A study was conducted to evaluate intake (DMI), digestibility (DMD), and fecal recovery of indigestible NDF (INDF) and ADF (INDF) by cattle offered bermudagrass [*Cynodon dactylon* (L) Pers] hays of varied qualities. Eight ruminally cannulated cows (594±100.3 kg) were allocated randomly to 4 bermudagrass-hay diets having a wide range of nutritional value providing two replicates per diet per period(n=24). Crude protein (CP) contents of the four hays offered in each period were 6.8, 10.5, 12.3, and 14.8; 7.8, 11.0, 13.3, and 16.4; and 9.0, 11.8, 13.8, and 18.1% DM; respectively for period 1, 2, and 3. Cows were housed in individual pens and offered their respective hay at 2% of BW in equal feedings at 0800 and 1700 h for a 10-d adaptation period followed by a 5-d total fecal collection period. Duplicate samples of each of the hay, ort, and fecal samples from each period were incubated for 140 h in the rumen of two cows for each of the digestion periods, followed by a sequential analysis of NDF and ADF. Recovery of INDF and IADF was expressed as the ratio of the quantity of marker excreted in the feces per unit of marker consumed. Data were analyzed as a replicated 4 × 4 Latin square design with one period missing using PROC GLM of SAS. Effects of cow, diet, and period were included in the model. Diet affected DMI (1.35, 1.63, 1.82, 1.73% BW, $P < 0.05$) and did not affect apparent DMD (53.0, 58.2, 57.7, 59.1% DM, $P > 0.05$). Marker recovery of INDF (68.2, 77.5, 85.1, 83.3%) was affected by diet ($P < 0.05$). Mean IADF recovery followed the same pattern with a slight increase in percentage of recovery. Mean IADF recovery was 70.0, 79.7, 88.9, and 87.5%; respectively for low, medium low, medium high and high CP content diets. Indigestible NDF and ADF determined by in situ incubation appeared not to be an adequate internal marker for varying quality of bermudagrass hay fed to cattle because of low recovery (less than 95%) and drastic variability across the range of bermudagrass hays tested.

Key words: bermudagrass nutritive value, internal marker, cattle

T118 In vitro gas production and microbial efficiency of *Paulownia tomentosa*. V. Gallardo-Santillan[1], R. Luevano-Escobedo[1], V. M. Llamas-Rodriguez*[1], M. Guerrero-Cervantes[1], H. Bernal-Barragán[2], A. S. Juárez-Reyes[1], and M. A. Cerrillo-Soto[1], *[1]Universidad Juárez del Estado de Durango, Durango,México, [2]Universidad Autónoma de Nuevo León, Nuevo León, México.*

This study was performed to determine the nutritional value of *Paulownia tomentosa* using in vitro estimations. Leaves from trees at three different stages of growth: juvenile (1 year), medium (4 years) and adult (10 years old) were collected during a period of three months. The collected samples were dried and ground through 1 mm screen. The samples (500 mg) were incubated in triplicate in calibrated glass syringes at 39°C. Rumen fluid from fistulated sheep fed alfalfa hay and concentrate (75:25) was used as inoculum. Gas production was recorded at 0, 3, 6, 9, 12, 24, 48, 72, and 96h. Data were fitted to the model $p= a+b\ (1-e^{-ct})$. Additional 24h incubations were utilized to estimate purine contents. The partitioning factor was also calculated from incubation residues which were refluxed with neutral detergent fiber solution. Data were analyzed for a completely randomized design for a 3 × 3 factorial arrangement with 3 maturity levels, (juvenile, medium and adult) and 3 cutting dates (August, September and October, 2010) using the SPSS program. Mean differences were separated using Tukey's test. No interactions were registered in the partitioning factor or fermentation parameters; however, interactions ($P < 0.05$) between maturity level*cutting date for purine contents were recorded. Partitioning factor values were similar during August and September (3.6 ± 0.2 mg substrate truly degraded/mL gas produced $_{24h}$ in vitro) but higher than those registered in October (2.9). Purine content was lower in foliage from adult samples in October (6.3 ± 0.6 µmol) than in medium (13 µmol) and juvenile (14 µmol). An effect of maturity

($P < 0.001$) was registered in the gas produced from the slowly but degradable b fraction; adult samples had lower values (36.5 ± 1.27 ml/500 mg) than juvenile (42 mL) and medium (45 mL). Similarly, the constant rate of gas production c in medium samples was higher (8.7 ± 0.004% h^{-1}) than juvenile (7.5% h^{-1}) and adult (6.3% h^{-1}). Data related to the rate and extent of gas production of the foliage of *Paulownia* at medium stages of growth support the fact this foliage is a promising animal feed resource.

Key words: *Paulownia*, in vitro gas production, purines

T119 Relationships between chemical composition, in vitro dry matter, neutral detergent fiber digestibility, and in vitro gas production of corn and sorghum silages. A. Corral-Luna*[1], D. Domínguez-Díaz[1], M. R. Murphy[2], F. A. Rodríguez-Almeida[1], C. Arzola[1], G. Villalobos[1], and J. A. Ortega-Gutierrez[1], *[1]Facultad de Zootecnia y Ecología, Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México, [2]Department of Animal Science, University of Illinois, Urbana-Champaign.*

Five corn (*Zea mays*) and 4 sorghum (*Sorghum bicolor* L. Moench) silages were used to investigate the relationship between chemical composition (CC), in vitro dry matter digestibility (IVDMD), in vitro neutral detergent fiber digestibility (IVNDFD) and in vitro gas production (IVGP). The corn hybrids were harvested at half milk line and sorghum varieties in soft dough stage and ensiled in laboratory silos. Silages were dried in a 60°C forced-air oven, ground to pass a 1 mm sieve and analyzed for CC, IVDMD, IVNDFD and IVGP. The IVDMD and IVNDFD were determined using the ANKOM Daisy^{II} incubator and the IVGP according to the Menke and Steingass technique. The amount of gas produced (AGP) was recorded at 1, 2, 3, 4, 5, 6, 9, 12, 24, 48 and 72 h of incubation using a pressure transducer. The Groot logistic model was fitted to analyze the cumulative AGP for each sample. Pearson correlations coefficients between CC and AGP parameter estimates were calculated. The capability to predict IVDMD and IVNDFD based on CC and AGP data was examined with linear regression analyses. Silage contents of NDF, ADF and lignin were negatively correlated ($P < 0.05$) with IVDMD (−0.52, −0.50 and −0.50, respectively), and CP with asymptotic AGP (−0.42), but positively correlated ($P < 0.01$) with the estimates of parameter B (Time at which the half of asymptotic AGP was reached; 0.85, 0.81 and 0.72, respectively). After 1 h of incubation, AGP was negatively correlated to lignin content ($P < 0.01$) and positively correlated ($P < 0.05$) with non-fibrous carbohydrate (NFC). After 12 h of incubation, the correlations between NDF and ADF with AGP were highest ($P < 0.01$) until 48 h (−0.56 and −0.53, respectively). The CC alone is a good predictor of IVNDFD ($R^2 = 0.66$), and combined with AGP data adequately predicted IVDMD ($R^2 = 0.93$).

Key words: in vitro gas production, chemical composition, in vitro digestibility

T120 Effect of blending ruminal digesta, and filtration procedure on in vitro gas production. M. de J. Marichal*, R. Crespi, M. de los A. Bruni, S. Furtado, and G. Arias, *Departamento de Producción Animal y Pasturas, Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay.*

Effect of blending ruminal digesta, and filtering through two or four layers of gauze or cheesecloth on in vitro gas production was evaluated. Rumen contents from two fistulated sheep were collected two hours after the morning meal (alfalfa hay, 1.6 kg DM/d, twice daily). Contents were combined, and blended for up to 1 min or not blended. Filtration was performed using 2 or 4 layers of either gauze or cheesecloth, resulting in eight combinations of inoculum preparation procedures. Samples (500 mg, milled 2 mm) of alfalfa hay (17% CP, 45% NDF) were weighed into 125 ml bottles, and mixed with ruminal fluid (10 ml), buffer (40 ml), and reducing (2 ml) solutions. All manipulations were done at 39$/deg;C, and with consistent CO_2 flushing. Time between rumen fluid collection, and inoculation was 40 min. Three bottles with substrate and three blanks were incubated per treatment. Pressure and gas volume gas were recorded at 1, 2, 3, 4, 6, and 8 h using a pressure transducer and calibrated syringe; venting the gas after each measurement. Gas accumulated at 8 h, and volume at each fermentation time, were analyzed (PROC MIXED, SAS) in a complete randomized design with a 2 × 2 × 2 factorial arrangement of treatments. Treatment effects on accumulated gas at 8 h were observed ($P < 0.01$), but no interactions ($P > 0.15$) among treatments existed. Accumulated gas was greater ($P < 0.001$) when digesta was blended previous to filtration (65 vs. 57 mL gas/g DM, respectively), when filtering through gauze than cheesecloth (65 vs. 59 ml/g DM, respectively), and 2 layers of either material, resulted in greater ($P < 0.01$) gas than 4 (66 and 57 mL gas/g DM, respectively). In all treatments, analysis of gas production at each fermentation time suggested ($P < 0.03$) a lag time of 4 h. When gas from blanks was subtracted from alfalfa gas, results were similar; the only difference was when comparing filtration materials, where no difference ($P = 0.22$) in accumulated gas existed (56 vs. 57 mL gas/g DM, for gauze and cheesecloth, respectively). It is important to consider all aspects of inoculum processing when comparing results of in vitro gas production experiments due to the potential variability between processing methods.

Key words: alfalfa, cheesecloth, layers

T121 Predictive accuracy of near-infrared reflectance (NIR) technology for fat and fatty acids in randomly selected TMR samples. R. T. Ward*[1], S. Weaver[1], and R. A. Patton[2], *[1]Cumberland Valley Analytical Services, Maugansville, MD, [2]Nittany Dairy Nutrition Inc., Mifflinburg, PA.*

Growing realization of the negative impact that consumption of unsaturated fats in general and linoleic acid in particular can have on the production of milk fat has led to a demand for determination of fatty acids, unsaturated fatty acid and linoleic acid in total mixed rations (TMR). At present this is an intensive process. In addition to extraction problems with high fat products, fatty acids must be separated by gas chromatography (GC). Development of an accurate test using NIR could provide a cost effective alternative that would allow more precise measurement and more control of these ration inputs. The objective of this study was to test whether NIR could adequately predict total fat content, total fatty acids, and total unsaturated fatty acids, as well as the C18 saturated and unsaturated fatty acids compared with chemical and GC analysis. Correlation and mean square prediction error (MSPE) were calculated in SAS using the methodology of Bibby and Toutenburg on 17 randomly selected TMR samples submitted in January 2011. Mean fat content of TMR was 4.35 ± 1.01% with a minimum of 2.60% and a maximum of 5.80% of DM. Fatty acid content was 3.87 ± 1.25% on a DM basis. NIR displayed good ability to predict fatty acids in quantities greater than 0.3% of dry matter. Below this level, ability to predict the mean was maintained, but correlation coefficients were decreased, and MSPE as percent of mean (RPE) was increased. Observed mean total unsaturated fatty acids were 2.47 ± 0.91% of DM, while NIR predictions were 2.46 ± 0.73 with a MSPE of 0.054 and R^2 of 0.98. Mean linoleic acid was observed to be 1.64

± 0.62% of DM and NIR predicted to be 1.64 ± 0.57% with MSPE of 0.024 and R^2 of 0.97. Similar value for C18:1 and C18:3 were respectively: mean observed, 0.69 ± 0.32 and 0.26 ± 0.08; mean predicted, 0.69 ± 0.16 and 0.26 ± 0.07; MSPE, 0.035 and 0.004; R^2, 0.89 and 0.64. We conclude that NIR has the potential to adequately predict fat, unsaturated fat and individual fatty acids when quantities are above 0.3% of DM.

Key words: NIR, fat, linoleic acid

T122 Relationships of fermentation characteristics in corn forage. R. Ward*[1] and D. R. Mertens[2], *[1]Cumberland Valley Analytical Services Inc, Maugansville, MD, [2]Mertens Innovation & Research LLC, Belleville, WI.*

Our objective was to study factors affecting the fermentation characteristics of corn forage using a database of analyses from Cumberland Valley Analytical Services, Inc. The initial database contained 4712 samples over 4 years from 41 states with analyses including fermentation characteristics such as titratible acidity (TA), ammonia (NH_3), acetic (Ac), lactic (La), and propionic (Pr) acids (measured chemically). Components such as DM, CP, ash, NDF, ADL, starch (St) and sugar (Su) were determined by chemical or NIR methods. Non-ammonia N (NAN) was calculated by difference between CP and NH_3. Data was analyzed using Proc MIXED in SAS. In order, TA was affected by Ac, La, Pr, NAN, St, Su, NH_3, ash and ADL ($P < 0.0001$). Intercept, Ac and La accounted for 0.61, 0.20 and 0.18, respectively, of the variation explained by the model. The coefficients for Ac, La, and Pr were positive and all other variables had negative coefficients. Average TA was 7.2 in Oct, increased to 8.0 by Jan and was maximum (8.9) in Apr (all different $P < 0.005$). Corn silage NH_3 (% DM) was related (in order) to Ac, La, CP, St, ADL and Pr ($R^2 = 0.54$). Intercept, Ac and La accounted for 0.40, 0.22 and 0.19 of model variation, respectively. All coefficients were positive. Average NH_3 was 0.77 in Oct, increased to 0.90 by Jan and was maximum (1.08) in May (all different $P < 0.0001$). When TA replaced individual acids (La, Ac, Pr) in the model, NH_3 was related (in order) to TA, CP, St and ADL ($R^2 = 0.52$); and TA accounted for 0.73 of model variation. Expressing NH_3 as % of CP, reduced the R^2 (= 0.45) and the influence of CP ($P = 0.093$). When months in storage was added to the NH_3 model with TA, CP, St, and ADL, the R^2 increased to 0.56, and the linear and quadratic effects of storage were significant ($P < 0.0001$). When Ac was grouped by level, DM, St and Su decreased, and fiber and NH_3 increased, as group Ac increased. Region or year had limited effects on any of the results. We concluded that NH_3 in fermented corn forage is related not only to the extent of fermentation as indicated by TA or acids (Ac, La, Pr), but also to time in storage. Fermentation relationships can explain changes in corn forage that affect utilization.

Key words: fermentation, corn silage, forage

T123 Factors affecting estimation of spoilage indices in silage. 1: Effects of culture media, temperature, and duration. J. Leite[1,2], K. G. Arriola[1], N. Cavalcanti[1,2], O. C. M. Queiroz[1], E. N. Muniz*[1,3], and A. T. Adesogan[1], *[1]Department of Animal Sciences, IFAS, University of Florida, Gainesville, [2]Universidade Federal Rural de Pernambuco, Recife, PE, Brazil, [3]Embrapa Tabuleiros Costeiros, Aracaju, SE, Brazil.*

The growth of yeasts and molds reduces silage quality and bunk life and can predispose to mycotoxin production and growth of pathogenic organisms. Little is known about effects of different culture media, temperatures, and durations on the growth of these fungi in silage. This trial was conducted to evaluate effects of 3 culture media, 2 temperatures, and 2 culture durations on the growth of yeasts and molds in corn silage. Fluid was extracted from corn silage (38% DM, 8.4% CP, and 39.8% NDF) and cultured on malt dextrose agar (MEA), potato dextrose agar (PDA) or on 3M film in triplicate at temperatures of 25 or 32°C for 3 or 5 d. The experimental layout was a 3 (media) × 2 (temperatures) × 2 (durations) factorial and the model included these terms and their interactions. Counts of the fungi were log-transformed and statistically analyzed with PROC GLM of SAS. No interaction was significant for mold counts ($P > 0.1$). Mold counts were similar on MEA and PDA, fewest ($P < 0.05$) on 3M film, and unaffected by culture temperature or duration. Culture temperature and duration had no effect on yeast counts on PDA, but yeast counts were fewer when cultured on 3M film at 25°C for 3 d than with other treatment combinations and they were lower when cultured on MEA at 25°C for 5 d than at 32°C for 3 d (media x temperature x duration interaction, $P = 0.007$). On average, yeast counts on MEA were fewer than on other media and counts at 32°C for 3 d were greater than for other temperature and duration combinations. This study shows that experimental conditions markedly affect the outcome of yeast and mold enumeration on silage.

Table 1. Effects of culture temperature, duration, and media on mean counts of molds and yeasts in corn silage

	Mold			
Media	PDA	MEA	3M	
	4.84^{b}	4.40^{b}	$<2^{a}$	
Temperature (°C)	25	32		
	3.31^{a}	2.85^{a}		
Time (days)	3	5		
	3.51^{a}	2.65^{a}		

	Yeast				
	25°C		32°C		
	3 d	5 d	3 d	5 d	Mean
PDA	6.57^{c}	5.04^{bc}	6.48^{c}	5.48^{bc}	5.89^{B}
MEA	2.14^{ab}	$<2^{a}$	4.72^{bc}	2.51^{ab}	2.34^{A}
3M	$<2^{a}$	7.75^{c}	8.02^{c}	5.41^{bc}	5.89^{B}
Mean	2.9^{A}	4.26^{A}	6.41^{B}	4.47^{AB}

T124 Relationship between residual feed intake, performance, and carcass parameters of pasture finished cattle. J. P. S. Neel*[1], E. E. D. Felton[2], S. K. Duckett[3], and W. S. Swecker[4], *[1]USDA-ARS-AFSRC, Beaver, WV, [2]West Virginia University, Morgantown, [3]Clemson University, Clemson, SC, [4]Virginia Tech University, Blacksburg.*

In 2009 and 2010, Angus-crossbred steers (n = 39) were used to evaluate the relationship between residual feed intake (RFI), pasture-finishing performance and carcass parameters. During RFI determinations before pasture finishing initiation in mid-April, animals were fed an alfalfa hay cube diet. Animals were adapted to facilities and cubes for a 10 d period before intake measurements. Intakes were measured utilizing GrowSafe 6000 (GrowSafe Systems, Ltd., Airdrie, Alberta, Canada) feeding nodes (2009 = 30d; 2010 = 56d) for RFI classification of animals. Each animal was assigned an RFI score based on individual intake and performance relative to population. Upon classification, animals were pasture finished on mixed-species pasture until harvest and carcass data collection in early November of each year (338 ± 41kg initial BW; 500 ± 40 kg final BW). During pasture fin-

ishing animals had an ADG of 0.81 ± 0.12 kg. Mean carcass measurements were: hot carcass weight (HCW) 260 ± 24 kg, fat thickness (FT) 0.445 ± 0.177 cm, ribeye area (REA) 67.4 ± 7.3 cm2, KPH 1.1 ± 0.4%, yield grade (YG) 2.0 ± 0.4, and marbling score (MS; 400–500 = slight) 477 ± 62. Data from both years along with Pearson correlation coefficients were utilized to assess RFI relationship with performance and carcass measurements. Residual feed intake was negatively ($P <$ 0.01) correlated with ADG (r = −0.42), and tended ($P = 0.086$) to be positively correlated with KPH (r = 0.28). Residual feed intake was not correlated with initial or final BW, HCW, FT, REA, YG, or MS. Correlations with ADG and KPH need further investigation to determine impact on pasture finishing systems.

Key words: residual feed intake, pasture, finishing

Forages and Pastures: Improving Pasture Quality and Utilization and Animal Performance

T125 Herbage accumulation in *Brachiaria humidicola* subjected to different frequencies and intensities of defoliation. H. H. Vilela[1], D. Nascimento Junior*[1], A. L. Santos[1], D. L. R. Henriques[1], B. D. Faria[1], C. A. S. Freitas[1], and A. F. Sbrissia[2], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil.*

The experiment was conducted to evaluate the herbage accumulation of *Brachiariahumidicola* cv. Humidicola Common, subjected to different frequencies and intensities of defoliation. Two defoliation intensities, stubble heights of 8 and 16 cm, and two defoliation frequencies [95 and 100% light interception (LI)] were evaluated. The experiment was a completely randomized block design with a 2 × 2 factorial treatment arrangement with 3 replicates. The light interception (LI) was measured using a canopy analyzer (LI-COR LAI 2000) at 4 points per experimental unit (314 m^2). Grazing was carried out by 200 kg Zebu mixed steers. At each point a reading above the sward and 5 readings on the soil surface were taken, resulting in 4 readings above the sward and 20 readings at ground level. Herbage mass was harvested pregrazing using a quadrat of 0.33 × 1.0 m at 3 points in each paddock. Forage was harvested to the stubble height of each residue treatment and weighed immediately after cutting. A sample was force-dried at 65°C for 72 h to determine dry matter (DM) content. After weighing, the herbage mass was calculated from the fresh weight multiplied by the harvested forage DM content. Presented data are from Dec. 2009 to Mar. 2010 and results were compared by the Student's t test, with a significance level of 10%. Herbage accumulation rate was influenced ($P < 0.10$) by the frequencies and intensities of defoliation. Greater herbage accumulation (4191 kg/ha) was observed at higher intensity of defoliation (8 cm). In relation to frequency of defoliation, the highest herbage accumulation (4173 kg/ha) was observed at lower frequency (100% LI). Lower frequency and greater intensity of defoliation presented the highest herbage accumulation rate.

Key words: DM production, light interception, sward target

T126 Sward bulk density in *Brachiaria humidicola* subjected to frequencies and intensities of defoliation. D. Nascimento Junior*[1], H. H. Vilela[1], A. L. Santos[1], B. D. Faria[1], B. M. L. Sousa[1], G. O. Rocha[1], and A. F. Sbrissia[2], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil.*

The experiment was conducted to assess the forage bulk density of *Brachiariahumidicola* cv. Humidicola comum, subjected to different intensities and frequencies of defoliation. Two defoliation intensities were evaluated, represented by stubble heights of 8 and 16 cm, associated with defoliation frequencies represening 95 and 100% light interception by the sward. Treatments were assigned according to a completely randomized block design with a 2 x 2 factorial treatment arrangement with three replicates. The light interception was measured using a canopy analyzer (LI-COR LAI 2000) at four points per experimental unit. At each point, a reading was taken above the sward and five on the soil surface (within the sward), resulting in four readings above the sward and twenty readings at ground level. Herbage mass was harvested pre-grazing using a quadrat of 0.33 x 1.0 m, at three points in each paddock. The forage was harvested to the residue stubble height for each treatment and the harvested forage was weighed immediately after cutting. A sample was forced- dried at 65°C for 72 h to determine dry matter (DM). Calculated herbage mass was divided by corresponding sward height to determine forage bulk density for each sward. Presented data are for the period of December 2009 to March 2010, and results were compared by Student's t test with a significance level of 10%. The bulk density of forage was influenced by defoliation frequency ($P < 0.10$) and the highest values (161.3±15.2 kg/ha.cm of DM) were obtained at the highest frequency (95% of light interception, LI). Lower frequency of defoliation (100% of light interception, LI) resulted in lower forage bulk density (110.3±15.2 kg/ha.cm of DM).

Key words: sward target, light interception, rotational grazing

T127 Herbage accumulation dynamics in pastures of *Pennisetum purpureum* submitted to grazing severities. D. Nascimento Junior*[1], B. M. L. Sousa[1], H. C. F. Monteiro[1], H. H. Vilela[1], M. C. T. Silveira[1], A. F. Sbrissia[2], and S. C. Da Silva[3], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil, [3]Escola Superior de Agicultura Luis de Queiroz, Piracicaba, SP, Brazil.*

The experiment was carried out from December 2009 to May 2010 to evaluate the herbage accumulation dynamics of *Pennisetum purpureum* 'Napiergrass' submitted to grazing severities. Three post-grazing heights were evaluated: 30, 50 and 70 cm. Grazing was initiated when the sward reached 95% of light interception during regrowth. A completely randomized block design with three replications was used. Monitoring of the light interception was done using the canopy analyzer (LI-COR LAI 2000). In the beginning of each regrowth period twelve tillers were marked in each experimental unit to evaluate the growth and development dynamics. Additionally, aerial tillers that appeared during the regrowth were monitored. In order to evaluate the herbage accumulation dynamics, on the last day of each evaluation period, all the tillers were cut, separated into stems and leaves, and placed in a forced air oven at 65°C for 72 h. After drying them, the material was weighted and the mass of each one was divided by its respective total length. A conversion factor was generated to transform the linear values (centimeters) of the leaf, stem and leaf senescence rates in weight values to area unit. The herbage accumulation rate was calculated by the difference between values of growth and senescence. The data was submitted to variance analysis using the Mixed Procedure of SAS (Statistical Analysis System) The herbage accumulation rate was influenced by the post-grazing height ($P = 0.0456$) and months of the year ($P < 0.0001$). The highest values were obtained in the post-grazing heights of 50 cm (110.1 kg/ha.day of DM) and 70 cm (119.7 kg/ha.day of DM). March and April in 2010 (105.0 and 112.1 kg/ha.day of DM, respectively) presented the highest values, followed by December in 2009 and January in 2010 (86.9 and 85.0 kg/ha.day of DM, respectively). February and March (66.3 and 70.7 kg/ha.day of DM, respectively) presented the lowest values. A:\\post-grazing height of 30 cm can drastically reduce the pasture accumulation rate.

Key words: post-grazing height, post-grazing height, light interception

T128 Pre-and post-grazing targets for mulato grass subjected to rotational stocking management. M. C. T. Silveira[1], D. Nascimento Junior*[1], S. C. Da Silva[2], K. S. Pena[1], C. S. Rodrigues[1], S. J. Souza[2], V. A. Limao[2], L. M. Barbero[2], and B. M. L. Sousa[1], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Escola Superior de Agricultura Luiz de Queiroz, Piracicaba, SP, Brazil.*

The objective of this experiment was to evaluate pre- and post-grazing condition targets on mulato grass subjected to rotational stocking management. The experiment was carried out at E.S.A. "Luiz de Queiroz" Universidade de Sao Paulo, from January 2008 to April 2009. Treatments corresponded to combinations between two pre- (95% and maximum canopy light interception - LI) and two post-grazing (15 and 20 cm residue) conditions, and were allocated to experimental units according to a 2 × 2 factorial arrangement in a randomized complete block design, with four replications. Canopy light interception was monitored using the LAI 2000 canopy analyser (LI- COR) at ten locations per experimental unit (1200 m^2 paddocks) and were followed by measurements of sward height at 100 points per paddock using a sward stick. Herbage mass and herbage morphological composition at pre- and post-grazing were estimated using three 0.90 x 0.37 m metallic frames per paddock. Data were analyzed as repeated measurements and means compared using t Student test at 5% significance. Post-grazing heights were consistently close to targets on swards managed at 95% LI, the same response did not occur on those managed at maximum LI (99%), particularly for the 15 cm target that became 20 cm after the first three grazing cycles. That was mainly due to increased accumulation of stem and dead material on swards managed at maximum relative to those managed at 95% LI. This was caused by intense competition for light when canopy light interception was allowed to increase beyond 95%, and caused difficulties to graze paddocks down to residue targets, deteriorating sward structure with potential negative effects on nutritive value and intake of the produced herbage. Pre-grazing height was larger on swards managed at maximum relative to those managed at 95% LI, regardless of post-grazing height for most of the experimental period, and values were relatively stable and around 30 and 40 cm. The results indicate that mulato grass should be grazed when paddocks reach 30 cm pre-grazing height (95% LI) using post-grazing heights of 15 to 20 cm.

Key words: *Brachiaria* sp. 'Mulato', canopy light interception, sward target

T129 Balance between the emergence and mortality of tiller in *Brachiaria decumbens* pastures under continuous stocking. M. E. R. Santos[1], V. M. Gomes[2], D. M. Fonseca[2], D. Nascimento Junior*[2], and A. F. Sbrissia[3], *[1]Universidade Federal de Uberlandia, Uberlandia, MG, Brazil, [2]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [3]Universidade do Estado de Santa Catarina, Lages, SC, Brazil.*

The experiment was conducted to evaluate 2 different strategies for managing *Brachiaria decumbens* under continuous stocking. From June 2008 to March 2009, the *B. decumbens* pastures were evaluated at the Departamento de Zootecnia of the Universidade Federal de Vicosa located in the State of Minas Gerais, Brazil. The experimental site was located at 651 m altitude, 20° 45′ S and 42°51′ W. Annual precipitation is around 1,340 mm. Maximum and minimum temperatures are 22.1°C and 15.0°C, respectively. The experimental area was made up of 8 plots (experimental units) of 0.3 ha. In one management strategy, *B. decumbens* pasture was maintained at height of 25 cm during the trial. In the other, the pasture was kept at an average of 15 cm high during the winter (July to September 2008), and at 25 cm from the beginning of winter until the summer (October 2008 to March 2009). The experiment was carried out using a randomized block design with 4 repetitions and subdivided plots. Both management strategies for the pasture correspond to the plots. The seasons of the year are the subplots. In each experimental unit, all tillers inside the frames with 0.0625 m^2 were counted and marked with colored plastic coated wire. Every 30 d, all tillers were recounted and new tillers were marked with a different wire color. The collected data was used to calculate the balance between the emergence and mortality of tiller (BAL). The BAL was lower ($P < 0.10$) in the winter (0.1%) and higher ($P < 0.10$) in the spring (22.3%) and summer (26.2%). These results characterize a high *B. decumbens* tiller turnover in the spring and the summer, resulting in more young tillers in the pasture. Lowering the pasture height to 15 cm in the winter increased ($P < 0.10$) the BAL (21.1%) if compared with the one kept at 25 cm (BAL equal to 11.3%). For lower canopies, the higher light incidence at the base of the plants stimulates tillering. Hence, to optimize the turnover of tillers, *B. decumbens* should be managed, under continuous stocking, to have 15 cm in height in the winter and 25 cm in the spring and summer.

Key words: grazing management, seasons of the year, sward height

T130 Forage utilization efficiency estimated in *Pennisetum purpureum* submitted to grazing severities. D. Nascimento Junior*[1], B. M. L. Sousa[1], H. C. F. Monteiro[1], F. C. Gomes[1], C. Z. Assis[1], H. H. Vilela[1], A. F. Sbrissia[2], A. L. Santos[1], and M. C. T. Silveira[1], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil, [3]Escola Superior de Agicultura Luis de Queiroz, Piracicaba, SP, Brazil.*

The experiment was carried out from December 2009 to May 2010 in order to estimate the forage utilization efficiency of *Pennisetum purpureum* 'Napier' submitted to different grazing severities. Three post-grazing heights were evaluated: 30, 50 and 70 cm. The grazings were performed when the sward reached 95% of light interception during regrowth. A completely randomized block design with three replications was used. The monitoring of the light interception was done using the canopy analyzer (LI-COR LAI 2000). In the beginning of each regrowth period, twelve tillers were marked in each experimental unit to evaluate the growth and development dynamics. Aerial tillers that appeared during the regrowth were also monitored. In the last day of each evaluation period, all the tillers were cut, separated into stems and leaves, and dried in a forced air oven at 65°C for 72 h, then weighed and the mass of each compound was divided by its respective total length. A conversion factor was generated to transform the linear values (cm) of the leaf, stem and leaf senescence rates in weight values to area unit. The total growth rate (leaf growth + stem growth) and the pasture senescence rate were calculated. It was possible to estimate the forage efficiency utilization: {(1 â€“ senescence/total growth) x 100}. The data was submitted to variance analysis using the Mixed Procedure of SAS (Statistical Analysis System) and compared by the Student's t-test, with 5% of significance. The forage utilization efficiency estimate was affected by the post-grazing height ($P = 0.0284$) and months of the year ($P < 0.0001$). The post-grazing heights of 70 (82.2%) and 50 cm (86.0%) presented the highest ($P = 0.0284$) forage utilization efficiency estimates, and the residue of 30 cm (73.0%), the lowest. December 2009 presented forage utilization efficiency estimated at 4.5%. This value reduced in January (73.9%) and February (68.8%) in 2010, but increased in March 2010 (80.7%), and reaching

a higher value ($P < 0.001$) in April (87.7%) and May (86.9%) in 2010. The post-grazing height of 30 cm gave the lowest forage utilization efficiency of *Pennisetum purpureum* 'Napier'.

Key words: grazing management, light interception, post-grazing height

T131 Grazing losses and grazing efficiency on mulato grass subjected to strategies of rotational stocking management. M. C. T. Silveira[1], D. Nascimento Junior*[1], S. C. Da Silva[2], C. S. Rodrigues[1], V. A. Limao[2], L. M. Barbero[2], S. J. Sousa[2], K. S. Pena[1], and B. M. L. Sousa[1], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Escola Superior de Agricultura Luiz de Queiroz, Piracicaba, SP, Brazil.*

This experiment evaluated grazing losses and grazing efficiency on mulato grass subjected to strategies of rotational stocking management. The experiment was carried out at Piracicaba-SP, from January 2008 to April 2009. Treatments corresponded to combinations between 2 pre- (95 and 99% canopy light interception - LI) and 2 post-grazing (15 and 20 cm residue) conditions, and were allocated to experimental units (1200 m^2paddocks) according to a 2x2 factorial arrangement in a completely randomized block, with 4 replications. Litter losses to the soil pathway were considered as all material lying on the ground as well as broken stems and green leaves still attached and hanging onto plants in paddock areas (2 2.0 × 1.0 m sites) previously prepared for measurements before each grazing. Preparation consisted of removal of all surface litter (un-rooted live and dead plant material). Grazing losses were weighed and values calculated as kg/ha. These were also calculated as percentage of the total herbage removed during grazing (difference between pre- and post-grazing herbage masses), and the results used to calculate grazing efficiency as their complement to 100. Data were analyzed as repeated measurements and means compared using Student's *t*-test at 5% significance. Litter losses were smaller ($P < 0.0001$) on swards managed at 95% than on those managed at maximum LI (99%) (795 ± 32.3 and 1305 ± 36.6 kg/ha, respectively), with larger values ($P < 0.0001$) recorded in autumn-winter-early spring (1400 kg/ha ± 134.7 SEM) relative to those recorded in late spring (1265 kg/ha ± 84.6 EPM), summer 2008 (660 kg/ha ± 22.0 SEM) and summer 2009 (880 ± 37.7 SEM). In relation to post-grazing heights, litter losses were larger ($P = 0,0188$) on swards managed at 15 cm relative to those managed at 20 cm (1120 and 980 kg/ha ± 38.1 SEM). Grazing efficiency was 24% larger on swards managed at 95% relative to those managed at maximum LI (70.2 and 56.7% ± 1.4 SEM), suggesting the pre-grazing target of 95% LI as ideal since it was associated with reduced herbage losses due and enhanced grazing efficiency.

T132 Relationship between canopy light interception and pre-grazing sward height in *Brachiaria humidicola* pastures subjected to frequencies and intensities of defoliation. H. H. Vilela[1], D. Nascimento Junior*[1], A. L. Santos[1], B. M. L. Sousa[1], G. O. Rocha[1], C. A. S. Feitas[1], and A. F. Sbrissia[2], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil.*

The light interception by the sward is correlated with pre-grazing sward surface height, becoming a practical management tool for farmers. The aim of this work was to evaluate the light interception and pre-grazing sward height of *Brachiaria humidicola* 'Comum' pastures subjected to frequencies and intensities of defoliation. Two defoliation intensities were evaluated (8 and 16 cm), associated with defoliation frequencies represented by 95 and 100% of the intercepted light by the sward. The experiment was assigned according a complete randomized block design in a 2 × 2 factorial arrangement with 3 replicates. The light interception was measured using a canopy analyzer (LI-COR LAI 2000) at 4 points per experimental unit (paddock). A reading was taken above the sward and 5 on the soil surface (within the sward), resulting in 4 readings above the sward and 20 readings at ground level. The evaluation of the sward surface height was performed using a ruler, on the same day the paddocks had their light interception measured. Sward height was measured at 20 points per paddock. The data presented are for the period from December 2009 to March 2010 and means were compared by Student *t*-test, 10% significance. ANOVA was performed on light interception (control variable). The interception of light by pastures in the treatment with the highest frequency was 94.86% and the treatment of lower frequency, 98.05%. The sward height was influenced ($P < 0.10$) only by the frequency of defoliation, with an average of 30.27 cm for the highest frequency (95% LI) and 49.76 cm for lower frequency (100% LI). Pre-grazing stubble height is an important feature on plant and animal performance. In this study, sward height was consistently correlated positively with light interception.

Key words: light interception, rotational grazing, sward target

T133 Tiller population density in *Brachiaria humidicola* pastures subjected to frequencies and intensities of defoliation. H. H. Vilela[1], D. Nascimento Junior*[1], A. L. Santos[1], B. M. L. Sousa[1], G. O. Rocha[1], C. A. S. Feitas[1], and A. F. Sbrissia[2], *[1]Universidade Federal de Vicosa, Vicosa, MG, Brazil, [2]Universidade do Estado de Santa Catarina, Lages, SC, Brazil.*

The maintenance and stability of grasslands can be obtained through appropriate management practices. The use of rotational grazing systems, based on defoliation frequencies determined by canopy light interception can ensure pasture persistence, since this management practice is closely related to the sward ecophysiology. This study was conducted to evaluate basal and aerial tiller population density at post-grazing in *Brachiaria humidicola* 'Comum' pastures subjected to frequencies and intensities of defoliation. Two defoliation intensities were evaluated, represented by stubble height of 8 and 16 cm, associated with defoliation frequencies determined by 95 and 100% of light interception by the sward. A randomized complete block design was adopted with 3 replicates in a 2 × 2 factorial arrangement. The light interception was measured with the canopy analyzer equipment (LI-COR LAI 2000). The assessment of population density of basal and aerial tillers (alive) was held at 3 points in each paddock, by counting the total number of basal and aerial tillers in a quadrat of 0.25 × 0.25 m. The data presented are for the period of December 2009 to March 2010 and results were compared by Student *t*-test with a level of significance of 10%. The population density of basal tillers was influenced ($P < 0.10$) by the intensities and frequencies of defoliation. Highest population density of basal tillers (3205 tillers/m^2 was observed at lower intensity of defoliation (16 cm). Regarding the frequency of defoliation, higher population density of basal tillers (3170 tillers/m^2 was observed at higher frequency (95% light interception). The aerial tiller density was not influenced by treatment ($P > 0.10$). More frequent grazing (95% light interception) and the use of lower intensity defoliation (16 cm), seems to improve stability and persistence of *Brachiaria humidicola* 'Comum'.

Key words: light interception, tillering, sward target

T134 Forage production and leaf area index of tropical grass cultivars under irrigation in the cerrado region of Minas Gerais, Brazil. E. A. da Silva*[1,6], W. J. da Silva[1], J. R. M. Ruas[2,5], D. S. Queiroz[3], M. C. M. Viana[4,6], J. M. V. Paes[1,6], and L. C. da Silva Júnior[7,8], *[1]EPAMIG, Uberaba, Minas Gerais, Brazil, [2]EPAMIG, Janaúba, Minas Gerais, Brazil, [3]EPAMIG, Viçosa, Minas Gerais, Brazil, [4]EPAMIG, Prudente de Morais, Minas Gerais, Brazil, [5]CNPq, Brasília, Federal District, Brazil, [6]FAPEMIG, Belo Horizonte, Minas Gerais, Brasil, [7]FAZU, Uberaba, Minas Gerais, Brazil, [8]FAPEMIG, Belo Horizonte, Minas Gerais, Brazil.*

The Leaf Area Index (LAI) is one of the most important biophysical variables used for crop modeling, and it is directly related to evapotranspiration, yield and light interception. The objective of this work was to estimate LAI of tropical grass cultivars under irrigation on 10 cutting dates. The experiment was carried out from December 2008 to December 2009. The experimental design was a complete randomized block in a split plot with 4 replications. The herbage was considered the main plot and cutting date the subplot. The treatments were: *Brachiaria decumbens* 'Basilisk', *Brachiaria brizantha* 'Marandu', *Brachiaria brizantha* 'Xaraes', *Panicum maximum* 'Mombaça', *Panicum maximum* 'Tanzania' and *Cynodon* spp. 'Tifton 85' and 10 cutting dates. The dry matter percentage and LAI were evaluated. The LAI was calculated as the green leaf area per unit of ground area. The data were subjected to ANOVA and when significant effects for the factors evaluated became the Tukey Test at 5% probability using the statistical package SAS (2001). The dry mass production of forage showed strong relationship with LAI. The dry mass accumulation of cultivars Basilisk, Marandu, Tanzania and Mombaça were superior ($P < 0.05$) to cultivars Tifton 85 and Xaraes production. The LAI showed seasonal variations with lower values in the winter. The cultivars Mombaça and Tifton 85 presented higher and lower LAI ($P < 0.05$), respectively. The satisfactory performance presented by cultivars, associated with other important characteristics of adaptability, show the importance of these cultivars as an alternative pasture for different cattle systems as well as a contribution to their sustainability. The differentiated productive behavior between cultivars must be considered for an adequate management of these grasses. (Research supported by FAPEMIG/CNPq, Brazil)

T135 Morphogenic characteristics of tropical grass cultivars under irrigation in the cerrado region of Minas Gerais, Brazil. E. A. da Silva*[1,5], W. J. da Silva[1], J. R. M. Ruas[2,6], M. C. M. Viana[3,5], D. S. Queiroz[4], J. M. V. Paes[1,5], and L. C. da Silva Júnior[7,8], *[1]EPAMIG, Uberaba, Minas Gerais, Brazil, [2]EPAMIG, Janaúba, Minas Gerais, Brazil, [3]EPAMIG, Prudente de Morais, Minas Gerais, Brazil, [4]EPAMIG, Viçosa, Minas Gerais, Brazil, [5]FAPEMIG, Belo Horizonte, Minas Gerais, Brazil, [6]CNPq, Brasília, Federal District, Brazil, [7]FAZU, Uberaba, Minas Gerais, Brazil, [8]FAPEMIG, Belo Horizonte, Minas Gerais, Brazil.*

The objective of this work was to estimate leaf area index of tropical grass cultivars under irrigation at 10 cutting dates. The experiment was carried out from January to December 2009. The experimental design was a complete randomized block in a split plot with 4 replications. The herbage was considered the main plot and cutting date the subplot. The treatments were: *Brachiaria decumbens* 'Basilisk', *Brachiaria brizantha* 'Marandu', *Brachiaria brizantha* 'Xaraes', *Panicum maximum* 'Mombaça', *Panicum maximum* 'Tanzania' and *Cynodon* spp. 'Tifton 85' and 10 cutting dates. To evaluate the morphogenic characteristics, 3 tillers were marked in each plot. Data were analyzed by ANOVA and means were compared by Tukey test ($P < 0.05$). The number of tillers per area of Tanzania did not ($P > 0.05$) vary with seasons and was 301/m^2. The number of tillers per area was 880, 526, 522, 292, 301 and 1147/m^2 for cultivars Basilisk, Marandu, Xaraes, Mombaça, Tanzania and Tifton 85, respectively. These values are consistent with those reported in the literature. The number of tillers in the sward was a function of grass cultivar and time of the year. The difference in number of tillers was statistically significant at the 5% probability level with the Tukey test. Highest values ($P < 0.05$) of tillers were recorded for Tifton 85 cultivar and the lowest ($P < 0.05$) for the 2 Panicum cultivars, whereas, *Brachiaria brizantha* cultivars ranked intermediate. Tiller population density varied with season of the year and cultivars, with lowest values being consistently recorded during winter. (Research supported by FAPEMIG/CNPq, Brazil)

T136 Effect of patch-burning mixed-grass prairie rangeland on cattle performance. S. A. Gunter*[1], T. L. Springer[1], E. T. Thacker[1], and R. L. Gillen[2], *[1]USDA-ARS, Southern Plains Range Research Station, Woodward, OK, [2]Western Kansas Agricultural Research Centers, Kansas State University, Hays.*

Patch burning, a range management tool, has gained favor in recent years to renovate degraded rangelands. By burning a portion of a pasture, it is hypothesized that cattle will concentrate grazing on burned sites and the increased disturbance will encourage forb establishment and lessen grazing in the unburned portion. To evaluate the effect of patch burning on the performance by stocker cattle grazing mixed-grass prairie in northwest Oklahoma, 3 pastures ranging in size from

24 to 13 ha were selected; 2 pastures had been reseeded to native grass <8 yr before the start of the experiment and the third site was go-back land with no record of reseeding since 1939. Each pasture was divided in half and all were burnt in March of 2005 before the start of the 4-yr experiment in 2006; the patch-burnt pastures had 25% burnt each March starting in 2006 through 2009. Each pasture was stocked with steer calves (248 ± 7.6 kg) at a rate of 5l.1 animal-unit-d/ha from mid-January to late-July. From January until mid-April, calves were fed 0.68 to 0.91 kg/steer of a 41% CP cottonseed meal-based supplement; cattle had access to water and plain salt during the entire grazing period. Cattle were weighed in January, mid-April, and late-July after an overnight-shrink without feed or water. Data were analyzed using GLIMMIX in SAS with treatment as the fixed effect and pasture and year as random effects. The ADG of calves on the patch-burned rangeland (0.83 kg) did not differ (P = 0.73) for cattle grazing unburned pastures (0.82 kg). Because BW did not differ (P = 0.77) in January and ADG did not differ, BW at the end of the grazing period in July did not differ (P = 0.88; average BW = 382 ± 12.6 kg). Body weight gain/ha by calves on the patch-burned rangeland (68 kg) did not differ (P = 0.48) for cattle grazing unburned pastures (69 kg). Using the patch-burning tool on mixed-grass prairie in northwest Oklahoma did not have a detrimental effect on cattle performance. If this technique proves to augment the ecological services rangelands provide, it may become widely used by land managers.

T137 Estimating pasture growth rates using local weather data. E. B. Rayburn and W. L. Shockey*, *West Virginia University, Morgantown.*

Climatic conditions in the Appalachian region of the US are generally conducive to forage production for use as ruminant livestock feed. Forage growth variations contribute to uncertainty about the number of ruminant livestock that can be supported at any given location in any given year or season of the year. A forage growth model was developed that predicts plant growth rates based on local weather data and Penman-type evapotranspiration. Based on field testing of the forage growth model with in-field weather and clipped forage production over 16 site years the model predicted yield compared with clipped yield with an R^2 of 0.81 and a residual SD of 965 kg/ha. The model was refined to use historical weather data to make a stochastic model that could evaluate yield variability based on historical weather variation. Thirty years of data were collected from 5 weather stations that are representative of a variety of elevations and mean monthly temperatures in northern WV. Data collected were latitude and daily maximum, minimum, and average temperatures, and rainfall. The stochastic model uses the local probability of rainfall frequency and amount to calculate random predictions of weather used in the calculation of the Plant Growth Rate (PGR) for each day of the modeled year for a location. A new model year for PGR is generated with each calculation of the spreadsheet model. By comparing the stochastically modeled PGR estimates which use the variability in the 30-year weather data, one might plan with some confidence, in light of the risk incurred due to variability in pasture growth across years and within the year, the number of animal units that can be supported on a farm that is located in the region supported by its weather station. Because the model estimates PGR for each the day of the year, livestock producers may more accurately plan the timing for changes in stocking rates, mechanical harvest of excess forage, or purchase of supplemental feed relative to the historical risk associated with a given weather station. With appropriate analysis of historical data from additional weather stations this stochastic model could be extended to other areas of the country.

T138 Impact of feeding strategies on milk production and income over feed cost: A case study of organic, grazing and conventional Wisconsin dairy farms. M. Dutreuil*, M. Wattiaux, R. Gildersleeve, B. L. Barham, and V. E. Cabrera, *University of Wisconsin, Madison.*

A survey was developed to understand feeding practices on Wisconsin dairy farms and their consequences on milk production and milk income over feed cost (IOFC). Farms were randomly selected across 3 management systems: conventional (CON), grazing (GRA) and organic (ORG). Preliminary results from 2 CON, 3 GRA and 3 ORG are presented. No statistical analysis is reported because of these small numbers of farms. Grains were used in similar amounts across the year 2010 on GRA and ORG, whereas CON used less than half grain in summer than in winter. Grains were partially replaced in CON by a protein mix that was used more than double in summer than in winter. Hay was the main component in the winter for all the farm systems, which was partially replaced by grazing during summer. Corn silage, haylage, and baleage were used in similar amounts throughout the year by CON and ORG, whereas GRA used an additional 3.9 kg DM/cow/d in summer. In total, DMI in winter (kg/cow/d) was higher for CON and GRA (24.6 and 23.8, respectively) than for ORG (15.0), which led to differences in milk production (kg/cow/d) and cost of feed, ($/cow/d) for CON (27.3 and 2.6), GRA (20.0 and 1.5), and ORG (10.4 and 1.5). Milk price for ORG ($60/100 kg milk) was about twice as much as CON and GRA. Calculated milk IOFC ($/cow/d) was higher for CON (6.8) in winter and for ORG (7.5) in summer. The use of grazing by ORG during summer improved milk production (+4.6 kg/cow/day) and decreased feed cost (−0.2 $/cow/day), which determined the highest milk IOFC. Our preliminary results indicate that, given 2010 prices, ORG could be as much profitable as CON or GRA systems when including the USDA's National Organic Program grazing standards.

Table 1. Feeding practices, milk production and income over feed cost (IOFC) on Wisconsin dairy farms

	Winter (January)			Summer (June)		
	CON	GRA	ORG	CON	GRA	ORG
Feed (kg DM/cow/d)						
Grain mix	6.3	4.0	4.3	3.0	4.0	4.3

T139 Performance of automatic milking during a whole herd transition to grazing. S. Utsumi*, M. Haan, R. Ashley, and J. Bronson, *Kellogg Biological Station, Michigan State University, Hickory Corners.*

The effect of the length of grazing sessions on the performance of automatic milking systems (AMS), and the milking behavior of a whole herd of Holstein cows transitioned for first time to pastures was evaluated. Two groups of cows (n = 49 ± 3, DIM = 213 ± 1 d, Age = 3.8 ± 01 yr, BW = 611 ± 6 kg) voluntarily milked with single-stall AMS at rates of 4 to 2 milkings/day (based on DIM and milk yield), were exposed to 1-wk adaptation periods of 0, 2, 4, 6, and 8 h of grazing followed by 6 1-wk periods of voluntary grazing for 12 h. Groups grazed at moderate levels (46 ± 8% utilization) on grass-legume strips located within 400 m from the barn. Exit to pasture was permitted via computer-operated gates if prescribed milking intervals (range: 6 to 12 h) were not exceeded. Fetching of cows with 12-h intervals since last milkings was conducted twice per day. Cows received once a day declining amounts of a forage-based TMR (5% orts) in addition to 1 kg of concentrate per 4 kg of milk. Contrast of linear and quadratic effects ($P < 0.05$) of the length of grazing periods on AMS performance and milking behavior of cows was conducted. Total milk, milking visits and the time AMS spent milking decreased linearly as grazing sessions extended. Performance of AMS was likely increasingly limited by lower milkings and milk yield of individual cows exposed to longer grazing sessions. Length of grazing sessions did not affect milk speed or duration of milking visits, but milking time and yield per milking dropped when the length of grazing session was intermediate. Optimization of AMS in pasture-based systems may require strategic planning of dynamic stocking rates to efficiently lessen declines in milking frequency and milk yield per cow.

Table 1. Automatic milking (AMS) performance and milk production of cows

T140 Corn and forage yield on degraded pasture recovered by integrated crop-livestock-forest system in the central region of Minas Gerais, Brazil. M. C. M. Viana*[1], M. H. T. Mascarenhas[1], W. M. Albernaz[2], F. M. Freire[1], R. C. Alvarenga[3], E. A. Silva[1], M. M. Gontijo Neto[3], and M. F. F. Teixeira[4,5], *[1]EPAMIG - Minas Gerais Agricultural Research Corporation, Belo Horizonte, Minas Gerais, Brazil, [2]EMATER MG - Minas Gerais Agricultural Assistance and Rural Extension, Belo Horizonte, Minas Gerais, Brazil, [3]Embrapa Maize and Sorghum, Sete Lagoas, Minas Gerais, Brazil, [4]FEAD, Belo Horizonte, Minas Gerais, Brazil, [5]FAPEMIG, Belo Horizonte, Minas Gerais, Brazil.*

The integrated crop-livestock-forest (iCLF) system has been used to recover degraded areas of crop and pastures in Brazil. To evaluate the influence of different eucalyptus arrangements and clones on the corn grain yield and pasture production in the first year of iCLF system a trial was carried out at Belo Horizonte, Brazil (19°28′ SE 45°15′W, 732 m) on *Brachiaria decumbens* degraded pasture. The experimental design was a randomized complete block in a split plot, with three replications. Eucalyptus arrangements: double rows (3 x 2) x 20 m; (2 × 2) × 9 m and single rows (9 × 2m) were distributed in the main plots, with 20 and 9 m between rows and 2 m between tree spacings. Eucalyptus clones: VM 58, GG100 and I144 were tested in the subplots. A corn (hybrid BRS3060) was intercropped with eucalyptus clones and cultivated as monoculture (control). Data were analyzed by ANOVA and means were compared by Tukey test ($P \leq 0.05$). Soil liming (2 t/ha), basal (300 kg/ha 08-28-16) and topdressed (350 kg/ha 20-00-20) corn fertilizations were accomplished. At the corn harvest, plant height, first ear height, number and weight of ears and grain yield were evaluated. Forty days after corn harvest dry matter (DM) production and chemical composition (CP, ADF, NDF and lignin contents) of *B. decumbens* regenerated from the soil seed bank were evaluated. There was no difference ($P \geq 0.05$) between corn in monoculture and corn intercropped with eucalyptus in all arrangements. The average corn grain yield in the iCLF system and as monoculture was 4.76 and 4.28 t/ha, respectively. Also there was no difference ($P \geq 0.05$) between the corn and forage growing under the eucalyptus clones. The DM yield and chemical composition of *B. decumbens* was not affected by the eucalyptus arrangements and clones. The soil liming and fertilizer applied to corn intercropped with eucalyptus contributed to the recovery of the pasture of *B. decumbens*. In the first year of iCLF establishment, the influence of eucalyptus shade is not a limitation to corn and pasture development. (Research supported by FAPEMIG/CNPq, Brazil)

Key words: agroforestry, forage, eucalyptus

T141 Supplement and stocking strategies for heavy-weight fall-born calves backgrounded on Tifton 85 bermudagrass. F. Rouquette*, J. Kerby, G. Nimr, and K. Norman, *Texas AgriLife Research, Overton.*

Fall-born calves weaned at 340 kg in early summer present management challenges for gain on bermudagrass (*Cynodon dactylon*) pastures (BG). Our objectives were to quantify gain/animal and gain/ha due to stocking rates (SR) and supplement (SUP) source and quantity. Simmental-sired calves with F-1 (Angus × Brahman) dams were allotted to SUP treatments in successive years (YR). In YR 1, a 2:1 soybean meal:cracked corn (SBM) 36% protein ration containing Rumensin 80, salt, and minerals was group-fed daily at 0.4% BW (4-SBM) to 3 steers and 2 heifers on each of 2 replicate pastures of Tifton 85 BG stocked at 12, 18.5, and 22 320-kg calves/ha. Calf average daily gain (ADG) from 28 June to 28 September increased ($P < 0.05$) with SUP (0.7 kg/d) compared with pasture only (PAS) at 0.31 kg/d. The ADG differed ($P < 0.01$) between each SR of low (LO) (0.75 kg/d), medium (ME) (0.52 kg/d), and high (HI) (0.32 kg/d). Resultant gain/ac for SUP was 980, 1300, and 1118 kg/ha, respectively, for LO, ME, and HI SR; and for PAS was 690, 470, and 241 kg/ha, respectively. The SUP:extra gain was 3.3:1 for calves on ME or HI SR and 6.2:1 for LO SR. In YR 2, the 4-SBM ration was compared with daily 0.4% BW and 0.8% BW each of 8% protein cracked corn (CRN) (4-CRN, 8-CRN) and pelleted 23% protein corn gluten (GLU) (4-GLU, 8-GLU). Two replicate pastures of the 6 treatments were stocked at LO to ME SR from 22 June to 14 October. With 13.5 320-kg calves/ha, ADG was similar for 8-CRN (0.97 kg/d) and 8-GLU (0.86 kg/d), and similar for 8-GLU, 4-CRN

(0.78 kg/d), and 4-SBM (0.75 kg/d). Calf ADG was similar for all SUP fed at 0.4% BW. The ADG from PAS was lower ($P < 0.01$) at 0.35 kg/d than all SUP. The SUP:extra gain for calves was 3.6:1 (4-CRN), 4.2:1 (4-SBM), 5:1 (8-CRN), 5.1:1 (4-GLU), and 6.1:1 (8-GLU). Gain/ha for 8-CRN was 1385 kg/ha, about 1065 kg/ha for 8-GLU, 4-CRN, and 4-SBM, 900 kg/ha for 4-GLU, and 450 kg/ha for PAS. Economic considerations of calf value, SUP costs, and SUP:extra gain favored ME SR and 0.4% BW SUP of energy (CRN) or protein with Rumensin (SBM) for backgrounding fall-born calves on Tifton 85 BG pastures.

Key words: supplement, bermudagrass, stocking rate

T142 Production of wheat and oats overseeded into Tifton-85 grass at different forage allowances. F. F. Simili*[1], A. C. Ruggieri[2], T. V. Bertolino[2], D. R. Casagrande[3], R. A. Reis[2], and R. Godoy[4], *[1]APTA, Ribeirao Preto, Sao Paulo, Brazil, [2]UNESP, Jaboticabal, Sao Paulo, Brazil, [3]UFAM, Parintins, Amazonas, Brazil, [4]EMBRAPA, Sao Carlos, Sao Paulo, Brazil.*

The overseeded technique has been used successfully for many years in southern Brazil and southern United States and it is considered an appropriate alternative to increase forage production during the winter when there is moisture available in the soil. The objective of the experiment was to evaluate forage mass of annual oat and wheat overseeded into perennial Tifton-85 grass (*Cynodon nlemfluensis* × *Cynodon dactylon*) grazed by sheep, which received three different forage allowances (FA). The experimental design was completely randomized with 3 x 3 factorial scheme and repeated measures (grazing periods), with three repetitions. The treatments were oat (*Avena bysantina*), var. UPF 86081, wheat (*Triticum aestivum* L.) 'BRS Figueira' and the combination of the two species wheat and oats. These grasses were grazed at three FA 4, 7 and 10% of body weight of animals. There was a significant interaction between FA and grazing cycle for all variables ($P < 0.05$). The dry mass production (DMP) by hectare (ha) of Tifton-85 grass was significantly higher ($P < 0.05$) in the third grazing cycle, with an average of 6,728 kg DMP/ha, but there were no differences among FA. The production of annual grass was lower ($P < 0.05$) in the first grazing cycle, with an average of 551.4 kg DMP/ha, but there were no differences among FA. The highest DMP of annual grasses was achieved with 10% of FA in the third grazing cycle, with an average of 2,488.8 kg DMP/ha. These results can be explained by occurrence of rain in October, at the same period of the third grazing cycle. The best ($P < 0.05$) percentage of annual grass plants was observed in the second grazing cycle with an average of 39.6%. However, Tifton- 85 grass presented the highest percentage of plants in all grazing cycles and FA. It was concluded that the overseeded technique to increase DMP for grazing animals was not successful in the environment that was studied.

T143 Effects of lack of shade on Wye Angus brood cows. M. S. Updike* and R. M. Harrell, *University of Maryland, College Park.*

In the Chesapeake Bay watershed, increased environmental regulations will likely result in cattle producers having to fence cattle out of the streams. One side effect of such fencing is that most of the shade (from trees) is provided along the streams and will no longer be available to the cattle. In addition, cost share programs in the Mid Atlantic region for fencing the streams do not include any cost share for adding shade elsewhere on the farms. This study was conducted to determine the effects of lack of shade on mature Wye Angus brood cows that had been adapted to shade in previous years. Forty cow calf pairs (bull calves) were rotationally grazed as normal with access to shade and 40 cow calf pairs (bull calves) were rotationally grazed with no access to shade. To minimize location effects, individual fields were split into paddocks so that shade treatment group had access to trees for natural shade. The study began July 1st which was immediately after the clean up bulls were pulled from the herd. Blood was collected in June before the beginning of the treatments, in July and in August. Cows were checked for pregnancy in the middle of August. Previous research has shown that heat stress causes has a greater impact on early stages of pregnancy. Therefore it was not surprising that 40% of the cattle with no shade were pregnant while 85% of the cattle with shade were pregnant. Blood was analyzed for hematocrit and other blood chemistries. No significant differences were found ($P < 0.05$) and all results were within normal parameters. These results have implications not just for farmers who must contend with changing regulations, but also government agencies and NGOs that are working with farmers to decrease nutrient loss into the watershed.

Key words: cattle, shade, stress

T144 Effect of stocking rate on forage production, soil compaction and root numbers in a swine pasture system. B. Renner*[1], S. Pietrosemoli[1], J.-M. Luginbuhl[1], C. Raczkowski[2], J. T. Green[1], and J. Grossman[1], *[1]North Carolina State University, Raleigh, [2]North Carolina Agricultural and Technical State University, Greensboro.*

Grazing experiments were conducted at the Center for Environmental Farming Systems in Goldsboro, NC from July to August 2008 and 2009 to determine the effect of swine stocking rate on subsequent forage production, soil compaction and root numbers. Pigs (18.4 and 118.5 kg initial and final body weight, respectively) were randomly assigned to each of 12 paddocks sized to equal stocking rates (SR) of 37, 74, 111, and 148 head/ha in a randomized complete block design. Animals had ad libitum access to water and concentrate feed. A winter cereal rye/annual ryegrass (*Secale cereale*/*Lolium perenne*) mixture was sown following removal of the pigs in fall 2009 from a mature bermudagrass (*Cynodon dactylon*) pasture. Forage harvested at early boot stage to 5cm stubble length in spring 2010 was followed by a sorghum-sudangrass hybrid no-till seeded into the plots and harvested at early boot stage to 7cm stubble in August and again at stem elongation stage in October 2010. Soil samples were taken in spring and fall 2010 following the final harvest of each forage crop. Soil compaction and root numbers were determined at depths of 15, 30, 45, 60, 90 cm, and 15, 30, 60, 90 cm, respectively. A Delmi soil penetrometer was used to determine soil compaction and root numbers were determined by counting the roots in the cross-sections of harvested soil cores. In spring, forage yield ($P = 0.72$), soil compaction ($P = 0.4$) and root numbers ($P = 0.8$) did not change with SR, but soil compaction ($P = 0.0001$) and root numbers ($P = 0.0001$) were affected by soil depth. Summer ($P = 0.08$) and fall ($P = 0.7$) sorghum-sudangrass yields were not affected by SR. Fall root numbers were not affected by SR ($P = 0.2$) but strongly affected by soil depth ($P = 0.0001$). Under the conditions of this experiment, SR rate had no effect on subsequent forage yield. Conversely, soil compaction and root numbers were affected by soil depth, the latter being most prevalent in the top 15 cm.

Key words: outdoor pig production, stocking rate, root count

T145 Average annual weight prediction of cows kept four years in a tough regime using a model of simulation. J. M. Tapia[1],

J.C. Martinez[2], H. Diaz[3], A. Moreno[4], J. A. Martinez[1], O. D. Montañez*[1], J. A. Ochoa[1], and G. Rocha-Chavez[1], *[1]CUSUR, U de G, Cd. Guzman, Jalisco, Mexico, [2]Univ Autonom de Tamaulipas, Cd. Victoria, Tamps, Mexico, [3]Univ Auton Agr Antonio Narro, Saltillo, Cohahuila, Mexico, [4]Instituto Tecnologico de Cd Victoria, Cd. Victoria Tamps, Mexico.*

The objective of this study was to predict the average annual weight of cows living in a tough environment using a simulation model. Software STELLA 8, was used and data for the model was obtained from farm systems of the Tamaulipas region in northern Mexico characterized by semi arid climate and low quality pastures including cactus plants. Farmers are usually poor peasants having an average of 3 cows used mostly for subsistence of their families. Cows in the study were 4-year-old crosses (creole-zebu) and were grouped (21 cows per group) into 4 diet regimens: (1) grazing only (buffel and native grass), (2) grazing in a silvopastoral system (mostly bushes), (3) grazing with silage and (4) grazing with corn-molasses nutritional blocks. Silage for supplementing group 3 diets was made with chopped green corn plants that were compressed in a silo and allowed to ferment. The silvopastoral system included grazing over small plants of prosopis farcta and celtis spinosa. Regimen was assessed for 48 mo with 21 simulation cycles totalizing 84 years for each regimen. Analysis of variance was used to compare means and significance was set to $P < 0.05$. As it can be seen in Table 1, the best average weight was for the silvopastoral system whereas the lowest finding corresponds to the grazing only group. No significant differences were found among groups 2 and 3 ($P < 0.05$). Simulation models are useful to predict potential real life scenarios; however, there are several environmental aspects (such as unusual rain) that may influence their outcome.

Table 1. Average annual weight of cows with several types of diets

Diet type	Cycles[1]	Avg annual weight (kg, mean ± SE)
Grazing only	21	331.91±11.32 [a]
Grazing + corn silo	21	343.21±7.90 [b]
Grazing + nutritional block	21	338.33±21.05 [b]
Grazing silvopastoral	21	347.40±10.55 [c]

[1]All values evaluated for each treatment representing a cycle of 48 months totalizing 84 years of evaluation. Different letters in the same column differs significantly ($P < 0.05$).

Key words: weight, cows, prediction

T146 Effects of stocking rate and supplementation on carcass traits of beef cattle grazing winter annual forages. B. C. Williamson*[1], M. L. Looper[2], F. M. Rouquette[3], G. E. Aiken[4], S. F. Tabler[2], J. B. Wolley[2], and C. F. Rosenkrans[1], *[1]University of Arkansas, Fayetteville, [2]USDA/ARS, DBSFRC, Booneville, AR, [3]Texas AgriLife Research, Overton, [4]USDA/ARS, FAPRU, Lexington, KY.*

Environmental and managerial conditions are known to affect subsequent performance and carcass traits of beef cattle. The objective of this study was to document the effect of stocking rate (SR) and supplementation on carcass traits. Steers and heifers (n = 856; BW = 274 ± 46) were allowed to graze 'Maton' rye (*Secale cereale* L.) and 'TAM90' annual ryegrass (*Lolium multiflorum* L.) pastures from January to mid-May of 1999 to 2005. Cattle were allotted to stocking rates (SR) of high (6.7 animals/ha), medium (5.2 animals/ha), or low (3.7 animals/ha), and supplemented (0 vs. 3.0 kg/d corn/cottonseed meal; 16% protein), and finished in commercial feedlots. Body condition score (BCS); ultrasound measurements of intramuscular fat (UIMF), LM area, and rump fat at end of grazing; ADG during stocker (119 d ± 25) and feedlot (125 d ± 28) phases; hot carcass weight (HCW); carcass rib fat; carcass LM area (CLMA); and yield grade (YG) were measured. The ANOVA determined the effects of year, sex, SR, supplementation, and interactions on ADG, ultrasound measurements, and carcass traits . A supplement x SR interaction affected ($P < 0.05$) YG. Cattle tended ($P < 0.10$) to have lower YG when grazed at low SR (YG = 2.7 ± 0.08) compared with cattle grazed at high SR (YG = 3.1 ± 0.08) when supplemented. An SR × sex interaction ($P < 0.05$) affected CLMA. Steer CLMA was not affected ($P > 0.25$) by SR; however, heifers grazed at high SR had the smallest ($P < 0.10$) CLMA. Supplement x SR interaction ($P < 0.05$) affected HCW. Cattle supplemented while grazing had increased ($P < 0.05$) UIMF (1.13%) compared with nonsupplemented cattle (0.94%). High SR cattle had lower ($P < 0.05$) UIMF then medium and low SR (0.79%, 1.05%, and 1.26%, respectively). Cattle allotted to low SR gained more ($P < 0.05$) than cattle on medium or high SR while grazing (1.28, 1.14, 0.77 kg/d, respectively). In the feedlot, cattle at high SR gained more ($P < 0.05$) than cattle at medium or low SR (1.84, 1.67, 1.69 kg/d, respectively). Stocking rate and supplementation of cattle grazing winter annuals affected subsequent performance and carcass traits.

Key words: carcass traits, stocker cattle, ultrasound

T147 Matching hay composition to cow requirements during the winter. W. M. Backus[1], B. T. Campbell[1], A. M. Saxton[1], D. K. Joines[2], and J. C. Waller*[1], *[1]The University of Tennessee, Knoxville, [2]Soil, Plant, and Pest Center, Nashville, TN.*

The objective of this study was to compare the nutrient composition of hays produced in Tennessee and their ability to meet the nutrient requirements of beef cattle during the winter. Crude protein (CP) and estimated total digestible nutrients (TDN) values from 2,076 samples [bermudagrass (*Cynodon dactylon*) - 392; tall fescue (*Festuca arundinacea*) - 607; grass/clover - 200; mixed grass - 793; orchardgrass (*Dactylis glomerata*) - 84] submitted from Jan. 2007 - Dec. 2009 to the Tennessee Forage Testing Lab were used to evaluate available hay for winter feeding. CP levels ranged from 4 to 30% with a mean of 12.98 ± 0.21, TDN levels ranged from 34 to 88% with a mean of 60.77 ± 0.39. Nutrient requirements for 6 herds of 90 cows were established (NRC, 1996), with hay consumption based on published estimates for dry matter intake. Calving distributions from 8 years of spring and fall calving data from the Research and Education Center at Ames Plantation were used to develop the distribution for a 60 d calving season; comprised of 10 6 d periods. Spring and fall herds were grouped into 3 categories by mature size of cows; small cow size (453.6 ± 45.4 kg), medium cow size (544.3 ± 45.4 kg) and large cow size (635.0 ± 45.4 kg), each having an average milking ability of 9.1 kg ± 4.5 kg, with milk production ranging from 4.5 kg to 13.6 kg within each herd. Spring and fall calving seasons began Feb. 1 and Oct. 1 respectively. Hay feeding began Nov. 15 and ended Mar. 15. All hays were compared with individual cow requirements in each 10 d period. Tall fescue comparisons are presented because this is the predominant hay fed to beef cows in Tennessee. The results of matching tall fescue hay to the nutrient needs of the medium cow size spring calving herd indicate that 99% of samples met CP requirements and 93% of samples met TDN requirements of 80% of the herd in Nov., while 57% of samples met CP and 28% of samples met TDN requirements for 80% of the herd in Mar. In the medium cow size fall calving herd 65% of samples met CP requirements and 27% of samples met TDN require-

ments of 80% of the herd in Nov., while 89% of samples met CP and 74% of samples met TDN requirements for 80% of the herd in Mar.

Key words: hay, cow

T148 Total fat and fatty acid composition of steaks from steers finished on three different forage systems in the Gulf Coast Region. G. Scaglia*[1], J. Rodriguez[2], K. McMillin[2], G. Gentry[2], and H. Boland[3], *[1]LSU AgCenter Iberia Research Station, Jeanerette, LA, [2]LSU AgCenter School of Animal Sciences, Baton Rouge, LA, [3]Prairie Unit Mississippi State University, Prairie.*

The objective was to evaluate the effect of 3 forage systems (S1, S2, and S3) on meat characteristics of spring weaned beef steers (n = 54; 257 ± 2.5 kg; 3/8 Gelbvieh, 3/8 Red Angus, and 1/4 Brahman). Steers were divided into 9 groups based on initial body weight (d 0) and randomly assigned to 3 replicates paddocks (average area of 2 ha) within system. Steers in S1 grazed bermudagrass (*Cynodon dactylon*) during summer, ryegrass (*Lolium multiflorum*) and ryegrass sod-seeded into bermudagrass paddocks in winter. Steers in S2 grazed bermudagrass in summer, dallisgrass (*Paspalum dilatatum*)/red (*Trifolium pratense*), white (*Trifolium repens*) and berseem (*Trifolium alexandrium*) clovers (clover mix) during fall and spring, and rye (*Secale cereale*)/ryegrass/clover mix during winter while those in S3 had access to bermudagrass and sorghum-sudan hybrid (*Sorghum bicolor* x *S. bicolor* var. sudanense)/forage soybean (*Glycine max*) during summer, dallisgrass/clover mix during fall and spring, and rye/ryegrass/clover mix during winter. Systems differ in complexity, total forage mass produced and/or nutritive value parameters of forages. Pastures were rotationally stocked with a stocking rate for the systems of one steer per hectare through the grazing period (324 d). Eighteen steers (6 per system) where harvested and steaks obtained for analysis of total fat and fatty acids. Data were analyzed using PROC MIXED with means separation conducted using Tukey (α = 0.05). Total fat (5.4, 4.4, and 4.3%), percent saturated fatty acids (50.4, 51.6, and 54.3%), and percent conjugated linoleic acid in fat (1.3, 1.6, and 1.9%) were not different ($P > 0.05$) between systems (S1, S2, and S3, respectively), but saturated fatty acids were higher than expected. Concentration (as % of total fat) of monounsaturated fatty acids, polyunsaturated fatty acids, omega-6 and omega-3 fatty acids, and omega-6/omega-3 ratio were not different ($P > 0.05$) between systems. Preliminary data indicate that the 3 forage systems for finishing beef in this study did not result in differences in total fat and fatty acids in beef.

Key words: forage-fed beef, forage systems, steers

T149 Effect of molasses or cornmeal on milk production and nitrogen utilization of grazing organic dairy cows. S. Ross*[1], A. F. Brito[1], K. J. Soder[2], K. Greene[1], A. Green[1], and P. Y. Chouinard[3], *[1]University of New Hampshire, Durham, [2]USDA-Agricultural Research Service-Pasture Systems and Watershed Management Research Unit, University Park, PA, [3]Université Laval, Quebec City, Quebec, Canada.*

Pasture is rich in soluble N which is rapidly converted to ammonia in the rumen reducing N utilization in lactating dairy cows. Sucrose is more quickly degraded in the rumen than starch, suggesting that feeding molasses (MOL) to balance energy and RDP supply in the rumen can be strategically used to improve N utilization in grazing dairy cows. Twenty lactating organic Jersey cows (DIM 119 ± 73) were blocked by parity and milk production, and assigned randomly to one of 2 energy sources: 1) liquid MOL (12% diet DM) or 2) cornmeal (CM; 12% diet DM). MOL and CM averaged (% DM), respectively: 5.35 vs. 7.85% CP, 0.12 vs. 68.9% starch, and 50.1 vs. 1.53% sucrose. Cows grazed for approximately 18 h/day on mixed species pasture consisting mostly of orchardgrass, tall fescue, timothy, white clover, red clover and alfalfa from early June to mid-September for a total of approximately 110 d. The energy sources were top-dressed on baleage containing perennial ryegrass, timothy, reed canarygrass, white clover and red clover (18% diet DM) and fed individually twice daily using Calan doors. Cows were split into 2 grazing groups with pasture intake estimated by group using a calibrated rising plate meter to quantify pre- and post-grazing herbage biomass. Data was analyzed using the MIXED procedure of SAS for a completely randomized design with repeated measures over time. Intake of supplement (baleage plus MOL or CM) was significantly higher for cows fed MOL vs. CM possibly due to enhanced palatability of MOL. Pasture and total DMI were numerically higher for cows fed MOL than those fed CM. Despite enhanced total DMI, no significant differences were observed for milk yield comparing MOL and CM. Likewise, yields and contents of milk components did not differ between MOL and CM. However, cows fed MOL had reduced MUN ($P = 0.03$) and PUN ($P < 0.01$) compared with those fed CM, which may be partially explained by the higher CP of CM vs. MOL. Compared with CM, MOL had no detrimental effect on animal performance and improved N utilization in organic dairy cows. Liquid MOL may be an alternative energy source for CM if economically competitive.

Table 1. Performance and N utilization

	Treatments			
	MOL	CM	SED	$P > F$
Pasture DMI, kg/d	11.5	10.0	-	-
Supplement DMI, kg/d	4.27	3.67	0.13	<0.001
Total DMI, kg/d	15.77	13.67	-	-
Milk yield, kg/d	12.8	11.8	1.53	NS

T150 Sensory properties and abundance of selected volatile compounds in milk from cows fed timothy grass as hay, silage or pasture. M. P. Villeneuve*[1,2], Y. Lebeuf[1,2], R. Gervais[1], G. F. Tremblay[3], J. C. Vuillemard[2,4], and P. Y. Chouinard[1,2], *[1]Département des sciences animales, Université Laval, Québec, QC, Canada, [2]Institute of Nutraceuticals and Functional Foods (INAF), Québec, QC, Canada, [3]Agriculture and Agri-Food Canada, Québec, QC, Canada, [4]Département des sciences des aliments et de nutrition, Université Laval, Québec, QC, Canada.*

To evaluate the effects of feeding different types of forage on milk flavor and volatile compounds, 21 Holstein cows (1st lactation and higher, 209 ± 52 DIM) were blocked according to calving date and randomly assigned to one of three dietary treatments, which consisted of timothy grass (*Phleum pratense*) fed ad libitum as hay (H), silage

(S), or pasture (P) for 27 d. Each cow also received 7 kg/d of concentrates in two equal meals. Cows fed P were grazing on the same parcel where hay and silage were harvested simultaneously at the mid-heading stage, the previous summer. On the last 3 d of the period (d25, d26, and d27), bulk milk from two consecutive milkings was collected separately from each group of cows. The 9 batches of milk thus obtained were standardized to 3.25% fat, homogenized, and pasteurized at 75°C for 16 sec. Samples of each milk produced on d25 were collected and stored at 4°C to be used for sensory evaluation. Additional samples from each batch (d25, d26, d27) were frozen at −20°C for further analysis of volatile compounds using solid- phase microextraction (SPME) and gas chromatography-mass spectrometry. Milk samples from d25 were evaluated in a triangle test by a panel of 30 untrained assessors to compare H vs. P, and H vs. S. Among assessors, 40% were able to distinguish H from S ($P = 0.28$), while 67% perceived a difference between H and P ($P < 0.01$). Milk samples from d25 were also evaluated in a sensory ranking test by a similar panel. Assessors were asked to rank H, S and P milk samples for aroma intensity, as well as sweet and grassy flavors on a scale of 1 to 3 (from less to more intense). For H, S, and P, respectively, sums of rankings were 54, 52, and 74 for aroma intensity, 70, 59, and 51 for sweet flavor, and 53, 54, and 73 for grassy flavor ($P < 0.05$). Chromatographic analyses of free fatty acids, alcohols, aldehydes, ketones, and lactones revealed that all these volatile compound families were present in H, S, and P milk samples. Further investigation is needed to assess the contribution of specific volatile compounds to sensory properties of milk as affected by forage types.

Key words: volatile compounds, milk flavor, SPME

T151 Is horse harvesting and processing plants a horse owner solution to the United States unwanted horse population? S. Lindsey and M. Nicodemus*, *Mississippi State University, Mississippi State.*

Unwanted Horse Coalition did a survey in 2009 to determine activities and perceptions related to the United States unwanted horse population. The survey collected solutions to reducing unwanted horse numbers finding the most favored solution by horse owners was the re-opening of horse harvesting and processing plants. Further questions concerning horse harvesting and processing was unavailable on the 2009 survey, and therefore, study objectives were to determine horse owners understanding and perceptions related to horse harvesting and processing plants. Researcher-developed, 15-item survey instrument focused on horse harvesting and processing plants was given to 89 horse owners. For each question the % of respondents selecting an answer was determined. Ownership of 1–3 horses made up the majority of survey respondents (56%) with the Quarter Horse being the most popular breed owned (48%). Only 46% of respondents supported opening horse harvesting and processing plants in their state, and of those not in support, only 25% would reconsider supporting these plants if restrictions were made against processing horse meat for human consumption. The majority (63%) were in favor of additional restrictions on what horses would be harvested with 75% wanting requirements that the horse should be suffering from a health issue. Awareness concerning horse harvesting and processing was lacking as the majority (79%) were unaware of their local facilities and 35% were unaware of the role of United States Department of Agriculture (USDA) concerning these facilities. For respondents aware of USDA involvement, 51% were unclear of all the USDA regulations associated with these plants. The majority (52%) admitted they were unsure of plant practices and handling methods with 46% getting their information from media. While re-opening of these plants is perceived by horse owners as a solution to the current unwanted horse population, survey respondents reflect the need for investigating additional solutions and the need for more thoroughly educating horse owners concerning these plants so they can make a more informed decision.

Key words: unwanted horses, horse ownership

T152 Selenium status declines in horses fed NRC adequate and low selenium diets. M. Brummer*, S. Hayes, J. E. Earing, S. M. McCown, and L. M. Lawrence, *University of Kentucky, Lexington.*

The NRC recommends a selenium (Se) intake of 1 mg/d for a 500kg horse, based on relatively short-term studies showing no added benefit from dietary Se beyond 1mg/d with regards to glutathione peroxidase activity (GPx). Further, the NRC suggests that 1 mg/d may overestimate the minimum Se requirement of mature horses. This study evaluated changes in whole blood Se (WBSe) and whole blood GPx in mature horses fed adequate (AS) and low (LS) selenium diets for 28 wk. This period was selected to allow for near complete red blood cell turnover. Twenty mares and 8 geldings, blocked by age and gender, were randomly allocated to one of 2 treatments. Horses received pasture (Se < 0.06 ppm DM), hay (Se < 0.05 ppm DM) and cracked corn (Se < 0.04 ppm DM). Horses were also individually fed supplements, so that AS (n = 7) and LS (n = 21) received 140% and 70% of daily recommended Se intake, respectively. More horses were allocated to LS in preparation for a subsequent study. Blood samples were taken before and every 4 wks during the study. Data were analyzed as repeated measures using SAS 9.1 and are reported as LS Means. Initial WBSe was similar ($P > 0.05$) between AS (261.1 ng/mL) and LS (251.2 ng/mL). WBSe decreased in both groups over time ($P < 0.05$), but the decrease was greater in LS (treatment x time; $P < 0.05$). Final WBSe was lower in LS (164.7 ng/mL) than AS (211.1 ng/mL; $P < 0.05$). Final WBSe of AS horses was also lower than their initial WBSe ($P < 0.05$). Whole blood GPx decreased over time in AS and LS. Initial GPx was different for AS and LS (72.5 and 61.11 mU/mg Hb respectively), but later time points were similar until the last 3 time points. Final GPx was higher for AS (55.00 mU /mg Hb) than LS (42.72 mU /mg Hb; $P < 0.05$). Final GPx of AS horses was also lower than their initial GPx ($P < 0.05$). The Se status of LS horses depleted over time as expected, but feeding 140% of recommended Se intake did not maintain WBSe or GPx over the 28 wk period. The current recommendation of 1mg Se/d may be enough to prevent deficiency symptoms, but was not sufficient to maintain WBSe or GPx in adult horses in this longer term study.

Key words: glutathione peroxidase, selenium requirement, equine

T153 Round-bale feeder design affects hay waste and intake during horse feeding. K. Martinson*, K. Cleary, K. Ross, J. Wilson, W. Lazarus, W. Thomas, and M. Hathaway, *University of Minnesota, St. Paul*.

Many horse owners find round bales are more convenient, less laborious and expensive, but report hay waste and horse weight gain compared to feeding other hay types. Objectives were to compare hay waste and intake from nine round- bale feeders and a no-feeder control when round bales were fed to horses. Nine round-bale feeders were tested: Cinch Net, Cone, Covered Cradle, Hayhut, Hay Sleigh, Ring, Tombstone, Tombstone Saver, Waste Less, and no-feeder control. Horse groups of similar age, weight, breed, and gender were formed from 25 Quarter Horse and Thoroughbred geldings and mares. Groups of horses were sequentially assigned to feeders using a 5 × 5 Latin Square. Each feeder was placed on the ground in one of 5 outdoor paddocks (30 × 20 m). Using a crossover design, 5 groups of 5 horses were fed in rotation for 4-d. Every fourth day, groups were rotated among paddocks and a new bale was fed. Five feeders were installed for days 1 through 20, and the remaining 4 feeders and the no-feeder control were installed on days 21 through 40. Hay on the ground surrounding the feeder was considered waste, collected daily, dried and weighed. Hay remaining in the feeder at the end of the 4-d period was removed, dried and weighed. Total 4-d hay waste was reported as percent of weight of the original bale minus the remaining hay. Intake was calculated by subtracting waste and remaining hay from original bale weight and dividing that by average initial pen weight. Feeders were compared using PROC Mixed of SAS. Both carryover and period effects were not significant and groups of horses were considered a random effect. Hay waste differed between round bale feeder designs ($P < 0.01$). Mean percent waste was Waste Less, 5%; Cinch Net, 6%; Hayhut, 9%; Covered Cradle, 11%; Tombstone Saver, 13%; Tombstone, Cone, and Ring, 19%; Hay Sleigh, 33%; and no feeder control, 57%. Feeder design did not affect horse intake; all feeders resulted in daily intake at 2.0 to 2.4% of body weight (BW). The no feeder control resulted in less intake at 1.3% BW ($P = 0.001$). The use of a round bale feeder is necessary to avoid excessive hay waste and reduced intake during horse feeding when compared to the no-feeder control.

Key words: round-bale feeder, waste, intake

T154 Glycemic and insulinemic responses of weanling horses to high and low protein diets. A. L. Wagner*[1], R. N. Digianantonio[1], S. L. Tanner[1], R. B. Ennis[1], P. A. Harris[2], J. T. Sylvester[3], and K. L. Urschel[1], *[1]University of Kentucky, Lexington, [2]WALTHAM Centre For Pet Nutrition, Melton Mowbray, UK, [3]Buckeye Nutrition, Dalton, OH.*

Currently, there is a basic understanding of the requirements of dietary protein to optimize growth in the young horse. However, little is known of the effects of dietary protein on the glycemic and insulinemic responses of weanling horses. Characterization of the insulinemic response is critical because insulin resistance has been linked to various diseases such as osteochondrosis. Thus, the objective of this study was to determine plasma glucose (GLC) and insulin (INS) concentrations in 6-mo-old weanling foals (n = 6) receiving isocaloric concentrates with either high (HP; mean ± SD, as fed; 3.04 ± 0.03 Mcal/kg DE; 18.3 ± 0.2% CP) or low (LP; mean ± SD, as fed; 2.86 ± 0.03 Mcal/kg DE; 9.0 ± 0.1% CP) crude protein content. Either HP or LP meals were offered at 1400 (t = 0 min) following an identical meal at 0700 h. Blood samples were collected every 15 min from t = 0 to 120 min, and then at 240 min. Blood samples were analyzed to determine plasma GLC and INS via the YSI Biochemistry Analyzer and Coat-A-Count®RIA kit, respectively. There was no effect of time or treatment on INS ($P > 0.05$). However, both time and treatment affected ($P < 0.05$) plasma GLC concentrations. There was an increase in plasma GLC in the LP compared with the HP group ($P = 0.04$). Specifically, plasma GLC in the LP group was elevated at 15, 30, and 45 min post-feeding over the HP group. However, regardless of treatment, the plasma GLC concentrations of all the foals did not exhibit the typically expected rise post-feeding followed by a return to baseline within the study period. Instead, a decrease post-feeding until t = 30 min was followed by an increase until t = 120 min. It has been previously shown that both INS and GLC show a greater response to feeding after a morning meal in mature horses. Our atypical glycemic and insulinemic responses therefore may be attributed to time of feeding as a result of circadium rhythms. Additional research is however necessary to confirm whether the differences seen are due to the diets or time of feeding in 6-mo-old weanling foals. Funded by Buckeye Nutrition and the WALTHAM Foundation.

Key words: horse, low protein diet, glycemic response

T155 The development, evaluation and implementation of an online safety course for youth working on equine facilities. E. A. Greene*[1], K. L. Waite[2], G. Heyboer[2], J. Whittle[3], C. D. Skelly[2], and K. Vignare[2], *[1]University of Vermont, Burlington, [2]Michigan State University, East Lansing, [3]University of Kentucky, Lexington.*

The estimated 9.2 million horses in the United States provide a popular recreational, competitive and occupational activity for young people. The labor force on equine facilities is often youth who are unpaid or work in exchange for opportunities to ride horses. In 2005, the US Consumer Product Safety Commission reported that an estimated 23,000 youth under the age of 20 years are annually treated in emergency departments for equestrian related injury. Several reports indicate that 20–30% of equestrian-related injuries occur when the handler is either leading or grooming the horse. There is clearly a gap in youth farm safety education for young people working with horses. To date there is no comprehensive, interactive online course designed to educate youth on best safety practices when working on equine facilities. The purpose of this project is to develop, test and implement an educational, interactive and engaging online safety course for youth working on equine facilities. Instant Survey software (www.instantsurvey.com) was utilized to conduct a national survey of adult volunteer horse leaders to identify interest in youth development focused equine courses and important topics. All methods and survey tools were approved by the Institutional Review Board. Data were analyzed using a binomial test via IBM SPSS Statistics 19 software. Approximately 295 online surveys were completed with 98% showing interest in this type of training. When comparing survey topics that received responses of "Very Interested" against "Not Interested" and "Mildly Interested" responses, there was a significant difference ($P < 0.001$) for all items in General Horse Care. Additionally, several national youth and adult focus groups identified horse health, nutrition, exercising horses, legal issues, and safety as critical components of a course. eXtension and My Horse University have partnered to develop 10 online educational units that are currently in peer review process and will be pre-launched for β testing within the next year. This peer reviewed Youth Equine Safety course will be available on the Internet at no charge to the user.

Key words: youth, online learning, equine safety

T156 Greener pastures, stable footing, and seeking balance: An easy-to-use land stewardship series for all horse owners. E. A. Greene*[1], R. Gilker[1], and K. Martinson[2], *[1]University of Vermont, Burlington, [2]University of Minnesota, St Paul.*

As livestock owners come under scrutiny regarding responsible land stewardship and negative impact on water quality, state agencies are implementing more stringent regulations. Horse facilities are also being monitored for nonpoint source pollution from mud issues, run off, and improper manure storage. Also, as feed/hay prices rise, horse owners are seeking maximum pasture utilization as an affordable component of their horses' diet. This educational series provides easy to understand management options for equine operations. The first ("Greener Pastures: Sacrifice a Little Pasture to Save a Lot!") provides horse owners land stewardship and cost information for renovating high traffic areas through written/pictorial methods. "Stable Footing for Your Horse: Practical Strategies for High Traffic Area Renovation" gives additional details for high traffic paddocks and their use in grazing systems. "Seeking Balance: Elements of a Successful Horse Grazing System" outlines strategies for better utilization of a limited land base to improve pasture quality and reduce feed costs. The overall goal is to motivate horse owners to take action to improve pasture quality and land stewardship. These booklets have been introduced in Pasture Walks, Seminars and Workshops throughout the Northeast and Midwest USA. Participants regularly report that they will apply the tools at their own facilities, demonstrating the national relevance of this information. A recent post-program evaluation at the 2010 Minnesota extension program for improving equine pasture and mud management systems measured the material effectiveness. A Likert scale was used to assess participant (n = 70, 60% response rate) knowledge gain on a scale of 1 (very little) to 5 (very much). Participants reported a knowledge increase from 3.2 to 4.1 on the topic of mud management. Furthermore, 85% of participants thought the information would be useful in the management of their horse operation; 58% planned to implement changes based on the presentation. This text and pictorial format provides an applicable method for equine owners to improve their land stewardship.

Key words: high traffic area, pasture, equine

T157 Genetic evaluation of annual earnings in Quarter Horses. J. A. V. Silva*[1], A. P. A. Silva[1], B. Langlois[2], C. B. Cyrino[1], and M.

D. S. Mota[1], [1]*Faculdade de Medicina Veterinária e Zootecnia, Unesp, Botucatu, São Paulo, Brasil,* [2]*Institut National de la Recherche Agronomique, Jouy en Josas, France.*

The aim of this study was to estimate the heritability of the annual earnings (AE) in Quarter Horse races to provide a reliable and objective tool for horse selection for owners, as a previous genetic evaluation of the breeding animals. Data comprised records from 1978 to 2009 with a total of 22,958 races and 5,218 horses, at the Sorocaba Jockey Club, state of São Paulo, Brazil. All the known ancestors of the recorded horses were included in the pedigree file until the fifth generation. The AE was analyzed for animals of 2 (AE2), 3 (AE3) and 4 (AE4) years old, using a multi-trait animal model based on Gibbs sampling algorithm, considering the effects of sex and year of the race, number of starts (covariate), besides the effects of animal, maternal and residual. The estimates of heritability were 0.26 ± 0.10, 0.12 ± 0.04 and 0.31 ± 0.10, for AE2, AE3 and AE4, respectively, and these values were within the range described in literature. The genetic correlations had moderate magnitude and positive values, varied from 0.19, between AE2 and AE4, to 0.52 between AE3 and AE4, suggesting that selection to improve AE at a specific age would promote, to a greater or lesser extent, a favorable genetic alteration in the remainder. Although considering animals with performance at only one racetrack, these results might be considered for future genetic evaluation including horses with performances at other Brazilian hippodromes.

Key words: equine, genetic correlations, heritability

T158 Genetic correlation between racing performance traits in Quarter Horses. M. D. S. Mota[1], B. Langlois[2], R. A. Curi[1], M. C. L. Dal Coleto[1], and J. A. V. Silva*[1], [1]*Faculdade de Medicina Veterinária e Zootecnia, Unesp, Botucatu, São Paulo, Brasil,* [2]*Institut National de la Recherche Agronomique, Jouy en Josas, France.*

Annual earning, an objective measure of horse racing performance, was recorded in 22,958 races and 5,218 animals, at the Sorocaba Jockey Club, state of São Paulo, Brazil. Annual earning measures were recorded for 3-yr-old animals (AE3) and career earning (CE). AE3 was used because it was the age with the greatest number of records in the database studied. In order to achieve a reasonable approximation to the normal distribution, the traits were transformed by log. The traits were analyzed using a multi-trait animal model based on Gibbs sampling algorithm, considering the effects of sex and year of the race, number of starts (covariate), besides the effects of animal, maternal and residual. The covariate age at last race was included for CE. The heritability estimates for AE3 and CE were 0.18 ± 0.04 and 0.19 ± 0.04, respectively. Genetic correlation across annual earning measurement was 0.97 ± 0.02, indicating a strong underlying genetic basis. The estimates for the simple correlation (Pearson) and for the rank correlation (Spearman) between classifications by breeding values of the top twenty animals considering AE3 were significant ($P < 0.01$) and both with high values (0.80 and 0.84, respectively). Selection based on measures of annual earning at three years old described in this study could be used to predict career performance in the Quarter Horse.

Key words: animal model, career, earning

T159 Genome-wide association of polymorphic gait in the horse. E. A. Staiger*[1], R. R. Bellone[2], N. B. Sutter[3], and S. A. Brooks[1], [1]*Department of Animal Science, Cornell University, Ithaca, NY,* [2]*Department of Biology, University of Tampa, Tampa, FL,* [3]*Department of Clinical Science, College of Veterinary Medicine Cornell University, Ithaca, NY.*

Following domestication, man selected the horse primarily for the purpose of transportation, rather than consumption; thus resulting in the appearance of divergent genetic traits for locomotion. In this regard the horse is a unique model for the study of gait development, as no other mammalian species is known to discretely segregate for preference in cadence and footfall patterns. At intermediate speeds, beyond the flat walk, horses can perform a range of diagonal and lateral, 2-beat or 4-beat, gaits known as trot, pace, foxtrot, rack, and running walk. Although heritability is unknown, a strong role for genetics is supported by the discrete segregation among breeds for the propensity to perform one gait or another indicating that genetic alleles contributing to gait type will be higher in breeds with the ability than those without, regardless of the subsequent influence of training. Our study aims to leverage this genetic trend by identifying loci common in gaited breeds and rare in trotting breeds. To investigate the contribution of genetics to this unique trait, blood or hair samples were collected from each of 3 horses representing 32 diverse breeds. For 3 of these breeds (Paso Fino, Icelandic Horse and American Saddlebred) the ability to perform a lateral 4-beat gait is a key characteristic of the breed. DNA from each these 95 horses were genotyped at 54,602 loci using Illumina Equine SNP50 beadchip at GeneSeek Inc. (Lincoln, NE) or the Genotyping Shared Resource at the Mayo Clinic (Rochester, MN). We used PLINK V1.07 (Purcell, 2007) to simultaneously test the resulting 5 million plus genotypes for significant association within naturally gaited breeds. Allelic association identified 2 independent statistically significant loci at ECA18 and ECA11 for a lateral 4-beat gait (Bonferroni adjusted *P*-values of 2.39E-09, and 7.46E-09). Confirmation of association by genotyping large populations segregating for gait type and sequencing of candidate genes at each of these loci is currently underway.

Key words: association test, horse, gait

T160 Aromatherapy treatment in horses. C. E. Ferguson*, H. Klienman, A. L. Browning, J. Browning, and E. L. Ferguson, *McNeese State University, Lake Charles, LA.*

In the equine industry an acute fear stress response can be deleterious to production. A novel treatment (trt) to reduce the effects of this stress response in excitable horses would benefit the equine industry. The objective of this experiment was to determine if aromatherapy using 100% lavender essential oil would reduce acute stress response in horses. A total of 7 mature horses were used in this experiment following a Latin square design where each horse received each trt 7 d apart. This procedure was performed with groups of 4 horses at a time with 2 receiving the control trt and 2 receiving lavender trt in a barn isolated from other study horses. The heart rate (HR) and respiratory rate (RR) was recorded for each horse at rest in a stall (−1 min) and then an air horn was blown (between 2 adjacent stalls) for 15 s, twice (0 min). The horses were allowed 60 s to calm and then the stressed HR and RR was recorded (1 min). Then control horses were treated with humidified air and aromatherapy horses were treated with humidified air with a 25% mixture of 100% pure lavender essential oil for 15 min. Following the 15 min control or aromatherapy trt the recovery HR and RR was recorded (15 min). The change in HR or RR was calculated by subtracting the recovery HR or RR (15 min) from stressed HR or RR (1 min). All statistical comparisons were performed using SAS Proc GLM. There were no statistical differences ($P > 0.05$) between the control and aromatherapy trt for resting HR 33.7 ± 3.6 vs. 34.0 ±

3.1 bpm (beats per min), stressed HR 38.8 ± 3.9 vs. 45.5 ± 5.3 bpm or recovery HR 39.14 ± 3.3 vs. 36.2 ± 3.8 bpm. However, the change in HR was significantly greater ($P < 0.02$) following aromatherapy −9.25 ± 3.4 bpm compared with the control trt 0.29 ± 1.5 bpm. The RR did not differ statistically ($P > 0.05$) between the control or aromatherapy trt for the resting 21.1 ± 1.4 vs. 21.5 ± 2.6 brpm (breaths per min), stressed 21.1 ± 1.7 vs. 19.6 ± 1.8 brpm and recovery, 20.3 ± 1.5 vs. 16.5 ± 1.2 brpm. These results demonstrate that lavender aromatherapy can significantly decrease heart rate following an acute stress response.

Key words: stress, horses, aromatherapy

T161 L-Arginine supplementation increases ovarian blood flow in postpartum mares. D. E. Kelley*, L. K. Warren, and C. J. Mortensen, *University of Florida, Gainesville.*

L-Arginine (ARG) is a precursor for protein synthesis and other bioactive compounds such as nitric oxide, polyamines, proline, creatine and glutamate. Nitric oxide has potent vasodilative properties and is important in regulating blood flow and angiogenesis. Supplementing diets with ARG has been shown to improve female reproductive performance in other species. The objectives of this study were to evaluate the effects of ARG supplementation on blood flow to the ovary in postpartum mares during the foal heat cycle. Mares were blocked by age, breed and expected foaling date (EFD) and then assigned randomly within block to one of 2 treatments: ARG supplementation (n = 8) or non-supplemented control (n = 8). Treatment mares were supplemented with 100g of ARG once daily mixed into the morning feeding beginning 21 d before the EFD. Mares underwent daily ultrasound examination beginning the day following parturition utilizing a digital color Doppler ultrasound (Micromaxx, Sonosite, Bothell, WA). Spectral-Doppler measurements (pulsatility index) were recorded for both ovarian arteries and calculated by the algorithm package in the Micromaxx ultrasound. Continuous data were analyzed by MIXED procedures of SAS (version 9.2; SAS Institute, Cary, NC) while data from a single day was compared using Student's *t*-test. Results indicated ARG-supplemented mares had improved blood flow to the ovulatory ovary before ovulation ($P \leq 0.05$). There was no difference between groups on arterial blood flow to the nonovulatory ovary. Perfusion to the ovulatory follicle on the day before ovulation tended to be greater in ARG-supplemented mares compared with control (40.6 ± 4.7% versus 28.6 ± 6.9%, respectively; $P = 0.08$). No differences were found between groups in the diameter of the dominant follicle at ovulation. Blood flow plays an important role in ovarian function and follicular perfusion has been correlated to increased pregnancy rates. Additionally, the lower perfusion of the preovulatory follicle in control mares raises the question of whether reduced ovarian blood flow following parturition may contribute to the reduced fertility associated with this period.

Key words: mare, ovary, blood flow

T162 Using glycerol-^{3}H to evaluate equine blastocyst capsule permeability. B. R. Scott*[1], D. B. Carwell[1], R. A. Hill[1], K. R. Bondioli[1,2], R. A. Godke[1,2], and G. T. Gentry[1,2], *[1]School of Animal Sciences, Louisiana State University AgCenter, Baton Rouge, [2]Reproductive Biology Center, Louisiana State University AgCenter, St. Gabriel.*

The limited success of the cryopreservation of equine blastocysts may be due to the presence of the glycoprotein capsule surrounding the early stage equine embryo preventing penetration of cryoprotectants. Currently, equine embryos destined for cryopreservation are collected from mares on d 6 post-ovulation at the morula stage because of higher survival rates following cryopreservation. Therefore, the objective of this study was to verify capsule impermeability by quantifying the amount of tritiated glycerol uptaken by equine blastocysts with intact capsules. Light horse mares of various breeds were used in this study. The mares (n = 14) ranged in age from 3 to 18 yrs and were in good body condition. Estrus detection was performed by chute teasing with a stallion and ovulation was predicted by transrectal ultrasonography followed by artificial insemination and nonsurgical embryo collection on d 7 post-ovulation. Recovered equine blastocysts (n = 30) were randomly assigned to 2 treatment groups. Embryos were incubated in a 500-μL drop of 1.4 *M* or 3.4 *M* tritiated glycerol with a total activity of 20 μCi for 15 min. After incubation embryos were washed 3 times in 500 μL of unlabeled glycerol identical to the treatment concentration. All samples were transferred to 1.5 mL microcentrifuge tubes and incubated overnight in 400 μL of nitric acid at 37°C. After incubation, vials were vortexed for 2 min and 350 μL of the supernatant was transferred to a scintillation vial and mixed with 5 mL scintillation fluor. Samples were then counted on a liquid scintillation counter with 65% efficiency. Results were then converted from disintegrations per minute to percent uptake of labeled glycerol by volume of the individual embryo. There were no differences ($P = 0.32$) in tritiated glycerol uptake between the 1.4 *M* (2.6% ± 1.4%) and 3.4 *M* (1.22% ± 0.53%) treatment groups, however, embryos <400 μm in the 1.4 *M* treatment had a higher glycerol concentration (8-fold increase) compared with embryos >400 μm ($P = 0.002$). This indicates the capsule may not be fully developed in the smaller embryos. These data further suggest that the capsule may be a cryoprotectant permeability barrier.

Key words: equine, cryopreservation, capsule

T163 Effect of centrifugation/freezing extenders and sperm concentrations on post-thaw motility and membrane integrity of frozen-thawed stallion spermatozoa. C. S. Ballard*[1], C. G. Loretan[2], and J. B. Davis[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]University of Vermont, Burlington.*

Two experiments were designed to compare combinations of centrifugation and freezing extenders and effect of spermatozoal concentration on post-thaw quality of frozen stallion semen. Three ejaculates from 3 Morgan stallions were collected in June/July, divided equally and assigned to a 2 × 2 factorial arrangement of centrifugation media (Kenneys Modified Tyrodes (KMT) or INRA96) and freezing media (lactose-EDTA-egg yolk containing 20% egg yolk and 5% glycerol (LAC-EDTA) or INRA-Freeze). Centrifugation media was added 1:1 to raw semen, equilibrated at room temperature for 10 min and centrifuged at 500 x g for 20 min. Supernatant was removed and sperm pellet resuspended with respective freezing media to a concentration of 100×10^6 sperm/ml. INRA-Freeze was cooled at 5°C for 75 min and loaded into 0.5 mL straws. Sperm resuspended with LAC-EDTA equilibrated at room temperature for 20 min before loading into 0.5 mL straws. All straws were frozen in vapor phase of liquid nitrogen (LN) for 10 min before immersion in LN. In Experiment 2, 3 ejaculates were collected in Dec/Jan from 2 of the same Morgan stallions and processed using KMT and LAC-EDTA based on the outcome of Exp. 1. After centrifugation, sperm pellets were resuspended with LAC-EDTA to one of 3 spermatozoal concentrations: 100, 250 or 500×10^6 sperm/ml and processed according to procedures described previously. For both studies, post-thaw progressive motility and membrane integrity (hypo osmotic swelling) were assessed and analyzed using the Proc Mixed procedures of SAS. Centrifugation media did not affect sperm

quality post-thaw (P = 0.94). Progressive motility and membrane integrity post-thaw was significantly higher for LAC-EDTA extender (37 vs. 31%, P = 0.03; 15 vs. 11%, $P \leq 0.01$, respectively). Post-thaw quality of sperm was similar for all freezing concentrations ($P \geq 0.10$). Under the conditions of this study, KMT and LAC-EDTA were the best extenders for processing and freezing stallion spermatozoa at concentrations ranging from 100 to 500 × 10^6 sperm/ml.

Key words: equine, spermatozoa, cryopreservation

T164 Evaluation of hCG or Deslorelin for enhancing ovulation and subsequent pregnancy rate in mares in a commercial setting. M. M. Tondre[1], M. M. Vogelsang*[1], C. A. Cavinder[1], C. M. Honnas[2], and S. G. Vogelsang[3], *[1]Texas A&M University, College Station, [2]Texas Equine Hospital, Bryan, TX, [3]Equine Reproductive Consultant, Hearne, TX.*

The variation in length of estrus, time of ovulation during estrus and size of the follicle at ovulation contribute to increased expense and decreased efficiency of breeding mares in today's horse industry. Inefficiency increases when using frozen semen or semen from stallions of marginal fertility. The purpose of this study was to compare efficacy of hCG and Deslorelin (IM) for enhancing ovulation in the mare. Breeding records of 153 mares at a commercial breeding facility were evaluated. The mares were administered either 2500 IU hCG (Chorulon; Intervet Inc., Millsboro, DE) or 1.5 mg/ml Deslorelin (Applied Pharmacy Services, Mobile, Al) after detection of a follicle >35 mm. Thirty-five mares received the hCG injection, 40 mares received the Deslorelin injection and 78 mares did not receive any treatment. Mares were inseminated using fresh, extended semen or cooled transported semen before ovulation. Pregnancy determinations were made using ultrasonography at d 15 and d 30 post-ovulation. Data were analyzed using χ^2 and values were considered significant at $P < 0.01$. Use of hCG (31 of 35; 88.6%) or Deslorelin (36 of 40; 90%) provided similar results for inducing ovulation within 48 h after detection of a 35 mm follicle. However, in untreated mares (17 of 78; 22%) fewer ovulated by 48 h and most took longer to achieve ovulation (15 by 72 h, 30 by 96 h). Pregnancy rate among the 3 groups of mares was not different (hCG, 58%; Deslorelin, 61% and untreated, 69%). In this study, the use of either hCG or Deslorelin for inducing ovulation within 48 h post-treatment yielded similar results. Pregnancy rates between the treatments were similar although not higher than in the mares which were not treated. The use of ovulation-enhancing hormonal stimulation is beneficial in the commercial horse breeding industry. If the time to ovulation can be more precisely controlled, more efficient use of the stallion can be made. Based on this and other studies, the choice of which product to use can rest with the breeding manager without having to be concerned about loss of effectiveness.

Key words: mares, hCG, Deslorelin

T165 Endoscope-guided insemination for off-season mares. G. Rocha-Chavez[1], J. C. Franco[1], E. O. Garcia[2], A. Sepulveda[1], J. G. Gonzalez[1], J. Torres[1], J. M. Tapia[1], and O. Montañez*[1], *[1]CUSUR Univ de Guadalajara, Guadalajara Jalisco Mexico, [2]CUCOSTA SUR, Autlan Jalisco Mexico.*

Although breeding season for equine arrives with the spring, in Mexico mares can be found cycling thorough the entire year and late born foals are always welcomed. The objective of this study was to determine fertility of mares inseminated with frozen/thawed semen during fall using the endoscope as a guide. Twelve mares of known fertility were inseminated deep in the uterine horn with 200 thousand frozen thawed spermatozoa with at least 30% motility. Mares were programmed to be inseminated no more than twice during this season and the estrous cycle was closely monitored via ultrasound to ensure insemination within 4 h post ovulation. Insemination was done with flexible intrauterine pipette guiding a 0.5 mL straw containing the thawed stallion semen that was deposited near the uterotubal junction. Pregnancy diagnosis was made 17 d post ovulation and pregnancy rates (PR) were compared using chi-squared test with same type of insemination made during spring without the aid of endoscope. PR was better for the fall group ($P < 0.05$) as illustrated in Table 1. More research is needed for off-season mares.

Table 1. Pregnancy rates of mares inseminated either on spring or fall

Season	No. of mares	Mares pregnant	Rate
Spring	12	5	41.6[a]
Fall	17	9	52.9[b]

[ab]Differ at $P < 0.05$.

T166 Milk and plasma iodine in Isfahan Holstein dairy cows. A. Nikkhah*[1] and G. Ghorbani[2], *[1]University of Zanjan, Zanjan, Iran, [2]Isfahan University of Technology, Isfahan, Iran.*

Iodine (I) is an essential element for efficient dairy cow metabolism. Iodine status is however not well known on farms. The objective was to measure milk and plasma I concentrations in a selected group of commercial dairy herds in central Iranian province of Isfahan. During summer of 1999 and winter of 2000, 11 dairy farms were randomly chosen and a minimum of 10 cows were sampled from each farm. Tail veins blood and milk samples from a total of 135 lactating Holstein cows in summer and 162 cows in winter were obtained. Totally, 367 blood samples and 297 milk samples were collected. The dairy herds had comparable nutritional (e.g., feed and diet types), reproductive (e.g., artificial insemination), and vaccination programs. Milk was sampled after washing and cleaning teat tips in the milking parlor. Management data including feed ingredients, and average milk properties were recorded. Total plasma and milk I concentrations were assayed using the Sandell-Kolthoff reaction. Data were analyzed as mixed models with acquired fixed effects of season and herd. Correlations among Milk and plasma I with milk production were determined. Iodine in plasma ranged from 9.9 to 46.2 μg/L in winter vs. 17.9–56.2 μg/L in summer. The plasma I in all herds in summer ($P < 0.01$) and in all except one herd in winter ($P < 0.05$) was lower than the minimum critical range in dairy cows (i.e., 50–100 μg/L). Total plasma I was lower in winter than in summer (27.1 ± 12.3 vs. 42.4 ± 16.6 μg/L). Milk I concentrations varied considerably among cows (CV = 14–62%). Across seasons, a negative correlation was found between milk fat % and milk yield ($r = -0.40$, $P < 0.01$), as was a positive correlation between milk and plasma I ($r = 0.22$, $P < 0.01$). In winter but not in summer, milk I concentrations positively correlated with milk fat % ($r = 0.31$, $P < 0.01$). Results indicate prevalent hypo-iodinemia in selected Isfahan dairy herds, suggesting inadequate I supply via feeds and supplements to maintain blood I within normal ranges. It is recommended to provide sufficient edible or non-edible supplemental I to lactating cows in Isfahan.

Key words: iodine, milk, plasma

T167 The effect of stocking rate and calving date on reproductive performance, body state, metabolic, health and welfare parameters of Holstein-Friesian dairy cows. B. McCarthy*[1,2], K. M. Pierce[2], L. Delaby[3], A. Brennan[1], and B. Horan[1], *[1]Animal and Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland, [2]School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin, Ireland, [3]INRA, AgroCampus Ouest, UMR 1080, Production du Lait, Saint-Gilles, France.*

The objective of this study was to quantify the effect of stocking rate (SR) and calving date (CD) on the reproductive performance, body condition (BCS) (or body state), metabolic and health and welfare of high EBI Holstein-Friesian (HF) dairy cows within systems designed to represent 3 alternative whole farm SRs in a post EU milk quota spring calving pasture-based production system. Two groups of HF dairy cows with differing mean CD were established from within the existing research herd at Moorepark (Teagasc, Ireland). Animals were assigned either to an early calving (EC; mean CD: 12th of February) treatment or a late calving (LC; mean CD: 25th of February) treatment. Animals within each CD treatment were randomly allocated to one of 3 SR (SR) treatments, Low (2.51 cows/ha), Medium (2.92 cows/ha) and High (3.28 cows/ha). A total of 138 and 137 spring-calving dairy cows, comprised of 2 strains of HF (North American HF and New Zealand HF genotypes), were used during 2009 and 2010, respectively. The effects of CD, SR treatment, genotype and their interactions on reproductive performance, body weight (BW), BCS and blood metabolite, hormone and immune profile concentrations and health status were analyzed. Stocking rate and CD had no effect on reproductive performance ($P < 0.05$) except for embryo mortality, with the low SR having greater embryo mortality (9.8%) compared with the medium or high SR (4.4 and 2.2%, respectively). Stocking rate and CD had no effect on immunological profiles or health status. Earlier calving and increased SR resulted in reduced BW, BCS and metabolic status in early lactation. The results show that earlier calving and increased SR can be achieved without adverse effect on overall reproductive performance. The existence of a SR by genotype interaction for several reproductive variables suggests that the smaller New Zealand genotype is better adapted to increased SR systems.

Key words: dairy cow, stocking rate, reproduction

T168 Evolution of raw bovine milk quality: the Hungarian experience (1984-2009). G. Császár[1], A. Unger[1], and L. Varga*[2], *[1]Hungarian Dairy Research Institute, Inc., Mosonmagyarovar, Hungary, [2]Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyarovar, Hungary.*

First class raw milk is an essential prerequisite for commercial production of high quality dairy foods. The major microbiological, hygienic and physicochemical properties of raw bovine milk produced in Hungary are graded on a regular basis, i.e., 3 times a month or once every 10 d, by the Central Laboratory of the Hungarian Dairy Research Institute. Having been in place for a quarter of a century now, this system has been updated and upgraded several times over the years. The primary purpose of the present study was to give an overview of the history and development of Hungarian raw milk grading and show how this ever-improving system has contributed to the evolution of milk quality in the country. A large pool of data has been accumulated and processed. The results showed that mean total plate counts gradually decreased from 849,000 cfu/ml in 1984 to 36.000 cfu/ml in 2009. As for somatic cell counts, a mean value of 500,000 cells/ml was observed in 1984, whereas only 280,000 cell/ml were measured in 2009. The percentage of samples containing detectable levels of inhibitory substances was as high as 3.7% back in 1984 (and 4.7% in 1985), which has decreased to 0.1% by 2009. The mean concentration of extraneous water in Hungarian raw bovine milk was found to be 0.52% 26 years ago, as opposed to 0.04% in 2009. In conclusion, there has been an enormous improvement in raw milk quality with respect to all the parameters tested. Since 2003 more than 97% of the raw milk produced in Hungary has met the legal requirements in terms of overall quality. However, it should also be noted that somatic cell counts and the percentage of samples positive for residues of inhibitory substances need to be decreased further in the coming years.

Key words: cow′s milk, raw milk quality, grading

T169 Bulk tank somatic cells and its relationship to milk production, milk composition, and revenue in dairy farms located in

central Thailand. D. Jatawa[1], S. Koonawootrittriron[1], M. A. Elzo*[2], and T. Suwanasopee[1], *[1]Kasetsart University, Bangkok, Thailand, [2]University of Florida, Gainesville.*

Quality and quantity of milk are important for price determination and revenue of dairy farmers. Bulk tank somatic cell count (BSC) is used in Thailand as an indicator of milk quality. The objectives of this study were to monitor BSC in Central Thailand and estimate the association between BSC and monthly milk yield per cow (MYC), fat % (FAT), protein % (PRO), lactose % (LAC), solids not fat % (SNF) total solids % (TS), and monthly revenue per cow (MRC). The data set included monthly milk production and composition data collected from 2004 to 2010 (28,580 records) in 811 farms located in Central Thailand (Muaklek, Wang Muang, Phattana Nikhom, and Pak Chong). Seasons were winter (November to February), summer (March to June), and rainy (July to October). Farm sizes were classified by number of milking cows into small (<10 cows), medium (10 to 19 cows), and large (>19 cows). The linear model contained year-season subclasses, farm size-farm location subclasses, and regression BSC as fixed effects, and residual as a random effect. The average BSC in this population was 681,430 ± 641,000 cells/ml. Milk produced in most farms (63%) had BSC values higher than 500,000 cells/ml. The BSC tended to increase over time (11,668 cells/ml/year-season; $R^2 = 0.74$). The BSC was linearly associated with milk production, composition, and revenue. Larger BSC were associated with lower MYC (−1.39 ± 0.12 kg/10^5 cells/ml; $P < 0.0001$), LAC (−0.0074 ± 0.0002%/10^5 cells/ml; $P < 0.0001$), SNF (−0.0022 ± 0.0002%/10^5 cells/ml; $P < 0.0001$), and MRC (−17.51 ± 1.84 Thai baht/10^5 cells/ml; $P < 0.0001$), but with higher FAT (0.0066 ± 0.0004%/10^5 cells/ml; $P < 0.0001$), PRO (0.0055 ± 0.0002%/10^5 cells/ml; $P < 0.0001$), and TS (0.0054 ± 0.0005%/10^5 cells/ml; $P < 0.0001$). These results indicated the need for farmers to implement management practices to reduce BSC to increase milk yield and revenue in central Thailand.

Key words: dairy, somatic cells, tropical

T170 Factors affecting carcass weight, dressing percent, and marbling score of crossbred beef cattle in tropical Thailand. S. Koonawootrittriron[1], M. A. Elzo*[2], C. Kankaew[1], and M. Osothongs[3], *[1]Kasetsart University, Bangkok, Thailand, [2]University of Florida, Gainesville, [3]Pon Yang Khram Livestock Breeding Cooperative NSC Ltd., Sakon Nakhon, Thailand.*

Carcass quantity and quality traits are economically important for the Thai beef cattle industry. Characterization of factors influencing these traits would help beef producers develop appropriate nutrition and management strategies for fattening beef cattle under the tropical conditions in Thailand. The objective of this study was to characterize factors affecting carcass weight (CWT), dressing percent (DP), and marbling score (MBS; 1 = low to 5 = high) of crossbred beef cattle raised under Thai tropical conditions. Data came from 40,107 bulls and heifers, fattened in 3,939 farms, and collected at the slaughter house of the Pon Yang Khram Livestock Breeding Cooperative NSC Ltd. from January 2004 to December 2010. Cattle breeds were classified as 1/2 Charolais 1/2 Brahman (CB), 1/2 Limousin 1/2 Brahman (LB), and 1/2 Simmental 1/2 Brahman (SB). Seasons were winter (November to February), summer (March to June), and rainy (July to October). The model included the fixed subclass effects of year-season, breed group, and sex, covariates for slaughter age and slaughter weight, and a random residual. Least squares means (LSM) for subclass effects were compared using Bonferroni *t*-tests. All subclass effects influenced ($P < 0.05$) CWT, DP, and MBS, except for sex that had no effect on MBS. Crossbred CB and LB animals had similar CWT and DP, but CB had higher ($P < 0.0001$) MBS (3.11 ± 0.01) than LB (3.06 ± 0.01). Crossbred SB had similar MBS to LB, but lower ($P < 0.0001$) CWT (SB: 336.84 ± 0.42 kg; CB: 341.08 ± 0.16 kg; LB: 341.81 ± 0.45 kg) and DP (SB: 55.66 ± 0.07%; CB: 56.32 ± 0.03%; LB: 56.49 ± 0.07%) than CB and LB. Bulls had higher CWT (343.18 ± 0.20 kg vs. 336.64 ± 0.37 kg) and DP (56.74 ± 0.03% vs. 55.57 ± 0.06%) than heifers. Results suggested that CB and LB would be the most advantageous to increase carcass quantity and quality of beef cattle under Thai tropical conditions.

Key words: beef, carcass, tropical

T171 Forage yield and quality of two genetic materials of corn (*Zea mays*) harvested at two different cutting heights in Costa Rica. J. A. Elizondo-Salazar*[1], J. A. Vargas-Elizondo[1], and E. E. Corea-Guillén[2], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]Departamento de Zootecnia, Facultad de Ciencias Agronómicas, Universidad de El Salvador.*

Corn silage is one of the most popular forages fed to dairy cows in Costa Rica and in many areas of the world due to its good agronomic and ensiling characteristics, high concentration of nutrients, and excellent palatability. It is common to place strong emphasis on total DM yield; however, this measurement alone is a poor indicator of nutritive value. For this reason an experiment was carried out at the Alfredo Volio Mata Experiment Station of the University of Costa Rica, located at an altitude of 1,542 m, with an average annual rainfall of 2,050 mm. The purpose of the study was to determine forage yield and quality of 2 corn cultivars evaluated at the same age and in similar physiological stage. A 2x2 factorial design was used (corn cultivars: hybrid and native, cutting height: 15 and 45 cm). Leaves, stalks, and ears were separated and analyzed for DM, CP, and NDF content. Native corn yielded more DM/ha ($P < 0.05$); however, increasing the height of cutting lowered yields of harvested DM/ha only in the native corn. Cutting height only affected DM content of leaves and ears in the native corn ($P < 0.05$).

Table 1.

	Hybrid 15 cm	Hybrid 45 cm	Native 15 cm	Native 45 cm
Leaves DM, kg/ha	3344.83[b]	3142.29[b]	5175.90[a]	3306.38[b]
Stalks DM, kg/ha	4492.48[c]	4000.43[c]	8622.81[a]	6882.76[b]
Ears DM, kg/ha	3142.19[a]	3280.57[a]	1480.57[b]	195.67[c]
Leaves DM, %	18.38[a]	18.89[a]	17.09[a]	14.84[b]
Stalks DM, %	12.91	14.11	10.12	10.72
Ears DM, %	10.64	10.60	9.47	10.14
Leaves CP, %	17.32	17.30	17.81	17.48
Stalks CP, %	7.30	7.14	7.79	8.04
Ears CP, %	11.91[b]	12.89[b]	16.88[a]	15.21[a]
Leaves NDF, %	68.87	66.89	66.98	66.42
Stalks NDF, %	77.56	77.26	77.13	78.02
Ears NDF, %	70.29[b]	66.37[b]	57.45[a]	56.80[a]

Key words: corn silage, cutting height, forage

T172 Comparison of chemical composition, in situ degradability and in vitro gas production of ensiled and sun-dried mulberry pomaces. Z. Bo*, Q. Meng, L. Ren, F. Shi, and Z. Zhou, *State Key Laboratory of Animal Nutrition, Beef Cattle Research Center, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The nutritive values of sun-dried (SDMP), naturally ensiled (NEMP) and microbial ensiled mulberry pomace (MEMP) were evaluated using chemical analysis, in situ and in vitro gas production techniques. Compared with SDMP, natural and inoculated ensiling treatment of mulberry pomaces did not change OM, NDF and NDF content ($P > 0.1$), but did decrease ($P < 0.05$) CP content by about 2 percentages, indicating protein degradation occurring during ensiling. Among 2 ensiled mulberry pomaces, treatment with microbial inoculation resulted in reduced pH, increased concentrations of lactate, acetate and propionate, but in unchanged concentration of ammonia in comparison with natural ensiling of mulberry pomaces. These results indicated that microbial inoculation is favorable for improvement of ensiling quality of mulberry pomaces. The in situ effective degradabilities of SDMP were 2.35 and 2.88 percentages higher ($P < 0.01$) for DM, and 10.83 and 7.13 percentages higher ($P < 0.01$) for CP than NEMP and MEMP, respectively, indicating that ensiling treatment of mulberry pomaces can supply more bypass CP and other nutrients to small intestines because of reduced ruminal degradabilities. The in vitro gas production of SDMP was higher ($P < 0.01$) than NEMP and MEMP, while methane proportion of SDMP was highest (63.3%), followed by MEMP (58.7%) and NEMP (48.2%). On the whole, ensiling treatment would be an appropriate way to store mulberry pomaces in terms of their reduced ruminal degradabilities of DM and CP, lower methane production and improved ensiling qualities, compared with sun-drying treatment.

Key words: mulberry pomace, sun-dried, ensiled, in situ, in vitro

T173 Immune status of water buffalo calves allowed to nurse their dams. J. A. Elizondo-Salazar*[1], B. Cáseres-Alvarez[1], and A. J. Heinrichs[2], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]The Pennsylvania State University, University Park.*

Water buffalo for milk and meat production has increased during the last decade in Costa Rica; however, there is a lack of information on how to improve the productivity and health of these animals. Passive transfer status has been established as a significant source of variation in growth performance of buffalo calves. Measurement of serum total protein (STP) by refractometer as an estimate of serum immunoglobulin concentration is the simplest test to give an indication of adequate passive transfer of immunity. A value of 5.0 g/dL has been established as the cutoff point for assessment of passive transfer status. Since there is no data on the immune status of water buffalo calves in Costa Rica, the objective of this study was to determine STP concentration in neonatal buffalo calves allowed to nurse the dam during the first hours of life. Blood samples were collected between d 1 and 7 of age from 53 heifer and 49 bull calves from one commercial farm in the Northern region of Costa Rica. All blood samples were collected into serum (red top) Vacutainer tubes, refrigerated overnight, centrifuged, and the serum separated from clot within 24 h of collection. A hand-held refractometer (Atago Master-Sur/Nα, Bellevue, WA) was used to measure STP. GLM procedure was used to establish differences between parity and breed of the dams, and sex of the calf. Descriptive statistics were generated to define percentage of failure of passive transfer by sex of the calf and parity of the dam. Overall failure of passive transfer of immunity was not as high as that seen in other species, 7.84% of calves had failure of passive transfer (heifers 9.43%, bulls 6.12%). There was no significant difference between sex of the calves for STP concentration (heifers 6.83 g/dL, bulls 7.01 g/dL). Calves coming from dams of second parity had higher ($P < 0.05$) STP concentration (7.42 ± 0.27 g/dL) than those coming from water buffalo cows with ≥4 calvings (6.55 ± 0.21 g/dL).

Table 1. Failure of passive transfer (%) by parity of dam and sex of neonates

Parity	Heifers	Bulls	Both
1	6.67	0.00	3.33
2	10.00	0.00	5.26
3	7.69	0.00	5.00
≥4	13.33	16.67	15.15

T174 Milk composition, blood cellular and chemical components of Saanen and local Lebanese goats. F. T. Sleiman*, H. H. Itani, E. K. Barbour, M. T. Farran, and Z. G. Kassaify, *American University of Beirut, Beirut, Lebanon.*

A study was conducted to determine the effect of prevailing Lebanese management conditions on the performance of imported Saanen goat breed compared with a local breed as reflected in milk and blood components. A total of 30 goats, 15 goats of each breed (5 lactating does, 5 doe kids and 5 bucks), were used and subjected to similar health management and feeding conditions. Daily milk yield, milk mineral and calcium percentages of Saanen goats were significantly higher ($P < 0.05$) than that of the local breed and averaged 5.2 vs. 0.6 L, 0.84 vs. 0.74% and 0.18 vs. 0.14%, respectively. Milk fat, protein and total solids percentages were not significantly different ($P > 0.05$). Does and bucks age (mature vs. kid) had a significant influence ($P < 0.05$) on blood parameters such as eosinophils (1.70 vs. 0.40%), monocytes (6.80 vs. 14.50%), total white blood cell count (12.61 vs. 22.79 × 10^3/mL), packed cell volume (22.90 vs. 33.00%), hemoglobin (7.50 vs. 10.56 g/dL) and plasma glucose level (62.50 vs. 102.90 mg/dL). Other blood components such as basophils, lymphocytes, neutrophils and red blood cells were neither significantly different among breeds nor among genders ($P > 0.05$). Results indicate that Saanen goat breed adapted well to prevailing health and feeding conditions of Lebanon.

Key words: blood components, milk composition, Saanen goat

T175 Assessment nutrient matrix values of three xylanase and β-glucanase on broilers performance fed wheat-based diet. S. A. Moftakharzadeh*, H. Moravej, and M. Shivazad, *Department of Animal Science, Agriculture and Natural Source Pardis, University of Tehran, KarajIran.*

The effect of feeding wheat-based diets supplemented with 3 commercial enzymes containing xylanase and β-glucanase activities based on nutrient matrix values were investigated on the performance, meat yield and jejunal digesta viscosity broiler chicks. A total of 208-d-old male broiler chicks (Ross 308) were allocated to 4 treatment groups, with 4 replicates per treatment group and 13 birds per replicate pen. All data were analyzed in a randomized complete design. Overall, from

0 to 42, only addition of enzyme B to wheat-based diet significantly ($P < 0.05$) increased average daily feed intake (ADFI) and average daily gain (ADG). Moreover, FCR of broilers were significantly ($P < 0.05$) improved when enzyme A added to basal diet. The relative weight of the breast, thigh, liver, and gizzard as percentage of live weight were not affected by enzyme supplementation ($P < 0.05$). The relative weight of the abdominal fat as proportion of live weight was also significantly ($P < 0.05$) increased by addition of enzymes A and B. Enzyme supplementation decreased viscosity of jejunal contents of chicks at d 23, but only enzymes A reduced significantly ($P < 0.05$) the viscosity of jejunum compared with control diet. In conclusion, enzyme A showed the best FCR among enzymes and this enzyme can be preferred choose for adding to wheat-based diets.

Key words: broiler, enzyme, matrix value, performance

T176 Evaluation of nutrient matrix values for different kinds of NSP enzymes on performance, water intake, litter moisture and jejunal digesta viscosity of broilers fed barley-based diet. S. A. Moftakharzadeh*, H. Moravej, and M. Shivazad, *Department of Animal Science, Agriculture and Natural Source Pardis, University of Tehran, KarajIran.*

In this study, we evaluate the effect of using different mixed enzymes on releasing of ME and amino acids (AA) from barley-based diets and compare the results with those fed barley and the corn diets without enzyme. Effects of enzyme on the performance, water intake, litter moisture and jejunal digesta pH and viscosity of chicks were investigated. In entire period, addition of all enzyme to the barley-based diet significantly ($P < 0.05$) increased average daily feed intake (ADFI) and the highest intake was for birds that were fed a diet containing enzyme A ($P < 0.05$). Overall, from 0 to 42 d, average daily gain (ADG) was significantly ($P < 0.05$) increased by enzyme supplementation and the highest body weight belonged to birds that received enzyme A ($P < 0.05$). Generally, from 0 to 42 d of age, feed conversion ratio (FCR) was significantly ($P < 0.05$) improved when diets containing enzyme were compared with barley-based diet without enzyme, but there were no significant differences among diets containing enzymes A and C and the corn-based diet. The carcass weight, and the relative weight of the abdominal fat were significantly ($P < 0.05$) increased by enzyme addition. Enzyme supplementation significantly decreased jejunal viscosity at Day 23 ($P < 0.05$), whereas pH jejunal digesta was not changed ($P > 0.05$). By adding enzymes, water to feed ratio decreased at 15, 25, and 33 d of age and litter quality was significantly improved ($P < 0.05$). In conclusion, considering nutrient matrix values for all used enzymes improved performance of broilers and can be used in formulating diets for decreasing cost of commercial broilers diets based on barley instead of corn.

Key words: broiler, enzyme, nutrient matrix value, performance

T177 The effects of albusin B (bacteriocins) of *Ruminococcus albus* 7 expressed by yeast on the lipid metabolism of mice. Y. H. Hsieh*[1], H. T. Wang[2], J. T. Hsu[1], and C. Y. Chen[1], *[1]National Taiwan University, Taipei, Taiwan, [2]Chinese Culture University, Taipei, Taiwan.*

In the previous study, we successfully isolated albsuin B (bacteriocin) from *Ruminococcus albus* 7 and mass-produced by the *Saccharomyces cerevisiae* expression system. We also found that broilers supplemented with albusin B had a better intestinal absorption of protein and carbohydrate, and caused a greater growth performance. The objective of this study was to elucidate the effect of albusin B on the lipid metabolism in a mouse model. Twenty-four of BALB/c healthy male mice with 6 weeks of age were randomly divided into 3 groups: normal saline (control), yeast (0.125μg /g body weight), yeast with albusin B (0.125 μg/g body weight) were supplemented continuously for 14 d then sacrificed. Compared with the control mice, mice supplemented with albusin B decreased body weight with no effects on feed intake. Neither body weight nor feed intake was changed by the yeast supplementation. In the intestinal morphology, mice with albusin B supplementation had the highest villus height in the jejunum than the other 2 groups ($P < 0.05$). Both yeast and albusin B supplemented mice had a higher mRNA expression of fatty acid binding proteins and acyl-CoA oxidase in the jejunum and liver than the control mice did. Mice with albusin B treatment had a lower mRNA expression of acetyl-CoA carboylase (ACC) and fatty acid synthase (FAS) in the jejunum and liver, while mice with yeast treatment had a higher mRNA expression of ACC and FAS in the jejunum and a lower mRNA expression of ACC and FAS in the liver. Albusin B supplementation caused a lower plasma level of triglyceride and free fatty acids, and a higher plasma level of high density lipoproteins ($P < 0.05$); while yeast supplementation did not modulate the plasma lipid compositions. These results implied that albusin B supplementation modulated the intestinal lipid metabolism, decreased the hepatic fatty acid synthesis, therefore improved the plasma lipid compositions, which might contribute to the lower body weight.

Key words: albusin B, lipid metabolism, mice

T178 Fermentation biomass can replace protein from fish and soybean meals in nursery diets. V. G. Perez*[1], H. Yang[1], T. R. Radke[1], J. Less[2], and D. P. Holzgraefe[1], *[1]ADM Alliance Nutrition Inc., Quincy, IL, [2]ADM Specialty Feed Ingredients, Decatur, IL.*

Fermentation biomass (FBM) is a co-product of threonine production, which contains about 81.5% CP, 5.1% Lys, and 3.9% Thr. A total of 128 pigs (about 21 d of age; 4.9 ± 0.20 kg BW) were used to determine the extent in which FBM can effectively replace fish meal (FM) and soybean meal (SBM) in nursery diets. The experiment was a randomized complete block design; blocks were 2 categories of initial BW. Dietary treatments had a 4 (FBM replacing 0, 25, 50, or 100% of FM) × 2 (FBM replacing 0 or 4% of SBM) factorial arrangement. The FBM replaced FM in feeding phases 1 (7 d) and 2 (12 d), or SBM in feeding phase 3 (10 d). The FM was included at 6, 4, and 0% of the diet in feeding phases 1, 2, and 3, respectively. All diets among treatments were formulated to provide similar ME, CP, and digestible Lys contents within feeding phase. The ME and coefficients of amino acid digestibility used in FBM were generated in broilers, as no swine data were available. Treatments were replicated with 4 pens of 4 pigs per pen. Results are presented by main effects of FM and SBM replaced by FBM because no interactions were detected. Replacing FM or SBM with FBM affected neither growth rate nor feed intake. Overall, pigs fed diets with FBM replacing 0, 25, 50, or 100% of FM had an ADG of 384, 398, 388, and 372 g/d (SEM = 13), respectively. Pigs fed diets with FBM replacing 0 or 4% of SBM had an ADG of 394 vs. 377 g/d (SEM = 9). The G:F was reduced ($P <$ or = 0.05) as more FBM replaced either FM or SBM. At the end of feeding phase 2 (d 19), pigs fed diets with FBM replacing 0, 25, 50, or 100% of FM had a G:F of 926, 886, 868, and 847 g/kg, respectively (FBM linear effect, $P < 0.01$; SEM = 17). Overall, pigs fed diets with FBM replacing 0, 25, 50, or 100% of FM had a G:F of 853, 832, 809, and 798 g/kg, respectively (FBM linear effect, $P = 0.01$; SEM = 14). Pigs fed diets with FBM replacing 0 or 4% of SBM had a G:F of 837 vs. 808 g/kg ($P = 0.05$; SEM = 11). The ME in FBM from broilers probably overestimated ME for swine, which may decreased G:F as more FBM was used. Fermented biomass can replace 100% of FM and up to 4% SBM in nursery diets without affecting growth rate.

Key words: threonine biomass, fish meal, pigs

T179 The digestibility marker used and their inclusion level influence the magnitude of ileal amino acid digestibility response to phytase supplementation of a swine diet. O. A. Olukosi[1], O. Bolarinwa[2], A. J. Cowieson[3], and O. Adeola*[2], *[1]Avian Science Research Centre, Scottish Agricultural College, Ayr, Ayrshire, United Kingdom, [2]Department of Animal Sciences, Purdue University, West Lafayette, IN, [3]Poultry Research Foundation, Faculty of Veterinary Science, The University of Sydney, Camden, Sydney.*

Six barrows fitted with simple T-cannula at the distal ileum were used in an experiment to determine whether the type of digestibility marker (TiO_2 or Cr_2O_3) or its level of inclusion (3 or 5 g/kg diet) affect the magnitude of apparent ileal amino acid digestibility (AIAAD) response to phytase (0 or 1000 FTU/kg diet). The pigs were allocated to 4 diets in a 6 × 4 Youden Square Design and a 2 × 2 factorial arrangement (phytase at 0 or 1000 FTU/kg and combination of digestibility markers TiO_2 and Cr_2O_3 at either 3 or 5 g/kg of diet). Each experimental period lasted 7 d and included a 5-d adjustment period and a 2-d ileal digesta collection. The AIAAD was calculated for each AA using each marker from analyses of diets and ileal digesta for AA, Ti, and Cr. The AIAAD data were analyzed as appropriate for a split-plot design. Phytase or dietary concentration of digestibility marker did not affect AIAAD. The AIAAD values calculated using Ti were greater ($P <$ 0.05) than those calculated using Cr (77.6 vs. 76.8%) but there were no effect of the inclusion level of the marker on AIAAD. By setting the AIAAD values at no phytase supplementation to zero, the magnitude of AIAAD response to phytase supplementation was determined for each AA using each marker. These values as calculated using Ti was greater ($P < 0.05$) than those calculated using Cr (5.03 vs. −0.82) at 3 g/kg. At 5 g/kg marker level, there were no differences in magnitude of AIAAD response as determined with either marker except for Asp and Ser, which had greater ($P < 0.05$) values for Ti than for Cr. At 3 g/kg marker level, Pro and Gly had the greatest magnitude of response to phytase where Glu, Trp, and Met had the least response. The greatest difference in magnitude of AIAAD response to phytase supplementation as measured with either Ti or Cr was for Cys and Thr whereas the least difference was for Arg and Trp. These data show that the type of marker used and the level of inclusion of the marker influence the magnitude of apparent ileal amino acid digestibility response to phytase supplementation.

Key words: amino acid, digestibility marker, phytase

T180 Evaluation of different lysine to threonine ratios on growth performance, relative organ weight, meat quality and blood profiles in broilers. H. W. Cho*, L. Yan, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

A study was conducted to evaluate Lys to Thr ratio on growth performance, relative organ weight, meat quality and blood profiles in broilers. One-d-old ROSS 308 broiler chicks were randomly assigned to 1 of 4 dietary treatments with 10 replicates of 13 chickens each. This experiment lasted for 4 wk. Dietary treatments included: 1) T1: 1.42% Lys: 0.93% Thr, 2)T2: 1.42% Lys: 0.99% Thr, 3)T3: 1.42% Lys: 1.06% Thr, and 4)T4: 1.42% Lys: 1.13% Thr. Growth performance was measured on d 7, 21 and 28 and other response criteria were measured on d 28. During the 1 to 3 wk, broilers fed T3 diet showed a higher ADG than broilers feed T4 diet ($P < 0.05$). Overall experimental period, T2 and T3 diets had a higher ADG than T1 and T4 diets. Moreover, T4 diet had a higher ADG than T1 diet. No changes in ADFI and G:F was observed in response to any of the treatments ($P < 0.05$). On d 28, the T4 treatment had higher blood creatinine level than other treatments ($P < 0.05$). On d 28, the gizzard breast meat, bursa of fabricius, liver, spleen and abdominal fat were removed by trained personel and weighed. Relative organ weight was not significantly different among all treatments. There were no differences in meat quality among all treatments (meat color, drip loss, and water holding capacity). In conclusion, the ratio of 1.42% Lys: 1.06% Thr can improve growth performance of broilers without influence on organ weight and meat quality.

Key words: growth performance, Lys:Thr ratio, broiler

T181 Essential amino acids to crude protein ratio in placenta and uterus during gestation. Y. L. Ma*[1], N. Trottier[2], J. Liesman[2], R. L. Payne[3], and M. D. Lindemann[1], *[1]University of Kentucky, Lexington, [2]Michigan State University, East Lansing, [3]Evonik-Degussa Corp., Kennesaw, GA.*

Because body tissues do not have similar AA profiles, it is necessary to analyze different tissues to accurately model protein accretion. Collected tissues from a separate study were available for analysis of the profiles for placenta and uterus. In that study, crossbred gilts (n = 69) were selected at 183 ± 2.7 d and 137 ± 10 kg BW and allotted to receive Se (0.3 mg/kg diet) as Na selenite or organic Se (Sel-Plex; Alltech Inc., Nicholasville KY). Gilts were then slaughtered at defined time points throughout gestation (d 43, 58, 73, 91, 101, or 108 of gestation; n = 6 to 12 gilts/d) for a variety of fetal and maternal measures. Placenta and uterus samples were each pooled within Se treatment and day of slaughter (n = 4 and 6/d of slaughter for placenta and uterus, respectively) and analyzed to characterize differences in essential AA (EAA) to CP ratio during gestation. There were no consistent effects of Se or day of slaughter on AA profile ($P < 0.05$). The EAA:CP profiles differed between placenta and uterus (Table 1). In general, the means of EAA:CP in uterus were greater than in placenta for lysine, arginine, isoleucine, methionine, and total sulfur AAs and were lower than in placenta for histidine, phenylalanine, tryptophan, and valine and were similar as placenta for leucine and threonine. Total EAA as a percentage of CP was 43.90% for placenta and 44.67% for uterus. The results demonstrate tissue differences in EEAs composition of placenta and uterus.

Table 1. Average of AA to CP ratio (g/16 g N) in placenta and uterus from d 43 to 108 of gestation

Amino acid	Placenta	Uterus	*P*-value	SEM
Lysine	6.36	6.92	< 0.01	0.13
Arginine	6.30	7.12	< 0.01	0.07
Histidine	2.68	2.45	< 0.01	0.07
Isoleucine	3.43	3.60	< 0.01	0.06
Leucine	8.08	8.00	0.33	0.15
Methionine	1.67	1.73	< 0.01	0.03
Total Sulfur	3.29	3.46	< 0.01	0.06
Phenylalanine	4.53	4.39	< 0.01	0.08
Threonine	4.17	4.20	0.65	0.10
Tryptophan	1.22	1.05	< 0.01	0.05
Valine	5.45	5.22	< 0.01	0.10

T182 Estimating fermentative amino acid catabolism in the upper gut of growing pigs. D. Columbus*, J. P. Cant, and C. F. M. de Lange, *Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada.*

Fermentative catabolism of dietary and endogenous AA in the upper gut of pigs (FAAC) reduces AA available for protein synthesis. Manipulating dietary fiber and protein levels may influence the microbes' preferred N and energy sources and alter FAAC. A 4 d continuous isotope tracer infusion was performed to determine whole body urea flux, upper gut ammonia flux and FAAC, and urea recycling in ileal-cannulated growing pigs individually fed a control diet (C, 20.6% CP; n = 6), a high fiber diet with 12% added pectin (F, 19.5% CP; n = 4) or low protein diet (LP, 14.9% CP; n = 6). ^{15}N-ammonium chloride and ^{13}C-urea were infused intragastrically and intravenously, respectively. Ileal ammonia flow was lower in pigs on LP compared with pigs on F (0.25, 0.47, and 0.13 mmol N/kg BW/d; $P < 0.05$). There was an impact of dietary protein level on urea flux (25.3, 25.7, and 10.3 mmol N/kg BW/d; $P < 0.05$), urea excretion (14.4, 15.0, and 6.2 mmol N/kg BW/d; $P < 0.05$), and urea recycling (12.1, 11.3, and 3.23 mmol N/kg BW/d; $P < 0.05$). ^{15}N enrichments in blood urea [(3.10, 4.46, and 4.89 atoms % excess (APE)] were higher than in ileal ammonia (0.45, 0.23, and 0.95 APE), suggesting rapid absorption of ammonia before the distal ileum and lack of uniformity for enrichment in the digesta ammonia pool. Simple isotope dilution calculations are, therefore, inappropriate for calculating FAAC. Assuming rapid absorption of ammonia and based on tracer kinetics, a 2 compartment model was developed with digesta ammonia and plasma urea as N pools and representing fluxes of FAAC, microbial AA synthesis, absorption and recycling of N, endogenous AA catabolism, and loss of N to the colon and urine, allowing for minimum and maximum estimates of FAAC in the upper gut. Maximum estimated FAAC was lower when dietary protein content was decreased (32.9, 33.5, and 17.4 mmol N/kg BW/d; $P < 0.05$) but there was no impact of dietary fiber on FAAC ($P > 0.05$). There are several challenges associated with quantifying FAAC in the upper gut of pigs. The 2-compartment model presented here allows for estimates of FAAC and further investigation to improve the model and estimates is warranted.

Key words: fermentative catabolism, amino acids, pigs

T183 Serum amino acid concentration and expression of amino acid transporter bo,+ in pigs fed diets with different protein and amino acid levels. H. García[1], A. Morales[1], A. B. Araiza[1], M. Cervantes*[1], J. Yáñez[2], and P. Carrillo[1], *[1]ICA, Universidad Autónoma de Baja California, Mexicali, BC, México, [2]Universidad Autónoma de Tlaxcala, Tlaxcala, Tlax, México.*

Cationic AA are mainly absorbed by the transporter protein bo,+, which exchanges Leu by cationic AA at the apical cell membrane. Lys is the first limiting AA in typical cereal-soybean meal diets that contain excess of Leu and Arg. Low protein diets may reduce the Leu and Arg excesses but become deficient in Lys. An experiment was conducted to analyze the effect of dietary protein level and supplementation of free Lys, Thr, Met, and Leu on the expression of the cationic AA transporter bo,+ and serum concentration (SC) of indispensable AA. Twenty crossbred pigs (BW of 14.9 ± 1.8 kg) were used. Treatments (T) were: T1, basal wheat-based diet; T2, as in T1 plus free 0.70% Lys, 0.27% Thr, and 0.10% Met; T3, as in T2 plus 0.80% Leu; and T4, wheat-soybean meal diet, 20.0% CP, 1.05% Lys, 0.75% Thr, control. At the end of a 28-d trial, all pigs were sacrificed; mucosa from jejunum and blood were collected to analyze expression of bo,+ and SC of AA. Four contrasts were constructed to analyze the effect of the protein level (basal vs. control), AA level (basal vs. free AA), and source of AA (protein-bound in control vs. free AA). Relative expression of bo,+ (arbitrary units, b0,+ mRNA Mol/18S rRNA Mol), was: 4.50, 20.79, 6.06, 0.49 for T1 to T4 respectively. Free AA in T2 increased the expression of bo,+ in jejunum, but Leu in T3 decreased it ($P < 0.05$). Serum AA concentration (μMol/ml) was: Arg, 0.08, 0.10, 0.16, 0.13; Ile, 0.03, 0.04, 0.01, 0.10; Leu, 0.04, 0.06, 0.11, 0.11; Lys, 0.01, 0.21, 0.12, 0.06; Met, 0.03, 0.04, 0.04, 0.08; Phe, 0.03, 0.05, 0.05, 0.06; Thr, 0.07, 0.26, 0.27, 0.12; Val, 0.07, 0.08, 0.09, 0.20, for T1 to T4, respectively. Supplemental Lys increased the SC of Lys; Leu increased the SC of Leu and Arg ($P < 0.05$). SC of Lys was higher ($P < 0.01$) in pigs fed the diet with free Lys than the protein-bound Lys diet. These data indicate that the dietary levels and source of protein and free AA affect the expression of cationic AA transporter and the cellular AA availability in growing pigs.

Key words: swine, amino acids, amino acid transporter

T184 Effect of dietary leucine and isoleucine on productive performance and myosin expression in growing pigs. V. Méndez[1], A. Morales*[1], M. Cervantes[1], B. A. Araiza[1], and M. A. Barrera[2], *[1]ICA, Universidad Autónoma de Baja California, Mexicali, B.C., México, [2]Universidad de Sonora, Hermosillo, Son., México.*

Branched chain AA, especially Leu, are recognized as activators of mTOR, which regulates protein synthesis in muscle cells; myosin is about 40% the total protein content in muscle. But, Leu also competes with Ile for absorption; high Leu in the diet may interfere with Ile for absorption. Thus, an experiment was conducted to evaluate the effect of adding Leu and Ile, above the NRC (1998) requirement, to wheat-based diets on the performance and the expression of myosin (Myo) mRNA in the Longissimus dorsi (LDM) and Semitendinosus (STM) muscles of growing pigs. The response variables were: ADG, ADFI, G:F, and expression of Myo. Twenty-four pigs, initial BW of 15.9 ± 0.6 kg, randomly distributed in 4 dietary treatments according to a randomized complete block design, were used. Treatments (T) were: T1, basal wheat-based diet fortified with 0.69% Lys, 0.27% Thr, 0.10% Met; T2, basal plus 0.50% Leu; T3, basal plus 0.50% Ile; T4, basal plus 0.50% Leu and 0.50% Ile. Pigs were sacrificed at the end of the experiment to collect samples from the LDM and the STM muscles. Performance of pigs, for T1 to T4 was: ADG, 541, 452, 447, 443, g/d; ADFI, 910, 970, 738, 733, g/d; G:F, 0.595, 0.466, 0.606, 0.604, respectively. ADG gain reduced because of the addition of Leu ($P = 0.032$), Ile ($P = 0.025$), or both ($P = 0.020$). ADFI and G:F were not affected by the individual or combined addition of any of these AA ($P > 0.10$). Relative expression values (arbitrary units) of Myo for pigs in T1 to T4 were: LDM, 1.8, 1.3, 6.9, 6.6; in STM, 16.0, 17.3, 2.2, 4.1. Relative expression of Myo in LDM increased because of Ile added alone or in combination with Leu ($P < 0.05$); but reduced in STM ($P < 0.01$). These results show that adding Leu and Ile, alone or in combination, to wheat-based diets, reduce growth rate and differently affect the expression of myosin in LDM and STM.

Key words: pigs, amino acids, myosin

T185 Preference for diets with free L-tryptophan in pigs with different tryptophan status. J. Suárez[1], E. Roura[2,3], I. Ipharraguerre*[2], and D. Torrallardona[1], *[1]IRTA-Mas de Bover, Constantí, Spain, [2]Lucta S.A., Barcelona, Spain, [3]Current address: University of Queensland, Brisbane, Australia.*

The chemosensorial system of pigs may have evolved to identify AA as indicators of protein in the feed, so the use of free AA could affect the palatability of the diet. A double choice test was conducted to determine the preference for diets with different free L-Trp levels in pigs under different Trp status. 108 piglets (18 ± 1.4 kg BW) were divided into 3 groups and adapted (1 wk) to diets that were either deficient (D), adequate (A) or excessive (E) in Trp (1.8, 2.4 or 3.0 g Trp/kg, respectively). After the period of adaptation, the animals were used in pairs to perform a series of double-choice tests (2 d) between diet D (taken as reference) and 3 diets with increasing levels of free L-Trp to provide Trp in excess (E1, E2 and E3; 3.0, 3.6 and 4.2 g Trp/kg, respectively). Diets only differed in their free L-Trp content, which was included at the expense of maize starch in the basal diet. For each double choice comparison and Trp status, a total of 6 observations were obtained. Preference for each tested diet was expressed as its proportional (%) contribution to total feed intake. Preference values were analyzed with ANOVA using the GLM procedure of SAS by considering the main effects of L-Trp level, Trp status, and their interaction. Additionally, each preference mean was compared with the neutral value of 50% (i.e., no difference between the reference and test diets) with the Student's *t*-test. No effects of pig's Trp status ($P = 0.924$), free L-Trp inclusion ($P = 0.995$) or their interaction ($P = 0.614$) on feed preference were observed. Overall, the addition of L-Trp resulted in a preference value of 41 ± 1.8%, which was lower ($P < 0.001$) than the neutral value of 50%. These results indicate that pigs have an aversion for the diets with free L-Trp. In conclusion, the addition of L-Trp decreases feed palatability in pigs, independently of its inclusion level and the Trp status of the animals.

Key words: palatability, double-choice, amino acid

T186 Effects of dietary inclusion of bioactive grape seed extract on protein and amino acid digestibility in broiler chicks. S. Chamorro[1], A. Viveros[2], C. Centeno[1], C. Romero*[3], I. Arija[2], and A. Brenes[1], *[1]Instituto de Ciencia y Tecnología de Alimentos y Nutrición, ICTAN, CSIC, Madrid, Spain, [2]Facultad de Veterinaria, Universidad Complutense de Madrid, Spain, [3]Escuela de Ingenieros Agrónomos, Universidad Politécnica de Madrid, Spain.*

Polyphenols are chemically and biologically active compounds. Grape seed extracts (GSE) have been widely used as a human food supplement for health promotion and disease prevention. However, there was little information regarding its application in animal nutrition. An experiment was conducted to investigate the effect of inclusion of GSE at levels of 0, 0.0025, 0.025, 0.25, and 0.50 g/kg in a wheat soybean basal diet on growth performance and apparent ileal digestibility (AID) of CP and AA at 21 d of age. Each treatment was randomly assigned to 7 replicates (5 birds/replicate). At 21 d-old, 15 birds/treatment were sacrificed, and ileal contents of 3 chicks from the same treatment were pooled (5 samples/treatment) to determine AID of CP and AA. Celite (10 g/kg) was added as an indigestible marker. Performance was not affected by dietary treatments except in the case of birds fed the highest GSE concentration which showed a reduction of body weight and G:F, by 5.7% ($P < 0.05$) and 5.1% ($P < 0.01$) respectively, compared with those fed the basal diet. Animals fed 0.0025 g/kg GSE diets had a higher protein AID than those fed basal diets (86.2 vs. 84.2%, $P < 0.005$). However, a reduction (from 84.2 to 82.2%, $P < 0.005$) in protein AID was observed in chicks fed 0.5 g/kg as compared with those fed the basal diet. Dietary supplementation with GSE increased the AID of arginine and alanine and reduced that of glutamic acid and histidine as compared with the basal diet. The addition of 0.025 g/kg GSE increased the AID of lysine, threonine, cystine, serine, and glycine. A further addition up to 0.5 g/kg GSE reduced the AID of methionine, leucine, isoleucine, valine, aspartic acid, phenylalanine, and proline. The results of this study indicated that dietary GSE addition up to 0.25 g/kg did not impair growth performance nor CP digestibility. Further inclusion worsened growth performance and the AID of CP and that of several AA.

Key words: apparent ileal digestibility, chicks, grape polyphenols

T187 Effect of levels of lysine and ractopamine on the performance of immunocastrated pigs from 97 to 124 kg. D. O. Fontes*[1], B. O. Rosa[1], U. A. D. Orlando[2], M. A. e Silva[1], and P. C. Silva[1], *[1]Department of Animal Science, Veterinary School of UFMG, Brazil, [2]BRF Foods, Brazil.*

This experiment was carried out to evaluate the effect of digestible Lys and ractopamine levels on the performance of immunocastrated pigs. A total of 240 pigs of a commercial line, with an initial BW of 97.72 ± 2.11 kg and final weight of 124.06 ± 4.12 kg were used in

a completely randomized experimental block design with 4 replications and 5 animals per experimental unit. The treatments consisted of a 4x3 factorial scheme, with 4 levels of digestible Lys (0.65, 0.80, 0.95, and 1.10%) and 3 levels of ractopamine (0, 5 and 10 ppm). Significant effect of digestible Lys was evaluated by the regression of the observed variable on digestible Lys level of diet while means of ractopamine supplemented animals were compared by SNK test at 5% probability level. No interaction effects of digestible Lys x ractopamine levels on the recorded variables were observed. The animals fed 10 ppm ractopamine supplemented diets were heavier at the end of the experiment (126.01 kg) than those fed non supplemented (122.25 kg) and 5 ppm supplemented diets (123.93 kg). The animals fed 10 ppm supplemented diets showed higher ($P < 0.05$) ADG (1.35 kg) in comparison to those fed non supplemented diets (1.17 kg) and 5 ppm ractopamine supplemented diets (1.25 kg). Animals fed 10 ppm supplemented diets showed an increase of 180 g in ADG, corresponding to an improvement of 13.33% in comparison to non supplement diet animal. No effects of ractopamine level ($P > 0.05$) on feed intake and on daily digestible Lys consumption were observed. The G:F of animals fed 10 ppm diets (0,384 kg/kg) and 5 ppm diets (0,362 kg/kg) were not different ($P < 0.05$), but bigger ($P < 0.05$) than no supplemented animals (0,331 kg/kg). No effects of digestible Lys ($P > 0.05$) on the performance traits were observed. The results suggest that 0.65% of digestible Lys (23.36 g/d) meets the requirement of immunocastrated pigs from 97 to 124 kg, and 5 and 10 ppm supplemented diets improve feed efficiency of pigs in 9.34 and 16%, respectively, in comparison to non supplemented animals.

T188 Effect of L-tryptophan supplementation on hypothalamic serotonin level and aggression of nursery pigs fed diets varying large neutral amino acid concentrations. Y. B. Shen, G. Voilqué*, and S. W. Kim, *North Carolina State University, Raleigh.*

Cerebral serotonin has been shown as a controlling factor of aggressive behavior of pigs. Serotonin synthesis in the brain largely depends on availability of tryptophan (Trp), which has to compete with large neutral AA (LNAA) for LNAA transporter to cross the blood-brain barrier. The ratio between Trp and LNAA in diets would affect serotonin synthesis in the brain, which may affect aggression through changing Trp availability in brain. Thus, this study evaluated the effect of L-Trp supplementation on serotonin production and aggression of nursery pigs fed diets varying LNAA concentrations. Forty-eight barrows at 6 wk of age were housed individually and randomly allotted to 4 dietary treatments based on a 2x2 factorial arrangement (n = 12). First factor was L-Trp supplementation (0 or 0.6%) and the second factor was LNAA concentrations (4.5 or 3.8%). Pigs were fed the diets for 7 d. On d 4, pigs within a treatment were paired in a pen and their behavior was recorded for 1 d. On d 7, all pigs were euthanized to obtain hypothalamus. Supplementation of 0.6% L-Trp increased ($P < 0.01$) hypothalamic serotonin (99.2 vs. 66.1 ng/mg) and 5-hydroxyindoleacetic acid (896.6 vs. 599.3 ng/mg) in pigs. Supplementation of 0.6% L-Trp reduced the occurrence (1.17 vs. 0.33/hr), total duration (9.83 vs. 1.17 s), and average duration (5.50 vs. 1.17 s) of mutual biting when LNAA concentration was 4.5%. However, there were no changes in aggressive behavior of pigs by L-Trp supplementation when LNAA concentration was 3.8%. Both L-Trp supplementation and dietary LNAA concentrations did not affect the percentage of time that pigs spent on other physical activities such as lying, sitting, standing, eating, and drinking. Overall, L-Trp supplementation increased hypothalamic serotonin synthesis, which may have reduced duration, and the number of occurrence of mutual biting when LNAA concentration was increased from 3.8 to 4.5%.

Key words: pig, tryptophan, serotonin

T189 Importance of sampling diets on the precision of ME studies with swine. G. J. M. M. Lima*, L. C. Ajala, and C. M. Marques, *Embrapa, Brazil.*

Energy balance studies with swine provide data of high variability. The main sources for it are animals and feed. Most studies are done with number of replicates (barrows) per treatment varying from 4 to 12 to improve energy estimate. However, there are no references of how many feed samples should be collected and analyzed. Errors in feed mixing and feed analysis can affect ME estimation. This study was carried out to evaluate the error of determining ingredient ME considering just one feed sample. Therefore, 16 energy balance studies were carried out with 32 ingredients. A total of 384 barrows (50 kg wt, in average) were used. Pigs were kept in individual conventional metabolic cages. Each trial (24 barrows, progeny of the same boar) consisted of one basal diet and 3 test ingredients replacing part of the basal diet. Tested ingredients, number of different batches of each ingredient and inclusion levels in the basal diet were, respectively: poultry viscera and feather meal (VFM), 5 batches, 20%; dry yeast from sugarcane fermentation (DY), 4 batches, 30%; yellow corn (C), 21 batches, 30%; and heated whole soybeans (WSB), 2 batches, 10%. The adaptation period lasted 7 d, followed by 5 d of total collection of urine and feces, separated. Iron oxide was added to feed as marker. Five samples of each test diet were gathered during the collection period. Ingredient ME values were calculated using each individual analyzed feed sample. Based on each sample, estimated ME values for the same batch were different ($P < 0.0001$), regardless the ingredient. Range among batch ME (kcal/kg DM) varied from: 3925 to 4326 for VFM; 3369 to 3572 for DY, 3668 to 4287 for C and 3933 to 4334 for WSB. The difference between the smallest and largest ME estimate (kcal/kg DM), considering individual sampling from a single ingredient batch, reached up to 1811 for VFM, 529 for DY, 236 for C and 1116 for WSB. These results demonstrate the importance of repeating sampling of test diets and use their average value to improve precision of ME estimate of feed ingredients.

Key words: digestibility, feedstuffs, methodology

T190 Influence of dietary net energy concentration provided during the finishing period on carcass, meat and fat characteristics of heavy gilts. M. A. Latorre*[1,2], J. Suárez[1], M. A. Sanz[2], G. Ripoll[2], and M. Joy[2], *[1]Universidad de Zaragoza, Spain, [2]Centro de Investigación y Tecnología Agroalimentaria de Aragón, Zaragoza, Spain.*

A total of 60 Duroc × (Landrace × Large White) gilts were used to study the influence of increasing the energy concentration in diet during the finishing period on carcass, meat and fat characteristics. The experimental diets were based on barley, wheat, corn and soybean meal, contained 13.5% CP and 0.70% lysine and were provided from 100 to 130 kg BW. Pigs were slaughtered at heavy weight because were intended for dry-cured ham industry. There were 3 treatments with 3 NE levels; 2,280, 2,350, and 2,420 kcal NE/kg of feed. Therefore, the NE:lysine ratio was not constant in the experimental diets (CP was 13.5% in all cases and NE was increasing). Each treatment was replicated 4 times and the experimental unit was the pen constituted by 5 pigs allocated together. SAS package was used to analyze data statistically. The model included dietary treatment as main effect and the REG procedure was used on each trait to analyze the responses to diet. The increase of NE in the diet did not modified ($P > 0.05$) pH or carcass or ham size but decreased carcass weight ($P < 0.01$) and carcass yield ($P < 0.05$) and tended to increase ($P < 0.10$) the fat thickness between the third and forth last ribs and at the gluteus medius muscle level. The increase of NE content in diet decreased ($P < 0.01$) the yield of main trimmed lean cuts (shoulder+ham+loin+sirloin) in carcass due to a decrease ($P < 0.01$) of the ham yield. Meat characteristics were not affected by dietary treatment ($P > 0.05$). Also, only some fatty acids were modified ($P < 0.001$) by NE content in diet decreasing as NE increased; C20:0, C21:0, C22:0 and C20:4. We can conclude that the effect of increasing the NE in diet provided during the finishing period on carcass, meat and fat quality of pigs were scarce. However, an increase of NE content from 2,280 to 2,350 kcal/kg might be interesting in the case of pigs intended for dry-cured products when a minimum carcass fat thickness is a criterion to select the carcasses.

Key words: dietary net energy, carcass and meat quality, pigs

T191 Metabolizable energy and digestibility of carbohydrates in cereal grains fed to growing pigs. S. K. Cervantes-Pahm* and H. H. Stein, *University of Illinois, Urbana.*

The objective of the experiment was to measure the ME and the apparent ileal (AID) and the apparent total tract (ATTD) digestibility of carbohydrates (CHO) and total dietary fiber (TDF) in 8 cereal grains. The 8 cereal grains were yellow dent corn (YD), NutriDense corn (ND), de-hulled barley, de-hulled oats, polished rice, rye, sorghum, and wheat. Each cereal grain was included in 1 diet and titanium dioxide (0.5% was included in each diet as an indigestible marker. Twenty-four ileally cannulated pigs (BW = 30.7 ± 3.2 kg) were randomly allotted to the 8 diets in a completely randomized design. Pigs were fed experimental diets during 3 14-d periods. In each period, 3 pigs were fed each diet for a total of 9 observations per diet and no pig was fed any diet more than once. Pigs were placed in metabolism cages and fecal samples were collected quantitatively from d 6 to 11 and ileal samples were collected on d 13 and 14 of each period. Results of the experiment indicated that ME in de-hulled oats was greater ($P < 0.01$) than in ND, barley, and rice. The ME in sorghum was not different from the ME in YD and rye. The AID of CHO was greatest ($P < 0.01$) in polished rice and least ($P < 0.01$) in sorghum. The ATTD of CHO in rice was greater ($P < 0.01$) than in all other grains and the ATTD of CHO in wheat was least ($P < 0.01$) among the grains. The AID of TDF in YD, ND, de-hulled barley, and rye were not different, but were greater ($P < 0.01$) than in de-hulled oats and rice. The AID of TDF in de-hulled barley was also greater ($P < 0.01$) than in sorghum and wheat. The ATTD of TDF was less ($P < 0.01$) in polished rice than in all other cereal grains, but no differences among the other grains were observed. In conclusion, rice had the greatest ATTD of CHO, but de-hulled oats had the greatest ME among all cereal grains.

Table 1. ME and digestibility of carbohydrates in cereal grains

Item	ME, kcal/kg	AID CHO	AID, TDF	ATTD, CHO	ATTD, TDF
YD	3,443^{bc}	81.4^{cd}	12.1^{ab}	95.3^{bc}	54.7^{a}

T192 Nutritional value of acerola meal for broiler chickens. L. H. Zanetti*[1], V. C. da Cruz[1], G. do Valle Polycarpo[2], A. C. Pezzato[2], J. R. Sartori[2], V. B. Fascina[2], R. F. de Oliveira[1], A. L. C. Brichi[1], M. L. Poiatti[1], O. J. Sabbag[1], F. Vercese[2], and F. B. de Carvalho[2], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil.*

This study was carried out at the experimental aviary of the Sao Paulo State University, Botucatu Campus, Brazil. A metabolism assay with 100 8- to 16-d-old male Cobb broiler chicks was carried out using the method of total excreta collection. The birds were stored in 20 cages that were previously adapted with plastic covered trays to collect excreta. The experimental design was entirely random with 4 treatments and 5 replications of 5 birds per experimental unit. Acerola meal (AM) was substituted at 10, 15 and 20% of reference feed formulated with corn and soybean meal. The GE values were obtained using a colorimetric pump of 4.143 kcal/kg, and from these results the apparent ME (AME) was calculated and apparent corrected by the nitrogen balance (AMEn) of AM. The bromatological analyses determined the DM, CP, ether extract (EE), mineral matter (MM), crude fiber (CF), NDF, and ADF. The values of AME and AMEn decreased linearly ($P < 0.05$) as AM addition to the diet increased (AME = 1,215.88 – 24.37x; $R^2 = 0.33$ and AMEn = 1,313.72 – 31.86x; $R^2 = 0.35$). The recommended value of AME and AMEn for the use of AM in the nutritional matrix of broiler chickens′ feed was the one of the treatment with 20% AM addition, corroborating the literature where the greater the feed ratio in the reference feed, the more precise its determination is. The values of AME and AMEn decrease as the AM additions increase. It can be inferred that the values of AME and AMEn for AM are 754 kcal/kg and 756 kcal/kg, respectively. The results of the chemical and bromatological composition of AM used in the experiment for the other analyses were: 89.15% (DM), 8.36% (CP), 4.57% (EE), 3.19% (MM), 46.27% (CF), 50.86% (NDF), and 41.33% (ADF).

Key words: bromatological composition, industrial by-product, metabolism

T193 Concentration of DE and ME in fermented soybean meal, conventional soybean meal, and fish meal fed to weanling pigs. O. J. Rojas* and H. H. Stein, *University of Illinois, Urbana.*

An experiment was conducted to measure the concentration of DE and ME in US-produced fermented soybean meal (FSBM), conventional soybean meal (SBM-CV), and fish meal fed to weanling pigs. A corn-based diet consisting of 96.4% corn was formulated. Three additional diets were formulated containing corn and each of the experimental ingredients (FSBM, SBM-CV, and fish meal, respectively.) Thirty-six growing barrows (initial BW: 22.0 ± 3.85 kg) were placed in metabolism cages and allotted to a randomized complete block design with 4 diets and 9 pigs per diet. Feces and urine were collected for 5 d after a 5 d adaptation period. The ATTD and concentrations of DE and ME were calculated in fish meal and the 2 soybean meals using the difference procedure. Results indicated that the ATTD of energy in SBM-CV was 91.1% which was greater ($P < 0.001$) than in corn (88.0%) and fish meal (84.1%), and the ATTD of energy in FSBM (89.4%) was greater ($P < 0.001$) than in fish meal. The concentrations of DE and ME in SBM-CV were 4,608 and 4,144 kcal/kg DM, which was greater ($P < 0.001$) than the DE and ME in FSBM (4,223 and 3,678 kcal/kg DM, respectively), corn (3,921 and 3,768 kcal/kg DM, respectively), and fish meal (3,819 and 3,361 kcal/kg DM, respectively). However, FSBM contained more ($P < 0.001$) DE than corn and fish meal and more ($P < 0.001$) ME than fish meal. In conclusion, the concentration of DE and ME are less in FSBM than in SBM-CV. However, DE and ME are greater in FSBM than in fish meal.

Key words: energy, fermented soybean meal, soybean meal

T194 The effect of n-3 fatty acid supplementation on growth performance, nutrient digestibility, blood profiles, meat quality and lean and adipose tissue fatty acid profiles in finishing pigs. J. P. Wang*, B. U. Yang, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effect of dietary n-3 fatty acid supplementation on growth performance, nutrient digestibility, blood profiles, meat quality and fatty acid profiles of lean and adipose tissue in finishing pigs. A total of 150 crossbred barrows (initial BW = 55.7 ± 1.4 kg) were randomly allotted into 1 of 3 treatments by their BW and litters (10 replicate pens per treatment, 5 pigs per pen). The 3 treatments were corn-soybean diet with 0% (CON), 1.5% (T1), and 3% (T2) of unrefined tuna oil at the cost of corn, and the diet were isolysinic and isocaloric by manipulation of soybean meal and fat source (soy oil). The trial lasted 12-wk, and the pigs were killed to measure the carcass characteristics at the end of experiment. Data were subjected to the GLM procedure of SAS. During the entire experiment, none of the tuna oil treatments had effects on growth performance and apparent total tract nutrient digestibility (ATTD) of DM, nitrogen and energy. No differences were shown on the blood total cholesterol, high density lipoprotein cholesterol (HDL), low density lipoprotein cholesterol (LDL), and triglycerides among treatments in this experiment. The pigs in T2 treatment had lower loin muscle area than CON treatment (45.91 vs. 51.46 cm^2, $P < 0.05$). Water holding capacity (WHC), ultimate (24 h) pH value, as well as backfat thickness were not different between treatments. There was a decrease ($P < 0.05$) in palmitric acid (T1:24.99, T2:25.27 vs. CON:26.26%) in lean tissue, whereas n-6 fatty acids (T1:2.73, T2:3.03 vs. CON:3.15%) largely decreased ($P < 0.05$). Dietary supplementation of tuna oil (at 3%) feeding resulted in a lower docosahexaenoic acid concentration, and total n-3 fatty acid contents in adipose tissue ($P < 0.05$). These results show that the inclusion of tuna oil (rich in n-3 fatty acids) had no negative effects on growth performance and the n-3 fatty acids ingested can be deposited in lean and adipose tissue in fattening pigs.

Key words: finishing pig, meat quality, n-3 fatty acid

T195 The granulated barley provided during growing or finishing period improves the major fatty acid composition in the intramuscular fat of longissimus dorsi muscle and of dry-cured ham from heavy pigs. A. Daza[1], M. A. Latorre*[2], and C. J. López-Bote[3], *[1]Universidad Politécnica de Madrid, Spain, [2]Universidad de Zaragoza, Spain, [3]Universidad Complutense de Madrid, Spain.*

A total of 48 Duroc × (Large White × Landrace) gilts of 46.8 ± 1.39 kg BW were used to study the effect of diet on fatty acid profile of intramuscular fat (IMF) of longissimus dorsi muscle (LD) and of dry-cured ham after 18 mo of ripening. Experimental diets were provided ad libitum according to the following treatments: i) control diet with 3,210 kcal ME/kg, 13.7% CP and 0.62% digestible Lys from 45.6 to 127.8 kg BW (group C), ii) control diet from 47.0 to 91.8 kg BW and granulated barley with 3,020 kcal ME/kg, 10.2% CP and 0.26% Lys from 91.8 to 129.7 kg BW (group C+GB) and iii) granulated barley from 47.9 to 93.1 kg BW and control diet from 93.1 to 135.1 kg BW (group GB+C). Each treatment was replicated 8 times with 2 gilts per replicate. Data were analyzed by ANOVA using SAS. The model included dietary treatment as main effect. The LD from C+GB gilts had 18% higher ($P < 0.05$) C18:1n-9 and MUFA than that from C gilts, whereas the C18:2n-6 and PUFA were lower in the LD from C+GB gilts than in that from C or GB+C gilts (8.2 vs 12.7 and 10.2; 9.7 vs 15.0 and 9.7; $P < 0.05$). The C16:0 was lower in LD from GB+C gilts than in that from C+GB (4%) or C (5%) gilts, and SFA was 4.7% lower ($P < 0.05$) in BG+C than in C gilts. A relation adjusted to a quadratic function between IMF percentage and C18:1n-9 proportion in LD was observed: C18:1n-9 = 25.75 + 6.64 IMF – 0.56 x IMF^2 ($R^2 = 0.78$, RSD = 1.24, $P < 0.001$). The diet had no effect ($P > 0.05$) on C16:0, C18:0 and SFA of IMF from hams. However, hams from C+GB and GB+C gilts had ($P < 0.05$) higher C18:1n-9 (37.9, 40.9 and 40.0%) and lower C18:2n-6 (13.2, 10.8 and 10.8%) and PUFA (17.1, 14.4 and 14.1) than those from C gilts. The MUFA was 8.4% higher in hams from C+GB gilts than in those from C gilts, but no differences were detected ($P > 0.05$) when hams from C and GB+C and from C+GB and GB+C gilts were compared. It is concluded that granulated barley given during growing or finishing periods to heavy gilts improved the major fatty acids profile in the IMF of LD and of dry-cured ham of heavy pigs.

Key words: barley, fatty acid composition, heavy pigs

T196 Sulfur addition in corn-soybean meal diets reduced nursery pig performance. V. G. Perez*, H. Yang, T. R. Radke, and D. P. Holzgraefe, *ADM Alliance Nutrition Inc., Quincy, IL.*

Dietary sulfur (S) from distillers dried grains has been suggested to be detrimental for pig growth. The objective of this study was to determine the effect of increasing concentrations of dietary S on pig performance. Corn-soybean meal-based diets were used to differentiate any S effect from distillers dried grains. The experiment was a randomized complete block design; blocks were 4 categories of initial BW. Treatments were the inclusion of dietary S at 0.0, 0.2, 0.4, or 0.6% of the diet. Each treatment was replicated with 8 pens of 4 pigs per pen. Polynomial contrasts were used to determine linear and quadratic effects of dietary S addition. Sources of added S were sodium bisulfate ($NaHSO_4$) and calcium sulfate ($CaSO_4 \cdot 2H_2O$); both were provided in equal amounts. The Na and Ca from these compounds replaced dietary salt and limestone, respectively. All diets were formulated to provide similar amounts of ME, CP, Ca, available P, and digestible Lys within feeding phase. Two feeding phases were used for 14 and 21 d, respectively. Pigs were weaned at about 21 d of age and the experiment started 2 wk after weaning. The treatment with 0.0% added S had the lowest concentration of analyzed dietary S, with 0.25 and 0.24% S in feeding phases 1 and 2, respectively. Pig growth and feed efficiency were reduced ($P < 0.05$) proportionally to the inclusion of dietary S (Table 1). Feed intake followed a similar pattern of response to dietary S on the overall period. The larger reduction in ADG was observed between treatments with 0.0 vs. 0.2% added S, which can explain the quadratic effect observed in G:F. Increasing concentrations of added S up to 0.6% of the diet, proportionally decreased pig performance.

Table 1. Dietary sulfur addition and pig performance

Item	0.0% S	0.2% S	0.4% S	0.6% S	SEM

T197 The effect of Kapok seed meal supplementation on growth performance, nutrient digestibility, blood characteristics, meat quality, and fatty acids profile in finishing pigs. H. J. Kim*, T. X. Zhou, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effect of Kapok seed meal supplementation on growth performance, nutrient digestibility, blood characteristics, meat quality, and fatty acids profile in finishing pigs. A total of 96 finishing pigs [(Landrace × Yorkshire) × Duroc] with an average initial BW of 67.0 ± 1.5 kg were used in a 10 wk trial. Pigs were allotted to 1 of 3 dietary treatments with 8 replicate pens per treatment and 4 pigs per pen. The treatments included: 1) CON (basal diet), 2) K1.5 (basal diet + 1.5% Kapok) and 3) K3.0 (basal diet + 3.0% Kapok). Data were subjected to the GLM procedure of SAS. Differences among treatments were evaluated by Duncan multiple test. Growth performance was unaffected. Apparent total tract digestibility (ATTD) of DM and N was lower (74.15 vs. 77.68, 73.76 vs. 78.71%; $P < 0.05$) in K3.0 treatment than in CON treatment. At the end of the experiment, K1.5 and K3.0 diets had higher low density lipoprotein (LDL) cholesterol concentrations than CON diet (53.25 vs. 42.50; $P < 0.05$). Redness (a*) of pigs fed K3.0 diet was greater than that of CON diet (18.85 vs. 17.82; $P < 0.05$). Marbling score was higher in K3.0 treatment than that in CON treatment (2.2 vs. 1.9; $P < 0.05$). Total SFA of pigs fed K3.0 diets were greater than those of pigs fed CON diet (57.37 vs. 38.01%; $P < 0.05$) in adipose tissue. Palmitoleic acid, and oleic acid in K1.5 and K3.0 treatments were lower than CON treatment (1.49 vs. 2.35%; $P < 0.05$) in adipose tissue and lean. Stearic acid in K1.5 and K3.0 diets was increased compared with CON diet (24.67 vs. 13.24%; $P < 0.05$). In lean, pigs fed K3.0 diets had a greater stearic acid than that of pigs fed CON and K1.5 diets (22.34 vs. 14.25, 16.63%; $P < 0.05$). However, no significant differences were

observed on myristic acid, palmitic acid, linoleic acid, linolenic acid, SFA, PUFA, and SFA/PUFA in this study. In conclusion, kapok seed meal can improve meat quality but decrease nutrient digestibility and unsaturated fatty acid (UFA) in adipose tissue of finishing pigs.

Key words: fatty acids, finishing pigs, Kapok

T198 Performance of 1-d-old to 42-d-old broiler chicks fed with increasing levels of acerola meal replacing corn in diet. V. C. da Cruz*[1], L. H. Zanetti[1], G. do Valle Polycarpo[2], R. F. de Oliveira[1], A. L. C. Brichi[1], D. D. Millen[1], L. C. Carvalho[1], D. O. dos Santos Gomes[1], O. J. Sabbag[1], and M. L. Poiatti[1], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil.*

This study, carried out at the São Paulo State University, Campus of Dracena, Brazil, aimed to evaluate the performance of 1 to 42-d-old broilers fed with different additions of acerola meal (AM) replacing corn (C) in the diet. Nine hundred eighty 1-d-old male Cobb chicks were housed with an initial density of 14 chickens/m^2. The experiment had a completely randomized design, 4 treatments: T0- basal diet - without addition of AM, T5- addition of 5% AM replacing C, T10- addition of 10% AM replacing C, T15- addition of 15% AM replacing C, and 7 replications with 35 birds each. At 42 d, a significant difference ($P < 0.05$) was observed in the final BW, ADG and G:F of chickens by regression analysis. Final BW and ADG decreased linearly with the addition of AM in diet (BW = - 8.7780x+2210.78; ADG = −0.2090x+51.5772). The G:F of birds, obtained from the gain-to-feed ratio, increased linearly with the addition of AM percentage in diets (G:F = 0.0038x +1.6784). Therefore, the AM effects on the body weight of the birds influenced the G:F. This situation was more evident in treatments with greater amounts of AM, which resulted in worse G:F. The ADFI was not influenced by the treatments ($P > 0.05$), corroborating previous research that evaluated byproducts in broilers' diets. Since the diets were isocaloric, it can be inferred that ADFI was not affected by the AM addition, because birds primarily satisfy their energy needs, except when there is a limitation in the capacity of digestive tract. This seems to have been primordial in the initial phase, but it could not be applied to the entire breeding period due to the development of the birds′ digestive tract. In this period, no difference ($P > 0.05$) among the treatments was observed for the production efficiency index (PEI). The AM addition becomes interesting at 5% without affecting the broilers′ performance. When analyzing the PEI, addition of 15% is still advantageous because it allows a smaller addition of corn.

Key words: poultry, residue byproducts

T199 Inclusion of acerola meal replacing corn in the diet of broilers of 1-d-old to 21-d-old. L. H. Zanetti*[1], V. C. da Cruz[1], G. do Valle Polycarpo[2], R. F. de Oliveira[1], A. L. C. Brichi[1], D. D. Millen[1], V. B. Fascina[2], M. L. Poiatti[1], and O. J. Sabbag[1], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil.*

This work, carried out at the São Paulo State University, Dracena Campus, Brazil, aimed to evaluate different levels of inclusion of acerola meal (AM) replacing corn (C) on the performance of broiler chickens during the initial phase (1 to 21-d-old). 980 1-d-old male Cobb chicks were housed with an initial density of 14 chickens/m^2. The experiment had completely randomized design, 4 treatments: T0- basal diet - without addition of AM, T5- addition of 5% AM replacing C, T10- addition of 10% AM replacing C, T15- addition of 15% AM replacing C, and 7 replications with 35 birds each. Throughout the experimental period, water and feed were provided ad libitum. The statistical analysis of data was done by ANOVA, and when the treatment effect was positive, it was unfolded by polynomial regression analysis. At 21 d old, the chickens were weighed to evaluate performance. It was observed that the addition of AM replacing C in the diets influenced ($P < 0.05$) G:F and ADFI, the latter having a linear reduction (ADFI = 3.1811x + 1091.19, $P < 0.01$) with the inclusion of AM in diet, which may be justified by the crude fiber level (43.34%) in this byproduct, which can decrease the density of the diet. The inclusion of AM exerted a quadratic effect on G:F (G:$F = 0.0004x^2 - 0.0082x + 1.4061$, $P < 0.05$), demonstrating that this variable was more efficient in the treatment with 5% of MA replacing C in diet, and from this point, G:F of chickens tends to worsen, showing undesirable results with higher inclusions. Otherwise, final BW, ADG and viability were not affected by the addition of AM ($P > 0.05$). For the phase (1–21-d), the different levels of AM inclusion replacing C does not interfere on broiler performance, which shows that the AM inclusion can be made up to 15% without causing damage to group.

Key words: animal feeding, industrial by-product, poultry

T200 Fatty acid content and sensory evaluation of trimmed loins as influenced by timing of feeding flaxseed or fish oil to pigs. H. R. Martínez-Ramírez*[1], L. M. Pivotto[1], I. B. Mandell[1], J. K. G. Kramer[2], and C. F. M. de Lange[1], *[1]Centre for Nutritional Modelling, Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Agriculture and Agri-Food Canada, Guelph, ON, Canada.*

Pork containing n-3 fatty acids (FA) can provide health benefits to consumers. The effect of timing of feeding n-3 FA from ground flaxseed (FS) or fish oil (FO) to pigs on the FA content and sensory evaluation of trimmed loins (Loin) was investigated. Either FS or FO was included in corn based diets and fed continuously (treatments FSC and FOC, 25 to 120 kg BW), only during the growing phase (FSG and FOG, 25 to 65 kg BW), or only during the finishing phase (FSF and FOF, 85 to 120 kg BW). The 7th treatment, a diet free of FS and FO served as control (CON). At 25 kg BW, 4 barrows and 4 gilts (Landrace × Yorkshire × Duroc) were assigned to treatments. Pigs were fed ad libitum and feed intake was recorded per pig. Cumulative intake of FS was similar for FSG, FSF, and FSC ($P > 0.10$; 6.8, 7.2, 7.2 kg/pig, respectively), whereas intake of FO was similar for FOG, FOF, and FOC ($P > 0.10$; 2.0, 2.0, 2.2 kg/pig, respectively). Growth performance and measures of Loin meat quality (color, drip loss, 24 h pH) were not influenced by dietary treatments ($P > 0.10$). In terms of FA content (mg/100 g fresh Loin), α-linolenic acid (ALA) was independent of FS feeding regimen ($P > 0.10$; 274, 237, 187 for FSG, FSF, and FSC, respectively), and higher ($P < 0.01$) than the other treatments (40.1, 38.6, 63.0, and 30.5 for FOG, FOF, FOC and CON, respectively). Content of highly unsaturated n-3 FA (sum of n-3 FA minus ALA) was independent of FO feeding regimen ($P > 0.10$; 122, 138, and 129 for FOG, FOF, and FOC, respectively), higher ($P < 0.01$) than FS (102, 66.8 and 77.4, for FSG, FSF and FSC, respectively); and lowest for CON (32.2; $P < 0.05$). Based on a trained taste panel analysis, off-flavor ratings were higher for FOF than FSC ($P < 0.05$; 1.47 vs. 0.54); whereas ratings were similar for FSG, FSF, FOG, FOC, and CON ($P > 0.10$; 1.10, 0.95, 1.27, 1.30, and 0.91). These results indicate that enrichment of n-3 FA in Loin appears independent of timing of when n-3 FA containing diets are fed during pig development, and that feeding FO in the pre-slaughter diet may reduce consumer acceptance of pork.

Nonruminant Nutrition: Gastrointestinal Physiology

T201 Intestinal short-chain fatty acid sensors, FFA2 and FFA3, and control of food intake. M. Al-Rammahi*, K. Daly, A. Moran, and S. Shirazi-Beechey, *University of Liverpool, Liverpool, UK.*

Dietary fiber and resistant starch are fermented by colonic microbiota to short-chain fatty acids (SCFA), acetate, propionate and butyrate. SCFA are known to have variety of physiological effects on gastrointestinal function. However, until recently little was known about the mechanism by which lumenal SCFA are sensed by colonic epithelial cells. Two orphan human G protein-coupled receptors, free fatty acid receptor 3 (FFA3; formerly GPR41) and free fatty acid receptor 2 (FFA2; formerly GPR43), have been cloned and demonstrated to be sensors for SCFA. It has been reported that, in response to dietary fiber, the large intestine secretes gut hormones such as glucagon-like peptide 1 (GLP-1) and peptide YY (PYY), which control appetite and food intake, and SCFA have been implicated in this effect. Here we report, using qPCR, that FFA3 and FFA2 are expressed in human and pig colon with FFA2 having higher expression. Using immunohistochemistry, we show that FFA2 and FFA3 proteins are solely expressed in enteroendocrine L- and enterochromaffin cells of pig and human colon and not on the luminal membrane of colonic absorptive epithelial cells or intra-cellularly as shown by Karaki et al. (2006, 2008). Furthermore we show that FFA2 and FFA3 are co-expressed in endocrine cells containing, GLP1, PYY and serotonin. In addition, using GluTag cells, a murine enteroendocrine L-cell model, we show that these cells express FFA2 and FFA3 and that they secrete GLP-1 in response to either 10 mM butyrate or 10 μM chloro-α-(1-methylethyl)-N-2-thiazolylbenzeneacetamide (4-CMTB), a specific activator of FFA2.

Key words: dietary fiber, food intake, nutrient sensing

T202 Gene expression of the L-amino acid–sensing receptor T1R1/T1R3 changes in gut tissues of pigs in response to dietary protein. G. Tedo[1], E. Roura[1,3], I. Ipharraguerre*[1], and X. Manteca[2], *[1]Lucta SA, Feed Additives Division, Montornes del Vallés, Barcelona, Spain, [2]Autonomous University of Barcelona, Bellaterra, Barcelona, Spain, [3]Current address: University of Queensland, Brisbane, Australia.*

We have shown that the porcine umami taste receptor T1R1/T1R3 is present in pig′s gut and its mRNA abundance increases in the small intestine after weaning. The aim of this study was to determine if the expression of the pT1r1/pT1r3 genes in taste and gut tissues changes in response to variation in the content of dietary CP and essential AA (EAA). Forty-eight Pietrain x Landrace piglets were used from weaning (26 d of age) to 20 d after weaning. Piglets were allotted to 3 dietary treatments (16 piglets/treatment): high CP diet (HCP, 24%CP, 15 g/kg of Lys), low CP diet (LCP, 17%CP, 9 g/kg of Lys) and LCP diet supplemented with all EAA (SAA, 17%CP, 15 g/kg of Lys). Four animals per treatment were sacrificed on d 20 after weaning to collect tissue samples of fungiform and circumvallate papillae (TC), stomach (S), liver (L), duodenum (D) and ileum (I). Remaining piglets (12 pigs/treament) were used to monitor animal performance. The relative abundance of mRNA of the pT1r1 and pT1r3 genes was quantified via real-time PCR using the tata box binding protein as housekeeping gene. Real-time data were analyzed using the GEE model with an exchangeable correlation structure and the GENMOD procedure of SAS. Fold change estimations were performed for sex, diet, tissue and their interaction relative to liver and the HCP group. The expression of the pT1r1 gene was upregulated ($P < 0.05$) in S (3-fold), D (22.6-fold) and I (7.9-fold) of the LCP group, whereas the expression of the pT1r3 gene was upregulated ($P < 0.05$) in TC (1.7-fold), S (2.8-fold) and D (1.6-fold) of the SAA group and tended ($P < 0.06$) to increase in D (2-fold) and I (3.2-fold) of the LCP group. In summary, the expression of the porcine umami taste receptor genes mainly responded to changes in CP intake. Interestingly, supplementing the LCP diet with essential AA to meet piglet′s requirement tended to prevent such a response in the pT1r1 gene. Taken together, these observations suggest that the porcine umami taste receptor plays a role in sensing the enteral supply of protein.

Key words: gut sensing, amino acids, umami taste receptors

T203 Gene expression of the porcine sweet taste receptor in tongue and gut tissues changes after weaning. G. Tedo[1], X. Manteca[2], I. Ipharraguerre*[1], M. Reina[3], D. Torrallardona[4], and E. Roura[1,5], *[1]Lucta SA, Feed Additives Division, Montornes del Valles, Barcelona, Spain, [2]Autonomous University of Barcelona, Veterinary School, Bellaterra, Barcelona, Spain, [3]University of Barcelona Cell Biology Dpt., Celltec-UB, Barcelona, Spain, [4]IRTA -Mas de Bover, Constanti, Tarragona, Spain, [5]Current address: University of Queensland, Brisbane, Australia.*

Sugars and artificial sweeteners are sensed by the sweet taste receptor T1R2/T1R3 present in taste buds. Recent studies in rodents showed that this receptor is also present in the gut forming part of the mucosal chemosensing system by which luminal glucose and other chemicals are sensed to trigger gut physiological responses. The aim of this study was to investigate the expression and changes during development of the porcine T1r2 and T1r3 genes in taste and gastrointestinal tissues of pigs. Fifty-six Pietrain x Landrace piglets were selected at birth and fed standard diets from weaning until 46 d of age. On d 0 (birth), 26 (weaning), 28 (48h after weaning), and 46 from birth, 4 piglets (2 of each sex) were sacrificed to collect tissue samples of fungiform and circumvallate papillae (TC), stomach (S), liver (L), duodenum (D), jejunum (J), and ileum (I). Remaining piglets (40) were used to monitor animal performance. The relative abundance of mRNA of the pT1r2 and pT1r3 genes was quantified via real-time PCR using the tata box binding protein as housekeeping gene. Real–time data (Ct values) were analyzed using the GEE model with an exchangeable correlation structure and the GENMOD procedure of SAS. Fold change estimations ($2^{-\Delta\Delta Ct}$) were performed for sex, age, tissue and their interaction relative to liver and the weaning group (d 26). Both genes were expressed ($P < 0.05$) in all tissues at all ages and the interaction between age and tissue for the expression of the pT1r2 gene tended to be significant ($P < 0.07$). On d 46, the expression of pT1r2 was upregulated ($P < 0.05$) in TC (4.7-fold), D (11.1-fold), and I (17.4-fold), but downregulated in L (0.14-fold). In conclusion, the receptor T1R2/T1R3 is present in taste buds and gastrointestinal tract of pigs and its expression changes remarkably after weaning.

Key words: sweet taste receptor, pig, weaning

T204 Evaluation of seaweed-derived polysaccharides on indices of gastrointestinal fermentation and selected populations of microbiota in newly weaned pigs challenged with *Salmonella* Typhimurium. S. Dillon[1], J. Fanning[2], T. Sweeney[1], J. Egan[2], C. J. O'Shea[1], M. Gutierrez[2], C. Mannion[2], F. Leonard[1], and J. V. O'Doherty*[1], *[1]University College Dublin, Dublin, Ireland, [2]Cen-*

tral Veterinary Research Laboratories, Backweston, Celbridge, Co. Kildare, Ireland.

Growing pigs encounter multiple stressors in the immediate post-weaning period, and become vulnerable to infection by microbial pathogens such as *Salmonella*. An experiment was conducted to investigate the effects of offering diets containing seaweed-derived laminarin or fucoidan on numbers of *Salmonella* Typhimurium in the distal gastrointestinal tract (GIT), in select tissue locations, and in fecal matter of pigs experimentally challenged with *Salmonella* Typhimurium. Twenty-four individually penned entire male pigs (n = 6), weaned at 24 d (7.9 kg) were assigned (d 0 to 32) to 1 of 4 dietary treatments: T1) basal diet (control); T2) basal diet + a commercial admixture containing organic acids and herbs (positive control; 3.6g/kg); T3) basal diet + laminarin (300 mg/kg); (T4) basal diet + fucoidan (240 mg/kg). Sampling of fecal matter was carried out periodically during the experiment and GIT contents and tissue samples were collected post-sacrifice (d 32). Consumption of diets containing fucoidan increased counts of lactobacilli in the cecum ($P < 0.05$) and the molar proportion of butyric acid in the cecum ($P < 0.05$) and colon ($P < 0.05$) and decreased the molar proportion of valeric acid in the cecum ($P < 0.05$) and colon ($P < 0.01$). However, fecal counts of *Salmonella* Typhimurium increased on d 2 ($P < 0.05$) and d 14 ($P < 0.05$) post-challenge (PC) of pigs offered fucoidan, and on d 14 ($P < 0.05$) and d 20 ($P < 0.05$) PC of pigs offered laminarin ($P < 0.05$) compared with the control. Diets containing the commercial admixture increased lactobacilli ($P < 0.05$) and butyric acid ($P < 0.05$) in the cecum and decreased counts of *Salmonella* Typhimurium ($P < 0.001$) in tonsil tissue. In conclusion, consumption of diets containing fucoidan induced increases in lactobacilli in the cecum, and butyric acid in the cecum and colon, however both laminarin and fucoidan increased shedding of fecal *Salmonella* Typhimurium at select sampling periods of the experimental study.

T205 Fermentation activity of colonic microbiota from piglets fed diets including alfalfa, citrus pulp or inulin. S. Brambillasca*[1], M. Hernández[1], A. Britos[1], L. Reyes[1], P. Zunino[2], and C. Cajarville[1], *[1]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Montevideo, Uruguay, [2]Departamento de Microbiología, Instituto de Investigaciones Biológicas Clemente Estable, MEC, Montevideo, Montevideo, Uruguay.*

The effect of including alfalfa, citrus pulp or inulin in diets for piglets on the fermentation activity of the colonic microbiota was studied. Twenty 4 cross breed piglets (12.1 ± 1.7kg BW) in a randomized complete block design were housed in metabolic cages and assigned to one of 4 diets for 23d: 100% corn and soybean meal based diet (CO), 97% CO+3% inulin (IN), 95.5% CO+4.5% fresh alfalfa (AL) and 95.5% CO+4.5% fresh citrus pulp (CP) in DM basis. The last day of the experiment all animals were euthanized and colonic digesta was individually sampled. In vitro gas production was performed using individual diluted colonic digesta as inoculum and pre-digested (pepsin+pancreatin) CO as substrate (6 flasks/animal, n = 144). Gas volume was recorded between 2 and 90h post inoculation. Asymptotic gas production (A, mL/g OM), time to reach 50% of the asymptote (B, h), maximal rate of gas production (Rmax, mL/h) and time of occurrence of Rmax (Tmax, h) were determined. DM disappearance (DMD) and organic matter disappearance (OMD) were determined by drying and ashing the fermentation residues respectively. Data were analyzed by PROC MIXED considering treatment effect, and means were separated by orthogonal contrasts. Rmax was the unique parameter affected by treatments and was highest for IN ($P = 0.003$). Gas production tended to be higher with fiber inclusion and AL tended to produce a higher B and Tmax than CP, whereas DMD for CP tended to be higher than AL. Piglets receiving IN presented a microbiota adapted to ferment substrates faster than the other treatments. Acknowledgments: ANII for scholarship of the first author.

Table 1. In vitro fermentation parameters for different treatments

	A (mL/g OM)	B (h)	Rmax (mL/h)	Tmax (h)	DMD (%)	OMD (%)

T206 Quantitative bioluminescence imaging of functional estrogen receptor activity within intact porcine ovarian follicles in vitro. S. Jung* and S. T. Willard, *Mississippi State University, Mississippi State.*

Activated estrogen receptors (ER) in response to estrogen bind to specific sequences (estrogen response elements; ERE) to induce transcription. The objective of this study was to evaluate whether the estrogen induced ER binding activity in granulosa cells of antral ovarian follicles can be detected by bioluminescence imaging in vitro, and correlated to estrogen concentrations in follicular fluid. In this study, we used lipid–mediated gene transfer and an ERE–luc reporter gene (which consisted of 3 tandem repeats of EREs upstream from the luciferase gene) to transfect granulosa cells within intact follicles. When the endogenous functional and activated ERs bind to the ERE–luc sequences within the transfected granulosa cells, the expression of luciferase is enacted for detection. A total of n = 58 follicles between 4.2 to 9.4 mm in diameter were dissected from the ovaries. DNA–lipid complexes were formed at a DNA (μg): lipid (μl) ratio of 1:3, by adding FuGene 6 in PBS to 3 μg of ERE–luc DNA and injected into each follicle using a microinjector. The follicles were cultured individually with αMEM and 45% O_2; 50% N_2; 5% CO_2 at 39°C. After 20 h post–transfection, the luminescence from each follicle was detected using an IVIS 100 imaging system. Each follicle was imaged with 10 min exposure and signal intensity was reported (and normalized) as mean ± SEM of photons per second (p/s). Estradiol concentrations of follicular fluid were measured by radioimmunoassay in each follicle. Regression coefficients were determined, and a *P*–value of <0.05 was considered significant. Concentrations of estradiol in follicular fluid significantly increased as follicle size increased (r = 0.607; $P < 0.05$). Estradiol total content in each follicle was positively correlated with ERE-driven luciferase expression level of follicles (r = 0.39; $P < 0.05$). These results demonstrate the initial development of a new methodology for measuring functional and ligand activated estrogen receptor activity within intact porcine ovarian follicles in vitro using bioluminescence imaging methodologies.

Key words: bioluminescence imaging, estrogen receptor, porcine ovarian follicles

T207 Propionate increases mitochondrial phosphoenolpyruvate carboxykinase mRNA in Madin-Darby bovine kidney epithelial cells. S. I. Tindell*, S. L. Koser, and S. S. Donkin, *Purdue University, West Lafayette, IN.*

Phosphoenolpyruvate carboxykinase (PEPCK) is a rate determining enzyme for gluconeogenesis that is present in both a cytosolic (PEPCK-C) and a mitochondrial (PEPCK-M) form in bovine liver. Considerable research has documented the importance and control of PEPCK-C however there is little information available on hormonal and nutritional control of bovine PEPCK-M. The objectives of this study were to clone the promoter region of bovine PEPCK-M, to determine the transcription factor binding sites within the proximal promoter region, and determine the response of bovine PEPCK–M to nutrients and hormones. Genomic DNA isolated from liver of lactating dairy cows was used to clone a 906 nucleotide (nt) sequence that includes promoter specific elements and the first few bases of the coding sequence for bovine PEPCK–M promoter. Computer assisted analysis of this sequence revealed that all the elements necessary for promoter activity are contained within 896 nt relative to the transcription start site and there is no sequence similarity between bovine PEPCK-M and PEPCK-C promoters. The direct individual effects of 1 μ*M* dexamethasone, 10 μ*M* Wy14643, 100 n*M* insulin, 4.5 n*M* somatotropin, 1 μ*M* cAMP, 2 m*M* propionate, 2 m*M* acetate, 2 m*M* butyrate, or 2 m*M* lactate for 24 h on bovine PEPCK-M mRNA were determined in Madin-Darby bovine kidney epithelial (MDBK) cells. The data indicate that expression of PEPCK-M mRNA is increased ($P < 0.05$) by propionate (1.62 vs. 2.94 ± 0.19; control vs. propionate, respectively) but there were no effects ($P > 0.05$) of the other hormones and metabolites tested. The data would suggest that PEPCK-M may be regulated by propionate supply which may serve to enhance the capacity for mitochondrial phosphoenolpyruvate flux and gluconeogenesis.

Key words: PEPCK, gluconeogenesis, gene

T208 Staining bovine sperm for sex-sorting: Concentration effects of seminal plasma, sperm and Hoechst 33342. C. A. Burroughs*[1], J. K. Graham[1], R. W. Lenz[2], and G. E. Seidel[1], *[1]Colorado State University, Fort Collins, [2]Sexing Technologies Inc., Navasota, TX.*

We investigated various combinations of sperm, seminal plasma, and Hoechst 33342 (H33342) concentrations during staining of bull sperm to improve sex-sorting of sperm. Ejaculates from 11 bulls with at least 60% motile and 70% morphologically normal sperm were collected by artificial vagina on 2 different days. Semen was centrifuged at 1,000 × *g* for 15 min to separate sperm from seminal plasma, which was then clarified by additional centrifugation (2,000 × g for 10 min). Sperm were resuspended in TALP (pH 7.4) at 160 × 10^6 or 240 × 10^6 sperm per ml with 0 or 10% seminal plasma. H33342 was added (final concentrations of 49, 65 or 81 μ*M*) followed by incubation for 45 min at 34.5°C. An equal volume of TALP (pH 5.5) containing red food dye was added; sperm were sorted using a MoFlo SX (Dako, Denmark) flow cytometer and analyzed for % live-oriented cells, X sort rate, % dead (sperm membrane permeable to red dye), and splitability (peaks to valley ratio - degree of separation of X and Y populations). Overall, staining with 0% seminal plasma resulted in higher % live-oriented cells (57.4% vs. 53.7%) and a faster sort rate (3.60 × 10^3sperm per s vs. 3.28 × 10^3sperm per s) compared with 10% seminal plasma (both $P < 0.01$). There was an interaction between sperm concentration and H33342 concentration for ability to separate X and Y populations and for sort rate (Table 1). Using 65 μ*M* H33342 was sufficient to optimally stain 160 × 10^6 sperm per ml, while 240 × 10^6 sperm required 81 μ*M* H33342 to reach similar splitability and sort rates. The optimal combination for staining bull sperm was 0% seminal plasma, 160 × 10^6 sperm per ml, and 65 μ*M* H33342.

Table 1. Sperm and H33342 concentration responses averaged over 0 and 10% seminal plasma

Sorting Parameter	Sperm Conc (10^6)	49μM H33342	65μM H33342	81μM H33342
% live-oriented cells	160	55.0^{ab}	57.1^{b}	56.8^{b}

T209 Effect of feed restriction on reproductive and metabolic hormones in dairy cows. H. Gencoglu[1,2], A. Nascimento[1], K. Hackbart[1], L. F. Ferraretto*[1], F. Dalla Costa[1], J. Guenther[1], R. Meyer[1], R. D. Shaver[1], and M. C. Wiltbank[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]Department of Animal Nutrition and Nutritional Diseases, Faculty of Veterinary Medicine, University of Uludag, Bursa, Turkey.*

The objective of this trial was to evaluate the effects of feed restriction (FR) on serum concentrations of glucose, nonesterified fatty acids (NEFA), progesterone (P4), insulin and follicle-stimulating hormone (FSH), and milk production in dairy cows. Eight pregnant multiparous Holstein cows, 114 ± 14 d in milk and 685 ± 39 kg body weight (BW) at trial initiation were randomly assigned to a replicated 4 × 4 Latin Square design with 14-d periods. During the first 8 d of each period, all cows were fed for ad libitum feed intake. On d 9 through d 12 of each period, the feed restricted groups were fed 25 and 50% of the average daily dry matter intake (DMI) based on previous 8-d ad libitum feeding. The 4 dietary treatments were: ad libitum (AL), 25% feed restriction (25FR), 50% feed restriction (50FR), and 50% feed restriction produced by adding 50% wheat straw to diet (50FRS). Blood samples were collected before feeding from jugular vein at 0700, 1500, and 2300h on d 8 and continuing through d 14 of each period. On d 12 of each period, blood samples were collected before and at 60, 120, 180, 240, 300, 360, 420, and 480 min after morning feeding. The conventional TMR compared with the TMR with straw was higher in crude protein (15.1 vs. 10.8%) and starch (26.8 vs. 17.0%) and lower in NDF (32.1 vs. 50.5%) concentrations. Cows fed AL had 6.7, 12.7, and 11.3 kg/d greater DMI than cows fed 25FR, 50FR, and 50FRS, respectively ($P < 0.0001$). Likewise milk production and glucose concentration followed the same linear decrease ($P < 0.0001$). Serum concentrations of insulin (μIU/mL) were lower ($P < 0.0001$) for cows fed 50FR (8.27) and 50FRS (6.24) than cows fed AL (16.65) and 25FR (11.16). Furthermore, plasma NEFA concentrations increased linearly ($P < 0.0001$) followed by linear BW ($P < 0.0003$) and BCS ($P < 0.02$) loss. In addition, serum P4 concentrations were lower for cows fed AL than cows fed 50FRS and 25FR ($P < 0.01$). FSH concentrations did not differ among treatments ($P > 0.10$). The current trial suggests that, FR results in lower glucose and insulin levels, fat mobilization, BW and BCS loss, and increased circulating P4 concentration.

Key words: feed restriction, reproductive hormones, dairy cows

T210 Fetal growth and maternal body condition following melatonin supplementation in adequately fed or nutrient restricted ewes. C. O. Lemley*, A. M. Meyer, L. E. Camacho, T. L. Neville, D. J. Newman, J. S. Caton, and K. A. Vonnahme, *North Dakota State University, Fargo.*

Low birth weight offspring often exhibit poor growth performance and lower daily rates of gross energy accretion. Using a maternal nutrient restriction model, we examined fetal growth following melatonin supplementation as a 2 × 2 factorial design. At d 50 of gestation 16 primiparous ewes were allocated to receive 100% (adequate; ADQ) or 60% (restricted; RES) of nutrient requirements and were supplemented daily with 5 mg of melatonin (MEL) or no melatonin (CON) until d 90. All ewes were exposed to a 12:12 light dark cycle with lights on at 0700 h and off at 1900 h. Ewes were fed a pelleted ration with or without melatonin 5 h before the end of the photophase (1400 h). Serum melatonin was determined over a 24 h period using an ELISA kit. Maternal BCS, back fat, and loin muscle area were examined at 50 and 90 d of gestation, while fetal growth was measured at d 48, 50, 60, 70, 80 and 90 of gestation using ultrasonography. The melatonin feeding schedule resulted in a melatonin treatment by h interaction ($P < 0.01$), where serum melatonin concentrations peaked at 1500 h in MEL. Melatonin concentrations remained elevated in MEL versus CON until the scotophase (1900 h). A gestational d by nutritional plane interaction ($P < 0.01$) was observed for maternal BCS, which was similar at d 50 and decreased in RES vs. ADQ at d 90. Moreover, a nutritional plane by melatonin interaction ($P < 0.05$) was observed for maternal BCS, where MEL-ADQ had a greater BCS vs. CON-ADQ and MEL-RES had a lower BCS vs. CON-RES. Maternal back fat tended ($P < 0.1$) to decrease while loin muscle area increased ($P < 0.05$) from d 50 to 90. All fetal growth parameters listed below increased ($P < 0.01$) with gestational day. Biparietal distance was similar between treatments ($P > 0.3$), while abdominal diameter tended ($P < 0.1$) to be larger in MEL vs. CON fetuses. Fetal kidney length and width were increased ($P < 0.05$) in MEL vs. CON. In conclusion, dietary melatonin appears to increase fetal kidney development, which may have direct implications in improving offspring performance.

Key words: fetal growth, melatonin, pregnancy

T211 Effects of realimentation after nutrient restriction during early to mid-gestation on uterine blood flow in pregnant beef cows. L. E. Camacho*[1,2], C. O. Lemley[1,2], B. W. Neville[1,2], C. R. Dahlen[1,2], G. P. Lardy[1,2], and K. A. Vonnahme[1,2], *[1]Center for Nutrition and Pregnancy; Department of Animal Sciences, Fargo, ND, [2]North Dakota State University, Fargo.*

During pregnancy, dramatic changes occur in the maternal cardiovascular system alongside prominent growth and development of the uteroplacental vascular bed. Pregnancy is associated with increases in cardiac output and uterine blood flow and a fall in systemic vascular resistance. We hypothesized the duration of nutrient restriction would impact uterine blood flow and vascular resistance. Moreover, we further hypothesized that upon realimentation, blood flow would ultimately surpass blood flow in control animals. Our objectives were to examine the effects of maternal realimentation after nutrient restriction during early to mid-gestation on uterine blood flow. Multiparous beef cows (n = 17) were assigned randomly to one of 3 treatments: 1) 100% NRC requirements from d 30 to 226 of gestation (CCC; n = 6); 2) 60% NRC from d 30 to 85, thereafter being re-alimented to 100% NRC to d 226 (RCC; n = 5); 3) or receive 60% NRC from d 30 to 140, thereafter being re-alimented to 100% NRC to d 226 (RRC; n = 6). Cows were individually fed once daily in a Calan gate system at 1500 h. Baseline measurements were obtained via Doppler ultrasonography at 0700 h on d 30 and every 14 d thereafter until d 226. Measurements include maternal heart rate (HR), uterine blood flow (BF), pulsatility index (PI), and resistance index (RI). Percentage change of each measurement from the initial measurement on d 30 was calculated. There was a treatment by day interaction ($P = 0.01$) for HR percentage change, where RCC reached a greater HR at d 156 compared with CCC and RRC was intermediate. Uterine BF percentage change was not affected by treatment ($P > 0.72$). However, there were treatment by day interactions ($P \leq 0.02$) for PI and RI where RRC cows had a greater reduction in resistance than CCC cows after d 140. In summary, although maternal realimentation after nutrient restriction did not affect uterine BF percentage change, maternal diet affected PI and RI percentage change. Further investigations in uterine and placental vascular reactivity may help explain the differences observed in resistance indices.

Key words: nutrient restriction, pregnancy, uterine blood flow

T212 Effects of propiogenic supplements on serum concentration of insulin and progesterone in nonlactating cows: I. Monensin. T. Leiva[1], M. Barbosa[1], R. O. Rodrigues[1], R. F. Cooke[2], and J. L. M. Vasconcelos*[1], *[1]UNESP – Faculdade de Medicina Veterinária e Zootecnia, Botucatu, SP, Brazil, [2]Oregon State University – Eastern Oregon Agricultural Research Center, Burns.*

Insulin has been shown to increase circulating progesterone (P4) concentrations by stimulating ovarian steroid synthesis and alleviating hepatic steroid catabolism. Therefore, the objective was to determine if monensin is a nutritional alternative to increase circulating concentrations of insulin and consequently P4 in forage-fed cows. Fifteen nonlactating ovariectomized Gir × Holstein cows were ranked by BW and BCS and randomly assigned to receive, in a crossover design, 0.1 kg/d of corn in addition to 2 g/d of kaolin (control) or 0.2 g/d of monensin Na (MO). During the study, cows were maintained in *Brachiaria brizantha* pastures, and received treatments individually in a feed bunk every morning. Each period contained 21 d, where the initial 5 d served as adaptation when MO and control cows received 0.1 kg/d of corn in addition to, respectively, 0.1 g of monensin or 1 g of kaolin. Within each period, cows received a previously used intravaginal P4 device (CIDR, originally containing 1.9 g of P4) on d 0, which was replaced by a new CIDR at the end of the adaptation period (d 5). Blood samples were collected on d 12, 13, 19, and 20 immediately before (0 h) and 6, 12, 18, and 24 h relative to treatment feeding. On d 12 and 19 cows had access to pastures between samplings, whereas on d 13 and 20 cows were maintained in the working facility without access to forage. Blood samples were analyzed for serum concentrations of insulin and P4. Within samples collected when cows had no access to pastures, a treatment × time interaction was detected ($P = 0.05$) for P4 and insulin. Cows receiving MON had greater ($P < 0.01$) P4 concentrations compared with control at h 18 (2.6 vs. 2.1 ng/mL, respectively) but reduced insulin concentrations at h 0 (4.9 vs. 6.9 μIU/mL, respectively; $P < 0.01$) and h 6 (3.3 vs. 4.7 μIU/mL, respectively; $P = 0.07$). No treatment differences were detected for insulin and P4 concentrations when cows had access to pastures. In conclusion, supplemental monensin reduced serum insulin concentration but increased, by alternative physiological mechanisms, serum P4 concentrations in feed restricted cows.

Key words: monensin, progesterone, insulin

T213 Effects of propiogenic supplements on serum concentration of insulin and progesterone in nonlactating cows: II. Propylene glycol. A. M. L. Madureira[1], M. A. S. Borges[1], R. O. Rodrigues[1], R. F. Cooke[2], and J. L. M. Vasconcelos*[1], *[1]UNESP – Faculdade de Medicina Veterinária e Zootecnia, Botucatu, SP, Brazil, [2]Oregon State University – Eastern Oregon Agricultural Research Center, Burns, OR, USA.*

Insulin can increase circulating progesterone (P4) concentrations by stimulating ovarian synthesis and alleviating hepatic catabolism. Therefore, the objective was to determine if propylene glycol (PPG) supplementation increases circulating concentrations of insulin and thus P4 in forage-fed cows under negative or positive nutritional balance. From d −7 to d 14, 15 nonlactating ovariectomized Gir × Holstein cows were maintained in a *Brachiaria brizantha* pasture with proper forage availability and received 2 kg of concentrate/d. From d 15 to d 42, cows were move to a *B. brizantha* pasture with reduced forage availability without supplementation. Cows were inserted with an intravaginal device containing 1.9 g of P4 on d −7, which was replaced every 14 d during the study. Mean cow ADG was 0.57 ± 0.1 kg/d from d −7 to d 14, and −0.37 ± 0.1 kg/d from d 15 to 28. On d 6 of the study, cows were ranked by BW and BCS and assigned to receive a drench with PPG or water (control) at 2.5 mL/kg of $BW^{0.75}$. Blood was collected, relative to treatment application (h 0), at −0.5, 0, 0.5, 1, 2, 3, 4, 5, 6, and 7 h for determination of serum insulin and P4 concentrations. Cows received concentrate and returned to pastures in-between samplings. On d 7, cows received the converse treatment in a crossover design and were sampled similarly as in d 6. On d 13 and 14, 20 and 21, and 27 and 28, cows were again assigned to the same crossover and sampling schedule, but were not fed during the collection period. When cows were on adequate nutritional status, independently if feed restricted or not, PPG cows had greater ($P < 0.01$) insulin but reduced ($P < 0.01$) P4 concentrations compared with control cows (8.5 vs. 4.3 μIU/mL of insulin and 1.89 vs. 2.04 ng/mL of P4, respectively). However, when cows were on negative nutritional balance, PPG cows had greater ($P < 0.01$) insulin and P4 concentrations compared with control cows (7.0 vs. 3.4 μIU/mL of insulin and 2.16 vs. 2.03 ng/mL of P4, respectively). In conclusion, PPG supplementation increased circulating insulin and P4 concentrations only in cows under negative nutritional balance.

Key words: propylene glycol, insulin, progesterone

T214 Follicular fluid composition in cyclic Hereford cows supplemented with rice bran in grazing conditions. L. Veloz[1,2], M. E. Trobo[1,2], C. García Pintos[1,2], C. Viñoles[2], and M. Carriquiry*[1], *[1]School of Agronomy, UdelaR, Montevideo, Uruguay, [2]National Research Institute for Agriculture, Tracuarembó, Uruguay.*

The aim of this study was to evaluate the effect of short-term supplementation with rice bran before initiation of the breeding period on follicular fluid composition of beef cows grazing native pastures. Fifteen non-pregnant nonlactating Hereford cows (492 ± 6 kg BW and 5.6 ± 0.1 BCS, scale 1–8) were randomly allocated to 2 groups: control, non-supplemented (CON, n = 7) and supplemented (SUP, n = 8). The supplement (2.5 kg/cow of whole rice bran; 90.3%DM, 10%CP, 9%EE, 14%NDF) was fed daily for 23 d. All cows grazed on native pasture. Cows were synchronized with 3 prostaglandin (PG) injections 11 d apart. Thirty-six hours after the last PG injection, cows were castrated and all follicles ≥5mm were dissected and follicular fluid was aspirated for metabolite and hormone analyses. Means from a mixed analyses were considered to differ when $P < 0.05$. Follicular size did not differ between cow groups and averaged 10.2 ± 1.0 mm. Estrogen (19750 vs. 10009 ± 16570 pmol/L) and progesterone (135.7 vs. 108.5 ± 29.9 ng/mL) concentrations as well as estrogen/progesterone ratio (229.9 vs 273.2 ± 188.1) in follicular fluid were not different between SUP and CON cows. Similarly, glucose, nonesterified fatty acids, and cholesterol concentrations in follicular fluid (74.3 vs. 81.1 ± 8.5 mg/dL, 0.87 vs. 0.82 ± 0.05 mmol/L, 111.0 vs. 95.3 ± 10.1 mg/dL, SUP vs. CON, respectively) were not affected by nutritional treatment. Glucose concentrations increased and cholesterol concentrations tended ($P = 0.09$) to increase with follicle size (3.8 ± 0.9 mmol/L and 2.9 ± 1.6 mmol/L for each mm of increase in follicle size, respectively). Results susggest that short-term supplementation did not affect follicular fluid composition in cyclic beef cows in good BCS on grazing conditions

Key words: cattle, nutrition, ovary

T215 Capability of a new or once-used CIDR to develop persistent follicles and the capability of additional progesterone for persistent follicle turnover in replacement beef heifers. G. H. L.

Marquezini*, T. E. Black, K. M. Bischoff, V. R. G. Mercadante, and G. C. Lamb, *North Florida Research and Education Center, University of Florida, Marianna.*

Two experiments evaluated the capability of new or once-used (for 7 d) CIDR to develop a persistent follicle and we hypothesized that high concentrations of progesterone with an additional CIDR would induce turnover of the persistent follicle. In Exp. 1, 59 crossbred heifers received a new (n = 29) or once-used (n = 30) CIDR from d 0 to 11. On d 8 heifers assigned randomly to receive either an injection of saline (n = 19), a second new CIDR from d 8 to 11 (n = 20), or follicular aspiration of all follicles ≥ 5mm (n = 20) resulting in a 2 × 3 arrangement of treatments. Transrectal ultrasonography was used daily to monitor follicular development and follicle turnover. When the dominant follicle had failed to turnover by d 8 the follicle was deemed to be persistent. Follicle turnover was defined as a dominant follicle that was present on d 8 that had disappeared by d 11. Heifers receiving the once-used CIDR (83%) tended ($P = 0.10$) to develop more persistent follicles than those receiving the new CIDR (64%). For treatments on d 8, 100% of heifers receiving follicular aspiration had follicle disappearance by d 11 which was greater ($P < 0.05$) than those receiving a second new CIDR (69%) which was greater ($P < 0.05$) than those receiving saline (32%). In Exp. 2, 41 heifers received a once-used CIDR from d 0 to 13 and all follicles ≥ 5mm were aspirated on d 0. On d 10 heifers were assigned randomly to one of 2 treatments: 1) injection of saline (Sal; n = 21); or 2) new additional CIDR insert for 3 d (CIDR; n = 20). Blood samples and ultrasonography were performed daily from d −10 to 16 to evaluate concentrations of progesterone (P4) and monitor follicle development and turnover. Concentrations of P4 were greater ($P < 0.01$) for CIDR than Sal at 4, 8, and 72 h after treatment on d 10. However, the ability of the CIDR (58%) and Sal (64%) treatments were similar. We conclude that a once-used CIDR develops more persistent follicles than new CIDR, whereas follicular aspiration was more effective at follicle turnover than an additional CIDR or saline treatments.

Key words: persistent follicle, beef heifer, progesterone

T216 Influence of CIDR-based protocols associated with supplementation of calcium soap on reproductive performance of Nellore cows. M. V. Biehl*[1], A. V. Pires[1,2], I. Susin[2], D. D. Nepomuceno[2], J. R. S. Gonçalves[4], L. H. Cruppe[3], F. M. Da Rocha[1], and M. L. Day[3], *[1]University of Sao Paulo, Pirassununga, SP, Brazil, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]Ohio State University, Columbus, [4]Experimental Station Georgina Hildegard von Pritzelwitz, Londrina, PR, Brazil.*

The aim of this study was to compare reproductive performance of lactating Nellore cows (n = 264) submitted to estrus synchronization using either 7 or 9 d CIDR+Estradiol Benzoate (EB) program and 3 mineral supplements. Cows were blocked according to BW (428.5 ± 50.4 kg) and BCS (2.84 ± 0.23, 1 to 5) in a 2x3 (2 protocols and 3 supplements) factorial arrangement. The supplement treatments were mineral mixture (MM); MM+Megalac E+Citrus Pulp (CP) (MEG); MM+Kaolim+CP (KAO). At the beginning of the experiment, cows were 55 ± 0.36 d postpartum. Supplementation treatments began 30 d before the initiation of the synchronization program and were terminated 30 d after timed AI. Blood samples for progesterone analysis were collected 10 d before and at CIDR insertion to classify cows as cyclic. The CIDR was inserted with a 2 mg injection of EB and it was removed either 7 or 9 d later. All cows received 25 mg PGF2α (Lutalyse) 48 h before CIDR withdrawal and 300 IU eCG (Novormon) and 0.6 mg estradiol cipionate (ECP) at CIDR removal. Treatments were defined as follow: 7dMM (n = 42; e.g., 7d CIDR and MM supplementation), 7dKAO (n = 46), 7dMEG (n = 47), 9dMM (n = 40), 9dKAO (n = 46), and 9dMEG (n = 43). Estrus was detected for 5 d after CIDR removal and timed AI was performed 50 h after CIDR withdrawal. Second estrus detection was performed 16 d after timed AI for 6 d and AI submitted. Pregnancy diagnosis was performed by US 60 d after timed AI and at the end of the breeding season. At CIDR insertion, 85% (224/263) of cows were in anestrus. Estrus was detected in 52.8% (139/263) of the cows and time to estrus (43.5 ± 5.7 h after CIDR removal) did not differ among treatments. Timed AI pregnancy rates did not differ between supplements MM, 51; KAO, 69.5; MEG, 54.7% or with 7 d, 57.1, 58.7 and 52.5%, 9 d of CIDR treatment. Pregnancy rates were not different at the end of the breeding season. In conclusion, supplementation with Megalac E or Kaolin, did not improve reproductive performance in this study. In addition, timed AI pregnancy rates did not differ between CIDR treatments of 7 or 9 d in the CIDR-EB program used in the present study.

Key words: Megalac E, estrus, cows

T217 Effect of dietary conjugated linoleic acid on reproduction and tissue responses in dairy cows. G. Esposito*[1,2], A. Schneider[3], V. A. Absalón Medina[2], S. H. Pelton[2], and W. R. Butler[2], *[1]University of Naples Federico II, Naples, Italy, [2]Cornell University, Ithaca, NY, [3]Universidade Federal de Pelotas, Pelotas, RS, Brazil.*

Feeding rumen-protected isomers of conjugated linoleic acid (CLA) to early lactation dairy cows reportedly improves fertility by reducing the postpartum interval to first ovulation and enhancing circulating IGF-I levels. CLA supplementation increases high density lipoprotein (HDL) cholesterol in mice. Also, in vitro studies with bovine granulosa and luteal cells have shown that HDL and LDL promoted granulosa cell viability and stimulated IGF-I production. The objectives of this study were to examine ovarian follicles, corpora lutea, and liver tissues for effects induced by dietary CLA supplementation (top-dressed once daily from 15 d before expected calving to 65 DIM). Twenty-four lactating Holstein cows were assigned to 2 treatments: control and CLA diet. Milk production and DMI were recorded daily and milk components every 10 d. At 26 DIM ovulation was synchronized with a vaginal controlled internal drug-releasing device and injection of GnRH followed by an injection of PGF2α after one week. Blood samples were collected every 4 d. Follicular fluids, from follicles larger than 9mm, were collected every 8 d from 34 DIM. Plasma and follicular fluid samples were analyzed for estradiol (E2), progesterone, IGF-I, cholesterol, LDL, and HDL. At 56 DIM ovulations were synchronized in all cows. The resulting CL and the liver were biopsied at 64 and 65 DIM, respectively. Tissues were analyzed for gene expression of IGF-I, GHR, VEGFA and ANGPT2 or for PPARα, IGF-I, GHR, PC and PECK, respectively. In the CLA treated cows milk fat production was lower ($P < 0.05$) and energy balance was improved ($P < 0.05$). No differences between the 2 groups were observed for milk production. CLA-supplemented cows tended to have higher plasma concentrations of E2 and LDL ($P < 0.1$) and plasma concentrations of IGF-I were higher ($P < 0.001$). No differences were observed for the mRNA expression in tissues. This study confirms the improvement of plasma IGF-I levels, but dietary CLA did not alter plasma lipoprotein concentrations in cows as had been shown in mice. Moreover, CLA supplementation failed to alter gene expression in the tissues examined.

Key words: CLA, ovarian follicles, corpus luteum, liver

T219 Endocrine and ovarian parameters associated with increased fertility after resynchronized timed artificial inseminations in lactating dairy cows. J. O. Giordano*, M.C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin, Madison.*

Lactating dairy cows failing to conceive to a previous timed AI (TAI) were resynchronized to receive TAI either using Double-Ovsynch (DO, Pre-Resynch, GnRH–7 d–PGF–3 d–GnRH, 7 d later Breeding-Resynch, GnRH–7 d–PGF–56 h–GnRH–16 h–TAI) or Ovsynch initiated 32 d after TAI (D32, GnRH–7 d–PGF–56 h–GnRH–16 h–TAI). All DO cows received the first GnRH injection of Pre–Resynch 22 d after TAI, and cows (n = 981) diagnosed not pregnant using ultrasonography (US) 29 d after TAI continued the protocol. All D32 cows received GnRH 32 d after TAI, and cows (n = 956) diagnosed not pregnant using transrectal palpation 39 d after TAI continued the protocol. In subgroups of DO and D32 cows, the proportion of cows with a functional corpus luteum (CL) at the first GnRH of Breeding-Resynch and D32 protocols (G1), CL regression after PGF, and ovulation to the last GnRH (G2) of both protocols was determined using US and serum progesterone (P4). Pregnancy diagnosis was performed 29 d after TAI using US. Overall, P/AI was greater ($P < 0.01$) for DO vs. D32 cows (38.7 vs. 30.0%). The proportion of cows with high (HP4) vs. low P4 (LP4; cutoff 0.5 ng/mL) at G1 was greater ($P < 0.01$) for DO vs. D32 cows [86.7 (368) vs. 62.5% (375)]. At 29 d after TAI, cows with HP4 at G1 had greater ($P < 0.01$) P/AI than LP4 cows [33.9 (554) vs. 19.5% (190)], and cows that ovulated to G1 had greater ($P < 0.01$) P/AI than cows that did not [32.6 (285) vs. 28.3% (466)]. Synchronization rate (HP4 at PGF, LP4 at G2, and ovulation to G2) was greater ($P < 0.01$) for DO vs. D32 cows [71.8 (223) vs. 50.5% (210)]. At 29 d, P/AI were similar between treatments for synchronized [D32 = 43.4 (106) vs. DO = 43.1% (160)] and non-synchronized [D32 = 9.6 (104) vs. DO = 4.8% (63)] cows. Similarly, synchronization rate was greater ($P < 0.01$) for cows with HP4 at G1 [69.2 (321) vs. 37.1% (105)] and for cows that ovulated to G1 [65.6 (151) vs. 58.9% (275)]. We conclude that resynchronized lactating cows that had high P4 at G1 and that ovulated after G1 had an increased synchronization rate resulting in increased fertility to TAI. Supported by Hatch project WIS01171

Key words: double-Ovsynch, resynchronization

T220 Use of the CIDR+EB synchronization program in prepubertal Nellore heifers. M. V. Biehl*[1], A. V. Pires[1,2], I. Susin[2], L. H. Cruppe[3], D. D. Nepomuceno[2], J. R. S. Gonçalves[4], F. M. Da Rocha[1], and M. L. Day[3], *[1]University of Sao Paulo, Pirassununga, SP, Brazil, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]Ohio State University, Columbus, [4]Experimental Station Georgina Hildegard von Pritzelwitz, Londrina, PR, Brazil.*

The objective of this study was to compare reproductive performance of prepuberal Nellore heifers (n = 407) using either a 5, 7, 9 or 11 d CIDR treatment with an estradiol benzoate (EB)-based synchronization program. Heifers were blocked to treatments based on body weight (282 ± 18 Kg) and body condition score (2.63 ± 0.21, scale of 1 to 5) in a 4 × 2 factorial arrangement. All animals received 2 mg EB at time of CIDR insertion, and after either 5, 7, 9 or 11d the CIDR was removed and all heifers received 25mg PGF2α (Lutalyse) and 300 IU of eCG (Novormon). Approximately half of the heifers in each treatment were administered 1mg EB at 48 h after CIDR withdrawal. Therefore, experimental treatments were designated as 5d-EB (n = 61; e.g., 5 d of CIDR with 1mg EB 48 after CIDR removal), 5d (n = 51; e.g., 5 d of CIDR without EB after CIDR removal), 7d-EB (n = 51), 7d (n = 47), 9d-EB (n = 49), 9d (n = 50), 11d-EB (n = 52) and 11d (n = 46). Estrus detection was performed for 5 d after CIDR removal and artificial insemination (AI) was performed according to the AM/PM protocol. Detection for return to estrus and AI, in heifers not conceiving to the initial AI, began 16 d after CIDR withdrawal and continued for 6 d. Pregnancy was diagnosed by ultrasonography 60 d after the first AI. Binominal data were analyzed using GLIMMIX procedures of SAS. During the synchronization period (5 d after CIDR withdrawal), a greater ($P < 0.05$) proportion (87.3%) of heifers that received EB presented estrus as compared with the proportion (54.6%) of heifers with no second EB treatment in estrus. Timing (68.1 ± 17.3 h after CIDR removal) and distribution of estrus did not differ among treatments. The additional EB did not increase conception rate, but tended ($P = 0.06$) to improve pregnancy at first AI (with EB, 21.6; without EB, 14.9%). Final pregnancy rates did not differ among treatments. Effects of the duration of CIDR treatment were not detected. In prepubertal Nellore heifers, inclusion of EB treatment at 48h after CIDR removal improved estrus response, did not influence conception rate, but tended to improve pregnancy rate following treatment with CIDR.

Key words: prepuberal, heifers, estradiol benzoate

T221 Effects of ethanol and acetic acid fed to high-producing dairy cows on blood parameters. J. L. P. Daniel*, L. G. Nussio, R. C. Amaral, E. H. C. Garcia, A. W. Bispo, F. C. L. Oliveira, I. F. Silva, and M. Zopollatto, *University of Sao Paulo, College of Agriculture "Luiz de Queiroz", Piracicaba, SP, Brazil.*

Ethanol and acetic acid are common end products from silages, especially from tropical forages. The objective of this study was to determine whether ethanol and acetic acid affect plasmatic glucose, insulin, ethanol, and gamma-glutamyl transferase (GGT) at peripheral blood. Hypothetically, ethanol present in the diet could reach portal blood, damage liver and increase GGT activity. Thirty lactating Holstein cows averaging 40 kg/d of milk at beginning of trial were grouped in 10 blocks and fed either: Control (33% Bermuda hay + 67% concentrates); Ethanol (control diet + 5% ethanol on DM basis); or Acetic acid (control diet + 5% acetic acid on DM basis) diets. Ethanol and acetic acid were diluted in water (1:2) and sprayed onto total mixed ration twice daily before feeding. The same amount of solution was replaced with water in the control diet. During the 1st week of trial the cows received half-dose of these chemical compounds. Blood was collected from coccyges vessels into evacuated tubes containing sodium heparin, 6 h after morning feeding on d 7, 14 and 42. Tubes were immediately centrifuged and plasma was frozen for a 28d period. Plasmatic concentration of ethanol was lower than 0.1 g/L in all cows. Diets did not affect ($P = 0.95$) plasmatic GGT (26.2, 27.0, and 26.6 U/L, respectively for control, ethanol and acetic acid diets). Insulin concentration was unaffected ($P = 0.96$) across diets (0.28, 0.27, and 0.29 mU/L, respectively). However, blood from cows supplemented with acetic acid showed lower ($P = 0.04$) glucose concentration (58.3 mg/dL) than those fed ethanol containing diets (62.7 mg/dL). It might be due to the lower dry matter intake observed, during 2nd and 3rd experimental weeks, from cows fed acetic acid (not showed). Control diet presented an intermediary blood sugar level (61.0 mg/dL). In conclusion, blood parameters were not altered by feeding ethanol to high producing dairy cows, up to studied level. The conversion of ethanol to acetate into the rumen might be a plausible explanation to understand the ordinary blood parameters to the alcohol containing diet.

Key words: GGT, insulin, glucose

T222 Estrous response in yearling and multiparous ewes during reduction on the synchronized luteal phase and eCG injection. J. L. Cordero[1], T. Sánchez[1], P. Molina[2], R. Nieto[1], J. Peralta[2], O. Mejía[3], L. Olivares[4], E. García*[5], and J. L. Figueroa[1], *[1]Colegio de Postgraduados, Texcoco, Estado de México, [2]Universidad Autónoma del Estado de Hidalgo, Tulancingo, Hidalgo, México, [3]FMVZ, Universidad Autónoma de México, Tres Marías, México, [4]Universidad Autónoma del Estado de México, Toluca, Estado de México, [5]CUCSUR, Universidad Autónoma de Guadalajara, Jalisco, México.*

The aim of the experiment was to evaluate the effect of reducing the synchronized luteal phase and eCG injection in yearling and multiparous ewes and their response on estrous and pregnancy rate. Seventy-nine ewes were divided according to their reproductive status in yearling (n = 36) and multiparous (n = 43), which were then randomly subdivided into groups for the assignment of hormonal treatments. Ewes were pre-synchronized with 2 doses of prostaglandin F2α (cloprostenol, 65 mg) 8 d apart, before sponge insertion. Yearling ewes (P) were synchronized with cronolone sponges (20 mg) for a 12 d period (P12+0, n = 8) without and with 100 IU of eCG injection (P12+eCG, n = 9); and for a 6 d period without (P6+0, n = 9) and with 100 IU of eCG injection (P6+eCG, n = 10), both eCG injections were given at sponge removal. Multiparous ewes (M) were synchronized by the same protocol (M12+0, n = 12; M12+eCG, n = 11; M6+0, n = 9 and M6+eCG, n = 11, respectively). All ewes (P and M) showed estrous response (100%) after sponge removal. There were no differences ($P \geq 0.05$) for reduction of the synchronized luteal phase and eCG injection in beginning and estrous duration in yearling ewes. However in multiparous ewes estrous duration was affected ($P \leq 0.05$) by reduction of the luteal phase (M12, 37.04 ± 1.9 vs M6, 45.2 ± 2.1) and eCG injection (M+0, 36.2 ± 1.5 vs M+eCG, 32.8 ± 1.1). There was no difference ($P \geq 0.05$) in gestation rate between groups (P = 86 and M = 81%). It is concluded that reducing the period of synchronization or eCG injection does not alter the response, onset and duration of estrous in yearling ewes, but it does alter estrous duration in multiparous ewes, so it should be considered when performing AI at fixed time or when yearling and multiparous are synchronized together.

Key words: *Ovis aries*, estrus synchronization, progestogen

T223 Fertility following fixed-time AI in infertile CIDR-treated dairy cows given rbST throughout extended (>500 d) lactations. A. Zúñiga-Serrano*, F. G. Véliz-Deras, J. Méndez-Lara, L. M. Tejada-Ugarte, and M. Mellado-Bosque, *Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México.*

With extended lactations (beyond 17 mo) due to the use of rbST throughout lactation, attempts to fecundate subfertile cows around 300 d in milk (DIM) can be commercially viable. Thus, the purpose of this study was to determine, using multiple logistic models, factors affecting pregnancy rates (PR) following fixed-time AI (FTAI) in subfertile (up to 12 services) cows treated with rbST throughout lactation. Four hundred ninety-eight Holstein cows of all parities, unable to become pregnant when approaching 300 d in milk received a CIDR device and 100 mg of GnRH on Day 0. CIDR removal and PGF2α (25 mg) treatment were done concurrently on Days 7. Estradiol benzoate (2 mg) was injected on d 8 and GnRH on d 9; cows were inseminated 16–20 h later. Cows that produced <15000 kg of milk in their previous lactation had only half the chance ($P < 0.05$) to become pregnant compared with cows with total lactations of > 15000 kg. Cows with an average milk fat <3% in their previous lactation were 43% more likely ($P < 0.05$) to become pregnant at FTAI than cows with milk fat >3%. Cows with <5 services had significantly increased chances of becoming pregnant than cows with >5 services at FTAI (PR 36 vs. 27%; $P < 0.05$). Cows with less than 2 lactations were 1.7 times more likely ($P < 0.05$) to become pregnant than older cows. Cows with >350 DIM were less likely to become pregnant (PR 27 vs. 35%; $P < 0.05$) than cows subjected to FTAI with <350 DIM. Cows with peak milk yields lower than 55 kg were 1.5 times more likely to conceived than cows with peak milk yields greater than 55 kg (PR 28 vs. 37%; $P < 0.05$). Cows subjected to FTAI with a temperature-humidity index (THI) <73 were 45% more likely ($P < 0.05$) to become pregnant than cows inseminated with a THA >73. It was concluded that an acceptable percentage of subfertile cows can become pregnant with the protocol used in the present study, and this practice seems to be biological feasibility and economically justifiable in dairy operations with 3X milking and the use of rbST throughout lactations, which would assure lactations >500 d.

Key words: reproductive performance, estrus synchronization, Holstein cows

T224 Adiponectin system and peroxisome proliferator-activated receptor gamma2 (PPARγ2) mRNA abundance in different bovine fat depots considering conjugated linoleic acids (CLA) or lactation stage related changes. B. Saremi*[1], H. Sauerwein[1], D. von Soosten[2], S. Dänicke[2], and M. Mielenz[1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

Adiponectin (Ad) is secreted from adipose tissue (AT) and exerts insulin sensitizing effects via Ad receptor 1 and 2 (AdR1/2) in humans. PPARγ2 increases plasma Ad concentrations and thus improves insulin sensitivity in monogastrics. We hypothesized that the CLA-induced reduction of milk fat might improve energy balance and insulin sensitivity in dairy cows. From 25 heifers, 5 were slaughtered on d 1 postpartum. Remaining heifers were randomly allocated to CLA (Lutrell pure, BASF, Germany, n = 10) or control fat supplementation (Silafat, BASF, n = 10) each at 100 g/d. Five animals per group were slaughtered at d 42 or 105. Subcutaneous (Sc) (chest, wither and tail head) and visceral (Vc) AT (mesenterial, omental and retroperitoneal) samples were collected. Ad, AdR1/2 and PPARγ2 mRNA abundance (Ab) was quantified by qPCR. Pearson correlation, GLM or non parametric tests were used for statistical analysis (SPSS 17; $P < 0.05$). Ad, AdR1 and PPARγ2 Ab increased from d 1 and 42 to d 105 in most VcATs. AdR1 Ab was highest at d 105 in all ATs except omental fat. In the merged data from VcATs, Ad and AdR2 were reduced in CLA-treated heifers at d 105. Comparing individual AT depots, Ad and AdR2 Ab was reduced in omental and retroperitoneal AT from CLA-treated animals. PPARγ2 was increased by CLA in Vc depots regardless of time. In general, the different depots had different Ab values, e.g., retroperitoneal AT displayed higher Ad, AdR1 and AdR2 Ab than mesenterial AT. Ad Ab was correlated to AdR1/2 and PPARγ2 (r = 0.5, 0.8, and 0.5, respectively). In conclusion, the observed CLA effects on Ad and AdR2 as well as the timely changes of Ad, AdR1 and PPARγ2 Ab were fat depot dependent. The increase in Ad and AdR1 Ab at d 105 (post peak lactation) is possibly regulated by PPARγ2, and might improve insulin sensitivity as compared with pre-peak lactation (d 42). As to whether the effects of CLA on the Ad system and PPAR expression will affect insulin sensitivity in the different depots and in the entire organism remains to be clarified.

Key words: adipose tissue, adiponectin, PPARγ2

T225 Relationship between follicular and ovulatory responses with embryo production during superovulatory treatment in cattle. H. Kohram[1,2] and M. Poorhamdollah*[1], [1]*Department of Animal Science, Faculty College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran,* [2]*Department of Clinical Sciences, Faculty of Veterinary Medicine, Shahid Chamran University, Ahvaz, Iran.*

The efficiency of embryo transfer technology is still limited because of high variability and unpredictability of superovulatory responses of the donor cows. The aim of this study was to investigate relationship between follicular and ovulatory responses with embryo production during superovulatory treatment in cattle. The experiment was carried out in one to 4 random cycles of superovulation in 47 Holstein cows, for a total of 88 superovulatory cycles. Animal were superstimulated between d 8 and 12 of estrous cycle with 400 mg Folltropin-v given in decreasing doses: 3.5; 3, 3; 2.5, 2.5; 2, 2; 1.5 mg (a.m. and p.m.) over 4 d and luteolysis was induced with 2 mg intramuscularly injection of Cloprostenol with the 7 injection of folltropin-v. The ovaries of all cows were examined by ultrasonography on the day of estrus following superovulatory treatment and on the day of embryonic collection (7 d after estrus). Ova and embryos were collected by a nonsurgical procedure, evaluated and classified as quality I (freezable), quality II (transferable) and degenerated embryos. Criteria used to classify each type of superovulatory responses as low, medium or high. For each type of the superovulatory responses, data were analyzed by means of the GLM procedure of the SAS. The results showed in Table 1. In conclusion the high follicular or ovulatory responses are not necessarily coupled with a high yield of embryos.

Table 1. Percent of superovulation cycles with various types of responses

	Class		
Type of response	Low (%)	Medium (%)	High (%)
Follicle ≥ 7 mm at estrus	10	21	69
Ovulations	23	24	53
Quality I embryos	59	22	19
Quality II embryos	77	18	5
Quality I+ II embryos	52	24	24
Degenerated embryos	80.6	17.1	2.3

Key words: embryo, superovulation, Folltropin-v

T226 Differentiation of estrus versus nonestrus cow cervix morphology: Verification of a cost-effective methodology. A. Nikkhah*, M. A. Sirjani, A. A. Assadzadeh, and H. Amanloo, *University of Zanjan, Zanjan, Iran.*

The increasing trend in milk solids secretion over the last few decades has noticeably depressed cow fertility. Accurate estrus detection has been a major challenge to achieve. Our objective was to quantify dairy cow cervix morphology during standing-estrus (SE) and nonestrus (NE) days of the estrus cycle. Four multiparous Holstein cows (50 ± 14 d in milk, 31 ± 3.6 kg milk yield, 643 ± 66 kg BW, 3.0 ± 0.18 BCS) were monitored daily for cervical region morphologies for an entire 21-d estrus cycle. The cervix was videotaped using a recording on-farm apparatus to score tissue morphology as affected by estrus. The apparatus had 45 cm length and 2.7 cm diameter, internal electrical settings, external polyvinyl coat, lights on the front, wires at its terminal, and a connection to a laptop computer with an image processing software. Cervix was scored for distinctness from surrounding vaginal tissues, central positioning, motility, and secretions on a 5-scale basis. The score of 1 described cervices with quite distinct, central, stable, and mucosal manifestation, and the score of 5 represented quite nonseparate, noncentral, moving, and dry appearance. Data were analyzed as a mixed model with fixed day effect and random effects of cow within day plus residuals. Findings demonstrated that cervix area was markedly ($P < 0.01$) more distinct (1.0 vs. 3.0), more central (1.1 vs. 3.6), more stable (1.5 vs. 2.8), and more mucosal (1.1 vs. 3.7) during SE than NE days. As such, on SE days, the cervix was rigidly observable in the central end of vaginal tract, whereas NE cervices were hardly separable from the surrounding tissues. The data verify our earlier results and establish the on-farm feasibility of using the new inexpensive technique (e.g., <US$200) to differentiate SE and NE cervices.

Key words: cervix, morphology, estrus

T227 Metabolic characteristics of pregnant gilts fed low and excess protein diets associated to intrauterine growth retardation (IUGR). C. C. Metges*[1], I. S. Lang[1], U. Hennig[1], M. Peters[1], K.-P. Brüssow[1], E. Kanitz[1], M. Tuchscherer[1], F. Schneider[1], J. Weitzel[1], A. Ooster[2], H. Sauerwein[2], G. Nürnberg[1], C. Rehfeldt[1], and W. Otten[1], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*Institute of Animal Science, Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany.*

Limited and excess dietary protein in pregnant gilts lead to IUGR (Rehfeldt et al. 2011, J. Anim. Sci.). To explore metabolic reasons, gilts' plasma metabolite and hormone concentrations were analyzed. Low (6.5%, LP), adequate (12%, AP), and high (30%, HP) protein diets were fed to 16, 17, and 15 pregnant gilts, respectively. At d −5, 24, 66, and 108 of pregnancy fasted blood was collected. Concentrations of glucose (Glc), triglyceride (TG), nonesterified fatty acids (NEFA), cholesterol (C), low density lipoprotein cholesterol (LDLC), high density lipoprotein cholesterol (HDLC), insulin, glucagon (Gg), leptin, insulin-like growth factor-1 (IGF1), cortisol and progesterone (P_4) were analyzed in plasma; urea (U) and protein were analyzed in serum. At d 92, in 9 gilts/group diurnal blood samples were analyzed for Glc, NEFA, TG, C, and U metabolic profiles. Diet effects were evaluated with repeated measure ANOVA. Concentrations of HDLC were reduced in HP compared with AP gilts ($P < 0.01$). In LP gilts LDLC was lowest ($P < 0.01$). Highest and lowest U were observed in HP and LP ($P < 0.001$). Serum protein was lowest in LP gilts ($P < 0.05$). In the HP group Gg was higher than in LP and AP, whereas IGF1 was lower in LP than in AP gilts at d 24 and 66 ($P < 0.05$). Plasma P_4 was higher in HP than in LP and intermediate in AP ($P < 0.05$). In HP gilts cortisol levels were lower than in AP gilts ($P < 0.05$). Metabolic profiles indicated that plasma Glc was lower in HP ($P = 0.04$) and LP ($P = 0.09$) gilts. In HP U was 3 times the values observed in AP whereas in LP U reached only 60% of AP ($P < 0.001$). Plasma TG levels tended to be lower in LP than in AP ($P = 0.09$) and HP ($P = 0.07$). In HP diurnal NEFA levels were higher compared with AP and LP ($P < 0.01$). In LP gilts C was higher than in AP and HP ($P < 0.01$). In conclusion, HP gilts have a low glucose and energy status as reflected in higher NEFA and lower body fat. In LP gilts, deficiency of essential amino acids altered lipoprotein and C metabolism and favored lipid disposal. Both conditions are related to IUGR. Supported by Deutsche Forschungsgemeinschaft ME1420/8-1 and OT 137/3-1 (PAK 24)

Key words: high protein, metabolites, pregnancy

T228 Induction of luteal tissue in PGF_{2a}-treated sows. D. Gandy*, A. L. Greathouse, H. Klienman, F. M. LeMieux, and C. E. Ferguson, *McNeese State University, Lake Charles, LA.*

In the sow, corpora lutea must be present the entire length of gestation in order for the pregnancy to result in normal parturition at ~114 d post-mating. The objective of this experiment was to determine if induced luteal tissue following PGF_{2a} treatment could support pregnancy in the sow. A total of 12 cross-bred mature sows between the ages of 2 and 5 years were mated with a boar and evaluated for pregnancy at 30 to 60 d post-mating via ultrasonography. Pregnant sows were then allotted to 1 of 2 treatments, control or induction of luteal tissue. Sows randomly selected for the control treatment (n = 5) received 15 mg of PGF_{2a} 12 h apart and were then administered 30.8 mg of matrix at time of PGF_{2a} treatment. Then the matrix dose (daily) was reduced in a declining manner from to 22 mg, 15.4 mg, 6.6 mg and 0 mg matrix in 7 d intervals. Treatment sows (randomly selected for ovulation induction) were maintained on the same matrix schedule however, they received 750 IU of eCG 7 d post-PGF_{2a} and 500 IU hCG 48 h post-eCG. Blood samples were collected on all sows at 0, 4, 8, 12 and 24 h post-PGF_{2a} and 48 h post-hCG. There were no differences in the number of sows aborting in the control group (5/5, 100%) and the treatment group (7/7, 100%). The time from the start of 0 mg matrix to abortion was not different between the control group (1.8 ± 0.3 d) and the treatment group (5.0 ± 2.8 d). Among treatment sows, 2/7 (29%) developed luteal tissue (≥2 ng/mL P_4 48 h post-hCG) in response to eCG and hCG treatment while 5/7 (71%) did not (≤2 ng/mL P_4 48 h post-hCG) and success of induced luteal tissue may have affected the length of pregnancy maintenance. The length of time from 0 mg of matrix to abortion for sows with induced luteal tissue was 13 ± 7.5 d compared with 5.0 ± 2.8 d for sows with no induced luteal tissue. There was a high positive correlation $r^2 = 0.90$ between P_4 levels 48 h post-hCG and days to abortion post-hCG. These results indicate that pregnancy can be maintained in a PGF_{2a}-treated sow and induced luteal tissue can extend gestation in the absence of supplemental P_4.

Key words: abortion, pregnancy, luteal

T229 Effects of increased GnRH dose post–TAI in Brahman influenced cattle. B. Pousson*[1], D. J. Kesler[2], M. Poole[1], W. Storer[1], and C. E. Ferguson[1], *[1]McNeese State University, Lake Charles, LA, [2]University of Illinois, Urbana-Champaign.*

Brahman cattle have a history of lower pregnancy rates following artificial insemination (AI) compared with European cattle. The decrease in pregnancy rates among Brahmans has been linked to the higher excitability in stressful situations in which an increase in cortisol can result in delaying or blocking ovulation. This experiment was designed to determine if an increased GnRH dose at AI would improve pregnancy rate in Brahman and Brahman–type cattle. From 6 different location in Texas and Louisiana a total of n = 50 heifers, n = 123, cross–bred Angus heifers (no Brahman influence), n = 83 lactating cross-bred Brahman cows were bred using conventional semen following a CO-Synch+CIDR schedule with timed artificial insemination (TAI) at 48 to 58 h. Additionally, n = 32 Brahman dry cows were bred using sex–sorted Brahman semen (sorted for Y–chromosome) and the same synchronization schedule and TAI. All females were randomly selected to receive either 100 μg (n = 84) or 200 μg (n = 81) of GnRH at TAI and ultrasound for pregnancy ~30 d post-TAI. The administration of 200 μg GnRH at TAI resulted in a significantly higher ($P < 0.004$) pregnancy rate (0.43 ± 0.05) compared with 100 μg GnRH (0.21 ± 0.04). This pattern existed in heifers receiving 200 μg of GnRH (0.63 ± 0.10) vs. 100 μg GnRH, (0.29 ± 0.09), cows receiving conventional semen and 200 μg (0.40 ± 0.08) vs. 100 μg (0.23 ± 0.67) and cows receiving sex–sorted semen and 200 μg (0.21 ± 0.11) vs. 100 μg (0.06 ± 0.06). Among non-Brahman heifers increasing the dose of GnRH at TAI did not affect pregnancy rates 200 μg (0.49 ± 0.06) compared with 100 μg (0.55 ± 0.06). These results indicate that increasing the dose of GnRH at time of AI can result in an increase in the pregnancy rate in Brahman and cross-bred Brahman cattle, however there was no effect on pregnancy rate among non-Brahman heifers.

Key words: Brahman, ovulation, stress

T230 Dynamics of fat cell turnover in visceral and subcutaneous fat tissue in dairy cows. S. Häussler*[1], S. Dänicke[2], K. Friedauer[1], D. Germeroth[1], D. von Soosten[2], and H. Sauerwein[1], *[1]University of Bonn, Germany, [2]Federal Research Institute, Braunschweig, Germany.*

Adipose tissue can expand either by cell proliferation, cell enlargement or both. The number of adipocytes seems constant in mature humans; in cattle, in particular dairy cows, dynamics of fat cell turnover were unknown. To characterize lactation-induced changes in fat cell number, we targeted cell proliferation (marker Ki67) and preadipocyte differentiation (marker Pref-1) using immunohistochemistry, and apoptosis via the TUNEL method in both a visceral (retroperitoneal (RP)) and a subcutaneous (tailhead (SC)) depot obtained from 25 Holstein heifers. The heifers were divided in a control (CTR) and a CLA group; from d 1 of lactation until sample collection, animals from the CLA group were fed with 100 g CLA (Lutrell Pure, BASF, Germany) per day. On d 1, 42 and 105 postpartum, 5 animals of CTR were slaughtered; from CLA, 5 cows were slaughtered each on d 42 and 105. For the detection of apoptosis and Pref-1, deparaffinized sections (12 μm), for Ki67 frozen sections (14 μm) were used. Bovine lymph nodes (apoptosis), placenta (Pref-1) and liver (Ki67) served as controls. The portion (%) of positive cell was defined as mean number of positive stained cells/mean number of total cells x 100 and analyzed using the general linear model and the Student's *t*-test (SPSS). An apoptosis-proliferation index (A:P index) was calculated from the portions of apoptotic and proliferating cells. The A:P index was lower in RP than in SC due to a higher apoptotic rate in SC ($P \leq 0.001$) and concomitantly very low cell proliferation rates, irrespective of time and treatment. The same applied for preadipocyte portions being similar in both RP and SC, with mean values of 1.17 ± 0.33% for RP and 1.76 ± 0.65% for SC, respectively. In addition to decreasing fat cell size demonstrated in our group recently, the reduction of fat mass in early lactation seems to be dominated by apoptosis. Further dynamics of fat cell turnover are more likely defined by activation of preadipocytes than by cell proliferation.

Key words: bovine adipocyte, cell turnover, CLA

T231 Insulin sensitivity in obese (Iberian) and lean (Landrace) 50-kg barrows. I. Fernandez-Figares*, L. Gonzalez-Valero, J. M. Rodriguez-Lopez, and M. Lachica, *EEZ-CSIC, Granada, Spain.*

The Iberian pig is a slow growing obese breed with a distinct serum hormone and metabolite profile compared with lean (Landrace) pigs (Fernandez-Figares et al., 2007 Livest. Sci.110:73-81). The objective of the present work was to explore the possibility that Iberian pigs show peripheral insulin resistance. An intravenous glucose tolerance test was performed using Iberian (n=4) and Landrace barrows (n=5), 50 kg average BW, fitted with permanent carotid artery catheters. After surgery recovery, they were injected intravenously 500 mg glucose/kg

BW and blood samples collected at −10, 0, 5, 10, 15, 20, 25, 30, 45, 60, 90, 120, 150 and 180 minutes. Plasma samples were frozen in aliquots until analysis for glucose and insulin. Glucose was determined using Precision PCx Blood Glucose Test Strips. Insulin was determined using a Linco porcine insulin RIA kit and human insulin was used as standard. Responses of plasma glucose and insulin to the intravenous glucose challenge test was evaluated by computing areas under the response curves (AUC) for the 3-hour period following glucose administration determined using trapezoidal geometry. Insulin/glucose ratios were used as an index of insulin resistance. Area under the curves were analyzed using the GLM procedure of SAS. Insulin/Glucose ratios were evaluated using a mixed ANOVA with repeated measures with breed, time of sampling and their interaction in the model statement. Concentration at time zero of the analyte was included as a covariate in the statistical analysis. Significant differences among treatments were assessed using Bonferroni's multiple-range test. Iberian pigs had increased plasma insulin AUC (67.9%, $P < 0.01$) and insulin/glucose ratio (78.8%, $P < 0.001$) although no statistical difference in plasma glucose AUC was found ($P = 0.18$) compared to Landrace pigs. In conclusion, Iberian pigs showed lower insulin sensitivity of peripheral tissues evaluated using an intravenous glucose tolerance test.

Key words: insulin sensitivity, Iberian pig, glucose tolerance

T232 Reproductive performance of replacement beef heifers when estrus was synchronized with progesterone (CIDR) for 5 or 7 d, GnRH, and $PGF_{2\alpha}$. K. M. Bischoff*[1], T. E. Black[1], R. D. Estermann[2], G. A. Bridges[3], G. C. Lamb[1], and J. V. Yelich[2], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]Depertment of Animal Sciences, University of Florida, Gainesville, [3]North Central Research and Outreach Center, University of Minnesota, Grand Rapids.*

We determined if reproductive performance differed in replacement *Bos indicus* × *Bos taurus* beef heifers when estrus was synchronized with one of 3 protocols that included CIDR, GnRH, and $PGF_{2\alpha}$ (PG). Reproductive tract scores (RTS; scale 1 to 5 with 1 = immature and 5 = estrous cycling) were determined on d −7 and used to stratify heifers to one of 3 treatments: 1) GnRH (100 μg) and a CIDR insert d −7 and PG (25 mg) and CIDR removal on d 0 (7dCIDR; n = 113); 2) GnRH and CIDR insert on d −5 and CIDR removal and PG on d 0 (5dCIDR; n = 113); 3) PG and CIDR on d −7, GnRH on d −5, and CIDR removal and PG on d 0 (7dMOD; n = 117). All heifers received a second PG (25 mg) 8 h after CIDR removal. Estrus was detected for 60 h after CIDR removal, with heifers detected in estrus inseminated using the AM/PM rule. Heifers not detected in estrus received TAI 72 h after CIDR removal coincident with GnRH (100 μg). Bulls were inserted 10 d following TAI for a 103 d breeding season. Transrectal ultrasonography was used to diagnose pregnancy 55 d after TAI and 30 d following bull removal. Estrous response was reduced ($P < 0.05$) in the 5dCIDR (21%) treatment compared to the 7dMOD (43%) and 7dCIDR (35%) treatments. A. greater ($P < 0.05$) percentage of heifers with RTS of 3 (40%), 4 (49%), and 5 (46%) exhibited estrus than those with a RTS of 1 (14%) or 2 (11%). Conception rates of heifers exhibiting estrus were greater ($P < 0.05$) for the 7dMOD (62%; 31/50) than the 5dCIDR (33%; 8/24) and 7dCIDR (39%; 15/39) treatments. For heifers failing to exhibit estrus, TAI pregnancy rates (16%) did not differ between treatments. Synchronized AI pregnancy rates were greater ($P < 0.05$) in the 7dMOD (38%) treatment than the 5dCIDR (20%), and 7dCIDR (23%) treatments. Synchronized pregnancy rates for heifers with RTS of 1 (10%) and 2 (16%) were less ($P < 0.05$) than those with RTS 3 (34%), 4 (36%), and 5 (32%). Breeding season pregnancy rates did not differ between treatments (81%). In summary, synchronized AI pregnancy rates were greatest with the 7dMOD protocol and RTS affected reproductive performance.

Key words: estrus synchronization, beef heifer, CIDR

T233 Fat mobilization during early lactation: Effects on milk performance, feed intake, body condition and metabolic changes in dairy cows. C. Weber*[1], F. Becker[1], C. Hametner[1], B. Losand[2], R. M. Bruckmaier[3], W. Kanitz[1], and H. M. Hammon[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]State Institute for Agriculture and Fishery, Dummerstorf, Germany, [3]Veterinary Physiology, Vetsuisse Faculty, Bern, Switzerland.*

Dairy cows mobilize body fat during early lactation to provide energy for milk production due to insufficient feed intake. However, there is huge individual variation in postnatal fat mobilization among cows indicated by a broad range of postnatal NEFA changes in blood plasma and liver fat concentration (LFC). The objective of the present study was to investigate feed intake, milk performance, and metabolic and endocrine changes in German Holstein cows (>11,000 kg milk/305 d in 2nd lactation) grouped according to different mean LFC on d 1, 14, and 28 after calving: L (<200 mg total fat/g DM; n = 10), M (200 – 300 mg total fat/g DM; n = 10), and H (>300 mg total fat/g DM; n = 7). Cows were studied from dry off up to 63 DIM in their 3rd lactation and were fed TMR ad libitum. DMI and milk yield were recorded daily, BW, BCS, and milk composition were measured weekly. Plasma concentrations of NEFA, BHBA, glucose, and insulin were measured in blood taken at 56, 28, 15, 5 d before expected calving and once weekly up to 63 DIM. Liver biopsies were taken at 1, 14, 28 DIM to measure total fat content. Data were analyzed by the Mixed Model of SAS with LFC and time as fixed effects. Mean hepatic fat concentration for H, M, and L were different ($P < 0.05$) among groups: 351 ± 14, 250 ± 10 and 159 ± 9 mg/g liver DM, for H, M, and L, respectively. DMI was lowest ($P < 0.05$) before calving in H, increased ($P < 0.01$) after calving in all groups, but was highest ($P < 0.05$) in L. Milk yield was not affected by LFC, but energy balance was least negative ($P < 0.01$) in L. BCS were highest ($P < 0.05$) before calving in H and the postnatal decrease was higher ($P < 0.05$) in H and M than in L. Plasma concentrations of NEFA and BHB increased more around calving ($P < 0.05$) in H than M and L, but plasma glucose was lowest in H. Plasma insulin concentrations after calving were highest in L. Greater fat mobilization in cows with elevated BCS before calving was associated with reduced DMI and a more severe negative energy balance, did not affect milk production, but influenced postnatal glucose and insulin status in cows.

Key words: dairy cow, fat mobilization, energy metabolism

T234 Fat mobilization around calving in high-yielding dairy cows affects hepatic gene expression of gluconeogenic enzymes but not enzymes involved in fatty acid oxidation. H. M. Hammon*[1], C. Weber[1], F. Becker[1], C. Hametner[1], B. Losand[2], and W. Kanitz[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]State Institute for Agriculture and Fishery, Dummerstorf, Germany.*

Energy demands largely increase after calving in dairy cows and hepatic energy metabolism is affected by elevated glucose output due to milk production. As cows differ in fat mobilization around calving the objective of the study was to investigate hepatic gene expression of key-enzymes involved in gluconeogenesis, fatty acid oxidation, and ketone body formation in cows with variable liver fat concentration

(LFC) after calving. German Holstein cows were grouped according to mean LFC (as indicator of fat mobilization) on d 1, 14 and 28 after calving in low (L) (<200 mg total fat/g DM; n = 10), middle (M) (200 – 300 mg total fat/g DM; n = 10), and high (H) (>300 mg total fat/g DM; n = 7). Cows were fed TMR ad libitum. Liver biopsies were taken at 56 and 15 d before calving and at 1, 14, 28, and 49 DIM to measure LFC, glycogen, and mRNA concentrations of pyruvate carboxylase (PC), cytosolic phosphoenolpyruvate carboxykinase, glucose-6-phosphatase, propionyl-CoA-carboxylase (PCCA), carnitine palmitoyl-transferase 1A, acyl-CoA-synthetase long chain, acyl-CoA-dehydrogenase very long chain, hydroxy methyl glutaryl-CoA-synthetase 2, and peroxisome proliferator-activated factor (PPAR)α. Data were analyzed by the Mixed Model of SAS with LFC and time as fixed effects. Mean hepatic fat concentration for H, M, and L differed ($P < 0.05$) among groups: 351 ± 14, 250 ± 10 and 159 ± 9 mg/g DM, for H, M, and L, respectively. Glycogen concentrations decreased after calving in all groups, but were lowest in H ($P < 0.05$). All measured enzymes changed with time during the experimental period. PC mRNA concentrations increased immediately after calving highest ($P < 0.05$) in H and M. PCCA and PPARα tended to be lowest in H. Elevated fat mobilization indicated by LFC during early lactation affected hepatic glycogen and gene expression involved in glucose production and nuclear energy sensing, but not gene expression referred to hepatic fatty acid oxidation and ketone body formation.

Key words: dairy cow, fat mobilization, hepatic energy metabolism

T235 Ovarian characteristics, serum estradiol and progesterone concentrations, and fertility in lactating dairy cows in response to equine chorionic gonadotropin (eCG). S. L. Pulley*, L. D. Wallace, H. I. Mellieon, and J. S. Stevenson, *Kansas State University, Manhattan.*

Numbers of FSH receptors are greatest in maturing follicles on d 4 of the first follicular wave of the estrous cycle when LH receptors are first detected in granulosa cells of the dominant follicle. After having acquired LH receptors dominant follicles respond to both LH and FSH or eCG. Because the potential for eCG to influence follicle size and estradiol secretion, objectives were to evaluate the effects of eCG on serum ovarian steroids, corpus luteum (CL) diameter, estrual activity, and timed AI pregnancy rates. Cows (n = 121) in a single herd were enrolled in a Presynch-Ovsynch program. Cows received 2 injections of prostaglandin F2α (PG) 14 d apart (Presynch), with the second injection given 11 d before the onset of the Ovsynch protocol (GnRH injection 7 d before [GnRH-1] and 56 h after PG [GnRH-2], with AI administered 14 to 18 h after GnRH-2). Cows randomly received either saline or 400 IU eCG concurrent with the PG injection of the Ovsynch protocol (d 0). Blood samples were collected to monitor serum progesterone (d −7, 0, 2, 4, 9, 16, and 33) and serum estradiol (d 0, 1, 2, and 3). Serum estradiol did not differ between treatments from d 0 to 3. Estrual activity also was not affected by treatment. Overall expression of estrus was poor (eCG: 15.4%; 10/65 vs. saline: 16.4%; 9/55). Treatment with eCG improved neither ovulation response (96.9% vs. 100%; $P = 0.15$) nor multiple ovulation rates (20.3% vs. 18.2%) after GnRH-2 injection. Administration of eCG tended to increase the number of CL and on d 9 ($P = 0.08$) and d 16 ($P = 0.09$) after PG. Volume of luteal tissue was increased ($P = 0.04$) only on d 16 in response to eCG. Pregnancy diagnosis was determined by transrectal ultrasonography on d 33. Timed AI pregnancy rates did not differ between eCG (36.9%) and saline-treated cows (41.8%) cows. We concluded that administration of eCG at the time of PG provided no profertility advantages to dairy cattle when programmed for a timed insemination at first service.

Key words: eCG, fertility, Ovsynch

T236 A mechanistic metabolic model of regulation of reproductive processes in dairy cattle. J. P. McNamara[1], S. L. Shields*[1], and I. Lean[2], *[1]Washington State University, Pullman, [2]University of Sydney, Camden, NSW, Australia.*

The objective was to expand and continue evaluation of a deterministic, mechanistic, dynamic model of reproductive processes in the dairy cow. This research model will be suitable for evaluation of data, concepts and hypotheses regarding underlying genetic, nutritional and physiological control of reproduction. We began with an existing model of metabolism in the cow, published and validated in the literature (Molly, UC Davis); which describes utilization of glucose, amino acids and fatty acids by muscle, adipose, visceral and mammary tissues at an aggregated metabolic pathway level. Elements of genetic background, response to nutritional environment and metabolic hormones are explicit. The physiological processes are integrated at the pathway level into one system to link genetic elements, nutrient use and reproductive processes. For example, equations link glucose, IGF-I and growth hormone to rates of follicle stimulating hormone, luteinizing hormone, and follicular growth. The days in milk at which cycling commences is directly related to amount of body fat (days at start cycling = 37.41 DIM − 0.1489 × body fat kg; $r^2 = 0.979$), which is an integral function of the sum of nutritional pathways. Degradation of estrogen and progesterone by the liver is a function of metabolic rate, as described by total ATP demand, so that for example, peak progesterone and estrogen in the first cycle are reduced by 10.9% and 6.3% as milk yield increases from 34 to 50 kg/d for the first 90 DIM. Related to feed intake, progesterone and estrogen first peak are reduced 15.2 and 8.1% as DMI increases from 19.6 to 27.0 kg/d. Progesterone directly affects early embryonic growth (energy used in embryonic growth (kcal/d) = 13.59 + 1.923 × (progesterone, ng/ml); $r^2 = 0.946$) and must be maintained at a pre-set level to allow embryonic growth to continue after 21 to 45 d after conception. The model behavior (pattern and direction of response) is consistent with literature values. This research model should be useful to frame specific hypotheses on control of reproductive processes by genetic and nutritional driven mechanisms.

Key words: reproduction model, nutrition, genetics

T237 Effect of prostaglandin $F_{2\alpha}$ on growth of *Escherichia coli* and *Streptococcus uberis* associated with bovine mastitis. C. Autran*[1], B. Shafii[2], M. McGuire[1], J. Dalton[3], and A. Ahmadzadeh[1], *[1]University of Idaho, Moscow, [2]Statistical Programs, College of Ag & Life Sci, Moscow, ID, [3]Caldwell R & E Center, Caldwell, ID.*

Certain fatty acids have been shown to inhibit the growth of mastitis pathogens. Moreover, prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$: dinoprost tromethamine) inhibits the growth of *Staph. aureus* in vitro. The objective was to determine the bacteriostatic effects of $PGF_{2\alpha}$ on growth of *E. coli* and *Strep. uberis* in vitro. In Exp. 1, flasks containing tryptic soy broth were inoculated with *E. coli*, and subsequently treated with $PGF_{2\alpha}$ at concentrations of 0, 1.2, 2.4, 4.8 and 9.6 mg/mL. Cultures were sampled every 4 h over 24 h to determine bacterial growth (log cfu). The experiment was repeated 3 times. In Exp. 2, *Strep. uberis* was treated with $PGF_{2\alpha}$ (0, 0.6, 1.2, 2.4 and 4.8 mg/mL). The procedures were identical to Exp. 1. Data were analyzed using ANOVA, and regression procedures. In Exp. 1 there was an effect of treatment by time interaction on mean log cfu ($P < 0.05$) for *E. coli*. Only the mean log cfu values of the 9.6 mg/mL $PGF_{2\alpha}$ were different ($P < 0.05$) at 12 h from

the control. The regression models showed that the pattern of bacterial growth over time for 4.8 mg/mL ($P = 0.05$) and 9.6 mg/mL $PGF_{2\alpha}$ ($P < 0.05$) were different from the control. Moreover, 9.6 mg/mL of $PGF_{2\alpha}$ was the most effective dose inhibiting *E. coli* growth. In Exp. 2, there was an effect of treatment and treatment by time interaction on mean log cfu for *Strep. uberis* ($P < 0.05$). At 12 and 24 h of growth, mean log cfu for all $PGF_{2\alpha}$ concentrations differed ($P < 0.05$) from the control, in a dose-dependent manner. Regression results revealed that the growth curve pattern of *Strep. uberis* over 24 h for each treatment was different compared with the control ($P < 0.05$), and the increase in growth rate over time for treatments 2.4 and 4.8 mg/mL was different from the control ($P < 0.05$). These results provide evidence for the first time that $PGF_{2\alpha}$ has inhibitory effects on growth of *Strep. uberis* in vitro; however, growth inhibition of *E. coli* was only achieved with the greatest concentration of $PGF_{2\alpha}$. Gram-positive mastitis causing bacteria (*Strep. uberis*) appear to be more susceptible to $PGF_{2\alpha}$ than gram-negative bacteria (*E. coli*).

Key words: prostaglandin $F_{2\alpha}$, *E. coli*, *Strep. uberis*

T238 Effects of sequential injections of GnRH at 17 and 24 d after AI on progesterone concentration and pregnancy losses. A. L. A. Scanavez*[1], J. G. N. Moraes[1], R. G. Bruno[2,3], K. J. Lager[2,3], J. A. H. Rivera[2], P. R. B. Silva[1], L. G. D. Mendonça[1], T. R. Bilby[2], and R. C. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [2]Texas AgriLife Research and Extension Service, Texas A&M System, Stephenville, [3]Department of Agricultural Science, West Texas A&M University, Canyon.*

Objectives of the current study were to determine whether sequential injections of GnRH at 17 ± 3 and 24 ± 3 d after pre-enrollment artificial insemination (AI), would reduce pregnancy losses between 31 ± 3 and 66 ± 3 d after AI by increasing progesterone concentrations (P4) at 24 ± 3 and 31 ± 3 d after AI. Lactating cows from 2 dairies (MN-Jersey cows and TX-Holstein cows) were enrolled in the study at 17 ± 3 d after pre-enrollment AI. At enrollment cows were grouped by parity and number of AI and assigned to 1 of 3 treatments in a ratio of 1:2:1. Cows assigned to the 2GnRH treatment received 100 µg of GnRH at 17 ± 3 and 24 ± 3 d after pre-enrollment AI; cows assigned to the 1GnRH treatment received 100 µg of GnRH at 24 ± 3 d after pre-enrollment AI; and, control cows received no GnRH. All cows were examined by ultrasound at 31 ± 3 d after pre-enrollment AI and those diagnosed pregnant were re-examined at 66 ± 3 d after pre-enrollment AI. Blood samples were collected from a subgroup of cows at 24 ± 3 (MN-123 cows and TX-160 cows) and 31 ± 3 (MN-142 cows) d after pre-enrollment AI for determination of P4. There were 514 2GnRH, 1099 1GnRH, and 648 control cows pregnant at 31 d after AI and re-examined at 66 d. At 24 d after pre-enrollment AI P4 was not ($P = 0.70$) affected by treatment (7.5 ± 0.2ng/mL). At 31 d after pre-enrollment AI P4 was greatest ($P < 0.01$) for 2GnRH cows (8.5 ± 0.4ng/mL), but was not ($P = 0.16$) different between 1GnRH (6.2 ± 0.4 ng/mL) and control (7.0 ± 0.5ng/mL) cows. Treatment ($P = 0.99$) and site ($P = 0.81$) did not affect pregnancy loss, but the interaction between treatment and site affected ($P = 0.04$) pregnancy loss. In the MN-dairy 2GnRH (7.5%) cows had fewer pregnancy losses than 1GnRH (11.8%) and control (10.4%) cows and in the TX-dairy 2GnRH (11.9%) had more pregnancy losses than 1GnRH (7.9%) and control (8.8%) cows. There was a quadratic correlation between P4 at 31 d after AI and pregnancy loss [pregnancy loss = 87.4 − (26.5xP4)+(2.1xP42); r2 = 99.7%]. Jersey cows treated with GnRH at 17 and 24 d after AI had greater P4 at 31 d after AI and reduced pregnancy losses, but Holstein cows did not benefit from GnRH treatment after AI.

Key words: dairy cow, pregnancy loss, GnRH

T239 Effect of GnRH treatment at critical stages of estrous cycle following artificial insemination on pregnancy rate in lactating Holstein dairy cows. Z. Hakimi, A. Z. Shahne, H. M. Yegane, and R. Masoumi*, *University of Tehran, Karaj, Karaj, Iran.*

Embryonic mortality is regarded as one of the major causes of reproductive failure in cattle resulting in reduced pregnancy rates, slower genetic improvement and substantial financial losses to dairy operations. Progesterone hormone deficiency after insemination has an important place among the causes of early embryonic death. Even though average fertilization rates of heifer and cows are between 88 and 90, 20% or more of the embryos are lost after insemination before 21th days. GnRH injections are applied from 4 to 15 d after insemination for the prevention of early embryonic death which is attached to inadequate progesterone hormone in cattle. The aim of present field study was to determine the effect of GnRH treatment on pregnancy rate of lactating Holstein dairy cows in critical stages of estrous cycle following AI. A total of 174 Holstein cows were randomly assigned into one of 5 following treatment groups: Cows in group A (n = 35) were not treated and served as control group. Cows in group B (n = 35) were treated intramuscularly with a GnRH analog (Gonadorelin acetate; 25 µg) on d 0 (at the time of AI). Cows in group C (n = 39) were treated with GnRH on d 0 and 5. Cows in group D (n = 36) were treated with GnRH on d 0 and 11. Cows in group E (n = 29) were treated with GnRH on d 0, 5 and 11. Pregnancy was diagnosed by rectal palpation 45–50 d after insemination. Dichotomous data were analyzed using PROC LOGISTIC of SAS. Pregnancy rate for treatment groups were 42.2, 60, 51.8, 63.9, 55.1%, respectively. Although, there was a notable difference between control and treatment groups in PR, but the differences were not statistically significant ($P < 0.05$). Therefore, GnRH administration to stimulate CL function using single or multiple doses of GnRH during the luteal phase could not increase pregnancy rate in present study.

Key words: GnRH, pregnancy rate, dairy cattle

T240 Effect of insemination timing on conception rates of dairy cows having high activity as identified by the Select Detect activity monitor. R. L. Nebel*[1], J. M. DeJarnette[1], and E. Harty[2], *[1]Select Sires Inc., Plain City, OH, [2]Dairymaster, Causeway, Co. Kerry, Ireland.*

The primary objective of this field trial was to determine the effects of interval to AI on conception rates of dairy cows identified as high activity using the Select Detect activity system. The Select Detect system uses neck-mounted sensors to scrutinize acceleration and intensity of movement with continuous 24-h surveillance of estrous related activity. Farm personnel inseminated cows at random intervals after onset of HA according to standard procedures, which in most herds was a once daily AI program. The hour activity exceeded the HA threshold was used to determine interval from onset to AI. Conception rates from 4,126 services were recovered from 19 herds located in 8 states. The mean duration of HA was 10.5 ± 0.1 h with a median of 10.0 h indicating a slightly skewed distribution. The distribution of duration of HA was as follows: ≤4 h, 15.8%; 5 to 8 h, 17.2%; 9 to 16 h, 46.2% and ≥16 h, 21.3%. The parity by AI interval interaction significantly influenced conception rates. Among primiparous cows, a curvilinear relationship was apparent with optimum conception occurring at AI intervals of 13 to 16 h after HA and trended lower for both earlier and later AI intervals. Among multiparous cows, conception rates at intervals ≤12 h were different that those >16 h with 13 to 16 h being intermediate. Specifically, conception rates for primiparous and multiparous cows respectively were 36 and 32.4% (0 to 4 h), 37.5 and 32.2% (5 to 8 h), 41.2 and 32.9% (9 to 12 h), 45 and 28.9% (13 to 16 h), and 37.7 to 23.3% (17 to 26 h). In conclusion, these results are consistent with similar studies based on observed mounting activity wherein optimum conception rates are obtained at AI intervals proximal to 12 h after detected estrus (HA) with shorter intervals appearing to be less compromising to conception rates that are longer intervals. The Select Detect system allows conception rates to be optimized because of 24-h surveillance and precision of determining activity related to estrus.

Key words: timing of AI, Select Detect, MooMonitor

T241 Reproductive performance in Mexican Holstein dairies by geographic region. H. Lopez*, F. Cavazos, A. Gonzalez, L. Ruiz, and C. Vergara, *ABS Global Inc.*

Our objectives were to compare reproductive indicators from Holstein dairies in 5 regions of Mexico and establish benchmarks for the 20% most efficient herds. Data from 119,097 cows and 377,025 inseminations were evaluated from January to December 2010 form 54 dairies in Region 1 (R1[BCN, BCS; n = 10 herds]), Region 2 (R2[CHH; n = 5 herds]), Region 3 (R3[AGU, JAL; n = 14]), Region 4 (R4[QUE; n = 6]), and Region 5 (R5[COA, DUR; n = 19]). Analyses were conducted with the MIXED procedure using herd as the experimental unit. Mean herd size was greater ($P < 0.05$) for R2 (4,178 ± 3,702) and R5 (3,308 ± 2,573) than R1 (735 ± 225), R3 (1,484 ± 866), and R4 (1,202 ± 735). Days for waiting period (R1 = 51 ± 4; R2 = 51 ± 2; R3 = 50 ± 4; R4 = 53 ± 9; R5 = 47 ± 6), pregnancy diagnosis (R1 = 41 ± 4; R2 = 37 ± 1; R3 = 40 ± 4; R4 = 42 ± 4; R5 = 40 ± 1), and reconfirmation (R1 = 120 ± 42; R2 = 94 ± 21; R3 = 114 ± 37; R4 = 105 ± 35; R5 = 91 ± 6) did not differ among regions. Insemination risk was greater ($P < 0.05$) for R2 (62%) and R5 (65%) than R1 (58%), and R3 and R4 (56%). Percentage of cows bred at estrus was greater ($P < 0.05$) for R3 (83%) and R4 (85%), intermediate for R2 (79%) and R5 (77%), and lower for R1 (71%). Conception rate for cows bred at estrus was greater ($P < 0.05$) for R1 and R2 (36%), intermediate for R3 and R4 (33%), and lower for R5 (29%). The % of cows bred after synchronization was greater ($P < 0.05$) for R1 (29%), intermediate for R2 (21%) and R5 (23%), and lower for R3 (17%) and R4 (15%). Conception rate for TAI cows was greater ($P < 0.05$) for R1 (34%), intermediate for R2 and R3 (29%), and R4 (31%), and lower for R5 (26%). Pregnancy rate was greater ($P < 0.05$) for R1 (20%) and R2 (22%) than R3 and R4 (18%), and R5 (17%). Percentage of cows pregnant by 100 DIM was greater ($P < 0.05$) for R1 (52%) and R2 (55%) than R3 and R4 (48%), and R5 (44%). The 20% most efficient operations had mean pregnancy rate of 23%, waiting period of 54 ± 3 d, insemination risk of 63%, conception rates to estrus of 38%, TAI of 35%, and percentage of cows pregnant by 100 DIM of 58%. Regional differences existed in reproductive parameters in Mexican dairies, which may be attributed to program compliance and differences in herd size.

Key words: fertility, reproduction, estrus

T242 Effects of 2.1 and 10 x 10^6 dosages of sex-sorted or conventionally processed sperm on conception rates of Holstein heifers. J. M. DeJarnette*[1], M. A. Leach[1], R. L. Nebel[1], C. E. Marshall[1], C. R. McCleary[2], and J. F. Moreno[3], *[1]Select Sires Inc., Plain City, OH, [2]Sexing Technologies Inc., Plain City, OH, [3]Sexing Technologies Inc., Navasota, TX.*

The conception rates of Holstein heifers after AI with 2.1 or 10 × 10^6 sperm dosages of sex-sorted or conventionally processed sperm were compared. Ejaculates collected by artificial vagina from 8 Holstein sires were cryopreserved at either 2.1 or 10 × 10^6 sperm per dose with or without sorting to 90% purity for X-chromosome bearing spermatozoa using flow cytometry. All treatments were processed in an egg-yolk (20%), TRIS, glycerol (7%) extender and packaged in color-coded 0.25-mL French straws. Straws (n = 350 straws/treatment per sire) were packaged and distributed in aliquots of 12 (3 straws of each treatment) to 51 herds of Holstein heifers. Straw color was recorded in the on-farm record keeping system at the time of AI and retrieved by electronic download. A total of 9,172 services were recovered providing a mean sample size of 287 ± 3.5 services/sperm dose per semen type within sire (range: 248 to 318). Conception rates (LSM) were influenced (Tukey test) by the main effects of herd, sire, semen type, sperm dosage, and service number. The herd by sperm dosage interaction was significant and implied some herds (technicians) are more proficient than others at maintaining high levels of conception with reduced sperm dosages. Across herds and sires, the conception rates of each semen type by sperm dosage combinations were as follows: 2.1 × 10^6 sex-sorted, 38%, n = 2,319; 10 × 10^6 sex-sorted, 44%, n = 2,279; 2.1 × 10^6 conventional, 55%, n = 2,282; 10 × 10^6 conventional, 60%, n = 2,292. The observation that conception rates of sex-sorted semen were improved by the 10 × 10^6 sperm dosage is encouraging toward the prospectus of development of a commercially available sex-sorted product with improved conception potential over existing technology. However, the failure of the 10 × 10^6 sex-sorted sperm dosage to achieve conception rates comparable to either dosage of conventional semen is somewhat discouraging toward the plausibility of comparable conception rates to conventional semen in the absence of major technological advances in efficiency of sperm sorting or cryopreservation.

Key words: sex-sorted semen, sperm dosage, flow cytometry

T243 IGF-I increases in vitro embryo production and protects against deleterious effects of heat stress in Nelore (*Bos indicus*) and Holstein (*Bos taurus*) breeds. R. A. Satrapa, E. M. Razza, C. F. Silva, T. Nabhan, R. A. L. Simoes, and C. M. Barros*, *Department of Pharmacology - IBB, University of São Paulo State, Botucatu, Sao Paulo, Brazil.*

In the present study the beneficial effect of IGF-I during in vitro culture of embryos was tested comparatively between a more tolerant (Nelore = N) versus a less thermo tolerant breed (Holstein = H). Oocytes, obtained in a local abattoir, from N and H females were matured and fertilized with semen from N (n = 6) and H (n = 6) sires, respectively. Embryos cultured was performed at 39°C, 90% N_2, 5% CO_2, and 5% O_2 in SOFaaci medium. In experiment 1 and 2, embryos from both breeds with ≥16 cells were randomly allocated in 4 groups: Control (maintained at 39°C all the time) HS (96 h after fertilization the embryos were subject to heat shock of 41°C for 9h and then returned to a temperature of 39°C), IGF (cultured in the presence of IGF, 100 ng/ml), and IGF-HS (IGF and HS). In experiment 1 cleavage, morula, and blastocyst rates were evaluated; whereas in experiment 2 apoptosis was determined by TUNEL, in both breeds simultaneously. The results were analyzed by logistic regression using the Proc GENMOD (SAS). In experiment 1, HS significantly decreased blastocyst rates in N (29.6 vs. 24.1%, control vs. HS, respectively) and H (20.1 vs. 15.5%). Adding IGF-I to the culture medium increased significantly blastocyst rates in both breeds N (23.3% vs. 29.9%, -IGF vs. +IGF, respectively) and H (15.7 vs. 21.4%). In experiment 2, HS increased ($P < 0.05$) apoptosis rates both in N (3.3 ± 0.2 vs. 4.1 ± 0.3) and H (4.8 ± 0.3 vs. 6.0 ± 0.4). It is concluded that adding IGF to the culture medium of embryos of both breeds increases blastocyst rate and decreases apoptosis. Additionally, Holstein were more sensitive to the deleterious effects of HS than Nelore embryos, since there was a higher decrease in blastocyst rate of heat stressed embryos from Holstein than from N cows, as well as a higher incidence of apoptosis in H embryos.

Key words: heat stress, IGF, embryo

T244 Cytological endometritis incidence in crossbred dairy cows. R. M. Santos*, L. C. Carneiro, J. P. E. Saut, A. F. Ferreira, M. F. S. Padua, and N. Bortoletto, *FAMEV-UFU, Uberlândia, Minas Gerais, Brazil.*

The objective was to evaluate the incidence and risk factors for cytological endometritis in crossbred dairy cows (Holstein/Gyr) maintained in a hot climate in Southwestern Brazil. The cytological endometritis diagnostic was performed in primiparous (n = 26) and multiparous (n = 100) cows, from a herd with 480 lactating cows maintained in pasture during the rainy season and at loose housing in the dry season. Average milk production was 18.75 kg/day. At 48.18 ± 9.10 DIM the cows had their body condition scored using a 5-point system and were examined by ultrasound to determine CL and uterine fluids. The vaginal discharge was evaluated by the gloved hand method. The cytological samples were collected only in cows with clear or translucent vaginal mucus and no uterine fluids. Cytological sample of the endometrium were collected using a cytobrush adapted for use in cattle. Slides for cytological examination were prepared on farm by rolling the cytobrush on a glass microscope slide and air-dried. The cytology slides were stained with modified Wright Giemsa stain. Each slide was examined at 400× magnification to perform the differential cell count of 200 cells (polymorphonuclear neutrophils and endometrial cells) by 2 observers. Cytological endometritis was defined when the proportion of neutrophils were ≥5% (Gilbert et al., 2005). The incidence of cytological endometritis was analyzed by the binary logistic regression including in the model calving season, BCS, presence of CL, parity and DIM. The cytological endometritis incidence in crossbred dairy cows was 25.40%. Cows calving at spring/summer season had tendency (34.04 vs. 20.25%; $P = 0.057$) to have higher cytological endometritis incidence than cows calving at autumn/winter. Cows with BCS ≤2.5 had higher (31.25 vs. 15.22%; $P = 0.04$) cytological endometritis incidence than cows with BCS ≥2.75. The effects of the CL, parity, and DIM were not different. In conclusion, cytological endometritis was related to BCS but not other production factors. Supported by FAPEMIG.

Key words: uterine disease, endometritis, dairy cows

T245 Effect of simultaneous thawing of multiple semen straws and sequence of insemination on pregnancy rate for timed-AI in suckled multiparous Nelore cows. L. Z. Oliveira*[1], V. F. M. Hossepian de Lima[1], R. M. Santos[2], T. Martins[3], R. F. G. Peres[4], H. B. Graff[4], E. R. Carvalho[4], A. F. C. de Andrade[5], and R. P. Arruda[5], *[1]FCAV-UNESP, Jaboticabal, SP, Brazil, [2]FAMEV-UFU, Uberlândia, MG, Brazil, [3]FMVZ-UNESP, Botucatu, SP, Brazil, [4]Agropecuária Fazenda Brasil, Nova Xavantina, MT, Brazil, [5]FMVZ-USP, Pirassununga, SP, Brazil.*

Because of large breeding herds and the frequent use of fixed-time artificial insemination (TAI) in Brazil, multiple cows are often bred simultaneously. This results in the routinely practice of thawing simultaneously more than one straw of semen. The objective of this study was to determine the effect of simultaneous thawing of multiple 0.5-mL semen straws and sequence of insemination on pregnancy rate (PR) at TAI in suckled multiparous Nelore cows. All cows (n = 479) received 2 mg of estradiol benzoate and an intravaginal progesterone releasing device on d 0. On d 8 the device was removed and the animals were treated with 500 µg of PGF2α, 300 UI of eCG and 0.5 mg of estradiol cipionate. At 48 h after device removal the cows were TAI. Ten 0.5-mL frozen straws were thawed simultaneously in an electric water-bath (36°C) for a minimum of 30s. Semen doses from 3 Angus bulls were utilized. The sires and the straw sequence were equally distributed across 2 AI technicians. The records also included sequence of insemination (first, second, third, until tenth) and time of seminal deposition. The cows were divided into different groups: cows inseminated with 1st, 2nd and 3rd semen straws (G1); cows inseminated with 4th, 5th and 6th semen straws (G2); cows inseminated with 7th, 8th, 9th and 10th semen straws (G3). Ultrasound pregnancy diagnosis was performed 40 d after TAI. The PR at TAI was analyzed using PROC LOGISTIC of SAS, including model effects of bull, inseminator and group. The mean time (±SD) of straws remaining in the thawing bath were 01:30 ± 00:51 (G1), 03:36 ± 01:10 (G2) and 06:13 ± 01:44 min (G3). The PR was affected ($P = 0.009$) by sequence of insemination (G1: 52.78%; G2: 53.85%; G3: 39.06%). An important point when considering simultaneous thawing of straw groups is the thawing bath would serve as an incubating environment for the semen, and could have influenced the sperm viability and the fertility of the spermatozoa.

Key words: Nelore, pregnancy rate, simultaneous thawing

T246 An individual cow-based model to aid in decision making about reproductive management of dairy cows. P. Federico*[1], A. De Vries[2], G. M. Schuenemann[3], and K. N. Galvão[2], *[1]Capital University, Columbus, [2]University of Florida, Gainesville, [3]The Ohio State University, Columbus.*

Many factors influence the reproductive and productive performance of dairy herds, consequently, profitability. Choosing the most effective reproductive protocol for a given herd is a critical managerial decision. To assess the effectiveness and profitability of different AI protocols, we developed an individual-based model to simulate a dairy herd. The reproductive status and milk production of each individual cow is tracked over time accounting for the stochastic nature of events such as estrus, conception, abortion, and mortality. Novel components of this model include: 1) implementation of various reproductive strategies [estrus detection (ED) only, Ovsynch, Presynch-Ovsynch, and Presynch-Ovsynch with ED]; 2) effectiveness of protocol implementation (e.g., accuracy of ED, compliance with administration of injections); 3) daily dynamic tracking of all events (e.g., milk, pregnancy, replacements, birth) that occur based on probability distributions; and 4) user-friendly interface to set up strategies, parameter values, and to visualize daily outcomes of the model. Components 1 and 2 provide quantitative information on best AI programs according to the effectiveness of protocol implementation (e.g., ED only is better than Ovsynch with poor compliance). Component 3 allows decision makers to estimate the timing to reach the new level of pregnancy and milk yield after a reproductive change is implemented at the farm level. Moreover, component 4 facilitates the understanding of the magnitude and the time to attain the expected true benefits. This is a key tool for outreach programs to motivate the adoption of best strategies for a particular farm. Additionally, the stochastic nature of the model helps the decision makers to be aware of the variability of the outcomes (e.g., percent pregnant) due to herd size and pure chance. Sensitivity analysis quantifies the influence of some of the factors affecting the reproductive performance. Through a mechanistic and bottom-up approach we obtained herd level parameters comparable to real on-farm values (e.g., percent pregnant, milking, or culled).

Key words: dynamic model, dairy cow, reproduction

T247 Efficacy of embryo transfer in lactating dairy cows during summer using fresh or vitrified embryos produced in vitro with sex-sorted semen. II. Calving data. T. R. Bilby*[1], J. Block[2], B. M. Stewart[1], P. Morelli[1], L. Bonilla[3], and P. J. Hansen[3], *[1]Texas AgriLife Research and Extension, Texas A&M System, Stephenville, [2]OvaTech LLC, Gainesville, FL, [3]Department of Animal Sciences, University of Florida, Gainesville.*

Objective of the study was to determine whether transfer of fresh or vitrified embryos produced in vitro with sex-sorted semen could improve calving rates and percentage of heifers born during summer in lactating dairy cows versus artificial insemination (AI). Lactating dairy cows (n = 722) were enrolled during summer at 2 commercial dairies in Texas. Cows were randomly assigned to one of 3 treatments: AI (n = 227), embryo transfer-vitrified (ET-V; n = 279) or embryo transfer-fresh (ET-F; n = 216). Embryos were produced in vitro using sex-sorted semen and cultured in BBH7 culture medium until d 7 after insemination. For vitrification, grade 1 expanded blastocysts were vitrified using the open-pulled straw method. Fresh embryos were grade 1 blastocysts and expanded blastocysts. Cows were submitted to an estrous synchronization protocol and either time-AI or AI following detected estrus (day of estrus = d 0). On d 7, cows were examined by ultrasound for presence of a corpus luteum (CL). An embryo was transferred to cows with CL in ET-V and ET-F groups. Cows were synchronized if progesterone was <1 ng/mL on d 0 and presence of CL on d 7. There were no treatment by farm interactions. The percentage of cows with live births was significantly increased for ET-F than for ET-V and AI among all cows (27.5 vs. 17.1 and 14.6%) and synchronized cows (29.9 vs. 18.5 and 20.0%). The percentage of cows giving birth to a live heifer was significantly increased for ET-F and ET-V compared with AI among all cows (79.1 and 72.5 vs. 50.0%) and synchronized cows (79.1 and 72.5 vs. 50.0%). There was no difference between ET-F and ET-V for percent live heifer births but both were greater than for AI. There was no effect of treatment on embryo loss. The transfer of fresh embryos produced in vitro using sex-sorted semen to lactating dairy cows during summer can effectively increase the percentage of cows that calve and also the percentage of cows that give birth to a live heifer compared with AI with conventional semen.

Key words: embryo, heat stress, dairy

T248 Economic evaluation of embryo transfer in dairy cows during the summer using linear programming. A. De Vries*[1], T. R. Bilby[2], J. Block[3], and P. J. Hansen[1], *[1]University of Florida, Gainesville, [2]Texas AgriLife Research and Extension, Texas A&M System, Stephenville, [3]OvaTech LLC, Gainesville, FL.*

The objective of this study was to estimate the economic value of the transfer of sexed female embryos (ET) to dairy cows in the summer compared with the use of conventional AI year round. Summer heat stress reduces fertility of dairy cows, but transfer of fresh sexed embryos in the summer may double the chance of pregnancy per transfer and result in more heifer calves. However, ET is more expensive than conventional AI, and the greater generation of pregnancies in the summer changes the calving pattern and seasonal cash flows. An economic analysis was carried out using a Markov chain dairy herd simulation model combined with linear programming. The model simulated cows from first calving up to the end of the ninth parity, used weekly steps, and assumed a 50% service rate. Seasonality was modeled as 52 periods per year. Heat stress was assumed to affect milk yield production, fat yield production, fertility, involuntary culling, and death risk. Decision variables were the number of purchased heifers per period. Embryo transfer was assumed to cost $60 per transfer compared with $20 per AI. Herd constraints were a maximum of 1300 cows (dry and lactating) or 1000 lactating cows during each week of the year. Results showed that the use of ET in the summer increased profit/cow per yr by $22 for the total cow constraint. Revenues were not changed, but the use of ET resulted in $39 less replacement cost per yr, as well as $20 greater total breeding costs and $3 greater feed cost. The use of ET reduced the maximum percentage of milking cows in the spring from 94% to 91% and reduced the number of dry cows. When the number of milking cows was the herd constraint, profit/milking cow per yr was increased by $42 when ET was used in the summer. Total costs were reduced by $4 per milking cow per yr and total revenues increased by $39, mostly due to increased milk sales and heifer calf sales. In conclusion, embryo transfer during the summer in heat stressed dairy cows is profitable, especially when the number of milking cows is the main constraint.

Key words: embryo transfer, heat stress, economics

T249 Economic comparison of two resynchronization protocols initiated at different intervals after insemination on fertility in lactating dairy cows. J. G. N. Moraes*[1], R. G. S. Bruno[2,3], P. R. B. Silva[1], A. L. A. Scanavez[1], L. G. D. Mendonça[1], J. A. Hernandez-Rivera[2], K. J. Lager[2,3], T. R. Bilby[2], J. Fetrow[1], and R. C. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [2]Texas AgriLife Research and Extension Service, Texas A&M System, Stephenville, [3]Department of Agricultural Science, West Texas A&M University, Canyon.*

Objectives were to evaluate the effect resynchronization protocol on rate of re-insemination and economic outcomes. Cows from 2 dairies (MN = 3,069 and TX = 2,149) at 17 ± 3 d after pre-enrollment AI (PreEAI) were enrolled in the study. Cows were examined for pregnancy 31 ± 3 d after PreEAI. Cows in the early presynchronized resynchronization (EG) and early resynchronization (EOV) treatments started the resynchronization protocol (Ovsynch56) at 24 ± 3 d after PreEAI and EG cows received a GnRH at 17 ± 3 d after PreEAI. Cows in the late presynchronized resynchronization (LG) and late resynchronization (LOV) treatments started the resynchronization protocol at 31 ± 3 d after PreEAI and LG cows received a GnRH at 24 ± 3 d after PreEAI. Cows were re-inseminated when observed in estrus throughout the study. Cost of GnRH and PGF were $1.92/dose, value of pregnancies $275, value of pregnant cow $1,000, value of non-pregnant cow $600, and cost of a day open $3. Pregnancy to PreEAI was not (P = 0.54) different among treatments (44.2%). Smallest (P < 0.01) percentage of EG cows were re-inseminated before pregnancy diagnosis (EG = 28.8, EOV = 44.1, LG = 42.6, LOV = 47.6%), re-insemination rate was smallest (P < 0.01) for EG cows, and more EG cows were re-inseminated at timed AI (EG = 65.9, EOV = 49.6, LG = 42.4, LOV = 38.7%). Interval between AI was smallest (P < 0.01) for EOV cows (EG = 31.2 ± 0.3, EOV = 29.0 ± 0.3, LG = 32.7 ± 0.3, LOV = 32.0 ± 0.3d). Treatment did not affect pregnancy per AI of cows diagnosed non-pregnant to PreEAI (29.2%;P = 0.24) and the percentage of cows pregnant to PreEAI and resynchronized AI (55.4%; P = 0.78). Cost of resynchronization was greatest for EG treatment (EG = 9.1 ± 0.1, EOV = 5.0 ± 0.1, LG = 5.6 ± 0.1, LOV = 2.8 ± 0.1), but return per resynchronized cow was not affected by treatment (EG = 778.8 ± 11.6, EOV = 766.6 ± 11.6, LG = 786.3 ± 10.9, LOV = 790.3 ± 10.2). Because the EG treatment suppressed estrus signs, the difference in interval between AI among treatments was very small and because treatment did not affect percentage of cows pregnant to re-insemination there were no differences in economic return per cow non-pregnant to PreEAI.

Key words: economics, dairy cow, resynchronization

T250 The effects of probiotic, prebiotic, and plant extract on egg quality in layer hens. V. Kalderon[1] and V. Akay*[2], [1]*Cakabey High School, Izmir, Turkey,* [2]*Global Nutritech Biyoteknoloji Ltd., Kocaeli, Turkey.*

Researchers have been looking for alternative solutions to antibiotics for several reasons including the ability of microorganisms to develop resistance against antibiotics, the detrimental effects of antibiotics on the environment, and the high cost. This study was conducted to determine the effects of probiotic, prebiotic and plant extract on hen weight, various egg parameters, and egg bacterial growth in layer hens. Fifty 16-wk-old Bovans Brown layer hens were purchased from a local company and at 24 wks of age were randomly assigned to 5 treatments and kept in cages (70 × 93 × 114 cm). Treatments were: 1) Control; 2) Probiotic [1 kg BENESACC (*Saccharomyces cerevisiae* NCYC R618, 4 billion cfu/gr)/ton feed, Global Nutritech Ltd., Turkey]; 3) Prebiotic [1 kg EXCELMOS (mannanoligisaccharides)/ton feed, Global Nutritech Ltd., Turkey]; 4) Probiotic+Prebiotic (1 kg BENESACC and 1 kg EXCELMOS/ton feed); and 5) Oregano extract (2 lt ROPADIAR/ton water, Ropa Pharm Inc., The Netherlands). Feed and water were provided ad libitum; feeding was done manually several times a day. Hens were weighed weekly. Egg yields and egg weights were recorded daily and eggs were kept at 4°C for later analysis of protein content and bacterial growth. The trial continued 6 wks, and data were reported on a weekly basis. There were no differences for hen weights among treatment groups. Egg weights increased during trial for only the Probiotic, Prebiotic and Oregano groups compared with the Control and Probiotic+Prebiotic groups. Egg size increased for only the Probiotic and Prebiotic groups compared with the Control, Probiotic+Prebiotic and Oregano groups. There were no differences among groups for egg protein content. No bacterial growth was observed for the Probiotic+Prebiotic group, while bacterial growth was recorded for other groups. In conclusion, probiotic, prebiotic and oregano extract, or a combination of probiotic and prebiotic, can be used in layer hens to improve egg quality. However, a combination of probiotic and prebiotic provided the best results against bacterial growth in eggs.

Key words: probiotics, prebiotics, layer hen

T251 The in vitro antibacterial activity of extracts by different extraction of Chinese pulsatilla root, purslane herb, dyers woad leaf, and ash barks—traditional Chinese medicine. F. Rejun*[1], W. Xiangrong[1], H. Jianghua[1], Y. Yulong[2], and C. Caihui[1], [1]*Department of Animal Science and Technology, Hunan Agricultural University, Changsha, Hunan, P. R. China,* [2]*Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, Hunan, P. R. China.*

Conventional drugs usually provide effective antibiotic therapy for bacterial infections but there is an increasing problem of antibiotic resistance and a continuing need for new solutions. The aim of present study is to develop novel antibacterials replacer to overcome effectively bacterial resistance. Aqueous extracts and ethanolic extracts from Chinese pulsatilla root, purslane herb, dyers woad leaf and ash barks, were screened against *E. coli* C 84008 and *Salmonella pullorum* C (79–13) by using the disk diffusion test technique. The minimum inhibitory concentrations (MIC) were determined by micro-dilution method. As a result of this finding, The ethanolic extract of dyers woad leaf was not inhibitory to *E. coli*. Chinese pulsatilla root, purslane herb, dyers woad leaf (water) extracts were active against all the bacteria tested. The aqueous extracts of Chinese pulsatilla root and dyers woad leaf and the ethanolic extracts of ash barks had the lowest MIC against Salmonella pullorum (0.025 g/mL); the ethanolic extracts of ash barks had the lowest MIC against *E. coli* (0.025 g/mL).

Key words: traditional Chinese medicine, aqueous extracts, ethanolic extract

T252 Effect of season on four categories of fresh and current new mastitis infections in Minnesota. R. F. Leuer* and J. K. Reneau, *University of Minnesota, Saint Paul.*

New infection rates are a leading indicator of a dairy's udder health. Seasonal climate changes make it challenging to produce milk at a consistent quality level. Identifying problem months is important to focus effort on preventing spikes of high new infections. The objective of this study was to identify and quantify the months where herds have the highest percent of fresh cows with new infections (FNI) and percent of current lactating cows with new infections (CNI). Minnesota DHIA monthly average herd somatic cell count (SCC) records were collected from January 2007 to November 2010. Monthly herd tests without SCC information were removed and only herds with an average of 10 tests per year over the collection period were included. Herds were divided into 4 categories based on average herd SCC over the collection period. Low herds (L) with less than 200,000 SCC (n = 325), medium low (ML) herds between 200,000 and 300,000 SCC (n = 547), medium high herds (MH) herds between 300,000 and 400,000 SCC (n = 470), and high herds (H) above 400,000 SCC (n = 438). Monthly records (n = 66,296) were analyzed using PROC GLM with

significant differences determined at $P < 0.05$ using Tukey's multiple comparisons test. FNI was different in all categories except for MH and H (L = 11.8, ML = 14.1, MH = 15.6, H = 15.7). The statistically highest month for FNI was June (L = 12.7, ML = 15.1, MH = 17.2, H = 17.6) for all categories, with FNI similar for MH and H. The 4 categories were all significantly different in overall average CNI (L = 8.1, ML = 10.5, MH = 12.5, H = 14.2). High months of CNI for L herds were July and August (9.1, 9.3), ML high months were July, August, and September (11.6, 11.9, 11.2), MH high months were July, August, and September (13.6, 13.6, 13.1), and H high months were January, February, July, and August (15.1, 14.4, 15.3, 14.9). The greatest challenge for FNI appeared to be spring when cows may be exposed to the dampest environments. The summer months were the worst for CNI, with the addition of the deep winter months for the poorest milk quality herds.

Key words: SCC, DHIA, new infections

T253 Effect of somatic cells counting on milk composition of Holstein cows. J. A. De Freitas*[1], A. F. Garcez Neto[1], J. C. De Souza[2], J. Da Silva[1], V. L. De Souza[1], and T. M. Dos Santos[1], *[1]Federal University of Parana, Palotina, Parana, Brazil, [2]Federal University of South Mato Grosso, Aquidauana, Mato Grosso do Sul, Brazil.*

The subclinical mastitis is among the main diseases causing changes in milk composition and reducing their quality. Therefore, the somatic cell counting has been widely used as a tool for monitoring milk quality, which is an important factor to the milk industry and the health of the mammary gland. The objective of this study was to evaluate the correlation between somatic cells counting (SCC) and the contents of fat, protein, lactose, total solids, urea and milk production in Holstein cows of a Brazilian herd. It were used 3544 data of milk yield and composition from 467 cows of a commercial heard with an average milk production of 27.46 L / day during the year of 2006. Animals were kept in free stall system receiving a ration presented 17% of crude protein and 75% of total digestible nutrients (TDN) in dry matter (DM). The roughage:concentrate ratio used was 50% in DM . The roughage was based in corn silage and the concentrate feed was composed by soybean meal, cottonseed meal, vitamin and mineral premix. Individual milk samples were made monthly and from each sample were analyzed the percentage of protein, fat, lactose, total solids, urea and SCC. Data of production and milk composition were compared using ANOVA and correlation. There was no significant effect ($P > 0.05$) between SCC and fat content although there was found inverse correlation between SCC and % of milk fat (Table 1). There were significant negative correlations ($P < 0.05$) between SCC and lactose, total solids, urea and milk production, and positive and significant correlation ($P < 0.05$) between SCC and protein content. It can be concluded that the increase in SCC affect negatively the milk quality.

Table 1. Coefficients of correlation between somatic cell counting (SCC) and the levels of fat, protein, lactose, total solids, urea and milk production in dairy cows

Component	Coefficients of correlation	Level of significance
% Fat	−0.02098	0.2117
% Protein	0.13497	0.0001
% Lactose	−0.36840	0.0001
% Total solids	−0.10684	0.0001
% Urea	−0.11734	0.0001
Daily milk production (kg/d)	−0.20438	0.0001

Key words: lactation, mastitis, milk quality

T254 Immunoglobulin G1 concentration and bacterial contamination of colostrum fed to newborn Holstein heifers in Central California dairies. I. Z. Zhelev*[1], N. D. Spiro[1], J. D. Robison[1], J. Quigley[2], and A. Lago[2], *[1]California State University, Fresno, [2]APC Inc., Ankeny, IA.*

Objectives of this study were to evaluate the current status of immunoglobulin G1 (IgG1) concentration and bacterial contamination of first feeding colostrum under existing management practices of 7 Central California dairies ranging in herd size from 800 to 4000 adult cows. Colostrum samples (n = 546) were collected before first colostrum administration to newborn Holstein heifers. Three of the 7 dairies added supplement to colostrum (n = 312). On these dairies, 2 colostrum samples were obtained, one before adding supplement and one after supplementation. Colostrum collection began July 2009 and continued monthly through June 2010. Samples were analyzed for IgG1 using ELISA and bacteriology assessed through Standard Plate Count (SPC). Mean (SD) IgG1 concentration of colostrum fed was 35.96 (±16.13) mg/ml with a range of 0.45 to 114.94 mg/ml. Within dairy mean IgG1 concentrations varied from 21.20 to 47.21 mg/ml. Within the 3 dairies supplementing colostrum, mean IgG1 concentrations before and after supplementation was 45.39 and 47.21 mg/ml, 32.13 and 35.39 mg/ml, 27.20 and 37.07 mg/ml, respectively. Colostrum fed contained SPC ranging from 13,420 to 2,171,835 cfu/ml. A total of 41 (17.52%) of the pure colostrum fed (n = 234) were contaminated (>100,000 cfu/ml). Supplemented colostrum fed (n = 312) was contaminated in 179 (57.37%) of the cases. Thus, 220 (40.29%) of the total 546 calves were fed contaminated colostrum. A dramatic increase in SPC (52,817 to 2,171,835 cfu/ml) in supplemented compared with unsupplemented colostrum was observed in one dairy. The range of colostral IgG1 and SPC concentrations between herds suggests the potential exists to produce quality colostrum. However, this same data also suggests major flaws in the consistency of colostrogenesis and management of colostrum being fed to calves. Colostrum supplementation may lead to increases in colostrum IgG1 concentrations. Colostrum management practices markedly influence SPC concentrations.

Key words: colostrum, immunoglobulin, standard plate count

T255 Use of a blood glucose meter compared with laboratory analysis in dairy calves . M. R. Stafne* and S. I. Kehoe, *University of Wisconsin-River Falls, River Falls.*

Measuring glucose levels in calves is a key component in many research studies. However, testing the glucose levels at a laboratory can prove to be expensive and can delay progression of a project if the data are needed immediately. As an alternative to laboratory testing, it was hypothesized that a hand-held glucose meter would provide the same accurate results but faster. Therefore, the objective of the study was to determine the accuracy of a glucose meter when used on dairy calves compared with results from a laboratory test. Sixty-eight samples were collected from 34 calves with a 2-wk interval between the 2 sampling periods. Testing and housing of the calves was performed at Merrick's Research Facility (Union Center, WI). The calves used were fed a standard 20/20 milk replacer at 10 oz. DM per day which included various supplements due to an ongoing nutrition trial. Calves were housed in plastic hutches and were fed water and grain (18% CP; Prince, Marshfield, WI) ad libitum. Blood was collected using a blood collection vacutainer containing sodium fluoride (BD Diagnostic Systems, Franklin Lakes, NJ). Samples were first tested on whole blood

using a glucose meter and then centrifuged. Plasma was extracted using a pipette and frozen for later analysis at Marshfield Laboratories (Marshfield, WI). Measurements were statistically analyzed using the Proc Ttest in SAS 9.2 and were determined significant at $P < 0.05$. Least squares means for the laboratory glucose test and glucose meter were 93.97 ± 17.79 mg/dL and 121.66 ± 25.84 mg/dL, respectively ($P < 0.001$). It was concluded that the 2 testing methods did not produce comparable results. The variation in glucose concentration may have been due to the type of blood sample needed to run each test. Additional research containing more samples and other various tests would be recommended.

Key words: glucose, calves, glucose meter

T256 Study on the metabolic mechanism of melamine in dairy cattle. X. Jin, Y. Zhang, S. Li*, H. Zhang, Q. Zhang, and Z. Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

This trial was to study the effects of dietary supplementation of melamine byproducts on residual concentration of melamine in rumen fluid, blood, urine, feces and milk of dairy cows. The further object was to reveal the metabolic mechanism of action of melamine in dairy cows by single factor experiment. The experiment was divided into 3 phases with 10 d in each phase (7 d for pre-feeding and 3 d for sampling). Five cannulated multiparous cows with similar milk yield and body weight were assigned to the experiments. There were 3 levels set in the melamine byproducts experiment, using 0.516%, 0.860%, 1.204% melamine byproducts to replace 3%, 5%, 7% soybean meal relatively. Feeding the dairy cows with the same concentration of pure melamine or melamine byproducts in each part of the experiments, the supplementing level was from low to high, and fed melamine byproducts to the cows with concentration in the morning. Data were analyzed as a completely randomized single factor design by ANOVA using the general linear model procedure in SPSS. The results showed that residual concentration of melamine in each kind of samples was durative increasing. When the melamine byproducts level rose to 0.860% in the concentration, the residual concentration of melamine in samples of milk was significantly different from that of 0.516% ($P = 0.02$), while the residual concentration in other samples were not significantly different; when the melamine byproducts level rose to 1.204%, the residual concentration in ruminal fluid and urine were very significantly different from that of 0.516 ($P \leq 0.01$), the residual concentration in blood, raw milk were significantly different from that of 0.516 ($P = 0.02$). The residual concentration in feces was not significantly different from that of 0.516% and 0.860% ($P = 0.27$), though the concentration of melamine was durative increasing; The concentration of melamine in the raw milk, feces and urine from the phase with the highest supplemental level were 1.31, 3.30 and 107.75mg/kg, respectively. It is concluded that renal excretion is the primary metabolic pathway of melamine while defecation and lactation are only auxiliary pathways. It was consistent with the report that melamine had negative effect on kidney.

Key words: dairy cattle, melamine, metabolic mechanism

T257 Association between milk urea nitrogen and fertility of Brazilian dairy cows. M. C. Doska[1], J. A. Horst[2], A. A. Valloto[2], and R. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]Associação Paranaense de Criadores de Bovinos da Raça Holandesa, Curitiba, PR, Brazil.*

The objective of this study was to associate milk urea nitrogen (MUN) values with reproductive performance of dairy cows from Paraná State, south of Brazil. With this purpose, 16,569 test-days from 2,145 dairy cows belonging to 3 large Holstein herds were analyzed. Monthly MUN concentrations measured using infrared test method before conception in these 3,926 lactations obtained from official milk recording program were used in this analysis. Generalized linear model methodology was adopted to determine the relationship between days open and the included fixed effects and the covariable peak milk yield, assuming gamma distribution. Animals were categorized into quartiles based on MUN values. General means in this data set were 154.4 ± 77.6 for days open, 48.6 ± 9.7 kg for peak milk yield, and 44.9 ± 21.2 mo of age. First, average, and maximum MUN values before conception were 13.85 ± 3.83, 15.36 ± 2.78, and 18.10 ± 3.57 mg/dL, respectively. Correlations between days open and the first MUN test after parturition (r = 0.03) and between days open and average MUN before conception (r = 0.07) were weak, but the association between days open and maximum MUN test before conception was higher (r = 0.30). Correlation between days open and peak milk yield also was positive (r = 0.16), which means that higher producing cows showed a trend for lower fertility. Days open from dairy cows calving in the fall were lower ($P < 0.01$) than in the remaining seasons; 135.5 ± 1.0 versus 152.6 ± 1.0, 155.4 ± 1.0, and 171.2 ± 1.0, respectively for summer, winter, and spring calving seasons. Primiparous cows showed lower ($P < 0.01$) days open than older cows; 144.9 ± 1.0 for first-lactation cows, 152.5 ± 1.0 for second-lactation cows, and 162.6 ± 1.0 for 3 or more lactation cows. Maximum MUN test before conception is more closely associated with increased days open than average MUN before conception or the first MUN test after calving. Maximum MUN values before conception greater than 15.5 mg/dL were associated with decreased fertility in Brazilian lactating dairy cows.

Key words: reproduction, protein, days open

T258 Metabolic profiles and immune status of periparturient dairy cows transitioning from conventional to organic management system. J. F. Odhiambo*, Q. Zebeli, S. Iqbal, D. A. Mansmann, U. Farooq, S. Sharma, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Metabolic profiles and plasma haptoglobin (Hp) in dairy cows transitioning from conventional to organic management system were compared with those of dairy cows managed conventionally. Blood samples were collected from Holstein and Jersey dairy cows during the dry period (DP), 0–30, 30–60, and 60–90 d in milk (DIM, n = 7 cows for each lactation stage). Concentrations of NEFA, BHBA, cholesterol, lactate and Hp in the serum were measured by ELISA. Data were analyzed by the mixed procedures of SAS. Results showed that concentrations of NEFA and BHBA were highest ($P < 0.001$) at 0–30, intermediate at 30–60 and 60–90 DIM, and lower during the DP. Interestingly, BHBA was greater ($P < 0.001$), at all stages of lactation, in conventional cows (e.g., 1289.4 ± 88.6 vs. 883.6 ± 47.5μmol/L at 0–30 DIM). Serum concentrations of cholesterol increased with increasing DIM and returned to nadir levels during DP and was higher ($P < 0.001$) in conventional than organic cows. Low glucose concentrations were observed 0–30 DIM, levels were intermediate at 30–60 and 60–90 DIM, and peaked during the DP ($P < 0.001$). Glucose concentrations did not differ ($P = 0.54$) between conventional and organic cows. Lactate did not ($P = 0.24$) vary with DIM or day × farm type but was higher ($P < 0.001$) in organic cows than in conventional ones. Serum concentrations of Hp were elevated during the DP; reached peak levels 0–30 DIM, and decreased gradually with increasing days postpartum

and were much higher ($P < 0.001$) at all periods in conventional than organic cows. Overall, concentrations of Hp were 528.1 ± 45.2 μg/mL in conventional cows vs. 261.1 ± 16.9 μg/mL in organic cows ($P < 0.001$). Taken together, data indicated that metabolic changes associated with initiation of lactation are preceded by an acute phase response in dairy cows, and that cows in organic systems seem to be healthier than cows under conventional systems. These differences might be due to differences in nutritional management and milk production expectations in the 2 systems.

Key words: organic dairy cows, metabolic profile, immunity

T259 Season and stage of lactation affected metabolic profiles and innate immunity of periparturient dairy cows. J. F. Odhiambo*, Q. Zebeli, S. Iqbal, D. A. Mansmann, U. Farooq, S. Sharma, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Blood metabolic profiles and innate immunity were evaluated in 4 dairy herds during their periparturient period. Blood samples were obtained during dry period (DP), 0–30, 30–60, and 60–90 DIM from dairy cows (n = 7 for each lactation group) by tail venipuncture during summer and winter of 2009 and 2010, respectively. Concentrations of NEFA, BHBA, glucose, cholesterol lactate and haptoglobin (Hp) in serum were analyzed by ELISA. Data were evaluated by the mixed procedures of SAS. Interactions between season and stage of lactation affected blood NEFA ($P < 0.001$) and Hp ($P < 0.02$) but tended ($P < 0.10$) to affect cholesterol and glucose. No effects were observed for BHBA and lactate. Concentrations of NEFA in cows during summer were greater 0–30 DIM, intermediate 30–60 DIM and DP, and lower between 60 and 90 DIM. The pattern was similar in winter except for greater values at 60–90 DIM compared with summer values (301.9 ± 29.3 vs. 174.2 ± 28.6 μEq/L, respectively). Concentrations of Hp in serum were elevated during the DP, peaked between 0 and 30 DIM and gradually declined to nadir levels between 60 and 90 DIM. At 0–30 DIM concentrations of Hp were higher in summer than in winter (495.9 ± 47.9 vs. 334.3 42.9 μg/mL, respectively). Cholesterol was lower ($P < 0.01$) during the DP and 0–30 DIM but higher ($P < 0.01$) 30–60 and 60–90 DIM in both seasons. In the latter periods, winter concentrations of cholesterol were numerically greater than those of summer (202.2 ± 8.7 vs. 187.7 ± 9.3, and 227 ± 9.2 vs. 207.6 ± 10.9 mmol/L, for 30–60 and 60–90 d, respectively). Glucose was higher during the dry period, lower immediately post calving, and gradually increased thereafter in both seasons. However, the concentrations during 0–30 and 30–60 DIM tended to be higher in the winter than during summer (46.6 ± 1.9 vs. 56.5 ± 1.7, and 52.9 ± 2.1 vs. 58.1 ± 1.8 mg/dL, respectively). In conclusion, differences in nutrition regimens and likely in milk yields for summer and winter seasons exacerbated cow responses to negative energy balance variably and the effects were more pronounced in summer than in winter.

Key words: dairy cows, season, metabolic profile

T260 Management factors affecting microbial contamination of bovine colostrum. E. Conrad*[1], K. Morrill[1], J. Quigley[2], and H. Tyler[1], *[1]Iowa State University, Ames, [2]APC Inc., Ankeny, IA.*

Our objective was to determine management practices that affect the level of bacterial contamination of maternal colostrum (MC) on US dairy farms. Samples of MC (n = 892) were collected from 65 farms in 12 states. Samples of MC were obtained from Holstein (n = 629), Jersey (n = 191), and unidentified (n = 102) breeds of cattle. Total plate count (TPC) and coliform count (CC) were determined for each sample (DHI, Dubuque, IA). An investigator completed a management survey assessing 53 factors associated with management practices on each farm. The average TPC for the MC was 5.50×10^5 cfu•ml^{-1}, well above the recommended industry standard of $<1.0 \times 10^5$ cfu•ml^{-1}. MC with TPC counts greater than $1.0x10^5$, $5.0x10^5$, and 10.0×10^5 accounted for 45.9, 27.2, and 16.6% of samples, respectively, indicating that bacterial contamination of colostrum is a significant problem. Industry standards recommend that MC CC be $<1.0 \times 10^4$ cfu•ml^{-1}. The average CC of MC was 115.16 cfu•ml^{-1}, 77.0% of the samples were <50.0 cfu•ml^{-1}, indicating that the industry standard of $<1.0 \times 10^4$ cfu•ml^{-1} may not be a good indicator of MC coliform contamination. Based on survey responses (n = 804) MC was transferred to an average of 2.48 containers before feeding. 42.29% and 8.96% of MC was transferred to >3 and >4 containers respectively. The average time from MC collection to the feeding or storage was 48 min, with 54.3% of the samples being fed or stored >60 min after collection. Colostrum was allowed to sit at room temperature for an average of 33 min after being removed from storage before feeding, with 20.1% of samples sitting out for >60 min before being fed. These survey results indicate that MC management practices may be responsible for the high levels of bacterial contamination observed in this data set.

T261 Effect of short-term treatment with bovine somatotropin on milk yield of Brazilian dairy cows. R. Almeida*[1] and S. L. Viechnieski[2], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]StarMilk Farm, Céu Azul, PR, Brazil.*

The objective of this trial was to evaluate short-term milk yield response of 2 commercial sources of bovine somatotropin (bST) administered every 14 d in a high-producing dairy herd. One hundred sixty Holstein cows from the StarMilk Farm, Paraná State, south of Brazil, averaging 53.9 ± 13.5 mo of age, 217 ± 148 DIM, 43.5 ± 11.7 kg/d of milk, 680 ± 65 kg of BW, and 2.90 ± 0.21 BCS were assigned to one of 2 treatments in a randomized block design using milk production during the 7-d pretreatment period as the blocking criterion. Treatments were 4 consecutive subcutaneous injections of 500 mg of bST (Boostin, Intervet Schering-Plough Saúde Animal, Brazil) or 500 mg of bST (Lactotropin, Elanco Saúde Animal, Brazil), both given at 14-d intervals. All cows were milked 3x a day and received the same TMR fed 5x daily, consisting of corn silage, ryegrass silage, corn grain ground, soybean meal, whole cottonseed, soybean hulls, urea, minerals, and vitamins. The DM, CP, and NDF contents of the offered diets were similar between treatments, as well as cow's BCS and reproductive status. The estimated nutritional levels of this diet were 53.7% DM, 1.64 Mcal/kg NE_{lac}, 17.0% CP, 33.3% NDF, 19.5% ADF, 19.0% $_{pe}$NDF, 38.0% NFC, and 4.2% EE. Each group of cows was housed in a side of a free stall and no cow entrance was allowed during the trial. Data was analyzed with the mixed procedure of SAS with a model containing the continuous effect of the covariate and the fixed effects of block, treatment, day, and the interaction between treatment and day. The mean square of cow nested within treatment was used as the error term to test the treatment effect. Boostin-treated cows yielded 1.6 kg/d more milk ($P = 0.02$) than Lactotropin treated cows; 38.8 ± 0.5 versus 37.2 ± 0.5 kg/d, respectively. Treatment and day interaction also was an important source of variation ($P < 0.01$), and milk yield differences between the 2 bST sources were observed mainly in the first half of each 14-d cycle of bST administration. In this short-term trial it was observed differences in the milk yield response between the 2 commercial sources of bST.

Key words: dairy cow, growth hormone

T262 Chop length, dry matter and density of corn and wheat silage structures in California dairies. N. Silva-del-Río*[1] and C. Heiman[2], *[1]University of California Cooperative Extension, Tulare, [2]Alltech, Lexington, KY.*

The aim of this study was to describe chop length, dry matter and density of corn (n = 25) and wheat (n = 16) silage structures in California dairies. Corn silage was stored in conventional piles (n = 22), drive over piles (n = 2), and bunkers (n = 1), that averaged 24 ft in height (range: 14–30 ft). Wheat silage structures were either conventional piles (n = 15) or bunkers (n = 1) and averaged 20 ft in height (range = 10–30 ft). Corn silage chop length was 1.3 cm (n = 6), 1.6 cm (n = 1), 1.9 cm (n = 14) and 2.2 cm (n = 4). Wheat silage chop length was 1.3 cm (n = 6), 1.9 cm (n = 9) and 2.2 cm (n = 1). Three density samples were taken at 6 ft from the bottom (B), and 2 samples at 6 ft from the top (T). The average of all the density samples collected was expressed as dry matter (DM) and as fed (AF). As fed density indicates porosity (resistance to air penetration) and may be a better indicator of silage preservation than DM density. Densities were compared with paired *t*-test (T and B) and chi-squared test (DM and AF). Average silage DM was 35.7% (range: 27.0–42.0%) for corn and 32.9% (range: 26.3–38.2%) for wheat. Silage DM was 35.4% (B) and 37.0% (T) for corn, and 35.5% (B) and 35.3% (T) for wheat. A greater ($P < 0.001$) proportion of corn silage structures met the desired density benchmark when expressed as DM (88.0%; 15 lb DM/ft3than AF (44.0%; 44 lb AF/ft3). Corn silage structures (88.0%) had at least one density sample below 44 lb AF/ft3, and 60.0% below 35 lb AF/ft3. Density of corn silage structures was higher at B than at T (47.6 vs. 36.6 lb AF/ft3; $P < 0.001$). There were no differences in the proportion of wheat silage structures meeting the desired density benchmark as AF (18.7%; 40 lb AF/ft3) or as DM (31.2%; 14 lb DM/ft3). Wheat silage structures (87.5%) had at least one density sample below 40 lb AF/ft3, and 68.7% below 30 lb AF/ft3. Density of wheat silage structures was higher at B than at T (40.0 vs. 29.1 lb AF/ft3; $P < 0.001$). The units (DM or AF) and sample location (B and T) need to be accounted for when interpreting silage density results. There are opportunities to improve silage packing density in California dairies.

Key words: corn silage, wheat silage, density

T263 Molecular aspect of laying hens feed cottonseed meal supplemented with lysine and enzyme. K. Pournia*, H. Kermanshahi, and A. Golian, *Ferdowsi University of Mashhad, Mashhad, Iran.*

The objective of this study was to evaluate the effect of cottonseed meal supplemented with lysine and NSP-depredating enzyme on jejunum cell efficiency and magnum protein synthesis as measured RNA:DNA and Protein:RNA ratio, respectively. Eighty White Leghorn hens (80 weeks old) were used in this experiment for 12 weeks. Hens were randomly divided into 4 treatments of 5 replicates with 4 birds in each. The experiment was conducted in 2 × 2 factorial experiment in completely random design (CRD). The hens were fed by mash basal diet supplemented with 1% lysine + 0% enzyme (Treatment 1), 1% lysine+0.025% enzyme (Treatment 2), 2% lysine+0% enzyme (Treatment 3), 2% lysine+0.025% enzyme (Treatment 4). Feed and water were provided ad libitum. The result indicated that protein content in magnum was not significantly affected by different levels of lysine and enzyme. Although magnum Protein: RNA ratio increased as lysine level increased ($P < 0.05$). However, results have shown that jejunum DNA concentration was not significantly affected by lysine ($P > 0.05$). Moreover, jejunum RNA: DNA ratio increased with 2% of lysine ($P < 0.50$). It was concluded cottonseed meal supplemented with lysine and enzyme had improved jejunum cell efficiency (RNA: DNA), and magnum protein synthesis (Protein: RNA) ratio in laying hens.

Key words: cottonseed meal, cell efficiency, protein synthesis

T264 Performance evaluation of Santa Ines ewes and lambs weaned at 60 days of lactation. M. M. Stradiotto*[1], A. D. Rodrigues[2], and J. A. Negrão[1], *[1]University of Sao Paulo – USP; Faculty of Animal Science and Feed Engineering – FZEA, Pirassununga, SP, Brazil, [2]University of Sao Paulo State – UNESP; Faculty of Agronomy and Veterinary Sciences – FCAV, Jaboticabal, SP, Brazil.*

The objective of this work was to verify how the maternal stress influenced lambs performance during suckling and after weaning. For that, milk production of 50 ewes was measured during 90 d of lactation. Before weaning, milk production was measured twice a month by the system weigh-suckle-weigh of lambs. Weaning occurred abruptly, at 60 d of lambs life, and after that, milk production was daily measured for 30 d. During lactation, animals were submitted to stressful stimulus called ACTH, where ewes received 1 mL/10kg BW of ACTH (adrenocorticotropic hormone) with saline solution 0.9%, which corresponded to the administration of 0.6 UI of the hormone by intravenous injection (jugular). Blood samples were collected by jugular vein puncture in 5 times: −20 min (20 min before the stressful stimulus ACTH), 0 min (soon after the stimulus) and 60, 120, and 300 min after the stimulus. The variables were analyzed in subdivided parcels, which means as repeated measures in time through MIXED procedure. Means were compared by Tukey test with a significance level of 0.05 and, when necessary it was performed the Pearson correlation analysis through statistical program SAS (2000). Mean milk production before weaning was influenced by cortisol levels at 60 min after ACTH administration, with linear correlation of 0.36 ($P < 0.01$). However, mean milk production after weaning and weight of lambs were not influence by imposed stress to the animals. Milk production was greater at 90 d, as in the fourth week after weaning, mean production was 195.2 mL (±17.74), showing that the breed has satisfactory mean milk production.

Key words: milk, sheep, weigh-suckle-weigh

T265 Comparison of pork characteristics of antibiotic free Yorkshire crossbreds raised in the hoop barn. S.-H. Oh*[1], D. Bautista[2], D. Hanson[2], M. Morrow[2], and T. See[2], *[1]North Carolina A&T State University, Greensboro, [2]North Carolina State University, Raleigh.*

The objective of this study is to compare pork characteristics for antibiotic free Yorkshire crossbreds to be raised in the hoop barn. The experiments have been accomplished in North Carolina Agricultural and Technical State University Farm and The Center for Environmental Farming Systems (CEFS) in Goldsboro, NC, where have been raising antibiotic free Yorkshire sows. Twenty 4 sows were impregnated in each research farm with the semen of Berkshire, Large Black, Tamworth and Yorkshire as a control group. Litters were weaned, and reared within deep-bedded hoop houses. The deep bedding, generally straw, corn stalks, or hay, was spread approximately 14–18 inches thick and provided a comfortable environment for the animals, which allows rooting and other natural behaviors. One hundred four pigs were used to compare pork characteristics which include pH, color score, L*, a*, b*, marbling score, drip loss, hot carcass weight, backfat thickness (BF), loin muscle area (LMA), and shear force. The data was analyzed with GLM in SAS 9.01 including research farm, season, breeding

group and sex as fixed effects. Backfat thickness, LMA, and drip loss were significantly different among breeding groups ($P < 0.05$). Large Black breeding group showed significantly higher backfat thickness followed by Berkshire, Yorkshire and Tamworth groups. However, Tamworth breeding group had significantly higher drip loss (4.50 g) than other groups; 3.77 g, 3.26 g, and 2.62 g in Yorkshire, Berkshire, and Large Black groups, respectively. This information helps the small farmers who raise rare breeds to choose better breed combinations for outdoor environments.

Key words: antibiotic-free Yorkshire, crossbred, pork characteristics

T266 Comparison of body weights in Berkshire and Large Black crossbreds produced by the use of antibiotic-free Yorkshire sows. S.-H. Oh*[1], M. Morrow[2], and T. See[2], *[1]North Carolina A&T State University, Greensboro, [2]North Carolina State University, Raleigh.*

The objective of this study was to compare body weights of Berkshire and Large Black crossbreds produced by the use of antibiotic free Yorkshire sows raised in a hoop facility. Pigs were reared within deep-bedded hoop houses at finishing phase. The swine unit at North Carolina A&T State University has a 48 × 96 ft hoop facility that is different from standard confinement facilities. The deep bedding, generally straw, corn stalks, or hay, is spread approximately 35–45 cm thick and provides a comfortable environment for the animals which allows rooting and other natural behaviors. It is relatively difficult to measure feed intake and growth rates for pigs raised in outdoor systems compared with confinement systems. Eight Feed Intake Recording Equipment (FIRE, Osborne Industries Inc. Osborne, Kansas) stations were used to collect body weight, feed intake, feeding time, feeding rate, number of feedings per day, and feed conversion. This abstract was limited to comparison of body weights among 3 breeding groups that were 23 finishing pigs (5 Berkshire × Yorkshire; 10 Large Black × Yorkshire; 8 Yorkshire × Yorkshire) in total. Before analysis, each individual′s feed intake records were evaluated for outliers by plotting feed intake by day and testing each feed intake observation with the Cook′s D test statistic and studentized residuals. After removal of outliers, 5 time points at 64, 125, 162, 176, 197, and 229 d of age, were selected to analyze the data with the repeated measurement method, which included 138 observations (30 records in Berkshire × Yorkshire; 60 records in Large Black × Yorkshire; 48 records in Yorkshire × Yorkshire). As a result, Berkshire breeding group (Berkshire × Yorkshire) showed significantly higher weights than Yorkshire purebred ($P < 0.05$), however, there was not significantly different between Berkshire and Large Black breeding groups as well as between Large Black and Yorkshire groups. This information helps the small farmers who raise rare breeds to choose better breed combinations for outdoor environments.

Key words: antibiotic free, Yorkshire, crossbred

T267 Evidence that maternal conjugated linoleic acid alters secondary metabolites in plasma of late-stage chick embryos that may lead to increased embryonic mortality. V. A. Leone*[1], D. Haughey[2], E. A. Bobeck[2], M. E. Cook[2], and F. M. Assadi-Porter[2], *[1]University of Chicago, Chicago, IL, [2]University of Wisconsin-Madison, Madison.*

Previous work in our lab shows that hens fed 0.5% conjugated linoleic acid (CLA) in a low-fat diet results in nearly 90% embryonic mortality in non-cooled, fertile eggs. Mortality appeared to be a result of decreased yolk lipid utilization by the developing embryo during the last week of development. Since the chick embryo relies on lipid for nearly 90% of its energy needs via β-oxidation during incubation, we hypothesized that if embryos from CLA-fed hens were lipid "starved," changes in blood secondary metabolites (metabolome) may be altered when compared with embryos from hens fed 0.5% canola oil. Single Comb White Leghorns (8 per treatment) were individually housed and fed standard layer mash with 0.5% canola oil or 0.5% CLA. After one month on diet, hens were artificially inseminated and eggs were incubated. On d 20 of incubation, 3 to 6 viable eggs from each treatment that had not pipped were removed from incubation and plasma was collected aseptically and immediately placed on ice. Plasma metabolites were analyzed via nuclear magnetic resonance (NMR) using a Varian 600 MHz instrument and integrated using MetaboAnalyst software. A 2-tailed *t*-test with unequal variance was conducted to determine significant differences ($P < 0.1$) using SAS. Embryos from hens fed CLA showed decreased plasma leucine ($P = 0.01$), alanine ($P = 0.03$), methionine ($P = 0.03$), glutamine ($P = 0.06$), tyrosine ($P = 0.03$), phenylalanine ($P = 0.07$), formate ($P = 0.06$), and glucose ($P = 0.01$). The significant decreases in plasma amino acids in embryos from CLA-fed hens suggest they are undergoing starvation, hence embryos from hens fed dietary CLA could be in a state of metabolic acidosis and undergoing protein catabolism to counterbalance these effects. This is further supported by the significant decrease in plasma glucose. These results provide preliminary data to show that embryos from CLA-fed hens exhibit a different pattern of metabolism than their control counterparts that may be associated with CLA's negative effects on embryonic mortality.

Key words: CLA, embryonic mortality, metabolomics

T268 Suitability of visual ear tags, electronic boluses and retinal images for tracing and auditing lamb traceability. M. A. Rojas-Olivares, G. Caja, S. Carné, A. Costa-Castro, A. K. K. Salama, A. Ait-Saidi, and M. Rovai*, *G2R, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Lamb traceability using different identification (ID) devices was studied under farm and slaughterhouse conditions. Lambs were intensive fattened and slaughtered as Spanish Recental lamb (23 to 25 kg BW). Lamb primary ID was done at birth with temporary official visual ear tags (V1; polyurethane rectangular flags, 2.8 g, 40 × 15 mm; n = 241) in the left ear. Lamb secondary ID was done at weaning with permanent official visual ear tags (V2; polyurethane triangular flags, 5.2 g, 38 × 39 mm; n = 104) inserted in the right ear and with electronic mini-boluses (MB; ceramic capsules, 19 g, 56 × 12 mm) applied orally. Moreover, 81 lambs were ID with glass encapsulated transponders s.c. injected (IT) in the left armpit for tracing carcasses through the slaughtering line. Electronic ID by MB and IT used 32-mm half-duplex transponders. Retinal images of live lambs (n = 98) were taken at 80 d of age (both eyes) for auditing lamb ID. Head position was compared (normal, n = 67; reversed, n = 31) after harvesting. On-farm traceability did not vary according to ID device ranging from 98.6 to 100%; $P > 0.05$). The V1 and V2 were removed at beheading, and MB at evisceration, enabling carcass ID that was assumed to be the same as the slaughtering order. Although only 78.8% IT were retained after slaughter, they proved that carcass order was altered at weighing, reducing the carcass traceability in the slaughterhouse to 68.3%. All retinal images matched in live lambs, but live vs. slaughtered image matching markedly decreased in the normal vs. reversed head position (56.4 vs. 75.0%; $P < 0.05$). In conclusion, V1, V2, MB and IT were efficient devices for individually tracing live lambs but all of them failed for tracing carcasses efficiently. Individual tracing from farm to

carcass using radiofrequency ID devices would be possible if carcass order is maintained in the slaughterhouse. Retinal images efficiently audited live lambs and most of carcasses. We do not recommend the use of injects for lamb ID, agreeing with previous research, but they may be a useful tool for tracing carcasses when their order is compromised.

Key words: traceability, electronic identification, retinal image

T269 Retrospective analysis of the effects of feeding pelleted versus meal diets on growth performance of 12- to 30-kg nursery pigs over a 5-year period. E. D. Frugé*[1], E. L. Hansen[1], S. A. Hansen[1], K. A. Frerichs[1], and C. W. Hastad[2], *[1]Hubbard Feeds, Mankato, MN, [2]New Fashion Pork, Jackson, MN.*

A retrospective analysis was conducted on 5 trials (TRL) over 5 years (2006–2010) to determine the effects of feeding pigs pelleted (P) vs. meal (M) diets on growth performance. The TRL were combined and analyzed as a randomized complete block design with TRL and BW as blocking factors. Treatment (TRT) replication for each TRL were 12, 6, 12, 5 and 5, for TRL 1 to 5, respectively for a total of 40 replicates, with 25 to 28 pigs per pen (n = 2,129; 12.3 ± 1.05 kg initial BW). Trials were conducted using the same research barn and similar genetics (FAST/PIC dam × TR4 sire). The TRT were; 1) meal diet; and 2) as 1 pelleted. All diets were corn-soybean meal-DDGS based and contained 15, 15, 30, 23.5, and 30% DDGS, in TRL 1 to 5, respectively. Diets were formulated to be adequate in all nutrients and contained 1.20% TID Lys in all TRL except TRL 2 at 1.10% TID Lys. The average TRL length was 26.6 d, ranging from 24 to 29 d between TRL. Consistent improvements in performance for pigs fed pelleted diets were noted in each TRL (Table 1). Overall ADG, GF, and final BW were improved ($P < 0.01$) in pigs fed pelleted diets. Pigs fed pelleted diets had increased ADG by 5.4% and improved GF by 5.9%. These data provide the ability to determine economic benefits of feeding pelleted vs. meal diets in nursery pigs.

T270 Comparative assessment of boar spermatozoa having different cryopreservation potential. J. M. Feugang*[1], M. M. Ferraz[2,1], J. C. Rodriguez-Munõz[1], B. S. Grillis[1], S. T. Willard[3], and P. L. Ryan[1,4], *[1]Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, [2]Faculdade de Medicina Veterinariae Zootecnia, Universidade de Sao Paulo, Brasil, [3]Department of Biochemistry and Molecular Biology, Mississippi State University, Mississippi State, [4]Department of Pathobiology and Population Medicine, Mississippi State University, Mississippi State.*

Introduction of semen cryopreservation is still limited in swine industries due to their poor freezability. Indeed, a subset of boars, known as "bad freezers" induces low pregnancy and farrowing rates compared with "good freezers" when using same amounts of spermatozoa per insemination. Numerous studies have been conducted to improve the cryosurvival of boar semen, but there are still no clear indicators of freezability potential of boar semen. To this end, the present study was conducted to evaluate the motility and viability of boar spermatozoa with known cryotolerance status. Commercial proven fertile boars were selected upon conception rates after artificial inseminations (AI) using fresh semen. Semen of 3 independent ejaculations were collected from 4 "good" and 4 "bad" freezers as indicated by their differential conception rates after AI using frozen-thawed semen. Collected-semen were diluted and either stored in cooling solution or frozen in 5-mL plastic straws. Both semen types were centrifuged through a discontinuous percoll gradient to remove all contaminants. Motile spermatozoa were washed in PBS-PVP or extender for motility (CASA) and viability analyses. The proportions of motile, progressive, rapid, and viable spermatozoa were evaluated. Data were analyzed using a Student′s *t*-test, and $P \leq 0.05$ was fixed as threshold of significance. Sperm motility of cool-diluted semen was similar between "good" and "bad" freezers (82 ± 20% and 78 ± 16%). After freezing-thawing, the proportions of motile (24 ± 8% vs. 22 ± 10%), progressive and rapid spermatozoa were comparable between both boar groups. The proportions of (viable) spermatozoa with intact plasma membrane (94 ± 7% vs. 95 ± 4%), acrosome (29 ± 11% vs. 23 ± 6%) and mitochondria (87 ± 11% vs. 87 ± 10%) membranes were not significantly different between "good" and "bad" freezers. Our data confirm the inability of routine criteria of sperm evaluation to identify the freezability status of boars, suggesting the existence of induced-molecular cryodamages that may characterize "bad" freezer boars′ semen. T271 Performance and carcass traits of bulls fed different levels of crude glycerin. J. R. R. Carvalho, M. M. Ladeira*, M. L. Chizzotti, T. M. Gonçalves, P. D. Teixeira, J. S. F. Hostalácio, P. T. Silva, and O. R. Machado Neto, *Federal University of Lavras, Lavras, MG, Brazil.*

The use of crude glycerin to partially replace corn in feedlot diets might be interesting if performance and carcass quality are unchanged. The aim of this study was to evaluate the performance and carcass traits of bulls finished in feedlot fed different levels of crude glycerin. Forty-four Red Norte bulls received the following levels of crude glycerin (83% glycerol): 0, 6, 12 and 18% of DM. The basal diet consisted of 30% of corn silage, 12% of soybean meal, 56% of ground corn grain and 2% of mineral mixture. Glycerin was added to partially replace corn and to achieve an isonitrogenous diet, corn gluten meal (21% CP) was used. The experiment lasted 112 d, with 28 d for adaptation. Animals were weighed at the beginning and at the end of the experiment to obtain the average daily gain (ADG). All animals were slaughtered after fasting for 16 h and hot carcass weight (HCW) was recorded. After 24 h of cooling at 4°C, there were measured cold carcass weight, subcutaneous fat thickness (SFT) and longissimus muscle area (LMA) between the 12nd and 13rd ribs. The experiment was conducted in a completely randomized design and data were analyzed using PROC GLM and PROC REG of SAS 9.1. The inclusion of glycerin in the diet did not affect ADG, HCW, LMA and SFT (Table 1). The dressing percentage (DP) increased linearly with glycerin inclusion, likely due to a higher energy intake. The level of 18% of crude glycerin in diet DM to finishing beef cattle does not compromise performance or carcass traits. Funded by Fapemig, CNPq, CAPES, and INCT-CA

T272 Effects of distillers grain supplementation on beef cow performance. M. J. Faulkner*[1], P. M. Walker[1], R. L. Atkinson[2], J. L. Veracini[1], L. A. Forster[3], J. M. Carmack[1], and K. L. Jones[2], *[1]Illinois State University, Normal, [2]Southern Illinois University, Carbondale, [3]Archer Daniels Midland Co, Decatur, IL.*

The objective of this 3-yr study is to determine the optimum inclusion rate for wet corn distillers grains with solubles (DGS) in late gestation and early lactation beef cow diets and the effect of including higher dietary levels of DGS on dystocia, postpartum conception rate, and other measures of cow and calf performance. During yr. 2, 128 cows were blocked by parity (first parity vs. 2 or more parities) and stratified by BW, subject to variation in BCS, to 16 pens, equivalent to 8 cows/pen. Four diets were fed until completion of timed (AI). Control cows (T1) were fed corn silage, shelled corn, and soybean meal based diets to meet NRC estimates. In treatment diets DGS replaced shelled corn, soybean meal, and a portion of the corn silage, resulting in DGS inclusion rates (DM basis) of 11.4% (T2), 39.2% (T3), and 54.4% (T4). Analyzed dietary values for CP intake were 10.0%, 10.6%, 14.8%, and 18.3%, for T1, T2, T3, and T4, respectively. Mean DMI were 6.2 ± 0.6, 5.5 ± 0.04, 7.3 ± 1.0, 7.7 ± 1.1kg for T1, T2, T3 and T4, respectively. No differences ($P > 0.05$) between treatments were observed for AI conception, calf birth weight, and milk production. Calving ease scores were not significantly different ($P = 0.27$) but a numerical increase toward increased difficulty was shown for T4 compared with other treatments. Differences in calf BW at AI ($P = 0.01$), cow BW change ($P = 0.001$), and cow BCS change ($P = 0.001$) were observed where T1 = T2 < T3 = T4. Higher ($P = 0.003$) DMI were observed for T3 and T4 than for T1 and T2. These data suggest that cows fed 39% to 54% of their diet as DGS consumed more DM and had increased BW, BCS and calf BW than cows fed to meet NRC recommendations with either DGS or shelled corn and soybean meal.

Key words: distillers grains, beef cow performance

T273 Effect of a mixture of cinnamaldehyde, carvacrol and capsicum oleoresin on performance and rumen development of weaning calves. C. Oguey*[1], J. Trautwein[2], H. Hendrik Kuhrmann[2], G. Dusel[2], and D. Bravo[1], *[1]Pancosma, Geneva, Switzerland, [2]Universtiy of Applied Sciences, Bingen, Germany.*

Weaning is a critical period for the calf as its diet changes from liquid to solid feeding. Plant extracts are known to optimize rumen function in ruminants and growth performance in ruminants and monogastrics. The objective was to test the effect of a blend of cinnamaldehyde, carvacrol and capsicum oleoresin (XT, XTRACT 6930 and XTRACT Instant Pancosma) on performance and rumen parameters of weaning calves. Forty suckling calves aged of 14 d (initial BW 45 kg) were randomly allocated to 2 treatments for 68 d: CT: standard milk replacer (MR) and concentrate feed (CF), and XT: MR + 250 ppm XT and CF + 100 ppm XT. Animals were restricted fed MR from d1 to 60, and ad libitum fed CF, hay and corn silage from d 1 to 68. Individual daily intakes of MR and CF, daily hay and silage intake per group, individual weekly BW and BWG and blood and rumen parameters at d 56 were recorded. Data were analyzed using the GLM procedure of SAS. For the whole weaning duration calves fed XT exhibited a concentrate intake greater by 26.4% ($P < 0.01$) compared to CT. XT increased BWG and final BW respectively by 8.11% ($P = 0.14$) and 3.8% ($P = 0.097$). From d 1 to 42, compared to CT, calves fed XT exhibited greater concentrate intake (90.89 vs. 174.03 g/animal daily, P = 0.015) and BWG (470.75 vs. 536.718 g/animal daily, $P = 0.012$). From d 43 to 68, XT tended to increase concentrate intake (+14.5%, $P = 0.125$), but did not affect BWG ($P = 0.300$). However, at d 56, animals fed XT tended to have greater blood leucocytes (+13.8%, $P = 0.11$), monocytes (+39.0%, $P = 0.19$) and basophiles (+60.0%, $P = 0.13$), suggesting that these calves were subject to an infection. XT did not affect ruminal concentrations of total VFA and acetate ($P > 0.76$), but numerically increased ruminal concentrations of propionate and butyrate (respectively +10.3%, $P = 0.64$ and +39.0%, $P = 0.15$), suggesting that calves supplemented with XT can be more prone to a quick development of their rumen.

T274 Effect of fescue toxicosis on the expression of selected hepatic genes in Angus cattle. J. Bryant*, J. Johnson, B. Scharf, D. Kishore, E. Coate, P. A. Eichen, K. Wells, J. Green, and D. E. Spiers, *University of Missouri-Columbia, Columbia.*

Fescue toxicosis may result from intake of ergot alkaloids found in endophyte-infected (E+) tall fescue. The liver is the major organ involved in the pathology of fescue toxicosis, as it is the site where the toxic ergot alkaloids are metabolized. A study performed with rats consuming an E+ diet reported increased expression of phase I detoxification enzymes and a decreased expression of antioxidants, to suggest an increase of cellular oxidative stress. This study was performed to determine if intake of E+ fescue had the same effect on the expression of detoxification enzymes and antioxidants in cattle. Missouri- (MO; n = 10; 513.6 ± 13.6 kg BW) and Oklahoma- (OK; n = 10; 552.8 ± 12.0 kg BW) derived Angus steers, maintained at 19–22°C air temperature, were fed diets containing either endophyte-free (E-) or E+ seed (30 µg ergovaline/kg BW/day) for 8 d. Feed intake (FI) was recorded daily. Blood and liver tissue samples were collected during pretreatment followed by blood samples at d4 and liver tissue samples on d8 of treatment. A significant reduction (2.84 kg, $P < 0.05$) in FI of E+ steers occurred from treatment start to Day 7. Blood alkaline phosphatase was significantly lower in E+ steers compared with E- steers with a difference of 14.5 U/L ($P < 0.05$) to confirm the presence of fescue toxicosis. Real-time PCR was performed to determine expression of selected hepatic phase I detoxification enzymes and specific antioxidant proteins. Illumina deep sequencing was performed on samples from the fescue-naïve OK steers. Tiling of the sequences to a ~23,500 member reference allowed for the quantification of mRNA transcript abundance in each sample. Real-time PCR demonstrated that cattle consuming E+ fescue did not have a significant change in the expression of phase I detoxification enzymes or antioxidants. Illumina transcriptome analysis confirmed that E+ fescue did not have any significant effect on the expression of phase I genes; however, there were over 250 genes whose expression was significantly affected by E+ fescue, including several genes involved in lipid and carbohydrate metabolism and several involved in phase II conjugation reactions.

Key words: cattle, fescue

T275 Evaluation of Nellore steers′ performance supplemented with two levels of concentrate and sugar cane in feedlot. R. M. Silva*[1,2], J. T. Pádua[2], J. Restle[2], R. Z. Taveira[1], B. A. S. R. Leite[1], and D. A. Lima[2], *[1]Universidade Estadual de Goiás, São Luís de Montes Belos, Goiás, Brazil, [2]Universidade Federal de Goiás, Goiânia, Goiás, Brazil, [3]FAPEG, Goiânia, Goiás, Brazil.*

The aim of this research was to evaluate the BW gain associated to the DMI of Nellore steers fed in feedlot. Two levels of concentrate, 40% and 60%, were used in the diets, which t were composed by 36.71% and 59.45% of sugar cane, 27.08% and 53.74% of ground corn, 9.55% and 5.45% of cottonseed meal, 0.91% and 0.98% of urea, and 3.01% and 3.12% of a mineral mix, respectively. Twenty animal′s with 24 mo of age and average weight of 347.60 kg were used. The animals were weighted every 21 d and on the last day of the trial, resulting in 90 d of trial. The mean intake of sugar cane was evaluated by weighing and colleting the orts twice a week. The mean results were compared by Tukey test ($P < 0.05$). The initial BW was not different among between ($P > 0.05$). There wasn′t a difference in the ADG between the first and fourth weightings ($P > 0.05$). However, differences in ADG between the fourth and fifth weightings were detected ($P < 0.05$). The DMI wasn′t different between the first and second weightings ($P > 0.05$). Considering the final mean weight, the increase in the concentrate level from 40% to 60% did not result in significant weight gain.

Key words: average daily gain, beef cattle, nutrition

T276 The influence of glycerol supplementation during late gestation on beef cow performance and dietary digestibility. S. J. Winterholler*, N. L. Hojer, R. H. Pritchard, and K. VanderWal, *South Dakota State University, Brookings.*

Glycerol (GLY) was evaluated as an energy supplement for spring-calving beef cows during late gestation (n = 30; 637 kg of initial BW; 5.8 initial BCS) consuming medium-quality forage. Treatments were formulated to provide equal CP and included (DM basis): 1) 1.06 kg/d soybean meal (SBM); 2) 1.06 kg/d soybean meal and 0.86 kg/d glycerol (GLY); 3) 0.65 kg/d soybean meal and 1.74 kg/d soybean hulls (SBH). Glycerol and SBH were fed for isocaloric intake; SBM was the positive control. Glycerol was mixed with SBM daily and diets were fed individually. Cows had ad libitum access to medium-quality bromegrass hay (7.6% CP%; 79% NDF, DM basis). Change in cow BW over the feeding period was similar among treatments (29 kg; $P = 0.20$). Change in BCS over the feeding period tended ($P = 0.12$) to be greater for GLY and SBH as compared with SBM (0.42, 0.15, −0.08, respectively). Cow BW (645 kg) and BCS (5.4) before breeding were similar among treatments ($P > 0.20$). Fecal grab samples were collected twice throughout the 60-d supplementation period and were composited to estimate dietary digestibility, using ADIA as an internal marker. Diet digestibility of DM (52.6%; $P = 0.64$), NDF (66.8%, $P = 0.82$), and ADF (68.3%, $P = 0.77$) were similar among treatments. Supplementation of GLY in a forage-based diet had no negative impacts on fiber digestibility. Additional energy from GLY was an effective replacement for SBH to maintain BCS during late gestation.

Key words: beef cow, glycerol, supplement

T277 The effect of feed additive and sulfur intake on rumen fluid pH and rumen gas cap hydrogen sulfide concentration in feedlot steers. K. L. Neuhold*[1], J. J. Wagner[1], T. E. Engle[1], E. M. Domby[1], and M. Branine[2], *[1]Colorado State University, Fort Collins, [2]Alpharma Animal Health, Canon City, CO.*

Crossbred yearling steers (n = 432) were used to study the effects of Cattlyst and Aureomycin (CA) vs. Rumensin and Tylan (RT) and variation in Sulfur (S) intake on rumen fluid pH and rumen gas hydrogen sulfide (H_2S) concentration. An unbalanced randomized block design using a 2 × 2 factorial was utilized. Factors included feed additive (CA vs. RT) and S concentration (constant vs. variable). The variable concentration (VAR) was intended to simulate the use of random loads of wet distillers grains (WDG). Random numbers were generated for each d of the study. High S diets (S = 0.60% of DM) were fed to VAR on d associated with an even number. Low S diets (S = 0.48% of DM) were fed to CON all d of the study and to the VAR only on d associated with an odd number. From d 0 through 35, a high S meal supplement was fed to VAR on the appropriate d. Since variation in S concentration in WDG is driven by rate of inclusion and S concentration in distillers solubles (DS), 2 DS based liquid supplements (low S, 0.99% vs. high S, 2.35%) were used to create the constant (CON) vs. VAR S intake from d 36 through slaughter. Sulfuric acid was added to the high S DS used to obtain the intended dietary S concentration. On d 35, 70, and 105 rumen fluid and gas cap samples were obtained via rumenocentesis from a subsample (3 hd/pen and 3 pens/treatment) of steers to determine rumen fluid pH and H_2S concentration. The effects

of feed additive, dietary S, or the interaction on rumen fluid pH were not significant ($P > 0.38$). An interaction between feed additive and dietary S treatment ($P < 0.02$) existed suggesting that the effect of feed additive on H_2S concentration was influenced by dietary S. Steers fed the CON diet receiving RT exhibited lower H2S concentration than steers fed CA (1053 vs. 2519 mL/L). Steers fed the VAR diet receiving RT exhibited a higher H_2S concentration than steers fed CA (2567 vs. 2187 mL/L). Rumen H_2S concentration was related to rumen fluid pH suggesting that management of rumen pH is likely a key in dietary S management.

Key words: sulfur, ionophore, antibiotic

T278 The effect of feed additive program and dietary sulfur concentration in steam-flaked corn diets containing wet distillers grains on feedlot performance and carcass merit in yearling feedlot steers. E. M. Domby*[1], K. L. Neuhold[1], J. J. Wagner[1], T. E. Engle[1], and M. Branine[2], *[1]Colorado State University, Fort Collins, [2]Alpharma Animal Health, Canon City, CO.*

Crossbred yearling steers (n = 432, BW = 329 ± 10.5 kg) were used in an unbalanced randomized block design to examine the effect of feed additives and dietary sulfur (S) on performance and carcass merit. Treatment factors were arranged as a 2 × 2 factorial and included ionophore and antibiotic [Rumensin/Tylan (R/T) or Cattlyst/Aureomycin (C/A)] and dietary S (constant or variable). High S diets (0.60% S, DM basis) were fed on random days to the variable (VAR) treatment. Low S diets (0.48% S, DM basis) were fed to the VAR treatment on remaining days and to the constant (CON) treatment all days. From d0 to 35 the high S diet was achieved by using a high S meal supplement; however, since S concentration in wet distillers grains (WDG) is associated with distillers solubles (DS) added to WDG and H_2SO_4 added to the DS, the VAR S diets were achieved from d36 to d159 by using 2 DS sources at 0.99 versus 2.35% S. Cause of cattle death was verified by necropsy. No interaction between S and additive treatments existed for feedlot performance; therefore, only main effects are presented. Steers receiving VAR had higher ($P < 0.05$) BW compared with CON supplemented steers. Overall DMI was greater ($P < 0.05$) for VAR compared with CON steers. Average daily gain and feed efficiency were similar for CON and VAR. Steers receiving VAR diets had a higher mortality rate ($P < 0.02$) than steers fed CON diets (5.21 versus 0.67%). Feedlot performance and carcass merit were similar for feed additive treatments. The S by feed additive interaction was significant ($P < 0.05$) for dressing percentage indicating that S treatment had no effect on dressing percentage if R/T was fed but when steers were fed C/A, dressing percentage was reduced by 0.72% ($P < 0.02$) if VAR diets were fed. All other carcass characteristics were similar across S treatments. Results indicate that performance and carcass characteristics were not affected by feed additive program. Varying S in diets increased mortality rate; however, feedlot performance and carcass merit were not affected.

Key words: sulfur, ionophore, antibiotic

T279 Effects of dietary chromium propionate on performance traits of stocker/growing cattle. J. L. Veracini*[1], P. M. Walker[1], M. J. Faulkner[1], and R. E. Hall[2], *[1]Illinois State University, Normal, [2]Cooperative Research Farms, Richmond, VA.*

Chromium propionate is a trace mineral when in the +3 state will increase the uptake of glucose by insulin sensitive organs. How this change in glucose metabolism affects growth performance has varied depending on the dietary concentrations of Chromium and the different substrates to which chromium is bound. The objective of this study was to determine if providing supplemental chromium to receiving calves in the feedlot improves growth performance and health status. Two hundred forty crossbred steer calves (260 ± 49 kg) were blocked by source and stratified within each block (3 blocks) by BW to 32 treatment pens (either 10 or 12 pens/block). All steers were fed a concentrate with or without chromium for 70 d, at 1.25% of BW along with forage ad libitum (ground grass hay for 55 d, followed by corn silage for 15 d). Two treatment concentrates containing either 0 (T1) or 717 ppb chromium (DM basis) from chromium propionate (T2) were randomly assigned to 16 pens each. Average chromium concentration in the total DM intake of steers on the chromium treatment was 328 ppb. There were no significant differences between treatments throughout the trial. Normal steer health status was maintained throughout the trial with the exception of d 14 to 28 when respiratory disease challenges were observed. Chromium supplementation (T1) tended to improve rate of gain 35% ($P = 0.074$) from d 14 to d 28 and 12% ($P = 0.058$) from d 0 to d 28. Feed efficiency tended to be improved 10% by chromium supplementation from d 0 to d 28 ($P = 0.106$). From d 28 to d 55, steers on the control diet (T2) exhibited some compensatory gain; which was nonsignificant. Steer performance subsequent to d 28 and for the overall 70 d trial was not ($P > 0.05$) influenced by chromium supplementation. The greatest advantage to chromium supplementation may occur during the receiving period when steers are subjected to respiratory disease challenges. During such periods ADG, and G/F may be improved up to 30% to 35%, respectively, for steers receiving supplemental chromium propionate compared with control steers.

Key words: chromium propionate, respiratory challenge, steers

T280 Nutrient digestibility and residual feed intake in Nellore heifers. R. H. Branco[1], E. Magnani[1], T. L. Sobrinho[2], S. F. M. Bonilha[1], L. T. Egawa[1], M. E. Z. Mercadante*[1], and F. M. Monteiro[1], *[1]Instituto de Zootecnia, Sertãozinho, São Paulo, Brasil, [2]Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brasil.*

Residual feed intake (RFI) as a tool for evaluating feed efficiency has been widely studied, however, associations among RFI, animal growth and nutrient digestibility are inadequate and existing data are contradictory. The objective of this study was to evaluate nutrient digestibility of Nellore heifers classified according to RFI. The experiment was conducted at Instituto de Zootecnia, Sertãozinho/São Paulo/Brazil with 32 Nellore heifers with 377 kg of average BW, previously classified according to RFI which was calculated by the difference between DMI observed and estimated by regression equation based on ADG and mid metabolic BW. Heifers were classified into high RFI (≥mean + 0.5 SD; less efficient) and low RFI (≤mean - 0.5 SD; more efficient). The diet was formulated with tifton hay, corn ground, cottonseed meal and urea, with 15.43% CP and 56.77% NDF. Animal feces were collected 2, 4 and 6 h after feeding, on consecutive 3 d, and analyzed for concentrations of DM, NDF, ADF, cellulose, ether extract (EE) and CP. Lignin was used as an internal marker. There were no differences between low and high RFI animals for CP digestibility (CPD; $P = 0.9506$) and EE digestibility (EED; $P = 0.6878$). Low RFI animals had higher DM digestibility (DMD), NDF digestibility (NDFD), ADF digestibility (ADFD) and cellulose digestibility (CELD) than the high RFI ones (Table 1). Differences in diet digestibility between RFI levels would be due to retention time and ruminal individual feeding behavior. Associations between RFI and nutrients digestibility, would indicate that the principle of equal digestibility for animals receiving similar diets would not be entirely accurate. Thus, it can be argued that small variations in nutrients digestibility provide great impact on

feed efficiency and may be a factor discriminating among levels of efficiency.

Table 1. Feed intake and nutrient digestibility of Nellore heifers classified for RFI

Traits	Low RFI	High RFI	CV	*P*-value
n	17	15		
RFI, kg/d	−0.419*	0.445	1.39E-4	<0.0001
DMI, kg/d	7.73*	8.43	10.4	0.0002

T281 Potential of calcium oxide-treated corn stover and modified distillers grains as a partial replacement for corn grain in feedlot diets. J. R. Russell*[1], D. D. Loy[1], and M. Cecava[2], *[1]Iowa State University, Ames, [2]Archer Daniels Midland Company, Decatur, IL.*

Effects of partial replacement of corn grain in the feedlot diets with calcium oxide (CaO)-treated corn crop residues and modified distillers grains with solubles (MDGS) were evaluated in sheep digestion and steer growth experiments. In 2009, corn stover (59.7% DM) was harvested and stored in silo bags untreated or treated with CaO at 5% of the DM. Large round bales of stover were also harvested, stored outdoors, and tub-ground before feeding. Baled stover was used as 5% of a Control diet containing corn grain, MDGS, and a mineral-vitamin supplement at 70, 20, and 5% of the DM. Three experimental diets containing 20, 35, 40, and 5% DM from baled (Baled diet), untreated (Untreated diet), or CaO-treated stover (CaO diet) with corn grain, MDGS, and mineral-vitamin supplements were also prepared. Baled, Untreated, and CaO-treated stover diets were fed at 1.5 × maintenance to 3 lambs (39 kg) in a 3 × 3 Latin-square digestion trial with 10-d adjustment and 5-d collection phases. Two hundred ten Angus-cross steers (294 kg) were allotted to 35 pens and fed the Control, Baled, Untreated, and CaO-treated stover diets to finish or fed the Baled, Untreated, and CaO-treated stover diets during growing to 454 kg and the Control diet to finish. The DM digestion coefficients ($P < 0.05$) were 75.9, 75.5, and 83.2% for the Baled, Untreated, and CaO-treated stover diets. Average daily gains (kg/d; $P < 0.05$) and feed-to-gain ratios (kg/kg; $P < 0.05$) of steers fed the Control, Baled, Untreated, or CaO-treated stover diets to finish and the Baled, Untreated, CaO-treated stover diets during growing and the Control diet to finish were 1.8, 5.5; 1.5, 6.2; 1.6, 5.8; 1.7, 5.2; 1.5, 5.8; 1.5, 5.5; and 1.6, 5.2 to finish. Steers fed the Control diet to finish had a higher ($P < 0.05$) marbling score than steers fed the stover diets. Economic returns per steers fed the CaO-treated stover diet to finish were greater than those fed the Control diet at a corn price of $4.00/bushel and became more favorable with increasing corn prices.

Key words: beef steers, corn stover, modified distillers grains

T282 Performance of Nellore steers from a genetic improvement program in feedlot. M. D. Freitas Neto[1,2], J. J. R. Fernandes*[1,2], D. A. Lima[1,2], P. L. P. Rezende[1,2], G. A. B. Queiroz[1], L. F. N. Souza[3], J. M. C. Silva[1], E. G. Moraes[3], and M. L. R. Pereira[1], *[1]Universidade Federal De Goias, Goiania, Goias, Brasil, [2]Conselho Nacional De Desenvolvimento Cientifico e Tecnologico, Brasilia, Distrito Federal, Brasil, [3]Nelore Qualitas, Goiania, Goias, Brasil.*

The objective of this trial was to evaluate the BW gain level of 113 Nellore non-castrated steers with an average age of 24 mo in feedlot. The animals were distributed into 16 pens, 15 pens with 7 steers and 1 pen with 8 steers, and divided into 4 treatments by grade of the genetic program: T1 = −0.067; T2 = 3.840; T3 = 7.049 and T4 = 10.763. The results were analyzed in a totally randomized design using the statistical software SAS (2002). The grade considers the BW at different ages and the scrotal circumference. The animals were fed once daily by a total mixed machine provided with a digital balance and the orts were weighed weekly. The diet was composed of 14.88% of sugar cane bagasse, 43.89% of corn germ, 4.36% of soybean meal, 19.15% of soybean hulls, 14.79% of cotton seed, 0.95% of urea and 1.99% of mineral. The animals were weighed before the beginning of the trial and then each 21 d. The animals with highest grade showed a higher DMI (kg/day) ($P < 0.05$), maybe because they had higher BW ($P < 0.05$). The treatments did not affect DMI (% of BW and $BW^{-0.75}$; $P > 0.05$). The steers with higher grades (T4) showed higher ADG than the steers with lowest grade (T1). For T4, LM area was higher than the others ($P < 0.05$). There were no differences in rib fat thickness and rump fat thickness ($P > 0.05$). Correlations between the grade and DMI (kg/day), grade and ADG, grade and LM area and grade and rib fat thickness were (r = 0.57; $P < 0.05$), (r = 0.66; $P < 0.05$), (r = 0.84; $P < 0.05$) and (r = 0.53; $P < 0.05$), respectively.

Key words: carcass, fat thickness, longissimus muscle area

T283 Effect of partial or complete replacement of barley grain with wheat bran on voluntary intake, apparent nutrient digestibility and rumen pH of beef heifers fed backgrounding rations. A. D. Friedt*[1], T. A. McAllister[2], and B. Wildeman[3], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge Research Centre, AB, Canada, [3]Pound-Maker Agventures Ltd., Lanigan, SK, Canada.*

Wheat bran (WB) is a high fiber, low starch by-product of the wheat processing industry. Few published studies are available on the nutritional value of WB for growing cattle. The objective of this trial was to evaluate the effect of replacing rolled barley (RB) with WB on apparent nutrient digestibility, voluntary intake and rumen pH of beef cattle fed a moderate energy growing diet. Five spayed and rumen cannulated Angus heifers (584 ± 40 kg) were used in a 5x5 Latin square design. The control diet consisted of 36% barley silage, 24% grass hay, 8% supplement and 32% RB (DM basis). Dietary treatments replaced RB with WB at 8, 16, 24 and 32% of the diet (DM basis). Voluntary DM intake was highest in the control ration and decreased ($P < 0.01$) as level of WB increased. Mean rumen pH, as well as duration (min) and area under pH cut off values of 6.0, 5.8 and 5.5 were not affected ($P > 0.05$) by WB inclusion. Maximum and minimum daily pH values were not affected ($P > 0.05$) by treatment. Feeding WB at levels greater than 8% of ration DM decreased ($P < 0.01$) DM and gross energy ($P < 0.05$) digestibility, while feeding WB at levels greater than 24% decreased ($P < 0.05$) organic matter digestibility. However, digestible energy content was not affected ($P > 0.05$) by WB treatment. Acid (ADF) and neutral (NDF) detergent fiber digestibility decreased ($P < 0.05$) in all

diets containing WB when compared with the control diet ($P < 0.05$) with the exception that NDF digestibility of the 24% wheat bran diet was similar to that of the control diet. Crude protein digestibility was not affected ($P > 0.05$) by treatment. These results indicate that due to reduced dry matter intake and apparent nutrient digestibility, WB is unlikely to support similar performance to barley grain in backgrounding diets for cattle.

Key words: wheat bran, digestibility, beef heifers

T284 Effect of different doses of chitosans to modulate ruminal fermentation in Nelore steers. F. P. Renno*[1,2], A. P. C. Araujo[1], J. E. Freitas Junior[2], J. R. Gandra[1], R. Gardinal[1], G. D. Calomeni[1], L. N. Renno[3], M. C. B. Santos[1], and R. T. Trimboli[1], *[1]University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [2]State University Julio de Mesquita, Jaboticabal, Sao Paulo, Brazil, [3]Vicosa Faculty of Life Sciences and Health, Vicosa, Minas Gerais, Brazil.*

The objective of this study was to evaluate the inclusion of different doses of chitosan in the diet of beef cattle on intake and in the pattern of ruminal fermentation. Eight Nellore steers (540 ± 28.5 BW/kg of SD) cannulated in the rumen were used and divided into 2 4 × 4 balanced Latin squares with a experimental period of 21 d, being 14 d for adaptation and 7 d of sample collection. The daily doses of chitosan (0, 50, 100 and 150 mg/kg BW) were inserted directly through the rumen cannula, twice daily. Daily intake was measured individually so to be kept a percentage of orts between 5 and 10% of the total supplied in the previous day. Samples of ruminal fluid were collected at 0 (before feeding) and 2, 4, 6, 8, 10 and 12 h after feeding. For variables measured at long time, the statistic model included treatment (doses), the time and the interaction between time and treatment as fixed effects. There was no effect of doses on the DMI, pH and NH3-N concentrations. There was linear effect for concentrations of propionate (mmol/L) with increasing doses of chitosan (21.40; 20.88; 21.66 and 22.08 for 0, 50, 100 and 150 mg/kg BW, respectively). There was linear effect for concentrations of acetate (mol/100mol) and decrease of relation C2/C3 with increasing doses of chitosan (69.17; 69.00; 68.67 and 67.97 for 0, 50, 100 and 150 mg/kg BW, respectively). Similarly there was a linear effect for concentrations of propionate (mol/100 mol of VFA) with increasing doses of chitosan (19.56; 19.57; 20.20 and 21.13 for 0, 50, 100 and 150 mg/kg BW, respectively). At the significance level of 5% the analysis in SAS 9.1 by Proc Mixed pointed as best dose for that occurs increase of the energy efficiency 150 mg/kg BW. The increase addition of chitosan in diets change the pattern of ruminal fermentation in Nellore steers.

Key words: energetic efficiency, intake, short chain fatty acids

T285 Evaluation of residual feed intake of Nelore bulls from a genetic improvement program. M. D. Freitas Neto[1,2], J. J. R. Fernandes*[1,2], D. A. Lima[1,2], P. L. P. Rezende[1], L. F. N. Souza[3], E. G. Moraes[3], R. A. Nogueira[1], and M. L. R. Pereira[1], *[1]Univerdidade Federal de Goias, Goiania, Goias, Brasil, [2]Conselho Nacional de Desenvolvimento Cientifico e Tecnologico, Brasilia, Distrito Federal, Brasil, [3]Nelore Qualitas, Goiania, Goias, Brasil.*

The goal of this trial was to evaluate the residual feed intake (RFI) relating to performance and carcass characteristics of 117 Nellore bulls from a genetic improvement program. The animals were an average of 24 mo of age and were located in individual pens. The production measures evaluated were: dry matter intake (Kg/day, %BW and g.BW$^{-0.75}$), average daily gain (Kg/day), feed efficiency (gain:feed), feed conversion (feed:gain). For carcass characteristics, longissimus muscle area (LMA), rib fat thickness (RFT) and rump fat thickness (RUFT) were measured by ultrasound. Dry matter intake (Kg/day) was determined weighing the orts every day. The diet was composed by 5.92% of corn silage, 30.89% of sugar cane bagasse, 26.01% of corn germ 15.12% of soybean meal, 19.53% of soybean hulls, 0.94% of urea and 1.60% of mineral mix. The animals were weighed in the beginning of the trial and each 21 d, so the average daily gain (ADG) could be determined. The estimated dry matter intake (Kg/day) was calculated by the regression of dry matter intake (Kg/day), ADG and BW$^{-0.75}$. The residual feed intake (RFI) was obtained by the difference between the DMI and the EDMI. The bulls were divided in 3 treatments: low, middle and high RFI and the results were analyzed using the statistical software SAS (2002). The animals with low RFI showed less dry matter intake (%BW and g.BW$^{-0.75}$) ($P < 0.05$). A better rate of feed efficiency and feed conversion was showed by the animals with low RFI ($P < 0.05$), because of low dry matter intake. Any difference was found for LMA, RFT and RUFT measured by ultrasound ($P > 0.05$). There were no difference ($P > 0.05$) for first weight, final BW and final BW$^{-0.75}$, showing no relation between RFI with final weight and feed conversion. Correlations between RFI and feed conversion, dry matter intake (%BW) and RFI and dry matter intake (g/Kg g.BW$^{-0.75}$) and RFI were (r = 0.27; $P < 0.05$), (r = 0.81; $P < 0.05$) and (r = 0.88; $P < 0.05$), respectively. No significant correlation for carcass characteristics (LMA, RFT and RUFT) and RFI was found.

Key words: feed efficiency, fat thickness, average daily gain

T286 Effect of different doses of chitosans on ruminal microbial protein synthesis in Nelore steers. F. P. Rennó*[1], A. P. C. Araujo[1], J. E. Freitas Junior[2], J. R. Gandra[1], G. D. Calomeni[1], R. Gardinal[1], L. N. Rennó[3], B. C. Venturelli[1], T. H. A. Vendramini[1], and F. G. Vilela[1], *[1]São Paulo University, São Paulo, São Paulo, Brazil, [2]State University Julio de Mesquita, São Paulo, Jaboticabal, Brazil, [3]Faculty of Life Sciences and Health, Facis, Viçosa, Minas Gerais, Brazil.*

The addition of controllers of rumen fermentation in ruminant diets has been explored in last year aiming to increase energy efficiency and the animal performance. The objective of this study was to evaluate the inclusion of different doses of chitosan in the diet of beef cattle on ruminal microbial protein synthesis. Eight Nellore steers (540 ± 28.5 BW/kg of SD) cannulated in the rumen were used and divided into 2 4 × 4 balanced Latin squares with a experimental period of 21 d being 14 d for adaptation and 7 d of sample collection. The daily doses of chitosan (0, 50, 100 and 150 mg/kg BW) were inserted directly through the rumen cannula, twice a day. Urine samples were collected on d 16 of the experimental period. The estimation of microbial protein synthesis was performed by the method of total excretion of purine derivatives. There was no effect of doses evaluated on concentrations of microbial nitrogen and microbial protein to the 5% level of significance by SAS Proc Mixed 9.1. The values observed for microbial nitrogen were 53.31; 59.53; 48.75 and 79.55 g/day for the doses 0, 50, 100 and 150 mg/kg BW, respectively. The values of microbial crude protein observed were 352.02; 373.33; 302.85 and 448.48 g/day for the doses 0, 50, 100 and 150 mg/kg BW, respectively. The addition of different doses of chitosan did not influence ruminal microbial protein synthesis in Nellore steers.

Key words: microbial nitrogen, purine derivatives, chitosan, beef cattle

T287 Effect of crude glycerin on nutrient intakes and apparent digestibility in Nellore feedlot steers. E. H. C. B. van Cleef*, J. M. B. Ezequiel, A. C. Homem Júnior, A. P. D'Áurea, J. B. D. Sancanari, F. B. O. Scarpino, D. A. V. Silva, and V. R. Fávaro, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Thirty Nellore steers (277.7 ± 23.8 kg BW) were used to compare effects of diets containing increasing levels of crude glycerin to a control on nutrient intake and apparent digestibility. Cattle were blocked by weight and assigned randomly to one of the 5 treatments during 103 d. Animal was the experimental unit, and model effects included block and treatment. Orthogonal contrasts were used to determine the linear, quadratic, and cubic effects of glycerin, and 0% glycerin vs glycerin treatment. Experimental diets consisted of 30% corn silage and 70% concentrate (corn grain, soybean hulls, sunflower meal, glycerin) and were labeled as: 1) diet with no added glycerin (CON), 2) 7.5% glycerin on diet dry matter basis (7.5GLY), 15% glycerin on diet dry matter basis (15GLY), 22.5% glycerin on diet dry matter basis (22.5GLY), 30% glycerin on diet dry matter basis (30GLY). Indigestible neutral detergent fiber was used as internal marker to determine nutrient apparent digestibility. Five ruminally cannulated Nellore steers were adapted to experimental diets and used to incubate diets, orts and fecal samples from the 30 finishing study animals for 264 h. DM intake tended ($P = 0.09$) to decrease linearly with glycerin level. NDF and EE intakes decreased ($P < 0.01$) when glycerin was added to the diets. CP intake was not influenced ($P > 0.05$) by the inclusion of glycerin, and the ADF intake showed a quadratic effect ($P = 0.04$). Feeding glycerin caused linear ($P = 0.03$) reductions in NDF apparent digestibility while simultaneously increasing CP apparent digestibility. The DM, EE and ADF apparent digestibilities were not altered ($P > 0.05$) by glycerin. The inclusion of crude glycerin in feedlot cattle diets becomes a viable alternative since it provides no significant decrease in dry matter intake and digestibility of most nutrients in Nellore cattle. Caution should be taken to the level of roughage used, once the glycerin has a negative effect on fiber digestibility. Further studies are needed to elucidate the relative feed value of glycerin and its effects on performance, carcass characteristics and meat quality.

Key words: biodiesel, co-products, feedlot cattle

T288 Performance and carcass traits of bulls fed lipids sources and ionophore. L. C. Santarosa, M. M. Ladeira*, O. R. Machado Neto, M. L. Chizzotti, T. M. Gonçalves, D. M. Oliveira, L. S. Lopes, J. S. F. Hostalácio, and M. C. L. Alves, *Federal University of Lavras, Lavras, MG, Brazil.*

The objective of this research was to evaluate the performance and carcass traits of Red Norte bulls fed soybean ground grain or protected fat (calcium salts) based on soybean oil, and with or without the inclusion of the sodic monensin. Forty animals were allotted in a completely randomized design using a 2 × 2 factorial arrangement. The diets had corn silage as forage (40% of DM basis), and were isonitrogenous (12.7% CP), with the same ether extract content (7.2%), and neutral detergent fiber (29%). When the ionophore was supplemented, the dosage used was 230 ppm/day. The animals were weighed every 28 d after fasting for 16 h. The duration of the experiment was 84 d, preceded by 28 d of adaptation. At slaughter, carcasses were identified, weighed, washed, divided into halves, and stored in a cold chamber for 24 h at 1°C temperature. After 24 h were measured cold carcass weight, the subcutaneous fat thickness and *Longissimus* muscle area between the 12th and 13th ribs. There were no interaction between lipid source and ionophore ($P > 0.15$) and for lipid source ($P > 0.13$). There were no effects of ionophore for most of the variables, except for dressing percentage (DP), which can be due to an improvement in the metabolizable energy content of the diet. It can be concluded that the ground soybean grain or protected fat did not affect the weight gain any of the carcass traits. Funded by Fapemig, CNPq, CAPES and INCT-CA

Key words: monensin, protected fat, soybean

T289 Effect of post-ruminal *Saccharomyces boulardii* on fecal parameters and nutrient digestibility in Holstein steers given abomasal oligofructose. K. Davison*, R. L. Hougentogler, C. Leonardi, M. M. McCarthy, L. M. Nemec, and T. F. Gressley, *University of Delaware, Newark.*

Dietary conditions that lead to increased carbohydrate fermentation in the large intestine of ruminants may damage gastrointestinal tissues. Probiotics such as *Saccharomyces boulardii* (SB) modify intestinal fermentation and may improve the response to a large intestinal carbohydrate load. This study evaluated the effects of SB on fecal parameters and nutrient digestibility in steers before and after an abomasal oligofructose challenge. Six ruminally cannulated Holstein steers were used in a crossover design experiment with 18 d periods. Treatments were abomasal delivery of 0 or 10 g/d SB. On d 16 of each period, steers were abomasally dosed with 0.25 g/kg BW oligofructose every 6 h for 24 h. Pre-challenge fecal samples were collected every 6 h for 24 h before the first dose, and post-challenge samples were collected every 6 h for 48 h following the first dose. Dry matter, pH, and organic acid concentrations were measured on each sample. Fecal samples were composited by day and used to quantify apparent total tract nutrient digestibility. For DM, pH, and organic acid data, pre- and post-challenge results were each statistically evaluated using a mixed model including fixed effects of treatment, hour, their interaction, sequence, and period, and the random effect of steer. Time was included as a repeated measure. For digestibility data, all results were analyzed in one model. Treatment did not affect pre-challenge fecal DM, pH, or organic acid concentrations ($P > 0.10$). Post-challenge, SB decreased total organic acid concentration (56 vs. 65 mM, $P = 0.05$) and tended to increase fecal pH (6.96 vs. 6.81, $P = 0.09$). Treatment did not affect digestibility of OM, starch, or CP, but there tended to be a treatment × time interaction for NDF ($P = 0.07$). Pre-challenge, SB increased NDF digestibility (45.8 vs. 43.2%), but there was no difference during or following the challenge. The SB treatment modified hindgut fermentation as evidenced by decreased fecal pH and VFA changes following a fermentable carbohydrate challenge and by increased NDF digestibility pre-challenge.

Key words: feces, hindgut, yeast

T290 Can forage-based nutritional strategies offset weaning stress in calves? S. R. Blevins*, A. E. Tanner, W. S. Swecker, B. F. Tracy, D. A. Fiske, J. P. Fontenot, and R. M. Lewis, *Virginia Tech, Blacksburg.*

Weaning is stressful for calves. Calves often vocalize and pace rather than eat, resulting in weight loss and poor gains. Spring-born calves are typically weaned in late summer or early fall, where forages adequate for a mature animal may be insufficient for the maintenance and growth requirements of newly weaned calves. The purpose of this study was to determine if alternate forages could increase gains of newly weaned calves. The study was conducted at a research farm in western Virginia (latitude: 37°56′ N; longitude: 79°13′ W; elevation: 537m). After weaning, 24 moderate and 24 large framed Angus-cross

steer calves were assigned to 1 of 4 forage types: (i) nil-ergot, endophyte-infected fescue, (ii) endophyte-free fescue, (iii) orchardgrass + alfalfa, and (iv) orchardgrass + red and white clover. Three replicates of each forage type (1 ha area each) were grazed for 42 d by 4 calves (2 per frame size). Blood and fecal samples, and BW, were collected on d 0 and 42. Serum was analyzed for blood urea nitrogen, NEFA, glucose, and cortisol. Fecal samples were analyzed for cortisol. The experiment was repeated over 2 years. Data were analyzed (GenStat) using a split-plot design, with year and replicate fitted as random. Fixed effects were forage type, frame size, and their interaction. Age at weaning was a covariate. Between April and September paddocks received on average 59 cm of rain. An additional 8 cm fell during the experiment. Forage on offer did not differ between paddocks (748 (SD 131) kg/ha; $P > 0.10$), with no difference in CP (13 (SD 4) % DM basis) or NDF (33 (SD 4) % DM basis) between forage types ($P > 0.10$). As expected, large frame steers were heavier than medium frame steers ($P < 0.01$) at both the beginning and end. However, no differences were detected ($P > 0.05$) in ADG (0.48 (SD 0.22) kg/d) among forage types or frame sizes. Blood and fecal chemistry results also did not differ among treatments ($P > 0.05$). The forage types considered did not result in different ADG. The question remains whether other forages may be better suited to increasing post-weaning gains in fall-weaned calves in forage-based systems.

Key words: alternative forages, stress, weaning

T291 Urea supplements for beef steers grazing on marandu-grass pastures during dry season in the Brazilian savannas. D. G. de Quadros*[1], H. N. de Souza[2], G. L. Franco[3], R. G. de Almeida[1], and D. N. de Oliveira[1], *[1]Universidade do Estado da Bahia (UNEB), Barreiras, Bahia, Brazil, [2]PETROBRAS, Rio de Janeiro, Rio de Janeiro, Brazil, [3]Universidade Federal do Mato Grosso do Sul (UFMS), Campo Grande, Mato Grosso do Sul, Brazil.*

During the dry season in the Brazilian savannas, pastures become mature, lowering the nutritive value. The objective of this work was to evaluate urea supplements on the grazing behavior and performances of beef steers grazing marandugrass (*Brachiaria brizantha* 'Marandu') pastures. Twenty Nellore steers, weighting 300 ± 24.9 kg of initial liveweight, were used, 5 for treatment, grazing on 5 paddocks of 4 ha, rotating every 7 d, from July to October of 2010, in Barreiras, Bahia, Brazil. The supplements tested were: commercial mineral (M), mineral + urea (MU), and 3 multiple mixes (45.5% TDN) with corn, soybean meal, and 10 (MM10), 15 (MM 15), and 20 (MM20) % of urea, containing 0, 70, 41, 51, and 63% CP, respectively. Grazing behavior was observed every 14 d, registering every type of behavior (grazing, feeding supplements, ruminating/resting, others) during a 24h period. Dry matter and height of pasture were sampled monthly. Weekly, the intake of supplements was measured and the cattle were weighted every 28 d. The experiment was conducted using a completely random design, with 5 treatments and 4 replications. Data were submitted to ANOVA, using Tukey test to compare average values ($P \leq 0.05$). Dry matter was reduced by almost 50% compared from the beginning (7 ton) to the finishing time, mainly leaves, although the height just decreased 10 cm (from 61 to 51 cm). Supplementation reduced grazing time and simultaneously increased rumination/resting time. However, the patterns of behavior were not affected by supplementation. The daily intake of supplements changed with treatment, being 106, 196, 852, 666, and 400 g for M, MU, MM10, MM15, and MM20, respectively. The utilization of mineral alone (M) resulted in expressively less liveweight (150 g/day). Urea in the supplement (MU) maintained cattle liveweight. However, if gains are expected, the mixes should be used. In these cases, liveweight gain reached 324 g/day. Comparing economic performance, the best treatment was MM20, followed by MM10. Urea supplements were shown to be an indispensable tool to beef cattle production.

Key words: multiple mix, performance, protein

T292 Influence of nonmedicated additives as alternatives to antibiotics on calf plasma and intestinal measurements. S. M. Katzman*[1], S. I. Kehoe[1], and D. B. Carlson[2], *[1]University of Wisconsin-River Falls, River Falls, [2]Milk Products LLC, Chilton, WI.*

Many producers use medicated milk replacers to prevent scours in dairy calves, however, a commonly added level of neomycin and oxytetracycline is no longer approved. The objective of this trial was to determine whether a milk replacer with a blend of nonmedicated additives would have similar benefits to a milk replacer with added neomycin and oxytetracycline on intestinal function and electrolyte profiles. Twelve bull calves were purchased from a local farm 3 separate times and were fed 1 of 3 treatments for a 5-week period. All treatments used a 20% fat, 20% crude protein milk replacer with either no additives (C), a blend of nonmedicated additives (NM; animal plasma, yeast cell wall extracts, inulin, and a direct-fed microbial), or neomycin and oxytetracycline (MED; 400 g/ton of neomycin; 200 g/ton of oxytetracycline). Two calves from each treatment were slaughtered during their second day of scouring and intestinal tissues were collected for morphological analyses of jejunum. Plasma samples were obtained weekly and analyzed for sodium, chloride, potassium, calcium, bicarbonate, phosphorus, BUN: creatinine ratio, and anion gap. Proc Mixed in SAS 9.2 was used with a repeated week statement to analyze blood results and repeated calf statement to analyze intestinal results. Plasma results indicate no significant differences between treatments except for sodium concentrations which were significantly lower for C calves (139.5, 140.1, and 141.5 for C, NM, and MED, respectively) and chloride concentrations which were significantly higher for MED (95.3, 95.4, and 97.3 for C, NM, and MED, respectively). Villus lengths were significantly longer for MED (40.4, 40.9, and 53.7 for C, NM, and MED, respectively). Crypt depths were significantly shorter for NM (28.8, 23.5, and 31.4 for C, NM, and MED, respectively). Villus diameter was not significantly different between treatments. These results indicate that medicated milk replacers may enhance intestinal morphology and both nonmedicated and medicated additives may improve electrolyte concentrations in the blood.

Key words: calves, milk replacer, intestinal morphology

T293 Effects of using near infrared spectroscopy to segregate and feed high and low energy barley on feedlot cattle performance, animal health, and carcass characteristics. E. M. Hussey[1], R. E. Peterson[1], D. Plett[2], C. W. Booker[1], G. K. Jim[1], L. O. Burciaga-Robles[1], and M. L. May*[1], *[1]Feedlot Health Management Services, Okotoks, AB, Canada, [2]Western Feedlots, High River, AB, Canada.*

The feed cost of gain accounts for 65–80% of the total cost of production, thus understanding the nutrient profile of the feed consumed by animals is important to investigate. A feeding trial was conducted to evaluate segregating barley by its estimated digestible energy value using near infrared reflectance spectroscopy (NIRS) measuring cattle health, performance, and carcass characteristics. In the study 9,007 heifers (initial BW 255.9 kg ± 4.59) were randomly allocated to one of 3 dietary treatments with 10 pens per treatment. The treatments were low energy barley (LOW), high energy barley (HIGH) and a 50:50

blend of the low and high energy barley (50:50). The data were analyzed as a randomized complete block design using the PROC MIXED (SAS Institute, NC) with the fixed effect of treatment and the random effect replicate with linear and quadratic contrasts. Compared with LOW, HIGH had greater ($P < 0.001$) DE, DM, fat, NE, CP, and bushel weight, with lower values ($P < 0.001$) of ash, ADF, crude fiber, and waste. There was an effect ($P < 0.05$) to increase overall mortality with increasing energy content of the diet (LOW 1.9%; 50:50 2.97%; HIGH 2.94%). In addition, increasing the barley energy increase ($P = 0.04$) metabolic mortality and ($P = 0.06$) miscellaneous mortality. Increasing the energy of the barley fed to cattle tended ($P = 0.06$) to decrease ADG, carcass adjusted ADG ($P = 0.08$), decrease DMI ($P < 0.001$) and decrease on G:F ($P < 0.05$). There was a linear effect to decrease ($P = 0.02$) Canada 2 yield grade carcasses with increasing energy of the diet, with no effect of dressing percentage, or quality grade ($P > 0.16$). Use of NIRS technology to procure feedstuffs has considerable merit, however the implications of segregating barley by its nutrient content needs to be better understood.

Key words: near infrared spectroscopy, feedlot cattle, barley

T294 Supplementation of methionine hydroxy analog, chelated trace mineral and dietary antioxidants in the diet of beef bulls for color stability. I. Castillo*, G. I. Zanton, and M. Vazquez-Anon, *Novus International Inc., St. Charles, MO.*

In the Mexican Southeast Beef Region during the winter of 2009 and spring of 2010, 2 experiments were conducted at commercial feedlots to evaluate methionine hydroxy analog, chelated trace minerals, and a dietary antioxidant on ribeye color stability. The 2 experiments were designed similarly with the same treatment and control diets. The treatment diets were supplemented with methionine hydroxy analog (5g/hd/d; MFP), chelated trace minerals (250 mg/d of Zn, 77 mg/d of Cu, 167 mg/d of Mn; Mintrex), 3 mg/d of Se yeast (Zorien SeY), and dietary antioxidants (125mg/kg DM of Agrado Plus); minerals for the control group were formulated according to NRC 2000. For each experiment, 100 bulls (Zebu x European; 18 ± 2 mo and 455 ± 5 kg) housed in a commercial feedlot were randomly assigned to the control or treatment group pens. Bulls were on trial for a minimum of 42 and maximum of 45 d. Bulls were fed an isoenergetic (1.10 Mcal NEg/kg) and isonitrogenous (14% CP) diet twice a day that was composed of 70% corn, 12% DDGS, 8% of tropical grass hay and 10% of base mix (sugar cane molasses, urea, soybean meal, and vitamins and trace minerals). Following harvest, color was assessed at time 0 (30 min after cut), 3, 6, 9, 12, 24, 48 and 72 h for color stability during cooler storage with a Minolta 508d spectrophotometer with d65 light at 10° observer and AUSMET color scale. For experiment 1, meat from treatment-fed bulls compared with control-fed bulls (n = 8/treatment/experiment) had significantly lower visual color assessment ($P < 0.05$) at time 6, 9, 12, 48, and 72 h while lightness (L*) was significantly higher at all times. For experiment 2, meat from treatment-fed bulls had significantly lower visual color assessment at all times and significantly higher lightness at all times except for 12 and 24 h. There were no differences in average daily gain (1.6 kg/d) during the trials. From these studies it can be concluded that supplementing methionine hydroxy analog, chelated trace minerals, and dietary antioxidant to diets fed to finishing bulls significantly improved beef color shelf life.

Key words: antioxidant, beef color, trace minerals

T295 Evaluation of bimodal distributions to determine meal criterion in heifers fed a high-grain diet. J. C. Bailey*, L. O. Tedeschi, E. D. Mendes, and G. E. Carstens, *Texas A&M University, College Station.*

Meals are clusters of bunk visit (BV) events separated by short intervals that are differentiated from the next meal by a non-feeding interval that is long compared with the intervals within a meal. The longest non-feeding interval considered to be part of a meal is defined as meal criterion. The objective of this study was to determine which combination of Gaussian normal (N) and Weibull (W) 2-population distribution models best fit non-feeding interval data to distinguish intervals within (1st population) and between (2nd population) meals in beef cattle. Feeding behavior traits were measured in 119 heifers fed a high-grain diet (3.08 Mcal ME/kg DM) using a GrowSafe system. BV frequency and duration averaged 75 ± 14 events/d and 73.0 ± 22.3 min/d. The following 2-population distribution models; NN, NW, WW and WN were fitted to the $\log_{10}$-transformed interval lengths between BV events for each animal using R mixdist package (2.9–2). The intersection of the 2 distributions was computed as the meal criterion and used to derive meal frequency and duration data. Akaike's Information Criterion (AIC) was used to assess goodness of fit of the 4 models. The range in AIC values for the 2-pool NN, NW, WW and WN distribution models were 580 to 2923, 575 to 2884, 509 to 3226, and 726 to 3227, respectively. The NN and NW models resulted in longer ($P < 0.0001$) meal criterion (15.3 and 14.2 ± 7.2 min) compared with WW and WN models (10.8 and 10.6 ± 7.2 min). Consequently, meal frequencies were shorter and meal durations were longer when the N distribution was used to describe the first population. Each of the 4 models was fitted to individual animal BV data, and the model with the lowest AIC identified. A Chi-squared analysis was conducted to assess the number of animals identified for each 2-popluation distribution model. The frequencies (2, 76, 2, and 39) were different ($X^2 = 126.55$, $P < 0.0001$) among treatments, suggesting that 63.9% of the heifers were best fit by the NW model. Therefore, these results indicate that the NW 2-population distribution model is most appropriate to define meal criterion in beef cattle fed high-grain diets.

Key words: meal criteria, normal, Weibull distribution

T296 Effects of temperament classification and breed type on feed efficiency and feeding behavior traits in heifers fed a high-grain diet. J. C. Bailey*, G. E. Carstens, J. T. Walter, A. N. Hafla, E. D. Mendes, L. O. Tedeschi, and R. K. Miller, *Texas A&M University, College Station.*

The objective of this study was to evaluate the effects of temperament classification and breed type on performance, feed efficiency and feeding behavior traits in heifers fed a high-grain diet. Six trials were conducted over 3 consecutive yr with Angus (AN; n = 185), Braford (BO; n = 241), Brangus (BN; n = 266) and Simbrah (SI; n = 196) heifers from the Deseret Ranch; with 2 trials conducted each yr during the fall (n = 415) and spring (n = 473). Initial ages were 337 vs. 501 ± 86 d for heifers used in the fall (younger) and spring (older) trials. DMI and feeding behavior traits were measured for 70 d using a GrowSafe system. Exit velocity (EV), which is defined as the rate at which heifers exit a squeeze chute, was used as an objective measure of temperament. Within trial, heifers were classified into calm, moderate and excitable temperament groups based on ± 0.5 SD from the mean EV. Initial BW (318 vs. 308 ± 9 kg), final BW (425 vs. 401 ± 11 kg), ADG (1.45 vs. 1.27 ± 0.06 kg/d) and DMI (10.29 vs. 9.62 ± 0.47 kg/d) were higher ($P < 0.0001$) for heifers with calm temperament compared with

excitable heifers. Feed conversion (F:G) (7.36 vs. 8.23 ± 0.21 kg/d) differed ($P < 0.005$) between calm and excitable temperament class, but residual feed intake did not. In BO and BN heifers, there were no differences in F:G between calm and excitable groups, but in AN and SI, F:G was lower in the calm temperament group (EV x breed interaction; $P = 0.02$). Calm heifers spent more time ($P < 0.0001$) at the feed bunk (58.3 vs. 50.6 ± 3.8 min/d) than excitable heifers, but bunk visit frequency was similar between temperament groups. Meal frequency was not affected by temperament classification, however, meal duration (138 vs. 132 ± 9 min/d), and the bunk visit per meal ratio (9.4, 9.3, 8.7 ± 1.1 events/meal) were higher ($P < 0.02$) for calm compared with excitable heifers. These results suggest that heifers with calm temperament have 13.5% greater ADG, consume 7.1% more DM, and have 10.6% lower F:G than heifers with excitable temperament.

Key words: feeding behavior, temperament

T297 Effect of concentration of flax hulls in the diet on intake, digestion, milk production, and milk composition of dairy cows. H. V. Petit*, *Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

A total of 45 lactating Holstein cows averaging 617 kg of BW were allotted at wk 20 of lactation to 9 groups of 5 cows blocked for similar DIM to determine the effects of feeding different concentrations of flax hulls (FH) on DMI, milk production, milk composition, and digestion. Cows within each block were assigned to one of the 5 isoenergetic TMR containing 0, 5, 10, 15 or 20% FH. The experiment was carried out from wk 20 to 24 of lactation and diets were fed for ad libitum intake. Milk samples were obtained from 2 consecutive milkings on wk 5 of the experiment and were analyzed separately to determine milk composition. Total tract digestibility was determined on wk 5. Data recorded during the digestibility trial were analyzed as a randomized block design and block and treatment were the main sources of variation. Data on production were analyzed as repeated measurements using PROC MIXED of SAS. Treatment sum of squares were partitioned to provide linear, quadratic, and cubic contrasts after a significant F-test (i.e., $P < 0.05$). There was no significant cubic effect of treatment on any parameter measured. Intake of DM averaged 20.9 kg/d and was similar among treatments. Concentration of FH in the diet had no effect on milk yield, proportions of protein and fat and yields of protein, fat and lactose. There was a linear increase in proportion of lactose in milk and a quadratic effect of feeding level of FH on somatic cell count. Total tract apparent digestibility of DM, ADF, and NDF was similar among diets. Ether extract digestibility increased with higher proportions of FH in the diet but the increase was more important from 0 to 50 g/kg. These data suggest that corn and barley can be partially substituted by flax hulls (up to 20% of the DM) as the energy source in the diet of mid-lactating dairy cows.

Key words: dairy cattle, flax, milk production

T298 Body condition score at the initiation of bST supplementation does not affect milk response in dairy cows of Chile. F. Bargo[1], S. Follert*[1], A. Hinostroza[1], L. Lastra[2], and R. Navarrete[2], *[1]Elanco Animal Health, Southern Cone (Argentina & Chile), [2]Ancali Dairy, Los Angeles, Chile.*

Three hundred Holstein dairy cows (150 primiparous and 150 multiparous) from the commercial dairy farm Ancali (Los Angeles, Chile) were used to evaluate the interaction between body condition score (BCS) at the beginning of recombinant bovine somatotropin (bST) supplementation at 67 DIM and milk response to bST in a completely randomized design. Cows were sorted out by lactation (primiparous vs. multiparous) in 2 free-stall corrals and within each corral randomly assigned to 2 treatments: control or bST (Lactotropina, Elanco Animal Health). Cows on bST received a total of 15 subcutaneous injections of 500 mg bST every 14 d during 210 d starting June 13th at 67 DIM. Daily milk yield (Alpro, De Laval), monthly BCS (scale 1 to 5 by 2 independent experienced observers), and days open (DC305) were measured. Data were analyzed by ANOVA with a repeated measures mixed model using the PROC MIXED procedure of SAS (1999) where cows nested within treatment were considered as random effect. A significant interaction between health status and milk response to bST was found ($P < 0.05$). Healthy cows showed a milk response to bST of 5.2 kg/d ($P < 0.05$), while cows with mastitis or foot problems did not respond to bST ($P > 0.05$). The interaction between BCS at 67 DIM (≤ 2.75 vs. ≥ 3.00) and milk response to bST was not significant ($P = 0.67$). Cows on bST did not loss BCS and at the end of supplementation gained 0.19 points of BCS (3.03 at 67 DIM vs. 3.22 at 277 DIM; $P < 0.05$). Days open did not differ ($P > 0.05$) between treatments and averaged 105.5 and 97.5 d in primiparous and multiparous cows, respectively. When bST supplementation was initiated at 67 DIM in healthy Holstein cows, milk response to bST was not related to initial BCS averaging 5.2 kg/d without affecting days open.

Key words: body condition score, bST, milk response

T299 Associations among digestive tract lesions and abnormal serum chemistries in cull dairy cattle. M. B. Hall*[1], G. R. Oetzel[2], G. B. Huntington[3], F. M. Moore[4], and D. M. Hertzke[4], *[1]U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI, [2]School of Veterinary Medicine, Univ. of Wisconsin, Madison, [3]Dept. of Animal Science, Univ. of North Carolina, Raleigh, [4]Marshfield Labs Veterinary Services, Marshfield, WI.*

All animals accrue tissue damage with age, but types and prevalence of damage are not known. Tissue lesions could signal impaired organ function, which could affect performance. The study objective was to assess prevalence of microscopic lesions in digestive tracts of cull dairy cows, and determine associations among lesions and with abnormal serum chemistry values. Cull dairy cows (79) were sampled at 3 commercial abattoirs on 5 occasions. Tissue samples from reticulorumen (RR), small intestine (SI), large intestine, pancreas (PAN), cecum, and liver (LIV), and a blood sample were obtained immediately postmortem. Additionally, jugular blood samples and RR biopsies of papillae were obtained from 19 clinically normal live, noncull, ruminally cannulated Holsteins (11 lactating cows and 8 nonlactating bred heifers). Associations among lesions and with serum chemistries were evaluated with logistic regression analysis. Odds ratios for pairs of lesions described the increased likelihood of presence of both if 1 was found. Infiltration by lymphocytes observed in all SI, large intestinal and cecal samples suggests that this is normal, possibly related to barrier immune function. Serum chemistries were generally not good predictors of specific tissue lesions. Noncull animals had lower prevalence of RR inflammation and pustules than cull cows ($P < 0.03$). For cull animals, no lesions were detected in 36% of RR, 49% of SI, and 64% of PAN samples. Only 8% of LIV samples showed no lesions. Associations among lesions were found between RR and PAN, and among PAN, SI, and LIV. Among the odds ratio results: 4.7 for RR pustules and PAN inflammation ($P = 0.12$), 8.7 for SI hemosiderin laden macrophages (HLM) and decreased PAN zymogen ($P < 0.01$), and 3.0 for HLM and LIV mineralization ($P = 0.06$). Interrelatedness of lesion prevalence suggests that impact of disorders that created the lesions was not confined to a single organ. With implications for improved animal health, well-being, longevity, and performance, further investigation is warranted into how treatment or prevention of primary disorders and traits of economic importance relate to development of tissue damage.

Key words: dairy cattle, digestion

T300 Influence of a reduced-starch diet with or without exogenous amylase on lactation performance by dairy cows. L. F. Ferraretto*[1], R. D. Shaver[1], M. Espineira[1], H. Gencoglu[2], and S. J. Bertics[1], *[1]Department of Dairy Science, University of Wisconsin-Mad-*

ison, Madison, [2]Department of Animal Nutrition and Nutritional Diseases, Faculty of Veterinary Medicine, University of Uludag, Bursa, Turkey.

The objective of this trial was to determine lactation performance responses in high-producing dairy cows to a reduced-starch (RS) with or without exogenous amylase addition versus a normal-starch (NS) diet. Forty-five multiparous Holstein cows, 68 ± 29 DIM and 696 ± 62 kg body weight (BW) were randomly assigned to 1 of 3 treatments in a completely randomized design; a 2-wk covariate adjustment period with cows fed the NS diet followed by a 10-wk treatment period with cows fed their assigned treatment diets. The NS TMR did not contain exogenous amylase (NS-). The RS diets, formulated by partially replacing corn grain and soybean meal with whole cottonseed and wheat middlings, were fed without (RS-) and with (RS+) exogenous amylase addition to the TMR. Starch and NDF concentrations averaged 27.0% and 30.9%, 22.1% and 35.0%, and 21.2% and 35.3% (DM basis) for the NS-, RS-, and RS+ diets, respectively. Cows fed RS- tended ($P < 0.06$) to consume 1.9 kg/d more DM than NS-. Expressed as a percentage of BW, DMI was greater for cows fed RS- than NS- ($P < 0.01$) or RS+ ($P < 0.05$). Intake of NDF ranged from 1.09% to 1.30% of BW among the treatments with RS- being 21% greater ($P < 0.001$) than NS-. Milk yield tended ($P < 0.07$) to be 2.2 kg/d greater for cows fed NS- than RS- and was 2.6 kg/d greater ($P < 0.04$) for cows fed NS- than RS+. Milk fat content and yield were unaffected ($P > 0.10$) by treatment. Milk protein content and yield were greater for cows fed NS- than RS- ($P < 0.04$) and RS+ ($P < 0.01$). The MUN concentrations were greater ($P < 0.001$) for cows fed RS diets than the NS- diet. BW, BW change, and BCS were unaffected by treatment ($P > 0.10$), except for a trend for BW change of cows fed RS- to be greater than RS+ ($P < 0.09$). Feed conversion (kg milk/kg DMI) was 10% greater on average for cows fed NS- than for cows fed the RS diets ($P < 0.001$ and $P < 0.03$), and tended to be 6% greater for cows fed RS+ than RS- ($P < 0.09$). Feeding a RS diet compared with a NS diet without addition of exogenous amylase to either diet reduced ($P < 0.001$) milk and component-corrected feed conversions.

Key words: amylase, lactating cow, starch

T301 Effects of different ratios of extruded soybeans and whole cottonseeds on production performance of cows and conjugated linoleic acids (CLA) in milk fat. R. Yan*[1,2], S. Y. Chen[2], C. Jiang[1], Y. J. Zhang[1], and J. G. Han[1], *[1]Department of Grassland Science, China Agricultural University, Beijing, China, [2]Department of Agronomy, University of Wisconsin-Madison, Madison.*

The objective of this study was to investigate effects of different ratios of extruded soybeans (ESB) and whole cottonseeds (WCS) on production performance of cows and conjugated linoleic acids (CLA) in milk fat. 40 multiparous Holstein cows (averaging 100 ± 22 DIM) divided into 6 groups, were used in a randomized block design for a 14-week period. In this study, there were 4 treatments (dry matter basis): adding no ESB or WCS (control), 10% ESB, 5% ES+5% WCS, 10% WCS. All diets included 30% alfalfa hay, 10% corn silage, 10% *Leymus chinensis* and 50% concentrates. After adding ESB or WCS, crude protein content and ether extract content increased. In vitro crude protein digestibility and in vitro ether extract digestibility increased with the supplementation of ESB or WCS. Neutral detergent fiber content and in vitro neutral detergent fiber digestibility increased when 10% WCS was added to the diet. No change of dry matter intake was found in all 4 treatments. Compared with control (30.1kg/d), milk yield increased by 4.6 kg/d, 4.3 kg/d, and 2.1 kg/d respectively for 10% ESB, 5% ES+5% WCS or 10% WCS treatments. Because of the increase of milk yield, milk protein yield, milk fat yield, milk lactose yield and milk total solid yield increased. Milk cis9, trans11-conjugated linoleic acids content increased when cows were fed ESB or WCS. Cis9, trans11-CLA content in milk was increased comparing with control (0.88 g/100 g fatty acids)) and highest when cows were fed 10% ESB (1.43 g/100 g fatty acids), followed by 5% ES+5% WCS (1.48 g/100 g fatty acids) diets and the 10% WCS diet (1.24 g/100 g fatty acids). These results suggested that adding ESB or WCS in the diets could increase milk yield and milk cis9 (trans11-CLA).

Key words: production performance, conjugated linoleic acid, extruded soybean and whole cottonseed

T302 Effects of supplemental whole cotton seeds on production performance and milk fatty acids of dairy cows fed diets with different ratios of corn silage and alfalfa hay. R. Yan*[1,2], S. Y. Chen[2], R. Z. Zhang[1], Y. J. Zhang[1], and J. G. Han[1], *[1]Department of Grassland Science, China Agricultural University, Beijing, China, [2]Department of Agronomy, University of Wisconsin-Madison, Madison.*

The objective of this study is to investigate the effects of different ratios of corn silage (CS): alfalfa hay (AH), and whole cotton seeds (WCS) on milk yield, milk compositions, blood metabolites, and fatty acids in milk fat and plasma. 90 multiparous Holstein cows (73 ± 27 DIM) were arranged in a randomized block design which lasted 14 weeks. There were 3x3 treatments with 3 levels of WCS (0%, 5% and 10%) and 3 levels of forage addition (one is 30% corn silage (CS) and 10% alfalfa hay (AH); another is 20% CS and 20% AH; and the third is 10% CS and 30% AH). When part of CS was replaced by AH, protein content and digestibility, organic digestibility and neutral detergent fiber digestibility increased. After supplementation of WCS in diets, protein and ether extract contents, digestibility of protein and neutral detergent fiber increased. There was no change of dry matter intake when cows were fed the experimental diets. As more AH was added to the diets, milk yield ($P = 0.004$), milk protein content and yield (($P < 0.01$), and trans-9, cis-11 conjugated linoleic acids (CLA) concentration in milk fat and plasma ($P < 0.01$) increased. When WCS were supplemented to the diets, milk yield ($P = 0.04$), and trans-9, cis-11 CLA concentration ($P < 0.01$) in milk fat and plasma increased. When 10% WCS was added to the diet containing 30% AH, trans-9, cis-11 CLA content (1.46 g/100 g of total fatty acids) in milk was the greatest among all treatments. It suggested that AH could replace part of CS and be a good forage source of diet for dairy cows to improve milk yield and milk composition. Meanwhile, WCS could be included in the diet with high AH to improve production performance of dairy cows.

Key words: alfalfa hay, whole cottonseed

T303 Energy expenditure, feeding behavior and locomotion of grazed versus zero-grazed dairy cows throughout the lactation period. F. Dohme-Meier*[1], L. D. Kaufmann[1], S. Görs[2], P. Junghans[2], C. C. Metges[2], and A. Münger[1], *[1]Agroscope Liebefeld-Posieux, Research Station ALP, Posieux, Switzerland, [2]Research Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

An experiment was conducted to determine the effect of grazing versus zero-grazing on energy expenditure (EE), feeding behavior and locomotion in dairy cows at different time points in lactation. Fourteen Holstein cows were subjected to 2 treatments in a repeated cross over design with 3 experimental series. At the beginning of each series, cows were on average 38, 94 and 171 ± 11.1 DIM, respectively. Each

series consisted of a 7-d adaptation and a 7-d collection period. Cows either grazed on pasture or had ad libitum access to grass cut from the same paddock in a free-stall barn. Grass intake was estimated using the double alkane technique. On each day of the collection period, EE of one cow in the barn and of one cow on pasture was determined by using the ^{13}C bicarbonate dilution technique, with blood sample collection done either manually in the barn or using an automatic sampling system on pasture. During the same time period cows′ locomotion and feeding behavior were recorded over 3 d using pedometers and behavior recorders. The model included production system, experimental series and their interaction as fixed effects (MIXED procedure of SAS). Milk yield decreased with increasing DIM ($P < 0.05$). Grass intake was lower ($P < 0.01$) for grazing cows (16.8 kg DM/d) compared with zero-grazing cows (18.9 kg DM/d). The lowest intake was observed in the first series and the highest in the second series ($P < 0.001$). Within the 6-h measurement period, grazing cows expended more ($P < 0.001$) energy (273 vs. 231 kJ/kg $BW^{0.75}$) than zero-grazing cows and differences in EE did not change with increasing DIM. Cows on pasture spent proportionally more ($P < 0.001$) time walking and less ($P < 0.001$) time standing and lying than cows in the barn. The proportion of time spent eating was higher ($P < 0.001$) and that of time spent ruminating was lower ($P < 0.001$) for grazing cows compared with zero-grazing cows. In conclusion, the unchanged milk production along with a lower feed intake indicates that grazing cows mobilized body reserves to cover additional energy requirements, which were at least partly caused by more locomotion.

Key words: dairy cows, energy expenditure, grazing

T304 Effects of combinations of probiotics on growth and blood biochemical parameters in preruminant calves. Y.-Q. Fu, Q.-Y. Diao, Y. Tu*, N.-F. Zhang, and C.-G. Jiang, *Key Laboratory of Feed Biotechnology of Ministry of Agriculture/Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P.R. China.*

This study examined the effects of different combinations of probiotics on growth performance and blood biochemical parameters in preruminant Chinese Holstein calves. Twenty-four newborn Holstein calves were randomly divided into 4 groups with 3 males and 3 females each group, and each group was offered a basal diet(a milk replacer and a starter) (control, group I), or the basal diet supplemented with *Bacillus licheniformis* (group II), or *Bacillus licheniformis* + *Bacillus subtilis* (group III), or *Bacillus licheniformis* + *Bacillus subtilis* + *Lactobacillus plantarum* (group IV). The ratio of each strain of *Bacillus* for group III and group IV was 1:1, 1:1:1, respectively. The amount of total probiotics supplemented to corresponding calves was at 200 × 10^8 cfu/(head•d) for 56d. Live weight of each calf was recorded fortnightly and blood samples were collected concomitantly to examine its blood biochemical parameters. Data were analyzed by mixed or GLM procedure of SAS software. Compared with the control, average daily gain of the calves from group II only was significantly higher than group I throughout the trial (0.65 vs. 0.53 kg/d, $P < 0.05$), and the average daily gain of the calves from group II was 15.1% and 14.0% higher than that from groups III and IV, respectively ($P > 0.05$). From 2 to 4 weeks of age, average daily gain of the calves from group II was higher ($P < 0.05$) than that from group I (0.46 vs. 0.28kg/d) or group III(0.46 vs. 0.25kg/d). At the end of the experiment, the serum concentration of globulin or total protein in group II was significantly lower than that in group IV ($P < 0.05$), and the serum concentration of glucose in group II was significantly higher than that in group IV ($P < 0.05$). No significant difference in the serum albumin or urea nitrogen was detected among groups. It was concluded that dietary probiotics, especially *Bacillus licheniformis*, improved growth of preruminant calves.

Key words: calves, probiotics, growth and blood biochemical parameters

T305 The limiting sequence and proper ratio of lysine, methionine and threonine for calves fed milk replacers containing soy protein. J.-H. Wang, Y. Tu*, N.-F. Zhang, X.-C. Xu, and Q.-Y. Diao, *Key Laboratory of Feed Biotechnology of Ministry of Agriculture/ Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P.R. China.*

This study estimated the amino acid (AA) sequence and relative ratio of AA for calves on milk replacers (MR) with 50% milk protein replacement from soy protein concentrate (39.8% CP) by supplementing lysine (Lys), methionine (Met), and threonine (Thr) to the MR. Method of partial deduction of AA was adopted, on the principle that N retention was determined by the intake of the first limiting AA. Twenty-four newborn calves were randomly offered 1 of 4 MR diets (22% CP, 14% fat) for 56 d (n = 6/diet, half males and half females): PC (2.34% Lys, 0.72% Met and 1.80% Thr) or the PC with either Lys, Met or Thr reduced by 30%, respectively (i.e., PC-Lys (1.64% Lys, 0.72% Met and 1.80% Thr), PC-Met (2.34% Lys, 0.50% Met and 1.80% Thr), and PC-Thr (2.34% Lys, 0.72% Met and 1.26% Thr)). MR were fed at 11% of BW, adjusted twice weekly as calves grew. Starter (20% CP, 1.03% Lys, 0.30% Met and 0.69% Thr) and hay (3.23% CP, 0.29% Lys, 0.12% Met and 0.23% Thr) were offered ad libitum beginning on d 36 and d 43, respectively. A 3-d total collection of feed refusals, feces, and urine were recorded starting at d 33 and d 54 of age, respectively. Observations of N balance trials were analyzed using the GLM procedure of SAS. The results showed that the limiting sequence of the 3 AA was ranked as Lys, Met and Thr; the proper ratio of Lys, Met and Thr was 100:29:70 for the calves on MR alone and 100:30:60 for the calves on MR, starter and hay. Compared with PC, absorbed N/intake N was significantly lower for calves fed PC-Lys from d 33 to 35 and from d 54 to 56 (67.5% vs. 78.3% and 80.6% vs. 87.7%, $P < 0.05$), and for calves fed PC-Thr from d 33 to 35 (70.3% vs. 78.3%, $P < 0.05$); retained N/intake N was significantly lower for calves fed PC-Lys from d 33 to 35 and from d 54 to 56 (42.2% vs. 62.0% and 63.2% vs. 71.7%, $P < 0.05$), and for calves fed PC-Met from d 54 to 56 (67.5% vs. 71.7%, $P < 0.05$), also for calves fed PC-Thr from d 33 to 35 (45.7% vs. 62.0%, $P < 0.05$). In conclusion, digestion and utilization of N were negatively affected by AA deletion. The average relative ratio of the 3 AA was 100:29.5:65 for calves from 2 to 10 wk of age.

Key words: limiting amino acid, milk replacers, soy protein

T306 Feeding frequency for individually fed early lactation cows: enlightening the perplexing strategy. A. Nikkhah*, S. M. Karimzadeh, B. Sorkhroo, S. Asghari, M. Avaz Khanloo, and L. Bahramkhani Zarrin Goli, *University of Zanjan, Zanjan, Iran.*

Due to dependence on several cow, dietary and housing factors, feeding frequency (FF) is a perplexing strategy. The objective was to determine FF effects on feeding behavior, metabolism and production of early lactation cows. Eight multiparous Holstein cows (70 d in milk, 577.5 kg BW) housed in free individual boxes (4 × 3 m) received either once daily (1 ×) at 0700 h, or 4 times daily (4 ×) at 0100, 0700, 1300 and 1900 h an alfalfa hay, barley-corn grain based TMR with 63% concentrate (DM-based). The TMR delivered had 81% DM, 17.6%

CP, and 27.3% NDF. The study design was a 2 × 2 crossover with 2 periods of 20 d. Data were analyzed as a linear mixed model with fixed treatment effect, and cow plus period random effects. Once instead of 4 × feeding increased ($P = 0.05$) intakes of DM (21.1 vs. 20.0 kg/d) and NEL (36.4 vs. 34.3 Mcal/d). Orts as a % of the TMR fed were similar between 1 × and 4 × groups (7.6 vs. 10%, respectively). Milk yield (31.5 vs. 30.7 kg/d, $P = 0.16$), milk NEL output (21.7 vs. 21.4 Mcal/d, $P = 0.72$), fat content (3.5 vs. 3.6%, $P = 0.66$), protein content (3.2 vs. 3.2, $P = 0.81$), BW changes (−70 vs. 180 g/d, $P = 0.53$) and fecal pH (6.64 vs. 6.62, $P = 0.67$) were similar between 1 × vs. 4 × FF, respectively. Urine pH was higher for 4 × than 1 × FF (8.12 vs. 8.00, $P < 0.01$). Daily duration of eating (323 vs. 284 min/d, $P = 0.49$), ruminating (302 vs. 326 min/d, $P = 0.66$), total chewing (624 vs. 609 min/d, $P = 0.37$), laying (537 vs. 586 min/d, $P = 0.40$), and standing (691 vs. 640 min/d, $P = 0.50$), were comparable for 1 × vs. 4 × FF, respectively, as were serum glucose, urea, BHBA, albumin, total protein and triglycerides. The first meal length (defined as the time interval between feeding and the first non-eating bout of ≥ 20 min) was 106 min in the 1 × cows, while being on average 49 min per feeding and 196 min per day in the 4 × cows ($P < 0.01$). As such, the post-feeding serum insulin and NEFA concentrations were respectively higher and lower with 1 × than 4 ×. Reduced urine pH by 1 × feeding suggests less alkaline extracellular body fluids. Improved energy intake by less frequent feeding possesses metabolic and health implications.

Key words: feeding frequency, early lactation, individual

T307 Prolonged provision of protected methionine improves milk contents and yields of fat and protein in lactating cows. A. Nikkhah*[1], D. Kianzad[2], A. Haj Hosseini[2], A. Zalbeik[2], and G. Ghorbani[3], *[1]University of Zanjan, Zanjan, Iran, [2]Animal Breeding Center, Karaj, Iran, [3]Isfahan University of Technology, Isfahan, Iran.*

Metabolic challenges of early lactation superimposed on environmental stresses such as high ambient temperatures alter lactation curve and compromise cow health. The objective was to establish productive effects of prolonged feeding of protected methionine (PMT) in dairy cows. Twenty 4 fresh Holsteins (27 ± 9 d in milk, 617 kg BW, 2.8 BCS) including 12 s lactation and 12 higher lactation cows were randomly assigned to an either control (CN) or PMT (Smartamine) supplemented TMR (51:49% forage:concentrate), fed continuously for 5 mo. Cows were housed in free stalls, milked 3 times daily at 0000, 0800 and 1600 h in a milking parlor, and offered TMR post-milking plus top-dress alfalfa hay. The study was conducted from May through November of 2009 in central Iranian province of Isfahan. The monthly collected production data were analyzed as a linear mixed model with fixed effects of treatment, parity, time and 2- and 3-way interactions, plus random effects of cow (parity × treatment × time) and residuals. To adjust for correlated repeated measures on the same subject, covariance structures with minimum fit criteria were modeled for all parameters. The PMT group had greater 5 mo-long average milk yield (42.4 vs. 37.4 kg/d, $P = 0.06$), milk fat content (3.30 vs. 2.75%, $P = 0.007$), fat yield (1.40 vs. 1.04 kg/d, $P = 0.002$), milk protein content (2.96 vs. 2.75%, $P = 0.01$) and protein yield (1.25 vs. 1.02 kg/d). Mature cows tended to produce more milk (42.2 vs. 37.6 kg/d, $P = 0.08$) and milk fat (1.30 vs. 1.13 kg/d, $P = 0.10$) than second lactation cows. Findings provide compelling evidence for beneficial effects of prolonged PMT provision (e.g., 5 mo) on milk fat and protein contents and yields in high-producing early-mid lactation cows exposed to summer high ambient temperatures.

Key words: Smartamine, methionine, prolonged feeding

T308 Rumen degradation patterns of ground and steam-processed broomcorn and ground barley. A. Nikkhah*, *University of Zanjan, Zanjan, Iran.*

The objective was to determine rumen disappearance behavior of ground broomcorn (GBC), whole and ground steam-flaked broomcorn (SBC) and ground barley (GB). Three ruminally fistulated Naeini ewes, fed at maintenance an alfalfa hay based partially mixed ration, were used in a randomized complete block design to monitor grain in situ digestion properties. The methodology involved rumen incubation of 8 × 12 cm nylon bags (50 μm pore size) containing approximately 3 g of processed grains. Grains were finely ground by a hammer mill (screen size of 2 mm). Broomcorn was steamed for about 60 min to increase grain moisture up to 18% vs. 13% pre-processing, and flaked between preheated large rollers (46 × 90 cm) for a desired flake density (380 to 400 g/L). Samples were incubated ruminally for 2, 4, 8, 16, 24 and 48 h subsequently and were taken out all at once. For 0 h, bags were put in 39°C water for 15 min. To further differentiate between steam-flaking and particle size effects on rumen degradation, the SBC was incubated as both whole and ground flakes. All bags were rinsed under running tap water until the effluent was clear. The bags were dried at 55°C for 48 h, weighed, and residues were ground to pass a 1-mm screen. Data were analyzed with Mixed Models procedures of SAS program with repeated measures. At 0 h, DM of ground SBC (21.0%) was degraded to a greater extent ($P < 0.05$) than that of whole SBC (13.0%), GBC (14.0%) and GB (13.6%). However, at 2, 4, 8, 16 and 24 h post-incubation, respectively, GB (53, 69, 75, 80, 86%) had greater degradation extent than ground SBC (33, 43, 51, 61, 71%), whole SBC (29, 39, 48, 58, 63%) and GBC (17, 21, 37, 44, 50%). Thus, steam processing compared with grinding considerably increased rumen DM degradation of broomcorn, getting closer to that of GB. Results demonstrate the effectiveness of steam-flaking in improving rumen digestibility of broomcorn, which possesses a harder endosperm than corn and grain sorghum. Given its lower price compared with barley and corn grains, broomcorn may be included in dairy diets at higher levels should it be effectively steam-processed.

Key words: rumen degradation, broomcorn, barley

T309 Steam-flaking of broom sorghum improves effective rumen degradation of DM while controlling that of CP. A. Nikkhah*, *University of Zanjan, Zanjan, Iran.*

The objective was to determine effective rumen DM and CP degradation of ground (GBS) and steam-flaked broom sorghum (SFB) grains comparing ground barley grain (GB). Three ruminally cannulated Naeini sheep were fed at maintenance and utilized in an in situ randomized complete block design study with a 2-week pre-study adaptation period. Grains were finely ground by a hammer mill (2 mm mesh size). Broom sorghum was steamed for 60 min and up to a moisture content of 18% before flaking through preheated corrugated rollers (46 × 90 cm) for a flake density of 380–400 g/L. Nylon bags (8 × 12 cm, 50 μm pore size) containing 3 g of differently processed grains were incubated ruminally for 2, 4, 8, 16, 24 and 48 h to be taken all out at once. For 0 h, bags were put in 39°C water for 15 min. Sample and blank bags were all rinsed under running tap water until clearing the effluent, were dried at 55°C for 48 h, weighed, and residues were ground (1-mm) for wet chemistry analysis. Disappearance patterns data were fitted into a nonlinear equation to estimate rates and extent of rumen CP and DM digestion: $Y = a + b (1- e^{-ct})$; a = soluble %, b = slowly digestible %, c = disappearance rate/h, and t = incubation hour. Effective rumen DM and CP degradations were calculated by the equation:

a + (b × c)/(c + k); k = fractional outflow rate. Data were analyzed with Mixed Models Procedures of SAS program. Steam-flaking compared with grinding considerably increased rumen effective degradation of broom sorghum DM while to some extent reducing that of CP. With rumen outflow rates of 5 and 8%, respectively, effective rumen DM degradation was greater ($P < 0.01$) for GB (74 and 70%), ground SFB (58 and 52%) and whole SFB (53 and 47%) than for GBS (43 and 35%). assuming 5%/h rumen passage rate. The respective modeled values for CP effective degradation were 70 and 63% for GB, 39 and 30% for GBS, 33 and 25% for ground SFB, and, 31 and 24% for whole SFB. Findings provide evidence that steam-flaking under special circumstances can successfully improve rumen degradation of broom sorghum grains without elevating CP degradability.

Key words: broom sorghum, degradation, steam-flaking

T310 Steam-flaked broom sorghum a viable substitute for ground barley in midlactation dairy rations. A. Nikkhah*, *University of Zanjan, Zanjan, Iran.*

An objective was to determine effects of feeding cows ground (GBS) vs. steam-flaked broom sorghum (SFB) vs. ground barley (GB). Ten mid lactation Holstein cows (140 ± 10 d in milk, 570 ± 40 kg BW) in tie stalls were used in a 5 × 5 replicated Latin square design with 5 21-d periods. Each period had 14-d of adaptation. Treatments were diets with 1) GB, 2) GB + GBS, 3) GBS, 4) GB + steam-flaked broom sorghum (SFB), and 5) SFB. Diets were fed as total mixed rations with 30% alfalfa hay, 15% corn silage, and 20% cereal grain (DM based). Data were analyzed as a linear mixed model with fixed effects of diet and period, and random effects of cow (diet) and residuals. Dry matter intake was similar among treatments (19.1–19.7 kg/d). Feeding GB+SFB (66.7%), SFB (64.1%) and GB (63.7%) vs. GBS (55%) improved total tract apparent CP digestibility ($P < 0.05$). Fat corrected milk yield (FCM) increased by 2.3 kg by feeding SFB instead of GBS based diets (24.4 vs. 22.1 kg, $P < 0.01$). The FCM was 2.8 kg greater for GB + SFB than for GBS (24.9 vs. 22.1 kg, $P < 0.01$). Milk contents of fat (3.63% and 3.55% vs. 3.44%), protein (3.02% and 3.04% vs. 2.94%), and total solids (11.86%, 11.88% vs. 11.61%) were greater for SFB and GB than for GBS, respectively, as were milk yields of fat (0.82 and 0.81 vs. 0.73 kg/d), protein (0.68 and 0.68 vs. 0.62 kg/d) and total solids (2.7 and 2.7 vs. 2.47 kg/d). Feeding SFB instead of GBS increased ($P < 0.05$) fecal pH (7.10 vs. 6.87) and feed efficiency (1.26 vs. 1.15). Feeding SFB and GB+SFB compared with GBS and GB+GBS decreased plasma urea (14.8 and 13.4 vs. 18.0 and 16.0 mg/dL) and increased plasma glucose (61 and 58 vs. 55 and 55 mg/dL) concentrations, respectively. Results demonstrate the effectiveness of steam-flaking over grinding in considerably improving feeding value of broom sorghum when included at 20% of diet DM. Hence, SFB may be feasibly fed to midlactation cows both alone and combined with GB.

Key words: broom sorghum, steam-flaking, milk

T311 Effect of dietary nitrogen levels and yeast supplementation on apparent diet digestibility and microbial population in the rumen content of dairy lactating cows. D. R. Ouellet* and J. Chiquette, *Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Sherbrooke (QC) Canada.*

Eight rumen-fistulated Holstein dairy cows (679 kg BW; SEM = 5) were used in a duplicated 4 × 4 Latin square design, with a 2 × 2 factorial arrangement of treatments to evaluate the effect of dietary nitrogen levels and yeast supplementation on apparent diet digestibility and rumen microbial population of dairy lactating cows. Isoenergetic diets, highly or moderately deficient in metabolizable protein [-22% (HD) or −14% (MD) less than requirements], were fed with or without yeast supplement (10 g/head/d of a mixture of *Aspergillus oryzae* and *Saccharomyces cerevisiae*). Total mixed ration (60:40 grass silage:concentrate barley based) was fed 12 times daily. Apparent digestibility of DM, OM, NDF, ADF and N were measured. Ruminal fluid content was sampled to estimate protozoa using microscopic-counting method, and cellulolytic and total viable bacterial count (TVC) by the most-probable-number method. Plasma urea concentration was determined. There were no interactions between treatments for items evaluated ($P > 0.10$). Apparent digestibility of N (69.5% vs. 65.9%; SEM = 1.6) and urinary N excretion (261g/d vs. 162 g/d; SEM = 6) were higher ($P < 0.01$) in MD than in HD. Apparent digestibility (average %) of DM (72.4; SEM = 1.1), OM (74.4; SEM = 1.1), ADF (52.5; SEM = 2.3), and NDF (57.8; SEM = 2.5) were similar among treatments. Yeast supplementation did not affect apparent digestibility parameters. Compared with MD, HD reduced by 48% plasma urea concentration (10.6 vs. 15.7 mg/dL; $P < 0.02$). Average microbial counts were unaffected ($P > 0.05$) by treatments. Protozoa counts [geometric means (cfu/mL) and 95% confidence interval (CI)] were: 2.3×10^5 (CI = 1.6×10^5 to 3.4×10^5), TVC: 3.1×10^9 (CI = 2.6×10^9 to 3.7×10^9) and cellulolytic bacteria: 3.9×10^7 (CI = 2.8×10^7 to 5.5×10^7). In conclusion, addition of yeast to diets containing up to −22% the requirements in metabolizable protein had no effect on the apparent digestibility of the diet, ruminal content parameters and plasma urea.

Key words: direct-fed microbials, metabolizable protein restriction, digestion

T312 Ground broomcorn in dairy rations. A. Nikkhah*, *University of Zanjan, Zanjan, Iran.*

A main purpose was to determine nutritional effects of feeding ground broomcorn (BC, 1% tannin) vs. ground barley grain (GB) based mixed rations on dairy cow performance. Ten tie-stall-housed Holstein cows (averaged 140 d in milk, 570 kg BW) were fed twice daily alfalfa hay-corn silage based mixed rations with 1) 20% GB, 2) 10% GB + 10% BC, or 3) 20% BC, in a duplicated Latin square design. Each 21-d period had 14-d for adaptation. Diets were balanced for CP (15%), NEL (1.6 Mcal/kg) and NDF (38%). Cows were milked 3 times daily. Data were analyzed as linear Mixed Models with diet and period fixed effects, and cow within diet plus residuals random effects. Total tract apparent CP digestibility was decreased by feeding 20% BC vs. 20% GB (55 vs. 63%, $P < 0.05$). DM intake (kg/d) was maintained by GB+BC (19.7) and BC (19.1) vs. GB (19.1). Fecal pH (7.01, 6.93, 6.87, $P < 0.05$), milk yield (24, 22.2, 22.1 kg/d), feed efficiency (1.26, 1.12, 1.15), and milk total solids percent (11.88, 11.64, 11.61%) and yield (2.70, 2.50, 2.47 kg/d) decreased ($P < 0.05$), and plasma urea increased (14.3, 16.0, 18.0 mg/dL) as BC replaced GB, with similar rumen pH (6.6, 6.7, 6.6), urine pH (8.12, 8.15, 8.16) and plasma glucose (56, 55, 55 mg/dL). The quite similar values for BC vs. GB+BC suggest that cows are able to adapt to high dietary BC levels. These data, while biologically light, may not support feeding BC to high-producing cows at 20% of diet DM, especially if the optimum goal is maximizing milk production. On the other hand, given the lower price of BC (0.20$/kg) than of BG (0.35$/kg), where commercially available, BC partially replacing the strategic costly GB in mid and late lactation rations is commercially pursued.

Key words: broomcorn, dairy, production

T313 Effect of naturally extracted vitamin E (RRR-α-tocopheryl acetate) vs. synthetic vitamin E on blood and milk levels of vitamin E in lactating dairy cows. M. B. de Ondarza*[1], K. Daniels[2], and D. Bunting[2], [1]*Paradox Nutrition LLC, West Chazy, NY,* [2]*ADM Alliance Nutrition Inc., Quincy, IL.*

The trial objective was to determine the effect of supplementing synthetic vitamin E (545 IU/d) (SYN) vs. naturally extracted vitamin E at one-half the level of milligrams (NAT) on blood and milk levels of vitamin E in high-producing multiparous dairy cows. Half of the cows (n = 57) received SYN and half (n = 57) received NAT for 6 weeks. Treatment groups were housed in separate pens with ad libitum access to TMR. Cow groups were balanced pre-trial for parity, previous ME305 production, and previous 14-d milk yield. After 14 d, daily milk yield of individual cows was recorded. Individual milk samples were analyzed for component content pre-trial, wk 5 and wk 6. Data was analyzed using JMP statistical software (SAS, Cary, NC) with pre-trial data as covariates. Milk yield (40.95 and 39.80 kg/d for SYN vs. NAT, respectively), % milk fat (3.63 and 3.64% for SYN and NAT, respectively), kg milk fat, % true protein, kg true protein, 3.5% FCM (kg), milk urea nitrogen (mg/dl), and SCC (x 1000) (395 vs. 431 for SYN vs. NAT, respectively) were unaffected ($P > 0.10$) by treatment. Pre-trial and wk 6, blood and milk samples were taken from each cow. Individual blood samples and super-composite milk samples for each treatment group were analyzed for vitamin E and cholesterol. Blood serum vitamin E status was not affected ($P > 0.20$) by treatment with means of 8.98 and 9.04 μg/mL for SYN and NAT, respectively. Blood serum cholesterol was not affected ($P > 0.20$) by treatment with means of 252 and 253 mg/dL for SYN and NAT, respectively. Blood serum vitamin E: cholesterol ratio was not affected ($P > 0.20$) by treatment with means of 3.62 and 3.61($\times 10^{-3}$) for SYN and NAT, respectively. Pooled milk vitamin E concentrations were 1.20 and 1.19 μg/mL for SYN vs. NAT, respectively. Considering that naturally extracted vitamin E was fed at one-half the weight amount, this form of vitamin E appears to be at least twice as potent as synthetic vitamin E at NRC recommended levels.

Key words: RRR-alpha-tocopheryl acetate, synthetic vitamin E, lactating dairy cattle

T314 Large-scale production effects of an intestinally releasable methionine product in dairy cows. A. Nikkhah*[1], R. Kowsar[2], and G. Ghorbani[2], [1]*University of Zanjan, Zanjan, Iran,* [2]*Isfahan University of Technology, Isfahan, Iran.*

The objective was to determine productive effects of feeding an intestinally releasable methionine product (Met, Mepron-85) in lactating cows. A total of 195 free-stall-housed Holstein cows were fed either a control (C, n = 110, 71 ± 51 d in milk, 47.0 ± 0.12 kg milk/d) or a Met-supplemented (M, n = 85, 85 ± 59 d in milk, 47.5 ± 0.12 kg milk/d) alfalfa hay-corn silage based mixed ration 4 times daily in a completely randomized design study. The DM in control vs. Met diet had, respectively, 1.78 vs. 1.70 Mcal/kg NEL, 19.6 vs. 19.0% CP, and 34.5 vs. 35.5% NDF. Cows were milked 3 times daily and monitored for 8 weeks. The weekly collected data were analyzed as linear Mixed Models with fixed effects of diet, week and the interaction, and random effects of cow (diet × week) plus residuals. To account for correlated repeated measures on the same cow, covariance structures with least fit criteria were adopted. DM intake was greater for M than for C (26.6 vs. 25.8 kg/d, $P < 0.05$), whereas NEL intake tended to be greater for C than for M (45.9 vs. 45.2 Mcal/kg, $P < 0.10$). Actual milk volume (40.1 vs. 40.7 kg/d) and milk lactose content (4.90 vs. 4.95%) were similar for M vs. C, while protein content was higher for M (3.1 vs. 3.0%, $P = 0.01$) and fat content tended to be higher for C (3.0 vs. 2.9%, $P = 0.06$). As a result, milk energy density (0.63 vs. 0.64 Mcal/kg) and output (25.5 vs. 26.3 Mcal/d) remained similar for M vs. C. Milk urea N (17.6 vs. 18.1 mg/dL) and urine N (4.24 vs. 4.37 g/kg) concentrations were lower for M vs. C ($P < 0.05$), supporting the increased milk protein by M. These data may imply reduced hepatic N detoxification into urea, and reduced environmental N excretion by feeding the rumen protected Met to high-producing cows.

Key words: methionine, protection, lactation

T315 Study on the metabolic mechanism of melamine in dairy cattle. X. Jin*, Y. Zhang, S. Li, H. Zhang, and Q. Zhang, *College of Animal Science and Technology, China Agricultural University, Beijing, China.* This trial was conducted to study the effects of dietary supplementation of melamine byproducts on residual concentration of melamine in rumen fluid, blood, urine, feces and milk of dairy cows. The further object was to reveal the metabolic mechanism of action of melamine in dairy cows by single factor experiment. The supplemental levels in the concentrate were 0.516%, 0.860% and 1.204%, respectively. The experiment was divided into 3 phases with 10 d in each phase (7 d for pre-feeding and 3 d for sampling). The same 5 Holstein dairy cows were fed the same experimental diet in each phase. The results showed that the residual concentration of melamine in milk, feces and urine were all increased with the growing supplementation level. The results showed that residual concentration of melamine in each kind of samples was durative increasing. When the melamine byproducts level rose to 0.860% in the concentration, the residual concentration of melamine in samples of milk was significantly different from that of 0.516% ($P = 0.02$), while the residual concentration in other samples were not significantly different; when the melamine byproducts level rose to 1.204%, the residual concentration in ruminal fluid and urine were very significantly different from that of 0.516 ($P < 0.01$), the residual concentration in blood, raw milk were significantly different from that of 0.516 ($P = 0.02$). The residual concentration in feces was not significantly different from that of 0.516% and 0.860% ($P = 0.27$), though the concentration of melamine was durative increasing. The concentration of melamine in the raw milk, feces and urine from the phase with the highest supplemental level were 1.31, 3.30 and 107.75mg/kg, respectively. It is concluded that renal excretion is the primary metabolic pathway of melamine while defecation and lactation are only auxiliary pathways. It was consistent with the report that melamine had negative effect on kidney.

Key words: dairy cattle, melamine, metabolic mechanism

T316 Conjugated linoleic acid (CLA) supplementation around calving affects glucose metabolism in dairy cows. H. M. Hammon*[1], K. Hötger[1], S. Görs[1], M. Becker[1], C. Weber[1], A. Tröscher[2], and C. C. Metges[1], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*BASF, Limburgerhof, Germany.*

CLA (in particular the t10,c12 CLA isomer) is well established for its reducing effects on milk fat content. Although CLA supplementation causes changes in fat metabolism of dairy cows, less is known about CLA effects on glucose metabolism. The objective of the study was to investigate endogenous glucose production (eGP), especially gluconeogenesis (GNG), in German Holstein cows supplemented either with 50 g rumen-protected CLA fat (10% t10,c12 CLA, Lutrell® pure, BASF, Ludwigshafen, Germany; n = 10) or 50 g linoleic acid (Ctrl; n

= 10) from 14 d before expected calving to 63 DIM. Diets based on grass and corn silage were fed *ad libitum*. DMI and milk yield were recorded daily, BW and milk composition were measured weekly, and BCS and back fat thickness every second week. Plasma concentrations of glucose, nonesterified fatty acids, and β-hydroxybutyrate were determined at 14 and 7 d before calving and once weekly up to 84 DIM. On 21 and 63 DIM, eGP was measured after overnight food withdrawal by primed [U-^{13}C]glucose infusion. Additionally, on 21 DIM, cows received 2 oral boli of deuterium-labeled water (70 atom% D) within 4 h (n = 7 per diet) and blood samples were taken to measure fractional GNG (GNG_{frac}) using deuterated glucose enrichment in plasma. Data were analyzed by SAS PROC MIXED with diet and time as fixed effects. Milk fat content was reduced ($P < 0.01$) and milk and lactose yield increased in both groups after calving and were higher ($P < 0.05$) from 35 DIM on in CLA cows than in Ctrl, respectively. Energy balance tended to be less negative ($P < 0.1$) in Ctrl than in CLA cows. Plasma concentrations of glucose were higher immediately after calving in CLA cows than Ctrl (diet × time interaction $P < 0.01$). The eGP increased ($P < 0.05$) from 21 to 63 DIM and CLA supplement reduced ($P < 0.05$) eGP on 21 DIM, but not on 63 DIM. GNG_{frac} on 21 DIM tended to be higher ($P < 0.1$) in CLA cows than in Ctrl. These findings suggest a glucose-sparing effect due to CLA supplementation, using less glucose for milk fat synthesis and more glucose for lactose production and other tissues, resulting in an increased milk yield and blood glucose level.

Key words: dairy cow, CLA, glucose

T317 Lactation performance and milk fatty acid profile in dairy cows fed linseed oil in diets with different forage to concentrate ratios. L. Saliba*[1,2], R. Gervais[1], Y. Lebeuf[1,2], J.-C. Vuillemard[1], and P. Y. Chouinard[1,2], *[1]Département des sciences animales, Université Laval, Québec, Québec, Canada, [2]Institute of Nutraceuticals and Functional Foods (INAF), Québec, Québec, Canada.*

The composition of basal diet is known to influence the response to dietary unsaturated fatty acids (FA) in lactating dairy cows. To evaluate the interaction between the levels of concentrates and linseed oil on milk yield and composition, 24 Holstein cows were used in a randomized complete block design based on DIM with a 2 × 2 factorial arrangement of treatments. Within each block, cows were fed one of 4 experimental diets containing 30% (LC) or 70% (HC) concentrates, with (LO) or without linseed oil (NLO) supplemented at 3% DM. After 4 weeks of treatments body weight was not different among treatments (654 ± 6 kg). Compared with LC, feeding HC increased ($P < 0.01$) DMI (20.5 vs. 24.7 kg/d), milk yield (26.1 vs. 33.1 kg/d), FCM (26.4 vs. 30.6 kg/d), milk lactose (4.59 vs. 4.76%; 1205 vs. 1582 g/d), and milk protein (3.22 vs. 3.50%; 832 vs. 1148 g/d). Milk fat content was lower (4.15 vs. 3.56%; $P < 0.01$), and milk fat yield tended to be higher (1076 vs. 1162 g/d; $P = 0.07$) for cows fed HC compared with LC. Feeding LO decreased DMI (23.5 vs. 21.7 kg/d; $P < 0.05$), milk fat content (3.99 vs. 3.72%; $P < 0.01$), and milk protein content (3.45 vs. 3.27%; $P < 0.01$) compared with NLO. Interaction between linseed oil and concentrates was observed for milk fat content of c9,c12,c15–18:3 (4.1, 3.2, 5.1, and 5.9 mg/g FA for LC-NLO, HC-NLO, LC-LO, and HC-LO, respectively; $P < 0.05$). Concentrations of c9,t11,c15–18:3 increased with LO compared with LNO (0.5 vs. 0.2 mg/g FA; $P < 0.001$), and decreased with HC compared with LC (0.3 vs. 0.4 mg/g FA; $P < 0.001$), while c9,t13,c15-C18:3 was not detected in any milk samples. Feeding linseed oil increased t11,c15–18:2 in milk fat, especially when cows were fed LC diets (1.6, 0.4, 9.8, and 3.6 mg/g FA for LC-NLO, HC-NLO, LC-LO, and HC-LO, respectively; $P < 0.01$). The same interaction was observed for t11–18:1 (11.5, 6.6, 24.1, and 11.0 mg/g FA for LC-NLO, HC-NLO, LC-LO, and HC-LO, respectively; $P < 0.01$). In conclusion, the level of concentrates in the basal diet influenced milk fat content of FA originating from rumen biohydrogenation in response to linseed oil supplementation.

Key words: concentrate levels, milk fatty acids, linseed oil

T318 Rumen volume and passage kinetics depend on feeding time (0900 vs. 2100 h). A. Nikkhah*[1], J. C. Plaizier[2], and A. D. Kennedy[2], *[1]University of Zanjan, Zanjan, Iran, [2]University of Manitoba, Winnipeg, MB, Canada.*

The objective was to determine effects of providing a total mixed ration (TMR) at either 0900 h or 2100 h on rumen volume as well as on fluid and solids retention time and outflow rates in lactating cows. Three primiparous and one multiparous Holstein cows (80 d in milk; 26 kg/d milk yield) with rumen cannula (10 cm d) were used in a crossover design study with 2 6-wk periods. Each period had 3-wk of adaptation. The diet had forage to concentrate ratio of 50.2:49.8 (DM based). Co-EDTA and Cr-mordanted alfalfa were used as markers to measure rumen outflow rates of fluid and solids, respectively. A total of 50 g Co-EDTA was dissolved in 300 mL of distilled water and ruminally infused via cannula at feed deliveries (0090 h vs. 2100 h). Simultaneously, 300 g of Cr-mordanted alfalfa fiber was dosed into 10 different rumen sites. Next, rumen fluid and solids were sampled subsequently at 2, 3, 4, 6, 8, 12, 16, 24, 36, 48, and 72 h post-marker-infusion. The rumen marker concentrations were regressed against time using a first-order exponential equation to acquire passage rates (slopes). Rumen fluid volume was calculated by dividing the amount of Co infused by the intercept for individual cows. Data were analyzed as Mixed Models with fixed feeding time (FT) effect and random period, cow within treatment, and residuals effects. Rumen fluid total volume tended to increase by feeding at 2100 h instead of at 0900 h (107 vs. 89 L; $P = 0.07$). Rumen fluid outflow rate (11.9 vs. 11.7%/h) and retention time (8.2 vs. 8.9 h), and rumen solids retention time (32.8 vs. 31.4 h) were similar between 0900 h and 2100 h FT, respectively. Feeding at 2100 h vs. 0900 h increased ($P < 0.05$) rumen solids outflow rate in primiparous cows (3.7 vs. 3.1%/h). Data suggest that rumen volume and passage kinetics depend on when TMR is delivered to once-daily-fed cows.

Key words: feeding time, rumen, kinetics

T319 Influence of method of surfactant supplementation on characteristics of digestion and feeding value of fat in Holstein steers fed a high-energy finishing diet. H. Dávila-Ramos*[1], A. Gonzalez-Castellon[1], A. Barreras-Serrano[1], A. Estrada-Angulo[2], M. A. López-Soto[1], J. V. Macias-Zamora[1], A. Plascencia[1], S. H. Vega[1], and R. A. Zinn[3], *[1]IICV - Universidad Autónoma de Baja California, México, [2]FMVZ - Universidad Autónoma de Sinaloa, México, [3]Department of Animal Science, University of California, Davis, El Centro.*

Four Holstein steers (271 ± 11 kg) with cannulas in the rumen and proximal duodenum were used to study the influence of method of surfactant (Tween 80) supplementation on characteristics of digestion and feeding value of fat. Treatments consisted of a steam-flaked corn-based finishing diet supplemented with: 1) no supplemental fat, no surfactant; 2) 6% supplemental fat (yellow grease, no surfactant; 3) 5.75% supplemental fat plus 0.25% Tween 80 (TW) added to the diet as part of the premix (TW was mixed with premix before incorporation with grain in the mixer, as second step in diet preparation), and 4) 5.75%

supplemental fat plus 0.25% TW combined directly with the supplemental fat (TW was mixed with supplemental fat before incorporation into the feed mix as penultimate step in diet preparation). The data was analyzed using MIXED procedures (SAS Inst. Inc., Cary, NC) based in a model for 4x4 Latin square experimental design Treatment effects were tested by means of orthogonal polynomials and differences were considered to be significant when $P < 0.05$. There were no surfactant by supplemental fat interactions ($P > 0.05$). Surfactant did not affect ($P > 0.05$) site and extent of OM, starch, N, ADF, and fatty acid digestion, or DE value of diet. Supplemental fat decreased ($P < 0.05$) ruminal and total tract digestion of OM and ADF and increased ($P < 0.05$) the DE value of diet. The decrease in postruminal FA digestion was mainly due to decreased ($P < 0.05$) digestion of C18:0. Digestible energy of supplemental fat averaged 6.87Mcal/kg. It is concluded, that independent of method of addition, supplementing high-fat diets with 0.22% of Tween 80 does not influence site and extent of digestion or the feeding value of supplemental fat.

Key words: fat supplementation, Holstein steers, surfactant

T320 Evaluation of limit feeding and bunk management strategies for gravid dairy replacement heifers. N. M. Esser[1], J. Larson[1], P. C. Hoffman*[1], C. L. Liu[2], and W. K. Coblentz[3], *[1]University of Wisconsin, Madison, [2]Northeast Institute of Geography and Agricultural Ecology, CAS, Harbin, Heilongjiang, China, [3]USDA-ARS Dairy Forage Research Center, Marshfield, WI.*

To assess effects of bunk access and limit feeding on dairy heifer growth and nutrient intake, 96 Holstein heifers (394 ± 31 kg) were fed one of 2 diets, and allotted to full (F) or partial (P) bunk access. Pens (n = 12) of heifers were limit fed a TMR without (NS) straw or fed a TMR with straw (S). Feed access times for NS and S were 6 and 24 h respectively. Heifers, fed NS or S, were assigned to pens with F (8 stalls/8 heifers) or P (4 stalls/8 heifers) to complete the 2 × 2 factorial arrangement (FS, PS, FNS, PNS). Heifers were evaluated for growth, and nutrient intake. Bunk occupancy time and rate, 0–6 h post-feeding, were evaluated using timed digital photography. Data were analyzed using PROC MIXED with pen replication as the experimental unit. Bunk occupancy for F was longer ($P < 0.01$; 149.8 vs. 111.2 min) than heifers allotted to P. Feeding S (S vs. NS) increased ($P < 0.02$) heifer bunk occupancy by 16.2 min. Bunk occupancy rate was 27.6, 20.0, 24.4 and 18.1 min/h for FS, PS, FNS and PNS respectively. Feeding S increased dietary NDF by 7.0% units and decreased ($P < 0.04$) DMI of heifers 0.28 kg/d as compared with limit feeding NS. Heifers fed S consumed 0.55 kg more ($P < 0.01$) NDF/d but consumed less ($P < 0.01$) CP, and Mcals of ME than heifers fed NS. Bunk access (F vs. P) had no effect ($P > 0.55$) on DMI or the intake of any nutrient. Despite lower CP and ME intakes, the ADG of heifers fed S or NS were similar ($P > 0.21$; 0.90 vs. 0.95 kg/d). Allotting heifers to F or P bunk access likewise had no effect ($P > 0.39$) on ADG (0.95 vs. 0.91 kg/d) and no interactions between bunk access and treatment diet on ADG were observed. Finally, bunk occupancy rate (min/h) and ADG were regressed using PROC REG procedures. For heifers assigned to PS ($r^2 = 0.25$) and FNS ($r^2 = 0.15$) there were weak positive relationships between bunk occupancy rate and ADG. For heifers assigned to FS or PNS there was no relationship between bunk occupancy rate and ADG. Data suggest adding straw to a limit fed diet with partial bunk access did not improve heifer nutrient intake, and induced a more variant relationship between bunk occupancy rate and ADG.

Key words: limit feeding, heifers, bunk space

T321 Effects of cinnamon essential oil, cinnamaldehyde and monensin on milk fatty acid profile of dairy cows. C. Benchaar*[1] and P. Y. Chouinard[2], *[1]Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC, Canada, [2]Université Laval, Département des Sciences Animales, Québec, QC, Canada.*

Eight multiparous lactating cows (BW = 614 kg; DIM = 71) were used in a duplicate 4 × 4 Latin square design (28-d periods) to examine the effects of no addition (CTL), or the addition of cinnamon essential oil (1 g/d; CIN), cinnamaldehyde (1g/d; CDH) and monensin (24 mg/kg DM; MON) on milk fatty acid (FA) composition. Analyses of FA were performed on pooled samples collected from 4 consecutive milkings (d 22 to 23). Differences between treatments were declared significant at $P \leq 0.05$ using the Tukey correction for multiple comparisons and trends were discussed at $0.05 < P \leq 0.10$. Feeding CIN and CDH to cows had no effect on milk FA composition (g/100 g of total FA) as compared with feeding CTL. Proportions of C18:0 (7.99 vs. 8.69%) tended to be lower while that of trans-11 C18:1 (0.74 vs. 0.70%) remained unchanged, those of trans-10 C18:1 were higher (0.39 vs. 0.30%), and those of cis-9, trans-11 C18:2 tended to be higher (0.40 vs. 0.35%) in milk fat of cows fed MON than in that of cows fed CTL. Cows fed CIN and CDH had lower proportion of trans-10 C18:1 (0.32%) than cows fed MON (0.39%). The proportion of trans-11 C18:1 was similar for cows fed CDH and those fed MON (0.74 and 0.66%) while it tended to decrease when cows were fed CIN as compared with MON (0.63 vs. 0.74%). The proportion of cis-9, trans-11 C18:2 was higher for cows fed MON than for cows fed CDH and CIN (0.40 vs. 0.35 and 0.34%, for MON, CDH and CIN, respectively). Results show that under the experimental conditions of this study, supplementing dairy cow diets with MON exerted minor effects on milk FA composition while no changes were observed when CIN and CDH were fed.

Key words: essential oil, monensin, milk fatty acid

T322 Fatty acids in milk of dairy cows fed diets containing propolis-based products. S. C. de Aguiar[1], S. M. Cottica[1], R. B. Samensari[1], E. M. de Paula[1], S. L. Franco[1], L. P. P. de Moura[1], G. T. dos Santos[1], J. V. Visentainer[1], W. B. R. dos Santos[2], E. H. Yoshimura[1], M. V. Valero[1], and L. M. Zeoula*[1], *[1]Universidade Estadual de Maringá, Maringá, Paraná, Brazil, [2]Instituto Federal do Amazonas, Maués, Amazonas, Brazil.*

Propolis is a resinous substance collected by bees from plants with various biological properties. The objective was to evaluate the addition of propolis-based products (PBP) in the diet of dairy cows, to decrease the amount of saturated fatty acids (SFA) in milk and the ratio of fatty acids (FA) n-6/n-3, as well as increase the amount of conjugated FA (CFA) and monounsaturated FA (MUFA). Four Holstein cows, with 550 kg of body weight and 147 d of lactation were subjected to 2 daily milkings (0600 and 1500h) and randomly assigned to a 4 × 4 Latin Square. The diets which were formulated with 60.27%:39.73% forage:concentrate, differed due to the inclusion or not of PBP as follows: control (no additives), PBP1, PBP2 and PBP3 (with 30.63, 71.88 and 78.45 mg of quercetin equivalents, respectively). Quercetin, a flavonoid, was used as a marker for flavonoids quantification. The PBP1 and PBP2 differ only in the concentration of propolis and have the same ethanol content, while the PBP3 has the same propolis concentration of PBP2 and higher ethanol content. Milk fat was transesterified and the methyl esters of FA were analyzed by gas chromatography. Quantification of FA was made in relation to the internal standard, methyl tricosanoate and the results expressed in $mg.g^{-1}$ of total lipids (Table 1). There was an increase in the amount of CFA in the milk from

PBP2 treatment when compared with control. Though, milk resulting from the addition of PBP3 treatment showed a significant increase in the amount of MUFA and n-3 FA, and a decrease (P = 0.00631) in the amount of SFA. The n-6/n-3 ratio decreased in all PBP treatments when compared with control. Concluded that the addition of PBP in dairy cows diets improves milk quality, which is more beneficial for human consumption.

Table 1. Sum of fatty acids in dairy cows milk for the different treatments

Fatty Acids (mg.g^{-1})	Control	PBP1	PBP2	PBP3
CFA	7.57 ^{c}	8.46^{c}	11.42^{a}	9.62^{b}
Polyunsaturated fatty acids	50.51^{a}	40.12^{c}	44.76^{b}	53.52^{a}
SFA	435.69^{a}	423.99^{ab}	432.90^{a}	403.01^{b}
MUFA	409.41^{b}	409.77^{b}	403.35^{b}	460.21^{a}
n-6	46.21^{a}	35.86^{c}	40.19^{b}	47.67^{a}
n-3	4.30^{b}	4.25^{b}	4.57^{b}	5.85^{a}
n-6/n-3	10.76^{a}	8.45^{b}	8.83^{b}	8.17^{b}
TOTAL	903.18	882.34	892.43	926.36

Different letters in the same line are statistically different (P < 0.05).

T323 Varying dietary dry matter concentration through water addition: Effect on nutrient intake of dairy cows in late lactation. J. A. Fish and T. J. DeVries*, *University of Guelph, Kemptville Campus, Kemptville, ON, Canada.*

Recent research suggests that adding water to a TMR containing wet forage sources can limit DMI. The objective of this study was to determine if DMI can be limited in late lactation cows through water addition to a TMR formulated for high production. Twelve lactating Holstein cows (214.8 ± 28.5 DIM) were exposed to 2 diets in a cross-over design with 28-d periods. Diets had the same ingredient composition (30.9% corn silage, 30.3% alfalfa haylage, 21.2% high-moisture corn, and 17.6% protein supplement; DM basis) and differed only in DM %, which was reduced by the addition of water. Treatment diets were: 1) DRY (61.7% DM) and 2) WET (51.9% DM). DMI and milk production (4% fat corrected milk; FCM) were recorded for the last 14 d of each treatment period. For the final 4 d of each period fresh feed and orts were sampled for particle size analysis. The particle separator had 3 screens (19, 8, 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each particle fraction expressed as a % of its predicted intake. Sorting values > 100% indicate selection for, while values < 100% indicate sorting against. Data were analyzed using a general linear mixed model. All cows sorted against long ration particles (P < 0.05); there was no difference in the extent of this sorting between the DRY and WET treatments (72.9 vs. 77.6%; SE = 4.5; P = 0.5). Across the study, there was no sorting (P > 0.05) for or against medium (99.9%) or small (101.4%) ration particles. There tended to be more sorting for fine ration particles on the DRY treatment compared with the WET (106.3 vs. 104.0%; SE = 1.0; P = 0.1). The addition of water had no effect on production parameters, with similar DMI (27.9 vs. 26.5 kg/d; SE = 1.1; P = 0.4), 4% FCM (28.7 vs. 27.6 kg/d; SE = 0.9; P = 0.4) and efficiency of production (0.98 vs. 1.00 kg 4% FCM/kg DMI; SE = 0.04; P = 0.6) between the DRY and WET treatments. The results suggest that, despite a tendency to reduce the degree of feed sorting, addition of water to a TMR had no effect on nutrient consumption and production efficiency of late lactation dairy cows.

Key words: dry matter, late lactation, sorting

T324 Effect of parity and stage of lactation on feed sorting behavior of lactating dairy cows. T. J. DeVries*[1], L. Holtshausen[2], M. Oba[3], and K. A. Beauchemin[2], *[1]University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]University of Alberta, Edmonton, AB, Canada.*

The objectives of this study were to determine if feed sorting differs between primiparous (PP) and multiparous (MP) cows, if sorting changes from peak lactation to peak DMI, and whether this sorting affects efficiency of production. Data on DMI, milk production, feed sorting (particle size of offered and refused feed), and plasma NEFA concentration were collected on 30 PP and 30 MP lactating Holstein dairy cows during 3 weeks of lactation. Cows averaged 53, 81, and 109 ± 10 DIM at each recording week. The particle separator had 3 screens (19, 8, 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each particle fraction expressed as a % of its predicted intake. Sorting values >100% indicate selection for, while values <100% indicate sorting against. Data were averaged per cow per week and analyzed in a repeated measures mixed model. Over the study period MP cows consumed more DM (25.2 vs. 21.9 kg/d; SE = 0.7, P < 0.001) and produced more milk (42.2 vs. 35.0 kg/d; SE = 1.5, P < 0.001) than the PP cows, but had similar efficiency of production (1.65 kg milk/kg DMI). Across the study period DMI increased (P = 0.002), while milk yield decreased (P < 0.001), resulting in decreased efficiency of production (P < 0.001) as cows moved further into lactation. All cows had higher plasma NEFA concentrations at 53 DIM compared with at 81 and 109 DIM (128.6 vs. 77.8 μEq/L; SE = 12.0; P < 0.001), suggesting they were mobilizing more body fat at that earlier stage of lactation. Across weeks all cows sorted against the long ration particles and sorted for fine ration particles. The PP cows sorted more against the long ration particles (92.8 vs. 95.5%; SE = 1.5; P = 0.05) and for the fine ration particles (104.0 vs. 102.9%; SE = 0.5; P = 0.01) than MP cows across all 3 recording weeks. The PP cows also sorted for the short ration particles (101.0%), while the MP cows did not (100.2%). The results demonstrate that despite changes in DMI, production, and efficiency, feed sorting remained consistent in cows across DIM. Further, our results demonstrate that PP cows engage in more feed sorting than MP cows.

Key words: parity, stage of lactation, sorting

T325 Effects of different physical processing of corn starter on performance of newborn Holstein dairy calves. A. Soltani[1], G. R. Ghorbani*[1], B. Omidian[3], M. Khorvash[1], S. Zaree-Shamsabadi[1], H. Beiranvand[1], M. Kazemi-Bonchenari[2], and M. Mirzaee[1], *[1]Department of Animal Sciences, Isfahan University of Technology, Isfahan, Iran, [2]Department of Animal Sciences, Arak University, Arak, Iran, [3]Department of Animal Sciences, Shahrekord University, Shahrekord, Iran.*

The objective of present study was to compare the effects of different corn processing of starter in neonatal dairy calves on feed intake, average daily gain (ADG), feed efficiency, rumen pH, and weaning weight. For this purpose, 20 Holstein dairy calves (10 male and 10 female) were used in a completely randomized block design. Calves were randomly allocated to 2 different treatments consisting of either steam flaked or finely ground corn. Starters were formulated to contain similar ingredients and nutrient compositions. The calves were housed

individually from d 3 after birth until 60 d old and the weaning also was done on 60 d old. Starter consumption was measured daily for each calf. Calves were weighed immediately after birth and also the weights were recorded weekly until 8 weeks. No significant differences were observed between calves received starter containing steam flaked versus finely ground corn for daily starter intake ($P = 0.28$). Calves fed steam flaked corn had significantly higher ADG compared with the calves fed grinded corn (0.89 vs. 0.68, $P < 0.01$). Consequently, feed efficiency was greater in calves consumed steam flaked versus grinded corn (0.73 vs. 0.56, $P < 0.01$). The reason probably is related to, lower rumen passage rate and higher digestibility of starch with steam flaked corn than grinded corn. As a result of higher feed efficiency and ADG, weaning weight tended to be higher for steam flaked corn compared with grinded corn ($P = 0.06$). Comparing the rumen pH on d 56 of experiment showed that no difference was observed between treatments ($P = 0.43$). In general, results of this study indicate that feeding steam flaked corn improve performance of newborn dairy calves in comparison to finely ground corn.

Key words: dairy calves, corn processing, starter

T326 Comparison of dairy cattle performance in Nebraska when fed silage and grain produced from second-generation insect protected (*B.t.*) corn (MON 89034), parental line, or reference corn grown during 2009. H. A. Paz*[1], E. Castillo-Lopez[1], K. Clark[1], T. H. Klusmeyer[2], G. F. Hartnell[2], and P. J. Kononoff[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]Monsanto Company, St. Louis, MO.*

Sixteen Holstein cows were used to evaluate the effects on intake and performance of feeding grain and silage from a genetically modified corn (MON 89034), a parental control or 2 reference hybrids of non-genetically modified corn. Cows were randomly assigned to one of 4 4 × 4 Latin squares and periods lasted 28 d. Dietary treatments were 1) control hybrid DKC63–78 (Control), 2) second-generation insect protected corn MON 89034 (*B.t.*), 3) reference corn hybrid DKC61–42 (Ref 1), and 4) reference corn hybrid DKC62–30 (Ref 2). Diets had similar ingredient composition except for the source of corn silage and corn grain. Intake of DM was highest ($P = 0.01$) for cows consuming the *B.t.* corn diet (26.6 ± 0.59 kg/d) compared with those consuming other corn hybrids diets (25.4, 25.0, 25.6 ± 0.59 kg/d for the Control, Ref 1, and Ref 2 diets, respectively). Additionally, cows consuming the *B.t.* diet tended ($P = 0.09$) to produce more milk (38.2, 36.4, 36.5, and 36.1 ± 0.98 kg/d for *B.t.*, Control, Ref 1, and Ref 2). Milk percentage and yield of protein (3.01 ± 0.05% and 1.11 ± 0.03 kg/d) and fat (3.3 ± 0.10% and 1.22 ± 0.05 kg/d), 3.5% fat corrected milk (FCM; 35.7 ± 1.07 kg/d), FCM/DMI (1.39 ± 0.03 kg/kg), and milk urea N (14.01 ± 0.49 mg/dl) were not different ($P > 0.10$) across diets. Results from this experiment demonstrated that MON 89034 was as nutritious as conventional, non-transgenic corn grain and corn silage when fed to dairy cows.

Key words: corn silage, genetically modified corn, dairy cow

T327 Morphology of the omasum of dairy cows fed of high or low grain content diet before parturition. D. de O. R. B. Santoro, J. C. de Resende Júnior*, T. da S. Teófilo, R. F. de Lima, J. L. P. Daniel, M. B. Moreira, P. P. Bueno, T. A. Dell Vale, G. P. Lenzi, T. M. França, and S. de F. Costa, *Universidade Federal de Lavras, Lavras, Minas Gerais, Brazil.*

The high-energy diet before parturition is able to induce the proliferation of ruminal epithelium. However, nothing is known about the morphological response of the omasum of dairy cows that consume high-energy diet pre-partum. The aim of this study was to investigate whether the transition diet, with high grain content, is able to induce changes in omasum morphology. Four Holstein cows with cannula in the dorsal sac of the rumen, were allocated to 2 treatments in 2 blocks of 2 cows, defined by the date of the expected parturition. Six weeks before the expected calving, cows were fed a standardization diet and 4 weeks before delivery were subjected to diets with high (HGC) or low (LGC) grain content. After delivery, all cows were fed a high energy lactation diet. Fragments of the omasum and the rumen were collected by biopsy on days –42, –28, –14, –7, 2, 14, 28, 42 and 56 in relation to parturition. Data were submitted to variance analyze considering in the model the effect of the block; treatment; day related to calving; and interactions. The animals that received HGC had higher DMI ($P < 0.01$), greater ($P < 0.01$) intake of CP, NDF, fat and minerals and higher milk production ($P = 0.04$), milk fat ($P = 0.07$) and protein ($P < 0.01$). The mitotic index (MI) of the omasum epithelium tended ($P = 0.11$) to be higher in HGC and was higher ($P < 0.001$) than the MI in the rumen, but it was highly ($R^2 = 0.80$; $P = 0.01$) correlated. The papillae of the omasum in cows that received HGC had greater height and larger area, between one week before and 2 weeks after delivery, a fact demonstrated by the tendency of interaction between treatment and collection day ($P < 0.09$). Cows that received HGC had lower thickness of the keratin layer ($P < 0.01$) and not keratinized layers ($P = 0.03$) of the omasum epithelium, showing that the LGC diet stimulates thick epithelium. We conclude that the mucosa of the omasum of dairy cows responds positively to the diet high in grains before parturition, a fact demonstrated by the higher height and larger area of the papillae and by the higher epithelium MI.

Key words: acidosis, histology, transition diet

T328 Enteric methane production from dairy cows fed different silages with and without rapeseed supplementation. M. Johannes*, A. L. F. Hellwing, P. Lund, M. R. Weisbjerg, and T. Hvelplund, *Faculty of Agricultural Sciences, Aarhus University, Denmark.*

Enteric methane (CH_4) production is closely related to feed composition, mainly NDF, fat and starch content. The aim of the experiment was to study the methanogenic potential of common Danish silages, the effect of fat supplementation as well as the interaction. The study was conducted with six ruminally and intestinally cannulated lactating Holstein-Frisian dairy cows receiving six diets over four periods of 28 days according to an incomplete 6x4 Latin square design. The cows were 271 days in milk (sd 67) and had an ECM yield of 24.0 kg/d (sd 6.2). During the third week, samples were taken in order to determine digestibility. Methane production was measured in four open-circuit respiration chambers during the fourth week. The diets were based on early first cut grass silage (EG, harvested May 26th, 329g NDF/kg DM), late first cut grass silage (LG, harvested June 15th, 484g NDF/kg DM) or maize silage (M, 390g NDF/kg DM) supplemented with low fat concentrate (LF) or concentrate with whole crushed rapeseed (high fat, HF). Other concentrate ingredients were wheat and rapeseed meal. Content of fat-free rapeseed was equal for all diets. Fatty acid content was 20 g/kg DM in the LF diets and 50 in the HF diets. All diets were fed as total mixed ration with 64% forage. Absence of interaction between silage and fat supplementation was consistent for all parameters ($P > 0.7$). Later maturity (LG) reduced dry matter intake (DMI) by 1.05 kg DM compared to EG ($P = 0.02$). There was no significant difference in DMI between EG and M ($P = 0.28$). Fat supplementation tended to reduce DMI by 0.58 kg ($P = 0.09$). Silage had a significant effect ($P < 0.001$) on CH_4 production per kg DMI with most CH_4 on

LG (31.4 L/kg), 28.4 L/kg for EG and 26.0 L/kg for M. Fat supplementation reduced CH_4 by 1.6 L per kg DMI ($P = 0.05$). Energy loss for the different silages were 6.1, 6.8 and 5.6% of gross energy for EG, LG and M, respectively ($P < 0.001$). Fat supplementation reduced energy loss by 9% ($P = 0.004$). The results confirm that highly digestible forage and fat supplementation can reduce enteric CH_4 production, and that effects were additive.

Key words: methane, forage, fat supplementation

T329 Particle size and endosperm type of dry ground corn alter apparent ruminal synthesis of B-vitamins in lactating dairy cows. M. Seck*[1,3], M. S. Allen[2], P. Y. Chouinard[3], and C. L. Girard[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada, [2]Department of Animal Science, Michigan State University, East Lansing, [3]Departement de sciences animales, Universite Laval, Quebec, Quebec, Canada.*

Effects of dry ground corn varying in particle size and endosperm type on apparent ruminal synthesis (AS) of thiamin (B1), riboflavin (B2), niacin (B3) and vitamin B6 (B6) were evaluated using 8 ruminally and duodenally cannulated dairy cows. The experiment was a duplicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Main effects were corn grain vitreousness (floury or vitreous) and particle size (medium or fine). Endosperm was 25% vitreous for floury treatment and 66% vitreous for vitreous treatment. The fraction of grain passing through a 1.18 mm sieve was 43% for medium, vitreous, 42% for medium, floury, 57% for fine, vitreous and 62% for fine, floury. Diets included alfalfa silage, corn treatments, protein supplement, minerals, vitamins, and contained 29.2% starch, 27.2% NDF and 18.3% crude protein. Corn grain treatments supplied 86.2% of the dietary starch. Grinding and endosperm type had no effects on daily intakes of B-vitamins except for B2 where fine grinding decreased daily intake (175 vs. 181 ± 8.6 mg/d, $P = 0.04$). Reducing particle size increased duodenal flow (DF) of B2 (391 vs. 327 ± 26.6 mg/d, $P < 0.01$), B3 (3513 vs. 2939 ± 317.0 mg/d, $P = 0.01$) and tended to increase DF of B1 (50.7 vs. 40.4 ± 3.7 mg/d, $P = 0.07$). Floury treatment increased DF of B3 (3453 vs. 3000 ± 317.0 mg/d, $P = 0.04$). Fine grinding increased AS of B2 (215 vs. 146 ± 23.8 mg/d, $P < 0.01$), B3 (2671 vs. 2083 ± 289.5 mg/d, $P < 0.01$) and B1 (8.4 vs. −1.4 ± 2.7 mg/d, $P = 0.05$) while floury endosperm increased AS of B3 (2602 vs. 2152 ± 289.5 mg/d, $P = 0.03$). DF and AS of B6 were not affected by treatments ($P > 0.13$). B1 AS was correlated negatively with true ruminal digestibility of organic matter expressed as percentage of intake ($P < 0.01$, r = −0.48) or as kg/d ($P = 0.02$, r = −0.40). Duodenal flow of microbial nitrogen was correlated positively with AS of B2 ($P < 0.01$, r = +0.52), B3 ($P < 0.0001$, r = +071) and B6 ($P = 0.02$, r = +0.41). B-vitamin supply to dairy cows is affected by dry corn particle size and to a lesser extent, by endosperm type.

Key words: dairy cow, B-vitamin, corn grain

T330 Abrupt changes in forage dry matter of one to three days affect intake and milk yield in late lactation dairy cows. J. Boyd*[1] and D. R. Mertens[2], *[1]US Dairy Forage Research Center, Madison, WI, [2]Mertens Innovation & Research LLC, Belleville, WI.*

Our objective was to determine if late lactation cows were susceptible to 1, 2, and 3d changes in forage DM. Forty-four Holstein cows (22 primiparous and 22 multiparous), averaging 155 DIM, 42.5 kg/d of milk, and 597 kg body weight, were used in a study conducted from Jan to Mar 2010. Within each parity, cows were assigned to 1 of 11 blocks based on production and DIM and one cow of each parity-block was randomly assigned to 1 of 2 groups. Study design was replicated 2 × 2 Latin Squares for each set of 1, 2, or 3 d treatments. Each period consisted of a 3-d pre-treatment, 1 to 3d treatment, and a 3-d post-treatment phase. Diets contained about 18% alfalfa and 36% corn silage (DM basis) and were control (Ctrl) with no water added and treatment (Trt) with water added to mimic rainfall events on a bunker silo and feeding an imprecise ration based on as-fed ratios of ingredients. Ctrl ration was adjusted daily to maintain constant DM ratios of ingredients during the study. Milk yield was recorded daily and component samples were taken 2x daily. Forages, TMR, and refusals were sampled daily and concentrates sampled 2x weekly. Chemical composition (DM, CP, NDF) of samples were determined by NIR. Alfalfa silage samples dried at 55C for 48h obtained 2%-units higher DM than predicted by NIR. Thus, water addition was underestimated, resulting in a 3%-unit change in forage DM instead of the target 8%-unit change that was planned. Data was analyzed using Proc MIXED of SAS with cow within parity-block as a random variable. On d1, DMI was reduced 1.22 ($P < 0.0001$), 0.67 ($P = 0.04$), and 2.06 kg ($P = 0.0001$), for the 1, 2, and 3d treatments, respectively. The amount of feed offered was adjusted based on refusal level, and DMI recovered during the following 1 to 3 d even during Trt phases. Milk yield and components were not affected by treatment ($P > 0.37$). We conclude that abrupt changes in forage DM reduce daily feed intakes, but a change >3%-units in forage DM is necessary to affect milk yields and components for late lactation cows.

Key words: DM changes, silage, feeding

T331 Effects of adding fibrolytic enzymes to diets containing bermudagrass silage harvested at two maturity stages on the performance of lactating Holstein cattle. O. C. M. Queiroz*[1], A. T. Adesogan[1], J. L. P. Daniel[2], J. J. Romero[1], J. H. Shin[1], C. R. Staples[1], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]University of Sao Paulo, Piracicaba, Sao Paulo, Brazil.*

The objective was to examine effects of adding fibrolytic enzymes to diets containing bermudagrass ensiled after 4 or 8 weeks (4-wk or 8-wk) of regrowth on the performance of Holstein cows. Fifty-eight lactating cows (22 ± 4 DIM) were assigned to treatments arranged in a 2 by 2 factorial design. Treatments were diets containing 4- or 8-wk bermudagrass silage without (4-C and 8-C) or with exogenous enzymes (4-E and 8-E). The cellulase-xylanase enzyme was applied at 2.5 g/kg of TMR DM during ration mixing immediately before feeding. Milk production and DMI of individual cows were recorded daily. Milk and feed ingredients were sampled weekly and chemically characterized. The statistical model included treatment, time, parity, and all interactions of these terms. No enzyme by maturity interaction was detected. Dietary treatment did not affect milk yield (lsmean = 38.4 kg/d, SEM = 1.00) or FCM:DMI ratio (lsmean = 2.09 kg, SEM = 0.08). Feeding the 4-wk diet instead of the 8-wk diet tended ($P < 0.07$) to increase DMI (22.6 vs. 21.4 kg/d; SEM = 0.7) and milk fat yield (1.83 vs. 1.71 kg/d, SEM = 0.06). Applying the enzyme increased ($P = 0.02$) lactose concentration (4.84 vs. 4.73%; SEM = 0.04), but did not affect milk protein or fat concentrations (2.70 vs. 2.65%; $P = 0.21$ and 4.41 vs. 4.49; $P = 0.44$, respectively) or milk protein yield ($P = 0.27$). Feeding the enzyme did not improve the performance of the cows.

Key words: fibrolytic enzymes, cellulase, xylanase

T332 Effects of *Bacillus subtilis natto* on intestinal morphology in pre and postweaning dairy calves. Y. Sun, J. Q. Wang*, P. Sun, D. P. Bu, G. C. Luan, and H. T. Zhang, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study investigated the effects of *Bacillus subtilis natto* on duodenal and jejunal morphology in pre and postweaning calves. Twenty 4 China Holstein calves were divided randomly into 3 groups: control group, fed milk and starter or basal diet only; 2 experimental groups, added *Bacillus subtilis natto* N1 and Na strains cultures respectively at a dose of 1×10^{10} cfu daily. Four calves selected randomly from each group were slaughtered and sampled at weaning, and the remaining calves were slaughtered 44 d after weaning. Results showed that *Bacillus subtilis natto* reduced calves diarrhea incidence. Supplementation of *Bacillus subtilis natto* N1 and Na strains in weaning calves increased villus height and villus height/crypt depth (V/C) in duodenum and jejunum ($P < 0.05$), elevated muscle layer thickness in duodenum and anterior jejunum ($P < 0.05$), but decreased crypt depth in duodenum, anterior jejunum and posterior jejunum ($P < 0.05$). Villus height, V/C and muscle layer thickness in duodenum and jejunum of postweaning calves fed N1 and Na strains were higher ($P < 0.05$) while the crypt depth was lower than control ($P < 0.05$). In conclusion, *Bacillus subtilis natto* may have the potential to prevent diarrhea and improve duodenal and jejunal morphology in dairy calves.

Key words: *Bacillus subtilis natto*, dairy calves, intestinal morphology

T333 Effect of dietary delivery product Force 6 on performances and antioxidant status of high-producing dairy cows. D. Éclache, P. Etienne, and V. Noirot*, *Phodé Laboratories, Terssac, France.*

High producing dairy cows are at risk of oxidative stress. Force 6 (Phodé Laboratories, France), a product containing curcumin and formulated to ensure product delivery and absorption in the gut, has been tested during 6 weeks on 2 groups of 17 Holstein dairy cows, matched in pairs according to the following criteria: parity, milking stage (DIM), dairy production (DP), milk solids content, live body weight and body condition score (BCS). The aim of this trial was to evaluate the effects of the product on dairy production parameters, as well as on the animal antioxidant status. At the beginning of the trial, the average DIM was 97 d and DP was 44.1 kg. The control group was fed non supplemented basal diet (corn silage based; 17% crude protein, 1530 kcal/kg), the treated group received the same basal diet supplemented with 2 g/animal/day of the tested product. Daily individual DP, weekly and daily milk solids contents and somatic cells counts (SCC), as well as body weight gain and BCS were measured. Blood samples were taken on the first day of the trial and then every fortnight, to assess plasma hydroperoxides content, an indicator of free radicals production (d-ROM kit, Dacron, expressed in U.CARR. - Carratelli units). Statistical analysis were performed using a linear model with treatment (n = 2), matched pairs (n = 1 to 17), week (n = 1 to 6) and the interactions matched pair × week and treatment × week as factors. Dairy production parameters measured 2 weeks before the trial and d-ROM values measured on the first day of the trial were used as covariates. Milk solids contents, ADWG and BCS were not significantly different. The treatment, however, improved DP (44.9 kg/day vs. 43.8 kg/day for the control group, $P < 0.05$), and decreased SSC (166,000 vs. 257,000 somatic cells/ml for the control group, $P < 0.05$). Plasma hydroperoxides contents were significantly lower for the treated cows (137.4 U. CARR. vs. 162.6 U. CARR. for the control $P < 0.05$). The increased dairy production and reduction of SCC for high producing dairy cows could be linked to their improved antioxidant status.

Key words: antioxidant status, dairy cow, milk yield

T334 Effects of abomasal infusion of linolenic acid on milk fat synthesis and composition in dairy cows. U. Moallem*[1], D. Vyas[2], B. B. Teter[2], P. Delmonte[3], and R. A. Erdman[2], *[1]Agriculture Research Organization, Bet Dagan, Israel, [2]University of Maryland, College Park, [3]FDA.*

In a recent study, feeding high rates of extruded flaxseed to dairy cows increased the milk C18:3n-3 by up to 2 percentage units (% of FA). However, enrichment of C18:3n-3 in milk fat was negatively correlated with milk fat percentage and yield, and C16:0 yields. We hypothesized that C18:3n-3 suppresses de novo synthesis of C16:0. Therefore, our objectives were to assess the transfer efficiency of abomasally infused C18:3n-3 into milk fat and the interaction with milk fat content and yield, and the proportion of C16:0 in milk fat. Three rumen fistulated multiparous mid-lactation Holstein cows were used in a 3x3 Latin square design, with 14 d experimental periods. Cows were milked twice daily and with treatments applied during last 7 d. Treatments consisted of twice daily (0600 and 1900h) abomasal infusion of: 1) Control - 110 mL water; 2) LFO - 110 mL/d flaxseed oil; and 3) HFO - 220 mL/d flaxseed oil, which provided 52 and 104 g/d C18:3n-3, respectively. Blood samples were collected twice weekly and milk samples were collected during the last 6 consecutive milkings of each period. No differences were observed in DMI, milk, and milk solids yields. However, milk fat and lactose percentages tended to be higher ($P < 0.1$; $P < 0.07$, respectively) in LFO and HFO treatments than in the control. Plasma C18:3n-3 was 2.9 and 4.0 times higher in the LFO and HFO treatments. The C18:3n-3 in milk fat was 9 and 15 higher in the LFO and HFO treatments, (1.89 and 3.30 vs. 0.21 in the control), whereas the C18:3n-3 yields were 8.5 and 16.3 times greater than in the control (26.4 and 50.6 vs 3.1 g/d; $P < 0.01$). The percentage of C16:0 decreased by 10% and 17% in the LFO and HFO compared with the control. There were no differences in C16:0 yields. The transfer efficiency of abomasally infused C18:3n-3 into milk fat averaged 45% for both groups. In summary, abomasal infusion of C18:3n-3 dramatically increased the C18:3n-3 concentration in plasma and milk fat with no effect on milk fat percentage. However, C16:0 percentage in milk fat was decreased in both flaxseed treatments which may indicate on inverse relationship of C16:0 and C18:3n-3 in milk fat.

Key words: flaxseed, milk fat, dairy cows

T335 The time of access to temperate pasture influences rumen pH and NH_3-N concentration in heifers. A. Félix[1], N. Hernández[1], N. Figueredo[2], M. Génova[2], M. Ibarra[2], A. Mendoza[1], M. Aguerre[1], A. Pérez-Ruchel[2], J. L. Repetto[1], and C. Cajarville*[2], *[1]Departamento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

Twenty-four Hereford × Angus heifers (BW = 153 ± 18 kg) were used in a randomized complete block design to determine the effect of time access to pasture (*Lolium multiflorum*, *Trifolium repens*; 19.1% CP, 48.2% NDF DM basis) on rumen pH and NH_3-N concentration. Pasture was daily cut and offered ad libitum as sole feed for 4, 6, 8 or 24 h. After 15 d of adaptation, individual rumen fluid samples were collected through a ruminal cannula, every hour for 24 h (h0 = 0800) and pH and NH_3-N concentration were determined. Results were

analyzed as repeated measures with a mixed linear model. pH was affected by treatment ($P = 0.048$), hour ($P < 0.001$) and treatment x hour ($P < 0.001$). Mean pH values were 6.70, 6.64, 6.47, and 6.30 (SEM = 0.10) for treatments 4, 6, 8 and 24h respectively. The main difference observed was that restricted groups led to higher pH values during fasting periods (20 to 0 h), suggesting lower concentrations of volatile fatty acids or higher buffer availability in relation to OM in the rumen. While pH in treatment 24h reached a minimum of 5.83 at hour 10, in restricted-fed reached minimum values of 5.77, 5.62 and 5.78 between hour 5 and 6 for treatments 4, 6 and 8h respectively (SEM = 0.08), and then increased linearly after hour 13. Minimum pH values did not differ among treatments. NH_3-N concentrations were affected by treatment ($P < 0.055$), hour ($P < 0.001$) and treatment x hour ($P < 0.001$). Mean NH_3-N concentrations were 26.8, 26.5, 28.8 and 30.7 mg/dL (SEM = 1.1) for treatment 4, 6, 8 and 24h respectively. NH_3-N concentrations increased after hour 0 and reached peak values between hour 6 and 7 of 66.0, 56.3 and 58.3 mg/dL (SEM = 2.8) for treatments 4, 6 and 8h respectively and then decreased linearly until hour 14, while in treatment 24h no variations were observed. Minimum NH_3-N concentrations differed among restricted treatments and treatment 24h ($P < 0.001$), being 7.6, 7.9, 9.8 and 19.0 mg/dL for 4, 6, 8 and 24h respectively (SEM = 1.2). Restricting the time of access to pasture significantly influenced dynamics of rumen pH and NH_3-N concentrations, while unrestricted animals had a more stable ruminal environment.

Key words: feed restriction, rumen pH, rumen NH_3-N

T336 The time of access to temperate pasture influences intake and feeding behavior in heifers. A. Félix[1], N. Hernández[1], N. Tortorelo[1], S. Roja[1], M. Aguerre[1], A. Pérez-Ruchel[2], J. L. Repetto[1], and C. Cajarville*[2], *[1]Departamento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

Twenty-four Hereford × Angus heifers (BW = 153 ± 18 kg) were used in a randomized complete block design to determine the effect of number of hours with access to pasture (*Lolium multiflorum*, *Trifolium repens*; 19.1% CP, 48.2% NDF DM basis) on DM intake (DMI), feeding behavior and DMI rate. Pasture was daily cut and offered ad libitum as sole feed for 4, 6, 8 or 24 h from 0800 h (h0). Daily DMI was measured for 10d and DMI rate was registered by weighting the amount of pasture offered and refused every hour for 4 h. Feeding behavior (eating, ruminating, drinking, and others) were recorded every 5 min for 4 h by visual observation. Feeding behavior and DMI rate (analyzed as repeated measures) and DMI were analyzed with a mixed linear model. Mean DMI was 2.03, 2.69, 2.87 and 3.49 kg/day (SEM = 0.19) for treatments 4, 6, 8 and 24h respectively, representing 1.30, 1.78, 1.91 and 2.26% of BW (SEM = 0.12). DMI was lower in the more restricted animals (4 and 6h) than in 24h ($P < 0.001$), but no differences were detected between treatments 6 and 8h, or 8 and 24h. Mean DMI rates were 0.51, 0.54, 0.52 and 0.37 kg/h (SEM = 0.04) for treatments 4, 6, 8 and 24h. During the first hour restricted animals ate more DM than those non restricted (0.90 vs. 0.63 ± 0.05, $P \leq 0.012$), but no differences between treatments were detected from hours 2 to 4. No treatment x hour interaction was detected for behavior activities. Restricted heifers (4 and 6h) had a greater proportion of time eating than non restricted ones ($P = 0.024$), but no differences were observed between restricted groups. Mean proportions for eating were 0.73, 0.76, 0.66 and 0.54 (SEM = 0.05) for treatments 4, 6, 8 and 24h respectively. Eating and ruminating activities were affected by time ($P < 0.001$ and $P = 0.014$, respectively). The proportion of animals eating decreased (0.93 vs. 0.46 ± 0.05, $P < 0.001$) and ruminating increased (0 vs. 0.08 ± 0.02, $P = 0.017$) from hour 1 to 4. DMI rate was affected by treatment ($P = 0.001$), hour ($P < 0.001$) and treatment x hour ($P < 0.095$). It is concluded that time of access to pasture lower than 8 h led to changes in feeding behavior that were not enough to compensate the DMI drop.

Key words: feeding behavior, intake, intake rate

T337 Effect of replacement of conventional corn silage with brown midrib corn silage on behavior and performance of lactating dairy cows. K. W. Cotanch*, H. M. Dann, C. Whitehouse, C. S. Ballard, and R. J. Grant, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Feeding forages with high NDF digestibility to high-producing cows has the potential to increase feed intake and milk yield. However, highly digestible forage-based diets may negatively affect feeding behavior and ruminal fermentation. Fourteen multiparous Holstein cows (6 ruminally fistulated) averaging 196 d in milk were used in a crossover design study with 2-wk periods (10-d adaptation, 4-d collection) to determine the effect of NDF digestibility of corn silage on chewing behavior, ruminal fermentation, total tract digestibility, and lactational performance. Dietary treatments consisted of 1:1 replacement (DM basis) of conventional corn silage (CONV) with brown midrib corn silage (BMR). The total mixed ration (TMR) contained 43% corn silage, 15% grass silage, and 42% corn-soybean based grain mix (DM basis). The NDF content was 37.7 and 42.0%, the physically effective NDF (peNDF) was 35.8 and 39.6%, and 24-h NDF digestibility was 42.3 and 57.0% NDF for the conventional and brown midrib corn silages, respectively. Data were analyzed as a crossover design using the MIXED procedure of SAS. Cows had higher DMI but lower feed efficiency when fed the BMR diet. Diet did not affect milk yield, milk composition, time spent eating, or time spent ruminating. However, cows chewed less per unit of NDF and had a lower mean pH over a 24-h period when fed the BMR diet. Highly digestible forage does not stimulate chewing to the extent that would be predicted based on standard laboratory methods, such as peNDF. Measurement of peNDF may need to be adjusted based on forage NDF digestibility since chewing response is a function of forage particle size and NDF digestibility.

Table 1.

Item	CONV	BMR	SE	*P*-value
peNDF, % of TMR	17.5	18.3	-	-
DMI, kg/d	25.2	27.8	0.7	<0.01
Milk, kg/d	40.6	42.2	3.3	0.26
Milk fat, %	3.62	3.71	0.14	0.30
Milk true protein, %	3.12	3.15	0.10	0.46
Milk/DMI	1.60	1.50	0.10	0.03

T338 Evaluation of protein supplementation strategies for low-starch diets fed to lactating dairy cows. K. W. Cotanch*[1], S. E. Boucher[1], H. M. Dann[1], C. S. Ballard[1], R. J. Grant[1], and K. Fujita[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]ZenNoh National Federation of Agricultural Cooperative Associations, Tokyo, Japan.*

The objective of this study was to evaluate the effect of varying concentrations of rumen undegraded protein (RUP) and primary source of RUP [distillers dried grains with solubles (DDGS) or SoyPass (SP)] on ruminal and lactational responses of lactating Holstein dairy cows fed low-starch diets. Sixteen multiparous cows (4 ruminally fistulated) averaging 121 d in milk were fed one of 4 diets in a replicated 4 × 4 Latin square design with 3-wk periods (14 d adaptation and 7 d collection). Diets contained (% of DM) 20% starch, 21% physically effective neutral detergent fiber, and 35.6% RUP (% of crude protein; CP), 38.5% RUP with DDGS, 38.8% RUP with SP, or 41.9% RUP. The diets contained 16.9, 15.4, 17.0, or 16.5% CP with a metabolizable protein balance (g/d) calculated using CNCPS version 6.1 of −60.3, −217, 17.1, and 87.6 for the 35.6% RUP, 38.5% RUP with DDGS, 38.8% RUP with SP, and 41.9% RUP diets, respectively. The data were analyzed as a replicated Latin square design using Proc Mixed (SAS version 9.1) with model effects for diet, period, and replicate. Diet had no effect ($P > 0.05$) on dry matter intake (DMI; 28.2 ± 0.4 kg/d), body weight (732 ± 14 kg), or solids-corrected milk production (43.7 ± 1.2 kg/d). However, milk urea N was least ($P < 0.01$) for cows fed the 38.5% RUP with DDGS diet compared with the 34% RUP, 38.8% RUP with SP, and 41.9% RUP diets (8.8, 12.3, 12.2, and 11.6, SEM = 0.33), whereas milk true protein/CP intake was greatest ($P < 0.01$; 0.33, 0.30, 0.29, 0.30, SEM = 0.01) for the 38.8% RUP with DDGS diet. Ruminal pH (6.05 ± 0.09), total volatile fatty acid concentration (131 ± 2.25 mM), and microbial N (614 ± 19 g/d) were unaffected by diet ($P > 0.05$). The acetate to propionate ratio was depressed for the 38.5% RUP with DDGS diet compared with the 34% RUP, 38.8% RUP with SP, and 41.9% RUP diets (2.57, 2.69, 2.67, 2.78, SEM = 0.04). Efficiency of N use was improved for cows fed DDGS as the primary source of RUP in these low-starch diets, although DMI and solids-corrected milk yield were unaffected by diet.

Key words: rumen undegraded protein, low-starch diets, dairy cattle

T339 Effect of time of access to food on fermentation capacity of rumen fluid in heifers consuming temperate pastures. N. Hernández[1], A. Félix[1], K. Saavedra[1], K. Rosano[1], A. Pérez-Ruchel[2], M. Aguerre[1], S. Brambillasca[2], C. Cajarville[2], and J. L. Repetto*[1], *[1]Departamento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay, [2]Departamento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

The objective of this study was to evaluate if the time of access to forage affects the fermentation capacity of rumen fluid in heifers consuming temperate pastures, using the gas production technique. Twenty 4 cannulated heifers (153.1 ± 18.1 kg BW) in a randomized complete block design were housed in individual cages and assigned to one of 4 treatments according to the time of access to fresh forage: 4, 6 and 8h/d (restricted groups), or 24h/d (unrestricted group). Animals within each treatment had forage available (*Trifolium repens - Lolium multiflorum* mix) as sole feed. After 15 d of adaptation, ruminal fluid was taken from each animal 1h after the beginning of the meal and placed at 39°C in flasks with 0.5g of the pasture consumed by the heifers. Gas pressure was measured at 2, 4, 6, 8, 10, 12, 18, 24, 48, 72 and 96h. Cumulative gas production was analyzed by PROC MIXED as repeated measures. Means between treatments were compared by Tukey test for each hour. There were differences between treatments ($P < 0.001$) and hours ($P < 0.001$) without significant interaction treatment x hour ($P > 0.10$). Animals fed all day produced more gas than animals fed 4h until hour 18 ($P \leq 0.04$), for example at hour 12 volumes of gas were 153.84 vs. 188.22 mL/gDM incubated for treatments 4h and 24h respectively ($P < 0.007$). No differences were observed between 6h and 8h treatments ($P > 0.10$). We concluded that unrestricted animals had higher fermentation capacity and suggests that the time of access to food affects the activity of microbial populations. Acknowledgements: ANII for scholarship of the first author.

Key words: in vitro gas production, time access, heifers

T340 Frequency of feed delivery affects feeding behavior of limit-fed dairy heifers. A. M. Greter[1], T. F. Duffield[2], B. W. McBride[3], T. M. Widowski[3], and T. J. DeVries*[1], *[1]Dept. Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [3]Dept. Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Limit feeding may improve feed efficiency while reducing feed costs and nutrient excretion, but also poses health and welfare concerns. The objective of this study was to determine the effect of feeding frequency on the feeding and competitive behavior of limit-fed growing dairy heifers. Twenty-four Holstein dairy heifers (178.2 ± 9.3 d old) were divided into 6 groups of 4 and exposed to each of 3 treatments using a replicated 3 × 3 Latin square design with 28-d periods. The treatments were providing a high-concentrate ration (containing 16.9% corn silage, 22.1% haylage, 44.1% high moisture corn, and 16.9% protein supplement, DM basis) in a limited amount (1.93% of BW): 1) 1x/d (0800 h), 2) 2x/d (0800 and 1600 h), and 3) 4x/d (0800, 1200, 1600, and 2000 h). The rations were formulated to meet the nutrient requirements of a dairy heifer growing at 0.8 kg/d. There was sufficient bunk space (0.34 m/heifer) for all heifers to feed simultaneously. Feeding behavior was recorded for the last 14 d of each period. Competitive behavior was recorded on d 23, 25, and 27 of each period. Lying time was recorded for the last 7 d of each period. DMI was recorded daily and ADG was recorded weekly. Data were analyzed in a general linear mixed model. DMI was similar between treatments (4.9 kg/d; $P = 0.5$). Daily feeding time was greatest when heifers were fed 1x/d (61.5 min/d, SE = 0.9; $P = 0.01$), followed by when fed 4x/d (51.8 min/d) and then when fed 2x/d (44.5 min/d). When fed 1x/d heifers tended to displace each other more often (4.5 displacements/d, SE = 0.6; $P = 0.08$) than heifers on the 2x or 4x treatments (1.9 and 2.8 displacements/d, respectively). Interestingly, heifers on the 1x/d treatment experienced higher ADG than heifers on the 2x or 4x treatments (0.9 vs. 0.7 kg/d, SE = 0.04; $P < 0.005$). Lying time (802.5 min/d; $P = 0.4$) and the number of lying bouts (11.9 bouts/d; $P = 0.1$) were similar between treatments. These results suggest that although competition at the feed bunk may be greater, when given sufficient feeding space, it may be beneficial to feed limit-fed dairy heifers 1x/d as this treatment improved ADG and increased the amount of time spent feeding per day.

Key words: limit feeding, dairy heifer, feeding behavior

T341 Effect of feeding brown midrib corn silage and dried distillers grains with solubles on bacterial diversity in rumen fluid of dairy cows using bacterial tag-encoded FLX amplicon pyrose-

quencing. H. A. Ramirez Ramirez*[1], L. O. Tedeschi[2], T. R. Callaway[3], S. E. Dowd[4], K. Nestor[5], and P. J. Kononoff[1], *[1]University of Nebraska-Lincoln, [2]Texas A&M University, College Station, [3]Food and Feed Safety Research Unit, USDA-ARS, College Station, TX, [4]Medical Biofilm Research Institute and Research Testing Laboratory, Lubbock, TX, [5]Dow AgroSciences LLC.*

Four ruminally fistulated cows were used in a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments to evaluate the bacterial diversity in rumen fluid (RF) of dairy cows fed dual purpose (DP) or brown midrib (bm3) corn silage, and the inclusion of dried distillers grains with solubles (DDGS). There were 4 28 d periods; in each period cows were assigned to one of 4 treatments: DP corn silage + 0% DDGS (CON); bm3 corn silage + 0% DDGS (BMR); DP corn silage + 30% DDGS (CONDG); or bm3 corn silage + 30% DDGS (BMRDG). On d 28 of each period RF samples were taken at 2 and 12 h post-feeding and were analyzed using 16s rDNA bacterial tag-encoded FLX amplicon pyrosequencing (bTEFAP). Two types of bacteria were of special interest and their populations were analyzed by grouping genera according to their known substrate affinity. *Butyrivibrio* sp, *Fibrobacter* sp, and *Ruminococcus* sp were grouped as cellulose digesters (CD); and *Butyrivibrio* sp and *Megasphaera* sp were grouped as bacteria involved in ruminal biohydrogenation of unsaturated fatty acids (BH). Population of CD was similar across treatments representing 8.4 ± 0.69% of the total DNA in the samples. When cows were fed bm3 corn silage, *Fibrobacter* sp tended ($P = 0.15$) to represent a larger proportion of the total bacterial DNA (1.8 vs 2.3 ± 0.28% for DP and bm3). There was a significant forage × DDGS interaction ($P = 0.05$) for *Ruminococcus* sp; DNA of these bacteria represented the largest proportion within the CD group at 5.26, 4.13, 3.34 and 5.03 ± 0.73% for CON, BMR, CONDG and CONBMR, respectively. The BH group was similar among treatments; on average it represented 2.0 ± 0.21% of the total DNA extracted. The ratio of Firmicutes:Bacteroidetes was reduced ($P < 0.01$) by DDGS; the ratio was 0.56 for 0%DDGS and 0.39 ± 0.03 for 30%DDGS. Feeding bm3 corn silage tended to increase the population of the fiber digesting bacteria *Fibrobacter* sp while feeding DDGS decreased the ratio of Firmicutes:Bacteroidetes as determined by the bTEFAP technique.

T342 Optimization for isolating ruminal *trans*-11 18:1 hydrogenating bacteria from dairy cow in vitro. D. Jin, J. Wang*, S. Zhao, D. Li, D. Bu, and L. Zhou, *Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The biohydrogenation of ruminal bacteria has a significant effect on milk fatty acid profile, and *trans*-11 18:1 (TVA) is the major biohydrogenation intermediate. The process of biohydrogenation can be regulated by modulating the metabolism of hydrogenation related bacteria. So far, only partial ruminal hydrogenating bacteria was isolated because of harsh conditions for pure culture. This study was aimed to establish the optimal conditions for enrichment and isolation of ruminal TVA hydrogenating bacteria in vitro. TVA was added into anaerobic mediums with different final concentrations (0, 30, 40, 50, 60 μg/mL). Mixed ruminal microbes were inoculated into mediums for continuous cultivation, samples were collected every 4 h and used for detecting TVA concentration and OD value. In addition, TVA was added into the anaerobic medium to a final concentration of 50 μg/mL, then the cultures were transferred for 6 generations for enrichment. Changes of the bacterial composition during enrichment were analyzed by DGGE profiling. The results showed that concentration of TVA in mediums was significantly decreased at 4 h during continuous incubation and then maintained constancy at 12 h. After incubation for 12 h, degradation rates of TVA were higher than others while initial TVA concentrations were 50 μg/mL and 60 μg/mL, and the final TVA concentrations are 16.1878 μg/mL and 15.0357 μg/mL respectively. Besides, the OD value of the culture initiate increased and reached the highest at 12 h and then decreased. The amounts and types of suspected TVA hydrogenated strains increased most significantly in the 4th generation. Sequencing results for the DGGE bands showed that most of them belonged to *Lactobacillus gasseri* and uncultured bacteria. In conclusion, the suitable TVA adding amount for isolating culture of ruminal TVA hydrogenating bacteria is 50 μg/mL, and the optimal transfer time and transfer generation for enrichment culture are 12h and the 4th generation respectively.

Key words: DGGE, isolation, TVA hydrogenating bacteria

T343 Differential expression of the transcriptome in adipose tissue of first lactation dairy cattle. J. P. McNamara[1], J. M. Thomson*[2], and J. Loor[3], *[1]Washington State University, Pullman, [2]University of Alberta, Edmonton, Alberta, Canada, [3]University of Illinois, Urbana-Champaign.*

Adipose tissue metabolism is an essential factor in establishment of a successful lactation. To continue our investigations into the control of adipose tissue metabolism, we conducted a transcriptomic analysis of adipose tissue of dairy cattle in late pregnancy and early lactation. Our objective was to determine the changes in gene expression in adipose tissue between 30 d prepartum and 14 DIM in first lactation animals, and to determine if changes in expression were related to practical production variables. Animals were Holstein heifers fed the same diet to NRC requirements, and adipose tissue was biopsied at 30 d prepartum and 14 DIM. Total RNA was extracted and used to determine gene expression on a bovine gene array. Genes that code for proteins controlling fatty acid transport were highly expressed including fatty acid binding proteins (FABP4 and FABP5) and lipoprotein lipase. Among those genes increasing in expression were those controlling lipolysis including the ADRB2 (52%) and LIPE (23%). Many genes coding for enzymes controlling lipogenesis decreased, including SREBP (−25%); TSHSP14 (−30.8%), LPL (−48.4%) and ACACA (−63.9%). Another novel finding on control of lipolysis is in the expression of the caveolar proteins, caveolin-1 and caveolin-2), which both decreased in early lactation ($P < 0.02$). This gene expression array analysis in adipose tissue of lactating dairy cattle identifies several key genes that are components of the adaptation to lactation that can be incorporated into models of nutritional efficiency and may be amenable to genetic or dietary manipulation. Further functional analysis of differentially expressed genes revealed changes in synthesis, transport, and metabolism of fatty acids in adipose tissue. The expression values were related to milk production and body fat changes. Other functions revealed were in cell cycle control, immunity, and inflammation. These results confirm some key metabolic control points that can be targeted for further research to define the genotypic and phenotypic control of metabolic efficiency in dairy animals.

T344 The survival of *Bacillus subtilis natto* in rumen and duodenum of Holstein dairy cows. S. H. Dong, J. Q. Wang*, H. Peng, S. Peng, D. P. Bu, L. Y. Zhou, and H. Y. Kang, *State Key Laboratory*

of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.

Experiments in vitro and in vivo were conducted to evaluate the survival laws of *Bacillus subtilisnatto* (BSN) in rumen and duodenum of Holstein dairy cows. In experiment 1: BSN spores were added at 10^5/mL to strained rumen fluid or duodenum fluid taken from a healthy dairy cow and incubated in vitro at 39°C. Strained rumen fluid or duodenum fluid with no BSN inoculants served as controls. Changes of BSN spore counts and volatile fatty acid in rumen fluid were monitored at 0, 6, 12, 24, 48 and 72 h. Changes of BSN spore counts in duodenum fluid were monitored at 0, 1, 2, 3, 4, 5 and 6 h. The results of rumen fermentation showed that spores increased in the first 24 h, and then decreased. The survival rate of BSN was 191.3% and 157.1% at 24 h and 72 h, respectively. In addition, BSN increased the concentration of propionate and butyrate in rumen fluid ($P < 0.05$), but reduced the concentration of acetic acid ($P < 0.01$). The results of duodenum fermentation showed that spore counts tended to increase in the first 2 h, and then decreased gradually. The survival rate of BSN was 124.4%, 92.4% and 50.4% at 2, 4 and 5 h, respectively. In experiment 2: 7 cows were randomly assigned to 2 groups. Four cows were infused with 10^{10} spores of BSN into rumen through rumen cannula, but the other 3 cows received no infusion. Rumen fluid, duodenum fluid and feces were collected at 0, 6, 12, 24, 48, 72 h after the infusion. Spore counts increased slightly in the first 6 h, and then decreased gradually in rumen fluid. They continued to decrease in duodenum as well as feces and almost cannot be detected at 48 h after infusion in all of the location. In conclusion, BSN spores have the ability to survive in rumen and alter rumen fermentation. Most of BSN spores are able to survive in duodenum fluid for 4 h. However, the spores cannot permanently colonize in the gastrointestinal tract of Holstein dairy cows.

Key words: *Bacillus subtilis natto*, rumen fluid, duodenum fluid

T345 Milk fatty acid composition of lactating dairy cows fed short and medium chain fatty acids. H. Cui, D. P. Bu, J. Q. Wang*, X. W. Zhao, X. Y. Xu, Y. Sun, P. Sun, and L. Y. Zhou, *Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to evaluate the response of dietary short and medium chain fatty acids (SMCFA) (C6:0 to C14:0, plus 50% of C16:0) on milk fatty acid composition. Thirty-six Chinese lactating Holstein cows (150 ± 30 DIM) were used for 8 wks in the experiment. The cows were blocked based on DIM and milk yield (21.43 ± 3.39 kg/d) and randomly assigned to 3 treatments and fed TMR with 1 of 3 dietary fat supplements. The 3 treatments consisted of fat supplements containing increasing amounts of SMCFA replaced LCFA which was imitated to ideal with typical fatty acid in dairy cows milk: 1) LCFA (59% cocoa butter, 16% olive oil and 25% palm oil) (400 g/d), 2) butter fat(400 g/d), and 3) SMCFA (C6:0–6.0%, C8:0- 4.0%, C10:0- 9.0%, C12:0- 10.0%, C14:0- 32% and C16:0- 39%) (400 g/d). Milk samples were collected every 2 wks for fatty acid analysis. Data were analyzed statistically by using PROC MIXED (SAS, 1999). Feeding SMCFA increased the proportion of C < 16:0, C16:0 and saturated fatty acid (SFA) in milk fat ($P < 0.05$) in a linear fashion. Otherwise, dietary SMCFA resulted in concentration of C > 16:0 and MUFA in milk fat decreasing linearly ($P < 0.05$). The concentration of PUFA in milk fat was no significant different between treatments (Table 1). In conclusion, increasing supplement SMCFA replaced LCFA caused the fatty acid composition in milk fat changed respectively.

Table 1. Effect of different type of lipids in milk fatty acid composition (% of total FA)

Lipids	LCFA (400 g/d)	Butter fat (400 g/d)	SMCFA (400g/d)	SEM	*P*-value
<16:0	25.20[b]	26.76[b]	30.17[a]	0.52	0.0001
16:0	29.44[b]	31.62[a]	31.30[a]	0.53	0.0291

T346 Veal calves deposit nitrogen from solid feed as efficient as nitrogen from milk replacer. H. Berends*[1], J. J. G. C. Van den Borne[1], C. G. Van Reenen[2], and W. J. J. Gerrits[1], *[1]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [2]Livestock Research, Animal Sciences Group, Lelystad, the Netherlands.*

This study was designed to substantiate the contribution of increasing solid feed intake (SF) to protein and energy supply of veal calves. Due to potential interactions between milk replacer and solid feed, occurring either at the level of digestion or post-absorptive, this contribution may differ from that in ruminants exclusively fed on concentrates and roughage. To this end, 48 Holstein Friesian male calves (55 kg, SD: 2.1 kg) were divided over 16 groups of 3 calves each. Groups were assigned to one of 4 solid feed intake levels: 0, 9, 18, or 27 g DM of SF kg $BW^{-0.75}$ d^{-1}. Solid feed consisted of 25% chopped wheat straw, 25% maize silage and 50% concentrates on a DM basis. All calves received 40.7 g DM milk replacer kg $BW^{-0.75}$ d^{-1} during the experimental period. Groups were housed in respiration chambers during the 4-d experimental period, at an average BW of 164 kg (SD: 10.3 kg). Within chambers, calves were housed individually on metabolic cages to allow quantification of nitrogen balance. Data were analyzed using regression procedures with SF intake related parameters as independent variables. Preliminary results show that SF0 calves (exclusively milk replacer) retained 241 kJ kg $BW^{-0.75}$ d^{-1} at an intake of 880 kJ kg $BW^{-0.75}$ d^{-1}. The incremental efficiency with which energy from SF ingested was retained was 0.33 ($P < 0.05$). The incremental efficiency with which digestible energy from SF was retained was 0.53 ($P < 0.05$). SF0 calves retained 0.62 g N kg $BW^{-0.75}$ d^{-1} at an intake of 1.38 g N kg $BW^{-0.75}$ d^{-1}. The incremental efficiency with which N from SF ingested was retained was 0.74. Surprisingly, the efficiency of N retention (% of intake) increased with increasing N from SF by 0.35% per g N ($P < 0.05$). With increasing SF intake, there was a substantial shift in N excretion from urine to feces ($P < 0.05$). In conclusion, results show that in veal calves, efficiency of N utilization from SF (fed on top of a milk replacer diet) is markedly higher when compared with N utilization of milk replacer. Interactions between SF and milk replacer, such as an increased recycling of urea-N, may be involved.

Key words: calf, feed intake, protein and fat retention

T347 Effect of *B2M* haplotype combinations on the expression of FcRn mRNA in mammary gland of dairy cows. X. Hu, J. Wang*, S. Zhao, J. Zhao, and D. Bu, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The Fc receptor (FcRn) is the specific transporter of IgG in mammary gland, which is encoded by FCGRT and B2M. The polymorphism of FcRn would influence the concentration and transportation of IgG in milk. We conducted this study to investigate the association of B2M haplotype combinations with FcRn mRNA expression by Real-time PCR, in hope of provide a basis for further study of the possible regulation mechanism of IgG transportation in mammary gland of dairy cows. The mammary gland samples were collected from 40 healthy Chinese Holstein cows immediately after slaughter (the animals were slaughtered in a permitted way in accordance with the policies of Chinese Academy of Agricultural Sciences) and preserved in liquid nitrogen. Total DNA was extracted from the frozen samples. Specific primers were designed to amplify B2M gene. The SNPs were identified after sequencing. Total RNA was purified from the tissues according to the haplotypes of B2M, and then transcripted reversely into cDNA. The level of FcRn mRNA expression was detected by Real-time PCR. The results showed that there were 3 SNPs in B2M gene. We found a transversion of G to T in SNP1, a transition of T to C in SNP3, and a 2-base deletion in SNP2 (the missing bases were A and T). The 3 SNPs assembled 4 haplotype combinations, which were named H1 (GG-deletion-TT), H2 (GG-AT-TC), H3 (GG-AT-TT), and H4 (GT-deletion-TT) respectively. The expression of FcRn mRNA in H4 was significantly higher than the others ($P < 0.05$), but there were no significant differences ($P > 0.05$) between H1, H2 and H3. We concluded that the haplotype combinations of B2M did produce an effect on the expression of FcRn mRNA.

Key words: B2M, dairy cows, real-time PCR

T348 Effect of feeding *Bacillus subtilis natto* fermentation production on hindgut fermentation and microbiota of Holstein dairy cows. H. Y. Kang, J. Q. Wang*, D. P. Bu, L. Y. Zhou, P. Sun, H. Peng, X. l. Wang, and S. H. Dong, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing,China.*

The effects of *Bacillus subtilis natto* fermentation production on hindgut fermentation and microbiota of early lactation Holstein dairy cows were investigated in this study. Thirty-six early lactation Holstein dairy cows were randomly allotted to 3 treatments: no *Bacillus subtilis natto* (CON), 6 g *Bacillus subtilis natto* fermentation production/d (DFM1), 12 g *Bacillus subtilis natto* fermentation production/d (DFM2). All cows were treated with 3 treatments after adaption feeding period of 14 d, and the whole trail lasted for 63 d. Fecal samples were collected directly from the rectum of each animal at 0, 1, 2, 3, 4, 6, 8 wk, after the adaption feeding period. The pH, NH_3-N and VFA concentration were measured, and fecal total DNA was extracted and analyzed by DGGE. The results showed that *Bacillus subtilis natto* fermentation production tended to decrease fecal NH_3-N concentration ($P < 0.1$), but had no effect on fecal pH and VFA. DGGE profile revealed that *Bacillus subtilis natto* fermentation production had some effects on fecal bacteria population. The diversity index of Shannon-Wiener in DFM1 decreased significantly ($P < 0.05$) compared with CON. Fecal *Alistipes* sp., *Clostridium* sp., *Roseospira* sp., *Beta proteobacterium* decreased but *Bifidobacterum* increased after supplementation of *Bacillus subtilis natto* fermentation production. This study demonstrated that *Bacillus subtilis natto* fermentation production has potential to improve hindgut microbiota balance. More researches are needed to describe the mode of action to improve the efficiency of probiotic use.

Key words: *Bacillus subtilis natto* fermentation production, dairy cow, fecal microbiota

T349 Effect of short- and medium-chain fatty acid on milk composition in lactating dairy cows. X. W. Zhao, J. Q. Wang*, D. P. Bu, H. Cui, X. Y. Xu, Y. Sun, L. Y. Zhou, and P. Sun, *Chinese Academy of Agricultural Sciences, Beijing, China.*

Short- and medium-chain fatty acids (SMCFA) (C6:0 to C14:0, plus 50% of C16:0), constitute about 45% of total milk fatty acid (FA) and originate from de novo FA synthesis in the mammary gland. The objective of this study was to investigate the effect of SMCFA on milk composition and its limitation to milk fat. The experiment was conducted for 8wks with 30 6 Chinese lactating Holstein dairy cows (150 ± 30 DIM). The cows were blocked based on DIM and milk yield and randomly assigned to 3 treatments. Cows fed corn silage based TMR were supplemented with 1 of 3 dietary lipids supplements (400 g/d). The 3 treatments consisted of lipids supplements containing mixtures of different ratio of long chain fatty acid (LCFA) and SMCFA: 1) LCFA (59% cocoa butter, 16% olive oil, and 25% palm oil), 2) butter fat (400 g/d), and 3) SMCFA (C6:0–6.0%, C8:0- 4.0%, C10:0- 9.0%, C12:0- 10.0%, C14:0- 32%, and C16:0- 39%). Dry matter intake (16.82, 16.82, and 16.90 kg/d; $P > 0.05$), milk production (24.06, 23.67, and 22.47 kg/d; $P > 0.05$), 4% fat-corrected milk (FCM) (23.94, 23.94, and 24.45 kg/d; $P > 0.05$), milk protein percentage (3.34, 3.38, and 3.52%; $P > 0.05$), milk protein yield (817.30, 783.82, and 815.23 g/d; $P > 0.05$), and milk fat yield (954.33, 964.70, and 1030.62 g/d; $P > 0.05$) were not different between treatments for LCFA, butter fat, and SMCFA, respectively. Whereas milk fat percentage (3.90, 4.16, and 4.45%; $P < 0.05$) were increased in linear level when improved SMCFA content in the diet. Furthermore milk fat percentage reached the peak point coupled with SMCFA. In conclusion, SMCFA supplementation has positive effect in milk fat compared with LCFA, which means SMCFA may promote milk fat secretion in mammary gland in dairy cows.

Key words: Short- and medium-chain fatty acids, milk composition, dairy cows

T350 Effect of feeding *Bacillus subtilis natto* fermentation production on milk production and composition, blood metabolites and rumen fermentation in early lactation dairy cows. H. Peng[1], J. Q. Wang*[1], H. Y. Kang[1,2], S. H. Dong[1,3], P. Sun[1], D. P. Bu[1], and L. Y. Zhou[1], *[1]Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and technology, Southwest University, Chongqing, China, [3]Faculty of Animal Sciences and Technology, Gansu Agricultural University, Lanzhou, China.*

This experiment was conducted to determine the effect of *Bacillus subtilis natto* fermentation production supplementation on blood metabolites, rumen fermentation, milk production and composition in early lactation dairy cows. Thirty-six multiparous Holstein cows (DIM = 29 ± 6 d, parity = 2.8 ± 1.1) were blocked by DIM and parity and then randomly assigned to 3 treatments (12 per treatment) in a 9-wk trial. Cows in control, DFM1, DFM2 were fed TMR diets supplemented with 0, 6, 12 g of *B. subtilis natto* solid state fermentation production per day per cow separately. Six and 12 g of supplements contained about 0.5×10^{11} and 1×10^{11} spores of *B. subtilis natto* respectively. Plasma nonesterified fatty acids tended to be lower ($P = 0.06$) in DFM1 and DFM2 compared with control cows (639, 633 vs. 685 μmol/L). Ruminal propionate proportion of cows in DFM1 and DFM2 tended to be higher ($P = 0.06$) than control cows (26.3 and 26.9 vs. 23.9 mol/100 mol). There were no significant differences among treatments for DMI, but milk yield was 3.1 kg/d and 3.2 kg/d higher for DFM1 and DFM2 than control cows on average across the 9-wk trial and significant differences

were observed during wk 5 to 9 of the trial, which resulted in 9.5% and 11.7% increases in feed efficiency (kg of milk per kg of DMI). No significant difference were observed in milk yield and feed efficiency between DFM1 and DFM2. Milk fat percentage, protein percentage and yield were not affected by treatment. Milk fat yield tended to be higher ($P = 0.07$) and lactose percentage was significantly higher ($P < 0.05$) for DFM1 and DFM2 (4.93 and 4.95%) compared with control cows (4.80%). The findings suggest that *B. subtilis natto* fermentation production has potential role to improve lactation performance of early lactation dairy cows by altering the rumen fermentation pattern without any negative effects on animal health.

Key words: *Bacillus subtilis natto* fermentation production, dairy cow, milk production

T351 Fermentative and nutritional dynamics of bovine colostrum silage for dairy calves liquid feeding. L. S. Ferreira[1,2], M. C. Soares[1], M. P. C. Gallo[1], M. R. Paula[1,2], and C. M. M. Bittar*[1,2], *[1]University of São Paulo/ESALQ, Piracicaba, SP, Brazil, [2]Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Brasília, DF, Brazil.*

The objective of this study was to characterize the fermentative and nutritional dynamics of bovine colostrum fermented under anaerobic conditions 56 d during storage at ambient temperature. Colostrum from the second and third milking was collected, pooled, and stored in plastic bottles, which were filled and lightly pressed before its closure to remove all space with oxygen, thereby creating an anaerobic condition. Bottles were stored in a dark room at ambient temperature and 5 bottles were opened at d 0,1, 2, 3, 4, 5, 6, 7, 14, 21, 28 and 56 after storage, to determine pH, titratable acidity and temperature values. Also, samples were collected for determination of total nitrogen, protein and non-protein fractions by the Kjeldahl method. The pH and the titratable acidity values showed great variation during the storage period, essential for the conservation of colostrum ($P < 0.001$). However, although the pH and titratable acidity has shown great variations during the fermentation process, the colostrum temperature dynamics and values were close to ambient. The non-protein nitrogen fraction presented a high increase during storage ($P < 0.001$) and the true protein values decreased ($P < 0.001$), and presented with very low values after 56 d of storage. The fermentative dynamics observed suggests that colostrum silage has a potential for use as a milk replacer, however the nutritional quality of the resulting product, especially in relation to protein fraction, is inadequate for dairy calves. Strategies for reducing true protein conversion to non-protein nitrogen should be further investigated. Supported by CNPq.

Table 1. Composition and fermentative characteristics of colostrum silage

	Storage days						
Item	0	7	14	21	28	56	SE

T352 Performance of dairy calves fed "colostrum silage" or milk replacer. L. S. Ferreira[1,2], J. T. Silva[1], G. G. O. Nápoles[1], C. E. Oltramari[1], and C. M. M. Bittar*[1,2], *[1]University of São Paulo/ESALQ, Piracicaba, SP, Brazil, [2]Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Brasília, DF, Brazil.*

The objective of this study was to evaluate the performance of male Holstein calves fed bovine colostrum fermented under anaerobic conditions as a replacement to traditional liquid diet. Following birth, 18 male Holstein calves were used in a completely randomized design and assigned to the following treatments: 1) Control: milk replacer (18.5% CP, 22.5% fat, 12.5% solids; Nattimilk, Auster Animal Nutrition) or 2) Anaerobically fermented colostrum (colostrum silage). The animals were housed in individual hutches, with free access to water, starter feed (18% CP; 72% TDN), and 4L of liquid diet (milk replacer or colostrum silage) until weaning which occurred abruptly at the eighth week of life. Colostrum from the second and third milking was collected, pooled, and stored in plastic bottles, which were filled and lightly pressed before its closure to remove all space with oxygen, thereby creating an anaerobic condition. After approximately 45 d of fermentation and at the time of calves feeding, bottles were opened and diluted in warm water in a 1:1 ratio, to ensure acceptance by the animals. The starter feed intake and fecal score were recorded daily and body weight measurements were taken weekly until the eighth week of age. Animals fed colostrum silage presented lower starter intake ($P < 0.07$) during the experimental period, as compared with control animals (238 vs. 412 g/day). As expected, there was an age ($P < 0.0001$) and treatment x age ($P < 0.05$) effect for starter intake, with increasing values throughout the experimental period. However, no effects were observed for average daily gain (0.278 vs. 0.183 kg/day) or body weight (42.3 vs. 40.6 kg for the control treatment and fermented colostrum, respectively). The fecal score was affected by treatments during the wk 2 ($P < 0.05$), with animals fed fermented colostrum showing abnormal and very dry feces (average fecal score = 1.65). Even though the anaerobic fermentation of colostrum may be a good alternative for its storage, feeding it as a liquid feed during all milk-feeding period does not result in adequate animal performance. Financial support provided by CNPq.

Key words: fermented colostrum, fecal score, liquid diet

T353 In situ dry matter degradation kinetics of fennel forage in Holstein cow. M. Chaji*, T. Mohammadabadi, and H. Eghbali, *Khuzestan Ramin Agricultural and Natural Resources University, Molassani, Khuzestan, Iran.*

The objective of this experiment was determination of DM degradability of fennel forage. Dry matter degradability of the samples was measured by in situ technique using 2 fistulated Holstein steers (400 ± 12 kg, body weight). The animals fed a 40:60 concentrate: forage diet. The experimental samples were milled (2-mm screen) and weighed (5 g, DM) into bags (12x19 cm) made of polyester cloth with 52 µm pore size (8 replicates per each treatment). The bag were incubated in the rumen for 2, 4, 6, 8, 16, 24, 48, 72 and 96 h after being soaked in distilled water (38°C) for 10 min. Bags also were washed with cold tap water to estimate the wash-out at zero time. After each incubation time, the removal bags were hand-washed with cold tap water, and then dried in a forced-air oven (60°C, 48 h). The degradable parameters of DM were determined using the equation of $P = a + b (1 - e^{-ct})$. Data of degradable parameters and effective degradability of DM (out flow rate = 0.08 h −1) were analyzed using GLM of SAS in a completely randomized design ($P < 0.05$). Results of the present experiment indicated that the rapidly degradable fraction (a), slowly degradable fraction (b) and fractional degradation rate (c) of DM of fennel forage was 0.29+0.035, 0.4+0.038 and 0.099+0.024, respectively. Potential of degradability and DM effective degradability of fennel forage was 0.68 and 0.61.

Key words: fennel forage, degradability, in situ

T354 The effect of exogenous phytase on ruminal degradation of inositol phosphate in dairy cows. J. Sehested*[1], D. N. Braks-Pedersen[1], V. Glitsø[2], L. K. Skov[2], and P. Lund[1], *[1]Department of Animal Health and Bioscience, Aarhus University, Tjele, Denmark, [2]Department of Feed Applications, Novozymes A/S, Bagsvaerd, Denmark.*

The effect of exogenous phytase on inositol phosphate degradation in the rumen of 4 lactating Danish Holstein dairy cows with ruminal, duodenal and ileal cannulas was investigated in a 4 × 4 Latin Square design with 4 dietary treatments (level of exogenous phytase) and 4 periods (21 d). The cows were offered a total mixed ration (TMR) with a total phosphorus (P) content of 3.8 g/kg dry matter (DM) and a high proportion of dietary P in inositol phosphate (1.7 g P/kg DM). The TMR was composed of (% of DM): Beet pulp (30), grass silage (26), rape seed cake (20), maize silage (17), cane molasses (5) and maize feed meal (2). The TMR was supplemented with one of 4 concentrations of exogenous phytase (phytase units/kg DM): CONTROL (0), LOW (2000), MEDIUM (4000), or HIGH (6000). Preliminary data show, that addition of exogenous phytase to the feed ration significantly increased ruminal degradability (%, $P < 0.001$, SEM = 1.82) and reduced duodenal flow (g/d, $P < 0.001$, SEM = 0.38) of myo-inositol hexakisphosphate (InsP6) compared with CONTROL (75%; 6.7 g/d), whereas there was no difference between LOW (92%; 2.1 g/d), MEDIUM (95%; 1.3 g/d) and HIGH (96%; 1.2 g/d). Ruminal pH, rumen degradability of NDF, and rumen NDF kinetics were not affected by treatment. The present study indicated that ruminal degradation of inositol phosphate was increased by adding exogenous phytase to the diet. The results indicated that max ruminal inositol phosphate degradation was obtained by adding 2000 phytase units/kg DM.

Key words: inositol phosphate, phytase, phosphorus availability

T355 Effect of sample processing on in situ organic matter degradability of distillers grains. M. L. Drewery*[1], J. E. Sawyer[1], N. M. Kenney[1], W. E. Pinchak[2], and T. A. Wickersham[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Research, Vernon.*

Determination of ruminal OM degradability is important when evaluating feedstuffs. Precise quantification of nutrient availability is important when formulating rations. Wet distillers grains (DG) have a high moisture content that challenges conventional sample processing methods. Our objective was to quantify the effect of sample processing on measures of rate and extent of OM degradation of wet DG samples. Three ruminally cannulated steers were given ad libitum access to a ration (15% CP) containing 38.5% corn, 28% hay, and 28% dried DG. Samples of DG from each plant were divided and a portion was frozen at −20°C while the remainder was dried at 55°C in a forced-air oven for 96 h. Dried samples were ground to pass a 2-mm screen. Five g of each sample was placed in Dacron bags, pre-incubated in tepid water, placed in a weighted mesh polyester bag, and incubated in the rumen for 4, 6, 12, 24, 48 and 72 h. Samples were rinsed in cold water and dried at 60°C. Organic matter was measured and fractionated into A, B, and C pools. Degradation rate of the B fraction was calculated as the slope of the natural log of N remaining against time. Rate of passage was set at 3%/h. The A fraction was larger ($P < 0.01$) for frozen than dried samples, 43.5 and 33.1%, respectively. In contrast, the B fraction was less ($P < 0.01$) for frozen (42.9%) than dried samples (52.6%). The C fraction was not significantly different ($P = 0.16$) between frozen (13.6%) and dried (14.4%). Similarly, the difference in the degradability of the B fraction was not significant ($P = 0.71$) for frozen than dried samples 5.38 and 5.57%/h, respectively. However, estimated degradability was observed to be greater ($P < 0.01$) for frozen than dry samples 69.2 and 65.4%, accordingly. Our observations suggest sample processing affects the fractionation of OM from DG, but not estimates of OM degradability.

Key words: distillers grains, degradability, organic matter

T356 Effect of tannins on in vitro ruminal degradability of purple prairie clover (*Petalostemon purpureum*) harvested at the two growth stages. L. Jin*[1,2], Z. Xu[1], A. D. Iwaasa[3], Y. G. Zhang[2], M. P. Schellenberg[3], T. A. McAllister[1], and Y. Wang[1], *[1]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada, [2]Department of Animal Science, Northeast Agricultural University, China, [3]SPARC-AAFC, Swift Current, SK, Canada.*

An in vitro study was conducted to assess the effects of maturity and tannins on the ruminal degradability of purple prairie clover (PPC; *Petalostemon purpureum*).Whole PPC plants were harvested from 3 pastures at the vegetative (VEG) and full-flowering/early seeding (FL) stages. Ground whole plant samples were placed into ANKOM F57 filter bags that were then incubated with a mixture of ruminal fluid and buffer in glass digestion jars in 3 DAISYII fermentors. Ruminal fluid was collected from steers fed forage (barley silage/grain/alfalfa hay) diet. ^{15}N labeled ammonium sulfate was included in the inoculum to assess microbial protein synthesis and feed colonization. Filter bags that contained the samples collected from the same pasture at the 2 growth stages were incubated in a same unit. Half (2) of the jars in each unit were supplemented with polyethylene glycol (PEG), yielding a 2 × 2 arrangement in each unit. Two bags were retrieved from each jar at 0, 1, 2, 4, 8, 12, 24, 48 and 72 h of incubation. All bags withdrawn were washed under running tap water until the water was clear, dried, and analyzed for DM, N and ^{15}N. Plants harvested at the VEG stage had higher ($P < 0.001$) true dry matter degradability (TDMD), total N degradability (TND) and potential degradable fraction (b) of DM and N than that harvested at FL stage. The rapidly degradable fraction (a) of DM was higher ($P < 0.001$) in VEG than in FL, whereas the same fraction of N was higher ($P < 0.01$) in FL than in VEG. Inclusion of PEG increased ($P < 0.01$) the rate at which b is degraded (c) for DM only, but no growth stage by PEG interaction was found for DM degradation parameters. Inclusion of PEG increased ($P < 0.01$) TND and the potentially degradable fraction of N of PPC harvested at the FL, but not at the VEG stage. Overall, the results indicated that PPC harvested at the VEG stage is more degradable in the rumen than that harvested at the FL stage, but it seemed that the high tannins concentrations had only inferiorly detrimental impact on PPC degradability.

Key words: purple prairie clover, tannins, ruminal degradability

T357 Effect of exogenous fibrolytic enzymes on dry matter in situ digestibility of two *Brachiaria* grasses. J. H. Avellaneda-Cevallos[1,2], O. D. Montañez-Valdez*[3], D. Romero-Garaicoa[1], R. Luna-Murillo[1], J. Bravo-Loor[1], and M. Peña-Galeas[1], *[1]Unidad de Investigacóin Científica y Tecnológica. Facultad de Ciencias Pecuarias. Universidad Técnica Estatal de Quevedo, Quevedo, Ecuador, [2]Jefatura de Investigacóin. Carrera de Pecuaria.Escuela Superior Politécnica Agropecuaria de Manabí Manuel Félix López. Campus Politécnico, Sitio El Limón, Calceta, Manabí, Ecuador, [3]Centro Universitario del Sur de la Universidad de Guadalajara, Ciudad Guzmán, Jalisco, México.*

The effect of an exogenous fibrolytic enzymatic compound on ruminal pH and in situ digestibility of 2 *Brachiaria* hays, *B. mulato* and *B. decumbens*, cut at 28 and 56 d was evaluated. Four ruminally cannulated steers (400 ± 15 kg body weight) were randomly assigned to a replicated 4 × 4 Latin square with 2 different squares for balancing carryover effects. Both squares had 4 steers and squares were conducted simultaneously. Each experimental period consisted of 11 d of adaptation to diets and 4 d of experimental measurements. The ruminal cannulas measured 7.5 cm center diameter (Bar Diamond, Parma, ID). Steers were housed in individual dry lot pens and offered the experimental diets twice a day at 0700, 1800 h for 90% of intake to allow no refusal. The fibrolytic enzyme preparation containing xylanase and cellulase activities (Fibrozyme, Alltech Inc., Nicholasville, KY, USA). The treatments were: T1) *B. mulato* and *B. decumbens* of 28 d with enzyme; T2) *B. mulato* and *B. decumbens* of 28 d without enzyme; T3) *B. mulato* and *B. decumbens* of 56 d with enzyme; T4) *B. mulato* and *B. decumbens* of 56 d without enzyme. Nylon bags were incubated with samples of hay with a size of 2 mm in the rumen at 0, 12, 24, 48 and 96 h and the DM and OM remaining at each incubation time was fitted to the nonlinear regression model using NLIN procedure of SAS and the pH was measured from the liquid ruminal to 0, 3, 6, 9 and 12 h were analyzed using MIXED procedure of SAS. The in situ digestibility of dry matter and ruminal pH, was not change by the application of the compound enzymatic exogenous ($P \geq 0.05$). We can conclude that the use of this enzymes do not affect the digestion of the dry matter of the hay of *B. mulato* and *B. decumbens* cut at 28 and 56 d.

T358 Method evaluation for determining digestibility of rumen undegraded amino acids in blood meal. S. E. Boucher*[1], S. Calsamiglia[2], M. D. Stern[3], C. M. Parsons[4], H. H. Stein[4], C. G. Schwab[5], K. W. Cotanch[6], J. W. Darrah[6], and J. K. Bernard[7], *[1]Kemin AgriFoods North America Inc., Des Moines, IA, [2]Universitat Autònoma de Barcelona, Bellaterra, Spain, [3]University of Minnesota, St. Paul, [4]University of Illinois, Urbana, [5]Schwab Consulting LLC, Boscobel, WI, [6]William H. Miner Agricultural Research Institute, Chazy, NY, [7]University of Georgia, Tifton.*

To evaluate various methods for estimating digestibility of rumen undegraded AA in blood meal (BM), 5 BM samples (2 bovine, 3 porcine) were obtained. One bovine sample was heated at 125°C for 2 h to generate an additional bovine sample and one porcine sample was heated at 110°C for 2 h (n = 6). Samples were ruminally incubated in situ for 16 h in 3 lactating cows fed a 55% forage diet. Rumen undegraded residues (RUR) were pooled by sample and analyzed for AA. Digestibility of AA in the RUR was determined via the mobile bag technique (MBT) in dairy cows, precision fed cecectomized rooster assay (CRA), modified 3-step procedure (MTSP), and homoarginine assay (HA; estimates available Lys). For the MBT, 0.8 g of each RUR was weighed into 24 polyester bags, soaked in a pepsin/HCl solution for 2 h, and introduced into 2 duodenally cannulated cows. Bags were collected from the feces and undigested residues were analyzed for AA. Digestibility of AA was calculated by disappearance. To calculate standardized AA digestibility using the CRA, RUR were tube fed to 4 birds per sample, and total excreta collected for 48 h and analyzed for AA. For the MTSP, 5 g of each RUR were weighed into 2 polyester bags and incubated (38°C) sequentially in a pepsin/HCl solution for 1 h then a pancreatic solution for 24 h in Daisy^{II} incubator bottles. Digestibility of AA was calculated by disappearance. For the HA method, RUR were guanidinated and analyzed for Lys and HA content. Percent Lys converted to HA was calculated. The REG procedure of SAS was used for data analysis. R^2 values for Lys digestibility using MTSP, CRA, and HA procedures compared with the MBT in cows (independent variable) were 0.89, 0.62, and 0.05, respectively, and the R^2 values for total essential AA (EAA) digestibility using MTSP and CRA compared with MBT were 0.89 and 0.92, respectively. Using MBT in dairy cows as a reference, it appears that HA method is not a good approach to determine available Lys in BM, CRA was adequate to determine digestibility of total EAA in BM, and MTSP is a good approach to estimate digestibility of both Lys and total EAA in BM.

Key words: blood meal, rumen-undegraded protein, mobile bag technique

T359 In vitro modification of ruminal and post ruminal metabolism by lignosulfonate and polysaccharide protected microminerals. M. Ruiz-Moreno*[1], E. Seitz[1], M. D. Stern[1], and J. Garrett[2], *[1]University of Minnesota, St. Paul, [2]Quali Tech Inc., Chaska, MN.*

Ruminal and postruminal availability of trace minerals is affected by chemical nature and presence of chelating agents such as lignin derived phenolic compounds. The aim of this study was to evaluate effects of lignosulfonate and polysaccharide-protected minerals on in vitro rumen fermentation, ruminal and post ruminal partition of Cu, Zn and Mn. Eight dual flow continuous culture fermenters were used during 2 consecutive 10-d periods in a 2 × 2 factorial arrangement of treatments. A synthetic diet consisting of 38% cellulose, 34% starch, 20% powdered whey, 5.3% vegetable oil and 2.5% sugar provided substrate for microbial metabolism. Sulfur was added as $NaSO_4$ or S-bound lignosulfonate to a final concentration of 0.75% of DM. Lignosulfonate was added at 0 (LIG0) or 5% (LIG5) of DM. Copper, Zn and Mn were added as $CuSO_4$, $ZnSO_4$ and $MnSO_4$ or as polysaccharide protected Cu, Zn and Mn (SQM protected minerals, Quali Tech Inc.; SQM- or SQM+, respectively) to a final concentration of 16, 56 and 71 ppm of DM, respectively. At the end of each period, solid and liquid fractions from fermenters outflows were subjected to pepsin-pancreatin enzymatic digestion. Apparent and true OMD (%) were not affected by treatments ($P > 0.05$). Addition of LIG5 decreased ($P < 0.05$) daily flow of non NH_3-N, efficiency of microbial protein synthesis, total VFA and molar proportion of acetic acid, but increased ($P < 0.05$) propionic, valeric and caproic acid while SQM+ decreased molar proportion of propionic acid. Addition of LIG5 increased ($P < 0.05$) ruminally soluble Cu and Mn, while SQM+ reduced ruminally soluble Cu. Concentration of bacterial Cu and Zn increased with SQM+ in absence of lignosulfonate ($P < 0.05$). Addition of LIG5 resulted in higher enzymatic release of Zn from solids outflow but lower from bacterial pellets ($P < 0.05$). Mean, minimum and maximum fermentation pH were higher ($P < 0.05$) with LIG5. Addition of lignosulfonate induced major changes in ruminal fermentation. Protected minerals decreased rumen soluble Cu and increased bacterial Cu and Zn without affecting predicted post ruminal release of minerals.

Key words: protected minerals, rumen, lignosulfonate

T360 Factors affecting estimation of spoilage indices in silage 2: Effects of amount of silage evaluated and type of container. N. Cavalcanti[1,2], J. Leite[1,2], L. G. Paranhos*[1], O. C. M. Queiroz[1], K. G. Arriola[1], and A. T. Adesogan[1], *[1]University of Florida, Gainesville, [2]Federal University of Pernambuco, Recife, Pernambuco, Brazil.*

Aerobic stability is a measure of the shelf life of silage and an indirect measure of the likelihood of undesirable microbial activity, which predisposes to heating, nutrient depletion and growth of pathogenic organisms. Different methods are used for this assay and this likely affects the outcome. This project aimed to examine effects of container type and amount of silage evaluated on the aerobic stability of corn silage. Three different amounts of corn silage, 1, 2, or 3 kg were packed at the same density (550 kg/m3) into 20 L plastic buckets (PB) or 20 L styrofoam containers (SC) in quadruplicate. Wireless temperature sensors were placed in the center of the silage mass in each container and set to record temperatures every 30 min for 14 d. Ambient temperature was similarly measured. Aerobic stability was estimated as the time (h) before silage and ambient temperature differed by more than 2°C. Maximum and minimum temperatures and an instability index estimated as the area under the temperature curve during the aerobic exposure period were recorded. The experiment had a ran-

domized complete block design and a 2 (container type) × 3 (amount of silage) factorial treatment arrangement. The statistical model contained silage amount and container effects and the interaction. Minimum temperature was greatest for 1 kg forage in SC and for 3 kg silage in PB (amount x container interaction, $P = 0.02$). Using SC resulted in greater aerobic stability (168.9 vs.79.9 h; $P < 0.01$) and greater minimum temperatures (2°C difference) compared with using PB. Using 3 kg of silage resulted in greater maximum temperature (37.4 vs. 29.0; $P < 0.01$), greater temperature range (20.3 vs. 11.2°C; $P < 0.01$), and greater area under the temperature curve compared with using 1 kg ($P < 0.01$). These data showed that container type and amount of silage evaluated influence the aerobic stability result.

Key words: aerobic stability, corn silage, methodology

T361 Infusion of marker solution into intact digesta for measurement of the ruminal clearance of volatile fatty acids. J. C. de Resende Júnior*, J. L. P. Daniel, F. da C. Meireles, M. B. Moreira, and R. F. de Lima, *Universidade Federal de Lavras.*

The removal (clearance) of volatile fatty acids (VFA) of the reticulorumen occurs by absorption through the wall or passage to the omasum. This study aimed to validate a new technique for infusion of marker solution into intact ruminal digesta comparing with another technique which has known efficiency for measurements of the ruminal clearance of VFA. Four cows were allocated to 4 treatments in split plot design, aligned in a 2 × 2 factorial arrangement which was diet and method of infusion of markers applied concurrently in 2 periods of 18 d. The 4 combinations were: forage diet and infusion of markers into intact (ID) or evacuated digesta (ED); forage plus concentrate and infusion of markers into intact or evacuated digesta. Four liters of markers solution containing Cr-EDTA associated with valeric acid were added to the ruminal digesta. Rumen fluid samples were serially collected and analyzed for pH, VFA concentration and Cr. The fractional clearance rate of total VFA was estimated by the exponential decay rate of the valerate concentration over time. The clearance of VFA by passage to the omasum was assumed to be equivalent to the decay in ruminal Cr concentration and the fractional clearance rate of absorption was estimated by difference. The fractional rates of total clearance (ID = 37.8%/h; ED = 30.5%/h) and absorption (ID = 26.0%/h; ED = 21.1%/h) of VFA did not differ between techniques ($P = 0.30$ and $P = 0.52$, respectively), demonstrating that the infusion technique into ID is comparable to the infusion technique into ED. The fractional rate of passage of the fluid phase (ID = 11.8%/h; ED = 9.4%/h), however, was lower ($P = 0.06$) when the marker solution was added into the evacuated digesta, probably reflecting the destabilization of the rumen environment during the evacuation and the largest volume of fluid observed in animals with evacuated digesta. It is concluded that the infusion of marker solution into intact digesta with homogenization performed by ruminal motility is effective and seems to be the better choice for the VFA ruminal clearance determination because it allows measurements under more normal physiological conditions.

Key words: acidosis, measurement of metabolizable energy, ruminant stomach

T362 Adjustment of in vitro rumen fermentation protocol for testing products based on rumen pH regulation and the impact of Acid Buf. S. Taylor*[1], E. Pennala[2], and J. Apajalahti[2], *[1]Celtic Sea Minerals Ltd., Cork, Ireland, [2]Alimetrics Ltd., Espoo, Finland.*

Investigating the mode of action of buffering materials by in vitro rumen fermentation is restricted because protocols normally use strong buffers to compensate for the lack of acid absorption from the system. Optimization of buffer strength and volume, and the amount / type of feed enables the mimicking of acidosis and the testing of products designed to impact on this challenge. Simulation protocol: The simulation used 1 g (DM) feed composed of 50% grass silage, 40% barley meal and 10% soy. The buffer based on bicarbonate and phosphate (Agriculture Handbook, Vol 379, USDA 1970) was diluted with 0.9% NaCl as indicated below. The study with 12 replicates was inoculated with 5% of fresh, strained rumen fluid from a cow on a high energy diet and continued for 12 hours at 37°C. Anaerobic techniques were applied throughout. The treatments were: undiluted buffer and this diluted to 1:2 and 1:4 in constant volume (40 ml) A treatment with 1:4 diluted buffer + 50 mg of Acid Buf/40 ml was included. Total gas production, pH, and short-chain fatty acids (SCFAs) were determined at various time points. Cumulative methane production and bacteria were analyzed at the end. SCFAs and methane were analyzed by GC and bacteria by flow cytometry. Dilution of the buffer allowed acidity to increase, which led to suppression of bacterial growth and metabolism. Addition of Acid Buf in the fermentation with the 1:4 diluted buffer significantly reduced the drop of pH and maintained higher bacterial activity. Methane to acid ratio (ml/mM) was lower than with the weaker buffering

Table 1. Results

	Buffer 1:1	Buffer 1:2	Buffer 1:4	Buffer 1:4 + Acid Buf
Gas production at 12 h (mL)	102[a]	86[b]	44[d]	60[c]
pH, 4 h	6.83[a]	6.42[b]	6.00[c]	6.10[c]
pH, 12 h	6.73[a]	6.15[b]	5.31[c]	5.69[b]
SCFA, 12 h (m*M*)	68[a]	67[a]	52[b]	65[a]
Acetate, 12 h (m*M*)	29[a]	24[b]	16[d]	21[c]
Propionate, 12 h (m*M*)	20[a]	19[a]	13[c]	17[b]
Methane 12 h (mL)	4.3[a]	4.1[a]	1.9[c]	2.9[b]
CH4/SCFA (mL/m*M*)	6.3%	6.1%	3.6%	4.5%

T363 Impact of different sources of hydrolysable and condensed tannins on rumen fermentation and methane production in vitro. F. Hassanat* and C. Benchaar, *Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Qc, Canada.*

Tannins added to animal diet may generate positive impact on energy and protein utilization in the rumen. The objective of this study was to examine the impact of different sources and levels of condensed and hydrolyzable tannins on rumen microbial fermentation in vitro (24-h batch cultures). Condensed tannin extracts from Acacia (AT; *Acacia mearnsii*; 82% DM) and Quebracho (QT; *Schinopsis balansae*; 90% DM) and hydrolysable tannin extracts from Chestnut (ChT; *Castanea sativa*; 75% DM) and Valonia (VT; *Quercia vallonea*; 71% DM) were used. In vitro incubations (repeated 4 times) were conducted in a completely randomized block design using a control (CTL; 0%) and each source of tannin at 2, 5, 10, 15 and 20% of total mixed ration DM. Each

treatment was tested in quadruplicate. Differences between treatments and CTL were declared significant at $P \leq 0.05$ using Dunnett's comparison test. Gas production (GP) was reduced at ≥5% of AT, while at 2% or more, QT produced less gas than CTL. At ≥5% concentration, both AT and QT reduced total volatile fatty acids (VFA) and CH_4 concentrations. No effect was observed on acetate (C_2) proportion at any level of AT or QT while propionate (C_3) proportion was slightly increased at ≥ 10% of AT or QT, resulting in lower C_2:C_3 ratio. Addition of ChT at ≥5% reduced GP, CH_4 and VFA concentrations compared with CTL. Proportion of C_2 increased when ChT was supplied at ≥10% while no effect of ChT was observed on C_3 proportion or C_2:C_3 ratio. Supplying VT at ≥2% reduced GP while a level of VT ≥5% was required to decrease CH_4 concentration. Total VFA concentration was reduced only at ≥10% of VT while C_2 proportion was increased at ≥2% VT and no change was noted for C_3 and C_2:C_3 ratio. Proportions of isovaleric, and valeric and ammonia concentration were decreased at all levels of tannin sources added, indicating reduced protein degradation. At low concentrations (2–5%), tannins have the potential to reduce CH_4 production and ruminal protein degradation without deleterious effects on fermentation.

Key words: in vitro fermentation, methane, tannins

T364 Changes in ruminal bacterial community composition following feeding of silage inoculated with a commercial silage inoculant. R. Mohammed*[1,2], D. M. Stevenson[1], K. A. Beauchemin[2], P. J. Weimer[1], and R. E. Muck[1], *[1]USDA-ARS, Madison, WI, [2]AAFC, Lethbridge, AB, Canada.*

Some silage inoculants yield an increase in milk production, possibly through altering the rumen microflora. We hypothesized that alfalfa silage treated with a commercial inoculant (*Lactobacillus plantarum*, LP) would alter rumen bacterial community composition (BCC) compared with silage without inoculant (Ctrl). Eight rumen-cannulated Holstein cows were allotted to 2 diets (Ctrl- or LP-treated silage) in a double crossover design with 4 28-d periods. Diets were formulated to contain (per kg DM) 280 g NDF and 162 g CP, and contained (g/kg DM): alfalfa silage, 509; corn silage, 206; high-moisture shelled corn, 214, soy hulls, 47; plus minerals and vitamins. Ruminal digesta were collected just before feeding on the last 3 d of each period, and were separated into solid and liquid phases. Microbial DNA was extracted from each phase, amplified by polymerase chain reaction (PCR) using domain-level bacterial primers, and subjected to automated ribosomal intergenic spacer analysis (ARISA) for comparison of BCC. Correspondence analysis of the 266 peaks in the ARISA profile across the 192 samples revealed that the first 2 components contributed 6.8% and 4.2% to the total variation in the profile. Data points representing the liquid and solid phases clustered separately, indicating that these phases differed in BCC. Treatment effects were not apparent from the ARISA profiles. However, the relative population size (RPS) of LP, determined by quantitative PCR, was greater in treated silage compared with the Ctrl ($P < 0.01$). Data points corresponding to certain individual cows clustered separately, and the most distinctive bacterial communities were those associated with milk fat-depressed cows. The RPS of one bacterial species, *Megasphaera elsdenii*, was greater in fat-depressed cows. However, mean RPS of *M. elsdenii* did not differ between the treatments. The results indicate that a silage inoculant can affect rumen bacterial composition beyond elevating the population of the specific microbial inoculant.

Key words: rumen, silage inoculant, microbial populations

T365 Effect of a dietary antioxidant with different substrate on rumen fermentation in vitro. Y. Wang*[1,2], J. Wang[1], M. Vazquez-Anon[2], H. Cao[2], G. Zanton[2], and J. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, P. R. China, [2]Novus International Inc., St. Louis, MO.*

The objective of the study was to evaluate the effect of a dietary antioxidant (AOX; AGRADO® Plus, Novus International) on rumen fermentation with different dietary ingredients as substrate in vitro, in the absence or presence of 500 mg/kg AOX. Data were analyzed as a completely randomized design using the MIXED procedure. Neither substrate nor AOX had significant effect on rumen pH. Inclusion of different substrates significantly affected gas production, organic matter digestibility, and total VFA ($P < 0.05$), where corn appeared to have highest values, while cotton seed had lowest ones, compared with extruded soybean and DDGS. Extruded soybean had higher NH_3-N than corn ($P < 0.05$), and cottonseed and DDGS were intermediate in NH_3-N levels. AOX had no significant effect on gas production, organic matter digestibility, NH_3-N, or total VFA production. However, addition of AOX significantly increased the molar proportion of propionate ($P < 0.05$), and tended to decrease the molar proportion of acetate ($P = 0.10$). Different substrates had similar anti-oxidative status in the rumen ($P > 0.05$). AOX significantly increased the total antioxidant capacity ($P < 0.01$), but did not change other antioxidant biomarkers (superoxide dismutase, malondialdehyde, glutathione peroxidase, and hydrogen peroxide). Except for *Fibrobacter succinogenes*, the population of *Ruminococcus flavefaciens*, *Ruminococcus albus*, fungi, protozoa and *Butyrivibrio fibrisolvens* were significantly affected by substrate treatment ($P < 0.01$). Addition of AOX increased *Ruminococcus albus* population ($P < 0.05$). There was no significant interaction between substrate and AOX for fermentation patterns, oxidative status or rumen microflora. It is concluded that different substrates significantly affected the fermentation pattern and microflora, but not for anti-oxidative status in the rumen. Addition of AOX improved the total anti-oxidative status, increased the molar proportion of propionate and *Ruminococcus albus* population, regardless of substrate type.

Key words: antioxidant, anti-oxidative status, rumen fermentation

T366 Effect of dietary roughage and sulfur concentration on hydrogen sulfide production from corn-based diets containing dried distillers grains. E. Seitz*, A. Carpenter, M. Ruiz-Moreno, M. D. Stern, and G. I. Crawford, *University of Minnesota, St. Paul.*

An in vitro rumen fluid incubation was conducted using differing dietary concentrations of roughage (R) and sulfur (S) in a 3 × 2 + 2 factorial arrangement of treatments during 4 consecutive 24-h periods. Isonitrogenous dietary treatments included a corn-based control diet with no distillers grains (DG), 9% R, and 0.18% S (CON); a high R treatment with 27% R, 40% DG and 0.50% S (HRHS), and 6 treatments arranged in a 3 × 2 factorial with 3 S concentrations (0.3, 0.4, and 0.5%; LS, MS, HS, respectively), and 2 R concentrations (3 and 9%; LR and MR, respectively). Grass hay served as the roughage source and S concentrations were achieved through combination of 2 DG with differing S concentrations. Rumen fluid adapted to each treatment was mixed with saliva in a 1:1 ratio (10 mL each) and incubated with 0.2 g substrate DM in crimp-sealed, 50 mL serum bottles (n = 24; 3 reps/trt) at 39°C. At 5 and 24-h post-incubation, gas production was measured and a subsample of headspace gas was analyzed for hydrogen sulfide (H_2S). Final pH was measured at the end of each 24-h incubation. These results indicate that DG inclusion generally increased

batch culture pH, and compared with CON, the MS and HS treatments had higher total μg H_2S and μg H_2S/mL gas.

Table 1. Effect of dietary roughage and sulfur concentration

Parameter	CON	LRLS	LRMS	LRHS	MRLS	MRMS	MRHS	HRHS	*P*-value
Final pH	5.44[a]	5.55[ab]	5.65[be]	5.62[bc]	5.67[ce]	5.66[be]	5.81[d]	5.95[f]	<0.0001
Total H_2S (μg)	28.3[a]	51.1[ad]	81.9[bd]	77.9[bd]	57.2[acd]	89.4[bd]	113.3[b]	93.1[bc]	0.01
Total gas (mL)	38.9[a]	35.9[bd]	35.0[bc]	37.8[ad]	35.8[bd]	37.1[acd]	37.0[acd]	33.4[b]	0.01
μg H_2S/mL gas	0.7[a]	1.4[ac]	2.3[bc]	2.1[bc]	1.6[ac]	2.4[bc]	3.0[b]	2.8[b]	0.005

T367 Effects of hops on rumen fermentation and bacterial populations using the rumen simulation technique. N. Narvaez*[1], Y. Wang[1], Z. Xu[1], T. Alexander[1], S. Garden[2], and T. McAllister[1], *[1]Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [2]John I. Haas Inc., Washington DC.*

A rumen simulation technique (Rusitec) experiment was conducted to assess the effects of supplementation of 3 varieties of hops on rumen fermentation and rumen bacterial communities. The treatments were Control (no hops) and 3 hop varieties (Cascade, CAS; Millenium, MIL and Teamaker, TM). Two RUSITEC with 8 vessels each were used. Each vessel was initially inoculated with rumen solids and liquids from cattle fed a barley silage-barley grain diet and fermenters were fed 10 g of a barley silage-barley grain diet daily. Hops extract (800 μg/mL) was added so as to have 2 replicate fermenters per variety. Microbial protein synthesis (MN) was estimated using ^{15}N labeled ammonium sulfate and principal ruminal bacteria were quantified using real-time polymerase chain reaction (qPCR). Addition of all hop varieties reduced ($P < 0.001$) total gas and CH_4 production per g of truly digested dry matter (TDDM). True DM disappearance was reduced ($P < 0.05$) by CAS and MIL but only MIL reduced ($P < 0.001$) neutral detergent fiber disappearance (NDFD). Productions of volatile fatty acids (VFA) and MN were unaffected by hops, but the acetate:propionate (A:P) ratio was decreased ($P < 0.001$) with all hop varieties. Proportions of 16S rDNA gene of *F. succinogenes* and *S. bovis* were decreased ($P < 0.05$) with addition of MIL and TM whereas *S. bryantii* was increased ($P < 0.001$) by CAS. The proportion of *Archae* marker gene in solid fraction was also reduced ($P < 0.05$) by all 3 hops. The decreased methane production by hops is likely due to their effects on altering rumen microbial community by reducing methanogens and cellulolytic bacteria and reducing A:P ratio of the VFA. Inclusion of hops in ruminant diet may have potential to reduce methane production and thereby improve feed efficiency.

Key words: hops, rumen bacteria, rumen fermentation

T368 Effect of nitrate, sulfate, monensin, and corn gluten feed on in vitro ruminal methane production. C. Davis[1], S. Ghimire*[1], T. Wiles[1], Z. Wen[2], M. A. McCann[3], and M. D. Hanigan[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Department of Biological Systems Engineering, Virginia Polytechnic Institute and State University, Blacksburg, [3]Department of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg.*

Two in vitro studies were conducted using hay and total mixed dairy ration (TMR) as substrates to evaluate the effect of nitrate and Monensin on methane production. Study 1 was conducted to compare the effectiveness of different doses of nitrate and Monensin on methane production, and study 2 tested the effects nitrate, sulfate, and corn gluten feed (CGF). Four levels of nitrate (0, 2.5, 5, and 7.5% of DM) and 2 doses of Monensin (0, and 4 mM) were tested for each diet in study 1. Two doses of nitrate, 2 doses of sulfate (0 or 4% of DM each), and the absence or presence of CGF in the diet (22% of DM) were tested in study 2. In study 1, nitrate was added without lowering the TMR protein level. Treatments were isonitrogenous in study 2. Each study was replicated 3 times and contained one bottle for each treatment to measure methane production and a second bottle to measure total gas production. Bottles were inoculated with 20 mL of strained rumen fluid plus 60 mL of McDougall's buffer. Ruminal fluid was collected from 2 nonlactating, Holstein cows, one on hay and the other on a lactating cow ration. Hay substrate was used for the hay diets and TMR for the TMR diets. Bottles were incubated for 48 h at 39°C. Total gas production was measured at different time intervals after incubation by water displacement and methane production was measured by displacement after removal of CO2 using sodium hydroxide. Cumulative methane production was greater ($P < 0.05$) for the TMR diet. Monensin, sulfate, and CGF did not have significant effects on methane production ($P > 0.05$). Nitrate reduced methane production in both studies. In study 1, the reduction as compared with the controls was 16.92%, 28.03%, and 30.43% for hay and 29.41%, 35.95% and 41.53% for TMR at concentrations of 2.5, 5, and 7.5% of DM, respectively. In study 2, nitrate reduced methane production by 25.74% for hay and 13.23% for TMR. Total gas production was reduced when nitrate was present ($P < 0.05$) in study 1, but the reduction was not significant in study 2. These results suggest that nitrate can be used as a strategy to reduce methane production in cattle.

Key words: dairy cow, ruminal methane, nitrate

T369 Effects of microwave irradiation on ruminal dry matter degradability of canola and corn gluten meal. M. Dehghan-Banadaky[1], H. Khalilvandi-Behroozyar*[1,2], H. R. Khazanehi[3], and N. Vahdani[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran, [3]Department of Animal Science, University of Manitoba, Manitoba, Canada.*

Microwave energy causes a rise in the temperature within a penetrated medium as a result of rapid changes of the electromagnetic field. This study was conducted to evaluate effects of 900 W microwave irradiation for 4 and 6 min on dry matter degradability of canola and corn gluten meals (CGM) using nylon bag technique. The DM of meals was determined by oven drying of a 1 g sample in triplicate. Based upon this value, sufficient water was added to increase the moisture content of 2 kg of canola meal to 250 g/kg. Two samples (each of 500 g) were subjected to microwave irradiation at a power of 900 W for 4 and 6 min. Dry matter degradability was determined using 3 ruminally fistulated non lactating Holstein cows, fed balanced rations with forage:concentrate ratio of 60:40. Samples were ground to pass 2 mm screen and 5 g was weighted into nylon bags with 50 micron pore size (sample size:surface area was 12.5 mg/cm^2). Duplicates were

incubated for 2,4,8,12,24 and 48 in ventral rumen. Effective degradability (ED) was calculated with NEWAY computer package. CRD design, GLM PROC of SAS 9.1 and Duncan test option was used for data analysis. In the case of canola meal results (Table 1) showed that microwave irradiation decreased rapidly degradable fraction and increased lag time ($P \leq 0.05$). Also, a trend ($P \leq 0.08$) was observed for increasing of potentially degradable fraction and reduction of the rate of degradation of b fraction with irradiation. Increasing the irradiation time, decreased effective degradability of dry matter ($P \leq 0.08$). Microwave irradiation resulted in statistically significant ($P \leq 0.05$) increase in DM ED of CGM in rumen outflow rates of 0.05 and 0.08 h^{-1}. Although treatments were resulted in increased b and reduction of a fraction ($P \leq 0.1$), degradation rate of b fraction also increased ($P \leq 0.12$). Previous reports about heat treatment of CGM revealed that ruminal effective degradability decreased with heat treatment, but our results showed increased DM degradability with irradiation. Further studies about effects of microwave irradiation on ruminal nutrient degradability of CGM, recommended.

Table 1. Rumen DM degradation parameters of untreated and microwave irradiated canola meal

	Control	4 min	6 min	SEM
a (percentage)	27.73[a]	26.59[b]	24.81[c]	0.048
b (percentage)	60.00	61.33	62.40	0.511

Key words: microwave irradiation, protein concentrate, dm degradability

T370 Evaluation of two protein hydrolyzates as a source of soluble protein to foster ruminal microbial growth. A. Aris[1], A. Serrano[1], F. Fabregas[1], J. Polo[3], C. Rodriguez[3], and A. Bach*[1,2], *[1]Ruminant Production, Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Caldes de Montbui, Barcelona, Spain, [2]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain, [3]APC EUROPE, S.A. R&D department, Granollers, Barcelona, Spain.*

The aim of this study was to determine whether the protein hydrolyzates AproCel and Pepton (APC Europe, Barcelona, Spain) would stimulate rumen microbial growth in comparison to Tryptone, which is the gold-standard of supplementary N for microbes. Ruminal samples from 3 different animals were incubated for 12 h following the Tilley-Terry procedure. There were 4 treatments applied to the ruminal samples: Negative control (CTR), with no N supplement added, positive control Tryptone added at the rate of 2% (TRY) and Pepton (PEP) and AproCel (APR) added at a rate (2.10 and 2.24%, respectively) providing the same amount of N as Tryptone 2%. After incubation, a liquid sample was obtained to determine total volatile fatty acids (VFA) concentrations, pH, and microbial growth (determined by quantitative real time PCR). Data were analyzed with an ANOVA using the treatment as the main effect. Total VFA production was numerically greater in all tubes with N supplementation in comparison to CTR (56.3mM ± 12.24), with this difference being significant ($P < 0.05$) for APR (100.7mM ± 12.24) and Tryptone (128.9mM ± 12.24). Pepton supplementation resulted in an intermediate VFA concentration. Ruminal fluid experienced in all cases a slight increase in pH compared with CTR (6.96 ± 0.03). Pepton (7.20 ± 0.03) showed the greatest increase of pH ($P < 0.05$). The increase in pH indicates that microorganisms used part of the N supplements as a source of energy leading to an excretion of NH_3. Probably the production of NH_3 was lowest with PEP, because this treatment resulted numerically in the least VFA production among the 3 protein supplements, and thus pH would be expected to be greater even in the absence of NH_3. Gram-positive bacteria grew equally among the 3 treatments, whereas gram-negative growth was highly stimulated ($P < 0.05$) by PEP (PEP: 4.52 ± 0.6 ratio to control vs CTR: 1.92 ± 0.6 ratio to control). In conclusion, both APR and PEP, are readily available N sources for microbial protein synthesis. In addition, PEP stimulates growth of gram-negative bacteria to a greater extent than TRY and APR.

Key words: microbial growth, protein hydrolyzate, supplementary nitrogen

T371 Effects of protein protection with orthophosphoric or malic acid and heat in lamb fattening diets. F. Díaz-Royón*, J. M. Arroyo, M. R. Alvir, V. Jimeno, S. Sanchez, and J. González, *University of Politécnica de Madrid, Madrid Spain.*

The objective of this study was to evaluate the efficiency of using acid-heat treated (121°C, 1 h, plus residual oven heat) sunflower and pea meals on diets fed to fattening lambs. Ninety "Entrefino" cross male lambs from three commercial farms (average initial body weight = 14.6; 15.3, and 13.3 kg) were randomly assigned to five diets with different levels of protein and acid treatment, and fattened to an average body weight at slaughter of 25 kg. The control diet (C; CP =18%) contained conventional soybean, sunflower and pea meals. In three of the treatment diets, orthophosphoric acid-protected meals (TM) replaced conventional sunflower and pea meals (CF; CP=18%) and soybean meal was progressively remove (SMF; CP=16.7% and STF; CP= 15.6%). In the last diet (SMM; CP= 16.7%) malic acid substituted ortophosphoric acid. Wheat straw (roughage source) and concentrate were offered. Eighteen lambs, 3 animals per pen, allocated to 6 pens, were assigned to each diet. Data were analyzed using a factorial analysis with initial body weight as covariate and farm of origin as block. Treatments were compared through the following contrasts: C. vs. CF, SMF, STF; CF vs. SMF, STF; SMF vs. STF; C. vs. SMM; SMF vs. SMM). Average daily gain (ADG), carcass yield (CY), dorsal fat (DF) and kidney pelvic fat (RPF) were analyzed by animal. Intake and feed conversion (FC), were analyzed by pen. There was no diet effect on any parameter observed which suggests that when protected proteins are used, it is possible to work with 15.6% CP (DM basis) reducing the need to include vegetable protein meals. Lambs on SMM had higher ADG (15.2%; P= 0.042), and better CY (1.3%; P= 0.037) than on SMF. Improved efficiency can be attributed to greater protection by malic acid (Arroyo, 2007) or a higher propionic acid production as result of a shift in rumen fermentation in response to malic acid inclusion.

Key words: acid-heat treatment, fattening lamb, protein protection

T372 Identification of several novel fungal species in feed samples from the southeast United States. J. D. Chapman*[2], Y. Q. Wang[1], and N. E. Forsberg[1], *[1]OmniGen Research, Corvallis, OR, [2]Prince Agri Products, Quincy, IL.*

Fungi grow freely on preserved feeds. Concerns about the presence of fungi include their production of mycotoxins, their invasive (mycotic)

potential and their metabolism of nutrients. Despite years of work in this area, the full spectrum of fungi which grow on silages and the implications of their growth have not been fully established. The goal of this study was to identify unknown fungi found growing on a balage sample in Georgia and on a corn silage sample in Florida. Samples of fungi-contaminated feeds were recovered and inoculated onto Sabouraud culture plates. Pure cultures were selected from the plates and DNA extracted from each. The ITS-1 domain was amplified by polymerase chain reaction (PCR) using pan-fungal primer sequences. PCR products were electrophoresed on agarose and the fragments corresponding to the ITS-1 fragment were excised, purified then sequenced. Four fungi were identified of which 3 were relatively unknown. The 4 included *Aspergillus clavatus* (a dark green-black fungus), *Coccidioides immitis* (a pale blue fungus), *Gibberella zeae* (also known as *Fusarium graminearum*; a red fungus), and *Neosartorya fischeri* (a white fungus). Based on the published abilities of these species to secrete mycotoxins and/or to cause invasive mycosis, each holds potential to adversely affect animal health. *A. clavatus* secretes a broad spectrum of mycotoxins including alanyltryptophan, cytochalasin E, kotanin, nortryptoquivaline, and patulin. *C. immitis* is a Level-III pathogenic fungus, resides principally in the Southern US and is responsible for Valley Fever. Reports of mammary *C. immitis* infections in dairy cattle exist. *G. zeae* secretes a variety of mycotoxins including deoxynivalenol, an important immunosuppressive toxin. Finally, *N. fischeri* secretes aflatoxin, fumetrimorgans and verrucologen. *C. immitis* has been reported to cause spasms and cramps in sheep and swine. Collectively, these observations further demonstrate the potential for adverse effects from feeding spoiled silages. Additional studies are needed to identify the specific effects of ingestion or inhalation of these and other feed-borne fungi.

Key words: dairy, fungi, silage

T373 Evaluating the inclusion of Met and Lys to mechanically extracted soybean meal with soy gums on the ruminally-undegraded Met and Lys content. C. A. Macgregor*[1], L. O. Tedeschi[2], and T. K. Miller-Webster[3], *[1]Grain States Soya Inc., West Point, NE, [2]Texas A&M University, College Station, [3]West Virginia University, Morgantown.*

Mechanically-extracted soybean meal (MES) with fresh soy gums (MESG) was compared with MESG with added dl-Methionine and Lysine (MESG-ML) to evaluate the impact of the added Met and Lys on the ruminally-undegraded Met (RUM) and Lys (RUL) using the in situ technique. Dacron bags containing the treatments (TRT), MESG or MESG-ML, were incubated in the rumen of 3 lactating cows for either 4 or 8 h (6 bags/cow/TRT/time) using the simultaneous removal method. Cows were 12, 45, and 222 DIM and milk production was 35.8, 41.3, and 24.4 kg/d, respectively. Met and Lys in the MESG-ML were added to soy gums simultaneously by means of 2 variable augers and mixed into the soy gums in an in-line mixer before soy gums were applied onto the MES at time of manufacture. Met content of MESG and MESG-ML was 0.65 and 0.70% DM and Lys content of MESG and MESG-ML was 2.67 and 2.72% DM, respectively. The RUM and RUL remaining in the Dacron bags at 4 and 8 h were reported as percent of the original sample DM. The statistical analysis was performed as a factorial arrangement (2 TRT × 2 incubation times) in a complete randomized block design, assuming cows as random factors. For Lys, there was no interaction between TRT (MESG vs. MESG-ML) and incubation time ($P = 0.7824$; 2.106 vs. 2.185% at 4 h and 1.707 vs. 1.805% at 8 h, respectively). As expected, the RUL was greater at 4 than at 8 h ($P < 0.0001$; 2.15 vs. 1.76%, respectively). The MESG-ML had a significantly greater RUL than MESG ($P = 0.0145$; 2.0 vs. 1.91%). Similarly, there was no interaction between TRT (MESG vs MESG-ML) and incubation time for Met ($P = 0.7834$; 0.536 vs 0.578% at 4 h and 0.445 vs 0.491% at 8 h, respectively), the RUM at 4 h was greater than at 8 h ($P < 0.0001$; 0.557 vs 0.468%, respectively), and treated MESG with dl-Methionine had greater RUM than control MESG ($P < 0.0001$; 0.534 vs 0.491%, respectively). Our analyses indicated that enriching MESG with dl-Methionine and Lysine using the method described above can increase the content of these 2 amino acids in the ruminally-undegraded protein pool.

Key words: amino acid, gums, soybean meal

T374 Effect of ghrelin on bovine myogenic differentiation. D. Montoya-Flores*[1,2], O. Mora[1], E. Tamariz[1], L. González-Dávalos[1], A. González-Gallardo[1], A. Antaramian[1], A. Shimada[1], A. Varela-Echavarría[1], and J. L. Romano-Muñoz[2], *[1]Universidad Nacional Autónoma de México, Querétaro, Querétaro, México, [2]Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias, Colón, Querétaro, México.*

Ghrelin is an acylated hormone, reported to influence food intake, energy metabolism, and reproduction, among others. Ghrelin may also stimulate proliferating myoblast cell differentiation and multinucleated myotube fusion. The aim of this work was to study the effect of human ghrelin (hGHRL) and human ghrelin fragment 1–18 (hGHRL1–18) on myoblast differentiation, measuring the effect of different concentrations on myogenic differentiation by analyzing myogenin expression at the mRNA and protein level. Two types of cells were tested, the cell line i28 obtained from mouse skeletal muscle and primary cultures of bovine myoblasts. Ghrelin and its N-terminal fragment hGHRL1–18 were used at concentrations of 0, 0.01, 0.1, 1, 10, and 100 nM. Treatments were applied to pre-confluent cultures and were maintained during 4 d. Myogenic differentiation of i28 cells was positively affected by hGHRL and hGRHL1–18, starting at a concentration of 0.1 nM ($P < 0.01$). On the other hand, only concentrations of 10 and 100 nM of hGHRL stimulated bovine myoblast differentiation. These results could be attributed to the presence of the mRNA for GHS-R1a and CD36 receptors, in both i28 cells and in bovine myoblasts. Hence, hGHRL might be useful in beef cattle production by promoting muscle differentiation.

Key words: ghrelin, bovine, myogenic differentiation

T375 Essential oil and rumensin affect ruminal fermentation in continuous culture. D. Ye*[1], S. K. R. Karnati[1], J. L. Firkins[1], M. L. Eastridge[1], and J. M. Aldrich[2], *[1]Ohio State University, Columbus, [2]Provimi-North America, Lewisburg, OH.*

The combination of Rumensin and essential oil could be beneficial for ruminal fermentation by suppressing protozoa and their associated methanogens, while maintaining normal rumen function. The objective of this study was to determine the effects of feeding Rumensin and Cinnagar (essential oil from cinnamon and garlic) in diets on ruminal fermentation characteristics. Four continuous culture fermenters were modified to retain protozoa (slower stirring and a special filter apparatus) and maintained at a liquid dilution rate of 7%/h and solids dilution rate of 5%/h in 4 periods of 10 d each (7 d of adaptation) in a 4 × 4 Latin square design. Four dietary treatments (fed in one meal per day) were arranged in a 2 × 2 factorial: (1) Control diet, 40 g of a 50:50 concentrate: forage (ground alfalfa hay) diet (40% NDF, 17% CP) containing no additive; (2) Rumensin at 11 g/909 kg of DM; (3) Cin-

nagar at 0.0043% (DM basis); and (4) combination of Rumensin and Cinnagar. There were no effects ($P \geq 0.36$) of treatment on concentrations of NH3-N or total VFA. Rumensin (main effect, no interaction) decreased ($P < 0.05$) molar percentages of acetate (62.6 vs. 64.4%) and valerate (1.78 vs. 1.86%); decreased acetate: propionate ratio (2.69 vs. 3.04) but increased ($P < 0.05$) propionate (23.3 vs. 21.3%) and isovalerate (1.94 vs. 1.67%). Rumensin increased ($P < 0.05$) the protozoa generation time (27.6 vs 21.6 h). Cinnagar tended ($P = 0.11$) to increase isovalerate (1.77 vs. 1.67%) and decrease the protozoa counts (14.9 vs. 18.5 × 10^3/mL). Rumensin and Cinnagar tended ($P = 0.06$) to interact for methane production (29.0, 22.4, 22.0, and 36.9 mmol/d, respectively). Under the conditions of our study, we did not detect an additive response for Rumensin and Cinnagar to decrease protozoal counts or methane production.

Key words: Rumensin, essential oil, continuous culture

T376 Energy value of co-products of bioethanol production: comparison between triticale grain and triticale DDGS. B. Liu and P. Yu*, *University of Saskatchewan, Saskatoon, Canada.*

The objectives of this study was to compare triticale grain and triticale DDGS on total digestible component nutrient and energy values, estimated using the NRC-2001 summary approach. The triticale grain and triticale DDGS samples were obtained from 3 years. The results showed that triticale DDGS had lower ($P < 0.05$) tdNFC (29.5 vs. 70.1%DM) and higher ($P < 0.05$) tdNDF (12.0 vs. 6.9%DM), tdCP (30.0 vs. 13.3%DM) and tdFA (5.5 vs. 0.5%DM). Triticale DDGS was also lower ($P < 0.05$) in TDN (76.9 vs. 84.5% DM). However there were no significant differences ($P > 0.05$) in DE1X, DE3X (3.34 in triticale DDGS vs. 3.42 Mcal/kg DM in triticale grain), ME3X (2.94 in triticale DDGS vs. 3.01 Mcal/kg DM in triticale grain), NEL3X (1.89 in triticale DDGS vs. 1.92 Mcal/kg DM in triticale grain) for dairy and NEm (2.99 in triticale DDGS vs. 3.06 Mcal/kg DM in triticale grain) and NEg (1.36 in triticale DDGS vs. 1.41 Mcal/kg DM in triticale grain) for beef cattle. The results suggested triticale DDGS as an alternative to triticale grain in dairy and beef diets.

T377 Molecular spectral features of functional groups mainly associated with lipid biopolymer in co-products (DDGS) from bioethanol production. P. Yu* and D. Damiran, *University of Saskatchewan, Saskatoon, Canada.*

To date, there is no study on bioethanol processing-induced changes in molecular structural profiles of lipid biopolymer in DDGS products. The objectives of this study were to (1) determine structural changes that were mainly associated with lipid biopolymer in the co-products that occurred on a molecular level during bioethanol proceesing; (2) quantify the asymmetric and symmetric CH3 and CH2 functional groups, carbonyl ester group and lipid unsaturated groups spectral intensities as well as their ratios, and (3) illustrate the multivariate analyses as a research tool for rapid characterization of biopolymer molecular structures in complex a plant-based feed system. The hypothesis of this study was that bioethanol processing changed the molecular structure profiles in the co-products as opposed to original cereal grains. These changes are highly related to lipid nutrient utilization in animals. The results showed that bioethanol processing had significant effects ($P < 0.05$) on the functional groups spectral profiles which are mainly related to lipid molecular structure in the co-products. The bioethanol processing decreased ($P < 0.05$) the CH3-(a)symmetric to CH2-(a)symmetric ratio, changed ($P < 0.05$) the spectral features of carbonyl C = O ester group and lipid unsaturated group. The results indicated that bioethanol processing changed lipid biopolymer structural conformation and the different types of cereal grains had different sensitivity to the bioethanol processing. The spectral profiles were different between their co-products (wheat DDGS vs. corn DDGS). Different bioethanol plants had different impact on the spectral profiles. The multivariate analyses distinguished the structural differences between the wheat and wheat DDGS and between the corn and corn DDGS. Further study is needed to quantify lipid molecular structural changes in relation to lipid nutrient utilization.

T378 Sheep performance on sorghum or sorghum-soybean silage diets. A. A. Melin[1] and H. M. Arelovich*[2], *[1]Coronel Suárez-Pasman Experimental Station, [2]Departamento de Agronomía-CIC-CERZOS.*

Silages of different species are extensively used in Argentina in a variety of dietary programs. Sorghum (Sor) crop is well adapted to environmental constraints of semiarid areas; however Sor silage is usually low quality. A mixed crop of Sor with Soybean (Soy) is expected to improve silage voluntary DM and protein intake. An assay was conducted to evaluate silage quality and sheep performance when receiving either of 4 silage diets: (1) Grain Sor (GS), (2) Sweet Sor (SS), (3) GS-Soy (85 to 15%) and (4) SS-Soy (85 to 15%). Pure or mixed crops were harvested and processed to a 20–25 mm particle size of green material, to be packed and sealed in 220-kg capacity plastic containers. Twenty Corriedale wethers (51.4 kg IBW) were randomly allocated to individual metabolism stalls. Following a 7-d adaptation period, silages were fed ad libitum on a daily basis previous collection of rejected material at 9 a.m. Feces were collected daily between 11 and 12 a.m. Offered and rejected materials were daily sampled and pooled. Samples were dried at 60°C, ground with a Wiley mill (1 mm) and saved for lab analyses. Diet quality, Daily DM intake (DMI), in vivo DM digestibility (DMD), digestible DMI (DDMI) and Total Protein Intake (TPI) data were analyzed by ANOVA as complete randomized design. Average silage pH was 3.9. Sor type has not affected silage quality, but Soy inclusion improved CP content. Average DMD increased 11% with Soy silages, with a trend for higher DDMI. Higher energy and CP consumption could be achieved by intercropping a minor proportion of Soy in Sor crops for silage.

Table 1.

Item	GS	SS	GS-Soy	SS-Soy	*P* =	CV, %
Diet, %						
DM	25.3	25.1	25.7	25.6	0.894	4.5
CP	5.1[a]	6.5[a]	8.7[b]	8.5[b]	0.0003	6.6
NDF	57.5	58.9	56.7	57.9	0.757	4.6

T379 The effect of sulfuric acid on in vitro gas production parameters of sugarcane top in Arabian sheep. S. Mahmoudi, M. Chaji*, M. Eslami, T. Mohammadabadi, and M. Bojarpour, *khuzestan Ramin Agricultural and Natural Resources University, Molassani, Khuzestan, Iran.*

The objective of this study was to investigate the effect of sulfuric acid (H2SO4) on chemical composition and in vitro gas production of sugarcane top (SCT) by Arabian sheep of Iran. Sugarcane top ensiled with different levels of sulfuric acid (0.9 and 1.8% acid) in laboratory silos for 45 d. Rumen fluid was supplied from 2 fistulated sheep were fed a 40:60 concentrate: forage, and the samples were incubated with 35 mL buffered rumen fluid in 100 mL glass syringes, for 2, 4, 6, 8, 10, 12, 16, 24, 48, 72 and 96 h, at 39°C. Cumulative gas production data were fitted to the exponential equation. The residues of each syringe were dried and used to calculate the cell wall degradation. The obtained data analyzed as a completely randomized design using the general linear model procedure of SAS. The results indicated that the ensiling SCT with 1.8% sulfuric acid caused to increase cell wall degradation, potential of gas production and rate constant in compared with the other treatments (48%, 140.2 mL and 0.04 mL/h, respectively; $P < 0.05$). The highest degradation and gas production at 24 and 72 h after incubation was for ensiled with 1.8% sulfuric acid (39 and 62 mL, respectively; $P < 0.05$). Therefore, the results of the present study demonstrated that ensiling with sulfuric acid improved in vitro gas production parameters of SCT.

Key words: degradation, sugarcane top, sulfuric acid

T380 The effect of urea, molasses and sulfuric acid on in vitro digestibility of sugarcane top by Arabian sheep. S. Mahmoudi, M. Chaji*, M. Eslami, T. Mohammadabadi, and M. Bojarpour, *Khuzestan Ramin Agricultural and Natural Resources University, Molassani, Khuzestan, Iran.*

The objective of this study was to investigate the effect of urea, molasses and sulfuric acid (H2SO4) on in vitro digestibility of sugarcane top (SCT) by Arabian sheep of Iran. Experimental treatments were including: untreated SCT (SCT), SCT ensiled with 10 g/kg DM urea+30 g/kg DM molasses (SCT1), SCT ensiled with urea+molasses+9 g/kg DM sulfuric acid (SCT2) in laboratory silos for 45 d. In vitro digestibility of dry matter (DM) and natural detergent fiber (NDF) was measured by procedure of Tilley and Terry. Rumen fluid was obtained from 2 Arabian sheep were fed a 40:60 concentrate: forage, then was mixed with McDougall buffer in a ratio 1:4, and incubated at 39°C. After 48 h fermentation, 6 mL of HCL (20%) and 5 mL pepsin solution (pepsin in HCL 0.1 N) were added and the incubated for 48 h simulating post-ruminal degradation. After incubation, the residual substrates of each tube were filtered and used to determine disappearance of DM and NDF. Data of disappearance of DM were analyzed as a completely randomized design using the general linear model procedure of SAS. The results of this experiment indicated that the SCT2 increased in vitro DM digestibility in compared with the other treatments (44.2, 43.6 and 41.04%, respectively; $P < 0.05$). Sugarcane top ensiled with urea+molasses+sulfuric acid had the highest NDF digestibility (79.77%). Therefore, the results of the present study demonstrated that urea+molasses+ 9 g/kg DM sulfuric acid improved in vitro NDF digestibility value of the SCT.

Key words: sugarcane top, molasses and urea, digestibility

T381 Interactions between nutrient supply and dietary flavors on diet selection by lambs. A. Bach*[1], J. J. Villalba[2], and I. R. Ipharraguerre[3], *[1]ICREA and Ruminant Production-IRTA, Barcelona, Spain, [2]Utah State University, Logan, [3]Lucta, S.A., Barcelona, Spain.*

Thirty-two crossbred lambs (BW = 36.7 ± 4.5 kg) housed in individual pens were used in 3 7-d experiments to investigate 1) the relationship

between protein status of the animals and diet selection based on dietary CP, 2) the interaction between dietary CP and preference for bitter, and 3) the interaction between protein supply and preferences for a caloric and a non-caloric sweetener. In Exp. 1, 16 lambs previously fed a low (LP; 10.9% CP) or a high (HP; 20.4% CP) CP diet for 42 d, received a double choice of the HP and LP diets. In Exp. 2, 16 lambs were offered a double choice of unflavored LP or HP diets or the same diets flavored (0.066%) with a bitter flavor. In Exp. 3, the 16 lambs from Exp. 1 were offered a double choice between an unflavored diet (LP or HP) or the same diet flavored with sucrose (0.2%) or a non-caloric sweetener (0.066%). Data were analyzed using a mixed-effects model with animal within treatment as a random effect, and treatment, time, and their interactions as fixed effects. When offered a choice between HP or LP (Exp. 1), lambs previously fed LP progressively ($P < 0.01$) increased total daily intake, whereas consumption was constant for lambs previously fed HP. On d 1, lambs previously offered HP showed a lesser ($P < 0.05$) preference for LP (23%) than those offered LP (30%), but preference for LP increased to about 50% at d 4, negating thereby differences in consumption between treatments. At the onset of Exp. 2, lambs were unresponsive to flavor; as time elapsed, however, lambs fed LP progressively reduced ($P < 0.05$) preference for the bitter flavor from 53 to 34%. In Exp. 3, lambs previously fed LP diets consumed less ($P < 0.05$) sweetener- than sucrose-supplemented diet, whereas lambs previously offered HP diets consumed more ($P < 0.05$) sweetener- than sucrose-supplemented diet. These results indicate that lambs are able to sense dietary CP content and modulate short-term consumption of flavored feeds based on nutrient requirements.

Key words: diet selection, sheep, flavor

T382 Effect of forage type in the diet on *Ruminococcus flavefaciens*, *Ruminococcus albus* and *Fibrobacter succinogenes* populations in sheep rumen content as determined by real-time PCR.
C. Saro[1,2], M. J. Ranilla*[1,2], and M. D. Carro[1], *[1]Dpto. Producción Animal, Universidad de León, León, Spain, [2]IGM (CSIC–ULE), Finca Marzanas s/n, Grulleros, León, Spain.*

The diet of the host is a major factor influencing the structure and function of ruminal bacterial populations. The objective of this study was to use real-time PCR to quantify the relative abundance of *Ruminococcus flavefaciens*, *Ruminococcus albus* and *Fibrobacter succinogenes* in the solid phase of the rumen of sheep fed 2 different diets. The diets had 70:30 forage:concentrate ratio and contained either alfalfa hay (AL) or grass hay (GR) as forage. Four rumen-fistulated sheep were fed the 2 diets in a crossover design. Rumen content samples (500 g) were collected before and 4 and 8 h after the morning feeding on 2 non-consecutive days, and strained through 2 layers of cheesecloth, and the solid content was thoroughly mixed before sampling. About 20 g of solid content were placed in sterile containers, and stored frozen at −80°C until DNA extraction. DNA was extracted from the samples using QIAamp DNA stool mini kit (Qiagen, Valencia, Spain) and hexadecyltrimethylammonium bromide (CTAB). Concentrations of *R. flavefaciens*, *R. albus* and *F. succinogenes* rDNA were measured by real-time PCR relative to total bacteria amplification. Validated primers specific for genes encoding 16S ribosomal DNA were used, and data were analyzed using repeated measures ANOVA. Relative abundance of *F. succinogenes* was greater ($P < 0.001$) for GR compared with AL, but no differences between diets were detected for *R. flavefaciens* ($P = 0.11$) and *R. albus* ($P = 0.56$). Post-feeding evolution of the 3 cellulolytic bacteria was similar for both diets. At 4 h after feeding the populations were greater ($P < 0.001$) than at 0 h, but they recovered initial values at 8 h post-feeding. The greater values observed at 4 h may be due to the attachment of new bacteria from the liquid phase or other particles and/or to bacteria proliferation on feed particles. *F. succinogenes* was the most predominant of the 3 species at all sampling times, and the only one influenced by forage type, which indicate the ecological and functional significance of this species in sheep receiving forage diets.

Key words: real-time PCR, ruminal cellulolytic bacteria, sheep

T383 The effect of replacing corn bran with water-soaked neem fruit on nutritive value and in vitro gas production characteristics of West African Dwarf sheep.
M. K. Adewumi*, *Department of Animal Science, University of Ibadan, Ibadan, Nigeria.*

Six male West African Dwarf (WAD) sheep (15.6 kg) divided into 2 groups were used in a complete randomized design to evaluate the effect of replacing corn bran with water-soaked neem (*Azadirachta indica*) fruit in a supplementary diet on nutritive value and nitrogen balance. Experimental treatments were (i) control containing 80:10:10 of cassava peels, fullfat soybean and corn bran and (ii) a test diet where corn bran was replaced with the water-soaked neem fruit (w/w). The animals were offered *Panicum maximum* hay ad libitum .The duration of the experiment was 21 d consisting of a 15-d adaptation phase and 7-d data collection phase. Ruminal fluids obtained from the 2 groups of animals were used in an in vitro gas production study to determine gas production characteristics of a standard maize substrate. Gas production was recorded after 24 h of fermentation. Apparent digestibility (g/100 g DM) of DM (56.60 vs. 57.80), CP (32.50 vs. 31.40), ether extract (56.00 vs 49.00) and ADF (63.00 vs. 41.50) were greater ($P < 0.05$) for the control. However, while N intake (g/d) (6.36 vs. 6.38) was similar ($P > 0.05$), nitrogen balance (1.66 vs. 1.37) was greater ($P < 0.05$) for the control. Metabolizable energy (MJ/kg DM) (8.27 vs. 8.36), short chain fatty acids (µml) (0.89 vs. 0.91) and organic matter digested (g/100g DM) (55.79 vs. 56.34) obtained from in vitro gas production were not different ($P > 0.05$) for the 2 diets. Replacement of corn bran with the water-soaked neem fruit increased($P < 0.05$) total gas produced(ml) (83.25 vs. 48.57) but reduced ($P < 0.05$) methane production (mL) (13.00 vs. 2.00).These results showed that replacing corn bran with water-soaked neem fruit has the potential to improve nutritive value and reduce energy loss through methane emission.

Key words: gas production characteristics, nutritive value, West African Dwarf sheep

Small Ruminant: Health, Growth, Extension, and Dairy

T384 Selected condensed tannin-containing plant extracts and their effects on *Haemonchus contortus* larvae. K. J. Stutts*, M. J. Thomas, M. M. Beverly, R. A. Lane, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Several studies have been conducted recently to determine if condensed tannins could be used to augment traditional deworming protocols since many plant extracts have exhibited anthelmintic properties in vitro. The objective of this study was to evaluate the effects of varying concentrations of crude plant extracts from selected condensed tannin containing-forages on motility of infective larvae of *H. contortus*. Extracts from sericea lespedeza (SL), white oak (WO), and black locust (BL) were evaluated in vitro for their effect on *H. contortus* motility. Larvae cultured from fecal samples collected from goats were exposed to one of 4 concentrations of plant extract. Extract concentrations were 2.5, 5, 10, and 20 mg/mL for each plant species. Treatment groups were compared with negative (distilled water) and positive controls (0.55 mg/mL albendazole). Motility was evaluated as an inferred measure of larvae morbidity using a 6 s rule. Motility counts were performed at 2, 6, and 12 h post-inoculation. At 2 and 6 h post inoculation, motility was lowest ($P < 0.05$) for the positive control, the 2 highest concentrations of WO, and the highest concentration of BL. At this time, motility was highest ($P < 0.05$) for the negative control and the lowest concentration of SL. At 12 h post inoculation, motility was lowest ($P < 0.05$) for the positive control, the 3 highest concentrations of WO, and the highest concentrations of BL and SL. At this time, motility was highest ($P < 0.05$) for the negative control and the lowest concentration of SL and BL. These results indicate that the 2 highest concentrations of WO and the highest concentration of BL were as effective in decreasing motility of *H. contortus* larvae in vitro as albendazole within 2 h of inoculation. Within 12 h of inoculation, the highest concentration of SL and BL, and the 3 highest concentrations of WO were all as effective in decreasing motility of *H. contortus* larvae in vitro as albendazole. These results indicate that there is potential for development of these plant species as a component of an anthelmintic regimen.

Key words: goats, parasite control, condensed tannins

T385 Effect of subclinical mastitis and stage of lactation on somatic cell count, composition and plasmin activity of goat milk. R. Shangguan[1,2], L. Spicer[2], C. DeWitt[2], J. Wang[1], and S. Zeng*[1], *[1]Langston University, Langston, OK, [2]Oklahoma State University, Stillwater.*

A total of 91 goat milk samples from individual udders of Alpine does during early, middle and late lactations were collected to investigate the impact of subclinical mastitis induced SCC increase on changes in composition and plasmin (PL) activity in milk. Samples were collected and analyzed for fat, protein, lactose, solids non-fat (SNF) and total solids (TS), SCC and PL activity. Within 3 stages of lactation, all milk samples were sorted into 3 groups based on levels of SCC (low $<2.5 \times 10^6$, middle = 2.5 to 5.0×10^6, high $>5.0 \times 10^6$) and statistically analyzed in a 3 × 3 factorial ANOVA. There were no interactions of level of SCC and stage of lactation on variables measured ($P > 0.05$). Log_{10} (SCC) and percentage lactose in milk were negatively correlated ($r = -0.34$, ($P = 0.001$). Fat, protein, SNF, TS and PL were altered by stage of lactation ($P < 0.05$). PL activity was greatest in early lactation. In conclusion, in high SCC milk, lactose content may be more indicative of SCC level than milk fat, protein, SNF, TS and PL activity during lactation. Stage of lactation is an important factor affecting milk composition and PL activity in goats with infection, and thus a necessary parameter in optimizing goat milk quality in conditions of sub-clinical mastitis.

Key words: dairy goat, subclinical mastitis, plasmin activity

T386 Hematological and spermatological evaluations of Honamli goat in Turkey. M. S. Gulay*[1], A. Ata[1], O. Elmaz[1], M. Saatci[1], N. Mamak[1], B. Dag[2], and A. H. Aktas[3], *[1]Mehmet Akif Ersoy University, Faculty of Veterinary Medicine, Burdur, Turkiye, [2]Selcuk University, Faculty of Agriculture, Department of Animal Science, Konya, Turkiye, [3]Bahri Dagtas Uluslararasi Hayvacilik Arastirma Enstitusu, Konya, Turkiye.*

Honamli goat is distributed throughout the mountains of south-west Mediterranean region in Turkey. This breed is an important breed among the goat breeds of Turkey. However there is no information available on their hematological and spermatological characteristics. Thus, packed cell volume (PCV), plasma protein (PP), hemoglobin (Hg), red blood cell (RBC), white blood cell (WBC), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentrations (MCHC) from the blood samples and ejaculate volume (EJ), motility (MT), dead spermatozoa (DS), abnormal spermatozoa (AS), spermatozoa concentrations (SC) and acrosomal abnormalities (AA) from freshly collected semen were evaluated from Honamli goats. One to 3 year old female goats (n = 35) were randomly selected from the 7 different farms located in different parts of the Mediterranean region. The does used in this study were 205–220 d in lactation and were on free range feeding with no additional supplements as it is traditionally done for this breed. Blood was withdrawn from the jugular vein into vacationer tubes containing EDTA and evaluated the same day. Sperm from 3 bucks were taken from the 3 different farms by artificial vagina (41–44°C) with the presence of females in estrus. The semen collection procedure was repeated weekly during the mating season for 4 total collections. All animals were healthy with no clinically signs of disease. PCV, PP, Hg, RBC, WBC, MCV, MCH, and MCHC were 22.1 ± 0.45%, 7.5 ± 0.17 g/dL, 8.2 ± 0.23 g/dL, $13.0 \pm 0.4 \times 10^6$ /μL, $5.2 \pm 0.17 \times 10^3$ /μL, 17.5 ± 0.47 fL, 6.6 ± 0.28 pg, and 37.6 ± 1.15%, respectively. EV, MT, DS, AS, and SC were 4.0 ± 1.1 mL, 75 ± 10%, 10 ± 4.0%, 10 ± 5.0%, and $3.25 \pm 1.15 \times 10^9$ /mL, respectively. Sperm with acrosomal abnormalities were 1%. Our results indicated that Honamli goats have smaller red blood cells with higher hemoglobin concentrations than other goat breeds. Moreover, spermatologic parameters of Honamli goats were very suitable for goat breeding.

Key words: hematology, spermatologic parameters, honamli goat

T387 Managing seasonal outbreak of foot rot in sheep flocks. T. Wuliji* and C. Clifford-Rathert, *Lincoln University, Jefferson City, MO.*

Foot rot in sheep flocks during hot, humid and rainy season in Midwest region of the US are on the increase. Foot rot is caused by the synergic activity and infection by bacteria *D. nodosus* and *F. necrophorum* species. In field inspection of a small sheep flock (n = 73), showed that 89% of the flock appeared to be suffering from mild to severe foot rot infection on either one, 2, 3 or 4 feet. Feet were examined for

lesions and assessed for the severity. Sick sheep were hoof trimmed and initially treated with KopperTox and "Purple Wound Spray," and re-examined in 2 weeks. Feet lesions were re-scored and the number of effected feet was recorded. The foot rot lesion scores and number of feet treated at the 2 intervals were analyzed for a Chi-squared goodness of fit test. The results showed a significant ($P < 0.05$) increase in the animals scored for 0, 1, 2 and 4 at the second interval from the first, which means there was improvement in alleviation of the symptoms in the lower score level groups while worsen for score level 3 and 4. The number of feet treated also significantly ($P < 0.05$) decreased at the second examination from the first attendance for all groups except 4 feet infection. Foot lesions from 4 lame sheep were swabbed for bacteria culture. Culture results revealed positive test for *F. necrophorum* and possibly *D. nodosus*. Animals with severe lameness were treated with antibiotic spray (3.9% tetracycline) and most of them responded favorably. However, 20 sheep were culled as result of precaution and management requirement. This case study demonstrated the potential foot rot infection, treatment and labor cost, and early culling of valuable animals by the seasonal foot rot outbreaks.

Key words: sheep, foot rot, *Dichelobacter nodosus*

T388 Comparison of nematode parasite-susceptibility and performance of Boer and Spanish goats supplemented with garlic. R. Zhong[1,2], Z. Wang*[1], A. Goetsch[1], S. Hart[1], and T. Sahlu[1], *[1]American Institute for Goat Research, Langston University, Langston, OK, USA, [2]Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, Jilin, China.*

Twenty Boer (B; 2–7 yr of age) and 20 Spanish (S; 4–6 yr of age) does with their single- or twin-kids (1–4 mo of age) were used to compare nematode parasite-susceptibility and performance of the 2 breeds supplemented with garlic. Initially, all does and kids were treated with a combination of Cydectin (0.8 mg/kg BW), Levasole (11.2), and Valbazen (21.6) on 2 consecutive d to clear existing nematode parasites. The goats were kept in a barn for 7 d and fecal samples from the does were checked for fecal egg count (FEC). Then all does and kids were moved to a pasture known to be contaminated with H. contortus. The goats grazed together for 3 wk before being assigned to 2 treatments for a 98-d experiment. Five does (3 B and 2 S, or 2 B and 3 S) with their kids grazed 8 0.4-ha pastures (68% bermudagrass, 32% other grasses and forbs). Treatments were control (C) and garlic (G), with 4 pastures per treatment. Control does received 200 g/d of concentrate (%: corn 54, SBM 26, molasses 13, dical 1.3, limestone 1.3, trace mineralized salt and vitamin mixes 3.4, $MgSO_4$ 0.7), garlic does received the same amount of concentrate plus 20 g/d of G powder. Kids were weaned on d 32 and removed from the experiment. On d 0, 32, 67, and 98, all goats were weighed and fecal and blood samples collected. Means were separated by LSD. Initial mean FEC was 533 (0 - 8,650) and 440 (0 - 2,050) for B and S does, respectively (SEM = 257; $P > 0.05$). The FEC was not different ($P > 0.05$) between breeds or treatments on any day. Likewise, ADG (−8 and −28 g/d vs 4 and −26 g/d, SEM = 8.0), packed cell volume (25 and 24 vs 25 and 26, SEM = 1.6), FAMACHA score (3.5 and 3.5 vs 3.3 and 3.3, SEM = 0.18), and body condition score (2.4 and 2.4 vs 2.4 and 2.4, SEM = 0.07) of does and ADG of kids (109 and 136 g/d vs 115 and 120 g/d, SEM = 11.0) were similar ($P > 0.05$) for B and S regardless of treatment. In conclusion, nematode parasite-susceptibility appears similar in these 2 common meat goats and garlic supplementation has no effect on internal parasitism under these experimental conditions.

Key words: garlic, goats, internal parasitism

T389 Effect of sericea lespedeza *(Lespedeza cuneata)* leaf meal pellets fed to gastrointestinal nematode infected goats. N. C. Whitley*[1], T. H. Terrill[2], J. E. Miller[3], J. M. Burke[4], K. Moulton[1], L. Townsend[5], J. R. Horton[5], J. French[6], A. K. Cooper[1], and D. S. Kommuru[2], *[1]North Carolina A&T State University, Greensboro, [2]Fort Valley State University, Fort Valley, GA, [3]Louisiana State University, Baton Rouge, [4]USDA-ARS, Booneville, AR, [5]NCDA-UMRS, Laurel Springs, NC, [6]NCDA-UPRS, Reidsville, NC.*

Thirty-six female and castrated male Boer crossbred goats were used at 227 ± 0.4 d of age and 24.0 ± 0.2 kg BW to determine the effect of sericea lespedeza leaf meal pellets (SLP) on gastrointestinal nematode (GIN) parasitism. Goats artificially infected with *Haemonchus contortus* were used when fecal egg counts (FEC) were ≥1000 eggs per gram (epg). Goats were individually penned and fed diets similar in available protein containing 0 (control; commercial alfalfa pellets) or 75% SLP with 18 goats/treatment. Animals were allocated to treatment for similar group d –1 FEC, BW and sexes. Pre-weighed rations were fed once daily to allow for 10% orts. Blood samples for packed cell volume (PCV) and fecal samples for FEC (using the Modified McMasters technique) were collected on d 0, 7, 14, 21 and 28 (d 0 = pen placement and first day of treatment). Orts were measured on sampling dates for estimation of intake; BW was measured on d 0. Data were log-transformed and analyzed using the MIXED procedure of SAS but lsmeans are reported. The FEC were influenced by a treatment by d interaction ($P < 0.02$) in which FEC were similar between treatments on d 0 and were lower ($P < 0.03$) for both treatments at all other sampling dates, and were lower ($P < 0.03$) for 75% SLP treated animals than for control on all other days (control: 5326, 4101, 2715, 2198 and 1858 ± 523 epg and SLP: 5272, 1534, 1376, 1181 and 777 ± 483 epg for d 0, 7, 14, 21 and 28, respectively). There was no influence of treatment on PCV, but there was an influence of d ($P < 0.001$) in which PCV for all animals was lowest on d 0 at 27.8 ± 1.14%, increased to 37.0 ± 1.15% by d 14 and decreased again to 30.9 ± 1.14% on d 28. Intake as a percentage of initial BW was not different between treatments at any time point measured ($P > 0.13$). However, intake for 0% SLP was lowest on d 7 than for any other time point and intake for 75% SLP was highest on d 14 than for any other time point measured ($P < 0.002$; treatment by d). Overall, SLP decreased GIN FEC, supporting the concept of using this pelleted forage-based supplement as a component of a small ruminant integrated GIN control program.

Key words: sericea lespedeza, parasites, goats

T390 Influence of type of pasture and transport stress on microbial loads in meat goats. A. Mechineni, S. Gujja, D. S. Kommuru, T. H. Terrill, G. Kannan*, B. Kouakou, and J. H. Lee, *Fort Valley State University, Fort Valley, GA.*

Livestock transport has been identified as one of the risk factors of microbial contamination in the red meat production. Sericea lespedeza (SL; *Lespedeza cuneata*), a leguminous forage high in condensed tannins, has been reported to reduce gut microbial loads in ruminants. This experiment was conducted to assess the effects of SL grazing and stress associated with transport on microbial load on skin and carcass of meat goats, as well as in their gastrointestinal tracts. In a Completely Randomized Design with split-plot, 30 Spanish intact male kids (6 mo of age; BW = 20.3 ± 3.28 kg) were grazed on either bermudagrass (BG; *Cynodon dactylon*), SL, or a combination of BG and SL pasture for 8 wk (n = 10 goats/treatment). At the end of the grazing period, 5 kids from each pasture were randomly selected, loaded onto a trailer, and then transported to the holding pen at the university abattoir after

driving 3 h. The rest of the kids were directly transported to the abattoir after loading onto the trailer. Animals were held overnight with access to water only before slaughter. Skin swab samples were made on the hind legs immediately after transportation and just before slaughter. Immediately after evisceration, carcass swab samples were taken and rumen and rectal content samples were also collected. Microbial counts in both rectal and rumen contents were not different ($P > 0.05$) among goats grazed on the experimental pastures. Neither pasture type nor transport stress significantly influenced ($P > 0.05$) *E. coli*, total coliform and aerobic plate counts on skin or carcasses. The *E. coli* counts on skin were 0.18 and 0.13 ± 0.091 (mean ± SEM) $\log_{10}$cfu/cm^2 in transport and non-transported groups, respectively. The aerobic plate counts on carcasses were 2.62, 2.91, and 2.41 ± 0.310 (mean ± SEM) $\log_{10}$cfu/cm^2, respectively, in goats grazed on SL, BG and BG plus SL pastures. The results indicate that neither pasture type nor transportation stress appear to significantly influence gut, skin, or carcass microbial loads in meat goats.

Key words: sericea lespedeza, transport, *E. coli*

T391 Gastro-intestinal parasitic infestation in meat goats and its relationships with production traits under a pasture-based performance test in Western Maryland. K. Nadarajah*[1], S. Schoenian[2], D. L. Kuhlers[1], M. D. Carpenter[1], and D. Rankins[1], *[1]Auburn University, Auburn, AL, [2]University of Maryland Extension, Keedysville.*

Variation among meat goats for gastro-intestinal parasitic (GIP) infestation and its relationships with production traits should be explored for selecting goats for resistance to GIP. The objective was to examine between animal variation for GIP infestation and growth performance of bucks participated in a pasture-based performance test in 2009 (n = 60) and 2010 (n = 72), respectively, in Western Maryland. Bucks were managed as a single group on pasture with access to free choice minerals, and were rotationally grazed among 5, 2 acre paddocks. Using SAS, data were analyzed within test-years for fecal egg count (FEC), FAMACHA score (FAM), BCS and growth performance of individual bucks at initial-entry-to-test (IT) and end-of-test (ET). Mean, SD and correlations among traits for IT-weight (IT-WT), IT-FEC, IT-FAM, and IT-BCS and similar parameter estimates for ET-weight (ET-WT), ET-FEC, ET-FAM, and ET-BCS, as well as overall ADG on test were computed. Mean ± SD of bucks on tests in 2009 and 2010 for IT-WT were 21.3 ± 4.8 kg and 20.1 ± 4.5 kg, respectively. For same years, means ± SD of bucks were 1,202 ± 1,614 and 682 ± 1,201 for IT-FEC, 1.82 ± 0.83 and 1.61 ± 0.78 for IT-FAM, and 2.68 ± 0.33 and 2.72 ± 0.40 for IT-BCS, respectively. Means and SD of bucks for ET-WT were 28.1 ± 4.8 kg and 26.3 ± 4.4 kg, for ET-FEC 1,584 ± 1,229 and 400 ± 417, for ET_FAM 2.4 ± 1.1 and 1.57 ± 0.53, and for ET-BCS 2.7 ± 0.4 and 1.6 ± 0.5 in 2009 and 2010, respectively. The mean ADG were 63.5 ± 30.8 g and 54.4 ± 25.8 g for 2009 and 2010, respectively. In both test years, the correlations between IT-FEC and IT-FAM with IT-WT were negative ($P = 0.5$), but IT-WT with IT-BCS was positive ($P < 0.001$). In 2010 test, correlation between IT-FEC and IT-FAM was positive ($P = 0.06$) and correlation between ET-FEC and ET-FAM was positive ($P = 0.08$) in 2009 test. Between variations among bucks for FEC were large. Lack of pedigree information on bucks restricted the estimation of genetic (co)variances from these data. Phenotypic parameters will be used to simulate performance and pedigree data to conduct genetic analyses.

Key words: gastro-intestinal parasite, meat goats, performance test

T392 Gastro-intestinal parasitic infestation and its relationships with growth performance in meat goats on pasture with supplemental grain feeding test at the Kerr Center in Oklahoma. K. Nadarajah*[1], M. Penick[2], D. L. Kuhlers[1], M. D. Carpenter[1], and D. Rankins[1], *[1]Auburn University, Auburn, AL, [2]Kerr Center, Poteau, OK.*

Understanding the relationships between growth performance and gastro-intestinal parasitic (GIP) infestation in meat goats was the objective in this study that should help in selecting goats for resistance to GIP infestation. Data used for this investigation were collected through the buck performance tests at the Kerr Center in Oklahoma in 2009 (n = 58) and 2010 (n = 60), respectively. Bucks on test were grazed on mixed pasture consisting of bermuda, fescue, lespedeza, warm season native grasses and forbs. Bucks also received approximately 340 g of distillers dried grain per head/d and free choice mineral. Using SAS, phenotypic means, SD and correlations among traits of interest were computed within test-years for fecal egg count (FEC), FAMACHA score (FAM) and growth performance of individual bucks at initial-entry-into-test (IT) and end-of-test (ET). Relationships among bucks for performance were estimated for IT weight (IT-WT), IT-FEC and IT-FAM and ET weight (ET-WT), ET-FEC and ET-FAM as well as overall ADG on test. The means ± SD of bucks entered for test in 2009 and 2010, for IT-WT were 22.5 ± 3.4 kg and 23.3 ± 3.5 kg, respectively. In the respective years, the means and SD of bucks for IT-FEC were 976 ± 1,239 and 405 ± 587, and for IT-FAM were 2.6 ± 0.56 and 2.6 ± 0.62. Means and SD of bucks on test in 2009 and 2010, respectively, at ET as follows: for ET-WT 24.6 ± 3.3 kg and 33.7 ± 3.9 kg, for ET-FEC 1,688 ± 2,540 and 1,290 ± 742, and for ET-FAM 2.1 ± 1.2 and 2.75 ± 0.47. Between variations among bucks were large for FEC across test years. The mean ADG in 2009 test was 19.9 ± 30.8 g and the mean ADG in 2010 was 99.8 ± 34.4 g. In 2009 test, correlation between ET-WT and ET-FAM was negative ($P = 0.09$) and ET-FEC and ET-FAM was positive ($P < 0.01$). In both years, correlations between ET-WT and ADG were positive ($P < 0.001$). Lack of pedigree information on individual bucks restricted the estimation of genetic (co)variances from this data. Phenotypic parameters from this study will be used to simulate pedigree and performance data to conduct genetic analyses.

Key words: gastro-intestinal parasite, meat goats, performance test

T393 Lamb immune status (blood IgG, IgM and chitotriosidase activity) during weaning, preliminary results. L. E. Hernandez-Castellano*[1], A. Morales-delaNuez[1], I. Moreno-Indias[1], D. Sanchez-Macias[1], A. Torres[2,1], A. Arguello[1], J. Capote[2], and N. Castro[1], *[1]Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Instituto Canario de Investigaciones Agrarias, La Laguna, Tenerife, Spain.*

The effect of weaning on some blood immune status-related parameters was investigated using 10 lambs (Canaria dairy breed). Lambs were raised with ewes until they reached 10 kg of live BW with open access to ewe feed. After that, to start the weaning period, lambs were removed from dams and placed in a pen for 6 wk, with free access to starter feed and water. The ewes were milked once a day (morning). During the first week, lambs had access to ewes twice daily (10:00 a.m. after milking, and 17:00 p.m.). During the second week, lambs accessed ewes once a day (17:00 p.m.), and thereafter, the lambs did not have access to ewes. A blood sample was obtained from lambs before the beginning of weaning protocol and subsequently once a week until the end of the experiment. IgG and IgM were measured using a commercial ELISA (Bethyl Laboratories, Montgomery, TX)

and chitotriosidase activity was determined using a fluorescence assay. Blood plasma IgG concentration before the beginning of weaning protocol was 5.14 mg/mL, which was higher than that at wk 4 of weaning protocol (3.93 mg/mL). At wk 6, the IgG concentration increased to values close to the initial ones (6.24 mg/mL). Weaning did not affect the blood plasma IgM concentration, which ranged from 0.64 to 0.76 mg/mL. Weaning did not affect blood serum chitotriosidase activity, which ranged from 2756 to 3292 nmol/mL/h. In conclusion, it would be necessary to improve the knowledge through further research to avoid decreases in blood IgG concentrations in lambs during the critical period in their growth.

Key words: immunoglobulins, chitotriosidase, lamb

T394 Comparison of FAMACHA scores and need for deworming in hair sheep and meat goats grazed together or sheep grazed alone. S. Hart*[1], T. A. Gipson[1], R. Pirtle[2], and W. Cubbage[2], *[1]E (Kika) de la Garza American Institute for Goat Research, Langston, OK, [2]Oklahoma State University Cooperative Extension, Stillwater.*

This study compared FAMACHA scores and need for deworming in hair sheep and goats being grazed together or hair sheep grazed alone. The study involved Boer and Spanish goats and hair sheep crosses of Katahdin, St. Croix, Dorper, Gulf Coast Native and Barbadoes Blackbelly. Treatments were 1) hair sheep grazed alone (88 hd/16.2 ha) or 2) goats and hair sheep grazed together (38 hd of hair sheep and 71 hd of goats/24.3 ha) on tallgrass native range during the summer (average annual precip. 922 mm). Animals were FAMACHA scored (FS) April 30 at the beginning of the study and animals scoring 4 and 5 were treated with moxidectin (MOX; 10 mL). Animals then were FAMACHA scored May 17, June 8, Jul 26, Aug 18 and Sep 20. Animals with FS of 4 were administered either 2.0 g. of copper oxide wire particles (COWP) or 3.4 g of Cayenne pepper (CP). Animals with a FS of 5 were treated with MOX. Animals that were dewormed were fecal sampled for determination of fecal egg counts (FEC) by McMaster procedure and an additional 3 to 6 animals that were not dewormed were fecal sampled. On the hair sheep and goat treatment, goats had higher FS than hair sheep (3.80 vs. 2.63; $P < 0.01$), higher FEC (532 vs. 188 epg; $P < 0.02$) and required more deworming (61.8 vs. 13.5%; $P < 0.001$). Hair sheep grazing alone had a lower FS than hair sheep grazing with goats (2.20 vs. 2.63; $P < 0.01$), lower FEC (50 vs. 188 epg; $P < 0.01$) and required less deworming (2.1 vs. 13.5%; $P < 0$ 0.001). When animals were administered CP, FEC at the subsequent sampling increased by 63%. whereas COWP decreased FEC 36% at the subsequent sampling. Administration of MOX reduced FEC 47% in the subsequent sampling. Hair sheep grazed with goats had lower FS, lower FEC and required substantially less deworming than the goats they grazed with, but sheep grazing with goats required more deworming than sheep grazing alone. COWP was more effective than CP in reducing FEC.

Key words: gastrointestinal nematodes, alternative anthelmintics

T395 Lack of an effect of pelletized diets containing pumpkin seeds on gastrointestinal nematode fecal egg counts in goats. M. Gooden*[1], E. N. Escobar[1], N. C. Whitley[2], D. J. Jackson-O'Brien[3], and H. Taylor[1], *[1]University of Maryland Eastern Shore, Princess Anne, [2]North Carolina A&T State University, Greensboro, [3]Delaware State University, Dover.*

This investigation evaluated the effect of diets containing ground pumpkin (*Cucurbita* sp.) seeds (PS) on an artificial *Haemonchus contortus* infection in goats. Thirty 6 to 8 mo old female and castrated male Boer-crossbred kids at an average body weight of 25.3 ± 4.9 kg were used. Following a 2-week adjustment period in 6-m^2 individual pens with slotted floors, kids were dewormed with albendazole (10 mg/kg) and moxidectin (0.2 mg/kg). After a 21-d dewormer withdrawal period, all kids were orally inoculated 3 times over 5 d with a 3 mL larval inoculum containing 1,450 H. contortus L3. A pelletized 15% crude protein diet was used as the control (C) feed. The treatment diet was formulated with the same ingredients in C diet plus PS. The pelletized treatment diet contained 200 g PS per kg of feed. Two treatment feed levels were used: PS1 had 100 g PS/kg and consisted of PS2 (treatment diet with 200 g PS/kg) mixed equally with the C feed. Weekly, the goats were weighed, fecal samples were taken to determine fecal egg counts (FEC, eggs/g) using the modified McMaster′s technique, and blood samples were collected to determine percentage packed cell volume (PCV). Only goats with FEC ≥200 epg were used for the study, resulting in 9 C, 4 PS1 and 6 PS2 treated animals. Goats were fed the experimental diets for 4 weeks and individual daily feed intake was recorded. Data were analyzed by SAS PROC MIXED. There was no effect of treatment on FEC or PCV; FEC averaged 608 ± 107 for C, 472 ± 134 for PS1 and 780 ± 160 eggs/g for PS2;PCV were C: 27.9 ± 0.5; PS1: 29.8 ± 0.6 and PS2: 28.5 ± 0.8). Average daily feed intake was higher (treatment by week, $P < 0.01$) for the goats eating C diet than PS1 or PS2 for the study′s first 2 weeks only and were similar for the last 2 weeks. Weekly BW was lowest for wk 1 for C but was similar for PS goats over time (treatment by week, $P < 0.05$). In this experiment, PS did not reduce gastrointestinal nematode fecal egg counts in goats, but more research is needed.

Key words: *H. contortus*, goats, fecal egg counts

T396 Comparative efficacies of alternative anthelmintics against natural nematode infection in grazing goats. P. B. Collyer* and E. G. Brown, *Stephen F. Austin State University, Nacogdoches, TX.*

The objective was to determine the efficacy of 3 anthelmintic treatments in East Texas Boer goats. Goats (n = 22) were treated based on sex, age, and initial fecal egg count (FEC). Goats were given a single treatment (TR) that included control (no anthelmintic), Cydectin oral sheep drench (CY, 0.4 mg/kg BW orally), copper wire particles (COWP) in a gel capsule (Copasure, goats <5 mo 1g, goats >5 mo 3 g orally) or cayenne pepper (CP) in a gel capsule (goats <5 mo 3g; goats >5 mo 6g orally). FEC were performed with the FECPAK system. Body weight, FAMACHA score and packed cell volume (PCV) were measured on the day before beginning TR, and weekly for 6 weeks. The obtained measurements were evaluated with a permutation test. COWP reduced nematode eggs ($P < 0.03$) for 2 weeks beginning the second week after TR. CP and CY reduced nematode egg numbers after one week ($P = 0.01$ and 0.03, respectively). FAMACHA scores decreased with COWP after one ($P = 0.01$) and after 3 weeks ($P = 0.03$). FAMACHA scores decreased with CY after 3 weeks ($P = 0.05$). Five weeks post treatment, FAMACHA scores were lower in goats that had been treated with CP compared with the COWP group ($P = 0.04$). Furthermore, COWP TR demonstrated higher FAMACHA scores than the control group after 5 weeks ($P = 0.04$), and also higher FAMACHA scores than CY treated goats after 5 weeks ($P = 0.04$). FAMACHA score and PCV were negatively correlated ($r = -0.31$, $P = 0.01$). Changes in PCV were not evident with any of the treatments. Increase in body weight was seen with COWP after one week of treatment ($P = 0.04$), three weeks ($P = 0.02$), four weeks ($P = 0.02$) and five weeks ($P = 0.02$). Goats treated with CP had an increase in body weight after

4 weeks ($P = 0.04$) and 5 weeks ($P = 0.05$) compared to goats who had received COWP. Results indicate that the onset of FEC reduction with COWP is later and the duration longer, compared to CY and CP, which demonstrated a comparable result in reducing FEC, but shorter in duration. Thus, as an affordable alternative treatment, CP might be considered for a short-interval dosing regimen.

Key words: cayenne pepper, goats, anthelmintic

T397 Effects of immunomodulatory substances added to milk replacer on white blood cell populations during weaning. S. Paez Lama, A. Morales-delaNuez, V. Mendoza-Grimon, L. E. Hernandez-Castellano, D. Sanchez-Macias, N. Castro, and A. Arguello*, *Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

To investigate the effect of immunomodulatory substances added to milk replacers on white blood cell populations during the first week of weaning, 21 goat kids (Majorera dairy breed) were randomly allotted into 3 groups. The first group was a control (CON), the second group received a daily dose of 200 mg/kg BW of *Echinacea purpurea* (ECH) and the third group received a daily dose of 20 mg/kg BW of *Polypodium leucotomos* (POL). Goat kids were artificially raised with a milk replacer ad libitum until they reach 10 kg of life BW. After that, animals were enrolled in the weaning protocol. Starter and fresh water were available throughout the weaning period. The first weaning week goat kids received 1 L/d of milk replacer twice daily (morning and afternoon). A blood sample was obtained before starting the weaning protocol and at the end of the first week in heparin containers. Immediately after collection, 50 µL of unclotted blood were added with 5 µL of CD4 (FITC) and 5 µL of CD8 (RPE) monoclonal antibodies (Serotec, Dusseldorf, Germany) and the reaction ran for 15 min at room temperature. After that, 50 µL of Optilyse (Beckman Coulter, Brea, CA) were added and the reaction ran for 15 min at room temperature to lyses red blood cells. Subsequently, 150 µL of saline serum were added to clarify the solution. Fifteen minutes later, the samples were redden using an FC500 flow cytometry device (Beckman Coulter, Brea, CA). An ANOVA (with repeated measures) procedure from SAS was used. Two white blood cell populations were observed clearly, lymphocytes plus macrophages (L+M) and polymorphonuclear (PMN) at both tested times. Control L+M, PMN and CD8 lymphocytes per mL were lower ($P \leq 0.05$) than in preweaning samples but no differences were observed with ECH and POL. Control and ECH CD4 lymphocytes per mL were lower ($P \leq 0.05$) than preweaning samples and POL kids. The addition of immunomodulatory substances would improve the immune status during the weaning in goat kids.

Key words: goat kid, weaning, immunomodulatory

T398 Goat browsing for invasive shrub and internal parasite control. J. C. Warren*[1], D. J. O'Brien[1], C. Heckscher[1], R. Beaman[2], and N. C. Whitley[3], *[1]Delaware State University, Dover, [2]Delaware Department of Transportation, Dover, [3]North Carolina A&T State University, Greensboro.*

The objectives of this study were to determine whether goats were effective in the control of Autumn Olive (AO; *Elaeagnus umbellate*), Multiflora Rose (MR; *Rosa multiflora*), and Japanese Honeysuckle (JH; *Lonicera japonica*) and whether browsing controls internal parasites in goats. 1.95 ha of land was divided into 5 fenced paddocks with 3 treatment (TRT; with goats; 0.45 ha each) and 2 control (CON; without goats; 0.30 ha each) paddocks at the study site, Wrangle Hill (WH). At the University farm site, Hickory Hill (HH), 1.35 ha of mixed grass/legume pasture was divided into 3 fenced paddocks (0.45 ha each). Seventy crossbred meat type goats averaging 745 ± 146 d of age and 39.3 ± 7.2 kg BW from the HH herd were used in the experiment (n = 35/location). Goats at WH were used to browse each TRT for 14 d, after which they were moved to the next TRT. At HH, goats grazed paddocks in the same 14-d rotations concurrently with WH goats. The study lasted 112 d. On rotation days, WH paddocks were analyzed for percentage ground cover and visual estimates were made for AO, MR, and JH using the double DAFOR method; additionally, at this time, for both sites, animal BW and FAMACHA scores were measured and recorded and fecal samples were collected to determine fecal egg counts (FEC) in eggs per gram (epg) using the modified McMaster′s technique. All data was analyzed using the PROC MIXED procedure of SAS. Visual Estimates of both AO and MR were similar between treatments, but JH decreased ($P < 0.01$) in the TRT paddocks compared with the CON over the study period. Browsing goats did not influence groundcover percentage. Goat BW and FAMACHA scores were not influenced by site and averaged 43.2 ± 3.3 kg and 3.1 ± 0.1, respectively. There was a location by d effect with WH goats having lower FEC ($P < 0.05$) than HH goats on d 14 (216 ± 90 and 476 ± 90 epg, respectively), d 42 (33.0 ± 63 and 206 ± 63 epg, respectively), d 56 (45.0 ± 66 and 368 ± 68 epg, respectively), and d 112 (219 ± 83 and 621 ± 82 epg, respectively). In summary, browsing reduced FEC in goats and decreased JH during one grazing season. Multiple grazing seasons may be required to have an impact on AO and MR.

Key words: goat, parasites, invasive shrubs

T399 Gastrointestinal nematode (GIN) resistance and GIN management on small ruminant farms in the mid-Atlantic U.S. D. J. O'Brien[1], K. K. Matthews*[1], E. K. Crook[2], N. C. Whitley[3], B. Storey[4], S. Howell[4], and R. Kaplan[4], *[1]Delaware State University, Dover, [2]Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, [3]North Carolina A & T State University, Greensboro, [4]University of Georgia, Athens.*

The objective was to characterize gastrointestinal nematode (GIN) anthelmintic resistance and parasite control programs on 20 goat and 13 sheep farms in DE (10 farms), MD (10 farms), VA (3 farms), WV (4 farms), and PA (6 farms). Farms were evaluated for GIN resistance to benzimidazole (BZ), ivermectin (IVM), moxidectin (MOX), and levamisole (LEV) using the DrenchRite Larval Development Assay. Fecal samples were collected rectally from at least 10 animals on each farm, placed into labeled zippered bags, and shipped to the University of Georgia for analysis. Completion of a survey to determine previous anthelmintic use and current integrated parasite management methods as part of an overall parasite control program was required of farmers participating. On 100% of farms tested, BZ was ineffective; IVM was ineffective on 79% (26/33) of farms, and MOX was ineffective on 48% (16/33) while LEV was only ineffective on 27% (9/33) of farms tested. Rotational grazing, FAMACHA, fecal egg counts, or mixed species grazing were strategies utilized to help control parasites on 62, 48, 14, and 7% of farms, respectively. The most common anthelmintics previously used by producers was a combination of BZ, IVM, and MOX on 72% of farms. Overall, 90, 79, and 31% of producers had previously utilized macrocyclic lactones (IVM and MOX), BZ and LEV, respectively; 86% of producers had utilized 2 or more classes of anthelmintics, while 17% of producers had utilized all 3 classes of anthelmintics. When asked about frequency of anthelmintic treatments, most participants utilized selective drenching techniques (41%) or used anthelmintics one to 3 times per year (41%). The remaining 17% treated with anthelmintics more than 4 times/year. Results indi-

cate that GIN resistance is a serious problem on small ruminant farms in the mid-Atlantic region, but that producers seem to be trying to utilize some types of integrated parasite control strategies to extend the efficacy of available anthelmintics.

Key words: small ruminants, parasite resistance, FAMACHA

T400 Effects of supplemental dried distillers grains on performance and internal parasites of grazing lambs. C. L. Pickworth*[1], T. L. Felix[1], I. Susin[2], L. M. Shoup[1], and S. C. Loerch[1], *[1]The Ohio State University, Wooster, [2]Universidade de São Paulo, Piracicaba, São Paulo, Brazil.*

Weaned lambs grazing on pasture have high susceptibility to internal parasites which can greatly reduce growth rates and can contribute to lamb mortality. The objective of these studies was to investigate the effects of supplementing weaned lambs grazing orchardgrass pastures with dried distillers grains with soluble (DDGS) or soybean hulls (SH) on parasitism, growth rate, and cost of production. In each experiment, lambs were assessed weekly for 10 wk for parasitism based on FAMACHA eye scores and BW was recorded. Every 3 wk, blood hematocrit and fecal egg counts were determined. Lambs with FAMACHA scores of ≥ 3 were treated with an anthelmintic. Each treatment was replicated in 2 paddocks and data were analyzed as a completely randomized design. In Exp. 1, 62 lambs (26.3 ± 0.1 kg) were allotted to 4 paddocks. The treatments were a control with no supplementation (CONT) or 0.53 kg/head supplemental DDGS (SDG1). The SDG1 lambs had greater ($P < 0.01$) ADG and decreased ($P < 0.01$) anthelmintic costs because fewer lambs were treated (19 vs. 90% for SDG1 and CONT, respectively). In Exp. 2, 96 lambs (25.1 ± 0.4 kg) were allotted to 6 paddocks. The treatments included a CONT, 0.61 kg/head supplemental SH (SSH), or 0.63 kg/head supplemental DDGS (SDG2). The SSH and SDG2 lambs had greater ($P < 0.01$) ADG as compared with CONT lambs (95, 188, and 224 g/d for CONT, SSH, and SDG2, respectively). Both SSH and SDG2 reduced ($P < 0.02$) percent of lambs treated with anthelmintics (31 and 9%, respectively) when compared with CONT (81%). The FAMACHA scores were improved ($P < 0.01$) for SSH and SDG2 lambs than CONT on d 22, 43, and 72. In Exp. 3, 92 lambs (21.0 ± 0.5 kg) were allotted to 6 paddocks. The treatments included CONT, 0.59 kg/head supplemental SH with 0.7% P from monosodium phosphate (SSHP), or 0.54 kg/head supplemental DDGS (SDG3).The ADG was greater ($P < 0.03$) for SDG3 and SSHP than CONT. Only 52% of SDG3 lambs were treated with anthelmintics as compared with 87.5% of CONT or 71.9% of SSHP lambs. In all 3 studies, supplementation of DDGS reduced parasitism and improved weaned lamb growth rates on pasture.

Key words: distillers grains, parasites, lambs

T401 Feeding North American panicled tick-clover containing condensed tannins to growing goats reduces *Haemonchus contortus* infection. N. M. Cherry[1], B. D. Lambert*[1,2], J. P. Muir[1], M. Bullinger[2], J. E. Miller[3], R. M. Kaplan[4], and T. R. Whitney[5], *[1]Texas Agrilife Research, Stephenville, [2]Tarleton State University, Stephenville, TX, [3]Louisiana State University, Baton Rouge, [4]The University of Georgia, Athens, [5]Texas Agrilife Research, San Angelo.*

A major obstacle for goat production, especially in warm humid and sub-humid regions, is gastrointestinal nematodes, specifically *Haemonchus contortus* (HC; barberpole worm). Recent concern over resistance to commercial anthelmintics has led to the search for other ways to suppress HC populations. Condensed tannins (CT) from *Lespedeza cuneata* (sericea lespedeza, SL) have proven effective in suppressing HC but this legume cannot be grown in some edapho-climatic conditions or situations in which aggressive exotics are not ideal. So the search for native legumes that contain equally effective CT while still providing crude protein (CP) continues. In this study alfalfa, SL and a native North American herbaceous legume *Desmodium paniculatum* (panicled tick-clover; PTC) were pelleted into a complete feed that contained 3.94% CT, 18% CP and 2.8 Mcal/kg digestible energy and fed to goats at 3.5% of their body weight. At d 0 average fecal egg counts (FEC) for all infected animals was 2190; by d 14, FEC in kids fed PTC were 2976 and by d 28 FEC were 2665 compared with 4920 and 4560 for infected alfalfa on d 14 and 28, respectively. By d 28 FEC for infected animals fed SL and PTC were not different from each other but were 44% lower than infected animals in the alfalfa treatment. Packed cell volumes throughout the trial were not different among goats fed SL, PTC, or alfalfa. Results indicate that the North American native legume panicled tick-clover has potential as an HC suppressant.

Key words: *Haemonchus contortus*, condensed tannin, panicled tick-clover

T402 Demographic factors of meat goat producers completing an online certification program. T. A. Gipson*, R. C. Merkel, and T. Sahlu, *American Institute for Goat Research, Langston Univ., Langston, OK.*

In 2006, an online training program for meat goat producers was unveiled, consisting of 22 learning modules (http://www2.luresext.edu/goats/training/qa.html). Participants take a pre-test for each module and if a score of 85% or greater is recorded, the post-test is not required. If required, participants may retake the post-test until a passing score of 85% or greater is achieved. For certification, passing scores are required on all 16 required modules and a minimum of 3 elective modules. Demographic data are collected upon enrollment. Participants had the option of not responding to certain demographic questions and those observations were removed from this analysis. As of the end of 2010, 198 of 1,430 enrollees successfully completed the certification program, with 182 from the US and 16 from foreign countries. For those 182 certified in the US, a higher percentage (62%, $\chi^2 = 143.2$, $P < 0.01$) was from the South than from any other region, followed by 22, 12, and 4% from the Midwest, West, and Northeast, respectively. All certified producers reported their gender and there were more males (60% vs. 40%, $\chi^2 = 8.1$, $P < 0.01$) than females. Of the certified, 92% responded to the question on race, and an overwhelming percentage classified themselves as white (89%, $\chi^2 = 686.5$, $P < 0.01$ for equal proportions); however, this is similar to the US population as a whole (89% vs. 80%, $\chi^2 = 0.1$, $P = 0.73$). The response to a question on farm size was 88%; 9% owned <2 ha, 43% 2–8 ha, 14% 9–16 ha, 13% 17–32 ha, 9% 33–65 ha, 8% 66–130 ha, and 4% > 130 ha ($\chi^2 = 162.5$, $P < 0.01$). An 84% of the certified responded to a question on occupation; 78% were part-time farmers and 22% were full-time ($\chi^2 = 53.2$, $P < 0.01$). The response of those certified to a query on herd size was 82%, with 46% owning less than 25 goats, 29% 25–49, 16% 50–99, 6% 100–250, and 3% greater than 250 ($\chi^2 = 103.9$, $P < 0.01$). Demographics indicate that the typical certified participant is a white male living in the southern US and farming part-time with less than 25 goats on 2–8 ha.

Key words: goats, online, training

T403 Variability among enumerators in assigning body condition scores in meat goats. R. C. Merkel* and T. A. Gipson, *Langston University, Langston, OK.*

Body condition score (BCS) is a subjective measure of an animal's condition. In research settings, teams of 3 enumerators determine a true BCS, defined as the median score. The variability among team member scores in determining an animal's true BCS is not well studied. Twenty-four Spanish (28 – 40 wk of age; 26.6 ± 4.43 kg) and 28 predominately Boer (B) blood (24 - 75%B, 4 – 100%B; 33 – 46 wk of age; 33.9 ± 6.99 kg) wethers were allocated to 4 groups having equal breed numbers. Goats were raised on pasture with unlimited access to alfalfa hay with 2 groups consuming either 0.5% or 1.5% BW of a pelleted diet (16% CP, 29% ADF, 60% TDN). BCS (1 = very thin, 5 = obese, 0.25 increments) was taken bi-weekly by the same 3 enumerators with the median value recorded as the true BCS. A total of 1728 observations (576 per enumerator) were recorded. Data was analyzed using repeated measures. The repeatability score was 0.6 ± 0.05. Median BCS and percent of individual scores at the median, respectively, for the BCS given throughout the trial were 2.0, 0.35; 2.25, 1.56; 2.5, 25.0; 2.75, 43.4; 3.0, 20.0; 3.25, 5.9; and 3.5, 3.8 ($\chi^2 = 107.1$, $P < 0.01$). On the same animal at the same time, all enumerators gave the same BCS 37.9 and 2 of the 3 enumerators agreed 56.4% of the time. When only 2 enumerators agreed, enumerators A and B, B and C, and A and C agreed 24.3, 17.7, and 14.4% of the time, respectively. In only 5.7% of animals were all 3 scores different. All scores were either at the median, 0.25 above, 0.25 below, 0.5 above, or 0.5 below (77.4, 10.8, 11.2, 0.23, and 0.46%, respectively; $\chi^2 = 166.2$ $P < 0.01$ for equal distribution). In no instance did an individual score deviate from the median by 0.75 of a score. Results show close agreement in assigning BCS to growing meat goats with 99.4% of scores given by enumerators either at or within 0.25 of the median score. In 94.3% of animals scored by 3 enumerators, at least 2 scores were at the median whereas combinations of 2 enumerators giving the same score ranged from 52.3 to 62.2%. Data confirms that 3 enumerators are preferable to 2 in determining an animal's true BCS.

Key words: body condition score, meat goats

T404 Comparative effect of implants with trenbolone-estradiol or zeranol on feedlot-performance of Katahdin × Pelibuey hair-lambs. B. Ortiz*[1], A. Camacho[1], N. E. Villalba[2], L. R. Flores[1], J. J. Lomeli[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Agricola Ganadera Mojolo, Culiacán, Sinaloa, México.*

The objective of this study was to compare the effect of trenbolone-estradiol and zeranol implants on feedlot-performance of Katahdin × Pelibuey lambs. Thirty-six lambs 3/4 Katahdin × 1/4 Pelibuey (24.23 ± SE 0.67 kg of initial BW) were assigned to 1 of 3 treatments. In groups of 3, lambs were placed in elevated (0.6 m) plastic floor pens (0.9 × 1.9 m). In a completely randomized block design lambs were assigned to next treatments: 1) Feeding with a 95% concentrate corn-canola meal based diet (14.2% CP; 2 Mcal of NEm/kg) without hormonal implant (CTRL); 2) Diet similar to CTRL and implanted with 12 mg of zeranol (one pellet of Ralgro implant; Intervet Schering-Plough Animal Health); and 3) Diet similar to CTRL and implanted with 40 mg of trenbolone acetate and 8 mg of estradiol (2 pellets of Component-TES; ELANCO). Lambs were weighed on d 28 and 49. During first 28 d, lambs implanted with trenbolone-estradiol were 8.5% heavier ($P = 0.02$), gain 27.8% more weight ($P = 0.03$), and had a gain/feed ratio 14% higher ($P = 0.05$) than CTRL. Zeranol was not different from the other 2 treatments ($P > 0.10$). From d-29 to 49, there was not effect of treatments ($P > 0.10$). Over the complete 49-d experiment, lambs implanted with trenbolone-estradiol gain 18.9% more weight than CTRL ($P = 0.04$). Zeranol implant did not show any effect ($P > 0.10$). It is concluded, that trenbolone-estradiol implants are better option than zeranol implants to promote feedlot performance of Katahdin × Pelibuey hair-lambs.

Key words: feedlot-performance, lambs, trenbolone

T405 Influence of zeranol implant on performance of Dorper × Katahdin feedlot lambs. B. Ortiz*[1], A. Camacho[1], N. E. Villalba[2], L. R. Flores[1], J. J. Lomeli[1], J. A. Romo[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]Agricola Ganadera Mojolo, Culiacán, Sinaloa, México.*

With the objective to determine the influence of zeranol implant on performance of feedlot lambs. A 35-d feedlot experiment was performed. Twenty-four lambs ¾ Dorper × ¼ Katahdin with 29.23 ± SE 0.87 kg of initial weight were used. In groups of three, lambs were placed in elevated (0.6 m) plastic floor pens (0.9 × 1.9 m) fitted with automatic drinker. Animal were blocked by weight, and in agreement with a completely randomized block design were assigned to 1 of 2 treatments: 1) Feeding with a 95% concentrate corn-canola meal based diet (14.18% CP; 2.002 Mcal of NEm/kg) without hormonal implant (CTRL); or 2) Diet similar to CTRL and ear implanted with 12 mg of zeranol. Commercial presentation of Ralgro implant cartridge (Intervet Schering-Plough Animal Health) contains 36 mg of zeranol (12 mg by each pellet). One Ralgro pellet was used to obtain the dosage of 12 mg of zeranol. Lambs were feed ad libitum. Final weight was not affected ($P > 0.20$) by implant (38.8 vs. 40.5 kg). Average daily gain was improved 20% ($P = 0.06$) by zeranol implant 273 vs. 329 g/d for CTRL and Zeranol, respectively. Dry matter intake (1.23 ± SE 0.03 kg/d) was not affected by treatments ($P > 0.20$). Lambs that received zeranol implant showed a feed/gain ratio 25% higher ($P = 0.02$) than non implanted lambs. It is concluded that implantation with 12 mg of zeranol is enough to improve feedlot performance of Dorper × Katahdin feedlot lambs

Key words: feedlot-performance, lambs, zeranol

T406 Seasonal changes in chemical composition of Hungarian raw goat′s milk. L. Varga*, *Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyarovar, Hungary.*

The aim of this research was to monitor the changes in chemical composition, acidity, and freezing point of raw caprine milk during lactation, from milking to refrigerated storage, on a Hungarian dairy goat farm. The herd involved in the study consisted of approximately 200 goats belonging to a Hungarian native breed. The following sampling locations were selected: (i) individual animals, (ii) milk sampling unit in pipeline, (iii) milk flowing from pipeline into refrigerated bulk tank, and (iv) refrigerated bulk tank. Four samples were taken each time at each sampling location, and samples were collected biweekly over a 7-mo period from May through November. The data was subjected to ANOVA using the general linear model procedure of Statistica data analysis software system, version 9.1 (StatSoft Inc., Tulsa, OK). Significant differences among the means were determined by using Duncan′s multiple comparison test at $P < 0.05$ (StatSoft). A total of 216 sample units were tested. In terms of all the chemical components analyzed, decreased values were found in the samples compared with the average gross composition of goat′s milk. Fat and protein contents

were especially low in the first 5 mo of the study, and the concentrations of these components were not influenced ($P > 0.05$) by the sampling location. Similarly, lactose levels were rather low with values ranging from 4.1% to 4.3% (w/w) all through the study. It is worth mentioning, however, that the raw goat milk samples collected contained no extraneous water and their pH was mostly acceptable. The low freezing points, together with the low lactose contents, suggested that the milk produced by Hungarian native goats must have contained high levels of minerals. In conclusion, because profitability of milk production and processing largely depends on the fat and protein contents of raw milk, the levels of these components need to be increased by genetic improvement and nutrition of goats.This work was supported by the National Development Agency of Hungary (Project No.: TÁMOP-4.2.1.B-09/1/KONV-2010-0006).

Key words: goat milk, chemical composition, freezing point

T407 Examination of microbiological and physicochemical quality of raw materials and end products during manufacture of cheeses from caprine and ovine milk. L. Varga*, *Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyarovar, Hungary.*

In Hungary, over 99% of the raw milk processed commercially is bovine milk. Only a few thousand tonnes of milk are produced annually by small ruminants. The majority of ovine and caprine milk is processed into various types of cheese, which have gained popularity among Hungarian consumers in recent years. For this reason, the purpose of the present study was to monitor the manufacturing process of semi-hard cheeses made from sheep and goat milk in a small-size cheesemaking factory located in the northwestern part of the country. Raw bulk milks were analyzed for aerobic mesophilic microorganisms, coagulase-positive staphylococci, inhibitory substances, total solids, fat, protein, lactose, solids-non-fat, pH and freezing point. In addition to detection of *Salmonella* spp. and *Listeria monocytogenes*, viable counts of the following microorganisms were enumerated in pasteurized milk and cheeses: coliforms, *Escherichia coli*, yeasts, molds, coagulase-positive staphylococci, and mesophilic sulfite-reducing clostridia. Pasteurized milk samples were also tested for the same physicochemical attributes as raw bulk milk samples. As for cheese samples, total solids and fat measurements were made. The results showed that the overall microbiological quality of raw goat milk was slightly better than that of raw sheep milk; however, total plate counts and coagulase-positive staphylococci counts were rather high in both types of milk. The mean protein content of caprine milk was as low as 2.99%, which should be considerably increased by breeding and feeding methods. By contrast, ovine milk had a mean protein level of 6.94%. None of the raw milk batches processed contained extraneous water because their freezing point was well below −0.520°C in each case. In conclusion, both raw goat and sheep milk were effectively heat-treated and this, together with the proper implementation of manufacturing technology, resulted in high quality and microbiologically safe finished products. This work was supported by the National Development Agency of Hungary (Project No.: TÁMOP-4.2.1.B-09/1/KONV-2010–0006).

Key words: goat milk, sheep milk, cheese

T408 Milk yield and milk composition of ewes fed diets with canola oil or linseed oil. C. P. Nolli*, I. Susin, A. V. Pires, M. O. Maia, E. M. Ferreira, R. S. Gentil, and D. Eysink, *University of São Paulo/ESALQ, Piracicaba, SP, Brazil.*

Sheep rations have a diversity of sources and some ingredients can improve animal growth and product quality. Additionally, vegetable oils can modify milk fatty acid profile and are an alternative to achieve nutritional requirements, especially in early lactation. Thirty 3 Santa Inês ewes (63.9 ± 9.3 kg BW and 12 ± 2 DIM) were penned individually and assigned to a randomized complete block design to determine the effects of adding canola or linseed oil on lactation performance. Ewes were fed a basal diet (13% CP and 54% NDF, DM basis) containing 50% concentrate and 50% coastcross hay. The experimental treatments included control (0% oil, CONT), canola oil (3% oil, CAN) or linseed oil (3% oil, LIN). Ewes were fed the diets from wk 2 to 8 of lactation. Milk production was determined every 7 d during the experiment. Ewes were separated from lambs, oxytocin (10 IU) was infused i.v. to stimulate milk letdown and ewes were mechanically milked. After 3 h the procedure was repeated, milk production recorded and a sample collected for milk composition analysis. Ewes were weighed for 3 consecutive days at the start and at the end of the experiment. Data were analyzed using the MIXED procedure of SAS and means compared by Tukey Test. No effect was observed on DMI among treatments (2.5, 2.2 and 2.3 kg/d for CONT, CAN and LIN, respectively). Milk production in 3 h (177, 164 and 152 g for CONT, CAN and LIN, respectively), milk fat, milk protein and total solids were not different ($P \geq 0.05$) among diets. Final BW was greater for LIN fed ewes compared with CAN fed ewes (64.9, 63.5 and 69.4 kg for CONT, CAN and LIN, respectively). Adding 3% of canola oil or linseed oil in diets had no detrimental effect on DMI, milk yield and milk composition of ewes.

T409 The mammary gland of the Canarian dairy goats undergone two different milking frequencies: morphological characterization of the tissular components. A. Suarez-Trujillo[1], J. Capote[2], A. Arguello[1], A. Arencibia[1], N. Castro[1], J. Morales[1], and M. A. Rivero*[1], *[1]Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Instituto Canario de Investigaciones Agrarias, La Laguna, Tenerife, Spain.*

The morphological characteristics of the tissular components of the mammary gland in Canarian dairy goats were studied. Furthermore, the influence of the milking frequency on the histological composition of the mammary parenchyma was determined. The udders of 9 goats of the 3 autochthonous breeds of the Canary Islands (Majorera, Tinerfeña and Palmera) were milked at different frequencies: right half udder was milked twice a day and left half udder was milked once a day. Two samples of each gland were obtained and histologicaly processed. The samples were photographed randomly choosing different fields, which were processed by morphometric analysis software (Image-Pro plus 4.5). The tissular components measured were the secretor tissue, connective tissue, excretor tissue and vascular tissue. In Majorera goats parenchyma the major percentage of tissue are secretor tissues, and the connective tissue was observed in a higher percentage in Tinerfeña goats than in the other studied breeds. No difference was observed between the 2 milking frequencies. We conclude that the use of once daily milking or twice daily milking does not have consequences on the histological structure of the mammary gland. However, the 3 Canary dairy goats have different tissular percentages, which could explain their distinct milk yield.

Key words: goat kid, mammary gland, milking frequency

T410 Effects of Actigen on peripheral blood immune cells in pigs experimentally infected with porcine reproductive and respiratory syndrome virus (PRRSV). T. M. Che*[1], M. Song[1], R. W. Johnson[1], K. W. Kelley[1], W. G. Van Alstine[2], K. A. Dawson[3], and J. E. Pettigrew[1], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Animal Disease and Diagnostic Laboratory, Purdue University, West Lafayette, IN, [3]Research, Alltech Biotechnology Center, Nicholasville, KY.*

This study evaluated effects of Actigen (ACT, a mannan preparation, Alltech, Inc.) on peripheral blood immune cells in pigs infected with PRRSV. Pigs (n = 64, 21 d old), free of PRRSV, were divided into uniform blocks on the basis of initial BW within sex. They were randomly assigned from within blocks to 1 of 4 treatments in a 2 × 2 factorial arrangement [2 types of diet: control (0%) and ACT addition (0.04%); 2 levels of PRRSV: with and without]. Sex and ancestry were equalized across treatments. Pigs were penned individually and considered experimental units. After 2 wk of an 8-wk period of feeding the treatments, pigs were intranasally inoculated with PRRSV or a sterile culture medium (Sham) at 5 wk of age. Subsets of blood leukocytes (n = 8/treatment) were measured by flow cytometry at d 0, 3, 7 postinoculation (PI), and subsequently weekly until d 42 PI. Data were analyzed as repeated measures over time using the MIXED procedure of SAS. The numbers of leukocyte subsets in the infected pigs markedly decreased at d 3 to 7 PI, increased at d 14 to 28 PI and started declining by d 35 PI. Overall, PRRSV infection increased the numbers of total leukocytes ($P < 0.03$), neutrophils ($P < 0.001$), natural killer cells ($P = 0.051$) and several T cell subsets ($P < 0.01$) as compared with Sham. There were significant effects of day ($P < 0.001$) and day x PRRSV interaction ($P < 0.05$) on subsets of leukocytes during the course of study. Dietary ACT increased ($P < 0.05$) the numbers of total leukocytes (16.5 vs. 15.2 × 10^6/mL), B cells (1.7 vs. 1.4 × 10^6/mL), cytotoxic T cells (2.0 vs. 1.7 × 10^6/mL) and γδ T cells as compared with the control. The diet x PRRSV interaction did not affect the numbers of total leukocytes or any subsets of immune cells. Briefly, feeding ACT to pigs results in increased peripheral blood leukocytes, B cells, and T cell subsets which may be beneficial, especially in bacterial co-infections. In addition, changes in subpopulations of immune cells over the experimental period would be a useful index of on-going processes of PRRSV infection and for designing future treatment approaches.

Key words: Actigen, pigs, PRRSV

T411 Effects of dietary multi-carbohydrases on growth performance, nutrient digestibility and blood characteristics in finishing pigs. J. P. Wang*, X. Y. Guo, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

The objective of this research was to evaluate the effect of multi-carbohydrases on growth performance, nutrient digestibility and blood characteristics in finishing pigs. A total of 100 crossbred barrows (initial body weight = 56.2 ± 1.3 kg) were randomly allotted to 1 of 5 treatments by their BW and litters (5 replicate pens per treatment, 4 pigs per pen). Treatments included: 1) CON (barley-soybean basal diet), 2) MIX (CON + 0.05% Mixture(α-galactosidase: β-mannanase = w1:w1), 3) MAN (CON + β-mannanase 0.05%), 4) GB1 (CON + 0.05% enzyme complex) and 5) GB2 (CON + 0.1% enzyme complex). The enzyme complex contained protease 2,601 U/g, amylase 7,716 U/g, cellulase 5,204 U/g, xylanase 799 U/g and α-galactosidase 176 U/g. During the 5 week trial, pigs fed MIX, GB1 and GB2 diets had higher ADG than that of CON treatment group ($P < 0.05$). There were no differences in ADFI and G:F among the treatments. Apparent total tract nutrient digestibility (ATTD) of DM and energy were increased by the MIX, GB1, and GB2 treatments as compared with the CON and MAN treatment ($P < 0.05$). Nitrogen digestibility in GB2 treatment was greater than that of the CON and MAN treatment group ($P < 0.05$). No differences in blood glucose, red blood cells (RBC), white blood cells (WBC), lymphocyte percentage and Immunoglobulin-G (IgG) concentration were observed among the treatments. After the feeding period, meat samples from pigs which reached marketing BW were collected from the slaughter house. No numerical differences were observed in backfat thickness, meat color, pH value and water holding capacity (WHC) among 4 treatments. In conclusion, the addition of α-galactosidase, along with β-mannanase or multi-carbohydrases can improve ADG and nutrient digestibility more than single enzyme supplementation in barley soybean based diet of finishing pigs.

Key words: α-galactosidase, β-mannanase, finishing pigs

T412 Effects of a natural feed additive in comparison to an antibiotic treated group to prevent gram-negative associated diseases in pigs. S. Schaumberger*[1], S. Masching[2], A. Ganner[1], and G. Schatzmayr[1], *[1]Biomin Research Center, Tulln, Austria, [2]Biomin Holding, Herzogenburg, Austria.*

Aim of this study was to prove the positive effect of a feed additive containing a yeast-derivate, a clay mineral and a plant extract on health status (diarrhea incidence) and performance of weaning piglets compared with a positive antibiotic treated group. 90 weaning piglets were chosen from 15 litters and randomly assigned to 3 groups (A, B, C) with 3 replications each. Group A was fed the standard diet without additive; Group B was fed the control diet and additionally received 100 mg Colistin/liter drinking water for the first 21 d of the trial; Group C was supplied with 0.2% of the feed additive over the whole trial period. Incidences of diarrhea were recorded daily. Weight of each single animal was recorded at the beginning, at d 14, 21, 42 and 56. The amount of feed distributed, feeding frequency and mixing ratio were recorded automatically per pen and day. All data generated out of the trial was subjected to statistical analysis by means of PASW 18.0 (formerly SPSS Statistics). On d 56 weight of piglets of group C was improved with a statistical difference of $P = 0.019$ compared with the control group. Daily weight gain (DWG) (d 1 to 56) showed significant differences ($p = 0.007$) between groups A and B and A and C. For feed conversion rate (FCR) and feed intake no statistical differences could be observed, but for group C FCR (1.77) was lower compared to groups A (1.83) and B (1.88). On day 7 single incidences of diarrhea occurred in some pens and lasted for 13 days in varying intensities: group A showed diarrhea for 8 days, group B for 7 days and group C only for 4 days. Conclusion of our study was that a feed additive consisting of specific clays capable of binding endotoxin, yeast derivates binding gram negative bacteria as well as acting anti-inflammatory and plant extracts with pro-inflammatory properties have a synergistic effect in vivo since in our study performance was enhanced and diarrhea incidence reduced.

Key words: piglet, feed additive, performance

T413 Effects of feeding Actigen on ex vivo immune responses of porcine leukocytes. T. M. Che*[1], R. W. Johnson[1], K. W. Kelley[1],

K. A. Dawson[2], and J. E. Pettigrew[1], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Research, Alltech Biotechnology Center, Nicholasville, KY.*

An experiment was conducted to evaluate whether feeding Actigen (ACT) to nursery pigs subsequently alters cytokine secretion, gene expression of cell receptors and phagocytic activity of leukocytes. Weaned pigs were blocked on the basis of initial BW within sex. Pigs (n = 6/treatment) were fed the control or 0.04% ACT diet for 2 wk and then euthanized for sample collection. Bronchoalveolar lavage cells (BALC) and peripheral blood mononuclear cells (PBMC) were stimulated in vitro with medium as a control, lipopolysaccharide (LPS; 1 μg/mL), or polyinosinic:polycytidylic acid (Poly I:C; 50 μg/mL) and incubated 24 h. Supernatants were collected for measurements of tumor necrosis factor (TNF)-α, IL-1β, interferon (IFN)-γ and IL-10. Gene expression of mannose receptor (MR), toll-like receptor (TLR) 3 and TLR4 in BALC only was measured using qRT-PCR. Phagocytic activity of BALC and whole blood polymorphonuclear cells (PMNC) were determined by flow cytometry. Data were analyzed as a randomized complete block design using the MIXED procedure of SAS. Dietary ACT increased TNF-α secretion by BALC, in response to in vitro microbial stimulations, as compared with the control (17.4 vs. 12.1 ng/mL; $P < 0.05$). Microbial stimulators increased BALC-produced TNF-α and IL-1β as compared with the control ($P < 0.001$). There was a diet x stimulator interaction for IL-1β ($P < 0.03$), as feeding ACT increased IL-1β production by BALC stimulated by Poly I:C (2.7 vs. 1.5 ng/mL; $P < 0.04$), but not in those cells stimulated by LPS. Cytokines produced by PBMC were not different among the treatments. There was a diet x stimulator interaction ($P < 0.05$) for expression of both MR and TLR4 genes, similar in pattern to the production of IL-1β. The expression of TLR3 gene was not detectable at 24-h postincubation. Dietary ACT enhanced the percentage of phagocytic PMNC as compared with the control (86 vs. 77%; $P < 0.01$). Briefly, these results suggest that ACT appears to have a greater immunomodulatory effect in response to a viral model than in response to a bacterial model. It may bring benefits by enhancing the proportion of phagocytic PMNC.

Key words: Actigen, immune response, pigs

T414 Effects of multiple sources and levels of dietary fiber on apparent total tract dry matter digestibility, growth performance, and concentration of fermentation indices in pigs. A. Woldeghbriel, S. Smith*, T. Barrios, and B. Bishop, *North Carolina Agriculture and Technical State University, Greensboro.*

Two experiments were conducted to investigate the effects of sources and levels of dietary fiber (DF) on apparent total tract digestibility (ATTD), growth performance, and concentration of fermentation indices in pigs. In Exp. 1, 16 barrows averaging 16 kg were randomly assigned to 1 of 4 diets after metabolic crate assignments with individual pig serving as the experimental unit. The pigs had free access to water, but feed allowance was limited to 10% of average body weight, fed twice d-1. The study period was split into 10d of adjustment, and 5d of urine and feces collection. In Exp.2, pigs (n = 96; 16.4 kg) were randomly assigned to 16 pens (6/pen; 2 pen/diet) and fed their respective diets for 70 d. Diets used include: corn-soybean based control (C), and 3 antibiotic-free diets (D1, D2, and D3) each containing 5% sugar beet pulp plus, a 1:2, 1:1, and 2:1 oats to barley ratio as sources of DF, respectively. The diets were isonitrogenous (18% CP) and isocaloric (3.415 Mcal DE/kg) supplemented with vitamins and minerals to meet nutrient requirements. Average daily feed intake and body weight gain of pigs that were fed D2 and D3 were higher ($P < 0.05$) than the C or the D1 feed pigs. Pigs that were fed diets containing higher proportions of oats were more efficient than the remaining groups. Fermentation indices, pH and VFA concentrations in particular were lower ($P < 0.05$) in pigs fed the C diet, and particularly in the distal colon. In general, pigs that were fed antibiotic-free, high-fiber diets performed better than pigs fed the control diet. This study demonstrates the potential benefits of adding different sources and levels of DF to the antibiotic-free diets of growing pigs. However, further work needs to be done to better understand the mode of action of DF from multiple sources and levels of fiber in the diet.

Key words: dietary fiber, growing pigs, antibiotic-free

T415 Addition of bee pollen to the sow feed and effects on body weight of piglets. C. H. Casillas-Gómez*, I. J. Ruíz-García, and J. R. Orozco-Hernández, *Departamento de Cienicas Biológicas, Centro Universitario de Los Altos, Universidad de Guadalajara, Twepatitlan de Morelos, Jalsico, Mexico.*

The first days of the piglets life is spent depending on the quality of the mother's milk to obtain nutrients and growth promoters as well as the immunity system. Multiparous (Pietrain × York + Landrace) sows lodged under commercial conditions were used to assess 3 levels of bee pollen (0, 31, 62, or 93 g/d) in the diet and the impact on the piglet performance before weaning. Piglet cumulative weight gain averaged 4.490 kg, and was affected by the addition of pollen to the sow's diet ($P < 0.05$; 5.116, 4.598, 3.504, and 4.109 kg for 0, 31, 62 and 93 g of pollen/day, respectively). Therefore, the addition of pollen to the sow's diet had a negative effect ($P < 0.05$) on the daily gain of weight (243, 219, 167, 196 g, for 0, 31, 62 and 93 g of pollen/day, respectively). Mortality was quite similar among treatments ($P > 0.05$). Based on the results it could be concluded that with the addition of bee pollen to the sow's diet had an adverse effect on the piglets before weaning.

Key words: bee pollen, sow, piglet

T416 Effects of thermal stress on liver xenobiotic metabolism gene expression in swine. J. A. Madden*, S. C. Pearce, N. K. Gabler, L. H. Baumgard, and A. F. Keating, *Department of Animal Science, Iowa State University, Ames.*

Thermal stress compromises intestinal integrity in growing pigs, resulting in increased circulating endotoxin concentrations and reduced pig performance. Thus, the study objective was to examine the effect of thermal stress on hepatic detoxification metabolism gene expression in growing *Sus scrofa*. Crossbred gilts (n = 48; 35 ± 4 kg BW) were housed in constant climate controlled rooms in individual pens and exposed to 1) thermal neutral (TN) conditions (20°C; 35–50% humidity) with ad libitum feed intake (n = 18), 2) HS conditions (35°C; 20–35% humidity) with ad libitum feed intake (n = 24) or 3) pair-fed (PF in TN conditions [PFTN], n = 6: to eliminate confounding effects of dissimilar feed intake [FI]). Animals were sacrificed at 1 or 7d of environmental exposure. RNA was isolated from the hepatic caudate lobe and RT-PCR used to quantify hepatic xenobiotic metabolism gene expression. Genes investigated were: 1) acyloxyacyl hydrolase (Aoah) – required for LPS deacylation, 2) aromatic hydrocarbon receptor (Ahr) and 3) NF-E2-related factor 2 (Nrf2) – transcription factors that regulate metabolism gene expression, 4) cytochrome P450 isoform 1A1 (Cyp1a1) – member of the cytochrome P450 family of enzymes with a wide substrate range and 5) glutathione S-transferase isoform mu (Gstm) – an enzyme that catalyzes xenobiotic glutathione conjuga-

tion. Compared with the TN pigs, there was no effect of HS on liver Aoah, Nrf2 or Gstm mRNA abundance. In contrast, relative to TN, HS decreased liver Ahr ($P = 0.05$) and Cyp1a1 ($P = 0.12$) mRNA expression on d7. There was also a decrease in both hepatic Ahr and Cyp1a1 mRNA expression over time in HS animals compared with the TN and PFTN pigs ($P < 0.10$). In conclusion, these data suggest that despite thermal stress-induced increased endotoxin concentrations, hepatic detoxification enzyme mRNAs are not upregulated. In fact, both Ahr and Cyp1a1 hepatic expression are decreased and this may indicate liver dysfunction and inadequate detoxification capability

Key words: heat stress, toxicology, liver

T417 Effect of sex and housing density on growth performance, carcass quality, and fatty acid profile of pigs slaughtered at 110 kg BW. J. I. Morales[1], M. P. Serrano[1], L. Cámara[1], J. D. Berrocoso[1], C. J. López-Bote[2], J. P. López[3], and G. G. Mateos*[1], *[1]Universidad Politécnica de Madrid, Madrid, Spain, [2]Universidad Complutense de Madrid, Madrid, Spain, [3]Copiso S.A., Soria, Spain.*

In total, 228 crossbred pigs (61 d of age) were used to study the effects of gender and housing density on growth performance, carcass quality, and fatty acid (FA) profile of the internal fat of m. gluteus medius (GM) in 110 kg BW pigs. There were 2 genders (gilts and barrows) and 2 rearing densities (0.84 and 0.76 m^2/pig) forming a 2 × 2 factorial. Each treatment was replicated 6 times (a pen with 10 or 9 pigs depending on tretament). For the entire experimental period, barrows had poorer (2.63 vs. 2.51; $P \leq 0.01$) F:G ratio than gilts. An interaction between sex and density were observed for ADFI and F:G ratio; both variables were improved in gilts as the space allowance decreased whereas the opposite effect was observed for barrows ($P \leq 0.05$ for the interaction). No differences among treatments were found for carcass yield and pH_{24} h postmortem. Furthermore, density did not affect any of the carcass quality traits studied. Trimmed ham (13.3 vs. 13.0%) and loin (5.96 vs. 5.67%) yield were higher ($P \leq 0.001$) for gilts than for barrows. Treatment did not affect palmitic acid, stearic acid, or polyunsaturated FA concentration in GM fat. However, oleic acid content was higher (43.8 vs. 42.6%; $P \leq 0.05$) for pigs reared at the higher density and linoleic (10.0 vs. 9.3%) and oleic (43.9 vs. 42.4%) acid content were higher ($P \leq 0.01$) for gilts than for barrows. In conclusion, fat from GM from pigs reared at 0.76 m^2/pig had more monounsaturated FA content than fat from pigs reared at 0.84 m^2/pig. Also, fat from gilts had more monounsaturated FA content than fat from barrows. We concluded, that under the conditions of the present experiment, a density of 0.84 m^2/pig for gilts and of 0.76 m^2/pig for barrows is recommended. Sex and space allocation affected the FA profile of pigs slaughtered at 110 kg BW.

Key words: carcass quality and fatty acid profile, housing density, pig performance

T418 Productive performance and carcass quality of gilts and surgically and immune-castrated male pigs from crossbreds of Duroc and Pietrain sire lines. J. I. Morales[1], M. P. Serrano[1], L. Cámara[1], J. D. Berrocoso[1], J. P. López[2], and G. G. Mateos*[1], *[1]Universidad Politécnica de Madrid, Madrid, Spain, [2]Copiso S.A., Soria, Spain.*

The influence of gender [intact females (IF), surgically castrated males (CM), and immune-castrated males (IMC)] and terminal sire line [Duroc (DU) and Pietrain (PI)] on growth performance and carcass quality was studied in pigs from 23.5 to 134 kg BW. The female line used was Large White × Landrace in all cases. Each treatment (3 × 2) was replicated 5 times (a pen with 10 pigs). The CM were castrated at 4 d of age and the IMC pigs were immunized against GnRF at 87 and 137 d of age (34 d before slaughter). Backfat thickness at P_2 and intramuscular fat (ITMF) at Longissumus dorsi were recorded. The IMC and CM had higher (1.08 vs. 1.08 vs. 1.02 kg/d; $P \leq 0.001$) ADG than IF. Furthermore, CM ate more feed (2.59 vs. 2.36 vs. 2.35 kg/d; $P \leq 0.001$) than IMC and IF. Consequently, IMC had better (2.17 vs. 2.40 vs. 2.31; $P \leq 0.001$) F:G ratio than CM, with IF being intermediate. Carcass yield was lower for IMC than for IF and CM (76.4 vs. 78.9 and 78.3%; $P \leq 0.001$). Trimmed ham and loin yields were higher ($P \leq 0.001$) for IF than for IMC and CM. The CM had more (28.6 vs. 26.7 vs. 26.1 mm; $P \leq 0.001$) BF than IF and IMC, and ITMF was lower (3.5 vs. 3.9 vs. 3.7%; $P \leq 0.05$) for IF than for CM, with IMC being intermediate. No differences were found between sire lines for carcass yield but crossbreds from PI had more ($P \leq 0.001$) trimmed ham and loin yields than crossbreds from DU. The ITMF was higher ($P \leq 0.001$) for DU crossbreds than for PI crossbreds. We conclude that IMC were more efficient but had lower carcass yield than CM and IF. Furthermore, IF have better carcass quality than IMC and CM and ITMF content is similar from IMC and CM. Crossbreds from PI sires have better carcass quality but poorer BW gain and meat quality traits than crossbreds from DU sires. Therefore, IMC and crossbreds from DU are preferred for the production of heavy pigs destined to the dry-cured industry.

Key words: productive performance and carcass quality, immune-castration, sire lines

T419 Fatty acid composition of piglet tissues changes during suckling time. M. Sini, A. Nudda, G. Pulina, S. P. G. Rassu, and G. Battacone*, *Dipartimento di Scienze Zootecniche, Università Degli Studi di Sassari, Sassari, Italy.*

Aim of this work was to determinate the fatty acid (FA) evolution in different tissue of piglets during the suckling time. Litters of 3 sows similar for age, parity and breed (L × LW), and inseminated with the same Landrace boar semen, were used. Starting a week after parturition one piglet from each litter was stunned, exanguinated, and eviscerated each week. Brain, liver, and skeletal muscle samples were removed from 4 piglets per sow. Fatty acid (FA) composition of total lipid extract from each tissue was determined by gas chromatography. Concentration of each FA was expressed as percentage of total FA. Data were analyzed with ANOVA to detect difference in FA composition between tissue during the suckling period. The mean of saturated fatty acid (SFA) increased during the sucking time, mainly due to the increase of C16:0 which represent about 50% of the total SFA. The mean values of unsaturated (UFA) and monounsaturated (MUFA) fatty acid and the PUFA-n3 decreased during the suckling time. FA composition differed significantly within tissues during the suckling time. In brain, the SFA decreased during suckling period, whereas SFA increased in liver and muscle. Conversely, UFA and MUFA increased in brain and decreased in liver and muscle. This leads to a significant decrease in relationships MUFA/SFA and SFA/UFA. These results confirm that the FA composition of the fat differed within the suckling time and suggest that the FA source in the diet must be adequate to support the growing piglets requirements.

Key words: fatty acid, piglet, tissues

T420 Opinions of farm versus urban freshman college students on issues involving animal agriculture before and after animal science instruction. E. A. Bobeck*, D. K. Combs, and M. E. Cook, *University of Wisconsin-Madison, Madison.*

Increasingly, incoming university animal science majors have urban demographics with no history of direct contact with farm animals and no or neutral opinion regarding issues facing animal farming. A study was conducted to determine 1) opinions of incoming students on critical issues involving animal farming practices, and 2) changes in their opinions after 4 mo of instruction involving basic principles and issues of animal farming. A class of 114 students was given 2 identical surveys (start and end of semester) with 14 questions regarding demographics and animal use issues. Students marked a continuous scale of 129mm where 1 = agree and 129 = disagree for issue questions and identified their survey with a student-generated identifier (favorite food+superhero). Paired *t*-test analyses were conducted only on students with strictly farm (n = 14) and strictly urban (n = 19) backgrounds who completed both surveys using the same identifier (33/114 students). Before education, students with urban backgrounds were less likely to agree with animal farming issues involving value to society (27.0mm), morality (28.4mm), welfare (53.8mm), humaneness of agricultural practices (61.0mm), and ethics of breeding livestock for valuable traits (29.3mm) than farm students (4.2mm, 7.2mm, 27.2mm, 38.7mm, and 12.4mm, respectively, $P < 0.05$). Urban students were more likely to purchase organic animal products (60.2mm) and animal products based on environmental/ welfare standards (57.5mm) than farm students (99.9mm and 94.5mm, respectively, $P < 0.05$). After education, the opinions of urban students did not differ from farm students for questions involving humaneness of agricultural practices (36.1mm vs. 24.5mm, $P > 0.05$), breeding for valuable traits (16.6mm vs. 10.1mm, $P > 0.05$), and purchase of animal products based on environmental/ welfare standards (72.4mm vs. 91.5mm, $P > 0.05$). Data showed that urban students tend to be neutral with regards to animal farming issues, but when exposed to science-based instruction on animal farming, attitudes change to agree more closely with students with farm backgrounds.

Key words: survey, student opinion, agriculture issues

T421 Connecting lecture to the real world in animal sciences. J. J. Parrish*, J. R. Schindler, and R. L. Monson, *University of Wisconsin, Madison.*

A structured authentic learning experience was devised to connect lecture and the real world in a reproductive physiology course in animal sciences. The course had on-line, podcast lectures (2/week) and a 2 h lab/week. There were 4 lab sections with 73 students total. A cow project was created in which groups of 4 students within a lab section were assigned 1 of 20 cows for the semester. Student groups completed experiences with or without instructors that included: observation of estrus, design and implementation of a timed artificial insemination (AI) scheme, actual AI of their cow, determine potential pregnancy by return to estrus and plasma progesterone levels, and ultrasound for pregnancy 63 d following insemination. The specific goals of the project were to: 1) understand estrus behavior, 2) identify and administer drugs used in timed AI, 3) understand how drugs used in item 2 effect physiological events, 4) make connections between molecular mechanisms of hormone action and physiological events, 5) AI and detection of potential pregnancy in the group's cow, and 6) teach students to handle, interact and develop the skills needed to work with a large domestic animal. Students were assessed in 2 ways. First, an individual essay exam was given in lab to assess goals 1 to 5. A separate question addressed each goal. Second, group reflection on the project was required at the end of the semester but content of that reflection was not specified. The reflection was scored for an overall increase (scale 1 to 5, none to multiple indications of an increase) in understanding of animal physiology and increase in understanding cattle behavior and ability to work with cattle via completion of the project. The average exam score ± SEM was 78 ± 2% and students deemed to have accomplished goals 1 – 5 satisfactorily (>65% exam score) was 82%. When the group self reflection was evaluated, the mean ± SEM score assigned for understanding of physiology and understanding how to work with cattle and their behavior was 4.2 ± 0.2 and 4.8 ± 0.1 respectively. The described cow project was an effective means of connecting lecture material to the real world in a structured authentic learning experience.

Key words: reproduction, cattle

T422 Enhancing the pool of underrepresented minorities in veterinary medicine. O. U. Bolden-Tiller*, *Tuskegee University, Tuskegee Institute, AL.*

The Tuskegee University School of Veterinary Medicine (TUSVM) has trained over 70% of all African American veterinarians in the United States. The Department of Agricultural and Environmental Sciences is home to almost 300 underrepresented minorities (URM) majoring in Animal Sciences, which has long served as a feeder program for TUSVM. A capstone course, Domestic Animal Anatomy (DAA) that is partially taught by TUSVM students, was initiated to enhance student performance in Veterinary Anatomy. The objective of the current study was to determine the impact of DAA on academic performance in veterinary school. Former students enrolled in DAA from 2007 to 2010 who had finished at least one semester of Veterinary Anatomy completed a survey consisting of quantitative items, primarily on a Likert scale, aimed to gauge students′ opinions on the impact of the course on their performance in Veterinary Anatomy. TUSVM students who participated in teaching DAA completed a similar survey aimed to gauge their opinion on how their participation in DAA impacted their performance in veterinary school. Overall, DAA had a positive impact on student performance in Veterinary Anatomy and other veterinary courses. Similarly, TUSVM students who participated in teaching DAA also tended to perform well in veterinary school. There remains a disparity in the number of underrepresented minorities in the field of veterinary medicine. Here we have identified a mechanism that enhances the performance of URM in veterinary school and provides a format for training future veterinarians in undergraduate teaching.

Key words: underrepresented minorities, veterinary medicine, anatomy

T423 Comparison of multiple choice and short essay assessment vehicles on student performance in an upper division animal reproduction course. L. J. Spicer* and M. E. Payton, *Oklahoma State University, Stillwater.*

The primary assessment vehicle in most basic science courses in undergraduate programs is the multiple choice question (MCQ) exam. Regular assessment of students' knowledge, comprehension, and com-

petence is also important for motivating learning. In addition, short essay question (SEQ) exams take longer to grade and grading can be subjective. The aim of this study was to compare student performance on MCQ and SEQ exams. This study analyzed exam performance records from 653 students collected over a 9 year period in an upper division animal reproduction class. Student numbers for each year ranged from 50 to 98. Records from each student included results from 3 exams given during a 15-week semester. Each exam varied between 20% to 80% of either MCQ or SEQ, and results for each question style were summarized as the percentage correct. One-third of the MCQ were true-false questions. The first analysis used the MIXED procedure of SAS to determine if differences in performance scores existed between MCQ and SEQ among exam 1, 2 or 3, using year as a random effect. MCQ scores were not significantly different for the 3 exams, but scores were significantly different for the SEQ. There was a difference ($P < 0.001$) in scores for MCQ and SEQ for exams 1 and 2. However, for exam 3, the difference was not significant ($P > 0.23$). Over all records, Pearson correlations coefficients revealed a significant positive correlation between MCQ and SEQ scores (r = 0.56, n = 1907) and this correlation did not differ among exam 1, 2 or 3. The correlation between MCQ and SEQ was similar regardless of whether SEQ point totals were 32–50 (r = 0.56, n = 796) or 20–30 (r = 0.59, n = 1111). Correlations conducted within year and exam also revealed positive correlations ($P < 0.001$) for all exams and years, but correlations ranged from a low of 0.46 (n = 50) to a high of 0.83 (n = 84). Results indicate that MCQ and SEQ, in general, provide similar student assessment scores, and that student scores in SEQ increase as they become familiar with examination style.

Key words: assessment, exams, undergraduate

T424 Variables that affect academic performance in undergraduate animal science courses. M. M. Beverly, K. J. Stutts, and S. F. Kelley*, *Sam Houston State University, Huntsville, TX.*

The objective of this study was to evaluate the effect of student absenteeism and student characteristics on academic success in undergraduate animal science courses. Data were collected on 2,129 students enrolled in animal science courses at Sam Houston State University during 2 fall and 2 spring 16-week semesters. Data collected included number of absences, gender, classification, major field of study, and final course grade for each student. Least squares means for absences and final course grades were calculated using the mixed procedure of SAS. All main effects and all 2-way interactions were included in the model. Mean number of absences for all students was 3.75 per course. Students were divided into 3 groups based on number of absences in a course during the semester: low (0–2), average (3–6), and high (7 or more). Students with a low number of absences had the highest ($P < 0.01$) mean final course grade (83.6). Students with an average number of absences (79.5) had a higher ($P < 0.01$) mean final course grade than students with a high number of absences (69.5). There was also a significant effect of gender and student classification on final course grade. Female students had a higher ($P < 0.01$) mean final course grade (81.3) than male (77.3) students. In addition, students classified as juniors (80.4) or seniors (81.6) had a higher ($P < 0.01$) mean final course grade than students classified as freshmen (78.2) or sophomores (77.0). Regarding absences, males (4.2) had a higher ($P < 0.01$) mean number of absences than females (3.4), and seniors (3.3) had a lower ($P < 0.01$) mean number of absences than freshman (4.2) and sophomores (4.0). These results indicate that students with a greater number of absences attained a lower final course grade and females outperformed males and upper classmen outperformed lower classmen in terms of final course grade in undergraduate animal science courses. Male students and students classified as freshmen or sophomores were more likely to have a greater number of absences than females or students classified as juniors or seniors.

Key words: undergraduates, attendance, course grades

T425 CyberSheep: Improving student understanding of animal breeding concepts with a virtual sheep flock. K. L. Kessler*[1], R. M. Lewis[2], J. P. Cassady[3], and K. M. Cammack[1], *[1]University of Wyoming, Laramie, [2]Virginia Polytechnic Institute and State University, Blacksburg, [3]North Carolina State University, Raleigh.*

Animal breeding educators have identified the need to develop genetic simulation tools that provide undergraduate students an opportunity to apply course concepts. The CyberSheep program, developed at Virginia Tech, is an online genetic simulation tool in which students manage a flock of sheep for 6 generations within a cooperative breeding scheme. Each generation occurs within a one-week time frame, enabling students to observe consequences of their culling and mating decisions in "real time". Flocks compete to accomplish one of 2 main objectives: 1) maximization of market weights or 2) maximization of flock net worth. Students are also challenged to eradicate a lethal recessive allele. Undergraduate students playing at the University of Wyoming and North Carolina State University were anonymously evaluated before and after the simulation to determine its contribution to their understanding of concepts presented in an introductory animal breeding course. Students were asked to evaluate their level of understanding of fundamental concepts used in CyberSheep, including animal evaluation based on genetic merit and level of inbreeding. Survey scores were analyzed using the GLM procedure of SAS. Based on a 5–point scale, students rated their initial understanding of these 2 concepts at 3.5, coinciding to a moderate level of understanding. Scores rose ($P \leq 0.014$) to 3.8 in the final survey, indicating a slight improvement in understanding of these same concepts with the use of CyberSheep. Greatest improvement was seen in understanding of cooperative breeding schemes with the score rising ($P < 0.001$) from 2.7 to 3.5. Survey scores were not affected by university ($P \geq 0.415$). In general, students were satisfied with their level of learning from CyberSheep with a score of 3.6, and found the simulation to be ′informative′ and ′fun′ with an average score of 3.5 for each. It was concluded that animal breeding students benefited in their understanding of fundamental concepts through the use of CyberSheep.

Key words: animal breeding, education, genetic simulation

T426 Academic preferences of freshman college students in the Department of Animal Industry of the University of Puerto Rico at Mayagüez. G. Ortiz-Colón*, J. M. Huerta-Jiménez, L. del Valle-Mercado, M. Pagán-Morales, and E. Jiménez-Cabán, *University of Puerto Rico at Mayagüez, Mayagüez, PR.*

The student retention in the College of Agricultural Sciences of the University of Puerto Rico at Mayagüez has been under 61% for at least the last 6 years. Within the College of Agricultural Sciences, the situation of the Department of Animal Industry (DAI) is not different. The last reported DAI student retention was only 59.4%. The reasons for this low retention in the DAI have not been previously investigated. We hypothesized that the DAI course work is not fulfilling the students' expectations. Surveys were developed to evaluate the professional interests of DAI freshman students and delivered to those taking the introductory course of Animal Industry. Of the 141 surveyed individu-

als, 68.8% were 18 years old and 56.1% were males. Most (69.8%) of these students had no previous agriculture experience, while only 7.2% had participated in 4H Clubs, and only 5.0% had been Future Farmers of America. Most (84.4%) of the students had not taken a course in agriculture before being accepted into the DAI. Moreover, 53.2% of the students came from urban settings (developments and condominiums). While 35% of the students intend to become veterinarians in the future, only 7.9% would like to become animal scientists and 7.1% expressed a desire to change to other academic programs. When students were asked to choose what species they would like to specialize in, 24.8% chose companion animals, 16.6% indicated wild animals, and 12.4% beef cattle. Because the DAI does not have the animals or facilities to supports course work related to companion animal management and wild animal management, 41.4% of the clientele might be dissatisfied with the curriculum offered by the DAI and this might contribute to the low retention rates observed in this department.

Key words: Hispanic serving institutions, animal science, student retention

T427 Impact of duration of an online animal science nutrition course on student learning assessments. K. D. Ange-van Heugten* and A. Renjifo McComb, *North Carolina State University, Raleigh.*

To determine whether learning assessments differ when the same online course is offered over 5 wk versus 10 wk semesters, Principles of Animal Nutrition was taught twice during the summer of both 2009 and 2010. All offerings had the same instructor and teaching assistant. Both 5 and 10 wk durations in 2009 started with 30 students and finished with 29, while for 2010, both 5 and 10 wk durations started with 35 and ended with 35 students for 5 wk and 31 for 10 wk. Assessments were identical between 5 and 10 wk, but varied between 2009 and 2010. The 2009 5 wk course had 4 students finish with an F grade, 3 of which dropped after final grade distribution. No students in the 10 wk class received an F or dropped after final grades. In 2010, both the 5 and 10 wk class had 1 student finished with an F. Students in the 5 wk course were compared with those in the 10 wk course with and without outliers (late withdrawals). When all students were included (5 wk n = 64 and 10wk n = 60), 2009 and 2010 did not differ. Similarly, when student outliers were deleted, 2009 and 2010 did not differ. When all students were evaluated, 5 wk students had lower exam 1 grades ($P < 0.01$), participation points, quiz and final grades ($P < 0.05$; 82% ± 2.2 vs. 87% ± 2.3). The total number of times logged into the course (65.2 vs. 100.3) and total amount of time (47 h vs. 65 h) were lower ($P < 0.001$) for the 5 wk course. When the 5 wk courses were compared with the 10 wk ones without the outliers, participation points (88% ± 1.0 vs. 91% ± 1.1) and exam 1 grades (81% ± 1.8 vs. 86% ± 1.8) tended to be lower ($P < 0.10$) for the 5 wk course and times logged in (69 vs. 101) and total time online (50 vs. 66 h) were higher ($P < 0.001$) for the 10 wk courses. Five wk students only had 11 d before exam 1 while 10 wk students had 22 d. Final grades were 88.5% for 10 wk and 86.9 for 5 wk, indicating students can be successful regardless of course duration. However, the greater number of late withdrawals in the 5 wk course, less time online and lower scores indicates that learning large amounts of material in the shorter course length is more overwhelming than some students anticipate.

Key words: distance education, course duration, nutrition

T428 Effectiveness of a university introductory course in developing student confidence in horse handling and riding. M. Nicodemus*, *Mississippi State University, Mississippi State.*

Horsemanship is the art of riding and managing horses. These skills are fundamental to those college students wanting a career in the equine industry and so Mississippi State University (MSU) equine students are required to take one horsemanship elective for their degree, which may include ADS 1132 Introduction to Horsemanship. While introductory courses are designed to cover the basics of a subject matter, covering the necessary horsemanship skills for those students going into the equine industry is difficult to accomplish in one semester; and thus, study objectives were to determine the effectiveness of an introductory course in developing student confidence in performing various horsemanship activities. Researcher-developed, 19 question survey instrument focused on horse riding and handling was given both at the start and end of the semester to 42 students taking ADS 1132 at MSU. Each question described a horsemanship activity that students gave a score ranging from 1 to 5 indicating their confidence in performing the activity with 5 reflecting *extreme confidence*. Means (SD) were determined for each question and one-way ANOVA was performed to determine the effect of the course on student confidence in their horsemanship skills ($P < 0.05$). While all questions showed improvement in confidence, only 7 questions demonstrated a significant increase in scores with only 2 of the improved scores focused on riding activities (Table 1; $P < 0.05$). Although most improvements were made in ground handling activities, these skills lay the foundation to more advanced horsemanship activities and are vital to those students going into the field of veterinary sciences in which 50% of the students were applying to veterinary school. Survey results assist in suggesting course development areas and indicate additional horsemanship courses may need to be required for equine students focusing on a career requiring advanced riding skills.

Table 1. Initial and final survey means (SD) of confidence levels on questions with significant score improvements ($P < 0.05$)

Animal Behavior and Well-Being 2

304 ASAS Early Career Award Presentation: Working to foster the discovery, sharing, and application of knowledge concerning the well-being of farm animals. A. Johnson*, *Iowa State University, Ames.*

In developed countries there has been intense marketing, social and political interest in farm animal well-being and husbandry procedures. The need for relevant science that can be applied in education, assessment, audits and legislation has escalated. Yet in the US there are minimal farm animal ethologists compared with the more traditional sciences of nutrition, physiology and reproduction. Ethologists have risen to this challenge by working together and across disciplines on farm animal well-being research and extension. This approach creates a more efficient delivery mechanism to share and apply contemporary scientific knowledge. Three central themes have driven my research and extension program (1) maintenance behaviors of farm animals (2) handling and system design for the finisher pig and (3) sow productive lifetime. It is certain that progress in these areas requires collaboration of experts in many disciplines and our efforts in developing handling and system designs for the finisher pig will be highlighted. Three important questions must be addressed in regards to the occurrence of market pigs that become injured, non-ambulatory or die during the marketing process (1) science; what is the etiology of the non-ambulatory pig? (2) economics; it was calculated that transport losses cost the US swine industry $50 to $100 million loss/yr (2009) and (3) legislation whereby if passed these animals would not be allowed into the human food chain resulting in approximately $500 million/loss/yr to the US swine industry alone. Several of our studies have addressed loading gantry design, pre-sorting and raising pigs in large and small pens. Data collected from these studies will provide science back to decision makers and information for extension such as the Transport Quality Assurance program, posters, flyers, media stories and fact-sheets in addition to peer review abstracts and papers. The overall aim of these efforts will be to reduce stressors that impinge on the pig at marketing, reduce transportation losses and maintain the well-being of the pig.

Key words: handling, swine, transport

305 The effect of reactive state on the physiology of dairy cows milked in a novel environment. M. A. Sutherland*[1] and G. A. Verkerk[2], *[1]AgResearch Ltd., Animal Behaviour and Welfare Group, Hamilton, New Zealand, [2]DairyNZ, Hamilton, New Zealand.*

Differences in the way animals react behaviorally and physiologically to a stressor may reflect differences in fearfulness or coping style. The objective of this study was to determine if reactive state affects the physiology of dairy cows being milked in a novel environment. The reactive states of multi-parus cows were assessed using 4 behavioral tests: restraint test, exit velocity, flight distance, and an approach test. After this initial testing, 20 cows were selected and separated into 2 groups: low responders (LR: n = 10) and high responders (HR: n = 10). Cows were milked according to their established routines in a rotary shed and physiological data as well as milk production parameters were collected over 5 consecutive days. On Days 2 and 5, blood samples were collected via the tail vein before and after milking to measure cortisol and oxytocin concentrations, and heart rate monitors were attached to measure autonomic responses during milking. The following week, cows were milked in a novel environment (herringbone parlor within the same farm facility) over 5 consecutive days, and the sampling program was repeated. Data were analyzed using the MIXED procedures of SAS. Pre-milking cortisol concentrations were greater ($P < 0.05$) in HR than LR cows, and cortisol concentrations were greater ($P < 0.05$) when cows were milked in the herringbone compared with the rotary parlor, regardless of reactive state. Pre-milking heart rate was greater ($P < 0.05$) in HR than LR cows, and heart rate was greater ($P < 0.05$) in HR cows in response to being milked in the herringbone parlor than in LR cows. Milk yield was greater ($P < 0.06$) and milking duration longer ($P < 0.05$) for LR compared with HR cows. Average milk flow did not differ ($P > 0.05$) between LR and HR cows, but the milk let-down pattern was affected ($P < 0.001$) by cow reactive state and milking environment. These results indicate that baseline physiological measures differ between cows of differing reactive states, and that a cow′s reactive state will affect the way she responds to a novel environment.

Key words: behavior, dairy, stress

306 The effect of reactive state and training on the behaviour and milk production of heifers during the first week of lactation. M. A. Sutherland*[1] and G. A. Verkerk[2], *[1]AgResearch Ltd., Animal Behaviour and Welfare Group, Hamilton, New Zealand, [2]DairyNZ, Hamilton, New Zealand.*

Differences in the way in which animals react behaviorally and physiologically to new situations may reflect differences in fearfulness or coping style. The objective of this study was to determine if training before calving could modulate the reactive state in heifers during their introduction to milking routines after calving. The reactive state of heifers was assessed pre-partum using 4 behavioral tests: restraint test, exit velocity, flight distance, and an approach test. On the basis of this testing, 40 heifers were selected and denoted as either low (LR: n = 20) or high (HR: n = 20) responders. One month before calving, half the heifers from each group were allocated randomly for training in the rotary milking-parlor over a 2 d period while the other heifers were left undisturbed in the paddock. During the first 5 d of lactation, behavioral and physiological data were collected from all heifers, including behavior during cup attachment, milk yield, milk flow rate, and residual milk volume. Data were analyzed using the MIXED procedures of SAS. Behavior scores during cup attachment (scale: 0 = no hind foot movement, 4 = backward kick with a hind leg) were higher ($P < 0.05$) in trained LR compared with non-trained LR heifers, indicating an increased level of reactivity; but training did not influence scores for behavior during cup attachment in HR heifers. Milk yield did not differ ($P > 0.05$) between trained and non-trained LR heifers, but was lower ($P < 0.001$) in trained HR compared with non-trained HR heifers. The patterns of milk flow-rate differed ($P < 0.01$) between trained and non-trained, LR and HR heifers, with trained HR heifers having the lowest flow rate. Percentage residual milk volume was lower ($P < 0.005$) in trained HR compared with non-trained HR heifers, and tended ($P = 0.07$) to be reduced in trained compared with non-trained LR heifers. Training to the milking parlor negatively affected the behavioral response of heifers to milking and milk production, and this response was further influenced by individual reactive state.

Key words: behavior, dairy, milk production

307 Effect of frequency of feed delivery on the behavioral patterns of dairy cows milked in an automatic system. J. A. Deming*[1],

R. Bergeron[2], K. E. Leslie[3], and T. J. DeVries[1], *[1]Dept. Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada, [3]Dept. Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The primary objective of this study was to determine the effect frequency of feed delivery has on the behavior of dairy cows milked in an automatic milking system (AMS); the secondary objective was to determine if this effect is influenced by lameness. Ninety lactating Holstein dairy cows, kept in a free-stall barn in 1 of 2 pens, each with a free-traffic AMS, were monitored on each of 2 treatments in a cross-over design with 35-d periods. The treatments were delivery of TMR: 1) 1x/d (at 0730h) and 2) 2x/d (at 0730 and 1730h). During the last 7 d of each period standing/lying behavior of the cows were recorded with data loggers, while milking frequency and yield were recorded by the AMS. Cows were lameness scored (scale of 1 = sound to 5 = severely lame) twice each period. Data were analyzed in a general linear mixed model including lameness score as a covariate. There was a tendency ($P = 0.06$) for cows to get milked more frequently when fed 2x/d (2.6 vs. 2.5 milkings/cow/d; SE = 0.08). Cows with higher lameness scores got milked less frequently ($P = 0.02$). Frequency of feed delivery did not affect ($P = 0.6$) milk yield (34.7 kg/d; SE = 1.9). Cows spent 10.9 h/d (SE = 0.2) lying down split into 7.2 lying bouts/d (SE = 0.3); these did not vary ($P = 0.2$) with treatment. Cows with higher lameness scores spent more time lying/d ($P = 0.045$) and had more lying bouts/d ($P = 0.03$). When fed 2x/d, cows milked in the AMS closer in time (SE = 57.9; $P < 0.001$) to feed delivery (milking on average 17.1 min from a feed delivery), while when fed 1x/d cows milked in the AMS at time points much further away from feed delivery (milking on average 264.5 min from a feed delivery). Despite having less of an incentive to remain standing, cows still spent more time standing after milking when fed1x/d (94.7 vs. 86.2 min; SE = 5.8; $P = 0.03$). Cows with higher lameness scores tended ($P = 0.09$) to lie down sooner after milking. The results suggest that frequency of ration delivery has some affect on the behavior of AMS-milked cows; further the results show that, regardless of feeding frequency, these behavioral patterns are affected by lameness.

Key words: automatic milking, behavioral pattern, lameness

308 Effect of yearly climate on milk yield in a sub-tropical environment. J. C. Lees* and J. B. Gaughan, *The University of Queensland, Gatton, Queensland, Australia.*

Heat load is a major cause of milk yield (MY) loss in tropical and subtropical dairy production. In this study the long-term effects of heat load on MY in a sub tropical environment were investigated. Individual daily MY was obtained from 250 Holstein-Friesian cows housed outside over 3 summers (340 d) and 2 winters (119 d). The cows had access to a feed pad and pasture. Ambient temperature (TA), black globe temperature (BG), and relative humidity (RH), were obtained at 10 min intervals from an automated on-site weather station. The effects of TA, BG, RH and THI on daily MY were determined for the herd (N) using Pearson partial correlation analysis (days in milk used as a co-variant). The relationship between daily MY and the climate variables at 0800, 1200, 1600, 2000, 0000 and 0400 h was established. The effects of previous heat load on current MY (d 0) were examined using the mean daily THI for d −1, −2, −3 and −4. Cows were categorised by MY as low (LO < 19kg/d), medium (MD 19 to 27kg/d) or high (HI > 27kg/d) and subjected to the same analysis as N. Increasing THI, BG and TA had negative correlations with MY on a herd basis. Climate data obtained at 0800 h had the highest correlations with daily MY. Whole herd correlations ($P < 0.0001$) between MY loss, TA, BG and THI at 0800 h were −0.39, −0.43, and −0.39 respectively. There were weak correlations ($P < 0.05$) between the climatic variables and MY of LO cows, and consistently strong negative correlations for MD and HI cows. The MY of HI cows had the best correlation (−0.54; $P < 0.0001$) with BG at 0800 h. The relationship between daily MY and mean daily THI was −0.38 for N, −0.10 for LO ($P > 0.05$), −0.31 for MD, and −0.45 for HI ($P < 0.0001$). The relationship between climatic variables on previous days was a better indicator of d 0 MY than on d 0. When lag effects were examined the best correlation for d 0 MY was mean THI on d −2 (−0.54; $P < 0.0001$). This suggests that effects of heat load on MY are cumulative. Heat stress models need to be developed that will account for the impact of cumulative heat load on production and welfare.

Key words: heat load, milk yield, dairy cows

309 Evaluation of two different cooling systems on a Sicilian dairy farm: Physiological parameters and milk aroma. R. Ben Younes[1,3], G. Azzaro[2], I. Schadt[2], G. Belvedere[2], M. Caccamo[2], R. Petriglieri[2], G. Licitra[3,2], and S. Carpino*[2], *[1]INAT, Tunis, Tunisia, [2]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [3]DISPA, Catania University, Catania, Italy.*

Two cooling systems were evaluated on a Sicilian dairy farm, during summer time, with regard to cows' responses in terms of respiratory rates (RR) and rectal temperatures (RT) and milk chemical composition. The effects on milk aroma were also evaluated, because cows′ body temperature might influence milk temperature, oxidation processes and stability as a result. Cows were assigned to 2 groups of 10 animals with similar average days in milk (DIM), milk production and composition. One group was cooled with a sprinkler system (SP) the other was cooled by showers (SH). Both had additional ventilation. Cows initial average values of DIM, milk yield (kg/cow/d), fat (%), protein (%), lactose (%) ± standard deviation in SP were 141 (±88.3), 36 (±10.2), 3.7 (±0.4), 3.2 (±0.1), 4.2 (±0.6), and 139 (±73), 35 ± 6.6), 3.6 (±0.4), 3.2 (±0.2), 4.6 (±0.5) in SH, respectively. Individual milk samples were analyzed for fat, protein and lactose content and RR and RT were measured 6 times with 15 d intervals, beginning at the end of June. At each test day, THI values were calculated. Milk samples of the last 3 test days were additionally analyzed by SmartNose for milk aroma profiles. THI values were 73.3, 79.7, 79.6, 77.8, 74.1 and 72.3 at test d 1 through 6, respectively. Cows cooled with SH compared with SP had significantly higher RT and RR ($P < 0.001$). Measured RT and RR (LSMeans ± SE) in SH and SP were 39.26 ± 0.001, 59.92 ± 0.018 and 38.95 ± 0.001 and 54.84 ± 0.018, respectively. SmartNose analysis highlighted differences in milk volatile composition between treatments. Fat, protein and lactose (%) were not different between groups ($P > 0.05$). These parameters were only affected by test day ($P < 0.001$). Relative humidity with SH might be higher compared with SP and might have increased heat stress of dairy cows. Milk aroma profile was apparently related to RR and RT and oxidation processes might be involved. Further investigations on the effects of cows′ body temperature on milk oxidation processes and stability might be needed.

Key words: cooling systems, heat stress, milk aroma profile

310 Assessment of a web camera to evaluate farm management and cow behavior. G. Licitra[1,2], G. Azzaro[1], R. Petriglieri[1], M. Cac-

camo[1], and J. D. Ferguson*[3], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]DISPA, Catania University, Catania, Italy, [3]University of Pennsylvania, PA.*

The objective of this project was to evaluate the use of a web camera to assess cow behavior and management activities on a dairy farm. Often advisors are requested to provide expert advice to management based on observation of cow behavior from a farm visit. This can be biased as often observations are made from a one-time visit, however to view the farm more frequently may be expensive if the advisor is coming from a distance. Using a web camera or digital videos taken at times throughout the day may provide views of cow behavior and facility use relative to management activities, such as feeding and milking, facilitating a more comprehensive evaluation of the farm avoiding the expense of repetitive farm visits. In addition, as developing countries expand their dairy industry, expert advisors may be contacted in countries with mature dairy industries to provide support and training of local professionals through the internet without a physical visit to the dairy in question. Use of digital media has the potential to expand interaction across regions and enhance training and support of novice dairy advisors and producers. Assessment of cow behavior, cleanliness, body condition, lameness, and facility comfort via web technology was evaluated against assessments made from farm visits. Assessments were made from 2 farms with 2 observers visiting the farm contemporary to an individual viewing the farm(s) via a web camera. Subsequently, observations by all 3 individuals were made using the web camera at different times of the day from separate computers. In general, cow behavior assessments between observers and methods were consistent, but there were differences in assessing BCS between methods and observers and in assessing cleanliness and lameness between methods. The web camera enabled assessment of management activities over successive periods. Results therefore demonstrate that visual assessment of animal behavior and management of a facility may be performed through distant imaging by precluding advisors a visit to the farm in working with dairy producers and local advisors.

Key words: cow behavior, management evaluation, visual assessment

311 Novel techniques for anesthesia during disbudding of calves. K. R. Tapper*[1], J. P. Goff[1], B. L. Leuschen[2], J. K. West[2], and S. T. Millman[1,2], *[1]Iowa State University Department of Biomedical Sciences, Ames, [2]Iowa State University Veterinary Diagnostic and Production Animal Medicine, Ames.*

The objective of this study was to evaluate novel anesthetics to alleviate pain during disbudding. Efficacy was determined by latency for loss of sensation (LS), as well as presence and duration of analgesic effect. Thirty calves were randomly assigned to one of 3 cornual anesthetic treatments: 100% ethanol (E), depot solution of 2% lidocaine suspended in peanut oil (D), or control 2% lidocaine (C). On Day 0, 2 mL/horn anesthetic was injected and LS was measured at 5 min increments using a needle prick test at 4 locations around the horn bud. Calves with sensation at +10 min received an additional 1 mL anesthetic injection. When LS was achieved, calves were disbudded using heat cautery. Presence and duration of analgesic effect were determined using pressure algometry (PA), which quantified mechanical nociceptive thresholds as kilograms of force (kgf) relative to a head withdrawal response. Four landmarks around each horn bud and a non-painful control location were measured hourly for the first 9 h on Day −1 and Day 0, and at 12 h increments on Day+1 through Day+3 post-disbudding. Mean latency for LS was analyzed in SAS version 9.2 using a mixed model. There was a significant difference in loss of sensation at 10 min, such that treatments differed for the number of calves that required an additional injection (E: 6/10 calves; D: 7/10 calves; Control: 2/10 calves, $P < 0.0001$). However, there was not a treatment difference for latency to LS (Latency to LS (min) ± SEM: E 26.40 ± 6.12; D 25.60 ± 4.78; Control 13.50 ± 4.47). PA data were analyzed using PROC GLIMMIX by treatment and trial day. Ethanol did not differ from C at hour +1, but displayed higher pain thresholds thereafter from Day0 through Day+3 (Raw Means, [kgf] ± SEM: Day0 = E 4.4 ± 0.1; C 3.6 ± 0.1; Day+3 = E 4.6 ± 0.1; C 3.3 ± 0.1; $P < 0.01$). Depot did not differ from C for PA response nor for latency to LS (Raw Means [kgf] ± SEM: Day0 = D 3.2 ± 0.1; Day+3 = D 3.0 ± 0.1). In conclusion, longer latency to LS was associated with E and D anesthetics compared with control (C). Ethanol provided superior analgesia compared with C, whereas D did not when pain was measured using PA.

Key words: analgesia, disbudding, pain

312 The effect of pain relief on the physiology and behavior of calves after castration and/or dehorning. M. A. Sutherland*[1,2], B. L. Davis[1], T. A. Brooks[1], and M. A. Ballou[1], *[1]Texas Tech University, Animal and Food Sciences Department, Lubbock, [2]AgResearch Ltd., Animal Behaviour and Welfare Group, Hamilton, New Zealand.*

Calves are commonly castrated and/or dehorned without pain relief once they enter the feedlot. The objective of this study was to determine the efficacy of pain relief to alleviate the pain caused by dehorning and/or castration in 3 mo old calves. This study comprised of 8 treatments (n = 10 per treatment): 1) control handling (SHAM); 2) castration (CAS); 3) dehorning (DH); 4) castration and dehorning (CD); 5) control handling plus analgesia (ANA); 6) castration plus analgesia (CAS+A); 7) dehorning plus analgesia (DH^+A); 8) castration and dehorning plus analgesia (CD+A). Analgesia involved administering local anesthetic around each horn (DH^+A, CD+A, and ANA) and/or into the testes (CAS+A, CD+A, and ANA treatments) before performance of the treatment and a non-steroidal anti-inflammatory drug (NSAID) was administered immediately after. Sequential blood samples were collected to measure leukocyte counts and percentages, and cortisol concentrations. Behavior was recorded using 5 min scan samples. Calves were weighed before and 24 h after treatments were performed. Data were analyzed using the MIXED procedures of SAS. At 360 min, the neutrophil to lymphocyte ratio was lower ($P < 0.05$) in CAS, DH, and CD calves that received analgesia compared with castrated and/or dehorned calves that did not receive analgesia. The integrated cortisol response was greater ($P < 0.05$) in CAS, DH, and CD compared with SHAM calves, but similar in CAS+A, DH^+A, CD+A, and SHAM calves. The frequency of tail wagging was greater ($P < 0.05$) and eating was reduced ($P < 0.05$) in CAS, DH, and CD compared with SHAM calves, but similar among castrated and/or dehorned calves that received analgesia compared with SHAM calves. Body weight decreased ($P < 0.05$) in CAS, DH, and CD calves compared with ANA calves. Administration of analgesia prevented body weight loss in CAS ($P = 0.05$) and DH ($P = 0.07$) calves, but not in CD ($P = 0.31$) calves. The behavioral and physiological changes caused by castration and/or dehorning are indicative that these animals experience pain, which can be reduced by administering a local anesthetic in combination with a NSAID.

Key words: dairy, pain, welfare

313 Physiological and immunological effects of surgical castration and amputation dehorning and the influence of anesthetics and analgesics in Holstein calves. M. A. Ballou*[1], M. A. Sutherland[1,2], B. L. Davis[1], T. A. Brooks[1], C. J. Cobb[1], and L. E. Hulbert[1,3], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Animal Behavior and Welfare Group, AgResearch, Hamilton, New Zealand, [3]Department of Animal Science, University of California at Davis, Davis.*

Objectives were to determine the physiological and immunological effects of surgical castration and/or amputation dehorning and the influence of anesthetics and analgesics in Holstein calves. Eighty 3-mo old Holstein bull calves were completely randomized to treatments in a 2 × 2 x 2 factorial arrangement with castration, dehorning, and anesthetic/analgesic as the main effects. Peripheral blood samples were collected before and 0.5, 1.5, 2.5, 4, 6, 24, and 72 h after the respective procedure and analyzed for total leukocyte and differential counts. Plasma cortisol and haptoglobin concentrations were also determined. Blood samples collected before and at 0.5 and 24 h after the procedures were analyzed for ex vivo innate immune responses. Both castration and dehorning elevated ($P < 0.01$) total leukocyte counts and neutrophil:lymphocyte ratios, and the administration of anesthetic/analgesic ($P < 0.01$) attenuated the leukocyte responses. Plasma cortisol and haptoglobin responses were increased ($P < 0.01$) following castration and/or dehorning and the combination of the 2 procedures was additive ($P < 0.01$). Anesthetics/analgesics reduced the peak and persistency of the elevated cortisol response ($P < 0.01$), and the haptoglobin concentrations at 24 h after the procedure ($P < 0.01$). Castration and dehorning together tended ($P = 0.09$) to decrease TNF-α secretion 24 h after the procedure, and administration of anesthetic/analgesics alleviated ($P < 0.01$) the response. In addition, anesthetic/analgesics lessened ($P < 0.01$) the suppressed neutrophil oxidative burst observed 24 h after castration and/or dehorning. Dehorning decreased ($P < 0.04$) neutrophil L-selectin expression and administration of anesthetic/analgesics reversed the response ($P < 0.05$). Both castration and dehorning cause distress and suppress innate immune responses. The administration of anesthetic/analgesic alleviated the adverse effects associated with castration and dehorning.

Key words: analgesia and anesthesia, castration, dehorning

314 Effects of pair housing versus limited social contact on the response of dairy calves to separation. L. R. Duve*[1], M. B. Jensen[1], and D. M. Weary[2], *[1]University of Aarhus, Tjele, Denmark, [2]University of British Columbia, Vancouver, British Columbia, Canada.*

There is much variety in the extent of social contact allowed to preweaned dairy calves; some are housed individually with no opportunity for physical contact, some are allowed limited physical contact with calves in neighboring pens, and others are group housed for part or all of the milk feeding period. A former study indicated that calves allowed limited physical contact still established a social bond; however, the strength of this relationship may differ from calves with full social contact. The aim of this study was to test the effect of the level of social contact on the strength of the social relations, as measured by calf responses during a 20 min period of separation (and 10 min after reunion) from their social companion. Twenty-seven pairs of calves were reared from birth until 6 weeks in either individual pens (with limited social contact between bars; L-calves), pair housed (with full social contact; F-calves), or in individual pens for 3 weeks and in pairs for the next 3 weeks (LF-calves). The separation test was conducted in the home pen when the calves were 34d old. Responses measured were the number of steps, time spent not moving, and maximum heart rate (MHR). Data were analyzed with a general linear mixed model (SAS). F and LF did not differ for any measure, but these calves spent more time standing (F: 850 ± 99, LF: 824 ± 104, L: 510 ± 99 s; $P < 0.01$), took more steps (F: 21 ± 2, LF: 20 ± 3, L: 13 ± 2; $P = 0.05$) and spent less time not moving (F: 779 ± 64, LF: 730 ± 68, L: 975 ± 64 s; $P = 0.03$) during the separation and reunion phase of the test, compared with those calves allowed limited social contact. MHR did not differ among treatments during separation ($P = 0.52$), but was higher for F than L (F: 172 ± 6, LF: 162 ± 7, L: 151 ± 6; $P = 0.04$) during the reunion phase (LF-calves did not differ from either treatment). In conclusion, calves housed in pairs from birth or from 3 weeks of age were more active when separated from their companion in the home environment at 5 weeks of age, suggesting that calves raised with full social contact have a stronger relation with their companion than do calves housed with limited contact.

Key words: dairy calves, social contact

315 Lameness, leg injuries and lying times on 122 North American freestall farms. A. K. Barrientos*[1], D. M. Weary[1], E. Galo[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, Canada, [2]Novus International Inc., St Louis, MO.*

The aim of the study was to describe the variation in lameness, leg injuries and lying behavior on dairy farms in 3 regions of North America: California (CA); North Eastern states (NE; New York, Pennsylvania and Vermont) and British Columbia (BC). Data were collected by the same 2 trained individuals from approximately 40 Holstein herds in each region. One group of high production multiparous cows was monitored on each farm. Cows were gait scored using a 5-point Numerical Rating System where 1 and 2 are considered non-lame, ≥ 3 clinically lame, and ≥ 4 severely lame. Prevalence of knee injuries was recorded based on swollen carpal joints (yes/no). Focal cows (n = 40), randomly selected from the assessment group, were evaluated for hock injuries on a scale of 1 to 3 (1 = healthy and 3 = evident swelling or severe lesion). Electronic data loggers recorded lying behavior of the focal cows at 1-min intervals for 3 d. The analysis was descriptive and all results are presented as means ± SD. Prevalence of clinical lameness averaged 30.8 ± 15.5% in CA, 54.8 ± 16.7% in NE and 27.8 ± 13.9% in BC; severe lameness averaged 3.6 ± 4.2% in CA, 8.2 ± 5.6% in NE and 7.1 ± 5.3% in BC. Prevalence of swollen knees was minimal in CA (0.3 ± 0.6%), but high (23.1 ± 16.3%) in the NE (not scored in BC). Overall prevalence of hock injuries (≥2) was 56.2 ± 21.6% in CA, 81.2 ± 22.5% in NE, and 40.7 ± 26.3% in BC; prevalence of severe injuries (3) was 1.8 ± 3.1% in CA, 5.4 ± 5.9% in NE and 3.5 ± 5.2% in BC. Lying times were similar across regions (10.4 ± 0.8h/d in CA, 10.6 ± 0.9h/d in NE, and 11.0 ± 0.6h/d in BC) but cows within farms varied from, 3.7 to 17.5h/d, 2.8 to 20.5h/d, and 4.2 to 19.5h/d in CA, NE and BC, respectively. These results show considerable variation in lameness and leg injury prevalence among freestall farms in North America. The very low prevalence of these ailments on some farms shows great opportunity for improvement on other farms.

Key words: cow comfort, welfare assessment

ARPAS Symposium: Understanding Meta-Analysis

316 Unsophisticated "cowboy" methods used traditionally to merge results from multiple experiments. F. N. Owens* and A. Hassan, *Pioneer Hi-Bred Int'l, Johnston, IA.*

Meta-analysis, initially used in 1904, is one statistical method for combining results from qualitative studies to develop and test relationships among multiple factors. Most concepts in nutrition and biology preceded or evolved without sophisticated meta-analysis. By checking the consistency of relationships across multiple experiments, often by within-trial regressions weighted by animal numbers in the mean, consensus opinions were reached to be substantiated or refuted by subsequent experiments. Scientific giants of the past (S. Brody, J. T. Reid) observed trends and relationships within masses of data and developed our basic concepts of growth and development. Similarly, the "equivalent body weight" concept presumably was developed by unweighted curvilinear regression. Mean energy values and nutrient analyses for 1,088 feeds in texts by F. B. Morrison were generated manually from 8,981 experiments after "outliers" were removed. Concepts in energy metabolism (the California Net Energy system) and amino acid requirements for growth (the Ideal Protein system) involved compilation of masses of measurements cleverly interpreted and merged by simplistic methods. The field of epidemiology is based on correlations across multiple data sets; its blunders illustrate that that correlations need not reflect cause-effect relationships. Meta-analyses helps to detect the statistical consistency of treatment effects among experiments, to reduce the cost of and need for animals or subjects in future experiments, and to define response curve shapes across diverse genetic and environmental conditions. Most granting agencies now require both α and β errors to be predicted. Though pre-packaged programs are widely available for complex statistical manipulations, scientists must understand both the upsides and the pitfalls involved with complex analyses. By including meta-analysis within publications of original research, misinterpretations by authors, readers, and the public could be reduced.

Key words: merged experiments, meta-analysis, statistical methods

317 Meta-analysis: The good, the bad and the ugly. I. J. Lean* and A. R. Rabiee, *SBScibus, Camden, NSW, Australia.*

Meta-analysis can be a powerful tool to provide a more precise estimate of the effect of treatment or risk factor for disease, or other outcomes, than any individual study contributing to a pooled analysis. It is also possible, and desirable, to examine new hypotheses using the pooled data that could not be readily tested using other forms of study. However, the confidence with which a user can apply these results depends on the conduct of the meta-analysis, the basal data that contribute to a meta-analysis and the biological responses of the treatments and responses under consideration. The role of publication bias and the value of unpublished results are explored. This presentation considers the base data that contribute to a meta-analysis and provides guidelines for presentation of results. Examples of meta-analyses will be used to examine sources of variability or heterogeneity in study results and strengths and weaknesses of different approaches to pooling data. Tools for assessing heterogeneity including the I^2 statistic and use of different funnel plots to assess publication bias are evaluated. The value and limitations of meta-regressions approaches to address causal relationships, especially in nutritional studies is addressed. Flaws in some approaches to the pooling of data will be explored with a view to achieving a greater consistency in approach to meta-analytical studies.

Key words: merged experiments, meta-analysis, statistical methods

318 Relationship between postweaning RFI in heifers and intake and productivity of mid-gestation beef females. A. N. Hafla*[1], G. E. Carstens[1], T. D. A. Forbes[2], J. C. Bailey[1], J. T. Walter[1], J. W. Holloway[2], and J. G. Moreno[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Research, Uvalde.*

Residual feed intake of growing cattle has been associated with between-animal variation in maintenance energy requirements. The objective of this study was to determine if RFI classification of beef heifers affects DMI and productivity of mid-gestation females. RFI was determined in 2 groups of growing Bonsmara heifers during 2 yr (n = 62 and 53/yr), and heifers with the lowest (n = 12/yr) and highest (n = 12/yr) RFI were retained for breeding. Nineteen second-parity cows from trial 1 and 23 primiparous heifers from trial 2 were used in this study. Cows and heifers were fed a chopped hay diet (ME = 2.11 Mcal/kg DM) in separate pens equipped with GrowSafe bunks to measure individual intake and feeding behavior. BW were measured at 7-d intervals, and BCS and ultrasound measurements of REA and rump fat thickness obtained on d 0 and 77 of the study. No interactions between RFI classification and age were found to be significant. Heifers had lower ($P < 0.05$) initial BW (505 vs 474 ± 9 kg), ADG (0.66 vs 0.47 ± 0.05 kg/d), and initial hip height (132 vs 129 ± 0.95 cm), but similar DMI (10.37 ± 2.66 kg/d) compared with cows. Heifers and cows had similar initial rump fat thickness (1.10 ± 0.32 cm) and BCS (5.1 ± 0.4). Bunk visit (BV) frequency was higher ($P < 0.0001$) in heifers than cows (142 vs 93 ± 7 events/d), but BV duration (174 ± 61 min/d) was not affected by age. Meal frequency was similar for heifers and cows, but heifers had longer ($P < 0.05$) meal duration (427 vs 387 ± 14 min) than cows. Females classified as having low RFI had lower ($P < 0.01$) DMI (9.00 vs 11.6 ± 0.54 kg/d) compared with females with high RFI, but initial BW and ADG were similar during the trial. Likewise, RFI classification did not affect initial or final rump fat thickness or BCS. BV frequency was similar, but BV duration was less ($P < 0.001$) for females with low compared with high RFI. Meal frequency and duration were not affected by RFI classification. Females classified as having low RFI as heifers continued to consume 22% less feed than females classified as high RFI while maintaining the same BW and BCS during the 2nd trimester of gestation.

Key words: residual feed intake, feeding behavior

319 Using a mechanistic nutrition model to identify efficient beef cows under grazing conditions. B. M. Bourg*[1], L. O. Tedeschi[1], A. D. Aguiar[5], F. R. B. Ribeiro[2], J. Genho[3], R. R. Gomez[1], D. Delaney[4], and S. Moore[4], *[1]Texas A&M University, College Station, [2]Texas A&M University, Commerce, [3]Eldon Farms, Woodville, VA, [4]King Ranch, Kingsville, TX, [5]University of Florida, Gainesville.*

The cow/calf phase of production represents a large expense involved in the cost of producing beef, and efficient beef cows use less resource to obtain the same outcome in a sustainable environment. The objective of this study was to utilize a mechanistic nutrition model to estimate ME requirement (MER) of grazing cows based on changes in cow BW and fatness measurements (body condition score, BCS) along with calf age and BW, as well as forage quality and quantity. In addition, energy efficiency index (EEI), which is computed as MER divided by calf weaning BW, was used to rank cows within a herd based on their efficiency of utilizing available forage to meet their maintenance requirements and support calf growth. Data were collected from one herd of approximately 140 Santa Gertrudis cows over a 4-year period, and analyzed per calving interval, conception to weaning. PROC CORR of SAS was used to determine phenotypic relationships between model-predicted peak milk and EEI with cow and calf performance and temperament data (exit velocity or chute score). Moderate significant ($P < 0.05$) correlations of EEI were found (r = 0.51) between year 1 and 2, year 1 and 3 (r = 0.46), year 2 and 3 (r = 0.43), year 1 and 4 (r = 0.39), year 2 and 4 (r = 0.53), and year 3 and 4 (r = 0.57), suggesting that the EEI may be consistently predicted for cows across years. A negative relationship was found between predicted peak milk and EEI, and model predicted values were also strongly correlated ($P < 0.05$) across years. Peak milk and EEI were not correlated ($P > 0.1$) to the collected temperament measures. Relationships between EEI and peak milk with ultrasound fat measures indicated that more efficient cows, with a lower EEI, were leaner, and cows with a higher peak milk were also leaner. Cow BCS was also positively correlated to both EEI and peak milk. Preliminary genetic assessment of EEI and MER, indicated additive genetic heritability (h^2) of EEI and MER of 0.58 and 0.05, respectively. In conclusion, the model's estimation of EEI might be moderately heritable and repeatable across years, and that efficient cows might have greater peak milk and be leaner.

Key words: modeling, efficiency, sustainability

320 Relationship among lifetime measures of body weight and frame size in beef cows. A. C. Echols*, D. A. Fiske, M. L. Wahlberg, and S. P. Greiner, *Virginia Polytechnic Institute and State University, Blacksburg.*

The beef cattle industry has placed increased focus on mature cow size as a result of its influence on production efficiency and profitability. The objective of this study was to evaluate relationships among lifetime measures of growth and frame size for commercial beef females in a pasture-based beef production system in the Appalachian region of the United States. Measurements of BW, hip height (HH), BCS, and calculated frame score (FS) were recorded at weaning (WN), breeding (BR), 2 (2YR), and 4 (4YR) yr of age for 232 Angus-cross females born 2004 through 2008. Mean age at WN, BR, 2YR, and 4YR were 230 (SD = 44), 395 (SD = 25), 805 (SD = 19), and 1745 d (SD = 20), respectively. Body weight at 2YR and 4YR were adjusted for BCS. Frame score at WN was related to FS at BR (r = 0.73, $P < 0.001$), and 2YR (r = 0.47, $P < 0$ 0.001), but not at 4YR ($P = 0.61$). Frame score at BR was related to FS at 2YR (r = 0.67, $P < 0.001$) and 4YR (r = 0.62, $P < 0.001$), and a strong relationship existed between FS at 2YR and 4YR (r = 0.83, $P < 0.001$). Similarly, body weight at WN was correlated to BW at BR (r = 0.76, $P < 0.001$), 2YR (r = 0.56, $P < 0.001$), and 4YR (r = 0.51, $P < 0.001$). Body weight at BR was correlated to 2YR (r = 0.56, $P < 0.001$) and 4YR (r = 0.65, $P < 0.001$). Body weight and FS were related at WN (r = 0.57, $P < 0.001$), BR (r = 0.64, $P < 0.001$), 2YR (r = 0.53, $P < 0.001$), and 4YR (r = 0.48, $P < 0.001$). Frame score and BW differed ($P < 0.001$) by birth yr. Mean FS at WN, BR, 2YR, and 4YR were 4.77 (SD = 0.72), 4.79 (SD = 0.84), 5.08 (SD = 0.80), and 5.47 (SD = 0.66), respectively, and did not differ ($P = 0.34$) over time for the same animal. Hip height and BW peaked at 4YR ($P < 0.001$). While BW and FS are related to the same measures taken at maturity, measurements taken at BR appear to be superior to those taken at WN when used to predict mature size of beef cows.

Key words: beef cow, frame score, mature size

321 A mineral survey of Louisiana beef cow/calf production systems. J. Rowntree*[1], K. Guidry[2], G. Scaglia[2], G. Gentry[2], and L. Southern[2], *[1]Michigan State University, East Lansing, [2]LSU Agricultural Center, Baton Rouge, LA.*

The purpose of this research was to determine the state and regional mineral status of Louisiana forages and beef cattle. Louisiana beef cattle operations (n = 25) were sampled and divided into 7 geographical regions, including the northwest (NW), northeast (NE), central (CE), southwest (SW), south central (SC), Florida parishes (FP) and southeast (SE) regions. Over a 2 year period, water and soil samples were collected from each operation annually, forage samples were collected quarterly in Aug to Sep, Nov to Dec, Feb to Mar and May to June and bovine serum samples were collected twice annually in the fall and spring seasons. The highest ($P < 0.05$) average regional water K and S concentrations were observed in the SE region and water Ca and Mg concentrations were the highest ($P < 0.05$) in the NE, CE and SE regions. Similar to water, soil Ca, Mg and K concentrations in our study, were higher ($P < 0.05$) in the SE compared with all other regions. Soil Cu concentrations were below critical levels in the CE region and all soil Zn concentrations, except the SE region, were lower than reported critical levels indicating soil deficiency. The average forage concentration for each mineral were: Ca (0.42%), P (0.28%), Mg (0.21%), K (1.83%), Na (0.10%), S (0.32%), Cu (8.12 ppm), Fe (323.46 ppm), Mn (254.85 ppm) and Zn (41.29 ppm). In addition, only mean forage Cu concentrations were lower than minimum requirements and regional forage K (NW region), Mg (FP region), Na (CE region) and S (NW and SE regions) concentrations were higher ($P < 0.05$) than other regions. The average regional serum K concentration in the NE region was higher ($P < 0.05$) than all other regions. Average bovine serum mineral concentrations in Louisiana were: Ca (9.02 mg/100 mL), P (13.62 mg/100 mL), Mg (1.92 mg/100 mL), K (21.66 mg/100 mL), Na (303.30 mg/100 mL), S (103.31 mg/100 mL), Cu (0.63 µg/ml), Fe (7.44 µg/ml), Zn (1.28 µg/ml), Mn (8.08 ng/ml) and Se (64.48 ng/ml). Furthermore, of these minerals, serum Mg, Na, Cu and Mn concentrations were lower than critical levels, indicative of deficiency.

Key words: beef cattle, forages, mineral

322 Finishing steers and bulls with high-vitamin E diets: Effect on pH and tenderness of beef. C. Reyes, C. Fuentes, and R. E. Larraín*, *Pontificia Universidad Catolica de Chile, Santiago, Chile.*

Release of glucocorticoids to the blood stream during stress may mobilize energy reserves in muscle. Reduced glycogen depots at the time of slaughter may lead to meat pH-values above 5.8, and meat with elevated pH is less tender. Vitamin E reduced activation of the hypothalamic-hypophysial-adrenocortical axis in farm animals. Thus, the objective of this study was to test if bovines finished with a high vitamin E diet produce beef with lower pH and increased tenderness. Thirty-eight steers and bulls were blocked by sex, then grouped in 16 pens of 2 or 3 animals of similar BW, and randomly assign to one of 2 treatments: a control diet designed to provide 60 IU vitamin E•animal^{-1}•d^{-1} and the control diet supplemented with 2,000 IU vitamin E•animal^{-1}•d^{-1}. Each pen was considered an experimental unit (n = 8). Feed was offered once daily to each pen to provide ad libitum access to feed. Initial and final BW were the average of 2 weights before feeding in consecutive days. After 123 d on feed, animals were transported for about 1.5 h to a local abattoir and harvested approximately 8 h after arrival. Beef pH was measured 48 h post-mortem in the longissimus muscle, using a spear-tip pH meter inserted between the 12th and 13th rib. Tenderness was evaluated in 1 × 1 cm strips, cut perpendicular to the fiber axis, using a Warner-Bratzler shear machine. Factors in the model were sex and treatment, and initial BW was included as covariate. Differences were considered significant when ANOVA had $P < 0.05$. There were no differences in ADG (1.16 ± 0.063 kg/d, $P = 0.49$), carcass yield (55.8 ± 0.4%, $P = 0.56$), pH (5.87 ± 0.09, $P = 0.96$) and WBS (2.17 ± 0.12 kg, $P = 0.54$) between treatments. High mean pH value of beef was due to 3 pens having an average pH above 6.0. All of these pens contained bulls, 2 from the control and 1 from the vitamin E treatment. We concluded that 2,000 IU vitamin E•animal^{-1}•d^{-1} produce no changes in pH and tenderness of beef.

Key words: vitamin E, pH, tenderness

323 Effect of beef cow age and calf sex on model-predicted energy efficiency. M. J. Baker*[1], L. O. Tedeschi[2], D. G. Fox[1], and G. Jacimovski[1], *[1]Cornell University, Ithaca, NY, [2]Texas A&M University, College Station.*

The identification of efficient beef cows under grazing conditions is important to ensure competitiveness and profitability. As the on-farm direct measurement of DMI is cost-prohibitive, a model (Cattle Value Discovery System, CVDSbc) was developed to predict an energy efficiency index (EEI, Mcal/kg) that is based on the predicted ME required (MER, Mcal/d) by the cow or cow + calf within a reproductive cycle divided by the calf weaning weight (WW, kg). The objective of this study was to evaluate the impact of cow age and calf sex on the EEI with or without adjusting WW for cow age and calf sex as per Beef Improvement Federation Guidelines. Data from predominantly Angus x Simmental spring calving cows (n = 37, BW = 628 kg) and monthly forage quality were used. The BW at 28% empty body fat (FBW, kg) was assumed 620 and 520 kg for steer and heifer calves, respectively. The CVDSbc computes MER based on cow and calf characteristics and forage quality, and iterates cow peak milk (PK, kg) until the predicted WW matches the observed WW. The statistical analyses were conducted with PROC GLM and PROC REG assuming cow age and calf sex as fixed factors in a completely randomized design. They were analyzed separately. When WW was not adjusted, the age of cow affected the predicted PK ($P = 0.0644$) in which 2 year-old cows tended to have a lesser PK than 3, 4 and 5 year-old cows (3.79, 5.39, 5.41, and 5.38, respectively), suggesting older cows produce more milk to support a greater ADG of the calves. The cow EEI was greater ($P = 0.049$) for heifer than steer calves (40.4 and 36.6 Mcal/kg, respectively). Similarly, the cow + calf EEI was greater ($P = 0.056$) for heifer than steer calves (42.9 and 39.2 Mcal/kg, respectively). These results were expected; at the same age steers have a greater BW which increases the dilution of the cow's MER compared with the lighter heifers. When WW was adjusted to calf sex, no differences ($P > 0.25$) were observed between age and calf sex on EEI and PK. The correlations between adjusted and unadjusted cow and cow + calf EEI were 0.896 and 0.884, respectively. These results suggest that cow age and calf sex have to be accounted for when comparing cow EEI.

Key words: cattle, modeling, selection

324 Selling prices of Arkansas beef feeder calves as affected by management practices. T. R. Troxel* and B. L. Barham, *University of Arkansas, Department of Animal Science, Little Rock.*

The objective of this study was to determine how management factors affected the selling price of beef calves. Data were collected from January 1 to December 31, 2010 at 14 Arkansas livestock auctions. The

database consisted of 38,346 lots consisting of 79,822 head of cattle representing 19% of the total calves sold. Information was collected by experienced livestock market news reporters and included body condition, castration, horn status, fill, health, and individual or group selling. Each factor was analyzed using GLM procedures using weight as a covariate, and least-squared means were generated. All prices are based on dollars per 45.45 kg of live weight. Body condition affected selling price ($P < 0.0001$) with fat, very thin, fleshy, average, and thin calves selling for $94.40, $98.05, $102.23, $108.36 and $110.11, respectively. Steers sold for $6.31 more ($116.16; $P < 0.001$) than bulls ($109.85), and polled calves sold for $8.03 more ($P < 0.001$) than horned calves. Heifers sold for $102.71. Fill affected selling price ($P < 0.0001$) with gaunt, shrunk, average, full and tanked calves selling for $114.40, $109.65, $106.28, $99.41 and $90.33, respectively. Healthy calves sold for $108.69, which was higher ($P < 0.001$) than dead hair ($98.43), stale ($87.21), sick ($62.48), bad eye(s) ($95.38) or lame ($68.57) calves. Calves that were announced as preconditioned sold for a higher price ($113.57; $P < 0.001$) than healthy calves. The selling prices of calves sold as singles, groups of 2 to 5 head or groups of 6 or greater were $107.81, $110.52 and $112.60, respectively ($P < 0.001$). Cattle classified as calves sold for $110.29, which was higher than cattle classified as yearlings ($104.81; $P < 0.001$). Beef cattle producers can greatly influence the selling prices of calves through managing calf body condition, castration, horns, fill, health and group selling.

Key words: selling price, beef calves, auctions

325 The relationship between climatic conditions and the incidence of calving. T. R. Troxel*[1], M. S. Gadberry[1], D. Hubbell[2], and W. Kellogg[3], *[1]University of Arkansas, Department of Animal Science, Little Rock, [2]University of Arkansas, Department of Animal Science, Batesville, [3]University of Arkansas, Department of Animal Science, Fayetteville.*

The object of this study was to examine the relationship of barometric pressure and maximum and minimum temperature with the incidence of calving. Calving data (2005 to 2009) from the Livestock and Forestry Station (Batesville, AR) and Savoy Research Unit (Savoy, AR) were used. All cows were multiparous, predominately Angus, and natural serviced. Both locations calved in the spring (Jan to Apr) and fall (Sep to Dec). Total calving observations were 1,547. Calving occurred on 54% of the days within the calving season. The climate data from the Fayetteville and Mountain Home, AR weather stations were obtained from the Southern Regional Climate Center, Louisiana State University, Baton Rouge and was used for the Savoy and Batesville research stations, respectively. There was a season by calving observation effect ($P < 0.05$) for all 3 climatic measurements. Spring barometric pressure on day of calving and 1, 2 and 3 d before calving was greater than corresponding non-calving dates ($P < 0.05$), but no differences were detected in the fall ($P > 0.10$). Spring maximum temperature was lower on day of calving and 1 and 3 d before calving than corresponding non-calving dates ($P < 0.05$), but fall maximum temperature was higher d 1 and 3 d before calving than corresponding non-calving dates ($P < 0.05$). Spring minimum temperature was lower on day of calving and 1, 2 and 3 d before calving than corresponding non-calving dates ($P < 0.05$), but fall minimum temperature was higher d 1, 2 and 3 d before calving than corresponding non-calving dates ($P < 0.05$). For spring-calving cows, an increase in barometric pressure and a decrease in maximum and minimum temperature were associated with calving. For fall-calving cows, an increase in maximum and minimum temperature with no barometric pressure relationship was associated with day of calving. This data suggest monitoring weather conditions may provide an indication of calving incidences and possibly prepare producers to monitor cows.

Key words: barometric pressure, temperature, calving

326 Selling price of Arkansas beef feeder calves as affected by phenotypic expression. B. L. Barham* and T. R. Troxel, *University of Arkansas, Department of Animal Science, Little Rock.*

A study was conducted to evaluate the impact of genetic factors on the selling price of beef calves marketed through Arkansas auction barns. Data was collected on 38,346 lots consisting of 79,822 head marketed through 14 auction barns in 2010. Data collection was conducted by experienced livestock market news reporters. Information pertaining to the phenotypic expression of calf genetics included subjective identification of breed, color, and USDA frame and muscle scores. Due to the unbalanced nature of the data set, variables were analyzed individually with calf weight as a covariate, and least squares means were generated. All prices are based on dollars per 45.45 kg of live weight. Breed, color (independent of breed), frame and muscle impacted ($P < 0.001$) feeder calf price. Twenty breed or breed groupings were evaluated. Five breed or breed types received the highest selling prices but were not different from each other ($P > 0.10$) were Angus x Brahman ($111.82), Angus x Herford ($111.70), Angus ($111.36), Charolais x Hereford ($110.48) and Hereford x Angus x Brahman ($110.22). Simmental ($99.90), Brahman ($94.34), and Longhorn/Longhorn cross calves ($71.75) were lower in price ($P < 0.001$) compared with other breeds. Black-white faced calves ($111.74) received the highest selling price ($P < 0.001$) followed by black ($110.23), yellow ($110.09), and yellow-white faced ($109.81) which were not different from each other ($P > 0.10$). Spotted calves ($82.16) received the lowest selling price ($P < 0.001$). The selling prices for large- ($108.81) and medium- ($108.67) framed calves were similar ($P > 0.10$) but were higher ($P < 0.001$) than small-framed calves ($86.71). Price also differed ($P < 0.001$) for muscle scores 1, 2, 3 and 4 ($110.82, $101.88, $78.41 and $53.64, respectively). Beef cattle producers can influence the calf-selling price through genetic selection.

Key words: feeder calves, market price, genetic factors

327 Using ultrasonography to determine reproductive tract development in beef heifers. R. A. Cushman*, L. A. Kuehn, R. M. Thallman, W. M. Snelling, and H. C. Freetly, *USDA-ARS U.S. Meat Animal Research Center, Clay Center, NE.*

Choosing replacement beef heifers is a decision with long-term implications for profitability for the cow-calf producer. If a replacement heifer fails to wean the number of calves necessary to recover her development costs, then she incurs a net loss for the ranch. To avoid such losses, it is imperative to develop technologies that aid in identifying heifers with little chance of weaning 3 or more calves. The first hurdle to reproductive competency is the establishment or reproductive cycles (puberty). No intensive research has evaluated the size of the ovaries or uterus in relation to reproductive status in beef heifers. Therefore, the objective of the present study was to use ultrasonography to measure the sizes of these structures and relate them to reproductive status in yearling crossbred beef heifers (n = 368). At weaning, heifers were moved to a feedlot and placed on a growing ration. At 13.6 ± 0.6 mo of age (range 12 to 15 mo), development of the reproductive tract was evaluated using ultrasonography. Each ovary was measured for length and height and a cross-sectional measurement of the endometrium was taken on the right side, approximately 1 cm

anterior to the uterine body. Antral follicles >3 mm and corpora lutea were counted. Percentages of Brahman, Continental, or British breeds were fitted as fixed covariates. Numbers of antral follicles increased as the percentage of Brahman influence in an individual heifer increased ($P < 0.0001$). There was no breed effect for ovarian size or endometrial diameter. Both ovarian size and endometrial diameter were greater in 15-mo-old heifers than 12-mo-old heifers ($P \leq 0.03$). The percent of heifers that had initiated reproductive cycles as determined by the presence of a corpus luteum at ultrasonography increased as age increased and as percent Brahman decreased ($P \leq 0.001$). The use of ultrasonography to evaluate the ovaries and uterus in yearling beef heifers is a practical tool to aid in determining the reproductive status of replacement heifers. USDA is an equal opportunity provider and employer.

Key words: beef heifer, reproductive tract, puberty

328 Characterization of feeding behavior of abrupt-weaned crossbred heifer calves. A. N. Loyd*[1,4], R. C. Vann[2], J. P. Banta[3], T. H. Welsh Jr.[1], J. A. Carroll[4], and R. D. Randel[5], *[1]Texas AgriLife Research, College Station, [2]MAFES, Mississippi State University, Raymond, [3]Texas AgriLife Extension, Overton, [4]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [5]Texas AgriLife Research, Overton, TX.*

Stress experienced by calves at weaning often culminates in poor post-weaning feed intake (FI) and growth performance. Understanding feeding behavior during this time is crucial to successful management of these calves. The objective of this study was to characterize the feeding behavior of calves post-weaning. Brahman x British heifers (n = 48) born in spring 2010 at the Brown Loam Branch Experiment Station in Raymond, MS were abruptly weaned from their dams at 199 ± 18 d of age. Heifers were penned in one of 2 dry-lots and received ad libitum access to a high roughage diet offered in GrowSafe bunks. Feeding behavior was monitored for 24–26 d post-weaning and BW was evaluated weekly beginning at weaning. Data were analyzed using the MIXED procedure of SAS with day as a repeated measure when applicable. The number and duration of daily meal events, the duration of daily head down time, and daily FI increased with time post-weaning ($P < 0.0001$). Body weight was similar for all time points ($P = 0.32$). However, there was great variation in the number of days it took heifers to first approach the feed bunks, eat feed for the first time, eat feed consistently for at least 5 d, and consume enough feed to meet estimated NE_m requirements (Table 1). To account for this variation, the proportion of Brahman influence was included in the statistical model as a covariate. Brahman-influenced heifers were slower to attend the bunks ($P < 0.0001$), begin consuming feed ($P < 0.0001$), consistently consume feed ($P < 0.0001$), and consume enough feed to meet NE_m requirements ($P < 0.03$). However, there was no effect ($P > 0.10$) of breedtype on feeding behavior or FI over the course of the entire feeding period. These data suggest there is considerable variation in post-weaning feeding behavior, of which some is attributable to breedtype. These data also highlight an important consideration when utilizing newly weaned calves in feeding trials, especially those using GrowSafe bunks.

Table 1. Feeding behavior traits of heifers post-weaning

Trait	Mean	SD	Minimum	Maximum
First attendance at bunk (d)	3.9	4.1	0	21
First feed consumption (d)	5.1	5.0	0	26
Consistent feed consumption (d)	8.3	6.2	0	26
NE_m requirement achieved (d)	10.7	4.6	3	21

Key words: feed intake, heifer, weaning

Breeding and Genetics: Genomic Selection and Whole-Genome Association II

329 Use of the Illumina Bovine3K BEAD chip in dairy genomic evaluation. G. R. Wiggans[1], T. A. Cooper*[1], K. M. Olson[2], and P. M. VanRaden[1], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]National Association of Animal Breeders, Columbia, MO.*

Genomic evaluations using genotypes from the Illumina Bovine3K BEAD chip became available in September 2010 and made official in December 2010. The approximately 4,000 samples a month submitted for this low cost chip are 79% hair, 10% blood, 10% nasal and 1% semen and tissue, and 93% are from females. To integrate the 3K genotypes into the evaluations, they are imputed from the 2,614 single nucleotide polymorphisms (SNP) used from the 3K chip to the 42,503 used in evaluation. Reliability is discounted to recognize errors associated with imputation. The average 3K genomic evaluation reliability is 5 points lower than for 50K evaluations. The accuracy of imputation is dependent on an animal's relationship to the genotyped population. The average imputed call rate for 3K genotypes is 95.2% and ranges from 71.0% to 97.0%. Animals that have a low imputed call rate are those who have unknown pedigree or no genotyped relatives. Animals tested using the 50K chip have at least one genotyped parent 94.5% of the time, whereas only 84.2% of 3K genotyped animals do. For approximately 8% of 3K genotypes, the sire is determined to be incorrect. If the true sire of an animal is genotyped, it can be identified with > 99% certainty. Other errors such as dam conflicts, unidentified identical twins / split embryos and breed conflicts prevent genotypes from being used. The chemistry used for the 3K chip is different from that of the 50K chip and causes greater variability in the accuracy of the genotypes. Because of this, a 3K specific check was added which excludes approximately 1% of samples. They are rejected because they have a high proportion of conflicts between SNP of the sire/dam and progeny. The performance of SNP also differed between chips, resulting in 272 SNP that were usable on the 50K chip being not usable on 3K. The 3K chip has been successful in extending genotyping to a larger portion of the cow population. The evaluation system has been modified to accommodate the characteristics of the chip. Improvements in accuracy of imputation and other improvements will further improve the accuracy of 3K based genomic evaluations.

Key words: 3K, genomic evaluation, parentage

330 Properties of different density genotypes used in dairy cattle evaluation. P. M. VanRaden[1], M. E. Tooker*[1], K. M. Olson[2], T. A. Cooper[1], G. R. Wiggans[1], and C. P. Van Tassell[3], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]National Association of Animal Breeders, Columbia, MO, [3]Bovine Functional Genomics Laboratory, ARS, USDA, Beltsville, MD.*

Dairy cattle breeders have used a 50K chip since April 2008 and a less expensive, lower density (3K) chip since September 2010 in genomic selection. Evaluations from 3K are less reliable because genotype calls are less accurate and missing markers are imputed. After excluding genotypes with <90% call rate and other edits, marker properties were compared for 8,305 animals with 3K, 54,643 with 50K version 1, 2,602 with 50K version 2, and 353 with a higher density (777K) chip. Animals were of 3 breeds, and all 4 chips were from Illumina. Numbers of markers selected were 2,614 from the 3K chip, 42,503 from 50K version 1, 41,019 from 50K version 2, and 632,665 from the 777K. Markers selected each had <20% missing genotypes and <2% parent-progeny conflicts, with proportionally stricter limits for markers with minor allele frequencies <0.5. The selected 3K markers averaged 0.7% missing genotypes vs. 0.4% for the 50K markers. Parent-progeny conflicts averaged 0.07% for the selected 3K markers vs. 0.01% for the 50K markers. Properties of the 777K chip are similar to the 50K chips, but only 38,201 markers that match the 50K chip currently are used. Genomic evaluations were examined for 319 animals that had 3K genotypes in December and then 50K in February. Means were nearly identical (within 1 pound for fat and protein). The 3K evaluations had SD about 96% as large as 50K, in agreement with the 95% expected from the lower published reliability (64 vs. 71% for net merit). The correlations ranged from 0.92 to 0.96 across traits as compared with 0.46 to 0.66 for parent average with 50K. Version 2 of findhap.f90 will improve the 3K correlations to 0.94 to 0.97, improve average reliability by 2%, and improve the percentage of correctly imputed genotypes to 96.3% from 93.8% with version 1. Breeders can increase reliability affordably using lower density to impute higher density genotypes.

Key words: genomic evaluation, imputation, marker density

331 Use of the partial least-squares regression to impute missing markers when some animals are genotyped with low-density SNP platforms. C. Dimauro*[1], S. Sorbolini[1], E. Pintus[1], J. T. van Kaam[2], and N. P. P. Macciotta[1], *[1]Università di Sassari, Sassari, Italy, [2]Associazione Nazionale Allevatori Frisona Italiana, Cremona, Italy.*

In genomic selection direct genomic values (DGV) are predicted by using genotype information provided by high-density SNP platforms. At present, genotyping process is very expensive and problems arise when genomic data extracted from different SNP platforms has to be joined. Recently, several algorithms aimed at imputing marker information not directly collected in some animals, have been suggested. In this work the partial least squares regression (PLSR) imputation method, previously developed by using only simulated data, was tested on a real experiment. Data were from 1,042 Italian Holstein sires genotyped with the Illumina BovineSNP50 BeadChip. Animals were divided in 2 groups. 900 old bulls constituted the training population with all SNP markers considered known. The remaining 142 young bulls were the prediction population where only 3,072 markers, corresponding to the Illumina Bovine 3K BeadChip, were considered known. Efficiency of PLSR imputation method was tested through the mean imputation error rate and the mean imputation accuracy. The first refers to the mean proportion of incorrectly imputed genotypes, the second to the mean correlation coefficient between actual and PLSR imputed genotypes. Moreover, DGV accuracies for milk, fat percentage and protein percentage were evaluated both for original and PLSR predicted data. The ratio between DGV accuracies obtained by using PLSR imputed data and original data was used as synthetic index of goodness of prediction. Results for mean imputation accuracy and mean imputation error rate were 0.70 and 0.18, respectively, whereas the DGV ratios were 0.975 for milk, 0.993 for fat percentage and 0.957 for protein percentage. These results are better than those obtained in a simulated scenario with a more favorable number of animals. Therefore, the PLSR imputation method works better with real than simulated data, thus promising a higher efficiency in SNP marker prediction if the number of genotyped animals increases.

Key words: imputation, genomic selection

332 Reduced dimensionality in GS models through Lassoed supervised principal components. C. Maltecca* and K. A. Gray, *North Carolina State University, Raleigh.*

The availability of high-density SNP panels and sequencing information poses a challenge in genomic data analysis due to highly over-parameterized models. Identification of linear combinations that exhibit large variation through principal components analysis is often employed to reduce model dimensionality. In this work we investigated the use of supervised principal components, an extension of principal components analysis aiming at obtaining a combination of features with both high variance and significant correlation with the outcome. De-regressed breeding values for milk, fat, and protein yield, were obtained for approximately 8,000 US-HOL bulls genotyped with the Illumina 50K chip. For each of the 36,768 SNPs available for the analysis a standardized univariate regression coefficient was calculated. For each value, of a threshold θ ($0 < \theta1 < \theta2... < \theta k$), a reduced data matrix was formed, consisting only of features that exceeded the absolute value θ. For features exceeding θ the first 3 principal components were calculated. Optimal values of θ for each trait were obtained through cross-validation. Soft thresholding employing the correlation of each feature with the supervised PC predictor was used in obtaining a reduced number of features. Subsequent genomic breeding value predictions were obtained through the use of Bayesian LASSO. Values of θ of 3.5, 3.1 and 3.6 were found for milk, fat and protein yield respectively. These values resulted in reduced panels of 1,213, 1,189, and 958 SNPs, respectively. Correlations between GEBVs and BV in a prediction set obtained splitting the data chronologically were of 0.691 (0.712 whole panel), 0.713 (0.743 whole panel), and 0.708 (0.731whole panel), while slopes for the regression of GEBV on BV in the prediction set were of 0.780 (0.765 whole panel), 0.801 (1.125 whole panel), and 0.804 (1.198 whole panel), respectively for milk, fat and protein. For all traits, reduced models recovered more than 90% of the overall information at a fraction of the computing cost.

Key words: genomic selection, supervised principal components, shrinkage estimators

333 FImpute - An efficient imputation algorithm for dairy cattle populations. M. Sargolzaei*[1,2], J. P. Chesnais[1], and F. S. Schenkel[2], *[1]L'Alliance Boviteq, Saint-Hyacinthe, QC, Canada, [2]University of Guelph, Guelph, ON, Canada.*

Imputation consists of approximating the high density (HD) genotype of an individual using information from its lower density (LD) genotype and from the HD genotypes of other individuals, which can be relatives of the imputed individual (family-based imputation) or members of the population at large (population-based imputation). An efficient imputation algorithm and program (FImpute) was developed using family followed by population imputation and optimized for memory and CPU time. The algorithm was first tested on a group of 6,246 Holstein animals genotyped for the 50K panel, which was representative of younger animals recently genotyped in the North America. Only the SNP used in the 3K panel were retained, and 50K genotypes were approximated using information from these SNP and the 50K genotypes of older animals in the North American Holstein population. Overall, the percentages of SNP imputed correctly, incorrectly and missing were 96.8, 1.44 and 1.76%, respectively. As expected the correct call rate was the highest when both parents where genotyped with 50K, but it remained above 90% for 96.2% of animals. A validation study was carried out to assess the effect of using imputed genotypes on GPA accuracy. The realized reliabilities for the GPA of validation bulls (n = 498) were only slightly lower when using imputed genotypes compared with actual 50K genotypes, by a range of 0 to 0.04 depending on the trait. FImpute was also used in the Jersey and Brown Swiss breeds, yielding imputation accuracies high enough to make adequate genomic predictions. When using the 3K panel, most of the imputation accuracy comes from family rather than population imputation. Population imputation would contribute more with a larger LD panel, e.g., when imputing from 50k to 777K. Using both types of imputation, as in FImpute, will nevertheless be required to obtain maximum imputation accuracy. FImpute is now used for imputation from 3k to 50k for official genomic evaluations in Canada.

Key words: imputation, software, validation

334 Estimation of linkage disequilibrium in four US pig breeds. Y. M. Badke*[1], R. O. Bates[1], C. W. Ernst[1], C. Schwab[2], and J. P. Steibel[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]National Swine Registry, West Lafayette, IN.*

The success of marker assisted selection depends on the amount of linkage disequilibrium (LD) across the genome. To implement marker assisted selection in the swine industry information about extent and degree of LD is essential, and LD can be used to estimate effective population size. The objective of this study was to estimate LD in 4 US breeds of pigs (Duroc, Hampshire, Landrace, and Yorkshire). To estimate LD, 351 animals from 117 sire/dam/offspring trios were genotyped using the Illumina Porcine SNP60 BeadChip. DNA was isolated from samples (blood or semen) obtained from purebred animals recorded with the National Swine Registry. The number of trios per breed was 30, 26, 29, and 32 for the Duroc, Hampshire, Landrace and Yorkshire breeds, respectively. After excluding SNP for low genotyping rate, failure to meet Hardy Weinberg equilibrium, and minor allele frequency below 5%, an average of 36,421 SNP with an average intermarker distance of 66Kb were used for the analysis. The genotypes were phased and pairwise r^2 was computed. Average r^2 across all chromosomes was 0.36 (sd = 0.028) in Landrace, 0.38 (sd = 0.039) in Yorkshire, 0.43 (sd = 0.036) in Hampshire and 0.45 (sd = 0.041) in Duroc. For markers 1Mb apart, r^2 ranged from 0.13 (sd = 0.037) in Landrace to 0.18 (sd = 0.057) in Duroc and Hampshire. The LD between neighboring markers was $r^2 > 0.3$ for 43% of marker pairs in Landrace, 47% in Yorkshire, 51% in Hampshire and 53% in Duroc. The current average estimated effective population size based on estimated r^2 was 105 for Hampshire, 111 for Landrace, and 125 for both Yorkshire and Duroc. These estimates of LD are lower than previously reported values based on a smaller marker panel, and lower than recently reported estimates for Finnish Landrace and Yorkshire pigs based on the SNP60 BeadChip. Estimates of effective population size in Finnish Landrace and Yorkshire pigs using genotypes and pedigree information were smaller than our estimates. Results of this study are relevant to the US purebred seedstock industry and critical for the design of programs of whole genome marker assisted evaluation and selection.

Key words: swine, linkage disequilibrium, effective population size

335 A major QTL for response to porcine reproductive and respiratory syndrome virus in pigs. N. Boddicker*[1], D. J. Garrick[1], J. M. Reecy[1], R. Rowland[2], M. F. Rothschild[1], J. P. Steibel[3], J. K. Lunney[4], and J. C. M. Dekkers[1], *[1]Iowa State University, Ames, [2]Kansas State University, Manhattan, [3]Michigan State University,*

East Lansing, [4]United States Department of Agriculture, Beltsville, MD.

Porcine reproductive and respiratory syndrome (PRRS) is an important disease in swine production. The objective of this study was to discover the genetic basis of host response to PRRS virus using data from the PRRS Host Genetics Consortium PRRS-CAP project by conducting a genome-wide association analysis. Three groups of 200 commercial crossbred pigs were infected between 18 and 28 d of age with virus isolate NVSL 97–7985. Blood samples and body weights were collected up to 42 d post infection (dpi). Pigs were genotyped with the Illumina Porcine 60k Beadchip. Whole genome analyses focused on viral load (VL = area under the curve for log-transformed RT-PCR based serum virus from 0 to 21 dpi) and weight gain (WG = gain from 0 to 42 dpi). Heritabilities estimated using pedigree information were 28 and 26% for VL and WG, with maternal effects estimates of 14 and 11%. Phenotypic and genetic correlations between VL and WG were −0.25 and −0.34. Associations with SNPs were identified using BayesB of Gensel software. Using Porcine sequence build 10, a 33 SNP region associated with both VL and WG was found on chromosome 4. The favorable correlation between the genomic estimated breeding values for VL and WG for the 33 SNP region was −1.0. The region explained 15.7% of genetic variance for VL and 11.2% for WG. The unfavorable allele for the most significant SNP had a frequency of 0.84 and estimated allele substitution effects were significant ($P < 0.01$) for each of the 3 groups when fitting the SNP as a fixed covariate in ASREML, with estimates of −3.9, −4.7, and-4.8 units for VL (phenotypic SD = 6.9), and 3.0, 1.5, and 1.9 kg (phenotypic SD = 3 kg) for WG. This region explains a substantial proportion of the genetic variance in response to experimental challenge with a specific strain of the virus. The SNPs in this region are in high LD, which makes further fine mapping difficult. This region may provide opportunities to select pigs for PRRS resistance, but validation is required. This work was supported by the PRRS CAP, USDA NIFA Award 2008-55620-19132, the NRSP-8 Swine Genome and Bioinformatics coordination projects, and by the breeding companies that provided pigs.

Key words: swine, PRRS, GWAS

336 Use of sample pooling in a genome-wide association study identifies chromosomal regions affecting incidence of bovine respiratory disease. L. A. Kuehn*, J. W. Keele, E. Casas, S. A. Jones, D. A. King, T. G. McDaneld, T. P. L. Smith, and T. L. Wheeler, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

We hypothesize that genome-wide association (GWA) based on high-density SNP arrays can be used to identify chromosomal regions affecting disease incidence using a case/control type approach. However, the large sample size required to map a lowly heritable trait like susceptibility to bovine respiratory disease complex (BRDC) makes the cost of such an effort prohibitive. We applied pooling of lung samples from slaughter animals with severe lung lesions (a proxy for incidence of respiratory disease) as the case group, and lungs from animals with no visible lesions as the control group (n = 1,000 for each group), to evaluate sample pooling as an approach to reduce the cost of GWA experiments on complex traits. Comparison of allele frequency estimates for each SNP was used to identify chromosomal regions influencing BRDC. We prepared 10 pools of equal volume lung tissue cores from 100 animals in each of the 2 groups (20 total pools), and DNA from each pool was genotyped in duplicate. Bead level data was used to estimate allele frequency for each pool and combined within group for comparison between case and control. Distances between pools and their replicates across 775,996 SNP were calculated and used to form a neighbor-joining phylogeny, such that individual SNP have minuscule effect on the resulting phylogeny. Allele frequency differences between case and control groups were conditionally compared using phylogenetic comparative methods, resulting in SNP with genome-wide significant associations ($P < 0.05$) in 7 chromosomal regions on BTA 9, 10, 13, 18, 20, 21, and 26. Two additional regions on BTA 7 and 17 harbor SNP under marginally less stringent correction (false discovery rate, FDR, 1%), while 1 or 2 regions on all bovine chromosomes are significant with a relaxed FDR of 5%. We conclude that the presence of lung lesions at slaughter is influenced by multiple loci, consistent with expectations from the multifactorial nature of BRDC, and that tissue pooling represents an economical means to dissect the genetic influences on this trait.

Key words: bovine respiratory disease, DNA pooling, genome wide association

337 Genetic analysis of dry matter intake in Holstein cows. D. Spurlock*, A. Wolc, D. Elkins, E. Scalese, J. Dekkers, and R. Fernando, *Iowa State University, Ames.*

Improving feed efficiency of lactating cows is gaining increased interest in the dairy industry. One strategy to improve feed efficiency is to select cows that consume less feed per unit of milk produced. However, selection for improved efficiency may contribute to undesirable correlated changes in fitness traits due to reduced feed intake at the onset of lactation. The objective of this research was to describe the genetic regulation of dry matter intake (DMI) in Holstein cows over the first 150 d in milk (DIM) using both quantitative and genomic approaches. Daily feed intake was recorded for 228 primiparous and 172 multiparous Holstein cows using the Calan Broadbent feeding system, and dry matter content of feed was determined weekly. Random regression models were used to estimate genetic parameters for DMI. Maximum heritability of daily DMI was 0.27 at 25 DIM, and declined to a minimum of 0.18 at 120 DIM. The genetic correlation between DMI on different days was close to unity when less than 60 d apart, and declined to 0.83 between DMI at 10 and 150 DIM. For genomic analyses, DMI was averaged over each of 5 monthly intervals. Genotypes were determined for all cows using the Illumina Bovine 50K SNP platform. Genomic regions associated with variation in DMI were identified using method BayesC implemented in the software package GenSel. Jointly, all genetic markers accounted for 26 to 50 percent of phenotypic variance in average DMI for months one, 2, 3 and 5, but only 4 percent in mo 4. Individual markers had relatively small effects. For each month of lactation, the 10 genomic regions explaining the greatest variance in average DMI were identified. Only 3 of these regions were shared between average DMI for the first and fifth month of lactation. Together, these analyses confirm that DMI is a moderately heritable trait, and that its genetic regulation changes with stage of lactation. The genetic correlation of daily DMI is high throughout the first half of lactation, but use of genetic markers may help to minimize undesirable change in DMI during early lactation as a correlated response to selection for improved efficiency.

Key words: dry matter intake, heritability, genomics

338 Genetic markers in bovine chromosome 14 are significant for residual feed intake in steers. A. K. Lindholm-Perry*, L. A. Kuehn, T. P. L. Smith, W. M. Snelling, and H. C. Freetly, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Genetic selection for animals that require less feed while still achieving acceptable levels of production could result in substantial cost savings for cattle producers. The purpose of this study was to identify DNA markers with predictive merit for differences among cattle for traits associated with feed efficiency. Crossbred steers (n = 1,195) were fed a high-corn diet for 140 d and average daily feed intake (ADFI), ADG, and residual feed intake (RFI) phenotypes were obtained. RFI was defined from the regression of ADFI on ADG and mid-metabolic BW. These animals were genotyped with the Illumina Bovine SNP50 BeadChip and an association analysis of these single nucleotide polymorphisms (SNP) was performed. A 1.6 Mb region at BTA14: 22.3 to 23.9 was identified as having significant association (nominal $P = 0.04$ to 0.0006) with RFI. To develop markers with the maximum ability to discriminate favorable alleles, 70 additional SNP, not present on the BeadChip, were genotyped within this chromosomal region. These new SNP were genotyped on the same animals and tested for association with ADFI, ADG, and RFI. The statistical model included fixed effects of year and location; covariates of age, heterosis, and breed percentage; and a random polygenic effect. Ten markers were nominally significant within this region for RFI, the most significant of these were clustered between 23.3 to 23.5 Mb. After conservative correction for multiple testing, one marker at 23.30 Mb remained significant. Many of these markers were also significant for ADG, although none were significant after correction. Alleles with positive effects on ADG correspond to negative effects on RFI, suggesting a marker effect of increased growth without increased feed intake. These markers may be useful as prediction tools for animals that utilize feed more efficiently; however, potential impact of these markers on additional production traits will need to be assessed.

Key words: beef cattle, feed efficiency, genomics

339 QTL-by-feeding period interaction for residual feed intake in crossbred steers: a genome selection approach. O. N. Durunna*[1], D. J. Nkrumah[2], S. S. Moore[1], and Z. Wang[1], *[1]University of Alberta, Edmonton, Alberta, Canada, [2]Pfizer Animal Genetics, Kalamazoo, MI.*

Most feeding trials are conducted within a single feeding period but growing cattle are fed across different feeding periods. It is important to understand whether different feeding periods contribute to differential performance of the QTLs that are associated with residual feed intake (RFI) in growing steers. Our objective was to determine whether similar QTLs associated with RFI in steers are detected during the fall and winter-feeding periods. Feeding trials were conducted over 7 years using crossbred steers fed a finisher diet during the fall (P1) or winter (P2). The number of steers evaluated in P1 and P2 were 319 and 532, respectively. Feed intake was measured with the GrowSafe system, and RFI calculated by linear regression. Genotyping was done using the Illumina BovineSNP50 Beadchip. Genome selection was implemented using a Bayesian approach in Proc QTL using 1407 evenly spaced markers from 40653 SNP. 5000 permutations were used to determine thresholds at 1% and 5% for each group. Group of steers fed in each feeding period was analyzed separately. No QTL was detected on chromosomes 13, 24, 25 and 27 in P1 while QTLs were absent on chromosomes 14 and 22 in P2. More QTLs were observed in the second feeding period than the first feeding period but there was no difference in the number of QTLs that were significant ($P > 0.05$) between the 2 groups at 1% or 5% thresholds. Majority of the QTLs had opposite effects from one feeding period to another. The results indicate that feeding period may contribute to the differential performance of QTLs associated with RFI, therefore it is suggested that effective application of makers in MAS or genome selection should consider their effects in all feeding periods.

Key words: QTL-by-environment interaction, residual feed intake, beef steers

340 Identification of genomic markers for feed efficiency in purebred Simmental, Angus and crossbred steers. N. V. L. Serão*[1], A. D. Markey[1], M. Pérez-Enciso[2], D. B. Faulkner[1], J. E. Beever[1], and S. L. Rodríguez-Zas[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Universitat Autònoma de Barcelona, Barcelona, Catalonia, Spain.*

The identification of genomic markers associated with feed efficiency in cattle is expected to help in understanding the role of genes, pathways and regulatory elements and accelerate the genetic improvement for this trait of utmost economic importance. The purpose of this study was to identify genomic markers associated with variation in feed efficiency. Genotypes of 703 steers were obtained using the Illumina Bovine SNP50 BeadChip. In total, 2,494 markers found on bovine chromosomes 6 were considered. The indicator of feed efficiency residual feed intake (RFI) was computed based on dry matter intake adjusted for average daily gain and mid-test metabolic weight. A model including the fixed effects of individual SNPs, breed (5 levels; Angus (AN), 3/4 AN, 1/2 AN 1/2 Simmental (SM), 3/4 SM and SM), diet (5 levels), breed-diet interaction, days on feed (covariate) and the random effects of harvest group within contemporary group (27 levels) and additive polygenic effect (pedigree including 3,786 animals) was used to identify SNPs associated with RFI. Maximum likelihood parameter estimation and fixed effects testing were implemented using Qxpak v 5.03. After multiple test adjustment, SNPs were deemed statistical significant at $P < 0.001$. From the 47 SNPs associated with RFI at $P < 0.01$, 7 were associated at $P < 0.001$. Among the 7 SNPs, 2 are harbored on gene regions. SNP rs41870471 is located on the intronic region of Ankrd17, a gene known to affect growth, metabolism, muscle, and aging in mice. SNP rs43451062 is located on the intronic region of Prss12, a member of the trypsin family of serine proteases associated with neurological processes. Breed by Diet interaction had a significant ($P < 0.05$) association with RFI for 6 of the top 7 SNPs. The exception was the model including rs41663978, which exhibited a significant effect of Diet on RFI. SNP rs43451062 had the highest allele substitution effect (1.90 ± 0.01), whereas rs29017713 showed the lowest (0.16 ± 0.01). The incorporation of these markers in genomic selection strategies is expected to accelerate the genetic improvement of feed efficiency.

Key words: residual feed intake, SNP, Association analysis

341 Prediction of genomic estimated breeding values for temperament at weaning in *Bos indicus* crossbreds using Bayesian Inference. L. L. Hulsman*[1], S. O. Peters[2], J. O. Sanders[1], A. D. Herring[1], C. A. Gill[1], and D. G. Riley[1], *[1]Department of Animal Science, Texas A&M University, College Station, [2]Department of Animal and Range Sciences, New Mexico State University, Las Cruces.*

Temperament in cattle influences animals handling and carcass traits. Genetic selection can modify this trait. The objective of this study was to predict GEBV for weaning temperament in crossbred cattle using Bayesian analysis of partitioned data sets for training and validation. Calves (n = 698) were from 13 full-sib embryo transfer Nellore-Angus F_2 families and 4 half-sib families sired by the same bulls in central Texas. Temperament was subjectively assessed by 4 evaluators, where

1 indicated docile and 9 indicated extremely nervous or wild. The average score was used as phenotype. All calves were genotyped using the BovineSNP50 assay (Illumina Inc., San Diego, CA). Markers with call rates <0.9, minor allele frequency <0.05, and Hardy-Weinberg Equilibrium proportions rejected at $P < 0.05$ were removed. Analyses were conducted with 34,980 markers using BayesC procedures. Effects of SNP were random in a mixture model with an inclusion fraction (1 - Π) of 0.001. Fixed effects included birth-year-season, breed of dam, family, and sex. Training was done (1) once using all animals in training, (2) 4 times using the progeny of all but one sire, (3) once using only embryo transfer F_2 progeny, and (4) once by random assignment. Each analysis had GEBV predicted; breeding values were also predicted using an animal model. The average of each animal's GEBV when included in training was compared with the predicted GEBV when included in validation. Each calf was included 5 or 6 times in training and 1 or 2 times in the validation. Correlation (r) between averaged GEBV and predicted GEBV was 0.56. For the best 10% of males, GEBV from Bayesian analyses were re-ranked as compared with traditional prediction (r ranged from −0.64 to −0.32; $P < 0.05$). Generally, GEBV for the best calves ranked similarly (r ranged from 0.24 to 0.84), regardless of their inclusion in training or validation. Re-ranks among analyses could be due to data set size, marker structure, or both.

Key words: Bayesian inference, genomic estimated breeding value, temperament

Companion Animals Symposium: Promoting Companion Animal Biology and Research in Animal Sciences

342 Reaching out: Opportunities for developing companion animal biology. C. L. Morris*, *Omaha's Henry Doorly Zoo, Omaha, NE.*

During the last century, Animal Science programs throughout the United States have provided outstanding leadership in scientific inquiry and education regarding livestock production. Changing demographics, including diversity of student populations in the past few decades, along with companion animal industry needs have highlighted the demand for advancement and development of Animal Science program opportunities. Along with demographic changes, career goals and interests of Animal Science students also have shifted. Fewer students are seeking traditional careers in livestock animal production and pursing opportunities in the areas of genomics, companion animals, exotic animals, and specialized interests in topics including behavior and animal welfare. As the US population of pet dogs and cats exceed the number of children in households, and with more than 175 million guests visiting US zoological institutions annually, growing opportunities in the pet and exotic animal industries are on the rise. These animal industries are evolving rapidly in areas such as nutrition, education, behavioral husbandry and training, conservation, outreach, shelter management, and small business management. With growing demand of these industries seeking well-trained professionals, Animal Science departments are charged with developing curricula that appropriately train students for careers in these fields. Currently, few universities have the professional staff with the breadth of expertise to provide teaching and outreach opportunities to students seeking these career directions. These changes in student demographics and educational goals provide exceptional opportunities for Departments of Animal Sciences to promote outreach opportunities and advanced technology education transfer when teaching staff are limited. Therefore, the objectives of this symposium will be to explore the important role of teaching and outreach in the area of companion and exotic animal biology and to discuss potential opportunities to expand teaching, outreach, and research through alternative methodology and technology in academics to reach industry needs.

Key words: companion animals, exotic animals, teaching and outreach

343 Wants and needs: What students want may not be what the current comparative animal industry needs. K. D. Ange-van Heugten*, *North Carolina State University, Raleigh.*

Companion animals are the top commodity preference of study for incoming freshman (Fr) in many North American animal science (ANS) departments. For example, incoming ANS Fr at NCSU are surveyed yearly about their species preference and 2010 data (n = 120) indicate the following as their first preference: companion animal (58%), equine (29%), beef cattle (3%), dairy cattle (3%), marine mammal (2%), swine (2%), sheep (1%), goats and lab animal (0), other (2%). These freshmen were 83% female and 92% want to be a veterinarian. Similarly, when 2 2011 companion animal courses (1 Fr level, n = 120; 1 senior level, n = 51) were surveyed they indicated that the primary determinants for their career were as follows in decreasing order of preference: discipline area, daily work with animals, species specific work, salary, flexible hours, and location. Within the senior course, 92% of the students indicated that they want their future career to involve companion or exotic species. The multibillion dollar companion and comparative animal industries need many specialists with the popular areas of veterinary medicine and behavior being minorities. Sources report the 10 most critical hiring criteria for employers as: communication, integrity, teamwork, interpersonal skills, work ethic, motivation, flexibility, analytical, computer, and organization skills. In contrast, students want: opportunity to advance, job security, benefits packages and friendly coworkers. In the current economy, job security, benefits and coworker choice are not reliable and many employers feel that new graduates lack communication, management and business etiquette skills. Thus, hiring agencies focus on personal skills and are less interested in species or veterinary preferences. Companion animal educators should emphasize that many vital comparative animal career paths exist in addition to veterinary or comparative species professions. In fact, work in other areas can be incredibly lucrative and vital for the industry. In addition, students need to sharpen their management skills while appreciating the critical difference between communicating with their peers and employers.

Key words: companion animal, education, industry

344 Cat and mouse: Utilizing technology and science to reach students. N. A. Dreschel*, *Pennsylvania State University, University Park.*

From simple applications such as blogs, video and the use of course management systems, to complete courses offered online, the availability of resources for companion animal instruction have increased tremendously. The benefits of using technology include improved student interaction, an ability to engage students with different learning styles, and an ability to reach nontraditional student audiences. An online general education animal science course examining the relationship of "Pets in Society" uses a variety of technologies to instruct both traditional, residential animal science students and nontraditional distance learners. Distance-learning students bring a wealth of experience and insight to an integrated course. Choosing appropriate and meaningful technology is important in instructional design. Examples of instructional techniques such as "rollover" animations, narrated PowerPoints, video interviews and online discussion forums will be presented. Technology used or created for online courses can also be transferred to in-class or "hybrid" courses, as well as to extension formats such as eXtension. Challenges in teaching with technology include the time needed to develop technology, faculty and student comfort with using technology, modifications of technology to meet the needs of students with disabilities, and institutional constraints on the ability to offer courses online. The variety of new technology available can be overwhelming; however, presents great opportunities for engaging and teaching students in both traditional and online environments.

Key words: teaching, technology, companion animals

345 Research and outreach: Blending the basic and the applied. L. K. Karr-Lilienthal*, *University of Nebraska-Lincoln, Lincoln.*

The opportunities to complete undergraduate research related to companion animals are limited. Assisting with traditional animal research projects can allow for students to develop a better appreciation for

how research is conducted and expand their interest in graduate school programs. However, universities with companion animal research programs are few. Opportunities to match students with industry partners to gain experiences are critical. Students may have opportunities to assist with research at pet food companies, zoos, or animal assisted therapy programs. Utilizing undergraduate students in community outreach programs provides an opportunity for students to develop critical skills required for employment, but also provides companion animal faculty with research opportunities. A variety of creative activities can be utilized to improve student learning and gain experiences outside of the classroom. Examples of successful programs include student organized dog training courses, service learning projects through humane societies or animal rescues, student involvement in feral cat control programs, and student assistance with spay/neuter programs. These activities can support student learning outcomes as well as provide a valuable community services. Measuring the impacts of these activities on student learning and life skills as well as community implications will be critical to evaluation of the success of the programs. Undergraduate research activities are a meaningful way to provide students with learning opportunities. Extension or outreach programs allow for opportunities for students to develop leadership skills. Undergraduate students serving as instructors in 4-H and other youth programs can provide both an impact on the education of the youth involved, but also develop a deeper understanding of materials to be taught. Undergraduate students can be involved in teaching health care, nutrition, and other topics related to companion animals to youth audiences. Utilizing classroom research can aid in more accurate assessment of program goals and the ability of the program to reach its learning outcomes.

Key words: undergraduate education, companion animals, outreach

346 Biodiversity is life: Teaching conservation biology with zoos and aquariums. R. L. Krisher*, *National Foundation for Fertility Research, Lone Tree, CO.*

Student interest in the conservation of exotic and endangered species is at an all-time high. In fact, more people visit zoological institutions each year than attend all professional sporting events combined. Increased access to video programming about exotic species, and improved access to travel abroad opportunities, has motivated many college students to become passionate about animal conservation as a career choice. Enrichment of traditional Animal Science academic programs with formal coursework to meaningfully fill this void and provide opportunities to Animal Science students in this area has been challenging. To fully understand the multifaceted, complex responsibilities related to conservation of species, topics related to ecology, taxonomy, conservation biology, population genetics, physiology and management of exotic species in a captive setting must be addressed and integrated. Zoos are now an essential part of worldwide conservation strategies, and captive breeding programs are an integral part of this mission. Thus, in addition to fundamental responsibilities such as nutrition and veterinary care, zoos must address reproduction and even assisted reproduction in a directed way. Research conducted in zoos has played a meaningful role in advancing care and maintenance of captive species. Methods to exhibit these species have also improved dramatically, along with attention to environmental enrichment to enhance animal wellbeing and positively impact visitor experiences. However, the ethics of maintaining captive animals must always be explored and addressed. Finally, the public education mission and impact of zoos cannot be overstated. Overseeing all of these activities are worldwide and national organizations of significance. For students to understand and appreciate these many perspectives of a zoo operation, development of critical thinking skills is highly effective to achieve the course objectives; students that are able to speak and write intelligently on current topics pertaining to animal conservation, and students able to create and defend their own informed opinions on the modalities employed in captive animal holding and conservation.

347 The future of companion animal biology in academics. A. Fischer*, *University of Illinois, Urbana.*

As companion animal programs continue to become established components of Animal Sciences departments, the diversity of topics addressed will expand. Likely targets for growth include the fields of human-animal relationships, and applied companion animal welfare. Academic interest in human-animal relationships is growing, as evidenced by recent initiatives to promote research on the human-animal bond and to quantify the benefits of sharing our lives with companion animals. We can expect continued collaborations across a variety of disciplines, such as psychology, sociology, anthropology, and law. In the field of applied companion animal welfare, specifically in animal sheltering, we have seen an increase in data-driven initiatives aimed at increasing adoptions and decreasing euthanasia across the country. We can expect to see a continued integration of applied research in animal sheltering operations, and an increasing number of professional positions for our graduates in the areas of animal advocacy, policy, and management.

Key words: companion animal, academics, careers

Contemporary and Emerging Issues Symposium: Emerging Animal Welfare Issues

348 Does high production increase the occurrence of health problems in dairy cows? K. D. Vogel*, *Department of Food and Animal Science, University of Wisconsin-River Falls, River Falls.*

Over the past 30 years, individual dairy cow production has increased substantially. The production efficiencies gained through genetic selection, improved nutrition, and changes in management practices has come largely through advances in scientific knowledge of animal breeding, physiology, metabolism, and nutrition. Historically, the primary goal of this research was increased animal productivity through increased milk secretion. Although the goal of maximal production was never malicious, but actually quite the contrary, increasing societal concern has arisen regarding the health and welfare of modern high-producing dairy cows. Some have hypothesized that modern production levels may be taxing the metabolic and physiologic capacities of dairy cows, resulting in increased incidences of lameness, mastitis, infertility, and mortality. However, the underlying factors in cases of lameness, mastitis, infertility and mortality vary widely. Recent studies have consistently identified not one, but multiple, underlying factors that culminated in the one common health problem under investigation. Multiple studies have identified genetic selection, management, nutrition, and environment as influential factors in the incidence of health and welfare issues in modern, high-producing dairy cattle. It appears that an interaction of all of these factors dictates the health and welfare state of the dairy cow. The need exists to integrate the current body of knowledge related to dairy cattle health and welfare to identify common contributors to the incidence of the most prevalent production-related diseases. Data suggest that production diseases are not resultant of milk production level alone, but production level does appear to be a risk factor in the development of health problems in dairy cows. Ultimately, the interaction of genetic predisposition, management, and environment dictate the development of the majority of production related health disorders observed in the modern dairy cow. Remediation of production related health issues requires the consideration of all factors included in the interaction.

Key words: dairy, production, welfare

349 Potential solutions for reducing lameness in dairy cows. N. Cook*, *University of Wisconsin, Madison.*

Lameness control is fundamental to the management of the modern confinement housed dairy herd. It is the most important condition impacting a cow's well-being, and it affects everything she does in her day, from resting, to eating, socializing and milking. Foot lameness is dominated by infectious lesions such as digital dermatitis and foot rot (phlegmon), and by lesions of the claw horn, such as white line disease and ulceration of the sole. Infectious hoof disease can be effectively controlled through good nutrition, improved foot hygiene and by the effective use of hoofbaths to clean and disinfect the foot on a regular basis. Copper sulfate, formalin and zinc compounds are the most commonly used disinfectants and all appear efficacious. However, more attention needs to be paid to the design and location of the hoofbath, to optimize its use within individual farm circumstances. Claw horn lesions may be triggered through poor feeding and poor transitions at calving time. However, white line disease is exacerbated in facilities with poor flooring that creates risk for trauma, wear and concussion. Strategic use of rubberized surfaces and improved concrete finishing greatly impacts the incidence of this disease. Increased standing time per day on hard surfaces appears to increase the risk for sole ulcer. Dairy facilities need to be designed so that both lame and non-lame cows can achieve at least 12 h of rest per day. This can be achieved with deep loose-bedded stalls with sand bedding, sized to accommodate the resting area of the cow, with freedom to front lunge in the stall without obstruction. Group sizes need to be matched to parlor size and throughput, to minimize time out of the pen to less than one hour per milking, and stocking rates need to be controlled to a maximum of 1.2 cows per stall. Strategic use of fans and soakers, or other cooling methods are essential components of lameness control in the summer. Finally, excellent hoof health requires a dedicated, well-trained hoof-trimmer rebalancing the claws of all the cows at least twice per year, and prompt effective treatment of the lame cow.

Key words: lameness, solutions

350 The national shortage of food animal veterinarians: What's being done to address the issue? D. G. Bristol*, *North Carolina State University, Raleigh.*

When the owner of a sick or injured animal cannot obtain access to prompt veterinary care for that animal, it creates a serious welfare issue. The cause of the shortages in food animal/production veterinarians is multifactorial, and while little can be done to change some of those causes, numerous actions have been taken to address the final result – the veterinary shortage. Survey data collected in 2006 and published by the AVMA indicated that only 10% of all veterinarians practice on food animals. This seminar will review both the causes and potential solutions to a shortage that impacts animal welfare and the safety of the US food supply. A survey by Lenarduzz et al. (2009) showed that contact with food animal practitioners during vet school was a factor in motivating a career choice in large animal practice. Experience with agriculture may encourage students to consider large animal practice. Some veterinary colleges have 4 or 5 places each year that are reserved for students interested in food animal agriculture. Some of these programs also include financial incentives to practice in rural areas. Other alternatives are developing centers for food animal excellence in several veterinary colleges. There is also a need to expose undergraduate students to food animals so they will develop an interest in them.

Key words: veterinarian, food animal, careers

351 Animal welfare issues: Organic and conventional. W. K. Fulwider*, *Cropp Cooperative, LaFarge, WI.*

The objective of this paper is to acknowledge differences between organic and conventional management regarding animal welfare. Lameness is the most serious welfare issue in dairy herds and leads to milk loss, more days to conception, and increased cull rates. Growth hormone (rBST) may negatively affect body condition, mastitis, and lameness. Parasites are one of the biggest challenges facing the organic industry. Organic management emphasizes prevention of lameness, parasites, displaced abomasums, acidosis, and problems associated with boredom such as tail-biting in swine by providing environments that reduce stress by allowing natural behaviors. Studies show that cattle with access to pasture have reduced lameness. Parasites can be

controlled with rotational and multi-species grazing. Chickens break up manure pats, Muscovy ducks keep fly numbers low, and Runner ducks help eliminate liver fluke problems. When in transition, new challenges make communication with experienced producers and specialists a must. Organic producers often use different breeds or genetic lines to prevent health problems. Hair sheep are resistant to parasites. Dairy cattle with New Zealand genetics may be better suited to grazing. Older genetic lines of Berkshire, Chester White, and Duroc hogs may be less aggressive and better suited to group systems and foraging. The US organic industry is often criticized for not allowing antibiotics. The organic standard states that an organic producer may not withhold medical treatment to preserve an animal's certified organic status. The treated animal must be permanently removed from organic production. Organic animals are housed more extensively to reduce stress and aggression so that procedures such as tail-docking hogs are unnecessary. Use of β-agonists such as ractopamine in swine and zilpaterol in beef may result in lower quality meat and increased welfare problems such as hoof cracking and animals that are difficult to handle. Organic farmers produce food humanely and without chemicals, hormones, or antibiotics. Good management, attention to detail, and continuous improvement are important components of every farm whether organic or conventional.

Key words: welfare, organic, livestock

352 Consequence of changing standards for somatic cell count on US Dairy Herd Improvement herds. H. D. Norman*, J. R. Wright, and R. H. Miller, *Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD.*

Consequence of noncompliance with European Union (EU) and current US standards for somatic cell count (SCC) as well as SCC standards proposed by the National Milk Producers Federation was examined for US herds. Somatic cell scores (SCS) from 14,854 Dairy Herd Improvement (DHI) herds were analyzed. Herds had between 15 and 26 DHI tests from Jan. 2009 to Oct. 2010 and ≥ 10 cows. The SCC for individual cows came from their SCS by SCC = $2^{(SCS - 3)}$(100,000). As a proxy for bulk tank SCC, herd test-day SCC were derived by weighting each cow′s SCC by her test-day milk yield and were the basis for determining herds and milk that were SCC noncompliant. A herd was noncompliant for the EU SCC standard after 4 consecutive rolling 3-test geometric means were > 400,000 cells/mL. A herd was noncompliant for US SCC standards after 3 of 5 consecutive SCC tests were > 750,000 (current), > 600,000 (proposed), > 500,000 (proposed), or > 400,000 (proposed) cells/mL. Results were examined by month, herd size, and state. For current SCC standards, weighted means for US herd noncompliance from Nov. 2009 through Oct. 2010 was 0.9% for US and 7.8% for EU standards; noncompliance for proposed US SCC standards of 600,000, 500,000, and 400,000 cells/mL were 2.7, 6.2, and 14.1%, respectively. Only a US standard of 400,000 cells/mL was more restrictive than the EU standard. Only 0.2% and 3.1% of US milk failed current US and EU SCC standards, respectively. Compliance for US herds generally increased with herd size. For the current US SCC standard, 1.7% of herds were noncompliant when herd size was < 50 cows, but ≤ 0.1% of each of 4 herd groups with ≥ 200 cows were noncompliant. For the EU standard, noncompliance declined from 10.6% for herds with < 50 cows to 0.5% for herds with ≥ 1,000 cows. Herd noncompliance ranged from 2 to 15% for 6 states and Puerto Rico for the current US standard and from 20 to 35% for 9 states for the EU standard. If US producers must meet more stringent EU or proposed US standards for SCC, they will need to place more emphasis on sound milking management practices and do more culling to improve milk quality.

Key words: somatic cell, standards, milk quality

353 Current level of compliance with EU bulk tank SCC standards and proposed US standards based on data from four Federal Milk Marketing Orders. J. E. Lombard[1], H. D. Norman*[2], C. A. Kopral[1], J. M. Rodriguez[1], and J. R. Wright[2], *[1]USDA-APHIS-VS, Centers for Epidemiology and Animal Health, Fort Collins, CO, [2]USDA-ARS, Animal Improvement Programs Laboratory, Beltsville, MD.*

Milk quality in the United States is evaluated annually using bulk-tank somatic cell count (BTSCC) data provided by 4 of the nation's 10 Federal Milk Marketing Orders. The data represents more than 30,000 producers and 50% of milk produced in the US. The reported BTSCC is used for regulatory purposes to determine compliance with the current US limit of 750,000 cells/ml. If 3 of 5 consecutive monthly shipments exceed 750K then regulatory action is taken. The objective of this study was to evaluate compliance of producers with the newly proposed US BTSCC limits. BTSCC data from producers that shipped between 15 and 22 shipments between Jan. 2009 to Oct 2010 were included in the analysis. Four different SCC levels of compliance based on US standards were evaluated: 750K; 600K; 500K; 400K. In addition, the EU standard of 400K based on a 3 mo geometric mean was evaluated. For the 12 mo period ending Oct 2010, 1.0% of producers and 0.2% of milk exceeded the current US limit of 750K; 4.7% of producers and 1.4% of milk exceeded the proposed 600K limit. Although the proposed 400K limit would be the same in the US and the EU, differences in how the limits are calculated and used for regulatory purposes change the percent of producers in compliance in the 2 countries. Although 23.3% of producers exceeded the proposed US 400K limit, only 16.1% of producers would have exceeded the current EU standard. For herds shipping < 907 t of milk in the 12 mo period, 28.0% would have exceeded the proposed 400K US limit and 19.5% would have exceeded the current EU standard. Only 4.1% and 2.2% of herds shipping more than 9,072 t would have exceeded the proposed 400K US limit and current EU limit, respectively. If implemented, the proposed phased in reduction to a 400K BTSCC limit would result in a substantial increase in producers and milk, primarily those with < 100 cows, which would exceed the regulatory limit. Producer education and implementation of programs to lower BTSCC will be critical in minimizing the impact of the proposed reduction in BTSCC.

Key words: somatic cell, standards, milk quality

354 Latinos and animal agriculture. S. Archibeque-Engle* and I. N. Roman-Muniz, *Colorado State University, Fort Collins.*

The hypothesis of this project is that Latinos are critical to the sustainability of animal agriculture in the United States. The intellectual merit of this project is that it quantifies the need for educated animal scientists and identifies potential areas for growth. Since 1903, Colorado State University (CSU) has served as a leader in the Animal Sciences industry. In the early days of the department, undergraduate students had a significant tie to production agriculture, many of those students left family farms to obtain an education and they returned to family farms to put their educations to work once they finished college. Those who did not return to family farms went to work in production agriculture and served as the leaders who shaped the food supply that our country now enjoys. Most undergraduate students who come to CSU to study Animal Sciences in the 21st century no longer have a

tie to production agriculture or agriculture at all. In fact, over 80% of our undergraduates report that they have no agricultural experience (unpublished departmental data). In 2009 the state of Colorado was 20.3% Hispanic (Latino) (www.quickfacts.census.gov) and 90% of farm workers in the west and midwest are Hispanic (Von Essen et al., 1998; Kirkhorn et al., 2002; Mines et al., 1997). In Colorado counties where there is a large livestock industry like Weld and Prowers there is an even larger Hispanic population (27.0% and 32.9% Hispanic, respectively; www.quickfacts.census.gov) However, the Department of Animal Sciences undergraduate population is 5.5% Hispanic (Colorado State University Census Data, Fall 2010). The luxury of excluding any population from an agricultural education, especially given the importance of agriculture to the success of our country, does not exist. We need to educate those who have traditionally come to us (students from family operations), those who are currently coming to us (students from urban and suburban backgrounds), and those who have worked in agriculture in the US for a long time but have been absent from higher education classrooms: Latinos.

Key words: agricultural workers, higher education, animal sciences

355 Effect of live yeast supplementation on milk production and health status of lactating camels (*Camelus dromedarius*). P. Nagy*[1], E. Chevaux[3], M. Khettou[3], O. Marko[2], S. Thomas[2], U. Wernery[2], and J. Juhasz[2], *[1]Industries for Camel Milk and Products, Dubai, United Arabic Emirates, [2]Central Veterinary Research Institute, Dubai, United Arabic Emirates, [3]Lallemand SAS, Toulouse, France.*

Dromedaries have not been considered as valuable milk producing animals in the past and limited data are available on their dairy potential and possibilities for improvement. The use of live yeast as a nutritional tool to optimize digestibility of the diet has been extensively documented on ruminants. Though, camels are not true ruminants, their foregut is similar to the rumen, so dairy camels could also benefit from the supplementation of live yeast. The present study aimed at comparing 90 dairy camels (165 d in milk) evenly randomized into 2 dietary treatments (Control (C) vs. Levucell SC (LSC)) during 5 mo. Animals were milked twice daily, sampled for milk composition once a month and for blood parameters every 2 mo. Feed intake was monitored on a daily basis. Data were processed with the mixed model of SPSS 17.0. The average milk production of the camels fed the live yeast (*S. cerevisiae* I-1077) increased ($P < 0.01$) by 10% (7.26 ± 0.14 vs 7.99 ± 0.17 kg/d), without affecting milk fat % (2.46 ± 0.04 vs 2.49 ± 0.04), protein % (2.81 ± 0.02 vs 2.80 ± 0.02), total solids % (10.46 ± 0.06 vs 10.41 ± 0.06) and solids non fat % (8.10 ± 0.04 vs 8.02 ± 0.04) content for C vs LSC, respectively. However, lactose content was higher ($P < 0.01$) for C (4.33 ± 0.02 vs. 4.25 ± 0.02%). Protein yield was increased ($P < 0.05$) for LSC over C (213.6 ± 4.7 vs. 199.3 ± 4.7 g/day) whereas fat yield was numerically higher for LSC (187.6 ± 4.9 vs. 176.8 ± 4.9 g/day). No difference was found on SCC or TVC. Hematology values remained within the normal range. However, some of the blood nutritional markers indicated some difference in metabolism of C animals as illustrated by higher ($P < 0.01$) levels of creatine kinase (162.7 ± 5.8 vs. 124.3 ± 5.6 U/L) and lactate dehydrogenase (333.7 ± 5.3 vs. 311.9 ± 5.2 U/L). The liver activity was also stimulated for C (79.9 ± 1.3 vs. 71.7 ± 1.3 U/L AST), so did the kidney metabolism ($P < 0.05$) as shown by creatinine (193.9 ± 2.7 vs. 186.3 ± 2.6 µmol/L) and BUN (11.1 ± 0.2 vs. 10.5 ± 0.2 mmol/L) when compared with LSC. The supply of Levucell SC to lactating dromedary camels supported higher milk production and seemed to have played a role in optimizing protein metabolism.

Key words: dairy camel, live yeast

356 Why people become vegetarian and/or vegan: Results of a survey of US self-identified vegans. S. D. Lukefahr*[1], R. A. Cheeke[2], and P. R. Cheeke[3], *[1]Texas A&M University-Kingsville, 27510 NE Todd Dr., Corvallis, OR, [3]Oregon State University, Corvallis.*

A survey to identify why people choose to become vegan/vegetarian (V/V) was given to people from 14 US states attending V/V trade shows and festivals (e.g., VegFest). Background data included gender, age, education, farm background, animal experience, and dietary habits. Participants were asked the importance of factors in their decision to not consume animal-derived products. The factors were: 1. I am opposed to killing animals; 2. I am concerned with health issues; 3. I am concerned about residues of chemical feed additives and hormones; 4. I am opposed to intensive, confinement systems; 5. I am concerned with food safety issues; 6. I believe that animal production competes with humans for grains; 7. I am concerned about environmental issues; 8. It is "cool" and trendy to be a vegetarian; and 9. I became vegetarian because of peer pressure. The initial scale used in the 2009 survey ranged from extremely important, important, and not important, which was modified in 2010 to a more quantitative scale with 7 classes, ranging from extremely not important to extremely important. Data from 2009 surveys (n = 121) were analyzed by Chi-Square to test for relationships between survey scores for each question (Q) and background of the individual. Data from 2010 surveys (n = 37) were analyzed by ANOVA involving background factors as sources of variation. Results for 2009 and 2010 showed that most participants surveyed were females over 20 years of age with a college or university education, but had animal experience with only pets and no farm background. For 2009, an association was found ($P < 0.05$) between education level and Q5 that dealt with food safety issues. For 2010, dietary habit influenced ($P < 0.01$ to 0.10) responses to Q1, Q7, Q8, and Q9, whereas education and farm background influenced ($P < 0.05$) responses to Q4 and Q6, respectively. In conclusion, no single issue seems to be the dominant explanation for the selection of a non-animal product lifestyle.

Key words: vegetarianism, dietary choices, contemporary issues

357 Does pre-slaughter stress affect pork safety risk? M. H. Rostagno*, S. D. Eicher, and D. C. Lay, *USDA-ARS-LBRU, West Lafayette, IN.*

Salmonella is the top food safety priority for the pork industry. Although contamination of pork occurs along the slaughter and processing line, infected live pigs entering the abattoir constitute the original *Salmonella* contamination source. However, the extent of carcass contamination is not only determined by the number of pigs infected, but also by the levels of *Salmonella* entering the abattoir in the intestinal tract of slaughtered pigs. Therefore, a series of experiments was conducted to determine if common stressors occurring before slaughter affect the prevalence and levels of *Salmonella* in market pigs. Initially, a field study was conducted to determine the effect of transportation and lairage on the frequency of *Salmonella* shedding in market pigs. A follow up study was conducted under controlled conditions to determine the effect of feed withdrawal and transportation on the levels of *Salmonella* in the intestinal tract of infected market-weight pigs. Finally, a third study was conducted to determine the effect of transportation and mixing with unfamiliar pigs on the susceptibility of market-weight pigs to *Salmonella* infection. In the first study, *Salmonella* shedding increased ($P < 0.05$) from pre-transport (11.3%) to post-transport (20%), and from post-transport to post-lairage (42%). In the second study, feed withdrawal by itself or combined with transportation caused increased levels of *Salmonella* in the ileum ($P < 0.05$), whereas only the combination of feed withdrawal and transportation caused increased levels of *Salmonella* in the cecum ($P < 0.05$). In the third study, pigs subjected to transportation and/or mixing were colonized by higher ($P < 0.05$) levels of *Salmonella* in the ileum, whereas only pigs subjected to both stressors combined were colonized by higher ($P < 0.05$) *Salmonella* levels in the cecum. It is concluded that pre-slaughter stressors, such as transportation, feed withdrawal and mixing, affect pork safety risk by increasing frequency and levels of *Salmonella* in the intestinal tract of market-weight pigs.

Key words: *Salmonella*, stress, swine

358 Salt and nitrite at concentrations relevant to meat processing enhances Shiga toxin II production by *E. coli* O157:H7. S. M. Harris*, S. A. Olsen, J. Hu, M. Du, and M. J. Zhu, *Department of Animal Science, University of Wyoming, Laramie.*

Escherichia coli (O157:H7 is a major food safety threat. It has ability to produce several virulence factors. Shiga toxins (Stxs) are the key virulence factors of *E. coli* O157:H7 that are responsible for hemorrhagic colitis and serious renal failure. Despite the extensive study of *E. coli* O157:H7 survival during meat processing, the production of Stxs by *E. coli* O157:H7 during these processes has not been studied. This becomes a very important question since Stx2 is resistant to heat treatment. The objective of this study is to elucidate the effect of 2 essential additives in processed meats, salt and nitrite, on Stx2 production by *E. coli* O157:H7. *E. coli* O157: H7 (86–24) was treated with different concentrations of salt (1%, 2%, and 3%, W/V) or sodium nitrite (0, 100, 200, 300 ppm) solutions for 6 h. The Stx2 production and cfu were analyzed. After 6 h incubation, the number of *E. coli* O157:H7 in nitrite-100 ppm was not different from that of control (0 ppm). However, the number of *E. coli* O157:H7 in nitrite-200 ppm ($P < 0.1$) and nitrite-300 ppm ($P < 0.05$) were lower than control. Western blotting analysis indicated that adding 100 ppm and 200 ppm of nitrite in LB medium increased ($P < 0.1$) Stx2 production. Similarly, including 2% and 3% of salt decreased ($P < 0.05$) the final *E. coli* O157:H7 population, but supplementing 2% salt increased ($P < 0.05$) Stx2 production per cfu compared with that of control (1% salt), while including 3% salt decreased ($P < 0.05$) Stx2 production. Since 2% salt and 100–200 ppm nitrite are commonly used in processed meats, the current study indicated that salt and nitrite at these concentrations promote Stx2 production. Therefore, not only the survival of *E. coli* O157:H7 during meat processing is important, Stxs production by *E. coli* O157:H7 is another critical control point for producing safe meat products. (USDA AFRI 2009–65203–05716, 2010–65201–20599, Agricultural Experiment Station at University of Wyoming, NIH-INBRE P20RR016474).

359 Detection of major serotypes of Shiga-toxin producing *E. coli* in bovine feces by multiplex PCR. Z. Paddock*, X. Shi, T. G. Nagaraja, and J. Bai, *Kansas State University, Manhattan.*

Shiga-toxin producing *E. coli* (STEC) serotypes, particularly O157, are major food borne pathogens. Recently, non-O157 STEC serotypes have also become a major public health concern. Unlike O157, isolation and detection procedures for non-O157 have not been fully developed. Confirmation of non-O157 strains is generally based on agglutination with serotype-specific antisera, which is labor intensive and sometimes nonspecific. We have developed a multiplex PCR, based on O-specific antigen coding genes, rfbE of O157, and wzx and wfqB of non-0157, to distinguish the 7 major STEC serotypes, O26, O45, O103, O111, O121, O145, and O157. The specificity of the procedure was confirmed with pure cultures of STEC strains (n = 138). Our objectives were to evaluate whether the procedure could be used to detect STEC in feces and screen fecal samples before subjecting them to detection by cultural procedures. Fecal samples spiked with different concentrations of a mixture of 7 STEC strains were tested before and after 6 h enrichment in *E. coli* (EC) broth. Fecal samples (108 from feedlot and 108 from dairy cattle) were collected, enriched in EC broth, tested by the multiplex PCR. All samples (n = 216) were cultured for O157, while a subset of samples (n = 24) were cultured for the non-O157 STEC. All 7 serotypes were specifically amplified in spiked feces with detection limits of 6.7×10^5 cfu/g before enrichment and 8.0×10^1 after 6 h enrichment in EC broth. The multiplex PCR revealed a high prevalence of STEC, except O45 serotype, in cattle feces (Table). All samples that were culture positive for STEC were also positive by the multiplex PCR. The multiplex PCR may be used to identify feces positive for the 7 STEC before subjecting the samples for cultural methods, however, additional studies are needed to validate the procedure.

Table 1. Prevalence of Shiga-toxin producing *E. coli* (STEC) in cattle feces

STEC	mPCR positive (n=24)	Culture positive (n=24)	mPCR positive (n=192)	O157 culture positive (n=192)
O26	14	5	165	-
O45	2	0	106	-
O103	10	4	140	-
O111	0	0	34	-
O121	5	4	98	-
O145	0	0	8	-
O157	16	14	149	51

360 Microbial contamination rates and antimicrobial resistance patterns in "no antibiotics added" labeled chicken products. J. Zhang*[1], A. Massow[1], M. M. Stanley[1], M. Papariella[1], X. Chen[3], B. Kraft[2], and P. D. Ebner[1], *[1]Purdue University Department of Animal Sciences, West Lafayette, IN, [2]Purdue University College of Veterinary Medicine, West Lafayette, IN, [3]University of Illinois at Urbana-Champaign Department of Animal Sciences, Urbana-Champaign.*

In the United States, poultry product labels can contain "no antibiotics added" if the animals were raised without the use of antimicrobials. In this study we compared microbial community structures of conventional chicken products (CONV; n = 201) with those of chicken products labeled as coming from birds raised without antimicrobials (NON; n = 201). Both CONV and NON products were equally likely to contain Enterococcus spp., (CONV: 17.4%; NON: 21.3%) or *Escherichia coli* (CONV: 25.9%; NON: 22.3%). CONV samples contained higher concentrations of coliforms (CONV: 3.0 $\log_{10}$cfu/mL; NON: 2.5 $\log_{10}$cfu/mL; $P < 0.05$). The number of samples positive for Salmonella was low in both groups, but statistically higher ($P < 0.05$) in NON (5.0%) vs. CONV (1.5%) samples. *E. coli* isolates from CONV samples were more frequently resistant to at least one antimicrobial (CONV: 61.3%; NON: 41.2%; $P < 0.05$). Four multidrug resistance patterns appeared twice or more in *E. coli* isolates obtained from both CONV and NON products. The most common patterns in both groups were tetracycline-sulfasoxazole followed by tetracycline-sulfasoxazole-trimethoprim/sulfamethoxazole and tetracycline-ampicillin. Enterococcus spp. isolates from both groups were equally likely to be resistant to at least one antimicrobial, but Enterococcus spp. isolates from CONV samples were more likely to be resistant to erythromycin, kanamycin or gentamicin ($P < 0.05$). Five multidrug resistance patterns were detected twice or more in Enterococcus spp. isolates from CONV products while 2 multidrug resistance patterns were detected in Enterococcus spp. isolates from NON products. In both groups the most common resistance pattern was erythromycin-tetracycline-tylosin tartrate. Taken together, these data indicate that CONV and NON products have similar contamination characteristics, however, bacteria isolated from CONV products may be more frequently resistant to some antimicrobials.

Key words: antimicrobial resistance, poultry, "no antibiotics added"

361 Antimicrobial activities and comparing bacterial membrane interactions of porcine lactoferricin derived peptides. F. Han*, Y. Liu, Y. Xie, Y. Gao, and Y. Wang, *Institute of Feed Science, Hangzhou, Zhejiang, China.*

Abstract: Antibiotic treatment of microbial infections is under scrutiny because of increasing conventional antibiotic resistance, and discovery of new classes of antibiotic agents is warranted. Antimicrobial peptides are part of innate defense system found almost in all organisms. Porcine lactoferricin (LFP-20) is an antimicrobial peptide identified in N terminus of porcine lactoferrin. To develop novel antimicrobial peptides with improved antimicrobial specificity as compared with LFP-20, we designed analogs LF-2, LF-4 and LF-6 with substituted alanine, serine, or tryptophan residues at the different positions of the molecule. Broth microdilution, hemoglobin release, WST-1 and $DiSC_35$ methods were used in this study. Statistical significance among independent groups was determined using one-way ANOVA. Analogs displayed a 2~16-fold higher antimicrobial activity than LFP-20 but did not induce increased hemolytic activity significantly ($P > 0.05$) to porcine erythrocyte below 32 μg/mL compared with LFP-20. Furthermore, the proliferations of porcine peripheral blood mononuclear cells were not influenced significantly ($P > 0.05$) by LF-2, LF-4 and LF-6 below 50 μg/mL. Except for 8 μg/mL and 16 μg/mL LF-4, the cytotoxicities of LF-2, LF-4 and LF-6 to PBMCs were not increased significantly ($P > 0.05$) below 32 μg/mL compared with LFP-20. To better understand the antibacterial mechanism of LFP-20 and its analogs, we studied their effect on the cytoplasmic membrane of *Escherichia coli*. LFP-20 was not effective in depolarizing the cytoplasmic membranes, whereas 3 analogs could gradually dissipated membrane potential of *Escherichia coli*, demonstrating a correlation between bactericidal activity and membrane depolarization. Compared with LFP-20, 3 analogs enhanced the *Escherichia coli* outer membrane permeability significantly ($P < 0.05$) at 8 ~32 μg/mL. LF-6 led to the most obvious inner membrane permeability of *Escherichia coli*. Collectively, these results suggest that the first target for 3 analogs on *Escherichia coli* may be the cytoplasmic membranes.

Key words: porcine lactoferricin, antimicrobial activity, antimicrobial mechanism

362 Nitrate and nitrite partition in cheese and whey during cheesemaking. F. F. Pinheiro, L. M. Fonseca*, M. O. Leite, M. M. O. P. Cerqueira, R. Rodrigues, C. F. A. M. Penna, and M. R. Souza, *Veterinary School/Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil.*

Nitrate is used in the dairy industry as a preservative to prevent cheese blowing due to bacterial growth. However, due to health concerns, concentration limits for usage in countries where it is allowed are usually fixed at 50 mg/kg of nitrate in cheeses of medium and low moisture. The objective of this work was to evaluate the amount of nitrate in the curd and whey after addition to the milk used for Minas cheese production. Five batches of cheese were processed, and for each batch, potassium nitrate was added to the pasteurized milk (LTLT) at the following concentrations: 5g/100L, 15g/100L, and 40g/100L. One treatment was done without any nitrate addition. Nitrate was measured by spectrophotometric determination following modified Jones Method (AOAC 976.14), and raw milk composition was measured by infrared spectroscopy (Combisystem 2300, Bentley). Compositional analysis of cheese and whey were according to International Dairy Federation methods. Differences were evaluated by Duncan Test. Average composition of raw milk was 3.75g/100g, 3.30g/100g, 4.39g/100g, 12.47g/100g and 8,83g/100g for, respectively, fat, protein, lactose, total solids, and solids non fat. Cheese composition was 48.7g/100g of fat in dry matter, and, respectively, 17.2g/100g and 59.1g/100g for protein and moisture. Nitrate concentration in cheese was, respectively, 0 (non detectable), 12.1, 23.3, and 64.93 mg of nitrate/kg of cheese for treatments with addition of 0, 5, 15, and 40 g of nitrate/100L of milk. Fermentation did not affect partition of nitrate in curd and whey phases. Nitrate retained in cheese curd was about 3% of the initial amount, while 97% of the original nitrate was detected in the whey. Results confirm that nitrate addition at levels higher than 20g/100L of milk are risky, since levels close to 30g/100L will result in approximately 50mg of nitrate in the cheese. Further study is necessary to evaluate the impact of this preservative in the whey, since high amounts of nitrate/nitrite will remain in this phase, with serious concerns related to concentrated and dehydrated whey products. Acknowledgments: FAPEMIG, CNPq

Key words: nitrate, cheese, nitrite

363 Prevalence of *Coxiella burnetii* in bulk tank milk and associations with herd characteristics on US dairy operations. J. E. Lombard[1], S. N. Gibbons-Burgener[2], and C. P. Fossler*[1], *[1]USDA-APHIS-VS, Centers for Epidemiology and Animal Health, Fort Collins, CO, [2]University of Wisconsin, Madison, Madison.*

The objectives of this study were to estimate the prevalence of *C. burnetii* and evaluate herd-level factors associated with its presence. During the National Animal Health Monitoring System's Dairy 2007 study, bulk tank milk was collected and tested via PCR for *C. burnetii*, the causative agent of Q fever. Information regarding dairy cow health, reproduction, and productivity was also collected. Samples were collected from 528 operations during the months of March through August 2007. After adjusting for study design and incorporating weighting procedures, 76.9% of dairy operations had PCR evidence of *C. burnetii* in bulk tank milk. *C. burnetii* was detected in bulk tank milk on 69.8% of operations with less than 100 cows, 90.8% of operations with 100–499 cows, and 98.8% of operations with 500 or more cows. A higher percentage of bulk tank milk from operations in the West region (90.1%) were PCR positive for *C. burnetii* compared with those in the East region (75.7%). Weighted log-linear regression models for count data, which adjusted for herd size and region, were used to assess the effect of *C. burnetii* on multiple morbidity and mortality outcomes. Positive operations had a significantly higher percentage of calves born dead (6.0%) and a higher percentage of abortions (4.1%) than operations that tested negative (4.6 and 3.2%, respectively). In addition, positive operations removed a significantly higher percentage of cows due to reproductive problems. These findings provide further evidence that *C. burnetii* is more prevalent in the US dairy herd than previously thought. In addition, *C. burnetii* infection appears to be associated with abortions, calves born dead, and cows removed for reproductive problems. More research needs to be conducted to determine the source of *C. burnetii* on dairy operations, define the causal relationship between health outcomes, and to determine management practices that are likely to decrease transmission of the organism.

Key words: *Coxiella burnetii*, bulk tank milk, prevalence

364 Bulk milk somatic cell penalties in herds enrolled in dairy herd improvement programs. K. J. Hand*[1], A. Godkin[2], and D. F. Kelton[3], *[1]Strategic Solutions Group, Puslinch, ON, Canada, [2]Ontario Ministry of Agriculture, Food and Rural Affairs, Elora, ON, Canada, [3]University of Guelph, Guelph, ON, Canada.*

The objective was to assess the risk of bulk milk somatic cell count (BMSCC) penalties for herds enrolled in dairy herd improvement (DHI) programs compared with nonparticipatory herds. The data consisted of monthly average BMSCC for 2898 CanWest DHI herds and 1186 non-DHI herds in 2009, Ontario, Canada for a total of 48,250 records. The median average BMSCC (10^3 cells / ml) for CanWest DHI herds was found to be 228; whereas, the median in non-DHI herds was found to be 250. Two threshold BMSCC (10^3 cells / ml) penalty levels were considered, 399 and 499. For both penalty levels, the odds of a BMSCC exceeding either penalty threshold for DHI herds was modeled using a generalized mixed model with a binary link function. Random effects included herd; covariates included season of BMSCC (summer, May through September and winter, October through April), total milk shipped per month (l), fat paid per month (kg) and protein paid per month (kg). Furthermore, the odds of a DHI herd incurring a penalty under the Ontario Milk Act (where 3 out of 4 consecutive BMSCC exceeded penalty thresholds) was also examined and modeled with a similar generalized mixed model. The likelihood of a BMSCC exceeding a penalty threshold in a non-DHI herd compared with a DHI herd was found to be significantly greater than 1 at both penalty levels ($P < 0.004$). The likelihood of incurring a BMSCC penalty under the Ontario Milk Act was found to be not significant for a penalty threshold of 499 ($P = 0.18$), but significant for the penalty threshold of 399 ($P = 0.004$).

Key words: bulk tank, SCC, penalty

365 A novel analysis strategy of detection hydrolysate protein adulteration in milk. Z. Chen[1] and D. M. Barbano*[2], *[1]Analysis and Testing Center, Shandong University of Technology, Zibo, Shandong Province, PRC, [2]Department of Food Science, Cornell University, Ithaca, NY.*

Hydrolysate protein (HP) which has the analytical characteristics of protein molecules in the Kjeldahl total nitrogen test could pollute milk or be illegally added into milk to improve protein content would cause big food safety problem. The main component of HP is true protein, so it is difficult to distinguish HP true protein from milk. Hydroxyproline could be only used as identification tag for animal source protein (ISO 3496–1994). Therefore, how to detect exogenous true protein adulteration in milk is still a big challenge for milk quality control and food safety. Our objective was to develop an effective and quick analysis method to figure out HP adulteration in milk. Ultrafiltration (UF) and infrared (IR) analysis were considered to be appropriate techniques. Lactalbumin hydrolysate, casein hydrolysate (acid) and Vegetable Peptone No1 were used to simulate HP adulteration in milk. Every HP experiment (0, 1250, 2500, 3750 and 5000 mg/kg) was replicated 3 times. Stirred Cell 8400 with Micon Ultrafiltration Membrane and LactoScope FTIR were chosen as experiment instruments. 35 psi and 200 g was preferred to operation condition of UF. Excluding the cleaning procedure of UF, it takes 50 minutes for permeate collection and IR detection of one milk sample. All permeate protein is significantly correlated with the 3 HP added in milk ($P < 0.01$), the R square of 3 linear equation is 0.986, 0.897 and 0.953 respectively. The recovery percent of the 3 HP in permeate ranges from 81.32% to 107.25%. Compared with ISO 3496-1994, the proportion of true protein adulteration could be quantificationally and directly detected. The upper bound of 95% confidence interval for control milk permeate protein (n=9) is 0.0401%, it could be the lower limit reference critical value to distinguish whether HP adulteration in milk or not ($P < 0.05$). This paper developed a novel analysis strategy (UF, IR, critical value judgment), and it is verified to be an effective and quick analysis method to solve milk HP adulteration problem.

Key words: hydrolysate protein, milk adulteration, detection

366 Identification of a short isoform of the porcine prolactin receptor and its variants. J. F. Trott*, A. Schennink, and R. C. Hovey, *University of California, Davis.*

Prolactin (PRL) acts through the dimerizing PRL receptor (PRLR) to regulate more than 300 biological processes, particularly during reproduction and lactation, which are both critical for successful swine production. The actions of PRL are mediated by both long (LF) and short isoforms (SF) of the PRLR, where SF can interfere with the essential signaling function of the LF. We have cloned a SF of the porcine PRLR using 3′ RACE. This novel isoform of the pPRLR contains a short intracellular domain of 38 aa that is encoded by splicing from exon 9 to exon 11 on chromosome 16, where the LF splices from exon 9 to exon 10. Analysis of the expression of pPRLR-LF and short pPRLR-SF mRNA by qRT-PCR revealed differential expression of these isoforms with an average ~1000-fold higher level of expression of pPRLR-LF mRNA in 19 tissues. We have also identified polymorphisms within exon 11 that give rise to 4 different coding sequences for the pPRLR-SF. Full-length cDNA for all 4 alleles was generated by PCR and cloned behind the elongation factor 1-α promoter for functional studies, using transiently-transfected of Chinese Hamster Ovary cells. None of the pPRLR-SF alleles were able to activate 342 bp of rat β-casein promoter in response to insulin, dexamethasone and pPRL. All 4 pPRLR-SF alleles functioned as dominant-negatives against the differentiative function of the long pPRLR, where 2 of them completely inhibited long pPRLR activity when they were present at 4-fold excess ($P < 0.05$) whereas the other 2 required 6-fold higher levels to have the same effect ($P < 0.05$). The binding affinity of the 4 alleles of these pPRLR-SF for pPRL was unaffected by differences in the intracellular domain coding sequence ($P > 0.05$). In conclusion, we have identified a unique pPRLR-SF that suppresses the differentiative function of the pPRLR-LF, where the 4 novel pPRLR-SF sequences may differentially impact the phenotypic effects of PRL in swine.

Key words: prolactin, prolactin receptor, short form

367 Comparative transcriptome analysis of laser microdissected cells from bovine mammary gland. K. M. Daniels*[1], R. K. Choudhary[2], C. M. Evock-Clover[3], R. W. Li[3], W. Garrett[3], and A. V. Capuco[3,2], *[1]The Ohio State University, Wooster, [2]University of Maryland, College Park, [3]USDA-ARS, Beltsville, MD.*

Bovine mammary parenchyma (PAR) is a heterogeneous tissue. Laser microdissection (LMD) offers a refined strategy for excision, capture and interrogation of user-defined cell populations. Our objective was to use LMD to obtain homogenous cell populations from prepubertal PAR, followed by microarray analysis to characterize molecular signatures of various cells in PAR and to gain insight into interactions among cell types. Cryosections of PAR from 5 prepubertal Holstein heifers were prepared. Each slide was fixed in acetone:polyethylene glycol and stained with 0.1% nuclear fast red in 5% AlSO4, rinsed with PBS and dehydrated through 3 grades of ethanol. Cells from 4 locations within and near terminal ductal units (TDU) were captured. Basal layer and embedded layers of epithelium were obtained, as were intralobular and interlobular stroma. The 4 categories of cells from each heifer were lysed, cDNA synthesized, amplified and labeled for microarray analysis. The microarray (Roche Nimblegen, Inc.) represented over 45,000 bovine sequences and over 3800 genes were included in the analysis. Transcriptome analysis ($P \leq 0.05$; ≥ 2-fold change) of basal vs. embedded epithelial cells showed many genes involved in differentiation, with an enrichment of transcripts for nestin (stem cell marker), a noncoding maternally imprinted gene (H19), extracellular matrix proteins and metalloproteinases in the basal epithelium. Conversely, there was enrichment of a telomerase inhibitor (POT1) and phosphodiesterases in the embedded epithelial cells. Evaluation of gene expression in the basal epithelium vs. adjacent intralobular stroma showed greater expression of keratin 7, Msh homeobox (MSX2; likely morphogen) and protein tyrosine phosphatase 14. There was an enrichment of MEOX2, a mesenchyme inducer, and sphingosine-1-phosphate receptor 1. Results suggest presence of stem or progenitor cells in the basal epithelium and induction of myoepithelial differentiation via stromal factors. Comparisons of interlobular and intralobular stroma showed a prevalence of lipid associated genes (SCD, DGAT2) in the former. Utility of LMD in bovine mammary tissue was demonstrated.

Key words: laser microdissection, microarray

368 Acute DNA methylation changes are associated with involution and re-initiation of lactation in dairy cows. K. M. Swanson*[1], K. Stelwagen[2], R. A. Erdman[3], and K. Singh[1], *[1]AgResearch Ltd., Ruakura Research Centre, Hamilton, New Zealand, [2]Agri-Search, Hamilton, New Zealand, [3]University of Maryland, College Park.*

The onset of bovine mammary gland involution following the termination of milking results in a decline in milk protein gene expression, including the major milk protein αS1-casein. In a previous study DNA methylation, in the αS1-casein-encoding gene at a functional STAT5 binding site approximately −10kbp, was increased after 7d of involution. The aim of the present study was to determine whether DNA methylation plays an acute role in the downregulation of milk production during the reversible and irreversible phases of involution. Non-pregnant cows at mid-lactation were divided into 5 groups (n = 5/group). Mammary alveolar tissue was obtained at slaughter from lactating cows 6 h post-milking (control), cows with extended non-milking periods of either 7- or 28-d, and cows where milking was resumed for 7 d following these 2 dry periods. Re-initiation of milking following 7- or 28-d non-milking periods resulted in milk yield recoveries of 93 and 25% respectively. Quantitative MassARRAY methylation analysis revealed that methylation levels of 2 5methylCpG dinucleotides at the STAT5-binding site −10kb in the αS1-casein promoter were increased to 32% ($P < 0.1$) and 33% ($P < 0.05$) respectively following 7-d non-milking, then further to 38% ($P < 0.05$) and 50% ($P < 0.05$) respectively following 28-d non-milking, compared with lactating cows (22% and 13% methylation, respectively). Furthermore, the full recovery of lactation following re-initiation of milking after 7-d non-milking was associated with de-methylation of DNA, returning to levels similar to lactating control cows. However, the DNA methylation levels remained significantly higher ($P < 0.05$) than the lactating control cows following the re-initiation of milking after 28-d non-milking, in association with the low, partial recovery of milk yields. These results suggest DNA methylation at a functional STAT5-binding site of the αS1-casein-encoding gene may play a role in regulating reversible and irreversible involution.

Key words: DNA methylation, bovine αS1-casein, mammary involution

369 Ontogeny of nuclear and cytoplasmic myoepithelial markers during prepubertal bovine mammary development. S. Safayi*[1], N. Korn[1], A. Bertram[1], R. M. Akers[2], A. V. Capuco[3], S. L. Pratt[1], S. Calcatera[1], C. Klein[1], and S. Ellis[1], *[1]Clemson University, Clemson, SC, [2]Virginia Polytechnic Institute and State University, Blacksburg, [3]USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD.*

We previously reported that ovariectomy alters prepubertal mammary myoepithelial cell (MC) development, but the mechanisms involved are not well understood. We therefore surveyed expression of transformation-related protein 63 (P63) and the common acute lymphoblastic leukemia antigen (CD10) as differentiation markers to track the ontogeny of MC development. At 40d of age, Holstein heifers underwent either an ovariectomy (OVX; n = 16) or sham (INT; n = 21) operation. At d55, 70, 85, 100, 130 and 160 of age, groups of heifers were slaughtered to provide mammary parenchyma samples for multispectral imaging and subjective assessment of immunofluorescent staining for MC markers. Our qualitative evaluation showed P63-/CD10+, P63+/CD10-, double positive and double negative cells in both basal and suprabasal layers. The P63+ nuclei were observed in the basal layer at regularly spaced intervals. The interval between P63+ nuclei was reduced in older heifers regardless of treatment. Stromal CD10 expression also appeared to be more prominent in older heifers. In both OVX and INT heifers, P63 and CD10 expression was more heterogeneous at the distal ends of the ductular units compared with the subtending ducts. In INT heifers, there was a reduction in the interval between P63+ MC nuclei, compared with OVX heifers. Our observations suggest that expression of P63 in the basal layer of parenchyma from INT heifers was more consistent than in OVX animals. Our results provide support for the hypothesis that ovarian secretions affect the expression of both P63 and CD10. Additional quantitative analyses are now required to substantiate our assertions from the qualitative inspection.

Key words: myoepithelial cell, p63, CD10

370 Multispectral analysis of myoepithelial cell development in prepubertal bovine mammary gland. S. Safayi*[1], N. Korn[1], A. Bertram[1], R. M. Akers[2], A. V. Capuco[3], S. L. Pratt[1], and S. Ellis[1], *[1]Clemson University, Clemson, SC, [2]Virginia Polytechnic Institute and State University, Blacksburg, [3]USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD.*

We have previously reported that ovariectomy alters prepubertal development of mammary myoepithelial cells (MC), but the mechanisms involved are not well understood. We therefore analyzed the MC expression of differentiation markers α-smooth muscle actin (SMA) and the common acute lymphoblastic leukemia antigen (CD10). On d40, Holstein heifers underwent either an ovariectomy (OVX; n = 16) or sham (INT; n = 21) operation. At d55, 70, 85, 100, 130 and 160 of age, samples were collected and used for multispectral imaging to quantitatively assess immunofluorescent staining for target MC markers. Fluorescent intensity (FI) of the markers on each slide were normalized against a control sample and then evaluated statistically using PROC MIXED in SAS. Our results showed 250% more CD10+ cells contacting the luminal space in OVX compared with INT ($P = 0.04$). In the basal layer, CD10 FI was lower ($P = 0.04$) and SMA FI was higher ($P < 0.01$) in OVX than INT. The FI ratio of SMA to CD10, as a proxy indicator for MC differentiation, increased in OVX compared with INT after d55 ($P < 0.01$), and remained approximately 4 times higher from d100 onwards ($P < 0.01$). Intracellular distribution of markers within the basal layer showed basal localization of SMA, but apical CD10 staining. In both INT and OVX, there were also double negative cells expressing neither CD10 nor SMA that appeared to contact both the basal and luminal spaces. Our results show that ovariectomy affects MC expression of both SMA and CD10 as well the pattern of MC development. Given that MC are known to limit parenchymal growth in other species; our observations open new avenues for future studies on the regulation of prepubertal mammary development.

Key words: myoepithelial cell, CD10, smooth muscle actin

371 Lactogenic hormones and IGF-I do not regulate glucose transporter gene expression in the bovine mammary gland during the transition period. Y. Shao*[1], E. Wall[1], Y. Misra[1], X. Qian[1], R. Blauwiekel[1], T. McFadden[2], and F.-Q. Zhao[1], *[1]Laboratory of Lactation Physiology, Department of Animal Science, University of Vermont, Burlington, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Glucose is essential for milk production as it is a major substrate and energy source for milk synthesis. Glucose uptake across the plasma membrane of mammary epithelial cells is mediated by transmembrane facilitative glucose transporters (GLUT). During the transition period, there is a marked increase in the expression of GLUT1, GLUT8, and GLUT12 in the bovine mammary gland. The objective of this study was to investigate whether the lactogenic hormones and/or IGF-I are the mediators of increased GLUT expression. In the first experiment, mammary tissue was obtained by biopsy from 2 primi- and 2 multiparous cows about 40 d before parturition. Mammary explants were cultured for 48, 72 and 96 h with the following hormone treatments: no hormone (control); 200 ng/ml IGF-I; 5 μg/ml insulin (INS); 5 μg/ml insulin + 1 μg/ml hydrocortisone + 5 μg/ml prolactin (IHPrl); and 5 μg/ml insulin + 1 μg/ml hydrocortisone + 5 μg/ml prolactin + 500 ng/ml estrogen (IHEPrl). The relative expression of β-casein, α-lactalbumin, GLUT1, GLUT8 and GLUT12 mRNA were measured by real time PCR. For β-casein and α-lactalbumin, IGF-I and INS had no effect, whereas IHPrl and IHEPrl increased mRNA several hundred fold ($P < 0.01$). Although insulin alone increased GLUT1 mRNA around 1.8 fold ($P < 0.05$), IGF-I, IHPrl and IHEPRL had no effect on GLUT1 or GLUT8 expression. There was no treatment effect on GLUT12 expression at 48 h, but IHPrl and IHEPrl decreased GLUT12 expression by 50% after 72 and 96 h ($P < 0.05$). In the second experiment, prolactin was administered twice a day to 5 cows during early lactation by intravenous injection at a dose of 1 μg/kg of BW. After 7 d of treatment, mammary tissue was obtained by biopsy from prolactin-treated cows and 5 control cows. Expression of GLUT1, 8 and 12 mRNA was measured by real time PCR, and there was no effect of prolactin on gene expression. Our data suggest that lactogenic hormones and IGF-I may not mediate the increase in GLUT expression in bovine mammary gland during the transition period.

Key words: glucose transporters, bovine mammary gland, lactogenic hormones

372 Lactogenic complex-induced mammary epithelial cell differentiation is associated with membrane compositional differences. N. Argov-Argaman*, K. Mida, and A. Shamay, *The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University, Jerusalem, Israel.*

Mammary gland epithelial cell differentiation is induced by insulin (I), hydrocortison (F) and prolactin (Prl). Although the mammary epithelial cell proteome is well established, differentiation-associated changes in its lipidome composition are not well defined. A murine mammary

gland epithelial cell line (HC11) was used to study alterations in lipid composition of the cell and its membrane during differentiation. HC11 cells were exposed to one of the following hormonal treatments: IPrl, PrlF, and IF. Differentiation medium consisted of prolactin, insulin and hydrocortisone (n = 3 for lipid and 4 for gene expression analysis;2 biological replicated for each experiment). Lipid composition of fat and membrane cellular compartments were determined. Gene-expression levels of lipogenic and lipolytic enzymes, as well as of genes encoding enzymes that modulate fatty acid length and unsaturation level (i.e., elongases and desaturases, respectively) were measured. Overall, insulin was the main factor inducing alterations in membrane composition, which consisted of increased phosphatidylethanolamine (12+0.5 and 15+0.4 for PrlF compared with IFPrl, $P = 0.004$) and decreased sphingomyelin concentrations (2+0.3 and 37+0.4 for PrlF compared with IFPrl, $P = 0.0002$). Nonetheless, the differentiation medium, (IFPrl), had a stronger effect on phospholipid composition than all other treatments which included insulin. In addition, insulin increased the concentration of monounsaturated fatty acids (46+0.5 and 53+0.1 for PrlF compared with IFPrl, $P < 0.001$), but decreased that of polyunsaturated fatty acids in the membrane (17.5+0.3 and 11.1+0.1 for PrlF compared with IFPrl, $P < 0.001$). Gene expression of both desaturases and elongases (ELOVL 1, 3, 5, 6 and 7, Δ5, Δ6 and Δ9 desaturase) was elevated by differentiation medium only relative to all other treatments. The results suggest that membrane compositional differences in both polar lipids and fatty acids occur concomitantly with the differentiation of the mammary epithelial cells and suggest a role for membrane lipid composition in the acquisition of mammary cell characteristics.

Key words: milk, membrane, phospholipid

373 Intravenous supplementation of acetate, glucose or essential amino acids to an energy and protein deficient diet in lactating dairy goats: effects on milk production and mammary nutrient extraction. S. Safayi*[1,2] and M. O. Nielsen[1], *[1]University of Copenhagen, Frederiksberg, Great Copenhagen, Denmark, [2]Clemson University, Clemson, SC.*

The objectives were to study how mammary supply of essential amino acids (EAA) versus energy yielding substrates in the form of acetate (ACE) or glucose (GLU) would affect mammary nutrient uptake and milk (protein) synthesis in early (EL) and late lactating (LL) dairy goats. Four goats were fed a basal diet deficient in energy (90% of requirements) and protein (80% of requirements), and randomly allocated to 4 treatments in a balanced 4 × 4 Latin Square design. The treatments consisted of 4-d continuous intravenous infusions of isoosmotic isoenergetic solutions of EAA, ACE and GLU with saline (SAL) as control, having a 3-d rest period in between. Simultaneous arterio-venous blood samplings over each udder half/gland were performed every 4 h during the last 24 h of infusion. Milk production was recorded, and its fat and protein contents as well as some of the blood/plasma parameters/components were determined. In EL, milk yield or energy corrected milk yield (ECM) was stimulated by GLU ($P = 0.01$) and tended to be increased by EAA ($P = 0.06$) and ACE ($P = 0.06$). ACE and EAA (but not GLU) stimulated milk protein yield ($P = 0.06$ and 0.03, respectively for ACE and EAA), illustrating the importance of amino acid as well as ATP generation for support of protein synthesis in EL. Highest fat yield in EL was observed on ACE ($P < 0.05$). In LL, only EAA could raise milk protein yield ($P < 0.01$) and ECM ($P = 0.06$). In LL, GLU lowered milk fat percentage ($P = 0.01$). We conclude that an insufficient amino acid supply to the mammary gland of dairy goats can be compensated in EL but perhaps not in LL by increased mammary supply and uptake of an energy yielding substrate, provided this substrate specifically contributes to ATP generation in mammary epithelial cells. This suggests there might be scope for development of differential protein recommendations for ruminants in early and late lactation, and this issue should be pursued in future studies.

Key words: mammary metabolism, mammary nutrient uptake, arterio-venous concentration difference

374 Expression profiles of microRNAs from non- and lactating bovine mammary glands. Z. Li*[1,2], H. Y. Liu[1,2], and J. X. Liu[1,2], *[1]Institute of Dairy Science, College of Animal Sciences, Hangzhou, P.R. China, [2]MOE Key Laboratory of Molecular Animal Nutrition, Hangzhou, P.R. China.*

The microRNAs (miRNA) are small non-coding RNA molecules that are approximately 22 nucleotides (nt) in length. It has been reported that miRNAs are involved in the regulation of milk protein synthesis and development of mammary gland. However, little information is available on the function of miRNA in regulation of lactation. Therefore, clarifying of miRNA expression profiles in mammary gland are crucial to the understanding of the mechanism of lactation initiation. In this study, one healthy cow each from both non- and lactating stages was selected to collect mammary gland tissues. Two miRNA libraries were constructed and sequenced, respectively. The miRNAs (18–30nt) were sequenced by Solexa sequencing method. A total of 11,964,909 clean reads were obtained from lactating cows and 15,968,116 clean reads from nonlactating cattle. The sequencing data were analyzed using ACGT101-miR program. There were 962 pre-miRNAs encoding for 985 miRNAs, of which 946 were unique and 521 (52.9%) were expressed in both periods. Among the unique sequences, 284 were known as bovine miRNAs registered in the miRbase database; 96 miRNAs were conserved in other mammalian; and 566 miRNAs were bovine-novel candidates. Real-time quantitative PCR was used for validation of the sequencing results of 32 selected miRNAs which indicated great difference between 2 periods. It is observed that the results of over 50% of these miRNAs were consistent with Solexa sequencing data. There were 17 miRNAs expressed in higher level in lactating than in nonlactating bovine mammary glands. The high percentage of bovine-novel candidates indicated that many miRNAs in bovine mammary gland have not been identified. Further research is warranted to examine what kinds of miRNAs are involved in lactation and how they function in regulation of lactation.

Key words: bovine mammary gland, lactation, miRNAs

Meat Science and Muscle Biology Symposium: Meat in the Diet

375 Meat and human cancer. L. R. Ferguson*, *The University of Auckland, Auckland, New Zealand.*

There is a burgeoning literature associating a high intake of meat, especially red meat and processed meat, with an increased risk of various types of cancer in various human populations. However, red meat in particular is an important source of various nutrients with anticancer properties, including selenium, vitamins B6 and B12, and vitamin D. Additionally, the current evidence base suggesting cancer risk is mostly from association studies. Risk may not be a function of meat intake per se, but could reflect high fat intake, and/or carcinogens generated through various cooking and processing methods. Meat contains several potential anti-carcinogens, including omega-3 polyunsaturated fatty acids, and conjugated linoleic acid (CLA). Cancers associated with high meat consumption may be reduced by the addition of anti-carcinogens, during meat preparation or meat consumption, or through modification of food preparation methods. For example, a diet high in dietary fiber may enhance the excretion, and reduce the metabolism and DNA interaction, of some of the potential meat carcinogens. Adjusting the nature of the meat, the cooking methods, and the balance between meat and other dietary components may be critical to protecting human populations against any potential cancer risks.

Key words: meat, cancer, humans

376 Meat lipids in human health. S. McNeill*, *National Cattlemen's Beef Association, Centennial, CO.*

This objective of this presentation is to review the current evidence on saturated fatty acid content of meat and its implications on human health. Since the first edition of the Dietary Guidelines for Americans was issued in 1980, nutrition guidance for the American public has emphasized the need to reduce the total fat, saturated fat and cholesterol content in their diet, as a means of reducing risk of heart disease and other chronic diseases. When nutrient-focused guidance is translated to food-based recommendations, animal foods such as red meat, are often cited as food sources that need to be reduced to decrease these nutrients. Yet, over the last 30 years, the amount of total and saturated fat from red meat in the American diet has been declining. Today, greater than 90% of the total fat and saturated fat in the American diet comes from sources other than beef. Although underappreciated, red meat's lipid composition is predominately monounsaturated fatty acids and contains limited amounts of polyunsaturated fatty acids. Saturated fatty acids make up most of the remainder of total lipid profile. About one-third of beef's saturated fat content is the cholesterol-neutral saturated fatty acid, stearic acid. Consistent evidence from clinical trials indicates that the inclusion of lean beef in a well-balanced diet designed to manage cardiovascular risk is equally as effective as a diet of lean white meat for low-density lipoprotein cholesterol reduction. Additionally, recent research has challenged conventional thinking of the role of dietary saturated fat in chronic disease and accumulating supportive evidence demonstrates the macronutrient mix of the diet (amount and type of carbohydrate, protein and fat) can influence the effect of dietary saturated fat.

Key words: red meat, saturated fat, human health

377 Perspective on IOM report: Strategies to reduce sodium in the United States. C. A. Mireles DeWitt*, *OSU Seafood Research & Education Center.*

Last year a committee of 14 individuals across varied disciplines compiled a consensus report that recommends the measures would needed to be taken to successfully reducing sodium intake in the United States. The committee considered past efforts such as labeling, consumer education, and voluntary efforts by the industry. The committee also considered current efforts such as state and local labeling initiatives and sodium reduction efforts in other countries. Economic incentives such as agriculture subsidies, tax incentives, salt tax, cap and trade, and leveraging sodium reduction by use of government food purchase specifications were also considered. A review of the current literature on the role of sodium in terms of taste, flavor and functionality in foods was also performed to provide a framework for the possibility of technological advances that might aid sodium reduction. The food environment and sources of sodium (from both food processor and restaurants) were evaluated as well. All of the aforementioned considerations helped to shape the final recommendations. The recommendations were multifaceted with the "primary" objective focused on modifying the GRAS status of salt. The objective is to overview the IOM recommendations and provide insights into the types of strategies processors can use to reduce sodium.

378 Nitrite and nitrate in health and disease: A paradigm shift. N. S. Bryan*, *Institute of Molecular Medicine, UT Health Science Center, Houston, TX.*

Objective: To present the most recent published literature on the biological effects of nitrite and nitrate to establish the context for potential health benefits vs. potential risks or adverse effects. Nitrite and nitrate are indigenous to our diet and are formed naturally within our body from the oxidation of nitric oxide (NO). Emerging health benefits from dietary sources of nitrite and nitrate contradict decades of epidemiological research that have suggested an association of nitrite and nitrate in foods, primarily cured and processed meat, with certain cancers. The major source of exposure of nitrite and nitrate comes from the consumption of nitrate enriched vegetables. The preponderance of epidemiological studies shows a very weak association with consumption of meats and certain cancers, which contain very little nitrite and nitrate. Nitrite and nitrate in certain foods and diets can be metabolized to NO and promote cardiovascular benefits and cytoprotection. Summary: The cardiovascular benefits of nitrite and nitrate are beginning to be translated in humans by the increasing number of clinical trials using nitrite and nitrate. The collective body of evidence suggests that foods enriched in nitrite and nitrate provide significant health benefits with very little risk.

Key words: nitrite, processed meats, nutrition

Milk Protein and Enzymes Symposium: Milk Proteins and Peptides: Bioactivity and Digestion

379 Structural bases for the nutritional and biological properties of the caseins. H. M. Farrell Jr.*[1], E. L. Malin[1], E. M. Brown[2], and A. Mora-Gutierrez[3], *[1]USDA, ERRC, Dairy and Functional Foods RU, Wyndmoor, PA, [2]USDA, ERRC, Biobased and Other Animal Coproducts RU, Wyndmoor, PA, [3]Cooperative Agricultural Research Center, Prairie View A&M University, Prairie View, TX.*

Our understanding of the nutritional and biological properties of the caseins has paralleled the description of the chemistry of these proteins. For example, following the first amino acid analyses of the caseins, it became apparent that these proteins are an excellent source of the essential amino acids needed for human nutrition, and casein became the standard reference protein for nutritional studies. Upon elucidation of the primary sequences of the caseins, it was discovered that inherent in these sequences were several peptides, the so-called casomorphins, which if liberated during digestion would have physiological (endorphin-like) activity. The enumeration of other potentially biologically active peptides followed. In addition, anti-bacterial activities have been ascribed to several other casein peptides. Although many of these activities have been demonstrated in vitro, few have been demonstrated in vivo in clinical or feeding studies. Notable exceptions to this rule have been antihypertensive peptides, an anti-stress peptide from α_{S1}-casein, and the role of phospho-peptides in calcium uptake. The advent of 3D molecular modeling has now allowed us to portray these peptides at the molecular level and will allow the comparisons of the structures of the various biologically active peptides, leading to a better understanding of the molecular mode of action of the casein peptides.

Key words: casein structure, casein bioactive

380 Digestibility of whey protein aggregates and fibrils under simulated gastro-intestinal environments. H. Singh*, M. Peram, S. Loveday, B. Libby, and Y. Aiqain, *Riddet Institute, Massey University, Palmerston North, New Zealand.*

The digestion and metabolism of proteins continues to generate considerable scientific interest, driven mainly by the need to understand the release of bioactive peptides, and factors affecting protein allergenicity and satiety. It is well known that β-lactoglobulin (β-Lg), which represents about 60% of whey proteins in bovine milk, is resistant to hydrolysis by pepsin under gastric conditions because of its stable, globular tertiary structure at low pH (<pH 3). However, denatured β-Lg (caused by heating or high pressure) can be readily digested by pepsin under gastric conditions. Under denaturing conditions, β-Lg is able to form different kinds of aggregates, including spherical aggregates and elongated fibrils, depending on the protein concentration, pH, temperature and heating time. Although many studies on the mechanism of β-Lg aggregate formation and structures have been carried out, little work has been carried out on the digestion of different forms and structures of these aggregates under gastro-intestinal conditions. Therefore the objective of our study was to understand the relationship between heat-induced structural changes in β-Lg and in vitro gastric digestibility. Heating of β-Lg at 90°C and neutral pH resulted in the formation of non-native aggregates of different sizes (dimmers, trimers, oligomers), linked through disulfide and non-covalent bonds. The digestibility of non-native β-Lg aggregates varied significantly depending on the type of aggregates. Some dimers were resistant to digestion, while high molecular weight aggregates were digested fast. β-Lg fibrils formed by heating β-Lg solutions at 80°C and pH 2.0 for 20 h consisted of peptides, generated through acid/heat-induced hydrolysis. Using matrix-assisted laser desorption/ionization mass spectometry (MALDI-MS), we found that the peptides in the fibrils were more susceptible for pepsin attack than the other peptides, possible because of their hydrophobic nature.

Key words: whey proteins, digestibility, protein aggregation

381 Peptides derived from whey protein: Endothelium and vascular bioactive function. E. D. Bastian* and L. W. Ward, *Glanbia Nutritionals Inc., Twin Falls, ID.*

Novel, high-leucine peptides derived from whey protein were tested for vascular, endothelial response in 20 young individuals. A randomized, placebo-controlled, crossover design was used which consisted of 2 wk supplementation, 2 wk washout, and 2 wk crossover supplementation. Peptide and placebo dose was 5 g/day. Subjects participated in 2 vascular testing days, each preceded by 2 wk of supplementation. After consuming the dose, vascular function in the forearm was measured serially for 120 min. Macrovascular and microvascular function was assessed using brachial-artery, flow-mediated dilation (FMD) and venous-occlusion, strain-gauge plethysmography. Six blood draws were taken across the 120 min measurement period and analyzed for total nitrates/nitrites. Placebo had no impact on FMD at 30, 60 and 90 min post ingestion. When peptides were ingested, FMD increased at the 3 time points by 14.0, 26.9, and 15.4% compared with placebo and baseline measurements. Plasma total nitrates/nitrites significantly decreased for the 120 min post-ingestion period and were lower at 120 min in placebo (−25%) compared with peptide (−18%). These data indicate that supplementation with high-leucine, whey-derived peptides improves vascular function in young, healthy individuals.

Key words: bioactive, peptide, vascular

382 The structure of dairy products modifies the kinetics of protein hydrolysis and the release of bioactive peptides in the gut during digestion. D. Dupont*[1,2], K. Bouzerzour[1,2], F. Barbe[1,2], Y. Le Gouar[1,2], and O. Menard[1,2], *[1]National Institute for Agricultural research, Rennes, France, [2]Agrocampus Ouest, Rennes, France.*

Digestion provides nutrients and energy essential to the survival and growth of the organisms. But little is known about the influence of food structure on its digestibility and nutritional properties. The objectives of our group are therefore to understand how dairy products are disintegrated during digestion and how the structure of the matrix will modify the protein digestibility. To reach this goal, static and dynamic in vitro models simulating what happens in the GI tract have been developed and in vivo experiments have been performed using the pig as a model. Digested samples collected in the different parts of the gut were characterized by SDS-PAGE, ELISA and/or mass spectrometry in order to quantify and identify milk proteins and peptides throughout the GI tract. Two applications will be presented. In a first experiment, digestion of an infant formula by 28 days-old piglets showed that caseins were rapidly hydrolysed in the stomach whereas whey proteins were partially resistant. Large milk protein fragments were shown to resist digestion and were detected in the ileum. Peptides

known to carry biological (anti-hypertensive, immunomodulating) properties were identified in the small intestine of piglets. In a second experiment, six dairy matrices (liquid milks, acid and rennet gels with or without heat-treatment) of similar composition but with different microstructure were manufactured from the same raw skim milk in a pilot plant. Each sample was given to six multi-catheterized adult mini-pigs. Effluents were then taken at the very end of stomach during 7 h after the meal and milk proteins and peptides quantified. Compares to liquid milks, acid gels showed a delayed gastric emptying and a slower release of caseins and β-lactoglobulin in the duodenum. When gel was stirred, an intermediate behaviour was observed. Results also showed that heat treatment of milk induced a slower release of caseins in the small intestine. All these results emphasize the role played by the structure of the food matrix on the digestion of dietary proteins.

Key words: digestion, dairy products, milk proteins

383 Effects of dietary milk fat globule membrane in the gut and on systemic lipid metabolism. R. Ward*[1], R. Jimenez-Flores[2], A. Zhou[1], and K. Hintze[1], *[1]Utah State University, Logan, [2]California Polytechnic State University, San Luis Obispo.*

In milk, fat droplets are coated by an epithelial membrane that results from a novel secretion process within the mammary gland. The milk fat globule membrane (MFGM) is composed of primarily polar lipids and membrane proteins and is the most diverse fraction of milk. While MFGM is present in all dairy products to some extent, it is present in several co products of dairy processes such as churn buttermilk and whey, and may be recovered for use a bioactive ingredient. Despite the fact that MFGM is a unique ingredient in the food supply and it is rich in potentially bioactive constituents, few studies have been conducted to measure its effect on physiology and nutrition. In the last several years our labs have begun to investigate the potential of this material as a food ingredient through studies with cells in culture, with rodents, and currently with humans. Our results to date indicate that MFGM has myriad effects within the gut, and also appears to affect systemic lipid partitioning. For example, MFGM reduces the number of aberrant crypt foci in a rat model of colon cancer and that it prevents gut leakiness and systemic inflammation induced by lipopolysaccharide in mice. Furthermore, supplementation of rat diets high in sucrose with MFGM appears to reduce the development of fatty liver via effects on gene expression and lipid transport. Lastly, dietary MFGM has significant effects on the fecal microbiome profile and presence of fecal small molecules. In sum, these results indicate that inclusion of MFGM into food products may have demonstrable and valuable bioactive effects.

Key words: MFGM, gut, metabolism

384 Effects of creep feeding and supplemental glutamine or glutamine plus glutamate (AminoGut) on pre- and post-weaning growth performance and intestinal health of piglets. R. Cabrera*[1], J. Usry[2], E. Nogueira[3], M. Kutschenko[3], A. Moeser[1], and J. Odle[1], *[1]North Carolina State University, Raleigh, [2]Ajinomoto Heartland LLC, Chicago, IL, [3]Ajinomoto Brazil, Brazil.*

We determined the impact of creep feeding and adding either L-glutamine (GLN) or AminoGut (AG) to pre- and post-weaning diets on pig performance and intestinal health. Litters (n = 120) were randomly allotted based on litter size and sow parity to 4 treatments: 1) Non-creep fed (NC, n = 45); 2) creep fed control diet (CFCD, n = 45); 3) creep fed 1% GLN (CFGLN, n = 15); 4) creep fed 0.88% AG (CFAG, n = 15). No effects of creep feed on intake, weaning weight or mortality were detected ($P > 0.25$). After weaning, the NC and CFCD groups were divided into 3 groups (n = 15 each), receiving either a control nursery diet (NC-CD, CFCD-CD) or a diet supplemented with GLN (NC-GLN, CFCD-GLN) or AG (NC-AG, CFCD-AG). The litters creep fed diets containing GLN or AG also were supplemented with those AA in the nursery diets (CFGLN-GLN, CFAG-AG). GLN was added at 1% in all 3 phases and AG was added at 0.88% in phase 1 and 2 and at 0.66% in phase 3. Pigs receiving GLN in pre- and post-weaning diets (CFGLN-GLN) had the best G:F for the first 3-wk period ($P < 0.056$), exceeding controls (CFCD-CD) by 35%. The NC-AG group had ($P = 0.02$) the greatest feed intake in the last 3 wk of the study, exceeding controls (CFCD-CD) by 12%. Pigs creep fed a control diet with or without glutamine and fed with a post-weaning diet supplemented with glutamine (CFGLN-GLN, CFCD-GLN respectively) had the greatest ($P < 0.05$) villi height exceeding those which were creep fed with a control diet and later supplemented with AminoGut (CFCD-AG) by 18% and 20% respectively. Although this treatment (CFCD-AG) had the shortest villi among all treatments, they had the widest ($P = 0.1$) villi. We found that pigs creep fed with a diet supplemented with AminoGut and fed with a post-weaning diet supplemented with AminoGut (CFAG-AG) had the deepest ($P < 0.01$) crypts of all the treatments. In conclusion, supplementation of nursery diets with GLN in the first 3-wk improved feed conversion and with AG improved feed intake in the last 3-wk implicating possible improvement in intestinal health.

Key words: creep feed, glutamine, Amino-Gut

385 Metabolomic analysis of the response to weaning and dietary L-glutamine supplementation in piglets using gas chromatography/mass spectrometry. Y. Xiao*[1], T. Wu[1], B. Dai[2], S. Luo[1], J. Feng[2], and A. Chen[1], *[1]Zhejiang University, Hangzhou, Zhejiang, China, [2]Zhejiang Gomore Group, Hangzhou, Zhejiang, China.*

A novel metabolomic method based on gas chromatography/mass spectrometry (GC/MS) was applied to determine serum metabolites involved in responses to weaning and dietary glutamine supplementation in piglets. Thirty-six 21-d-old piglets were randomly assigned into 3 groups. One group continued to suckle from the sows, whereas the other 2 groups were weaned and their diets were supplemented with 1% L-glutamine (wt:wt) or isonitrogenous L-alanine, representing glutamine-supplemented group and weaned group. Serum samples were collected to characterize metabolites at 28-d-old. The GC/MS data was analyzed following the 2 sample *t*-test ($P < 0.05$)to explore the potential maker metabolites, and principal component analysis (PCA) was used to classify the different groups. Results showed that 17 metabolites were downregulated by both weaning and glutamine treatment compared with suckling piglets. These were mostly carbohydrates ($P < 0.05$) and lipids ($P < 0.05$), except for 2-hydroxybutanoic acid ($P = 0.031$), 4-hydroxypentenoic acid ($P = 0.048$), and phosphoric acid ($P = 0.0011$). Another 3 metabolites, creatinine ($P = 0.0208$), D-xylopyranose ($P = 0.0439$), and glyceryl monostearate ($P = 0.0414$), were reduced in weaned group . The level of 2-hydroxybutanoic acid ($P = 0.0077$), creatinine ($P = 0.0003$), D-xylopyranose ($P = 0.0006$), palmitelaidic acid ($P = 0.0016$) and α -L-galactofuranose ($P = 0.0495$) were greater in the glutamine-supplemented piglets than in the weaned ones. Based on the data, correlation network for weaned and suckling piglets revealed that weaning disturbed the lipid, carbohydrate and amino acid metabolism, whereas the metabolic state was partially improved by glutamine supplementation. Principal component analysis demonstrated that suckling piglets were metabolically distinct from their weaned and glutamine-supplemented counterparts, and yielded a separate clustering of profiles between glutamine group and weaned group. These novel findings provide fresh insight into the complex metabolic mechanisms of weaning and show the influence of dietary glutamine supplementation in piglets.

Key words: glutamine, metabolomics, weaning

386 Feed efficiency of 7- to 16-kg pigs is maximized when additional lysine is supplied by L-Lys instead of intact protein, but is not affected when diets are supplemented with differing sources of non-essential amino acid nitrogen. C. K. Jones*[1], J. A. Acosta[2], M. D. Tokach[3], J. L. Usry[4], C. R. Neill[5], and J. F. Patience[1], *[1]Iowa State University, Ames, [2]Universidad Nacional de Colombia, Bogotá, Columbia, [3]Kansas State University, Manhattan, [4]Ajinomoto Heartland LLC, Chicago, IL, [5]Pig Improvement Company, Hendersonville, TN.*

Little is known about how the pig′s response to Lys changes due to differences in protein source. A total of 540 (Exp. 1, 6.7 kg, 6 pigs/pen) or 450 (Exp. 2, 6.6 kg, 5 pigs/pen) PIC pigs were used in 2 14-d experiments to evaluate if the source of non-essential AA nitrogen (NEAA; Exp. 1) or source of additional Lys (Exp. 2) affects the Lys requirement of pigs. In both experiments, there were 9 replicates/treatment. The NEAA were supplied by L-Glu and L-Gly or L-Gly, L-Ala, L-Pro, and L-His, while additional Lys was supplied by L-Lys HCl or SBM. Pigs were fed 1 of 10 dietary treatments that included 1 of 5 levels of standardized ileal digestible Lys (1.2, 1.3, 1.4, 1.5, and 1.6%). There were no ($P > 0.24$) protein source × Lys level interactions. In Exp. 1, ADG increased linearly ($P < 0.0001$) and quadratically ($P = 0.02$) with increasing Lys level, while G:F increased in a linear ($P < 0.0001$) manner. Linear 1-slope broken-line analyses of all treatments revealed optimum ($P = 0.0004$) ADG was obtained at 1.36% Lys. The source of NEAA did not affect ADG ($P = 0.82$) or G:F ($P = 0.90$). In Exp. 2, both ADG and G:F increased linearly ($P < 0.0001$) with increasing Lys level. Broken-line analyses showed optimum ($P = 0.0001$) ADG was obtained at 1.47% Lys. While the source of Lys did not affect ($P = 0.48$) ADG, supplying Lys from L-Lys rather than SBM resulted in improved ($P = 0.01$) G:F, particularly at the level closest to the breakpoint (pairwise comparison of additional Lys sources at 1.5% Lys: $P = 0.01$). In summary, feed efficiency of nursery pigs is affected by Lys source, but not by source of non-essential AA nitrogen.

Table 1.

Source of non-essential AA	Exp. 1 Lys level	ADG, g/d	G:F	Source of additional Lys	Exp. 2 Lys level	ADG, g/d	G:F
L-Glu and L-Gly	1.2	330	0.73	L-Lys	1.2	312	0.74
	1.3	362	0.76		1.3	338	0.80
	1.4	401	0.80		1.4	368	0.81
	1.5	375	0.80		1.5	381	0.85
	1.6	395	0.85		1.6	367	0.85

P =	NEAA source	0.82	0.90	*P* =	Additional Lys source	0.48	0.01

Key words: lysine, nutrient requirement, pig

387 Effect of increasing levels of lysine in the diet on growth performance and carcass and meat quality of growing-finishing pigs. L. Cámara[1], M. P. Serrano[1], J. I. Morales[1], E. Alcázar[2], J. L. Sánchez[2], and G. G. Mateos*[1], *[1]Departamento de Producción Animal, UPM, Ciudad Universitaria, s/n. [28040], Madrid, [2]S.A.T. Vallehermoso, Ctra. La Solana a Infantes, km [9]. [13248], Alhambra, Ciudad Real.*

A trial was conducted to study the effect of level of Lys in the diet on productive performance and carcass and meat quality of pigs from 26 to 124 kg BW. A total of 480 crossbreds pigs (Large White × Landrace females crossed with Duroc male and PIC 410 sires) were used. Half of the animals were gilts and half males castrated at 4 d. The feeding program consisted of 5 periods with 5 dietary Lys levels each. Diets within each period were formulated to have the same NE (2,425 kcal/kg) but differed in digestible Lys content (1) Control (C); 2) C - 6%; 3) C - 12%; 4) C + 6%; and 5) C + 12%). The digestible Lys content of the control diets was 1.02, 0.86, 0.75, 0.70, and 0.58% for each of the 5 periods. In all cases, the other indispensable AA were formulated on an ideal protein basis. Each treatment was replicated 8 times. The experimental unit was the pen for all traits (12 pigs each for productive traits and 4 carcasses chosen at random for carcass and meat quality traits). From 26 to 44 kg BW, pigs fed diets with +12% and +6% Lys had better G:F than those fed the −6% and −12% Lys diets ($P = 0.024$) with pigs fed the control diet being intermediate. From 63 to 80 kg BW pigs fed diets with +12% and +6% Lys had better G:F than fed the control or the −6 and −12% Lys diets ($P = 0.042$). Cumulatively, pigs fed +12% and +6% Lys diets and control diet had better G:F ($P = 0.007$) than pigs fed −6% and −12% Lys diets. An increase in Lys content of the diet increased linearly carcass lean ($P = 0.011$) and quadratically the percentage of protein of the meat ($P = 0.020$), but no differences were detected for carcass fat or percentage of primal cuts. Under the conditions of the experiment, the use of 1.08%, 0.91%, 0.80%, 0.70%, and 0.58% digestible Lys for each of the periods considered in diets containing 2,425 kcal NE/kg, is recommended.

Key words: carcass and meat quality, dietary lysine, pig growth

388 Apparent prececal digestibility of amino acids and performance of broiler chickens fed soybean meal-based diets. A. F. Agboola*[1] and E. A. Iyayi[1], *[1]Department of Animal Science, University of Ibadan, Ibadan, Oyo, Nigeria, [2]University of Ibadan, Ibadan, Oyo, Nigeria.*

The apparent prececal amino acid digestibility of soybean meal (SBM) at varying levels of inclusion (0, 10, 20, and 30%) was determined for broiler chicks in a 7-d experiment. The feed ingredient SBM used served as the sole source of amino acids, as other feed ingredients were fixed. The birds received a commercial broiler starter diet during the first 14 d posthatch. On d 14, birds were sorted by body weight and randomly distributed into 4 dietary treatments in a completely randomized design. Each diet was comprised of 4 replicates of 5 birds per replicate from d 14 to 21 posthatch. On d 21 posthatch, birds were asphyxiated with CO2 and digesta samples from the terminal ileum were collected. Titanium dioxide was included as the indigestible dietary marker. In general, the concentration of essential amino acids (AAs) was highest in the 30% SBM diet as compared with other diets with the least in the control diet. The digestibility of all the essential AAs shows significant ($P < 0.05$) increases with inclusion of SBM in the diets. Arginine digestibility in birds fed 20% SBM was highest (94.92%) as compared with other essential amino acids, whereas threonine had the lowest digestibility value across the treatments. Lysine and methionine digestibilites in birds improved significantly ($P < 0.05$) at 20% SBM inclusion level. Increasing amounts of soybean meal had no significant effect on the weights of the birds but birds on the SBM diets had significantly ($P < 0.05$) higher weights and weight gain than those on the control diet. Feed intake was significantly increased ($P < 0.05$) in birds with increasing SBM levels while the feed conversion ratio was significantly ($P < 0.05$) improved. In conclusion, the data from the present study show that there are considerable differences in varying levels of SBM in the digestibility of their amino acids and growth performance for broiler starters. Therefore, it is imperative to consider lower levels of SBM inclusion, as levels above 20% resulted in decreased digestibility of amino acids.

Key words: prececal digestibility/amino acids, performance/soybean meal, broiler chickens

389 Amino acid digestibility and energy content in Dried Fermentation Biomass, Peptone 50, and P.E.P. Two Plus fed to weanling pigs. R. C. Sulabo*[1], J. K. Mathai[1], J. L. Usry[2], B. W. Ratliff[3], D. M. McKilligan[3], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Ajinomoto Heartland LLC, Chicago, IL, [3]TechMix LLC, Stewart, MN.*

Two experiments were conducted to determine the standardized (SID) ileal digestibility of AA (Exp. 1) and the DE and ME content (Exp. 2) in Dried Fermentation Biomass (DFB), Peptone 50 (PEP50), and P.E.P. Two Plus (PEP2+) fed to weanling pigs and to compare these values to those in fish meal. DFB (Ajinomoto Heartland LLC) is a co-product from AA production and PEP50 and PEP2+ (TechMix LLC) are produced from hydrolyzed pig intestines. In Exp. 1, 12 barrows (BW: 11.5 ± 1.1 kg) were allotted to a replicated 6 × 6 Latin square design with 6 diets and 6 periods. One diet was based on SBM as the sole source of AA and 4 additional diets were formulated based on a combination of SBM and DFB, PEP50, PEP2+, or fish meal. A N-free diet was used to calculate endogenous losses of AA. The SID of Lys in DFB were greater (93.8 vs. 87.2%; $P < 0.01$) than in fish meal, but were similar for all other indispensable AA. The SID of Lys was less ($P < 0.01$) in PEP2+ (84.1%) than in DFB, but was similar to those in PEP50 (87.5%) and fish meal. Except for the SID of Thr, PEP50

had similar SID for all indispensable AA compared with fish meal. The SID of all indispensable AA except for Trp was less ($P < 0.05$) in PEP2+ than in any of the other ingredients. In Exp. 2, 40 barrows (BW: 12.8 ± 1.4 kg) were used with 5 diets and 8 replicate pigs per diet. A basal diet consisting of 96.4% corn and 4 diets with corn and DFB, PEP50, PEP2+, or fish meal were formulated. The DE (5,781 kcal/kg DM) and ME (5,560 kcal/kg DM) in DFB were similar to those in PEP2+ (5,300 and 4,959 kcal/kg DM), but were greater ($P < 0.01$) than in PEP50 (5,003 and 4,744 kcal/kg DM) and fish meal (4,586 and 4,180 kcal/kg DM). The DE and ME in PEP2+ were also greater ($P < 0.01$) than in fish meal, but were similar to those in PEP50. The ME in PEP50 was not different from the ME in fish meal. In summary, DFB, PEP50, and PEP2+ had similar AA digestibility, but greater energy value than fish meal.

Key words: alternative feedstuffs, amino acids, pigs

390 Digestibility of amino acids in corn, corn co-products, and bakery meal fed to growing pigs. F. N. Almeida*, G. I. Petersen, and H. H. Stein, *University of Illinois, Urbana.*

The objectives of this experiment were to measure the apparent ileal digestibility (AID) and the standardized ileal digestibility (SID) of CP and AA in bakery meal, corn gluten meal, corn gluten feed, corn germ meal, and hominy feed and to compare these values to the AID and SID of CP and AA in corn and distillers dried grains with solubles (DDGS). Eight growing barrows (initial BW: 82.5 ± 5.5 kg) were randomly allotted to an 8 × 8 Latin square design with 8 diets and 8 periods. Diets contained corn, DDGS, bakery meal, corn gluten meal, corn gluten feed, corn germ meal, or hominy feed as the sole source of protein and AA. An N-free diet was used to measure basal endogenous losses of AA and protein. Pigs were fed the experimental diets during 8 7 d periods with ileal digesta being collected on d 6 and 7 of each period. Results indicated that the SID of Lys in corn gluten meal (78.7%) was greater ($P < 0.01$) than in DDGS, bakery meal, corn germ meal, and hominy feed (46.0, 48.4, 68.4, and 58.8%, respectively). The SID of all indispensable AA except Arg, Leu, and Met in bakery meal were not different from DDGS. For corn gluten feed, the SID of all indispensable AA were not different from corn, except Arg, His, Leu, and Met, which had SID values that were less ($P < 0.01$) than in corn, but for most indispensable AA, the SID in corn gluten feed was not different from the SID in DDGS. The SID of all indispensable AA in corn germ meal except Arg, His, Leu, and Met were not different from corn. Likewise, the SID of all indispensable AA in corn germ meal except Arg and Leu were not different from DDGS. For most of the indispensable AA in hominy feed, the SID was not different from corn. All indispensable AA in hominy feed had SID values that were not different from the SID of AA in DDGS, except for Arg and Lys, which had greater ($P < 0.01$) SID than in DDGS. In conclusion, bakery meal is a poor source of digestible AA when compared with other corn co-products. Corn gluten meal has SID values for most AA that are greater than in DDGS, bakery meal and other corn co-products.

Key words: AA digestibility, corn co-prodcuts, pigs

391 Effect of L-Trp supplementation on growth performance pigs transitioning from nursery to finisher pens in a commercial farm. Y. B. Shen*[1], G. Voilqué[1], D. Kendall[2], D. Sykes[2], and S. W. Kim[1], *[1]North Carolina State University, Raleigh, [2]Murphy-Brown LLC, Rose Hill, NC.*

Transition period from nursery to finisher pens can be a stressful time for pigs physically and socially. Tryptophan serves as the precursor for the synthesis of serotonin which is a cerebral neurotransmitter with a key role in stress adaption. The aim of this study was to evaluate the effect of L-Trp supplementation on growth performance of nursery pigs transitioning from nursery to finisher pens. Six-hundred 74 pigs in 40 pens were used in a randomized complete block design study. Pigs were allotted to 2 treatments representing supplementation of 0% and 0.8% L-Trp. Both diets were isonitrogenous using L-Ala as a non-specific N source. Two neighboring pens shared a common feeder, and thus 2 neighboring pens were the experimental unit (n = 10 per treatment). Experimental period was composed of 5 d in nursery and 7 d in finisher. After 12 d feeding of experimental diets, pigs were provided a common diet for additional 7 d. Pigs in 2 neighboring pens were mixed on d 5 (when pigs were moved from nursery to finisher) and again on d 8. Body weight and feed intake were measured on d 5, 8, 12, and 19. During the first 5 d in nursery pens, growth performance was not affected by L-Trp supplementation. During d 5 to 8 in finisher pens, supplementation of 0.8% L-Trp improved ADG (549 vs. 669 g; $P = 0.017$) and G:F (0.558 vs. 0.690; $P = 0.001$) whereas ADFI was not affected by L-Trp supplementation. During d 8 to 12, supplementation of 0.8% L-Trp did not affect ADG, ADFI, and G:F. During the entire 12-d L-Trp supplementation period, pigs fed diet with 0.8% L-Trp tended to grow faster (511 vs. 556 g; $P = 0.092$) and more efficiently (G:F; 0.559 vs. 0.611; $P = 0.043$) compared with pig fed diet with 0% L-Trp. During the entire 19-d, pigs fed diet with 0.8% L-Trp had greater ADG (654 vs. 696 g; $P = 0.016$) and G:F (0.603 vs. 0.646; $P = 0.001$) compared with pig fed diet with 0% L-Trp but without affecting ADFI. Collectively, dietary L-Trp supplementation improved growth performance of pigs transitioning from nursery to finisher pens with new physical and social environment.

Key words: pig, transition period, tryptophan

392 Effect of L-Trp supplementation on growth and stress responses of nursery pigs fed diets varying large neutral amino acid concentrations. Y. B. Shen*, G. Voilqué, and S. W. Kim, *North Carolina State University, Raleigh.*

Tryptophan competes with large neutral amino acids (LNAA) for LNAA transporter to cross the blood-brain barrier. Availability of Trp in the brain is a limiting factor of serotonin synthesis. Thus, the ratio between Trp and LNAA in diets would affect serotonin synthesis in the brain, which plays a critical role in mediating stress. This study evaluated the effect of L-Trp supplementation on nursery pigs fed diets varying LNAA concentrations. Forty-eight barrows at 6 wk of age were housed individually and randomly allotted to 4 dietary treatments based on a 2x2 factorial arrangement (n = 12). First factor was L-Trp supplementation (0 or 0.6%) and the second factor was LNAA concentrations (4.5 or 3.8%). Pigs were fed the diets for 7 d. Body weight was measured on d 4 and 7. Saliva and blood were collected on d 4 and 7. During the first 4 d, pigs fed diets with 0.6% L-Trp increased ADG (341 vs. 264, g; $P = 0.022$) and G:F (0.453 vs. 0.321; $P = 0.001$) compared with pigs fed diets with 0% L-Trp and the effects of L-Trp on ADG and G:F were enhanced by 74% ($P = 0.079$) and 59% ($P = 0.040$), respectively, when dietary LNAA concentration was reduced from 4.5 to 3.8%. During the entire 7 d, L-Trp supplementation improved ($P = 0.004$) G:F of pigs (0.423 vs. 0.345) and lowering LNAA further enhanced ($P = 0.025$) the effects of L-Trp by 79%. Supplementation of 0.6% L-Trp reduced malonedialdehyde in plasma (19.16 vs. 25.14, μM; $P = 0.027$) and hypothalamus (24.92 vs. 34.47, μmol; $P = 0.024$) indicating reduced lipid peroxidation. Sali-

vary cortisol concentration was not affected by L-Trp supplementation but reduced (1.90 vs. 2.46, ng/mL; $P = 0.017$) when dietary LNAA concentration was reduced from 4.5 to 3.8%. Plasma urea nitrogen was reduced (5.18 vs. 4.29, μg/mL; $P = 0.018$) by L-Trp supplementation. Collectively, supplementation of 0.6% L-Trp improved G:F, and reduced systemic and hypothalamic lipid peroxidation. These effects were further enhanced by reducing dietary LNAA concentration.

Key words: pigs, stress, tryptophan

393 Feeding modality affects muscle protein deposition by influencing protein synthesis but not degradation in muscle of neonatal pigs. S. W. El-Kadi*[1], A. Suryawan[1], M. C. Gazzaneo[1], R. A. Orellana[1], N. Srivastava[1], H. V. Nguyen[1], R. Murgas-Torrazza[1], G. E. Lobley[2], and T. A. Davis[1], *[1]USDA/ARS Children's Nutrition Research Center, Dept. Pediatrics, Baylor College of Medicine, Houston, TX, [2]Division of Obesity and Metabolic Health, Rowett Institute of Nutrition and Health, University of Aberdeen, Aberdeen, UK.*

Neonatal pigs can serve as dual-use models for nutrition research in animal agriculture and biomedical fields. To determine how feeding modality by either intermittent bolus or continuous schedule affects protein anabolism and catabolism, neonatal pigs (n = 6/group, 9-d-old) were overnight fasted (FAS) or fed continuously (CON) or intermittently (INT; 7 × 4 h meals) for 28h. During the last 8 h, pigs were infused with [$^2H_5$]phenylalanine and [$^2H_2$]tyrosine and amino acid (AA) net balances were measured across the hindquarters for the last 4h. Glucose, insulin, branched-chain AA (BCAA), phenylalanine (Phe) and tyrosine (Tyr) arterial levels, and whole body Phe and Tyr rates of appearance were greater ($P < 0.05$) in INT after the meal but not in the CON or FAS groups. Whole body Phe hydroxylation was greatest for INT ($P < 0.05$). Across the hindquarters, BCAA, Phe, and Tyr were net removed (different from zero, $P < 0.05$) for INT and CON but not for FAS pigs. Hindquarters net protein deposition was stimulated following the meal for INT as compared with CON and FAS groups ($P < 0.001$). This was because protein synthesis increased following feeding for INT ($P < 0.001$) but remained unchanged for CON and FAS pigs, while no temporal changes in protein degradation occurred in any of the diet treatments. These results suggest that muscle protein accretion is enhanced with intermittent to a greater extent than continuous feeding, mainly by increasing protein synthesis. (Supported by NIHAR444474 and USDA/ARS 6250–51000–055)

394 Arginine deficiency is responsible for high rates of mortality in low-birth-weight piglets. G. Wu*, X. L. Li, R. Rezaei, and D. A. Knabe, *Texas A&M University, College Station.*

Pigs exhibit the most severe naturally occurring intrauterine growth retardation (IUGR) among livestock species. Under current feeding conditions, approximately 25% of live-born piglets have a birth weight of less than 1.1 kg, and they represent 76% of preweaning deaths. In the present study, we conducted 2 series of experiments to test the hypothesis that arginine deficiency may contribute to high rates of mortality in IUGR piglets. In Experiment 1, normal-birth-weight (NBW) and IUGR piglets, which were 1.43 ± 0.03 and 0.90 ± 0.04 kg ($P < 0.01$) at birth, respectively, were used for blood sampling at birth and thereafter. In Experiment 2, beginning at birth, IUGR piglets received oral administration of either L-arginine-HCl (0.1 g/kg BW) or an isonitrogenous amount of L-alanine twice daily. In each experiment, there were 40 piglets per group at birth. Data, expressed as means ± SEM, were analyzed by ANOVA and X2 analysis. Results of Experiment 1 indicated that concentrations of arginine in plasma of NBW and IUGR piglets at birth were 145 ± 4 and 81 ± 2 μM ($P < 0.01$), respectively. Concentrations of ammonia in plasma of NBW and IUGR piglets at birth were 72 ± 3 and 128 ± 5 μM ($P < 0.01$), respectively. During the first 3 wk of life, 7.8% and 46% of NBW and IUGR piglets died ($P < 0.01$), respectively. Analysis of blood samples obtained from IUGR piglets immediately after death revealed low concentrations of arginine (48 ± 4 vs. 130 ± 6 μM; $P < 0.01$) but high concentrations of ammonia (279 ± 13 vs. 145 ± 10 μM; $P < 0.01$), when compared with surviving IUGR piglets. Findings from Experiment 2 showed that arginine administration increased ($P < 0.01$) concentrations of arginine in plasma by 58%, while reducing ($P < 0.01$) concentrations of ammonia in plasma by 47% and preweaning mortality by 83%. Interestingly, arginine administration only modestly enhanced ($P < 0.01$) the daily weight gain of IUGR piglets by 21%. Thus, arginine deficiency is primarily responsible for high rates of mortality in IUGR piglets, but their maximal growth is limited by yet an unidentified factor. (Supported by AFRI-USDA grants.)

Physiology and Endocrinology: Growth and Metabolism

395 ASAS Early Career Award Presentation: Placental programming: How the maternal environment can impact placental growth and function. K. A. Vonnahme*, C. O. Lemley, L. E. Camacho, L. A. Lekatz, D. A. Redmer, L. P. Reynolds, and J. S. Canton, *Center for Nutrition and Pregnancy, Department of Animal Sciences, NDSU, Fargo.*

As placental growth and vascularity precedes exponential fetal growth, not only is proper establishment of the placenta important, but a continual plasticity of placental function throughout gestation. Inadequate maternal environment has been documented to alter fetal organogenesis and growth, thus leading to improper postnatal growth and performance in many livestock species. The timing and duration of maternal nutritional restriction appears to influence the capillary vascularity, angiogenic profile, and vascular function of the placenta in cattle and sheep. Moreover, upon realimentation, it appears as if the placenta may try to "overcompensate" allowing for enhanced blood flow and nutrient delivery. In environments where fetal growth and/or fetal organogenesis are compromised, potential therapeutics may augment placental nutrient transport capacity and improve offspring performance. Supplementation of specific nutrients, including selenium and protein, as well as hormone supplements, such as indolamines during times of nutrient restriction may assist placental function. Current use of Doppler ultrasonography has allowed for repeated measurements of uterine and umbilical blood flow including assessment of uteroplacental hemodynamics in cattle and sheep. Moreover, these variables can be monitored in conjugation with placental capacity and fetal growth at specific time points of gestation. Elucidating the consequences of inadequate maternal intake on the continual plasticity of placental function will allow us to determine the proper timing and duration for intervention.

396 Blood metabolites and hormones as potential markers of body reserves dynamic and energetic balance in ruminants. E. González-García*[1], N. Debus[1], P. Hassoun[1], S. Camous[2], M.-R. Aurel[3], F. Bocquier[1], and F. Barillet[4], *[1]INRA UMR[868], Systèmes d'Èlevage Méditerranées et Tropicaux (SELMET), Montpellier, France, [2]INRA UMR[1198], Biologie du Développement et Reproduction (BDR), Domaine de Vilvert, Jouy-en-Josas Cedex, France, [3]INRA UE[0321], Domaine Expérimental de La Fage, Roquefort-Sur-Soulzon, France, [4]INRA UR[0631], Station d'Amélioration Génétique des Animaux (SAGA), Chemin de Borde Rouge, Auzeville, BP [52627], Castanet-Tolosan Cedex, France.*

Under strict controlled conditions, and throughout a whole lactation period, we evaluated the consistence of some plasma metabolites and hormones as potential markers of body reserves status (mobilization or accretion) in ruminants. Forty-eight confined primiparous (PRIM; n = 48) and multiparous (MULT; n = 48) dairy Lacaune ewes were monitored from late pregnancy to late lactation in a 2 × 2 × 2 factorial design. Parity (PRIM or MULT), litter size (singletons –SING– or twins –TWIN) and energetic balance (milked once –ONE– or twice –TWO) were the fixed effects. NEFA, glucose (GLUC) and triglycerides (TRIG) plasma metabolites, and leptin (LEPT), insulin (INSU) and tri-iodothyroidine (T3) hormones were monitored. Animals received a 70:30 hay:concentrate TMR diet. Blood samples (10 mL) were individually collected (≈biweekly) early morning by jugular venipuncture in EDTA or heparin tubes. Plasma was harvested from blood samples that were centrifuged immediately after collection. After centrifugation, samples were transferred to 5-mL tubes and frozen at –20°C until analyses. Energy restriction (i.e., TWO higher energy expenditure than ONE) resulted in higher concentrations of NEFA (PRIM, $P < 0.001$; MULT, $P < 0.05$); in contrast, concentrations of INSU (PRIM, $P < 0.05$; MULT, $P < 0.001$) decreased until 1 mo after ONE; in MULT ewes, LEPT consistently decreased in TWO when compared with ONE (11.15 ± 0.571 vs. 14.31 ± 0.676, $P < 0.05$). However, LEPT was affected ($P < 0.05$) by litter size × number of milking interaction in PRIM, SING × ONE and SING × TWO ewes showing the highest (12.33 ± 1.04) and lowest (7.36 ± 0.989 ng.mL^{-1}) values, respectively. Ewes with TWIN had higher NEFA and lower INSU or LEPT than SING from before lambing until weaning. T3 results showed contradictory variability. Either for parity or number of milking, no differences at all were found for TRIG. For GLUC, differences (ONE > TWO) appeared just 1 wk after passing to ONE. Even when differences in BW or BCS were not found, NEFA, LEPT and INSU showed the higher sensitivity as potential markers of body reserves mobilization under the conditions of this experiment.

Key words: metabolites, hormones, markers of body reserve status

397 Metabolic gene expression in bovine ruminal tissue in response to age and pre and postweaning plane of nutrition. A. Naeem*, J. Stamey, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

We evaluated expression of 22 genes encoding enzymes involved in ketogenesis, cholesterogenesis, TCA cycle flux, long-chain fatty acid (LCFA) oxidation, and transcriptional regulation in ruminal tissue of male Holstein calves fed a conventional milk replacer (20% CP, 20% fat; 1.25% of birth BW as solids) and starter (19.6% CP, DM basis; control) or enhanced milk replacer (28.5% CP, 15% fat; 2% of BW; ENH) and enhanced starter (25.5% CP, DM basis). All calves were weaned on d 42. Groups of calves in control and ENH were harvested after 43 d (wk 5) and 71 d (wk 10) of feeding. There was marked upregulation of HMGCS2, the rate-limiting enzyme of hepatic mitochondrial ketogenesis in non-ruminants, between wk 5 and 10 regardless of diet. This response paralleled an increase in plasma BHBA concentration (0.09 vs. 0.24 mmol/L) between wk 5 and 10. Expression of other ketogenic (BDH1, HMGCL), cholesterogenic (HMGCS1), and TCA cycle-related enzymes (LDHA, GOT2, PCCA) also increased by wk 10 regardless of diet. A higher expression of CPT1A and ACADVL at wk 5 in calves fed ENH vs. control suggested greater LCFA oxidation potentially driven by the greater intake of LCFA from milk replacer. This suggestion is supported by the greater concentration of plasma NEFA (128 vs. 95 μEq/L) at wk 5 due to ENH vs. control. Expression of peroxisome proliferator-activated receptor-δ increased ~8-fold between wk 5 and 10 regardless of diet, suggesting a role for this nuclear receptor in postweaning ruminal tissue development. In conclusion, several metabolic enzymes were upregulated at wk 10 regardless of diet suggesting a coordinated response to support ruminal tissue development. The mRNA of HMGCS2 accounted for ca. 50% of total genes measured (e.g., HMGCS1 was 0.2%), suggesting this enzyme is key for regulating ketogenesis in ruminal epithelium as in liver. Enhanced nutrition during the first 5 wk of life had minor effects on the selected genes.

Key words: ketogenesis, nuclear receptor, dairy calf

398 Functional genomics of liver in crossbred beef cows in two forage allowances during gestation and lactation period. J. Laporta*[1], G. Greif[2], P. Zorrilla[2], H. Naya[2], G. J. M. Rosa[3], and M. Carriquiry[1], *[1]Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay, [2]Instituto Pasteur, Montevideo, Uruguay, [3]University of Wisconsin, Madison.*

Beef cows in rangeland conditions are subjected to climate variations that affect pasture quality and availability along the year as cow physiological stage changes from pregnancy (autumn-winter) to calving (spring) and lactation (spring-summer). A large-scale microarray experiment was conducted using 8 Angus-Hereford crossbred cows in high and low forage allowances (10 vs. 6 kg of DM/100 kg of LW/d) to study the molecular basis of such physiological processes. Liver biopsies were collected at −170, −15, +15 and +60 d relative to parturition and total RNA was extracted. RNA integrity and quality were evaluated using the Agilent 2100 Bioanalyzer (RIN 6.4 ± 0.4). A single-channel microarray analysis was performed using Agilent 4x44K Bovine (v2) Gene Expression array. After data cleaning and normalization, a 2-way ANOVA test was performed using Agilent GeneSpring (v11.5) Software. Significance levels were adjusted for multiple comparisons using a false discovery rate of 0.2. Out of 2,484 differentially expressed genes, 2,353 changed across time (169 ≥ 2.5 fold change), and 146 with forage allowance, but there was no significant interaction between the 2 factors. Differentially expressed genes were hierarchically clustered to study expression profiles and a Gene Set Enrichment Analysis was performed. More than 45 significant ($P \leq 0.01$) gene sets across time (only for −170 vs. −15 d) with positive (metabolism of RNA, mRNA splicing, proteasome, protein export, TGF signaling pathway) and negative (fatty acid, pyruvate, steroid, glucose, glycolysis and gluconeogenesis, lipid and lipoprotein metabolism; cholesterol biosynthesis; PPAR signaling pathway, among others) enrichment scores (ES) were identified. No genes sets were enriched for peripartum and lactation period. Only 3 genes sets were positively enriched ($P \leq 0.01$) when high vs. low forage were compared: glycolysis, gluconeogenesis, and glucose metabolism. These results contribute to identify pathways that are up or downregulated as physiological stage of cows change as well as due to the different levels of nutrition in grazing conditions.

Key words: microarrays, liver, grazing

399 Alterations in the somatotropic axis during a dual stress and *M. haemolytica* challenge in beef steers. S. M. Falkenberg*[1], J. A. Carroll[2], M. A. Ballou[5], J. L. Sartin[3], J. O. Buntyn[1], T. Elsasser[4], S. Kahl[4], and T. B. Schmidt[1], *[1]Mississippi State University, Mississippi State, [2]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [3]Auburn University College of Veterinary Medicine, Auburn, AL, [4]Bovine Functional Genomics Lab, USDA-ARS, Beltsville, MD, [5]Texas Tech University, Lubbock.*

The objective of this trial was to characterize the potential impact of individual and multiple stressors before, simultaneously, and post *M. haemolytica* (MH) challenge on the somatotropic axis. Forty-eight beef steers (207.7 ± 22.1 kg BW) vaccinated against MH were randomly assigned to 1 of 8 treatments (trt). Treatments consisted of steers that received MH (given at 0 h for all 8 trts) and corticotrophin releasing hormone + arginine vasopressin in tandem as the stressor (Stress) administered before, simultaneously, or after the challenge. The 8 trt were: 1) MH only; 2) Stress at −7 h + MH; 3) Stress at 0 h + MH; 4) MH followed by Stress at 7 h; 5) Stress at −7 h and 0 h + MH; 6) Stress at −7 h and 7 h + MH; 7) Stress at 0 h and 7 h + MH; and 8) Stress at −7 h, 0 h and 7 h + MH. Steers were fitted with jugular catheters and rectal temperature (RT) probes on d −3, moved to stanchions, given a day to acclimate (d −2), baseline samples obtained on d −1, and the challenge was given on d 0. There were trt x time interactions or trt effects ($P < 0.05$) observed for cortisol (CORT), growth hormone (GH), insulin-like growth factor-I (IGF-I), and RT. Differences were observed ($P > 0.05$) in overall GH and IGF-I as well as concentrations before the MH challenge for trts that received multiple Stress challenges or Stress during and after the MH challenge. No differences were observed ($P > 0.05$) for change in GH and IGF-I concentrations after the MH challenge. Furthermore, no differences were observed ($P > 0.05$) in GH and IGF-I for trts that did not receive any Stress or Stress trt before the MH challenge. The results indicate the MH challenge altered GH and IGF-I in vaccinated calves regardless of the timing associated with the applied stress. However, the data also suggest that stressors can impact the overall regulation of GH and IGF-I when stressors occur during and after infection with MH even in animals protected by vaccination against MH.

Key words: cattle, immune, stress

400 Effects of plane of nutrition and 2,4-thiazolidinedione on insulin responses and adipose tissue gene expression in dairy cattle during late gestation. K. M. Schoenberg* and T. R. Overton, *Cornell University, Ithaca, NY.*

The objective was to determine effects of an insulin–sensitizing agent (thiazolidinedione, TZD) and dietary energy level on glucose and fatty acid metabolism during late gestation. Multiparous Holstein cows (n = 32) 50 d before expected calving date were assigned to 1 of 2 dietary energy levels for 3 wks (High, 1.52 Mcal/kg NEL; or Low, 1.34, Mcal/kg NEL) and received daily 4.0 mg TZD/kg BW (TZD) or Saline i.v. for the final 2 wk. Cows administered TZD had higher plasma glucose (62.5 vs. 59.6 mg/dL; $P = 0.03$) than Saline cows and cows fed the High diet had higher plasma insulin (35.1 vs. 25.3 μIU/mL; $P = 0.03$) compared with those fed the Low diet. All cows were subjected to an i.v. glucose tolerance test (GTT; 0.25 g dextrose/kg BW) and an insulin challenge (IC; 1.0 μg/kg BW) 110 min later. High cows tended to have a lower area under the curve (AUC) for plasma glucose during GTT (1895 vs. 2410 mg/dLx90 min; $P = 0.13$) than Low cows; however, Low cows had more negative NEFA AUC (–4838 vs –2137 μEq/Lx90 min; $P = 0.04$) and greater NEFA clearance rates (1.35 vs. 0.63%/min; $P = 0.01$) during GTT, suggesting differential responses of glucose and fatty acid metabolism in response to diet. During IC, TZD cows had more negative glucose AUC (–45.0 vs. –12.1 mg/dLx15 min; $P = 0.08$) than Saline, suggesting that TZD–treated cows had greater responses to insulin. Interactions of diet and TZD were only significant ($P = 0.04$) for NEFA responses to IC such that Low cows receiving TZD had a negative AUC (–80 μEq/L x 15 min), cows fed the High diet and treated with either saline or TZD had slightly positive AUC (65 and 67 μEq/L x 15 min, respectively), and cows fed the Low diet receiving Saline had the most positive AUC (517 μEq/Lx15 min). Cows fed the High diet had greater lipoprotein lipase mRNA expression (2.2 vs. 1.6; $P = 0.10$) and peroxisome proliferator–activated receptor–γ expression (2.4 vs. 1.3; $P = 0.02$) in adipose tissue collected by biopsy at the end of the study. These results indicate that energy level and insulin–sensitizing agents affect glucose and lipid metabolism during the dry period.

Key words: insulin, thiazolidinedione

401 Effects of overstocking on glucocorticoid production and analytes associated with energy metabolism. J. M. Huzzey*[1], D. V. Nydam[1], R. J. Grant[2], and T. R. Overton[1], *[1]Cornell University, Ithaca, NY, [2]W. H. Miner Institute, Chazy, NY.*

The objective of this study was to determine if overstocking alters energy metabolism and glucocorticoid production. Four groups of 10 dry Holstein cows (~60 d prepartum) were exposed to 2 treatments: Control (1 lying stall/cow and 0.67m linear feed bunk (FB) space/cow) and Overstocked (0.5 stalls/cow and 0.34m FB/cow) in a replicated 2 × 2 crossover design with 14–d treatments. Plasma NEFA, glucose and insulin were measured from blood sampled every 2 d of each treatment and during an intravenous glucose tolerance test (GTT: 0.25g dextrose/kg BW) performed on d 13. Feces, collected every 2 d, were analyzed for fecal cortisol metabolites (FCORT). Plasma cortisol response to an intravenous ACTH challenge (0.125 IU ACTH/kg BW) was measured on d 14. Data from individual cows were averaged to create a group mean and all statistical analyses used group as the experimental unit. Average DMI per cow was greater during the overstocked treatment relative to the control period (15.9 vs. 14.9 kg/d, $P < 0.001$). NEFA and glucose concentrations were higher during the overstocked treatment (0.11 vs. 0.09 mEq/L and 65 vs. 64 mg/dl respectively, $P < 0.05$); however, when stratified by parity these responses were limited to heifers ($P < 0.01$). Overstocking had no effect on insulin concentration during the treatment period ($P > 0.20$) while FCORT tended to be higher (19 vs. 16 ng/g fecal DM, $P \leq 0.14$) during overstocking. During the GTT, cows took longer to return to basal glucose concentration (55.1 vs. 51.5 min, $P = 0.05$), tended to have greater area under the curve estimates for glucose (2837 vs. 2630 mg/dl × 120 min, $P = 0.06$), had lower peak insulin concentrations (201 vs. 260 μIU/L, $P = 0.02$), and tended to have a reduced rate of NEFA decline from circulation (1.4 vs. 1.9 μEq/L per min, $P = 0.1$) following the overstocked treatment. Cortisol production after administration of ACTH was not affected by stocking density treatment ($P > 0.48$). Overstocking alters energy metabolism. These effects seem to be mediated through changes in insulin production rather than insulin resistance; the role of glucocorticoids in influencing these effects is still unclear.

Key words: overstocking, energy metabolism, cortisol

402 Effect of milking frequency and feeding level in early lactation on metabolites in grazing dairy cows. J. K. Kay*, C. V. C. Phyn, A. G. Rius, S. R. Morgan, T. M. Grala, and J. R. Roche, *DairyNZ, Hamilton, New Zealand.*

Study objectives were to investigate the effect of milking frequency (MF) at 2 feeding levels (FL) in early lactation on plasma metabolite content. Multiparous Holstein-Friesian cows (n = 120), grazing a generous pasture allowance (residuals of 1,600 kg DM/ha) and milked twice daily (2X) from calving until 34 ± 6 DIM were allocated to one of 4 treatments in a 2 × 2 factorial arrangement. Treatments were 2 MF (2X or once daily; 1X) and 2 FL (UnRes: 15 kg DM/cow/d or Res: 9kg DM /cow/d) for 3 wk. After treatment, all animals were offered a generous pasture allowance and milked 2X for 20 wk. Individual blood samples collected weekly from 2 wk pre- until 20 wk post-treatment were analyzed for NEFA, BHBA, glucose, aspartate aminotransferase (AST) and glutamate dehydrogenase (GDH). Differences were significant when $P < 0.05$. During the treatment period plasma glucose decreased with pasture restriction and increased with reduced MF. A MF x FL interaction indicated that increases in glucose during 1X milking were greater in Res compared with UnRes cows. One to 8 wk post-treatment, glucose remained less in Res cows and greater in cows milked 1X; however, by 9–20 wk post-treatment there was no effect of MF or FL. Plasma NEFA and BHBA increased with pasture restriction and decreased with reduced MF. When cows were milked 1X, the decrease in NEFA with reduced MF was greater in UnRes than Res cows, while the decrease in BHBA was greater in Res than UnRes cows. Post-treatment (1–8 wk) there was no effect of MF on NEFA or BHBA, however NEFA was greater in UnRes compared with Res cows. By 9–20 wk post-treatment neither NEFA nor BHBA were affected by FL. Liver function enzymes (AST and GDH) increased during pasture restriction but were not affected by MF. These metabolite data are consistent with the previously reported decrease in milk production and improved LWT with reduced MF. In summary, results indicate reducing MF improves energy balance in both restricted and unrestricted grazing cows and may have implications for management strategies when pasture availability is limited.

Key words: milking frequency, nutrition, grazing

403 Insulin-glucose clamps and intramammary LPS challenge: cross reactions between metabolism and mammary immune response. M. C. M. B. Vernay, L. Kreipe, H. A. van Dorland, R. M. Bruckmaier, and O. Wellnitz*, *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.*

Insulin, a central regulator of carbohydrate and fat metabolism, influences the immune system. The aim of this study was to evaluate the effects of a 3-d hypoglycemia and hyperinsulinemia/euglycemia on the bovine mammary immune system. Seventeen midlactating, non pregnant, anestric dairy cows received an insulin infusion (HypoG; n=5; constant plasma hypoglycemia of 2.32 ± 0.3mmol/l), an euglycemic hyperinsulinemic clamp (EuG; n=6; insulin infusion rate: 0.62mU/kg/min), or saline solution (control; n=6) for 56 h. 48 h after the start of infusion two udder quarters were challenged with lipopolysaccharide (LPS). Only significant results ($P \leq 0.05$) are shown. Intramammary LPS challenge induced an insulin resistance indicated by an increase of plasma insulin (between 32 and 252μU/L) in all groups, while glucose remained stable in controls, glucose infusion rates in EuG had to be markedly reduced (from 2.9 to 0.9 mmol/kg/min), and insulin infusion rates in HypoG had to be increased (from 0.2 to 0.9 mU/kg/min) to maintain constant glucose levels. AUC of plasma insulin was 333 in control, 875 in EuG, and 529 in HypoG. Hourly measurements of SCC showed increases to $>10^6$ cells/mL in LPS treated quarters without differences between groups. mRNA abundance of immune parameters in mammary tissue biopsies before and 8 h after LPS administration was quantified by qRT-PCR: LPS induced an increased expression (between 2.1 and 8.4 crossing points) of tumor necrosis factor-α, interleukin (IL)-8, −1β, and −10, and serum amyloid A (SAA). IL-1β, IL-10, and SAA were higher expressed (difference between 2.2 and 3.6 crossing points) in LPS treated quarters of EuG than of HypoG. In conclusion, intramammary LPS challenge induces insulin resistance characterized by increased insulin release independently of insulin and glucose plasma concentrations before challenge. Increased plasma insulin occurs concomitantly with changes of the mammary immune response to LPS based on mRNA expression of measured immune factors. The results indicate cross-reactions between insulin resistance and cytokine release in the bovine mammary gland.

Key words: insulin, mammary immunity, intramammary LPS challenge

404 Insulin sensitivity in tropically adapted cattle selected for residual feed intake. G. L. Shafer*[1,2], A. W. Lewis[1], L. C. Caldwell[2], A. N. Hafla[2], G. E. Carstens[2], T. D. A. Forbes[3], T. H. Welsh Jr[2], and R. D. Randel[1], *[1]Texas AgriLife Research, Overton, [2]Texas AgriLife Research, College Station, [3]Texas AgriLife Research, Uvalde.*

Residual feed intake (RFI) identifies animals requiring less feed to achieve the same performance. This study evaluated the effect of a glucose (G) challenge on efficient (L) and inefficient (H) tropically adapted yearling bulls and heifers. Bonsmara heifers (n = 24) and Santa Gertrudis bulls (n = 16) were tested at different times and data analyzed separately. Animals were infused with a 50% dextrose solution at 0.5 mL/kg BW by catheter. Blood was collected at −5, 0, (heifer: 5), 10, 15, 20, (bull: 30), 40, 60, 80, 100, 120, 140, 160, and 180 min relative to challenge. Insulin (I) was determined by RIA and G by colorimetry. Repeated measures ANOVA were conducted using the MIXED model of SAS for analysis of RFI, time, and their interactions on I, G and insulinogenic index (IND). Time to peak I and half-life of G were analyzed using GLM. In bulls, time affected ($P < 0.001$) I and G. RFI did not affect ($P > 0.05$) I peak or peak time in bulls. L and H bull I peaks were (mIU/mL) 50.6 ± 13.3 and 67.7 ± 13.3, respectively and I peak times (min) were 46.2 ± 23.1 and 81.2 ± 23.1, respectively. RFI did not affect ($P > 0.05$) G half life in bulls. IND was affected by RFI ($P < 0.05$), but not time. L and H bull IND ($\Delta I/\Delta G$) were 0.17 ± 0.02 and 0.26 ± 0.02, respectively. Among heifers time affected ($P < 0.0001$) I and G. There was no RFI x time interaction ($P > 0.05$) for I or G. RFI did not affect ($P > 0.05$) I peak or peak time. L and H heifers had I peaks (mIU/mL) of 108.0 ± 12.0 and 75.5 ± 12.6, respectively and I peak times (min) were 16.6 ± 1.0 and 18.6 ± 1.0, respectively. RFI did not affect ($P > 0.05$) G half life in heifers. L and H heifer G half lives were (mg/dL) 80.0 ± 3.1 and 77.0 ± 3.2, respectively and G Half life times (min) were 33.2 ± 2.5 and 36.9 ± 2.6, respectively. IND was affected by RFI ($P < 0.05$), but not time. L and H heifer IND ($\Delta I/\Delta G$) were 0.44 ± 0.02 and 0.29 ± 0.03, respectively. L heifers had a higher I response than H heifers. The opposite response was seen in bulls. There may be differences in energy metabolism between genders and breeds. Further research will be required to explain the opposite results of Bonsmara heifers and Santa Gertrudis bulls.

Key words: insulin, glucose, residual feed intake

Production, Management and the Environment & Forages and Pastures Joint Symposium: Environmental Impact of Beef and Dairy Systems

405 An overview of the environmental impact of beef and dairy systems. J. L. Capper*, *Washington State University, Pullman.*

The livestock industry faces the challenge of providing sufficient safe, affordable, nutritious animal protein to feed the population while maintaining environmental stewardship. Ruminant production systems have been criticized for their contribution to global greenhouse gases, yet US beef and dairy systems have considerably reduced resource use and carbon emissions over time. Advances in nutrition, genetics and management allowed dairy cow productivity to increase 4-fold between 1944 and 2007, with 21% of the animals, 23% of the feed, 35% of the water and 10% of the land required to produce one kg of milk in 2007 compared with 1944. Similar advances in the US beef industry facilitated a 31% increase in beef yield per animal and 124-d reduction in the time period from birth to slaughter between 1977 and 2007. Feedstuff use was thus reduced by 19%, water use by 14%, land use by 34% and the carbon footprint was 18% lower per kg of beef in 2007. Environmental gains result from a combination of improved productivity and reduced resource requirements within the non-productive sector of the supporting population. Individual cow and herd data records suggest that the dairy industry may continue to considerably improve milk yield before a plateau is reached. Further gains may be made by reducing population body mass – producing cheddar cheese from Jersey cows (454 kg mature weight) with increased milk component concentrations (4.8% fat and 3.7% protein) compared with their Holstein cohorts (680 kg mature weight; 3.8% fat and 3.1% protein) reduced the carbon footprint per kg of cheese by 20% despite the greater Holstein milk yield (29.1 kg/d vs. 20.9 kg/d). Within the beef industry, desirable slaughter weight appears to have plateaued at an average of 590 kg, yet resource use and waste output may be mitigated by improving growth rate. Indeed, growth-enhancing technology use within conventional beef production reduced land use by 45% and carbon emissions by 42% per kg of beef compared with grass-finished systems. To improve future environmental sustainability it is crucial to maintain access to management practices and technologies that improve productivity.

Key words: greenhouse gases, environmental impact, productivity

406 Whole farm assessment—Using precision agriculture to assess, measure, and mitigate environmental impacts of on-farm practices. Y. Wang*, *Dairy Research Institute, Rosemont, IL.*

The objective of this presentation is provide an example of a modeling tool that helps individual dairy producers assess and mitigate on-farm GHG emissions. The greenhouse gas (GHG) life cycle assessment (LCA) for fluid milk, commissioned by the Innovation Center for US Dairy and conducted by the Applied Sustainability Center at the University of Arkansas, evaluated GHG emissions for milk production in the United States. On-farm activities accounted for more than 70% of emissions. A compendium study is also underway to assess other impacts such as eutrophication, land use, biodiversity, and toxicity. Together, these LCAs will provide the basis for the development of easy-to-use measurement tools for producers. One such tool is Dairy FarmSmart, a modeling tool that allows farmers to assess, measure, and mitigate on-farm environmental impacts based upon farm-specific climate, air quality, soil, land, and watershed information. Two existing modeling tools, DeNitrification-DeComposition (DNDC) and Water Use and Quality Assessment, are integrated and enhanced. DNDC is used for predicting crop growth, soil temperature and moisture regimens, soil carbon dynamics, nitrogen leaching, and emissions of trace gases. The Water Use and Quality Assessment is based on the fluid milk LCA. It includes implementation of the P-eutrophication model at a local scale and a multi-scale link to the larger scale with the 0.5 by 0.5 degree watershed (approximately 50 km by 50 km.); hydrological balance of the local streams and river from plot scale up to the 0.5 degree regional scale; evaluation of local impacts of water use at farm level; and integration of the farm's direct local impact within the overall life cycle impact assessment. The desired outcome is to give producers the ability to identify on-farm management practices that will minimize GHG emissions and maximize conservation efforts.

Key words: greenhouse gas emissions (GHG), life cycle assessment (LCA), environmental impact

407 Measurement strategies for reducing enteric methane from beef and dairy production. K. A. Beauchemin* and S. M. McGinn, *Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

There is considerable uncertainty in the estimates of enteric methane (CH_4) production from ruminants attributed to variability at the farm level due to diet and management. Quantification of enteric CH_4 emissions is essential for understanding underlying processes controlling methanogenesis, assessing mitigation practices and producing national greenhouse gas inventories. Various techniques are available for measuring enteric CH_4 production, and several factors need to be considered when selecting the most appropriate technique. Most important is an understanding of the required level of accuracy and precision. When evaluating mitigation strategies, it is essential to use a measurement technique and experimental design that will enable detection of differences between treatments, which are often small (<15%). Whole animal chambers have a high degree of accuracy and precision, and are therefore ideal for treatment comparisons. However, dry matter intake and diet composition of animals in chambers can differ from their herd mates. The sulfur hexafluoride (SF_6) tracer technique allows measurement of enteric CH_4 emissions of ruminants in their natural environment. A permeation tube filled with SF_6 is inserted into the rumen of the animal and a collection apparatus is mounted on or near the animal. The tracer technique has greater between-animal and within-animal variability than chambers, and consequently a large number of animals (~4-times more than chambers) and multiple measurement days are needed. Micro-meteorological techniques are useful for measuring emissions from groups of animals (pens, small paddocks, entire feedlots, barns) and are ideal for inventory purposes. Recent advances have shown that they can also be used to evaluate treatment differences, although replication of groups can be difficult. Several newer methods such as laser guns, feeders equipped with sensors, and assessment of milk fatty acid profiles may offer potential for monitoring emissions on commercial farms. Each technique for measuring enteric CH_4 has its advantages and limitations, and the ideal method of choice depends on the objective of the study.

Key words: methane, greenhouse gases, measurement

408 Dairy cropping systems and air quality. F. M. Mitloehner*, *University of California, Davis.*

Recent studies have identified animal feeds as a significant volatile organic compound (VOC) source contributing to regional ozone challenges. Specifically, the ozone formation potentials of livestock feed emissions were measured on representative field samples using a transportable smog chamber. Seven feeds were considered: cereal silage (wheat grain and oat grain), alfalfa silage, corn silage, high moisture ground corn (HMGC), almond shells, almond hulls, and total mixed ration. The VOC flux measured from silage and total mixed ration was two orders of magnitude higher than comparable fluxes from animal waste. Chamber measurements confirm that animal feed VOC emissions are significantly higher than animal waste emissions and several of the animal feed derived VOCs have potentially high ozone formation potentials. While recognizing the importance of this environmental challenge, it is important to note that loss of these volatile gases has also financial implications to the dairy producer. Dry matter losses can range from 10 to 25% and while the majority of gas losses is CO_2, VOC constitute a significant portion of overall feed losses that might be preventable though optimized silage management.

Key words: silage, ozone, volatile organic compounds

409 Cow of the future—A research roadmap for mitigating enteric methane emissions from dairy cattle. W. R. Wailes*[1], J. R. Knapp[2], and M. D. Welch[3], *[1]Colorado State University, Fort Collins, [2]Fox Hollow Consulting LLC, Columbus, OH, [3]Dairy Research Institute, Rosemont, IL.*

The Innovation Center for US Dairy has committed to reducing greenhouse gas emissions from dairy production by 25% (from 2008 levels) by 2020. Enteric methane emissions are the largest contributor to greenhouse gas emissions in the dairy chain, comprising approximately 35% of the total greenhouse gas emissions associated with US dairy production. The objective of this presentation is to present a roadmap for future research that reduces enteric methane per unit of milk produced by cows during the process of feed digestion. This roadmap, called the Cow of the Future Research Agenda, identifies and evaluates research opportunities that will lead to future mitigation technologies and applications. An expert panel of university and industry-based scientists identified 8 categories of future research needs: rumen microbial genomics and ecology; rumen function and modifiers; enhancing feed quality and feed ingredient usage to improve digestibility and feed efficiency; genetic approaches to increase individual cow productivity; management approaches to increase individual cow productivity; management of herd structure to reduce number of cow-days of non-productive animals (replacement heifers and dry cows); development and refinement of methane measurement techniques; and modeling efforts to quantitatively integrate the knowledge gained in the above areas. Implementation of existing technologies and management practices in the dairy industry along with continued genetic progress in milk yields is expected to result in 10 to 12% reductions of methane emissions per unit of milk over the next decade. To achieve the additional 13 to 15% reduction to reach the overall goal of a 25% reduction requires investment in research to identify and develop new strategies. The desired outcome of the Cow of the Future Research Agenda is to encourage research and development in the designated categories by fostering collaborative grant submissions and providing opportunities for collegial interaction by hosting symposia such as Production, Management and the Environment & Forages and Pastures Joint Symposium and other conferences.

Key words: dairy, enteric methane, greenhouse gas emissions (GHG)

410 Diet formulation as an effective tool for mitigating the environmental impact of dairy and beef cattle operations. A. N. Hristov*, *Pennsylvania State University, University Park.*

Dairy and beef cattle operations are responsible for a significant portion of the N, P, ammonia, and green-house gas (GHG) agricultural emissions in the US In watersheds with intensive animal production (the Chesapeake Bay, for example), agriculture can account for as much as 30 to 50% of the total N and P loads. Gaseous emissions from animal facilities or field application of manure can also be a significant contributor to the environmental footprint of the livestock industries. It has been repeatedly demonstrated that nutrient emissions from animal operations are directly related to composition of the diet fed and whole-farm nutrient inputs. In all cases, the possibility of reducing the environmental impact of dairy and beef cattle operations through nutrition is intrinsically related to improving feed efficiency. For example, an average dairy cow will utilize approximately 25 to 28% (SD = 41 and 36, respectively) of the feed N for milk protein secretion. Beef cattle typically retain 10 to 20% of the intake N as weight gain. Highly efficient dairy systems, however, may capture up to 38 or even 40% of the feed N into milk protein. To a large part, this increased efficiency is a result of diet formulation and reduced feed N input. More efficient utilization of feed N for production purposes corresponds to lower manure N losses and gaseous emissions. Feeding to or below NRC requirements (both dairy and beef) has been shown to have a marked impact on P losses with no measurable effect on animal productivity, reproduction, or health. Reducing inputs of some nutrients (particularly N), however, can negatively impact animal productivity (or milk composition in dairy cows). Formulating for metabolizable protein and perhaps supplementation with synthetic amino acids, for example, may be a feasible approach for maintaining production with low-N input rations. In some cases, targeting efficiency, not necessarily maximum production, may be a viable nutrient management strategy.

Key words: environmental impact, diet formulation, livestock

411 Managing the environmental impact of pasture production systems. K. A. Johnson* and C. D. Gambino, *Washington State University, Pullman.*

All animals impact their environment. The form and magnitude of that impact depends on the animal system. There is increasing interest in producing animal products using pasture systems and these systems must be designed and managed to be productive and minimize environmental impact. Grazing cattle affect the environment through plant selection, trampling of plants, deposition of fecal and urinary nutrients, leaching of nitrogen (N), and emission of greenhouse gases (GHG) from enteric fermentation or soil biogeochemical processes. Grazing cattle spatially redistribute plant-N which causes N-cycling changes in plants and soil which alters the carbon:N ratio of plants. Trampling can increase litter turnover, and nutrient cycling can accelerate in patches where manure and urine are deposited. The primary GHG associated with pasture systems are methane (CH_4) and nitrous oxide (N_2O) although some ammonia (NH_3) losses do also occur. Manipulation of pasture composition through fertilization, management-intensive grazing systems, and strategic supplementation can affect the GHGs emitted by livestock and soils. Factors affecting N_2O emissions from grazing lands include the ecosystem (pasture or rangeland), animal management (timing and duration of grazing and stocking rate),

riparian area management, and fertilization (timing and application method). Grazing animals affect soils in both direct and indirect ways. Manure deposition on the soil directly affects soil microbial activity, N mineralization rate, and ultimately plant productivity. Indirectly, grazing can lead to death of leaves, decomposition of litter, enhanced soil microbial activity, N mineralization and altered plant productivity. Management intensive grazing strategies that maintain plants in the vegetative stage (reduced fiber) can alter ruminal fermentation to decrease CH_4 emissions. Fertilization strategies that provide plants with N when they are actively growing reduce leaching of NO_3-, NH_3 volatilization and N_2O emissions. Prior to implementation, pasture production systems should be designed, assessed and managed as a dynamic system to minimize environmental impact.

Key words: pasture, greenhouse gases, management

412 Ruminal degradable sulfur from organic and inorganic sources in beef cattle finishing diets. J. O. Sarturi*, G. E. Erickson, T. J. Klopfenstein, and C. D. Buckner, *University of Nebraska, Lincoln.*

The relationships between ruminal hydrogen sulfide concentration ([H_2S]) and ruminal degradable S intake (RDSI), total sulfur intake (TSI) or pH variables were evaluated in beef cattle finishing diets. Ruminally cannulated steers (n = 5; BW = 486 ± 39 kg) were assigned randomly in a 5 × 5 Latin square design and fed once daily during five 21-d periods. Steers were fed a corn control diet (CON), inorganic S source (ammonium sulfate; INORG), organic S source (corn gluten meal; ORG) fed at 9.8 or 23.3%, or wet distillers grains with solubles (WDGS) fed at 50%. Dietary S was 0.20, 0.37, 0.31, 0.46 and 0.50% for CON, INORG, low and high ORG, and WDGS, respectively. A laboratory procedure was developed to estimate RDS coefficients for individual ingredients, and used as base for the RDSI calculations. Samples (1.5 g of DM) were incubated (26 h) in triplicate with 75 mL of ruminal fluid (heifers [n = 2; BW = 320 kg] fed 60% corn base diets) and 75 mL of McDougall's Buffer. After incubation, bottles were cooled in ice, centrifuged (18,623 g; 20 min; 4°C), decanted, and the precipitate was dried at 100°C and analyzed for S. Standards containing 25:75, 50:50 and 75:25% of starch: solkafloc were used to estimate incorporated S due to bacterial growth, and subtracted from the other samples based on digestibility coefficients. Statistical analyses were conducted using the GLIMMIX procedure of SAS, with day as a repeated measure for RDSI, pH and [H_2S]. The TSI were 21.9, 37.0, 34.0, 50.5 and 54.9 g/d (SEM = 1.89) and RDSI were 16.5, 32.1, 19.9, 24.4 and 36.2 g/d (SEM = 1.06) for CON, INORG, low and high ORG, and WDGS diets, respectively ($P < 0.01$). The RDSI was able to explain 64.9% of the [H_2S] variation through a linear (y = −34.74 + 2.36 * RDSI) relationship ($P < 0.01$), whereas TSI explained only 24.4%. When area below pH 5.6 was added to the RDSI model it accounted for 3.5 more percentage units of the [H_2S] variation. Availability of S for ruminal fermentation provides an important tool for ruminal [H_2S] prediction; more than total S intake or ruminal pH.

Key words: hydrogen sulfide, intake, ruminal degradable sulfur

413 Effects of trace mineral injections on measures of growth and trace mineral status of pre-weaned beef calves. J. D. Arthington*[1] and L. J. Havenga[2], *[1]University of Florida, Range Cattle Research and Education Center, Ona, [2]Multimin USA Inc., Fort Collins, CO.*

The objective of this experiment was to determine the effects of injectable trace minerals (ITM) on measures of trace mineral status and performance in pre-weaned beef calves. Brahman x Angus beef calves were assigned to treatment in alternating birth order (n = 75 calves/treatment). Treatments consisted of 1 mL s.c. of ITM (MultiMin 90; MultiMin USA, Inc., Fort Collins, CO) or 1 mL of sterile saline. The ITM product contained 60, 10, and 15 mg/mL of Zn, Mn, and Cu, as disodium EDTA chelates, and 5 mg/mL of Se, as Na selenite. Treatments were re-administered to all calves 2 additional times before weaning (approximately 100 and 200 d of age) for a total of 3 treatment administrations. Calves were weaned at approximately 250 d of age. Throughout the study, cow and calf pairs grazed summer bahiagrass pastures with free choice access to a salt-based mineral premix containing 14% Ca, 9% P, 24% NaCl, 0.20% K, 0.30% Mg, 0.20% S, 0.005% Co, 0.15% Cu, 0.02% I, 0.05% Mn, 0.004% Se, 0.3% Zn, 0.08% F, and 82 IU/g of vitamin A. Individual calf body weight was recorded at birth (d 0) and on d 100, 150, 200, and 250 (weaning). Trace mineral status of calves was assessed in liver biopsy samples (n = 12 heifers/treatment) collected on d 150, 200, and weaning (d 250). Liver samples were analyzed for concentrations of Co, Cu, Fe, Mn, Mo, Se, and Zn. Individual calf was the experimental unit. Administration of ITM had no impact on calf BW gain (average = 0.79 kg/d; SEM = 0.015). Although bull calves were heavier ($P < 0.001$) at birth compared with heifers (35.4 vs. 30.8 kg; SEM = 0.73), there were no gender x treatment interactions. Trace mineral status of calves was nutritionally adequate for both treatments on all sampling dates; however, administration of ITM resulted in greater ($P \leq 0.02$) overall average concentrations of liver Cu and Se and a lesser ($P = 0.05$) liver Fe concentration compared with saline-injected calves. In summary, injectable trace minerals administered to mineral-adequate, pre-weaned beef calves, provided greater liver Cu and Se concentrations, but did not impact ADG, compared with saline-injected control calves.

Key words: beef, calves, trace minerals

414 Effect of chromium supplementation on finishing Nellore bulls performance, carcass characteristics, and liver abscesses. R. S. Marques[1], A. M. Pedroso*[2], C. T. S. Dias[1], L. R. M. Pinto[1], and F. A. P. Santos[1], *[1]University of Sao Paulo, College of Agricultural Sciences, Piracicaba/SP, Brazil, [2]Embrapa Cattle Southeast, Sao Carlos/SP, Brazil.*

This trial was designed to determine the effects of increasing organic chromium levels on performance of finishing Nellore bulls fed rations containing (DM%) 16.7% sugar cane bagasse, 69.97% fine ground corn, 9.73% soybean meal, 1.01% urea, 2.58% mineral and vitamin mix, and 30mg/kg of monensin. Four treatments were compared: 0; 0.2; 0.4 or 0.6 mg/kg DM of organic chromium. Two hundred and 30 7 Nellore bulls (337 kg initial BW) allotted in 40 pens (10 pens/treatment) were used in a complete randomized blocks design. Parameters evaluated were dry matter intake (DMI), average daily gain (ADG), feed efficiency (ADG/DMI), hot carcass weight (CW), fat thickness (FT), rib eye area (REA) and liver abscesses. Data were analyzed using PROC GLM of SAS. Dry matter intake, average daily gain, feed efficiency, hot carcass weight, fat thickness and rib eye area were not affected by treatments. Incidence of liver abscesses was negligible.

Table 1. Dry matter intake (DMI), average daily gain (ADG), feed efficiency (ADG/DMI), hot carcass weight (CW), fat thickness (FT) and rib eye area (REA)

	Cr, mg/kg DM					
	Control	0.2	0.4	0.6	*P*-value	SEM
ADG (kg/d)	1.54	1.48	1.50	1.50	0.8889	0.042
DMI (kg/d)	9.41	9.74	9.58	9.69	0.5893	0.179
ADG/DMI	0.165	0.156	0.157	0.158	0.4699	0.014
CW (kg)	277.58	260.49	278.96	279.97	0.1581	6.81

415 Meta-analysis of the effect of dietary sulfur on feedlot health. C. A. Nichols*[1], V. R. Bremer[1], A. K. Watson[1], C. D. Buckner[1],

J. L. Harding[1], D. R. Smith[2], G. E. Erickson[1], and T. J. Klopfenstein[1], *[1]Department of Animal Science, University of Nebraska-Lincoln, Lincoln, [2]School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln.*

A meta-analysis of University of Nebraska-Lincoln (UNL) finishing trials was conducted to evaluate the effect of dietary sulfur and other dietary components on feedlot health. Health outcomes included polioencephalomalacia (PEM), bovine respiratory disease, infectious pododermatitis (foot rot), and, ruminal tympany (bloat). Likewise, ruminal degradable sulfur (RDS) concentration is proposed as an alternative to S concentration, with degradability assigned to feed ingredients similar to protein degradability. The effect of RDS on PEM was also evaluated. The analysis used Poisson regression to evaluate health records and diet information from 17,080 cattle from 69 feeding trials conducted within an 8 year time period in the UNL research feedlot and included only finishing periods. There was no significant relationship ($P > 0.05$) between dietary sulfur level and footrot (n = 484 cases), and, bloat (n = 21 cases). An interaction between dietary sulfur and forage NDF ($P < 0.01$) affected the incidence of PEM cases. For a given level of forage NDF, the incidence of PEM increased as dietary sulfur concentration increased in the diet; however, for a given dietary sulfur concentration, the relative risk for PEM decreased as forage NDF increased. Also, in this multivariable model cattle diagnosed with respiratory disease were more likely to be diagnosed with PEM ($P = 0.02$). A significant relationship was detected between RDS and PEM ($P < 0.01$). As RDS as a % of DM increased in the diet, the incidence of PEM increased. Unlike total dietary sulfur, there was no significant interaction between RDS and forage NDF ($P = 0.12$). In this multivariable model, increasing forage NDF decreased the risk for PEM. Conversely, respiratory disease diagnosis increased the risk but the cause and effect are unclear. Increasing total dietary sulfur, or increasing RDS increased the incidence of PEM in feedlot cattle. Model fit and lack of forage NDF interaction support that using RDS is likely a better predictor of PEM.

Key words: distillers grains plus solubles, polioencephalomalacia, sulfur

416 Effect of delaying the feeding of high sulfur diets to feedlot cattle until after adaptation to a finishing diet. M. E. Drewnoski* and S. L. Hansen, *Iowa State University, Ames.*

Elevated concentrations of dietary sulfate have been shown to decrease intake and reduce gain of cattle and can lead to a neurological disorder called polioencephalomalacia (PEM). Sulfate is reduced by ruminal bacteria to toxic hydrogen sulfide (H_2S). Both the incidence of PEM and ruminal concentrations of H_2S in feedlot cattle appear to be greatest during the first 30 d on a full finishing diet. We hypothesized that delaying exposure to high sulfate diets until cattle are fully adapted to a high concentrate diet would reduce the peak ruminal H_2S concentration and thus reduce potential for toxicosis. Sixty Angus crossbred steers (386 kg SE ± 13) were blocked by weight and randomly assigned to 1 of 12 pens and one of 3 dietary treatments, including 1) a control diet (0.3% sulfur) fed throughout the trial (C), 2) a high S diet (0.6% sulfur) fed throughout the trial (HS), or 3) the control diet fed during the transition period and for the first 28 d of the finishing period then switched to HS diet for the reminder of the trial (DS). Rumen H_2S concentrations and pH of 2 steers per pen were measured 6 h after feeding on d 1, 7, 14, 28, 35, 42, 56 and 70 of finishing. Ruminal pH did not differ due to treatment ($P = 0.79$) but was greater ($P < 0.05$) on d 56 (5.85) compared with previous days (5.57). Peak H_2S concentration of DS (3425 ppm) occurred on d 56 (28 d on HS diet) but was lower ($P < 0.05$) than peak H_2S for HS (5288 ppm) which occurred on d 7. Peak H_2S of the C (2583 ppm) occurred on d 7 and did not differ ($P = 0.23$) from the peak of DS but was less ($P < 0.05$) than HS. Sulfur intake (39.3 g/hd) of C at peak H_2S was less ($P < 0.01$) but DM intake (13.0 kg/hd) of C was greater ($P < 0.01$) than DS (66.8 g/hd; 12.7 kg/hd) and HS (65.7 g/hd; 10.8 kg/hd) at peak H_2S. Sulfur and DM intake of DS did not differ ($P > 0.60$) from HS at peak H_2S. These data suggest that potential for toxicosis was reduced by delaying feeding of high S diets until after steers had received a high concentrate finishing diet for 28 d.

Key words: cattle, hydrogen sulfide, sulfur

417 Effects of zinc and copper source and concentration on feedlot performance and carcass characteristics in yearling steers. M. G. Dib*[1], J. J. Wagner[1], K. Perryman[2], J. W. Spears[3], and T. E. Engle[2], *[1]Colorado State University, Fort Collins, [2]Micronutrients, Indianapolis, IN, [3]North Carolina State University, Raleigh.*

Crossbred steers (n = 288; initial BW = 320 kg ± 10.2) were used in a randomized complete block design to evaluate the effect of source and concentration of Zn and Cu on live performance and carcass characteristics. Steers were blocked by weight and randomly assigned to one of the 4 treatments (8 pens per treatment). Treatments included: 1) 90 ppm of Zn from ZnSO4 and 15 ppm of Cu from CuSO4 (Control, 100% sulfate); 2) 67.5 ppm of Zn from ZnSO4 plus 22.5 ppm of organic Zn and 11.25 ppm of Cu from CuSO4 plus 3.75 ppm of Cu from organic Cu (Organic, 75% sulfate, 25% organic); 3) 90 ppm of Zn from tetra-basic ZnCl and 15 ppm of Cu from tri-basic CuCl (100% Hydroxy); and 4) 54 ppm of Zn from tetra-basic ZnCl and 9 ppm of Cu from tri-basic CuCl (reduced Hydroxy, 60%). All steers were fed a typical high concentrate steam flaked corn based finishing diet twice daily. Steers were individually weighed on d −1, 0, 35, 70, 104, 173 and 174. On d 175, steers were transported to a commercial abattoir for slaughter. Initial and final BW, average daily gain, dry matter intake, and gain-to-feed were similar ($P > 0.10$) across treatments and averaged 318.9 kg, 586.5 kg, 1.54 kg/hd/d, 8.80 kg/hd/d, and 0.1753, respectively. Furthermore, hot carcass weight, subcutaneous adipose depth, Longissimus muscle area, calculated YG, marbling score and dressing percentage were similar ($P > 0.10$) across treatments. There was a trend ($P < 0.12$) for treatment to affect the likelihood that an individual carcass within each pen would grade USDA average Choice or higher (7.1, 9.7, 19.7, and 16.4% for the Control, Organic, Hydroxy 100, and Hydroxy 60 treatments, respectively). Results suggest that supplementing Zn and Cu from tetra-basic ZnCl and tri-basic CuCl at 60% of the level provided from sulfate or a sulfate-organic mixture will result in similar performance and carcass characteristics. Further research is necessary to determine the response of different amounts of tetra-basic ZnCl and tri-basic CuCl in finishing diets on cattle performance and carcass merit.

Key words: trace mineral source, tetra-basic zinc, tri-basic copper

418 Effects of supplemental copper and Linpro on performance and carcass characteristic of beef heifers. C. A. Alvarado*, C. C. Aperce, K. A. Miller, C. L. van Bibber, S. Uwituze, and J. S. Drouillard, *Kansas State University, Manhattan.*

Crossbred yearling heifers (n = 261; 351 ± 23 kg initial BW) were used in a randomized complete block experiment with a 2 × 2 factorial treatment arrangement to evaluate effects dietary copper (10 or 100 mg/kg

added copper) and Linpro (0 or 10% of diet DM) on feedlot performance and carcass traits. Linpro is an extruded blend of flaxseed and field peas containing added vitamins and minerals (22% CP; 23% fat). Heifers were blocked by initial BW into heavy and light groups and assigned randomly to experimental pens containing 10 or 11 heifers each. Pens (n = 24) were assigned randomly to each of the 4 treatments. Cattle were fed once daily and had ad libitum access to feed and water. Basal diets included (DM basis) 35% wet corn gluten feed, 35% dry-rolled corn, 15% pelleted soybean hulls, 10% corn silage, vitamins, and minerals, and provided 14% crude protein, 300 mg/d monensin, 90 mg/d tylosin, 2200 IU/kg vitamin A, 0.7% Ca, and 0.7% K. For Linpro treatments, the extrudate was added at 10% of the diet DM, replacing soybean hulls. Heifers were implanted (Revalor-200), dewormed (Safe-Guard), and vaccinated against common viral and clostridial diseases (Vista 3, Vision 7). Starting 23 d before harvest, zilpaterol was added to the diet for 20 d. Heavy and light blocks were harvested on d 117 and 132, respectively. There were no interactions between levels of copper and Linpro ($P > 0.10$), and copper level had no impact on performance or carcass traits ($P > 0.10$). Cattle fed Linpro treatments consumed less DM than their counterparts fed diets without (13.6 vs 14.1 kg/d; $P < 0.05$) and had greater gain efficiency (0.137 vs 0.129; $P < 0.01$), but there were no effects on ADG ($P > 0.05$). Carcass traits (HCW, LM area, KPH, 12th-rib fat thickness, marbling, and USDA quality and yield grades) were unaffected by diet ($P > 0.10$). Cattle fed Linpro had fewer severe (A+) liver abscesses ($P < 0.05$), but total incidence of liver abscesses was not different ($P > 0.10$). Results indicate that elevated copper levels do not impact performance or carcass traits of finishing cattle. Linpro can be used effectively as an energy source in finishing cattle diets.

Key words: copper, flaxseed, Linpro

419 Chromium supplementation alters the performance and health of feedlot cattle during the receiving period. B. C. Bernhard*[1], R. J. Rathmann[1], D. N. Finck[1], W. Rounds[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Kemin Industries Inc., Des Moines, IA.*

Crossbreed steers (n = 180; 230 ± 6 kg) were fed during a 56-d receiving period to determine if supplementing chromium (Cr; KemTRACE Chromium Propionate 0.04%, Kemin Industries) would improve feedlot performance and health of newly received cattle. A completely randomized block design (36 pens; 9 pens/treatment; 4 pens/block; 5 steers/pen) was used. Chromium premixes were supplemented to add 0 (Con), 0.1, 0.2, or 0.3 mg/kg of Cr to the total diet on a DM basis. Cattle were weighed every 14 d. Shrunk body weights, ADG, DMI, G:F, and number of times treated for morbidity (treated if rectal temperature ≥39.7°C) were recorded. Feedlot performance and morbidity data were analyzed as orthogonal contrasts in the MIXED and GLIMMIX procedure of SAS, respectively, with pen serving as the experimental unit. No differences were detected between treatments for BW, ADG, DMI, and G:F through the first 14 d ($P \geq 0.14$). From d 0 to d 28, DMI tended to linearly increase ($P = 0.07$) and ADG increased linearly ($P = 0.04$) as Cr levels increased. During the same period, BW and G:F showed a significant quadratic effect ($P \leq 0.05$) with 0.1 mg/kg being the least desirable and 0.3 mg/kg being the most accelerated. From d 0 to d 56, BW ($P = 0.08$) and DMI ($P = 0.12$) displayed a tendency to increase linearly, and consequently ADG and G:F increased linearly ($P \leq 0.05$) as Cr concentrations increased. Morbidity results showed a tendency ($P = 0.07$) for a linear decrease in the number of head treated at least once for respiratory symptoms as the Cr concentration was increased. The addition of 0.3 mg/kg of Cr resulted in the greatest performance advantages and reductions in the incidences of morbidity; and when specifically compared with the Con displayed an 8 kg improvement in BW ($P = 0.12$), 4.2% increase in G:F ($P = 0.10$), 10.8% enhancement on ADG ($P = 0.04$), and over 18% fewer cattle were treated at least once ($P = 0.05$). Results of this study indicate that supplementation of Cr to the basal diet can have beneficial effects on the performance and health of newly received steers during the first 56 d on feed.

Key words: chromium propionate, receiving cattle, feedlot performance

420 Chromium supplementation alters the glucose and lipid metabolism of feedlot cattle during the receiving period. B. C. Bernhard*[1], N. C. Burdick[2], R. J. Rathmann[1], D. N. Finck[1], J. A. Carroll[2], A. N. Loyd[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX.*

Crossbreed steers (n = 20; 235 ± 4 kg) were fed 53 d during a receiving period to determine if supplementing chromium (Cr; KemTRACE ChromiumPropionate 0.04%, Kemin Industries) would alter the glucose or lipid metabolism of newly received cattle. Chromium premixes were supplemented to add 0 (Con) or 0.2 mg/kg of Cr to the total diet on a DM basis. Cattle were fitted with jugular catheters on d 52. A glucose tolerance test (GTT) and an insulin sensitivity test (IST) were conducted on d 53 by infusing the steers with 1 mL of a 50% glucose solution/kg of BW (Dextrose 50%, Durvet, Inc.) at 0900 h and 0.1 IU of bovine insulin/kg of BW at 1400 h, respectively. Blood samples were collected at −60, −45, −30, −15, 0, 7.5, 15, 30, 45, 60, 90, 120, and 150 min relative to each infusion. Serum was isolated to determine glucose, insulin, and nonesterified fatty acid (NEFA) concentrations. Data were analyzed using the Mixed procedure of SAS specific for repeated measures with each steer serving as the experimental unit and fixed effects of treatment, time, and their interaction. Throughout the GTT no differences were detected in glucose concentrations or pre-infusion insulin concentrations ($P > 0.50$), but insulin concentrations post-infusion tended to be greater for the Cr steers ($P = 0.06$). In addition, NEFA concentrations during the GTT were lower ($P \leq 0.01$) for Cr steers both pre- and post-infusion. During the IST there was no treatment effect on glucose concentrations pre-infusion ($P = 0.38$), while post-infusion glucose concentrations were greater ($P < 0.01$) in the Cr steers. During the same test, there was no treatment effect detected for insulin concentrations ($P > 0.33$), but at 7.5 min there was a trend for the insulin concentrations of the Con steers to reach a higher peak ($P = 0.12$). Concentrations of NEFA were lower ($P < 0.01$) both pre- and post-infusion during the IST for Cr steers. Results of this study indicate that supplementation of Cr to the basal diet can alter insulin sensitivity and lipid metabolism of newly received steers during the first 53 d on feed.

Key words: chromium propionate, receiving cattle, glucose and lipid metabolism

Ruminant Nutrition: Dairy: Forages and Fiber

421 Milk production responses to soybean meal and canola meal in dairy cows fed grass silage based diets—A meta-analysis. P. Huhtanen*[1], M. Hetta[1], and C. Swensson[2], *[1]Swedish University of Agricultural Sciences, Umeå, Sweden, [2]Swedish Dairy Association, Lund, Sweden.*

Most feed protein evaluation predict a higher metabolizable protein (MP) for soybean meal (SBM) compared with canola meal (CM), but the data from production trials comparing SBM and CM have generally failed to prove this. A data set from production trials in which SBM, CM, heat-treated-CM (TCM) and a mixture of SBM and fishmeal (SFM) was collected from milk production trials. Prerequisites of the data to be included were that detailed information of diet composition, intake and milk production were reported and that the protein feeds were fed at least at 2 levels. Grass silage or mixtures of grass and whole-crop silages were used as forages and cereal grains (barley, oats and corn) were the major concentrate ingredients. The data set included in total 292 treatment means (122 comparisons) that were distributed as follows: SBM 46 (22), CM 120 (55) TCM 82 (29) and FSM 44. A mixed model regression analysis with random study effect was used to compare intake and production responses between the protein sources. Dietary CP concentration or intake of CP and ME were used as independent variables. All protein sources increased DMI, but the responses of 0.29 and 0.34 kg/1%-unit increase in dietary CP concentration was greater ($P < 0.01$) compared with SBM (0.11) with SFM displaying an intermediate response (0.20). Feeding CM or TCM produced greater ($P < 0.01$) milk yield responses than SBM (3.4 ± 0.19 and 3.7 ± 0.25 vs. 2.1 ± 0.25) per kg increase in CP intake. However, because of different DMI effects ECM responses to incremental ME intake were similar (0.16 to 0.18 kg ECM/MJ ME). Marginal milk protein yield responses (g/kg increase in CP intake) were greater ($P < 0.01$) with CM (136 ± 5.4) and TCM (133 ± 8.5) compared with SBM (988.0), but not when compared with SFM (125 ± 9.4). The difference between CM and SBM was even greater when expressed per kg MP predicted according to NRC (2001) system (381 ± 18 vs. 197 ± 17 g/kg MP). It is concluded that CM can be substituted for SBM on isonitrogenous basis without compromising milk production, and that MP systems tend to underestimate productive value of CM compared with SBM.

Key words: canola meal, milk production, soybean meal

422 Intake and milk production of dairy cows fed diets including low lignin/high fiber digestibility corn silage. N. B. Litherland*[1], H. G. Jung[1,2], and J. G. Linn[1], *[1]University of Minnesota, St Paul, [2]USDA-ARS, St Paul, MN.*

The objective of this study was to evaluate the effect of increasing digestible NDF content of lactating dairy cow diets on DMI and milk yield by feeding increasing proportions of low lignin (BMR) corn silage (CS). Control (B73) and BMR (B73bm3) inbred corn lines were ensiled in a poly-bag in September 2009. Silage pH was 3.8 for both silages and lactic-to-acetic acid ratio was 3.7:1 for control and 3.2:1 for BMR silages. Control and BMR CS, respectively, contained (DM-basis) 9.7 and 8.3% CP, 46.6 and 45.8% NDF, 2.9 and 2.6% lignin, and 15.8 and 17.7% starch. In vitro 48 h NDF digestibility was greater for BMR (72.1%) than control (57.0%) CS. Fifty Holstein and cross-bred dairy cattle producing 43.5 kg milk/d and 80 d in milk were assigned to 5 treatments. Diets included 0%BMR-100% Control (0BMR), 25%BMR-75% Control (25BMR), 50%BMR-50%Control (50BMR), 75% BMR-25%Control (75BMR), or 100%BMR-0%Control (100BMR) CS. All diets contained equal amounts of CS (43% of diet DM) and were balanced for 25 kg DMI and 43 kg of milk. Because the control CS contained less grain, more dry ground corn was added to the amount of control CS in the diets to keep starch equal. Diets contained 51.1% DM, 23.3% forage NDF, 17.2% CP, 19.0% ADF, 31.1% NDF and 24.5% starch. Cows were fed the diets for 56 d from February through April 2010. Data were analyzed using Proc Mixed in SAS as a completely randomized design with repeated measures and the least significant difference test was used for mean separations when main effects were significant ($P < 0.05$). DMI averaged 24.5 kg/d (SEM = 1.9) and was similar among diets (100BMR DMI was only 1.9 kg/d greater then 0BMR). Milk yield and 3.5%FCM yield averaged 48.6 kg/d (SEM = 2.1) and 37.1 kg/d (SEM = 1.8), and were similar among diets (100BMR averaged 1.7 kg/d greater milk yield than 0BMR). Dairy efficiency was not different and averaged 1.6 (SEM = 0.1). Milk fat and protein were similar among diets and averaged 3.2% (SEM = 0.1) and 3.1% (SEM = 0.1), respectively. Although BMR CS typically improves cow performance, in this trial greater in vitro digestibility of CS NDF did not enhance DMI or milk production.

Key words: corn silage, fiber, digestibility

423 Effects of supplementing starch or sugar pre-and postpartum to dairy cows fed TMR with wheat straw or grass hay prepartum: Performance, metabolism and health. N. B. Litherland*[1], L. Davis[2], S. Emanuele[2], and H. Blalock[2], *[1]University of Minnesota, St Paul, [2]Quality Liquid Feeds Inc., Dodgeville, WI.*

The objectives of this study were to determine if varying prepartum forage source and periparturient supplemental energy source affects periparturient performance and health. Sixty multiparous Holstein and crossbred cows were used in a completely randomized design with 4 treatments:1) Wheat straw (WS) prepartum (12.5% CP, 42.2% NDF, and 1.4 Mcal/kg NEL) + corn pre and postpartum (WSC), 2) WS prepartum (12.7% CP, 41.8% NDF, and 1.4 Mcal/kg NEL) + molasses-based Liquid Feed (LF) pre and postpartum (WSL), 3) Grass hay (GH) prepartum (13.8% CP, 37.8%NDF, and 1.5 Mcal/kg NEL)+corn pre and postpartum (GHC), 4) GH prepartum (13.9% CP, 37.4%NDF, and 1.5 Mcal/kg NEL) + LF pre and postpartum (GHL). Prepartum dietary treatments were initiated at dry off and postpartum diets were fed from parturition through 56 d in milk. After calving, cows were fed one of 2 diets formulated to support 45 kg/d of 3.5% FCM. The LF diets provided 2.7% of diet DM prepartum as supplemental sugar, and 1.5% postpartum. Data were analyzed using PROC MIXED in SAS as a randomized design with 4 treatments. WSC and GHC tended ($P = 0.08$) to consume more starch and WSL and GHL cows consumed more ($P < 0.05$) sugar. For WSC, WSL, GHC, and GHL treatments, prepartum DMI averaged 13.3, 12.8, 15.0 and 13.6 kg/d (SEM = 0.9; $P = 0.45$), postpartum DMI averaged 20.1, 17.8, 21.0 and 18.8 kg/d (SEM = 1.0; $P = 0.15$), yield of 3.5% FCM averaged 45.8, 45.2, 43.1 and 44.2 kg/d (SEM = 1.7; $P = 0.71$), and dairy efficiency (kg 3.5% FCM/kg DMI) averaged 2.4, 2.6, 2.2, and 2.4 (SEM = 0.1; $P = 0.27$), respectively. Yield and percentage of fat and protein were similar. There were no differences in prepartum or postpartum condition score or body weight loss. Prepartum energy balance tended ($P = 0.06$) to be higher for WSC and GHC compared with WSL and GHL. Prepartum serum NEFA were higher for WSL and GHL (SEM = 18.9; $P < 0.05$) and averaged 85.5, 177.1, 92.2, and133.1μ/mL for WSC, WSL, GHC,

and GHL. In conclusion, cows fed diets varying in energy and forage source performed similarly during the periparturient period.

Key words: energy source, forage, transition cow

424 Alternative models of kinetics impact indigestible neutral detergent fiber and estimates of ruminal digestibility. D. R. Mertens*, *Mertens Innovation & Research LLC, Belleville, WI.*

This project evaluated the interactions among models of digestion kinetics and methods of estimating indigestible NDF (iNDF) on steady-state predictions of ruminal digestibility. In vitro fermentations > 96 h suggest that some forages may have 2 pools of potentially digestible NDF. A sequential multi-pool equation was used to simulate digestion curves from known inputs (indigestible fraction = 0.2 or 0.4 of NDF; slowly digestion fraction = 0.3, 0.2, or 0.1 of NDF; lag rate = 0.25/h; fast and slow digestion rates = 0.06, 0.12, or 0.18 and.012, 0.008 or 0.004/h) that mimic typical digestion kinetics of alfalfa (A) and grass (G) forages. Kinetic parameters were estimated from simulated data using SAS NLIN for a 2-pool model (discrete lag, single digestible and iNDF pools) using results for 3, 6, 9, 12, 18, 24, 36, 48, 60 and 72 h; and for a 3-pool model (discrete lag, rapidly and slowly digesting and iNDF pools) using results for 6, 12, 24, 48, 72, 96, 120, 144, 192 and 240 h. Fitting a 2-pool model to simulated 3-pool digestion curves resulted in compromised estimates of rates of digestion and iNDF. The 2-pool model generated iNDF that were 1.3 (A) and 1.6 (G) larger than the known iNDF; whereas, rates of digestion were 0.63 (A) and 0.67 (G) of the known fast digestion rate. The 2-pool kinetic parameters resulted in ruminal digestibilities that were 0.95 of the known calculated values for A and G. For a 2-pool model, iNDF is estimated most closely by 72 h measurements. Even with no random variation and long fermentation times, fitting the 3-pool model generated iNDF pools that were 0.88 (A) and 0.85 (G), and fast and slow digestion rates that were 0.7 to 0.8 of the known values. The 3-pool model resulted in ruminal digestibilities that were 0.98 of the true values for A and G. At 240 h, the residue was 1.1 to 1.2 larger than the known iNDF. It was concluded that adding a second slowly digesting pool to describe NDF digestion results in improvements in the estimation of ruminal fiber digestion that are small in relation to the variation among in vitro measurements and kinetic parameters using nonlinear estimation.

Key words: digestion kinetics, rate, indigestible fiber

425 Comparison of alternative methods, sample grinds, and fermentation times for determining indigestible neutral detergent fiber. J. Boyd*[1] and D. R. Mertens[2], *[1]US Dairy Forage Research Center, Madison, WI, [2]Mertens Innovation & Research LLC, Belleville, WI.*

The objectives of this study were to evaluate the effects of sample grind, fermentation method, and time on the determination of indigestible neutral detergent fiber (iNDF). Samples of alfalfa hay and silage; corn stalks and silage; and ryegrass and mixed grass hays were ground through 2-mm and 1-mm screens in a cutter mill and 1-mm screen in a cyclone mill. Both 1-mm ground samples were fermented in flasks (in vitro, IV) or in F57 filter bags in a rotating jar system for 0, 48, 72, 96, or 144 h. In situ (IS) samples were fermented for 0, 48, 72, 96, 144, 240, and 288 h in animals fed either TMR, alfalfa silage, or grass hay, and these same donors were used to make a composite inoculum for the in vitro and rotating jar fermentations. For in situ, 2-mm samples were fermented in Ankom in situ bags and 1-mm cyclone samples were fermented in F57 filter bags. Fermentation residues were extracted in neutral detergent using crucibles with silica sand for IV or using the A200 fiber analyzer for all bags. Only samples fermented for > 96 h were evaluated as estimates of iNDF. Data were analyzed using Proc MIXED of SAS with run within method and repetition within run as random variables. Across all samples, 288 h IS obtained the smallest iNDF for the 1- and 2-mm grinds, and they were not different ($P < 0.05$) from 1- and 2-mm grinds of 240 h IS or from both 1-mm grinds for 144 h IV. Bags appeared to impede measurement of iNDF. At 144 h, the IV results of both grinds were lower ($P < 0.05$) than both grinds in F57 bags in the rotating jar system and the 1-mm cyclone grind in F57 bags fermented IS. The 2-mm grind fermented in IS bags at 144 h IS were not different from IV results at 144 h. In general, IS fermentation took nearly twice as long to obtain iNDF similar to IV results. Differences in iNDF among treatments were greater for more slowly fermenting substrates (corn stalks and mixed grass hay). In summary, measurement of iNDF is affected by time and fermentation system, but less so by grinding through 1- or 2-mm screens.

Key words: Indigestible fiber, digestion kinetics, in vitro, in situ

426 Effects of daily ingredient dry matter adjustment of total mixed ration using Intelligent Ration Monitoring (IRM) NIR forage analyzer on commercial dairy farm performance. D. N. L. da Silva*[1], A. Barbi[2], A. Ghiraldi[2], D. Allen[3], and N. B. Litherland[1], *[1]University of Minnesota, St Paul, [2]Dinamica Generale, Poggio Rusco, Italy, [3]Gar-Lin Dairy, Eyota, MN.*

The objectives of this study were to determine the effects of daily adjustment of ingredient dry matter (DM) using a near-infrared reflectance (NIR) IRM (Intelligent Ration Monitoring) system on diet composition, dry matter intake (DMI), and milk and component yield. We hypothesized that daily mechanical adjustment of DM would reduce TMR DM variability and improve dairy efficiency (DE) compared with conventional ingredient DM adjustment (weekly hand sampling). Five hundred dairy cows in 2 pens (n = 250) on a commercial dairy were used in a crossover design with 9 week periods. Pens were balanced by milk yield (52.9 and 51.8 kg/cow/d) and days in milk (110.5 and 111.8). Two dietary treatments: (Control) weekly correction of ingredient DM of corn silage, alfalfa silage and high moisture corn by drying for 12 h 100C oven; (IRM) the IRM system scanned individual ingredients and adjusted DM at each feeding. Diets had the same composition and only varied by method of DM adjustment. Cows were fed twice and milked 3 times daily. Data were analyzed using Proc Mixed in SAS with repeated measures when appropriate and PDIFF used for mean separation when main effects were significant ($P < 0.05$). Control and IRM TMR DM averaged 45.9 and 46.0% (SEM = 0.83;P = 0.93). TMR starch, CP, ADF and NDF were similar. Nutrient composition of TMR refusals was not different. DMI per cow averaged 26.5 and 26.9 kg/d (SEM = 1.3; $P = 0.7$). DM refusal %/cow/d averaged 5.0 and 4.7 (SEM = 1.5; $P = 0.6$). Milk and 3.5% FCM yield averaged 52.9 and 52.8 (SEM = 1.3; $P = 0.9$) and 56.5 and 54.6 (SEM = 2.3; $P = 0.1$) for control and IRM. Percent milk protein was higher (2.9 vs. 3.0 SEM = 0.2) (Trt × week; $P < 0.05$) for IRM but protein yield was similar between treatments. Milk fat % and yield averaged 3.8 and 3.7 (SEM = 0.2; $P = 0.7$) and 2.0 and 1.9 kg/d (SEM = 0.1; $P = 0.3$) for control and IRM. DE averaged 2.2 and 2.0 (SEM = 0.1; $P = 0.1$) for control and IRM. IRM cows performed as well as those fed using traditional DM adjustment.

Key words: NIR, precision feeding, dry matter

427 Effects of prepartum supplementation of starch or sugar to dairy cows fed TMR with thirty percent wheat straw or grass hay on colostrum yield and composition. N. B. Litherland*[1], L. Davis[2], S. Emanuele[2], and H. Blalock[2], *[1]University of Minnesota, St Paul, [2]Quality Liquid Feeds Inc., Dodgeville, WI.*

Sixty multiparous Holstein and crossbred cows, balanced by 305ME and parity, were used in a completely randomized design (CRD) with 4 prepartum treatments: 1) Wheat straw (WS) + corn (WSC) (12.5% CP, 42.2% NDF, 20.1% starch, 3.6% sugar and 1.4 Mcal/kg NEL), 2) WS + molasses-based Liquid Feed (LF) (WSL) (12.7% CP, 41.8%NDF, 18.7% starch, 6.3% sugar and 1.4 Mcal/kg NEL), 3) Grass hay (GH) + corn (GHC) (13.8% CP, 37.8%NDF, 20.1% starch, 5.1% sugar and 1.5 Mcal/kg NEL), 4) GH + LF (GHL) (13.9% CP, 37.4%NDF, 18.7% starch, 7.9% sugar and 1.5 Mcal/kg NEL). The LF diets provided 2.7% of diet dry matter as supplemental sugar. Prepartum diets were formulated to meet NRC, 2001 recommendations at 28 kg DMI/d. Treatments were fed from dry-off until calving; 41 d SEM = 2.0. Data were analyzed using Proc Mixed in SAS as a CRD and PDIFF used for mean separation when main effects were significant ($P < 0.05$). WSC and GHC tended ($P = 0.08$) to consume more starch and WSL and GHL cows consumed more ($P < 0.05$) sugar prepartum. DMI averaged 13.3, 12.8, 15.0 and 13.6 kg/d SEM = 0.9; $P = 0.45$). Calf birth weight averaged 46.1, 48.3, 49.1, 48.0 kg ($P = 0.91$; SEM = 3.0). First-milking colostrum yield averaged 9.2, 9.6, 9.0, and 10.9 kg for WSC, WSL, GHC, and GHL ($P = 0.67$; SEM = 1.6). Among treatments, 13.3% of cows produced <5.0 kg of colostrum. Pearson correlation for colostrum yield, prepartum intake of DM, OM, CP, NDF, ADF, starch, and DMI one week prepartum were not significant. Colostrum yield tended to be positively correlated with prepartum sugar intake ($P = 0.07$). Colostrum DM % tended to be higher for WSL compared with WSC ($P = 0.07$; SEM = 1.2) and averaged 26.6, 31.1, 30.8, and 28.3 for WSC, WSL, GHC, and GHL. Colostrum minerals were analyzed using inductively coupled plasmid analysis. Colostrum mineral yield was similar and averaged (SEM) 25.4g (3.7) Ca, 21.6 g (3.1) P, 3.8 g (0.6) Mg, 15.7 g (2.3) K, 15.0 g (2.0) S, and 6.7 g (1.0) Na. Prepartum sugar intake, colostrum yield and composition should be further explored.

Key words: transition cow, colostrum, sugar

428 Effects of corn gluten feed and effective NDF on ruminal pH and productivity of lactating dairy cattle. M. L. Sullivan*[1], K. N. Grigsby[2], and B. J. Bradford[1], *[1]Department of Animal Science and Industry, Kansas State University, Manhattan, [2]Cargill Incorporated, Blair, NE.*

Corn gluten feed (CGF), a by-product of the wet milling industry, is commonly substituted in lactating dairy rations for corn, corn silage, and alfalfa hay. Previous research at Kansas State University showed that increasing CGF in the diet decreased ruminal pH. The objective of this study was to maintain at least 10% of particles ≥18 mm in length across diets. We hypothesized that as CGF increased in the diet, DMI and milk yield would increase while ruminal pH would be maintained. Seven ruminally cannulated, lactating Holstein cows (4 multiparous, 3 primiparous) were used in an incomplete 4 × 4 Latin square design. Treatments included 0, 11, 23 or 34% CGF while utilizing alfalfa to maintain particle size. Four 21 d periods were used with 17 d of adaptation and 4 d of sample collection. Free floating ruminal pH probes were utilized during sampling periods and recorded pH every 5 min. Particle size of TMR and orts were analyzed using a Penn State Particle Separator. Across treatments CP and NDF were held constant. Results were analyzed with mixed models to test the fixed effect of treatment. All diets contained >10% of particles ≥18 mm; however, as CGF increased, the percent of particles ≥18 mm significantly ($P = 0.01$) decreased. Interestingly, with increasing CGF, cows sorted for the particles ≥18 mm ($P = 0.03$) while sorting against particles on the bottom screen ($P = 0.002$) and pan ($P = 0.01$). With increasing CGF, ruminal pH was not affected, yet DMI ($P = 0.02$) and milk yield ($P = 0.02$) significantly increased in a quadratic fashion with peak response for the 23% diet. Milk protein, lactose and fat percentages were not affected; however, milk protein ($P = 0.004$) and lactose ($P = 0.02$) yields showed a significant increase as a result of the increased milk production. Additionally, efficiency was not affected by the treatments as there were no differences in ECM/DMI. Thus it was demonstrated that if minimal particle size is maintained as CGF increases in the diet, DMI and milk yield increase while maintaining ruminal pH.

Key words: corn gluten feed, ruminal pH, particle size

429 Feeding forage cubes to identify divergence for residual feed intake in dairy cows. G. C. Waghorn*[1], K. A. Macdonald[1], S. R. Davis[2], and R. J. Spelman[3], *[1]DairyNZ, Hamilton, New Zealand, [2]Via-Lactia Biosciences, Auckland, New Zealand, [3]Livestock Improvement Corporation, Hamilton, New Zealand.*

Selection for divergence between individuals for efficiency of feed utilization (residual feed intake, RFI) has widespread application in the beef industry and is usually undertaken when animals are fed diets based on silages with grain. The objective of this research was to develop a feeding system (using Gallagher, Hamilton, New Zealand, electronics) and measure RFI for growth in Holstein/Friesian heifers (aged 5–9 mo), and evaluate divergent individuals for RFI for lactation. A forage diet (alfalfa cubes) was fed because the New Zealand dairy industry (4.4 milking cows in lactation) relies heavily on forage feeding. Genetic markers will be identified for the trait. The evaluation was undertaken over 3 years with 1052 animals fed in a facility for 6 weeks, and weighed 3 x weekly. The mean age at entry was 170 d, BW 171 kg, and mean daily dry matter (DM) intakes averaged 7.9 kg. BW gain (all animals) averaged 0.88 kg/day. RFI was determined as the residuals from the regression of mean intake on mean $BW^{0.75}$ and daily BW gain of individuals. Actual and fitted intakes were strongly related (R2 = 0.82). In terms of gross efficiency (feed intake/BW gain), RFI + year explained 43% of the variation, BW gain + year, 66% and RFI + BW gain + year 79% of variation (all $P < 0.001$). Daily BW gains (kg) of the most and least efficient 10% averaged 0.88 sd 0.15 and 0.88 sd 0.12 ($P = 0.568$) respectively, and the divergence between mean intakes was 1.72 kg DM/d. Comparable values for the most and least efficient 5% were 0.86 sd 0.15 and 0.90 sd 0.12 kg/d respectively ($P = 0.067$), and the divergence in mean intakes was 2.24 kg DM/d. Justification for using RFI for gain in peri-pubertal heifers to identify divergence for lactation was based on the biochemical bases of efficiency for production (milk or meat) and maintenance, and the high proportion of dietary energy used for maintenance in growing cattle and over a cows lifetime. The selection is currently being evaluated in lactating cows.

Key words: residual feed intake, forages, divergence

430 A mathematical model to predict the size and rate of digestion of a fast and slow pool of NDF and the indigestible NDF. E. Raffrenato*, C. F. Nicholson, and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

Many models that predict rate and extent of digestion of neutral detergent fiber (NDF) in the rumen assume first-order processes, in which the rates of digestion and passage are proportional to the mass of NDF in the rumen. Our objective was to improve the prediction of digestible NDF and to quantify, using a minimum of fermentation points, 2 pools of potentially digestible NDF, pdNDF1 and pdNDF2, and their respective rates. Based on fermentations from 0 to 240 h among 34 forages (grasses, conventional and bmr corn silages, alfalfas) 3 pools were described by NDFt = pdNDF1 * $e^{-k1(t-L)}$ + pdNDF2 * $e^{-k2(t-L)}$ + iNDF, where NDFt is the residue at time t; L is the lag; k1 is the rate of digestion of pdNDF1; k2 is the rate of digestion of pdNDF2; and iNDF the indigestible NDF on NDF basis. A non-linear estimation allowed the computation of the pool sizes and respective rates. Using 3 points on the degradation curve, with 240 h as the proxy for iNDF, we optimized the same model in Vensim® (Ventana Systems Inc., Belmont, MA, 2005) to obtain rates and pools. In addition, the same optimization was also performed with 2 points and a forage group-specific range for iNDF. Parameters (with and without iNDF) obtained per forage were compared with kinetics data from the non-linear estimation, using R^2 and RMS at convergence for ranking purposes, for the whole equation, and RMSE and MSPE. The highest R^2 (0.98) and lowest RMS (0.0010) were obtained when using 48, 120 and 240 h of NDF residual or when using 30 and 120 h and a range for the forage group-specific iNDF (R^2 = 0.92; RMS = 0.0021). Correlations were in both cases consistently high for all parameters (r = 0.76 to 0.99). Results demonstrate that a better description of the heterogeneity of NDF disappearance is possible with a minimum of fermentation time points. Due to the variable nature of the pool sizes and rates, forage specific equations should be developed for better estimations of the forage specific characteristics and iNDF estimation.

Key words: modeling, NDF digestibility, rate of digestion

431 Rates of particle size reduction and passage are faster for legume compared to C3 grass resulting in lower rumen fill and less effective fiber. K. L. Kammes* and M. S. Allen, *Michigan State University, East Lansing.*

Rates of particle size reduction in, and passage from, the rumen were evaluated for diets containing legume (alfalfa, A) or C3 grass (orchardgrass, O) silages as the sole forage using 14 ruminally and duodenally cannulated cows. The experiment was a crossover design with 2 18-d treatment periods. Silages were chopped to 1 cm theoretical length of cut and contained 42.3 and 58.2% neutral detergent fiber (NDF) for A and O, respectively. Both diets contained 25% forage NDF and 30% total NDF. Feed, orts, rumen, and duodenal samples were wet sieved to fractionate particles above (large, L) and below (small, S) 2.36 mm. Indigestible NDF (iNDF), determined by 240 h in vitro fermentation, was used as a flow marker. Milk yield (36 kg/d), milk components, and dry matter intake (24 kg/d) were similar for A and O ($P > 0.10$). Particle size distributions of NDF consumed (75% L and 25% S) were similar for both treatments, but iNDF (% of total NDF) consumed was much greater for A compared with O (54.2 vs. 27.4%, $P < 0.0001$). Rumen pools of L NDF, total NDF, and dry matter (3.2 vs. 4.4 kg, 6.2 vs. 6.8 kg, and 10.6 vs. 12.6 kg, respectively; $P < 0.05$) and total rumen contents wet weight and volume (83 vs. 93 kg and 98 vs. 109 L, respectively; $P < 0.01$) were smaller for A compared with O. Ruminating time per kg forage NDF consumed was 7% greater for O than A ($P < 0.05$). Rate of reduction of iNDF from L to S was greater for A than O (5.7 vs. 3.1%/h, $P < 0.0001$) as was rate of passage of iNDF and potentially digestible NDF in S (6.3 vs. 4.9%/h, $P < 0.05$). The proportion of NDF in the rumen below the threshold for passage (S) was 62.9 and 55.3% for A and O, respectively. However, the rate of passage of iNDF in S was positively correlated with the rate of reduction of iNDF from L to S for A ($P < 0.05$) but not for O ($P = 0.56$). Faster rate of passage of S for A suggests less selective retention because of a smaller rumen pool of L NDF for A compared O. Although particle size reduction is a prerequisite to passage, it is less of a constraint to passage for C3 grass compared with legume.

Key words: particle size, passage kinetics, rumen fill

432 Individual variability of NDF intake and feed conversion efficiency in pasture-based systems. S. C. Garcia*[1], F. Bargo[2], and R. K. Jhajj[1], [1]*The University of Sydney, Camden, NSW, Australia,* [2]*Elanco Animal Health Southern Cone (Argentina & Chile), Buenos Aires, Argentina.*

Mean daily intake and milk yield data of lactating Holstein-Friesian dairy cows from 7 studies (mostly grazing) conducted in USA, Australia and New Zealand were combined to quantify the variability in neutral detergent fiber intake (NDFI) and its relationship with feed conversion efficiency in pasture-based systems. Intake of grazing cows was estimated by external markers. Within study, data from individual cows were classified according to milk yield level (low, medium or high) to avoid confounding effects with study of origin. Data were analyzed using a mixed-effects model and by regression analysis. On average, mean body weight (BW) was similar ($P \geq 0.05$) across the 3 groups. Milk yield varied from 17 to 30 L/cow $^{-1}$) but mean dry matter intake (DMI) increased ($P \leq 0.001$) by only 13% (as % of BW) between low and high milk yield groups, respectively. Mean daily NDFI (1.28% body weight) was similar ($P \geq 0.05$) across the 3 groups and close to the widely accepted upper maximum (≈1.2% BW) for lactating cows. However, the variation in NDFI among individual cows was much larger than expected. Consistently across all studies NDFI (%BW) by individual cows increased linearly as total actual daily NDFI (kg/cow) increased, when a flatten of the relationship would be expected to occur at ≈1.2% BW if a true physical limitation to intake were present. The NDFI by individual cows ranged from 0.5 to 2.9% of BW, with the upper 20% of the cows in the data set eating in excess of 1.6% BW. The observed variability was similar in pattern across all studies, suggesting it was more related to intrinsic animal than feed factors. Feed conversion efficiency increased as milk yield increased, but was unrelated ($P \geq 0.05$) to individual variation in DMI per cow. Feed conversion efficiency decreased as NDFI (% BW) increased, particularly for cows in the high and medium yield categories. Results indicate that using a fixed value of maximum potential NDFI for individual cows would be misleading, particularly for grazing animals, highlighting the need of more individualized approaches to feeding management of cows in pasture–based systems.

Key words: NDF intake, dairy cows, feed conversion efficiency

433 Cereal nutrition of periparturient ewes: Corn versus wheat-barley. A. Nikkhah*, M. Karam Babaei, and H. Mirzaei, *University of Zanjan, Zanjan, Iran.*

The objective was to establish effects of peripartal dietary grain choice, grain level, and interactions on ewe metabolism. Twenty Afshari × Merino ewes (80.3 ± 2.0 kg BW) were used in a completely randomized design study from 24 d prepartum through 21 d postpartum. Ewes were kept indoor in individual boxes (1.5 × 2.5 m) and received once daily at 0900 h an either 1) higher or 2) lower concentrate total mixed ration (TMR), based on either 1) solely corn grain (CO) or 2) 50:50 blend of wheat and barley grains (WB). Ewes were stepped into the postpartum diet via feeding 2 prepartum diets. DM based dietary forage for all groups had 3:1 ratio of chopped alfalfa hay:corn silage, mixed with concentrates. For the higher grain level, forage to concentrate ratio was respectively 65:35 and 60:40 for the 2 prepartum diets, and 50:50 for the postpartum diet. The respective ratios for the lower grain level were 75:25, 70:30 and 65:35. Prepartal DMI increased by feeding CO vs. WB. Feeding CO, and not WB, at higher vs. lower level improved postpartum DMI (2.3 vs. 2.0 kg/d, $P < 0.05$). Lambing DMI tended to increase with the higher vs. lower WB (1.59 vs. 1.37 kg/d, $P < 0.10$). DM intake was greater postpartum vs. lambing (2.1 vs. 1.5 kg/d, $P < 0.05$). Feeding CO vs. WB, and feeding both CO and WB at lower vs. higher level increased fecal pH. Postpartal rumen pH decreased by feeding the higher vs. lower WB (5.7 vs. 6.2, $P < 0.05$). Rumen propionate decreased (20.4 vs. 18.9 mmol/L), and acetate (67 vs. 70 mmol/L) and acetate to propionate ratio (3.3 vs. 3.7) decreased by feeding higher vs. lower levels of both CO and WB. Colostrum properties, peripartal urine pH, lamb weight, and placenta weight and expulsion time were unaffected. Milk yield (1.64 vs. 1.27 kg/d) and fat yield (99 vs. 81 g/d) were increased by higher levels of CO and WB. Plasma glucose was higher for higher vs. lower WB (57.6 vs. 52.2 mg/dL). Feeding CO vs. WB tended to reduce peripartal plasma NEFA (0.25 vs. 0.28 mmol/L) and increased insulin to NEFA ratio (2.47 vs. 1.77). Novel findings provide evidence on independent and interactive effects of dietary cereal choice and level on periparturient sheep metabolism and performance.

Key words: cereal, periparturient, sheep

434 Effect of replacement of barley grain with oak acorn (*Quercus persica*) on Markhoz kids' performance. E. Foroutan*, O. Azizi, G. H. A. Sadeghi, F. Fatehi, and S. H. Karimi, *Department of Animal Science, Faculty of Agriculture, College of Agricultural and Nature Science, University of Kurdistan, Sanandaj, Kurdistan, Iran.*

The past researches have showed that Oak acorn can be replaced by barley grain in ruminant ′s diet. The results of some studies indicate that acorns contain an anti-nutritional factor (tannin) that has some effects on ruminants such as a reduction in nutrients digestibility. High level of tannin can reduce voluntary feed intake, whereas low to moderate level may improve the digestive utilization of feed mainly due to a reduction in protein degradation in rumen and an increase in amino acid flow to the small intestine. There is evidence that goats may be less susceptible to toxic effects of tannin, and microbial tanninase enzymes are thought to be responsible. Therefore, the aim of this study was to investigate the effect of replacing oak acorn with barley grain on dry matter intake (DMI), water intake (WI), live weight (LW), average daily gain (ADG) and feed conversion ratio (FCR). Twenty-four Markhoz kids (mean BW 16.93Â ± 1.25 kg and 4–5 mo of age) were used in a randomized complete design with 4 treatments (diets) including: a) control (barley), b) 8% oak acorn, C) 17% oak acorn, and d) 25% oak acorn of dry matter diet. The forage to concentrate ratio was a 60:40 in diets. The experimental period lasted for 105 d. the Last square means of dry matter intake (g/d) and water intake (l/d) were 880, 903, 942, 961 and 2.578, 2.653, 2.753, 2.798, respectively for treatments 1 to 4 and there was not any significant effect of treatments on these parameters ($P > 0.05$). LW, ADG, and FCR were 30.683, 31.117, 31.567, 31.950 and 130, 136, 140, 141 and 6.87, 6.67, 6.78, 6.86, respectively for treatments 1 to 4 and there were not any significant effects between treatments for LW (kg), ADG (g/d) and FCR ($P > 0.05$). Based on our results it can be concluded that acorns can substitution with barely at 25% without any problem on kid′s performance.

Key words: Markhoz kids, oak acorn, performance

435 Performance of pre-weaned WAD lambs fed Mexican sunflower leaf meal (MSLM) based diets. A. H. Ekeocha*, A. O. Akinsoyinu, and O. Makinde, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Studies were conducted using 16 West African Dwarf (WAD) lambs selected from 16 ewes brought to heat (estrus) by synchronization and served by 2 rams. The experimental animals were placed at 6 weeks of age and were fed with grass (*Panicum maximum*) plus concentrate diet mixture of sunflower leaves (MSL) and wheat bran (WB) such that 0%, 15%, 30% and 45% of wheat bran was replaced by weight with MSL gravimetrically. Diet A served as control while animals on diets B, C and D received Mexican sunflower leaf (MSL) at 15, 30 and 45% respectively. The experiment lasted for 7 weeks. Feed and water were provided ad libitum and routine vaccination and medication administered. Parameters measured were weight gain, dry matter intake, weaning weight and feed conversion ratio (FCR). The dry matter intake (DMI)g/day was highest for lambs on diet C (30%MSL)(156.94) followed by B (15%MSL)(156.53) > A (0%MSL)(154.29) > D(45%MSL) (152.04) g/day respectively. This increase was numerically higher than observed values for animals on treatments A (0%MSL) and B(15%MSL) but statistically significant ($P < 0.05$) when compared with animals on treatments D(45%MSL). This trend was observed for weight gain and weaning weight. Values obtained for FCR (2.30, 2.33, 2.30 and 2.38) for lambs on treatments A,B,C and D respectively were not significantly affected by treatment ($P > 0.05$). The low FCR (2.30–2.38) obtained in this study is an indication of high digestibility and utilization of the experimental rations by pre-weaned lambs and this could be attributed to low fiber content (15.70–17.50%), low ADL (7.92–9.85) of the rations, high daily weight gain (63.85 - 68.16 g/day) and lamb weaning weight (7.40 – 8.00 kg). Results from this study showed that 30% MSLM based diet were acceptable to the pre-weaned lambs as it supported dry matter intake, optimum weight gain, weaning weight and feed conversion ratio before diminishing return sets in.

Key words: performance, pre-weaned, West African dwarf lambs

436 Effects of including okara into the diet of weanling crossbred Boer goats and its impact on growth and performance. L. L. Ramsey*, F. R. B. Ribeiro, J. J. Heitholt, J. A. Carter, W. S. Stewart, and D. D. Weir, *Texas A&M University-Commerce, Commerce.*

Reducing the total cost of feedstuffs is a primary concern for livestock producers. Okara shows promise as a byproduct feedstuff because it

provides an excellent source of protein and can be substituted in an animal's diet to minimize feed costs. The objective of this study was to determine if including okara, to the diet of weanling crossbred Boer goats would impact their growth and performance. Okara is a cost-free insoluble pulp extract remaining after producing soymilk that has 35.5% CP, 13.6% ADF, 19.8% NDF, 1.15 Mcal/lb NE_m and 0.81 Mcal/lb NE_g. A preliminary study in 2009 with 10 yearlincrossbred Boer does, half of which received a 10% okara diet, indicated no effects on growth and performance. In this 2010 study, 25 weanlings (14 wethers and 11 does) were blocked by gender and randomly assigned based on BW to one of 2 treatments, an okara group (OG, n = 13) and a control group (CG, n = 12). Measurements were taken every 14 d and consisted of hip height (HH) girth circumference (GC), BW and daily feed intake. Variables that were calculated were ADG, HH gain (HHG), GC gain (GCG) and daily DMI (DDMI). All weanlings grazed on a 2-acre paddock that consisted of coastal bermudagrass, coastal bermudagrass hay and water ad libitum. The CG were fed daily a diet that was composed of commercially available pelleted feed, 16% CP, at a rate of 1.5% of their BW for 98 d. The OG diet was composed of 80% commercial feed and 20% oven-dried okara, at a rate of 1.5% of their BW for 98 d. There were no gender effects or interactions with treatment were found for any of the variables measured; thus, only means for treatment are presented. Results showed that there were no significant differences ($P > 0.05$) in HHG (0.046 vs. 0.050 cm), GCG (0.040 vs. 0.035 cm), ADG (0.046 vs. 0.044 kg) and DDMI (193 vs. 182 g/day) between the CG and OG, respectively. These 2010 results, combined with those of 2009 preliminary study, indicate that replacement of a commercial feed with up to 20% okara in the diet of crossbred weanling Boer goats will not compromise their growth and performance.

Key words: goat, okara, performance

437 Energy and protein requirements of Canindé, Moxotó and Boer crossbred goats in semi-arid region of Brazil. M. L. Chizzotti*[1,2], K. C. Busato[2,1], T. S. Silva[2], R. T. S. Rodrigues[2], C. W. S. Wanderley[2], I. F. Silva[2], and G. G. L. Araújo[3], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal do Vale do São Francisco, Petrolina, PE, Brazil, [3]Embrapa CPATSA, Petrolina, PE, Brazil.*

This study was designed to determine protein and energy requirements for growth and maintenance of the Brazilian indigenous breeds Canindé and Moxotó and F1 Boer crossbreds with nondescript goats raised on semi-arid region of Brazil. A comparative slaughter trial was conducted with 60 goats (20 of each breed group), averaging 15 kg of initial body weight (BW). The baseline group consisted of 5 animals of each breed group. The remaining goats were allocated on 3 treatments: ad libitum intake and fed 50 or 75% of the ad libitum intake, and were fed 90 d. Diet consisted of 40% of *Pennisetum purpureum* and 60% of concentrate. A digestion trial was conducted in parallel to determine the metabolizable energy intake (MEI). Animals were kept in individual stalls, partially shaded, in the middle of a native Caatinga area, to replicate the semi-arid environment. The maintenance requirement for net energy (NEm) was calculated by the equation $HP = a \times e^{(b \times MEI)}$, where HP is the heat production. The net energy requirement for growth (NEg) was determined by the equation $a \times EBG^b \times EBW^{0.75}$, where EBW is the empty BW, a and b are the antilog of the intercept and the slope of the linear regression of the log of RE (kcal/kg $EBW^{0.75}$) on the log of the empty body gain (EBG), while the growth requirement for net protein (NPg) was calculated by the equation $NPg = w \times z \times EBW^{z-1}$, where w and z are the coefficients of the regression of the logarithm of the body protein on the logarithm of EBW. The NPm was assumed to be 6.25 times the intercept of the linear regression of the retained N on N intake. There were no differences ($P > 0.05$) in NEm and NPm among breeds, and the overall values found were 74.1 $kcal.kg^{-0.75}$ of $EBW.d^{-1}$ for NEm and 1.9 g $CP.kg^{-0.75}$ of $EBW.d^{-1}$ for NPm. There were also no differences ($P > 0.05$) in NEg and NPg among breeds, which can be estimated as NEg (Mcal d^{-1}) = $0.1560 \times EBW^{0.75} \times EBG^{0.716}$ and NPg (d^{-1}) = $0.217 \times EBW^{-0.0574} \times$ EBG. The requirements of Brazilian indigenous and crossbred goats raised on semi-arid were lower than those recommended by NRC (2007) for local or meat goats. Funded by CNPq and FACEPE.

Key words: comparative slaughter, Caatinga, maintenance

438 Effect of yeast culture and direct-fed microbes on the growth performance of lambs. S. P. Doto*, J. K. Wang, and J. X. Liu, *Institute of Dairy Science, College of Animal Sciences, Zhejaing University, Hangzhou 310029, P.R. China.*

An experiment was conducted to determine the effect of yeast culture and direct-fed microbes on the growth performance of weaned lambs. Thirty-two male lambs of Hu sheep with initial weight of 22.2 (±0.75) kg were fed on a basal diet with grass hay and concentrate at a ratio of 2:1, and randomly assigned to 1 of 4 treatments: (1) basal diet without additive (control), (2) added with yeast culture (YEC, Diamond V Mills, Inc., Iowa, USA), (3) yeast culture plus *Bacillus licheniformis* (YBL, Zhejiang Future, Hangzhou, China), and (4) yeast culture plus *Clostridium butyricum* (YCB, Zhejiang Future). The direct-fed microbes in powder form consisted of live microbes and their respective carrier fermentation media. Yeast culture was offered at a dose of 15 g per head per day, while *B. licheniformis* and *C. butyricum* were offered at 2.3 g per head per day. Average daily gain of growing lambs was 102, 114, 90, and 89 g/d in control, YEC, YBL, and YCB, respectively, with no significant difference ($P > 0.05$) among treatment, but the carcass weight was significantly higher ($P < 0.05$) in the YEC-added lambs than in other treatments. There were little differences in blood glucose and plasma urea-N concentrations among 4 treatments, while blood creatinine concentration (μmol/L) was significantly higher ($P < 0.05$) in YBL (97.9) and YCB-added lambs (92.1), compared with the control (77.3) and YEC (79.6). Solid-associated fungi population relative to total rumen bacteria 16S ribosomal DNA was significantly lower ($P < 0.05$) in the lambs on YBL (3.55) compared with those on YCB (23.12). From the results obtained in the current study, it is inferred that yeast culture can significantly improve growth performance of weaned lambs and that no additional advantage can be expected from combined addition with either B. licheniformis or C. butyricum. Further study is needed to investigate the effects of these additives using an adjusted diet formulation.

Key words: yeast culture, direct-fed microbes, growth performance

439 Mineral profile of lactating West African Dwarf ewe fed Mexican sunflower leaf meal based diets. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

A study was conducted to determine the mineral balance of lactating West African Dwarf (WAD) ewe. Sixteen lactating WAD ewes weighing between 22.80 – 26.03 kg on a basal diet of *Panicum maximum* were allotted into 4 treatment groups of 4 replicates each. The experiment was conducted using completely randomized design with 4 replicates. The Mexican sunflower leaf (MSL) replaced wheat bran (WB) gravimetrically at 0,15,30,45%. The control treatment (treatment A) had no MSL but treatments B, C and D had 15, 30 and 45% MSL

as graded replacement for WB. The experiment lasted for 13 weeks. Feed and water were provided ad libitum and routine vaccination and medication administered. Parameters measured include macro minerals i.e Calcium (Ca), Magnesium (Mg), Phosphorus (P), Potassium (K), Sulfur (S), Sodium (Na) in terms of apparent digestibility, balance and retention and micro minerals i.e Copper (Cu), Zinc (Zn), Manganese (Mn) in terms of apparent digestibility, balance and retention. Animals on treatments 0, 15 and 30% MSL were significantly higher ($P < 0.05$) than animals on treatments D in calcium and sulfur digestibility. Mineral balance were not significant ($P > 0.05$) among treatments. Animals on treatment D had less apparent sulfur digestibility and retention. Inclusion of up to 30% MSLM in the diets of lactating ewe appeared most beneficial to sheep as it had no negative effects on mineral profile.

Key words: mineral profile, lactation, West African dwarf ewe

440 Mineral profile of pregnant West African Dwarf ewe fed Mexican sunflower leaf meal based diets. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Minerals are useful indicators of nutritional and physiological status. In view of this a study was conducted to determine the mineral balance of pregnant West African Dwarf (WAD) ewe. Sixteen pregnant WAD ewe weighing between 17.50 and 17.88 kg on a basal diet of *Panicum maximum* were allotted into 4 treatment groups A, B, C and D of 4 replicates each. The MSL replaced wheat bran (WB) gravimetrically at 0, 15, 30, 45%. Treatment A served as control, while animals in treatments B, C and D received Mexican sunflower leaf (MSL) at 15, 30 and 45% respectively. The experiment lasted 5 mo. Feed and water were provided ad libitum and routine vaccination and medication administered. Parameters measured were macro minerals such as Calcium (Ca), Magnesium (Mg), Phosphorus (P), Potassium (K), Sulfur (S), Sodium (Na) in terms of retention, balance and apparent digestibility and micro minerals such as Copper (Cu), Zinc (Zn), Manganese (Mn) in terms of retention, balance and apparent digestibility. The treatment effects on observed variations were not significant ($P > 0.05$) for mineral balance. Animals on treatments 0, 15, and 30% Mexican sunflower leaf meal (MSLM) were significantly higher ($P < 0.05$) in calcium, magnesium and sulfur retention than animals on treatments D (45% MSL). Animals on treatments 0, 15, and 30% MSLM were significantly higher ($P < 0.05$) in sulfur and magnesium apparent digestibility than animals on treatments D (45%MSL). Mineral balance were not significant ($P > 0.05$) among treatments. Inclusion of dietary Mexican sunflower leaf meal up to 30% improved the mineral digestibility, balance and retention of pregnant ewe.

Key words: mineral profile, pregnant ewe, Mexican sunflower leaf meal

441 Nutritive value of palm kernel cake-brewers dried grain (PKC-BDG) based diets supplemented with exogenous enzymes for growing-finishing pigs. A. O. K. Adesehinwa*[1], O. O. Obi[1], M. A. Adesina[2], B. A. Makanjuola[1], O. O. Oluwole[1], T. O. Olorungbohunmi[1], and O. Fagbiye[3], *[1]Institute of Agricultural Research and Training, Obafemi Awolowo University, Ibadan, Oyo State, Nigeria, [2]National Agricultural Extension & Research Liaison Services, Ahmadu Bello University, Zaria, Kaduna State, Nigeria, [3]Federal College of Animal Health & Production Technology, Ibadan, Oyo State, Nigeria.*

Forty-eight (48) growing pigs (averaging 41.20 ± 1.41kg initial body weight) were randomly assigned to 4 dietary treatment groups in a completely randomized design to determine the nutritive value of PKC-BDG based diets supplemented with either of 2 exogenous enzymes (Allzyme Vegpro 5X or Allzyme SSF) or their combination for growing-finishing pigs. The basal control diet was formulated to contain 10, 45, 30, 10 and 5% of maize, palm kernel cake, brewers' dried grain, groundnut cake and micro-nutrients respectively. Pigs were provided ad-libitum access to the diets and water throughout the 56-d duration of the study. Record of weekly weight gain and feed intake was taken and used to compute all the data generated. All the data obtained were subjected to ANOVA and where statistical significance were observed, the means were compared using the Duncan's Multiple Range (DMR) test (Steel and Torrie, 1980). The SAS Computer software package (1988) was used for all statistical analyses. The result of the proximate analysis of the basal diet revealed that the diet contained 7.9, 17.3, 7.5, 6.8 and 9.2% moisture, crude protein, ether extract, crude fiber and ash contents respectively. The feed intake, weight gain, feed conversion ratio and dressing percentage (%) of the pigs were neither significantly ($P > 0.05$) affected by the individual nor combination of the enzymes. The rate of growth of the pigs on the diet supplemented with Allzyme SSF was significantly ($P < 0.05$) superior to that of pigs on the other 3 diets over the 8-week experimental period. However, final weights of the pigs were not significantly ($P > 0.05$) different across the groups. Hence, since there was no superiority in the performance of pigs fed diets containing either or combination of Allzyme Vegpro 5X and SSF relative to the control diet (without enzyme inclusion), it could therefore be concluded that there was no advantage derived from using either or combination of the enzymes in this PKC-BDG based diet for growing-finishing pigs.

Key words: agro-industrial by-product, enzyme utilization, pig feed

442 The influence of low and standard energy diets on efficiency, carcass value, and pork quality in Berkshire swine. M. J. Bishop*[1], H. N. Zerby[1], S. J. Moeller[1], P. S. Kuber[1], J. M. DeRouchey[2], and K. S. Betts[1], *[1]The Ohio State University, Columbus, [2]Kansas State University, Manhattan.*

The present study addressed the influence of dietary-induced, reduced growth rate in purebred Berkshire pigs (n = 140) on subsequent daily growth rate (ADG), pen gain:feed ratio (FC), ultrasonic backfat (BF) and loin area (LMA), and pork loin quality when fed to a target 113.6 kg live weight (LW). A randomized complete block design, conducted in 3 replications, assessed 3-phase dietary regimens fed at standard (SE; ME = 3234, 3243, 3247 kcal/kg, respectively) and low (LE; ME = 2857, 2864, and 2868 kcal/kg, respectively) energy content with TID lysine:ME ratios of 2.90, 2.37, and 2.06 g/Mcal in phases 1, 2, and 3, respectively. Dietary treatment resulted in harvest at 6 (6) and 7 (7) months of pig age. To avoid total confounding harvest date with pork quality assessment, litter-mate pigs were randomly assigned to one of 4 treatments (6LE, 6SE, 7LE, and 7SE), with 6LE and 7LE representing harvest weight outside of a desired packer range. Pig weight and pen FC were measured weekly. Loin quality data were collected at 24h postmortem. Data were analyzed using mixed model procedures with treatment as a fixed effect, litter within replication as a random effect for all traits, and a random harvest date effect for meat quality traits. As expected, 6LE (0.62 kg/d) and 7LE pigs (0.61 kg/d) grew at a reduced rate when compared with 6SE (0.82 kg/d) and 7SE (0.81 kg/d) ($P < 0.05$); however, 6LE and 7LE pigs consumed more feed and had poorer FC (0.19 kg/kg) when compared with 6SE (0.27 kg/kg) and 7SE (0.28 kg/kg) pens of pigs ($P < 0.05$). While 7LE pigs had less BF than 6SE pigs (20.3 vs. 22.8 mm, $P < 0.05$) at harvest, they also had less LMA (35.0 vs 37.5 cm2, $P < 0.05$), resulting in no difference in estimated lean (49.1 vs 49.2%, respectively). Loin color (3.09 vs. 3.09), L* (51.0 vs. 49.9), ultimate pH (5.91 vs. 5.91), marbling score (2.01 vs. 2.04) and slice shear force (12.9 kg vs. 12.1 kg) were not different between 7LE and 6SE, respectively. Feeding a lower energy diet reduced FC, and did not improve lean content or pork quality; therefore, SE diets offer the best economic return when feeding Berkshire pigs.

Key words: pork quality, swine, carcass composition

443 Effects of ractopamine on performance, carcass and meat quality in purebred Berkshire swine. K. S. Betts*[1], S. J. Moeller[1], H. N. Zerby[1], J. M. DeRouchey[2], M. D. Cressman[1], M. J. Bishop[1], A. S. Gress[1], and F. L. Fluharty[1], *[1]The Ohio State University, Columbus, [2]Kansas State University, Manhattan.*

The study evaluated the effects of a 28 d pre-harvest ractopamine (RAC) feeding program on average daily gain (ADG), feed conversion efficiency (FC), backfat (BF) and loin muscle area (LMA) and pork quality in purebred Berkshire pigs (n = 62) utilizing a randomized complete block design with 3 treatments (Control (C) 0 ppm; RAC5, 5.0 ppm; RAC10; 10 ppm) in 2 replicates. Litter-mate pigs were randomly assigned to each RAC treatment. Ultrasonic BF and LMA and pig weight were measured at 0, 7, 14, 21, and 28 d of the feeding period. Carcass composition and pork quality (NPPC, 2000; visual color (VC), marbling (M), firmness (F), wetness (W), ultimate pH, and Minolta L*, a*, b* were assessed at 24h post-harvest. Warner-Bratzler shear force (WBSF) was assessed on one chop after a 7 d aging period. Mixed model procedures were used in analyses with fixed effects of treatment and a random effect of litter within replicate. Live weight (93.5 kg) and BF (20 mm) were not different, while LMA was different (C = 32.3 cm2; RAC5 = 34.4 cm2, RAC10 = 33.1 cm2; $P < 0.05$) at 0 d. Daily gain was numerically greater from 0 to 7 d and significantly greater from 0 to 14, 0 to 21, and 0 to 28 d for pigs fed RAC when compared with pigs fed a C diet ($P < 0.05$). Pigs fed RAC10 had greater ADG than pigs fed RAC5 from 0 to 21 and 0 to 28 d. At 21 d, RAC5 and RAC10 pigs had greater LMA than C, at 28 d LMA of RAC5 was intermediate and not different from either C or RAC10 with C different from RAC10 ($P < 0.05$), and carcass LMA of RAC10 was greater than RAC5 and C. No differences were observed across treatments for ultrasonic or carcass BF. Trends for greater lean percentage (LP) ($P = 0.06$) and improved gain feed ratio (G:F) ($P = 0.11$), whereby RAC10 (49.8%, 0.31 kg/kg) carcasses had numerically greater lean LP and G:F than RAC5 (47.8%, 0.28 kg/kg) and C (47.8%, 0.26 kg/kg) carcasses. Neither RAC5 or RAC10 diets influenced fresh loin quality with no differences in VC, M, F, W, L* or WBSF, whereas ultimate

pH was greater (0.06 units, $P < 0.05$) for the RAC10 treatment when compared with C. Ractopamine improved value and efficiency without negatively influencing quality.

Key words: swine, ractopamine, meat quality

444 The effects of diet ingredients on gastric ulceration and salivary pH in gestating sows. S. L. Wisdom*[1], B. T. Richert[1], J. S. Radcliffe[1], D. C. Lay Jr.[2], and J. N. Marchant-Forde[2], *[1]Purdue University, West Lafayette, IN, [2]USDA-ARS-LBRU, West Lafayette, IN.*

Diet and stress are thought to have significant influence on the development of ulceration of the pars esophagea (UPE) region of the stomach in swine. The objective of this experiment was to determine the effects of diet ingredients on UPE and salivary pH in breeding sows. Forty-eight sows were randomly assigned to 1 of 4 treatment groups with parities (avg. 1.81 ± 0.21) balanced across treatments. Treatments were: 1) control, a commercial gestating sow diet; 2) proton pump inhibitor, a commercial gestating sow diet plus a single daily dose of 60 mg omeprazole; 3) sodium bicarbonate, a commercial gestating sow diet with sodium bicarbonate included at 2% of the diet; 4) roughage, a high fiber diet (25% SB hulls) fed at a higher feed intake to an equal total ME as control. Treatments began on d 30 of gestation and all diets were fed once per day. All sows underwent initial endoscopic evaluation at d 30 to assess UPE already present and initial salivary pH was measured. Salivary pH and UPE were also investigated at d 60 and d 90 of gestation. Ulcers were scored using a 7-point scale, ranging from 0, showing no visible lesions, to 6, showing deep ulcerations in > 20% of the pars esophagea. Salivary pH was measured 5 times throughout the day at 0700 h, 1000 h, 1300 h, 1600 h and 1900 h. Data were analyzed using mixed procedure of SAS. UPE differed between groups before treatment was applied ($P < 0.01$), but using initial UPE as a covariate, there were no effects of treatment on d 60 or d 90 (both $P > 0.05$). Treatment also had no effect on litter size, piglet weight, or lactation feed intake ($P > 0.05$). The average UPE score was 1.06 ± 0.23 ranging from 0 to 6, with the largest individual score difference changing from score 5 to 0. Salivary pH did not correlate with UPE and there was no treatment effect (both $P > 0.05$), but there was a change in salivary pH throughout the day ($P < 0.01$) with the highest pH (8.99 ± 0.05) at 0700 h and lowest pH (8.88 ± 0.02) at 1300 h. The results indicate that the selected treatments did not influence UPE. To evaluate the impact of natural changes in salivary pH, further investigations are needed.

Key words: swine, gastric ulcer, salivary pH

445 Effect of dietary glutamine supplementation on the apparent total tract digestibility of energy and nutrients and jejunal gene expression in weaned piglets. A. Chen*, Y. Xiao, T. Wu, Q. Hong, and C. Yang, *Zhejiang University, Hangzhou, Zhejiang, China.*

Glutamine plays essential roles in the beneficial function to improve nutrition status in young mammals. This study was conducted to examine the effect of dietary L-glutamine supplementation on apparent total tract digestibility (ATTD) of dietary energy and nutrients in 21-d-old weaned piglets, and the expression of jejunal gene related to intestinal health. A total of 128 piglets were blocked by litter and assigned to one of 2 group, representing supplementation with 1% L-glutamine (wt:wt) or isonitrogenous L-alanine (control) to corn- and soybean meal-based diets. After 10-d treatment, the fresh fecal samples were collected to determine apparent total tract digestibility of dry matter (DM), digestible energy (DE) crude protein (CP) and amino acid (AA), and jejunum were obtained to access the expression of peroxisome proliferator-activated receptor gamma (PPARγ), mammalian target of rapamycin complex 1 (mTORC1) and pyruvate kinase (PK). The results show that the apparent total tract digestibility of energy or nutrients was higher ($P < 0.05$) in dietary glutamine supplementation piglets. The total tract digestibility of DM, DE, and CP averaged 81.02, 82.18, and 86.73%, respectively, for glutamine treatment piglets and 74.29, 76.79, and 83.83%, respectively, for control piglets. A significant increase of AA digestibility was observed ($P < 0.01$) except for alanine which was reduced by 8.19% ($P < 0.01$). Besides, dietary glutamine supplementation resulted in increased expression of jejunal mTORC1 by 22.10% but decreased PK by 29.75% ($P < 0.05$). Jejunal PPARγ mRNA abundance was not affected by glutamine treatment. In conclusion, 1% L-glutamine supplementation to post-weaned piglet diet enhanced the apparent total tract digestibility of energy or nutrients and modified jejunal gene expression.

Key words: glutamine, digestibility, gene expression

446 Effect of feeding Bt (MON810) maize to pigs from 12 days post-weaning for 110 days on growth performance, body composition, carcass characteristics, organ weights and intestinal morphology. S. G. Buzoianu*[1,2], M. C. Walsh[1], G. E. Gardiner[2], M. C. Rea[3], R. P. Ross[3], and P. G. Lawlor[1], *[1]Pig Development Department, Moorepark Animal and Grassland Research and Innovation Centre, Teagasc, Fermoy, Co. Cork, Ireland, [2]Department of Chemical and Life Sciences, Waterford Institute of Technology, Waterford, Ireland, [3]Moorepark Food Research Centre, Teagasc, Fermoy, Co. Cork, Ireland.*

Increased use of genetically modified (GM) ingredients worldwide makes sourcing non–GM ingredients more difficult and expensive. The aim of this study was to assess the effects of feeding GM Bt (MON810) maize to pigs from 12 d post–weaning to slaughter for 110 d on growth performance, body composition, carcass characteristics, organ weights and intestinal health. Seventy 2 male pigs (10.7 ± 1.9 kg) were blocked by weight and litter and assigned to one of 4 treatments: T1: non-GM maize (nGMm) to slaughter; T2: GM maize (GMm) to slaughter; T: nGMm for 30 d followed by GMm to slaughter; T4: GMm for 30 d followed by nGMm to slaughter. Individual BW and feed disappearance were recorded on d 0, 30, 60, 100 and at slaughter. Body composition (fat %, bone mineral content and area bone mineral density) was determined by dual energy X-ray absorptiometry on d 80 of the study (n = 10/trt). On d 110 of the study, 10 pigs/trt were slaughtered and the heart, kidney, spleen, liver, stomach and small intestine (SI) were removed and weighed. Sections of SI were processed for histological examination of villus height, width, crypt depth and goblet cell number/villus. Carcass weight was also recorded at slaughter. All data were analyzed as a one-factor ANOVA using the GLM procedure of SAS. Organ weights were analyzed using body weight at slaughter as a covariate in the model. There was no treatment effect for body composition. Growth parameters (ADG, F:G and ADFI, BW at slaughter) were not influenced by treatment. Organ and carcass weight and kill-out percentage did not differ between treatments. Values for all parameters measured were within normal ranges for pigs of a similar age and weight. Intestinal morphology was not affected by treatment. In conclusion, feeding GM Bt maize from 12 d post weaning to slaughter had no adverse effect on pig growth performance, body composition, organ weights, carcass characteristics or intestinal morphology. This research will help assure both farmers and consumers as to the safety of GM Bt maize.

Key words: Bt maize, pig health, MON810

447 Effect of feeding genetically modified Bt (MON810) maize to pigs from 12 days post-weaning for 110 days on serum and urine biochemistry. S. G. Buzoianu*[1,2], M. C. Walsh[1], G. E. Gardiner[2], M. C. Rea[3], R. P. Ross[3], and P. G. Lawlor[1], *[1]Pig Development Department, Moorepark Animal and Grassland Research and Innovation Centre, Teagasc, Fermoy, Co. Cork, Ireland, [2]Department of Chemical and Life Sciences, Waterford Institute of Technology, Waterford, Ireland, [3]Moorepark Food Research Centre, Teagasc, Fermoy, Co. Cork, Ireland.*

Perceived health risks are among the main reasons for low acceptability of genetically modified (GM) feed ingredients. The aim of this study was to evaluate the effect of feeding GM maize to pigs from 12 d post-weaning to slaughter for 110 d on health as assessed by serum and urine biochemistry. Seventy-two entire male pigs (10.7 ± 1.9 kg live weight) were blocked by weight and litter and randomly assigned to 1 of 4 treatments (d 0); T1: non-GM maize (nGMm) in diet to d 110; T2: GM maize (GMm) in diet to d 110; T3: nGMm in diet for 30 d followed by GMm to d 110; T4: GMm in diet for 30 d followed by nGMm to d 110. Serum collected on d 0, 30, 60, 100 and 110 (n = 10/trt) was analyzed for liver and kidney health indicators (alanine aminotransferase, aspartate aminotransferase (AST), γ-glutamyl transferase, alkaline phosphatase, total protein (TP), urea (SU) and creatinine (SC). Creatinine and protein were measured in urine collected on d 110 to further assess kidney health. Statistical analysis was performed by a one–factor ANOVA using the GLM procedure of SAS. For serum biochemistry, d 0 values were used as a covariate in the model. On d 30, SU was lower for T3 compared with T1, T2 and T4 (2.9 vs 3.9, 4.7 and 4.2 mmol/L, respectively; SEM = 0.37; $P = 0.03$). On d 110, there was a higher concentration of SC in pigs fed T3 and T4 compared with T1 and T2 (181.5 and 177.6 vs 163.9 and 155.9 μmol/L; SEM = 5.63; $P = 0.001$). Serum TP was lower on d 110 in pigs fed T4 compared with T1, T2 and T3 (57 vs 60.5, 59.3, 61.1 g/L; SEM = 1.62; $P = 0.02$). On d 110, serum AST tended to be lower in pigs fed T2 compared with T1 (37.2 vs 53.5 units/L; SEM = 4.01; $P = 0.06$). Although statistically significant differences were found, values remained within the normal ranges for pigs of similar age and weight. No parameter was consistently affected throughout the study, therefore changes detected are unlikely to be of clinical importance. This study shows no adverse effects of feeding Bt GMm to pigs between weaning and slaughter on serum or urine biochemistry and should help to assure consumers as to the safety of Bt maize.

Key words: Bt maize, pig health, MON810

448 Supplementation of xylanase to improve DDGS and corn germ meal utilization by finishing pigs as measured by performance and carcass yield in a commercial environment. D. D. Hall*[1], M. U. Steidinger[2], J. C. Remus[3], M. Hruby[3], and A. J. Veldkamp[3], *[1]Hall Farms Consulting, LLC, Noblesville, IN, [2]Swine Nutrition Services, Anchor, IL, [3]Danisco Animal Nutrition, Waukesha, WI.*

Two experiments were conducted to test a hypothesis that dietary supplementation of xylanase (Danisco Porzyme 9302 @ 4,000 units/kg) improves nutrient utilization of commercially available corn co-products in diets consisting of 30% dried distillers grains and solubles (DDGS) or a combination of 30%DDGS and 20% corn germ meal (CGM) by growing-finishing pigs. In both experiments, pigs were housed at 30–32 pigs/pen with pen space at 6.75–7.4 sq.ft./pig. Each trial consisted of 8 reps (Exp. 1 initial wt. 26kg) or 7 reps (Exp. 2 initial wt. 33kg) Statistical analysis (SAS.JMP) was block design with block = (rep. initial wt.). All diets had equal phytase addition (Danisco Phyzyme XP@750 units/kg). Withdrawal of DDGS was tested in 2 × 2 factorial design with Xylanase in both experiments (Table 1). There were no differences in daily gain or feed intake in Exp. 1. In Exp. 2, addition of CGM reduced ADG compared with Control (DDGS) fed pigs (d43–97; 0.932 vs 0.841 kg/d;$P < 0.05$). Feed/gain ratio was improved in both Exp. 1 (d41–81;$P < 0.06$) and Exp. 2(d43–97;$P < 0.001$) by addition of xylanase to the corn co-product diets of DDGS or DDGS + CGM (Table 1). Supplementation of xylanase and DDGS withdrawal resulted in carcass yield equal to the corn-soy control fed pigs in both experiments (Table 1).

449 Monitoring muscle proteolysis in pig plasma. K. L. Price* and J. Escobar, *Virginia Polytechnic Institute and State University, Blacksburg.*

Nτ-methyl-L-histidine (NτMH, CAS number 332-80-9, archaic 3-methylhistidine) is released from skeletal muscle during proteolysis, cannot be reused for protein synthesis, and it is excreted from the body in urine. In humans, free NτMH is the main form found in plasma and urine. In healthy rodents NτMH is predominately found in the acetylated form (Ac-NτMH). Furthermore, changes in urinary Ac-NτMH, and not free NτMH, are associated with muscle breakdown during sickness. Our objective was to quantify free and Ac-NτMH in pig plasma during health and disease. We chose plasma over urine because blood samples are usually easier, more reliable, and faster to collect than urine samples. Plasma samples were subjected or not to acid hydrolysis (6 M HCl for 24 h at 110°C) to quantify total and free NτMH, respectively. Plasma samples were then subjected to pre-column derivatization with phenylisothiocyanate, and separation and quantification using HPLC. To determine how much NτMH was acetylated, free NτMH was subtracted from total NτMH. Pigs (33.41 ± 1.05 kg, n = 9) were fitted with indwelling jugular catheters. Blood samples were collected before ($t = 0$) and 12 h after a bolus of *E. coli*-derived lipopolysaccharide (LPS, 10 μg/kg BW i.v.). In healthy pig plasma ($t = 0$), the major representation of NτMH was in the acetylated form (71% Ac-NτMH). Plasma free NτMH was not different ($P = 0.490$) between $t = 0$ and $t = 12$ (30.60 ± 1.80 μM vs 29.14 ± 0.93 μM, respectively). Total plasma NτMH increased 39% ($P = 0.048$) from 86.4 ± 8.6 μM

at t = 0 to 120.2 ± 13.2 μM at t = 12. Ac-NτMH increased 56% (P = 0.0546) from 57.3 ± 9.2 μM at t = 0 to 89.6 ± 12.6 μM. Finally, plasma concentrations of 3-methyl-L-histidine (3MH, CAS number 368–16–1, archaic 1-methylhistidine) were not detected at either time point. In summary, our findings indicate that a) 3MH is not detectable in plasma; b) free NτMH remained unaffected after LPS treatment and hence may not be a reliable indicator of muscle proteolysis; and c) the majority of plasma NτMH is present in the acetylated form in health and sickness. Additionally, our results demonstrate that to accurately monitor NτMH fluctuations, pig plasma needs to be acid hydrolyzed.

Key words: methylhistidine, HPLC, acid hydrolysis

450 Effect of independent laboratory assessment, freezing volume, and other factors influencing post-thaw quality of frozen boar sperm. J. M. Ringwelski* and R. V. Knox, *Department of Animal Sciences, University of Illinois, Champaign-Urbana.*

Frozen boar sperm shows lower fertility compared with liquid semen. This has been partly classified based on post-thaw lab assessments. Experiment 1 was performed to evaluate effects of independent lab assessment of post-thaw motility following freezing in 5 mL (Lab 1) or 0.5 mL (Lab 2) straws. Ejaculates(n = 117) from 27 mature boars of Landrace(n = 5), Large White(n = 15), Duroc(n = 5), and Other(n = 2) breeds were collected and frozen across seasons (winter-summer) from Feb to Jun 2010. Ejaculates were collected, diluted 1:1 in Modena, and held at 17°C until processing(Lab 1) or upon arrival the next day(Lab 2). All samples were frozen within 24 h of collection. Once frozen, straws were stored at −196°C until analysis. Straws were thawed at 50°C for 45 s for 5 mL straws and 20 s for 0.5 mL straws and evaluated at 37°C upon thawing. Data were analyzed using SAS for the effects of lab and volume, breed and season. There was no effect (P > 0.05) of lab and volume(47.4 vs. 49.8%), breed or season on motility. Experiment 2 was conducted to determine the effect of independent lab on pre-freeze concentration and motility, and also effects of breed, season, and collection number on post thaw quality measures in 0.5 mL straws. Straws(n = 47) from 26 boars were thawed and evaluated for motility and membrane integrity using propidium iodide. Data were analyzed in SAS for effects of lab assessments on pre-freeze motility, concentration, and total sperm cells. Effect of breed, season, and collection number on motility and viability were also evaluated in 0.5 mL straws. Measures of concentration (0.82), motility (0.78), and total cells (0.67) were all positively related for independent lab assessments (P < 0.001). Motility (47%) and membrane integrity (51%) were not affected by breed, season, or collection number (P > 0.05). The results of these experiments suggest that independent lab assessments post-thaw can be highly related, and there is no significant difference related to freezing in 5 or 0.5 mL straws. In boars in active collection rotations, breed and season had no impact on post-thaw quality of frozen boar sperm.

Key words: boar, spermatozoa, cryopreservation

451 Characteristics of the work habits and demographics of caretakers on swine finishing facilities in Ohio. S. M. Crawford*[1], S. J. Moeller[1], P. H. Hemsworth[2], C. C. Croney[1], N. A. Botheras[1], and H. N. Zerby[1], *[1]Ohio State University, Columbus, [2]University of Melbourne, Melbourne, Victoria, Australia.*

Contract finishing farms representing 2 integrated swine entities (n = 32) within Ohio were observed to study daily work habits and characterize the demographics of the caretaker(s) (n = 40) working on the farms. The farms used in the research housed a minimum of 1000 pigs. A standard observer visited each farm for 2 consecutive days, at a time designated by the caretakers, and recorded human behaviors during the daily work. A questionnaire was administered to collect demographic data. Of the 40 persons observed, 33 completed the questionnaire. The data was summarized to characterize attributes that may influence animal care and caretakers attitudes and actions. On average, the caretakers were 41.2 yrs of age (range 21 to 60 yrs), had worked with pigs for 16.9 yrs (range 1 to 40 yrs; mode = 8 yrs), and worked in contract finishing for 7.4 yrs (range 1 to 20 yrs; mode = 1 yr). Males were the predominant gender (93.9% male; 6.1% female). Thirty caretakers indicated employment off-farm, including responses such as grain farming, dairy farming, beef feedlot manager, electrician, truck driver, postal worker, mechanic, seed sales, plumber, and financial services. When asked why they initiated a finishing production contract, responses included diversification, enjoyment, income, and risk reduction. Thirty-one of 33 caretakers had completed Pork Quality Assurance Plus® training. On observation days, caretakers spent 36.43 s per pen, with a wide range from 5.76 to 128.8 s. A significant association was observed between the time spent per pen and the number of words spoken (r = 0.71) and verbal sounds (whistles, hoots, etc) (r = 0.72). Salivary cortisol levels that were collected from 2 or 3 pigs in each pen, over a 2-d period, were different (P < 0.01) indicating different stress levels across farms. The summary results are indicative of the large variation that is observed within contract finishing farms within the given integrated system and suggest that caretakers may need additional training to improve animal well-being. Also, the knowledge of these variations can aid in determining training/education needs for the caretakers in the future.

Key words: pigs, caretaker

452 Survey of animal welfare and dairy management practices on 91 Organic Valley dairy farms. W. K. Fulwider*, *CROPP Cooperative, LaFarge, WI.*

The objective of this survey was to evaluate animal welfare on Organic Valley dairies across the United States. Cows were scored on 91 dairies between May 10, 2010 and January 20, 2011 in California, Indiana, Iowa, Michigan, North Carolina, Ohio, Oregon, Pennsylvania, Tennessee, Vermont, and Wisconsin. Dairies were selected from tight knit clusters in each area so the most farms possible would be surveyed in one week. All cows on each dairy were scored. Data were collected on body condition, locomotion, hygiene, hock lesions, broken and docked tails, hair coat, housing, and euthanasia. Body condition scores ranged from 1 to 5, with 1 being thin and 5 heavy. The percentage of cows with body condition score of 1 was 0.1, 2 was 69.1, 3 was 29.1, 4 was 4.8, and 5 was 0. Locomotion scores ranged from 1 to 5, with 1 being excellent and 5 unable to bear weight on at least one limb. Percentage of cows with locomotion score 1 were 97.0, 2 were 2.1, 3 were 1.0, 4 and 5 were 0. Hygiene scores ranged from 1 to 5, with 1 being clean and 5 soiled. Percentage of cows with hygiene scores of 1 were 67.2, 2.0 were 29.5, 3.0 were 1.9, 4.0 were 0.4, and 5.0 were 0. A tarsal score of 1 represented hair loss, 2 was moderate, and 3 indicated severe swelling. Percentages of cows with hock score 1 were 13.4, 2 were 1.1, and 3 were 0.1. A knee score of 1 represented hair loss, 2 swelling, and 3 severe swelling. Percentages of cows with knee score 1 were 2.0, 2 were 0.2, and 3 were 0. Percentage of cows with broken tails was 3.8. Percentage of cows with docked tails before organic transition or due to injury was 2.8. No bald spots, lice, or mange were observed on cow hair coats. Housing consisted of 32 farms with tie-stalls, 28 free-stalls, 18 bedded packs, 7 stanchion barns, and 4 other. Some farms had more than one housing type. Gun was the preferred euthanasia method (92.1), followed by i.v. (7.9). Bedding cows housed due to inclement weather on a daily basis may improve hygiene scores. Incidence of broken tails was higher on larger farms with hired milkers. This is the most comprehensive survey to date of animal welfare and management on US organic dairy farms.

Key words: dairy, organic, welfare

453 A dairy quality assurance program for New Mexico dairy producers. F. A. Rivera*[1], G. R. Hagevoort[1], M. L. Kinsel[2], and M. A. Smith[1], *[1]NMSU Ag Science Center, Clovis, NM, [2]Agricultural Information Management Inc., Ellensburg, WA.*

The New Mexico Dairy Quality Assurance program was developed to evaluate management practices on dairies including biosecurity, animal care, calf management, milking barn management, nutrition, reproduction and animal health management. Input was obtained through a combination of producer interviews and animal observations. The program was developed to be compatible with the NMPF's FARM program (Farmers Assuring Responsible Management), but additionally address particular issues facing New Mexico producers. To date, about 25% of New Mexico's dairy producers have participated in the program. Many of the interview questions refer to the use of protocols for standardization of management practices. Eighty-three percent of producers stated they do have a written form of a herd health plan. All participating producers stated they had protocols for fresh cows, udder health, worker training, and non-ambulatory animals; however, most these protocols are not in a written form indicating a high level of reliance on verbal training of employees on procedures and protocols. Thirty 6 percent of producers indicated written protocols for fresh cows, while 36% indicated written udder health protocols, 37% for worker training, and 39% for non-ambulatory animals. Less than one half of the producers indicated to have protocols directly pertaining to biosecurity. Ninety-four percent of producers record withdrawal periods: 60% of which utilize some computer software. Utilizing the FARM method to determine the number of observations required to observe animal management and welfare practices proved to be a challenge on the large dairies in New Mexico (average herd size 2200). Specifically, dairies with large heifer programs with limited body condition or locomotion score problems tend to mask issues apparent in the adult milking strings. Results on New Mexico dairies showed that including a large heifer program in the evaluation can cut the percentage of body condition or locomotion scores in half, to a level where it seems not to warrant any further action and may go unreported.

Key words: quality assurance program, animal welfare, biosecurity

454 Effect of prior grazing experiences on grazing behavior and performance of lactating cows. F. Lopes*[1], N. M. Esser[1], P. C. Hoffman[1], W. K. Coblentz[2], and D. K. Combs[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]USDA-ARS, Marshfield, WI.*

The impact of grazing experiences early in life on grazing behavior and performance of lactating dairy heifers was evaluated in a 3-year study. Sixty-four Holstein and Holstein x Jersey calves were randomly assigned to one of 4 treatments (n = 16) in 2008. Treatments were combinations of managing heifers in confinement or on pasture: T1, grazed 2008 and 2009; T2, grazed 2008 and confined in 2009; T3, confined in 2008 and grazed in 2009; T4, confined in 2008 and 2009. All animals grazed as lactating cows in 2010. In 2008, T1 and T2 heifers were on pasture from August through October, and T3 and T4 were housed in bedded pack pens. In year 2, T1 and T3 grazed from June–September, 2009, while T2 and T4 remained in confinement. All 4 treatment groups calved between January and April, 2010, and grazed as primiparous cows from May through July. In 2009 and 2010 grazing activities were assessed by visual observations (9h/d) and by measuring movements with GPS units attached to each animal. Daily milk was also recorded in 2010. All data were analyzed using proc mixed (SAS) as a completely randomized design, with treatment and day as fixed effects. Paddock was the random effect. In 2009 on d1, heifers that had grazed in 2008 spent more time grazing than heifers with no grazing experience (78 vs. 35% of the time, $P < 0.05$). In 2010 on d1, time spent grazing was 62, 59, 76, and 13% for T1, T2, T3 and T4, respectively, with T4 ranking lowest ($P < 0.05$). In 2009 and 2010 on d 1–3, experienced heifers walked a greater distance in the pasture than inexperienced animals. Milk production was lowest initially for cows with no previous grazing experience (T4). Animals that had not grazed in 2009 (T2 and T4) produced less milk than those that had grazed in 2009 (T 1 and T3) on d 1–3. However, average (61d) daily milk over the entire experiment was not significantly different ($P > 0.05$) (30.5, 30.1, 31.5 and 29.6 kg for T1, T2, T3 and T4). Results indicate that previous grazing experience can impact behavior and milk production during the first 3 d on pasture. After that, no behavioral differences ($P > 0.05$) were noted in after d-3 in either study.

Key words: heifers, behavior, grazing

455 Effects of acute and chronic stress on immune- and inflammatory-response gene expression in beef calves. C. Terrill*, T. Friend, J. Sawyer, P. Riggs, L. Berghman, S. Garey, D. Riley, A. Adams, and M. Carter, *Texas A&M University.*

Transport stress research has shown correlations between stress, morbidity, and mortality in calves subjected to the traditional US market system, indicating compromised immune function. The objective of this study was to determine if expression of specific immune- and inflammatory-response genes differed between calves that were subjected to an acute stress (AS, weaned and handled for 1.5 h) and a chronic stress (CS, weaned, handled and transported over 3–4 d. Two groups of 40 calves, *Bos taurus* (n = 20) and *Bos indicus* cross (n = 20), weighing 181 to 250 kg were used in this study. Jugular venipuncture blood samples (9mL) were collected from AS calves within 1.5 h of separation from their dam, and from CS calves upon arrival at a north Texas feed yard. For gene expression analysis, RNA was extracted from leukocytes obtained from blood samples by filtration. The remaining sample was then centrifuged for measurement of plasma cortisol. A diagonal covariance mixed model ANOVA was used to determine effects of treatment, breed, and breed by treatment interaction on cortisol concentrations. Mean cortisol did not differ significantly between AS (16.40 ± 1.08ng/ml) and CS calves (18.06 ± 1.14ng/ml) ($P > 0.296$). Expression values for each gene were analyzed using linear models that considered the effects of treatment (AS and CS) and breed (*Bos taurus* and *Bos indicus*). An interaction of effects was detected for 3 genes ($P < 0.029$). Breed was influential for 5 genes ($P < 0.046$). After adjustment for multiple comparisons in expression values for AS and CS, significant differences were found in relative quantification for 33 genes ($P < 0.047$), with mean treatment differences ranging from 0.309 – 913.19. Similar cortisol concentrations in both the AS and CS calves indicate that both groups experienced significant stress. However, the gene expression differences show a greater immune response in the calves subjected to CS, indicating that these measurements may be more useful than cortisol for identifying detrimental long-term stress.

Key words: transport, cortisol, gene expression

456 Estimation of genetic parameters for gait in Canadian Holstein cows. N. Chapinal*[1,2], F. Miglior[3,4], A. Sewalem[3,4], A. M. de Passille[5], J. Rushen[5], M. A. G. von Keyserlingk[2], and D. M. Weary[2], *[1]Department of Population Medicine, University of Guelph, Guelph, ON, Canada, [2]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [3]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, ON, Canada, [4]Canadian Dairy Network, Guelph, ON, Canada, [5]Agriculture and Agri-Food Canada, Agassiz, BC, Canada.*

Lameness is one the most important welfare and economic problems in modern dairy herds. No direct genetic selection for lameness resistance has been done so far. The objective of this study was to estimate the genetic parameters of gait for Holstein cows from a research farm in British Columbia. A total of 265 cows had their gait assessed from 1 to 26 times (mean ± SD = 7 ± 5 times) throughout their productive lives. Data were collected in different experimental studies, but only cows assigned to control groups, or data collected before treatments were applied were used. Overall gait was assessed using a 1-to-5 scale with half-integers where 1 = not lame and 5 = severely lame, based on 6 different gait components (head bob, back arch, asymmetry of the steps, tracking-up, joint flexion and reluctance to bear weigh in a particular limb). A linear animal model was used to analyze overall gait. The statistical model included the fixed effects of parity (1 to 9), the interaction between year and season of calving (2001 to 2009, 2 seasons/yr), the interaction between experiment and observer (11 experiments and 6 observers), the linear and quadratic regression of time at gait assessment (expressed as number of days before or after calving, if in dry or lactation period, respectively). The random effects of the model included animal, permanent environment and residual. Variance components were estimated with REML procedure using a DMU software package. Estimate of heritability for overall gait was 0.09. Research is in progress to estimate variance components of individual gait components.

Key words: lameness, heritability, linear animal model

457 Automatic estimation of body condition score from digital images. M. Caccamo*[1], G. Azzaro[1], G. Gallo[2], G. C. Guarnera[2], J. D. Ferguson[3], and G. Licitra[1,4], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]IPLAB, Catania University, Catania, Italy, [3]University of Pennsylvania, PA, [4]DISPA, Catania University, Catania, Italy.*

Body condition score (BCS) is an indicator of cows' health status based on visual or tactile inspection. The human intervention in assessing BCS is the main limiting factor since it is subjective and requires time and well-trained experts. For these reasons, to fully automate scoring, or at least to assist the human expert in this task, state-of-the-art computer vision is an important application that can reduce subjectivity and speed the scoring process. The objective of this study was to explore the possibility to efficiently automate the process of quantitatively estimating the BCS of cows using images acquired by commercial low-cost digital cameras. Images were acquired using 2 cameras at 3 m from the ground placed above an exit alley from the milking robot in such a position to allow capturing images of the dorsal area of cows. The BCS of each cow was estimated on site by 2 technicians and properly associated to the cows' images. A statistical region merging algorithm was applied to the H channel of the hue, saturation and value (HSV) color space to segment images. Cows' shapes were extracted from the binarized images, cleaned from noise and aligned in a unique reference frame. The standardized contours were described then in terms of arc-length parameterization with a uniform sampling. A standard principal component analysis was applied to determine the components describing the many ways in which the body shape of different cows tend to deviate from the average shape. This mathematical representation allowed a mapping of cow's shapes into a vector space, whose metric was used for automatic estimation of BCS through regression approach. The proposed method was tested on a benchmark data set containing 148 images available through the Internet (www.corfilac.it/bcs) by means of the leave one out cross validation procedure and the regression error characteristic curves. Experimental results confirmed the effectiveness of the proposed technique (mean error 0.26) that outperformed other state-of-the-art approaches proposed in the context of dairy cattle research.

Key words: body condition score, digital imaging, body shape

458 Use of infrared thermography to identify thermoregulatory differences between heat-sensitive and heat-tolerant breeds of *Bos taurus* cattle. R. E. Chaffin[1], K. J. Hoernig[1], J. S. Johnson[1], J. K. Bryant[1], B. Scharf[1], D. K. Kishore[1], P. A. Eichen[1], E. S. Dierenfeld[2], and D. E. Spiers*[1], *[1]University of Missouri, Columbia, [2]Novus International, Inc., St. Charles, MO.*

Previous studies have shown that a breed of heat-tolerant *Bos taurus* cattle (i.e., Romosinuano; RO) maintain a lower core temperature than more heat-sensitive Angus cattle (ANG) even with a lower respiration rate during heat stress. A new study was performed to further identify regional skin differences between RO (Florida-derived; n = 5) and ANG (Missouri/Oklahoma-derived; n = 10). Animals were tested in the Brody Environmental Chambers (University of Missouri), with an adjustment period of 8 d at thermoneutrality (TN; 19–22°C), followed by 2 weeks of cycling heat stress (HS; 26–36°C). A thermal imaging camera (Fluke Corp., Everett, WA) was used to create thermal images of hooves, legs, rump, and shoulder areas during TN, early HS (HS1; d 10) and late HS (HS2; d 21) periods. Measured skin sites were shaved before the study, with rump and hoof sites being ~10x10cm. Only maximum values from each site were used to avoid wet areas. Temperature of all sites increased in the heat, with no shift from HS1 to HS2. Rump and hoof sites showed no differences across breed. ANG shoulder temperature was 1.9°C higher ($P < 0.05$) than ROMO in the heat. In contrast, overall leg temperature of RO was 1.9°C higher ($P < 0.05$) than ANG, with greater breed differences ($P < 0.05$) at TN and HS1 (2.3 and 2.0°C respectively), and no difference after adaptation at HS2. These results suggest that increased heat dissipation through the leg at all air temperatures may be a major avenue by which the heat-tolerant breed may efficiently radiate excess heat to the environment and maintain a lower core body temperature.

Key words: radiant, breed, heat stress

459 Effect of climatic on body temperature of dairy cows. J. C. Lees* and J. B. Gaughan, *The University of Queensland, Australia.*

It is generally accepted that body temperature (BT) is a reliable indicator of heat load status. However the effects of previous heat load on BT have not been determined. The aim of this study was to determine the effect of climate on BT, and to establish if BT lags changes in climatic conditions. BT of lactating Holstein-Friesian cows (n = 83) were collected at 10 min intervals over 5 to 7 d using temperature loggers (HOBO Pro V2) placed in the vagina. Cows had access to a feed pad and pasture and were kept outside in a sub-tropical environment. Ambient temperature (TA), black globe temperature (BG), and relative humidity (RH) were obtained every 10 min from an on-site weather station. Data were obtained during summer Jan/Feb (E), winter Jul/Aug (M) and summer Nov/Dec (L). Hourly means for BT, THI, BG, TA and RH were calculated for E, M and L. Multivariate ANOVA was used to determine residual correlations using partial correlation coefficients between BT and the climate variables. The lag effects of the variables on BT at h 0 were assessed by determining the relationships at −1, −2 and −3 h before 0 h. There were moderate correlations between BT, THI (0.51; $P < 0.001$) and TA (0.48; $P < 0.001$) at 0 h during E; and between BT, THI (0.47; $P < 0.001$) and TA (0.49; $P < 0.001$) at 0 h during L. There were weak correlations ($\leq$-0.07; $P > 0.05$) at 0 h between BT, THI, TA and BG during M. At 0 and – 1 h, the relationship between BT and BG was moderate during E (0.41 and 0.42 respectively; $P < 0.001$), whereas during L there was a stronger association at 0 h (0.42; $P < 0.001$), and at −1 h (0.40; $P < 0.001$). There was a weak relationship between BT and RH at 0 h during E (−0.14; $P < 0.001$), a moderate relationship during L (−0.35; $P < 0.001$), and a weak relationship during M (−0.06; $P > 0.05$). The lack of correlation between BT and climatic variables during M confirms that there was no adverse heat load during winter. It appears that BT is primarily driven by current or at the most the previous h ambient conditions during summer, at least on a herd basis. The relationship between BT and climate variables, in low, moderate and high production cows needs to be determined.

Key words: body temperature, dairy cows, heat load

460 Repeatability of subjective and objective measures of exit velocity as an indicator of temperament in feedlot cattle. M. D. D. Vetters*, T.E. Engle, J.K. Ahola, and T. Grandin, *Colorado State University, Fort Collins.*

Observations were collected for the purpose of comparing exit velocity evaluation; including a subjective rank scoring system (walk, trot, or run) and an objective measurement, to determine the repeatability of each measurement over time. Squeeze chute exit velocity was obtained for 1,100 crossbred yearling steers using a subjective (Sub) and objective (Obj) temperament scoring system. The Obj scoring system utilized infrared sensors to determine the time taken for an animal to traverse a fixed distance of 1.83 m, immediately after exiting the squeeze chute. The Sub temperament scoring measurement of: 1 = walk, 2 = trot, or 3 = run was assigned by 2 different observers when each steer crossed a fixed point between the infrared sensors. Observers also noted any incidence of jumping or falling by each steer. All animals were scored for each system (Sub and Obj) simultaneously upon exiting the squeeze chute on d 0 and d 21 of the experiment. The Sub score between observers on a single day showed considerable agreement (weighted Kappa 0.60) indicating the system is repeatable between different observers. However, the agreement for a single observer between d was only moderate (weighted Kappa 0.40) indicating a d effect for Sub score. In addition, although the mean velocities for d were not different ($P > 0.18$; 2.98 and 3.02 ± 0.04), the consistency of Obj exit velocity for each animal between the 2 weighing events was low (Spearman rank correlation coefficient = 0.25). These data indicate that the Sub and Obj measurement systems used in this experiment are reliable instruments for assessment on a given day; however, substantial variation exists for Sub and Obj temperament scoring across days. If this variation can be accounted for it could be possible to more accurately compare these systems of temperament assessment.

Key words: beef cattle, exit velocity, temperament

461 Group pasture versus stall housing effects on cortisol and DHEA concentrations in young Quarter Horses. S. M. Garey*, T. H. Friend, L. R. Berghman, J. E. Sawyer, M. M. Vogelsang, A. L. Adams, C. L. Terrill, and M. J. Carter, *Texas A&M University, College Station.*

Individual stall housing of horses is common in the US Whether horses are able to adapt to the stress of isolation, or if this type of housing presents a long-term stress for the animal is unclear. The objective of this study was to determine if cortisol or dehydroepiandrosterone (DHEA) differed among groups of young horses when housed in individual stalls versus in a group on pasture. Fourteen 2 to 3 year-old Quarter Horses were randomly assigned to either stall or pasture housing for 28 d. The 3.66 × 3.66 m stalls had solid concrete side and rear walls with a small ventilation window, while the front allowed horses to view the alley of the barn. The stalled horses were allowed 15 min of exercise 3 d per week. The 7 pasture horses were in one group on a novel 0.2 km^2 pasture. All horses were fed concentrate 2 times per day, while pastured horses had coastal grass, and stalled horses had coastal hay. Jugular blood samples were drawn at 24 h and 0.5 h before treatment, then every 12 h for 3 d, every 24 h for 5 d, and every 48 h for the

final 20 d. Plasma was analyzed by ELISA to determine cortisol and DHEA concentrations, and all samples were normalized against pre-treatment concentrations. A mixed model repeated measures ANOVA with unstructured covariance determined effects of treatment, sample time and sample time by treatment interaction. Stalled horses had significantly higher cortisol concentrations (4.62 ± 0.43 ng/ml) than pastured horses (3.27 ± 0.46 ng/ml, $P = 0.05$), although no significant differences were observed in DHEA ($P = 0.34$). There was no sample period by treatment interaction ($P = 0.55$). Plasma cortisol differences between treatment groups decreased in the final 4 d of the study, becoming equal by d 28. In conclusion, differences in cortisol concentrations between the treatment groups were significant, but diminished toward the end of the study. These results suggest that horses housed in an individual stall over an extended period of time may acclimate to the stress of isolation.

Key words: housing, stall, cortisol

462 Cortisol and DHEA concentrations in foals identified as high versus low behavioral responders during weaning. S. M. Garey*, T. H. Friend, L. R. Berghman, J. E. Sawyer, M. M. Vogelsang, A. L. Adams, C. L. Terrill, and M. J. Carter, *Texas A&M University, College Station.*

Weaning of young animals from their dams has been shown to induce stress. Frequent whinnying and increased movement displayed by foals are common behavioral indicators of distress. The objective of this study was to determine if cortisol or dehydroepiandrosterone (DHEA) differed among foals identified as high versus low behavioral responders during weaning. Fifteen 5 to 6 mo-old Quarter Horses were weaned by removal and relocation of their dams. Post-separation, the foals were housed in groups of 3 to 4 with ad libitum coastal hay and water. Jugular vena puncture blood samples were collected from the foals at 24 h and 0.5 h before separation, then every 24 h for 3 d and a final sample on d 5. To minimize stress during blood sampling, foals were handled and restrained in familiar stocks, with 2 foals per stock. Scan sampling at 2-min intervals for 30 min per day was done for 3 d post-separation to record movement, activity and number of vocalizations. Three observers also ranked the foals' display of distress relative to other foals in the study. Behavioral data were analyzed to rank and identify the 5 most distressed (MD) and 5 least distressed (LD) foals. A mixed model repeated measures ANOVA with unstructured covariance was used to determine differences in plasma cortisol and DHEA concentrations between MD and LD foals as well as sample time effects, and a Spearman correlation was used to identify associations between rank and average cortisol and DHEA. Cortisol ($P = 0.262$) and DHEA ($P = 0.298$) did not differ between MD and LD foals pre-weaning, and no interaction was found between the behavioral groups and sample time ($P = 0.167$). Overall, cortisol and DHEA did not differ between MD foals (9.97 ± 1.66 ng/ml, 3.39 ± 1.17 ng/ml) and LD foals (7.29 ± 1.66 ng/ml, $P = 0.287$; 0.38 ± 1.17 ng/ml, $P = 0.110$), respectively. Average DHEA was correlated with rank (r = 0.661, $P = 0.038$), however average cortisol was not (r = 0.071, $P = 0.80$). This study suggests that high responding and low responding foals may be experiencing similar distress during weaning.

Key words: weaning, behavior, cortisol

463 Preference for condensed tannins by sheep in resoponse to challenge infection with *Haemonchus contortus*. J. Juhnke[1], J. Miller[2], F. Provenza[1], J. Hall[3], and J. Villalba*[1], *[1]Utah State University, Department of Wildland Resources, Logan, [2]Louisiana State University, Department of Pathobiological Sciences, Baton Rouge, [3]Utah State University, Department of Animal Dairy and Veterinary Sciences, Logan.*

We determined the ability of parasitized lambs to modify their preference for a condensed tannin (CT)-rich feed after they experience the antiparasitic effects of CT. Twenty 2 lambs were familiarized with beet pulp (BP) and beet pulp + 8% quebracho tannins (BP+CT) and then given choices between the 2 feeds (before a parasitic infection). Subsequently, each animal was dosed with 10,000 infective larvae of *Haemonchus contortus*, and 22 d later they were exposed to BP (Control group; n = 11) or BP+CT (Treatment group; n = 11) for 24 d. After this exposure, animals in both groups were given a choice between the 2 feeds for 14 d. Feed intake, preference for BP+CT, fecal egg counts (FEC), and blood parameters were analyzed as a split-plot design with lambs (random factor) nested within group and day as the repeated measure. All lambs preferred BP to BP+CT throughout the study ($P < 0.001$) and no difference in preference for BP+CT was detected between groups before a parasitic infection ($P > 0.10$). However, during a parasitic infection, intake of and preference for BP+CT was higher for the Treatment than for the Control lambs ($P < 0.05$). When parasitic infections were terminated by chemotherapy, differences between groups in preference for BP+CT disappeared ($P > 0.05$). Preference for BP+CT by the Treatment group was higher during a parasitic infection than after chemotherapy ($P < 0.05$). Treatment lambs had lower FEC ($P < 0.05$), and red cell parameters indicated a lower degree of anemia in the Treatment than in the Control group ($P < 0.09$), suggesting tannins attenuated parasitic burdens. Thus, lambs needed to experience the beneficial antiparasitic effects of CT (Treatment) to increase their preference for the CT-containing food, indicating this behavior was learned. Preference for CT in the Treatment group was a function of parasitic infection as it subsided after chemotherapy. It may be possible through management programs to enhance utilization of tannin-rich forages and feeds by parasitized animals.

Key words: diet selection, endoparasites, foraging

464 Lack of acclimation in Holstein calves exposed to repeated transport. A. L. Adams*, T. H. Friend, G. A. Holub, S. M. Garey, C. L. Terrill, M. J. Carter, and A. J. Krenek, *Texas A&M University, College Station.*

Little is known about the adaptation of livestock to repeated transport stress. This study determined how repeated transport affected plasma cortisol (CORT) concentrations and post-transport calf behavior. Thirty-six 4-mo-old Holstein steer calves were housed in groups of 6 with each group randomly assigned to either transport (T) or control (C) treatments. T calves were transported for 6 h in their groups in a 7.3 m x 2.4 m goose-neck trailer divided into 3 compartments, at an average density of 0.87 m^2/calf, every 7 d for 5 consecutive wk. Location of groups within the trailer rotated. Simultaneous blood samples were obtained in the trailer or home pen via jugular venipuncture before loading, and after 2, 4, and 6 h of transport. Behavior was recorded for transported calves at 5-min intervals for 1 h after return to their home pens. CORT was analyzed as a repeated measure in a mixed model ANOVA. Latency to eat and lie down were analyzed in a mixed model ANOVA. Spearman rank correlations showed no association between CORT and behavior. The location of the calves in the trailer did not significantly affect CORT and basal CORT concentrations did not differ significantly for T calves. CORT during transit increased with each repeated transport, except during wk 5 ($P = 0.043$). CORT

concentrations peaked after 2 h of transit (11.17 ± 0.84 ng/ml) and decreased after 4 and 6 h of transit (4 h: 8.21 ± 1.17 ng/ml, 6 h: 5.73 ± 0.74 ng/ml, $P < 0.0001$). T calves had higher CORT concentrations than C calves after 2 h (C: 6.98 ± 0.86 ng/ml) and 4 h (C: 6.94 ± 1.2 ng/ml) of transit, but had lower CORT than C calves after 6 h of transit (C: 7.28 ± 0.76 ng/ml, $P < 0.0001$). Calves transported in the rear of the trailer were the first calves to lie down when returned to their pens ($P = 0.0008$) and the last calves to attend the feed bunk ($P = 0.022$). As temperature-humidity index increased, calves located in the rear of the trailer began to lie down sooner post-transport ($P = 0.018$). These results suggest that calves did not start to acclimate after being transported 5 times and that calves transported in the rear compartment of the trailer were the most fatigued.

Key words: calves, cortisol, transport

Bioethics Symposium: The Ethical Food Movement: What Does it Mean for Animal Agriculture?

465 Food production using animals: The roles of media coverage and societal values in shaping opinions about ethics. S. Priest*, *University of Nevada, Las Vegas.*

While the news media may set the agenda for public debate about science, they rarely cover ethics in any depth, and yet much news about science is fraught with ethical implications. Social amplification theory argues that media accounts can help amplify, as well as attenuate, risks. However, news producers do not create these effects independent of other influences. Both information subsidies and levels of cultural resonance are also important, and the technical definition of risk is not the only determinant of public opinion. Expectations and beliefs, including non-risk-related concerns such as perspectives on ethics, come into play. This is illustrated by data from a pilot study using student subjects that looks at initial reactions to the use of nanotechnology, genetic engineering, and synthetic biology with respect to genetic alteration of either cattle or bacteria; the results show that the type of organism involved is more important than the technology, indirectly suggesting the relevance of ethical considerations. While this small study may not be generalizable to a different population, it serves to remind us that public thinking is not solely a function of scientific understanding. The agricultural community could benefit by being more responsive to public (that is, consumer) opinion. Science itself cannot resolve what are essentially disagreements about values. When agriculturists and scientists blame the news media for negative public reactions, this can become a rationale for disregarding popular criticisms rather than taking them seriously. Not only is this ethically questionable, it is not necessarily in the strategic interests of the scientific and agricultural communities. Arguably, the GM food controversy arose in part because agriculture initially ignored the views of the public, including their ideas about ethical agricultural practices. It is a basic tenet of progressive public relations practice that communication should be 2-way and take public opinion into account.

Key words: animal agriculture, media role, bioethics

466 The (mis)appropriation of science in framing the ethics of animal production: Environmental issues. J. L. Capper*, *Washington State University, Pullman.*

Today's consumer has a heightened awareness of environmental issues relating to animal production. All foods have an environmental impact, yet the desire to "know where your food comes from" and idealistic views of "traditional" or "natural" production systems have led to product differentiation based on environmental claims. Various niche markets have reported that extensive systems are more environmentally sustainable. This exacerbates the challenge faced by the conventional livestock industry in providing sufficient milk, meat and eggs to feed the growing population while maintaining environmental stewardship. Yet low productivity within extensive systems significantly increases resource use per kg of milk or meat produced. For example, grass-based beef finishing systems require 77% more animals, 83% more land, 326% more water and emit 74% more greenhouse gases (GHG) per kg beef than corn-based systems using modern technologies. Scientific results are also being inappropriately used to further the agendas of anti-animal agriculture groups. A recent report from the FAO concluded that improved productivity and intensification are necessary to reduce livestock's environmental impact, yet these recommendations were overshadowed by the widely-reported (and since disproved) conclusion that animal agriculture accounts for 18% of global GHG emissions. This figure has since been incorrectly applied as representative of animal agriculture's impact in all regions, regardless of variations in efficiency. International averages have also been used to represent regional systems in media reports of comparative water use for animal production, leading to misinformation and consumer confusion. The popular assumption that transportation is a major contributor to the environmental impact of food production has furthered interest in "local food" and "food miles," despite the increased fuel costs of individual vs. mass food transport. Scientific principles and logic must be used to communicate with the consumer and improve their understanding of environmental issues, while maintaining respect for social and personal belief systems.

Key words: environmental impact, beef, local food

467 What did they just say? Science, politics, and animal welfare. J. A. Mench*, *University of California, Davis.*

Scientific information is becoming increasingly important not only in framing the debate about farm animal welfare but in propelling significant changes in public policy. The media, often unfamiliar with animal production practices, rely on scientific reports as critical background for their stories. Multi-national retailers use scientific information when they develop their animal welfare programs and farm auditing standards, and in making purchasing decisions. So that's a good thing, right? But hold on. Why does there seem to be so much confusion about what the science, and the animal welfare scientists, are saying? Of course, disagreement in science is normal, expected, and healthy. In any socially relevant field of science value judgments inevitably come into play when scientists attempt to reconcile the incomplete, complex and often contradictory information that results from research. As long as the values underlying these differences of opinion are transparent, both science and the public dialog about contentious issues are well served. Unfortunately, it seems instead that the contradictions and complexities inherent to farm animal welfare research are increasingly being ignored, or even worse skillfully (mis)appropriated, to advance particular agendas. This has ramifications for the credibility of animal welfare science, and also suggests that a new tack needs to be taken in communicating with the public about animal welfare issues and the role that science plays in addressing them.

Key words: animal welfare, science, ethics

468 The (mis)appropriation of science in framing the ethics of animal production: The use of antibiotics. M. D. Apley*, *Kansas State University, Manhattan.*

At the scientific levels of regulatory agencies, such as the Food and Drug Administration Center for Veterinary Medicine (FDA/CVM), the agricultural antimicrobial use debate revolves around risk assessments, surveillance data, movement of resistance genetics, and antimicrobial selection pressures. Unfortunately, we are sometimes hampered by data-gathering abilities that are more advanced than our interpretive skill sets. An example of a regulatory challenge is eliminating most of the uses of antimicrobials for improvement in rate of gain or feed efficiency as proposed in FDA/CVM Draft Guidance 209 (2010). This

action assumes that the lowest, longest antimicrobial exposures are a primary driver for resistant subpopulation selection in food animals. Without evidence for this assumption, the danger in this approach is that the precedent for the future regulation of prevention, control, and therapeutic uses of antimicrobials is not based on scientific evaluation of risk and benefit. Current FDA/CVM thinking related to microbial safety is outlined in Guidance Documents 152 and 159. But as the debate moves upward in the regulatory environment and spills over into the political arena, these scientific principles tend to be reduced to sound bites augmented by agenda-related dips into selected data. Additional key debates subject to scientific horseplay include the impact of modern production methods on disease incidence, the quantity of antimicrobials used in animal agriculture, transfer of resistant bacteria and resistance genetics between animals and humans, and in vivo vs. in vitro pharmacodynamic properties of antimicrobials. Oversimplification of the resistance issue is also used to mislead the public. But even with all of the scientific shortcuts in the public arena, the food animal industry cannot act as if we do not cause changes in susceptibility profiles with our antibiotic use; we can affect antimicrobial populations, and bacteria can transfer through the food chain. The challenge is keeping all parties on the high road when deciding the actual effects and what to do about them.

Key words: antibiotics, resistance, ethics

Breeding and Genetics: Dairy Cattle Breeding I

469 Assessing accuracy of heat detection in dairy herds. H. Seegers*[1], D. Billon[1], E. Bossard-Apper[2], C. Ponsart[3], B. Grimard[4], and N. Bareille[1], *[1]Research Group Epidemiology and Risk Analysis Oniris-INRA, Nantes, France, [2]Agriculture School, Angers, France, [3]UNCEIA, Maisons-Alfort, France, [4]Veterinary School, Maisons-Alfort, France.*

Herd reproductive performance depends on accuracy of heat detection and conception rate. Assessing the accuracy of the detection practices on a farm is a quite difficult exercise. Therefore, the objective was to provide a method to estimate the accuracy of heat detection in dairy herds, using quite only data available in fertility reports (mainly information about calving and insemination dates). A first step relied on the development of a simulation model to represent the biological processes (cyclicity resumption, detectability of ovulation, conception rate, embryonic and fetal deaths) and managerial processes (detection, submission rules, culling decisions) involved. This simulation tool was then used to generate fertility reports for 384 scenarios with known levels in sensitivity and specificity of heat detection, in combination with different levels for other parameters (especially herd size, milk yield, conception rate and managerial rules). At second step, the simulation outcomes were analyzed with stepwise multiple regression models to obtain prediction equations for the accuracy criteria, using as predictors the criteria present in a classical fertility report. Accuracy criteria were the % detected within detectable heats (separating 2 periods: until 1st AI and After 1st AI) and the % of AIs outside an ovulation period. At third step, these prediction equations were applied to a data set of 40,000 yearly fertility reports to obtain the distribution of estimated accuracy criteria in a population of 10,000 French farms with Holstein herds. Raw estimates calculated from the data set were almost considered plausible by authors and external experts. The % of detection averaged 55.3% (Q1 = 40.1; Q2 = 58.2; Q3 = 73.7) until the 1st AI and 50.1% (Q1 = 38.2; Q2 = 50.1; Q3 = 63.4) later. The % of AIs done outside an ovulation period averaged 6.3% (Q1 = 2.9; Q2 = 5.7; Q3 = 9.1). A test of the method is ongoing, based on confrontation with AI technicians guesses for a sub-sample of farms. If consistency reached is deemed sufficient, a use on a semiquantitative scale (very good, good, intermediate, low and very low) seems to be an acceptable way to express the results for farmers and advisors.

Key words: dairy cow, estrus, detection

470 Heritability and repeatability estimates for twinning rate in the Irish dairy and beef cattle. A. M. Doyle[1], R. D. Evans[2], and A. G. Fahey*[1], *[1]University College Dublin, Belfield, Dublin [4], Ireland, [2]Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland.*

Twinning rate is a complex threshold trait with a binary phenotype (1 = single, 2 = twin) and a quantitative phenotype. Increasing the twinning rate in beef cattle and decreasing twinning rate in dairy cattle could have positive economic effects for both industries. In beef cattle twinning can increase the rate of production if problems associated with twinning such as dystocia, longer rebreeding and retained placentas can be overcome. Decreasing twinning in dairy cattle would be beneficial as although twinning can increase milk production, fertility problems and the occurrence of freemartins make it disadvantageous. The objective of this study was to estimate the heritability and repeatability for twinning rate in 6 dairy (n = 1,070,457) and 10 beef (n = 83,476) breeds in Ireland using SAS 9.1 Software and DMU Animal Breeding Software. Heritability and repeatability estimates were analyzed using a linear animal model with fixed effects for herd-year-season, parity, age, heterosis and recombination; while sire and dam were included as random effects. Heritability was estimated to be between 0.002 and 4.0% and 0.0–4.1% for dairy and beef breeds respectively, and repeatability was estimated to be between 0.002 and 6.1% and 0.002–8.1% for dairy and beef breeds respectively. Twinning rate increased as parity increased. A comparison of gestation length between single and twin births found gestation length of twins to be significantly ($P < 0.05$) shorter than single births. The analysis suggests that there is a genetic component to twinning rate in dairy and beef breeds and this trait could be included in national selection index to reduce the incidence of twinning in dairy cattle and increase the rate of twinning in beef cattle due to a cumulative effect over time.

Key words: twinning, repeatability, heritability

471 Genetic analysis of ovulatory disorders in Austrian Fleckvieh cows: A comparison between linear models and survival analysis. A. Koeck*[1,2], B. Fuerst-Waltl[2], J. Sölkner[2], C. Egger-Danner[3], and G. Meszaros[2], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Division of Livestock Sciences, University of Natural Resources and Life Sciences, Vienna, Austria, [3]ZuchtData EDV-Dienstleistungen GmbH, Vienna, Austria.*

The aim was to compare linear models and survival analysis for genetic analysis of ovulatory disorders, which included veterinary treatments of silent heat/anestrus and cystic ovaries. Data of 23,450 daughters of 274 Austrian Fleckvieh sires were analyzed. For linear model analyses, ovulatory disorders were defined as a binary response (presence or absence) in the time periods from calving to 150 d after calving and from calving to 300 d after calving. For survival analysis, ovulatory disorders were defined either as the number of days from calving to the day of the first treatment for an ovulatory disorder (uncensored record) or from calving to the day of culling, or the last day of the period under investigation (until 150 or 300 d after calving; censored record). Estimates of heritability were very similar (0.016 to 0.020) across methods and periods. Correlations between sire EBV from linear model and survival analysis were 0.98; whereas correlations from different time periods were slightly lower (0.95 and 0.96).

Key words: ovulatory disorder, linear model, survival analysis

472 Montbeliarde-sired crossbred cows compared to pure Holstein cows for production, SCS, days open, and survival during their first three lactations. A. R. Hazel*, L. B. Hansen, B. J. Heins, and J. G. Linn, *University of Minnesota, St. Paul.*

Montbeliarde × Holstein crossbred cows (MH, n = 58) and Montbeliarde × Jersey/Holstein crossbred cows (MJH, n = 78) were compared with pure Holstein cows (HO, n = 122) for 305-d milk, fat, and protein production, SCS, days open (DO), and survival during the first 3 lactations. Cows were in 2 research herds of the University of Minnesota and calved from October 2005 to June 2010. Best Prediction was used to calculate production for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. Cows were required to have at least 250 DIM for DO, and cows with DO greater than 250 d were truncated to 250 d. For production, SCS, and DO, independent variables for statistical analysis were the fixed effects of herd, parity group (primiparous or multiparous), breed, interaction

of herd and parity group, lactation number (2 or 3) nested within multiparous parity group, herd-year of calving nested within interaction of herd and parity group, interaction of herd and breed, interaction of lactation number nested within parity group and breed, interaction of herd, lactation nested within parity group, and breed, and random cow nested within breed. The MH, MJH, and HO, respectively, were not significantly different ($P > 0.05$) for fat plus protein production during first lactation (503 kg, 496 kg, 514 kg), second lactation (605 kg, 604 kg, 605 kg), or third lactation (675 kg, 645 kg, 656 kg). The MH (2.11) had lower SCS ($P < 0.05$) than MJH (2.57) and HO (2.70) during second lactation, and MH (2.67) had lower SCS ($P < 0.05$) than HO (3.39) during third lactation. The MH (133 d) and MJH (122 d) had fewer DO ($P < 0.01$) in first lactation than HO (170 d). During second lactation, MH (141 d) and MJH (140 d) had fewer DO ($P < 0.05$) than HO (179 d). The MH had higher survival rates ($P < 0.01$) than HO to third (62% vs. 39%), fourth (44% vs. 16%), and fifth (32% vs. 8%) calving. The MH (4%) and MJH (4%) had lower mortality rates ($P < 0.05$) than HO (17%) within 3 years of first calving.

Key words: crossbreeding, heterosis, Montbeliarde

473 Joint estimation of genetic parameters for test day somatic cell count and mastitis using a random regression model in the United Kingdom. R. Mrode*, T. Pritchard, M. Coffey, and E. Wall, *Scottish Agricultural College, Penicuik, Midlothian, UK.*

Genetic parameters were estimated in a joint analysis of log-transformed somatic cell count (SCC) and mastitis (MAS) in Holstein/Friesian cows for the first 3 parities using a random regression model. There were 67175, 30,617 and 16,366 cows with records for SCC in parities 1, 2 and 3 respectively. Corresponding numbers for MAS were 9070, 6009 and 4012 respectively. The percentage incidence for MAS was 14, 20 and 25% in parities 1, 2 and 3 respectively. The model for SCC included herd-test-day, fixed lactation curves nested with calving year-groups, age and month at calving, random regressions with Legendre-polynomials of order 2 for animal and permanent environmental (PE) effects. The model for MAS included fixed herd-year-season, age and month of calving, random animal and PE effects. Two separate analyses were implemented with MAS analyzed as binary trait or as number of infections in the lactation. The analyses were carried out using Gibbs sampling with a chain length of 120,000, of which the first 40,000 were discarded as burn-in period. Estimates of heritability were 0.11, 0.14 and 0.15 for SCC in parities 1, 2 and 3 respectively. Corresponding estimates for MAS were 0.05, 0.07 and 0.09 as a binary trait. Estimates for MAS using number of infections were similar at 0.06, 0.07 and 0.12. Posterior standard deviations were about 0.01 for all estimates. The genetic correlation of 0.75 estimated between parities 1 and 2 for SCC was lower than the 0.92 between parities 2 and 3. The corresponding estimates for MAS were 0.54 and 0.89 respectively from the binary analysis. SCC in the first 3 parities had genetic correlations of about 0.55 with MAS in the first parity but this increased to about 0.63 with MAS in parity 2. However, the genetic correlations between SCC in parities 1 and 2 with MAS in parity 3 were about 0.48 while it was 0.68 between SCC and MAS in the third parity. It is intended that the new parameters will be used in setting up a national evaluation system for the joint analysis of SCC and MAS.

Key words: somatic cell count, mastitis, genetic parameters

474 Estimation of genetic parameters for health and survival in Canadian Holstein calves. C. E. McCorquodale*[1], F. Miglior[2,3], A. Sewalem[2,3], D. Kelton[1], A. Robinson[4], and K. E. Leslie[1], *[1]Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada, [2]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, Ontario, Canada, [3]Canadian Dairy Network, Guelph, Ontario, Canada, [4]Department of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to estimate the genetic parameters of calf survival and health in a population of Ontario Holsteins. Heifer calves on 16 south-western Ontario dairy farms were followed from time of birth to approximately 4 mo of age. Visits were made at 1–8 (T1), 14–22 (T2), 35–43 (T3) and 90–120 (T4) days of age. At each visit, the height, weight, temperature, and a health score were collected. A blood sample was taken at T1 to measure serum total protein using refractometry. Details of birth events and colostrum feeding information were recorded on individual birth records. Information on treatment for illness events and death information was collected for the duration of the study. In total 1,462 calves, sired by 246 different bulls were included in the study. Two linear animal models were used to analyze survival and treatment separately. Survival of calves was measured as a binary trait (0 = survived to T4; 1 = dead before T4) and treatment of calves at T1, T2 and T3 was recorded as a binary trait (0 = not treated; 1 = treated). Both models included the fixed effects of herd, season of birth with 4 classes, calving ease score with 4 classes, type of birth with 2 classes (1 = single birth and 2 = twin), and weight group with 5 classes. Fixed regressions included the total volume of colostrum consumed during the first 24 h and the serum total protein score. The random effects of the models included animal and residual. Estimates of heritability for treatment during T1, T2 and T3 were 0.11, 0.05 and 0.09, respectively. The heritability estimate for survival was 0.05. Similar to recently published data from Norway and New York State, heritability estimates for calf survival and health in Ontario calves give additional reason to consider routine genetic evaluation for these traits.

Key words: Canadian Holstein, calf health and survival, genetic parameters

475 Genetic parameters of lactation yield in the tropical carora breed with random regression test-day models. E. Tullo*[1], S. Biffani[2], C. Maltecca[3], and R. Rizzi[1], *[1]University of Milan, Faculty of Veterinary Medicine, Department of Veterinary Science and Technology for Food Safety, Milan, Italy, [2]Parco Tecnologico Padano, Lodi, Italy, [3]Department of Animal Science, North Carolina State University, Raleigh, NC, USA.*

In tropical environments, lactation curves with lower peaks and higher persistencies might be desiderable from both an economical and a physiological standpoint. The objective of this study was to obtain genetic parameters for test day yields (TD), and persistencies (P) for the tropical breed Carora and to compare these with results from a standard 305-yield animal model. A random regression animal model (RR-AM) was employed for the analysis of 181,810 test day records collected in the west-central part of Venezuela from 1992 to 2009, and belonging to 7,075 Carora cows, daughters of 436 sires. Milk TD yields (kg), comprised between 5 and 305 DIM, were analyzed with a model that included fixed effects of class of age, year and month of calving, herd and third order Legendre polynomials of days in milk. Random effects were fitted for the interaction herd-year-month-of-test and for the additive genetic and permanent environmental effects. Third order Legendre polynomials were applied as random regression covariates for both additive genetic and permanent environmental effects. Estimated daily

heritabilities for milk yields ranged from 0.15 to 0.25, with the lowest values around the peak of the lactation. Within lactation repeatabilities ranged from 0.39 to 0.48. Genetic correlations among test days within lactation ranged from −0.20 to 0.99. To investigate differences among models, the re-ranking between EBVs for 305d yield, obtained with Lactation Animal Model (L-AM) and RR-AM was investigated. For the top 100 sires a rank correlation of 0.54 was found. The average re-ranking among sires was of 21.9 ± 16.93. Correlations between persistency and 305d milk yield EBV ranged from 0.06 (P as a deviation from the peak) to 0.32 (P as production difference between the first and the second stage of lactation). Understanding persistency trends with respect to milk yield, in tropical enviroment should allow selecting individuals able to express their potential genetic values without incurring in excessive heat stress losses.

Key words: random regression test-day model, tropical dairy cattle, persistency

Breeding and Genetics: Quantitative Animal Breeding

476 Cooperation under directional selection with kinship-based groups. F. Siewerdt*[1], A. D. Franklin[1], J. A. Carrillo[1], A. K. Sasikala-Appukuttan[1], A. S. Schierholt[2], T. E. Callicrate[1], M. A. Campbell[1], and H. L. M. Moreira[3], *[1]University of Maryland, College Park, MD, [2]Universidade Federal Rural da Amazônia, Belém, PA, Brazil, [3]Universidade Federal de Pelotas, Pelotas, RS, Brazil.*

The goal of this selection experiment was to determine if the accumulation and expression of genes with associative genetic effects is dependent on selection being performed in the presence of closely related individuals. Laboratory colonies of *Tribolium castaneum* were assigned to 3 selection lines and 3 replications. A selection line consisted of 64 demes of 16 adults, placed in small glass jars with a small amount of medium (95% flour and 5% yeast) in a walk-in incubator with controlled temperature and humidity. The medium was a limiting factor for census growth of the deme, creating competition between individuals and the opportunity for reduction in reproductive activity and manifestation of cannibalism. Two lines were group selected for increased number of adults at 35 d after establishment of the demes. The best demes were used to place as many demes in the following generation as possible. In one selection line kinship structure was preserved in consecutive generations by placing new demes only with beetles from the same original deme. In the other selection line the deme structure was disrupted at each generation by placing the new demes with beetles coming from 16 different demes in the previous generation. A randomly selected control was kept; adult counts were expressed as deviations from this line. Each selected line was split into 2 lines at generation 11. One newly formed line was kept on the original selection strategy and the other was placed on the competing selection strategy. After 16 generations of selection, genetic gains suggest that accumulation and expression of associative genetic effects may be dependent on the presence of kin. Average cumulative genetic gains in the selected lines with intact deme structure and with disrupted deme structure were, respectively, 49.8 ± 10.1 and 28.9 ± 2.7 adults. Between-deme variability was 5.5 times higher in the lines with intact deme structure. Swapping selection strategies at generation 11 had no effect on genetic progress measured at generation 16. There may be latency in the expression of accumulated associative genetic effects, which could only occur in the presence of close kin.

Key words: *Tribolium castaneum*, Associative genetic effect

477 A recursive binomial model for piglet mortality. L. Varona*[1] and D. Sorensen[2], *[1]Unidad de Genetica Cuantitativa y Mejora Animal, Universidad de Zaragoza, Zaragoza, Spain, [2]Department of Genetics and Biotechnology, University of Aarhus, Tjele, Denmark.*

Several interesting traits in animal production do not follow a Gaussian distribution. Statistical procedures based on Bayesian analysis allows to model successfully unconventional distributions of data. However, sometimes is not clear how to model environmental correlation between traits. Structural models may provide a useful alternative to model this relationship. In this study, we have developed a recursive procedure between a linear (litter size) and a binomial trait (number of piglets born dead) and we have tested the procedure with data from 2 Danish pig breeds: Landrace and Yorkshire. The Landrace data set included 5178 litter size records and a pedigree file of 8800 individuals, whereas the Yorkshire data set consisted of 3938 litter size records and a pedigree file of 7143 individuals. The posterior mean (and standard deviation) estimates of the recursive parameter of litter size on the logit-transformation of the probability of born dead were 0.094 (0.005) and 0.121 (0.007) for Landrace and Yorkshire, respectively. These results indicate that as litter size increase, the probability of a piglet to born dead also does. Moreover, the procedure provides a useful alternative to model non genetic relationship between traits. The adequacy of the model was tested by the logarithm of the conditional predictive ordinate of data, showing that the proposed model improves the predictive ability over the one that does not include the recursive relationship with litter size.

Key words: recursive models, pig, Bayesian analysis

478 Genetic correlation between purebred piglet birth weight and crossbred performance. C. Y. Chen*[1,2], I. Misztal[1], S. Tsuruta[1], J. Holl[3], W. O. Herring[3], and M. Culbertson[3], *[1]Department of Animal and Dairy Science, University of Georgia, Athens, [2]Newsham Choice Genetics, Chesterfield, MO, [3]Smithfield Premium Genetics Group, Rose Hill, NC.*

The objective was to estimate the genetic correlation between purebreds and crossbreds for several weight traits. Data consisted of 157,600 purebreds (Durocs) and 94,185 crossbreds (Duroc x (Large White x Landrace). Traits were purebred birth weight (PBWT), crossbred birth weight (CBWT), crossbred carcass weight per day of age (CWDA), and binary crossbred hot carcass weight (CHCW) with cutpoint at 75 kg. Two linear 3-trait models (PBWT, CBWT, and CWDA) and one linear-threshold 3-trait model (PBWT, CBWT, and CHCW) were used. Fixed effects included sex, parity, and litter size for all models with age at slaughter for CHCW. Contemporary groups were fitted differently for linear traits (fixed) and CHCW (random). Random effects of litter and residual were included for all models. Genetic effects were fit differently for purebreds (animal additive) and crossbreds (animal or sire additive). A dam effect (composed of genetic and environmental) was also evaluated for crossbreds. Heritability was 0.18 for PBWT with all models. For CBWT, estimates of heritability were 0.07 with the animal model and from 0.03 to 0.05 with the sire models. For CWDA, same estimates were 0.17 and 0.12 for animal additive and sire genetic effects, respectively. Heritability was 0.08 for CHCW. Estimates of genetic correlations ranged from 0.77 to 0.89 for PBWT-CBWT, 0.16 to 0.30 for PBWT-CWDA, 0.13 to 0.56 for CBWT-CWDA, 0.45 for PBWT-CHCW, and 0.13 for CBWT-CHCW. The selection for birth weight in purebreds is efficient for selection of birth weight in crossbreds. Such a selection is also useful in achieving market weight in crossbreds.

Key words: birth weight, crossbreds,, genetic correlation, pigs

479 Construction of individual breeding values for feed intake of Piétrain boars based on mean pen feed intake, weight and weight gain test station records. M. Dufrasne*[1], V. Jaspart[2], J. Wavreille[3], and N. Gengler[1,4], *[1]Animal Science Unit, University of Liege, GxABT, Gembloux, Belgium, [2]Walloon Pig Breeders Association, Ciney, Belgium, [3]Walloon Agricultural Research Centre, Gembloux, Belgium, [4]National Fund for Scientific Research, Brussels, Belgium.*

The aim of this study was to predict genetic merit of Piétrain boars for feed intake by constructing an index combining individual residual feed intake (RFI), average daily gain (ADG) and live weight (LW) of their progeny. Reliabilities of estimated breeding values (EBV) of 50

recently tested boars for individual Estimated Feed Intake (EFI) and for Index Feed Intake (IFI) were compared. Data were collected on pigs in test station in context of the genetic evaluation system of Piétrain boars for crossbred performances in the Walloon Region of Belgium. Because there were no facilities to record individual feed intake, individual EFI was computed as the total pen feed intake divided by number of individuals per pen. Data file contained 1 397 records of individual EFI. Model developed was an animal model with sex and pen as fixed effects. EBV for ADG between 100 and 210 d and for LW at 100 d were defined as linear covariables, therefore EBV are expressing RFI. Mean EFI was 1 876.8 g/d with a SD of 177.5 g/d. Heritability for EFI considered without regressions on ADG and LW was 0.08 and mean reliability of EBV was 0.16 which was low to base selection decision. Coefficients of linear regression estimated were used to estimate IFI as followed: IFI,g/d = RFI,g/d + 2.61 LW,kg + 214.37 ADG,kg/d. Heritability for RFI was 0.06 and was low compared with literature. Heritability for IFI was 0.09 which was more consistent with literature values. Mean reliability for RFI was 0.13 and mean reliability for IFI was 0.35. Therefore, thanks to combining RFI with EBV for ADG and LW which have high mean reliabilities (0.71 for ADG and 0.72 for LW) accuracy of EBV for individual feed intake was increased. These results show that with index combining genetic values of growth and live weight with RFI, genetic potential for individual feed intake of boars could be estimated more accurately than with only individual EFI.

Key words: feed intake, index, reliability

480 Genetic correlations between purebred Limousin and F1 Limousin*Angus. R. Davis*[1], I. Misztal[1], M. Lukaszewicz[1,2], S. Tsuruta[1], and J. K. Bertrand[1], *[1]University of Georgia, Athens, [22] Polish Academy of Sciences, Institute of Genetics and Animal Breeding, Jastrzębiec, Poland.*

The purpose of this study was to estimate correlations between purebred and crossbred animals to verify efficiency of current models used in crossbreeding selection. Records on 3 weight traits: birth weight (BW), weaning weight (WW) and post-weaning gain (PW) from a purebred Limousin line (L) and a crossbred line made of Limousin*Angus F1 progeny (F1), were used to estimate correlations between crossbred and purebred animals as well as other genetic parameters using single trait models (ST; weights are the same traits in both populations) and a multiple trait crossbred model (MT; weights are different traits). For BW there were 148,647 records for L and 17,981 for F1, for WW 81,585 for L and 21,778 for F1, and for PW 37,687 for L and 11,021 for F1. Fixed effects in all models for L and F1 animals were contemporary group and month. Random effects for L animals in both models were direct genetic, maternal genetic and maternal permanent environment. Random effects for F1 were sire genetic and dam environmental. The pedigree for Angus dams was unavailable and therefore these dams were assumed unrelated. In the ST model, direct heritability estimates for purebred animals were 0.38, 0.22 and 0.31 for BW, WW and PG, respectively. For F1, the same estimates were 0.21, 0.34 and 0.34. Genetic correlations estimates between purebreds and crossbreds were 0.4, 0.6 and 0.3 for BW, WW and PG, respectively. The purebred selection in is only partially effective on crossbreds, especially for BW and PG. The selection is effective for WW where the lower genetic correlation is compensated by higher heritability. Estimates in this study may be biased by the ignoring of maternal pedigrees in F1.

Key words: crossbreeding, F1, correlation

481 The heritability of lean color and its influence on beef tenderness. P. Johnson*[1], D. Moser[2], and M. Miller[1], *[1]Texas Tech University, Lubbock, [2]Kansas State University, Manhattan.*

The objective of this study was to determine heritability estimates of lean color, as measured by subjective scoring and Hunter Colorimeter readings, and its phenotypic and genetic correlation with tenderness in beef. Data were collected over 5 years on the longissimus dorsi muscle of 1,277 head; 12 different breeds were represented. Tenderness was measured by Warner-Bratzler shear force (WBSF) and quantitative ratings were given for initial tenderness and sustained tenderness by trained sensory panelists. Phenotypic correlations were found using the GLM procedure of SAS and variance and covariance components were obtained using MTDFREML. Lean color was found to be moderately heritable (0.34 ± 0.122) while the heritability estimates of Hunter colorimeter readings varied; 2 were moderately heritable: a* (0.29 ± 0.115) and b* (0.28 ± 0.120), while the third was lowly heritable, L* (0.09 ± 0.087). Phenotypic correlations found to be significant ($P < 0.01$) were: lean color and WBSF, a* value and WBSF, L* value and WBSF, lean color and initial tenderness, L* value and initial tenderness, lean color and sustained tenderness, L* value and a* value, L* value and b* value and a* value and b* value. Both a* and b* values were found to be highly and negatively correlated genetically with WBSF (−0.71 and −0.72, respectively). The genetic correlation between lean color and WBSF was −0.46. The genetic correlations of a* value and b* value with WBSF were both high, −0.71 and −0.72, respectively. The genetic correlation between lean color and initial tenderness was also high, 0.56, while that between a* value and initial tenderness was 0.43; similar to that found between b* value and initial tenderness, 0.44. The genetic correlations between lean color and sustained tenderness, a* value and sustained tenderness and b* value and sustained tenderness were all found to be high at 0.58, 0.70 and 0.58, respectively. The genetic correlation between a* value and b* value was also found to be high, 0.63. In conclusion, regardless of how lean color is measured, it is not only heritable, but has also been shown to be moderately and highly correlated with measurements of tenderness in beef.

Key words: beef, tenderness, color

482 Multivariate characterization of morphological traits in Nigerian sheep. A. Yakubu[1], M. Okpeku[2], M. Wheto[3], S. Amusan[3], B. O. Agaviezor[4], M. A. Adefenwa[5], B. M. Ilori[3], O. Ajayi[3], G. O. Onasanya[3], J. Ekundayo[3], T. Sanni[3], C. O. N. Ikeobi[3], M. I. Takeet[6], and I. G. Imumorin*[7], *[1]Dept of Animal Science, Nasarawa State University, Lafia, Nigeria, [2]Department of Livestock Production, Niger Delta University, Amassoma, Nigeria, [3]Department of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [4]Dept of Animal Science and Fisheries, University of Port-Harcourt, Port-Harcourt, Nigeria, [5]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [6]Dept of Veterinary Microbiology and Parasitology, University of Agriculture, Abeokuta, Nigeria, [7]Dept of Animal Science, Cornell University, Ithaca, NY.*

Principal component and discriminant analyses were performed to investigate distinction and patterns of morphological variation among 4 indigenous sheep breeds sampled from all over Nigeria. Body weight and 9 linear type traits (withers height, rump height, body length, ear length, fore cannon bone length, tail length, chest girth, chest depth and rump width) were measured in 402 randomly selected West African Dwarf (WAD), Yankasa, Uda and Balami sheep, respectively. The morphometric traits of Uda and Balami sheep were significantly ($P <$

0.05) higher than those of Yankasa sheep, which in turn had a comparative advantage over their WAD counterparts. There was variation in the pattern of the loading traits of the principal components (PCs) of each sheep breed. This was further revealed by the differences in the degree of accuracy when body weight was predicted from the scores derived from the PCs of each genetic group. Based on Mahalanobis distances, the least differentiation was observed between Uda and Balami sheep (0.298) while that between WAD and Balami sheep was longest (18.004). While 93.33% of WAD sheep were correctly assigned into their source genetic group, 63.93% of Yankasa, 45.16% of Uda and 61.15% of Balami sheep were classified into their source population in the nearest neighbor discriminant analysis. The present phenotypic information could be exploited in designing appropriate management, conservation and breeding programs for Nigerian indigenous sheep.

Key words: multivariate analysis, sheep, Nigeria

483 Multivariate analysis of morphological differentiation in Nigerian goats. A. Yakubu*[1], M. Okpeku[2], M. Wheto[3], S. Amusan[3], B. O. Agaviezor[4], M. A. Adefenwa[5], B. M. Ilori[3], O. Ajayi[3], G. O. Onasanya[3], J. Ekundayo[3], T. Sanni[3], C. O. N. Ikeobi[3], M. I. Takeet[6], and I. G. Imumorin[7], *[1]Dept of Animal Science, Nasarawa State University, Lafia, Nigeria, [2]Department of Livestock Production, Niger Delta University, Amassoma, Nigeria, [3]Department of Animal Breeding and Genetics, University of Agriculture, Abeokuta, Nigeria, [4]Department of Animal Science and Fisheries, University of Port-Harcourt, Port-Harcourt, Nigeria, [5]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria, [6]Dept of Veterinary Microbiology and Parasitology, Abeokuta, Nigeria, [7]Dept of Animal Science, Cornell University, Ithaca, NY.*

The objective of the study was to morphologically characterize Nigerian indigenous goats using multivariate statistical analyses. Body weight and 9 biometric traits were measured in 352 randomly selected West African Dwarf (WAD), Red Sokoto (RS) and Sahel (SH) goats of both sexes categorized into 3 age groups from across Nigeria. The univariate analysis showed that breed, sex and age of the animals significantly ($P < 0.05$) affected the body parameters. The principal component analysis revealed variation in the morphometric characters of the goats. Stepwise discriminant analysis showed chronologically that tail length, rump width, rump height, ear length and body length were the most discriminating variables among different pair-wise breeds' comparisons. In the canonical discriminant analysis, the first canonical variate was significant and accounted for 95.5% of the variability among the goat breeds. The longest Mahalanobis distance was that between WAD and SH goats (11.44; $P < 0.001$) while the shortest was recorded for RS and SH goats (1.50; $P < 0.01$), respectively. The dendrogram showed 2 large clusters indicating that WAD and the 2 other goat breeds are separate genetic entities. Discriminant functions correctly allocated 65.79% of individual goats to their a priori breeds, although a sort of genetic introgression was observed between RS and SH goats. The present findings combined with molecular characterization could aid the formulation of management, breeding and conservation strategies for Nigerian indigenous goat resources.

Key words: multivariate analysis, goats, Nigeria

484 Searching for causal relationships among five traits of European quails. B. D. Valente*[1,2], G. J. M. Rosa[1,3], M. A. Silva[2], R. B. Teixeira[4], and R. A. Torres[4], *[1]Department of Animal Sciences, University of Wisconsin, Madison, [2]Departamento de Zootecnia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [3]Department of Biostatistics and Medical Informatics, University of Wisconsin, Madison, [4]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Structural equation models (SEM) allow modeling multiple traits expressing casual links among them. The number of different causal structures that can be used for fitting a SEM is typically huge, even when only a few traits are studied. In recent applications of SEM in mixed model settings, causal structures were pre-selected based on prior beliefs alone. Alternatively, causal structure spaces can be explored using algorithms that search for structures that are compatible with the joint distribution of the traits. However, in mixed models settings, the search cannot be performed directly on the joint distribution of the phenotypes as causal relationships are possibly masked by genetic covariances. In this context, it has been proposed that such search could be performed by applying the Inductive Causation (IC) algorithm to the joint distribution of phenotypes conditionally to unobservable genetic effects. Here, we applied this approach to a data set of 5 traits of European quails: birth weight (BW), weight at 35 d of age (W35), age at first egg (AFE), average egg weight from 77 to 110 d of age (AEW), and number of eggs laid in the same period (NE). We focus the discussion on the challenges and difficulties resulting from applying this method to field data. Statistical decisions were based on different Highest Posterior Density (HPD) interval contents (70, 75, 80, 85, 90, and 95%). Resulting causal structures were fitted and models were compared using the Deviance Information Criterion (DIC). In addition, we used temporal information to perform additional edge orienting, overriding the algorithm output when necessary. As a result, the final causal structure consisted of 2 separated substructures: BW→AEW and W35→AFE→NE.

Key words: causal relationships, European quails, structural equation models

Companion Animals Symposium: Living Beyond 20: Discoveries in Geriatric Companion Animal Biology

486 Living beyond 20: Discoveries in geriatric companion animal management, nutrition and behavior. C. L. Morris*, *Omaha's Henry Doorly Zoo, Omaha, NE.*

It has traditionally been the responsibility of the animal science community to develop management, nutrition, health and well-being protocols for animals raised for production purposes. The vast array of scientific inquiry dedicated to production livestock have been instrumental in the management of these animals to optimize a value-based end product. Within the last several decades however, the animal science landscape has changed and diversified to include companion and exotic animals. In contrast to production animals, companion and exotic animals typically are not managed for production purposes; therefore, shifting the goals of animal husbandry away from production and toward longevity. Companion animals are valued in the home for their companionship and service, while exotic animals are typically managed for exhibit, education, research, or species conservation programs. This diversification of species included within the scope of the Animal Science community has provided a new direction for research efforts as the majority of these animals should live healthy lives that allow them to reach their senior years. Approximately 25% of dogs and cats in the United States are over 7 years of age and a large number of captive zoo animals are considered geriatric. In fact, many exotic animal species live longer in captivity due to managed health practices, genetics, optimal nutrition, and appropriate husbandry. These are significant and growing animal populations with specialized needs regarding nutrition, veterinary care, and behavioral husbandry management. While research efforts have been invaluable in promoting the health and longevity of these aging animal populations, additional research efforts are still needed to better understand the physical, physiological, and cognitive changes of geriatric animals and how to apply those discoveries to animal husbandry. The objectives of this symposium are to explore the scientific discoveries specific to the quality of life, nutrition and well-being of geriatric companion and exotic animals and to encourage and promote future research related to these growing animal populations.

Key words: geriatric animals, husbandry

487 Longevity, not production: When rate of gain is not the focus. T. A. Faber and G. C. Fahey Jr.*, *University of Illinois, Urbana.*

Feeding companion animals involves a different focus and strategy than feeding livestock. Diets for companion animals must be designed to supply the nutrient needs of the animal not only for today but for years to come. Changes in health and appearance associated with animal aging are based on genetic control, gradual loss of homeostasis of physiological systems, accumulation of toxic compounds (i.e., lipofuscin and free radicals), or combinations thereof. To enhance longevity, the process begins in utero. Proper development is dependent on the nutritional status of the mother, as she is the sole source of nutrients. After birth until weaning, the animal is mainly dependent on mother's milk. The mother's diet influences the nutrient composition of her milk and, thus, the nutrients the offspring receives. Post-weaning, factors such as body weight gain, calcium:phosphorus ratio, and essential fatty acid intake, play a role in the physical and mental development of the animal. Promoting the proper development of these systems may prevent health issues that may occur later in life. As an adult, the animal's nutrient intake should allow maintenance of a healthy body weight and proper nutrient balance to limit stress on physiological systems. A healthy body weight alone has been shown to play an important role in longevity. As the animal enters a geriatric state, the body's physiological systems begin to slow and they lose the ability to replenish themselves. Energy requirements may decrease by 20%, while protein and essential fatty acid requirements increase. Feeding a highly digestible, highly nutrient bioavailable diet, may improve nutrient absorption and keep the body nourished. In addition, feeding supplements such as glucosamine and antioxidants may improve joint health and limit free radical damage, respectively. Targeted feeding strategies throughout life may enhance the longevity of the companion animal.

Key words: companion animals, health, longevity

488 Obesity: What is wrong with being fat? D. P. Laflamme*, *Nestle Purina PetCare Research, St. Louis, MO.*

Few diseases in modern pets are "diet-induced." One possible exception to this is obesity, which is ultimately caused by consuming more calories than needed by the dog or cat. While fat is the most concentrated and efficiently stored source of calories, and protein least so, an excess of calories from any source will contribute to adiposity. Obesity is an excess of body fat sufficient to result in impairment of health or body function. In people, this is generally recognized as 20–25% above ideal bodyweight. This degree of excess is important in dogs as well. A lifelong study in dogs showed that even moderately overweight dogs (mean body condition score [BCS] of 6.7 out of 9) were at greater risk for earlier morbidity and a shortened lifespan. In addition, these dogs required medication for chronic health problems sooner than their lean-fed siblings. The average difference in body weight between groups was approximately 25%. Obese cats also face increased health risks, including an increased risk of arthritis, diabetes mellitus, hepatic lipidosis and early mortality. The risk for development of diabetes increases about 2-fold in overweight cats and about 8-fold in obese cats. Altered adipokine secretion appears to be an important mechanism for the link between excess body weight and so many diseases. Adipose tissue, once considered to be physiologically inert, is an active producer of hormones such as leptin and resistin and cytokines, including many inflammatory cytokines such as tumor necrosis factor α (TNFα), interleukins 1β and 6, and C-reactive protein. The persistent, low-grade inflammation secondary to obesity is thought to play a causal role in chronic diseases such as osteoarthritis, cardiovascular disease, diabetes mellitus and others. TNFα, for example, alters insulin sensitivity by blocking activation of insulin receptors. In addition, obesity is associated with increased oxidative stress, which also may contribute to obesity-related diseases. Management of obesity involves nutritional modification as well as behavioral modification.

Key words: obesity, canine, feline

489 Cognition and behavior in geriatric animals: If they had Sudoku what would it look like? K. L. Overall*, *University of Pennsylvania, Philadelphia.*

Especially when it comes to pets, we often think that decrements in mental and physical acuity are "normal aging changes." What if such

changes are the result of an interaction of "lack of use" with physiological/molecular responses to a life of exposure to stressors? If this is true, and there is a now considerable evidence to suggest that it is, we may be able to ameliorate age-related cognitive changes through a series of interventions including medication, diet, exercise and targeted cognitive stimulation. The type of stressor may matter. Military working dogs who are deployed live longer than those who are not deployed: their world is stressful, but it also is stimulating. The trick may be to define "targeted cognitive stimulation" in non-humans. In short, what does Sudoku look like if you don't have written language? Problem solving can be tactile, olfactory, visual-spatial, social, et cetera, yet few of these avenues are pursued. New evidence from dogs suggests that there are creative interventions that can ensure that we may delay decrements in cognitive function in canines and other animals who depend on us. In turn, these animals may be excellent models for testing interventions for humans.

Key words: canine cognition, dog, brain aging

490 Skinny old critters: Managing diet and expectations. C. L. Morris[1] and J. Cline*[2], [1]*Omaha's Henry Doorly Zoo, Omaha, NE* [2]*Nestle Purina Petcare Product Technology Center, St. Louis, MO.*

There are significant unstoppable changes in multiple organ systems as animals age. The age at which visible or clinical signs of aging occur is dependent on species, genetics, lifestyle, environment and diet. Though aging is a natural progression of physiology, emerging research indicates that many changes may be delayed through appropriate dietary management and alterations in lifestyle and environment of geriatric animals. The aging process may impact diet palatability, intake and food preference in some geriatric animals as a result of physical changes in nasal epithelium, hyposmia, hypoguesia, or food fatigue/aversion. Additionally, a more serious "visible" sign of aging is the reduction in nutrient utilization along with energy demands that may be in conflict. For example, old dogs require about 40% more protein than young dogs of the same size (Wannamaker and McCoy 1966); however, energy demands in some animals may be elevated or reduced. Although obesity is a major concern in both pet animals and zoo animals, many pet cats and captive exotic felids lose body condition throughout the aging process. Up to 33% of cats over 11 have compromised fat digestibility and 25% of cats over 11 have decreased protein digestibility (Perez-Camargo 2010; Cupp 2010). With obesity being a major concern for companion and zoo animals, caloric restriction without malnutrition throughout the lifetime remains a proven method for extending lifespan and slowing the aging process in mammals (Anderson et al., 2009). During a 14 year study in dogs, it was concluded that age at which chronic disease required treatment could be delayed by about 2 years through calorie restriction during their lifetime. Most animals that live their natural lifespan will likely develop an age related disease. Prevalent "aging" diseases in companion and zoo animals include neoplasia, hypo/hyperthyroidism, diabetes, kidney, liver or heart disease. Management of animal's environments, diet, plane of nutrition, managing expectations of caregivers, and public perceptions will be discussed.

Key words: geriatric animal nutrition, companion animals, exotic animals

491 Bones and joints: Improving mobility in senior years. B. Lussier*[1,2], [1]*Department of Clinical Sciences, Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, Quebec, Canada,* [2]*University Hospital Research Center, University of Montreal, Montreal, Quebec, Canada.*

Osteoarthritis (OA) is frequently encountered in small animal practices. It is a chronic, crippling disease. It has been reported to affect 20% of the canine population in the USA. It is a degenerative process invariably leading to joint effusion, fibrosis and pain thus reducing the quality of life of dogs. OA in dogs is secondary to conformational, hereditary, degenerative and traumatic diseases. The most frequent causes of OA in dogs are hip dysplasia, elbow dysplasia, osteochondrosis and rupture of the cranial cruciate ligament. Some of these are hereditary conditions, while the causes of others are unclear. It has been established that nutrition may play a role in modulating the occurrence or severity of these diseases. At a young age, nutrition is important to prevent or decrease the expression of developmental diseases of dogs. It has been reported that lifetime food restriction has a significant impact on the lifespan of dogs. It significantly increases median lifespan and decreases the prevalence and severity of OA in several joints. In the latter months or years, when dogs are clinically afflicted by OA, its treatment is multimodal. Management of OA consists of the following: surgically treating the primary cause if possible, reducing the patient's weight, using adapted activity combined with physical therapy, using therapeutic nutrition and finally using pharmacological therapy. The nutritional management of OA is 2 fold: weight management and therapeutic nutrition. It is well recognized that weight reduction can alleviate the clinical signs of OA in dogs and that a weight increase is detrimental to function in OA dogs. Therapeutic nutrition must thrive to provide nutrients that may help reduce inflammation and pain, support cartilage repair, slow the degenerative process, thus improving function of the patient. Specifically developed diets and supplements have been used. They contain: Ω-3 fatty acids, greenlipped mussels, L-carnitine, chondroitin sulfate, glucosamine, antioxidants, vitamins E and C. In conclusion, nutrition plays an important role in the prevention/delay of OA, in modulating the severity of OA and in the treatment of dogs clinically afflicted by OA

Key words: osteoarthritis, canine, nutrition

Dairy Foods Symposium: Innovations in Dairy Processing Unit Operations

492 Plate heat exchangers. J. C. Bohn*, *AGC Heat Transfer Inc., Bristow, VA.*

The role of the plate heat exchanger in pasteurization makes it arguably one of the most essential pieces of equipment in modern dairy operations. Plates designed specifically for sanitary applications have emerged with flow patterns that improve clean-in-place response, with pressing depths that cater to viscous flows, with surface finishes that enhance clean-ability, and with material thicknesses that yield improved mechanical strengths to withstand the process stresses as well as frequent opening and closing cycles. These plate characteristics have improved the overall operational efficiency of plate heat exchangers. The use of rheological data to characterize formulated dairy products, along with improved computational algorithms, has increased design accuracies of plate heat exchangers. The demand for increased production has forced plate manufactures to utilize various methods in designing units to accommodate extended run times as well as achieving good clean-in-place response. Ice pigging, using pump-able slurry, has been introduced as a new method of reducing product losses, improving cleaning times and reducing biological oxygen demand loads. Modern dairy operations have benefited from easily opened and closed hydraulically driven twin screw frames that improve worker safety while easing the burden of field inspecting the internal product contact surfaces at an appropriate frequency. Third party field inspection of plate heat exchangers has become a standard practice in most all dairy operations, is recommended by 3-A standard 11–09, and has proven to be a valuable tool in ensuring the operational readiness of dairy pasteurizers.

Key words: pasteurization, rheology, pasteurize

493 Dairy processing efficiency and safety gains from double-seat valve technology. L. W. Clem*, *Electrol Specialties Company, South Beloit, IL.*

Double-Seat or Mixproof valve technology has undergone design changes within the last few years that allow the US dairy processor to significantly benefit from their application. The valve design allows separation of 2 product streams or a product and cleaning solution stream in the space of a single hygienic valve all while under automatic control and position monitoring. The design improvements include technologies to further enhance the separation of liquid streams through specialized seat contours and/or the use of deflector discs to assure safety and complete separation of fluid streams. These new valve types are allowed specialized process operational consideration and are recognized by the Pasteurized Milk Ordinance as acceptable means to provide for separation of pipelines. The double seat valve can be applied without reservation in product receiving and storage, fluid batching and blending operations, thermal process systems, and everywhere there is a need to segregate products or cleaning solutions. Elimination of process openings or connection points reduce or eliminate potential product contamination and/or personnel exposure to fluids including hot or streams potentially containing chemical solutions for cleaning.

Key words: dairy processing, equipment, valves

494 Innovations in homogenizer and separator technology for the modern dairy plant. W. Rowlands*, *Rowlands Sales Co. Inc.*

Demand for improved shelf life, higher flow rates, and lower operating costs are affecting design and integration of homogenizers and separators in today's efficient dairy operation. Modern innovations must incorporate energy reduction and natural resource sustainability. Machinery longevity, possible negative product attributes, and additional maintenance burdens all need to be considered. Evolving trends in homogenizer design include noise and vibration reducing drives, energy conserving low pressure homogenizing valves, cylinder blocks with improved CIP path, water reclamation systems and hands free automation. Emerging separator technology includes enhanced cleanability, hermetic machine design, longer bowl shoot intervals and additional machine automation. All improve product quality, while some minimally increase certain product yields. Water saving technology increases natural resource sustainability. Energy efficient drivetrains lower electric consumption while reducing surrounding workplace noise and vibration.

Key words: homogenizer, separator

495 Filtration systems. D. Weber*, *Parker Hannifin Process Advanced Filtration, Oxnard, CA.*

This symposium presentation will provide updated information important to efficient operation of membrane filtration systems. An overview of filtration technology including new developments in dairy applications and membrane products will be provided. Element configuration including material limiting factors, trends in system configurations, and cost versus configuration options will also be discussed.

Key words: membrane, filtration

Dairy Foods: Microbiology and Probiotics

496 Use of high pressure processing to control *Listeria monocytogenes* in packaged Queso Fresco. P. Tomasula*[1], L. Leggett[1], R. Kwoczak[1], D. Van Hekken[1], M. Tunick[1], J. Renye[1], M. Toht[1], S. Mukhopadhyay[2], A. Porto-Fett[3], and J. Luchansky[3], *[1]USDA/ARS/ERRC/Dairy and Functional Foods Research Unit, Wyndmoor, PA, [2]USDA/ARS/ERRC/Residue Chemistry and Predictive Microbiology Research Unit, Wyndmoor, PA, [3]USDA/ARS/ERRC/Food Safety Interventions Research Unit, Wyndmoor, PA.*

Queso Fresco (QF), a fresh, Hispanic-style cheese, is manufactured using pasteurized milk; however, its high pH (>6) and moisture content (>50%) coupled with post-pasteurization labor intensive practices may lead to contamination with Listeria monocytogenes (LM). The objective of this study was to evaluate the effectiveness of high pressure processing (HPP) as an intervention applied to QF after packaging to control LM. QF was manufactured from pasteurized milk using a commercial-make procedure. In preliminary experiments, about 8 kg of the dry, finely milled and salted curd was packed into a mold and held at 4°C overnight before the mold was removed. QF was then cut into slices with dimensions of about 12.7 cm x 7.6 cm x 1 cm. QF slices were surface inoculated on both sides with 50 µL of a 5-strain LM cocktail (ca. 5.0 $\log_{10}$cfu/g), individually double vacuum-packaged and then cooled to 4°C. The slices were then warmed to either 22 or 40°C and treated using HPP at pressures of 200, 400, and 600 MPa for holding times of 0, 5, 10 or 20 min. Only HPP treatment at 600 MPa, at both temperatures and all holding times, reduced LM to below the detection level of ≤0.91 $\log_{10}$cfu/g. Processing at 40°C resulted in visible textural changes and significant "wheying-off" of the cheese and was not investigated further. In subsequent experiments, QF slices were treated at 22°C and 600 MPa at holding times of 0, 3, 10 and 20 min and then stored at 4 and 10°C for 7 d. For the 3 min holding time, LM populations increased to 2.65 ± 0.92 and 4.50 ± 0.50 $\log_{10}$cfu/g, when QF was stored at 4 and 10°C, respectively. For the 10 min holding time, LM populations in QF remained below the detection level when stored at 4°C but increased to 2.00 ± 0.00 $\log_{10}$cfu/g when stored at 10°C. For the 20 min holding time, LM populations were not evident in QF when stored at 4°C but approached the detection level at 10°C. These results show that HPP was most effective when conducted at 600 MPa for 20 min, but HPP pressures >600 MPa, pulsed HPP, or addition of antimicrobials, may be necessary for ultimately controlling this pathogen.

Key words: *Listeria monocytogenes*, high-pressure processing, cheese

497 High-pressure processing of lowfat Cheddar cheese. M. Ozturk*[1], S. Govindasamy-Lucey[2], J. J. Jaeggi[2], K. Houck[2], M. E. Johnson[2], and J. A. Lucey[1], *[1]University of Wisconsin, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

A major problem with lowfat cheese is the difficulty in attaining a strong flavor that is typical of full fat versions. Some studies have suggested that the use of high hydrostatic pressure (HHP) can accelerate cheese ripening by increasing starter lysis. Our objective was to investigate the use of HHP on lowfat Cheddar cheese with the goal of improving or accelerating flavor and texture development. To study the impact of pressure and holding time on the rheological, physical, chemical and microbial characteristics of lowfat Cheddar cheese, we used a central composite rotatable design with response surface methodology. A 2–level factorial experimental design was chosen to study the effects of the independent variables (pressure and holding time) with 2 star points (α = 1.414) and 2 replicates of the center point. Pressures varied from 50 to 400 MPa and holding times ranged from 2.5 to 19.5 min. We performed the design in 2 blocks (i.e., replicated the design), and validated its predictions with another trial. HHP was applied one week after cheese production, and analyses were performed at 2 wk, and 1, 3, and 6 mo. With an increase in pressure, cheeses had higher pH and residual lactose levels, and lower starter and non-starter bacteria counts. Compared with untreated cheeses, all HHP-treated cheeses had lower acid/base buffering areas due to solubilization of residual insoluble calcium phosphate. Cheeses treated with higher pressures were softer and had more homogeneous texture. Pressure had a larger impact on cheese properties than holding time. Several conditions exhibited buttery flavor notes in cheeses that were perceptible within a few weeks of HHP treatment. High pressure treated cheeses also had "sweet" notes due to their high pH. We did not observe any significant difference in proteolysis rates. This study indicates that holding times of around 5 min and pressures of ≥300 MPa could potentially be used to improve excessive firm textured cheese or reduce unwanted microbial activity.

Key words: high-pressure processing, lowfat cheese

498 The effect of UV light treatment and processing method on the microbial reduction of pasteurized whole milk. J. Tharani*, A. Laubscher, A. M. Lammert, and R. Jimenez-Flores, *Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

UV (UV) irradiation does not involve heat to kill microorganism. Therefore, it is of interest to the dairy food industry as a potential low cost non-thermal method of preservation. The objective of this study was to determine the impact of UV treatment immediately before or after pasteurization on microbial reduction in whole milk. A total of four controls and four test variables were produced. The controls were single or double pasteurized milk with or without the UV equipment. The test variables were UV light followed by pasteurization or pasteurization followed by UV at either 138 J/L or 920 J/L. Raw whole milk was standardized to 3.5% fat and each variable thermally processed at 166°F for 16 seconds and homogenized at 500/2000 psi. A Sure Pure Photo-Purification unit was used for UV treatment. Microbial testing was completed every 3 d until 21 d post processing. All variables were replicated 5 times. The results show that the reduction in microbial load was from 91,000 cfu/ml to 20 cfu/ml, 16 cfu/ml, 13 cfu/ml and 19 cfu/ml for the controls of single pasteurized with UV, single pasteurized without UV, double pasteurized with UV and double pasteurized without UV respectively. Alternatively, the reduction in microbial load was from 91,000 cfu/ml to <10 cfu/ml, 13 cfu/ml, <10 cfu/ml and 14 cfu/ml for UV treatment at 920 J/L followed by pasteurization, UV treatment at 138 J/L followed by pasteurization, pasteurization followed by UV treatment at 920 J/L and pasteurization followed by UV treatment at 138 J/L respectively. At the end of three weeks, the microbial load increased for all controls and test variables except for UV treatment at 920 J/L followed by pasteurization where the microbial population was still below 10 cfu/ml. After 3 d, differences were found in cardboard, fruity, and light oxidized flavors. Results indicate that when raw whole milk is treated with UV light at 920 J/L followed by pasteurization, there is a reduction in microbial load and the low microbial load is maintained throughout 21 d.

Key words: fluid milk, UV light

499 Tina wooden vat biofilms used in Sicilian PDO Ragusano cheese provide a new cluster of *Streptococcus thermophilus* strains. V. Florence[1,2], C. Delorme[3], C. Pediliggieri[4], M.-N. Madec[1,2], V. Chuat[1,2], S. Parayre[1,2], S. Carpino[4], P. Campo[4], P. Renault[3], S. Lortal*[1,2], and G. Licitra[4], *[1]INRA, UMR1253, STLO, Rennes, France, [2]Agrocampus Ouest, UMR1253, STLO, Rennes, France, [3]INRA, Micalis, Jouy en Josas, [4]CoRFiLaC, Ragusa, Sicily, Italy.*

Ragusano cheese (PDO) is a brine-salted pasta filata cheese from Sicily. Raw milk is directly placed in the traditional wooden vat (tina) for cheese making. The biofilm present on this tina was shown to be a safe and very efficient lactic acid bacteria delivering system. Depending on the farm, the biofilm exhibited 2 to 10 co-dominant species, thus representing a valuable source of biodiversity. In this work, *S. thermophilus* was shown, by RT-PCR-TTGE, to be the more active species in 3 different tinas over a 2 years period. To explore the biodiversity within *S. thermophilus*, 25 clones per tina and per year were isolated from M17 plates and analyzed by Pulsed field gel electrophoresis (PFGE) and multi locus sequence typing (MLST). Many different PFGE profiles were obtained highlighting the strain biodiversity within each tina. Some of the profiles were highly related suggesting clones from the same initial strain derived by minor variations; however, each tina contained at least 4 co-dominant strains of *S. thermophilus*. From the cheese at d 1, 22 clones were also isolated and analyzed by PFGE. Most of the profiles were similar to the one of the biofilm, confirming the crucial role of the tina in inoculating *S. thermophilus* for the acidification step. A MLST analysis was applied on 50 strains of *S. thermophilus* isolated from the biofilm using the 6 following genes glck, ddlA, tkt, proA, ptsi, serB. Seven completely new sequence types were found. When compared with 170 other strains of *S. thermophilus* coming from all over the world analyzed by MLST in the same conditions, strains isolated from Tina whatever the year and the farms formed a completely separated group, a new cluster. Special phenotypic traits of these new strains of *S. thermophilus* are under investigation.

Key words: cheese, *Streptococcus thermophilus* biodiversity, biofilm

500 Molecular identification and characterization of *Lactococcus lactis* ssp. *lactis* and *Lactococcus lactis* ssp. *cremoris* by FTIR and its utilization for Cheddar cheese production. H. U. Rehman*[1], M. Nasir[1], S. U. Rehman[2], M. A. Jabbar[1], and M. A. Ali[1], *[1]University of Veterinary & Animal Sciences, Lahore, Punjab, Pakistan, [2]University of Agriculture Faisalabad, Faisalabad, Punjab, Pakistan.*

Cheese starter cultures are expensive and precarious in subcontinent countries like Pakistan. Hence, it is imperative to isolate and characterize indigenous cultures for sustainable and low priced cheese production in the country. The present study was designed to isolate, identify and characterize the *Lactococcus lactis* ssp. *lactis* and *Lactococcus lactis* ssp. *cremoris*, from milk samples. The cultures were isolated through agar media, from milk samples collected from different locations of Faisalabad, Pakistan and then identified on morphological basis by Gram staining, sugar fermentation and catalase tests. Phenotypic characterization of commercial and local made cultures was done by FT-IR spectroscopy; a rapid and novel phenotypic finger printing method, that creates holistic biochemical profile of microorganisms by developing spectra in a specific range. The preservation of isolated bacterial cultures was done at 4°C, which decreased significantly ($P \leq 0.05$) with time but the viability was non-significant compared with commercial culture. Isolated and commercial culture were used at 1% to produce Cheddar cheese for physico-chemical and sensory evaluation. The texture of test cheeses produced with local culture was less elastic compared with control cheese sample produced with commercial culture. The color, flavor and overall acceptability scores of cheese samples with different cultures were not significantly different ($P \geq 0.05$). It is concluded that cheese prepared from indigenous isolated culture was comparable with that of commercial culture cheese and therefore, further studies should be carried out for commercial production of various cheese cultures.

Key words: Cheddar cheese, starter culture, FTIR

501 Transcriptional and physiological responses of *Bifidobacterium animalis* ssp. *lactis* strains to hydrogen peroxide stress. T. S. Oberg*[1], R. E. Ward[1], J. L. Steele[2], and J. R. Broadbent[1], *[1]Utah State University, Logan, [2]University of Wisconsin, Madison.*

Consumer interest in probiotic foods containing bifidobacteria is increasing, but industry efforts to secure high cell viability in foods is undermined by the sensitivity of these anaerobes to oxidative stress during food production or storage. To address this limitation, we investigated transcriptional responses of 2 fully sequenced *Bifidobacterium animalis* ssp. *lactis* strains, BL04 and DSM10140, to hydrogen peroxide (H_2O_2) exposure. Although the genome sequences for these strains are virtually identical, they display different levels of intrinsic and inducible H_2O_2 resistance. For transcriptomics, late log phase cells were exposed to a sub-lethal H_2O_2 concentration for 5 or 60 min, then mRNA was isolated, converted to cDNA, and hybridized to an Affymetrix microarray. Data analysis by the limma/eBayes method found significant ($P < 0.05$) changes in 158 genes in BL04 after 5 min, and 30 differentially expressed genes after 60 min. Surprisingly, no significant changes in gene expression were detected in DSM10140 at either time. Examination of genomic data for each strain suggested differences in H_2O_2 stress resistance might be related to membrane lipid composition, due to genetic mutations in genes for long chain fatty acid-coA ligase. To address this hypothesis, membrane fatty acids were isolated and analyzed by GC-MS. Results confirmed the 2 strains had significantly different lipid profiles. In particular, the BL04 membrane contained higher percentages of C14:0 and C16:0, and lower percentages of C16:1n7 and C18:1n9. These differences could affect membrane fluidity and, potentially, transduction of stress signals, either of which could explain the observed contrasts in H_2O_2 stress resistance.

Key words: *Bifidobacterium*, stress response, hydrogen peroxide

502 Fresh cheese containing higher inoculation of *L. acidophilus* and its effect on the functionality and metabolism of probiotic culture. A. Cruz, J. Faria*, W. Castro, R. Cadena, and H. Bolini, *University of Campinas (UNICAMP).*

This work aimed to evaluate the effect of supplementation with increasing *L. acidophilus* counts on the physicochemical parameters and functionality of fresh Minas cheese. Probiotic fresh cheese (Minas cheese) was supplemented with *L. acidophilus* La-14 (0, 0.4 or 0.8 g/L milk) being submitted to physico-chemical analysis (pH, proteolysis and organic acids levels) and microbiological analysis (probiotic and starter viable count) for 21 d refrigerated storage. In addition, conventional and probiotic commercial cheese supplemented with *Bifidobacterium animalis* Bi-07 were submitted to the same analysis. It was observed an effect of the storage time on the physical-chemical parameters and the microbiological counts ($P < 0.05$). Probiotic cheeses inoculated with increasing concentrations of *L. acidophilus* and the

commercial probiotic cheese presented lower pH values, greater proteolysis level and organic acids production along the refrigerated storage. *L. acidophilus* ranged from 9.42 to 9.11 log cfu/g, maintaining the functionality of the product throughout the shelf life. *B. animalis* counts ranged from 8.36 and 8.91 log cfu/g, while *Lactococcus lactis* count ranged from 8.93 to 7.49 log cfu/g. Additional consumer test should be performed to evaluate the changes due the supplementation of higher *L acidophilus* counts during the fresh cheese processing.

Key words: probiotic cheese, *L. acidophilus*, functionality

503 Microbiological and physico-chemical properties of probiotic whey beverages processed with different whey concentrations. W. Castro, A. Cruz, J. Faria*, M. Bisinotto, and R. Celeghini, *University of Campinas (UNICAMP).*

The use of whey in probiotic beverage formulations can be an option to address environmental challenges faced by the dairy industry. This work aimed to evaluate the microbiological and physico-chemical properties of probiotic whey beverages processed with increased whey concentrations. Whey probiotic beverages were manufactured with 0, 20, 35, 50, 65 and 80% (w/w) liquid sweet whey (pH = 6.48, Minas fresh cheese whey) concentrations and were subjected to physico-chemical analysis (pH, proteolysis, color values) and microbiological count (*Streptococcus thermophilus*, *Lactobacillus bulgaricus*, and *Lactobacillus acidophilus*). The whey concentration had an effect on all parameters analyzed. The pH values ranged from 4.07 to 4.14 ($P > 0.05$), while proteolysis was inversely proportional to the whey concentration. The color values (Hunter Lab Color, Minolta) were inversely proportional to the whey concentration, without difference between samples except for 65 and 80% whey ($P > 0.05$). *S. thermophilus* counts ranged from 8.37 to 9.05 log cfu/mL ($P > 0.05$), while *L. bulgaricus* count ranged from 8.01 to 8.31 log cfu/mL ($P < 0.05$). Regardless of the whey concentration, all products presented high values for *Lactobacillus acidophilus* count (minimum value of 8.1 log cfu/mL; $P > 0.05$), suggesting that the whey beverage was an adequate food matrix to be supplemented with probiotic bacteria. The findings indicate that increased whey concentrations had and effect on the physico-chemical parameters of whey probiotic beverages. Additional consumer testing is needed to evaluate their acceptance.

Key words: whey probiotic beverage, functionality, stability

504 A dairy safety program: Considering human and animal safety. M. A. Smith*, G. R. Hagevoort, and F. A. Rivera, *NMSU Ag Science Center, Clovis.*

The dairy industry in the Southwest has experienced a decade of expansion in regards to the number of milking cows and concomitant number of employees. In this process, a new management structure, historically absent from dairy farms with fewer employees, is being developed. It has been recognized that there is a need for middle management positions, responsible for training and supervising employees, much like positions established within other similar sized industries. In the past, the task of training and supervision of employees typically was that of upper management. With increasing employee numbers, this task is often delegated to employees with seniority. NMSU Dairy Extension was asked by producers to assist in providing training tools for large open lot dairies, permitting room for inclusion of dairy particular protocols. This has led to the development of a dairy safety training program consisting of a DVD and a manual (in English and Spanish) for on dairy training purposes entitled Considering Human and Animal Safety: Dairy Safety Training for New Mexico Dairy Producers. The format allows supervisors and managers the opportunity to establish safety protocols within their individual farms. The program is based on the notion that well trained workers have high regards for their own safety as well as that of the safety of others and the safety and well-being of the animals they provide for. The program can be regarded as an essential part of an overall Quality Assurance Program. The program raises awareness of unsafe or potentially harmful working conditions, which with early detection may take minimal correctional action. By presenting guidelines on how to safely handle dairy cows in various common situations on the dairy farm, as well as how to work with heavy equipment in a safe manner, management can train both new and current employees. Emphasis is put on understanding animal behavior as the basis for safely working with and around animals. Part II is currently being developed and will specifically focus on individual positions on the dairy such as: milkers, outside caretakers, feeders and calf raisers.

Key words: animal well-being, dairy quality assurance, employee safety training

505 Assessing a comprehensive dairy cattle economic program for practicing dairy veterinarians. G. M. Schuenemann*, D. Shoemaker, D. Breece, S. Bas, and J. D. Workman, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The purpose of the study was to assess the effectiveness of a team-based educational program designed to enhance the flow of applied economic information to dairy veterinarians. A comprehensive dairy cattle economic program was developed and participants from 11 veterinary practices located in 5 States (IN, NY, PA, NM, and OH), serving an estimated 186,150 dairy cattle in 469 herds, participated in the advanced dairy cattle economic modules (2 d each, ~40 h of learning). Financial statements (balance sheet, profit and loss); production and financial factors that affect business performance; financial ratios and business analysis; net farm income per cow (cost of production), milk pricing, economic decision tools (value of a pregnancy, number of milking times, income over feed cost, borrowing money); economics of uterine diseases and mastitis; grains and biofuels outlook; and transitioning the dairy farm to the next generation were discussed. Educational materials were delivered through in-class lectures followed by case-based learning, group discussions, and participant presentations of out-of-class assignments. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained in both modules. Participants evaluated the program and provided feedback at the conclusion of each module. Veterinarians reported that the overall program, presentations and discussions were useful and of great immediate use to them. The presented materials and the educational delivery methods substantially increased the knowledge level of the attendees (18% increase from pre- to post-test scores; $P < 0.05$). Importance of knowing the costs of production, costs of diseases, business objectives (profitability, liquidity, and solvency), written record-keeping for small dairies, regular meetings with the production team, and the use of computerized decision-making tools were listed as learned concepts that participants can apply in their practices. Results suggested that both economic modules were relevant and effective; offering practical economic information with immediate field application.

Key words: dairy cattle economics, education, veterinary

506 III. Dairy calving management: Assessment of a comprehensive program for dairy personnel. G. M. Schuenemann*, S. Bas, E. Gordon, and J. Workman, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The purpose of the study was to assess the effectiveness of a comprehensive educational program (CEP) designed to improve calving management practices of calving personnel and communication within the farm team. Calving personnel (n = 47), attending an estimated of 13,100 cows from 12 Ohio dairies, attended the calving management program (~2 h of training and ~1 h of demonstration). Bovine reproductive anatomy, behavioral signs of normal parturition (stages 1–3), dystocia (presentations and positions), hygiene practices during the assistance procedure, strategies for intervention (when and how to intervene), record-keeping, communication (when to call for help), and newborn care were discussed. Post-training follow ups (2 per yr) were available for participating herds. The impact of the CEP on stillbirth was assessed in 1 herd (292 births). Educational materials were delivered through lectures followed by group discussions and hands-on demonstrations. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained during the training program. Participants evaluated the program and provided feedback at the conclusion of the program. Dairy personnel reported that the overall program, presentations, and discussions were useful. The presented materials and demonstrations substantially increased the knowledge level of the attendees by 16.1 percentage points from pre- to post-test scores ($P < 0.05$). Identification of cows in need of calving assistance, hygiene practices at calving, record-keeping, and communication with the farm team were reported as learned concepts. The follow-up assessment with participant herds revealed that they were able to implement the learned skills, communicate calving records with the farm team, and have written calving protocols. The incidence of stillbirth was reduced by 9 percentage points (from 15.5% to 6.5%; $P < 0.05$). Results suggested that the CEP was relevant and effective, offering information with immediate field application. Impact outcomes such as calf-dam survival, herd performance (fertility), and long-term adoption of practices need further investigation.

Key words: calving management, education, stillbirth

507 Virtual town hall meetings as a method for engaging the public and dairy industry on contentious topics: The case of tail docking. D. M. Weary*, C. Schuppli, and M. A. G. von Keyserlingk, *University of British Columbia.*

As dairy farm numbers decline and the general population becomes increasingly urbanized, there is increasing scope for producer practices to fall out of step with public values. One method to engage producers and the public is through virtual town hall meetings where participants can state their views and see the perspectives of others. Here we report on the results of our 'Cow Views' on-line engagement designed to create discussion on tail docking and document the reasons participants put forward for and against the practice. A total of 178 people participated; 30% were producers, 23% were veterinarians, 25% had no experience with the dairy industry and 22% included a mixture of teachers, students and industry professionals. Approximately 79% of participants were opposed to docking. Responses varied with participant demographics (e.g., females were more likely than males to oppose docking), but in every demographic sub-group (e.g., by sex, age, country of origin and dairy production experience) the majority of respondents were opposed to tail docking. Common reasons for opposition to docking included the lack of scientific evidence that docking improves cleanliness or udder health, that docking is painful for cows, that docking is unnatural and that tails are important for controlling flies. Some respondents in favor of docking also cited cow cleanliness as an issue, as well as concerns about milker comfort. These results can be used to better target extension efforts (e.g., improving producer education on the lack of positive effects of docking on cleanliness and udder health, and design features of milking parlor that prevent contact with the tail). More generally, the results illustrate the use of this type of on-line discussion in providing a safe and productive format for producers, industry professionals and the public to share perspectives on contentious topics.

Key words: animal welfare, attitudes, survey

508 The Missouri Show-Me-Select Replacement Heifer Program. D. A. Mallory*, J. M. Nash, M. F. Smith, S. E. Poock, and D. J. Patterson, *University of Missouri, Columbia.*

The Missouri Show-Me-Select Replacement Heifer Program was designed to improve reproductive efficiency of beef herds in Missouri and increase individual farm income. The program objectives include: 1) a total quality management approach for health and management of heifers from weaning to late gestation; 2) increased marketing opportunities for and added value to Missouri raised heifers; and 3) the creation of reliable sources of quality commercial and purebred replacement females. The program was initiated as a pilot project in 2 regions of Missouri in 1997 with 33 farms and 1,873 heifers. During the past 14 years, 703 farms enrolled 91,776 heifers in the program. Regional extension livestock specialists serve as coordinators of the program locally and work closely with the 205 veterinarians involved with the program state wide. State specialists provide program support to regional extension field staff and participating veterinarians. The reproductive goals for heifers enrolled in the program are aimed at improving breeding performance during the heifers′ first breeding period, minimizing the incidence and severity of dystocia, with the resulting delivery of healthy, vigorous calves, and successful rebreeding of heifers during the subsequent breeding season. Heifers are now eligible to qualify as Tier 2 replacements on the basis of minimum accuracies of the heifer′s sire for specified traits at the time of sale. The marketing component of the program facilitated the sale of 22,807 heifers in 107 sales across Missouri from 1997 through the fall sales in 2010. These sales generated interest from 7,063 prospective buyers that formally registered to buy heifers, and 2,560 individuals that purchased heifers from the various sales. Heifers from the program have now sold to farms in AR, AZ, CO, FL, GA, IA, IL, IN, KY, KS, LA, MO, NE, OK, SC, TN, and TX. Collectively, 107 sales have generated $25,406,700 in gross sales. The program is estimated to have contributed $50 million to Missouri′s economy. The Missouri Show-Me-Select Replacement heifer Program is the first statewide on-farm development and marketing program of its kind in the US

Key words: beef cattle, heifer development, reproductive management

509 Enhancing knowledge and technology adoption in a misunderstood discipline: The weight trait project. M. L. Spangler*[1], E. J. Pollak[2], G. L. Bennett[2], K. J. Hanford[1], S. D. Kachman[1], L. A. Kuehn[2], W. M. Snelling[2], and R. M. Thallman[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]US Meat Animal Research Center, Clay Center, NE.*

Currently several commercial DNA marker panels are available for complex traits. In the fall of 2009, the American Angus Association integrated the results of an Angus-specific marker panel into their national cattle evaluation for carcass traits. Despite this advancement, there still exists tremendous confusion by producers as to the efficacy of DNA diagnostics. The Weight Trait Project (WTP) began in the summer of 2009 and was designed to address issues associated with creating and implementing DNA-based selection in conjunction with Expected Progeny Differences (EPD). The WTP is an ongoing unified effort among researchers, breed associations (n = 7), and seedstock producers (n = 20) to improve the process of developing and validating DNA tests and to investigate the infrastructure necessary for the flow of information required to deliver Marker-Assisted EPD to producers. The objectives of the current study were to illustrate methodology for incorporating DNA marker information into EPD predictions for the trait of weaning weight and develop mechanisms for disseminating this information to producers. To gauge changes in knowledge, practices, and behavior, a survey was sent to participants. The 17 respondents (85% return rate) indicated that collectively they own 20,125 beef cows. Increases in knowledge were rated from 0 (none) to 4 (significant). Mean survey results were 1.5, 2.8, 2.0, 3.4, 2.4, 2.7, 2.8, and 2.9 for EPD, genomics terminology, parentage verification, marker assisted selection, across breed genomic predictions, whole genome selection and panel development, test validation, and accuracy improvement of EPD, respectively. Producers indicated adoption of methods to improve the following production practices: making mating decisions (40%), efficient use of DNA technology (75%) and selection (bull buying) decisions (47%). Mean responses for changes in behavior (1 = none; 5 = very likely) were 3.9, 3.8, 4.3, and 4.6 for making more informed selection decisions, better educating their clientele, feeling comfortable with terminology, and desiring to stay abreast of DNA technology, respectively.

Key words: beef cattle, genomics, producer education

510 Evaluating cow efficiency at the producer level: The Northwest Minnesota Beef Improvement Program. R. S. Walker*[1], S. L. Bird[2], G. I. Crawford[3], and A. DiCostanzo[4], *[1]LSU AgCenter, Homer, LA, [2]University of Minnesota North Central Research & Outreach Center, Grand Rapids, [3]University of Minnesota Extension, Hutchinson, MN, [4]University of Minnesota, St. Paul.*

Measuring cow efficiency through cow size and calf weaning weight may provide opportunities to cull more strategically to improve herd efficiency. With the increase in production cost, cow size, and depressed cattle markets, profitability is narrow for the cow/calf producer. In Northwest Minnesota, bovine tuberculosis (TB) was recently detected in 12 beef herds. This resulted in a downgrade in Minnesota′s TB status, which significantly impacted movement and testing regulations and caused additional costs for marketing animals. The Northwest Minnesota Beef Improvement Program was developed to provide assistance for producers by evaluating cow size and calf performance and develop strategies for improving cow efficiency. In addition, information gained would be used as educational tools for enhancing producer awareness on the impacts of cow efficiency on profit margins. Cow and calf production and BW data were collected from each herd and summarized with a follow-up consultation with each participating producer by the University of Minnesota Beef Team. In the evaluation process for measuring cow efficiency, adjustments (ADJ) were made for cow BW (BCS 5.0 and age 5.0 yr) and calf BW (205 d of age) at weaning. In the fall of 2009, 9 beef producers and over 1,250 beef cow-calf pairs among 5 breeds were represented. Breeds consisted of Angus, Angus cross, Hereford, Gelbvieh, and Simmental. Means ± SD from all herds combined for cow age, cow ADJ BW at weaning, cow BCS at weaning, calf ADJ BW at weaning, and calf ADJ BW as a percentage of cow ADJ BW at weaning were 5.5 ± 2.8 yr, 626 ± 57.3 kg, 5.3 ± 0.7, 266 ± 35 kg, 0.43 ± 0.06, respectively. Mean cow and calf ADJ BW at weaning varied among herds ranging from 593 to 675 kg and 227 to 289 kg, respectively. Ranges in cow and calf ADJ BW means for cows with ADJ BW above the herd average compared with cows with ADJ BW below the herd average were 68 to 124 kg and –3 to 11 kg, respectively. Variations observed in calf weaning weight based on cow size across all herds indicate opportunities for commercial producers to improve herd efficiency through cow efficiency.

Key words: body weight, cow size, herd efficiency

511 The benefits of using StockPlan to assist producers make management decisions before and during dry spells or drought. M. J. McPhee*[1], M. B. Whelan[2], B. L. Davies[3], G. P. Meaker[4], P. Grahman[5], and P. M. Carberry[6], *[1]Industry and Investment NSW, Armidale, NSW, Australia, [2]Southern Cross University, Lismore, NSW, Australia, [3]Industry and Investment NSW, Paterson, NSW, Australia, [4]Industry and Investment NSW, Goulburn, NSW, Australia, [5]Industry and Investment NSW, Yass, NSW, Australia, [6]Formerly Industry and Investment, Cala, NSW, Australia.*

The StockPlan workshop assists cattle, sheep meat, and wool producers explore the financial consequences of management options before and during dry spells or drought. An independent survey of 345 properties in the central western area of New South Wales, Australia was conducted. The survey found that 195 properties participated in a StockPlan workshop. The benefits achieved from the 195 properties indicated that 75% of respondents received at least one benefit from the StockPlan workshop: 63% improved ground cover, 25% reduced stress, 24% increased productivity, and 15% maintained or increased stocking capacity. The StockPlan workshop demonstrates how to use Drought Pack, Feed Sell Agist (FSA) Pack, and ImPack. Two case studies illustrate the assistance that producers receive. FSA Pack was used to assist cattle producers determine whether they should "feed," "sell," or "agist" cattle. A sensitivity analysis of the buying and selling options was performed. FSA Pack assisted the beef producers decide that the "sell" option had the lowest associated risk. The second case study used ImPack to evaluate 3 options: "sell 10% of stock"; "keep and feed all stock"; or "sell progeny as weaners and keep and feed cows" for a mixed cropping and beef enterprise. A -year breeding herd re-structure was performed for each of the 3 options. The ImPack analysis based on a cash-flow analysis indicated that "sell 10% of stock" was a better option because it reduced interest payments early in the planning period and therefore assisted in reducing the overall debt.

Key words: case study, cash flow, sensitivity

512 Carcass and meat quality characteristics of exhibition swine. S. J. Moeller*, H. N. Zerby, K. S. Betts, M. J. Bishop, S. M. Crawford, M. D. Cressman, and A. S. Gress, *The Ohio State University, Columbus.*

The objective was to characterize performance and pork quality of barrows exhibited at the Ohio State Fair (OSF) from years 2000 to 2010. Data set one (MQP; n = 181 Duroc, n = 553 crossbred pigs) pigs were weighed (~20.5 kg), placed on test (~102 d) at the exhibitor's operation, and exhibited at the OSF based on start weight. Data set 2 (CH) included 419 grand- and reserve-champion barrows (n = ~42 annually) from 10 purebred and one crossbred population, and pigs were exhibited based on live weight. Carcass backfat (BF), loin area (LMA) and loin quality (visual color (C), marbling, firmness (F), and wetness (W) and Minolta L*) were recorded. Mixed models for MQP and CH included breed and year fixed effects for production traits. Year was included as a random effect for measures of pork quality. In the MQP, live weight (116 kg), average daily gain (0.94 kg/day), and BF (20 mm) were not different between Duroc and crossbred pigs; however, crossbred carcasses had greater LMA (48.3 vs. 45.3 cm2; $P < 0.001$) and percent carcass lean (53.5 vs. 53%; $P < 0.05$) resulting in a greater rate of lean growth per day on test (0.40 vs. 0.39 kg/day; $P < 0.01$) than the Duroc. Loins from MQP Duroc carcasses were darker based on visual color (2.7 vs. 2.3; $P < 0.001$) and L* (55.2 vs. 56.3; $P < 0.001$) measurements and had a firmer visual appearance (2.2 vs. 1.9; $P < 0.001$) with a less exudative appearing surface (2.2 vs. 1.9; $P < 0.001$). Lean growth rate of MQP barrows, after the first year (0.32 kg/day) were variable, ranging from 0.38 to 0.42 kg/day, likely an indication of year-to-year variation in both genetics and weather conditions. In the CH group, LMA of crossbred (57.9 cm2) and Hampshire (56.7 cm2) barrows were greater ($P < 0.01$) resulting in a greater percentage carcass lean (57.3 and 56.6%, respectively) when compared with the other breeds. Carcasses in MQP and CH competitions with visual scores of 1 for C, F, or W were disqualified, resulting in 29 and 30% of MQP and CH loins, respectively, disqualified across the period. Results indicate that exhibition swine represent a significant challenge for packers due to the high proportion of pale, soft and or exudative pork produced.

Key words: exhibition, pork quality, swine

513 SowBridge: A breeding herd distance education program allowing on-farm delivery. M. H. Whitney*, *University of Minnesota Extension, Mankato.*

The US pork industry has changed significantly the past 30 years. Small farrow-finish operations have been largely displaced by larger specialized production systems. While decision makers still attend educational events, employees often have few opportunities to increase their educational level. SowBridge was designed for owners, managers, employees, and consultants involved with breeding, gestation, and farrowing operations. The program is coordinated through the extension programs of U of Minnesota, U of Iowa, U of Nebraska, South

Dakota State U, Ohio State U, Purdue U, U of Illinois, Kansas State U, Michigan State U, U of Nebraska, and North Carolina State U. Participants in the program receive a CD in the mail 1 week before each monthly session, containing a slide set of the presentation and supporting materials. Presenters are from participating universities as well as industry. Participants call at 11:30am CT to a toll-free telephone number. A moderator introduces the topic and speaker, then 30 min are designated for the presentation, followed by time for questions. During the presentation, the speaker explains the material while participants follow along on their own computers. A total of 167 participants from 19 states and 4 other countries have participated in the program the past 3 years. Participants include animal caretakers, breeding technicians, managers, owners, veterinarians, consultants, students, and ag educators. Number of participants per site has ranged from 1 to 12. When asked to provide a monetary value of the program for their production units, responses were: $200 - $500 (27%), $500 - $1000 (46%), and $1000+ (27%). The most cited positive aspects of the program were the ability to receive information without travel and ability to use as quality training for employees. SowBridge is a distance education program that is effective in providing information directly to employees and managers in swine breeding and farrowing units, and can be utilized to reach individuals both nationally and internationally.

514 Content appraisal: A tool for analyzing web content and its effectiveness. J. Nadeau*[1], N. Heidorn[2], and N. Broady[3], *[1]University of Connecticut, Storrs, [2]Louisiana State University, Baton Rouge, [3]University of Kentucky, Lexington.*

Effective website content that keeps clientele engaged includes short, concise snippets of information supplemented with pictures, videos, and related websites including links to related social media outlets such as YouTube, Facebook and Twitter. Translating research-based information into web based searchable content can be challenging for the traditionally trained research/extension professional. Content appraisal is a way to make your web information relevant and useful to clientele. This simple, qualitative content appraisal system will identify easy modifications to make website material more effective. This system provides a thorough evaluation of content and results in a report that focuses on key aspects of content strategy, identification of trouble spots, and provides recommendations for improvement. The criteria examined include knowledge level, interrelatedness, relevance, usability, actionability, and differentiation. Updates to improve impact may include linkages to relevant topics on other websites or social media, keeping items current, search engine optimization, increasing online discoverability, changes in formatting and writing style to increase overall readability, a clear call to action, and the incorporation of items that fill a unique need. eXtension (pronounced e-extension)'s first Community of Practice (CoP), HorseQuest, recently applied a content appraisal process in an attempt to document the efficacy and impact of their web content. HorseQuest has produced approximately 1,277 articles, 495 news items, 1,130 published answers to ask-an-expert questions, 13 learning lessons, and 21 videos. Since its launch, there have been 1,658,539 total views. HorseQuest is the first CoP to implement the content appraisal system. This appraisal resulted in immediate and simple improvements to our web content, increasing the site′s potential impact.

Key words: content appraisal system, extension, internet based learning

515 Challenges and benefits of the participation of youth in creating youth-friendly material: Horses and Humans for a Healthy Habitat. M. Philbrick, J. Nadeau*, and T. Hoagland, *University of Connecticut, Storrs.*

As a part of the program Horses and Humans for a Healthy Habitat, youth were recruited to evaluate if creating a youth-friendly brochure intended to instruct youth in good environmental practices with horses was beneficial to the youth. The youth worked with a knowledgeable environmental coordinator to create fact sheets and learning activities. They based their work on the adult version of the Horse Environmental Awareness Program in CT (HEAP). They meet in focus groups of 5–6 interested youth. To determine if these activities were educational for the youth, the youth (n = 30) were surveyed before the activities began and after they completed the teaching material. The survey consisted of groups of questions which covered 4 sections of HEAP and were answered on a Likert 5 class scale. The majority of participants were grade 7 or higher, however they ranged from grade 3 to 12. The majority of the youth (58%) owned horses and managed them at their own homes. Eighty-eight % of the youth participated in horse care. The greatest challenge was attendance due to lack of interest and busy school and horse schedules. Each youth did not answer each question, therefore the response numbers for each question varies. The distribution of the responses was evaluated by chi-squared analyses to see if the response distributions were different from random. In most cases, (10 out of 19 questions) the youth answered the questions in a distribution that would indicate they already knew something about the topic. Yet in all cases (19 questions), after developing the learning material the youth responded with a distribution of responses that clearly indicated that they had learned from the activity and more of the distributions were found (18 out of 19 questions) to be significantly different from random at $P < 0.003$ and clearly in the correct (increased knowledge of practice or increased environmental awareness) direction. Youth participating in focus groups to increase environmental awareness for a targeted group results in increased knowledge for the participants and generates useful products.

Key words: environment, extension, youth

Growth and Development Symposium: Understanding and Mitigating the Impacts of Inflammation on Animal Growth and Development

516 Containing inflammation is essential for animal growth and health. T. A. Niewold*, *Nutrition and Health Unit, Department of Biosystems, Faculty of Bioscience Engineering, Katholieke Universiteit Leuven, Heverlee, Belgium.*

It is well established that infection leads to inflammation and release of pro-inflammatory cytokines. Cytokines activate immune cells and have a profound effect on growth by reducing intake and increasing catabolism of muscle tissue. Less is known about the postprandial (low-grade) inflammatory response in the intestines, a normal physiological response, called metabolic inflammation (MI). The extent of MI is related to energy value and glycemic index of feed as well as specific (e.g., fatty acid) constituents in the feed. To maintain integrity in the body, MI is tighly regulated. The host benefits from downregulation of inflammatory responses directly (e.g., tissue integrity, nutrient transport, and energetically) and indirectly (e.g., Lawsonia and Clostridium benefit from inflammatory responses). Tight control of MI is often disrupted due to the regulatory mechanisms being overwhelmed by high-energy feed intakes fed in production settings. Moreover, feed may also contain pro- and anti-inflammatory components. Prime examples of the latter are the antimicrobial growth promoters (AGP). Initially, beneficial effects of AGP were attributed to their antibiotic characteristics; however this is highly unlikely for a variety of reasons. A prime reason is the sub-therapeutic concentrations in commercial rations. Thus, AGP are much more likely to work as growth permitters as direct inhibitors of intestinal inflammatory responses. This theory is corroborated by the good correlation between the (in vitro) direct anti-inflammatory effect of certain antibiotics, and their effectiveness as AGP. It also explains why non-antibiotic anti-inflammatory compounds like acetylsalicylic acid have a similar effect. It is concluded that effective growth promoters are inhibitors of the intestinal inflammatory response. Their proximal intestinal uptake should be low to maintain effective concentrations in the distal small intestine. Inflammation, whether it results from feed or disease, is inversely related to growth and health. Therefore, research should focus on anti-inflammatory compounds and anti-inflammatory feed composition.

Key words: inflammation, anti-inflammatory, antimicrobial growth promoter

517 Impacts of inflammation on cattle growth and carcass merit. C. R. Krehbiel*, C. L. Maxwell, C. A. Gifford, and R. L. Mills, *Oklahoma State University, Stillwater.*

Inflammation caused by bovine respiratory disease (BRD) continues to be one of the greatest challenges facing beef cattle producers and feedlot managers. Inflammation decreases DMI, ADG, and G:F in feedlot calves decreasing rate of growth and increasing days on feed which results in performance based economic losses during the feeding period. In the past decade, marketing of feedlot animals has drastically switched from selling cattle on a live basis to a grid-based marketing system. When cattle are marketed on a live basis, the economic effects of BRD stop at decreased feedlot performance, carcass weight and death loss. However, when cattle are marketed in a grid-based system, inflammation has the potential to also affect carcass cutability, quality, and consumer acceptability. The effects of inflammation on feedlot cattle in regards to performance are well understood; however, effects on cattle growth and ultimately carcass merit are not as well described. Recent studies in feedlot cattle have suggested that the incidence of BRD decreases both HCW and marbling. Research in other species has demonstrated that during the acute phase response, pro-inflammatory cytokines promote skeletal muscle catabolism to supply amino acids and energy substrates for immune tissues. Further, during this early immune response, the liver changes its metabolic priorities to the production of acute phase proteins for use in host defense. Together these dramatic shifts in systemic metabolism may explain the detrimental effects on performance and carcass traits commonly associated with BRD in feedlot calves. Moreover, recent studies relative to human health have revealed complex multilevel interactions between the metabolic and immune systems and highlighted inflammation as being a significant contributor to major metabolic diseases. The objective of this paper is to gather recent data to help explain the economical and physiological effects of inflammation on cattle growth and carcass merit.

Key words: bovine respiratory disease, carcass merit, cattle growth

518 Endotoxin, inflammation, and intestinal function in swine. N. K. Gabler*, L. H. Baumgard, and V. Mani, *Iowa State University, Ames.*

Circulating endotoxin or lipopolysaccharide (LPS) can stimulate localized or systemic inflammation via activation of toll-like receptors (TLR) and the immune system. This may partition energy away from growth and toward immune system requirements. Furthermore, inflammation can regulate intestinal epithelial function by altering intestinal integrity and nutrient transport. The gastrointestinal tract is a large reservoir of both gram-positive and negative bacteria in which bacterial populations gradually increase from approximately 0 to 10^3/mL of luminal contents in the duodenum to 10^{11}/mL in the colon. Thus, gram-negative bacteria serve as a source of endotoxin in the intestine, which can enter the systemic circulation, resulting in localized or systemic inflammation. Inflammation can alter feed intake, small intestinal nutrient transport, and growth. Furthermore, environmental factors can modulate intestinal endotoxin transport via altering either: 1) nonspecific paracellular transport through the tight junctions or 2) transcellular transport, potentially through lipid raft membrane domains via TLR4-mediated endocytosis. Paracellular endotoxin transport occurs through reduced tight junction integrity, which may be a result of enteric disease, inflammation, or stress, causing a dissociation of tight junction protein complexes. Lipid rafts involved in transcellular transport are specialized membrane regions rich in glycolipids, sphingolipids, cholesterol, and saturated fatty acids. Endotoxin-related signaling proteins such as TLR4, CD14, and MD2 assemble in the lipid raft, which permits endotoxin signaling or endocytosis. Either transport pathway may be altered by dietary and membrane fatty acid composition or environmental stresses and inflammation. This presentation will discuss the role of endotoxin and inflammation in regulating intestinal function as it relates to pig growth performance.

Key words: endotoxin, lipid raft, intestine

519 The role inflammation plays during clinical mastitis on the performance and health of dairy cows. M. A. Ballou*, *Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

Genetic selection for increased milk production in dairy cattle over the past half a century was not associated with an attenuated inflammatory response. The systemic and local inflammatory responses contribute to the altered metabolism, reduced production performance, and high cull rate of lactating dairy cows with clinical mastitis. More aggressive inflammatory responses were observed in early lactation when compared with late lactation following an intramammary challenge with purified endotoxin. The epidemiology of clinical mastitis indicates the highest incidence is observed during the peripartum period; therefore, an enhanced inflammatory response may be involved in the etiology and severity of the clinical mastitis observed during the peripartum period. Milk production losses and compositional changes are observed among all mammary quarters from a cow with clinical mastitis, but the responses are more severe and sustained among culture-positive quarters. The culture-positive mammary quarters reflect both the systemic and local reactions; whereas culture-negative quarters only represent the systemic response. The systemic effects of the inflammatory response include: reduced dry matter intake, hyperthermia, and changes in whole-body nutrient partitioning affecting mammary epithelial substrate availability; whereas the local inflammatory effects include: the energetic requirements of the increased inflammatory leukocyte pool, decreased synthetic capacity of mammary epithelium independent of substrate availability, and paracellular leakage of milk components from the alveolar lumen into the extracellular fluid. Research has focused on either improving other host immunological defenses or attenuating the inflammatory response to limit the deleterious effects during peripartum mastitis. This paper will highlight recent research on the production losses associated with the inflammatory response during mastitis as well as potential management strategies to reduce or prevent those losses.

Key words: dairy, inflammation, performance

520 Nutritional costs of inflammation and consequences for animal growth and production. K. C. Klasing*, *University of California at Davis, Davis.*

The pro-inflammatory response to microbes or trauma results in decreased growth, impaired efficiency of nutrient use, altered nutrient requirements, and a clear stress response. Pro-inflammatory cytokines (IL-1 and IL-6 in chickens and IL-1, IL-6, and tumor necrosis factor in mammals) mediate many of these changes, either by direct effects on cells or by altering the endocrine milieu (e.g., corticosteroids). Other cytokines, including interferon gamma and IL-18 may also contribute. Growth and efficiency of nutrient use are diminished by changes in food intake, nutrient absorption, metabolism, and tissue accretion. Decreases in intestinal absorption of nutrients are also important and are greatest for lipids (including fat-soluble vitamins) and some trace minerals. Metabolic inefficiencies caused by inflammation are due to increased turnover of muscle and bone. Skeletal muscle and bone accretion are impaired, but liver accretion is increased due to increased production of lipids and acute-phase proteins. In aggregate, these alterations change the requirements for many amino acids and trace nutrients. Although accommodating these proportional changes in nutrient needs via dietary adjustments improves feed efficiency, growth cannot be completely normalized by nutritional means. Dampening the acute-phase response to inflammation by nutrients with regulatory properties (e.g., n-3 PUFA) has some utility, but diminishing the frequency and intensity of inflammatory challenges is the most useful strategy. This can be accomplished by sanitation, vaccination, and feeding prophylactic antibiotics or other antimicrobials.

Key words: inflammation, acute-phase response, growth

521 Warner-Bratzler and slice shear force measurements of three beef muscles in response to various aging periods following anabolic implant and zilpaterol hydrochloride supplementation of finishing beef steers. A. J. Garmyn*[1], L. F. Hightower[1], J. C. Brooks[1], B. J. Johnson[1], S. L. Parr[1], R. J. Rathmann[1], J. D. Starkey[1], D. A. Yates[2], J. M. Hodgen[2], J. P. Hutcheson[2], and M. F. Miller[1], *[1]Texas Tech University, Lubbock, [2]Intervet/Schering-Plough Animal Health, DeSoto, KS.*

Our objectives were to determine the effects of zilpaterol hydrochloride (ZH) and the payout pattern of trenbolone acetate and estradiol-17β on Warner-Bratzler shear force (WBSF) and slice shear force (SSF) of longissimus lumborum (LL) and the WBSF of gluteus medius (GM) and psoas major (PM) in response to various aging periods. British × Continental steers (n = 168) were assigned to treatments in a 3 × 2 factorial. The main effects of treatment were implant [no implant (NI); Revalor-S (REV-S), Revalor-XS (REV-XS)] and ZH (0 or 8.3 mg/kg of DM for 20 d). Harvest group was included as a random effect to account for the variation in days on feed (153 or 174 d). Loins (n = 96) were fabricated to obtain strip loin, top sirloin butt, and tenderloin subprimals. Five 2.54-cm steaks were cut from each subprimal and assigned to 1 of 5 aging periods (7, 14, 21, 28, or 35 d postmortem). Feeding ZH increased ($P < 0.01$) LL WBSF and SSF values at each aging period compared with controls. Implanting increased ($P < 0.05$) LL WBSF values at 14 and 21 d, but did not affect LL SSF values ($P > 0.05$). Only REV-S increased WBSF values at 28 and 35 d compared with NI or REV-XS. The percentage of LL steaks with a WBSF value <4.6 kg did not differ ($P > 0.05$) between ZH supplementation or implant strategy at any aging period, and by d 28 over 99% of LL steaks registered WBSF values <4.6 kg. Feeding ZH increased ($P < 0.05$) GM WBSF values only on d 21. Implant had no effect ($P > 0.05$) on GM WBSF values. The percentage of GM steaks with a WBSF value <4.6 kg did not differ ($P > 0.05$) between ZH supplementation or implant strategy at any aging period. Neither ZH nor implant strategy affected PM WBSF values ($P > 0.05$). All PM WBSF values were <4.6 kg on d 7. The results of this study indicated feeding ZH increased WBSF and SSF of LL steaks, regardless of aging period; however, the percentage of steaks with WBSF <4.6 kg did not differ due to ZH or implant. Implanting increased LL WBSF, but not SSF values.

Key words: anabolic implant, shear force, zilpaterol hydrochloride

522 The effects of anabolic growth implant and restricted feed intake on proliferation of bovine primary skeletal muscle cells. T. L. Lee*, D. U. Thomson, B. W. Wileman, L. K. Mamedova, B. J. Bradford, and C. D. Reinhardt, *Kansas State University, Manhattan.*

Sixteen crossbred steers (BW 293 ± 19.3 kg) were used to evaluate the impact of a steroid implant and nutrient intake on nutrient metabolism and muscle cell growth of steers. Steers were trained to Calan gates and randomly assigned to 1 of 4 groups: (1) implant (Revalor XS; 200 mg trenbolone acetate, 40 mg estradiol), high intake (2 × ME for maintenance); (2) implant, restricted intake (1 × ME for maintenance; (3) no implant, high intake; and (4) no implant, restricted intake. Serum was collected on d 0, 14, and 28 for application to satellite cells (previously isolated from non-study steers and frozen). Satellite cells were incubated with serum treatments (20% of total media) for 72 h. Protein abundance of myosin heavy chain (MYH; d 0, 14, and 28), phosphorylated extracellular signal related kinase (pERK; d 0 and 28), and phosphorylated mammalian target of rapamycin (pmTOR; d 0 and 28) were analyzed in differentiated satellite cells to determine effects of implant, intake, and their interaction (applied via the serum). MYH is used as a marker of myotube formation, and pERK and pmTOR are growth factor protein indicators of cell proliferation. Intake had no effect on MYH but implant increased MYH abundance ($P < 0.01$). There was no interaction between intake and implant on MYH abundance. Implant increased the abundance of pERK ($P < 0.01$), but intake had no effect, and there was no interaction between intake and implant on pERK. At high intake, implant increased abundance of pmTOR ($P = 0.02$) but implant had no effect on pmTOR at restricted intake ($P = 0.21$, interaction $P < 0.01$). These results demonstrate that a circulating factor in implanted cattle promotes satellite cell differentiation, possibly mediated by ERK phosphorylation.

Key words: implant, satellite cells, nutrient

523 Identification of tough beef carcasses from epigenetic changes detectable in blood. M. S. Updike*, C. Zhao, Y. Yu, F. Tian, and J. Song, *University of Maryland, College Park.*

For decades, inconsistency in beef tenderness has been a major problem identified by consumers. Currently a variety of methods to segregate palatable carcasses from unpalatable carcasses such as quality grade and camera technologies are used. Much of the research has focused upon changes in the muscle as this will become the beef. By taking a step back and asking what are some of the reasons that muscle can turn into tough beef, other methods may be identified. One factor that has previously been identified as causing tougher beef is stress on the live cattle such as that from hardware disease. To mimic hardware disease in this study, yearling Wye Angus cattle were surgically implanted with cannulas into the rumen. The cattle were fed a pelleted forage diet sufficient for maintenance, but not growth. Two months after the surgery, the cattle were serially slaughtered. Blood was collected during exsanguination and longissimus dorsi samples were collected 24 h after harvest, vaccum packed, aged for 14 d and then frozen. The steaks underwent Warner Bratzler shear force (WBS) analysis. The blood was used to detect epigenetic changes in the CpG islands of promoter regions of selected genes. As expected, the steaks from the negative control were more tender than the steaks from the treatment group. However, of greater interest was the bimodal distribution of tenderness within the stress group. Some stressed cattle were relatively tender while other stressed cattle had very tough beef. We also found that the methylation levels of NAALAD2, a member of the N-acetylated α-linked acidic dipeptidase (NAALADase) gene family, significantly increased in stress groups in blood samples ($P < 0.05$), compared with the non-stress group, although the methylation change is higher in the tender-stress group than in the tough-stress group, indicating that the methylation variation of the gene in blood mainly relates to stress stimuli.

Key words: epigenetics, stress, tenderness

524 Carcass and production characteristics of grass-fed Angus cattle through spring, summer, winter and fall. C. Zhao, J. Song, B. Bequette, and M. S. Updike*, *University of Maryland, College Park.*

Consumers are demanding that grass fed beef be available year round. This can pose challenges for grass fed beef producers as feeding harvested forages is one of the most expensive aspects of grass fed beef

production. Some producers choose not to finish cattle on forages over the winter due to increased costs. To examine the effects of seasonal effects, including feeding harvested forages during the winter, the production and carcass characteristics of Angus cattle finished on grass were examined. The Wye Angus based Angus cattle were rotationally grazed on 100% Alflalfa pasture, when available, during the spring, summer and fall. During the winter, the cattle were fed ad libitum alfalfa baylage. Cattle were harvested based upon both demand for additional beef and visual appraisal for degree of finish. Longissimus dorsi samples were aged for 14 d and then frozen before Warner Bratzler shear force (WBS) analysis. Season had no effect on any of the production or carcass characteristics of these grass fed Angus cattle ($P > 0.5$). The mean age at slaughter was 22.5 mo, the mean carcass weight was 291.3 kg, 62% of the carcasses graded choice, and the mean WBS was 2.9 kg.

Key words: grass-fed, beef, tenderness

526 Effect of castration and slaughter ages on animal performance and meat quality of Holstein bulls fed high-concentrate diets. S. Marti*[1], C. E. Realini[2], A. Bach[3,1], M. Perez-Juan[2], and M. Devant[1], *[1]Department Ruminant Production, IRTA, Barcelona, Spain, [2]Carcass Quality Subprogram, IRTA, Girona, Spain, [3]ICREA, Barcelona, Spain.*

The aim of this study was to evaluate the effect of castration and slaughter ages on performance and meat quality of Holstein bulls fed a high-concentrate diet. One hundred and 20 4 animals (97 ± 2.4 d of age) were randomly allocated in 6 pens following a 3x3 factorial arrangement of treatments. Three castration ages (bulls: INT, 116 ± 3.7 kg; castration at 3 mo: CAS3, 115 ± 3.7 kg; and castration at 8 mo of age: CAS8, 117 ± 3.7 kg) and 3 slaughter ages (10, 12, and 14 mo of age) were evaluated. Animal intake was recorded daily using a computerized concentrate feeder, and BW was recorded every 14 d. The 9–10–11th rib section was removed at 24 h post-mortem and dissected into lean, fat and bone, and meat quality evaluated on the Longissimus thoracis. Data were analyzed using a mixed-effects model including castration and slaughter ages and their 2-way interaction as fixed effects, and initial BW as a covariate. Castration, at 3 or 8 mo of age, reduced animal growth and muscle pH, and increased marbling, and tenderness ($P < 0.001$). As slaughter age increased, feed efficiency was reduced ($P < 0.001$), and carcass weight, marbling and tenderness increased ($P < 0.001$). An interaction ($P = 0.01$) between castration and slaughter ages affected percentage of subcutaneous fat. The percentage of subcutaneous fat was greater in castrated animals and increased between 10 (INT: 3.7 ± 0.75%; CAS8: 5.7 ± 0.75%; CAS3: 7.6 ± 0.75%) and 12 mo at slaughter age (INT: 8.3 ± 0.75%; CAS8: 10.9 ± 0.75%; CAS3: 13.2 ± 0.75%). However, subcutaneous fat percentage decreased in animals slaughtered at 14 mo of age (INT: 7.0 ± 0.75%; CAS8: 9.7 ± 0.75%; CAS3: 7.5 ± 0.75%) and was similar for rib-sections from INT and CAS3. Interactions between castration age and slaughter age tended to be significant for intermuscular ($P = 0.07$) and intramuscular fat ($P = 0.06$). Castration at 3 or 8 mo of age reduces ADG and improves meat tenderness. As slaughter age increases feed efficiency decreases and carcass weight and meat tenderness increases, and depending on castration age increases or decreases subcutaneous, intermuscular and intramuscular fat percentages.

Key words: beef, castration, meat quality

527 Establishing a molecular fingerprint of high versus low-quality beef carcasses. K. J. Thornton*, K. Chapalamadugu, and G. K. Murdoch, *University of Idaho, Moscow.*

Beef cattle raised in the US exhibit undesirable carcass variability, despite similar production practices. Given that "uniformity" is one of the primary areas of improvement identified by the NCBA Beef Quality Audit, carcass characteristic variability observed in the northwest is less than ideal. In accordance with improved uniformity, producers are driven to select for less variance and higher quality animals. Therefore, it is important that underlying physiological causes for carcass quality differences are identified. To address this, post-mortem longissimus dorsi samples were collected from a random population of 500 cattle from different producers in the northwest, for the purpose of identifying key carcass characteristics that vary across this population. The whole transcriptome and proteome of the top 5% (high quality carcass grade) and bottom 5% (low quality carcass grade) of samples were analyzed using custom Nimblegen bovine microarrays and 2D proteomics, respectively. A total of 48 samples were evaluated representing 4 different groups: high-quality steers (HS, n = 12), low-quality steers (LS, n = 12), high-quality heifers (HH, n = 12), and low-quality heifers (LH, n = 12). The protein samples were pooled by group for proteome analysis, whereas microarray studies were conducted using individual samples balanced across the 12-plex microarray. When HS and LS were compared, 52 unique proteomic features differed by at least a 1.25 fold change in protein expression. Similar analysis between HH and LH showed that 61 proteins differed by at least a 1.25 fold change of expression. Differentially expressed proteins between the high and low quality groups are involved in pathways that regulate anabolism such as myogenesis and adipogenesis. Protein and mRNA differences between the 2 groups will provide insight into the molecular pathways contributing to high-quality cattle. In conclusion, we are generating a combined transcriptome and proteome fingerprint for high vs. low-quality beef carcasses. This may allow producers to employ altered management and genetic selection practices that promote greater uniformity with respect to carcass quality.

Key words: beef quality, proteome, muscle

528 Localization and abundance of DLK1 in skeletal muscle of cattle. E. Albrecht*[1], J. Kuzinski[1], T. Gotoh[2], and S. Maak[1], *[1]Leibniz Institute for Farm Animal Biology, Muscle Biology and Growth, Dummerstorf, Germany, [2]Kyushu University, Kuju Agricultural Research Center, Kuju-cho, Oita, Japan.*

The delta-like 1 homolog (DLK1), also known as preadipocyte factor 1 (PREF1), is a transmembrane protein involved in the differentiation of several cell types including adipocytes. Cell culture models demonstrated high expression in preadipocytes and complete disappearance during differentiation to adipocytes. Consequently, it can be expected that DLK1 expression decreases during life of cattle with increasing fat deposition. Furthermore, cattle which exploited their full potential for intramuscular fat (IMF) deposition are expected to have low DLK1 expression, independent of the final IMF content. We therefore investigated the localization and protein abundance of DLK1 in skeletal muscle of steers, known to have different capabilities to store IMF, in comparison with newborn calves and fetal muscle tissue. Six Japanese Black (JB), 5 Holstein (HS), and 6 Charolais (CH) steers were fed a high energy diet to maximize IMF deposition. When slaughtered at 26 mo of age, the IMF content in longissimus muscle was 34.3%, 20.4%, and 6.4% for JB, HS, and CH, respectively. Immunohistochemistry showed that DLK1 was localized in the cytoplasm of cells in muscle

perimysium. Many DLK1-positive cells were detected in fetal and newborn calf muscles, but only few in adult muscles. The abundance of DLK1 protein, determined by Western blot analysis, was accordingly lower in adult muscle tissue. A specific ~50 kDa band showed high variability between animals and reflected well the immunohistochemical results. The protein abundance and the number of DLK1-positive cells in a muscle cross section were highest in HS ($P < 0.05$), but similar in JB and CH ($P > 0.05$). Differences in mRNA abundance were not significant between breeds. According to our hypothesis, the results suggest that JB and CH, rather than HS steers, have widely exhausted their potential to generate new adipocytes or clusters of adipocytes growing to visible marbling flecks. This may indicate a more advanced maturity state of intramuscular adipose tissue in JB and CH steers at 26 mo of age.

Key words: intramuscular fat, cattle, preadipocyte

Nonruminant Nutrition Symposium: Nutrient and Neuroendocrine Regulation of Gastrointestinal Function

529 Involvement of gut neural and endocrine systems in pathological disorders. J. B. Furness*, *Department of Anatomy and Cell Biology, University of Melbourne, Melbourne, Australia.*

The gastrointestinal tract depends on a complex, integrated neural and endocrine control which has major influences on its functions, particularly on the secretion of water and electrolytes, motility, blood flow and mobilisation of digestive juices. Pathologies involving the enteric nervous system can be life threatening, including diarrheas in which toxins, such as cholera toxin, massively excite secretomotor neurons and Chagas' disease, in which trypanosomes cause degeneration of enteric neurons. Gut endocrine cells are involved in serious pathologies, including in the acute effects of gluten challenge in celiac disease, Zollinger-Ellison syndrome and watery diarrhea syndrome. There are also important interactions between the immune system and enteric neural and endocrine control systems, that are manifested in inflammatory bowel diseases and in ischemia/ reperfusion injury to the intestine, for example. The enteric nervous system is also a conduit for the transmission of infective prions. This is important for major commercial herd animals, such as sheep and cattle, in which the enteric nervous system may have a role in sporadic prion disease becoming endemic. There is now a comprehensive knowledge of the organization and functioning of the neural and endocrine control systems of the healthy digestive tract, with some exceptions, such influences on nutrient absorption being under researched. In contrast, in many cases there is very poor understanding of the changes in enteric neurons and endocrine cells in disease states, to the extent that it may not be clear whether changes that are observed are causes or consequences of the disorder. There has been a corresponding failure to identify suitable therapeutically-relevant molecular targets within the enteric nervous system and entero-endocrine cells. A new approach to digestive disorders that is being investigated is the use of neural stem cells. It has recently been shown that neural stem cells that are transplanted into the region of enteric ganglia can proliferate, differentiate into several appropriate phenotypes, and can integrate into existing nerve circuits.

Key words: enteric neurons, entero endocrine cells, digestive diseases

530 Neurogastroenterology and food allergies. J. D. Wood*, *Department of Physiology & Cell Biology and Internal Medicine The Ohio State University, Columbus.*

Neurogastroenterology is a subspecialty encompassing relations of the nervous system to the gastrointestinal tract. The central concept is emergence of whole organ behavior from coordinated activity of the musculature, mucosal epithelium and blood vasculature. Behavior of each effector is determined by the enteric nervous system (ENS). The ENS is a minibrain positioned close to the effectors it controls. ENS neurophysiology is in the framework of neurogastroenterology. The digestive tract is recognized as the largest lymphoid organ in the body together with a unique compliment of mast cells. In its position at the "dirtiest" of interfaces between the body and outside world, the mucosal immune system encounters food antigens, bacteria, parasites, viruses and toxins. Epithelial barriers are insufficient to exclude fully the antigenic load thereby allowing chronic challenges to the immune system. Our observations in antigen-sensitized animals document direct communication between the mucosal immune system and ENS. Communication is functional and results in adaptive responses to circumstances with the lumen that are threatening to the functional integrity of the whole animal. Communication is paracrine and incorporates specialized sensing functions of mast cells for specific antigens together with the capacity of the ENS for intelligent interpretation of the signals. Immuno-neural integration progresses sequentially beginning with immune detection followed by signal transfer to the ENS followed by neural interpretation and then selection of a neural program with coordinated mucosal secretion and a propulsive motor event that quickly clears the threat from the intestinal lumen. Operation of the defense program evokes symptoms of cramping abdominal pain, fecal urgency and watery diarrhea. Our approaches to immuno-ENS interactions merge the disciplines of mucosal immunology ENS neurophysiology into the realm of neurogastroenterology.

531 Nutrient and neuroendocrine regulation of intestinal glucose absorption. S. P. Shirazi-Beechey*[1], A. W. Moran[1], D. M. Bravo[2], and M. Al-Rammahi[1], *[1]University of Liverpool, Liverpool, United Kingdom, [2]Pancosma, Geneva, Switzerland.*

The intestinal Na^+/glucose cotransporter, SGLT1, is the major route for the transport of dietary sugars from the lumen of the intestine into enterocytes. Regulation of this protein is essential for the provision of glucose to the body and avoidance of malabsorption. Data produced in various laboratories have suggested that the intestinal lumenal sugar concentration, the gut hormone, GLP-2, and the enteric nervous system participate in pathways regulating SGLT1 expression. To this end, it has been shown that i) expression of SGLT1 is upregulated in response to increased dietary sugars, ii) the serosal application of GLP-2 enhances SGLT1 expression, iii) raised lumenal glucose concentrations in the ileum results in SGLT1 upregulation in more proximal regions and iv) the upregulation of SGLT1 in response to high lumenal glucose is only achieved in intact mucosa and not in isolated enterocytes. However detailed network of pathways by which the lumenal sugar, gut hormones and the enteric nervous system interact to regulate SGLT1 expression has not been known. Experimental evidence in our laboratory has shown that the intestinal glucose sensor, the taste receptor1 subunit heterodimers, T1R2+T1R3, expressed on the luminal membrane of endocrine cells, senses lumenal glucose concentration. Lumenal glucose when above a threshold activates in endocrine cells, a signalling pathway involving T1R2+T1R3, the transducer G-protein, gustducin, and other signalling elements, resulting in secretion of GLP-1, GLP-2 and GIP. Binding of GLP-2 to its receptor on enteric neurons elicits a neuronal response which is transmitted to subepithelial regions evoking the release of a neuropeptide. Binding of the neuropeptide to its receptor on the basolateral membrane of absorptive enterocytes enhances intracellular cAMP, thereby increasing the stability of SGLT1 mRNA and levels of functional SGLT1 protein. The identification of molecular and cellular processes controlling SGLT1 expression will assist recognition of targets for modulating the capacity of the gut to absorb dietary sugars. This has important nutritional and clinical implications.

Key words: enteric neurons, entero endocrine cells, glucose absorption

532 The role of GLP-2 in controlling intestinal function in human infants: Regulator or bystander? D. Sigalet*, *Alberta Children's Hospital / University of Calgary, Calgary, AB, Canada.*

The regulation of nutrient absorptive capacity is a critical factor in the normal growth and development of an infant. This is especially important following surgical resection; the process of adaptation, or upregulation of nutrient transport capacity is the physiologic process which allows patients to transition to enteral feeding. The specific mechanisms which control this are still relatively poorly understood. Many actions of the entero-endocrine hormone, Glucagon-like Peptide 2, suggest that it may be a key regulator both in regulating physiological nutrient absorptive capacity and the process of adaptative upregulation of nutrient absorption following resection. This talk will review the biology of GLP-2 including the production in the L cell, regulation of GLP-2 release, sites of action, which include the enteric neurons, and pericryptal myofibroblast, and the effects on the intestinal mucosa. We will examine ontogeny of this system in the developing human infant and the evidence that GLP-2 is pivotal in the regulation of adaptation, with the implications for clinical practice.

Key words: enteric neurons, entero endocrine cells, ontogeny

Physiology and Endocrinology Symposium: Factors Controlling Puberty in Beef Heifers

533 Management implications associated with the onset of puberty and persistence of estrous cycles in beef heifers. G. C. Lamb*[1], K. M. Bischoff[1], T. E. Black[1], V. R. G. Mercadante[1], G. H. L. Marquezini[1], R. F. Cooke[2], and N. DiLorenzo[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]Eastern Oregon Agricultural Research Center, Oregon State University, Burns.*

For optimal economic return and lifetime productivity, replacement beef heifers need to attain puberty and conceive early during their first breeding season. Significant costs are associated with development and management of replacement beef heifers; therefore, management strategies that maximize the number of replacement heifers attaining puberty before their first breeding season are vital for the efficiency of cow-calf operations. We demonstrated that fertility in replacement beef heifers was not compromised by delaying the majority of weight gain until the last third of the developmental period before the onset of the breeding season, and BW at the onset of the breeding season and weight at puberty were not compromised compared with heifers on a constant rate of gain during the developmental period. Periods of reduced nutrient intake are analogous with losses in BW, BCS, decreases in luteal activity, and cessation of estrous cycles. Persistence of estrous cycles after establishment of puberty are affected by dietary energy restriction and repletion, but may be activated gradually in response to dietary manipulation, unrelated to many metabolite changes. Reproductive development also may be accelerated with the use of exogenous hormones such as progestins for synchronization of estrous and/or ovulation. The use of protocols containing progestins initiate estrous cycles of prepubertal heifers and results in pregnancy rates that are 15% greater than untreated controls. Acclimation of heifers to human handling after weaning may also be an alternative to hasten puberty attainment and improve pregnancy rates. In both *Bos taurus* and *B. indicus* heifers, the use of acclimation techniques reduced stress-related physiological responses and increased the percentage of replacement heifers that were pubertal at the initiation of the breeding season. Incorporation of nutritional, reproductive, and stress management during the development of replacement beef heifers increases the percentage of heifers that reach puberty at the onset of the breeding season and enhances overall reproductive performance of beef cattle operations.

Key words: puberty, beef heifer, management

534 How SNP chips will advance our knowledge of factors controlling puberty and aid in selecting replacement females. W. M. Snelling*[1], R. A. Cushman[1], G. L. Bennett[1], J. W. Keele[1], L. A. Kuehn[1], T. G. McDaneld[1], R. M. Thallman[1], and M. G. Thomas[2], *[1]USMARC, USDA-ARS U.S. Meat Animal Research Center, Clay Center, NE, [2]New Mexico State University, Las Cruces.*

The promise of genomic selection is that genetic potential can be accurately predicted from genotypes. Simple DNA tests might replace low accuracy predictions based on performance and pedigree for expensive or lowly heritable measures of puberty and fertility. The promise is greatest if the DNA variants affecting puberty and other measures of fertility are known with some certainty. Several of the 50,000 SNP in a standard assay have tentatively been associated with age at puberty, antral follicle count, pregnancy and related traits measured on different sets of heifers. At best, these SNP may be imperfectly correlated with causal variants and indicate genomic regions affecting puberty, but sample sizes are too small and SNP density too sparse to be definitive. Associations between individual SNP and similar phenotypes are inconsistent across data sets, and genomic predictions do not appear applicable to unrelated cattle. Discrepancies may be a result of different QTL segregating in the sampled populations, differences in linkage disequilibrium (LD) patterns so the same SNP are not correlated with the same QTL, and spurious correlations with phenotype. Larger samples and denser SNP will increase power to detect real associations with SNP having more consistent LD with underlying QTL. Meta-analysis combining results from different studies will effectively increase sample size. High-density genotyping with heifers pooled by early and late puberty, or extremes for quantitative indicators of puberty, can be a cost-effective means to sample large numbers. Networks of genes, implicated by associations with multiple traits correlated with puberty and fertility, could provide insight into the complex nature of these traits, especially if corroborated by functional annotation, established gene interaction pathways, and transcript expression. Integrating information about gene function and regulation with statistical associations from whole-genome SNP genotyping assays will enhance knowledge of genomic mechanisms affecting puberty, enabling development of more reliable DNA tests to guide heifer selection decisions.

Key words: genomics, puberty

535 Nutritional aspects of developing replacement heifers. R. N. Funston*, *University of Nebraska West Central Research and Extension Center, North Platte.*

Studies in numerous species provide evidence that diet during development can partially control physiological changes necessary for puberty. Numerous studies have reported inverse correlations between postweaning growth rate and age at puberty and pregnancy rates in heifers. Thus, rate of postweaning growth was determined to be an important factor affecting age of puberty, which influenced pregnancy rates. This and other research conducted during the late 1960s through the early 1980s indicated puberty occurs at a genetically predetermined size, and only when heifers reach their target weight can high pregnancy rates be obtained. Guidelines were established indicating replacement heifers should achieve 60 to 65% of their expected mature body weight by breeding. Traditional approaches for postweaning development of replacement heifers used during the last several decades have primarily focused on feeding heifers to achieve or exceed an appropriate target weight, and thereby maximize heifer pregnancy rates. Intensive heifer development systems may maximize pregnancy rates, but not necessarily optimize profit or sustainability. Since inception of target weight guidelines, subsequent research demonstrated the pattern of growth heifers experience before achieving a critical target weight could be varied. Altering rate and timing of gain can result in periods of compensatory growth thereby providing an opportunity to decrease feed costs. Recent research from our laboratory has demonstrated feeding replacement heifers to traditional target weights increased development costs without improving reproduction or subsequent calf production relative to development systems where heifers were developed to lower target weights ranging from 50 to 57% of mature BW.

Key words: beef cattle, heifer development, target weight

536 Harnessing basic knowledge of factors controlling puberty to improve synchronization of estrus and fertility in heifers. G. A. Perry*, *South Dakota State University, Department of Animal and Range Sciences, Brookings.*

The development of replacement heifers is a major economic investment for all beef and dairy operations. The costs associated with heifer development cannot be recovered if heifers do not conceive and remain productive in the herd; therefore, heifers need to conceive on schedule or risk being culled from the operations. Previous research has reported up to a 21% increase in fertility from a heifer′s pubertal estrus to the third estrus. The use of reproductive tract scores to determine pubertal status has demonstrated that peripubertal and pubertal heifers have an increased pregnancy success to synchronization protocols compared with heifers that were prepubertal. The development of radioimmunoassays has allowed for accurate measurement of changes in hormone profiles to characterize the pubertal process and determine when puberty occurs. This basic knowledge has increased our understanding of the mechanisms that control puberty and sexual development in heifers. In addition, understanding the hormonal changes that occur during the estrous cycle has allowed for the development of estrous synchronization protocols that result in increased control of follicular growth, regression of luteal tissue, and ovulation. Transrectal ultrasonography has resulted in an increased understanding of the endocrine regulation of follicular waves and development of methods to synchronize follicular waves for purposes of fixed-time AI. Current topics of research include the affect of antral follicle count on fertility and the affect of maternal nutrition (on the fetus in utero) on subsequent reproductive potential of a heifer (e.g., fetal programming). Advancements in genomic technologies will likely provide a powerful tool for selecting heifers at birth that will have a high probability of being reproductively successful if managed correctly. Therefore, the basic knowledge gain through research has improved and will continue to improve heifer development and pregnancy success.

Key words: heifer development, estrous synchronization, puberty

537 Estimation of heritability and non-genetic factors influencing calf temperament. A. N. Loyd*[1,2], D. G. Riley[1], D. A. Neuendorff[2], A. W. Lewis[2], R. C. Vann[3], T. H. Welsh, Jr.[1], and R. D. Randel[2], *[1]Texas AgriLife Research, College Station, [2]Texas AgriLife Research, Overton, TX, [3]MAFES, Mississippi State University, Raymond.*

Brahman (n = 771) and F_1 Brahman × Hereford (n = 56) calves born over 9 years (2002 to 2010) from 33 sires and 355 dams at the Texas AgriLife Research Center in Overton were utilized to evaluate the genetic and non-genetic factors influencing calf temperament. Calves were evaluated for pen score (PS), exit velocity (EV) and temperament score (TS) 28 d before weaning, at weaning, 28 d post-weaning, 56 d post-weaning, and as yearlings. Mixed models were used to determine non-genetic factors influencing PS, EV and TS at each sampling day and also as repeated records analyses. Contemporary group (calves of the same sex and weaned together) and dam age group were fixed effects, calf age at weaning and proportion Brahman were linear covariates, and sire and calf nested within sire were random effects. Exit velocity, PS and TS differed across contemporary groups ($P < 0.05$) and by day ($P < 0.0001$) but not by proportion Brahman ($P = 0.63$). Dam age group was significant for PS ($P < 0.03$) but not for TS ($P = 0.07$) or EV ($P = 0.17$). Solutions for calf age at weaning were 0.0048, 0.0033 and 0.0040 for PS, EV and TS, respectively ($P < 0.02$; average SE = 0.001). Table 1 presents means for temperament traits by day. Animal models were subsequently used to estimate heritability of PS, EV and TS at weaning: 0.48, 0.29 and 0.43, respectively (average SE = 0.08). From repeated records analyses, the proportion of phenotypic variance due to permanent environmental effects were 0.31, 0.43 and 0.25 (average SE = 0.02) and heritability estimates were 0.44, 0.28 and 0.41 (average SE = 0.07) for PS, EV and TS, respectively. These results suggest temperament is moderately to highly heritable and is influenced by contemporary group, dam age, calf age at weaning, and permanent environmental effects.

Table 1. Means for temperament traits by day[1]

Day	Records, n	PS	EV	TS
28 d pre-wean	519	2.53 ± 0.09[a]	2.18 ± 0.08[abd]	2.35 ± 0.07[a]
Wean	824	2.59 ± 0.08[a]	2.28 ± 0.08[bc]	2.43 ± 0.07[b]
28 d post-wean	520	2.79 ± 0.09[b]	2.33 ± 0.08[c]	2.56 ± 0.07[c]
56 d post-wean	485	2.79 ± 0.09[b]	2.13 ± 0.08[d]	2.45 ± 0.07[b]
Yearling	79	2.43 ± 0.12[a]	1.99 ± 0.12[a]	2.20 ± 0.09[a]

[a,b,c,d]Means within a column lacking a common superscript differ ($P < 0.05$).

[1]PS = pen score; EV = exit velocity; TS = temperament score.

538 Effects of transportation and lipopolysaccharide (LPS) challenge on vaginal temperature in crossbred heifer calves. A. N. Loyd*[1,4], R. C. Vann[2], J. P. Banta[3], T. H. Welsh, Jr.[1], J. A. Carroll[4], and R. D. Randel[5], *[1]Texas AgriLife Research, College Station, [2]MAFES, Mississippi State University, Raymond, [3]Texas AgriLife Extension, Overton, [4]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [5]Texas AgriLife Research, Overton.*

This study evaluated the effects of transportation and subsequent LPS challenge on heifer vaginal temperature (T_{vag}). Brahman × British heifers (n = 44) from Raymond, MS were weaned and acclimated to a high roughage diet fed in GrowSafe bunks for 25 d. Heifers were blocked by BW and breed and randomly assigned to a transportation treatment group: transport (Trans; n = 14); no transport with access to feed and water (Feed; n = 15); and no transport without access to feed and water (NoFeed; n = 15). Hobo loggers were fitted onto blank CIDR devices and inserted to monitor T_{vag}. Trans heifers were loaded onto a livestock trailer, Feed heifers were returned to the GrowSafe bunks, and NoFeed heifers were placed in a dry-lot. Transport ensued for 12 h before Trans heifers were unloaded in Overton, TX. Trans and NoFeed heifers were then allowed access to hay and water for 6.5 h. Trans heifers were transported 12 h back to MS. NoFeed heifers were restricted from feed and water during this time. Feed heifers had access to feed and water throughout the study. Following transport, all heifers had ad libitum access to water and feed in GrowSafe bunks for 12 h. Heifers were then injected subcutaneously with LPS (0.5 µg/kg BW; n = 22) or saline (4.5 µL/kg BW; n = 22). T_{vag} data were analyzed using mixed models specific for repeated measures. Fixed effects for transport T_{vag} included transport, time and their interaction. Fixed effects for post-LPS T_{vag} included transport, LPS, time and all interactions. Trans T_{vag} was maximal (39.7°C) at the onset of transport and declined through 5 h below that of Feed and NoFeed (transport x time; $P < 0.01$). Trans T_{vag} remained lower than Feed and NoFeed for the remainder of both transports. No transport x LPS interaction was observed ($P = 0.92$) post-LPS. LPS-treated heifers had elevated ($P = 0.01$) T_{vag} above that of saline-treated heifers from 1 h to 7 h, with peak T_{vag} (39.6°C) occurring 4 h post-LPS. At 7 h, T_{vag} of LPS- and saline-treated heifers were similar. These results indicate that handling and loading of calves before transport induced a transient febrile response that subsided once transportation began.

Key words: cattle, LPS, transport

539 Chromium supplementation enhances the metabolic response of steers to lipopolysaccharide (LPS) challenge. N. C. Burdick*[1], B. C. Bernhard[2], J. A. Carroll[1], A. N. Loyd[1], D. N. Finck[2], R. J. Rathmann[2], and B. J. Johnson[2], *[1]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [2]Department of Animal and Food Sciences, Texas Tech University, Lubbock.*

The effect of chromium (Cr; KemTRACE Chromium Proprionate 0.04%, Kemin Industries) supplementation on the metabolic response to LPS challenge was examined. Steers (n = 20; 235 ± 4 kg BW) received a premix that added 0 (Con) or 0.2 mg/kg Cr to the total diet (DM basis) for 55d. Jugular catheters were placed before challenge. Blood samples were collected every 30min from −2 to 8, and at 24h relative to LPS challenge (0.5 µg/kg BW). Individual BW were recorded at cannulation, and 24h and 7d post-LPS. Concentrations of glucose, insulin, and nonesterified fatty acid (NEFA) were measured. Data were analyzed using the Mixed procedure of SAS specific for repeated measures with fixed effects of treatment (trt), time, and their interaction. Initial BW did not differ ($P = 0.37$) for Cr (314 ± 8 kg) and Con (324 ± 8 kg). Twenty-four hours post-LPS, Cr steers had lost less weight ($P = 0.03$; −7 ± 2 kg) than Con steers (−14 ± 2 kg). Overall, Con steers tended to lose weight (initial compared with 7d post-LPS BW; −2.4 ± 3.6 kg) and Cr steers tended to gain weight (6.4 ± 3.6 kg; trt $P = 0.09$). Pre-LPS glucose did not differ for Con and Cr steers ($P = 0.97$). Post-LPS there was a time x trt interaction ($P < 0.01$) in that glucose peaked within 0.5h in Cr (153 ± 4 mg/dL) but not Con (111 ± 4 mg/dL)

steers. Glucose then decreased in Cr steers and also decreased in Con steers at 2h compared with baseline ($P < 0.01$). Insulin concentrations were not different between trt pre-LPS ($P = 0.63$). Post-LPS insulin increased ($P < 0.01$), peaking at 2h before returning to baseline. There was a trend for insulin to be greater in Con (1.1 ± 0.1 ng/mL) than Cr (0.9 ± 0.1 ng/mL) steers ($P = 0.13$). Concentrations of NEFA did not differ pre-LPS ($P = 0.54$). Post-LPS NEFA increased ($P < 0.01$), with Cr steers producing greater peak NEFA (0.21 ± 0.02 nmol/L) at 0.5h than Con steers (0.16 ± 0.02 nmol/L; $P < 0.04$). Following peak values, NEFA decreased before increasing again at 3.5h in Cr ($P = 0.04$) and 4h in Con ($P < 0.01$), and remained elevated 24h post-LPS. These data suggest supplementation of Cr enhanced the availability of energy resources, attenuated weight loss, and allowed for a quicker recovery following LPS challenge.

Key words: chromium, LPS, metabolism

540 Effects of transportation and lipopolysaccharide (LPS) challenge on body weight and feed intake of crossbred heifers. A. N. Loyd*[1,4], R. C. Vann[2], J. P. Banta[3], T. H. Welsh Jr.[1], J. A. Carroll[4], and R. D. Randel[5], *[1]Texas AgriLife Research, College Station, [2]MAFES, Mississippi State University, Raymond, [3]Texas AgriLife Extension, Overton, [4]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [5]Texas AgriLife Research, Overton.*

An experiment was conducted to examine the effects of transportation and LPS challenge on feed intake (FI) and BW of calves. Brahman x British heifers (n = 44) from Raymond, MS were acclimated to a high roughage diet fed in GrowSafe bunks. Heifers were blocked by BW and breed and randomly assigned to a transportation treatment group: transport (Trans; n = 14); no transport with access to feed and water (Feed; n = 15); and no transport without access to feed and water (NoFeed; n = 15). Trans heifers were loaded onto a livestock trailer, Feed heifers were returned to the GrowSafe bunks, and NoFeed heifers were placed in a dry-lot. Transport ensued for 12 h before Trans heifers were unloaded in Overton, TX. Trans and NoFeed heifers were then allowed access to hay and water for 6.5 h. Trans heifers were loaded onto the trailer and transported for 12 h to Raymond, MS. During this time, NoFeed heifers were restricted from feed and water. Feed heifers had continual access to feed and water throughout the study. After transport, all heifers had ad libitum access to feed and water for 12 h. Heifers were then injected subcutaneously with LPS (n = 22) or saline (n = 22). BW was recorded before transport, after the second transport, before LPS challenge, and 24 and 48 h post-LPS. Daily FI was monitored when heifers had access to GrowSafe bunks. Mixed models were used to analyze FI and BW with transport, LPS, day and all interactions as fixed effects. During the 12-h post-transport period, NoFeed heifers had greater ($P < 0.01$) FI than Trans heifers, which had greater ($P < 0.01$) FI than Feed heifers (8.5, 5.9 and 2.4 kg). Post-LPS FI did not differ among treatments ($P > 0.10$). During the transport period Trans and NoFeed heifers lost more BW ($P < 0.01$; −34.4 and −25.9 kg) than Feed heifers (1.21 kg); BW change was not different ($P > 0.20$) between NoFeed and Trans heifers. Change in BW from pre- to 24 h or 48 h post-LPS was not different ($P > 0.20$). These results suggest that shrink observed in transported calves is likely the result of feed and water withdrawal. However, stress associated with transport may hinder FI immediately following transport.

Key words: cattle, feed intake, transport

541 Microbial diversity in bovine papillomatous digital dermatitis in Holstein dairy cows from upstate New York. T. Santos and R. Bicalho*, *Cornell University, Ithaca, NY.*

Papillomatous digital dermatitis (PDD) is one of the most contagious diseases of cattle adversely affecting the dairy industry by its negative effect on milk production and reproductive performance. Despite this, all the precise factors that predispose to its occurrence are not well understood and, although it is suspected that bacteria play a critical role in the pathogenesis of the lesion, the main agents involved in the etiology remains unclear. The purpose of this study was to use culture-independent methods to determine the microbial diversity in 3 strata of Holstein dairy cows PDD lesions, analyzing whether major differences exist comparing to foot skin of non-infected cows. Both group-specific 16S rDNA PCR-DGGE and clone library sequence of broad-range 16S rDNA showed differences between the microbial composition of healthy dairy cows and the different strata of the lesion. The predominant bacterial community in the lesion, regardless the stratum, consisted of 166 specific phylotypes that fell into 7 bacterial phyla; Firmicutes, Proteobacteria, Spirochaetes, Bacteroidetes, Tenericutes, Synergistetes, and Actinobacteria. Firmicutes and Spirochaetas (particularly, treponemes) were the most prominent group detected. Additionally, one phylotype phylogenetically affiliated with uncultured Archaea was detected in 2 strata of the lesion. Sequences from healthy foot skin samples revealed 86 specific phylotypes that were affiliated with Firmicutes and Proteobacteria, with the latter being the most diverse and frequent. Our study showed a previously unrecognized complexity of the microbial composition in bovine PDD infections from dairy cows. It corroborated the theory that treponemes are involved in PDD disease etiology and it suggested, for the first time, the presence of archaeal members in this particular infection.

Key words: digital dermatitis, microbial diversity, *Treponema*

542 Non-steroidal anti-inflammatory drug administration and repeated muscle biopsies affect the phosphorylation of translation initiation factors. A. L. Wagner*, R. B. Ennis, and K. L. Urschel, *University of Kentucky, Lexington.*

Protocols for measuring protein synthesis (PS) or phosphorylation (P) of translation initiation factors (eIF) require the collection of repeated biopsies (RB) for 48 h post anabolic stimuli. The effect of local inflammation (I) due to RB on the P of eIF has yet to be determined after 48 h. Non-steroidal anti-I drugs (NSAID) have been reported to blunt or not affect muscle PS in response to exercise when administered oral or local in humans, respectively. However, this has not been examined in the horse. The objective of this study was to determine if 5 d of RB in muscle with (+; n = 6) or without (–; n = 6) oral NSAID (phenylbutazone 2g/d) administration would affect the P of eIF in the gluteal muscle of mature horses in response to a feeding stimulus (3g/kg BW of 32.5 ± 0.04% CP as fed). The effects of treatment (treat; + or – NSAID), side, sampling day (day) and treat*day interaction were tested on P of eIF using repeated measures in the MIXED models procedure of SAS. Muscle biopsies were taken 60 min post-feeding from both the left and right gluteal muscles to measure the P of eIF (Akt at Ser^{473}, 4EBP1 at $Thr^{37/46}$, rpS6 at $Ser^{235/236;240/244}$, and p70 S6 Kinase at Thr^{389}) using Western blotting. Within each day, the P of all eIF studied was the same in both the left and right gluteal muscles ($P > 0.05$). For p70 S6 Kinase, rpS6, and 4EBP1 there was a treat*day interaction ($P < 0.05$); where there were increases in the P forms over time in horses not receiving NSAID, and no change in the NSAID group. There was no treat*day interaction for Akt; however, there was

a decrease with day ($P < 0.05$), regardless of treat. Total abundance of rpS6 and 4EBP1 were affected by time ($P < 0.05$), increasing and decreasing, respectively. These results show potential increases in local I due to RB elevates P of eIF after a meal; however, oral NSAID administration eliminates this response. Additional research is needed to determine if increased P of eIF after a meal due to RB in horses not receiving NSAIDs results in elevated PS. Further research is necessary to determine if RB cause locally elevated I cytokines.

Key words: horse, inflammation, mTOR

543 Infusion of interferon-τ into the uterine vein protects the corpus luteum from prostaglandin F2α induced down-regulation of cell survival genes. A. Q. Antoniazzi* and T. R. Hansen, *Animal Reproduction and Biotechnology Laboratory, Department of Biomedical Sciences, Colorado State University, Fort Collins.*

The ovine conceptus secretes interferon-T (IFNT), acts in a paracrine manner to silence upregulation of endometrial estrogen receptor and as a result, the oxytocin receptor; thus preventing luteolytic pulses of prostaglandin F2α (PGF). IFNT also is released into the uterine vein (UV) and has endocrine action on the corpus luteum (CL) through activating IFN stimulated genes (ISGs) such as ISG15. Recently, we described protection of the CL from a 5 mg injection of PGF through 12h pre-exposure to infusion of 200 μg roIFNT/day into the UV on Day 10 of the estrous cycle. It was hypothesized herein that an endocrine role of IFNT during early pregnancy is to stabilize cell survival genes in the CL. Osmotic pumps delivering 200 μg BSA or roIFNT over 24h were surgically installed on Day 10 of the estrous cycle with catheters entering the UV in 20 ewes (n = 10/group). One half (n = 5) of the ewes in each group received a single injection of PGF (5 mg) 12h after pump installation. CL collected 24h following insertion of pumps were examined for ISG15, AKT, BCL-XL, and XIAP mRNA concentration with semiquantitative RT-PCR. All differences described are significant at $P < 0.05$. Infusion of roIFNT into the UV increased ISG15 mRNA concentrations in CL confirming endocrine delivery of roIFNT to the CL. AKT mRNA concentrations were similar in CL from BSA, roIFNT and roIFNT+PGF groups, but were downregulated in the BSA+PGF group. XIAP mRNA concentrations increased in CL from roIFNT-infused ewes and decreased in CL from BSA+PGF infused ewes compared with BSA-infused ewes and IFN-infused ewes injected with PGF. Infusion of roIFNT resulted in BCL-XL mRNA concentrations that were similar to BSA-infused ewes, and following injection with PGF to levels that were lower than IFN-infusion alone, but greater than IFNT-infused and PGF injected ewes. It is concluded that AKT, BCL-XL and XIAP mRNAs are downregulated within 12h in response to PGF. Endocrine action of IFNT on the CL stabilizes these cell-life genes, which may contribute to luteal resistance to luteolysis during pregnancy. USDA AFRI 2011–67015–20067.

Key words: interferon, pregnancy, corpus luteum

544 The influence of the addition of heparin binding protein and tissue inhibitors of metalloproteinases-2 to sexed bovine semen on conception rate and pregnancy rate. B. J. Agado*[1,2], D. A. Neuendorff[2], G. L. Shafer[1,2], M. E. Kjelland[4], J. Moreno[4], M. A. Lammoglia[5], S. Romo[6], A. W. Lewis[2], T. H. Welsh Jr.[1,3], and R. D. Randel[2], *[1]Texas A&M University, College Station, [2]Texas AgriLife Research-Overton, Overton, [3]Texas AgriLife Research, College Station, College Station, [4]Sexing Technologies, Navasota, TX, [5]Universidad Autonoma de Veracruz, Tuxpan, Veracruz, Mexico, [6]Universidad Nacional Autonoma de Mexico, Cuautitlan, Estado de Mexico, Mexico.*

The addition of heparin binding protein (HBP) and tissue inhibitors of metalloproteinases-2 (TIMP-2) to enhance fertility of bovine semen sexed by flow cytometry was evaluated. Hereford bulls (n = 2) were transported to Sexing Technologies (Navasota, TX) for semen collection and isolation of X chromosome bearing sperm. Addition of exogenous HBP and TIMP-2 to semen samples was verified by immuno-fluorescence. Brahman heifers (n = 26) and cows (n = 86) were randomly and equally assigned to one of 2 treatment groups, HBP/TIMP-2 (HBP) addition or no HBP/TIMP-2 (C) addition. The females were artificially inseminated (AI) by 2 technicians. Thirty-seven cows were AIed with conventional Brahman bull semen to determine a baseline herd fertility. Females were AIed 12 h after the onset of standing estrus. The straw concentrations were 2.1×10^6 cells/straw for sexed semen and $25*10^6$ cells/straw for the conventional semen. Post thaw motilities of sexed sperm cells are: Sire 1 C = 55%, HBP = 60%; Sire 2 C = 50%, HBP = 50%. Pregnancy was determined via rectal palpation 45 d after the end of the breeding season (15 May to 22 June 2010). Two criteria were contrasted: 1st service conception rate (FSCR) and pregnancy rate (PR). Data were analyzed by Pearson Chi-Square test. The addition of HBP did not influence FSCR (HBP: 28.1% vs. C: 38.2%; $P = 0.2554$) or PR (HBP: 45.6% vs. C: 52.7%; $P = 0.4616$). Sire influenced FSCR (Sire 1: 41.7% vs. Sire 2: 23.1%; $P = 0.0370$) and PR (Sire 1: 65.0% vs. Sire 2: 30.8%; $P = 0.0003$). Parity did not influence FSCR (cow: 30.2% vs. heifer: 42.3%; $P = 0.2513$) but tended to influence PR (cow: 44.2% vs. heifer: 65.4%; $P = 0.0581$). Conventional Brahman semen had a 56.8% FSCR compared with 33.0% for sexed semen ($P = 0.0103$) and PR of 75.7% with conventional semen compared with 49.1% for sexed semen ($P = 0.0048$). The addition of HBP/TIMP-2 did not improve fertility in female Brahman bred using AI. Sire was a major source of variation in fertility of sexed semen. Conventional frozen semen had greater fertility than sexed frozen bull semen.

Key words: sexed semen, heparin binding protein, bovine

545 Effects of acclimation to handling on performance, reproductive, and physiological responses of *Bos taurus* beef heifers. B. I. Cappellozza*, R. F. Cooke, F. N. T. Cooke, and D. W. Bohnert, *Oregon State University–Eastern Oregon Agricultural Research Center, Burns.*

Thirty-eight Angus × Hereford heifers were initially evaluated, within 45 d after weaning, for body weight (BW) and puberty status (d 0 and 10), and temperament by measurements of chute score and exit velocity (d 10 only). On d 11, heifers were stratified by puberty status, temperament, BW and age, and randomly assigned to receive or not (control) an acclimation treatment. Acclimated heifers were exposed to a handling process 3 times weekly (Mondays, Wednesdays, and Fridays) for 4 weeks (d 11 to 39 of the experiment). The acclimation treatment was applied individually to heifers by processing them through a handling facility, whereas control heifers remained undisturbed on pasture. Heifer puberty status, evaluated via plasma progesterone concentrations, and BW were assessed again on d 40 and 50, d 70 and 80, d 110 and 120, d 140 and 150, d 170 and 180, and d 210 and 220 of the study. Blood samples collected before (d 10) and at the end of the acclimation period (d 40) were also analyzed for plasma concentrations of cortisol, haptoglobin, and ceruloplasmin. Heifer temperament was assessed again on d 40 and d 220. No treatment effects were detected for BW gain ($P = 0.88$). Acclimated heifers tended ($P = 0.08$) to have greater

exit velocity after the acclimation process, but reduced ($P = 0.02$) exit velocity on d 220 compared with control cohorts. Acclimated heifers had reduced plasma concentrations of cortisol ($P = 0.04$) and haptoglobin ($P = 0.01$) compared with control heifers after the acclimation period (25.7 vs. 34.1 ng/mL for cortisol and 5.3 vs. 5.9 absorbance at 450 nm × 100 for haptoglobin, respectively). Puberty attainment was hastened in acclimated heifers compared with control ($P = 0.01$). At the end of the study (d 220), a greater ($P = 0.02$) number of acclimated heifers were pubertal compared with control cohorts (63.1 vs. 31.6% of pubertal heifers, respectively). Results from this study indicated that acclimation to human handling after weaning reduced circulating concentrations of substances associated with behavioral stress and hastened puberty attainment in *Bos taurus* beef heifers.

Key words: *Bos taurus* heifers, acclimation to handling, puberty

546 Effects of temperament on reproductive and physiological responses of beef cows. R. F. Cooke*[1], D. W. Bohnert[1], F. N. T. Cooke[1], C. Mueller[2], and T. DelCurto[2], *[1]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [2]Oregon State University–Eastern Oregon Agricultural Research Center, Union.*

A total of 435 multiparous lactating Angus × Hereford cows, located at 2 different research stations (Burns, n = 243; Union, n = 192) were sampled for blood and evaluated for BCS and temperament before the beginning of the breeding season. Temperament was assessed by chute score and chute exit velocity score, which were combined into a final temperament score (1 to 5 scale; 1 = calm temperament, 5 – excitable temperament). Cows were classified according to the final temperament score (≤3 = adequate temperament, > 3 = excitable temperament). Blood samples were analyzed for plasma concentrations of cortisol, haptoglobin, and ceruloplasmin. During the breeding season, cows were exposed to mature Angus bulls for a 50-d breeding season (1:18 bull to cow ratio). However, cows located at the Union station were also assigned to an estrus synchronization + timed-AI protocol before bull exposure. Pregnancy status was verified by detecting a fetus with rectal palpation approximately 180 d after the end of the breeding season. Plasma cortisol concentrations were greater ($P < 0.01$) in cows with excitable temperament compared with cohorts with adequate temperament (19.7 vs. 15.1 ng/mL, respectively). No effects were detected ($P > 0.26$) for BCS and plasma concentrations of haptoglobin and ceruloplasmin. Pregnancy rates tended to be reduced ($P = 0.10$) in cows with excitable temperament compared with cohorts with adequate temperament (89.3 vs. 94.0% pregnant cows/total exposed cows, respectively). Further, the probability of cows to become pregnant during the breeding season was affected quadratically ($P = 0.05$) by temperament score (91.4, 95.0, 94.3, 87.6, and 59.3% of pregnancy probability for temperament scores of 1 through 5, respectively). Results from this study indicate that excitable temperament is detrimental to reproductive performance of *Bos taurus* beef cows, independently of BCS and breeding system.

Key words: beef cows, temperament, reproduction

Production, Management and the Environment: Beef Production I

547 Relationships between feedlot morbidity, performance, and carcass quality in Angus steers. M. L. Hands[1], L. R. Corah[2], T. T. Marston[3], D. W. Moser[1], and C. D. Reinhardt*[1], *[1]Kansas State University, Manhattan, [2]Certified Angus Beef, Manhattan, KS, [3]University of Nebraska, Norfolk.*

Performance data from Angus steers (n = 17,919) fed at a single feedlot in southwestern Kansas between 1997 and 2007 were used to evaluate the interrelationships between various demographic and phenotypic characteristics (season of arrival, geographic origin, health status, rate of gain, quality grade, and yield grade) on feedlot health, performance, and carcass traits. Cattle were not commingled before or following arrival at the feedlot and were predominantly preconditioned and backgrounded before shipment to the feedlot. Data were analyzed using a mixed model with the main and interactive effects of number of times treated per animal (0, 1, 2, ≥ 3) and arrival BW as fixed effects and year of arrival as a random effect. Morbidity was associated with reduced ADG (1.64 vs. 1.48 kg/d for healthy [0 times treated] vs. morbid steers [treated ≥3 times]; $P < 0.01$). Quality grade and initial BW decreased linearly with increasing number of treatments ($P < 0.01$). In steers not treated for disease, there was little association between arrival BW and percentage Choice (68.3 vs. 70.2% for steers with arrival BW <295 vs. > 409 kg; linear $P = 0.02$). Morbid steers had a lower percentage Choice vs. healthy steers (69 vs. 57% Choice for healthy vs. morbid steers; $P < 0.01$); however, in steers marketed at yield grade 3, the difference in percentage Choice narrowed (73.1 vs. 64.0% Choice for healthy vs. morbid steers; $P < 0.01$). Also, in yield grade 3 steers, there was no difference in ADG (1.65, 1.69, and 1.64 kg/d; SEM = 0.051) or HCW (375, 377, and 375 kg; SEM = 4.8) between Prime, Choice, or Select carcasses; although compared with Choice-grading cattle, ungraded cattle had lower ADG (1.49 vs. 1.69 kg/d; $P < 0.01$) and HCW (368 vs. 377 kg; $P < 0.01$). Morbidity dramatically reduced feedlot performance and quality grade, but the reduction in quality grade and HCW was less severe by marketing morbid cattle at yield grade 3.

Key words: morbidity, quality grade, feedlot

548 Impact of beef heifer development systems on ADG, reproduction, and feed efficiency. S. P. Weber*, A. F. Summers, T. L. Meyer, and R. N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte.*

Two experiments were conducted to evaluate the effect of winter management strategies during heifer development on growth and reproductive performance. In Exp. 1, 299 weaned crossbred Angus heifers, from a 3 year study, were randomly assigned to one of 2 treatments: (1) to graze winter range then be fed in a dry lot (DL; 248 ± 4 kg)or (2) placed on corn residue (CR; 247 ± 4 kg). In Exp. 2, 118 AI pregnant heifers from each year of Exp. 1 (yr 1 = 40; yr 2 = 38, yr 3 = 40) were stratified by weight and winter development system into pens and individually fed during late gestation. In year 1 of Exp. 2, diets contained 90% grass hay (11% CP; DM basis) and 10% supplement (21.8% CP; DM basis). In years 2 and 3 of Exp. 2 heifers received one of 3 dietary supplements: no supplement; a distillers grain based supplement; or a dried corn gluten feed supplement. Supplements in yr 2 and 3 were designed to be isonitrogenous (29% CP), isocaloric, but differed in RUP. In Exp. 1 heifer BW and ADG did not differ ($P = 0.48$) during winter treatment. After winter treatment, DL tended to have increased ADG ($P = 0.057$) and differences in BW were greater ($P = \leq 0.01$) for DL compared with CR heifers. Pre-breeding BW and breeding BW were also greater ($P = 0.02$; $P = 0.03$, respectively) for DL compared with CR (350 vs. 313 ± 9 kg; 374 vs. 350 ± 12 kg). Percent of heifers cycling pre-breeding, AI conception, AI pregnancy, and overall pregnancy rates were similar ($P \geq 0.41$) between treatments. DMI, ADG, and G:F in Exp. 2 were not different ($P = 0.32$) for heifers developed on CR or DL, although final weight of CR (493 ± 3 kg) was lower ($P = 0.03$) than DL (503 ± 3 kg) approximately one month before calving. These data indicate that although heifers developed on CR have decreased ADG and BW through breeding, there is no difference in reproductive performance compared with DL developed heifers. These findings also provide evidence for reducing input costs for developing heifers without sacrificing reproductive performance.

Key words: beef cattle, heifer development, pre-breeding weight

549 Late gestation supplementation impacts primiparous beef heifers and progeny. A. F. Summers*, S. P. Weber, T. L. Meyer, and R. N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte.*

A 2-yr study utilizing primiparous crossbred beef heifers (yr 1 = 38; yr 2 = 40) was conducted to determine the effects of protein supplement during late gestation on cow and progeny performance. Pregnant heifers were stratified by heifer development system, initial BW, and service sire. Heifers were individually fed meadow hay (11.3% CP) from early November to mid February and provided no supplement (CON; yr 1 = 12; yr 2 = 13), 0.91 kg/d of a dried distillers grain based supplement (HIGH; yr 1 = 13; yr 2 = 14) or 0.91 kg/d of a dried corn gluten feed based supplement (LOW; yr 1 = 13; yr 2 = 13). Supplements were designed to be isonitrogenous (29% CP), isocaloric, but differ in RUP with HIGH (59% RUP) having greater levels of RUP than LOW (34% RUP). After the individual feeding period, heifers were placed in a dry lot for calving. All heifers were bred using a fixed-timed AI protocol and pairs moved to a commercial ranch in the Nebraska Sandhills for summer grazing. Approximately 10 d after AI, a bull was placed with the cows for 60 d. Pregnancy rates were determined via rectal palpation at weaning and calves placed in a feedlot. Feeding period initial age, initial BW and midterm BW did not differ ($P \geq 0.57$) among groups. Final off test BW was greater ($P = 0.05$) for supplemented heifers compared with CON heifers (509 vs. 434 kg ± 4 kg). Supplemented heifers had greater ($P \leq 0.06$) ADG, NE DMI, and G:F during the individual feeding period compared with CON heifers. The following calf data are only for the first year. Calving date and calf birth BW did not differ ($P \geq 0.24$) among groups. Weaning calf BW and BW at feedlot entry were greater ($P \leq 0.07$) for LOW compared with CON calves (261 vs. 239 kg ± 7 kg; 275 vs. 255 ± 7 kg) and feedlot entry BW tended ($P = 0.13$) to be greater for HIGH (273 ± 7 kg) compared with CON (255 ± 7 kg) calves. Re-implant interim feedlot BW and ADG did not differ ($P > 0.30$) among groups. Protein supplementation improved heifer ADG and G:F and calves from heifers fed lower levels of RUP had greater weaning BW and feedlot entry BW compared with calves from non supplemented dams.

Key words: beef cattle, maternal nutrition, protein supplementation

550 Cattle performance comparison in three feedlot facility designs in South Dakota. B. P. Holland*, E. R. Loe, and R. H.

Pritchard, *Department of Animal and Range Sciences, South Dakota State University, Brookings.*

The Opportunities Farm, located in southeastern South Dakota, contains 3 feedlot facility designs. Each facility design contains 4, 80 head pens. The open (OPN) design has concrete bunk aprons and mounded earthen pen floors and provides 25.5 m^2/head. The partially covered (PTL) design has a monoslope building over the feed alley and 6 m of pen, and the remainder of the pen is mounded earthen surface (20.0 m^2/head). The Confined (CON) pens are completely roofed in a monoslope building (11 m deep) with concrete floors (4.3 m^2/head) and are managed with deep pack bedding. All pens contain 24.3 m of bunk space. Beginning in 2004, cattle were sourced by lot (204 to 252 cattle/lot; 6,615 total) and randomly allotted at arrival to one pen in each housing facility. Yearling or backgrounded cattle (28 lots; BW = 215 ± 93; range = 285 to 455 kg) were managed similarly as to diet, health and implant protocols, and days on feed (117 to 226 d) across facilities within lot. Lots were closed during quarter 1 (Jan-Mar; n = 8), 2 (Apr-Jun; n = 8), 3 (July–Sep; n = 6), and 4 (Oct-Dec; n = 6). Closeout data were analyzed using mixed models with main effects of facility design, quarter closed, and their interaction. Lot was included as a random effect. Facility design × quarter closed interactions were significant ($P < 0.01$) for final BW, ADG, and G:F. Quarter 1 final BW and ADG were lowest ($P < 0.01$) for OPN compared with PTL and CON (600, 616, 617 kg and 1.45, 1.54, and 1.56 kg, respectively), and G:F was lowest for OPN (0.125), intermediate for PTL (0.134) and greatest for CON (0.138). Similarly, quarter 2 ADG and G:F were lowest for OPN compared with PTL and CON (1.66, 1.71, and 1.72 kg and 0.152, 0.159, 0.158, respectively). Performance was similar across facilities during quarters 3 and 4. Overall performance for OPN, PTL, and CON, respectively were: ADG 1.61^b, 1.66^a, 1.64^a ± 0.03 kg ($P = 0.003$); DMI 11.1, 11.1, 11.0 ± 0.17 kg ($P = 0.18$); and G:F 0.145^b, 0.150^a, 0.149^a ± 0.002 ($P < 0.001$). Averaged over the year, cattle gained faster and were more efficient when finished with protection of a building, but advantages in performance are dependent on quarter closed.

Key words: beef cattle, feedlot, housing

551 Season of arrival affects feedlot performance, health, and carcass traits of Angus steers. M. L. Hands[1], T. T. Marston[2], L. R. Corah[3], D. W. Moser[1], and C. D. Reinhardt*[1], *[1]Kansas State University, Manhattan, [2]University of Nebraska, Norfolk, [3]Certified Angus Beef, Manhattan, KS.*

Performance data from Angus steers (n = 17,919) fed at a single feedlot in southwestern Kansas between 1997 and 2007 were used to evaluate the interrelationships between various demographic and phenotypic characteristics (season of arrival, geographic origin, health status, rate of gain, quality grade, and yield grade) on feedlot health, performance, and carcass traits. Cattle were not commingled before or following arrival at the feedlot and were predominantly preconditioned and backgrounded before shipment to the feedlot. Season of arrival was categorized as winter (December, January, and February), spring (March, April, and May), summer (June, July, and August), or fall (September, October, and November). Data were analyzed using a mixed model with the main and interactive effects of season and arrival BW as fixed effects and year of arrival as a random effect. Steers which arrived during fall had the lowest ADG and those which arrived during the summer had the greatest morbidity ($P < 0.01$), but there were also interactions between the effects of season and arrival BW ($P < 0.01$) on quality grade and ADG. There was a range of 20 percentage units from the greatest to lowest percent Choice by season of arrival in the light steers (295–330 kg; 62 vs. 82% for spring and summer, respectively), an 11 unit range in the medium steers (331–375 kg; 68 vs. 79% for spring and summer, respectively) and only a 3 unit range in the heavy steers (>375 kg; 74 vs. 77% for winter vs. fall, respectively). A similar interaction was noted for ADG; there was a 0.23 kg/d range in the light steers (1.51 vs. 1.74 kg/d for fall vs. spring, respectively) and a 0.11 kg/d range in heavy steers (1.63 vs. 1.74 kg/d for fall vs. winter, respectively). Season of arrival was associated with differences in performance and carcass quality, but the degree of the seasonal impact diminished with increasing arrival BW.

Key words: feedlot, season, morbidity

552 Relationships between feedlot performance, yield grade, and quality grade in Angus steers. M. L. Hands[1], T. T. Marston[2], L. R. Corah[3], D. W. Moser[1], and C. D. Reinhardt*[1], *[1]Kansas State University, Manhattan, [2]University of Nebraska, Norfolk, [3]Certified Angus Beef LLC, Manhattan, KS.*

Performance data from Angus steers (n = 17,919) fed at a single feedlot in southwestern Kansas between 1997 and 2007 were used to evaluate the interrelationships between various demographic and phenotypic characteristics (season of arrival, geographic origin, health status, rate of gain, quality grade, and yield grade) on feedlot health, performance, and carcass traits. Cattle were not commingled before or following arrival at the feedlot and were predominantly preconditioned and backgrounded before shipment to the feedlot. Data were analyzed using a mixed model with the main effects of quality grade (Prime, Choice, Select, or Ungraded), yield grade group (yield grade 1 and 2, yield grade 3, and yield grade 4 and 5), daily gain (<1.36, 1.36 to 1.55, 1.56 to 1.81, and > 1.81 kg/d), and arrival BW group (295–330, 331–375, > 375 kg) and the interactions between quality grade, yield grade, and daily gain with arrival BW as fixed effects and year of arrival as a random effect. Increasing yield grade from 1 and 2 to yield grade 3 increased percentage Choice by 12.1 points ($P < 0.01$); there was no additional gain in quality grade moving to yield grade 4 and 5 (quadratic $P < 0.01$). More rapidly gaining steers had greater final BW, HCW, and yield grade at marketing ($P < 0.01$) and had greater quality grade ($P < 0.01$) in all but steers with initial BW >375 kg. Average daily gain did not differ greatly among cattle which graded Prime, Choice, and Select (1.61, 1.68, and 1.63 kg/d, respectively; SEM = 0.025), although ADG was lower for cattle which were ungraded (1.50 kg/d; $P < 0.01$). These data suggest that producers do not need to choose between performance and quality grade; instead, much of the difference in quality grade can be explained by differences in yield grade.

Key words: feedlot, performance, quality grade

553 Relationship of feed efficiency of replacement beef heifers to subsequent feed efficiency as 3-year old suckled beef cows. T. E. Black*[1], K. M. Bischoff[1], V. R. G. Mercadante[1], G. H. L. Marquezini[1], C. C. Chase Jr.[2], S. W. Coleman[2], and G. C. Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]USDA-ARS, SubTropical Agricultural Research Station, Brooksville, FL.*

We determined the correlation between Residual Feed Intake (RFI) measured as post-weaned growing heifers (phase 1) and RFI measured as lactating beef cows (phase 2) in the same cohort. Individual performance and daily DMI were evaluated in 74 yearling heifers, and

were subsequently reevaluated upon the birth of their second calf. For both phases, a 14-d acclimation period preceded a 70 d test using the GrowSafe System (GrowSafe Systems Ltd., Alberta, Canada) to record individual feed intakes. Forage-based diets fed in both phases were formulated to support 1 kg/d in phase 1 and lactation maintenance requirements in phase 2. Cattle were weighed every 14 d and for phase 2 cows were milked on d 14 (lactation d 28 ± 7) and d 70 (lactation d 84 ± 7) to determine energy corrected milk (ECM) production. Fat thickness over the 13th rib (BF) and ribeye area (REA) were determined by ultrasound. Heifers were ranked by RFI and placed into Low (<0.5 SD; n = 24), Med (<0.5 SD > ; n = 24), and High (>0.5 SD; n = 26) RFI groups. Daily DMI differed for all groups ($P < 0.0001$) and was greatest (10.82 ± 0.23 kg/d) for High; intermediate (9.63 ± 0.24 kg/d) for Med; and lowest (8.47 ± 0.24 kg/d) for Low RFI heifers. Phase 2 RFI model included d 28, d84 ECM and d 84 BF which explained 36%, 11%, and 3%, respectively, of the variation in DMI not explained by ADG and MBW. Cows which were most efficient as heifers (Low) had lower ($P < 0.05$) daily DMI and RFI values (13.6 ± 0.6; −1.17 ± 0.5 kg/d, respectively) than cows ranked as Med (15.5 ± 0.6; 0.8 ± 0.5 kg/d) or High (15.7 ± 0.6; 0.24 ± 0.46) as heifers. In addition, cows which were least efficient as heifers (High) had the greatest d28 and d84 ECM (6.27 ± 0.36 ; 5.4 ± 0.31 kg/d) compared with cows that were more efficient heifers (4.66 ± 0.38 and 4.58 ± 0.33 kg/d Low; 4.66 ± 0.38 and 4.0 ± 0.33 kg/d Med). Pearson rank correlation between heifer and cow RFI was r = 0.19 ($P = 0.12$). We conclude that ECM and BF are important sources of variation affecting evaluation of RFI in lactating beef cows and heifers ranked as more efficient subsequently consumed less as cows.

Key words: residual feed intake, beef cows, dry matter intake

554 Effect of injectable trace minerals on the humoral immune response to multivalent vaccine administration in beef calves. J. D. Arthington*[1] and L. J. Havenga[2], *[1]University of Florida, Range Cattle Research and Education Center, Ona, [2]Multimin USA Inc., Fort Collins, CO.*

The objective of this experiment was to investigate the effects of injectable trace minerals (ITM) on humoral responses of calves receiving a viral vaccination. Steer calves (n = 99; average BW = 302 ± 4.2 kg), seronegative for bovine herpesvirus-1 (BHV-1) and bovine viral diarrhea virus, genotypes 1 and 2 (BVDV-1 and BVDV-2) were sourced from 2 locations. All calves, except 15 non-vaccinated (sentinel) calves, received a single dose of a multivalent modified live vaccine (Titanium 5; AgriLabs, St. Joseph, MO) containing BHV-1, BVDV-1, BVDV-2, bovine parainfluenza virus type 3, and bovine respiratory syncytial virus. Among the vaccinated calves, 2 treatments were concurrently and randomly applied; including, 1) ITM (n = 42; 7 mL s.c.; MultiMin, Fort Collins, CO) containing 15, 40, 10 and 5 mg/mL of Cu, Zn, Mn (all as disodium EDTA salts) and Se (as Na selenite), or 2) saline-injected control (Control; n = 41). Neutralizing antibody titers were measured on d 0, 14, 30, 60 and 90 relative to vaccine and treatment administration. All calves were seronegative for each of the 3 viruses on d 0 and sentinel calves remained seronegative throughout the study. Serum mineral concentrations were evaluated on d 0 and 14. No differences ($P \geq 0.30$) in serum Cu, Zn, Mn, or Se were observed between treatments on d 0. Control steers had a decrease ($P < 0.001$) in serum Zn and Se and ITM steers had an increase ($P = 0.007$) in serum Cu on d 14 relative to d 0 values. On d 14, serum Zn and Se concentrations were greater ($P < 0.01$) in ITM compared with Control steers. All vaccinated calves experienced increases in neutralizing antibody titers by d 30 following vaccine administration. Calves receiving ITM at the time of vaccination had greater ($P \leq 0.003$) neutralizing antibody titers to BHV-1 on d 14, 30, and 60 compared with Control. These results demonstrate that the ITM formulation evaluated in this study does not impair humoral immune responses in beef calves. Further, concurrent administration of ITM and BHV-1 vaccine may enhance the production of neutralizing antibodies to BHV-1 in previously naïve beef calves.

Key words: trace mineral, vaccine, calves

555 The effect of beta-agonists on feedlot performance and carcass merit in yearling steers. R. K. Peterson*[1], J. J. Wagner[1], T. E. Engle[1], and T. C. Bryant[2], *[1]Colorado State University, Fort Collins, [2]JBS Five Rivers Cattle Feeding, Greeley, CO.*

Yearling steers (n = 864; BW = 347 kg) were used to study the effects of β-agonist (BA) treatment on feedlot performance and carcass merit. Steers arrived at the feedlot in 2 groups and were ranked by BW within each group and divided into 4 BW blocks. Within each BW block, each successive set of 12 ranked steers were randomly assigned to 1 of 12 pens of 9 head. After an average of 111 d on feed, steers were weighed and all 96 pens were ranked by BW and each pen was assigned to 1 of 8 BW blocks (12 pens/BW block). Within each BW block, pens were randomly assigned to 3 BA treatments (32 pens/treatment). Treatments included: 1. Control (no BA), 2. Optaflexx (OPT, 200 mg/hd/d for 28 d), and 3. Zilmax (ZIL, 8.33 mg/kg diet DM about 75 mg/hd/d for 20 d). A 3 d withdrawal from ZIL was used. All steers were fed steam-flaked corn based finishing diets 2X daily. Cattle were started on their respective BA treatments and slaughtered in 3 groups by BW block. Average final BW and ADG the final 28 d for steers treated with BA were greater ($P < 0.01$) than no BA supplemented steers. Treatment had no effect on DMI and gain-to-feed ratio was improved ($P < 0.001$) during the final 28 d by 35% for steers fed BA compared with no BA. There was no difference in final BW for OPT versus ZIL. Least squares means for HCW, adjusted for BW at the initiation of the BA feeding, were heavier ($P < 0.01$) for ZIL compared with no BA and heavier ($P < 0.05$) for ZIL than OPT. Dressing percentage (DP) was higher ($P < 0.001$) for steers fed ZIL compared with OPT and no BA (64.4, 63.2, and 63.4%, respectively). Yield grades (YG) were similar for OPT and ZIL steers and both were reduced ($P < 0.05$) compared with no BA. Average marbling score for no BA carcasses was greater ($P < 0.01$) than BA carcasses but was similar for OPT and ZIL. Carcasses from steers receiving no BA had a greater likelihood ($P < 0.01$) of grading low choice or higher than steers fed BA. The effect of OPT and ZIL on BW appears similar; however, an increase in DP for ZIL as compared with OPT or no BA resulted in a 5.8 and 9.2 kg heavier HCW for ZIL as compared with OPT and no BA, respectively.

Key words: beta-agonists, ractopamine, zilpaterol

556 Moderate exercise alters blood constituents, growth performance, and carcass characteristics in finishing heifers. A. D. Stickel[1], L. N. Edwards[1], T. A. Houser[1], J. R. Jaeger[2], T. G. Rozell[1], L. D. Hollis[1], S. Uwituze[1], C. L. Van Bibber[1], K. A. Miller[1], J. J. Higgins[1], and J. S. Drouillard*[1], *[1]Kansas State University, Manhattan, [2]Kansas State University, Hays.*

Crossbred heifers (n = 30; 448 ± 27 kg initial BW) were used in an randomized complete block experiment to assess impact of exercise regimen on serum IGF-1 and insulin, plasma glucose and lactate, feedlot performance, and carcass characteristics. Heifers were stratified by initial BW and body condition and assigned randomly, within strata,

to Sedentary and Exercised groups. Cattle were housed in individual pens (1.5 m X 6.5 m) and fed a finishing diet consisting of 93% concentrate and 7% roughage. Each Mon, Wed, and Fri, Exercised cattle were removed from their pens and moved by a caretaker at a pace of 5 to 6 km/h (20 min/d for the first 2 wk, 30 min/d for the next 2 wk, and 40 min/d thereafter). Blood samples were collected via jugular puncture before exercise on d 0, 28, and 60; ultrasound measures of LM depth, 12th rib fat thickness, and marbling were collected on d 0 and 60; and heifers were harvested on d 62. Data were analyzed using Proc Mixed of SAS, with fixed effect of exercise regimen and random effects of strata and exercise regimen x strata. Study day and the interaction between study day and exercise regimen were included as fixed effects for repeated measures. Exercise decreased insulin (exercise x d interaction, $P = 0.06$; exercise effect, $P = 0.01$), but had no effects ($P \geq 0.10$) on IGF-1, glucose, or lactate, or ultrasound measures of LM depth and marbling. Exercised cattle had poorer ADG (0.79 vs 1.14 kg/d), DMI (8.98 vs 10.06 kg/d), and gain:feed (0.083 vs 0.111) compared with Sedentary cattle ($P \leq 0.05$), but yielded similar HCW (312 vs 321 kg; $P \geq 0.10$), marbling (Slight^{74} vs Small^{01} ; $P \geq 0.10$), LM area ($P \geq 0.15$), and KPH ($P \geq 0.80$), and had less 12th rib fat (1.09 vs 1.45 cm; $P \leq 0.01$) and lower yield grades (2.22 vs 2.86; $P \leq 0.01$). Feed intakes were not different between days of exercise and rest ($P \geq 0.10$). Response to exercise was highly variable, and decreased performance was largely attributable to 2 heifers that gained no BW during the 62-d trial. Moderate physical activity in feedlot cattle alters insulin concentrations, feed intake, gain, efficiency, and carcass fatness.

Key words: exercise, cattle, feedlot

557 Acidosis challenge effects on ruminal pH and temperature in beef cattle. D. L. Christensen*, J. L. Wahrmund, A. K. Sexten, C. L. Goad, C. R. Krehbiel, and C. J. Richards, *Oklahoma State University, Stillwater.*

Twelve ruminally cannulated steers with ruminal pH and temperature monitoring devices were used to determine the effects of an acidosis challenge on ruminal pH and temperature. Steers were offered the control diet at 2% BW/d before the challenge and starting 24 h after the challenge. Challenges were ruminal dosing of 2% BW of 62% concentrate diet (CON), mixture of 50:50 dry rolled corn:wet distillers grains (MIX), or 100% dry rolled corn (DRC) at 0 h. Bolus readings for pH and temperature were recorded every minute for 72 h after dosing and compiled in 3 h increments for repeated measures analysis. Ruminal fluid samples were obtained every 3 h for 72 h after dosing and analyzed with a repeated measures analysis. For ruminal fluid samples, pH of MIX was lower ($P < 0.05$) than CON for h 3 to 27, 57 and 63. DRC pH was lower ($P < 0.05$) than CON for h 3 to 27 and 57. MIX pH was lower ($P < 0.05$) than DRC for h 3 to 15. All ruminal temperatures less than 37.8°C were considered to be associated with water consumption and were removed before analysis. Continuous ruminal pH measures resulted in significant treatment and sampling time effects ($P < 0.01$) with CON > DRC > MIX. Continuous ruminal temperatures resulted in a sampling time ($P < 0.08$) trend and significant treatment ($P < 0.01$) effect with DRC greater ($P < 0.01$) than CON or MIX. These results indicate that increased availability of highly fermentable substrates in the rumen that result in decreases in rumen pH also result in increases in ruminal temperatures. However, the type of fermentable substrate may change the relationship between ruminal temperature and pH, particularly when substrates such as distillers grains that have a low pH are included in the diet.

558 Fatty acid profile of muscle and subcutaneous fat of Red Norte bulls fed ionophores and lipids sources. M. M. Ladeira, L. C. Santarosa, O. R. Machado Neto, M. L. Chizzotti*, T. M. Gonçalves, E. M. Ramos, L. S. Lopes, J. S. F. Hostalácio, D. M. Oliveira, and M. C. L. Alves, *Federal University of Lavras, Lavras, MG, Brazil.*

The objective was to determine the fatty acids (FA) profile of muscle and subcutaneous fat of Red Norte bulls fed ground soybean grain (GSG) or rumen protected fat (RPF), with or without the inclusion of the sodic monensin. Forty animals, with initial LW of 359 kg, were allotted in a completely randomized design using a 2x2 factorial arrangement. The diets had 12.7% CP, 29.0% NDF and 7.2% EE. When the ionophore was supplemented, the dosage used was 230 ppm/day. The concentrate:forage ratio was 60:40 and it was used corn silage as roughage. The diets was fed ad libitum, and presented 17.2% of GSG or 4.2% of RPF, as DM basis. The duration of the experiment was 112 d, and the animals were slaughtered with on average 497 kg. The determination of FA was performed using GC. The data were analyzed using PROC GLM of SAS 9.1. There was no effect of monensin on FA profile ($P > 0.05$). The diets do not affected the C14:0 (2.3%) and C16:0 (22.7%) contents ($P > 0.05$). The meat of animals that received RPF had higher C18:1 content in muscle (38.1% vs. 34.5%, ($P < 0.01$), which can be explained by partial protection to rumen biohydrogenation. The CLA (cis-9, trans-11 C18:2) content was higher in muscle from animals fed soybean (0.72% vs. 0.60%, ($P < 0.01$), which can be justified by the higher exposure of FA from soybean to biohydrogenation. The GSG diet promoted greater concentration of linoleic acid in the muscle, than RPF (10.1% vs. 7.51%, ($P < 0.01$). However, linolenic acid was found in higher concentration in muscle of animals feeding RPF (0.48% vs. 0.31%, ($P < 0.01$), despite the higher concentration of this FA in soybean, which can be also justified by the partial protection of this ingredient. Subcutaneous fat from animals fed GSG presented lesser C12:0 and C14:0 content ($P < 0.01$), and had a greater C18:0 content (21.1% vs. 18.3%, ($P < 0.05$). The inclusion of RPF increased levels of C18:1 (41.3% vs. 38.3%, ($P < 0.01$) and CLA (0.84% vs. 0.37%, ($P < 0.01$) in subcutaneous fat. The concentrations of C18:2 and C18:3 were increased with the use of GSG, compared with RPF. The monensin did not affect the FA profile of meat. Funded by Fapemig, CNPq, CAPES and INCT-CA

Key words: cla, monensin, soybean

559 Effects of energetic supplementation strategies on performance of growing cattle grazing tropical forage and on animal performance during the feedlot finishing phase. L. R. D. Agostinho Neto, J. R. R. Dorea, V. N. Gouvea, A. L. Marra, and F. A. P. Santos*, *University of Sao Paulo/ESALQ, Piracicaba, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of strategies of energetic supplementation to growing cattle grazing well managed tropical pastures during the summer and fall season on animal ADG, pasture stocking rate and on animal performance during the feedlot finishing phase. Seventy 6 crossbred bull calves, averaging 208 kg initial BW and 8 mo of age, were used in a randomized block design trial to compare 3 energetic supplementation strategies: T1) Control: grazing animals fed only a mineral mixture; T2) Constant level: constant daily feeding of energetic supplement at 0.6% of BW; T3) Increased level: daily feeding of energetic supplement at increasing levels of 0.3, 0.6, and 0.9% BW, according to the experimental period. Animals were allocated in a 8.5 ha area of *Brachiaria brizantha* 'Marandu' pasture under a rotational grazing system with a variable defoliation interval. Supplemented animals had greater ADG ($P < 0.05$) than animals not supplemented (0.535, 0.787, and 0.867 kg/animal per d), respectively for the control, constant, and increasing treatment levels. Furthermore, animals in the increasing supplementation group presented a higher ADG when compared with the constant supplementation, although animals from both treatments have consumed similar amounts of supplement. Supplementation also increased ($P < 0.05$) the pasture stocking rate, which averaged 5.94, 7.13, and 6.90 AU/ha, respectively for the control, constant, and increasing treatment levels. Supplementation strategies during the grazing period had no effect ($P > 0.05$) on animal DMI, ADG and feed efficiency during the feedlot finishing phase.

Table 1. Animal performance, pasture stocking rate, dry matter intake, ADG:DMI

	Pasture Phase				
	Control	Constant level	Increased level	*P*-value	SEM
ADG (kg/d)	0.535c	0.787b	0.867a	*	0.016
Stocking rate (AU/ha)	5.94b	7.13a	6.90a	*	0.01
	Feedlot Phase				
	Control	Constant level	Increased level		
ADG (kg/d)	1.07	1.02	1.08	ns	0.05
DMI (kg/d)	7.89	8.04	8.34	ns	0.32
ADG/DMI (g/kg)	0.136	0.127	0.130	ns	0,005

560 Effect of rate of gain on fat deposition during grazing and final carcass characteristics in growing beef cattle. E. D. Sharman*, P. A. Lancaster, C. P. McMurphy, G. G. Hilton, C. R. Krehbiel, and G. W. Horn, *Oklahoma Agricultural Experiment Station, Stillwater.*

Recent evidence suggests that a moderate rate of gain is required throughout an animal′s life to achieve desirable quality grades in beef cattle. The objective of this study was to determine the effect of rate of gain to similar initial finishing BW on fat deposition during grazing and final carcass characteristics in growing beef cattle. Angus steers (n = 72; 259 ± 28 kg) were allotted on Dec. Four in a completely randomized design with 4 grazing treatments: (1) grazing dormant native range (NR) plus a protein supplement (1.0 kg•hd^{-1}•d^{-1}) followed by season-long grazing NR (CON); (2) grazing dormant NR plus a corn-based supplement (1% of BW) followed by short-season grazing NR (CORN); (3) grazing wheat pasture (WP) at a high stocking rate (3.0 steers/ha) for a moderate ADG (LGWP); and (4) grazing WP at a low stocking rate (1.0 steers/ha) for a high ADG (HGWP). Supplements met DIP requirements and were individually fed 5 d/wk during the first 130 d of grazing. When steers in each treatment reached an estimated carcass weight of 200 kg, 4 steers were randomly selected for intermediate harvest (Table 1). The remaining steers were transitioned to the finishing phase and fed to a backfat endpoint of 1.27 cm. At final harvest, steers had similar ($P > 0.14$) HCW, backfat, and marbling scores (456, 404, 421, and 426 ± 17.04; treatments 1–4, respectively). These data indicate that rate of gain during grazing does not significantly impact final marbling score suggesting that wintering beef steers at low rates of gain will not negatively affect final quality grade when cattle are fed to a similar backfat endpoint.

Table 1. Grazing performance and intermediate carcass characteristics

Item	CON	CORN	LGWP	HGWP
Grazing ADG, kg/d	0.49^{a}	0.63^{b}	0.84^{c}	1.41^{d}
HCW, kg	207^{ab}	201^{a}	226^{b}	204^{a}
Dressing %	52.08^{a}	52.29^{a}	59.23^{c}	54.98^{b}

561 Nutrient mass balance and performance of feedlot cattle fed barley based diets with and without dried distillers grains plus solubles. E. M. Hussey*[1], G. E. Erickson[1], R. E. Peterson[3], and L. O. Burciaga-Robles[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]Feedlot Health Management Services Ltd., Okotoks, AB, Canada, [3]Western Feedlots Ltd., High River, AB, Canada.*

Crossbred yearling heifers (n = 9,538, 32 pens, 492 ± 50 kg initial BW, days on feed = 81) were assigned randomly at reimplant to a 2 × 2 factorial arrangement of treatments. Main effects included LOW or HIGH starch:NDF barley and 0 or 20% inclusion of dried distillers grains plus solubles (DDGS). Barley was determined to be HIGH (starch:NDF >3.25) or LOW (starch:NDF <3.25) at feedlot arrival based on values determined by Near Infrared Spectroscopy. The objective was to evaluate the impact of HIGH or LOW barley and 0% or 20% DDGS on feedlot performance, carcass characteristics and N and P mass balance. Data were analyzed using Proc Mixed, with fixed effects of treatments and the random effect of replicate. No barley x DDGS interactions were observed. Intake, ADG, and HCW were greater ($P < 0.02$) and carcass adjusted G:F tended to be greater ($P = 0.10$) for LOW starch:NDF barley. Barley treatment did not affect yield or quality grade ($P \geq 0.18$). Intake, retention, and excretion of N and P were greater ($P \leq 0.01$) and removal of N and DM from the pen tended to be greater ($P = 0.09$) for LOW. Loss and excretion of N on a kg per heifer basis was greater ($P = 0.05$) for LOW, but was not different when expressed as a % of N excretion, averaging 85%. Intake and G:F based on live ADG were greater ($P < 0.01$), and G:F tended to be greater on a carcass basis ($P = 0.07$) for 20% compared with 0% DDGS. Fat depth and the percentage of Yield grade 4 carcasses were greater ($P \leq 0.05$) for 20% DDGS compared with 0%, but no differences in quality grade were observed ($P \geq 0.25$). Intake and excretion of N and P were greater ($P < 0.01$) for 20% DDGS. Removal of N, P, and DM were not different ($P \geq 0.17$) between 0 and 20% DDGS. Losses of N (82% vs. 87%) and P were greater ($P \leq 0.01$) for 20% compared with 0%. Feeding low starch:NDF barley improved feedlot performance, increased DM removed from the pen, and increased N loss. Feeding 20% DDGS increased DMI, had a slight negative impact on G:F, and increased N and P losses.

Key words: barley, distillers grains plus solubles, mass balance

562 Effects of levels of energetic supplementation on forage intake and ruminal fermentation in beef cattle grazing tropical pastures. J. R. R. Dórea[1], L. R. D. Agostinho Neto[1], V. N. Gouvêa[1], M. A. C. Danés[1], L. G. R. Pereira[2], J. A. G. Azevêdo[3], and F. A. P. Santos*[1], *[1]University of Sao Paulo/ESALQ, Piracicaba, São Paulo, Brazil, [2]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil, [3]State University of Santa Cruz, Ilhéus, Bahia, Brazil.*

The objective of this trial was to evaluate the effects of increasing levels of energetic supplementation on forage intake, ruminal parameters, microbial synthesis and N retention in beef steers grazing tropical pastures (12 to 15% CP), during the rainy season in the southeast region of Brazil. Treatments were: 0, 0.3, 0.6 and 0.9% BW of an energetic supplement containing fine ground corn plus monensin fed once a day. Eight Nellore steers (410 kg) with cannulas in the rumen were used in a replicated 4 × 4 Latin-square experiment. One hectare of pasture of *Brachiaria brizantha* ‘Marandu’ was used for the experiment. Chromium oxide was used as a digesta marker. Increasing levels

of supplementation decreased linearly ($P < 0.05$) forage DMI and increased total DMI. There was a dramatic decrease in forage intake with the low level of energetic supplementation (0.3% of BW) with subsequent smaller decreases with 0.6 and 0.9% BW levels. Because of the dramatic decrease in forage DMI the low level of supplementation (0.3% BW) had negligible effect on total DMI. However the 0.6 and 0.9% supplementation levels were very effective to increase total DMI of grazing steers. Ruminal pH and total VFA concentration were not affected by treatments ($P > 0.05$). Increasing levels of energetic supplementation increased linearly ruminal propionate ($P < 0.05$). The concentrations of rumen ammonia were decreased linearly ($P < 0.05$) and microbial synthesis and N retention were increased ($P < 0.05$) with energetic supplementation. The decrease on forage DMI caused by the energetic supplementation was not associated to inadequate ruminal pH or impairment of fiber degradation (in vitro gas production method).

Table 1. Forage and total intake, ruminal parameters, microbial synthesis and nitrogen retention

	Levels of supplement (%BW)				*P*-value	Contrast	
	0	0.3	0.6	0.9	trat	Linear	SE
Forage intake, %BW	1.90	1.64	1.55	1.50	*	*	0.11

563 The relationship between rumen acidosis resistance and expression of genes involved in regulation of intracellular pH in rumen epithelial cells in steers. N. Schlau*, L. L. Guan, and M. Oba, *University of Alberta, Edmonton, AB Canada.*

The objective of this study was to compare the expression of genes involved in regulating intracellular pH in rumen epithelial cells between acidosis-resistant (AR) and acidosis-susceptible (AS) steers. Acidosis indexes (area under pH 5.8 divided by DMI) were measured for 17 steers, and the 3 steers with the lowest (1.4 ± 1.2) and the 3 with the highest (23.9 ± 7.4) values were classified as AR and AS, respectively, and used for the subsequent study. The steers were force-fed a meal consisting of a diet containing 85% grain at 60% of expected DMI (5.8 ± 0.8 and 5.6 ± 0.6 kg for AR and AS, respectively). Rumen papillae were biopsied at 0, 2, 4, and 6-h after feeding, and RNA was extracted and quantified using quantitative real time reverse transcriptase PCR. Mean rumen pH over the 6-h period was higher for AR compared with AS steers (6.02 vs. 5.55; $P < 0.01$). Relative mRNA abundance of monocarboxylate cotransporter isoform 1, sodium hydrogen exchanger isoform 2, and downregulated in adenoma (an anion exchanger) did not differ between AR and AS groups or among time points relative to feeding. However, an hour by group interaction ($P < 0.05$) was detected for relative mRNA abundance of sodium hydrogen exchanger isoforms 1 and 3 (NHE1 and NHE3), both of which import Na^+ to the cell and export H^+ to the rumen. Relative expression of NHE1 and NHE3 did not differ between AR and AS group at 0 and 6-h after feeding, but that of NHE1 was 56% ($P = 0.05$) and 72% ($P = 0.04$) greater, and that of NHE3 was 17% ($P < 0.001$) and 235% ($P < 0.001$) greater in AR compared with AS group at 2 and 4-h after feeding, respectively. Additionally, relative mRNA abundance of putative anion transporter isoform 1 (PAT1), which imports dissociated VFA to the cell and exports HCO_3^- to the rumen, and that of NHE1 increased linearly ($P < 0.001$) for the 6-h period. These results suggest that genes coding for transport proteins involved in intracellular pH regulation can be upregulated by supply of fermentation substrates, and the extent can differ between AR and AS steers.

Key words: acidosis resistance, gene expression, ruminal acidosis

564 Evaluation of diet net energy calculations on intake and gain compared to prediction equations for finishing steers. M. F. Wilken*, L. L. Berger, G. E. Erickson, and K. J. Hanford, *University of Nebraska-Lincoln, Lincoln.*

Four years of data collected at the University of Illinios-Urbana were utilized to evaluate 3 intake prediction equations (NRC, 1996; Galyean et al., 2009; Owens et al., 2002) calculated one of 2 ways: diet energy determined by hand (HAND = feedstuff inclusion*feedstuff NE (NRC, 1996)) or by a quadratic equation (QUAD; Zinn et al., 2003). Individual DMI and ADG were analyzed for 1,794 individually fed calf-fed steers. Thirteen treatments were utilized containing corn, dry and modified wet distillers grains plus solubles, dry and wet corn gluten feed, soybean hulls, corn silage, and/or brome hay. Observed DMI (ObsDMI) was compared with the 6 intake prediction equations (PredDMI). Observed ADG (ObsADG) was also compared with a predicted ADG (PredADG) calculated using HAND or QUAD from ObsDMI. Analysis of ObsDMI vs PredDMI showed that all 3 equations overestimated intake ($P < 0.01$), regardless of energy value calculation for all treatments. The NRC QUAD PredDMI was not different from ObsDMI within 5 treatments ($P > 0.05$) and was closest to the ObsDMI for 12 of the 13 diets consumed. The Galyean QUAD PredDMI was statistically similar to the NRC QUAD PredDMI for steers consuming byproduct containing diets ($P > 0.05$). The Owens PredDMI was the most overestimated and was statistically different ($P < 0.05$) for all treatments regardless of HAND or QUAD. For steers fed diets containing corn, there was no difference ($P > 0.05$) in ObsADG vs PredADG and energy value calculation was not significant ($P > 0.15$). However steers consuming diets containing byproducts, PredADG was overestimated compared with ObsADG ($P < 0.05$) for both HAND and QUAD. These findings suggest that the NRC equation is the most accurate but overestimation from calculations containing HAND energy values could be from inaccurate byproduct energy values in the NRC. Additionally, QUAD energy values are more accurate but vary with animal response and does not allow for a defined diet energy value.

Key words: dry matter intake, feedlot cattle, prediction equation

565 Effect of finishing system (feedlot or pasture) on energy requirements of Zebu cattle. M. L. Chizzotti*[1], M. I. Marcondes[2], S. C. Valadares Filho[2], M. P. Gionbelli[2], P. V. R. Paulino[2], and M. F. Paulino[2], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The aim of the present study is to evaluate the effect of the finishing system, pasture or feedlot, in the energy requirements of Zebu cattle. A database of 20 feedlot finishing studies (n = 626) and 5 pasture finishing studies (n = 127) with Zebu cattle using the comparative slaughter technique was used in a meta-analysis using PROC MIXED of SAS 9.1 to evaluate the fixed effect of finishing system on net energy requirements for maintenance and growth, assuming random effect of studies. Breed (Nelore purebred or Nellore crossbred with Bos Taurus) and gender (bulls, steers and heifers) effects were also tested and included as fixed effect if they are significant at $P < 0.10$. The coefficients AIC and BIC were used to choose the best structure of the variance-(co)variance matrix. Net energy requirements for maintenance (NEm) was obtained by the regression of heat production (HP) on metabolizable energy intake (MEI), on Mcal/kg $EBW^{0.75}$/d basis: $HP = NEm \times e^{B \times MEI}$. The metabolizable energy requirement for maintenance (MEm) was calculated by iteration to equals MEI to HP. The net energy for gain (NEg) was obtained by a multiple regression on equivalent $EBW^{0.75}$ ($eqEBW^{0.75}$) and empty body gain (EBG), according to: $NEg = C \times eqEBW^{0.75} \times EBG^{D}$. There was effect ($P < 0.05$) of finishing system in the relation empty body weight/ shrunk body weight, which was of 0.895 for feedlot and 0.863 for pasture finishing system. The relation of MEI and HP for feedlot and pasture were $HP = 0.0742 \times e^{3.703 \times MEI}$ and $HP = 0.0717 \times e^{4.439 \times MEI}$, respectively. There was no difference ($P > 0.05$) for NEm between finishing system but there was a difference ($P < 0.05$) for MEm which was of 112 and 125 kcal/$EBW^{0.75}$/d for feedlot and pasture finishing systems, respectively. There was gender effect for C coefficient of NEg for feedlot, which was of 0.053, 0.064 and 0.072 for bulls, steers and heifers, respectively. There was effect of finishing system on D coefficient of NEg, which was of 1.095 and 1.062 for feedlot and pasture, respectively. Pasture finishing Zebu cattle presented MEm 11% greater than feedlot and lower energy concentration in the gain. Funded by INCT-CA CNPq, CAPES, FAPEMIG.

566 A chemical evaluation of the chemical composition of four corn milling co-products with focus on fatty acids. C. S. Dose*[1], P. J. Kononoff[1], T. C. Jenkins[2], L. O. Tedeschi[3], and K. Karges[4], *[1]Department of Animal Science, University of Nebraska-Lincoln, Lincoln, [2]Department of Animal and Veterinary Sciences, Clemson University, Clemson, SC, [3]Department of Animal Science, Texas A&M University, College Station, [4]Dakota Gold Research Association, Sioux Falls, SD.*

Technological advancements in ethanol production have resulted in corn milling co-products that, when compared with those most commonly produced, may differ in chemical composition. The objectives of this study were to further characterize major nutrient fractions and evaluate differences in fatty acid profile of a range of corn milling co-products. The 4 corn milling co-products evaluated in this study were: corn bran (BRAN), dehydrated germ (GERM), high protein dried distillers grains (HP), and dried distillers grains and soluble (BPX) which were produced without exposure to heat before fermentation. Over the course of 4 mo, samples of each feedstuff were collected weekly until a total of 30 replicate samples of each feedstuff were collected. Data was analyzed as a completely randomized design with treatment (feedstuff) considered as a fixed effect. The average CP was significantly different ($P < 0.01$) among the co-products and was highest for HP (44.06 ± 0.227) followed by BPX (31.17 ± 0.227), GERM (15.74 ± 0.227), and BRAN (14.45 ± 0.227). The average NDF content, with sodium sulfite, of the co-products were similar ($P < 0.01$) between HP (29.42 ± 0.5195) and BPX (29.27 ± 0.5195), with BRAN (25.70 ± 0.5195) and GERM (24.36 ± 0.5195) to follow. The average ether extract (EE) of GERM was the highest value (19.48 ± 0.1607) and HP had the lowest (4.67 ± 0.1607), with BPX (11.63 ± 0.1607) and BRAN (10.27 ± 0.1607) being similar ($P < 0.01$). Similarly, the mean concentration of total fatty acids (TFA) was also different ($P < 0.01$) and observed to be 15.7, 6.00, 9.84 and 8.3 ± 0.125% DM for GERM, HP, BPX and BRAN respectively. The proportions of C16:0, C18:0, C18:1, C18:2 and C18:3 were also different ($P < 0.01$) and averaged as follows (% TFA): GERM = 11.9, 1.65, 26.3, 55.4, and 1.11; HP = 16.2, 2.47, 22.8, 52.9, and 2.00; BPX = 13.7, 2.06, 25.0, 54.8, and 1.44; BRAN = 14.1, 2.21, 24.7, 53.3, and 1.62., respectively. Our analyses defined differences of CP, NDF, TFA, and the profile of TFA.

Key words: chemical composition, co-products, fatty acid

567 Evaluation of polyclonal antibodies in cattle adapted or not to highly fermentable carbohydrates diets. T. Barros[1], C. Marino*[1], R. Pacheco[2], F. Ferreira[1], F. Perna Jr.[1], E. Cassiano[1], M. Martins[1], M. Arrigoni[2], and P. Rodrigues[1], *[1]University of Sao Paulo, FMVZ-USP, Pirassununga, Sao Paulo, Brazil, [2]University of Sao Paulo State, FMVZ-UNESP, Botucatu, Sao Paulo, Brazil.*

The objective of this work was to evaluate the effect of polyclonal antibodies (PAP) against specific rumen bacteria *Streptococcus bovis*, *Fusobacterium necrophorum* and *Lactobacillus* on rumen fermentation parameters (pH, total volatile fatty acids (tVFA) and ratio acetate:proprionate Ac:Pr) in ruminally cannulated cows adapted or not to highly fermentable carbohydrates diets (HFC). The experimental design was 2 Latin squares 3 × 3 in a factorial arrangement of treatments 3 × 2 regarding 2 feed additives (PAP in powder presentation (PAPP) and PAP in liquid presentation (PAPL)) plus control group (CON) and 2 managements of diets adaptation resulting in 6 treatments. The first Latin square had a step-up adaptation diet: from D0 to D4 – 100% forage; D5 to D9 – 30% HFC and D10 to D14 – 60% HFC. The second Latin square received 100% forage from D0 to D14 (no adaptation). Each experimental period had 15 d, where rumen fluid samples for pH and volatile fatty acids analysis were collected from D0 to D14 at 3 h postfeeding. Data were analyzed by MIXED procedure with a significance level of 0.05. It was observed an interaction between time and adaptation ($P < 0.0001$) for rumen pH in the d 2 and 4–14, where the non-adapted group had higher values compared with adapted (6.80 vs. 6.34, respectively). It was observed an interaction between time and adaptation ($P < 0.0001$) for total VFA at D1 to 14, where the group adapted had higher values when compared with non-adapted animals (99.72 vs. 74.96 mM, respectively). It was also observed an interaction between time and adaptation ($P < 0.0001$) to ratio Ac:Pr, in D2, 5 to 7 and 12 to14, where the adapted group had lower values than non-adapted group until D7 (1.96 vs. 2.29) and after D12 (2.69 vs. 2.33) the position reversed and the adapted group had greater values. From these results, it was concluded that step-up adaptation reduced rumen pH and increased total VFA as expected by the total highly fermentable carbohydrate available. This effect was dependent on time and independent from feed additive used.

Key words: acidosis, feed additive, passive immunization

568 Evaluation of polyclonal antibodies in cattle adapted or not to highly fermentable carbohydrates diets after an acidosis challenge. T. Barros[1], C. Marino*[1], R. Pacheco[2], F. Ferreira[1], F. Perna Jr.[1], E. Cassiano[1], M. Martins[1], M. Arrigoni[2], and P. Rodrigues[1], *[1]University of Sao Paulo, FMVZ-USP, Pirassununga, Sao Paulo, Brazil,*

[2]*University of Sao Paulo State, FMVZ-UNESP, Botucatu, Sao Paulo, Brazil.*

The objective of this work was to evaluate the effect of polyclonal antibodies (PAP) against specific rumen bacteria Streptococcus bovis, Fusobacterium necrophorum and Lactobacillus on rumen fermentation parameters (pH, volatile fatty acids (VFA)) in ruminally cannulated cows adapted or not to highly fermentable carbohydrates diets (HFC) after an acidosis challenge. The experimental design was 2 Latin squares 3 × 3 in factorial arrangement of treatments 3 × 2 regarding 2 feed additives (PAP in powder presentation (PAPP) and PAP in liquid presentation (PAPL)) plus control group (CON) and 2 managements of diets adaptation resulting in 6 treatments. The first Latin square had a step-up diet adaptation: from D0 to D4 – 100% forage; D5 to D9 – 30% HFC and D10 to D14 – 60% HFC. The second Latin square received 100% forage from D0 to D14. For pH and total concentration of VFA analysis, samples of rumen fluid were collected at 0 and every 3 h postfeeding totalizing 36 h (D15 and D16) of challenge with a diet of 80% of HFC. Data were analyzed by MIXED procedure with a significance level of 0.05. It was observed an interaction between time and adaptation for pH ($P < 0.0001$). The adapted group had lower values of pH than non-adapted until 24 h and at 36 h after the start of challenge (6.18 vs. 6.55 and 5.92 vs. 6.08, respectively). For VFA total concentration, it was also observed an interaction between time and adaptation ($P < 0.0001$), where from 0 to 9 h (109.38 vs. 82.26 mM) and at 36 h (121.11 vs. 107.62 mM) after the start of challenge the adapted group had greater values compared with non-adapted group. At 24h and 27h, the non-adapted group had greater values compared with adapted (114.75 vs. 127.4 mM). From these data, it is concluded that step up adaptation was not efficient in preventing the drop of rumen pH in conditions of great availability of highly fermentable carbohydrates. High total VFA concentration was expected in adapted group due to the adaptation of rumen microbial population to the substrate, increasing their fermentative capacity.

Key words: feed additive, passive immunization

569 Optimizing barley grain feeding and processing for post-modern dairy cows. A. Nikkhah*, *University of Zanjan, Zanjan, Iran.*

Optimum dietary barley grain (BG) use and processing leads our efforts in improving starch utilization. Grinding is considered a risk to diet palatability and healthy rumen while is steam-processing rationalized to reduce BG fermentation rate and the risk of subacute rumen acidosis. The main objective of the first study was to determine effects of feeding either (1) finely ground, (2) steam-rolled, (3) finely dry-rolled, or (4) coarsely dry-rolled BG on rumen fermentation, digestibility and milk production. Eight multiparous Holsteins (85 ± 15 d in milk) were used in a replicated 4 × 4 Latin square design with 4 periods of 21-d. Diets contained 256 g BG/kg DM. Processing did not affect milk yield (28 kg/d) and composition, DMI (23.5 kg/d), rumen pH and volatile fatty acids (VFA), fecal and urine pH, and nutrient digestibility. Results established that finely ground BG was no different than dry-rolled and steam-rolled BG in stimulating DMI and productivity. The objective of another study was to compare grinding vs. steam-rolling of BG at 30% vs. 35% of diet DM on DMI, chewing time, rumen fermentation, and milk production. Eight multiparous Holstein cows (85 ± 9 d in milk) were used in a replicated 4 × 4 Latin square design with 4 21-d periods. Treatments included ground (GB) or steam-rolled (SB) BG fed at either 35% or 30% of diet DM. Diets were prepared as a mixed ration and fed twice daily at 0730 and 1600 h. Neither processing method nor dietary BG% affected DMI, daily eating, ruminating and chewing times, rumen pH and major VFA molar %, or milk % and yields of fat and protein. Energy-corrected milk yield increased for SB compared with GB at 35% (37.5 vs. 35 kg/d, $P < 0.05$) but not at 30% BG (37.8 vs. 37.3 kg/d). Feed efficiency was increased by SB vs. GB (1.54 vs. 1.46, $P < 0.01$), but was unaffected by dietary BG %. Therefore, at 30% grain, GB resulted in similar productivity as SB, and that SB did not affect productivity when BG rose from 30% to 35%. Regardless of BG level, GB vs. SB effectively maintained DMI (24.9 vs. 24.4 kg/d) and rumen pH (5.71 vs. 5.72) at 4 h post-feeding. Increasing dietary BG starch did not improve DMI and productivity.

Key words: barley, inclusion rate, processing

570 Potassium reduces the accumulation of trans-10, cis-12 conjugated linoleic acid and trans-18:1 in continuous cultures of mixed ruminal microorganisms regardless of dietary fat level. T. C. Jenkins*[1], E. Block[2], and P. H. Morris[1], *[1]Clemson University, Clemson, SC, [2]Arm & Hammer Animal Nutrition, Princeton, NJ.*

Previous studies demonstrated that K addition to continuous cultures of ruminal microorganisms caused shifts in conjugated linoleic acid (CLA) production that based on the biohydrogenation theory of milk fat depression, explained reports of increased fat percentages in milk of lactating dairy cattle fed potassium carbonate. This study was done to determine if level of dietary fat affected K effects on biohydrogenation pathways. Six dual-flow continuous fermenters were fed 60 g/d of 1:1 forage (10% alfalfa hay and 90% corn silage) to concentrate mix in 2 equal portions at 0800 and 1600 h. The study was done as a randomized block design consisting of 4 blocks (4 10 d periods) and 6 treatments arranged in a 2 × 3 factorial to examine 2 levels of soybean oil (0 and 4%, designated 0F and 4F) and 3 levels of added K (0, 1.5, and 3%). Culture pH was adjusted daily to maintain pH values above 6. Potassium was injected just before each feeding using a 10% (w/w) stock potassium carbonate solution to provide the equivalent of 0.9 (K1.5), and 1.8 (K3) g added K/d. Culture pH over the last 5 d of each period was held between 6.0 and 6.3 for all treatments. Addition of K to the cultures decreased ($P < 0.05$) propionate and increased ($P < 0.05$) acetate and acetate/propionate for 0F but K had no effect on volatile fatty acids for 4F. Adding K to the cultures had no effect on daily losses of unsaturated fatty acids from the cultures. Addition of K increased ($P < 0.05$) stearic acid and cis-9, trans-11 CLA but decreased ($P < 0.05$) daily production of trans-C18:1 and trans-10, cis-12 CLA biohydrogenation intermediates. This study showed that K addition to cultures of mixed ruminal microorganisms, regardless of dietary fat level, decreased production of trans-C18:1 and trans-10, cis-12 CLA that have been linked to milk fat depression.

Key words: potassium, conjugated linoleic acid, continuous culture

571 Metabolic effects of feeding supplemental tallow to lactating Nili-Ravi buffalo. H. Nawaz[1], M. Yaqoob*[2], J. I. Sultan[1], M. Sarwar[1], and M. Younas[2], *[1]Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan, Faisalabad, Punjab, Pakistan, [2]Faculty of Animal Husbandry, Dept. Livestock Management, University of Agriculture, Faisalabad, Pakistan, Faisalabad, Punjab, Pakistan.*

Four early lactating Nili-Ravi buffaloes were fed 4 experimental diets containing 0, 2, 4 and 6% tallow in an experiment conducted in a 4 × 4 Latin Square design to study the effect of feeding different levels of tallow on nutrient intake, digestibility, rumen fermentation and blood metabolites. The intakes of DM, OM, CP, ADF and NDF decreased ($P < 0.01$) but intakes of EE ($P < 0.01$) increased with increasing level of tallow in the diets. The intakes of NEL and DE did not decrease with the reduction of DM intake. Digestibility of DM, OM, ADF and NDF improved in buffaloes fed diets containing 2 and 4% tallow but beyond 4% it tended to decline significantly. Digestion coefficients of CP did not differ, while that of EE improved ($P < 0.01$) from 68.2 to 74.5%. Rumen pH did not differ significantly ($P > 0.05$) but acetate content decreased significantly ($P < 0.01$) as the level of dietary tallow increased, whereas, propionate molar percentages increased ($P < 0.01$) with increasing level of tallow in the diets. However, butyrate contents were not statistically different among different treatment groups. Acetate to propionate ratio decreased linearly ($P < 0.05$) with increasing level of tallow in the diets. Blood pH and concentration of glucose did not vary significantly but cholesterol, triglycerides and total lipids increased ($P < 0.01$) as the level of tallow increased in the diets. These results suggest that tallow up to 4% of diet dry matter is a suitable fat supplement as an energy source for lactating Pakistani Nili-Ravi buffaloes.

572 Use of a mechanistic, dynamic model of metabolism to investigate the biological basis for variation in genetics of feed conversion efficiency in lactating dairy cattle. J. Onken[1], G. Hobgood[2], S. L. Sheilds*[1], and J. P. McNamara[1], *[1]Washington State University, Pullman, [2]North Carolina State University, Raleigh.*

In dairy cattle, efficiency of feed use must take into account metabolic flux in body tissues, primarily in visceral, muscle, and adipose tissues. These processes are affected by genotype, phenotype, and intake, and are under control of hormonal and neural systems. In continued work

with the objective of identifying the patterns of metabolic flux in the most efficient dairy cattle, an existing mechanistic metabolic model (Molly, UC Davis) was used, which explicitly includes elements of genetics, including metabolic interactions in the viscera and body. Data were collected from 2nd to 4th parity cows (n = 80) in the first 3 to 4 mo postpartum, from studies that measured nutrient intake, milk component output, changes in adipose tissue lipid, visceral and body protein and lipid, and metabolism rates and gene expression in adipose tissue. Explicit inputs into the model included nutrient intake, initial body fat and protein, milk production, fat, and protein output. Body fat, body protein and visceral protein all varied ($P < 0.05$) in daily flux and overall change in direct relation to their milk productive efficiency. Intake energy ranged from 89 to 139 Mcal/d; maintenance energy ranged from 20 to 42 Mcal/d and milk energy secretion ranged from 19 to 34 Mcal/d. Efficiency of milk synthesis varied in a narrow range (81 to 84%), while visceral energy use averaged 37% of intake energy (range 33 to 46%) and 68% of maintenance energy (range 63 to 73%). The variation in maintenance energy accounted for 37.6% of the variation in milk energy efficiency (milk energy/absorbed energy). Expression of several genes coding for metabolic enzymes in adipose tissue were also related to efficiency of milk production. The model identified visceral energy and body energy (muscle protein turnover) ($P < 0.05$) as the 2 major contributors to variation in milk production efficiency. Using a systems model at the metabolic level will increase understanding of the reasons for inefficiency and speed improvement of milk productive efficiency.

Key words: lactation, feed efficiency, systems model

573 Ruminal Mg transport and assessment of Mg intake in dairy cows: Two sides of one coin. H. Martens* and F. Stumpff, *Dept. of Veterinary Physiology/Freie Universitaet Berlin, Berlin-Germany.*

The objective of this compilation of published data was to combine knowledge about Mg transport mechanisms in the rumen with a recent meta-analysis about Mg absorption for a better understanding of Mg absorption in vivo and prediction of Mg intake in lactating cows for the daily requirement. Ruminal Mg absorption is mediated by 2 apical uptake mechanisms: A potential-dependent or K-sensitive (K-s) and a potential-independent or K-insensitive (K-ins) mechanism. The K-s mechanism is suggested to work at low and the K-ins one at high Mg concentrations. The negative effect of K on Mg absorption should be high at low Mg (uptake via K-s) and low at high Mg intake (uptake via K-ins). This suggestion was confirmed in a model study with sheep (Ram et al., J. Dairy Sci. 1997 [81]: 2485–2492). In a recent meta-analysis of Mg absorption in dairy cows Schonewille et al. (J. Dairy Sci. 2008 [91]: 271–278) demonstrated that the true Mg absorption depends on Mg intake and K concentration: True Mg absorption (g/d) = 3.6(g/d) + 0.2 x Mg intake(g/d) – 0.08(kg/d) x K(g/kg DM)[1]. An endogenous Mg secretion of 2.8 g/d has to be subtracted to yield the apparent Mg absorption (g/d) = 3.6(g/d) - 2.8(g/d) + 0.2 x Mg intake (g/d) – 0.08(kg/d) x K (g/kg DM)[2]. This equation clearly shows that the effect of K on Mg digestibility is high at low Mg intake and vice versa: Apparent Mg absorption and digestibility is 3 g/d and 20% at Mg intake of 15 g/d and a K content of 10/kg. An increase of K content to 40 g/kg reduces apparent Mg absorption and digestibility to 0.6 g/d and 4%, respectively. At Mg intake of 60 g/d the effect of K (40/kg) is much less pronounced and reduces apparent Mg absorption and digestibility from 12 g/d and 20% to 9.6 g/d and 16%, respectively. In lactating cows, apparent Mg absorption has to cover both the secretion in milk (M l/d x 0.12 g/l) and endogenous secretion (2.8 g/d). Entry of these values into equation [2] yields Mg intake (g/d) = M (l/d) x 0.6 (g/l) + 0.4(kg/d) x K (g/kg DM) + 10 (g/d)[3]. Equation [3] permits the quantitative calculation of Mg intake according requirement and dietary K concentration.

Key words: magnesium, dairy cow, rumen

574 Effects of direct-fed microbes and their combinations with yeast culture on in vitro rumen fermentation characteristics. S. P. Doto* and J. X. Liu, *Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, P.R. China.*

This experiment was conducted to determine the effects of different doses of *Bacillus licheniformis* (Bl) and *Clostridium butyricum* (Cb) (Zhejiang Future, Hangzhou, China) and their combinations with yeast culture, Diamond V Mills, Inc., Iowa, USA) on in vitro rumen fermentation characteristics. A 2-way factorial design was employed involving Bl or Cb at 0, 0.5, 1, 5 and 10 mg and yeast culture at 0, 18, 27, 36 and 60 mg per 200 mg substrate, respectively. The in vitro gas test based on syringes was conducted and gas volume was recorded at 2, 4, 6, 9, 12, 24, 36, 48 and 72 h incubation. The 24 h gas value was used to estimate the in vitro organic matter digestibility (IVOMD). Effects on pH, VFA, ammonia-N, microbial crude protein and populations of solid- and liquid-associated microbes were investigated after 24 h of incubation. The IVOMD was not influenced ($P > 0.05$) by addition with Bl or Cb alone, but was improved ($P < 0.05$) in the 60 mg yeast culture treatment, with the highest ($P < 0.05$) IVOMD observed when Bl or Cb was combined with a high dose of yeast culture, implying that Bl and Cb may have a synergistic effect with yeast culture. Potential gas production or gas production from the insoluble fraction was not influenced significantly ($P > 0.05$) by Bl or Cb alone, but increased ($P < 0.05$) by 60 mg of yeast culture. The rate constant of gas production was not influenced by Bl or Cb, but increased ($P < 0.05$) with inclusion of yeast culture. The pH was influenced by Bl and yeast culture ($P < 0.01$), but not by Cb ($P > 0.05$). However, all the pH values were in normal range. Significant interaction effect ($P < 0.05$) was observed on ammonia-N between Bl or Cb and yeast culture. Total VFA was affected by Bl and yeast culture ($P < 0.01$), but not by Cb ($P > 0.05$). Treatment did not have significant influence ($P > 0.05$) on microbial crude protein yield. Solid-associated microbes were not affected by any treatments, but liquid-associated *R. flavefaciens* populations were significantly influenced ($P < 0.05$) by combination treatment.

Key words: direct-fed microbes, rumen fermentation, yeast culture

575 Effects of grain, fructose and histidine on ruminal pH, fermentation products and histamine in an induced subacute acidosis protocol. H. M. Golder[1,2], P. Celi[1], A. R. Rabiee[1,2], C. Heuer[3], E. Bramley[4], D. W. Miller[4], R. King[5], and I. J. Lean*[1,2], *[1]University of Sydney, Faculty of Veterinary Science, Camden, New South Wales, Australia, [2]SBScibus, Camden, New South Wales, Australia, [3]Massey University, Epicentre, Institute of Veterinary, Animal and Biomedical Sciences, Palmerston North, New Zealand, [4]Murdoch University, School of Veterinary and Biomedical Sciences, Murdoch, Western Australia, Australia, [5]Dairy Australia, Southbank, Victoria, Australia.*

We investigated the effects of grain, fructose and histidine on ruminal pH and fermentation products. Holstein heifers (n = 30) were randomly allocated to 5 treatments; 1. Control (no grain), 2. Grain (1.2% liveweight (LW) rolled triticale)(GR), 3. Grain (0.8% LW) + fructose (0.4% LW)(FR), 4. GR + histidine (6g/head) (HIS) and 5. FR + HIS in an incomplete factorial design. Heifers were fed 1kg of grain daily with ad libitum access to mixed silage and alfalfa hay for 10 d. Feed

was withheld for 14 h before challenge day, on which heifers were fed 200g alfalfa hay, and immediately after their treatment diet. Rumen samples were collected 5 min after diet ingestion, 60 min later and at 3 further 50 min intervals. Samples were analyzed for ruminal pH immediately. Ruminal histamine, volatile fatty acids, ammonia and D- and L-lactate measures were made after storage at −20°C. The main effects and interactions of grain, fructose, histidine and time were examined using a PROC MIXED repeated measures model. Grain significantly reduced ruminal pH (6.70 ± 0.04), compared with control (7.14 ± 0.87) and increased ammonia, acetate, butyrate, propionate and valerate concentrations. The addition of grain had no effect on log-transformed ruminal D- and L-lactate concentrations. Fructose markedly decreased ruminal pH (6.49 ± 0.06), compared with the no fructose groups (6.92 ± 0.06) and markedly increased log-transformed D- and L-lactate concentrations (0.97 ± 0.35 and 0.23 ± 0.43 mM) compared with diets not containing fructose (−2.14 ± 0.35 mM and −2.87 ± 0.43 mM). Fructose increased butyrate and decreased valerate concentrations. While histidine did not have a marked effect on ruminal fermentation or histamine concentrations, the interactions between histidine, grain and fructose was significant ($P < 0.001$). The interactions between grain, fructose and histidine were significant for all ruminal parameters with the exception of log-transformed D- and L-lactate and caproate. This study demonstrates that the substitution of grain for fructose results in decreased ruminal pH and increased lactate concentrations.

Key words: fructose, histidine, subacute acidosis

576 Dry matter intake, ruminal pH and fermentation capacity of rumen fluid in heifers fed temperate pasture, total mixed rations or both. A. Santana*[1], J. Ubilla[1], M. Berrutti[1], T. Konrath[1], M. Aguerre[1], A. Britos[2], C. Cajarville[2], and J. L. Repetto[1], *[1]Facultad de Veterinaria, UdelaR, Depto. Bovinos, Montevideo, Uruguay, [2]Facultad de Veterinaria, UdelaR, Depto. Nutricion, Montevideo, Uruguay.*

The aim of this work was to evaluate dry matter intake, ruminal pH and fermentation capacity of rumen fluid in heifers fed total mixed rations (TMR), pasture as sole fed or a mix of both. Nine individually housed cross-breed heifers (214 ± 18kg BW) provided with permanent ruminal cannulas were fed total mixed rations (TMR), a temperate pasture ad libitum (*Trifolium repens* and *Lolium multiflorum*) (Pa) or TMR for 18h plus 6h of pasture (P6h) in a triplicated 3 × 3 latin-square design. Each experimental period consisted in 10 d of adaptation and 8 d for sampling and DMI when measured. On d 5, ruminal pH was determined hourly during 24 h. Fermentation capacity of ruminal microbiota was estimated through the in vitro gas production of at 12 h, using the inocula of each heifer and 3 different forages as substrates (*Digitaria sanguinalis*, *Medicago sativa*, and a mixture of *Trifolium repens*, and *Lolium multiflorum*). All data were analyzed with Proc Mixed of SAS. DMI of P6h was higher than TMR treatment (7.74 vs 6.37 kg DM/day; $P < 0.05$) and only pasture (7.74 vs 5.45 kg DM/day; $P < 0.01$). Ruminal pH for Pa group was higher than TMR and P6h group ($P < 0.01$). Mean daily pH values for pasture, TMR and P6h were 6.87, 6.51 and 6.46 respectively (SEM = 0.04). No differences on in vitro gas production were observed among groups for any substrate. The combination of pasture with TMR resulted in increased DMI, but not affected fermentation capacity of rumen microbiota.

Key words: feeding management, pasture, total-mixed ration

577 Protein and fertility in lactating dairy cattle: A meta-analysis and meta-regression. I. J. Lean*[1,2], P. Celi[1], J. McNamara[3], H. Raadsma[1], and A. Rabiee[1], *[1]Faculty of Veterinary Science, The University of Sydney, Camden, New South Wales, Australia, [2]SBScibus, Camden, New South Wales, Australia, [3]Department of Animal Sciences, Washington State University, Pullman.*

Treatment designs used to evaluate the effects of dietary intervention on fertility are subject to confounding, because modification of one nutritional input requires a change in at least one other input. Meta-analytical modeling allows an examination of a main intervention for a series of studies, but also an examination of a series of related effects through use of meta-regression. We examined the effects of dietary protein on fertility using this approach. Literature searches and contact with workers in the field produced 23 studies containing 36 comparisons that had fertility data and met the eligibility criteria for meta-analysis of randomized controlled trials providing information on diets used. The search strategy was to identify papers that contained data on prospective, examining the effects of dietary protein, either concentrations or degradability, or the effects of a specific feed ingredient intervention (e.g., fishmeal) on fertility. Data recorded included pregnancy or conception rates (n = 36 trials); milk production (n = 23 trials) and blood urea nitrogen (n = 24 trials). The most commonly reported fertility indicator was conception rate (CR) was used as the measurement of fertility. Details on dietary formulation and diet intake were extracted from papers, as were measures of urea in blood (BUN). Estimated fixed and random effects relative risks showed that risk of conception was lower in cows fed higher protein or more degradable protein diets (Fixed effect (M-H Relative Risk) = 0.91 (95% CI 0.84 to 0.98); $P = 0.040$). This effect was homogenous ($I^2 = 0\%$) and not influenced by difference in BUN, duration of intervention, breed, parity, milk production or type of diets (TMR vs. PMR). Significant associations among protein components of the diet and carbohydrate fractions supported the hypothesized potential for confounding. However, multivariate meta-regression to evaluate the effects of differences in dietary components between the treatment and control groups found that soluble protein eaten (kg) was a significant covariate. This work supports the concept that soluble protein eaten (kg) is a significant contributor to the biological action of protein on fertility.

578 Effect of increasing proportions of energy concentrates on in vitro gas production estimates. A. Britos*[1], J. L. Repetto[2], and C. Cajarville[1], *[1]Departmento de Nutrición Animal, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay, [2]Departmento de Bovinos, Facultad de Veterinaria, UdelaR, Montevideo, Uruguay.*

The aim of the study was to evaluate the effect of energy supplementation of pasture silage on in vitro gas production. Mixtures of pasture silage with soyhulls (SH), corn (C) or barley (B) from 0 to 100% (by 10% steps) were used as substrates. 0.5g of each substrate (n = 31) was weighed in triplicate into 125mL fermentation flasks and 38.5mL of N-free media was added before inoculum addition (10mL). Inoculum was collected from a lactating cow after 15d eating pasture silage. Gas measures were made at 2, 4, 6, 8, 10, 12, 18, 24, 48, 72 and 96h. Data were fitted to a simple exponential model with lag time. Linear (L) and quadratic (Q) regression analysis were performed according to level of each concentrate included and linear equations were compared between concentrates by making dummy variables that combine concentrate*level. Potential gas production (a) of SH (L: $P < 0.001$, $R^2 = 0.953$; Q: $P < 0.001$, $R^2 = 0.873$), C (L: $P < 0.001$, $R^2 = 0.973$; Q: $P < 0.001$, $R^2 = 0.656$) and B (L: $P < 0.001$, $R^2 = 0.965$; Q: $P < 0.001$, $R^2 = 0.714$) increased; while fractional rate of gas production (kd) of SH (L: $P < 0.001$, $R^2 = 0.920$; Q: $P < 0.001$, $R^2 = 0.658$), C (L: $P < 0.001$, $R^2 = 0.980$; Q: $P < 0.001$, $R^2 = 0.902$) and B (L: $P < 0.001$, R^2

= 0.944; Q: $P < 0.001$, $R^2 = 0.521$) decreased as inclusion level raised. Lag time (l) was extended as inclusion levels of C (L: $P < 0.001$, $R^2 = 0.708$; Q: $P < 0.001$, $R^2 = 0.621$) and B (L: $P < 0.001$, $R^2 = 0.$ 0.628; Q: $P < 0.001$, $R^2 = 0.762$) increased, when SH only had Q effect ($P = 0.022$, $R^2 = 0.336$). Responses to concentrate level increases differed between concentrates for 'a', 'kd' and 'l'. Regression coefficients for 'a' differed among concentrates ($P = 0.007$), slopes decreased as SH > C > B. Slopes of the curves for 'kd' were different ($P < 0.001$), B showed the lowest regression coefficient, followed by SH and finally C. Regression coefficient of B tended to be lower than that of C ($P = 0.052$) for 'l'. Effects on 'kd' and 'l' as concentrate inclusion increased could be due to use a donor fed only forage, with a microbiota adapted to fiber degradation. Reduction of 'kd' as SH proportion raised suggests that its fiber is degraded by microbiota in a different manner than forage fiber. Funded by PEDECIBA and ANII.

Key words: carbohydrates, silage, fermentation

579 Hypophagic effects of propionate are greater for cows with elevated hepatic acetyl CoA concentration. S. E. Stocks* and M. S. Allen, *Michigan State University, East Lansing.*

We previously showed that propionate (PR) was more hypophagic than acetate (AC) when infused intraruminally in cows in the postpartum period and that the degree of hypophagia from short-term infusion (18 h) was related to hepatic acetyl CoA concentration. The objective of this experiment was to evaluate adaptation to treatment with longer-term (3 d) infusions. Twelve multiparous cows (2–13 d postpartum) were blocked by calving date and randomly assigned to treatment sequence in a crossover design experiment with a covariate period. Treatments were 1.0 M propionic acid or 1.0 M acetic acid, infused intraruminally at 0.5 mol VFA/h beginning 6 h before feeding and continuing for 78 h with 3 d between infusions. PR decreased DMI relative to AC (15.9 vs. 17.0 kg/d; $P < 0.05$) by decreasing DM consumed in the first 4 h after feeding (DMI-4h; 6.95 vs. 7.87 kg; $P = 0.004$). No interactions were detected between day within period and treatment for DMI and DMI-4h indicating a sustained effect of treatment across the 3-d infusion periods. PR decreased hepatic acetyl CoA concentration (2.74 vs. 5.78 nm/g; $P < 0.01$) and plasma concentrations of NEFA (640 vs. 800 μEq/L; $P = 0.08$) and BHBA (5.6 vs. 15.8 mg/dl; $P < 0.001$) and increased plasma concentration of glucose (53.2 vs. 48.7 mg/dl; $P < 0.01$) relative to AC. However, a period by treatment interaction was detected for DMI ($P = 0.07$). During period 1, PR decreased DMI relative to AC (14.3 vs. 17.5 kg/d; $P < 0.01$) because of a reduction in meal size (1.30 vs. 1.65 kg; $P < 0.05$) with no effect on intermeal interval ($P = 0.72$). PR decreased DMI-4h (5.82 vs. 8.15 kg; $P < 0.01$) but did not affect DMI 4 h to 24 h after feeding ($P = 0.25$). The depression in DMI in period 1 was positively related to covariate hepatic acetyl CoA concentration. PR was increasingly more hypophagic than AC when hepatic acetyl CoA concentration was high (interaction $P = 0.07$ for daily DMI and $P < 0.01$ for DMI-4h). These results suggest that propionate is more hypophagic when hepatic acetyl CoA concentrations are elevated such as when cows are in a lipolytic state.

Key words: propionic acid, feeding behavior, lipolytic state

580 Effects of added direct-fed microbials on rumen microbial fermentation in continuous culture. W. L. Braman* and I. Knap, *Chr. Hansen Animal Health and Nutrition, Milwaukee, WI, and Horsholm, Denmark.*

The purpose of this trial was to determine the benefits of *Enterococcus faecium* bacteria (EF) and live cell yeast *Saccharomyces cerevisiae* (Y) on in vitro ruminal fermentation when added to a lactating dairy TMR diet. The experiment using continuous culture of rumen contents (Hoover et al., 1976) compared a control (C), the control with a commercial product Probios TC (TC), and the control with a product containing 2 proprietary strains of EF (CH212 and CH273) and Y (EF+Y). Direct-fed microbial additions were based on a predicted intake of 24.5 kg cow/day and microbials were added at the rate of 2.0g/head/day. All diets were incubated in 1164 mL fermenters in triplicate for 8 d in continuous cultures, with effluent samples for analysis composited over the last 3 d. Experimental diet (DM basis) consisted of 22% alfalfa hay, 34% corn silage, 23% ground corn, 17% soybean meal, and 6% concentrate mix. Major diet components measured 18.2% crude protein, 29.7% NDF, 20.8% ADF, 34.9% NSC, 30.4% starch and 42.6% NFC. Results were analyzed using ANOVA with treatment sum of squares partitioned into orthogonal comparisons. The addition of EF+Y resulted in increases ($P < 0.05$) in NDF digestion (69.2 vs. 56.4%), and decreases ($P < 0.05$) in rumen ammonia (8.68 vs.14.26 mg/dl) and D-lactic acid production (0.67 vs 1.09 mmoles/day) compared with C. The addition of EF+Y resulted in significant increases ($P < 0.05$) in NDF digestion (69.2 vs. 54.8%) compared with TC. Except for reduced ($P < 0.05$) ammonia (mg/dl) and increased ($P < 0.05$) calculated by-pass N (g/day), there were no differences between TC and C. There was a tendency ($P < 0.10$) for TC and EF+Y to increase L-lactic acid production (mmoles/day). These data indicate that EF CH212 and CH273 +Y increased fiber digestibility, increased L-lactic acid and decreased D-lactic acid accumulation in this in vitro model suggesting this combination could improve rumen health in lactating dairy cows fed high starch and high NSC diets which requires further research.

Key words: direct fed microbials, yeast, rumen

581 Evaluation of weaning hair sheep lambs at 63 or 120 d of age in an accelerated lambing system in the tropics. R. W. Godfrey* and A. M. Hogg, *University of the Virgin Islands, Agricultural Experiment Station, St. Croix, VI.*

This study was designed to evaluate the impact of weaning age on lamb and ewe productivity in an accelerated lambing system. St. Croix White ewes (STX; n = 25) and lambs (n = 43), and Dorper x St. Croix White ewes (DRPX; n = 33) and lambs (n = 44) were used. Lambs were weaned at 63 (CTRL; n = 44) or 120 d of age (LATE; n = 43) based on breed, sex and litter size. After weaning lambs were fed concentrate (2% BW/d) and grazed guinea grass. Ewes grazed guinea grass at all times. Weights were analyzed using breed and weaning age as main effects. Pregnancy was determined after a 35-d breeding season using transrectal ultrasonography. Ewe weight at breeding before the first lambing was the same ($P > 0.10$) as at the subsequent breeding (41.9 ± 1.1 vs. 41.6 ± 1.1 kg, respectively). At the start of the subsequent breeding 100% of LATE and 0% of CTRL ewes were nursing lambs ($P < 0.0001$). There was no difference ($P > 0.10$) in days to first heat in the breeding season between LATE and CTRL ewes (16.2 ± 1.3 vs. 14.0 ± 1.5 d, respectively). Lambing rate after the subsequent breeding was not different ($P > 0.10$) between LATE and CTRL ewes (72.4 vs. 75.9%, respectively). At weaning LATE lambs were heavier ($P < 0.0001$) than CTRL lambs (20.5 ± 0.6 vs. 11.9 ± 0.5 kg, respectively) and DRPX were heavier ($P < 0.0001$) than STX lambs (18.7 ± 0.5 vs. 13.7 ± 0.6 kg, respectively). At 63 d LATE and CTRL DRPX lambs were heavier ($P < 0.0001$) than LATE and CTRL STX lambs (15.4 ± 0.7 and 13.7 ± 0.6 kg vs. 11.5 ± 0.7 and 10.2 ± 0.7 kg, respectively). At 120 d LATE DRPX were heavier ($P < 0.006$) than CTRL DRPX lambs (23.6 ± 0.9 vs. 20.2 ± 0.8 kg, respectively) and LATE STX were heavier ($P = 0.09$) than CTRL STX (17.3 ± 0.9 vs. 15.1 ± 0.9 kg, respectively). Weaning lambs at 120 d of age in an accelerated lambing system resulted in heavier lambs at weaning with no negative impact on ewe productivity. Late weaning led to a decrease in the amount of time that lambs received high cost, imported feed resulting in a savings of $10 per lamb.

582 Comparison of two forage systems for performance of lactating doe and kid meat goats in Kentucky. K. Andries* and E. Sherrow, *Kentucky State University, Frankfort.*

Meat goat producers are looking at forage based systems of production as possible ways to reduce cost of production and access higher value markets. To be successful, research is needed to evaluate different forages during critical production periods, especially around lactation. Many producers in the upper southeast region have difficulty finding forages to meet the needs of lactating animals in spring. This study was designed to evaluate differences in doe and kid performance on tall Fescue (*Festuca arundinacea*) and cereal rye (*Secale cereale* L.) during early lactation in spring kidding meat goats. Sixty-six crossbred meat goat does with 106 Boer sired kids were available for use in this project. Two 0.88 ha pastures were available for this project. One was seeded in the fall of 2009 to cereal rye and the other had an established stand of tall fescue. Does were evenly divided between the 2 treatments with consideration for the number of kids and age. Grazing started April 20 and continued for 28 d. Data collected included starting and ending weights for both kids and does, doe body condition score, and color score of the mucous membranes of the eye. Average daily gain was calculated for each kid and doe on the project. The data was analyzed using Proc GLM in SAS. Both kids and does on the rye pasture had significantly ($P < 0.01$) higher average daily gains. Kids on the rye pastures gained 5.36 kg while those on the fescue pastures only gained 2.60 kg in the 28 d period. The does in both groups lost weight but the ones on the rye group lost 1.68 kg and the fescue group lost 3.57 kg over the 28 d. In the kid data birth type was not significant for average daily gain or total weight gain of the kids, number of kids nursing was not significant for any trait on the doe data set. There was a significant ($P < 0.01$) change in eye membrane color score with does in the rye group having improved scores while the fescue group had poorer scores. This research indicates that there is potential for forage based goat production in the upper southeast if the proper forages are utilized to ensure adequate nutrition for the doe during lactation.

Key words: meat goat, forage

583 Effect of synchronization protocols (Ovsynch vs 2PG) and GnRH on reproductive performance in goats. N. Ahmad*, H. Riaz, and M. Abdullah, *University of Veterinary and Animal Sciences, Lahore, Punjab, Pakistan.*

The objective of the experiment 1 was to determine if the estrus response and pregnancy rate are similar between the 2 synchronization protocols Ovsynch vs 2PG(2 PGF2α injections 10 d apart) in Pakistani goats. Ovsynch goats (n = 14) received an intramuscular injection of GnRH analog (12.5 µg lecirelin, Dalmaralin, Fatro, Italy) on Day 0 and treated with injection of PGF2α analog (37.5µg d-cloprostenol, Dalmazin, Fatro, Italy) on Day 7 followed by second injection of GnRH analog after 48 h (Day 9). 2PG goats (n = 14) received 2 intramuscular injection of PGF2α analog 10 d apart. Onset of estrus and its duration were assessed by aproned male while follicular development, ovulation rate and pregnancy rate were determined by transrectal ultrasonography. All does were bred naturally 12 h after standing heat. Estrus response was non-significant ($P > 0.05$) between regimens (Ovsynch 71%, 2PG 100%). Interval from standing heat to ovulation (24 ± 3.7 h and 30 ± 2.7 h), ovulatory diameter (7.1 ± 0.2 mm, 7.0 ± 0.2 mm), pregnancy rate (43% (6/14) and 78% (11/14) and fecundity (1.6 ± 0.5, 1.6 ± 0.7) did not differ ($P > 0.05$) between Ovsynch and 2PG groups respectively. The objective of experiment 2 was to determine if administration of GnRH at the time of natural breeding enhances the pregnancy rate in goats. Goats were randomly allocated into 2 groups (GnRH, n = 11 and Control, n = 14). GnRH does received 0.63µg lecirelin on the day of natural breeding (12 h after standing heat) while control does did not receive any treatment. Interval from standing heat to ovulation (31.2 ± 2.9 h, 36 ± 5.3 h ($P > 0.05$), ovulatory diameter (6.7 ± 0.1mm, 7.2 ± 0.5 mm ($P < 0.05$), pregnancy rate (54% (6/11) and 64% (9/14), ($P > 0.05$) and fecundity (1.5 ± 0.5, 1.7 ± 0.5, ($P > 0.05$) were evaluated between GnRH and control does respectively. It is concluded that Ovsynch appears to be similar to 2PG protocol in terms of the reproductive performance; however, this needs to be tested on larger sample size. Furthermore, use of GnRH at the time of breeding does not improve reproductive parameters in goats.

Key words: synchronization, estrus response, pregnancy rate

584 Carcass fat and muscle measurements in terminally sired F1 lambs. M. R. Mousel*[1], T. D. Leeds[2], D. R. Notter[3], H. N. Zerby[4], S. J. Moeller[4], and G. S. Lewis[1], *[1]USDA, ARS, US Sheep Experiment*

Station, Dubois, ID, [2]USDA, ARS, National Center for Cool and Cold Water Aquaculture, Leetown, WV, [3]Virginia Polytechnic Institute and State University, Blacksburg, [4]The Ohio State University, Columbus.

Science-based data for growth and carcass traits of terminal-sire breeds of sheep can be used to improve the value of market lambs, but information for modern terminal-sire breeds in the United States is limited. Thus, the effects of terminal-sire breed on live weight, chilled carcass weight, loin muscle area, and 3 measures of fat were determined in F1 wether lambs. Over a 3-yr period, Columbia, USMARC Composite, Suffolk, and Texel rams were mated with mature Rambouillet ewes. From weaning until harvest each year, the F1 lambs (n = 518) were fed a step-up finishing diet and harvested in 3 groups at a targeted mean BW of 54.5, 61.4, or 68.2 kg. Lamb BW was measured before transport to the abattoir. The following traits were measured on each carcass: kidney pelvic fat (KPF), chilled carcass weight (CCW), 12th and 13th rib loin muscle area (LMA), backfat thickness (BF), and body wall thickness (BWT; approximately 12.7 cm ventral to the dorsal midline). All traits were analyzed with mixed models that included fixed effects of sire breed, year of harvest (YR), harvest group (HG), weight-on-test deviation from the breed mean, and random effects of sire and maternal grandsire. The YR and HG were significant ($P < 0.03$) in all models. Sire breed was significant ($P < 0.03$) for all traits except BF ($P > 0.09$) and BWT ($P > 0.06$). Suffolk-sired lambs had the largest BW and CCW, 65.66 and 32.56 kg, respectively, and Texel-sired lambs had the smallest, 59.43 and 29.06 kg, respectively. Suffolk-sired lambs had the most KPF, 1.29 kg, and Columbia-sired lambs had the least, 1.13 kg. Texel- and Suffolk-sired lambs tended to have the greatest BF and BWT, while Columbia-sired lambs tended to have the least. The LMA for Suffolk- and Texel-sired lambs was greater than that for Columbia- and Composite-sired lambs, 17.05, 16.79, 15.47, and 16.049 cm^2, respectively. Producers can use data such as these to select a terminal-sire breed of sheep that will match their production system and improve the value of their market lambs.

Key words: lamb, terminal sire, carcass

585 Compositions of volatile compounds in fat tissues from male and female Hu sheep. Y. J. Peng*, J. Lin, and J. X. Liu, *Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou [310029], P. R. China.*

Fat tissue is rich in the volatile compounds that determine the flavor of meat. Hu sheep is widely distributed breed in Southern China. In this study, the compositions of volatile compounds in fat tissue from male and female Hu sheep were analyzed to investigate the characterization of Hu sheep meat. Twenty-four Hu sheep,12 male and 12 female, were slaughtered as 2 year-olds. The perirenal and caudal subcutaneous fat tissues were sampled and vacuum-packed from all the sheep. After aging at 4°C for 24 h, the samples were stored at −80°C to avoid oxidation, and then were moved to −20°C before analysis. Solid-phase microextraction technique was used to extract the volatile compounds from 1 g of sample with 50/30 μm divinylbenzene-carboxen-polydimethylsiloxane fiber at 120°C. The volatile compounds were then analyzed by gas chromatography-mass spectrometry technique. All data were analyzed using the GLM procedure of SAS software system. Fifty-seven volatile compounds were detected in the fat tissue samples. Forty compounds were found to distinguish ($P < 0.05$) between male and female sheep, among which 17 compounds were aldehydes, including hexanal, heptanal, octanal, nonanal, undecanal and dodecanal. Fat tissues in female sheep contained more aldehydes than those from male sheep. Since these compounds were mainly derived from lipid oxidation, it is suggested that different anti-oxidation level caused the varying contents of aldehydes, which accounted for the difference in contents of volatile compounds between male and female sheep. A principal component analysis showed that nonanal, triacetin, butylated hydroxytoluene were the main compounds played the most important role in the first principal component. Contrast to the sexual factor, location of fat tissue caused less difference, and only 23 compounds were found to be different between 2 kinds of fat tissues ($P < 0.05$). These results suggested that sexual factor mainly contribute to the characterization of volatile compounds composition.

Key words: fat tissue, volatile compounds, sheep

586 Chemical composition of milk of West African Dwarf (WAD) ewe fed Mexican sunflower leaf meal based diets during early and late lactation. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

Milk composition of major and minor components is affected by feeding regimens, ration components and forage: grain ratios. In view of this a study was conducted to determine the chemical composition of milk of WAD ewe fed MSLM based diets during late lactation. Sixteen lactating WAD ewes weighing between 22.80 and 26.03 kg on a basal diet of *Panicum maximum* were allotted into four treatment groups of four replicates each. The experiment was conducted using completely randomized design with four replicates. The Mexican sunflower leaf (MSL) replaced wheat bran (WB) gravimetrically at 0,15,30,45% . The control treatment (treatment A) had no MSL but treatments B, C and D had 15, 30 and 45% MSL as graded replacement for WB. The experiment lasted 6 weeks . Feed and water were provided ad libitum and routine vaccination and medication administered. Parameters measured include milk total solids, butter fat, crude protein, lactose, casein, energy, calcium and phosphorus. Apart from milk ash, observed variation were not significant ($P > 0.05$) during early and late lactation, although values of milk composition were higher during late lactation for milk total solids, fat, protein, ash, casein, energy, calcium and phosphorus while lactose values were reduced during late lactation. Inclusion of up to 45% MSLM based diets enhanced the milk composition of ewe and can be used successfully in place wheat bran without any adverse effect.

Key words: milk composition, West African dwarf ewe, Mexican sunflower leaf

W1 Effects of low doses lipopolysaccharide infusion on plasma proteome in lactating cows using comparative proteomics. T. J. Yuan, J. Q. Wang*, Y. X. Yang, D. P. Bu, S. S. Li, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Subacute ruminal acidosis (SARA) increases the concentration of lipopolysaccharide (LPS) in the rumen. Previous studies have indicated that LPS could translocate into the peripheral blood and increase acute phase proteins, such as serum amyloid A, haptoglobin. The objective of this study was to investigate the effects of infusing low dose LPS into external pudic artery on plasma proteome in lactating dairy cows using comparative proteomics, and to explore the mechanism of host response to LPS challenge. All cows (n = 6) were infused LPS (0.01μg/kg body weight) via external pudic artery. Milk and blood samples were collected at different times after infusing LPS. Two-dimensional electrophoresis gel coupled with MALDI-TOF-TOF spectrometry was used. Plasma proteins at 0, 6, 12 and 24 h after LPS infusion were separated by 2-dimensional electrophoresis. After visualization proteins with Coomassie Brilliant Blue G250 solution, protein spots were detected by PDQuest 8.0.1 software and differential proteins were identified by MALDI-TOF-TOF spectrometry. Milk SCS started to increase after infusing LPS and peaked at 6 h, and then gradually decreased to the level before infusing LPS at 24 h. Eight protein spots were upregulated at 6, 12 and 24 h in cows after infusing LPS, but there was not significantly different among 6 to 24 h, and were identified to be 4 proteins including vitamin D-binding protein precursor, serpin A3–6, α-1 antitrypsin and serpin A3–1 precursor. These results suggests that vitamin D-binding protein precursor, serpin A3–6, α-1 antitrypsin and serpin A3–1 precursor may play an important role in response to LPS challenge, and further study was needed.

Key words: lipopolysaccharide, dairy cow, plasma proteome

W2 Evaluation of endotoxin (LPS) activity in bovine blood using neutrophil dependent chemiluminescence. S. Kahl*[1], T. H. Elsasser[1], and C. V. Obiezu-Forster[2], *[1]USDA, Agricultural Research Service, Beltsville, MD, [2]Spectral Diagnostic Inc., Toronto, ON, Canada.*

The purpose of this study was to evaluate the applicability of a neutrophil chemiluminescence-based assay for the measurement of LPS stimulatory activity in bovine whole blood. The assay is based on the capacity for LPS to trigger the respiratory oxidative burst activity (RBA) of autologous neutrophils. This RBA is then detected as photons released from oxidized added luminol in a chemiluminometer. In the protocol, chemiluminescence (CL) of blood samples without (CL_{BL}) and with an added reference quantity of LPS (100 ng/ml, CL_{BL+LPS}) was measured in luminol/zymosan solution and the relative LPS blood activity (EA_R) was expressed as a CL_{BL}/CL_{BL+LPS} ratio. EDTA-stabilized whole blood was collected from 16 healthy steers, 9 cows diagnosed with advanced mastitis of gram(-) bacterial etiology, and 4 steers given an i.v. bolus of low (0.25 μg/kg BW) or high (2.0 μg/kg BW) LPS. In the in vitro recovery studies a linear relationship was observed between added LPS (up to 100 ng/ml) and EA_R ($R^2 = 0.99$, $P < 0.01$). Estimated mean (±SE) blood EA_R in healthy cows was 0.058 ± 0.010 and increased to 0.353 ± 0.062 ($P < 0.01$) in cows with mastitis. Individual EA_R values exceeded a calculated clinical cut-off value of 0.137 (upper limit of 95% confidence interval of observed EA_R in healthy group) in 78% of infected cows. After the in vivo injection of high LPS dose, estimated blood EA_R values exceeded clinical cut-off value at 2 min (0.317 ± 0.057; n = 2) and 5 min (0.163 ± 0.018), but returned to baseline at 10 min (0.084 ± 0.027). Within 10 min after low LPS dose injection, estimated EA_R values remained below cut-off value, although animals showed clinical symptoms of initial proinflammatory response. Results indicate that bovine neutrophil chemiluminescence assay has the potential to detect LPS stimulation of neutrophil respiratory burst activity in bovine blood and to discriminate between healthy cows and cows infected with gram(-) bacteria displaying clinical mastitis. Additional studies are needed to evaluate the specificity of the assay while further modifications to this protocol may result in increased sensitivity.

Key words: bovine, chemiluminescence, endotoxin assay

W3 Evaluation of yeast nucleotides on intestinal barrier function in vitro. A. Ganner*, M. Werner, S. Henikl, and G. Schatzmayr, *BIOMIN Research Center, Tulln, Lower Austria, Austria.*

Yeast contains between 3 and 18% of ribonucleic acid. During manufacturing process and autolysis, the RNA breaks down in its monomers. Nucleotides have been considered nutritionally as semi-essential, they are synthesized de novo using amino acids as precursors, or by salvage of dietary amino acids and nucleotide breakdown. Under field conditions, challenge and stress, the endogenous synthesis may not be capable of supplying the animal's actual nucleotide needs. Nucleotides are involved in various essential biochemical processes; in animal studies they have been shown to have positive effects on performance, growth, gut health and the immune system. Target of the present study was to evaluate the effect of purified nucleotides (adenosine monophosphate (AMP), adenine, adenosine, guanosine monophosphate (GMP), guanine, guanosine, inosine monophosphate (IMP), inosine, uridine, uracil, cytidine and cytosine) and commercially available yeast nucleotide products on intestinal barrier function using a porcine intestinal epithelial cell line (IPEC-J2). IPEC-J2 cells were incubated in 24-well plates with Transwell inserts in the presence of the respective test substance at 41 °C and 5% CO2 for a maximum of 15 days. Transepithelial electrical resistance (TER) was measured daily by a volt-ohm meter. Results were expressed as increase in TER compared to untreated cells (0%). TER was increased up to 200% by AMP. Adenine and adenosine increased TER up to 80% and 140%, respectively. GMP, guanine and guanosine showed an increase in TER over the first 2 days. IMP and inosine showed an increase in TER up to 100% and 60%, respectively. Uridine and uracil, cytidine and cytosine increased TER between 30% and 70%. Five commercially available yeast nucleotide or yeast extract samples with analyzed nucleotide profile were tested in different dos-

ages. Increase in resistance was noticed between 80 and 170%. Our results indicate that nucleotides improve the intestinal barrier function by increasing the TER in a dose-dependent manner. Thus, yeast nucleotides may have protective effects to the intestine and as a result to exert beneficial effects on animal's health.

Key words: yeast nucleotides, gut epithelial cell line, TER

W4 Oral treatment of pregnant cows with lipopolysaccharide and lipoteichoic acid modulated selected plasma metabolites and innate immunity in newborn calves. S. Iqbal*, Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Immunization of pregnant dams is commonly used to enhance the newborn immune status. The aim of this study was to orally challenge prepartum dairy cows with repeated doses of lipopolysaccharide (LPS) and lipoteichoic acid (LTA) and evaluate clinical disease, and metabolic and immune status of their newborn calves. Thirty pregnant Holstein dairy cows were blocked by parity and the anticipated day of calving, and were randomly allocated to 2 groups, 28 d before the expected day of parturition. Cows were orally administered 2 mL of saline solution (CTR), or 2 mL of saline solution containing 3 increasing doses of LPS from *Escherichia coli* 0111:B4 as follows: 1) 0.01 μg/kg BW on d −28 and −24, 2) 0.05 μg/kg BW on d −21 and −18, and 0.1 μg/kg BW on d −14 along with a flat dose of LTA from *Bacillus subtilis* (i.e., 120 μg/animal). Ten calves per group were randomly selected to determine the disease incidence and evaluate their health and metabolic and immune status collecting blood samples at wk 1 to 4 after birth and analyzing for glucose, lactate, β-hydroxybutyric acid (BHBA), nonesterified fatty acids (NEFA), cholesterol, and haptoglobin. Results demonstrated that the group of calves from treated cows had greater plasma cholesterol (140 vs.120 mg/dL; $P = 0.02$), and a numerical increase of BHBA in the plasma (152 vs. 133 mmol/L; $P < 0.10$). Furthermore, this group of calves showed better energy status with greater plasma lactate (107 vs. 81 mmol/L; $P < 0.01$), although treatment did not affect concentration of plasma glucose and NEFA ($P > 0.05$). Interestingly, the calves from the treated cows had greater plasma haptoglobin (234 vs. 119 mg/dL; $P = 0.04$). No effect of treatment was observed on calf diarrhea, number of medications given to calves, and their mortality rate. In conclusion, oral treatment of dams with LPS and LTA modulated selected plasma metabolites and markers of innate immunity in their newborns suggesting that treatment of pregnant cows with bacterial immunogens might improve the immunity and wellbeing of newborn dairy calves.

Key words: lipopolysaccharide, lipoteichoic acid, newborn calves

W5 Repeated oral administration of lipopolysaccharide and lipoteichoic acid modulated post-treatment plasma metabolites and innate immunity of prepartal dairy cows. S. Iqbal*, Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

The transition period is critical for the health and productivity of dairy cows due to high incidence of metabolic diseases. The objective of this study was to investigate metabolic, immune, and clinical responses to repeated oral administration of lipopolysaccharide (LPS) and lipoteichoic acid (LTA) in prepartal dairy cows. Thirty pregnant Holstein dairy cows were blocked by parity and the anticipated day of calving, and were randomly allocated to 2 groups 28 d before the expected day of parturition. Cows were orally administered 2 mL of 0.85% saline solution (CTR), or 2 mL of saline solution containing 3 increasing doses of LPS from *Escherichia coli* 0111:B4 as follows: 1) 0.01 μg/kg BW on d −28 and −24, 2) 0.05 μg/kg BW on d −21 and −18, and 0.1 μg/kg BW on d −14 along with a flat dose of LTA from *Bacillus subtilis* (120 μg/animal). Clinical responses including rectal temperature, respiration and rumen contraction rates were evaluated during the 5 h post-treatment and blood samples were collected from the tail vein before and after administration of each dose at 1, 3, and 5 h post-treatment. Blood samples were analyzed for plasma glucose, lactate, NEFA, BHBA, cholesterol, and haptoglobin (Hp). Results demonstrated that treatment did not affect rectal temperature and respiration rate; however, it numerically lowered rumen contraction rate ($P < 0.10$). Moreover, treatment increased plasma glucose (76 vs. 62 mg/dL; $P < 0.01$) and lactate (78 vs. 63 mmol/L; $P < 0.01$) especially at 1 h post-injection for lactate ($P = 0.02$) and 3 and 5 h for glucose ($P < 0.01$). In addition, treated cows tended to have greater concentration of circulating NEFA (102 vs. 92 mmol/L; $P = 0.06$) and lower plasma cholesterol (130 vs.167 mg/dL; $P = 0.01$), and plasma Hp (554 vs. 753 mg/dL; $P = 0.04$). There was no effect of treatment on plasma BHBA ($P > 0.05$). Overall, repeated oral administration of LPS and LTA modulated post-treatment patterns of selected plasma metabolites, clinical responses, and markers of innate immunity in transition dairy cows.

Key words: lipopolysaccharide, lipoteichoic acid, metabolic and clinical response

W6 Diets enriched in barley grain treated with lactic acid and heat lowered rumen endotoxin and improved innate immunity in dairy cows. S. Iqbal*, Q. Zebeli, A. Mazzolari, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Feeding early lactation dairy cows high grain based diets is associated with an inflammatory state and high incidence of various metabolic diseases. The aim of the present study was to investigate the effects of feeding barley grain steeped in lactic acid (LA) and heat on ruminal endotoxin and plasma biomarkers of innate immunity. Eight mid-lactation (170 DIM) rumen-fistulated Holstein cows were used in a 2 × 2 crossover design with 2 21-d periods, with the first 11 d used for diet adaptation and the last 10 d for measurements. Cows were fed once daily a total mixed ration containing barley silage and rolled barley grain (31.5% DM basis) steeped for 48 h in equal quantity of tap water (CTR), or in 1.0% LA and heat at 55°C (LAH). The rumen fluid and blood samples were collected on d 11, 15, and 21 shortly before the morning feeding of each experimental period. Postprandial patterns of rumen endotoxin and plasma haptoglobin (Hp) were evaluated collecting rumen fluid and blood samples every 2 h starting at 0800 to 2000 on the last day of each experimental period. The principal component analysis revealed that each of the 2 diets fed could be distinguished on the basis of the measured rumen and plasma variables. Data revealed that cows fed LAH diet had lower concentration of preprandial rumen endotoxin (472 vs. 793 ng/mL; $P < 0.01$), however, treatment had no effect on plasma Hp ($P > 0.05$). Results of postprandial responses showed that LAH diet had numerically lower concentration of plasma Hp (586 vs. 679; $P < 0.10$) and a treatment by time interaction for rumen endotoxin ($P < 0.01$), suggesting a role for both the treatment and the time of sampling on this variable. Interestingly, cluster analysis showed a cluster between rumen endotoxin and plasma Hp indicating strong interrelationship between these 2 variables. Overall, results of this study indicated that feeding barley grain steeped in LAH lowered concentration of rumen endotoxin and modulated postprandial innate responses in mid-lactation dairy cows.

Key words: barley grain, lactic acid and heat, innate immunity

W7 Oral administration of bacterial lipopolysaccharide and lipoteichoic acid modulated milk composition and efficiency in transition dairy cows. S. Iqbal*, Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

The transition period is characterized by high incidence of metabolic disorders, which influence subsequent milk production and composition of dairy cows. The objective of this study was to evaluate the production response of postpartal dairy cows to repeated oral administration of lipopolysaccharide (LPS) and lipoteichoic acid (LTA). Thirty pregnant Holstein dairy cows were blocked by parity and the anticipated day of calving, and were randomly allocated to 2 groups, 28 d before the expected day of parturition. Cows were orally administered 2 mL of 0.85% saline solution (CTR), or 2 mL of saline solution containing 3 increasing doses of LPS from *Escherichia coli* 0111:B4 as follows: 1) 0.01 μg/kg BW on d −28 and −24, 2) 0.05 μg/kg BW on d −21 and −18, and 0.1 μg/kg BW on d −14 along with a flat dose of LTA from *Bacillus subtilis* (i.e., 120 μg/animal) prepartum. Feed intake was obtained during the 4 wk before and 4 wk after parturition, whereas milk data were collected during 4 wk after calving to determine milk production and composition. The data showed that treatment tended to increase milk energy efficiency (1.30 vs. 1.06; $P = 0.06$) and was associated with a trend for lower feed intake (31 vs. 34 kg/d; $P = 0.10$). Furthermore, the overall variance analysis demonstrated that treatment group had greater fat to protein ratio (1.37 vs. 1.25; $P = 0.04$), and fat-corrected milk to feed intake ratio (milk fat efficiency; 0.82 vs. 0.68; $P = 0.01$). Milk lactose yield was higher only in primiparous cows in the treatment group (1.41 vs. 1.19 kg/d; $P = 0.01$). In addition, primiparous cows in this group, showed a tendency for greater fat yield and 4% fat corrected milk ($P < 0.10$). Treatment increased milk urea nitrogen in treated multiparous cows ($P < 0.01$) and lowered protein yield ($P = 0.04$). No effect of treatment was observed on other milk components and on the overall milk production ($P > 0.05$). In conclusion, the results indicated that repeated oral administration of LPS and LTA modulated milk production and composition in dairy cows postpartum.

Key words: oral lipopolysaccharide, lipoteichoic acid, milk production and composition

W8 Oronasal exposure to lipopolysaccharide differentially affected blood metabolites in multiparous dairy cows. A. Hosseini*, D. A. Mansmann, Q. Zebeli, S. Iqbal, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Translocation of endotoxin into blood circulation causes alterations in blood metabolites and immunity. In this study, we evaluated the hypothesis that repeated oronasal application of lipopolysaccharide (LPS) prepartum might improve the metabolic and immune status of periparturient dairy cows. One hundred primiparous (PP) and multiparous (MP) Holstein dairy cows (PP and MP with ~BW 620 and 720 kg, respectively) were randomly assigned into control (CTR; PP = 18; MP = 32) and treatment (TRT; PP = 19; MP = 31) groups. Either carrier alone (3 mL of 0.85% saline) or 3 increasing doses (0.01, 0.05, and 0.1 μg/kg BW) of LPS from *E. coli* 0111:B4 were applied oronasally (1 mL nasally and 2 mL orally) twice a week on wk −4, −3, and −2. Several blood variables including β-hydroxybutyric acid (BHBA), cholesterol, glucose, lactate, nonesterified fatty acids (NEFA) and haptoglobin (Hp) were measured during d −28, −25, −21, −14, −7, 2, 14, 21, and 28; however, HP was measured only in MP cows. All data were processed statistically by the MIXED procedure of SAS. Overall results indicated that TRT increased concentrations of cholesterol ($P = 0.06$) and lactate in the serum ($P < 0.01$) of all cows. Data also showed that parity affected ($P < 0.01$) concentrations of cholesterol, NEFA and lactate. Interestingly, concentration of NEFA in serum was greater in PP cows ($P < 0.01$). Furthermore, an effect of day ($P < 0.01$), and interactions of day × parity ($P = 0.03$) and TRT × parity ($P = 0.04$) were obtained for serum glucose with a decreased concentration postpartum in all cows. The results showed that serum BHBA was increased ($P < 0.01$) on d 14 in PP cows. Additionally, concentrations of glucose, cholesterol, and lactate were influenced by TRT × parity interactions ($P < 0.10$), while TRT × day interaction influenced ($P < 0.10$) serum Hp. In conclusion results of this investigation indicated potential involvement of LPS in alteration of blood metabolites in dairy cows. Moreover, the oronasal treatment with LPS might be used to improve the metabolic status and immunity of transition dairy cows.

Key words: oronasal lipopolysaccharide, blood metabolites, innate immunity

W9 Oral administration of lipopolysaccharide and lipoteichoic acid modulated plasma metabolites and decreased the risk of metabolic diseases in periparturient dairy cows. S. Iqbal*, Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

The transition period imposes enormous stress on the dairy cow and may impair long-term herd health. The aim of this study was to investigate metabolic and health status of periparturient dairy cows repeatedly administered orally with lipopolysaccharide (LPS) and lipoteichoic acid (LTA). Thirty pregnant Holstein dairy cows were randomly assigned to one of the 2 treatment groups starting at 28 d before the expected day of parturition. Cows received orally either 2 mL of 0.85% saline solution (CTR), or 2 mL of saline solution containing 3 increasing doses of LPS from *Escherichia coli* 0111:B4 as follows: 1) 0.01 μg/kg BW on d −28 and −24, 2) 0.05 μg/kg BW on d −21 and −18, and 0.1 μg/kg BW on d −14 along with flat dose of LTA from *Bacillus subtilis* (i.e., 120 μg/animal). Blood samples were collected on d 1 and 3 of wk −4, and then once on wk −3, −2, −1, +1, +2, +3, and +4 around parturition and analyzed for glucose, BHBA, NEFA, lactate, and cholesterol. Cows were monitored for metabolic and infectious disease incidence, body condition score (BCS), manure score, and urine pH throughout the experimental period. Results showed that oral administration of LPS and LTA lowered plasma lactate in the treated cows (2.58 vs. 3.67 mmol/L; $P < 0.01$) and had a tendency to increase plasma cholesterol (152 vs. 137 mg/d; $P < 0.10$). Treatment did not affect concentrations of BHBA, NEFA, and glucose in the plasma ($P > 0.05$). Interestingly, repeated oral LPS and LTA showed a tendency for lower incidence of metritis, laminitis, retained placenta, and uterine discharges ($P < 0.10$). Furthermore, the incidence of uterine horn fluctuations was lower in the treated group ($P = 0.01$). No effect of oral treatment was obtained for BCS, manure score, and urine pH ($P > 0.05$). In conclusion, oral administration of LPS and LTA modulated selected plasma metabolites related to carbohydrate and lipid metabolism and lowered the incidence of multiple metabolic diseases in periparturient dairy cows.

Key words: lipopolysaccharide, lipoteichoic acid, blood metabolites and metabolic diseases

W10 Bovine acute-phase response following different doses of corticotrophin-releasing hormone (CRH) challenge. R. F. Cooke*[1], J. A. Carroll[2], F. N. T. Cooke[1], B. I. Cappellozza[1], C. Trevisanuto[1], V. D. Tabacow[1], J. Dailey[2], and D. W. Bohnert[1], *[1]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [2]USDA–ARS Livestock Issues Research Unit, Lubbock, TX.*

Fourteen weaned, halter-trained Angus steers (BW = 191 ± 2.1 kg) were fitted with indwelling jugular catheter and rectal temperature monitoring device on d −1 of the study. On d 0, steers were ranked by BW and randomly assigned to receive 1 of 3 infusion treatments (i.v.): 1) 0.1 μg of bovine CRH/kg of BW (CRH1), 2) 0.5 μg of bovine CRH/kg of BW (CRH5), and 3) 10 mL of saline. Blood samples were collected via catheters, relative to treatment infusion (0 h), hourly from –2 to 0 h and 4 to 8 h, and every 30 min from 0 to 4 h. Rectal temperatures were recorded every 30 min from −2 to 8 h relative to infusion. Blood samples were collected via jugular venipuncture and rectal temperatures were assessed using a digital thermometer every 6 h from 12 to 72 h, and every 24 h from 96 to 168 h. Samples collected from −2 to 8 h relative to CRH infusion were analyzed for plasma concentrations of cortisol, ceruloplasmin, and haptoglobin, whereas samples collected from 12 to 168 h were analyzed for plasma concentrations of ceruloplasmin and haptoglobin only. Plasma cortisol peaked at 0.5 h for CRH1 steers (58.9 ng/mL) but returned to baseline levels at 1 h relative to infusion (time effect; $P < 0.01$). Within CRH5 steers, plasma cortisol peaked at 0.5 h (51.3 ng/mL) and returned to baseline levels 3 h relative infusion (time effect; $P < 0.01$). Plasma cortisol concentrations did not change after infusion for saline steers (time effect; $P = 0.42$). Rectal temperatures were greater ($P < 0.05$) for CRH1 steers compared with CRH5 and saline steers at 36 and 42 h relative to challenge. Plasma haptoglobin concentrations in CRH1 steers increased significantly and were greater ($P < 0.02$) compared with CRH5 and saline steers from 48 to 96 h relative to challenge (time effect; $P < 0.01$). Conversely, plasma haptoglobin concentrations were similar ($P > 0.23$) and did not change across time for CRH5 and saline steers (time effect; $P > 0.48$). No treatment effects were detected on plasma ceruloplasmin concentrations. In conclusion, both CRH5 and CRH1 increased plasma cortisol concentrations, but only CRH1 elicited an acute-phase protein response in beef steers.

Key words: acute-phase, bovine, CRH

W11 Feasibility of high immune response technology as a health management tool to characterize immune response profiles of dairy cattle. L. C. Wagter*, S. Cartwright, and B. A. Mallard, *Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada.*

High immune response (HIR) is a patented evaluation technology that has the potential to improve the health and food quality of dairy cattle through the reduction of antibiotics and enhanced resistance to economically important diseases such as mastitis. The test includes a blood sample to evaluate antibody-mediated immune response (AMIR) and a skin thickness measurement to evaluate cell-mediated immune response (CMIR) together. Dairy cattle with high immune response following immunization with specified test antigens are at a lower risk for developing disease compared with average and low responding animals. To determine if HIR technology would be utilized by the dairy industry, 2 focus groups were conducted within 2 important Ontario dairy regions. Qualitative market information gathered from those focus groups indicated a significant interest in using HIR to test calves or cows for HIR (75% of producers), and that they would use this information for culling decisions, grouping, breeding and/or treating animals. Pre-commercialization research is currently underway to test the transferability of HIR to the dairy marketplace and includes: 1) a quantitative market assessment of interest in HIR throughout Ontario (n = 400 producers; 10% of Ontario herds) to build on previous qualitative focus group data; 2) a validation study of previous research to rank cattle based on antibody from milk in lieu of blood (n = 26 cows); 3) β-testing the application of HIR on one to 2 Ontario dairy herds to demonstrate the economic value of HIR (n = 2; 350–450 animals per herd); 4) HIR testing of Gencor AI cull-sires to demonstrate the ability of the sire immune system to respond to test antigens without adverse reactions and to confirm no cross-reactivity to governmental health testing. In 10 cull-sires tested to-date no cross-reactivity was noted for the tuberculosis DTH test and other serological tests thus indicating that HIR should benefit all sires including young sires before entering a bull-test facility. All research including analysis should be completed by June 2011.

Key words: high immune response, health management, breeding for health

W12 Influence of blood sample storage temperature and latency until analyzed on various ex vivo innate immune response assays in Holstein heifers. M. A. Ballou*[1] and L. E. Hulbert[1,2], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Department of Animal Science, University of California at Davis, Davis.*

Objectives were to determine the influence of peripheral blood sample storage temperature and how quickly the blood samples needed to be processed for ex vivo innate immune responses. Eight Holstein heifers, approximately 1 yr old, were briefly restrained in self-locking stanchions and 2, 10 mL heparinized vacutainers were collected via jugular venipuncture. One sample from each heifer was placed immediately on ice (ICE; 0.18 ± 0.39°C) while the other was placed in an ice chest with no–ice (NI; 21.88 ± 0.51°C). Samples were serially analyzed for ex vivo innate immune parameters at 2 (baseline), 4, 6, 8, 10, and 24 h after collection. Data were analyzed by ANOVA with the fixed effects of heifer, storage temperature (ST), time, and the interactions of heifer x ST and ST x time. The ICE samples had more leukocytes than NI samples (ST, $P < 0.001$). All samples had decreased total leukocyte counts (time, $P < 0.05$) from baseline measurements at 10 and 24 h for ICE and NI samples, respectively (ST x Time $P < 0.01$). Neutrophil proportions in ICE samples did not change with time, but NI samples were lower at 2 h and increased over time (ST x time, $P < 0.03$). The NI samples had greater neutrophil proportions at 8 h compared with 2 h (time $P < 0.01$). Hematocrits were lower (ST, $P < 0.01$) in ICE samples and were above baseline (ST x time $P < 0.01$) at 24 h after collection. More (ST, $P < 0.01$) TNF-α was secreted after NI whole blood samples were stimulated with LPS than ICE samples. NI samples had lower neutrophil L–selectin expression expression compared with ICE samples, except at 24 h (ST x time, $P < 0.03$). At 2 h, samples stored on ice had a greater neutrophil oxidative burst response than NI samples (ST x time, $P < 0.01$). There were no differences ($P < 0.10$) in neutrophil oxidative burst response between ICE or NI samples from 4 to 10 h, but at 24 h, samples stored on ice had less intense oxidative burst (ST x time, $P < 0.01$). These data indicate that ST and latency until analyzed influences ex vivo innate immune response measurements and should be controlled for when designing experiments.

Key words: immune, time, temperature

W13 Caprylic acid fractionation of serum followed by refractometry to predict serum IgG in preweaned calves. C. Rodríguez[1], N. Saborido[1], L. Castillejos[2], M. Rodríguez[2], A. Lago*[3], J. Campbell[3], J. Quigley[3], and J. Polo[1], *[1]APC Europe, S.A., Granollers, Spain, [2]Animal Nutrition and Welfare Service, Autonomous University of Barcelona, Barcelona, Spain, [3]APC Inc., Ankeny, IA.*

We evaluated the use of caprylic acid (CA) fractionation of IgG from serum followed by refractometry of supernatant as a rapid method to predict IgG concentration in young calves. Jugular blood samples were collected from calves (n = 100) between 2 and 60 d of age from 4 farms in Girona, Spain. Calves were managed according to standard management practices on each farm. Serum was separated by centrifugation and total protein (TP; automatic analyzer Mira Plus, ABX Diagnostics), IgG (radial immunodiffusion) and refractive index (nD; Refracto 30PX Refractometer, Mettler Toledo) were measured. Serum (1 mL) was placed in a 1.5 mL tube and 0.06 mL of CA was added. The tube was left at room temperature for 15 min and stirred vigorously every 5 min; thereafter, it was centrifuged and nD of the supernatant was measured. Mean nD of CA supernatant was 1.338 ± 0.0002 and ranged from 1.333 to 1.343. Mean serum IgG was 17.74 ± 0.60 mg/mL and ranged from 4.01 to 33.21. Mean serum TP was 4.73 ± 0.12 g/dL and ranged from 2.81 to 7.60. Mean serum nD was 1.345 ± 0.0001 and ranged from 1.343 to 1.349. The nD of the CA supernatant was highly correlated with serum IgG (r = 0.86; IgG = 3591.3 x nD - 4787.3) and serum TP (r = 0.87; TP = 446.1 x nD - 591.53). Similarly, nD of whole serum was highly correlated with serum IgG (r = 0.90; IgG = 4405 x nD - 5908.3). Finally, serum TP was less well correlated with serum IgG (r = 0.74; 3.877 x TP - 0.699). The CA fractionation method was useful for rapidly measuring IgG level in serum of young calves and was highly correlated with serum IgG and TP. Direct measurement of nD to predict serum IgG was also precise. Serum TP, currently the most common on-farm test to estimate serum IgG, was a less precise method to estimate serum IgG than both nD of whole serum and nD of the CA supernatant.

Key words: calves, immunoglobulin, caprylic acid

W14 Development of a rapid method to estimate IgG in bovine colostrum. K. M. Morrill*[1], J. D. Quigley[2], A. Lago[2], and H. D. Tyler[1], *[1]Iowa State University, Ames, [2]APC Inc., Ankeny, IA.*

Caprylic acid (CA) has been utilized to fractionate colostral IgG for further laboratory purification and analysis. The objective of this study was to develop a rapid, cow-side test for determining colostrum IgG concentration using CA fractionation followed by refractometry of the IgG-rich supernatant. Frozen colostrum samples (n = 85) obtained from Holstein cattle, were warmed to room temperature in a water bath and treated with varying concentrations of CA and acetic acid (AA). Samples were then centrifuged or allowed to sit for an allotted time to precipitate non-IgG proteins. Supernatant liquid was then analyzed with a digital refractometer (SPER Scientific, model 300034) to determine refractive index (nD). The nD of Ig-rich fraction was compared with total colostral IgG concentration determined by radial immunodiffusion (Triple J Farms; Bellingham, WA). The nD of supernatant was positively correlated (r = 0.96) to RID when 1 mL of colostrum was added to a tube containing 75 µL CA and 1 mL 0.06 M AA, shaken for 10 s and not centrifuged. Refractive index was measured within 1 min of addition of CA. Decreasing AA to 1 mL or increasing AA to 2 mL decreased the correlation (r = 0.73 and r = 0.63, respectively) between nD and IgG. For centrifuged samples, altering the sitting time before centrifugation from 30 min to 0, 10 or 20 min numerically increased correlation (r = 0.82 to 0.87, 0.85 and 0.87, respectively), but these were not statistically different. When the centrifuge step was removed, nD after samples sat for 1 min was highly correlated (r = 0.96) with IgG; however visible separation of supernatant and precipitate did not occur in samples with IgG concentrations >20 mg/ml until after 10 min. Total protein (TP) was measured on a subset of 45 samples and weakly correlated (r = 0.41) with IgG; this suggests that TP is a poor method to determine colostral IgG concentration. These results indicate that a simple procedure requiring only CA, AA and a refractometer may rapidly and effectively estimate colostral IgG concentration in bovine colostrum.

Key words: colostrum, refractometer, IgG

W15 The effect of treatment with long-acting antibiotic upon arrival at a custom heifer rearing facility on non-specific fever, otitis media, neonatal calf diarrhea complex and growth. A. L. Stanton*[1], S. J. LeBlanc[1], L. K. Fox[2], J. Wormuth[3], D. F. Kelton[1], and K. E. Leslie[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Washington State University, Pullman, [3]CY Heifer Farm, Elba, NY.*

The primary objective of the study was to evaluate a single subcutaneous injection of tulathromcyin (TUL) in the early postnatal period, administered upon arrival at a commercial heifer rearing facility, on the incidence of disease in young dairy calves. A second objective was to describe the risk factors for morbidity and the impact of disease on growth of these calves. The third objective was to investigate the role of *Mycoplasma bovis* in the incidence of otitis media in this population of calves. Calves (n = 788) were randomly assigned to study treatment with TUL or a placebo (CONTROL) upon arrival at the heifer raising facility and were observed for disease daily for 8 weeks by farm staff. Microbiological culture and speciation of *M.bovis* was performed on nasal swabs collected from a subset of (n = 66) calves at 0, 2 and 4 weeks of age. All analyses were conducted using SAS v9.1 and controlled for source farm and group as random effects. Linear mixed models were used to analyze ADG. Generalized linear mixed models with a logit-transformation were used to analyze morbidity. CONTROL calves were 1.7 (CI: 1.2–2.6;$P < 0.01$), 3.7(CI: 1.6–9.1; $P < 0.005$), and 1.7 (CI: 1.2–2.5; $P < 0.005$) times more likely than TUL calves to be treated for neonatal calf diarrhea complex, unilateral ear droop and bilateral ear droop, respectively. The ADG of TUL calves was 0.03 ± 0.01 kg greater than CONTROL calves ($P < 0.01$). Failure of passive transfer (FPT), non-specific fever, bovine respiratory disease complex and neonatal calf diarrhea complex decreased ADG. The largest decrease in ADG (0.14 ± 0.04 kg) associated with disease was seen in calves with non-specific fever ($P < 0.05$). Of animals sampled for *M. bovis*, 26% tested positive, and 4 different strains were identified. In summary, TUL was associated with decreased the incidence of several common calfhood diseases in the early post-natal period. *M. bovis* was present in this population but not clearly associated with otitis media.

Key words: tulathromycin, otitis media, calfhood disease

W16 Immune status of calves that naturally suckle their dams in dairy farms of Costa Rica. J. A. Elizondo-Salazar*[1], J. Sánchez-Salas[1], J. Rodríguez-Zamora[1], and A. J. Heinrichs[2], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, [2]The Pennsylvania State University, University Park.*

The measurement of serum total protein (STP) in dairy calves by refractometer as an estimate of serum immunoglobulin concentration is the simplest test to give an indication of adequate passive transfer of immunity. A value of 5.0 g/dL has been established as the cutoff point for assessment of passive transfer status. Since there is no data on the immune status of dairy calves in Costa Rica, the objective of this study was to determine STP concentration in neonatal dairy calves that naturally suckle their dams. Blood samples were collected between d 1 and 7 of age from 417 heifer and 105 bull calves from more than 40 farms in different regions of Costa Rica. All blood samples were collected into serum (red top) Vacutainer tubes, refrigerated overnight, centrifuged, and the serum separated from clot within 24 h of collection. A hand-held refractometer (Atago Master-Sur/Nα, Bellevue, WA) was used to measure STP. GLM procedure was used to establish differences between parity and breed of the dams, and sex of the calf. Descriptive statistics were generated to define percentage of failure of passive transfer by sex of the calf and parity of the dam. Calves coming from dams of first and second parity had statistically ($P < 0.05$) higher STP concentration (6.40 ± 0.14 and 6.21 ± 0.14 g/dL) than those coming from cows with 3 or ≥4 calvings (6.01 ± 0.15 and 5.91 ± 0.12 g/dL). There was no significant difference between sex of the calves (heifers 6.13 g/dL, bulls 6.14 g/dL). Jersey calves had higher STP concentrations than Holstein, Holstein-Jersey cross, or other breeds (6.43 ± 0.11 vs. 6.18 ± 0.11, 6.01 ± 0.21 and 6.01 ± 0.16, respectively). Overall, 21.5% of calves had failure of passive transfer (heifers 22.5%, bulls 17.1%).

Table 1. Failure of passive transfer (%) by parity of dam and sex of neonates

Parity	Heifers	Bulls	Both
1	7.6	10.3	8.3
2	21.0	22.2	21.1
3	28.6	18.2	26.3
≥4	28.2	19.4	26.6

Key words: calves, passive transfer of immunity, serum total protein

W17 Determining the heritable component of dairy cattle foot lesions. A. M. Oberbauer*, S. L. Berry, J. M. Belanger, and T. R. Famula, *Department of Animal Science, University of California, Davis.*

Lameness and hoof health impacts dairy producers both as an animal welfare issue as well as being implicated in lowered milk production. Further, it is one of the top 3 reasons dairy cattle are culled prematurely, following infertility and mastitis, thus contributing to the overall carbon footprint of the dairy industry due to the environmental costs associated with raising replacement dairy heifers. Selection schemes for dairy cattle focus on sire contribution to milk production with little consideration to the cow′s physical structure. On a commercial California Holstein dairy, 2 binary hoof phenotypic traits, hoof lesions (sole lesion/upper limb lameness) and lameness due to abscesses or ulcers, were recorded. Monthly lactation records were collected from December 2006-April 2009 with weekly hoof health evaluations. Data on cows (n = 2247), in addition to hoof information, included birth date, freshening date, lactation number, and sire (n = 235) and dam information; total animals including those to build pedigrees were 5809. Lesions had a prevalence of 7.0% and abscess/ulcer lameness had a prevalence of 16.5%. The probability of any lameness (both conditions considered together) increased with increasing lactation number (0.018, 0.055, 0.082, 0.168 for first, second, and third plus lactations, respectively). Using a threshold model with a genetic term, σ_G^2, a permanent environment term, σ_{PE}^2, and residual term, σ_E^2, $h^2 = (\sigma_G^2)/(\sigma_G^2 + \sigma_{PE}^2 + \sigma_E^2)$ were calculated for each binary trait. The narrow sense heritability for lameness risk was estimated to be 0.24 for hoof lesion and 0.26 for abscess/ulcer lameness. The data suggest a significant genetic contribution to hoof health that is coupled with a greater risk of lameness with increasing lactation number (or age which cannot be ascertained by this study). The genetic component lends support for undertaking a SNP genome wide association study to identify loci contributing to the phenotype.

Key words: lameness, dairy cow, heritability

W18 Effects of cold pasteurizing colostrum with formic acid on bacteria counts and calf IgG absorption. L. A. Vickers*[1] and D. M. Veira[2], *[1]Animal Welfare Program, University of British Columbia, Vancouver, British Columbia, Canada, [2]Agriculture and Agri-Food Canada, Agassiz, British Columbia, Canada.*

Colostrum is vital to the health of the newborn calf; however, farm practices often lead to bacterial contamination. We set out to determine if 'cold' pasteurizing colostrum with formic acid (FA) in combination with refrigeration would lower bacteria counts; further, we tested the effects of feeding FA treated colostrum on IgG absorption by newborn calves. Fresh colostrum from 8 cows was subjected to 1 of 4 treatments: 1) addition of FA to achieve a pH of 4.3 and refrigerated; 2) addition of FA to a pH of 4.3 and left at 20°C; 3) no FA and refrigerated; or, 4) no FA and left at 20°C. Samples from each treatment were frozen at 0, 24, 48, 96 and 192 h. The addition of FA immediately lowered aerobic bacteria counts (2.7 ± 0.2 vs 4.2 ± 0.2 $\log_{10}$ cfu/ml; $P < 0.001$) and continued to do so for up to 192 h (1.1 ± 0.4 vs. 7.6 ± 0.42 $\log_{10}$ cfu/ml; $P < 0.001$) compared with untreated colostrum. Untreated colostrum had lower aerobic bacteria counts over 192 h when refrigerated compared with being left at 20°C (5.2 ± 0.22 vs. 7.7 ± 0.2 $\log_{10}$ cfu/ml; $P < 0.0001$). Colostrum IgG was not affected by the addition of FA (62.9 ± 15.2 g IgG/L $P = 0.99$). In a separate trial, 24 Holstein bull calves were fed 3L of colostrum through an esophageal feeder 2 h after birth from to 1 of 3 treatments: A) harvested and frozen immediately B) left at 20°C for 4 h then frozen or C) left at 20°C for 4hr then treated with FA to a pH of 4.3. IgG level of colostrum fed to calves did not differ between treatments (69.7 ± 18.1 g IgG/L; $P = 0.99$). A blood sample was taken 24 h after feeding to determine serum IgG. The addition of FA lowered bacteria counts compared with untreated colostrum (2.0 ± 0.3 vs 4.9 ± 0.3 $\log_{10}$ cfu/ml; $P < 0.0001$). There was no difference in 24 h calf serum IgG (20.1 ± 6.6 mg/L; $P = 0.9$) or apparent efficiency of absorption (41.6 ± 6.2%; $P = 0.8$) between treatments. In conclusion, the use of formic acid as a way to cold pasteurize colostrum is effective at lowering aerobic bacteria counts in colostrum and does not interfere with IgG levels or absorption in calves.

Key words: colostrum, formic acid, dairy calf

W19 Allelic variations in the bovine vitamin D receptor gene: Correlations with periparturient hypocalcemia? M. Reiche, C. Deiner, A. Mösch, and H. Martens*, *Institute of Veterinary Physiology, Faculty of Veterinary Medicine, FU Berlin, Institute of Veterinary Physiology, Faculty of Veterinary Medicine, FU Berlin, Berlin, Germany.*

Periparturient hypocalcemia (milk fever) is a disorder of the Ca metabolism in dairy cattle primarily affecting multiparous cows. The major reasons of the rapid decrease of blood Ca concentration are the prompt

increase of Ca secretion into the colostrum and the delayed activation of Ca regulation mechanisms including calcitriol, a metabolite of vitamin D. Vitamin D receptor (VDR) gene polymorphisms are reported to be associated with variations of Ca metabolism in man. The present study investigated the potential existence of VDR gene polymorphisms in German Holstein Friesian cows and correlated resulting variations with the incidence of hypocalcemia. Blood DNA was isolated from 26 high-yielding cows in their 4th to 6th lactation, out of which 17 had experienced hypocalcemia with ionized serum calcium levels < 0.9 mmol/l at least once, whereas nine cows had never undergone periparturient hypocalcemia in their lifetime. The 10 VDR exons and parts of adjacent introns were sequenced and compared with the *Bos taurus* VDR sequence published on NCBI based on breed Hereford. In total, 8 sequence alterations were detected in the fragments, which were primarily heterozygous. However, only 4 of them were located on exons with a potential change of the encoded amino acid. Calculated *P*-values (Fisher's exact probability test) were all >0.05, hence, the sequence variations found in this study were not correlated with the incidence of periparturient hypocalcemia.

Key words: periparturient hypocalcemia, vitamin D receptor, gene polymorphism

W20 Strategies to control the cattle tick, *Rhipicephalus microplus*, in dairy herds in the Brazilian Southwestern Amazon region: Technical recommendations. L. G. Brito*[1], F. da Silva Barbieri[1], and M. C. de Sena Oliveira[2], [1]*Embrapa Rondônia, Porto Velho, RO, Brazil,* [2]*Southeast Embrapa, Sâo Carlos, SP, Brazil.*

One of the most serious sanitary problems faced by dairy farmers in Brazil is infestation of their herds by the cattle tick *Rhipicephalus microplus*. This infestation is closely related to the region's climate conditions, mainly the high average temperature and rainfall. During the period between October 2004 and November 2009, 14 dairy cows (cross-breeds) were monitored at the Porto Velho experimental field of the Embrapa Rondônia research center, and climate data were obtained from the local weather station. From October 2004 to March 2006 the animals were not treated with any pesticides, to enable obtaining the seasonal fluctuation of *R. microplus* under the prevailing climate conditions of the Brazilian Southwestern Amazon region. Multiple linear regression analysis was used to reveal the influence of climate factors on the tick infestation in the herds. During this period without use of pesticides, the cattle had mean infestation of 201 ticks/animal. There was a significant decline in this rate during the dry season (May to September), when it was 72 ticks/animal, as opposed to 237 ticks/animal in the rainy season. Rainfall was the climate factor with the greatest influence on the tick infestation rate ($R^2 = 0.64$). In April 2006 integrated control strategies were implemented for the entire herd at the experimental station, composed of 111 animals of variable genetic composition, including *B. taurus* × *B. indicus* and *B. indicus*. The integrated tick control strategies entailed application of high-efficacy pesticides, as demonstrated by the adult immersion test, utilization of animals to attract larvae and pasture rotation of lactating cows. After implementing these integrated control measures, the mean infestation of *R. microplus* on the lactating cows fell from 201 ticks/animal to only 1.1 ticks/animal. By using the strategies listed was obtained an effective control of the cattle tick population in CEPV, where in the period between October 2007 and October 2009 did not require any treatment directed to control of ticks in the dairy herd in this period.

Key words: control, cattle tick, Brazilian Southwestern Amazon

W21 Ruminal binding characteristics of Mycopurge against various aflatoxins in in vitro. M. R. Akkaya[1], M. A. Bal[1], and V. Akay*[2], [1]*Kahramanmaras Sutcu Imam University, Turkey,* [2]*Global Nutritech Ltd., Kocaeli, Turkey.*

The objective of this experiment was to determine the ruminal binding characteristics of modified yeast extract and HSCAS containing mycotoxin adsorbent (MP, Mycopurge) against various aflatoxins in an in vitro study. Ninety milliliters of certified aflatoxin mixture [aflatoxins B1 (AFB1), B2 (AFB2), G1 (AFG1), G2 (AFG2)] in a liquid form was mixed with 30 mL of ruminal in vitro medium providing the final concentrations of 6 ng AFB1, 1.5 ng AFB2, 6 ng AFG1 and 1.5 ng AFG2, respectively. Treatments were: 1) aflatoxin mixture + water (Control); 2) aflatoxin mixture + rumen fluid (AR); 3) aflatoxin mixture + MP (6 mg) + rumen fluid (ARMP). Wheat starch was used as a substrate for AR and ARMP treatments. After various incubation time points (0, 3, 6, 12, 24 h) at 39°C, aflatoxin concentrations in ruminal medium were detected with HPLC. Although AFB1 concentration at 0 h was 6 μg/L, it was reduced to 2.50 and 1.68 μg/L in Control, 0.86 and 0.50 μg/L in AR, and 0.34 and 0.20 μg/L in ARMP at 3 and 12 h, respectively ($P < 0.001$). In addition, AFB1 concentration in ARMP treatment was in a steady-state after 3 h of incubation compared with Control and AR treatment where AFB1 concentrations became stabilized after 12 h of incubation ($P < 0.001$). Similar type of binding pattern was observed for ARMP treatment in ruminal incubation of AFB2, where the concentration was reduced down to the lowest level at 6 h (0.21 μg/L) compared with Control (0.74 μg/L) and AR (0.36 μg/L) treatment. In addition, concentrations of both AFG1 and AFG2 were in a steady-state condition for AR (0.67 and 0.48 μg/L) and ARMP (0.46 and 0.38 μg/L) treatments after 12 h of ruminal incubation. However, binding capacity of MP for AFG1 and AFG2 was always in favor of ARMP treatment at all time points ($P < 0.001$). There was no treatment effect on ruminal in vitro gas production across all treatments, averaging 53.5 mL at 24 h. Results indicate that aflatoxins can be degraded by the heat of incubation medium along with microbial degradation. In addition, MP can help to bind those respective aflatoxins and reduce their concentrations in the rumen before they enter into the blood stream.

Key words: modified yeast extract, aflatoxin, ruminal binding

W22 Factors affecting the selling price of calves sold in Texas livestock markets. K. J. Stutts, M. M. Beverly*, S. F. Kelley, and B. M. Freel, *Sam Houston State University, Huntsville, TX.*

Most cow-calf producers in Texas market their calves through local livestock auctions. When calves enter the sale ring, buyers must rapidly assess many physical and management factors to determine a value for the calves. The objective of this study was to determine which factors affect the selling price of calves in Texas livestock markets. Data were collected from 9 Texas livestock auctions on 1,420 lots consisting of 7,073 head. The data collected included gender, weight, breed type, color, muscle thickness, horn status, frame score, fill, condition, health, and selling price. An ANOVA was performed using SPSS. Calf characteristics were analyzed individually as dependent variables in which the model included BW as a covariate. Least squares means were generated for each variable and separated based on predicted differences. All selling prices are reported in US dollars per 45.45 kg of BW. Selling prices for steers ($132.34), heifers ($118.46), and bulls ($107.63) were different from each other ($P < 0.01$). Polled calves ($127.78) sold for a higher ($P < 0.01$) price than horned ($104.91) calves. Regarding breed type, British calves ($128.440) sold for the highest ($P < 0.03$) price, and calves that appeared to be predominantly American ($111.08) received the lowest price. Black ($122.51) calves sold for a higher ($P < 0.02$) price than red ($117.67) or yellow ($115.29) calves. Calves advertised as preconditioned ($131.38) and healthy ($121.27) calves sold for the highest ($P < 0.01$) price, and calves that were sick ($86.14) sold for the lowest ($P < 0.01$) price. Selling price of calves increased incrementally as lot size increased. Calves sold in groups of 20 or more ($129.07) had the highest ($P < 0.01$) selling price and calves sold as singles ($109.03) had the lowest selling price. These results indicate that many factors affect the selling price of calves in Texas livestock auctions. Some of these factors are associated with management and others are genetic. Producers could increase the value of their calves by changing their management strategy and through selection or modification of their breeding objectives.

Key words: feeder cattle, livestock auction, selling price

W23 Sources of sire-specific genetic variance for birth weight and weaning weight in the Bruna dels Pirineus beef cattle breed. M. Fina*[1], L. Varona[2], J. Piedrafita[1], and J. Casellas[1], *[1]G2R, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Departamento de Anatomía, Embriología y Genética Animal, Universidad de Zaragoza, Zaragoza, Spain.*

The Bruna dels Pirineus is an autochthonous beef cattle breed reared under traditional valley-mountain grazing systems in the Pyrenees Mountains of Catalonia (Spain). The breeding program of the Bruna dels Pirineus focused on birth weight (BWT) and weaning weight standardized to 185 d (WW185) since its implementation in 1990. Within this context, our analyses were performed on 8,130 BWT and 1,245 WW185 records from 12 and 2 purebred herds, respectively, collected between years 1986 and 2010. All animals included in the study were registered in the Yield Recording Scheme of this breed. This research investigated 2 sources of sire-related genetic effects on BWT and WW185, the influence of genes located in the non-autosomal region of the Y chromosome and the effect of paternal imprinting. Both BWT and WW185 were analyzed using a univariate Bayesian linear animal model and the relevance of paternal imprinting and Y chromosome-linked effects were checked by the deviance information criterion (DIC). In addition to sire-specific and direct genetic effects, our model accounted for random permanent effects (dam and herd-year-season) and 3 systematic sources of variation, sex of the calf (male or female), age of the dam at calving (2, 3, 4, 5, 6 and > 6 years), and birth type (single or twin). Both traits evidenced remarkable effects from the Y chromosome, whereas paternal imprinting was only revealed in WW185. Note that differences in DIC between the preferred model and the remaining ones exceed 39,000 and 2,800,000 DIC units for BWT and WW185, respectively. It is important to highlight that Y chromosome accounted for ~2% and a ~6% of the total phenotypic variance for BWT and WW185, respectively, and paternal imprinting accounted for ~13% of WW185 phenotypic variance. These results revealed 2 relevant sources of sire-specific genetic variability with potential contributions to the current breeding scheme of the Bruna dels Pirineus beef cattle breed.

Key words: Bruna dels Pirineus, paternal imprinting, Y chromosome

W24 Relationships between feed efficiency traits and body weight, age, backfat, rumpfat and circulating serum metabolites in pregnant beef cows. K. M. Wood*[1], Y. R. Montanholi[1], B. W. McBride[1], and K. C. Swanson[2], *[1]Dept. of Animal and Poultry Science, University of Guelph, Guelph, Ontario, Canada, [2]Dept. of Animal Sciences, North Dakota State University, Fargo.*

Sixty-three mature pregnant beef cows, primarily of Angus and Simmental breeding, were used to investigate the relationship between feed efficiency traits with ultrasound measures of backfat (BF), rumpfat (RF) and serum metabolites. Cows were randomly assigned to pen and individually fed a haylage/wheat straw-based TMR for 105 d leading up to parturition. Cows were weighed every 28 d and ultrasounded for backfat and rumpfat. Blood samples were obtained via jugular venipuncture on d 1, 56, 105, and serum was frozen for later analysis of urea, glucose, BHBA, NEFA and total cholesterol. Pearson correlations were conducted in SAS between performance and feed efficiency traits and ultrasound measures and serum metabolite concentrations and P-values adjusted using Benjamini Hochberg false discovery rate correction. Residual feed intake (RFI) was calculated using PROC GLM in SAS. Dry matter intake was not ($P \geq 0.14$) correlated with average body weight (BW), cow age, initial BF and RF, change in BF or RF, or serum metabolites. Average daily gain was negatively correlated ($P = 0.02$) with average BW but not ($P \geq 0.08$) with age, ultrasound measures or serum metabolites. Feed to gain was not ($P \geq 0.07$) correlated with BW, age, ultrasound measures or serum metabolites with the exception of d 56 serum glucose concentration, which was positively correlated ($P = 0.02$). The basic model for RFI ($R^2 = 0.08$) was not correlated ($P \geq 0.17$) with age, BW, ultrasound measures or circulating serum metabolites. Body weight, age, ultrasound measures and blood metabolites may not be good indicators of differences in feed efficiency traits, and there is considerable variation in measures of feed efficiency in mature pregnant cows.

Key words: beef cows, feed efficiency, serum metabolites

W25 Effect of preconditioning days, feeder cattle grade, and sire breed type on growth performance and carcass characteristics of beef cattle participating in a calf to carcass program in southwest Louisiana. D. M. Gandy*, D. R. Goodwin, T. H. Shields, W. A.

Storer, and F. M. LeMieux, *McNeese State University, Lake Charles, LA*.

One hundred 30 - one weanling steer calves (initial BW = 280 ± 78 kg) of various breeds were enrolled in a preconditioning program in southwest Louisiana. Steers were identified by sire breed, tagged, and assigned a USDA feeder calf grade. Calves entered the program in mid-September of 2008 and 2009 and were preconditioned for 36 ± 6 d. Cattle were grouped by weaning age and housed (25- 30 calves) in 0.81 ha paddocks with a mixture of bermudagrass, bahiagrass and carpetgrass and free choice alicia and bermudagrass hay (≥8% CP). A 14% CP preconditioning diet fed in troughs was provided with DMI of 1–2% of live BW. After preconditioning, calves were shipped 1,283 km to Henry C Hitch feedyard in Guymon Oklahoma. Calves were fed to an average harvest weight of 602 kg (range 445 to 727 kg) and harvested at a commercial processing facility. Feeder calf grade, steer sire breed, and preconditioning d were used to determine differences in growth and carcass performance. Large framed calves with at least moderate muscling had increased ($P < 0.05$) preconditioning ADG, harvest weight, and carcass weight when compared with medium framed calves with at least moderate muscling. Growth (preconditioning and feedlot ADG) were not different ($P > 0.05$) when steers were grouped by sire breed American (n = 29) or British (n = 101). Steers with British sires had heavier ($P < 0.05$) harvest weights than steers born of American sires. Steers that were maintained on a preconditioning routine for 37 to 42 d had increased ($P < 0.05$) harvest weight, carcass backfat and numerical USDA yield grade. When calves were preconditioned 36 d or less numerical yield grade was lower ($P < 0.05$). Feeder calf grades continue to be a reliable source for predicting harvest and carcass weights. Breed of sire did not affect carcass characteristics and preconditioning d influences carcass yield grade.

Key words: feeder calf grade, preconditioning, growth

W26 Effect of castration status on arrival of ultra-high risk calves on feedlot performance and health during a 61-d preconditioning program. L. Clark[1], C. Flaig[1], O. C. Schunicht[1], M. L. May[1], R. E. Peterson[1], C. W. Booker[1], C. R. Krehbiel[2], G. K. Jim[1], and L. O. Burciaga-Robles*[1], *[1]Feedlot Health Management Services Ltd., Okotoks, Alberta, Canada, [2]Department of Animal Science, Oklahoma State University, Stillwater.*

Ultra-high risk calves (n = 80; BW = 242.5 ± 4.2 kg) were allocated to evaluate the effect of castration status on arrival on feedlot performance and health during a 61-d preconditioning program. Upon arrival, 40 intact males (BULLS) were identified as candidates for the trial. Based on initial weight (±2.5 kg) and hide color, a matched pair was identified as a castrated male (STEERS) from the same truckload and was allocated as a case control. Arrival processing included a metaphylactic treatment for control of BRD and proprietary health procedures based on animal health risk assessment (Feedlot Health Management Services, Ltd. Okotoks, Alberta, Canada). Individual number and electronic ear tags were also applied. Intact males were band castrated. After initial processing, cattle were allocated to one of 2 pens (20 case controls/pen) equipped with individual feed intake data collection systems (GrowSafe Systems Ltd., Airdrie, Canada) and fed for 60 d. Cattle were observed by trained personnel for detection and treatment of disease during the trial. Cattle were re-weighed on d 30 and d 61. Animal performance was analyzed using PROC GLIMMIX (SAS Institute, NC). Animal was the experimental unit, and the model included the fixed effect of treatment and the random effects of block and pen. Animal health parameters were analyzed using a chi-squared procedure of SAS. A total of 6 animals (3 BULLS, 3 STEERS) were removed from the trial and not included in the analysis. In addition, 2 (5.0%) BULLS and 1 (2.5%) STEERS died ($P = 0.52$) and were removed from the analysis; no difference in animals treated for BRD was detected (15.5 vs 20.0% for BULLS and STEERS respectively; $P = 0.20$). No differences were observed for BW, ADG, DMI, or GF ($P > 0.05$) from d 0 to 30. However by d 60, BULLS had lower BW (305 vs 315 kg; $P = 0.05$), ADG (1.02 vs 1.18 kg/d; $P = 0.02$), and tended to have lower G:F (0.171 vs 0.185; $P = 0.09$) when compared with STEERS. Thus, purchase price discounts for bulls when compared with steers should consider a 13.5% decrease in ADG and a 7.6% decrease in G:F in addition to increased mortality.

Key words: castration, feedlot performance, BRD

W27 Effects of *Bos indicus* breeding on plasma pregnancy-associated glycoprotein (PAG) concentrations and fetus size in early gestation. P. M. Morelli*[1], D. O. Rae[2], S. E. Johnson[1], and A. D. Ealy[1], [1]*University of Florida, Department of Animal Sciences, Gainesville,* [2]*University of Florida, Department of Large Animal Clinical Sciences, Gainesville.*

Cross-breeding *Bos indicus* and *Bos taurus* breeds improves various production traits for cattle maintained in hot climates. Limited information exists describing pregnancy specific events that are influenced by these cross-breeding strategies. In this study, transrectal ultrasonography was used to measure fetal size at 52 to 55 d of gestation in cows composed of Angus (>80% Angus; n = 17), Brangus (n = 15) and Brahman (≥25% Brahman; n = 58) genetics. Blood was collected for the measure of plasma pregnancy associated glycoprotein (PAG) content by ELISA. Multiparous cows were used in a timed AI protocol for this study. Multiples sires were used to generate fetuses with varying degrees of Angus/Brahman cross-breeding. Blood was harvested once between d 52 and 55 post-TAI. Day of blood collection and ultrasonography was used as a covariate. PAG concentrations were greater ($P \leq 0.05$) in Brangus and Brahman cows than Angus cows (9.8, 10.4 and 5.9 ng/ml, respectively; SE = 1.93). Fetus size was smaller ($P \leq 0.05$) in Brangus and Brahman cows than Angus cows (27.7, 28.8 and 34.8 mm, respectively; SE = 3.24). No differences in PAG concentrations and fetus size were observed based on the amount of Angus, Brangus and Brahman genetics in the fetus. In summary, both PAG concentrations and fetus size differed based on the degree of Angus/Brahman cross-breeding of the cow but not the fetus. This suggests that the maternal system plays an active role in controlling placental activity and early fetal development, and Brahman-based cows control these events differently than Angus cows during early pregnancy.

Key words: cross-breeding, pregnancy associated glycoprotein (PAG), fetus size

W28 Genetic parameters and genetic trends for growth and reproductive traits in a Colombian multibreed beef cattle population. O. D. Vergara[1] and M. A. Elzo*[2], [1]*University of Cordoba, Monteria, Colombia,* [2]*University of Florida, Gainesville.*

Genetic parameters and trends for weaning weight adjusted to 240 d of age (WW240; n = 9,668), and weight gain from weaning to 24 mo of age (GW730; n = 1,357), age at first calving (AFC; n = 1,615), and interval between first and second calving (CI1; n = 1,189) were estimated in a Colombian beef cattle population composed of Blanco Orejinegro, Romosinuano, Angus, and Zebu straightbred and crossbred animals. Variance components and genetic parameters were estimated by Restricted Maximum Likelihood. The 4-trait mixed model included the fixed effects of contemporary group (herd-year-season-sex; sex = sex of progeny for CI1), age of dam (WW240 only), breed direct genetic effects, breed maternal genetic effects (WW240 only), individual heterosis, and maternal heterosis (WW240 only). Random effects for WW240 were calf direct genetic, dam maternal genetic, permanent environmental maternal, and residual. Random effects for GW730 were calf direct genetic and residual; and random effects for AFC and CI1were cow direct genetic and residual. Program AIREML was used to perform computations. Heritabilities estimates for additive direct genetic effects were 0.19 ± 0.003 for WW240, 0.53 ± 0.004 for GW730, 0.11 ± 0.007 for AFC, and 0.05 ± 0.001 for CI1. Maternal heritability was 0.11 ± 0.002 for WW240. The high direct heritability for GW730 suggests that selection for this trait is feasible in this population. The genetic correlation between direct and maternal additive effects for WW240 was negative (−0.18 ± 0.009). Correlations between additive direct genetic effects for all traits were close to zero. Calf and cow weighted yearly means showed negative trends for direct growth traits (−0.53 ± 0.19, $P < 0.05$ for WW240; −2.64 ± 0.55, $P < 0.001$ for GW730), and AFC (−0.04 ± 0.02, $P < 0.05$). Cow direct genetic CI1 yearly means showed positive trends (3.01 ± 0.42, $P < 0.001$). This suggests that some selection for AFC existed in this population during these years and other traits were neglected.

Key words: cattle, growth, reproduction

W29 Combining ability of nine tropically adapted and temperate breeds for growth and ultrasound traits in Colombia. C. A. Martinez[1], C. Manrique[1], M. A. Elzo*[2], and A. Jimenez[1], [1]*Universidad Nacional de Colombia, Bogota, Colombia,* [2]*University of Florida, Gainesville.*

Colombia is currently using crossbreeding strategies involving tropically adapted and temperate cattle breeds to improve beef cattle productivity for growth and carcass traits under pasture conditions. The objective of this research was to compare the combining ability of sires from 2 tropically adapted *Bos taurus* breeds (Blanco Orejinegro: BON; Romosinuano: RS), 3 tropically adapted *Bos indicus* breeds (Gray Brahman: GB; Guzerat: GZ; Red Brahman: RB), and 4 temperate *Bos taurus* breeds (Braunvieh: BV; Limousin: LIM; Normand: NM; Simmental: SIM) when mated to Gray Brahman cows for birth weight (BW), and adjusted weights (W), ultrasound ribeye area (REA) and backfat (BF) measured at 4 (W4, REA4, BF4), 7 (W7, REA7, BF7), 12 (W12, REA12, BF12), and 15 (W15, REA15, BF15) mo of age. Data were from 352 calves from 2 herds (22 to 100 per breed group) sired by 37 bulls (3 to 12 sires per breed). The model included breed group of calf, contemporary group (herd-year-season-sex) and age of calf (ultrasound traits only) as fixed effects, and sire and residual as random effects. Least squares means (LSM) for BW, W4 and W7 were similar across breed groups, whereas calves from SIM sires were heavier than calves from GB sires at 12 (42.8 ± 9.9 kg; $P < 0.0009$) and 15 mo of age (35.0 ± 7.9 kg; $P < 0.0008$). The LSM for REA were similar for crossbred calves from sires of all breeds, except for calves from LIM sires whose REA were larger than those of calves from GZ (11.4 ± 3.0 mm^2; $P < 0.0078$), NM (11.0 ± 2.9 mm^2; $P < 0.0103$), SIM (10.3 ± 2.8 mm^2; $P < 0.0143$) and RB sires (11.3 ± 2.4 mm^2; $P < 0.0002$) at 4 mo of age, and from GB sires at 4 (11.3 ± 2.4 mm^2; $P < 0.0002$), 7 (6.8 ± 1.9 mm^2; $P < 0.0174$), 12 (9.7 ± 1.8 mm^2; $P < 0.0224$), and 15 mo of age (11.3 ± 2.8 mm^2; $P < 0.0051$). The LSM for BF were similar across breed groups and calf ages.

W30 Genetic parameters and trends for age at first calving in Brahman cows raised in Brazil. J. C. DeSouza*[1], M. Silveira[2], M. A. Pereira[3], P. B. Ferraz Filho[4], J. A. DeFreitas[5], R. M. DaSilva[2], C. H. M. Malhado[6,10], C. H. M. Cavalari[3], M. F. Mota[7], H. J. Fernandes[8], and W. R. Lamberson[9], [1]*Mato Grosso do Sul Federal University, CPAQ/Animal Science, MS, Brazil,* [2]*Student of MSc. of animal science course, UFMS, Campo Grande, Brazil,* [3]*Brazilian Association of Zebu Breeders, Uberaba, Brazil,* [4]*Mato Grosso do Sul Federal University, Tres Lagoas, Brazil,* [5]*Paraná Federal University, Palotina, Brazil,* [6]*South*

Bahia State University, Jequie, Brazil, [7]Paranaense University - UNIPAR, Umuarama, Brazil, [8]State University of Mato Grosso do Sul, Aquidauana, MS, [9]University of Missouri, Columbia, [10]Scholarship - CNPQ, Brazil.

In 1997 the Brahman breed was introduced in Brazil to potentially increase at Brazilian beef cattle production. For this to occur, reproductive traits are very important. The objective of this study was to estimate genetic parameters and genetic trend for age at first calving in Brahman Beef cattle. The data were 5,432 ages at first calving from 1997 at 2008 provided by the Brazilian Zebu Cattle Association and included information on different regions of the country. The genetic parameters were estimated by using the MTDFREML package with an animal model and included the fixed effects of contemporary group (year, season, conception type (1: not in vitro fertilization; VF; 2: in vitro fertilization), nutrition type (1: Pasture, 2: pasture + concentrate, 3: Feed lot) and a random animal effect. The genetic trend was estimated by linear regression of the breeding value of calving interval on cow birth year. The genetic trend was −0.053 d/year ($P = 0.03$) and the R2 of model was 0.38. The estimated genetic variance was 8.89 and phenotypic variance was 49.67 yielding a heritability of 0.18 ± 0.05 and the environmental proportion of the total variance was 0.82 ± 0.05. The genetic gain was small, but in the favorable direction. Breeding values averaged −0.107 in 1997 and improved to −0.707 in 2008 for a total reduction in the age at first calving of 0.599 mo. The genetic variance for age at first calving is small and suggests that the trait not a good candidate for direct selection.

W31 Allometric growth study of Guzerá cattle under a performance test on grazing regimen. R. C. Sousa*[1], I. G. Pereira[1], P. V. R. Paulino[2], S. D. J. Villela[1], R. A. M. Oliveira[1], A. P. L. Tonaco[1], F. S. Coelho[1], and F. A. Carvalho Neto[3], *[1]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil, [2]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [3]Colorado State University, Fort Collins.*

A performance test of Guzerá cattle grazing on *Brachiaria brizantha* pasture was conducted on a private ranch in Brazil during 294 d. The study was assisted by the Brazilian Association of Zebu Breeders. During this performance test the development of the animals were measured by morphometric traits (rump height, body length, and heart girth), scrotal circumference, rib eye area (by ultrasound) and body weight. Forty-five Guzerá bulls were used with an initial body weight of 219.9 ± 38.05 kg and age of 325.8 ± 28.0 d old. The animals grazed on *Brachiaria brizantha* pastures and were supplemented with loose supplements during the performance test duration to overcome protein deficiencies in the pasture. A 70 d adaptation period was allowed and thereafter the animals were weighed and evaluated every 56 d. An exponential model was used to study the allometric growth of these animals. A log-transformation of the initial model was performed to produce a linear model. Growth was considered isogonic when $b = 1$ and heterogonic when $b \neq 1$ ($b > 1$, positive and $b < 1$, negative). The allometric growth of all traits evaluated was heterogonic and negatively correlated to body weight and age of the animals (Table 1). However, coefficients of determination from the allometric equations had moderate values, suggesting that more studies with larger group of animals should be conducted to gather greater amount of information to describe the growth pattern of Guzerá bulls under tropical grazing conditions.

Table 1. Allometric coefficients of morphometric traits, scrotal circumference and rib eye area related to BW of Zebu bulls

Trait	a	b	s(b)	R^2	*P*-value
RH	54.09	0.16	0.01	0.63	*
BL	32.43	0.24	0.01	0.65	*
HG	31.64	0.28	0.01	0.75	*
SC	0.43	0.71	0.02	0.80	*
REA	1.78	0.51	0.02	0.74	*

*$P < 0.01$. a = intercept of linear regression; b = allometric coefficient; s(b) = standard error of the allometric coefficients; R^2 = coefficient of determination; RH = rump height; BL = body length; HT = heart girth; SC = scrotal circumference, REA = rib eye area.

W32 Growth curves of Guzera bulls on grass regimen under performance test. R. C. Sousa[1], I. G. Pereira*[1], P. V. R. Paulino[2], A. V. Pires[1], F. F. Silva[1], R. A. M. Oliveira[1], A. P. L. Tonaco[1], and F. A. Carvalho Neto[3], *[1]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil, [2]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [3]Colorado State University, Fort Collins.*

Data derived from a performance test of Guzera bulls on pasture regimen was used to analyze the growth pattern. Forty-five post-weaning bulls (325.8 ± 28 d old) with initial body weight of 219.9 ± 38.05 kg were used. The animals grazed on *Brachiaria brizantha* pastures and were also supplemented to attain a body weight gain of up to 1.5 kg/d. All animals were maintained under the same feed regimen for a period of 294 d. Body measurements were taken every 56 d throughout the study. The objective of the study was to develop a nonlinear function that could best describe the growth pattern of these animals. All models tested converged, but it was observed that there was a significant variation on asymptotic weights and mean square error (MSE) between models. The models of Von Bertalanffy and Brody showed more realistic values compared with the other models (Table 1). We observed that the values produced by the Bertalanffy model were slightly lower than the values from the Brody model when comparing the estimates of the asymptotic weights from the 2 models (Table 1). The asymptotic weight estimated by the Gompertz model proved to be a little lower, while the value was much lower than the others in the Logistic model (Table 1). In most studies in the available literature, the Brody model presents the largest estimates of asymptotic weight, and the Logistic model consistently produces lower estimates. It can be observed that the growth curves fitted by Von Bertalanffy and Brody models had lower mean square error (MSE) and higher coefficient of determination when compared with the other models. The Von Bertalanffy model was chosen as it best represented the growth curve of the Guzerá animals as it had the best fit to the data considering the criteria used.

Table 1. Parameter estimates of growth curves of grazing Guzera bulls under performance test

Model	A	B	K	r^2	MSE
Von Bertalanffy	627.97	0.60	0.00	0.97	641.98
Brody	787.71	0.95	0.00	0.97	681.16
Gompertz	568.26	2.53	0.00	0.97	703.73
Logistics	466.39	7.51	0.01	0.96	939.39

MSE = mean square error; A = asymptotic weight when t tends to plus infinity; B = an integration constant, related to the initial BW; K = maturation rate, an indicator of the speed with which the animal approaches its mature; r^2 = coefficient of determination.

W33 Variance components in growth traits of Guzera cattle breed with different models. I. S. Silva*[1], I. U. Packer[2], C. M. R. Melo[3], L. O. C. Silva[4], and R. A. A. Torres Junior[4], *[1]University of Brasília - UnB, Brasília /DF, Brazil, [2]University of São Paulo - USP/ESALQ, Piracicaba/SP, Brazil, [3]University of Santa Catarina - UFSC, Florianópolis/SC, Brazil, [4]Embrapa Gado de Corte, Embrapa Gado de Corte, Campo Grande/MS, Brazil.*

A total of 130,424 body weight records of Guzera cattle collected in 8 periods every 90 d were used to estimate (co)variance components. REML was used with 4 models: model 1 included genetic direct (GA), genetic maternal (GM) environmental permanent maternal (AM) and residual random effects; model 2 excluded GM; model 3 excluded AM and model 4 excluded both GM and AM. Likelihood ratio test did not show significant differences ($P < 0.05$) between models 1 and 2 in almost all ages. Estimates of direct heritabilities h^2 in models 1 and 2 were similar. The values of h^2 decreased from birth to second age then maintained the same value until the weaning and increased after that. Direct heritability estimates for weight in age classes close to 205, 365 and 550 d, by models 1 and 2, were respectively 0.15, 0.12 and 0.14. Estimates of the same parameter obtained by models 3 and 4 were respectively 0.15, 0.14, 0.15 and 0.26, 0.19, 0.17. Heritability estimates from model 3 were larger due to the exclusion of the AM term of the analysis. Estimates of additive variance were greater with model 4. Model 2 adjusted better the data and required lesser processing time. The model comparison indicated that the GM effect did not improve fit.

Key words: beef cattle, maternal effects, estimates of variances

W34 Estimates genetic parameters for growth traits of Guzera cattle breed by single-trait and two-trait analysis. I. S. Silva*[1], I. U. Packer[2], C. M. R. Melo[3], L. O. C. Silva[4], and R. A. A. Torres Junior[4], *[1]University of Brasília - UnB, Brasília /DF, Brazil, [2]University of São Paulo - USP/ESALQ, Piracicaba/SP, Piracicaba/SP, Brazil, [3]Federal University of Santa Catarina - UFSC, Florianópolis/SC, Brazil, [4]Embrapa Gado de Corte, Campo Grande/MS, Brazil.*

The study aimed to estimate components of (co)variance and genetic parameters, comparing different single-trait and 2-trait models, for weight adjusted for the age-standard. A total of 55,063 body weights records adjusted to 120 (W120), 205 (W205), 365 (W365) and 550 (W550) days of age, from 22,949 animals belonging to 46 herds of Guzera breed, referring to the period of 1975 to 2001. In the single and 2-trait analyses 2 models were used to estimate the genetic parameters by the REML: model 1, as a complete model,, included direct and maternal genetic effects, as well as, maternal permanent environmental and residual effects; the model 2, as a reduced model, included the direct genetic effect and the maternal permanent environmental and residual effects. Likelihood ratio test did not show significant differences ($P < 0.05$) between models 1 and 2 in almost all ages. Estimates and behavior of variances for models 1 and 2 were similar, by the single-trait and 2-trait analyses. In the model 1 the maternal genetic variance estimates were low, mainly before the weaning. Direct heritability estimates by single-and 2-trait analysis for W120, W205, W365 and W550 were 0.15, 0.10, 0.17, 0.14 and 0.13, 0.10, 0.16, 0.15, respectively. Direct heritability estimated by models 1 and 2 were similar in the single-trait and 2-trait analyses. Estimates of maternal heritability were low for all ages. The genetic correlations were similar for models 1 and 2. The direct genetic correlation by models 1 and 2 for W120/W205, W120/W365, W120/W550, W205/P365, W205/W550 and W365/W550 were 0.80, 0.54, 0.54, 0.74, 0.62, 0.95 and 0.80, 0.54, 0.53, 0.74, 0.62, 0.95, respectively. Phenotypic and environmental correlations presented lower values when birth weight was involving. Overall it was observed a good agreement between the results for both models. The comparison between the models indicates that the reduced model was equivalent to the complete model.

Key words: beef cattle, maternal effects, variance components

W35 Real-time ultrasound measurements for the selection of growing animals of Bruna dels Pirineus beef cattle breed. M. Fina, J. Tarres, and J. Piedrafita*, *Grup de Recerca en Remugants, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain.*

The application of ultrasound technology as a research tool allows the evaluation of carcass attributes in live animals. In addition, these measurements have potential to increase the rate of genetic progress including estimation of heritabilities and genetic correlations in genetic evaluation programs for carcass merits. The objective of this study was to estimate genetic parameters for real-time ultrasound measurements of loin area (LA), loin depth (LD) and subcutaneous fat thickness over the rump (SF) in Bruna dels Pirineus beef cattle, a breed selected for meat from the old Brown Swiss and similar to the American Braunvieh. The measurements were obtained using a Sonovet 2000 ultrasound unit equipped with a 3.5-MHz 17 cm linear transducer. A unique ultrasound technician preformed all measurements. Every animal (n = 352) was scanned 2 to 5 times for each variable to estimate the accuracy of ultrasonic records. The weight at scanning ranged from 158 kg to 608 kg. Intraclass correlations for LA, LD and SF measurements were 0.964, 0.988 and 0.875, respectively. Heritabilities and genetic correlations were estimated using multiple-trait restricted maximal likelihood. The final animal model included only one ultrasonic measurement per animal (the closest to the mean for each animal), fixed effects for year-season (7 breeding year-seasons over a 2.5-yr period) and feedlot, and the interaction of weight by sex as a linear covariate. The pedigree included 936 animals. Heritabilities for LA, LD and SF were 0.37 ± 0.13, 0.36 ± 0.12, and 0.27 ± 0.13, respectively. Genetic correlations between LA and LD, LA and SF, and LD and SF, were 0.63 ± 0.17, 0.36 ± 0.28, and -0.41 ± 0.42, respectively. The estimates of heritabilities and genetic correlations indicate that a relevant additive genetic variance exists for all 3 traits and supports the use of live animal ultrasonic measurements as a selection tool in breeding cattle.

Key words: real-time ultrasound, beef, selection

W36 Linear B-splines to model longitudinal weight records in Tabapuã cattle. G. R. O. Menezes*[1,2], R. A. Torres[2], R. A. A. Torres Júnior[1], L. O. C. Silva[1], A. Gondo[1], and R. F. Euclydes[2], *[1]Embrapa Beef Cattle, Campo Grande, MS, Brazil, [2]Federal University of Vicosa, Vicosa, MG, Brazil.*

This work was aimed at evaluating the feasibility of a random regression model with linear B-splines (RRM) to estimate (co)variance components and breeding values for body weight in beef cattle. Data comprised 359,707 body weight records from 1 to 600 d of age on 84,215 animals of the Tabapuã breed. RRM included as fixed effects contemporary group, age of dam and deviation of the animal's birth date to the average day of the calving season. As random effects, direct and maternal additive genetic and direct and maternal permanent environment effects were included. Six residual variance classes were assumed: 1–60, 61–180, 181–300, 301–420, 421–540 and 541–600 d. Six knots located at ages 0, 120, 240, 360, 480 and 600 d were considered. To compare the results obtained with RRM, a multi-trait model (MTM) was applied to standard pre-adjusted weights at 120, 240, 360 and 480 d of age. MTM's fixed and random effects were almost the same of the RRM, except for the direct permanent environment random effect. (Co)variance components were estimated using a Bayesian approach with Gibbs sampling. RRM presented good results, providing reliable (co)variance components and genetic parameters along the range of ages evaluated. Additionally, RRM showed no convergence problem. (Co)variance components and genetic parameters estimates generated by RRM and MTM were similar for all ages evaluated. For instance, direct heritabilities for body weights at 120, 240, 360 and 480 d of age, estimated by RRM and MTM, were 0.20 and 0.18; 0.21 and 0.18; 0.21 and 0.19; 0.24 and 0.19, respectively. These estimates were close to the ones obtained in other studies with Tabapuã cattle. For the ranking based on estimated breeding values, the models were similar, with larger differences among animals with less information, i.e., cows and calves. RRM allowed for better and greater use of available data. Data file used for RRM was 67% larger than the one used for MTM what can improve accuracies of the genetic evaluations. Thus, RRM is a feasible and interesting alternative to be applied in genetic evaluations for longitudinal growth traits in beef cattle.

Key words: random regression, beef cattle, growth

W37 Genetic variability for calf mortality in Nellore cattle. L. C. Magalhães Silva*, F. Baldi, L. G. Albuquerque, and M. J. R. Paranhos da Costa, *São Paulo State University, Unesp, Jaboticabal, São Paulo, Brazil.*

The objective of this work was to estimate genetic parameters for calf mortality in Nellore cattle. Calf mortality (CM) was defined as a binary trait, with 1 = success, indicating a calf born alive after the pregnancy diagnosis and 0 = failure, indicating a calf failing to reach the end of gestation, stillborn, or dead within the first 48 h after calving. Pregnancy diagnoses were performed on cows 90 d after the end of breeding season. After consistency checks 68,307 records for calf mortality from 31,583 cows and 646 sires belonging to Agropecuaria Jacarezinho Ltda, Sao Paulo, Brazil, were available for subsequent analyses. The mortality frequency obtained from the data was of 2.0%. CM was analyzed using a sire model. The age of the cow at the beginning of the breeding season (in classes, ranging from 1 to 13 years) was included as fixed effect in the model, while contemporary group (CG), defined by year, farm and breeding season of the cow and the additive genetic effect of the sire were fitted as random effects. The pedigree file contained 861 sires. Bayesian inference using a threshold model was applied and a Gibbs Sampler was employed to obtain the marginal posterior mean and standard deviation of all variance components. A single Markov chain of 500,000 cycles was generated with a sampling interval of 100 iterations, using the THRGIBBS1F90 software. The posterior distribution for CM heritability was obtained from effective samples (10,000 samples). The descriptive statistics (mean and standard deviation) and the highest posterior density (HPD at 95%) region were estimated for CM heritability using the BOA package (R program). For CM heritability, the mean h2 ± standard deviation and HPD [lower bound – upper bound] were 0.21 ± 0.07 and [0.087- 0.37], respectively. The results of the present study pointed out that, applying a sire model to evaluate CM, there is enough genetic variability to select for decreased calf deaths in beef cattle. Financial support: FAPESP.

Key words: calves, heritability, mortality

W38 Selection effect for growth traits on energy requirements in reproduction females of three production cycles. I. D. P. Solar Diaz*[1], F. R. de Araujo Neto[1], G. M. Ferreira de Camargo[1], R. Barbosa Lobo[2], and H. N. de Oliveira[1], *[1]Sao Paulo State University, Jaboticabal, Sao Paulo, Brasil, [2]Sao Paulo University, Ribeirao Preto, Sao Paulo, Brasil.*

The objective was to evaluate the effect of selection for growth traits on energy requirements in reproductive females from 3 production cycles (C). Records of weights from Nellore cows were used to calculate the average weights in the reproductive stage (after 730 d). The average number of days that females remain in each category (pregnant lactating, non-pregnant lactating, pregnant nonlactating and empty and dry) for the period of one year considering the average calving interval of 365 (C1), 450 (C2) and 550 (C3) days were calculated as well. The energy requirement was measured by total net energy (T.N.E.) which was obtained by the sum of net energy for maintenance, activity, pregnancy and lactation. The prediction equations of NRC were used. The selection effect was analyzed using the estimates of coefficients of regression which were obtained from a previous analysis (not shown) of genetic parameters from birth to mature ages of cows. A selection intensity of 1.76 u.d.p was used. The following selection criteria were used: weights of 120, 210, 365, 450, 550 and 730 d and the weights gains between these phases. The increase of N.E. was not significant when different selection criteria were used, however the increase was observed between the production cycles. There is a tendency of increase in T.N.E. from C1 (4,864–5,070 Mcal) to C2 (4,935–5,148 Mcal), however the C3 (4,503–4,700 Mcal) was relatively inferior compared with the others. As expected, the nutritional requirements, on an annual basis, decreases with an increasing calving interval, as part of the T.N.E. is assigned to less productive classes (or nonproductive in the case of C3) and therefore less demanding. However, when considering the production of calves, the cost-effectiveness is impaired. In general, considering the genetic parameters used in this study, we conclude that the selection criteria used did not interfere in the females energy requirements regardless of their reproductive efficiency.

Key words: beef cattle, net energy

W39 Effect of model structure on direct and maternal (co)variance and heritability estimates for 210 d weight in Nellore cattle. L. Pascoa*[1,2], A. de los Reyes[2], M. A. Elzo[3], J. L. Ferreira[4], L. A. F. Bezerra[5], and R. B. Lobo[5], *[1]Federal Institute of Brasilia, Planal-*

tina, Distrito Federal, Brazil, [2]Federal University of Goias, Goiânia, Goiás, Brazil, [3]University of Florida, Gainesville, [4]Federal University of Tocantins, Araguaina, Tocantins, Brazil, [5]National Association of Farmers and Researchers, Ribeirão Preto, São Paulo, Brazil.

Actual and adjusted weights to 210 d of age from 72,731 male and female Nellore calves born in 40 PMGRN Nellore Brazil herds from 1985 to 2005 were used to compare the effect of different models on direct and maternal (co)variance and heritability estimates. Four structures of contemporary groups (CG) were defined: CG1: CG_B – semester of birth; CG2: CG_B – trimester of birth; CG3: CG1 – SC; CG4: CG2 – SC, where CG_B: herd – year of birth – management group at each age. Four analytical models were defined: M1: Weight = α + CG1 + SC + DAC + ε; M2: Weight = α + CG2 + SC + DAC + ε; M3: Weight = α + CG3 + DAC + ε; M4: Weight = α + CG4 + DAC + ε; where, α = constant; SC = sex of calf; DAC = class of cow age at calving, ε = random residual effect. (Co)variances were estimated using a derivative-free restricted maximum likelihood procedure, considering CG fixed (F) or random (R). Estimates of additive direct and maternal genetic variance (σ^2_d, σ^2_m) and direct and maternal heritability (h^2_d, h^2_m) were larger in models with semester than with trimester of birth in CG (Table) likely due to greater variation among weights when the season of birth considered in CG was longer. These estimates were similar in models with and without sex of calf in CG. Models with random CG yielded higher estimates of σ^2_d, σ^2_m, h^2_d and h^2_m and lower estimates of residual variance (σ^2_e) than models with fixed CG.

Table 1. Estimates of direct and maternal (co)variances (kg^2) and heritabilities for adjusted / actual weights at 210 days of age in Nellore cattle

M	CG	σ^2_d	σ^2_m	σ^2_e	h^2_d	h^2_m

W40 Age of dam as phenotypic source of variation for body weight in Nellore beef cattle. D. A. Lino*[1,2], S. Tsuruta[1], I. Misztal[1], E. N. Martins[2], and L. O. C. Silva[3], *[1]University of Georgia, Athens, [2]State University of Maringa, Maringa, PR, Brazil, [3]Embrapa Gado de Corte, Campo Grande, MS, Brazil.*

Prior to the inclusion of effects in genetic evaluation models, tests should be carried out to quantify their influence. The objectives of this study were to verify the trend caused by age of dam (AOD) on weight and on phenotypic variance of weight in Nellore beef cattle from birth until 385 d. Data from the Brazilian Association of Zebu Breeders were used. A total of 2,915,879 body weight records from 1975 to 2009 were divided into 5 periods of measurement: birth weight (BW), weight taken at age 91 ± 59 d (W1), 188 ± 53 d (W2), 290 ± 86 d (W3), and 383 ± 82 d (W4). The AOD at measurement was divided into 11 categories, ranging from 4 to 14 years. A model separate for each weight considered AOD as a fixed effect. The adjusted phenotypic variance was obtained from the residual variance of the model separately for each AOD class. To compare the effect of AOD in all periods, the estimated values were standardized by phenotypic variance. The effect of AOD on BW, W1, W2, W3, and W4 explained 1.5, 7.3, 6.3, 4.4, and 3.1% of the differences in weight, respectively. When the standardized values were considered, the changes were basically the same for all periods. The AOD at measurement accounted for 8.9% of the phenotypic variance observed in BW with the highest variance at 4–7 years of age and declining variance outside of this range. For W1, the phenotypic variance was 468 at AOD = 4, increased to 483 at AOD = 7, and declined to 446 at AOD = 14. Therefore, the AOD was responsible for 8.8% of the changes in phenotypic variance for W1. For weight and phenotypic variance of weight, the BW showed a linear trend, whereas W1 showed a quadratic behavior. For W2, W3, and W4, the change in phenotypic variance ranged from 2.9 to 6.0%, without any special trend along AOD. The age of dam influences the phenotypic variance up to 130 d of age but less afterward.

Key words: age of dam, phenotypic variance, beef cattle

W41 Additive genetic variation of residual feed intake and its components in Nellore cattle. M. E. Zerlotti Mercadante*, A. C. Del Claro, S. F. Martins Bonilha, J. N. dos Santos Gonçalves Cyrillo, and R. H. Branco, *Instituto de Zootecnia, Sertãzinho, São Paulo, Brazil.*

The objective was to investigate the importance of additive genetic effects on residual feed intake (RFI) in Nellore cattle. Performance tests for individual feed intake were conducted at Instituto de Zootecnia, Sertãzinho-SP, Brazil. Records of 491 animals (247 males and 244 females), born from 2004 to 2009, progeny of 50 sires and 345 dams, were analyzed. The pedigree file included up to seventh generation of animals with records, and contained 1,652 animals, with 3 sires and 24 dams with own performance and progeny. The averages of test duration, initial age and BW, ADG, DMI and ME were 86 ± 23 d, 290 ± 43 d, 224 ± 53 kg, 0.923 ± 0.220 kg/d, 6.645 ± 1.169 kg/d and 2.151 ± 0.083 Mcal/kg. ADG was estimated as the slope of regression of BW on test d. Phenotypic RFI (RFI_P) was obtained as residuals of linear regression of DMI on MBW ((mid-test BW)$^{0.75}$) and ADG. The model included contemporary group (CG, n = 8), defined by birth yr and sex, as fixed effect and initial age as linear covariate. Variance components were estimated by REML. Genetic RFI (RFI_G) was obtained from linear regression of DMI on EBV of MBW and EBV of ADG, including also the effects of CG and age in the model. EBV were obtained in a 2-trait animal model analysis of MBW and ADG, including CG and age. The heritabilities of DMI, RFI_P and RFI_G were estimated in one-trait animal model analysis, including CG and age (only for DMI). EBV for RFI_P and RFI_G ranged from −0.329 to 0.490 kg/d (SD = 0.136) and from −0.410 to 0.435 kg/d (SD = 0.120), and the average of accuracy values were 0.573 and 0.491 for RFI_P and RFI_G EBV, respectively. The rank correlation between RFI_P and RFI_G EBV was 0.694.

Table 1. Variance components and heritability ± SE for ADG, MBW, DMI, RFI_P and RFI_G

Trait	σ^2 additive genetic	σ^2 phenotypic	h^2±SE
ADG	0.010	0.021	0.464±0.106
MBW	18.853	61.821	0.305±0.094
DMI	0.449	1.000	0.449±0.116
RFI_P	0.037	0.209	0.178±0.098
RFI_G	0.053	0.283	0.186±0.092

W42 Relationships among beef cattle temperament and tenderness traits using repeated performance records. T. T. Taxis*[1], W. R. Shafer[2], L. L. Berger[3], D. B. Faulkner[4], J. E. Beever[4], M. M. Rolf[1], D. L. Dow[1], J. F. Taylor[1], C. L. Lorenzen[1], and R. L. Weaber[1], *[1]University of Missouri, Columbia, [2]American Simmental Association, Bozeman, MT, [3]University of Nebraska, Lincoln, [4]University of Illinois, Urbana.*

Beef cattle temperament has been associated with a variety of performance measures, including steak tenderness. The American Simmental Association provided performance data and pedigree records to elucidate the relationship between temperament (exit velocity; EV) and tenderness (Warner-Bratzler shear force; WBSF) in *Bos taurus* breeds. EV were recorded on d 0 (EV1) and d 42 (EV2) of a feeding trial. The edited data set included 2,819 WBSF, 917 EV1 and 976 EV2 phenotypes in 176 contemporary groups (CG) with 13,418 pedigreed animals. Four different statistical models were analyzed. A trivariate and repeated records model were utilized to assess EV, and 2 bivariate models were utilized to assess WBSF. The trivariate animal model with fixed effects (CG, sire and dam breed composition) and a random animal effect was fit revealing a 0.99 genetic correlation between EV observations. A repeated records analysis of EV using the same fixed effects provided a better model fit ($P < 0.0001$; via likelihood ratio). Heritabilities were 0.19 (0.06) and 0.39 (0.08) for WBSF and EV, respectively, with a −0.10 (0.20) genetic correlation. Animals with multiple WBSF measurements, were analyzed using 2 bivariate models (both included WBSF and EV) to elucidate the effects of within animal WBSF variation. WBSF was analyzed using average peak shear force (APSF) and individual core values as repeated records. EV was analyzed using repeated records in both models. Heritability for WBSF using APSF was 0.06 (0.06) and 0.06 (0.05) from the repeated records model. Heritabilities for EV were unchanged in both models. Genetic correlations between WBSF and EV were −0.62 (0.47) and −0.63 (0.47). The analysis using individual core values provided a better model fit (p, 0.00001; via likelihood ratio). A whole genome association study using BovineSNP50 genotypes is planned for WBSF and EV.

W43 Carcass and meat palatability trends in cattle ranging from 100% Angus to 100% Brahman. M. A. Elzo*, D. D. Johnson, J. G. Wasdin, and J. D. Driver, *University of Florida, Gainesville.*

Carcass and meat palatability characteristics constitute key factors for the success of beef cattle operations. Consumers prefer meat that has desirable levels of tenderness, marbling, juiciness, and flavor. Cattle in the Southern region of the US contain some Brahman to enable them to cope with hot and humid climatic conditions, thus decreasing meat tenderness and affecting the desirability of these animals for branded beef products. The objective of this research was to estimate additive genetic differences between Angus (A) and Brahman (B), heterosis, and least squares means (LSM) for 6 carcass and 6 meat palatability traits for groups of cattle ranging from 100% Angus (A) to 100% Brahman. Carcass traits were hot carcass weight (HCW), dressing percent (DP), ribeye area (REA), fat over the ribeye (FOE), kidney, pelvic and heart fat (KPH), and marbling score (MAB). Meat palatability traits were Warner-Bratzler shear force (WBSF), and tenderness (TEND), connective tissue (CTI), juiciness (JUIC), flavor (FLAV), and off-flavor (OFLAV) scores. Data came from 1367 steers from the Angus-Brahman multibreed herd of the University of Florida collected from 1989 to 2009. Estimates of additive genetic breed differences indicated that B carcasses had higher DP ($P < 0.0001$), lower MAR ($P < 0.0001$), smaller REA ($P < 0.0001$), and less FOE ($P < 0.0001$) than A carcasses. Brahman beef was also tougher ($P < 0.0001$), had more connective tissue ($P < 0.0001$), and it was less juicy ($P < 0.001$) than A beef. Heterosis increased HCW ($P < 0.0001$), DP ($P < 0.017$), REA ($P < 0.0001$), FOE ($P < 0.0001$), and KPH ($P < 0.01$) in crossbred steers. The LSM for HCW, REA, FOE, and KPH increased from A to 1/2 A 1/2 B, and then they decreased toward B. The LSM for MAB, TEND, CTI, and JUIC decreased whereas the LSM for WBSF increased from A to B. Results indicated that crossbred steers with percentage Brahman up to 50% showed limited negative impact on meat quality while maximizing meat yield due to heterosis.

Key words: carcass, meat quality, multibreed

W44 Role of cytoplasmic inheritance on preweaning traits in a closed breeding nucleus Angus herd. J. A. Carrillo* and F. Siewerdt, *University of Maryland, College Park.*

The importance of cytoplasmic inheritance was investigated in an elite Angus herd that has been closed to outside breeding for 70 years. Historical data included full pedigree information on 10,838 animals and phenotypic information (up to 7,986 animals) on body weights collected at birth (WB) and weaning, hock length (HL) at birth and scrotal circumference at weaning (SC). Adjusted body weights to 205 d (W205) were obtained and individual average daily gain from birth to 205 d was also computed. Each animal was traced back to one of 18 founder cows, all from distinct female lineages. Data were analyzed with an animal model that included contemporary group and the random effects of animal, maternal, permanent environment, and cytoplasmic line. The ratios of cytoplasmic variances to phenotypic variances ranged from 0.000 ± 0.002 (WB) to 0.005 ± 0.006 (SC) indicating a very small participation in the determination of genetic and phenotypic variability. In contrast, the much higher genetic maternal variances had ratios to the phenotypic variances ranging from 0.044 ± 0.046 (SC) to 0.156 ± 0.029 (WB) and were typically 50 times higher than the cytoplasmic variances. The observed ranges for cytoplasmic breeding values (BV) for W205, SC, and HL were of 2.62kg, 0.252cm, and 0.053cm, respectively, suggesting that a small but not negligible amount of genetic gain could be amassed by including cytoplasmic BV in the selection index. Selection indexes were computed for all traits individually, with or without inclusion of the cytoplasmic BV. A 20-fold weight on the desired genetic gain was placed on the cytoplasmic BV compared with the direct and maternal BV. Inclusion of the cytoplasmic information in the index reduced the predicted genetic gain in direct and maternal BV by less than 1.5% indicating that this small reduction in genetic gains could be compensated by gains in cytoplasmic BV. Selection for cytoplasmic effects can lead to increased inbreeding by focusing on few maternal lines of animals. Rapid exhaustion of what little cytoplasmic genetic variation is present will happen, unless new variation is created by mutations.

Key words: animal model, quantitative genetics, beef cattle

W45 Heritability and effect of breed and diet on complementary feed utilization traits in Simmental, Angus and crossbred steers. N. V. L. Serão*[1], J. E. Beever[1], D. B. Faulkner[1], M. Pérez-Enciso[2], and S. L. Rodríguez-Zas[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Universitat Autònoma de Barcelona, Barcelona, Catalonia, Spain.*

Phenotypic data from 1,488 steers were used to estimate genetic parameters for average daily gain (ADG), dry matter intake (DMI), gain to feed (GF), residual feed intake (RFI), residual average daily gain (RADG), carcass backfat (BF) and rib-eye area (REA). RADG

was adjusted for DMI and mid-test metabolic weight (MMW), whereas RFI was adjusted for ADG and MMW. All analyzes were carried out using Qxpak v 5.03, with an animal model including the pedigree (3,786 animals), the fixed effects of breed (5 levels; Angus (AN), 3/4 AN, 1/2 AN 1/2 Simmental (SM), 3/4 SM and SM), diet (5 levels), breed- diet interaction, days on feed (covariate) and the random effect of harvest group within contemporary group (32 levels). The heritabilities were estimated using maximum likelihood and fixed effects were considered significant at 0.05. ADG presented low heritability estimate ($h^2 < 0.20$), whereas GF, RADG and REA showed moderate estimates ($0.20 < h^2 < 0.40$) and DMI, RFI and BF presented high heritabilities ($h^2 > 0.40$). Breed-diet interaction was significant for BF, REA and RFI. The main effect of diet was significant for RADG and GF, and the main effect of breed was significant for ADG and DMI. The heritability of RADG ($h^2 = 0.30$) was higher than that for ADG ($h^2 = 0.16$). This suggests that genetic selection for RADG would result in higher genetic improvement than for ADG in this population, since the adjustments for DMI and MMW decrease the phenotypic variation of the trait. In contrast, RFI showed a similar heritability to DMI, respectively $h^2 = 0.43$ and $h^2 = 0.42$, suggesting that the adjustment for ADG and MMW did not offer major gains in estimating the heritability in this population. Although the selection for either trait may result in similar genetic gains, RFI represent a more suitable indicator of feed efficiency than DMI. Finally, the estimates for RADG and RFI indicate that, for the population studied, selection based on intake-based indicators is expected to result in superior genetic improvement for feed utilization than selection based on gain-based indicators with lower undesirable increase in body weight.

Key words: genetic parameters, RADG, RFI

W46 Comparison of body weight genetic evaluation accuracy by random regression with splines and multi-trait model in Limousins. M. Lukaszewicz*[1,2], I. Misztal[1], A. H. Nelson[1], J. P. Sánchez[1], and J. K. Bertrand[1], *[1]University of Georgia, Athens, [2]Institute of Genetics and Animal Breeding, Jastrzebiec, Poland.*

This study compared multibreed EPDs obtained by multi-trait (MT) and random regression (RRS) models. RRS allows using weight records outside standard ranges in MT but EPDs by RRS may contain artifacts. The data on birth (BW), weaning (WW), and yearling (YW) weights were provided by the North American Limousin Foundation. After editing, data comprised 1,382,305 BW; 986,777 WW; and 412,977 YW RRS-analysis-ready records. Both models fit direct and maternal additive genetic, contemporary group, animal's age, direct and maternal heterosis effects, and direct and maternal additive genetic means of the breed effects. The RRS fit additionally the direct permanent environment effect. WW and YW record numbers in MT were 94% and 93% of those in RRS. The validity of using RRS was assessed by correlating EPDs from both methods. Correlations between BW direct EPDs, computed on all animals, were 0.99 in both sexes. They dropped to 0.95–0.97 for the later weights. For maternal EPDs the correlations for BW and WW were 0.95 and 0.90 in bulls and 0.96 and 0.92 in cows. In bulls with the RRS EPD accuracy > 0.6 for given trait, the correlations between BW, WW, and YW EPDs for direct effect increased to 1, 0.98, and 0.98 while those between maternal EPDs to 0.99 and 0.96, for BW and WW. For bulls with accuracy < 0.6 under MT and > 0.6 under RRS (for each trait at a time) the correlations between direct EPDs were 0.99, 0.97, and 0.97. For cows with accuracy < 0.45 under MT and > 0.45 under RRS (for each trait at a time) the correlations between direct EPDs were 0.99, 0.93 and 0.91 for BW, WW, and YW while between maternal EPDs 0.71 and 0.86, for BW and WW. When few additional records are available for RRS, RRS and MT provide nearly identical EPD for most animals. Most changes are for animals with additional information beyond that possible with MT.

W47 Growth curves for buffaloes (*Bubalus bubalis*) using random regression mixed models with different structures of residual variances. D. M. Bolivar[1,2], M. F. Cerón-Muñoz[2], M. A. Elzo*[3], E. J. Ramirez[2], and D. A. Agudelo[4], *[1]National University of Colombia, Medellin, Colombia, [2]University of Antioquia, Medellin, Colombia, [3]University of Florida, Gainesville, [4]Lasallian University Corporation, Caldas, Colombia.*

The objective of this study was to analyze buffalo growth based on body weight (BW), Longissimus dorsi muscle area (AOL), and fat deposition over the hip (FOH) using random regression mixed models of first (FORRM) and second order (SORRM), each with 9 different variance structures. Ten measurements for each trait were taken on 26 animals during the first performance test (93 d test plus 23 d adaptation period) developed for buffaloes in Colombia. Computations were performed using the lme procedure of the nlme library of program R. Preliminary analyses determined that an SORRM was appropriate for BW and FOH and an FORRM was suitable for AOL. The maximum likelihood ratio (MLR), the Akaike information criterion (AIC) and the Bayesian information criterion (BIC) were used to compare models. The best models were an SORRM with homogeneous residual variances for BW, an FORRM with heterogeneous animal residual variances for AOL, and an SORRM with heterogeneous residual variances among farms times an exponential function of age for FOH. Heterogeneity of residual variances was likely due to environmental differences among farms, and to genetic differences among buffaloes not accounted for by FORRM and SORRM. Fixed intercepts with the best models for each trait were 227 ± 7.90 kg for BW, 34.82 ± 0.99 cm2 for AOL, and 4.19 ± 0.229 mm for FOH. Fixe linear regression coefficients were 1.289 ± 0.073 g/d for BW, 0.0584 ± 0.0042 cm2/d for AOL, and 0.0035 ± 0.0032 mm/d for FOH. The fixed quadratic regression coefficient indicated that BW rate decreased after one year of age whereas FOH rate continued to increase until the end of the test. Random regression coefficients suggested that there was considerable variability among trait curves for individual buffaloes, particularly for FOH.

W48 Estimates of genetic and phenotypic trends for body weight traits of Zandi sheep obtained by a univariate and multivariate animal model analysis. H. Mohammadi* and M. Moradi Shahrebabak, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The objective of the present study was to estimate genetic changes for body weights at different ages in Zandi sheep. Traits included were birth weight (BW, n = 8366), 3 mo weight (3MW, n = 6360), 6 mo weight (6MW, n = 4350), 9 mo weight (9MW, n = 2890), and yearling weight (YW, n = 2430). The data and pedigree information used in the current research were collected at the Breeding Station of Zandi sheep (Tehran province, Iran) during 1991–2007. Variance components were estimated from a 5-trait analysis, based on the best model of analysis

for each trait, using the ASReml program. The final model included the fixed effects of year-season, sex of lamb and parity of dam, birth type, and the linear covariate effect of age of dam and random direct and maternal genetic effects. The most suitable model was determined based on likelihood ratio tests for each trait. Breeding values of individual animals were predicted with Best Linear Unbiased Prediction (BLUP) methodology and genetic trends were obtained by regressing the means of predicted breeding values on year of birth for each trait. Direct genetic trends were positive and significant ($P < 0.05$). The additive genetic trends for BW, WW, 6MW, 9MW, and YW using univariate and multivariate analysis were estimated 2.1 and 3.9, 98.5 and 106.28, 89.63 and 95.47, 26.35 and 32.22, 41.53 and 49.83 g/year, respectively. Also, maternal genetic trend for BW was 5.40 and 4.92 g/year. The phenotypic trends for traits were estimated −8.5 and −8.9, −422.2 and −427.2, −90.60 and 90.53, −357.1 and −359.2, −133.32 and −134.31 g/year, respectively. The environmental trends for traits were −11 and −11.5, −444 and −447, −387 and −395, −212 and −215, −296 and −302 g/year, respectively. The results showed that improvement of body weights of Zandi sheep seems feasible in selection programs.

Key words: Zandi sheep, growth traits, genetic and phenotypic trends

W49 Genetic and phenotypic correlations between reproduction and production traits in Zandi sheep. H. Mohammadi* and M. Moradi Shahrebabak, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The objective of this study was to estimate heritabilities and genetic and phenotypic correlations among production and reproduction traits over 4 parities in the Zandi sheep to formulate a breeding plan for this breed. Genetic and phenotypic correlations were estimated between production and reproduction traits in a flock of Zandi sheep reared at the Khojir Research Station by ASREML procedures using bivariate mixed models, included fixed effects (year of mating and age of ewe; for BW traits, additionally sex of lamb; for weaning weight (WW), additionally number of d to weaning as a covariate) and random effects of animal direct genetic, permanent environment (repeated records of ewes) and residual. Production traits investigated were birth weight (BW) and WW, and reproduction traits, including 2 basic and 2 composite traits. The basic traits were conception rate (CR) and total number of lamb born (NLB).The composite traits were total litter weight at birth per ewe lambing (TLWB/EL) and total litter weight at weaning per ewe lambing (TLWW/EL). Direct additive estimates of heritability (h2 ± S.E.) were: 0.24 ± 0.03; 0.26 ± 0.02; 0.05 ± 0.02; 0.14 ± 0.02; 0.11 ± 0.02; 0.10 ± 0.02; for BW, WW, CR, NLB, TLWB/EL and TLWW/EL, respectively. Estimates of the direct genetic and phenotypic correlations between the reproductive and growth traits are shown in Table 1. Genetic correlation estimates between the investigated traits ranged from −0.05 for BW–CR to 0.45 for WW–TLWW/EL. Phenotypic correlations ranged from 0.03 for BW–CR to 0.19 for WW–TLWW/EL. This study provides estimates of genetic correlations that will improve the accuracy of genetic evaluation and prediction of the outcomes from breeding programs for meat objective that include reproduction.

Table 1. Estimates of genetic and phenotypic correlations (±SE) between reproductive and growth traits in Zandi ewe

Genetic correlations	CR	NLB	TLWB/EL	TLWW/EL
BW	–0.05 ± 0.07	0.24 ± 0.10	0.35 ± 0.06	0.13 ± 0.06
WW	0.10 ± 0.04	0.16 ± 0.08	0.23 ± 0.05	0.45 ± 0.07
Phenotypic correlations				
BW	0.03 ± 0.02	0.07 ± 0.01	0.09 ± 0.05	0.05 ± 0.06
WW	0.07 ± 0.02	0.03 ± 0.02	0.09 ± 0.06	0.19 ± 0.06

W50 Estimation of genetic trend for some reproductive traits in Zandi sheep breed. H. Mohammadi* and M. Moradi Shahrebabak, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

Knowledge of genetic parameters and trends is necessary to optimize animal breeding schemes. An estimate of the genetic progress achieved by selection programs is necessary to describe the genetic changes progress, to assess the benefits of the selection program and to introduce necessary adjustments. The aim of this study was to estimate genetic parameters and genetic trends of reproductive traits. Genetic parameters from both single-trait and bivariate analyses for reproductive traits were estimated using REML with animal models for Zandi sheep from data collected from 1991 to 2007 at the Breeding Station of Zandi sheep in Tehran province, Iran. Traits included were litter size (LS, n = 5025), litter mean weight per lamb born (LMWLB, n = 4338), litter mean weight per lamb weaned (LMWLW, n = 4172), total litter weight at birth (TLWB, n = 4338) and total litter weight at weaning (TLWW, n = 4172). Estimates of heritability with ASREML software analyses were 0.05 for LS, 0.13 for LMWLB, 0.08 for LMWLB, 0.11 for TLWB, and 0.10 for TLWW. The genetic trends were calculated by regression of the average predicted genetic values per year for each trait versus the dam year of birth. Estimated genetic trends of LS, LMWLB, LMWLW, TLWB and TLWW were −0.001, 0.02, 0.013, 0.023 and 0.26, respectively. From 1991 to 2007, average estimates of breeding values from the multiple-trait analysis increased at a greater rate than average estimates from the single-trait analysis. The rate of yearly genetic improvement was very small for LS, LMWLB, LMWLW, and TLWB traits. However, the reproductive traits of Zandi breed may still be improved by selection. Positive genetic correlations between reproductive traits and growth traits showed that simultaneous genetic improvement of the traits may be possible.

Key words: genetic trends, reproductive traits, Zandi sheep

W51 Estimates of genetic and phenotypic trends for body weight traits of Zel sheep obtained by univariate and multivariate animal model analysis. H. Mohammadi* and M. Sadeghi, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The objective of the present study was to estimate genetic trends for body weight traits at different ages in Zel sheep. Traits included were birth weight (n = 10723), 3 mo weight (n = 8108) and 6 mo weight (n = 5236). The data and pedigree information used in the current research were collected by Jahad-e-Keshavarzi organization (Mazandaran province, Iran) during 1994–2009. Variance components were

estimated from a 3-trait analysis, based on the best model of analysis for each trait, using the ASREML software. The final model included the fixed class effects of year-season, sex of lamb and parity of dam, birth type, the linear covariate effect of age of dam and random direct and maternal genetic effects. The most suitable model was determined based on likelihood ratio tests for each trait. Breeding values of individual animals were predicted with Best Linear Unbiased Prediction (BLUP) methodology and genetic trends were obtained by regressing the means of predicted breeding values on year of birth for each trait. Direct genetic trends were positive and significant for BW, WW and 6MW ($P < 0.05$). The direct genetic trends for BW, WW, and 6MW using univariate and multivariate analysis were estimated 1.90 ± 0.07 and 2.53 ± 1.1, 98.5 ± 10.4 and 105.38 ± 25.2, 73.23 ± 21.2 and 78.46 ± 33.40 g per year, respectively. The maternal genetic trend for BW was 2.94 ± 1.21 and 3.07 ± 2.49 g per year. The phenotypic trends for traits were estimated −6.5 ± 22.60 and −6.9 ± 22.50,-152.2 ± 251 and −147.2 ± 239, −100.60 ± 48 and 100.53 ± 45 g per year, respectively. The environmental trends, measured as the difference between phenotypic and genetic trends, were −21.1 ± 0.02 and −21.5 ± 0.05, −244 ± 16 and −247 ± 19, −287 ± 30 and −295 ± 26 g per year, respectively. Negative phenotypic and environmental trends could be due to bad environmental conditions, especially to nutrition of the sheep in an unsuitable climate during the study years.

Key words: Zel sheep, growth traits, genetic and phenotypic trends

Breeding and Genetics: Genomic Selection and Whole-Genome Association

W52 Accuracy and bias of multiple-trait genomic evaluations for linear type traits in US Holsteins. S. Tsuruta*[1], I. Misztal[1], I. Aguilar[2], and T. Lawlor[3], *[1]University of Georgia, Athens, [2]Instituto Nacional de Investigación Agropecuaria, La Piedras, Canelones, Uruguay, [3]Holstein Association USA Inc., Brattleboro, VT.*

The objectives of this study were to conduct multiple-trait (MT) genomic evaluations and to compare bias and accuracy of genomic breeding values (GBV) with those from single-trait (ST) genomic evaluations, using different genomic relationship matrices (G). Genomic evaluations were conducted for 18 linear type traits of US Holsteins using genomic and phenotypic combined data. For each of 6931 bulls, 38,416 SNP markers were used as genomic information. A single-step approach was used to predict GBV with G that assumed various allele frequencies: equal (p = q = 0.5) (GE), base (GB), current (GC), and current with scaled G (GCS). Data sets contained 8,865,120 records for 5,657,787 cows from 2009 data and 7,715,925 records for 4,813,726 cows from 2004 data. Coefficients of determination (R^2) and regressions (δ) of 2004 GBV on 2009 daughter deviations were calculated, as statistics of accuracy and bias, respectively, for 1307 young bulls. Parent averages (PA) were also calculated for 2004 data with no genomic information. With MT (ST) models, average R^2 (%) were 20.5 (18.6) and 37.9 (34.6), 37.3 (34.1), 35.9 (34.2) and 37.7 (34.5), and average δ (× 100) were 76.7 (77.3) and 79.8 (79.4), 76.3 (75.0), 74.7 (73.8) and 76.7 (76.2), for PA and for GBV with GE, GB, GC and GCS, respectively. When the weight for the inverse of the numerator relationship matrix for genotyped animals was reduced to 0.7, R^2 remained almost identical while the average δ increased to 92.7 with GE, 90.7 with GB, 89.2 with GC, and 91.9 with GCS for MT models. The ST models required a stricter convergence criterion of 10^{-14} than that of 10^{-11} for MT models to achieve the same accuracy. The GBV obtained from MT models are more accurate than those from ST models. Modifying the weight for pedigree relationships of genotyped animals reduces bias in GBV. Multiple trait large-scale genomic evaluation is computationally feasible.

Key words: genomic evaluation, linear type trait, US Holstein

W53 Genomic imputation and evaluation using 342 high-density Holstein genotypes. P. M. VanRaden[1], D. J. Null*[1], G. R. Wiggans[1], T. S. Sonstegard[2], and E. E. Connor[2], *[1]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD, [2]Bovine Functional Genomics Laboratory, ARS, USDA, Beltsville, MD.*

Genomic evaluations for 73,749 Holsteins were computed using 636,967 of the 777,000 markers on the Illumina high density (HD) chip. Observed data included 342 animals with HD genotypes, 54,676 animals with 42,503 marker (50K) genotypes, 17,371 animals with 2,614 marker (3K) genotypes, and 1,360 nongenotyped dams (0K) with >90% of haplotypes imputable from progeny. The HD genotypes were from 180 influential sires, 138 Beltsville research cows, and 24 other females. Percentages of correctly imputed genotypes were estimated using an example simulated chromosome for this same population structure with 1% of genotypes missing and 0.02% incorrect initially from each chip. Over all animals, 94.4% of genotypes were missing initially. After imputation of missing markers, 99.9% of genotypes were correct from HD, 98.0% from 50K, 88.4% from 3K, and 93.8% from 0K genotypes. These imputation rates with version 2 of program findhap.f90 are several percent higher than with version 1. Version 2 begins with long segments to improve haplotype matches for close relatives and ends with short segments to detect matches from more remote ancestors instead of choosing just one optimal segment length. Evaluations were tested using imputation of actual genotypes and August 2007 phenotypes to predict deregressed evaluations of bulls proven after August 2007. For 29 traits tested, estimated genomic reliability averaged 54.3% using 636,967 markers vs. 54.8% using 42,503 regressions vs. 29.9% from traditional parent average. Squared correlations with future data were higher for 10 traits and lower for 19 with HD than with 50K evaluations. The largest marker effects were located at very similar positions, but new markers from the HD chip often had larger effects than the best markers from the 50K chip. Results were less favorable than the 1.6% increase in reliability expected from simulation, but more animals with HD genotypes will improve imputation and reliability. Also, multi-breed evaluation could produce larger gains than the single-breed evaluation investigated here.

Key words: genomic evaluation, imputation, marker density

W54 Genomic evaluation of Angus-Brahman multibreed cattle for feed efficiency and postweaning growth using the Illumina 3k chip. M. A. Elzo*[1], G. C. Lamb[2], D. D. Johnson[1], M. G. Thomas[3], I. Misztal[4], D. O. Rae[1], J. G. Wasdin[1], and J. D. Driver[1], *[1]University of Florida, Gainesville, [2]North Florida Research and Education Center, Marianna, [3]New Mexico State University, Las Cruces, [4]University of Georgia, Athens.*

Lower density chips provide an affordable alternative to evaluate animals and characterize traits. The objective of this research was to evaluate 620 bulls, steers, and heifers ranging from 100% Angus to 100% Brahman (B) using phenotypes from for 4 postweaning feed efficiency and growth traits, pedigree, and SNP genotypes from 2900 loci (Illumina3k chip). Traits were residual feed intake (RFI), daily feed intake (DFI), feed conversion ratio (FCR), and weight gain (WG). Data was collected in a GrowSafe automated feeding facility from 2006 to 2010. Calves remained in pens for the 21-d pre-trial and 70-d trial periods. Animals were assigned to pens by sire group and sex. Concentrate consisted of cottonseed hulls, corn, molasses, and a protein, vitamin, and mineral supplement. Calves were evaluated using a polygenic-genomic mixed model. Fixed effects were contemporary group (year-pen), age of dam, sex of calf, age of calf, B fraction of calf, and heterozygosity of calf. Random effects were animal polygenic (AP; mean zero; variance = A*Vg; A = additive relationship matrix, Vg = additive genetic variance), additive SNP (AS; mean zero; variance = additive SNP variance), and residual effects (mean zero, common residual variance). Variance components and heritabilities were estimated using option VCE (Markov Chain Monte Carlo) of program GS3. Heritabilities were 0.18 for RFI, 0.30 for DFI, 0.16 for FCR, and 0.33 for PWG. The fraction of the additive genetic variance explained by the 2900 markers of the Illumina3k chip was 15% for RFI, 11% for DFI, 37% for FCR, and 20% for PWG. The AS, AP, and TA EBV for all traits tended to decrease as B fraction increased, suggesting that high percent B calves were genetically more efficient (lower RFI), but had lower WG.

Key words: feed efficiency, genomic, multibreed

W55 A neural network approach for association between a low-density whole genome SNP marker panel for 19 traits in beef

cattle. E. Hay*[1], H. Wang[1], X. Liu[1], B. Woodward[2], S. Bauck[2], and R. Rekaya[1], *[1]University of Georgia, Athens, [2]Merial Limited, Duluth, GA.*

The predictive ability of a low-density SNP panel derived from the Illumina Bovine SNP50 and developed for marbling, back fat, carcass weight, rib eye area, yearling weight, and heifer pregnancy rate was evaluated for 19 traits (residual feed, intake, dry matter intake, birth weight, weaning weight, docility, milk yield, average daily gain, yearling weight, carcass weight, marbling scores, rib eye area, back fat, mature weight and height, scrotal circumference, calving ease direct, calving ease maternal, heifer pregnancy). Data consisted of the genotypes of 2,245 Angus animals and their corresponding EPDs with missing rate (on phenotypes) ranging from 0 to 54% (heifer pregnancy). Missing genotypes were replaced with the most likely genotype. Linear regression (LR) and Neural Network (NN) approaches were implemented and compared. For LR, a cross validation procedure was adopted where the data was randomly divided into 5 groups with equal size. In each one of the 5 replicates, 80% of the data was used for training and the remaining 20% for validation. For the NN approach, randomly 2/3 and 1/3 of the data were used for training and validation, respectively. The process was replicated 5 times. A NN is an artificial system of massively interconnected neurons. The network architectures and the learning algorithm define the manner in which the neurons are related and structured. In this study, a feed-forward NN with one hidden layer was used. The parameters of the NN such as the number of neurons in the hidden layer, and learning rate were set heuristically. For both approaches, the lowest correlation between true and estimated breeding values was for docility and (0.52) and scrotal circumference (0.57). The highest accuracy was for yearling weight (0.82 for LR and 0.83 for NN). Across the 19 traits, the differences in performance between LR and NN range from 2 to 5% with superiority for the NN approach, except for weaning weight where the LR was slightly superior (0.27%), the superiority of the NN approach could be due to its ability to intrinsically accommodate the non-linear relationship between variables.

Key words: SNP, whole genome, beef cattle

W56 Whole genome association analyses for ultrasound and carcass merit traits in beef cattle. H. Li*, Z. Wang, P. Stothard, and S. S. Moore, *University of Alberta, Edmonton, Alberta, Canada.*

Carcass merit traits in beef cattle are of high interest in the beef industry and are quantitative in nature. The goal of this study was to identify genetic markers and potential candidate genes associated with meat quality traits in beef cattle. A genome-wide association study (GWAS) for 40,809 single-nucleotide polymorphism (SNP) markers using Bayesian methods was conducted in a total of 922 steers. Five carcass merit traits including carcass weight (CWT), carcass average backfat (CABF), carcass rib eye area (CREA), carcass grade fat (CGF), carcass lean meat yield (CLMY) and 3 ultrasound measurement traits including ultrasound marbling (UMAR), ultrasound backfat (UBF) and ultrasound ribeye area (UREA) were analyzed. The proportion of phenotypic variance explained by markers was 0.50 for CWT, 0.25 for CABF, 0.37 for CREA, 0.27 for CGF, 0.24 for CLMY, 0.39 for UBF, 0.63 for UMAR and 0.37 for UREA. SNPs with large substitution effects indicated that major genes exist for meat quality traits in beef cattle. For instance, the largest SNP on BTA6 explained 6.67% of the phenotypic variance for CWT. Many of the large effect SNPs coincided with previously identified QTL. Positional candidate genes (e.g., 49 for CWT) were identified within 1 Mbp windows flanking the top 10 SNP markers. Potential functional genes (e.g., *NCAPG*, *MED28* on BTA6 and *LYN* on BTA14 for CWT) were selected from these positional genes based on predicted and known functional information associated with the genes or their orthologs. Overall, this WGAS provides a list of markers and potential functional candidate genes associated with beef carcass merit traits that could be used to improve beef production and quality via marker-assisted selection.

Key words: beef cattle, genome-wide association study, carcass merit

W57 Large-scale SNP association analyses for somatic cell score in Canadian Holstein cattle. H. Li*[1], Z. Wang[1], F. S. Schenkel[2], M. Sargolzaei[3], S. S. Moore[1], and P. Stothard[1], *[1]University of Alberta, Edmonton, Alberta, Canada, [2]University of Guelph, Guelph, Ontario, Canada, [3]L'Alliance Boviteq, Saint-Hyacinthe, Québec, Canada.*

Genetic studies in dairy cattle have found that selection for higher milk production brings with it slightly higher rates of mastitis. Mastitis is the most common and most costly disease of dairy cattle and there are no affordable or prevailing methods for directly measuring mastitis. Somatic cell score (SCS) is an excellent indirect trait for selection for mastitis as the genetic correlation between SCS and mastitis is 60% to 80%. The goal of this study was to identify genetic markers and potential candidate genes associated with SCS in dairy cattle. A genome-wide association study for 29,552 single-nucleotide polymorphism (SNP) markers was conducted in a total of 647 Canadian Holstein bulls. The analyses used a combination of Bayesian models to predict individual SNP effects. The proportion of the variance of the bulls' deregressed SCS EBVs explained by markers was 0.76. SNPs with large substitution effects indicated that major genes exist for SCS. The10 SNPs with largest effects were on BTA6, 14, 21, 18, and 19. Many of the large-effect SNPs coincided with previously identified QTL. One hundred and 32 positional candidate genes were identified within 2 Mbp genomic regions flanking the top 10 SNPs. Potential functional genes (e.g., GC and NPFFR2 on BTA6, LY6D on BTA14, MFGE8 and AP3S2 on BTA21, and FOXL1, CYLD and NOD2 on BTA18) were selected from these positional genes based on predicted and known functional information associated with the genes or their orthologs. Functional annotation revealed that these genes are involved in the regulation of immune system activity and inflammation. For instance, the CYLD gene on BTA18 is a crucial negative regulator of inflammation and subsequent immune response in antibacterial defense. This finding reinforces the role of the genetic control on immune response to bacterial infections. The list of SNPs and potential functional candidate genes may prove useful for prevention of mastitis via marker-assisted selection.

W58 Comparison of selective genotyping strategies for prediction of breeding values in a population undergoing selection. A. A. Boligon*[1,2], N. Long[2], L. G. Albuquerque[1], K. A. Weigel[3], D. Gianola[2,3], and G. J. M. Rosa[2], *[1]Department of Animal Sciences, Sao Paulo State University, Jaboticabal, SP, Brazil, [2]Department of Animal Sciences, University of Wisconsin, Madison, [3]Department of Dairy Science, University of Wisconsin, Madison.*

A simulation study was used to evaluate the predictive ability of genomic selection under different strategies of selective genotyping. The genome consisted of 10 chromosomes, each with 202 markers and 100 QTLs evenly spread across 100 cM. After 5,000 generations of random mating with an effective population size of 100 (50 males

and 50 females), a reference population (G0) was generated by a full factorial mating between the 50 males and 50 females. In G0 animals were selected based on their phenotypes (highest phenotypic values) or at random, at different selection intensities, to produce generation G1. Five genotyping strategies were considered to choose 500 animals in G0 as a training set: random sampling (R); highest phenotypic values (H); lowest phenotypic values (L); extreme (low and high) phenotypic values (E); and subset of less related animals (I). The number of individuals in G0 and G1 was fixed at 2,500, and heritability was set to 0.10, 0.25 and 0.50. Additionally, all 5 genotyping strategies were applied also to an indicator trait with a genetic correlation of 0.5 with the target trait. The selective genotyping strategies were compared in terms of their ability of predicting the genetic values of the animals in G1, using a Bayesian Lasso model with all 2020 markers simultaneously. For all simulated traits, the lowest correlation between predicted and true breeding values (GEBV and TBV, respectively) was obtained when using the L genotyping strategy. For E, R, and I strategies, the correlation between GEBV and TBV became slightly higher as selection intensity decreased, and was largest when no selection occurred. These 3 strategies were better than H. In addition, the E, R, and I approaches had lower prediction mean squared errors (PMSE), followed by H and then by L. Overall, genotyping strategy E led to the best predictive ability of breeding values, indicating that animals with extreme phenotypic values in a reference population are the most informative when training genomic selection models.

Key words: Bayesian Lasso, molecular markers, predictive ability

W59 Estimating genomic breeding values in crossbred animals. E. H. Hay*, S. Smith, and R. Rekaya, *University of Georgia, Athens.*

For several livestock species and traits, the accuracies of predicted molecular breeding values are significantly higher than those obtained using parent averages and similar to those obtained for proven animals. These exciting results are unfortunately valid only when animals of the same breed are used in the training and validation sets. Unfortunately, in several applications admixture and crossbred animals are present making the training and validation sets very heterogeneous. Several studies have shown that using SNP estimates from pure breeds on other breeds or crossbred animals have little success. Alternative solutions using different mixture of animals (pure breeds, crossbreds) in training and validation sets were proposed with promising results in some cases. In this study a different approach is adopted where estimates of SNP effects in pure breeds are used to predict molecular breeding values in crossbred animals via the projection of these effects based on the percentage contribution of each pure breed in the crossbred individual. To test the performance of the proposed procedure, a simulation was conducted involving 2 breeds (A and B) with 1,500 animals each and 3 crosses 50/50, 75/25, and 25/75% of A and B breeds, respectively. Genotypes for a low density panel of 384 SNPs were also simulated for all animals without missing. Four analyses were conducted for estimating the SNP effects: 1) using only data from breed A, 2) using only data from breed B, 3) used data from breeds A and B, and 4) using data from A, B and the crossbreds. The results indicated that estimating SNP effects in analysis 4 led to the highest accuracies in crossbreds compared with the other 3 alternatives. However, when our approach was used based on the projection of the SNP estimates from analyses 1 and 2 as a function of the breed composition of the crossbreds, the best results were obtained. In fact, the accuracies in crossbreds increased by 28% compared with the results obtained in analysis 4. Based on this results, it seems that there a possibility of using pure bred estimates of SNP marker effects to predict the molecular breeding values of some crossbred animals.

W60 Accounting for new mutations in the genomic relationship matrix. J. Casellas*, *G2R, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

In this abstract, procedures for calculating the genomic relationship matrix are adapted to accommodate the occurrence of new mutations in the autosomal genome, i.e., the mutational genomic relationship (G_m) matrix. These algorithms derived from the original development by N. R. Wray for the additive numerator relationship matrix and accommodated genomic data from massive genotyping technologies. Assume as starting point g non-overlapping generations with n individuals per generation, all of them being genotyped for m single nucleotide polymorphism (SNP) markers spread across the whole autosomal genome. Moreover, assume $p_{k(l)}$ as the allelic frequency of the kth SNP in the lth generation and $\pi_{k(l)} = 2(p_{k(l)}\text{-}0.5)$ as a correcting factor to set mean values of allele effects to 0; the genotype of the ith individual at the kth SNP (γ_{ik}) was assumed as −1, 0 or 1 (i.e., homozygote, heterozygote and other homozygote, respectively). The general structure of the G_m matrix can be defined as $G_m = G_1 + G_2 + \ldots + G_g$, G_q being a genomic relationship matrix where individuals from generation q were treated as founders and the rows and columns linked to ancestors from previous generations were fixed to 0. To avoid the successive computation of all intermediate G_q matrices, the final mutational genomic relationship between individuals i and j (ρ_{ij}; i being older than j) reduced to the following expression $\rho_{ij} = \sum_{0>r>m}\sum_{0>s>g^*}[(\gamma_{ir} - \pi_{r(s)})(\gamma_{jr} - \pi_{r(s)})]/[2\sum_{0>q>m}p_{q(s)}(1 - p_{q(s)})]$, where g^* was the generation of origin of individual i. This matrix could be straightforwardly implemented within the structure of the genomic BLUP model in order to account for the genetic variability originated from young mutations.

Key words: genomic relationship, matrix, mutation

Dairy Foods: Cheese

W61 Effect of the use of rennet substitute on composition and yield of Minas Padrão cheese. J. Camisa[1], S. T. Di Cicco[1], K. Sivieri[2], P. C. B. Vianna*[1], and C. M. V. B. De Rensis[1], *[1]UNOPAR, Londrina, PR, Brazil, [2]UNESP, Araraquara, SP, Brazil.*

The objective of this research was to determine the effect of the use of rennet substitute on composition and yield of Minas Padrão cheese. Pasteurized and standardized milk (3.0% fat) was divided into 2 parts and prepared for each treatment varying the rennet: batch 1(BOV), commercial calf rennet (Chymosin and pepsin) and batch 2 (QPF), commercial rennet substitute Chy-max (Chymosin) and converted to cheese following traditional cheese making procedure. Milk, whey and cheese compositions were determined according official methods. Fat and protein recoveries and yield were determined. Differences on the rennet had no significant influence ($P > 0.05$) on chemical composition of the cheeses. Cheeses made with QPF and BOV showed no significant difference on fat and protein recoveries but QPF showed tendency for higher fat and protein recoveries. The use of Chy-max showed no significant influence on cheese actual yield. The adjusted yield also showed no significant difference with the use of Chy-max, although it had a tendency of increase yield with the rennet substitute.

Key words: calf rennet, chymosin, fat and protein recoveries

W62 Effects of gelation temperature and cutting time on the rheology and quality of curd made from buffalo milk: A comparison with cows' milk. I. Hussain*, J. Yan, A. E. Bell, and A. S. Grandison, *Department of Food and Nutritional Sciences, University of Reading, Reading, Berkshire, UK.*

The rheology and overall quality of curds made from buffalo and cows' milks were measured at gelation temperatures of 28, 34 and 39°C, and cutting times of 45, 60, 75 and 90 min after chymosin addition. The maximum curd firmness (G′) was obtained at a gelation temperature of 34°C in both types of bovine milk. The viscoelasticity (Tan δ) of both curds were increased with the increasing gelation temperature. The rennet coagulation time was reduced with increase of gelation temperature in both types of milk. Frequency sweep (0.1–10 Hz) was used 90 min after of chymosin addition, and both milk samples showed characteristics of weak viscoelastic gel systems. When both milk samples were subjected to shear stress to break the curd system at constant shear rate, 95 min after chymosin addition, the maximum yield stress was obtained at the gelation temperatures of 34°C and 28°C in buffalo and cows' curd respectively. The curd yield and moisture content were decreased with the increase in gelation temperature, while whey fat losses increased. The different cutting times slightly affected the yield and overall quality of curds made from both milk types. Two different curd drainage methods were used to compare the final overall curd quality.

Key words: rheology, gelation temperature, cutting time

W63 Cheese making properties of milk protein concentrate powder as affected by storage at high temperature. N. Rémillard and M. Britten*, *Food Research and Development Centre, Agriculture and Agri-Food Canada, St-Hyacinthe, (QC), Canada.*

Milk protein concentrate is extensively used to fortify cheese milk and increase cheese plant productivity. Long-term storage is known to alter the physicochemical properties of spray dried protein ingredients and might reduce their ability to produce high quality cheeses. To accelerate the storage effect, spray dried milk protein concentrate was stored at 50°C for up to 28 d. After various storage periods, the powder was dispersed in water and characterized for solubility, average particle size, rheology (flow curves) and kinetics of rennet gel formation. Model cheeses were also produced from milk standardized to 3.0% casein and 4.4% milk fat. The casein fraction originating from milk protein concentrate was fixed to 25%. Cheese composition, yield, protein and fat retention coefficients were determined. The solubility of milk protein concentrate decreased during storage at 50°C. Solubility loss averaged 1.8% per day. Casein micelles showed evidence of aggregation with average particle diameter increasing from 200 to 800 nm after 28 days. With increasing storage time, lower flow index and higher consistency were measured on milk protein dispersions. Rennet clotting time was increased and gelation rate was reduced after 7 days storage. These changes are explained by the adsorption of whey protein to casein micelles during storage. Long-term storage of milk protein concentrate slightly increased protein retention in cheese but also increased fat losses in whey, resulting in reduced cheese yield. This study suggests that during the storage of milk protein concentrate powders, mixed aggregates can form between casein micelles and whey proteins, which act as passive fillers and interfere with cheese matrix formation.

Key words: milk protein powder, storage, cheese

W64 Influence of different cheese matrix structures on lipid digestion in a simulated gastro-intestinal environment. S. Lamothe[1], M.-M. Corbeil[1], S. Turgeon[2], and M. Britten*[1], *[1]Food Research and Development Centre, Agriculture and Agri-Food Canada, St-Hyacinthe, (QC), Canada, [2]Dairy Research Centre STELA, Faculty of Agriculture and Food Science, Université Laval, Quebec, (QC), Canada.*

In normal individuals, lipid digestion and absorption are highly efficient processes but in diseases such as short gut, cystic fibrosis and pancreatic deficiencies, the bioavailability of lipids is greatly reduced. Hence, it could be relevant to increase bioavailability of ingested lipids. On the other hand, it could be advantageous to reduce lipid bioavailability for populations with high blood lipid levels and at a high risk of cardiovascular disease and obesity. The objective of this study was to compare the kinetics of fatty acids release and matrix degradation of different cheeses in a gastro-intestinal environment. The relation between physical characteristics of the cheeses (microstructure, texture) and matrix degradation during simulated digestion was also studied. Compositional analysis, rheological measurements and microstructure by SEM were measured on mild cheddar, aged cheddar, light cheddar and mozzarella cheese. Cheese (4.5 g) was cut into small cubes and submitted to simulated digestion. Matrix degradation index, free oil, free fatty acids and microstructure by optical microscopy were analyzed on chime after 5, 30, 60, 120, 150, 180 and 240 min digestion. Fatty acids release kinetics varied markedly according to the type of cheese. Mozzarella showed higher rate and extent of fatty acids release compared with other cheeses. This was paralleled by a greater rate of matrix degradation and amount of free oil. This result could be attributed to the higher moisture content of mozzarella cheese combined with the lower mineral content that weakened the protein network, as shown by a decrease of the firmness, elasticity and cohesiveness. Rate and concentration of fatty acids released from mild

cheddar was markedly lower compared with other cheeses. Limited degradation of the matrix was observed during the digestion. Higher mineral and lower moisture content of mild cheddar resulted in a more cohesive and firm matrix that made it more resistant to degradation. These results suggest that kinetic of fatty acids release is modulated by cheese matrix structure and rheological characteristics.

Key words: cheese, lipids, digestion

W65 Effects of high pressure processing on the chemical, functional and rheological properties of fresh Queso Fresco. D. L. Van Hekken*, M. H. Tunick, R. Kwoczak, and P. M. Tomasul, *USDA, ARS, Wyndmoor, PA, USA.*

Although Queso Fresco (QF), a popular high moisture Hispanic-style cheese sold in the US, is made from pasteurized milk it is subject to post pasteurization bacterial contamination. High pressure processing (HPP) of cheese is being considered because of its lethality to bacteria and potential to extend shelf life. However, little research has been performed to determine the effects of HPP on the functional and rheological properties of QF. Fresh QF, made from pasteurized homogenized milk without starter cultures, was cut into 45x45x150mm^3 blocks, double packaged in vacuum bags, and received the following HPP treatments: 200, 400, or 600 MPa for either 0, 5, 10, or 20 min; samples were stored at 4°C but were warmed to an internal temperature of either 22 or 40°C just before HPP treatment. Between d 6 and 10, samples were assayed for compositional, functional (meltability, initial color, and change in color after heating) and rheological (texture profile, torsion, and small oscillatory shear analyses) properties. The moisture content of the cheese was stable when QF was processed at 22°C but whey was forced out of the cheese matrix and accumulated in the packaging when processed at 40°C. HPP of QF at 22 or 40°C did not affect the non-melt property, the initial bright white color, or the changes in color after heating of QF. Compared with HPP at 22°C, conducting HPP at 40°C resulted in QF having higher values for hardness, chewiness, cohesiveness, shear stress and shear strain. Cheese samples had variable responses to HPP as pressure and length of treatment increased; springiness and cohesiveness were lowest for 600 MPa treatments, shear rigidity at the point of fracture was highest at 600 MPa, and HPP treatment had little effect on viscoelastic properties. High pressure processing altered the rheological properties of QF and, when conducted at 40°C, resulted in excessive wheying-off. As new safety intervention processes are explored, it is essential that the quality traits of the cheese be maintained.

Key words: cheese, high pressure processing, Queso Fresco

W66 ACE-inhibitory activity of commercial Wisconsin Cheddar cheeses during ripening. Y. Lu*, S. Govindasamy-Lucey, and J. Lucey, *University of Wisconsin - Madison.*

ACE-inhibitory (ACEI) peptides have been found in cheeses that have been reported to have anti-hypertensive properties. More types and concentrations of ACEI peptides may be produced with ripening. The objective of this study was to quantify the ACEI activity of Cheddar cheeses during ripening and determine the types of ACEI peptides formed in these cheeses of different ages. Water soluble extracts (WSE) were prepared from commercial Wisconsin Cheddar cheeses at ages of 3–6 d, 2, 6 and 9 mo, 1 and 2 years manufactured from the same plants. Centrifugation and ultra-filtration were used to remove fat and to fractionate the WSE into 3 molecular weight (MW) fractions: <3000 Da, 1000–3000 Da and <1000 Da, respectively. The fractions were subjected to HPLC-Tandem mass spectrometry (MS) and HPLC-electrospray ionization (ESI)-time-of-flight (TOF) MS to identify the ACEI peptides. The fractions with MW <3000 Da were used to conduct ACE-inhibitory activity tests. With age, higher ACEI activity was observed in the WSE of cheese and more types of ACEI peptides were also found. Some of the ACEI peptides, such as, IPP, VPP, EKDERF, VRYL and YPFPGPIPN were synthesized and quantified using HPLC-MS. The concentration of these ACEI peptides increased up to a certain ripening time. The maximum contents of IPP, VPP and EKDERF were 2.8, 7.4 and 5.3 mg/100g cheese, respectively and these levels were found in a 1-year Cheddar cheese. The maximum content of VRYL was found in a 2-year Cheddar cheese with amounts as high as 7.5 mg/100g cheese while the maximum content of YPFPGPIPN was 6.8 mg/100g cheese, which was found in a 6-mo Cheddar cheese. Aged Cheddar cheese is a good source of ACEI peptides and we predicted (based on previous clinical studies with these purified ACEI peptides) that a measurable anti-hypertensive effect in individual consumers would be expected if around ~100 g/day of this 1-year Cheddar cheese was consumed.

Key words: ACE-inhibitory activity, ACE-inhibitory peptides, mass spectrometry

W67 Influence of cooking temperature on the behavior of enterococci and the production of diacetyl in Coalho cheese. P. L. Mamede, J. M. Perri, A. Y. Kuaye, and W. H. Viotto*, *UNICAMP, Campinas, São Paulo, Brazil.*

Coalho cheese, a typical Brazilian cheese, is a semi-hard, white-colored cheese made from cow′s milk. Its elastic or rubbery texture and its low melting capacity are the principal attributes of Coalho cheese in the grilled form, but flavor also plays an important role. Bacteria of the genus *Enterococcus* were the predominant micro biota in Coalho cheeses that displayed a buttery flavor and aroma. The behavior of the *Enterococcus* genus during the different stages of cheese making, and the influence of cooking temperatures on the diacetyl/acetoin content of Coalho cheeses during refrigerated storage were evaluated. Three vats of cheese were made at different curd cooking temperatures (40, 45 and 50°C), using pasteurized milk previously standardized to casein: fat ratio = 0.83 ± 0.04. Cheese making was repeated on 3 different days, resulting in 9 experiments. Cheeses were stored at 4°C during 90 d. The milk pasteurization process was not effective to eliminate the enterococci. Both the steps of curd cooking and curd salting selectively favored the growth of this genus, known to tolerate high salt concentrations, resist high temperatures and lowering of the pH. The growth of *Enterococcus* was favored by curd cooking, but was not affected by variations in the cooking temperature. The *Enterococcus* population and the production of diacetyl/acetoin increased significantly with the storage time of the Coalho cheeses. The production of diacetyl/acetoin and the consequent development of a buttery flavor and aroma in Coalho cheese can be associated with the development of *Enterococcus*. The authors are grateful to CNPq (Brazilian Natl. Research Council) for their financial support.

Key words: cheese, *Enterococcus*, diacetyl

W68 Identification of the main esterase involved in lipolysis by *Propionibacterium freudenreichii*. M. C. Abeijón Mukdsi[3,4], H. Falentin[1,2], M.-B. Maillard[1,2], R. B. Medina[3,4], S. Parayre[1,2], S.-M. Deutsch[1,2], S. Lortal*[1,2], and A. Thierry[1,2], *[1]INRA, UMR1253, Rennes, France, [2]Agrocampus Ouest, Rennes, France, [3]CERELA-CONICET,*

Tucumán, Argentina, [4]Universidad Nacional de Tucumán, Tucumán, Argentina.

Free fatty acids are important flavor compounds in cheese, where they bring pungent, rancid, cheese, and fruity notes. They mainly result from the lipolytic activity of cheese microorganisms. *Propionibacterium freudenreichii*, a species used as a ripening culture in Swiss cheese, is the main agent of Swiss cheese lipolysis, with 96% of the free fatty acids released during the ripening resulting from *P. freudenreichii* activity [Dherbécourt et al. 2010 J. Agric. Food Chem. 58:11732-11739]. Our aim was to identify the most probable lipolytic esterase(s) involved in cheese lipolysis by *P. freudenreichii*. Since cheese lipolysis mainly occurs during *P. freudenreichii* growth, we focused our study on surface-exposed or secreted esterases. Out of the 12 putative esterases previously predicted from the genome sequence of *P. freudenreichii* CIRM-BIA1 [Dherbécourt et al. 2008 Microb. Cell Fact. 7], the lipolytic esterase PF#279 was shown to be secreted, and the putative esterase PF#774 was predicted to be anchored in the plasma membrane [Dherbécourt et al. 2010 Appl. Environ. Microbiol. 76:1181-1188]. To evaluate the respective role of these 2 proteins in lipolysis, *P. freudenreichii* CIRM-BIA1 was knocked out and then complemented for the genes encoding these 2 proteins, separately. Each of these genes was also overexpressed in *P. freudenreichii* CIRM-BIA1. All these genetically modified strains were assessed for their lipolytic activity during their growth in a medium containing an emulsion of milk fat. Results showed that the mutants inactivated for PF#279 showed a very low residual lipolytic activity, whereas inactivating or overexpressing PF#774 had no impact on lipolysis level. This study shows that only one lipolytic esterase, PF#279, is involved in milk fat hydrolysis in *P. freudenreichii* CIRM-BIA1 and is a key component in Swiss cheese lipolysis.

Key words: lipolysis, *Propionibacteria*, Swiss cheese

W69 Characteristics of the chemical composition and lipolysis during ripening of Emmental cheese. N. S. Oh*, Y. K. Shin, J. P. Ok, and Y. H. Park, *Institute of Dairy Food Research, Seoul Dairy Co-op., Institute of Dairy Food Research, Seoul Dairy Cooperative, Ansansi, Kyunggi, South Korea.*

The objective of this study was to characterize the lactate metabolism and lipolysis in Emmental cheese made of Korean raw milk throughout the ripening periods; 14 d at 10°C, 42 d at 23°C, and 30 d at 4°C. Emmental cheese was made using commercial starter culture with propionic acid bacteria (PAB) and without PAB as control at the pilot plant scale. The changes in contents of 5 organic acids, which were citric acid, lactic acid, formic acid, acetic acid and propionic acid, and individual free fatty acids (FFAs) were measured using HPLC/PDA and GC/FID. As a result of propionic fermentation by PAB, the concentration of acetic and propionic acid was increased up to 1.6 and 5.7 g/kg, respectively and mainly increased dramatically in the stage of hot room (23°C). Lactic, citric and formic acid contents were 2.6, 2.5 and 0.8 g/kg at the end of ripening. As a result of lipolysis, the amount of total free fatty acids (FFAs) was 7.2 g/kg. Compared with control, levels of individual FFAs from butyric (C4:0) to linoleic (C18:2) acids increased significantly ($P < 0.05$) during ripening period. Especially in the 23°C room, 79% of total FFAs was released and most abundant FFAs are palmitic (C16:0) and oleic acid (C18:1). Then, it showed that the lipolysis of Emmental cheese was strongly affected by bacterial lipase from PAB.

Key words: Emmental cheese, organic acids, lipolysis

W70 Oxidative stability of Prato cheese added with lutein. D. Maus, A. A. O. Xavier, M. T. K. Kubo, R. A. Jorge, A. Z. Mercadante, and W. H. Viotto*, *UNICAMP, Campinas, São Paulo, Brazil.*

The carotenoid lutein has been associated to the reduction and prevention of age-related macular degeneration (AMD), the leading cause of irreversible blindness in the elderly people. Since this carotenoid is not synthesized by the human body, its addition to cheese is an option of lutein supplementation in the diet, and it can also act to prevent photo-oxidation of cheese. The storage conditions of cheese in supermarkets may lead to changes in the product due to the presence of riboflavin (RBF), which under light stimulus promotes oxidation of vitamins, lipids and proteins, leading to nutrient losses and sensory changes. The objective of this work was to evaluate the stability of lutein added to the cheese and RBF, in the presence and absence of light, during 56 d of refrigerated storage. The formulation of lutein used was Lutein 20% FS - natural coloring of lutein for food, from DSM Nutritional Products (Basel - Switzerland). Prato cheeses without addition and with addition of 0.04% formulation of lutein on the mass of milk (estimated content of 80 μg/g milk) were evaluated as the behavior of RBF and lutein during storage at 12°C. A split-split-plot design was used for analyses of lutein and riboflavin contents and the results were evaluated by ANOVA. There was degradation of 35.3% of riboflavin in cheese without the addition of lutein exposed to light. For cheeses with added lutein, there was no degradation of riboflavin in both the absence and presence of light. In all cheeses, the levels of lutein remained virtually constant throughout the period of storage, allowing the assumption that all added lutein remained available at the end of storage period. These facts indicate that lutein, when present in cheese, has a protective role by preventing the degradation of riboflavin.

Key words: carotenoids, cheese, photo-oxidation

W71 Comparison of texture and sensory attribute between Gouda cheese and cholesterol-removed Gouda cheese during ripening. H. J. Jung*, E. J. Ko, and H. S. Kwak, *Sejong University, Seoul, South Korea.*

The present study was carried out to examine the texture and sensory evaluation between Gouda cheese and cholesterol-removed Gouda cheese made by crosslinked β-cyclodextrin (β-CD). Both cheeses were ripened at 14°C, 85% RH for 6 mo. The texture and sensory characteristics of the cheeses were measured during ripening (0, 1, 2, 3, 4, 5 and 6 mo). To analyze the texture properties, the 2-bite compression test was performed using by texture analyzer, and to evaluate sensory properties, 9-trained panelists examined the cheeses. In chemical composition analyses, moistures were significantly different between cheese (42.96%) and sample cheese (48.44%) ($P < 0.05$). But fat and protein in the control and the sample were 32.99, 22.51 and 31.45, 20.45%, respectively, and were not significantly different ($P < 0.05$). The amount of cholesterol was 82.41 mg/100 g and the percentage of cholesterol removal was 91%. In the texture analysis, hardness, gumminess and chewiness were significantly increased, but cohesiveness and springiness were not increased in both cheeses during ripening periods ($P < 0.05$). In comparison of the control and sample cheeses, hardness and springiness were not significantly different, but cohesiveness, gumminess and chewiness were different ($P < 0.05$). In sensory properties, appearance (yellowness and dryness), aroma (butyric, fruity, musty and nutty), flavor and taste (butyric, sour, salty, bitter and after taste) and texture (hardness, springiness, crumbliness, sticky, dryness and mouth coating) were significantly increased except buttery,

nutty in aroma and sweetness in taste in both cheeses during ripening ($P < 0.05$). And appearance, aroma, flavor and taste, and texture were not significantly different between the control and sample cheeses ($P < 0.05$). Therefore, this study may suggest that the quality of cholesterol-removed Gouda cheese is not different from the control cheese.

Key words: Gouda cheese, cholesterol removal, sensory evaluation, texture

W72 Influence of pH on flavor of low fat Cheddar cheese. M. M. Motawee*[1] and D. J. McMahon[2], *[1]National Organization for Drug Control and Research, Cairo, Egypt, [2]Western Dairy Center, Utah State University, Logan.*

Low fat cheddar cheese typically lacks flavor characteristic of full fat cheddar cheese. This study investigated whether flavor or low fat cheese could be improved by modifying cheese pH and lowering storage temperature. Cheese was made from 700 kg of 0.6%-fat milk using lactococcal starter culture and lactobacilli adjunct culture. Milk was renneted at 31°C, cooked to 35°C, drained, curd washed with cold water, dry stirred, salted, and pressed into 9-kg blocks and stored at 3, 6, and 10°C. Make procedure was varied to produce cheese with pH (at 60 d) from 5.08 to 5.55 with similar moisture, salt and fat. Sensory descriptive analysis was performed using the Spectrum scale after 4 mo on cheese aged at 3 and 6°C and compared with retail-purchased full fat cheeses. Scores for cooked, fruity, oxidized, pineapple, rancid, sulfur and whey flavors were negligible (≤0.5) for both low fat and full fat cheeses. There were few differences in flavor scores of low fat cheese attributed to pH or storage at 38 or 42°F. There was a consistent tendency for cheese aged at 3°C to receive slightly lower scores, such as 2.4 vs. 2.9 for sour and 1.4 vs. 1.7 for umami flavor. Sour, umami and salty flavors of low fat cheeses were not influenced by pH and these were all slightly less compared with full fat cheese, i.e., 2.7 vs. 4.4, 1.6 vs. 2.1, and 2.9 vs. 3.8, respectively. Low fat cheeses also scored lower for lactone (0.8 vs. 1.6), nutty (0.8 vs. 1.4) and buttery (0.8 vs. 1.8) flavors. Cheese microflora was studied by plating on Elliker agar for total lactic acid bacteria, and on Rogosa agar for lactobacilli, with the difference between them being attributed to lactococci. Starter culture levels were about 10^7 cfu/g initially and between 10^6 to 10^7 by d 30, and stayed about 10^6 cfu/g through 90 d then dropped off by 120 d to being much less than the nonstarter bacteria (this occurred earlier in cheese stored at 10°C). Lactobacilli levels were about 105 after 5 d of storage, increased to 10^6 by 30 d for all cheeses, and reached 10^7 cfu/g by 90 d in the 10°C cheese. Levels of thermophilic bacteria stayed relatively constant at 10^3 to 10^4 cfu/g throughout storage irrespective of temperature.

Key words: Cheddar, low fat, flavor

W73 Free fatty acid compositions of low-fat and full-fat goat milk cheeses stored under refrigeration for three months. W. Nouira[1], Z. Guler[2], and Y. W. Park*[1], *[1]Fort Valley State University, Fort Valley, GA, [2]Mustafa Kemal University, Hatay, Turkey.*

Amount of free fatty acid (FFA) is an indicative of degree of lipolysis in dairy foods. The objective of the study was to determine differences in composition and total FFA contents between low-fat (LF) and full-fat (FF) plain soft goat milk cheeses stored for 3 mo at 4oC. The 2 types of cheeses were manufactured using a bulk tank goat milk collected from the Fort Valley university farm. LF cheese was manufactured after cream removal from the whole milk. FFAs of all LF and FF cheeses were extracted in diisopropyl ether using polypropylene chromatography column, and FFA concentration was determined using a gas chromatography, equipped with a fused silica capillary column. Moisture, fat, protein contents (%) and pH of fresh LF and FF cheeses were: 55.1, 52.3; 1.30, 25.6; 3507, 22.5; 5.40, 5.42, respectively. The concentrations (mg/g cheese) of FFAs in the fresh FF and LF cheeses before the storage for C4:0, C6:0, C8:0, C10:0, C12:0, C14:0, C16:0, C18:0, C18:1, and C18:2 were: 0.020, 0.072; 0.070, 0.035; 0.061, 0.055; 0.181, 0.167; 0.073, 0.047; 0.174, 0.112; 0.579, 0.152; 0.308, 0.202; 0.521, 0.174; and 0.057, 0.026, respectively. The respective FFA to total fatty acids ratios for 0, 1 and 3 mo aged FF and LF cheeses were 8.44, 12.4; 6.31, 16.91; 12.03, 14.19. Total FFA contents of LF cheeses at 0, 1 and 3 mo aging were 48.0, 96.8 and 36.4% of those in FF cheeses. It was concluded LF cheese generated more FFA than FF cheese although total FFA amount was significantly ($P < 0.05$) lower in LF cheese.

Key words: lipolysis, free fatty acid, goat milk cheese

W74 Increasing functionality of low fat mozzarella cheese using polysaccharides. E. N. Oberg*, W. R. McManus, and D. J. McMahon, *Utah State University, Logan.*

We examined the ability of polysaccharides to function as fat mimetics in low fat mozzarella string cheese to improve functionality by acting to form protein fibers during cheese extrusion. Low fat (LF) mozzarella cheese curd made from 273 kg of 0.7%-fat milk was salted at a rate of 10 g/kg then divided into 3.6-kg batches that were hand-stretched in hot (80°C) 5% brine and formed into a homogeneous mass. The hot cheese was hand mixed with a hot (80°C) polysaccharide slurry and placed into a small piston-driven extruder and cheese forced through a 16-mm die to form the string cheese and cut manually into about 15-cm lengths. From preliminary trials using starches (waxy corn, waxy rice, and instant tapioca starch), xanthan and guar gum, and polydextrose we determined that LF string cheese made using xanthan gum most resembled retail string cheese. Cheese was then made using 10% xanthan gum slurry added at 0.25%, 0.5%, 1.0%, 1.5%, and 2.0% levels as well as a control with no added gum. Cheeses were analyzed for fat, salt, pH, and moisture. After 2 wk of 4°C storage, the cheese was analyzed for extent of stringiness by pulling apart the cheese longitudinally, visually observing and photographing size, length and appearance of individual strings of cheese, consumer liking, and hardness using a penetrometer shear test. Using a hedonic scale (1 to 9) for overall liking the LF with 1% added xanthan slurry (score = 6.8) was liked more ($P < 0.05$) than a retail comparison string cheese (score = 6.2) and the LF cheese with no added gum scored lower (5.9). When considered on a JAR scale, 71% of panelists scored the LF cheese with added xanthan as having the right texture, while only 49% did so for the retail cheese. The no added gum LF cheese was considered too firm. By visual comparison, adding the xanthan gum slurry produced greater fiber formation with the longest and best string separation. After 8 wk storage, the LF cheeses had softened extensively with fracture stress for LF cheese decreasing from 11.8 to 20.5 kg at 2 wk to 2.22–3.45 kg at 8 wk. Extent of stringiness also decreased considerably during storage.

Key words: mozzarella, string cheese, low fat

W75 The effects of incorporating sweet potato and peanut flours on sensory properties of probiotic yogurt in Mwanza, Tanzania. S. Hekmat* and S. Varriano, *Brescia University College, London, Ontario, Canada.*

Yogurt is a nutrient-dense product that serves as an excellent vehicle to transfer probiotic microorganisms and other nutritional additives to consumers. Vitamin A deficiency and protein-energy malnutrition are the 2 common dietary deficiencies in some resource-poor African communities. Addition of sweet potato and peanut flours in certain African staples has been an effective method to increase the pro-vitamin A content of the diet and to alleviate protein-energy malnutrition, respectively. The objective of this study was to evaluate the effects of incorporating sweet potato and peanut flours on sensory properties of probiotic yogurt in Mwanza, Tanzania. Standardized milk (3.5% fat) with 4 and 6% sweet potato flour (SPF), 4% peanut flour (PF), 3 and 5% milk powder (MP), and one with no additives (C) were prepared. The samples were heat treated at 85°C for 30 min, cooled to 37°C and inoculated with standard yogurt cultures and *Lactobacillus rhamnosus* GR-1 (4%). All yogurt samples were fermented and cooled to 4°C. Consumer taste panels were conducted. A 9-point hedonic scale was used to evaluate and compare the samples. The SPF (4%) sample was rated significantly ($P < 0.05$) higher for flavor and overall acceptability compared with MP (5%), PF (4%), and SPF (6%) samples. However, the SPF (6%) yogurt had a significantly ($P < 0.05$) lower appearance score compared with MP (3%) and C samples. The addition of PF (4%) was not desirable and resulted in low flavor and overall acceptability scores. This study suggests that addition of moderate amount of sweet potato flour to yogurt improves the flavor and overall acceptability of the product and can potentially be used as a nutritional additive to combat vitamin A deficiency in Africa.

Key words: yogurt, sweet potato flour, peanut flour

W76 Riboflavin photodegradation in yogurt with added lutein. L. D. Domingos, A. A. O. Xavier, R. A. Jorge, A. Z. Mercadante, A. J. Petenate, and W. H. Viotto*, *UNICAMP, Campinas, São Paulo, Brazil.*

Lutein is a carotenoid possessing biological activity against degenerative diseases, such as the decrease and prevention of the occurrence of age-related macular degeneration. It also shows antioxidant properties and can exert a protective function in foods. Dairy products are light sensitive due to the presence of riboflavin, a sensitizer capable of absorbing luminous energy and transferring it to reactive oxygen molecules, unleashing oxidative components on the milk components, resulting in nutritional losses and sensory alterations. The current work evaluated the oxidative stability of yogurt with an added lutein-based preparation, in the presence and absence of light and stored for 35 d under refrigeration. The 0.3% lutein formulation used was obtained from Vegex Lutein WS and is a natural dye from Christian Hansen (Horsholm, Denmark) used for food purposes. Yogurts were manufactured with and without the addition of 1.5 mg per 120g portion (estimated value of 11.5 µg/g yogurt) in the final product, and characterized with respect to their total carotenoid and riboflavin contents. Degradation of the riboflavin and lutein were monitored during refrigerated storage at 5°C. A split-split-plot design was used for analyses of lutein and riboflavin contents and the results were evaluated by ANOVA. In the yogurts without lutein and exposed to light, there was a reduction in the riboflavin content and the formation of oxidized riboflavin products. In the yogurts with lutein, the riboflavin and lutein contents remained constant throughout the entire storage period in the light, the same occurring in the samples stored in the dark. The dye lutein impeded the photo-degradation of riboflavin in the yogurt exposed to light. All the samples presented constant lutein contents throughout the entire refrigerated storage period, signifying that all the lutein added remained available up to the end of the storage period.

Key words: yogurt, lutein, riboflavin

W77 The physicochemical and sensory properties of milk supplemented with dispersable nanoginseng during storage. Y. J. Ahn* and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study was carried out to investigate the dispersibility of nanoginseng (600 ~1,000 nm) in milk and to determine the effects of the addition of the ginseng into the milk on the physicochemical and sensory attributes of the milk during storage. To be dispersable nano- ginseng, 0.5% nano ginseng powder was added into the sterilized water, swelled at 80°C for 2 h, added 0.3% polyglycerol monostearate, stirred at room temperature with 800rpm for 24 h and obtained the supernatant after centrifugeting. The dispersable nanoginsengs (2, 4, 6, 8%) were added into milk and stored at 5°C for 16 d, and pH, DPPH for antioxidation, color and sensory evaluation were studied. The pH was ranged from 6.65 to 6.79 during storage. DPPH showed that the additions of 2, 4, 6 and 8% dispersable nanoginseng increased 1.3, 1.7, 2.0 and 2.2 times higher activity, respectively. The color value, L, in the milk, was not significantly influenced by adding the nanoginseng solution (2 ~8%, v/v) ; whereas the a and b values significantly increased with the solution ($P < 0.05$). In sensory attribute, earthy, bitterness, astringency and overall acceptability were not significantly different between control and 4% addition of the solution ($P < 0.05$). Based on the data obtained from this study, it is concluded that the low concentrations (2 ~4%) of the nanoginseng solution could be used to develop a nanopowdered ginseng-added milk without significantly adverse effects on the physicochemical and sensory properties.

Key words: nanoginseng, dispersibility milk

W78 Optimum condition for crosslinked β-cyclodextrin and recycling for cholesterol removal in milk and cream. Y. K. Lee* and H. S. Kwak, *Sejong University, Seoul, South Korea.*

This study was carried out to investigate the optimum condition of crosslinked β-cyclodextrin (β-CD) and the recycling for cholesterol removal in milk and cream. The crosslinked β-CD was prepared with 15% adipic acid solution, and water solubility of the β-CD was measured for the optimum condition based on mixing temperature (20, 40, 60 and 80°C), mixing time (1, 2, 3 and 4 h), crosslinking temperature (20, 40, 60 and 80°C), crosslinking reaction time (24, 36, 48 and 60 h) and cooling time (48, 72, 96 and 120 h). For recycling study, recyclable yield and cholesterol removal rate were measured by 2 and 15% adipic acid added crosslinked β-CD in milk and cream, respectively. In the results of this study, optimum condition was 80°C mixing temperature, 2 h mixing time, 60°C crosslinked temperature, 24 h crosslinking reaction time and 48 h cooling time. After being determined the optimum condition, the recyclable yields of the crosslinked β-CD ranged from 90.01 to 55.17% in 6 times of recycling and the percentage of cholesterol removal by 15% crosslinked β-CD was over 90% till 8th time recycling. On the basis of the results, this study suggested that

15% adipic acid added crosslinked β-CD maximized recyclable yield and during recycling cholesterol removal was improved.

Key words: optimization, crosslinked β-cyclodextrin, recycling, milk, cream

W79 Optimization of water in oil in water (W/O/W)-microencapsulated iron for milk fortification (I). S. Y. Lee*, S. I. Ahn, and H. S. Kwak, *Sejong University, Seoul, South Korea.*

This study was designed to examine the microencapsulation efficiency of iron and to measure the stability and bioavailability of iron microcapsules in vitro. Core material was ferrous sulfate and coating materials were medium-chain triglyceride (MCT) for W/O and whey protein isolate (WPI), arabic gum (AG) or maltodextrin (MD, DE 18) for W/O/W. The highest emulsion stability index (ESI) for W/O iron emulsion was 98% when the ratio of water to oil was 4:6 and 1% polyglycerol polyricinoleate (HLB 0.6) was added as primary emulsifier. The highest yield of W/O/W iron emulsion was 93% when the ratio of W/O to water was 2.5:7.5, coating material was 30% WPI, 1% ferrous sulfate as a core material and 1% (w/v) polyoxyethylene sorbitan monolaurate (HLB 16.7) as a secondary emulsifier. The smallest size of spray dried microcapsule was 10.1Î1/4m with WPI and the largest 22.6Î1/4m with AG. The moisture content of the capsules were within 2% with all coatings used. The maximum absorbed moisture contents were 28, 24 and 30% with MD, WPI, and AG, respectively, under 98% relatively humidity. In the in vitro study only 1.0~2.1% of iron was released in simulated gastric fluid at 37°C pH 2 for 0, 30, 60, 90 and 120 min. Comparatively, iron release increased dramatically to 70, 60, and 46% with WPI, MD, and AG, respectively, in the simulated intestinal fluid at 37°C pH 7 for 0, 30, 60, 90 and 120 min. Based on our results, WPI was the most efficient, stable and bioavailable.

Key words: W/O/W, microencapsulation, iron

W80 Water in oil in water (W/O/W)-microencapsulation iron for milk fortification (II). S. Y. Lee*, S. I. Ahn, and H. S. Kwak, *Sejong University, Seoul, South Korea.*

This study was carried out to investigate the fortification of iron into milk by means of W/O/W microencapsulation technique. Coating materials were medium-chain triglyceride (MCT) for W/O and whey protein isolate (WPI) for W/O/W. Core material was ferrous sulfate. Spray dried iron microcapsules were made and added (0.1, 0.3, 0.5 and 0.7%) into milk and the pH, released iron, TBA, color and sensory attributes of iron microcapsules in milk were measured during storage at 4C for 0, 4, 8, 12 and 16 days. All experiments were run in triplicate. Iron fortified milk had kept pH between 6.78 and 6.88 during storage. The amounts of the released iron from the capsules in the milk were 0.17~0.20, 0.48 and 0.71ng/ml from 0.1~0.3, 0.5 and 0.7%, respectively. The TBA value for fat oxidation showed in the range of 0.17 to 0.22 absorbance at 450nm, which has no significant difference between control and samples during storage ($P < 0.05$). In color, b- and a- values of the sample milk containing 0.5~0.7% iron microcapsules were significantly different from control ($P < 0.05$). In sensory evaluation, rancidity, cooked and metallic parameters revealed significant differences with increased iron encapsulated microcapsules, however, overall acceptability did not show significant difference during storage ($P < 0.05$). Based on the data obtained from this study, it is concluded that 0.3% powdered iron microcapsule could be applicable for iron-fortified milk.

Key words: W/O/W, microencapsulation, iron fortification, milk

W81 Development and characterization of synbiotic quark cheese. A. F. Carvalho*[1], M. M. Gonçalves[1], G. M. Tavares[1], J. Y. Suda[1], N. F. Nogueira Silva[2], and J. B. P. Chaves[1], *[1]Federal University of Viçosa, Viçosa, MG, Brazil, [2]Institut National de la Recherche Agronomique STLO, Rennes, Bretagne, France.*

A current food market trend is the consumers search for healthier, low fat, low sugar and more nutritious products. In this context, functional dairy products often added with probiotics and prebiotics stand out among other products of similar nature. Probiotic bacteria are live microorganisms which when consumed promote health benefits to the host. Prebiotics are non-digestible ingredients that stimulate the selective growth of beneficial bacteria in the intestine. This work aimed to develop a symbiotic skimmed Quark cheese, using a new manufacturing technology, which is feasible for small volume production. The prebiotic ingredient inulin (BENEO Raftiline) and 3 probiotics (*Lactobacillus acidophilus* LA5, *Bifidobacterium animalis* BB12 and *Lactobacillus delbrueckii* UFV H2b20) were used. Three formulations were produced, differing in the probiotic added to the fermented mass, in 3 replications. Microbial cell viability was monitored during storage at refrigerated temperature. Effects of probiotic addition on the cheese physico-chemical and rheological characteristics and sensory acceptance were determined at 5, 15 and 25 d. Regression analysis did not detect significant change ($P > 0.05$) in microbial count up to 25 d storage, with high counts as log cfu.g-1 in the range of 6.4 to 6.9. There was no significant change ($P > 0.05$) in cheese acidity over time. The product was characterized as a pseudoplastic fluid and its rheological characteristics did not vary significantly ($P > 0.05$) in cheeses with different probiotics. Addition of stabilizers, thickeners and fiber raised consistency and apparent viscosity levels of the product. The new technology allowed the production of a type cheese with good sensory acceptance and probiotics addition did not cause any change perceived by consumers. This product can be considered, therefore, a potential carrier for probiotic microorganisms.

Key words: prebiotic, probiotic, cheese

W82 Comparison of quantitative neutral volatile compounds in regular cream cheese and cholesterol-removed cream cheese. S. S. Jeon*, S. J. Lee, and H. S. Kwak, *Sejong University, Seoul, Korea.*

This study compared quantitative flavor compounds in regular cream cheese (RCC) and cholesterol-removed cream cheese (CRCC), which was treated by crosslinked β-cyclodextrin, and were stored at 7°C for 4weeks. To quantify the volatile compounds, the cheeses (0, 1, 2, 3 and 4weeks) were extracted and analyzed by solid-phase microextraction (SPME) and gas chromatography (GC), respectively. Tentatively identified flavor compounds were mainly 11 from fatty acid. One amine was present in RCC, and 2 lactones and miscellaneous were in CRCC and one was in RCC, respectively. However, 2 ketones were present in both cheeses. In quantitative analysis, hexanoic acid and octanoic acid were not significantly developed ($P < 0.05$) in both cheeses. N-Decanoic acid was produced higher in RCC (0.158 ppm) than in CRCC (0.155 ppm). Benzoic acid appeared at 3 week storage and developed from 0.1321 to 158 ppm in RCC and from 0.106 to 0.130 ppm in CRCC. Dodecanoic acid was found at an insignificant amount in both samples. Tetradecanoic acid kept ranged from 0.151 to 0.161 ppm in both cheeses. However, z-11-tetradecanoic acid produced in only CRCC from 0.120 to 0.135 ppm. Tridecanoic acid was lower than

other acids. N-hexadecanoic acid was produced at 0.153 ppm in RCC and 0.139 ppm in CRCC and remained constant. Oleic and 9, 12-octadecadienoic acid developed only from 0.118 to 0.144 ppm and from 0.034 to 0.073 ppm in CRCC, respectively. The ketone, 2-tridecanone was produced 0.032 and developed to 0.050 ppm only in RCC and 2-pentadecanone produced 0.060 and developed to 0.083 ppm in both cheeses. The lactone, 2H-pyrane-2-one, tetrahydro-6-pentyl, was produced 0.050 ppm and developed to 0.074 ppm in both cheeses. However, 2H-pyran-2-one, 6-heptyltetrahydro kept 0.140 ppm only in CRCC. As amine, 5-(p-aminophenyl)-4-(o-tolyl)-2-thiazolamine and as other, phenol, 4, 6-di (1, 1-dimethylenthyl)-2-methyl kept 0.050 ppm only in RCC. On the basis of our results, we conclude that the quantity of flavor compounds in regular cream cheese and cholesterol-removed cream cheese was similar except for a few components.

Key words: cream cheese, cholesterol removal, flavor

W83 Comparison of lipolytic and proteolytic changes between commercial bovine milk and caprine milk yogurts stored under refrigeration. J. Oglesby and Y. W. Park*, *Fort Valley State University, Fort Valley, GA.*

In European and Asian countries, there is a long tradition of consumption of fermented milks such as yogurt, which is associated with good nutrition and health benefits of the products. A study was conducted to determine storage stability of caprine milk yogurt compared with bovine milk counterpart in relation to lipolysis and proteolysis. Commercial bovine milk yogurt (CBY) and commercial caprine milk yogurt (CCY) were purchased from local retail stores, and Fort Valley State University plain caprine milk yogurt (FVCY) were manufactured using direct vat set (DVS) lactic culture (YC-180, Chr. Hansen, Inc., Hoersholm, Denmark). The caprine milk used was the late lactation bulk milk from the University dairy goat herd consisted of Saanen, Alpine, and Nubian breeds. All experimental yogurt samples were subjected to 4°C refrigeration storage for 4 weeks. Acid degree value (ADV), pH, water soluble nitrogen (WSN) and basic nutrient contents of all yogurt samples were analyzed to compare lipolytic and proteolytic changes between the products during 0, 2 and 4 weeks of storage. Mean dry matter and fat content (%) of CBY, CCY and FVCY products were 11.28, 3.05; 13.1, 3.65; 11.03, 3.40, respectively, indicating the CCY contained the highest total solids and fat contents among all tested varieties. The initial and final ADVs of CBY, CCY and FVCY were 0.503, 1.009; 0.756, 0.685; 0.707, 1.094, respectively, showing significant lipolysis occurred in the CBY and FVCY, while CCY showed a minimal lipolytic change. The pHs of all 3 products ranged from 4.05 to 4.12, suggesting no significant changes occurred in pH, while the respective WSN (%) of CBY and CCY at 0, 2, and 4 weeks were 3.40, 5.55; 3.93, 4.77; 5.07, 6.75, showing proteolysis was increased in the products. It was concluded that the commercial caprine yogurt had less lipolysis than the CBY and FVCY, probably due to the added stabilizer, whereas proteolysis of all 3 products steadily increased during the storage.

Key words: yogurt, lipolysis, proteolysis, caprine milk

W84 impact of protein content, total solids, and milk protein solids on the functionality of nonfat yogurt. K. N. Shah* and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

Nonfat yogurt is a popular fermented product available in various forms. In the US, the Code of Federal regulations requires >8.25% milk solids in the yogurt base. NDM is a common ingredient utilized to provide milk solids in yogurt produced in the US. However, in International markets, skim milk powder (SMP), milk protein concentrate (MPC), and dried permeate are utilized in yogurt formulations. The protein content, total solids (TS) and source of milk protein may have an impact on the functionality of yogurt. Additionally, storage of dairy ingredients can result in quality deterioration. For example, the storage of high protein MPC at > 20°C for more than 6 mo results in loss of solubility of MPC. The objective of this study was to evaluate the effect of different milk solids sources at various protein/TS ratios and impact of storage of powders on the viscosity and whey separation of nonfat yogurt. Three different lots of SMP, NDM, MPC40 and MPC70 were collected from US manufacturers and each lot was divided into 3 portions. A portion was analyzed after 3, 9, and 15 mo of storage at 25°C. A Rapid Visco Analyzer method was utilized to produce yogurt from each formulation. At each storage time, yogurt formulations with protein (%)/TS (%) ratios (4/12.5, 4.5/13.5 and 5/15.5) were produced from each lot of SMP, NDM, MPC40, and MPC70.Varying amounts of deprotonized whey powder were included to standardize the TS content. The data was analyzed by repeated measures using PROC GLM in SAS. SMP and NDM yogurt viscosity were significantly ($P < 0.05$) higher than MPC40 and MPC70 at each protein/TS ratio. Additionally, MPC70 yogurt viscosity was significantly ($P < 0.05$) lower than MPC40 yogurt viscosity at each protein/TS of yogurt. Whey separation values of SMP were significantly ($P < 0.05$) higher than NDM at each protein/TS of yogurt. The viscosity of yogurt manufactured from all powders were significantly ($P < 0.05$) affected by storage. However, the change in viscosity during storage was small in all treatments at all protein/TS ratios. The usage of various milk protein sources significantly affects the functional attributes of nonfat yogurt.

Key words: nonfat yogurt, viscosity

W85 Sensory evaluation of various probiotic yogurts in Mwanza, Tanzania. S. Hekmat*[1,2], J. Hemsworth[1], H. Soltani[1], and G. Reid[2], *[1]Brescia University College, London, Ontario, Canada, [2]Canadian Research and Development Center for Probiotics, London, Ontario, Canada.*

Yogurt fermented with *Lactobacillus rhamnosus* GR-1 has shown therapeutic properties and its introduction into a dietary regimen of certain population in Mwanza, Tanzania has been an effective method in treating and preventing urogenital infections and in improving the nutritional status of people living with HIV/AIDS. The objective of this study was to evaluate sensory properties of various probiotic yogurts containing local fruits and vegetables found in Mwanza, Tanzania. The yogurt mother culture was prepared by fermenting a milk mixture (3.25% fat) containing 0.33% yeast extract and 0.4% inulin. Four flavors of probiotic yogurt containing at least 10^7 cfu/ml of *Lactobacillus rhamnosus* GR-1 were made using widely available fruits and vegetables in Mwanza such as mango, pineapple, cucumber, and orange at the rate of 10% w/v. Consumer taste panels were conducted using a Hedonic scale of 1–9 (1 = dislike extremely; 9 = like extremely). The results showed that the mango yogurt had the highest overall mean score (7.3) and the cucumber yogurt had the least overall mean score (6.1). The mango and orange yogurts were rated significantly higher than the cucumber yogurt ($P < 0.05$). The appearance and texture of cucumber yogurt were rated significantly lower ($P < 0.05$) than the other yogurts with the mean scores of 6.0 and 5.6, respectively. These findings will be used as a guide to formulate a probiotic yogurt that is feasible and acceptable by consumers in Mwanza, Tanzania.

Key words: probiotics, yogurt, sensory

W86 Effect of pasture feeding and dairy cattle breed on vitamin E and β-carotene content in milk. V. M. Marino[1], I. Schadt[1], S. La Terra[1], M. Caccamo[1], G. Licitra[2,1], and S. Carpino*[1], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]DISPA, Catania University, Catania, Italy.*

It has been shown that several factors such as breed, feed source, and animals′ health status might influence milk vitamin E and β-carotene (AO). The aim of this study was to examine the effects of pasture feeding and dairy cattle breed on AO concentrations in milk. Four dairy farms located in southeastern Sicily were selected; 2 with both Holsteins (H) and Brown Swiss (BS) cows and 2 with only Modicana (M) local breed cows. Bulk milk of each breed per farm was sampled 4 times during 3 experimental periods (P1 = March / April, P0 = June / July, and P2 = November / December). Samplings within period occurred with weekly intervals. Pasture was available in P1 and P2 but not in P0. Periods P1 and P2 differed by botanical composition and plant maturity. During P0 cows were grazing stubble. Additional hay and concentrate was supplemented during all periods. Pasture intakes have been calculated using CPM-Dairy. Milk AO contents were analyzed by HPLC. Both, milk β-carotene and α-tocopherol were highest during P1, lowest during P2 and intermediate during P0 ($P < 0.001$). Least squares means (μg / g fat) ± standard deviations during P1, P2 and P0 of β-carotene were $9.68^{a} \pm 0.07$, $0.84^{c} \pm 0.07$, $2.45^{b} \pm 0.07$, respectively, and relative to α-tocopherol $16.15^{a} \pm 0.05$, $11.15^{c} \pm 0.05$, $13.28^{b} \pm 0.05$, respectively. Milk from BS contained more β-carotene compared with H ($P < 0.05$), but α-tocopherol levels were not affected. Milks from M had the same levels of β-carotene compared with BS cows and had significantly higher levels of α-tocopherol ($P < 0.05$) compared with the milks from the other breeds. However, the latter results might have been confounded by the significant higher pasture intake of M relative to the BS and H. Low AO milk contents measured during P2 could be explained by cows′ vitamin consumptions of body tissue resources during the summer period, when AO were lacking in the diet. Body resources during P2 first had to be restored before AO could be released into milk. Pasture benefits relative to AO milk content might be obtained only after a minimum necessary exposure period of cows to pasture.

Key words: milk, breed, antioxidants, pasture

W87 The fatty acid composition and properties of summer and winter butter. O. Tsisaryk*, *Lviv National University of Veterinary Medicine and Biotechnologies, Lviv, Ukraine.*

The objective of the study was to determine the fatty acid composition, nutritional value and spreadability of summer butter (S) manufactured from milk when dairy cows were grazing and winter butter (W) when cows were fed indoors. Milk was collected from dairy cows in August and December, and butter was manufactured, 3 times for each period. Butter samples were conserved at –20°C until fatty acid analysis by GLC and stored at 4°C per rheological properties and sensory analysis. The fatty acid methyl esters were separated on a column SP-2560 (100 m × 0.25 mm i.d. × 0.20 μm 100% bis-cyanopropyl polysiloxane, Supelco) in a chromatograph Hewlett Packard 6890. The nutritional value of butter was analyzed under the indices. Butter samples were tested for resistance to penetration. The percentage of the sum medium-chain saturated fatty acids (C12-C16) decreased ($P < 0.05$) from 49.5 in W butter to 48.5% in S butter, especially C16:0 – from 32.9 in W butter to 30.9% in S butter. There was an increase ($P < 0.05$) in the ratio of unsaturated to saturated fatty acids in S butter. The sum of unpaired fatty acids and branched-chain ones also increased in S butter. The concentration of cis-9, cis-12, cis-15 C18:3 increased from 0.4 in W butter to 0.9% in S butter, unlike cis-9, cis-12 C18:2, which decreased from 2.3 in W butter to 1.5% in S butter. The ratio of n-3 to n-6 fatty acids increased to 0.63 ($P < 0.05$) in S butter from 0.23% in W butter. The total trans-isomer concentrations were higher in S butter. The concentration of trans-11 C18:1 increased from 1.2 in W butter to 2.0 in S butter and cis-9, trans-11 C18:2 increased from 0.6 to 1.1 respectively. Atherogenicity, thrombogenicity and health promoting indices were 2.82, 1.98 and 0.40 in W butter and 2.69, 1.90 and 0.41 in S butter respectively. Penetrometer readings indicated that S butter was softer at 4°C and the spreadability index also was higher in S butter. Thus, S butter was found to have a higher biological value and a better texture.

Key words: summer and winter butter, fatty acids, properties

W88 Hungarian Trappist (*Trapista*) cheese production from Holstein and Jersey cows′ milk. L. Varga*, *Department of Dairy Science, Institute of Food Science, Faculty of Agricultural and Food Sciences, University of West Hungary, Mosonmagyarovar, Hungary.*

Milk composition is widely known to affect the yield and quality of subsequent dairy foods. Hungarian Trappist (Trapista) is a traditional semi-hard cow′s milk cheese with a mild flavor and good melting properties. Making up approximately 70% of the total ripened cheese consumption, Trapista is by far the most popular cheese in Hungary. The objective of the current experiments was to compare the composition of milk and the quality, yield and production costs of Hungarian Trappist cheese from Holstein and Jersey cows. From November 2008 through July 2009, a total of 260 tonnes of Holstein and Jersey milk were processed in a cheese factory located in the western part of Hungary. Raw bulk milks were analyzed for somatic cell count (SCC), fat, protein and extraneous water. As for Trappist cheese, major chemical components (i.e., total solids, fat and protein) and pH were determined and cheese yield and production cost calculations were also made. The results showed that Jersey milk had higher concentrations of most milk components measured, including protein, fat and SCC, than did Holstein milk. No extraneous water was detected in the raw milk batches processed. The mean total solids and fat-in-DM contents of Trappist cheese from Holstein milk were found to be 56.80% and 50.17%, respectively, whereas the levels of the same components in cheese from Jersey milk were 55.92% and 49.12%, respectively. The 2 cheese products had an identical mean pH value of 5.15 after salting. Jersey milk yielded 4.4% more cheese per kg than Holstein milk using fat standardized cheesemilk. In addition, compared with Holstein Trappist, the manufacture of each kg of Jersey Trappist resulted in the production of 95.2 g more milkfat. All things considered, at October 2009 prices, the production costs of Trappist cheese from Jersey milk were 0.55–0.70 USD/kg lower than those of Holstein Trappist in Hungary.

Key words: Trappist cheese, Holstein milk, Jersey milk

W89 Long-term ethanol or acetic acid supplementation do not impair sensory milk quality. J. L. P. Daniel*, L. G. Nussio, M. H. F. Spotto, T. L. Cardoso, A. Sá Neto, and M. Zopollatto, *University of Sao Paulo, College of Agriculture "Luiz de Queiroz", Piracicaba, SP, Brazil.*

Ethanol and acetic acid are common end products from tropical silages. The objective of this study was to determine whether high dose of ethanol or acetic acid might affect sensory milk quality. Thirty lactating Holstein cows averaging 40 kg/d of milk at beginning of trial were grouped in 10 blocks and fed one of the 3 diets during 7 weeks: Control (33% Bermuda hay + 67% concentrates); Ethanol (control diet + 5% ethanol, DM basis); and Acetic acid (control diet + 5% acetic acid, DM basis). Ethanol and acetic acid were diluted in water (1:2) and sprayed onto total mixed ration twice daily. The same amount of solution was replaced with water in the control diet. During the 1st week of the trial, cows received half-dose of these chemical compounds. Unpreserved and unpasteurized milk was sampled on 6th week of trial and judged immediately after milking for appearance, aroma, taste, and global quality by a sensory panel of 56 non-trained persons. Scores were evaluated on a 9-point scale (where 1 = poor quality to 9 = high quality). Since original data did not fit normal distribution, a Box-Cox transformation was performed. All diets led to well accepted milk batches (score means >6.6). Milk sensory attributes were similar across treatments ($P > 0.15$), except for global quality ($P = 0.02$), where acetic acid and ethanol treatments were slightly improved than control milk (7.56, 7.48 and 7.28 respectively). Long-term ethanol and acetic acid supplementation did not impair sensory milk quality which is in agreement to the blood parameters (not showed).

Key words: aroma, taste, appearance

Forages and Pastures: Improving Forage Conservation and Quality

W90 Dry matter yield and silage nutritive value of winter cereals in the southern High Plains. F. E. Contreras-Govea*[1], H. Gonzalez Garcia[2], D. M. VanLeeuwen[3], and J. Idowu[4], *[1]New Mexico State University, Plant and Environmental Sciences Department, Artesia, [2]Universidad Autonoma de Ciudad Juarez, Departamento de Ciencias Veterinarias, Ciudad Juarez, Chihuahua, Mexico, [3]New Mexico State University, Agricultural Biometrics Service, Las Cruces, [4]New Mexico State University, Extension Plant Sciences Department, Las Cruces.*

This study was conducted to assess DM yield and silage nutritive value of 3 winter cereals harvested at different dates in Southern High Plains. Triticale (× Triticosecale Wittm. Ex A. Camus), wheat (*Triticum aestivum* L.), and barley (*Hordeum vulgare* L.) were sown on 15 October 2009 in a split plot randomized block design with harvest date (HD) as whole plot and cereal as subplot. Cereals were harvested on 20 April, 4 May, and 10 May, 2010. Maturity at harvest ranged from boot to early milk, anthesis to early dough, and caryopsis water ripe to soft dough respectively. Triticale was the most immature and barley the most mature cereal with wheat intermediate. At harvest, 10 kg of each cereal from each plot was chopped to a theoretical length of cut (TLC) of 25 mm. Chopped cereal (500 g) was placed in a plastic bag, vacuum sealed, and stored at room temperature (20°C) for fermentation for 30 d. Pre-ensiled and ensiled cereals were analyzed for nutritive value and fermentation characteristics for the ensiled cereals. Data analysis were conducted using the MIXED procedure of SAS, with HD, cereal, and HD*cereal interaction as fixed effect and replicate as random effect. There was no HD by cereal interaction among variables ($P > 0.05$). Harvesting in April, DM yield was lower (13.2 Mg/ha) than in 4 May (16.5 Mg/ha) or 10 May (16.3 Mg/ha) ($P < 0.05$), but nutritive value was higher. In vitro digestibility and NDF digestibility were greater ($P < 0.05$) in April (862 g/kg and 761 g/kg) than in 4 May (827 g/kg and 713 g/kg) or 10 May (813 g/kg and 688 g/kg). Among cereals, barley had greater ($P < 0.05$) nutritive value, followed by wheat, and triticale. All 3 cereals fermented well, but pH values were high in all 3; barley 5.84, wheat 5.93, and triticale 6.05. Lactic and acetic acid concentration did not differ ($P > 0.05$) among cereals. Harvesting in May increased DM yield by 23%, but decreased nutritive value. Fermentation was similar across cereals, but the high pH may be was an indicator of unstable fermentation.

Key words: winter cereals, silage fermentation, dry matter yield

W91 The effects of substituting corn silage and alfalfa hay with Master Graze on feed intake, milk yield and milk composition. A. Salamone*[1], A. A. AbuGhazaleh[1], C. Stuemke[1], R. Atkinson[1], and B. Dodd[2], *[1]Southern Illinois University, Carbondale, [2]Masterschoice, Anna, IL.*

The objective of this study was to evaluate the effect of using Master Graze (Master's Choice, IL) as a forage source for dairy cows. Sixteen Holstein cows in early-mid lactation (90±19 DIM) were divided into four treatment groups (4 cows/treatment) and fed treatment diets for 4 consecutive periods with each period consisted of 21 days. Cows on the control group (T1) were fed a 60:40 forage:concentrate diet (DM basis) with corn silage and alfalfa hay as forage source (1:1; DM basis). For treatment groups, the Master Graze silage substituted the forage mix at 16% (T2), 33% (T3) and 50% (T4) on DM basis. All diets were formulated to be isonitrogenous. Cows were fed treatment diets as TMR once daily for ad libtium consumption and amounts fed and refused were recorded daily. Substituting the corn silage-alfalfa hay mix with the Master Graze at the three tested levels had no effects ($P > 0.05$) on feed intake (19.4, 19.2, 19.7, and 19.2 kg/d for T1 to T4, respectively) or milk production (23.1, 22.7, 22.7, and 22.9 kg/d). Milk fat percentages (3.91, 3.82, 3.85, and 3.9) and yields (0.89, 0.85, 0.86, and 0.88 kg/d), and milk protein percentages (3.04, 3.06, 3.04, and 3.03) and yields (0.70, 0.68, 0.69, and 0.69 kg/d) were all similar ($P > 0.05$) among treatment diets. Treatment diets had also no effects ($P > 0.05$) on milk urea nitrogen, milk SCC, and cows body weight and body condition score. In conclusion, results from this study show that the Master Graze may replace 50% of dietary corn silage-alfalfa hay mix in dairy cows ration without any adverse effects on feed intake, milk production or milk composition.

Key words: Master Graze, forage, dairy

W92 Ruminal degradability of *Albizia lebbeck* silage. T. Clavero*, R. Razz, and O. Araujo-Febres, *Centro de Transferencia de Tecnologia en Pastos y Forrajes. Universidad del Zulia, Maracaibo, Estado Zulia, Venezuela.*

An experiment was carried out at the tropical western region of Venezuela in order to evaluate *in sacco* dry matter degradability of four levels of supplementation of *Albizia lebbeck* silage. The rations used were: 100% *Brachiaria humidicola* hay (HBH); 75% HBH + 25% silage *Albizia lebbeck* (ALS); 50% HBH + 50% ALS; and 25% HBH + 75% ALS. Samples (10g) milled to pass a 3 mm screen were weighed into 9 x 18 nylon bags, which were incubated for 0, 6, 12, 24, 48, 72 and 96 hours in rumen-fistulated steers. Residues were washed and dried at 65°C to estimate in sacco DM degradation. The animals were fed a diet consisting of *Echinochloa polystachia* ad libitum and 2 kg of a corn-soybean meal based concentrate. Digestion parameters were obtained by means of non linear regression, a randomized model with three replications was analyzed and treatments means separated by the Tukey test. The results showed significant effects ($P < 0.05$) of diets on in sacco degradability kinetics of DM. For ruminal degradation, the lowest soluble fractions (23.42 ± 1.4%) and degradation rate ($0.005h^{-1}$) were observed in HBH. However, positive effects were observed with the other diets, presenting the highest values in maximum degradation (56.39 ± 2.7%), degradation rate ($0.015h^{-1}$) and potential degradation (85.18 ± 3.1%) when 25% HBH + 75% ALS was offered ($P < 0.05$). It can be concluded that *Albizia lebbeck* silage diets had high DM rumen degradability and indicate that these diets could be used as ruminant feed supplements to enhance forage digestibility.

Key words: *Albizia lebbeck*, silages, rumen degradability

W93 Characterization and identification of *Lactobacilli* stains from tropical grasses. J. P. S. Rigueira[1], O. G. Pereira*[1], K. G. Ribeiro[2], A. S. Cezário[1], and W. F. Souza[1], *[1]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Minas Gerais, Brazil.*

The grasses of *Brachiaria* and *Panicum* genera have constituted one of the most important forage for pasture in Brazil. There has been recent interest in using these forages for the silage production. In this work, we characterize and identify lactobacilli strains isolated from grasses *Panicum maximum* 'Mombaça' and *Brachiaria decumbens*. The isolation of predominant lactic acid bacteria (LAB) in forage before ensiling was carried out on Rogosa SL Agar (Difco), at 37°C, for 48 h.

Forage samples were randomly collected from the pasture after 70 d of regrowth. For the 10^1 dilution, 25 g of forage was mixed with 225 mL of sterile phosphate buffer solution and homogenized in a blender for 1 minute. Decimal dilutions were made ranging from 10^1 to 10^6 and plated on sterile Petri dishes. We carried out the Gram stain test reaction to catalase, growth at different pH and temperatures beyond the morphology of the isolated stains. Isolate identification was obtained using the API 50 CH carbohydrate fermentation test kit (bioMérieux, Inc., France). All isolated strains showed negative reaction to catalase and were Gram stain positive. They grew at pH 7.2 and were inhibited at pH 9.6. All the stains showed growth at temperature from 15°C to 45°C.The morphology of the bacillus stains was identified as *Pediococcus pentosaceus* and *Leuconostoc mesenteroides* and showed the coccus form. Table 1 shows the isolated species in tropical grasses. *Lactobacillus fermentum* and *Lactobacillus plantarum* the predominant species in both forages. Financial support by CNPq and FAPEMIG.

Table 1. Species indentified by API 50 CH test in *Brachiaria* (B) and *Panicum maximum* (M) forages and the respective percentage abundance (ID)

Code	Species	%ID	Code	Species	%ID
B3	*Leuconostoc mesenteroides*	88.9	M2	*Lactobacillus lactis* ssp. *lactis*	83.8
B4	*Lactobacillus fermentum*	99.5	M4	*Lactobacillus fermentum*	93.7
B5	*Lactobacillus brevis*	70.7	M16	*Lactobacillus paracasei*	80.8
B6	*Lactobacillus fermentum*	96.2	M21	*Lactobacillus plantarum*	94.9
M1	*Pediococcus pentosaceus*	93.5	M17	*Lactobacillus paracasei*	80.8

Key words: lactic acid bacteria, tropical grass, silage

W94 Milk production response to feeding alfalfa silage inoculated with *Lactobacillus plantarum*. R. E. Muck*[1], G. A. Broderick[1], A. P. Faciola[2], and U. C. Hymes-Fecht[1], *[1]USDA, ARS, US Dairy Forage Research Center, Madison, WI, [2]University of Wisconsin-Madison, Madison.*

In mini-silo trials, silages treated with a *Lactobacillus plantarum* inoculant (Ecosyl, Yorkshire, UK) had increased in vitro rumen microbial biomass production. Our objective was to determine if alfalfa silage treated with this inoculant could produce a milk production response commensurate with the in vitro responses. Alfalfa (240 g CP/kg DM, 300 g NDF/kg DM, 500 g DM/kg) was ensiled with (LP) and without (C) Ecosyl inoculant. Twenty-eight multiparous Holstein cows in early lactation were blocked by DIM and randomly assigned to 2 diets (C or LP-treated silage) in a double crossover design with 4 28-d periods. Diets were formulated to contain 162 g CP and 280 g NDF/kg DM, and the diets fed consisted of (g/kg DM): alfalfa silage (509), corn silage (206), high moisture corn (214), soy hulls (47) and vitamin/mineral mix (25). Milk production and DMI were recorded for the last 14 d of each period. Milk samples were collected from each cow at both milkings on d 20, 21, 27 and 28 for analysis of milk composition. Means for LP were compared against means for C before and after LP using a paired *t*-test in Proc MIXED of SAS. The LP diet increased milk production but did not affect DMI or milk/DMI. Milk composition and production of milk components were largely unaffected by diet except as noted in the table. The increased milk production and reduced MUN in the current study support the hypothesis that the inoculated silage is producing more rumen microbial biomass.

Table 1. Milk production and composition from diets containing alfalfa silage made with (LP) and without (C) inoculant

Item	C	LP	SE	*P*-value
Milk, kg/d	39.6	40.4	0.26	0.03
Milk Protein, %	2.81	2.78	0.009	0.05
Milk Lactose, %	4.82	4.89	0.013	<0.01
Milk Urea N, mg/dL	12.7	11.6	0.17	<0.01

Key words: silage inoculant, milk production, alfalfa

W95 Biomin BioStabil Plus enhances the fermentation characteristics, aerobic stability, and intake by rams of native tropical grass silage. C. Rosario[1], A. A. Rodriguez*[1], and Y. Acosta-Aragon[2], *[1]University of Puerto Rico, Mayaguez, PR, [2]Biomin Holding GmbH2, Herzogenburg, Austria.*

The effect of Biomin BioStabil Plus (BSP, blend of homo and heterofermentative lactic acid bacteria) on the ensiling characteristics, aerobic stability, and intake by rams of native tropical grasses (NTG) silage was determined. Forage (mix of *Panicum maximun*, *Sorghum halapense*, and *Digitaria decumbens*; 6-week regrowth) was chopped and treated with or without BSP. Treatments were applied to weighed portions of forage, manually mixed and packed into PVC micro-silos. Fresh forage and samples of 3 silos for each treatment opened at 4, 7, 14, 21, 28 and 35 d were analyzed for pH and fermentation products. Statistical analysis was performed as a Completely Randomized Design (CRD) with a 2 (treatments) by 7 (d) factorial arrangement. Aerobic stability was determined on 3 silages from each treatment exposed to air. The pH and temperature were measured after 0, 24, 72 and 96 d, and 0, 6, 12, 24, 30, 48, 72, 96 and 120 h of aerobic exposure, respectively. Statistical analysis of pH and temperature data was performed as a CRD with a 2 (treatments) by 4 (d) or 2 by 10 (h) factorial arrangement, respectively. To determine the effects of NTG fermented with BSP on DMI, chopped NTG were ensiled with or without the inoculant in 208-L capacity plastic bags for a minimum of 35 d. Six rams were used in a CRD trial with 3 replicates per treatment. Diets containing 50% grass hay and 50% NTG treated with or without BSP, were offered daily at 3% of ram BW/dry matter basis. Rams were allowed a 6-d diet adaptation, prior to a 5-d data collection period. Forage fermented with BSP had lower ($P < 0.05$) pH and higher ($P < 0.05$) lactic acid content than untreated silage. Vegetative material treated with BSP and exposed to air for 5 d had lower ($P < 0.05$) pH than control, but no effect on temperature was observed. Silage intake as proportion of total DM offered and as percentage of total DMI was improved ($P < 0.05$) by 8.13% and 4.42% when rams were fed with the inoculated silage. The ensiling of NTG with BSP enhanced the fermentation characteristics and improved forage consumption by rams.

Key words: tropical grasses, silage, BioStabil Plus

W96 Fermentation characteristics and aerobic stability of tropical corn ensiled with additives containing homo-fermentative or hetero-fermentative bacterial strains. V. Rivera[1], L. Solorzano[2], and A. Rodriguez*[1], *[1]University of Puerto Rico, Mayaguez, PR, [2]Chr. Hansen, Fitchburg, WI.*

The fermentation characteristics and aerobic stability were determined on tropical corn (TC; *Zea mays*) ensiled with additives containing homo-fermentative (*L. plantarum*) or a blend of homo and hetero-fermentative (*L. buchneri, E. faecium and L. plantarum*) lactic acid-producing bacteria (LAPB). Corn (38% DM) was chopped (2.5 cm), untreated or treated with both products to weighed portions of forage, manually mixed, and packed into PVC microsilos (1.5 kg) to ferment for 0, 15, 30, and 58 d. Three samples of fresh forage and silage for each treatment (trt) and ensiling d were analyzed to determine pH and fermentation products. Statistical analysis was performed as a Completely Randomized Design (CRD) with a 3 (trt) by 4 (d) factorial arrangement. For aerobic stability, 3 samples from each trt and ensiling d were exposed to air for 120 h. The pH and temperature were measured after 0, 1, 3 and 5 d, and 0, 6, 12, 18, 24, 48, 72, 96 and 120 h of aerobic exposure, respectively. Statistical analysis of pH and temperature data was performed as a CRD with a 3 (trt) by 3 (length of fermentation) by 4 (d) or 3 by 3 by 9 (h) factorial arrangement, respectively. Corn fermented with homo-fermentative LAPB tended to have lower ($P < 0.09$) pH and higher ($P < 0.07$) lactic acid content than untreated silage or TC fermented with hetero-fermentative LAPB. After 24 h of aerobic exposure TC fermented with both products had lower ($P < 0.01$) pH than the control. The pH was also higher ($P < 0.01$) in untreated silage than TC treated with additives after 15 and 30 d of ensiling, but similar when fermented for 58 d. Forage fermented with both products resulted in silage with lower ($P < 0.05$) temperature after 1 d of aerobic exposure. Inoculation prevented the start of the temperature rise by 18 and 24 h in TC treated with homo or hetero-fermentative strains, respectively. In summary, homo-fermentative strains improved the fermentation characteristic and delayed the deterioration of TC silage, but a greater response of the product containing hetero- fermentative bacteria on aerobic stability was observed.

Key words: tropical corn, silage, additives

W97 The aerobic stability and dry matter losses of high moisture corn ensiled as whole or ground grain using *Lactobacillus buchneri* alone or in association with *Lactobacillus plantarum*. R. Coudure[1], J. G. Cazaux[1], F. Skiba[1], E. Chevaux*[2], V. Demey[2], and J. Sindou[2], *[1]Arvalis - Institut du végétal, Montardon, France, [2]Lallemand SAS, Blagnac, France.*

The goal of this trial was to study the effect of addition of a single additive or a combination of silage additives on the fermentation, aerobic stability and nutritional value of High Moisture Corn (HMC). The trial was designed as a 3 × 2 × 2 factorial with the following factors: (i) no additive (C) vs *Lactobacillus buchneri* NCIMB 40788 (LB) (300000 cfu/g HMC) vs *L.buchneri*+ *Lactobacillus plantarum* MA18/5U (LBLP) (LB 150000 cfu/g HMC + LP 100000 cfu/g HMC), (ii) whole grain (WG) vs ground(G) (2 mm) and (iii) 36% vs 32% moisture (of the corn). Each experimental group had 6 replicates (microsilos). The anaerobic and aerobic phases lasted 144 and 13 days respectively. Dry matter (DM) losses were determined by weighing all silos individually at the start and end of each phase. Samples were taken for DM, pH and chemical composition determinations at d 11 and 20 of the anaerobic phase, at opening of silos and 13 days after opening. In the case of 36% moisture HMC, lower DM losses were seen with the combination LBLP. For GHMC as well as WGHMC, a higher fraction of the total DM was conserved at the end of the aerobic phase, compared to C (i.e. +5.3% vs. +2.4% resp., $P < 0.01$). The use of LB alone conserved 2.6% more DM in GHMC at the end of the aerobic phase. For WGHMC, little differences were seen in DM losses between C and LB alone. In terms of variations in pH, the values for LB and LBLP treated GHMC were higher ($P < 0.01$) than C at the end of the anaerobic phase (4.5 ± 0.03 and 4.2 ± 0.10 vs. 4.0 ± 0.03 resp.). However at opening, the pH of LB and LBLP treated silos stayed stable, whereas the pH of the C increased ($P < 0.05$) rapidly (4.6 ± 0.05 and 4.3 ± 0.06 vs. 5.5 ± 0.37). In WGHMC the pH measured at opening was 4.5 for all experimental groups and rose by 0.5 units during the aerobic phase. The chemical composition of HMC was not affected by the silage additives when compared to C. Similar trends were observed for the parameters tested for the 32% moisture HMC, however differences observed seemed less pronounced compared to the 36% moisture HMC.

Key words: high moisture corn, *L.buchneri*, *L.plantarum*

W98 Effect of dry matter density on fermentation and nutrient preservation in brown mid-rib (BMR) corn silage within bunker silos. K. Griswold[1], P. Craig[2], J. Graybill[1], and R. Ward*[3], *[1]Penn State Cooperative Extension, Lancaster, [2]Penn State Cooperative Extension, Dauphin, [3]Cumberland Valley Analytical Services, Maugansville, MD.*

The objective was to determine the relationship of dry matter (DM) density to fermentation and nutrient preservation in BMR corn silage within bunker silos. Poly-weave nylon bags (36 per silo) containing chopped BMR corn were buried in 3 bunker silos during filling on the same farm in 2 successive years. Bags were blocked by depth from bunk end, 10.6 m (Front), 27.8 m (Center), and 44.9 m (Back), level from silo floor, 0.6 m (Low), 1.5 m (Middle), and 2.2 m (High), and within level, location from the east wall, 0.9 m (I), 4.7 m (II), 8.4 m (III), and 12.2 m (IV). At feed-out, all bags at a specific depth were retrieved, and silage cores for DM density at each bag position were collected with a 5.08 cm diameter stainless-steel coring tube. Corn and silage subsamples were analyzed for nutrient content and fermentation profile by NIR and wet chemistry. Data were analyzed by PROC MIXED and REG within SAS. The model included fixed effects of depth, level, location, all interactions, and random effects of silo and year. Significance was set at $P < 0.05$, and trends at $0.05 \leq P \leq 0.10$. There were no significant interactions. Density was affected ($P < 0.0001$) by depth, level, and location. Density was 221, 274, and 273 kg DM/m^3 for front, center, and back, respectively. Density was 282, 265, and 221 kg DM/m^3 for low, middle, and high, respectively. Density was 238 and 231 kg DM/m^3 for I and IV compared with 279 and 275 kg DM/m^3 for II and III, respectively. Fermentation was affected ($P < 0.05$) by depth and level but not location. Total VFA were 9.7, 10.8, and 10.4% of DM for front, center, and back, and 11.2, 10.3 and 9.5% of DM for low, middle and high, respectively. There was a trend ($P = 0.059$) for NDF content to be affected by level with 37.8, 38.6, and 40.4% of DM for low, middle, and high, respectively. Regression analysis showed a weak linear inverse relationship ($R^2 = 0.05$) between DM density and NDF content. Starch content was unaffected ($P > 0.10$) by DM density across all positions. These results suggest that DM density of BMR corn silage may affect fermentation, but likely does not affect starch and NDF content.

Key words: corn silage, density, fermentation

W99 Effects of the levels of silage additives on the fermentation quality and in situ digestibility of reed (*Phragmites australis* Cav.) silage harvested at different maturity stages. B. W. Kim*, K. I. Sung, and J. S. Shin, *College of Animal Life Sciences, Kangwon National University, Chuncheon, Kangwon-Do, South Korea.*

This study was conducted to determine the optimum levels of silage additives on reed silage harvested at different maturity stages. Reed

plants harvested at early boot (23% DM), late boot (24% DM) and early heading stages (26% DM) were chopped to an average particle length of 1 cm and ensiled in 500 g mini silos, with and without additive treatment. The additives used were formic acid applied at 0.2, 0.4 and 0.6% of the fresh crop weight and molasses applied at 0.5, 1.0 and 2.0% of the fresh crop weight. Treatments were allocated in a randomized complete block design with three replicates. The silage pH, acid and NH_3-N/TN concentrations, and the situ DM disappearance at 0, 12, 24, 48 h of incubation in Korean beef cattle were examined. The silage fermentation quality and in situ digestibility were not affected by the different maturity stages. Silage treated with formic acid had the lower pH (4.5, 4.3 and 4.0 at 0.2, 0.4 and 0.6%, respectively) than the molasses (5.0, 4.8 and 4.4 at 0.5, 1.0 and 2.0%, respectively) and untreated (5.2). While the lactic acid concentrations increased with the higher levels of molasses, the higher levels of formic acid resulted in lower concentrations of lactic acid ($P < 0.05$). The formic acid and molasses treatments were markedly effective for reducing the ammonia production which was similar at most addition levels (less than 10% NH_3-N/TN at all addition levels). Higher in situ digestibility resulted from adding additives, especially with formic acid treatment (about 10% at 0.2% level; $P < 0.05$). No significant difference was found between the addition levels of both additives. It is concluded that formic acid or molasses applied at ensiling produced better fermented silage and enhanced silage digestibility compared with untreated reed silage. The highest quality of reed silage was observed at 0.2% of formic acid and 2.0% of molasses, which are considered as the optimum levels of addition in this study.

Key words: reed, silage, additive

W100 Ruminal parameters of sheep fed corn silage inoculated with *Lactobacillus buchneri* and *L. buchneri* associated with *L. plantarum*. F. C. Basso*, P. A. R. Salvo, F. H. Kamada, J. P. R. Costas, W. L. da Silva, and R. A. Reis, *Animal Science Departament, College Agricultural and Veterinary Sciences, São Paulo State University, Jaboticabal, São Paulo, Jaboticabal.*

Silages inoculated with certain heterofermentative bacteria show improvement in aerobic stability. Many studies are done on silages, however few studies are reported about the effect of microbial inoculants on ruminal parameters in sheep. Therefore, the aim was to evaluate the effect of microbial inoculants in corn silage on sheep ruminal parameters. Three stack silos containing 10 t of corn silage were prepared. The corn silages were treated with nothing (CS, 32% of DM); or with either *L. buchneri* NCIMB 40788 (1×10^5cfu/g of forage; 35.5% of DM, CSB) or with *L. buchneri* (1×10^5 cfu/g; 31.7% of DM) plus *L. plantarum* MA18/5U (1×10^5 cfu/g, CSBP). Silage samples were collected during the experiment. The DM content, pH value, ammonia nitrogen content and yeast and mold counts (log cfu/g) were measured. Six castrated 10 mo-old, rumen cannulated male rams (40kg) were used. The animals were fed 80% of corn silage and 20% of commercial concentrate (57.5% soybean meal, 7% wheat bran, 5% cottonseed meal, 16% ground corn, 12.5% citrus pulp and 2% of mineral salt). The daily dry matter intake (DMI) was measured. Rumen fluid samples were collected 0, 3, 6, 9, 12 hours after feeding to measure pH values and ammonia levels. The experimental design was Latin square (3 × 3) repeated twice. Data was subjected to ANOVA and means compared by the Tukey test ($P < 0.05$). The DM content was different ($P < 0.05$) among treatments (CS: 31.68%; CSB: 33.42% and CSBP: 30.80%), probably because at ensiling, the DM content also was different among the forages. The pH value of CSB was lower (4.03) than CS (4.12) and CSBP (4.11) ($P < 0.05$). Ammonia nitrogen content (CS: 12.94%, CSB: 11.86% and CSBP: 14.51%) and yeast and mold counts (<3.00 log cfu/g of silage) were not different among treatments. Average DMI was 0.930; 0.962 and 0.881 kg/d, respectively for CS, CSB, and CSBP. The difference between CSBP and CSB was significant ($P < 0.05$). Ruminal pH (6.06, 6.12 and 6.07, respectively) and ruminal ammonia (17.09, 13.87 and 15.11 mg/dL) were not affected by the microbial inoculants in silage. In conclusion, addition of microbial inoculant in corn silage did not affect the ruminal parameters evaluated.

Key words: ammonia, microbial additives, pH values

W101 In vitro fermentation on cactus forage (*Opuntia* spp.) inoculated with *Kluyveromices lactis* yeast. C. Rodríguez-Muela*[1], D. Díaz-Plascencia[1], P. Mancillas-Flores[1], O. Ruiz-Barrera[1], F. Salvador-Torres[1], G. Corral[1], S. Mena[2], R. Copado-García[1], and L. Duran[1], *[1]Universidad Autónoma de Chihuahua, Chihuahua, México, [2]Universidad de Guadalajara, Jalisco, México.*

In order to evaluate the effect of use of *Kluyveromyces lactis* yeast (Kl) obtained from apple byproducts by solid state fermentation, on cactus forage (*Opuntia spp*), two treatments (Tr) were used: T1) 10 kg of paste of cactus forage (CF) and T2) 10 kg of CF + 100 ml of an inoculate of Kl (1.2×10^9cells/mL). Each Tr was added with 20 g of urea, 2 g of ammonium sulfate, and 5 g of mineral supplement. There were six replications per Tr and samples were fermented in an aerator for 48h to support the growth of yeasts. Tr was mixed for 15 min every 12h, and samples were taken at 0, 12, 24 and 48h. The variables evaluated were: temperature (T), pH, ammonia (AM), lactic acid (LA), yeasts count (YC), soluble sugars (SS) and crude protein (CP). The statistical design used was a completely randomized design, considering the random effect of the aerator nested in Tr (plot). Data were analyzed with the Proc Mixed procedure of SAS. The results showed that T increased ($P < 0.01$) from 0 to 12h, showing an inoculate*time interaction, with values of 22.4°C and 24.1°C in T1, and 20.7°C and 24.6°C in T2. Values of pH in T1 decreased ($P < 0.04$) from 4.9 to 4.6, and from 4.8 to 4.4 in T2 from 0 to 48h (respectively). Values of AM increased ($P < 0.01$) from 0.31 to 0.44 mM/mL in T1, and from 0.29 to 0.38 mM/mL in T2 from 0 to 48h (respectively). Values of LA increased ($P < 0.01$) from 2.30 to 2.63 mM/mL in T1, and they decreased from 1.55 to 0.91 mM/mL from 0 to 48h in T2. YC increased ($P < 0.01$) from 8.3×10^6 to 1.8×10^7cells/mL in T1 and from 3.2×10^7 to 4.9×10^7cells/mL of 0h to 48h in T2. There was an effect of time ($P < 0.01$) on SS, with a trend to decrease over fermentation time. An interaction was found for inoculate*time on CP ($P < 0.01$) with values in T1 of 9.4, 12.2 and 11.7% at 0h, 24h and 48h, and of 14.7, 19.4 and 18.0% at 0h, 12h and 48h, in T2, respectively. It can be concluded that the use of Kl on the in vitro fermentation of cactus forage increased significantly CP content and yeast counts with a marked reduction of SS and LA.

Key words: yeast, fermentation, cactus

W102 Comparison of an inoculant and enzymes, separate and in combination, on the fermentation of alfalfa silage. S. J. Z. Hansen* and A. H. Smith, *Danisco, Waukesha, WI.*

Fermented feedstuffs are one of the key components of the dairy ration, where stability and digestibility are important characteristics. The objective of this study was to compare the use of inoculants and enzymes, separate and in combination, on alfalfa silage to determine whether a more stable, digestible forage was produced. Treatments tested in the mini-silos were untreated (Ctrl), Agmaster XV inoculant (XV) and 2 enzymes, Clampzyme 20 (C20) and Clampzyme HIGO100

(HG) (Genencor). Agmaster XV contains *Pediococcus pentosaceus* P751, *Lactobacillus plantarum* LP115 and *Lactobacillus brevis* LBR35 and was applied at 1.8 e 11 cfu/ton of haylage. Glucose oxidase and cellulase are the active ingredients of C20 (3500 carboxymethylcellulose (CMC) Units/g) and HG (3600 CMC Units/g) and these were applied at 0.91 g/ton of haylage. Mini-silos used were airtight 5-gallon buckets containing haylage at a density of 240 kg/cubic meter. Alfalfa was wilted for 24 h before it was chopped. The moisture of the alfalfa was 51.4%, within the ideal level for ensiling when packed. Three mini-silos from each treatment, at Day 1, 3, 7 and 14, were opened and homogenized, with samples taken for volatile fatty acid (VFA) analysis, pH, enumeration of lactic acid bacteria and spoilage organisms (coliforms, yeasts, molds), and ADF, aNDF, NDFD48 and CP. Statistics, using 2-way ANOVA analysis, established the inoculant and both enzyme treatments improved fermentation by decreasing pH and increasing lactate (Table 1), however a synergistic effect of the inoculants with enzymes was noted. All treatments decreased spoilage organisms, and the inoculant with enzymes increased digestibility, as measured by NDFD48, on d 7 when compared with the control ($P < 0.001$). The use of inoculants and enzymes improved the fermentation of alfalfa silage, increasing the quality of the feed.

Table 1. Lactate (% DM) accumulation after ensiling

	Days of ensiling			
	1	3	7	14
Ctrl	0.5	1.9[a]	3.9[a]	3.6[a]

W103 Effects of sodium bisulfate on alfalfa silage preservation. M. Terré[1], D. Seale[2], C. Knueven[3], and A. Bach*[4,1], *[1]Institut de Recerca i Tecnologia Agroalimentàries, Caldes de Montbui, Barcelona, Spain, [2]DS AgriTech Ltd., Reading, Berkshire, UK, [3]Jones-Hamilton, Co, Walbridge, OH, [4]Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.*

Sodium bisulfate (SBS) is proposed as an acidifier to produce a rapid acid condition during the ensiling process by releasing the bisulphate ion HSO_4^-. The objective of this study was to evaluate the effects of SBS on pH, silage fermentation and aerobic stability of alfalfa silages. Third-cut alfalfa was harvested and chopped mid July 2010, wilted to 43.1% DM, and ensiled in 14 30–L capacity microsilos, and stored at ambient temperature (18–25°C). Half of them were treated with SBS at the dose of 8 g/kg of fresh alfalfa (Jones-Hamilton Co., OH) (SBS) and the other half was not treated with any preservative (C). On d 0, samples were analyzed for pH, DM, water-soluble carbohydrates (WSC), CP, NDF, ash and buffering capacity (BC). On d 3, 3 microsilos per treatment were opened to determine pH, BC, and ammonia–N. On d 100, 4 microsilos per treatment were opened to determine pH, DM, ammonia-N, WSC, lactic, acetic, propionic and butyric acid, ethanol, CP, and aerobic stability was monitored for 7 d. Lactate-assimilating yeasts and molds were enumerated on d 100 and 107. Data were analyzed with an ANOVA with silo treatment as main effect. The pH was lower ($P < 0.05$) in SBS than in C silos on d 0 (4.80 vs. 5.94 ± 0.127, respectively), and this difference was maintained on d 100 (4.52 vs. 4.88 ± 0.041, respectively, $P < 0.001$). Buffering capacity was also modified with the addition of SBS, being lower ($P < 0.05$) in SBS compared with C silos on d 0 (1208 vs. 1478 ± 53.3, respectively) and 3 (1114 vs. 1347 ± 77.5, respectively). All silages were well preserved and no differences in the NDF, WSC, CP and ashes content, the fermentation profile, in yeast and molds counts, in lactate-assimilating yeast counts, or in temperature changes during the aerobic stability measurements were observed between treatments. In conclusion, sodium bisulfate reduced silage pH (in agreement with an observation already made in grass silages) and lowers the buffering capacity of alfalfa silage, both of which could be expected to aid preservation under more difficult ensiling conditions than those encountered in this trial.

Key words: alfalfa, silage, sodium bisulfate

W104 Nutritive value and fermentation parameters of 'Tifton 85' bermudagrass and 'Mulato II' brachiariagrass silage in Florida. A. D. Aguiar*[1], J. M. B. Vendramini[1], A. T. Adesogan[2], L. E. Sollenberger[2], L. Galzerano[1], L. Custodio[1], E. Alves[1], and G. R. Manarim[1], *[1]Range Cattle Research Education Center, Ona, FL, [2]University of Florida, Gainesville.*

The objective of this study was to investigate the nutritive value and fermentation parameters of Mulato II (*Brachiaria* sp.) and Tifton 85 bermudagrass (*Cynodon* sp.) silages treated with sugarcane (*Saccharum officinarum* L.) molasses [M; 1 kg molasses (DM)/50 kg forage (As fed)], inoculants [I; EcoSyl, MTD/1; 100 mg/50 Mg forage (As fed)] (I), molasses plus inoculants (MI), and control (C). The experiment was conducted in Florida and harvested in the summer (21 July) and fall (6 October) 2010. Tifton 85 plots were distributed in a randomized complete block design with 4 replicates, and Mulato II plots in a complete randomized design with 4 replicates. The data were analyzed using PROC MIXED with treatment as fixed effect, and block and replicates as random effects. Forage was harvested, wilted on the field for 4 h, packed into a mini-silo at a density of approximately 382 kg fresh forage/m^3, and ensiled for 90 d. In the summer, there were no differences ($P > 0.10$) among treatments for the parameters evaluated in Mulato II silage. In Tifton 85 silage, treatments C and I had greater concentrations of acetic acid than M ($P = 0.05$, 0.33 vs. 0.55%), however, the C treatment had greater NH3-N and lesser NDFD concentration than M and I ($P = 0.03$, 8.0 vs. 6.0% total N). During the fall, the I treatment had lesser lactic acid ($P = 0.09$, 1.8 vs. 3.9%), and NH3-N concentrations than the C ($P = 0.03$, 7.0 vs. 11.0% total N) in Mulato II silage. The M treatment had greater concentrations of water-soluble carbohydrates than C and I ($P = 0.06$, 9.9 vs. 6.7%) and the NDFD was greater ($P = 0.09$) for MI (61%) than C, I, and M (Mean = 54%). Tifton 85 fall silage treated with molasses had greater water-soluble concentration than C and I ($P = 0.04$, 3.8 vs. 1.9%). The NH3-N concentration was greater for I than C ($P = 0.04$, 17 vs. 10% of total N) but there was no difference ($P > 0.10$) between C and M, and M and I. The effects of molasses and inoculants were inconsistent in this study and further investigation is necessary to evaluate the benefits of those management practices on warm-season grasses silage.

Key words: warm-season grass, inoculants, silage

W105 Effect of new mixtures of silage additives in grass and maize on fermentation quality and aerobic stability. J. Jatkauskas[1], V. Vrotniakiene[1], C. Ohlsson[2], and B. Lund*[2], *[1]Institute of Animal Sci-*

ence of Lithuanian University of Health Sciences, Baisogala, Lithuania, [2]Chr Hansen A/S, Hoersholm, Denmark.

The aim was to evaluate the effect of five new silage additives (A - E) containing lactic acid bacteria on fermentation characteristics and especially aerobic stability. The additives were compared to a positive and negative control in laboratory-scale experiments. The treatments were different combinations of inoculants containing *Lactobacillus plantarum* DSM16568 (B,C,D,E), *Enterococcus faecium* DSM 22502 (B,C,D,E), *Lactobacillus buchneri* DSM 22501 (A,B), *Lactococcus lactis* DSM 11037 (E) and NCIMB 30117 (B,C) at 150,000 cfu/g forage and one treatment was supplemented with sodium benzoate at 400 g/ton forage (C). The positive control was an inoculant of *Lactobacillus plantarum* at 100,000 cfu/g. The 3-liter mini-silos were filled with chopped ryegrass-timothy (DM 26.5%, WSC 2.7% of fresh matter (FM)) or whole-crop maize (DM 27.5%, WSC 2.7% of FM) with 5 replications per treatment and crop. Silos were stored at 20°C for 90 days before measuring the following parameters: pH, dry matter (DM) losses, fatty acids, ethanol, N-NH_3 and aerobic stability. Data were statistically analyzed as a randomized complete block by using the GLM procedure of SAS. In both grass and maize, additives A - E and the positive control resulted in significantly reduced ($P < 0.05$) DM loss, pH, acetic acid, butyric acid, propionic acid, alcohols and/or N- NH_3while lactic acid increased compared with untreated silage ($P < 0.05$). Additives A, B and C designed for improved aerobic stability, had lower temperatures ($P < 0.05$) at the end of the 7-day period of air exposure compared with the negative and positive controls in both silages. Untreated grass silages were stable for 4 days, the positive control 7 days, whereas additives A, B, C, D and E were stable for >13, 10, 7.5, 7 and 7 days, respectively. Untreated maize silage was stable for 2 days, the positive control 3 days, whereas A, B, C, D and E were stable for 6, 5.5, 6, 3 and 4 days, respectively. Additives A - E significantly improved fermentation quality and additives A, B and C significantly improved aerobic stability when compared to the positive control in both silages.

Key words: inoculant, silage additive, aerobic stability

W106 Identification and characterization of spoilage yeasts from high moisture corn and corn silages. M. C. Santos*[1], C. Golt[1], R. D. Joerger[1], G. D. Mechor[2], and L. Kung[1], *[1]University of Delaware, Newark, [2]Elanco Animal Health, Greenfield, IN.*

The objectives of this study were to identify and characterize yeasts associated with aerobic spoilage of high moisture corn (HMC) and corn silage (CS) and to compare 3 methods of yeast identification. Silages were sampled from 21 US dairy farms and shipped to the University of Delaware for analysis. Water extracts were prepared by homogenizing 25 g of silage with 225 mL of quarter-strength ringer's solution for 1 min. Silage pH was measured and yeasts were enumerated by pour plating in malt extract agar and incubated at 32°C for 48 h. Colonies were randomly picked from plates with the highest serial dilutions and taxonomically identified by fatty acid methyl ester (FAME) analysis (MIDI Inc., Newark, DE). An isolate of each species with the highest FAME similarity index was also characterized by DNA sequencing and biochemical tests (ID 32 C system, bioMerieux, Marcy l'Etoile, France). Average pH was 4.3 (ranging from 3.9 to 4.8) and 3.7 (ranging from 3.5 to 4.1) and average yeast counts were 6.3 $\log_{10}$ cfu/g (ranging from 4.3 to 7.9) and 5.4 (ranging from 4.2 to 7.0) for HMC and CS, respectively. Of 266 colonies isolated, 87.3% were identified by FAME in 24 known species and 12.8% were unknown. *Candida valida* (33.1% of total isolates), *Saccharomyces cerevisiae* (10.2%), *C. holmii* (7.1%), *Zygosaccharomyces bisporus* (7.1%) and *C. milleri* (4.1%) were the most prevalent species. The remaining 25.7% of isolates belonged to 19 other species. *C. valida* and *Z. bisporus* were lactate utilizers whereas *S. cerevisiae*, *C. holmii* and *C. milleri* were able to metabolize glucose and sucrose, but not lactate. *C. valida* was the most common species isolated from HMC and CS (35.1 and 30.5%, respectively). *S. cerevisiae* (12.8%) and *C. holmii* (13.6%) were the second most common isolates from HMC and CS, respectively. Yeast diversity was higher in HMC than in CS (21 species vs. 11 for CS) but the later had a higher percentage of unknown species (22.9% vs. 4.7%). Identification of yeasts using DNA analysis generally corresponded with identification using biochemical tests; however, FAME analysis did not generally agree with these 2 methods.

Key words: *Candida valida*, silage, spoilage

W107 Ruminal parameters of cattle fed corn silage inoculated with microbial additive. P. A. R. Salvo*, F. C. Basso, F. H. Kamada, J. V. Yamaguchi, V. V. Naves, and R. A. Reis, *Animal Science Department, College Agricultural and Veterinary Sciences, São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Microbial inoculants containing heterofermentative bacteria are used in corn silage to improve the aerobic stability, however few studies are reported about the effect of microbial inoculants on cattle ruminal parameters. The aim this study was to evaluate the effect of *Lactobacillus buchneri* and *Lactobacillus buchneri* associated with *Lactobacillus plantarum* in corn silage on ruminal parameters of cattle. Therefore, six rumen cannulated beef steers (470 kg) were used. The steers were fed with 80% of corn silage and 20% of commercial concentrate (8% of soybean meal, 87% of ground corn and 5% of mineral salt). The treatments were the corn silages inoculated with *L. buchneri* NCIMB 40788 (1×10^5 cfu/g of fresh forage, CSB); corn silage inoculated with *L. buchneri* NCIMB 40788 (1×10^5 cfu/g) in combination with *L. plantarum* MA18/5U (1×10^5 cfu/g, CSBP) and untreated corn silage (CS). Average daily dry matter intake (DMI) was measured. Rumen fluid samples were collected 0, 3, 6, 9, and 12 hours after feeding. The pH values were evaluated with a pH meter. Approximately 1mL of H_2SO_4 (1:1) was added to the suspensions to stop the microbial activity. Samples were frozen and subsequently, ammonia concentrations were measured by the Kjeldahl method using KOH (2N). The experimental design was a Latin square (3×3) duplicated in time. Data were subjected to analysis of variance and means compared by the Tukey test at a significance level of 5%. Each experimental period consisted of 7 days of adaptation and 3 days of data collection. Average daily DMI, ruminal pH and ruminal ammonia were not affecting by the microbial inoculants in corn silage ($P > 0.05$). Average DMI was 6.99, 6.92 and 6.78; ruminal values of pH were 6.12, 6.09 and 5.99 and the ruminal ammonia levels were 10.61; 9.91 and 9.73 mg/dL, respectively in the CS, CSB, and CSBP silages. Ruminal parameters evaluated were normal. In conclusion, the microbial inoculant treatment of corn silage did not affect the ruminal pH and ammonia concentrations of cattle.

Key words: ammonia, *Lactobacillus buchneri*, *Lactobacillus plantarum*

W108 Investigation of microbial additives on fermentation quality of alfalfa silage. F. Kazemi, M. Dehghan-Banadaky*, A. Zali, and K. Rezayazdi, *Animal Science Department, Campus of Agricul-*

tural and Natural Resources, University of Tehran, Karaj, Tehran, Iran.

The objective of present study was to investigate the effects of microbial additives on physical and chemical characteristics of alfalfa silages. In this experiment treatments included: 1-untreated corn silage (control), 2-treated with Ecosyl (EC) (0.125mg/kg), 3-Lacticil Maize (LM) (0.2 mg/kg), and 4- combination of both them Ecosyl (0.063 mg/kg), Lacticil Maize (0.1 mg/kg) were added to pilot silages. Silages were opened on days 10, 20, 30 and 40 after ensiling. Silage quality was assessed using pH, ammonia nitrogen and VFAs concentrations, Flieg point (ratio between dry matter concentration and pH), crude protein, dry matter, neutral detergent fiber and organic matter concentrations. Treatment 3 had the lowest pH and highest Flieg point compared with the others ($P < 0.05$). While treatment 2 had the highest pH and lowest flieg point. Concentration of Ammonia nitrogen in treatment 4 was higher than the other treatments ($P < 0.05$). Also treatment 2 had the lowest dry matter percentage. The results indicated that among those tested, Lacticil Maize is the preferred microbial additive for alfalfa silage due to improving fermentation quality.

Key words: microbial additives, alfalfa silage, fermentation quality

W109 Volatile organic compounds emissions from different silages and cattle feed. I. L. Malkina[1], R. B. Franco*[1], A. Kumar[2], P. G. Green[3], and F. M. Mitloehner[1], *[1]Department of Animal Science, University of California-Davis, [2]Crocker Nuclear Laboratory, University of California-Davis, Davis, [3]Department of Civil and Environmental Engineering, University of California-Davis, Davis.*

The San Joaquin Valley (SJV) in Central California exhibits high ground-level ozone pollution that may affect human, animal, and plant health. Silage and other feedstuffs were identified as one of the major sources of volatile organic compounds (VOCs), which in reaction with nitrogen oxides (NOx) contribute to ozone formation in this area. For reference, urban concentrations in the SJV represent 125 ppb of VOCs, while the rural concentrations in the SJV represent 62.5 ppb of VOCs. Detailed characterization of VOCs is relevant to ozone formation potential because the impact of different VOCs on ozone formation varies significantly. This study identified and quantified the VOCs emitted from silages and other feedstuffs in environmental chamber experiments conducted under controlled conditions. Approximately 80 VOCs were identified and quantified from corn (*Zea mays* L., alfalfa (*Medicago sativa* L.), cereal (wheat [*Triticum aestivum* L.] and oat [*Avena sativa* L.] grains) silages, total mixed ration (TMR), almond (*Amygdalus communis* L.) shells and hulls using gas chromatography-mass spectrometry (GC/MS) and high performance liquid chromatography (HPLC). Four air samples of silages and TMR, and 2 air samples of almond hulls and almond shells were collected using 6-L SUMMA canisters and DNPH cartridges. High concentrations of emitted alcohols, predominantly ethanol (1615.5 ± 188.6 nL/Lfrom cereal silage and 1043.7 ± 184.9 nL/L from corn silage) and other oxygenated compounds were measured. Highly reactive alkenes and aldehydes, were also detected but in lower concentrations. Further studies in quantification and monitoring of these emissions are critical for assessment of and response to the specific needs of the air quality in the SJV.

Key words: volatile organic compounds, silage, ethanol emissions

W110 Production and quality of corn silage cultivated on integrated crop-livestock-forest system in a Cerrado region of Minas Gerais, Brazil. M. C. M. Viana*[1], W. Botelho[1], P. A. Viana[2], D. S. Queiroz[1], E. A. Silva[1], M. S. Viana[4], and C. G. Guimarães[3], *[1]EPAMIG - Minas Gerais Agricultural Research Corporation, Belo Horizonte, Minas Gerais, Brazil, [2]Embrapa Maize and Sorghum, Sete Lagoas, Minas Gerais, Brazil, [3]UFVJM University, Diamantina, Minas Gerais, Brazil, [4]FEAD University, Belo Horizonte, Minas Gerais, Brazil.*

The trial was carried out at Santa Rita Experimental Farm (19°28′ S, 45°15′W, 732 m) on *Brachiaria decumbens* degraded pasture to evaluate the interference of different eucalyptus structural arrangements and clones on the production and chemical composition of maize silage cultivated in an agroforestry system (iCLF). The experimental design was a randomized complete block in a split plot, with 3 replications. Eucalyptus arrangements: double rows (3 × 2) × 20 m; (2 × 2) × 9 m and single rows (9 × 2m) were distributed in the main plots, with 20 and 9 m between rows and 2 m between tree spacing. Eucalyptus clones: VM 58, GG100 and I144 were tested in the subplots. The corn (hybrid BRS3060) was intercropped with eucalyptus clones. The maize cultivar used was BRS 3060. The maize silage yield, DM, ADF, NDF, lignin and cellulose contents were evaluated. Termites, white grub, wireworm, diplodes and corn rootworm larvae were the main soil pest observed in the experimental area. No difference was observed for maize productivity in relation to structural arrangements and eucalyptus clones in the first year of crop establishment. Also, the DM, ADF, NDF, lignin and cellulose were not influenced by the clones and the various structural arrangements of eucalyptus. The clones and the structural arrangements of eucalyptus did not influence the production and chemical composition of silage corn in the first year of crop establishment in the iCLF system in the Cerrado region of Minas Gerais State. (Research supported by FAPEMIG/CNPq)

Table 1. Dry matter (DM) yield (t/ha) and chemical composition of corn intercropped with eucalyptus in the first year of integrated crop-livestock-forest (iCLF) system

Arrangements	DM Yield (t/ha)	DM (%)	CP (%)	ADF (%)	NDF (%)	Lignin (%)	Cellulose (%)
(3 × 2)+20 m	10.24 [a]	37.27 [a]	4.73 [a]	31.1 [a]	58.55 [a]	4.79 [a]	25.73 [a]
(2 × 2)+9 m	6.03 [a]	36.03 [a]	4.86 [a]	31.26 [a]	59.07 [a]	4.86 [a]	25.72 [a]
(9 × 2) m	10.75 [a]	35.58 [a]	5.02 [a]	31.96 [a]	59.40 [a]	5.46 [a]	25.89 [a]

W111 Effect of molasses, starch and enzyme enrichment of sorghum and corn silage on chemical composition and rumen degradability. M. Dehghan-Banadaky*, M. Ghiasvand, and S. Sadeghi, *Animal Science Department, Campus of Agricultural and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The present study investigated the effects of enzyme (1 g Natuzyme per kg DM) and carbohydrate (molasses and barley, 5 g per kg DM) enrichment in sorghum silage and comparison with corn silage. Sorghum and corn were harvested at maturity stage with 25% dry matter. Forage chopped to 3-5 cm length and ensiled. After 60 days, silages were opened and evaluated for odor, color, material tissue, the amount of mold and pH (5 replicates for each treatment). Chemical composition was measured including dry matter digestibility, dry matter (DM), crude protein (CP), neutral detergent fiber (NDF), non fibrous carbohydrate (NFC), acid detergent fiber (ADF), and fermentation products such as ammonia nitrogen and volatile fatty acids. Three rumen fistulated Holstein cows were used for degradability experiment at 0, 6, 12, 24, 48, 72 and 96 h incubation. Corn silage dry matter was signifi-

cantly greater than sorghum silage (28 vs. 25, $P < 0.05$). Silage with barley flour and molasses enrichment had more dry matter. NDF and ADF concentration in sorghum silage with barley flour and molasses additive were significantly lower than sorghum silage without additive and corn silage ($P < 0.05$). Dry matter digestibility, digestible energy and total digestible nutrients in sorghum silage with barely flour and molasses significantly greater than other silages. Results of sensory evaluation showed that sorghum silage without additive had the lowest score and sorghum silage with molasses, barley flour and corn silage had very good quality. The in situ wash fraction was increased in sorghum silage with molasses and barley flour additive equal to corn silage. The potentially degradable fraction significantly increased in sorghum and corn silage with enzyme additives. The degradation rate and effective degradation at passage rates of 2, 5 and 8 percent per hour increased in corn and sorghum silage with barley flour and molasses. Sorghum silage enriched with molasses and barley flour in most parameters did not differ significantly with corn silage. We conclude that the quality of sorghum silage can be improved by adding molasses or barley flour.

Key words: sorghum silage, molasses, corn silage

W112 Effect of processed and unprocessed canola straw on growth performance, feeding behavior and rumen metabolites in Holstein feedlot calves. M. Ghiasvand, M. Dehghan-Banadaky*, and K. Rezayazdi, *Animal Science Department, Campus of Agricultural and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

Studies on the nutritional value of canola straw are very limited, therefore this forage is unknown to farmers and often is not used in ruminant nutrition. This experiment used 24 Iranian Holstein male calves with 266 ± 64 kg live weight. The study had a randomized complete design with three experimental diets with 25 to 75, forage: concentrate ratio. Diet 1 contained 10% corn silage and 15% alfalfa hay, diet 2 and 3, alfalfa was substituted with unprocessed and processed canola straw respectively. Energy density and protein content of the diets were similar. Canola straw was processed with NaOH (5% of dry matter). Calf live weight was recorded monthly. Calf feeding behavior was recorded for 24 h. Rumen fluid was collected 4 h after morning feeding at the end of experiment. Calves fed diet 2 had significantly less individual DMI than other groups. Final BW and average daily gain were not different between diets (p>0.05). Feed conversion ratio for calves fed diet 2 was significantly less than calves fed diet 1 (5.75 vs. 6.72, $P < 0.05$). Digestibility of DM and OM in calves' fed diet1 were significantly lower than diet 2 and 3. Protein and cell wall digestibility in diets 2 were more than diet 1 and there was no significant difference between diets 2 and 3. Ruminal pH in calves fed diet 3 was significantly greater than calves fed diet 1 and 2 (6.05, 5.90, and 6.27 for treatments 1-3 respectively). There was no significant difference among the calves fed different diets ($P > 0.05$) in rumen total volatile fatty acids and NH3-N concentration. Total ruminating time was greatest in calves fed diet 2. Ruminating time per kg of dry matter, per kilogram of NDF and per kilogram of forage NDF (fNDF) in calves fed diets containing unprocessed canola straw was significantly greater than calves fed diets 1 and 3 . Results indicate that unprocessed canola straw can be used as a roughage source in feedlot calf diets.

Key words: canola straw, Holstein male calves, feeding behavior

W113 Kinetics of solid-state fermentation of waste peach (*Prunus persica*) to be used as animal feed. Y. Castillo[1], O. Ruiz*[2], J. C. Gomez[1], E. Peru[1], H. Gonzalez[3], A. Orozco[3], C. Angulo[2], I. Ramos[3], and M. R. Murphy[4], *[1]División multidisciplinaria, UACJ, Nuevo Casas Grandes, Chihuahua, Mexico, [2]Facultad de Zootecnia y Ecologia, UACH, Chihuahua, Chih., Mexico, [3]Instituto de Ciencia Biológicas, UACJ, Ciudad Juárez, Chihuahua, Mexico, [4]Animal Science Department, University of Illinois, Urbana.*

Feed produced by solid state fermentation (SSF) has been added to ruminant diets to improve the nutritional value, including the true protein content. The aim of the present study was to determine the effect of incubation duration on the fermentation profile and chemical content of fermented peach residues collected after processing in a mill. Peach waste was ground and mixed with 1.5% urea, 0.2% ammonium sulfate, 0.9% calcium carbonate, and 0.5% of a mineral salt mixture. These ingredients were mixed and then 200 g portions were distributed to separate sterile 250 ml flasks for solid-state fermentation (SSF). Each flask was plugged with cotton and incubated under static conditions at 32°C for 0, 24, 48, and 72 h. At each sampling time, four flasks were withdrawn from the incubator. A completely randomized design was used with 4 replications at each time of incubation and data was analyzed with the GLM procedure of the SAS. Results showed that pH decreased ($P \leq 0.0001$) progressively over time (5.80, 4.81, 4.72 and 4.54 for 0, 24, 48 and 72 hours, respectively). Counts of yeast colonies (log cells/ ml) increased ($P \leq 0.0001$) over time. Dry matter (DM) was constant during the first 48 hours and then decreased ($P \leq 0.03$). Neutral and acid detergent fiber (NDF and ADF) increased in the first 24 hours and decreased subsequently ($P \leq 0.001$ and $P \leq 0.003$), respectively). Hemicellulose (HEM) developed in the same way ($P \leq 0.0001$), but showed no changes after 24 h. Crude protein showed no statistical differences during incubation. True protein content did not improve in the first 24 h, but it increased at 48 h ($P < 0.05$), with no changes subsequently (4.62, 5.04, 5.42 and 5.18% for 0, 24, 48 and 72 h, respectively). According to these results, it can be concluded that a fermentation time of 48 h is enough to accomplish an improvement of the nutritional value of residues of the peach industry.

Key words: fermentation, peach, chemical

W114 Chemical additives on sugarcane ensilage: Fermentation parameters, digestibility and intake by sheep. A. F. Pedroso*[1], S. N. Esteves[1], W. Barioni[1], G. B. Souza[1], C. Carbello[2], and G. G. Chiquitin[2], *[1]Brazilian Agricultural Research Corporation - Embrapa, São Carlos, SP, Brazil, [2]Fund. Educacional de Andradina, Andradina, SP, Brazil.*

The objective was to determine the apparent digestibility and intake by sheep of sugarcane silages produced with and without chemical additives, and to evaluate the effectiveness of additives at controlling alcoholic fermentation in the silages. Mature sugarcane (22 ºBrix) was ensiled in 200 L metal drums without treatment (control) or treated with (fresh forage basis): urea (5 g/kg) + sodium benzoate (0.5 g/kg); sodium propionate (4 g/kg); calcium hydroxide (10 g/kg). Silos were opened 80 d after ensiling and silages were fed to 16 wethers (averaging 45 kg live body weight - LW) housed in metabolic cages. Animals were distributed among treatments (four diets based on the different silages) in a complete randomized design with four replicates. Soybean meal and a mineral supplement were used to respectively balance protein content and minerals in diets. Silage DM digestibility and intake were calculated by difference since soybean digestibility was known. All silages had adequate pH (<4.2; Table 1). All additives reduced alcoholic fermentation in the silages but calcium hydroxide had the greatest effect (83% less ethanol relative to control). Urea +

benzoate and calcium hydroxide improved silage digestibility similarly (18% higher) but did not affect silage intake (relative to LW) compared to the untreated silage. Treatment with sodium propionate had no effect on silage digestibility and intake compared to control.

Table 1. Fermentation parameters, apparent digestibility and intake by sheep of sugarcane silages produced with and without additives

Silage	pH	Ethanol (g/kg DM)	Digestibility (% DM)	DM Intake (% LW)
Control	3.55^{c}	96.6^{a}	37.2^{b}	1.8^{ab}
Urea + benzoate	3.77^{b}	67.3^{b}	43.7^{a}	1.7^{ab}
Sodium propionate	3.72^{b}	76.8^{b}	38.2^{b}	1.3^{b}
Calcium hydroxide	4.08^{a}	11.6^{c}	44.3^{a}	2.0^{a}
SE	0.045	6.94	3.03	0.37

^{abc}Means in rows with unlike superscript differ by the *t* test ($P < 0.05$); LW = live body weight.

W115 Effects of the form of applying virgin lime and the treatments duration on the temperature and pH of sugarcane. E. Z. Ramos*, M. D. S. Oliveira, A. C. Rego, M. P. R. Sforcini, and V. B. Ferrari, *UNESP, Jaboticabal, São Paulo, Brazil.*

This study aimed to evaluate the effects of the form of applying virgin lime (powder or solution) and the treatment duration (0, 3 and 6 h) on hydrolysis of sugarcane with particle sizes of 4 or 10 mm. Control samples were untreated at time 0. Each treatment had four replications, and the treatment arrangement was a 2 × 2 × 3 factorial. Virgin lime was applied at the rate of 0.5% (fresh weight basis) to sugarcane. Treatment effects on the cell wall were monitored using Scanning Micrographs (SEM), and effects on temperature and pH were also recorded. The experimental data were analyzed using AgroEstat software and means were compared with the Tukey test at the 5% probability level. Table 1 shows that temperature increased with the treatment duration such that the lowest temperatures occurred at 0 h (24.1°C), and the highest values at 6 h (27.2°C). There was an interactions of treatment duration and temperature and of particle size and duration. Treatment with the powder resulted in higher temperatures (26.1°C) than the solution (25.7°C). Lime-treated samples had higher pH, regardless of the treatment duration, such that values were (5.7) for the control, and (10.3) and (9.8) after lime application for 3 and 6 h, respectively. In conclusion, the application of lime powder proved more efficient than in solution, but the particle size did not affect the results. Treatments duration increased sample temperature, but had no influence on pH values. The SEM images revealed that, regardless of other treatments, application of lime degraded the cell wall and potentially released cell contents that could be utilized by animals.

Table 1. Temperature and pH values

	Virgin lime		Particle size (mm)		Treatment duration (h)		
	Powder	Solution	4	10	0	3	6
Temperature (°C)	26.1^{a}	25.8^{b}	26.0^{a}	25.9^{a}	24.1^{c}	26.5^{b}	27.2^{a}
pH	8.7^{a}	8.6^{a}	8.5^{a}	8.7^{a}	5.7^{b}	10.3^{a}	9.8^{a}

W116 Effect of calcium chloride fertilization on the dietary cation-anion difference of forage crops in northern New York. E. O. Young[1], C. S. Ballard*[1], and S. Mishra[2], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]TETRA Technologies, Inc., The Woodlands, TX.*

Maintaining forage with an ideal dietary cation-anion difference (DCAD) for non-lactating cows can be challenging. The objective of this experiment was to determine if the application of liquid calcium chloride could increase chloride content and reduce DCAD of grass and mixed alfalfa-grass stands. In June 2010, three replicate plots were established on grass and alfalfa-grass fields at each of four sites at Miner Institute in Chazy, NY. Within plot, treatment was randomly assigned to subplot (with or without calcium chloride). Treatment subplots received 80 kg/ha of chloride as liquid calcium chloride applied one week after first cutting. Plots were harvested near the third week of June 2010 (second cut), and a second harvest was taken at the end of July (third cut). Analysis of variance was used to determine treatment effects on yield, DCAD, and forage nutrient content for each harvest. Results showed that calcium chloride application nearly doubled the chloride content of both forages at each harvest ($P \leq 0.001$) and significantly reduced DCAD ($P \leq 0.001$). For alfalfa-grass, calcium chloride fertilization reduced DCAD from 317 to 179 mEq/kg for the first harvest ($P \leq 0.001$), and 432 to 326 mEq/kg for the second harvest ($P \leq 0.05$). Grass DCAD was reduced from 115 to −108 mEq/kg with calcium chloride fertilization ($P \leq 0.001$) for first harvest and 293 to 91 mEq/kg for second harvest ($P \leq 0.001$). There was no impact on yield from chloride addition ($P \geq 0.58$) and no apparent impacts on forage nutritive value ($P \geq 0.15$) besides chloride content. Fertilizing alfalfa-grass or grass stands with liquid calcium chloride appears to be a viable approach to reduce DCAD in forages fed to non-lactating dairy cattle in Northern NY. Future work will compare the cost- effectiveness of chloride fertilization of forages versus addition of supplements to animal rations to reduce DCAD.

Key words: forage quality, nonlactating cows, dietary cation-anion difference

W117 In vitro ruminal fermentation of dairy cows diets with eight yeast strains isolated from apple byproducts. D. Díaz-Plascencia*[1], C. Rodríguez-Muela[1], P. Mancillas-Flores[1], F. Salvador-Torres[1], C. Arzola[1], L. Durán[1], J. Jiménez[1], and S. Mena[2], *[1]Universidad Autónoma de Chihuahua, Chihuahua, México, [2]Universidad de Guadalajara, Jalisco, México.*

In order to evaluate the effect of the inclusion of eight strains of yeasts isolated from apple byproducts on the in vitro fermentation of dairy cows diets samples, were developed eight yeast inoculums with the following strains (strains 2, 9, 11 and 13 of *Kluyveromyces lactis* (Kl), 3 and 8 of *Issatchenkia orientalis* (Io), 4 and 6 of *Saccharomyces cerevisiae* (Sc) to be assessed by the in vitro gas production technique. Exactly 0.2 g sample, 10 ml rumen fluid, 20 ml artificial saliva and 1 ml of yeast inoculum were evaluated in 72 glass bottles in triplicate for 12, 24, and 48 h at 39° C. Variables evaluated were ammonia nitrogen (AN), lactic acid (LA) and yeast count (YC). The data were evaluated with a completely random design with a split plot in time. Results of the LA variable are showed in Table 1. There were strain and fermentation time effect on AN, LA and YC ($P < 0.01$). Lowest values of AN were obtained with Kl2 ($P<0.01$) and highest with Io3, Io8 and Sc6 (22.5, 24.8, 24.8 and 24.1 mM/L at 48h, respectively). Highest values of YC were obtained with Kl2, Kl9, Kl11, Kl13 and Sc6 with values of 1.9, 1.3, 1.2, 1.1 and 1.0E+07 cells/ml respectively at 48h ($P < 0.01$).

We conclude that *K. lactis* yeast showed to be the most effective on the in vitro rumen fermentation, with better performance on yeast count and lactic acid reduction.

Table 1. Lactic acid values (mM/L) on the in vitro rumen fermentation of dairy cow diets with eight different strains of yeast

	Time (h)

W118 Effect of exogenous fibrolytic enzymes on in vitro ruminal fermentation kinetics and energy utilization of three Mexican tree fodder species. D. López[1], R. Rojo*[1], A. Z. M. Salem[1], J. Cedillo-Monrroy[1], B. Albarrán[1], A. González[2], J. L. Martínez-Benites[1], J. Morales-Diaz[1], and J. Tinoco-Jaramillo[1], *[1]Centro Universitario UAEM-Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México, [2]Universidad Autónoma de Tamaulipas, Cd. Victoria, Tamaulipas México.*

A factorial experimental treatment structure (3 x 3) was used to evaluate the effect of exogenous fibrolytic enzymes (EFE) on in vitro ruminal fermentation kinetics and energy utilization of three browse tree foliages (*Pithecellobium dulce*, *Heliocarpus velutinus* and *Guazuma ulmifolia*). A commercial exogenous fibrolytic enzyme (EFE) mixture (Fibrozyme, Alltech Inc., Nicholasville, KY) was added to browse species leaves at three levels: 0 (control), 3.5 and 7.0 mg/g. Browses species were harvested during dry season (April/May 2009) and incubated with goat ruminal inoculum. Chemical composition, plant secondary metabolites [total phenolics (TP), saponins (SAP), aqueous fraction (AF)] as well as in vitro ruminal gas production kinetics were determined using a general compartment model. Short chain fatty acids (SCFA) and metabolizable energy (ME) were estimated. Seven replicates of each treatment were used and data were analyzed using a randomized complete design. Differences among means were determined using a least squares means test. Addition of EFE improved the fermentation kinetics of the browse tree leaves. The CP content of *P. dulce* was higher ($P < 0.05$) than those of the remaining tree species. The NDF and SAP concentration of *G. ulmifolia* was higher ($P < 0.05$) than those of the other species. *P. dulce* and *G. ulmifolia* had high ($P < 0.05$) contents of TP. Gas production at 24 (h) (GP24) of *P. dulce* at the high EFE level (i.e., 7 mg EFE /g DM) showed a higher ($P < 0.01$) ruminal fermentation after 24 h of incubation than that of *G. ulmifolia*. The asymptotic gas production (b) (ml/g DM) and rate of gas production (c) (/h), were affected ($P < 0.01$) by enzyme treatment while the lag phase was not affected. The lower ($P < 0.01$) extent of gas production occurred in *G. ulmifolia* at 0 mg EFE /g DM as well as the c and b values. *P. dulce* with high levels of EFE (7.0 mg/g DM) showed the highest ($P < 0.05$) values for ME and SCFA while the *G. ulmifolia* without EFE showed the lowest values for ME and SCFA. Addition of EFE improved the fermentation kinetics of the browse tree leaves.

Key words: browse species, exogenous fibrolytic enzyme, plant secondary metabolites

W119 Effects of pH and temperature on fibrolytic enzyme activities of various commercial exogenous enzyme preparations. K. G. Arriola*, J. J. Romero Gomez, and A. T. Adesogan, *Department of Animal Sciences, Institute of Food and Agricultural Sciences, University of Florida, Gainesville.*

The objective of this study was to evaluate how the enzyme activity of commercial fibrolytic enzymes differed with the prevailing pH and temperature. Eighteen commercial fibrolytic enzymes from 5 companies were assayed in triplicate for xylanase and endoglucanase activity at pH 4.0, 5.0, 6.0, 7.0 and 8.0 at 39°C (Experiment 1) and at 20, 30, 40, and 50°C at pH 6.0 (Experiment 2). Xylanase was assayed in a 15-mL test tube containing 1.0 mL of 1.0% (wt/vol) oat spelts xylan as substrate and 0.9 mL of citrate-phosphate buffer (pH 6.0). After preincubation for 10 min., 0.1 mL of diluted enzyme was added to initiate the reaction and the suspension was incubated for 5 min. The reaction was terminated by adding 3 mL of dinitrosalicylic acid reagent. Endoglucanase was assayed as described above using 1.0% (wt/vol) carboxymethyl cellulose as substrate. The unit of enzyme was the amount of enzyme required to release 1 μmol of reducing sugars as xylose (xylanase) or glucose (endoglucanase) equivalents min-1 mg-1. Treatments were arranged in an 18 (enzymes) x 5 (pH) or 4 (temperatures) factorial layout and data analyzed with a model including these terms and the interaction using Proc Mixed of SAS. Xylanase activity was optimal at 20, 30, 40 and 50°C for 0, 11, 6, and 83% of the enzymes; whereas endoglucanase activity was optimal for 11, 0, 11, and 78% of enzymes at the respective temperatures. Xylanase activity was optimal at pH 4, 5, 6, 7, and 8 for 17, 44, 17, 5, and 17% of the enzymes, whereas, endoglucanase activity was optimal for 44, 33, 17, 6 and 0% of the enzymes at the respective pH. Xylanase and endoglucanase activities of most enzymes were optimal at 50°C and at pH 4 - 5. Therefore, few (<25%) of the 18 enzymes exhibited optimal activity under ruminal conditions (pH 6–7, 39°C).

Key words: xylanase, endoglucanase, exogenous enzymes

W120 Fiber digestibility of cool-season grasses. T. W. Downing*, *Oregon State University, Corvallis.*

Forage grass production is an important component of profitable dairying along the Pacific Northwest coast. Neutral detergent fiber digestibility (NDFD) is increasingly being used in ration formulation and forage benchmarking. However, data on differences in NDFD between and within cool-season grass species is limited. The objective of this study was to determine if NDFD differs between species and varieties. Eighteen cool-season grass varieties were replicated 3 times each in 6-m^2 randomized field plots. Included were 6 varieties each of perennial ryegrass (*Lolium perenne*), orchardgrass (*Dactylis glomerata*), and tall fescue (*Lolium arundinaceum*). Plots were mechanically harvested six times at approximately 28 d intervals beginning in March each year and harvested over a two year period. Forty eight-hour in vitro neutral detergent fiber (NDF) digestibility was determined using 0.3 g of sample in F57 bags in a DaisyII Incubator (Ankom Technology, Fairport, NY). Neutral detergent fiber was less ($P < 0.001$) for ryegrass (49.5±1.58) compared to both orchardgrass (57.5±3.64) or tall fescues (53.5±1.4). Neutral detergent fiber digestibility was greater

for ryegrass compared to orchardgrass and tall fescue (79.4±1.3, 76.2±1.4, and 76.5±1.1% of NDF respectively; $P < 0.01$). The fescues and orchard grasses were similar in NDF and NDFD. Neutral detergent fiber increased and NDFD decreased ($P < 0.05$) as the growing season progressed. These results indicate ryegrasses when managed intensively were significantly different from orchard grass and fescues.

Key words: neutral detergent fiber digestibility, cool-season grass, in vitro digestibility

W121 Comparison of chemical composition and digestibility among wheat straws treated with *Pleurotus djamur*. O. D. Montañez-Valdez*[1], J. A. Reyes-Gutierrez[1], J. A. Martínez-Ibarra[1], G. Rocha-Chavez[1], J. M. Tapia-Gonzalez[1], C. E. Guerra-Medina[2], J. J. Martínez-Tinajero[3], and J. H. Avellaneda-Cevallos[4], *[1]Centro Universitario del Sur, Ciudad Guzmán, Jalisco, México, [2]Centro Universiario de la Costa Sur, Autlán de la Grana, Jalisco, México, [3]Facultad de Ciencias Agrícolas, Universidad Autónoma de Chiapas, México, [4]Universidad Técnica de Estatal de Quevedo, Quevedo, Los Rios, Ecuador.*

A study was conducted to evaluate the effect of *Pleurotus djamur*, on chemical composition of maize stover. Maize stover treated and untreated with *Pleurotus djamur*, were obtained from a commercial facility. Ten samples of maize stover used previously as substrate to culture edible fungus were collected randomly. The negative control group consisted of the pasteurized maize stover untreated with *Pleurotus djamur*. All samples were analyzed to determinate dry matter (DM), organic matter (OM), crude protein (CP), neutral detergent fiber (NDF), acid detergent fiber (ADF), cellulose (C), hemicellulose (HC) and lignin (L). Data were analyzed by mean comparison using a Student′s *t*-test. No differences ($P \geq 0.05$) between treatments were found for DM, OM, CP, C, and L; however, treated maize stover ($P \leq 0.02$) showed higher percentages of ADF, as well as a lower NDF and HC value. We do not found change on in situ digestibility of DM ($P \geq 0.05$; Table 1). The growth of *Pleurotus djamur*, on maize stover changes its chemical composition by decreasing hemicellulose content and modifying cell wall components, this did not improve the nutritional quality of agricultural byproducts. This suggests that *Pleurotus djamur*-treated maize stover is not an ideal forage for ruminants.

Table 1. Chemical composition and in situ digestibility of maize stover treated with and without *Pleurotus djamur* (%)

Component	NC[1]	TMS[2]

W122 Effect of crude protein content on intake and digestion of coastal bermudagrass hays by horses. C. L. Spurgin, J. A. Coverdale, K. N. Winsco*, and T. A. Wickersham, *Texas A&M University, College Station.*

Forage is an essential component of the equine diet; however, relatively little information is currently available regarding the effects of CP content of bermudagrass (*Cynodon dactylon*) hay on intake and digestion in horses. Therefore, this study was conducted to determine the effect of forage CP content on intake and digestion of bermudagrass hay by horses. Four cecally fistulated geldings (BW 548 ± 23 kg) were used in a 4 × 4 Latin square. Geldings were provided ad libitum access to bermudagrass hay of 4 CP levels (6.9, 9.8, 12.7, and 15.6% CP; L, ML, MH, and H, respectively). Hay was offered daily in 2 equal feedings at 0600 and 1800 each day. Experimental periods were 15 d long, with 9 d of adaptation to treatment. Forage intake was determined from d 10 through d 13 to correspond with total fecal collections from d 11 through d 14. On d 15 cecal fluid samples were collected before feeding (0 h) and 4, 8, and 12 h, after the 0600 feeding. Forage OM intake was not significantly ($P > 0.21$) affected by CP content and was 8.97, 8.60, 9.53, and 10.98 kg/d for L, ML, MH, and H, respectively. In contrast, digestible OM intake increased linearly ($P = 0.04$) with increasing CP content and ranged from 3.70 to 5.35 kg/d for L and H, accordingly. Digestion of OM increased quadratically ($P = 0.03$). This response was largely driven by the increase between L and ML hays from 41.1 to 55.0%, followed by a leveling off at 48.8 and 48.5% for MH and H, respectively. Cecal pH responded in a cubic manner ($P < 0.01$) to CP content of the hays; however, all values were in the acceptable range for promoting fiber digestion. Plasma glucose concentrations increased linearly ($P = 0.04$) with increasing CP content and ranged from 68.8 for L to 73.7 mg/dL for H. Forage intake did not increase in response to increasing CP content; however, utilization, measured as the combination of intake and digestion, was sensitive to increasing CP content, suggesting nutritive value determinations of bermudagrass hay are justified when purchasing bermudagrass hay for horses.

Key words: horses, bermudagrass, intake

W123 The effect of silage nutrient variations on milk prediction outcomes of the Cornell Net Carbohydrate and Protein System. C. T. Hill*[1], M. J. Tetreault[1], and H. M. Dann[2], *[1]Poulin Grain Inc., Newport, VT, [2]William H. Miner Agricultural Institute, Chazy, NY.*

Variability in forages and forage samples is inevitable and measurable. The objective of this study was to determine the amount of variation of key nutrients in typical corn silage and haylage bunkers and how it may affect milk production. Samples were taken from 6 bunker silos [3 corn silage (CS) and 3 haylage (H)] on 24 of 28 consecutive days on 3 Vermont dairy farms. Samples were taken daily at 7, 30-cm intervals up to 2.1 m high, mixed, and sent for NIR analysis. Means were calculated for NIR results of nutrient parameters for each bunk and used to enter each forage into CNCPS (version 6.1.36). A base diet was created for each CS utilizing an alfalfa silage from the CNCPS library. The H base diets utilized a library CS. Forage ratios were 64.1% for the CS diets and 58.5% for the H diets. The ratio of CS to H was approximately 2:1 on a DM basis for all diets. Standard deviations were calculated (Microsoft Excel, 2007) within bunks for DM, CP, NDF, starch, and K_d. Diets of plus or minus one SD for each nutrient were created

for comparison to the base diets. Mean nutrient values and SD for each bunk are shown in Table 1. Variations in DM resulted in a predicted AF difference up to 2.6 kg. There was a 1.2 kg and 1.7 kg increase in ME and MP milk respectively for plus one versus minus 1 SD for CS1 K_d. Minus one SD resulted in approximately 1.0 kg of increased ME and MP milk for all CS NDF. All other variations resulted in less than 1.0 kg difference in ME and MP predicted milk. Although silages may appear uniform throughout a silo, frequent sampling may reduce variation in diets and improve the accuracy of model predictions.

Table 1. Silage mean nutrient values and standard deviations

	Forage					
Nutrient	CS1	CS2	CS3	H1	H2	H3
DM	36.8	36.4	36.4	36.1	43.0	33.5

W124 Partially replacing alfalfa and corn silages with fescue silages maintained fat corrected milk production. W. D. Verbeten*, D. K. Combs, and D. J. Undersander, *University of Wisconsin Madison, Madison.*

Meadow fescue or tall fescue silage was fed in combination with alfalfa and corn silage to evaluate the effects on milk production in early lactation dairy cows. Four treatment diets were fed to 52 early lactation (60.7 DIM ± 46.4 DIM) Holstein dairy cows (39 multiparous, 13 primiparous) producing 46.4 kg ± 11.7 kg of milk per day at the University of Wisconsin-Arlington research station. The feeding trial was a continuous lactation trial with a covariate period (2 weeks) before 6 treatment periods (2 weeks each). The cows were randomly assigned in pairs to electronic feeding gates, with 1 of the 4 treatment diets randomly assigned to each gate. Each gate was an experimental unit. The 4 diets varied in forage composition: the meadow fescue diet contained 4.6 kg DM of meadow fescue silage, 4.6 kg DM alfalfa silage, and 4.6 kg DM corn silage; the tall fescue diet contained 4.6 kg DM of tall fescue silage, 4.6 kg DM alfalfa silage, and 4.6 kg DM corn silage; the positive control diet contained 5.6 kg DM of alfalfa silage, 5.6 kg DM of corn silage, and 2.2 kg DM of wheat straw; the negative control diet contained 6.8 kg DM of corn silage and 6.8 kg DM alfalfa silage. All diets contained between 11 and 12 kg DM of concentrate feeds. The meadow fescue, tall fescue, and positive control diets were formulated to 30% NDF, while the negative control diet was formulated to 27% NDF. Total covariate adjusted 84 d, 3.5% FCM yields were analyzed in a mixed effects model, where the gate was the random effect and the diet was the fixed effect. The milk yields for the meadow fescue, tall fescue, positive control, and negative control diets were not statistically different at $P > 0.05$ (7219.94 kg/gate, 7110.19 kg/gate, 7352.60 kg/gate, and 7197.18 kg/gate, respectively). This data indicates that high quality meadow and tall fescue silages can be fed to high producing dairy cows without a decrease in fat corrected milk production.

Key words: meadow fescue, tall fescue, wheat straw

W125 Processed and unprocessed canola straw in Holstein male calves diets changed blood parameters and carcass characteristics. M. Ghiasvand, K. Rezayazdi, and M. Dehghan-Banadaky*, *Animal Science Department, Campus of Agricultural and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

Canola has been vastly cultivated for edible oil production. After harvesting, the canola straw remains in the field and is burnt. This research used 24 Iranian Holstein male calves with 266 ± 64 kg live weight in an experiment with a completely randomized design with three diets. Diet 1, included 10% corn silage and 15% alfalfa hay and in diet 2 and 3, alfalfa substitute with unprocessed and processed canola straw. Energy value and protein content of the diets were similar. The animals were housed in individual concrete-floor tie stalls and individually fed. The experimental period lasted 90 days and at the end of experiment, four hours after the morning meal, blood samples were taken. After slaughter some carcass characteristics were measured and beef quality was evaluated by a sensory panel. Blood glucose level was significantly decreased in calves fed diet 2 ($P < 0.05$) and cholesterol level was significantly lower in calves fed diets 2 and 3 ($P < 0.05$). Effect of diet 3 on T3 (tri-iodoothyronine) hormone was significant, calves fed this diet had higher levels of T3 ($P < 0.05$) but values in calves fed diets 2 and 1 did not significantly differ. Hormone levels of T4 (thyroxine) and thyroid weight had no significant difference among calves. Hot carcass weight, visceral fat weight, back fat thickness, carcass length and muscle cross section were not affected by diets. But the effect of different diets on dressing % was significant ($P < 0.05$). Calves fed diet 2 had the highest dressing % and calves fed diet 3 the lowest ($P < 0.05$). The results indicated that chemical composition and sensory quality of meat did not differ among treatments. Canola straw can be used in the diet of male calves for fattening particularly under drought conditions and or when there is a shortage of other forage sources.

Key words: canola straw, Holstein male calves, carcass characteristics

W126 Chromium acetate induces adipogenesis of bovine intramuscular adipocytes through reduced phosphorylation of adenosine monophosphate–activated protein kinase α. K. Y. Chung*, R. T. Tokach, and B. J. Johnson, *Texas Tech University, Lubbock.*

Chromium sources have positive effects on glucose uptake in both cattle and pigs. Chromium aids in insulin signaling in insulin-sensitive cells such as adipocytes. Adenosine monophosphate-activated protein kinase α (AMPKα) can affect lipid metabolism in the bovine intramuscular (i.m.) and subcutaneous (s.c.) adipocytes. We hypothesized that chromium acetate (CrAc) may affect AMPKα phosphorylation state in bovine i.m. and s.c. adipocytes. Bovine i.m. and s.c. preadipocytes were incubated with similar differentiation factors such as 10 μM insulin, 10 μM ciglitizone, 1 μM dexamethasone, and 100 μM oleic acid. Multilocular lipid droplets accumulated in the cultured i.m. adipocytes, but unilocular lipid droplets accumulated in the s.c. adipocytes after 96 h of CrAc treatment. Data were analyzed as a completely randomized design using the MIXED model, each treatment performed in triplicate. Difference between control and treatments were determined using the LSD procedure. Quantity of mRNA was measured by agarose gel electrophoresis and OD calculation. Western blot analysis revealed that CrAc reduced ($P < 0.05$) phospho-AMPKα to AMPKα in i.m. adipocytes but had no effect in s.c. adipocytes. Relative PPARγ mRNA concentrations were greater ($P < 0.05$) in i.m. adipocytes with CrAc treatments compared with the control cultures. Treatment with 10 μM sodium acetate compared with CrAc did not differ ($P > 0.05$) from control for PPARγ, glucose transporter 4 (GLUT4), and GPR43 mRNA concentrations. Total amount of PPARγ mRNA was 5 times greater in s.c. than in i.m. adipocytes ($P < 0.05$). Although GLUT4 level was not different in i.m. adipocytes, there was a dose-dependent effect of CrAc in the s.c. adipocytes. The mRNA concentrations of GPR43, a short-chain fatty acid receptor, tended to be increased ($P = 0.08$) in i.m. adipocyte cultures. Chromium acetate can induce adipogenic development in the i.m. preadipocytes potentially by reducing phosphorylation of AMPKα, and the GPR43 membrane protein may be involved in this process.

Key words: chromium acetate, adenosine monophosphate–activated protein kinase α, adipocyte

W127 Palmitoleic acid regulation of lipid metabolism in primary bovine adipocytes could involve genes associated with fatty acid oxidation. A. K. G. Kadegowda*, T. A. Burns, S. L. Pratt, and S. K. Duckett, *Clemson University, Clemson, SC.*

Palmitoleic acid (C16:1n7) is a proposed lipokine that regulates systemic metabolism. The objective was to determine the effect of C16:1 on fatty acid metabolism gene expression in adipocytes. Bovine primary preadipocyte cultures were isolated from intermuscular fat from rib sections of 18-mo old Angus crossbred heifers (n = 3) fed a concentrate diet. Preadipocytes were differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μ*M* dexamethasone (DEX), 20 μ*M* troglitasone (TRO), 0.5 m*M* isobutylmethylxanthine (IBMX), and 10 m*M* acetate] for 2 d. Cells were further differentiated from D2 to D12 in differentiation media [with out DEX and IBMX] containing 1 of 4 levels of C16:1 (0, 50, 150, or 300 μ*M*). Cells were harvested on D6 and D12 for fatty acid analysis using GLC and mRNA expression by RT-qPCR. We measured the expression of *Acyl-Coenzyme A oxidase 2 (ACOX2), Acyl-CoA dehydrogenase, long chain (ACADL), Phytanoyl-CoA 2-hydroxylase (PHYH), Caveolin1 (CAV1)* and *Adipose differentiation-related protein (ADFP)*. The geometric mean of *Eukaryotic translation initiation factor 3, subunit k* (*EIF3K*) and *Ubiquitously expressed transcript* (*UXT*) was used for normalization. Increasing the concentration of C16:1 in the media increased the cellular concentration of C16:1 ($P < 0.05$) and C18:1cis11 ($P < 0.05$), a C16:1 elongation product but decreased ($P < 0.05$) the cellular levels of C16:0, C18:0, C18:1c9. Of the measured genes related to fatty acid oxidation, *ACADL* increased by 2.36 fold ($P < 0.07$) while *PHYH* increased by 95.5 fold ($P < 0.01$) compared with controls on D6 suggesting potential increase in mitochondrial β-oxidation and peroxisomal α-oxidation, respectively. The increase in the mRNA expression of lipid droplet associated proteins *CAV1* (1.47 fold, $P < 0.07$) and *ADFP* (3.4 fold, $P < 0.01$), could be a consequence of increase in lipid droplet content due to increase in C16:1 level. The results from the study shows that C16:1 regulates lipid metabolism in the adipose tissue and could potentially involve mechanisms related to fatty acid oxidation.

Key words: palmitoleic acid, adipocyte, fatty acid oxidation

W128 Effect of anabolic implant and quality grade on lipogenic gene expression in subcutaneous adipose tissue. S. K. Duckett*, S. L. Pratt, and J. W. Long, *Clemson University, Clemson, SC.*

Angus-cross steers (n = 24; 488 kg) were randomly allotted to either non-implant (CON) or implant (IMP) treatments to explore the effects of anabolic implants on lipogenic gene expression in subcutaneous adipose depots by quality grade. Steers allocated to IMP received a single Revalor-S (24 mg estradiol, 124 mg trenbolone acetate) on d 0. All steers were individually fed a high-concentrate diet for 72 d and slaughtered. At slaughter, adipose tissue samples were collected from subcutaneous adipose depots, flash-frozen, and stored at −80°C for subsequent RNA extraction. Carcass weight and skeletal maturity were greater ($P < 0.05$) for IMP than CON. Other carcass variables including marbling score, quality grade and yield grade did not differ among treatments. For qPCR, a sub-sample (n = 8) was selected from each treatment based on quality grade, LOW (Select-) vs. HI (Choice-). Data were analyzed with implant treatment, quality grade, and 2-way interaction in the model. Total RNA yield from subcutaneous adipose tissues averaged 36.2 μg/g and was not affected by treatment or quality grade. All 2-way interactions were significant ($P < 0.05$) for the lipogenic genes evaluated. Stearoyl-CoA desaturase (SCD) is the rate-limiting enzyme in the conversion of saturated fatty acids to monounsaturated fatty acids. The SCD mRNA expression was downregulated ($P < 0.05$) by 11.3-fold in IMP-LOW subcutaneous adipose tissues compared with CON-LOW. Expression of SCD did not differ ($P > 0.05$) for CON-HI or IMP-HI compared with CON-LOW. Fatty acid synthase (FASN) is 1 of 2 enzymes regulating de novo fatty acid synthesis. The mRNA expression of FASN was downregulated ($P < 0.05$) in IMP-LOW by 11.6-fold and IMP-HI by 1.9-fold compared with CON-LOW. Fatty acid elongase (ELOVL6) is the enzyme responsible for the elongation of fatty acids. ELOVL6 mRNA expression was downregulated ($P < 0.05$) in IMP-LOW by 6-fold compared with CON-LOW. ELOVL6 mRNA expression did not differ ($P > 0.05$) in IMP-HI or CON-HI compared with CON-LOW. Lipogenic gene expression was downregulated in subcutaneous fat from implanted steers with low quality grades.

Key words: beef, implant, gene expression

W129 Signaling pathways mediating the effects of insulin-like growth factor-I on proliferation, protein synthesis, and protein degradation in bovine satellite cells. X. Ge and H. Jiang*, *Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg.*

The objective of this work was to identify the signaling pathways mediating the effects of IGF-I on proliferation, fusion, protein synthesis, and protein degradation in bovine muscle cells. Satellite cells were isolated from adult cattle skeletal muscle and were allowed to activate and proliferate or were induced to form myotubes following standard protocols. Cell proliferation was determined by measuring the numbers of viable cells at different times. Protein synthesis and degradation were determined by measuring the accumulation of 3H-phenylalanine in cellular protein and the release of 3H-phenylalanine to the medium, respectively. The signaling pathway involved was identified by including in the medium rapamycin, LY294002, or PD98095, which are specific inhibitors of the IGF-I receptor signaling molecules mTOR, AKT (PKB), and ERK (MAPK), respectively. Western blotting confirmed that IGF-I action caused phosphorylations of p70S6K (a signaling molecule immediately downstream of mTOR), AKT, and ERK, and that these phosphorylations were completely or near completely blocked by their corresponding inhibitors. Proliferation of bovine myoblasts was stimulated by 500 ng/mL IGF-I ($P < 0.01$), and this stimulation was partially blocked by PD98059 ($P < 0.05$), and was completely blocked by rapamycin or LY294002 ($P < 0.01$). Protein degradation in myotubes was inhibited by approximately 20% by 500 ng/mL IGF-I ($P < 0.05$), and this inhibition was completely relieved by LY294002 ($P < 0.01$), but not at all by rapamycin or PD98095. Protein synthesis in myotubes was increased by 30% by 500 ng/mL IGF-I ($P < 0.01$), and this increase was completely blocked by rapamycin, LY294002, or PD98059 ($P < 0.01$). Addition of IGF-I to the culture medium had no effect on fusion of myoblasts into myotubes. These data suggest that IGF-I stimulates proliferation of bovine myoblasts and protein synthesis in bovine myotubes through both the PI3K/AKT and the MAPK signaling pathways, and that IGF-I inhibits protein degradation in bovine myotubes through the PI3K/AKT pathway only from the IGF-I receptor.

Key words: IGF-I, muscle, signaling

W130 Effects of energy intake and age on the expression of adipogenic genes in subcutaneous and intramuscular fat in bovine Spanish Pirenaica breed. B. Soret*, P. Tiberio, A. Arana, JA Mendizabal, and L. Alfonso, *Universidad Publica de Navarra, Pamplona, Navarra, Spain.*

An improved understanding of the molecular mechanisms that drive adipose tissue development in livestock may allow for new strategies to modify adipose tissue distribution to improve meat quality by enhancing intramuscular fat (IMF). The objective of this study was to investigate the effects of dietary energy and age on the expression of key adipogenic genes in Pirenaica, a very low fattening breed widely used in cattle production systems in Navarra, Spain. Sixteen half-sibling young Pirenaica bulls were distributed into 4 groups (n = 4) and slaughtered at 6, 12, and 18 mo of age; the later assigned to 2 groups differing in energy density in the ration (ME 3.29 and 2.87 Mcal/kg DM). Subcutaneous fat (SCF) and IMF were harvested at slaughter for mRNA isolation. Gene expression was measured by reverse transcription and quantitative PCR. Relative gene expression (Ct method) was calculated by normalizing against β-actin using the 6-mo-old group as calibrator. Backfat thickness (BFT), IMF chemical fat content, and adipocyte diameter were measured. Statistical analysis was performed by ANOVA. No differences in gene expression for *PPARγ*, sterol regulatory element binding protein (*SREBP*), fatty acid binding protein (*FABP*), lipoprotein lipase, and acetyl-CoA carboxylase (*ACC*) were found in IMF, maybe related to the low state of development of that depot in these animals which only had 2.4% chemical fat. Energy content of the diet did not affect SCF expression of any of the genes evaluated. In contrast *FABP* ($P < 0.01$) and *ACC* ($P < 0.001$) were affected by age, showing the higher values at 12 mo. Also BFT and the diameter of the SCF adipocytes showed the higher increase between 6 and 12 mo ($P < 0.05$); thus, some genes involved in lipogenesis changed with age accordingly to changes in cell size in a depot-dependent manner. Differences between depots in expression of *FABP*, *PPARγ*, and *SREBP*($P < 0.001$) were found. This, together with changes with age for SCF only, may suggest depot-specific patterns of gene expression during fattening.

Key words: adipogenic gene, intramuscular fat, bovine

W131 Age post weaning but not birth weight and sex affects the small intestinal glutathione redox status of piglets. J. Michiels*[1,2], E. Claeys[2], A. Ovyn[2], and S. De Smet[2], *[1]Faculty of Biosciences and Landscape Architecture, University College Ghent, Ghent, Belgium, [2]Laboratory for Animal Nutrition and Animal Product Quality, Department of Animal Production, Ghent University, Melle, Belgium.*

Glutathione (GSH) serves as the major endogenous antioxidant in gut tissue and cells keep it predominantly in the reduced state, i.e., a low oxidized to reduced glutathione (GSSG/GSH) ratio. The aim of the study was to assess the effect of birth weight, sex, and age post weaning on small intestinal mucosal glutathione redox status of piglets. Newborns from 17 Danbred hybrid sows were weighed and tagged. At weaning (18.8 ± 0.44d) pairs of intra-uterine growth-retarded (IUGR) and normal birth weight sex-matched littermates were selected and fed a starter ad libitum until 1h before sampling at 0, 2, 5, 12, and 28d post weaning. An IUGR pig was defined as having a birth weight <1 kg and < mean litter birth weight – 1.5 SD. Mucosa was collected from 2 small intestinal sites; at 5% (≈end of duodenum) and at 75% of total length. GSH and GSSG were determined by HPLC using γ-Glu-Glu as internal standard following the reaction of thiols with iodoacetic acid to form S-carboxymethyl compounds and derivatization with 2,4-dinitrofluorobenzene. Data were analyzed by linear models with birth weight, sex, and age post weaning as fixed factors and presented as adjusted means. Birth weight and sex showed no significant effects. A temporal decline in GSH content at d2 and increase in the GSSG/GSH ratio at d5 in the proximal small intestinal mucosa indicates that oxidative stress occurred in that time window (Table 1). At 75% of length of the small intestine there was a gradual decrease of the GSSG/GSH ratio with time. The higher GSH content and GSSG/GSH ratio in the proximal small intestine might illustrate the higher need for antioxidant action against dietary pro–oxidants at that site.

Table 1. Effect of age post weaning (d) on glutathione redox status of small intestinal mucosa in piglets (n = 16)

	Age post-weaning (d)						
	0	2	5	12	28	SEM	*P*-value
5% of length							
GSH (μmol/g)	1.94[c]	1.79[c]	2.11[c]	2.65[b]	3.27[a]	0.075	<0.001

W132 Feed restriction alters reactivity of body fat after catabolic stimulation in growing pigs. B. U. Metzler-Zebeli, S. Görs, K. Giggel, R. Krüger, H. M. Hammon, and C. C. Metges*, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Birth weight (BIRTH) and feed restriction (FR) may affect later body composition due to persistent alterations in catabolic and anabolic processes. Therefore, we investigated the effect of BIRTH and FR on the reactivity of body fat after stimulation of catabolic processes by pST-Clenbuterol (ST+C). Two female littermate pigs from 20 sows each with low (≤1.1 kg) or normal birth (1.4 to 1.6 kg) weight were used. Half of the pigs were fed ad libitum whereas the other half was restrictively fed (50% ad libitum) between ages d 78 and 98. Subsequently, all pigs were (re)fed ad libitum. At d 84 of age, 20 pigs were fitted with catheters in A. carotis and V. jugularis. After intravenous ST+C administration, plasma lipids, glycerol, and glucose concentrations were determined over 12 h at ages d 96, 104, and 118. Body fat content was determined using DXA measurement at ages d 75 and 96. The statistical model included BIRTH, feeding type, time, litter size group, interactions, and random factor sow. Mobilization of body fat and glycogen due to ST+C was confirmed by increased ($P < 0.01$) plasma triglycerides (TG; 1 to 8 h after ST+C), glycerol (1 to 6 h after ST+C) and glucose (0.5 to 6.5h after ST+C) concentrations at d 96. Plasma TG, glycerol, and glucose were not affected by BIRTH and FR. In contrast, plasma NEFA were greater ($P < 0.01$) in restrictively compared with ad libitum-fed pigs after ST+C at d 96 indicating increased lipolysis. The enhanced catabolic status in restrictively-fed pigs was confirmed by their lower body fat as compared with ad libitum-fed pigs at age d 96 ($P < 0.05$). Although TG increased after ST+C stimulation at ages d 104 and 118, NEFA release did not differ among pigs at age d 104. Interestingly, after ST+C stimulation at d 118 plasma NEFA were again greater in pigs that were restrictively fed between d 78 and 98 of age ($P < 0.05$), but were not affected by BIRTH. In conclusion, FR causes alterations in the catabolic reactivity of body fat not only during the immediate FR period but also at 3 wk of refeeding. However, BIRTH did not affect body fat mobilization after catabolic stimulation. Supported by BMBF (VISION EPIFOOD).

Key words: lipolysis, body fat, NEFA

W133 The effect of different methods of using zilpaterol hydrochloride on growth performance in Japanese quail. M. Mohammadi*, A. Towhidi, H. Moravej, and A. Zareh Shahne, *Department of Animal Science, University of Tehran, Karaj, Alborz, Iran.*

Zilpaterol hydrochloride is a β2-adrenergic agonist which has been shown to increase lean muscle and decrease fat deposition. It seems that the chronic supplementation of β-agonists diminishes the response because of desensitizing of the receptors. This study was designed to compare 2 methods of using zilpaterol hydrochloride including once a day and skip 2 d on growth performance in Japanese quail. Ninety-six quail of 33 d of age were assigned to 3 groups with 4 replications. Treatments were defined as: T1 as control, T2 received zilpaterol skip 2 d, and T3 received zilpaterol once a day. Diets were based on corn and soybean meal in the finisher period (24% CP and 2.9 Mcal/kg of ME) and the birds orally received 0.225 mg/kg of live weight/d zilpaterol for 14 d and slaughtered at 50 d of age. The complete randomized design in GLM procedure was used to analyze the data. Results showed zilpaterol supplementation improved weight gain ($P < 0.0001$) and feed conversion ratio ($P < 0.001$) in both treatments compared with control, but did not affect feed intake at d 33 to 40 ($P = 0.10$), whereas at d 40 to 47, zilpaterol did not have a significant effect on growth performance ($P > 0.05$). Furthermore, there were no significant differences in weight gain ($P = 0.15$), feed conversion ratio ($P = 0.21$), or feed intake ($P = 0.31$) between the 2 treatments that received zilpaterol at 40 to 47 d. The feed conversion ratio ($P = 0.23$) and weight gain ($P = 0.13$) were negatively affected in the period of 40 to 47 d in all groups. It seems that maturity and hormonal modification had considerable effects on growth performance. It was concluded that zilpaterol hydrochloride could improve growth performance when used by either method for the 33 to 40 d of quail rearing. However, considering the economics, the skip 2 d was better than once-a-day consumption and will have less cost.

Key words: zilpaterol hydrochloride, Japanese quail, growth performance

W134 Effects of dietary supplementation of sodium stearoyl-2-lactylate in a low-energy density diet on growth performance, blood profiles, and relative organ weight in broilers. S. M. Hong*, J. P. Wang, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

The aim of this study was to investigate the effects of supplementation of a dietary emulsifier sodium stearoyl-2-lactylate (SSL) in a low-energy density diet on growth performance, blood profiles, and relative organ weight in broilers. A total of 260 male and female ROSS 308 broiler chicks (2-d old, average BW = 45 ± 1.0 g) were randomly allotted to 1 of 5 treatments with 4 replications per treatment and 13 chicks per pen. The diets were fed during the experiment in 2 phases consisting of a starter phase from d 0 to 21 and a finisher phase from d 22 to 35. A corn-soybean meal-based diet was formulated as a control diet and dietary treatments were as follows: 1) NC (negative control; −200kcal ME/kg energy down spec diet), 2) PC (positive control; 3,150kcal ME/kg), 3) P1 (−50 kcal ME/kg energy down spec diet + 0.05% SSL), 4) P2 (−150kcal ME/kg energy down spec diet + 0.05% SSL), and 5) P3 (NC + 0.1% enzyme and 0.05% SSL). Body weight gain (BWG) was greater in PC, P1, and P3 treatments than in NC treatment ($P < 0.05$) and feed intake (FI) was lesser ($P < 0.05$) in P2 treatment than in P3 treatment throughout the whole experiment. The PC and P1 treatments had greater ($P < 0.05$) FCR than NC and P3 treatments overall during the experiment. Lymphocyte percentages in NC and PC treatments were greater ($P < 0.05$) than that in P1 treatment. Birds fed PC, P1, and P3 diets resulted in an increased triglyceride level compared with birds fed NC diet ($P < 0.05$). The relative spleen weight was decreased ($P < 0.05$) in P3 treatment compared with CON treatment. The bursa of Fabricius was heavier in P3 treatment than

that in PC, P1, and P2 treatments. In conclusion, SSL administration partially improved BG, FCR, and triglyceride level.

Key words: broiler, emulsifier, growth performance

W135 Insulin-like growth factor-I (IGFI), IGF binding proteins (IGFBP), and growth hormone receptor (GHR) mRNA concentration in fetal liver and duodenum in response to variable maternal nutrition during gestation. M. Field*, R. Anthony, T. Engle, S. Archibeque, and H. Han, *Colorado State University, Fort Collins.*

Undernutrition during gestation is known to influence fetal development and predispose offspring to the metabolic syndrome. We investigated the mRNA concentration of IGFI, IGFBP-2 and −3, and GHR in liver and duodenum from twin fetal lambs. Multiparous whiteface ewes were randomly assigned to 1 of 3 treatments at 21 d of gestational age (dGA). Ewes were either fed 100% (Control; n = 7) or 50% of nutrient requirements from 28 to 78 dGA and readjusted to 100% beginning at 79 dGA (50–100; n = 5) or 50% of requirements from 28 to 110 dGA, followed by a 5% increase at 5-d intervals until 135 dGA (50–50; n = 7). Fetal liver (L) and duodenum (D) were collected at 135 dGA. Concentration of each mRNA was corrected by ribosomal protein S15 mRNA concentration. Concentration of IGFI mRNA did not differ in fetal liver ($P = 0.54$) and duodenum ($P = 0.32$), but was numerically greater in 50–100 (L = 0.90 ± 0.02, D = 0.58 ± 0.05) than Control (L = 0.87 ± 0.02, D = 0.54 ± 0.04) and 50–50 (L = 0.87 ± 0.02, D = 0.64 ± 0.04) fetuses. There were no differences in expression of IGFBP3 mRNA between treatments in either liver or duodenum. Liver expression of IGFBP2 mRNA did not differ and concentrations were low or undetectable in duodenum. Liver GHR mRNA was numerically greater ($P = 0.15$) in 50–100 fetuses (0.92 ± 0.02), than Control (0.90 ± 0.02) and 50–50 (0.87 ± 0.02) fetuses. Duodenal GHR mRNA did not differ (Control 0.78 ± 0.03; 50–100 0.72 ± 0.04; 50–50 0.81 ± 0.03; $P = 0.266$). Natural intrauterine growth restriction in twin pregnancy may contribute to lower IGFI and GHR concentrations while realimentation from mid-gestation may induce elevated GHR and IGFI expression, which contributes to compensatory fetal growth during late gestation in twin pregnancy. This project was supported by National Research Initiative Competitive Grant no. 2009–35206–05273 from the USDA National Institute of Food and Agriculture.

Key words: sheep, insulin-like growth factor I, growth hormone

W136 Effects of variable maternal undernutrition on uterine and umbilical IGF-I, insulin, and ghrelin concentrations in near-term sheep twin pregnancies. M. Field*, R. Anthony, T. Engle, S. Archibeque, and H. Han, *Colorado State University, Fort Collins.*

Maternal undernutrition during gestation alters the developmental environment of a fetus and predisposes the offspring to the metabolic syndrome in later life. We investigated the impact of maternal undernutrition on IGF-I, insulin, and ghrelin concentrations in uterine and umbilical blood in near-term twin pregnant sheep. Multiparous whiteface ewes were randomly assigned to 1 of 3 treatments and acclimation to individual pens (7 d) begun at 21 d of gestational age (dGA). Ewes were either fed 100% (Control; n = 7), or 50% of nutrient requirements from 28 to 78 dGA and readjusted to 100% beginning at 79 dGA (50–100; n = 5) or 50% of requirements from 28 to 110 dGA, followed by a 5% increase at 5-d intervals until 135 dGA (50–50; n = 7). During cesarean section uterine and umbilical blood was collected while the fetus was viable. Blood hormone concentrations were determined by RIA and analyzed using the PROC MIXED model of SAS. Uterine artery IGF-I and insulin concentrations were not different between treatments. Umbilical vein (UV) IGF-I was greater ($P = 0.02$) in 50–100 (74.4 ± 6.7 ng/mL) than Control (50.9 ± 5.9 ng/mL) and 50–50 (46.7 ± 5.6 ng/mL). Umbilical artery (UA) IGF-I exhibited a similar trend ($P = 0.10$) where 50–100 (91.4 ± 9.0 ng/mL) was greater than Control (67.9 ± 8.1 ng/mL) and 50–50 (66.6 ± 7.5 ng/mL). Insulin in UA was greater ($P = 0.08$) in 50–100 (0.70 ± 0.15 ng/mL) than Control (0.30 ± 0.14 ng/mL) and 50–50 (0.24 ± 0.13 ng/mL). The UV and UA ghrelin concentrations were not different between treatments, although UV and UA ghrelin were numerically greater in 50–50 (UA = 44.5 ± 10.3, UV = 31.8 ± 7.5 pg/mL) than both Control (UA = 29.6 ± 11.1, UV = 25.3 ± 8.0 pg/mL) and 50–100 (UA = 24.5 ± 12.5, UV = 23.0 ± 8.8 pg/mL). The IGF-I and insulin concentrations in 50–100 umbilical V and A indicate a shift in IGF-I and accelerated fetal growth as a result of nutrient deprivation followed by realimentation.

Key words: undernutrition, IGF-I, blood

W137 Transfer of omega-3 fatty acids from dams to calves in dairy cows. M. Zachut*[1,2], A. Romanenco[1,2], H. Lehrer[1], A. Arieli[2], and U. Moallem[1], *[1]Agriculture Research Organization, Bet Dagan, Israel, [2]Faculty of Agriculture, Hebrew University, Rehovot, Israel.*

In many species fatty acid (FA) composition of the maternal diet during pregnancy can affect the FA composition of the fetus. Omega-3 FA have a crucial role in neonatal brain development, yet the transfer of long chain FA through the placenta in ruminants is very limited. The objectives were to examine 1) the plasma FA composition in newborn calves, and 2) the transfer of various omega-3 FA from dams into calves' plasma. Twenty 7 multiparous Israeli-Holstein dry cows (256 d pregnant) were assigned to 3 groups and supplemented with 300 g/d per cow of encapsulated fat that contained: (i) control - saturated FA; (ii) FLX - 51.3 g/d per cow 18:3n-3 (ALA) from flaxseed oil, and (iii) FO - 3.6 C22:5n-3 (DPA) and 3.0 g/d per cow C22:6n-3 (DHA) from fish oil. Blood samples were collected from cows twice a week and from calves immediately after calving, before colostrum offering. FA composition was determined in dams in the last sample before parturition. Data were analyzed using the GLM model of SAS. Across treatments analysis revealed that the proportions of saturated and mono-unsaturated FA in plasma were greater in calves than in cows (49.8 vs. 42.5% and 30.0 vs. 12.7%, respectively), while the proportion of polyunsaturated FA (PUFA) was 2-fold greater in dams than in calves (44.8 vs. 20.1%, respectively). The proportion of ALA in plasma of FLX cows was elevated to 5.2% as compared with 2% in the control; however, this FA was not transferred into calves' blood. Greater plasma proportions of DPA (0.32 vs. 0.16%) and DHA (0.30 vs. 0.02%) were found in the FO cows than in the controls, respectively, and the proportion of DHA was nearly doubled in the FO calves' blood as compared with controls (0.47 vs. 0.26%, respectively). Furthermore, the FO calves had greater proportions of total PUFA in plasma as compared with both other groups (23.9 vs. 18.5%, respectively). In summary, the low permeability of the placenta to FA resulted in a very different plasma FA composition in newborn calves as compared with dams. Furthermore, dietary DHA, but not ALA, passages from dam to fetus in cows, perhaps in an active transfer due to the essentiality of this FA to fetal development.

Key words: omega-3, calf, fatty acid composition

W138 Temporal changes in the proteome of the uterine histotroph in cattle. M. P. Mullen*[1], A. C. O. Evans[2], G. Elia[3], M.

Hilliard[3], N. Forde[2], M. H. Parr[1], M. G. Diskin[1], and M. A. Crowe[2], *[1]Animal and Bioscience Research Department, Animal and Grassland Research and Innovation Centre, Teagasc, Athenry, Co. Galway, Ireland, [2]School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland, [3]Conway Mass Spectrometry Resource, University College Dublin, Belfield, Dublin 4, Ireland.*

The composition of the uterine fluid (or histotroph) that bathes the early embryo is critical for its growth and development as it is the sole supply of nutrients. The objective of this study was to characterize the proteome of the bovine histotroph during key stages of the estrous cycle. The uterine horn ipsilateral to the corpus luteum of Holstein-Friesian heifers on Day 7 (n = 6) and Day 13 (n = 6) of separate estrous cycles was non-surgically flushed with 50 mL of 100 mM Tris pH 7.2. Global protein abundance was analyzed using a label-free shot gun proteomics approach encompassing SCX fractionation coupled with reversed phase LC–MS/MS analysis. Thresholds for defining proteins more abundant on either day included (i) an average spectral count value ≥ 2, (ii) signal in at least 3 animals and (iii) spectral count ratio of ≥ 5 between days. This led to the classification of 20 proteins more abundant on Day 7 vs. Day 13 including serpins, immune related complement proteins, structural cytokeratins, and hypothetical proteins. In addition, 35 proteins were more abundant on Day 13 vs. Day 7 and included novel bovine histotroph proteins such as members of the Cathespin family B, D, Z, and L2; previously reported bovine histotroph protease modulators Legumain (LGN), Metalloproteinase inhibitor 2 (TIMP2), Tripartite motif-containing protein 25 (TRIM25); metabolic proteins Actin and Lysosomal α-mannosidase (MAN2B1) and growth factor binding proteins IGFBP-1 and −5. Furthermore, uncharacterized and structural proteins were only identified on Day 7 while proteins involved in stressful microenvironment management were more abundant on Day 13. Lowering the spectral count ratio threshold to include proteins with a ratio of 2 to 4 resulted in an additional 28 proteins more abundant on Day 7 vs. Day 13 and 46 proteins more abundant on Day 13 vs. Day 7. Because temporal changes in uterine gene expression between Day 7 and Day 13 are associated with embryo development, we propose that the abundance of these proteins is similarly supportive of embryo development and required for the establishment of pregnancy in cattle. Funded by Science Foundation Ireland 07/SRC/B1156.

W139 Effect of maternal diet on the ontogenetic development of the hepatic proteome in intrauterine growth-restricted porcine offspring. M. Peters, B. Kuhla, I. S. Lang, E. P. Rudolph, and C. C. Metges*, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

We determined the effect of intrauterine growth restriction (IUGR) caused by excess and low-protein gestation diets (Rehfeldt et al. J Anim Sci 89:329, 2011) on development of hepatic proteome of pre- and postnatal porcine offspring. Gilts (n = 58; 241 d, 150.6 kg) were randomly assigned to 3 diet groups. The isocaloric diets contained adequate (AP, 12.1%), high (HP, 30%) or low (LP, 6.5%) protein levels at the expense of carbohydrates. Pigs were killed and liver samples of light (L) and heavy (H) offspring at d 94 post conception (dpc), d 1, 28, and 188 post natum (dpn) were analyzed by 2D-SDS-PAGE and MALDI-TOF MS. The model (SAS PROC MIXED) included maternal diet, offspring BW class (94 dpc, 1 dpn), sex, all interactions, and Tukey-Kramer test ($P \leq 0.05$). In HP fetuses and LP neonates the same number of proteins related to glycolysis (GL) and glycogen synthesis (GS) were diet dependently affected, whereas proteins of gluconeogenesis (GNG) were increased in HP and L neonates and L offspring at 28 dpn (Table 1). The LP fetuses had an increased expression of GL-related enzymes and a reduced expression of proteins related to GS. Proteins related to TCA cycle were upregulated in HP, LP, and L fetuses, as well as in LP and L offspring at 28 dpn, but downregulated in HP, LP, and L neonates and HP offspring at 28 dpn, whereas they could not be detected at 188 dpn. Validation of 6 selected proteins at 1 dpn via Western blot confirmed the expression pattern obtained from 2D analysis. In conclusion, maternal LP and HP diets persistently changed the offspring proteome profile of major metabolic pathways. Different diet-dependent profiles indicate different intrauterine regulatory mechanisms leading to offspring IUGR. Supported by DFG (ME 1420/8-1) and BMBF (Fugatoplus-FEPROeXPRESS)

Table 1. Effect of maternal gestation diet and BW class on offspring hepatic protein expression ratios related to glucose metabolism

Effect	94 dpc	1 dpn	28 dpn	188 dpn
HP vs. AP	GS = GL = 0.94	GNG = 1.04	GL = 0.87	GL = 1.13
LP vs. AP	GL > GS = 1.18	GS = GL = 1.13	GL = 0.95	GL = 1.32
L vs. H	GL = 1.11	GL, GNG = 1.11	GNG = 1.45	GL = 1.18

W140 Changes in plasma amino acid concentrations in preterm and term born calves. J. Steinhoff-Wagner*, S. Görs, J. Flor, C. C. Metges, and H. M. Hammon, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Neonatal development is characterized by ontogenic maturation and high nitrogen (N) turnover. Adequate amino acid (AA) availability is important for protein and nucleic acid synthesis, but might be impaired in immature calves. The objective of the present study was to investigate dependency of plasma AA changes on ontogenic development and colostrum feeding in neonatal calves. Calves were delivered by Cesarean section 9 d before term (preterm; PT) or were born at term (T). Calves of PT and T were not fed during first 24 h of life. Calves of TC were born at term and were fed colostrum at 8% of BW during first 24 h of life (n = 7/group). Blood samples were taken at 2 to 3 h and 24 h after birth and before feed intake (TC) for determination of total protein (TP), urea, and free AA plasma concentrations. Data were analyzed by Mixed Model of SAS with ontogenic stage and postnatal feeding as fixed effects. Plasma concentrations of TP increased ($P < 0.05$) during 24 h only in TC due to immunoglobulin absorption. Plasma urea concentrations were greatest ($P < 0.05$) at birth and 24 h after birth in PT. At birth, plasma concentrations of Phe, Val, Leu, Ile, Glu, and Tyr were greater ($P < 0.05$) in PT than T and TC, whereas after 24 h plasma concentrations of Lys, Thr, Glu, Asp, Asn, Ala, Cys, Ser, Orn, and Pro were greater ($P < 0.05$) in PT than T. Colostrum feeding resulted in greater ($P < 0.05$) plasma concentrations of Leu, Val, Ile, Trp, His, and Tyr in TC than in T and PT, and greater ($P < 0.05$) plasma concentrations of Asp and Pro than in T. Plasma concentrations of Thr, Gly, Ala, Cys, Ser, and Orn were greater ($P < 0.05$) in PT than in TC. Plasma concentrations of Glu increased ($P < 0.05$) in TC and were greatest ($P < 0.05$) 24 h after birth in TC, whereas Gln increased in PT, but decreased in TC and were lowest ($P < 0.05$) 24 h after birth in TC. Greater essential AA (EAA) in PT than in T and greater non-EAA and urea plasma concentrations in PT than in T and TC suggested enhanced protein breakdown and AA degradation in PT. Colostrum

feeding leads to an improved EAA status and less AA degradation, but indicates enhanced N use for anabolic metabolism.

Key words: calf, preterm, amino acid

W141 Placental and fetal plasma amino acid uptake and release in mid and late pregnancy of gilts fed limited- and excess-protein diets associated with intrauterine growth retardation (IUGR). C. C. Metges*, S. Görs, I. S. Lang, K.-P. Brüssow, G. Nürnberg, C. Rehfeldt, W. Otten, and B. U. Metzler-Zebeli, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Low- and high-protein diets fed to pregnant gilts lead to IUGR (Rehfeldt et al. 2011, J Anim Sci). To explore underlying mechanisms, maternal, umbilical, and fetal amino acid (AA) concentrations were analyzed. Eighteen gilts each were fed isoenergetic diets with low (6.5%, LP), adequate (12.1%, AP), or high (30%, HP) protein levels, starting at insemination. Gilts and fetuses were examined at d 64 and 94 of pregnancy. Blood was collected during Caesarian section from maternal V. jugularis, umbilical vein (V) and artery (A), and fetal V. cava cranialis (4 fetuses/gilt). Fetal weight was recorded. Plasma AA concentration was analyzed by HPLC. Placental and fetal AA uptake (UPT) and release (REL) were calculated by V-A differences. Effects were evaluated by ANOVA with diet, fetal litter size, sex and weight class, interactions and random factor gilt. In HP, fetal weight was lower than in AP at d 94 but not at d 64 ($P < 0.05$). In LP maternal plasma, Leu, Phe, Tyr, Thr, and Trp were lesser and Ala was greater at d 64, whereas at d 94 Leu, Trp, Val, Cys, and Tyr were lesser and Ala and Gly were greater than in AP ($P < 0.05$). In HP gilts at d 64, Ile, Thr, and Val concentrations were greater and Ala and Gly were lesser than in AP gilts whereas at d 94, Ile, Lys, and Val were greater and Ala, Gly, and Glu were lesser ($P < 0.05$). At d 64 and d 94, placental UPT of Ile, Leu, Trp, and Val was greater in HP than in LP. Placental Lys REL did not differ at d 64 but was lower in HP and LP than in AP at d 94 ($P < 0.05$). At d 64, Thr was taken up by the placenta in HP while it was released in LP; at d 94, placental Thr REL was greater in LP and AP than in HP ($P < 0.05$). At d 64, fetal AA UPT did not differ among diets, whereas at d 94 Leu and Lys UPT was lower in LP and HP than in AP ($P < 0.05$). Thus, placental AA metabolism largely compensated the imbalanced maternal AA patterns. In LP, but also in HP, fetal utilization of Leu and Lys was limited, which relates to lower birth weights in both groups.

Key words: amino acid, high protein, intrauterine growth retardation

W142 Hormonal regulation of suspected components of bovine IgG1 transcytosis mechanism in primary bovine mammary cells in vitro. A. Stark[1], E. Vaschkova[2], O. Wellnitz*[1], R. M. Bruckmaier[1], and C. R. Baumrucker[3], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Switzerland, [2]Trakia University, Stara Zagora, Bulgaria, [3]Penn State University, State College.*

Colostrogenesis is distinguished by the specific transfer of IgG1 from the blood to mammary secretions. It occurs during the last 2–3 weeks of pregnancy when steroid concentrations of estradiol (E2) and progesterone (P4) are high. Rodent intestinal uptake of immunoglobulin G has indicated this transcytosis process is mediated by a receptor termed Fc fragment of IgG, Receptor, Transporter, α (FcGRT) and supported by light chain β2 Microglobulin (β2M). The bFcGRT has been cloned by others and mRNA exists in the mammary tissue and intestines of ruminant species. We hypothesized that steroid hormone treatments E2 and P4 of bovine mammary cells in vitro would induce changes in mRNA expression indicating which components are involved in IgG1 transcytosis. Two different cultures (passage 6 to 14) of primary bovine mammary cells were evaluated by qPCR. Cells on plastic and rat tail collagen were treated with hormonal combinations (steroids/lactogenic). Evaluated components were bFcGRT, bβ2M, and various bRab GTPases; the latter components direct endosomal transcytosis movements in other eukaryotic cells. All tested components showed strong expression of mRNA in the cells. Plastic experiments showed that FcGRT, Rab11b, Rab25, were significantly regulated ($P < 0.05$) by steroid hormones while Rab11A and β2M were not changed. Experiments on collagen gels showed that lactogenic hormones increased expression of bLf mRNA (8X; $P < 0.0001$) in both mammary cells. Less increased expression of FcGRT was principally stimulated by steroids (E2), while the Rab25 was increased by lactogenic and steroid treatments. These results indicate that some suspected components of IgG1 transcytosis have their mRNA altered by hormones in vitro. However the 2 different primary cultures of bovine mammary cells show different expression patterns, perhaps reflecting animal to animal variation that is experienced by in vivo experiments. Mammary cell bFcGRT, and bRab25 are candidates that are hormonally altered for the colostrogenesis period.

Key words: colostrum, IgG, cattle

W143 Reducing metabolic stress of dairy cows during the transition period by partial milking or nursing. É. Carbonneau*[1], A.-M. De Passillé[2], J. Rushen[2], B. G. Talbot[1], and P. Lacasse[3], *[1]Université de Sherbrooke, Sherbrooke, QC, Canada, [2]AAFC-Pacific Agri-Food Research Centre, Agassiz, BC, Canada, [3]AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

During the transition from pregnancy to lactation, the sudden increase in nutrient demand for milk production causes metabolic perturbations and high incidences of metabolic diseases in high yielding cows. We previously showed that limiting milk yield by milking once a day during the first wk of lactation improved metabolic status but reduced milk production during the following weeks. In this study, we examined if limiting milk harvest postpartum while maintaining milking-induced endocrine stimulus could improve the metabolic status of cows without reducing overall milk production. Forty-seven Holsteins cows were allocated to 3 treatments, balanced for parity and milk production: 1) cows were milked completely twice a day from calving (control); 2) cows were partially milked twice a day until d5 after calving (partial); 3) cows were left with the calf to suckle from the dam until d5 and were milked once a day from d3 to d5 (nursing). All cows were milked twice a day from d6 to the end of the experiment (d63). During the treatment period (d1 to d5), milk production averaged 27.3 and 9.7 kg/d for control and partial, respectively. There was no residual effect ($P = 0.7$) of treatments on milk production which averaged 47.5, 45.9 and 46.4 kg/d for the control, partial and, nursing, respectively, between wk2 and 9. The DMI of the cows were similar during and after treatment ($P > 0.2$). From wk2 to 9, milk protein and lactose content were not affected by treatments, but milk fat content tended ($P = 0.06$) to be higher in control cows than in cows where milk harvest was limited (partial + nursing). Blood concentrations of glucose ($P < 0.001$) and phosphorus ($P < 0.05$) were lower and the concentrations of NEFA ($P < 0.05$) and BHBA ($P < 0.0001$) were higher in control cows than in the other cows during the treatment period. The positive effects on glucose and BHBA remained significant ($P < 0.05$) up to d28. There was no effect of treatments on blood urea, calcium and haptoglobin. These results suggest that reducing milk harvest postpartum while maintaining milking stimuli reduces metabolic stress without compromising productivity of high yielding dairy cows.

Key words: milking management

W144 Analysis of the bovine milk transcriptome by RNA sequencing. S. Wickramasinghe, G. Rincon, A. Islas-Trejo, and J. F. Medrano*, *Dept. of Animal Science, University of California-Davis, Davis.*

Even though the chemical and physical properties of cow milk are well characterized, very limited research has been done on characterizing the milk transcriptome. The objective of this project was to perform a comprehensive expression profiling of genes expressed in milk somatic cells in Holstein cows. Milk samples were collected from 6 Holstein cows at d 15 (transition milk) and 250 (late) of lactation and RNA was extracted from the pelleted milk cells. Expression analysis was performed by RNA sequencing (RNaseq) using the Illumina GAII analyzer. Reads were assembled, annotated and analyzed in CLC Genomics workbench 3.7. Data was normalized by calculating the "reads per kilo base per million mapped reads" (RPKM) for each gene and annotated with Ensemble bovine annotation (24,580 unique genes). *t*-test was performed to identify the genes with significant changes in expression between the 2 stages of lactation. GenMAPP and MAPPFinder applications were used to determine the most significant gene ontology (GO) classifications (permutation $P \leq 0.05$) among these genes. The RPKM value of 0.3 was set as the threshold for detectable gene expression. The transition milk had 11,876 genes and late milk had 12,553 genes above the threshold. Genes encoding milk proteins had the most abundant transcripts in transition milk, and genes involved in immune regulation and cell defense had the most abundant transcripts in late lactation. Transition milk was enriched with gene ontology (GO) terms for Golgi vesicle transport while late milk was enriched with GO terms for DNA replication and signal transduction. ~8,000 genes had ubiquitous expression in milk and most of these genes were localized to intracellular organelles and intrinsic membranes. 4359 genes had significant change in expression ($P \leq 0.05$ and FDR $q \leq 0.2$) between the 2 stages, and these genes were mostly localized in extracellular matrix or vesicles. This is the first study to describe the comprehensive bovine milk transcriptome. Our results revealed that 48–51% of anno-

tated genes are expressed in the bovine milk and provided a valuable insight into the bovine lactome.

Key words: cow milk, gene expression, RNAseq

W146 Residual effects of incomplete udder emptying during milking in dairy cows. J. Guinard-Flament*, A. Albaaj, P.-G. Marnet, and C. Hurtaud, *UMR Production du Lait, INRA/Agrocampus OUest, Saint-Gilles, France.*

Extended milking intervals reduce milk yield with residual effects on following milking intervals, which could depend on the quantity of milk stored in the udder. The aim of this trial was to simulate milk accumulation by decreasing udder emptying (100, 70, 40, and 0%) at one milking to describe the short-term effects on milk yield in relation with mammary morphology and epithelium permeability. Sixteen dairy cows (55 DIM) were assigned to treatments 100, 70, 40, and 0% according to a Latin square design with 4 7-d periods. Cows were milked twice daily at 0700 and 1730. Treatments were applied at the morning milking called M0 and milk yield was recorded on following milking (from M0 to M7). Changes in the udder morphology were assessed 1 and 10 h after M0 milking by estimating the distance between the 4 teat tips and the cisternal surface area using ultrasonography. The permeability of mammary epithelium was estimated using lactose concentrations in blood plasma measured 1 h before M0 and 4, 7, and 10 h after M0. The quantity of milk collected at M1 linearly increased as udder emptying decreased at M0. Nevertheless, because of milk accumulation in the udder, milk yield of M0+M1 curvilinearly decreased with treatments (42.9, 41.1, 36.4, 26.9 kg for 100, 70, 40 and 0%, respectively; SEM = 1.14). Residual effects on milk yield were observed only for 40 and 0% on M2 and M3 milking, and did not differ between 40 and 0% (e.g., 20.8 and 20.4 vs 21.9 kg for 100% at M2; SEM = 0.745). The udder cistern area was maximal just after M0 for 70, 40 and 0% treatments. However, udder continued to distend as shown by measurement of the distance between teats. Before M1, this distance was higher than after M0 and linearly increased as udder emptying decreased at M0. Increase in concentration of lactose in blood plasma occurred only for 40 and 0% and were observed respectively 10 and 4h after M0. In conclusion, dairy cows are poorly sensitive to low amounts of milk forgotten in the udder at one milking. When observed, residual effects on milk yield were associated with loss of the mammary epithelium integrity.

Key words: milk yield, incomplete milking, dairy cow

W147 Effect of prolactin-release inhibition on milk production and mammary gland involution at drying-off. S. Ollier*[1], X. Zhao[2], and P. Lacasse[1], *[1]AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada, [2]Department of Animal Science, McGill University, Sainte-Anne-de-Bellevue, QC, Canada.*

Drying-off is a challenging period for high-yielding cows as they are often dried off while still producing significant quantities of milk and, consequently, are highly susceptible to new intra-mammary infections. Once active involution is completed, the mammary gland becomes much more resistant to infection. Therefore, it is of critical importance to develop strategies to reduce milk production before the drying-off and to accelerate mammary gland involution. In this study, we assessed the effect of an inhibition of the lactogenic signal driven by prolactin (PRL) on milk production and on evolution of involution markers. Sixteen Holstein cows in late lactation were assigned to 2 treatments based on milk yield, somatic cell count and parity. Eight cows received twice daily i.m. injection of quinagolide (2 mg per injection), a specific inhibitor of PRL-release, from 4 d before drying-off to 3 d after (Quin). The 8 others received injections of the solvent (water, Control). Blood and milk (mammary secretion) samples were collected on the last 5 d before and 1, 3, 5, 7, 10, and 14 d after the last milking. On the day preceding the first injection and the following day, several blood samples were also collected around milking time. Quinagolide reduced ($P < 0.01$) basal serum PRL concentrations on all the injection days and PRL released in blood during milking. The PRL inhibitor induced a decrease ($P < 0.05$) in milk production before drying-off, which averaged, over the last 3d of lactation, 19.3 and 15.5 kg/d for the control and the Quin groups, respectively. Quinagolide had no significant effect on milk citrate:lactoferrin and Na:K ratios, which decreased and increased respectively ($P < 0.001$) during the first 2 wk of the dry period. Nevertheless, the increases ($P < 0.001$) in somatic cells and bovine serum albumin in milk during early involution were greater ($P < 0.01$) in the Quin than the control cows. This experiment shows that inhibition of PRL-release induces a decrease in milk production of cows in late lactation. Changes in mammary secretion composition suggest that this approach is also hastening mammary gland involution.

Key words: quinagolide, dry period

W149 Putative stem/progenitor cell markers in lactating and re-developing bovine mammary glands. E. Brijs*, K. Singh, and A. Molenaar, *AgResearch Ltd., Ruakura Research Centre, Hamilton, New Zealand.*

The study of stem and progenitor cells in the bovine mammary gland is still developing, especially in the area of stem cell regenerative capacity during lactation. The objective of this study was to investigate whether the putative stem/progenitor cell markers integrin β 3 (CD61), keratin 5 (K5) and integrin β 1 (CD29) used in murine and human studies are expressed in the bovine mammary gland. Mammary gland biopsies were collected from 16 multiparous cows at near-peak (66 ± 3 DIM) and late lactation (226 ± 6 DIM), and at 30 (29 ± 10) and 10 (11 ± 6) days prepartum to the next lactation season. Qualitative immunohistochemistry (IHC) analysis demonstrated the presence of CD61 positively labeled cells in the basal epithelium, intra-alveolar cells and stromal cells at all 4 time points; however the tissue sections from late lactation and 30 d prepartum appeared to have a greater number of positively stained cells. The putative bipotent marker K5 had intense cytoplasmic labeling in the majority of the basal epithelium during the prepartum period in comparison to near-peak lactating tissue. Positive cells were also found in a luminal position. IHC analysis indicated that as alveolar become more differentiated in prepartum tissue there was a decrease in K5 expression. Real-time RT-PCR confirmed this expression pattern showing a 4.4- and 3.3-fold increase at 30 ($P < 0.001$) and 10 ($P < 0.001$) days prepartum, respectively, in comparison to near-peak lactation. Preliminary IHC analysis of CD29 indicated diffuse staining in the majority of basal epithelium at all 4 time points. However, RT-PCR showed a similar expression pattern to K5, with a 1.8-fold increase at 30 d prepartum ($P < 0.001$) and 1.5-fold increase at 10 d prepartum ($P < 0.01$) in comparison to post-peak lactation. Collectively these preliminary data show that these cell markers can be used to study stem/progenitor cells in bovine mammary tissue and suggest that stem cell activity is upregulated during mammary gland re-development.

Key words: stem cell markers, mammary gland, dairy cows

W150 Responses to steroidal doses and growth hormone treatment of nulliparous dairy ewes induced to lactate. M. Ben Khedim, G. Caja, A. K. K. Salama, A. Schalageter, E. Albanell, and M. Rovai*, *G2R, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

With the aim of improving the response to lactation induction protocols in dairy ewes, 2 treatments based on s.c. injections of estradiol and progesterone (d 1 to 7) at reduced doses (half dose: HD, 0.25 and 0.63 mg/kg BW, respectively; one third dose: TD, 0.17 and 0.42 mg/kg BW, respectively) and hydrocortisone (d 18 to 20; 50 mg/d), compared with a previously-tested protocol (Ramírez et al., 2008, J. Dairy Sci. 91), were applied in 47 ewes of 9 mo of age (Manchega, n = 24; Lacaune, n = 23). Ewes were penned in 8 groups and fed ad libitum a TMR. Machine milking (twice daily) started on d 21 and lactation success (Manchega, > 0.2 L/d; Lacaune > 0.4 L/d) was evaluated on d 35. Ewes under these thresholds were dried-off. Lactating ewes were treated with growth hormone (bST, 250 mg) on d 48 and 62 of lactation. Group intake was recorded daily during the experiment (4 wk before and 10 wk after milking started) with individual estimations during lactation by using polyethylene glycol 6000 (50 g/d for 14 d). Treatments decreased DM intake according to the steroidal dose used (HD, –28%; TD, –18%; $P < 0.05$) but recovered thereafter. Lactation success was in the range of the standard protocol (55% on average) and did not vary by steroidal dose or breed. Onset of lactation increased DM intake 16% in both breeds ($P < 0.01$). Lacaune ewes produced nearly 2 times more milk than Manchega on d 14 of lactation and this varied with treatment (HD, 817 mL/d; TD, 458 mL/d; $P < 0.01$), whereas milk yield in Manchega did not vary with treatment (351 mL/d). No differences in milk composition were detected according to breed or treatment during the first 14 d of lactation. Milk yield increased with exogenous bST (Manchega, 114%; Lacaune, 90%; $P < 0.01$), but only a decrease in milk protein content ($P < 0.01$) and a numerically greater DM intake ($P = 0.16$) were detected when bST and control lactating ewe-lambs were compared. In conclusion, lactation induction success did not vary with treatment, but a breed × treatment effect was observed in ewes induced to milk, and this was related to the hormonal environment and milk potential of each breed.

Key words: lactation induction, bST, sheep

W151 Traceability of animal byproducts in quail (*Coturnix coturnix japonica*) tissues using carbon-13 and nitrogen-15 stable isotopes. C. Mori*[2], E. A. Garcia[1], C. Ducatti[1], J. C. Denadai[1], and K. Pelicia[1], *[1]São Paulo State University, Botucatu, São Paulo, Brazil, [2]São Paulo State University, Registro, São Paulo, Brazil.*

Consistent information on meat products consumed by the public is essential. The technique of stable isotopes is a powerful tool to recover consumer confidence, as it allows the detection of animal byproduct residues, particularly in quail meat. This study aimed at checking the presence of poultry byproduct mixtures in quail diets by applying the technique of carbon ($^{13}C/^{12}C$) an nitrogen ($^{15}N/^{14}N$) stable isotopes in quail breast muscle, keel, and tibia. Sixty 4 one-day-old male quails were obtained from commercial farm. Birds were randomly distributed into 8 experimental treatments, and fed diets containing poultry offal meal (POM), bovine meat and bone meal (MBM) or poultry feather meal (PFM), or their mixtures. Four birds per treatment were slaughtered at 42 d of age, and breast (Pectoralis major), keel, and tibia were collected for analyses. Isotopic analyses of feed ingredients, feeds, and tissues were carried out at the Center of Stable Environmental Isotopes of the Biosciences Institute (CIE/IB), UNESP, Botucatu campus. Isotopic carbon (13C/12C) and nitrogen (15N/14N) ratios were determined in a isotopic ratio mass spectrometer (IRMS) type DELTA S (Finnigan Mat) coupled to an Elementary Analyzer (EA 1108 CHN) The obtained isotopic results were submitted to multivariate analysis of variance (MANOVA) using GLM (General Linear Model) procedures of SAS statistical software. Data were generated by error matrices for each tissue, which were later graphically distributed in regions (ellipses) with 95% confidence of observing possible differences between experimental treatment means and control treatment means. The inclusion of animal byproducts in quail diets was detected by $^{13}C/^{15}N$ analyses in the tissues of the birds; however, it was not possible to specify which byproducts were used. It was concluded that quail meat can be certified by the technique of stable isotopes.

Key words: animal byproducts, meat quails, stable isotopes

W152 Meat quality of Pelibuey sheep finished with different levels of alfalfa. V. Resendiz-Cruz[1], O. Hernadez-Mendo[1], J. Gallegos-Sanchez[1], I. Guerrero-Legarreta[2], P. A. Martinez-Hernandez[3], and G. Aranda-Osorio*[3], *[1]Colegio de Postgraduados, Montecillos, Estado de Mexico, Mexico, [2]Universidad Autonoma Metropolitana-Iztapalapa, Mexico D.F., Mexico, [3]Universidad Autonoma Chapingo, Chapingo, Estado de Mexico, Mexico.*

The objective of this study was to evaluate the effect of feeding different levels of alfalfa to sheep on meat quality and fatty acid profile. For this purpose, 36 Pelibuey male sheep with initial live weight mean of 22.3 ± 0.3 kg were finished for 11 weeks. They were distributed homogeneously into 4 groups of 3 each, with 3 replicates per group, and then randomly assigned to each of the following treatments: 0, 20, 30 and 40% alfalfa (dry basis). Meat chemical composition, color, shear force in raw and cooked meat, water activity (Aw), water holding capacity (WHC) and fatty acid profile (FAP), were evaluated. A completely random design under Proc GLM of SAS was used, and a mean comparison with Tukey test was done. Results about ether extract are stated later and includes discussions of fatty acid content. The red index (a) of meat was more intense ($P \leq 0.05$) for the control animals diet than for the alfalfa treatments. The resistance to the cut of raw and cooked meat, and the WHC, did not show differences ($P \geq 0.05$) between treatments, averaging 1.4 and 2.5 kg/cm^2, and 18.5 mL/100 g of meat, respectively. The Aw was higher when animals were fed with no alfalfa in the diet ($P \leq 0.05$). Within the fatty acid profile, only myristic, palmitic, palmitoleic, stearic and oleic acids, were higher ($P \leq 0.05$), 49.6, 553.8, 47.9, 326.6, and 1075.4 mg/100g, respectively, when sheep received no alfalfa, followed by those with 20, 30 and 40% alfalfa. CLAc9 was higher (18.8 mg/100g) ($P \leq 0.05$) when included 20% alfalfa in the diet, followed by those with 40, 30 and 0% alfalfa, with values of 15.0, 14.7, and 12.0 mg/100g, respectively. Meat from animals fed with alfalfa in the diet, had lower ($P \leq 0.05$) amounts of fatty acids, with higher proportion of unsaturated fatty acids, compared with those with the control diet. These results suggest that including alfalfa in the diet of finishing sheep, improves fatty acid profile and, it is proposed as a viable alternative to meet current demand of healthier food.

Key words: lambs, alfalfa, meat characteristics

W153 Meat quality of lambs fed fresh or dehydrated spineless cactus (*Opuntia ficus-indica*). M. I. Aguilar-Yañez[1], O. Hernadez-Mendo[1], G. Aranda-Osorio*[2], J. E. Ramirez-Bribiesca[1], I. Guerrero-Legarreta[3], and M. M. Crosby-Galvan[1], *[1]Colegio de Postgraduados, Montecillos, Estado de Mexico, Mexico, [2]Universidad Autonoma Chapingo, Chapingo, Estado de Mexico, Mexico, [3]Universidad Autonoma Metropolitana-Iztapalapa, Mexico D.F., Mexico.*

The objective of this study was to evaluate meat quality and fatty acid profile of lambs supplemented with fresh or dehydrated spineless cactus (*Opuntia ficus-indica*). Twenty-seven crossbred male lambs with initial live weight mean of 21.4 ± 2.18 kg were finished for 11 weeks of different treatment diets. They were distributed homogeneously into 3 groups of 9 each, and then randomly assigned to each of the following treatments: (T1) control diet, (T2) diet with 17% (dry basis) of dehydrated cactus, and (T3) diet with 17% (dry basis) of fresh cactus. Color, texture of raw and cooked meat, water activity (Aw), water holding capacity (WHC) and fatty acid profile were evaluated. A completely random design under Proc GLM of SAS was used, and when statistical differences were observed, a mean comparison was done using the Tukey test. Meat chemical analysis, color and texture, were not different ($P \geq 0.05$) between treatments, neither were the percentage of total fatty acids, saturated, monounsaturated or polyunsaturated. The only difference was found on WHC ($P \leq 0.001$), which was greater when feeding fresh and dehydrated cactus, than that with no cactus, with values of 32.13, 30.50, and 25.58 mL/100g of meat, respectively. These results suggest that the inclusion of cactus into the finishing lamb diets, had similar benefits on meat quality than that of the commercial one, which makes cactus a viable feeding strategy.

Key words: cactus, sheep, meat characteristics

W154 Qualitative characteristics of meat from lambs fed with sunflower seeds and vitamin E. F. A. Almeida*, A. G. Silva Sobrinho, G. M. Manzi, N. L. L. Lima, N. M. B. L. Zeola, V. Endo, and J. C. Barbosa, *Universidade Estadual Paulista - Unesp/ Campus de Jaboticabal, Jaboticabal, São Paulo, Brasil.*

Health professionals recommend diets low in saturated fatty acids. It is possible to obtain learner carcasses or to increase levels polyunsaturated acids in meat from cattle and sheep by feed them with sun-

flower seeds. Supplementation of diets with vitamin E increases the Î ± -tocopherol concentration of muscle and improves color stability of beef and lamb meat. The objective of this study was to evaluate the qualitative characteristics pH, color, water holding capacity, cooking loss and tenderness of the Longissimus dorsi muscle from Ile de France lambs fed with diets that contain sunflower seeds and vitamin E. Thirty 2 lambs were used with an average body weight of 15 kg, which were housed in individual stalls. The work consisted of 4 treatments as it follows: D1 - sugarcane + concentrate without sunflower seeds; D2 - sugarcane + concentrate with sunflower seeds; D3 - sugarcane + concentrate without sunflower seeds and 1000 mg vitamin E/kg of dry matter (DM) from the diet; D4 - sugarcane + concentrate with sunflower seeds and 1000 mg vitamin E/kg of DM from the diet. The experimental design was completely randomized, with a factorial scheme 2x2 (2 diets (with or without the inclusion of sunflower seeds) x 2 levels of vitamin E (0 and 1000mg/kg DM diet)). The qualitative characteristics were not influenced by the sunflower seeds and vitamin E with the exception of the variable b * (yellowness) was higher in meat of the lambs fed with diets that contain sunflower seeds and vitamin E (3.74), sunflower seeds without vitamin E (2.47) and vitamin E without sunflower seeds (2.20), than in meat of the lambs fed with diets without sunflower seeds and vitamin E (−0.12). The meat pH ranged from 5.47 to 5,57, L* (lightness) from 39.42 to 40.85, a* (redness) from 12.70 to 13.79, water holding capacity from 60.96 to 64.87, cooking loss from 36,16 to 38.01 and tenderness from 2.35 to 2.64. Finally, it could be concluded that the values found for the qualitative characteristics studied are consistent with the guidelines for lamb meat. Sunflower seeds and vitamin E may be used to feed lambs without harming the quality of meat.

Key words: qualitative characteristics, lamb meat, nutrition

W155 Effects of nutritional plane and selenium supply during gestation in primiparous ewes on offspring skeletal muscle development. C. A. Schwartz*, W. L. Keller, T. L. Neville, L. P. Reynolds, D. A. Redmer, A. M. Meyer, C. J. Hammer, K. A. Vonnahme, J. S. Caton, and K. R. Maddock-Carlin, *Department of Animal Sciences, North Dakota State University, Fargo.*

To investigate the effects of nutritional plane and selenium (Se) supply during gestation, serviced ewes were stratified by BW and randomized to receive diets formulated to contain either adequate Se (ASe; 3.5 μg Se•kg BW^{-1}•d^{-1}) or high Se (HSe; 65 μg Se•kg BW^{-1}•d^{-1}). On d 40 of gestation 42 ewes from each Se treatments were assigned randomly to 1 of 3 nutritional planes supplying 60% (RES), 100% (CON), or 140% (HI) of NRC requirements. At birth, lambs were given artificial colostrum for the first 20 h and then ad libitum access to feed and milk replacer. On d 21, lambs were stunned and exsanguinated. LM, semimembranosus (SM), and psoas major (PM) muscles were harvested and snap frozen for later analyses of μ-calpain autolysis by Western blotting, cellularity, myosin heavy chain types 1 and 2 by SDS-PAGE, and μ-calpain and calpastatin mRNA expression by RT-PCR. Autolysis of μ-calpain in the PM was greater ($P = 0.01$) in lambs from HSe supplemented ewes as compared with ASe ewes. The LM DM percentage in lambs from HI ewes was greater ($P = 0.02$) than that in lambs from RES ewes. Protein in the SM from HI lambs was greater ($P = 0.03$) than that from RES lambs. The RNA and RNA:DNA in the LM were greater ($P < 0.02$, $P < 0.04$, respectively) in the ASe RES lambs than in the ASe HI lambs. HSe RES lambs had lower LM protein than that from ASe HI. The RNA:DNA in the LM HSe HI was greater ($P < 0.03$) than that in the HSe RES. Overall, the protein:DNA was greater in the PM than in LM and SM while the RNA:DNA was greater in SM than in PM and LM. μ-Calpain autolysis was less ($P < 0.01$) in the PM of HSe RES lambs than in the PM of HSe HI lambs while autolysis in the LM of the ASe CON tended ($P < 0.07$) to be greater than all other treatment groups. Of all muscles, the LM had less ($P < 0.04$) μ-calpain autolysis than both the SM and PM muscles. Maternal Se supply and nutritional plane appeared to have an influence on offspring skeletal muscle protein expression and cellularity. We can conclude that the interaction of maternal Se and nutritional supplementation may affect fetal skeletal muscle growth and development.

Key words: skeletal muscle, selenium, calpain

W156 Maternal dietary protein affects transcriptional regulation of myostatin gene distinctively at weaning and finishing stages in skeletal muscle of Meishan pigs. X. Liu, J. Wang, R. Li, X. Yang, Q. Sun, and R. Zhao*, *Nanjing Agricultural University, Nanjing, P. R. China.*

Skeletal muscle is susceptible to nutritional programming and myostatin is identified as a potential mediator of offspring phenotype. In this study, we determined the effects of maternal dietary protein on transcriptional regulation of myostatin in skeletal muscle of pig offspring. Sixteen Meishan sows were fed either low-protein (LP) or standard-protein (SP) diets throughout gestation and lactation, and myostatin expression in the longissimus dorsi muscle were determined both at weaning and finishing stages. Myostatin mRNA abundance was downregulated at weaning, but upregulated at finishing in LP pigs, indicating stage-specific transcriptional regulation of myostatin. At weaning, CCAAT enhancer binding protein (C/EBPβ) expression in nuclear lysate was decreased in LP piglets, associated with diminished binding of C/EBPβ to all the 3 putative binding sites at myostatin promoter. None of the histone modification marks showed differences between SP and LP piglets. Among 12 microRNAs predicted to target myostatin, none was differently expressed between 2 groups. At finishing stage, C/EBPβ expression remained unchanged, but the binding of C/EBPβ to 1 of the 3 putative binding sites increased in LP pigs. H3Ac and H3K27Me3 modifications on myostatin promoter were increased, while H3K9Me1 decreased in LP pigs. Moreover, ssc-miR-136 and ssc-miR-500 expression reduced significantly. These results indicate that maternal dietary protein affects myostatin expression through distinct transcriptional regulation mechanisms at different stages. The immediate effect at weaning is mediated by C/EBPβ binding without epigenetic modifications, whereas the long-term effect at finishing stage involves both C/EBPβ binding and epigenetic regulations including histone modification and microRNA expression.

Key words: Meishan pig, maternal dietary protein, skeletal muscle

W157 Linear mixed models built with the stepAIC function in the R environment for evaluation of TPA and WBSF. A. Dufek*[1,2], J. Subrt[3], and J. Simeonovova[3], *[1]Research Institute for Cattle Breeding, Ltd., Vikyrovice, Czech Republic, [2]Agriresearch Rapotin Ltd., Vikyrovice, Czech Republic, [3]Mendel University in Brno, Brno, Czech Republic.*

The first aim of this work was to test the significance of selected fixed and random effects on Warner-Bratzler Shear Force (WBSF [N]) and Texture Profile Analysis (TPA [$N.cm^{-2}$]). The second aim was to determine the efficiency of the R software for quick fitting linear mixed models using a new combination of 2 functions: the lme function in the package nlme to test significance of random effects and the stepAIC function in the MASS package to test the significance of fixed effects.

Random effects were put into the models at nested levels – animals within a sire. Further, the stepAIC selected automatically from the fixed effects: aging time, sex and age of animal, carcass mass, length of quarters, weight and proportion of longissimus muscle (LM), and others. Log-transformed and centered data were used in the case of aging time in relation to the WBSF decline. The LM (n = 70) was divided into 4 samples, vacuum packed, stored at 2–4°C and analyzed 48 h, 16, 30 and 44 d post-mortem. In both cases (WBSF and TPA) the random effects analyses showed that only the subject affected dependent variables. In the case of model for WBSF, the stepAIC selected 5 significant fixed effects (AIC declined from 2786.8, model with no fixed effect, to 2347.8 for the final model): the estimates of parameters of the final model revealed that higher values for aging time, weight of fat and weight of LM resulted in lower values of WBSF (reg. coef. −24.2,-2.7,-3.7, resp.). Higher values for age of animals resulted in higher WBSF (reg. coef. 0.1). Steers had lower WBSF (74 N) than heifers (81 N) or bulls (84 N). In the case of model for TPA the stepAIC selected 5 significant fixed effects (AIC declined from 3313.7 to 3303.8): the parameters of the final model revealed that higher values for proportion of separable fat and length of quarters resulted in lower values of TPA (reg. coef. −9.9,-2.1, resp.). Higher values for aging time, weight of bones and age of animals resulted in higher values of TPA (reg. coef. 1.2,4.0,0.2, resp.). Data indicate that the lme and stepAIC functions are useful for fitting of mixed models when hypotheses on more fixed effects are tested.

Key words: AIC, mixed, meat

W158 Effect of kidney matrix on the detection of β-lactam and tetracycline residues by UPLC-MS/MS. M. P. Almeida[1,2], M. O. Leite*[2], S. V. Cançado[2], M. R. Souza[2], and M. M. O. P. Cerqueira[2], *[1]Lanagro-MG/Ministério da Agricultura, Pecuária e Abastecimento, [2]Escola de Veterinária - Universidade Federal de Minas Gerais.*

Antimicrobials are widely used in veterinary medicine, mostly in livestock as therapeutic, prophylactic, and growth promoters. The indiscriminate use of them may lead to the presence of their residues in foods. Most methods recommended for β-lactam and tetracycline detection use ultra performance liquid chromatograph (UPLC) connected to a mass spectrometer, commonly referred to as UPLC/MS/MS system. Biological matrices are very complex and interfere on the analytes compromising their quantification. The aim of this work was to study the influence of the kidney matrix on the detection and quantification of β-lactam and tetracycline residues by UPLC-MS/MS. The following drugs were studied: β–lactam - ampicillin, cefazolin, penicillin G, nafcilin, cloxacillin, dicloxacillin, oxacillin, penicillin V, and penicillin G deuterated (N-etilpiperidin) as internal standard, and tetracyclines – chlortetracycline, oxytetracycline, and tetracycline. Pure standard calibration curves and matrix curves were prepared at the concentrations of 0.50, 0.75, 1.00, 1.25, and 1.50xLMR7 in 3 different days. The matrix curve was prepared from the extraction of swine kidney blank samples (2g) with water/acetonitrile (8:2), followed by purification in hexane, and Bond Elut C18 dispersive phase. The curves were simultaneously injected and compared by F test and Student′s t- test, point to point, at 95% significance level. The slopes and intercepts were also compared by *t*-test using the same aforementioned significance level. Significant effect of matrix on the studied analytes was observed even with the use of β-lactam internal standard. Tests of slope and intercept at 95% significance level indicated a significant effect of the matrix in search of the tetracyclines. Penicillin G was the only substance that had no effect on all tests. As significant influence of the kidney matrix on the detection and quantification of β-lactam and tetracycline residues by UPLC-MS/MS was observed, kidney samples should be carried out using the matrix curve.

Key words: antimicrobial residues, matrix effect, mass spectrometry

W159 Extent of μ-calpain autolysis differs depending on the extent of destructered tissue in the ham. M. Müller[2], C. Biolley[1], P. Silacci[1], and G. Bee*[1], *[1]Agroscope Liebefeld Posieux Research Station (ALP), Posieux, Switzerland, [2]Swiss College of Agriculture, SHL, Zollikofen, Switzerland.*

Destructured zones in cooked hams cause great economic losses to the Swiss meat industry. In previous studies it has been reported that these zones can be observed already at 24 h postmortem (pm) in the outer portion of the semimembranosus muscle (SM). These observations suggested that pm processes might be causally linked to these problems. Thus the objective of the study was to determine the relationship between the extent of tissue destruction, muscle pH decline, μ-calpain autolysis and desmin degradation in the SM. To achieve these objectives, 12 pigs were selected the day after slaughter and their SM were classified into 1 of 3 classes: 1 = none; 2 = mild and 3 = strong tissue destruction in the outer portion of the SM. Using a cylindrical cutting device, muscle samples from the outer (O), middle (M) and deeper (D) portion of each muscle were obtained. The samples were prepared for immunoblotting with antibodies against μ-calpain 80-kDa subunit and desmin. The class 1 SM originated from lighter (7.7 vs. 8.2 and 8.2 kg; $P < 0.10$) hams than those from class 2 and 3. Compared with class 3, the SM in class 1 tended (5.7 vs. 5.4; $P < 0.10$) to have higher 3 h pm pH with intermediate values for those in class 2 (5.5). No ($P > 0.10$) pH differences among classes were observed at 45 min and 24 h pm. In the M- and I-portion but not the O-portion, marked class effects were observed for the relative abundance of the unautolyzed (80 kDa) μ-calpain subunit and its autolysis products (78 and 76 kDa) at 24 h pm. Compared with the classes 2 and 3, the 80-kDa band was less ($P < 0.10$) abundant and the 76-kDa band was more ($P < 0.10$) abundant in the M- and I-portion of class 1 samples. In the I-portion the abundance of intact desmin was lower ($P = 0.05$) in class 1 than class 2 with intermediate values for class 3. In accordance, the abundance of a degradation product was numerically higher ($P = 0.14$) in class 1 samples. These data indicate that extent of visible tissue destruction may affect autolysis of μ-calpain also in the deeper portion of the muscle.

Key words: μ-calpain autolysis, proteolysis, ham

W160 Early adaptation of sarcoplasmic reticulum Ca^{2+} pump in bovine myofiber under chronic low-frequency electrical stimulation. T. Sakurada*[1], E. Kitagawa[1], M. Miyake[1,2], S. Ohwada[1], H. Aso[1], and K. Watanabe[1], *[1]Tohoku University, Sendai, Japan, [2]The University of Tokushima, Tokushima, Japan.*

SERCA (Sarcoplasmic reticulum Ca^{2+} pump, Ca^{2+}-ATPase) is one of crucial regulators of muscular contraction, which is involved in transferring of cytosolic Ca^{2+} into sarcoplasmic reticulum (SR). SERCA is classified into 2 isoformes: fast-type SERCA1a in fast myofiber and slow-type SERCA2a in slow myofiber. Chronic low-frequency electrical stimulation (CLFS) changes myofiber type from fast to slow. The fast-to-slow transformation of myofiber by CLFS exhibits drastic turnover of myofilaments and finally remodeling of whole myofiber, however, in bovine, no information of CLFS effect on muscle has been reported. In this study, we investigated mechanism of adaptation for CLFS in the bovine longissiumus lumborum (LL) muscle, especially

focused on expression of SERCA. Six Holstein male calves were used: 3 calves were CLFS group (5 Hz, 24 h/day) and 3 calves were control group. After 30 d of CLFS, calves were slaughtered and the LL muscles were removed. Muscle samples were quickly frozen by a mixture of dry ice and acetone. Serial frozen sections (10 μm thick) were cut on a cryostat. Then the serial sections were stained immunohistochemically with anti-myosin heavy chain (MyHC: fast and slow) and anti-SERCA (1a and 2a) antibodies. Myofiber types were classified into fast, slow, and hybrid (fast and slow co-expressed) myofibers by MyHC staining pattern. Expressions of MyHC and SERCA in myofiber types were measured by a microscopic densitometry using image analyzing software (Scion Image). Thirty days of CLFS increased percentages of slow and hybrid myofibers in the bovine LL muscle ($P = 0.051$). This change of myofiber types indicated functional adaptation for endurance muscle contraction by CLFS. Expression of SERCA2a in CLFS myofibers were higher in order of slow, hybrid and fast myofibers ($P < 0.01$). In CLFS hybrid myofibers, expression of slow MyHC increased in advance, and expression of SERCA2a rose subsequently. This fast-to-slow transition pattern suggests that the CLFS induced transformation of SERCA may need preceding upregulation of slow MyHC in the early phase of bovine myofiber type adaptation.

Key words: myofiber types, SERCA, CLFS

W161 Effects of temperament classification on carcass characteristics, tenderness and value in Angus-based composite steers. J. W. Behrens*[1], R. K. Miller[1], D. S. Hale[1], J. T. Walter[1], J. C. Bailey[1], A. N. Hafla[1], T. Machado[2], L. O. Tedeschi[1], and G. E. Carstens[1], *[1]Texas A&M University, College Station, [2]Texas A&M University at Kingsville, Kingsville.*

Angus-based composite steers (n = 508; initial BW = 310 ± 56 kg) obtained over 3 years from Rex Ranch were used in this study. Steers were fed a high-grain diet (ME = 3.08 Mcal/kg DM) and feed intakes measured using a GrowSafe system for 70 d. Thereafter, steers were fed in group pens and harvested at an average backfat thickness of 1.2 cm in 2 groups. Exit velocity (EV), measured as the rate of distance traveled (m/s) while exiting from a squeeze chute, was used as an objective measure of temperament. Within year, steers were classified into calm, moderate and excitable temperament groups based on ± 0.50 SD from the mean EV. Steers were commercially harvested and USDA Yield and Quality grade characteristics determined. Carcass weights tended ($P = 0.13$) to be lighter in excitable than calm steers (312.7 vs 306.7 ± 3.37 kg). Warner-Bratzler (WBSF) and Slice shear force (SSF) values were measured on top loin steaks after 1, 7, and 14 d of vacuum-packaged storage at 2°C. Carcasses from calm and moderate steers had lower ($P = 0.005$) d 7 SSF values (9.29 and 9.09 vs 9.99 ± 2.58 kg) and tended to have lower ($P = 0.06$) d 7 WBSF values (2.08 and 2.02 vs 2.14 ± 0.053 kg) than excitable steers, respectively. One and 14 d WBSF and SSF values and carcass Yield and Quality grades were not affected ($P > 0.10$) by temperament classification. Carcass value ($/kg) was determined using a grid formula based on premiums for Quality grade (Prime = +0.11), and discounts for carcass weight (<250 kg = −0.37; > 454 kg = −0.44), Quality grade (Select = −0.18; Standard = −0.44), Yield grade (>5 = −0.40; > 4 and <5 = −0.24) and tenderness assessment (WBSF >3.9 kg = −0.44). Carcass value tended ($P = 0.09$) to be lower for steers with excitable temperaments compared with steers with calm temperaments (1038.11 vs 1013.93 ± 11.89 $/carcass, respectively). Temperament classification did not affect carcass characteristics, but tended to affect carcass value of Angus-based steers. Steers with excitable temperaments had higher 7 d SSF values, suggesting that temperament classification of steers may influence carcass tenderness.

Key words: temperament, tenderness

W162 Rump measurements as related to others carcass traits. M. N. Bonin*[1], S. L. Silva[1], J. B. S. Ferraz[1], D. P. D. Lanna[2], F. Manicardi[1], R. C. Gomes[1], M. H. A. Santana[1], V. N. Barbosa[1], F. Novais[1], J. H. A. Campo[1], and F. Syuffi[1], *[1]University of Sao Paulo, College of Animal Science and Food Engineering, Pirassununga, Sao Paulo, Brazil, [2]University of Sao Paulo, College of Agricultural Sciences, Piracicaba, Sao Paulo, Brazil.*

Ultrasound carcass traits, such as ribeye area (UREA), backfat thickness (UBFT) and rump fat thickness (RFT) are used to estimate carcass composition in beef cattle. Additionally, others traits obtained on the rump may also be correlated to traditional carcass traits and contribute to predict retail product yield in beef cattle. Therefore, the aim of this study was to evaluate the correlations between rump measurements and carcass traits evaluated by ultrasound. A total of 410 Nellore bulls, with 18 mo of age, grass fed and reared in the Paraná State, Brazil, were evaluated by ultrasound scanning. A first image was collected of Longissimus dorsi muscle at 12th and 13th ribs for measures of UREA and BFT. A second image was obtained from Gluteus medius muscle to measure RFT and Gluteus medius depth (GDT). Images were collected utilizing an Aloka 500V equipment with a 3.5–Mhz, 17.2–cm linear array transducer. Other traits obtained were the rump width (RWD) and length (RLG), defined as the distance between the tuber coxae extremities and between the hip and the pin bone, respectively. The traits were correlated by simple Pearson correlations analyses using the statistical procedure PROC CORR of SAS. Positive correlations were found between UREA and GDT (r = 0.50; $P < 0.0001$), RWD (r = 0.39; $P < 0.0001$), RLG (r = 0.38; $P = 0.0001$), UBFT (r = 0.09; $P = 0.08$) and RFT (r = 0.16; $P = 0.002$). The high correlation between UREA and GDT indicates that these measures could be adequate indicatives of rump primal cuts yield. High correlations were found between UBFT and RFT (r = 0.53; $P < 0.0001$) and a low correlation between BFT and GDT (r = 0.08; $P = 0.12$) and between RFT and GDT (r = 0.10; $P = 0.04$), indicating that GDT measurements could not explain large variations in the rump fat depth. The GDT presented medium correlation with RWD (r = 0.28; $P < 0.0001$) and RLG (r = 0.26; $P < 0.0001$). Results suggest that measurements obtained on the rump can be used as auxiliary in vivo measures to predict carcass composition and rump primal cuts yield in beef cattle.

Key words: *Bos indicus*, gluteus medius, ultrasound

W163 Effect of finishing heifers on tall fescue, tall fescue with grain, or alfalfa on: I. carcass and LM quality. S. K. Duckett*[1], M. C. Miller[1], T. A. Burns[1], and M. L. Wahlberg[2], *[1]Clemson University, Clemson, SC, [2]Virginia Tech University, Blacksburg.*

Angus heifers (n = 40) were used to evaluate the effect of finishing on endophyte-free tall fescue (TF), TF with grain (TF+G), or alfalfa (AL) on carcass and LM quality. Heifers were finished on TF or AL to 2 time endpoints, which corresponded to 161 or 189 d of grazing. The TF+G heifers also grazed TF for 161 or 189 d and after adaptation were offered corn grain ad libitum for a total of 56 or 84 d before slaughter. Carcasses were graded at 24 h postmortem and one rib obtained. Two steaks were removed from the posterior end of the rib for Warner-Bratzler shear force (WBS) and proximate composition. Hot carcass weight was greater ($P < 0.05$) for AL than TF and TF+G.

Fat thickness, KPH, marbling score and quality grade were higher ($P < 0.05$) for AL than TF and TF+G. There was a 10% incidence of dark cutters; however, no effect of dietary treatment or slaughter time was observed. Longissimus muscle pH and objective color scores (L*, a*, b*) did not differ ($P > 0.05$) by dietary treatments or slaughter time. Supplementation of corn grain during the grazing period did not alter ($P > 0.05$) WBS in ribeye steaks aged 14 d. Warner-Bratzler shear force averaged 2.89 kg across all treatments. Total lipid content of the ribeye steaks was higher ($P < 0.05$) for AL than TF or TF+G. Total saturated fatty acid concentration was higher ($P < 0.05$) for AL and TF compared with TF+G. Monounsaturated fatty acid concentration was higher ($P < 0.05$) for TF+G than TF. Omega-6 polyunsaturated fatty acid (PUFA) concentration was highest ($P < 0.05$) for TF+G-84d and lowest ($P < 0.05$) for TF-189d. The ratio of omega-6 to omega-3 PUFA was higher ($P < 0.05$) for TF+G-84d than for TF+G-56d, which were both higher ($P < 0.05$) than AL or TF. Concentration of conjugated linoleic acid (CLA), cis-9 trans-11 isomer, was highest ($P < 0.05$) for TF+G-56d and TF-189d. Extending time of grain supplementation on TF lowered ($P < 0.05$) CLA levels compared with TF+G-56d and TF-189d. Finishing heifers on alfalfa increased carcass weight, fat thickness and marbling score. Corn grain feeding on TF increased linoleic acid and the ratio of omega-6 to omega-3 PUFA.

Key words: beef, forages, fatty acids

W164 Effect of finishing heifers on tall fescue, tall fescue with grain, or alfalfa on: II. fatty acid composition and lipid oxidation in ground beef. S. K. Duckett*[1], M. C. Miller[1], T. A. Burns[1], and M. L. Wahlberg[2], *[1]Clemson University, Clemson, SC, [2]Virginia Tech University, Blacksburg.*

Angus heifers (n = 40) were used to evaluate the effect of finishing on endophyte-free tall fescue (TF), endophyte-free tall fescue with grain (TF+G), or alfalfa (AL) on fatty acids and lipid oxidation in ground beef. Heifers were finished on TF or AL to 2 time endpoints, which corresponded to 161 or 189 d of grazing. The TF+G heifers also grazed TF for 161 or 189 d and after adaptation were offered corn grain ad libitum for a total of 56 or 84 d before slaughter. Carcasses were graded at 24 h postmortem and one rib obtained from each. The rib (6–11th rib) was trimmed to a similar fat thickness and ground. Ground beef patties were held at 2°C under lights for 0, 2, 5, 7, 9, and 11 d for lipid oxidation (TBARS) and objective color (L*, a*, b*) measurements. Ground beef samples were also packaged in vacuum packages or chubs for frozen storage and measurement of lipid oxidation over time (0, 30, 60, 90, 180, and 360 d). Hydrophilic and lipophilic ORAC values did not differ ($P > 0.05$) by finishing treatment or slaughter time. Total lipid content was higher ($P < 0.05$) for AL than TF and TF+G. Total saturated fatty acid percentage was greater ($P < 0.05$) for TF and AL than TF+G. Total MUFA concentration was highest ($P < 0.05$) for TF+G and lowest ($P < 0.05$) for TF. Omega-3 polyunsaturated fatty acid concentration (PUFA) was highest ($P < 0.05$) for AL and lowest ($P < 0.05$) for TF+G. Trans-11 vaccenic acid (TVA) concentration was higher ($P < 0.05$) for TF and TF+G than AL in the first slaughter time but TVA decreased in TF+G with increased time of grain feeding. Length of grain feeding increased ($P < 0.05$) linoleic acid and omega-6 PUFA concentration in TF+G. Lipid oxidation on a total lipid basis (mg TBARS/kg lipid) in fresh ground beef was higher ($P < 0.05$) for TF+G than TF or AL at 9 and 11 d of retail display. In frozen ground beef samples, AL had higher ($P < 0.05$) TBARS values than TF and TF+G in chub packages but TBARS did not differ ($P > 0.05$) among treatments in vacuum packages. Finishing heifers on TF with grain increased omega-6 PUFA levels and lipid oxidation rates in fresh ground beef.

Key words: beef, forages, lipid oxidation

W165 Gene expression profile of M. longissimus in Japanese Black, Holstein, and Charolais steers fed a high-energy diet. E. Albrecht*[1], S. Ponsuksili[1], K. Wimmers[1], T. Gotoh[2], and S. Maak[1], *[1]Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany, [2]Kyushu University, Kuju Agricultural Research Center, Kujucho, Oita, Japan.*

Cattle breeds differ largely in their capability for intramuscular fat (IMF) deposition. In an experiment comprising each 3 Japanese Black (JB), Holstein (HS), and Charolais (CH) steers, the animals received a high-energy diet typical for the production of highly marbled beef in Japan. The animals were slaughtered at 26 mo of age. The breeds differed significantly in marbling, measured via image analysis as fat area percentage (JB > HS > CH; $P = 0.001$) and in the average diameter of the adipocytes (JB > HS > CH; $P = 0.04$) in M. longissimus (LM). Total RNA was isolated from LM and RT-qPCR was conducted for selected candidate genes for marbling. There were neither significant differences in the expression of adipogenic transcription factors (CEBPB, CEBPA, PPARG) nor in downstream targets (PLIN1, ADIPOQ). A subsequent genome wide expression analysis confirmed these results (Affymetrix GeneChip Bovine Genome Array). However, pathway analyses revealed, among others, differential regulation of genes involved in calcium signaling. Beside muscle specific genes significantly upregulated in CH compared with JB and HS (RYR1, ATP2A1), we found significant differences in mRNA abundance for members of the S100 calcium binding protein family (S100A1, S100A16, S100B). Genes of this family have been linked only recently to adipogenesis and obesity in cell cultures and human, respectively. Separate analyses of their expression in dissected IMF from JB and HS revealed a more than 2.3-fold upregulation of S100B in JB ($P = 0.005$). In contrast, no differences were found in IMF between both breeds for S100A1 and S100A16, indicating that the observed differential expression in LM is linked to muscle cells rather than to adipocytes. Our results demonstrate that the mRNA abundance of S100 calcium binding protein B is related to IMF content in LM of intensively fed cattle. These results underline the necessity of separate expression analyses of LM (usually containing IMF) and dissected IMF to identify markers for differences in IMF deposition between breeds.

Key words: cattle, gene expression, intramuscular fat

W166 Effect of genotype on fatty acid composition of bovine muscles fattened with maize silage and flaxseed supplemented concentrate. G. Hollo*[1], T. Somogyi[1], K. Loki[1], I. Anton[2], and I. Hollo[1], *[1]Kaposvár University, [2]Research Institute for Animal Breeding and Nutrition.*

The aim of this study was to determine the intramuscular fat level (IM) and fatty acid composition in longissimus dorsi, (LD) semitendinosus (ST)and psoas major (PM) muscles of young bulls kept under the same condition and fed with flaxssed supplemented concentrate in the finishing period. Sixty-two growing bulls from Angus (A), Charolais (CH), Holstein (H), Hungarian Grey (HG), Hungarian Simmental (HS), Charolais x Hungarian Grey (CHxHG) were used. The diet consisted of maize silage ad lib., grass hay 2 kg/day, and 2-4 kg concentrate. After 450 kg live weight the concentrate contained 25% linseed supplementation. The average slaughter weight was 598.89+25.11 kg.

Muscle samples were taken after 24 hours chilling from the right half carcass. The effect of genotype and muscle was evaluated with multivariate analysis of variance GLM III (SPSS 10.0). The differences were evaluated with Tukey's test (P <0.05). A bulls had the highest IM level (3.76), particularly in PM (4.74), followed by HG (3.40), CHxHG (3.05), CH (2.33), HS (2.21), with the lowest level for H (2.11). IM for LD (2.87) and ST (1.77) were significantly lower than PM (3.60). SFA was significantly higher for the PM, due to the high level of IM. ST contained the highest PUFA (12.99), followed by LD (10.30) and PM (10.19). The n-6 fatty acids were affected either by breed, or by muscle type. The linoleic acid was the highest in H bulls except for PM, whilst the lowest was in all cases in A bulls. The same tendency can be seen for long chain n-6 fatty acids. The n-3 fatty acids differed among genotypes from 1.36 to 1.80%. Significant differences were shown only for PM. The n-3 long chain fatty acids were the highest level in ST of H, in LD of CH and in PM of HS bulls. The n-6/n-3 ratio was ranged from 4.48 to 6.22 and significantly higher in H than in A bulls. The highest CLA level was detected in all cases in HG bulls. The results demonstrate the clear effect of genotype on intramuscular fat content and fatty acid composition of beef despite the same housing and feeding conditions.

Key words: cattle, beef, fatty acid composition

W167 Quality characteristics of dried meat laver made from different beef muscle types. G. D. Kim*[1], E. Y. Jung[1], H. U. Seo[1], J. Y. Jeong[2], S. J. Hur[3,1], H. S. Yang[1], and S. T. Joo[1], *[1]Division of Applied Life Science (BK21 Program), Gyeongsang National University, Jinju, Republic of Korea, [2]Swine Scientic and Technology Center, Gyeongnam National University of Science and Technology, Jinju, Republic of Korea, [3]College of Biomedical and Health Science, Department of Applied Biochemistry, Konkuk University, Chungju, Republic of Korea.*

The aim of this study is to find adequate muscle type for making dried meat laver which can be used for making rice rolls. In general, a dried laver from seaweed is used for making steamed rice roll (Kimbab). However, a meat laver was made from beef meat instead of seaweed and investigated the quality characteristics of meat laver. Four types of meat lavers were made from different beef muscles: Semimembranosus m. (SM), Semitendinosus m. (ST), Gracilis m. (GR) and Extensor carpi radialis m. (EC). A homogenate made of 20 g of meat and 180 g of water was spread on the fabric (0.2x0.2 mm). The homogenate was dried for 7 h in the oven (DS-80–1, Dasol Sci. Co., Ltd., Korea) of 60°C. The quality traits of meat laver such as yield (%), proximate composition (%), surface color (CIE L*a*b*) and textural properties (folding test, cutting strength) were investigated. Fat content was significantly higher in meat lavers made from SM (26.62%) and EC (26.75%) muscle than in those of ST (24.28%) or GR (24.99%) muscle ($P < 0.05$). However, moisture, crude protein and crude ash content were not significantly different among the meat lavers ($P > 0.05$). Yield of meat laver range from 40.57% to 41.85%, but there were no significant differences between meat lavers ($P > 0.05$). The meat laver made from EC muscle had the highest CIE a* value (45.76) of surface color among meat lavers ($P < 0.05$), however, CIE L* or CIE b* value were not significantly different among meat lavers ($P > 0.05$). The meat laver made from SM muscle had the lowest value of folding test (2.30 cm) and cutting strength (1780.00 g/cm2), however, there were no significant differences in cutting strength and folding test of meat lavers between ST muscle (2605.00 g/cm^2 and 3.07 cm, respectively) and EC muscle (2835.00 g/cm^2, 3.33 cm, respectively) ($P > 0.05$). Therefore, the results of folding test (2.30 cm) and cutting strength (1780.00 g/cm2), which are the lowest values among the meat lavers, indicate that meat laver made from SM muscle is neither flexible nor useful for making rice rolls. In conclusion, EC muscle or ST muscle could be used for making a more flexible and red meat laver.

Key words: laver, beef, muscle type

W168 Carcass characteristics of bullocks of different genotype finished under feedlot conditions. O. V. Vazquez-Mendoza, G. Aranda-Osorio*, M. Huerta-Bravo, E. J. Maldonado-Siman, and J. C. Garcia-Ortiz, *Universidad Autonoma Chapingo, Chapingo, Estado de Mexico, Mexico.*

The objective of this study was to evaluate the effect of breed type on carcass characteristics of young bulls finished in feedlot. There were 90 tropical bullocks fattened in a temperate region of Mexico with the following distribution: Zebu (Z) n = 5 (initial liveweight 385.6 ± 24.7 kg); European Brown Swiss (EBS) n = 8 (365.1 ± 112.4 kg); Holstein (H) n = 9 (401.6 ± 63.4 kg); Z × European Brown Swiss (Z × EBS) n = 28 (423.4 ± 46.4 kg); Z × American Brown Swiss (Z × ABS) n = 19 (399.6 ± 49.9 kg); and Z × H (Z × H) n = 21 (428.7 ± 32.6 kg). The cattle were fed with a diet based on: ground corn (43%), bakery waste (24%), corn stalks (20%), soybean meal (8%), mineral premix (1.5%), bypass fat (Enervit®, Zuavit; 1%), buffer (18.2% Na and 8.4% Mg; 0.5%) and zilpaterol hydrochloride (Zilmax®, Intervet; 6.7 mg kg^{-1}) to fulfill the requirements for this type of livestock. Variables evaluated for feedlot performance were: average daily gain (ADG) and final liveweight (FLW). Variables evaluated for carcass attributes were: hot carcass weight (HCW), hot carcass yield (HCY), backfat depth (BFD), ribeye area (REA), physiological age (PA), fat percentage on kidney, pelvis and heart (KPH), marbling score (M), carcass conformation (CONF), and carcass fatness (CF). Data were analyzed using the GLM procedure of SAS, taking days of finishing, type of breed × days of finishing and initial and final liveweight as covariates. The Z × ABS presented the highest ($P = 0.001$) ADG. The greatest ($P = 0.017$) FLW was for Z × ABS ≥ EBS ≥ H. The genotype did not affect ($P = 0.161$, 0.143, 0.218) HCW, HCY or BFD, but the REA was larger ($P = 0.012$) for the EBS. The H and EBS bullocks exhibited the lowest ($P = 0.001$) PA; although the H cattle had greater ($P = 0.006$) KPH. The best ($P = 0.014$) CONF was obtained by the Z × ABS and Z × EBS genotypes. The greatest amount of M ($P = 0.001$) was found for the H breed. There were not differences ($P \geq 0.05$) on CF among genotypes. The crossbred genotypes showed better feedlot performance and carcass characteristics, and it seems that Holstein breed could have a potential from the marbling score point of view.

Key words: beef cattle, finishing, carcass attributes

W169 Relationship between meat quality and the expression of related genes in the muscle of two different genetic groups of cattle. J. Giusti[1], E. P. Castan[1], S. R. Baldin[2], M. D. B. Arrigoni[2], M. Dal Pai-Silva[2], and H. N. Oliveira*[1], *[1]State University of Sao Paulo, Jaboticabal, Sao Paulo, Brazil, [2]State University of Sao Paulo, Botucatu, Sao Paulo, Brazil.*

All body functions and traits of living beings are controlled by specific genes, and for meat quality is not different. In this paper we correlate μ-calpain, m-calpain, Thyroglobulin (TG), diacylglycerol acyltransferase 1 (DGTA1) and leptin (LEP) gene expression to meat quality of longissimus dorsi in 2 beef cattle genetic groups: Nellore and Canchim. We analyzed 15 young bulls of each breed. The animals were kept at the experimental feedlot facilities of the College of Veterinary

Medicine and Animal Science of UNESP, Botucatu. They were fed with the same diet and kept under the same management conditions. Animals were slaughtered at minimum weight of 470 kg and 4 mm of fat thickness accessed by ultra–sound. Samples of longissimus dorsi were collected for meat traits analysis (marbling), total lipids contents (TL), shear force (SF) and myofibrillar fragmentation index (MFI) at zero and 7 d postmortem and gene expression analysis, using qRT-PCR technique. Among the meat quality traits, MFI and TL contents were different between groups ($P < 0.01$ and $P < 0.03$, respectively). The calpains did not show differential gene expression or correlations with meat traits between groups. Among genes involved in metabolism of fat, DGTA1 did not show difference between groups ($P < 0.87$). However, a positive correlation was observed between DGTA1 and SF ($r = 0.51$, $P < 0.05$) and negative correlation between DGTA1 and MFI ($r = -0.52$, $P < 0.05$) at 7 d postmortem. In Nellore breed, in contrast, the correlation was negative to SF at the d 7 ($r = -0.75$, $P < 0.01$). The TG gene expression did not differ between groups ($P < 0.15$), however it has been negatively correlated in both breeds to the MFI on day zero ($r = -0.52$, $P < 0.05$). With the results, we conclude that the tender meat phenotype is not obtained only by the action of genes related to it, but by the handling of carcasses in the postmortem. Therefore, more studies should be conducted joining these parameters to understand the processes between gene expression and phenotype, enabling the development of breeds adapted to produce quality beef.

W170 Measurement of loin muscle in the carcass of Nellore breed on *Brachiaria brizantha* 'Marandu' with two levels of concentrate supplementation. S. L. S. Cabral Filho*[1], R. V. Oliveira[1], J. M. S. Diogo[1,2], R. A. Mandarino[1], C. F. Lobo[1], F. A. Oliveira[1], and G. S. Firmino[1], *[1]Universidade de Brasília, Brasilia, Distrito Federal, Brasil, [2]Fazenda Experimental Agua Limpa, Brasilia, Distrito Federal, Brasil.*

The objective of this study was to measured loin muscle area in the carcass of Nelore cattle grazing in *Brachiaria brizantha* 'Marandu', with 2 levels of concentrate supplementation. A total of 30 Nellore bulls at 22 mo of age with average weight of 330.42kg and final slaughter weight of 477.94 kg were used. The supplement consisted of corn, sunflower meal, soybean hulls, urea and minerals, and the treatments were SCONF1 - average daily intake of supplement of 0.91% of body weight in dry matter (DM) and SCONF2 - average intake of daily supplement of 1.42% of live weight, DM basis. The statistical design was randomized blocks with 2 treatments and 3 replications. Data were subjected to ANOVA the averages were compared by Duncan test at 5% of significance level. After the slaughter the carcass was proceeded to skinning, gutting, separation of the 2 symmetrical halves of the body (right and left), weighed and cooled for 24 h at 3°C. Longissimus dorsi area (AOL) and subcutaneous fat (SF) were measured between the 12th and 13th rib. There was no statistical difference ($P > 0.05$) among treatments for AOL, which showed average values of 74.50 and 70.33 cm2 for SCONF1 and SCONF2, respectively. However, levels of supplementation affected ($P < 0.05$) SF, and the treatment SCONF2 showed higher values (2.70 mm) compared with SCONF1 (2.00 mm). Supplementation did not impact AOL but increased subcutaneous fat with a higher supplementation level.

Key words: *Bos indicus*, supplement, meat quality

W171 Frame size and sex effects on meat quality characteristics of Nellore cattle. S. L. Silva*, R. C. Gomes, A. F. Rosa, M. D. Poleti, M. N. Bonin, T. M. C. Leme, J. L. F. Souza, L. M. Zoppa, and P. R. Leme, *Universidde de São Paulo (FZEA/USP), Pirassununga, SP, Brazil.*

Large frame cattle and intact males produce leaner carcasses which can affect meat tenderness due to cold shortening during the chilling process. Because the beef meat production in Brazil is based on Nellore (*Bos indicus*) intact males, it is necessary to investigate the effects of sex and frame size (FS) on carcass quality in this breed. The aim was to evaluate carcass and meat quality traits of Nellore young bulls and steers from different FS, finished under feedlot conditions. Throughout 2009 and 2010, Nellore bulls (n = 75, 500 ± 4.5 BW, 23-mo old) and steers (n = 80, 474 ± 6.1 BW, 23-mo old) from small (n = 51), medium (n = 53) and large (n = 50) frame size, according to BIF, were finished in feedlots receiving high-grain diets for 50d to 140d. Following slaughter, carcasses were weighed (HCW), chilled for 24h (0–2°C) and then ribbed between 12th/13th ribs for determination of Longissimus muscle (LM) area (LMA) and backfat thickness (BFT). LM samples were removed, vacuum packaged and aged 1d, 7d or 14d postmortem for Warner-Bratzler shear force (WBSF) and cooking loss (CL) determinations. Data analysis included the fixed effects of sex, FS, year and sex x FS interaction. There were no sex x FS interactions for any trait ($P > 0.05$). Intact males had heavier carcasses (154 vs. 142 kg; $P < 0.0001$), greater LMA (73.7 vs. 67.3 cm^2; $P < 0.0001$) and lower BFT (4.8 vs. 5.5 mm; $P = 0.0012$) than castrated males. Sex did not affect WBSF on 1d (9.7 kg) and 14d postmortem (6.7 kg) but WBSF was lower for castrated cattle than for intact males (7.7 vs 8.5 kg; $P < 0.0001$). Large FS cattle showed heavier HCW than small FS animals (151 vs. 145 kg, $P = 0.0028$). There was no effect of FS in LMA (70 cm^2), BFT (5.1 mm) and WBSF (9.3, 7.7 and 6.8 kg for 0, 7 and 14 d of aging, respectively). Meat CL were not affected by sex or frame size. Despite the high WBSF values observed in this work (greater than 4.5 kg), the results indicate that meat quality attributes are not greatly affected by sex or FS in Nellore cattle. It is likely that the fat thickness of carcasses from both intact and castrated males was enough to avoid problems of cold shortening during chilling process.

Key words: beef cattle, carcass, tenderness

W172 Carcass traits obtained at the fifth rib level to predict retail cuts in Nellore (*B. indicus*) cattle. J. L. F. Souza*, S. L. Silva, R. C. Gomes, M. N. Bonim, P. Z. Silva Neto, and P. R. Leme, *Universidade de São Paulo/ Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, São Paulo, Brazil.*

Measurements conducted on Longissimus muscle (LM) at the 12th rib level are traditionally associated to lean meat yield. However, in the Brazilian industry, carcasses are sectioned into hindquarter and forequarter at the 5th to 6th ribs, making unfeasible the exposure of LM at the 12th rib in packing plants. Therefore, the objective was to estimate predicting equations of retail product weight (RPW) and percentage (RPP) in relation to cold carcass weight (CW) using traits measured on LM at the 11th/12th (LM12) and 5th/6th (LM5) by video image analysis (VIA) of Nellore bulls carcasses. Seventy-six bulls were feedlot finished and slaughtered (523 ± 34 kg BW, 22-mo old) following humanitarian procedures. The left carcass side was broken into wholesale cuts and digital images were taken of the LM5 and LM12 surfaces. Wholesale cuts were weighed and broken into retail product, bones and trimmings. Retail product was defined as the sum of all cuts trimmed to a fat thickness of 5 mm. The Lince software (M&S Consultoria Ltda. Pirassununga, SP, Brazil) was used to analyze LM images. For the LM5 images, the evaluated traits were rib eye area (REA5), rib thickness (RIBT), intermuscular fat thickness (INTERFAT5) and

subcutaneous fat thickness (SFT5). In LM12 images, the rib eye are (REA12) and subcutaneous fat thickness (SFT12) were obtained. Multiple regression analyses were carried out to estimate predicting equations for RPW and RPP using measurements obtained by VIA as independent variables. Traits that best explained RPW and RPP were selected using stepwise regression and entered into the prediction equation. Using LM12 traits, the best equations for RPW and RPP were RPW (kg) = 10.63502 + 0.06402*REA12 + 0.76071*CW (R^2 = 0.94; SEP = 2.38); and RPP (%) = 67.47563 + 0.06252*REA12; R^2 = 0.09; SEP = 1.56). Using LM5 traits, the best equations were RPW (kg) = 14.78075 + 0.23758*REA5 + 0.28579*BFT5 + 0.79065*CW; (R^2 = 0.94; SEP = 2.38) and RPP (%) = 62.87192 + 0.16159*REA5 – 0.17820*BFT5 + 0.04108*CCW; R^2 = 0.21; SEP = 1.46). Results indicated that LM measurements obtained at the 5th rib level can be used to predict retail product yield in Nellore cattle.

Key words: edible portion, Longissimus muscle, video image

W173 The influence of two levels of supplementation on the yield of hindquarter cuts of Nellore in *Brachiaria brizantha* 'Marandu'. R. V. Oliveira*[1], F. A. Barbosa[2], J. M. S. Diogo[1], G. S. Firmino[1], J. F. A. Oliveira[1], J. F. B. Guedes[1], I. S. Silva[1], and G. A. Carneiro[1], *[1]Faculty of Agronomy and Veterinary Medicine, University of Brasília - UnB, Brasília, DF, Brazil, [2]School of Veterinary Medicine, Federal University of Minas Gerais - UFMG, Belo Horizonte, MG, Brazil.*

This study was conducted to evaluate the yields of cuts from the carcasses from of the young cattle raised under semi-confinement system, grazing Brachiaria brizantha cv Marandu with 2 levels of dietary supplementation (0.91 or 1.42% of BW, dry matter basis). Thirty Nellore bulls were used, with medium age of 22 mo, average of 330.42 kg live weight and 477.94 kg slaughter weight. The dietary supplementation was based on corn, sunflower meal, soybean hull, urea and minerals. The statistical design was randomized blocks design with 2 treatments and 3 replications, and the Duncan test was applied at 5% significance level. After slaughter, the carcasses were cooled during 24 h at 3°C. The right half-carcasses (hindquarter) were separated in the following cuts: eye of rump, cap of rump, flatround, inside, loin, tenderloin, eye of round and knuckle. There was no influence ($P > 0.05$) of the supplementation levels on the weights of the cuts, which had average values of 4.28 kg of eye of rump, 1.60 kg of cap of rump; 6.40 kg of flatround, 10.30 kg of inside; 8.16 kg of loin; 2.47 kg of tenderloin, 2.86 kg of eye of round and 5.58 kg of knuckle. The yields of the cuts were not affected by treatments ($P > 0.05$), obtaining average values of 6.57% of eye of rump, 2.46% of cap of rump, 9.81% of flatround, 15.79% of inside, 12.52% of loin, 3.79% of tenderloin, 4.38% of eye of round and 5.58% of knuckle. The different levels of supplementation resulted in similar weight and yields for all cuts, suggesting the use of the intake level of 0.90% to Nellore without negatively affecting in the carcass quality.

Key words: *Bos indicus*, commercial cuts, concentrated

W174 Influence of two levels of supplements on the characteristics of cuts yields of carcass in Nellore cattle grazing *Brachiaria brizantha* 'Marandu'. R. V. Oliveira*[1], J. F. A. Oliveira[1], F. A. Barbosa[2], F. F. Gouveia[1], G. A. Carneiro[1], J. M. S. Diogo[1], J. F. B. Guedes[1], and R. A. Mandarino[1], *[1]Faculty of Agronomy and Veterinary Medicine, University of Brasília - UnB, Brasília, DF, Brazil, [2]School of Veterinary Medicine, Federal University of Minas Gerais - UFMG, Belo Horizonte, MG, Brazil.*

The objective of this study was to evaluate the yields of carcass cuts of cattle submitted to the semi-confinement system, with 2 different levels of supplement intake during 6 mo, grazing Brachiaria brizantha cv. Marandu. Thirty Nellore bulls 22 mo old were used, with an average body weight (BW) of 330.42 kg and final slaughter weight of 477.94 kg. The supplement consisted of corn, sunflower meal, soybean hulls, urea and minerals. There were 2 treatments: SCONF1 - average daily intake of 0.91% of BW of supplement in the dry matter (DM); and SCONF2 - average daily intake of 1.42% of BW of supplement, in the DM. The statistical design was randomized blocks design with 2 treatments and 3 replications, and the Duncan test was applied at 5% significance level. After the slaughter, the carcass was divided in 2 symmetrical halves, weighed and cooled for 24 h at 3°C. The right half-carcasses were separated in the following cuts: hindquarter (HIND) which covers the posterior region of the carcass separated in the fifth and sixth ribs at a distance of approximately 20 cm from the spine; forequarter (FORE), which includes neck, shoulder, arm and 5 ribs; and spare ribs (SR) which includes the region of the sixth rib over the abdominal muscles. The cuts were weighed individually and their proportion to the cold half-carcass determined. There was no influence of the supplementation level on the cuts weights, which presented values of 60.85 and 66.53 kg for FORE, 64.45 and 65.20 kg for HIND and 15.50 and 15.47 for SR, in treatments SCONF1 and SCONF2, respectively. The yields of FORE, HIND and SR were 44.21, 45.05 and 10.74%, respectively, and did not show statistical difference between treatments ($P > 0.05$). The different supplementation levels provided similar weights and yields of cuts, suggesting that ingestion of 0.91% of BW of animals can be adopted in semi-confinement systems, without losing carcass quality.

Key words: *Bos indicus*, beef cattle, special hindquarter

W175 Effect of different levels of whole raw soybean grain on performance and meat characteristics of feedlot finished Nelore steers. N. R. B. Consolo*, A. S. C. Pereira, J. R. Gandra, R. Gardinal, C. S. Takiya, P. Barros J. Carvalho, F. P. Renno, J. E. Freitas Junior, G. D. Calomeni, and R. D. Mingoti, *Universidade de Sao Paulo, Pirassununga, Sao Paulo, Brasil.*

The aim of this study was to evaluate the performance and carcass quality of steers fed whole raw soybeans at increasing inclusion levels. Fifty-four Nellore with mean weight and age of 350 kg and 24 mo were fed for 84 d with 4 isoproteic diets of 15% crude protein: T0, with 0% of whole raw soybean grain, T8, with 8% whole raw soybean grain, T16, with 16% whole raw soybean grain and T24, with 24% whole raw soybean grain, on dry matter basis. Steers were allotted to 4 pens and assigned to a completely randomized design. Animals were weighed at 28 d intervals after 18 h fasting to evaluate the performance. Animals were slaughtered in the commercial plant, according to proper welfare guidelines, and hot carcass weight, carcass yield, liver weight were evaluated. Twenty-four hours later, *Longissimus* muscle area and backfat thickness was measured at the interface of the 12th and 13th ribs. Longissimus muscle samples were aged 14 d with temperature varied between 0°C and 4°C for Shear force (SF) analysis. SF was obtained with Warner Bratzler equipment. Effects of treatments were evaluated using SAS software. No difference ($P > 0.05$) was observed for the measured variables: performance (1.82 ± 0.09 kg/d), hot carcass weight (284.07 ± 4.65kg), carcass yield (53.45 ± 0.52%), liver weight (5.69 ± 0.19kg), muscle area and backfat thickness (74.61 ±

2.46mm^2 and 2.08 ± 0.26mm). However, shear force characteristics had a quadratic effect ($P > 0.05$) with the highest scores for the treatment with 8% of soybean grain (7.17 kgf), which differed from the T0 (5.61 kgf) treatment but not the other treatments. The inclusion of whole raw soybean grain in beef cattle diets at the trial levels did not affect performance and carcass traits except for a slight increase in shear force at 8% grain inclusion levels.

Key words: protein source, tenderness, ruminants

W176 Genetic group and slaughter weight influence on meat color of feedlot cattle. R. Mello*[1], A. C. de Queiroz[2], F. D. de Resende[3], L. A. de Miranda Gomide[2], P. B. Costa[2], and W. da Silva Cotrim[2], *[1]Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil.*

The purpose of this study was to investigate the genetic group and slaughter weight influence on meat color of the cattle. Thirty-six young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) were used. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of shrunk body weight (SBW). A completely randomized experimental design of a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. The animals were slaughtered in a commercial slaughter-house. The meat color evaluation was carried out in the Longissimus dorsi muscle at 13th rib. Data were analyzed with SAS® software using initial SBW as a covariate. The table below shows the least squares means of L* (luminosity), a* (redness), b* (yellowness), c* (saturation) and h* (hue). There was no effect ($P > 0.05$) of genetic group on color indexes. The interaction between genetic group and slaughter weight was not significant ($P > 0.05$) for all color traits. As the slaughter weight increased, the hue (h*) increased ($P < 0.05$) and a*/b* ratio decreased ($P < 0.05$). Accordingly, lighter weight animals at slaughter produced meat with better visual appearance of color than animals slaughtered at heavier weights, regardless of breed.

Table 1. Least squares means

	Genetic Group (GG)		Slaughter Weight (SW)				
	½ RA ½ N	½ BA ½ N	480	520	560	CV	SEM
L*	39.73	40.24	39.29	40.46	40.21	4.6	0.30
a*	4.87	5.07	4.89	5.39	4.64	14.9	0.12
b*	6.60	7.32	6.44	7.14	7.30	16.2	0.20
c*	8.24	8.93	8.12	8.97	8.66	13.4	0.20

W177 C18:1,2,3 fatty acid isomers from intramuscular fat influenced by genetic group and slaughter weight. R. Mello*[1], A. C. de Queiroz[2], F. D. de Resende[3], D. P. D. Lanna[4], M. H. de Faria[3], and E. da Costa Eifert[4], *[1]Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil, [4]Universidade de São Paulo – Escola Superior de Agricultura 'Luiz de Queiroz', Piracicaba, São Paulo, Brazil.*

The work was carried out to evaluate the effect of genetic group (GG) and slaughter weight (SW) on C18:1, C18:2 and C18:3 fatty acid isomers of intramuscular fat from Longissimus dorsi muscle at 13th rib. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) at 447.7 ± 5.8 kg of shrunk body weight (SBW) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) at 444.3 ± 6.5 kg of SBW were used. The animals were in compensatory growth because previously to the beginning of the experiment they remained for 2 mo at Brachiaria brizantha pasture under continuous grazing system. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of SBW. A completely randomized experimental design in a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. Data were analyzed with SAS software using initial SBW as a covariate. The table below shows the least squares means of dependent variables. The backfat thickness increased ($P < 0.05$) as slaughter weight rised, being 2.1, 2.7 and 4.4 mm, respectively, for animals slaughtered at 480, 520 and 560 kg. The 1/2 BA 1/2 N young bulls had higher ($P < 0.05$) cis-13 C18:1 and cis-9 trans-11 C18:2 (CLA) levels than 1/2 RA 1/2 N young bulls. As the slaughter weight rised the trans, trans-9, trans-11 and trans-16 C18:1; cis-9 trans-11 and trans-10 cis-12 C18:2 (CLA); and cis-9,12,15 and cis-6,9,12 C18:3 levels decreased ($P < 0.05$); while cis, cis-9 and cis-12 C18:1 levels increased. The interaction between GG and SW was not significant ($P > 0.05$) for all levels of C18:1,2,3 fatty acid isomers. Therefore, crossbred F1 Blonde D′Aquitaine × Nellore young bulls and lighter animals had better profile of C18:1,2,3 fatty acid isomers in the intramuscular fat than F1 Red Angus × Nellore young bulls and heavier animals.

Table 1. Least squares means

	Genetic Group		Slaughter Weight		
	½ RA ½ N	½ BA ½ N	480	520	560
C18:1					
cis-9	32.42	33.49	32.01^b	32.3^{ab}	34.53^a

W178 Fatty acids profile of intramuscular fat from crossbreed young bulls slaughtered at different body weights. R. Mello*[1], A. C. de Queiroz[2], F. Dutra de Resende[3], D. P. D. Lanna[4], M. H. de Faria[3], and E. da Costa Eifert[4], *[1]Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Agência Paulista de Tecnologia dos*

Agronegócios, Colina, São Paulo, Brazil, [4]Universidade de São Paulo – Escola Superior de Agricultura 'Luiz de Queiroz', Piracicaba, São Paulo, Brazil.

The aim was to investigate fatty acids profile of intramuscular fat from Longissimus dorsi muscle at 13th rib of crossbred bulls at different body weights. Thirty 6 young (20 mo) bulls, 18 crossbred F1 Red Angus × Nellore (1/2 RA 1/2 N) at 447.7 ± 5.8 kg of shrunk body weight (SBW) and 18 F1 Blonde D′Aquitaine × Nellore (1/2 BA 1/2 N) at 444.3 ± 6.5 kg of SBW were used. The animals were in compensatory growth. The young bulls were feedlot finished and slaughtered at 480, 520 and 560 kg of SBW. A completely randomized experimental design in a 2 × 3 (2 genetic groups × 3 slaughter weights) factorial arrangement with 6 replicates was used. Data were analyzed with SAS® software using initial SBW as a covariate. The table below shows the least squares means of dependent variables. The backfat thickness increased ($P < 0.05$) as slaughter weight rised, being 2.1, 2.7 and 4.4 mm, respectively, for animals slaughtered at 480, 520 and 560 kg. The 1/2 BA 1/2 N young bulls had higher ($P < 0.05$) monounsaturated fatty acids levels than 1/2 RA 1/2 N young bulls. As the slaughter weight rised the n-3 fatty acids levels decreased ($P < 0.05$). Thus, crossbred F1 Blonde D′Aquitaine × Nellore young bulls and lighter animals had better fatty acids profile in the intramuscular fat than F1 Red Angus × Nellore young bulls and heavier animals.

Table 1. Least squares means

	Genetic Group		Slaughter Weight			
FA	½ RA ½ N	½ BA ½ N	480	520	560	SEM

W179 Effects of modified wet corn distillers grains containing 6.7% fat on beef quality and rib fat composition. J. L. Veracini*[1], P. M. Walker[1], B. R. Wiegand[2], H. L. Evans[2], R. L. Atkinson[3], M. J. Faulkner[1], and L. A. Forster[4], *[1]Illinois State University, Normal, [2]University of Missouri, Columbia, [3]Southern Illinois University, Carbondale, [4]Archer Daniels Midland Co., Decatur, IL.*

As the demand for ethanol increases, the availability of modified wet corn distillers grains (DGS) for inclusion in cattle diets increases. Several studies evaluating the effects of dietary DGS on performance characteristics have been reported. Fewer studies have evaluated high inclusion levels (over 50% diet DM) of DGS in finishing cattle diets on the effects on beef quality and adipose profile. The objective of this study was to compare beef quality characteristics and rib fat profile of steers fed 0, 25, 40 and 70% DGS (DM basis). Following a 48 h chill, rib sections (ribs 10 to 12) were removed, individually tagged, bagged and refrigerated. Rib sections were allowed to age for 7 d at 4°C before they were deboned, sliced into 2.54 cm steaks, and evaluated for Minolta color, cooking loss, shear force, % fat, % moisture and intramuscular fat (IMF) fatty acid composition. There were no differences ($P > 0.05$) in % moisture, % fat, shear force, or cooking loss between treatments. Steers fed 70% DGS diets produced ribeye steaks with significantly lower a* values ($P < 0.05$), and a trend for lower b* ($P < 0.10$) values compared with ribeye steaks from steers fed 0, 25, or 40% DGS. Lower redness scores (a*) can be associated with oxidation of unsaturated fatty acids that can trigger oxidation of myoglobin. Fatty acid analysis showed a linear increase ($P < 0.05$) in SFA (44% vs. 48% for 0% and 70% DGS, respectively) at the expense of MUFA (50% vs. 43% for 0% and 70% DGS, respectively). Linear increases were observed in PUFA/SFA, CLA, and ω6 fats, with increasing DGS level. Citing a decrease in C18:2n6c from 3.51 to 4.50 to 5.23 to 6.69 for 0%, 25%, 40% and 70% DGS, respectively. Since DGS can have 3 to 12% (depending on extraction and blending methods) corn oil and corn oil has a high percentage of linoleic acid, it appears that increasing dietary DGS resulted in increased rumen bypass or incomplete rumen biohydrogenation of corn oil, thus shifting fatty acid profiles of IMF.

Key words: DGS, beef color, fat profile

W180 Diet and genotype effects on the quality index of beef Nellore and F1 Nellore × Brahman produced in feedlot. R. A. Mandarino*[1], F. A. Barbosa[2,1], I. S. Silva[1], S. L. S. Cabral Filho[1], J. L. Vilela[1], and C. F. Lobo[1], *[1]University of Brasília, Brasília, DF, Brazil, [2]Federal University of Minas Gerais, Belo Horizonte, MG, Brazil.*

This experiment evaluated the effect of diet and genetic group on meat tenderness and the initial (pHi) and final pH (pHf) of the carcass after slaughter. The experiment lasted 96 d. The herd was composed of 42 bulls with a average age of 23 mo composed of 21 breed Nellore (NEL) and 21 crossbreed Nellore x Brahman (NBR). Each genetic group was divided into 3 diets, with 7 animals each: SIL - corn silage and concentrate (corn grain, soybean meal, soybean hulls, urea and mineral supplement) at a ratio of 25:75 (in dry matter), PEL - exclusive diet of pellets; GRN - diet with whole grain corn and pellets. The experiment was conducted in a randomized scheme in a 2 × 3 factorial, divided as follows: NELSIL, NELPEL, NELGRN, NBRSIL, NBRPEL and NBRGRN. The average initial body weights were 352.36 kg for genetic group NEL and 377 kg for the NBR animals. The final body weight averages were 481.37 kg for NEL and 461.4 kg for the NBR animals. The results of the pH measured 2 h (pHi) after slaughter were higher for NEL compared with NBR, 6.11 and 5.85, respectively ($P < 0.05$). There was a influence by the diet on the pHi with higher value to GRN when compared with PEL and SIL, 6.08, 5.99, 5.86, respectively ($P < 0.05$). The results of pH measured 24 h (pHf) after slaughter were higher for NEL compared with NBR, 5.92 and 5.28, respectively ($P < 0.05$) but were not influenced by the diets ($P > 0.05$). The meat tenderness, measured by shear force, was only numerically higher for NEL with a value of 4.97 and 4.62 kgf for NBR but were not influenced by genetic or by diet ($P > 0.05$). For both genetic groups the meat can be considered as a moderately soft meat and resilient to consumption. The pH can be influenced by genetics or the diet. The results also showed a normal value for pH what is expected to be 2 h and 24 h after slaughter.

Key words: shear force, tenderness, pH

W181 Beef quality parameters of Nellore bulls finished with cottonseed cake as fat source. A. P. Neto*[1,2], R. H. Branco[3], S. F. M. Bonilha[3], T. L. S. Corvino[3], E. N. Andrade[2], and R. de Oliveira

Roça[2], *[1]Universidade Federal do Mato Grosso, Sinop - Mato Grosso/Brazil, [2]Universidade Estadual Paulista, Botucatu - São Paulo/Brazil, [3]CAPTA Bovinos de Corte - Instituto de Zootecnia, Sertãozinho - São Paulo/Brazil.*

Cottonseed cake (CSC) is a residue obtained by mechanical extraction of oil seed upon biodiesel manufacturing. This study aimed to evaluate effects on beef quality of CSC inclusion as fat source in finished diets of Nellore bulls. Forty bulls were slaughtered with averages of 21 mo for age and 451 kg for BW, after 102 d under feedlot conditions. CSC inclusion was based on diet ether extract (EE): 3%, 4% and 5%. Other treatments, with 3% and 5% of EE, having soybean (SB) products as fat source were also tested. Beef quality parameters evaluated were: pH 24 h, shear force, beef color objectively by Minolta CR-410 [L* = brightness; a* = red; b* = yellow] and subjectively using score of 1 = extremely light red to 7 = extremely dark red. Means were tested using 4 non-orthogonal contrasts: C1 = 3%SB vs. 3%CSC; C2 = 5%SB vs. 5%CSC; C3 = 3%CSC vs. 5%CSC; and C4 = 3%CSC and 5%CSC vs. 4%CSC. Contrasts were analyzed by Scheffé test. Beef quality parameters evaluated were not influenced by fat source and EE level. Means of 5.71 for pH 24 h, 5.70 kg for shear force, 38.8 for brightness, 16.7 for red color, 4.6 for yellow color and 3.75 for subjective color score were observed. The meat traits evaluated indicated high quality beef. Therefore, CSC did not influence beef traits and can be used as fat source on finishing diets of Nellore bulls.

Table 1. Beef quality parameters of Nellore bulls feed with cottonseed cake (CSC) and soybean (SB)

	SB		CSC			*P*[1]			
	3%	5%	3%	4%	5%	C1	C2	C3	C4
pH 24 h	5.70	5.65	5.59	5.66	5.97	NS	NS	NS	NS
Shear force, kg	6.02	5.93	5.62	6.03	4.91	NS	NS	NS	NS
L*	39.1	39.2	39.6	38.2	37.9	NS	NS	NS	NS
a*	16.5	16.4	17.8	16.3	16.7	NS	NS	NS	NS
b*	4.64	5.13	5.37	4.10	3.82	NS	NS	NS	NS
Color score	3.87	3.37	3.00	3.87	4.62	NS	NS	NS	NS

[1]C1 = 3%SB vs 3%CSC; C2 = 5%SB vs 5%CSC; C3 = 3%CSC vs 5%CSC; and C4 = 3%CSC and 5%CSC vs 4%CSC. NS = no significance ($IYI \geq S$; $\alpha = 0.05$).

Key words: biodiesel, byproducts, feedlot

W182 Meat tenderness of Nellore cattle classified for residual feed intake. T. L. Sobrinho[1], K. Zorzi[2], R. H. Branco[3], S. F. M. Bonilha[3], L. T. Egawa[3], E. Magnani[3], and M. E. Z. Mercadante*[3], *[1]Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brasil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brasil, [3]Instituto de Zootecnia, Sertãozinho, São Paulo, Brasil.*

Residual feed intake (RFI), expressed as the difference between DM intakes observed and estimated by regression equation as function of metabolic BW and ADG, is an alternative measure of feed efficiency and can be used as tool to reduce costs of beef production. This study aimed to evaluate Warner-Bratzler shear force (SF) and myofibrillar fragmentation index (MFI) of meat from low (more efficient) and high (less efficient) RFI animals. The experiment was conducted at Instituto de Zootecnia, Sertãozinho/São Paulo/Brazil, with 59 Nellore bulls slaugthered with 447 kg of average BW and 20 mo of age. Carcasses were chilled at 2°C for 24 h and then steak samples of Longissimus dorsi muscle, with 2.5 cm of thickness, were removed from 11th rib for SF and MFI determination. Steaks were aged for 7 and 21 d at 0–2°C and then were frozen, totaling 3 samples for animal, with 1, 8 and 22 d post mortem. Data were analyzed using GLM procedure of SAS, and means were compared using *t*-test. RFI variation was 0.740 kg of DM per d, with averages of −0.330 and 0.410 kg, respectively, for animals more and less efficient. No difference was detected for MFI between RFI levels, being MFI averages 35.8 and 40.6 (d 1; $P = 0.0877$), 49.3 and 50.5 (d 8; $P = 0.800$) and 70.9 and 78.8 (d 22; $P = 0.249$), respectively for low and high RFI levels. Low RFI animals had higher SF than the high RFI ones. SF averages were 4.30 and 3.83 kg (d 1; $P = 0.0424$); 4.00 and 3.47 kg (d 8; $P = 0.0339$); and 3.12 and 2.58 kg (d 22; $P = 0.005$), respectively for low and high RFI levels. MFI increases with aging result from proteolytic enzymes, among them calpains, that act on muscle fibers and promote meat tenderness. However, despite not showing up significant difference for MFI, low RFI animals had higher SF values, indicating less tender meat. According to literature, more efficient animals have stronger action of calpastatin, responsible for inhibiting calpain action, resulting in less tender beef.

Key words: beef quality, efficiency, shear force

W183 Effects of purified zearalenone on serum reproductive hormone, immunoglobulin, antibody titer and spleen pro-inflammatory cytokines mRNA in young gilts. S. Z. Jiang*[1], Z. B. Yang[1], W. R. Yang[1], S. L. Johnston[2], and F. Chi[2], *[1]Department of Animal Sciences and Technology, Shandong Agricultural University, Taian, Shandong, China, [2]Amlan International, Chicago, IL.*

A study was conducted to evaluate the effects of 1 to 3 mg/kg purified dietary zearalenone (ZEA) on reproductive hormones, immune response, and antibody production in young gilts. Seven days postweaning, 20 gilts (LxYxD) (BW = 10.36 ± 1.21 kg) were randomly allotted to 4 treatments, which were 0, 1, 2, or 3 mg/kg additions of purified ZEA to a basal diet fed for 18 d. Data were analyzed using the GLM procedure of SAS with individual pig as the basis for analysis. Difference was determined as $P < 0.05$. Pigs received classical swine fever (CSF) vaccine 1-d before the study. Blood was collected on d-6 and d-12 for CSF antibody titer determination. Fasted pigs were injected with LPS (50 μg/kg BW) 3 h before blood collection and euthanasia on d-18. Blood samples were used for estrogen, progesterone, testosterone, LH, FSH, and prolactin measurements, and for IgA, IgG, IgM, and IL-2 level determination. Lymphocytes from the blood and spleen were used to determine the lymphocyte proliferation rate (LPR). Spleen mRNA of IL-1β, IL-6, IFN-γ, and TNF-α was determined by real time PCR. There was no difference on CSF titer levels on d-6 or 12 but d-18 titers decreased as ZEA increased ($P < 0.001$). A similar result was observed in IgG but there was no effect on IgA or IgM level. Serum testosterone, estradiol, LH, and FSH decreased as ZEA increased. Progesterone tended ($P = 0.058$) to decrease and prolactin increase with increasing ZEA. No effect was found in FSH level ($P > 0.05$). The IL-2 and LPR of blood and spleen cells decreased ($P < 0.05$) as ZEA increased. Spleen mRNA of IL-2 and IL-6 increased as ZEA increased. As ZEA increased IFN-γ mRNA decreased but TNF-α showed no effect. Dietary ZEA at 1 to 3 ppm level negatively affects the pig′s reproductive hormone, immunoglobulin, and antibody production, and may increase the inflammatory response.

Key words: zearalenone, immune response, hormone

W184 Ameliorate effect of Calibrin Z enterosorbent on serum reproductive hormone, immunoglobulin, antibody titer in young pigs fed purified zearalenone. S. Z. Jiang*[1], Z. B. Yang[1], S. L. Johnston[2], and F. Chi[2], *[1]Department of Animal Sciences and Technology, Shandong Agricultural University, Taian, Shandong, China, [2]Amlan International, Chicago, IL.*

Thirty-six pigs (BW = 8.9 ± 0.2 kg) were used to evaluate the effect of Calibrin-Z (CZ) on the effects of zearalenone (ZEA) on immune response in piglets. The pigs were allotted to 6 treatments (TRT). The 6 TRT were: 1) Control (Con); 2) Con + 0.1% CZ; 3) Con + 1 ppm ZEA; 4) Con + 1 ppm ZEA + 0.1% CZ; 5) Con + 1 ppm ZEA + 0.2% CZ; 6) Con + 1 ppm ZEA + 0.4% CZ. Data were analyzed using the GLM procedure of SAS with individual pig as the basis for analysis. Each pig received classical swine fever (CSF) vaccine 1-d before the study, serum samples were collected weekly for CSF antibody titer determination. On d 21, blood and spleen samples were collected for hormone, immunoglobulin, interleukin (IL) cytokine analyses, and lymphocyte proliferation rate (LPR). Gilts fed TRT 3 had lower ($P < 0.05$) progesterone (75% of 1 and 2), and testosterone (74% of 1 and 2) levels than TRT 1 and 2. Adding clay improved serum hormone levels and the elevated hormone was clay dosage dependent. Male pigs fed TRT 3 showed similar results as gilts except serum estrodial was not different. Serum IgA and IgM were not different, IgG level was reduced ($P < 0.01$) in TRT 3 (77% of 1 and 2) compared with TRT 1 and 2. It increased linearly ($P < 0.05$) in TRT 4, 5, and 6 but remained lower ($P < 0.05$) than TRT 1 and 2 (84% of 1 and 2).The LPR from blood and spleen cells followed a trend similar to IgG. Serum IL-2 followed results similar to those of the hormones; pigs fed TRT 3 had the lowest IL-2 but an addition of 0.4% clay restored the levels equal to TRT 1 and 2. There was no difference on d-7 or d-14 on CFS titers. On d-21, pigs fed TRT 2 had the highest titer against CSF and greater ($P < 0.01$) than pigs fed TRT 3, 4, 5, and 6; but not different than TRT 1. Feeding 1 ppm of purified ZEA caused adverse effects on immunity in pigs; which were ameliorated by CZ. Feeding CZ without ZEA had the greatest antibody titer production, implying that the Calibrin-Z adds value to feed with or without a mycotoxin challenge.

Key words: zearalenone, titer, immunoglobulin

W185 Dietary effect of short-chain organic acids on growth performance, mortality, and development of intestinal lymphoid tissues in young non-medicated rabbits. C. Romero*[1], P. G. Rebollar[1], A. Dal Bosco[2], C. Castellini[2], and R. Cardinali[2], *[1]Universidad Politécnica de Madrid, Spain, [2]Università degli Studi di Perugia, Italy.*

This work aimed to test the effect of a dietary inclusion of formic and citric acids (0.4%) on growth performance, mortality, jejunal histology, and development of intestinal lymphoid tissues in growing non-medicated rabbits. For that purpose, a diet including the acids (diet A) was compared with a control diet (diet C). Sixty rabbits weaned at 28 d were submitted to each diet. At 56 and 77 d, 10 rabbits were slaughtered to assess cecal traits, jejunal histology, and follicular development in the caudal ileal Peyer′s patch and in the appendix. In the 56–77 d period, average daily weight gain of rabbits fed diet A was greater than that of control rabbits (48.0 vs. 43.9 g, $P = 0.019$). Mortality rate was not affected by the diet (6.12% on average). Cecal pH was lower at 77 than at 56 d (6.02 vs. 6.19, $P = 0.016$). The concentration of ammonia in the cecal contents increased from 9.62 to 14.2 mmol/l ($P = 0.003$) when rabbits reached 77 d of age. The appendix was heavier (9.75 vs. 4.30 g, $P < 0.001$), longer (13.3 vs. 10.4 cm, $P < 0.001$), and wider (1.74 vs. 1.45 cm, $P = 0.006$) at 77 than at 56 d. Rabbits of 56 d of age fed diet C had shorter villi than the mean value of the other 3 treatments (662 vs. 807 μm, $P < 0.001$). In the Peyer′s patch, the average follicle area was greater at 77 than at 56 d of age (118 vs. 88.4 × 10^3 μm^2, $P < 0.001$) and was also greater in rabbits fed diet C than in those fed diet A (109 vs. 97.5 × 10^3 μm^2, $P = 0.049$). In the appendix, no differences on the average follicle area were found at 56 d of age (115 × 10^3 μm^2) whereas, at 77 d, the area increase was higher for rabbits fed diet C than for those fed diet A (95.5 vs. 50.8%, $P < 0.001$). In conclusion, including formic and citric acids in growing rabbit diets improves weight gain, has a trophic effect on the jejunal mucosa, and controls the development of gut-associated lymphoid tissues.

Key words: gut histology, lymphoid tissue, organic acids

W186 Casein glycomacropeptide and mannan-oligosaccharides reduce the enterotoxigenic *E. coli* (ETEC K88) adhesion to IPEC-J2 cell line. R. G. Hermes*[1], E. G. Manzanilla[1], S. Martin-Orue[1], J.

F. Perez[1], and K. C. Klasing[2], *[1]Universitat Autonoma de Barcelona, Barcelona, Catalonia, Spain, [2]University of California, Davis, Davis.*

The aim of this study was to elucidate the ability of different feedstuffs sources to block the attachment of ETEC (K88) to the intestinal pig epithelium using an in vitro model. An adhesion test was done in polystyrene 96-well plates covered with an IPEC-J2 (intestinal porcine epithelial cell line isolated from the jejunum epithelia of neonatal piglets). Triplicates samples of wheat bran (WB), casein glycomacropeptide (CGMP, Lacprodan, Arla Foods, Denmark), mannan-oligosaccharides (MOS, Bio-Mos, Alltech, USA) or *Aspergillus oryzae* fermentation extract (AO, Fermacto, Molimen S.L., Spain) were evaluated as likely blockers of the ETEC attachment. Feedstuffs were diluted in PBS at 0.8% (w/v), sonicated 3 times, and centrifuged. Supernatant (1mL) of feedstuffs were incubated first with 1mL of an ETEC K88 strain (10^8 cfu/mL diluted in PBS), isolated from a clinical case of colibacillosis in piglets, for 30 min at room temperature and second with the IPEC-J2 monolayer cell culture in the well plates at 37°C/5% CO_2 for 1 h. After that, plates were washed twice with sterile PBS to remove non-attached bacteria and then CO_2-independent media was added to promote the growth of attached bacteria. Plates were incubated at 37°C/10h in a spectrophotometer and optical density (OD, 650 nm) was recorded every 10 min. The OD data were analyzed by nonlinear regression using SAS. The resulting parameters thus obtained were used to calculate the delay time (h) for the cultures to reach an OD of 0.05 ($t_{OD = 0.05}$). Analysis of variance of the $t_{OD = 0.05}$ values between treatments was done using the PROC GLM of SAS. Results showed that CGMP and MOS delayed ($P < 0.05$) $t_{OD = 0.05}$ to 3.4 ± 0.07 and 3.5 ± 0.26 h, respectively, in comparison to the negative control (2.4 ± 0.13 h). The values obtained for WB (3.2 ± 0.05) and AO (3.0 ± 0.06) were intermediate and different ($P < 0.05$) from the negative control. Our results suggest that some dietary ingredients may act as "anti-adhesive" compounds against pathogenic *E. coli*, which may have a positive effect on the intestinal health.

Key words: casein glycomacropeptide, mannan-oligosaccharides, *E. coli* K88

W187 The effects of a galactoglucomannan-arabinoxylan complex on eimeria acervulina infection in broiler chicks. T. A. Faber*[1], R. N. Dilger[1], A. C. Hopkins[2], N. P. Price[3], and G. C. Fahey[1], *[1]University of Illinois, Urbana, [2]Temple-Inland, Diboll, TX, [3]National Center for Agricultural Utilization Research, Peoria, IL.*

Fermentable carbohydrates are thought to enhance the ability of the gastrointestinal tract to defend against pathogenic infection. We hypothesized that a mannose-rich, galactoglucomannan-arabinoxylan (GGM-AX) complex would positively affect the immune status and prevent weight loss resulting from acute coccidiosis (*Eimeria acervulina*) infection. Using a completely randomized design, day-old commercial broiler chicks (n = 160; 4 reps/treatment; 5 chicks/rep) were assigned to one of 4 corn-soybean meal-based diets containing supplemental GGM-AX (0, 1, 2, and 4%) that replaced dietary cellulose. On d 8 post-hatch, an equal number of chicks on each diet were inoculated with either distilled water (sham control) or *E. acervulina* (1×10^6 oocysts). All birds were euthanized on d 7 post-inoculation for collection of cecal contents and duodenal tissue. At 7 d post-inoculation, infected birds fed the 0% GGM-AX treatment had heavier ($P < 0.03$) body weights than infected birds fed 1 or 2% GGM-AX. Feed intake was decreased ($P = 0.01$) by coccidial infection, but not affected by dietary treatment ($P = 0.69$). Cecal pH was greater ($P < 0.01$) in infected birds compared with uninfected birds. As dietary GGM-AX increased, cecal pH linearly decreased ($P = 0.001$), regardless of infection status. Coccidial infection increased ($P < 0.02$) cecal concentrations of propionate, butyrate, and total short-chain fatty acids, but not acetate ($P = 0.28$). Additionally, cecal propionate concentration decreased ($P < 0.01$) as dietary GGM-AX supplementation increased, whereas acetate, butyrate, and total SCFA concentrations were not affected by diet ($P \geq 0.48$). Dietary GGM-AX did not affect mRNA expression of interferon-gamma, interleukin (IL)-6, or IL-15 cytokines in duodenal tissue. An infection x diet interaction ($P = 0.02$) was observed for duodenal IL-12β and IL-1β mRNA expression. Based on these data, we conclude that GGM-AX supplementation was unable to mitigate the negative impact of an acute *E. acervulina* infection in broiler chicks.

Key words: chick, coccidiosis, galactoglucomannan oligosaccharide

W188 The effects of feed-borne *Fusarium* mycotoxins on performance, serum chemistry, and hematology of fryer rabbits. M. A. Hewitt*, M. Brash, and T. K. Smith, *University of Guelph, Guelph, Ontario, Canada.*

Mycotoxins are secondary metabolites produced by fungal synthesis. In many species, the effects of *Fusarium* mycotoxins have been documented. Very few studies, however, have been conducted on rabbits. The objective of the current study was to determine the effects of feeding grains naturally contaminated with *Fusarium* mycotoxins on growth and metabolism of fryer rabbits. Thirty 5-wk old male New Zealand white rabbits were used. Each rabbit was randomly assigned to 1 of 3 diets: (1) a control, (2) contaminated diet and (3) contaminated diet + 0.2% Glucomannan mycotoxin adsorbent (GMA). The control diet contained 0.2µg/g deoxynivalenol (DON), the contaminated diet contained 4.3µg/g DON and the GMA diet contained 4.9µg/g DON. Zearalenone and 15-acetyl DON were minor contaminates. The rabbits were given feed and water ad libitum for 21 d. Feed intake was measured daily and water intake was measured every 3 d. On d 21, blood samples were taken for serum chemistry analysis, and tissue sections were taken for pathology. Data was analyzed by ANOVA using a PROC GLM model. A Tukey test was used to compare least squares means among treatments and comparisons were considered significant at $P \leq 0.05$. Average daily gain was increased in rabbits fed the GMA diet ($P < 0.05$), and feed efficiency and average daily water intake were increased in rabbits fed the contaminated and GMA diet, when compared with controls ($P < 0.05$) (Table 1.1). Urea levels were also increased in rabbits fed the GMA diet and alkaline phosphatase (ALP) levels were decreased in rabbits fed the GMA diet when compared with controls ($P < 0.05$) (Table 1.1). An increase in water consumption could indicate improper kidney function. The increased weight gain seen in rabbits fed both the contaminated and GMA diets could be reflected by the increased water consumption. High urea and low ALP levels are signs of impaired protein metabolism. It was concluded that the feeding of diets naturally contaminated with *Fusarium* mycotoxins could adversely affect protein metabolism in immature rabbits.

Table 1. Effect of feed-borne *Fusarium* mycotoxins[1]

Diet	Average Gain (g)	Feed Efficiency (g/g)[2]	Average Water Intake (ml)	Urea (mmol/L)	Alkaline Phosphatase (U/L)
Control	37.08	0.347	142.49	3.19	212.6
Contaminated	40.33	0.377	173.45	3.57	171.8
GMA	41.02	0.385	184.4	3.85	162.6
SEM	± 1.0	± 0.01	± 7.69	± 0.164	± 12.1
1 vs. 2	NS[3]	0.05	0.02	NS	NS
1 vs. 3	0.026	0.011	0.002	0.024	0.02
2 vs. 3	NS	NS	NS	NS	NS

[1]Values are mean ± SEM; for each diet n=10.

W189 Effects of plant extracts on peripheral blood immune cells and inflammatory mediators of weaned pigs experimentally infected with a pathogenic *E. coli*. Y. Liu*[1], M. Song[1], T. M. Che[1], J. A. Soares[1], D. Bravo[2], C. W. Maddox[1], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]Pancosma SA, Geneva, Switzerland.*

A study evaluated the effects of 3 different plant extracts (PE) on immune responses of weaned pigs experimentally infected with a pathogenic F-18 *E. coli*. Weaned pigs (n = 64, 6.3 ± 0.2 kg BW, 21 d old) were housed in individual pens in disease-containment chambers for 15 d: 4 d before and 11 d after the first inoculation (d 0). Treatments were in a factorial arrangement: with or without an F-18 *E. coli* challenge (toxins: LT, STb, and SLT-2; 10^{10} cfu/3 mL oral dose; daily for 3 d from d 0) and 4 diets (a nursery basal diet (CON), 10 ppm capsicum oleoresin (CAP), garlic (GAR), or turmeric oleoresin (TUR)). Blood was collected on d 0, 5, and 11 to measure total and differential white blood cell (WBC) counts and serum tumor necrosis factor-α (TNF-α), interleukin-10 (IL-10), transforming growth factor-β (TGF-β), C-reactive protein (CRP), and haptoglobin (Hp). The *E. coli* infection increased ($P < 0.05$) lymphocytes (LYM), TNF-α, and Hp on d 5, and WBC, neutrophils (NEU), LYM, monocytes (MONO), and Hp on d 11, but decreased ($P < 0.05$) IL-10 on d 5 and TGF-β on d 11 compared with the unchallenged group. In the *E. coli* challenged group, CAP decreased ($P < 0.05$) TNF-α (61.8 vs. 79.6 pg/ml) and Hp (823 vs. 1400 μg/ml) on d 5, and WBC (21.6 vs. 32.2 × 10^3/μl) and NEU (10.3 vs. 17.0 × 10^3/μl) on d 11; GAR decreased ($P < 0.05$) LYM (5.35 vs. 8.25 × 10^3/μl) and Hp (888 vs. 1400 μg/ml) on d 5, and WBC (23.0 vs. 32.2 × 10^3/μl), LYM (7.63 vs. 13.48 × 10^3/μl), and Hp (164 vs. 1272 μg/ml) on d 11; TUR decreased ($P < 0.05$) TNF-α (63.1 vs. 79.6 pg/ml) on d 5 and NEU (10.2 vs. 17.0 × 10^3/μl) on d 11 compared with the CON. In the unchallenged group, on d 5, CAP decreased ($P < 0.05$) Hp; GAR increased ($P < 0.05$) MONO and decreased ($P < 0.05$) Hp compared with the CON. PE did not affect IL-10, TGF-β, and CRP in both sham and *E. coli* challenged groups. In conclusion, the 3 PE tested affected total WBC, the populations of immune cells, and inflammatory mediators in *E. coli*-infected piglets, which may be beneficial to pig health.

Key words: *E. coli*, plant extracts, weaned pigs

W190 Acute toxicity of aqueous extract of *Moringa oleifera* leaf in growing poultry. J. O. Ashong* and D. L. Brown, *Cornell University, Ithaca, NY.*

The objective of the present study was to evaluate the safety of an aqueous extract of *Moringa oleifera* and its impact on feed intake in growing poultry. At 21 d of age, 75 White-leghorn type chicks were weighed and randomly divided into 5 groups, G1, G2, G3, G4 and G5. Chicks in G1, G2, G3, and G4 were gavage (orally) with aqueous moringa extract: 200, 400, 800, 2000 mg/kg BW, respectively, while chicks in G5 were gavage with distilled water (control group). Each group was made up of triplicates with 5 chicks per replicate. All chicks were fed basal chick feed. All the chicks were observed at the first 6 h and once daily thereafter over 14 d for signs of abnormal behavior and/or toxicity and mortality. Daily feed intake and weekly BW were recorded for the duration of the study. Post-trial postmortem examination conducted included weighing of kidney, liver and heart and biochemical analyses such as uric acid, thyroxine (T4), creatinine, aspartate transaminase (AST), alkaline phosphatase (ALP), cholesterol and total protein. Liver and kidney tissues were harvested for histopathological examination. There were no observed signs of abnormal behavior and/or toxicity and mortality in the course of the study. Macroscopic and microscopic observations showed no alterations and differences in the liver and kidneys of G1, G2, G3, G4 and G5 even though the liver weight was heaviest in G4 and lightest in G2. Similarly, there were no differences in feed intake and weight gain among the treatment groups. In the biochemical study, no changes and differences were observed among circulating biochemical indicators ($P > 0.05$); however, ALP decreased ($P < 0.05$) with increasing moringa leaf extract concentration, while total protein and albumin also decreased ($P < 0.05$) with increasing moringa leaf extract from 400 to 2000 mg/kg BW. In conclusion, oral administration of an aqueous extract of moringa at doses of 200, 400, 800 and 2000 mg/kg BW for 14 d to growing poultry did not induce any short-term toxicity and had no impact on feed intake

Key words: *Moringa oleifera*, acute toxicity, poultry

W191 Effects of spray-dried plasma on growth and reproductive responses of pregnant mice to lipopolysaccharide as a model for inflammation in sows. M. Song*[1], Y. Liu[1], J. A. Soares[1], J. J. Lee[1], T. M. Che[1], J. M. Campbell[2], J. Polo[2], J. C. O'Connor[3], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]APC Inc., Ankeny, IA, [3]University of Texas Health Science Center, San Antonio.*

A study evaluated the effects of spray-dried plasma (SDP) on growth and reproductive responses of pregnant mice (C57BL/6 strain) to lipopolysaccharide (LPS; *Salmonella typhimurium*) as a model for inflammation in sows. The mated female mice (n = 250; 4 replicated groups, 62 or 63 mice/group) were shipped from Bar Harbor, ME to Urbana, IL on the day the vaginal plug was found (gestation day (GD) 1), arriving at the laboratory on GD 3. They were housed in individual cages, randomly assigned to dietary treatments with or without 8% SDP (SDP or CON), and fed for 15 d. The diets were formulated to similar ME, CP, and AA levels without antibiotics. On GD 17, pregnant mice (n = 61; 26.5 ± 1.65 g BW) were randomly assigned to intraperitoneal injections with or without 2 μg LPS in 200 μL PBS (LPS or PBS) and euthanized 6 h (6H) or 24 h (24H) later. Measurements were growth performance, pregnancy loss, fetal death, average live fetal and placental weight (WT), and organ WT (intestine, liver, spleen, and lung). The SDP improved BW gain (6H: 0.13 vs. −0.14 ± 0.12 g, $P = 0.06$; 24H: 0.81 vs. 0.30 ± 0.08 g, $P < 0.05$), feed intake (6H: 0.20 vs. 0.06 ± 0.05 g, $P < 0.05$; 24H: 2.8 vs. 2.4 ± 0.18 g, no significant (NS)), G:F (6H: no data; 24H: 0.30 vs. 0.11 ± 0.03, $P < 0.05$), average live fetal WT (6H: 0.65 vs. 0.56 ± 0.03 g, $P < 0.05$; 24H: 0.76 vs. 0.71 ± 0.02 g, $P = 0.09$), and the ratio between average live fetal and placental

WT (6H: 6.1 vs. 4.9 ± 0.6, $P = 0.07$; 24H: 7.2 vs. 6.4 ± 0.8, NS), and reduced spleen WT (6H: 0.29 vs. 0.35 ± 0.03% of BW, $P = 0.08$ (SDP effect larger under the LPS challenge (interaction, $P = 0.09$)); 24H: 0.29 vs. 0.25 ± 0.01% of BW, NS) compared with the CON. There were no interactions between diet and challenge on the other responses. The LPS challenge reduced BW gain and feed intake, and increased pregnancy loss (48 vs. 0%, $P < 0.05$), fetal death (5.3 vs. 0.6%, $P = 0.08$), and spleen WT compared with the PBS challenge. In conclusion, SDP improved growth performance of pregnant mice and their fetal WT after the challenge, but did not affect pregnancy loss or fetal death.

Key words: mice, reproductive responses, spray-dried plasma

W192 Effects of spray-dried plasma on immune responses of pregnant mice to lipopolysaccharide as a model for inflammation in sows. M. Song*[1], Y. Liu[1], J. J. Lee[1], J. A. Soares[1], T. M. Che[1], J. M. Campbell[2], J. Polo[2], J. C. O'Connor[3], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]APC Inc., Ankeny, IA, [3]University of Texas Health Science Center, San Antonio.*

A study evaluated the effects of spray-dried plasma (SDP) on immune responses of pregnant mice (C57BL/6 strain) to lipopolysaccharide (LPS; *Salmonella typhimurium*) as a model for inflammation in sows. The mated female mice (n = 125; 2 replicated groups, 62 or 63 mice/group) were shipped from Bar Harbor, ME to Urbana, IL on the day the vaginal plug was found (gestation day (GD) 1), arriving at the laboratory on GD 3. They were housed in individual cages, randomly assigned to dietary treatments with or without 8% SDP (SDP or CON), and fed for 15 d. The diets were formulated to similar ME, CP, and AA levels without antibiotics. On GD 17, pregnant mice (n = 17; 27 ± 1.7 g BW) were randomly assigned to intraperitoneal injections with or without 2 μg LPS in 200 μL PBS (LPS or PBS) and euthanized 6 h later to collect gestational tissues (uterus (U) and placenta (P)). Measurements were pro-inflammatory cytokines (PRO; tumor necrosis factor-α (TNF-α) and interferon-γ (IFN-γ)) and anti-inflammatory cytokines (ANTI; interleukin-10 (IL-10) and transforming growth factor-β1 (TGF-β1)) by ELISA, and total protein (TP) using Bradford's reagent and bovine serum albumin to normalize those cytokines. The LPS challenge increased ($P < 0.05$) PRO and reduced ($P < 0.05$) ANTI in both U and P, except IL-10 in P, compared with the PBS challenge (Table). The SDP reduced ($P < 0.05$) PRO in U and P and ANTI in U only compared with the CON (Table). The SDP attenuated the LPS effect on PRO (interactions: TNF-α in P ($P = 0.09$), IFN-γ in U ($P = 0.08$) and P ($P < 0.05$); Table). In conclusion, SDP attenuated acute inflammation caused by LPS.

Table 1. Effect of SDP on immune responses in gestational tissues of pregnant mice to LPS

Cytokines/ TP	CON PBS	CON LPS	SDP PBS	SDP LPS	SEM	*P*-value LPS	*P*-value SDP	*P*-value Interaction

W193 Wheat bran and casein glycomacropeptide may regulate the immune response of IPEC-J2 cells challenged with enterotoxigenic *E. coli* (ETEC K88). R. G. Hermes*[1], E. G. Manzanilla[1], S. Martin-Orue[1], J. F. Perez[1], and K. C. Klasing[2], *[1]Universitat Autonoma de Barcelona, Barcelona, Catalonia, Spain, [2]University of California, Davis, Davis.*

The objectives of the present study were to measure the innate immune response of the IPEC-J2 cell line challenged with an ETEC (K88) or a non-fimbriated *E. coli* (NFEC), and measure the impact of feedstuffs on the response. Triplicates samples of wheat bran (WB), casein glycomacropeptide (CGMP, Lacprodan®, Arla Foods, Denmark), mannan-oligosaccharides (MOS, Bio-Mos®, Alltech, USA) or *Aspergillus oryzae* fermentation extract (AO, Fermacto®, Molimen, Spain) were evaluated. Feedstuffs were diluted in PBS at increasing doses of 0.1, 0.2, 0.4 and 0.8% (w/v), sonicated 3 times and centrifuged. Then, 1mL of feedstuffs supernatants were incubated (30 min./room temperature) with 1mL of ETEC K88 or NFEC cultures (10^8 cfu/mL, diluted in PBS), added to confluent monolayer of IPEC-J2 cells and incubated for 2 h at 37°C/5% of CO_2. Cells were washed twice with sterile PBS, and IL-8 and TNF-α expression was quantified using Cyclophilin-A, as a housekeeping gene, and related to a non-challenged treatment. Gene expression results were analyzed by ANOVA using the PROC GLM of SAS. The ETEC K88 challenge increased ($P < 0.05$) the inflammatory response, compared with NFEC challenge for IL-8 (33.1 ± 5.44% vs. 6.8 ± 2.42%) and TNF-α (28.9 ± 4.92% vs. 1.8 ± 0.85%) gene expression. Regarding the effect of feedstuffs, the incorporation of WB or CGMP reduced ($P < 0.05$) the IL-8 (7.3 ± 5.26% and 15.4 ± 9.54%, respectively) and TNF-α gene expression (13.0 ± 7.67% and 6.9 ± 3.94%, respectively) in comparison to the AO treatment (IL-8, 35.8 ± 4.08% and TNF-α, 25.9 ± 4.67%). The incorporation of MOS promoted an intermediate response for IL-8 (19.1 ± 6.40%) and similar results to WB and CGMP for TNF-α (13.3 ± 4.49%). In summary our results suggest that WB and CGMP regulate the inflammatory response of IPEC-J2 cells to an ETEC (K88) challenge, likely due to interference in microbial adhesion to the epithelial cells.

Key words: wheat bran, casein glycomacropeptide, *E. coli* K88

W194 Importance of evaluating piglet daily weight gain during the first week after weaning. G. J. M. M. Lima* and L. S. Lopes, *Embrapa, Brazil.*

Performance after weaning is crucial for pig growth. There are few reports describing ADG over the first wk after weaning. Some individuals show low gains while others lose weight (wt) during this period, providing highly variable results. To study wt gain during the first wk after weaning, an experiment was conducted to determine the effects of 4 combinations of lactose sources with or without growth promoter (GP): T1 = whey - GP; T2 = whey + GP; T3 = lactose + GP; T4 = whey permeate + GP. Ninety-six pigs (7.10 ± 0.12 kg) were weaned at 21 d of age and distributed to pens according to a random block design with 8 replicates of 3 animals. Diets met or exceeded 1998 NRC levels and pigs had free access to feed and water. Animals were weighed daily and had no clinical signs of diseases. Diarrhea frequencies were similar among diets (X2 test, $P = 0.69$). Overall average pig wt (n = 96) at d 22, 23, 24, 25, 26, 27 and 28 were 6.90, 6.88, 6.98, 7.17, 7.25, 7.33 and 7.50 kg, respectively, with coefficients of variation (CV) from 11.72 to 12.66%. However, overall average individual ADG for this period were, respectively, −0.205, −0.022, 0.102, 0.184, 0.084, 0.079 and 0.165 kg, with CV ranging from –818.31 to 281.17%. There were no differences in ADG among treatments by ANOVA for any d ($P > 0.35$) or for the first wk period (0.055 kg/d, CV = 123.92%, $P = 0.46$). A diet effect was detected when all individual ADG were combined through multivariate analysis ($P = 0.15$ by Wilks' Lambda test and $P = 0.002$ by Roy's test). Overall frequencies of negative, zero and positive ADG in the first wk period were 16.73, 3.00 and 80.27%, respectively, and there were differences among diets ($P = 0.03$, X2 test). It was detected that T1 (without GP) showed more animals with negative gain in the first wk compared with other treatments ($P < 0.05$, X2 test). It is important to study ADG during the first wk after weaning in these experiments. Multivariate analysis and frequency study of ADG provides useful information for a better understanding of this critical period for pigs.

Key words: Swine, multivariate analysis, X2 test

W195 Acquisition of garlic conditioned preference enhances the flavor hedonic power of porcine digestive peptides (PDP) in post-weaned piglets. J. Figueroa*[1], D. Solà-Oriol[1], S. L. Vinokurovas[1], E. Borda[2], and J. F. Pérez[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain, [2]Bioibérica, Barcelona, Spain.*

Piglets are reluctance to eat unfamiliar ingredients after weaning, which implies that innately preferred ingredients are commonly used in the design of these diets. However, the preference for a novel feed or flavor may be acquired as a result of an association with an intrinsically positive consequence. The aim of the present study was to explore the ability to increase the attraction and hedonism of a protein source in piglets by using synergy between their innate attraction and a flavor conditioned preference. A total of 240 non-deprived weanling piglets were trained during 8 d (alternate sessions) with a 2% Porcine Digestible Peptides (PDP) + 2% Garlic flavor solution and water (Synergy group), and with a 2% Garlic flavor and a 2% PDP solution (Control Group) in odd and even days, respectively. Double choice test (DCHT) between PDP+Garlic v/s PDP in water were performed on d 16, 23 and 30 after weaning. The first contact (number of piglets/pan for the first 15 s; FC) and 30 min solution intake were measured. Data was analyzed by using the GLM procedure of SAS. Higher FC values were observed for PDP+Garlic over PDP solution on d 16 and 23 (4.8 vs. 2.3 and 4.5 vs. 2.8; $P < 0.05$) for the Synergy group. No differences were observed for the Control group. Synergy group showed also a higher intake of PDP+Garlic than PDP at d 30 (773mL vs. 503mL; $P < 0.05$). No differences were observed in the intakes achieved for the Control group. The present results indicate that a garlic conditioned preference may enhance the attraction of PDP solutions, showing a synergy effect. This effect may be used to increase piglet acceptance and reduce neophobia for new feed ingredients.

Key words: protein, piglets, hedonic

W196 Nutrient composition changes in pigs and associated liver from birth to 21 days of age. Y. L. Ma*[1], M. D. Lindemann[1], J. L. Pierce[2], and G. L. Cromwell[1], *[1]University of Kentucky, Lexington, [2]Alltech Inc., Nicholasville KY.*

The objective of this study was to characterize nutrient composition in pigs and associated liver from birth to d 21 of age with specific interest in N and P for use in future determinations of lactation needs of sows for N and P. A week before the expected farrowing day, crossbred gilts (n = 10) were moved to farrowing crates and monitored. Two pigs were randomly selected and euthanized at d 0 (within 2 h after birth; nursing deprived), 7, 14, and 21 from each litter. Pigs (whole body without liver and gastrointestinal tract) and associated liver were analyzed for N, ether extract (EE), P, and total ash on a dry matter (DM) basis. With advancing age, BW increased linearly (1.59, 3.00, 4.63, 6.27 kg; $P < 0.01$), DM increased (19.8, 27.0, 29.2, 30.0%; $P < 0.05$ for linear [L], quadratic [Q], and cubic [C] responses), N decreased (9.77, 8.37, 8.24, 8.40%; $P < 0.01$; Q), EE increased 6-fold from birth to d 7 (5.7, 34.3, 35.8, 37.1%; $P < 0.01$; Q), P decreased (3.49, 2.27, 1.82, 1.78%; $P < 0.01$; Q), total ash decreased, in particular during first 7 d (20.0, 11.9, 10.0, 10.0%; $P < 0.01$; Q), and the unaccounted portion (carbohydrates) decreased, especially for the first 7 d (13.3, 1.5, 2.6, 0.3%; $P < 0.01$; C). As for pig liver, weight increased linearly (44.0, 114.4, 144.5, 190.8 g; $P < 0.01$), DM decreased linearly (29.3, 28.4, 26.2, 25.4%; $P < 0.01$), N increased (6.7, 10.2, 10.1, 10.4; $P < 0.01$; C), EE remained constant (6.8, 6.6, 6.8, 7.4%), total ash increased (4.53, 5.93, 6.16, 5.99%; $P < 0.01$; Q), and the unaccounted portion decreased (47.0, 23.6, 24.0, 21.8%; $P < 0.01$; C) with advancing age. The results characterize the nutrient composition change in pigs and associated liver from birth to 21 d of age, with the greatest change occurring in the first 7 d.

Key words: pigs, body composition, liver

W197 Evaluating performance of dairy replacement calves housed in different group numbers with the same space/calf. K. Shore* and A. Roy, *Grober Nutrition, Cambridge, Ontario, Canada.*

Pre-weaned dairy replacement calves were evaluated for growth and health differences in different group sizes given the same space/calf (2.2 m^2). Sixty-five calves (40.2 ± 4.2 kg BW; 81 ± 3.3 cm height) were used in a 1-way ANOVA model and randomly assigned at arrival to one of 4 treatments: individual (I) pen (n = 23), paired (P) pen (n = 5; 10 calves), small group (SG) of 6 calves (n = 2; 12 calves), large group (LG) of 11 calves (n = 2; 22 calves). All calves were offered 9 L of milk replacer (1.35 kg of dry matter) on a daily basis. I and P calves were offered milk by pail; SG and LG groups were fed by

automatic calf feeder. All milk refusals were recorded; BW and heights were measured weekly. Health was evaluated daily using an adapted version of the University of Wisconsin calf scoring sheet. Calves were on trial for 10 wk, 8 wk on milk replacer, grain and hay and 2 wk on grain and hay only. Water was offered free choice to all calves. Body weight gain was not different between the groups over the 10 wk (I = 61.6 ± 6.2 kg; *P* = 57.0 ± 10.9 kg; SG = 62.0 ± 12.6 kg; LG = 64.4 ± 7.6 kg). There was no difference in ADG between groups throughout the 10 wk (I = 0.881 ± 0.089 kg/d; *P* = 0.829 ± 0.147 kg/d; SG = 0.885 ± 0.179 kg; LG = 0.920 ± 0.109 kg). There was a difference in height to start, such that I and P pens were taller however by 10 wk there was no difference in height (I = 98.2 ± 1.3 cm; *P* = 98.0 ± 2.4 cm; SG = 97.2 ± 3.2 cm; LG = 98.4 ± 3.1 cm). Health was measured in the number of events throughout the trial period, there was a difference between groups such that I (1.7) and P (1.2) were not different from each other but had less events (*P* = 0.04) than group calves (LG = 2.6; SG = 2.3) (LG and SG were not different). Morbidity was highest in the first 2 wk as was mortality. Mortality was greatest in the P group. In summary, the number of calves in a group when given the same space did not affect growth parameters. The number of health events did not increase with more calves in a group.

Key words: calf, group size, milk replacer

W198 Comparison of moisture determination methods for feed ingredients. J. Y. Ahn*, D. Y. Kil, and B. G. Kim, *Department of Animal Science and Environment, Konkuk University, Seoul, Republic of Korea.*

Accurate determinations of moisture content in feed ingredients and mixed diets are very important in animal nutrition experiments, feed sales, and feed storage conditions. While several methods are available for moisture determination in the literature, an oven method drying at 135°C for 2 h (AOAC Method 930.15) is one of the most widely employed procedures for feed moisture analysis. The objective of the present study is to compare oven-drying methods for determining 'loss-on-drying (LOD)' in feed ingredients and mixed diets. Feed ingredients tested in this study included corn, soybean meal (SBM), distillers dried grains with solubles (DDGS), permeate, whey, spray-dried porcine plasma (SDPP), and fish meal. A diet containing these ingredients was also analyzed for LOD. The LOD contents in these samples were determined by oven drying the samples at 135°C for 2 h or at 105°C for 3 h (NFTA 2.2.2.5) in triplicate. Additionally, the samples were dried at 105°C for 6, 9, 12, or 15 h. Drying the samples at 135°C for 2 h resulted in greater LOD contents in corn (12.3 vs. 11.9%), SBM (10.7 vs. 10.3%), DDGS (12.0 vs. 9.3%), permeate (7.5 vs. 3.1%), whey (8.9 vs. 3.0%), SDPP (7.8 vs. 7.5%), and fish meal (8.1 vs. 7.8%) compared with drying at 105°C for 3 h (*P* < 0.05). After drying the samples at 105°C for 3 h, further drying DDGS, permeate, and whey for 12 more h caused more LOD (1.9, 2.3, and 2.3 percentage units, respectively; *P* < 0.01). It was notable that the DDGS and permeate were considerably darkened by drying at 135°C for 2 h. The LOD contents in the individual ingredients were fairly additive: the difference between the calculated LOD contents in the mixed diet based on ingredient analysis and analyzed values ranged from −0.1 to 0.3 percentage units. Taken together, the method of oven-drying at 135°C for 2 h may be inappropriate for determining moisture content in some ingredients, such as DDGS, permeate, and whey, and thus, in diets containing these ingredients.

Key words: drying methods, feed ingredients, moisture content

W199 The effect of diet and creep feed on feed intake by weanling pigs. J. Shea, D. A. Gillis, and A. D. Beaulieu*, *Prairie Swine Centre, Inc., Saskatoon, SK, Canada.*

A growth lag at weaning may be related to delayed initiation of feed intake. The objective of this experiment was to determine if creep feeding, or phase 1 diet complexity, could alleviate this. Trts, arranged as a 2 × 2 × 3 factorial, were 2 BW groups (heaviest [H] and lightest [L] pigs in a weaning group);creep (CR, weaning groups 1–8) or no creep (NoCR, weaning groups 9–15) and 3 diet regimens (complex d 0 to 1, simple d 2 to 14 [Com1]; complex d 0 to 4, simple d 5 to 14 [Com4] and simple d 0 to 14 [Sim14] post-weaning). Pigs were weaned at 28 d of age. Creep feed (commercial phase 1) was available for 1 wk pre-weaning. The heaviest and lightest pigs (n = 48 /wk, 30% of available) from a weaning group were randomized within BW group to one of the diet trts and housed 4 per pen. Diets met nutrient requirements (NRC 1998) but only the complex diet contained whey, plasma, blood meal and fish meal. BW and ADFI were determined on d 0 (weaning), 1, 4, 7 and 14. Pens were videotaped for 24 h post-weaning and at each diet change to enumerate feeder approaches (head over a feeder) per hour. Data were analyzed as a split plot with creep as a main plot, pens within nursery as sub plots and feeder visits as a repeated measure. Post hoc, feeder visits were separated into active (1 to 6 and 18 to 24 h) and resting phases (7 to 17 h post-feeding). CR pigs were 130 g heavier on d 0 (8.49 kg, *P* = 0.35) primarily due to H pigs (creep by BW, *P* = 0.01). NoCR pigs grew faster overall (0.20 vs 0.17 kg/d; *P* = 0.05). H pigs were heavier than L pigs on d 0 (10.40 vs 6.44 kg; *P* < 0.01) but H pigs lost more weight and had lower ADFI during the initial 24 h post-weaning (*P* < 0.01). Overall ADG was greatest in L pigs (*P* < 0.01). Sim14 pigs lost more BW than Com1 or Com4 on d 0 (*P* = 0.02). ADG, d 0 to 14, and final BW were unaffected by diet (*P* = 0.14). During the first 24 h; NoCR had more feeder approaches than CR (*P* = 0.02) and, significant only during the active phase, L pigs more feeder approaches than H. Com4 pigs had more feeder approaches on d 1 and 4 (*P* = 0.05). Weaning wt, creep feed, and diet regimen had only modest effects on growth post-weaning, in pigs housed with minimal competition.

Key words: swine, creep feed, weaning

W200 Effects of creep feed frequency on pre-weaning and post-weaning growth performance and behavior of piglet and sow. J. H. Cho*, S. Zhang, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effects of creep feeding frequency on pre- and post-weaning growth performance and behavior of piglet and sows. A total of 30 sows (Landrace × Yorkshire) and their litters were employed in this study. Sows were randomly assigned with 1, 2 or 3 + parities into 1 of 3 treatments. Dietary treatments included: 1) CON (creep feeding 3 times daily), 2) TRT1 (creep feeding 4 times daily) and 3) TRT2 (creep feeding 5 times daily). The behavior of sows (nursery, eating and standing) and piglets (eating, sleeping and fighting) in each treatment was observed throughout the experiment. Each piglet was weighed on d 5, 10, 15, 21 and 7 after weaning to evaluate ADG. Sows and piglets were bled on the weaning day to evaluate the blood characteristic. Backfat and estrus interval were investigated to evaluate the effect of flavor supplementation on the sows. Varying creep feed frequency did not affect the pre-weaning and post-weaning piglet growth performance (pre-weaning: ADG = 214 vs 225, 231 g, ADFI = 15 vs 16, 15 g; post-weaning: ADG = 201 vs 206, 208 g, ADFI = 210 vs 214, 219 g, G:*F* = 0.957 vs 0.962, 0.949; *P* > 0.05). Pigs

with different frequency did not affect ($P > 0.05$) the IgG (427.9 vs 456.2, 472.6 mg/dl), epinephrine (282.3 vs 277.7, 290.4 pg/ml), norepinephrine (886.2 vs 870.0, 868.2 pg/ml) and cortisol (1.93 vs 1.83, 1.97μg/dl) concentration, as well as the post-weaning diarrhea scores and behaviors in the current study. Moreover, creep feeding frequency did not affect ($P > 0.05$) the weanling-to-estrus interval (5.36 vs 5.22, 5.28 d) and backfat loss (3.9 vs 3.4, 3.8 mm) of sows in the current study. Varying dietary frequency did not affect ($P > 0.05$) the cortisol (6.72 vs 6.28, 6.47μg/dl), epinephrine (37.15 vs 34.58, 35.39 pg/ml) and norepinephrine (202.8 vs 191.2, 188.4 pg/ml) in this study. No differences ($P > 0.05$) in eating (18.6 vs 19.4, 18.4%), standing (23.8 vs 25.8, 24.6%), and lying times (57.6 vs 54.8, 57.0%) during lactation were noted in the current study. In conclusion, varying creep feeding frequency did not affect the performance and behavior of piglet and sow in this study.

Key words: behavior, creep feed, frequency

W201 Effect of a partial replacement of limestone by a $CaSO_4$-zeolite mixture combined with a slight protein reduction on production indices, egg quality and excreta pH in laying hens. C. Romero*[1], E. M. Onyango[2], W. Powers[3], R. Angel[4], and T. J. Applegate[5], *[1]Universidad Politécnica de Madrid, Spain, [2]East Tennessee State University, [3]Michigan State University, East Lansing, [4]University of Maryland, [5]Purdue University, IN.*

A commercial diet (CM diet; 17.4% CP and 4.37% Ca) was compared with a diet with 35% replacement of limestone by a $CaSO_4$-zeolite mixture (5.76% $CaSO_4$ and 1.18% zeolite) and a 0.4 percentage units reduction in protein content (RE diet) in laying hens. Apparent N retention, egg production, egg composition and excreta pH were measured. Previous studies demonstrated that the RE diet reduced ammonia emissions by 48%. Laying hens (192 total; 48 replicate cages per diet with 2 hens per cage; 1441 ± 135 g initial BW) were fed experimental diets from 33 to 49 wk of age. Apparent N retention averaged 48.2% ($P > 0.05$). Egg production (83.6%) and number of shell-less eggs (0.18%) were not affected by the diet. Eggs tended to be heavier (59.4 vs. 58.8 g/egg, $P = 0.06$) and yolk percentage (29.7 vs. 29.0%, $P = 0.013$) was greater with the RE diet. At 48 wk of age, the total solids content per egg was also greater from hens fed the RE diet (13.2 vs. 12.6 g/egg, $P = 0.032$). Other egg components were not influenced by diet (58.1% of albumen and 9.04% of shell). Feeding the RE diet resulted in a higher specific gravity (1.0786 vs. 1.0656 g/g, $P = 0.014$) only when hens were 44 wk-old. At the end of the experiment, excreta were collected from all cages (excreta from 3 cages were mixed and pooled; 16 pools of excreta per diet). At collection, excreta of hens fed the RE diet had lower pH (5.89 vs. 6.54, $P < 0.001$) and higher moisture content (74.0 vs. 70.9%, $P < 0.001$) than those of hens fed the CM diet. After 7 d of storage, excreta pH of hens fed the RE diet continued to be lower (6.30 vs. 8.36, $P < 0.001$). A slight reduction in dietary protein and replacing a portion of the Ca from $CaCO_3$ with $CaSO_4$ did not affect egg production nor did it impair shell quality. Feeding the RE diet to laying hens resulted in a reduction in excreta pH, even after 7 d of storage, as compared with laying hens fed the CM diet.

Key words: calcium sulfate, egg quality, protein reduction

W202 Dietary sources of selenium in nulliparous sows: The importance of vitamin B_6 status for some aspects of antioxidant status and ovulation during the peri-estrus period. M. Roy*[1,2], I. Audet[1], M.-F. Palin[1], H. Quesnel[3], F. Guay[2], and J. J. Matte[2], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]Laval University, Québec, QC, Canada, [3]Institut National de la Recherche Agronomique, St-Gilles, France.*

In this experiment, it was hypothesized that there is an interaction between pyridoxine (B_6) and selenium (Se) metabolisms for an adequate flow of organic Se (Se-cysteine) toward the glutathione peroxidase (GPX) system in response to oxidative pressure induced by the peri-estrus period in sows. Forty-five gilts received one of the 5 dietary treatments (n = 9/group): 1) basal diet (Se = 0.2 mg/kg and B_6 = 2.5 mg/kg) (C); 2) # 1 + 0.3 mg/kg Na-Se ($MSe0B_6$); 3) # 2 + 10 mg/kg B_6 ($MSe10B_6$); 4) # 1 + 0.3 mg/kg Se-yeast ($OSe0B_6$) and 5) # 4 + 10 mg/kg B_6($OSe10B_6$). Treatments started at first pubertal estrus and lasted up to 3 d after fourth estrus. Blood was collected from all gilts at each estrus. At slaughter, liver and kidneys were collected and corpora lutea were counted. At fourth estrus, blood Se was lower in C vs Se gilts and higher in OSe's vs MSe's (229.0, 251.2, 250.7, 288.9 and 282.6 µg/L in groups 1, 2, 3, 4 and 5, respectively, SE = 7.3)($P < 0.01$) while blood GPX activity was higher in MSe vs OSe gilts and both were higher vs C's (117.6, 148.3, 145.6, 125.6 and 131.9 mU/mg hemoglobin in groups 1, 2, 3, 4 and 5, respectively, SE = 6.4)($P < 0.01$). In spite of Se effects (as in blood, $P < 0.01$) on Se in liver (0.7, 0.8, 0.7, 1.0 and 1.0 µg/g in groups 1, 2, 3, 4 and 5, respectively, SE = 0.1) and kidneys (2.5, 2.5, 2.4, 2.7 and 2.7 µg/g in groups 1, 2, 3, 4 and 5, respectively, SE = 0.1), there was no treatment effect ($P > 0.50$) on GPX activity in these tissues. However, gene expressions of cytosol GPX (GPX1) and Se-cysteine oxidase (control of the flow of Se-cysteine to the GSH-Px system) in both liver and kidneys were 50 to 70% higher in $OSe10B_6$ gilts than in others (interaction Se x B_6, $P < 0.01$). Ovulation rate were 17.4, 16.7, 17.7, 16.9 and 21.2 (SE = 0.9) in groups 1, 2, 3, 4 and 5, respectively (B_6 effect $P < 0.01$, Se effect $P < 0.06$ and interaction B_6 x Se, $P < 0.09$). In conclusion, dietary B_6 is a modulating factor of the metabolic pathway of organic Se toward the GPX system and may be involved in ovarian function leading to optimal ovulation conditions.

W203 Effects of high dietary selenium supplementation on fasting plasma glucose and lipid profiles of young pigs. E. Isaacs*, K. Roneker, and X. G. Lei, *Cornell University, Ithaca, NY.*

Recent animal and human studies have shown an intriguing pro-diabetic, hyperglycemic, or hyperlipidemic effect of high dietary intakes of Se that are suggested for cancer prevention. This experiment was conducted to establish a pig model to determine whether a high Se concentration in a corn-soybean meal basal diet (BD) affected plasma glucose concentrations and lipid profiles. A total of 16 weanling pigs (BW = 7.47 ± 0.78 kg) were divided into 2 groups (n = 8/group) and fed the BD supplemented with 0.3 or 1.0 mg Se/kg (as sodium selenite) for 8 wk. Growth performance and fasting plasma glucose, total triglyceride, and total cholesterol concentrations were measured at initial and then biweekly. Weekly or overall ADG, ADFI, and gain/feed efficiency were similar between the 2 dietary Se concentrations. There was no significant effect ($P = 0.1$) of dietary Se supplementation on fasting plasma glucose concentrations (mg/L) (from Wk 0 to Wk 8 = 1207.9 ± 336.8 to 727.9 ± 84.5 vs. 1359.9 ± 169.7 to 845.6 ± 195.6). Likewise, fasting plasma concentrations of total triglyceride and total cholesterol were not different ($P = 0.85$) between the 2 dietary Se groups. In conclusion, supplementing the corn-soy diet with 1 mg of Se/kg for 8 wk might not be sufficient to alter fasting plasma glucose or lipid profiles of weanling pigs.

Key words: glucose, lipid, model pigs, plasma, selenium

W204 Bioavailability of zinc from zinc propionate in chicks. M. A. Brooks*, J. L. Grimes, S. Verissimo, K. L. Murphy, and J. W. Spears, *North Carolina State University, Raleigh.*

The purpose of this experiment was to evaluate the relative bioavailability value (RBV) of Zn propionate (ZnProp) relative to feed-grade $ZnSO_4$ using body weight gain and bone zinc as response criteria. One hundred day-old Ross chicks were fed a semi-purified starter diet deficient in Zn for 7 d post-hatching (22 mg Zn/kg). Chicks were randomly sorted into one of 5 treatments (n = 20) with 5 replicate pens of 4 birds per pen. The experimental control diet (20 mg Zn/kg) differed from the starter diet in that ground corn replaced approximately 30% of the

dextrose and starch present in the semi-purified starter diet. Using corn in the diet increased the level of phytate, an important Zn antagonist in nonruminant animals. The control diet was supplemented with 0, 6 or 12 mg Zn/kg from feed grade $ZnSO_4$ or ZnProp. Chicks were housed in heated, thermostatically controlled Petersime batteries with raised wire floors and fed the treatment diets from 8 to 21 d. Feed and water were offered ad libitum. Individual body weights and feed intake (by pen) were measured at 7-d intervals for determination of gain, feed intake, and feed efficiency (feed:gain). At the end of the study, tibia bones were excised and used for Zn determination. Zinc RBV was determined using $ZnSO_4$ as a standard source by multiple linear regression and slope-ratio methodology. Analyzed supplemental Zn intake was used in the regression analysis. As supplemental dietary Zn increased, there was a dose dependent increase ($P < 0.05$) in feed intake, weight gain, total Zn intake, tibia Zn concentration and total tibia Zn. Feed efficiency (feed:gain) was poorer ($P < 0.01$) in the control diet (0 mg supplemental Zn/kg) compared with Zn addition to the diet, but did not show a dose response with additional Zn ($P > 0.05$). ZnProp RBV was 119%, 116% and 116% using weight gain, tibia Zn concentration, and total tibia Zn, respectively. RBV was greater than $ZnSO_4$ ($P \leq 0.04$) for total tibia Zn, but was not different in regards to weight gain and tibia Zn concentration ($P > 0.05$). In summary, based on these results, bioavailability of Zn from ZnProp is greater than $ZnSO_4$.

Key words: poultry, zinc, relative bioavailability

W205 Effects of copper concentration and source on performance, bile components, copper metabolism and gastrointestinal microbial distribution in nursery swine. M. A. Arnold*[1], J. S. Schutz[1], K. Sellins[1], R. J. Harrell[2], and T. E. Engle[1], *[1]Department of Animal Science, Colorado State University, Fort Collins, [2]Novus International Inc., St. Charles, MO.*

One hundred twenty weaned nursery pigs (6.12 ± 0.56 kg) were utilized in this experiment to determine the effects of Cu concentration and source on performance, bile components, Cu metabolism, and gastrointestinal microbial distribution in nursery pigs blocked by weight and gender and placed in pens containing 5 pigs of similar weight distribution per pen. Pigs were fed one of 4 dietary treatments for 21 or 22d. Treatments consisted of: 1) Control (5 mg of Cu/kg from CuSO4); 2) 250 mg of Cu/kg from CuSO4, (250-sulfate) 3) 75 mg of Cu/kg from Cu-Mintrex Cu (75-Min; Novus International, Inc., St. Charles, MO), and 4) 75 mg of Cu/kg from CuSO4 (75-sulfate). On d 22 and 23, equal numbers of pigs per treatment were slaughtered. Post slaughter, blood, liver, intestinal tissue and contents, and bile samples were obtained. Body weights, ADG, and ADFI were similar across treatments ($P \geq 0.20$). Feed efficiency was greater ($P \leq 0.05$) for pigs receiving 250-sulfate compared with controls (0.53 vs. 0.43 ± 0.03, respectively), and pigs fed 75-Min (0.47 ± 0.03) or 75-sulfate (0.44 ± 0.03) were intermediate. Pigs receiving 250-sulfate had greater ($P \leq 0.05$) bile (7.05 vs. 2.06 ± 0.49; respectively) and liver (124.4 vs. 53.3. ± 24.6; respectively) Cu concentrations than controls. Bile components, intestinal bacterial populations, and small intestine gene expression profiles (Ctr-1, Atox-1, Cox-17, ATP7a, and ATP7b) associated with Cu absorption and homeostasis were similar across treatments ($P \geq 0.20$). Antimicrobial effects of bile (determined by measuring the diameter of the zone of inhibition; mm) tended ($P \leq 0.20$) to be higher for 250-sulfate and 75-Min treatments compared with controls. Data from this experiment indicated that Cu dose influenced pig performance, but dose or source did not influence measured bile components, intestinal bacterial populations, or intestinal gene expression profiles associated with Cu absorption.

Key words: nursery pigs, performance, copper

W206 Different levels of chelated selenium (Se) addition on the performance, and internal and external quality of Japanese quail eggs. V. C. da Cruz*[1], L. C. Carvalho[1], G. do Valle Polycarpo[2], L. H. Zanetti[1], R. F. de Oliveira[1], D. D. Millen[1], R. G. A. Cardoso[1], A. L. C. Brichi[1], M. L. Poiatti[1], and O. J. Sabbag[1], *[1]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil, [2]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil.*

To evaluate the performance, and internal and external quality of eggs of Japanese quail fed diets supplemented with chelated Se, this study was carried out at the São Paulo State University, Dracena Campus, Brazil. 240 7-wk-old birds were distributed in an entirely random design with 5 treatments (T1: control; T2: 0.25 ppm of Se; T3: 0.50 ppm of Se; T4: 0.75 ppm of Se; T5: 1.00 ppm of Se), 8 replications and 6 birds per cage. Water and feed were ad libitum. The feeding was done twice/d, at 0800 h and at 1800 h, and only the empty feeders were filled up. The light program was 18 h light and 6 h dark, using 60-W incandescent light bulbs. The obtained results for the performance indexes (average egg weight, egg yield, egg mass, feed intake, feed conversion per egg mass and feed conversion per egg dozen) from 0 to 40 d (76-d of age) did not present differences ($P > 0.05$) among the treatments. When the different levels of chelated Se addition on the internal and external quality of quail eggs were analyzed, the Haugh Unit (HU) presented quartic effect ($HU = -1.9E\text{-}06\ x^4 + 0.0003\ x^3 - 0.0192\ x^2 + 0.2530\ x + 93.2758$, $P < 0.05$), and so did the albumen height (AH) ($AH = -3.5E\text{-}07\ x^4 + 6.6E\text{-}05\ x^3 - 0.0036\ x^2 + 0.0451\ x + 5.1615$, $P < 0.05$). The yolk height (YH) presented cubic effect ($YH = 6.3E\text{-}06\ x^3 - 0.0008\ x^2 + 0.0192\ x + 10.3502$, $P < 0.05$), and the shell weight (SW) had linear effect ($SW = -0.0003\ x + 0.8768$, $P < 0.05$), and in all those variables, the best result was observed for the eggs of birds that received only inorganic minerals (control treatment). In the other evaluated variables, specific egg weight, albumen index, yolk index and shell thickness, there were no differences ($P > 0.05$) among the treatments. In the studied levels, the microminerals of associated organic sources do not affect the bird performance. The diet supplementation of quail with chelated Se was inefficient in the improvement of bird performance, but it influences the internal quality of the eggs.

Key words: *Coturnix coturnix japonica*, chelated mineral

W207 Recovery of bone mineralization and strength after a marginal dietary calcium deficiency in growing pigs. L. A. Iwicki*, J. L. Reichert, J. R. Booth, D. K. Schneider, and T. D. Crenshaw, *University of Wisconsin, Madison.*

During recovery from dietary energy or amino acid deficiency, animals compensate by improved efficiency of nutrient use. The objective was to determine if efficiency of dietary Ca and P improved in growing pigs after 5 wk consumption of a diet with marginal Ca deficiency. In the first 5 wk (P1), 40 kg crossbred pigs (n = 72/diet) were fed diets with either 70% (LCa) or 115% (HCa) of Ca required (50 to 80 kg). All diets provided 98% of P requirement. During wk 5 to 10 (P2, 80 to 120 kg), pigs were allotted to either continue LCa or HCa diets or were switched in a crossover design to the opposite diet to provide 4 dietary groups of LLCa, LHCa, HLCa, or HHCa. Selected pigs from each sex and diet group were scanned at 40 (n = 6), 80 (n = 24), and 120 (n = 48) kg using dual energy x-ray absorptiometry (DXA, GE

Prodigy v11.4) to determine whole body bone mineral content (BMC). Scanned pigs were killed, femurs were collected, scanned for femur BMC (FmBMC), and subjected to a 4-point bending test (Instron, model 5566). At 80 kg pigs fed LCa had 15.9% less ($P < 0.01$) BMC, 15.2% less ($P < 0.01$) FmBMC, and 29.9% lower femur bending moment (yBM) than pigs fed HCa. Ca and P efficiency was calculated as g retained (derived from DXA scans) per g consumed. Pigs fed LCa until 80 kg were 23.5% more ($P < 0.03$) efficient in Ca use than pigs fed HCa, but were 29% less ($P < 0.001$) efficient in P use. Over the entire trial no differences ($P > 0.20$) were detected in growth or feed consumption. Pigs fed LLCa had expected reductions ($P < 0.05$) in BMC (13.2%, 1966 v 2265 g), FmBMC (9.0%, 67 v 74 g), and yBM (23.1%, 294 v 382 kg/cm) with improved Ca efficiency (28.7%, 0.71 v 0.55), but a reduction in P efficiency (16.1%, 0.34 v 0.40) compared with pigs fed HHCa. Pigs fed the LHCa or HLCa diets had reduced ($P < 0.05$) Ca efficiency (16.5%, 0.60 v 0.71), but improved ($P < 0.05$) P efficiency (7.1%, 0.36 v 0.34) compared with pigs fed LLCa. No evidence was identified that supported improvement in P efficiency in pigs during recovery from marginal Ca deficiency.

Key words: bone mineral content, P efficiency, bone strength

W208 Ionomic profile changes in the intestine, liver, kidney, serum and gall bladder contents due to Cu source and concentration. B. Aldridge*[1], R. F. Power[2], K. A. Dawson[2], and S. Radcliffe[1], *[1]Purdue University, Department of Animal Science, West Lafayette, IN, [2]Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

Eighty crossbred barrows were weaned at 20 ± 1 d of age and used in 2 blocks (5 reps/block) of a 2 × 3 factorial experiment to investigate the effects of Cu source ($CuSO_4$ and Bioplex Cu (Alltech Inc.)) and concentration (4, 25 or 125 ppm) on ionomic profile concentration changes in the proximal jejunum (PJ), liver, kidney (KD), serum and gall bladder contents (GBC). Pigs were blocked by BW and randomly assigned to diets offered in 2 daily feedings at 9% of metabolic BW ($BW^{0.75}$) per day for a total of 14 d. Samples from the PJ, liver, kidney, serum and GBC were frozen and stored at −20°C until ICP-MS mineral analysis. The PROC MIXED procedure in SAS was used to determine the main effects of Cu source and concentration and their interactions on other mineral concentrations. In addition, PROC GLM linear and quadratic contrasts were determined for increasing supplemental Cu. Pig served as the experimental unit. Increasing Cu concentration did not affect ($P > 0.05$) proximal jejunal [Se], but linearly increased liver [Se] ($P < 0.001$) for both Cu sources. [Se] was decreased ($P < 0.05$) by 30% in GBC when Cu was fed at 125 ppm. Feeding Cu at 125 ppm tended to increase ($P = 0.06$) PJ [Fe], while liver stores were not altered ($P > 0.05$). As dietary Cu increased from 0 to 125 ppm, kidney [Fe] linearly decreased ($P < 0.02$), while at all levels [Fe] was greater when fed Bioplex Cu versus $CuSO_4$. Changes in other mineral GBC include ($P < 0.03$) [Zn] and [Mn] which doubled at the 4 ppm dietary [Cu], when compared with the 25 or 125 ppm level from either Cu source. Zn concentration in the KD increased ($P < 0.001$) when [Cu] was supplemented at 125 ppm, whereas in the liver, Bioplex Cu quadratically altered [Zn] through a reduction of [Zn] at the 25 ppm concentration. This similar trend ($P = 0.1$) was noted in the PJ for both Cu sources.Other altered mineral concentrations include increasing [Co] in the kidney and serum ($P < 0.001$), as dietary Cu increased. These results indicate protagonistic/antagonistic ionomic effects can occur in various organs at select dietary Cu concentrations, which can differ between Cu sources.

Key words: copper, pig, ionomics

W209 Microarray analysis of commonly regulated genes in the jejunum of weanling pigs given dietary Cu proteinate or $CuSO_4$. B. Aldridge*[1], R. Xiao[2], D. Mallonee[2], R. F. Power[2], K. A. Dawson[2], and S. Radcliffe[1], *[1]Purdue University, Department of Animal Sciences, West Lafayette, IN, [2]Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

To illustrate the effect that Cu has on metabolic processes and commonly regulated genes, 2 different types of Cu were used to demonstrate Cu specific cellular pathway changes. Thirty crossbred barrows (n = 10/trt) were weaned at 20 ± 1 d of age and used to determine the effect of a 2 wk supplementation of 0 or 25 ppm Cu from Cu proteinate (Bioplex Cu, Alltech Inc., Nicholasville, KY) or $CuSO_4$ to weanling pig diets on gene expression in the proximal jejunum using microarray analysis. Dietary $CuSO_4$ and Bioplex Cu altered the expression of 545 and 387 genes ($P < 0.05$, FC > 1.2), respectively, compared with control fed pigs. Of these genes, 71 transcripts were commonly altered by $CuSO_4$ and Bioplex Cu, indicating Cu-specific cellular functions.Network pathways of these Cu-specific genes are involved in hematological system development, immune cell trafficking and inflammatory response, and include genes such as modulator of frizzled homolog 4 (FZD4), protein tyrosine phosphatase, protein phosphatase 2 (PPP2R1B), aptoptosis 1 (MOAP1), mitogen-activated protein kinase 3 (MAPK3), chemokine receptor 7 (CXCR7), chemokine ligand 2 (CXCL2) and cytochrome c (CYCS). Additional biological networks altered following Cu supplementation include cellular assembly and organizational pathways, neurological and inflammatory disease, as well as cell death, growth and proliferation. Select genes involved include cyclin A2 (CCNA2), vascular endothelia growth factor C (VEGFC), protein kinase (PKIA), phosphoinositide-3-kinase C3 (PIK3C3), and the Na^+ coupled neutral amino acid transporter 6 (NAT-1). Links to fatty acid metabolic related genes include peroxisomal trans-2-enoyl-CoA reductase (PECR) and the fatty acid transporter SLC27A6. Potential alterations to gut permeability are suggested by altered channel proteins: K^+ large conductance calcium-activated channel (KCNMB1) and gap junction protein (GJA1). These data represents novel commonly regulated pathways between $CuSO_4$ and Bioplex Cu point to Cu specific genes and verify transcriptionally Cu related functions involved in apoptosis, cell signaling and cellular immune responses in swine.

Key words: copper, pig, microarray

Nonruminant Nutrition: Mineral and Sow Nutrition

W210 A lactation curve model in sows. A. V. Hansen*[1,2], A. B. Strathe[1], E. Kebreab[1], and P. K. Theil[2], *[1]Department of Animal Science, University of California, Davis, [2]Department of Animal Health and Bioscience, Faculty of Agricultural Sciences, Aarhus University, Blichers Allé 20, 8830 Tjele, Denmark.*

A quantitative description of the functional form of the sows lactation curve is crucial in understanding energy and nutrient partitioning and for estimation of nutrient requirements. The aim of the investigation was to modify a mathematical function and estimate its parameters from milk yield (MY) measurements. Three Danish studies on sows (Yorkshire x Danish Landrace) were used and MY was measured by D_2O dilution technique. The first study included 4 sows (n = 4) and MY was measured on d 4, 11 and 18 of lactation, in the second (n = 8) MY was measured on d 10, 17 and 24 and in the third (n = 48) MY was measured on d 9, 16 and 23, respectively. The litter size (LS) varied from 5 to 14 piglets while litter weight gain (LG) varied from 0.21 to 4.2 kg/d. A modified Gompertz function ($y(t) = (y_m/t_m) \times t \times \log(t_m \times e/t)$, $0 < t \leq t_m \times e$) was adopted and parameterized to include MY at peak lactation (y_m), the time to peak lactation (t_m) and e is the exponentiation to 1. The function is right skewed, and hence the acceleration in MY to peak lactation is faster than the deceleration in late lactation. The function was implemented in a Bayesian hierarchical model where the parameters describing the between sow variability were modeled as log-normally distributed. Its mean structure included covariates study, LS and LG, which were centered before entering the analysis. Non-informative priors were assigned to the parameters as the likelihood should dominate the posterior. The analysis was conducted in WinBUGS. Parameters y_m and t_m were affected by study, LS and LG ($P < 0.05$) as indicated by the 95% credible intervals. The mean MY at peak lactation was 12.7 (12.1; 13.2) kg/d at d 21 (19; 22) and the associated between sow variability in ym and tm was 15% and 24%, respectively. The following relationships were established between parameters and LS and LG ($y_m = \exp(2.54_{(SE:0.02)} + 0.043_{(SE:0.02)} \times (LS-11) + 0.23_{(SE:0.05)} \times (LG-2.7))$) and (($t_m = \exp(3.02_{(SE:0.04)} + 0.027_{(SE:0.03)} \times (LS-11) + 0.74_{(SE:0.09)} \times (LG-2.7))$), which is applicable in predicting MY in sows with known LS and LG. The data analysis also revealed that although LS and LG affected y_m their effects on the shape of the lactation curve were minor.

Key words: milk production, Gompertz, sows

W211 Impact of ergot infested sorghum on the reproductive performance of sows. G. M. Abdelrahim*[1], R. C. Richardson[2], and A. Gueye[3], *[1]Alabama A&M University, Normal, [2]Texas State University, San Marcos, [3]Mt. Ida College, Newton, MA.*

The objective of this research was to evaluate effects of ergot infested sorghum (EIS) in sows' diets on animal and reproductive performance throughout 2 parities, including number of live born pigs (LBP), weight of live born pigs (WLBP), survival of pigs at d 28(S- 28 d), weight gain of pigs at d 28 (W- 28 d), weight gain at d 56 (W- 56 d), lactation feed intake (LFI), lactation weight change (LWC), and weaning-to-estrus interval (WEI). Total alkaloid concentration in the mature ergot sphacelia/sclerotia was 235 mg/kg (77% as dihydroergosine). In the experiment, 18 later-parity sows (BW = 155 ± 17 kg; n = 18) stratified by BW (n = 6 sows/diet) were fed 3 treatments consisting of a sorghum-based control diet mixed with 1) 0% EIS; 2) 5% EIS and 3) 10% EIS (which equaled 0, 11.75 and 23.50 mg/kg, respectively). There was no effect ($P > 0.05$) on LBP, S- 28 d, W- 56 d, and LWC when we fed up to 10% EIS to sows during the first and second parity; similar results were obtained when LBP, S- 28 d, W- 56 d, and LWC data of the 2 parities were combined. An increase in WLBP was observed ($P < 0.05$) when 5- 10% EIS was included in the second parity's diets, although LFI was significantly ($P < 0.05$) reduced when EIS was included in that parity's diets. Although W-28 d was not affected when 10% EIS was included in the first and second parities' diets and when W-28 d data of the 2 parties were combined ($P > 0.05$), piglets weight gain at 28 d was reduced ($P < 0.05$) when 5% EIS was included in the first parity's diet and when W-28 d data of the 2 parities were combined ($P < 0.05$) Although, treatment diets did not affect ($P > 0.05$) WEI of pigs in the second parity and when WEI of the 2 parties were combined ($P > 0.05$), and no response ($P > 0.05$) was recorded when 5% EIS was fed during the first parity, the inclusion of 10% EIS had significantly decreased the WEI ($P < 0.05$). Overall, variables that were affected by the inclusion of ergot sclerotia in the diets were WLBP, W- 28 d, LFI, and WEI.

Key words: ergot alkaloids, sows reproductive performance, sorghum

W212 Improved retention rates and reduced culling for lameness for sows fed a chelated trace mineral blend. J. Zhao*[1], L. Greiner[2], G. Allee[3], M. Vazquez-Anon[1], C. D. Knight[1], and R. J. Harrell[1], *[1]Novus International Inc, St Charles, MO, [2]Innovative Swine Solutions, Carthage, IL, [3]University of Missouri, Columbia, MO.*

Our objectives of this study were to improve sow retention rates by feeding a chelated trace mineral blend (Mintrex, Novus) from weaning and continuing through the reproductive phases. Two sister sow farms with a common grandparent farm were used. One farm was fed an inorganic control (ITM) and the other was fed a Mintrex blend (Zn, Mn, and Cu), which replaced 50% of the ITM, with target supplementation levels of Zn, 165 ppm, Cu, 16 ppm, and Mn, 38 ppm in the final diet. Replacement gilts were blocked by group on the basis of each monthly supply of weaned gilts. The group of sows was the experimental unit for statistical analyses. Results indicated that gilts fed Mintrex (n = 10,725) had lower removal rates than gilts fed ITM (n = 10,729) from first service to farrowing (8.0% vs. 8.8%, $P = 0.04$). Subsequent retention rates were analyzed for sows that were on treatment from weaning to parity 4 (n = 3994 and 4418 for Mintrex vs. ITM, respectively). Sows fed Mintrex had higher ($P < 0.01$) retention rates than sows fed ITM at both Parity 3 and Parity 4 (72.1% for sows fed Mintrex and 63.5% for those fed ITM, respectively). The involuntary removal rate and relative removal rate due to locomotion were reduced with Mintrex supplementation. In gilts, relative removal rates due to locomotion were 9.0 vs 13.8% ($P < 01$) for Mintrex and ITM, respectively. The involuntary removal rates were reduced ($P < 0.01$) for gilts fed Mintrex (17.3%) compared with gilts fed ITM (27.1%). Similar results were observed in sows in that removal rates due to locomotion were reduced by 55% with Mintrex supplementation (10.4% vs. 16.1%; $P < 0.01$) compared with sows fed ITM. The involuntary removal rates were reduced by 45% with Mintrex supplementation (19.4 vs 28.1%; $P < 0.01$) compared with sows fed ITM. Overall mortality was reduced with 8.6% mortality for sows fed Mintrex and 10.4% for those fed the control. In summary, Mintrex is beneficial for maintaining sow skeletal health and improving welfare assessed by higher survival rates to parity 4 and lower removal rates due to locomotion.

Key words: sow, lameness, chelated trace mineral

W213 A blend of chelated trace minerals improved sow cumulative reproduction and farrowing rate. J. Zhao*[1], L. Greiner[2], G. Allee[3], M. Vazquez-Anon[1], C. D. Knight[1], and R. J. Harrell[1], *[1]Novus International Inc., St Charles, MO, [2]Innovative Swine Solutions, Carthage, IL, [3]University of Missouri, Columbia.*

In many commercial units sow output falls considerably short of the potential to produce weaned piglets per her lifetime, with over 50% of sows culled before reaching their third or fourth parity. Our objectives were to determine if feeding a chelated trace mineral blend (Mintrex®, Novus International Inc.) from weaning and throughout the reproductive phases in commercial farms would improve farrowing rates and cumulative reproductive performance. Two sister PRRS-stable sow farms (6,400 sows each) using PIC C22 and C29 genetics with a common grandparent farm were fed either an inorganic control (ITM) or a Mintrex blend (Zn, Mn, and Cu), which replaced 50% of the ITM, with target supplementation levels of Zn, 165 ppm, Cu, 16 ppm, and Mn, 38 ppm in the final diet. Replacement gilts were blocked by group on the basis of each monthly supply of weaned gilts. The experiment was conducted for 3 years from April 2007 to April 2010. To calculate cumulative reproduction performance up to parity 4, only sows within groups that were old enough to produce at least 4 parities were included in the data analyses. This included a total of 8,412 sows for the analyses. Farrowing rate was improved 2.3 percentage units with Mintrex supplementation (86.8% vs. 84.5% for Mintrex and ITM, respectively, $P < 0.001$). The benefit was observed across parities except in parity 2 with farrowing rates of 86.4% vs. 83.6%, 84.9% vs. 83.9%, 87.7% vs. 85.8%, and 88.9% vs. 85.4% from parity one to parity 4 for Mintrex vs. ITM, respectively. Sows fed Mintrex had more total born (44.1 vs. 40.8, $P = 0.02$) and born alive (41.6 vs. 38.9, $P = 0.04$), and tended to have more weaned pigs (36.4 vs. 34.6, $P = 0.07$) compared with those fed ITM. Presence of mummies was not affected by treatment (0.69 vs. 0.67, $P = 0.47$). Sows fed Mintrex had more stillborns compared with sows fed ITM (1.8 vs. 1.2, $P < 0.01$). In summary, sows fed Mintrex had higher farrowing rates and better cumulative production performance up to parity 4.

Key words: sow, chelated trace mineral, reproduction

W214 Improved progeny performance from sows fed a chelated trace mineral blend. J. Zhao*, M. Vazquez-Anon, C. D. Knight, and R. J. Harrell, *Novus International Inc, St Charles, MO.*

Our previous study indicated sows fed Mintrex produced heavier piglets at birth compared with sows fed inorganic mineral. We hypothesized that piglets with heavier birth weights should perform better from weaning to market weight. Trial design consisted of a 2*3 factorial arrangement with 2 progeny sources from sows fed either inorganic trace minerals (ITM) or Mintrex and 3 dietary mineral programs. The 3 dietary mineral programs included an ITM or Mintrex supplementation at 50% of NRC levels (Zn 50 mg/kg, Mn 2 mg/kg, and Cu 3 mg/kg), and ITM at 2X NRC levels. A total of 2400 weanling pigs (PIC, 20 d of age, 6.07 ± 0.07 kg) were randomly allotted to 6 treatments with 16 replications per treatment and 25 pigs per pen. Data was analyzed by PROC GLM for main effect of progeny, dietary minerals, and 2-way interaction. No interaction of progeny source and dietary mineral treatment was observed on performance or carcass traits ($P > 0.10$). Overall, no differences were observed among pigs fed the 3 different dietary mineral programs ($P > 0.10$). The main finding in this trial was the effect of progeny source. No differences were observed in starting pig weights (20 d of age, $P = 0.27$) between progeny source. However, compared with progeny from sows fed ITM, progeny from Mintrex sows were heavier by d 10 post-weaning (8.09 vs. 7.25 kg, $P < 0.01$) and remained heavier until the end of the study on d 161 (118.5 vs. 116.5 kg, $P = 0.02$). During the nursery period (d 0–42), Mintrex progeny ate more ($P < 0.01$), gained more ($P < 0.01$) and were 2.5 kg heavier at the end of nursery ($P < 0.01$) compared with pigs from sows fed ITM. Overall (d 0–161), progeny from sows fed Mintrex ate more (1.75 vs. 1.72 kg/day, $P < 0.01$), gained more (0.701 vs. 0.686 kg/day, $P < 0.01$) and tended to have greater loin depth (47.3 vs. 45.6 cm^2, $P = 0.09$) compared with progeny from sows fed ITM. No treatment differences were observed on G:F, carcass yield, and meat quality traits ($P > 0.10$). In summary, progeny from sows fed Mintrex performed better and had greater loin depth than piglets from sows fed ITM and demonstrates that sow mineral source affects their progeny performance.

Key words: pig, Mintrex, trace mineral

W215 Comparison of serum progesterone concentrations from new and used CIDR in Holstein heifers. J. T. Whitley* and C. S. Whisnant, *North Carolina State University, Raleigh.*

The aim of the present study was to determine the progesterone release and concentrations of used Eazi-Breed CIDR (CIDR) devices when compared with new/unused CIDR's. Although used CIDR have been utilized in synchronization protocols data comparing progesterone (P4) concentrations are limited. Pubertal Holstein heifers (13–14 mo of age, 375 ± 11.5 kg BW) were used and randomly assigned to receive either a new (n = 7) or used CIDR (n = 7). A used CIDR in this study was one that was previously removed in a cow for a period of 7 d, removed, washed, and stored. Washing was done by first rinsing with water followed by rinsing with Nolvasan and being allowed to air dry. Storage was in a climate controlled room in a closed drawer. CIDR was inserted 24 h after treatment with prostaglandin F2 α to induce luteolysis. Blood samples were taken by tail vein puncture at 4 times: just before the CIDR was inserted, 1 h later, 24 h later and finally when the CIDR was removed at the end of 7 d. Blood samples were placed on ice for transport and centrifuged, with serum stored at −20°C until assayed for P4 concentrations using a commercially available RIA validated in our laboratory for use with bovine serum. Data were analyzed using PROC GLM of SAS 9.2 for type of CIDR (new vs. used), time and the time by type of CIDR interaction. Serum P4 concentrations (ng/mL) were not different between types of CIDR (Table 1). Serum P4 concentrations increased ($P \leq 0.01$) from time of insertion to 1 h later and remained elevated at all other times. Both new and used CIDR provided a rapid and sustained increase in serum P4 concentration in Holstein heifers.

Table 1.

CIDR	Time 0	1h	24h	7d
NEW[a]	0.6 ± 0.2	4.2 ± 0.5	5.3 ± 0.6	5.1 ± 0.5
USED[a]	0.7 ± 0.2	4.6 ± 0.5	4.8 ± 0.4	4.4 ± 0.6

[a]P4 concentrations ng/mL.

W216 Correlation between residual feed intake and metabolic parameters of Nellore heifers. R. H. Branco[1], E. Magnani[1], L. T. Egawa[1], T. L. Sobrinho[2], S. F. M. Bonilha[1], M. E. Z. Mercadante*[1], J. N. S. G. Cyrillo[1], and L. A. Figueiredo[1], *[1]Instituto de Zootecnia, Sertãozinho, São Paulo, Brasil, [2]Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brasil.*

Selection against residual feed intake (RFI) has the potential to improve feed efficiency without affecting growth performance or body size, but measuring this trait in cattle is costly. Identification of RFI physiological indicators may facilitate early detection of more efficient heifers. The objective of this study was to examine correlations among RFI, growth performance and metabolic parameters. Nellore heifers (n = 32) from Instituto de Zootecnia – Sertãozinho, São Paulo, Brazil, with averages of 364 kg for BW and 502 d for age were evaluated. Animals were classificated for RFI: low RFI (≤mean + 0.5 SD; n = 17) and high RFI (≥mean + 0.5 SD; n = 15). Creatine phosphokinase, IGF-I, leptin and cortisol were analyzed. Pearson correlations among variables were calculated by CORR procedure of SAS, and significant correlation between RFI and DMI (Table 1) was found. However, RFI was not correlated with ADG, once the animals classified as more or less efficient show no difference in the gain. Also correlations between RFI and metabolic parameters were not detected. Cortisol was negatively correlated to leptin, suggesting that animals under stress have lower intake, since the increase in serum cortisol levels lead to reductions in leptin, and this related to the regulation of energy metabolism and feeding behavior. In this study, the animals were not subjected to stress. Thus, more research is needed to identify physiological and genetic markers, which can explain the variations in the physiological bases of the RFI.

Table 1. Pearson correlations among metabolic parameters blood and efficiency measures in Nellore heifers

	ADG	RFI	CPK	IGF-I	LEP	CORT

W217 Follicular and ovulatory responses following superovulation treatment with rFSH and HMG in dairy cattle. M. Poorhamdollah*[1], H. Kohram[1,2], and A. Nejati-Javaremi[1], *[1]Department of Animal Science, Faculty College of Agriculture and Natural Resources, University of Tehran, Karaj, Iran, [2]Department of Clinical Sciences, Faculty of Veterinary Medicine, Shahid Chamran University, Ahvaz, Iran.*

The unpredictability in the FSH/LH ratio of gonadotropin preparations is considered to be a factor causing variability of superovulatory responses. The aim of this study was to investigate the superovulatory responses in terms of follicular and ovulatory responses during a superovulatory treatment with rFSH and HMG together. Five Holstein dairy cows were selected randomly from the university herd. The estrous cycles were synchronized by 2 successive injections of PGF2α (vetglan, cloprostenol, Aburaihan, Iran) 11 d apart. Treatments for superovulation were initiated between d 9 to 14 of the estrous cycles with 10 successive injections of 4 shots of rFSH (Gonal-F, Follitropin α, Serono, Switzerland) and 6 shots of HMG (human menopausal gonadotropin, Merional, hFSH-hLH, IBSA, Lugano) at 12-h intervals. A single prostaglandin F2α injected with the 4th injection of HMG. The ovaries of all cows were examined by ultrasonography (B mode; Pimedical, Falco 100, 8 MHz) on d 9 (day of initiation of the superovulatory treatment), 10, 11, 12, 13, 14 (day of estrus following superovulation) for follicular and ovulatory response, and 7 d after estrus for number of CL and number of non-ovulation follicles. All follicles measured at their largest diameter size. The results showed that the mean number of large follicles (≥7mm) at estrus, CL and non-ovulation follicles at 7- days after estrus were 11.2 ± 1.8, 9.4 ± 1.5 and 1.8 ± 0.8, respectively. There was a high positive correlation (84 and 58%) between the number of CL and the mean number of large follicles at estrus and the number of small follicles (≥4mm) at initiation day of

superovulatory treatment (d 9), respectively. In conclusion, there was a high ovulatory response, high positive correlation between number of ovulated follicles at estrus and numbers of CL 7 d after estrus. Also, the homogeneity between follicles following superovulatory treatment when rFSH and HMG are used together for inducing superovulation was high.

Key words: superovulation, Gonal-f, HMG

W218 Adipocyte cell turnover in subcutaneous fat of heifers related to adipocyte cell size. D. Germeroth, S. Häussler*, H. Akter, and H. Sauerwein, *University of Bonn, Germany.*

Adipose tissue mass results not only from adipocyte volume, but also from their number, the latter being determined by cell proliferation and cell loss. In humans, adipocytes probably perish with increased size through apoptosis. In obese subjects apoptosis is presumably overcompensated by emergence of new cells. We hypothesized that the rate of apoptosis and cell proliferation in cattle might depend on adipocyte size. Subcutaneous tailhead fat was collected from 12 non-lactating, non-pregnant Simmental heifers (mean BCS = 5) and from 25 early lactating (d 1 to 105 in milk) Holstein heifers (mean BCS = 3) from different feeding trials. Deparaffinized sections (12 µm) were used for apoptosis detection (TUNEL method); cell proliferation was characterized on cryosections (14 µm) using Ki67-staining. Bovine lymph nodes (apoptosis) and liver (Ki67) were used as positive and negative controls. The portion of apoptotic and proliferating cells was calculated from the mean number of positive stained cells/mean number of total cells x 100. Parametric (Students t-Test) and non-parametric (Mann-Whitney-U-test and Spearman's Rank correlation) tests were used to evaluate the data (SPSS), differences were considered significant at $P \leq 0.05$. The adipocytes from Simmental were larger ($p \leq 0.001$) than from Holstein heifers with mean areas of 8230 ± 240 µm^2 and 5146 ± 491 µm^2, respectively. Adipocyte area and apoptotic portion were negatively correlated ($r = -0.614$; $p \leq 0.001$), represented by a higher apoptotic portion for heifers having small adipocyte size (11.37 ± 2.21%) compared to animals with larger ones (1.03 ± 0.59%). In addition, low cell proliferation rates were observed in both Simmental (0.43 ± 0.44%) and Holstein (0.02 ± 0.01%) heifers. Reduction of adipocyte size as observed in early lactating heifers seems to be accompanied by increased apoptosis in fat cells. This loss of cell number is nowhere near enough compensable by cell proliferation. In conclusion, the rate of apoptosis rather than cell proliferation depends on adipocyte size in cattle.

Key words: apoptosis, cell proliferation, adipocyte size

W219 Effect of short-term supplementation and temporary weaning on follicular liquid composition in first-calved Hereford cows. L. Veloz[1,2], M. E. Trobo[1,2], C. García Pintos[1,2], C. Viñoles[2], and M. Carriquiry*[1], *[1]School of Agronomy, UdelaR, Montevideo, Uruguay, [2]National Research Institute for Agriculture, Tracuarembó, Uruguay.*

To evaluate the effects of short-term supplementation and temporary weaning on follicular fluid composition, first calved Hereford cows (n = 32, 388 ± 7 kg BW and 3.6 ± 0.2 units of BCS, scale 1–8) in anestrus and their calves (120 ± 2 kg BW) were used in a randomized block design with a 2 × 2 factorial arrangement of supplementation (SUP vs. CON), and temporary weaning (with and without), before initiation of the breeding period (103 ± 1 d postpartum). The supplement (2.5 kg/cow of rice bran, 90.3% DM, 10% CP, 9% EE, 14% NDF) was fed daily for 23 d and calves were temporary weaned by applying nose plates for 14 d. Cows were injected with 3 prostaglandin (PG) injections 11 d apart. Thirty-six hours after the last PG injection, cows were castrated and all follicles >5 mm were dissected and follicle fluid was aspirated to determine metabolite and hormone composition. Means from a mixed analyses were considered to differ when $P < 0.05$. Follicle size did not differ among groups and averaged 7.0 ± 0.5 mm. Concentrations of estrogen tended ($P = 0.08$) to increase with suckling restriction (4651.1 vs. 1155.2 ± 1777.3 pmol/L). In contrast, progesterone concentrations tended ($P = 0.10$) to increase with supplementation (102.6 vs. 147.0 ± 18.5 ng/mL). The estrogen/progesterone ratio tended to increase ($P = 0.08$) with suckling restriction (34.1 vs 10.0 ± 14.3). Glucose concentrations were greater in SUP than CON cows (50.8 vs. 57.6 ± 2.5 mg/dL) and suckling restriction tended ($P = 0.08$) to increase glucose in follicular fluid (56.6 vs. 51.7 ± 2.5 mg/dL). Follicular fluid concentrations of NEFA and cholesterol were not affected by nutritional treatment, suckling restriction, or their interaction. Concentrations of estrogen, glucose, and cholesterol as well as the ratio estrogen/progesterone increased with follicle size. In conclusion, nutrition and/or suckling restriction before initiation of the breeding period, in primiparous beef cows in grazing conditions, affected the microenvironment of follicles which could affect reproductive performance

Key words: nutrition, suckling control, ovary

W220 Estrus quantification of early lactation cow cervix physiology: An economical farm innovation. A. Nikkhah*, M. A. Sirjani, and A. A. Assadzadeh, *University of Zanjan, Zanjan, Iran.*

The objective was to quantify cow cervix morphology during estrus phases. Cervix distinctness, central positioning, motility and mucosal secretions were scored daily on a 5-scale basis during proestrus (PE), standing estrus (SE), diestrus (DE) and metestrus (ME) phases in 4 black-white multiparous Holstein cows (50 ± 14 d in milk, 31 ± 3.6 kg milk yield, 643 ± 66 kg BW, 3.0 ± 0.18 BCS) on multiple occasions (n = 8). The design was a split-plot with estrus phases as plots. The cervix was video-recorded using a farm apparatus of 45 cm length and 2.7 cm diameter, with internal electrical settings, external polyvinyl cover, front lights, and terminal wires connected to a laptop computer with an image processing program. The score of 1 represented cervices with fully distinct, central, stable, and mucosal manifestation, and the score of 5 described fully non-separate, non-central, motile, and non-mucosal cervices. Data were analyzed as mixed models with fixed effect of estrus phase (plot) plus random effects of 'cow within phase' and residuals. Regression was used to relate changes of rectal temperature (RT) and cervix morphology. Results demonstrated a significant ($P < 0.01$) differential order, for SE > PE > DE > ME of an increased cervix distinctness (1.00, 1.20, 3.10, 3.62), greater central positioning (1.13, 1.50, 3.73, 4.15), greater stability (decreased motility) (1.00, 1.50, 2.58, 4.33), and greater mucosal secretions (1.00, 1.50, 3.88, 4.13), respectively, on SE vs. non-SE. The RT was not different ($P = 0.51$) among ME, DE, PE and SE, respectively (38.66, 38.33, 38.58, and 38.83°C ± 0.22). Minor links were found between RT and cervix morphology on SE vs. non-SE phases ($P > 0.20$), except for cervix central positioning (y) and RT (x) changes during ME vs. SE ($y = 3.34 - 1.9\ x$)($P = 0.07$). The innovative method proves to be easily applicable to differentiate cervices on different estrus phases in dairy cows. Its cost-effectiveness (<200 $US) encourages further research on monitoring reproductive tract health and physiology.

Key words: estrus, physiology, quantification

W221 Effects of maternal metabolizable protein level in late gestation on circulating amino acid concentrations in the ewe and the fetus. L. A. Lekatz*[1], M. L. Van Emon[2], C. S. Schauer[2], K. R. Maddock Carlin[1], and K. A. Vonnahme[1], *[1]Center for Nutrition and Pregnancy, Department of Animal Sciences, North Dakota State University, Fargo, [2]Hettinger Research Extension Center, North Dakota State University, Hettinger.*

We have previously reported that feeding 60% of MP requirements during the last third of gestation decreases fetal weight, without altering placental weight, compared with controls by d 130. We hypothesize this fetal weight reduction is due to a decrease in circulating amino acids. Our objective was to examine the effects of maternal MP level during late gestation on circulating amino acid concentrations in the ewe and fetus. Multiparous ewes (n = 11) carrying singletons were assigned with receive an isocaloric diet with 60% (60, n = 4), 80% (80, n = 4), or 100% (100, n = 3) of MP requirements from d 100 until d 130. At surgery on d 130, blood was collected from the maternal saphenous artery (maternal artery, MA), uterine vein of the pregnant horn (UVP), umbilical vein (UMBV) and umbilical artery (UMBA) and amino acids were analyzed. In the MA, Gly was lower ($P = 0.04$) in the 100 compared with the 80 and 60 ewes (226 vs. 369 and 408 ± 46.1 nmol/ml). In the UVP, Ser, Gly, and Gln were each lower ($P \leq 0.04$) in the 100 compared with the 80 and 60 ewes (27.3 vs. 38.0 and 40.9 ± 2.91 nmol/ml, 178 vs. 367 and 417 ± 60.8 nmol/ml, and 192 vs. 229 and 246 ± 11.4 nmol/ml for Ser, Gly, and Gln, respectively). In the UMBV, Gly was lower ($P = 0.04$) and Val was greater ($P = 0.04$) in the 100 compared with the 80 and 60 ewes (429 vs. 734 and 648 ± 74.9 nmol/ml and 323 vs. 235 and 175 ± 36.4 nmol/ml for Gly and Val, respectively). In the UMBA, Gly was lower ($P = 0.02$) and Leu was greater ($P = 0.03$) in the 100 compared with the 80 and 60 ewes (388 vs. 641 and 595 ± 56.7 nmol/ml and 219 vs. 132 and 101 ± 28.0 nmol/ml for Gly and Leu, respectively). Also, Val and Ile were greater ($P \leq 0.05$) in the 100 compared with the 60 ewes (302 vs. 156 ± 33.3 nmol/ml and 113 vs. 50.0 ± 16.0 nmol/ml, for Val and Ile, respectively), with the 80 ewes being intermediate (214 ± 33.3 nmol/ml and 69 ± 16.0 nmol/ml for Val and Ile, respectively). Overall, it appears that decreasing maternal MP from 100% to 80 or 60% of requirements alters amino acid concentrations in both maternal and fetal circulations.

Key words: amino acids, metabolizable protein, pregnancy

W222 Functional genomics and role of integrin beta 5 in cattle fertility. L. Koenig[1], X. Wang[1], A. Kaya[2], S. Bridges[1], and E. Memili*[1], *[1]Mississippi State University, Mississippi State, [2]Alta Genetics, Inc., Watertown, WI.*

Fusion of male and female gametes at the fertilization is one of the most important events in mammalian developmental biology. Integrins play multiple roles in fertilization, embryogenesis, and implantation. We recently identified a single nucleotide polymorphism in Integrin Beta 5 (ITGB5) associated with bull fertility. Functional significance of this mutation and roles of ITGB5 in fertilization and early embryogenesis are not known. The objectives of this study were to: 1) identify conserved sequence domains and motifs between bovine ITGB5 protein with mouse, human, dog, and rat ITGB5 proteins, 2) determine expression patterns of itgb5 transcripts in bovine oocytes and early embryos and analyze the results using one way analyses of variance (ANOVA), and 3) determine ITGB5 protein expression in sperm from bulls of varying fertility. Comparative functional genomics, reverse transcriptase real time PCR, and immunoblotting were used to accomplish our objectives. Our results showed that 1) There is an extraordinary degree of conservation (>90% identity of amino acid sequences) of ITGB5 across the mammals indicating that this protein may serve a very important functional role in many species, 2) Transcripts of ITGB5 were highly expressed in bovine oocytes and early embryos; highest expression was at the 2-cell ($P < 0.05$), and 3) ITGB5 protein was detectable in bull spermatozoa. These results provide molecular evidence that ITGB5 is expressed in bovine gametes and embryos and might play important roles at the onset of mammalian development. The findings will help us better understand early mammalian development and identify molecular biomarkers for fertility.

Key words: cattle, fertility, integrin

W223 Male goat vocalizations stimulate LH secretion and estrous behavior in sexually experienced but not in sexually inexperienced goats. J. A. Delgadillo*, J. Vielma, H. Hernández, J. A. Flores, G. Duarte, I. G. Fernández, and G. Fitz-Rodríguez, *Centro de Investigación en Reproducción Caprina, Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, Mexico.*

The objective of the current study was to determine the response of sexually inexperienced and experienced goats to buck vocalizations by measuring their secretion of LH and estrous behavior. Males (n = 3) were rendered sexually active during the non-breeding season by exposure to 2.5 mo of long days (16 h of light by d) from November 1st. From 20 d of age, females were isolated from any auditory, visual and tactile cues from males so that, once in adulthood, they had no sexual experience. By contrast, a group of females had visual, auditory, olfactory and tactile contact with male goats, but copulations were prevented by a fence. On April 4th (d 0; 11:00 h) a stimulus group (n = 5) of anestrous females was exposed to photoperiod treated males in a light proof-building; under these conditions, males produced vocalizations that were reproduced through a microphone-amplifier-loudspeaker system. The anestrous sexually inexperienced and experienced groups (n = 6 each, females had 15 mo of age,) were kept in 2 open pens and exposed during 5 consecutive days to the buck vocalizations coming from the males exposed to stimulus females. LH pulsatility was determined every 15 min from 4 h before to 8 h after introducing the males. Behaviors were recorded twice daily. The LH pulses frequency was analyzed by a 2-way ANOVA with repeated measurements (group and time). The estrous behavior was compared by the Fisher exact test. The number of LH pulses did not differ between sexually inexperienced and experienced goats before exposition to vocalizations of bucks (0.4 + 0.2 in both groups; $P > 0.05$). In contrast, vocalizations induced an increase of pulses of LH in experienced (1.7 + 0.4) but not in inexperienced females (1.0 + 0.3; $P < 0.05$). The frequency of mounting attempts (50) and the acceptance of mounts (36) were greater in experienced than in inexperienced females (1 and 7, respectively; $P < 0.01$). These results indicate that the lack of sexual experience of females is associated with low endocrine and behavioral responses to buck vocalizations.

Key words: caprine, sexual behavior, endocrine activity

W224 Profiling bioenergetics and metabolic stress in cells derived from commercially important fish species. B. Beck* and A. Fuller, *Stuttgart National Aquaculture Research Center, Stuttgart, AR.*

As organisms intimately associated with their environment, fish are sensitive to numerous environmental insults which can negatively affect their cellular physiology. For our purposes, fish subject to intensive farming practices can experience a host of acute and

chronic stressors such as changes in dissolved oxygen, temperature, and water quality; all of which can result in metabolic perturbations on a cellular level. Thus, in the present study, we sought to further our understanding of cellular metabolism in fish and to examine the stress response of cells derived from commercially relevant fish species (catfish, white bass, fathead minnow). We employed a Seahorse Bioscience XF24 Extracellular Flux (EF) Analyzer, an instrument which detects changes in oxygen (O2) levels and pH within the media directly surrounding cells. By measuring the O2 consumption rate (OCR), an indicator of mitochondrial respiration, we determined that all cells tested exhibited a markedly aerobic phenotype (OCR > 100 pMol/min). Simultaneously, we measured the extracellular acidification rate (ECAR), an indicator of glycolysis, and found that in all cell lines tested the ECAR was very low (<5 mpH/min). Next, we performed a mitochondrial function protocol whereby compounds modulating mitochondrial respiration were sequentially exposed to cells (oligomycin→FCCP→rotenone). For each cell type, this assay provided us with basal and maximal OCR, O2 consumption dedicated to ATP production, O2 consumption from ion movement across the mitochondrial inner membrane, the reserve respiratory capacity, and O2 consumption independent of Complex IV of the electron transport chain. From these informative bioenergetic parameters we generated distinct metabolic signatures for each cell type. These findings are the first description of EF technology employed on fish cell lines and provide key proof-of-concept data demonstrating the utility of fish cells as tools for modeling bioenergetics. We hope to extend these findings to develop assays predictive of how fish may cope with cellular insults encountered in production settings.

Key words: extracellular flux, mitochondria, bioenergetics

W225 Conjugated linoleic acid and rosiglitazone attenuate lipopolysaccharide-induced TNF-α production by bovine immune cells. M. C. Perdomo and L. Badinga*, *University of Florida, Gainesville.*

Lipopolysaccharide (LPS) modulates innate immunity through alteration of cytokine production by immune cells. The objective of this study was to examine the effect of exogenous conjugated linoleic acid (CLA) and peroxisome proliferator-activated receptor gamma (PPAR-γ) agonist, rosiglitazone, on LPS-induced tumor necrosis factor α (TNF-α) production by cultured blood from prepubertal Holstein heifers (mean age = 5.5 mo). Compared with unstimulated cells, addition of LPS (10 μg/mL) to the culture medium increased peripheral blood mononuclear cell (PBMC) proliferation up to 2.5-fold. Co-incubation with interferon gamma (IFN-γ, 5 ng/mL) further stimulated ($P < 0.01$) the proliferative response to LPS. Lipopolysaccharide increased ($P < 0.01$) TNF-α concentration in cultured whole blood in a dose- and time -dependent manner. The greatest TNF-α stimulation occurred after 12 h of exposure to 1 μg/mL of LPS. Co-incubation with trans-10, cis-12 (t10,c12) CLA isomer (100 μM) or rosiglitazone (10 μM), a PPAR-γ agonist, decreased LPS-induced TNF-α production by 13 and 29%, respectively. Linoleic acid (LA) and cis-9, trans-11 (c9,t11) CLA isomer had no detectable effects on LPS-induced TNF-α production. The PPAR-γ agonist-induced TNF-α attenuation was reversed when blood was treated with both rosiglitazone and GW9662, a selective PPAR-γ antagonist. Addition of rosiglitazone to the culture medium tended to reduce NF-κBp65 concentration in nuclear extracts isolated from cultured PBMC. Results demonstrate that LPS is a potent inducer of TNF-α production in cultured bovine blood, and that t10,c12 CLA and PPAR-γ agonists attenuate the TNF-α response to LPS in vitro. Additional studies are needed to fully characterize the involvement of NF-κB in LPS-signaling in bovine blood cells.

Key words: CLA, TNF-α, cattle

W226 Influence of nitrogen and sulfur intake on bovine uterine pH. J. K. Grant*[1], P. Steichen[2], C. L. Wright[1], K. A. Vonnahme[2], M. L. Bauer[2], J. S. Jennings[3], and G. A. Perry[1], *[1]Department of Animal and Range Sciences, South Dakota State University, Brookings, [2]Department of Animal Science, North Dakota State University, Fargo, [3]Alltech Animal Nutrition, Brookings, SD.*

Previous research has reported that high protein and sulfur intake decreases uterine pH in cattle. Therefore, the objective of this study was to determine the effect of high N and S intake on uterine pH. Holstein and Angus-cross heifers (n = 20; 337.5 ± 8.4 kg of BW) were randomly assigned to 1 of 4 diets: control (C; 13.4% CP and 0.17% S); high N (N; C plus urea supplement to achieve 18.5% CP); high S (S; C plus calcium sulfate to achieve 0.43% S); or both high N and S (NS). Diets were individually fed at 2.6% of BW using Calan gates and estrus was synchronized to occur on d 12 after the experiment began. Blood samples were collected daily to determine plasma urea nitrogen (PUN), sulfate (d 0, 3, 7, 11, and 15), and progesterone concentrations. Uterine pH was measured on d 15, 19, 23, and 27 (d 3, 7, 11, and 15 of the estrous cycle). There was a treatment, time, and treatment x time interaction ($P < 0.01$) on PUN concentrations. Starting on d 2, PUN concentrations were increased in N and NS, which were not different ($P > 0.05$), compared with C and S ($P < 0.01$), which were not different ($P > 0.05$). There was an effect of treatment ($P < 0.01$) on sulfate concentrations, with concentrations being increased in S compared with C, N, and NS ($P \leq 0.01$), with NS increased compared with C ($P = 0.04$). In addition, sulfate concentrations were increased on d 3 compared with d 7 ($P = 0.04$) and 15 ($P < 0.01$), but there was no treatment x time interaction ($P = 0.81$). There was no effect of treatment ($P = 0.55$) or a treatment x time interaction ($P = 0.16$) on progesterone concentrations, but there was an effect of time ($P < 0.01$), with increasing concentrations after estrus consistent with normal CL formation. Uterine pH was increased in N and NS compared with C ($P < 0.02$), while S was not different from any treatment ($P > 0.11$). There was no effect of time ($P = 0.26$) or treatment x time interaction ($P = 0.71$) on uterine pH. In summary, uterine pH was increased in N and NS compared with C, while S was intermediate, and correlated with increased PUN concentrations.

Key words: nitrogen, sulfur, uterine pH

W227 Influence of sperm fertility-associated antigen status on nulliparous Nelore heifer fertility at first-service timed AI. J. C. Dalton*[1], L. Deragon[2], J. L. M. Vasconcelos[3], A. Ahmadzadeh[4], and R. F.G. Peres[5], *[1]University of Idaho, Caldwell, [2]Alta Genetics Brazil, Uberaba, MG, Brazil, [3]FMVZ-UNESP, Botucatu, SP, Brazil, [4]University of Idaho, Moscow, [5]Agropecuária Fazenda Brazil, Barra do Garças, MT, Brazil.*

The objective was to determine whether the presence of sperm fertility-associated antigen (FAA; a 31 kDA heparin binding protein) can be used to assess potential fertility of sperm for use at first-service timed AI (TAI). Following determination of FAA status by use of a lateral flow cassette, 6 Nelore bulls were selected based on FAA status (FAA-negative: n = 3; FAA-positive: n = 3) and their ability to produce neat semen with characteristics equal to or greater than 70% morphologically normal sperm and 60% estimated progressive motility

before cryopreservation. Ejaculates were collected by artificial vagina and extended semen was cryopreserved in 0.25-mL straws (30×10^6 sperm). Nulliparous Nelore heifers (n = 617) at a single location in Mato Grosso, Brazil, were evaluated for body condition score (BCS; 1–5 scale) and enrolled in a first-service TAI program. On d 0 heifers received an intravaginal insert containing 1.9 g progesterone (CIDR) and an injection of estradiol benzoate (2.0 mg i.m.). On d 7, all heifers received an injection of prostaglandin $F_{2\alpha}$ (12.5 mg i.m.). On d 9 CIDR inserts were removed and all heifers received an injection of estradiol cypionate (0.6 mg i.m.) and an injection of eCG (200 IU i.m.). On d 11, all heifers received TAI 48 h after CIDR removal. Fertility, as measured by pregnancy/TAI (P/TAI), was different ($P = 0.04$) between FAA-positive and FAA-negative bulls (33.7% vs. 40.7%, respectively). There was no effect of AI technician or BCS on P/TAI. In this study using a limited number of bulls (FAA-negative: n = 3; FAA-positive: n = 3) and TAI, it appears that FAA-negative status was not a limiting factor as nulliparous Nelore heifers achieved greater P/TAI with sperm from FAA-negative bulls. These results appear to be contradictory to a previous report of greater fertility following the use of FAA-positive bulls in AI (Sprott et al., J. Anim. Sci. 2000:78:795–798).

Key words: sperm, timed AI, fertility

W228 Feeding rumen-protected polyunsaturated fatty acids (PUFA) to high-producing dairy cows: II. Effects on serum concentrations of progesterone and insulin. M. M. Reis[1], R. F. Cooke[2], B. I. Cappellozza[2], and J. L. M. Vasconcelos*[1], *[1]UNESP – Faculdade de Medicina Veterinária e Zootecnia, Botucatu, SP, Brazil, [2]Oregon State University–Eastern Oregon Agricultural Research Center, Burns.*

The objective was to determine if the productive and reproductive benefits of rumen-protected PUFA supplementation to high-producing dairy cows are due to increased circulating concentrations of progesterone (P4) and insulin. In this study, 765 primiparous and multiparous lactating Holstein cows, with estimated production of at least 9,000 kg of milk/yr, were randomly allocated approximately 30 d postpartum to 1 of 10 free stalls, where they remained throughout the lactation. Each free stall was assigned randomly to receive a diet, balanced to meet the nutritional requirements of lactating dairy cows, without (control) or with (PF) the inclusion of 250 g/cow daily of a rumen-protected PUFA source (Megalac-E; QGN, Rio de Janeiro, Brazil). Control and PF diets were iso-energetic and iso-nitrogenous, and the PUFA source was offered during the first feeding of the day (0600 h). Between 45 and 60 d postpartum, cows were randomly assigned to fixed-time AI (TAI) or embryo transfer (ET). Blood samples were collected 7 d after TAI or on the day of ET for determination of serum P4 and insulin concentrations. Primiparous PF cows had greater ($P < 0.01$) P4 concentrations compared with control cohorts (4.4 vs. 3.2 ng/mL, respectively), whereas no treatment differences were detected in multiparous cows ($P > 0.61$). Similarly, PF primiparous tended ($P = 0.08$) to have greater insulin concentrations compared with control cohorts (10.5 vs. 7.5 μIU/mL, respectively), whereas no treatment differences were detected in multiparous cows ($P > 0.43$). When P4 and insulin were analyzed independently of treatments, primiparous cows with insulin concentrations equal or greater than the median (7.35 μIU/mL) had greater ($P < 0.01$) P4 concentrations compared with primiparous cows with insulin below the median (5.4 vs. 3.3 ng/mL, respectively). The same outcome, however, was not detected among multiparous cows ($P > 0.29$). In summary, rumen-protected PUFA supplementation at 250 g/d increased circulating concentrations of P4 in primiparous lactating cows, which may be attributed to concurrent increases in insulin concentrations.

Key words: PUFA, insulin, progesterone

W229 Feeding rumen-protected polyunsaturated fatty acids (PUFA) to high-producing dairy cows: I. Effects on milk production and reproductive performance. M. M. Reis[1], R. F. Cooke[2], S. Soriano[4], F. L. Aragon[3], M. B. Veras[3], and J. L. M. Vasconcelos*[1], *[1]UNESP – Faculdade de Medicina Veterinária e Zootecnia, Botucatu, SP, Brazil, [2]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [3]Pioneiros Veterinary Clinic, Carambei, PR, Brazil, [4]Colorado Dairies, Araras, SP, Brazil.*

The objective was to determine if rumen-protected PUFA supplementation benefits performance and reproduction of high-producing dairy cows. In this study, 1,083 primiparous and multiparous lactating Holstein cows, with estimated production of at least 9,000 kg of milk/yr, were randomly allocated approximately 30 d postpartum to 1 of 10 free stalls, where they remained throughout the lactation. Each free stall was assigned randomly to receive a diet, balanced to meet the nutritional requirements of lactating dairy cows, without (control) or with (PF) the inclusion of 250 g/cow/d of a rumen-protected PUFA source (Megalac-E; QGN, Rio de Janeiro, Brazil). Control and PF diets were iso-energetic and iso-nitrogenous, and the PUFA source was offered during the first feeding of the day (0600 h). Milk production and composition were evaluated during the initial 43 wk of lactation. Between 45 and 60 d postpartum, cows were randomly assigned to fixed-time AI (TAI), embryo transfer (ET) or conventional AI. Pregnancy was verified by transrectal ultrasonography 60 d after TAI, ET or AI. Results were analyzed using the PROC MIXED and GLIMMIX of SAS. Cows receiving PF had greater ($P < 0.01$) milk production compared with control (38.7 vs. 36.2 kg/cow/d, respectively). However, PF cows had reduced ($P < 0.01$) milk protein and fat content compared with control cows (3.09 vs. 3.11% of protein and 3.42 vs. 3.55% of fat, respectively). Still, PF cows had greater ($P < 0.01$) fat corrected milk production (3.5% milk fat) compared with control cows (37.3 vs. 36.0 kg/cow/d, respectively). Independently of breeding procedure (TAI, AI, or ET), no treatment effects were detected on first service pregnancy rates (18.7 vs. 20.2% of pregnant cows/total cows for PF and control, respectively; $P = 0.78$) or number of services required for pregnancy (2.23 vs. 2.28 services per pregnancy for PF and control cows, respectively; $P = 0.73$), even when milk production served as covariate. In summary, rumen-protected PUFA supplementation to high-producing dairy cows enhanced milk production without impairing reproductive performance.

Key words: PUFA, milk production, reproduction

W230 Puberty induction in Nelore heifers receiving eCG and/or estradiol cypionate at the end of the estrus synchronization protocol. A. Rodrigues[1], R. Peres*[3], A. Lemes[2], T. Martins[1], F. Aono[1], M. Pereira[1], H. Graff[3], E. Carvalho[3], and J. L. M. Vasconcelos[1], *[1]FMVZ-UNESP, Botucatu, SP, Brazil, [2]ESALQ-USP, Piracicaba, SP, Brazil, [3]Agropecuaria Fazenda Brasil, Barra do Garça, MT, Brazil.*

The aim of this study was to evaluate if eCG and/or estradiol cypionate (ECP) administration at the end of an estrus synchronization protocol containing a previously used (4th use) intravaginal progesterone device (CIDR) increases induction of puberty in prepubertal Nelore heifers. Heifers were evaluated for puberty status 7 d before and at CIDR insertion (d 0) via transrectal ovarian ultrasonography and classified as prepubertal if a corpus luteum was not detected. Only prepubertal heifers were utilized in the present study. After CIDR removal (d

12), heifers detected in heat were inseminated according to the Trimberger system for 7 d, whereas 8 d after CIDR removal heifers not detected in estrus were again evaluated for corpus luteum presence. Data were analyzed by logistic regression using PROC LOGISTIC of SAS. In Exp. 1, 896 heifers were used and randomly received 200 IU of eCG (G2) or no treatment (control) at CIDR removal (d 12). Heifers that received G2 had greater ($P < 0.01$) puberty induction and heat detection compared with control (71.9 and 53.3% of puberty induction and 34.3 v. 27.5% heat detection rate, respectively). Conception rates were not affected ($P > 0.10$) by treatments (45.1 vs. 43.5% for G2 and control, respectively). In Exp. 2, 401 heifers randomly received G2, 200 IU of eCG + 0.5 mg ECP (G3), or control at CIDR removal (d 12). Heifers that received G3 had greater ($P = 0.01$) estrus detection and puberty induction compared with G2 and control heifers (56.1, 34.8 and 21.5% estrus detection rate and 88.3, 75.0 and 45.6 puberty induction, respectively). Conception rate were similar ($P > 0.10$) among treatments (46.7, 34.7, and 33.3 for control, G2, and G3, respectively). In Exp 3, heifers randomly receive 0.5 mg of ECP (E1), G2, G3, or control at CIDR removal (d 12). Heifers receiving G3 had greater ($P = 0.02$) puberty induction compared with E1, G2, and control (88.7, 75.3, 82.2, and 57.9%, respectively). In conclusion, the use of ECP, eCG, and particularly eCG + ECP at CIDR removal increased the number of Nelore heifers cycling and detected in heat at the beginning of the breeding season.

Key words: heifers, estradiol and eCG, puberty

W231 Repeated exposure to human chorionic gonadotropin causes development of antibodies in some lactating dairy cows. J. O. Giordano*, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Our objective was to determine if repeated exposure of lactating dairy cows to human chorionic gonadotropin (hCG) would induce an antibody (Ab) response against hCG. Cows (n = 45) enrolled in a synchronization of ovulation experiment either received an hCG injection (hCG; 2000 IU i.m.) or no treatment (CON) at 18 d after a timed AI. A subgroup of cows (n = 27) from the original group received a 2nd hCG injection 35 d after the 1st injection, and another subgroup (n = 18) of cows received a 3rd hCG injection 35 d after the 2nd hCG injection. Blood samples were collected at 0, 7, 14, 21, and 28 d after hCG or CON. A binding radioimmunoassay for hCG Ab was used to detect hCG Ab in serum samples. A positive Ab response (6.34% bound) was defined as 3 standard deviations above CON binding. The proportion of cows presenting an Ab response at 0 and 14 d after hCG was compared through one tailed Fisher's exact test, whereas difference in Ab bound at 0, 7, 14, 21, and 28 d was compared with PROC MIXED of SAS. No cows had hCG Ab at Day 0 before 1st hCG. At 14 d after 1st hCG, no difference ($P = 0.48$) was observed between CON (0/22) and hCG (1/20) cows for percentage Ab positive. At 2nd hCG, no difference ($P = 0.59$) was observed on Day 0 between CON (0/11) and hCG (1/16) cows, whereas a tendency ($P = 0.06$) was observed at 14 d [(CON = 0/5) vs. (hCG = 8/16)]. At the 3rd hCG injection no difference ($P = 0.16$) was observed on Day 0 between CON (0/6) and hCG (4/12) cows, whereas a greater ($P = 0.05$) proportion of hCG cows (6/9) had hCG Ab at 14 d vs. CON cows (0/4). Treatment, time, and treatment by time affected ($P < 0.05$) the average % Ab bound after the 2nd and 3rd hCG injection. Cows that received hCG had greater % Ab Bound at 7, 14, 21, and 28 d after hCG, with the greatest binding observed at 14 d. We conclude that some but not all lactating dairy cows developed an Ab response after repeated exposure to hCG and that maximum response is observed within 14 d of hCG injection.

Key words: hCG, immune response, dairy cow

W232 Synchronization of dairy heifers with a modified 5-day CIDR-$PGF_{2\alpha}$-GnRH timed AI protocol. J. Howard*[1,2], K. Carnahan[1], C. Autran[1], J. Branen[2], R. Kasimanickam[3], G. Sasser[2], and A. Ahmadzadeh[1], *[1]University of Idaho, Moscow, [2]BioTracking LLC, Moscow, ID, [3]Washington State University, Pullman.*

It has been shown that the use of a CIDR insert, in conjunction with a GnRH-$PGF_{2\alpha}$ fixed time AI(TAI) protocol improves pregnancy per AI (P/AI). But due to variability in the results of previous studies it is not clear whether the 1st GnRH administration at the time of CIDR insertion in a 5-d CIDR protocol improves P/AI in heifers. The objective of this experiment was to evaluate the effect GnRH at the time of CIDR insertion, in a 5-d CIDR-Cosynch timed artificial insemination (TAI) protocol on P/AI in dairy heifers. Holstein replacement heifers (n = 234), received a CIDR on d 0. Subsequently heifers were paired by age and assigned randomly to receive either 100 ug of GnRH (GnRH-CIDR; n = 117) or no GnRH treatment (Control; n = 117). On d 5, the CIDR was removed and all heifers received 25 mg $PGF_{2\alpha}$ (d 5). On d 8 (72 h after CIDR) all heifers received GnRH and TAI. Estrus activity was monitored using tail chalk methods from d 5 to d 8. Pregnancy was diagnosed by ultrasound and a Pregnancy specific protein B (PSPB) based ELISA (BioPRYN) on d 32 and 45 after AI. Blood samples were collected in a subgroup of heifers (n = 113) on d 0 to determine progesterone (P4) concentrations. There was no effect of bull or technician on P/AI on d 32 or d 45. Mean P4 concentrations on d 0 were not different between groups and averaged 3.6 ± 0.5 ng/mL. Pregnancy per AI did not differ between treatments (GnRH CIDR 57.2% vs. Control 61.5%) on d 32 or 45. Only 18% of heifers were not detected in estrus and P/AI was less ($P < 0.05$) in heifers that were not detected in estrus (41.8% vs. 63.3%). The results of this experiment indicate GnRH administration at CIDR insertion, in 5-d CIDR-Cosynch may not have beneficial effects on P/AI in Holstein heifers.

Key words: dairy heifer, timed AI, GnRH

W233 Prepartum 2,4-thiazolidinedione administration increases plasma tumor necrosis factor alpha in transition dairy cows. K. M. Schoenberg*[1], K. L. Perfield[2], J. K. Farney[3], B. J. Bradford[3], and T. R. Overton[1], *[1]Cornell University, Ithaca, NY, [2]Elanco Animal Health, Greenfield, IN, [3]Kansas State University, Manhattan.*

Thiazolidinediones (TZD) are potent ligands for peroxisome proliferator–activated receptor–gamma (PPARγ), and TZD administration has been shown to alter lipid metabolism and energy status in transition dairy cows. Tumor necrosis factor α (TNFα) is an inflammatory cytokine which may also play a role in metabolic health during the transition period. The objective of this experiment was to determine the effect of prepartum TZD administration on plasma TNFα and further characterize TNFα throughout the transition period. Holstein cows (n = 31) entering their second or greater lactation were administered 0, 2.0, or 4.0 mg TZD/kg BW by intrajugular infusion once daily from 21 d before expected parturition until parturition. Plasma samples were analyzed for TNFα on d –14, –3, –1, 1, 3, 7, 35, and 49 relative to parturition via a recently developed bovine TNFα enzyme-linked immunosorbent assay (ELISA). Results were analyzed with a mixed model including repeated measures over time and a covariate sample collected at d –22. Data transformation was required to meet assumptions of normality for statistical analysis and values reported are back-transformed. Independent of day, plasma TNFα was increased linearly

by increasing TZD dose (2.63, 3.72, 3.95 pg/mL; $P = 0.01$). The temporal pattern (effect of day; $P < 0.01$) for plasma TNFα was such that it lowest (2.85 pg/mL) during the postpartum period (d + 7 to d + 49), highest (4.18 pg/mL) during the prepartum period (d −14) and intermediate (3.32 pg/mL) during the transition period (d −3 to +3). Contrasts of the effect of period showed that prepartum values were significantly different from both the transition period ($P < 0.01$) and the postpartum period ($P < 0.001$). These results suggest that TNFα may be an important metabolic regulator during the transition period. Somewhat surprisingly, TZD administration increased TNFα concentrations independent of day relative to calving. The effects of TZD on TNFα may be confounded in this case with effects on other regulators such as leptin.

Key words: transition cow, thiazolidinedione, tumor necrosis factor alpha

W234 Effect of dietary β-glucan on growth performance, fecal microbial shedding and immunological responses after lipopolysaccharide challenge in weaned pigs. T. X. Zhou*, B. U. Yang, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

Two experiments were conducted to investigate the effects of β-glucan on growing performance and immune function in weaned pigs after LPS challenge. In Exp. 1, 40 weaned pigs (7.89 ± 0.84 kg of BW and 21 ± 2 d of age) were used in a 28 d feeding trial. All pigs were randomly allotted to 1 of 2 treatments (0 or 0.1 g/kg of β-glucan in the diet) with 4 replicate pens per treatment and 5 pigs per pen. Dietary β-glucan decreased ($P < 0.05$) the number of *E. coli*. In Exp. 2, a total of 20 weaned barrows (6.69 ± 0.24 kg of BW and 21 ± 2 d of age) were used to investigate the immunological response after LPS challenge. Pigs were fed 0 or 0.1 g/kg dietary β-glucan for 42 d. On d 42, pigs (n = 5) in each treatment were injected i.p. with *E. coli*. lipopolysaccharide or sterile saline solution at a concentration of 100 μg/kg of BW. Dietary β-glucan increased leukocytes counts at 2, 4 and 6 h, and lymphocyte concentration at 2, 4 and 6 h, and LPS challenge increased ($P < 0.05$) leukocytes counts at 2, 4, 6, and 8 h and increased ($P < 0.05$) lymphocyte concentration at 2, 4, and 6 h post-challenge and a interaction ($P < 0.05$) was observed. LPS challenge increased the rectal temperature at 2, 4, 6, and 8 h post-challenge. Dietary β-glucan reduced plasma TNF-α concentration while LPS challenge increased ($P < 0.05$) blood TNF-α concentration at 2, 4, and 6 h. Dietary β-glucan increased ($P < 0.05$) the concentration of the cluster of differentiation antigens 4 and 8 (CD4+ and CD8+) cells at 2, 4, 6 h and 4, 6 h post-challenge, respectively, and LPS challenge increased ($P < 0.05$) CD4+ and CD8+ cell concentrations at 2, 4 and 6 h post-challenge; an interaction ($P < 0.05$) between β-glucan and LPS challenge was observed. The CD4+: CD8+ ratio was decreased ($P < 0.05$) by LPS challenge and dietary β-glucan at 2, 4, 6 and 8 h post challenge and a interaction ($P < 0.05$) was observed at 4 and 6 h post challenge. In conclusion, dietary β-glucan can decrease *E. coli* numbers but not affect growth performance in weaned pigs and offer benefits on immune function in weaned pigs challenged with LPS.

Key words: beta-glucan, lipopolysaccharide challenge, pigs

W235 Difference in the expression of components of the GHR/IGF-I axis in follicular granulosa cells and corpus luteum in cows. A. Schneider[1,2], L. F. M. Pfeifer[1], M. N. Corrêa[1], and W. R. Butler*[2], *[1]Universidade Federal de Pelotas, Pelotas, RS, Brazil, [2]Cornell University, Ithaca, NY.*

The aim of this work was to evaluate the difference in the expression of components of the GHR/IGF-I axis in follicular granulosa cells and corpus luteum (CL) in cows. Expression of IGF-I in granulosa cells is controversial, even though it is easily detected in the CL. Ovaries were collected from cows during slaughter. Follicles (7 estrogen-active follicles [EAF] and 7 atretic follicles [ATF]) were dissected from the stroma, FFL was aspirated and the follicle walls immersed in RNALater. To recover granulosa cells, follicular walls were removed from the RNALater, halved, scraped and washed with cold saline. Granulosa cells were recovered by centrifugation at 2000 x g for 3 min. The CL (n = 7) were also dissected. Total RNA was isolated and real-time PCR used to evaluate suppressor of cytokine signaling (SOCS-1, −2 and −3), GHR, IGF-I, IGF-II and ERα mRNA expression according to the ΔΔCt method. Estradiol (E2), progesterone (P4) and IGF-I were evaluated in FFL. In EAF and ATF, FFL E2 concentration was 137 ± 40 and 21 ± 6 ng/mL, with E2/P4 ratio of 2 and 0.4, respectively. IGF-I in FFL was 96 ± 18 and 85 ± 25 ng/mL for EAF and ATF, respectively. Expression of GHR, IGF-I, IGF-II, SOCS-1 and SOCS-2 mRNA was higher in the CL than EAF and ATF. GHR mRNA expression was 8 times higher, while IGF-I mRNA was 25 times higher in CL than in follicles. SOCS-3 and ERα expression was not different between CL and follicles. No difference between EAF and ATF for the genes studied was found. Regarding follicles, SOCS-2 was correlated to GHR ($r = 0.62$, $P < 0.05$), ERα ($r = 0.87$, $P < 0.0001$) and FFL E2 ($r = 0.55$, $P < 0.05$). In the CL, SOCS-2 was correlated to GHR ($r = 0.85$, $P < 0.05$) and ERα ($r = 0.85$, $P < 0.05$). The IGF-I and SOCS-2 to GHR ratio was lower ($P < 0.01$) in follicles than CL, which indicates that there is more IGF-I and SOCS-2 mRNA production per unit of GHR in the CL. In sum, SOCS-2 and IGF-I mRNA expression in EAF was not different from ATF, although SOCS-2 expression was correlated to FFL E2 concentration. Moreover, GHR effectiveness in stimulating IGF-I seems reduced in the follicle when compared with the CL.

Key words: granulosa cells, GHR, IGF-I

W236 Functional genomics of liver in purebred beef cows in two forage allowances during gestation and lactation period. J. Laporta*[1], G. Greif[2], P. Zorrilla[2], H. Naya[2], G. J. M. Rosa[3], and M. Carriquiry[1], *[1]Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay, [2]Instituto Pasteur, Montevideo, Uruguay, [3]University of Wisconsin, Madison.*

In rangeland conditions, pasture quality and availability vary throughout the year affecting energy balance of pregnant and lactating beef cows. A large microarray experiment was conducted using purebred cows (PU; Angus and Hereford) in high (H) and low (L) forage allowances (10 vs. 6 kg DM/100kgLW/d) to study liver gene expression during gestation and lactation periods. Four cows per treatment (PU-H and PU-L) were used. Total RNA was extracted from liver biopsies (−170, −15, +15 and +60 d relative to parturition). Integrity and quality were evaluated using Agilent 2100 Bioanalyzer (RIN 6.4±0.4). A single-channel microarray analysis was performed using Agilent 4x44K Bovine Gene Expression array. Data was normalized, filtered, and a 2-way ANOVA, to evaluate the effect of time and forage allowances, was performed using GeneSpring (v11.5) Software. Significance levels were adjusted for multiple testing using a false discovery rate of 0.2. Out of 806 differentially expressed genes (DEG), 795 changed only across time (140 ±2.5 fold change), and 12 with forage allowance. There were no significant interactions between time and forage allowance. The DEG were clustered to study expression profiles and a Gene Set Enrichment Analysis was performed. More than 15 significant ($P \leq 0.01$) gene sets across time (only for −170 vs. −15 d) with posi-

tive (IGFI-MTOR pathway, spliciosome, and MAPK pathway) and negative (PPAR signaling pathway, triacylglyceride biosynthesis, and pyruvate metabolism, etc.) enrichment scores (ES) were identified. Only PPAR signaling pathway was enriched in −15 vs. +15 d. Steroid metabolism, cholesterol biosynthesis, glucogen and glycogenolysis, among others, were positively enriched for +15 vs. +60 d. Only four genes sets were significantly ($P \leq 0.01$) and negatively enriched when high vs. low forage were compared: amine hormones, glucose SLC sugar transporters, neuotransmitter release and MAPK signaling pathway. These results contribute to understand liver function in regulating alterations in metabolism in response to the level of nutrition and physiological stage in beef cattle along the year on grazing conditions.

Key words: microarrays, liver, grazing

W237 Conjugated linoleic acids (CLA) and lactation related changes of serum amyloid A3 (SAA3) and IL-6 mRNA abundance in different bovine tissues with a focus on different adipose depots. B. Saremi*[1], M. Mielenz[1], D. von Soosten[2], S. Dänicke[2], and H. Sauerwein[1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Federal Research Institute for Animal Health, Braunschweig, Lower Saxony, Germany.*

The adipokine SAA3 is linked to obesity and insulin sensitivity of adipose tissue (AT) and respective inflammatory response, at least in mice. SAA3 is not related to the plasma concentrations of SAA. In contrast, SAA3 could be found in medium of cultured adipocytes. SAA3 is known to be upregulated by IL-6 in mice. In dairy cows, CLA interfere with energy homeostasis and fat metabolism by milk fat reduction. We hypothesized that the mRNA abundance (Ab) of SAA3 and IL-6 could be affected by CLA or days postpartum. From 25 Holstein heifers, 5 animals were slaughtered on d 1 postpartum. Remaining heifers were randomly allocated to CLA (Lutrell pure, BASF, Germany, n = 10) or control fat supplementation (Silafat, BASF, n = 10) each at 100 g/d. Five animals per group were slaughtered at d 42 or 105. Liver, skeletal muscle, udder, pancreas and fat samples [subcutaneous (Sc) (chest, wither and tail head) and visceral (Vc) (mesenterial, omental and retroperitoneal)] were collected. Total RNA was analyzed by qPCR. Pearson correlation and statistical analysis using the general linear model or non parametric tests were done in SPSS 17 ($P < 0.05$). Decreasing Ab of SAA3 from d 1 to d 42 and 105 was observed in all tissues except mesenterial AT in which SAA3 was constantly expressed. In ScATs and muscle tissue, CLA reduced SAA3 Ab in comparison to control group regardless of time. In general, 2 to 26 fold differences in the SAA3 Ab in different ATs compared with omental AT (highest SAA3 Ab) were observed. IL-6 Ab was reduced from d 1 to d 42 and 105 in ScATs and vice versa in liver. IL-6 Ab was neither affected by CLA nor correlated to SAA3 Ab. In conclusion, a regulatory effect of IL-6 on SAA3 in mice was not supported for dairy cattle. Reduced SAA3 Ab in ScATs and muscle regarding to CLA, might be a hint of local anti-inflammatory effects of CLA and improved insulin sensitivity in these tissues.

Key words: SAA3, IL-6, adipose tissue

W238 Role of nuclear receptors in the metabolism of boar taint compounds in Leydig cells. M. A. Gray* and E. J. Squires, *University of Guelph, Guelph, Ontario, Canada.*

Boar taint is an unpleasant odor and taste caused by accumulation of androstenone and 3-methylindole (3MI, skatole) in fat of male pigs. The objective of this work was to determine the effects of the nuclear receptors constitutive androstane receptor (CAR), pregnane X receptor (PXR), and farnesoid X receptor (FXR) on the production of total 16-androstene steroids (16A) and androgens (AND) from pregnenolone (PREG) in Leydig cells. Treatment of Leydig cells with CAR or PXR agonists resulted in 25.0 ± 2.7% and 26.0 ± 2.8% conversion of PREG to 16A, respectively, which was significantly ($P < 0.05$) higher than the 16.0 ± 2.2% conversion found with the DMSO control. Treatment with a FXR agonist did not significantly affect conversion of PREG to 16A. Conversely, treatment with agonists for CAR, PXR and FXR significantly ($P < 0.05$) decreased the percentage of PREG converted to AND to 40.8 ± 2.6%, 40.2 ± 1.9%, and 46.2 ± 3.9%, respectively, compared with the DMSO control (58.8 ± 4.7%). Treatment of Leydig cells with 3MI did not significantly alter 16A or AND production. Activation of CAR, PXR, or FXR all resulted in significant upregulation of several genes involved in the conversion of PREG to 16A or AND, as measured using real-time PCR. Although transcription of CYP17A1, the enzyme that converts PREG to both AND and 16A, was not significantly altered, expression of CYB5A and CYB5R1 increased with activation of each receptor. These genes are accessories to CYP17A1 and increase CYP17A1 andien-β synthase activity instead of 17α-hydroxylase and C17,20 lyase activities, thus favoring 16A production over AND production. Treatment with 3MI resulted in decreased expression of key target genes for each receptor, indicating that skatole acts as an inverse agonist for these receptors. Taken together, the functional and transcriptional effects of transactivation of CAR, PXR, and FXR suggests that activation of these receptors favors the production of 16A, and thereby will result in an increase in boar taint.

Key words: boar taint, nuclear receptor, steroidogenesis

W239 Effects of heat stress on Na^+/K^+ATPase activity in growing pigs. S. C. Pearce*, A. J. Harris, N. K. Gabler, and L. H. Baumgard, *Iowa State University, Ames.*

Na^+/K^+ATPase pumps are involved with cellular transport processes, osmotic balance and account for a substantial portion of whole body energy expenditure. However, how heat stress (HS) affects Na^+/K^+ATPase activity in various tissues has not been studied in a porcine model. Crossbred gilts (n = 48; 35 ± 4 kg BW) were housed in constant climate controlled rooms in individual pens and exposed to 1) thermal neutral (TN) conditions (20°C; 35–50% humidity) with ad libitum intake (n = 18), 2) HS conditions (35°C; 20–35% humidity) with ad libitum intake (n = 24) or 3) pair-fed (PF in TN conditions [PFTN], n = 6: to eliminate confounding effects of dissimilar feed intake [FI]). Pigs were sacrificed at 1, 3, or 7d of environmental exposure and jejunum, longissimus dorsi (LD), and liver samples were collected and analyzed for Na^+/K^+ATPase activity. HS pigs had an increase ($P < 0.01$) in body temperature (39.3 vs. 40.8°C), a doubling in respiration (54 vs.107 bpm) and an immediate decrease in FI (47%; $P < 0.05$) which continued through d7; by design PFTN controls FI mirrored the HS group. Over the 7d period, TN pigs had increased ADG compared with the HS pigs (1.14 vs 0.24 kg/d) while HS pigs lost 2.7 kg BW. Overall, compared with the TN pigs, HS pigs had increased LD Na^+/K^+ ATPase activity (52%; $P = 0.06$). There was an environment by day interaction in jejunum Na^+/K^+ATPase activity as it was markedly increased (175%; $P < 0.05$) on d1, but returned to TN levels by d3. Liver Na^+/K^+ATPase activity was not different between the TN and HS pigs. However, PFTN pigs had decreased pump activity compared

with the HS and TN pigs (30%; $P = 0.06$). Irrespective of environment, TN pigs tended to have tissue differences in Na^+/K^+ATPase activity ($P = 0.08$) as liver activity was lower (27%) compared with jejunum; LD was not different from either tissue. These data indicate HS induces tissue specific increases in Na^+/K^+pump activity and suggests that ion pump energy expenditure (and presumably total body energetic cost) increases during a thermal load and is more pronounced during acute HS.

Key words: heat stress, energetics, Na^+/K^+ pump

W240 Serum shock did not synchronize clock gene expression in primary bovine hepatocyte cultures. C. A. Kurman*, M. M. McCarthy, L. M. Nemec, and T. F. Gressley, *University of Delaware, Newark.*

Circadian rhythms are regulated by clock gene expression. In the liver, clock genes are controlled by hormonal and neural signals to result in 24 h patterns of metabolism and nutrient availability. Studying circadian rhythms in vitro requires artificial synchronization of clock gene expression, accomplished by serum shock in monogastric hepatocyte culture systems. Our objective was to determine whether serum shock of primary bovine hepatocyte cultures would synchronize clock gene expression patterns. Monolayer cultures were established from hepatocytes isolated from a 1 wk old Holstein bull calf. At 0 h, cells were serum shocked for 2 h with 50% fetal bovine serum (FBS) followed by 0% FBS for 46 h (treatment = SS) or treated with media containing 10% FBS for 48 h (NSS). Cells were harvested every 4 h and mRNA was isolated. The mRNA levels of 7 clock genes were quantified relative to control genes (RPS9 and β -actin) using qPCR. The experiment was conducted on 2 occasions (Exp. 1 and Exp. 2). Results were statistically evaluated using a model containing fixed effects of treatment, hour, and their interaction. We expected to observe: 1) characteristic 24 h clock gene expression patterns, and 2) more distinctive patterns for SS compared with NSS. Contrary to this hypothesis, anticipated treatment time interactions were observed only for *Per2* in Exp. 2 (Table 1). Although treatment and hour affected various clock genes in each experiment (Table 1), effects of time and treatment were not consistent with published monogastric studies. The serum shock protocol used in these experiments was unsuccessful at synchronizing bovine hepatocyte clock gene expression.

Table 1.

		Treatment			*P*-value		
	Gene	NSS	SS	SEM	Treat.	Hour	Treat × Hour
Exp. 1	Clock	2.04	1.38	0.22	0.04	0.15	0.63

W241 Effect of short-term supplementation in hepatic gene expression in cycling Hereford cows grazing native pastures. F. Bialade[1], A. L. Astessiano*[1], M. P. Grignola[1], J. Laporta[1], C. Viñoles[2], and M. Carriquiry[1], *[1]School of Agronomy, UDELAR, Montevideo, Uruguay, [2]Research Institute for Agriculture, Tacuarembo, Uruguay.*

Short-term supplementation before the breeding season has been associated with an increase in early pregnancy rate, however, the metabolic changes involved in this response are not clear. To evaluate the impact of a short-term energy supplementation before the breeding season on changes on the hepatic gene expression associated with the GH-IGF axis, adult non-gestating nonlactating Hereford cows (n = 9) were used in a randomized block design. Cows (478 ± 11 kg BW, 5.3 ± 0.1 units BCS, scale 1–8) were allocated to 2 groups: control, non-supplemented (CON, n = 5) and supplemented (SUP, n = 4). The supplement consisted in 2.5 kg of rice barn/cow (90.3%DM, 10%CP, 9%EE, 14% NDF) offered daily for 23 d. All cows grazed on native pastures (forage availability of 603 kg DM/ha). Liver biopsies were obtained at the beginning (d 0) and end (d 23) of the supplementation treatment. The abundance of mRNA of growth hormone receptor (GHR), insulin-like growth factor-I (IGF-I), IGF binding proteins-2 (IGFBP2),-3 (IGFBP3), and insulin receptor (INSR) were measured by real time RT-PCR normalized by hypoxanthine phosphoribosyltransferase (HPRT) and β-actin as endogenous controls. Means from a mixed model analysis were considered to differ when $P < 0.05$. Cow BCS did not differ between groups and increased, for all cows, 0.6 ± 0.1 units of BCS during the supplementation period. The expression of all 5 genes: GHR (0.66 vs. 0.57 ± 0.10), IGF-I (0.54 vs. 0.89 ± 0.47), IGFBP2 (4.41 vs. 4.41 ± 1.23), IGFBP3 (1.04 vs. 0.80 ± 0.12), INSR (19.10 vs. 31.06 ± 5.30) mRNAs did not differ ($P > 0.15$) between CON and SUP cows. Expression of GHR and IGFBP3 mRNA (r = 0.62, $P = 0.005$), GHR and INSR mRNA (r = 0.45, $P = 0.056$) and INSR and IGFBP3 mRNA (r = 0.57, $P = 0.011$) were positively correlated. We conclude that short-term energy supplementation before the breeding period has no effect on hepatic gene expression associated with the GH-IGF axis in grazing cyclic beef cows in good BCS.

Key words: mRNA, cattle, nutrition

W242 Effect of charcoal extracted bovine follicular and testicular fluids on testes and endocrine organ weights of pre-pubertal male rabbits. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

The effect of charcoal-extracted bovine follicular and testicular fluids on testes and endocrine organ weights of pre-pubertal male rabbits was investigated. A total of 15 young male rabbits of various strains with age range of 11–12 weeks old and weighing 1.0 ± 0.2kg were randomly divided into 3 groups, each consisting of 5 rabbits. The treated groups and the control group were injected intramuscularly with charcoal-extracted bovine follicular fluid, charcoal extracted bovine testicular fluid and charcoal treated distilled water respectively, at the rate of 0.2mL per rabbit on every other day and on 3 different occasions. After administration of the different treatments, testes weight and endocrine organ weights were conducted or carried out. Endocrine organ weights included: thyroid gland, adrenal gland, pituitary gland and kidney. There were no significant differences ($P > 0.05$) in paired testes weights among the 3 different groups. There were no significant differences ($P > 0.05$) in paired thyroid gland, paired adrenal gland between control and treated groups. Contrarily there was a significant increase ($P < 0.05$) in paired kidney weights between testicular fluid treated groups and control and follicular fluid treated groups. There

was a significant decrease ($P < 0.05$) in pituitary gland weight between control and treated groups. Administration of charcoal extracted bovine follicular and testicular fluids to pre-pubertal male rabbits decreased the weights of pituitary gland, which implies that the administration of inhibin to immature rabbits affects the hypo-thalamo-pituitary function as well as block FSH dependent steps in spermatogenesis.

Key words: charcoal extracted, testes, male rabbits

W243 *Caspase* 3 is upregulated in murine spermatogonia and Leydig cells treated with aflatoxin B_1. K. J. Austin*, R. R. Cockrum, K. L. Speiser, and K. M. Cammack, *University of Wyoming, Laramie.*

Aflatoxin B_1 is hepatotoxic and carcinogenic in a variety of livestock species including cattle, sheep and swine. In addition to poor performance and health, AFB_1 in food sources can lead to infertility in livestock, rodents and humans. The objective of these experiments was to examine the molecular mechanisms associated with reduced fertility using male mice as the model. Specifically, apoptosis and *Caspase* 3, a primary activator of protein cleavage and DNA fragmentation, were investigated. Male ICR mice 4 wk of age were treated with 50 μg/mL BW AFB_1 (n = 9) or placebo consisting of corn oil/ethanol (n = 9) daily for 45 d via IP injection. Following treatment, males were mated to 4 females each for 8 d to determine number of pups sired. Males were then sacrificed for testes collection. Spermatogonia and Leydig cell lines were cultured in vitro and treated with 0, 5, 10 or 20 μg/ mL AFB_1 (n = 3 wells/treatment) for 20 h . Effects of treatment were estimated using the GLM procedure of SAS. Message for *Caspase* 3, as analyzed by semi- quantitative real- time RT-PCR, did not differ ($P = 0.20$) in testes of treated males compared with control males. However, spermatogonia treated with 10 μg/mL AFB_1 showed an upregulation ($P = 0.004$) of *Caspase* 3 when compared with control (0 μg/mL AFB_1) treated cells. Tunel staining of spermatogonia also showed an increase ($P = 0.03$) in the number of positively stained cells in the treated cultures (5 and 10 μg/mL AFB_1) compared with control cultures. Leydig cells treated similarly showed greater ($P = 0.02$) message for *Caspase* 3 at the 10 and 20 μg/mL levels than controls. This is the first report to our knowledge linking aflatoxicosis to apoptosis in reproductive tissues. Results imply that apoptosis may be in part responsible for damage to the testes/testicular cells, resulting in decreased testosterone levels and reduced fertility. More research is needed to determine other components of the apoptotic pathway affected by AFB_1, and whether the upregulation in *Caspase* 3 observed in this study occurred as a direct result of insult with AFB_1.

Key words: apoptosis, *Caspase* 3, aflatoxin

W244 Muscle resident adipogenic progenitors are fiber type specific, Pax3/Myf5-independent and form white adipocytes by default. Y. Q. Liu* and S. H. Kuang, *Purdue University, West Lafayette, IN.*

Ectopic accumulation of adipose tissue in skeletal muscles (intermuscular fat, IMF) has been associated with muscle wasting, insulin resistance and diabetes. However, the developmental origin and regulation of postnatal progenitors that give rise to IMF in comparison to other fat depots are unclear. We found that adipogenic progenitors are more enriched in slow than fast muscles. Cre/LoxP-mediated lineage tracing demonstrated that IMF progenitors are exclusively derived from a Pax3/Myf5-independent lineage and readily differentiate into white adipocytes in culture. In contrast, brown adipose tissue progenitors are derived from a Pax3/Myf5 double positive lineage. Interestingly, progenitors residing in anatomically distinct white adipose depots are all from a Myf5-independent lineage but are heterogeneous for Pax3 lineage dependence. Diphtheria toxin-mediated lineage ablation confirmed that Myf5 cell lineage is required for brown, but not white, adipocyte differentiation. In addition, ablation of Myf5-dependent myogenic lineage enhances adipocyte differentiation, whereas ablation of aP2- dependent adipocyte lineage impairs muscle regeneration in vivo. In old mice, reduced myogenic capacity is accompanied by accumulation of IMF. Finally, we showed that Dlk1 inhibits the differentiation of both white and brown adipocytes. These results demonstrate surprising heterogeneity of tissue-specific adipogenic progenitors and dynamic interactions between skeletal muscle and adipose tissues.

Key words: intermuscular fat, Myf5, Pax3

W245 Effect of urea on interferon-tau response in the bovine endometrium. A. Ahmadzadeh*, T. Davis, and K. Carnahan, *University of Idaho, Moscow.*

High concentrations of blood and uterine urea associated with high dietary protein have been shown to reduce fertility in dairy cows. The objective of this study was to determine the direct effects of urea on protein expression of the endometrial cells of the bovine uteri in response to interferon-tau (IFN-tau) in vitro. The objective was to determine the direct effect of urea on the production of 2 IFN- tau stimulated proteins, ISG15 and Mx1 in bovine endometrial (BEND) cells. Bovine endometrial cells were cultured to 80% confluency and treated with media containing 0, 5, 7.5, or 10 mM urea for 24 h. Subsequently, BEND cells were challenged with 0 or 10,000 antiviral units of recombinant IFN-tau and cells were incubated for an additional 24 or 36 h in media containing 0, 5, 7.5, or 10 mM urea. Cells were in culture for the same period of time regardless of treatment and then harvested. BEND cells were lysed with MPER and the protein concentrations determined by the Bradford assay. Proteins were separated by SDS-page and subjected to Western blot analysis and immunoblotting to assess the production of Mx1 and ISG15. Based on optical density of the images on x-ray film from a chemiluminescent signal, IFN-tau increased ($P < 0.01$) Mx1 and ISG15 production regardless of treatment after 24 and 36 h. There was no effect of urea treatment or urea by IFN-tau interaction on Mx1 and ISG15 production after 24 ($P = 0.9$) or 36 h ($P = 0.4$) of culture. Moreover, there was no effect of either 24 or 36 h or time by urea treatment interaction on the production of Mx1 and ISG15, in response to IFN-tau. These results show that there is no disruption of IFN- tau-stimulated Mx1 or ISG15 production, when BEND cells were exposed to various concentrations of urea in vitro.

Key words: urea, interferon-tau, bovine endometrial cells

W246 Short-term supplementation and temporary weaning on metabolic and endocrine parameters in anestrous and cyclic Hereford cows grazing native pasture. A. L. Astessiano*[1], L. Veloz[1,2], C. García Pintos[1,2], M. E. Trobo[1,2], F. Bialade[1], C. Viñoles[2], and M. Carriquiry[1], *[1]School of Agronomy, UDELAR, Montevideo, Uruguay, [2]National Research Institute for Agriculture, Tacuarembo, Uruguay.*

Two experiments were conducted to study the effect of a short-term supplementation (Exp.1 and 2) and temporary weaning (Exp.1), before initiation of the breeding period, on metabolic and endocrine parameters in grazing beef cows. In Exp.1 primiparous beef cows (n = 32, 3.6 ± 0.02 BCS) in anestrus were used in a randomized block design with a 2 × 2 factorial arrangement of short-term supplementation (non-

supplemented, CON vs. supplemented, SUP) and temporary weaning (with vs. without). In Exp.2, adult non-gestating nonlactating beef cows (n = 15, 5.3 ± 0.1 BCS) were used in a randomized block design with 2 treatments: CON vs. SUP. The supplement consisted in 2.5 kg of rice bran/cow (90.3% DM, 10% CP, 9% EE, 14% NDF) offered daily for 23 d (Exp.1 and 2) and temporary weaning was performed by applying nose plates to calves for 14 d (Exp.1). Blood samples were collected 3 times a week during the treatments. Means from mixed analyses differed when $P < 0.05$. In Exp.1, cow BCS was not affected by treatments. Insulin concentrations were greater ($P < 0.01$) in temporary weaned than suckled cows (2.31 vs. 1.29 ± 0.21 uU/mL), but plasma glucose and cholesterol did not differ among groups. Concentrations of NEFA were greater ($P = 0.04$) in SUP-suckled than in SUP-temporary weaned and CON cows (0.48 vs. 0.33 ± 0.05 mmol/L). In Exp.2, BCS did not differ between groups and increased 0.6 ± 0.1 units during the period evaluated. Insulin (2.89 vs. 3.80 ± 0.55 uU/mL) and glucose (1.1 vs. 1.2 ± 0.05 mmol/L) concentrations were lower ($P = 0.04$) in SUP than CON cows but this effect was most evident in wk 2 and 3. Plasma NEFA did not differ between treatments but cholesterol was greater ($P = 0.01$) in SUP than CON cows (281.9 vs. 234.6 ± 11.3 mg/dL). Metabolic/endocrine changes reflected a better energy balance in short-term supplemented and temporary weaned primiparous cows in anestrus whereas short-term supplementation in cycling cows with good BCS altered glucose/insulin metabolism.

Key words: cattle, nutrition, hormones

W247 Liver gene expression of GH-IGF1 axis and fatty acid metabolism genes of beef cows on grazing conditions. I: Winter-gestational period. J. Laporta*, A. L. Astessiano, V. Gutierrez, A. C. Espasandín, P. Soca, and M. Carriquiry, *Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay.*

In spring-calving cows on rangeland conditions pregnancy occurs in winter, period of limited forage availability, affecting the energy balance of beef cows. Adult pregnant cows (n = 32) in a factorial arrangement of genetic group (Angus and Hereford, vs. their crosses; PU vs. CR) and forage allowances (6 vs. 10kgDM/100kgLW/d; LO vs. HI) were used to evaluate the hepatic expression of somatotropic axis genes (*insulin like growth factor I*, IGF1; *IFG1 binding protein 3 and 2*, BP3, BP2; *growth hormone receptor*, GHR; *GHR isoform-1A*, GHR1A), fatty acid oxidation genes (*acyl-CoA oxidase-1 palmitoyl*, ACOX1; *acyl-CoA dehydrogenase very long chain*, ACADVL), *peroxisome proliferator activated receptor-α* (PPARA) and, *fibroblast growth factor-21* (FGF 21).Means from a mixed model were considered to differ when $P \leq 0.05$. Liver biopsies were collected in May, August, September and, October (110 ± 10, 210, 240 and 270 ± 3 d of gestation, dgest). Expression of GHR, PPAR, and FGF21 mRNA were not affected ($P > 0.18$) by any of the factors. Abundance of GHR1A and IGF1 mRNA decreased from 110 to 270 dgest (20 to 9 ± 3; 1.6 to 0.9 ± 0.02, respectively; $P < 0.013$), and BP3 tended ($P = 0.10$) to decrease only at 210 dgest to return thereafter to initial values. The BP2 mRNA increased ($P = 0.002$) at 240 dgest and remained elevated until 270 dgest. Abundance of ACOX mRNA increased throughout gestation in winter, and ACADVL mRNA increased at 240 dgest, returning to initial values at 270 dgest ($P < 0.01$). Expression of BP3, BP2 and ACOX1 mRNA during winter-gestation also depended on cow genetic group ($P < 0.045$). The BP3 mRNA decreased at 210 and 240 dgest in PU, whereas it increased at 240 dgest in CR cows. The BP2 mRNA was greater in PU than CR cows at 110 dgest, and BP2 mRNA increased in both groups (PU at 270 and CR at 240 dgest). The ACOX1 mRNA increased earlier in gestation in PU (210 dgest) than CR cows (240 dgest). Dynamics of the GH-IGF1 axis genes and the increased expression of \β;–oxidation genes in the liver reflect changes required to meet energy demands of pregnancy during winter in beef cows on grazing conditions

Key words: somatotrophic axis, energy balance, cattle

W248 Liver gene expression of GH-IGF1 axis and fatty acid metabolism genes in beef cows on grazing conditions. II: Peripartum and lactation period. J. Laporta*, A. L. Astessiano, V. Gutierrez, A. C. Espasandín, P. Soca, and M. Carriquiry, *Facultad de Agronomía, Universidad de la República, Montevideo, Uruguay.*

Beef cows in rangeland conditions are subjected to climate variations that affect pasture growth and variability as cow physiological stage changes from pregnancy to calving and lactation, altering their energy balance. Adult pregnant cows (n = 32) in a factorial arrangement of genetic group (Angus and Hereford, vs. their crosses; PU vs. CR) and forage allowances (6 vs. 10kgDM/100kgLW/d; LO vs. HI) were used to evaluate the hepatic expression of somatotropic axis genes (*insulin like growth factor I*, IGF1; *IFG1 binding protein 3 and 2*, BP3, BP2; *growth hormone receptor*, GHR; *GHR isoform-1A*, GHR1A), fatty acid oxidation genes (*acyl-CoA oxidase-1 palmitoyl*, ACOX1; *acyl-CoA dehydrogenase very long chain*, ACADVL), *peroxisome proliferator activated receptor-α* (PPARA) and, *fibroblast growth factor-21* (FGF 21).Means from a mixed model analysis were considered to differ when $P < 0.05$. Liver biopsies were collected at −15 ± 3, 15 ± 3 and 60 ± 3 d relative to parturition, dpp). Expression of IGF1, GHR and, GHR1A were not affected ($P > 0.45$) by any of the factors evaluated. The BP3 and BP2 mRNA abundance decreased ($P < 0.015$) from −15 to 15 dpp, to return then to initial values at 60 dpp. The BP3 mRNA was also affected by the interaction between genetic group and time ($P = 0.04$), while it was not affected in CR cows, it decreased markedly at 15 dpp in PU cows. The expression of BP2 mRNA tended to be greater ($P = 0.09$) in LO than HI cows. The mRNA abundance of 2 key genes involved in fatty acid oxidation varied across time; ACADVL mRNA tended to increase ($P = 0.10$) at 60 dpp, whereas ACOX1 mRNA decreased ($P = 0.004$) from −15 to 15 dpp to return to elevated initial values at 60 dpp. Hepatic PPARA and FGF21 mRNA were not affected ($P > 0.60$) by any of the factors evaluated. We describe the dynamic of the GH-IGF axis during the peripartum and lactation period in beef cows on grazing conditions. Only IGFBPs mRNA abundance was altered. The increase of ACADVL mRNA and the elevated levels of ACOX mRNA can reflect the need to oxidize fatty acids during postpartum period to meet energy demands of lactation.

Key words: somatotropic axis, fatty acid oxidation, cattle

W249 Uterine gene expression in beef cows grazing different forage allowances of native pastures. M. Carriquiry*[1], F. Bialade[1], M. P. Grignola[1], P. Soca[1], A. C. Espasandín[1], C. Viñoles[2], and A. Meikle[3], *[1]School of Agronomy, UdelaR, Montevideo, Uruguay, [2]National Research Institute for Agriculture, Tracuarembó, Uruguay, [3]School of Veterinary Sciences, UdelaR, Montevideo, Uruguay.*

The aim of this study was to evaluate the effect of long-term nutrition at 2 different forages allowances of native pastures on uterine gene expression in beef cows. Adult cows (Angus, Hereford and F1 crossbred) were used, from May 2007 to May 2010, in a complete randomized block design with 2 forage allowances throughout the year (6 vs. 10 kgDM/100kgBW/d; LO vs. HI) . At the end of the third year, at 178 ± 15 d postpartum, cows were synchronized with 2 prostaglandin (PG)

injections 11 d apart and slaughtered 32 ± 1 h after the last PG injection. Uterine tissue from the middle third of the uterine horn ipsilateral to the corpus luteum was collected from all cows that had at least 2 previous ovulations (n = 8 and 6 for HI and LO, respectively). Relative expression of estrogen (ERα) and progesterone (PR) receptors, growth hormone receptor (GHR), insulin-like growth factor-I (IGF-I), IGF-II, IGF receptor-1 (IGFR1), IGF binding proteins (IGFBP) −2, −3, −4, −5, and −6 mRNA was determined using SYBR-Green real time PCR and normalized to the expression of hypoxanthine-phosphoribosyltransferase and β-actin mRNA. Data were analyzed with a mixed model that included forage allowance and block as fixed and random effects, respectively. At slaughter, cow BCS did not differ ($P = 0.318$) between groups and averaged 3.9 ± 0.08 (scale 1–8). Expression of ERα, PR, GHR, IGF-I, IGF-II, IGFBP3, IGFBP5, and IGFBP6 mRNA did not differ ($P > 0.128$) between forage allowances. However, uterine IGFBP2 tended ($P = 0.092$, 0.30 vs. 0.15 ± 0.08) to be greater and IGFBP4 mRNA was greater ($P = 0.017$, 2.52 vs. 1.25 ± 0.97) in LO than HI cows. Uterine GHR mRNA was correlated ($P < 0.017$) to ERα (r = 0.65), IGFBP4 (r = 0.60) and IGFBP5 (r = 0.69) mRNA while IGF-I mRNA was negatively correlated ($P = 0.043$, r = −0.53) to IGFBP5 mRNA and IGF-II mRNA was positively correlated ($P = 0.023$, r = 0.58) to IGFBP6 mRNA. Nutritional plane may influence IGF availability in the uterus of beef cows indirectly through changes in expression of IGFBPs.

Key words: cattle, grazing, reproduction

W250 The effect of leptin on primary cultured adipocytes of pigs. J. Liang, X. Zhang, Y. Zheng, S. Pan, R. Zhao, and X. Yang*, *Nanjing Agricultural University, Nanjing, P. R. China.*

To investigate the effect of leptin on primary cultured adipocytes of pigs and the possibly mechanism mediated by perilipin. SV cells were separated from subcutaneous adipose tissue of weaned piglet. Cells were cultured to 80% confluence followed by differentiation for 3 d, then treated with 10–8 M and 10–7 M leptin respectively for 4h (short-term treatment) or 48h (long-term treatment). Oil-red O and immunofluorescence histochemistry were used to identify adipocytes, lipid droplets and perilipin. Cultured media were collected for quantization of glycerol content. Perilipin, HSL and ATGL mRNA levels were determined by Real-time RT-PCR. Activity of lipases (HSL and ATGL) was determined. Perilipin and phosphorylated perilipin protein levels were quantitated by Western blot analysis. The results showed that after leptin treatment for 4h, the viability of cells was increased significantly in 10–7 M leptin group; cells in 10–7 M and 10–8 M groups released significantly more glycerol than in the control; Perilipin, HSL and ATGL mRNA expression were significantly increased by 10–7 M leptin treatment, whereas 10–8 M leptin treatment increased the mRNA expression of ATGL only; there was no alteration of lipase activity and perilipin content, and the phosphorylation of perilipin was even not observed in both concentration groups. After leptin long-term treatment for 48h, cells in 10–7 M and 10–8 M groups released significantly more glycerol than in the control; Perilipin mRNA was downregulated by 10–8 M leptin; the perilipin protein content showed downregulate tendency ($P = 0.1$) in 10–7 M leptin group, whereas the phosphorylated perilipin content were detected significantly higher in both treatment groups. The results indicate that the mechanism of the glycerol release in adipocyte induced by leptin short-term and long-term treatment may be different. The leptin short-term treated influence mRNA expression of related genes, and long-term leptin treatment increased lipolytic activity of adipocytes possibly by activating phosphorylation of perilipin.

Key words: adipocyte, leptin, perilipin

W251 Injection of 100 µg of GnRH 31 d after AI does not reduce pregnancy loss in lactating dairy cows. A. L. A. Scanavez*, L. G. D. Mendonça, P. R. B. Silva, J. G. N. Moraes, and R. C. Chebel, *Department of Veterinary Population Medicine, University of Minnesota, St. Paul.*

Objectives of the current study were to determine whether treatment with 100µg of GnRH 31 ± 3 d after artificial insemination (AI) reduces pregnancy losses and whether exposure to heat stress affects this outcome. Lactating cows from 2 dairies were enrolled in the study at 31 ± 3 d after AI. At enrollment cows were grouped by parity and number of AI and assigned to 1 of 2 treatments in a ratio of 1:2. Cows assigned to the GnRH treatment received 100 µg of GnRH at 31 ± 3 d after AI and cows assigned to the control treatment did not receive GnRH. All cows were examined by manual palpation per rectum at 38 ± 3 d after AI (first pregnancy diagnosis) and those diagnosed pregnant were re-examined 66 ± 3 d after AI (second pregnancy diagnosis). Data regarding daily temperature and humidity were recorded and temperature humidity index (THI) was calculated from 4 weeks before to 9 weeks after AI. At pregnancy diagnosis 38 ± 3 d after AI there were 606 pregnant GnRH cows and 1,303 pregnant control cows. No cows were exposed to heat stress (THI > 72) between AI and pregnancy diagnosis and average THI between AI and first pregnancy diagnosis was 53.0 ± 0.1. Average THI from AI to first pregnancy diagnosis was 58.9 ± 0.1 and average THI between first and second pregnancy diagnosis was 63.9 ± 0.1. Average THI from AI to the second pregnancy exam was 60.1 ± 0.1, cows were exposed to 0.5 ± 0.1 week with weekly average THI > 72, and 21.1% of cows were exposed to at least one week of heat stress (weekly average THI > 72). Pregnancy loss from 38 ± 3 to 66 ± 3 d after AI was not ($P = 0.42$) affected by treatment (GnRH = 5.9, control = 5.1%). Similarly, site ($P = 0.94$), parity ($P = 0.99$), and exposure to heat stress did not affect pregnancy loss from 38 ± 3 to 66 ± 3 d after AI. Average projected 305-d milk yield was 11,218.6 ± 42.2 kg and projected 305-d milk yield affected ($P < 0.01$) pregnancy loss from 38 ± 3 to 66 ± 3 d after AI because cow in the lower 2 quartiles (Q1 = 2.7 and Q2 = 4.2%) had smaller ($P < 0.07$) incidence of pregnancy loss than cows in the higher 2 quartiles (Q3 = 7.7 and Q4 = 6.9%). Treatment with GnRH 31 d after AI does not reduce pregnancy loss regardless of exposure to heat stress.

Key words: dairy cow, pregnancy loss, GnRH

W252 Replacing grain and silage with wheat distiller grains affects feeding behavior of finishing beef cattle. W. Z. Yang*[1], T. A. McAllister[1], J. J. McKinnon[2], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]Department of Animal & Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

A study was conducted to evaluate DMI and feeding behavior of feedlot beef steers fed diets that varied in the proportion of wheat dried distillers grains with solubles (DDGS), with DDGS replacing barley grain or silage. Eighty crossbred steers (486 ± 28 kg) were randomly allotted to 8 pens (2 pens per treatment). The pens were fitted with the GrowSafe system and the steers were tagged with transponders enabling continuous recording of feeding behavior of individual steers, including frequency and duration of visits to the feed bunk and individual feed intake. Steers were fed 1 of 4 diets: control, low (25DDGS), medium (30DDGS), and high (35DDGS) wheat DDGS (DM basis). The control diet consisted of 15% barley silage, 85% barley grain concentrate; the 3 DDGS diets were formulated by substituting 20% barley grain and 5, 10 and 15% silage, respectively, with 25, 30 and 35% wheat DDGS such that the 35DDGS diet contained no silage. In comparison to control, calves fed 25DDGS had greater ($P < 0.01$) DMI (9.5 vs. 11.3 kg/d) and feeding time (84 vs. 112 min/d), but feeding rate (115 vs. 108 g/min), meal frequency (9.3 vs. 10.8, meal/d), and meal length (9.9 vs. 10.9 min/meal) were not different. With increasing substitution of wheat DDGS for silage, DMI (11.3 to 10.7 kg/d; $P < 0.05$), feeding time (112 to 89 min/d; $P < 0.01$), and meal length (10.9 to 8.3 min/meal; $P < 0.01$) linearly decreased, but feeding rate (108 to 134 g/min) and meal frequency (10.8 to 15.4 meal/d) linearly increased ($P < 0.01$). The results indicate that feeding a diet containing moderate levels of wheat DDGS with adequate silage increased DMI but longer feeding time was required. In contrast, when diets contained minimal (i.e., 5%) or no silage, steers increased feeding rate and meal frequency to consume more feed.

Key words: feeding behavior, feedlot beef cattle, wheat DDGS

W253 Inclusion of anti-phospholipase A2 antibody (aPLA2) to backgrounding diet enhanced feed efficiency in growing beef calves. V. R. G. Mercadante*, K. M. Bischoff, T. E. Black, G. H. L. Marquezini, N. DiLorenzo, and G. C. Lamb, *North Florida Research and Education Center, University of Florida, Marianna.*

We determined whether supplementation of anti-phospholipase A2 antibody (aPLA2; BIG BEEF, Aova Technologies, Madison, WI) for growing beef cattle would alter voluntary DM feed intake and feed efficiency of growing calves. Individual performance and daily DMI was measured on 70 crossbred weaned calves (53 steers and 17 heifers) during a 70-d period using a GrowSafe system (GrowSafe Systems Ltd., Alberta, Canada) at the University of Florida NFREC Feed Efficiency Facility. All calves where submitted to a 21-d period of adaptation to facilities and diets. Calves were fed a growing forage-based TMR diet (0.97 Mcal NEg/kg DM, 14.7% CP) to support growth rates of 1 kg/d (NRC, 1996). Calves were blocked by weight and sex and then assigned to pens to receive either no additional supplement (Control, n = 35) or receive a supplement that delivered aPLA2 at an inclusion rate of 0.6% of the dietary DM (BIG BEEF, n = 35). Body weight (BW) was recorded at 14-d intervals over the 70-d period. Linear regression of BW against day on test was used to establish ADG. Initial BW (245.5 ± 5.3 kg and 246.2 ± 5.3 kg for Control and BIG BEEF, respectively; $P = 0.93$), final BW (318.6 ± 5.8 kg and 317.7 ± 5.8 kg for Control and BIG BEEF, respectively; $P = 0.91$), and ADG (1.01 ± 0.03 kg and 1.01 ± 0.03 kg for Control and BIG BEEF, respectively; $P = 0.99$) were similar between treatments. However, daily DMI was greater ($P < 0.0001$) for Control (8.47 ± 0.19 kg) than BIG BEEF (7.87 ± 0.19 kg). In addition, G:F tended ($P = 0.10$) to be greater for BIG BEEF (0.1294 ± 0.004) than Control (0.1206 ± 0.004) and residual feed intake was greater ($P < 0.01$) for Control (0.624 ± 0.291 kg/d) than BIG BEEF calves (−0.624 ± 0.291 kg/d).We conclude that the supplementation of anti-phospholipase A2 (BIG BEEF) for growing beef cattle decreased daily DMI while maintain ADG, therefore, improving feed efficiency.

Key words: beef cattle, feed efficiency, phospholipase A2

W254 Productive performance during fattening phase of Nelore fed diets with two concentrate levels. G. S. Firmino*[1], I. S. Silva[1], F. A. Barbosa[2], S. L. S. Cabral Filho[1], J. F. B. Guedes[1], G. A. Carneiro[1], F. F. Gouveia[1], and J. F. A. Oliveira[1], *[1]University of Brasília - UnB, Brasília, DF, Brazil, [2]Federal University of Minas Gerais - UFMG, Belo Horizonte, MG, Brazil.*

The experiment evaluated the performance of feedlot cattle divided into 2 experimental groups and submitted to 2 diets during 90 d. The herd consisted of 30 bulls aged 22 mo, with an initial average body weight (IBW) of 350.25 kg, which were divided into 2 groups of 15 animals per treatment. The experimental groups were: DIE70 - concentrate (corn grain, sunflower meal, soybean hulls, urea and mineral) and corn silage at a ratio of 70:30 on dry matter and DIE85 - concentrate (corn grain, sunflower meal, soybean hulls, urea and mineral) and corn silage in proportion of 85:15 on a DM basis. The experiment was conducted in a completely randomized design with 2 treatments and 15 repetitions (n = 30). The average initial body weight (IBW), final body weight (FBW), average daily gain (ADG) and hot carcass yield (HCY) were compared by Duncan test with significance level of $P < 0.05$. There was no statistical difference ($P > 0.05$) between IBW with averages of 344.86 kg and 351.61 kg and also between the FBW, 444.66 kg and 441.77 kg for the treatments DIE70 and DIE85 respectively. The ADG and HCY among treatments DIE70 and DIE85 did not differ; the values were 1.16 kg for DIE70 and 1.04 kg for DIE85, and 57.26% for DIE70 and 57.04% for DIE85. In this study, the 85% concentrate diet did not improve animal performance compared with diets containing 70% of concentrate.

Key words: performance, carcass, beef cattle feedlot

W255 Effect of maternal feed efficiency as growing heifers and lactating cows on feed intake and performance of their suckling offspring. K. M. Bischoff*[1], T. E. Black[1], V. R. G. Mercadante[1], G. H. L. Marquezini[1], C. C. Chase[2], S. W. Coleman[2], and G. C. Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]USDA-ARS, SubTropical Agricultural Research Station, Brooksville, FL.*

We determined whether suckling calf DMI and performance was associated with feed efficiency, feed intake, and performance of their dam as a growing heifer or lactating cow. Feed efficiency was established in

74 growing heifers that subsequently gave birth to their second calf as 3-yr old cows. For the heifer and cow phases, females had a 14-d acclimation period before initiating a 70-d feed efficiency test period. Individual daily feed intakes were recorded using the GrowSafe System (GrowSafe Systems Ltd., Alberta, Canada) to determine average DMI. A forage-based diet consisting of 86.7% Tifton 85 Bermudagrass silage, 12.4% dried distillers grains plus soluble, 0.7% range mineral, and 0.2% salt was fed ad libitum to cow-calf pairs. Cows were milked on d 14 (lactation d 28 ± 7) and d 70 (lactation d 84 ± 7) of the test to determine individual energy corrected milk (ECM). Average DMI of calves was determined by the sum of DMI of feedstuffs and the DMI of ECM from suckling. Weights of calves were collected on d 0 and 70. During the 70-d test calves had ADG of 0.51 kg/d and consumed 0.44 kg/d of feed and 3.98 kg/d ECM (0.52 kg/d on a DM basis). The correlation between total DMI of calf and residual feed intake (RFI) of dam during lactation ($P = 0.88$, r = 0.0191) or RFI of dam as a heifer were similar ($P = 0.97$, r = 0.004). In addition, there was no correlation between DMI of the dam as a lactating cow ($P = 0.172$, r = 0.160) or as a heifer ($P = 0.34$, r = 0.112) to the total DMI of the calf. The gain:feed (G:F) of the calf was not correlated to dam RFI as a cow ($P = 0.30$ r = −0.125) or heifer ($P = 0.74$ r = 0.039). There was no correlation in DMI from feed consumed to DMI from ECM ($P = 0.50$, r = 0.080). However, there was a correlation between G:F and DMI of feed of the calf ($P < 0.001$, r = 0.424); however, there was no correlation between DMI of ECM consumed and the G:F of calves ($P = 0.04$, r = −0.238). We conclude that DMI and performance of suckling calves is not related to feed efficiency, feed intake, and performance of their dam as a growing heifer or lactating cow.

Key words: calf performance, dry matter intake, feed efficiency

W256 Temperament evaluation of Nelore (*Bos indicus*) cattle in Brazilian commercial cow-calf operations. M. Meneghetti*[2], R. F. Cooke[1], B. I. Cappellozza[1], D. W. Bohnert[1], and T. C. Losi[3], *[1]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [2]Pfizer Animal Health, São Paulo, SP, Brazil, [3]Lageado Consultoria Agropecuária, Mineiros, GO, Brazil.*

Temperament impacts several production parameters in beef cattle, including growth and reproduction. Excitable temperament is frequently detected in *Bos indicus* breeds such as Nelore, which represents the majority of the beef cattle in Brazil – country that holds the largest commercial cattle herd, and is the main exporter and second main producer of beef in the world. However, there is a lack of research studies characterizing temperament of Nelore cattle. Therefore, efforts to determine incidence of excitable temperament and its effects on productivity of Nelore cattle will benefit not only beef production in Brazil, but also availability of beef in many parts of the planet. The objective of the present study was to evaluate temperament in Nelore brood cows, assess the incidence of aggressive cattle in commercial ranches, and correlate temperament measurements with production traits. A total of 855 lactating, multiparous Nelore cows, from 4 different commercial cow-calf ranches (ranch 1, n = 231; ranch 2, n = 195; ranch 3, n = 236; ranch 4, n = 193) were evaluate for BCS, chute core (CS; 1 to 5 scale), and exit velocity (EV; m/s using infrared sensors) when processed for AI. Based on EV and CS (±1 SD from the mean), cows were classified as docile, moderate, or aggressive. Across all ranches, CS and EV were correlated ($P < 0.01$, r = 0.47). A ranch effect was detected ($P = 0.05$) because the correlation coefficient between CS and EV different among ranches (0.47, 0.65, 0.45, and 0.72 for ranches 1, 2, 3, and 4, respectively), which is likely due to differences in the design of the handling facilities. No significant correlations were detected among CS or EV with BCS ($P > 0.11$). Across all ranches, 12% of cows were classified as docile, 74% were classified as moderate, and 14% were classified as aggressive. In conclusion, temperament did not influence BCS of Nelore beef cows at the beginning of the breeding season. However, additional efforts to determine if temperament affects other production parameters in Nelore beef cows are warranted due to the reduced proportion of docile cattle in commercial cow-calf ranches in Brazil.

Key words: Nelore, temperament, productivity

W257 Influence of propionate salt levels on young cow reproductive performance. J. A. Walker*, G. A. Perry, and K. C. Olson, *South Dakota State University, Brookings.*

A supplementation study was conducted to evaluate level of propionate salt on young cow performance. Two- and 3-yr-old cows (n = 60) were allocated to one of 3 treatments at calving. Propionate salt was incorporated in a protein supplement (30% CP, 73% TDN) at a rate of 0, 80 or 160 g/d of propionate salt. Cows were individually supplemented twice weekly at 1.14 kg/d. Cows had access to pasture and hay (6.9% CP, 59.7% TDN). Blood was collected weekly to determine postpartum interval (≤1 ng P_4/ml). Weights and BCS were assigned at calving, end of supplementation, start of breeding season, and weaning. No differences in cow weight ($P = 0.11$) and BCS ($P = 0.17$) were found between treatments. Cow weight changed through the study ($P < 0.01$, 418, 443, 468 and 475 kg for calving, end of supplementation, start of breeding season and weaning, respectively). Cow ADG had a treatment by period interaction ($P < 0.05$): ADG displayed a quadratic response ($P < 0.05$) to levels of propionate salt during the supplementation period with 80 g displaying the highest ADG, but no response during the end of supplementation to breeding or breeding to weaning periods. Cow BCS changed through the study ($P < 0.01$, 4.46, 4.87, 4.90 and 4.73 for calving, end of supplementation, start of breeding season and weaning, respectively). Cows BCS increased during supplementation ($P < 0.01$, 0.42) and decreased from breeding to weaning (−0.17). Calf weight was not different ($P = 0.38$) between treatments. Calf weight increased through the study ($P < 0.01$, 36.1, 101.3 and 197 kg at birth, start of breeding season, and weaning, respectively). Pregnancy rates did not differ between treatments ($P = 0.24$). Pregnancy rates differed by cow age ($P < 0.01$, 77% and 100% for 2- and 3-year-olds, respectively). Cows initiating estrous cycles before the breeding season were greater ($P < 0.05$) for 160 g (47.6%) compared with 0 g (15.6%) and tended to be greater than 80 g ($P < 0.10$, 20.0%). Based on ultrasonography, 3-year-old cows conceived earlier ($P < 0.01$, 183.7 d) than the 2 year cows (207.0 d). Propionate salt did not influence cow weight or BCS; however, propionate salt did influence reproductive performance.

Key words: propionate salt, young beef cows

W258 Methane emission potential and nutritional composition of four *Panicum* sp. forage genotypes in the Brazilian Cerrado region. L. Bezerra da Silva*[1], S. L. S. Cabral Filho[1], R. Guimarães Júnior[2], A. L. Abdalla[3], A. K. B. Ramos[2], and F. D. Fernandes[2], *[1]Universidade de Brasília, Brasília, Distrito Federal, Brasil, [2]Embrapa Cerrados, Planaltina, Distrito Federal, Brasil, [3]Universidade de São Paulo, Piracicaba, São Paulo, Brasil.*

Four genotypes of *Panicum* sp. were evaluated, namely 2 accessions called PM34 and PM46, as well as 2 commercial cultivars, *Panicum maximum* 'Massai' and *Panicum maximum* 'Mombaça'. The purpose of the evaluation was to evaluate nutritional features, and to assess methane emission potential ensuing from the respective chemical composition characteristics of each genotype. The experiments were conducted both at an EMBRAPA unit called Cerrados, which is located in Planaltina town, Federal District (DF) and at the Animal Nutrition Laboratory on the Federal University of Brasília – UnB, within the period from September 2007 to May 2010. The genotypes' methane emission potential was assessed by applying the semi-automated in vitro gas production technique combined with the gas chromatography method concerning methane gas production at 8, 12 and 24 h post-inoculation. The split plot and split block experiment design with 3 repetitions was the experimental approach employed in laboratory analyses. Tukey's test at 5% probability level was applied to compare the means obtained and the data analysis was performed by using the SAS software (2000 version). The dry matter rate was 24.88%, and the neutral detergent fiber (NDF), non-fiber carbohydrate and NDF-nitrogen rates were respectively 67.85%, 11.34%, and 52.58%. Significant differences ($P < 0,05$) were found among the analyzed cultivars in respect to cumulative gas production (CGP), dry matter digestibility (DMD), amount of methane gas produced (ACH_4), as well as the amount of methane gas produced by each gram of dry matter digested (CH_4GDMD). It was observed that CH_4GDMD was negatively related to the level of non-fiber carbohydrates (−0.9063) and positively related to the percentage of nitrogen linked to the neutral detergent fiber (NDF) in the genotypes analyzed (0.9925). In conclusion, a higher methane emission potential was observed for the genotype PM34 after 24 h fermentation, which presented a higher CH_4GDMD rate (32.37 mL/g) combined with a lower DMD rate (35.92%) ($P < 0.05$).

W259 Methodology for estimating intermuscular, subcutaneous, and intramuscular fat in primal cuts. M. J. McPhee*[1,2], J. P. Siddell[1,2], B. J. Walmsley[1,2], W. H. Johns[1,2], and P. L. Greenwood[1,2], *[1]Cooperative Research Centre for Beef Genetic Technologies, Armidale, NSW, Australia, [2]Industry and Investment NSW, Armidale, NSW, Australia.*

In this study 6 whole beef rumps (3.67 to 5.05 kg) were purchased to evaluate the accuracy of estimating subcutaneous (SUB) and intermuscular (INTER) fat content from computer-aided tomography (CT)-scanned images. A full dissection by 2 operators of SUB and INTER fat was used to evaluate the accuracy of the CT prediction. The rumps were scanned using a Picker Ultra Z Spiral CT scanner (Philips Medical Imaging Australia, Sydney NSW) in the Meat Science CT unit at the University of New England Meat, Armidale. Voltage and current were set at 130 kV and 100 mAs, respectively. A pitch of 1.5, field of view of 480 mm, slice thickness of 5mm and distance between slices of 15mm were used. One hundred and 10 axial slices from 6 primal cuts were created. Total fat and lean in each rump were calculated using image analysis software. Boundaries for fat and lean were set at 10 to 128 and 129 to 210 gray scale units, respectively, with an image diameter of 487mm. INTER fat was removed from each slice using an elliptical tool in ImageJ (public domain software). Images only containing SUB fat were then analyzed to estimate the amount of SUB fat (kg). INTER fat (total fat – SUB fat) was calculated by difference. The SUB and INTER fat dissections were weighed and vacuum packed. Bags were then scanned to determine the amount of fat and lean in each dissected fat depot. The ratio of SUB and INTER fat to the dissected weight (kg) was used to account for any associated errors. The linear relationships between scanned (y) vs. dissected (x) fat for total, sub, and inter fat were $y = 1.0x + 0.02$ (SE = 0.22; $AdjR^2 = 0.98$), $y = 0.92x + 0.01$ (SE = 0.01; $AdjR^2 = 0.99$), and $y = 0.98x + 0.07$ (SE = 0.02; $AdjR^2 = 0.83$), respectively. These results demonstrate that fat deposition in beef primal cuts from scanned data are feasible and can be done with a high degree of accuracy. The amount of intramuscular fat has also been estimated from the scanned images of a Beef Cooperative Research Centre serial slaughter investigating marbling and fat distribution in Angus, Hereford, and Wagyu × Angus steers after SUB and INTER fat has been removed from each slice using the elliptical tool in ImageJ.

Key words: beef cattle, fat deposition

W260 The influence of two levels of concentrate on the performance characteristics and carcass yield in Nellore cattle in *Brachiaria brizantha* compared to Marandu pastures. G. A. Carneiro*[1], F. A. Barbosa[2], S. L. S. Cabral Filho[1], R. V. Oliveira[1], G. S. Firmino[1], C. E. Souza[1], F. F. Gouveia[1], and J. F. A. Oliveira[1], *[1]University of Brasilia, Brasilia, DF, Brazil, [2]Federal University of Minas Gerais, Minas gerais, MG, Brazil.*

The aim of the study was to evaluate the effects of 2 levels of concentrate on the performance characteristics and carcass yield in cattle in *Brachiaria Brizantha* compared with Marandu pastures. The experimental period went from August 2010 to January 2011. The animals used were 30, 22 mo-old Nellore steers with average initial body weight of 330.42 kg, divided into 2 treatments: SCONF 1 – average daily intake of the concentrate (corn, sunflower bran, soybean hulls, urea and minerals) offered at 0.91% the average body weight (ABW; dry matter - DM); SCONF 2 – average daily intake of the concentrate (corn, sunflower bran, soybean hulls, urea and minerals) offered at 1.42% the ABW in DM. The experiment was conducted in a randomized block design with 2 treatments and 3 replications. The Duncan test was used with 5% significance for comparison of treatments for performance and animal's carcass yield. The average final BW obtained was 477.94 kg, therefore there was no statistical difference in the average daily gain (ADG) and in the carcass yield between treatments SCONF 1 and SCONF 2 (ADG 0.867 kg/head/day for both treatments, and carcass yield of 56.00% for SCONF 1 and 56.03% for SCONF 2 ;$P > 0.05$). The 1.42% daily intake in DM of the concentrate did not improve weight gain and carcass yield compared with the daily intake of 0.91% in DM.

Key words: beef cattle, weight gain, grass

W261 Two methods to estimate milk yield in beef cattle grazing systems. A. C. Espasandin*, A. Casal, V. Gutierrez, M. Cadenazzi, and M. Carriquiry, *School of Agronomy, UdelaR, Uruguay.*

The objective of this work was to compare 2 different methods to estimate milk yield (MY) of a beef cattle herd at the Experimental Station Bernardo Rosengurtt, School of Agronomy, Uruguay. Hereford, Angus and F1-crosbred (n = 24) primiparous cows were used to estimate MY, once a month from birth to weaning, with Weight-suckle-weight (WSW) and Milking Machine (MM). All cows grazed native

pasture (2300 kg MS/ha of forage allowance). Two groups were created, each group with one method to estimate milk yield, and then the method was inverted. In WSW method calves were weighted before and after suckling (weight losses by urine and feces were registered previously). Difference between pre and post-suckling weights was recorded as estimated milk production of the dam. In MM method, cows were milked in the morning and afternoon, after receiving oxytocin. Milk was weighted in the afternoon. Estimations of MY, adjusted to 24 h, were analyzed with a repeated measures model including of sex of calves, month of lactation, group, cow breed, calf breed as fixed effects, postpartum days as a covariate, and the cow(breed) as random effect. To compare the 2 methods (WSW or MM), the effect was included in the previous model. Reproducibility of the 2 methods was studied by the Gage r&R (repeteability&Reproducibility) variance components. The MY estimated along lactation period was different between the 2 methodologies, WSW method estimates more MY than MM method. The Effect of method was significant ($P < 0.03$). The r&R coefficients range 83% (r = 0.72 and R = 0.41) suggesting low correlations. MM method estimates the potential capacity of the cow to produce a quantity of milk in a delimited period. Whereas, WSW method estimates milk consumption of calves but it is not an accurate method to estimate the real milk production of the dams. Standard errors analysis for the 2 methods show different variation associated to the estimated mean. The mean variation coefficient was 6% and 18% in MM and WSW method, respectively. Based on variability observed in this experiment, MM method is a more accurate method to estimate milk production in beef cattle systems.

Key words: beef cattle, Gage r&R, milk yield
