bacterial DNA in feces suggests, but does not prove, colonization of the gut by the respective bacterial populations.

Key Words: DGGE, horse, microbes

124 Stallion spermatozoal parameters of motility and conception rates on a large commercial ranch. A. L. Garcia[1], H. A. Brady*[1], M. A. Ballou[1], D. D. Varner[2], C. C. Love[2], and G. Blodgett[3], [1]*Texas Tech University*, *Lubbock,* [2]*Texas A&M University*, *College Station,* [3]*6666 Ranch*, *Guthrie, TX*.

Stallion ejaculate values and variability over a breeding season based large numbers are not available for clinical and research use. Further, there are conflicting reports on the predictive value of motility for fertility in the horse. The objectives of this study were to evaluate ejaculates from a large number of stallions over an entire breeding season with advanced techniques and to evaluate the relationships of motility to conception rates of mares. Semen collections (n = 602) from a total of 19 stallions at a ranch in Guthrie, Texas, were evaluated over the 2008 breeding season. Ejaculates were evaluated using a new advanced system, the NucleoCounter (Chemometic, Allerød, Denmark) and the IVOS system (Hamilton Thorne, Beverly, USA). The mean total sperm, concentration, and gel-free volume were 11.25 billion (±2.5), 247.6 million/ml (±72.1) and 50.42 mL (±15.1), respectively. It was determined there were high inter- and intra-stallion variability in parameters of motility studied. Highest intra-stallion variables were moderately progressive cells (cv = 42.7) and total concentration (cv = 37.7) and the least variable parameters were flagellar beat frequency (BCF) (cv = 5.7) and % linearity (cv = 8.0). Highest inter-stallion variables included mount attempts (cv = 47.5) and % moderately progressive cells (cv = 30.5), and the least variable parameters included the BCF (cv = 7.6) and % straightness (cv = 9.6). An odds-ratio procedure and backward logistical regression procedure was used to calculate the influence of motility and concentration parameters on the pregnancy outcome. A total of 328 on-the farm mares were bred by A.I. with a 91% pregnancy rate. No correlation between motility parameters and the pregnancy binomial status was found; however, all stallions were very fertile and the on-site breedings were under consistent management. In summary, this study has provided important clinical standards on ejaculate values based on a large group of ejaculates using advanced techniques. These values have important clinical implications for more accurate standards within the breeding soundness examination of the stallion.

Key Words: stallion, spermatozoa, motility

125 Weight estimation in miniature horses and Shetland ponies. AM Bruce*, EL Wagner, and PJ Tyler, *Auburn University*, *Auburn, AL*.

Reliable weight estimation in the small breeds of horses is critical to the animals' well-being. To properly feed or medicate, bodyweight needs to be as accurate as possible to reduce the risk of error. The 2 common weight estimation practices used for average sized horses are commercially available weight tapes and an established formula, where estimated weight (lbs), (kg) = (heartgirth^2 × body length)/(330 in^3), (11880 cm^3). The objectives of this study were 1) evaluate the accuracy of the weight tape and current formula in estimating body weight of the small breed horse and 2) calculate a more exact formula for miniature horses and Shetlands. Fifty-four miniature horses and 15 Shetland ponies of varying ages were measured. Actual weight was determined via a calibrated electronic livestock scale. Other measurements included height at the withers, body length as measured from the point of the shoulder to the point of the buttock, heart girth, and weight tape. Mean age of the animals was 4.23 ± 3.47 years, with a mean height of 92.21 ± 10.36 cm, and a mean body condition score of 6.3 ± 0.85 based on a 9 point scale. Paired *t*-tests were used to compare the tape weight and formula weight with the actual weight. There was a significant difference ($P < 0.05$) between the tape weight (112.66 ± 33.99 kg) and the actual weight (108.71 ± 31.44 kg). The difference between actual weight and the formula estimated weight (100.52 ± 30.83 kg) was also significant. Linear regression was used to determine a more accurate denominator for the formula. Using the new denominator of 11061 cm^3 (307 in^3) a new mean estimated weight of 108.12 ± 33.16 kg was calculated, which was significantly different from weight calculated by the previous equation. The new denominator appears to be a more accurate method of estimating weight in miniature horses and Shetland ponies. To validate the new equation more miniature horses and Shetland ponies need to be evaluated.

Key Words: weight estimation, body measurements, miniature horse

126 Evaluation of body weight estimation methods in horses. E. L. Wagner* and P. J. Tyler, *Auburn University*, *Auburn, AL*.

Weight tapes and body weight estimation formulas are routinely used to help determine the body weight of a horse when a scale is not available. The formula incorporates measurements of body length and heart girth circumference to estimate body weight in mature horses, where estimated weight (lbs), (kg) = (heartgirth^2 × body length)/(330 in^3), (11880 cm^3). Two variations of the body length measurement have been published. One measures the distance from the point of the shoulder to the ischial tuberosity (point). The other measures the distance from the point of the shoulder to the midpoint of the distance between the widest part of the stifle and the tail when viewed from the rear (stifle). The objective of this study was to evaluate the accuracy of a commercial weight tape and the body weight estimation formula using both body length measurements in estimating weight of adult horses. Seventy-one horses of various breeds were weighed on a portable livestock scale. Horses were measured for height at the withers, heart girth circumference and body length using the point and stifle measurements. A commercial weight tape was used to estimate body weight on 36 of the horses. Statistical analysis was performed by paired *t*-tests and simple linear regression using STATA statistical software with significance set at $P < 0.05$. Mean height was 159.34 ± 9.27 cm with a mean scale weight of 516.94 ± 81.93 kg. Point body length was significantly longer than stifle body length (170.56 ± 9.27 cm and 161.99 ± 8.14 cm, respectively).This resulted in a significant difference between the formula estimated weights using the 2 length measurements. The 2 formula weight estimations (n = 71)

and the weight tape estimation (n = 36) were significantly different from the actual weight and from each other. The mean difference between actual weight and tape weight (n = 36) was 65.35 ± 46.23 kg, whereas the differences between actual weight and the formula estimations (n = 71) were 19.83 ± 38.99 kg for the point measurement and 43.44 ± 39.74 kg for the stifle measurement. The estimation formula using body length measurement with the ischial tuberosity endpoint most closely estimates the actual body weight of the horses.

Key Words: horse, weight estimation

National ADSA Dairy Foods Oral: Dairy Foods Oral Student Competition

127 The effect of sodium gluconate on pH, lactose, lactic and, and water soluble Ca changes during Cheddar cheese ripening. C. Phadungath*[1] and L. E. Metzger[2], [1]*Midwest Dairy Foods Research Center, University of Minnesota*, *St Paul,* [2]*Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

Sodium gluconate increases the solubility of calcium late in model solutions by forming soluble sodium-lactate-gluconate complexes. However, its effect on the main components responsible for calcium lactate crystals in Cheddar cheese, which are lactic acid and water soluble calcium, has not been reported. The objective of this study was to determine the effect of sodium gluconate on pH, lactose, lactic acid, and water soluble Ca changes during Cheddar cheese ripening. Six Cheddar cheeses with 2 salting levels (2 and 2.5%) and 3 sodium gluconate levels (0, 0.5 and 1%) were manufactured in triplicate. Composition and chemical analysis was performed at 1 week of ripening, and at 1 week, 3, 6, 9, and 12 mo of ripening. Cheeses were analyzed for pH, lactose and lactic acid, and water soluble calcium (WSC). Compositional analyses at 1 week indicated that sodium gluconate addition had a significant effect on cheese pH, moisture, Na, lactose, and lactic acid. Cheddar cheeses from both 2% and 2.5% salt levels with higher concentration of sodium gluconate exhibited higher pH than the control cheeses throughout the ripening time, which corresponded to the concentration of lactic acid in the cheeses. HPLC results from Cheddar cheeses from both 2% and 2.5% salt levels indicated that cheeses with higher concentration of sodium gluconate addition had higher concentration of lactose, but lower concentration of lactic acid when compared with the control cheeses throughout the ripening time. WSC results indicated that Cheddar cheeses from both 2% and 2.5% salt levels with higher concentration of sodium gluconate addition had lower WSC concentration when compared with the control cheeses throughout the ripening time. From the results, we concluded that sodium gluconate could have an effect on starter culture activity and could also act as buffering agent, which would cause a higher cheese pH. A higher cheese pH resulted in less soluble of calcium in the cheese serum; thus, resulting in less calcium and lactate ions in the cheese serum.

Key Words: calcium lactate crystal, water soluble calcium, sodium gluconate

128 The impact of starter culture and annatto on the flavor and functionality of whey protein concentrate. R. E. Campbell*, R. E. Miracle, and M. A. Drake, *North Carolina State University*, *Raleigh*.

The flavor of whey protein can carry through into ingredient applications and negatively influence consumer acceptance. Understanding sources of flavors in whey protein is crucial to minimize flavor. The objective of this study was to evaluate the impact of annatto color and starter culture on flavor of whey protein concentrate (WPC). Cheddar cheese whey with and without annatto (15mL/454kg with 3% norbixin content) was manufactured using a mesophilic lactic starter culture or by addition of lactic acid and rennet (rennet-set). Pasteurized fat-separated whey was then ultrafiltered and spray dried into WPC62. The experiment was replicated 4 times. Flavor of liquid wheys was evaluated by sensory and instrumental volatile analyses, and sensory and instrumental analyses, color analyses (Hunter Lab and norbixin extraction) and functionality (solubility and heat stability) were performed on WPC. Both main effects (annatto, starter) and interactions were investigated. No differences in sensory properties or functionality were observed among WPC ($P > 0.05$). Lipid oxidation compounds were higher ($P < 0.05$) in WPC manufactured from whey with starter culture compared with WPC from rennet-set whey. WPC with annatto had higher concentrations of p-xylene, diacetyl, pentanal, and decanal ($P < 0.05$) compared with WPC without annatto. Interactions ($P < 0.05$) were observed between starter and annatto for hexanal, suggesting that annatto may have an antioxidant effect when present in whey made with starter culture.

Key Words: whey, antioxidant, flavor

129 Exopolysaccharides modify the functional properties of whey protein concentrate. G. Deep* and A. Hassan, *Midwest Dairy Foods Research Center, Dairy Science Department*, *South Dakota State University, Brookings*.

The objective was to study the effect of exopolysaccharides (EPS) on the functional properties of whey protein concentrate (WPC). Exopolysaccharides producing cultures are used to improve the physical properties of reduced fat cheeses. It was hypothesized that EPS released in the whey would modify the functional properties of WPC due to their interaction with whey proteins. An EPS-producing culture of *Lactococcus lactis* ssp. *cremoris* (JFR), an EPS-producing culture of *Streptococcus thermophilus* (DP) and an EPS-nonproducing commercial cheese culture (DVS 850) were used in this study. Cultures were grown overnight in reconstituted WPC (10% w/w) which was then added, directly or after overnight cooling, at 2% to rehydrated dry whey (6% w/w). This gave a level of EPS similar to that found in whey from cheese made with EPS-producing cultures. Whey was then pasteurized at 75°C for 35 s and ultrafiltered 5 times. Ultrafiltered whey (retentate) was spray dried at inlet and outlet air temperatures of 200°C and 90°C, respectively. The protein level in WPC was about 32%. Results showed that EPS decreased ($P < 0.05$) the minimum gelling concentration and protein denaturation, and increased emulsifying capacity and gel hardness of WPC. Exopolysaccharides from DP culture showed more pronounced changes in functionality of WPC than did EPS from the JFR culture. Cooling of the fermented medium containing EPS, before its addition to whey, increased ($P < 0.05$) gel hardness and emulsifying capacity of WPC. This is possibly due to effect of cooling on interactions within EPS molecules and between EPS and proteins. This study demonstrated that application of EPS-producing cultures in cheese making modified the functional properties of WPC. Further studies will be directed toward understanding the effect of EPS structure and their interaction with whey protein on WPC functionality.

Key Words: exopolysaccharides, whey protein concentrate, functional properties

130 Evaluation of the effects of cheese milk fat content on the lipid composition and flavor of liquid whey and whey protein concentrate. A. E. Croissant*[1], L. Dean[2], and M. A. Drake[1], [1]*North Carolina State University*, *Raleigh,* [2]*USDA-ARS, North Carolina State University*, *Raleigh.*

Lipid oxidation is generally considered the most important degradation process to food products, and whey products are no exception. Ongoing research has established that lipid oxidation is initiated during the cheese make process. A relationship between lipids and phospholipids and flavor and flavor stability of WPC80 has not been established. The objective of this study was to evaluate the effect of 3 milk fat levels in cheese milk on the lipid composition of fluid whey and WPC80 and subsequent effects on flavor and flavor stability. WPC80 was manufac-

tured from uncolored Cheddar whey in triplicate. For each replication, pasteurized whole, low fat, and skim milk (3.25, 1, and 0.25% milk fat, respectively) were acquired from a single batch of milk. Spray dried WPC80 was produced from each milk on successive days and order was balanced between replications. WPC80 were evaluated by sensory and instrumental analyses as well as proximate analyses. Lipid concentrations in WPC80 from whole, low fat, and skim milk were 5.03, 3.90, and 3.45%, respectively. Whole milk WPC80 was higher in cardboard flavor ($P < 0.05$) compared with low fat and skim WPC80. WPC80 from whole milk also had higher relative abundances of oxidation reaction products including heptanal, hexanal, octanal, nonanal, and 1-octen-3-one ($P < 0.05$) compared with low fat and skim WPC. Results indicate that cheese milk lipid concentration does impact the lipid composition of WPC as well as the flavor and volatile compounds associated with lipid oxidation. Currently, low and reduced-fat cheese whey streams are combined with full-fat cheese whey streams in WPC manufacturing. Reduced-fat cheese production is situated to increase greatly given the growing consumer and governmental interest in fat reduction. The examination of the impact of reduced-fat cheese production on the flavor and lipid composition of whey protein concentrates has the potential to influence the creation of a value-added whey protein product.

Key Words: WPC, lipids, low fat

131 Growth and production of volatile compounds by *Lactobacillus casei* in Cheddar cheese extract under cheddar cheese ripening condition. H. Cai*[1], M. Budinich[1], W. Tan[1], E. Miracle[2], J. Broadbent[3], M. A. Drake[2], and J. Steele[1], [1]*University of Wisconsin*, *Madison*, [2]*North Carolina State University*, *Raleigh*, [3]*Utah State University*, *Logan*.

Lactobacillus casei are commonly used as adjunct cultures for the control of off-flavors, as well as the intensification and acceleration of beneficial flavors in bacterial-ripened cheeses. In this study, 22 *Lb. casei* strains were screened in a model system for attributes likely to influence their potential to serve as adjunct cultures for the manufacture of Cheddar cheese. The model system used was 4-mo-old Cheddar cheese extract supplemented with citrate (4mCCE–cit) and the experiment was conducted under Cheddar cheese ripening condition (pH5.1, 3.1% NaCl, and 8°C). The attributes screened for were the ability to dominate the NSLAB microbiota, produce volatile flavor compounds, and hydrolyze bitter peptides. None of the *Lb. casei* strains examined could degrade the model bitter peptide β-CN(f193–209) under the condition examined. Six strains (A2-309, CRF28, L9, M36, UW1 and UW4) exhibited growth parameters in the model system, relatively short lag phase, rapid growth rates, and high final cell densities, likely to be associated with the ability to dominate the NSLAB microbiota of Cheddar cheese. Significant increases in 2,3-butanedione accumulation was observed with 7 of the *Lb. casei* strains examined; 2,3-butanedione is strongly associated with the beneficial buttery note in young Cheddar cheese. Significant decreases in phenylethanal concentrations were observed for 9 strains and significant increases in phenylethanol concentrations were also observed for 9 strains. The use of culture adjuncts that reduce the level of phenylethanal would likely result in Cheddar cheese with a reduced rosy note. The results of this study provided a starting point for the rational selection of culture adjuncts to control cheese flavor development in Cheddar cheese.

Key Words: *Lactobacillus casei*, volatile, Cheddar cheese ripening

132 Interaction between casein micelles and serum protein/κ–casein complexes during renneting of heat–treated skim milk. P. Kethireddipalli*, A. R. Hill, and D. G. Dalgleish, *University of Guelph*, *Guelph, ON, Canada*.

Heat-induced complexes of whey protein (WP) and κ-casein (κ-CN) can impair rennet clotting of native casein micelles; coagulation can be mostly restored by dialyzing the complex–laden serum against unheated milk (to be published). The present study investigated the mechanism of interaction between casein micelles and WP/κ-CN complexes during renneting of heat-treated milk. Native casein micelles were separated from unheated skim milk and re–suspended in the serum of heated (90°C, 10 min) milk, with and without dialysis of the serum against unheated milk. Using size exclusion chromatography, it was found that in both milk systems, the WP/κ-CN complexes progressively bind to the casein micelles as renneting proceeded. At about 85% κ-CN cleavage (caseinomacropeptide was quantified), the protein complex peak area decreased by 30 ± 5% and at 90% cleavage (prior to onset of clotting), peak area reduction was 50 ± 4%. In the absence of micelles, renneting of protein complexes in isolation showed no significant self aggregation, even when 90% κ-CN had been proteolyzed. Enzyme treatment of the dialyzed serum, however, resulted in significant aggregation of complexes (20 ± 2% at about 90% κ-CN cleavage), but to a much lesser extent than when casein micelles were present. Similar trends were noted when casein micelles from milk heated at native pH 6.7 (some surface-bound WP/κ-CN complexes), pH 7.1 (nearly complex-free micelle surface) or pH 6.3 (complex-saturated surface) were suspended in the serum of heated milk. No matter what the micelle surface was, all micelles were capable of binding more serum protein complexes in the course of renneting. These results are strong evidence that impaired rennet clotting of native casein micelles suspended in the serum of heated milk is due to the binding of WP/κ–CN complexes to the micelle surface prior to the onset of micelle aggregation, thereby sterically impairing the aggregation process. For reasons possibly related to ionic equilibria, heat-induced protein complexes in serum dialyzed against unheated milk are less detrimental to micelle fusion.

Key Words: whey protein/κ-casein complexes, heated milk, rennet

133 Starter cultures and cattle feed manipulation enhance conjugated linoleic acid levels in Cheddar cheese. M. S. Mohan*, S. Anand, K. F. Kalscheur, and A. N. Hassan, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

Conjugated linoleic acid (CLA) is a fatty acid that provides several health benefits to humans. In our previous research, a CLA-producing starter culture of Lactococcus lactis (CI4b) increased the CLA content in Cheddar cheese. Addition of fish oil to cattle diets has also been reported to increase the CLA content in milk. Thus, it was hypothesized that the use of the CLA-positive starter (CI4b) along with high CLA milk (obtained through dietary manipulation in cattle) would enhance the CLA content in Cheddar cheese. A diet containing fish oil (0.75% of dry matter) was fed to 32 dairy cows grouped in a pen for 15 d. This increased the CLA cis-9, trans-11 (CLA1) and CLA trans-10, cis-12 (CLA2) content from 0.8 and 0.13 g/100 g of fatty acids in the normal milk to 1.22 and 0.27 g/100g fatty acids in the treatment milk, respectively. A 2 × 2 factorial treatment design was used to test the effect of culture (DVS vs. CI4b) and type of milk (normal vs. treatment milk) on CLA content in Cheddar Cheese. A commercial cheese starter (DVS) was selected as the CLA nonproducing culture. Chemical composition (moisture, salt, fat, protein) of cheese was not affected by the type of culture used ($P > 0.05$). The textural properties (hardness, gumminess, chewiness) showed an interaction between milk and culture ($P < 0.05$) in the 1 mo old cheese. The 1 mo old cheese made from normal milk with DVS culture, normal milk with CI4b culture, treatment milk with

DVS culture and treatment milk with CI4b culture contained 0.34, 0.39, 1.03, 1.10 (±0.09) of CLA1 concentration and 0.06, 0.10, 0.18, 0.21 (±0.13) of CLA2 concentration (g/100 g of fatty acid), respectively. The treatment milk resulted in increased ($P < 0.01$) CLA1 and CLA2, while the CI4b culture increased only CLA2 levels ($P = 0.03$) in cheese. The results indicated that the combination of a CLA producing starter culture and dietary manipulated milk could enhance levels of CLA (CLA1 + CLA2) in Cheddar cheese by up to 3.3 times.

Key Words: conjugated linoleic acid, fish oil, cheddar cheese

134 Transcriptional stress responses to hydrogen peroxide in *Bifidobacterium longum*. T. S. Oberg*[1], J. L. Steele[2], S. C. Ingham[2], and J. R. Broadbent[1], [1]*Utah State University*, *Logan,* [2]*University of Wisconsin*, *Madison*.

Commercial application of bifidobacteria probiotics in function foods has increased dramatically in recent years. Due to the anaerobic nature of bifidobacteria, however, oxidative stress can significantly diminish viability of bifidobacteria during food production and storage. To better understand mechanisms for oxidative stress resistance in these cells, we examined the transcriptional stress responses to hydrogen peroxide (H_2O_2) of *Bifidobacterium longum* NCC2705, a strain that exhibits oxidative stress resistance, and *B. longum* D2957, a strain that does not. Bacteria were grown in MP5 medium to late logarithmic phase under anaerobic conditions with pH control, then suspended in MP5 with 0.625 mM H_2O_2 and incubated 5 or 20 min (NCC2705) or for 5 or 60 min (D2957). mRNA was isolated from each sample, converted to cDNA, and hybridized to a custom made Affymetrix DNA array. Three biological replicates of each treatment were performed. The microarray data was preprocessed using the RMA-MS method, filtered to only include genes with high signal intensity and a low coefficient of variation, then tested for differential expression using the limma/eBayes method (P value <0.05). Results showed *B. longum* NCC2705 had 316 genes that were differentially expressed after the 5-min treatment and 131 differentially expressed genes after the 20-min treatment. In contrast, D2957 had only 24 and 116 differentially expressed genes after the 5-and 60-min treatments, respectively. Both strains showed upregulation of genes associated with an oxidative stress response, including thioredoxin reductase, peroxiredoxin, ferridoxin and glutaredoxin. However, NCC2705 showed more extensive upregulation of genes involved in transcription regulation, a greater number of downregulated genes involved in sugar transport and metabolism, and several other differences. These observations provide a platform for future functional genomics research to determine the molecular basis for differences that are observed in oxidative stress resistance among strains of *B. longum*.

Key Words: probiotics, bifidobacteria, oxidative stress

135 Positive influence of milk on the expression of some stress-induced genes in *Bifidobacterium longum*. W. Dominguez* and D. J. O'Sullivan, *University of Minnesota*.

The objective of this study is to define the genes encompassing the yogurt fermentation stress regulon in *B. longum* DJO10A. A genome-wide microarray analysis was conducted on total RNA from samples taken at different time points during a yogurt fermentation with *B. longum*DJO10A. A control yogurt fermentation revealed that cross-hybridization of the yogurt starter culture transcripts with the microarray was essentially negligible under these fermentation conditions. During the fermentation, a set of genes located in 5 clusters, some of which have previously been associated with stress protection, were significantly expressed. These consisted of the *dnaK* and ibpA gene clusters, *groL*, a predicted gene BLD_1532, and genes encoding the F_0F_1-type ATP synthase. These 5 gene clusters were defined as the bifidobacteria stress regulon for yogurt fermentation and 4 genes were selected for further analysis using real-time PCR. Primers and TaqMan probes were designed to monitor the expression of these genes when the culture was exposed to milk and media supplemented with glucose or lactose and when the pH was decreased to 4.5. As the pH dropped in the media, low upregulation (<2 times) was observed in all the tested genes, except for *ibpA*, which was 8 times higher at the final pH (4.5) compared with the initial pH (6.4). However, when the cells sensed the pH drop in milk, they responded by upregulating *ibpA* and BLD_1532 by 30 and 5 times respectively. The expression of *ibpA* is induced by acid stress and milk components, other than lactose. A low pH in milk upregulates *ibpA* at a higher level than the presence of acid by itself and BLD_1532 expression is upregulated at low pH only when milk components are present. This suggests that the higher expression of these stress-induced genes in milk may afford a protective effect on bifidobacteria from acid or other stresses.

Key Words: bifidobacteria, probiotics, microarray

136 Impact of color of low fat Cheddar cheese on consumer preference. R. Wadhwani*, D. J. McMahon, and C. Maughan, *Utah State University*, *Logan*.

To observe if color impacts low fat cheese consumer preference, 9 batches of low fat Cheddar cheeses were manufactured at USU with 3 different levels of annatto (0, 7.34, and 22 g/100 kg) and TiO_2 (0, 7.67, and 40 g/100 kg) in a 3 × 3 completely randomized block design and aged 60 d before consumer liking assessment. The IRB approved consumer panel was conducted with 120 panelists recruited from the vicinity through newspaper advertisements, emails, and flyers. Panelists evaluation and responses were recorded anonymously in computers using SIMS 2000 program. Population studied were 18 to 35 years of age with >60% were frequent cheese consumers. Among 9 combinations, cheese with no color, intermediate and maximum level of annatto and TiO_2 combination were rated significantly higher for overall liking than other combinations ($P < 0.05$) on a 9-point hedonic scale of degree of liking. Interestingly, maximum level of TiO_2 when added singly, was rated higher (6.27) along with the combination of both TiO_2 and annatto, however, annatto when added singly, was rated significantly lower (4.82). Regarding the flavor and appearance liking, exactly same responses were observed and both intermediate and maximum levels of both colors in combination and maximum level of TiO_2 were rated significantly higher than other levels tested. However, texture rating was slightly different than previous attributes. For texture liking, consumers did not prefer the maximum level of TiO_2 and rated significantly lower (5.52) than intermediate and maximum levels. Panelists were also asked to evaluate these samples for the sharpness level on a 4-point scale where 1 = mild and 4 = extra sharp. The panelists rated maximum level of TiO_2 as significantly milder (1.48) and maximum level of annatto as significantly sharper (2.76) than other levels of color ($P < 0.05$). All panelists unanimously responded that these samples contained 24–26% fat when asked to assume the fat level wherein reality they all contained 6% fat. This study clearly indicated a significant impact of color on overall liking of Cheddar cheese and consumers' responses were driven by the appearance of cheese.

Key Words: color, Cheddar, liking

Nonruminant Nutrition: Amino Acids 1

137 Dietary supplementation of L-glutamine and L-glutamate to newly hatched broiler chickens. Y. Zhao*[1], P. R. Ferket[1], G. Wu[2], K. Nakagawa[3], and S. W. Kim[1], [1]*North Carolina State University*, *Raleigh*, [2]*Texas A&M University*, *College Station*, [3]*Ajinomoto Co. Inc.*, *Tokyo, Japan*.

This study was conducted to evaluate effects of supplemental L-glutamine (Gln) and L-glutamate (Glu) on growth and physiological responses in broiler chickens. Within 8 h after hatching (36.1 ± 1.1 g BW), 480 broiler chickens were allotted randomly to 6 dietary treatments: NC (without Gln or Glu), GN5 (with 0.5% Gln), GN10 (with 1.0% Gln), GU5 (with 0.5% Glu), GU10 (with 1.0% Glu), and AG10 (with 1.0% AminoGut, consisting of L-Gln >10% & L-Glu >10%, Ajinomoto). Each treatment had 8 replicates with 10 birds per cage. Diets were fed ad libitum for 6 wk. Body weight and feed intake were measured weekly. At the end of wk 1 and 6, one bird per cage was selected randomly to measure the weights of gut, breast muscle, thigh muscle, liver, and abdominal fat pad, and to obtain blood samples. Jejunum samples from wk 1 were used to measure villus height and crypt depth. Blood samples from wk 1 and 6 were used to measure plasma IgG and IgA concentration. Initial BW did not differ among treatment groups. During the entire period, weight gain of GN10 was greater ($P < 0.05$) than those of GN5, GU5, and NC. The weight gain of AG10 was greater ($P < 0.05$) than that of NC. Feed intake of birds did not differ among treatment groups during starter, grower, and finisher phases. There was no difference in feed:gain among treatment groups during the entire period. At the end of wk1, villus height or crypt depth of birds did not differ among treatment groups. There were no difference in the % weight of each tissue among treatment groups when measured at the end of wk 1 and wk 6. Plasma IgA concentration of AG10, GN5, and GU5 were greater ($P < 0.05$) than that of NC at wk 6. Plasma IgG concentration of AG10 was greater ($P < 0.05$) than that of other treatment groups at wk 6. This study shows potential benefits of supplemental glutamine or AG to broiler chickens.

Key Words: broilers, glutamate, glutamine

138 The digestible lysine requirement of Cobb 500 x Hubbard M99 male broilers from 35 to 49 days. M. D. Dimova*[1], R. B. Shirley[2], J. L. Usry[2], P. B. Tilman[2], M. E. Freeman[1], and A. J. Davis[1], [1]*University of Georgia*, *Athens,* [2]*Ajinomoto Heartland, LLC*, *Chicago, IL*.

An experiment was conducted to determine the digestible lysine (dLys) requirement of the male, Cobb 500 fast-feathering female × Hubbard M99 male cross during the withdrawal period (35 to 49 d of age). Day-of-hatch birds were randomly allotted to 96 floor pens (4 rooms, 24 pens per room, 50 chicks per pen) and reared on used litter from 3 previous flocks. All chicks were fed the same starter (0 to 7 d), grower (7 to 21 d), and finisher (21 to 35 d) diets and these diets were formulated to exceed the Cobb 500 guidelines. On d 35 the number of birds was adjusted to 42 birds per pen and the 96 pens were assigned to one of 8 dietary treatments (12 replicates per treatment, 3 replicate pens per treatment in each room). The treatment diets were derived from a common base diet and common summit diet. The common base diet supplied 3,215 kcal/kg, 13.71% crude protein (CP) and 0.62% dLys, and the common summit diet supplied 3,215 kcal/kg, 23.59% CP and 1.24% dLys. By blending the base and summit diets, 6 intermediate levels of dLys were produced (0.71, 0.80, 0.89, 0.97, 1.06, and 1.15%). The minimum ideal essential amino acid ratios were maintained between the 8 diets; however, the dietary CP changed by an increment of 1.41% as the level of dLys changed. Broken-line regression analyses estimated the dLys requirement per bird in the withdrawal phase to be 24.45 g for body weight gain, 28.56 g for feed consumption, 25.61 g for feed conversion, and 25.28 g for total white meat yield (Pectoralis major and minor). The dLys requirement as a % of diet for body weight, feed consumption, feed conversion and total white meat was 0.86, 1.07, 0.91 and 0.90, respectively. This study aids in further defining the dLys requirement of the 35–49 d-old male, Cobb 500 fast-feathering female × Hubbard M99 male cross.

Key Words: broiler performance, meat yield, amino acid requirement

139 The effect of dietary pea and amino acid levels on the performance of broiler chickens. S. M. Ebsim*[1], T. D. Warkentin[2], and H. L. Classen[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*, [2]*Crop Development Centre, University of Saskatchewan*, *Saskatoon, Saskatchewan, Canada*.

Pea is an important crop in Western Canada with considerable potential as a feed ingredient for broilers. Pea has also been recognized for its slowly degraded starch, which has been suggested to reduce the amino acid requirement of broilers. Therefore, an experiment was designed to investigate maximum inclusion levels of pea in broiler diets and the interaction of dietary pea and amino acid inclusion. A growth trial with 3,480 broiler chickens was conducted in a 6 × 2 factorial arrangement evaluating 6 levels of pea inclusion (0, 150, 300, 450, 600, 750 g/kg) and 2 levels of amino acids (100% and 85% of Ross × Ross 308 requirement). Each treatment was offered to 5 pens of 58 males from 0 to 35 d. No interactions were found between pea inclusion and amino acid level for all studied parameters. The higher level of amino acids increased breast meat ($P = 0.0267$) and improved mortality corrected feed efficiency ($P = 0.0437$). Pea inclusion level affected performance in an age dependent manner. Body weight gain from 0 to 10, 10 to 25 and 25 to 35 d decreased when pea level exceeded 300, 600 and 600 g/kg, respectively. Mortality corrected feed to gain ratio was increased by pea inclusion when values exceeded 600 and 300 g/kg for 0 to 10 and 10 to 25 d periods but was unaffected by pea level from 25 to 35 d. Broilers fed pea levels above 450 g/kg had reduced carcass and breast weight ($P = 0.0001$) as a proportion of live weight. High levels of pea inclusion decreased proportional breast (600 and 750 g/kg) and drum skin (750 g/kg) weight. In conclusion, maximum pea inclusion levels increase with broiler age and no interactions were found between dietary treatments at the levels of amino acids used in this research.

Key Words: broilers, pea, starch, amino acid

140 Effect of a mono component protease on true amino acid digestibility of full fat soy for broiler chickens using different methods. R. K. G. Messias[1], L. F. T. Albino[1], J. O. B. Sorbara*[2], and H. S. Rostagno[1], [1]*Universidade Federal de Viçosa*, *Viçosa, MG, Brazil*, [2]*DSM Nutritional Products*, *São Paulo, SP, Brazil*.

Different methods have been used to determine the true amino acid digestibility (TAAD) of feed ingredients. All methods were always used to estimate the TAAD of only one ingredient and were not developed to determine the effect of an additive (ex. enzymes) on a single ingredient.

Based on this, a digestibility trial was conducted to determine the effect of 2 different methods on TAAD of full fat soy (FFS) when using a mono component protease. The trial was conducted with 336 broiler chicks from 12 to 22 d of age placed on wire cages, in a complete randomized experimental design with 8 treatments and 6 replicates of 7 birds each. The first 4 treatments were used to evaluate the classic method using a protein free diet (PFD) where FFS replaced 30% of starch in the PFD with and without the protease addition. Treatments 5 to 8 were used to evaluate a second method. Treatment 5 was a corn soy basal diet with 30% starch and treatment 6 was the basal diet (T5) but FFS replaced the starch. Treatments 7 and 8 were the same T5 and T6 with protease addition. The mono component protease used (dose 200 ppm) was RONOZYME ProAct with 75000 Prot Units/g. At 22 d all birds were sacrificed and ileal digesta collected. Acid insoluble ash (Celite) was used as inert marker. Feed and water were provided ad libitum. At 22 d of age all birds were sacrificed and ileum content collected. The samples were freeze-dried at −40°C for 72 h. No interaction was observed between method and protease addition. Protease addition increased ($P < 0.05$) TAAD of FFS by 3%, 3%, 9%, 7%, 2%, 7%, 4%, 5%, 6%, 12%, 8%, 7%, 8%, 8% for Lys, Met, M+C, Thr, Val, His, Arg, Phe, Gly+Ser, Asp, Glu, Ala, Pro, Tyr, respectively. The method with the basal diet plus FFS showed 18% lower TAAD (mean sum of AAs) as compared with the PFD method. In conclusion the protease supplementation improved TAAD of FFS on average 6% independently of the method used.

Key Words: enzyme, nutrition, method

141 Ileal digestibility of the amino acids of soybean meals of different origin in broilers. M. Frikha[1], M. P. Serrano[1], D. G. Valencia[2], C. Centeno[3], R. Lázaro[1], and G. G. Mateos*[1], [1]*Universidad Politécnica de Madrid*, *Madrid, Spain*, [2]*Nutral S.A.*, *Madrid, Spain*, [3]*CSIC*, *Madrid, Spain*.

A trial was conducted to determine the apparent (AID) and standardized (SID) ileal digestibility of CP and AA of 22 soybean meals (SBM) from 3 different origins; USA, Brazil (BRA), and Argentina (ARG) in 21-d-old broilers. There were 7 to 8 samples of SBM per origin and 6 replicates (6 chicks each) per each SBM sample. On DM bases, the average CP was 53.5, 55.3, and 52.3% for USA (n = 8), BRA (n = 7), and ARG (n = 7) meals, respectively. The concentration of Lys and Met per unit of protein was highest ($P < 0.01$) for the USA meal and lowest for the BRA meal with ARG meal being intermediate. The KOH solubility was higher for USA than for BRA and ARG meals (86.5, 82.8, and 80.0%; ($P < 0.05$) but trypsin inhibitor activity (TIA) was similar for all origins (3.0 mg/g DM). Chicks were fed a commercial corn-soybean meal diet from 1 to 17 d and then, their respective experimental diets, with the SBM tested as the only source of CP (20%), from 18 to 21 d of age. In addition, a N-free diet was used to estimate ileal endogenous losses of the AA in 6 extra replicates. The AID of the 22 SBM samples ranged from 82.9 to 88.0 for CP, from 85.0 to 90.5 for Lys, and from 66.4 to 75.0 for Cys. In general, the AID of CP and of most indispensable AA were similar for USA and BRA SBM meals and for both higher (($P < 0.01$) than for ARG meal (i.e., 88.2 and 88.1 vs. 86.7 for Lys and 88.0 and 89.1 vs. 86.6 for Met, respectively). The SID values of the 22 SBM samples ranged from 89.3 to 94.6 for CP, from 90.1 to 94.9 for Lys, and from 78.5 to 85.4 for Cys. The SID values of most indispensable AA were similar for USA and BRA meals and higher for both (($P < 0.05$) than for the ARG meal (i.e., 93.0 and 92.7 vs. 91.8 for Lys and 95.6 and 96.9 vs. 94.9 for Met). It is concluded that the ileal digestibility of CP and AA varies considerably among commercial SBM samples. In fact, in this study, USA and BRA SBM had a higher AID and SID than ARG SBM.

Key Words: soybean meal origin, ileal amino acid digestibility, broilers

142 Nutrient density and balanced amino acids to ME ratio are drivers of growth, feed efficiency and carcass yield in broiler chickens. L. F. Romero*[1] and V. Ravindran[2], [1]*Danisco Animal Nutrition*, *Marlborough, UK*, [2]*Massey University*, *Palmerston North, New Zealand*.

Broiler nutritionists typically consider ME, CP (%), and essential amino acids (%) as criteria for diet formulation based on a set of recommended values per unit of feed mass. However, nutrient density, and balanced amino acids to ME ratio may be better explanatory variables of animal performance. Two 42-d performance trials, each with a total of 480 male broilers (Ross 308) were conducted to evaluate growth, feed efficiency, and carcass yield in response to 2 levels of nutrient density (Starter: 2,875 or 3,200 kcal ME/kg; Finisher: 3,020 or 3,315 kcal ME/kg; other nutrients proportional to ME), and 3 levels of digestible lysine (dlys) to ME ratios (Starter: 3.5, 3.9, 4.3 g dlys/Mcal ME; Finisher: 3.0, 3.5, 3.9 g dlys/Mcal ME). Diets were based on corn, soybean meal, corn gluten (= <5%), wheat middlings (= <5%), and A/V fat blend (0.5–7.5%). Other amino acids were balanced relative to lysine. Data were analyzed as a factorial design using the Mixed Procedure of SAS. Significance was evaluated at $P < 0.05$. Birds fed the low density diet exhibited a lower BW gain from 0 to 42 d compared with birds on the high density diet (3,252 g vs. 3,346 g; $P < 0.05$). Increments of dlys:ME resulted in significant increments of BW gain from 3,133 to 3,328 and 3,435 g. Increasing dlys:ME resulted in linear reductions of feed per gain, both in high and low density diets, ranging from 1.66 g/g in low dlys:ME x low ME to 1.44 g/g in high dlys:ME × high ME diets. High density increased caloric intake (16.22 Mcal/bird) versus low density diets (15.29 Mcal/bird). Low density diets had reduced caloric conversion (4.71 kcal/g BW) compared with high density diets (4.85 kcal/g BW). Caloric conversion linearly decreased with increments in dlys:ME (4.97, 4.77 and 4.60 kcal/g BW). Carcass and breast yields increased, and abdominal fat yield decreased with increasing dlys:ME ratios, in both low and high ME diets. More predictable responses of broiler performance by the use of nutrient density and dlys:ME as flexible criteria in diet formulations will enable accurate profit optimization of broiler operations.

Key Words: amino acid, broiler chicken, diet optimization

143 Digestible lysine requirements of Cobb × Cobb 700 male broilers from twenty-eight to forty-two days of age. W. A. Dozier III*[1], A. Corzo[2], M. T. Kidd[2], and P. B. Tillman[3], [1]*Auburn University*, *Auburn, AL*, [2]*Mississippi State University*, *Mississippi State,* [3]*Ajinomoto Heartland LLC*, *Chicago, IL*.

Research addressing digestible (dig) Lys requirement data of modern broilers from 4 to 6 wk of age is limited. This study examined growth and meat yield responses of broilers provided experimental diets varying in dig Lys, to determine the dig Lys requirements, from 28 to 42 d of age. Three-thousand male Cobb × Cobb 700 chicks were randomly distributed into floor pens at 1 d of age and were fed common starter and grower diets until 28 d of age. At 28 d of age, all pens were equalized with 23 birds (0.09 m^2/bird) and fed the experimental diets until 42 d of age. Two diets (dilution and summit) consisting of corn, soybean meal, meat and bone meal, and peanut meal were formulated to be adequate in all other amino acids. The dilution and summit diets were blended to create 7 intermediate diets, for a total of 9 titration diets. A control diet containing adequate dig Lys was used for comparison with the titration diets. Each treatment was represented by 12 replicate pens. Body

weight gain, feed intake, dig Lys intake, dig Lys intake/BW gain, feed conversion, mortality, carcass yields, and physiological parameters were assessed during experimentation. Dig Lys requirements were estimated using a quadratic broken-line model. Dig Lys requirement for male Cobb × Cobb 700 broilers ranged from 0.965 to 1.030% for BW gain, feed conversion, carcass weight, total breast meat weight, and total breast meat yield. Dig Lys requirements for male Cobb × Cobb 700 broilers were estimated at 0.995% based upon averages of live performance and meat yield responses. These data support a higher dig Lys requirement of male broilers from 28 to 42 d of age on a percentage basis than previous research as noted by less feed intake per unit of BW gain and a greater meat accretion rate.

Key Words: amino acid, broiler, lysine

144 Maximizing the use of supplemental amino acids in diets for 7-kg pigs. V. D. Naranjo*[1], T. D. Bidner[1], R. L. Payne[2], and L. L Southern[1], [1]*LSU Agricultural Center*, *Baton Rouge,* [2]*Evonik-Degussa Corporation*, *Kennesaw, GA*.

Three (14-d) experiments were conducted to determine the Lys requirement of 7-kg pigs and then to determine the maximum level of supplemental L-Lys along with DL-Met, L-Thr, and L-Trp that can be added in these diets. In all experiments, pigs were fed a common diet during wk-1 post-weaning. On d 7, pigs were blocked by initial BW and sex, and littermates were balanced across treatments. In Exp. 1 (5 reps of 3 or 4 pigs per pen; initial BW = 7.4 ± 1.2 kg), pigs were fed corn-soybean meal-peanut meal (C-SBM-PM) diets containing 0.754, 0.879, 1.004, 1.129, and 1.254% standardized ileal digestible (SID) Lys. A positive control (PC) diet without PM contained 1.254% SID Lys. Daily gain (257, 329, 364, 399, 440; 449 g/d), ADFI (620, 781, 700, 737, 804; 782 g/d), and G:F (0.42, 0.42, 0.52, 0.54, 0.55; 0.57) were linearly increased ($P < 0.01$) as SID Lys increased. Based on ADG, the SID Lys requirement was estimated at 1.221% ($P = 0.02$). In Exp. 2 (5 pens of 4 pigs per pen; initial BW = 6.30 ± 0.8 kg) and Exp. 3 (5 reps of 4 pigs per pen; initial BW = 6.9 ± 1.0 kg), C-SBM diets were formulated to contain 1.221% SID Lys. Only supplemental Met, Thr, and Trp were added to the diets to keep a constant ratio to Lys. In Exp.2, dietary treatments included 6 levels of supplemental L-Lys: 0, 0.049, 0.099, 0.149, 0.198, and 0.248%. There were no linear or quadratic effects ($P > 0.10$) in ADG (358, 361, 386, 357, 351, and 356 g/d), ADFI (861, 786, 856, 822, 819, and 893 g/d), or G:F (0.42, 0.47, 0.46, 0.44, 0.43, and 0.41) of supplemental L-Lys. In Exp. 3, dietary treatments included 5 levels of supplemental L-Lys: 0.198, 0.248, 0.298, 0.347, and 0.397%. Daily gain (376, 384, 379, 351, and 344 g/d; $P = 0.03$) and G:F (0.62, 0.54, 0.56, 0.52, and 0.50; $P < 0.01$) were linearly decreased, but ADFI (615, 718, 682, 675, and 696 g/d) was not affected. The results of this research indicate that up to 0.298% supplemental L-Lys along with supplemental Thr, Met, and Trp can be added in diets for 7-kg pigs without affecting ADG, but G:F is reduced at levels greater than 0.198% supplemental Lys.

Key Words: amino acids, pig, nursery

145 Well-fed piglets prefer amino acids that elicit umami taste. G. Tedo*[1], E. Roura[1], M. Reina[2], J. L. Ruiz-de la Torre[3], and X. Manteca[3], [1]*Lucta SA*, *Barcelona, Spain*, [2]*Celltec-University of Barcelona*, *Barcelona, Spain*, [3]*Autonomous University of Barcelona*, *Barcelona, Spain*.

Pigs perceive the umami taste via the pT1r1/pT1r3 receptor present in their tongue. In vitro studies, using a proprietary cell reporter system (CRS) that expresses this heterodimer, showed that it is tuned to detect amino acids (AA). The objectives of this work were (1) to evaluate preferences of piglets for AA and (2) to correlate preference data with outcomes from the CRS for the same AA. Forty-eight weaned piglets (10.7 ± 1.20 Kg of BW, mixed sexes) were distributed in pairs/pen, with ad libitum access to water and pelleted starter feed (2521Kcal NE/Kg, 19.1% CP, 1.32% Lys). Preferences were assessed using a double-choice model that consisted of 10-min training sessions conducted twice daily (9AM, 12PM) over 2 consecutive days followed by 2-min test sessions conducted twice daily (9AM, 12PM) over 5 d. During training, plain and sweetened (500mM sucrose) water were offered simultaneously in stainless steel containers (250g/container); whereas, in test sessions, water was offered along with water (control) and 50mM solutions of monosodium glutamate (MSG), D,L-Met, Gly, L-Ala, L-Gln, L-Glu, L-Lys, L-Thr and L-Trp. Preference (%) data [g test solution / (g test solution + g water) x 100] were analyzed using a mixed model approach that included the effects of pen (random), day, time, and treatment. Preferred solutions ($P < 0.01$) were MSG (79.6 ± 2.03), Glu (79.8 ± 2.45), Lys (77.2 ± 3.91), Gln (73.4 ± 3.37) and Ala (67.6 ± 4.46), whereas Trp (25.6 ± 4.40) was rejected. Additionally, solutions of Met (64.4 ± 9.58), Gly (59.9 ± 4.41) and Thr (49.5 ± 10.05) were not different from control (46.1 ± 3.18). Results from CRS were positively correlated ($R = 0.92$, $P < 0.05$) with preferences of Ala, Gln, Glu and MSG. Lys was also preferred but did not stimulate the umami receptor. In summary, well-fed piglets mainly preferred AA that stimulated the umami taste receptor expressed in the CRS. Therefore, the umami taste has a positive hedonic (pleasant) valence (value) for pigs.

Key Words: umami, amino acids, intake

146 Effect of fat source and levels, with lysophospholipids, on broiler performance, fatty acid digestibility and apparent metabolizable energy content in feed. B. K. Zhang*[1], H. T. Li[2], Y. M. Guo[1], and D. Q. Zhao[1], [1]*China Agricultural University*, *Beijing, China*, [2]*Kemin Industries Co. Ltd*, *Zhuhai, China*.

Three fat sources (soybean oil, tallow, and poultry fat), at 2 levels of addition (24 or 30 g/kg diet) with or without a lysophospholipid emulsifier (0 or 500 mg/kg) were incorporated into broiler feed. A total of 504 one day-old male Arbor Acres broiler chickens were randomly allocated to 12 treatments with 7 replicates of 6 birds each. The experimental period lasted 21 d. The lysophospholipid emulsifier (LPL) was a commercial powder preparation mainly containing lysophosphatidylcholine. The performance of the broilers, fatty acid digestibility and apparent metabolizable energy (AME) of the feed was studied. The source of fat had a clear effect ($P < 0.01$) on body weight gain and feed conversion ratio. Body weight gain was lower ($P < 0.01$) for broilers fed diets containing tallow than for those fed diets containing soybean oil or poultry fat. Levels of fat addition did not significantly influence the body weight gain of broilers. The addition of LPL increased the body weight gain of broilers ($P = 0.030$) and also increased the AME ($P < 0.05$) and AMEn ($P < 0.05$) of the diets. The LPL enhanced body weight gain for chickens fed the poultry fat diet (563 g vs. 539.5 g), and to a lesser extent with the tallow diet (532.5 vs. 514.5 g), but not for the birds given the soybean oil diet. The sources of fat had a clear effect ($P < 0.01$) on the digestibility of most fatty acids. Addition of LPL increased digestibility of C16:0, and C18:0 fatty acids in the starter period ($P < 0.05$), but had no effect on the digestibility of the other fatty acids under the conditions tested. The AME and AMEn of the diets were not significantly affected by sources of fat ($P > 0.05$), but were significantly improved by LPL ($P < 0.05$). The digestibility of CP and DM were not affected ($P > 0.05$) by LPL, fat sources or the levels of fat addition. There was no significant interaction between growth parameters, digestibility and AME of the diets ($P > 0.05$). These data indicated that the effect of LPL on broiler performance was dependent upon the types of dietary fat.

Key Words: lysophospholipids, fats, broiler

147 Effect of dietary fat on the production and composition of emu oil. D. C. Bennett*, W. E. Code, and K. M. Cheng, *University of British Columbia*, *Vancouver, BC, Canada*.

Emus (*Dromaius novaehollandiae*) are large flightless birds that are farmed for their meat and fat. The fat from both the subcutaneous and retroperitoneal adipose depots is rendered into oil, which is purported to have anti-inflammatory and anti-oxidant properties. Dietary fatty acid composition influences the fatty acid composition of the oil, but its affect on fat deposition or on the amount of oil produced after rendering has not been reported. Work on broiler chickens has shown that dietary fatty acid composition influences both the accumulation and fatty acid composition of abdominal fat. Therefore, the objective of the present study is to examine the effect of 2 dietary sources of fat on the amount and fatty acid composition of emu oil. Forty 3-year-old emus were fed a barley-alfalfa base diet that was supplemented with either tallow or canola oil at 2 levels (4% or 8%; 5 males and 5 females per dietary group); an additional 10 birds (5 males and 5 females) remained on the barley-alfalfa diet as controls. Birds were fed these diets for 6 mo before being slaughtered in October. Body weight and meat and fat yields were unaffected by the diet and averaged 44.2, 14.1 and 9.7 kg/bird, respectively. Females weighed more than males (45.6 and 42.9 kg, respectively), but fat yield did not differ between the sexes (9.4 and 10.0 kg/bird, respectively). Similarly, diet did not affect the total amount of oil produced after rendering, which averaged 6.8 kg/bird. Analysis of fatty composition of the oil is currently underway. These results indicate that, unlike chickens, neither the source nor the level of fat in the diet affected the amount of fat deposition in emus.

Key Words: emu, fat production, dietary fat

148 Whole body retention of highly unsaturated n-3 fatty acids (HUFA) and apparent conversion from 18:3n-3 are independent of body weight in pigs fed flaxseed diets. H. R. Martínez Ramírez*[1], J. K. G. Kramer[2], and C. F. M. de Lange[1], [1]*Centre for Nutritional Modeling, Department of Animal and Poultry Science, University of Guelph*, *Guelph, ON, Canada, N1G2W1*, [2]*Agriculture and Agri-Food Canada*, *Guelph, ON, Canada, N1G5C9*.

A total of 28 Yorkshire growing gilts were used in a serial slaughter study to determine the content of n-3 fatty acid (FA) and the apparent conversion (AC) of 18:3n-3 to HUFAs (18:4n-3, 20:3n-3, 20:5n-3, 22:5n-3, 22:6n-3) on a whole body basis, fed 3 feeding programs (n = 8). Four pigs were slaughtered at 25 kg BW to determine initial body composition. Corn-wheat-soy based diets were fed to growing gilts containing ground flaxseed (FS): T1, FS diet (10%) between 25 and 50 kg BW, and control diets (C, low in n-3 FA) thereafter until 110 kg BW; T2, C between 25 and 85 kg BW, and FS diet (6%) thereafter until 110 kg BW; and T3, C between 25 and 110 kg BW. Feed intake was fixed at 95% of the voluntary feed intake according to NRC (1998). Pigs on T1 and T2 consumed equal amounts of FS (5.1 vs. 5.2 kg, $P > 0.10$). The FA content in whole body was expressed as mg/100 g of empty BW. No treatment effect was observed for growth performance, composition of growth, and chemical and physical body composition across treatments ($P > 0.05$). Contents of 18:3n-3 and HUFA were larger in T1 and T2 than T3 ($P < 0.05$), except for 22:6n-3. Content of 18:3n-3 was lower in T1 than T2 (522 vs. 611; $P < 0.01$), whereas no such effect was observed for either total HUFA (136 vs. 140; $P > 0.10$) or n-6/n-3 ratio (4.5 vs. 4.0; $P > 0.10$). Expressed as a portion of 18:3n-3 intake, the largest AC among n-3 FA in T1 and T2 was to 20:3n-3 (9.1 vs. 10.3%) and 22:5n-3 (3.1 vs. 3.3%), whereas the total AC of n-3 FA was not affected by previous feeding program (8.7 vs. 13.6%; $P > 0.10$). These results suggest that the rate of AC of n-3 FA and HUFA content is independent of BW which provides flexibility as to when n-3 FA might be fed to produce n-3 enriched pork.

Key Words: apparent conversion, n-3 fatty acid, pigs

149 Effect of dietary conjugated linoleic acid on markers of intramuscular adipocytes in pork. K. M. Barnes*[1], N. Winslow[1], A. Shelton[1], and M. J. Azain[2], [1]*West Virginia University*, *Morgantown,* [2]*University of Georgia*, *Athens*.

Dietary conjugated linoleic acid (CLA) has been reported to decrease backfat and increase marbling in hogs. Our objective was to determine if the increased marbling was related to increased intramuscular adipocyte development. Barrows (n = 20, 53 kg) were penned in pairs and pens were randomly allotted to receive finishing diets containing 1% soybean oil (SBO) or 1% CLA oil (60% mixed CLA isomers) for 6 wks. Body weight and feed intake were determined weekly. At slaughter loin samples were obtained and flash frozen for RNA extraction and real time RT-PCR analysis of gene expression. Following a 24 h chill, carcasses

were ribbed and loin eye area (LEA) and backfat depth were measured, and subjective marbling and color scores were assigned. Loin, backfat, and belly fat samples were obtained for fatty acid analysis by gas chromatography. Dietary CLA did not affect body weight or feed intake at any point, nor did treatment groups differ in hot carcass weight, LEA, or color. CLA-fed pigs did have less ($P < 0.05$) backfat than SBO-fed pigs (25 vs. 30 mm, respectively) and had a non-significant ($P = 0.164$) increase in marbling score (3.1 vs. 2.4, respectively). The cis9,trans11 and trans10,cis12 CLA isomers were incorporated ($P < 0.001$) into backfat and belly fat but only trans10,cis12 CLA was increased ($P < 0.001$) in the loin of CLA-fed pigs. In all 3 tissues, the proportion of saturated fatty acids were increased ($P < 0.001$) by CLA. Relative gene expression for markers of preadipocytes (Pref-1), differentiating adipocytes (PPARγ), and mature adipocytes (Ap2 and Perilipin) were determined and normalized to the expression of acidic ribosomal phosphoprotein. No significant differences were detected but the expression of PPARγ (1.49 vs. 1.21, $P = 0.374$), Perilipin (1.81 vs. 1.44, $P = 0.485$), and Ap2 (1.75 vs. 1.21, $P = 0.205$) all were numerically greater in CLA-fed pigs than SBO-fed pigs. These preliminary results indicate that the increase in marbling in pigs fed CLA may be related to increased intramuscular adipocytes.

Key Words: conjugated linoleic acid, marbling, pork

150 Effects of dietary polyunsaturation level and genistein supplementation on performance and meat quality in quails reared under heat stress. N. Sahin* and C. Orhan, *Firat University Faculty of Veterinary Medicine Department of Animal Nutrition*, *Elazig, Turkey*.

This experiment was conducted to investigate the effects of dietary polyunsaturated fatty acids (PUFA) level (15 *vs*. 45%) and genistein supplementation (GS, 0, 400, and 800 mg/kg) on performance and muscle lipid profile in quails (*Coturnix coturnix japonica*, n = 360) reared under thermoneutral (TN, 22°C) and heat stress (HS, 34°C) conditions. Data were analyzed by 3-way ANOVA using the MIXED Procedure. Each treatment was replicated in 10 cages, each containing 3 birds, from d 10 to 42. HS condition decreased body weigh gain (BWG, 137 *vs*. 150 g) and cumulative feed intake (CFI, 657 *vs*. 708 g) and increased feed conversion ratio (FCR, 4.82 *vs*. 4.72) compared with TN condition ($P < 0.0001$ for all). Increasing dietary PUFA level was associated with decreases in BWG (5.26%; $P < 0.0001$) and CFI (6 g; $P < 0.01$) and an increase in FCR (4.61%; $P < 0.0001$). There were linear increases in BWG from 142 to 145 g and FCR from 4.83 to 4.73, with increasing GS ($P < 0.05$). Quails reared under TN condition had greater proportions (g/100 g fat) of PUFA (25 vs. 21), monounsaturated fatty acid (MUFA, 45 vs. 43), ω-6 (13 vs. 11), and ω-3 (12 vs. 10.38) and a less proportion of saturated fatty acid (SFA, 30 vs. 36) than quails reared under HS condition ($P < 0.0001$ for all). Quails fed diet containing 15% PUFA had greater MUFA (52 vs. 35) and SFA (36 vs. 31) and less PUFA (12 vs. 34), ω-6 (10 vs. 14), and ω-3 (2 vs. 20) than quails fed diet containing 45% PUFA ($P < 0.0001$ for all). Muscle FA profile did not vary by GS. Quails that were reared under HS condition (0.48 vs. 0.29 µg/g) and quails that were fed diet containing 45% PUFA (0.91 vs. 0.78 µg/g) had greater muscle malondialdehyde (MDA) content than their counterparts ($P < 0.0001$ for both). GS did not affect muscle MDA content. There were variable 2-way treatment interaction effects on response variables. In conclusion, increasing dietary PUFA level and GS may improve performance and meat quality in heat stress.

Key Words: PUFA, genistein, quail

151 Evaluating the efficacy of OptiCal under varying levels of dietary fat inclusion. J. D. Hamburg*[1], A. B. Batal[1], and S. D. Frankenbach[2], [1]*University of Georgia*, *Athens,* [2]*JBS United Inc.*, *Indianapolis, IN*.

Fat inclusion in diets has been shown to decrease gut transit which increases the energy availability of the diet. Thus, the objective of these studies was to determine the efficacy of OptiCal in diets with various levels of fat inclusion. Two 4 × 2 factorial studies were conducted in which a standard corn-soybean meal-distillers dried grains plus soluble diet was fed to broilers for performance and AME determination and also to roosters for TME_N determination. There were 4 levels of fat: 0, 1, 2, and 3% and 2 levels of Optical, 0 and 0.25lbs/ton. The diets were formulated to meet digestible amino acid requirements; however the ME of the diets varied with fat inclusion. The calculated ME of the control diet (0% fat and no Optical) was 2,900 kcal/kg and the ME increased 84 kcal/kg for every 1% inclusion of fat. To determine TME_N, a traditional precision-fed rooster assay in which 8 birds per diet were fasted for 24 h then crop intubated with 35 g of the test diets. Excreta were then collected for 48 h. For the chick assay 288 male broiler chicks were placed in Petersime battery brooders and fed a standard corn-soybean meal crumble diet. At 4 d of age, 9 replications of 4 chicks were weighed and assigned to one of the 8 dietary treatments. Body weight and feed intake were measured at 9 and 18 d of age. Excreta were collected at d 18 for AME determination. The TME_N values of the diets increased as the fat inclusion in the diets increased from 0 to 3% fat (3,036 to 3,234 kcal/kg, respectively). The efficacy of Optical on releasing energy, increasing the TME_N value improved as the inclusion of fat increased, on average the TME_N value of the diets with Optical were 57 kcal/kg higher than the diets without Optical. There was no effect of the addition of Optical on the diet without any fat inclusion. The inclusion of fat improved the feed:gain ratio as compared with the diets without fat (1.50 to 1.73, respectively). There was a interaction between fat inclusion and enzymes on the feed:gain ratios at 18 d of age. Based on the results of these studies fat inclusion levels in the diet appears to have an effect on enzyme efficacy.

Key Words: fat, enzymes, OptiCal

152 Fat digestibility in enzymatically treated soybean meal without and with choice white grease and vegetable oil. K. P. Goebel* and H. H. Stein, *University of Illinois*, *Urbana*.

An experiment was conducted to measure the digestibility of fat by weanling pigs fed enzymatically treated soybean meal and either soybean oil or choice white grease. Two sources of enzymatically treated soybean meals were used (HP-300 and HP-350). These meals are similar with the exception that an emulsifier, lecithin, is included in HP-350, but not in HP-300. The HP-300 meal contained 57.07% CP, 1.44% acid-hydrolyzed ether extract (AEE), and 2.30 trypsin inhibitor units (TIU) per mg, and HP-350 contained 53.60% CP, 3.73% AEE, and 1.50 TIU per mg. Two diets were formulated by mixing cornstarch, sugar, and each source of soybean meal. Two additional diets that were similar to the initial 2 diets with the exception that 6% choice white grease or 6% soybean oil was added to these diets were also formulated. Thirty-two weanling barrows (initial BW: 13.3 ± 0.8 kg) were randomly allotted to the 4 diets with 8 replicate pigs per diet in a 2 × 2 factorial design. Pigs were housed in metabolism cages. Pigs were fed experimental diets for 14 d with total collections of feces during the final 5 d. Feed intake and DM output were not different among treatments. The apparent total tract digestibility (ATTD) of DM and GE were not different among treatments regardless of soybean meal and fat source. The ATTD of AEE in HP-300 and HP-350 mixed with soybean oil was not differ-

ent (80.4 and 75.7%, respectively). The ATTD of AEE in HP-300 and HP-350 mixed with choice white grease was also not different (80.2% and 79.3%, respectively). Results indicated that the added lecithin in HP-350 did not increase fat digestibility in pigs fed diets supplemented with soybean oil or choice white grease.

Key Words: fat digestibility, lecithin, soybean meal

153 Effect of dietary DHA levels and different sources of oil (fat) on egg yolk DHA and ω-3 fatty acids levels. M. K. Manangi*, B. Wuelling, J. Hux, S. Carter, C. D. Knight, and M. Vazquez-Anon, *Novus International, Inc.*, *St. Charles, MO*.

A 5 wk experiment was conducted to evaluate the effect of different levels of DHA (docosahexaenoic acid) as DHA GOLD (a dried whole cell algae product, derived from *Schizochytrium* sp., contains a minimum of 18% DHA by weight) and sources of oil (fat) on egg yolk DHA and ω-3 fatty acids deposition. A total of 216 Hy-Line W-36 commercial laying hens, 40 wk old, were randomly assigned to 6 treatments with 36 cages/treatment and one hen/cage. The trial design was a 2 × 3 factorial with 2 levels (0 and 1%) of DHA GOLD and 3 sources (canola, flax and corn oil) of oil. Results indicate that DHA GOLD and oil sources had significant ($P < 0.05$) interaction on DHA, and total ω-3s fatty acids in eggs. Supplementation of DHA GOLD to diets with canola, flax and corn oil increased ($P < 0.05$) the DHA deposition from 19 to 163, 33 to 158 and 19 to 170 mg/egg, respectively. Supplementation of DHA GOLD to diets with canola oil and corn oil increased total ω-3s from 125 to 338 and 111 to 376 mg/egg, respectively. The DHA GOLD and flax oil combination did not affect ($P > 0.05$) total ω-3s. In summary, under present experimental conditions dietary supplementation of DHA GOLD increased egg DHA content that meets toward recommended daily allowance irrespective of tested oil sources. Total ω-3s in eggs increased in response to supplemental DHA GOLD for canola and corn oil diets but not for flax oil.

Key Words: layer, DHA, ω-3s

154 Effect of different levels of flaxseed and DHA GOLD on egg yolk DHA deposition. M. K. Manangi*, B. Wuelling, J. Hux, S. Carter, C. D. Knight, and M. Vazquez-Anon, *Novus International, Inc.*, *St. Charles, MO*.

A 5 wk experiment was conducted to evaluate the effect of different levels of flaxseed, and DHA (docosahexaenoic acid) as DHA GOLD (a dried whole cell algae product, derived from *Schizochytrium* sp., contains a minimum of 18% DHA by weight) on egg yolk DHA. A total of 216 Hy-Line W-36 commercial laying hens, 24 wk old, were randomly assigned to 9 treatments with 24 individual cages per treatment and one hen per cage. The trial design was a 3 × 3 factorial with 3 levels (0, 0.5 and 1%) of DHA GOLD and 3 levels (0, 3 and 6%) of flaxseed. All diets were isolipidic and soybean oil was used to replace oil from flaxseed. Results indicated a significant ($P < 0.05$) interaction of DHA GOLD and flaxseed levels on DHA, total ω-3 fatty acids, and vitamin E levels. DHA and ω-3s content in egg increased linearly with the addition of DHA GOLD by itself or in the presence of flaxseed. Addition of 3% flaxseed improved DHA egg content from control but was less effective than DHA GOLD treatments. Further increase of flaxseed from 3 to 6% did not result in additional DHA deposition in egg, except when 0.5% DHA GOLD was present in the diet. The optimum DHA level of 173mg/egg was achieved by feeding hens' 1% DHAGOLD + 3% flaxseed compared with 35.9mg DHA/egg for hens fed the control diet ($P < 0.05$). The combination of 1% DHA GOLD and 3% flaxseed also resulted in significantly ($P < 0.05$) higher total ω-3s (389mg/egg) compared with hens fed diets supplemented with 0 or 0.5% DHA GOLD in combination with 0, 3 or 6% flaxseed. Supplementation of 1% DHA GOLD alone with no flaxseed resulted in a deposition of 141mg of DHA/egg whereas 6% flaxseed with no DHA GOLD resulted in 52mg of DHA/egg. Eggs from hens fed 1% DHA GOLD showed an increase of 373% vitamin E compared with eggs from non-DHA GOLD supplemented hens. In summary, DHA GOLD supplementation was more effective at enriching eggs with DHA than flaxseed by itself. Combination of 3% flaxseed with 1% DHA GOLD optimized the deposition of DHA in egg.

155 The interaction of dietary fatty acids on the egg yolk fatty acid composition. R. Poureslami*[1,4], K. Raes[2], and E. Delezie[3], G. Huyghebaert[3], A. B. Batal[1], and S. De Smet[4], [1]*University of Georgia*, *Athens,* [2]*University College West-Flanders*, *Kortrijk, Belgium*, [3]*Institute for Agricultural and Fisheries Research*, *Melle, Belgium*, [4]*Ghent University*, *Melle, Belgium*.

Two experiments were conducted to investigate the interaction of dietary fatty acids (FA) on the egg yolk FA composition. In Exp I, 288 ISA-brown laying hens (45–50 wk of age) were divided into 32 dietary treatments in 3 replicates. Diets were prepared mixing a type of fish oil (FO) with 4 vegetable oils in different proportions resulting in a wide range of diet FA composition. Two levels of fat were introduced to the diets (3 and 6%). In Exp II, 63 hens were assigned to each of 7 dietary groups. A mixture of 2 levels and 3 types (differing in 20:5n-3/22:6n-3 ratio) of FO in combination with 2 vegetable oils were applied. Stepwise multiple regression and ANOVA were used to analyze the data in Exp I and II respectively. In Exp I, dietary saturated (SFA), monounsaturated (MUFA), polyunsaturated (PUFA) FA and the interaction between them affected SFA and MUFA proportions in the egg. The egg 18:2n-6 proportion was mainly explained by the dietary provision of 18:2n-6 (Partial R^2 55%) followed by the inverse impact of dietary MUFA. The 20:4n-6 composition in the egg was inversely related to the dietary n-3 long chain (LC) PUFA (Partial R^2 50%), more than to the dietary level of the precursor 18:2n-6. The linear effect of dietary 18:3n-3 was very determinant for the egg 18:3n-3 proportion (Partial R^2 93%) while, it had a negligible impact on the n-3 LC PUFA composition in the egg (Partial R^2 7%). About 77% of the variation in the egg yolk 22:6n-3 composition was explained by 22:6n-3 proportion in the diet. In Exp II, the level of FO (2 v. 1%) was more effective than its type on the n-3 LC PUFA composition in the egg. In conclusion, interactions between dietary FA affect SFA and MUFA composition in the egg while, direct dietary provision is the most crucial factor in achieving high deposition of n-3 FA in the egg yolk.

Key Words: fatty acids, interaction effect, egg yolk

156 The effect of omega-3 fatty acid rich algae biomass supplementation on production and egg and plasma components from 61 to 69 weeks of age. H. M. Yakout*[1], C. L. Novak[2], and Z. Wen[3], [1]*Alexandria University*, *Alexandria, Egypt*, [2]*Land O'Lakes Purina Feed*, *Kansas City, MO,* [3]*Virginia Tech*, *Blacksburg*.

Commercial White Lohmann LSL-Classic hens (n: 192) were randomly assigned to one of 4 dietary treatment groups to test the use and response of omega-3 fatty acid containing algal biomass supplementation on egg production parameters and egg components. Biomass was supplemented to a corn-soybean meal based diet at a rate of 0, 2, 4 or 8% establishing treatments 1, 2, 3 and 4, respectively. All diets were iso-caloric and iso-nitrogenous and were fed ad libitum from 61 to 69 wks of age. Cage was considered the experimental unit (4 hens/ cage) with each treatment replicated 12 times. Overall, Trt had no affect on feed consumption which averaged 117.6 g/ h/ d. Egg production ranged from 89.8 to 91.7% for all treatments ($P \geq 0.05$) with the highest producing hens consuming diet 1 and lowest consuming diet 4. Additionally, no significant differences were observed among trt for feed efficiency which averaged 0.517 g. egg mass /g. feed. Trt 1 had numerically higher egg weights (68.1 g.) compared with biomass supplemented trt with an average of 66.53 g/ egg. Trt 1 had numerically the greatest egg mass (62.4 g.) and dietary treatments had no significant effects on wet egg components. Trt 2 had numerically the best specific gravity value (1.087). Overall, increasing dietary biomass resulted in elevated yolk color ($P \leq 0.001$) with the darkest noted in eggs from hens consuming trt 4 (7.2; using a Roche Color fan), while trt 1 was the lightest (6.5). Yolk and plasma total lipids, and yolk phospholipids were similar among treatments, while plasma phospholipids were reduced ($P \leq 0.06$) in hens consuming trt 3 (524.7 mg/dL) as compared with hens fed trt 1 (736.0 mg/dL). Yolk DHA content was significantly increased with all dietary biomass levels up to 8% (2.64%) as compared with the control (0.31%). Based on the information from this trial, supplementing a corn-soybean meal based diet with biomass up to 8% during late first cycle lay resulted in minimal affects on production parameters. Additionally, yolk color and DHA content was increased while plasma phospholipids were reduced by feeding 4 or 8% biomass.

Key Words: biomass, plasma phospholipids, laying hens

Nonruminant Nutrition Symposium: Nutrigenomics

157 Practical uses of nutrigenomics and gene expression patterns to develop and evaluate nutritional strategies. K. A. Dawson*, *Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition*, *Nicholasville, KY*.

In addition to providing information on the regulation of physiological activities; applications of nutrigenomic and transcriptomic techniques are providing new tools for evaluating the value and effectiveness of nutritional strategies in domestic livestock. Detailed studies of gene expression patterns associated with different forms and levels of selenium in animal diets have begun to elucidate the critical hidden effects of specific mineral forms in several species. While it is clear that diets which use selenium incorporated into growing yeast (selenium yeast) can significantly and uniquely influence the expression of genes associated with recognized antioxidant systems, such materials also have other significant effects on genes and metabolic pathways that influence basic cellular repair mechanisms, the production of stress proteins, energy production systems, immunological systems, neurological function and reproductive systems. Tissue specific gene expression patterns determined with standardized microarrays clearly indicate major differences in various dietary forms of selenium and can be used to differentiate the effects of selenium yeast from those associated with sodium selenite. Such genomics tools have allowed for an understanding of the effects of specific nutrients in unprecedented detail and have opened new frontiers in nutrition and dietary manipulations. Gene expression patterns also provide useful tools for initially comparing dietary treatments and can be used to rapidly screen for key nutritional effects and to evaluate supplementation strategies. Using these comparison techniques, it has been possible to compare alternative antioxidant systems that can partially replace traditional dietary ingredients like vitamin E in animal feed. In chickens, the value of comparing the effects of diets using gene expression patterns and marker genes has been validated by examining more traditional methods for determining antioxidant status in the serum and by examining meat quality. In the future, Nutrigenomics approaches will undoubtedly improve the efficiency of techniques for evaluating dietary formulations and provide basic biochemical information that will lead to a new understanding of basic nutritional principles.

158 Early life nutritional conditioning with dietary phosphorus. C. M. Ashwell*[1] and R. Angel[2], [1]*Department of Poultry Science, North Carolina State University*, *Raleigh*, [2]*Department of Animal and Avian Sciences, University of Maryland*, *College Park*.

The recent technologies that have led to the new field of functional genomics are providing a clearer understanding of how organisms interact with their environment and in particular their diet. We are beginning to learn how the diet may have long-term influence on performance and health. A form of epigenetic regulation has been recently described called fetal "programming." We have observed similar apparent programming by dietary manipulation in the perinatal period of the chicken. When birds are challenged with a diet low in phosphorus (P) for 90 h immediately post-hatch they obtain the ability to better utilize P later in life. This increased utilization of P (1.24-fold, $P < 0.001$) from the diet can partially be explained by an enduring increase (2.4-fold, $P < 0.05$) in the expression of the intestine-specific Na/P cotransporter (NaPcoT) IIb gene during programming as well as later in life when fed P restricted diets. The resulting data provide the first evidence for neonatal programming of gene expression in an oviparous species. Studies are ongoing to determine if the mechanism of persistent responses of gene expression to stimuli are epigenetic in nature. If epigenetic regulation is involved in dietary conditioning the opportunities for nutrition to impact both the animal and its offspring are almost limitless.

159 Using nutrigenomics to elucidate interrelationships in trace mineral metabolism. S. L. Hansen*[1], J. W. Spears[2], and R. S. Fry[2], [1]*Iowa State University*, *Ames*, [2]*North Carolina State University*, *Raleigh*.

Nutrigenomics is the study of dietary influence on gene expression. This presentation will focus on the area of trace mineral metabolism and the information that can be gained through the use of nutrigenomics. Numerous interactions between certain trace minerals may occur as minerals compete for intestinal absorption and transport throughout the body. Because of these interactions it has become apparent that it is no longer appropriate to examine the metabolism of a single mineral without consideration for the mineral "ionome" as a whole. Nutrigenomics presents a new way of looking at an old problem; while we have known for many years about the antagonistic relationship between minerals such as iron, manganese, and copper, it is only in recent years that specific gene products have been identified as potential points of interaction between these elements. For example, in 2 experiments where weaned pigs were fed varying levels of dietary iron, a strong negative relationship between dietary iron and tissue manganese concentration was observed. Using quantitative-PCR it was found that intestinal expression of divalent metal transporter 1 (dmt1) was depressed in pigs fed high dietary iron. Elucidating points of interaction, such as dmt1, which is a transporter for both iron and manganese, allows nutritionists to more accurately formulate diets. Utilizing nutrigenomics in the field of mineral metabolism has many potential benefits, including redefining mineral requirements of animals in the face of a new generation of plant and animal genetics, and diminishing environmental impacts by decreasing excessive oral supplementation of minerals. In summary, nutrigenomics provides biological targets at which to aim studies of animal trace mineral metabolism, which should increase our knowledge of mineral interactions and lead to more accurate dietary mineral recommendations.

Key Words: interactions, minerals, nutrigenomics

160 A functional genomics view of selenium in energy metabolism, obesity, and diabetes. X. G. Lei*, *Cornell University*, *Ithaca, NY*.

The trace element Se and Se-dependent glutathione peroxidase-1 (GPX1) have been considered to protect against diabetes. Intriguingly, we found a spontaneous development of type 2 diabetes-like phenotypes in GPX1 overexpressing mice at 6 mo of age. Later, other laboratories demonstrated similar deleterious effects of overexpression of other antioxidant proteins on sensitizing mice to diabetes. Most striking, 8 major human studies have recently shown hyperglycemic, hypolipidemic, and pro-diabetic effects of Se supplement. Because pigs are an excellent model for human nutrition, we have conducted a series of experiments to elucidate functional genomics of porcine selenoproteins in glucose and lipid metabolism. We first identified all 25 porcine selenoproteins using *in silico* cloning followed by PCR. We then determined the effects of dietary Se deficiency and excess on gene expression of all 25 selenoproteins in various tissues of pigs using quantitative real-time Q-PCR. Recently, we induced obesity in pigs by feeding them with a high-fat diet and determined effects of obesity on gene expression of the 25 selenoproteins. Our results indicate that gene expression of

13 selenoproteins was altered by dietary Se deficiency or excess non-unilaterally. The induced-obesity enhanced or decreased gene expression of 17 selenoproteins in various tissues of pigs. Microarray data have been generated from the dietary Se and fat experiments to establish systems biology related to body energy metabolism, selenogenome, and porcine genome. Our findings will reveal novel metabolic roles of Se in energy metabolism, obesity, and diabetes.

161 Alternative protocols to presynchronize estrous cycles in dairy cattle before a timed AI program. J. S. Stevenson*, *Kansas State University*, *Manhattan*.

Our objective was to test potential presynchronization protocols applied before a timed AI (TAI) protocol to improve the percentage of cows having a functional CL, high concentrations of progesterone, and successful ovulation after both GnRH injections. At calving, cows were assigned randomly to receive either of 5 presynchronization treatments. Three Presynch protocols were tested in which 2 injections of $PGF_{2\alpha}$ (PGF) were administered 14 d apart, with either 14 d (PRE14; n = 122), 12 d (PRE12; n = 123), or 10 d (PRE10; n = 151) intervening before initiating a TAI protocol. Two treatments were a progesterone (P4) insert (CIDR) for 7 d plus PGF at insert removal. Insert removal occurred either 10 d (CIDR10; n = 157) or 3 d (CIDR3; n = 117) before initiating a TAI protocol. The TAI protocol was a standard Cosynch protocol (GnRH 7 d before and 72 h after PGF with TAI at 72 h after PGF). Cosynch was the control (n = 157) with cows starting this protocol at random stages of the estrous cycle. From a subset of cows (49 to 51 cows per treatment), blood samples were collected at d −28, −14, 0 (onset of TAI protocol), 7, 9, 14, and 21 d. Ovarian scans occurred on d 0, 7, 9, and 14. Diameter of follicles and CL were measured at each exam and ovulation response to both GnRH injections was determined at d 7 and 14. Ovulatory incidence after the first and second GnRH injections varied but did not differ among treatments. Concentrations of P4 were greater ($P \leq 0.05$) before the first GnRH injection in all treatments compared with CIDR3. Before the second GnRH injection, P4 was greater ($P \leq 0.05$) in the CIDR3 treatment than in all other treatments. Luteal regression and synchronization rate (successful luteolysis and ovulation after second GnRH injection) did not differ among treatments. Pregnancy rate per AI (PR/AI) at 60 d post timed AI was less ($P \leq 0.05$) in CIDR3 cows compared with all other treatments. It was concluded that none of the Presynch treatments improved key responses (ovulation, luteolysis, and synchronization rate) known to improve PR/AI compared with a standard Cosynch protocol without presynchronization.

Table 1. Key responses of treated cows during the timed AI ovulation synchronization protocol

Treatment	n	First GnRH Ovulation, %	P4 ng/mL	2nd GnRH Ovulation, %	P4 ng/mL	Luteal regression, %	Synch rate, %	n	60-d PR/AI
PRE14	50	62.0	3.9[a]	86.0	1.0[a]	93.9	86.0	122	28.7
PRE12	51	60.8	3.7[a]	88.2	0.5[c]	100	88.2	123	33.6
PRE10	49	67.3	2.4[b]	79.6	0.7[ac]	95.7	79.6	151	30.5

162 Effects of presynchronizations with GnRH/$PGF_{2\alpha}$ vs. progesterone before Ovsynch in noncyclic dairy cows. G. Yilmazbas-Mecitoglu*[1], A. Keskin[1], A. Gumen[1], E. Karakaya[1], R. Darici[2], and H. Okut[3], [1]*University of Uludag*, *Bursa, Turkey*, [2]*Tarfas Co.*, *Bursa, Turkey*, [3]*University of Yuzuncu Yil*, *Van, Turkey*.

The aim of this study was to compare efficiency of GnRH/PGF2α vs. progesterone (P4) presynchronizations (Presynch) on overall Ovsynch (OVS) outcome in noncyclic dairy cows. Ultrasonographic examinations were done with 7 d interval to determine cyclicity. Noncyclic cows (n = 157; no CL in each ovary at both examinations) were randomly divided into 3 groups. In GP group (n = 61), PGF2α was administrated 7 d after GnRH injection and OVS was started 11 d after PGF2α administration (GnRH-7d-PGF2α-11d-OVS). In PR group (n = 54), cows were treated for 7 d with an intravaginal P4 implant (PRID; without oestradiol capsule) then 11 d after removing the implant OVS was started (7d PRID-11d-OVS). Control group (n = 42) did not receive any presynch protocol and OVS was started at the same time with other groups. Spontaneous recovery in control and presynch rates in GP and PR groups (cows became cyclic at the beginning OVS) were found to be different ($P < 0.004$) between control (47.6%; 20/42) and presynch groups (72.1%; 44/61 in GP and 77.8%; 42/54 in PR groups). Response to first GnRH of OVS did not differ among groups (73.8%; 31/42 in control, 73.8%; 45/61 in GP and 70.4%; 38/54 in PR groups). Interestingly, response to first GnRH of OVS was higher ($P < 0.0007$) in cows that did not respond to presynch than cows responded in GP and PR groups (96.5%; 28/29 and 47.8%; 55/86). Synchronization rates were similar among groups (78.6%; 33/42 in control, 88.5%; 54/61 in GP and 85.2%; 56/54 in PR). Conception rate (31 d) did not differ among groups (42.9%; 18/42 in control, 47.5%; 29/61 in GP and 46.3%; 25/54 in PR). Embryonic loss (between 31 and 62 d) did not differ among groups (4 cows in control, 1 cow in GP and 1 cow in PR). However, conception rate (31 d) was greater ($P < 0.001$) in cows that responded to presynch than those that did not respond in GP and PR groups (55.8%; 48/86 and 20.7%; 6/29). Although conception rate did not differ among groups, cows that responded to presynch had higher conception rate than cows that did not respond.

Key Words: Ovsynch, presynchronization, noncyclic dairy cows

163 Comparison of estrus and ovulation synchronization protocols: effects on ovarian follicular dynamics, corpus luteum growth, and circulating steroid concentrations in lactating dairy cows. M. M. Herlihy*[1,2], M. A. Crowe[2], M. G. Diskin[3], and S. T. Butler[1], [1]*Teagasc Moorepark DPRC*, *Cork, Ireland*, [2]*University College Dublin*, *Ireland*, [3]*Teagasc Athenry APRC*, *Galway, Ireland*.

This study compared estrus and ovulation synchronization protocols at first service in lactating dairy cows (n = 61) > 42 d postpartum. At 10 d before AI animals were randomly assigned to: 1) d −10 GnRH (10 μg i.m. Buserelin) and CIDR insert (1.38 g P4); d −3 $PGF_{2\alpha}$ (25 mg i.m. dinoprost); d −2 CIDR out and AI at observed estrus (CIDR_OBS); 2) same as CIDR_OBS, but GnRH 36h after CIDR out and TAI (timed AI) 18h later (CIDR_TAI) or 3) same as CIDR_TAI, but no CIDR (OVSYNCH). Transrectal ultrasound was used to assess follicle size before ovulation and on d8 and d15 after AI to measure the corpus luteum (CL). Blood samples were collected to determine concentrations of estradiol (d −3, d −2, d −1, d0) and progesterone (d −2, d −1, d0, d1, d4, d6, d8, d11, d15). P4 concentrations immediately before CIDR removal were greater ($P < 0.001$) for CIDR_OBS and CIDR_TAI compared with OVSYNCH (1.78, 1.59 and 0.62 ng/mL; CIDR_OBS, CIDR_TAI and OVSYNCH, respectively). At the time of the second GnRH, E2 was higher ($P < 0.06$) for CIDR_OBS and CIDR_TAI compared with OVSYNCH (2.78, 2.57 and 1.69 pg/mL). E2 concentrations at the time of expected AI were higher ($P < 0.001$) for CIDR_OBS compared with CIDR_TAI and OVSYNCH (1.59, 0.36 and 0.33 pg/ml). Diameter of the DF before ovulation was greater ($P < 0.05$) for CIDR_OBS compared with OVSYNCH (18.3 vs. 16.1 mm).

An interaction ($P < 0.05$) was observed for P4 concentrations, where P4 tended to be lower in CIDR_OBS on d4 and 6, but greater on d15 compared with CIDR_TAI and OVSYNCH. CL diameter and volume was not affected by treatment on d8, but both CL volume (9991, 7808, and 8186 mm^3; $P = 0.1$) and diameter (27.0, 23.9, and 24.0; $P = 0.08$) on d15 tended to be affected by treatment (CIDR_OBS, CIDR_TAI and OVSYNCH, respectively). Both P4 supplementation and GnRH on the day before TAI impact ovulatory follicle size, E2 concentrations, and postovulatory P4 profiles.

Key Words: Ovsynch, CIDR, dairy cow

164 Effects of reducing interval from GnRH to $PGF_{2\alpha}$ in Ovsynch protocol on pregnancy rate in cyclic lactating dairy cows. A. Gumen*[1], G. Yilmazbas-Mecitoglu[1], A. Keskin[1], E. Karakaya[1], Y. Celik[2], and H. Okut[3], [1]*University of Uludag*, *Bursa, Turkey*, [2]*TARFAS Co.*, *Bursa, Turkey*, [3]*University of Yuzuncu Yil*, *Van, Turkey*.

Ovsynch protocol was designed to synchronize ovulation, thereby allowing timed artificial insemination (TAI) of all cows without detection of estrus and Ovsynch has been proven to be an acceptable alternative to estrus detection programs in large dairy farms. The aims of this study were 1) to ovulate one day younger follicle by decreasing interval between first GnRH to PGF2α of Ovsynch 2) to compare pregnancy rates in Ovsynch vs. Modified Ovsynch (interval between first GnRH to PGF2α decreased to 6 d) in cycling lactating dairy cows. The day of first GnRH of Ovsynch was designated d 0. The ovaries of cows were examined by ultrasonography twice, one week apart, to determine cyclic cows (had Corpus Luteum on either ovary) from −7 to 0 d. Cyclic cows (n = 859) were divided into 2 groups: OVS group (n = 421) received the Ovsynch protocol (GnRH-7d-PGF2α-56h-GnRH-18h-AI) and cows in MOV group (n = 438) had a Modified Ovsynch (MOV) protocol (GnRH-6d-PGF2α-56h-GnRH-18h-AI). Ultrasonography were performed at the time of first GnRH and PGF2α administration to detect first ovulatory response, at the time of AI to determine maximal follicle size and 7 d after AI to determine second ovulatory response. Pregnancy diagnosis was performed 30 and 60 d post insemination by ultrasonography. Response to first GnRH of Ovsynch was similar between OVS (54.2%, 228/421) and MOV (55.3%, 242/438) groups. Synchronization rate (ovulatory response to second GnRH of Ovsynch) was higher ($P < 0.004$) in MOV (90.4%, 396/438) than OVS (83.8%, 353/421). Pregnancy rate was similar in OVS (42.5%, 179/421) and MOV cows (37.9%, 166/438). Follicle size at the time of AI was greater ($P < 0.0001$) in OVS (16.01 ± 0.1 mm) than MOV (15.3 ± 0.1 mm). Thus, Modified Ovsynch protocol not only increased synchronization rate but also decreased follicle size. Unexpectedly, this protocol did not improve pregnancy rate in cycling dairy cows.

Key Words: synchronization, Ovsynch, dairy cows

165 Presynchronization with hCG 7 d before initiation of Resynch improves fertility similar to a double–Ovsynch Resynch protocol in lactating dairy cows. J. O. Giordano*, J. N. Guenther, M. S. Ares, M. C. Wiltbank, and P. M. Fricke, *University of Wisconsin*, *Madison*.

Our objective was to compare a Double-Ovsynch protocol for resynchronization of ovulation (Resynch) to a novel Resynch protocol that reduces the interbreeding interval (IBI) to 35 d. Lactating Holstein cows on a commercial dairy received a Resynch protocol using GnRH and cloprostenol (PGF) as follows: (d 0, 200 μg GnRH; d 7, 750 μg PGF; 56 h, 100 μg GnRH; 16 h, TAI). Cows were blocked by parity and were randomly assigned to one of 3 treatments to receive: 1) Resynch–25 (C), Resynch protocol initiated 25 d after a prior TAI (n = 418, IBI = 35 d). 2) HGPG, hCG (2000 IU Chorulon on Day 18 after TAI) 7 d before Resynch–25 (n = 450, IBI = 35d); 3) Double–Ovsynch (DO), a modified Ovsynch protocol (d 0, 100 μg GnRH; d 7, 500 μg PGF; d 10, 100 μg GnRH) which was initiated 22 d after a prior TAI followed 7d later by Resynch–39 (DO, n = 405, IBI = 49 d). Pregnancy was diagnosed 29 d after Resynch TAI using ultrasound and 53 d after Resynch TAI using palpation to determine pregnancies per AI (P/AI). Based on logistical regression analysis, P/AI 29 d after TAI was not affected ($P = 0.42$) by parity, and HGPG and DO cows had more ($P < 0.01$) P/AI than C cows [HGPG = 37.3% (168/282; DO = 35.8% (145/260); C = 28.0% (117/301]. When analyzed separately, P/AI did not differ ($P = 0.64$) between HGPG and DO cows. Pregnancy loss from 29 to 53 d after TAI was not affected ($P = 0.88$) by lactation and did not differ ($P = 0.34$) among treatments [HGPG = 11.0% (18/145); DO = 6.3% (9/135); OV = 8.6% (10/106)]. At 53 d after TAI, HGPG and DO cows continued to have more ($P = 0.02$) P/AI than C cows [HGPG = 32.6% (145/300); DO = 33.4% (135/269); OV = 25.4% (106/311)], and P/AI did not differ ($P = 0.80$) for HGPG and DO cows. We conclude that the HGPG Resynch protocol increased fertility of resynchronized cows similar to that of a Double-Ovsynch Resynch protocol while reducing the interbreeding interval by 14 d.
Supported by Hatch project WIS01171.

Key Words: Double-Ovsynch, hCG, resynchronization

166 Comparison of responses to Ovsynch for Holstein–Friesian and Swedish–Red cows. A Keskin*[1], G Yilmazbas-Mecitoglu[1], A Gumen[1], E Karakaya[1], Y Celik[2], H Okut[3], and M. C. Wiltbank[4], [1]*University of Uludag*, *Gorukle, Bursa, Turkey*, [2]*TARFAS Co*, *Karacabey, Bursa, Turkey*, [3]*University of Yuzuncu Yil*, *Van, Turkey*, [4]*University of Wisconcin-Madison*, *Madison*.

The Ovsynch protocol was designed to synchronize ovulation, thereby allowing timed artificial insemination (TAI) of all cows without detection of estrus; however, the effectiveness of Ovsynch in different breeds of dairy cows has not been previously compared. The aim of this study was to compare the response to Ovsynch in cycling lactating dairy cows of 2 different breeds (Holstein–Friesian [HF] vs. Swedish–Red [SR]). A total of 495 cyclic cows (n = 347 HF, n = 148 SR) were housed together and treated with Ovsynch (GnRH–7d–PGF2α–56h–GnRH–18h–TAI). Cows were not presynchronized before the Ovsynch. Milk production was different ($P < 0.001$) between breeds (40.3 ± 0.5 in HF and 34.9 ± 0.7 in SR). Ovulatory responses, synchronization rate, maximal follicle size at the time of AI, and percentage pregnant per AI (%P/AI at 31 and 62 d after AI) were compared between breeds. Ultrasonography was performed during Ovsynch at first GnRH, PGF2α, at time of AI, and 7 d after AI. Ovulatory response and synchronization rate were similar in HF vs. SR cows (60.2% vs. 62.1%; 88.4% vs. 88.5%, respectively). Cows that ovulated to the first GnRH of Ovsynch had reduced ($P = 0.02$) follicle size at time of AI (15.9 ± 0.12 vs. 16.4 ± 0.16 mm). Maximal follicle size at time of AI was greater ($P < 0.004$) for HF (16.4 ± 2.2 mm) than SR (15.5 ± 2.3 mm) cows. The %P/AI tended to be greater for SR than HF cows at the 31 d pregnancy diagnosis (58.1% vs. 51.1%; $P = 0.16$) and was greater in SR than HF cows at the 62 d pregnancy diagnosis (56.1% vs. 46.1%; $P = 0.04$). Embryonic loss was greater ($P = 0.04$) in HF (10.1%) than SR (3.4%) cows between 31 and 62 d of pregnancy. Hot season significantly decreased %P/AI in HF cows ($P < 0.001$), but not in SR cows. Thus, although the GnRH treatments of Ovsynch were equally effective in SR and HF cows, there was better fertility following Ovsynch in SR than HF cows, probably due to the decrease in fertility during the hot season in HF but not SR cows.

Key Words: Ovsynch, breed, reproduction

167 Manipulation of protein feed levels during Ovsynch TAI and early embryonic development to improve fertility in lactating dairy cows. M. B. Gordon* and R. Rajamahendran, *University of British Columbia*, *Vancouver, BC, Canada*.

This study compared the effects of feeding 2 levels of crude protein (CP, 16% vs. 18.5%) on fertility and milk production in lactating dairy cows subjected to a timed insemination. To achieve its milk yield potential the modern dairy cow is dependent on a high intake of dietary nitrogen. However, excessive protein intake, particularly rumen degradable protein is associated with reductions in fertility, plasma progesterone concentrations, and exacerbation of negative energy balance. Although Ovsynch timed artificial insemination (TAI) program allows for the control of ovarian follicular and corpus luteum development without the need for estrus detection, pregnancy rates are still far from the satisfactory rates achieved over 30 years ago. Lactating Holstein dairy cows (n = 180) were synchronized for first service breeding using Ovsynch TAI (2 treatments of GnRH, 9 d apart with a treatment of PGF2α 48 h before the second GnRH treatment, and TAI 16–18 h later). Cows were blocked for similar parity and DIM. Group 1 (control) was fed a diet consisting of 18.5% CP (High). Group 2 was fed a diet consisting of 16% CP (Low), which began 7 d before initiation of Ovsynch and continued until pregnancy diagnosis at 32 d. Groups were housed together with access to feed via Insentec electronic feed intake bins. Pregnancy per AI was 24.4% and 34.1% ($P = 0.08$) for High and Low groups, respectively. Parity had an affect on pregnancy per AI. A lower average milk production during the 49 d of treatment was observed in multiparous cows in the Low group (47.8 ± 1.05 kg) compared with the High group (50.2 ± 1.03 kg, $P = 0.11$). However, no differences in milk production were observed in the 3 weeks preceding and following treatment. Lower milk urea nitrogen was observed on d 7 and d28 in the low group ($P = 0.02$). No differences in progesterone concentrations were observed between treatments. In summary, feeding a diet with a slightly lower protein content increased pregnancy to TAI, with minimal effects on milk production.

Key Words: Ovsynch, fertility, crude protein

168 Reproductive tract differences in repeat-breeder cows. R. A. Cushman*, J. R. Miles, and S. E. Echternkamp, *U.S. Meat Animal Research Center*, *Clay Center, NE*.

The objective of the study was to evaluate the reproductive tracts of repeat-breeder cows that failed to calve in 2 consecutive years compared with cows that calved regularly. The hypothesis was that repeat-breeder cows would have smaller reproductive tracts and fewer antral follicles. Beef cows ranging from 3 to 13 years of age were classified as repeat-breeder (n = 37) or control (n = 34) cows. Cows were examined twice daily for behavioral estrus and artificially inseminated 12 h after observed estrus. Three to 8 d after estrus, cows were slaughtered, reproductive tracts were recovered and transported to the laboratory. All visible antral follicles were counted, ovaries were measured and weighed, and the diameter of the endometrium was measured in a subset of cows (n = 44) at the thickest point on the horn ipsilateral to the corpus luteum. The uterus was flushed and embryos were collected. Granulosa cells from small antral follicles (<5 mm) were pooled and frozen for real-time RT-PCR analysis. Reproductive traits were analyzed using the GLM or GLIMMIX procedure of SAS with group as the independent variable and day and age as co-variates. Repeat-breeder cows had smaller ovaries ($P \leq 0.006$) when corrected for day ($P > 0.13$) and age ($P > 0.17$), and fewer follicles ($P = 0.02$) when corrected for day ($P = 0.0009$) and age ($P = 0.42$). There was no difference in endometrial diameter ($P = 0.46$), or granulosa cell anti-Mullerian hormone ($P = 0.87$) or Pentraxin 3 ($P = 0.63$) mRNA levels between repeat-breeder and control cows when corrected for day ($P > 0.0.16$) and age ($P > 0.44$), but embryo recovery rate tended to be greater in control cows ($P = 0.06$). Regression analysis identified a positive relationship of antral follicle count to endometrial diameter ($P = 0.009$) and ovarian size ($P < 0.0001$). Fewer ovarian antral follicles in repeat-breeder cows may contribute to reduced fertility. The positive relationship between antral follicle count and endometrial diameter suggests that the number of ovarian follicles may influence proliferation of the endometrium in the early luteal phase of the cow.

Key Words: cow, reproductive tract, fertility

169 The effect of supplementation with conjugated linoleic acid on the reproductive performance of lactating dairy cows. I. A. Hutchinson*1,2, P. Lonergan[2], A. C. O. Evans[2], R. J. Dewhurst[3], and S. T. Butler[1], [1]*Teagasc*, *Moorepark DPRC, Cork, Ireland*, [2]*University College Dublin*, *Dublin, Ireland*, [3]*Teagasc*, *Grange, Meath, Ireland*.

Spring-calving dairy cows (n = 389) on a single pasture-based commercial dairy farm were randomly assigned to one of 2 dietary treatments (lipid encapsulated conjugated linoleic acid (Lutrell, BASF, Germany; CLA, n = 192) or No supplement (Control, n = 197)). The CLA cows received 50 g/day of a lipid supplement containing 5 g of both trans-10, cis-12 and cis-9, trans-11 CLA from 0 to 60 d in milk. Milk samples were collected 3 times per week, and each sample was analyzed for progesterone using a competitive ELISA test to determine interval to first ovulation. Milk yield and composition were measured fortnightly. Breeding commenced on a fixed calendar mating start date (Apr 8 2009), and continued for 16 weeks. Trans-rectal ultrasonography was carried out at 30–36 d and 60–66 d post AI to diagnose pregnancy. Milk yield, milk composition, and interval to first ovulation data were analyzed using mixed model analysis. All other reproductive data was analyzed using Chi-squared analysis. A reduction in milk fat concentration (36.9 vs. 30.7 g/kg; $P < 0.001$) and yield (0.91 vs. 0.84 kg/day; $P = 0.031$) was observed in CLA cows during supplementation. Milk yield was increased during CLA supplementation (24.7 vs. 27.2; $P = 0.003$). There was no effect of CLA on interval to first ovulation postpartum (40.2 vs. 44.4 d, CLA and control, respectively), conception rate to first service (35.1 vs. 37.0%), embryo mortality (14.3% vs. 21.4%) or 6-week in-calf rate (43.6% vs. 37.0%, all $P > 0.1$). In conclusion, supplementing dairy cows with CLA reduced milk fat synthesis but did not improve measures of reproductive performance, perhaps indicating energy availability was not the most limiting factor influencing herd fertility in this study.

Key Words: CLA, reproduction, dairy cows

170 The impact on pregnancy rates in dairy cattle artificially inseminated with semen prepared by number of progressivley motile sperm. L. Rabinovitch*[1], U. Shalit[1], M. Deutsch[1], Y. Zeron[2], and P. Chenoweth[3], [1]*Medical Electronic Systems*, *Caesarea, Israel*, [2]*Sion A.I. Company*, *Shikmim, Israel*, [3]*Charles Sturt University*, *Wagga Wagga, New South Wales, Australia*.

The trial objective was to evaluate the pregnancy rates of dairy cattle inseminated with varying amounts of progressively motile sperm, post thaw (PMPT). In phase 1, straws were prepared to contain specific numbers of progressively motile sperm, post thaw. In phase 2, cows were inseminated and pregnancy rates were analyzed. All semen testing and dosing was performed at an operating AI stud facility (SION A.I. Company) using an SQA-Vb, automated sperm quality analyzer for bulls (Medical Electronic Systems). Forty ejaculates collected from four bulls were split into four groups and 2000 straws per group were targeted

to contain: Group A, B and C; 1.5, 3.5 and 7.0 million PMPT sperm/straw respectively. The target for group D (Control) was 15.0 million total sperm per straw per the AI stud routine. Two hundred twenty-eight straws from groups A, B and C were quality control tested based on mean (+/− SE) values for PMPT sperm and demonstrated: (A) 1.5 (+/− 0.05); (B) 3.0 (+/− 0.09) and (C) 6.2 (+/− 0.18) million. Seventy-six straws from Group D (Control) established a mean (+/− SE) value of 13.6 (+/− 0.15) million. In total, 6,494 cows in over 500 farms were blindly inseminated between January and April 2009. At approximately 42 days post-insemination, pregnancy rates (per cow per cycle) were determined per rectal palpation by group as follows: (A) 34.2%; (B) 39.3%; (C) 43.2%; (D) 38.6%. The relative difference in pregnancy rates for groups A, B and C versus the control (D) were: −11.4%, 1.8% and 11.9%, respectively. Pregnancy rates in groups A, B and C correlated to the number of progressively motile sperm (r = 0.96). It is concluded that the number of progressively motile sperm per AI dose significantly impacts subsequent bovine pregnancy rates. Further, it is possible to accurately produce AI straws based on the number of PMPT sperm. Use of these findings could help improve bovine AI reproductive performance while allowing more effective utilization of superior bulls.

Key Words: bovine semen, SQA-Vb, bull AI

171 Effect of flunixin meglumine on prostaglandin metabolites and progesterone in lactating dairy cows. A. Ahmadzadeh*[1], S. Read[1], K. G. Carnahan[1], and J. C. Dalton[2], [1]*University of Idaho*, *Moscow*, [2]*University of Idaho*, *Caldwell R&E*.

Strategies to inhibit or reduce secretion of $PGF_{2\alpha}$ during early embryonic development may reduce embryonic loss and increase reproductive performance of dairy cattle. The objective was to examine the effect of flunixin meglumine (FM), a non-steroidal, anti-inflammatory drug, on $PGF_{2\alpha}$ secretion and luteal function by characterizing plasma prostaglandin metabolites (PGFM) and progesterone (P4) concentrations in lactating dairy cows during the luteal phase of the estrous cycle. Starting on d −35, estrous cycles of cows were synchronized using Presynch-Ovsynch. On d −9 (12 d after the second $PGF_{2\alpha}$ injection), and after detection of a corpus luteum (CL), Ovsynch was initiated. Ultrasonography was performed on d 0, 3, 7 and 15 to confirm ovulation and presence of a CL. Cows were not inseminated. On d 15 cows were assigned randomly to 2 groups: 1) FM group (n = 9) received 2.0 mg per kg BW (i.m.) of FM, 2) Control group received saline (n = 8). Jugular blood samples were collected at 30 and 0 min before treatment and at 30 and 60 min and each h thereafter for 6 h. Blood samples were also collected daily from d 15 to d 22. Mean P4 concentrations on the day of treatment (d 15) were not different between groups (6.3 vs. 7.2 ± 0.5 ng/mL). Plasma PGFM concentrations were not different between groups before treatment. Flunixin meglumine caused a transient decrease ($P < 0.05$) in plasma PGFM concentrations (58 ± 8.5 pg/mL) within 60 min after administration and concentrations remained low throughout the sampling period. Plasma PGFM remained unchanged in saline-treated cows (150 ± 9.2 pg/mL). Mean P4 concentrations decreased ($P < 0.05$) during 7 d after treatment; however, the rate of P4 decline over time tended ($P = 0.09$) to be greater for Control compared with FM. The results suggest that FM decreased plasma PGFM, suggesting FM negatively affects $PFG_{2\alpha}$ secretion in lactating dairy cows during the luteal phase of the estrous cycle. Moreover, FM may enhance luteal function by decreasing $PFG_{2\alpha}$.

Key Words: flunixin meglumine, prostaglandin $F_{2\alpha}$, dairy cows

172 Development of a mechanistic metabolic model of regulation of reproductive processes in dairy cattle. P. Celi[2], I. Lean[2], H. Raadsma[2], A. Rabiee[2], and J. P. McNamara*[1], [1]*Washington State University*, *Pullman,* [2]*University of Sydney*, *Camden, NSW, Australia*.

The objective was to construct and begin evaluation of a deterministic, mechanistic, dynamic model of nutritional and genetic control of reproductive processes in the dairy cow. The objective of this conceptual research model is to describe control of reproductive processes in dairy cattle at the metabolic level; and to be suitable for evaluation of data, concepts and hypotheses regarding underlying genetic, nutritional and physiological control of reproduction. We began with an existing model of metabolism in the cow, published and validated (Molly, UC Davis), which describes utilization of glucose, amino acids and fatty acids by muscle, adipose, visceral and mammary tissues at an aggregated metabolic pathway level. Elements of genetic background, response to nutritional environment and metabolic hormones are explicitly embodied in equation forms and parameter values. Next, a model of reproductive processes was developed that included flux of follicle stimulating hormone, luteinizing hormone, estrogen and progesterone in cycling and pregnant animals; as well as development of the calf to term. The models are integrated into one system to link genetic elements (for example, genetic merit for milk); nutrient use and reproductive processes, with an integration interval of one day. Based on published data, equations describe production of estrogen and LH, breakdown of estrogen and progesterone by the liver (mass action related to rate of metabolism); growth of the follicles as a function of glucose, IGFI and growth hormone (Michaelis-Menten); conception and growth of a single calf to term as a function of progesterone, glucose, amino acids and total energy (Michaelis-Menten). Degradation of steroids is related to metabolic rate through both intake of nutrients and output of milk components and to continuation of pregnancy. The model behavior for these variables (pattern and direction of response) is consistent with literature values from studies not used in the development. This research model should be useful to frame specific hypotheses on control of reproductive processes by genetic and nutritional driven mechanisms.

Key Words: reproduction, nutrition, research model

173 Effect of dietary supplementation of mannan-oligosaccharides and *Lactobacillus*-based probiotics on indigenous intestinal bacterial ecology and intestinal microarchitecture of broilers reared under heat stress. M. U. Sohail*, I. Ahmad, H. Rehman, K. Ashraf, S. Yousaf, S. Ashraf, and H. Zaneb, *University of Veterinary and Animal Sciences*, *Lahore, Punjab, Pakistan, 54000.*

The present study aims at evaluating the effects of dietary supplementation of prebiotics or probiotics alone or in combination on growth performance, relative-weight of viscera, mucosal microarchitecture and some selected intestinal microbiota in broilers reared under hot humid conditions. Day-old broilers (n = 250) were randomly divided into 5 groups. Birds in the control group were reared under standard management conditions and fed a corn-based basal diet without any dietary supplementation. The birds exposed to cyclic-heat stress (35°C and 75%RH, 8hr/d, 1000–1800 h from d22 to 42), were fed a basal diet (HS group) alone or supplemented with 0.5% mannan-oligosaccharides (MOS), or 0.1% *Lactobacillus*-based probiotics (LP) or combination of both (symbiotic). On d 42, 15 birds from each group were killed to determine relative-weights of visceral organs, mucosal morphometry and numeration of jejunum and cecal *Clostridium perfringens*, coliform and *E. coli*. The data were analyzed using ANOVA. Results revealed that heat stress decreased ($P < 0.01$) body weight gain, feed conversion ratio (FCR) and relative weights of organs compared with the control group. Dietary supplementations increased the FCR ($P < 0.05$), relative weights of spleen ($P < 0.01$), small intestine ($P < 0.01$) and cecum ($P < 0.01$) compared with HS group. However, supplemented diets did not affect the relative weights of bursa of Fabricius ($P = 0.07$) liver, pancreas, gizzard and heart. Heat stress increased the cecal population of coliform, ($P < 0.05$) *Clostridium perfringens* ($P < 0.01$) and *E. coli* ($P < 0.05$) compared with control group without affecting the jejunal ($P = 0.61$) bacterial count. Supplementation of MOS alone or probiotics reduced ($P < 0.05$) the cecal count of *Clostridium perfringens*. The villus height was more ($P < 0.05$) in supplemented groups compared with the HS group. In conclusion, supplementation of prebiotics and probiotics is a good tool for maintaining production performance of broilers during hot humid months.

Key Words: broiler, heat stress, prebiotics, probiotics

174 Effects of turning frequency during incubation on broiler embryonic development. Y. M. Lin*[1], J. T. Brake[1], S. Yahav[2], and O Elibol[3], [1]*North Carolina State University, Department of Poultry Science, Scott Hall*, *Raleigh,* [2]*Institute of Animal Science, ARO, The Volcani Center*, *Bet-Dagan, Israel 50250*, [3]*Department of Animal Science, Faculty of Agriculture, University of Ankara*, *Ankara, Turkey*.

The effects of turning broiler hatching eggs 24 (24X) or 96 (96X) times daily to E15 was studied. Eggs were obtained from Ross 344 male x Ross 708 female broiler breeders at 36 wk of age. Freshly laid eggs were weighed and selected to provide equal egg weights in each turning treatment before storage for 1 d at 16 C and 60% RH followed by preheating at 24 C for 12h prior to setting. Each of 180 individually weighed eggs per turning treatment constituted a replicate. The 24X treatment was turned 24 times daily to E18, while the second group was turned 96X from E0 to E15 followed by 24X to E18 before transfer to hatching baskets in individual pedigree bags. Incubators were operated at 53% RH at all times and an air temperature of 37.5 C until E12, 37.3 C from E13 to E 18, and 36.9 C thereafter in Natureform NMC-1000 incubators. At E15 of incubation, 30 fertile eggs were necropsied to determine embryo length, and weights of the egg, embryo, yolk sac, and embryonic fluids. Chick BW and length were measured on all chicks at E20.5. A T-test was used to compare means and variances. Embryo length at E15 was greater ($P < 0.05$) in the 96X treatment but with a greater variance ($P < 0.05$) as well as a greater variance ($P < 0.05$) in relative yolk sac weight and embryo weight. However, at hatching (E20.5) chick weight relative to initial egg weight and chick length was greater ($P < 0.05$) in the 24X treatment but there was greater variance ($P<0.05$) in the relative chick weight. These data indicated that more frequent turning to E15 resulted in a faster growing but less uniform embryo at E15. However, after the 96X turning frequency was discontinued at E15 the 96X treatment regained its uniformity as embryo growth relative to the 24X treatment apparently slowed to E20.5. These data suggest that embryo growth and development is affected by turning frequency

Key Words: broilers, incubation, turning

175 Effects of arginine, vitamin E and mannanoligosaccharides after coccidiosis vaccination and challenge in broiler chickens. D. J. Chan-Diaz*[1,2], D. Caldwell[1], S. Pohl[1], G. Casco[1], A. Pro[2], S. Fitz-Coy[3], and C. A. Ruiz-Feria[1], [1]*Texas A&M University*, *College Station*, [2]*Colegio de Postgraduados*, *Montecillos, Mexico*, [3]*Intervet/Schering-Plough Animal Health*, *Millsboro, DE*.

Arginine (ARG), vitamin E (VE) and mannanoligosaccharides (MOS) have immunomodulatory effects. One d old broiler chicks (n = 200) were housed in wire cages and assigned to one of 8 treatments in a 2 × 4 factorial experiment: vaccinated (VA; Coccivac-B, 1X dose / chick at d 1) or non-vaccinated (NV) and fed a control diet (CTL, 3100 kcal / kg of EM, 22% CP, 1.4% ARG, and 40 IU of VE / kg of feed) or CTL plus ARG and VE (AVE; 0.3% and 40 IU, respectively); CTL plus MOS (MOS, 0.2%), or CTL plus ARG, VE and MOS (AEM, same levels). At 24 d, all birds were orally challenged with 2×10^5 oocysts from a mixed field-strain *Eimeria* inoculum (*E. acervulina*, *E. maxima* and *E. tenella*). The BW was recorded weekly; intestinal lesion score (LS) and immune organ weight (bursa of Fabricius, spleen, and thymus) were measured at d 30 (9 birds / treatment); oocyst shedding (OS; oocysts / g of feces) was measured from d 29 to d 31. Data were analyzed (ANOVA) and means separated using the Tukey procedure ($P < 0.05$). At wk 4, VA birds were heavier than NV birds, but the effect of diet was not significant. The spleen and bursa were not affected by treatment, but birds in the group VA-MOS had the highest thymus weight. Birds in the VA-MOS and NV-CTL group had the highest LS (1.56 ± 0.2), whereas birds in the VA-CTL group the lowest LS (0.67 ± 0.2) in the upper intestine (duodenum). The OS was not affected by treatment at d 29 or 31, but at d 30 VA birds had less oocysts in feces (556,342.5 ± 140,756.2) than NV birds (1,021,775.0 ± 140,756.2). Thus, MOS supplementation increased LS but also increased the thymus weight. Vaccinated birds were heavier and had lower OS than NV birds irrespective of diet. The beneficial effects of ARG and VE were not noticeable, perhaps because birds were kept in cages and oocyst cycling was prevented.

Key Words: arginine, vitamin E, coccidiosis

176 The effect of double interspiking on fertility, stress, and hormone levels in broiler breeder males in heat-stressed environments. K. M. Chung*, M. O. Smith, and H. G. Kattesh, *University of Tennessee*, *Knoxville*.

The male management technique of double interspiking is sometimes used to counteract fertility decline experienced by broiler breeders. The objective of this experiment was to investigate the effects of this practice on flock fertility, testosterone concentrations, and stress responses of broiler breeder males undergoing double interspiking in heat stressed environments. In a completely randomized design study, 2 hundred and 88 pullets and 36 roosters (Ross 708) were assigned to 3 groups at 21 weeks of age. All groups were housed on plastic slatted floor pens and experienced a simulated heat stress environment in which room temperature cycled from 23.8 to 30°C. Double interspiking was carried out among 2 groups at 42 and 52 weeks of age. Beginning when birds were 32 weeks of age, eggs were set every 2 weeks, candled at d 12, and percent fertility calculated. Testosterone and corticosterone levels were measured by RIAs at specific time points, and heterophils (H) and lymphocytes (L) were counted to calculate H:L ratios. All data were analyzed using the mixed model ANOVA (ANOVA) procedure of SAS 9.1 (SAS Institute, Cary, NC, USA), and least squares means used to determine significance. Introduction of new males resulted in a fertility increase ($P < 0.01$) of 21.8% between control birds and spiked birds after the first interspike and a sustainment of fertility levels after the second interspike. Testosterone concentration declined ($P < 0.0001$) from 1.95 ng/mL to 0.11 ng/mL as the birds aged. The male management practice of double interspiking shows promise in increasing fertility levels in a broiler breeder flock.

Key Words: broiler breeder, double interspiking, heat stress

177 Effects of breeder feeding and trace mineral source on leg health and bone traits of broiler progeny. P. E. Eusebio-Balcazar*[1], E. O. Oviedo-Rondón[1], A. Mitchell[2], J. Brake[1], M. J. Wineland[1], V. Moraes[1,3], and N. Leandro[1,4], [1]*North Carolina State University*, *Raleigh,* [2]*USDA-ARS, BARC*, *Beltsville, MD*, [3]*Universidade Estadual Paulista, UNESP*, *Jaboticabal, SP, Brasil*, [4]*Universidade Federal de Goiás*, *Goiania, GO, Brasil*.

This study evaluated the effects of breeder feeding practices and trace mineral (TM) sources for breeders on leg health and bone traits of broiler progeny at 49 d. Cobb 500 breeders were fed either corn (C) or wheat (W) based diets during rearing and production using either sigmoid late fast (LF) or sigmoid late slow (LS) feed allocation programs until peak egg production. At 23 wk, 69 females representing the BW distribution of each pen were placed in a 2/3 slat layer house where feeder space remained the same (S) or increased (M). From 56 to 62 wk of age, breeders were fed corn-soybean diets with 5% DDGS and either inorganic (ITM) or an organic (OTM) source (Mintrex P) to replace 30% of Cu, Zn, and Mn. Total levels of the TM evaluated were 25, 125, and 125 ppm, respectively. Eggs produced at 62 wk of age were incubated. Progeny were placed in 64 floor pens with 15 males and 15 females/pen and 4 replicates per breeder treatment. Broiler gait scores (GS) and prevalence of leg problems were evaluated at 11 and 47 d. Bone mineral density (BMD) and mineral content (BMC) were determined with DEXA. Data were analyzed as a 2 × 2 × 2 × 2 factorial design considering main factors of diet type, feeding program, feeder space and TM source. For GS data, the log odds of probabilities were modeled within factorial effects to obtain the likelihood of observing each leg problem using GLIMMIX. Results indicated that broilers coming from breeders fed diets with 30% OTM were more likely to have better walking ability than broilers from breeders fed ITM in both GS evaluations. Broilers from breeders fed ITM and having M feeder space in production were more likely to have valgus deformations than the same group fed OTM. Wheat diets fed to breeders and broilers caused lower BMD and BMC in broilers at 49d. OTM fed to breeders caused thicker shanks in broilers. Shank BMD and BMC was higher in broilers from breeders fed OTM compared with those breeders fed only ITM in the LS and S groups only. It appeared that 30% OTM in breeder diets may help to reduce some leg health issues observed in broiler progeny influenced by breeder feeding practices.

Key Words: breeder nutrition, trace minerals, leg problems

178 Dietary vitamin E supplementation and shelf life of ground broiler chicken meat during refrigerated storage. B. Saenmahayak*, M. Singh, J. B. Hess, W. A. Dozier III, and S. F. Bilgili, *Auburn University*, *Auburn, AL*.

This study was conducted to determine the microbial spoilage and oxidative stability of ground raw and cooked breast and thigh meat from broiler chickens fed graded levels of vitamin E during refrigerated storage. A total of 480 female broilers were assigned to 4 dietary vitamin E treatments (IU/kg of feed): 30 (basal level), 60, 120 and 240. Each of the 4 dietary treatments was fed in a 3 stage feeding program to 12 replicate pens of 10 birds and reared to 49 d of age. Upon processing, one-half of the replicate pens from each dietary treatment were used for raw and the other half for cooked meat treatments. Boneless-skinless breast and thigh meat (5 birds per pen) was ground, pooled by pen, formed into patties, vacuum packaged (oxygen impermeable) either raw or cooked (internal temperature of 80°C), and held under 2°C. Samples were analyzed for microbial spoilage (aerobic plate counts; APC, lactic acid bacteria; LAB, and yeast and molds; YAM) and lipid oxidation (TBARS) following 1, 3, 6, 12 d of refrigerated storage. Microbial numbers increased with storage time in both raw breast and thigh meat ($P < 0.05$), with APC counts on thigh meat reaching 7 $\log_{10}$ CFU/g after 12 d of storage. Cooking reduced microbial counts and slowed the rate of microbial growth in breast and thigh meat during refrigerated storage. Vitamin E supplementation affected microbial counts only for raw (APC on 6 d) and cooked (APC and LAB on 6 and 12 d, and YAM on 12 d) for thigh meat, with levels of 240 IU/kg significantly impeding microbial growth as compared with basal levels. Lipid oxidation increased during refrigerated storage on both raw and cooked ground meat (breast < thigh meat). Dietary vitamin E supplementation at levels > 120 IU/kg significantly reduced the rate of lipid oxidation in cooked ground breast and thigh meat as compared with the basal level. In this study, microbial and oxidative changes that occur during refrigerated storage of ground cooked broiler meat appeared to correlate and were positively influenced by dietary vitamin E supplementation.

Key Words: vitamin E, shelf-life, lipid oxidation

179 Impact of feeding time and photoperiod on egg production patterns in broiler breeder females. D. C. Paul*, M. J. Zuidhof, Ali Pishnamazi, and R. A. Renema, *University of Alberta*, *Edmonton, Alberta, Canada*.

The purpose of this study was to determine the effects of feeding time, dietary energy and photoperiod on egg production patterns in broiler breeder females. A total of 192 Ross 708 broiler breeder females were housed in 6 light- and temperature-controlled environmental chambers and each chamber containing 32 individual cages. The experiment was a 4 × 2 × 2 factorial of design, with 4 feeding time treatments (morning, noon, afternoon, or split feeding with 50% of the daily feed allotment split between morning and afternoon); 2 dietary metabolizable energy levels (high, 2900 or low, 2700 kcal/kg); and 2 photoperiods (24L:0D or 16L:8D). Standard breeder BW targets were achieved using daily feed restriction throughout the study period. Individual body weight was measured once per week. SAS Proc mixed was used to analyze the data.

Split feeding had increased egg weight compare to other feeding time ($P = 0.1$). Moreover, the split feeding, high energy (2900 kcal/kg) and photoperiod (16L:8D) interaction had the highest egg weight. Hens were energy efficient with split (two times) feeding system than one time and shorter photoperiod. However, the main effects of dietary energy and photoperiod had no significant effect on egg weight and egg production. Efficiency of broiler breeder female can be improved ensuring split feeding, dietary high energy and photoperiod (16L:8D).

Key Words: feeding time, photoperiod, egg production

180 Dietary camelina meal for broiler chickens: 1. Growth performance at 0, 5, and 10% inclusion rates. R. M. Hulet*, P. H. Patterson, A. Y. Pekel, and T. L. Cravener, *The Pennsylvania State University*, *University Park*.

Camelina sativa is an oilseed plant from the Brassicaceae family. It has recently been grown in N. America for biodiesel production with the residual meal utilized as a dietary protein supplement with a significant complement of omega-3 fatty acids. An experiment was conducted to examine the effect of dietary camelina meal (CM) supplementation on broiler live performance. A total of 864 Ross × Cobb-500 straight run chicks were allocated to control (Con), 5% or 10% CM diet treatments with 8 replicated pens per treatment from 1 to 35d. Data were analyzed using a 3-way ANOVA design with significance determined at the $P \leq 0.05$ level. The CM utilized in this study contained 33.6% CP, 15.0% Fat and 4.22% total omega-3 fatty acids. Birds were given water and feed ad libitum. Birds and feed were weighed at 0, 14, 28, and 35 d of age. Body weight, feed intake and conversion were calculated at each period. Cumulative feed intake was not significantly different between dietary treatments. However, body weight at both 28 and 35 days, respectively, was significantly less for broilers fed the 10% CM diet (1.38, 2.52 kg) when compared to the broilers fed 5% CM (1.48, 2.20 kg) and Con (1.46, 2.17 kg) diet. Mean body weight was similar between the broilers on the Con and 5% CM dietary treatments at both 28 and 35 d. Therefore, feed conversion for the 0 to 35 day period was significantly greater for the 10% CM fed broilers (1.783) over the 5% CM (1.702) and Con (1.698) fed broilers. Mortality was not significantly different at any period or cumulatively with an overall average of 5.44% for the experiment. Based on this study, broiler growth performance equal to a Con diet can be achieved by feeding diets with an inclusion rate of at least 5% CM.

Key Words: *Camelina sativa*, broiler chickens, biofuel

181 Evaluation of a poultry house for the presence of *Salmonella* and fungi at different sites through the broiler production continuum. J. A. Byrd*, C. L. Sheffield, and T. C. Crippen, *USDA-ARS-Food and Feed Safety Research Unit*, *College Station, TX*.

Companies continue to produce safe and wholesome products while facing increased regulatory pressure to control foodborne pathogens in poultry. Although many risk factors that contribute to *Salmonella* concentrations have been identified, precise identification of the most effective sites for intervention have not been established. The present observational study evaluates a new poultry house with different environmental parameters on *Salmonella* and fungal incidence at different points of production. One broiler house with 4 consecutive flocks was studied. Preharvest sample points included tray pads (2/sample point), litter (12/sample point), water (3/sample point), feed (3/sample point) and birds (20/sample point) sampled at d 0, 18, 32, 46, and 62. All samples were evaluated for *Salmonella* and fungi. Prior to placemen on the farm, *Salmonella* and fungi was detected in all water, feed, hatchery (traypads), and in 18% of the litter samples. Water samples were 100% positive for *Salmonella* at Days 1 and 18 in Flocks 1–3. Similarly, *Salmonella* was detected in high levels (60–100%) in Flocks 1 and 3 on Days 1 and 18. However, ceca samples evaluated for *Salmonella* were found under 5% on all days except for Flock 3 which had Salmonella 95% (Day 1) and 25% (Day 18). Fungal samples tend to decrease as the broilers get closer to market. The relationship between *Salmonella* and fungi will be evaluated. The data demonstrates the importance of pathogen-free environmental conditions even on new farm. Data from this study may help poultry professionals understand how environmental factors including fungi may affect foodborne pathogens in poultry and the difficulty that may be encountered in making risk management decisions.

Key Words: environmental, *Salmonella*, fungi

182 Effect of abrupt versus gradual changes to daylength on productivity of broilers. K. Schwean-Lardner* and H. L. Classen, *University of Saskatchewan*, *Saskatoon, SK, Canada*.

With the objective of determining the impact of an abrupt change in day length and light intensity on productivity and welfare of broilers, 3 lighting programs were tested using Ross x Ross 308 broilers (2,160 male and 2,565 female). Birds were housed within 10 sex-separate pens in each of 9 rooms at 30 kg/m^2. The lighting schemes tested were: 1. Control (C) - 23Light (L) (20 lx (l)):1Dark (D) (0 l) from d 0–38, 2. Abrupt (A) - 23L (20 l):1D (0 l) to d 10, then an abrupt change to 14L (1 l):10D (0 l) to d 38, 3. Gradual (G) d 0 - 23L (20 l):1D (0 l); d 1 - 21L (20l):1 dusk:1D: (0l):1 dawn; followed by gradual changes in day length and intensity until d 10 - 13.5L (6l): 1 dusk: 8.5D (0l) 1 dawn. Data were analyzed with a nested design of Proc GLM, and when significant, Duncan's Multiple Range test for mean separation. Specific comparisons between abrupt and gradual data were analyzed using A Priori contrasts. At 14 and 21 d of age, birds raised under the A and G program were lighter than those raised under the C program, and contrasts show G birds were heavier than A. Daily feed consumption, measured from d 7 to d 13, showed a significant drop in intake when the abrupt lighting change took place, while no decline was noted in the gradual change. Birds on C ate the most until 21 d and overall. G birds ate more than A from 7 to 14 d and 14–21 d, but less from 21 to 38 d. Overall, birds on these 2 programs ate similar amounts. Gain to feed ratios were poorest for C birds, and were better for G vs A birds until 14 d and thereafter the ratios were similar. Mortality or uniformity did not vary with lighting program. Birds raised on C had a higher percentage of carcass based on live weight than A, higher breast yield than A or G, and a higher percentage of wings than G birds. In conclusion, abrupt changes to a lighting program cause an immediate and dramatic decline in feed intake and feed conversion efficiency that are not noted when the changes are made gradually.

Key Words: broiler, daylength

183 Influence of long-bright, increasing-dim, and split-dark-bright lighting programs and strain on broiler performance. R. J. Lien*, J. B. Hess, and S. F. Bilgili, *Auburn University*, *Auburn, AL*.

Broilers were provided lighting programs either historically used to maximize growth, or meeting US National Chicken Council or European Union guidelines, to determine their influence on performance. Forty males of tray pack (TP) or breast yield (BY) strains were placed by strain in each of 2 1.5 by 3.7 m pens in 12 light controlled rooms. Four rooms were provided a long-bright photoperiod treatment (LB) (23L:1D and 2 footcandles [FC]). Four rooms were provided increasing-dim treatment

(ID) (1–7 d, 23L:1D; 8–14 d, 12L:12D; 15–21 d, 14L:10D; 22–28 d, 17L:7D; 29–35 d, 20L:4D; 36–47 d, 23L:1; 1 FC to 7 d and 0.25 FC thereafter). Four rooms were provided a split dark period and bright intensity treatment (SDB) (16L:4D:2L:2D and 2 FC). Ten birds per pen were processed at 47 d to determine parts weights and yields. Data were analyzed by GLM of SAS at a significance of $P < 0.05$ for live and $P < 0.10$ for processing variables. Feed consumption and BW were reduced in ID relative to LB and SDB at 15 and 21 d (all Ps < 0.0001). BW were greater ($P = 0.036$) in ID and SDB than LB at 47 d. Feed conversion was improved ($P = 0.006$) at 15 d in ID relative to LB and SDB, but otherwise unaffected ($P > 0.05$). Weight and consumption were usually more ($P < 0.05$) in TP than BY, and TP feed conversion was better at 15 ($P = 0.011$) and 22 d ($P = 0.023$). Mortality was greater ($P = 0.003$) in TP than BY. Carcass yields were unaffected by treatment ($P = 0.75$) or strain ($P = 0.87$). Wing ($P = 0.038$) and drum ($P = 0.028$) weights were greater in ID than LB and SDB. Total breast ($P = 0.08$) and fillet ($P = 0.086$) yields were greater in LB than ID, with SDB intermediate. Tender yields were greater ($P = 0.059$) in LB than SDB, with ID intermediate. Wing yields were greater ($P = 0.029$) in LB and ID than SDB. All parts were heavier ($P < 0.10$) in TP than BY and there were no strain effects ($P > 0.10$) on parts yields. Fat pad weights ($P = 0.033$) and yields ($P = 0.002$) were greater in BY than TP. These results confirm our previous observations that broiler lighting can influence performance to a greater extent than strain, particularly with respect to breast yield.

Key Words: broiler, lighting, production

184 Free-choice feeding of free-range meat chickens. A. C. Fanatico*[1], V. B. Brewer[2], C. M. Owens[2], and A. M. Donoghue[1], [1]*USDA Agricultural Research Service, Poultry Production and Product Safety Research*, *Fayetteville, AR,* [2]*University of Arkansas Department of Poultry Science*, *Fayetteville*.

Specialty poultry production is growing, including free-range, organic, and small flocks. Feed is a high cost, particularly for organic producers and small-scale producers. Free-choice feeding, where feed ingredients are provided in separate containers, may offer cost savings, including the use of on-farm ingredients, reduction in feed transportation, and milling costs. A study was conducted to determine the impact of free-choice feeding on performance in free-range meat chickens. Pens of slow-growing chickens (20 birds per pen) were randomly assigned to one of 2 treatments: fully formulated diet (FF; control) or free-choice (FC) diet. There were 5 replications of these treatments. Birds were raised in floor pens in a naturally ventilated house; popholes provided access to grassy yards during the day. During the starter period (wk 0–3), formulated feed was provided to both treatments. During the grower period (wk 4–6), FC treatment also received formulated feed along with free-choice ingredients for training, and during the finisher period (wk 7–12), FC only received free-choice ingredients. Birds were commercially processed at 83 d. The formulated diet was a commercial product with an average of 20.75% crude protein (1.04% total sulfur amino acids); while the free-choice diet chosen by birds at 11 weeks was 13.2% crude protein (0.70% total sulfur amino acids). Final live weights were analyzed by *t*-test (SAS 9.2) and did not differ between treatments ($P > 0.05$); however, ready-to-cook yields and breast yields were higher in the birds from the FF treatment ($P < 0.05$). These higher yields are most likely due to amino acid supplements in the formulated feed. The diet chosen by FC birds at end of finisher period was less expensive than the formulated diet ($0.07/kg vs. $0.08/kg). These data indicate that while free-choice feeding of free-range chickens resulted in a 1.4% lower breast yield than formulated feeding, FC feed cost was lower. The USDA National Organic Program is planning to ban synthetic methionine, and when that occurs, there may be no difference in yield among birds from formulated and free-choice diets.

Key Words: dietary self selection, poultry, free-range

185 Omega-3 PUFA and lutein enrichment: Different feeding strategies and effect on storage stability. S. Nain* and R. A. Renema, *University of Alberta*, *Edmonton, AB, Canada*.

Enrichment diets high in ground flax may cause irritation to the gut, which may affect absorption of omega-3 polyunsaturated fatty acids (ω-3 PUFA) from flax as well as other dietary enrichment ingredients. This study assessed the egg enrichment with ω-3 PUFA and Lutein when provided alone in the diet, in combination, or when fed in alternate day patterns. A total of 144 individually caged Lohman White Leghorn layers (56 wk) were fed 1 of 6 diets balanced for energy and protein for 60d as follows: Control (C) = Standard hen ration; Lutein (L) = 500 ppm lutein; Flax (F) = 10% flaxseed; Lutein/Flax mix (LF); Alternating L and F diets every day (Alt1) or second day (Alt2). Egg traits were determined and yolks collected at 0d, 14d, 28d and 56d. Eggs from 57d were stored at 4 C for 30d for assessment of oxidative stability through TBARS analysis. Data were analyzed using proc Mixed of SAS. Hen diet did not affect egg production, egg weight, albumin height or shell thickness. Although, absolute yolk weight was higher in birds on C diet as compare to other diets, but % yolk weights were similar. Total ω-3 PUFA in LF and F eggs averaged 13.9 mg/g yolk compared to 11.6 mg/g yolk in Alt1 and Alt 2 eggs and 8.8 mg/g in L and C diets. Lutein followed a similar enrichment pattern, with birds fed L or LF having the highest egg content (25.7 µg/g yolk). While L and LF eggs had 3-fold more lutein than C or F eggs (8.4 µg/g), those from alternate day fed hens had 2-fold more lutein. Including both flax and lutein in the hen ration did not reduce egg lutein enrichment. Inclusion of lutein generated the lowest TBARS values (0.60 mg/MDA in L and LF) compared to diets without lutein (0.75 mg/MDA in C and F), demonstrating a potential antioxidant role in the egg. Yolk lutein concentration was positively correlated to canthaxanthin (r= 0.65, P=<.0001) and β-carotene (r= 0.40, P<.0001). Egg storage did not affect yolk lutein and β-carotene amount, whereas canthaxanthin was reduced. Lutein enrichment improves the overall carotenoid profile and also enhances stability during storage of egg, and was not negatively affected by ω-3 PUFA enrichment using flaxseed.

Key Words: lutein, ω-3 PUFA, TBARS

186 Effect of egg storage conditions on gene expression during turkey embryonic development. J. A. Hamidu*[1], M. Li[1], G. M. Fasenko[2], and L. L. Guan[1], [1]*University of Alberta*, *Edmonton, Alberta, Canada*, [2]*University of New Mexico*, *Albuquerque*.

Different conditions of avian egg storage before incubation are known to cause variation in embryonic mortality in poultry species. We hypothesized that genes regulating apoptosis (*Blc-2, Bcl-xL, Bax, Bak* and *Bok*) or early embryo development (*Btg1*) could be differentially expressed under different storage conditions which may play a role to control turkey embryonic development. In this study, eggs from Hybrid turkey flocks were stored for 4 d and 14 d under standard storage conditions Total RNA was extracted from pooled embryo samples (n = 5 per treatment) after incubating the eggs for 6 d at 37.5°C and 56% RH. The expression levels of *Blc-2, Bcl-xL, Bax, Bak, Bok* and *Btg1* genes were compared using quantitative real time PCR analysis. The data was analyzed by PROC MIXED model procedure of SAS at $P \leq 0.05$. LSmean differences between egg storage treatments were separated by PDIFF. The results showed that the genes associated with pro-apoptotic processes were differentially expressed in 14 d vs. 4 d egg storage treatment: *Bax* and *Bok* were upregulated ((*Bax*, 1.71 fold, $P = 0.0428$; *Bok*, 1.39 fold, $P = 0.007$) while *Bak* was downregulated but not significant (0.37 fold, $P = 0.0628$). Moreover, the genes associated with anti-apoptotic events were upregulated (*Bcl-2*, 1.34 fold, $P = 0.3026$; *Bcl-xL*, 1.23 fold, $P = 0.0003$). However, the expression of *Bcl-2* was not statistically different between treatments. These genes were identified to be involved in different KEGG pathways of apoptosis: mitochondrial pathway or p53 pathway. The *Btg1* gene, was also downregulated following egg storage for 14 d compared with 4 d (0.54 fold, $P = 0.0150$). Our findings demonstrate increased expression of apoptosis events and decreased response to growth and development at the molecular level following egg storage for 14 d. This study shows that the probability to control some of the effects of egg storage commercially is promising if apoptosis can be controlled.

Key Words: egg storage, RNA, gene expression

187 Body weight change, breast muscle, and reproductive tract development in broiler breeder hens and their effects on fertility and egg production. N. Leksrisompong*, J. T. Brake, and E. O. Oviedo-Rondon, *North Carolina State University, Department of Poultry Science, Scott Hall*, *Raleigh*.

A study was conducted to determine the effects of the relationship among changes in BW gain, breast muscle, and reproductive tract development in broiler breeder females. Pullets were reared in 16 litter floor pens from hatching to 22 wk of age. Females that represented the BW distribution of each pen were selected and moved at 22 wk to 128 individual cages. Individual BW was taken at 22, 25, 26, 33, 48, and 53 wk of age. BW change between each period was determined. Breast muscle weight was estimated in vivo with real-time ultrasound (RTU) at 25, 26, 48, and 53 wk. A multiple linear regression equation that included BW, area of breast muscle (BM) taken by RTU and strain was estimated. Fertility was measured at 31 and 48 wk. Total egg production per hen was recorded. At 53 wk, all hens were necropsied to determine weights of BM, ovary, and oviduct segments. Results indicated that RTU can be used to estimate BM weight (r2 = 0.91) in broiler breeders. It was found that BW change between 22 to 26 wk was positively correlated with BM weight (r = 0.70), but negatively correlated with total egg production (r = 0.37). Breast muscle at any age was negatively correlated with infundibulum (r = 0.25) and with total egg production (r = 0.26). Breast muscle was also negatively correlated with fertility when evaluated at 31 wk, but not at 48 wk. Changes in BW in time periods other than 22 to 26 wk were not correlated with total egg production or fertility. It would appear that, in the presence of excess feed between 22 and 26 wk, hens developed their breast muscle at the expense of their infundibulum, and this may affect fertility, and total egg production.

Key Words: real-time ultrasound, broiler breeder, oviduct

188 Effects of temperature on egg size and quality. A. G. C. DesLauriers*, M. J. Zuidhof, R. A. Renema, D. Paul, and A. Pishnamazi, *University of Alberta*, *Edmonton, Alberta, Canada*.

Environmental temperature has a large impact on broiler breeder maintenance requirements. Energy for maintenance accounts for up to 3/4 of total energy intake. Therefore incremental changes in maintenance requirements may substantially influence energy available for other processes such as growth or egg production. Thus temperature is important for egg production, egg size and chick size. An experiment was conducted to determine the effect of temperature on egg size and

quality. A total of 192 individually caged broiler breeders were exposed to differing environmental temperature treatments (15, 19, 23, and 27°C). The treatments were randomly assigned to 6 individual environmental chambers for 2 week periods, with 15 replicates of each temperature treatment over a 20 week trial period. All eggs were collected, weighed and graded daily. Temperatures were recorded using automated data loggers positioned at bird head height, on a 30 min interval and were averaged for the 24 hour period prior to oviposition. Data were analyzed as a 2 way ANOVA using the mixed procedure of SAS. Significant differences were reported at $P < 0.05$. Egg size increased from an average of 57.5 ± 0.24 g in the 15°C treatment with each increasing temperature trial up to 23°C (60.0 ± 0.24 g); a further temperature increase to 27°C resulted in a drop in egg size (58.0 ± 0.24 g), presumably due to heat stress. Temperature was found to have a significant effect on production of grade A eggs with the highest percent of grade A's in the 19°C and 23°C treatment. The 27°C treatment had the lowest percentage of grade A eggs and the highest incidence of soft shelled eggs. Shelless eggs were also highest in the 27°C treatment (0.708 ± 0.123%) although not significantly different from the 19°C treatment. The 15°C treatment had the lowest incidence of misshapen shells (0.302 ± 0.252%). Overall the data suggested that maintenance energy requirements increased with decreasing environmental temperatures and at the highest environmental temperature tested, there was indirect evidence of metabolic stress (reduced egg size and quality).

Key Words: temperature, egg size, egg quality

189 The impact of distillers dried grains plus solubles (DDGS) diets on hen performance, egg quality, and manure nutrients. P. H. Patterson, A. Y. Pekel, A. Adrizal, H. K. Burley*, T. L. Cravener, E. F. Wheeler, and P. A. Topper, *The Pennsylvania State University*, *University Park*.

Diets including 10% DDGS with (D+P) or without (D) the probiotic Provalen (500g/1000kg) were compared with a corn-soybean based control diet (CON) in a commercial hen house. Three groups of 39,800 Lohmann LSL-Lite hens were fed isocaloric, amino acid balanced research diets from 20 to 65 wk of age with 2 of 6 rows of stacked cages with manure belts assigned randomly per diet. Replicated monthly data, including hen body wt (BW), egg production (EP) and weight (EW), albumen height (AH), Haugh units (HU), yolk color (YC), and shell strength (SS) and thickness (ST), was collected from 558 hens in a section of each cage row. Feed/water intake, BW, EP, case weight, mortality, feed cost (FC), and egg income (EI) was also tallied weekly by the egg company for each diet. Monthly samples of fresh manure were taken off the manure belts (6/treatment) and from the manure storage building (2/treatment) and analyzed for moisture and agronomic nutrients. Statistical analysis was done with SAS version 9.1 using Tukey's mean comparisons with $P \leq 0.05$ deemed significant. Diet did not significantly impact BW, EW, HU, SS, or ST ($P > 0.05$); however, CON hens had lower EP, AH, and YC than D and D+P hens ($P \leq 0.05$). Manure moisture, total nitrogen (N), ammonium-N (NH_4-N), organic-N, and total potash (K_2O) did not differ significantly by diet, although manure total phosphorus (P_2O_5) was higher for CON samples ($P < 0.05$). Stored manure samples from CON had greater moisture and less NH_4-N than samples from D and D+P hens ($P < 0.10$). Weekly company data summarized for the entire study showed that EP averaged 85.8, 85.2, 85.7% and total eggs per hen housed at 65 wk of age were 271, 270 and 271 for CON, D, and D+P diets, respectively. Mean feed intake and feed conversion were 100.0, 100.0, and 104.3 g/hen/d and 1.91, 1.95, 1.95 kg feed/dozen eggs for the CON, D, and D+P diets, respectively. Weekly EI from selling eggs to the breaker market averaged $12,851, $12,801, and $12,864, weekly FC averaged $6,705, $6,599, and $6,671, and, therefore, weekly EI minus FC (e.g., farm revenue) averaged $6,146, $6,215, and $6,209 for CON, D, and D+P diets, respectively.

Key Words: distillers grains, hen performance, manure

190 Breeder hen age affects chick early innate immune function. M. L. Johnson* and D. R. Korver, *University of Alberta*, *Edmonton, Canada*.

Newly hatched broiler chicks do not possess a well-developed acquired immune system, therefore they rely to a large extent on innate immunity. As hens age, chick quality is usually considered to increase, however this is typically assessed on physical parameters such as chick weight and body length, rather than on disease resistance. The objective of this study was to examine the effects of broiler breeder hen age on innate immune function in young broilers. Hens were fed a commercial-type diet and fertile eggs were collected and incubated weekly at 3 hen ages: Early (30–33), Mid (44–47) and Late (57–59) wk of hen age. Hen body weight, settable egg production, hatchability, chick body weight at hatch were assessed. Whole blood was collected from chicks at 1 and 4 d of age to assess the ability of chick lymphocytes to kill *Escherichia coli* in vitro. Data were analyzed as a mixed model ANOVA in SAS. Differences were considered significant at $P \leq 0.05$. Hen body weight increased by 12% and settable egg production decreased by 38% from Early to Late production. Hatchability during the Late period was 11 and 9% lower than the Early and Mid periods, respectively. Hen fertility decreased from Mid to Late production. Chick body weight at hatch increased by 21% between the Early and Late production periods. At the Early hen age, the bactericidal activity of chick immune cells increased by 27% between 1 and 4 days of age; there were no chick age-related differences in bactericidal activity at either Mid or Late hen ages. At d 1, chick immune cell bactericidal activity at the Early hen age was 4.6- and 16.1-fold greater than at the Mid and Late breeder age, respectively; at d 4, bactericidal activity at the Early hen age were 3.4- and 4.8-fold greater than at the Mid and Late hen ages, respectively. At the Mid and Late hen ages, chick immune cell bactericidal activities were not different from each other at either chick age. As hens age, chick hatch weight increases, but chick innate immune cell bactericidal activity is greatest when hens are at the early stages of the production cycle.

Key Words: broiler breeder age, innate immunity, chick quality

191 Sperm production and testicular development of broiler breeder males reared on shortened growth cycles. J. R. Moyle*, S. M. Whipple, D. E. Yohoo, and R. K. Bramwell, *University of Arkansas*, *Fayetteville*.

Feed restriction is an important tool used in the rearing of broiler breeds to control growth and maintain body weight. Feed restriction during the growing phase is typically 60–80% less than what birds would eat ad libitum, resulting in a perceived animal welfare issue. Because males are typically more severely feed restricted than females, this is perceived to be especially stressful to the growing cockerels. During this time the reproductive systems of the males are going through formative stages and improper management can have lifelong effects on their reproductive performance. Therefore, the objective of this study was to raise males under feed management programs that would require less sever feed restriction while still rearing replacement breeder males to the recommended target body weight of 3.060kg at 12, 15, 18, 21 and 24 wks of age, respectively. Males were placed at 3 wk intervals so that all males were light stimulated at the same time but at different ages with the same body weight. There were a total of 5 treatment groups based

on the age of the male at the time of light simulation. All males were reared in the same light controlled house at the University of Arkansas Research Farm. Males were light stimulated and testes development, semen analysis, fertility and mating activity were recorded for each group of males. To measure semen production, males were housed in individual cages, with 24 males from each treatment tested. All data were analyzed using ANOVA and means were considered significantly different when P values were less than 0.05. Results found that males lit at 18 wks of age had the highest semen volume (0.46mL) followed by males lit at 24 (0.31mL), 15 (0.29mL), 21(0.27mL) and 12 wks (0.27mL), respectively. Sperm count per ejaculate was highest for the males lit at 18 wks of age followed by males lit at 21, 24, 15, and 12 wks, respectively. Males that were 21 wks or older at the time of lighting responded quicker to light stimulation than did younger males.

Key Words: broiler breeder, sperm production, lighting

192 Germination of *Bacillus subtilis* C-3102 in the gut of conventional and germ-free chicken. T. Hamaoka*[1], N. Otomo[1], B. Y. Lee[1], Y. Tadano[2], T. Marubashi[2], J. Marshall[3], and A. Van Kessel[3], [1]*Calpis U.S.A., Inc.*, *Mt.Prospect, IL*, [2]*Calpis co. Ltd.*, *Tokyo, Japan*, [3]*University of Saskatchewan*, *Saskatchewan, Canada*.

Bacillus subtilis C-3102(BSC) is utilized in a probiotic product Calsporin (Calpis Co. Ltd., Japan) and made available worldwide. Shifts in intestinal microbial colonization patterns are observed when there is an improvement in production performance by BSC. To determine the mechanism of action of BSC, we have conducted 2 trials to investigate the germination of BSC spores in gastrointestinal tract of conventional and ex-germfree monoassociated chickens. Ten 28-d old conventional broilers (Cobb) were assigned to individual cages. A corn-soybean based diet was fed with 3.0×10^5 CFU/g of BSC spores. At the age of 55-d, 10 birds were killed to collect gut contents from crop, gizzard, jejunum, ileum, cecum and feces. Samples were diluted and plated directly to enumerate spores plus vegetative cells (total count). Remaing sample was heat treated (60°C for 30min) and plated again to enumerate spores. The total count (log CFU/g) of BSC at each gut location ranged from 4.85 to 5.47 and was not different. Spore ratio was 61% and 95% of total count in gizzard and cecum, respectively, suggesting germination of spores at these locations. Germ-free chickens (Ross308) were reared in HEPA-filtered sterilized isolators by methods developed at the University of Saskatchewan. Chicks were fed *ad libitum* a gamma irradiated corn-soybean diet supplemented with $3x10^5$ CFU/g of BSC spores. At 14-d of age, 10 birds were killed and intestinal contents were collected for enumeration of BSC as above. The total count (log CFU/g) increased ($P < 0.05$) from 5.78 in crop to 7.16 in cecum. The spore ratio ranged from 59.2% to 82% of total count and is consistent with the conventional birds which showed lower ratio in gizzard (68.5%) and cecum (59.2%). We conclude that BSC spores germinate in the chicken gastrointestinal tract, primarily in gizzard and cecum.

Key Words: *Bacillus subtilis*C-3102, Calsporin, germ-free

193 Examining the sitter duck condition. K. Murdoch[1], K. Seward[1], J. Riley[1], D. T. Ort[2], and M. J. Wineland*[2], [1]*Maple Leaf Farms*, *Milford, IN,* [2]*North Carolina State University*, *Raleigh*.

The sitter duck condition observed in the duck industry can cause downgrading at the plant. During the loading and unloading process of driving the ducks onto and off the truck some ducks would sit and not continue walking the ramp during the process resulting in the following ducks stepping over and on the sitter ducks causing scratches which results in downgrading of the carcasses. Observations were made pertaining to level on truck transport, duration of transport. Ducklings were evaluated at unloading at the plant for 2 trials. Thirteen blood parameters were measured using an i-Stat Analyzer in both trials. Additionally in the second trial CK and LDH were determined. Parameters were evaluated by condition of sitter or normal and by sex of bird in trial 1. In trial 2, sitter and normal ducklings were evaluated on 6 farms, and on 2 of these farms the initially sampled ducklings were evaluated 24 h later after being held in the holding pen with feed and water. Data was analyzed in a factorial design using GLM Procedure of SAS. Sitter ducks were more prevalent when transported on the upper levels of the transport truck where they were required to walk a steeper incline at loading and unloading. In the first trial sitter ducks demonstrated significantly elevated pCO2, Na^+ (30.97 versus 29.41) and (141.27 versus 138.45) respectively and significantly lower K+ (4.10 versus 4.23). In the second trial Na^+, glucose and ionized Ca was significantly elevated. Approaching significance was K+ where it was lower in the sitter than the normal duckling. CK and LDH was significantly greater in the sitter ducks than the normal ducklings (3913 versus 2506 and 861 versus 444 respectively). Ducklings which were evaluated at unloading and then again 24 h later in the holding pen demonstrated a reduction in the sitter duckling to levels comparable to the normal duckling. Evidence suggests that the sitter condition is related to exertion and ramp slope during unloading. Additionally tissue damage is indicated by the elevated CK and LDH as well as the elevated plasma Na^+ and decreased K+ levels.

Key Words: duckling, immobility, blood parameters

194 The effects of body weight on production and overall fertility and duration of fertility in broiler breeder hens. R. K. Bramwell*, D. E. Yoho, J. R. Moyle, and S. M. Whipple, *Department of Poultry Science, University of Arkansas*, *Fayetteville*.

Evaluating fertility problems in commercial broiler breeder flocks has traditional been targeted at the management and well being of the male. However, previous research has shown variation in the ability of individual broiler breeder hens within a flock to become fertilized. This variability is consistent with specific hens throughout their reproductive life and may or may not be related to age or body weight. This study was designed to evaluate the physiological capacity of broiler breeder hens to become fertilized under conditions of age and body weight. Two hundred pullets from each of 4 broiler breeder hen strains of were obtained from a commercial hatchery and reared into production according to industry standards. At 21 wks of age, birds were light stimulated and separated into one of 2 groups; either at or below target weight (C), or heavy or above target weight (H) and housed in individual cages. H birds were maintained at +300 g as compared with the C group until 60 wks of age. At 30 wks of age, hens were artificially inseminated with 100 million spermatozoa in a 0.05cc volume from a pooled semen sample. Inseminations continued at 5 wk intervals until 60 wks of age. All eggs were collected daily to determine fertility by day and week post-insemination. Values were analyzed by breeder hen strain and body weight group for 3 wks following each single insemination with all fertility values calculated from the single insemination until fertility ceased. Data were analyzed using JMP statistical software using ANOVA with means compared using the LSD method with significance determined when $P < 0.05$. Results from this trial indicate that the C groups had higher weekly egg production values as compared with the corresponding H groups. While fertility varied by age, the C group had consistently better fertility (48.5% and 40.0% life of flock fertility) and average duration of fertility (16.70 and 14.71 d) as compared with the H groups, respectively. Results indicate that body weight has a significantly

detrimental effect on fertility values and duration of fertility in most breeder hen strains regardless of age.

Key Words: broiler breeder, fertility, reproduction

195 Comparing the physiological capacity for fertility in caged broiler breeder hens from four commercial strains. R. K. Bramwell*, J. R. Moyle, S. M. Whipple, and D. E. Yoho, *Department of Poultry Science, University of Arkansas*, *Fayetteville*.

Maintaining fertility in commercial broiler breeder flocks, along with egg production, is one of the critical factors and goals of the breeder manager. However, previous research has shown genetic variability of broiler breeder hen strains to all reproductive characteristics. This variability may be consistent with hen strains, particularly yield type strains, but can often be altered with management programs. This study was designed to evaluate the physiological capacity of different strains of broiler breeder hens to become fertilized using artificial insemination, therefore eliminating natural mating and male libido effects. Two hundred pullets from each strain of broiler breeders were obtained from a commercial hatchery and reared into production according to industry standards. At 21 wks of age, birds were light stimulated and 100 hens per strain were separated into blocks of 10 individually caged hens with 10 replicate blocks per strain. Additional hens were housed in floor pens and were used to replace caged hens that had died or ceased egg production during the trial. At 30 wks of age all caged hens were artificially inseminated with 100 million sperm in a 0.05cc volume from a pooled semen sample. Inseminations continued at 5 wk intervals until 60 wks of age. All eggs were recorded and collected daily to determine fertility by day post-insemination. Values were analyzed by hen strain until the cessation of sperm activity was determined. Data were analyzed using JMP statistical software using ANOVA with means compared using the LSD method with significance determined when $P < 0.05$. Results indicate that while each hen strain varied in overall fertility following the single inseminations (from 42.7 to 46.1%), age had little effect on these hens (low of 38.4 and a high of 49.8%). There was no difference in overall duration of fertility for any of the hen strains with all strains averaging a duration of fertility between 15.6 and 15.8 d post- insemination. Results indicate that when hens are caged and natural mating factors are eliminated, fertility values are very similar for the 4 hen strains included in this study.

Key Words: broiler breeder, fertility, reproduction

196 Modeling energy utilization of broiler breeder hens is affected by environmental temperature and dietary energy. A. Pishnamazi*, M. J. Zuidhof, R. A. Renema, and D. Paul, *University of Alberta*, *Edmonton, Alberta, Canada*.

The accurate prediction of energy requirement affects the effectiveness of feed allocation decisions. This analysis was conducted to identify a model to estimate partial coefficients of ME partitioning of broiler breeder (BB) hens. A total of 288 hens (Ross 708) were individually caged in 1 of 6 environmentally controlled chambers at 21 wk. Ten, 2-wk temperature treatments were imposed from 21 to 41 wk, with 4 randomly rotating temperature treatments (15, 19, 23, and 27 C). Birds in each chamber were fed either a High Energy (HE, 2900 kcal/kg) or a Low Energy (LE, 2700 kcal/kg) diet. An energy utilization model was used to account for average daily ME intake twice/wk and calculate maintenance energy requirements (MEm). This model used a metabolic BW coefficient of 0.67. The nonlinear mixed model employed a normally distributed term associated with hen metabolic BW, and exponential terms of average daily gain (ADG), egg mass (EM) and temperature. The MEm at 21 C was 159.38 kcal/kg0.67, with a temperature adjustment of −0.2995 kcal/C. The ME requirement for gain was 0.4013 kcal/g, with a temperature adjustment of −0.0234 and EM was 0.6183 kcal/g. According to this model, a broiler breeder hen weighing 3.0 kg, gaining 15g/d and producing 60g egg/d require 382, 376, or 369 kcal/d at 15, 21, and 28 C, respectively. This translates to 136.4, 134.3, or 131.8 g/d of 2,800 kcal ME/kg feed, respectively. Birds fed HE had a higher ADG coefficient than birds on the LE diet. However, both MEm and EM coefficients did not differ. The greatest impact of temperature is on MEm, whereas dietary energy affected growth.

Key Words: energy requirements, broiler breeders, environmental temperature

198 Use of dried distillers grains throughout a beef production system: I. Stocker phase. E. K. Buttrey*[1,2], F. T. McCollum III[1], J. C. MacDonald[2,3], and K. H. Jenkins[3], [1]*Texas AgriLife Extension Service*, *Amarillo*, [2]*West Texas A&M University*, *Canyon*, [3]*Texas AgriLife Research*, *Amarillo*.

During the winters of 2008 and 2009, a study was conducted at the Texas AgriLife Research facilities in Bushland, Texas, to evaluate dried distillers grains as a supplement to wheat pasture. Each yr, 60 preconditioned Hereford steers (initial BW = 198 kg ± 3) were revaccinated against viral and Clostridial pathogens and implanted with 36 mg of zeranol. Steers were stratified by BW and randomly assigned to one of 15 2.2-ha wheat pastures (4 steers/pasture). Treatments were assigned within 5 blocks of 3 pastures. Treatments were: 1) Control (CON)- no supplement, 2) dry rolled corn (DRC), and 3) dried distillers grains (DDG). DRC and DDG were fed at 0.5% BW (DM) daily, pro-rated and delivered 6 d/wk. Full BW was measured and supplement amounts were adjusted every 28d. All steers had ad libitum access to water and a monensin-containing mineral supplement throughout grazing. Forage mass was measured by clipping at initiation and termination of grazing. Across yr, steers grazed an average of 128 d. Initial forage mass was not different among treatments ($P = 0.49$; Table 1). However, treatment affected final forage mass. At the end of grazing, DRC pastures had more ($P = 0.02$) residual forage mass than CON and DDG was intermediate. Gain was greater for DDG steers than CON and DRC ($P < 0.01$). Final forage mass suggests DRC depressed forage intake, while DDG had less influence on intake while increasing weight gain.

Table 1. Effect of stocker treatment on forage mass and steer performance

Item	CON	DRC	DDG	SE
Initial forage, kg DM/ha	2515	2750	2696	202
Final forage, kg DM/ha[a,1]	640	969	848	134
Gain, kg/d[b]	1.29	1.31	1.40	0.03
Adjusted gain, kg/d[b,2]	1.30	1.29	1.40	0.03

[a]Treatment effect, $P = 0.07$; pairwise CON < DRC, $P = 0.03$.
[b]Treatment effect, $P = 0.003$; pairwise DDG > CON, DDG > DRC, $P < 0.01$.
[1]Initial forage mass used as covariate.
[2]Final forage mass used as covariate.

Key Words: dried distillers grains, supplement, wheat pasture

197 Use of dried distillers grains throughout a beef production system: II. Finishing phase. E. K. Buttrey*[1,2], F. T. McCollum III[1], J. C. MacDonald[2,3], and K. H. Jenkins[3], [1]*Texas AgriLife Extension Service*, *Amarillo*, *West Texas A&M University*, *Canyon*, [3]*Texas AgriLife Research*, *Amarillo*.

To evaluate the effects of feeding dried distillers grains throughout a beef production system, a 2-yr study was conducted using a 3 × 2 factorial arrangement of treatments. Factors were wheat pasture supplement (no supplement, dry-rolled corn, and dried distillers grains; CON, DRC, and DDG, respectively) and finishing diet (steam-flaked corn based diet containing 0 or 35% DDG, SFC and 35DDG, respectively). Each yr, 60 preconditioned Hereford steers (initial BW = 198 kg ± 3) were stratified by BW and randomly assigned to one of 15 2.2-ha wheat pastures (4 steers/pasture). Supplements were assigned within 5 blocks of 3 pastures. Supplements were fed at 0.5% BW daily, pro-rated and delivered 6 d/wk. Following the grazing period, pastures within supplement treatment were randomly assigned to SFC or 35DDG. Steers were fed once daily ad libitum and pens of steers were harvested when estimated fat thickness reached 1.27 cm. A 3-way interaction between supplement, finishing diet, and yr was detected for HCW ($P = 0.08$) and carcass-adjusted total system weight gain ($P = 0.04$). Wheat pasture ADG was greater for DDG steers compared with CON and DRC steers ($P < 0.01$; 1.40, 1.30, and 1.29 kg/d for DDG, CON and DRC, respectively). With the exception of carcass-adjusted G:F for which DRC was greater than CON and DDG was intermediate ($P = 0.03$; 0.161 vs. 0.150, DRC and CON, respectively, 0.154 DDG), finishing performance and carcass traits were not affected by wheat pasture supplement ($P \geq 0.12$). Initial and final BW, DMI, and ADG were similar for SFC and 35DDG steers ($P \geq 0.20$). Steers receiving SFC had greater carcass-adjusted G:F ($P < 0.01$, 0.160 vs. 0.149), dressing percent ($P = 0.01$, 63.6 vs. 62.8), and twelfth rib fat thickness ($P < 0.01$, 1.27 vs. 1.12 cm) than 35DDG steers. The use of dried distillers grains as a supplement to wheat pasture results in greater ADG on wheat. However dried distillers grains included in steam-flaked corn based finishing diets appears to reduce G:F and dressing percent.

Key Words: dried distillers grains, stocker, finishing

199 Comparison of wheat or corn dried distillers grains with solubles on rumen fermentation and nutrient digestibility in feedlot heifers. L. J. Walter*[1], T. A. McAllister[2], W. Yang[2], K. Beauchemin[2], and J. J. McKinnon[1], [1]*University of Saskatchewan*, *Saskatoon, SK, Canada,* [2]*Agriculture and Agri-Food Canada Research Centre*, *Lethbridge, AB, Canada.*

A 5 × 5 Latin square design trial was conducted to evaluate rumen fermentation and apparent nutrient digestibility in 5 rumen cannulated heifers (420 ± 6 kg) fed diets supplemented with wheat (WDDGS) or corn (CDDGS) dried distillers grains with solubles. The composition of the control diet was 88.7% rolled barley grain, 5.5% supplement and 5.8% barley silage (DM basis). Treatments included replacement of barley grain at 20 or 40% of the diet DM with WDDGS or CDDGS. Contrasts included CDDGS vs. WDDGS; Control vs. CDDGS or WDDGS; 40% WDDGS vs. 40% CDDGS. Rumen pH, duration and area under pH curve thresholds of 5.8, 5.5 and 5.2 were not affected ($P > 0.05$) by treatment. WDDGS increased ($P \leq 0.05$) rumen NH_3-N levels relative to the control and CDDGS treatments, but decreased ($P = 0.04$) propionate relative to the control. Both DDGS sources increased ($P \leq 0.03$) rumen butyrate concentration and the digestibility ($P \leq 0.04$) of NDF, ADF and ADIN. WDDGS decreased ($P \leq 0.02$) DM and GE digestibility while CDDGS increased ($P \leq 0.001$) CP digestibility. With the exception of ADF ($P = 0.78$), feeding 40% WDDGS reduced ($P \leq 0.02$) nutrient digestibility relative to 40% CDDGS. Inclusion of WDDGS and CDDGS increased ($P < 0.001$) N and P intakes as well as excretion, with WDDGS having the greatest ($P < 0.001$) effect. Fecal N and P excretion was increased ($P < 0.001$) for WDDGS, but not for CDDGS ($P = 0.56$ and 0.27). Both DDGS sources resulted in higher ($P < 0.001$) urinary N and P output. Replacement of barley grain with up to 40% WDDGS or CDDGS did not mitigate rumen fermentation conditions associated with acidosis. CDDGS had the largest beneficial influence on apparent nutrient digestibility, while both DDGS sources altered the amount and route of N and P excretion.

Key Words: corn DDGS, wheat DDGS, nutrient digestibility heifers

200 Effects of wet distillers grains plus solubles concentration in steam-flaked corn-based finishing diets on nutrient digestibility. M. K. Luebbe*[1], K. H. Jenkins[1], J. Patterson[1], E. K. Buttrey[2], and J. C. MacDonald[1,3], [1]*Texas AgriLife Research*, *Amarillo*, [2]*Texas AgriLife Extension*, *Amarillo*, [3]*West Texas A&M University*, *Canyon*.

Six ruminally and duodenally cannulated crossbred steers (BW = 481 ± 18 kg) were used to determine effects of corn and sorghum based (<15% sorghum) wet distillers grains plus solubles (WDG) on nutrient digestibility. Seven periods consisted of 17 d of adaptation and 4 d collection of feces, duodenal and ruminal samples. Steers were fed twice daily in equal proportions. Fecal and duodenal samples were collected 3 times daily with sampling time advancing 1 h to represent every hour between feeding. Ruminal fluid samples were collected in the same manner with the addition of samples collected before feeding and 8 h post-feeding each d during the 4 d collection period. Wet distillers grains (0, 15, 30, 45, and 60% dietary inclusion; 0WDG, 15WDG, 30WDG, 45WDG, and 60WDG, respectively) replaced cottonseed meal, supplemental fat (yellow grease), urea, and steam-flaked corn (SFC). Additionally, a dry-rolled corn control diet (DRC) was included. Dietary fat was set at a minimum of 6.5% and alfalfa hay was included at 10% of diet DM. Contrasts included DRC vs. SFC, and linear and quadratic effects of WDG level. Average ruminal pH was not different ($P = 0.99$). Change in ruminal pH was lowest ($P < 0.01$) for the DRC treatment. Dry matter and OM intake were not different ($P > 0.15$) among WDG level. Intake of NDF linearly increased ($P < 0.01$) with WDG level. Starch intake responded quadratically ($P = 0.06$) with WDG level. Total tract DM, OM, and NDF digestibility decreased linearly ($P < 0.01$) with WDG level. Total tract starch digestibility responded quadratically ($P < 0.01$) with WDG level (98.1, 99.0, 98.6, 98.2, and 97.4%; 0WDG, 15WDG, 30WDG, 45WDG, 60WDG, respectively). Dry-matter, OM, and starch intake was not different ($P > 0.80$) for DRC and SFC whereas intake of NDF was greater ($P = 0.04$) for DRC compared with SFC. Total tract DM and OM digestibility was not different ($P > 0.45$) for DRC and SFC. Total tract starch and NDF digestibility were greater ($P < 0.01$) for SFC compared with DRC. Level of WDG concentration and corn processing method impacts nutrient intake and digestibility.

Key Words: wet distillers grains, digestibility, corn processing

201 Effects of wet distillers grains plus solubles concentration in steam-flaked corn-based finishing diets on performance and carcass characteristics of beef steers. M. K. Luebbe*[1], T. C. Davis[1], K. H. Jenkins[1], F. T. McCollum III[2], N. A. Cole[3], and J. C. MacDonald[1,4], [1]*Texas AgriLife Research*, *Amarillo*, [2]*Texas AgriLife Extension*, *Amarillo*, [3]*USDA-ARS*, *Bushland, TX*, [4]*West Texas A&M University*, *Canyon*.

Six hundred crossbred steers (365 ± 35 kg) were used in a randomized complete block design to determine effects of a corn and sorghum based (<15% sorghum) wet distillers grains plus solubles (WDG) on animal performance and carcass characteristics in steam-flaked corn (SFC) diets. Forty-eight pens were utilized resulting in 8 replications per treatment. Wet distiller′s grains (0, 15, 30, 45, and 60% dietary inclusion; 0WDG, 15WDG, 30WDG, 45WDG, and 60WDG, respectively) replaced cottonseed meal, supplemental fat (yellow grease), urea, and SFC. Additionally, a dry-rolled corn control diet (DRC) was included. Dietary fat was set at a minimum of 6.5% with supplemental fat from yellow grease. Alfalfa hay was included at 10% of diet DM. Contrasts included DRC vs. SFC, and linear and quadratic effects of WDG concentration. Final BW, ADG, G:F, HCW, and fat depth were greater ($P \leq 0.05$) for SFC than DRC. Dry-matter intake tended ($P = 0.06$) to be greater for DRC than SFC. Marbling score, dressing percent, and LM area were not different ($P > 0.40$) for DRC and SFC. Final BW, ADG, HCW, fat depth, and marbling score decreased linearly ($P < 0.01$) with WGDS inclusion level. Gain efficiency and DMI responded quadratically ($P < 0.01$) across WDG inclusion levels. Dressing percent tended to decrease linearly ($P = 0.07$) with WDG level and LM area was not different ($P = 0.31$) across WDG inclusion levels. Feeding SFC improved animal performance and carcass characteristics compared with DRC. The relative energy content of WDG in SFC-based diets appears to dilute the energy density of the diets and negatively impacts animal performance.

Table 1. Distillers grains and animal performance

Item	0WDG	15WDG	30WDG	45WDG	60WDG	DRC	SEM
Final BW, kg[a]	616	614	600	597	581	601	7
DMI, kg	11.3	11.5	11.5	11.4	10.5	11.7	0.2
ADG, kg[a]	2.05	2.02	1.91	1.89	1.75	1.92	0.05

202 Supplementing modified wet distillers grains with solubles to long yearling steers grazing native range. K. M. Rolfe*, W. A. Griffin, T. J. Klopfenstein, and G. E. Erickson, *University of Nebraska, Lincoln*.

A 2-yr study was designed to evaluate the effects of supplementing modified wet distillers grains with solubles (MDGS) to long yearling steers while grazing native range (warm season grass). Steers (n = 240; BW = 229 ± 16 kg) were backgrounded on cornstalk residue from late fall to mid-spring (144 d). While grazing cornstalks calves were supplemented 2.27 kg/steer daily of Sweet Bran. Following backgrounding steers were allowed to graze smooth bromegrass pastures for 21 d. After grazing smooth brome calves were weighed, stratified by BW, assigned randomly to summer grazing treatments, and relocated to graze Sandhills range. Summer grazing treatments included: grazing native range with no supplementation (CON); and grazing native range with MDGS supplementation at a level of 0.6% BW (SUPP). Modified wet distillers grains with solubles was fed daily on the ground. Steers were allowed to graze Sandhills range for the remainder of the summer grazing period (137 d) before entering the feedlot in early fall. Upon time of harvest cattle were serially slaughtered in 2 groups within each summer grazing treatment. At the time of summer treatment assignment, BW was not different between SUPP and CON steers ($P = 0.36$). However at feedlot entry, SUPP steers were 47 kg heavier ($P < 0.01$) than CON steers. Therefore, SUPP steers had 0.31 kg greater ($P < 0.01$) ADG than CON steers. Because SUPP steers were heavier than CON steers at feedlot entry, 24 fewer days on feed in the feedlot ($P < 0.01$) were required to achieve the same final BW ($P = 0.85$). Feedlot ADG and DMI were not different between SUPP and CON steers ($P > 0.47$). Similarly, HCW, LM area, and BF did not differ between the 2 summer grazing treatments ($P > 0.19$). These data show that MDGS can be fed on the ground, increase gains during summer grazing, and decrease days on feed in the feedlot.

Key Words: modified wet distiller grains, supplementation, yearling steer

203 Influence of feeding dried distillers grains plus solubles in potato byproduct-based finishing diets. J. I. Szasz*[1,4], D. S. Secrist[2], K. K. Karges[3], C. W. Hunt[1], K. A. Johnson[4], and T. N. Bodine[5], [1]*Univer-*

sity of Idaho, *Moscow,* [2]*Agri Beef Co.*, *Moses Lake, WA*, [3]*Poet Nutrition*, *Sioux Falls, SD*, [4]*Washington State University*, *Pullman,* [5]*Performix Nutrition Systems*, *Nampa, ID*.

One hundred 44 crossbred yearling beef steers (mean BW = 372 kg) were used in a randomized complete block study to evaluate the influence of dried distillers grain plus solubles (DDGS; 10, 20, 30, or 40%, DM basis) fed in place of dry-rolled corn in finishing diets containing wet potato byproduct. Pen served as the experimental unit. Steers were fed twice daily in equal proportions using a bunk management approach that minimized accumulation of refused diet. Final BW ($P = 0.05$), DMI ($P = 0.05$), ADG ($P = 0.07$), and HCW ($P = 0.02$) increased quadratically with DDGS level, reaching maximum (636, 11.7, 2.17, and 405 kg, for final BW, DMI, ADG, and HCW, respectively) at the 20% DDGS level. Dry feed conversion (DMI/ADG) increased ($P = 0.04$) linearly from 5.31 to 5.53 for 10 and 40% DDGS, respectively, and performance-based diet NEg tended ($P = 0.11$) to decrease linearly from 1.444 to 1.382 Mcal/kg for 10 and 40% DDGS, respectively. Similar responses were noted for carcass-adjusted performance, with the exception that dry feed conversion was not different between dietary treatments. Dressing percentage and percentage of cattle grading USDA Choice or Prime were similar between dietary treatments; although, marbling score increased ($P = 0.07$) quadratically with DDGS, reaching maximum (508) at the 20% DDGS level. Liver abscess incidence and other measures of performance were similar across dietary treatments. DDGS fed in place of dry-rolled corn improved ADG when fed up to 20% of the diet DM, yet negative effects on feed conversion were realized with increasing DDGS level. These results parallel findings from published trials where ADG was improved between 20 and 30% DDGS, but are in conflict with research demonstrating optimized feed conversion near 20% DDGS in the finishing diet. Future research should identify possibilities for this discrepancy as well as evaluate graded levels of DDGS in potato byproduct-based finishing diets containing more aggressively processed grain (e.g., high-moisture, steam-flaked).

Key Words: feedlot, distillers grains, finishing cattle

204 Effect of feeding modified distillers grains and wet corn gluten feed compared to forage on ruminal pH, intake and digestibility when adapting cattle to finishing diets. M. G. Dib*[1], G. E. Erickson[1], T. J. Klopfenstein[1], J. O. Sarturi[1], R. Lindquist[2], K. M. Rolfe[1], C. D. Buckner[1], and V. R. Bremer[1], [1]*University of Nebraska*, *Lincoln,* [2]*Archer Daniels Midland*, *Columbus, NE*.

A 39-d grain adaptation metabolism study was conducted comparing a combination of modified distillers grains plus solubles and wet corn gluten feed (BYP) fed at decreasing levels (87.5% to 35%) to a traditional grain adaptation (CON) with decreasing forage (45% to 7.5%). In both adaptation schemes, dry-rolled corn increased (up to 57.5%). Measurements included DMI, ruminal pH, ruminal H2S, and DM digestibility (DMD) for the first adaptation diet and the finishing diet. Six yearling steers (BW = 405 ± 20 kg) were assigned randomly to 1 of 2 treatments in a CRD with 3 steers per treatment (BYP and CON). Cattle were fed ad libitum once daily. Five adaptation diets were used to increase corn with diets fed 9, 7, 7, 7, and 9 d, respectively. The last 9-d period consisted of a common finishing diet containing the combination of gluten feed and distillers grains (30% of diet DM). Intake and pH (wireless pH probes) measurements were collected every minute during the entire study. Ruminal gas samples were collected 8 h post feeding on the last 2 d of each period, and H2S concentrations were analyzed. Data were analyzed using the GLIMMIX procedure of SAS. During adaptation, DMI expressed as % of BW tended ($P = 0.09$) to be greater for steers fed CON compared with BYP during the first period, but was not different in subsequent adaptation diets ($P > 0.20$). Average pH was lower ($P < 0.01$) for BYP on adaptation 1 and 2 compared with CON (5.76 vs. 6.18; 5.75 vs. 6.07, respectively). No difference ($P > 0.44$) was observed between treatments in ruminal pH for adaptation 3 and 4. Average pH was lower ($P < 0.01$) for CON on the last period when both treatments were being fed the same diet (5.61 vs. 5.80). Both adaptation methods resulted in safe ruminal pH (>5.6) and H2S concentrations (<36 µmol/L gas). No difference ($P > 0.15$) was observed for DMD between treatments. Results suggest that decreasing inclusion of a combination of distillers grains and gluten feed was as effective as the traditional method using forage for adapting feedlot cattle to high-concentrate diets.

Key Words: byproducts, grain adaptation, metabolism

205 Effects of wet distillers grain and a direct-fed microbial on finishing performance and carcass characteristics of beef steers fed a sorghum-based finishing diet. J. R. Jaeger*[1], J. W. Waggoner[1], K. C. Olson[2], J. W. Bolte[1], and S. R. Goodall[3], [1]*Western Kansas Agricultural Research Centers, Kansas State University*, *Hays*, [2]*Kansas State University*, *Manhattan*, [3]*Nova Microbial Technologies*, *Omaha, NE*.

Angus x calves (n = 406; initial BW = 441 ± 31 kg) were stratified by BW and ultrasonically measured longissimus muscle characteristics and assigned randomly to 1 of 4 ration treatments (4 pen replicates per treatment). Ration treatments were: 1) soybean meal protein supplement (CON); 2) control plus direct-fed microbial (CON+DFM); 3) wet distiller′s grain plus solubles (WDGS; 15% of diet DM); and 4) WDGS plus direct-fed microbial (WDGS+DFM). Steers were fed for 106 d before harvest. Longissimus muscle characteristics were measured ultrasonically on d 0 and 70 of the feeding period. Increase in backfat thickness was greater ($P < 0.01$) for steers receiving WDGS compared those receiving the control diet during the first 70 d on feed. In addition, increase in longissimus muscle depth was greater ($P < 0.01$) for cattle receiving DFM compared those receiving no microbial treatment. Change in marbling score was similar ($P = 0.44$) among treatments. Steer ADG during the entire feeding period was greater ($P < 0.01$) for WDGS than for CON (1.66 and 1.43 ± 0.02 kg/d, respectively). Likewise, harvest BW was greater ($P < 0.01$) for steers receiving WDGS compared with steers receiving the control diet. Carcass weight was greater in steers fed WDGS+DFM compared with WDGS, but was lower in steers fed CON+DFM compared with CON (WDGS × DFM; $P = 0.01$). Dressing percent and LM area were similar ($P > 0.30$) between treatments. USDA yield grade ($P = 0.41$) and quality grade ($P = 0.45$) were also similar among treatments with 69.0% of steers grading choice or better. Under the conditions of our study, these data were interpreted to suggest that sorghum-based feeding diets containing WDGS and a direct-fed microbial may improve finishing performance and carcass merit compared with diets containing no distiller′s grains. Further research is needed to elucidate optimal use conditions of direct-fed microbials in sorghum-based finishing diets.

Key Words: beef cattle, distillers grains, direct-fed microbial

206 Feeding *Lactobacillus acidophilus* combined with *Propionibacterium freudenreichii* to determine performance and carcass characteristics in feedlot heifers fed with or without wet distillers grains plus solubles. B. K. Wilson*[1], B. P. Holland[1], T. G. Nagaraja[2], and C. R. Krehbiel[1], [1]*Oklahoma State University*, *Stillwater,* [2]*Kansas State University*, *Manhattan*.

Increasing corn prices related to increased ethanol production have had a significant impact on the cost of gain for cattle producers who rely on

corn-based diets, and the inclusion of wet distiller's grains plus solubles (WDGS) in feedlot diets has become a common practice in many regions of the US In addition, direct-fed microbials (DFM) have been shown to improve ADG and feed efficiency, alter ruminal fermentation, and decrease fecal shedding of harmful pathogens in feedlot cattle. The objective of this experiment was to evaluate the effects of *Lactobacillus acidophilus* (LA) combined with *Propionibacterium freudenreichii* (PF) on performance and carcass characteristics in feedlot heifers fed with or without WDGS. Crossbred heifers (n = 288; initial BW = 295 ± 28 kg) were assigned to 1 of 4 treatments in a randomized complete block design with a 2 × 2 factorial arrangement of treatments. Across the feeding period, heifers fed 30% WDGS tended ($P = 0.09$) to have greater ADG and had greater carcass-adjusted ADG ($P = 0.05$) compared with heifers fed dry-rolled corn. Dry matter intake was not affected ($P = 0.65$) by diet, although carcass adjusted F:G tended ($P = 0.08$) to be improved for heifers fed WDGS. Heifers fed 30% WDGS tended ($P \leq 0.10$) to have greater fat thickness at the 12th rib, lower marbling scores, and higher yield grades. The inclusion of LA combined with PF in the diet had no effect ($P > 0.10$) on performance or carcass merit in the present experiment. Feeding 30% WDGS to feedlot heifers improved animal performance. Similar results can be anticipated when a DFM is included in the diet.

Key Words: beef cattle, direct-fed microbials, wet distillers grains plus solubles

207 Growth performance of finishing steers fed dry or wet distillers grains plus solubles differing in sulfur content. J. O. Sarturi*, G. E. Erickson, T. J. Klopfenstein, J. T. Vasconcelos, W. A. Griffin, and J. R. Benton, *University of Nebraska*, *Lincoln*.

A finishing study was conducted to determine the effect of dietary sulfur on beef cattle finishing diets formulated with wet or dry distillers grains with soluble (DGS). Sulfur concentration in DGS was either 0.82 or 1.16% and similar between wet or dry DGS. Steers (n = 120, BW = 345 ± 34kg) were assigned to 1 of 13 treatments in a RCBD (9 steers/diet, except 12 steers for control) and fed for 151 d. Cattle were fed ad libitum once daily using Calan individual bunks. Treatments were designed with 3 DGS inclusion (20, 30, and 40%), fed either wet or dry that consisted of low or high sulfur concentration in DGS as a 3 × 2 × 2 factorial. A corn control diet was included resulting in a 3 × 2 × 2 +1 treatment design. All diets contained 15% corn silage, 5% supplement and a blend (60:40) of high-moisture and dry-rolled corn. Initial BW was based on weighing 3 d following a limit-feeding period of 5 d at 2% of BW. Final BW, ADG, and G:F were based on HCW using a 62% dressing percentage. Data were analyzed using the GLIMMIX procedures of SAS as a 3 × 2 × 2 factorial. Orthogonal contrasts were used for comparing DGS to the control diet. Intake linearly increased ($P = 0.02$) when dry 0.82% S DGS was included in the diet, but DMI was not affected when wet 0.82% S DGS was fed. When wet and dry 1.16% S DGS was added, DMI decreased linearly ($P < 0.01$) and quadratically ($P < 0.01$), respectively. Gain decreased linearly ($P = 0.02$) as wet DGS that was 1.16% S increased in the diet. Other diets did not result in a similar pattern. Steers fed wet DGS had improved G:F with similar ADG. A quadratic response ($P < 0.05$) was observed for G:F when wet DGS increased in the diet, with the greatest values at 20 and 30%, regardless of sulfur content. A linear ($P < 0.05$) decrease was observed for HCW and fat thickness as wet and dry 1.16% S DGS increased in the diet, while no changes were observed for wet and dry 0.82% S DGS diets. High sulfur DGS reduces DMI, ADG, and G:F when fed at high levels in beef cattle finishing diets, but depends on whether fed wet or dry.

Key Words: distillers grains plus solubles, feedlot cattle, sulfur

208 Comparing dry, wet, or modified distillers grains plus solubles on feedlot cattle performance. B. L. Nuttelman*, W. A. Griffin, J. R. Benton, G. E. Erickson, and T. J. Klopfenstein, *University of Nebraska, Lincoln*.

A finishing experiment was conducted to compare dry, wet, and modified (partially dried) distillers grains plus solubles. Crossbred, yearling steers (n = 440; initial BW = 353 ± 20 kg) were utilized in a RCBD with steers stratified within block, and assigned randomly to one of 55 pens (8 steers/pen). Pens were assigned randomly to one of 10 treatments as a 3x3+1 factorial. Diets contained 3 inclusions (20, 30, or 40%) of 3 different types: wet distillers grains plus soluble (WDGS, 34.8% DM), modified distillers grains plus soluble (MDGS, 50.6% DM), or dried distillers grains plus soluble (DDGS, 91.4% DM). The 0% inclusion, corn control was repeated within replication (10 replications) whereas all other treatments had 5 replications. Basal ingredients consisted of high-moisture and dry-rolled corn fed at a 60:40 ratio (DM basis), 15% corn silage, and 5% dry supplement (DM basis). No interactions between type and inclusion were observed ($P > 0.16$) for any variables. No difference was observed in ADG ($P = 0.30$) between WDGS, MDGS, or DDGS. Steers fed WDGS had 0.73 and 1.04 kg/d less ($P < 0.01$) DMI than MDGS and DDGS, respectively. Steers fed WDGS (0.165) had greater G:F ($P < 0.01$) compared with steers fed MDGS or DDGS (0.158 or 0.150, respectively). Cattle fed MDGS tended ($P = 0.06$) to have greater G:F than steers consuming DDGS. Type had no impact ($P > 0.15$) on carcass traits. A linear increase ($P = 0.01$) in DMI, quadratic response ($P = 0.04$) in ADG, and a linear increase ($P < 0.01$) in G:F were observed as distillers grains increased from 0 to 40%. Generally, ADG and G:F increased from 0 to 20% inclusion and little change from 20 to 40% inclusion. Increased levels of distillers grains increased HCW quadratically ($P = 0.05$) and increased fat depth ($P < 0.01$). Based on G:F, the feeding value of WDGS was 35.4 and 17.8% greater than DDGS and MDGS, respectively. Feeding value of WDGS, MDGS, and DDGS were 45.7, 26.5, and 9.3% greater than corn-based diets when included at 20, 30, or 40% of the diet DM, respectively.

Key Words: dried distillers grains plus solubles, finishing cattle, wet distillers grains plus solubles

209 Dietary saturated fatty acid source and parity influence lactational performance of early lactation Holstein dairy cows. M. Hollmann* and D. K. Beede, *Michigan State University*, *East Lansing*.

Dietary coconut oil (CO), a source of saturated, predominantly medium-chain fatty acids (FA), reduced enteric methane emission, but also reduced DMI and milk yield in our earlier studies. Here, we examined lactational performance of early lactation cows fed 2 sources of saturated FA, differing in predominant chain lengths. Dietary treatments were: no added fat (CTRL); 2.7% of DM as saturated long-chain FA (Energy Booster 100; EB) or 2.7% CO; or, a 2.7% mixture of equal parts EB and CO (INT). Primiparous (PP; n = 31) and multiparous (MP; n = 36) Holstein cows 10 to 14 d postpartum were fed one of 4 treatments for 16 wk in a randomized complete block design. CTRL diet contained corn and alfalfa silages (53% of DM), dry ground corn, soybean meal, plus mineral and vitamin supplement; it was formulated to contain 26.5% NDF (83% from forages), 17.6% CP, 29.6% starch, and 3.6% fat. Milk yield and DMI were recorded daily, and blood was collected weekly. Main effects of diet, parity, time (repeated measures), and relevant interactions were tested by least-squares ANOVA. Reported values differed ($P < 0.05$). Overall, cows fed CTRL had the greatest DMI. Fat source with greater chain length increased DMI linearly for MP cows (CO: 22.7; INT: 24.7; EB: 27.0 kg/d), and quadratically for PP cows (18.5; 21.0; 20.3 kg/d). Similar interactions of treatment by parity were observed for yields of solids-corrected milk and milk components. CO reduced milk fat (3.1%) and lactose (4.73%) concentrations compared with EB (3.8% and 4.92%), pooled across time and parity. Plasma glucose concentration did not differ among fat treatments and CTRL across the 16 wk. Fat source interacted with parity; INT had the lowest glucose concentration for PP, but highest for MP. During wk 1 to 4 of study, MP had lower plasma glucose than PP (52 vs. 58 mg/dL), which coincided with greater plasma BHBA (7.0 vs. 4.8 mg/dL) and NEFA (710 vs. 380 μeq/L) concentrations in MP. Body condition loss through wk 4 was greater for CO and CTRL than for INT and EB. Overall, dietary CO reduced DMI compared with EB leading to a greater FA mobilization in early lactation.

Key Words: dairy cow, fatty acid, metabolism

210 Adaptations in the transcriptome of adipose tissue in transition dairy cattle. S. Rocco[1], G. Duncan[1], J. Loor[2], J. Vierck[1], and J. P. McNamara*[1], [1]*Washington State University*, *Pullman,* [2]*University of Illinois*, *Urbana*.

Metabolic adaptations in adipose tissue are a critical part of establishment and maintenance of lactation. Our objective was to determine changes in the transcriptome of adipose tissue during the transition period. A total of 48 cows were grouped by their sire PTAM: High Genetic (PTAM = 870 kg), or Low Genetic (PTAM = 378); and half of each group was fed either to requirements (NE) or to 90% of energy requirements (LE), other components fed to requirements. Feed intake from 21 to 1 d prepartum was 13.6 (NE) and 12.7 kg (LE) DMI/d for (SE = 1.5): from 1 to 56 DIM it was 21.2 and 17.4 kg/d (SE = 1.4). Milk production was 36.1 and 33.3 kg/d for HG and LG cows from 27 to 56 DIM ($P < 0.05$). Adipose tissue biopsies at −21, −7, 7, 28 and 56 d around parturition extracted from a subset of these animals and the transcriptome was determined using the Affymetrix Bovine Gene Array on a subset of 21 animals and a total of 28 arrays. Analysis was done using standard array statistical techniques and pathway analysis. Further analysis and pathway analysis were conducted on genes that changed at least 2-fold with a *P*-value of 0.05) Genes that code for enzymes in the anabolic pathways (lipid uptake and synthesis) were consistently decreased to only 20 to 50% of prepartum, including thyroid hormone receptor spot 14, lipoprotein lipase, ATP-citrate lyase, acetyl-CoA carboxlyase and other genes in that pathway. Genes that code for enzymes involved in lipolysis (hormone sensitive lipase, β-2 adrenergic receptors, perilipin) were either unchanged or only moderately increased. Genes involved in synthesis of cellular components and cell cycle control (PPAR gamma, ADFP, ribosomal proteins) were highly expressed and slightly elevated in early lactation. Additional canonical pathways including cell morphology, intercellular signaling, connective tissue synthesis, and disease states all showed changes during the early lactation period. These data can be used to help understand the myriad of changes as cows rapidly lose body fat and can be integrated into systems models for dairy cattle metabolism and health.

Key Words: adipose, transcriptome, lactation

211 Use of omega-3 fatty acid rich algae and their oil as a feed supplement for dairy cattle. J. A. Stamey*[1], D. M. Shepherd[1], M. J. de Veth[2], and B. A. Corl[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Balchem Corp.*, *New Hampton, NY*.

Fish oil is used as a ration additive to provide omega-3 (n-3) fatty acids to dairy cows. Fish do not synthesize n-3 fatty acids; they must consume microscopic algae or other algae-consuming fish. New technology allows for the production of algal biomass for use as a ration supplement for dairy cattle. Lipid encapsulation of the algal biomass allows n-3 fatty acids to remain inert in the rumen, avoid biohydrogenation, and be available for absorption and utilization. Our objective was to examine use of algal biomass as a source for n-3 fatty acids. Four late-lactation Holsteins were assigned to a 4 × 4 Latin Square design. Their rations were supplemented with 1X or 0.5X rumen protected (RP) algal biomass supplement, 1X RP algal oil supplement, or no supplement. Supplements were lipid encapsulated (Balchem Corp., New Hampton, NY). The 1X supplements provided 29 g/d docosahexaenoic acid (DHA) and 0.5X provided half of this amount. Treatments were analyzed by orthogonal contrasts. Supplementing dairy rations with rumen protected algal supplements did not affect feed intake, milk yield, or milk composition ($P > 0.05$). Milk fat yield was 1.0, 1.1, 1.0, and 1.0 ± 0.07 kg/d for cows fed control, 0.5X RP algae, 1X RP algae, and 1X RP oil, respectively. Short- and medium-chain fatty acid yields were not influenced by supplements ($P > 0.05$). Both 0.5X and 1X RP algae supplements increased ($P < 0.01$) daily milk fat yield of DHA (0.5 and 0.6 ± 0.10 g/d, respectively) compared with 1X RP oil (0.3 ± 0.10 g/d), but all supplements were greater ($P < 0.01$) than control (0.1 ± 0.10 g/d). Yield of trans-18:1 fatty acids in milk fat was also increased by supplementation, suggesting supplements may have influenced rumen microflora. Trans-11 18:1 yield (13, 20, 27, and 15 ± 3.0 g/d for control, 0.5X RP algae, 1X RP algae, and 1X RP oil, respectively) was greater for supplements than control ($P = 0.05$). Rumen protected algal biomass provided better DHA yield than algal oil.

Key Words: micro-algae, n-3 fatty acid, rumen protection

212 Additive effects of propionate, trans10,cis12-CLA and acetate on milk fat production and composition in dairy cows. G. Maxin*[1], H. Rulquin[1], J. L. Peyraud[1], and F. Glasser[2], [1]*INRA-Agrocampus ouest*, *Rennes, France*, [2]*INRA*, *Theix, Saint-Genes-Champanelle, France*.

Several nutrients affect dairy cow mammary lipogenesis and thus milk fat production and composition. The individual effects of these nutrients have been long studied by digestive infusions, but it is still not known whether they are additive or interactive. The present study aims to investigate the effects on milk fat secretion of 3 of these nutrients: propionate (C3), acetate (C2) and trans10,cis12-CLA, supplied alone or together to dairy cows. Six Holstein cows were used in a 6 × 6 Latin square design with 14-d periods. The treatments were: control; C2 (ruminal infusion of 1500 g/d of C2); C3 (ruminal infusion of 800 g/d of C3); CLA (duodenal infusion of 1.60 g/d of trans10,cis12-CLA); C2+C3 (ruminal infusion of 400 g/d C3 + 750 g/d C2); and CLA+C3 (ruminal infusion of 800 g/d C3 + duodenal infusion of 1.60 g/d trans10,cis12-CLA). Milk yield and composition were measured at each milking and milk fatty acids (FA) at the end of each period. Compared with control, C3 and CLA decreased milk fat content and yield by 9% and 15% on average ($P < 0.05$). C2 tended to increase milk fat content ($P = 0.08$), but did not alter milk fat yield. CLA decreased the yields of all milk FA, except trans10,cis12-CLA, which increased. C3 decreased the yields of all even-chain FA ($P < 0.05$) and increased the yields and percentages of the odd-chain FA (C5 to C17, $P < 0.05$). C2 did not modify the secretion of the FA, except C16, which sharply increased ($P < 0.01$). The interactions between C3 and C2, and C3 and CLA on all the variables measured were never significant ($P > 0.15$), whatever the nutrient individual effects. When the 2 nutrients had the same individual effects, their effects added up when infused together (e.g., CLA+C3 on milk fat content); when they had opposite effects, there was compensation (e.g., C2+C3 on milk fat content). Under our experimental conditions, C2 and C3, and C3 and trans10,cis12-CLA had thus additive effects on mammary lipogenesis.

Key Words: dairy cows, milk fat, nutrients

213 Regulation of adipose tissue metabolism by coordinated changes in gene transcription during the transition period. S. Rocco*, G. Duncan, J. Kay, R. Bose, J. Vierck, and J. McNamara, *Washington State University*, *Pullman*.

Metabolic adaptations in adipose tissue are a critical part of establishment and maintenance of lactation. Adipose tissue not only stores and releases energy but also secretes a metabolic regulators and cytokines. Previous work determined that several enzymes and pathways adapt in a coordinated fashion to support establishment and success of lactation. Our objective was to identify specific changes in gene transcription that relate to adaptations in lipogenesis and lipolysis in the adipose tissue of transition dairy cattle. A total of 48 cows were grouped by their sire PTAM: High Genetic (PTAM = 870 kg), or Low Genetic (PTAM = 378); and half of each group was fed either to requirements (NE) or to 90% of energy requirements (LE), other components fed to requirements. Feed intake from 21 to 1 d prepartum was 13.6 (NE) and 12.7 kg (LE) DMI/d for (SE = 1.5): from 1 to 56 DIM it was 21.2 and 17.4 kg/d (SE = 1.4). Milk production was 36.1 and 33. Three kg/d for HG and LG cows from 27 to 56 DIM ($P < 0.05$). Adipose tissue biopsies at −21, −7, 7, 28 and 56 days around parturition were used to measure lipolysis, lipogenesis and gene expression by RT-PCR or gene array chips. Rates of lipogenesis were lower during lactation and lower in LE cows while lipolysis rates were higher for both conditions ($P < 0.05$). The mRNA expression of the beta-2 adrenergic receptor, hormone sensitive lipase and the co-lipase, perilipin, was several-fold higher ($P < 0.05$) in animals on restricted energy. The mRNA for caveolin-1 and caveolin-2 decreased 20 to 40% ($P < 0.05$) in lactation consistent with the increase in lipolysis and HSL activity. The gene expression array showed coordinated decreases in genes regulation lipogenesis (TRPSP14, −26%; AcCoCarb, −76%; LPL, −57%; ATP-Citrate Lyase, −22% (<0.05) as examples) and no change or moderate increases in those controlling lipolysis. Lactation is supported by coordinated change in gene expression and metabolic rates in adipose over varied dietary and genetic situations.

Key Words: lactation, adipose, regulation

214 Effects of dietary protein concentration and coconut oil supplementation on nitrogen utilization and production in dairy cows. C. Lee*, A. N. Hristov, K. S. Hyler, T. W. Cassidy, and M. Long, *Pennsylvania State University*, *PA*.

The objective of this experiment was to investigate the effect of dietary protein concentration and coconut oil (CO) on N utilization in lactating dairy cows. The experiment was conducted for 10 wks with 36 cows (132 ± 7.0 DIM; 13 primiparous and 23 multiparous) including 6 cannulated cows. Following a 2–wk covariate period, cows were blocked based on DIM and milk yield (average: 38.4 ± 1.2 kg/d) and assigned to the following treatments: 16% CP (DM basis, HighCP, control), 14% CP (LowCP) and 14% CP diet supplemented with 600 g/cow/d coconut oil (LowCPCO). The HighCP and LowCP diets contained 2.5% (DM basis) Megalac. Samples (ruminal fermentation, nutrients digestibility, N losses, and milk production) were collected at wks 5, 6, 7 and 8 of the trial. Compared with LowCP and HighCP, LowCPCO decreased DMI (21.5 vs. 23.7 and 24.7 kg/d; $P < 0.003$), milk yield (34.7 vs. 36.5 and 39.7 kg/d, $P = 0.01$) and milk fat content (3.1 vs. 3.6 and 3.7%; $P = 0.001$) and yield (1.1 vs. 1.3 and 1.4 kg/d; $P < 0.001$, respectively). Milk protein content and yield were not affected by diet. Compared with HighCP, the LowCP diet decreased milk yield (39.7 vs. 36.5; $P = 0.04$). Apparent digestibilities of DM, OM, NDF, ADF and N were greater ($P = 0.03$ to < 0.001) for HighCP compared with LowCP and LowCPCO. Ruminal ammonia ($P = 0.03$), blood urea–N ($P < 0.001$) and milk urea–N ($P < 0.001$) were increased by HighCP compared with LowCP and LowCPCO. Urinary N excretion was greater ($P < 0.001$) for HighCP compared with LowCP and LowCPCO. Cows fed the LowCPCO diet had lower ($P = 0.001$) fecal N excretion compared with the other diets and the highest ($P < 0.001$) milk N efficiency (36%) followed by LowCP (32%) and HighCP (28%). In conclusion, the 14% CP diet decreased urinary N losses and increased feed N efficiency, but decreased milk yield. Coconut oil supplementation decreased feed intake and milk yield, but increased feed N utilization efficiency compared with the control and LowCP diets.

Key Words: dietary protein, coconut oil, dairy cow

215 The effect of feeding ruminally protected lysine (RPL) on production performance and plasma amino acid profile of early lactation dairy cattle. J. E. Nocek*[1] and I. Shinzato[2], [1]*Spruce Haven Farm and Research Center*, *Auburn, NY*, [2]*Ajinomoto Co., Inc.*, *Tokyo, Japan*.

Thirty-six lactating Holstein cows were used to examine the effects of ruminally protected lysine (RPL) supplementation and dosage on production performance and plasma amino acid profile of high-producing dairy cows. Multiparous cows were balanced across treatments based on their 4 week of lactation average milk production as follows: Control, 75, 150, 225 g/d of RPL. These treatments were designed to deliver 0, 12, 24 and 36 g/cow/d of supplemental intestinally available lysine, respectively. Cows started the experimental period on the fifth week post-calving and remained on treatment for 4 weeks. Prior to treatment administration, all cows received the control diet for one week, which contained 75% of forage from corn silage. Control diet was fed to all cows throughout the experimental period, however, in addition, cows

received 500 g/d of corn meal premix top dressed once daily to deliver 0, 75, 150 or 225 g/d of RPL. Blood samples were taken for each cow before daily feeding on d 0 and 28 of the study for amino acid analysis. Dry matter intake was not affected by RPL dose when expressed as a percentage of body weight. Mean milk yield was the highest ($P < 0.03$) for cows receiving 150g RPL than Control or 225g RPL, with 75g RPL not being different than others (47.7, 43.2, 42.7 and 44.6kg, respectively). FCM was higher ($P < 0.05$) for cows receiving 75g RPL compared with control. Fat % was higher ($P < 0.05$) for 75g and 225g RPL compared with Control and 150g RPL, whereas protein %, lactose, MUN, and SCC were not affected by RPL dose. Protein yields, however, were the highest ($P < 0.01$) for 150g RPL and the lowest for 225g RPL. At 28d, plasma lysine showed a numeric tendency to be the lowest for 150g and the highest for 225g RPL, with 225g RPL having a 17.6% increase ($P = 0.12$) from d 0 to 28. Under the conditions of this study, 75g or 150g RPL provided the most efficient and consistent response in production performance of early lactation dairy cows.

Key Words: ruminally protected lysine, milk production, plasma AA

216 Effect of Protein Edge on ruminal microbial protein production and performance of lactating dairy cows. S. E. Boucher*[1], H. M. Dann[1], K. W. Cotanch[1], C. S. Ballard[1], R. J. Grant[1], and K. Yagi[2], [1]*William H. Miner Agricultural Research Institute*, *Chazy, NY,* [2]*ZEN-NOH National Federation of Agricultural Co-operative Associations*, *Tokyo, Japan*.

Sixteen lactating Holstein cows (4 ruminally cannulated; mean ± SD) 95 ± 17 d in milk were used in a 4 × 4 replicated Latin square design with a 2 × 2 factorial arrangement of treatments to determine the effects of Protein Edge (PE; Agriformulations, Inc., Waddington, NY) supplementation of diets varying in rumen undegraded protein (RUP) content on ruminal microbial protein production, ruminal fermentation, and lactation performance. Protein Edge is a blend of bacterial and fungal fermentation extracts that was reported previously to increase microbial protein production in vitro. The RUP content of the diets was either 36 (LoRUP) or 40% (HiRUP) of crude protein (CPM v.3.0), and PE was added at 0.11% of dry matter (DM). Treatments were: 1) no PE, LoRUP, 2) PE, LoRUP, 3) no PE, HiRUP, and 4) PE, HiRUP. Experimental periods were 21 d with a 15-d adaptation. Microbial protein production was estimated via urinary excretion of purine derivatives. Data were analyzed using the MIXED procedure of SAS. There was no effect of PE or RUP level ($P > 0.10$) on ruminal pH (mean ± SE; 6.0 ± 0.2) or ruminal concentrations of NH_3-N (9.0 ± 0.8 mg/dL), total free AA (2.2 ± 0.22 m*M*), or total VFA (135.6 ± 3.6 m*M*). Protein Edge increased ruminal microbial protein production ($P < 0.01$) with the no PE and PE diets averaging 527 ± 20 and 557 ± 20 g of microbial N/d, respectively. Protein Edge tended ($P = 0.07$) to increase milk yield (MY; no PE = 51.5 ± 1.7 and PE = 52.3 ± 1.7 kg/d). However, there was no effect of PE or RUP level ($P > 0.10$) on DM intake (26.2 ± 0.4 kg/d), fat-corrected MY (49.4 ± 1.6 kg/d), milk component yields or content, feed efficiency (1.99 ± 0.06), or feed-N efficiency (0.34 ± 0.01). Other than a trend for a slight increase in MY, there were no effects of PE on lactation performance. However, PE may be a useful additive to increase metabolizable protein supply because PE increased ruminal microbial protein production.

Key Words: Protein Edge, microbial protein production, lactating cows

217 Use of plasma concentrations to estimate bioavailability of methionine in rumen-protected products fed to dairy cows. G. A. Broderick*[1], S. M. Reynal[2], R. A. Patton[3], W. Heimbeck[4], and P. Lodi[5], [1]*U.S. Dairy Forage Research Center*, *Madison, WI*, [2]*University of Wisconsin*, *Madison*, [3]*Nittany Dairy Nutrition, Inc.*, *Mifflinburg, PA*, [4]*Evonik Degussa GmbH*, *Hanau, Germany*, [5]*Universidad Nacional de Rosario, Argentina*, *Rosario, Argentina*.

Plasma AA level was used to estimate Met bioavailability in 2 sources of rumen-protected Met (RPM): Mepron (RPM1) and Smartamine M (RPM2). Eight cows consuming 22 kg DM/d, yielding 34 kg milk/d and fitted with ruminal cannulas were fed a basal TMR containing (DM basis) 14% alfalfa silage, 54% corn silage, 7% grass hay, 9% ground shelled corn, 13% soybean meal, 3% additives, 15.7% CP and 36% NDF. The TMR were fed at 6-h intervals in 4 equal portions each day. For the calibration phase, cows were blocked by DIM into 2 squares and randomly assigned to balanced 4 × 4 Latin squares with 3-d periods. Solutions of DL-Met were infused into the abomasa via tubes inserted through the ruminal cannulas and omasal orifice to provide 0, 8, 16 and 24 g Met/d. Amounts actually infused were measured daily. Blood samples were collected from alternate jugular veins every h over the last 6 h of the 3-d period. Blood plasma was deproteinized and stored at –20°C until analyzed. For the feeding phase, cows were re-randomized within square and assigned to 4 treatments: 0.24 g Met/d fed as 28.2 g/d of RPM1 or 31.6 g/d of RPM2, or 24 g DL-Met infused into the abomasum. Both RPM1 and RPM2 were fed 4x daily by hand mixing 1/4 the daily dose into the TMR. Design and blood sampling were the same as the calibration phase except periods were 7-d; abomasal Met infusion was for the last 72 h of each period. Plasma Met (PMet) concentrations were determined by ion-exchange chromatography with ninhydrin detection. Plasma Met concentration was regressed on Met infusion levels using Proc GLM in SAS to develop the response curve used to estimate Met bioavailability after correction for recovery of DL-Met infused during the feeding phase. The regression equation from the calibration phase was: Plasma Met (μM) = 0.498*Met infused (g/d) + 3.42 μ*M* ($P < 0.0001$; $r^2 = 0.533$). Rearranging and applying this equation yielded a mean recovery of infused Met of 95%. Mean (±SE) bioavailabilities, corrected to 100% recovery of infused Met, were 75 (±20)% for RPM1 and 88 (±23)% for RPM2. These bioavailabilities were not different ($P = 0.51$) within the precision of this study.

Key Words: methionine, rumen-protection, blood

218 Evaluation of a ruminally protected lysine product to increase milk protein production and plasma lysine concentration. S. E. Boucher*[1], H. M. Dann[1], K. W. Cotanch[1], C. S. Ballard[1], R. J. Grant[1], and I. Shinzato[2], [1]*W.H. Miner Agricultural Research Institute*, *Chazy, NY*, [2]*Ajinomoto Co., Inc.*, *Tokyo, Japan*.

Fifteen multiparous Holstein cows (mean ± SD) 122 ± 38 d in milk were used in a replicated 3 × 3 Latin square design to evaluate the efficacy of a ruminally protected Lys (RPL; Ajinomoto Co., Inc.) product to increase milk protein production and plasma Lys concentration. Experimental periods were 21 d with a 15-d adaptation. Dietary treatments were 1) control diet adequate in metabolizable protein (MP)-Lys, 2) diet deficient in MP-Lys, and 3) Lys deficient diet made adequate in MP-Lys with RPL. The RPL was assumed to contain 20% bio-available Lys and was added to the Lys deficient diet at 0.65% of dry matter (DM). The basal diets contained 50% forage and 50% concentrate. The MP-Lys contents of the Lys adequate, Lys deficient, and RPL diets were 6.5, 5.7, 6.7%, respectively, and the MP-Met content of the diets was 2.3% (CNCPS v.6.1; AMTS.Dairy, AMTS LLC, Cortland, NY). Cows were fed once and milked 3 times daily. Milk samples were collected from 3 consecutive milkings on d 18 and 19 of each period. Blood was collected on d 19 and 20 of each period at 2, 4, 6, and 8 h after feeding and compos-

ited by cow and period for AA analysis. Data were analyzed using the MIXED procedure of SAS. There was no effect of diet on DM intake (mean ± SE; 29.6 ± 0.76 kg/d), milk yield (49.9 ± 1.64 kg/d), milk fat % (3.71 ± 0.12%), milk fat yield (1.85 ± 0.07 kg/d), milk true protein (TP) % (3.19 ± 0.04%), or milk TP yield (1.59 ± 0.06 kg/d). There was an effect ($P < 0.001$) of diet on plasma Lys concentration (% of total plasma AA) with the Lys adequate diet resulting in the highest (4.27 ± 0.06%), the RPL diet was intermediate (3.74 ± 0.06%), and the Lys deficient diet was the lowest (3.52 ± 0.06%). Based on the plasma data, the Lys adequate diet and RPL increased MP-Lys supply compared with the Lys deficient diet. However, improved MP-Lys supply did not result in increased milk protein production in this experiment.

Key Words: ruminally protected lysine, milk protein, plasma lysine

219 Effect of rumen-protected lysine and methionine on lactating performance in lactating water buffalo. C. X. Zou*[1], Q. F. Tang[2], G. S. Qin[1], B. Z. Yang[1], S. L. Li[1], S. J. Wei[1], K. Liang[1], L. L. Li[1], X. W. Liang[1], and Z. S. Xia[2], [1]*Buffalo Research Institute*, *Nanning 530001, China*, [2]*College of Animal Science, Guangxi University*, *Nanning 530005, China*.

The present experiment was undertaken to determine the effects of RPLys (rumen protected lysine) and RPMet (rumen protected methionine) supplements on lactating performance in lactating water buffalo. Fifteen early lactation, healthy lactating water buffaloes were selected, according to species, last lactation milk yield, calving time and similar parity. Animals were randomly divided into 5 group, using 5 × 5 Latin square design with 5 periods and 5 treatments, i.e., the control group1 (basal diet CP = 16%), the control group2 (basal diet CP = 20%), treatment 1: basal diet CP = 16% plus RPLys 40g/d; treatment 2: basal diet CP = 16% plus RPMet 15g/d; treatment 3: basal diet CP = 16% plus RPLys30 g/d plus RPMet 6 g/d. The results showed: (1) Effect of RPLys and RPMet supplements on lactating performance in lactating water buffalo showed non-significantly difference ($P > 0.05$), but RPLys and RPMet supplements could improve lactating performance in lactating water buffalo and RPLys was the better. Compared with control group1 and control group2, RPLys supplements increased milk yield by 10% and 5.9%. (2) Effect of RPLys and RPMet supplements on dry matter intake (DM) in lactating water buffalo showed non-significantly difference ($P > 0.05$), but RPLys and RPMet supplements could reduce dry matter intake (DM) in lactating water buffalo. (3) RPLys and RPMet supplements can improve milk protein, milk total solid matter, non-fat milk solid content and lactose content in lactating water buffalo, compared with control group1, milk protein of RPLys, RPMet and RPLys+ RPMet supplements increased by 29%, 36.8% and 54.3% ($P < 0.05$), compared with control group2, Milk protein increased by 3.9%, 10.2% and 24.4% ($P < 0.05$). Only RPLys supplements could increase milk fat in lactating water buffalo, and only RPMet supplements could improve milk fat in lactating water buffalo. Therefore, RPLys and RPMet supplements could improve lactating performance in lactating water buffalo.

Key Words: RPLys, RPMet, lactating water buffalo

220 Effect of rumen protected γ-aminobutyric acid on performance and health status of early lactating dairy cows. D. M. Wang, Z. Liu, F. Yang, H. Y. Liu, C. Wang*, Y. M. Wang, and J. X. Liu, *Institute of Dairy Science, Zhejiang University*, *Hangzhou 310029, P. R. China*.

The objective of this study was to investigate the effects of rumen-protected γ-aminobutyric acid (GABA) addition on DMI, milk performance, and plasma metabolites in Chinese Holstein dairy cows. Forty-eight cows (days in milk = 60 ± 5; average milk yield = 37.3 ± 5.4 kg/d) were blocked based on days in milk, milk production, and parity and were randomly assigned to one of 4 treatments. Dietary treatments were 4 adding levels of GABA: 0 (control), 30, 60, and 90 g/day, respectively. The experimental period was 7 weeks. Milk yield and milk composition (fat, protein, and lactose) were recorded weekly, and serum parameters of antioxidant status, neuropeptide Y, and GABA were analyzed on wk 1, 4, and 7. The DMI of grass hay was significantly higher ($P < 0.05$) in the GABA-added cows than those on control. Milk yield increased ($P < 0.05$) in 30 g GABA-added cows, but leveled off in 90 g GABA-added animals. Milk protein yield was higher ($P < 0.05$) when 30 or 60 g of GABA was added but there was no difference ($P > 0.05$) between control and 90 g GABA-added animals. Milk fat content was not different among treatments ($P > 0.05$). Serum glutathione peroxidase increased for 60 g group ($P < 0.05$), and serum malondialdehyde reduced for all GABA-added group ($P > 0.05$) compared with the control. No statistical difference was observed in the neuropeptide Y between all the treatments ($P > 0.05$). In summary, addition of rumen-protected GABA at 30 g could increase feed intake, improve milk performance, and is beneficial to the dairy cow health.

Key Words: γ-aminobutyric acid, dry matter intake, milk performance

ADSA-SAD Undergraduate Competition: Dairy Foods

221 Chocolate milk as a sports recovery drink. H. L. Weeks*, D. R. Winston, and R. E. James, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Exercise depletes muscle tissue of energy and the body of fluids and nutrients. Athletes constantly seek the best recovery drink following exercise. However, which is best? Milk, nature's most nearly perfect food, must be included in the debate. Water replaces fluids lost during exercise, but lacks protein, vitamins, and other nutrients that chocolate milk offers. Sports drinks, like Gatorade and Powerade, replace fluid losses from sweat and are a source of electrolytes and energy such as glucose. However, excess sugar in sports drinks is not easily digested immediately after exercise. Fortunately, casein protein in milk is easily digested. Milk also contains vitamins A, B2, B12, D and E. Tryptophan in milk helps produce serotonin to reduce stress and relax muscles. Calcium strengthens bones and helps to build muscle, useful after exercise when muscles are depleted of energy. Reduced-fat chocolate milk is superior to plain milk after exercise because it includes other factors, such as caffeine and sugars. Caffeine decreases fatigue and sugar is a source of energy. Two similar studies conducted with 9 trained cyclists show that endurance athletes, like long distance runners and cyclists, were able do to exercise longer before feeling fatigued. Both studies analyzed cyclists who worked until exhaustion, received one of 3 beverages during a 4-h rest period, and cycled again until exhaustion. Three cyclists were assigned to each beverage. Both studies used a fluid replacement drink (Gatorade) and a carbohydrate replacement drink (Endurox R4). One study used low-fat chocolate milk and the other whole chocolate milk, containing 2% and 3.5% fat respectively. Cyclists consuming low-fat chocolate milk became fatigued at the same time as cyclists consuming Gatorade. However, cyclists drinking chocolate milk in the second study easily exceeded the cycling time for athletes drinking Gatorade by 9 min and Endurox R4 by 11 min. Consuming reduced-fat chocolate milk after exercise is the best way to replenish fluids, carbohydrates and protein. Chocolate milk restores muscle tissue in endurance athletes better than water, sports drinks or plain milk.

Key Words: sports recovery, chocolate milk

222 Dairy foods and the prevention of childhood obesity. J. E. Anderson* and C. C. Williams, *Louisiana State University*, *Baton Rouge*.

For the past decade, overweight and obesity have been on the rise, with the most significant increase occurring in children and adolescents. Overweight and obesity are defined as body mass indexes (BMI) of ≥25 and ≥30, respectively. BMI is calculated using the equation weight/height^2, and the equation differs slightly for children. Overweight and obesity have also been shown to increase the possibility of certain diseases and health problems. The National Health and Nutrition Examination Surveys (NHANES; 1976–1980 and 2003–2006) show that for children aged 2–5 years, prevalence increased from 5.0% to 12.4%; for those aged 6–11 years, prevalence increased from 6.5% to 17.0%; and for those aged 12–19 years, prevalence increased from 5.0% to 17.6%. As a result, the National Dairy Council has partnered with the National Football League to start the Fuel Up and Play 60 program. This program incorporates good nutrition and physical activity to help children develop better lifelong habits. Studies have shown that inadequate consumption of nutrient-rich foods, specifically low-fat and fat-free dairy foods, fruits, and vegetables and whole grains, can contribute to obesity in young adults. Three to 4 servings of dairy products per day not only promote healthy bone development but may also aid in weight loss. So, stocking the refrigerator with milk, yogurt, and cheese may make it easier to lose weight without forfeiting calories necessary for proper growth and development in children and adolescents.

Key Words: dairy foods, childhood obesity

223 Understanding the ropy milk test. R. A. Russell* and C. D. Thompson, *University of Kentucky*, *Lexington*.

Ropy milk is a stringy or slimy condition of milk that is caused by bacteria that contaminate milk after leaving the udder. It also represents a source of much debate and controversy within the dairy industry with regard to the appropriateness of the test. The 2 most common bacteria believed to cause ropiness are *Alcaligenes viscolactis* and *Enterobacter aerogenes*. These bacteria are able to contaminate the milk because of improperly cleaned or sanitized areas. The bacteria can originate from both the farm and the plant. Ropiness in milk became a problem before 1920 and was resolved, but the problem has risen again in recent years. A trend to larger dairy farms is reported as one possible reason for ropiness because it takes more care and precaution to keep facilities clean. Another potential reason ropiness has reappeared is because of transporting milk longer distances. Ropiness appears in the milk about 12 h after it is removed from the cow. It normally occurs in pasteurized milk but is sometimes not observed because it is consumed before sufficient bacterial growth has taken place. While the milk may be thicker than usual, flavor does not differ. Another reason it may not be detected is that many of the organisms that cause ropiness grow slowly at refrigerated temperatures. Testing of milk for ropiness can be done by incubating a small sample of the milk at temperatures of 15 to 22°C for 24 to 36 h. After the allotted time, to test for ropiness, a wooden stick can be inserted into the milk looking for a stringy condition. Instead of using the wooden stick, the milk could also be slowly poured from the vial looking for strands of rope or slime. Bacteria that cause ropy milk have been found in bedding, cooling tanks, barnyards, pastures, pipe lines, and milk cans. These bacteria may originate from farms or milk plants. Thus, the key to keeping ropy milk from becoming a problem is proper cleaning and sanitizing of facilities. Controversy around the ropy milk test centers on concerns that the repeatability of the test, using clean equipment, has been low.

Key Words: ropy milk, ropiness, milk quality

224 Conjugated linoleic acid in milk is related to the diet of lactating dairy cows. H. L. M. Tucker* and E. L. Karcher, *Department of Animal Science, Michigan State University*, *East Lansing*.

Conjugated linoleic acid (CLA) is a naturally occurring fatty acid in milk that has beneficial human health properties. Researchers are interested in increasing *cis-9, trans-11* CLA in milk. Implications to enhance *cis-9, trans-11* CLA in milk are to decrease the risk of heart disease, cancer, and diabetes in humans. Sources of CLA include mixed grains, vegetable oils, and animal products. However, concentrations of CLA are higher in dairy products and products made from other ruminant animals (Beaulieu, 1998). Manipulation of the diet of dairy cows may be one way to increase concentrations of CLA in milk. The addition of 0.5% fish oil and 2.5% oil from extruded soybeans to the diet of lactating dairy cows caused a 3.5-fold increase of *cis-9, trans-11* CLA in milk fat

(AbuGhazaleh et al., 2006). Management practices may also influence CLA concentrations. For example, pasture grazed cattle produce more CLA compared with grain fed cattle. Dairy cows grazing pasture and receiving no supplemental feed had a 500% increase of CLA in milk fat compared with cows fed typical lactating cow rations (Dhiman et al., 1999). The dairy industry can potentially market products with increased concentrations of CLA to human consumers. The products made from milk with increased CLA have similar properties when compared with non-enriched products. Butter from enriched milk has comparable spread ability and storage temperatures (Jones et al., 2005). The opportunity to enrich products with CLA without compromising on taste and texture represents an opportunity for a niche market. This market may increase revenue for the dairy industry by appealing to consumers who want healthier products and do not want to change their eating habits.

Key Words: conjugated linoleic acid, pasture

225 Using microfiltration to extend milk shelf life. E. W. Cloninger*, *Pennsylvania State University*, *University Park*.

The goal of the United States dairy industry is to sell a wholesome, nutritious product. To accomplish this goal, the industry must remain economically competitive. Shelf life stability can offer a competitive advantage. Pasteurization using the ultra-high-temperature (UHT) method achieves the desired extended shelf life but has the undesirable consequence of a cooked flavor. As a result, membrane processes such as microfiltration (MF) have led to new advancements in the dairy processing world by providing a lower temperature option that allows for minimal flavor changes while extending shelf life. MF is defined as the passage of products under relatively low pressure through a semi permeable membrane with pore size ranging from 0.2 to 5 μm. It is because of this small pore size that contaminants such as bacteria can be filtered out. According to a study conducted at Cornell University, MF was shown to significantly decrease total bacterial counts by 3.79 logs. The study also found that MF reduced the SCC in the milk permeate to undetectable levels. It also showed that microbial shelf life was extended to more than 92 d when MF was used in conjunction with HTST pasteurization. Although MF did decrease the bacterial population, the rate of proteolysis that contributes to off-flavors during refrigeration was not seen to be reduced. MF has already been commercially used by companies in Canada and the United Kingdom. These 2 companies promote the fresh taste, nutritional quality, and long-shelf life of their milk. Additional research will show more uses for MF in improving milk quality. In summary, combining MF with current technologies can maintain a nutritious, wholesome product while extending milk's shelf life.

Key Words: microfiltration, shelf life

226 Reducing milk price volatility through innovative programs at the local and global level. W. Robinson*, *Clemson University*, *Clemson, SC*

The sustainability of dairy marketing has been the primary question on the minds of dairy farmers across the globe. Record low milk prices have severely plagued the dairy industry especially during 2009. This trend of unstable marketing in the dairy industry has endangered the future of many dairy producers at an international level. Though decreased milk prices have exposed many dairy farmers to the possibility of bankruptcy, many innovative programs have been introduced to the industry to counteract these causes and therefore prolong the futures of many dairy producers. The programs created to ensure survivability of dairy marketing are comprised of both governmental and private innovations. Smaller scale, grass-roots, programs are typically constructed and operated by private producers and companies within the dairy industry. Some of the practices involved with these small scale programs focus on many aspects of niche marketing such as practicing methods of organic farming, producing products of specialized quality, processing and marketing products on-farm, as well as utilizing free-range grazing. The governmental innovations which have been discovered and are now practiced to fight the epidemic of unstable milk prices and include both single and united governmental plans which are used internationally. Single governmental plans include such programs as Cooperatives Working Together (CWT), Component Pricing, as well as the Hayvanciligi Destek program. Furthermore, the united plans regarding governmental innovations to reduce instability in milk prices include specialized marketing networks as the North American Free Trade Agreement as well as marketing techniques currently utilized by the European Union. Through active involvement in one or more of these programs dairy producers are learning how to overcome the epidemic of low priced milk and maintain their livelihood in the dairy industry. These practices also allow for a greater degree of security in milk prices and greater opportunity for the marketing of US dairy products in the future

Key Words: CWT, government programs, milk price

Teaching/Undergraduate and Graduate Education: Graduate and Undergraduate Teaching 1

227 The Missouri Pathways Partnership—Inroads in distance education. E. L. Walker*[1], S. P. Webb[1], J. D. Ulmer[2], and A. Evert[3], [1]*Missouri State University*, *Springfield,* [2]*Texas Tech University*, *Lubbock,* [3]*Redlands Community College*, *El Reno, OK*.

The Agriculture Pathways Partnership was developed in 2004 to offer place-bound students the opportunity to earn Bachelor's of Applied Science (B.A.S) degree from Missouri State University (MSU). The ultimate goal of the Partnership is to increase the number of 2–year college students earning B.A.S. degrees and as a result improve the trained workforce in the agriculture industry. Students earn a B.A.S. degree in Agriculture after completing up to 85 h at a community college and a minimum of 40 h of upper division hours, with a minimum of 30 upper division hours through MSU. Students taking courses through MSU have the option of taking courses offered via interactive television (ITV), internet, weekend, intersession, and internship experiences. Faculty, staff, and students from 5 Missouri and 2 Oklahoma locations participate in the program. An evaluation was conducted to determine the impact of the program on student learning, satisfaction, and suggestions for improvement. The mixed–methods evaluation design was used and included student surveys, focus groups, and personal phone interviews. According to student surveys, courses offered via ITV are perceived as comparable to the face-to-face courses. Over 73% of student participants agreed or strongly agreed that Pathways courses were successful, that they liked the course format, and felt they would continue to take other courses through Pathways. Eighty-five percent of the faculty participating in Pathways agreed or strongly agreed that the Pathways courses were as rigorous as traditionally taught courses. However, students reported problems in student support ranging from enrolling, gaining access to blackboard, and applying for graduation. Students have also reported lack of motivation when no instructor was present in the classroom. Other factors which are challenges to the Pathways Program include regional weather variation, non-matching site academic calendars, ITV technology, personal student conflicts, and state–wide differences in degree requirements and regulations.

Key Words: distance education, teaching, agriculture degree

228 The effect of supplemental online resources in distance education format on undergraduate animal science laboratory instruction. J. Q. Bing*, S. E. Pratt-Phillips, and C. E. Farin, *North Carolina State University*, *Raleigh*.

The objective of this study was to determine if using supplemental online resources (SOR) in a distance education (DE) format would be effective in enhancing student learning. Seventy-two students in an undergraduate animal science laboratory course completed a pre-test on anatomy as well as completed a pre-survey to determine their experience with, and attitudes toward, SOR. The SOR were made available for randomly selected laboratory lessons through online modules. Two laboratory practical exams were administered, one mid-semester and one at the end of the semester, and included questions from labs for which SOR was made available as well as labs that had no SOR. Questions from the pre-test were included in the exams and these responses generated the "post-test" scores. At the end of the semester, students completed a post-survey regarding their opinions of the usefulness of SOR. Student learning and performance was evaluated using an ANOVA model that included test scores, SOR availability and their interactions. Results are presented as mean ± SEM. Post-test scores (87 ± 2%) were higher ($P <$ 0.0001) than pre-test scores (34 ± 2%), indicative of student learning. On Lab Practical 1, students scored higher ($P < 0.0001$) on questions from SOR laboratories compared with non-SOR laboratories (77 ± 2% and 74 ± 2%, resp.). In contrast, on Lab Practical 2, students scored higher ($P < 0.0001$) on questions from non-SOR laboratories compared with SOR laboratories (86 ± 2% and 83 ± 2%, resp.). In the post-survey, 62 of 72 (86%) of students believed the SOR was at least somewhat useful for improving their grade; however, student perceptions of the value of SOR to impact their performance were not consistent with actual performance. Factors other than SOR may play a greater role in influencing student performance.

Key Words: anatomy, online, supplemental online resources

229 APPLAUSE—A tool for improving student presentations. M. M. Beck* and R. Johnson, *Clemson University*, *Clemson, SC*.

Increasingly, clear and effective communication skills are sought by professional schools, potential graduate mentors, and employers; as educators of both graduate and undergraduate students, we are remiss if we fail to impart techniques that enhance the ability of our students to communicate effectively. Many resources exist for developing PowerPoint presentations with effective use of color schemes and fonts. Fewer resources exist for students to use in developing effective presentation skills and such techniques are typically not a curricular focus. APPLAUSE is a conceptual framework for students to use in developing and giving effective oral presentations. Using the letters of the acronym as a guide, students have the following prompts: A – Audience analysis; P – Pause then grab; P – Pointer precision; L – Lively voice; A – Adjust in action; U – Use appropriate gestures; S – Simplicity; E – Expect questions. These simple but straightforward prompts are useful regardless of the context; most speakers at scientific meetings know their subject matter well and, with attention to these details, could turn mediocre or good presentations into great presentations. Paying particular attention to the 2 P's – the first at the beginning to better ensure audience connection and the second, precise use of the pointer – can have immediate and marked effects on the presentation; misuse of both are among the most common distractions to effectiveness. Student feedback from 6 classes of ~15 students each, primarily senior undergraduates, indicates that use of the APPLAUSE framework made a positive difference in the effectiveness of their presentations.

Key Words: student presentations, communication effectiveness

230 Student performance is enhanced by pedagogical shift to lecture podcasts. J. J. Parrish* and R. L. Monson, *University of Wisconsin*, *Madison*.

The study examines the effects in reproductive physiology of comparing traditional lecture to use of enhanced podcasts. The course was taught at the junior-senior level and consisted of 2, 50-min lectures and a 2-h wet lab, for each of 15 weeks in the fall semester. Baseline data from the traditional course was from 2006. In 2007, enhanced podcasts replaced traditional lectures, which allowed replaying the broadcast in iTunes software so that viewing was computer platform independent. No change was made to the laboratory over the course of the study. Due to a sabbatical leave of the instructor in 2007, all students were required to view the podcasts for the lecture material. In 2008 and 2009 students had the option of viewing the podcasts or attending live lecture. Scores on 3

lecture exams were recorded in years 2006 – 2009, with years hereafter referred to as year 1–4. There were 44, 61, 53 and 67 students completing the class in years 1 - 4 respectively. Exams consisted of multiple choice, true-false, and essay questions. However no change was made in the exams over the 4 years and while students could review exam results in class, no exams were returned to students during this period. There were significant effects of exam, year and exam by year interaction, $P < 0.05$. The lsmean percentage scores on exams over the course of the 4 years were 80.8, 83.1 and 82.2 for exams 1 – 3 respectively. While exams scores were different ($P < 0.05$) and there was some variation over the years ($P < 0.05$), differences were minor. When the lsmean percentage overall exam score for each year was examined, the scores were 78.8, 82.7, 83.9, and 82.9 for years 1 – 4 with year 1 different ($P < 0.05$) from years 2 - 4 but no difference was found between years 2 - 4 ($P > 0.05$). Attendance in live lectures was 98%, 0%, 15% and 1% in years 1 – 4 respectively. In year 2 no live lecture was offered. However, in years 3 and 4 a live lecture was offered but attendance was low. The results demonstrate that lectures given via an enhanced podcast improve exam performance and given the choice, students chose to take the podcast over the live lecture.

Key Words: podcast, learning assessment, reproductive physiology

ADSA Southern Section Symposium: Dairy Cattle Grazing in the Southern USA

231 Why dairy producers are choosing to graze (again) in southeastern United States. M. E. Sowerby*, *University of Florida*, *Gainesville*.

Grazing dairy cows between milkings was the norm, not the exception, in southeastern United States until herd sizes began out-growing available pasture and environmental rules forced cows to be confined to ensure soil nutrient loads were managed. Free stall barns and total mixed rations increased cow comfort, milk production and cost of production. The current trend to intensive rotational grazing of cows in the Southeast is an adapted version of the New Zealand model, with low requirements for machinery (tractor and bush hog, minimally) and buildings (milking center only). Southeastern dairy producers like their rotational grazing systems because of: 1) low labor needs, 2) less machinery and buildings to purchase or build and maintain, 3) greater cow longevity, 4) less herd health problems, 5) flexibility to add more feed (and consequently more production) when feed and milk prices are favorable, 6) more free time for owners, and 7) greater return on assets. Challenges noted by rotational graziers include: 1) optimizing grass growth and quality, 2) mud, 3) cow comfort in hot, cold and inclement weather, and 4) cash flow, especially with seasonal milk production. With lower start up costs, however, more new dairies are grazing dairies in the Southeast.

Key Words: rotational, grazing, dairy

232 Nutritional and management strategies for lactating dairy cows housed on pasture-based systems in the southeastern US. C. R. Staples*[1], L. E. Sollenberger[1], J. H. Fike[2], B. Macoon[3], and R. S. Fontaneli[4], [1]*University of Florida*, *Gainesville*, [2]*Virginia Tech University*, *Blacksburg*, [3]*Mississippi State University*, *Raymond*, [4]*Embrasa Brasileira de Pesquisa Agropecuaria*, *Brazil*.

Well-managed grazing systems for lactating dairy cows in southern climes offers several advantages including 1) year-around grazing, 2) forages of comparable or better quality than those mechanically harvested, and 3) substantially reduced farm costs (feed and overhead) compared with barn housing. During 2 summers of study, lactating Holstein cows (n = 106; 116 DIM) were assigned to treatments in 3 periods examining 2 forage species, 2 rotational stocking rates, and 2 supplementation rates. Bermudagrass (BG; *Cynodon* spp. Cv. 'Tifton 85') supported less milk (16.2 vs. 17.3 kg/d) per cow but more milk per ha (118 vs. 87 kg/d) than the legume *Arachis glabrata*. Lower production per cow grazing BG was likely due to lower quality of BG (58.8 vs. 71.2% IVOMD) and lower forage intake (7.6 vs. 11.3 kg/d). Greater production per land area was due to a greater mean pregraze herbage mass (7270 vs. 4650 kg of DM/ha), herbage allowance (1.9 vs. 1.5 kg of DM/kg of body weight), and optimal stocking rate (10 vs. 5 cows/ha) on BG pastures. Supplementing concentrate at 0.5 vs. 0.33 kg per kg of milk increased milk production by 2.1 kg/d, with the increased response being more efficient for cows grazing BG vs. legume (0.87 vs. 0.43 kg of milk per d) due to less substitution of forage with concentrate (0.18 vs. 0.51 kg per kg). In winter, concentrate-supplemented Holstein cows rotationally grazing rye-ryegrass (*Secale cereale* L. and *Lolium multiflorum* Lam.) pastures produced more milk (23.5 vs. 20.5 kg/d) at 2.5 vs. 5.0 cows/ha stocking rate. In a 276-d study, Holstein cows housed in cooled free stalls and fed a TMR produced more milk (29.8 kg/d) than concentrate-supplemented cows managed on pastures of rye plus ryegrass in winter and BG in summer (25.0 kg/d) or on rye-ryegrass plus clovers in winter and pearl millet (*Pennisetum glaucum*) in summer (25.2 kg/d).

Key Words: grazing, dairy, nutrition

233 Nutrient management considerations for grazing dairies. S. R. Hill*, *Department of Animal and Dairy Science*, *Mississippi State University, Mississippi State*.

Waste and nutrient management concerns have grown in recent years as people demand a safe food product, but also clean and environmentally friendly methods of producing food. Grass based or grazing dairies do not seem to fit the typical description of a Concentrated Animal Feeding Operation (CAFO). In a true grazing system, cows are not confined for more than 45 d of the year and, by definition alone, grazing dairies sustain forage growth for the majority of the year. According to the Clean Water Act, these are 2 requirements to be considered an Animal Feeding Operation and to be called a CAFO the farm must meet certain size requirements (>700–1000 head). However, State governments have the ability to restrict these regulations and in some areas farms as small as 70 to 100 cows could be considered a CAFO and be required to hold an NPDES permit. This means that despite not fitting the image of a CAFO, grass based grazing dairies must also make waste and nutrient management a top priority. A case study done in the Netherlands showed that using more homegrown feeds such as pasture and reducing inputs from purchased feeds and organic fertilizers decreased the total amounts of N and P surplus at the whole farm level. Certain practices common on grazing dairies (i.e., irrigation, rotational grazing, watering methods) may increase the potential for surface water contamination. Some grazing dairies also face issues not common to confinement dairies, such as protecting wetlands and conserving wildlife areas, where waste regulations are concerned. Some nutrient budgets for grazing animals have been established, but more research is needed to determine the effect grazing practices have on waste and nutrient management, at the whole farm level.

Key Words: nutrient management, grazing

234 Reproduction and genetic programs for seasonal pasture-based dairy production systems. S. P. Washburn*, *North Carolina State University*, *Raleigh*.

The objective is to discuss concepts and challenges associated with reproductive management in seasonal breeding and calving in pasture-based dairy production systems. Seasonal breeding and calving as part of a pasture-based dairy system is an attractive option for some dairy producers for reasons of lifestyle as well as for matching cattle nutritional requirements to forage quality and availability. In hotter climates, seasonal systems also allow producers to avoid breeding or calving at times of the year when heat stress would have a more negative impact. Herd fertility needs to be high enough to consistently achieve more than 80% of cows and heifers conceiving within breeding seasons of 8 to 12 weeks. Such success requires greater than 80% of cows to be cyclic at the start of breeding with conception rates at first insemination typically above 50%. This corresponds with 21-d pregnancy rates that exceed 40%, well above rates achieved in confinement systems. Breed differences in fertility are evident but improved fertility within breed can likely be achieved over time by placing more emphasis on daughter pregnancy rates in selecting sires to use. Use of crossbreeding is very common in

pasture-based dairy herds and data from crossbreeding studies have documented heterosis for reproduction among crossbred cows. Dairy producers with interests in seasonal breeding and calving may either choose to use a selection index that places more weighting on fertility or choose to avoid use of sires with negative fertility evaluations for their daughters. On commercial pasture-based dairy herds, the use of short periods of AI followed by use of bulls with natural service is common. As with any dairy production system, differing strategies will likely be optimal for producers with differing resources and goals. Although milk production per cow is often less, lower facility and equipment costs, lower feed costs, improved animal health, and the ability to expand the herd internally by improved reproductive efficiencies provide the opportunity for well-managed seasonal pasture-based dairy systems to be economically competitive.

Key Words: reproduction, seasonal, pasture-based

235 Comparisons of the economics and costs of producing milk on conventional versus grass-based "New Zealand style" dairies in Mississippi. C. W. Herndon*, *Mississippi State University*, *Mississippi State*.

Enterprise budgets were employed to estimate the costs of producing milk and income over various costs categories for conventional dairies and compared these costs to grass-based "New Zealand style" dairies in Mississippi. Conventional dairies in Mississippi utilize a corn silage, protein concentrate feed ration along with some pasture grazing to supplement nutrient requirements during limited period of the year. Grass-based dairies rely on intensively managed pasture grazing to provide the vast majority of dairy cow nutrient requirements while feeding very limited amounts of feed concentrate throughout the year. Economic analyses were conducted in 2009 which estimated the costs of producing milk on a dollar per kilogram (kg) basis on a 500-cow conventional dairy and a 1,200-cow grass-based dairy. Findings indicate for the 500-cow conventional dairy using a 10,435 kg rolling herd average that the cost of feed concentrates alone constituted almost 50% of total direct costs, or 15.4 cents per kg. Including corn silage, hay, and pasture management, these costs increased to 64% of total direct costs, or 20.1 cents per kg compared with total direct costs of 31.3 cents per kg. Comparing similar cost categories on a 1,200-cow grass based dairy with a 5,445 kg rolling herd average found that feed concentrates accounted for only 25% of total direct cost, or 6.6 cent per kg. When adding costs for hay, silage and pasture management, costs increased to 9.0 cents per kg, or 33% of the 27.1 cents per kg total direct cost. Total direct costs were not the same between the 2 types of Mississippi dairies because the grass-based dairy included salaries of $145,000 for a farm manager, herdsman, and additional staff. These costs clearly show when feed costs escalate, as has been the case since 2006, conventional dairies face greater risks of suffering economic losses which threaten the continued survival of this style of dairy operation. However, a grass-based dairy operation could survive when feed cost increase dramatically due to less reliance on feed concentrates for cow nutrient requirements.

Key Words: dairy cost of production, grass based dairy

ADSA-SAD Undergraduate Competition: Dairy Production

236 Precision feeding for improved sustainability efforts. V. J. Eubanks*, *Clemson University*, *Clemson, SC*.

With an increase in environmental awareness, sustainable agriculture has taken a forefront in the minds of Americans. Sustainable agriculture, for all aspects, is focused conservation and preservation while maintaining economic stability for producers. In relation to dairy farming, this concept is widely centered on the excreta and how to alter contaminants of excreta through dietary changes to lower the occasional excess amounts of certain substances, most notably phosphorous (P) and nitrogen (N). Excess P and N levels in the soil can lead to groundwater pollution, acid rain due to volatilization N into NH3, and formation of algal blooms which harm ecosystems and contaminate human drinking water. Current research is investigating the potential of reducing excess production of P and N through altering the nutrient intake of the dairy cattle and changing the excreta without adversely affecting milk production. Precision feeding management (PFM) is being utilized to achieve these efforts. Nutrient management through PFM is focused on 2 main points: analyzing forages for nutrient content and balancing the diet precisely to NRC requirements outlined for P and CP content. While most forages and concentrate mixes are analyzed, many producers choose to feed their cows more P than necessary due to the correlation previously reported between P and reproductive performance. Research has found this only be true at extremely deficient amounts. According to Ghebremichael and colleagues, it was found that decreasing excess dietary P by 22% resulted in a 25% reduction of P content in excreta (2008). Nitrogen excretion can be reduced by reformulating CP content in the diet, identifying those animals that require additional amounts of CP. Studies have shown that precision feeding for CP led to increased milk production due to more efficient use of dietary nutrients and additionally decreased feed costs associated with these animals. Ultimately, PFM is focused on efficiently feeding dairy animals the NRC required diet without feeding excess P and CP. In addition, this will enhance sustainability for dairy productions systems which, in turn, will ease consumer concerns and improve public perception.

Key Words: PFM, nitrogen, phosphorus

237 The benefits of anaerobic digestion as a waste management procedure on dairy farms. C. M. Munz*, A. C. Wilkie, and M. E. Sowerby, *The University of Florida*, *Gainesville*.

The increased urbanization of rural areas in addition to an increase in the concentration of intensive livestock operations have produced great awareness and concern for the proper storage, treatment and utilization of livestock manure. The waste management procedures on dairy farms are thus receiving a great deal of attention. Manure is not only a valuable source of crop nutrients, it is a substantial bioenergy resource if processed by anaerobic digestion. Anaerobic digestion refers to the decomposition of organic matter in an engineered methanogenic process that involves bacteria which decompose the manure in a way similar to the natural decomposition that occurs in a cow's stomach. The renewable resources produced are part of a closed carbon cycle and do not add to the atmospheric concentration of CO_2. In addition, quality fertilizer is still derived from the manure after digestion. Anaerobic digestion therefore boosts environmental quality as a waste management technology and is a sustainable energy-producing technology. Multiple studies have been conducted to determine the effects of implementing anaerobic digestion as a waste management protocol on dairy operations, as well as its economic feasibility. Benefits of using a digester on a dairy farm include waste treatment, reducing odors, flies, and pathogens, eliminating green house gas emissions, conserving nutrients, and recovering a significant amount of energy in the biogas that is captured. In addition, implementation of anaerobic digestion on dairy farms contributes to a socially desirable "green image" and to compliance with impending air emission regulations.

Key Words: anaerobic digestion, waste management, sustainability

238 Changing the attitude towards tail docking dairy cattle. B. A. Wenner* and E. L. Karcher, *Department of Animal Science, Michigan State University*, *East Lansing*.

A recent survey report listed that over 80% of dairies surveyed practiced tail docking in Midwestern states (Fulwider et al., 2008) and while this is commonly considered as a sanitary and time saving method among dairy farmers, this process is coming under increasingly harsh criticism. Tail docking was recently banned by the California legislature on October 12, 2009, and became official in California on January 1, 2010. This legislation will likely appear in many states to follow, including another big dairy state, New York, following the release of an undercover video depicting cows being tail docked (AP, 2010). The perceived purpose of tail docking is to improve milking comfort and udder health, and to decrease disease transmission for the cow by reducing contact between the tail, manure and the udder during milking. Additionally, the removal of the tail helps to prevent employee discomfort and illness from possible contraction of disease from contact with urine and tail during milking (Stull et al., 2002). In controlled studies, there is no significant impact of tail docking on udder cleanliness, cow cleanliness or udder health compared with dairy cattle with intact tails (Tucker et al., 2001). In another study no significant differences in udder health, bacterial prevalence, and milk production were found between docked or non-docked cattle, but significant farm differences were observed especially for contagious pathogens present (Schreiner et al., 2002). Further, on a farm research study in New Zealand, 33% of employees were found to have contracted leptospirosis. However, this was not linked to whether or not dairy cattle were tail-docked but rather correlated to clinical history of leptospirosis in the herd (Mackintosh, 1980). Also, the tail is used for communication between cows, vulvular protection, and to avoid insects. Fly counts were higher in those animals who were tail docked (Eicher et al., 2001). We suggest that cessation of tail docking as an industry practice will have no negative effects on cows or people and will serve a major positive public relations effect for the national dairy industry.

Key Words: tail docking, welfare

239 Improving freestall housing to address animal welfare and cow comfort. R. M. Smith*, D. R. Winston, and C. S. Petersson-Wolfe, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Animal welfare and cow comfort have become very hot topics among American dairy farmers. With the airing of a Northern New York dairy farm's "inhumane" treatment of cattle on a national network, consumers have been provided with information that is not representative of the entire dairy industry. Animal welfare is important to the producer because the better designed and managed facilities reduce the risk that cows will become sick or lame. Housing facilities such as freestall barns, pack barns, as well as conventional access to pasture have all been analyzed for the pros and cons related to cow comfort and well being. Bedding types, application rates, and usage have also been examined.

Research has been conducted on freestall design to examine the type and size is most desirable for cow comfort. Improving freestall design will improve cow comfort and in return may improve public perception of the dairy industry. Animals rested an average of 0.7 h less in stalls measuring 106 cm than in stalls measuring 116 or 126 cm (Tucker et al., 2004). A second experiment showed that the difference in lying time was 1.2 h in stalls measuring 112 cm versus 132 cm (Tucker et al., 2004). Overall, animals preferred wider stalls. The amount of fecal matter increased 2.4 times in stalls measuring 126 cm, and 1.6 times more for 116 cm in width, compared with 106 cm stalls (Tucker et al., 2004). Stocking density, bunk space, surface type, and barrier type all have different effects on the performance and comfort of the animal. Time spent lying can comprise 40 to 60% of a cow's life, and the surface is important for both the health and comfort of the animal (Tucker et al., 2003). Although cattle prefer deep bedding, deep bedding is more difficult for the producer to maintain and may cause more mastitis. Research generated by universities, professional organizations, research institutes, as well as personal experience should be considered when deciding on improvements or new facilities. Educated decisions on facility design will greatly improve cow comfort as well as the overall well-being of the animal.

Key Words: animal welfare, cow comfort, freestall

240 Off to a good start. J. C. Landry* and C. C. Williams, *Louisiana State University*, *Baton Rouge*.

Calves are the future lactating cows on the farm, so ensuring their health and well-being is vital to the dairy operation. A neonatal calf is born with an immature immune system, meaning that these animals are not able to produce antibodies when challenged with a disease causing pathogen. This type of immunity, called active immunity, is acquired and begins to develop after the first 2 mo of life. Therefore, the neonatal dairy calf relies on passive immunity to fight diseases during this early part of life. The passive transfer of immunity is obtained by gut absorption of the antibodies present in colostrum. Without this passive transfer of antibodies, or immunoglobulins, into the blood, the calf will be at greater risk for many diseases. Colostrum, the first and most important feed given to a newborn calf, is the primary source of nutrients for the calf and also provides essential and irreplaceable antibodies. The 3 essential factors to consider in colostrum feeding and management are quality, quantity, and time. The calf′s ability to absorb the antibodies declines within hours after birth, and by 24 h the intestine is closed to absorption. Failure of passive transfer may occur if the calf is not given enough high quality colostrum within the first 24 h of life. According to the latest National Animal Health Monitoring System (NAHMS) data, failure of passive transfer of immunity on US dairy farms has dropped dramatically since 1991–1992′s level of more than 40%. But passive transfer failure still occurs on US dairy farms at the rate of 19.2%. A successful heifer-rearing program begins with the proper management of the newborn calf. The quality, quantity, and timing of colostrum are critical for passive transfer of immunity to the neonatal calf. Using recommended management practices for feeding colostrum to the newborn calf will get these young animals off to a good start in life.

Key Words: calves, immunity, passive transfer

241 Hemorrhagic bowel syndrome: The mysterious killer. B. P. Cashell*, *Pennsylvania State University*, *University Park*.

Hemorrhagic bowel syndrome (HBS) is an acute sporadic enteric disease that affects the small intestine of mature dairy cattle. It has been estimated that HBS is responsible for 2% of cattle deaths in North America. The disease is characterized by dark bloody stools, bloody diarrhea, shock, depression, and acute death. The cow's extremities become cool, mucous membranes become pale, and rectal temperature is lower than normal. The disease occurs most frequently in the first 100 d of lactation. Sudden death is common, with large blood clots found in the intestinal area. It is estimated that 85% of HBS cases are fatal, and treatment methods are rarely successful. While the cause of HBS has not been specifically identified, there are many possible contributors to its onset. Several pathogens have been linked to HBS. *Clostridium perfringens* has been most strongly associated with the condition. According to Colorado State University, 82% of HBS cases had moderate to heavy growth of *C. perfringens* from fecal material. An Oregon State study implicated *Aspergillus fumigates,* a contaminant in fermented feeds, as another associated pathogen. Since treatment of HBS has been largely unsuccessful and its exact cause is unclear, current approaches to control HBS have included identifying and correcting management and environmental factors that may impair immunity. Other possible methods of prevention include vaccines and feed additives. Careful cost analysis associated with these measures is necessary before implementing expensive methods of HBS prevention that have undetermined effectiveness. The mystery of HBS will be unraveled through further research into the causes and risk factors associated with this condition.

Key Words: hemorrhagic bowel syndrome, *Clostridium perfringens*

242 Compost bedded pack barns: Opportunities, challenges, and management considerations. C. M. Sheaffer* and J. M. Bewley, *University of Kentucky*, *Lexington*.

A compost bedded pack barn, which relies on a large, open resting area, usually bedded with sawdust or dry, fine wood shavings, is a relatively new alternative for management of dairy cattle and their waste in a confinement setting. The soft, dirt-like texture of the compost absorbs shock, provides safe footing, and provides a comfortable resting surface for cows to lie down. Heat detection is improved as compared with concrete, because of less concern of slipping. The heating of the compost may kill some harmful bacteria, including mastitis-causing pathogens, which can help reduce the occurrence of environmental mastitis. When the compost is working properly and dry, it can also be conducive to cleaner cows. Properly composted material emits little odor and can be dried and spread onto fields. This may ultimately lead to better nutrient utilization and the dried compost is more easily handled than liquid manure. Adequate ventilation, achieved through high, open sidewalls, open-ridges, and appropriately placed fans, is essential. Daily turning and aeration of the compost is necessary to provide oxygen (12 to 16%) to the microbial population. Most producers use a cultivator, tines, or a rotary tiller attached to the rear of a skid steer or small tractor to stir the pack. The temperature of the pack should be monitored daily and must be maintained between 54 and 66°C to ensure an optimal environment for the bacterial population. For proper function, the amount of moisture added by cows through urination and defecation should be limited to 46 to 64% total moisture in the pack. To achieve this, an appropriate stocking rate is one cow per 80 to 100 ft^2. Bedding particle size is also an important factor and should be a balance between coarse wood chips and sawdust to maximize absorbency and available carbon. New bedding is added to the pack when existing bedding is moist enough to stick to the cows when they get up. Though applications for compost bedded pack barns may be limited because of limited sawdust supplies, they remain a viable alternative for small dairy herds or special needs groups within larger herds.

Key Words: compost bedded pack, dairy housing, composting

ADSA-SAD Undergraduate Competition: Undergraduate Original Research

243 The effects of metaphylaxis antibiotics on health and development of neonatal bull calves. K. G. DeHaan*, G. A. Holub, and M. A. Tomaszewski, *Texas A&M University*, *College Station*.

A study evaluating the effects of metaphylaxis antibiotics and milk replacer additives on the health and development of Holstein bull calves (n = 52; mean body weight = 42.28 kg + 3 kg; starting age < 3 d) was conducted. The calves were placed into a completely random 3 × 4 factorial design with each group receiving either tilmicosin phosphate (TIL), ceftiofur crystalline free acid (CEF), or saline solution (CON) injected subcutaneously into the neck area. For the duration of the study, the calves also received a commercial milk replacer powder (22% crude protein / 20% crude fat) fed at 1.1% BW. Within metaphylaxis treatment, calves were randomly assigned to receive either; 1) 4 g/d for 7 d and then 2 g/d for 14 d of an egg-based probiotic (PR); 2) 2 g/d of 96% betaine (BE); 3) both PR and BE (BP); or 4) no additives . The calves were housed in individual fiberglass hutches with commercial calf starter and water provided ad libitum. The body weight of each calf was recorded twice weekly in addition to daily recordings of fecal scores (1 = firm to 4 = watery) for 54 d. Medical treatments provided to each calf for scours, respiratory distress, or febrile events were recorded daily. The cumulative response of these incidences were analyzed and used as an index of morbidity. None of the additive effects were significant for any of the measured variables. The use of metaphylaxis did not significantly affect the average daily gain ($P > 0.60$) as the average daily gain was ~0.45 kg. However, when examining fecal scores, CEF and TIL significantly reduced teh average fecal score over the control ((1.85 vs. 1.97 vs. 2.20 respectively) ($P < 0.01$)). The incidences of fever nor respiratory issues ($P > 0.20$) were influenced dramatically by metaphylaxis. Overall, the average daily treatment for fever was only 0.66 events and 0.39 events for respiratory distress. Metaphylaxis did not influence the occurrence of scours (fecal score > 2) ($P > 0.87$). Other than fecal score, these results indicate the use of metaphylaxis did not enhance productivity or reduce morbidity of Holstein neonatal bull calves.

Key Words: calf, metaphylaxis

244 Effects of Purina Cornerstone 20 AMPLI-CALF DX30 on calf growth. A. A. Blasi*[1], C. C. Stanley[2], C. R. Krehbiel[1], D. A. Jones[2], and W. Hurst[1], [1]*Oklahoma State University*, *Stillwater*, [2]*Land O'Lakes Purina Mills LLC*.

Proper calf nutrition is key life-long productivity of the cow. Investments in a heifer during the first 12 weeks of life can affect her productive potential in adulthood. Proper milk replacer and calf starter that meets all of a calf's needs is essential for full growth potential. The objective of this study was to compare commercially available Purina Cornerstone 20 AMPLI-CALF DX30 to a mill prepared calf starter (contained 16.3 mg/kg Bovatec 68). Each had a similar composition on a DM basis with AMPLI-CALF containing 21.89% CP and the mill calf starter containing 21.23% CP. AMPLI-CALF was fed without oat hay until 12 wks of age with oat hay presented starting at 6 wks of age to the milled starter group. Twenty Holstein heifer calves born at the OSU dairy were placed at random in one of 2 feed treatment groups. Calves were housed individually in fiberglass hutches with wire panel runs and given free choice water. All calves received 3.79 L of premium colostrum within 24 h of birth. Calves were fed twice daily with Land O'Lakes 28:20 Cow's Match milk replacer. All calves were weaned at 9 wks old. Orts were recorded every day at 1600 and appropriate feed amounts were adjusted and fed ad libitum to allow for excess feed. Water was offered ad libitum. To determine calf growth, measurements of weight, heart girth, pelvic width, pelvic height and wither height were taken on 1, 28, 56 and 84 d. Measurements were taken in the afternoon before new feed was presented. There was no difference ($P > 0.10$) in ADG from d 1–28, 28–56 or 1–84. However, from d 56–84 ADG was greater ($P = 0.05$) for calves fed AMPLI-CALF (1.30 kg/d) compared with control calves (1.10 kg/d). There were no differences ($P > 0.10$) in body weight, heart girth, pelvic width, pelvic and whither heights, as-fed feed intake or gain efficiency on d 1–28, 28–56, 56–84 or 1–84. Although overall growth was not affected, AMPLI-CALF increased post-weaning ADG of heifer calves compared with the milled calf starter.

Key Words: calf nutrition, heifer growth, performance

245 Use of omega-3 fatty acid rich algae and their oil as a feed supplement for dairy cattle. D. M. Shepherd*[1], J. A. Stamey[1], B. A. Corl[1], M. J. de Veth[2], and D. R. Winston[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Balchem Corp.*, *New Hampton, NY.*

Studies have shown that ω-3 fatty acids can improve reproductive performance in dairy cattle. Microscopic algae are a source of ω-3 fatty acids that could be used as a supplement for dairy rations. Availability of ω-3 fatty acids from the diet is limited due to their biohydrogenation in the rumen. A potential solution is to encapsulate the algal biomass in a lipid coating, theoretically allowing ω-3 fatty acids, specifically docosahexaenoic acid (DHA) found in algae, to remain inert in the rumen for absorption and utilization post-ruminally. To examine the supply of DHA for incorporation into milk fat by lipid encapsulated algal supplements, 4 late-lactation Holstein cows were assigned to a 4 × 4 Latin Square design. Their rations were supplemented with treatments: 1X rumen-protected algal biomass, 1X rumen protected algal oil, or 0.5X rumen-protected algal biomass. Supplements were lipid encapsulated (Balchem Corp., New Hampton, NY). The control treatment was unsupplemented. The 1X supplements supplied 29 g of DHA/d and the 0.5X supplement supplied half this amount. Data were compared using orthogonal contrasts. Supplementation did not affect feed intake, milk yield, or milk composition. Algal biomass supplements increased DHA content of milk fat (0.47 vs. 0.10 g/d; $P < 0.05$). Algal biomass was more effective at transferring DHA to milk fat than algal oil (0.55 vs. 0.30 g/d; $P < 0.05$). Supplements increased the milk fat content of trans-18:1 fatty acids. The effect on trans-18:1 fatty acids suggests that some of the supplemented fatty acids may have influenced the rumen biohydrogenation microflora. The transfer efficiency of dietary DHA to milk fat across treatments ranged from 0.5% to 3%. In conclusion, there was a significant increase in the amount of DHA present in milk fat.

Key Words: omega-3 fatty acid, algal biomass, milk fat

246 Effect of rumen sampling on time budget of lactating Holstein dairy cows. J. Deming*, P. D. Krawczel, and S. E. Boucher, *W.H. Miner Agricultural Research Institute*, *Chazy, NY.*

There is increasing evidence that a relationship exists between a dairy cow's ability to maintain her time budget and her productivity. This suggests that sampling regimens that alter behavior could potentially mask treatment effects in nutrition trials. The objective of this experiment was to determine differences in the feeding, ruminating, and lying behaviors

of ruminally cannulated lactating Holstein dairy cows housed in tie-stalls during the adjustment and sampling periods of a dairy nutrition experiment. We hypothesized that sampling would decrease time spent feeding, ruminating, and lying. Thirteen cows were assigned to the concurrently conducted nutrition trial, and all cows were subject to the same sampling schedule. Time spent eating, ruminating, drinking, lying, standing, or in the milking parlor was quantified by direct observation. Behavior was recorded at 5-min intervals for 24 h during both the adjustment and sampling periods. Data were analyzed as a completely randomized design using the Mixed procedure of SAS. Due to differences in time outside of the pen during sampling period (63.0 ± 0.9 min/d) and adjustment period (80.3 ± 0.9 min/d; $P < 0.001$), feeding, ruminating, and lying behaviors were evaluated as percentage of time within the tie-stall. Feeding (18.7 ± 1.2%) and ruminating (40.3 ± 1.3%) were not affected by sampling ($P > 0.10$). Lying decreased from 55.0 ± 3.2% during the adjustment period to 49.3 ± 3.2% during the sampling period ($P = 0.003$). Ruminating while lying was also reduced by sampling (from 28.3 ± 2.9 to 24.7 ± 2.9%; $P = 0.03$). The results of this study suggest that sampling can impact some aspects of a dairy cow's time budget. The number of times cows are disturbed for the collection of samples should be considered when designing sampling regimens.

Key Words: dairy cow, behavior, sampling

247 Effect of coliform mastitis on osteopontin expression in mammary tissues of Holstein dairy cows. K. M. Jackson*[1], J. C. Gandy[2], L. M. Sordillo[2], and E. L. Karcher[1], [1]*Department of Animal Science, Michigan State University*, *East Lansing*, [2]*Department of Large Animal Clinical Sciences, Michigan State University*, *East Lansing*.

Mastitis caused by gram-negative bacteria is often characterized by uncontrollable inflammation. Osteopontin (Opn) is a proinflammatory factor that plays a role in initiating the innate immune response by promoting cellular adhesion and eliciting proinflammatory cytokines. The objective of this study was to evaluate Opn gene expression in the mammary tissue of Holstein cows naturally infected with coliform mastitis compared with healthy controls. Parencyhmal tissue was collected from 3 lactating cows killed for reasons relating to natural coliform infection and 3 lactating cows killed for non-infectious reasons. All animals were from a commercial herd. Real-time PCR was performed to evaluate the expression of the following cytokine genes in parenchymal tissue: Opn, tumor necrosis factor (TNF)-α and interleukin (IL)-1. Additional samples were collected from the external pudendal artery and analyzed for Opn gene expression. Osteopontin and IL-1 expression did not differ between the natural coliform infected parenchymal tissues and that of the control tissues. There was a trend for greater TNF-α expression in infected tissues compared with control tissues (20.5 ± 16.6 vs. 2.2 ± 1.9; $P < 0.07$). Variability within infected and control parenchymal tissue was high which may be a result of the collection periods and the heterogeneous population of cells. The severity and duration of coliform infection was not controlled in this study and expression of proinflammatory genes will be affected by these 2 factors. There was a 4.2-fold increase in Opn expression between the infected and control external pudendal artery samples (4.3 ± 0.5 vs. 1.0 ± 0.3; $P < 0.001$). Unlike the parenchymal tissue, the vasculature represents a more homogeneous population of cells. The variability between these samples was diminished compared with the parenchymal tissues. In conclusion, this is the first study to evaluate the presence of Opn in parenchymal tissue and external pudendal arterial samples. Further controlled studies are needed to reduce the variability observed between the infection groups.

Key Words: osteopontin, mastitis, mammary tissue

248 Evaluation of dairy cattle lying behavior in commercial freestall barns. C. Gravatte*, C. Coombs, and J. Bewley, *University of Kentucky*, *Lexington*.

Animal activity monitoring sensors have been developed to measure lying behavior and have been validated using direct visual observations. These sensors may prove useful for assessment of facility functionality and animal well-being. However, to properly evaluate results, within and across herd variations must be understood. The objective of this research was to describe physiological factors impacting automatically recorded lying times across multiple commercial dairy farms using freestall barns. The lying times of 247 Holstein cows were measured using an animal activity monitor in 12 commercial dairy herds in Kentucky. Herds were categorized by production level (high, medium, and low) using rolling herd average milk. Within herds, project cows were distributed equally among lactation stage (60 to 400 DIM, mid and late lactation) and production level (high, medium, and low) categories. Cows that exhibited clinical lameness were excluded. For cows exhibiting estrus, the day of and the day before breeding were removed. When hours lying or number of steps taken within an individual day differed from an individual cow's weekly average by 2 or more standard deviations, these observations were removed. An IceTag animal activity monitoring sensor (IceRobotics Ltd., Edinburgh, Scotland, UK), which measures posture (lying versus standing) and number of steps, was attached to the hind leg of each cow above the fetlock for 14 d. The MIXED procedure of SAS was used to develop models to describe hours lying. Mean lying time (n = 3298) was 11.19 2.70 h/d while mean locomotion score was 1.37 0.56. Cows that were in mid lactation (11.04 0.39 h/d) had significantly lower lying times than cows in late lactation (12.42 0.39 h/d, $P < 0.0001$). Lying time decreased with increasing milk yield ($P = 0.03$). Though the difference only approaches significance ($P = 0.11$), cows with a locomotion score of 3 spent more time lying (12.31 0.71 h/d) than cows with a locomotion score of 1 or 2 (11.16 0.14 h/d). Consideration of lactation stage, milk yield, and locomotion score is necessary for interpretation of results obtained from automatic activity monitoring sensors.

Key Words: lying behavior, activity monitor, precision dairy farming

249 Associations of DNA marker profiles for dry matter intake and efficiency with DNA marker profiles for fat-corrected milk yield and body weight. D. E. Brown*[1], C. D. Dechow[1], J. M. Daubert[1], W. Liu[1], and S. Bauck[2], [1]*Pennsylvania State University*, *University Park,* [2]*IGENITY Livestock Production Unit*, *Duluth, GA*.

The objective of this study was to estimate the associations of DNA marker profiles for dry matter intake (DMI) and dry matter efficiency (DME) with DNA marker profiles for fat-corrected milk (FCM) and body weight (BW). DMI and BW were recorded within 7 d of monthly DHI milk testing on 11 Pennsylvania tie-stall dairy farms. Farms were visited once per month over a 6-mo period to measure feed intake on all cows, and blood was collected for DNA extraction. Genotypes were obtained at 86 loci that had a major allele frequency of < 95 for 796 cows. There were 35,390 test day FCM, 3,999 test-day DMI, and 2,195 test-day BW records available for analysis. Test-day records were used to derive 305 d total FCM (3,558 records), average BW (1,095 records), 305 d DMI (994 records) and 305 d DME (993 records) for analysis. Two 3 trait models (FCM, BW and either DMI or DME) were used to conduct genetic evaluations that included marker genotypes as fixed effects and a random polygenic animal effect in ASREML. Correlations for DNA marker effects were positive between DMI and FCM (0.29), DMI and BW (0.63), and DME and FCM (0.80). Correlations were negative between DMI and DME (−0.33) and DME and

BW (−0.15). Correlations of the polygenic effects were also strongly positive between DMI and FCM, DMI and BW, and DME and FCM and negative polygenic correlation was found between DME and BW. This study also showed genetic variation for feed intake and for feed efficiency. These findings indicate that it may be possible to use DNA markers to select for higher DME.

Key Words: dry matter efficiency, fat-corrected milk, DNA marker profiles

250 Evaluating the effectiveness of "cow-side" tests to identify animals with a dominant follicle at the time of insemination in a TAI protocol. T. L. Crouch* and J. L. Fain, *Clemson University*, *Clemson, SC*.

This study investigated changes in metabolic functions and their tendency to correlate with an adequate preovulatory follicular size (>15 mm) and secondary signs of estrus to better determine whether insemination should be performed in a TAI protocol. A total of 26 non-pregnant lactating Holstein and Jersey dairy cattle (n = 21; n = 5, respectively) of unknown estrous cycle status were synchronized ($PGF_{2\alpha}$, d-18; GnRH, d-16; GnRH, d-10; $PGF_{2\alpha}$, d-3, GnRH,d-1) and were inseminated 12 h after the final GnRH injection, d0. Temperature, urine pH and milk weights were collected at 12 h intervals beginning 48 h before TAI with the final collection occurring at insemination. The size of the largest follicle for each animal was determined by transrectal ultrasonography 12 h before TAI. On d 0, milk samples were collected and progesterone concentrations analyzed using a rapid milk P4 test. The results were qualitatively recorded on a scale from 1 (P4 = 0–1 ng/mL) to 3 (P4 = 5 ng/mL). Secondary signs of estrus were recorded 12 h before and at TAI with scoring based on the following observations: 1 = behavioral change, 2 = mucosal discharge, and 3 = mucosal discharge and mounting or standing activity. No strong correlations (> ±0.4) were realized between any "cow side" sampling method and the incidence of a dominant follicle or increased estrus expression. No differences ($P > 0.05$) in parameters were found regardless of the presence of a dominant follicle at TAI. When reproductively inefficient cows, as indicated by > 250 DIM and > 3 previous services, were excluded from the results (n = 7), a moderate positive correlation of 0.57 was identified with urine pH increasing in the 24 h before TAI in animals with larger follicles 12 h before TAI. Animals with an identifiable dominant follicle also had a greater increase in urine pH 24 h before TAI when compared with animals with the largest follicle being <15 mm in diameter (0.32 and 0.02, respectively; $P < 0.05$). Anomalies within the data are being overcome with additional sampling and correlation with blood serum P4 concentrations as well as pregnancy rate data.

Key Words: cow side

251 Effects of temperature on X chromosome carrying compared to Y chromosome carrying bovine sperm cells: preliminary results. L. A. Krueger*[1], J. L. Herring[1], and R. Wilborn[2], [1]*Alabama A&M University*, *Normal,* [2]*Auburn University*, *Auburn, AL*.

Climatic conditions and slight differences in a female's internal environment can influence the gender of her offspring (Cameron et al., 2008; Bonier et al., 2007). An observation by Roche, et al. (2006) revealed that air temperature raised by 1°C at the time of breeding increased the likelihood of the conception of a male calf by 1%. This observation suggests that X and Y chromosome carrying sperm cells are affected differently by raised environmental temperature. The purpose of this experiment was to compare the effects of female body temperature against X chromosome and Y chromosome carrying sperm. Eighteen gender sorted bovine semen straws of Genex Bull AN01043 were subjected to time temperature treatments. Nine straws were sorted for the X chromosome (group A), and nine sorted for the Y chromosome (group B). Experimental Groups A and B each consisted of three subgroups (1, 2, and 3) of three semen straws each, so each subgroup contained three semen straws. The straws were incubated in randomly assigned water baths after thawing simultaneously for 40 seconds at 34°C according to the procedure recommended by Genex. The control (subgroups A1 and B1), was incubated at 37.94°C representing the normal internal body temperature of a cow. Subgroups A2 and B2 were incubated at 38.89°C and subgroups A3 and B3 at 39.72°C to represent the internal body temperature of a cow under increasing heat stress (McGhee et al., 2008). One straw was drawn from each subgroup at six hours, representing bovine sperm cell capacitation, at nine hours, and at twelve hours for examination of motility using Sperm Vision (minitube, Mt. Horeb, WI). Data were to be analyzed with an unpaired t-test at $P < 0.05$.
The test results at six hours of incubation revealed 10% motility for all subgroups, with all motile sperm cells labeled nonprogressives. Due to the nature of the data, time temperature treatments were stopped for all samples. This study is being revised to examine time temperature differences on fresh bovine unsexed semen. This revision will aid in the determination of adjustments necessary for continuation and retrial of this experiment.

Key Words: temperature, sperm, bovine

252 Corn grain and liquid feed as non-fiber carbohydrate sources in diets for lactating dairy cows: digestibility trial. E. M. Eilenfeld*, M. L. Eastridge, and J. L. Firkins, *The Ohio State University*, *Columbus*.

We hypothesized that sugars in liquid feeds would maintain or improve measures of ruminal fermentation and diet digestibility to a greater degree when corn grain is processed to have a lower rumen degradable starch concentration. Five rumen cannulated cows were used in a 5 × 5 Latin square design and fed a control diet with steam-flaked corn (SFC) or 4 diets with dry corn that was finely or coarsely ground (FGC or CGC at mean particle sizes of 0.8 or 1.9 mm, respectively) factorialized without or 3.5% liquid supplement (LF; Quality Liquid Feeds, Dodgeville, WI) replacing corn grain. All diets contained a constant 24% corn silage and 16% alfalfa hay and 6% grass hay that were adjusted to maintain 36% NDF and 20.3% forage NDF. Diets were formulated to contain 36% non-fiber carbohydrates. Each period consisted of 2 wk, cows were fed and milked twice daily, and chromic oxide was dosed via the rumen as a digestibility marker. Contrasts were SFC vs. dry corn (SFC vs. the 4 ground corn diets) and the main effects and interaction of particle size and LF. The SFC decreased ($P < 0.05$) ruminal acetate and increased ($P < 0.05$) propionate concentrations. Finer particle size reduced ($P < 0.05$) ruminal pH (5.99 vs. 6.16), reduced ($P < 0.10$) ruminal concentration of acetate, and increased ($P < 0.05$) propionate concentration. Liquid feed reduced ($P < 0.10$) acetate, and there was an interaction for butyrate (LF increased with FGC but no effect with CGC). Finer particle size ($P < 0.10$) and SFC ($P < 0.05$) reduced ruminal NH3 concentration. There were no treatment effects on digestibilities of DM (65.9%), OM (67.7%), or NDF (54.9%). The DMI was similar (24.6 kg/d), but SFC increased ($P < 0.10$) milk yield (38.0 vs. 35.9 kg/d). Milk fat (3.51%) was similar, but there was an interaction for milk protein - LF reduced ($P < 0.10$) milk protein with CGC but not with FGC. Milk urea N was lower ($P < 0.05$) with finer particle size (11.8 vs. 13.0 mg/dl). The SFC and finer particle size appeared to be more rapidly fermented in the rumen, without adversely affecting intake or apparent diet digestibility. Liquid feed appeared to be more beneficial with FGC than CGC.

Key Words: particle size

Animal Behavior and Well-Being: Poultry 1: Ducks, Layers, and Turkeys

253 Who did it and why: Floor laying by Pekin ducks. M. M. Makagon* and J. A. Mench, *University of California, Davis*.

Floor eggs, which are eggs laid outside of nest boxes, are a common problem in poultry production systems. We investigated factors contributing to the laying of floor eggs by Pekin ducks. In a 2 × 2 factorial design, 16 groups of 18-wk-old ducks (8 per group) were provided access to either 2 or 8 closed-topped or open-topped nest boxes in their pens. Egg locations were recorded daily for 16 weeks following nest box introduction. Video analyses were used to determine the sources of a sample of floor eggs laid during wk 1–4, 8, 12 and 16. An analysis of nontoxic dye deposition in the egg yolk was conducted on wk 12, 14 and 16 to determine each duck's contribution to floor laying. Repeated measures ANOVA revealed that the proportion of floor eggs decreased over weeks ($F_{3,9}$ = 29.29, P < 0.0001), and was greater among the groups with only 2 nest boxes ($F_{1,11}$ = 24.09, P = 0.0005), but was not affected by nest box design ($F_{1,11}$ = 0.08, P = 0.776). Not all available nest boxes were used on a given day. In 8-box pens, for example, on average only 3 to 4 boxes were used per day. Of the 202 floor eggs identified on video, 65% were laid in the 4 h after the lights went on (0300–0700). This corresponded to the time of highest nest box use and competition. However, 32% were laid during the dark phase (2100–0300) when nest box activity and competition were low, and 1% were laid in the afternoon. The remaining 2% of floor eggs were ejected from nest boxes by the ducks. Yolk stain analysis indicated that 67% and 52% of ducks housed with 2 and 8 boxes, respectively, laid floor eggs, although none laid exclusively on the floor. Taken together these results suggest that floor laying by Pekin ducks may in part be a product of competition for nests, and can be decreased by optimizing the nest box to duck ratio. However, since 33% of floor eggs were laid during periods of low competition and not all boxes were used each day, other factors probably also contribute to the problem.

Key Words: nesting behavior, domestic duck, floor eggs

254 Nest choices of Pekin ducks. M. M. Makagon*, C. B. Tucker, and J. A. Mench, *University of California, Davis*.

To encourage nest use by breeder flocks, it is important that nest boxes are attractive to hens. Few studies have evaluated factors affecting nest attractiveness and nest choices of ducks. We assessed the effects of nest box experience and features of nests on nest site selection by sexually mature Pekin ducks. Hens were tested individually in pens containing different nest box choices. Nest preferences were determined based on the locations of 14 successively laid eggs. Experiment 1 assessed the effects of nest box experience and degree of nest enclosure. Ducks (n = 24) were reared with access to either open-top (OP) or closed-top (CL) nest boxes. They were then allowed to choose between 4 nest boxes varying in level of enclosure: OP, CL, OP with a nest curtain (OP-C), or CL with a nest curtain (CL-C). Ducks laid twice the expected proportion of eggs in the CL-C boxes (t_{22} = 4.21, P = 0.0004), demonstrating a preference for a high level of enclosure that was independent of previous nest box experience (t_{21} = 0.65, P = 0.53). CL boxes were used as predicted by chance (t_{22} = −0.33, P = 0.746), while OP and OP-C contained only half the expected number of eggs (OP t_{22} = −2.64, P = 0.015; OP-CL t_{22} = −2.86, P = 0.009). Experiment 2 assessed the effect of the presence of an egg in the nest. Ducks (n = 24) were provided with 2 nest boxes, one of which contained a single egg from the previous day. Each day, the newly laid egg was marked and either placed back in the nest box where they were found (Handled) or moved into the adjacent nest box (Moved). Handled and Moved ducks laid 97.6% and 79.8%, respectively, of their eggs in boxes containing the previous day's egg. While ducks in the Handled group were consistent in their choice throughout the test, those in the Moved group developed this preference over time (Wilcoxon S = 17.5, P = 0.039), suggesting that the preference for laying in a nest containing an egg may be influenced by experience. These results indicate that nest box enclosure and the presence of an egg are important in determining the nesting choices of Pekin ducks. Incorporating these features into nest boxes may be useful for increasing consistency of nest use by breeder flocks.

Key Words: Pekin duck, nest site selection, nest design

255 The effect of human induced stressors on the vocalizations of commercial brown and white egg laying hens. E. Otu-Nyarko*[1], J. An[3], P. M. Scheifele[2], D. B. Miller[1], M. T. Johnson[3], and M. J. Darre[1], [1]*University of Connecticut*, *Storrs,* [2]*University of Cincinnati*, *Cincinnati, OH,* [3]*Marquette University*, *Milwaukee, WI*.

A study was conducted at a commercial cage layer poultry farm in Connecticut to determine the effect of human induced stressors on the vocalizations of brown and white egg layers of various ages. Vocalizations and behavioral data were collected from 13 groups of 320 hens per group. A uni-directional Shure 10L Prologue microphone with a frequency sensitivity of between 20Hz and 15,000Hz was connected to a Compaq laptop computer with Cool Edit Pro 2.0 sound analysis software to record and edit vocalizations. A Hidden Markov Model modified for use as a speech recognition algorithm and statistical tool was used to classify the vocalizations. The accuracy of the classification was determined using a confusion matrix. Three different human induced stressors were applied to them. These were abrupt noise, touch, and walking through the coop in front of the birds. Non-stressed vocalizations were also obtained for comparison with the treatments. Of the entire vocalization spectral envelope, the Greenwood Function Cepstral Coefficients were extracted for the determination of the level of accuracy with the classification of vocalization using the modified Hidden Markov Model and a confusion matrix. It was found that the non-stressful vocalizations were significantly different ($P \leq 0.05$) from the stress induced vocalizations for both breeds with classification accuracy of 77% and 75% for white and brown egg layers respectively. For the stress induced vocalizations there were significant differences in vocalizations made as a response to abrupt noise, touching, and walking through the coop at an accuracy level of 81.2%, 74.29% and 36.3% respectively with abrupt noise being the most stressful to the chickens, resulting in the most recognizable and repeatable vocal response. Both breeds at peak production (28–29weeks) had similar vocalizations under all the conditions as indicated by a lower accuracy of about 64% in comparison with all other age groups for both stress-induced and non-stressed vocalizations. The brown egg strain was less susceptible (89%) to the effect of the stressors than the white leghorn laying hens (92%).

Key Words: vocalization, stress, hidden Markov model

256 Influence of environmental management methods on the expression of glucocorticoid receptors in the laying hen's ovary. D. V. Arbona*, L. A. Bola, and J. B. Hoffman, *North Carolina State University*, *Raleigh*.

In commercial egg production, increasing public scrutiny regarding the welfare of laying hens has led to the development of alternative manage-

ment practices including free-range housing in addition to conventional battery style cages. To ascertain the effects of layer housing management methods on ovarian susceptibility to corticosterones via expression of follicular glucocorticoid receptors (GR), ovarian follicles were collected from 6 Hy-line brown layers reared in a free-range system with access to a forage covered area divided into 4 paddocks as well as an enclosed range hut with feed, water, and nests. For comparison, ovarian follicles were collected from 6 Hy-line brown layers reared in conventional battery style cages stacked directly on top of one another with troughs for feed and nipple waterers. Separated granulosa and theca tissues from the F1-F4 hierarchical, and combined granulosa and theca tissues from the small yellow and large white non-hierarchical follicles were collected by manual dissection for GR characterization. Characterization of the GR in the ovarian tissues was performed following Total RNA extraction followed by 2-step real-time PCR. Relative quantification of the GR was completed using the $\Delta\Delta C_T$ method and data was expressed as the fold-difference relative to the F1T sample. Differences in the expression were determined by ANOVA using the GLM procedure ($P < 0.05$). No significant differences in non-hierarchical follicular GR expression were noted between free-range (0.69 ± 0.11) vs. battery style hens (0.75 ± 0.16) ($P < 0.05$). However, total GR expression in the hierarchical follicles was significantly higher in the free-range hens (1.35 ± 0.05) compared with the battery style hens (0.69 ± 0.04) ($P < 0.001$). These observations combined with previous data showing significantly decreased production of grade A eggs by free-range hens suggest that the free-range environment may negatively influence reproductive fitness due to differences in follicular stress susceptibility caused by altered glucocorticoid receptor expression.

Key Words: glucocorticoid receptor, free-range, battery cages

257 The influence of cage housing system and laying hen strain on bone quality pre and post slaughter. A. McMillan[1], K. Juurlink[1], B. Rathgeber[2], and M. Jendral*[1], [1]*Nova Scotia Agricultural College*, *Truro, Nova Scotia, Canada*, [2]*Agriculture Agri-food Canada*, *Truro, Nova Scotia, Canada*.

The influence of cage housing system and laying hen strain on bone quality traits pre and post slaughter was determined for 3 strains of laying hens (Shaver White (SW), Lohmann Lite (LL), Lohmann Brown (LB)) housed in conventional cages, and furnished colony units, and processed under commercial conditions. During the laying period, hens were either housed in conventional cages (60cm × 45cm) (n = 24 cages per strain; 5 hens per cage) or furnished colony cages (240cm × 110cm) (n = 12; 4 per strain; 40 hens per cage). Furnished cages contained a nestbox (60cm × 55cm), 3 hardwood, semi-circular perches (240cm × 5cm) and a dustbathing facility (60cm × 20cm). At 80 weeks, all hens were palpated before slaughter to assess fractures to the furculum, keel, humerus, radius, ulna, femur, tibia and pubis bones. Post slaughter (no evisceration), 25 randomly selected hens per colony cage, and all 5 hens in 9 randomly selected conventional cages per strain were re-palpated for fractures of the above bones. Additionally, right femur, tibia and humerus bones were isolated from 6 randomly selected hens per colony cage and all 5 hens in 9 conventional cages per strain and frozen for later analysis of bone densitometry and breaking strength. Conventionally caged hens exhibited higher incidence of pre slaughter humerus and radius fractures ($P < 0.05$). Furculum breaks occurred most frequently post slaughter; however, no treatment or strain differences were determined for the furculum. LL and LB hens exhibited fewer wing and leg breaks pre and post slaughter ($P = 0.05$), however LL hens exhibited the highest incidence of keel fractures before slaughter. These results indicate that bone fractures throughout the laying period and at processing are more common in conventionally housed laying hens, and that strain differences are apparent.

Key Words: laying hen, bone quality, furnished cages

258 Astroturf as a dustbathing substrate for laying hens. G. Alvino*, G. Archer, and J. Mench, *University of California*, *Davis*.

During dustbathing bouts, birds distribute a friable substrate like sand through their feathers. This behavior helps to maintain good plumage condition and hence the insulative value of the feathers. Many designs of furnished cages for laying hens contain a dustbathing area comprised of an Astroturf (AT) pad, which may be sprinkled with feed with the intent of promoting both foraging and dustbathing. We evaluated the behavior of hens exposed to AT or AT plus feed to determine if these substrates stimulate dustbathing. Hy-Line CV20 laying hens (n = 30) that had no prior exposure to friable substrate were housed singly in 91.4cm x 45.7cm x 45.7cm cages beginning at 34 weeks of age. Groups of 10 hens were randomly provided with either sand (control); a 33 × 36.5cm AT pad; or an AT pad of the same size covered each day with 200 g of laying hen feed (ATF). After the hens had been exposed to these substrates for 17 d, behavior was video recorded from 0600 - 2200 h (photophase duration). Data were analyzed using Kruskal-Wallis and Dwass-Steel- Critchlow- Fligner non-parametric tests. There were significant differences in the total number of dustbathing bouts ($H_2 = 8.21$, $P = 0.017$), with control hens performing fewer bouts (mean = 3) than AT (13); ATF were intermediate (6). The proportion of bouts performed on substrate ($H_2 = 13.94$; $P = 0.001$) and the wire floor of the cage ($H_2 = 12.68$; $P = 0.0018$) differed, with the control hens that dustbathed performing a higher proportion in substrate (1.0) and a lower proportion on wire (0) than both AT (0.13; 0.87) and ATF hens that dustbathed (0; 1.0). There were also differences in total time dustbathing on wire ($H_2 = 12.32$, $P = 0.002$) and substrate ($H_2 = 9.32$, $P = 0.010$), with control hens dustbathing for significantly less time on wire (mean = 0 min) than both AT (26) and ATF (28) hens and significantly more time on substrate (19) than ATF hens (0). These findings need to be confirmed with additional observations, but suggest that an AT pad does not provide an adequate substrate even with feed added, since hens with AT dustbathe mainly on the wire floor of the cage rather than on the AT.

Key Words: Astroturf, sham dustbathing, chicken

259 The behaviour of laying hens in commercial aviary systems. M. P. de Villareal*[1] and I. Estevez[1,2], [1]*Neiker-Tecnalia*, *Vitoria-Gasteiz, Spain*, [2]*IKERBASQUE*, *Bilbao, Spain*.

Here we present preliminary results of a larger ongoing study in which we compare the behavior of laying hens maintained under different production conditions. For this part of the study, data were collected by video footage in 7 single tier aviary commercial farms with and without access to an outdoor park. Flock sizes ranged between 6,000 to18,000 birds. The lines used were Bovan brown, ISA brown, and Lohman white. Video recordings took place from 7.00 to 9.00, 11.00 to 13.00 and 17.00 to 19.00 for morning, midday and afternoon periods. Video sequences were imported into the software The Observer for visualization and analysis. From the recordings, behavioral time budgets and frequency of transitions, defined as the number of behavioral changes per unit of time, were obtained by continuous focal sampling of 3 randomly chosen hens in each video sequence. Data were standardized according to sequence duration. Means per farm, week and time period were calculated and used for statistical analysis, a mixed model repeated measures ANOVA (SAS, V 9.1). Results indicate differences in time budgets across layer line and housing system ($P < 0.01$), but

no effect of time period was detected ($P > 0.05$). Interactions across factors were non significant ($P > 0.05$). Lohman whites had the highest proportion walking and foraging whereas standing was most prominent in Bovan and ISA brown. Problematic behaviors such as aggressive pecks, threats and feather pecking were unusual events for all lines. The differences according to systems were important with higher frequencies of standing and foraging observed in aviaries without access to parks, and higher proportions of resting and less standing and foraging observed in free range. Behavioral transitions varied according to hen type and housing system only ($P < 0.05$). In conclusion, across strains the Lohman white hens were the most active, however no differences were detected related to problematic behaviors such as aggressive or pecking behaviors. Contrary to expectations, birds with access to an outdoor park were less active when indoors as compared with birds in aviaries without access to parks.

Key Words: laying hens, behavior, aviary systems

260 On-farm survey of beak characteristics in White Leghorns as a result of hot blade or infrared beak trimming. T. Gabrush[1], C. Carruthers*[1], K. Schwean-Lardner[1], T. Knezacek[1], C. Bennett[2], and H. L. Classen[1], [1]*University of Saskatchewan*, *Saskatoon, SK Canada*, [2]*Manitoba Agriculture, Food & Rural Initiatives*, *Winnipeg, MB Canada*.

Treating the beaks of White Leghorns is a common practice used primarily to reduce cannibalism. However, opposition to this procedure is based partially on the assumption that trimming may cause deformities, inhibiting the ability of hens to eat and perform normal behaviors. Infrared (INF) systems are currently becoming more prevalent in industry, replacing hot blade (HB) beak trimming. This on-farm survey examined the effects of HB or INF treatment on beak characteristics in commercial flocks. Hens on 3 farms were observed between 21 and 24 and between 53 and 60 weeks of age. Two farms housed hens of the same strain that had been HB trimmed at the hatchery while a third housed 2 strains that had been INF treated at the hatchery. Overall, 91% of the beaks measured were 10.0 to 13.9 mm in length, approximately 52 to 73% of the expected length of an intact beak. The remaining hens had beaks less than 10 mm (4%) or ≥14 mm (5%). HB trimmed beaks averaged 12.36 mm (SEM = 0.060) and 12.40 mm (SEM = 0.063) at 21–24 weeks of age, and 12.39 mm (SEM = 0.064) and 12.80 mm (SEM = 0.071) at 53–60 weeks of age. INF trimmed beaks averaged 11.33 mm (SEM = 0.058) and 11.14 mm (SEM = 0.043) at 21–24 weeks of age, and 12.03 mm (SEM = 0.053) and 11.35 mm (SEM = 0.059) at 53–60 weeks of age. Deformities were observed at low frequencies, and included abnormal re-growth (7.42%), blisters (0.54%), cracks (3.50%), angled beaks (not perpendicular; 2.88%) and cases where the bottom beak was longer than the top (BLTT) (11.63%). Although a direct comparison between HB and INF trimming was not possible because the hens were of different strains and were housed in different environments, cracks and abnormal re-growth were observed more frequently in HB (6.58% and 11.42%, respectively) compared with INF trimmed hens (0.42% and 3.42%, respectively). HB and INF treatment resulted in similar beak lengths and characteristics, however comparisons of treatment type within strain and environment is warranted.

Key Words: cannibalism, feather pecking, welfare

261 Effects of different infrared beak treatment protocols on chicken welfare and physiology. R. L. Dennis* and H. W. Cheng, *LBRU, USDA-ARS*, *West Lafayette, IN*

Infrared beak treatment (IR) provides an alternative to conventional hot blade beak trimming (HB), which purports to be more welfare friendly. To improve the efficiency of the IR system, different interface plates (25/23C and 27/23C) and lamp power settings (44, 48 and 52) were tested in this study. Infrared beak treatment was conducted at the hatchery and HB was performed at 7 to 10 d of age in a commercial setting. Physiological and behavioral measures were taken at 5, 10, 20 and 30 weeks of age after beak trimming (BT). Although all birds followed a similar growth curve, IR birds using 27/23C-48 protocol were the heaviest at 10, 20 and 30 weeks of age. Alternately, birds using the 25/23C-44 protocol were the lightest at 20 and 30 weeks of age. Upper and lower beak growth curves were also established showing birds trimmed with 25/23C interface plates to have a shorter upper and lower beak compared with 27/23C or HB trimmed birds. Birds trimmed using 27/23–44 and −48 consistently had the longest upper and lower mandibles among all birds. Feed wasted was greatest in HB and 27/23C-52 birds and tended to be less than HB in 27/23–48 and 25/23–48 and −52 trimmed birds ($P < 0.10$). Behavior analysis revealed that birds treated using 27/23C protocols walked and drank more than HB birds ($P < 0.05$). Feather scores (FS; scored 0–5; 0 = perfect plumage and 5 = bare with skin damage) taken at 20 and 30 weeks showed higher breast FS in HB and 25/23C-44 birds compared with 27/23C birds ($P < 0.05$). Back FS was the highest in 25/23C-48 birds compared with the birds trimmed using HB or other IR protocols ($P < 0.05$). At 5 and 10 weeks of age, 27/23C-44 and −48 birds pecked significantly more at the novel object (a synthetic feather) than the birds trimmed using HB or other IR protocols ($P < 0.05$). However, HB and 25/23C birds had the highest synthetic feather damage score (scored 0–5; 0 = no damage and 5 = completely stripped shaft; $P < 0.05$). Our data show evidence that welfare and traits affecting feed efficiency can be improved with IR over HB in laying hens and that the IR protocol used can be adjusted to optimize these measures.

Key Words: beak trim, infrared, laying hen

262 Brain and skull lesions in turkeys resulting from non-penetrating captive bolt, cervical dislocation, cervical crushing and blunt trauma. M. A. Erasmus*, P. V. Turner, S. G. Nykamp, and T. M. Widowski, *University of Guelph*, *Guelph, Ontario, Canada*.

Previously, live observations of brainstem reflexes and time to death were conducted on different weight classes of turkeys to assess the effectiveness of on-farm killing methods. Three experiments were conducted: 1) a non-penetrating captive bolt (Zephyr) and cervical crushing were examined in turkey hens (11.4 ± 0.1 kg) at a research facility; 2) the Zephyr and blunt trauma were examined in turkey toms (13.1 ± 0.2 kg) at 2 commercial farms; 3) the Zephyr, blunt trauma and cervical dislocation were examined in broiler turkeys (4.1 ± 0.3 kg) at a commercial farm. Immediate insensibility resulted when the Zephyr or blunt trauma were used, but not with cervical crushing or cervical dislocation. Based on these results, the objectives of the present study were to assess brain damage resulting from the different killing methods. The severity of skull fractures and subcutaneous and subdural hemorrhage was assessed using post mortem macroscopic scores. Samples in each weight category were submitted for CT scans and histology. Macroscopic scores were compared among treatment groups using a mixed model (Expt. One and 2) and general linear model (Expt. 3); subcutaneous hemorrhage was greater with the Zephyr (Hens: $F = 27.8$, $P = 0.01$; Toms: $F = 5.4$, $P = 0.02$; Broilers: $F = 11.6$, $P = 0.0003$) and skull fractures were more severe for toms and broilers killed with the Zephyr vs. blunt trauma (Toms: $F = 65.0$, $P < 0.0001$; Broilers: $F = 5.4$, $P = 0.03$). Subdural hemorrhage was present in all turkeys regardless of treatment. Microscopic brain damage was present in all turkeys killed with the Zephyr and blunt trauma, but only 1 of 4 turkeys killed with

cervical crushing and 1 of 4 turkeys killed with cervical dislocation. The Zephyr and blunt trauma likely caused death by directly disrupting brain function, whereas cervical crushing and cervical dislocation likely resulted in death from cerebral hypoxia and ischemia. Based on tests of sensibility and post mortem investigations into the degree of brain damage produced, the Zephyr and blunt trauma appear to be effective and humane for on-farm killing of turkeys.

Key Words: turkey, brain damage, humane killing

263 An experiment in transmission of *Mycoplasma bovis* in sand bedding to naive dairy calves. D. J. Wilson*[1], A. Justice-Allen[1], T. J. Baldwin[1], R. T. Skirpstunas[1], K. B. Cavender[1], and G. Goodell[2], [1]*Utah State University*, *Logan*, [2]*The Dairy Authority*, *Greeley, CO*.

The study evaluated possible transmission of *Mycoplasma bovis* from sand bedding to naive dairy calves. Screening of a closed herd showed 99% probability that the herd was free of mycoplasma in calves. Neonatal calves (n = 12) from the herd were blocked by weight and height and randomly assigned as controls (n = 6) bedded with quarry sand, or exposed (n = 6) bedded with *M. bovis*-positive bedding sand (confirmed by PCR) from another farm. Calves were housed at Utah State University in calf hutches, fed commercial milk replacer and calf starter, with strict biosecurity and separation between groups. Exposed group sand cultured positive for *Mycoplasma* spp. during weeks 1, 5, 6, 7, 11 and negative for the rest of the 15 week study; control group sand was always mycoplasma-negative. Exposed group calves were bedded on mycoplasmal bedding for 138 total calf-days. All 94 sera tested for antibody against *M. bovis* were negative. All 16 tracheal swabs and all 67 nasal and ear swabs collected from all calves were mycoplasma culture-negative. Two calves died and 3 were euthanized before the end of the study; the remaining 7 calves were euthanized after 15 weeks. All calves were necropsied and full diagnostic testing was performed. No exposed or control calves had any gross lesions of mycoplasma infection. All post-mortem culture (n = 60) and PCR (n= 48) tests on trachea (cultured only), deep lung, peri-bronchial lung, retropharyngeal lymph node, and carpal or tarsal joint fluid from all 12 calves were negative for *Mycoplasma* spp. The PCR could differentiate *M. bovis* if positive. Using test sensitivity and sequential probability, the probability of each calf being detected positive at least once if they had become infected with mycoplasma following 4 weeks of exposure was calculated. For the 9 calves that survived beyond 25 days of age, probabilities of detection were between 96.5% and 99.3%. There was no evidence that *Mycoplasma bovis*-positive bedding sand was a source of infection to naive dairy calves. Further studies in lactating cows are still indicated because of the possibility of infection through teat ends.

Key Words: mastitis, *Mycoplasma*, bedding

264 Effect of supplementing fatty acids to prepartum Holstein cows on transfer of passive immunity to calves. M. Garcia*, L. F. Greco, M. G. Favoreto, R. S. Marsola, L. T. Martins, D. Wang, W. W. Thatcher, J. E. P. Santos, and C. R. Staples, *University of Florida*, *Gainesville*.

The aim of this study was to evaluate supplementing linoleic acid (LA) to cows during the last 2 mo of pregnancy on transfer of passive immunity to calves. Cows (n = 89) were fed diets formulated to supply minimum amounts of LA and supplemented without fat, with saturated fatty acids (SFA; Energy Booster 100, MSC) at 1.75% of dietary DM, or with Ca salts of unsaturated fatty acids enriched in LA (UFA; Megalac-R, Church and Dwight, Co.) at 2% of dietary DM. Within 2 h of birth, calves were given 4 L of colostrum from their own dam or from a dam fed the same dietary treatment as the calf's dam using an esophageal feeder. Acquisition of passive immunity was assessed by measuring concentration of IgG in colostrum and in serum, as well as total protein concentrations in serum at 0 and 24 h of life. Apparent efficiency of absorption was calculated considering serum as 9.9% of BW. Body weight at birth did not differ among treatments (39.6 kg), however calves born from multiparous cows were heavier ($P < 0.05$) than those born from primiparous cows (42.6 vs. 36.5 kg). Concentration of colostral IgG was greater from multiparous cows fed fat than from those not fed fat prepartum (116 vs. 96 g/L) whereas the opposite was true for primiparous cows (83 vs. 101 g/L). As a result intake of IgG by calves born from multiparous cows fed fat prepartum was greater than that by calves born to cows not fed fat (459 vs. 383 g). Therefore serum concentrations of IgG tended to be greater ($P = 0.10$) at 24 h in calves born from multiparous cows fed fat compared with those not fed fat (26.7 vs. 21.1 g/L). Concentrations of serum protein did not differ among treatments (3.8 and 5.3 g/100 mL at 0 and 24 h, respectively). Calves born from cows fed fat prepartum tended to be more efficient at absorption of IgG (26.8 vs. 23.3%). Feeding supplemental fat prepartum to multiparous cows resulted in greater IgG concentration in colostrum and better efficiency of IgG absorption.

Key Words: calves, passive immunity, linoleic acid

265 Effect of a yeast autolysate combined with probiotics on performance and gut health of broilers. A. Ganner*[1], S. Masching[2], N. Reisinger[1], G. Schatzmayr[1], and T. Applegate[3], [1]*BIOMIN Research Center*, *Tulln, Austria*, [2]*BIOMIN Holding GmbH*, *Herzogenburg, Austria*, [3]*Purdue University*, *West Lafayette, IN*.

The present study was conducted to evaluate the efficacy of a product, consisting of yeast autolysate, lactobacilli, *Enterococcus* sp., *Pediococcus* sp. and bidifobacteria, on performance and jejunal structure of broilers. In a 35 d study, 300 1-d-old broilers were distributed to 2 experimental groups with 8 replicates: control group A, group B (1 kg yeast autolysate per ton feed combined with probiotic mixture of 10^8 CFU/kg feed). Directly after housing the chicks were supplied with the experimental diets. Feed and water were provided for *ad libitum* intake, feeding was done manually several times a day. On d 35 birds were killed and the distal jejunum taken from 8 chickens per group (1/pen). Paraffin sections were stained with periodic acid Schiff (PAS) and hematoxylin. The length of the villi and the depth of the crypt were determined with an ocular micrometer via light microscopy. The goblets cells were counted on 6 villi/ bird as well under the microscope and an average was taken. Similarly, 12 villi/ bird were measured for villus length and crypt depth. In the course of the feeding trial a positive influence could be observed by the product consisting of autolysate and probiotics. Weight on d 14 and daily weight gain (DWG) 1–14 were improved ($P = 0.0001$), as well DWG 15–35 ($P = 0.002$). Weight on d 35 (1433g) and DWG 1–35 (39.9g) were slightly improved in comparison to the control (1381g weight d 35, 38.4g DWG; $P = 0.08$). Mortality was reduced in the trial group (2.7%) in comparison to the control (5.3%). The goblet cell number was slightly increased by the trial group with 126 cells/villus (control 98cells/villus, $P = 0.1$). Villus height and crypt depth were not affected. Our results indicate that the product consisting of autolysate and probiotics is able to improve gut health and to enhance bird performance.

Key Words: yeast autolysate, probiotics, gut health, broiler performance

266 Effect of NuPro supplementation on intestinal *Clostridium perfringens* levels in broiler chickens. . R. Thanissery*[1], J. L. McReynolds[2], D. E. Conner[1], K. S. Macklin[1], P. A. Curtis[1], and Y. O. Fasina[1], [1]*Auburn University*, *Auburn, AL*, [2]*SPARC-USDA-ARS*, *College Station, TX*.

Clostridium perfringens (CP) is the causative bacteria for necrotic enteritis (NE) in poultry. Yeast extract contain immunomodulatory nucleotides, and may therefore serve as a non-antibiotic feed additive for reducing intestinal CP in broilers. In a 42-d floor pen trial, the efficacy of NuPro (a yeast extract) in reducing intestinal CP levels in broiler chickens was evaluated. Chicks (n = 600) obtained from a commercial hatchery were randomly assigned to 6 treatments. Treatment 1 (CX) consisted of chicks fed corn-soybean meal (SBM) diet without bacitracin methylene disalicylate (BMD) or NuPro added. Treatment 2 (MX) consisted of chicks fed corn-SBM basal into which BMD was added at 0.055g/kg. Treatment 3 (LN) consisted of chicks fed corn-SBM basal into which NuPro was added at 2% level throughout experiment. Treatments 4 (PCX), 5 (PMX), and 6 (PLN) consisted of chicks fed diets similar to those given to CX, MX, and LN treatments, respectively, and were additionally challenged with 3.5 mL of CP inoculum (10^8 CFU/mL) on d 14, 15, and 16 of experiment. Post-challenge (PC) assessment of intestinal CP levels was done on d 1, 7, and 21 PC. Growth performance (body weight (BW) and body weight gain (BWG)) was also assessed at 3 and 6 weeks. Results showed that by d 21 PC, the NuPro-containing diet significantly reduced intestinal CP levels ($P < 0.05$) in PLN treatment by 1.50 $\log_{10}$ CFU/g compared with NuPro-free PCX treatment. Also, the efficacy of BMD antibiotic and NuPro in reducing intestinal CP in PMX and PLN, respectively, was similar throughout the experiment. BW and BWG were similar ($P > 0.05$) among CP-challenged chicks (PCX, PMX, and PLN treatments), indicating that the NuPro-induced reduction of CP in PLN treatment occurred without any adverse effect on bird performance. In conclusion, dietary supplementation of NuPro at 2% level of diet effectively reduced intestinal CP during broiler production cycle.

Key Words: *Clostridium perfringens*, NuPro, broiler chickens

267 A modified in vitro larvae migration inhibition assay using rumen fluid to evaluate *H. contortus* viability. T. R. Whitney*[1], D. R. Klein[2], A. E. Lee[1], C. B. Scott[2], and T. M. Craig[3], [1]*Texas AgriLife Research*, *San Angelo*, [2]*Angelo State Univ.*, *San Angelo, TX*, [3]*Texas A&M Univ.*, *College Station*.

The objectives of this study were to evaluate how forage material added to an in vitro system affects rumen fluid parameters, which may unintentionally affect larvae viability (LV), and define effective concentrations of common additives, i.e., polyethylene glycol (PEG), quebracho tannins (QT), and ivermectin used in this modified in vitro larvae migration inhibition (LMI) assay. Rumen fluid was collected and pooled from goats (n = 3), mixed with buffer solution and a treatment (1 jar per treatment), and placed into an anaerobic incubator for 20 h. Ensheathed *H. contortus* larvae (<3 mo old) were then anaerobically incubated with treatment rumen and buffer fluid (repeated in 2 to 3 runs; 3 cups/treatment) for either 2, 4, or 16 h depending on the Trial; pH, ammonia N, and VFA were evaluated just before and after larvae were incubated. Larvae were then transferred into a well (n = 4 to 6 wells per treatment cup) containing treatment rumen fluid, within a Multi-Screen 96-well plate and incubated over night; larvae that passed through the 20-µm screen were considered viable. Data were analyzed using the MIXED procedure with run as the repeated measure and cup (rumen parameters) or well (LV) as the subject. Adding dry or fresh juniper material (representative of 40% of diet DM intake) reduced ($P < 0.05$) pH, ammonia N, and isobutyric, butyric, and isovaleric acids, and increased ($P < 0.001$) acetic, propionic, and total VFA. The PEG concentrations of 0, 0.4, 0.8, 1.4, and 2% w/v quadratically reduced ($P = 0.07$) LV. The QT concentrations of 0, 0.15. 0.6, and 1.2% w/v quadratically reduced ($P < 0.001$) LV; 89.4, 65.5, 22.8, and 9.2%, respectively. Ivermectin concentrations of 0, 0.05, 0.10, 0.50, 1, 1.5, 2, 3, 6 and 15 µg/mL quadratically reduced ($P < 0.001$) LV; 90.2, 82.6, 73.6, 66.3, 51.9, 56.5, 43.5, 41.9, 29.3, and 19.9%, respectively. Effects of altering in vitro rumen parameters and the use of PEG on LV needs to be further investigated. Concentrations of QT and ivermectin sufficiently decreased LV; thus, can be used in trials evaluating effects of in vitro rumen treatments on *H. contortus* viability.

Key Words: juniper, secondary compounds, internal parasites

268 Effect of feeding nitarsone medicated ration on the acquisition and development of nematode parasites in the chicken. F. D. Clark*[1], C. A. Tucker[1], J. Reynolds[1], T. A. Yazwinski[1], S. Clark[2], V. Smith[2], and K. Dobson[2], [1]*University of Arkansas*, *Fayetteville,* [2]*Alpharma, Inc*, *Bridgewater, NJ*.

This study was conducted to investigate the anthelmintic efficacies of nitarsone when fed at recommended dietary levels (Histostat at 0.01875%) to artificially infected chickens. Birds were obtained at 1 d of age (experiment d 1), and kept parasite free until artificially infected. Four experimental groups of chickens were established, 2 pens of 24 birds per pen in each group: TRT 1, non-medicated and uninfected; TRT 2, non-medicated and artificially infected on d 14, 21 and 28; TRT 3, medicated from d 42 to d 56 and artificially infected on d 14, 21 and 28; and TRT 4, medicated from d 7 to 56 and artificially infected on d 14, 21 and 28. For each day of scheduled artificial infection, each bird in a pen designated for infection was gavaged with a 1 mL suspension containing 500 *Ascaridia galli*, 500 *Heterakis gallinarum* and 1000 *Capillaria obsignata* eggs that contained infective larvae. Every 7 d from d 35 to 63, 5 fresh droppings were obtained from each pen, combined by pen and homogenized, and processed 3 times by homogenate for egg per gram counts (EPG). Additionally, randomly obtained birds from each pen were necropsied for nematode recoveries and counts on d 42 (3/pen; 6/exp grp) and 63 (12/pen; 24/exp grp). No ascarid eggs were found in any droppings during the study. *Capillaria* eggs were found in droppings from birds of treatment groups 2, 3 and 4 from d 35 to 63, with no quantitative effect of treatment on the EPG counts. *Heterakis* eggs initially appeared in droppings from birds of treatment groups 3 and 4 on d 42, but by d 63, a negative treatment effect was demonstrated for the respective EPG counts ($P < 0.05$). Worm counts performed on birds posted on d 42 and d 63 indicated a lack of treatment effect on total (larval plus adult) worm burdens as *Capillaria*, *Heterakis* or *Ascaridia*. However, for d 63 observations, negative treatment effects were noted for adult *Ascaridia galli* numbers, adult female sizes and the number of fully developed eggs per adult female ($P<0.05$).

Key Words: nitarsone, chickens, nematode parasitisms

269 Effect of a *Lactobacillus* probiotic and nitrate in feed on *Salmonella* colonization in broiler chicks. A. D. Wolfenden*, N. R. Pumford, M. J. Morgan, S. L. Layton, C. Kremer, G. Tellez, and B. M. Hargis, *University of Arkansas*, *Fayetteville*.

In our previous studies, we have found a consistent reduction of *Salmonella enteritidis* (SE) using a lactic acid probiotic culture (B11) in neonatal chicks. In vitro studies suggest that nitrate (NO_3) may potentiate this effect. An in vitro crop assay model was used to evaluate the effect of NO_3 in combination with B11 against SE. B11 with NO_3 at1000ppm reduced SE by 6.54 $\log_{10}$ as compared with non-treated control during a 24h incubation at 40C. Two in vivo studies were then initiated to determine if addition of NO_3 in the feed could further reduce SE colonization in the crop and cecal tonsils of broiler chicks. Briefly, 180 d-of–hatch chicks were randomly assigned to 6 groups: control, B11,

or B11with NO_3 at 1, 10, 100 or 1000 ppm. All groups were challenged by oral gavage with approximately 10^4 cfu of SE (n = 30/group). One hour later, all groups except control were treated by oral gavage with approximately 10^7 cfu of B11. Twenty-four hours and 72 h after treatment, chicks were humanely killed (n = 15/group), and crop and cecal tonsils were cultured for SE. In exp. 1, at 72h there was a significant ($P < 0.05$) decrease in the percent of SE positive crops from the B11+ $NO_3$100ppm (57%) and B11+ $NO_3$10ppm (67%) as compared with the control (93%). A significant reduction in the percent positive cecal tonsils in all groups was observed at 24h, however at 72h, only the B11 (47%) and B11+ $NO_3$100ppm (14%) were different from the control (93%). Exp. 2 was similar to exp. 1 with the following exceptions: chicks assigned to 3 groups (n = 40/group): control, B11, B11+NO_3 100ppm. In exp. 2, significant reductions of SE positive crops in both treated groups compared with control were noted: control: 24h 100%, 72h 100%; B11 24h 10%, 72h 65%; B11+ $NO_3$100ppm 24h 60%, 72h 10%. Similar results were noted in the cecal tonsil: control 24h 95%,72h 95%; B11 24h 10%, 72h 35%; B11+ $NO_3$100ppm 24h 15%, 72h 25%. These experiments indicate that the addition of NO_3 potentiated the effects of the lactic-acid bacteria probiotic in vitro and in vivo. It is postulated that this effect is through increased production of nitric oxide by the beneficial bacteria.

Key Words: *Salmonella*, nitrate, probiotic

270 Effect of food additives on intestinal microflora in caeca of broilers challenged with *Eimeria* species analyzed using 16S rDNA pyrosequencing. A. Nalian*[1], M. Manoharan[1], J. Bray[1], S. Dowd[2], and A. Martynova-Van Kley[1], [1]*Stephen F. Austin State University*, *Nacogdoches, TX,* [2]*Research and Testing Laboratory*, *Lubbock, TX*

The effect of food additives (coccidiostat and natustat) on composition of cecal microflora of *Eimeria* challenged broilers was studied using 454 pyrosequencing of 16S rDNA. We collected a total of 36 cecal samples from pre- and post-challenged birds from 4 treatment groups: natustat, coccidiostat, combination of both and control (no treatment). More than 170,000 sequences were obtained from pyrosequencing (~5000 sequences of an average 450 bp length per sample). The taxonomical lineage of the sequences was determined using RDP classifier and BLAST programs. Absolute majority of the sequences belonged to kingdom *Bacteria* and only 4 sequences belonged to kingdom *Archaea*. More than 94% of all the sequences belonged to phylum *Firmicutes* and 5% belonged to phylum *Proteobacteria*. Redundancy analysis of the relative percent abundance data from pre-challenged birds with Monte Carlo permutation test showed that there was no significant difference in microflora composition between different treatments. Whereas in post-challenged birds, we observed significant differences in microflora composition between treatment groups ($P = 0.01$) and also challenged and control groups ($P = 0.03$). In pre-challenged birds, the dominant taxa were *Lachnospiraceae* and *Faecalibacterium*. Generalized additive model showed that coccidiostat ($P = 0.001$) and combination of coccidiostat with natustat ($P = 0.002$) significantly lowered the number of bacterial taxa in ceca of chickens. In addition, in post-challenged birds, irrespective of treatment groups, the coccidia challenge lowered the relative percent abundance of *Faecalibacterium* taxa ($P = 0.001$). Our results show that pyrosequencing could be used to monitor the changes in microflora due to different treatments. We expect that pyrosequencing will be widely used in poultry for studying microbial communities and their interactions with the host and the environment.

Key Words: *Eimeria*, natustat, pyrosequencing

271 Genetic line and dietary immunomodulator effects on expression of CXCLi2 in chicken heterophils responding to *Salmonella enteritidis*. S. B. Redmond*, P. Chuammitri, D. Palic, C. B. Andreasen, and S. J. Lamont, *Iowa State University*, *Ames*.

The performance of leukocytes in the response to pathogens is influenced by genetic background and diet. Dietary immune modulation can alter the mechanisms by which leukocytes, such as chicken heterophils, respond to bacteria. This experiment evaluated the effects of genetic line and dietary immune modulation over time on chicken heterophil expression of interleukin-8 (CXCLi2), an important chemotactic chemokine which recruits leukocytes to the site of an infection. Chickens (n = 64) from highly inbred Leghorn and Fayoumi lines received basal or immune modulating diets enhanced with 0.1% β-glucans, 0.1% ascorbic acid, or 0.01% corticosterone from 8 to 11 weeks of age. Heterophils were isolated from blood samples pooled within line and diet (n = 4 birds/pool) on d 1, 3, 7, and 21 after the start of diet treatments, and then exposed to *Salmonella enteritidis* (SE) bacteria in vitro for 3 h. Heterophil isolates were assayed for CXCLi2 expression mRNA by quantitative RT-PCR. Cycle threshold values were analyzed by ANOVA for the fixed effects of genetic line, diet, and day post treatment, with hatch and plate as random effects. Collection day post treatment was not significant. Leghorn line heterophils expressed significantly higher levels of CXCLi2 than those from the Fayoumi line ($P < 0.01$), suggesting that the Leghorn response to SE relies more heavily on chemotactic signaling. Heterophils from birds fed the corticosterone diet expressed less CXCLi2 than those of birds fed the basal diet ($P < 0.05$), reflecting corticosterone's ability to inhibit immune response. This result suggests that stress-induced corticosterone increases can inhibit the ability of heterophils to produce chemotactic signals. There was no significant difference in CXCLi2 expression by heterophils of birds fed the β-glucans or ascorbic acid enhanced diets, indicating that these immune stimulants likely alter mechanisms other than chemotaxis to enhance immune response.

Key Words: dietary immune modulation, heterophils

272 Nitric oxide synthesis by chicken macrophages results in coordinated changes in the mRNA abundance of multiple arginine transporters. M. Moulds* and B. D. Humphrey, *California Polytechnic State University*, *San Luis Obispo*.

Nitric oxide (NO) is synthesized by macrophages when arginine (ARG) is cleaved by inducible nitric oxide synthase (iNOS). In mammals, ARG uptake for NO synthesis is controlled by CAT-2B, but in Aves the requisite system(s) are unknown. Therefore, ARG transporter mRNA abundance was quantified during a NO response from a chicken macrophage (HD-11) cell line and peripheral blood monocytes (PBM). PBM were isolated from Hyline W36 white leghorn hens (n = 3). PBM were cultured in RPMI complete media at 10^5/well (n = 3) while HD-11 cells were cultured in IMDM complete media at 4×10^5 HD-11 cells/well (n = 6). To induce NO production, cells were cultured with 0 (control) or 1 μg/ml *E. coli* lipopolysaccharide (LPS) for 48 h. NO was measured indirectly by means of media nitrite concentration. Total RNA was isolated from cultured macrophages and was reverse transcribed for measurement of iNOS and ARG transporter mRNA abundance by quantitative real-time PCR. LPS increased HD-11 nitrite concentration by 7,600% and PBM by 8.7% ($P < 0.05$). LPS also increased HD-11 and PBM iNOS mRNA abundance 8.5-fold and 2.6-fold, respectively ($P < 0.05$). CAT-2B mRNA was undetectable in both HD-11 and PBM cell types. In HD-11 cells, LPS induced CAT-1 and CAT-3 mRNA abundance from undetectable levels, and also increased CAT-2A mRNA abundance 1.6-fold ($P < 0.05$). The exporter y^+LAT1 mRNA abundance decreased by 71% in HD-11 cells ($P < 0.05$), but no change occurred in

y^+LAT2 mRNA abundance ($P > 0.05$). In PBM, LPS increased CAT-1 and CAT-3 mRNA abundance 11-fold and 13-fold, respectively ($P < 0.05$). In LPS treated PBM, mRNA abundance of y^+LAT2 decreased 67% ($P < 0.05$), but y^+LAT1 mRNA abundance did not change ($P > 0.05$). NO production increased ARG transporter mRNA in HD-11 cells (CAT-1, CAT-2A, CAT-3) and PBM (CAT-1, CAT-3) and decreased ARG exporter mRNA in HD-11 cells (y^+LAT1) and PBM (y^+LAT2). These data indicate that multiple ARG systems may be involved in ARG uptake for NO production in avian macrophages.

Key Words: arginine, macrophage, nitric oxide

273 Dietary cinnamaldehyde enhances intestinal protective immunity against *Eimeria acervulina*, *E. maxima* and *E. tenella* in broiler chickens. S.-H. Lee*[1], H. Lillehoj[1], S.-I. Jang[1], K.-W. Lee[1], M.-S. Park[1], and D. Bravo[2], [1]*Animal and Natural Resources Institute, Agricultural Research Service-U.S. Department of Agriculture*, *Beltsville, MD,* [2]*Pancosma S.A.*, *Grand Saconnex, Geneva, Switzerland*.

The protective effect of dietary treatment of cinnamaldehyde on challenge infection with *E. acervulina* (EA), *E. maxima* (EM), or *E. tenella* (ET) (20,000 oocysts/bird) was evaluated in broilers. Three days after hatch, broiler chickens were continuously fed with a standard diet (20/group) or standard diet supplemented with cinnamaldehyde (20/group) for 4 weeks and challenge infection was given at 2 weeks of age. Body weight gains, antibody titers, and cytokine gene expression were measured following oral challenge infection with EA, EM or ET. When body weight gains were measured at 5 and 9 d post infection (dpi), cinnamaldehyde-fed birds showed 10~30% increases over ($P < 0.05$) the untreated birds following challenge infection with EA, EM or ET. Cinnamaldehyde-fed chickens produced 2 folds higher IgY antibody titers ($P < 0.05$) against coccidia at 9 dpi compared with the control group. Finally, the levels of intestinal lymphocyte cytokine transcripts of IL-1β, IL-6, IL-15, and IFN-γ were 2–5 folds higher in the cinnamaldehyde-fed chickens compared with the controls. This study provides the first immunological evidence that dietary cinnamaldehyde significantly enhances host innate immunity against coccidiosis.

Key Words: Cinnamaldehyde, immunity, broiler

274 Immune system stimulation and sulfur amino acid intake alter the pathways of glutathione metabolism at transcriptional level in pigs. A. Rakhshandeh*[1], A. Holliss[2], N. A. Karrow[1], and C. F. M. de Lange[1], [1]*University of Guelph, Department of Animal and Poultry Science*, [2]*University of Guelph, Advance Analysis Centre*, *Guelph, Ontario, Canada*.

The synthesis rate of GSH increases during immune system stimulation (ISS) and is highly dependent on availability of sulfur amino acids (SAA). The expression of key regulatory genes was determined to evaluate the impact of ISS and SAA intake on pathways of GSH metabolism. Restricted-fed barrows (BW 21.5 kg) were allotted to one of 2 levels of SAA intake (1.1 and 3.2, g/d) and injected with either saline (n = 8) or increasing amounts of *Escherichia coli* lipopolysaccharide (n = 16) every 48 h for 7 d. Pigs were then killed to collect liver tissue for total RNA extraction. Liver and an internal standard (KANr) RNA were then reverse transcribed, and expression of selected genes was simultaneously determined by multiplex PCR amplification of cDNA from liver, the housekeeping gene (β-2-microglobulin) and the internal standard in the presence of their corresponding florescent labeled primers. The interactive effect (ISS × SAA) resulted in lower and higher expression, respectively, of GSH synthetase (GSH-S) and GSH reductase (GSR) at the low level of SAA intake in ISS animals ($P < 0.04$). Increased SAA intake decreased expression of GSH-S and GSR but increased expression of GSH peroxidase 3 (GPX3; $P < 0.03$). Expression of glutamate-cysteine ligase modifier (GCLM) was decreased by ISS ($P < 0.01$). However, ISS increased expression of glutamate-cysteine ligase (GCS), GPX1, GPX3 and GSR ($P < 0.4$). No treatment effect on expression of γ-glutamyl hydrolase (GGH) or GPX4 was observed. This study demonstrates that ISS and SAA intake alter GSH metabolism pathways at the transcriptional level in liver of pigs.

Key Words: sulfur amino acids, immune system stimulation, gene expression, multiplex PCR, glutathione

Animal Health-Johne's Disease (JDIP): Epidemiology and Transmission

275 Cost-effectiveness of diagnostic strategies to identify *Mycobacterium avium* ssp. *paratuberculosis* super-shedder cows in a large dairy herd. S. S. Aly*[1], R. J. Anderson[2], R. H. Whitlock[3], T. L. Fyock[3], S. McAdams[3], T. M. Byrem[4], J. Jiang[5], J. M. Adaska[6], and I. A. Gardner[1], [1]*Department of Medicine and Epidemiology, School of Veterinary Medicine, University of California, Davis*, [2]*California Department of Food and Agriculture, Animal Health Branch*, *Sacramento,* [3]*Johne's Research Laboratory, New Bolton Center, School of Veterinary Medicine, University of Pennsylvania*, *Kennett Square,* [4]*Antel BioSystems, Inc*, *Lansing, MI,* [5]*Department of Statistics, University of California, Davis*, [6]*California Animal Health and Food Safety Laboratory, Tulare*.

Paratuberculosis-infected cows that shed *Mycobacterium avium* ssp. *paratuberculosis* (MAP) in excess of 10,000 CFU/g of feces have been termed super-shedders and contribute the most to MAP bioburden on a dairy. Identification of super-shedders in a large dairy herd is challenging given their low prevalence, cost of MAP diagnostic tests, and hence, the large sample size needed. Several diagnostic strategies to detect super-shedders are possible given the different MAP organism- and antibody-detection tests and specimens available to test. The objective of this cross-sectional study was to compare the cost-effectiveness of diagnostic strategies to detect MAP super-shedders in a large dairy herd. The study herd of 3577 Jersey cows had a MAP seroprevalence of 3.5% based on routine testing at dry-off. Cows were housed in 14 freestall pens and the herd manager requested not to move cows between pens during the study. A whole herd survey (reference) and 14 other diagnostic strategies were evaluated and their cost-effectiveness calculated. The reference strategy included quantitative real-time PCR (qrt-PCR) on fecal pools, followed by qrt-PCR of the individual cow fecal samples from the positive pools and a random sample of individual cow fecal samples from suspect and negative pools. The remaining strategies included combinations of serum ELISA, milk ELISA and environmental and pooled fecal samples tested using qrt-PCR. Twenty super-shedders (0.5% of the herd; 2% of qrt-PCR MAP positive cows) were identified and had a mean of 82,040 colony-forming units (CFU)/g of feces. The whole herd survey using qrt-PCR was the most sensitive strategy but sensitivity was ≤ 80% for all 15 strategies. The most cost-effective strategy was to rank lactating cow pens by MAP bioburden, milk ELISA test cows in pens ≤ 32 CT followed by qrt-PCR testing of fecal samples from milk ELISA positive cows. Environmental samples collected using a standardized protocol as part of a diagnostic strategy can improve the cost-effectiveness of detecting super-shedders compared to a whole herd survey by qrt-PCR.

Key Words: cost-effectiveness, MAP super-shedder

276 Correlation between culture and quantitative real-time PCR results for *Mycobacterium avium* subspecies *paratuberculosis* in pooled fecal and environmental samples. S. S. Aly*[1], B. L. Mangold[2], R. H. Whitlock[3], R. W. Sweeney[3], R. J. Anderson[4], J. Jiang[5], Y. H. Shukken[6], E. P. Hovingh[7], D. R. Wolfgang[7], J. S. Van Kessel[8], J. S. Karns[8], J. E. Lombard[9], J. M. Smith[10], and I. A. Gardner[1], [1]*Department of Medicine and Epidemiology, School of Veterinary Medicine, University of California, Davis*, [2]*Tetracore, Inc.*, *Rockville MD,* [3]*Department of Clinical Studies-New Bolton Center, School of Veterinary Medicine, University of Pennsylvania*, *Kennett Square,* [4]*California Department of Food and Agriculture, Animal Health Branch*, *Sacramento,* [5]*Department of Statistics, University of California, Davis*, [6]*Section of Epidemiology and Quality Milk Production Services, Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University*, *Ithaca, NY* [7]*Department of Veterinary and Biomedical Sciences, Pennsylvania State University*, *University Park,* [8]*Environmental Microbial and Food Safety Laboratory, ANRI, USDA-ARS*, *Beltsville, MD,* [9]*Centers for Epidemiology and Animal Health, Animal and Plant Health Inspection Service, USDA*, *Fort Collins, CO,* [10]*Department of Animal Science, University of Vermont*, *Burlington*.

Quantitative real-time PCR (qPCR) testing for *Mycobacterium avium* subspecies *paratuberculosis* (MAP) in fecal samples is a rapid alternative to culture on Herrold's egg yolk medium (HEYM), the traditional reference test for MAP. Although the sensitivity and specificity of these 2 tests has been described, the correlation between qPCR cycles-to-threshold (Ct) values and colony-forming units (CFU) on HEYM has not been evaluated. The objective of the present study was to estimate the correlation between qPCR and HEYM culture results in fresh and frozen pooled fecal and environmental samples and model the association between results of both assays. Quantitative HEYM culture results for 1997 pooled fecal samples from cows in 14 herds in 4 states, and 802 environmental samples from 113 dairies nationwide were correlated with their respective qPCR results. The Spearman's rank correlation between assays was good (−0.66) in both fresh and frozen pooled fecal samples and excellent (−0.76) and good (−0.61) in fresh and frozen environmental samples, respectively. Furthermore, the correlation varied from good (−0.53) to excellent (−0.90) depending on size of fecal pools. Truncated linear regression models indicated a significant negative association between CFU and Ct in fecal pools of all sizes and in both individual and pooled environmental samples. The use of qPCR instead of HEYM can yield more timely quantitative MAP detection on a herd basis and allow for incorporation of qPCR in many dairy herd testing strategies to reduce the risk of MAP transmission.

Key Words: culture PCR correlation, pooled and environmental samples, *Mycobacterium avium* ssp. *paratuberculosis*

277 Fecal culture and direct PCR in determining *Mycobacterium avium* ssp. *paratuberculosis* infectivity. C. C. Wu*[1], J. E. Williams[2], T. L. Lin[1], and G. R. G. Monif[3], [1]*Purdue University*, *West Lafayette, IN*, [2]*University of Florida*, *Gainesville,* [3]*Infectious Diseases Incorporated*, *Bellevue, NE*.

The present study was conducted to evaluate the utility of fecal culture, direct fecal real-time PCR, and direct fecal nested PCR in determining the status of *Mycobacterium avium* ssp. *paratuberculosis* (Map) infectivity in dairy herd. Eight hundred and 27 (827) fecal samples were collected from 2 dairy herds participating in Johne's Disease Demonstration Herd Program. Fecal culture was carried out by using Trek ESP system with IS900 PCR confirmation. Direct fecal Map real-time PCR uses heat shock protein gene (hsp) as the target in PCR (VetAlert TM Johne's Real-Time PCR, Tetracore). Direct fecal Map nested PCR is based on IS1311 (FecaMap, Infectious Diseases Inc.). The percentages of fecal samples positive for Map were 13.5% by culture, 11.6% by real-time PCR, and 21.8% by nested PCR. Using positivity by direct fecal culture as the gold standard, 35 samples were positive for Map by real-time PCR with 83.3% accuracy and 51positive for Map by nested PCR with 77.3% accuracy. Using positivity by culture or both PCR as the gold standard, 112 samples were positive for Map by culture with 97.3% accuracy, 49 positive for Map by real-time PCR with 85.0% accuracy, and 65 positive for Map by nested PCR with 78.8% accuracy. The results indicated that using positivity for Map by culture or both

PCR as the gold standard is a more accurate tool in determining the status of Johne's disease infectivity in dairy herd.

Key Words: *Mycobacterium paratuberculosis*, fecal culture, direct fecal PCR

278 Estimation of test parameters for fecal culture and serum ELISA for detection of *Mycobacterium avium* ssp. *paratuberculosis* fecal shedding. L. A. Espejo*[1], F. J. Zagmutt[2], H. Groenendaal[2], and S. J. Wells[1], [1]*University of Minnesota*, *St. Paul*, [2]*Vose Consulting*, *Boulder, CO*.

The objective of this study was to estimate the probability of the fecal culture and serum ELISA to correctly identify cattle that shed high, low, and no fecal concentrations of *Mycobacterium avium* ssp. *paratuberculosis* into the environment. The results of 12,957 parallel fecal culture (HEY media) and serum ELISA (IDEXX) from 8 dairy herds enrolled in the Minnesota Johne's Disease Demonstration Herd Program over a 9 year period were used for this study. The conditional probabilities that test results indicate high, low, and no fecal shedding, given the true shedding status of the animal P(test results|true status) were estimated using Bayesian Markov-Chain Monte Carlo methods. The model assumed no gold standard test, independence between both tests and Dirichlet distribution for the priors. The shedding levels using fecal culture were categorized as high with ≥ 50 colonies/slant, low with 0 < colonies/slant < 50, and no fecal shedding with no detectable colony growth on the slants. Likewise, levels for serum ELISA were established based on OD values, with ≥ 1.0 (high), ≥ 0.25 and < 1.0 (low), and < 0.25 (negative). Informative prior distributions of the conditional probabilities were given by one of the co-authors (SJW). The probability of the serum ELISA to correctly identify high fecal shedders (P(High| High)) was 69%, while the same probability for fecal culture was 59%. The probability of incorrectly identifying animals that were high fecal shedders as no shedding (P(No shedding| high)) was 10% for serum ELISA and 3% for fecal culture. The probability of correctly identifying animals that were not shedding (P(No shedding|no shedding)) was 99.8% for serum ELISA and 98.9% for fecal culture. These posterior conditional distributions improve understanding of the fecal culture and serum ELISA, and this information can be used to model the transmission of Johne's disease on dairy farms taking into account the uncertainty of these tests.

Key Words: Johne's disease, diagnostic tests, Bayesian inference

279 Effect of delaying exposure to Johne's disease until adulthood on development of new infections in adult dairy cows. S. J. Wells*, N. Kubat, L. A. Espejo, and S. M. Godden, *University of Minnesota*, *St. Paul*.

Control programs for Johne's disease (JD) in US dairy cattle are designed with focus on preventing exposure by *Mycobacterium avium ssp. paratuberculosis* (MAP) in young replacement cattle, as these cattle are considered to be at highest risk of infection. The objective of this study was to compare rates of subclinical and clinical MAP infection in cattle raised in an environment presumed free of JD to those of cattle raised in an infected environment. Through a survey of uninfected Minnesota dairy herds (Levels 3 or 4 of the Voluntary Johne's Disease Herd Status Program for Cattle), we identified JD infected herds that previously purchased replacement cattle from uninfected herds. Over a 3 year period, blood and fecal samples were collected in infected herds from 78 purchased replacement cattle that were raised in uninfected herds (exposed) and homebred cows of similar age and stage of lactation (non-exposed controls). Serum samples were tested using an ELISA (IDEXX) for detection of antibodies to MAP and fecal samples were tested for detection of MAP using bacterial culture (HEY media). While results from the first year of testing of cattle across multiple ages indicated that dairy cattle raised in JD low risk herds (Level 3 or 4) and introduced to Johne's infected herds were less likely to test positive for MAP than herdmates raised in infected herds, results over time from survival analyses showed that this difference in risk was reduced later in life. The hazard ratio point estimate from Cox regression for exposed compared with unexposed cattle was 0.70 (95% CI = 0.40,1.23) and 0.64 (95% CI = 0.33,1.24) for fecal culture and ELISA, respectively. These results suggest risk of MAP infection in adult dairy cattle which should be considered in development of comprehensive JD control programs.

Key Words: Johne's disease, susceptibility

280 Importance of latent infected animals in MAP infection dynamics in dairy herds. Y. H. Schukken*[1], A. K. Pradhan[1], R. M. Mitchell[1], Z. Lu[1], R. Smith[1], Y. T. Grohn[1], R. H. Whitlock[2], E, Hovingh[3], J. Smith[4], J. A. VanKessel[5], J. Karns[5], and D. Wolfgang[3], [1]*Cornell University*, *Ithaca, NY*, [2]*University of Pennsylvania*, *Kennett Square,* [3]*Pennsylvania State University*, *State College,* [4]*University of Vermont*, *Burlington,* [5]*ARS-USDA*, *Beltsville, MD*.

Mycobacterium avium ssp. *paratuberculosis* (MAP) is an important infectious disease of dairy cattle. Prevalence of test positive cows in dairy herds is often low. Prevalences between 0 and 10% are most common. Such low infection prevalences would be expected to result in infection die-out in a proportion of herds due to culling that is unrelated or related to MAP infection status. In reality MAP infection die-out in dairy herds is not observed. At the very least it is not reliably documented. This would imply that complex mechanisms play a role in MAP infection maintenance in dairy herds. The objective of this presentation is to investigate the role of latent infected animals in endemically MAP infected dairy herds. Animals with a latent infection are defined as animals that are not detected to shed the organism while being tested using common testing schemes used in MAP control programs, but that turn out to be tissue positive when sampled and cultured at slaughter. We studied the potential contribution of latent infected animals to the vertical transmission route of infection and the contribution to a low rate of low shedding of these animals while in a high stress period. High stress periods were assumed to occur when an animal was calving and when severe clinical diseases such as mastitis, DA and lameness occurred. The importance of latent infected animals was evaluated in a previously described MAP model. We used simulation modeling to evaluate scenarios with intermittent shedding of latent MAP infected animals, increased vertical transmission in these animals and shedding while in high stress periods. Modeling the potential contribution of latent infected animals resulted in a better description of long-term low test prevalence herds and a more accurate prediction of a very low probability of infection die-out in dairy farms.

Key Words: MAP, modeling, latent infection

281 Impact of Johne's disease vaccines on a dairy herd: a mathematical modeling approach. Z. Lu*, Y. H. Schukken, R. L. Smith, and Y. T. Gröhn, *Cornell University*, *Ithaca, NY*.

The objective of this study was to investigate the potential impact of Johne's disease vaccines on the dynamics of MAP infection in a dairy herd using a mathematical modeling approach. To reduce the prevalence of MAP infection, vaccination has been applied as a control measure in some dairy herds. However, Johne's disease vaccines are imperfect and

several types of vaccine efficacy have been observed, i.e., vaccines may provide a partial protection for susceptible calves, reduce infectiousness/shedding level of animals shedding MAP, lengthen the latent period of infected animals, slow the progression from low shedding to high shedding in infectious animals, or reduce clinical disease. To quantitatively study the impacts of Johne's disease vaccines, we developed a deterministic multi-group vaccination model consisting of 18 nonlinear ordinary differential equations. The model was parameterized using data from US dairy herds. An analytical expression of the reproduction ratio (R) incorporating several vaccine efficacies was obtained. Our analytical and numerical results show that Johne's disease vaccines may have a positive, zero, or negative effect in the reduction of prevalence. Some vaccine efficacies are beneficial to individual animals, but may not be useful to a herd-level control plan. We also studied the impact of multiple vaccine efficacies on the dynamics of MAP transmission. This work is helpful to understand various outcomes in field studies of Johne's disease vaccines and to provide a tool to evaluate vaccine efficacies in Johne's disease control.

Key Words: Johne's disease, vaccination, modeling

282 Estimating the efficacy of imperfect paratuberculosis vaccines in dairy cattle from longitudinal field data with Markov Chain Monte Carlo models. R. L. Smith*, Y. H. Schukken, Z. Lu, and Y. T. Grohn, *Cornell University*, *Ithaca, NY*.

The purpose of this study was to determine the efficacy of vaccination against paratuberculosis in dairy cattle. For this purpose, a statistical model has been developed to analyze longitudinal field data from dairy herds with endemic paratuberculosis and control programs involving vaccination. Infection with *Mycobacterium avium* ssp. *paratuberculosis* (MAP) is difficult to detect, due to the long latent period and imperfect diagnostics. In commercial dairy herds, many animals could be culled before their infection status can be verified diagnostically. Due to this uncertainty as to true prevalence, it is challenging to obtain an unbiased estimate of vaccine efficacy. In addition, vaccines can do more than just decrease susceptibility to disease; vaccination against MAP may also decrease infectiousness, increase the duration of latency, or slow progression of clinical disease. To overcome the observed complexity of early censoring (culling) and multiple potential vaccine efficacies, we developed a Markov Chain Monte Carlo model. The potential vaccine effects are inter-related, but may have different and even opposite economic impacts. Markov Chain Monte Carlo (MCMC) models have been used extensively to estimate parameters for stochastic models from data sets with missing information. These models allow for simultaneous estimation of several variables in the presence of nonlinear relationships. In this study we developed an MCMC model to estimate 5 different possible vaccine effects (on vertical transmission probability, horizontal transmission rate, duration of latency, duration of subclinical disease, and rate of progression to clinical disease), while correcting for missing information (such as true infection status and time of infection). The 50% confidence intervals of the model's posterior distributions contain the true value of the parameters of interest when simulated over a wide range of vaccine efficacies. This is an effective tool for estimating vaccine efficacy from field data.

Key Words: Johne's disease, vaccine, statistics

283 Molecular epidemiology of *Mycobacterium avium* ssp. *paratuberculosis* in three dairy herds in the northeastern United States. A. K. Pradhan*[1], R. M. Mitchell[1], A. J. Kramer[2], J. Dieguez[3], R. H. Whitlock[4], J. M. Smith[5], E. Hovingh[6], J. S. Van Kessel[7], J. S. Karns[7], and Y. H. Schukken[1], [1]*Cornell University*, *Ithaca, NY,* [2]*Utrecht University*, *Utrecht, the Netherlands*, [3]*University of Santiago de Compostela*, *Santiago de Compostela, Spain*, [4]*University of Pennsylvania*, *Kennett Square,* [5]*University of Vermont*, *Burlington,* [6]*Pennsylvania State University*, *University Park,* [7]*Environmental Microbial and Food Safety Laboratory, ANRI, USDA-ARS*, *Beltsville, MD*.

The objectives of this study were to evaluate (i) whether low shedders of *Mycobacterium avium* ssp. *paratuberculosis* (MAP) were passive shedding animals or whether they were truly infected, (ii) whether these animals could have been infected as adults by contemporary high-shedding animals (super-shedders), and (iii) whether animals in the herds shared the same MAP strains with that were obtained from environmental samples. The MAP isolates were obtained from a longitudinal study of 3 dairy herds in the northeastern United States. Selected isolates from fecal samples and tissues from all animals that were culture-positive at the same time that super-shedders were present in the herds and all environmental isolates were strain typed using a multilocus short sequence repeat technique. We found 15 different MAP strains from a total of 142 isolates from fecal samples and tissues. Eight different strains were found from a total of 102 environmental isolates; 6 of these strains were present in these selected animal isolates. Results indicated herd-specific infection patterns; a clonal infection in herd C with 89% of animals sharing the same strain, whereas herds A and B showed several different strains. Shedding levels and MAP strain typing showed that at least 50% of low shedders have the same strain as that of a contemporary super-shedder. About 57, 50, and 94% of environmental samples shared the same strains as super-shedders on Farms A, B, and C, respectively, which suggests that super-shedders may represent a risk of spreading MAP-infection among adult herd mates. Results suggested that in a dairy herd few cows could be classified as passive shedders whereas more low-shedding cows are truly infected. The sharing of same strain of low shedders with the contemporary super-shedders suggests that low shedders may have been infected as adults by super-shedders. Sharing of same strains of both environmental and animal samples suggests the spread of MAP-infection through environment.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, longitudinal study, MLSSR analysis

284 Field evaluation of TG marker IS1311 PCR-REA for rapid differentiation of Indian Bison type *Mycobacterium avium* ssp. *paratuberculosis*. J. S. Sohal, S. V. Singh*, P. K. Singh, and A. V. Singh, *Central Institute for Research on Goats*, *Makhdoom, Farah, Mathura (UP), India, 281 122*.

The availability of MAP genome in the public database opened various areas including the analysis of native isolates (comparative genomics). Comparative genomics studies at our laboratory have identified some key variations in the genome of native MAP. Studies has highlighted that "Indian Bison type" may represent a new MAP Biotype so far not reported outside India. One important variation in the genome of Indian Bison type isolates is the deletion of TG in the IS1311 element. Taking advantage of this variation on specific PCR-REA based test using BsaJI restriction enzyme was designed to distinguish Bison type isolates of Indian origin from other isolates. Present study analyzed and evaluated the use of this new assay for its practical utility in field for molecular epidemiological investigations. In total 45 previously characterized Bison type DNA samples of Indian origin from different parts of the country were analyzed. Results of the present study showed that all isolates belonging to Bison type genotype from different host species and agro-climatic region of the country had TG deletion in the IS 1311 element. Presence of this variation in all the Indian isolates belonging

to Bison type genotype is indicative of the fact that this variation has been established in all Bison type isolates of Indian origin. Hence this assay can be used in future molecular epidemiological investigations. Also this assay should be used in other parts of the world in order to study the distribution of newly identified MAP biotype.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, TG deletion, IS 1311 PCR-REA

285 Rising incidence of *Mycobacterium avium* ssp. *paratuberculosis* in the North Indian population of animal keepers suspected for IBD/CD. S. V. Singh*, A. Shishodiya, A. Panwar, B. Singh, and A. Kumar, *Central Institute for Research on Goats*, *Makhdoom, Farah, Mathura (UP), India, 281 122*.

Mycobacterium avium ssp. *paratuberculosis* (MAP) infection is highly endemic in domestic livestock population in India. However, limited information exist on the association of MAP with human's Inflammatory bowel disease (IBD)/Crohn's disease (CD) in the country. Therefore, present study aimed to investigate the association of MAP in animal keepers from peri-urban areas of North India (Ghaziabad and Saharanpur cities) with symptoms of IBD/CD, using multiple diagnostic tests. A total of 131 samples (25 stool, 53 blood and 53 serum) and 108 samples (14 stool, 47 blood and 47 serum) were collected from 54 animal keepers having clinical profiles indistinguishable to IBD (suspected for CD) and from 47 animal keepers without symptoms of IBD (not suspected for CD), respectively. Animal keepers were in contact with animals for variable duration and some of them had habit of raw milk consumption. Stool samples were screened by microscopy and specific IS 1311 PCR-REA. Blood and serum were screened by IS 1311 PCR-REA and indigenous ELISA kit, respectively. Of the animal keeper suspected for CD, 36.0 (9/25), 28.0 (7/25), 12.9 (7/54), and 12.9% (7/54) samples and of animal keepers without symptoms of IBD (not suspected for CD), 14.2 (2/14), 7.1 (1/14), 2.1 (1/47) and 4.2% (2/47) samples were positive for MAP by stool microscopy, stool PCR, blood PCR and indigenous ELISA kit, respectively. According to habits of animal keepers, results showed high occurrence of MAP in humans with habit of raw milk consumption and smoking. All MAP DNA samples were genotyped as 'Indian Bison type' (pre-dominant type of MAP in animals of India). Presence of 'Indian Bison type' genotype and higher prevalence of MAP infection in cases of suspected animal keepers as compared to not-suspected animal keepers, strongly indicated the role of MAP in causing CD.

Key Words: *Mycobacterium avium* ssp. *paratuberculosis*, Crohn's disease, inflammatory bowel disease

286 Herd-level prevalence of Johne's disease on dairy farms in Utah and the surrounding Intermountain West. D. J. Wilson*[1], K. A. Rood[1], and J. D. Trujillo[2], [1]*Utah State University*, *Logan*, [2]*Iowa State University*, *Ames*.

The objective was to determine dairy herd-level prevalence of Mycobacterium avium ssp. paratuberculosis (MAP) infection, the causative agent of Johne's disease (JD) in Utah and some surrounding states. A signed permission slip was required for participation in the study. Two milk samples were collected from each bulk tank on study farms, one month apart. The farms shipped milk to two major milk buyers in Utah, with all milk collected at one of two milk processors. Milk haulers collected an extra bulk tank milk sample for use in the study. Identity of the farms was coded for anonymity by milk plant personnel. An ELISA test for IgG1 antibody against MAP and a PCR to detect MAP, both designed for pooled bulk tank milk were performed on each milk sample. Each bulk tank was to be tested 4 times, twice on each of the 2 samples. The number of tank samples tested per farm ranged from 1 to 24 (most farms had 2 or 4 samples from one or two bulk tanks, respectively). The 2 farms with the most bulk tanks had 6 and 12 tanks, respectively. JD was detected at least once on 67/170 farms tested (39%). The most common positive test results were 1 or 2 positives/4 JD tests (n = 28 farms). The lowest proportions of all tests positive for JD on a given farm were 2/48, 1/8 (n = 3), and 2/12 (n = 2). Highest proportions of positive tests were 8/8, 4/4, 10/12, 9/12, 6/8, 7/12, and 13/24. The finding of 39% of herds positive for JD is similar to other recent estimates of herd prevalence, indicating increased levels of the disease compared with national estimates 15-20 years ago. Some herds were enrolled in a demonstration project to evaluate the effectiveness of using the individual cow JD milk ELISA test and culling to reduce prevalence of the disease. Analysis of data and reporting of results from that study will be completed in the future.

Breeding & Genetics and Physiology & Endocrinology Symposium: Bridging the Gap Between Physiology and Genomics

287 Spanning research from QTL to functional unit of a gene. J. M. Reecy*, *Iowa State University*, *Ames*.

Since the dawn of modern genetics, researchers have been working toward the elucidation of genetic pathways that control variation in traits of interest. Along the way, new breakthroughs in technology have lead to new insights. The determination of the structure of DNA and the subsequent explosion in molecular biology, enabled researchers to identify genes responsible for many processes in a cell (e.g., glycogenesis, transcription, etc). Eventually, geneticists began to utilize these new molecular techniques to identify regions of the genome that contain genetic variation that was associated with phenotypic variation (quantitative trait loci; QTL). To date, molecular geneticists have identified almost 10,000 QTL in cattle, pigs and chickens. The speed with which new QTL are identified is ever increasing. Unfortunately, the identification of quantitative trait nucleotides (QTN) lags significantly behind. However, now that the genomes of all major livestock species have been sequenced a new suite of techniques have been unleashed. New genotyping and statistical techniques have made it possible to not only identify QTL and fine map them, but to also account for a large amount of total genetic variation associated with a trait of interest. For some traits there are a large number of small effect QTL (i.e., infinitesimal model), while for other traits there appear to be a limited number of QTL. In addition to genotyping and statistical breakthroughs, whole, or even partial, genome re-sequencing and transcriptomics (RNA-seq) are providing new insights into genome and gene structure. We can now combine phenotype, genotype and gene expression data to understand the mechanisms underlying traits of interest in greater detail than ever before. We have entered an era where molecular/quantitative genetic techniques need to be directed beyond production to consider animal health, animal welfare, climate change mitigation, and consumer health traits.

Key Words: genomics, transcriptomics, whole genome association

288 Advancing toward functional genomics. H. L. Neibergs*, *Washington State University*, *Pullman*.

Complex traits are difficult to identify at the molecular level. Because many genes are involved, many with modest effects, it is difficult for them to be detected in genomic studies. To identify loci responsible for complex traits, multidisciplinary collaborations between genetics and physiology are essential. Integration of computational biology, molecular biology and physiology enhances the genomics discovery process because the connections between the functions of the gene products will lead us to the genes involved in the phenotype. To make the link between genome and phenotype, tools such as gene set enrichment combined with single nucleotide polymorphism analysis offer approaches to evaluate biological pathways in the context of genomic variation. Evaluation of the unique transcription profiles of a cell at different points in the life of the animal, whether conducted with microarrays or RNA sequencing, adds information about the transcription regulation of the genome. Proteomics extends the transcriptional message to the proteins being produced in and around the cell and the post-translational modifications that affect the protein′s function. The identification of alternative splicing of the mRNA transcripts and the interaction of proteins with other protein and RNA molecules must also be investigated to determine how a phenotype is expressed. By understanding the biological process of transcription, translation, and interactions of the proteins, the variation present in the genome is placed in context to the phenotype. Progress toward solving the basis of complex traits may well begin with the biological process, rather than the QTL. Genetics may be the foundation of animal improvement, but true genetic progress will be made when we expand our field of view to include gene function.

Key Words: functional, genomics

289 Genomic analysis of data from physiological studies. D. J. Garrick*, *Iowa State University*, *Ames.*

Physiologists have long been undertaking research to discover and elucidate the mechanisms involved in particular metabolic processes such as maintenance, growth, reproduction, and disease. Animal breeders have focused their research endeavors on understanding genetics, the study of inheritance, to implement breeding programs that can systematically advance the genetic merit and phenotypic performance of food animal systems, by exploiting selection of above-average candidates to be the parents of the next generation. Prerequisite characterization of the genetic merit of selection candidates has principally been achieved by visualizing the genomes of the candidates solely through measurement of phenotypes on the candidate itself, or on its close relatives. The resulting artificial selection has made use of those genes that are responsible for variation in performance, without requiring or taking advantage of any knowledge of causality, in the same manner that natural selection can alter populations. Accordingly, selection could rightfully have been described as resembling a black-box. Leveraging on sequencing activities undertaken in various livestock genomes, high-density genotyping systems have become available that allow inheritance of individual genome fragments to be traced from one generation to another and related to variation in performance by quantifying their substitution effect. Genomic selection can then be undertaken by predicting merit by summing up the values of an individual's chromosome fragments. A by-product of this approach is that it identifies genomic regions contributing to variation in performance that can be queried in bioinformatic databases that accumulate knowledge of gene location and function. Collectively this information can extend the scope of physiological studies beyond the underlying mechanisms of average performance to explain the causes of variation in performance.

Key Words: genomic selection

290 Genomic information for physiologists. M. G. Thomas*, K. L. DeAtley, S. O. Peters, G. A. Silver, and A. M. Clayshulte, *New Mexico State University*, *Las Cruces*.

Furthering knowledge of genes and understanding their mechanistic-role is a focus of physiology research. Specifically, this research furthers understanding of transcripts that are translated into proteins and considers their relevance in the whole animal. Development of tools to work with genomic data have enhanced gene discovery for physiology and molecular biology research. Some of these tools also provide data for estimating genome-assisted breeding values for livestock improvement programs. For example, SNP-chip data can be used for QTL detection as well as genetic prediction. Once a QTL is discovered or queried from a database, the process of fine mapping to determine the DNA sequence inferring the physiology from the underlying genes involves numerous

strategies. These include resequencing and denser DNA marker association studies and (or) investigation of transcriptome and proteome reference resources to reveal candidate genes, which can be visualized in pathway software to help design studies to investigate their functions. An example of such a process involved detection of a QTL on chromosome 2 for heifer pregnancy (n = 830 and BovineSNP50 genotypes). Bioinformatic tools (animalgenome.org) were used to visualize 10 QTL and 10 annotations in a 4 Mb region flanking the SNP inferring this QTL. Since hypothalamus is part of the reproductive endocrine axis, RNA was harvested from this tissue of pre- and post-pubertal heifers and deep sequenced (RNA-Seq). Transcriptomes were aligned with the bovine genome (ver. 4.0) to evaluate presence and level of expression of candidate genes with Alpeus. Three genes with differing levels of expression were identified and their ontology suggested neuron function and cell signaling. Most importantly, these genes were new discoveries for this research program and provide opportunity for their visualization in pathways and consideration in design of experiments to decipher their physiological relevance. These considerations could also include evaluation of allele-specific variation. Advancements in genomics have expanded the ability of physiologist to discover genes and explore their functions.

Companion Animals Symposium: Microbes and Health

291 Introduction: Microbes and health. K. S. Swanson*, *University of Illinois*, *Urbana*.

Despite human claims to superiority, it can be legitimately argued that microbes rule the world. Whether it is an ocean reef, a landfill, or a gastrointestinal tract, invisible communities of highly active and adaptable microbes prosper. Over time, mammalian species developed a symbiosis with microbes that are now important inhabitants not only in the intestines, but also in the mouth, skin, and vaginal tract. In the gut, commensal microbes are a critical element for the development of the gut-associated lymphoid tissue, pathogen resistance, nutrient digestion (fermentation), and intestinal epithelial cell gene expression. Proper balance is key, however, as microbial imbalances contribute to inflammatory bowel diseases, gastrointestinal cancers, and other intestinal disorders. Microbial colonization also plays a crucial role in oral disease, which is now the most common form of disease in dogs and cats. Recent evidence also suggests a role of intestinal microbiota on the metabolic phenotype and disease risk (e.g., obesity, metabolic syndrome) of the host. A significant hindrance to studying gut microbiota has traditionally been the inability to effectively identify and quantify microbial species. Researchers have been reliant upon microbial culturing methods that are not only laborious, time-consuming, and often inaccurate, but also greatly limited in scope. High-throughput, DNA-based methods have been developed recently and have changed the research environment dramatically. Recent experiments using these techniques have begun to characterize the identity and metabolic activity of the entire gastrointestinal microbiota and their association with health and disease. Despite this recent progress, more research is needed to provide deeper coverage of the oral and intestinal microbiomes, evaluate effects of age, genetics, or environment (e.g., diet) on its composition and activity, and identify its role in disease.

Key Words: microbe, gastrointestinal health, oral health

292 Bacterial influences on mammalian gut development. R. K. Buddington*, *University of Memphis*, *Memphis, TN*.

The interactions between the gastrointestinal tract (GIT) and the resident bacteria play critical roles in influencing GIT development and the health and nutrition of young mammals and begin at birth when the sterile GIT is colonized by bacteria from the environment, particularly the maternal urogenital tract. Postnatal changes in the bacterial assemblages continue for months and are the result of shifts in dietary inputs, maturation of GIT and host physiology, and interactions among the resident bacteria. The interactions between the bacteria and the developing GIT are evident from the different patterns of GIT gene expression for gnotobiotic and conventional animals. Although postnatal development progresses smoothly for most animals, the overly reactive mucosal immune system of the immature GIT and the unstable assemblages of bacteria increase the risk of adverse and damaging inflammatory responses, such as neonatal necrotizing enterocolitis (NEC). Attempts to identify specific bacteria as causative agents of NEC have been inconclusive. The association of NEC with fermentation of undigested components of the diet and altered proportions of volatile fatty acids suggest bacterial metabolites may be better predictors of NEC risk than species composition. This presentation describes how the development, health, and disease resistance of the GIT are responsive to management of the bacterial assemblages. Antibiotic induced disturbances in the developing assemblages of bacteria can have profound and long-term adverse impacts on the GIT and the host. Encouraging results have been achieved by administration of probiotics to accelerate acquisition of bacterial assemblages that promote health. However, to be effective probiotics must be matched with the unique GIT environment of each host, and perinatal exposure is essential for colonization and long-term persistence. Prebiotics are an alternative that represent metabolic substrates for specific health promoting bacteria and include galactooligosaccharides, fructooligosaccharides and other complex carbohydrates.

Key Words: gastrointestinal, neonatal, infant

293 Microbes and gastrointestinal health of dogs and cats. J. S. Suchodolski*, *GI Laboratory, Texas A&M University*, *College Station*.

Recent molecular studies have revealed a complex microbiota in the canine and feline intestine, compromising several thousand bacterial, fungal, and viral phylotypes. The microbiota plays an important role in the development of the immune system. Studies have demonstrated a microbial dysbiosis in humans, cats and dogs with inflammatory bowel disease (IBD). In humans, the microbiota is implicated as inflammation develops in areas with the highest bacterial counts and antibiotic therapy improves clinical signs in a subset of patients. In rodent models with genetic susceptibility, intestinal inflammation develops only in the presence of bacteria. Current theories for the development of chronic intestinal inflammation favor a combination of environmental factors, the intestinal microbiota, and a genetic susceptibility of the host (e.g., polymorphism in the NOD2/CARD15 in Crohn's disease). New evidence suggests that genetic susceptibility predisposes to infection with enteric organisms. Polymorphisms in specific genes (e.g., interleukin-8, lactoferrin) have been associated with diarrhea in humans. It is suspected that intestinal inflammation causes a dysbiosis toward gram-negative bacteria, perpetuating the disease in genetically susceptible hosts. Most common microbial changes observed in intestinal inflammation are a decrease in the bacterial phyla *Firmicutes* and *Bacteroidetes*, with concurrent increases in *Proteobacteria*. Individuals with intestinal inflammation show a reduced diversity of *Clostridium* clusters XIVa and IV (i.e., *Lachnospiraceae*, *Ruminococcaceae*, *Faecalibacterium prausnitzii*), suggesting that these bacterial groups, important producers of short-chain fatty acids, may play an important role in promoting intestinal health. Similar changes (i.e., reduction in *Clostridium* clusters XIVa and IV) have been observed in dogs and cats with IBD. Boxer dogs with histiocytic ulcerative colitis harbor adherent and invasive *Escherichia coli* (AIEC) that share similarities to AIEC isolates obtained from ileal tissues of humans with Crohn's disease. Underlying genetic susceptibilities are currently an area of intense research in companion animals with chronic enteropathies.

Key Words: 16S rRNA gene, pyrosequencing, IBD

294 The oral microflora and periodontal health in dogs. Z. Marshall-Jones*, *Waltham Centre for Pet Nutrition, Waltham-on-the-Wolds*, *Melton Mowbray, Leicestershire, UK*.

The microbial ecology of the oral cavity is rich with over 500 species estimated to be represented. This diversity may be enhanced by the variety of niches available. Biofilms reside both on the dentition, as dental plaque, and the oral mucosa including the buccal mucosa and the tongue with its undulating papillae providing a range of microenvironments. Salivary microbial populations meanwhile exist in a planktonic niche outside of these biofilm communities.

Studies suggest periodontal disease is the most widespread oral health disease in dogs with between 56 and 80% of dogs estimated to have periodontal disease. Although the specific organisms or processes involved are unclear, the aetiological agent of periodontal disease is considered to be dental plaque. Virulence determinants including enzymes secreted by plaque bacteria are thought to initiate the host immune response, including the activation of host matrix-metalloproteinases, which are the major cause of tissue damage and inflammation. Despite the relatively detailed knowledge regarding plaque formation and the microorganisms associated with disease in humans, the oral microflora in dogs is relatively undescribed. Several studies have assessed the species in the canine oral cavity and detected substantial differences in the oral flora of dogs compared to humans. Studies of canine plaque and saliva have found as little as 28% of organisms identified by 16S rRNA gene sequence are indigenous to the human oral flora. In one such study over half of the taxa cultured were novel species with no similar organisms represented in the GenBank database. The classic human periodontal pathogens, including *Porphyromonas gingivalis, Tannerella forsythensis*, and *Aggregatibacter actinomycetemcomitans* were not detected in canine subgingival plaque. Disparity between *Porphyromonas* isolates from humans and companion animals were initially detected as differences in the catalase activity between human *P. gingivalis* (catalase-negative) and veterinary isolates. The veterinary *P. gingivalis*-like organisms are now thought to represent a related species *Porphyromonas gulae*. The potential of these species in disease causation is however unclear.

295 Using "humanized" mice to study the effect of diet on the human gut microbiome. P. Turnbaugh*, *Harvard University*, *Cambridge, MA*.

Unraveling the interrelationships between diet, energy harvest, and the gut microbial community (microbiota) and its gene content (microbiome) is confounded by large variations in microbial ecology between individuals. We created an animal model of the human gut ecosystem by transplanting fresh or frozen adult human fecal microbial communities into germ-free C57BL/6J mice. Metagenomic analysis of the temporal, spatial and intergenerational patterns of bacterial colonization showed that these humanized mice were stably colonized, and reproduced much of the bacterial diversity of the donor's microbiota. Switching from a low-fat, plant polysaccharide-rich diet to a high-fat/high-sugar "Western" diet shifted the structure of the microbiota within a single day, changed the representation of metabolic pathways in the microbiome, and altered microbiome gene expression. Reciprocal transplants involving various combinations of donor and recipient diets revealed that colonization history influences the initial structure of the microbial community, but that these effects can be rapidly altered by diet. Humanized mice fed the Western diet have increased adiposity; this trait is transmissible via microbiota transplantation. Humanized gnotobiotic mice will be useful for conducting proof-of-principle "clinical trials" that test the effects of environmental and genetic factors on the gut microbiota and host physiology.

Key Words: gut, microbes, diet

Dairy Foods Symposium: Microbiology and flavor of cheese: Impact of Lower Salt-In-Moisture Content of Low Fat and Reduced Sodium Cheeses

296 How model cheese composition, texture and structure influence aroma and salt mobility, release and perception. A. Saint-Eve*, M. Panouille, I. Deleris, C. Trelea, and I. Souchon, *UMR 782 Genie et Microbiologie des Procedes Alimentaires, INRA, AgroParisTech*, *78850 Thiverval-Grignon, France*.

To limit the impact of food on health issues as obesity, hypertension, or coronary diseases, the reduction of salt or fat content in food products without modifications of organoleptic properties remains a real industrial challenge. A better understanding of the mechanisms involved in release and perception could lead to a better formulation of diet dairy products. In this context, model dairy products with different contents of ultrafiltration retentate milk powder, milk fat and rennet were studied to better understand and quantify the role of texture and structure on physicochemical and sensory properties. The characterization of dairy products was performed by sensory methods (profile, time-intensity and temporal dominance of sensations) and by rheological (small amplitude oscillation tests, compression and texture profile analysis), structural (confocal microscopy) and physicochemical methods (determination of aroma and salt partition properties and diffusion coefficients). Salt and aroma releases in mouth (in vivo conditions) were also followed respectively by in-nose measurement (proton transfer reaction-mass spectrometry) or by measuring the evolution of saliva conductivity during consumption. A preponderant effect of fat on aroma and salty perceptions was observed, in agreement with aroma compounds and salt behaviour during in vitro and in vivo measurement.
However, relating sensory perception and food product properties is a complex issue, because of the variety of phenomena occurring in the mouth during consumption (dilution with saliva, break-down during mastication etc.). To identify main mechanisms explaining release in mouth, mechanistic models, based on the description of mass transfer of salt and aroma compounds in the mouth and taking both physiological and physicochemical parameters into account, have been developed. From the predicted release kinetics of stimuli (in agreement with experimental data), the respective roles of physiological parameters and of product properties can be established.

Key Words: modeling, release, flavor

297 Flavor development in low fat cheese. M. A. Drake*, *Southeast Dairy Foods Research Center, North Carolina State University*, *Raleigh*.

Flavor and flavor development in Cheddar cheeses with a fat reduction greater than 50% are markedly altered from full fat cheese. Similar alterations in flavor are noted with sodium reductions below 20%. Both a lack of flavor and the presence of off-flavors are generally noted and these changes are due to differences in flavor release as well as changes in the biochemistry of flavor development. Recent studies have highlighted homofuraneol and phenyl compounds (phenylacetic acid and phenylacetaldehyde) as sources of meaty/burnt/brothy and rosy off-flavors in low fat and reduced sodium cheeses. Concentrations and odor activity values of these compounds increased in Cheddar cheese with increased fat reduction. Addition of sodium gluconate to low fat cheeses decreased levels of these compounds up to 50% but did not impact sensory perception. Decreasing sodium in low fat Cheddar cheeses increased bitterness and aromatic off-flavors but interactions were noted between starter culture and salt concentration suggesting that strain selection would be beneficial for sodium reduction. Collectively, these results confirm the complexity of cheese flavor development and that a combination of approaches will be required to optimize cheese flavor with fat and/or sodium reduction.

Key Words: cheese flavor, fat reduction, sodium reduction

298 Influence of salt-in-moisture on starter and nonstarter lactic acid bacteria. J. L. Steele*[1] and J. R. Broadbent[2], [1]*University of Wisconsin-Madison*, *Madison,* [2]*Utah State University*, *Logan*.

The microbiota of ripening Cheddar cheese consists of the starter lactic acid bacteria (LAB) and non-starter LAB (NSLAB). Starter LAB are intentionally added to milk at the beginning of cheese manufacture, while non starter LAB (NSLAB) are adventitious microorganisms. These organisms have primary roles in the development of cheese flavor. Unfortunately, the mechanisms by which these organisms influence cheese flavor remain, in large part, unknown. This has made the development of cheeses with non-traditional compositions difficult, as it has not been possible to predict how changes in cheese composition would influence cheese flavor development. For example, flavor development in low-fat or low-sodium Cheddar cheeses is consistently troubled by a lack of desirable or characteristic Cheddar flavor, and by the emergence of pronounced undesirable "off-flavors." It is interesting to note that in both of these cheeses with non-traditional compositions the salt-in-moisture level is significantly reduced compared with Cheddar cheese with traditional composition. There are 2 primary hypotheses for how cheese composition can influence the development of cheese flavor: 1) that the microbiota of cheeses with non-traditional composition differs from that of cheeses with traditional composition; 2) that the microbiota is similar in both the traditional and non-traditional cheeses, but that the physiology of the SLAB and/or NSLAB is significantly different and hence they produced significant flavor compounds. Previous research in our groups and other groups worldwide have demonstrated that cheeses with intrinsic properties less restrictive to microbial growth accommodate a wider diversity of NSLAB, supporting the first hypothesis. Research is currently underway to evaluate the second hypothesis.

Key Words: cheese microbiota, cheese flavor, salt-in-moisture

299 Cheesemaking processes and strategies for manufacture of low fat and reduced sodium cheeses. T. P. Guinee* and K. N. Kilcawley, *Moorepark Food Research Centre, Teagasc*, *Fermoy, Co. Cork, Ireland.*

Cheese is a concentrated gelled product that structurally consists of a calcium-phosphate casein/para-casein matrix, enclosing fat and moisture. Both the concentration of the matrix and the level of interaction between the casein aggregates making up the matrix are key determinants of the physical properties. The quality of low fat cheese variants is not as acceptable as that of their conventional full-fat counterparts owing to their higher concentration of protein, higher degree of casein fusion, and unbalanced flavor. Hence, a key strategy in the manufacture of low-fat (<6%) fat cheese is to reduce the volume fraction of the casein matrix and to reduce the extent of casein aggregation. This may be achieved by dilution of the protein matrix on increasing moisture via manipulation of a range of process variables: including inter alia: heat treatment of milk, reduction in pH at rennet addition, gel firmness at cut, curd particle size,

scalding rate, scald temperature, length of time in vat, pH at whey drainage, salting and milling (Cheddar), rate of cheddaring, and pre-salting before plasticization (pasta-filata cheese). The degree of aggregation is particularly influenced by the ratio of denatured whey protein-to-casein, calcium-phosphate to casein, the ionic strength (affected by the level of NaCl and time of salting), and pH. Reducing the contents of fat and salt in cheese adversely affects both the development and release of key compounds associated with cheese flavor. Moreover, it is important to ensure that the ratios of degradation products of protein and fat per gram of protein or fat, respectively, in low-fat, low-salt cheese are altered to convey flavor perception similar to that of cheeses of normal fat and salt content. The regulation of these factors are critically influenced by the type of starter culture, the level and proteolytic activity of the rennet, curd washing, ripening condition, and rate of curd cooling.

Key Words: cheese, low-fat, low-sodium

300 The effect of intrinsic and extrinsic factors on the fate of pathogens in specialty and lower fat/reduced sodium cheese. J. B. Luchansky*, P. M. Tomasula, D. L. Van Hekken, and A. C. S. Porto-Fett, *USDA/ARS Eastern Regional Research Center*, *Wyndmoor, PA*.

Although the United States maintains one of the most abundant and wholesome food supplies in the world, based on the nature and number of recent illnesses and recalls, we should continue to improve our ability to recover, characterize, and control pathogenic microbes in foods, especially for specialty/ethnic products such as lower fat/reduced salt cheese. Pathogens of primary concern would include *Listeria monocytogenes*, Shiga toxin producing *Escherichia coli*, and *Staphylococcus aureus*. Various intrinsic and extrinsic factors can determine whether or not these microbes die, grow, or merely survive in cheese. A variety of biological (e.g., bacteriophage, bacteriocins), physical (e.g., high pressure processing, pasteurization), and chemical (e.g., organic acids, smoke, oxidizing agents) interventions have been used to better manage pathogenic microbes in cheese. However, salt, moisture, and fat content, as well as temperature, quite arguably have the most significant effect on the fate of pathogens in foods. The ability to optimize salt and fat levels to maintain product safety/quality without causing untoward effects on the attendant sensory properties of lower fat/reduced salt cheese will be the focus of this presentation. With a trend toward consumption of cheese that are more convenient, as well as lower in salt, fat, and preservatives, the sole barriers against microbial contamination, persistence, and/or proliferation may be adherence to Good Manufacturing Practices, formulation, and refrigeration, coupled with enhanced awareness.

301 Temperature and vacuum conditions for removal of added carbon dioxide from milk. D. M. Barbano* and J. H. Hotchkiss, *Cornell University*, *Ithaca, NY*.

Our objective was to determine the temperature and vacuum relationships for efficient removal of added CO_2 from raw milk. Added CO_2 in milk and dairy products inhibits the growth of spoilage organisms during refrigerated storage and shipping. As milk and milk concentrates are shipped over longer distances, the use of CO_2 is becoming more common to maintain raw milk quality. In most cases, some or all of the CO_2 needs to be removed from the milk before further processing. Raw milk before CO_2 addition typically contained about 100 to 200 ppm CO_2 and had a pH of about 6.9 at 4°C. In the present study, about 1600 kg of 4°C raw milk was continuously injected with CO_2 with a holding time of 15 s at 172 kPa to achieve a concentration of 2000 ppm. Milk containing added CO_2 was stored at 4°C for 24 h before initiating the CO_2 removal process. The cold milk containing CO_2 was pumped through a plate heat exchanger at 24.5 kg/min directly into the spray nozzle inlet of a pilot-scale APV vacuum deaerator system equipped with a spray nozzle that produced a cone shaped spray pattern into a vacuum chamber. Six different milk temperatures (51.5, 57.5, 63, 68, 74, and 79.5°C) and 5 different vacuum levels at each temperature (in the range of 621 to 1293 mmHg Torr) were evaluated. The CO_2 content (Mocon CO_2 analyzer) of milk and milk pH were measured for each treatment and control milk. The experiment was replicated 3 times with a new milk source each time. The CO_2 content of milk decreased and pH increased with increasing temperature and vacuum. As temperature increased, less vacuum was required to achieve complete CO_2 removal. Milk pH was highly correlated with CO_2 removal and pH can be used as a rapid measurement method to determine if CO_2 removal is near completion. A linear regression model (r-square 0.98) was developed that defines the relationship between temperature and vacuum required to reduce the CO_2 content of the milk to a level not significantly different form the milk before CO_2 addition.

Key Words: carbon dioxide, pH, vacuum

302 Processing factors that influence casein (CN) and serum protein (SP) separation by microfiltration (MF). E. E. Hurt* and D. M. Barbano, *Cornell University*, *Ithaca, NY*.

Our objective was to demonstrate the impact of skim milk composition, heat treatment of skim milk, concentration factor (CF) and diafiltration factor (DF), control of CF and DF, and SP rejection by the membrane on the performance of a MF system designed to process skim milk to separate CN from SP. A mathematical model of a skim milk MF process was developed with 3 stages, plus a 4th stage to standardize the micellar CN concentrate (MCC) to 9% true protein (TP) and allow calculation of yield of MCC (liquid, 9% TP) and milk SP isolate (MSPI) (90% SP on a dry basis). The model predicted the effect of the 5 factors on: retentate and permeate composition, SP removal, and MCC and MSPI yield. When the TP of skim milk increased from 3.2 to 3.8% MCC and MSPI yield increased by 19% and 18%, respectively. Increased heat treatment (73 to 85°C) of skim milk caused CN as a percentage of TP in skim milk as measured by Kjeldahl analysis to increase from 82 to 86% and the yield of MSPI to decrease by 22%. A CF and DF of 2X gave a 3rd stage retentate TP concentration of 5.38% compared to 13.13% for a CF and DF of 5X and 3rd stage cumulative SP removal increased from 89 to 99%, respectively. Variation in the balance between CF and DF (instead of equal CF and DF) caused a progressive increase or decrease in TP concentration in each stageâ€™s retentate depending on whether CF > DF (increasing TP in retentate) or CF < DF (decreasing TP in retentate). Increased rejection of SP by the membrane from a SP removal factor of 1 to 0.6 caused a 17% reduction in MSPI yield and 3rd stage cumulative SP removal decreased from 97 to 80%. Within the ranges of the factors studied, the TP content of the 3rd stage retentate was most strongly impacted by the target CF and DF and skim milk composition. Cumulative SP removal was strongly impacted by heat treatment of skim milk, SP removal factor, and target CF and DF. Yield of MCC and MSPI was strongly impacted by skim milk composition. Yield of MSPI was also impacted by the heat treatment of milk and SP removal factor.

Key Words: microfiltration, serum protein

303 Multistage process with ceramic graded permeability (GP) microfiltration (MF) membranes to produce high casein content micellar casein concentrate (MCC) with low lactose. J. Zulewska*[2], M. W. Newbold[1], and D. M. Barbano[1], [1]*Cornell University*, *Ithaca, NY,* [2]*University of Warmia adn Mazury*, *Olsztyn, Poland*.

The objective was to determine if 0.1 μm Membralox GP membranes perform differently than 0.1 μm Membralox uniform transmembrane pressure (UTP) membranes. The 4th, 5th and final stage were run as finishing stages with purpose of lowering the lactose content of the final retentate to < 0.2% and adjusting the final protein concentration to > 9%. Raw milk was cold (4°C) separated and then the skim milk was pasteurized (72°C, 16 s) and microfiltered (320 kg) in a continuous bleed-and-feed 3X process using 0.1 μm ceramic GP membranes at 50oC. The retentate from stage 1 was diluted with pasteurized reverse osmosis (RO) water in 1:2 ratio and microfiltered (stage 2) with GP system. This was repeated 3 more times with total 5 stages (Stage 1 = MF; Stage 2 to 5 = diafiltration (DF)) of processing. To bring the protein content of the retentate to at least 9%, the final retentate from stage 5 was microfiltered using the same membrane at 1.75X CF without addition of RO water. The experiment was replicated 3 times. Data for the UTP system were obtained in a separate experiment from the GP data. Flux was significantly higher in GP than UTP system (72.5 vs. 54.0, 84.5 vs. 54.0, 92.7 vs. 54.6 kg/m^2 per hour in 1st, 2nd and 3rd stages for GP and UTP, respectively). The average retentate recirculation flow for GP and UTP were 714 and 644 L/min, respectively. The SP removal was higher in 1st stage of the UTP system than GP (63.7 vs. 56.0 for UTP and GP, respectively) with 2nd and 3rd stage being higher for GP system (26.7 vs. 21.9%, 13.8 vs. 9.7%, respectively). No difference in cumulative percentage of SP removal was detected for GP and UTP membranes, 96.5 and 95.2%, respectively. GP membranes had higher SP removal rate (kg/m^2 per hour) for 3 stages than UTP membranes: GP 0.69 and UTP 0.46 kg/m^2 per hour. Final retentate contained 0.09% lactose and 9.82% of crude protein.

Key Words: microfiltration, graded permeability, micellar casein concentrate

304 Functional modification of whey protein concentrate by microfiltration. H. Somni* and V. V. Mistry, *Midwest Dairy Foods Research Center, South Dakota State University*, *Brookings*.

Microfiltration (MF) (0.1 μm) of raw milk results in a permeate stream (MFP) with composition similar to cheese whey. The objective of this study was to compare ($P \leq 0.05$) the functional properties (gelation,

emulsion, and foaming) of whey protein concentrate (WPC) obtained from different sources. Clarified Cheddar cheese whey was pasteurized and split into 2 parts (3 replications); one part was ultrafiltered (UF) to 10X concentration and spray dried (CWPC), remaining was MF (0.1 μm) before process like CWPC (DWPC). MWPC was manufactured from MFP by UF and spray drying similar to CWPC and DWPC except that none of the stream was pasteurized (4 replications). The moisture, protein, fat, and ash content were, respectively, 6.4, 34.8, 2.8, and 5.4% in CWPC, 7.2, 37.2, 1.4, and 5.6% in DWPC, and 6.6, 48.7, 1.6, and 4.5% in MWPC. Gelation measured as 'least concentration endpoint' was lower for CWPC and DWPC. Emulsion stability of DWPC (1.3%) and MWPC (1.6%) was lower than CWPC (5.4%). While CWPC failed to produce stable foam, the overrun of DWPC (1059.7%) was higher than MWPC (952.7%). However, the foam stability after 30 min for MWPC (51%) was higher than DWPC (29%). Thus, the functional properties of WPC were different. In addition, protein solutions of DWPC and MWPC in water were devoid of turbidity unlike WPC manufactured by conventional process. Such differences are caused by major and minor compounds like glycomacropeptide (GMP), minerals, and MFGM associated compounds like phospholipids and lipoproteins. While some of these compounds like MFGM associated compounds could be removed by MF and removal of minerals depends on their state, substances like GMP are not removed by MF alone. Such compounds affect the functional properties. Microfiltration also improves shelf stability of products by removal of microorganisms and suspended matter. This opens an avenue for WPC in beverage application.

Key Words: microfiltration, whey protein concentrate, functional properties

305 Ultrafiltration of milk at high temperature. M. Lewis*, A. Grandison, N. On-Nom, and D. Wang, *University of Reading*, *Reading, Berkshire, UK*.

UF of milk has been performed at temperatures between 30 to 120°C to examine the effects on mineral partitioning, permeation rate (PR) and membrane fouling. Experimental protocols were developed to measure PR and fouling of membranes at different temperatures over a period of 40 min for milk UF, followed by water rinsing for 5 min. These initial UF runs were replicated 3 times. It was found that pH, ionic calcium and soluble calcium decreased in permeates, as temperature increased, whereas freezing point depression increased. Similar trends were found when milk was dialyzed at similar temperatures. The initial PR increased as UF temperature increased up to 100°C, but rapid PR decline was observed at 80 and 100°C. In contrast, at 50°C there was no noticeable decline in PR over a 40 min period. After about 20 min, PR was higher at 50°C compared with 80°C and it was even lower at 100°C, suggesting more severe membrane fouling at higher temperatures. When average PR was measured over a period of 30 min between 50 and 80°C, it was found to increase to a maximum at 60°C and declined thereafter. During water rinsing, PR recovered much more quickly at 50°C, compared with 80 and 100°C. Ultrafiltration at high temperature is a useful tool for measuring pH and ionic calcium of milk at high temperatures and showed that pH and ionic calcium of milk were highly temperature dependent. In contrast, the properties of permeates produced at high temperature, showed little change of pH and ionic calcium with temperature, but only at temperatures below that which they had been separated by UF. Measurement of pH and ionic calcium at high temperatures will permit a better understanding of their role in heat stability of milk.

Key Words: ultrafiltration, pH, ionic calcium

306 A method for spirulina production using cheese whey. K. M. Miranda[1,2] and L. M. Fonseca*[1], [1]*Federal University of Minas Gerais*, *Belo Horizonte, MG, Brazil*, [2]*Fundação Centro Tecnológico de Minas Gerais*, *Belo Horizonte, MG, Brazil*.

Cheese whey is a product with high nutritional value. However, because of processing costs in several countries it has limited use in the dairy industry. The objective of this work was to evaluate the use of cheese whey as an alternative media for spirulina production. spirulina (*Arthrospira platensis*), a blue-green algae used as a supplement and as whole food, has a protein content of up to 70% in the dry matter. One of the media used for spirulina production is the Zarrouk media. For this experiment, cheese whey reconstituted to 3g/100mL and 6g/100mL was clarified by heating and centrifugation, and the pH corrected to pH 9.0. Samples containing 500 mL of whey, clarified or not, were inoculated with 0.1 g/L and 0.2 g/L of spirulina and submitted to alternated 12-h photoperiod (3.0 Klux) at 25°C, during 10 d. The experiment was repeated in 5 batches. The algae growth was monitored by turbidimetry (560nm). After growth, the material was filtered, washed, pressed, and dried (50°C/8 hours). The biomass final composition was analyzed using standard methods, and the results submitted to analysis of variance. Spirulina did not grow well in non-clarified cheese whey, due to turbidity and low light transmittance through the medium. The maximum growth of spirulina was obtained with clarified cheese whey reconstituted to 3g/100mL with production of up to 1.83 g of spirulina for 1000 mL of medium. This production was reached in the sixth day, and was approximately 80% higher when compared to standard Zarrouk media. It is concluded that spirulina production using cheese whey is a feasible and low cost method, with higher production when compared to the standard industrial media. However, because of turbidity, a clarification step is necessary.

307 Investigation on coagulant properties of *Calotropis procera* and stabilization of its proteolytic enzymes. G. Belvedere[1], F. La Terra[1], M. Manenti[1], S. Lortal[2], J. C. Codjia[3], S. Doko[4], and G. Licitra*[1,5], [1]*CoRFiLaC, Regione Siciliana*, *Ragusa, Italy*, [2]*UMR Science et Technologie du Lait et de L'Oeuf*, *Rennes Cedex, France*, [3]*University of Abomey-Calavi*, *Benin*, [4]*University of Parakou*, *Benin*, [5]*DACPA, Catania University*, *Catania, Italy*.

Coagulant properties present in the latex extracted from *Calotropis procera* (fam. Asclepiadaceae) are well known. This extract is used by Peuhl community in Benin to produce Wagashi, a cheese known in West African states. From literature it is known that a wide number of chemical compounds were extracted, including cardiac glycosides, flavonoids, phenol compounds, terpenoids, and 2 proteolytic enzymes: calotropain FI and calotropain FII. Proteolytic enzymes that are present in the latex of *Calotropis procera* undergo easily oxidizing phenomena and for this reason their activity declines after 1 or 2 d. The aim of this study was to investigate whether the proteolytic enzyme present in *Calotropis procera* is the only factor influencing milk coagulation, and finally if it can be stabilized. The extract from Calotropis was autoclaved at 100°C to denaturate the proteolytic enzyme used for the milk coagulation. Its gelation activity was also verified. Several trials on the stabilization of the proteolytic enzyme, which contained active sites of cystein, were performed using extract from potato or natural flour from tapioca, gari, carob gum, and an antioxidant compound rich in cystein, glycin, and glutamic acid. The best results were obtained

with extract from potato tuber and the antioxidant compound. Results showed clearly that the coagulation process of milk was exclusively enzymatic. The proteolytic enzymes calotropain FI and calotropain FII present in *Calotropis procera* were stabilized successfully for several months and preserved their proteolytic activity in both types of trials. This would allow in the future to have a proteolytic enzyme readily available to produce Wagashi cheese in a traditional way.

Key Words: Wagashi cheese, proteolytic enzymes, *Calotropis*

308 Quality of raw and pasteurized milk (invited Pioneer speaker, 30 min presentation). C. H. White*[1,2], [1]*Mississippi State University*, *Mississippi State,* [2]*Randolph Associates, Inc.*, *Birmingham, AL*.

Milk must be safe and of high quality. Fortunately, high quality milk is normally safe, especially by microbiological standards. The definition of high quality milk must encompass the various pertinent standards and testing protocols. While raw milk is being sold to consumers under certain conditions in some states, from a microbiological standpoint this practice is questionable. Raw milk is considered by some to have more cheese flavor than cheese made from pasteurized milk. Is this a safe and reasonable practice even though it may result in a delicious cheese? Raw milk quality also impacts the shelf-life of pasteurized milk. The shelf-life is the length of time milk retains desirable sensory properties at a specified temperature. In the past 50 years, the shelf-life of commercial pasteurized milk has increased from 3 or 4 d at 7°C to 21 or more days. Extended shelf-life milk, as well as, ultra high temperature (UHT) milk can last for many weeks (even under non-refrigerated conditions for UHT products). How do dairy processing plants determine a products shelf-life? What are the key factors affecting this shelf life? Beneficial bacteria, such as certain member of the genera *Lactobacillus* and *Bifidobacterium* are routinely added to selected fluid milk for the nutritional well being of the consumer. These bacteria are thought to aid in the digestive processes and are believed to prevent or at least combat various diseases. These bacteria at least help to ensure a healthy microflora in the gut, a most desirable situation. What then is the overall quality of pasteurized milk? How is this quality determined? Does the dairy industry have enough new workers entering the field to ensure this quality? The dairy industry, in general, has well trained people producing the milk, and is fortunate have a dairy processing industry that been at the foundation of our food supply.

Key Words: milk quality, shelf-life, raw milk

Growth and Development Symposium: Intestinal Development and Growth

309 Strategies to alter intestinal development, health and function of poultry to improve growth performance. T. J. Applegate*, *Purdue University*, *W Lafayette, IN*.

The gastrointestinal tract (GIT) in chickens, turkeys and ducks is a dynamic organ system. During early posthatch growth, there is a tremendous energetic allocation to GIT growth. While most research has focused on ontogenic changes to nutrient transporter and/or enzyme production, the structural aspects of intestinal maturation often is not studied in tandem, which may be more limiting to growth. Similarly, researchers often use simple morphometric measures of intestinal structure (villus height, crypt depth, goblet cell numbers). However, these crude measures may not be as reflective of enterocyte proliferation, migration, apoptosis, and necrosis. Remarkably, the turnover of the bird′s intestine ranges from less than 2 to over 5 d, but our knowledge of what factors affect cell cycle and functionality are largely lacking in poultry. Recent work has noted that appearance of indigestibility by the young bird is due in part to changes in the pH of the proventriculus and endogenous secretion differences. For example, 60 to 80% of the apparent digestibility differences in amino acid utilization during the first week and later in life are due to differences in basal endogenous amino acid losses. Recent research has also focused on the maintenance needs of the intestine, particularly as it relates to preserving its barrier functionality with or without sub-therapeutic antibiotics. The GIT barrier is far from being static and responds to many challenges through changes to: a) peristalsis, b) enterocyte turnover, c) mucin production, adaptation of commensal microflora, d) innate immune responsiveness (including inflammation and acute phase response), and/or e) alterations to secretions. The extent and duration of each of these responses encompasses the nutrient and growth cost for maintenance of this barrier function. While most antibiotic replacement strategies are not capable of similar physiological and microbiological responses, some probiotic bacteria and plant extracts are able to modify mucin production, preserve intestinal tight junctions and enterocyte cell cycle, as well as alter inflammatory responses within the intestine.

Key Words: intestine, poultry

310 Nutritional support of intestinal health: Insights from a piglet model. J. Odle*, S. K. Jacobi, A. J. Moeser, and A. T. Blikslager, *North Carolina State University*, *Raleigh*.

Early postnatal morbidity and mortality of mammalian neonates represent significant challenges to the agricultural and medical sciences. While many stressors impinge on the newborn, gastrointestinal maladies predominate. This is not surprising given the quiescent state of the intestine in utero and the rapid ontogeny that ensues following birth. Furthermore, the intestinal mucosa, initially sterile, must be protected from viral and bacterial pathogens that are ubiquitous in the postnatal environment. Because the intestine is a "supply organ," overall vitality of the neonate hinges on its proper function. Our studies have employed rotaviral-gastroenteritis and ischemic-injury models to examine the effects of various nutrients on intestinal restitution and recovery. We have been unable to measure beneficial effects of enteral glutamine or alanyl-glutamine. However, supplemental arginine increased intestinal protein synthesis via mTOR signaling, increased crypt depth, and improved transepithelial resistance (TER). Supplemental plasma-protein also effectively abrogated gastroenteritis following rotaviral challenge. Most recently we investigated prophylactic intervention with dietary long-chain polyunsaturated fatty acids using an ischemic-injury model. Arachidonic acid (ARA) reduced initial villus denudation and accelerated acute restitution, measured as increased TER. Restitution effects of ARA were attenuated by indomethacin, suggesting possible prostaglandin mediation. Our collective findings suggest positive (but modest) effects of selected nutrients on intestinal repair. Further research is needed to understand better the complex interplay between nutrients, growth factors, immunological, and bacterial determinants which impact intestinal health and ultimately neonatal vitality.

Key Words: rotavirus, arachidonic acid, arginine

311 Integral role of the gut in growth signal transduction between the environment and host. D. G. Burrin*, *USDA Children's Nutrition Research Center, Department of Pediatrics, Baylor College of Medicine, Houston, TX.*

The gut epithelium serves as a vital biological interface between the environmental microbiota, luminal dietary factors and the mammalian host. The function of the gut barrier is especially critical during early neonatal development and weaning when the diet changes markedly and the immune system is immature in rapidly growing animals. In addition to functioning as a physical barrier, the gut epithelium contains specialized cells and receptors that serve to recognize specific molecules derived from the diet and microbes. The enteroendocrine cell comprises a small proportion (<5%) of gut epithelial cells, but their effects are magnified via release of several hormones that positively impact animal growth and development. The endocrine L-cell is capable of sensing multiple luminal molecules, including glucose and bile acids that trigger the secretion of gut hormones, such as glucagon-like peptide 1 and 2. These 2 hormones have an important stimulatory effect on insulin secretion, insulin sensitivity, glucose absorption and gut epithelial growth. Recent studies also have show that bile acids taken up by enterocytes can activate the nuclear receptor, farnesoid X receptor (FXR), stimulating the release of fibroblast growth factor 19 (FGF19). FGF19 functions as a hormone that alters hepatic lipid metabolism and bile acid homeostasis. In addition to nutritionally significant molecules, the gut epithelium also senses the presence of the microbiota through toll-like receptors (TLR) that transmit signals to the underlying cells within the immune and neuroendocrine systems. The activation of TLR by bacterial products can result in negative feedback on key elements of growth, such as appetite, gut motility, and anabolic hormone signaling. The presentation will discuss the essential role of the gut in novel aspects of these growth signal transduction pathways in the developing animal.

Key Words: glucagon-like peptides, bile acids, toll-like receptors

312 Nutrient transporters in support of ruminant growth and development: novel and updated findings. J. C. Matthews*, *University of Kentucky*, *Lexington*.

This literature review summarizes recent findings in cattle (primarily) about urea, SCFA, thyroid hormones, amino acid, and calcium transporters. In ruminants, the relationship between diet and urea cycling is complex. Expression of urea transporter-B (UT-B; SLC14A1) is upregulated throughout the rumen in response to high vs low concentrate diets, but apparently not increased levels of rumen ammonia. In growing lambs, the relative tissue content of UT-B in gastrointestinal tract epithelia, liver, kidney, and parotid salivary glands, was not affected by varying dietary CP. Monocarboxylate transporters (MCT) 1 (SLC16A1) and 4 (SLC16A3) are expressed throughout the ruminant gastrointestinal

tract and are likely responsible for the absorption of SCFA across these tissues, especially the rumen. However, a recent finding suggests that at least rumen tissue content of MCT4 mRNA and fractional rate of SCFA absorption appear insensitive to increased rumen fluid SCFA concentrations in cattle fed high vs low concentrate diets. Regarding the fate of absorbed ruminal SCFA during lactation, the cellular localization of MCT1 and 4 in the mammary gland of lactating Holsteins has been identified, along with a thyroid hormone transporter (MCT8, SLC16A2), and the aromatic amino acid transporter TAT1 (SLC16A10). In Belgian Blue cattle, association mapping has identified a mutation in the neuronal glycine transporter GLYT2 (SLC6A5) that leads to a decrease in presynaptic accumulation of glycine and is likely the cause of congenital muscular dystonia 1. Similarly, a mutation in $Ca2^{+}$ATPase (ATP2A1) results in decreased cytosolic $Ca2^{+}$, thus impaired fast-twitch muscle function. In summary, several recent and important findings have been made in delineating existing relationships between nutrient transporter expression and specific physiological states of cattle. When combined with results of additional functional capacity studies, these findings will lead to a greater understanding of ideal physiological conditions required to support optimal nutrient use by cattle.

Key Words: biological transport, nutrient-gene interaction, SLC

313 Out of the black box and back to the future: New frontiers and challenges for rumen microbiology to advance animal growth and development. M. Morrison*[1,2], [1]*CSIRO, St. Lucia, Queensland, Australia*, [2]*The Ohio State University*, *Columbus*.

Ruminant microbiology has been studied for more than a century, initially via microscopic examinations of rumen fluid providing morphological and compositional descriptions of the microbiota. Cultivation techniques for obligate anaerobes were developed in the mid-20th Century, and the principal way of studying rumen microbiology shifted, to culture and isolate as many species as possible then study select physiological processes. In the late ‘80s and ‘90s, with the development of tools such as PCR, and the application of reverse transcriptase and DNA polymerases, the field of rumen microbial ecology was transformed to a largely cultivation-independent field of inquiry, using 16S rRNA and/or the gene encoding that molecule as a semantide. During this period, recombinant DNA technologies also made an impact on the field of rumen microbiology, principally via a level of reductionism that provided deeper knowledge about fewer rumen microbial interactions and processes. In the first decade of the 21st Century, microbial biology has advanced from the sequencing of individual genomes, to comprehensive assessments of microbial diversity and the genetic potential resident within entire microbial communities. This has been driven largely by the appreciation that culturable microbes represent only a small percentage of the microbial world and advances in high throughput sequencing technologies. As such, there has been a renewed interest in the interrogation of rumen and other gut microbiomes via (meta)genomic approaches. So, are these efforts resulting in more of the same, or something “new” in relation to our understanding of the microbial biology underpinning rumen function, nutrient availability, and animal growth and development; and from which, new opportunities might emerge? This presentation will examine some of the latest observations and findings arising from the study of individual rumen bacteria, as well as rumen microbiomes. The field of rumen microbiology still has something to offer the animal industries, as well as other sectors of science and industry.

Key Words: rumen microbiology, growth and development, microbial genomics

314 The human intestinal microbiome—Applications to animal agriculture. D. N. Frank*, *University of Colorado*, *Boulder*.

Advances in DNA sequence-based technologies now permit genetic analysis of complex microbial populations without the need for prior cultivation. My talk will summarize the molecular methods of culture-independent microbiology (“metagenomics”) as exemplified by their application to studies of the human gastrointestinal tract in both health and disease. Such culture-independent metagenomic surveys reveal unprecedented microbial biodiversity in the human intestine. Large-scale shifts in gut commensal populations (“dysbiosis”), rather than occurrence of particular microorganisms, are associated with several gastroenterological conditions, including antibiotic-associated diarrhea, Crohn’s disease, ulcerative colitis, and obesity. These findings demonstrate the importance of commensal microorganisms in maintaining GI health and suggest that redress of disease-associated imbalances may ameliorate human pathogenic conditions. Metagenomic techniques are readily applicable to animal agricultural science and are likely to provide important new microbiological perspective, as they have in human biomedicine.

Key Words: microbiome

Lactation Biology Symposium: Novel Mechanisms Regulating Milk Secretion and Mammary Involution

315 High fat diet suppresses de novo fatty acid synthesis in mammary epithelial cells independent of SREBP regulated gene expression. S. M. Anderson*, M. C. Rudolph, E. A. Wellberg, and M. C. Neville, *University of Colorado School of Medicine*, *Aurora*.

The lipid component of milk is an important energy source and a critical nutrient for proper development of the newborn. The lactating mouse secretes her entire body weight in fat during a normal lactation period. Fatty acids in milk triglyceride are blended from preformed sources (dietary and adipose stores), and de novo synthesized fatty acids. Factors that control lipogenic differentiation of mammary epithelial cells have not been identified. Gene expression profiling has identified potential controller genes including SREBP1c, Src, Spot14 (THRSP), Akt1, and the long form of the prolactin receptor. Metabolic genes that increase at parturition include the glucose transporter GLUT1, citrate synthase (CS), malic enzyme 1 (ME1), citrate transporter (SLC25a1), ATP citrate lyase (ACLY), acetyl-CoA carboxylase 1(ACC1), fatty acid synthase (FASN), and stearoyl-CoA desaturase 2 (SCD2). SREBP1c regulates transcription of several of these genes in the liver; however, SREBP1c knockout mice do not display a lactation defect. Mice deficient in SCAP (SREBP Cleavage Activation Protein) have a significant lactation defect characterized by a 25% decrease in de novo synthesized fatty acids in milk and a 50% decrease in pup growth. Expression of FASN, Insig1, SLC25a1, and SCD2 in mammary epithelial cells is reduced, but there is no change in ACC1 and ACLY. This suggests SREBP-dependent and -independent regulation of lipid biosynthetic enzymes in mouse mammary epithelium. To compensate for loss of de novo fatty acid biosynthesis in SCAP null dams, we fed them a high fat diet (45% kCal). Although pup growth improved, lactation competency was not restored completely. Interestingly, the mRNA levels of ACC1, ACLY, FASN, SCD2, and SLC25a1 did not change, but the protein levels of ACC1, ACLY, and FASN were significantly reduced. This implies post-transcriptional regulation of fatty acid biosynthetic enzymes in mammary epithelial cells in response to dietary fat, rather than at the transcriptional level. Current efforts are focused upon understanding aspects of this post-transcriptional regulation in mammary epithelial cells.

Key Words: lactation, triglyceride, SREBP

316 Serotonin: A homeostatic regulator of bovine lactation. N. Horseman*, *University of Cincinnati*, *Cincinnati, OH*.

Serotonin, a central neurotransmitter and peripheral hormone, was discovered in the mammary glands of mice using molecular genetic and gene expression profiling approaches. Physiological studies demonstrated that serotonin functions as a homeostatic regulator in the mouse mammary gland. Studies in human and bovine mammary gland experimental systems permitted us to generalize that serotonin is a conserved homeostatic regulator of lactation among mammals. Based on a foundation of basic science that has elucidated fundamental physiological, cellular, and molecular aspects of serotonin signaling in lactation, we have embarked on a variety of studies to understand the practical implications of serotonin signaling in human and bovine lactation, and in breast cancer. An extraordinary variety of drug targets and non-drug interventions can selectively impact serotonin signaling, providing a rich resource for modifying mammary gland cell functions.
This project was supported by National Research Initiative Competitive Grant no. 2009-35206-05178 from the USDA Cooperative State Research, Education, and Extension Service.

Key Words: serotonin

317 Stanniocalcin-1 and local control of mammary involution. P. Lacasse*, *AAFC-Dairy and Swine R&D Centre*, *Sherbrooke, QC, Canada*.

Stanniocalcin-1 (STC-1) is a hormone that was first identified in fish and recently in mammals. In euryhaline teleost fishes, gill calcium uptake is decreased by STC-1, an action opposed by prolactin. In mice, some evidence suggests that STC-1 is implicated in lactation. Indeed, STC-1 is only detectable in blood during gestation and lactation, wild-type pups suffered growth retardation when fed by transgenic mothers overexpressing human STC-1, and passive immunization against STC-1 induced an alteration of milk composition and caused growth retardation of pups. Therefore, we have initiated a research program on the role of STC-1 in the regulation of bovine lactation. We have first demonstrated that injections of estradiol to lactating cows, while reducing milk production, increased the expression of STC-1 by the mammary cells and increased by several fold the concentration of STC-1 in milk. In a second experiment, we have measured STC-1 levels in blood and milk during lactation. We found that, as lactation progressed, STC-1 concentrations increased in milk but not in blood. In another experiment, cows were milked differentially for 8 wk, with half of the gland milked 1X and the other half milked 3X daily. Milk production and lactation persistency were greater in the udder half milked 3X while indicators of mammary involution, such as milk BSA and proteinase activity, increased in the udder half milked 1X. Milking 1X caused an increase in milk concentration of STC-1, an effect that persisted beyond the treatment period. Using unilateral milking, we have investigated the role of STC-1 during involution. Milk STC-1 concentration increased in the unmilked quarters and was correlated with milk proteinase activity and BSA. Mammary epithelial cells cultured in the presence of milk from the involuting quarters had more apoptotic cells and a reduced metabolic rate as compared with those cultured in milk from the milked quarters. Interestingly, the metabolic rate was negatively correlated with the STC-1 concentration in milk. These results suggest that STC-1 is implicated in the progression of involution. Nevertheless, more research will be needed to determine the target and function of this hormone.

318 The role of Ca^{2+}-ATPases in milk secretion and involution. T. A. Reinhardt*, *National Animal Disease Center, ARS/USDA, Ames, IA*.

The means by which calcium is transported into the milk is a poorly understood process. An older hypothesis is that calcium arrives in milk via exocytosis of secretory products from the Golgi pathway. This is consistent with more recent data showing that the secretory pathway Ca^{2+}-ATPases (SPCA1 and 2), are induced in lactating mammary tissue. However, greater expression of the plasma membrane Ca^{2+}-ATPase isoform 2bw (PMCA2bw) occurs during lactation. PMCA2bw expression is more strongly correlated with increases in milk calcium secretion and PMCA2bw's apical location suggested that calcium might be secreted directly into milk via this pump. This hypothesis was confirmed by examining calcium secretion in PMCA2 gene knockout mice compared with wild type controls. Milk from PMCA2-null mice have 60% less calcium than milk from wild-type mice. Total milk protein concentration was lower, and an indirect measure of milk production (litter weights) suggested that the PMCA2-null mice produce significantly less milk. These data demonstrated that PMCA2bw is required for maximal milk production and secretion of much of the calcium in milk. This major secretory function represents a novel biological role for the PMCA's, which were previously regarded as premier regulators of intracellular

Ca^{2+} for cell signaling and general fine control of cell calcium homeostasis. The data available to date suggest that calcium transport into milk involves both the Golgi secretory pathway via the activities of SPCA1 and 2 as well as a major role for the apical pathway via PMCA2. It follows that lactating mammary cell calcium homeostasis is maintained by the high expression of PMCA2, SPCA1 and 2. Within 24 h after abrupt cessation of lactation, PMCA2 and SPCA1 and 2 expression decreased 80–95%. The abrupt loss of Ca^{2+}-ATPases, required by the mammary gland to maintain cell calcium homeostasis, could lead to accumulation of cell calcium, mitochondria Ca^{2+} overload, calcium mediated cell death and thus may play a part in early signaling of mammary involution.

Key Words: mammary calcium transport, Ca^{2+}-ATPase, involution

319 Effect of vitamins E and C on collagen turnover by bovine intramuscular fibroblasts. A. C. Archile*[2,1], I. B. Mandell[1], S. P. Miller[1], M. C. Cha[1], and P. P. Purslow[1], [1]*University of Guelph*, *Ontario, Canada*, [2]*University of Zulia*, *Maracaibo, Venezuela*.

Intramuscular collagen contributes to the variation in background toughness of meat. Vitamin E may reduce intramuscular collagen maturity, while vitamin C has been reported to improve meat texture in beef. The objective of this study was to investigate whether vitamins E and C are able to regulate collagen turnover in bovine intramuscular fibroblasts, the cells responsible for its synthesis and degradation by secretion of matrix metalloproteinases (MMPs). Fibroblasts were isolated from *longissimus dorsi* (LD) and *semitendinosus* (ST) muscles from a yearling animal and grown in DMEM + 10% FCS. Fibroblasts were treated with vitamins E and C for 24 h as follows: 1) with 50 or 100 μ*M* of vitamin E, 2) 50 μ*M* of vitamin C, 3) either 50 μ*M* vitamin E+50 μ*M* vitamin C, or 100 μ*M* vitamin E+50 μ*M* vitamin C. Control cells received no vitamins. After treatment for 24 h, media were collected and analyzed for MMP-2 activity by zymography. Cell lysates were tested for total collagen synthesis (TC) using the Sircol assay. Data were analyzed by 2-way ANOVA, Fisher's LSD and Pearson bivariate correlation. Vitamins E and C each increased ($P < 0.05$) the activity of MMP-2 secreted by fibroblasts from both muscles, but the effect was stronger ($P < 0.05$) in cells derived from LD than from ST. A synergistic effect between vitamins E and C on MMP-2 activity was observed for cells from both muscles. Both vitamins increased TC in cells from both muscles above the controls to a different extent; higher TC values ($P < 0.05$) were found for ST cells versus LD cells. There was a strong positive correlation ($P < 0.05$) between MMP-2 activity and TC synthesis. These results confirm the hypothesis that both vitamins may increase collagen turnover in intramuscular fibroblasts, which could have direct implications for the response of these muscles to the animal's diet, affecting collagen turnover in vivo. A high rate of collagen turnover may lead to increased collagen solubility in muscles which can affect meat tenderness.

Key Words: vitamins E and C, collagen turnover, meat tenderness

320 Fatty acid composition of Jersey beef was affected by finishing diet and tissue type. T. Jiang*[1], C. J. Mueller[2], J. R. Busboom[1], M. L. Nelson[1], J. O'Fallon[1], and G. Tishida[2], [1]*Washington State University*, *Pullman,* [2]*Oregon State University*, *Corvallis*.

Our objective was to determine the impacts of finishing diet energy level and tissue type on fatty acid composition and palatability of Jersey beef. Steers (n = 20) were assigned to a randomized complete block (RCB) design with initial weight as blocks (Light, 228.0 vs. Heavy, 261.4 ± 0.4 kg) and finishing diet (70 vs. 85% corn) as treatments. Ribeye steaks were collected for sensory evaluation and were dissected to obtain muscle, seam, and subcutaneous (s.c.) fat. In addition, fat samples were collected from s.c. tissue (BF), kidney (KPH), and the intestinal tract (VIS). Data for fatty acids and sensory evaluation were analyzed as a split-plot design and a RCB design, respectively. Saturated fatty acid (SFA) level was lower ($P < 0.05$) and monounsaturated fatty acid (MUFA) was higher ($P < 0.05$) in s.c. fat than in muscle or seam fat, which could be explained by higher ($P < 0.05$) myristoleic and vaccenic acid levels in s.c. fat. Oleic acid (C18:1) level was higher ($P < 0.05$) in s.c. fat than in seam fat, accompanied by a higher ($P < 0.05$) Δ9 desaturase index in s.c. fat. Trans fatty acid (TFA) and CLA levels were lower ($P < 0.05$) in muscle than in seam or s.c. fat. Increased concentrate in the diet decreased ($P < 0.05$) n-3, n-6 and total polyunsaturated fatty acid (PUFA) levels in muscle; however, n-6: n-3 ratio remained the same. SFAs and TFAs, n-6: n-3 ratio, and elongase index were lower ($P < 0.05$) in BF than in KPH or VIS. Increased concentrate in the diet increased ($P < 0.05$) TFA in BF, KPH, and VIS and linolenic acid (C18:3n-3) and elongase index in BF. Finishing diet did not impact sensory attributes of the beef steaks ($P > 0.05$). All the steaks were acceptable in palatability with an initial tenderness score of 6.4 ± 0.2 and a beef flavor score of 5.5 ± 0.1 based on a 10 cm scale. In conclusion, fatty acid composition differed depending on fat location in the body. The lower concentrate diet produced beef with a more health-beneficial fatty acid composition, without affecting beef eating quality.

Key Words: finishing diet, tissue, fatty acid composition

321 Effects of frame size and animal age on beef carcass quality and tenderness. S. K. Duckett*[1], J. P. S. Neel[2], R. M. Lewis[3], W. Swecker[3], M. L. Wahlberg[3], J. P. Fontenot[3], and W. Clapham[2], [1]*Clemson University*, *Clemson, SC,* [2]*USDA-ARS*, *Beaver, WV,* [3]*Virginia Tech University*, *Blacksburg*.

Angus-cross steers (n = 96) were used to determine the effects of frame size (medium, MED or small, SM) and animal age on beef carcass quality and tenderness in a forage finishing system. Steers grazed mixed pastures (bluegrass/white clover) and were slaughtered at 16.6, 18.6, and 20.3 mo of age in a 2-yr study. At 24 h postmortem, carcass traits were collected and a rib from each carcass obtained for Warner-Bratzler shear force (WBSF) analysis. In yr 1, postmortem aging treatments included 14 and 28 d. In yr 2, postmortem aging treatments included 2, 4, 7, 14, and 28 d. Hot carcass weight, fat thickness, and skeletal maturity scores increased ($P < 0.05$) with animal age. Marbling scores, quality grades, and yield grades were greater ($P < 0.05$) for 20.3 than 16.6 mo. Longissimus muscle color was lighter ($P < 0.05$) and less red ($P < 0.05$) in 16.6 than 20.3 mo. Subcutaneous fat color was lighter ($P < 0.05$) and yellower ($P < 0.05$) for older than younger carcasses. Hot carcass weight and ribeye area were greater ($P < 0.05$) for MED than SM. Frame size did not alter other carcass parameters. In both years, the interaction between animal age and postmortem aging was significant. In yr 1, WBSF values at d 14 were lower ($P < 0.05$), indicating greater tenderness, for 16.6 mo than 18.6 and 20.3 mo. Extending the postmortem age to 28 d did not change ($P > 0.05$) WBSF values in young and intermediate ages but did improve tenderness ($P < 0.05$) for the older age group. In yr 2, WBSF values were lower ($P < 0.05$) at d 2 of postmortem aging for 16.6 mo than 18.6 or 20.3 mo. At 14 d postmortem, steaks from 16.6 and 18.6 mo were more tender ($P < 0.05$) than 20.3. By d 28, WBSF values did not differ ($P > 0.05$) among animal ages. In pasture-based beef finishing systems, increasing animal age results in larger carcasses with more external fat and marbling; however tenderness of ribeye steaks decreases with advanced age such that longer postmortem aging times are required to achieve similar tenderness level.

Key Words: beef, forages, tenderness

322 Effect of skeletal separation and moisture enhancement on eating quality of cull cow beef. P. Streiter*, C. Campbell, and I. Mandell, *University of Guelph*, *Guelph, Ontario, Canada*.

Sixty-two cull beef cows of known age and breed were slaughtered without electrical stimulation to investigate skeletal separation and moisture enhancement effects on eating quality. Carcass sides were designated to one of 4 postmortem processing treatments: 1) No

additional processing (Control), 2) prerigor skeletal separation (SS) after carcass dressing, 3) moisture enhancement (ME) using calcium ascorbate (CaAsc) 24 h postmortem and 4) Combination of SS and ME. Skeletal separation involved severing the pelvic bone at the narrowest part of the body of the ilium, and detaching vertebrae and connective tissue between 6th and 7th thoracic and 5th and 6th lumbar vertebrae. At 24 h postmortem, longissimus muscle from the ribeye (RE) and loin along with semimembranosus and semitendinosus (ST) muscles were excised from each carcass side with designated muscles injected with CaAsc (11% by wt). All muscles were cut into steaks for subsequent meat quality evaluation including shear force (SF) determination of tenderness for 7, 14, and 21 d aged product. A 10 member trained taste panel assessed treatment differences in palatability attributes for 14 d aged RE steaks as well as comparing sensory findings for cull cow vs. red branded beef from AA (USDA Select) and AAA (USDA Choice) quality grade carcasses. Skeletal separation reduced SF ($P < 0.001$) for RE steaks while moisture enhancement reduced SF ($P < 0.021$) for RE and ST. Postmortem aging for 14 vs. 7 d reduced SF to a lesser extent for SS vs non-skeletal separated sides, resulting in a SS by postmortem aging interaction ($P < 0.01$). Skeletal separation and moisture enhancement improved ($P < 0.01$) taste panel ratings for tenderness with an additive effect when combining SS with ME. Moisture enhancement tended to improve ($P < 0.07$) juiciness scores. While beef flavor was not affected by postmortem processing, ME increased ($P < 0.0001$) off-flavor scores. The combination of SS and ME may provide an additive effect for enhancing tenderness in the longissimus but at the expense of undesirable off-flavors.

Key Words: cull cows, skeletal separation, calcium ascorbate

323 Accuracy of real-time ultrasound for body composition traits for evaluating carcass traits in medium wool crossbred lambs. F. R. B. Ribeiro*[1], J. A. Carter[1], C. A. Hughes[1], W. S. Ramsey[2], J. W. Savell[2], R. R. Riley[2], C. Sharpton[2], and R. G. Tait Jr.[3], [1]*Texas A&M University-Commerce*, *Commerce,* [2]*Texas A&M University*, *College Station,* [3]*Iowa State University*, *Ames, IA*.

The objective of this study was to evaluate the accuracy of real-time ultrasound (RTU) measurements of body composition for evaluating lamb carcass traits. Data for this study were obtained from 25 medium wool crossbred lambs. Animals were scanned 2 to 5 d before harvest. The RTU measured traits were ultrasound BW (uBW, mean = 59.2 kg), 12–13th rib fat thickness (uBF, mean = 0.50 cm), and 12–13th rib *longissimus lumborum* muscle area (uLMA, mean = 18.6 cm^2), and carcass traits were HCW (mean = 35.3 kg), 12–13th rib fat thickness (cBF, mean = 0.56 cm), and 12–13th rib *longissimus lumborum* muscle area (cLMA, mean = 19.3 cm^2). Measurements were collected using an Aloka 500 with a 12-cm 3.5MHz transducer, each animal′s wool was clipped to no longer than 0.64 cm, and vegetable oil was used as a coupling agent to increase image quality. In addition to these traits, body condition score (BCS), hip height (HH), and ultrasound-measured rump fat thickness (uRUMP) also were collected. Data were analyzed using the PROC REG and PROC CORR procedures of SAS. Accuracy of RTU was determined by calculating the correlation, mean bias, and standard error of prediction (SEP) between RTU measurements and carcass measurements. The correlation, mean bias, and SEP between uBF and cBF were 0.90, −0.06 cm, and 0.09 cm, respectively, and for uLMA and cLMA were 0.66, −0.65 cm^2, and 2.12 cm^2, respectively. BCS was correlated ($P < 0.05$) to uLMA, uRUMP, and HH (0.62, 0.43, and 0.43, respectively). HH was correlated ($P < 0.05$) to uBF, uLMA and uRUMP (0.53, 0.41, and 0.60, respectively). These results suggest that RTU can be used as a non-invasive technique to accurately measure carcass traits in live lambs.

Key Words: ultrasound, carcass composition, lambs

324 Farming system changes fatty acids profile and lipid oxidation in meat of Sarda-breed suckling lambs. A. Nudda*, G. Battacone, M. G. Manca, R. Boe, A. Fenu, G. Spanu, and G. Pulina, *Dipartimento di Scienze Zootecniche, University of Sassari*, *Sassari, Italy*.

A study was carried out to evaluate the fatty acid composition of meat of suckling lambs raised in different breeding systems. Thirty-six pregnant ewes grazing on natural pasture (8 h/d) were divided into 2 groups supplemented with low (200 g/d; group L) or high (600 g/d; group H) amounts of concentrate. At lambing the ewes were divided in 2 subgroups (12 lambs each) balanced for single animals and twins: lambs kept indoor during the grazing time of the ewes (group I) and lambs which followed the mother on pasture (group O). Lambs were slaughtered at 27 d of age. After 24 h of refrigeration at 4°C, the tight muscles were dissected from each right half-carcass. Fatty acid profile and lipid oxidation (thiobarbituric acid test, TBARs) were studied. The data were analyzed with a linear model that included the fixed effects of supplementation (L vs H) and management (O vs I) and their interaction. In general, lamb meat from L ewes did not ($P > 0.10$) differ from the lamb meat from H ewes for the fatty acids analyzed, except for t11 C18:1 ($P < 0.01$). Management had relevant effect on the level of several fatty acids. The meat from O lambs had a lower ($P < 0.05$) content of C14:0, C16:0 and a higher ($P < 0.05$) content of C18:2 n6 and C18:3 n3 than that from I lambs. The content of DHA, PUFA n3 and PUFA n6 tended ($P < 0.10$) to be higher in O lambs than I lambs. The TBARs were not ($P > 0.10$) influenced by the 4 breeding systems. Interaction effects were significant ($P < 0.05$) for C18:0, C18:1 t10, C18:1 c9, C18:2 n6, PUFA n6, n6/n3 and TBARs. In conclusion, the dose of 600 g/d of concentrate supplemented to the ewes did not modify the FA profile and the lipid oxidation of the meat of their suckling lambs compared with the dose of 200 g/d of concentrate. Lambs, which followed the mother on pasture, produced meat with a higher content of C18:3 n3, probably because of the presence of grass in their diet.

325 Comparisons of different muscles metabolic enzymes and muscle fiber types in Jinhua and Landrace pigs. J. Guo*, T. Z. Shan, T. Wu, Y. F. Zhang, and Y. Z. Wang, *Institute of Feed Science*, *Hangzhou, Zhejiang, China*.

Western and indigenous Chinese pig breeds show obvious differences in muscle growth and meat quality. However, the underlying molecular mechanism remains unclear. The objective of the present study was to investigate the variations in meat quality, muscle fiber type and enzyme activity of local Jinhua and exotic Landrace pigs at the same age (180 d of age, 4 animals individually). Using real-time RT-PCR, we detected the mRNA levels of myosin heavy chain isoforms such as oxidative (type I and type II a), glycolytic (type II b), and intermediate (type II x) fibers in longissimus dorsi and soleus muscles. Furthermore, the metabolic enzyme activities of lactate dehydrogenase (LDH), succinic dehydrogenase (SDH) and malate dehydrogenase (MDH) in longissimus dorsi and soleus muscles were also detected. The results showed that the Jinhua breed exhibited a higher intramuscular fat ($P < 0.01$) content and lower drip loss compared with Landrace ($P < 0.05$). Meanwhile, the

mRNA levels of oxidative and intermediate fibers were elevated in the Jinhua breed, whereas the glycolytic fibers were more highly expressed in the Landrace ($P < 0.01$). Furthermore, the Jinhua pigs possessed a higher oxidative capacity than did the Landrace ($P < 0.05$). These results suggested that the elevated expression of the oxidative and intermediated fibers in Jinhua breed is related to higher activities of oxidative enzymes and meat quality as indicated by a higher intramuscular fat and lower drip loss. These results may provide valuable information for understanding the molecular mechanism responsible for breed specific differences in growth performance and meat quality.

Key Words: Jinhua pigs, myosin heavy chain, meat quality

326 Effects of cage versus floor litter environments on blood parameters and meat quality in broilers. J. Yuan*, C. H. Huang, B. Wang, S. H. Zhou, and Y. Guo, *State Key Laboratory of Animal Nutrition, China Agricultural University*, *Beijing, China*.

The study was conducted to determine the effects of cage vs. floor rearing on some blood parameters and meat quality in broilers. At 3-wk of age broilers were allocated into 2 pens (9 birds/0.7 m^2/pen) of litter floor pens; one-story cages and battery cages, separately. At the end of 7 wk the experiment was terminated. Nine birds of every treatment were harvested. Breast muscle yield, muscle fiber characteristics, meat quality and blood parameters were determined. We observed that the breast muscle yield was lowered ($P < 0.05$) in broilers reared in the battery cages compared with those on floors. There were no ($P > 0.05$) differences for myofiber density of breast muscle among different rearing systems. Birds reared in battery cages, however, tended ($P < 0.10$) to be smaller in diameter of breast myofibers and exhibit lower drip loss than birds reared on floor. The pH (24h) of breast muscle was lower ($P < 0.05$) in broilers reared in one-story cages than those reared on litter floors or in battery cages. Higher ($P < 0.01$) levels of serum Insulin-like factor-1 (IGF-1) and plasma triglyceride (TG) were observed in broilers reared in one-story cages than birds on litter floor or in battery cages. No ($P > 0.05$) differences were found in the activities of plasma lactate dehydrogenase, creatine kinase, glutamic oxalacetic transaminase, glutamate-pyruvate transaminase (GPT), concentrations of plasma pyruvic acid (PA), lactic acid, triglyceride, nonesterified fatty acids, malonaldehyde, glucose and uric acid and serum corticosterone. Rearing in one-story cages and battery cages, however, tended ($P < 0.10$) to lower the concentrations of plasma GPT and PA in boilers. The results suggest that one-story cages do not affect the breast muscle yield and meat quality of broilers, and the energy, protein and lipid metabolisms of broilers. Battery cages rearing lowers myofiber diameter and consequently reduces breast muscle yield, which can be attributed to the lower protein synthesis and negative energy balance.

Key Words: rearing environment, meat quality, broilers

327 Effect of dietary selenium yeast (Sel-Plex) and vitamin E supplementation to broilers on meat quality characteristics of raw and marinated breast fillets. A. D. Quant*[1], A. J. Pescatore[1], J. L. Pierce[1], K. M. McClelland[2], G. R. Rentfrow[2], A. H. Cantor[1], M. J. Ford[1], and W. D. King[1], [1]*Alltech-University of Kentucky Nutrition Research Alliance*, *Lexington,* [2]*Department of Animal and Food Sciences, University of Kentucky*, *Lexington*.

A study was conducted to evaluate the effects of dietary supplementation of selenium (Se) and vitamin E (Vit.E) to broilers on meat quality characteristics of raw and marinated breast fillets. This study utilized 576 Cobb500 broilers that were randomly allotted to 4 treatments with 48 pens of 12 birds/pen in a 2x2 factorial design (12 replicates/treatment). Broilers were fed a corn-soybean meal control diet with no added Se or Vit. E, supplemented with either 0.3 mg Se/kg diet as Se yeast (Sel-Plex, Alltech, Inc., Nicholasville, KY), or 30 IU Vit. E/kg as all-rac-α-tocopheryl acetate, or a diet supplemented with both Se and Vit. E. Broilers were humanely harvested at 49 and 56 d of age (raw and marinated portion, respectively) and breast fillets were sampled for analysis of meat quality characteristics. Marinated breast fillets were soaked in a 3.2% sodium pyrophosphate and 4% NaCl solution for 13 h (marinade pH: 9.74). In raw breast fillets, Se yeast supplementation significantly decreased drip loss at 3d compared with the control ($P = 0.049$) and Vit. E ($P < 0.01$) treatments, however by 7d, the only observed improvement was Se yeast compared with Vit. E ($P < 0.01$). Oxidative stability at 7d (as indicated by thiobarbituric acid reactive substance values) of the raw breast fillets was improved by Se yeast supplementation with ($P = 0.095$) or without added Vit. E ($P < 0.01$) compared with the control treatment. In the marinated breast fillets, there was no effect of dietary treatment on drip loss, however oxidative stability at 7d was significantly improved by all 3 antioxidant containing treatments ($P < 0.01$) compared with the control. Antioxidant supplementation did not affect color stability, carcass yield (WOG, front half, saddle), breast fillet pH, cooking loss, and tenderness values in both the raw and marinated breast fillets. These results indicate that dietary supplementation of Se yeast in broiler diets decrease drip loss and improve oxidative stability in raw breast fillets, and greatly improve oxidative stability in marinated breast fillets.

Key Words: selenium, meat quality, marination

328 Effect of three different postmortem electrical stimulation methods on quality of early-deboned broiler breast meat. H. Zhuang*, E. M. Savage, and K. C. Lawrence, *USDA-ARS*, *Athens, GA*.

The present experiment was carried out to evaluate the effects of electrical stimulation (ES) immediately pre-scalding (PS), ES immediately post-defeathering (PD) or PS combined with PD (PSPD) on the quality of early-deboned (2 h) broiler breast muscles, pectoralis (p.) major (fillets) and p. minor (tenders). No stimulation, early-deboned (2 h) and 24 h deboned (24 h) fillets were used for the comparison. The 42-d-old broiler carcasses were electrically stimulated with pulsed current at 200 V for 30s (1min total for PSPD), and breast meat was deboned 2 h postmortem. Quality indicators evaluated were: CIELAB L*, a* and b* color and pH of the raw fillets; Warner-Bratzler (WB) shear force (cooked meat) and cook yields of the fillets and tenders. There were no differences in raw fillet color and pH between the 3 ES treatments. Effects of different ES methods on meat WB shear force values and cook yields varied with breast muscles. For the fillets, the average WB shear force values of both the PS and PSPD samples, which were not different from each other, were significantly lower than those of the PD samples. There were no differences in cook yields between the PS and PD, or between the PS and PSPD, although cook yield of the PD samples was significantly higher than the PSPD samples. For the tenders, there were no differences in the average shear force values and cook yields between the 3 ES treatments. Regardless of ES method and muscle type, early-deboned broiler breast meat from ES carcasses required significantly less force to shear than the 2 h control, and more force than the 24 h control. These results indicate that ES can tenderize early-deboned poultry breast muscles; however, the effectiveness of ES tenderization varies with ES method for the fillets. Single PS is more effective in reducing fillet shear values than single PD, and there is no further reduction in shear values with double PSPD compared with the single PS.

Key Words: broiler, electrical stimulation, breast meat

329 Optimization of the time of marination for early deboned broiler breast fillets. V. A. Kuttappan*, V. B. Brewer, J. F. Meullenet, and C. M. Owens, *University of Arkansas*, *Fayetteville*.

Marination is an effective method which can be used to improve the tenderness of the early deboned breast fillets. However, there is little information available on the impact of the time at which fillets are marinated. The present study was intended to optimize the time of marination for chicken fillets deboned at 2h postmortem (PM). In this study, a total of 300 broilers (43–46days) were processed using an in-line system and deboned at 2h PM over 5 replications. Fillets were marinated at either 2.5, 4, 6, 8 or 24h PM. A non-marinated control was included. The fillets were vacuum tumbled (20 min) with a 15% marinade (final concentration of 0.5% salt and 0.45% phosphate). The left fillets were held for 24h in cooler before freezing while the right fillets were frozen immediately after marination to simulate various commercial practices. Marination pickup, retention, thaw loss, cook loss and Meullenet Owens Razor Shear energy (MORSE) values were measured. There was a significant increase in marinade pickup as the time of marination increased from 2.5 to 24h PM. Marination retention varied slightly among treatments. Thaw loss was significantly higher for fillets marinated and immediately frozen compared with those held until 24h PM before freezing, with the exception of fillets marinated at 8 and 24h PM. There was a significantly higher cook loss for the control fillets when compared with all marinated fillets suggesting that marination resulted in better water holding capacity. There was no significant difference between MORSE values of the non-marinated control and the fillets marinated at 2.5h PM. However, the MORSE values for the marinated fillets significantly decreased as the time of marination increased from 2.5 to 24h PM. The tenderizing effects of marination were only observed when marinated at 4h PM and later in this study. The fillets marinated at 8 and 24h PM had significantly lower MORSE than other treatments. Freezing immediately after marination did not impact MORSE values. The results of this study suggest that time of marination can impact marination pickup and quality factors such as tenderness.

Key Words: marination, early deboned, broiler fillets

330 Consumer acceptance of visual appearance of broiler breast meat with varying degrees of white etriping. V. A. Kuttappan*, J. F. Meullenet, and C. M. Owens, *University of Arkansas*, *Fayetteville*.

White striping is a condition associated with heavier broiler breast fillets and is observed grossly as white striations seen parallel to the direction of the muscle fibers. The present study was intended to assess the consumer acceptance of broiler fillets with different degrees of white striping condition. High resolution digital images of fillets, representative of varying degrees of white striping, were shown to 75 consumers in a blind study. Individual images were presented using a completely balanced randomized design. There were 4 replicates of individual fillets within each white striping category (Normal-NORM, Moderate-MOD, and Severe-SEV) and one picture of tray pack (3 fillets) for each category. The consumers were asked to express their overall liking for appearance with a 9-point hedonic scale (9 = like extremely; 1 = dislike extremely), purchase intent using a 5-point scale (5 = definitely would buy; 1 = definitely would not buy). An open ended comments section was also included. The results showed that NORM fillets had a significantly higher ($P < 0.05$) hedonic score (6.9) than the MOD fillets (6.1) which was also significantly higher ($P < 0.05$) than the SEV fillets (4.5), indicating that as severity of white striping increased, the consumer acceptance decreased. From the distribution of the responses, 10.7, 22.4 and 56.7% of the consumers disliked the NORM, MOD, and SEV fillets, respectively. Furthermore, the average purchase intent score for the NORM fillets (3.6) was significantly higher ($P < 0.05$) than those with 2 degrees of white striping (2.4 and 2.5, respectively), suggesting that the consumers were more likely to buy NORM fillets. Over 50% of the consumers indicated that they would probably/definitely not buy MOD or SEV fillets. The open-ended comments revealed the major reasons for the dislike of the white striped meat were that the fillets looked more fatty or marbled and/or that they thought the meat would be “tough.” The results of the study suggest that the white striping does affect the consumer acceptance based on the appearance of the fillets.

Key Words: white striping, consumer acceptance, broiler fillets

Nonruminant Nutrition: Enzymes 1

331 Efficacy of a thermally processed exogenous enzyme cocktail on broiler performance. K. R. Beaman*, K. G. S. Lilly, L. K. Shires, S. A. Loop, and J. S. Moritz, *West Virginia University*, *Morgantown*.

Feed ingredient price has influenced nutritionists to maximize diet nutrient availability through use of exogenous enzymes. Poultry are almost exclusively fed pelleted diets that entails feed being subjected to conditions of high moisture, temperature and pressure that could partially denature added enzymes. Exogenous enzyme efficacy may be decreased or completely lost if enzymes are not able to survive the pelleting process. The objective of the current studies was to properly assess the efficacy of a commercially available exogenous enzyme cocktail subjected to increasing steam conditioning temperatures during pelleting (82, 88, 93oC). All studies used male Cobb 500 broilers obtained from the same commercial hatchery. The experimental period was from d 3–21 with 8 birds per pen and 8 replications per treatment. Study 1 established significant differences between the Positive Control (PC) and Negative Control (NC) diets ($P < 0.05$). However, the exogenous enzyme cocktail did not show improved performance. Study 2 was designed to improve the opportunity for the exogenous enzyme cocktail to demonstrate a benefit. This study utilized increased mixer-added lipid addition in the diet formulation that may decrease frictional heat production in the pellet die, and a decreased metabolizable energy difference between the positive and negative control. Again, performance differences were observed between the PC and NC control diets ($P < 0.05$), with no beneficial effect demonstrated for the exogenous enzyme at any temperature ($P > 0.05$). In Study 3, diet formulations were similar to Study 2; however, temperatures were decreased (71, 77, 82oC) and an additional unconditioned mash (UCM) treatment was added. Significant differences were obtained between NC diets with and without exogenous enzyme cocktail in the UCM for live weight gain and feed conversion ratio (FCR) and at 82oC for FCR ($P < 0.05$). However, only numerical differences in performance were shown between the PC and NC diets.

Key Words: exogenous enzyme cocktail, enzyme efficacy, broiler performance

332 Growth performance and nutrient utilization of broiler chickens fed diets supplemented with phytase alone or in combination with citric acid and multi-carbohydrase enzyme. T. A. Woyengo*[1], B. A. Slominski[1], and R. O. Jones[2], [1]*Department of Animal Science, University of Manitoba*, *Winnipeg, Canada*, [2]*Canadian Bio-Systems Inc.*, *Calgary, Canada*.

An experiment was conducted to determine the effect of supplementing a corn-soybean meal-based diet with phytase alone or in combination with citric acid (CA) or multi-carbohydrase, a preparation of non-starch polysaccharide-degrading enzymes (MC) or both on growth performance and nutrient utilization. A total of 360 one-day-old broiler chicks were assigned to 6 dietary treatments, each consisting of 12 pens of 5 birds each, and were fed experimental diets from 1 to 21 d of age. The diets included a positive control (PC) (0.46% non-phytate P; 1.1% Ca), a negative control (NC) (0.26% non-phytate P; 0.89% Ca), and NC without or with phytase (600 U/kg) alone, phytase plus CA (5 g/kg), phytase plus MC (Superzyme OM; 0.6 g/kg), or phytase plus CA and MC. Birds fed the PC diet had higher ($P < 0.05$) BWG (764 vs. 594 g/21 d) and tibia ash content (50 vs. 38%) than those fed the NC diet. Phytase improved ($P = 0.03$) BWG (632 g/21 d), which increased further ($P = 0.018$) to 673 g/21 d for the phytase plus MC diet. In contrast to phytase alone, phytase plus MC supplementation improved ($P < 0.05$) FCR of the NC diet from 1.37 to 1.32. Tibia ash content for the NC diet increased ($P < 0.05$) from 38 to 42% due to phytase and a trend ($P = 0.136$) in its further increase to 44% was noted for the phytase plus MC diet. Phytase improved ($P < 0.05$) ileal digestibility of P from 29 to 43%, and the addition of CA or MC or both to phytase-supplemented diet further increased ($P < 0.05$) P digestibility to 52, 53 and 54%, respectively. Phytase addition improved ($P < 0.05$) diet AMEn content from 2959 to 3068 kcal/kg, which tended ($P < 0.06$) to increase further following CA (3150 kcal/kg) or MC (3142 kcal/kg) addition. No interactions were detected between CA and MC on all response criteria measured. The results show that addition of MC to the phytase-supplemented broiler diets can result in improved nutrient utilization and growth performance.

Key Words: broiler, enzyme, citric acid

333 Intestinal histology and amino acid digestibility of broilers fed increasing dietary phytic acid during a live coccidia vaccination. R. N. Lehman*[1], A. J. Cowieson[2], C. L. Walk[1], and A. P. McElroy[1], [1]*Virginia Tech*, *Blacksburg,* [2]*AB Vista*, *Wiltshire, Marlborough, UK*.

Day-old Cobb 700 male broilers were obtained from a commercial hatchery, weighed, and half were spray-vaccinated with a live coccidia vaccine (Coccivac-B) before placement into one of 72 floor pens with clean pine shavings (35 chicks/pen). Vaccinated and non-vaccinated birds were given one of 3 diets with different phytic acid (PA) levels (low = 0.20% phytate-P; medium = 0.28% phytate-P; high = 0.36% phytate-P) for a total of 6 vaccination X diet treatments (12 replications/treatment). The non-vaccinated birds received no coccidiosis control. On d 21, ileal digesta was collected for amino acid (AA) digestibility and duodenal, jejunal, and ileal tissue samples were collected for histological examination. In the duodenum, there was a significant diet by vaccination interaction ($P < 0.05$) on villus height (VH) with non-vaccinated birds having a shorter VH than vaccinated birds on the low PA diet, but a greater VH than the vaccinated birds when fed the medium and high PA diets. The VH to crypt depth (CD) ratio (VCR) remained constant for the non-vaccinated birds as dietary PA increased, whereas VCR decreased ($P < 0.05$) in the vaccinated birds as PA increased. Vaccinated birds and birds given the medium PA diet had deeper ($P < 0.05$) crypts compared with all other treatments. In the jejunum, vaccinated birds had deeper ($P < 0.05$) crypts and larger VCR. Vaccinated birds fed the low PA diet had larger VH than non-vaccinated birds, but a smaller VH than non-vaccinated birds fed the medium and high PA diets. In the ileum, vaccination alone caused a larger ($P < 0.05$) VH, CD, and VCR. Vaccination caused a decrease in total AA digestibility ($P < 0.05$), and the high PA diet resulted in the highest AA digestibility. These results suggest that interactions between the level of dietary PA and coccidia vaccination could alter intestinal morphology and subsequently have an effect on AA digestibility in broilers. An improved AA digestibility seen with the high PA diet may be due to exceeding a critical PA:protein ratio that may cause protein insolubility at intermediate levels.

Key Words: phytate, vaccination, histology

334 Effects of NSP-enzymes on in vitro digestibility and intestinal microbiota activity in broilers fed two different wheat cultivars. B. Bouza, C. Clavaud, P. A. Geraert, and E. Devillard*, *ADISSEO SAS*, *03600 Commentry, France*.

Non-starch polysaccharide (NSP) enzymes or carbohydrolases are commonly used in poultry diets to improve feed digestibility. These enzymes modify substrates reaching the different parts of the gastrointestinal tract and thus could have similar effects to that of prebiotics on intestinal microflora. The aims of the present study were to determine in vitro the effects of carbohydrolase complex (Rovabio Excel) on the digestibility of 2 wheat cultivars, Caphorn (Ca) and Isengrain (Is) differing by their NSP composition, and on the consequences on broiler intestinal microbiota activities. A first in vitro incubation step was carried out to mimic digestion in the upper digestive tract with pepsin/HCl and pancreatin incubations with supplementation or not with carbohydrolases (Rovabio Excel AP at 0.5 mg/g substrate). In vitro digestibilities of energy (dE) of the 2 cultivars were different, with Ca being less digestible than Is (−3%, $P < 0.009$). The effects of Rovabio depended on wheat cultivars, with an improvement of dE of 6.4% ($P = 0.005$) and 2.1% ($P = 0.081$) for Ca and Is, respectively. The resulting materials were used in an anaerobic incubation with ileal contents from broilers. More gas (+38 mL, $P = 0.0004$) and more short chain fatty acids (SCFA) (+164 m*M*, $P = 0.025$) were produced with Ca than Is in relation with dE of the wheat cultivars (Is > Ca). When carbohydrolases had been used in the first incubation step, there was a decrease in gas and SCFA productions. These effects were more important for Ca than for Is. Finally, the enzymes effects were also observed on SCFA profile, with more butyrate and less propionate produced from enzyme-treated substrates than from untreated substrates. In conclusion, this study showed a positive effect of NSP-enzymes on the in vitro digestibility of energy of both wheat cultivars, which leads to changes in intestinal microbiota characteristics. There were also differences between cultivars, in term of effects of NSP-enzymes, probably linked to NSP composition of the two substrates.

Key Words: NSP-enzymes, wheat digestibility, ileal fermentation

335 Assessment of phytase in broilers undergoing a coccidiosis challenge. A. L. Shaw*, J. P. Blake, and K. S. Macklin, *Auburn University*, *Auburn, AL*.

An experiment was conducted to assess the effects of a phytase enzyme on broilers undergoing a coccidiosis challenge through 21 d of age. Twenty one days before the experiment, 120 chicks were placed in 24 of 48 floor pens to produce a coccidia challenge. At 10 d of age they were orally dosed with a cocktail containing 100,000 and 5,000 sporulated *E. acervulina* and *E. tenella* oocysts, respectively, for litter seeding. Straight run broiler chicks (1008) were placed across 48 floor pens (21 birds/pen, 6 reps/trt) on either fresh or seeded litter. All birds were fed a corn-soybean meal diet (22% CP, 3087 kcal/kg) adequate in all nutrients but Ca and available phosphorus (aP). Treatments were created using a combination of 2 Ca-aP levels (0.9% Ca, 0.45% aP vs. 0.7% Ca, 0.25% aP and 500 FTU Optiphos), 2 coccidia challenges (unchallenged vs. challenged), and 2 vaccination strategies (unvaccinated vs. vaccinated with CoccivacB prior to placement). On d 10, 18, and 21 bodyweight (BW) and feed consumption (FC) were recorded for each pen. Five birds/trt were sacrificed and intestinal samples were obtained for visual and microscopic lesion scoring on d 10 and 18. At 21 d 18 birds/trt were selected for removal of left tibia to assess bone strength. BW and FC were unaffected (P>0.05) by inclusion of phytase or vaccination strategy. From 0-10d birds exposed to the seeded litter had a higher FCR (P<0.05). Upon conclusion of the experiment, birds exposed to coccidia had lower BW and FC, as well as a higher feed conversion (P<0.05) in comparison to those not challenged. Regardless of treatment, bone breaking force as well as visual and microscopic scoring of the duodenum and ceca showed no differences (P>0.05). Although there were no statistical differences in cocci scoring, incidence of cocci was greater in challenged vs. unchallenged birds. Results indicate that phytase was ineffective in improving the performance or P utilization of birds vaccinated and/or subjected to a coccidiosis infection.

Key Words: Broiler, *Eimeria* spp., phytase

336 Dietary supplementation of *Peniophora lycii* phytase improves mineral bioavailability in broiler chickens. A. Kollanoor Johny*[1], K. Syam-Mohan[1], T. V. Viswanathan[1], and A. Jalaludeen[2], [1]*Department of Animal Nutrition, College of Veterinary and Animal Sciences, Kerala Agricultural University*, *Mannuthy, Kerala, India*, [2]*Centre for Advanced Studies in Poultry Science, College of Veterinary and Animal Sciences, Kerala Agricultural University*, *Mannuthy, Kerala, India*.

An investigation was carried out to study the effect of dietary *Peniophora lycii* phytase on the growth and mineral bioavailability in broiler chickens. Day-old, straight run commercial broiler chicks (n = 96) were randomly divided into 8 identical groups containing 12 birds each, reared under deep litter system for 8 weeks. The groups were randomly allotted to 2, maize-soy based diets: control and experimental, with 4 replicates per treatment. Birds in the control group received a standard broiler ration (SBR) whereas, the treatment group received SBR supplemented with phytase at 750 U/kg diet. Feed and water were supplied *ad libitum.* Body weight and feed intake were recorded, and feed conversion ratio (FCR) and protein efficiency ratio (PER) were calculated. Two birds from each replicate were sacrificed at sixth and eighth week and, liver, spleen, tibia and blood samples were collected for analyses. At the end of 8 weeks, a 3-d metabolism trial was carried out using 2 birds selected randomly from each replicate, and housed in individual metabolism cages with facilities for feeding, watering and collection of droppings. Body weight, dry matter (DM) intake, FCR and PER did not differ significantly between the groups ($P > 0.05$). Also, DM and nitrogen retention between the groups were not different. However, the availability of calcium (Ca), phosphorus (P), magnesium (Mg), copper (Cu), and iron (Fe) was significantly improved ($P < 0.05$) with phytase supplementation and were 39, 55, 54, 24, and 65% more, respectively compared with the control. The concentration of Fe in the liver was significantly higher ($P < 0.05$) in the phytase-treated groups at sixth and eighth week of trial, whereas its concentration in the spleen did not differ between groups. Tibial weight and tibial ash content at sixth week were significantly higher ($P < 0.05$) for the phytase-treated groups. However, serum concentrations of Ca, P, Mg, Cu, Fe and Zn did not differ between the groups. Results of the study indicate that *Peniophora lycii* phytase could potentially improve the bioavailability of minerals in broiler chicken.

Key Words: *Peniophora lycii* phytase, mineral bioavailability, broiler chicken

337 Mineral excretion and bone mineral content as affected by phytase and feed additives in broilers. M. R. Dalmagro*[1], E. O. Oviedo-Rondón[1], A. Mitchell[2], A. B. Leytem[3], N. A. Barbosa[4], N. K. Sakomura[4], J. W. Wilson[5], and C. Paulus[5], [1]*North Carolina State University*, *Raleigh,* [2]*USDA-ARS, BARC*, *Beltsville, MD*, [3]*USDA-ARS*, *Kimberly, ID*, [4]*Universidade Estadual Paulista, UNESP*, *Jaboticabal, SP, Brasil*, [5]*DSM Nutritional Products Inc.*, *Parsippany, NJ*.

One broiler study was conducted to evaluate the effects of feed additives (FA) in diets containing phytase on mineral excretion and bone mineral content (BMC) for broilers up to 43 d of age. Corn-soybean diets with 5% inclusion of DDGS were used as basal diets. All diets contained ionophore Coban. The treatments evaluated consist of a control without phytase (C), and 7 treatments that contained phytase Ronozyme P

formulated to release 0.1% of phytate phosphorus (P) to have an equal amount of available P compared with C. These 7 treatments included diets without any other FA (PC), GP antibiotic (BMD), 3 probiotics: BC30 (*B. coagulans*), B2B (*B. licheniformis*, *B. subtilis*), and Calsporin (*B. subtilis*), and 2 EO: Crina POULTRY Plus (CPP) at 300 ppm and Crina PoultryAF (CPF) at 100 ppm. Day-old Ross 708 broilers were randomly assigned to 96 floor pens with previously used litter. Ten males and 10 females were placed in each pen. Fresh excreta were collected at 40 d and one male per pen was sacrificed at 44 d of age to collect bones. Data were analyzed as a completely randomized block design with 12 replicates per treatment. The highest excretion of P (Pex) and water extractable P (WEP) was observed in C chickens. Excreta from C chickens had the highest moisture, but the lowest K and Mg. These chickens also had the lowest tibia and femur BMC. The Pex was reduced by addition of phytase in all diets. GP and the EO did not cause further reductions on Pex, but all probiotics reduced Pex. WEP was reduced by PC, GP and CPP. Excreta of chickens fed diets containing only phytase had the highest concentration of Ca, Mn, and Mg. Calcium excretion was reduced by probiotics and EO. The highest tibia and femur BMC was observed in B2B chickens. The excreta of these B2B chickens had the highest concentration of K and the lowest concentrations of Na, Zn, and Mn. Concentrations of Cu in the excreta were not affected by treatments. It was concluded that FA may affect mineral metabolism in chickens fed diets with phytase. Probiotics seem to have a positive effect on P retention and bone mineral deposition.

Key Words: probiotics, essential oils, growth promotants

338 Use of the precision-fed rooster assay and a chick AME trial to determine the best method for enzyme efficacy. J. Brandon* and A. B. Batal, *The University of Georgia*, *Athens*.

The beneficial effects of exogenous enzyme addition to poultry diets have been well documented. However, the results have been variable depending on the in vivo method used. The most common methods employed to assess the bioefficacy of exogenous enzymes in vivo are performance trials and metabolism studies, such as the precision-fed rooster assay. There has been criticism of the use of the precision-fed rooster assay. Thus, the objective of these studies was to compare the precision-fed rooster assay with the chick AME trial to determine which method best measures enzyme efficacy. In 2 studies 6 different enzymes mixed in a complete diet (as well as a control diet with no enzyme, for a total of 7 treatments per study) were evaluated using the precision-fed rooster TME assay alongside a more conventional chick AME trial. The rooster assays were traditional precision-fed rooster assays in which 8 birds per diet were fasted for 24 h then crop intubated with 35 g of the test diet and excreta was then collected for 48 h. However, to keep consistent with the chick AME trial, the roosters were 'primed' on the experimental diets. They were allowed ad libitum access to the experimental diets for 5 d before the fasting and crop intubation. The chick AME trials used 728 d old Cobb 500 by-product male chicks (7 replications per treatment, 8 chicks per replication) that were fed the same experimental diets for 5 d and excreta was collected at 18 d of age for the determination of AME. Regardless of the method used, in both studies no significant increase was observed due to exogenous enzyme supplementation on the TME values determined from the precision-fed rooster assays or the AME values determined from the chick digestibility trials. The determined TME values were significantly higher than the AME values. However, no correlation was observed between the determined ME values for the control or enzyme diets between the rooster and the chick assay, suggesting the assay used could affect the measured efficacy of the enzymes.

Key Words: enzymes, TME, AME

339 The effects of the addition of phytase and an enzyme cocktail to high and low nutrient density diets with DDGS or MBM in laying hens during phase II. D. Hahn*[1], S. Scheideler[1], E. E. M. Pierson[2], and C. L. Novak[3], [1]*University of Nebraska-Lincoln*, *Lincoln,* [2]*Danisco Animal Nutrition*, *St. Louis, MO,* [3]*Land O' Lakes Purina Feed, LLC*, *Kansas City, MO, and Lincoln, NE*.

The objective was to test the addition of Avizyme 1502, a blend of protease, amylase and xylanase (Danisco, UK Ltd.) in laying hen diets containing dried distillers grains (DDGS) or meat and bone meal (MBM) during phase II of egg production. All diets contained phytase (300 FTU minimum; Phyzyme XP 5000 G Feed Enzyme). Three hundred eighty-four Hy-Line W-36 laying hens were used in this study, from 35 to 52 weeks of age. There were 12 replicate pens with 4 hens per pen. The experiment consisted of 8 dietary treatments arranged in a 2 × 2 × 2 factorial design: diets (DDGS or MBM), metabolizable energy (ME) levels (2880 Kcal/kg or 2800 Kcal/kg), and 2 enzyme levels (0 or 0.0375% Avizyme) to provide protease at 8000U/g, amylase at 800U/g and xylanase at 600 U/g of product. All diets contained Phyzyme at 60 g MT (~300 FTU) and were formulated to contain 0.30% avP and a Ca adjustment as recommended by Phycheck software tool (10% decrease). Response variables measured included: daily egg prod, biweekly egg wt, weekly feed intake; body wt, Haugh unit, yolk wt, albumen wt, shell wt, shell strength and specific gravity were taken monthly. There was a significant effect for feed intake between high and low ME diets ($P = 0.0349$), with diet 3 (2880 Kcal/kg, MBM, Phyzyme) having significantly lower intake when compared with the other 7 treatments. However, there were no differences noted between treatments for hen weight, egg production and egg quality parameters ($P > 0.05$). Thus, reducing ME, P and Ca with the addition of enzymes had no negative effect on egg production and quality. Given Nov 2009 commodity prices, there was a cost savings shown in regards to high (2880 Kcal/g) vs low (2800 Kcal/g) energy diets when MBM was in the diet. There was a cost savings with the addition of Avizyme.

Table 1. Kg feed cost/Doz. eggs produced

	DDGS		MBM	
ME	-Avzym	+Avzym	-Avzym	+Avzym
2880	$0.253	$0.227	$0.322	$0.240
2800	$0.251	$0.238	$0.269	$0.261

Key Words: metabolizable energy, Avizyme1502, laying hens

340 Justifying phytogenic feed additive matrix values in conjunction with exogenous feed enzymes. L. K. Shires*, S. A. Loop, C. K. Gehring, K. R. Beaman, and J. S. Moritz, *West Virginia University*, *Morgantown*.

Phytogenic feed additives (PFA) are purported to possess antimicrobial properties as well as nutrient sparing characteristics that may aid in alleviating high diet costs; however, in order for PFAs to assist nutritionists in decreasing diet cost, matrix values must be determined and implemented in feed formulation. On d4, 1,344 male Cobb 500 broilers were weighed and randomly allotted to 1 of 64 floor pens. Floor pens were located in 2 separate rooms, composed of one block each. Study 1 evaluated proposed matrix values for a commercially available PFA and assessed nutrient sparing when the product was combined with commercial phytase, carbohydrase and protease. The most remarkable proposed matrix values were 14.6 kcal/lb for metabolizable energy and 0.07% for Ca and AP. The objective of Study 2 was to determine true amino acid digestibility (TAAD) and nitrogen corrected true metabolizable energy (TME_n) using 32 cecectomized SCWL roosters. Dietary

treatments for both studies included a basal, basal with phytogenic product matrix value, basal with phytogenic product matrix value and phytogenic product, and similar treatments evaluating the phytogenic product matrix with exogenous enzyme products. Decreasing the basal diet by the proposed phytogenic matrix values decreased broiler live weight gain and increased feed conversion ratio ($P \leq 0.05$). However, when the same diet included the phytogenic feed additive, live weight gain and feed conversion ratio were restored to that of the basal diet ($P > 0.05$). The proposed matrix values of the specific PFA tested were justified; however, the PFA was not additive or synergistic with exogenous enzymes. Nitrogen corrected true metabolizable energy and TAAD data did not differ when the diets varied based on the PFA per se ($P > 0.05$). However, when the PFA was incorporated using proposed matrix values and used in conjunction with exogenous enzyme matrix values, several tested TAAD values were decreased ($P \leq 0.05$). Decreased nutrient digestibility may involve reductions in gut microflora due to the PFA as well as simultaneous reduction in substrate concentrations.

Key Words: phytogenic feed additives, matrix values, true amino acid digestibility

341 The effect of phytase and energy enzyme inclusion on growth and bone ash in low phosphorus diets. J. R. Coppedge*[1], J. Klein[1], K. Jessen[1], A. Jordan[1], B. Brown[2], F. Ruch[2], and J. T. Lee[1], [1]*Texas A&M University*, *College Station,* [2]*Enzyvia LLC*, *Sheridan, IN*.

An experiment was conducted to evaluate the effect of varying levels of phytase with and without NSPase inclusion on broiler performance when supplemented in corn/soybean meal diets low in available phosphorus. The objective was to determine if NSPase inclusion enhances phytase activity in relation to growth parameters and bone ash in broilers reared in batteries through 14 d of age. Four diets with selected available phosphorus levels of 0.15%, 0.20%, 0.25%, and 0.30% were included in the experimental design to develop a dose response curve to calculate phosphorus release from experimental treatments. An additional 6 treatments were evaluated that included 3 levels of phytase (150, 200, and 250 FTU/kg) with and without NSPase inclusion in a diet containing 0.15% available phosphorus. Evaluated parameters included body weight, feed conversion ratio, mortality and bone ash percentage. Body weight and bone ash percentage were positively influence with increases in available phosphorus levels. Phytase inclusion positively influenced growth performance and bone ash percentage. Broilers fed the 200 and 250 FTU/kg phytase inclusion levels outperformed the broilers fed the 150 FTU/kg inclusion level. Addition of NSPase with 150 FTU/kg phytase resulted in increased broiler body weight as compared with the 150 FTU/kg phytase diet alone. Using regression equations determined from dose response treatments for body weight, bone ash (mg), and bone ash percentage, NSPase inclusion increased phosphorus release at the 150 FTU/kg level from 0.06% to 0.09%. These data indicate that NSPase inclusion may increase phytase effectiveness when co-administered during early stages of growth.

Key Words: bone ash, phytase, broiler

342 Transforming coccidiosis mediated lesion score effects into estimates of performance and calorific costs in the form of ADG, FCR, malabsorption and effective caloric value throughout the broiler growth curve to 48 days of age. R. G. Teeter*[1], A. Beker[1], C. Brown[1], C. Broussard[2], F. Fitz-Coy[2], J. Radu[2], and L. Newman[2], [1]*Oklahoma State University*, *Stillwater,* [2]*Schering-Plough Animal Health*, *Summit, NJ*.

Methodologies enabling the conversion of intestinal lesion score into calorific cost estimates have been developed. Coccidiosis, the major disease challenge for broilers, reduces ADG and elevates FCR. Birds normally develop immunity during the production cycle, but uncertain timing can lead to intestinal lesion scores ranging throughout the growth curve. Vaccination at hatch speeds immunity development, reduces lesion score severity and shifts lesion scores to the early weeks. To examine the caloric cost of immunity development 2 groups of birds were reared in cocci free environments with one vaccinated at hatch (Coccivac-B) and the other maintained as naive to cocci. Birds were selected from the 2 backgrounds at 5 weekly intervals for metabolic chamber placement. The 5 challenge periods consisted of an oral dose of sterile saline or a mixture of 3 *Eimeria* species as oocysts. Metabolic costs of cocci challenge included appetite suppression, maintenance energy cost, malabsorption as excreta calorie elevation and reduced performance. Though immunity development occurring early in the production cycle, had energy costs, birds with late growth curve immunity development exhibited significantly higher costs in all categories. In this study coccidiosis mediated lesion scores 6 d post oocysts challenge at 14, 21, 28, 35, and 42 d, exhibited highly significant deleterious impact with marked elevation late in the growth curve (35, 42 d). Lesion score 1 and 2 reduced the dietary effective caloric value from an initial 3,200 kcal/kg ration by 125 and 596 kcal for 800 g broilers and by 625 and 2,277 kcal/kg for 3000g birds, respectively. Calorimetry data substantiated the lesion consequence with increased maintenance energy need, heat production and malabsorption. Timing of immunity development is critical to performance as late growth curve cocci challenges markedly exacerbated energy costs for birds lacking immunity.

Key Words: coccidiosis, immune response, energy

343 Mintrex-Zn improves tibia Zn deposition and antioxidant status of broilers under stress with coccidiosis challenge. S. D. Bun* and Y. M. Guo, *China Agricultural University*, *Beijing, China*.

An experiment was conducted to investigate the beneficial effects of the organic zinc (Mintrex-Zn) vs inorganic zinc for broilers chicks reared under stress with coccidiosis challenge. Tibia Zn, bone breaking strength, and oxidative enzymes were examined during study. A total of 480 one day-old male chicks were randomly placed into 80 cages of 6 chicks each. A corn-soybean meal diet containing Zn 29.64 mg/kg was used as a basal diet for the negative control group, supplemented with Zn at 20, 40 and 60 organic Zn per kg of diet, respectively. Treatment 2 is the positive control supplemented with reagent-grade zinc sulfate at 40 mg/kg while Mintrex-Zn (a methionine hydroxyl analog chelate) was used as an organic source for the treatment 3, 4 and 5. Half of the chicks in each treatment were inoculated by gavage with 1.5×10^4 *E. tenella* sporulated oocysts at 21 d of age. For the non-infected group, the tibia Zn deposition and bone breaking strength of chicks fed Mintrex-Zn was higher ($P < 0.05$) than those fed inorganic Zn at the same levels (40 mg/kg). Similar tendency, supplementation of Mintrex-Zn resulted in significant increase in GSH-Px activity ($P < 0.001$), and tended to elevate ($P = 0.08$) Cu/Zn-SOD activity while LPO (lipid peroxidation) was markedly decreased ($P < 0.05$). For the infected group, tibia Zn retention, bone breaking strength of chicks fed Mintrex-Zn at 40 mg/kg were highest among the treatments ($P < 0.001$) and reached the plateau thereafter. The maximum Cu/Zn-SOD and GSH-Px activities and decreased LPO were also observed in the chicks fed diet supplemented with Mintrex-Zn vs inorganic corresponding. It can be concluded that Mintrex-Zn enhanced tibia Zn deposition and could be considered to be more protective than zinc sulfate in terms of reducing the negative effect of oxidative stress induced by coccidiosis infection.

Key Words: organic zinc, antioxidant enzymes, broilers

344 Effects of type and level of dietary fiber on digestive traits and nutrients digestibility in broilers. E. Jiménez-Moreno*[1], J. M. González-Alvarado[2], S. Chamorro[3], C. Romero[1], R. Lázaro[1], and G. G. Mateos[1], [1]*Universidad Politecnica de Madrid*, *Madrid, Spain*, [2]*Universidad de Tlaxcala*, *México*, [3]*Consejo Superior de Investigaciones Científicas*, *Madrid, Spain*.

The effects of inclusion of oat hulls (OH) and sugar beet pulp (SBP) in the diet on total tract apparent of retention (TTAR) of nutrients were studied in broilers from 1 to 21 d of age. A control diet based on cooked rice that contained 3,260 kcal AME_n/kg and 1.6% crude fiber (CF) was diluted with 0, 2.5, 5.0, and 7.5% of either OH or SBP. Each treatment was replicated 6 times (a cage with 12 chicks). Digestive traits and nutrient retention were recorded at 7, 14, and 21 d of age, and jejunal histology at 14 d of age. Broilers fed additional fiber had heavier gizzards with higher digesta contents and lower pH than those fed the control diet ($P \leq 0.001$). As the level of fiber increased the relative weight of the gizzard increased linearly ($P \leq 0.001$) and gizzard pH was reduced ($P \leq 0.05$). Broilers fed OH had heavier gizzards ($P \leq 0.001$) with less digesta content ($P \leq 0.001$) and higher pH ($P \leq 0.01$) than those fed SBP. Villus height was reduced ($P \leq 0.05$) and crypt depth tended to be shorter as the level of fiber increased. Also, the inclusion of SBP but not OH, reduced villus height: crypt depth ratio linearly ($P \leq 0.05$). Fiber inclusion affected TTAR of nutrients in different manners depending on nutrient, type, and level of fiber considered. In general, the inclusion of 2.5% fiber improved nutrient digestibility with the effects being more pronounced with OH ($P \leq 0.001$ for DM, N, and AME_n). However, the inclusion of 7.5% fiber reduced nutrient digestibility ($P \leq 0.001$), especially when OH was used. We conclude that the inclusion of up to 7.5% OH or SBP increases the weight the gizzard and reduces its pH. The inclusion of 2.5% fiber improves TTAR of nutrients. However, a further increase to 7.5% has negative effects. Young chicks have a minimal requirement of at least 2.3% CF in the diet.

Key Words: fiber sources, nutrient digestibility, broiler

345 The effects of 1.2 ppm T-2 Toxin on performance, lesions, and general health of male broilers and the efficiency of an organoaluminosilicate (mycotoxin binder). J. C. Medina[1], J. A. Fierro*[1], J. Lara[1], V. Brito[2], and M. Forat[2], [1]*NUTEK S.A de C.V.*, *Tehuacan, Puebla, Mexico*, [2]*EURO-NUTEK Premix S.A. de C.V.*, *El Marques, Queretaro, Mexico*.

Mycotoxin presence has become a major problem in the Mexican livestock industry; thus producers trend is towards the use of binders to alleviate its effects. T-2 toxin is a mycotoxin that affects broilers health and performance (CAST, 2003). A trial was performed to evaluate the

toxic effect of a contamination (1.2 ppm) of T-2 and the efficiency of a commercial organoaluminosilicate. Ninety Ross 308 male broilers were randomly allocated in five groups: group 1 (negative control group), group 2 positive control (1.2 ppm T-2 toxin), group 3 (1.2 ppm T-2 toxin + 1.5 kg/ton organoaluminosilicate binder), group 4 (1.2 ppm T-2 toxin + 3.0 kg/ton organoaluminosilicate binder), and group 5 (3.0 kg/ton organoaluminosilicate binder). 18 replicates with one bird each. The birds were fed their respective diets from 10 days of age, up to 39 days, date in which they were sacrificed. We recorded the individual weight of the birds at the beginning and end of the experiment. At day 39 consumption and weight gain, feed conversion and mortality were calculated. Mean weights were: Group 1: 2307.7 g (a), Group 2: 2031.9 g (b), Group 3: 2254.3 g(a), Group 4: 2234.1 g (a), Group 5: 2246.3 g (a). Lesions of the oral cavity were scored. The results shown statistical significantly differences in weight gain, and numerical differences in feed intake, feed conversion and mortality. The effects of the T-2 toxin in the broilers were practically eliminated by the incorporation of any of both doses of the organoaluminosilicate in the diet. The weight difference between the control group and the intoxicated group is of 11.2%. The weight of the challenge group (organoaluminosilicate + T-2 toxin) represents a weight recovery of 83%. We observed that T-2 toxin is of dermal toxicity and that the oral lesions reduce feed intake. The organoaluminosilicate in the diet of the animals that were given T-2 toxin, reduced the negative effects caused by the aforementioned mycotoxin.

Key Words: organoaluminosilicate, T-2 Toxin, mycotoxin binder

346 Strategies to reduce preharvest *Salmonella* in organic broilers. K. G. S. Lilly*, K. R. Beaman, B. N. West, L. K. Shires, S. A. Loop, P. J. Turk, G. K. Bissonnette, and J. S. Moritz, *West Virginia University*, *Morgantown*.

Antibiotics are popularly used to combat bacteria, such as *Salmonella*. However, due to the concern of antibiotic resistant bacteria, organic poultry products have gained consumer interest. Outdoor rearing requirements for organic poultry could increase exposure to bacteria, including *Salmonella*. The objective of this USDA NIFSI funded project was to assess the effects of prebiotics and probiotics (Study 1) and acidifying water treatments (Study 2) on organic broiler performance and the presence of *Salmonella*. Study 1: A prebiotic (MAN), 2 probiotics (PRO1 and PRO2) and a control treatment (CON) were implemented. Study 2: Raw apple cider vinegar (RACV), organic acid blend (OA), hydrogen peroxide (H2O2) and a control treatment (CON) were incorporated into watering systems. For both studies, 300 1-d-old Cobb 500 male chicks were randomly assigned to treatment and pen. On d-21 birds were weighed and designated to one of 13 weight classes for each treatment and allocated 13 per pen within each of the 5 housing locations which included pasture access at the West Virginia University Certified Organic farm. Data collection occurred from d-21–49. For Study 1, PRO1 and MAN demonstrated the highest d-21 bird weight (BW), followed by CON and then PRO2 ($P < 0.05$). Study 1 treatments did not affect feed intake, live weight gain, feed conversion or ending BW ($P > 0.05$). For Study 2, on d-21, OA were the largest, followed by CON, H2O2 and RACV ($P < 0.05$). OA consumed more feed than H2O2 and RACV birds, but the same amount as CON. Water intake was consistent for OA, CON and RACV, while H2O2 consumed the least ($P < 0.05$). On d-49, OA had higher BW than H2O2 and RACV, but the same as CON ($P < 0.05$). RACV and CON d-49 BW were the same and H2O2 had the lowest ending BW ($P < 0.05$). For both studies, on d-29 and d-50, samples were taken to determine the presence of *Salmonella* in feed, litter and water. An additive x location and an additive × sampling day interaction was observed for the presence of *Salmonella* ($P < 0.05$).

Key Words: antibiotic alternatives, organic broilers, *Salmonella*

347 Cecal microbial populations of young chicks fed several prebiotic-type compounds as determined by DGGE and quantitative PCR. C. M. Jacobs*, P. L. Utterback, and C. M. Parsons, *University of Illinois*, *Urbana*.

The objective of the current studies were to investigate the prebiotic effects of supplementing Grobiotic (GB) and Dairylac-80 (International Ingredient Corporation, St. Louis, MO), Temulose (Temple Inland, Diboll, TX), lactose, and Alternan (USDA, Peoria, IL) on cecal microbial populations in young chicks fed corn-SBM diets using DNA–based qualitative (denaturing gradient gel electrophoresis; DGGE) and quantitative (qPCR) techniques. In Experiment 1, 5% GB, 0.5% Temulose, and combinations thereof were fed for 3 or 7 d post–hatch. In Experiment 2, 5% GB, 1% lactose from Dairylac-80 or pure lactose were fed for 3, 7, or 21 d post–hatch. In Experiment 3, 1 or 2% Alternan was fed for 3, 7, or 21 d post–hatch. In Experiment 1, bacterial enumeration by qPCR did not detect any positive significant differences in bifidobacteria, lactobacilli, or *E. coli* populations when GB, Temulose, or combinations thereof were included in the diet for 3 or 7 d, but DGGE dendrograms and unrooted trees showed that replicates were clustered together by diet. In Experiment 2, at 3 and 7 d of age, there was an increase ($P < 0.10$) in bifidobacteria for all GB, Dairylac–80, and lactose treatments when compared with the basal diet treatments. At 21 d, 1% lactose decreased *E. coli* populations at every collection period. The DGGE indicated that replicates were clustered more by diet than age. In Experiment 3, the addition of Alternan had no positive effects on any selected microbial populations across all age periods. Replicates were clustered both by diet and age. When considering the effect of age for a single dietary treatment, there was a linear decrease ($P < 0.05$) for all selected microbial populations with increased age. Our results indicate that cecal microbial populations of young chicks can be affected by the addition of prebiotic–type compounds to the diet, but the changes in microbial populations as the birds age is not as clear.

Key Words: chick, denaturing gradient gel electrophoresis, polymerase chain reaction

348 Turkey response to the inclusion of a *Saccharomyces cerevisiae* fermentation product, Original XPC, in antibiotic free diets following a coccidia vaccination. D. M. Paiva*[1], C. L. Walk[1], R. Lehman[1], J. R. Sottosanti[1], C. F. Honaker[1], D. T. Moore[2], and A. P. McElroy[1], [1]*Virginia Polytechnic Institute and State University*, *Blacksburg,* [2]*Diamond V Mills, Inc.*, *Cedar Rapids, IA*.

Saccharomyces cerevisiae fermentation products are among feed additives with potential to support intestinal integrity and immune defense to improve intestinal health of commercial poultry. The objective of this study was to evaluate the effect of XPC (a commercially available fermentation product) supplementation on turkey performance to 63d during a mild intestinal challenge from a commercial live coccidia vaccine. Day old female, Hybrid Converter turkeys were obtained from a commercial hatchery, weighed and randomized (22poults/pen) into 8 treatment groups. The experiment was a 4 × 2 factorial design with 4 dietary treatments and 2 coccidia vaccination treatments (vaccinated and non-vaccinated). Vaccinated and non-vaccinated birds were given one of the 4 diets with different inclusion levels of XPC (no XPC = negative control; 0.0625% = 0.5X, 0.125% = 1X; 0.250 = 2X), and each dietary treatment was replicated by 18 pens (9 vaccinated and 9 non-

vaccinated). Body weight (BW) and feed intake were measured on d 0, 28, 42 and 63 and cumulatively (d0–63), and mortality was recorded daily. Adjusted feed conversion was calculated for each of these periods, corresponding to diet changes, and cumulatively. Birds fed with XPC had heavier ($P < 0.001$) BW than control fed birds at d28 and 42 and increased BW gain during pre-starter (d0–28) and starter (d28–42) feeding periods. Vaccinated birds were significantly heavier ($P < 0.004$) than non-vaccinated at d63 and had increased BW gain compared non-vaccinated birds during d42–63 ($P < 0.006$) and d0–63 ($P < 0.004$). Feed consumption was higher ($P < 0.05$) for birds fed diets containing XPC at 0.5X and 1X during d0–28. Feed conversion was only different during the d0 to 28 period with 2X inclusion of XPC resulting in the most efficient conversion. These results suggest that XPC was able to promote intestinal health and maintain turkey performance during mild challenge to the intestine from a live coccidia vaccine.

Key Words: fermentation product, coccidia vaccination, turkey

349 Effect of diet on equine gut microbiota. K. Daly*[1], C. J. Proudman[1], H. J. Flint[2], and S. P. Shirazi-Beechey[1], [1]*University of Liverpool*, *Liverpool, UK*, [2]*Rowett Institute of Nutrition and Health*, *Aberdeen, UK*.

The horse has evolved as a highly adapted hindgut fermenter, with a voluminous large intestine (LI) containing specialized microbial populations. Dietary plant fiber is fermented by intestinal microbiota to short chain fatty acids (SCFA) notably acetate, propionate and butyrate. SCFA, once absorbed, not only provide a significant proportion of horse's energy requirements, but are also important in regulating physiological processes essential for the maintenance of LI health. Today's horse, however, is fed diets supplemented with readily digestible hydrolysable carbohydrates (hCHO), generally in the form of grain, to provide further energy for the demands of work and performance. It is proposed that when horses are introduced abruptly to diets containing high levels of hCHO, a substantial proportion of starch reaches the LI. There it is fermented to metabolites which can cause drastic alterations in intestinal pH and composition of microbiota, disposing the horse to intestinal dysfunction e.g., colic. Using 16S rRNA oligonucleotide hybridization technology, we previously characterized and identified the major bacterial groups inhabiting the LI of horses maintained on pasture forage. Aims: to determine changes in microbiota and fermentation products measured in large intestinal content of i) 12 horses fed grain based diets and euthanized for conditions other than gastrointestinal disease and ii) 12 horses suffering from simple colonic obstruction and distension (SCOD). Results: In response to grain feeding and in disease, compared with grass-fed horses, the relative abundance of saccharolytic, lactate producing bacteria increased by up to 2-fold ($P < 0.05$), with a concomitant 2–4 fold ($P < 0.01$) decrease in the relative population abundance of acid intolerant cellulytic bacteria. Furthermore, there were significant increases in the intestinal concentration of lactic acid (up to 8-fold [$P < 0.01$]). Changes in both microbial population and fermentation products were exaggerated in horses suffering from SCOD. These alterations not only result in significant decline in SCFA, but also promote lactic acid and gas production, disposing the horse to intestinal dysfunction.

Key Words: horse, diet, gut microbiota

350 Spatial alternative splicing of Mucin 2 (*Muc2*) mRNA in chicken intestine. Z. Jiang*, C. Troche, A. C. Lossie, and T. J. Applegate, *Purdue University*, *West Lafayette, IN*.

Mucins are a large class of diverse, complex proteins that respond to their constantly changing intestinal environment by altering their production of specific protein isoforms. The complexity and diversity of gel-forming mucin isoforms within the gastrointestinal tract are largely regulated by its primary encoding gene, Mucin 2 (*Muc2*). We hypothesized that the protein diversity was generated by alternative splicing events, particularly within different regions of the intestine. Therefore, we isolated total RNA from 4 regions of the chicken intestinal mucosa (duodenum, jejunum, ileum and cecal tonsil; n = 4/each tissue) and performed RT-PCR across different domains of the *Muc2* gene on DNase treated RNA. A hypothetical chicken *Muc2* cDNA (XM_421035) localized the gene to Chr 5. Cross species comparisons indicated that the chicken gene shows 50 to 67% homology to zebrafish, cattle, mouse, chimpanzee and human. Based on this sequence, we designed 13 sets of primers to clone the chicken *Muc2* gene. These amplicons spanned bases 25–7961 of the 7968 bp predicted cDNA. Sequence data from these clones indicated a match with the predicted *Muc2* cDNA. PCR analysis demonstrated that all 13 amplicons were detected across the 4 intestinal tissues. Interestingly, primers that span exons 5 to 9 detected variably sized products. Ileal and cecal tonsil samples produced slightly smaller cDNA amplicons than duodenal and jejunal tissues. Further sequencing and correlation with *Muc2* protein would help understand the role of these tissue-specific alternatively spliced products.

Key Words: chicken, intestine, mucin

351 Differences in carbohydrate composition of barley varieties influence Salmonella transmission among pen mate weaned piglets. J. Bindelle[1], R. Pieper[2], J. K. Marshall[3], G. Malik*[3], B. R. Rossnagel[3], P. Leterme[4], and A. G. Van Kessel[3], [1]*University of Liege, Gembloux Agro-Bio Tech,*, *Liege, Wallonia, Belgium*, [2]*Freie Universitat*, *Berlin, Germany*, [3]*University of Saskatchewan*, *Saskatoon, SK, Canada*, [4]*Prairie Swine Centre Inc.*, *Saskatoon, SK, Canada*.

Indigestible carbohydrate (CHO) composition can vary markedly between barley varieties. They induce changes in intestinal ecophysiology and enhance growth of health-promoting bacteria. An experiment was undertaken to assess whether these changes could influence *Salmonella typhimurium* (ST) infection in pigs and transmission between penmates. A challenge study was undertaken using 84 recently weaned piglets divided in 12 pens, and fed one of the 4 experimental diets (3 pens/diet), according to the barley variety. Three hullless and one hulled varieties were chosen according to their differing CHO composition (amylose/amylopectin, β-glucan, and insoluble non-starch polysaccharides). After 14 d of adaptation, 2 pigs per pen (Trojan pigs, TrojP) were orally infected (8.0 log cfu/animal) with a low virulent, nalidixic acid and novobiocin resistant ST strain. The other animals were considered as Contact pigs (ConP) to assess ST transmission. Over 5 d following inoculation, pigs were monitored for detection of ST in the feces using plate counts. On d 6, 2 TrojP and 2 ConP per group were killed and intestinal samples as well as organ samples (liver, spleen, and lymph nodes) were analyzed for ST. The results showed that in TrojP, the cereal variety had no influence on ST fecal shedding over time and gastrointestinal tract (GIT) colonization. All pigs were positively tested for ST. Translocation of ST to lymph nodes was observed frequently but not to other organs. In ConP, compared with hulled barley, hulless barleys reduced the number of animals shedding ST ($P < 0.05$ for d 2) and the number of ST (cfu/g) in cecum on d 6 ($P < 0.01$). Although hulless barleys did not protect against colonization when directly challenged at a high oral dose, these barleys may be useful to reduce natural ST transmission among penmates.

Key Words: barley, pigs, Salmonella

352 Histomorphology and small intestinal sodium-dependent glucose transporter 1 gene expression in piglets fed phytic acid and phytase-supplemented diets. T. A. Woyengo*[1], J. C. Rodriguez-Lecompte[1], O. Adeola[2], and C. M. Nyachoti[1], [1]*University of Manitoba*, *Winnipeg, Manitoba, Canada*, [2]*Purdue University*, *West Lafayette, IN*.

An experiment was conducted to determine the effect of dietary phytic acid (PA) and phytase supplementation on small intestinal histomorphology and sodium-dependent glucose transporter 1 (SGLT1) gene expression in piglets. Twenty-four piglets with an average initial BW of 7.60 ± 0.73 kg (mean ± SD) were randomly assigned to 3 experimental diets to give 8 piglets per diet. The diets were a casein-cornstarch-based diet that was supplemented with 0, 2% PA (as sodium phytate), or 2% PA plus an *Escherichia coli*-derived phytase at 500 FTU/kg. The basal diet was formulated to meet NRC (1998) energy, amino acids, minerals and vitamins requirements for piglets. After 10 d of feeding, the piglets were killed for determining histomorphology and small intestinal SGLT1 gene expression. Phytic acid supplementation did not affect ($P > 0.05$) villous height (VH) and VH to crypt depth (CD) ratio, but decreased ($P < 0.05$) CD in the jejunum. Phytase supplementation did not affect ($P > 0.05$) VH, CD and VH to CD ratio. Phytic acid supplementation reduced SGLT1 gene expression in duodenum, jejunum and ileum by 1.1, 5.4 and 2.4 folds, respectively. Phytase supplementation increased SGLT1 gene expression in jejunum by 2.6 folds, but reduced the expression of the same in the duodenum and ileum by 2.0 and 4.0 folds, respectively. In conclusion, PA reduced the CD in the jejunum and the SGLT1 gene expression in the duodenum, jejunum and ileum, whereas phytase supplementation increased the expression of the SGLT1 in the jejunum. The reduced SGLT1 gene expression by PA implies that the latter reduces nutrient utilization in pigs partly through reduced expression of the SGLT1 that is involved in glucose and sodium absorption. The increased expression of the SGLT1 in jejunum by phytase supplementation implies that the latter alleviates the negative effects of PA partly through increased expression of the SGLT1.

Key Words: phytic acid, phytase, piglets

353 Effects of essential oils on *Clostridium perfringens* infections in broilers. T. Steiner*[1], F. van Immerseel[2], and R. Ducatelle[2], [1]*BIOMIN Holding GmbH*, *Herzogenburg, Austria*, [2]*Department of Pathology, Bacteriology and Avian Diseases, Ghent University*, *Merelbeke, Belgium*.

Clostridium perfringens-induced necrotic enteritis (NE) has become a major problem in broiler flocks. Application of essential oils in the drinking water was evaluated as potential alternative to reduce the incidence of NE. Mixed-sex Ross broilers were assigned to 3 dietary treatments (cages) with 30 birds per treatment: (1) Uninfected, untreated (Negative Control, NC), (2) Infected, untreated (Positive Control, PC), (3) PC + liquid phytogenic additive containing essential oils from oregano, anise, and citrus peel (Biomin P.E.P. sol) applied in the drinking water (60 mL/1000 L) from day 15-25. Birds were fed diets based on wheat, rye and soybean meal. From day 17 onwards, the diets contained 30% fishmeal as protein source. A Gumboro vaccine (Nobilis Gumboro D78, Intervet, Mechelen, Belgium) was applied in the drinking water at day 16 in all treatments. Furthermore, Treatments 2 and 3 were challenged orally three times a day with 4×10^8 CFU of *C. perfringens* strain 56 at days 17, 18, 19 and 20. At day 18 all birds were orally inoculated with a ten-fold dose of Paracox-5 (Schering-Plough Animal Health, Brussels, Belgium). At days 22, 23 and 24, 10 animals of each group were euthanized and intestinal lesions in the duodenum, jejunum and ileum were evaluated using a lesion score (ranging from 0, no gross lesions, to 6, severe necrosis typical of field cases). Lesion scores of 2 or more were classified as NE-positive. The data were analyzed with SPSS 16 software using the multivariate logistic regression method to compare the number of NE-positive animals in the test group with the number of NE-positive animals in the Positive Control group. Cage was the experimental unit. Birds in the NC had no intestinal lesions, whereas the PC had the highest percentage (58.6%) of birds with lesions. In comparison with the PC, the percentage of birds with lesions was reduced ($P < 0.05$) in Treatment 3 (27.6%). Lesions were found in the duodenum and jejunum, but not in the ileum, of birds in Treatments 2 and 3. In conclusion, application of essential oils in the drinking water has potential to prevent, at least in part, the development of NE infections in broilers.

Key Words: broilers, *Clostridium perfringens*, essential oils

Nonruminant Nutrition Symposium: Rethinking Equine Nutrition

354 Defining amino acid requirements in horses: Application of the indicator amino acid oxidation technique. K. L. Urschel*[1], R. J. Geor[2], and P. A. Harris[3], [1]*University of Kentucky*, *Lexington,* [2]*Michigan State University*, *East Lansing,* [3]*Waltham Centre for Pet Nutrition*, *Melton Mowbray, UK*.

Relatively little is known about the indispensable amino acid (AA) requirements of horses and how they are affected by physiological status. In the 2007 *Nutrient Requirements of Horses*, only lysine requirements are given and these requirements were not measured, but were extrapolated from the crude protein requirements. Because horses have a requirement for each indispensable AA rather than crude protein itself, it is important to know the individual AA requirements independent of crude protein. Most equine research has used either average daily gain or nitrogen retention to determine dietary AA adequacy; however, there are methodological drawbacks for each method. The indicator amino acid oxidation (IAAO) technique has been used extensively to determine AA requirements in pigs and humans and shows promise for use in horses. This method is based on the principle that indispensable AA are partitioned between protein synthesis and oxidation. The IAAO method measures the oxidation of an infused ^{13}C-labeled AA (the 'indicator') in response to graded levels of intake of another AA ('test' AA). As test AA intake increases from deficient to adequate, more protein synthesis can occur and less indicator is oxidized, until the requirement is met and indicator oxidation remains low and constant. The IAAO method has 2 key advantages: 1) it is sensitive, reducing the number of subjects required and 2) it requires only a short adaptation period to each level of AA intake and therefore each subject can be studied at each level of test AA intake over a short period. Work has begun in developing the IAAO method for use in horses: isotope infusion and breath sampling methodologies have been established, an isotopic method to measure total CO_2 production has been validated, and the 'indicator' infusion rate has been verified to result in measureable amounts of $^{13}CO_2$ in the exhaled breath samples. Using the IAAO to determine indispensable AA requirements in horses will allow for improved equine diet formulation to more closely meet the AA requirements and minimize the amount of excess dietary protein.

355 Current knowledge on the relative role of the equine small and large intestine in amino acid absorption. N. L. Trottier* and A. D. Woodward, *Michigan State University*, *East Lansing*.

The role of the small intestine as main site of amino acid absorption has been demonstrated using both in vivo and in vitro models of monogastric animals. There is limited information on the large intestine's contribution to the host N (nitrogen) homeostasis. Forage-fed equids rely on microbial fermentation of structural carbohydrates in the cecum and proximal large intestine; however, the accessibility of plant cell wall proteins to microbial proteases for amino acid availability and host absorption in the aborad gastrointestinal regions remain enigmatic. Knowledge of the small and large intestinal capacity for amino acid absorption would further our understanding of amino acid utilization in equids. Globally, the large intestine appears to significantly supply dietary N for absorption. Studies report larger contribution to total apparent N digestion from the large intestine compared with the small intestine. The relatively short time of passage through the small intestine parallels the lower digestive efficiency in that segment of the equine gastrointestinal tract, with digestive compensation mediated by post-cecal absorption. Earlier work demonstrated that protein metabolized by the equine cecum yields amino acids, urea, and ammonia; however, the relative role of these N products to total N absorption during large intestinal passage are largely unknown. Genes known to transport cationic and neutral amino acids across epithelial cells of other animal species are expressed in the equine large intestinal epithelium. These transporters may facilitate the absorption of microbial and dietary-derived amino acids across the epithelium of the large intestine. In conclusion, some evidence points to the large intestine as a site for N and amino acid absorption. Unless equids have a requirement for N, such evidence may mitigate the contradiction between the high estimates of maintenance protein requirement and the purported absence of large intestinal indispensable amino acid absorption in the solely forage-fed equid

Key Words: horse, intestine, amino acid

356 Importance of volatile fatty acid metabolism for horses. J. K. Suagee*, B. A. Corl, and R. J. Geor, *Virginia Polytechnic Institute and State University*, *Blacksburg*.

Horses evolved on sparse grasslands and have thus developed digestive mechanisms for extracting energy from energy-poor feeds. The upper portion of the equine digestive system is capable of digesting non-structural carbohydrates, such as starches and disaccharides to monosaccharides, while the cecum and large colon are sites for bacterial fermentation of structural carbohydrates. Thus, both diet-derived glucose and fermentation end products such as acetate, propionate, and butyrate are available to horses. The assumption that horses evolved on forages rich in structural carbohydrates, such as cellulose and hemicellulose, rather than non-structural carbohydrates, suggests an evolved capacity to meet energy requirements through volatile fatty acid metabolism. Horses primarily use acetate to synthesize fatty acids de novo in adipose tissue and lack the enzymatic pathway to covert glucose to acetate for fatty acid synthesis. The minimal capacity of the liver to synthesize lipids may indicate that the horse evolved to rely on hepatic gluconeogenesis. Estimates suggest that when fed a 100% forage diet, the horse can derive 50–60% of its glucose from propionate. Modern horse diets commonly consist of up to 50% grain-based supplemental feeds that are higher in non-structural carbohydrates. The effect of modern feeding practices on both hepatic gluconeogenesis and peripheral glucose metabolism is unknown. Future research should focus on determining how modern feeding practices alter volatile fatty acid production and metabolism. A further step would include investigating the effect of altered volatile fatty acid metabolism on the development of metabolic disorders that are associated with diets high in supplemental grain-based concentrates.

Key Words: acetate, propionate, horse

357 Glucose sensing and regulation of equine intestinal glucose transport. S. Shirazi-Beechey*, D. Arora, J. Dyer, and K. Daly, *University of Liverpool*, *Liverpool, UK*.

Glucose is transported across the luminal membrane of enterocytes by the sodium/glucose cotransporter 1, SGLT1. This also activates water absorption in the intestine. Regulation of SGLT1 is essential for the provision of glucose to the body and thus is important for maintenance of glucose homeostasis. The major aim of this talk is to report on recent progress made toward identifying mechanisms involved in regulation of equine intestinal glucose transport in response to a change in diet.

Cloning and sequencing the cDNA encoding equine SGLT1 and the determination of SGLT1 amino acid sequence allowed us to determine SGLT1 expression in equine small intestine. In the horse, glucose is transported mainly across the brush membrane of enterocytes by SGLT1. In horses maintained on pasture forage the highest rate of glucose transport was in proximal > mid with little in distal part of the small intestine. However, in horses fed controlled diets containing different ratios of hay and grain, SGLT1 expression is enhanced, with time, in response to increased dietary hydrolysable carbohydrate, not only in the proximal, but also in the distal small intestine. We have shown that sweet taste receptor, T1r2+T1r3 and its coupled G protein, gustducin, are expressed in enteroendocrine cells of the intestine of several species including the horse. Dietary sugars and artificial sweeteners act in the intestine, on the sweet taste receptor to elicit upregulation of SGLT1. Furthermore, knocking out either gustducin or T1r3 abolished the ability of mouse intestine to upregulate SGLT1 expression in response to increased dietary carbohydrate. Thus the equine intestinal sweet taste receptor has the potential to be used as a novel nutritional target to increase intestinal glucose and water absorption with the attendant promise of enhancing performance and overcoming the detrimental effects of post exercise dehydration.

Financial support of Horserace Betting Levy Board is gratefully acknowledged.

Key Words: SGLT1, equine, intestine

358 Blue-and-gold Macaw (*Ara ararauna*) postmortem semen collection. J. M. Silva[1], S. K. Cunha[1], C. D. Corcini[1], A. S. Varela Junior[2], A. P. N. Albano[1], A. L. S. Valente[1], and D. C. Bongalhardo*[1], [1]*Universidade Federal de Pelotas*, *Pelotas, RS, Brazil*, [2]*Universidade Federal de Rio Grande*, *Rio Grande, RS, Brazil*.

The blue-and-gold Macaw (*Ara ararauna*) is a Neotropical parrot from South America. It is rated as Least Concern by Bird Life International; however, there is a very heavy wild-caught trade of this species. In December 2008, one adult male was brought to the Wildlife Rehabilitation Center from the Federal University of Pelotas shortly after death. The main objective of this work was to perform a postmortem semen collection in this bird, aiming to recover sperm for cryopreservation. As a complement, testicular histology was observed to confirm that the macaw was sexually active. Necropsy was made approximately 3 h after death; at this time the testes, epididymis and deferent ducts were removed and placed in a Petri dish. Epididymis and deferent ducts were washed with Lakes diluent and the suspension was brought to the laboratory, where recovered sperm was evaluated by motility. Dry slides were made to observe sperm morphology, using 5 different stains: orcein, eosin, eosin-nigrosin, Giemsa, and Coomassie Blue. The testes were fixed in 10% buffered formalin; after 24 h they were dehydrated in crescent concentrations of alcohol, immersed in xylol at 100%, impregnated in Paraplast Xtra, and sliced (5 μm). The cuts were stained with Harris hematoxylin and eosin and observed in optical microscope. Few sperm were recovered from the epididimys and deferent ducts and motility was lower than 1%, therefore it was not possible to proceed with cryopreservation. The low motility could be attributed to the time elapsed between the death and the necropsy. Eosin was the only stain that allowed clear visualization of the sperm cell, which presented normal morphology. Histology of the testes showed intense seminiferous tubules activity; a multi stratified epithelium containing sperm in different stages of development could be observed, as well as polygonal Sertoli cells. The results show that the testis were fully functional and producing sperm with normal morphology. It was also demonstrated that it is possible to collect motile sperm from dead birds, however, to attempt cryopreservation, it is still necessary to acquire higher motility.

359 To move or not to move? Gait analysis of the modern broiler and its implications. H. Paxton*, M. A. Daley, S. A. Corr, and J. R. Hutchinson, *Royal Veterinary College*, *Hatfield, Hertfordshire, UK*.

Ever since Darwin, it has been well recognized that artificial selection could bring about changes in animal behavior, physiology and morphology by the simple selection of human-desired traits. But what happens when these selection pressures begin to alter the locomotion of an animal and potentially result in an increase in musculoskeletal pathologies? The modern broiler has changed dramatically reaching its market weight faster and having an increased meat yield. Research indicates that these changes may predispose some of the broilers to leg pathologies which are a welfare concern. We therefore investigate whether the modern broiler and its 2 great-grandparent lines have adopted different locomotor strategies as a result of their altered morphology. We also investigate whether any changes might prevent these birds from walking economically or stably and perhaps predispose them to locomotor pathology. We collected force plate and kinematic data from 27 chickens (350 steps), including a commercial broiler strain and 2 great-grandparent lines (A and B) over a range of walking speeds, to quantify the 3D dynamics of the center of mass and determine how these birds modulate the force and mechanical work of locomotion. Walking speeds were slow (0.10 – 0.99 ms^{-1}) and ranges differed between groups with the fastest walking speeds recorded in the broiler population. There was greater variability in step width than step length, likely linked to increased mediolateral forces and control strategies for stability. We only found right-left limb asymmetries in the great-grandparent lines, with line B showing a decrease in step length with speed ($P = 0.01$) that is not commonly seen in ground birds. Based on current empirical models for cost, the differences in locomotor mechanics among lines suggest that Line B is likely to have a 10% higher cost of locomotion due to significantly higher stride frequencies ($P < 0.001$) and shorter step lengths. Thus selection for desirable traits in the broiler chicken lineage has carried along different gait characteristics that we have quantified for the first time.

Key Words: broiler chicken, locomotion, lameness

360 Effects of commercial in ovo injection of carbohydrates on broiler embryogenesis. W. Zhai*, R. Pulikanti, S. Womack, D. E. Rowe, and E. D. Peebles, *Mississippi State University*, *Mississippi State*.

The effects of in ovo injection of different carbohydrate solutions on hatch rate, hatch time, BW, body moisture, yolk sac weight, and yolk sac moisture of Ross × 708 broiler chicks, hatched from eggs laid by a 34-wk-old breeder flock, were investigated. Eggs containing live embryos were injected in the amnion on d 18.5 of incubation using an automated multiple-egg injector with 0.1, 0.4, 0.7, or 1.0 mL of commercial diluent or a carbohydrate dissolved in diluent. Commercial diluent containing 25% of the following carbohydrates were injected into eggs: glucose, fructose, sucrose, maltose, and dextrin. The results showed that no carbohydrate type or volume affected hatch time. Absolute and relative BW on hatch day were positively related to injection volume ($P < 0.0001$). However, hatch rate was negatively related to injection volume ($P < 0.0001$). To realize a 90% hatchability of fertilized eggs, injection volume could not exceed 0.7, 0.4, 0.4, 0.7, and 0.7 mL for glucose, fructose, sucrose, maltose, and dextrin, respectively. Yolk-free BW was negatively related to fructose and sucrose injection volume ($P < 0.004$), but was not related to diluent, glucose, maltose, and dextrin injection volume. Similarly, absolute and proportional yolk sac weights were positively related to fructose, sucrose, and dextrin injection volume ($P < 0.01$), but were not related to diluent, glucose, and maltose injection volume. Yolk sac moisture was positively related to injection volume for all injectables including diluent ($P < 0.03$). However, body moisture and yolk-free body moisture were not related to injection type or volume. In conclusion, the use of carbohydrates added to commercial diluent for the in ovo injection of broiler hatching eggs requires the use of appropriate volumes to promote growth and nutrient utilization without adversely affecting rate of hatch.

Key Words: BW, hatch rate, in ovo injection

361 The effect of egg weight loss on embryonic development in Chinese painted quail (*Coturnix chinensis*) exhibiting parthenogenesis. J. B. Wells, H. M. Parker*, A. S. Kiess, and C. D. McDaniel, *Mississippi State University*, *Mississippi State*.

Parthenogenesis, the development of an unfertilized egg, has been studied extensively in turkeys. Recently it has been revealed that

parthenogenesis occurs in the eggs of Chinese painted quail and the percentage of eggs exhibiting parthenogenesis is negatively correlated with egg production as well as clutch size. In broiler breeders it has been reported that the first egg of a sequence loses less moisture during incubation. Because the incidence of parthenogenesis is greater and egg weight loss is less in the first egg of a sequence, it is possible that parthenogenesis is also affected by egg moisture loss. Therefore, the objective of this study was to determine if a relationship exists between egg weight loss and parthenogenesis. In this experiment individual eggs were collected from 157 hens daily and labeled with hen number and date. Eggs were stored for 0 to 3 d at 20°C before incubation at 37°C. To determine egg weight loss, eggs were weighed on the day of collection and again after 10 d of incubation. Pearson's correlation coefficients were used to determine if relationships exist between egg weight loss and the percentage of eggs exhibiting parthenogenesis, parthenogen size, egg storage, and clutch position. The percentage of egg weight loss was negatively correlated with the incidence of parthenogenesis in eggs ($r = -0.56$; $P < 0.001$), parthenogen size($r = -0.49$; $P < 0.001$), and egg storage ($r = -0.24$; $P < 0.003$). However, the percentage of egg weight loss was positively correlated with average clutch position ($r = 0.32$; $P < 0.001$). In conclusion, it appears that eggshell quality possibly influences the incidence of parthenogenesis in Chinese Painted quail eggs because as the percentage of egg weight loss decreases, the incidence of parthenogenesis increases.

Key Words: parthenogenesis, moisture loss, clutch sequence position

362 Relationships of Ross × 708 broiler post-hatch development to embryonic temperature, incubation length, and eggshell water vapor conductance. R. Pulikanti, E. D. Peebles*, W. Zhai, A. Bello, C. N. Obi, and A. O. Sokale, *Mississippi State University*, *Mississippi State*.

To establish relationships between post-hatch broiler development, egg incubation length (IL), and eggshell water vapor conductance (G), Ross × 708 broiler hatching eggs were randomly set on 8 replicate tray levels of an incubator (20 eggs per replicate). On 10.5 d of incubation, transponders were implanted in the air cells of 4 embryonated eggs per replicate for determination of internal egg temperatures (embryo temperatures; IT) through d 18.5. External egg temperatures were determined using 2 water filled vials and 2 infertile eggs containing transponders per each replicate level. Hatch was monitored every 12 h between 18.5 and 21.5 d of incubation. The chicks were placed in corresponding replicate floor pens and grown through 49 d of age. On 28 and 48 d post-hatch, at least 2 chicks per pen were necropsied for determination of BW, and the relative weights and moisture contents of the liver, breast muscle, and left gastrocnemius muscle. Also, IL, G, relative G (RG), and the conductance constant (C) of each embryonated egg were determined. Mean IL, G, RG, and C were 20.7 d, 14.2 mg water/d × Torr, 24.6 mg water/d × Torr × 100 g egg weight, and 5.05. The IT was negatively correlated with relative chick BW and relative gastrocnemius muscle weight on d 28 post-hatch. However, IL was positively correlated with relative gastrocnemius muscle weight on d 28 but negatively correlated with gastrocnemius muscle moisture on d 48 post-hatch. Nevertheless, RG and C were negatively correlated with liver and breast muscle moisture contents on d 28 post-hatch. Correlations were considered significant at $P \leq 0.06$. Within physiological limits, RG was negatively associated with chick hydration status on d 28 post-hatch. The observed relationships were more pronounced initially during early post-hatch life and subsided as the chick reached market age.

Key Words: broiler, eggshell conductance, embryo temperature

363 NADH oxidase generated superoxide reduces nitric oxide availability in lungs of hypoxic broilers chickens. J. Bautista–Ortega*, E. A. Ellis, and C. A. Ruiz–Feria, *Texas A&M University*, *College Station*.

Xanthine (XO) and NADH oxidase (NOX) are important sources of superoxide in cardiovascular diseases including pulmonary hypertension syndrome (PHS). Previously we localized XO and NOX in the pulmonary artery endothelium of hypoxic broilers. Nitrotyrosine is a biomarker for peroxynitrite which is negatively correlated with the availability of nitric oxide (NO). Cytochemical localization of XO and NOX (reflectance units), and colloidal gold based immunocytochemical localization of nitrotyrosine (N of colloidal gold particles) were used to determine oxidative and nitrosative (reduced availability of NO) stress in lungs of broilers exposed to hypoxia (d 7 to d 36, simulated 3,000 m above sea level) and fed a control diet (CTL), or control plus arginine (ARG, 0.8% wt/wt), or CTL plus ARG and vitamins C (500 mg / L water) and E (200 IU / kg of feed) (AEC). Also, a group of normoxic broilers were fed the CTL diet (NOR). Nitrosative stress was also determined in hypoxic broilers with PHS and in clinically healthy ones. The XO activity was higher in NOR birds (586 ± 43) than in both AEC (456 ± 39) and ARG birds (394 ± 31), whereas CTL birds had the lowest XO activity (313 ± 27). The NOX activity or NO availability was not affected by dietary or hypoxia conditions in clinically healthy birds. Nevertheless, hypoxic birds that developed PHS had higher nitrotyrosine (145 ± 19) than hypoxic but clinically healthy birds (56 ± 11). Increased levels of superoxide generated by NOX may have resulted in decreased availability of NO as measured by nitrotyrosine. To our knowledge, this is the first time that XO and NOX activity has been semi–quantitatively determined in situ in lung samples of hypoxic broiler chickens. Supplementation with ARG and antioxidant vitamins C and E tended to produce NOX–derived superoxide levels similar to those in the normoxic chickens probably preserving NO in the system but significance was not reached probably due to limited number of birds. The dual role of XO, which produces superoxide and uric acid (antioxidant), may have buffered the effects of superoxides in clinically healthy birds.

Key Words: hypoxia, nitrotyrosine, pulmonary hypertension

364 Genistein effects on fatty liver syndrome induced by estrogen. L. M. Stevenson*, S. S. Oates, J. B. Hess, and W. D. Berry, *Auburn University*, *Auburn, AL*.

Soy phytoestrogens, such as genistein, have been demonstrated to have a protective effect against fatty liver syndrome in rats. A study was performed with old laying hens to determine if genistein had a protective effect against avian fatty liver syndrome induced by exogenous estrogen. Twenty-four 5 year-old laying hens were randomly selected and divided into 6 treatment groups. Each treatment group consisted of 4 hens. Genistein doses were given by a daily gavage for 14 d. The treatments were: Sham Control (gavage and injections of sesame oil), Estrogen Control (7.5 mg estrogen/kg body weight per dose), Genistein Control (20 mg genistein/kg body weight daily), Low Genistein (7.5 mg estrogen/kg body weight per dose and 10 mg genistein/kg body weight daily), Medium Genistein (7.5 mg estrogen/kg body weight per dose and 15 mg genistein/kg body weight daily), and High Genistein (7.5 mg estrogen/kg body weight per dose and 20 mg genistein/kg body weight daily). Estrogen doses were estrogen diproprionate and were given by injection in the subcutaneous tissue in the back of the neck 3 times during the experiment. All treatments were dissolved in sesame oil. Birds were weighed at placement and at the end of the study. There were no significant differences in body weights for any treatments at

placement ($P > 1.0$) or at the end of the study ($P > 0.6$). Blood samples were collected at placement and at the end of the study. Plasma genistein was analyzed by high performance liquid chromatography (HPLC). Levels of genistein in the plasma were significantly increased in birds on the genistein treatments ($P < 0.05$). Livers were removed, weighed, and samples were collected after the study. There were no significant differences in liver weights ($P > 0.5$) or livers as a percent of their final body ($P > 0.4$). Pictures were taken of all of the livers and visually scored to determine the degree of fatty liver. Birds in the Estrogen Control treatment had an increase in yellow coloring of the liver as compared with the other treatments.

Key Words: genistein, estrogen, liver

365 Gene expression of thyroid hormone regulating elements in reproductively photosensitive and photorefractory turkey hens. S. W. Kang*, S. Kosonsiriluk, and M. E. El Halawani, *University of Minnesota*, *St. Paul*.

Thyroid hormones are important in the reproductive neuroendocrine response to changing photoperiod in birds. Regulation of thyroid hormone homeostasis in the brain is mainly determined by thyroid hormone transporter (transthyretin (TTR)), type II iodothyronine deiodinase (Dio2), type III iodothyronine deiodinase (Dio3) and thyrotropin-releasing hormone (TRH). TTR plays a key role in transporting thyroid hormones into the brain via the choroid plexus (CP). Tuberal hypothalamus (TuH) is a well known site in the brain where Dio2 is involved in converting thyroxin (T4) into triiodothyronine (T3). In this study, to gain insights into seasonal photoperiodic mechanism(s) that govern reproductive photoresponsiveness and photorefractoriness of turkey hens, we investigated gene expression of thyroid hormone regulating elements (i.e., TTR, Dio2, Dio3, and TRH) in the brain of photosensitive and photorefractory hens using real-time PCR. The expression of each gene was determined in microdissected brain areas from reproductively inactive short day photosensitive hens (SD), long day photostimulated photosensitive hens (LD), and long day photorefractory hens (RF) at 2 circadian time points (CT14, CT19). In TuH of LD, Dio2 was significantly greater (2.8 fold, $P < 0.01$) and Dio3 was repressed (42%, $P < 0.05$) when compared with that of SD. In LD, TTR was 2.5 fold greater relative to that in SD ($P < 0.01$). And, TTR expression was downregulated (3.5 fold, $P < 0.01$) in long day RF relative to LD. Also, TTR was greater (45%, $P < 0.05$) during the photosensitive phase (CT14) than during the dark phase (CT19). CP Dio2 was significantly higher (2.1 fold, $P < 0.01$) in LD compared with that of SD and RF. TRH in the paraventricular nucleus was 2.8 fold greater in LD compared with that of RF ($P < 0.01$), and the levels in RF were 22% ($P < 0.05$) lower when compared with SD. In summary, Dio2 in CP as well as TuH appears to be an important gene involved in the expression of photorefractoriness. TTR in CP might be a significant thyroid hormone transporter involved in photoperiodic response of turkey hens.

366 Identification of a nonclassical glucocorticoid responsive region of the growth hormone gene during chick embryonic development. K. A. Heuck-Knubel* and T. E. Porter, *Department of Animal & Avian Sciences, University of Maryland*, *College Park.*

Growth hormone (GH) affects growth and contributes to a lean phenotype in broiler chickens; however, exogenous GH has little effect on post-hatch growth. Elucidation of the regulation of the GH gene could result in alternative approaches for maximizing growth in broilers. GH secretion occurs naturally between embryonic day (e) 14 and e16, concomitantly with a rise in adrenal corticosterone (CORT) secretion. Treatment of chicken embryonic pituitary (CEP) cells with CORT induces GH secretion prematurely. Inspection of the regulatory region of the GH gene reveals no glucocorticoid (GC) response element (GRE). Pretreatment of e11 cells with a protein synthesis inhibitor, CHX, resulted in blockage of the CORT-induced increase in GH mRNA. This leads to the hypothesis that a GC-responsive intermediary protein is necessary for the CORT induced increase in GH. Characterization of the upstream region of the GH gene may identify such a protein. −1727/+48 bp of the GH gene was cloned into a luciferase reporter plasmid and transfected into e11 CEP cells. Treatment with 100 nM CORT increased luciferase activity 10-fold (n = 3; $P < 0.05$). Truncation of this construct to −954 abolished activity. Thirteen additional constructs were tested, revealing an inhibitory region from −1467 to −1430 and a GC-responsive region (GCRR) from −1045 to −954 ($P < 0.05$; n = 3). Other constructs showed that the GCRR is position-, orientation-, and context-dependent. Potential transcription factor motifs in the GCRR include ETS1, ELK4, and a GC-binding region (GBR). Mutation of the ETS1 site or the GBR in the −1045/+48 reporter resulted in a loss of Luciferase activity. Nuclear proteins bind to a GCRR probe in a CORT-regulated manner in gel shift assays, and unlabeled competitor can compete off binding. In a single experiment, an ELK4 antibody (ab) did not result in a supershift, but an ETS1 ab abolished protein binding to the probe. The chicken GH gene is GC responsive and contains a putative ETS1 and GBR site at −1017 to −985. Investigation of protein binding to the GCRR is underway using gel shift assays and chromatin immunoprecipitation.

Key Words: luciferase, corticosterone, pituitary

367 Detection and expression of the glucocorticoid receptor in the laying hen's oviduct. L. A. Bola*, D. V. Arbona, and J. B. Hoffman, *North Carolina State University*, *Raleigh*.

The hen's oviduct is critical in the process of egg formation and ovipositioning. Specifically, the components of the oviduct including the infundibulum, magnum, isthmus, uterus/shell-gland, and vagina are responsible for both interior egg quality as well as exterior shell quality. Due to the sensitivity of the oviduct during hormonal and cellular changes that occur during the formation of the egg, stress susceptibility may have a significant impact on egg quality and formation. Specifically regulation of hormonal action on the oviduct is subject to paracrine modulation by steroids such as glucocorticoids. The presence of glucocorticoid receptors (GR) in the oviduct that bind corticosterone, the avian glucocorticoid, may be an indicator of oviductal tissue sensitivity to stress. The expression of GR was characterized in the oviducts of 6 Leghorns at 27 weeks of age. Tissue samples were removed from the infundibulum, isthmus, magnum, uterus/shell-gland, and vagina from each hen by manual dissection. Subsequently, RNA extraction and real-time RT-PCR analyses were performed. Our results showed expression of the GR in each of the tested regions of the oviduct tissue. These results suggest that corticosteroids may directly act on the oviduct to influence the process of egg formation and overall egg quality.

Key Words: glucocorticoid receptor, oviduct, egg quality

368 Detection and expression of glucocorticoid receptors in the germinal disc (GD) and non-germinal disc (NGD) regions of the laying hen's hierarchical ovarian follicles. J. B. Hoffman*, D. V. Arbona, and L. A. Bola, *North Carolina State University*, *Raleigh*.

The influence of corticosterones on fertilization and developmental events post-fertilization has yet to be fully characterized in the laying hen. Because the left adrenal gland is embedded in the ovary, it is possible that corticosterones may act through a paracrine mechanism to influence fertilization, sex-ratio distributions, and embryological development. However, paracrine mediation by corticosterones is dependent upon the presence of glucocorticoid receptors (GR) in the germinal disc (GD) region of the F1 hierarchical follicle where fertilization occurs. Additionally, differences in expression of GR in the GD versus the non-germinal disc region (NGD) which is not involved in the process of fertilization may further elucidate the degree to which corticosterones are involved in regulating these processes. In this study, the expression of GR was characterized in the granulosa tissue of the GD and NGD from the F1-F4 hierarchical follicles of 6 Leghorns at 32 weeks of age. Tissue samples (3 cm x 3 cm) were removed from the GD and NGD by manual dissection. Subsequently, RNA extraction and real-time RT-PCR analyses were performed. Our results showed expression of the GR in the GD and NGD regions of the F1-F4 hierarchical follicles suggesting that corticosterone may influence the process of fertilization and post-fertilization events.

Key Words: germinal disc, glucocorticoid receptor, fertilization

369 Molecular cloning and characterization of chicken and zebrafish prostaglandin receptors. A. H. Y. Kwok*, Y. Wang, and F. C. Leung, *The University of Hong Kong*.

Prostaglandin E2 (PGE2) and F2α (PGF2α) are autocrine/paracrine mediators responsible for regulation of vital physiological processes, ranging from systemic effects such as fever generation and ACTH-related stress response, to tissue-localized effects such as inflammation, vascular homeostasis and reproduction. Four receptor subtypes have been identified for PGE2, namely prostaglandin E receptor subtypes 1 (EP1), EP2, EP3 and EP4, and prostaglandin F receptor (FP) for PGF2α. Though the receptors were extensively studied in mammals, little is known about their functionality and expression in non-mammalian vertebrate species. Complementing our previous study on chicken EP2 (cEP2), cEP3, cEP4 and cFP (including cFPa and a novel middle-truncated isoform, cFPb) in which full-length cDNAs were first cloned and preliminarily characterized, in the present study, we furthered our investigation, first, by quantitative real-time PCR, the relative expression of cFPa and cFPb were detected in 12 adult chicken tissues and hen oviduct, wherein both isoforms were found to be widely expressed. Interestingly, the putative functional ortholog cFPa was expressed in abundance in testis, in contrast, only minimal signal of cFPb was detected; an inverse expression ratio was observed in ovary. As EP1 appears to be absent in chicken (neither found in genome database nor detected by degenerate primers designed), we proceeded to examine whether EP1 was present in other lower vertebrates, such as fish. Three full-length EP1 cDNAs were identified from zebrafish (Danio rerio), they were named zEP1a, zEP1b and zEP1-like (zEP1-L) respectively, based on their corresponding sequence identities to mammalian EP1 orthologs (from 38% to 42%). By semiquantitative reverse transcription (RT-) PCR, zEP1a and zEP1b were found in all 9 adult tissues examined, while zEP1-L was detected only in brain and kidney. Subsequent functional assays for the cloned receptors are under way, which, in combination with the above results, would help to elucidate the physiological roles of PGE2 and PGF2α and their receptors in target tissues of non-mammalian vertebrate.

Key Words: chicken, prostaglandins, prostaglandin receptors

370 Effect of seminal plasma progesterone on sperm hole penetration in White Leghorns. E. M. Anderson* and K. J. Navara, *University of Georgia*, *Athens*.

While there has been significant interest in identifying the hormonal contributions passed on with gametes by female birds, the hormone content of fluids contributed during reproduction by the male remains relatively unstudied. We aimed to characterize the hormone content, and the potential function of those hormones, in avian seminal plasma. First, we measured the concentrations of 5 hormones within seminal plasma collected from White Leghorn roosters, including progesterone (P4), testosterone (T), dihydrotestosterone (DHT), estrogen (E) and corticosterone (B). P4 levels were higher in seminal plasma compared with other hormones analyzed, ranging from 0 to 14.8 ng/ml (all other levels were <1.1ng/ml). Given this relatively high concentration of seminal plasma progesterone, we then attempted to determine how progesterone in seminal plasma may function in fertility. White Leghorn hens were assigned to 2 treatment groups: progesterone-treated or control (n = 24 hens per treatment). Semen was collected via abdominal massage from 24 White Leghorn roosters. Each semen sample was divided into 2 equal volumes, one treated with progesterone (0.4 ng/50 μL) and the other with a control of diluent and artificially inseminated into each treatment group of hens. Eggs were collected 2 d after insemination. A perivitelline layer sperm hole assay, a method that can be used as a predictive measure of fertility, was performed for each egg and the number of sperm holes was counted under a microscope. The effects of treatment were then analyzed and the number of sperm holes were significantly less in the progesterone treated group compared with the control on the second day after insemination ($P = 0.0307$). These results suggest that progesterone has a detrimental effect on the ability of sperm to penetrate the IPVL, and that males that deposit more progesterone into seminal plasma may have a decreased capability to fertilize an egg.

Key Words: seminal plasma, progesterone, white leghorn

371 *Salmonella* recovery following air chilling for matched neck-skin and whole carcass sampling methodologies. R. J. Buhr*, N. A. Cox, J. A. Cason, L. L. Rigsby, and D. V. Bourassa, *USDA-ARS Russell Research Center*, *Athens, GA*.

The prevalence and serogroups of *Salmonella* recovered following air chilling were determined for both enriched neck skin and matching enriched whole carcass samples. Commercially processed and eviscerated carcasses were air chilled to 4°C before removing the neck skin (8.3 g) and stomaching in 83 mL buffered peptone water. The remaining carcass was subjected to whole carcass enrichment in 500 mL buffered peptone water. Both neck skins and whole carcasses were incubated at 37°C for 24 h before aliquots were transferred to selective enrichment broths (RV and TT) and incubated at 37°C for 24 h. Following incubation, BGS and MLIA plates were streaked and incubated at 37°C for 24 h. Three typical colonies were individually stabbed into TSI and LIA slants and incubated at 37°C for 24 h. For neck skin samples, 14/18 were Salmonella-positive with 5 identified as serogroup C1, 8 serogroup C3, and 2 serogroup E. For whole carcasses 16/18 carcasses were Salmonella-positive with 1 identified as serogroup B, 6 serogroup C1, 9 serogroup C3, and 2 serogroup E. Two *Salmonella* serogroups were detected from one neck skin (C3/E) sample and 2 *Salmonella* serogroups were detected from 2 non-matched carcasses (C1/C3 and C3/E). All 4 of the Salmonella-negative neck skin samples had Salmonella-positive matching whole carcasses and the 2 Salmonella-negative whole carcasses had Salmonella-positive matching neck skin samples. Selecting 3 individual colonies, versus only one, from BGS and MLIA plates resulted in 2 additional Salmonella-positive neck skin samples (C1) and 2 additional Salmonella-positive carcasses (C1 and C3). In this study, individual neck skin enrichment (78%) and whole carcass enrichment (89%) sampling methodologies were comparable in the prevalence detection of *Salmonella* from matched air-chilled carcasses.

Key Words: *Salmonella* serogroups, whole carcass enrichment, neck skin enrichment

372 Effect of ultrasonication and phosphate level during marination on numbers of *Salmonella* and *Escherichia coli* on broiler breast meat. D. P. Smith*, *Poultry Science Dept., North Carolina State University*, *Raleigh*.

Four trials were conducted to determine the effect of ultrasonic treatment and phosphate level during marination on numbers of *Salmonella* and *Escherichia (E.) coli*. In each trial 2 whole boneless, skinless chicken breasts were obtained from a retail store and split into paired fillets. One fillet from each pair was assigned to marination either with or without ultrasonication for 20 min. Trials 1 and 2 marination solution contained 91% water, 6% NaCl, and 3% sodium tripolyphosphate (STP); for Trials 3 and 4 the solution consisted of 91% water, 6% STP, and 3% NaCl. Ten min before marination fillets were inoculated with 1.0 mL of a culture containing nalidixic acid-resistant strains of *Salmonella* Typhimurium, Enteritidis, *heidelberg*, and *montevideo* (mean count of 7.1 $\log_{10}$), and an *E. coli* strain (mean count of 6.1 $\log_{10}$). After marination fillets were shaken for 1 min in a 50 mL rinse of 1% BPW. Serial dilutions were plated onto BGA with sulfapyridine with 200 ppm nalidixic acid and incubated at 37°C for 24 h, and onto *E. coli*/coliform Petrifilm and incubated at 35°C for 24 h. Post-treatment marination solutions were sampled and average *Salmonella* counts of 1.7 $\log_{10}$ were recovered; no *E. coli* were recovered. Bacterial counts were transformed to $\log_{10}$ CFU/ml, data main effects analyzed by ANOVA, and mean differences due to treatment analyzed by *t* test. There were no significant ($P < 0.05$) differences due to ultrasonication for either *Salmonella* (mean count 4.6 $\log_{10}$ CFU) or *E. coli* (mean count of 2.8 $\log_{10}$ CFU). Higher STP significantly reduced *Salmonella* numbers (from 4.7 to 4.5 $\log_{10}$ CFU) but had no effect on *E. coli*. The reduction of *Salmonella* numbers was small and would have limited usefulness in practical application. Ultrasonic treatment during marination was not effective for reducing numbers of *Salmonella* and *E. coli* on broiler breast meat.

Key Words: broiler breast meat, ultrasonic marination, *Salmonella*

373 The enrichment of breast and thigh meat in broilers for DHA using supplemental DHA. M. K. Manangi*, B. Wuelling, J. Hux, S. Carter, and M. Vazquez-Anon, *Novus International, Inc.*, *St. Charles, MO*.

A 44-d experiment was conducted to evaluate the enrichment levels of DHA (docosahexaenoic acid) in broiler breast and thigh meat along with various other tissues using supplemental source of DHA (DHA GOLD) in a corn-SBM based diet. A total of 540 Ross-708 male broiler chicks were raised in floor pens up to d 23 of age using starter and grower diets. On d 23, 432 birds were assigned to 3 treatments with 12 pens/treatment and 12 birds/pen under completely randomized block design. The 3 treatments were: 1) 0% DHA GOLD; 2) 1% DHA GOLD; 3) 1.5% DHA GOLD supplementation. DHA GOLD was supplemented as 'on-top' addition from d 23 to 44. DHA was quantified in various tissues at d 37 and only for breast meat at d 44. D 37 data indicates significant ($P < 0.05$) increase in DHA content due to supplemental DHA for breast and thigh meat and skin, liver, and fat pad. D 44 breast meat data also indicates a significant ($P < 0.05$) increase in DHA content. Supplementing broilers diets with 0, 1, and 1.5% DHA GOLD on top for 14 d (d 23 - 37) resulted in 17, 26 and 34 mg of DHA/100g of breast muscle; 17, 32, and 43 mg of DHA/100 g of thigh muscle; 20, 160, and 274 mg of DHA/100g of breast skin; 27, 119, and 253 mg of DHA/100 g of thigh skin; 4, 80, and 160 mg of DHA/100 g of liver; and 13, 179, and 289 mg of DHA/100 g of fat pad, respectively. Supplementing broilers with diets containing 0, 1, and 1.5% DHA GOLD on top for the last 21 d (d 23 - 44) resulted in 13, 35, and 54mg of DHA/100g of breast muscle, respectively. Data also indicates that supplementing up to 1.5% of DHA GOLD on top in the broiler diets does not affect ($P > 0.05$) weight gain and F:G. In summary, supplemental DHA GOLD can be used to enrich broiler meat with levels of DHA to satisfy recommended daily allowance. Further increase in enrichment was possible by extended period of dietary DHA inclusion. DHA GOLD is a dried whole cell algae product, derived from *Schizochytrium sp*, contains a minimum of 18% DHA by weight.
DHA GOLD is a registered trademark of Martek Biosciences Corporation, USA.

Key Words: broiler, DHA

374 Effect of feeding hatchery waste meal processed by different techniques on egg quality and productive performance of laying hens. A. Mahmud*[1], Saima[1], M. A. Jabbar[1], A. W. Sahoota[1], Z. Ali[2], and M. Z. U. Khan[1], [1]*University of Veterinary & Animal Sciences*, *Lahore, Pakistan*, [2]*Big Feeds (Pvt) Ltd.*, *Lahore, Pakistan*.

The present experiment was conducted in 2 phases. In the first phase, hatchery waste (HW) was subjected to the following processing techniques; cooking, autoclaving and extrusion to prepare hatchery waste

meal (HWM). Prepared HWM was chemically analyzed. In the second phase, an optimum inclusion level for each type of processed HWM was determined in layer diets. For this purpose, 3 hundred White Leghorn hens were randomly distributed to 10 dietary treatments. A negative control diet was prepared without HWM, while 9 experimental diets contained 4, 8 or 12% of cooked, autoclaved or extruded HWM, respectively. Completely randomized design was used and statistical analyses were carried out with SAS version 9.1 using Duncan multiple range test for mean comparisons at 5% probability. Results showed that maximum egg production was achieved with 4% HWM processed by autoclaving. Processing of HW with extrusion significantly reduced egg production and a more pronounced decrease was found with 12% of extruded HWM. Egg mass and feed conversion followed the same trend observed for egg production. Average egg weight due to different treatments fell within a very narrow range and showed no difference ($P > 0.05$) among treatments. Shell, yolk and albumen weights, as a percentage of egg weight, were not significantly affected with the use of different levels and processing of HWM. Maximum values for albumen height as well as Haugh units were obtained by feeding the 4% autoclaved HWM. Other egg quality parameters like shell thickness, yolk index and color were independent of the dietary treatments. The findings of this study suggest that autoclaving of hatchery waste is better than extrusion or cooking techniques and 4% of autoclaved HWM may be included in layer rations to get more production than diets without HWM. Nevertheless, layer diets up to 8% HWM could be used to feed the laying hens to maintain reasonably good production without detrimental effects on egg quality.

Key Words: hatchery wastes, processing, layers

375 Effect of feeding flaxseed and two types of antioxidants on quality parameters of omega-3 enriched eggs during storage. Z. Hayat*[1,2], G. Cherian[3], T. N. Pasha[2], F. M. Khattak[2], and M. A. Jabbar[2], [1]*University College of Agriculture, University of Sargodha, Sargodha-40100, Pakistan*, [2]*University of Veterinary and Animal Sciences, Lahore-54000, Pakistan*, [3]*Department of Animal Sciences, Oregon State University, Corvallis*.

Inclusion of flaxseed to enhance omega-3 content of eggs is well documented. However, increasing omega-3 fatty acids perpetuates the extent of fatty acid unsaturation, leading to oxidative damage of yolk lipids and reduction in egg quality. This phenomenon is aggravated during storage, and needs suitable strategies to combat deterioration of egg quality. Currently, a limited number of antioxidants are available that poses major challenge for the feed industry to use them efficiently. Therefore, the aim of present study was to examine the effect of 2 types of antioxidants and storage on quality parameters of eggs enriched with omega-3 fatty acids. ISA brown layer pullets were fed corn-soybean meal-based diet with no added antioxidants (Control) or 10% flax seed and 2 types of antioxidants (α-tocopherols, butylated hydroxytoluene, [BHT] at 0, 50, 100, 150 IU or mg/kg). A total of 384 eggs (48/diet) were collected and stored at 4°C for 60 d. On d 0, 20, 40, and 60 of storage, 2 eggs from each replicate (totaling 12 eggs per treatment) were selected randomly. Egg quality parameters such as egg weight, yolk weight, yolk color, albumen weight, albumen height, shell weight, shell thickness and Haugh unit were measured. Storage over 20 d affected all the parameters except egg weight, shell weight and shell thickness ($P < 0.05$). Supplementation of antioxidants at higher levels (150 IU or mg/kg) was found to be effective in reducing the drop in egg quality. This may be at the expense of antioxidants as storage led to over 50% reduction in egg tocopherols content ($P < 0.05$). The interaction of storage with diet was not significant on all egg quality parameters tested ($P > 0.05$). Egg weight, shell thickness and shell weight as percentage of total egg weight were not affected by diet or storage ($P > 0.05$). These data demonstrate that added antioxidant supplementation may be needed in improving the quality parameters during storage in eggs from hens fed flaxseed.

Key Words: flaxseed, antioxidants, egg quality

376 Quality of shell eggs stored under modified atmosphere packaging. T Yalamanchili*, C. Z. Alvarado, L. D. Thompson, and C. J. Brooks, *Texas Tech University*, *Lubbock*.

The processing of shell eggs involves collecting of eggs and transporting them to a packaging plant where they are cleaned, sorted and packaged. However, the cooling capacity at the farm, storage, and the transportation trucks as well as time to the retail outlet can decrease egg quality. The objective of this experiment was to determine the effect of a modified atmosphere packaging (MAP) on the quality of USDA Quality grade AA shell eggs placed in a Master bag (Cryovac 33cm × 55.88cm) and stored at 4°C. Shell eggs were subjected to one of the 2 packaging treatments: (1) control–air; (2) 20% CO_2 and 80% N_2. Packaged eggs were stored for 28 d in the master bag at 4 ± 1°C. A total of 5760 eggs were used in 2 experiments, with 2 trials and 5 replications each. Five master bags were used for analyses on 1, 7, 14, 21, and 30d. In Experiment 2, and the packages were allowed to sit at 4 ± 1°C for 24h before testing for quality attributes. Analyses included albumen pH, Haugh units, yolk index, color (hard cooked and raw), foam ability, foam stability and TBARS. The data were analyzed by ANOVA in a 2 (packaging treatment) × 5 (time points) × 2 (trial) factorial design. In both the experiments, pH of the albumen of the eggs stored in MAP was lower than the eggs stored in air. The albumen of the raw eggs stored in MAP was lighter than those stored in air. However, in both the experiments, the albumen of the raw eggs stored in MAP were more yellow than the eggs stored in air. The hard cooked albumen of the eggs stored in MAP showed increased brightness and intensity in color. The yolk of the eggs stored in MAP maintained a more vivid and lighter yellow color. The carbon dioxide present in the MAP lowered the pH of the egg and thus may have prevented the green ring formation. Thus, packaging eggs in a MAP master bag was effective in reducing egg deterioration and loss of some functional quality during storage at refrigerated temperatures.

Key Words: shell eggs, packaging, quality

377 Evaluation of fatty acids and proteins in eggs from cage and range laying hens. L. K. Kerth*[1], P. A. Curtis[1], K. R. Willian[2], C. R. Kerth[1], and K. E. Anderson[3], [1]*Auburn University, Auburn, AL,* [2]*Tuskegee University, Tuskegee, AL,* [3]*North Carolina State University, Raleigh*.

Consumer trends and new legislation have furthered the transition of caged layers to range. However, little research has evaluated the impact that these environmental rearing changes will cause to the egg itself. This study was designed to compare what changes occur in the egg when layers are raised on a range system versus traditional cage system. In the 37th North Carolina Layer Performance and Management Test Hy-Line Brown hens were used in both the range environment and the cage. This strain was selected because it is the current brown egg strain used in the US. Hens were reared according to what environment they were going into and all other rearing husbandry was identical. On a quarterly basis, eggs were gathered from layers at 17 to 82 wk of age. Once collected eggs were pooled into 2 replicates and functional and proximate analyses were conducted in duplicate on each pooled set. Remaining egg samples were stored for further testing. Initial findings found that angel food cake volume was significantly higher ($P < 0.05$)

for caged eggs when compared with range. However, that difference could not be attributed to the ph and percent fat of the albumen as neither was different ($P > 0.05$). Upon further investigation it was discovered that the percentage of solids and protein were higher ($P < 0.05$) in range eggs. When the functional properties of the yolk were evaluated range eggs had a stronger ($P < 0.05$) emulsion in both fresh and stored mayonnaise. Conversely, there were no differences ($P > 0.05$) in pH, percentage of solids, fat or protein in the yolk from cage or range eggs. The frozen samples were tested for fatty acid methyl ester profiles on the yolk samples and SDS-PAGE on the albumen samples to identify and quantify fatty acids and proteins. The amount of saturated and omega-3 fatty acids present in the yolk, were highest ($P < 0.05$) in the last sampling period. Saturated fatty acids were also found to be higher ($P < 0.05$) in eggs from caged birds as opposed to a range birds.

Key Words: eggs, fatty acids, proteins

378 Intermittent feeding strategies of ractopamine hydrochloride on growth performance and carcass characteristics of feedlot steers. M. G. Dib*[1], G. E. Erickson[1], T. J. Klopfenstein[1], J. R. Benton[1], W. A. Griffin[1], J. J. Sindt[2], and W. T. Choat[2], [1]*University of Nebraska*, *Lincoln,* [2]*Elanco Animal Health*, *Greenfield, IN*.

The objective of this experiment was to evaluate intermittent feeding of ractopamine hydrochloride (OPT) on growth performance and carcass characteristics. Crossbred steers (n = 320; initial BW = 480 + 12 kg) were used in a randomized complete block design with 4 treatments, 8 pens/treatment, and 2 weight blocks. Treatments consisted of no OPT (NEGCON), OPT fed continuously during the last 35 d prior slaughter (POSCON), OPT fed for 7 d followed by 4 d of withdrawal (4-dINT) and OPT fed for 7 d followed by 7 d of withdrawal (7-dINT). All treatments receiving OPT (POSCON, 4-dINT and 7-dINT) received OPT for a total of 35 d but on different days. Before the experiment, each steer was weighed on 2 consecutive days after feed restriction (decrease of 1 kg/d of DM) for 3 d in an attempt to minimize variation due to gut fill. Pens of animals were weighed weekly, with a 4% shrink, throughout the 63 d of the experiment before slaughter. Steers were slaughtered on the same day after 165 d on feed, and 63 d of treatment. Data were analyzed using a mixed model analysis with treatment and block included in the model as fixed variables and pen as the experimental unit. Final BW increased ($P < 0.04$) by 6 kg for steers fed OPT compared with NEGCON when measured on a live basis. Final BW on a carcass-adjusted basis and HCW were not impacted by treatment ($P > 0.18$). Feed intake was 0.3 kg greater ($P < 0.05$) for 7-dINT compared with the other treatments. Gain based on live BW was greater for OPT compared with NEGCON, which tended ($P = 0.09$) to increase G:F for steers fed OPT compared with NEGCON. Carcass performance or traits were not affected ($P > 0.18$) by feeding OPT compared with NEGCON except for calculated USDA Yield grade. No differences were observed for ADG, G:F, or carcass traits between POSCON, 4-dINT, and 7-dINT in this study. Further research may be necessary to determine the response to re-stimulation of β-receptors in cattle.

Key Words: beef cattle, performance, ractopamine hydrochloride

379 Effectiveness of ractopamine when fed as a top dress in beef steers. K. L. Neuhold*[1], P. T. Grubb[1], J. J. Wagner[1], T. E. Engle[1], R. K. Peel[1], and A. L. Schroeder[2], [1]*Colorado State University*, *Fort Collins,* [2]*Elanco Animal Health*, *Greenfield, IN*.

A clinical trial was conducted to investigate the effectiveness of ractopamine (RAC) as a top dress (TD) pellet during the final 42 d of feeding. Crossbred yearling steers (n = 144) were selected for the study. Steers were housed in 9 animals per pen with 8 pens per treatment. Treatments consisted of a steam-flaked corn based feedlot diet plus 0.9 kg per animal per d of TD containing 1) no RAC (Control) or 2) 400 mg/animal/d of RAC (400-RAC). Steers were fed 3 times daily. Top dress was applied evenly over the top of the total mixed ration immediately after the second feeding. Initial steer weights (526.8 kg) were similar ($P > 0.94$) between treatments. Final steer weight ($P < 0.03$) and average daily gain ($P < 0.02$) were greater for 400-RAC when compared with control (615.8 vs 605.2 ± 6.3 kg and 2.1 vs 1.86 ± 0.13 kg/day, respectively). Steers consuming 400-RAC had lower daily DMI ($P < 0.04$) compared with control (10.9 vs 11.4 ± 0.32 kg/animal/day). Gain to feed ratio was greater ($P < 0.001$) in steers fed 400-RAC (0.194 vs 0.164 ± 0.46). Dressing percentages ($P > 0.96$) were similar across treatments resulting in greater hot carcass weights ($P < 0.002$) for 400-RAC supplemented steers (373.5 vs 367.4 ± 2.3 kg). There were no differences between treatment groups for 12th rib fat depth ($P > 0.54$) and KPH ($P > 0.69$). Steers receiving 400-RAC had increased ($P < 0.007$) longissimus muscle area than controls (96.39 vs 91.03 ± 0.19 cm^2). Longissimus muscle area expressed per unit hot carcass weight was greater ($P < 0.04$) for 400-Rac steers compared with control steers indicating that RAC increased carcass muscling. Yield grades tended ($P < 0.19$) to be lower RAC-400 steers compared with controls (2.34 vs 2.52 ± 0.08). No differences in marbling score or carcass quality grade were observed between treatments. These data indicate that feeding RAC in a TD application for the final 42 d of the finishing period will increase rate of gain, final weight, hot carcass weight and gain to feed ratio while maintaining carcass quality.

Key Words: steers, ractopamine, top dress

380 Effects of prepartum rumen-protected choline supplementation on performance of beef cows and calves. L. A. Pacheco*[1], J. R. Jaeger[2], L. R. Hibbard[1], M. J. Macek[1], N. A. Sproul[1], G. J. Eckerle[1], E. A. Bailey[1], J. W. Bolte[2], and K. C. Olson[1], [1]*Kansas State University*, *Manhattan,* [2]*Western Kansas Agricultural Research Center*, *Hays*.

The objective of our study was to evaluate the effect of prepartum ruminally-protected choline (RPC) supplementation on cow and calf performance. Angus crossbred cows and heifers (n = 403; average initial weight = 533.2 ± 4.0 kg) grazing native range were blocked by weight and parity and assigned randomly to 1 of 2 treatments: a 40% CP soy-corn supplement (CON) or a 40% CP soy-corn supplement containing RPC. Treatments were applied during a 60 d period that immediately preceded the earliest predicted calving date; each cow was fed 2.38 kg/hd/d of CON or RPC 6 × per week. The feeding rate of choline averaged 4.5 g/cow/d. Body weight, BCS, and ultrasonically measured longissimus muscle characteristics of cows and BW of calves were recorded at intervals from January to October. Changes in cow BW, BCS, backfat thickness, and intramuscular fat between the outset of the trial and pregnancy diagnosis were similar ($P \geq 0.25$) between treatments. Cows fed RPC tended to lose more ($P = 0.10$) longissimus muscle depth between the outset of the trial and pregnancy diagnosis. Conversely, BW of cows fed RPC tended to be greater ($P = 0.07$) at pregnancy diagnosis than that of cows fed CON. Calf BW at birth, at pregnancy diagnosis, and at weaning were not different ($P \geq 0.39$) between treatments; however, ADG from pregnancy diagnosis to weaning tended ($P = 0.06$) to be greater for calves of RPC-fed dams than for calves of CON-fed dams. Within parity class, timed-AI pregnancy and overall pregnancy were not affected ($P \geq 0.14$) by treatment. Under the conditions of our study, prepartum RPC supplementation had minimal effects on performance of beef cows and calves.

Key Words: beef cows, choline, supplementation

381 Evaluation of ractopamine fed in a top dress feed on growth and standard carcass characteristics of crossbred cattle. A. L. Schroeder*[1], T. H. TerHune[2], M. Edmonds[3], R. P. Lemenager[4], S. L. Lake[4], F. K. Mckeith[5], and J. J. Wagner[6], [1]*Elanco Animal Health*, *Greenfield, IN*, [2]*HMS Veterinary Development*, *Tulare, CA*, [3]*Johnson Research*, *Parma, ID*, [4]*Purdue University*, *West Lafayette, IN,* [5]*University of Illinois*, *Urbana*, [6]*SECRC-Colorado State University*, *Lamar*.

Ractopamine (RAC) was originally approved for feeding continuously to cattle during the last 28 to 42 d of the finishing period. Growth per-

formance and standard carcass characteristic effects of feeding RAC one time daily at: 1) 0 mg or 2) 400 mg/h/d (RAC400) in a top dress (TD) feed during the last 42 d was evaluated in 560 steers at 4 sites. A randomized complete block design was used at each site. Eight replicates (blocks) per site resulted in 32 experimental units (8–10 steers/pen, depending on location) per treatment. Cattle were fed either 2 or 3 times daily with RAC TD fed on top of existing feed in the bunk after the first or second feeding (depending on feeding frequency) in 0.45 or 0.9 kg of TD feed per head per day. Initial weights were similar ($P \geq 0.72$) between treatments. Final weight ($P \leq 0.02$) and average daily gain ($P \leq 0.006$) was increased for the RAC400 treatment compared with control (613.0 vs. 603.3 ± 9.75 kg and 1.91 vs. 1.68 ± 0.19 kg per day, respectively). Dry matter intake (DMI) was not different ($P \geq 0.15$) between treatments (11.21 for control and 10.96 ± 0.20 kg for RAC400, respectively). Gain to feed ratio was greater ($P \leq 0.006$) and DMI to gain ratio was improved ($P \leq 0.02$) for RAC400 compared with control animals (0.174 vs. 0.150 ± 0.016) and 5.28 vs. 6.03 ± 0.15, respectively). Dressing percentages were similar ($P \geq 0.78$) resulting in heavier hot carcass weights ($P \leq 0.008$) for the RAC400 treatment compared with controls (366.8 vs. 360.4 ± 13.4 kg). No differences existed in 12th rib fat ($P \geq 0.30$) and KPH ($P \geq 0.58$). RAC400 supplemented animals had larger longissimus muscle area ($P < 0.008$) than controls (91.1 vs. 87.3 ± 2.89 cm^2, respectively). Yield grade was improved ($P < 0.02$) for RAC400 carcasses compared with control carcasses (2.47 vs. 2.66 ± 0.13, respectively). Marbling score and quality grades were similar ($P \geq 0.10$) between treatments. The data demonstrate RAC fed in a TD feed for the last 42 d of the finishing period will increase average daily gain, live weight, HCW, LM area and yield grade without adversely affecting marbling score and carcass quality.

Key Words: cattle, top dress, ractopamine

382 Ractopamine hydrochloride did not affect growth or fermentation of ruminal bacteria in pure culture. C. E. Walker*, J. M. Heidenreich, and J. S. Drouillard, *Kansas State University*, *Manhattan.*

Catecholamines have been observed to enhance pure culture bacterial growth in vitro. In this research, effects of the synthetic catecholamine ractopamine hydrochloride (RAC) on bacterial growth were evaluated in vitro. Representative strains of bacterial species commonly found in the rumens of high-concentrate fed cattle, particularly species involved in proteolysis, were evaluated. Pure cultures of *Butyrivibrio fibrisolvens*, *Clostridium aminophilum*, *Clostridium sticklandii*, *Fusobacterium necrophorum*, *Megasphaera elsdenii*, *Prevotella ruminicola*, *Selenomonas ruminantium*, and *Streptococcus bovis* were obtained from the American Type Culture Collection. Cultures were grown in Hobson M2 media and incubated at 39°C. Treatments were 0 mg (Control) or 2.26 mg RAC/L added to culture tubes immediately before inoculation with bacterial cultures. Bacterial growth was evaluated as changes in optical density at 650 nm using a spectrophotometer. Change in pH and redox potential for each tube were determined after incubation was complete. Cultures were then centrifuged and the resulting pellet was dried at 105°C to determine impact of RAC on bacterial cell yield. To measure the impact of RAC on fermentation, concentrations of VFA and lactate were analyzed using gas chromatography, and ammonia and α-amino N were analyzed colorimetrically by an auto analyzer. The Mixed models procedure of SAS was used with fixed effects of RAC, bacterial strain, and time to assess changes in optical density. A mixed model including effects of RAC and strain was used to evaluate effects on fermentative end products. RAC did not affect pure culture growth, culture pH, redox potential, or bacterial cell yield ($P > 0.10$). Additionally, RAC did not affect concentrations of VFA, lactate, ammonia, or amino acid in vitro ($P > 0.10$). Growth or fermentative end products of pure cultures containing select strains of ruminal bacteria were not affected by the presence of ractopamine hydrochloride.

Key Words: ractopamine hydrochloride, ruminal bacteria, fermentation

383 Accelerated step-up regimen with 44 mg/kg monensin. C. E. Walker*, G.L Parsons, K. A. Miller, L. K. Thompson, J. J. Higgins, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

Crossbred steers (n = 720; initial BW = 453 kg) were used to evaluate effects of monensin concentration and step-up regimen on feedlot performance and carcass traits in a randomized complete block experiment with a 2 × 2 factorial treatment arrangement. Factor 1 consisted of 33 or 44 mg/kg monensin (MON) fed for the entire 153 d trial; and factor 2 was length of the step-up period (10 or 21 d). Cattle from wheat pastures were received into the feedlot and fed chopped hay and salt for 2 wk. On d 1 of the study, cattle were stratified by BW and allotted to pens of 15 cattle each, with 12 pens/treatment. Starting d 1, a 3-diet (60, 77, and 93% concentrate) step-up system was used in which cattle were fed ad libitum 60% concentrate am (0900 h) and pm (1300 h) for step 1; 60% concentrate am and 77% concentrate pm for step 2; 77% concentrate am/pm for step 3; 77% concentrate am and 93% concentrate pm for step 4; and 94% concentrate am/pm for the final finishing diet. Diet changes were implemented on d 6, 11, 16, and 21 for the traditional regimen, and on d 4, 6, 8, and 10 for the accelerated regimen. BW were determined on d 0, 50, and before shipping to a commercial abattoir on d 153. There were no interactions between level of MON and step-up regimen ($P > 0.10$) and no effects of step-up regimen on performance or carcass traits ($P > 0.10$), but steers on the accelerated regimen consumed less roughage ($P < 0.05$). Increasing MON from 33 to 44 mg/kg decreased DMI during the first 50 d ($P < 0.01$) and the entire 153-d study period ($P < 0.01$), and improved gain efficiency by 8% for the first 50 d ($P < 0.10$) and by 3% for the 153-d trial ($P < 0.05$). Yield grades were lower for steers fed 44 mg/kg MON compared with steers fed 33 mg/kg MON ($P < 0.05$), but other carcass traits were not affected ($P > 0.10$). Steers can be transitioned to high-concentrate diets in 10 d without compromising performance, and less roughage is used. Steers fed 44 mg/kg MON were more efficient than steers fed 33 mg/kg MON.

Key Words: step-up, monensin, roughage

384 Effects of Zilmax on blood metabolites in finishing cattle. C. L. Van Bibber*, G. L. Parsans, K. A. Miller, L. K. Thompson, and J. S. Drouillard, *Kansas State University*, *Manhattan*.

Effects of Zilmax (Z) on blood metabolites and carcass traits were evaluated in crossbred finishing steers (n = 18) that were stratified by BW and randomly assigned, within strata (block), to control (C) or Z treatments. Cattle were fed once daily ad libitum in individual feeding pens (9 pens/treatment). Z was fed 23 d and withdrawn 3 d before harvest. Blood samples and measures of BW were taken on d 0, 7, 14, and 21. Metabolites were analyzed as repeated measures using Proc Mixed, with fixed effects of treatment, day, and treatment × day, and random effects of block and block × treatment. Performance and carcass traits were analyzed with treatment as fixed effect, and block and block × treatment as random effects. Concentrations of β-hydroxybutyrate (BHB), glucose, and lactate were determined in whole blood, and NEFA, urea nitrogen (PUN), and long-chain fatty acids (LCFA) were analyzed in plasma. Adipose tissue samples were analyzed for LCFA profiles. Feeding Z decreased DMI by 8% ($P < 0.10$), but did not impact BW gain or efficiency ($P > 0.10$). Feeding Z resulted in greater HCW and LM

area ($P < 0.10$), numerically decreased marbling score and yield grade, but did not influence other carcass traits ($P > 0.10$). Z increased plasma concentrations of elaidic, vaccenic, and docosapentaenoic acids ($P < 0.10$), but adipose tissue concentrations of LCFA were unaffected ($P > 0.10$), suggesting no preferential oxidation of specific fatty acids. Blood metabolites for d 0 and 21 of the study are shown in the table.

Table 1. Effects of Zilmax on Blood Metabolites

Item, mM	C d0	Z d0	C d21	Zd21	SEM
Glucose‡	3.32	3.39	3.48	3.09	0.24
Lactate	2.83	2.80	2.16	1.54	0.48
NEFA	126	175	140	174	36
BHB	0,01	0.08	0.02	0.06	0.83
PUN† ‡	4.15	3.74	4.44	3.26	0.24

The symbols † and ‡ denote effects of Z and Z × d interaction, respectively ($P < 0.10$).

Key Words: zilpaterol hydrochloride, plasma urea nitrogen, glucose

385 Intake and digestion of cotton co-product and distillers grain blocks fed as a cattle hay replacement. G. M. Hill* and D. J. Renney, *University of Georgia*, *Tifton*.

A new compressed block product (CPM, 0.34% S; A. G. Daniel Co., Eastman, GA) that contained cotton gin trash (59%), distillers dried grains with solubles (DDG, 0.66% S), wheat middlings, a molasses product and minerals, was formulated to replace hay in cow diets. Brangus and Angus crossbred steers (n = 30; age 2 yr; initial BW 453.6 ± 33.9 kg) selected to mimic beef cow intake, were ranked by BW, randomly assigned to treatments, and individually-fed diets for 18 d. Supplements (SUP) were fed with or without free-choice coarsely ground hay (H; Tifton 85; DM, CP, NDF, TDN, %: 87, 9.3, 77, 52). Treatments were: hay only (HAY); H with whole cottonseed (WCS) fed at 0.5% BW daily (HWCS), H with DDG (HDG); H with CPM (HCPM); or free-choice CPM (CPMFC). The DM, CP, NDF, crude fat, TDN (% DM), respectively, were: WCS, 91.4, 23.4, 53.5, 18.1, 71; DDG, 86.7, 31.6, 31.7, 82; CPM, 89.3, 16.4, 56.6, 5.2, 48. Chromic oxide was fed (10 g/steer, d 9 to d 18), and fecal samples (11/steer, d 14 to d 18) were analyzed to determine apparent digestion. Hay DMI was highest (Table 1; $P < 0.01$) for HAY, HWCS, and HDG, and lowest for HCPM. Steers had more than double total DMI for HCPM and CPMFC ($P < 0.01$) compared with other treatments. The OM digestibility was highest ($P < 0.02$) for HCPM, and CP digestibility was highest ($P < 0.01$) for HCPM, intermediate for HWCS, HDG, and CPMFC, and lowest for HAY. Digestibility of ADF and NDF were highest for HAY ($P < 0.01$); but NDF digestibility was lowest for CPMFC ($P < 0.01$), and similar for HWCS, HDG, and HCPM. The CPM treatments demonstrated adequate OM digestibility, but feeding CPM increased DMI compared with traditional cow wintering diets.

Table 1.

Item	HAY	HWCS	HDG	HCPM	CPMFC	SE	P <
Hay DMI, kg	6.68	5.30	5.15	1.98	0.00	0.23	0.01
SUP DMI, kg	0.00	1.88	1.49	13.09	15.61		
Total DMI, kg	6.77	7.20	6.67	15.51	15.64	0.37	0.01
Apparent digestion, %							
OM	70.58	69.13	70.29	74.03	72.25	1.00	0.02
CP	63.66	69.78	70.84	73.33	71.15	1.06	0.01
ADF	69.91	57.91	57.55	61.68	57.81	1.41	0.01
NDF	70.66	66.57	66.89	65.70	62.66	1.32	0.01

Key Words: steer, cottonseed, digestion

386 Late gestation supplementation of beef cows: Effects on cow and calf performance. D. W. Bohnert*[1], R. Mills[1], L. A. Stalker[3], A. Nyman[1], and S. J. Falck[2], [1]*Oregon State University*, *Burns*, [2]*ARS-USDA*, *Burns, OR*, [3]*University of Nebraska*, *North Platte*.

We conducted a 2-yr study to evaluate the influence of cow BCS and dried distillers grains (DDGS) supplementation during late gestation on cow and calf productivity. The experimental design was a 2 × 2 factorial; 2 BCS (4 or 6) and supplemented or not supplemented. Approximately 12.7 kg/cow of low quality meadow hay (6.4% CP) was provided each day and supplemented cows received 1.81 kg/cow of DDGS every Monday and Wednesday and 2.72 kg/cow on Friday. On each supplementation day, supplemented cows were gathered and sorted into pens based on their respective blocking structure. After completing consumption of their allocated supplement, cows were returned to a common pasture. Performance data and binomial data were analyzed as a randomized complete block using PROC MIXED and PROC GLIMMIX in SAS, respectively. Calf birth weight was greater with BCS 6 cows compared with BCS 4 ($P = 0.002$) and for supplemented compared with unsupplemented cows ($P = 0.05$). In addition, weaning weight was greater for BCS 6 compared with BCS 4 ($P = 0.05$) and calf weaning weight and ADG to weaning were greater for the offspring of supplemented compared with unsupplemented cows ($P \leq 0.02$). We noted no differences in post-weaning calf performance or carcass characteristics ($P > 0.10$). However, BCS 6 cows had approximately 10% more live calves at birth and at weaning ($P < 0.001$) compared with BCS 4 cows. Also, pregnancy rate was 91% for BCS 6 compared with 79% for BCS 4 cows ($P = 0.005$). Supplementation during late gestation resulted in an estimated net return of $7/cow if calves were sold at weaning compared with not supplementing. More importantly, because of additional weaned calves, the estimated net return for BCS 6 cows at weaning was $71/cow more than BCS 4. Likewise, with retained ownership, BCS 6 cows yielded a net return of $130/animal more than BCS 4 cows. This research demonstrates the potential consequences of not maintaining cows in good BCS (>5) at calving; greater calf losses, less weaned calves, decreased pregnancy rate, and lower economic return.

Key Words: supplementation, fetal programming, protein

387 Effect of forage energy intake and supplementation on gene expression of adipose tissue in growing beef cattle. P. A. Lancaster*, E. D. Sharman, G. W. Horn, C. R. Krehbiel, and U. DeSilva, *Oklahoma Agricultural Experiment Station*, *Stillwater*.

Additional benefit to the stocker cattle production phase could be realized by influencing adipose tissue development before finishing. Previous research has indicated that nutritional management can affect fat deposition in growing cattle. Our objective was to evaluate forage energy intake and type of fermentation on gene expression of adipose tissue in growing steers. Angus steer calves (n = 68; 258 ± 29 kg BW) were randomly allotted by BW to 4 treatments: (1) 1.02 kg•hd^{-1}•d^{-1} of a 40% CP supplement (CON) to meet their DIP requirement while grazing dormant native range; (2) CON plus corn-based supplement at 1% BW (CORN) while grazing dormant native range; (3) grazing wheat pasture at a high stocking rate to achieve a low ADG (LGWP); and (4) grazing wheat pasture at a low stocking rate to achieve a high ADG (HGWP). Supplements were fed individually 5 d per week. Following winter grazing, 3 steers per treatment were harvested and subcutaneous (SC), perirenal (PR), and intramuscular (IM) adipose tissue collected. Total RNA was extracted and gene expression determined using qRT-PCR. Performance and carcass data are presented in a companion abstract (Sharman et al., 2010). There were no treatment × adipose tissue interactions for any genes evaluated indicating that each

adipose tissue responded similarly to the treatments. mRNA expression of genes involved in triglyceride synthesis (glycerol-3-phosphate dehydrogenase, fatty acid synthase, and diacylglycerol acyltransferase 2) and glucose utilization [ATP citrate lyase (ACLYS) and NADPH malate dehydrogenase (MDH)] were greater ($P < 0.05$) for HGWP and LGWP compared with CON and CORN. ACLYS mRNA expression was greater in SC and PR compared with IM, and MDH mRNA expression was greater in PR compared with SC and IM. Further analyses will evaluate genes related to adipogenesis. These data indicate that greater propionate type of fermentation increased triglyceride synthesis and glucose/lactate utilization for fatty acid synthesis, and SC and PR had increased glucose/lactate utilization compared with IM irrespective of forage energy intake or type of fermentation.

Key Words: adipose tissue, gene expression, stocker cattle

388 Angus and Simmental calves exhibit differential trace mineral metabolism. S. L. Hansen*, E. L. Richter, and M. E. Drewnoski, *Iowa State University*, *Ames*.

To examine the effects of cattle breed on the clearance rate of an injectible mineral 10 Angus and 10 Simmental calves were blocked by breed and initial BW (332 ± 33 kg) and injected with either Multimin90 (MIN) or sterilized saline (CON) at a dose of 1 mL/45 kg BW. The Multimin90 contained 60 mg Zn/mL (as Zn disodium EDTA), 10 mg Mn/mL (as Mn disodium EDTA), 15 mg Cu/mL (as Cu disodium EDTA), and 5 mg Se/mL (as sodium selenite). Calves were weight matched and treatment was balanced within pens (2 head per pen). Calves received a corn-silage based diet and Mn, Cu, Zn, and Se were supplemented at NRC recommended levels. Jugular blood for plasma mineral analysis was collected immediately before injection and at 8 and 10 h post injection, and on d 1, 8 and 15 post injection. Liver biopsies for mineral analysis were collected 3 d before injection and on d 1, 8 and 15 post injection. Plasma concentrations of Mn and Se were greater ($P < 0.001$) at 8 and 10 h and d 1 post injection in MIN calves compared with CON calves. Plasma Se remained elevated ($P < 0.05$) through d 8 in MIN calves vs. CON calves. Regardless of treatment, Simmental calves exhibited lower ($P = 0.05$) plasma Cu at 10 h post injection and tended ($P = 0.07$) to have greater plasma Mn on d 1 compared with Angus calves. Plasma concentrations of Cu, Zn and Mn did not differ due to treatment by d 8. Liver concentrations of Cu and Se were greater ($P < 0.01$) in MIN calves compared with CON calves on d 1, 8 and 15 post injection. Liver Zn concentrations were greater ($P < 0.01$) on d 1 in MIN calves versus CON calves. Liver Mn concentrations were greater ($P < 0.05$) on d 8 in MIN calves compared with CON calves, but did not differ among treatments on d 1 or 15 post injection. Interestingly, Simmental calves exhibited greater ($P < 0.01$) liver Mn concentrations on d 15 compared with Angus calves, regardless of treatment. In summary, these data suggest that Angus cattle clear Mn from the body at a faster rate than Simmental cattle, which may have implications on supplementation strategies.

Key Words: cattle, mineral, breed

389 Effects of polyunsaturated fatty acid (PUFA) supplementation on performance and acute-phase response of transported beef steers. R. F. Cooke*[1], A. B. Scarpa[1], F. M. Nery[1], F. N. T. Cooke[1], P. Moriel[2], B. W. Hess[2], R. R. Mills[3], and D. W. Bohnert[1], [1]*Oregon State University*, *Burns,* [2]*University of Wyoming*, *Laramie,* [3]*Oregon State University*, *Pendleton*.

The objective was to compare ADG, DMI, and acute-phase response of steers supplemented or not with PUFA for 30 d before shipping to the feedlot. Seventy-two Angus steers weaned at 7 mo of age (d −55) were stratified by BW on d −30 of the study, and randomly allocated to 18 drylot pens (4 steers/pen). Pens were assigned to receive a grain-based supplement (avg. 1.4 kg/steer/d) without (CO) or with 0.15 kg/steer/d of a PUFA source (PF; Megalac-R, Church and Dwight, Princeton, NJ) or a saturated fatty acid source (SF; Megalac, Church and Dwight). Treatment intakes were formulated to be iso-caloric, iso-nitrogenous, and offered daily from d −30 to d 0. Mixed alfalfa-grass hay was offered in amounts to ensure ad libitum access during the same period. On d 0, steers were loaded onto a commercial livestock trailer and transported for approximately 350 km over a 6 h period. However, steers remained in the truck for a total of 24 h before unloaded into a commercial feedlot (d 1), where steers were maintained in a single pen, managed similarly, and received a diet not containing PF or SF. Forage DMI was evaluated daily from d −30 to d −1. Shrunk BW was collected on d −33 and 1 for ADG calculation. Blood samples were collected on d 0, 1, and 3, and analyzed for plasma concentrations of interleukin 1 and 6, tumor necrosis factor (TNF)-α, haptoglobin, ceruloplasmin, cortisol, and fatty acids. No treatment effects were detected for ADG ($P = 0.54$) or F:G ($P = 0.56$). During the study, DMI was often reduced for PF steers compared with CO and SF (treatment × day interaction; $P < 0.01$). Concentrations of PUFA were greater in PF steers compared with CO and SF before and after transportation (treatment × day interaction $P < 0.01$). Following transportation, concentration of TNF-α increased for CO, did not change for SF, but decreased for PF steers (treatment × day interaction, $P < 0.01$). In conclusion, PUFA supplementation during preconditioning had detrimental effects on DMI, but did not impair ADG and reduced plasma concentrations of TNF-α following transportation and feedlot entry.

Key Words: polyunsaturated fatty acids, transportation, beef steers

390 Effect of feeding polyphenols from pomegranate extract on health, growth, nutrient digestion, and immunocompetence of calves. M. C. Perdomo*[1], R. A. Oliveira[1], C. D. Narciso[1], R. S. Bisinotto[1], M. A. Ballou[2], M. Dreher[3], and J. E. P. Santos[1], [1]*University of Florida*, *Gainesville,* [2]*Texas Tech University*, *Lubbock,* [3]*POM Wondersull*, *Los Angeles, CA*.
