Late-Breaking Original Research

LB1 Performance of Illumina and Affymetrix bovine high-density genotyping platforms in Holsteins and Jerseys. G. Rincon[1], K. Weber[1], A. Van Eenennaam[1], B. L. Golden[2], and J. F. Medrano*[1], *[1]Department of Animal Science, University of California Davis, Davis, [2]Dairy Science Department, California Polytechnic State University, San Luis Obispo.*

Two high-density single nucleotide polymorphism (SNP) genotyping arrays have recently become available for bovine genomic analyses, the Illumina High-Density Bovine BeadChip Array (777,962 SNP) and the Affymetrix Axiom Genome-Wide BOS 1 Array (648,855 SNP). These products each have unique design and chemistry attributes, and the extent of marker overlap and their potential utility for QTL fine mapping, detection of copy number variation, and multi-breed genomic selection are of significant interest to the cattle community. This study compares the performance of these 2 arrays using DNA samples from 16 dairy cattle (10 Holstein, 6 Jersey). Data were analyzed with SVS7 software (Golden Helix) filtering to remove SNP having a call rate less than 90% and linkage disequilibrium (LD) pruning was used to remove linked SNP ($r^2 \geq 0.9$). Maximum, average, and median gaps were calculated for each analysis based on genomic position of SNP on the bovine UMD3.1 genome assembly. The Illumina and Affymetrix arrays include 49,345 and 47,741 SNP from the widely used Bovine Illumina SNP50, respectively. All samples were successfully genotyped (≥98% SNP genotyped) with both platforms. Average number of genotyped SNP in the Illumina platform was 775,681 and 637,249 for the Affymetrix platform. Only 96,640 SNP were shared between the 2 platforms, and the average SNP concordance at these loci was 99.9%. Despite fewer total SNP on the Affymetrix array, 19% more SNP remained (480,196) after LD pruning resulting in a smaller average gap size of 5,159 bp relative to the Illumina array where 388,263 SNP remained resulting in a 6,881 bp average gap size. However, only 224,115 Illumina and 241,038 Affymetrix SNP remained following removal of SNP with a minor allele frequency (MAF) of zero in these Holstein and Jersey samples, resulting in an average gap size of 11,887 bp and 11,018 bp, respectively. Combining the 354,348 informative ($r^2 \geq 0.9$), polymorphic (MAF ≥ 0), unique SNP data from both platforms reduced the average gap size to 7,560 bp. This marker density of informative SNP has been projected to be sufficient to obtain consistent marker effects across breeds.

Key Words: SNP, genomics, cattle

LB2 Independent assessment of commercial DNA tests for beef cattle production traits. K. L. Weber* and A. L. Van Eenennaam, *Department of Animal Science, University of California, Davis.*

Two commercial companies offer DNA tests to improve the accuracy of selection in Angus cattle. The American Angus Association (AAA) national cattle evaluation incorporates DNA test information using genetic correlations estimated from the genetic relationship between DNA test results and phenotypic data in their database. The genetic correlation between the target trait and test results is expected to decrease as the relationship between the training and evaluation populations becomes more distant. The objective of this study was to estimate the genetic correlation between DNA test results and target traits in typical commercial ranch bulls (born 2003–2007) sourced from the Angus seedstock sector. Molecular breeding values (MBV) from Igenity (Duluth, GA) and HD 50K molecular value predictions (MVP) from Pfizer Animal Genetics (Kalamazoo, MI) were obtained for 29 registered Angus bulls that had sired 1852 progeny with commercial cows on 3 northern California ranches. Each bull had at least 20 progeny weaning weight records or 10 carcass records. Traits evaluated were weaning weight (WW; n = 1734), ADG (n = 341) from feedlot entry to estimated feedlot final weight (derived from HCW/0.63), HCW (n = 455), ribeye area (RE; n = 455), and marbling score (MS; n = 455). DNA test results were correlated with the target trait using a bivariate animal model with the DNA test treated as a second trait. REML estimates of the genetic correlation ± SE estimated in this data set (and those estimated by AAA where available) for Igenity MBV were WW 0.12 ± 0.22 (0.45), ADG −0.01 ± 0.42, HCW 0.33 ± 0.27 (0.54), RE 0.35 ± 0.24 (0.58), and MS 0.61 ± 0.19 (0.65). For Pfizer MVP, genetic correlations were WW 0.51 ± 0.17 (0.52), ADG 0.10 ± 0.39, HCW 0.08 ± 0.28 (0.48), RE 0.57 ± 0.21 (0.60), and MS 0.71 ± 0.17 (0.57). Genetic correlation estimates were generally positive and somewhat lower than the AAA value, although estimates had large SE. Incorporating the DNA test information as a correlated trait to improve the low accuracy AAA EPD associated with yearling bulls did not consistently improve rank order correlation with commercial ranch estimated breeding values based on observed progeny performance.

Key Words: genomic selection, beef, accuracy

LB3 Multivariate factor analysis of genomic correlation matrices in three US dairy cattle breeds. N. P. P. Macciotta*[1] and J. B. Cole[2], *[1]Dipartimento di Scienze Zootecniche, Università di Sassari, Sassari, Italy, [2]Animal Improvement Programs Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

High-density marker maps allows the prediction of genomic values both genome-wide (GW) and for each chromosome (CHR). The comparison of correlations between traits on the GW and CHR levels may be of great help for understanding the genetic architecture of single or groups of traits. Multivariate factor analysis (MFA) models the (co) variance of a multivariate system by extracting latent variables able to reconstruct the common (co)variance structure. In this work, GW and CHR (*Bos taurus* autosomes (BTA) 6, 14, and 18) correlation matrices for 3 US dairy cattle breeds were analyzed with MFA. Data refer to 2,038 Brown Swiss (BS), 63,615 Holstein (HO) and 8,084 Jersey (JE) cattle, respectively. A total of 23 productive and functional traits were considered. About 80% of the (co)variance was explained by 6 or 7 latent factors. The comparison of correlations between the factors and the traits highlighted some similarities between breeds at the GW level. Latent factors associated (r > = 0.60) with milk yield

traits, milk composition, udder morphology, strength, and functional traits (productive life, SCS, daughter pregnancy rate) were extracted. Some differences were observed at CHR level. On BTA6 BS showed an overlapping of yield and composition with a single factor, whereas they tend to remain distinct in HO and JE. However, in HO and JE there are 2 latent factors associated with functional traits on BTA6, which harbors genes affecting milk production and reproduction. The analysis of BTA14 highlighted in the JE a factor associated with both milk yield and composition traits, except for protein percentage, and differences between GW and CHR was noted, which is consistent with the presence of genes known to affect selected traits (DGAT1). Results for GW and CHR were similar for BTA18, which is known to harbor a QTL affecting calving traits and conformation in Holsteins. Multivariate factor analysis is capable of identifying differences in genetic correlations among traits across the genome and on individual chromosomes, and may be a useful tool to identify regions of the genome affecting multiple traits for further study.

Key Words: genomic selection, chromosome, factor analysis

LB4 Transcriptional profiling during pig fetal skeletal muscle development using direct high-throughput sequencing and cross-platform comparison with gene expression microarrays. C. W. Ernst*[1], J. P. Steibel[1], B. P. Sollero[1,2], G. M. Strasburg[1], S. E. F. Guimarães[2], and N. E. Raney[1], *[1]Michigan State University, East Lansing, [2]Federal University of Viçosa, Viçosa, MG, Brazil.*

§%§Skeletal muscle fiber formation is under genetic control, but little is known about the specific genes involved or how their expression patterns are coordinated. The aim of this study was to identify differentially expressed genes in *longissimus dorsi* muscle of Yorkshire × Landrace pigs at 40 and 70 d of gestation (encompassing the transition from primary to secondary fibers). Total RNA was pooled from 3 fetuses from gilts at each gestational age (n = 3). Transcriptional profiling was performed by direct sequencing (RNaseq) with an Illumina GAIIx revealing 6,299 differentially expressed tags (FDR <0.10). The same samples were previously evaluated using the Pig-oligoarray microarray comprised of 20,400 70-mers, and qPCR was completed for a subset of genes. To perform a cross-platform comparison between RNaseq and microarray analyses, microarray results were expressed as log-fold change (FC) with associated p-value and q-value (FDR), and comparisons filtered with FDR <0.10 (n = 1,218). Microarray oligonucleotides were matched to RNaseq tags based on HGNC annotation resulting in 1,410 matching pairs of oligonucleotides and sequenced transcripts (with multiple transcripts mapping to the same oligonucleotide). Correlation of log-FC between the technologies was 0.72. Expression patterns obtained with RNaseq for 11 genes assayed by qPCR (annotated in Build 9) were validated. These included 4 non-differentially expressed genes (FDR >0.10 in both assays; CTNNB1, HPRT1, STAT1, TIMP3), 6 genes more highly expressed at 70 d (FDR <0.10; CA3, DLK1, FBXO32, MYOZ1, NRAP, USP13), and 1 gene more highly expressed at 40 d (FDR <0.10; TNC). Relative FC from RNaseq and qPCR for all genes agreed in both direction and magnitude. As expected, RNaseq identified additional differentially expressed transcripts over the microarray results. However, this analysis demonstrated that the microarray results were repeatable, and results of both technologies were comparable to qPCR. Thus, both microarrays and RNaseq are reliable and RNaseq may complement and extend microarray studies.

Key Words: RNAseq, microarray, skeletal muscle

LB5 Growth, DXA skeletal traits, and spinal curvature are compromised within four weeks in pigs fed diets with no supplemental vitamin D. L. A. Rortvedt*, Z. Hassen, and T. D. Crenshaw, *University of Wisconsin, Madison.*

Recent necropsies from commercial operations implied vitamin D (D) deficiencies in young pigs, which are not typical. In 2010, we reported that kyphosis, an abnormal spine curvature, was induced in young pigs fed D-limited diets for 9 or 13 wk. The current objective was to evaluate relationships among dietary D, Ca, and P on skeletal traits and assess methods for early detection of kyphosis. In 2 trials (n = 72 ea) pigs weaned at ~3 wk were fed diets with no supplemental D for 1 wk then 1 of 8 diets (corn-SBM) for 4 wk. Treatments included supplementation with D, 0 (-D) or 280 (+D) IU/kg; Ca, 75% (0.53%) or 150% (1.05%); P, 95% (0.57%) or 120% (0.72%) of requirements. On d 28 pigs were killed and scanned using DXA (GE Lunar Prodigy) to determine bone mineral content (BMC, g/pig) and density (BMD, g/cm^2). Gain was depressed ($P < 0.01$) in pigs fed -D and tended ($P < 0.12$) to be altered by interactions between D, Ca, and P. Differences in BMC were detected due to D ($P < 0.01$). Expected responses to Ca and P ($P < 0.01$) were observed, but dependent on D ($P < 0.01$). Differences in BMD, which accounts for size, were also detected. Pigs fed -D had reduced BMD ($P < 0.01$). Excess P suppressed BMD in pigs fed -D, but increased BMD in pigs fed +D ($P < 0.07$). Differences were detected in serum Ca and P at 4 wk due to D, Ca, and P ($P < 0.01$). Two methods to assess spinal curvature involved angle measurements from digital images versus a polynomial fit derived from lateral DXA scans. No differences among treatments were detected using angle measurements. Differences ($P < 0.02$) due to D were detected in all polynomial coefficients. Thus, a polynomial fit of the spine offers a method to detect differences due to D within 4 wk.

Table 1.

Vit D, IU/kg	0	0	0	0	280	280	280	280	
Ca, %	75	75	150	150	75	75	150	150

LB6 Effect of *trans*-palmitoleic acid (*trans*-16:1 n-7) on lipid metabolism and cellular proliferation in primary bovine adipocytes. A. K. G. Kadegowda*, T. A. Burns, M. Miller, and S. K. Duckett, *Clemson University, Clemson, SC.*

Trans-palmitoleic acid (*t*-16:1) has been suggested to have beneficial effects on human health including lower adiposity. Objectives were to quantify the amounts of *t*-16:1 in meat samples and to determine the effect of *t*-16:1 on cellular proliferation and lipid metabolism in bovine primary adipocytes. For the first objective, *t*-16:1 in LM samples from steers finished on 2 different forage-finishing systems were analyzed by GC. For the second objective, bovine primary preadipocyte cultures were isolated from intermuscular fat of 18 mo-old Angus

crossbred heifers (n = 2). Preadipocytes were differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μ*M* dexamethasone (DEX), 20 μ*M* troglitasone, 0.5 m*M* isobutylmethylxanthine (IBMX), and 10 m*M* acetate] for 2 d. Cells were further differentiated from D2 to D6 in media without DEX and IBMX. From D0 to D6, cells were treated with 1 of 4 levels (0, 50, 150, or 300 μ*M*) of *t*-16:1 and for fatty acid analysis by GC and gene expression by RT-qPCR. The effect of *t*-16:1 on cell proliferation of pre-differentiated and differentiated cells was assayed using Cell Counting Kit-8. The treatment effects were analyzed by ANOVA using Proc Mixed (SAS). The *t*-16:1 content in meat samples varied from 0.56 to 1.18 g/100 g total FA. Increasing *t*-16:1 supplementation linearly increased ($P < 0.05$) total cellular FA, decreased ($P < 0.01$) C18:1c9, increased *t*-16:1 ($P < 0.01$), its elongation product t11 18:1($P < 0.01$) which was desaturated to c9t11 CLA ($P < 0.01$). Decreased C18:1c9 was probably due to increased availability of alternative FA (*t*11–18:1) for desaturation. *Trans* 16:1 increased ($P < 0.01$) FASN and ELVOL6 (at 50 μ*M*) but did not affect SCD1. *t*16:1 affected cell proliferation of pre-differentiated cells ($P < 0.05$) but did not affect the differentiated cells. Results showed that meat samples are a source of *t*-16:1and the effects of *t*-16:1 are probably mediated through c9t11 CLA in the differentiated adipocytes.

Key Words: *trans*-palmitoleic acid, adipocyte, lipid metabolism

LB7 Ferric citrate decreases ruminal hydrogen sulfide production in feedlot cattle fed diets high in sulfate. M. E. Drewnoski*[1], P. H. Doane[2], and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]ADM Research, Decatur, IL.*

Sulfate content of ethanol co-products often limits inclusion in cattle diets. Dissimilatory reduction of sulfate by sulfate-reducing bacteria in the rumen produces sulfide, which can lead to a buildup of the toxic gas hydrogen sulfide (H_2S) in the rumen, resulting in reduced performance and occasionally toxicosis. We hypothesized that adding ferric ions would competitively inhibit ruminal sulfate reduction. The objectives of these studies were to determine the effects of ferric citrate on ruminal fermentation, ruminal sulfate reduction, and DMI of cattle. The effects of 5 levels (0, 25, 50, 100, 150, 200 mg/kg of additional Fe in the in vitro fluid) and 2 sources (ferric citrate or ferric ammonium citrate) of ferric ions on in vitro H_2S production, IVDMD, total gas production, and fluid pH were examined (n = 6 per treatment). Rumen fluid was collected from a steer that was adapted to a high concentrate, high sulfate diet (0.51% S) and mixed with an equal volume of McDougall's buffer, without the reducing solution. Addition of either source of ferric ions decreased ($P < 0.01$) H_2S concentration without affecting gas production ($P = 0.38$), fluid pH ($P = 0.80$), or IVDMD ($P = 0.38$) after a 24 h incubation. An in vivo experiment was conducted using 8 ruminally fistulated steers (455 kg) in a replicated Latin square design with 4 periods and 4 treatments. The treatments included a high concentrate, high S control diet (0.46% S) or the control diet plus ferric ammonium citrate at 200, 300, or 400 mg Fe/kg diet DM. Each period lasted 11 d with a 3 d washout period where all cattle were fed the control diet, and an 8 d period in which steers were fed their experimental diet. Intake was determined during the last 4 d in a period. Inclusion of ferric ions in the diet of steers did not affect DMI ($P = 0.21$) or ruminal pH ($P = 0.48$). There was a linear ($P < 0.01$) decrease in the concentration of ruminal H_2S as ferric ion addition increased. Ferric citrate appears to be an effective way to decrease ruminal production of H_2S, which could allow producers to safely increase inclusion of co-products containing elevated sulfate.

Key Words: distillers grains, iron, sulfur

LB8 Adding an anti-inflammatory lactic acid bacteria to a *Bacillus*-based direct-fed microbial improves calf performance. M. Duersteler*[1], K. N. Novak[1], C. A. Wehnes[1], M. E. Davis[1], D. R. Shields[2], and A. H. Smith[1], *[1]Danisco USA Inc., Waukesha, WI, [2]Merrick's Inc., Union Center, WI.*

Enhanced immune development in calves was observed when scouring calves were treated with an electrolyte containing a *Bacillus*-based direct-fed microbial (DFM) selected for reducing bacterial pathogens. The objective of this experiment was to determine the effect of adding anti-inflammatory lactic acid bacteria (LAB) to the *Bacillus*-based DFM on immunity and calf performance. *Enterococcus faecium* ID7 was selected for anti-inflammatory activity from a library of LAB isolated from healthy calves. Rat intestinal epithelial IEC-6 cells (3×10^5) were treated with *Bacillus* spores (10^7 cfu), high and low dose *E. faecium* ID7 (10^8 cfu, 10^7 cfu), or *Bacillus* spores with high and low dose *E. faecium* ID7 for one hour. *Bacillus* spores increased ($P < 0.05$) expression of inflammatory cytokines (IL-1β, IL-6, TNF-α and MIP-2). High and low dose ID7 reduced ($P < 0.05$) expression of inflammatory cytokines caused by *Bacillus* spores. Calves (72) were randomly assigned to 3 treatments; control, *Bacillus*-based DFM (2×10^9 cfu/head/day) or *Bacillus*-based DFM plus *E. faecium* ID7 (2×10^9 *Bacillus*, 1×10^9 ID7 cfu/head/day). Treatments were administered in non-medicated 20:20 all milk replacer fed at 1.25 lbs/day until weaning at 6 weeks, and calves were given starter feed ad libitum throughout the 8 weeks of the trial. The *Bacillus* DFM plus *E. faecium* ID7 increased average daily gain over wk 5–6, 7–8 and over all 8 weeks ($P = 0.03$) compared with the control calves. These results indicate that providing a balanced immune response by adding an anti-inflammatory LAB to a pathogen reducing *Bacillus*-based DFM improves calf performance.

Table 1. Average daily gain (kg) per period and over trial

Week	Control ± SE	*Bacillus* DFM	*Bacillus* DFM plus ID7
1-2	0.23 ± 0.03	0.26 ± 0.03	0.31 ± 0.03
3-4	0.58 ± 0.04	0.60 ± 0.04	0.63 ± 0.04
5-6	0.78 ± 0.03^{a}	0.86 ± 0.03^{ab}	0.91 ± 0.04^{b}
7-8	1.01 ± 0.05^{a}	1.06 ± 0.05^{ab}	1.16 ± 0.05^{b}
Overall ADG	0.65 ± 0.03^{a}	0.70 ± 0.03^{ab}	0.75 ± 0.03^{b}
Total Gain	36.39 ± 1.49^{a}	38.94 ± 1.52^{ab}	42.18 ± 1.56^{b}

Means with different letters are significantly different ($P < 0.05$) within rows; means separation by least square difference. Statistical analysis by Proc Mixed procedure (SAS 9.1.3).

Key Words: direct-fed microbial, calf, immunity

SYMPOSIA AND ORAL SESSIONS
Triennial Lactation Symposium: Lactation Biology Training for the Next Generation—A Tribute to Dr. H. Allen Tucker

1 Bovine mammary epithelial cell lineages and parenchymal development. S. Ellis*[1], R. M. Akers[2], A. V. Capuco[3], and S. Safayi[1], *[1]Clemson University, Clemson, SC, [2]Virginia Polytechnic Institute, Blacksburg, VA, [3]USDA-ARS, Beltsville Agricultural Research Center, Beltsville, MD.*

Mammary development proceeds from an aggregation of cells in the ventral ectoderm to the establishment of an elaborate tree of alveoli, ducts, and cisternae. However, despite abundant data on endocrine regulation of ruminant mammary growth, we know comparatively little about cell lineages, expression of differentiation markers, and plasticity in mammary cell phenotype. Histologic analyses have revealed cell populations with distinct histochemical profiles, but functional assessment of the cell populations during development has been limited to analysis of proliferation and frequency estimations of morphotypes. The lack of transplantation models, limited availability of validated antibodies with reactivity to bovine antigens, and similar technical challenges have generally hindered the pace of discovery, but the application of new technologies like laser microdissection, transcriptional profiling, and multispectral image analysis are yielding important cues into bovine mammary cell ontogeny and developmental regulation. Our analyses have shown that prepubertal ovariectomy affects epithelial architecture, increases the proportion of cells expressing the estrogen receptor, and increases myoepithelial cell development, all concomitant with dramatic reduction in the mass of parenchymal tissue. Our observations point to a dual role for ovarian secretions in the control of not only the rate of epithelial development, but also the nature of the parenchymal development. The balanced stimulus and inhibition pathways are likely to cooperatively regulate mammary growth. The increased reliance on objective staining analyses and quantitative approaches will ensure broader repeatability, application, and extension of the findings. Advances in the understanding of mammary epithelial cell ontogeny, coupled with the established knowledge of endocrine factors affecting mammary development may yield intervention strategies to improve dairy profitability.

Key words: mammary development, cell lineage, prepubertal mammary growth

2 Prolactin—The multi-faceted potentiator of mammary growth and function. R. C. Hovey*, J. F. Trott, A. Schennink, W. K. Petrie, and M. K. VanKlompenberg, *University of California, Davis.*

Prolactin (PRL) confers numerous biological effects including its principle actions on the mammary glands during growth and lactation. These effects are mediated by dimers of the transmembrane PRL receptor (PRLR) and subsequent activation of numerous downstream signaling cascades. Traditional interpretations of how PRL acts on the mammary glands have generally built upon the concept that PRL acts directly, and independently, on the target epithelium during periods of mammary gland growth and lactation. In this presentation we will first review PRL action during mammary gland growth and lactation in several species with a focus on similarities and differences across PRLR and the control of its expression. We will then outline several lines of evidence to support the notion that many effects of PRL are mediated by additional mechanisms intrinsic to the mammary glands. Specifically, the effects of PRL on mammary gland growth are tightly coordinated by concomitant changes in the circulating levels of estrogen and progesterone, which in turn can modulate both PRLR expression and downstream gene expression. Furthermore, PRL not only acts on the epithelial population, but also modifies the stromal microenvironment by facilitating processes such as tissue remodeling and angiogenesis. Taken together, these modes of action highlight the many pathways by which PRL coordinately regulates and facilitates mammary gland growth during gestation before it initiates and regulates lactation.

Key words: prolactin, mammary gland, lactation

3 The lactocrine hypothesis: Programming reproductive tract development. F. F. Bartol*[1], J. C. Chen[2], D. J. Miller[1], A.-L. Frankshun[2], A. A. Wiley[1], A. J. Silva[1], M. E. Camp[2], K. M. Ferio[2], and C. A. Bagnell[2], *[1]Auburn University, Auburn, AL, [2]Rutgers University, New Brunswick, NJ.*

For eutherian mammals, a continuum of maternal support insures that development of progeny follows an optimal program. Beginning in utero, such support extends into the early neonatal period when nutrients and bioactive factors are communicated from mother to offspring in colostrum/milk. Defined as lactocrine signaling, communication of milk-borne bioactive factors (MbFs) from mother to offspring as a consequence of nursing is important for development of many somatic tissues, including the female reproductive tract. Endometrial development in the neonatal pig is estrogen receptor (ESR1) dependent. Disruption of ESR1-dependent, estrogen-sensitive developmental events shortly after birth (postnatal day = PND 0) that alter tissue developmental trajectory as determined on PND 14 can have long-term consequences for uterine function and reproductive capacity in adults. The lactocrine hypothesis for maternal programming of porcine endometrial development was proposed initially to explain how bioactive colostral relaxin (a porcine MbF), acting via its cognate receptor which is expressed in uterine tissues at birth, induces uterine expression of ESR1 and the parallel expression of other morphoregulatory factors such as vascular endothelial growth factor (VEGFA). This, it was proposed, insures propagation of down-stream signaling events essential to the success of endometrial development. To test the lactocrine hypothesis, patterns of uterine and endometrial gene expression and morphogenesis were evaluated at PND 2 and PND 14 in gilts that either nursed normally or were maintained in a lactocrine-null state on porcine milk replacer for defined periods from birth. Imposition of the lactocrine-null state for 48h from birth suppressed endometrial expression of morphoregulatory factors, including ESR1 and VEGFA, inhibited endometrial cell proliferation and retarded uterine gland development

by PND 14. Results provide the first evidence of cell compartment-specific, lactocrine-mediated endometrial morphogenesis and indicate that lactocrine signaling contributes to the palette of factors affecting reproductive tract development in the neonate.

Key words: lactocrine, uterus, development

4 Opportunities for improving milk production efficiency in dairy cattle. E. E. Connor*[1], J. L. Hutchison[2], K. M. Olson[2], and H. D. Norman[2], *[1]USDA-ARS, Bovine Functional Genomics Laboratory, Beltsville, MD, [2]USDA-ARS, Animal Improvement Programs Laboratory, Beltsville, MD.*

Increasing feed costs and the desire to improve environmental stewardship have stimulated interest in improving feed efficiency of livestock, including that of US dairy herds. For instance, USDA cost projections for corn and soybean meal suggest a 20% increase over 2010 pricing for a 16% protein mixed dairy cow ration in 2011, which may lead to a reduction in cow numbers to maintain profitability of dairy production. Furthermore, an October 2010 study by The Innovation Center for US Dairy to assess the carbon footprint of fluid milk found that the efficiency of feed conversion is the single greatest factor contributing to variation in the carbon footprint, due to its effects on methane release during enteric fermentation and from manure. Thus, we are conducting research to identify the most efficient dairy cattle at conversion of feed to milk using residual feed intake (RFI), a measure used successfully to identify the most efficient beef cattle at conversion of feed to gain. Residual feed intake is calculated as the difference between predicted and actual feed intake to support maintenance and production (e.g., growth in beef cattle, or milk in dairy cattle). Selection for a lower RFI phenotype can reduce feed intake, methane production, nutrient losses in manure, and visceral organ weights substantially in beef cattle. We have evaluated RFI measures during the first 90 d of lactation for the USDA-Beltsville Holstein herd and found the heritability of RFI to be 0.16 (n = 254). A difference in net feed intake of 8.3 kg/d DM was found between the least and most efficient animals. Mean actual DMI differed by 3.7 kg/d ($P < 0.0001$) between the efficient and inefficient groups (±0.5 SD from the mean RFI of 0), with no differences ($P > 0.20$) in mean BW, ADG, or ECM exhibited between the 2 groups. These results suggest promise for using RFI in dairy cattle to improve feed conversion to milk. Previous and current research on the use of RFI in lactating dairy cattle will be discussed, as well as opportunities to improve production efficiency of dairy cattle using RFI for milk production.

Key words: dairy cow, feed efficiency, residual feed intake

5 Lactational imprinting: The mechanism underlying the mammary response to changes in milking frequency? E. H. Wall*[1], J. P. Bond[2], and T. B. McFadden[3], *[1]Department of Animal Science, University of Vermont, Burlington, [2]Vermont Genetics Network Bioinformatics Core, University of Vermont, Burlington, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Regular removal of milk from the mammary gland is critical to maintaining milk secretion. Early studies in rodents demonstrated that changes in milking frequency influenced mammary cell number, DNA content and cell activity, and blood flow. Later studies in ruminants confirmed these observations, and confirmed that the response was regulated locally within the mammary gland. In addition, it was discovered that frequent milk removal during early lactation stimulated an increase in milk production that partially persisted through late lactation, indicating long-term effects on mammary function. The local mechanisms regulating the mammary response to changes in milking frequency are poorly understood, although several have been proposed. To gain insight into the mechanisms underlying the mammary response to changes in milking frequency, and to identify genes associated with the response, we used a functional genomics approach and conducted experiments on dairy cows exposed to unilateral frequent milking (UFM; twice daily milking (2X) of the left udder half, 4-times daily milking (4X) of the right udder half). Across multiple experiments, we were unable to detect an effect of UFM on mammary cell proliferation or apoptosis. We have identified, however, distinct transcriptional signatures associated with the mammary response to milk removal, milk stasis, and UFM during early lactation. Sequential sampling of mammary tissue revealed that when UFM was imposed during early lactation, a group of genes was coordinately regulated with changes in differential milk production. Moreover, some genes were persistently differentially expressed after UFM and were associated with the long-term increase in milk yield. We conclude that a coordinated transcriptional response underlies the increase in milk yield elicited by frequent milking during early lactation, and that the transcriptional signature may be a marker for the autocrine regulation of milk production. Moreover, we propose that we have identified a novel form of imprinting associated with long-term alteration of mammary function, which we term "lactational imprinting."

Key words: gene expression, imprinting, mammary gland

6 Mammary metabolism of amino acids in dairy cows. H. Lapierre*[1], L. Doepel[2], G. Raggio[3], and S. Lemosquet[4], *[1]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]College Alfred, Guelph University, Guelph, ON, Canada, [4]UMR1080 Dairy Production, INRA, Saint-Gilles, France.*

The mammary gland (MG) is the major net user of essential AA (EAA) supply. The MG metabolism of AA is not, however, a straightforward process. In the late 70s, 2 major groups of EAA were identified: Grp 1 [His, Met, Phe (+Tyr), Trp] for which MG uptake was similar to MP output, and Grp 2 (Ile, Leu, Val, Lys) for which uptake was greater than MP output. To confirm this and to expand our knowledge of MG metabolism, we have adapted and refined techniques including: measuring net flux with AA concentrations determined by isotopic dilution on individual rather than pooled samples, and measuring total flux using AA labeled with stable isotopes. Mammary net fluxes indicate that the stoichiometric transfer of Grp 1 AA is maintained under changing supply: the uptake to output ratio (U:O) is not different from 1. Using labeled Phe, we observed that doubling Phe supply did not result in any mammary oxidation of Phe + Tyr, indicating no alteration of the U:O. For Grp 2 AA, not only does the MG remove them in excess of MP secretion, but this excess increases with increasing supply. Using labeled Leu, we observed that Leu taken up in excess of MP secretion is oxidized within the MG, and that oxidation increased further with increased Leu excess induced by duodenal casein infusion. It is hypothesized that the excess uptake of Leu (and other Grp 2 AA) can provide ATP to support increased protein synthesis induced by increased protein supply or supply carbon skeleton for the synthesis of non-EAA or both. Using labeled Lys, we observed that under normal feeding conditions, Lys U:O averaged 1.37 with the N of Lys taken up in excess mainly transferred to Glx, Asx, Ser and Ala; with Lys depletion, lower Lys mammary excess (12%) was also transferred to other AA, but at lower rates. Arg is a unique EAA

as its U:O varies between 2 and 3. Deletion of Arg from an abomasal infusate decreased the U:O from 2.5 to 2.1 but did not alter MP output, suggesting that other sources of N can cover Arg deficiency. The MG metabolism of EAA is coordinated with splanchnic metabolism: the liver removes a large fraction of the portal absorption of Grp 1 AA whereas it removes, on a net basis, little if any Grp 2 AA.

Key words: dairy cow, amino acid, mammary

7 Stress effects on postpartum reproduction in dairy cows. M. A. Crowe* and E. J. Williams, *Veterinary Sciences Centre, University College Dublin, School of Agriculture, Food Science and Veterinary Medicine, Belfield, Dublin 4, Ireland.*

The objective of the presentation is to review the effects of production stressors on reproductive performance of dairy cows. It has been well documented that genetic selection for milk yield over the last 50 years has been associated with reduced fertility. In addition to negative associations between yield and conception rate, there is also an association between milk production and expression of behavioral estrus. Stress caused by production diseases in high yielding dairy cows also contributes to the problems of poor fertility. Lameness results in reduced intensity of estrus, and can contribute to ovulation failure, which is largely due to reduced pre-ovulatory estradiol secretion and failure of the LH surge. Mastitis has been associated with prolonged intervals to dominant follicle selection, and in animals with uterine infection the dominant follicle grows slower and produces less estradiol. In a recent study we identified that milk yield was associated with an increased incidence of uterine infection, which is known to contribute to reduced fertility and prolonged calving to conception intervals. The incidence of uterine disease was 73% in high yielding, compared with 45% in low yielding cows. As well as effects at the ovary, various models of stress have also been shown to perturb endocrine secretion in the hypothalamus and anterior pituitary. In conclusion, the adverse affects on fertility associated with genetic selection for yield in dairy cows is in part associated with increased incidences of production disease induced stress but is also associated with high milk yield. Funded by SFI (07/SRC/B1156).

POSTER PRESENTATIONS

Animal Behavior and Well-Being

M1 Validation of an automated method for recording the feeding behavior of dairy cows using a Calan Broadbent Feeding System. L. M. Klaiber*, P. D. Krawczel, S. S. Thibeau, and H. M. Dann, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Assessing feeding behavior is important in understanding the effects of nutrition and management on the well-being of dairy cows. Historically, collection of behavioral data from cows fed with a Calan Broadbent Feeding System required the labor-intensive practices of direct observation or video review. The objective of this study was to validate the output of a HOBO change-of-state datalogger, mounted to the door shell and latch plate, against video data summarized with continuous sampling. Data (number of feed bin visits per day and feeding time in minutes per day) were recorded with both methods from 26 lactating cows and 10 nonlactating cows for 3 d per cow (n = 108). The agreement (established by non-significant R^2) of the datalogger and video methods was evaluated using the REG procedure of SAS to compare the mean response of the methods against the difference between the methods. The maximum allowable difference (MAD) was set at ± 3 for bin visits and ± 20 min for feeding time. Ranges for feed bin visits (2 to 140 per d) and feeding time (28 to 267 min per d) were established from video data. Using all the data, agreement was established between the datalogger and video methods for feed bin visits (P = 0.47; $R^2 < 0.005$), but was not established for feeding time ($P < 0.001$; $R^2 = 0.25$; $y = -0.64x + 92.5$). The complete data set was screened to remove visits of a duration ≤ 3 s reflecting a cow unable to enter a feed bin (7% of all data) and ≥ 5400 s reflecting a failure of the door to close properly (<1% of all data). Using the screened data set, agreement was established for feed bin visits ($P = 0.57$; $R^2 < 0.003$) and feeding time ($P = 0.13$; $R^2 = 0.01$). For bin visits, 4% of the data were outside of the MAD. For feeding time, 3% of the data were outside of the MAD and 83% of the data were within ± 3 min. The agreement between the 2 methods indicates that the use of a datalogger is a viable method for the assessment of feeding behavior for cows using the Calan Broadbent Feeding System. Use of the screening criteria before analyzing data resulting from the datalogger method is recommended.

Key words: validation, feeding behavior, Calan

M2 Animal welfare assessment of intensive dairy farms from central zone of Chile under confinement with different housing systems. M. J. Castro, C. Kobrich, and M. S. Morales*, *Departamento Fomento de la Produccion Animal, Facultad de Ciencias Veterinarias y Pecuarias, Universidad de Chile, Santiago, RM, Chile.*

The objective was to evaluate dairy welfare in 2 types of confinement systems in central Chile. Nineteen dairy farms were free stall (FS, n = 9) or California corral (CC, n = 10). Herd size ranged from 40 to 1100 lactating cows; animal welfare was assessed using the Welfare Quality® protocol for dairy cattle which considers animal based measures to evaluate the overall welfare (OW) at the farm, using 4 welfare principles: good feeding, good housing, good health and appropriate behavior, and 11 welfare criteria, giving a score (excellent, enhanced, acceptable and not classified) to each. Results from the scores by criteria, principles and OW were statistically described and analyzed by Kruskal-Wallis ANOVA using Minitab. No differences between housing systems for OW and the different principles were observed; while among the 11 welfare criteria considered in the evaluation; only absence of prolonged hunger, expression of social behavior (ESB) and good human-animal relationship (GHAR) showed statistical differences ($P \leq 0.05$) between FS and CC, where FS had higher scores for ESB and GHAR than observed for CC. The OW ranged between acceptable and enhanced, no farm showed an excellent level, and only one was nonclassified. The welfare principles good feeding and good housing among dairy farm systems ranged excellent to enhanced, while good health was acceptable and appropriate behavior ranged between acceptable and not classified. Results reflect that animal behavior generally is not considered a productive issue, whereas nutrition and feeding, housing and health management do receive more attention because of their direct effects on production. Confinement systems did not differ in measures of animal welfare quality and both systems had acceptable welfare quality. Funded by European Union-Latin American cooperative project (Nº FOOD-CT-2004–506508) and CONICYT.

Key words: animal welfare, dairy cows, housing systems

M3 Effect of dietary starch on the behavior of early postpartum dairy cows. P. D. Krawczel*[1], B. H. Nelson[1,2], H. M. Gauthier[1], L. M. Klaiber[1], R. E. Clark[1], R. J. Grant[1], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Department of Animal Science, The University of Vermont, Burlington.*

Propionate, a product of starch fermentation, may be the signal for satiety in ruminant species, which suggests that altering the starch content of a ration may alter feeding behavior. The objective of this study was to evaluate the feeding and lying behavior of multiparous dairy cows (n = 13/treatment) fed a total mixed ration containing L (21.0 ± 0.3% of DM), M (23.2 ± 0.3% of DM), or H (25.5 ± 0.3% of DM) dietary starch levels from 1 to 14 d in milk (DIM). Housing consisted of sand-bedded freestalls and a Calan Broadbent Feeding System. Following a completely randomized design, behavioral data from 8 to 14 DIM were captured using dataloggers (feeding recorded continuously and lying recorded at 1-min intervals). The bimodal distribution of intervals between visits to feed bins was used to calculate a meal criterion, which was used to establish the mean meals per day, the mean duration of each meal, and the meal time per day (active feeding time plus additional within-meal time). Lying behavior consisted of mean lying time per day and the mean daily bouts. Data were analyzed by ANOVA with the MIXED procedure of SAS using treatment and day as fixed factors and cow within treatment as a random factor. Dry matter intake increased from d 8 (19.7 ± 0.6 kg/d) to d 14 (20.7 ± 0.6 kg/d; $P < 0.001$), but no treatment or treatment by day interaction was evident ($P \geq 0.55$). Meals (10.4 ± 0.5 n/d), meal duration (17.1 ± 0.9 min/meal), and lying (696 ± 37 min/d) did not differ by treatment ($P \geq 0.36$), day ($P \geq 0.18$), or treatment by day interaction ($P \geq 0.31$). Feeding and meal times had treatment by day interactions ($P \leq 0.04$)

with the response of the L cows on d 14 (172 ± 10 min/d and 202 ± 12 min/d), relative to H (138 ± 10 min/d and 164 ± 12 min/d) and M (140 ± 10 min/d and 157 ± 12 min/d) cows, most likely responsible for this effect. A treatment by day interaction was evident ($P = 0.05$) for lying bouts, but the range of the mean of bouts (from 10 to 14) did not suggest a biologically meaningful effect. Treatment-by-day interactions suggest the possibility of behavioral responses in early postpartum dairy cows to dietary starch that merit further evaluation.

Key words: behavior, starch, transition cow

M4 Effects of a high forage prepartum diet on feeding behavior of dairy cows. L. A. Vickers*[1], D. M. Weary[1], D. M. Veira[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, BC, Vancouver, British Columbia, Canada, [2]Agriculture and Agri-Food Canada, Agassiz, British Columbia, Canada.*

Feeding higher forage diets prepartum is known to reduce energy intake before calving and improve postpartum health in dairy cows, but the effects of these diets on feeding behavior has not been described. The aim of this study was to compare the feeding behavior of cows fed either a traditional close up diet (NEL = 1.46 Mcal/kg; 24.3% concentrate, 76.8% forage) or a higher forage diet (NEL = 1.41 Mcal/kg; 13.4% concentrate, 86.6% forage) prepartum. Treatments were assigned to cow (n = 20 healthy multiparous Holsteins) within the same pen. Alternate electronic Insentec feeders provided access to feed and were programmed to allow access only to cows assigned to that diet. The number, duration and intake for each feeder visit was recorded electronically, and these data were used to calculate daily DMI, feeding time, and the number and duration of meals (with meals defined using the distribution of intervals between feeder visits). Time spent ruminating was measured using an electronic collar. All measures were recorded from 2 wk before calving until the day of calving. Cows fed the higher forage diet had lower DMI before calving (13.2 ± 0.6 vs. 16.0 ± 0.6 kg/d; $P = 0.003$), but spent more time ruminating (517 ± 12 vs. 411 ± 12min/d; $P < 0.0001$) compared with cows fed the traditional pre-calving diet. Cows on the higher forage diet ate fewer meals (9.4 ± 0.4 vs. 10.9 ± 0.4 meals/d; $P = 0.02$), but spent more time consuming meals (388.3 ± 13.8 vs. 324.3 ± 13.8 min/d; $P = 0.005$) than those on the traditional pre-calving diet. The number of separate visits to the assigned feeder (where cows were allowed access to feed) averaged (±SD) 70 ± 23 visits/d and did not differ between treatments. Cows also attempted to enter feeders assigned to the alternate treatment diet; these attempts were recorded but access to feed was denied. The number of attempted visits was higher for cows fed the higher forage vs. traditional diet (17.4; 95% CI = 17.0–22.9 vs. mean = 4.3; 95% CI = 3.5–5.2; $P = 0.02$). In conclusion, cows fed higher forage diets prepartum period consumed less DM, but ruminated more, consumed fewer and longer meals and made more attempts to access feed from the alternate treatment.

Key words: forage, dairy cow, behavior

M5 Diurnal grazing behavior of cattle fed a concentrate supplement during the dry-rainy transition season in tropical conditions. H. J. Fernandes*[1], V. Siqueira[1], L. O. Tedeschi[2], G. C. Coelho[1], L. M. Paiva[1], C. Guaraldo[1], and J. C. Souza[3], *[1]State University of Mato Grosso do Sul, Aquidauana, MS, Brazil, [2]Texas A&M University, College Station, [3]Federal University of Mato Grosso do Sul, Aquidauana, MS, Brazil.*

The objective of this study was to evaluate the effect of a concentrate supplementation on the grazing behavior of cattle under tropical conditions. Twenty-four Nellore bulls, with average initial BW of 384 ± 28.8 kg were divided into 4 groups and grazed Mombaça grass (*P. maximum*, Jacq.) pastures in the beef cattle center of the State University of Mato Grosso do Sul, in Aquidauana, Brazil, at the beginning of the transition of the dry to the rainy season. Two groups received concentrate supplementation and other 2 received only mineral supplementation. After 28 d of adaptation, animals were individually identified and their grazing behavior was observed using binoculars from 0600 to 1800 h, every 5 min, during 6 consecutive day. At each observation, the animals' behavior was classified as standing in leisure, standing ruminating, lying in leisure, lying ruminating, walking, grazing, consuming supplement, or drinking water. The total time ruminating was calculated as the sum of time standing and lying while ruminating. The total time of leisure was calculated as the sum of time standing and lying in leisure. The daily time spent in each behavior was analyzed considering the effect of the type of the supplement. The diurnal time standing in leisure in animals receiving concentrate was greater than those receiving mineral supplement (Table 1). Also the time spent on diurnal period to consume supplement was greater for those animals. The diurnal grazing time was greater for animals that received mineral supplement. The other observed behaviors were not affected by the type of supplement provided.

Table 1. Means of diurnal behavior (min/d) of cattle during the dry-rainy transition season

Behavior	Type of Mineral	Supplement Concentrate	SE	*P*-value
Standing in leisure	51.3	59.6	3.00	0.054
Standing ruminating	4.35	4.38	0.88	0.976
Lying in leisure	191	191	11.3	0.982
Lying ruminating	43.7	42.7	5.90	0.901
Total time ruminating	48.0	47.1	6.31	0.918
Total time of leisure	242	251	12.6	0.628
Walking	20.8	22.8	1.70	0.423
Grazing	392	354	7.99	0.001
Consuming supplement	9.47	37.6	1.46	<0.001
Drinking water	7.13	7.52	0.629	0.664

Key words: behavior, grazing animals, supplementation

M6 Competition and feed restriction affect feeding and competitive behavior of group-housed dairy cows. L. K. M. Collings*[1], D. M. Weary[1], N. Chapinal[1,2], and M. A. G. von Keyserlingk[1], *[1]University of British Columbia, Vancouver, BC, Canada, [2]University of Guelph, Guelph, ON, Canada.*

The effects of overstocking at the feed bunk are known, but no research has focused on the effects of restricting feed access time, or feeding to a slick bunk in group-housed cows. Our aim was to determine the effects of temporal and spatial competition on the feeding behavior of group-housed cows. Using a replicated Latin square design 48 Holstein cows were randomly assigned to groups of 6 cows; groups were assigned to either a competitive (2:1 cows:bin) or non-competitive (1:1 cow:bin) treatment and provided feed access for either 14 or 24 h/d. DMI, feeding time and rate were measured for 24 h and 2 h following fresh feed delivery for the last 4 d of the 7 d periods. Displacements were recorded for 2 h after the delivery of morning feed (peak

feeding period) and 2 h following afternoon milking. DMI tended to decline when feed access was restricted (27.0 vs. 25.7 ± 0.5 kg/d, P = 0.06), but was not affected by competition (26.4 ± 1.9, mean ± SD). Feed restricted cows had lower daily feeding times (190.9 vs. 207.9 ± 6.1 min, P = 0.005). When fed competitively restricted access cows had increased feeding rates during the day (136.9 vs. 155.6 ± 3.8 g/min, P < 0.0001) and during the peak feeding period (146.5 vs. 175.2 ± 4.3 g/min, P < 0.0001). In the peak feeding period, competitive cows had lower DMI (6.1 vs. 6.9 ± 0.3 kg/2 h, P = 0.02) and feeding times (41.5 vs. 51.6 ± 2.1 min/2 h, P = 0.0001) and increased feeding rates (160.9 vs. 137.8 ± 3.9 g/min, P < 0.0001). In contrast, feed restricted cows had higher DMI (7.8 vs. 5.2 ± 0.3 kg/2 h, P < 0.0001) and feeding time (54.7 vs. 38.5 ± 2.1 min/2 h, P < 0.0001). Restricting feed access in conjunction with limited feed bunk access resulted in the greatest increase in daily displacements (15.0 vs. 7.4 ± 1.4, P < 0.0001), with the majority of these occurring during the peak feeding period (11.2 vs. 4.8 ± 1.1, P < 0.0001). Adequate space and time to access feed is essential to minimize the welfare concerns that can arise with indoor group housing systems.

Key words: feeding behavior, competition, dairy

M7 Effect of residual feed intake in reactivity of Nellore heifers. T. L. Sobrinho[1], L. T. Egawa[2], R. H. Branco[2], E. Magnani[2], S. F. M. Bonilha[2], and M. E. Z. Mercadante*[2], *[1]Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brazil, [2]Instituto de Zootecnia, Sertãozinho, São Paulo, Brazil.*

Residual feed intake (RFI) is the difference between DMI observed and predicted by regression equation as function of mid metabolic BW and ADG. This study aimed to evaluate reactivity of Nellore heifers classified as high, medium and low RFI. The experiment was conducted at Instituto de Zootecnia - Sertãozinho/São Paulo/Brazil. Fifty-six Nellore heifers with averages of 282 kg for BW and 9 mo for age were evaluated during 6 weighings. Reactivity score was obtained using qualitative behavioral measure (temperament score), based on movement, posture, breathing, stress level and presence or absence of kicks and vocalisation being classified on scale from 1 (docile) to 5 (aggressive). High RFI animals and the low RFI ones consumed, respectively, on average, 7.13 and 6.32 kg of DM/d, corresponding to a difference of 0.810 kg of DM/d between less and more efficient animals. There was no significant difference (P = 0.4943) in reactivity among RFI levels. Docile animals when compared with the agitated ones use less energy, but the relationship between reactivity and ADG is not always antagonistic, depending of each animal. Reactivity not always defines temperament, that is a measure of complex expression, which justifies differences in physiological and productive traits.

Table 1. Performance, DMI and reactivity of Nellore heifers classified for RFI

Traits	High RFI	Medium RFI	Low RFI	P-value
n	18	21	17	
DMI, kg/d	7.13[a]	6.63[b]	6.32[c]	<0.0001
RFI, kg/d	0.406[a]	0.010[b]	−0.442[c]	<0.0001
ADG, kg/d	0.832[a]	0.858[a]	0.861[a]	0.7508
Reactivity	2.06[a]	2.47[a]	2.29[a]	0.4943

[a-c]Means within a row followed by the same letter do not differ (P > 0.05) by Tukey test.

Key words: behavior, efficiency, temperament

M8 Effect of different short- and long-term heat stress exposure periods and fescue toxicosis on the immune system. P. A. Eichen*[1], D. K. Kishore[1], M. R. Waldron[1], T. J. Evans[2], K. L. Fritsche[1], and D. E. Spiers[1], *[1]University of Missouri, Division of Animal Sciences, Columbia, [2]University of Missouri, Department of Veterinary Pathobiology, Columbia.*

Fescue toxicosis and heat stress have each been shown to independently impact immune function of animals. The primary objective of this study was to investigate how heat stress, in combination with fescue toxicosis, affects the immune system. A secondary objective was to assess the effect of length of exposure to these stressors. Rats (n = 144) were housed at thermoneutrality (TN; 21°C) and fed diets containing ergopeptine alkaloids (E+), no alkaloids (E-), or pair-fed (PF to E+) for one week. They were then divided into TN or heat stress (HS; 33°C) groups and exposed for a 3-d short-term (ST) or 21-d long-term (LT) period. Blood samples, collected at the end of the trial, were analyzed by flow cytometry for various lymphocyte subpopulations, including: T cells, natural killer (NK) cells, B cells, CD4+ and CD8+ T cell subsets. In both ST and LT, daily food intake (FI) was reduced as a result of consumption of E+ diet (50% and 40%, respectively) with additional decrease during HS. During LT HS, there was partial recovery of FI by Day 4. Individually, neither E+ nor HS in ST affected proportions of NK, T- or B-lymphocytes present in the circulation. However, acute exposure to both stressors elevated NK cells % (P < 0.05), while diminishing B-cell % in turn (P < 0.05). These changes in lymphocyte subpopulations were clearly not a consequence of FI reduction from E+ and HS, because PF to E+ rats fed to the same intake failed to show these immune cell profile shifts. In contrast to ST effects, LT exposure to HS alone elevated NK cells % (P < 0.05). However, it took the combination of LT HS and E+ exposures to reduce T-lymphocyte % in the blood (P < 0.05). In summary, acute- and long-term exposures to HS and/or E+ can lead to alterations in circulating immune cell subpopulations. Additional studies are needed to determine if such shifts in circulating lymphocytes might affect host response to infection.

Key words: heat stress, immune, fescue toxicosis

M9 Intake and feeding behavior in growing heifers fed a high concentrate diet and offered a total mixed ration or dietary components separately. S. P. Iraira, M. Rodríguez-Prado, X. Manteca, J. L. Ruíz de la Torre, S. Calsamiglia*, and A. Ferret, *Universitat Autònoma Barcelona, Bellaterra, Barcelona, Spain.*

Calves fed high concentrate diets consume low amounts of forage when dietary components are offered separately. Total mixed ration could be a good approach to promote a greater intake of roughage. Eight Simmental heifers (118 ± 3.8 kg initial BW) were used to study the effects of feeding method on intake and animal behavior in a cross-over design experiment. Treatments consisted of feeding concentrate and chopped barley straw as: 1) choice (CH; concentrate and straw in separate feed bunks), or 2) as total mixed ration (TMR; concentrate and straw mixed in one feed bunk). Feeds were offered on an ad libitum basis, but always maintaining a concentrate to straw ratio of 90 to 10. The experiment was performed in 2 21-d periods, and sampling was carried out in the last week of each period. At the end of each period, heifers changed treatment, so the final number of animals per treatment was 8. Intake was recorded over 7 consecutive days. Barley straw was coarsely chopped with a chopping machine. Animal behavior was video-recorded for 24-h on d 2 and d 6 of each sampling week. Differences were analyzed by using the MIXED procedure of SAS, for

intake variables, and the GLIMMIX procedure of SAS, for behavior variables. Concentrate intake and total DMI of heifers fed with the CH feeding method were higher than when fed with the TMR (5.1 and 5.3 kg vs. 4.7 and 5.0 kg, for CH and TMR; $P = 0.002$ and $P = 0.021$, respectively). Conversely, intake of barley straw was higher in heifers fed with the TMR feeding method than in heifers fed CH (0.21 vs. 0.31 kg, for CH and TMR; $P = 0.001$). Total NDF intake was similar in both treatments. In contrast, NDF intake from barley straw was higher in heifers fed with the TMR feeding method than in heifers fed with CH (0.16 vs. 0.23 kg, for CH and TMR; $P = 0.001$). Feeding method did not affect eating and drinking behaviors but it did affect ruminating behavior and heifers fed TMR spent more time ruminating than heifers fed concentrate and barley straw separately (287 vs. 376 min, for CH and TMR; $P = 0.007$).

Key words: feeding behavior, feeding method, high-concentrate diet

M10 Validation and cross-prediction of a single or dual accelerometers for the prediction of grazing, standing/walking, and lying behavior of beef cattle using linear discriminant analysis. M. S. Gadberry[1], W. Whitworth*[2], G. Montgomery[2], and K. Simon[1], *[1]University of Arkansas, Cooperative Extension Service, Little Rock, [2]University of Arkansas, Southeast Research and Extension Center, Monticello.*

The objective of this study was to evaluate Hoboware's Pendant G 3-axis accelerometer data logger for the prediction of grazing (G), standing/walking (SW), and lying (L) behavior in beef cattle. Three mature, nonlactating Beefmaster cows (C1, C2, and C3) of mild temperament were monitored. On Jun 28, accelerometers were halter mounted, aligned posterior to the poll (P1) or placed within a patch and adhered to the hide, caudal to the shoulder and centered over the thoracic vertebrae (P2). Data logging was programmed to begin Jun 30 at 0700 for 1 s intervals. Cattle behavior was recorded by 3 observers using a spreadsheet with a timestamp script, recording the change in cow behavior from G, SW, and L. Linear discriminant analysis (LDA) was used to predict behavior within cow using a 50% random sample as the training data set and the remaining observations as a test data set. The prediction of one cow's behavior using another cow's prediction coefficients was also examined. At 1 s intervals, logger capacity (16,270 obs) was reached at 1130. Observed time G, SW, and L differed among cows ($P < 0.001$). Among cows, the percentage of accurate predictions for G tended to differ ($P = 0.06$) for P1, P2 and combined position (P1P2), 85.5%, 81.9%, and 93.1%, respectively. Percent accuracy for L activity differed ($P < 0.001$) for P1, P2 and (P1P2), 76.4%, 97.6%, and 98.1%, respectively. Percent accuracy for SW activity differed ($P = 0.002$) for P1, P2 and (P1P2), 63.5%, 84.0%, and 91.9%, respectively. For C1 and C2, G and L could be cross-predicted with >90% accuracy. However, SW was less predictable at 36% and 67% accuracy when C1 was used as the predictor of activity for C2 and vice versa, respectively. C3 coefficients could not predict C1 or C2 and vice versa for G and SW (less than 10% accuracy). These results indicate LDA, based on 2 positions of a 3-axis accelerometer, can predict G, SW, and L with greater than 90% accuracy, however, prediction of one cow's behavior from another cow's prediction coefficients does not appear viable.

Key words: accelerometer, beef cattle, behavior

M11 Comparison of logging intervals for accelerometer predicted grazing, standing/walking, and lying behavior of beef cattle. M. S. Gadberry*[1], W. Whitworth[2], G. Montgomery[2], and K. Simon[1], *[1]University of Arkansas, Cooperative Extension Service, Little Rock, [2]University of Arkansas, Southeast Research and Extension Center, Monticello.*

Because extending logging interval for a fixed capacity data logger increases the total observation time, the objective of this study was to evaluate logging interval of Hoboware's Pendant G 3-axis accelerometer data logger for the prediction of grazing (G), standing/walking (SW), and lying (L) behavior in beef cattle. One mature, nonlactating Beefmaster cow (C1) of mild temperament was monitored. On Jun 28, an accelerometer was halter mounted and aligned posterior to the poll and another placed within a patch and adhered to the hide, caudal to the shoulder and centered over the thoracic vertebrae. Data logging began Jun 30 at 0700 for 1 s intervals. Logger capacity was reached at 1130. Cattle behavior was recorded by a single observer using a spreadsheet with a timestamp script, recording the change in behavior from G, SW, and L. Using the C1 data set, linear discriminant analysis (LDA) was used to predict behavior using separate training and test observations. Five replications of training and test samples were drawn at 60, 30, or 15 s intervals and a t-test was used to determine if the percentage of predicted time differed from actual. Training sets were >90% accurate at predicting G and L at all 3 intervals. Training sets were 83%, 91%, and 88% accurate for predicting SW using 60, 30, and 15 s intervals, respectively. Actual percentage time G, SW, and L was 27, 22.5, and 50.5%. Percentage of time predicted G at 60, 30, and 15 s intervals was 29.8 ($P = 0.03$), 23.4 ($P = 0.002$), and 31% ($P = 0.001$), respectively. Percentage of time predicted SW using 60, 30, and 15 s intervals was 25.2 ($P = 0.04$), 24 ($P = 0.05$), and 22.4% ($P = 0.88$), respectively. Percentage of time predicted L using 60, 30, and 15 s intervals was 45 ($P = 0.002$), 52.6 ($P = 0.001$), and 46.4% ($P = 0.001$), respectively. No interval produced a best match to the actual observed G and L activity. As a result, prediction inaccuracies resulting from extended logging intervals must be considered in using this technology for estimating behavior on pasture.

Key words: accelerometer, beef cattle, behavior

M12 A comparison of lipopolysaccharide-induced febrile responses across heat-tolerant and -sensitive *Bos taurus* cattle in different thermal environments. R. E. Chaffin*[1], B. Scharf[1], J. S. Johnson[1], J. K. Bryant[1], D. K. Kishore[1], P. A. Eichen[1], J. A. Carroll[2], C. C. Chase[3], S. W. Coleman[3], N. C. Burdick[2], R. L. Weaber[1], and D. E. Spiers[1], *[1]University of Missouri, Columbia, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]USDA-ARS, SubTropical Agricultural Research Station, Brooksville, FL.*

Accurate detection of fever in cattle is an important step in maintaining health of a herd. There is little information on several fronts regarding the differences in febrile response to a lipopolysaccharide (LPS) challenge. These include differences in hot (HS) and thermoneutral (TN) environments and between heat-tolerant and -sensitive cattle. Likewise, there has been no comparison of febrile responses across different regions of the body. Eighteen–month–old Angus (ANG; n = 11; 306.7 ± 25.87 Kg BW) and Romosinuano (RO; n = 10; 312.9 ± 31.96 Kg BW) heifers, all derived from Florida, were fitted with ruminal telemetric transmitters (Tru; SmartStock, Pawnee, OK), rectal temperature dataloggers (Tre; Reuter et al., JAS 88:3291), and vaginal temperature dataloggers (Tvg; iButton, Maxim, Sunnyvale, CA). Animals were housed in separate stanchions in 4 temperature-controlled environmental chambers (Brody Environmental Center, University of Missouri). Ambient temperature was within cycling thermoneutral

range (TN; 18.5–23.5°C) for a one wk adjustment period, followed by an increase in 2 chambers to cycling heat stress level (HS; 18.5–38°C) for another 2 wks. On Day 20 of study, an *Escherichia coli* (O111:B4; Sigma-Aldrich, St Louis, MO) LPS (0.5 µg/Kg BW) was administered intravenously to all heifers at approximately 1000 h. Although LPS effect on Tru showed no differences ($P > 0.05$) across breed or environment, there was an approximate 1°C increase in HS animals within 5 h following injection. Tre increased by over 2.0°C within 5 h of injection, with higher values (~0.4°C; $P < 0.05$) for ANG versus RO and HS versus TN. During HS, RO heifers appeared to exhibit the largest increase in Tre. Although Tvg increased by over 2°C 6 h post-LPS injection ($P < 0.05$), there were no general breed or environment differences. These results show that there are regional differences in thermal response to LPS injection, with Tre providing the greater separation across breed and environment. Additional studies are needed to verify a heat-induced increase in the febrile response following an LPS challenge.

Key words: heat stress, cattle, LPS

M13 Effects of alternative housing and feeding systems on the performance of dairy heifer calves. J. A. Pempek*, M. L. Eastridge, N. A. Botheras, C. C. Croney, and W. S. Bowen, *The Ohio State University, Columbus.*

This study investigated the effects of housing and milk feeding method on the production performance of dairy calves. Eighty-two female Holstein calves were allocated to treatments at 6 ± 3 d of age and monitored for approximately 9 wk. Treatments were as follows: individual housing fed with a bucket, individual housing fed with a bottle, paired housing fed with a bucket, or paired housing fed with a bottle. Two experimental sites were utilized. Calves were housed in hutches (non-tethered, wire pen) at Site 1 (n = 34) and in wire-panel pens in a feed commodity shed at Site 2 (n = 48). Calves allocated to the individual treatment were housed in a single hutch at Site 1, whereas calves assigned to the paired treatment were housed by joining 2 adjacent hutches with doubling of the pen size. Pasteurized whole milk was fed via bucket or bottle twice a day (6 L/d). Calves had ad libitum access to calf-starter (same at both sites) and water. Gradual weaning commenced at wk 6 by reducing the calves' milk allowance by 2 L/wk. Calves were weaned at the beginning of wk 8. Grain consumption and body weight were monitored on a weekly basis and wither height measured at the beginning and end of the experiment. Data were analyzed using the MIXED model procedure of SAS. Total DM intake (grain and milk solids) was higher for calves housed in pairs compared with those housed individually (1764 ± 28 versus 1686 ± 27 g/d; $P = 0.04$). Average daily gain (ADG) was higher for Site 1 compared with Site 2 (1.6 ± 0.05 versus 1.4 ± 0.05 kg/d; $P = 0.001$). Bottle feeding also increased ADG compared with bucket feeding (1.6 ± 0.04 versus 1.4 ± 0.05 kg/d; $P = 0.01$). Change in wither height was greater at Site 1 (13.5 ± 0.5 versus 9.5 ± 0.4 cm; $P < 0.0001$) and for calves housed individually (12.2 ± 0.4 versus 10.8 ± 0.5 cm; $P = 0.03$). In conclusion, housing young calves in pairs may enhance performance due to social facilitation.

Key words: dairy calves, paired housing, performance

M14 Environmental enrichment influence on feedlot cattle performance. B. J. Howell*[1], J. R. Brethour[2], and J. R. Jaeger[2], *[1]Fort Hays State University, Hays, KS, [2]Kansas State University, Hays.*

Feedlot cattle are able to consume feedstuffs rapidly, quickly meeting DM intake requirements, and therefore have much more idle time in a confined space compared with grazing animals. The objective of 2 experiments was to investigate the effects of providing an environmental enrichment device consisting of a large brush on live and carcass performance in steers in a feed yard environment. In Exp. 1, yearling crossbred steers (n = 156) were allotted by weight to 2 treatments, no brush (control) or access to a brush (brush). Steers were fed for 73 d using 3 replications per treatment (n = 26 hd/replication). Steers were implanted with Synovex Plus and were not treated for parasites. In Exp. 2, yearling crossbred steers (n = 165) were blocked by weight and projected harvest date to 3 replications per treatment (n = 25 to 33 hd/replication). Steers had been previously implanted with Synovex-S, and were treated with Atroban for lice. Replication 1 was harvested (48 d), replication 2 (80 d), and replication 3 (110 d). All cattle were fed a high-energy finishing ration comprised primarily of dry-rolled milo and included sorghum silage, soybean meal, urea, ammonium sulfate and 300 mg Rumensin, 90 mg Tylan, and 30,000 IU Vitamin A per head. The brush treatment increased 12th rib fat thickness in Exp. 1 ($P < 0.05$), but not in Exp. 2 ($P > 0.05$). No differences ($P > 0.05$) were observed between treatments for average daily gain, dressing percentage, calculated yield grade, marbling, proportion grading Choice, kidney, or pelvic and heart fat. Daily dry matter intake was not different between treatments in Exp. 1 ($P > 0.10$), but was greater ($P = 0.03$) in Exp. 2 for steers housed with a brush compared with control steers (13.02 vs. 12.73 kg, respectively). Continual interaction occurred with the brush device in all brush replications throughout both trials, indicating it did provide a stimulus for the cattle.

Key words: environmental enrichment, beef cattle, feedlot

M15 Lack of the expressive associations between temperament, aggression and weight gain in finishing weight feedlot cattle. D. R. Soares*[1], K. Schwartzkopf-Genswein[2], A. C. Sant'anna[1], T. da Silva Valente[1], P. M. Rueda[1], J. N. dos Santos Gonçalves Cyrilo[3], and M. J. R. P. da Costa[4], *[1]Sao Paulo State University, Animal Science Posgraduation, Jaboticabal, Sao Paulo, Brazil, [2]Agriculture and Agri–Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada, [3]Animal Science Institut of Sertaozinho, Sertaozinho, Sao Paulo, Brazil, [4]Animal Science Department, Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

The aim of this study was to determine the relationship between temperament, aggressive behavior and average daily gain (ADG), in feedlot cattle. Behavioral observations were conducted for 10 d (0700 to 1800) using a continuous sampling method. Fifty–3 bulls (35 Nelore and 18 Nelore cross with an average age of 30 ± 3 mo.) were observed in one feedlot pen. The frequencies of 2 types of aggressive behavior were recorded: displacement (DISP; physical contact where the initiator pushed with his head, horn or body resulting in a change in the receivers position) and non-displacement (NDISP; as described above, without any change of the receivers position). Temperament was assessed, in the pen during at weights registers on d 1, d 29 and d 54 at the end of fattening period, using flight distance (FD: proximity (m) to which a stock person could come to an individual animal before it would move away) and flight speed (FS: speed (m/s) at which the animal exited a handling chute). Average daily gain was calculated using animal weights obtained on d 1 and d 54 at the end of the fattening period and Pearson correlation coefficients were estimated for all variables. There were significant positive correlations ($P < 0.05$) between FD and FS (r = 0.58), DISP and NDISP (r = 0.74) and negative correlations between NDISP and FS (r = –0.29). No correlations

($P > 0.05$) were observed between NDISP and FD (r = –0.17), DISP and FD (r = –0.06), DISP and FS (r = –0.13), or between ADG and any of the other variables (NDISP: r = 0.07, DISP: r = 0.03, FD: r = 0.09 and FS: r = –0.03). Based on these results we conclude that there is no expressive association between temperament, intra-specific aggression, or ADG. Financial support: CNPq and ETCO Group.

Key words: behavior, confinement, reactivity

M16 Relationship between temperament, blood flow and area in the external jugular vein, and body temperature in crossbred beef calves. H. L. Sanchez-Rodriguez*, R. C. Vann, E. Baravik-Munsell, S. T. Willard, and P. L. Ryan, *Mississippi State University, Mississippi State, MS.*

The relationship between temperament, blood flow and dimension of the external jugular vein, and body temperature was assessed in Angus crossbred calves [223.4 ± 33.2 kg BW; 262.72 ± 24.94 d old (mean ± SD)] during December, 2010. An average between exit velocity and pen score was used to classify the calves according to their temperament (calm, intermediate, and temperamental). Calves (n = 91) were weighed and the hair of the neck over the jugular vein was clipped. Pulsatility Index (PI) and area of the lumen of the external jugular vein were measured via Duplex Doppler and B mode ultrasound, respectively. The luminal area of the jugular vein was standardized by body weight. Rectal and superficial temperatures of the neck region (over the hair and over the skin) were also recorded. Blood samples were collected for future plasma cortisol analysis. There was a tendency for higher PI values ($P = 0.09$) in temperamental than in calm calves [1.78 ± 0.16, 1.87 ± 0.15, and 2.28 ± 0.18 for the calm (n = 31), intermediate (n = 32), and temperamental (n = 28) groups, respectively]. Luminal areas of the jugular vein were not affected by temperament ($P = 0.65$; 0.254 ± 0.016, 0.242 ± 0.015, and 0.263 ± 0.018 mm^2/kg BW for the calm, intermediate, and temperamental groups, respectively). Rectal temperatures were greatest ($P = 0.01$) in temperamental than in calm and intermediate calves (39.38 ± 0.13, 38.92 ± 0.12, and 38.90 ± 0.11°C, respectively). There was no effect of temperament on the superficial temperature of the hair ($P = 0.10$; 24.08 ± 0.65, 26.00 ± 0.61, and 25.15 ± 0.72°C) or the skin ($P = 0.84$; 33.23 ± 0.55, 33.59 ± 0.51, and 33.17 ± 0.61°C) in the neck region for the calm, intermediate, and temperamental calves, respectively. In this study there was a relationship between temperament and some important indicators of the animal′s physiological status (internal body temperature and Pulsatility Index). The effect of these physiological changes can influence the performance of beef cattle and therefore these markers may be beneficial in developing better tools for selection of beef cattle.

Key words: beef calves, temperament, blood flow

M17 Pre-separation behavior of calves being weaned by different methods. H. T. Boland*[1,5], S. T. Willard[2], K. Umemura[3], G. Scaglia[4], J. A. Parish[5], and T. F. Best[1], *[1]Mississippi State University, Prairie Research Unit, Prairie, [2]Mississippi State University, Department of Biochemistry and Molecular Biology, Mississippi State, [3]National Agricultural Research Center for Hokkaido Region, Toyohira, Sapporo, Japan, [4]Louisiana State University Agricultural Center, Iberia Research Station, Jeanerette, [5]Mississippi State University, Department of Animal and Dairy Sciences, Mississippi State.*

Two-stage weaning can potentially reduce stress associated with abrupt weaning of calves. British crossbred beef cattle (n = 96 cow-calf pairs) were used to evaluate 3 weaning methods: "one-size fits all" nose-clips (ONE), adjustable size nose-clips (ADJ), and fence-line weaning (FL). In a fourth control treatment group (CTRL) calves remained in pastures with their dams. Nose-clips were placed on ONE and ADJ calves on d −4 and FL calves were placed in pastures adjacent to their dams on d −4. All calves were completely separated from cows the morning of d 0. Calves wore bite counters and IceTag sensors to evaluate pre-separation grazing behavior and locomotor activity. Three trial periods were conducted in sequential weeks in Fall 2010. There were 2 replicate groups (4 cow-calf pairs per group) of each treatment per wk and each group grazed an area of 2.0 ha. Pasture assignment was randomized for treatment each week to minimize effects of differently shaped paddocks on behavior. A standard stride length of 65 cm was used to estimate distance traveled. Data were analyzed using PROC MIXED of SAS. There was no effect of weaning method on number of bites and steps, distance traveled, and time spent standing or lying per day ($P > 0.05$). On d −4, bites/d were less while steps/d and distance traveled/d were greater compared with d −3, −2, and −1 ($P < 0.05$). This was likely due to cattle being handled the morning of d −4 to start the experimental treatments and being introduced to new pastures. Unseasonably high ambient temperatures during wk 1 may have led to an effect of wk ($P < 0.05$) on bites/d with values being less in wk 1 than wk 2. Average high temperatures during wk 1, 2, and 3 were 36, 27, and 25°C, respectively. Time spent standing was greater, and consequently time spent lying was less in wk 1 compared with wk 3 ($P < 0.05$). On d −4 FL calves spent more time standing ($P < 0.05$) than CTRL calves, but only tended ($P = 0.07$) to stand more than ONE calves. The data indicate that use of these gradual weaning methods did not greatly alter behavior of calves during the first stage of the weaning process compared with calves that continued to nurse.

Key words: weaning methods, grazing behavior, pedometers

M18 Predictors of body thermal status in heat-tolerant and -sensitive *Bos taurus* cattle exposed to different temperature loads under controlled conditions. D. E. Spiers*, H. L. Vellios, P. A. Eichen, B. Scharf, J. S. Johnson, D. K. Kishore, and R. L. Weaber, *University of Missouri, Columbia.*

There have been attempts to derive predictors of thermal status for cattle, with the ultimate goal of developing practical models. There have been few studies under controlled conditions that have compared cattle with different sensitivities to thermal stress. There has been little attempt to identify shifts in predictors of thermal strain that occur with adaptation to heat stress. The present study evaluated multiple potential determinants of thermal status over repeated exposures to heat stress to determine shifts in correlation coefficients (R). Heat-sensitive Angus steers from Oklahoma (n = 6 per trial) and Missouri (n = 6 per trial) were compared against heat-tolerant Romosinuano steers (n = 5 per trial) from Florida in the Brody Environmental Center (University of Missouri). Air temperature (Ta), rectal temperature (Tre) and respiration rate (RR), as well as skin temperatures for ear, shoulder, rump, upper tail and lower tail were measured hourly for 24 h during one day midway through each temperature interval. Two different groups of animals were used in 2 separate trials. Cattle were exposed to a constant 20–22°C (TN) for 8 d, followed by 2 separate 7 d cyclic heat stress (HS) periods. Ta in Trial 1 cycled 26–36 then 28–37°C for the 2 cycles, and in Trial 2 cycled 28–38 then 30–40°C. In no case was Ta a reliable predictor of Tre or RR. Likewise, there was no skin temperature or Tre that served as a reliable determinant ($P > 0.05$) of RR. All additional comparisons examined skin temperature predictions of Tre. Trunk sites were closely related ($P < 0.05$) across breed and environment (TN and HS), with lower R between extremities. Rump and

shoulder sites were better Tre predictors under all conditions. Shift from TN to HS environments generally increased R from ~0.50 to 0.60. Use of only times when daily Ta increased (0500 to 1500) further improved R (~0.70) for many sites. Trial 2 with higher Ta did not increase R. Trunk temperature, and not RR or Ta, during the daily temperature rise is the best predictor of rectal temperature across heat-tolerant and -sensitive breeds.

Key words: cattle, heat stress, model

M19 Sexual behavior of Nellore cattle in the Pantanal. J. C. DeSouza*[1], U. G. P. Abreu[2], J. R. B. Sereno[3], C. H. M. Malhado[4], J. A. Freitas[5], P. B. Ferraz Filho[6], H. J. Fernandes[7], R. L. Weaber[8], and W. R. Lamberson[8], *[1]Mato Grosso do Sul Federal University – UFMS/ Animal Science, Aquidauana, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuária - CPAP-EMBRAPA, Corumbá, Brazil, [3]Empresa Brasileira de Pesquisa Agropecuária - CPAC - EMBRAPA, Brasília, DF, Brazil, [4]South of Bahia State University - UESB, Bahia, Brazil, [5]Parana Federal University - UFPR, Palotina, Brazil, [6]Mato Grosso do Sul Federal University - UFMS, Tres Lagoas, Brazil, [7]State University of Mato Grosso do Sul, Aquidauana, Brazil, [8]Animal Sciences, University of Missouri, Columbia.*

The objective of this study was to evaluate the sexual behavior of Nellore bulls and cows by observing the duration of courtship, the hierarchy of bulls, the distance maintained between bulls, and the behavior of Nellore cows with respect to the choice of bull in a natural service mating system in the Pantanal Region of Mato Grosso do Sul, Brazil. Behavior was observed between 6:00 a.m. to 7:00 p.m. for a total of 380 h over 2 years. Thirty-six bulls were observed, of which 9 were more than 60 mo old, (GE5); 15 were 24 to 30 mo in year one (GE2_3) with 12 of these retained for a second year (GE2_4). The bull to cow ratio was 1:20 (average). All bulls from GE5 group maintained 10 M separation from each other, with one being the leader in a clear hierarchy. When GE2_3 bulls, in lots of 3, were exposed to cows, they spent the first days together, interacting through touching, licking and smelling each others' testicles. From the third day on, they started to exhibit the Flehmen response and mounting cows, but without completing sexual intercourse. The first service was observed on d 5. The hierarchical ranking among GE2_3 bulls was established only in the second year. Bulls from GE2_4 group were more precocious, completing sexual intercourse by the third day. A total of 32 matings were observed with 6 being repeated. Only 5 of the 26 serviced cows were observed to choose the male to mate. Among the 26 first matings, 11 took place before 10:00 a.m., 8 occurred from 10:00 a.m. to 4:00 p.m., and 13 occurred after 4:00 p.m. The mean duration of courtship was 68.45 min; and ranged from 17 to 186 min. Of the observation courtship, 75.76% lasted 60 min or less, 15.15% lasted between 60 and 120 min, and 3.0% lasted more than 120 min (Chi-Square = 26.91; $P < 0.0001$). It was observed in many cases that the bull and cows copulation once and then part with no further courtship or copulation. The presence of hierarchical (dominant) bulls may hinder fertility rate since it results in uneven distribution of matings among bulls.

Key words: courtship, ethology, Nellore

M20 Behavioral reactivity to psychosocial stress determines the effects of lavender oil on anxiety in sheep. P. Hawken[1], C. Fiol*[2], and D. B. Blache[1], *[1]UWA Institute of Agriculture (Animal Production), The University of Western Australia, Perth, Western Australia, Australia, [2]Departamento de Bovinos, Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

The aim was to determine the effects of lavender (*Lavendula augustofolia*) oil on individuals that innately differ in their reactivity to stress. Merino ewes (n = 24) selected for high (nervous) and low (calm) expression of behavioral reactivity to isolation were allocated to 1 of 4 groups: Calm Lav; Calm Con; Nerv Lav; Nerv Con. Ewes were fitted with a mask that contained wool scented with 10% lavender (Lav) or peanut (Con) oil for 30 min before entering an isolation box for 5 min. Agitation score and activity in the box were recorded using a video camera and calibrated agitation meter. Blood was sampled before fitting the mask; before entering and after exiting the box, and 30 min after exiting the box. Behavioral and cortisol data were analyzed with 2-way and repeated measures ANOVA, respectively. Agitation score, central line crosses, vocalizations, and cortisol after exiting the box were lower for calm than nervous ewes, irrespective of exposure to Lav (Table 1; $P < 0.001$). Exposure of calm ewes to Lav decreased vocalizations, central line crosses (Table 1; $P < 0.05$), and cortisol before entering the box compared with calm control (14.6 ± 0.9 vs. 24.4 ± 3.4 ng/mL; $P < 0.05$). Among the nervous ewes, exposure to Lav increased vocalizations, escape attempts (Table 1; $P < 0.05$), and cortisol 30 min after exiting the box (37.1 ± 5.8 vs. 14.8 ± 3.0 ng/mL; $P < 0.05$). In conclusion, lavender decreased anxiety in sheep selected for calm temperament but increased some measures of anxiety in sheep selected for nervous temperament. Differences in behavioral reactivity to psychosocial stress appear to determine the effect of lavender oil on anxiety in sheep.

Table 1.

	Calm Con	Calm Lav	Nerv Con	Nerv Lav
Agitation score	67.8±20.0^{a}	28.1±7.46^{a}	299±43.8^{b}	374±72.0^{b}
Central line crosses	16.6±4.23^{a}	3.42±0.81^{b}	53.8±4.38^{c}	57.2±6.18^{c}
Vocalizations (bleats/min)	1.95±0.86^{a}	0.34±0.19^{b}	5.60±1.01^{c}	9.2±1.13^{d}
Escape attempts	1^{ab}	0^{ac}	0^{ac}	4^{b}
Mean cortisol after exiting box (ng/mL)	32.0±2.8^{a}	34.6±1.0^{a}	58.5±4.2^{b}	53.3±1.5^{b}

$^{a-d}$Different superscripts indicate significant differences between treatments (at least $P < 0.05$).

M21 Characteristics and welfare of horses used for transportation in northeast Ohio. K. Bennett-Wimbush*, M. Amstutz, and D. Willoughby, *Ohio State University Agricultural Technical Institute, Wooster.*

Horse transportation is common in some geographical locations, often dictated by cultural beliefs and practices. However, little information is available on welfare issues concerning this sub-segment of the US equine population. The purpose of this study is to characterize factors that influence travel speed and document welfare and safety concerns of horses used as primary modes of transportation. Horse drawn vehicles/riders (n = 306) were observed at 8 different locations, representing 3 distinct communities in northeast Ohio during summer 2010. Environmental conditions (slope, heat index), gait characteristics (hitch, gait, speed, lameness) and driver/rider factors (gender, vehicle type, safety equipment) were recorded. Differences between variables

were determined by Least Square Means, GLM and Fisher's Exact Test, SAS. Travel speed was correlated with terrain slope ($P < 0.01$), community ($P < 0.001$), heat index ($P < 0.05$), gait ($P < 0.001$) and lameness grade ($P < 0.05$). Most notably, horses traveled slower uphill (slope > 1.0), during periods of high (>25°C.) heat index and when exhibiting a grade 3 lameness, using the AAEP 0–5 lameness scale. Overall, there was a trend ($P = 0.10$) for double hitches to travel slower than single hitches. Travel speed within vehicle type was observed. Wagons (4.63 ± 0.25 m/sec) traveled slower ($P < 0.01$) than buggies (5.00 ± 0.10 m/sec) which traveled slower ($P < 0.05$) than open buggies (5.35 ± 0.13 m/sec). This was most likely due to the vehicle and cargo weight. Pacing accounted for 2.6% of the observations at 5.14 ± 0.38 m/sec while 92.8% of the horses trotted (5.14 ± 0.07 m/sec), although speeds were not different. Grade 3 lameness was observed in 4.1% of the horses which slowed ($P < 0.05$) travel speed to 4.23 ± 0.35 m/sec compared with non-lame horses (5.07 ± 0.07 m/sec). Youth drivers were more likely to drive lame horses than women or adult men. The frequency of displayed slow-moving vehicle signs on horse drawn vehicles varied by community from 41.3 to 94.6%. This is a safety concern for both the occupants and animals. In this study, lameness was minimal and appropriate animal welfare allowances were observed.

Key words: equine, welfare

M22 Female mate choice in the domesticated goat (*Capra hircus*). K. M. Longpre* and L. S. Katz, *Rutgers University, New Brunswick, NJ.*

Female mate choice is the tendency for females to distinguish among and mate selectively with one specific phenotype. In promiscuous species such as the goat, in which males contribute genes only, females should choose to mate with high quality males. This sexual selection can account for the display of dimorphic characteristics not attributed to Darwin′s theory of natural selection. Female mate choice has not been studied in most domesticated species, in part due to single-male breeding programs and the use of artificial insemination. Both of these practices inhibit the opportunity for mate choice. Therefore, the appearance of mate choice in a domesticated species, when the environment or management system allows it to be expressed, suggests that the underlying mechanisms of mate choice are robust. We find that female goats are able to distinguish among and show preference for males with higher serum testosterone (T) concentrations ($P < 0.05$). Our studies indicate that morphological cues, specifically T-dependent neck and shoulder musculature are not used to distinguish among males. Instead, females use T-dependent physiological and/or behavioral cues, which increase in frequency and intensity during the breeding season, to assess potential mates. Specifically, males that emit potent chemical cues ($P < 0.001$) and high frequency courtship cues ($P < 0.001$) are preferred by estrous females. It is males with higher circulating T concentrations that emit more potent chemical cues ($P < 0.05$), and display higher frequency courtship cues ($P < 0.01$). Furthermore, high circulating T concentrations impose high energetic costs as males with higher T concentrations lose more body weight during the breeding season ($P < 0.05$), likely due to the increased frequency of T-dependent behavior expression. We conclude that female mate choice exists in the domestic goat, and circulating T concentrations and the resulting T-dependent behaviors in males may serve as an honest indicator of a male′s overall quality.

Key words: goats, sexual selection, mate choice

M23 Effects of spray-dried porcine plasma (SDPP) administered as an oral gavage on indicators of health, welfare, and performance in pigs transported after weaning. L. M. Wittish* and M. J. Estienne, *Virginia Polytechnic Institute and State University, Blacksburg.*

Transportation of swine is an emerging welfare issue, especially for pigs weaned and then transported to other farms for grow-finish. Weaned pigs fed starter diets containing SDPP show improved growth performance. The objective of this study was to determine the effects of SDPP, administered as an oral gavage during suckling, on indicators of health, welfare, and performance in transported weaned pigs. At weaning (4 wk of age), pigs were assigned to one of 4 treatments: I. SDPP (0.375 g/mL) + transport, II. Water + transport, III. SDPP + no transport, and IV. Water + no transport (n = 10 barrows and 10 gilts per treatment). Pigs received 25 mL of the assigned gavage 2x/d for 5 d before weaning. Pigs were moved from the farrowing barn, loaded on a livestock trailer and transported on a 5-h roundtrip or were moved directly to the on-site wean-to-finish barn. Rectal temperatures and blood samples were obtained at weaning and after relocation. Pig BW was determined at weaning, after relocation and at weekly intervals for 5 wk thereafter. Rectal temperature increased in all groups, but the magnitude of increase was greatest for groups I and II (treatment x time, $P < 0.01$). Effects of treatment x time ($P < 0.01$) were detected for several blood measures. Creatinine levels increased in all groups, but the magnitude was greatest for groups I, II, and III. Circulating concentrations of cortisol, urea nitrogen, and chloride increased, and calcium decreased, in groups I and II only. Potassium increased in group I only. That levels of phosphorous and sodium increased in group II only suggests a protective effect of prior treatment with SDPP in transported pigs. There was a trend ($P = 0.08$) for an effect of treatment x time for BW, and BW were greater at wk 4 and 5 after weaning for group I compared with group IV. In summary, transportation impacted physiological indicators of health and welfare in weaned pigs. Providing SDPP before weaning prevented transportation-induced changes in blood levels of phosphorous and sodium.

Key words: pig, spray-dried porcine plasma, transportation

M24 Castration is no laughing matter, nitrous oxide can′t even help. J. L. Rault*[1] and D. C. Lay[2], [1]*Department of Animal Sciences, Purdue University, West Lafayette, IN,* [2]*USDA-ARS-Livestock Behavior Research Unit, West Lafayette, IN.*

Surgical castration is performed on all male pigs in the United States. However, castration is painful and analgesics are being considered to relieve pain. Inhalant gases with analgesic properties allow for a fast induction, short-term and reversible effects, and are a needle-free option. Isofluorane, halothane and carbon dioxide have been tested to alleviate castration-induced pain in pigs with variable success. The use of those gases also raises practical or ethical concerns. Nitrous oxide (N_2O) or "laughing gas" has been widely used in human surgery and dental offices as an analgesic, sedative and anxiolytic drug. Yet, N_2O has not been thoroughly investigated for use in farm animals. N_2O possesses appealing features for the animal industry: It is not regulated as a drug, it is widely available, relatively inexpensive, and harmless. We hypothesized that the analgesic effect of N_2O may reduce the pain induced by castration. We used 24 piglets from 12 litters, one piglet receiving N_2O (N) and a littermate receiving air as a control (C). After 150 s under the gas, castration was performed while the piglet remained under the gas. Behaviors and squeal lengths were recorded during castration. Behavioral observations were continued for 3 d

using a scan-sampling interval recording method, and weight gain was measured. Data were analyzed using a mixed model in SAS. N_2O successfully induced anesthesia in all N pigs, as validated by a skin pinch test and the loss of palpebral reflex. Squeal length was shorter in N pigs during the induction phase ($P < 0.001$) but not different during castration itself as N pigs awoke and squealed as much as C pigs. Agitation scores during the whole procedure were reduced in N pigs, in both frequency ($P = 0.02$) and intensity ($P = 0.02$). For 2 h following castration, N pigs displayed less huddling behavior than C pigs ($P < 0.05$). Over the 3 d, N pigs performed more tail wagging ($P < 0.01$) and slept less ($P < 0.05$) than C pigs. N_2O was effective in inducing anesthesia in neonatal pigs. Nonetheless, its anesthetic effect seemed ineffective in preventing castration-induced pain.

Key words: castration, analgesic

M25 The effect of using carbon dioxide gas and/or a NSAID to reduce the pain associated with castration in pigs. B. L. Davis*[1] and M. A. Sutherland[1,2], *[1]Texas Tech University, Lubbock, [2]Ruakura Research Centre, AgResearch, Hamiliton, New Zealand.*

Surgical castration is routinely conducted on commercial swine farms to prevent boar taint and reduce aggressive behaviors. However, the procedure of castration causes acute pain which is an animal welfare concern. The objective of this study was to evaluate the effect of general anesthesia (carbon dioxide: CO2) and a non-steroidal anti-inflammatory drug (NSAID) either singularly or combined on the pain caused by castration in pigs. Pigs were allocated to one of 7 treatments (n = 10 pigs per treatment): 1) sham castration (CON), 2) administration of CO2 only (CO2), 3) administration of NSAID only (NSAID), 4) castration (CAS), 5) castration while the pig was anaesthetized with CO2 gas (CAS+CO2), 6) castration plus NSAID administered at the time of castration (CAS+N), and 7) castration conducted while the pig was anesthetized with CO2 plus NSAID administered at the time of castration (BOTH). Blood samples were collected before (0), and 30, 60, 120, 180 min after administration of treatments for analysis of cortisol concentrations. Behavior was recorded (live observations) in the farrowing crates using 1-min scan sampling for up to 180 min after castration. Body weight was measured before and 24 h after experiment. Data were analyzed using the MIXED procedures of SAS. Cortisol concentrations were elevated ($P < 0.005$) in all castrated pigs 30 min after castration regardless of pain relief treatment. Cortisol concentrations remained elevated ($P < 0.05$) in CAS pigs for up to 180 min after castration, but were lower in CAS-CO2 pigs at 60, 120, and 180 min after castration as compared with pigs castrated without pain relief. Pigs castrated without pain relief spent more ($P < 0.05$) time lying without contact compared with non-castrated pigs and CAS+N and BOTH pigs spent less ($P < 0.06$) lying without contact compared with CAS pigs. Change in body weight did not differ ($P > 0.05$) among treatments 24 h after castration. Pain relief in the form CO2 and/or a NSAID appeared to have some beneficial effects on the physiological and behavioral response to castration in pigs.

Key words: pigs, castration, welfare

M26 The effects of group size on aggression when mixing unacquainted sows in outdoor paddocks. J. N. Marchant-Forde*[1], J. P. Garner[2], A. K. Johnson[3], R. M. Marchant-Forde[2], and D. C. Lay[1], *[1]USDA-ARS, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, [3]Iowa State University, Ames.*

Aggression is a challenge when pigs are kept in groups. Sows fight at mixing when space is limited but this project sought to determine the amount and type of aggression observed when unacquainted Berkshire sows were mixed in pairs or in 2 established sub-groups of 3 in outdoor paddocks. Treatment 1 (PR) used 16 pairs of sows mixed into a 5000 m^2 paddock. Treatment 2 (GP) used 28 unacquainted groups of 3 sows, with 2 groups mixed into a 5000 m^2 pen. Behavior was recorded continuously for 60 min post-mixing and all-occurrences sampling was used to extract social interactions. The data were analyzed to determine the number of social interactions that did or did not contain aggressive components (i.e., pushing, knocking or biting) and fighting defined as interactions that contained 10 or more reciprocated, aggressive component actions. Within each interaction, data were analyzed to determine the number of component actions and the number of aggressive component actions. The data were compared using a GLM, with treatment as a fixed effect. The number of social interactions was similar in GP (15.7 ± 2.7) and in PR (14.4 ± 2.5, $P < 0.001$). The number of interactions that contained aggression was also similar (6.9 ± 1.4 v. 5.6 ± 1.2, $P > 0.05$), but GP interactions contained more aggressive components (26.8 ± 2.5) than PR interactions (16.6 ± 1.4, $P < 0.05$). Twelve of the 16 PR pairs fought and aggression occurred quickly, beginning with biting after 2.1 ± 0.4 interactions and 17.3 ± 6.9 components. In GP mixing, 8.5 ± 0.3 of the 15 possible pair combinations per group interacted, of which 5.6 ± 0.4 interacted aggressively and 1.5 ± 0.4 fought. A higher proportion of unacquainted pairs interacted aggressively (0.57 ± 0.07) and fought (0.17 ± 0.05) than acquainted pairs (0.10 ± 0.04 and 0 respectively, $P < 0.01$). Bites were delivered quickly after 2.2 ± 1.7 interactions and 9.2 ± 2.6 components. Mixing pairs or groups of sows in paddocks did not prevent aggression. Aggression occurred quickly but reduced rapidly, with sows using space for avoidance. The results further our understanding of aggression at mixing and will help to identify best practice for producers.

Key words: aggression, pigs, mixing

M27 Association of sow fear with prolactin and cortisol concentrations pre- and post-farrowing. C. E. Phillips*[1], Y. Z. Li[2], L. J. Johnston[2], G. C. Shurson[1], J. Deen[4], and C. Farmer[5], *[1]University of Minnesota, St. Paul, [2]West Central Research and Outreach Center, Morris, MN, [3]University of Minnesota-Morris, Morris, [4]College of Veterinary Medicine, St. Paul, MN, [5]Agriculture and Agri-Food Canada, Dairy and Swine R & D Centre, Sherbrooke, Quebec, Canada.*

A study was conducted to investigate associations among sow fear and circulating concentrations of prolactin and cortisol peripartum. Multiparous sows (n = 63) were subjected to human approach and novel object fear tests on wk 12 post-breeding. A fear score for each sow was calculated using Principal Component Analysis. Fear scores ranged from 0 to 7.88. Sows were classified as fearful (n = 31, scores = 7.32 ± 0.42) or less fearful (n = 32, scores = 4.36 ± 1.83). A subset of sows (7 fearful; 7 less fearful) from 2 winter farrowing groups were chosen to collect blood samples. Two days before the expected farrowing date of the first sow, sows were moved into the farrowing facility, anesthetized, and had an indwelling ear vein catheter inserted. The farrowing facility housed 8 sows, where sows shared a communal area and farrowed in individual pens. A blood sample was collected from each sow 2 d pre-farrowing, the day of farrowing, and 2 d post-farrowing between 1000 and 1100h. Catheters in 11 sows (5 fearful and 6 less fearful) remained functional for the sampling period. Serum samples were analyzed for prolactin and cortisol concentrations using RIA. Data were analyzed using repeated measures for day with the Glimmix

Procedure of SAS. There was no association ($P > 0.60$) of sow fear with prolactin (fearful 37.7 ± 3.8 ng/ml, less fearful 37.8 ± 3.7 ng/ml) or cortisol (fearful 4.2 ± 0.5 ug/dL, less fearful 4.5 ± 0.5 ug/dL) concentrations on any day. Prolactin concentrations 2 d before farrowing were lower ($P < 0.01$) than on all other days. Cortisol concentrations 1 d before farrowing and the day of farrowing were greater than 1 d post-farrowing ($P < 0.05$) and 2 d post-farrowing ($P < 0.01$). Results corroborate an increase in prolactin concentrations in sows on the day before farrowing to initiate the lactogenic process. They also suggest that cortisol concentrations are indicative of a greater stress level closest to the time of farrowing. Nevertheless, sow fearfulness as measured in this study, was not related to circulating concentrations of prolactin or cortisol pre- and post-farrowing.

Key words: sow, fear, parturition

M28 Molecular basis of virulence in *Staphylococcus aureus* ovine mastitis. C. Le Maréchal[1,2], N. Seyffert[1,4], J. Jardin[1,2], D. Hernandez[5], G. Jan[1,2], V. Azevedo[4], P. François[5], J. Schrenzel[5], S. Even[1,2], N. Berkova[1,2], R. Thiéry[3], J. R. Fitzgerald[6], S. Lortal*[1,2], and Y. Le Loir[1,2], *[1]INRA STLO, Rennes, France, [2]AGROCAMPUS OUEST STLO, Rennes, France, [3]ANSES, Sophia-Antipolis, France, [4]ICB/UFMG, Belo Horizonte, MG, Brazil, [5]University of Geneva Hospitals (HUG), Geneva, Switzerland, [6]University of Edinburgh, Edinburgh, Scotland, United Kingdom.*

Staphylococcus aureus is one of the main pathogens involved in ruminant mastitis worldwide. The severity of staphylococcal infection is highly variable, ranging from subclinical to gangrenous mastitis and is dependent on host as well as bacterial factors. This work represents an in-depth characterization of *S. aureus* mastitis isolates to identify bacterial factors involved in severity of mastitis infection. We employed genomic, transcriptomic and proteomic approaches to comprehensively compare 2 clonally related *S. aureus* strains that were responsible for severe (strain O11) and milder (strain O46) mastitis in ewes, respectively. Variation in the content of mobile genetic elements, iron acquisition and metabolism, transcriptional regulation and exoprotein production was observed. In particular, O11 produced relatively high levels of exoproteins, including toxins and proteases known to be important in virulence. A characteristic we observed in other *S. aureus* strains isolated from clinical mastitis cases. Our data are consistent with a dose-dependent role of some staphylococcal factors in the hypervirulence of strains isolated from severe mastitis. Mobile genetic elements, transcriptional regulators, exoproteins and iron acquisition pathways constitute good targets for further research to define the underlying mechanisms of mastitis severity.

Key words: *Staphylococcus aureus*, mastitis, omic approaches

M29 Serological proteome analysis of *Staphylococcus aureus* strains isolated from gangrenous and subclinical ewe mastitis reveals core and accessory seroproteomes. C. Le Maréchal[1,2], J. Jardin[1,2], G. Jan[1,2], S. Even[1,2], D. Hernandez[4], P. Francois[4], J. Schrenzel[4], D. Demon[5], E. Meyer[5], N. Berkova[1,2], R. Thiéry[3], E. Vautor[3], S. Lortal*[1,2], and Y. Le Loir[1,2], *[1]INRA STLO, Rennes, France, [2]AGROCAMPUS OUEST STLO, Rennes, France, [3]ANSES, Sophia-Antipolis, France, [4]University of Geneva Hospitals (HUG), Geneva, Switzerland, [5]Ghent University, Faculty of Veterinary Medicine, Merelbeke, Belgium.*

Staphylococcus aureus is a major cause of mastitis in ruminants. In ewe mastitis, symptoms range from subclinical to gangrenous mastitis. *S. aureus* factors or host-factors contributing to the different outcomes are not completely elucidated. In this study, experimental mastitis was induced on primiparous ewes using 2 *S. aureus* strains, isolated from gangrenous (strain O11) or subclinical (strain O46) mastitis. Strains induced drastically distinct clinical symptoms when tested in ewe and mice experimental mastitis. Notably, they reproduced mild (O46) or severe (O11) mastitis in ewes. Ewe sera were used to identify staphylococcal immunoreactive proteins commonly or differentially produced during infections of variable severity and to define core and accessory seroproteomes. Such SERological Proteome Analysis (SERPA) allowed the identification of 89 immunoreactive proteins, of which only 52 (58.4%) were previously identified as immunogenic proteins in other staphylococcal infections. Among the 89 proteins identified, 74 appear to constitute the core seroproteome. Among the 15 remaining proteins defining the accessory seroproteome, 12 were specific for strain O11, 3 were specific for O46. Distribution of one protein specific for each mastitis severity was investigated in 10 other strains isolated from subclinical or clinical mastitis. We report here for the first time the identification of staphylococcal immunogenic proteins common or specific to *S. aureus* strains responsible for mild or severe mastitis. These findings open avenues in *S. aureus* mastitis studies as some of these proteins, expressed in vivo, are likely to account for the success of *S. aureus* as a pathogen of the ruminant mammary gland.

Key words: *Staphylococcus aureus*, mastitis, seroproteome

M30 Changes of plasma fatty acid and metabolites during the transition period in dairy cows with or without subclinical mastitis after calving. Y. Yang[1,2], J. Wang*[1], S. Li[1], D. Bu[1], T. Yuan[1], L. Zhou[1], and P. Sun[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences,, Beijing, China, [2]Institute of Animal Science and Veterinary Medicine, Anhui Academy of Agricultural Sciences, Hefei, China.*

The transition period is especially critical and present considerable physiological challenges to homeostasis that may contribute to the onset of most health disorders, and the biggest challenge is mastitis. To explore specific blood metabolic markers as risk factors for the development of mastitis during early lactation. Thirty-two Holstein primiparous cows were selected and separated into healthy cows (n = 18) and subclinical mastitic cows (n = 14) in 7–21 DIM according to the veterinary treatment records and milk somatic cell counts with 500,000 cells/mL. Blood samples were collected from the tail vein of the cows at 21, 14 and 7 d prepartum, and 1, 4, 7, 14 and 21 d postpartum. Distribution of fatty acids in plasma and metabolic parameters (glucose, blood urea nitrogen, total bilirubin, cholesterol and β-hydroxybutyrate, as well as aspartate aminotransferase) of serum are observed and presented identical profile in the transition cows that were healthy and developed subclinical mastitis. Plasma 18:2 *cis*-9,*cis*-12 was the main fatty acid and its weight percentage increased significantly during early lactation compared with values before calving and during the first week after calving, while stearic acid values gradually decreased from 21 d before parturition through early lactation. Oleic acid increased around the calving and then gradually decreased, 18:3 significantly decreased after calving and then gradually increased. Glucose, blood urea nitrogen, total bilirubin, cholesterol, high density lipoprotein and β-hydroxybutyrate, as well as aspartate aminotransferase activity of serum metabolites around the time of calving in cows were abruptly altered. During the gestation period and calving, no difference was observed in fatty acids and metabolic parameters in the transition cows with or without subclinical mastitis after calving. However, the multiplication product of aspartate aminotransferase at 21 and 14 d before calving from the subclinical mastitic cows was significantly higher than healthy cows and may have value as a potential marker for risk of mastitis during early lactation.

Key words: metabolites, fatty acid, cow

M31 iTRAQ quantitative analysis of changes of serum protein from the cows in the periparturient period. S. S. Li, J. Q. Wang*, H. Y. Wei, Y. X. Yang, D. P. Bu, T. J. Yuan, and P. Sun, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Serum potentially carries an archive of important histological information whose determination could serve important source of immune-related biomarkers. The objective of this study was to elucidate the molecular mechanisms of immune system suppressed in the periparturient cows. In this study, blood samples were collected at 21 d before expected calving and 1 d after calving from healthy Chinese Holstein heifers (n = 8) considered free of mastitis, milk fever and endometriosis based on the somatic cell count and clinical diagnosis. Developmental changes were examined using an integrated proteomic approaches consisting of minor abundance protein enrichment by ProteoMiner, protein label by isobaric tags for relative and absolute quantification (iTRAQ), protein identification by liquid chromatography coupled with tandem mass spectrometry (LC–MS/MS). In total, 78 serum proteins were identified and 19 proteins showed to be differentially expressed at 1 d after calving compared with 21 d before calving. In particular, 4 proteins including conglutinin, apolipoprotein A-II, deoxyhemoglobin and ECM1 protein were downregulated 11.24-, 2.27-, 2.17- and 1.68-fold at 1d postpartum, respectively, while 15 proteins were up-regulated, such as haptoglobin and lipopolysaccharide binding protein. Western blotting validated the relative increases of haptoglobin, which was in agreement with the LC–MS/MS data. These results may provide valuable information to elucidate immune system response at the protein level during the transition period.

Key words: periparturient, dairy cow, isobaric tags for relative and absolute quantification

M32 Prevalence, transmission and impact of bovine leukosis in Michigan dairies. T. M. Byrem*[1], J. T. Houseman[1], R. J. Erskine[2], P. C. Bartlett[2], C. Render[2], C. Febvay[2], D. H. Norman[3], and J. R. Wright[3], *[1]Antel BioSystems Inc., Lansing, MI, [2]Michigan State University, College of Veterinary Medicine, East Lansing, [3]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Bovine leukosis, caused by infection with the bovine leukemia virus (BLV), has been characterized as a benign disease of the immune system. Previous National Animal Health Monitoring Surveys indicate complacency has resulted in high BLV prevalence in US dairies (89%) and cows (40%). Recent evidence that BLV affects immunological responses to both pathogenic challenges and vaccination increases the importance of BLV monitoring and control programs to improve overall health and productivity of dairy cows. A herd profiling index utilizing Dairy Herd Improvement (DHI) milk samples was designed to determine the estimated BLV prevalence (EBP) and its relationship to herd management practices and productivity. Management surveys were conducted in Michigan dairies (113) and on DHI test date, milk samples from a subset of animals ($8 \leq n \leq 10$) in each of 1st, 2nd, 3rd, and ≥4th lactations were tested for antibodies to BLV by ELISA. Correlation between testing all lactating animals and the herd profiling index to determine BLV prevalence in 4 herds was 0.997 ($P < 0.01$). Infection with BLV was detected in 88% of the herds. Average EBP within herd was 29% (0–76%) and within lactation, increased from 20% in 1st lactation cows to 45% in ≥4th lactation cows ($P < 0.05$). Multivariate analysis of management variables identified recent animal purchases, bull breeding, palpations per pregnancy diagnosis in heifers, and straw bedding use for breeding heifers as significant ($P < 0.05$) practices associated with EBP. For every 10% increase in EBP, rolling herd average decreased by 115 ± 60 kg. Individual mature-equivalent lactation records were available for 3899 study animals. Significant effects of leukosis on milk, fat and protein yields were evident within all lactation groups. Across all lactation groups, BLV positive cows had lower milk (−488 kg), fat (−15 kg), and protein (−16 kg) than negative cows ($P < 0.001$). Infection with BLV reduces cow productivity and is associated with purchasing replacements and breeding practices for heifers. Herd profiling using DHI milk samples is an effective strategy to determine and monitor the prevalence of infection in BLV control programs.

Key words: bovine leukosis, milk ELISA, DHI

M33 Relationship between test-day somatic cell count with test-day milk yields in Iranian Holstein cows. A. Laki, S. Babai, and M. Dehghan-Banadaky*, *Department of Animal Sci., Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

Mastitis is considered worldwide the most costly production disease in dairy herds. The assessment of the economic worthiness of control plans for mastitis has to be anal supported by reliable evaluations of the economic losses caused by the disease. Decrease in milk production is one of the largest components of the economic losses due to clinical and subclinical mastitis. Previous study showed that there is a negative relationship between somatic cell count and test day milk yield. So, the aim of the current study was to determine relationship between somatic cell count and test day milk yield in Iranian Holstein dairy herds. Ten Tehran large commercial Holstein dairy herds were involved in the investigation from October 2005 to September 2008. All test day milk compositions (n = 36433) analyzed by infrared test method at the Tehran milk quality laboratory. Test day milk yield of individual cows was collected from each dairy herd. Milk composition and yield data analyzed by SAS and procedure Correlation (SAS institute 2003). The result of this research showed that relationship between test day somatic cell count and milk yield is negative (−0.14). Also, average somatic cell count in this study was 401.66 × 103 cell/mL. It can be concluded that a large amount of milk in Iranian dairy herds wasted by subclinical mastitis.

Key words: test-day milk yield, somatic cell count, Holstein cows

M34 Effects of drying the udder using paper versus cloth towels on bacterial contamination of teat ends of lactating dairy cattle. C. N. Baloun*, S. I. Kehoe, and L. E. Baumann, *University of Wisconsin-River Falls, River Falls.*

Milking cows are prepared for milking with a standard routine of cleaning and wiping to remove dirt and bacteria as well as stimulate milk letdown. A typical routine consists of using a sanitizing agent and wiping it off with either a paper towel or cloth towel before attaching the milking unit. There are many reasons why producers would choose to use either paper or cloth towels however there is no previous research evaluating whether one is better than the other in drying teats after sanitation. Therefore, the objective of this experiment was to determine whether paper towels are better than cloth towels at reducing bacterial contamination at the teat end. Eight cows were chosen and sampled over 4 weeks (total number of samples used for analysis ranged from 150 to 190 depending on bacterial species) where half of the udder was dried with a paper towel and the other half was dried with a cloth towel after sanitation. Immediately after drying, premoistened swabs were wiped over the teat ends in a repeated circular manner and transported back to the lab in a transport broth (Zadoks et al., 2003). Swabs were vigorously swirled in the broth before plating onto Petrifilm plates (3M Petrifilm) to quantify aerobic, coliform, and staphylococcus spp. Statistical analysis was done using SAS 9.2 (2009) where bacterial counts were log-transformed and a proc mixed procedure with cow as the repeated measure was used. Results indicated no

significant differences between cloth and paper towels for coliform or staphylococcus species ($P > 0.05$). The least squares means for log counts of coliform spp. for cloth towels were 1.75 ± 0.5 and paper towels were 1.78 ± 0.05; log counts of staphylococcus spp. for cloth towels were 2.05 ± 0.04 and paper towels were 2.02 ± 0.04. There was a trend ($P < 0.10$) for log counts of aerobic spp. to be higher for cloth towels (2.93 ± 0.04) than for paper towels (2.85 ± 0.04). These results showed little difference between using either a cloth or paper towel to dry udders after sanitation, however, the trend for aerobic counts to be higher in cloth towels should be further evaluated.

Key words: teat, bacteria, milking preparation

M35 Metabolic and clinical responses of dairy cows to increasing oral doses of lipoteichoic acid. S. Iqbal*, Q. Zebeli, D. A. Mansmann, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Lipoteichoic acid (LTA), a cell wall component of gram-positive bacteria (GPB), might be involved in the patholphysiologic and metabolic responses observed in dairy cows during infections by GPB. This study aimed at establishing metabolic and clinical responses to increasing oral doses of LTA and the oral dose that will initiate clinical symptoms in dairy cows. Seven late lactating Holstein dairy cows of an average BW of 800 ± 30 kg were randomly allocated to an oral administration of 2 mL saline solution containing one of the following LTA doses 20, 40, 70, 100, 120, 150, and 200 μg to each cow, respectively. Blood samples were collected from the tail vein at −15 min, 1, 3, and 5 h, whereas clinical responses were observed at −15 min, 1, 2, 3, 4, 5, and 6 h after the oral administration of each dose of LTA. Blood data demonstrated that oral administration of LTA increased concentration of glucose in the plasma with the highest doses (150 and 200 μg) having the highest plasma glucose ($P < 0.01$). Furthermore, plasma glucose linearly increased with time after oral administration of LTA ($P < 0.01$). Interestingly, cows also showed greater concentrations of plasma cholesterol at the highest doses of 150 and 200 μg ($P < 0.01$). Also, concentrations of nonesterified fatty acid in the plasma were found higher at 150 and 200 μg doses ($P < 0.01$). No effect of any of the doses of LTA used was observed on the concentration of β-hydroxybutyric acid in the plasma ($P > 0.05$). On the other hand, clinical data indicated that oral LTA influenced rectal temperatures and respiration rates, although the variations were within the normal ranges ($P < 0.01$ and $P < 0.01$, respectively). Interestingly, the highest doses of LTA (150 and 200 μg) lowered rumen contractions ($P < 0.01$), whereas all other doses did not have an effect on this variable. Overall, oral administration of increasing doses of LTA modulated plasma patterns of selected metabolites and clinical responses of late lactating dairy cows. It was also determined that the clinical safe dose of oral LTA to be used in future experiments was 120 μg.

Key words: oral lipoteichoic acid, plasma metabolites, dairy cows

M36 Repeated oronasal application of lipopolysaccharide affected milk yield and composition in transition dairy cows. A. Hosseini*, D. A. Mansmann, Q. Zebeli, S. Iqbal, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Previously we showed that ruminal endotoxin was associated with depression of milk fat content and lowering of milk energy efficiency (MEE) in mid-lactation dairy cows. In this study, we tested the hypothesis that repeated oronasal application of lipopolysaccharide (LPS) during the transition period might affect milk yield and composition, MEE, and feed intake in transition dairy cows. One hundred primiparous (PP) and multiparous (MP) Holstein dairy cows, with average body weights of 620 and 720 kg, respectively, were randomly assigned into control (CTR; PP = 18; MP = 32) and treatment (TRT; PP = 19; MP = 31) groups. Either carrier alone (3 mL of 0.85% saline) or 3 increasing doses (0.01, 0.05, and 0.1 μg/kg BW) of LPS from *E. coli* 0111:B4 were applied oronasally (1 mL nasally and 2 mL orally) twice a week on wk −4, −3, and −2. Milk fat, protein, lactose, urea nitrogen (UN), somatic cell counts (SCC), and total solids (TS) and milk fat, protein, and lactose yields were determined weekly during wk 1–4 postpartum. Milk energy efficiency was calculated as milk fat yield over DMI consumed. Dry matter intake was recorded daily starting at 4 wk before and up to 4 wk after parturition, whereas milk yield data were recorded daily during the first 4 wk after parturition. All data were processed statistically by the MIXED procedure of SAS. Overall data indicated that TRT tended to increase milk yield in all cows ($P < 0.1$) with higher impact on MP cows ($P < 0.01$) during 4 wk postpartum. Milk fat, fat yield, TS, and MEE tended to decrease ($P \leq 0.07$) in relation with TRT × parity × week, although TRT did not affect ($P > 0.1$) milk fat, protein, lactose, UN, SCC, TS and MEE. The overall DMI was affected ($P \leq 0.001$) by parity with higher levels in MP cows. An effect of parity was obtained in relation with fat ($P < 0.01$), protein ($P < 0.001$), and lactose yields ($P < 0.01$) with greater levels in MP cows. In conclusion results of this study showed potential involvement of LPS in modification of milk yield and composition, and that the oronasal treatment with LPS might be used to increase milk yield in dairy cows.

Key words: LPS, oronasal application, milk metabolites

M37 Mortality patterns in Midwest DHIA herds. M. Q. Shahid*, M. I. Endres, J. K. Reneau, R. Chebel, and H. Chester-Jones, *University of Minnesota, St. Paul.*

The objective of this study was to describe the mortality patterns and identify risk factors for mortality in Midwest dairy herds. A total of 5,080,849 lactation records for cows that calved between January 2006 and December 2009 from 10 Midwest states were used. Overall mortality rate was 6.4 per 100 cow years with an increasing trend from 6.2 in 2006 to 6.7 in 2009. Herd level mortality rate was 5.6 ± 2.0 (mean ± SD). The distribution of mortality rates were estimated by categories of parity, stage of lactation and season. The association between mortality rate and different risk factors was investigated by using proportional hazards regression. Low first test day milk, parity, somatic cell score (SCS), fat to protein ratio (FPR), previous lactation dry period length, and breed were significantly associated with mortality ($P < 0.001$). Within herd, cows with higher 1st test day milk yield (>mean plus 1SD) had 0.95 times (5% less) hazard rate of mortality than cows with average milk yield (mean plus 1SD); however, cows with lower 1st test day milk yield (mean minus 1SD) had 1.49 times (49%) higher hazard rate of mortality than cows with average milk yield. Similarly, cows with FPR > 1.7 and < 1.0 at first test had 48 and 18%, respectively higher hazard rate of mortality than cows with FPR between 1.0 and 1.7. Every 1 unit increase in SCS was associated with a 6% increase in hazard rate of mortality. Cows with dry period >70 and <30 d had 1.38 and 1.22 times higher hazard rate of mortality, respectively than cows with dry period between 30 and 70 d. Crossbred cows had 14% less hazard rate of mortality than Holsteins; however, Jersey cows had 19% higher hazard rate of mortality than Holsteins. These results indicate that first test day records could be a useful tool to identify

cows at high risk of mortality. In addition, higher milk yield was not associated with higher mortality.

Key words: mortality, risk factors

M38 Cost analysis of feeding varying doses of *Saccharomyces cerevisiae* fermentation product on a commercial dairy. C. M. Shriver-Munsch*[1], E. M. Ramsing[1], J. R. Males[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe[1], *[1]Department of Animal Science, Oregon State University, Corvallis, [2]Diamond V, Cedar Rapids, IA.*

Feeding 56 g/d of *Saccharomyces cerevisiae* fermentation product (Diamond V Original XP; XP) improves milk production in most studies, suggesting increased profit margin. A double dose of XP may further increase profit. This study focused on the cost benefits associated with feeding a single or double dose of XP on a commercial dairy. Multiparous Holstein cows were fed a supplementation mixture of 0 (n = 32), 56 (n = 33), or 112 g/d (n = 31) of XP, corn, and molasses, provided as a top dressing starting at 28 d before the expected calving date and ending 28 d postpartum. During the supplementation period, milk yield and composition were measured twice weekly from the afternoon milking on non-consecutive days. The incurred cost included expenses for XP, medical treatment, and milk profit lost due to discarded milk and culling. Income was calculated from milk and cow sales. The difference between incurred costs and income was defined as net gain. Because we could not measure feed intake or hours of labor, general feed and labor costs were not included in the calculation. Overall, supplementation with XP did not significantly increase net profit, however, a double versus a single dose of XP decreased total daily cost by $2.00/cow ($P = 0.06$) and tended to increase daily milk income by $1.65/cow ($P = 0.17$), resulting in a greater daily net profit of $2.73/cow ($P = 0.15$). The daily net profit was significantly greater in second lactation cows ($5.99/cow; $P = 0.05$). Although there were several potential confounding factors that could not be controlled on the commercial dairy, our results support the original hypothesis that higher dosages of XP during the peripartal period may further increase profit.

Key words: cost analysis, dairy, yeast culture

M39 The effect of feeding pasteurized or non-pasteurized waste milk on fecal populations and prevalence of *Salmonella* in dairy calves. J. A. Garcia*[1], T. S. Edrington[2], G. R. Hagevoort[1], R. F. Farrow[2], T. R. Callaway[2], N. A. Krueger[2], R. C. Anderson[2], and D. J. Nisbet[2], *[1]NMSU Ag Science Center, Clovis, NM, [2]Food and Feed Safety Research Unit, Southern Plains Agricultural Research Center, USDA-ARS, College Station, TX.*

Waste milk is often used as a feed source for young calves. To reduce the potential transmission of pathogens, some producers pasteurize waste milk. To assess the effect of pasteurization on *Salmonella* in dairy calves, 2 groups of calves were randomly allotted to receive either pasteurized (PWM; n = 128 calves) or non-pasteurized waste milk (NPWM; n = 83 calves) and fecal samples collected weekly for the first month of life and at weaning (approximately 2 mo of age). Calves were housed and managed on a single commercial dairy in the southwestern United States; however some calves were born on other dairies and transported at one day of age. A total of 8 collections were made and fecal samples (n = 1118) were quantitatively and qualitatively cultured for *Salmonella*. Fecal concentrations of *Salmonella*, as determined by direct plating, were significantly different at a few collections but similar ($P > 0.10$) when averaged over all collections [3.2 and 3.1 cfu (log10)/g feces for NPWM and PWM, respectively]. The percentage of *Salmonella* positive fecal samples following qualitative culture averaged 68 and 69% for NPWM and PWM, respectively, and ranged from a low of 23 to a high of 88% positive during the experimental period. A treatment effect ($P < 0.05$) was observed only during the fifth collection. Dairy of origin for the calf had a far more significant impact on *Salmonella* prevalence during individual collections, but not when data was combined across collection ($P = 0.12$). Nine different serogroups were identified: C1 (41%), C2 and E1 (approx. 17%), and B (12%). No treatment differences were observed in serogroup prevalence with the exception of the B group which was more common in the PWM treatment (19 versus 6%). Four calves died during the study, 3 in the PWM and 1 in the NPWM treatments. While the results did not find any significant effect of waste milk pasteurization on *Salmonella* prevalence in dairy calves, we do not discourage this practice due to beneficial effects of killing other pathogens such as *Mycobacterium paratuberculosis* possibly present.

Key words: *Salmonella*, waste milk, dairy calf

M40 Effect of paste or wrap oxytetracycline treatment on papillomatous digital dermatitis. J. H. Higginson*[1], J. Walter[1], G. Cramer[1,2], and D. F. Kelton[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Cramer Mobile Bovine Veterinary Services, Stratford, Ontario, Canada.*

The objective of this study was to determine if application of oxytetracycline in a topical paste without bandaging would be as effective as an oxytetracycline wrap for the treatment of papillomatous digital dermatitis (PDD). Mature lactating Holstein cows diagnosed with PDD during routine trimming were randomly assigned to one of three treatments, oxytetracycline in a paste, oxytetracycline powder under a wrap, or a negative control. The paste treatment consisted of oxytetracycline 1000 mixed with glycol and vinegar, while the wrap treatment consisted of an equivalent amount of oxytetracycline 1000 powder held against the lesion with a wrap for 3 days. Examination of the affected hooves was carried out at Day 0 (Exam=1), Days 3-7 days post-treatment (Exam=2), and Days 8-12 post-treatment (Exam=3). Data were analyzed using a logistic model with a binary outcome (lesion active or lesion healed). Lesions were considered active if the cow reacted to pressure from an algometer and tissue was still pink and/or inflamed. Sixty-five and 54 cows enrolled in the trial were re-examined at Days 3-7 and 8-12 days post-treatment, respectively. Both Exam and treatment were significant ($P < 0.05$). Cows receiving the paste treatment had 9.5 (1.88, 95.62) times greater odds of recovering from digital dermatitis over the study period than the no treatment cows ($P = 0.01$). Similarly, cows receiving the wrap treatment had 18.6 (3.70, 188.56) times greater odds ($P < 0.0001$) of recovering from digital dermatitis over the study period than cows receiving no treatment. There was no statistically significant difference between the paste and wrap treatments ($P = 0.20$). Oxytetracycline is effective for the treatment of PDD and the use of it in a paste form rather than a powder alone could eliminate the need for bandage application and subsequent removal.

Key words: lameness, dairy cattle, digital dermatitis

M41 Association between virulence factors of *Escherichia coli*, *Fusobacterium necrophorum*, and *Arcanobacterium pyogenes* and uterine diseases of dairy cows. M. Bicalho*, R. Bicalho, and V. Machado, *Cornell University, Ithaca, NY.*

The objective of this study was to evaluate the relationship of bacteria specific virulence factors (VF) present at 3 different stages of lactation (4 ± 2, 12 ± 2, and 35 ± 2 d in milk (DIM)) with the incidence of metritis and clinical endometritis. The following VFs were investigated in this study; for *A. pyogenes* - plo (pyolysin - hemolytic exotoxin, which promotes hemolysis of red blood cells and immune cells), cbpA (collage- binding protein, necessary to collagen rich tissue), and fimA (fimbriae expression, key component in the cell-to-cell or cell-to-surface adherence), for *Escherichia coli*, fimH (type 1 pili), and for *Fusobacterium necrophorum* lktA (leukotoxin). Uterine swab samples were collected from 117 postpartum dairy cows housed on a commercial dairy farm located near Ithaca, New York. Samples were collected from April 2010 through June 2010. Isolation of total DNA was performed using a QIAmp DNA minikit (Qiagen, Santa Clara, CA) according to manufacturer instructions for DNA purification from blood and body fluids. PCR was used for the evaluation of the presence plo, cbpA, fimA, fimH, and lktA. Cows were classified as VF positive when the appropriate amplicon size was observed in the electrophoresis gel and negative when no amplicons were visible in the gel. Data was analyzed by multivariable logistic regression using the logistic procedure of SAS (Cary, NC). The *A. pyogenes* virulence factor cbpA was only detected in 4 samples and was excluded from the association analysis. In summary, *E. coli* (fimH) was significantly associated with metritis and endometritis when detected at 4 ± 2 DIM, *Fusobacterium necrophorum* (lktA) was significantly associated with metritis when detected at 4 and 12 ± 2 DIM and with endometritis when detected at 35 ± 2 DIM, and *Arcanobacterium pyogenes* (fimA and plo) was associated with metritis (fimA) when detected at 4 DIM and endometritis (fimA and plo) when detected at 12 and 35 ± 2 DIM. These findings support the hypothesis that the bacterial etiology of uterine infection is dynamic and multifactorial.

Key words: metritis, *E. coli*, FimH

M42 Repeated oronasal application of lipopolysaccharide lowered the incidence of metabolic diseases in periparturient dairy cows. A. Hosseini*, D. A. Mansmann, Q. Zebeli, S. Iqbal, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Metabolic diseases such as udder edema (EU), laminitis, retained placenta (RP), and mastitis are common in dairy cows around parturition, and have major consequences on health and economic sustainability of dairy farming. In this study, we evaluated the hypothesis that repeated oronasal application of lipopolysaccharide (LPS), during the transition period, might influence the incidence of the aforementioned diseases, body condition score (BCS), and manure score (MS) in both primiparous (PP) and multiparous (MP) dairy cows. One hundred Holstein dairy cows (PP and MP with ~BW 620 and 720 kg, respectively) were randomly assigned into control (CTR; PP = 18; MP = 32) and treatment (TRT; PP = 19; MP = 31) groups, and were allowed for ad libitum access to feed and water. Either carrier alone (3 mL of 0.85% saline) or 3 increasing doses (0.01, 0.05, and 0.1 µg/kg BW) of LPS from *E. coli* 0111:B4 were applied oronasally (1 mL nasally and 2 mL orally) twice a week on wk −4, −3, and −2. The UE was evaluated on wk −2, −1, 1 and 2, whereas RP was evaluated during 72 h postpartum. Laminitis was approved in 2 d intervals from −28 to 28 d, while mastitis was evaluated once a wk for 4 wk. The BCS was measured every 2 wk from −4 to 4 wk, whereas MS evaluated on wk −2, 1, 2 and 3. All data were processed statistically by Chi-squared test and the MIXED procedure of SAS. Overall results indicated that TRT lowered the incidence of UE in PP cows ($P = 0.041$), while week, parity and their interaction ($P < 0.001$) on UE was obtained. Data indicated that TRT tended to reduce ($P = 0.074$) the incidence of RP in all cows, while no effect was observed on laminitis and mastitis. In both PP and MP cows BCS decreased ($P < 0.001$) postpartum. The MS decreased by parity ($P = 0.027$), week ($P < 0.001$), and TRT × parity interaction ($P = 0.015$) in PP cows. In conclusion results of this investigation indicated potential involvement of LPS in the etiology of metabolic diseases, and that the oronasal treatment with LPS might be used to lower the incidence of UE and RP in periparturient dairy cows.

Key words: oronasal, lipopolysaccharide, metabolic disease

M43 Peripartal intravaginal application of probiotic bacteria lowered the incidence of uterine infections and improved fertility in dairy cows. S. Sharma*, Q. Zebeli, S. Iqbal, S. M. Dunn, J. F. Odhiambo, M. Gäenzle, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Uterine infections affect cow performance and the efficiency of dairy farming. The objective of this study was to investigate the prophylactic effect of intravaginal probiotic bacteria on postpartum uterine infections, uterine involution patterns, and the overall reproductive performance of dairy cows. Eighty-two pregnant primiparous and multiparous Holstein cows, 2 wk before the expected day of calving, were randomly assigned into treatment (TRT; received 1 mL of probiotic bacteria in reconstituted skim milk at 10^{10} to 10^{12}cfu/treatment) and control group (CTR; received 1 mL of carrier only; reconstituted skim milk). Intravaginal infusions were performed once during wk −2, −1, +1, +2, +3, and +4 relative to parturition with probiotic bacteria isolated from the vaginal tracts of healthy cows including a mixture of *Lactobacillus sakei* FUA 3089, *Pediococcus acidilactici* FUA 3140, and *P. acidilactici* FUA 3138. Results showed that probiotic treatment lowered the incidence of metritis (17.1 vs. 51.2%; $P < 0.001$) and tended to lower the incidence of pyometra (12.2 vs. 26.8%; $P = 0.06$) in TRT cows. Treatment also lowered the overall incidence of cases with vaginal purulent discharges between 3 and 5 wk postpartum (10.1 vs. 27.8%; $P < 0.01$). Furthermore, a decrease in the number of cows with abnormal cervical size (28.5 vs. 43.0; $P < 0.0001$), abnormal uterine horn symmetry (40.8 vs. 67.2%; $P < 0.001$), and abnormal uterine fluctuations (18.5 vs. 36.8%; $P < 0.05$) was obtained. Additionally, differences were observed with regard to uterine infections and involution indicators at 3 wk postpartum in treatment group. A tendency to increase the overall pregnancy rates (87.9 vs. 73.5%; $P = 0.08$) was demonstrated in TRT group. The peak concentration of Hp was lower ($P < 0.0001$) in probiotic treated cows than in the CTR group. In summary, intravaginal application of a mixture of lactobacilli in periparturient dairy cows improved the overall postpartum uterine health and performance ands warrants further research into the mechanism(s) involved and potential applications in the future.

Key words: dairy cows, reproduction, probiotic lactobacilli

M44 Partitioning innate immune response variation: How much variation is due to the animal? M. D. Sellers*[1], L. E. Hulbert[1,2], C. J. Cobb[1], and M. A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Department of Animal Sciences, University of California-Davis, Davis.*

The objective was to partition the between-calf variation in ex vivo innate immune responses from Holstein bull calves. Innate immune responses evaluated included total leukocyte and differential counts, neutrophil L-selectin expression, tumor necrosis factor-α (TNFα) secretion from lipopolysaccharide (LPS)-simulated whole blood,

and neutrophil phagocytosis and oxidative burst responses to *E. coli* 0111:H8. Sixty 8 Holstein bull calves were observed for a period of 12 wk. At 21, 24, 28, 45, 49, 63, 66, 70, and 84 ± 2.3 d of age, peripheral blood was collected in heparinized vacutainers for ex vivo immunological analyses. Between-calf variation was partitioned using PROC MIXED in SAS (SAS v9.2). The model included the fixed effect of day. The compound symmetry covariance structure was used for the within-calf variation measurement. The between-calf variation ($V_{between}$) was determined as the variation between subjects after the fixed effect of day was removed. The within-calf variation (V_{within}) was estimated as the mean of the residual variation after the effects of day and $V_{between}$ were removed. Data are reported as ranges on 95% confidence intervals of the proportion of the variation due to $V_{between}$ ([$V_{between}$ / V_{within} + $V_{between}$] x 100). The study was conducted during February–April, 2010. These data suggest that a calf's immune response is highly dependent upon it's interaction with the environment. Identifying and controlling for environmental variation decreases V_{within}, which increases the consistency in immune responses within a calf. This could lead to identifying and managing subpopulations with unique immune responses.

Table 1. Between-calf variation in innate immune parameters in Holstein bull calves

Parameter	Day	$V_{between}$	$V_{between}$MIN	$V_{between}$MAX	$CV_{between}$	CV_{total}
P <	%					
Total leukocyte count	0.001	34.2	21.0	45.3	9.5	27.6
Neutrophil percentage	0.001	22.5	12.1	33.2	8.9	39.4
Whole blood TNF-α secretion	0.001	31.4	19.3	42.0	23.1	73.5
Neutrophil L-selectin expression	0.001	11.3	4.2	18.8	10.3	91.0
Neutrophil phagocytosis	0.001	43.1	29.3	54.0	20.1	46.6
Neutrophil oxidative burst	0.001	33.8	21.0	44.6	9.5	28.1
Cortisol	0.001	14.4	6.2	22.6	11.1	76.8
Glucose	0.001	12.4	4.3	20.7	2.2	17.8

Key words: cattle, immune, variation

M45 Effect of various dosages of *Saccharomyces cerevisiae* fermentation product on health and metabolism of multiparous dairy cows. C. M. Shriver-Munsch*[1], E. M. Ramsing[1], J. R. Males[1], W. K. Sanchez[2], I. Yoon[2], and G. Bobe[1], *[1]Department of Animal Science, Oregon State University, Corvallis, [2]Diamond V, Cedar Rapids, IA.*

Increased nutritional demands and suppressed immune function increase the risk for metabolic and infectious diseases in dairy cows during the transition period. These problems increase with parity number and result in significant losses in milk production and early culling. Supplementation of *Saccharomyces cerevisiae* fermentation product (Diamond V Original XP; XP) may support immune function and greater nutritional demands; thereby, XP may decrease the risk of infectious and metabolic diseases. Doubling feeding rates of XP may provide greater health benefits to dairy cows. The objective of the current study was to evaluate whether feeding a single or double dose of XP during the transition period may decrease the risk of metabolic and infectious diseases in multiparous dairy cows. Multiparous Holstein cows housed in the same pen were given a supplement containing either 0 (control; n = 32), 56 (n = 33); or 112 g (n = 31) of XP daily during morning lock-up as a top dressing to their TMR. The supplement consisted of 0, 56, or 112 g of XP mixed with 84 g of molasses and 168, 112, or 56 g of corn meal, respectively. Serum samples were analyzed for glucose, BUN, NEFA, and BHBA. Feeding XP, regardless of dosage, decreased BHBA concentrations ($P = 0.04$) and increased serum glucose ($P = 0.08$) and BUN concentrations ($P = 0.02$) at the d of calving. Feeding a double dose of XP additionally increased supplement consumption at the d of calving ($P = 0.05$ versus control) and decreased log10 somatic cell scores (SCS) in milk during the supplementation period ($P = 0.10$ versus control). Cows fed a single dose of XP also tended to have lower SCS by wk 4 versus control-fed cows ($P = 0.14$). Our results support the original hypothesis that XP may support immune function and greater nutritional demands in transition dairy cows. Higher XP doses may provide greater health benefits during time periods of increased stress.

Key words: dairy, health, yeast culture

M46 Influence of starch sources in prepartum diet on colostrum quality and blood immunoglobulin concentration of calves. F. Fatahni[1], H. Mirzaei Alamouti*[2], and A. Shahsavar[1], *[1]Department of Animal Science, University of Ilam, Iran, [2]Department of Animal Science, University of Zanjan, Iran.*

The main objective of this study was to evaluate the effect of dietary inclusion of wheat or corn as the main source of starch in prepartum diets on plasma metabolites of cows, colostrum composition, colostrum IgG1 and IgG2 concentrations and calves serum IgG1 and IgG2 concentrations. For this purpose, 30 primiparous and 20 multiparous Holstein cows were used in a randomized complete block design and cows were blocked by parity and expected calving dates and assigned to treatments at 22 ± 7 d before calving. Dietary treatments were either a corn-based diet or a diet containing wheat at 18.5% of diet dry matter. The cows blood were sampled at −21, −14, −7, and −1 d relative to expected calving dates. Calves blood samples were drawn before the first colostrum feeding (0 h) at birth and 24 h of life. The results indicated that Prepartum diets did not affect plasma concentrations of glucose, nonesterified fatty acids and triglyceride of cows, however, plasma total concentrations of proteins in cows fed the wheat-based diet was higher compared with those fed the corn-based diet. Lactose, fat and IgG2 concentrations in colostrums did not respond to dietary treatment, but protein, total solids, IgG1 and total IgG concentrations in colostrums were significantly higher for cows fed wheat containing diet. At 24 h of age, calves fed colostrums from cows fed wheat containing prepartum diet had significantly higher serum IgG1 and total IgG concentrations. But serum IgG2 concentrations were similar between treatments. Prepartum starch source did not affect apparent efficiency of IgG1, IgG2 and total IgG absorption. Results suggested that feeding wheat-based diet in prepartum increased colostrum quality and serum IgG1 concentrations of calves and may have a profound effect on the survival, health and growth of newborn calves.

Key words: prepartum diet, colostrums, calf

M47 Development of a lab-on-a-chip immunoassay system for diagnosis of Johne's disease. A. Wadhwa*[1], K. Yang[1], X. Liu[1], J. Bannantine[2], S. Eda[1], and J. Wu[1], *[1]University of Tennessee Knoxville, Knoxville, [2]United States Department of Agriculture, Ames, IA.*

Johne's disease (JD) is caused by infection of mostly ruminants (including dairy cattle) with *Mycobacterium avium* ssp. *paratuberculosis* and is responsible for a significant economic loss to the US dairy industry. Diagnosis of JD is currently conducted in diagnostic laboratories, creating dairy farmers costly expenses for veterinary service, sample handling, and shipping. An automated on-site diagnostic device for JD would reduce the diagnosis-related costs. Lab-on-a-chip (LOC) technology has been used in various analytical processes and is offering opportunities for the development of on-site diagnostic devices. In this report, we developed and tested a LOC immunoassay system based on AC electrothermal (ACET) effect for detection of JD-specific antibodies in bovine serum samples. The LOC used in this study was composed of poly-dimethylsiloxane microchannels sealed over an ACET electrode chip. The surface of the ACET electrode chip was coated with *M. paratuberculosis* antigen and, after blocking uncoated surface, reacted sequentially with bovine serum sample and fluorescently labeled secondary antibody. Liquid flow was electrically controlled by ACET micropumping effect. The level of antibody binding was then measured by using a LED-induced fluorescence with a low cost mini-spectrometer. JD-positive and JD-negative serum samples were tested with this LOC immunoassay system. Antibody binding in JD-positive serum was detected by this ACET-based system after loading the serum and secondary antibody for 3 min each. Without the ACET effect, the antibody binding was not detectable after the 3-min reactions. The level of antibody binding in the JD-positive serum was greater than that of JD-negative serum. Higher antibody binding was observed at the electrode edges and we assumed that ACET caused a swirl of liquid around the electrode and thereby accelerated the antibody-antigen interaction. This assumption was supported by our theoretical prediction and numerical simulation. This ACET-based LOC immunoassay may form a basis for the development of an on-site JD diagnostic method.

Key words: Johne's disease, diagnosis, lab-on-a-chip

M48 Immune activation after immunization of neonatal calves with a commercial heat-killed vaccine. J. R. Stabel*[1], W. R. Waters[1], J. P. Bannantine[1], and K. Lyashchenko[2], *[1]USDA-ARS-National Animal Disease Center, Ames, IA, [2]Chembio Diagnostic Systems, Medford, NY.*

A major drawback of current whole-cell vaccines for *Mycobacterium avium* ssp. *paratuberculosis* (MAP) is the interference with diagnostic tests for bovine tuberculosis and paratuberculosis. The current study was designed to explore cross-reactivity of the current USDA commercial vaccine for MAP with diagnostic tools for bovine TB and to assess host responses to vaccination. Neonatal dairy calves were assigned to treatment groups consisting of: 1) Control – no vaccine (n = 5); and 2) Vaccinate – Mycopar vaccine (n = 5). Peripheral blood mononuclear cells were isolated before and after vaccination and stimulated in vitro for measurement of interferon-(IFN)-γ, interleukin (IL)-4, IL-10, and IL-12, and to assess differences in lymphocyte populations by flow cytometry. Results from this study demonstrated a rapid initiation of MAP-specific IFN-γ in Vaccinate calves by 7 d, with robust responses continuing throughout the study. Vaccinate calves also had IFN-γ responses to BoPPD, with moderate reactivity to ESAT-6/CFP-10, an *M. bovis* recombinant fusion protein. Interestingly, IL-4 and IL-10 were markedly decreased in Vaccinate calves only on d 7 and 14 of the study and thereafter were similar to Controls. Vaccinate calves began to seroconvert at 4 mo with all calves having detectable MAP antibody by 6 mo. Only one Vaccinate calf had a positive (suspect) skin test response to *M. bovis* PPD and none of these calves reacted in *M. bovis* serologic tests. These results suggest that vaccination with Mycopar will interfere with diagnostic tools for the detection of paratuberculosis but have low interference with *M. bovis* diagnostics.

Key words: *Mycobacterium avium* ssp. *paratuberculosis*, cattle, bovine tuberculosis

M49 Phenotype array analysis of *Mycobacterium avium* ssp. *paratuberculosis* K10 phoP mutant and wild-type. J.-W. Chang, J. Scaria, and Y.-F. Chang*, *Cornell University, Ithaca, NY.*

Mycobacterium avium ssp. *paratuberculosis* (MAP) is recognized as a broad host range mycobacterial pathogen with the ability to initiate and maintain systemic infection and chronic inflammation of the intestine of a range of histopathological types in many animal species. Even though MAP can survive in a variety of environments, it is extremely slow growing and fastidious. A better understanding of the complete physiology of MAP can lead to novel preventive strategies and identification new vaccine candidates in MAP genome. Therefore we have compared the complete metabolic parameters of MAP phoP mutant and its wild-type. A phoP mutant was constructed using allelic exchange method in MAP strain K10. Biolog phenotype MicroArray (PM) is a respiration-based assay system that can test up to 2,000 phenotypic traits simultaneously. The complete metabolic profile of the MAP mutant and wild-type was obtained by screening against Biolog phenotype microarray (PM) panels 1 through 8. For each PM panel, 30% increase in signal intensity over negative control was considered positive. The PM analysis revealed that deletion of phoP had a global impact on MAP metabolism. The greatest impact of phoP deletion was on utilization of nitrogen, sulfur and phosphate sources. Likewise phoP deletion severely impaired the ability of MAP to utilize nutritional supplements, such as hematin, thymine, deferoxamine and N-Acetyl-D-Glucosamine. Alteration of utilization of carbon sources such as L-Arabinose, Acetoacetic acid, D-Psicose and Pyruvic acid was also observed. In several bacteria it has been established that PhoPR 2-component system is the master regulator and in *Mycobacterium* tuberculosis PhoPR 2-component system is essential for virulence. Our results in the present study are consistent with these observations and a detailed study of metabolism related genes identified in this analysis can be good candidates for drug intervention or vaccine development.

M50 Characterization of monoclonal antibodies specific for molecules uniquely expressed on bovine dendritic cells. G. S. Abdellrazeq*[1], S. Tomida[2], and W. C. Davis[2], *[1]Alexandria University, Edfina, Behara Province, Egypt, [2]Washington State University, Pullman.*

Progress in elucidating the function of dendritic cells (DC) in cattle has been limited by the availability of monoclonal antibodies (mAbs) that

identify lineage restricted molecules expressed on DC. In this report, we describe the development and characterization of a set of mAbs (LND25A, LND41A, DC5A, and DC77A, all IgG1 isotype) that react with molecules expressed on DC. Initial analysis using flow cytometry show the mAbs label a population of CD14-MHCII+CD11c+ cells that comprise less than 1% of peripheral blood mononuclear cells. Cross comparison of specificity of the mAbs using Zenon IgG1 s step reagents conjugated with different fluorochromes showed the mAbs recognize 2 different molecules, one recognized by LND25A and LND41A the other recognized by DC5A and DC77A. In vitro studies with cultures of adherent cells derived from peripheral blood mononuclear cells revealed LND41A labeled a population of loosely adherent cells with the phenotypic features of DC5. The cells possessed numerous dendrites similar to those seen on DC. Preliminary use of LND41A to identify DC present in the ileum of cows at the clinical stage of Johne's disease showed that the mAb recognizes a population that is distinct from macrophages. Further studies are in progress to show the mAbs recognize molecules expressed on all DC.

Key words: dendritic cells, monoclonal antibodies, Johne's disease

M51 Identification of *Mycobacterium avium* ssp. *paratuberculosis* genotypes on Alberta dairy farms with high-resolution melt analysis of multiallelic short sequence repeats. J. David, R. Mortier, H. Barkema, and J. De Buck*, *Dept. of Production Animal Health, Fac. Veterinary Medicine, Calgary, Alberta, Canada.*

Disease prevention through epidemiology-based management practices might be the best option for Johne's disease (JD) control at the moment. This strategy depends partly on a thorough understanding of the genotypic diversity of MAP in Canadian herds as natural strain variants may possess unique pathogenicities that may require tailored management practices. Strain discrimination is also important for epidemiological investigations to understand origins of infection and identify risk factors that influence transmission. Molecular epidemiology might also allow visualization of how specific genotypes are more successful in spreading. In this study we aimed to develop an accurate and rapid genotyping technique based on known short sequence repeat (SSR) variants and to identify the genetic variability of MAP within Alberta. Methods: Serum, milk and fecals were collected from 1917 individual animals over 3 years of age on 24 dairy herds in Southern Alberta. Fecals were cultured using the liquid culture ParaJem system. Positive cultures were subcultured on solid media to obtain single colonies. Genomic DNA from these pure isolates was prepared for genotyping. Apart from sequencing of 3 SSR loci (G1, G2, GGT), high resolution melt (HRM) assays were developed to identify the allelic diversity. Results: Thirty-five isolates were obtained from 10 of the herds. Respectively 3, 3 and 2 alleles were discovered for the 3 SSR loci, resulting in several different genotypes. HRM proved more reliable than sequencing due to problems to resolve the exact number of guanine repeats in G1 and G2 by the classical approach. Farms with multiple genotypes were discovered. The same herds are currently being resampled. Genotyping of the new isolates will allow us to determine the true genotypic diversity on those farms more accurately. Genotyping using SSR HRM analysis is a useful tool to elucidate the distribution of MAP genotypes in a geographic area.

Key words: paratuberculosis, genotyping, transmission

M52 Complete genome sequence of a *Mycobacterium avium* subspecies *paratuberculosis* Isolate from a patient with Crohn's disease. L. Li*[1], J. P. Bannantine[2], S. Sreevatsan[3], and V. Kapur[1], *[1]Penn State University, University Park, [2]National Animal Disease Center USDA-ARS, Ames, IA, [3]University of Minnesota, St. Paul.*

Mycobacterium avium subspecies *paratuberculosis* (MAP) has been identified in some human patients with Crohn's disease. To identify genetic differences between MAP isolates recovered from humans and those associated with bovine Johne's disease, we characterized the complete genome sequence of strain MAP4 recovered from the breast milk of a Crohn's disease patient. Massively parallel sequencing approaches were used to generate a total of 88.5 million base pairs from a randomly sheared MAP4 genomic DNA library, which were assembled into contiguous sequence fragments with an estimated 60 large (~2kb) and 350 small (<0.5kb) gaps physical or sequence gaps. A primer walking approach with Sanger based sequencing was applied to close all remaining gaps in a iterative manner and areas with low quality sequence re-sequenced to obtain an assembled single high quality genome sequence. Compared with the described previously bovine MAP K10 genome, the size of MAP4 genome is about 3.0kb smaller as a result of several sequence deletions, including in one copy of the insertion sequence element, IS900. Importantly, the analysis revealed no large genome scale rearrangements in MAP4 as compared with strain K10, and ~3kb of deletions and ~300 bp of insertions were distributed across the genome. The results also confirmed the presence of 59 additional SNPs, which together with the 174 SNPs identified in our preliminary studies account for a total of 233 SNPs between these 2 isolates. Interestingly, more than half of the newly identified SNPs were located in 2 genes (MAP1432 and MAP2495), both of which contain repetitive sequences and are orthologs of *Mycobacterium tuberculosis* Rv1173 that encodes a cell wall protein. Taken together, our analysis of the MAP4 and K10 genome sequences confirmed the high similarity between strains from these 2 different mammalian hosts, and suggest a relative paucity of genetic variation among strains recovered from humans and cows.

Key words: *Mycobacterium avium* subspecies *paratuberculosis*, genome sequence, Crohn's disease

M53 *Salmonella* delivery system to develop an efficient vaccine against *Mycobacterium avium* ssp. *paratuberculosis*. S. Chandra, J.-W. Chen, S. M. Faisal, S. P. McDonough, M. A. S. Moreira, C.-F. Chang, and Y.-F. Chang*, *College of Veterinary Medicine, Cornell University, Ithaca, NY.*

Salmonella antigen delivery system is an efficient tool to develop an effective and low-cost vaccine. Since *Salmonella* has the ability to enter inside macrophage cells which are very versatile antigen presenting cell, and can deliver the antigen into cytosol using its type III secretion system. Hence, type III secretion system of *Salmonella* presents an efficient antigen delivery to elicit protective immunity especially cytotoxic T lymphocyte (CTL) response. As *Mycobacterium avium* subspecies *paratuberculosis* (MAP) is an intracellular pathogen, type III secretion system of attenuated *Salmonella* could be a efficient vehicle to deliver MAP's immunogenic antigens into cytosol to induce CTL response for better protection in cattle against MAP infection. To induce better protection, we constructed fusion of immunogenic fragment of Ag85A, Ag85 B, and SOD, and 74F using an efficient delivery component of *Salmonella* (sopE promoter and sopE104) in pSU39 expression vector and tested the delivery efficiency of *Salmonella* expressing pSU39-constructs to deliver MAP antigens(Ag85A Ag85 B, SOD, and 74F) into culture medium via type III secretion system. After that we carried out vaccination experiment

in moue model using C57BL/6 mice. Our results show that *Salmonella* Typhimurium (Δ aroA ; Δ yej) a genetically attenuated strain can deliver MAP antigen via type III secretion system. Further, the animal experiment data proved that *Salmonella* expressing MAP antigen can elicit CTL response to induce protective immunity against MAP infection. Immunological and histopathological analysis show that protective immunity mounted by *Salmonella* delivery system against MAP is equivalent to positive controls. Hence, our data indicate that *Salmonella* antigen delivery system could be proven a better tool to develop an effective vaccine to management of Johne's disease in cattle.

Key words: *Mycobacterium avium* ssp. *paratuberculosis*, delivery system, vaccine

M54 Exploring *M. paratuberculosis* pathogenesis using an in vitro cell culture passage model. J. L. Everman*[1] and L. E. Bermudez[2], [1]*Department of Microbiology, College of Science, Oregon State University, Corvallis,* [2]*Department of Biomedical Science, College of Veterinary Medicine, Oregon State University, Corvallis.*

Mycobacterium avium ssp. *paratuberculosis* (MAP) is the etiological agent of Johne′s disease, a chronic intestinal inflammatory disease that affects ruminants worldwide. Once infected, cattle remain in the subclinical stage of infection for many years before the disease progresses to clinical symptoms. The transition from the subclinical to the clinical stage of the disease has been described as a shift from a T_H1 type response to an antibody-dominated type response; however, the cause for the shift and the onset of the infectious process remains to be determined. We describe an in vitro cell culture passage model in an attempt to gain a further understanding of the changes that occur during the host immune response as well as the bacterial changes that occur during the progression of the disease. By passing MAP through MDBK epithelial cells, RAW 264.7 macrophages, and MDBK epithelial cells sequentially, and utilizing real-time PCR to determine transcript levels of immune signals we have observed that cytokine and chemokine levels do not change after 3 passages through RAW 264.7 macrophages. However, a lower passage number results in a higher level of immune signal transcripts of IL-6 and IL-8. These data, as well as previous findings that demonstrate an increase of an invasive phenotype of MAP after intracellular growth in macrophages, suggest that the serial passage of MAP between macrophage populations may select for a population of bacteria that optimizes infection. A more invasive bacterial population allows for increased survival, while the population also appears to be less inflammatory, resulting in less host damage. To fully understand the mechanisms behind these observations, MAP phenotypes have been obtained and RNA will be extracted for DNA microarray analysis at 1 d and 3 d after infection. This hypothesis could potentially explain why the subclinical phase of the disease persists for so many years and our work begins to decipher the dynamics of antigen expression and host response that occur during the progression of Johne′s disease.

Key words: Johne's disease, paratuberculosis, immune response

M55 Effects of *Saccharomyces cerevisiae* fermentation product on ruminal VFA production when supplemented to various beef feedlot diets. I. Yoon*, C. Belknap, J. Butler, J. Lin, A. Brainard, and T. Werner, *Diamond V, Cedar Rapids, IA.*

Feedlot rations vary greatly in both ingredient and nutrient composition depending on the type of animal being fed, stage of production, feeding objective, feed manufacturing capabilities and availability of feedstuffs. An in vitro study was performed to determine the effects of *Saccharomyces cerevisiae* fermentation product (Diamond V Original XPC, XPC) on ruminal VFA production when supplemented to beef feedlot diets obtained from major beef cattle production areas in the US Feedlot diets collected and tested include: finishing diets from feedyards in Illinois (IL), Nebraska (NE1 and NE2), and Texas (TX1), and a backgrounding diet from a feedyard in Texas (TX2). Rations represented a cross-section of ingredients commonly used within the industry. Rumen inocula were obtained from 2 cannulated cows and pooled on an equal volume basis. Forty milliliters of a 1:20 ruminal fluid-to-buffer solution were introduced into 100 mL fermentor bottles containing 0.25 g of diet supplemented with 0.15 g (DM basis) of either XPC or control grain used in production of XPC and incubated for 12 and 24 h at 39°C (n = 10 per treatment). After the 12 h fermentation, XPC increased ($P < 0.05$) propionate and total VFA across all diets compared with the Control. Acetate production was higher ($P < 0.05$) with XPC in the IL, NE1 and TX2 diets. After the 24 h fermentation, XPC increased ($P < 0.05$) propionate across all diets. Total VFA was increased ($P < 0.05$) in the NE1 and NE2 diets. Diamond V Original XPC improves rumen fermentation across a wide variety of feedyard diets, resulting in consistently higher propionate concentrations.

Table 1. Effect of Original XPC on percent increase in VFA production versus Control[1]

	IL	NE1	NE2	TX1	TX2
12 h fermentation					
Acetate	**6.8**	**7.9**	3.2	**4.9**	**8.5**
Propionate	**28.4**	**29.3**	**18.3**	**22.8**	**20.5**
Total VFA	**14.1**	**15.1**	**9.5**	**11.6**	**13.4**
24 h fermentation					
Acetate	4.3	**7.9**	3.2	−0.2	1.9
Propionate	**8.7**	**13.2**	**8.0**	**5.4**	**7.5**
Total VFA	5.4	**9.2**	**5.6**	1.9	4.0

[1]Bold values represent significant percent difference versus Control at $P < 0.05$.

M56 Body components on finishing crossbred beef heifers of different residual feed intake groups. S. F. Reis*[1], P. V. R. Paulino[1], S. R. Medeiros[2], G. L. D. Feijó[2], R. A. A. Torres Júnior[2], D. A. Fausto[3], M. A. Rezende[2], and S. C. Valadares Filho[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Embrapa Gado de Corte, Campo Grande, Mato Grosso do Sul, Brazil, [3]Universidade de São Paulo, Piracicaba, São Paulo, Brazil.*

Studies have suggested that 37% of the total variation in the residual feed intake (RFI) would be related to energetic expenditure with metabolism of the tissues (mainly liver and gastrointestinal tract). This trial aimed to evaluate the weight of body components (non-carcass) of 31 3-cross beef heifers finished in feedlot, fed with same diet, during 84 d. The animals were classified in 3 groups according to their RFI value (high, medium or low). The RFI was calculated as the difference between an animal′s actual and predicted feed intake. The actual dry matter intake was obtained daily during 84 d of feedlot and the predicted feed intake according to the equation: $-3.82593 + 0.15438 \times MBW + 1.09531 \times ADG$. At the end of 84 d all animals were slaughtered using conventional humane procedures. The blood was weighed and the body was separated into individual components, which were separately weighed. Included were internal organs (liver, heart, lungs, trachea, kidneys, reproductive tract, and spleen), cleaned digestive tract (rumen, reticulum, omasum, abomasum, and small and large intestines), tongue, tail, hide, head, feet, and carcass. The trial was conducted in a completely randomized design and data were analyzed using the PROC GLM of SAS ($\alpha = 0.05$). The classes of RFI were different for DMI kg/d ($P < 0.05$), the means were: 12.61(high RFI); 11.72 (medium RFI) and 11.00 (low RFI). No differences were found among classes of RFI for the body components evaluated in percentage of empty body weight (EBW) or in kg/d ($P > 0.05$). The overall averages were: 20.32% EBW (organs and viscera); 6.85% EBW (visceral fat); 289 kg (initial EBW), 415.33 kg (final EBW), and 1.22 kg/d (EBW gain). Viscera and internal organs are largely responsible for energy expenditure in ruminants suggesting a role in feed efficiency determination. No difference in the liver weight ($P > 0.05$) among RFI classes was found. The means measured for high and low RFI were respectively 1.41% EBW and 1.36% EBW. Body components (non carcass) do not differ among finishing crossbred beef heifers of different RFI classes, other factors associated with metabolism may have greater influence on feed efficiency.

Key words: beef cattle, net feed intake, internal organs

M57 Finishing steers and bulls with high-vitamin E diets: Effect on circulating immune cells and creatine kinase at time of slaughter. C. Reyes, C. Fuentes, and R. E. Larraín*, *Pontificia Universidad Catolica de Chile, Santiago, Chile.*

Release of glucocorticoids to the blood stream after stress may change the number of immune cells circulating in blood within minutes. A stressful event may also increased creatine kinase (CK) in blood if muscle tissue is damaged or mobilized. Vitamin E reduced activation of the hypothalamic-hypophysis-adrenocortical axis in farm animals, so the objective of this study was to test if finishing bovines with a high vitamin E diet modulate changes in immune-cells counts and CK at time of slaughter. Thirty-eight steers and bulls were blocked by sex, then grouped in 16 pens of 2 or 3 animals of similar weight, and randomly assign to 1 of 2 treatments: a control diet design to provide 60 IU vitamin E•animal^{-1}•day^{-1} and the control diet supplemented with 2000 IU vitamin E•animal^{-1}•day^{-1}. Each pen was considered an experimental unit (n = 8). Feed was offered once daily to each pen to provide ad libitum access to feed. A blood sample was taken by jugular venipuncture at d 0 to be used as baseline for CK. After 123 d on feed, animals were transported for about 1.5 h to a local slaughterhouse and killed approximately 8 h after arrival. A sample of trunk blood was taken at the time of slaughter. Factors in the model were sex and treatment, and initial weight was included as covariate. Differences were considered significant when ANOVA had $P < 0.05$. We observed no changes in any of the variables analyzed, concluding that feeding 2000

IU vitamin E•animal^{-1}•day^{-1} produced no changes in immune cells counts and CK at time of slaughter.

Table 1. Immune cells (cells/μL) and creatine kinase (CK, U/L) after slaughter in bovines fed vitamin E

Item	Control	Vitamin E	*P*-value
Leucocytes	9,329 ± 591	9,298 ± 586	0.98
Bacilliforms	30.3 ± 13.2	53.9 ± 13.0	0.19
Neutrophils	4,840 ± 331	4,823 ± 328	0.97
Lymphocytes	4,149 ± 351	4,305 ± 348	0.74
Monocytes	65.7 ± 24.9	45.6 ± 24.7	0.55
Eosinophils	124 ± 55.2	124 ± 54.7	0.99
Basophiles	29.5 ± 13.0	24.2 ± 12.9	0.76
Change in CK from d0	751 ± 239	735 ± 237	0.96

Vitamin E: 2000 IU•animal^{-1}•day^{-1}.

M58 Vitamin D_3 effect on metabolite levels in plasma and longissimus musle of steers fed zilpaterol hydrochloride. K. T. Korn*, M. C. Claeys, R. P. Lemenager, and J. P. Schoonmaker, *Purdue University, West Lafayette, IN.*

Two hundred and ten Angus × Simmental steers (init. BW 314 ± 11 kg) were allotted by BW to a 3 × 2 factorial arrangement of 6 treatments (5 pens per treatment; 3 heavy, 2 light blocks) to determine the effect of supplemental vitamin D_3 (0 IU [none], 250,000 IU for 165 d [long-term D], or 5×10^6 IU for 10 d [short-term D]) on plasma total calcium and tissue vitamin D and total calcium levels in steers fed 0 or 8.38 mg/kg zilpaterol hydrochloride (Zilmax) daily for 21 d. Steers were implanted with Revalor XS and fed a growing phase diet (30% corn silage, 20% distillers grains, 1150 IU/kg vitamin D) for 54 d. Finishing phase diets (15% corn silage, 20% distillers grains, 750 IU/kg vitamin D) were fed for 111 d. Zilmax or placebo was added to the diet 24 d and short-term D was added 13 d before slaughter. Treatments were removed from all diets 3 d before slaughter. Plasma was collected at the start of the experiment (0 d), the introduction of Zilmax to the diet (141 d), the start of short-term D (152 d), the withdrawal of treatments (162 d), and the day before harvest (165 d). Longissimus muscles were collected and ground for total calcium and vitamin D analysis. Kidney and liver were collected for vitamin D_3, 25-hydroxyvitamin D_3, and 1,25 dihydroxyvitamin D_3 determination. Short-term D increased ($P < 0.01$) total calcium in plasma at the 162 and 165 d time points compared with none or long-term D. Zilmax increased plasma total calcium at 162 d in steers fed short-term D but not in steers fed long-term D or not fed D (interaction, $P < 0.01$). At 165 d, Zilmax did not increase plasma total calcium in steers fed long or short-term D, but tended ($P = 0.06$) to increase total calcium when steers were not fed supplemental vitamin D (interaction, $P < 0.01$). In conclusion, Zilmax affects plasma total calcium levels depending on dietary concentrations of vitamin D. However, total plasma calcium concentrations do not explain changes in tenderness after 21 d of aging seen previously for Zilmax and long-term D feeding.

Key words: beef, vitamin D, zilpaterol hydrochloride

M59 Early metabolic imprinting events increase marbling scores in fed cattle. M. A. McCann*[1], J. M. Scheffler[1], S. P. Greiner[1], M. D. Hanigan[2], G. A. Bridges[3], S. L. Lake[4], J. M. Stevenson[1], H. Jiang[1], T. L. Scheffler[1], and D. E. Gerrard[1], *[1]Dept. of Animal and Poultry Sciences, Virginia Polytechnic Institute and State University, Blacksburg, [2]Dept. of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [3]University of Minnesota, North Central ROC, Grand Rapids, [4]Dept. of Animal Sciences, University of Wyoming, Laramie.*

Early weaning of calves to a high concentrate diet results in greater fat deposition and suggests that postnatal metabolic imprinting events that may be exploited as a management tool to improve cattle value. The objective of this study was to determine the ability of a short, high energy dietary intervention for subsequently increasing intramuscular fat deposition in finishing cattle. Twenty 4, fall-born Angus-sired steer calves from primiparous cows were stratified by sire and randomly assigned to normal weaned (NW) or metabolic imprinted (MI) treatments. NW calves remained on their dam until 251 ± 6 d of age, whereas MI calves were weaned at 105 ± 6d (135kg) and were transitioned to a diet containing 20% CP and 1.26 Mcal/kg NEg. MI calves were offered 1.0 kg/d of grass hay and were hand-fed twice daily to approximate ad libitum intake. CP levels of the diet were transitioned from the initial level of 20% to 14.5% through the course of the feeding period. Seven days post-weaning of the NW both treatment groups were combined and grazed on a mixed summer pasture from mid-May until early Oct. Post-grazing, steers were adapted to a corn silage-based feedlot diet and performance monitored on a 28-d interval. Ultrasound fat was determined after 75d on feed to stage harvest groups with an estimated 1.0–1.2 cm of backfat. Cattle were harvested and carcass measurements were recorded 24h postmortem. MI calves were heavier ($P < 0.05$) than NW calves (341 vs. 265 kg) at normal weaning age. During the grazing phase NW steers gained more weight than ($P < 0.05$) MI steers (0.69 vs. 0.35 kg/d). Feedlot performance, BF and USDA yield grade were similar between treatments. However, MI steers produced heavier ($P < 0.05$) carcasses (564 vs. 524 kg) with a higher ($P < 0.001$) marbling scores (645 vs. 517; 400 = Sm^0, 500 = Md^0 and 600 = Mt^0). Calves consuming a high concentrate diet for a short period of time early postnatal yielded a higher quality carcass and suggest that metabolic imprinting mechanisms exist in growing beef cattle and may be used for economic gain by cattle producers and feedlot managers.

Key words: calf, weaning age, pasture

Breeding and Genetics: Dairy Cattle Breeding

M60 Differences in the production and reproduction traits of embryo transfer full siblings living under different and identical conditions. J. Bezdicek*[1] and J. Riha[2], *[1]Agriresearch Rapotin Ltd., Rapotin, Czech Republic, [2]Research Institute for Cattle Breeding, Ltd., Rapotin, Czech Republic.*

Embryo transfer plays an important role in terms of using valuable maternal genotypes. The offspring of such embryo transfers are found not only on donors' farms but also on other farms. The aim of this study was to evaluate differences in milk production and reproduction traits in full siblings living on different farms. Evaluation was made in first lactation for 110 sibling pairs (experimental group). For the evaluation, differences full siblings under different conditions comparison was made for milk production differences in full siblings (n = 620) living on identical farms (control group). For production traits we observed milk production in first lactation (in kg), fat production (in % and kg) and protein production (in % and kg). For reproduction we observed age at first calving. The data were analyzed with Statistica 8 (2008, StatSoft Inc., Tulsa, OK) using descriptive statistics and t-tests. Analyzed were Holstein cows (H100) born in the Czech Republic in the years 2000–2005. Observed differences between full sibling pairs under different and under identical conditions (farms) were the following (in parentheses standard deviation): milk production in kg 1149.9 vs. 998.9$^{n.s.}$ (1122.8 vs. 798.1 kg); fat content in percent 0.42 vs. 0.38$^{n.s.}$(0.31 vs. 0.30%); fat production in kg 48.95 vs. 39.86* (40.81 vs. 31.29 kg); protein content in per cent 0.21 vs. 0.17* (0,16 vs. 0,14%); protein content in kg 38.9 vs. 31.6* (33,63 vs. 25,44 kg). For age at first calving the differences between experimental and control group were as follows: 76.6 vs. 65.4* (56.26 vs. 54.9 d). Significant differences is marked * ($P \leq 0.05$); n.s. (nonsignificant). Even though in full sibling pairs, living under different conditions, was found for milk production greater differences (1149.9 kg milk) these differences were not statistically significantly greater than full sibling pairs living under identical conditions. For milk composition and age at first calving the differences were statistically significant. Of the 2 groups there was greater variability in siblings living under different conditions.

Key words: milk production, full siblings

M61 Female fertility in a Guzerat dairy herd: Heterogeneity of variance components for calving intervals. J. C. C. Panetto*[1,2], J. E. Val[3], C. R. Marcondes[4], M. G. C. D. Peixoto[2], R. S. Verneque[2], J. B. S. Ferraz[5], and B. L. Golden[6], *[1]Curso de Veterinária, Universidade de Uberaba, Uberaba, MG, Brazil, [2]Embrapa Gado de Leite, Juiz de Fora, MG, Brazil, [3]Faculdade de Medicina de Ribeirão Preto - USP, Ribeirão Preto, SP, Brazil, [4]Embrapa Pecuária Sudeste, São Carlos, SP, Brazil, [5]Faculdade de Zootecnia e Engenharia de Alimentos - USP, Pirassununga, SP, Brazil, [6]Dairy Science Department, California Polytechnic State University, San Luis Obispo.*

Our objectives were to determine if variance components of calving intervals varied with age and if considering calving intervals as a longitudinal trait would be a superior approach for fertility analysis of zebu dairy herds. Calving records from females born from 1940 to 2006 in a Guzerat dairy subpopulation in Brazil were analyzed in the present study. Contemporary groups, formed by year and farm at birth or at calving, ages at calving, equivalent inbreeding coefficients and day of the year were included as fixed effects in the models. Calving interval (CI) was first analyzed by fitting a random regression model with Legendre polynomials of order 3 for the fixed effect of age at calving, and random effects of animal and permanent environment. In a second approach, a multivariate analysis was conducted, including age at first calving (AFC), first calving interval (CI1), calving interval for young females (CIY) and calving interval for mature females (CIM). Finally, a bivariate analysis was performed for AFC and CI where calving intervals were considered as a single trait in a repeatability model. Additionally, ranking of sires were compared among approaches. Calving intervals decreased with age until females were about 80 mo old, remaining nearly constant after that age. A quasi-linear increase of 11.5 d on the calving intervals was observed for each 10% increase in the female's equivalent inbreeding coefficient. Heritability of AFC was 0.37 from both analyses. In the case of CI, the genetic variance ratios ranged from 0.064 to 0.141, depending on the approach and on the ages at calving. Differences among genetic variance components for calving intervals observed along the animal′s lifetime confirmed the longitudinal aspect of this trait, indicating the importance of such consideration when accessing fertility of zebu dairy females in situations where the available information relies on their calving intervals. Changes observed in the ranking of sires suggested that the genetic progress of the population can be affected by the approach chosen for the analysis of calving intervals.

Key words: calving intervals, female fertility, heterogeneous variances

M62 Detection of early pregnancy and embryonic loss in dairy cows using BioPRYN and a NEW PSPB-based ELISA. J. R. Branen*[1], J. O. Giordano[2], C. Passavant[1], J. M. Howard[1], P. M. Fricke[2], and R. G. Sasser[1], *[1]BioTracking LLC, Moscow, ID, [2]University of Wisconsin, Madison.*

BioPRYN, a blood-based pregnancy test is used in reproductive management of cattle and utilizes antibodies developed against pregnancy-specific protein B (PSPB). There were 2 objectives of this study: 1) measure the number of days since insemination in dairy cows for a change in pregnancy classification using BioPRYN and a new PSPB-specific ELISA (NEW), 2) measure the number of days since induced embryonic loss (in a subset of cows from 1) for a change in pregnancy classification using BioPRYN and NEW. The NEW assay was developed using a PSPB obtained after Butler et al. (1982. Biol. Reprod 26:925–933). Serial blood samples, collected 3 times a week until 29d after timed AI (TAI) from 60 lactating crossbred (75% Holstein, 25% Jersey) cows, were analyzed and categorized for time of changing from an Open status or, changing, after embryonic death, from a Pregnant status (to recheck or open) using the BioPRYN and NEW assays. Sampling continued until 39d for 30 cows found pregnant at 29d using transrectal ultrasound (TUS) while open cows were not analyzed further. At 39d pregnancy was reconfirmed by TUS and 7 cows were treated with PGF2α (PGF; 25 mg, i.m.; n = 4) or an infusion of 120 mL hypertonic saline (INF; 25%, v/v; n = 3) into the uterine horn containing the embryo. Blood samples were then collected every 12h for 6.5d and daily from 6.5d to 10d. Death of the embryo was confirmed by TUS by cessation of an embryonic heartbeat. BioPRYN categorized the 30 pregnant cows as positive at 25d (n = 20), 27d (n = 7) and 29d (n = 3). NEW was compared with BioPRYN for 11 of those cows and provided positive result of all at 25d while BioPRYN classified 5 at 25d, 4 at 27d and 2 at 29d. Following embryonic death in 7 cows, NEW changed the classification at 0, 1, 1, 2, 2, 2, 3, and 4d

earlier than BioPRYN. The NEW can add to the value of BioPRYN in testing for early pregnancy and when there is early embryonic loss.

Key words: PSPB, pregnancy loss, blood-based pregnancy detection

M63 Comparison of BioPRYN and a new pregnancy-specific protein B (PSPB) enzyme-linked immunosorbent assay (ELISA) for determination of early pregnancy status in dairy cattle. J. R. Branen*[1], C. Passavant[1], A. Phatak[2], D. Snider[3], J. Azevedo[4], J. M. Howard[1], D. Pals[1], and R. G. Sasser[1], *[1]BioTracking LLC, Moscow, ID, [2]Consulting Veterinarian, Waterford, CA, [3]Strategy Lab & Dairy Consulting, Visalia, CA, [4]Alta California, Hilmer, CA.*

Pregnancy specific protein B (PSPB) is a protein fraction derived from ruminant placenta that can be used to develop immuno-assays to detect placental proteins in the maternal circulation. Since 2002 a PSPB-based ELISA, BioPRYN, has been commercially used for detection of pregnancy in cattle at least 30 d since last heat (DSLH) and after 89 d in milk (DIM). The objective of this study was to compare the accuracy of BioPRYN and a new PSPB-based ELISA (NEW) for pregnancy status at 28 ± 2 DSLH. NEW was developed using a PSPB protein fraction isolated as described in 1982 (Biol. Reprod. 26:925–933). Lactating Holstein (n = 385) and Jersey (n = 67) cows 70 or more DIM from 10 commercial dairies in California were used in the study. Blood samples were collected at 28 ± 2 DSLH (T1). These and subsequent samples were assayed for pregnancy status using BioPRYN and NEW. A second blood sample was collected at 33–42 DSLH (T2) concurrently with rectal palpation (RP) or trans-rectal ultrasonography (TUS) by trained professionals. A matching result of T2 ELISAs with RP or TUS was considered the true value for pregnancy status. A mismatch at T2 was rectified by ELISA and RP or TUS at 3–10 d following T2 (T3). Animals not available for T3 analysis were removed from the study (n = 82), leaving a total of 370 cows used for analysis. BioPRYN showed 100% sensitivity (100 X pregnant or recheck at T1 or T2/ true pregnant at T2 or T3) at 28 DSLH or later (Truly pregnant, n = 137). NEW showed 100% sensitivity at 28 DSLH or later (Truly pregnant, n = 137) and >98% (95% CI: 95–99%) with the inclusion of 27 DSLH animals (Truly Pregnant, n = 196). Ten true open animals at T2 and positive by BioPRYN at T1 (between 70 and 88 DIM) were categorized open at T1 by NEW. NEW shows promise for earlier testing after insemination and earlier testing in the postpartum period.

Key words: PSPB, blood-based pregnancy detection

M64 Survey of genetic selection practices on pasture-based dairy farms in the United States. K. D. Gay*, T. D. Nennich, and M. M. Schutz, *Purdue University, West Lafayette, IN.*

A survey was mailed to dairy graziers across the country to ascertain their genetic selection practices, but included background information on feeding, production, and health. The overall aim was to collect data to allow eventual development of a genetic selection index. Mailing addresses were obtained from extension cooperators, NRCS advisors, and commercial companies. Producers were able to respond to the survey by mail or internet. Respondents to the survey included 77 farmers in 22 states. Producers were asked questions about the grazing history of their herd and average milk and component production. They were also asked questions about breeding practices to determine number utilizing seasonal grazing and to gain an understanding of breeds present in their herds. Producers were asked to rank genetic traits by the amount of selection pressure they felt should be applied to those commonly available. Traits were ranked from negative 5 to positive 5 with negative being selection against a trait and positive being selection for a trait. Respondents averaged 15.95 ± 9.12 years of grazing history, 129.1 ± 128.52 milking head, and grazed 224.5 ± 60.47 d a year. Production was 20.9 ± 4.89 kg of milk per cow per day, 4.0 ± 0.42% milk fat, and 3.6 ± 0.23% milk protein. Also, 46.7% of producers participated in seasonal calving, defined as 75% of cattle calving in any 3 mo window. Further, 70% utilized crossbreeding to the extent that at least 10% of the herd was crossbred. Percentage of herds that included at least some genetics from major breeds were: 70% Jersey, 65% Holstein, 26.7% Ayrshire, 21.7% Swedish or Norwegian Red, and 20% Milking Shorthorn. The average rank of genetic traits were: productive life 3.87, udder composite 3.57, somatic cell count –3.15, feet and legs 3.08, daughter pregnancy rate 3.05, fat percentage 2.97, calving ability 2.95, protein percentage 2.83, body size –2.73, fat yield 2.69, protein yield 2.56, and milk yield 2.27. It appears that pasture-based dairy producers place more emphasis on traits relating to longevity and fertility and less on production traits than the most widely used US selection indexes.

Key words: grazing, genetics, management

M65 Estimating field conception rates for Holstein sires in US herds (ACE index) and conception rate correlation from the same sires used for AI after natural estrus and timed AI breedings. A. H. Souza*[1,2], H. Rivera[2], P. Crump[1], and V. Cabrera[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]Accelerated Genetics, Baraboo, WI.*

The aim of this retrospective study was to validate a fertility index of Holstein sires from one AI stud in the United States (accelerated conception evaluation – ACE index), using for comparison the sire conception rate index (SCR, AIPL-USDA) as the industry official standard. A second objective was to compare conception rate (CR) rankings from same sires used for AI after natural estrus (EAI) and timed-AI (TAI) breedings. Confirmed CR records from 3 national data centers (AGSource, ATA, DRMS) and farm backups from non-testing herds were merged and used as basis for this data analysis. Criteria edits in the data set were: breedings from last 4 years with confirmed conception results; sires with 300 breedings minimum; herd's CR within 20 and 60%; 30 breedings per herd minimum; sires used in a minimum of 10 herds with no more than 40% breedings in one herd; 1 to 5 breedings occurring within 45 to 375 DIM; and cows within 1 to 5 lactations. After editing 1,142,859 breeding records were available for analysis. A subset of the data (n = 801,636) was used to classify breeding codes into either AI to estrus or timed-AI based on weekly insemination profile in each herd. The procedure Glimmix of SAS took into account effects of state, farm, cow id, breeding month, year, parity, DIM at breeding, and service sire. Then, sire fertility classification was based on standard deviations from the population mean. The Spearman-correlation between ACE and SCR was 0.79 ($P < 0.01$). The same model was used independently for the 2 differing breeding codes and fertility classification within breeding code was done for sires with >700 (94 sires) and again for >1,000 (n = 56 sires) breedings in both EAI and TAI. Spearman-correlation of the rankings produced with EAI and TAI were 0.81 ($P < 0.01$; for >700 breedings) and 0.84 ($P < 0.01$; for >1,000 breedings). Thus, these results indicate a significantly good correlation between ACE and the industry gold standard index-SCR. In addition, conception rankings of the same sires used for EAI and TAI were highly correlated.

Key words: sire fertility, conception rate, dairy cow

M66 Effects of dam's dry period length on heifer development. H. D. Norman and J. L. Hutchison*, *Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD.*

Effect of dam's days dry (DD) on calving ease (CE) score (1–5), stillbirth (SB) rate, heifer age at first breeding (AFB), and heifer survival to first calving (SURV1) was investigated with US Holstein records from 1997 through 2010: 774,821 for CE, 347,462 for SB, 27,932 for AFB, and 300,725 for SURV1. The small number of records for AFB was because breeding records for heifers were not stored until 2003 and reporting is minimal. Heifer SURV1 was a binary trait (0 = no, 1 = yes) and included only female calves. Dam calving date was required to be within 10 d of expected calving date (previous calving date + previous days open + 280) to ensure producers knew calving date and dry period length. Dam DD were grouped into 12 categories: 0–30, 31–35, 36–40, ..., 66–70, 71–80, 81–90, 91–120 d. The linear fixed-effects model for analysis of CE and SB included dam calving herd-year and year-state-month, parity, calf sex, and DD category; the AFB model included heifer breeding herd-year and year-state-month as well as DD category. The SURV1 model included dam calving herd-year and year-state-month, dam parity, and heifer parent average for daughter pregnancy rate. For AFB and SURV1 analyses, heifer birth dates were required to be before January 2008 to allow time for completion of a first lactation. Calving difficulty increased linearly as dam DD increased until about 70 d and then leveled off: 1.29 for 0–30 DD, 1.36 for 56–60 DD, and 1.42 for 91–120 DD; corresponding SB were 4.15, 2.36, and 3.33%. Differences between DD categories were all significant ($P < 0.0001$) for CE and SB. For corresponding dam DD, heifer AFB were 463, 458, and 458 d; corresponding heifer SURV1 were 64.6, 70.1, and 68.8%. Heifer AFB and SURV1 differences were significant ($P < 0.05$) between 0 and 30 and 56–60 DD but nonsignificant between 56 and 60 and 91–120 DD.

Key words: days dry, calving ease, heifer survival

M67 Changes in the use of young bulls. K. M. Olson*[1], J. L. Hutchison[2], P. M. VanRaden[2], and H. D. Norman[2], *[1]National Association of Animal Breeders, Columbia, MO, [2]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Availability of genomic information since 2008 has increased accuracy of genetic evaluations for young bulls in Holstein (HO), Jersey (JE), and Brown Swiss (BS). As a result, AI organizations have been aggressively promoting young bulls and producers have been using young bulls more extensively. Number of inseminations by breeding year and service sire (SSR) age at the time of insemination was investigated using US breeding records from 2007 through 2010. There were a total of 65,686 BS, 14,319,994 HO, and 771,766 JE inseminations. Age of SSR was categorized into 3 groups: young bulls (0.8 to 3.9 yr), first crop sires (4.0 to 7.9 yr), and older sires (≥8.0 yr). There was an increased use of young bulls between 2007 and 2010 for HO and JE (Table 1); increase in inseminations by young bulls was 14 percentage units for HO and 7 percentage units for JE. This was not surprising, because HO gain more in accuracy from genomics than the other breeds. First crop sire usage decreased for HO (14 percentage units) and JE (3 percentage units). Older sire usage remained constant at 15 to 18% for HO, 16 to 23% for JE, and 33 to 36% for BS. Economic ($) rankings have been converted to percentile rankings since 1980 with the average of proven bulls being 50%; as a comparison, the 294 young HO bulls currently being marketed averaged +459 Net Merit and a 83 percentile ranking. When young bulls have reliabilities >60%, simulations indicate that the optimum usage of young bulls may increase to > 90% of the market share. Current average genomic reliabilities for Net Merit are 73, 60, and 48% for HO, JE, and BS, respectively. The shift to increased inseminations to young bulls is likely to continue.

Table 1. Percentages of inseminations by breeding year, service sire (SSR) age, and breed

Breeding year	Service-sire age (yr)	Brown Swiss	Holstein	Jersey
2007	0.8 - 3.9	35	29	25
	4.0 - 7.9	29	56	55
	≥ 8.0	36	15	19
2008	0.8 - 3.9	32	30	27
	4.0 - 7.9	33	52	50
	≥ 8.0	35	18	23
2009	0.8 - 3.9	33	39	31
	4.0 - 7.9	33	44	50
	≥ 8.0	34	17	19
2010	0.8 - 3.9	33	43	32
	4.0 - 7.9	34	42	52
	≥ 8.0	33	15	16

Key words: breeding, insemination, service-sire age

M68 Body condition score comparisons of crossbred Normande-sired cows with herd mates sired by Ayrshire, Holstein, and Jersey. D. E. Brown* and C. D. Dechow, *The Pennsylvania State University, University Park.*

The objective of this study was to investigate the body condition score (BCS) of Normande sired crossbred cows with their herd mates sired by Ayrshire, Holstein, and Jersey. Eight farms in the Northeastern states of Massachusetts, New York, Pennsylvania, and Vermont were visited once during the months of January or February to BCS. The farms varied from year round confinement with large amounts of concentrate supplementation to herds with little confinement and minimal concentrate or silage supplementation. Data included observations for 46 Normande sired crossbreds, 52 Ayrshire sired, 263 Holstein sired, and 55 Jersey sired cows. 42 of the Ayrshire sired cows, 254 Holstein sired cows, and 42 Jersey sired cows were purebred. The Mixed procedure of SAS 9.1.3 was used to analyze the data. Significant fixed effects included days in milk ($P < 0.05$) and sire breed ($P < 0.0001$). Random effects included dam breed and farm. The Normande sired crossbreds had a significantly higher least-square-means for BCS (3.64) than cows from other breeds. Ayrshire cattle had the second highest least-squares-means estimate (2.76), followed by Holstein (2.61) and Jersey (2.35). The Ayrshire sired cow's estimated BCS was significantly higher than Jersey, but not significantly higher than Holstein. Holstein and Jersey sired cows were not significantly different from each other. These results suggest that crossbreeding with Normande may result in substantially higher levels of BCS in a range of herd environments.

Key words: Normande, crossbreed, Ayrshire

M69 Use of cow culling to help meet compliance for somatic cell standards. H. D. Norman and J. R. Wright*, *Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD.*

Stricter SCC standards are expected in the United States. The relationship between a single high herd test-day SCC and SCC noncompliance was examined for US DHI herds, and the use of cow culling for maintaining herd compliance was investigated. Data were SCS from 14,346 herds with 15 to 26 tests from January 2009 through October 2010 and ≥10 cows for all tests. Cow SCC were derived from cow SCS by SCC = $2^{(SCS - 3)}$(100,000). Herd test-day SCC was a proxy for bulk tank SCC and was determined by weighting individual cow SCC by test-day milk yields. Herd test-day SCC was used to determine whether a herd would be SCC noncompliant under current or proposed US standards because 3 of 5 consecutive SCC tests exceeded 750,000, 600,000, 500,000, or 400,000 cells/mL. Percentage of herds that were SCC noncompliant 4 mo later for each SCC limit was determined for starting dates of October 2009, February 2010, and June 2010. Effectiveness of 3 different culling approaches was examined: culling cows with a high (above limit) current SCC, culling cows with a high index of previous and current SCC, and culling all cows above a designated parity. The culling objective was to eliminate cows that were likely to have a high SCC for each of their next 4 tests. Culling was simulated by deleting various percentages (1 to 5) of cows with high SCC from the herd when a herd test-day SCC exceeded one of the alternative limits. Herd-test-day SCC were recalculated without the high-SCC cows so that herd compliance for the next 4 tests could be compared with compliance without simulated culling. For herds with a starting test-day SCC of >400,000 cells/mL and no subsequent culling for SCC, percentage of noncompliant herds 4 mo later was 55% for October 2009, 62% for February 2010, and 66% for June 2010. Culling 5% of high-SCC cows lowered herd noncompliance to 46, 50, and 55% for the same starting months; culling cows with parity >4 reduced herd noncompliance to 48, 53, and 56%, respectively.

Key words: culling, somatic cell count, milk quality

M70 The association of high and low parent average with performance for yield, somatic cell score, and productive life in individual herds. C. D. Dechow*[1], H. D. Norman[2], R. C. Goodling[1], and J. R. Wright[2], *[1]Pennsylvania State University, University Park, [2]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

There have been efforts to demonstrate to dairy producers the value of genetic selection by evaluating response to selection within their own herds. The objective of this study was to evaluate how frequently results conform to expectations for various traits and for herds of varying sizes. Parent averages (PA) and standardized records of milk yield, fat yield, protein yield, somatic cell score (SCS), and productive life (PL) were obtained from the Animal Improvement Programs Laboratory at USDA for 1,042,361 sire-identified Holstein cows that calved from 2005 through 2009 in 3334 Pennsylvania herds. Parent averages were obtained from evaluations occurring before a cow's first calving date to prevent part-whole bias. The top 25% (Q1) and bottom 25% (Q4) of cows for PA were identified within each herd and year of calving for each trait. The mean milk, fat and protein yield, SCS, and PL in Q1 and Q4 was determined for all herd-years. Results conformed to expectations when the average for Q1 exceeded the average for Q4. Most herd-years had higher values for Q1 cows than Q4 cows regardless of the number of sire-identified daughters present in the herd, with results ranging from 60% for PL to 78% for fat yield. The mean difference in PA from Q1 to Q4 for fat yield was 34 kg, which was close to the phenotypic difference in fat yield (36 kg). For productive life, the mean difference in average PA from Q1 to Q4 (4.8 mo) was greater than the phenotypic difference (1.5 mo). Greater than 89% of herd-years met expectations for yield traits when the number of cows exceeded 10 per quartile, compared with 74% of herd-years for SCS and 67% of herd-years for PL. All herds with 125 or more cows per quartile met expectations for yield traits compared with 98% for SCS and 68% for PL. Within-herd comparison of top and bottom cows for PA demonstrated a favorable response to selection for yield traits even in herds with relatively few sire-identified daughters. Results were less predictable for lower heritability traits, but the majority of herd-years still conformed to expectations.

Key words: parent average, genetic selection

M71 Genetic differences between New Zealand and North American dairy cows alter milk production and gluconeogenic enzyme expression. H. M. White*[1], S. S. Donkin[1], M. C. Lucy[2], T. M. Grala[3], and J. R. Roche[3], *[1]Purdue University, West Lafayette, IN, [2]University of Missouri, Columbia, [3]DairyNZ Ltd., Hamilton, New Zealand.*

Continuous selection of dairy cows for production traits may alter the regulation of metabolic pathways. High-producing North American (NA) cows produce more milk and have a larger degree of somatotropic axis uncoupling than less intensively selected New Zealand (NZ) cows. The objective of this study was to determine if production-based selection priorities (i.e., NA cows) have altered the regulation of the gluconeogenic pathway differently than selection priorities based on production and longevity traits (i.e., NZ cows). In this study, NZ (n = 27) and NA cows (n = 27) were monitored from 1 wk before calving to 12 wk post calving. Cows were pasture-fed and supplemented with 0, 3, or 6 kg DM of concentrate/d. Liver biopsy samples were collected at −7, +7, and +28 d relative to calving (DRTC) for mRNA analysis. Milk production of NA cows was greater ($P < 0.05$) during wk 5 to 11 postpartum and concentrate supplementation increased ($P < 0.05$) milk production for both NA and NZ cows. There was no genotype (NA vs. NZ) by diet interaction on blood glucose, NEFA, or insulin. Expression of pyruvate carboxylase (PC) mRNA was increased ($P < 0.001$) at +7 and +28 DRTC relative to −7 DRTC (3.04 and 2.42 vs. 1.25 ± 0.13 arbitrary units) and expression of cytosolic phosphoenolpyruvate carboxykinase (PEPCK-C) mRNA was increased at +28 compared with −7 and +7 DRTC (4.78 vs. 2.18 and 2.48 ± 1.41 arbitrary units). Expression of PC mRNA tended to be greater ($P = 0.12$) in NZ cows and declined with concentrate supplementation ($P < 0.05$) in both NZ and NA cows. Gluconeogenic enzyme expression in liver increased postpartum in both NZ and NA cows, with the 2 strains tending to differ for PC expression (greater in NZ cows). Grain supplementation reduced PC mRNA expression regardless of genetic strain. This project was supported in part by DairyNZ, Ltd. and in part by Grant no. 2009-35900-05970 from the USDA National Institute of Food and Agriculture.

Key words: pyruvate carboxylase, genetic selection, concentrate supplementation

M72 Verification of factors to estimate daily milk yield from one milking of cows milked twice daily. M. M. Schutz*[1] and H. D. Norman[2], *[1]Purdue University, West Lafayette, IN, [2]USDA-ARS Animal Improvement Programs Laboratory, Beltsville, MD.*

The objective of this research was to verify factors to predict daily milk yield when milk is sampled once per day for cows milked twice (2x) per day. Milk weights for both milkings were recorded automatically by 30 herds and collected by Dairy Herd Improvement supervisors. Data was split into 2 subsets for developing (FACT) and testing

(TEST) factors. Following edits, 179,064 daily milk weight records of 2941 first lactation (L1) cows and 298,905 records of 4757 later lactation (L2) cows remained in FACT and 177,299 records 2120 L1 cows and 335,692 records of 3319 L2 cows remained in TEST. Factors currently in use to adjust single milking yields for milking interval (MINT) were applied. Also, 3 methods were compared with estimate factors or equations to predict daily milk yield. First, factors were estimated as the ratio of the sum of daily yield to the sum of partial yield within a parity-MINT class (13 intervals in 2 parities) [Method 1] or as the sum of the ratios of daily yield to partial daily yield for each cow-day divided by the number of cow-days within parity-MINT class [Method 2]. Resulting factors from both methods were smoothed, applied to data, and residuals were regressed on days in milk (DIM) for FACT and applied to TEST. Regression equations (n = 168) were also developed within parity-MINT-DIM classes (2x7x12) [Method 3] to jointly account for MINT and DIM. Separate factors were derived for milking 1, and 2, for L1 and L2. Method 3 resulted in consistently strongest correlations between estimated and actual yields, and smallest variances of estimates, and root mean squared errors (rMSE) for milkings in L1 and L2 for FACT. When applied to TEST, Method 1 resulted in rMSE of 2.07 (Milking 1, L1), 2.12 (Milking 2, L1), 2.64 (Milking 1, L2), and 2.85 kg (Milking 2, L2); compared with rMSE of 2.13, 2.26, 2.68 and 2.83 kg, respectively, from current factors for the same milkings for L1 and L2. Methods 1 and 3 provide more accurate prediction of daily milk weight from a single milking for herds milking 2x daily than factors currently in use.

Key words: milking interval, adjustment factor, milking frequency

M73 Estimation of daily yield of major fatty acids from single milking. V. Arnould[1,2], E. Froidmont[4], H. N. Nguyen[5], F. Dehareng[5], P. Dardenne[5], A. Gillon[2,6], N. Gengler[2,3], and H. Soyeurt*[2,3], *[1]CONVIS, Herdbuch Service Élevage et génétique, Ettelbruck, Luxembourg, [2]University of Liège, Gembloux Agro Bio-Tech, Animal Science Unit, Gembloux, Namur, Belgium, [3]National Fund for Scientific Research, Brussels, Brussels, Belgium, [4]Production and Sectors Department, Walloon Agricultural Research Centre, Gembloux, Namur, Belgium, [5]Quality of Agricultural Products Department, Walloon Agricultural Research Centre, Gembloux, Namur, Belgium, [6]Walloon Breeding Association, Ciney, Namur, Belgium.*

There are cost savings when the frequency of milk recording is reduced. Milk recording organizations have implemented alternative schemes that rely on milking interval (MI), but MI can be unreliable. Moreover, nothing is available for milk fatty acids (FA). The aim of this study was to build a model for estimating accurately the daily yields of major FA from single milking without using the MI. The hypothesis was that MI can be reflected by the changes of milk yield and composition. Five Holstein cows were followed generally every day at each milking between March 2008 and December 2010. FA were measured by mid-infrared. The database contained 1,440 records. Eight models were tested to estimate daily yields from morning or evening milking. Different effects were included progressively. The first ones were related to the characterization of the milk production (i.e., days in milk, month of calving, month of test, milk yield, and lactation number). The other effects were related to the milk composition (i.e., fat and protein contents). Models were compared from the coefficient of determination and the mean square errors between estimated and observed daily yields. Results showed that R^2 were higher when the milk composition effects are introduced in the model. For the different studied FA traits, R^2 ranged between 0.87 and 0.88, when daily yields were estimated from morning milking and between 0.75 and 0.86 when daily yield were estimated from evening milking. By comparison, the model approved by ICAR and proposed by Liu et al. in 2000 gave R^2 ranged from 0.81 to 0.84 from morning milking; and from 0.74 to 0.85 from evening milking. Therefore, the introduction of these milk composition effects permit to replace the MI. It was also observed that daily yields estimated from evening data are less accurate than those estimated from morning data. After a larger validation, the best accurate model could be used to evaluate the fatty acid data collected in alternate milking recording and used for breeding purposes.

Key words: milk, fatty acid, daily prediction

M74 Comparison of lactation performance in a panel of genetically diverse inbred mouse strains. D. L. Hadsell*[1], W. Olea[1], J. Wei[2], L. A. Hadsell[1], and P. Williamson[2], *[1]Baylor College of Medicine, Houston, TX, [2]The University of Sydney, Sydney, NSW, Australia.*

Inbred mouse lines have been a powerful tool in the mapping and identification of genes underlying a variety of different qualitative and quantitative traits. Their use in mapping lactation-related traits has been limited. Recently, the application of mapping panels based on existing inbred mouse strains has had some success in identifying quantitative trait loci. The current study compared quantitative indices of lactation performance among a panel of inbred mouse strains with the ultimate goal of apply this data with association mapping strategies to identify potential genes determining variation in milk production. Females from each of 32 inbred strains (n = 8 mice/strain) were studied during the first 8 d of their second lactation. Weight gain (LWG) of cross-foster litters (10 pups/litter) served as the primary indicator of milk production (19.9 ± 8.9 g, mean ± S.D.) and varied ($P < 0.0001$) among strains (range 5.3 – 32.1 g). The number of pups born per litter (7 ± 3) also varied ($P < 0.0001$) among strains (range 4 – 13) and was significantly correlated to crossfoster litter gain ($r = 0.47$, $P < 0.0001$). Maternal body weight and maternal food intake also had significantly positive correlations to crossfoster litter gain ($P < 0.0001$). Initial haplotype association analysis using the 132 k SNP database publically available from the Broad Institute identified suggestive ($P < 10^{-5}$) associations to LWG on chromosomes 4, 11, and 13. These data indicate that significant phenotypic variation exists among genetically inbred mouse strains for traits indicative of milk production. Such variation should be useful to map QTL genes for lactation. Supported by NICHD grant #1R21HD059746–01A1.

M75 Statistical comparison of persistency among calving seasons of Iranian Holsteins. R. Izadkhah*, H. Farhangfar, M. H. Fathi Nasri, and H. Naeemipour, *Birjand University, Birjand, Iran.*

In this study, Wilmink exponential function ($y = a+bt+ce(-0.05*t)$) was utilized to evaluate the effect of calving season on persistency. The function was fit on 130,668 monthly test-day milk yields belonging to 15,183 first lactation Iranian Holstein cows calving between 2000 and 2009. Persistency was calculated based upon predicted milk yield by the function [(milk305/peak yield*305)*100]. Effect of calving season on persistency was analyzed by a linear mixed model. In the model, fixed effect of geographical location, herd, year, season, sire's sperm origin, as well as linear covariables of calving age, peak yield, peak time, days to first milk recording, and sire random effect were included. The model was fit by Mixed Procedure of SAS software. The results indicated that all factors had significant ($P < 0.001$) affect on persistency. Least squares means of persistency were 84.68, 85.45,

85.77 and 84.75% for spring, summer, autumn and winter calvers, respectively. There were no significant differences between spring and winter seasons and between summer and autumn seasons. With respect to positive correlation between persistency and total lactation milk yield, providing constant peak yield, cows calving in autumn and summer are expected to have higher milk yield as compared with spring and winter calvers.

Key words: Wilmink function, persistency, Iranian Holstein

M76 Genetic parameters estimates to Colombian buffalo milk yield under random regression models. N. Hurtado-Lugo*[1,2], S. Sousa Júnior[1], M. Cerón[2], R. Aspilcuelta[1], E. Acevedo[1], S. Gutierrez[2], L. Albuquerque[1], G. de Camargo[1], D. Santos[1], and H. Tonhati[1], *[1]UNESP Faculty of Agriculture and Veterinary Sciences, State University of São Paulo, Jaboticabal, SP, Brazil, [2]Genetics and Animal Improvement Group, Faculty of Agriculture Sciences, University of Antioquia, Medellín, Colombia.*

The random regression model (RRM) has been proposed as an alternative approach to analyze longitudinal data, for instance milk yield records that are collected repeatedly over a lactation, because it considers such data as repeated measures. Buffalo production is part of the agribusiness in developing countries such as Colombia, and there is still little research using RRM. This study has the aim to estimate the genetic parameters using RRM for test-day milk yield in dairy buffalo in Colombian northern coast. First lactations from 10,929 buffalo were recorded monthly from 1998 to 2008. The archive was composed of 11,148 animals, 10,929 female buffaloes and 219 bulls. The fixed effects were contemporary group that was composed of month and year of control, and milking days (the fixed regression to the population mean). The age at calving was used as covariate (linear and quadratic regression) and the random effects were the direct genetic and the permanent environment. The most appropriate model was the one using a Legendre′s polynomial function of 3rd order for the genetic effect and 6th order for the permanent environmental effect. The residual variances were heterogeneous, modeled by a step function, containing 2 classes of variances. The variance components were estimated using the statistical package WOMBAT. Models were compared by Akaike Information and Schwarz Bayesian′s criteria. The heritability varied from 0.33 to 0.17; the highest values were observed at the beginning of the lactation, and the lowest at the end. The genetic and phenotypic correlations were high and positive; it indicates the necessity to model the residual with a heterogeneous structure. Financial support: FAPESP, Foundation for Research Support of São, SP, Brazil.

M77 Mathematical modeling of the lactation curve of domestic donkey (*Equus asinus*). A. M. Guastella*[1], A. Criscione[1], S. Bordonaro[1], D. Marletta[1], R. Steri[2], and N. P. P. Macciotta[1], *[1]Università di Catania, Catania, Italy, [2]Università di Sassari, Sassari, Italy.*

Donkey farming for milk production is getting an increasing interest in Italy mainly for pharmaceutical and cosmetic purposes but also for human nutrition. Actually donkey milk is suitable for people intolerant to cow milk protein and is able to fulfill nutritional requirements of babies. The knowledge of the lactation curve may be of interest for a first definition of production attitudes and nutrition requirements of this species. Data were 453 test day records for milk yield, fat and protein percentage and somatic cell count (SCS) of 62 donkeys farmed in 2 commercial herds located in Sicily. Animals were grouped according to age classes (<5, 5, 6, 7–10 and >10 years respectively). Average lactation curves for age class were estimated with a mixed linear model that included fixed effects of herd, calving season, age class, days in milk interval (9 intervals of 30 d each) and the random effect of the animal. Repeatability was 0.55, 0.14, 0.10 and 0.07 for milk yield, fat and protein percentage and scc logarithm, respectively. Almost all factors included in the model significantly affect milk yield and protein percentage. Youngest donkeys had curves with lower peak and higher persistency compared with older animals. Average curves for fat percentage showed an opposite trend compared with milk yield, even though with a high variability between classes of age. Protein content was characterized by a continuous decreasing trend along the lactation. Somatic cell count was constant throughout the lactation, below 20,000 cell/mL, with a slight increase only at the end. The fitting of individual patterns for milk yield with the incomplete gamma function of Wood resulted in a frequency of 0.43 of curves without a lactation peak. This result is mainly due to the scarce availability of data in early lactation, being the milk of the first month suckled by the foal. Standard curves had an overall mean of 68 d for time at peak occurrence and a peak yield of 2.28 kg/d. Younger animals have later peak occurrence (160 d) than older animals (between 45 and 76 d) and lower peak productions (1.6 kg/d vs. 2.3 kg/d) respectively.

Key words: donkey, lactation curve, mathematical modeling

M78 Genetics of immunocompetence traits in Aseel native chicken of India. S. Choudhary*[1], S. Kumar[2], and B. Nautiyal[1], *[1]MJP Rohilkhand University, Bareilly, U.P. India, [2]Central Avian Research Institute, Bareilly, U.P. India.*

Breeding chickens for higher immunocompetence and disease resistance provides a valuable approach for commercial poultry production. Several immunocompetence traits that can be considered for improving genetic resistance to diseases in poultry are greater antibody response to sheep RBC, lysozyme activity and high titer of immunoglobulin G (IgG) in the serum. Antibody titers against sheep RBC and serum IgG level are the indicators of humoral immune response, whereas bacteriolytic activity of serum lysozyme is the indicator of non-specific immune response. In the present study Aseel (n = 301), an Indian breed of chicken, was studied for high and low immune response by assessing their immunocompetence traits using 3 different tests - hemagglutination (HA) test, lysozyme plate assay and serum IgG level estimation. The data generated on immunological traits were analyzed by least squares ANOVA. The average (expressed as mean+ standard error) HA titer, serum lysozyme activity and IgG level was 8.14 ± 0.35, 4.85 ± 0.20, 10.82 ± 0.64 in males and 8.15 ± 0.31, 4.48 ± 0.22, 12.64 ± 0.75 in females, respectively. Sex of the birds had no effect ($P > 0.05$) on HA titer, lysozyme level and serum IgG level. However, male birds revealed higher IgG level ($P < 0.07$) than the female. We concluded that Aseel has high immune competence status in comparison to broiler and desi fowl chicken reported earlier in the literature.

M79 Study on the diversity of Yunnan original chicken meat using NIR spectroscopy based on principal component analysis and cluster analysis. J.-L. Wu[1], X. Gao*[1], Y.-Z. Li[3], Y.-F. Yin[1], and Y. Li[2], *[1]Yunnan Animal Science and Veterinary Institute, Kunming, Yunnan, China, [2]Sweden Perten Instruments Representative Office in China, Beijing, China, [3]University of Minnesota, Morris.*

The aim of this study was to investigate the feasibility of using near-infrared (NIR) spectroscopy to identify genetic characteristics of meat quality of Yunnan original chicken breeds. A total of 1310 breast muscle samples collected from 25 original breeds of chicken in 28 counties located in 14 regions of Yunnan Province were analyzed using PERTEN DA7200 NIR spectrophotometer. Data were analyzed by using principal component analysis (PCA) of the Unscrambler (CAMO) software and cluster analysis (CA) of the SPSS software. The results show that the NIR of the 25 breeds of Yunnan original chicken are basically identical. Spectra transformed by SNV, 9 point smoothing, and the first derivative, indicate that absorption band of each breed was significantly different in the range of 1000 to 1050nm, 1130 to 1150nm and 1370 to 1400nm. The greatest difference was observed between the Nixi and the Xichou chicken breeds. Principal component analysis indicated that the NIR spectra of each breed was different, particularly in 5 breeds of the Xichou, Zhenyuan-Piao, Nixi, Luxi Ae, and Huaping-Wu chicken. After pretreatment with Euclidean distance spectrum of the CA, a certain Euclidean distance can be divided into distinctive breeds. The Xichou and Nixi chicken had the most remarkable specificity, with the Euclidean distance of 1 between the 2 breeds. Xichou chicken distribute the southeast of Yunnan and Nixi chicken distribute chicken distribute the northwest of Yunnan, the 2 breeds did not show any genetic connections, probably due to the longest geographical distance of their origin. These results suggest that the 5 breeds are best represent genetic resources of the original chicken, with the greatest conservation value. Meanwhile, this study indicates that NIR can be used to accurately and quickly analyze genetic characteristics of meat quality in chicken breeds and identify genetic resources of special chicken breeds.

M80 Breed and egg size effects on weight loss during incubation of Broiler eggs. O. T. F. Abanikannda*, A. O. Leigh, and A. O. Giwa, *Lagos State University, Ojo-Lagos, Nigeria.*

Physiological processes that take place during incubation of eggs often resulted in changes in egg weight during the period. This study investigates the effect of breed and egg sizes on weight loss at 3 points between incubation and hatching viz: pre-incubation, 18th day of incubation, chick weight at hatching. A total of 1002 hatchable eggs from 3 strains; Anak (n = 361), Marshall (n = 359) and Ross (n = 282) of Broiler breeders were weighed and measured using digital weighing scale and digital caliper. Weight, length and width were taken before incubation, while shape index was also computed. Weight losses from incubation to 18 d (WtLoss1), 18th day to hatching (WtLoss2) and incubation to hatch (WtLoss3)] were computed. The Minitab statistical software was used for basic descriptives, regression analyses and statistical modeling of the data. The model used for the regression analysis is described by $Y_{ijklm} = \mu + \alpha_i + \beta_j + \theta_k + \rho_l + \varepsilon_{ijklm}$ describing each of the 3 response variables. Egg weight was between 44.60g and 81.70g, while egg length ranged between 49.99mm and 69.98mm, and egg width was between 38.54mm and 56.75mm, while shape index was between 61.44% and 99.02% across the 3 strains studied. The largest source of variation was breed effect, which was highly significant ($P < 0.001$) on all 4 variables. Similarly, breed significantly ($P < 0.001$) impacted on WtLoss1 and Wt Loss3 but was not a significant ($P > 0.05$) source of variation on WtLoss2. All the predictor variables were significantly ($P < 0.05$) correlated to the response variables except shape index, which had negative and non-significant ($P > 0.05$) correlation with the weight losses. The very low negative and non-significant correlation between egg weight and egg weight loss up to the 18th day of incubation indicated that weight loss was slower in bigger eggs compared with relatively smaller eggs. The study revealed that breed was a significant source of variation on weight loss at the 18th day of incubation (WtLoss1) and throughout the entire period of incubation and hatching (WtLoss3) but was not significant on weight loss after the 18th day (WtLoss2).

Table 1. Egg weight loss at different stages of incubation and hatching by breed

Breed	N	WtLoss 1 (%)	WtLoss 2 (%)	WtLoss 3 (%)
Anak	361	13.75±0.19[a]	19.12±0.47	32.87±0.44[a]
Marshall	359	12.86±0.15[b]	18.37±0.42	31.22±0.42[b]
Ross	282	11.69±0.25[c]	19.41±0.40	31.10±0.36[b]
Combined	1002	12.85±0.11	18.93±0.25	31.78±0.24

M81 Estimation of genetic parameters for body weight traits in Mazandaran indigenous chicken. S. Niknafs*, A. Nejati Javaremi, H. Mehrabani Yeganeh, and A. Fatemi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

A breeding station for Mazandaran native chicken was established in 1988 with 2 main objectives: extension and genetic improvement of the local breed. For 18 generations, selection was done for 8-wk BW (BW8), egg number, age at first egg and average egg weight as selection criteria. Besides these traits, some other traits were recorded. As the aim of the current study we estimated genetic parameters for body weight traits including body weight at hatch (BW1), at 8 (BW8), at 12 weeks of age (BW12) and at sexual maturity (WSM). Univariate (for estimating variance components) and bivariate (for estimating covariance components) animal models were fitted using ASREML procedure. The highest and lowest magnitude of heritability estimates belonged to WSM and BW8, respectively. BW8 has been included in selection criteria, so relatively lower heritability may be due to decreased genetic variance during selection process. Genetic correlation between BW8 and BW12 was close to unity. Also, high genetic correlation between BW12 and WSM was observed. Other genetic relationships were moderate generally. No remarkable environmental correlations were obtained among these traits except for moderate environmental relationship between BW8 and BW12.

Table 1. Statistical description of data set, heritabilities (diagonal in bold), genetic (above diagonal) and environmental (below diagonal) correlations of investigated traits (±SE)

Trait	BW1	BW8	BW12	WSM
No of Animal in Data File	35287	43067	38297	31147

M82 Genetic and phenotypic trends for body weight and egg production in Mazandaran indigenous chicken. S. Niknafs*, A. Nejati Javaremi, H. Mehrabani Yeganeh, and A. Fatemi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

The study of genetic trends is a way for monitoring the selection process. Phenotypic information collected during 1988 to 2009 (18 successive generations of selection) in breeding station of Mazandaran native chicken were analyzed to estimate genetic and phenotypic trends. This population has been selected for traits body weight at 8 weeks, egg number, sexual maturity age and egg weight. Univariate animal model in ASREML software was applied to estimate breeding values. Trends for breeding values and phenotypic performance were obtained by regression of average breeding values and phenotypic least squares means, respectively, on generation number. The table below shows regression coefficients of genetic and phenotypic trends. Results showed that selection can lead to genetic progress in whole recorded traits, except for traits EW28 and EW12. Significant changes in phenotypic level were observed just for BW1, BW8 and WSM, which could be caused by negative environmental trends. Also, inbreeding coefficient on average has increased with the rate of 0.0058 ($P < 0.0001$) per generation of selection.

Table 1. Regression coefficients of average breeding values and phenotypic LSM on generation with *P*-values

Trait	Genetic Trend	*P* <	Phenotypic Trend	*P* <
BW1	−0.035	0.0001	−0.36	0.0164

M83 Heritability and genetic correlation estimates for egg production related traits in Mazandaran indigenous chicken. S. Niknafs*, A. Nejati Javaremi, H. Mehrabani Yeganeh, and A. Fatemi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

The best way to improve the productivity of indigenous chickens, without altering any of the morphological characteristics, is to select for production traits within a given population. Such strategy needs accurate estimates of genetic parameters. To achieve this purpose phenotypic information for 18 successive generations which was collected during 1988–2009 in the breeding station of Mazandaran native chicken (north of Iran) were analyzed. Univariate and bivariate animal models in ASREML procedure were used to estimate (co) variance components for traits of age at sexual maturity (ASM) (31349 records), egg number (EN) (31349), average egg weight at 28 (EW28) (17225), 30 (EW30) (19031), 32 (EW32) (18955) weeks of age and average egg weight for first 12 weeks of production (EW12) (18847). Heritabilities, genetic and environmental correlations are shown in the table below. Heritability estimates of egg production traits varied from 0.17 ± 0.01 to 0.43 ± 0.01. Among these traits egg number seemed to be less heritable than others. Genetic correlations among egg weight traits (EW28, EW30, EW32 and EW12) were close to unity. Also, rather moderate environmental correlations among these traits were found. Low negative genetic correlations were obtained between egg number and egg weight traits. Sexual maturity age is moderately negatively genetically correlated with egg number, whereas it has low positive genetic correlations with egg weight traits.

Table 1. Heritabilities (diagonal), genetic (above diagonal) and environmental (below diagonal) correlations (±SE)

M84 Effects of salts on foaming properties of milk protein concentrate at neutral pH. J. Han* and B. Vardhanabhuti, *University of Missouri, Columbia.*

Milk protein concentrate (MPC) is one of the major ingredients in foods due to its nutritional and functional properties including solubility, water binding, foaming, and emulsification. The foaming ability of milk proteins could potentially allow them to replace egg white protein; however, there is a lack of research on foaming properties of MPC. The goal of this study was to investigate the effects of salts on foaming properties of MPC. Calcium chloride, sodium citrate, and sodium chloride were mixed with MPC solutions and pH was adjusted such that the final solutions contained 5% w/w protein, 0–20 m*M* $CaCl_2$ and 0–40 m*M* citrate, or 0–100 m*M* NaCl at pH 7.0. Foam was generated by whipping MPC solutions in a KitchenAid mixer. Foaming properties were determined by measuring overrun and drainage ½ life. Physical properties of pre-foam solutions, including solubility, turbidity, and particle size were measured. Interfacial shear rheology was determined using a controlled- strain and rate rheometer with a bicone geometry. Addition of 20 m*M* $CaCl_2$ caused a reduction in overrun ($P < 0.05$) but no significant effect on foam stability. Either with or without of $CaCl_2$, increasing citrate concentration significantly increased overrun ($P < 0.05$) and drainage ½ life of MPC foam. However, samples having higher citrate concentration (40 m*M*) only showed improvement in overrun but a decrease in drainage ½ life. Sodium chloride significantly improved overrun ($P < 0.05$) but had no effect on drainage ½ life. Enhanced overrun corresponded to a reduction in particle size and turbidity and an increase in solubility of pre-foam solutions. Interestingly, interfacial rheology revealed that pre-foam solutions with $CaCl_2$ exhibited higher interfacial viscosity and interfacial elastic modulus, while the presence of citrate reduced interfacial viscosity and interfacial elastic modulus. These results indicated that appropriate concentrations and combination of salts are needed to optimize foaming properties of MPC.

Key words: milk protein concentrate, foaming properties, salts

M85 Microencapsulation of probiotic cultures using polymerized whey proteins as wall material. Z. Zheng[1], Y. Jiang[1], X. Chen[2], J. Wang[2], J. Cheng[1], H. Zhang[2], and M. Guo*[1], *[1]University of Vermont, Burlington, [2]Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China.*

Commonly used probiotics are sensitive to the environment and processing conditions. The objective of this study was to develop a microencapsulation technique using polymerized whey proteins (PWP) as a wall material for protecting probiotic cultures. PWP was prepared by heating whey protein isolate solution (12%, w/v, pH 8.0) at 85°C for 40 min. The solution was then adjusted to pH 7.0 after cooling. The ratio of the PWP solution to the probiotic culture *Lactobacillus acidophilus* NCFM (8.31×10^8 cfu/mL) was 7:3. The mix was extruded using a 50-mL syringe through a needle (0.6 mm) to the cross linker $CaCl_2$ solution (16.7%) containing Tween-20 (0.4%, v/v) at 40°C while stirring. After being kept in the $CaCl_2$ solution for 20 min and rinsed twice with 0.9% NaCl solution, the beads were freeze-dried after mixing with protecting agents including non-fat dry milk (20%), peptone (1%), and ascorbic acid (0.4%). Microencapsulation using sodium alginate (SA) was prepared as a control. The microencapsulated cultures by PWP and/or SA, and free culture were subject to artificial digestions (gastric juice for 3 h and intestinal juice for 6 h) to determine the survival rate. The diameters of PWP based and SA based beads were 2.70 ± 0.22 mm and 1.28 ± 0.09 mm, respectively. The entrapment yield for the PWP method (89.3 ± 4.8%) was significantly higher ($P < 0.01$) than the control method (73.18 ± 1.4%). Viable counts of the culture after digestion processes were $3.63 \pm 1.48 \times 10^4$, $1.83 \pm 1.10 \times 10^4$ and $1.35 \pm 0.72 \times 10^2$ cfu/mL for the PWP beads, SA ones and free culture, respectively. Results showed that the PWP based microencapsulation seems more effective in protection of probiotics than SA method in the model system. Survivability of PWP encapsulated probiotic cultures in fermented milk products will be further investigated.

Key words: microencapsulation, polymerized whey protein, probiotic

M86 Proteolysis in UHT milk produced with CO_2 added raw milk. P. C. B. Vianna[1], E. H. M. Walter[2], M. E. F. Dias*[3], J. A. Faria[3], F. M. Netto[3], and M. L. Gigante[3], *[1]Universidade Norte do Paraná, Londrina, SP, Brazil, [2]Universidade Federal do Pampa, Bagé, SP, Brazil, [3]Universidade Estadual de Campinas, Campinas, SP, Brazil.*

The goal of this work was to evaluate the effect of CO_2 addition to raw milk on proteolysis of UHT milk during storage. Control milk (without CO_2 addition) and treated milk (added with CO_2 until pH 6.2) were stored in bulk tanks at 4°C during 6 d. After storage, milks were processed using indirect heating (140°C/5s). Samples were aseptically packed in low density polyethylene pouches and stored in the dark at room temperature. Raw milk was evaluated at reception and after 6 d-storage to standard plate and psychrotrophic bacteria count. UHT milk samples were analyzed for proteolysis twice a month until 120 d-storage. Increased in non casein nitrogen as a percentage of total nitrogen was used as index of proteolysis. Analysis of peptides of non casein nitrogen filtrates by RP-HPLC was performed after 1 and 120 d of storage. Split-plot design was used and the complete experiment was replicated 3 times. The results were evaluated by ANOVA and Tukey's test ($P \leq 0.05$). Raw milk presented standard plate and psychrotrophic bacteria counts of 2.8×10^3cfu/mL and 5.2×10^2 cfu/mL, respectively. After 6 d-storage, these counts increased 3 and 4 log cycles for milk without CO_2 addition, respectively, while in the CO_2 added milk the counts remained constant, resulting in a better microbiological quality of raw milk to UHT processing. The proteolysis increased significantly during 120 d of storage to both treatments, but the increase was 1.4 times faster for UHT control milk (UHT_C) than UHT produced from raw milk with CO_2 addition (UHT_{CO2}). One day after processing, the chromatograms showed similar peaks for both milks, corresponding to hydrolysis by plasmin and heat resistant psychrotrophic proteases. However, after 120 d the amount of peptides in UHT_{CO2} milk was almost constant, while peptides produced by plasmin and proteases of psychrotrophic increased in UHT_C, indicating higher proteolysis in this sample. The better microbiological quality of CO_2 added raw milk resulted in less proteolysis and possibly less susceptibility of age gelation in UHT milk, the main problem that limits its shelf life.

Key words: UHT milk proteolysis, carbon dioxide, psychrotrophic

M87 The effect of commercial sterilization regimes on micellar casein concentrates (MCC). C. M. Beliciu, A. Sauer*, and C. I. Moraru, *Cornell University, Ithaca, NY.*

The increasing interest of using micellar casein concentrates (MCC) obtained by membrane separation in the manufacture of shelf-stable,

high protein beverages creates a need to understand the effect of processing conditions, particularly sterilization, on the stability of this ingredient. In this work, MCCs of 5% - 10% casein concentration were subjected to both continuous-flow UHT treatment and in-container retorting, at the same cumulative value of the lethality factor (F_0 = 9.9). The effects of sterilization on the stability and physical properties of MCCs were investigated by determining their rheological properties, zeta potential, particle size and mineral distribution. The study was performed in triplicate. Significant differences among samples were determined at $P \leq 0.05$. Sterilization led to significant changes in zeta potential, from −37mV to −24mV for the controls (non-heat-treated MCCs), to −30 mV to −17mV in retorted MCCs and −34 mV to −20mV in the UHT treated MCCs. This was attributed to the re-distribution of minerals, specifically a loss in solubility of calcium phosphate at the micelle level; soluble Ca content decreased by an average of 30% as a result of the UHT treatment and by 21% as a result of retorting, as compared to untreated samples. Average particle diameter increased as a result of heat treatment: 240nm in retorted samples vs. 180nm in the untreated MCCs (control). UHT treatment led to formation of aggregates visible with the naked eye. Retorting of MCCs led to a 50% decrease in apparent viscosity as compared to the untreated samples, while the UHT treated MCCs had higher apparent viscosity than the controls. For the UHT treated samples, dynamic rheological testing revealed a solid-like behavior at a casein concentration >5%, which was indicative of structure formation. An evaluation of sterilization behavior of MCCs obtained by reconstitution of spray dried powders showed that drying enhanced the instabilities that occurred during sterilization. The results of this study are particularly relevant for using MCCs obtained by membrane separation for the manufacture of shelf stable milk protein beverages.

Key words: micellar casein, zeta potential, retorting

M88 The crystallization of large lactose crystals in skim milk concentrate. B. Toledo* and F. X. Milani, *University of Wisconsin-Madison, Madison.*

The presence of lactose crystals greater than 10 μm in concentrated skim milk is normally considered a quality defect. These large crystals can be avoided by manipulating process parameters such as cooling rate, seed concentration and agitation speed. The objective of the present study is to investigate the formation, characterization and performance of large α- lactose monohydrate crystals in concentrated skim milk at 40% total solids. A 2-level, fractional factorial design with 4 factors was used for the study. The factors tested were holding temperature (5 and 10°C), lactose seed concentration (0.005% and 0.010%), lactose seed size (200 and 40 mesh), and agitation speed (50 and 100 RPM). Lactose crystallization in concentrated skim milk was done by reconstituting skim milk powder to 40% total solids and allowed to hydrate for 24 h at 5°C. After reconstitution, the concentrate was pasteurized, cooled, and seeded with α- lactose monohydrate crystals. Lactose crystallized during 24 and 48 h in a 150 mL stirred reactor. Crystallization started at the selected temperatures and continued with a cooling rate of 0.02 to 0.04°C per hour. Photomicrographs were taken and analyzed with ImageJ 1.44i software. The formed crystals had mean sizes of 71 ± 35 μm and 93 ± 45 μm at 24 and 48 h, respectively. Analysis of the present model concluded that a 24 h crystallization period is significantly influence by the lactose seed size and holding temperature. As the lactose seed size increased, the mean value of crystals increased by 12 μm. When the holding temperature increased, the mean value of the crystals decreased 5 μm. Analysis for 48 h crystallization did not reveal significant influence from any of the tested factors. This is associated with shattering of large crystals, which diminished the influence of initial experimental design factors. The results from the present study are intended to be used as preliminary information in the design of skim milk processes and products that utilize large lactose crystals as a value added feature.

Key words: crystallization, lactose, skim milk

M89 Investigation of twin-screw extrusion puffing of non-fat dry milk powder and starch to produce puffs and crisps for snack and ingredient uses. A. J. Tremaine* and T. C. Schoenfuss, *University of Minnesota, Department of Food Science and Nutrition, St. Paul.*

The use of twin-screw extrusion to produce puffs and crisps for cereals and snacks is widely used in the food industry. Soy protein is the leading protein used in extrusion puffing, but caseinates and whey protein concentrates and isolates have also been researched extensively. Less research has focused on non-fat dry milk (NDM). NDM has the advantage of an abundant and inexpensive supply, has the full amount of calcium found in milk, and has a cleaner flavor than whey protein concentrates. One disadvantage of NDM is the difficulty in creating protein-protein interactions in the extruder to obtain a stable puff. The objective of this study was to evaluate the effect of acid addition and varying moisture levels on the attributes of expanded puffs containing high levels of NDM. Varying concentrations of low-heat NDM were combined with modified cornstarch and processed on a Buhler 44mm twin-screw extruder. Extruded product was collected in ropes, cut into 2 inch lengths, and dried on a fluidized bed dryer. The experimental parameters included three NDM concentrations (45, 65, 85%), three lactic acid levels (0, 33, 50% of the moisture) and two moisture levels (6.5, 7.3 kg/h). Process (die temperature, die pressure, motor torque and specific mechanical energy) and product responses (color, solubility, expansion ratio and bulk density) were statistically analyzed to assess the effects of NDM, acid and moisture levels, and response surface plots were generated. The results obtained indicate that NDM concentration, moisture and acid level all affected process and product responses. These results will be useful in product development in the food industry when incorporating NDM into extruded products.

Key words: extrusion, non-fat dry milk, response surface plots

M90 Browning and pH of UHT whole milk as influenced by time and temperature of storage. M. E. F. Dias*[1], P. C. B. Vianna[2], and M. L. Gigante[1], *[1]Universidade Estadual de Campinas, Campinas, SP/Brazil, [2]Universidade Norte do Paraná, Londrina, PR/Brazil.*

The CO_2 addition has been used in maintaining the quality of refrigerated storage of raw milk. The objective of this work was to evaluate the effect of time and temperature of storage on pH and browning of UHT whole milk produced from refrigerated raw milk with or without CO_2 added. Raw milk (250 L) with and without CO_2 addition was stored in bulk tanks at 4°C during 6 d before UHT treatment. The milk was sterilized by direct steam injection (143°C/4 s, homogenization pressure 220 bar), cooled to 25°C and packaged in Tetra Brik (125 mL). The samples were stored at 25, 35 and 45°C for 180 d. During storage, samples were taken at random after 1, 30, 60, 90, 120, 150 and 180 d and evaluated for pH and browning. The color was assessed with a colorimeter Hunterlab ColorQuest II, with D65 illuminant according to conditions provided by the manufacturer. The increase in Hunter b* value (measures blue [-] to yellow [+]) was used for determination of browning. The pH was measured in milk samples at 20°C using a combined pH glass electrode fitted to a pH meter (Digimed Model DM 22).

The split-split-plot design with 3 replications was used. The results were evaluated by ANOVA (ANOVA) and Tukey′s test ($P \leq 0.05$). The CO_2 addition to raw milk significantly affected the pH of UHT milk and it was 6.66 and 6.70 for samples with or without CO_2 added, respectively. The rate of browning for UHT samples obtained from raw milk without CO_2 was higher than the rate obtained for samples from raw milk added of CO_2. During storage the pH of all samples decreased, while browning, as indicated by b* values, increased. The lower pH and increase of browning was greater at 45°C, followed by samples at 35°C and 25°C. After 6 mo storage period, UHT milk stored at 45°C showed pH value of 6.24 while this value was 6.74 at 25°C. At the same time, b* values were 18.93 and 7.03 for UHT milk stored at 45°C and 25°C, respectively. Changes in pH and browning are related to Maillard reactions.

Key words: browning, UHT milk, CO_2

M91 Evaluation of vacuum packaging on physical properties and solubility of dry dairy ingredients. H. Eshpari* and P. Tong, *California Polytechnic State University, San Luis Obispo.*

Dry dairy ingredients can have a longer shelf life if packaged and stored properly. Vacuum packaging can be an attractive method for keeping quality and provides added value because of the inherent compactness of the products. Vacuum packaged dry dairy ingredients may also have added ease of handling for end users. However little is known about the impact of vacuum packaging on the properties of dry dairy ingredients. The objective of this study was to determine the effects of vacuum packaging on particle size, (particle, bulk, and tapped) densities, flowability, compressibility, color, and solubility of 6 types of dry dairy ingredients. Commercial samples of nonfat dry milk powder, whole milk powder, buttermilk powder, milk protein isolate whey protein concentrate 80, and sweet whey powder were repackaged in duplicate using multi-wall foil side gusseted bags under varying degrees of vacuum (1, 0.7, 0.4 bar) and a control with no vacuum, and then stored for 3, 6, and 12 mo at 25°C and 60% relative humidity. Each powder was sampled and analyzed in duplicate for all the quality attributes mentioned above upon receiving and after 3, 6, and 12 mo storage. At $\alpha = 0.01$: particle size, (particle bulk and tapped) densities, and flowability of the powders increased (P-values = 0.001), while the compressibility decreased ($P = 0.004$) due to the significant effect of storage time. Powders packaged under vacuum showed a higher mean of L- color value ($P = 0.003$), but significantly lower means of (a- and b-) color values, (p-values = 0.005, and 0.001 respectively) due to the significant effect of vacuum pressure. This change in color values was more dramatic in high fat containing powders such as whole milk powder. No significant change was observed in solubility of the powders. The results suggest that the proposed vacuum packaging method may be beneficial to maintain the quality of the powders studied.

M92 Hydrophobic aroma encapsulation in whey protein nanoparticles. H. J. Giroux and M. Britten*, *Food Research and Development Centre, Agriculture and Agri-Food Canada, St-Hyacinthe, (QC), Canada.*

The development of foods with health benefits prompts the manufacturers to review products formulation and processing conditions. The modification of food components or processing can impact directly on flavor release and perception. Moreover, aroma compounds are volatile, sensitive and might be degraded during manufacturing, storage or digestion. Encapsulation technologies have been proposed to entrap, protect and deliver sensitive or bioactive components and improve the sensory properties of functional foods. Because the interest in reducing capsule size to further reduce the impact of encapsulated ingredients on food texture, protein nanoparticles present a good potential to serve as carriers and delivery systems. The objective of this study was to encapsulate hydrophobic aroma in whey protein nanoparticles. Aroma-loaded nanoparticles ($d < 300$ nm) were prepared by cross-linking denatured whey protein through pH-cycling. The effect of nanoparticulation conditions (aggregation pH, calcium addition) and aroma concentration on the physicochemical characteristics of nanoparticles and the dynamic release profile of aroma was studied. The release behavior of aroma encapsulated in nanoparticles was compared with those of aroma added to native or denatured whey protein. Better retention of aroma was observed for nanoparticles produced at pH 5.0 and 5.5 without calcium addition. These nanoparticles are characterized by a less compact and more porous internal structure allowing a higher loading of aroma. Increasing aroma concentration increased the diameter and the voluminosity of the aroma-loaded nanoparticles. The percentage of aroma retention showed an increase from 7 to 24% over the tested concentration range while the value averaged 2% for native or denatured whey protein. Encapsulation of ethyl hexanoate in whey protein nanoparticles reduced the mass transfer of aroma at the surface of the matrix and improved its retention.

Key words: encapsulation, whey protein, aroma

M93 Formation of β-lactoglobulin/alginate nanoemulsion containing coenzyme Q10. H. N. Choi*, M. R. Lee, and W. J. Lee, *Division of Applied and Life Science (Institute of Agriculture & Life Science), Jinju-si, South Korea.*

The bioavailability of poorly water soluble nutrients, such as coenzyme Q10 (Co Q10), can be enhanced by the use of nanoemulsion system. It is hypothesized that exposed hydrophobic residues of β-lactoglobulin (β-lg) from heat treatment and additional protection from the complex formation of β-lg/alginate may affect physicochemical properties of nanoemulsion as a Co Q10 delivery system. The objectives of this study were to produce oil-in-water β-lactoglobulin/alginate nanoemulsion loaded with Co Q10 (β-lg/AL NE) and to investigate how processing variables, such as heating temperature and alginate concentration, affect the physicochemical properties and encapsulation efficiency of β-lg/AL NE. β-lg/AL NE was prepared at different heating temperatures from 60 to 70°C. Alginate concentration was varied from 0 to 0.05%. Morphologies of β-lg/AL NE were observed using a transmission electron microscopy. Size and zeta-potential values of β-lg/AL NE were measured by electrophoretic light scattering spectrophotometer. High performance liquid chromatography was used to assay encapsulation efficiency of Co Q10. The spherical shapes of β-lg/AL NE with the size of 150 to 250 nm were successfully formed. There was an increase in size from 160 to 240 nm and encapsulation efficiency from 70 to 80% with increasing heating temperature from 60 to 70°C. A significant ($P < 0.05$) increase in zeta-potential value from −5 to −13 mV was observed with increasing heating temperature from 60 to 70°C. Increasing alginate concentration from 0 to 0.05% resulted in a significant ($P < 0.01$) increase in encapsulation efficiency from 70 to 80%. In Split plot design, both heating temperature and alginate concentration had a significant ($P < 0.05$) effect on encapsulation efficiency of Co Q10. In conclusion, heating temperatures and alginate concentrations, which were β-lg/AL NE manufacturing variables,

were the key-processing factors to affect size, zeta-potential value, and encapsulation efficiency of β-lg/AL NE.

Key words: β-lactoglobulin, nanoemulsion, coenzyme Q10

M94 Homogenization and lipase addition influence methyl ketone generation. M. Cao*, E. L. Anderson, and S. A. Rankin, *University of Wisconsin-Madison, Madison.*

Specific methyl ketones contribute to the characteristic flavor of blue cheese. Various metabolic and enzymatic pathways contribute to the generation of these methyl ketones including the β-oxidation of fatty acids by the mold *Penicillium roqueforti*. Little recent research has explored means by which methyl ketone production can be altered or controlled. Earlier work and current industry practices have implicated milk or cream homogenization and exogenous lipase addition as means to alter methyl ketone production. Thus, the objective of this work was to determine the effects of milk homogenization and lipase addition on methyl ketone production in milks inoculated with *P. roqueforti*. Milks were homogenized pressures (e.g., 3.5 MP/3.5 MP, 10.5 MP/3.5MP). Homogenized milks were randomly treated with one of 3 lipases (porcine pancreatic, *P. roqueforti* and calf), inoculated with *P. roqueforti* spores and allowed to incubate (24 h, 20°C). Changes in milkfat size and milkfat globule surface areas were determined by laser scattering. Fatty acid and methyl ketone concentrations were determined using GC/MS. In general, average milkfat globule size decreased from 3.5 to 0.37 μm and surface areas increased from 1.8 to 25 m2/g. Concentrations of FFAs varied dramatically as a function of lipase treatment. Even-chain fatty acids from C4 to C10 increased as a function of homogenization treatment with approximately 10- and 2-fold increases in fatty acid concentrations for the calf and *P. roqueforti* lipase treatments, respectively. FFA levels from the porcine lipase treatment were not consistently affected by homogenization, yet had high levels of FFA. There was an interaction between pressure and lipase treatment that affected the concentrations of specific methyl ketones. In general, the *P. roqueforti* lipase treatment resulted in the highest levels of methyl ketone generation. Ketone concentration did not correlate well to particle size, milkfat globule surface area or initial level of free fatty acid. This study demonstrates that lipase treatment and homogenization alter accumulation of methyl ketones as affected by the metabolic activity of *P. roqueforti*.

Key words: blue cheese, methyl ketone, lipase

M95 Use of fluorescence spectroscopy for monitoring vitamin D fortification of skim milk. J. K. Amamcharla* and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

It is well recognized that a sufficient level of vitamin (vit.) D is necessary in the human diet. Most animals and plants have the ability to synthesize vit. D when exposed to sunlight. However, various factors can reduce the cutaneous synthesis of vit. D and products can be fortified with vit. D. In this regard, retail milks in the United States are fortified with 400 IU/quart of vit. D. In a recent release of the Dietary Guidelines for Americans 2010, USDA and Department of Health and Human Services recommended 600 IU/day of vit. D for children and most adults. As per the regulations of the FDA, milk fortified with vit. D is required to be at least equal to the declared value on the label with no regulations on the upper limit. In a recent study, 51% of 120 retail milk samples contained either below 400 IU/quart or above 501 IU/quart of vit. D. The lack of control of vit. D fortification of milk may be due to the fact that the current methods for vit. D analysis are laborious and precision of the method is dependent on the experience of the analyst. The objective of the present work was to develop a rapid method for measurement of vit. D in skim milk using front face fluorescence spectroscopy. For this purpose, comingled raw whole milk was fat separated, pasteurized and stored under refrigerated conditions. Sixty-six skim milk samples with various concentrations of vit. D (0, 200, 400, 600, 800, and 1000 IU/quart) were prepared using water dispersible vit. D and A mixture. Fluorescence spectra of vit. D (excitation: 360nm; emission: 400 to 600nm) were collected on each sample at 37°C using a front-face accessory. The spectra were normalized, mean-centered, and partial least square regression (PLSR) and neural network (NN) models were developed. Coefficient of determination (r^2), root mean square error of cross validation (RMSECV, IU/quart), and relative standard error of prediction (RSEP, %) were 0.98, 41.8, and 0.9, respectively, for PLSR and 0.97, 54.0, and 1.2, respectively, for NN model. The results indicate that the proposed method can be used as an effective tool to monitor vit. D fortification of skim milk.

Key words: vitamin D, skim milk fortification, fluorescence spectroscopy

M96 Milk composition evaluation as screening criteria to investigate fraudulent addition of cheese whey to milk. M. M. Falcão, F. A. P. Paula, M. O. Leite*, C. F. A. M. Penna, L. M. Fonseca, M. M. O. P. Cerqueira, and M. R. Souza, *Universidade Federal de Minas Gerais.*

Fraudulent addition of cheese whey to milk is a detected practice in several countries around the world. Low cheese whey costs and high costs for fraud detection, together with other aspects are factors that result in this problem for the dairy sector. The method worldwide accepted for detection of cheese whey addition to the milk is the caseinomacropeptide (CMP) index determination by HPLC. However, it is a high cost method for routine screening. To evaluate the milk composition as a principal components analysis for screening of fraudulent addition of cheese whey to milk, 30 individual raw milk samples were pooled to 6 samples containing milk from 5 animals. Each of the 6 samples was split and cheese whey was added to a final concentration of 0%, 5%, 10%, 20%, and 40% (vol/vol) of whey in the milk. Milk composition was evaluated by infrared (Bentley CombiSystem 2300), and obtained data evaluated by ANOVA with average composition by Student Newman Keuls (SNK) test. Average composition for the normal samples was 4.04 g/100g, 4.11g/100g, 4.38g/100g, and 13.56g/100g for, respectively, fat, protein, lactose and total solids. For the samples added with 40% (vol./vol.) cheese whey average composition was 2.48 g/100g, 2.36 g/100g, 4.73 g/100g, and 10.74 g/100g for, respectively, fat, protein, lactose and total solids. The results were statistically different among different treatments, and in practice this method can be used as screening tool with a logistic regression treatment of data in the results database.

M97 Measuring milk treatments and storage temperature effects on fat globules aggregation. N. Fucà[1], G. Impoco[1], M. Caccamo*[1], and G. Licitra[1,2], *[1]CoRFiLaC, Regione Siciliana, Ragusa, Italy, [2]DISPA, Catania University, Catania, Italy.*

Milk treatments and storage temperatures cause changes to the microstructure of the lipidic phase. This study aims to demonstrate that confocal microscopy (CLSM) and quantitative analysis of resulting

images can give useful clues to estimate fat globules' aggregation. Two experiments were carried out. First, 5 types of milk subject to different treatments (homogenization-UHT, homogenization-high pasteurization, homogenization-pasteurization, pasteurization, microfiltration) and one sample of raw milk (used as control) were compared, to evaluate the effects of treatments on the lipidic phase. Then, the same milk types were analyzed at 2 different storage temperatures (4 and 16°C). Milk samples were stained with Nile Red to visualize lipids. Images were acquired using 60x objective lens and 1.5 zoom factor of a confocal laser scanning microscope. Image analysis was used to quantify fat globules aggregation in CLSM micrographs. Aggregation favors non-homogeneity both of distribution and volume of fat clusters. These 2 effects can be measured more reliably than aggregation itself. Eleven measures were computed on each image to capture variation in size and distribution of fat globules. After pairwise correlation assessment, 6 out of these 11 measures were chosen for their statistical independence and significance, and for their realistic description of the geometry of the lipidic phase. As expected, treatments did affect distribution and size of clusters. High significant difference ($P < 0.0001$) was found among the measurements related to the 5 types of milk. Statistical analysis revealed that storage temperature significantly affected distribution and size ($P < 0.0001$) as well, promoting aggregation. Quantitative analysis of CLSM micrographs turned out to be capable of capturing fundamental effects of fat globules' aggregation due to milk treatments and storage temperature.

Key words: milk, microstructure, quantitative analysis

M98 Effects of residual lactose and galactose on cheese moisture determination. H. Lee*, F. X. Milani, and S. A. Rankin, *University of Wisconsin-Madison, Madison.*

Accurate measurement of moisture in cheese is important to maximize yield and ensure economic parity. Official methods determine moisture based on the mass lost due to the thermal volatilization of available water. Because cheese is a chemically complex and variable medium, there is a potential that additional volatile compounds may be created during analytical moisture determination. Maillard browning and other various thermally catalyzed reactions may alter the final mass after drying. Based on their reactivity, the residual sugars lactose and galactose are 2 components in cheese that may be natively present at varying levels and that may participate in reactions capable of artificially elevating moisture determination. The objective of this study was to examine the effects of residual lactose and galactose on cheese moisture determination. In this study, 4 medium cheddar and 4 mozzarella cheese samples were analyzed for moisture content in triplicate using a microwave system (CEM Corporations, Matthews, NC). Cheese samples were manufactured with 5% added α-lactose monohydrate or galactose as the reducing sugar treatments. For reasons of control and comparison, an untreated sample and treatments containing 5% added sucrose or natrium carboxylmethyl cellulose (non-reducing carbohydrates) were included. There was an effect ($\alpha < 0.05$) for the main treatments of cheese type and sugar type. In general, the lactose and galactose samples had higher moisture levels than the non-reducing treatments. Compared with the untreated controls, the reducing treatments overestimated the moisture content by approximately 1.4% for the cheddar samples and 2.4% for the mozzarella samples. The samples with reducing sugars also displayed substantial dark brown color after the drying process as compared with minimal color change for other samples. There was no difference between the lactose and galactose treatments. This study demonstrates that the presence of residual reducing sugars may result an overestimation of cheese moisture concentration and that these effects may be different for cheeses of varying composition.

Key words: cheese, moisture, sugar

M99 Quantification of textural properties of composite milk gels using laser-scanning fluorescence confocal microscopy and image texture analysis. R. Hennessy*[1], L. Laiho[1], A. Laubscher[2], and R. Jimenez-Flores[2], *[1]Cal Poly Biomedical Engineering, San Luis Obispo, [2]Cal Poly, DPTC, San Luis Obispo.*

Current techniques of food texture analysis require destruction of the sample, ignore the spatial relationship between principal constituents, or require subjective data that depends on the skill of human subjects. A 2-dimensional, non-destructive, objective measurement technique is needed to quantify the spatial relationship between the principal constituents of dairy products. Our purpose was to investigate whether textural properties can be measured using laser-scanning fluorescence confocal microscopy (LSFCM) by quantifying the spatial relationship between the principal constituents of dairy products. In this study, 2 different types of composite milk gels were created, and stabilized by either freeze drying or baking. The milk gels were stained with the fluorescent markers; Nile red, for lipids, and fast green FCF, for protein. LSFCM was used to image the stained composite milk gels. For each sample, a stack of 30 images, each 5μm apart, were captured to create a 3-dimension set of data. Maximum intensity projection (MIP) was then performed on the stack of images to create a single image where the entire field of view contains pixels that are in focus. Using the MIP image, the following parameters were calculated: 1) fat/protein ratio (FP), 2) fat and protein overlap (OL), and 3) the image texture (T). All three parameters were calculated using an algorithm written in MATLAB. FP was calculated by counting the number of pixels labeled as fat and divides that number by the number of pixels labeled as protein, OL was calculated by counting the number of pixels labeled as both fat and protein and dividing that number by the total number of pixels in the image, and T was calculated using the gray level co-occurrence matrix of the image. OL was found to be the best parameter for distinguishing between baked and freeze dried gels, with $OL = 0.67 \pm 0.12$ for baked gels, and $OL = 0.23 \pm 0.09$ for freeze dried gels. A high OL was found to indicate a chewy texture, while a low OL was found to indicate a more brittle texture that commonly occurs from freeze drying.

Key words: texture, confocal microscopy, composite gels

M100 Evaluation of two kits based on microbial inhibition for detection of antimicrobial residues in milk. A. D. Lage, L. P. Freire, N. M. A. Silva, M. M. P. Araújo, R. D. P. Santos, G. M. Resende, A. F. Cunha, M. R. Souza, C. F. A. M. Penna, L. M. Fonseca, M. O. Leite, and M. M. O. P. Cerqueira*, *Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

Two kits based on microbial inhibition (Charm Cow Side II Test and Charm Blue Yellow II Test) were evaluated for detection of antimicrobial residues in milk in different concentrations. The ability of both kits to detect the tetracycline group in a lower concentration of that considered by the Brazilian law was also tested. Milk samples were inoculated with standard solutions of 23 different antimicrobial agents and metabolites of ceftiofur in 2 different concentrations: the lower limit of detection stated by the manufacturer (level 1) and the maximum residue limit (MRL) (level 2) established by the Brazilian legislation. The results were submitted to the McNemar test at 95% of confidence.

Both kits were effective in detecting most of antimicrobials tested in 2 concentrations. It is necessary to review information from the manufacturer of the kit Charm Cow Side II Test for the detection of residues of oxacillin, penicillin G, spiramycin, and sulfonamides and Charm Blue Yellow II Test for the detection of erythromycin, cloxacillin, sulfadiazine, tylosin, and penicillin G in milk. Both kits detected residues of tetracyclines given the MRLs required by the Brazilian law and can be safely used for monitoring these drugs in milk. Ceftiofur and their metabolites were detected by the 2 kits and can be safely monitored by the methods tested.

Key words: milk, antimicrobials, residues

M101 Validation of CombiScope FTIR for milk urea evaluation in raw milk. M. C. P. P. Oliveira*, N. M. A. Silva, L. P. F. Bastos, R. S. Conrrado, L. M. Fonseca, M. M. O. P. Cerqueira, R. Rodrigues, and M. O. Leite, *Veterinary School/Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil*.

The measurement of milk urea nitrogen (MUN) concentration in raw milk is a useful tool for herd nutritional evaluation. The aim of this study was to validate the CombiScope FTIR (Advanced/Delta Instruments) for analysis of urea content in raw milk samples, based on non protein nitrogen calculated urea (NPN-CU). A total of 513 samples of bulk tank raw milk were screened in the Laboratory for Milk Quality Analysis (Veterinary School, Universidade Federal de Minas Gerais) for this study. Calculated urea results generated by Fourier Transform Infrared in the CombiScope FTIR were compared with urea concentration obtained from analysis of the same samples by enzymatic automated method (Chemspec 150 Analyzer; Bentley Instruments). The repeatability of CombiScope was tested using 20 pools of raw milk samples preserved with bronopol. Each pool was distributed in 10 vials and each vial was placed in a rack, to complete 10 racks containing 20 samples each. There was no significant difference ($P > 0.05$) between the results generated by both methods. The FTIR showed an average of 9.93 mg/dL of urea, while the average for the automated enzymatic method was 9.49 mg/dL of urea. The standard deviation and coefficient of variation were, respectively, 3.31 mg/dL and 33% for FTIR and 4.22 mg/dL and 44% for enzymatic methods. The result of repeatability of the FTIR analysis of urea showed an average of 10.22 mg/dL, standard deviation of 0.87 mg/dL, coefficient of variation of 8.42% and repeatability limit of 2.43 mg/dL. Therefore, FTIR is a reliable method to be used for urea analysis in raw milk, with the advantage of being a rapid, efficient, versatile and low cost method. Acknowledgments: FAPEMIG, CNPq, CAPES, Laboratório de Análise da Qualidade do Leite/EV-UFMG/FUNDEP.

Key words: milk, FTIR, urea

M102 Identification of starch in cheese using laser scanning confocal microscopy. W. R. McManus, E. N. Oberg, R. Wadhwani, K. M. Brown, and D. J. McMahon*, *Western Dairy Center, Utah State University, Logan.*

Polysaccharides such as starches and gums have been used to modify texture in dairy products. However, there has been little published on the microstructure of these additions to foods unless they are large microparticles because of the difficulty in identifying them in a complex matrix. Laser scanning confocal microscopy (LSCM), is able to optically dissect thin layers through a food sample and identify multiple components when they have an attached fluorophore. For example, in cheese, fat can be labeled with Nile red, a hydrophobic fluorophore, excited by light with wavelength of 488 nm, and protein can be labeled with several fluorophores, including Rhodamine B (RHODB) excited at 568. There has not been a method for readily attaching fluorophores to polysaccharides. To do so, we have developed a method for chemically modifying starch in a food gel (after fixing protein and fat), so that it can bind a fluorophore. Milk gels, Cheddar and Mozzarella cheese containing starches were fixed with osmium tetroxide, as vapor or as a 1.0% (aq) solution, then oxidized using 0.5%(aq) periodic acid, stained with 1% (aq) Acriflavin HCl (ACRFL), and 0.01% (aq) RHODB. The fluorophores were excited and their fluorescence collected separately (using filters of 512 to 532 nm and above 585 nm, respectively) to generate images in which there was strong imaging of the locations of both polysaccharide by ACRFL and protein by RHODB. Control images of samples containing no polysaccharides demonstrated there was no cross reactivity of ACRFL with the fixed protein. Fixation in LSCM is not commonly used, however, using periodic acid to produce reactive dialdehyde groups on starch that can bind ACRFL mandates fixation, so that the proteins are not degraded. This also physically traps the polysaccharides within the protein gel, assuring that in an LSCM image of a milk gel or cheese, the relationship of the polysaccharides to fats and proteins has not changed from their original position.

Key words: cheese, starch, microstructure

Extension Education

M103 Assessing a comprehensive udder health and mastitis control program for practicing dairy veterinarians. G. M. Schuenemann*, P. Rajala-Schultz, E. Gordon, S. Bas, and J. D. Workman, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The purpose of the study was to assess the effectiveness of a team-based educational program designed to enhance the flow of applied, research-based, information to dairy veterinarians. A comprehensive udder health and mastitis control program was developed and participants from 11 veterinary practices located in 5 states (IN, NY, PA, NM, and OH), serving an estimated 186,150 dairy cattle in 469 herds, attended the program (~2.5 d and ~20 h of learning). Mammary gland and host defenses; epidemiology, treatment and preventive strategies for clinical and subclinical mastitis (i.e., chronic mastitic cows); dry cow therapy; environmental interactions (physical and biological); record-keeping (new infections, SCC, cure rate, and monitoring dry cow therapy); training to dairy personnel; facilities (bedding and ventilation); assessment of milking routines; and milking machine analysis (on-farm evaluation of equipment) were discussed. Educational materials were delivered through in-class lectures followed by case-based learning, group discussions, and an out-of-class assignment. Attendees were assessed using pre- and post-tests of knowledge to determine the level of knowledge gained in the program. Participants evaluated the program and provided feedback at the conclusion of the module. Veterinarians reported that the overall program, presentations and discussions were useful. Attendees found the presented information relevant for their work and of great immediate use to them. The presented materials and the implemented educational delivery methods substantially increased the knowledge level of the attendees (17.9% points increase from pre-test to post-test scores; $P < 0.05$). Interpreting culture and bulk tank results; milking machine assessment; treatment principles; dry cow management and selective dry cow therapy; managing new infections; and cleanliness of dry cow facilities were listed as learned concepts that participants can apply in their practices. Results suggested that the udder health module was relevant and effective; offering management practices with immediate field application.

Key words: education, mastitis, veterinary

M104 The relationships between weight, age, and average daily gain of Georgia 4-H & FFA commercial dairy heifers. M. L. London, J. K. Bernard, M. A. Froetschel, J. K. Bertrand, and W. M. Graves*, *University of Georgia, Athens.*

Studies were conducted to evaluate growth of dairy heifers involved in Georgia Extension youth programs where heifers are shown by weight. In the first study, 1,744 heifers were evaluated to determine effects of growth from Georgia 4-H & FFA Commercial Dairy Shows from 2007 to 2010. Birth weights were determined using breed averages (with crossbreeds being the average of the 2 parent breeds). Average daily gains (ADG) were calculated and ranked for age, weight and placing. Data were analyzed using the Spearman correlation calculations in SAS. Age and ADG were inversely correlated ($r = -0.89$, $P < 0.0001$). Mean ADG for all heifers was determined to be 0.65 kg, below NRC recommendations of 0.7–0.8 kg. No strong relationship ($r = -0.07005$, $P = 0.0034$) was observed between ADG and placing. Heavier heifers, within a class, showed a small positive ($r = 0.10399$, $P < 0.0001$) relationship with placing. In Study 2, a total of 238 Holstein heifers shown at the 2010 Georgia Junior National Livestock Show were evaluated for ADG, body weight, age, wither height, hip height, hip width, jaw width, placing and switch clearance from the ground. Height at withers had a moderate relationship ($r = 0.42$, $P < 0.0001$) with placing, followed by hip height ($r = 0.32$, $P < 0.0001$). A positive relationship ($r = 0.65$, $P < 0.0001$) was observed between wither and hip height. The correlation between weight and placing was determined ($r = 0.11$, $P = 0.10$). Age and ADG had a strong inverse relationship ($r = -0.87$, $P < 0.0001$). Switch clearance from ground positively ($r = 0.17$, $P < 0.01$) correlated with placing. Study 3 evaluated 1,489 Holstein heifers shown from 2007 to 2010. Data were analyzed using the Penn State Growth Spreadsheet. A total of 63.75% did not meet recommendations for body weight gain and indicates these heifers are under-fed. These animals will likely require more time before they enter the milking herd. The Commercial Dairy Heifer Program is vital for youth development in Georgia. However, management practices must be improved, growth monitored and weight requirements increased.

Key words: average daily gain, heifer growth, weight and size, Georgia Commercial Dairy Heifer Program

M105 Advising and technical support for the formulation and evaluation of diets for dairy cows and goats: The extension experience of Antonio Narro Agricultural University in north Mexico. P. A. Robles-Trillo*[1], F. G. Veliz-Deras[1], R. Rodriguez-Martinez[1], M. A. De Santiago-Miramontes[1], and C. A. Meza-Herrera[2], *[1]Universidad Autonoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, Mexico.*

Production of food of animal origin for human consumption requires adequate animal feeding strategies. The aim of this extension project was to establish a link between the University and the productive sector by providing advice and technical support in the design and evaluation of rations for dairy cows and goats in local farms, while offering technical training to students involved as practitioners and social service providers. The technical support and training was completed by visiting these local farms and performing the following activities: a) formulation and evaluation of rations, b) management of feed and water intake, c) chemical analysis of ration ingredients d) storage and care of ration ingredients, e) evaluation of the physical, reproductive, and productive state of livestock, and f) determination of milk chemical characteristics. The project covered approximately 9,000 animals that produce approximately 250,000 L of milk daily, distributed in 9 dairy farms in the states of Coahuila and Durango (i.e., Comarca Lagunera). Fifteen students participated as social service providers, while 120 students performed as animal nutrition practitioners, generating a total of 200 technical visits. Regarding technical information generated from this project, 2 technical papers were published in a regional journal (Agropecuaria Laguna). The Comarca Lagunera is one of the most important dairy producing areas in Mexico. Therefore, linking both technical and academic activities through projects like this should help to increase the productive efficiency of dairy goats and cows in this region, thus increasing the economic profit of producers while rising milk availability for human consumption.

Key words: extension, feeding, ruminant

M106 An extension tool to assess forage production and utilization on dairy farms. M.-C. Coulombe*[1], D. Pellerin[1], R. Roy[2], G. Allard[1], P. Savoie[3], D. Parent[1], and E. Charbonneau[1], *[1]Université Laval, Quebec, Quebec, Canada, [2]Valacta, Dairy production centre of expertise, Ste-Anne-de-Bellevue, Quebec, Canada, [3]Agriculture and Agri-Food Canada, Soils and Crops Research and Development Centre, Quebec, Quebec, Canada.*

The optimal utilization of forages on dairy farms is an important factor for their profitability. However, tools to diagnose forage use on farms are rare. The present study aims to develop an evaluation tool to assess the production and utilization of forages on dairy farms. Parameters concerning the optimal usage of forages on dairy farms were identified as forage production (quality and yield), production cost, harvest efficiency and utilization by the herd. Evaluation criteria and methods were defined to measure these parameters and to develop the evaluation tool. This tool was tested on 21 Quebec dairy farms with different forage management. Forage quality was evaluated using a quality index that includes ingestibility, total digestible nutrients and digestible protein. A reference forage (53.8% NDF, 1.14 NEL, 16.3% CP) was given an index of 100. All forage samples (n = 147) had an index of 131 ± 16.7 (mean ± SD). Average annual forage yield per farm was 6.1 ± 1.8 TDM/ha (n = 18). When corrected for nutrient contents, yield was enhanced to 6.5 ± 1.9 eqTDM/ha. Production cost of forages is highly correlated (r = 0.85) to total machinery cost. Thus, to simplify on-farm data collection, forage production cost was estimated as a multiple of machinery cost. The estimated forage production cost was 210 ± 87 $/TDM (n = 17). To evaluate harvest efficiency, the daily capacity of machinery available was compared with the farm′s annual forage needs and the number of days available for harvesting during the optimal cutting periods. Most farm machinery sets (18/25 sets observed on 21 farms) were considered efficient, i.e., able to harvest required forage within the available time. Milk from forage (MF) averaged 2785 ± 1024 kg/cow per year (n = 17) while mean potential MF was 6939 ± 1692 kg/cow per year. Within a herd, efficient forage utilization would be reflected by a small difference between potential and observed MF. The diagnosis included an assessment of actual vs. predicted DM intake, and milk urea N and protein:fat ratio. Using our evaluation tool, producers can identify strengths and weaknesses, and correctly assess actions to improve performance.

Key words: dairy cow, forage, on-farm tool

M107 Fiber production and fiber characteristics of alpacas farmed in United States. T. Wuliji*, *Lincoln University, Jefferson City, MO.*

The alpaca is the most important fiber producing member of the South American camelids. This paper presents the recent analysis of both huacaya (n = 714) and suri (n = 502) alpacas sampled at 18 alpaca ranches located within the west, central and eastern regions in US There are 2 types of alpacas introduced into the United States, namely, huacaya and suri; however, most alpacas are that of the huacaya breed. Currently, there are 171,316 alpacas registered to the Alpaca Registry Inc. (ARI) from 1986 to 2010 in the US Alpacas can be found in every state of the United States and are farmed in various geographical environments ranging from hot desert to high mountain ranges. Alpacas were shorn at 10 to 18 mo of fiber growth intervals and produced 2 kg per head fleece per year. Coat color is widely varied in the alpacas, ranging from white to black and various shade combinations in 22 different natural color categories. Body weight, average fiber diameter, fiber diameter variation and fiber bulk characteristics were significantly ($P < 0.05$) different between huacaya and suri alpacas (Table). There was no difference in mean staple length (74.5 mm vs. 75.5 mm) but comfort factor estimate was significantly ($P < 0.01$) higher for huacayas (81.4%) over suris (77%). Although it appeared that suri alpacas were heavier for body weight and about 1.5 micron coarser than huacaya fleeces tested in this study, there was no evidence for any fiber production or fiber characteristic superiority in the one breed over the other except the preference of a breed specialty trait.

Table 1.

	Huacaya breed		Suri breed		SE
Traits	N	Mean	N	Mean	P-value
BWT kg	104	61.8	382	65.5	3.5*
AFD µ	713	24.9	471	26.5	1.5*
FDcv%	713	19.4	471	20.7	1.2*
Bulk cm3/g	421	20.5	449	16.5	1.0**

BWT: body weight; AFD: average fiber diameter (µ); FDcv%: fiber diameter variation; SE: standard error of mean.

Key words: alpaca, coat color, fiber diameter

M108 Advice from the experts: Processor assessment of planning considerations for an on-farm dairy processing enterprise. E. A. Chaney* and J. M. Bewley, *University of Kentucky, Lexington.*

Across the dairy industry, many producers are considering on-farm processing to add value to the milk produced on their farms. Like any other business venture, proper planning is imperative to establishing a successful business. The primary objective of this research was to survey existing processors to provide a compilation of advice for future on-farm processors. An electronic survey (Key Survey, Braintree, MA) was distributed to 120 on-farm processing businesses across the United States. A total of 31 surveys were completed (26%). Questions focused on cash flow, financing, sources of information used to start a business, and advice given to prospective business owners. The time needed to attain positive cash flow varied tremendously among survey respondents. Cheese (68%), milk (58%), and ice cream (33%) were the most common products manufactured on-farm. Funding needed to start the business was obtained from bank loans (68%), personal savings (58%), family loans or gifts (45%), and grants (35%). Factors influencing the decision to start the business venture included commodity milk prices (61%), desire to work with the public (42%), opportunity to promote the dairy industry (39%), desire to maintain or expand a family business (29%), and desire to differentiate a product (16%). When asked to describe the most difficult part of starting the business, the most frequently cited challenge was dealing with regulations (26%) followed by product marketing (19%), manufacturing technicalities (19%), and securing funding (16%). The most frequently used sources of information used in developing the business were existing processors (87%), books (65%), and the Internet (58%). The majority of respondents indicated they were either extremely satisfied (52%) or satisfied (44%) with their decision to start on-farm processing while 3% of respondents were neutral. When asked for advice to future processors, common themes included market research, business plans, seeking advice from existing processors, and thorough planning. Results of this research may be useful for entrepreneurs considering a value added dairy enterprise.

Key words: on-farm processing, survey, value-added

M109 Using whole farm assessment tools to identify strategies for change to increase dairy farm profitability. R. A. White*, L. A. Holden, A. Ishler, G. A. Varga, and M. B. Douglass, *The Pennsylvania State University, University Park.*

The objectives for this project were to use the Profitability Assessment Dairy Tool (PA Dairy Tool) and the Income Over Feed Cost (IOFC) Tool to 1) identify bottlenecks that limited dairy farm profitability on Pennsylvania dairy farms and 2) to show dairy producers how to make improvements to both overall profitability and IOFC. The PA Dairy Tool calculates key financial ratios, capital efficiency, operational efficiency as well as economic losses in 5 areas of dairy production management that directly impact profitability: milk yield (MY) and components, reproduction, milk quality and udder health, culling, and replacements. Farms were invited to participate in the project by farm advisors and 38 farms completed both tools in year one. The PA Dairy Tool data utilized year-end numbers for 2009. Herd size averaged 184 with a range 31 to 1,582 cows; average milk production was 29 kg per cow per day (15–41); return on assets averaged −0.7% with a range of −10.2 to 8.7%. The PA Dairy Tool showed the greatest economic losses were due to milk yield ($296 per cow per year) but the majority of farms had economic losses with replacements (age at first calving; 31 of 38 farms), udder health (somatic cell linear score >4.0; 29 of 38 farms), and reproduction (pregnancy rate; 25 of 38 farms). From January through October 2010, IOFC ranged from $3.08 to $10.61 per lactating cow per day. Quarterly reports are sent to participants throughout the project that include summarization of data and educational materials. In year 2 of the project, monthly IOFC will be continuously collected and year-end numbers will be collected for the PA Dairy Tool. Follow up work will be completed on farms that have economic losses in production areas that will enable the producer to focus on specific management improvements to decrease these economic losses. Effective use of evaluation assessments like the PA Dairy Tool and IOFC Tool are effective strategies in helping producers to target the most economically beneficial areas for changes to improve their bottom line.

Key words: benchmarking, feed costs, profitability

M110 Evaluation of the use of pasture pork demonstration sites for on-farm educational programming. N. C. Whitley* and M. L. Eley, *North Carolina A&T State University, Greensboro.*

Farms with pasture-based swine production systems were identified and developed as demonstration sites for selected best management practices that are environmentally and animal welfare friendly. The objective of this project was to evaluate the use of those demonstration sites for educational farm tours. Two eastern region farms were toured in Year 1, 3 in Year 2. Topics discussed included nutrient management and animal feeding, riparian buffers, ground cover and soil testing among others. Farmers discussed their farm and production practices. A multiple question survey was developed and provided to participants after each tour. The second year, a follow-up survey was used to determine first year tour impact. There were 19 surveys distributed and 11 returned (58% response rate) for Year 1; 82% raised hogs outdoors. The producers (100%) indicated they would make changes on their farm based on things they learned during the tour. After the tour, 91% agreed they had a better understanding of environmental issues/planning related to raising hogs on pasture; 100% had a better understanding of (and 91% would apply for) USDA/State programs and/or other grant or certification programs. For Year 2, approximately 30 surveys were distributed and 24 were returned (80% response rate), however, at least half of the respondents were NRCS staff and other agricultural professionals attending to learn more so they could, in turn, train farmers. Participants agreed they learned more about: water sources and location (96%), buffers to filter nutrient run-off (96%), crops to remove nutrients (92%), managing woodlots containing hogs (87%), pasture rotating and stocking rates (80%) and soil testing (76%). Only 60% indicated they would make changes on their farm. Of participants responding to the first year follow-up survey, 71.4% had made changes to create a more environmentally– and animal–friendly farm. The types of changes made included planting more forages and rotating animals, adding new pastures and shelters, giving pigs more space and moving pigs away from streams. Due to the success of these tours, more are being planned.

Key words: environment, outdoor pork, pasture based swine

M111 Summary of Texas Panhandle dairy producer forage use. K. J. Lager* and E. R. Jordan, *Texas AgriLife Extension Service, Texas A&M System, College Station.*

To calculate the mix of forages used on Texas Panhandle dairies, dairy producers in the region from Select Milk Producers, a milk marketing cooperative, were sent a one page questionnaire regarding the forages raised and purchased to feed the dairy cows and heifers in their herd. Surveys from 14 milking herds were returned. Two herds had heifer operations associated with them that raised heifers for other individuals. One heifer operation had separate feed inventories. In the second operation, heifers from 6 to 12 mo were fed from the combined feed inventory. Heifer roughage consumption in this operation was estimated and removed from the remaining calculations. Weighted estimates were calculated after these adjustments. The mean (±SD) of animals was 7643 ± 2961 with total owned ha ranging from 0 to 2274 ha and an average (±SD) of 857 ± 632 ha. Herds averaged 86.4% of the cows in milk; comparable to industry standards. No adjustment for the bulls/steers in herds was made since many herds use bulls in various reproductive roles. Total forage dry matter per milking cow was 19.3 kg/d (16.7 kg/d if total cows) and includes the dry land small grains produced and forages from outside the area. Total irrigated ha within Texas averaged 0.37 ha per milking cow or 0.32 ha per cow (milking and dry). Approximately 10% of total ha or roughly 39% of double cropped ha required per cow was irrigated using water captured in retention control structures. Table 1 displays the weighted average number of ha of forages raised by the producer or purchased locally needed to feed either one milking cow or one adult cow with the associated young stock and bulls/steers in Texas Panhandle herds for one year.

Table 1. Hectare per milking cow or per total cows required to raise forages being fed (CS = corn silage; SS = sorghum silage; SGS = small grain silage)

	Mean	SE	Per Milking Cow and Replacement	Per Total Cows and Replacement
Irrigated Raised Forages, ha				
CS	468	105	0.13	0.11
SS	143	40	0.04	0.03
SGS	402	69	0.11	0.09
Alfalfa	145	50	0.04	0.03
Of the Raised Forage Land, ha				
Double Cropped Owned	373	90	0.09	0.08
Double Cropped, RCS Water	158	47	0.04	0.03
Irrigated Purchased Forage from Panhandle, ha

M112 An overview of compost bedded pack management in Kentucky. R. A. Black*, J. L. Taraba, G. B. Day, F. A. Damasceno, and J. M. Bewley, *University of Kentucky, Lexington, KY, United States.*

Compost bedded pack (CBP) barn design and pack maintenance procedures vary considerably, making advising and problem-solving challenging. The objectives of this research were to characterize herd performance and management practices employed by CBP managers in Kentucky (45 farms and 54 CBP facilities). Mean (±SD) producer-reported bulk tank SCC and daily milk yield per cow were 238,162.2 ± 81,702.5 cells per mL (n = 37) and 27.3 ± 4.8 kg, respectively (n = 46). The TTEST procedure of SAS (Cary, NC) was used to compare herd performance metrics for the year before and year after transitioning to a CBP for farms using DHIA (n = 9). No significant differences ($P > 0.10$) were observed for changes in SCC (325,222.2 ± 197,188.9 to 274,888.9 ± 135,102.2 cells per mL), rolling herd average milk yield (9,476 ± 601.7 kg to 9,363.1 ± 586.4 kg), heat detection rates (21.6 ± 20.7% to 24.3 ± 23.1%), or culling rates (32.2 ± 8.9% to 28.6 ± 5.7%). Kiln-dried sawdust was used by 25 producers (53.2%) with green sawdust used by 15 producers (31.9%) and 7 using a mix of green and kiln-dried sawdust (14.9%). Mean (±SD) time between additions of new bedding to the pack in summer was 15.3 ± 12.7 d and 11.7 ± 10.4 d in winter. With regard to pack stirring, 38 producers (80.8%) used a field cultivator while 6 used a rototiller (12.8%) and 3 alternated between using a cultivator and rototiller (6.4%). Mean (±SD) daily stirring frequency was 1.6 ± 0.5 d in summer and 1.7 ± 0.5 d in winter. The mean pack area was 9.5 ± 3.8 m^2 per cow. Mean (±SD) herd average locomotion and hygiene scores were 1.51 ± 0.30 (n = 35) and 2.20 ± 0.28 (n = 38), respectively. Most frequently cited benefits of CBP included cow comfort (n = 28), cow cleanliness (n = 15), and improved health and longevity (n = 14). Recommendations to other producers included securing an adequate bedding supply (n = 8), stirring twice daily (n = 8), and using kiln-dried shavings (n = 5). Criteria for adding new bedding included pack moisture (n = 30), compost sticking to cows (n = 12), and cow cleanliness (n = 7).

Key words: compost bedded pack barn, facilities

M113 Weighted cost of capital on dairy farms in Florida. K. Kaniyamattam*[1], A. De Vries[1], and D. T. Galligan[2], *[1]University of Florida, Gainesville, [2]University of Pennsylvania, Kennett Square.*

The objective of this study was to describe the weighted cost of capital (WACC) for dairy farms in Florida. Proper analysis of investment opportunities on dairy farms requires that the expected changes in cash flow need to be discounted by the cost of capital. The preferred discount rate is the WACC which is calculated as rd * (1 - tax rate) * D/(E + D) + DER * E/(E + D) where rd is debt rate, D is debt/cow, E is equity/cow and DER is the desired equity rate. Hence the WACC is farm specific. Financial farm-year records from 2000 to 2008 (n = 80) were obtained from the Florida Georgia Dairy Business Analysis Project database. Equity rates were calculated from the relative differences of farm equity on January 1 of each year. Debt rates were calculated as interest expenses divided by average outstanding loan amounts. Tax rate was set at 33%. Average ± SD for assets/cow, debt/cow, and equity /cow were $5,008 ± 2,226, $1,389 ± 777, $3,620 ± 2,264 respectively. Average debt rate and equity rate were 6.3 ± 3.9% and 6.3 ± 8.6% respectively. The Pearson correlation coefficient between assets/cow and equity/cow was 0.94. The correlations between equity rate, and assets/cow and equity/cow were −0.29 and −0.29 respectively. Other correlations were not significant. At 5% DER, WACC was 4.7 ± 0.6% (range 3.0% to 6.3%) and at 10% DER, WACC was 8.2 ± 1.2% (range 5.3% to 10.7%). At 5% DER, the correlation between WACC and debt rate was 0.82. Other correlations were not significant. At 10% DER the correlation between WACC, and debt rate, assets/cow, debt/cow, equity/cow were 0.45, 0.29, −0.70, and 0.52 respectively. The regression analysis of WACC (5% DER) with year, assets/cow, debt/cow, milk sold/cow, average number of cows showed significant effects of year and average number of cows(R2 = 0. 37). At 10% DER, greater assets/cow and greater milk sold/cow were associated with greater WACC (R2 = 0.72). In conclusion, WACC for dairy farms in Florida for DER varying from 5% and 10% ranged from 3.0% and 10.7% and were on average similar to textbook cost of capital of 5% to 10% per year.

Key words: interest, investment, profit

M114 Current situation and further training needs: A case of Master Goat Producers. U. Karki*[1], N. K. Gurung[1], O. Bolden-Tiller[1], and L. B. Karki[2], *[1]Tuskegee University, Tuskegee, AL, [2]PadmaDal Memorial Foundation, Auburn, AL.*

Master goat producer's certification training program (MGPCTP) is being conducted by Tuskegee University annually to train goat producers, basically from Alabama and neighboring states. Finding out whether trainees have improved their enterprises after the training, and if they still have problems and training needs is important to improve the existing training program and/or organize further training. Objectives of this study were 1) to evaluate the current situation of goat farms belonging to master goat producers, 2) to assess the impact of master goat producer's certification training program, and 3) to identify further training needs of master goat producers. A set of structured questionnaire was developed and all master goat producers were requested to fill it. Also, goat farms of all producers who agreed to participate in this study were inspected. Almost all producers were rais-

ing meat goats, and more than 70 percent producers had Boer goats. The most common marketing was to sell directly to the consumers followed by bringing to stockyards. Average herd size was 24, and average pasture and woodland acreage were around 10 and 11 respectively. Almost all farms were pasture-based and supplementing with hay and concentrate was a common practice when forage production was low. Seventy-three percent of the producers were found to provide mineral mix regularly. Majority of the producers mentioned that they improved different aspects of their farms after attending MGPCTP: 85 percent improved farm structures and pastures, 70 percent improved health care, and 67 percent improved record keeping. More than 70 percent of the producers expressed that parasite was the major problem. Most of the producers stated that they need more training on various aspects of goat enterprises, such as marketing, parasite and disease control, record keeping, and pasture management. Results indicate that 1) majority of the producers are small-scale, pasture-based, meat-goat producers, 2) these producers improved their farm and production practices after attending MGPCTP, and 3) there are still many problems producers are facing, and they need further training to solve these problems.

Key words: Alabama, Boer, meat goats

M115 Judging Pro: A dynamic software program for scoring judging contests. M. L. Eastridge*, B. Cobanov, A. Moffett, L. A. Winkelman, and A. E. Radunz, *The Ohio State University, Columbus.*

Judging contests continue to be valuable educational programs for teaching youth about selection of high merit animals, animal product quality, and life skills, especially in communication and working together as a team. Scoring of these contests can be quite laborious and a limited number of computer programs are available and those available are not very dynamic in presentation of the results. In addition, other computer programs will typically score only one type of contest. Judging Pro was developed for scoring judging contests with dairy cattle, livestock, equine, and poultry. The contest setup allows the user to define placing classes, questions for classes, and classes with reasons. Optional events in the contest setup include written questions, keep/cull, grading, retail cuts, specified stations, team problems, and linear evaluation. After the contest setup is completed, the animal and breed divisions are then defined and the proper placing and assigned cuts entered. Age category and designations of open, FFA, or 4-H are provided for each team and individual entered. Contestant placings and special event scores are entered, along with any specified event team scores. The program calculates placing scores based on the entered official placing and cuts. Reports can be designed by the user to provide the results of interest. Scores can be tallied by age division, youth membership category, and animal division (e.g., breed). Total scores can be summed for individuals and teams. Individuals and scores can be sorted in ascending or descending order. Results can either be printed or copied into a spreadsheet. Additional information about the program and ordering details are available at http://barnyardsoft.com.

Key words: computer software, judging contests, youth education

Forages and Pastures: Antinutritive Compounds in Forages

M116 Fermentation and microbial protein synthesis from anthocyanidin accumulating Lc-alfalfa in rumen liquid. A. Jonker[1,2], M. Y. Gruber[2], Y. Wang[3], D. A. Christensen[1], J. J. McKinnon[1], and P. Yu*[1], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Saskatoon Research Station, Agriculture and Agri-Food Canada, Saskatoon, Saskatchewan, Canada, [3]Lethbridge Research Station, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada.*

It is well documented that mono/polymeric anthocyanidin have the capacity to regulate ruminal fermentation and degradation characteristics of feed. Therefore, alfalfa was modified with a maize leaf color (Lc) gene to synthesize these metabolites. Three of these modified Lc-alfalfa progeny (BeavLc1, RambLc3, RangLc4) that expressed a purple-green phenotype were harvested at a vegetative pre-bud stage to determine fermentation and microbial protein synthesis. Ground freeze-dried samples were compared for their ruminal fermentation characteristics in rumen liquid with 15N as marker for microbial N using an in vitro gas production system. The 3 Lc-progeny had a similar anthocyanidin concentration with an average of 232 μg/g DM. Gas production rate was faster for RamLc3 ($P < 0.001$) than the other 2 Lc-progeny and faster for RangLc4 than BeavLc1. Methane production rate tended to be faster for RambLc3 ($P = 0.07$) compared with the other 2 Lc-progeny but total methane production was similar. Ammonia accumulation was faster ($P = 0.04$) but total ammonia accumulation and branch chain fatty concentration were lower ($P < 0.001$) for BeavLc1 compared with the other 2 Lc-progeny. Total volatile fatty acid accumulation was higher for RangLc4 ($P = 0.001$), propionate was higher and acetate lower for RambLc3 ($P < 0.001$) and butyrate was lower and acetate higher for BeavLc1 ($P < 0.001$). Microbial protein synthesis was higher for BeavLc1 ($P < 0.001$) compared with the other 2 Lc-progeny. In conclusion, all 3 Lc-alfalfa progeny accumulated anthocyanidin and fermentation profiles and end products differed between the 3 progeny.

Key words: anthocyanidin-accumulating alfalfa, in vitro ruminal fermentation and microbial-N, methane and ammonia

M117 How tannin deactivation can affect nutrient digestibility and metabolizable energy contents of sainfoin (*Onobrychis viciifolia*). H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Nutritive value of forages for ruminants is inherently variable and depends on many factors such as forage species, climate, degree of maturity, anti nutritional factors, etc. The objective of this study was to examine tannin deactivation effects on energy and nutrient availability from sainfoin. Second cut forage was shade dried and chopped (3 –5 cm length), and then exposed to nothing (Control) or 5% (w/v) solution of polyethylene glycol (PEG 6000 MW) that was sprayed on the forage (v/w ratio of 1:1). Water soaking was applied with tap water (v/w ratio of 4:1). Treatments were carried out at an ambient temperature of 25°C for 20 min with hand shaking for water, and overnight for PEG. Water was added to forage just before feeding in an in vivo trial. The extractable CT content was determined (Butanol–HCl reagent). Ruminally fistulated Holstein cows (3 multiparous, 680±20kg of BW) were used in 3×3 change over design. Each period consisted of 10 days for adaptation and 7 days for total fecal and forage sample collection. Forages were fed as sole diet (0800 and 1600) along with mineral/vitamins to meet 110% of maintenance requirements of dairy cows. Digestibility coefficients determined and ME estimated with ME= 0.0157 × DOMD. MIXED PROC of SAS 9.1 was used for statistical analysis at 0.05 probability level. Water and PEG deactivated 92.06 and 98.57% of CT, respectively. Digestibility coefficients of EE and ADF were not statistically different ($p \leq 0.05$). Differences of means for OM, NDF and CP digestibility and ME among treatments were statistically significant. Digestibility of NDF was 512.5^{b} for control and 610.1^{a} and 613.4^{a} g/kgDM for water and PEG groups respectively. Digestibility coefficients for CP were 649.8 ^{b}, 753.9 ^{a} and 770.4 ^{a} and for OM were 592.3 ^{c}, 731.4 ^{a} and 709.9 ^{b} g/kgDM for control, water and PEG groups respectively. ME content increased from 8.69 ^{c} to 10.72 ^{a} and 10.22 ^{b} for water and PEG treated forages. Tannin deactivation might be responsible for increasing ME.

Key words: sainfoin, polyethylene glycol, metabolizable energy

M118 Effects of sainfoin (*Onobrychis viciifolia*) processing for tannin deactivation on nitrogen content of cell wall and available nitrogen. H. Khalilvandi-Behroozyar*[1,2], K. Rezayazdi[1], and M. Dehghan-Banadaki[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

The objective of this study was to examine the effectiveness of tannin deactivation on potential nitrogen availability of sainfoin. DM was determined by drying at 105°C overnight. Extractable condensed tannin content of second cut sainfoin was determined using the butanol-HCl reagent. Forages were chopped, and then exposed to nothing (Control) or 5%(w/v) solution of polyethylene glycol (PEG 6000 MW) that was sprayed on the forage (v/w ratio of 1:1). Soaking with water was applied using tap water (v/w ratio of 4:1). Treatments were carried out at an ambient temperature of 25°C for 20 min with hand shaking for water, and overnight for PEG. Treated forages (3 replicates) were then exposed to 40°C temperature in a forced air oven, for 48 h. Neutral detergent fiber and ADF analyzed using Fibertech system. Sodium sulfite not included in NDS solution. Nitrogen content of entire feed and ADF and NDF residues were measured by the Kjeldahl method. Crude protein was calculated as N×6.25 and available nitrogen was considered TN-ADIN. Comparison of means was done using GLM procedure of SAS 9.1(SAS, 2002). CRD and Duncan's multiple range test was conducted to comparison of means between treatments were used ($p \leq 0.05$). Condensed tannin content declined from 21.3^{a} (control) to 1.7 ^{b} and 0.3 ^{c} g/kg DM respectively for water and PEG treated forages. On the other hand total nitrogen content (g/kgDM) was increased for treated forages due to DM losses of 19.4^{c} to 20.7^{a} and 19.9^{b} for water and PEG treatments, respectively. Acid detergent insoluble nitrogen decreased from 6^{a} (unprocessed forage) to 2.1^{b} and 2.2^{b} g/kgDM for water and PEG treatments, respectively. Also, NDIN decreased from 6.3^{a} in untreated forage to 5.7^{b} and 5.1^{c} g/kgDM for water and PEG treatments, respectively and this contributed to increased available nitrogen content (38.8 and 32.1%). Efficient deactivation of tannins can is likely responsible for the results.

Key words: sainfoin, available nitrogen, tannin

M119 Effects of tannin deactivation with different chemicals on protein fractions of sainfoin (*Onobrychis viciifolia* Scop.) in Cor-

nell Net Carbohydrate and Protein System (CNCPS). H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Sainfoin (*Onobrychis viciifolia* Scop.) is tanniferous legume forage. Reports about sainfoin crude protein and condensed tannin contents have a wide range from 102 to 285 and 25.2 to 100 (g/kg of DM), respectively. Cornell Net Carbohydrate and Protein System (CNCPS) is a growing feed evaluation and ration balancing system in the world and create data about feed protein fractions is essential for accurate ration balancing for dairy cattle to improve cattle performance and reduction of environmental pollution due to nitrogen excretion from dairy industry. To our knowledge this is the first report on CNCPS protein fractions of sainfoin and effects of tannin deactivation on this measure. Sainfoin hay was treated with different chemicals to deactivate tannin. Treatment procedure and data about phenolic compounds content after treatment were presented in a companion abstract (M124). The CNCPS protein fractions of sainfoin, determined according to standardized procedure where the A fraction (non-protein N including ammonia, peptides and amino acids and considered to be completely soluble) was determined using trichloroacetic acid solution. Neutral detergent insoluble nitrogen and ADIN were determined as N content of residuals after neutral and acid detergent procedures, respectively. The B_2 fraction was calculated by difference, and results are presented as percentage of CP. All chemical analysis and forage treatments were done in triplicate. Data were analyzed by SAS 9.1, using GLM procedure for a completely randomized design ($P \leq 0.05$). Total phenolics, total tannins and condensed tannins content of sainfoin were 39.4 ± 0.6, 38.5 ± 1 and 21.3 ± 0.4 g/kg of DM respectively. Crude protein content was 121.3 ± 1.7g/kg of DM. Results (Table 1) showed that in untreated forage a large portion of crude protein was in the C fraction, which is unavailable the for animal. This can be due to condensed tannin- protein complexes. Tannin deactivation treatments improved nutritional availability of protein by decreasing the C fraction and increasing the A and B3 fractions.

Table 1. Effects of tannin deactivation on CNCPS protein fractions of sainfoin. (CP percentage)

	A	B_1	B_2	B_3	C
Control	16.8 ^{c}	9.7 ^{b}	28.6 ^{c}	13.9 ^{d}	30.9 ^{a}

M120 Effects of chemical treatments for tannin deactivation on in situ organic matter degradability of sainfoin (*Onobrychis vicifolia*). H. Khalilvandi-Behroozyar*[1,2], K. Rezayazdi[1], and M. Dehghan-Banadaky[1], *[1]Department of Animal Science, University of Tehran, Karaj, Tehran, Iran, [2]Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Sainfoin is a temperate legume forage, with medium to high concentrations of condensed tannins (CT). The objective of present study was to examine the effectiveness of tannin deactivation on ruminal organic matter (OM) degradability of sainfoin. Forages (second cut) were chopped and treated without (control) or with solutions of NaOH (0.05 *M*) and wood ash (180g/l) with forage to solution ratio of 1:4. Also, 5% solution of PEG (6000 MW) was sprayed on the forages (1:1 w/v). The pH of solutions were determined (12.28 and 12.13 for NaOH and wood ash, respectively). condensed tannin contents were determined using butanol-HCl reagent. Organic matter degradability was determined using three ruminally fistulated Holstein cows, fed balanced rations with forage:concentrate ratio of 60:40. samples were ground to pass 2 mm screen and 5 g was weighed into nylon bags with 50 micron pore size (sample size:surface area was 12.5 mg/cm^2). Duplicates were incubated for 4,8,12,24,48,72 and 96 in the ventral rumen. Effective degradability (ED) was calculated with NEWAY computer package. Complete randomized block design (animals as block), GLM PROC of SAS 9.1 and Duncan's Test were used for data analysis ($P \leq 0.05$). The CT concentration of the control forage was 21.3+0.4 g/kg dry matter. PEG caused a marked increase in the soluble fraction, but not in the "b" fraction. NaoH slightly increased the "a" fraction but wood ash decreased it compared with control. Only wood ash increased the rate of degradation of the "b" fraction, although this was not statistically significant. Effective degradability (K=0.05) were 54.83^{b} + 1.91, 54.33^{b} + 3.40, 50.30^{c} + 0.56 and 62.70^{a} +0.61 for control, NaoH, wood ash and PEG treatments, respectively.

Key words: sainfoin, organic matter, tannin

M121 Chemical compositions and anti-nutritive factors of *Acacia mangium*. T. Clavero* and R. Razz, *Centro de Transferencia de Tecnologia en Pastos y Forrajes, Universidad del Zulia, Maracaibo, Estado Zulia, Venezuela.*

A field experiment was carried out under tropical dry forest conditions in northwest Venezuela to determine the chemical compositions and anti-nutritive factors of *Acacia mangium*. The study included 3 defoliation frequencies (6, 9, 12 weeks). Treatments were replicated 3 times in a randomized block design. Measurements included total nitrogen (TN), in vitro dry matter digestibility (IVDMD), non-structural carbohydrates (TNC), Ca, Mg, P and anti-nutritional compounds (condensed tannins-CT-, saponins-S-, phenols, alkaloids-ALK-, steroids-ST-). Data were subjected to ANOVA, using general linear models procedures of SAS statistical package. Treatments means were contrasted using Tukey test. Several chemical changes of *A. mangium* were noted from 6 to 12 weeks of growth. At each interval TN content declined significantly ($P < 0.05$). The highest value of IVDMD (56.4% ± 2.1) was obtained on 6 weeks of growth and declined on 12.9 digestible units from 6 to 12 weeks. TNC did not differ ($P > 0.05$) among treatments. Concentrations of Ca, Mg, P were affected significantly ($P < 0.05$) by maturity. Mineral concentrations decrease due to translocation from leaves to stems with increasing maturity. The highest concentrations of CT, phenols and ALK (0.48, 2.91 and 0.80%) respectively, were observed at 6 weeks of growth and significantly affected ($P < 0.05$) by the stage of growth. In contrast, S and ST were not affected by stage of growth. Young leaves had higher content of secondary metabolites than older leaves. Because the levels of CT and phenols were under 4% in all treatments, no adverse effects in ruminants would be expected. The chemical compositions and anti-nutri-

tional values of *Acacia mangium* indicate that this specie has potential as feed source in tropical ruminant diets.

Key words: *Acacia mangium*, chemical compositions, anti-nutritional factors

M122 Nutrient composition, polyphenolic compound content, in situ degradation and in vitro rumen fermentation characteristics of leaves from three mulberry species. H. J. Yang* and W. X. Wang, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Mulberry leaves of 14 cultivars of *M. atropurpurea* Roxb. (MAR), 7 cultivars of *M. alba* Linn (MAL) and 8 cultivars of *M. multicaulis* Perr (MMP) were harvested in May and June in Guangzhou city of China and assessed for differences in nutritive value and potential for use as an alternative forage by chemical analysis, in situ ruminal degradation and in vitro batch culture. CP (N × 6.25), NDF, ADF and ether extract (EE) in the leaves ranged from 243 to 262, 260–289, 162–177 and 32–42 g/kg DM, respectively. Means and standard errors (s.e) for CP, NDF, ADF and EE in mulberry leaves were 253 ± 4.5, 275 ± 7.1, 169 ± 3.5 and 37 ± 2.5, respectively. No differences were found for CP or NDF. EE content was ranked: MMP > MAL > MAR ($P < 0.05$), with the highest mean (60 g/kg DM) of cultivar Tongxiangqing in MMP. Total phenol, total tannin and condensed tannin contents were lower than those reported for other tree leaves in literature and did not differ among mulberry species. In situ degradation rate (c) of either DM or CP in 3 cannulated lactating dairy cows, fitted to an exponential curve of the type: $Y = a + b \times (1- e^{-c \times time})$, was similar for mulberry species. However, differences were found in the effective degradation of DM (0.48 in MAR, 0.45 in MAL and 0.41 in MMP with a pooled s.e of 0.008; $P < 0.01$), CP (0.40 in MAR, 0.40 in MAL and 0.36 in MMP with a pooled s.e. of 0.012; $P = 0.05$) and in vitro DM disappearance ($P < 0.01$), and all of these parameters consistently were ranked: MAR > MAL > MMP. In vitro cumulative gas production (also fitted to the same exponential curve), ammonia N, volatile fatty acid characteristics showed no differences among mulberry species. Total phenolic and tannin content were positively correlated with the degradation rate of DM and CP ($P < 0.05$). MAR had the lowest total tannin content and was more degradable in the rumen than MAL and MMP. In general, mulberry leaves had a higher protein and lower fiber content. Consequently, mulberry leaves could be an acceptable and highly digestible rumen-by-pass protein feed supplement for use by ruminant animals on the occasions when silkworm production is not always profitable.

Key words: mulberry leaves, in situ degradation, cumulative gas production

M123 Fluoride content of leaves and stems of alfalfa hay at different stages of maturity. C. Arzola*[1], M. R. Murphy[2], J. Salinas[3], R. Copado[1], A. Corral[1], O. Ruiz[1], C. Rodriguez[1], E. Santellano[1], and H. Gaytan[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico, [2]University of Illinois, Urbana-Champaign, [3]Universidad Autonoma de Tamaulipas, Cd. Victoria, Tamaulipas, Mexico.*

Fluoride (F) accumulation by forages can be of great significance for cattle nutritionists because high-contents of this element can cause dental and osseus lesions on cattle. Besides ingestion of fluoride by drinking water, alfalfa which is a very common forage for dairy cattle can be a source of fluoride. Because there is some concern about the F content of water in some areas of the central part of the state of Chihuahua in Mexico, it is believed that crops can accumulate F. To investigate the pattern and amount of fluoride deposition of 2 varieties of alfalfa ('Cuff-101' and 'Excellent multileaf') harvested on 2 seasons (summer and fall), F content was analyzed in leaves and stems of hay harvested over a range of maturity following an initial phenologic stage characterized by an average stem length of about 0.3 m, (but not visible buds, flowers, or seedpods) within the 2 seasons. Within each season, plots were clipped initially (d 0) and then additional sampling dates were scheduled at 5-d intervals for the next 20 d, resulting in a total of 5 clipping dates (0, 5, 10, 15, and 20 d). Data were analyzed as a split-plot experiment, the plots arranged factorially in a randomized complete block design, being the alfalfa varieties and season the main effects, and maturity the subplot term. The overall mean content of fluoride in the alfalfa hay (94.24 ppm as fed basis) was in general high as compared with typical fluoride concentration reported in tables. When comparing F values in hay samples of the whole plant, no differences ($P > 0.05$) were detected between varieties, season, or stage of maturity. In leaves there was a greater ($P < 0.05$) concentration of F in Cuff-101 variety (104.53 ± 9.97 ppm) than in Excellent multileaf (82.99 ± 10.28). In stems, Cut-101 also had a greater ($P < 0.05$) of F as compared with Excellent multileaf (97.66 ± 9.76 and 86.75 ± 9.60, respectively). A general conclusion was that F content was high regardless of the stage of maturity and harvesting season of hay. A more detailed study should be conducted to determine the levels of F in ingesta to provide information regarding the F status of cattle consuming alfalfa hay.

Key words: fluoride, alfalfa, *Medicago sativa*

M124 Distribution of antiherbivory compounds in *Flourensia cernua*. R. E. Estell*, E. L. Fredrickson, D. K. James, and D. M. Anderson, *USDA-ARS, Jornada Experimental Range, Las Cruces, NM.*

Flourensia cernua is used as a shrub model to study the influence of terpenes on intake by livestock at the Jornada. Two studies (20 plants per study) were conducted using a completely randomized design to examine within plant distribution of volatile compounds to improve sampling protocol. Leaves from 3 positions (outer canopy, subcanopy, and basal) were collected from 4 quadrants (northeast, southeast, northwest, southwest) in Exp. 1. Leaves were removed from 2 leaders of current year's growth for each position in each quadrant. In Exp. 2, 10 leaders of current year's growth were collected from the outer canopy in each quadrant and 3 leaf age categories were formed by separating leaders into thirds and removing leaves. Terpenes were extracted from 5 leaves in duplicate with ethanol and analyzed with gas chromatography/mass spectrometry. Data were log-transformed and analyzed by univariate ANOVA and means separated using Tukey's honestly significant difference. Ninety-three compounds (including 15 unknowns) were present on the leaf surface of *F. cernua*. Only 7 compounds in Exp. 1 and 9 in Exp. 2 differed ($P < 0.05$) among quadrants, and no consistent effect of quadrant was observed in either study. In Exp. 1, 31 compounds differed ($P < 0.05$) among leaf positions, but outer canopy and subcanopy leaves did not differ for any compound. Basal leaves contained greater concentrations than outer canopy and subcanopy leaves for 10 compounds, and less than the other 2 positions for 10 compounds. Thirty-two compounds differed for leaf age in Exp. 2, with immature leaves containing greater concentrations than mature leaves for 30 compounds and greater than the middle age category for 26 compounds ($P < 0.05$). Total concentration (cumulative concentration of all compounds) did not differ among leaf positions but differed for leaf age (greater in immature than mature leaves; $P <$

0.05). Terpenes that differed in Exp. 1 were represented about equally by mono- and sesquiterpenes, whereas compounds affected by leaf age were predominantly sesquiterpenes (3 of 32 were monoterpenes). Both leaf position and age affect terpene concentrations and sampling variability in this shrub.

Key words: terpenes, chemical distribution, leaf age

M125 Degradation kinetics of calcium caseinate incubated in vitro with increasing levels of tannin extract from *Acacia mearnsii* with or without polyethylene glycol addition. D. Zeni*, A. C. Fluck, G. V. Kozloski, A. A. Martins, F. Zanferari, and S. Stefanello, *Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

The effects of tannin extract from *Acacia mearnsii* and polyethylene glycol (PEG) on in vitro gas production from calcium caseinate was evaluated in a study with a 3 × 2 factorial treatment arrangement. Approximately 1 g of calcium caseinate was incubated in triplicate for 48 h with 100 mL of buffered-ruminal fluid in 160 mL glass jars. Treatments were 0 (no tannin) or 20, 40 or 60 g tannin extract/kg of calcium caseinate with presence (+PEG) or absence (-PEG) of 2 g of PEG. Inoculum was obtained from a rumen fistulated steer receiving ad libitum fresh ryegrass (*Lolium multiflorum*). Pressure in the jars, which was converted into gas volume, was measured at 2, 3, 4, 5, 6, 9, 12, 18, 24, 36, and 48 h after incubation. Gas production data were fitted to an exponential unicompartmental model to estimate degradation kinetic parameters. ANOVA analysis was performed and when the treatment effect was significant ($P < 0.05$), linear and quadratic effects were tested by regression analysis. Gas volume increased at increased levels of tannin with addition of PEG ($P = 0.040$) and was not affected without PEG addition (Table 1). Degradation) rate linearly decreased at increasing levels of tannin addition without PEG ($P = 0.047$), but remained constant when PEG was added. Lag time was not affected by tannins without addition of PEG whereas it decreased linearly (P= 0.078) when PEG was added to the incubation media. In conclusion, the tannin extract did not negatively affect calcium caseinate fermentation in vitro.

Table 1.

Tannin	Gas volume (mL)		Degradation rate (%/h)		Lag time (h)	
(g/kg DM)	-PEG	+PEG	-PEG	+PEG	-PEG	+PEG
0	80.7*	57.0	2.83	3.71*	10.3	9.80

Key words: tannins, PEG, rumen degradable protein

M126 Degradation kinetics of cellulose incubated in vitro with increasing levels of tannin extract from *Acacia mearnsii* with or without polyethylene glycol addition. D. Zeni*, A. C. Fluck, G. V. Kozloski, A. A. Martins, F. Zanferari, and T. R. Longo, *Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

The effects of tannin extract from *Acacia mearnsii* and polyethylene glycol (PEG) on in vitro gas production from cellulose was evaluated in a study with a 3 × 2 factorial treatment arrangement. Approximately 1 g of crystalline cellulose (AVICEL) was incubated in triplicate for 48 h with 100 mL of buffered-ruminal fluid in 160 mL glass jars. Treatments were 0 (no tannin) or 20, 40 or 60 g tannin extract/kg of cellulose DM in the presence (+PEG) or absence (-PEG) of 2 g of PEG. Inoculum was obtained from a rumen fistulated steer fed ad libitum fresh ryegrass (*Lolium multiflorum*). Pressure in the jars, which was converted into gas volume, was measured at 2, 3, 4, 5, 6, 9, 12, 18, 24, 36, and 48 h after incubation. Gas production data was fitted to an exponential unicompartmental model to estimate degradation kinetics parameters. ANOVA analysis was performed and when the treatment effect was significant ($P < 0.05$), linear and quadratic effects were tested by regression analysis. Gas volume was not affected by tannin extract with or without PEG addition (Table 1). However, PEG increased gas volume ($P < 0.05$) independently of tannin level. Gas production rate linearly decreased at increased levels of tannin extract, independently of PEG addition ($P < 0.05$). Lag time, in turn, increased linearly with tannin levels without PEG ($P < 0.05$) whereas it was not affected by tannins when PEG was added to the incubation media. Tannin extract negatively affected cellulose fermentation in vitro. However, this effect was not clearly overcome by PEG inclusion. This implies that the contribution of PEG alone to gas production should be accounted for when it is used as a tannin inhibitor in in vitro assays.

Table 1. Degradation kinetics from cellulose incubated in vitro with 20, 40, or 60 g/kg DM of tannin extract with or without PEG

Tannin	Gas volume (mL)		Degradation rate (%/h)		Lag time (h)	
(g/kg DM)	-PEG	+PEG	-PEG	+PEG	-PEG	+ PEG
0	221	229.3*	3.86*	3.54	5.97	5.45
20	225*	205.3	3.74*	3.49	5.43	6.76*
40	219*	210.6	3.32	4.01*	6.16*	5.31
60	222*	212.3	3.71*	3.65	5.2	5.6
SD	7.93	10.3	0.25	0.34	0.54	0.38
P-value[1]	0.821	0.332	0.036	0.024	0.849	0.016

M127 Nutrient and tannin contents of purple prairie clover (*Petalostemon purpureum*) harvested at different growth stages. L. Jin*[1,2], Z. Xu[1], A. D. Iwaasa[3], Y. G. Zhang[2], M. P. Schellenberg[3], T. A. McAllister[1], and Y. Wang[1], *[1]Agriculture and Agri-Food Canada, Lethbridge Reserach Centre, Lethbridge, AB, Canada, [2]Department of Animal Science, Northeast Agricultural University, China, [3]SPARC-AAFC, Swift Current, SK, Canada.*

The native legume purple prairie clover (PPC; *Petalostemon purpureum*) is well adapted to the prairie region of Canada and is considered an important palatable component of prairie hay. However, there is no information available on its nutritive value for ruminants. Whole plants of PPC were harvested from 5 regions of native pastures at Swift Current, SK, Canada at vegetative (VEG) and full-flowering/early seeding (FL) stages (4 samples for each maturity stage in each region). Proportions of leaf, stem and flower were determined. Whole plants were analyzed for organic matter (OM), N, neutral detergent fiber (NDF) and acid detergent fiber (ADF). Leaf, stem, flower and whole plant were also analyzed for total phenolics, total tannins and condensed tannin (CT). Plant had higher ($P < 0.001$) proportion of leaf, but lower ($P < 0.001$) proportion of flower at VEG than at FL stage. Contents of OM, NDF, ADF and their associated N were higher ($P < 0.01$), but

N content was lower (21.4 vs. 26.7 g/kg DM; $P < 0.01$) for FL than for VEG stage. Condensed tannin was detected in all tissues (i.e. leaf, stem and flower) of the plant; with flower containing the highest (198-213 g/kg DM) and stem containing the lowest (17-18 g/kg DM) levels. Contents of total phenolics, total tannins and total CT in leaf were all higher ($P < 0.01$) at the VEG than at the FL stage, whereas they were present at similar concentrations in stem and flowers at both growth stages. Whole plant harvested at the VEG contained lower (59 vs. 94 g/kg DM; $P < 0.001$) level of CT than that harvested at the FL stage, due to the increased proportion of flower at the FL stage. Overall, PPC is characterized by its high level of N content and a unique array of bioactive compounds and therefore may have considerable potential as a high-quality forage for beef cattle. Its yield and persistence need to be further evaluated.

Key words: purple prairie clover, nutrient, tannins

M128 Evaluation of tannins in indigenous forage plants of the Brazilian semi-arid. M. L. Chizzotti*[1,2], F. R. B. Oliveira[2], R. T. S. Rodrigues[2], K. C. Busato[2], T. S. Silva[2], J. A. Siqueira[2], and F. H. M. Chizzotti[1], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal do Vale do São Francisco, Petrolina, PE, Brazil.*

This experiment was conducted to evaluate the presence of tannins in indigenous plants of the Brazilian semiarid region Caatinga. Samples of seedling and adult leaves of fourteen species were used: *Albizia inundata*, *Amburana cearensis*, *Anadenanthera colubrina*, *Caesalpinia ferrea*, *Erythrina velutina*, *Handroanthus impetiginosus*, *Handroanthus spongiosus*, *Hymenaea martiana*, *Myracrodruon urundeuva*, *Pseudobombax marginatum*, *Spondias tuberose*, *Syagrus coronata*, *Tabebuia aurea* and *Ziziphus joazeiro*. The condensed tannin complexing agent, Polyethylene glycol (PEG), was used to evaluate the presence of tannins by semi- automated in vitro gas production and in vitro digestibility after 96 h. Five replicates were dried at 55° C and ground (1 mm) and 100 mg of samples were incubated with or without 200 mg of PEG. The fermentation kinetic parameters were fitted to the following exponential model: $Y = b \times (1 - e^{(-c \times (t - L))})$, where Y is the accumulated gas, mL/100g of incubated DM; b is the asymptote of gas production, mL/100g of incubated DM; c is the fractional rate of gas production, %/h ; t is the time, h; and L is the lag time, h, for t>L. The 95% confidence interval was used to compare coefficients. There was an effect of PEG ($P < 0.05$) on asymptote of gas production for the leaves of adult plants *A. colubrina*, *H. martiana*, and *M. urundeuva*, indicating the presence of tannins in these species. For the rate of gas production, there was an effect of PEG ($P < 0.05$) for seedling leaves of *A. colubrina*, *H. martiana*, *M. urundeuva*, and *P. marginatum*. The DM digestibility after 96 h of incubation was higher ($P < 0.05$) in the presence of PEG for the adult and seedlings leaves of *A. colubrina* (56.5% vs. 39.4% and 74.2% vs. 61.0%, respectively), for seedling leaves of *M. urundeuva* (72.4% vs. 59.0%), and for adult leaves of *C. ferrea* (51.5% vs. 47.4%) and *H. martiana* (47.7% vs. 29.3%). The leaves of species *Albizia inundata*, *Amburana cearensis*, *Erythrina velutina*, *Handroanthus impetiginosus*, *Handroanthus spongiosus*, *Spondias tuberose*, *Syagrus coronata*, *Tabebuia aurea* and *Ziziphus joazeiro* did not present a significant content of tannins. Funded by FACEPE, CRAD and CNPq.

Key words: anti-nutritional factors, Caatinga, polyethylene glycol

M129 Effect of grazing toxic tall fescue prior to or immediately following insemination on beef cattle reproductive performance. M. G. Burns*[1], J. G. Andrae[1], S. L. Pratt[1], W. C. Bridges[1], and F. N. Schrick[2], *[1]Clemson University, Clemson, SC, [2]University of Tennessee, Knoxville.*

The impact of toxic tall fescue (F) on beef cattle reproductive performance has been sporadically addressed, and few studies examine the effect that exposure timing has on conception rates. The objective of this study was to determine if F affects cattle reproduction differently when cattle are exposed before or immediately following insemination, to assess effects during gamete development or in altered uterine environment, respectively. Two and 3 yr old beef cows (99 hd total) were blocked by breed, BCS and age and allotted to groups (n = 50) grazing F-(>92% wild-type infected) or alternate forages (O; common bermudagrass and annual ryegrass) for 210 d before timed insemination. On d −8 all cows were subjected to a standard 5-d CIDR estrous synchronization program and were artificially inseminated on d0. Immediately following insemination, 25 cows from each group were switched to the alternate grazing treatment for the remainder of the trial, consistent with a 2 × 2 factorial arrangement. This resulted in 4 total forage treatment combinations when grazed pre and post breeding: fescue-fescue (FF n = 25), fescue-other (FO n = 25), other-fescue (OF n = 24), and other-other (OO, n = 25). Cows were visually checked for estrus behavior from d0 to d10 after which bulls were placed with cows for 60d. Blood was collected on d-18 and d-8 for P4 analysis to assess cyclicity. Blood was also collected on d-8 and d10 for prolactin concentrations. Pregnancy was determined using ultrasonography at d 130 and verified with calving records. Data were analyzed using PROC GLM of SAS. Cattle grazing tall fescue on d-8 had lower ($P < 0.05$) serum prolactin levels than cattle grazing O. There was a F x O interaction ($P < 0.05$) for serum prolactin on d10. Prolactin concentrations of FF and OF did not differ and were lower ($P < 0.01$) than both OO and FO groups. Prolactin levels of FO were higher ($P < 0.05$) than OO at d10. Pre AI treatment had no effect ($P > 0.05$) on final pregnancy rate. Cattle grazing F post AI had lower ($P < 0.01$) final pregnancy rates compared with O.

Key words: fescue, beef cattle, reproduction

M130 Endophyte-infected tall fescue seed extract induces constriction of bovine vasculature. A. P. Foote*[1], D. L. Harmon[1], K. R. Brown[2], J. R. Strickland[2], K. R. McLeod[1], L. P. Bush[1], and J. L. Klotz[2], *[1]University of Kentucky, Lexington, [2]USDA-ARS, FAPRU, Lexington, KY.*

Ergovaline (ERV) has been extensively used to study vasoactive effects of endophyte (*Neotyphodium coenophialum*) infected tall fescue (*Lolium arundinaceum*). However preliminary in vitro tests show that an extract of toxic tall fescue seed (E+EXT) is more potent than ERV alone indicating other compounds contribute to vasoconstriction. Thus, experiments were conducted to determine if vasoactivity of an E+EXT is different than a mixture of ergot alkaloids (ALK) of equal concentration and to determine if an endophyte-free extract (E-EXT) is vasoactive. Segments of lateral saphenous vein and right ruminal artery and vein were collected from steers (n = 6) shortly after slaughter. Vessels were cleaned of excess connective tissue and fat and sliced into segments that were suspended in a multi-myograph chamber with 5 mL of continually oxygenated Krebs-Henseleit buffer, equilibrated for 90 min, and exposed to a reference compound, 120 m*M* KCl for ruminal vessels and 0.1 m*M* norepinephrine for saphenous vein. Increasing concentrations of each treatment (E+EXT,

E-EXT, ALK, and ERV) were added to the respective chamber every 15 min following buffer replacement. Data were normalized as a % of maximal contractile response of the reference compound and analyzed as a CRD. For saphenous vein, ALK and E+EXT induced similar responses ($P = 0.19$ for $10^{-6}M$; $P = 0.28$ for $10^{-7}M$) that were greater than $10^{-6}M$ ERV ($P < 0.01$ and $P = 0.09$ respectively) and $10^{-7}M$ ERV ($P < 0.01$ and $P < 0.01$ respectively). The potency of ALK and E+EXT was greater than ERV ($P < 0.01$) in saphenous vein. For ruminal artery, ALK and E+EXT induced similar responses ($P = 0.31$ for 10^{-6}; $P = 0.06$ for 10^{-7}) that were greater than ERV at $10^{-6}M$ ($P < 0.01$ and $P < 0.01$ respectively) and $10^{-7}M$ ($P = 0.04$ and $P < 0.01$ respectively). For ruminal vein, ALK and E+EXT induced similar responses ($P = 0.13$) but E+EXT did not differ from ERV ($P = 0.61$). The E-EXT did not induce a contractile response in any vessel tested ($P > 0.1$). Although low in concentration, non-ergovaline alkaloids in E+EXT contribute to the observed contractile response and should be considered when studying fescue toxicosis.

Key words: tall fescue, vasoconstriction

M131 Contractile response of bovine lateral saphenous vein to ergovaline, serotonin$_{2A}$, α_{2A}-, and α_{2C}-adrenergic receptor agonists relative to time off endophyte-infected tall fescue. J. L. Klotz[1], G. E. Aiken[1], A. P. Foote*[2], L. P. Bush[2], K. R. Brown[1], B. M. Goff[2], and J. R. Strickland[1], *[1]USDA-ARS-FAPRU, Lexington, KY, [2]University of Kentucky, Lexington.*

Previous research has demonstrated differences in contractile responses to ergot alkaloids, serotonin (5HT), and adrenergic agonists by lateral saphenous veins collected from cattle that grazed either endophyte (*Neotyphodium coenophialum*)-infected or endophyte-free tall fescue (*Lolium arundinaceum*), possibly influenced by an altered vascular biogenic amine receptor profile. To aid in understanding of how cattle recover after exposure to toxic tall fescue, lateral saphenous vein biopsies were conducted on 21 predominantly Angus steers (357 ± 3 kg) at 0 (n = 6), 7 (n = 6), 14 (n = 5), and 28 d (n = 4) after removal from grazing KY31 tall fescue pasture (3.0 ha) for 126 d. Off-pasture, animals were housed in a dry lot and fed a corn silage and soybean hull mixed diet. Biopsied segments of vein were sliced into 2–3 mm cross-sections and suspended in myograph chambers containing 5 mL of oxygenated Krebs-Henseleit buffer (95% O_2/5% CO_2; pH = 7.4; 37°C). Veins were exposed to increasing concentrations (1×10^{-11} to $10^{-4}M$) of ergovaline (ERV), TCB2 ($5HT_{2A}$ agonist), guanfacine HCl (GF; α_{2A}-adrenergic agonist), and (R)-(+)-m-nitrobiphenyline oxalate (NBP; α_{2C}-adrenergic agonist). Data were normalized to a reference addition of $1 \times 10^{-4}M$ norepinephrine and analyzed as a CRD for main effects of days off pasture, agonist concentration, and d off pasture × concentration with steer as experimental unit using mixed models of SAS. Agonist concentration and day (d 7 and 14 were greater than d 0 and 28) were significant ($P < 0.01$), but days off pasture × concentration was not significant ($P > 0.1$) for all 4 compounds tested. Ergovaline and TCB2 had the greatest maximal responses and 2 adrenergic agonists elicited relatively smaller responses. Response to increasing concentrations GF was the least and varied most across days. The α_{2C} agonist NBP, was the more vasoactive adrenergic agonist. The effect of animal recovery during the 28-d off of tall fescue did not affect the relative response through changes in the biogenic amine receptor profile as evaluated pharmacologically in the bovine saphenous vein.

Key words: Bovine, ergovaline, tall fescue

M132 Differences in chemical composition of crown rust resistant and susceptible oat cultivars in Northern Mexico. H. Bernal-Barragán*[1,4], M. A. Cerrillo-Soto[2,4], A. S. Juárez-Reyes[2,4], F. G. Ríos-Rincón[3,4], E. Gutiérrez-Ornelas[1,4], M. Guerrero-Cervantes[2,4], N. C. Vásquez-Aguilar[1], and J. E. Treviño-Ramírez[1], *[1]Facultad de Agronomía UANL, Escobedo, N.L., México, [2]Facultad de Medicina Veterinaria y Zootecnia UJED, Durango, Dgo., México, [3]Facultad de Medicina Veterinaria y Zootecnia UAS, Culiacán, Sin., México, [4]Red Internacional de Nutrición y Alimentación en Rumiantes, México.*

Forage nutritive value of 2 groups of oat (*Avena sativa* L.) cultivars (about 120 days growing season) bred in Mexico were determined and related to their differences in the susceptibility to crown rust disease caused by *Puccinia coronata*. Three crown rust resistant oat cultivars (CRR= code cultivars L112, L124 and L164), released in 2007 from the Agronomy Department at the University of Nuevo Leon (UANL) in Mexico, and two commercial crown rust susceptible oat cultivars (CRS=Guelatao and Chihuahua), were sown in December 2007. No crown rust disease was present in any of the plots during this experiment. Three random whole plant samples were collected from small plots at 101, 110 and 117 days of growth. Samples were oven dried at 55° C, and ground to pass through 1-mm screen. dry matter, ash, CP, fat, NDF, ADF, and ADL, were determined and expressed on a DM basis and contents of cellulose, and hemicellulose were calculated. A 2 × 3 factorial arrangement with two groups of oat cultivars (resistant and susceptible), and three cutting stages (101, 110, and 117 days), was used in a complete randomized design, with three replicates per cultivar. There were no significant interactions between the main factors. Ash content was lower ($P < 0.05$) in CRS (12.1%) than in CRR (13.1%). Differences in CP ($P < 0.05$) were found between 101 (11.1%) and 117 days (8.5%). Fat content was similar ($P > 0.05$) between groups of oat cultivars; however fat content at 117 days (3.5%) was higher than at 101 and 110 days (2.9% in average). Crown rust resistant cultivars had higher ($P < 0.05$) NDF (56.6%) than CRS (54.6%). There were no differences ($P > 0.05$) in ADF (31.0%), hemicellulose (24.6%) and cellulose (26.4%) between CRR and CRS; however cellulose content at 101 days (27.7%) was higher ($P < 0.05$) than at 117 days (24.8%). There were small ($P = 0.051$) differences in lignin content between CRR (4.8%) and CRS (4.3%) oat cultivars, and between cutting at 101 (4.2%) and 117 days (4.9%). In conclusion, differences in ash, NDF and lignin contents were detected between crown rust resistant and susceptible oat varieties cultivated in northeastern Mexico.

Key words: *Avena sativa*, nutritive value, crown rust resistance

M133 Dry matter yield and chemical composition of twenty-eight alfalfa cultivars grown in Brazil. P. R. Meirelles*, C. Costa, M. A. Q. Vieira, M. A. Factori, and E. A. R. Santana, *College of Veterinary Medicine and Animal Science, UNESP, Botucatu, Sao Paulo, Brasil.*

An experiment was conducted at the forage sector of the College of Veterinary Medicine and Animal Science, Botucatu-SP, with the objective of evaluating 28 alfalfa cultivars in terms of dry-matter yield and crude protein (CP), neutral detergent fiber (NDF) and acid detergent fiber (ADF) contents. The cultivars were the Crioula, Monarca, BR 4, Alto Great, MH 4, SW 9210 A, P 5929, BR 1, El Grande, P 5715, MH 15, Valley Plus, BR 2, Rio, SW 8210, Maricopa, ICI 990, P 5888, P 30, Alfa-200, WL 516, SW 8112 A, BR 3, Florida 77, Araucana, Falcon, Semit 921 and Sutter. The soil chemical characteristics in the experimental area were: pH in water 4.3, Al=0.70 meq/100cm^3, Ca=12.0 mmolc.dm^3, Mg=10.0 mmolc.dm^3, K=0.9 mmolc.dm^3, P=4.0 mg/dm^3. Lime was applied at the rate of 6 t/ha, followed by pre- planting fertilization, which consisted of 600 kg superphosphate/ha, and 150 kg potassium chloride/ha. The seeds were planted in rows 30 cm apart at the rate of 15 kg/ha. A randomized block design with three replicates was used. The Monarca cultivar was the most productive and its dry matter yield differed ($P < 0.05$) from that of MH 15, Valley Plus and SW 8112. Crude protein content differed ($P < 0.05$) among cultivars, with the highest value in Valley Plus (22.39%) and the lowest in Semit 921 (18.8). NDF content did not differ ($P < 0.05$), but there were statistical differences for ADF; the highest value (36.01%) occurred in ICI 990 and the lowest (29.44%) in P 30, with no difference ($P < 0.05$) detected among others treatments. The most promising cultivars for the ecological characters of Botucatu-SP are the following: Monarca, because of its higher dry matter yield, followed by Rio, Sutter, Alto and Crioula, due to their low decrease in dry matter yield over three harvest years.

Key words: neutral detergent fiber, *Medicago sativa* L., acid detergent fiber

M134 Tillering pattern and dry matter production of Mombasa grass submitted to nitrogen fertilization during regrowth. A. F. Garcez Neto*[1,3], K. F. Gobbi[2,3], T. M. Dos Santos[1], E. E. B. Baldasso[1], and J. Da Silva[1], *[1]Federal University of Parana, Palotina, Parana, Brazil, [2]Agronomic Institute of Parana, Paranavai, Parana, Brazil, [3]Federal University of Vicosa, Vicosa, Minas Gerais, Brazil.*

Increase in forage growth rate can be related to different factors, such as energy supply for photosynthesis process and tillering potential. This work was carried out with the aim to study how a tropical forage with extensive growth potential (*Panicum maximum* Jacq. 'Mombaça') responds to different levels of nitrogen (N) fertilization during its regrowth, in terms of its tillering capacity and forage yield. The tillering capacity was measured by the number of tillers and tiller weight. Three levels of N were used (N0 = 0 mg/dm^3; N25 = 25 mg/dm^3 and N50 = 50 mg/dm^3) and six regrowth times (1, 2, 4, 8, 16 and 32 days after an initial staging or standardization cut). Nitrogen was provided weekly from 30 days before the standardization cut up to the last regrowth cut. The statistical analyses were performed using a randomized block design with a 3 × 6 factorial treatment arrangement, with 3 replicates. At each harvest the number of tillers per plant were counted and all the aboveground biomass was weighed (g DM/plot). A significant interaction ($P < 0.05$) between levels of N and the regrowth times was found for all variables studied. No effect was found for regrowth time to the number of tillers for N0. A lower number of tillers was found for N25 compared to N50 during all regrowth times (Y=64.8408+0.7771x, R^2=0.795; Y=67.4411+1.5982x, R^2=0.854, respectively for N25 and N50). In N0, the increase in tiller weight (g DM/tiller) occurred linearly during regrowth times, but at very low intensity (Y=0.2+0.175x, R^2=0.979) compared to N25 and N50. The tiller weight responded quadratically to N in N25 and N50 treatments (Y=0.2752+0.259x+0.0006x^2, R^2=0.996; Y=0.2946+0.0093x+0.0014x^2, R^2=0.997, respectively to N25 and N50). The aboveground biomass production also followed the same pattern found for tiller weight during regrowth times between N levels (Y=11.366+0.8546x, R^2=0.986; Y=17.993+1.7056x+0.0789x^2, R^2=0.995; Y=18.4238+1.1575x+0.1674x^2, R^2=0.999, respectively to N0, N25 and N50). The highest N fertilization can be supplied to the grass from 16 days after regrowth.

Key words: grass, partition, tiller

M135 Effects of growing conditions on alfalfa hay quality and production. A. Palmonari*, M. Fustini, G. Canestrari, and A. Formigoni, *Dipartimento Scienze Mediche Veterinarie, Universita degli Studi di Bologna, Bologna, Italy.*

Alfalfa hay is one of the most utilized forages in Italy. Its growth is ensured by environmental and climate conditions, which usually allow farmers to obtain 5 or sometimes more cuts per year. Numerous studies have shown that yield and quality of forages are affected by growth stage, forage species, cultivar, climate (e.g., rainfall, temperature), and growing condition. In alfalfa, growth conditions are probably the main factors responsible for changes in quality, due to the physiological modification of several tissues. This study focused on the quantification of these changes in fibrous and protein fractions and changes in fiber digestibility as a consequence of increased maturity. Within one field, 6 plots were designed and then paired in 3 treatments (A,B,C,A,B,C). Each treatment was harvested at 3 cutting intervals; trt A every 21 d (pre bloom), trt B every 28 d (first bloom) and trt C 35 d (full bloom) for 4 times each during 2008 spring and summer. Rainfall, temperature and yield were recorded for each cut and each pair of treatments during the trial. Fibrous and protein fractions, along with in vitro NDF digestibility at 24h were evaluated. Statistical analysis was performed among treatments using the ANOVA model with repeated measures of the software STATISTICA. CP, along with SolP and NPN, was significantly higher ($P < 0.01$) for trt A (20.8% DM) than trt B or C (17.3% DM and 17.0% DM respectively). Similar results were observed for ADL and in vitro NDF digestibility at 24 h (trt A = 44.0% DM, trt B = 37.8% DM, trt C = 34.1% DM respectively; $P < 0.01$). Increased maturity resulted in increased lignin deposition and loss of protein. This situation is reflected in fiber digestibility, which was compromised as maturity increased. Moreover, treatment A yielded similar amount of dry matter as treatment C (103.8 kg and 116.5 kg respectively), while the lower production was obtained from treatment B (96.2 kg). Together with analytical fractions, production results indicated that quantity of product is not always related to days of growth, which are typically correlated inversely with forage quality.

Key words: alfalfa, maturity, chemical composition

M136 Nutritional value and silage fermentation parameters of elder (*Sambucus nigra*) as a supplement for dairy cattle in the Colombian Tropics. L. Reyes, L. C. Bernal*, and A. Conde, *Universidad de La Salle, Bogotá, Colombia.*

The aim of this study was to determine the nutritional value and fermentation parameters of an ensiled mixture of elder with corn bran and potato by-products. Elder leaves were cut after 90 days of regrowth and 2 years of establishment. Eight treatments and four replicates per treatment were evaluated. The elder leaves were chopped and mixed with either corn bran or potato bran, at inclusion levels of 20, 40, 50 and 60% for the respective brans. These mixtures were stored in a microbag (1 kg capacity) for 42 days. At the end of the fermentation period, samples were taken for analysis of nutritional quality (dry matter DM, crude protein CP and Gross Energy GE) and fermentation parameters (pH, ammonia nitrogen and its relation with total nitrogen). The experimental design was a 2 × 4 factorial, (Factor a. corn bran vs. potato bran; factor b. 20, 40, 50 and 60% inclusion level of corn bran or potato bran). Data were analyzed using the GLM procedure of SAS. Inclusion of corn bran resulted increased ($P < 0.001$) dry matter DM (60.83 vs. 19.38%) and gross energy GE concentrations (4.4 vs. 3.9 Mcal/Kg) as compared to inclusion of potato bran. Inclusion of potato bran resulted in increased ($P < 0.001$) CP (16 vs. 12%) as compared to inclusion of corn bran. The ratio of ammonia nitrogen/total nitrogen was greater for the potato bran treatments (14.4 vs. 6.8%). There was no difference in pH ($P > 0.001$) but the critical value of pH and water activity required for stabilizing a silage were not achieved in the elder leaves with potato bran silage because the DM values were low (DM 19% and pH 4.47). In the elder leaves with corn bran, the DM values were high (DM 60% and pH 4.39) which indicates the silage was stabilized. The DM, CP and GE values increased ($P < 0.05$) with inclusion level of corn bran in the silage whereas those variables decreased ($P < 0.05$) with increasing inclusion level of potato bran. Finally, the results of fermentation and nutritional quality showed that use of elder leaves mixed with corn bran at 50% is a good option and may be a viable alternative as a dietary supplement for dairy cows.

Key words: *Sambucus nigra*, corn bran, silage

M137 Organic fertilization improves growth of *Paulownia* spp. V. M. Llamas-Rodríguez*, R. Luevano-Escobedo, V. Gallardo-Santillan, A. S. Juárez-Reyes, and M. A. Cerrillo-Soto, *Universidad Juárez del Estado de Durango, Durango, México.*

The genus *Paulownia* exhibits rapid juvenile growth with excellent characteristics for timber, fodder, ornamental and medicinal uses. A study was conducted to estimate the effect of applying either organic or inorganic fertilizer to plants of *P. tomentosa* maintained in field conditions. The study area is located in a semiarid region of Northern Mexico at an altitude of 1921 m above sea level and temperature ranging from −18 to 35°C. Five treatments were applied to plants of 15 d of age. Two fertilizers; inorganic (based on N, P, K with doses of 20%, 8% and 4%, respectively in 100 mL of solution) and organic humic acid (n = 11.5%, $P = 9.5\%$, K = 10.0%, Ca = 0.9% and S = 0.8%) and 2 types of application (foliar and radicular) and a control (water) were evaluated. One hundred milliliters of solution was mixed in 1 L of water and applied every 15 d during 13 weeks. Height of the trees and amount of leaves were recorded. Data were analyzed according to a completely randomized design with 20 replications using ANOVA while mean comparison were performed using Tukey's test. Radicular application of inorganic fertilizer resulted in higher heights, while no effects were recorded due to inorganic foliar application. On the contrary, organic fertilization in both ways of application resulted in positive effects. The amount of leaves was positively affected by the inorganic fertilizer applied in soil (radicular), whereas the organic humic acid favored this variable after both radicular and foliar applications ($P < 0.01$). No differences were recorded between the foliar application of inorganic fertilizer and the control (water). Foliar and radicular application of organic fertilizer improved growth of *Paulownia* spp. compared to no treatment. Therefore, use of organic fertilizers might promote growth with less chance of soil contamination.

Table 1. Effect of type of fertilizer on height and number of leaves in *Paulownia tomentosa*

	Treatments					
	Inorganic		Organic		Control

M138 Ruminal degradability of crude protein of Marandu grasses. A. J. D. Pacheco Junior*[1], F. A. P. Santos[1], C. M. M. Bittar[1], L. R. D. Agostinho Neto[1], R. A. M. Vieira[2], L. O. Tedeschi[3], B. C. Matos[1], and G. B. Mourão[1], *[1]University of São Paulo, University of Sao Paulo, USP/ESALQ, Piracicaba, SP, Brazil, [2]State University of North Fluminense Darcy Ribeiro, State University of North Fluminense Darcy Ribeiro, Campos dos Goytacazes, RJ, Brazil, [3]Texas A&M University, Texas A&M University, College Station.*

This study aimed to characterize the degradation rates of degradable fractions of CP (in situ methods) in samples of Marandu grass (Brachiaria brizantha cv. Marandu) managed with high stocking rates and variable intervals of grazing according 95% of light interception (LI) during spring, summer and fall. The study was conducted in University of São Paulo, Piracicaba, São Paulo, Brazil. We used 3 paddocks of 0.26 ha each, which were fertilized with 260 kg N/ha between the months of evaluation. The criterion for entry of animals in the paddocks was when they reached 25 cm in height and the stubble was 15 cm. Samples of Marandu grass to determine the rate of degradation of CP (in situ), represented the mean value from 20 sampling points per paddock. We collected the entire canopy above the height of stubble (15 cm). The samples were incubated in the rumen for 0, 3, 6, 12, 18, 24, 30, 36, 48, 60, 72, 96 and 120 hours. The data analyses were performed using Generalized Compartmental Model of Digestion and PROC MIXED of SAS. Estimation of in situ degradability of CP did not differ ($P < 0.1$) among seasons (Table 1). Crude protein contained approximately 50% of soluble protein (Fraction A) and 40% of potentially degradable fraction of protein (Fraction B), respectivally.The rates of degradation of fraction B were low and effective degradability was approximately 69%.

Table 1. Composition of crude protein fractions (in situ) in samples of Marandu grass along spring, summer and fall

	Season				
Fraction[1] (%)	Spring	Summer	Fall	SE	Pr > |t|
A	54.5	44.2	50.4	4.4	0.3
B	33.3	45.4	38.3	3.5	0.1
C	12.2	10.4	11.3	1.4	0.7
Kd (%/h)*	6.3	7.6	8.0	1.3	0.5
λ (%/h)**	4.4	5.5	5.9	1.1	0.4
Effective degradability (%/h)	63.1	71.3	72.5	4.3	0.2

[1]A = soluble fraction; B = potentially degradable fraction; C = undegradable fraction.

*Degradation rate of fraction B; **asymptotic age-dependent fractional availability rate of the fraction B.

M139 Effect of stage of maturity of alfalfa hay upon in vitro dry matter and crude protein digestibility. R. Copado-Garcia*[1], O. Serna[2], C. Arzola[1], O. Ruiz[1], C. Rodriguez[1], A. Corral[1], and H. Gaytan[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico, [2]INIFAP, Chihuahua, Chihuahua, Mexico.*

Alfalfa (*Medicago sativa*) dry matter is readily fermented in the rumen. Even though this phenomenon has been extensively studied in relation to the effects of the conservation method, there are not many studies regarding the effect of maturity upon the rumen degradability of dry matter and protein of alfalfa hay. To evaluate the effect of maturity upon those traits, 2 varieties of alfalfa ('Cuff-101' and 'Excellent multileaf') harvested in 4 seasons (spring, early, late summer and fall), were sampled and dry matter (IVDMD) and protein digestibility (IVCPD) were determined in vitro using an Ankom digester. Eight, 4 square m plots were harvested over a range of sampling periods (0, 5, 10, 15, and 20 d following Stage 2, (when stem length was > 0.40 m, but no buds, flowers, or seedpods were visible). An exclosure was subdivided into 5 sections at each of 8 locations in Delicias, Chih., Mexico, and sampled within 5 d intervals after an initial cut. Data were analyzed with a subplot design, with variety and period as main effects and day of cutting as sub-plot term. Statistical analysis used the GLM procedure of SAS. Alfalfa maturity, expressed as the number of days of cut after alfalfa had attained stage 2, did not show a significant difference ($P > 0.05$) on IVDMD. However, in late summer and fall the CP tends to increase, but in fall IVCPD decreased noticeably, likely as result of a more rapid maturation of the plant. Also, as the maturity of the plants increased, CP increased, and IVCPD decreased linearly ($P < 0.01$). We concluded that it is useful to take in consideration the stage of maturity to manage the nutritional quality of alfalfa in terms of digestibility of protein.

Key words: alfalfa, IVDMD, IVCPD

M140 Nutrient composition, metabolizable energy, in situ rumen degradation and in vitro fermentation characteristics of linted cottonseed hulls, delinted cottonseed hulls and cottonseed linter waste. H. J. Yang* and Y. K. Bo, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Dietary supplementation with conventional linted cottonseed hulls (LCSH) is a common practice in livestock production all over the world. However, supplementation with mechanically delinted cottonseed hulls (DCSH) and cottonseed linter waste (CSLW) has not been well accepted by local farmers in Xinjiang province of China. In this study, representative samples of DCSH, LCSH and CSLW were collected in different areas of Xinjiang and assessed by chemical analysis, in situ and in vitro degradation methods. The CP (N × 6.25) content of CSLW (302 ± 3.2 g/kg DM) was approximately 3 times that of LCSH and 5 times that of DCSH. The ether extract (EE) content was 3 times higher in CSLW (269 ± 3.12 g/kg DM) than that of LCSH and 4 times higher than that of DCSH. NDF (311 ± 2.0) and ADF (243 ± 6.2) contents of CSLW were less than half values of DCSH or LCSH. Metabolizable energy, based on in vitro gas production and chemical analyses, ranked: CSLW (12.58 ± 0.65 kJ/kg DM) > LCSH (6.81 ± 0.61 kJ/kg DM) > DCSH (5.90 ± 0.60 kJ/kg DM) ($P < 0.05$). The in situ degradation of DM and CP were fitted to an exponential equation: $Y = a + b \times (1 - e^{-c \times time})$. CSLW showed the highest effective degradabilities for DM (0.36 ± 0.01) and CP (0.52 ± 0.04) ($P < 0.05$). One step in vitro ruminal DM disappearance and 2 step Tilley and Terry ′s digestibilities of DM, NDF and ADF ranked: CSLW > LCSH > DCSH ($P < 0.05$). The 72-h batch culture experiment also showed the highest production of volatile fatty acids occurred in CSLW ($P < 0.05$), but the maximum gas production did not differ among the 3 cottonseed by-products. Molar proportions of methane in the fermentation gases were 23.5%, 25.0% and 17.5% for DCSH, LCSH and CSLW with a pooled standard error of 2.5, respectively. Dietary inclusion of CSLW could be beneficial to host ruminants by providing more glucogenic precursors (e.g., propionate) than non-glucogenic acids (e.g., acetate and butyrate). In general, CSLW appears to be valuable as a substitute for conventional protein feed for ruminant animals, with less potential for greenhouse gas emission than either LCSH or DCSH.

Key words: cottonseed by-products, in situ degradation, cumulative gas production

M141 Chemical composition and nutritional value of *Prosopis laevigata* harvested at three differents maturation stage. R. Rojo*, E. Castelán, A. Z. M. Salem, J. F. Vázquez, B. Encarnación-Elizalde, M. Palma-González, and J. Cedillo-Monrroy, *Centro Universitario UAEM-Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México.*

A experiment was carried out to evaluate chemical composition and nutritional value of *Prosopis laevigata* pods harvested at three different maturity stages (IMP=immature pods, SMP=semi- mature pods, MAP= mature pods). Chemical analyses were: CP, NDF, ADF and Total condensed tannins (TCT) and nutritional components were: in vitro dry matter degradability (IVDMD), gas production (GP24), fermentation kinetic parameters (b: asymptotic gas production, c: rate of gas production from the slowly fermentable feed fraction b (/h) and lag time), short chain fatty acids (SCFA), metabolizable energy (ME), net energy (NE) and partition factor (PF). The inoculum was obtained from two adult male goats fitted with a ruminal fistula, fed a 40:60 forage:concentrate diet. Data were submitted to variance analysis by the GLM procedure and mean effects were separated by the Tukey test. The content of CP (g/kg DM) was greater ($P < 0.05$) in IMP (28.1%) pods ($P < 0.01$) compared to SMP (11.0%) and MAP (11.4%). The NDF and ADF were greater ($P < 0.05$) in MAP in comparison with IMP and SMP. The TCT (g/kg DM) (TCT) was greater ($P < 0.05$) in MAP (37.08) and SMP (36.77) than IMP (12.63). The gas production at 24 hours and kinetic gas production parameters (b y c) were greater ($P < 0.05$) in SMP and MAP compared with IMP; the oppo-

site occurred with the lag time, with IMP having the lowest value ($P = 0.0001$). The SCFA production was greater in SMP and MAP ($P = 0.0001$) than IMP. However; PF and IVDMD were greater in IMP ($P<0.05$). Measures of energy (i.e, ME and NE) were not affected by the maturity stage. Based on the results we conclude that MAP and SMP of *Prosopis laevigata* are promising nutritional alternative food sources for small ruminants, especially in the dry season.

M142 The influence of process time and heat treatment on bleaching efficacy of liquid whey and retentate. X. Li* and M. A. Drake, *North Carolina State University, Raleigh.*

The residual annatto colorant in fluid whey is removed by bleaching to provide a desired neutral color in dried whey ingredients. Studies have established that bleaching negatively influences whey ingredient flavor. Optimization of bleaching parameters is necessary to minimize flavor effects on finished ingredients. Studies are needed to determine if the cheesemake procedure or processing factors influence bleaching efficacy. The objective of this study was to evaluate if starter culture, whey pasteurization, fluid whey storage, or spray drying affected the bleaching efficacy of liquid whey and retentate. Cheddar cheese whey with annatto (15mL/454kg with 3% norbixin content) was manufactured using a mesophilic lactic starter culture or by addition of lactic acid and rennet (rennet-set). Pasteurized fat-separated whey was ultrafiltered to 9% solids (w/w) and spray dried to 34% whey protein concentrate (WPC34). Aliquots of liquid whey were bleached at 60°C for 1 h (hydrogen peroxide, 250 ppm) immediately (no fat separation or pasteurization), before pasteurization and after fat separation, after pasteurization and fat separation, after storage at 3°C for 24 h, and after freezing at −20°C for 1 week. Aliquots of retentate were bleached analogously immediately and after storage at 3 or −20°C. Freshly spray dried WPC34 was rehydrated to 9% (w/v) solids and bleached. Bleaching efficacy was measured by extraction and quantification of norbixin. Proximate analyses and color analyses (Hunter Lab) were also conducted. Each experiment was replicated 3 times. Starter culture (fermentation), fat separation or pasteurization, or spray drying did not impact bleaching efficacy ($P < 0.05$). Cold or frozen storage decreased bleaching efficacy of fluid whey compared with immediate bleaching ($P < 0.05$). These results confirm that processing steps, particularly hold times, can influence bleaching efficacy.

Key words: whey, retentate, bleaching

M143 Impact of bleaching on flavor of 34% whey protein concentrate and benzoic acid concentration in dried whey proteins. M. A. Listiyani*, R. E. Campbell, R. E. Miracle, L. O. Dean, and M. A. Drake, *North Carolina State University, Raleigh.*

Previous studies have shown that bleaching negatively impacts flavor of 80% whey protein concentrate (WPC80) but bleaching effects on lower protein products have not been established. Benzoyl peroxide (BP), a whey bleaching agent, degrades to benzoic acid (BA) and may elevate BA concentrations in dried whey products. There is no legal limit in the US for BP use in whey, but international concerns exist. The objectives of this study were to determine the impact of hydrogen peroxide (HP) or BP bleaching on the flavor of WPC34 and to evaluate residual BA in commercial and experimental WPC bleached with and without BP. Cheddar whey was manufactured in duplicate. Pasteurized fat-separated whey was subjected to hot bleaching with either HP at 500 mg/kg, BP at 50 or 100 mg/kg, or no bleach. Whey was ultrafiltered and spray dried into WPC34. Color (L*a*b*) measurements and norbixin extractions were conducted to compare bleaching efficacy. Descriptive sensory and instrumental volatile analyses were used to evaluate bleaching effects on flavor. Benzoic acid was extracted from experimental and commercial WPC34 and commercial WPC80 and quantified by high performance liquid chromatography. The b* value and norbixin concentration of BP bleached WPC34 were lower than HP bleached and control WPC34 ($P < 0.05$). HP bleached WPC34 displayed higher cardboard flavor and had higher volatile lipid oxidation products than BP bleached or control WPC34 ($P < 0.05$). BP bleached WPC34 had higher BA concentrations than unbleached and HP bleached WPC34 ($P < 0.05$) and BA concentrations were also higher in BP bleached WPC80 compared with unbleached and HP bleached WPC80, with smaller differences than those observed in WPC34. Benzoic acid extraction from permeate showed that WPC80 permeate contained more BA than WPC34 permeate ($P < 0.05$). These results suggest that BP is more effective in color removal of whey and results in fewer flavor side effects compared with HP and that BA is removed by ultrafiltration and diafiltration.

Key words: whey, bleaching, flavor

M144 The influence of bleaching agent, solids concentration and temperature on bleaching efficacy and volatile components of fluid whey. A. J. Fox* and M. A. Drake, *North Carolina State University, Raleigh.*

Whey protein is desirable as a neutral flavored, uncolored powder. Fluid whey is often bleached to remove residual annatto and previous research has demonstrated that this process causes off-flavors in dried whey proteins. The objective of this research was to determine the impact of temperature, solids, and bleaching agent on bleaching efficacy and volatile components in fluid whey. A standard Cheddar cheese make-procedure was used to manufacture liquid whey at 6.7% solids. The whey was concentrated to 12% solids (w/v) and 80% protein (w/w) by ultrafiltration and diafiltration. Liquid whey or concentrated whey (retentate) were bleached using benzoyl peroxide (BP) at 100 mg/kg (w/w) or hydrogen peroxide (HP) at 250 mg/kg (w/w) at 5°C for 16 h or at 50°C for 1 h. An unbleached control was subjected to a similar temperature profile. The experiment was replicated 3 times. Annatto destruction (bleaching efficacy) among treatments was compared by solvent extraction and quantitation of norbixin of each treatment compared with an unbleached control. Volatile compounds were extracted and separated using solid phase microextraction gas chromatography mass spectrometry (SPME GC-MS). Bleaching efficacy of BP was higher than HP ($P < 0.05$) for fluid whey at both 5°C and 50°C. HP bleaching was significantly increased in retentate compared with liquid whey ($P < 0.05$). In retentate, there was no significant difference between bleaching with HP and BP at 50°C or 5°C ($P > 0.05$). Retentate bleached with HP at either temperature had significantly higher relative abundances of pentanal, hexanal, heptanal, and octanal than BP bleached retentate ($P < 0.05$). These results suggest that optimal bleaching of liquid whey is achieved using BP at 50°C and that optimal bleaching of retentate is achieved at 50°C with HP or BP. These results also suggest that bleaching with BP is less detrimental to flavor than bleaching with HP.

Key words: whey, bleaching, annatto

M145 Activation of lactoperoxidase for the bleaching of fluid whey. R. E. Campbell*[1], E. J. Kang[1], E. Bastian[2], and M. A. Drake[1], *[1]North Carolina State University, Raleigh, [2]Glanbia Nutritionals Inc., Twin Falls, ID.*

Lactoperoxidase (LP) is a heat stable peroxidase in raw milk that can generate oxidized substrates with antimicrobial activity. Activation of LP with low levels of hydrogen peroxide (HP) (5 – 10 ppm) is required

and this system has been used to preserve raw milk quality. Commercial bleaching of fluid whey with HP alone requires high concentrations (250 – 500 ppm HP) and recent studies have demonstrated that off flavors are generated during bleaching that carry-through to spray dried whey proteins. Bleaching of fluid whey with naturally present LP may be a viable alternative to traditional whey bleaching. The objective of this study was to monitor LP stability in fluid milk and whey, to determine the optimum level of HP for LP whey bleaching and to compare bleaching efficacy of fluid whey with LP to that of HP. Fluid Cheddar whey was manufactured in triplicate from pasteurized whole milk. LP activity was monitored in raw and pasteurized milk and in whey before and after pasteurization by UV-VIS spectrophotometry. The optimum concentration of HP (0 to 100 ppm) for LP activation was determined by monitoring loss of color in fluid whey via reflectance measurement. The optimum HP concentration for LP activity was 20 ppm. In subsequent experiments, fat separated whey was bleached at 35 or 50C with LP (with 20 ppm HP) or by the addition of 250 ppm HP. A control with no bleaching was also evaluated. Bleaching efficacy was determined by measuring norbixin destruction compared with the unbleached control and volatiles were measured by gas chromatography mass spectrometry (GCMS). LP was active in raw and pasteurized milk and whey, although concentrations decreased with pasteurization. Temperature did not affect bleaching efficacy ($P > 0.05$) while treatment (LP or HP) impacted bleaching efficacy ($P < 0.05$). Bleaching of fluid whey with LP (and 20 ppm HP) resulted in higher bleaching efficacy (color loss) than bleaching with HP alone at 250 ppm ($P < 0.05$). Fluid whey bleached with 250 ppm had higher concentrations of volatile lipid oxidation products compared with LP bleached or control whey. These results suggest that LP bleaching may be a viable and desirable alternative to HP bleaching for fluid whey.

Key words: bleaching, whey, lactoperoxidase

M146 Bleaching efficacy of ozone gas in liquid whey and its effects on flavor of 80% whey protein concentrate. T. J. Smith* and M. A. Drake, *North Carolina State University, Raleigh.*

Bleaching of whey is a necessary commercial practice but recent studies have demonstrated that hydrogen peroxide and benzoyl peroxide bleaching can cause off flavors. The objective of this study was to determine the viability of ozone as an alternative whey bleaching agent. Flavor effects and bleaching efficacy of ozone gas on whey and retentate were evaluated in benchtop experiments before pilot scale manufacture of 80% whey protein concentrate. Cheddar whey and retentate were produced in triplicate. Bleaching variables tested included bleaching temperature (35 and 60°C), ozone (200mg/h in 600mL whey) exposure time (15, 30, and 45 min), and whey solids (6.7 and 12%). Bleaching efficacy was evaluated by measurement of norbixin relative to an unbleached control. Based on benchtop results, hot bleaching of liquid whey with 1h ozone exposure was selected for WPC80 production. To ensure safety, ozone bleaching was performed at a lower level (1.6g/h in 94.5 L whey) and compared with a control (no bleaching) and hydrogen peroxide (HP) bleaching (250ppm). WPC80 was manufactured in triplicate. Bleaching of retentate with ozone was higher at 35°C compared with 60°C ($P < 0.05$); temperature did not affect liquid whey bleaching with ozone ($P > 0.05$). In benchtop studies, a 63% decrease in norbixin content was observed in fluid whey after 45 min ozone exposure. In pilot scale manufacture, WPC80 from HP bleached whey had a 27% norbixin destruction while that bleached with ozone had a 9% reduction. Ozone-treated WPC80 exhibited animal and flour/pasta flavors and HP bleached WPC80 was characterized by cabbage and fatty flavors. These flavors were not present in the control unbleached WPC80. Higher levels ($P < 0.05$) of nonanal and decanal were present in the ozone WPC80 while higher levels ($P < 0.05$) of pentanal, DMDS, hexanal, heptanal, 2-pentylfuran, and octanal were present in the HP WPC80 compared with the control WPC80. These results suggest that ozone bleaching does not represent a promising alternative to approved bleaching agents in whey protein production although it could possibly remain feasible at or close to saturation levels.

Key words: whey, bleaching, ozone

M147 The impact of sodium reduction on the flavor, texture and flavor chemistry of full fat and low fat Cheddar cheese. M. K. Kim*[1], R. E. Miracle[1], D. J. McMahon[2], and M. A. Drake[1], *[1]North Carolina State University, Raleigh, [2]Utah State University, Logan.*

Sodium and fat reduction are key issues for food processors. Salt plays a crucial role in the ripening of natural Cheddar cheese in both flavor and texture development. However, modest reductions in sodium may be acceptable and a quantitative study on the impact of various sodium reductions on flavor and texture development of Cheddar cheese has not been conducted. The objective of this study was to evaluate the role of salt reduction on the flavor and texture of full fat and low fat Cheddar cheese. Low fat and full fat Cheddar cheeses that contained 0.7%, 1.2%, 1.7%, 2.2% 2.7% or 3.25% (wet weight) salt were manufactured in triplicate at Utah State University. Cheeses were ripened at 8°C and samples were taken following 3, 6, or 9 mo for sensory and instrumental volatile analyses. A trained sensory panel (n = 10) documented flavor and texture attributes. Volatile compounds were extracted by solid phase microextraction and identified using gas chromatography mass spectrometry. Selected compounds were quantified using external standard curves. Consumer acceptance tests were conducted after 3 and 9 mo aging. Salty taste and to a lesser extent umami taste, increased with increasing sodium concentration ($P < 0.05$). Firmness of cheeses decreased with decreased sodium after 3 mo ripening and other attributes were impacted with further ripening. Aromatic flavor attributes of cheeses were not distinct at 3 mo ($P > 0.05$) but differences ($P < 0.05$) were documented as cheeses aged. Brothy and rosy flavors and bitter taste were associated with sodium reduction after 6 mo ripening in low fat cheeses and after 9 mo in full fat cheeses. Changes in flavor and texture attributes due to sodium reduction were larger for low fat cheeses compared with full fat cheeses. Cheeses with lower salt concentrations had higher relative abundances of volatile phenyl compounds compared with cheeses with 3.25% salt. Consumer acceptance of cheeses decreased when sodium was decreased by more than 50 percent. Sodium reduction alters flavor and texture properties of Cheddar cheeses and these changes are pronounced with ripening.

Key words: Cheddar cheese, sodium reduction, fat reduction

M148 Fortification of milk for Cheddar cheese manufacture using skim milk powder. A. C. Moynihan* and P. L. H. McSweeney, *University College Cork, Cork, Ireland.*

Using powders to fortify cheesemilk could have potential applications in ingredient cheese or to overcome problems caused by milk seasonality. The objective of this study was to make cheese from milk fortified with skim milk powder (SMP) and to determine its effect on cheese yield, composition, texture, meltability, proteolysis and microbiology. Skim milk (40 L) was fortified with 3.75 kg SMP to make a

milk stock with a higher casein content and the casein to fat ratio was standardized to 0.7 using cream. This mixture was added to cheese vats and made up to 50 L with pasteurized milk to give cheese milk with casein levels of 2.61% (CSMP), 2.86% (LSMP), 3.22% (MSMP) and 3.83% (HSMP) and Cheddar cheese was made therefrom. Significant differences ($P < 0.05$) were observed in moisture-adjusted cheese yields (9.76, 10.84, 12.06 and 14.99 kg/100kg milk for CSMP, LSMP, MSMP and HSMP, respectively). No significant difference ($P > 0.05$) was observed between the cheeses in terms of moisture in non-fat substances. pH values tended to be higher as SMP fortification level increased. Texture analysis showed that low level addition of SMP had no significant ($P > 0.05$) effect on the hardness values of the cheese throughout ripening compared with CSMP but higher levels of addition of powder resulted in increased hardness. The meltability of all cheeses increased with ripening time but HSMP and MSMP melted less than CSMP and LSMP cheeses. As cheese ripening progressed levels of proteolysis increased significantly ($P < 0.05$) in all cheeses but higher levels of SMP fortification resulted in slower proteolysis. Numbers of non-starter lactic acid bacteria (NSLAB) were higher in the fortified cheeses; as the level of powder addition increased so did the numbers of NSLAB. Fortifying Cheddar cheese with SMP had significant effects on yield, textural, melt, proteolytic and microbiological properties of the cheese without having major effects on its composition. Lower levels of fortification can give a cheese with similar properties to the control but with increased yield.

Key words: Cheddar cheese, skim milk powder, yield

M149 Rapid measurement of lactose concentration in cheese whey by using handheld blood glucose meter. A. C. Biswas*, J. K. Amamcharla, and L. E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

Whey is a valuable byproduct of cheese production, and is used to manufacture a variety of whey based products. In addition to whey protein, lactose is an important component of whey, and influences the quality and cost of whey-based products. A blood glucose meter method was previously developed for determination of the lactose content of raw milk and process cheese. The objective of the current research was to modify the previously developed blood glucose meter method, and apply it to the analysis of whey. Additionally, a new generation ReliOn Confirm glucose meter was utilized. In the method, 1 g of whey was diluted with 20 g of 0.1 *M* phosphate buffer (pH 7.4). Five ml of diluted whey and 0.1 mL of β-galactosidase enzyme were mixed, and incubated at 40°C to hydrolyze the lactose into glucose and galactose. After 10 min, the sample was analyzed with 4 different lots of test strips to evaluate the variation between the lots. An individual calibration curve was developed for each test strips lot using the model whey solutions that had a constant protein content of 0.8%, and different lactose concentrations ranging from 2 to 6%. These model whey solutions were standardized and prepared by mixing ultra-filtered whey retentate, whey permeate, lactose powder, and water in different ratios to obtained the final concentration (2%, 3%, 4%, 5%, and 6%) of lactose. A universal calibration curve was also developed by pooling the data from all 4 test strips lots. Simultaneously, the calibration standards were analyzed for lactose concentration using an HPLC-based reference method. The slopes and intercepts of individual calibration curves were between 0.945 to 1.009, and −54.96 to −38.73, respectively. The slope and intercept of universal calibration curve was 0.978 and −46.775, respectively. Future study will focus on validation of the universal calibration curve equation for analysis of whey with a range of lactose concentration typically observed during cheese manufacture.

Key words: cheese whey lactose, rapid method, glucose meter

M150 Organic acid identification and quantification in low-fat Cheddar cheese by capillary zone electrophoresis. R. Kumar* and T. C. Schoenfuss, *University of Minnesota, Department of Food Science and Nutrition, St. Paul.*

Low fat cheese can lack important sensory attributes due to the reduction in fat. The biochemical changes during ripening are related to the development of characteristic flavor. When fat replacement ingredients are used in a cheese, these ingredients could be metabolized by culture and non-starter organisms to create flavor compounds. The objective of this study was the identification and quantification of organic acids in low-fat Cheddar compared with full-fat control by capillary zone electrophoresis using a commercial anion analysis kit (Beckman Coulter, Inc., Brea, CA). Eight organic acids (acetic, butyric, citric, formic, lactic, propionic, pyruvic and oxalic) were measured in cheese samples produced with and without whey protein concentrate (Avonlac 180, Glanbia Nutritionals, Monroe, WI) and polysaccharide fat replacers (Novagel RCN 15, FMC Biopolymer, Philadelphia, PA) and Pectin (XSS 100, Danisco USA Inc., New Century, KS). Separations were performed on a P/ACE MDQ capillary electrophoresis with indirect UV detection at 230 nm. Samples were prepared by solubilizing cheese in water, centrifuging and filtering supernatant before analysis. The separations were carried out on a 50 cm, 75μm i.d. bare fused silica capillary. The sample was injected with pressure at 3448 Pa (0.5 p.s.i.) for 10 s at 30kV with reverse polarity and separation was performed at 25°C. An internal injection standard (sodium octanoate) was used for the quantification of the anions. All quantifiable organic acids were present in significantly greater concentrations in low-fat cheese than full fat control. Among low fat cheeses, formic acid was significantly higher in Novagel treatment cheese and acetic acid was higher in cheese with whey protein concentrate. It was demonstrated that the anion analysis kit can be used effectively in identification and quantification of organic acids in cheese.

Key words: low fat cheese, organic acids, capillary electrophoresis

M151 Stability of sterilized micellar casein concentrates (MCC) during storage. A. Sauer* and C. I. Moraru, *Cornell University, Ithaca, NY.*

The use of micellar casein concentrates (MCC) obtained by membrane separation is receiving increasing interest from the dairy industry. Currently, there is a lack of knowledge regarding the storage behavior of sterilized MCCs. This work aimed at evaluating the stability, particularly the occurrence of aggregation and sedimentation, in sterilized MCCs during storage at 25°C. MCCs with casein concentrations of 5–10% were subjected separately to continuous-flow UHT treatment and in-container retorting, and subsequently stored for 8 weeks at 25°C. As control, non-heat treated MCC with added preservative (Broad Spectrum Microtabs II) was used. Sedimentation was evaluated by measuring the protein content in the bottom layer of the storage containers. Samples were analyzed weekly for protein content, particle size and pH. The study was performed in triplicate. Particle size in control samples increased up to wk 5 of storage, while particle sizes in retorted samples remained constant throughout storage. Control samples were stable for up to 8 weeks (no significant sedimentation was observed), while retorted samples showed significant sedimenta-

tion, with up to 22% increase of protein content in the bottom layer of the storage container. For the retorted samples, sedimentation was the least pronounced in the 10% MCC samples, and most pronounced in the 5% MCC samples. Very strong sedimentation was observed in all UHT treated samples, with large variability between replicates. To estimate sedimentation over prolonged storage, sedimentation kinetics was established for all samples. The rate of sedimentation for 10% MCCs in replicates 1 and 2 was 0.02% protein/day, in replicate 3 it was 0.06%protein/day. Overall, it was concluded that UHT treated MCC preparations were unstable during storage, and may require additional stabilization to increase their storage stability, while the retorted preparations were relatively stable. The results of this study provide valuable information about the storage stability of sterilized MCC obtained by membrane filtration, which can be used for the manufacture of shelf stable, protein rich beverages.

Key words: micellar casein concentrate, sterilization, storage stability

M152 Use of capillary gel electrophoresis for quantification of individual milk proteins in ultra- and microfiltration retentate. P. Salunke*, C. Marella, and L. E. Metzger, *Midwest Dairy Foods Research Centre, South Dakota State University, Brookings.*

Quantification of milk protein into various fractions has technological and functional significance. For determination of the casein (CN) and whey protein (WP) content of milk and milk products a multistep precipitation technique that includes non-casein nitrogen (NCN), non-protein nitrogen (NPN) and total nitrogen (TN) analysis is typically utilized. This method results in a crude fractionation of milk protein and does not quantify the individual protein fractions. However, capillary gel electrophoresis (CE) is emerging as an effective method for qualitative and quantitative separation of individual milk proteins based on molecular weight (MW). The objective of the present work was to utilizing CE to separate various protein fractions in skim milk, milk protein concentrate (MPC) and micellar casein concentrate (MCC), and compare the results to the traditional NCN, NPN and TN analysis. Three samples each of skim milk, MPC and MCC (9 total samples) were collected and CE was performed in triplicate on each sample using a Beckman P/ACE MDQ capillary electrophoresis system (Beckman-Coulter, Fullerton, CA) equipped with a UV detector set at 214nm. Separation was obtained using a 50µm bare fused silica capillary of 30.2cm. SDS-MW analysis kit (Beckman-Coulter) was used for the separation. The area of each peak was calculated from the electropherogram. The TP, NCN and NPN protein of each sample was also determined. The ratio of peak areas for αS1-CN: αS2-CN: β-CN: κ-CN: γ-CN as determined by CE was similar in the skim milk, MPC and MCC samples. The ratio of WP/true protein was significantly ($P < 0.05$) lower in MCC as compared with skim milk and MPC. Additionally the CN/True protein ratio obtained using CE was similar to the CN/True protein ratio determined with Kjeldahl analysis. The results indicate that CE can be used to determine the CN/True protein ratio of skim milk, MPC, and MCC and can be used to determine the relative concentration of individual milk proteins.

Key words: capillary electrophoresis, milk protein concentrate, micellar casein concentrate

M153 Incorporation of whey:buttermilk heat-denatured protein aggregates in model set-type yogurt. M. Saffon*[1], V. Richard[1], S. F. Gauthier[1], M. Britten[2], and Y. Pouliot[1], *[1]STELA Dairy Research Center, Institute of Nutraceuticals and Functional Foods (INAF), Université Laval, Québec, QC, Canada, [2]Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada, St-Hyacinthe, QC, Canada.*

Previous work showed that it was possible to generate aggregated protein material by heating buttermilk in the presence of whey. It was hypothesized that addition of these protein aggregates would increase serum retention and improve firmness of yogurts. Whey and buttermilk protein mixtures (25:75) were adjusted to pH 4.6 and heated at 90°C for 25 min. Set-type model yogurts were prepared from milks standardized to 15% (w/v) total solids and 4.2% (w/v) protein using skim milk powder (SMP). Whey:buttemilk aggregates were introduced to substitute 40, 60, 80 or 100% of the proteins from SMP. Enriched milks were heated at 85°C for 20 min. After cooling at 42°C, milks were inoculated with a commercial yogurt starter (*S. thermophilus*, *L. bulgaricus*) and incubated until pH 4.6 was obtained. Syneresis was determined by centrifugation at 222 × *g* during 10 min at 4°C and texture properties were obtained by penetration using a TA-XT2 texture analyzer. All yogurt preparations were performed in triplicate and textural properties of yogurts were compared with those of control yogurt using *t*-tests. Addition of new aggregates significantly decreased ($P < 0.001$) forces of fracture, firmness, adhesiveness and relaxation. Syneresis was also increased. Substituting 60% of the proteins from SMP using aggregates had the least impact on the textural properties of yogurts. Particle size distribution analyses of milks before and after heating milks showed that unheated milks contained 2 populations of particles while heated milks contained only one population of particles. This suggests that whey:buttermilk aggregates may interact with milk protein during heating. Overall, our results show that whey:buttermilk aggregates can be used as protein ingredient in yogurt formulas, however, more work is needed to maximize heat-induced interactions between whey:buttermilk aggregates and milk proteins.

Key words: heat-denatured protein, yogurt, texture properties

M154 Linking environmental and sensory qualities of a Vermont artisan cheese. A. Greenbaum*[1], S. Carpino[2], M. Almena[1], S. Bosworth[1], P. Kindstedt[1], and A. Trubek[1], *[1]University of Vermont, Burlington, [2]CoRFiLaC, Ragusa, Italy.*

In collaboration with the Vermont Agency of Agriculture, Food and Markets, researchers at the University of Vermont have created the Taste of Place Initiative, involving research and outreach with cheesemakers to understand the quality of their product by identifying unique sensory characteristics. This particular research project investigates how the natural environment influences the final sensory characteristics of a particular alpine style farmstead cheese by identifying and characterizing key differences in sensory notes and chemical flavor compounds, and determining whether those differences are attributable to differences in the makeup of the pasture and practices of 2 Vermont artisan cheesemakers and their facilities. During this project SmartNose and gas chromatography-olfactometry analysis, sensory panels, observation, sample collection and cheesemaker interviews were conducted. First, pasture samples were collected from both farms on the same 2 d in early summer and 2 d in the fall. The pasture samples and aged cheese samples from 2 wheels of the cheese made the day of summer pasture collection and fall pasture collection were frozen and stored in a −32°C freezer until they were shipped to the CoRFiLaC lab in Ragusa, Sicily, and later analyzed using SmartNose, gas chromatography-olfactometry to identify similarities in volatile compounds between the pasture and corresponding cheese samples. A half-kilogram of each wheel of cheese sent for SmartNose and GC-O

analysis was also sampled during sensory analysis using Quantitative Descriptive Analysis. Preliminary results revealed overlaps across methodologies as similar descriptors found during QDA were defined during cheesemaker interviews and also correlated with environmental observation. The correlation between pasture and cheese samples has yet to be determined. By defining unique sensory characteristics of this artisan cheese, the results can impact struggling rural areas by keeping historically local products in production, thus creating rural employment and stabilizing rural population.

M155 Chewing activities of dairy heifers precision-fed a low or high forage ration at four levels of dry distillers grain. F. X. Suarez-Mena*, G. J. Lascano, and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

The objective of this study was to determine the effects of differing forage to concentrate ratios (F:C) and corn dry distillers grain with solubles (DDGS) inclusion rates on chewing behavior, rumen pH, and rumen fill in precision-fed dairy heifer rations. A split plot design with F:C as whole plot and DDGS inclusion level as sub-plot was administered in a 4-period (19 d) 4 × 4 Latin square. Eight rumen cannulated Holstein heifers (12.5 ± 0.5 mo and 344 ± 15 kg, age and BW respectively) housed in individual stalls were allocated to 2 F:C (50:50 LF or 75:25 HF; DM basis) and to a sequence of DDGS inclusion (0, 7, 14 and 21%; DM basis). Forage was a mix of 50% corn silage and 50% grass hay (DM basis). Diets were fed to provide equal amounts of nutrients to allow 800 g/d BW gain and fed 1X/d. Chewing behavior was visually monitored for 48 h at 5–min intervals. Rumen contents were sampled at –2, 0, 2, 4, 6, 8, 10, 12, and 20 h after feeding for pH determination. Total rumen evacuation was performed at –2 and 5 h after feeding. Statistical analysis was conducted using the MIXED procedure of SAS. DMI linearly decreased as DDGS increased (6.61to 6.11 ± 0.09 kg/d; $P < 0.01$). No differences were found for rumen pH. Time spent eating tended to be longer for HF (151 vs. 112 ± 14 min/d; $P = 0.09$) and was not different for DDGS inclusion. Ruminating time did not differ by F:C but linearly increased as DDGS increased (421 to 450 ± 15 min/d; $P = 0.03$). Total chewing time tended to be longer for HF (593 vs. 516 ± 28 min/d; $P = 0.10$) and to increase linearly as DDGS increased (553 to 579 ± 23 min/d; $P = 0.09$). Wet rumen digesta weight (46.6 vs. 37.6 ± 2.2 kg; $P = 0.03$) and volume (51.5 vs. 41.5 ± 2.5 L; $P = 0.03$) were greater for HF. Total chewing time increased by the addition of DDGS and higher F:C. DDGS influenced ruminating time with no effect on eating time while F:C affected eating time. Higher F:C increased rumen digesta weight and volume. F:C or DDGS levels in the ration did not affect rumen pH.

Key words: heifer, chewing, dry distillers grain with solubles

M156 Effect of one or two treatments of prostaglandin $F_{2\alpha}$ prior to Cosynch in lactating dairy cattle. K. D. Baldock*[1], M. E. Wilson[2], and D. L. Smith[1], [1]*Eastern New Mexico University, Portales,* [2]*West Virginia University, Morgantown.*

Many dairies in the United States use $PGF_{2\alpha}$ treatment, as part of a presynchronization (Presynch) program. The objective of this experiment was to study the effects of one versus 2 $PGF_{2\alpha}$ Presynch treatments, before a Cosynch program. Analysis included: the effects on first service conception rates (FSCR), number of days open (DO), services per conception (SC), and days to first service (DFS). Lactating, Holstein cows (n = 748) were randomly assigned to the treatment group (n = 376; first treatment with $PGF_{2\alpha}$ between d 30 and 36 postpartum, second treatment with $PGF_{2\alpha}$ between d 44 and 50 postpartum) or the control group (n = 372; received one treatment with $PGF_{2\alpha}$ between d 44 and 50 postpartum). For both groups a cow found in estrous was bred and tracked for pregnancy. Data were further analyzed as bred before Cosynch treatment (n = 489) and completing Cosynch treatment (n = 259). Overall, there were no differences ($P > 0.05$) between the treatment and control groups in FSCR (0.43 ± 0.03 for both groups), DO (91.40 ± 1.96 and 91.67 ± 2.06), SC (2.00 ± 0.06 and 2.08 ± 0.06) and DFS (60.49 ± 0.51 and 59.77 ± 0.55). Of the cows removed from the experiment (n = 210) 47.9% were culled for reproduction and mastitis and 52.1% remained open, with no effect of treatment ($P > 0.05$). There was no difference ($P > 0.05$) between treatment and control for cows bred before completing Cosynch treatment (i.e., bred at observed estrus) including FSCR (0.45 ± 0.04 and 0.45 ± 0.03), DO (84.84 ± 0.2.33 and 85.13 ± 2.37), SC (2.00 ± 0.07 and 2.07 ± 0.08) and DFS (54.84 ± 0.47 and 54.30 ± 0.56), respectively. Further, no difference ($P > 0.05$) was found between treatment and control, among those completing Cosynch, in FSCR (0.38 ± 0.04 and 0.40 ± 0.04), DO (103.38 ± 3.33 and 104.41 ± 3.73), SC (2.02 ± 0.09 and 2.08 ± 0.11) and DFS (70.82 ± 0.24 and 70.46 ± 0.30). Finally, parity and day of Presynch treatment had no effect ($P > 0.05$) on any of the treatment groups. These results indicate, within the reproductive parameters studied, one $PGF_{2\alpha}$ Presynch was as effective as the 2 $PGF_{2\alpha}$ Presynch treatment.

Key words: prostaglandin $F_{2\alpha}$, presynchronization, Cosynch

M157 The effects of extruding wheat dried distillers grains with solubles with peas or canola meal on ruminal fermentation, nutrient digestion and milk production in lactating Holstein dairy cows. R. M. Claassen*, D. A. Christensen, and T. Mutsvangwa, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

The objective of this study was to examine the effects of feeding extruded and non-extruded mixtures of wheat dried distillers grains with solubles with peas (WP) or canola meal (WC) on ruminal fermentation, total tract nutrient digestion, and milk production in dairy cows. Eight Holstein cows (BW 712 ± 54 kg, 90 ± 31 DIM) were used in a replicated 4 × 4 Latin square design (28-d periods) with a 2 × 2 factorial arrangement of dietary treatments. Four cows in one Latin square were fitted with rumen cannulas for the measurement of ruminal fermentation characteristics. Treatment diets contained either WP or WC combinations fed in an extruded or non-extruded form (16% of DM intake). Diets were isonitrogenous (17.1% CP) and contained 50% concentrate and 50% forage (DM basis). DM intake was not affected ($P > 0.05$) by dietary treatment. Total tract digestibilities of ADF and NDF were not affected by dietary treatment; however, total tract digestibilities of crude protein ($P = 0.014$) and ether extract ($P = 0.002$) were higher, and that of DM tended ($P = 0.070$) to be higher for cows fed extruded when compared with those fed non-extruded diets. Total tract digestibility of ether extract tended to be higher ($P = 0.083$) in cows fed WC compared with those fed WP diets. Ruminal pH was higher in cows fed non-extruded WC compared with those fed extruded WC, but there was no difference in ruminal pH in cows fed WP diets (interaction; $P = 0.047$). Milk yield ($P = 0.021$) and milk protein yield ($P = 0.036$) were higher for cows fed WP compared with those fed WC diets. Milk contents of fat, protein and milk urea nitrogen, and milk fat yield were not affected by dietary treatment; however, milk lactose content was higher ($P = 0.013$) for cows fed the extruded compared with those fed non-extruded diets. In summary, these results indicate that the dietary inclusion of WP can potentially increase milk yield when compared with WC. Extrusion had positive effects on total tract nutrient digestion.

Key words: dairy cow, extrusion, wheat dried distillers grains with solubles

M158 Ruminal degradation and intestinal protein digestion of steam-flaked soybeans. H. R. Bruns*[1], K. J. Herrick[1], K. F. Kalscheur[1], D. J. Schingoethe[1], R. Rosenboom[2], G. Doppenberg[2], and A. R. Hippen[1], *[1]South Dakota State University, Brookings, [2]Deluxe Feeds, Sheldon, IA.*

This research used in situ and in vitro techniques to evaluate the rumen degradability and intestinal digestibility of steam-flaked soybeans (Deluxe Feeds – EnRG Flakes; Sheldon, IA) as well as investigate the effect of particle size on protein and dry matter degradability of steam-flaked soybeans (SFSB). In the first experiment, 3 cannulated, lactating Holstein cows were used to determine rumen protein degradability of SFSB, solvent extracted soybean meal (SSBM), expeller soybean meal (ESBM) and raw, whole soybeans (WSB). The WSB and SFSB were ground through a 2-mm screen and all feeds were ruminally incubated in Dacron bags for 0, 2, 4, 8, 16, 24 or 48 h. Rumen undegradable protein (RUP) was least for WSB, similar for SFSB and SSBM and greatest for ESBM (20.7, 28.3, 30.1, and 52.5%; $P < 0.01$). Intestinally absorbable dietary protein (IADP) ranged widely with WSB being the least absorbable followed by SFSB, SSBM and ESBM (12.6, 23.6, 29.0 and 51.5%; $P < 0.01$). Total digestibility of dietary protein (TDP) was least for WSB followed by SFSB and was greatest for SSBM and ESBM (92.0, 95.4, 98.9 and 99.3%; $P < 0.01$). These results indicated that SFSB are similar to SSBM with regards to ruminal degradability, and have greater overall digestibility than WSB. Previous in situ determinations suggested that particle size may influence rumen degradability parameters of SFSB, thus, a second in situ study evaluated the effects of particle size of SFSB on rumen degradability. In this study, 4 particle sizes (2mm grind, 4mm grind, coarsely chopped, or whole) were compared as described above. Rapidly and potentially degradable protein (fractions A and B) disappearance was similar for all treatments while acid detergent-insoluble protein (fraction C) was greatest in 2mm and 4mm particle sizes and least in chopped and whole SFSB (10.5, 9.9, 6.2, and 6.0%; $P < 0.01$). RUP increased with particle size (30.3, 30.8, 40.8 and 42.2%; $P < 0.01$). Overall, this research demonstrates that decreasing the particle size of SFSB also decreases RUP. Additionally, maintaining whole SFSB results in RUP values greater than that of SSBM and more similar to that of ESBM.

Key words: steam-flaked soybeans, degradability, particle size

M159 A simulation assessment of long-term nitrogen runoff reduction from dairy pastures. R. White* and J. L. Capper, *Washington State University, Pullman.*

A 20-yr assessment was run simulating a pasture on a dairy to determine the effect of various harvesting techniques on Nitrogen (N) removal from the system. The aim was to identify a treatment that resulted in the greatest uptake of N by plant matter thereby diminishing N loss through runoff. Grass, shrubs and trees were modeled to function as they would in a riparian system, grass diffused water to allow absorption by soil, whereas shrubs and trees functioned to absorb nutrients. The pasture was located next to a dairy from which runoff inputs were given as N, Carbon and water sources. Other inputs to the system were historical data for monthly rainfall, temperature and soil attributes. The output was expressed as N runoff from the soil profile. The model was run over 20 yrs to view the long-term consequences of treatments. Mowing, grazing and planting were hypothesized to stimulate a grass density increase inhibiting water flow from the system while pruning and burning plants were thought to stimulate growth and increase nutrient uptake from the soil. These hypotheses were tested via 5 treatments: mowing grass to a stubble height of 0.1 m^2, pruning 1 m^2 from trees and 0.5 m^2 from shrubs, planting 90 kg of grass/acre, grazing of 450 kg of cattle/acre, and burning 70% of the biomass. A total of 4.335 kg N per acre was calculated to runoff during the 20-yr time period. Annual planting in October, burning before yr 5 and pruning after yr 3 were all found to significantly decrease N runoff. When grazing during the spring N runoff increased to 5.16 kg; however, during the winter, runoff did not significantly increase. Mowing did not change N runoff. The most effective reduction resulted from annual fires in the first 5 yrs, pruning annually in August starting in yr 7, grazing cattle annually starting in yr 6 and annual planting of grass in October. This combination of treatments resulted in a runoff reduction to 1.09 kg N, nearly a 75% decrease. This reduction shows that good riparian area management, including use by cattle, can reduce N runoff from dairy pastures.

Key words: nitrogen, runoff, dairy

M160 Characterization of management practices utilized by low somatic cell count Kentucky dairy herds. A. E. Sterrett* and J. M. Bewley, *University of Kentucky, Lexington.*

Recent market changes have renewed interest in lowering bulk tank SCC, particularly in the southeastern United States where the highest SCC in the country is observed. The objective of this research was to summarize management practices utilized by Kentucky dairy herds with low SCC. Herds with an annual mean SCC < 250,000 cells per mL were identified from DHIA and milk cooperative records. A 54 question survey was mailed to 71 producers with 48 producers (67.6%) responding. Herd size ranged from 25 to 750 cows with a mean (±SD) of 144.96 ± 297.39. Mean (±SD) DHIA SCC and producer-reported SCC were 190,333 ± 36,281 (n = 27) and 223,475 ± 71,257 (n = 40) cells per mL, respectively. The most common management practices incorporated by these producers were post-dipping (100%, n = 47), drying teats before attaching milkers (95.8%, n = 46), pre-dipping (91.7%, n = 44), dry treating all quarters of all cows (85.4%, n = 41), incorporating DHIA as a SCC management tool (83.3%, n = 40), using individual towels to dry teats (77.1%, n = 37), receiving bulk tank SCC (77.1%, n = 37), trimming hooves at least annually (75.0%, n = 36), performing a milking system evaluation annually (72.9%, n = 35), and vaccinating for mastitis pathogens (68.8%, n = 33). Of the mastitis vaccines used, J-Vac (Merial Ltd., Duluth, GA) was most common (40.6%, n = 13), followed by J-5 Bacterin (Pfizer Inc., New York, NY) (25.0%, n = 8), Endovac-Bovi (Immvac Inc., Columbia, MO) (15.6%, n = 5), and Lysigin (Boehringer Ingelheim, St. Joseph, MO) (15.6%, n = 5). When asked to identify the management practice that contributed the most to their low SCC level, the most frequently cited practices were (1) keeping cows and facilities clean (n = 31), (2) maintaining dry, clean bedding (n = 14), (3) adhering to a consistent milking routine (n = 10), (4) forestripping (n = 7), and (5) pre- and post-dipping (n = 6). Producers with different housing strategies were represented in this study including freestalls, tie-stalls, compost bedded packs, bedded packs, and no housing. Results of this survey may be used to promote best management practices among other producers attempting to lower SCC.

Key words: best management practices, low SCC, dairy survey

M161 Evaluation of an electronic cow-side glucose meter for diagnosing insulin resistance in Holstein dairy cows. J. A. M. Wittrock*[1], T. F. Duffield[1], S. Riuzzi[2], and S. J. LeBlanc[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]University of Padua, Padova, Italy.*

The purpose of this study was to evaluate the diagnostic performance of a hand-held electronic glucometer (Precision Xtra; Abbott) for cow-side use in dairy cattle. This device has been validated for measuring blood concentrations of β-hydroxybutyrate in dairy cows. This study was designed to assess the accuracy of whole blood glucose measurements from the glucose meter relative to a reference chemical analyzer in a diagnostic lab. Additionally, the suitability of the glucometer to classify cows as insulin resistant with a glucose tolerance test (GTT) was evaluated with the ratio of (glucose concentration at 80 min after dextrose infusion/concentration before infusion) > 1.05 being defined as insulin resistant. Blood analyzed in the lab were duplicate samples taken from the same cows at the same time, from either serum with the preservative sodium fluoride (gray top tube, the gold standard for glucose analysis) or without any additives (red top tube). Blood samples were collected from cows at time points between 3 wk before and after calving, with the GTT being conducted at 1 or 3 wk before, or 1 week after parturition. There was a strong correlation in 366 samples from 65 cows between the Precision Xtra and serum from samples preserved with NaF ($R^2 = 0.84$, $P < 0.0001$), and in 746 samples from 89 cows between the Precision Xtra and blood without additives ($R^2 = 0.88$, $P < 0.0001$). In 284 glucose-tolerance tests, the Precision Xtra had a sensitivity of 64% and specificity of 92% ($P < 0.0001$) for correctly diagnosing insulin resistance. Dichotomizing at various cut points to identify the optimal test threshold, a cut point of 0.91 for the insulin resistant ratio yielded sensitivity of 90% and specificity of 87% relative to serum preserved with NaF and analyzed in a diagnostic lab. With the identification of a more suitable cut point, and the strong correlation between glucose concentrations obtained from whole blood by the Precision Xtra and serum glucose concentrations, the hand-held glucometer appears suitable for rapid measurement of glucose including glucose tolerance and insulin resistance under field conditions in dairy cattle.

M162 Effect of treatment with human chorionic gonadotropin (hCG) on day 5 after timed artificial insemination (TAI) on fertility in lactating Holstein cows. R. W. Bender*, A. B. Nascimento, A. H. Souza, H. Ayres, R. R. Araujo, J. N. Guenther, and M. C. Wiltbank, *Department of Dairy Science, University of Wisconsin - Madison, Madison.*

Reproductive management programs that synchronize ovulation can result in a smaller than normal follicle potentially resulting in inadequate progesterone (P4) concentrations after AI. The present analysis combining 5 field studies tested the hypothesis that an injection of hCG on d 5 after TAI will raise circulating P4 in diestrus, and consequently improve pregnancies per AI (P/AI). Lactating Holstein cows (n = 2979) from 6 commercial dairy herds in WI had synchronized ovulation and TAI after Presynch-Ovsynch or Double Ovsynch for first AI and Resynch-32 for later AIs, stratified by parity, and breeding number; and then randomly assigned to 2 groups: control (no further treatment, n = 1519) or hCG (Chorulon; 2,000 IU [in 4 of the herds] or 3,300 IU [in 2 herds]; n = 1460). In a subset of cows, blood samples were collected on d 5 and 12 after TAI for analysis of serum P4. Pregnancy was diagnosed by ultrasound at 35 ± 3d after AI. Binomial data were analyzed with Proc Glimmix of SAS with farm and cow treated as random effects. The Mixed procedure of SAS was used to evaluate P4. Circulating P4 concentrations were similar ($P > 0.05$) on d 5, but greater ($P = 0.001$) in hCG (5.3 ng/mL) compared with control cows (4.3 ng/mL) on d 12. Overall Pregnancies/AI (P/AI) was greater ($P = 0.01$) in cows treated with hCG (41.9%; 612/1460) than control cows (37.0%; 562/1519). Interestingly, a 3-way interaction among treatment, parity, and times bred was observed. In primiparous cows, there was greater ($P = 0.013$) P/AI in first service cows treated with hCG (56.2%; 176/313) than controls (46.3%; 152/328). In second service primiparous cows there was greater ($P = 0.012$) P/AI in hCG (40.5%; 90/222) than control (29.2%; 63/216) cows. However, multiparous cows treated with hCG (n = 925) had similar P/AI as controls (n = 975) for both first ($P = 0.26$; 40.5% vs. 37.1%) and later services ($P = 0.13$; 29.6% vs. 34.6%). Thus, targeted use of hCG on Day 5 after TAI increases the circulating P4 on d 12 post AI and enhanced fertility in primiparous cows at both first and later services, but did not increase fertility in older cows.

Key words: hCG, cow, Ovsynch

M163 Evaluation of three-dimensional accelerometers to monitor motion changes relative to estrus behavior. W. A. Smith*, J. M. Bewley, and W. J. Silvia, *University of Kentucky, Lexington.*

Three-dimensional (3D) accelerometers may be used as an estrus detection aid by monitoring changes in cow leg or neck movement. Limited research has been conducted to characterize the changes in movement captured by accelerometers for monitoring estrus behavior. The objective of this study was to utilize a motion index (MI), provided by a commercially available accelerometer, to describe estrus behavior. IceTag (IceRobotics Ltd., Edinburgh, Scotland, UK) accelerometers were attached to 15 Holstein or crossbred cows (DIM 40 to 90) at the University of Kentucky Coldstream Dairy Research Farm. Three IceTags were attached to each cow with high grade Velcro (right rear leg, left front leg, and neck). Cows were synchronized using an OVSYNCH protocol preceded by G6G. The first injection of prostaglandin F2α (PGF) was administered 40 to 90 days postpartum. The OVSYNCH protocol was modified by omitting the last injection of GnRH, allowing for the synchronized expression of estrus. Transrectal ultrasonography was utilized to track follicular development. Beginning 72 h after PGF, behavior observations were recorded. Human observers recorded times when cows were mounting (MG, n=116) other cows and being mounted (MD, n=167), for an 8 h period or until estrus ended. The MI was used to describe the degree of motion (0= no motion), and is defined as total 3D acceleration. A rolling mean (± 2 min) MI was calculated for each estrus event (RME). The GLM procedure of SAS was used to compare RME to the motion index during periods where no estrus behavior (NE) was observed. Least Square Means (LSM ± SE) RME for MD events were significantly higher than LSM for NE (0.847 ± 0.043 ($P < 0.01$), 0.733 ± .038 ($P < 0.01$), 0.05 ± 0.004 ($P < 0.01$) for front leg, hind leg, and neck, respectively). The LSM (± SE) RME for MT events were significantly higher than LSM for NE (0.748 ± 0.043 ($P < 0.01$), 0.727 ± 0.048 ($P < 0.01$), 0.055 ± 0.005 ($P < 0.01$), respectively). Motion index is a useful indicator of estrus behavior.

Key words: estrus behavior, accelerometers, estrus detection

M164 Effects of hutches and fortified waste milk on growth and health in preweaned Holstein dairy calves. . K. L. Machado*[1], R. E. James[1], M. L. McGilliard[1], and T. J. Earleywine[2], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Land O Lakes Animal Milk Products, Shoreview, MN.*

Large California dairies often find it economical to feed pasteurized waste milk and house calves in elevated wooden crates. The objective of this field study in 2 herds was to evaluate the influence of diet and housing type on growth and morbidity in 84 Holstein heifer calves

in a 2 by 2 factorial experiment. Calves were housed in either plastic hutches or elevated wooden crates with slatted floors. Diets consisted of pasteurized waste milk or the same waste milk supplemented to provide approximately 454 g of additional milk replacer solids containing 25% protein and 10% fat (LOL Balancer) twice daily. Calves were randomly placed in 1 of 4 treatment groups 48 h after birth and were monitored until weaning (60 d of age). Body weights and hip heights were measured at time of enrollment and weaning. Milk samples of pasteurized waste milk were obtained to measure standard plate count 332,171 ± 733,487 cfu/ mL, percent of fat 3.51 ± 0.59, protein 3.13 ± 0.30, and total solids 11.64 ± 1.05. All calves were fed 3.12 L via bottle at 0730 and 1530 h. Calves were monitored daily for respiratory and digestive illness and treated according to protocols. Origin of dairy had no impact on weight gain or hip height. Housing ($P = 0.05$) and diet ($P = 0.01$) affected weight gain, but there was no interaction. Least squares weight gain means for crate and hutches were 0.52 ± 0.024 and 0.59 ± 0.024 kg/d, respectively. Least squares weight gain means for waste milk and balancer were 0.52 ± 0.024 and 0.60 ± 0.024 kg/d, respectively. Calves housed in crates fed balancer had similar gain to calves housed in hutches fed waste milk. Housing or diet did not affect hip height (0.196 ± 0.007). A nonparametric test of maximum fecal score showed no effect due to housing or diet. Calves fed pasteurized waste milk supplemented with balancer or calves housed in plastic hutches had more rapid daily weight gain than calves housed in crates or fed waste milk. The importance of this advantage warrants economic evaluation.

Key words: calves, diet, housing

M165 Effect of postpartum diseases on reproduction of grazing dairy cows. E. S. Ribeiro*, F. S. Lima, H. Ayres, L. F. Greco, R. S. Bisinotto, M. Favoreto, R. S. Marsola, A. P. A. Monteiro, W. W. Thatcher, and J. E. P. Santos, *University of Florida, Gainesville.*

Objectives were to determine the incidence of postpartum diseases and their impact on reproduction of grazing dairy cows subjected to timed AI at the beginning of the breeding season. A total of 957 cows were evaluated in the postpartum period and incidence of diseases recorded. At calving, dystocia, twin birth, stillbirth, and retained placenta were recorded and grouped as calving problem. On d 7 ± 3 and 14 ± 3 postpartum, cows were evaluated for metritis and blood was sampled and analyzed for concentrations of NEFA and BHBA. Cows were considered in severe negative energy balance if NEFA >0.70 mEq/L, and with subclinical ketosis if BHBA >10 mg/dL in at least one of the 2 samples. Clinical endometritis was evaluated on d 28 ± 3 postpartum by scoring the vaginal mucus, and uterine cytology was collected on d 49 ± 3 for detection of subclinical endometritis. Ovaries were scanned on d 35 ± 3 and 49 ± 3 postpartum. Other diseases were also recorded. Cows were then categorized as healthy, when no clinical or subclinical disease was diagnosed, or as having a single or multiple disease events. The body condition was scored on d 7 ± 3, 35 ± 3, 85 ± 3 and 115 ± 3. Cows received timed AI at d 85 ± 3. Pregnancy per AI (P/AI) was determined 30 and 65 d after AI. Data were analyzed using PROC Logistic of SAS with either individual or categories of diseases. Incidence of disease was high and it was associated with reductions in the proportion of cyclic cows and pregnancy per AI. Calving problems and uterine diseases reduced maintenance of pregnancy in grazing dairy cows.

Table 1. Incidence of health problems and their impact on reproduction at first AI

Category	Incidence	Cyclic	Pregnant d 30	Pregnancy loss
Health	41.8	91.6[a]	70.9[a]	10.4
1 case of disease	31.1	90.8[a]	61.4[b]	9.0
> 1 case of disease	27.1	82.2[b]	48.5[c]	15.0
Disease				
Calving problem	8.2	83.6	44.8*	26.9*
Metritis	5.7	73.9*	38.6*	31.2*
Clinical endometritis	14.7	90.2	54.1	20.6*
NEFA > 0.7mEq/L	20.0	82.5*	45.6*	6.6
Subclinical ketosis	35.4	88.1	56.8*	8.3

M166 Effects of using protective cover sheaths at the time of AI on fertility of lactating dairy cows. S. Bas*, G. M. Schuenemann, A. Hoet, E. Gordon, D. Sanders, and K. N. Galvao, *Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

The objective of this study was to evaluate the effectiveness of using a disposable sheath protector (SP) on top of the regular AI sheath to minimize contamination of the AI catheter (AIC) on pregnancies per AI (PAI) in lactating dairy cattle. Services (n = 2843) during spring (67%) and summer (33%) from lactating Holstein cows [primiparous (PRIM; n = 1158) and multiparous (MULT; n = 1062)] in 3 commercial herds were included in this study. Animals were presynchronized with 2 injections of PGF2α (PG) given 14 d apart (starting at 26 ± 3 DIM) followed by Ovsynch (GnRH-7d-PG-56 h-GnRH-16 h-Timed AI) or Cosynch (GnRH-7d-PG-72 h-GnRH+Timed AI) 12 d later. Cows presenting signs of standing estrus at any time during the protocol were AI while the remaining cows were subjected to Timed-AI. At the time of AI, services were randomly (every other cow) assigned to 1 of the 2 groups: 1) with (TRT; n = 1405) or 2) without (CON; n = 1438) the use of SP. In TRT, the AIC protected with a SP was introduced into the vagina and only the AIC was manipulated through the cervix into the uterine body for semen deposition. CON cows were AI without the use of SP. Sterile cotton swab samples were collected from the AIC (n = 102) immediately after AI (from TRT and CON) for bacteriology. Pregnancy diagnosis was determined by ultrasonography 40 ± 5 d after AI. Data were analyzed using GLIMMIX (PAI) and FREQ (culture) procedures of SAS. Swab samples revealed that the use of SP was effective in minimizing contamination of the AIC at the time of AI in TRT (51.9%) compared with CON cows (98%; $P < 0.05$). Overall, PAI was greater ($P = 0.01$) for cows in TRT (30.1 ± 1.7%) than in CON (25.4 ± 1.9%). Results from this study suggested that the use of SP reduced contamination of the AIC at the time of AI and improved PAI in lactating dairy cows. To achieve consistent reproductive outcomes over time, the cleanliness of the AI procedure and equipment should not be compromised for convenience.

Key words: dairy cattle fertility, AI, sheath protector

M167 Metabolism of ruminally dosed butyrate and lactose in lactating dairy cows. K. J. Herrick*[1], A. R. Hippen[1], K. F. Kalscheur[1], D. J. Schingoethe[1], S. C. Moreland[2], and J. E. van Eys[2], *[1]South Dakota State University, Brookings, [2]Nutriad Inc., Elgin, IL.*

The objective of this research was to investigate the effect of ruminal butyrate on metabolites of lactating dairy cows. Jugular catheters were inserted into 4 ruminally-fistulated Holstein cows (45.5 ± 2.1 kg milk/d; 152.5 ± 26.9 DIM) in a 4 × 4 Latin square with 3-d periods. At d-1 of each period, 2 h after feeding, cows were ruminally dosed with one of four treatments: 2 L of water (CON), 1 g/kg BW of lactose (LAC), 1 g/kg BW of butyrate (1G), or 2 g/kg BW of butyrate (2G). Sodium butyrate was the source of butyrate and NaCl was added to CON, LAC and 1G to provide equal amounts of sodium as the 2G treatment. All treatments were dissolved in 2 L of water. Serial blood samples were collected at −2, −1, −0.5, 0, 0.25, 0.5, 0.75, 1, 1.5, 2, 3, 4, 6, and 8 h relative to dosing. Samples of rumen fluid were collected at similar intervals. Area under the curve (AUC) was calculated using the pre-dosing values as a baseline to determine treatment response (see table). Butyrate had a significant ($P < 0.05$) effect on plasma glucose and β-OHB and altered rumen VFA. There were no significant ($P > 0.05$) changes in AUC for plasma insulin or NEFA, but there were numerical differences. Milk protein (2.60, 2.85, 2.82 and 3.13%), MUN (11.5, 9.5, 11.8 and 13.4 mg/dL), and fat yield (1.58, 2.29, 1.95 and 1.63 kg/d) for the CON, LAC, 1G and 2G treatments respectively were affected ($P < 0.05$) 24 h post dosing. Rumen pH (6.1, 5.9, 6.3 and 6.6) was increased ($P < 0.01$) by butyrate while AUC for rumen ammonia (−8.1, −22.3, −38.1 and −35.6 mg/dL•h) decreased ($P < 0.01$). Results demonstrate that butyrate dosed in the rumen increases plasma β-OHB and decreases blood glucose.

Table 1. Least squares means of AUC responses by dairy cows to butyrate or lactose

	Treatment[1]				
Metabolite	CON	LAC	1G	2G	SEM
Blood					
Glucose (mg/dL•h)	91.7[a]	−18.7[b]	−76.7[bc]	−131.4[c]	27.3

M168 Antioxidant activity of calf milk replacers. M. A. Soberon*, D. J. R. Cherney, and R. H. Liu, *Cornell University, Ithaca, NY.*

A milk replacer (MR) is designed to mimic the nutritional benefits of milk in an effort to nourish a newborn calf, reduce calf mortality, strengthen immunity and increase animal life span and productivity. Antioxidants (AO) can enhance immune defense by reducing oxidative damage, but milk replacers are traditionally not formulated for AO activity. The objective of this study was to compare total AO activities of bovine milk with 6 calf MR (Table 1), varying in amount and source of fat and protein. MR was donated by Milk Products, Inc. Milk was obtained from the Cornell Dairy Research Farm bulk tank, representing milk produced within 24 h by 455 cows. MR was mixed to 150 g/L with 40°C, purified water. All samples were extracted in triplicate. Following hexane lipid extraction, both milk and MR samples were extracted 5 times with ethyl acetate, and then evaporated and reconstituted with 70% methanol/water. Samples were assessed for total AO activity using the peroxyl radical scavenging capacity assay where each sample was diluted to 5 descending concentrations, plated in triplicate. Ascorbic and gallic acids were standards for each plate. Results for total AO activity are expressed as umol of vitamin C equivalent(VCE)/mL of milk or reconstituted MR. The only known distinguishing feature of MR A, which exhibited the highest total AO activity (86.0 umol VCE/mL; $P < 0.001$) is its soy protein whereas natural bovine milk (52.7 VCE/mL) is distinguished by its increased fat content. Fat ($P = 0.057$) as opposed to protein ($P = 0.140$) content

may have an effect on AO activity. Total fat content may explain the difference between the 2 MR with similar amounts of NeoTec4, a commercial essential fatty acid supplement, (44.2 umol VCE/mL versus 14.9 umol VCE/mL). Future research is warranted to compare MR with a broader range of fat content as well as the effect of additional compounds in milk that may impact AO activity.

Table 1. Characterization of milk and milk replacers

ID	Description	Protein Source	Animal Fat, %	Vegetable Fat, %	VCE, umol[1]	SE
A	21% CP, 20% fat	50% milk, 50% soy	100	0	86.0[a]	1.92

M169 In situ ruminal degradability of diets, dried distillers grains with solubles and soybean meal under different rumen conditions. S. D. Ranathunga*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings.*

The objective of this study was to investigate the in situ degradability of diets, distillers grains with solubles (DG) and soybean meal (SBM) under different ruminal conditions. Four Holstein cows with ruminal fistulae were assigned to a 4 × 4 Latin square in a 2 × 2 factorial arrangement of treatments. Diets contained low forage (LF; 41% of diet DM) or high forage (HF; 60% of diet DM) and DG at 0 or 18% of diet DM. Forage consisted of 80% corn silage and 20% alfalfa hay (DM basis). Ground corn and soybean feeds were partially replaced by DG from 0% DG diets to formulate 18% DG diets. Dacron bags containing DG, SBM, and dietary TMR were incubated in duplicate in the rumens of the cannulated cows at 0, 2, 4, 8, 12, 24, 48, and 72 h on d 15 each period. Each TMR was incubated only in cows assigned to the corresponding diet. Rumen passage rate (Kp) was greater for HF (6.2 vs. 6.6%/h) and 0 DG (6.5 vs. 6.3%/h) diets. Effective degradability (ED) of DM for TMR was lower for 18% DG diets (64.8 vs. 62.7%). Similarly, ED of DM for DG (55.8 vs. 55.0%) and SBM (72.0 vs. 70.1%) were lower in 18% DG diets. For TMR, ED of NDF was greater in HF (28.0 vs. 34.5%) and 18% DG diets (29.9 vs. 32.6%) whereas ED of NDF for DG was greater in HF diets (37.1 vs. 40.4%). ED of CP for TMR was lower in HF (54.7 vs. 53.3%) and 18% DG diets (54.9 vs. 53.0%). Similarly, ED of CP for DG was lower for HF (50.6 vs. 48.6%) and 18% DG diets (50.1 vs. 49.0%). For SBM, CP was degraded to a lower extent for the 18% DG diets (62.7 vs. 60.4%). Results suggest that forage and DG concentration in diets affect ruminal degradability of nutrients.

Table 1.

	ED, %					
	LF	LF	HF	HF		
Feed	0DG	18DG	0DG	18DG	SEM	P^1
TMR-DM	64.8	62.5	64.8	63.0	0.74	D

M170 Effect of air-flow controlled chambers and cows of contrasting feed efficiency on methane emission. C. Arndt*[1], M. A. Wattiaux[1], J. M. Powell[2], and M. J. Aguerre[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]USDA-ARS U.S. Dairy Forage Research Center, Madison, WI.*

The objective of this study was to determine the effect of chamber on methane (CH_4) emission, the number of days needed for adaption to chambers (using DMI as an indicator), and CH_4 emission between 2 high feed efficient (HE) and 2 low feed efficient (LE) cows (2nd parity, 101±11 DIM) as determined by MY/DMI. Emission of the 4 individual cows was measured in 4 chambers in a modified tie-stall barn. Cows were rotated among chambers every 4 d and measurements during each 4 d period included DMI, MY, and CH_4 emission (average duration of CH_4 measurements 18.5 h/d, using a Photo-acoustic Multi-gas Monitor; Innova Model 1412). All cows were fed the same TMR at 0800h and were milked twice daily. Data was analyzed as a 4x4 Latin square design with proc mixed procedure of SAS assuming cow efficiency as fixed treatment effect (1 df), cow within feed efficiency as random effect (2 df term used to test cow efficiency), days as repeated measures, and chamber and period as blocking factors. Chamber did not affect CH_4 emission ($P = 0.38$). An effect of period and period by day interaction ($P < 0.05$) was observed for DMI. Dry matter intake was greater in period 4 (28.8 kg/d) than in period 1 and 2 (averaged 26.3 kg/d), but not period 3 (27.4 kg/d). Although no consistent patterns were detected, DMI differed among days within all periods except period 4. These results suggest that cows were adapted to chambers by the beginning of period 4, although rotation among chambers may have extended required time for adaptation. Compared to LE cows, HE cows (1.90 vs. 1.52 (MY/DMI); $P = 0.01$) tended to have a greater MY (50.3 vs. 42.2 kg/d; $P = 0.06$), lower CH_4 emission (802 vs. 1000 g/d; $P = 0.08$), CH_4/DMI (30.3 vs. 36.0 g/kg; $P = 0.10$), CH_4/MY (16.0 vs. 23.7 g/kg; $P = 0.01$), and $CH_4/(NE_l+NE_m)$ (19.3 vs. 24.5 g/Mcal; $P = 0.02$). Although the effect of feed efficiency was tested against 2 degrees of freedom only, our preliminary results suggested that HE was associated with lower CH_4 emission. In addition, designs of future experiments do not require rotation of treatments among the chambers, which had no effect on CH_4 measurements in this study.

Key words: methane, feed efficiency, chambers

M171 Comparison of two resynchronization protocols initiated at different intervals after insemination on fertility in lactating dairy cows. R. G. S. Bruno*[1,2], J. G. N. Moraes[3], J. A. Hernández-Rivera[1,2], K. J. Lager[1,2], P. R. B. Silva[3], A. L. A. Scanavez[3], L. G. D. Mendonça[3], R. C. Chebel[3], and T. R. Bilby[1], *[1]Texas AgriLife Research and Extension Service, Texas A&M System, College Station, [2]Department of Agricultural Science, West Texas A&M University, Canyon, [3]Department of Veterinary Population, University of Minnesota, St. Paul.*

The objective of this study was to evaluate effects of 2 resynchronization timed AI (TAI) protocols beginning at different intervals after AI on fertility in dairy cows. Lactating cows from 2 dairies located in TX (n = 2233) and MN (n = 3077) were assigned to 1 of 4 TAI protocols 17 ± 3 d after AI. All cows were examined for pregnancy 31 ± 3 d after AI. Cows assigned to EOV or OV received the OvSynch56 starting 24 or 31 d after AI, respectively. Cows assigned to EGGPG or GGPG received a presynchronizing GnRH 17 or 24 d after AI, respectively, 7 d before the start of OvSynch56. Any cow observed in estrus was AI on the same day. Ovaries were examined and blood was sampled for progesterone concentration (P4) on day of first GnRH and PGF of Ovsynch56. Pregnancy was diagnosed at 31 and 66 d after resynchronized AI. Fewer EGGPG ($P < 0.01$) and more OV ($P < 0.01$) cows were re-inseminated in estrus (EGGPG = 23.7, GGPG = 49.0, EOV = 41.6 and OV = 57.6%). Treatment did not affect ($P > 0.66$) P/AI at 31 or 66 d for cows re-inseminated in estrus. Cows re-inseminated in estrus, however, had greater ($P < 0.01$) P/AI at 31 (40.0 vs. 27.5%) and 66 d (36.0 vs. 23.9%) than cows that received TAI. Among cows completing the TAI protocols, EOV reduced ($P < 0.03$) P/AI at 31 d (EOV = 22.2, EGGPG = 30.3, GGPG = 28.3, OV = 28.7%). Overall P/AI at 31 d after AI was reduced ($P < 0.01$) in EOV (29.3%) compared with other treatments (OV = 34.6, EGGPG = 33.3, and GGPG = 34.3%). However, treatment did not affect ($P = 0.11$) P/AI 66 d after re-insemination (EOV = 26.1, EGGPG = 29.4, GGPG = 30.4, OV = 30.4%). On day of first GnRH of Ovsynch56, more EGGPG and GGPG cows had CL (EGGPG = 83.8, GGPG = 88.8, EOV = 76.6, OV = 73.2%, $P < 0.01$) and P4 > 1ng/mL (EGGPG = 63.1, GGPG = 76.3, vs. EOV = 50.0, OV = 59.0%, $P < 0.01$). However, percentage of cows ovulating to first GnRH of Ovsynch56 was not affected ($P = 0.91$) by treatment. In conclusion, early start of resynchronization and presynchronization with GnRH reduced number of cows re-inseminated in estrus. Neither the timing nor the resynchronization protocol affected overall P/AI.

Key words: dairy cows, GGPG, resynchronization

M172 Antimicrobial usage on large herds in Wisconsin. L. Oliveira* and P. L. Ruegg, *University of Wisconsin, Madison.*

The objective of this study was to describe the antimicrobial usage on dairy herds in Wisconsin. A survey was conducted (March to August, 2010) in 50 dairy herds with >200 lactating animals. The questions included information about inventory and expansion, production, clinical and subclinical mastitis, dry-off therapy, pre-calving heifers, respiratory disease, uterine infections, foot problems, diarrhea, calves, and feeding. A total of 33,935 lactating cows were included, herd size ranged from 170 to 2,728 lactating cows, and daily milk production per cow was 33 kg. Occurrence of mastitis, respiratory diseases, and uterine infection were reported for all participants, but only 36% (n = 18) reported occurrence of diarrhea in adult cows. Dry cow therapy was used in all herds and 46% (n = 23) of the herds had used the same treatment over the last 5 years; preferred drugs were penicillin and streptomycin (n = 37 farms). Internal teat sealant was used in 84% (n = 42) of farms but only 16% (n = 8) use external sealant. Eight intramammary antimicrobials were used to treat mastitis and the most common were ceftiofur (n = 45 farms) and pirlimycin (n = 29 farms). Almost all farms use systemic antimicrobial to treat clinical mastitis, and the preferred drug was ampicillin (n = 20 farms). On 14% (n = 7) of the dairy herds, sulfadimethoxine was used to treat mastitis. On 40% (n = 20) of the herds, pre-calving heifers were treated with antimicrobials to treat or prevent mastitis. For respiratory disease in adult cows, farmers used from 1 to 5 drugs, and preferred drugs were ceftiofur and florfenicol. For uterine infection and foot problems, the preferred drugs were ceftiofur and ampicillin. For disease in calves such as respiratory disease and diarrhea, the preferred drug used was tulathromycin. On 22% of farms, calves were fed with medicated milk replacers; on 50% of farms, calves were fed with medicated calf starter. Results showed that antimicrobials were used extensively on dairy herds and ceftiofur was the most widely used. Further investigation will quantify antimicrobial drug usage on farms.

Key words: antimicrobial usage, dairy farm, disease

M173 Milk production, milk composition and first service pregnancy rate in lactating Holstein cows fed a lipid-encapsulated supplement containing *trans*-10, *cis*-12 and *cis*-9, *trans*-11 conjugated linoleic acids. C. L. Bailey*, R. G. Morell, B. L. Fisher, B. F. Jenny, G. T. Gentry, K. R. Bondioli, R. A. Godke, and C. F. Hutchison, *Louisiana State University Agricultural Center, Baton Rouge.*

Primiparous (n = 15) and multiparous (n = 24) Holstein females were randomly allotted to experimental diets after stratification by previous (cows) or expected (heifers) milk production, lactation number and expected date of parturition. Cows received a corn silage based TMR enriched with either a lipid-encapsulated supplement containing trans-10, cis-12 and cis-9, trans-11 conjugated linoleic acids (CLA) or a rumen-protected calcium salts of palm oil. Diets were formulated to be isoenergetic and isonitrogenous and to provide 100 g per hd/d supplement to respective treatment diets from parturition through 118 ± 14 DIM. Milk yield was assessed at each of 2 daily milkings by electronic meters and milk composition was analyzed weekly from consecutive AM and PM milk samples. Cows were estrous synchronized for fixed-time artificial insemination (FTAI; 98 ± 8 DIM) using a modified Double Ovsynch protocol. Pregnancy status was assessed at 34 ± 5 d of gestation by transrectal ultrasound or return estrus was recorded. Milk yield, milk composition and BW were analyzed using the GLM procedure and pregnancy status was analyzed using chi-squared (SAS). Body weight was similar between treatment groups ($P \geq 0.76$) at 12 ± 2 DIM (610 ± 16 kg) and 94 ± 2 DIM (620 ± 17 kg). Mean weekly milk yield was greater ($P = 0.002$) for cows fed CLA (38.5 ± 0.5 kg) compared with cows fed Ca salts (36.3 ± 0.5 kg). Percent milk fat ($P < 0.001$) and milk fat yield ($P = 0.002$) were reduced in cows fed CLA compared with cows fed Ca salts (3.25 vs. 3.92 ± 0.05%; 1.33 vs. 1.53 ± 0.04 kg, respectively). Percent protein ($P = 0.24$), protein yield ($P = 0.35$), energy corrected milk ($P = 0.98$) and 3.5% fat corrected milk ($P = 0.08$) were not influenced by dietary treatment. First service pregnancy rate was similar ($P = 0.30$) between cows supplemented CLA (n = 8/16, 50.0%) and Ca salts (n = 5/17, 29.4%), respectfully. The lipid-encapsulated CLA appears to be a viable supplement for lactating cows and deserves further investigation.

Key words: dairy cows, dietary fat supplementation, milk production

M174 A hoof biopsy procedure of front and rear claws for gene expression analysis and its relation to locomotion in dairy cows. J. S. Osorio*, E. F. Garrett, B. C. Fraser, D. E. Graugnard, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

Lameness represents a significant health problem and one of the main causes of death in dairy cows in the USA. Impacts of environmental and dietary factors such as floor system hoof trimming, and dietary carbohydrate overload have been assessed through behavioral indicators including time budgets and locomotion scores, as well as hoof appearance and incidence and severity of hoof diseases. Evaluation of post-mortem corium tissue has generated important information at the molecular level on these effects. The current experiment was conducted to evaluate a biopsy procedure to extract tissue specimens through the hoof wall between the epidermis and pedal bone of dairy cows via regional anesthesia. The aims of the experiment were to: 1) determine the feasibility of performing hoof biopsies without impairing locomotion or inducing pathological alterations of affected tissues; 2) evaluate the feasibility of using biopsied tissue for RT-PCR by analyzing quantity and purity of extracted RNA; and 3) compare relative expression by claw position of genes involved in cell differentiation, proliferation, inflammation, and keratin formation. Biopsies were performed on 6 Holstein cows yielding 2 tissue specimens per cow from front and hind limbs. Cows were monitored for lameness daily for 7 d after biopsy and then weekly for 8 wk. Total RNA yield from tissue was within acceptable ranges (4.64–23.84 ug). Preliminary analysis by claw position showed that the transcription regulator NFKB1 had greater expression ($P = 0.02$) in front than rear claws. Also, within medial and lateral hind claws there was a tendency ($P = 0.09$) for greater expression of NFKB1 in lateral claws. Other genes of interest included SOD2, KLF10, NR3C1, SAA3, STAT3, MYD88, and TLR4. Lameness assessment after biopsies did not reveal difficulty in the cow's locomotion. Overall, results suggest that this hoof biopsy procedure was suitable to obtain and analyze laminar corium tissue at the molecular level. Further research using this procedure on peripartal cows is warranted, for example to assess the effects of prepartal plane of nutrition on hoof transcriptomics.

Key words: laminitis, gene expression, biopsy

M175 Variation in failure of passive transfer and growth rates of calves on 38 farms in British Columbia. G. B. Bond, M. A. G. von Keyserlingk, G. Zobel*, and D. M. Weary, *Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada.*

Two basic indicators of success in calf rearing programs are failure of passive transfer (FPT) of immunoglobulins from colostrum, and growth rates, but little data are available to producers to benchmark their performance against industry norms. The aim of this study was to describe variation among farms in FPT, calf weight gains during the milk-feeding period (<8 wk of age), and weight gains of older heifers (11 to 20 mo of age). Thirty-eight farms were randomly selected in the lower Fraser Valley region of British Columbia within the criteria that herds were registered Holsteins, using the DHI recording system, and with a minimum of 50 heifer calves born per yr. Blood was sampled from 10 calves (2 wk old or less) per farm, and FPT defined as age corrected serum protein < 5.5 g/dL. Heart girth tapes were used to estimate BW (using 14 ± 5 pre-weaned calves and 17 ± 6 older heifers per farm); gains were estimated using the within-farm slope from the line equation, BW = age. Serum protein averaged 5.9 ± 0.4 g/dL. FPT averaged 31 ± 25%; 7 of the 38 farms had 100% success, but on 10 farms more than 50% of the calves failed. ADG pre-weaning averaged 0.7 ± 0.2 kg/d, but was highly variable (among farm range 0.4 to 1.2 kg/d). ADG for older heifers averaged 0.8 ± 0.1 kg/d, and was less variable (among farm range 0.6 to 1.0 kg/d). These results provide benchmarking data for producers, and illustrate that low rates of FPT and gains averaging 1 kg/d are achievable for farms in this region.

Key words: calf welfare, benchmarking, on-farm assessment

M176 Comparisons of udder health and milk quality in North Carolina organic and conventional pasture-based dairy herds. K. Mullen*, L. Gentry, R. Lyman, S. Washburn, and K. Anderson, *North Carolina State University, Raleigh.*

This observational study compared milk quality and herd health management of 7 organic and 7 conventional dairies in North Carolina. Published comparisons between organic and conventional dairy systems with regard to milk quality are sparse for the southeastern region of the United States. Management practices vary between organic and conventional dairies because of differences in farming philosophy and in government regulations. Organic dairies are prohibited from using certain drugs and antibiotics that are commonly used on conventional dairies. The objective of this study was to elucidate the relationship between management type and milk quality. To assess milk quality, milk samples were aseptically collected from each quarter of each cow in the milking herd at the time of sampling and somatic cell scores were obtained for individual cows. A total of 4988 quarter milk samples (2608 conventional, 2380 organic) were collected from 1247 cows (652 conventional, 595 organic). Milk samples were cultured and bacterial growth was identified using protocols consistent with those of the National Mastitis Council. The proportion of cows with positive microbiological results did not differ ($P > 0.10$) between organic (56.1%) and conventional (52.9%) dairies. However, differences in species present in positive cultures were observed: conventional herds had significantly more (22.4% vs. 15.3%, $P < 0.01$) coagulase-negative staphylococci infections per cow whereas organic herds had more *Corynebacterium* sp. (12.9% vs. 4.1%, $P < 0.01$) and *Staphylococcus aureus* (12.6% vs. 8.1%, $P < 0.01$) infections per cow. Conventional herds did have a lower proportion of infected quarters (27.0% vs. 36.3%, $P < 0.001$). Somatic cell scores did not differ between organic (3.0 ± 0.1) and conventional (3.0 ± 0.1) herds. Despite differences in herd management, milk culture results and SCS measurements were remarkably similar between organic and conventional NC dairies compared for this study.

Key words: mastitis, comparison, organic

M177 Effect of conjugated linoleic acid supplementation on in vitro bovine embryo production and cryopreservation. V. A. Absalón Medina*[1], S. J. Bedford Guaus[1], R. O. Gilbert[1], L. C. Siqueira[2], G. Esposito[3], A. Schneider[4], S. H. Cheong[1], and W. R. Butler[1], *[1]Cornell University, Ithaca, NY, [2]Universidade Federal de Santa Maria, Santa Maria, RS, Brasil, [3]Università degli Studi di Napoli Federico II, Portici, Napoli, Italia, [4]Universidade Federal de Pelotas, Pelotas, RS, Brasil.*

Conjugated linoleic acid isomers (CLAs) and other polyunsaturated fatty acids can affect the membrane lipid profile and signaling in cells thereby altering their function. The objectives were systematic evaluation of in vitro supplementation of CLA isomers (c9,t11 and t10,c12) on bovine oocytes or parthenotes (experiment 1) and fertilized preimplantation embryos (experiment 2 and 3) and to assess the optimal dose(s), and/or developmental stages during culture. The effects of CLAs on

embryonic survival after vitrification (experiment 4) were also evaluated. A total of 6267 oocytes were used in this project. Higher doses (50, 100, 200 μM) of CLA during in vitro maturation (IVM), or during the entire in vitro embryo culture (IVC) were compared with lower doses (15, 25, 50 μM) for effects before and after activation on subsequent development of bovine parthenotes. Low doses of both isomers tested the effect of CLAs on performance of fertilized embryos during IVM/IVC. Experiment 3 examined lowest doses (15, 25 μM) of CLA at specific stages during culture (i.e., IVM vs. IVC only) and finally, resistance to cryopreservation viz. post thaw survival rates of vitrified embryos supplemented with CLA was assessed. Overall, parthenotes and preimplantation embryo blastocyst rates (~35%) were not different among low CLAs levels ($P > 0.05$). Although low CLA resulted in better blastocyst rates for fertilized embryos, higher CLAs concentration (≥100 μM) reduced blastocyst rates to 7–15%. Vitrifying embryos after supplementation with 100 μM c9,t11 for a short period of time resulted in high survival rates comparable to the vitrified control (38 and 35%, respectively), but importantly the development of thawed embryos was comparable to control embryos not undergoing cryopreservation (total cell count equaled 161 ± 43 vs. 174 ± 39 [$P > 0.05$], respectively). In conclusion, no beneficial effect of supplemental CLA was found on embryo performance, however, inclusion of 100 μM c9,t11 before vitrification improved post thaw survival and development of bovine embryos.

Key words: CLA, parthenogenetic activation, bovine in vitro fertilization

M178 Net requirements of calcium and phosphorus for gain of Nellore and Nellore x *Bos taurus* crossbreds. M. P. Gionbelli*[1], M. I. Marcondes[1,3], S. C. Valadares Filho[1,3], L. F. Prados[1], and M. L. Chizzotti[2], *[1]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [2]Universidade Federal de Lavras, Lavras, MG, Brazil, [3]Instituto Nacional de Ciência e Tecnologia - Ciência Animal, Brazil.*

This study aimed to understand and estimate net requirements of calcium (Ca) and phosphorus (P) for gain of Nellore and crossbred Nellore × *B. taurus* cattle. A database containing 283 animals from 11 comparative slaughter studies was used. There were 190 Nellore and 93 Nellore × *B. taurus*, being 99 intact males, 115 steers, and 69 heifers. Allometric and quadratic regression models were used to describe the relationship between Ca and P in the equivalent EBW (EQEBW, kg). It was also determined the point at which there was no more significant addition of these mineral in the EQEBW by the linear plateau method. This represents the point at which the net requirements of these minerals for gain are considered equal to zero. Allometric and quadratic equation allowed equal adjustments, although quadratic equation represents better the biological deposition of Ca and P. There was a linear reduction in the net requirement of Ca and P per unit of gain due to the increase of animal weight (Table 1). The plateaus of deposition of Ca and P were observed at 413 kg of EQEBW (470 and 497 kg of SBW for Nellore and Crossbred, respectively) for Ca and 412 kg of EQEBW (468 and 495 kg of SBW for Nellore and Crossbred, respectively) for P. Therefore, utilization of a common plateau for Ca and P at 412 kg of EQEBW is suggested. The effects of gender and genetic group were not tested, however the breed impact seems to be well controlled, given that the EQEBW adjusts the degree of maturity. We conclude that the net requirements for Ca and P in Nellore and Crossbred decrease with the increase of BW and reaches zero with 412 kg of EQEBW. Acknowledgment: Sponsored by INCT-Ciência Animal, Brazil.

Table 1. Allometric and quadratic equations and net requirements for Ca and P for Nellore and Crossbred cattle

Mineral	Model	Equation
Calcium	Allometric	Ca_{EBW} (kg) = 0.17 × $EQEBW^{0.60}$
		NRG_{Ca} (g) = EBG × (102 × $EQEBW^{-0.40}$)
	Quadratic	Ca_{EBW} (Kg) = 0.2 + 0.024 × EQEBW – 0.0000225 × $EQEBW^2$
		NRG_{Ca} (g) = EBG × (24 – 0.045 × EQEBW)
Phosphorus	Allometric	P_{EBW} (kg) = 0.042 × $EQEBW^{0.71}$
		NRG_P (g) = EBG × (29.8 × $EQEBW^{-0.29}$)
	Quadratic	P_{EBW} (Kg) = – 0.3 + 0.013 × EQEBW – 0.0000119 × $EQEBW^2$
		NRG_P (g) = EBG × (13 – 0.0238 × EQEBW)

M179 Effects of maternal body condition and breeding season forage type on beef heifer growth. J. D. Patterson*[1], M. L. Looper[2], B. C. Williamson[1], and C. F. Rosenkrans[1], *[1]University of Arkansas, Fayetteville, [2]USDA/ARS DBSFRC, Booneville, AR.*

Gestational malnutrition of the dam may affect postnatal growth of offspring. Our objective was to determine effects of forage type grazed during conception and body condition (BC) during pregnancy of cows on heifer growth. Brahman-influenced cows (n = 40; BCS = 5.9 ± 0.1) were assigned to graze either common bermudagrass (CB) or toxic tall fescue (E+) during a 60-d breeding season; BC was assessed at d 0, 30, and 60 of the breeding season. Cows were classified into 1 of 2 BCS change categories: gain/maintain (n = 22 cows; mean gain = 0.8 BCS units) or lose (n = 18 cows; mean loss = 1.1 BCS units) BC during the first 2 trimesters of pregnancy. Cows were managed to achieve marginal (BCS = 4.3 ± 0.8) or good (BCS = 6.3 ± 0.8) BC during the last trimester. Birth weight of heifers was recorded. During development, heifers were equally assigned to CB or E+ and weaning weight (WW), hip height (HH), hip width (HW), pelvic height (PH), pelvic width (PW), and pelvic area (PA) were measured at 9 to 10 mo of age. Influence of forage, BC, and BC change on heifer growth was determined by ANOVA. Cows grazing E+ had heifers weighing less ($P < 0.01$) at birth (32.7 ± 0.8 kg) compared with heifers from cows grazing CB (35.6 ± 0.6 kg). Change in BC of cows during the first 2 trimesters did not influence ($P > 0.10$) birth weight, WW, HW, PH, PW or PA; HH tended ($P = 0.12$) to be increased in heifers (117 ± 1 cm) from cows losing BC during the first 2 trimesters compared with heifers (115 ± 1 cm) from cows gaining BC. Heifers (244 ± 7 kg) from cows in good BC tended ($P < 0.10$) to have heavier WW than heifers (228 ± 7 kg) from cows in marginal BC during the last trimester. Actual BCS of cows during the last trimester was correlated ($P < 0.05$) with birth weight (r = 0.34), WW (r = 0.40), HW (r = 0.38), and tended ($P < 0.10$) to be correlated with heifer HH (r = 0.27). Consumption of toxic tall fescue during breeding may reduce birth weight of subsequent offspring. Further, BC loss in cows late in gestation can decrease WW of their calves. Improper nutrition during conception, gestation, or both may impact postnatal growth.

Key words: beef cow, body condition, postnatal growth

M180 Effects of colostrum intake and pre-weaning nutrient intake on post-weaning feed efficiency and voluntary feed intake. F. Soberon* and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

Non-nutritional factors in colostrum have long been recognized as valuable for the development of the newborn calf, however, the benefits of colostrum intake surpass those related to the immune system. We hypothesized that some of the non-nutritional factors in colostrum as well as the nutrient availability during the pre-weaning period have permanent effects on feeding behavior or efficiency of nutrient utilization. Calves were fed either 2 L (n = 19) or 4 L (n = 32) of pooled colostrum, within 1 h of birth. Calves receiving 4 L of colostrum were fed another 2 L of colostrum 12 h after the first feeding while the calves fed 2 L were fed 2 L of milk replacer (MR, 28% CP, 15% fat, Excelerate, MSC). Plasma IgG content was determined for all calves 24 to 48 h after the first colostrum feeding. After the second feeding, all calves were fed MR by an automated feeder (Förster-Technik). Half of the calves on each colostrum treatment were allowed to consume 4 L/ d of MR while the other half were allowed to consume up to 12 L/d and intake was recorded by the feeders. Calves had access to a calf starter. All calves were weaned at 52 d and offered the same ration and DMI was recorded daily for 1 mo post weaning. All calves had plasma IgG concentrations above 12 mg/mL. Treatment comparisons were made using the mixed procedures of SAS and significance was determined at $P < 0.05$. Calves fed 4 L MR had similar ADG pre-weaning regardless of colostrum (0.35 ± 0.04 kg/d, $P = 0.56$). However, calves offered 12 L/d MR demonstrated greater ADG when they had 4 L of colostrum at birth (0.78 kg/d vs. 0.55 kg/d, $P < 0.01$). Also, during the post-weaning period, calves fed 4 L colostrum had greater DMI than calves receiving 2 L of colostrum independent of previous MR intake (2.8 vs. 2.2 kg/d;

$P = 0.01$). Calves that received 4 L of colostrum also had greater feed efficiency regardless of MR treatment (0.38 vs. 0.32 kg gain:kg DM, $P = 0.02$). We concluded that some non-nutritional components of colostrum are altering metabolic programming responsible for regulating appetite and nutrient utilization in calves.

Key words: colostrum, feed efficiency, appetite

M181 Interactions of residual feed intake and other performance parameters of Japanese Black (Wagyu) bulls. M. McGee*[1], C. M. Welch[1], J. B. Hall[2], and W. Small[3], *[1]University of Idaho, Moscow, [2]University of Idaho Nancy M. Cummings Research, Education, and Extension Center, Carmen, [3]AgriBeef Snake River Farms, American Falls, ID.*

Wagyu cattle are unique due to a propensity for accumulation of extraordinary levels of intramuscular fat as animals mature. Unfortunately, the Wagyu breed exhibits slow growth and poor feed efficiency. Objectives of the present study were to characterize these performance parameters, to accumulate data describing performance of Wagyu cattle, and to improve growth and feed efficiency while simultaneously optimizing marbling. Ninety–2 yearling Wagyu and Wagyu cross bulls were evaluated for residual feed intake (RFI) and other performance variables during a 70-d RFI test. Individual daily feed intake (GrowSafe, Alberta, Canada) and BW gain (BW measured at the beginning and end of test and at 2-wk intervals) were recorded. During the test period, bulls were fed a corn–based TMR (1.90 Mcal/kg NEm, 1.25 Mcal/kg NEg, 15.05% CP) formulated to match the nutritional equivalent of the diet fed to finishing Wagyu cattle. The RFI was positively correlated with DMI (r = 0.56; $P < 0.0001$) and F:G ratio (r = 0.49; $P < 0.0001$) but was not correlated with ADG, metabolic BW, ultrasound REA, or ultrasound rib fat. There was a tendency toward a favorable correlation between RFI and IMF (r = −0.17; $P = 0.11$). To facilitate further analysis, bulls were classified into RFI groups as efficient (n = 32), marginal (n = 34), and inefficient (n = 26), based on deviations from the mean RFI value. The RFI groups exhibited differences in F:G ratio ($P = 0.003$), and DMI ($P < 0.0001$), but there were no differences for metabolic BW, ADG, or ultrasound estimates of IMF, REA, and rib fat. The inefficient group had greater DMI ($P < 0.0001$) and F:G ratio ($P = 0.0003$) than the efficient group. The marginal group also had greater DMI ($P < 0.0001$) than the efficient group. This phenotypic evaluation of Wagyu bulls provides an indication that RFI is related to other measures of intake and feed efficiency, however does not influence growth and carcass performance. It is expected that accumulation of these data as greater numbers of bulls are characterized will facilitate simultaneous improvements in feed efficiency, BW gain, and optimized marbling in Wagyu cattle.

Key words: Wagyu, residual feed intake, efficiency

M182 Feeding or passive transfer of Anti-IL-10 peptide antibodies suppresses growth and feed efficiency in chicks. J. M. Sand*, J. Abazi, T. Fullmer, and M. E. Cook, *University of Wisconsin-Madison, Madison.*

Previous work from our lab showed that feeding antibody to the pro-inflammatory protein secretory phospholipase A2 (sPLA2) increased chick growth and feed efficiency (Cook ME, 2004 J. Appl. Poult. Res. 13:106–119). Here we attempt to suppress chick growth rate and or feed efficiency using an antibody to chicken interleukin-10 (IL-10), a cytokine responsible for downregulation of inflammatory processes. Egg antibody directed against 4 hydrophilic, antigenic, and accessible peptides of IL-10 were produced in Single Comb White Leghorn laying hens and measured using ELISA. Egg yolks were collected and lyophilized; the yolk powder was then added to feed at 3.41 g/kg feed to determine chick response. Treatment differences were determined using a 2-sided *t*-test. Anti-IL-10 peptide 4 (EPTCLHFS) suppressed growth in a study of mixed-sex chicks 6% (20/treatment, $P = 0.03$) whereas anti-IL-10 peptide 3 (EKMDENGI) decreased feed efficiency 3% in a study of mixed-sex chicks (35/treatment, $P = 0.069$). Hens producing the anti-IL-10 antibodies were artificially inseminated and chicks were hatched to determine the effects of passive transfer of anti-IL-10 peptides on growth and response to a lipopolysaccharide (LPS) challenge. Day-old mixed-sex chicks from hens producing any anti-IL-10 peptide antibodies (25 chicks/group) were smaller than chicks from adjuvant-injected controls (23 chicks) (3.4 to 9%, $P < 0.05$). Weight gain was reduced approximately 7% in chicks from hens injected with peptides 3 and 4 ($P = 0.08$). Chicks with passive anti-peptide 2 (VLPRAMQT) and anti-peptide 4 had reduced weight following LPS injection compared with saline-injected controls ($P = 0.05$). In summary, the feeding or passive transfer of antibody to specific peptides on chicken IL-10 reduced the rate of gain and may serve as a host targeted model for mimicking immune regulation of growth.

Key words: interleukin-10, inflammation, growth

M183 Empty body composition of Nellore bulls classified for residual feed intake. E. F. M. Bonilha[1], F. L. Araújo[2], S. F. M. Bonilha*[1], and R. H. Branco[1], *[1]Instituto de Zootecnia, Sertãozinho, São Paulo, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Residual feed intake (RFI) is an efficiency measure calculated as the difference between DMI observed and estimated based on metabolic BW and ADG. High RFI animals (less efficient) consume more than expected to a certain ADG, while the low RFI ones (more efficient) consume less than expected. This study aimed to evaluate empty body composition (EBC) of Nellore bulls classified in divergent levels of RFI. The experiment was conducted at Instituto de Zootecnia, Sertãozinho/São Paulo/Brazil, with 33 Nellore bulls, which were previously evaluated for RFI. From 60 evaluated bulls, 15 were classified as low RFI (≤mean + 0.5 SD) and 18 as high RFI (≥mean + 0.5 SD). Animals were slaughtered when they reached the minimum of 4 mm of subcutaneous fat thickness, with an average of 399 kg for BW and 18 mo for age. The EBC was obtained after grinding, homogenizing, sampling, analyzing, and combining blood, hide, head, feet, viscera, and carcass. Empty body percentages of water, ether extract (EE), protein, and ash were determined. Data were analyzed by GLM of SAS and means were compared by Tukey test at 5% of probability. There was no significant difference ($P = 0.9526$) in empty BW, showing that low and high RFI animals had similar body sizes. No significant differences were detected for empty body percentages of water ($P = 0.1266$), EE ($P = 0.6663$), protein ($P = 0.2800$), and ash ($P = 0.4627$), showing that low RFI animals (more efficient), for the same body composition, had a lesser feed intake, which contributes to the system economic viability.

Table 1. Means of empty BW, percentages of water, EE, protein, and ash in Nellore bulls from divergent levels of RFI

	Low RFI	High RFI	CV (%)	*P*-value
n	15	18	—	—
EBW, kg	367	366	12.5	0.9526
Water, %	63.9	63.1	2.39	0.1266
EE, %	13.6	14.0	15.5	0.6663
Protein, %	17.7	18.3	8.66	0.2800
Ash, %	4.76	4.67	7.69	0.4627

Key words: feed efficiency, body fat, body water

M184 Body and carcass fat of Nellore bulls classified for residual feed intake. S. F. M. Bonilha*[1], R. H. Branco[1], K. Zorzi[2], M. E. Z. Mercadante[1], J. N. S. G. Cyrillo[1], and L. A. Figueiredo[1], *[1]Instituto de Zootecnia, Sertãozinho, São Paulo, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Efficiency of food utilization is directly related to production system profitability, because food is the major cost in intensive beef production. Residual feed intake (RFI), expressed as the difference between DM intakes observed and estimated by a regression equation as a function of metabolic BW and ADG, is a measure of feed efficiency and can be a tool to reduce beef production costs. The study objective was to evaluate differences in body and carcass fat of Nellore bulls from low (≤mean - 0.5 SD; n = 32) and high (≥mean + 0.5 SD; n = 27) RFI levels. The experiment was conducted at Instituto de Zootecnia - Sertãozinho/São Paulo/Brazil, with 59 Nellore bulls finished in individual pens until they reach 4 mm of subcutaneous fat thickness (FT), assessed by ultrasound in LM, and slaughtered with averages of 447 kg for BW and 20 mo for age. The KPH was collected and weighed and FT was measured at 11th rib of LM. A steak sample of LM, with 2.5 cm of thickness, was removed from 11th rib for LM ether extract (LMEE) determination on a DM basis. Data were analyzed using GLM procedure of SAS, and means were compared using *t* test. The RFI variation was 0.740 kg of DM/d, with averages of −0.330 ± 0.034 and 0.410 ± 0.037 kg, respectively, for low and high RFI animals. No differences were detected between low and high RFI animals for slaughter BW (442 ± 11.1 and 454 ± 12.1 kg; $P = 0.4615$) and HCW (271 ± 7.30 and 279 ± 7.95 kg; $P = 0.4608$), respectively, showing that more and less efficient animals had similar body sizes. For KPH, FT, and LMEE, no significant differences were found between low and high RFI animals. The KPH averages were 8.88 ± 0.596 and 9.72 ± 0.649 kg ($P = 0.3447$); FT averages were 4.29 ± 0.281 and 4.37 ± 0.306 mm ($P = 0.8413$); and LMEE averages were 40.8 ± 1.24 and 39.7 ± 1.35% ($P = 0.5463$), respectively for low and high RFI animals, showing that more and less efficient animals had similar body and carcass fat content.

Key words: beef cattle, fat thickness, feed efficiency

M185 Describing DMI and growth patterns in beef steers during the finishing period. N. Vargas Jurado*[1], G. Scaglia[2], W. S. Swecker[1], D. A. Fiske[1], J. P. S. Neel[3], J. P. Fontenot[1], and R. M. Lewis[1], *[1]Virginia Tech, Blacksburg, VA, [2]Louisiana State University, Iberia Research Station, Jeanerette, [3]USDA-ARS, Beaver, WV.*

Feed intake is central to animal production systems, as it impacts efficiency and represents a substantial fraction of the total costs. The objectives of this study were to: (i) assess feed intake, weight gain, and feed efficiency in Angus crossbred steers during finishing on a total mixed diet; and, (ii) describe the pattern of their growth using the Brody function. The experiment was conducted at a research farm in western Virginia. Feed intake and BW data were collected on 18, 22, and 11 steers in 2005, 2006, and 2007, respectively. Animals were on average 420 d of age, and weighed 357 kg, when housed in a drylot with access to an individual feeding system (Calan Gate System, American Calan, NH). Across years, steers were fed a similar diet (9.7% CP and 15.6% NDF DM) ad libitum for 90 to 128 d. Daily feed intake (DFI), ADG, and feed conversion ratio (FCR) were evaluated. In addition, mature size (A), daily rate of growth (k), and initial BW at the start of the study (W_0), were estimated by fitting the Brody function $W_t = A - ((A - W_0)*\exp(kt))$, where W_t is weight at time t. Mean DFI were 15.4 ± 0.1, 16.6 ± 0.1, and 17.6 ± 0.1 kg/d, for 2005, 2006, and 2007, respectively, with significant differences among years ($P < 0.001$). Growth rate was constant (linear) over the finishing period ($P < 0.001$; $R^2 = 0.93$). The mean ADG in 2006 (1.25 ± 0.09 kg/d) was less ($P < 0.01$) than in 2005 (1.66 ± 0.07 kg/d) and 2007 (1.53 ± 0.13 kg/d). Mean FCR was better ($P < 0.01$) in 2005 (10.0 ± 0.4) than in 2006 (13.1 ± 0.7), with 2007 intermediate (12.1 ± 1.1). The estimates of A and k, the 2 key parameters of the Brody function, were similar across years: A was 742 ± 158, 734 ± 298, and 730 ± 269 kg while k was 0.0065 ± 0.0041, 0.0065 ± 0.0110, and 0.0072 ± 0.0092/d, for 2005, 2006, and 2007, respectively. The correlation between A and k was −0.99, indicating a strong relationship between their estimated values. Differences in intake, ADG, and FCR were observed among years although cattle genotype and husbandry were similar. Even with those differences, the Brody function appeared to provide a useful general description of growth in steers during the finishing period.

Key words: Brody function, cattle, feed intake

M186 Effects of heat stress on proliferation, protein turnover, and levels of heat shock protein mRNAs in cultured porcine muscle satellite cells. E. Kamanga-Sollo, M. Pampusch, M. White, M. Hathaway*, and W. Dayton, *University of Minnesota, St. Paul.*

It is well established that heat stress (HS) negatively impacts growth rate in swine. Although reduced feed intake undoubtedly plays a significant role in this reduction, studies in laboratory animals and other non-swine species indicate muscle growth also is affected by heat-stress-related alterations in muscle physiology. Heat shock proteins (Hsp) may play an important role in regulating rate and efficiency of muscle growth. The effects of HS on rates of satellite cell proliferation, protein synthesis, and protein degradation may play an important role in determining the rate and extent of muscle growth. We have examined the effects of mild HS (40.5°C for 48 h) on rates of proliferation (^{3}H-thymidine incorporation rate), protein synthesis (^{3}H-phenylalanine incorporation), and protein degradation (^{3}H-phenylalanine release from pre-labeled cultures) and on levels of Hsp90, Hsp70, and Hsp25/27 mRNA (qRT-PCR) and protein in cultured porcine muscle satellite cells (PSC). Data were analyzed using the mixed procedure of SAS. When significant interactions were detected ($P < 0.05$), least squares means were separated using LSD tests. Mild HS of PSC cultures resulted in 2.5-, 1.4-, and 6.5-fold increases ($P < 0.05$) in the levels of Hsp90, Hsp70, and Hsp25/27 mRNAs, respectively, relative to the levels in control cultures. Levels of Hsp 90, 70, and 25/27 proteins were also increased in HS PSC cultures compared with those in control cultures. Proliferation rates in HS PSC cultures were 35% lower ($P < 0.05$) than those in control cultures. Protein synthesis rates in HS fused PSC cultures were 85% higher ($P < 0.05$) than in control cultures and protein degradation rates in HS fused PSC were 23% lower ($P < 0.05$) than in control cultures. In light of the crucial role satellite cells play in postnatal muscle growth, the HS-induced changes

we have observed in rates of proliferation, protein turnover, and in levels of Hsp mRNA and protein in PSC cultures indicate that mild HS affects the physiology of PSC in ways that could affect muscle growth in swine.

Key words: porcine, satellite cell, heat stress

M187 Effects of increased protein and energy fed in milk replacer and heat stress on growth parameters of neonatal Holstein bull calves. A. J. Krenek*[1], G. A. Holub[1], T. A. Tomaszewski[1], and C. C. Stanley[2], *[1]Texas A&M University, College Station, [2]Land O Lakes Purina Feed, Amarillo, TX.*

The objective was to evaluate if calves fed 6 L of milk replacer with higher protein levels (HPMR; 1135 g/d, 28% CP, 20% fat) had improved performance compared with calves fed 4 L of a conventional milk replacer (CMR; 454 g/d, 20% CP, 20% fat) in heat stress and non-heat stress environments. Holstein bull calves (n = 52) < 3 d of age were assigned to a 2 X 2 factorial trial based on initial BW, physical health score, and total serum protein levels to either a heat stress (HS) or non-heat stress environment (NHS), with one half of each environment receiving HPMR and the other half receiving CMR. The study was conducted for 56 d from June 19 to August 13, 2010. The average thermal heat index (THI) was calculated for each day by averaging the 24 recorded temperatures and % relative humidity. The 56-d average, low, and high range THI for the HS were 79, 67, and 86 respectively, while THI for the NH were 69, 66, and 74 respectively. Weekly measurements of BW, body length (BL), hip width (HW), wither height (WH), heart girth (HG), and hip height (HH) were measured and ADG and average daily change were calculated. Water consumption (WC) and starter intake (SI) were measured daily. Data were analyzed using Proc Mixed of SAS 9.2. Calves on HPMR had a greater ($P < 0.01$) WH, HG, BL, HH, and ADG than the CMR calves (1.81 VS. 1.28 ± 0.004), (0.20 vs. 0.14 ± 0.009), (0.27 vs. 0.22 ± 0.01), (0.37 vs. 0.28 ± 0.008), and (0.82 vs. 0.58 ± 0.04) respectively. Calves in HS had a greater ($P < 0.01$) WC than the NHS calves (4365.56 vs. 2526.97 ± 102.2), respectively. The HPMR calves also had a greater WC ($P < 0.01$) than the CMR calves (4235.6 vs. 2656.96 ± 102.2), respectively. The CMR calves had a greater SI ($P < 0.05$) than HPMR calves (942.38 vs. 435.99 ± 0.39), respectively. There was no significant difference in growth parameters in HS or NHS in calves of like feeding strategies. The increased amount of protein and energy fed in the HPMR treatment did have an effect on WH, HG, HH, BL, WC, SI, and ADG.

Key words: calf, milk replacer, heat stress

M188 Indirect methods for estimation BW of crossbreed Holstein-Jersey heifers. B. C. Matos*, C. M. M. Bittar, W. R. S. Mattos, and L. F. Silveira, *University of São Paulo, University of Sao Paulo, USP/ESALQ, Piracicaba, SP, Brazil.*

This study's aim was to develop an estimation equation of BW on prepubertal Holstein-Jersey heifers from measures of growth parameters, and to compare them with the values obtained by mechanic scale and classical prediction equations described in the literature. Biweekly, 12 heifers of ~90 d of age were evaluated for BW, withers height (WH), hip width (HW), and heart girth (HG). The measures were taken until the animals attained 280 to 300 kg of BW. Regression analyses to estimate BW from measurements of growth parameters were developed using Proc Reg of SAS (1999). Regression analysis estimates and classical prediction equations were also used to estimate BW of heifers of different ages. Analysis of variance of estimated and mechanical scale data was performed using Proc GLM of SAS, with the average values compared by the Tukey test, and significance level of 5%. The measurement of HG presented the best coefficient of determination (R^2) with BW values. Linear regression resulted in lower R^2 values, especially for WH and HW. There were no statistical effects ($P > 0.05$) for the estimation measure. However, significance was found for age and interaction of age and estimation measure ($P < 0.001$). For the age range of 3 to 5.9 mo only WH linear regression overestimated the values of BW ($P < 0.05$). During the period of 6 to 7.9 mo the linear regressions of WH, HG, and HW overestimated the BW in relation of those found on a mechanical scale ($P < 0.05$). Estimating BW by classical prediction equations numerically underestimated the BW values as compared with the scale values. For the age range from 11 to 13 mo, WH and HW linear regression underestimated the BW of dairy heifers. Use of HG, WH, and HW measurements and classical prediction equations for BW estimation of crossbred dairy heifers was efficient, indicating that use of these measures, in lieu of a mechanical scale, may support improvements in on-farm management of nutrition and reproduction.

M189 Effects of rice or wheat straw as ingredients in a TMR on Holstein heifer growth. R. E. Rauch*[1,2], G. A. Nader[2], P. H. Robinson[2], and L. J. Erasmus[1], *[1]University of Pretoria, Pretoria, South Africa, [2]University of California, Davis.*

Rice straw (RS) is not common in dairy heifer rations, partly due to its low NE value and tough physical properties. To compare 2 RS harvesting methods (sickle chop or slicer baled), 5 dairies received ~12 t of each and a survey was conducted to compare dairyman experiences. The best RS (slicer baled) was used in a Latin square study with 2 treatments (i.e., RS- and wheat straw (WS)-based diets, both at 18% DM), 2 periods of 28 d and 4 pens of ~180 Holstein heifers each (age 14 to 18 mo) to compare effects on DMI, digestibility, BCS, and growth. The general linear model (GLM) procedure of SAS was used for statistical analyses. The RS heifers had a lower DMI (9.5 vs. 11.1 kg/d, $P < 0.01$) but greater ($P < 0.01$) digestibility of DM (57.8 vs. 52.4%), CP (57.6 vs. 54.5%), fat (82.2 vs. 78.4%), and ADF (40.4 vs. 36.9%, $P = 0.01$). The RS had lower intakes of digestible DM, aNDFom (amylase-treated ash-free NDF), and fat (5.5 vs. 6.0 kg/d, $P = 0.09$; 2.16 vs. 2.41 kg/d, $P = 0.04$; 0.26 vs. 0.28 kg/d, $P = 0.0497$, respectively). Change in BCS, tailhead height (TH), and hip width (HW) was lower for RS than WS (−0.0141 vs. +0.008 units/30 d, $P < 0.01$; 0.44 vs. 1.28 cm/30 d, $P < 0.01$ and 0.68 vs.1.63 cm/30 d, $P = 0.01$, respectively). A heifer frame score (HFS) was developed to create a 2-dimensional measure of skeletal growth while removing effects of BCS change on HW, as: HFS = corrected HW x TH, where: corrected HW (mm) = HW - BCS correction (BCS*c*), and BCS*c* (mm) = (3.2 x BCS) + (0.8 x age in mo) - 6.09. The BCS*c* was determined using a calliper to measure pin bone skin and fat thickness. The RS heifers had lower HFS change (3.82 vs. 8.46 cm^2/30 d, $P < 0.01$) and calculated NE output (i.e., NE_M, growth based on HFS, BCS loss/gain, and fetal growth), and diet NE concentration than WS (10.5 vs. 13.5 Mcal/d, $P < 0.01$; 1.10 vs. 1.21 Mcal/kg DM, $P = 0.049$, respectively). Lower feed efficiency with RS may be due to increased rumen retention time and fermentation energy loss (e.g., methane), a difference in DCAD for WS and RS diets (264.9 vs. 319.9 mEq (Na^+K-Cl^-S)/kg), or compensatory growth of WS heifers, as they had been fed a RS diet before the study.

M190 Effects of pre-weaning nutrient intake in the developing mammary parenchymal tissue and fat pad. F. Soberon* and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

The mammary gland is considered to grow at an isometric rate during the first 2 mo of life followed by an allometric rate until peri-puberty. Multiple reports describe an association between growth rate before puberty and altered mammary gland development, primarily due to an increase in the size of the fat pad while parenchymal growth is restricted. Twelve dairy heifer calves were fed either a constant amount of a 28% CP 15% fat milk replacer (MR) per day equivalent to 0.18 Mcal intake energy/kg $BW^{0.75}$ (Control, n = 6) or 0.3 Mcal intake energy/kg $BW^{0.75}$ (Enhanced, n = 6). All calves had full access to water and calf starter. Calves were harvested at 54 ± 2 d. The Control group consumed 32.6 kg of MR and 6.7 kg of calf starter and the Enhanced group consumed 69.5 kg of MR and 1.9 kg of calf starter. Initial and final BW for the Control and Enhanced treatments were 39.2, 61.0, 39.7, and 83.2 kg, respectively. At harvest, weights of liver, kidneys, pancreas, whole skinned mammary gland, and mammary parenchyma were measured. Growth rate was calculated for each organ as the change in organ weight as a percentage of BW. Treatment comparisons were made using the mixed procedures of SAS and significance declared at $P < 0.05$. The mammary glands with Enhanced treatment were heavier at harvest ($P < 0.01$) and when calculated as %BW, resulted in 4x greater parenchymal growth. We conclude that in early life, the mammary gland is responsive to nutrient intake and this differs from post-weaning mammary growth responses. Based on differences in nutrient supply, allometric growth was initiated pre-weaning. Understanding which cells are responding to nutrient supply may aid in understanding the effect of early life nutrient intake on future milk production.

Table 1.

	Control	Enhanced	SE	*P*-value

M191 Effect of diet metabolizable protein:metabolizable energy ratio on growth parameters and mammary gland development of crossbred Holstein-Jersey heifers reared on an accelerated growth program. B. C. Matos*, C. M. M. Bittar, W. R. S. Mattos, G. B. Mourao, and L. F. Silveira, *University of Sao Paulo, USP/ESALQ, Piracicaba, SP, Brazil.*

The aim of this trial was to evaluate the effect of metabolizable protein:metabolizable energy (MP:ME) ratio in diets based on tropical grasses and concentrate composed of by-products formulated for high growth rate during the prepubertal phase on growth parameters and mammary gland development of Holstein-Jersey heifers. Twelve heifers (90 d of age) were housed in individual pens, with free access of water and shade. Heifers were allocated to control (MP:ME = 39 g/Mcal) and high MP:ME ratio (MP:ME = 44.5 g/Mcal), according to a completely randomized statistical design. Biweekly, heifers were weighed on a mechanical scale until BW had attained between 280 and 300 kg, the expected weight of puberty. Measures of withers height (WH), hip width (HW), and heart girth (HG) were also taken. Monthly, size and length of teats were measured, and blood samples were collected for progesterone analysis. Heifers were considered pubertal when levels of progesterone were > 1.0 ng/mL. The MP:ME ratios observed were higher than those first predicted by NRC (2001), with values of 44.39 and 52.98 g/Mcal, respectively for control and high MP:ME treatment. The average value of DMI was 5.3 ± 1.8 kg DM/d with no effect of diet ($P < 0.05$). Body weight, HW, HG, and WH increased during the experiment ($P < 0.05$) and were not influenced by treatment. Measures of mammary gland development increased ($P < 0.05$) during the experimental period however no statistical effect of diet was found. The age at puberty of treatments occurred at 10.6 and 11.4 mo, respectively for high MP:ME and control; no effect of diet was observed. Measurement of growth parameters and mammary gland development were not influenced by diet MP:ME ratio. Increasing values were a result of animal growth. Formulating diets for prepubertal dairy heifers based on MP:ME requirements is efficient because it minimizes the occurrence of protein deficiency, which might occur in growing heifers, especially in mammary and skeletal tissues.

Key words: growth parameter, puberty, heifer

M192 Milk diet affects glucose transporters in skeletal muscle of neonatal calves. U. Schönhusen, C. Rehfeldt, J. Steinhoff-Wagner, and H. M. Hammon*, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

Colostrum feeding improves glucose status in neonatal calves by stimulating intestinal glucose absorption. Elevated systemic glucose availability may also lead to an altered substrate flux between tissues. We have tested the hypothesis that gene and protein expression of facilitative glucose transporters GLUT1 and GLUT4 in skeletal muscle depends on milk diet. Calves were fed twice daily either colostrum (C; n = 7) or a milk-based formula with same nutrient density as colostrum, but no biologically active factors (F; n = 7). Amounts fed per meal were 4% of BW on d 1 and 5% of BW on d 2 to d 4. Nutrient and lactose contents of C and F were identical. On d 4, calves were slaughtered 2 h after feeding. Masseter (M), longissimus dorsi (LD) and semitendinosus (ST) muscles were removed for measurement of mRNA and protein expression of GLUT1 and GLUT4 by real-time PCR and SDS PAGE immunoblot, respectively. Muscles were classified as oxidative and glycolytic according to isocitrate dehydrogenase (ICDH) and lactate dehydrogenase (LDH) activities. Data were analyzed by the Mixed Model of SAS with diet, muscle, and diet × muscle interaction as fixed effects and individual calves as random effect. ICDH was highest ($P < 0.001$) and LDH was lowest ($P < 0.001$) in M; ICDH tended to be higher ($P < 0.1$) and LDH tended to be lower ($P < 0.1$) in ST than in LD. Protein expression of GLUT4 was highest ($P < 0.001$) in M and protein expression of GLUT1 was higher ($P < 0.05$) in LD than in M. For GLUT4, protein expression in M, LD, and ST tended to be higher ($P < 0.1$) in C than in F, whereas gene expression was lower ($P < 0.05$) in ST and tended to be lower ($P < 0.1$) in LD of C compared with F. Gene expression of GLUT1 in ST was higher ($P < 0.05$) in F

than in C. Elevated GLUT4 protein expression in C than in F is in line with previously shown higher postprandial plasma concentrations of insulin after colostrum feeding, probably resulting in a greater insulin-stimulated glucose uptake in oxidative as well as glycolytic muscles. The elevated mRNA expression of GLUT4 in glycolytic muscles of F vs. C may point at a compensatory transcriptional response to lower protein expression.

Key words: calf, muscle, glucose transporter

Lactation Biology 1

M193 Essential amino acids significantly contribute to the energy status in short-term MAC-T cell cultures. V. S. Lyman[1], M. L. Bell[1], W. A. D. Nayananjalie*[1], E. M. England[1], J. A. D. R. N. Appuhamy[2], and M. D. Hanigan[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]University of Guelph, Guelph, ON, Canada.*

Acetate is a major energy source for ruminant mammary glands. Supplementation of AA increases milk protein synthesis, but the mammary glands have been found to take up some essential AA (EAA) beyond requirements for protein synthesis. Catabolized AA contribute to the energy supply of mammary cells. The in vivo contribution to ATP production is small, but that may not be the case in vitro. The present study was designed to investigate the effects of acetate and EAA on ATP levels and phosphorylation of AMP-activated protein kinase (AMPK). Reduced AMPK phosphorylation is indicative of improved energy status. A bovine mammary epithelial cell line, MAC-T was incubated in glucose free Dulbecco's Modified Eagle's Medium Ham's Nutrient Mixture F-12 (DMEM/F12) with 0 or 3.5 m*M* EAA and 0 or 5 m*M* acetate in a 2 × 2 factorial arrangement with 3 replicates. All media contained 10 ng/mL insulin. Cells were harvested after 1 h of incubation in treatment media and cell lysates were subjected to analysis for ATP (μmol/mg of protein) and total protein (mg/ml) content. The experiment was repeated on a different day and the cell lysates were subjected to Western immunoblotting analysis of AMPK phosphorylation state (phosphorylation at Thr172: total AMPK). Supplementation of EAA increased ($P = 0.07$) ATP content in MAC-T cells by 27% (60.4 ± 4.1 vs.78.2 ± 4.6 μmol/mg of protein) whereas added acetate was noneffective ($P = 0.46$). Consistent with the ATP results, EAA supplementation reduced ($P = 0.04$) phosphorylation of AMPK by 33% (0.95 ± 0.10 vs. 0.64 ± 0.10) whereas added acetate was associated with a numerical ($P = 0.20$) decline of 21% (0.89 ± 0.10 vs. 0.70 ± 0.10). There were no significant interactions between acetate and EAA on the ATP content or the phosphorylation of AMPK. ATP concentrations were highly correlated (r = - 0.90) with AMPK phosphorylation. In MAC-T cells, AMPK phosphorylation was responsive to ATP concentrations as observed in other cell types. Essential AA were much more potent in eliciting an ATP and AMPK response suggesting that these cells have limited ability to metabolize acetate.

Key words: amino acids, energy status, mammary cells

M194 Mammary uptake of fatty acids varying in chain length and unsaturation supplied by intravenous triglyceride infusion. J. A. Stamey*, J. K. Suagee, C. Caldari-Torres, and B. A. Corl, *Virginia Tech, Blacksburg.*

Supplementing dairy cows with feeds rich in omega-3 fatty acids does not readily increase excretion in milk fat of dairy cows. Previous results demonstrated that very long chain omega-3 fatty acids are primarily transported in the phospholipid fraction of blood, making them largely unavailable to the mammary gland for enrichment of milk fat. Our objective was to compare fatty acids of increasing chain length and unsaturation delivered intravenously as triglyceride emulsions to uncover any regulation of fatty acid uptake by the mammary gland. Late lactation dairy cows were assigned to a completely randomized block design to prevent carryover effects. Cows were fed a total mixed ration formulated to meet nutrient requirements and allowed an acclimation period of 5 d. Treatments were intravenous triglyceride emulsions enriched with oleic, linoleic, linolenic, or docosahexaenoic acid and were delivered continuously at 16 mL/h for 72 h. Each treatment supplied 30 g/d of the target fatty acid. Treatments did not affect feed intake, milk yield, or milk composition. Each target fatty acid demonstrated increased proportion in plasma triglyceride. Increases of target fatty acids, especially linolenic and docosahexaenoic, were evident in plasma phospholipid and cholesterol ester fractions, suggesting re-esterification in the liver. Transfer efficiencies were 31.6, 46.4, and 13.0%, and d 3 total milk fatty acyl yields were 37.5, 19.4, and 3.9 g (±1.36 pooled SEM) for linoleic, linolenic, and docosahexaenoic acid. Variation in oleic acyl yield prevented calculation of oleic acid transfer efficiency. Mammary uptake of fatty acids was reduced with increased chain length and unsaturation. Both liver and mammary mechanisms might regulate transfer of long chain polyunsaturates.

Key words: fatty acid, lipid metabolism, transfer efficiency

M195 Conjugated linoleic acid-induced milk fat depression in lactating ewes is accompanied by reduced expression of genes involved in mammary lipid synthesis. M. Hussein*[1], K. H. Harvatine[2], W. M. P. B. Weerasinghe[3], L. A. Sinclair[3], and D. E. Bauman[1], *[1]Cornell University, Ithaca, NY, [2]Pennsylvania State University, University Park, [3]Harper Adams University College, Newport, Shropshire, UK.*

Conjugated linoleic acids (CLA) are produced during rumen biohydrogenation and exert a range of biological effects. The t10, c12 CLA isomer is a potent inhibitor of milk fat synthesis in lactating dairy cows and some aspects of its mechanism have been established. CLA-induced milk fat depression (MFD) has also been observed in small ruminants and our objective was to examine the molecular mechanism in lactating ewes. Multiparous lactating ewes (n = 16) were fed a basal ration (0.55:0.45 concentrates to forage; dry matter basis) and randomly allocated to 2 treatments. Treatments were zero CLA (Control) or 15 g/d of lipid-encapsulated CLA supplement containing c9, t11 and t10, c12 CLA isomers in equal proportions. Treatments were for 10 wk and CLA supplement provided 1.5 g/d of t10, c12. There were no effects on milk yield or milk composition for protein or lactose at wk 10 of the study ($P > 0.1$). In contrast, CLA treatment decreased both milk fat percent ($P < 0.01$) and milk fat yield (g/d) ($P = 0.07$) by almost 22%. The de novo synthesized fatty acids (FA) (<C16) decreased in proportion (15%) and daily yield (27%) due to CLA treatment ($P < 0.05$). In addition, the proportion of preformed FA (>C16) increased ($P < 0.05$) and there were numerical decreases in the yields of 16 carbon FA (15%) and >16 carbon FA (6%). Consistent with the FA pattern, mRNA abundance of FASN, ACACA and SCD1 decreased by 35 to 45% in the CLA-treated group ($P < 0.05$). Similarly, CLA treatment decreased mRNA abundance of GPAT ($P = 0.15$) and DGAT1 ($P = 0.09$), genes involved in fatty acid esterification, by almost 30%. The mRNA abundance for SREBP-1 and INSIG1, genes involved in regulation of transcription of lipogenic enzymes, was decreased by almost 60% with CLA treatment ($P < 0.05$). Furthermore, mRNA abundance of LPL decreased by almost 30% due to CLA treatment ($P = 0.06$). In conclusion, the mechanism for CLA-induced MFD involved the SREBP transcription factor family and a coordinated downregulation in transcript abundance for lipogenic enzymes involved in mammary lipid synthesis.

Key words: CLA, lactation, mammary

M196 Characterization of a novel bovine mammary epithelial cell line. P. Bernier-Dodier*[1,2], G. Tremblay[1], and P. Lacasse[2], *[1]Université de Sherbrooke, Sherbrooke, QC, Canada, [2]AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

Milk contains several cell types, including exfoliated mammary epithelial cells. Since the available bovine cell lines poorly differentiate at best (meagre milk proteins expressions and leaky tight junctions), we have isolated primary mammary epithelial cells from milk for in vitro experimentations. Although a high proportion of contaminant immune cells were initially present, they were rapidly loss since they have a relatively short survival time. Out of the 7 isolations accomplished, one cell population, isolated from the milk of a Holstein cow at approximately 200 DIM, was successfully maintained in culture for a prolonged period. Interestingly, those epithelial cells have survived and to proliferated for at least 50 passages without any sign of senescence, suggesting that they have spontaneously immortalized. Because only a small number of bovine mammary epithelial cell (BMEC) lines are currently available, we undertook the characterization of this novel cell line named HERA-2. Their epithelial origin was confirmed by an immunohistochemical detection of cytokeratins and by PCR detection of the cytokeratin-18 gene expression. The bovine origin of the cell line was confirmed by karyotype analysis of 12 cells and by sequencing the gene *cytochrome C oxidase I*. At all the tested passages, the HERA-2 cells formed tight inter-cellular junctions as evaluated by transepithelial electrical resistance measurement that generally reached more than 1500 ohm*cm^2. When the HERA-2 cells are cultured on matrigel in presence of lactogenic hormones (prolactin, dexamethasone and insulin), they form mammospheres and duct-like structures. Up to now, none of the culture conditions tested was able to induce significant expression of lactogenic differentiation markers (αs1-casein, β-casein and α-lactalbumin encoding genes). In conclusion, the HERA-2 is a novel BMEC line that could constitute a good alternative to the MAC-T cells since they were not immortalized with the SV-40 large T-antigen. Their use as a model could facilitates the study on the regulation bovine mammary cells functions.

Key words: mammary gland, tight junction

M197 Further study on the role of SREBP-1 in lipogenesis in bovine mammary epithelial cells. L. Ma* and B. A. Corl, *Virginia Tech, Blacksburg.*

Sterol regulatory element binding proteins (SREBPs) are transcription factors that regulate lipid metabolism. Among the 3 isoforms, SREBP-1a, −1c and −2, SREBP-1a and −1c regulate fatty acid synthesis. The objective of this study was to further determine the role of SREBP-1 in regulating lipogenesis in bovine mammary epithelial cells (MAC-T cells). Cells were seeded to plates at a density of 2×10^4 cells/cm^2 and incubated in basal medium (DMEM+10% FBS) overnight. Then cells were transfected with small interfering RNAs (siRNA) against SREBP-1 (SSI), a random sequence as negative control (NEG), and no siRNA as untreated control (UNT), according to protocol (Dharmacon Inc.). After 48 h, cells were harvested for real-time quantitative PCR, immunoblotting, and radiolabeled-oleate incorporation assays. Our previous study showed that SREBP-1 mRNA and SREBP-1 proteins were reduced by SREBP-1 siRNA significantly ($P < 0.0001$). Acetate incorporation and mRNA expression of de novo lipogenic enzymes (acetyl-CoA carboxylase (ACC) and fatty acid synthase (FAS)) also decreased with SSI ($P < 0.001$). In the current study, we observed a significant reduction in mRNA expression of acyl-CoA synthetase short-chain family member 2 (ACSS2), isocitrate dehydrogenase 1 (IDH1), and fatty acid binding protein 3 (FABP3) ($P < 0.0001$). The protein expression of stearoyl-CoA desaturase 1 (SCD1) and ACC was decreased as well. Although we did not observe any reduction in triglyceride synthetic enzymes in previous study, phosphatidic acid phosphatase-1(Lipin1) mRNA level dropped with SSI treatment. However, adipophilin (PLIN2) had a 3.5-fold increase. De novo fatty acid synthesis starts with acetate which is converted to acetyl-CoA by ACSS2. Acetyl-CoA is used to synthesize malonyl-CoA by ACC, and FAS is responsible for fatty acid chain elongation. IDH1 generates NADPH as a reducing equivalent for de novo lipogenesis. In conclusion, SREBP-1 regulates lipogenesis in MAC-T mainly through de novo lipogenic enzymes. This project was supported by National Research Initiative Competitive Grant no. 2009–35204–05358 from the USDA National Institute of Food and Agriculture.

Key words: SREBP-1, small interfering RNA, bovine

M198 Capturing circadian mammary gene expression of cows using RNA from milk fat globule. J. Crodian*, T. Casey, and K. Plaut, *Purdue University, West Lafayette, IN.*

The overall objective of this study was to measure mammary gene expression over a circadian cycle in the lactating cow. Rather than isolating RNA from repeated mammary biopsies, total RNA was isolated from the cytoplasmic crescent of the milk fat globule. Three lactating Holstein cows were housed in tie stalls with water and feed provided ad libitum. Cows at 125 d into lactation with an average SCC of 105,000 were milked every 4hrs over a 48hr period. Milk samples were analyzed by DHIA for %fat, %protein, %lactose and MUN. Milk fat was separated by centrifugation and total RNA was isolated using QIAZOL. qPCR analysis was performed and expression of ACACA (acetyl-CoA carboxylase α), CSN2 (β-casein), PER2 and ARNTL were measured. Expression of core clock genes, PER2 and ARNTL showed diurnal variation (Table 1), with peak (16–20h; dark phase) and trough (32–36h; light phase) of expression significantly different ($P < 0.05$). Although ACACA and CSN2 showed diurnal variation, peak and trough of gene expression were not different. Diurnal patterns of MUN and %fat were also evident. Mean peak of %fat (4.18+/−0.11; 32–36h; light phase) and trough (3.52+/−0.17; 16–20h; dark phase) were different ($P < 0.01$), and opposite in phase of PER2 and ARNTL. These results suggest that mammary clock genes and milk components exhibit circadian rhythms.

Table 1. Fold change in gene expression relative to average expression across 48 hrs (log base 2*).

Time (h)	PER2*	SEM	ARNTL*	SEM
0	−0.48	0.56	−1.18	0.69

Key words: circadian, mammary, gene expression

M199 Expression of PEPCK isoforms in the mammary gland of dairy goats is regulated by insulin status. S. J. Mabjeesh*[1], A. Sahmay[2], N. Argov-Agrman[1], C. Sabastian[1], and B. J. Bequette[3], *[1]The Robert H. Smith Faculty of Agriculture, Food and environment, The Hebrew University of Jerusalem, Rehovot, Israel, [2]Institute of Animal Science, The Volcani Center, Bet Dagan, Israel, [3]University of Maryland.*

Phosphoenolpyruvate carboxykinase (PEPCK) isoforms (c, cytosolic; m, mitochondria) are expressed in the liver and mammary gland. PEPCK-c is a rate-controlling enzyme for gluconeogenesis and glyceroneogenesis whose activity is decreased by insulin, whereas PEPCK-m expression is constitutive and functions to channel lactate towards gluconeogenesis. We hypothesized that the increase in milk protein but decrease in milk lactose and fat when the hyperinsulinemic-euglycemic clamp (HIEC) is applied to dairy goats is due to a decrease in expression of mammary PEPCK-c mRNA. Late lactation goats (n=4;150 ± 30 DIM) were subjected to saline infusion and HIEC (104 µg insulin/h) for 4-d periods in a 2×2 cross-over design. Goats were milked two times per day and milk yields and components were determined. On day 4 of each period, a mammary biopsy (~1g) was taken from an udder half for expression of PEPCK-m and -c mRNA by rtPCR. Plasma insulin increased (P< 0.002) 3.5-fold due to the HIEC and euglycemia was maintained. The HIEC decreased (P < 0.005) DMI (40%) and milk yield (26%). Whereas milk fat content was not affected, HIEC increased (P < 0.001) milk protein content (2.82% vs. 3.09%) but decreased (P < 0.001) milk lactose content (4.22% vs. 4.03%). Expression of PEPCK-m mRNA was 8-fold higher (P < 0.031) than PEPCK-c. The HIEC decreased PEPCK-c mRNA 7-fold but increased PEPCK-m mRNA by 30%. These results demonstrate that insulin regulates mRNA expression of mammary PEPCK isoforms, and this may underlie the changes in milk component synthesis observed when the HIEC is applied.

Key words: insulin, casein, goat

Nonruminant Nutrition: DDGS

M200 Amino acids and energy utilization in zero tannin faba bean and co-fermented wheat and corn distillers dried grains with solubles (DDGS) fed to growing pigs. E. Kiarie*[1], R. K. Kahindi[1], P. Lopez[2], C. Furedi[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]The Puratone Corporation, Niverville, MB, Canada.*

Nutritional characterization of locally available feedstuffs may stimulate their inclusion in swine diets and contribute to whole farm nutrient management programs. We determined the nutritive value of Manitoba grown zero-tannin fava beans (ZTFB, < 1% tannin) and co-fermented wheat and corn DDGS (wcDDGS) from a local ethanol plant. Corn DDGS (cDDGS) was also included for comparison. In Exp. 1, 6 ileal-cannulated barrows (BW = 29.3 kg) were fed 3 diets in a replicated 3 × 3 Latin square design to determine the apparent (AID) and standardized (SID) ileal digestibility of AA. The 3 diets contained either ZTFB or wcDDGS or cDDGS as the sole source of AA. The SID was calculated using values of basal endogenous AA losses from our previous studies. In Exp. 2, 12 intact barrows (BW = 22.5 kg) were fed 4 diets in a 2 15-d period crossover design to determine DE and ME contents of the test ingredients by difference method. The diets were a basal corn-based diet or the basal diet with corn replaced by 46% ZTFB or wcDDGS or cDDGS. The concentrations (DM basis) of GE (kcal/kg), CP (%) and Lys (%) in ZTFB were 4,136, 27 and 1.6, respectively; corresponding values for wcDDGS were 5,175, 31.5 and 0.85. The ZTFB had higher ($P < 0.05$) SID of Lys (83.2%) compared with wcDDGS (72.1%) and cDDGS (67.8%); as a result the SID content (g/kg DM) of Lys in ZTFB (13.5) was greater ($P < 0.05$) than that of either wcDGGS (6.03) or cDDGS (6.68). The DDGS samples had higher ($P < 0.05$) SID and contents of sulfur AA (Met and Cys) compared with ZTFB. The ME content (kcal/kg DM) of ZTFB (3,548) was lower ($P < 0.05$) than that of cDDGS (3,851) whereas the ME content of wcDDGS (3,669) was similar ($P > 0.05$) to that of ZTFB or cDDGS. The results show that ZTFB has higher digestible Lys whereas wcDDGS has higher digestible sulfur AA but both ingredients have comparable ME content. Thus, a blend of these 2 ingredients can serve as excellent source of AA and energy for swine.

Key words: energy and nutrient utilization in swine, zero tannin faba beans, co-fermented wheat and corn DDGS

M201 Glucanase, xylanase and microbial inoculants improve feeding value of DDGS for liquid-fed finishing pigs. C. L. Zhu*, M. Rudar, D. Wey, and C. F. M. de Lange, *University of Guelph, Guelph, ON, Canada.*

Fiber degrading enzymes and microbial inoculants are likely more effective in improving the feeding value of DDGS in liquid feeding than in conventional dry feeding systems. A study was conducted to determine the impact of feeding corn DDGS steeped with exogenous enzymes (xylanase and glucanase) or microbial inoculants (*Pediococcus* in Exp. 1 and *Enterococcus* plus *Bacillus* in Exp. 2) on growth performance, nutrient digestibility, and carcass and meat quality in finishing pigs. A total of 384 Yorkshire pigs (192 in each Exp; initial BW 66 kg; 4 gilts and 4 barrows per pen; equal number of pens per treatment) were liquid-fed corn and soybean meal based diets containing 30% DDGS (DM basis) using a computerized liquid feeding system. The DDGS was mixed with water (17% DM basis) and steeped in one of 4 fermentation tanks, representing 4 treatments: (1) control, DDGS only, (2) DDGS+enzymes, (3) DDGS+inoculants, (4) DDGS+enzymes+inoculants. Samples of supernatants were taken after at least 48 h of steeping for analysis. Fecal samples were collected at 90 kg BW for determining apparent nutrient digestibility, using titanium as an indigestible marker. At the final BW (110 kg) carcass quality was evaluated according to the Canadian grading scheme. Responses to treatments were similar in Exp. 1 and 2 ($P > 0.05$). Steeping DDGS with enzymes, inoculants and enzymes plus inoculants increased ($P < 0.05$) lactic acid content in the supernatants (for all responses treatments 1 to 4, respectively: 1.69, 1.94, 1.98, and 2.37%; SE 0.10). Steeping DDGS with enzymes, inoculants or enzymes plus inoculants increased ($P < 0.05$) ADG (1.04, 1.15, 1.16, and 1.22, kg/d; SE 0.02) and ADFI (2.50, 2.73, 2.78, and 2.87, kg/d; SE 0.05). A numerical increase ($P = 0.07$) in digestibility of N was observed (82.0, 83.7, 84.0 and 84.2%; SE 0.60). Hot carcass weight, back fat depth, loin depth and estimated carcass lean yield did not differ among treatments ($P > 0.05$). Through steeping and using fiber degrading enzymes or microbial inoculants the feeding value of DDGS for liquid fed finishing pigs was improved.

Key words: pigs, liquid feeding, DDGS fermentation

M202 Determination of dry matter content in feces of pigs fed three different sources of DDGS. K. Kock* and C. Hostetler, *South Dakota State University, Brookings.*

An experiment was conducted to determine the differences in dry matter output between 3 different sources of DDGS. A total of 72 crossbred barrows were placed in metabolism crates at an average initial body weight of 55.2 kg. Dietary treatments were either a corn-based basal diet with no DDGS (Control; n = 9) or the basal diet with 30% DDGS from one of 3 commercially available sources (Diets A, B and C; n = 21 respectively). Pigs were fed their respective diets at 3% of BW for 9 d before a 4 d collection period. During the 4 d collection period, pigs were fed half their ration twice daily and all feces were collected once per day at the morning feeding. Feces were weighed, pooled within pig and frozen until analysis of dry matter content. Dry matter content was determined by drying approximately 1 kg of the pooled sample in a forced air oven at 70°C for 48 h. There was no difference between treatments in total dry matter intake over the entire 4 d collection period (5.89, 5.94, 5.98 and 6.00 kg for Control, A, B and C respectively; $P > 0.1$). There was a significant difference between treatments for total manure output (0.99 vs. 1.94, 1.73 and 1.95 kg for Control vs. A, B and C respectively; $P < 0.01$), resulting in approximately 1.5 to 2 times the amount of manure from pigs fed diets containing DDGS compared with the corn only diet. Additionally, there were differences due to treatment in manure %DM (53.6 vs. 44.6, 46.7 and 45.5 for Control vs. A, B and C respectively; $P = 0.04$) and total DM output (531 vs. 847, 798 and 872 kg for Control vs. A, B and C respectively; $P < 0.01$) which is an increase of approximately 50% in DM output compared with corn only diets. However, there was no difference between sources of DDGS in total manure output, manure %DM or total DM output. These data indicate that diets containing DDGS add a significant amount of volume to manure output; therefore, manure storage facilities may reach capacity more quickly when feeding a high level of DDGS in swine diets.

Key words: swine, DDGS, dry matter

M203 Effects of dietary enzyme fermented wheat on growth performance, nutrient digestibility, blood characteristics, and fecal noxious gas emission in growing pigs. X. Y. Guo*, H. Y. Baek, and I. H. Kim, *Dankook University, Cheonan, Choognam, South Korea.*

This research was conducted to evaluate the effect of dietary enzyme fermented wheat (FW) on growth performance, nutrient digestibility, blood characteristics, and fecal noxious gas in growing pigs. A total of 120 pigs with initial BW of 29.6 ± 1.9 kg [(Landrace × Yorkshire) × Duroc] were randomly allotted into 1 of 5 dietary treatments with 6 replicate pens per treatment and 4 pigs per pen. Every pen was equipped with semi-automatic feeder and nipple drinker. The pigs were housed in an environmental controlled, slatted-floor facility in 30 adjacent pens and were allowed ad libitum access to feed and water. The temperature and humidity of animal house were maintained at 24°C and 60%, respectively. This experiment lasted for 6 wk. Pigs were fed a common corn-soybean meal based diet for a 3 d adjustment period and then fed experiment diets. The experiment diets were formulated based on corn-soybean meal with FW at different levels of 0%(FW0), 5%(FW5), 10%(FW10), 15%(FW15) and 20%(FW20). All experiment diets contained a total of 20% of wheat. The FW were treated by protease (26,014 U/g), amylase (7,176 U/g) xylanase (799 U/g), cellulose (5,204 U/g) and a-galactosidase (176 U/g) for 72 h. Pigs fed FW15 diet had higher ADG than pigs fed FW0 diet ($P < 0.05$), however, no difference was observed in ADFI and G:F among all dietary treatments ($P > 0.05$). Apparent total tract digestibility (ATTD) of DM and N in FW10, FW15 and FW20 treatments were higher (84.63, 84.60, 84.47 vs. 82.40%, $P < 0.05$) than that in FW0 group. Concentrations of blood glucose, RBC, WBC and lymphocyte percentage were not affected ($P > 0.05$) by dietary FW. There was no difference ($P > 0.05$) in fecal noxious gas concentration (H_2S, Acetic acid and NH_3) among all treatments. In conclusion, ADG can be improved by FW15 and ATTD of DM and N can be enhanced by FW10, FW15 and FW20.

Key words: fermented wheat, growing pigs, growth performance

M204 The effect of enzyme fermented corn on growth performance, nutrient digestibility, blood profile, and fecal gas emission in growing pigs. P. Y. Zhao*, S. C. Kim, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effect of fermented corn (FC) on growth performance, nutrient digestibility, blood profile, and fecal gas concentration in growing pigs. A total of 96 pigs [(Landrace × Yorkshire) × Duroc] with an average initial BW 24.4 ± 1.1 kg were used in a 6 wk trial. All pigs were randomly allotted to 1 of 4 treatments (6 replicate pens per treatment with 4 pigs per pen). The experiment lasted for 6 wk. Treatments included: 1) CON (0% FC), 2) FC1 (10% FC), 3) FC2 (20% FC) and 4) FC3 (30% FC). All treatment diets contained 30% corn. The FC was pre-treated xylanase, cellulose and hemicellulase. Data were subjected to the GLM procedures and Duncan multiple range test was used to compare the means of the treatments. The FC were treated by protease (26,014 U/g), amylase (7,176 U/g)xylanase (799 U/g), cellulose (5,204 U/g) and a-galactosidase (176 U/g) for 72 h.There were no differences on growth performance among all dietary treatments during the overall period. Apparent total tract digestibility (ATTD) of DM and energy were higher in FC2 than CON, FC1, and FC3 throughout the experiment (83.37 vs. 81.36, 80.17, 81.72; 86.81 vs. 84.01, 82.59, 84.28%; $P < 0.05$). Blood glucose concentration in FC1 treatment was decreased compared with CON treatment (106.75 vs. 114.72 mg/dl; $P < 0.05$) and there were no differences on white blood cells (WBC), red blood cells (RBC) counts, and lymphocyte percentage among all the dietary treatments. Fecal H_2S measured on d 5 and 7 was reduced (6.7, 6.6 vs. 8.6; 6.9, 7.0 vs. 8.6 mg/kg; $P < 0.05$) in FC2 and FC3 treatments compared with CON. Acetic acid was lower (21.8, 23.5 vs. 25.8 mg/kg; $P < 0.05$) in FC2 and FC3 treatments than CON treatment on d 7. In conclusion, feeding enzyme fermented corn in growing pig diet improves nutrient digestibility without any negative effect on growth performance and meat quality. Furthermore, fermented corn can reduce fecal noxious gas emission content.

Key words: fermented corn, growing pigs, nutrient digestibility

M205 Effects of enzyme fermented oat on growth performance, digestibility, blood profile, and fecal gas emission of growing pigs. S. Zhang*, J. M. Lee, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

The objective of this study was to evaluate the effects of enzyme fermented oat (FO) on growth performance, digestibility, blood profile, and fecal gas in growing pigs. A total of 125 pigs [(Landrace × Yorkshire) × Duroc] with an average initial BW of 20.5 ± 0.8 kg were used in a 6 wk growth trial, and were allotted to 5 dietary treatments in a randomized complete block design. There were 5 pens per treatment with 5 pigs per pen. Dietary treatments included: 1) CON (100% nature oat), 2) FO1 (75% nature oat + 25% FO), 3) FO2 (50% nature oat + 50% FO), 4) FO3 (25% nature oat + 75% FO) and 5) FO4 (100% FO). The oats, before added to diets, were treated by protease (26,014 U/g), amylase (7,176 U/g) xylanase (799 U/g), cellulose (5,204 U/g) and a-galactosidase (176 U/g) for 72 h. Data were subjected to the GLM procedure of SAS. In result, there was no difference in growth performance (ADG, ADFI, and G:F) among dietary treatments ($P > 0.05$). Apparent total tract digestion (ATTD) of DM was higher in FO2 group than CON group throughout the experiment ($P < 0.05$), as well as no difference was observed among FO2, FO3 and FO4 groups ($P > 0.05$). ATTD of energy was higher in FO2, FO3 and FO4 than CON group, throughout the experiment ($P < 0.05$). Plasma glucose concentration, red blood cell (RBC) and white blood cell (WBC) counts, and lymphocyte percentage did not differ among treatments. No difference was observed in fecal gas (H_2S, Acetic acid, NH_3). In conclusion, the FO has a beneficial effect on the ATTD of DM and energy.

Key words: fermented oat, growing pigs, growth performance

M206 Effects of emulsifier and multi-enzyme on growth performance, organ weight, meat quality and blood characteristics in broilers. S. C. Kim*, H. J. Kim, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effects of emulsifier and multi-enzyme on growth performance, organ weight, meat quality and blood characteristic in broilers. A total of 672 Ross 308 broilers with an initial BW of 34 ± 5 g were allotted into 1 of the 6 treatments (16 broilers per pen and 7 replicate pens per treatments). Dietary treatment included: 1) PC (basal diet), 2) NC (basal diet - 100 kcal down spec.), 3) R05 (NC + 0.05% emulsifier), 4) R10 (NC + 0.10% emulsifier), 5) E05 (NC + 0.05% multi-enzyme), and 6) E10 (NC + 0.10% multi-enzyme). The experiment lasted for 35 d. Data were subjected to the GLM procedures and Duncan multiple range test was used to com-

pare the means of the treatments. Overall the experiment, BWG was higher in R10 and E10 treatments than NC treatment (1,454, 1,446 vs. 1,358 g; $P < 0.05$). Liver weight was higher in E10 treatment than NC and R10 treatments (3.75 vs. 2.45, 2.54%; $P < 0.05$). Spleen weight was increased in R05, E05 and E10 treatments compared with PC, NC and R10 treatments (0.16, 0.14,0.18 vs. 0.09, 0.10, 0.10%; $P < 0.05$). Breast muscle weight was higher in PC, R05 and E05 treatments than E10 treatment (9.86, 9.28, 9.20 vs. 7.24%; $P < 0.05$). Abdominal fat weight was greater in E10 treatment than other treatments (2.12 vs. 1.28, 0.51, 1.24, 1.16, 1.12%; $P < 0.05$). NC treatment had a higher WHC than other treatments (80.67 vs. 73.83, 69.71, 68.08, 63.86%; $P < 0.05$). Lightness of breast meat was higher in NC treatment than that in PC, R10 and E05 treatments (64.33 vs. 57.12, 57.92, 58.17%; $P < 0.05$). In drip loss, NC treatment was higher compared with PC, R05, R10 and E05 treatments on d1 (6.52 vs. 2.70,, 3.51, 3.56, 2.97%; $P < 0.05$), NC treatment was higher compared with PC and E05 treatments on d3 (14.74 vs. 8.75, 8.26%; $P < 0.05$), and NC treatment was higher compared with PC treatment on d5 (18.29 vs. 10.50%; $P < 0.05$). In conclusion, the dietary supplementation emulsifier and multienzyme can bring benefit on BWG, relevant organ weight, WHC, breast meat color and drip loss.

Key words: broilers, emulsifier, multi-enzyme

M207 Hydrolysis of native starches by gastric enzymes in vitro: 1. Relationship between starch hydrolysis and organic matter digestibility. O. O. Adeleye*[1], A. D. Ologhobo[1], P. A. Iji[2], and O. A. Adebiyi[1], *[1]Department of Animal Science, University of Ibadan, Department of Animal Science, University of Ibadan Ibadan, Oyo State, Nigeria, [2]School of Environmental and Rural Sciences, University of New England, School of Environmental and Rural Sciences, University of New England Armidale, NSW, Australia.*

An investigation was carried out using a 2-step enzymatic model simulating foregut digestibility to study the relationship between starch hydrolysis and organic matter digestibilities of different native starches. Starches of sago, rice, wheat, corn, sweetpotato, arrowroot and potato as well as sweetpotato meal, cassava pulp and tapioca were selected based on their starch content ranging from 575.1 to 846.3mg/g OM. Substrates were incubated in a pepsin/HCl solution for 1.5 h and subsequently in potassium phosphate buffer containing pancreatin and amylase for 1, 2, 3 and 6 h. Hydrolyzed starch and residual organic matter were measured at each time point. Starch hydrolysis ranged from 9.8% in potato starch to 85.5% in sago starch with their corresponding organic matter digestibilities of 22.36% and 95.04% respectively at 6 h of incubation. Relationship between starch hydrolysis and organic matter digestibility for all substrates could be described by: Starch hydrolysis (mg/g OM) = −93.1 + 0.91 × organic matter digestibility at incubation time t, $R^2 = 0.8$. While relationship between starch hydrolysis and organic matter digestibility for individual substrates were described with R^2 ranging from 0.8 to 0.99. Organic matter digestibility was also seen to precede the take off of starch hydrolysis for all substrates studied confirming that digestion of non-starch fractions occurred prior and simultaneously with starch hydrolysis. Variations in starch hydrolysis for the different substrates were attributed to their granular sizes and crystalline structures.

Key words: starch hydrolysis, organic matter digestibility, in vitro

M208 Performance of 1- to 42-day-old broilers fed diets containing multienzyme complex and lipid sources. G. do Valle Polycarpo*[1], A. C. Pezzato[1], V. C. da Cruz[2], J. R. Sartori[1], V. B. Fascina[1], F. B. de Carvalho[1], F. Vercese[1], N. C. Alexandre[1], L. P. Centenaro[1], I. M. G. P. de Souza[1], P. G. Castelo[1], E. M. Muro[1], W. T. da Silva[1], V. C. Pelícia[1], P. C. de Araujo[1], *[1]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil, [2]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil.*

This work was carried out at the São Paulo State University, Botucatu Campus, Brazil, with the aim of evaluating the performance of broilers fed diets containing a multienzyme complex (MeC) and different lipid sources from 1 to 42 d of age. A total of 840 1-d-old male Cobb chicks were housed, allotted in a completely randomized design featuring a 2 × 2+2 factorial arrangement, 2 lipid sources (soybean oil and poultry fat) with 2 inclusion levels (2% and 4%) in feeds supplemented with MeC; and 2 control treatments without added lipids – a positive control using MeC-supplemented feed, and a negative control without added MeC. There were 4 replications with 35 broilers per experimental unit (density = 14 birds/m^2). Mean initial chick weight was 44.55 g. The different feeds featured similar energy and AA levels within each breeding phase, and were formulated based on corn and soybean meal. Water and feed were supplied ad libitum. There was no interaction ($P > 0.05$) between lipid source and inclusion level for the following studied variables: BW, ADG, ADFI and G:F. Birds fed diets containing lipids in feed showed greater ($P < 0.01$) BW and ADG than those fed lipid-free diets. Lipid sources did not influence ($P > 0.05$) broiler performance, which can be attributed to the higher ratio of unsaturated and polyunsaturated fatty acids in poultry fat as compared with other animal fat sources, making it an excellent alternative to soybean oil. The inclusion of 4% lipid in feed led to greater ($P < 0.01$) BW (2.812 g vs. 2.701 g), ADG (2.768 g vs. 2.657 g) and ADFI (4.827 g vs. 4.579 g) compared with 2% inclusion, which demonstrates that incorporating higher levels of oil into feed benefits growth and increases intake. G:F was not influenced ($P > 0.05$) by the treatments. The inclusion of 4% lipid in feed increases ADG and BW of birds, regardless of lipid source. Diets without lipid inclusion – with or without MeC – show inferior performance to the others.

Key words: poultry fat, soybean oil

M209 Carcass and cuts yield, and abdominal fat level in 42-day-old broilers subjected to diets containing multienzyme complex and lipid sources. A. C. Pezzato*[1], G. do Valle Polycarpo[1], V. C. da Cruz[2], J. R. Sartori[1], V. B. Fascina[1], F. Vercese[1], N. C. Alexandre[1], L. P. Centenaro[1], I. M. G. P. de Souza[1], P. G. Castelo[1], E. M. Muro[1], W. T. da Silva[1], A. C. Stradiotti[1], M. K. Maruno[1], F. Barros de Carvalho[1], *[1]São Paulo State University, Botucatu Campus, Botucatu, São Paulo, Brazil, [2]São Paulo State University, Dracena Campus, Dracena, São Paulo, Brazil.*

This work was carried out at the experimental slaughterhouse of the São Paulo State University, Botucatu Campus, Brazil, with the aim of evaluating carcass yield, cuts and abdominal fat level in broilers fed diets containing multienzyme complex (MeC) and different lipid sources at 42-d of age. A total of 840 1-d-old male Cobb chicks were housed in 24 boxes at an experimental aviary, with density equal to 14 birds/m^2. The broilers were raised from 1 to 42 d of age in a completely randomized design featuring a 2 × 2+2 factorial arrangement, 2 lipid sources (soybean oil and poultry fat) with 2 inclusion levels (2% and 4%) in feeds supplemented with MeC; and 2 control treatments without added lipids – a positive control using MeC-supplemented feed, and a negative control without added MeC. There were 4 replications with 35 broilers per experimental unit. The different feeds featured similar

energy and AA levels within each breeding phase, and were formulated based on corn and soybean meal. Water and feed were supplied ad libitum. At 42 d of age, 5 birds per replication were slaughtered following an 8-h fast to determine carcass and cuts yield, and abdominal fat percentage. Carcass yield was determined by considering the weight of the dressed and eviscerated carcass (without feet, head and neck) in relation to live fasting weight obtained just before slaughter. For the other cuts (breast, drumstick and thigh, back and abdominal fat), yield was calculated in relation to eviscerated carcass weight. The treatments did not influence ($P > 0.05$) any of the variables. Multienzyme complex and lipid sources do not influence carcass and cuts yield, or abdominal fat level of broiler chickens.

Key words: poultry fat, soybean oil

M210 Effect of dietary phytase on performance, digestive enzymes and intestinal morphology in weaned pigs. M. C. Shields*[1], E. van Heugten[1], C. H. Stahl[1], A. J. Moeser[2], P. W. Plumstead[3], and M. H. Borgmann[1], *[1]Department of Animal Science, North Carolina State University, Raleigh, [2]Department of Clinical Sciences and Molecular, Biomedical Sciences, College of Veterinary Medicine, North Carolina State University, Raleigh, [3]Danisco Animal Nutrition, Marlborough, Wiltshire, UK.*

This study was designed to evaluate the effect of an *E. coli* phytase on weaned pig performance, trypsin and chymotrypsin activity in the small intestine, and intestinal morphology. Pigs (n = 40; BW = 9.72 ± 0.36 kg) were weaned at 21 d of age and housed individually. Pigs were acclimated and fed a common starter diet for 14 d before being assigned to 1 of 5 dietary treatments. Treatments consisted of a positive control diet (PC) without phytase (0.6% total P and 0.29% available P) and a negative control diet (NC) (0.45% total P and 0.14% available P) supplemented with 1 of 4 levels of phytase (0, 500, 1000, 2000 FTU/kg). Diets were corn-soybean meal based with 1.2% SID lysine and fed in mash form for 2 wk. Phytase supplemented at 2000 FTU/kg diet tended to increase ADG in a step-wise manner with increasing phytase dose ($P = 0.10$) to the highest phytase dose of 2000 FTU/kg. Increasing dietary phytase content linearly improved G:F ratio ($P < 0.05$; 0.52, 0.57, 0.59, 0.78 for 0, 500, 1000 and 2000 FTU of phytase, respectively). Phytase supplementation also tended to decrease linearly ADFI ($P = 0.07$; 0.78 0.73, 0.73, 0.67 kg/d). As dietary phytase increased, there was a numerical increase in duodenal trypsin activity (quadratic $P = 0.13$; 79.3, 97.8, 133.7, 108.9 units/mg protein). Phytase supplementation did not impact ileal trypsin ($P = 0.83$) or chymotrypsin activity ($P = 0.44$). Phytase linearly decreased duodenal villi height ($P = 0.03$; 310, 191, 193, 177 µm). Ileal villi height was lower for PC than NC ($P < 0.05$; 150.3 vs. 177.8 µm), and duodenal ($P = 0.07$; 55.6 vs. 67.0 µ) and ileal ($P = 0.09$; 54.2 vs. 62.3 µ) villi width tended to be lower for PC compared with NC, but they were not impacted by phytase. Dietary treatments did not impact crypt depth in the duodenum ($P = 0.84$) or ileum ($P = 0.19$). Phytase supplementation did not affect pH in the stomach ($P = 0.92$), duodenum ($P = 0.38$) or ileum ($P = 0.29$). Duodenal pH was increased ($P = 0.05$) in PC (5.92) when compared with NC (5.62). In conclusion, phytase improved nursery pig performance, increased trypsin activity in the duodenum, and decreased duodenal villi height in weaned pigs.

Key words: phytase, pigs, enzymes

M211 Effect of carbohydrolase complex and phytase combined in corn-soybean meal diet for pigs. M. Ceccantini*[1], B. V. Freitas[2], M. M. Mota[3], N. B. Petroli[3], C. C. Silva[3], C. S. S. Araujo[2], and L. F. Araujo[3], *[1]Adisseo, Sao Paulo, SP, Brazil, [2]FMVZ/USP, Pirassununga, SP, Brazil, [3]FZEA/USP, Pirassununga, SP, Brazil.*

This experiment was conducted to evaluate the effect of a multiple enzyme complex containing carbohydrolases and 6-phytase (Rovabio Max AP, Adisseo) on the performance and carcass characteristics of pigs fed a corn-soybean meal diet. 96 barrows (7 wk old) were assigned to a randomized block design and fed 3 experimental diets with 8 replicates (4 pigs/pen) for 100 d. The positive control diet was a standard diet formulated to meet the requirement of all nutrients, while the negative control diet was reformulated with reductions in energy (85 kcal ME/kg at initial phase, and 65 kcal ME/kg at the other phases), 3% of protein, 3% of digestible AA, 0.15% of Av.P, and 0.10% of Ca. The treatments were: T1- Positive control diet, T2 - Negative control diet supplemented with enzyme, T3- Negative control diet. At 100 d, one barrow/pen was slaughtered and fat thickness, muscle thickness, lean meat and muscle color were measured. For the purpose of distribution of pig carcasses into commercial classes according to SEUROP system methods, which is a method that classifies carcass according to lean percentage, all carcass sides were categorized into different classes (S, > 60%; E, 55 to 60%; U, 50 to 55%; R, 45 to 50%; O, 40 to 45%; and P, < 40% carcass lean). Barrows fed a diet supplemented with enzymatic complex showed better ADG (0.875, 0.913, and 0.856, respectively), G:F (2.44, 2.34, 2.46, respectively), and lower fat thickness (29, 24, and 26 mm respectively) than other treatments ($P < 0.05$). None of treatments resulted in classification of carcasses into the meat class of highest meat ratio (S) or lowest meat ratios (P). However, the use of the enzyme complex resulted in higher carcass ratio U (12.5, 37.5, and 12.5% respectively) than other treatments, and positive control treatment showed higher carcass ratio O (75, 25, and 37.5%, respectively). There was no difference to the other characteristics. The results indicated that dietary enzyme supplementation in corn and soybean meal based diet is efficient in reducing costs, by reducing nutrients requirements, without compromising performance and carcass characteristics.

Key words: carcass characteristics, enzymatic complex, performance

M212 Effects of β-glucan and probiotics (*Bacillus subtilis* and Kefir) supplementation on growth performance, blood profile, relative organ weight and meat quality in broiler chickens. J. H. Jang*, L. Yan, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to determine β-glucan and probiotics (*Bacillus subtilis* and Kefir) on growth performance, blood profile, relative organ weight and meat quality in broilers. A total of 315 Ross 308 broilers with an initial BW of 46 ± 5 g were allotted into 1 of 7 treatments (15 broilers per pen and 3 replicate pens per treatment). Dietary treatments included: 1) NC, basal diet (antibiotics-free diet); 2) PC, NC + 40 mg/kg avilamycin; 3) B, NC + 0.1% β-glucan; 4) P, NC + 0.1% *Bacillus subtilis*; 5) K, NC + 0.1% Kefir; 6) BP, NC + 0.1% β-glucan + 0.1% *Bacillus subtilis*; and 7) BK, NC + 0.1% β-glucan + 0.1% Kefir. The experiment lasted for 35 d. Data were subjected to the GLM procedures of SAS and Duncan's multiple range test was used to compare the means of the treatments. On d 21, broilers in PC, B, P, K, BP and BK treatment had a higher ($P < 0.05$) ADG than broilers in NC treatment group. On d 35, broilers fed BP had a higher ($P < 0.05$) ADG than those fed NC diet. Overall, ADG in PC, B, P, K, BP and BK treatments was higher ($P < 0.05$) than that in NC treatment. G:F was higher ($P < 0.05$) in PC treatment group compared with NC treatment group. The BP treatment increased ($P < 0.05$) relative liver weight. Broilers in BK treatment group had a higher ($P < 0.05$) relative breast meat and gizzard weight than those in NC treatment group. Broilers fed PC, B, BP and BK diets had a higher ($P < 0.05$) redness than those fed NC diet. Furthermore, the yellowness was higher ($P < 0.05$) in BP treatment than in K treatment. On d 5 and 7, drip loss was decreased ($P < 0.05$) by dietary supplementation of 0.1% β-glucan + 0.1% Kefir. Cooking loss was lower ($P < 0.05$) in BP and BK treatment groups than that in NC treatment. In conclusion, dietary supplementation of β-glucan and/or probiotics could increase the growth performance of broilers and 0.1% β-glucan along with 0.1% Kefir could improve broiler′s relative organ weight and meat quality.

Key words: β-glucan, probiotics, broiler

M213 Effects of caprylic acid and *Yucca schidigera* extract supplementation on growth performance, nutrient digestibility, fecal microflora and blood profiles in growing pigs. B. U. Yang*, S. Zhang, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effects of caprylic acid and *Yucca schidigera* extract supplementation on growth performance, nutrient digestibility, excreta microflora and blood profiles in growing pigs. A total of 120 [(Landrace × Yorkshire) × Duroc] pigs with a initial body weight (BW) of 23.3 ± 1.74kg was used in a 6–wk experiment. Pigs were randomly allotted to 1 of 6 treatments with 5 replicate pens per treatment and 4 pigs per pen. Dietary treatments included: 1) NC (Antibiotic free diet), 2) PC (NC + 0.01% Apramycin), 3) B1 (NC + 0.05% Caprylic acid + 0.05% Yucca extract), 4) B2 (NC + 0.1% Caprylic acid + 0.1% Yucca extract), 5) B3 (NC + 0.15% Caprylic acid + 0.15% Yucca extract) and 6) B4 (NC + 0.2% Caprylic acid + 0.2% Yucca extract).Overall the experiment, pigs fed the B2 had a greater ADG and G:F but lower ADFI than those fed the NC diet ($P < 0.05$). The ATTD of DM and N was higher in B2, B3, B4 and C1 treatments than that the NC treatment ($P < 0.05$). and ATTD of energy was higher in B4, C1, B3, PC, B2 and B1 groups than that in NC group ($P < 0.05$). The number of *Lactobacillus* was greater in B2 treatment than that in NC, PC and B4 treatments ($P < 0.05$). NC had a higher *E. coli* number compared with other treatments ($P < 0.05$), further more PC and B3 treatments had a lower *E. coli* concentration than B1, B2 and C1 treatments ($P < 0.05$). The total protein concentration in the blood was increased in B1 treatment ($P < 0.05$). Moreover, the IgG concentration was increased in both B1 and C1 treatments compared with the NC treatment ($P < 0.05$). NC treatment had a higher HDL-cholesterol concentration than B3 and C1 treatments ($P < 0.05$), furthermore LDL-cholesterol concentration was higher in B3, B1 and PC treatments compared with the other treatments ($P < 0.05$). It is concluded that caprylic acid and *Yucca schidigera* extract at level of 0.1 or 0.2% can improve growth performance, nutrient digestibility, fecal microflora and blood profiles in growing pigs.

Key words: caprylic acid, growing pigs, yucca extract

M214 Effect of fructooligosaccharide and levan on growth performance, nutrient digestibility, blood characteristic and diarrhea in growing pigs. L. Yan*, X. Y. Guo, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

A total of 100 commercial cross-bred pigs [(Duroc × Yorkshire) × Landrace, weaned at 21 d, BW = 5.97 ± 0.46 kg] were allocated to 1 of 5 treatments [4 replicates with 5 pigs per pen (3 barrows and 2 gilts)] to determine the effects of fructooligosaccharide (FOS) and levan (LV) on growth performance, nutrient digestibility, blood characteristic and diarrhea in weaning pigs. The experiment lasted for 6 wk. The experimental treatments were: 1.NC, basal diet; 2.PC, NC + 0.01% apramycin; 3. LV, NC + 0.1% levan; 4. BM, NC + 0.1% FOS and 5. LB, NC + 0.05% levan + 0.05% FOS. Data were subjected to the GLM procedures and Duncan multiple range test was used to compare the means of the treatments. Pigs fed PC, BM and LB diets led to a higher (410, 399, 394 vs. 306 g; $P < 0.05$) ADG than the NC diet during 0–14 d. Dietary supplementation of 0.1% FOS increased (402 vs. 327 g; $P < 0.05$) the ADG compared with the NC treatment through the entire period. No difference ($P > 0.05$) was observed on the ADFI and G:F among treatments in the present study. Administration of PC, BM and LB led to higher (84.38, 85.82, 85.42 vs. 78.71; 81.33, 82.73, 83.69 vs. 77.27; 83.43, 86.14, 86.27 vs. 78.91%; $P < 0.05$) DM, N and energy digestibility compared with the NC treatment at the end of 14 d. A lower diarrhea score was detected for the BM treatment compared with the NC treatment during 0–7 d ($P < 0.05$). No difference was observed on the ($P > 0.05$) blood characteristic in the current study. In conclusion, the inclusion of levan or fructooligosaccharide could benefit the growth performance and nutrient digestibility during 0–14 d. Administration of fructooligosaccharide decreased the diarrhea scores and increased the growth performance when the entire period was evaluated.

Key words: fructooligosaccharide, growth performance, levan

M215 Effects of dietary sodium stearoyl-2-lactylate supplementation on growth performance, nutrient digestibility, and blood profiles in growing pigs. B. U. Yang*, H. Y. Baek, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effects of dietary sodium stearoyl-2-lactylate (SSL) supplementation on growth performance,

nutrient digestibility, and blood profiles in growing pigs. A total of 144 [(Landrace × Yorkshire) × Duroc] pigs with an initial BW of 24.62 ± 1.32 kg were used in a 6-wk experiment. Pigs were randomly allotted to 1 of 6 treatments. Dietary treatments included: 1) PC (basal diet), 2) PCS (basal diet + 0.05% SSL), 3) P50 (50 kcal/kg down spec design (−50 kcal/kg comapred with basal diet)), 4) P50S (P50 + 0.05% SSL), 5) P100 (100kcal/kg down spec design (−100 kcal/kg comapred with basal diet)) and 6) P100S (P100 + 0.05% SSL). There were 6 replicates per treatment with 4 pigs per pens (2 barrows and 2 gilt). Throughout the experimental period, pigs fed the PC, PCS and P50S treatments had greater ADG than those fed the P100 diets (647, 680, 671 vs. 671 g; $P < 0.05$). Average daily gain was decreased as SSL level increased (680, 671 vs. 658 g; $P = 0.025$). Pigs fed P100S diet had greater blood glucose concentration than those fed the PC and PCS diets (90.8 vs. 77.2, 79.3 mg/dL; $P < 0.05$). The blood glucose concentration was increased as energy source decreased (78.3, 83.0 vs. 88.65 mg/dL; $P = 0.018$). However, the triglyceride concentration was decreased as SSL level increased (46.8, 46.0 vs. 45.8mg/dL; $P = 0.022$). In conclusion, SSL at level of 0.05% can improve growth performance and blood profiles in growing pigs.

Key words: blood profile, growing pigs, growth performance

M216 Effect of dietary zootechnical feed additive supplementation on sow and litter performance. D. Solà-Oriol*[1], P. S. Agostini[1], S. L. Vinokurovas[1], B. T. Lund[2], and J. Gasa[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Chr. Hansen, Hørsholm, Denmark.*

The aim of the present study was to evaluate the effect of Bioplus 2B supplementation of sows' diet on sows and litter performance. Bioplus 2B is a zootechnical additive containing *B. licheniformis* and *B. subtilis* in a 1:1 ratio. A total of 72 crossbred sows were fed one of 2 experimental treatments from matting to 21 d of lactation. Treatments were: control diet (CTL, n = 35) and CTL + 0.4 ppm of Bioplus 2B (B2B, n = 37). Cereal and soybean meal based diets were formulated to contain 12.2 MJ/kg ME and 6.23 g/kg Lys during gestation and 13.1 MJ/kg ME and 8.93 g/kg Lys during the lactation. At matting, sows were distributed into 2 experimental treatments according to parity number, BW, BCS and backfat (BFP2). Sow BW, BCS and BFP2 were individually monitored at 0, 35 and 110 d of gestation and at 21 d post-farrowing. Feed intake was individually adjusted according to BCS (every 3 wk during gestation) and an ad libitum feeding program was used during lactation. Total feed intake (TFI) of sows was individually recorded during gestation and lactation. Sow and litter performance was controlled until 21 d of age. Litters were standardized in number and weight by cross fostering within each treatment. No difference in BCS or BFP2 was observed between treatments during gestation and lactation periods ($P > 0.10$). Lower and higher TFI was observed for sows fed B2B than those fed CTL diets for the gestation (320 vs. 336 kg; $P < 0.05$) and lactation (129 vs. 121 kg $P < 0.05$), respectively. The total piglets born and piglets born alive was not afected ($P > 0.10$) by the treatments used. A reduction of stillbirth piglets and piglets dead during the suckling period was observed for the sows fed the B2B diet than those fed the CTL diet (1.27 vs.. 2.05 and 1.32 vs.. 2.09; $P < 0.01$, respectively). Total mortality rate during lactation tended to be reduced for the B2B supplemented sows (9.6 vs.. 14.6%; $P = 0.105$). No differences were observed on the number of piglets weaned, litter weight at weaning, or weaning to oestrus interval ($P > 0.10$). It is concluded that B2B may improve sow farrowing performance by reducing piglet mortality at farrowing.

Key words: feed additive, sow, stillborn

M217 Effect of a wheat dextrin and a fructooligosaccharide as prebiotics on nursery pig performance. V. G. Perez*, H. Yang, T. R. Radke, and D. P. Holzgraefe, *ADM Alliance Nutrition Inc., Quincy, IL.*

The wheat dextrin (PMD) and fructooligosaccharide (FOS) selected for this experiment were used as prebiotics to promote pig growth. Both PMD and FOS were added in nursery diets at the dose recommended by their vendors to determine whether or not they have additive effects on promoting pig performance. The experiment was a randomized complete block design; blocks were 3 categories of initial BW. Treatments had a 2 (0 vs.. 0.2% PMD) × 2 (0 vs.. 0.1% FOS) factorial arrangement. Each treatment was replicated with 12 pens of 4 pigs per pen. Pigs were weaned (about 21 d of age) and fed the experimental diets for 28 d, using a 3-phase feeding program (7, 7, and 14 d for feeding phases 1, 2, and 3, respectively). All diets were formulated to provide same amount of nutrients within feeding phase. Carbadox was added at 55 mg/kg of diet to all treatments. The PMD and FOS interacted on the ADG ($P < 0.05$) and G:F ($P < 0.01$). During the first 7 d, PMD increased ADG by 35 g/d in the absence of FOS, but decreased it by 25 g/d in the presence of FOS. Overall, PMD increased ADG by 37 g/d in the absence of FOS, but decreased it by 10 g/d in the presence of FOS. The same pattern of response was observed for G:F in both periods, but no effect was detected for ADFI (Table 1). No main effects of PMD or FOS were detected. These results were consistent with previous dose-response company studies, in which the inclusion of up to 0.2% of prebiotic in nursery diets improved pig performance, but then reduced performance with larger doses of prebiotic. In summary, the inclusion of PMD at 0.2% of the diet improved pig performance only in the absence of FOS.

Table 1. Effect of wheat dextrin (PMD) and fructooligosaccharide (FOS) on pig performance

Item	None	PMD	FOS	PMD+FOS	SEM
Initial BW, kg	5.84	5.85	5.86	5.88	0.02
Days 1-7

M218 Effects of ractopamine feeding duration on performance and carcass traits of finishing pigs. V. V. Almeida*[1], A. J. C. Nuñez[2], C. Andrade[1], J. C. C. Balieiro[2], and V. S. Miyada[1], *[1]USP/ESALQ, Piracicaba, SP, Brazil, [2]USP/FZEA, Pirassununga, SP, Brazil.*

The β adrenergic agonist ractopamine is increasingly used in the swine industry due to its ability to improve performance and carcass leanness by directing nutrients from adipose tissue toward skeletal muscle. However, the response may vary as a function of ractopamine treatment duration. Therefore, 80 barrows weighing 69.23 ± 7.74 kg BW were used to determine the effects of ractopamine feeding duration on performance and carcass traits of finishing pigs. A randomized complete block design experiment was carried out to evaluate 5 treatments with 8 replications per treatment and 2 pigs per experimental unit

(pen). Dietary treatments included control (without ractopamine for 28 d) and 10 ppm of ractopamine fed for 7, 14, 21 or 28 d before slaughter. Diets were based on corn-soybean meal, formulated to contain 0.88% of digestible lysine and 3.23 Mcal/kg ME. Feed intake and live body weight were recorded weekly to determine ADG, ADFI, and G:F. After 28 d on test, pigs were slaughtered at 101.94 ± 9.06 kg BW and carcass measurements made at 24 h postmortem. Treatment effects were assessed by ANOVA and regression analysis using the GLM procedure of SAS. G:F was quadratically improved (0.331, 0.352, 0.369, 0.377, and 0.367 ± 0.03; $P < 0.05$) as the duration of ractopamine feeding increased from 0 to 28 d; however, ADG and ADFI were not affected ($P > 0.05$) by treatments. Increasing ractopamine feeding duration from 0 to 28 d before slaughter resulted in linear increases on loin eye area (40.28, 42.24, 43.37, 45.03, and 48.86 ± 5.79 cm^2; $P < 0.01$) and loin depth (62.69, 63.69, 66.06, 65.69, and 70.19 ± 6.21 mm; $P < 0.01$). Ractopamine feeding duration did not affect ($P > 0.05$) carcass weight, carcass length, dressing percentage, backfat thickness and lean percentage. These results suggest that the maximum improvement in performance of finishing pigs is achieved within 21 d of ractopamine feeding, while the magnitude of carcass response seems to be directly dependent on ractopamine feeding duration.

Key words: beta-adrenergic agonist, carcass leanness, swine

M219 Effect of zilpaterol hydrochloride supplementation on growth performance in male Japanese Quails. M. Mohammadi*, A. Towhidi, H. Moravej, and A. Z. Shahneh, *Department of Animal Science, university of Tehran, Karj, Karaj, Alborz, Iran.*

Zilpaterol hydrochloride is a β-adrenergic agonist that has been shown to increase lean muscle and decrease fat deposition. In this study, 128 birds at 33 d of age were randomly assigned to 4 treatments. Each treatment consisted of 4 replicates of 8 birds. Diets were formulated based on corn and soybean meal for finishing period (24% CP and 2.9 Mcal/kg of ME) that were supplemented with 0, 0.2, 0.225, or 0.25 mg/kg of live weight d^{-1} of zilpaterol. Quails were fed the diets until d 47 and then slaughtered on d 50. Data were analyzed with using the GLM procedure of SAS. Results showed that during d 33–47, zilpaterol supplementation improved G:F ($P < 0.04$), and live weight gain in group 0.2 and 0.225 compared with control, but did not affect feed intake (Table 1). Birds fed zilpaterol had lower abdominal and subcutaneous fat percentage ($P < 0.05$). Dietary zilpaterol did not affect carcass, thigh, breast and liver weight. It was concluded that zilpaterol hydrochloride supplementation in japans quail improved growth performance and the optimal level of this β-agonist was 0.225 mg/kg of live weight d^{-1}.

Table 1. Effect of zilpaterol supplementation on growth responses in Japanese Quails

Item	T_1 0	T_2 0.2	T_3 0 .225	T_4 0 .25	SEM	*P*-value
Total weight gain(g)	64.31[a]	71.71[b]	75.28[b]	69.87[ab]	2.23	0.03
Feed intake(g)	363.34	369.4	372.87	357.06	6.77	0.4
gain:feed	0.176[a]	0.194[b]	0.202[b]	0.195[b]	0.005	0.041

[ab]Means in each row without a common superscript letter differ ($P < 0.05$).

$T_{1, 2, 3, 4}$: 0, 0.2, 0.225, 0.25 mg/kg of LW^{-1} d^{-1} zilpaterol, respectively.

Key words: zilpaterol hydrochloride, Japanese quail, growth performance

M220 Safety and efficacy of *Moringa oleifera* powder for growing poultry. J. O. Ashong* and D. L. Brown, *Cornell University, Ithaca, NY.*

Leaves from *Moringa oleifera* have been reported to have a remarkable range of qualities from superior nutritional composition, therapeutic applications and prophylactic uses for both humans and animals. Most of these claims are based on anecdotes or uncontrolled observations. The objective of the present study was to evaluate the safety and nutritional efficacy of *Moringa oleifera* leaf meal. At 7 d of age, 60 White-leghorn type chicks were randomly assigned to 4 isocaloric and isonitrogenous experimental diets formulated to contain 0% (control group), 10%, 20% and 30% moringa leaf powder. There were 5 chickens per cage with 3 replicates per diet. Daily feed intake and weekly BW were recorded for the duration of the 5 wk study. Chicks were observed for any signs of abnormal behavior and/or toxicity. Post-trial postmortem examination conducted included weighing of kidney, liver and heart and biochemical analyses such as, cholesterol, uric acid, thyroxine (T4), total protein and iron. There were no signs of abnormal behavior and/or toxicity and mortality during the entire period of the experiment. The control group had a higher feed intake ($P < 0.05$) with a corresponding higher weight gain ($P < 0.0001$) compared with the other treatment groups. Chicks fed with 10% moringa leaf meal, had the lowest feed intake although it did not correspond to the lowest weight gain. Heart, liver and kidney weights were heaviest in the control group even though the kidney weight was not significantly ($P > 0.05$) different from the kidney weights of chicks on the treatment diets. The heart weight decreased with increasing percentage of moringa leaf powder in the meal. The control group had significantly higher levels of cholesterol; triglyceride and uric acid. These results suggest that although incorporation of moringa leaf meal may reduce intake and rate of gain, this ingredient otherwise is not toxic to growing poultry and has some effects on blood lipids profiles that may be of interest to human nutritionists.

Key words: *Moringa oleifera*, safety, poultry

M221 Singular consumption of either *Lactobacillus plantarum* or inulin reduces manure odor from finishing pigs; however, this is negated when offered in combination. C. J. O'Shea, T. Sweeney, B. Bahar, M. Ryan, and J. V. O'Doherty*, *University College Dublin, Dublin, Ireland.*

A 2 × 2 factorial experiment was conducted to investigate the effects of inulin (0 vs. 12.5 g/kg) and/or *Lactobacillus plantarum* (LP) inclusion (0 vs. 0.5 g/kg) on nutrient digestibility, nitrogen excretion, distal gastrointestinal tract (dGIT) fermentation and manure ammonia and odor emissions from finishing pigs. Consumption of diets containing LP and inulin had no influence on apparent total tract nutrient digestibility when offered either singularly or in combination ($P > 0.05$). In the colon, pigs offered diets containing LP decreased concentrations of propionic acid ($P = 0.048$) and valeric acid ($P = 0.007$) when compared with unsupplemented diets. Consumption of inulin-supplemented diets decreased concentrations of isobutyric acid ($P = 0.050$) in the colon when compared with unsupplemented diets. Consumption of diets containing LP increased the *Lactobacillus* spp.:*Enterobacteriaceae* ratio (2.12 vs. 1.66; sem 0.14; $P = 0.034$) when compared with unsupplemented diets. Pigs offered diets containing inulin had decreased numbers of *Enterobacteriaceae* (5.85 vs. 6.66; sem 0.256; $P = 0.035$) compared with unsupplemented diets. There was an interaction between dietary inulin and LP supplementation on fecal *Clostridia* ($P = 0.004$). Singular consumption of either

inulin or LP had no effect on fecal *Clostridia*, however when offered in combination fecal *Clostridia* were increased when compared with the C diet. There was an interaction between dietary inulin and LP supplementation on manure odor at 72h. Consumption of diets supplemented with LP reduced manure odor ($P = 0.007$) when compared with the C diet, however there was no effect of LP when offered in combination with inulin on manure odor emissions. In summary, consumption of a LP-supplemented diet modified the distal gastrointestinal contents and increased the ratio of *Lactobacillus* spp. to *Enterobacteriaceae* in fecal matter. Consumption of LP singularly reduced manure odor, however when offered in combination with inulin this beneficial event was negated.

Key words: pig, odor, microbes

M222 Standardized total tract digestibility of P in Dried Fermentation Biomass, Peptone 50, and P.E.P. 2 Plus fed to weanling pigs. J. K. Mathai*[1], R. C. Sulabo[1], J. L. Usry[2], B. W. Ratliff[3], D. M. McKilligan[3], and H. H. Stein[1], *[1]University of Illinois, Urbana, [2]Ajinomoto Heartland, LLC, Chicago, IL, [3]TechMix, LLC, Stewart, MN.*

Forty barrows (BW: 12.4 ± 1.3 kg) were used to measure the apparent (ATTD) and standardized total tract digestibility (STTD) of P in Dried Fermentation Biomass (DFB), Peptone 50 (PEP50), and P.E.P. Two Plus (PEP2+) fed to weanling pigs and to compare these values to those in fish meal. The DFB product (Ajinomoto Heartland LLC) is a co-product from AA production and PEP50 and PEP2+ (TechMix LLC) are produced from hydrolyzed pig intestines. Pigs were housed individually in metabolism cages and were randomly allotted to 5 diets with 8 replicate pigs per diet. Four diets were formulated with DFB, PEP50, PEP2+, or fish meal as the sole source of P in the diet. A P-free diet was used to measure basal endogenous P losses (EPL). Feces were collected for 5 d based on the marker to marker approach after a 5-d adaptation period. Analyzed total P in DFB, PEP50, PEP2+, and fish meal were 0.88, 0.74, 0.80, and 3.25%, respectively. Daily P intake of pigs fed DFB, PEP50, and PEP2+ were less (0.80, 0.82, 0.96 g/d; $P < 0.01$) than in pigs fed fish meal (1.77 g/d). Fecal P concentration (0.41, 0.57, 1.12, 2.56%) and daily P output (0.08, 0.09, 0.27, 0.62 g/d) were less ($P < 0.01$) in pigs fed DFB and PEP2+ than in pigs fed PEP50 and fish meal. The amount of P absorbed was different ($P < 0.01$) between all treatments (0.56, 0.72, 0.87, and 1.15 g/d in PEP50, DFB, PEP2+, and fish meal, respectively). The ATTD of P was greater ($P < 0.01$; SEM = 1.8) in DFB (90.4%) and PEP2+ (90.6%) than in PEP50 and fish meal (68.0 and 65.5%, respectively). The basal EPL was measured at 148 ± 63 mg/kg DMI in pigs fed the P-free diet. The STTD of P in DFB (96.9%) and PEP2+ (97.6%) were greater ($P < 0.01$; SEM = 2.2) than in PEP50 and fish meal (76.2 and 68.5%, respectively). Likewise, PEP50 had greater ($P < 0.01$) STTD of P than in fish meal. Therefore, DFB, PEP50, and PEP2+ had greater STTD of P, but lower concentration of P, than fish meal.

Key words: alternative feedstuffs, phosphorus, pigs

M223 Digestibility of green banana flour (*Musa cavendishi*) in roosters. E. Toledo*[1], F. Martínez–Bustos[2], and A. G. Borbolla[1], *[1]Department of Swine Medicine and Production, School of Veterinary Medicine, Universidad Nacional Autónoma de México, Mexico City, Mexico, [2]CINVESTAV, IPN, Unidad Queretarétaro, Querétaro, Qro. Mexico.*

Banana flour can be used in swine and poultry, as an alternative energy source, when the fruit is locally available and cheaper than the cereals regularly fed to these species. The aim of this study was to evaluate the fecal digestibility of banana flour in roosters (Ross, 308). Green bananas were chopped in pieces (1cm thickness/10cm length), and heat dried in a convection oven (Yakomoto 900, YKN), at 55, 70, 80 and 90°C, for 48 h. The trial was conducted in 12 roosters, which were randomly assigned to 4 groups (3 roosters/group). Each treatment (temperature of dehydration), was changed every wk using a Latin Square Model. Digestibility of the flour was evaluated using the methodology described by Douglas et al. (1997), where each bird received 32 g of banana flour in one shot daily. Feces were collected after 48 h and dehydrated in a convection oven at 60°C for 48 h. The percentage of digestibility was determined using the following formula: {[(feed, g – feces, g) / feed, g] * 100}.The resulting data was analyzed using the statistical package SPSS 17.0. The amount of feces collected was higher ($P < 0.05$), for those animals that consumed the flour dehydrated at 80°C (19.97 g ± 2.05), than the other 3 treatments (55°C = 12.88 g ± 1.73; 70°C = 11.38 g ± 1.62 and 90°C = 13.83 g ± 1.37). Therefore, the digestibility of the flour dried at 80°C was lower ($P < 0.05$), than the values observed for the other drying temperatures (36.63% ± 6.41 vs.. 59.12% ± 5.32; 63.88% ± 5.02 and 56.14% ± 4.27; for 80, 55, 70 and 90°C, respectively). Banana flour dehydrated at 55 and 70°C showed the highest digestibility and the lowest amount of feces produced by roosters. According to these results, it can be concluded that roosters had a better use of the nutrients of the banana flour, when it is dried at low temperature (55 and 70°C). Banana flour might be considered a good source of energy for monogastric species such as swine and poultry.

Key words: banana flour, digestibility, rooster

M224 Effects of increasing levels of dietary turmeric on growth performance and immune response of nursery pigs. M. R. Bible*[1], S. D. Carter[1], H. J. Kim[1], T. M. Walraven[1], C. Houchen[2], S. Anant[3], and R. Ramanujum[4,5], *[1]Oklahoma State University, Stillwater, [2]University of Oklahoma Health Sciences Center, Oklahoma City, [3]University of Kansas Medical Center, Kansas City, KS, [4]Swaath Inc., Oklahoma City, OK, [5]ADNA Inc., Dublin, OH.*

Turmeric is a common dietary spice used in India and Southeast Asia that contains the active ingredient curcumin, a potent polyphenolic phytochemical. Curcumin and curcuminoids in turmeric are known to have anti-inflammatory and anti-microbial activities. Therefore, 32 crossbred (D x (L x Y)) barrows (7.5 kg; 20 d of age) were weaned and used to determine the effects of dietary turmeric on performance and immune response. Pigs were blocked by BW and ancestry, and allotted randomly to 4 dietary treatments in a randomized complete block design. Pigs were housed individually in metabolism crates in an environmentally-controlled building (8 pigs/trt). During a 3-d adjustment period to the crates, barrows consumed a standard, phase 1, nursery diet. After the adjustment period, the experimental diets were fed for 21 d. A corn-soybean meal-based diet (1.44% SID Lys) containing no antibiotics served as the control. The experimental diets contained increasing levels of turmeric at 2, 4, and 8 g/kg of diet, respectively. ADG, ADFI, and G:F were calculated weekly. Turmeric consumption per day (linear, $P < 0.0001$) was 0, 89, 181, and 354 mg/kg BW, respectively. Turmeric increased (quad, $P < 0.03$) final BW (14.8, 15.8, 16.3, 15.5 kg), ADG (350, 389, 417, 382 g), ADFI (458, 487, 508, 459 g), and G:F (0.762, 0.798, 0.820, 0.826; linear, $P < 0.03$). On d 20 of the experiment, a lipopolysaccharide (LPS) challenge was performed. Pigs were administered intraperitoneally saline-based *E. coli* O111:B4 LPS (25 μg/kg of BW). Rectal temperature was measured and blood was collected for the analysis of tumor necrosis factor-α (TNF-α) at 0

h, and 3, 6, 12, and 24 h post-injection. Turmeric decreased (quad, $P < 0.05$) rectal temperature at h 3 (41.0, 40.6, 40.8, 40.7°C) with a corresponding numerical decrease (quad, $P = 0.12$) in blood serum TNF-α (2509, 805, 1300, 1585 pg/mL). In general, there were no differences observed for TNF-α concentrations or rectal temperature at any other hour post-LPS. In conclusion, dietary turmeric increased performance and lowered the inflammatory cytokine, TNF-α, during an *E. coli* LPS challenge in weanling pigs.

Key words: pig, turmeric, performance

M225 Evaluation the effect of inositol monophosphate supplementation on growth performance, blood profiles and nutrient digestibility in weaning pigs. H. Y. Baek*, H. W. Cho, and I. H Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

This study was conducted to evaluate the effect of inositol monophosphate (IMP) supplementation on growth performance, blood profiles and nutrient digestibility in weaning pigs. A total of 200 weaning pigs [(Yorkshire × Landrace) × Duroc] with an initial BW 6.21 ± 0.90 kg were randomly assigned to 5 dietary treatments as follows: 1) CON (basal diet), 2) IMP02 (basal diet + 0.2% IMP), 3) IMP04 (basal diet + 0.4% IMP), 4) IMP06 (basal diet + 0.6% IMP) and 5) IMP10 (basal diet + 1.0% IMP). There were 8 replicate pens per treatment and 5 pigs per pen. Average daily gain (ADG) was higher ($P < 0.05$) in IMP04 treatment than that in IMP10 treatment during the overall experiment. Dry matter digestibility was higher ($P < 0.05$) in IMP06 treatment compared with that in CON, IMP02 and IMP10 treatments and CON treatment was lower ($P < 0.05$) than that in IMP04 and IMP06 treatments on d14. Nitrogen digestibility was higher ($P < 0.05$) in IMP04 treatment than that in CON treatment. Also, energy digestibility was higher ($P < 0.05$) in IMP04 treatment compared with that in CON, IMP02 and IMP10 treatments. On d28, nitrogen digestibility was higher ($P < 0.05$) in IMP04 treatment compared with that in CON and IMP10 treatments. IgG concentration was higher ($P < 0.05$) in IMP04 treatment than that in CON, IMP02 and IMP06 treatment on 28d. However, total cholesterol, Red blood cell (RBC), White blood cell (WBC) and lymphocyte were not affected by dietary treatments during this experiment ($P > 0.05$). Jejunum crypt depth was lower ($P < 0.05$) in IMP04 treatment compared with that in CON treatment ($P > 0.05$). In conclusion, growth performance was enhanced by supplementation of 0.4% IMP, and nutrient digestibility was increased by 0.4 and 0.6% IMP, and IgG concentration was improved by the supplementation of 0.4 and 1.0% IMP, and villi and crypt statue of small intestine was improved by the supplementation of 0.4 and 1.0% IMP.

Key words: growth performance, pigs, nutrient digestibility

M226 Effects of probiotics and probiotics mix on growth performance and blood characteristics. J. M. Lee*, S. M. Hong, and I. H. Kim, *Dankook University, Cheonan, Choongnam, South Korea.*

A total of 150 weaned pigs with an average BW of 6.42 ± 0.91 kg were used in a 4 wk study to investigate the effects of *Bacillus subtilis* and *Bacillus licheniformi* mix (BBM) (1:1) and *Bacillus subtilis* (BS) on growth performance, blood characteristics and nutrient digestibility. Pigs were allocated to 1 of 6 dietary treatments with 5 replicate pens per treatment and 5 pigs per pen. Dietary treatments included: 1) NC (no antibiotics), 2) PC (antibiotics), 3) NBP (NC + 0.04% BBM), 4) PBP (PC + 0.04% BBM), 5) NCP (NC + 0.05% BS) and 6) PCP (PC + 0.05% BS). Data were subjected to the GLM procedures of SAS and Duncan multiple range test was used to compare the means of the treatments. On d 14, pigs fed NBP, PBP and PCP diets showed a higher ADG than pigs fed NC diet (286, 282, 282 vs. 228 g; $P < 0.05$). The ADFI was greater in NBP treatment than that in NCP treatment (345 vs. 271 g; $P < 0.05$). On d 28, pigs fed NBP and PCP diets showed a higher ADG than NC diet (604, 641 vs. 490 g; $P < 0.05$). The ADFI was greater in PC, NBP, BPB and PCP treatments than that in NCP treatment (779, 795, 792, 812 vs. 713 g; $P < 0.05$). G:F was greater in NCP treatments than NC treatment (0.812 vs. 0.652; $P < 0.05$). Overall the experiment, NBP, PBP and PCP diets had a higher ADG than NC diet (445, 435, 462 vs. 359 g; $P < 0.05$) and ADFI was greater in NBP and PCP treatments than NC and NCP treatments (570, 575 vs. 522, 492; $P < 0.05$). G:F was greater in NCP treatment than NC treatment (0.831 vs. 0.688; $P < 0.05$). On d 28, IgG was higher in PC and NCP treatments than that in NC, PBP and PCP treatments (434, 428 vs. 348, 357 mg/dl; $P < 0.05$). Dry matter digestibility was greater in PC treatment than that of NC treatment (82.18 vs. 78.39%; $P < 0.05$). Nitrogen digestibility was higher in PC treatment than that of NC and PCP treatments (74.18 va 67.85, 69.85%; $P < 0.05$). Energy digestibility was higher in PC, PBP and NCP treatments than that of NC and PCP treatments (81.51, 80.30, 80.46 vs. 77.65, 78.22%; $P < 0.05$). In conclusion, dietary supplementation of *Bacillus subtilis* and *Bacillus licheniformi* mix and *Bacillus subtilis* can be considered as an alternative to antibiotics.

Key words: growth performance, probiotics, weaned pig

Physiology and Endocrinology I

M227 ACTH-induced stress impairs the expression of genes involved in steroidogenesis and angiogenesis in dairy cow preovulatory follicles. D. Biran[1], R. Braw-Tal[2], Y. Lavon[1], and Z. Roth*[1], *[1]Department of Animal Sciences, The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University, Rehovot, Israel, [2]Institute of Animal Science, Agricultural Research Organization, Bet Dagan, Israel.*

Ovulation failure, follicular persistence and follicular-cyst formation are known to impair dairy cow fertility. While the mechanism is not entirely clear, stress-induced alteration in adrenal hormone secretion can cause such ovarian pathologies. We examined changes in genes involved in steroidogenesis and angiogenesis upon ACTH-induced stress. Six synchronized lactating cows were scanned daily by ultrasound (Aloka SSD-900) and plasma samples were taken throughout the experiment. Treated cows (n = 3) were administered ACTH analog (Synacthen Depot; 1mg, s.c.) every 12h from d 15 to d 21 of the cycle. Control cows (n = 3) were administered $PGF_{2\alpha}$ (Estroplan) on d 6 of the cycle to induce development of a preovulatory follicle. Ovaries from both control and treated cows were collected at the slaughterhouse 40h after the last $PGF_{2\alpha}$ administration and on d 23 of the cycle, respectively. Follicular diameter was measured and follicular fluids were aspirated to determine steroid concentrations. Slices of the follicular wall were taken for total mRNA isolation and sqRT-PCR. Administration of ACTH increased ($P < 0.02$) cortisol concentration in the plasma and reduced ($P < 0.01$) milk production, indicating stress. Androstenedione and estradiol concentrations in the follicular fluids were lower ($P < 0.05$) in ACTH-treated follicles relative to controls. The expression of mRNA for LH receptor, 3Î²-HSD and P450arom was lower ($P < 0.02$) in the ACTH-treated group than in controls but P450scc, StAR protein and P450c17 mRNA levels did not differ between the groups. mRNA expression for angiopoietin-1 and angiopoietin-2 did not differ between the groups but that for VEGF120 and VEGF164 was higher ($P < 0.01$) in controls than in ACTH-treated follicles. Findings indicate that ACTH induced stress, and impaired follicular steroidogenesis and angiogenic capacity, characterized by reduced follicular-fluid steroid concentration and low expression of genes involved in these processes. Such alterations might explain, in part, the mechanism underlying ovulation failure and the formation of persistent or cystic follicles under stress.

Key words: persistent follicle, cyst

M228 Comparison of different staining methods on sperm from Holstein bulls. A. Ata, M. E. Inanc, O. Kankavi, O. Yildiz Gulay*, and M. S. Gulay, *Mehmet Akif Ersoy University, Faculty of Veterinery Medicine, Burdur, Turkiye.*

The aim of the current study was to compare effectiveness of various semen staining methods in frozen-thawed and epididymal cattle semen. Frozen semen (American Breeder Service and Ege-Vet) were placed in a water bath first at 37°C for 30 s and thawed. Epididymal semen from cauda epidiymis was obtained from slaughter house (Güç-Birligi, Burdur, Turkiye) and diluted with phosphate buffer solution (PBS). After preliminary examination under the microscope, frozen-thawed and epididymal semen samples were smeared on glass microscope slides using another glass slide and air-dried. Sperm on the slides were stained with Coomassie Blue, Silver nitrate, May–Grünwald+Giemsa, Ponceau-S, Naphthol yellow-S+Eritrosin-B, Ponceau-S+Naphthol yellow-S+Eritrosin-B, Trypan Blue+Giemsa, Eosin+Coomassie Blue and modified Wright′s stain. Stained froty samples were examined under bright field microscopy (Nikon E-600). From all froties at least 100 spermatozoa were investigated. Different staining methods were compared by one way ANOVA. Differences between epididymal and frozen-thawed samples were analyzed by *t*-test procedure. Equatorial region of intact spermatozoa was well defined and acrosomal region was stained differently than other regions by some staining methods (Coomassie Blue, May-Grünwald+ Giemsa, Ponceau-S, Naphthol yellow-S+Eritrosin-B, Eosin+Coomassie Blue; $P < 0.05$). Equatorial regions of spermatozoa with corrapted acrosomes were not stained well. Epidiymal spermatozoa were stained better than frozen-thawed spermatozoa in all staining methods investigated in the present study ($P < 0.05$). This could be because of the substances used in frozen semen as cryoprotectans (proteins of animal origin, etc.). In conclusion, our results demonstrated that Eosin+Coomassie Blue staining method is simple, inexpensive, and reliable method for staining semen from Holstein bulls. The method works quickly, needs fewer methodological steps, and does not require complex laboratory conditions for assessment of establishing live-dead spermatozoa and acrosomal/morphological status in frozen-thawed and epididymal semen obtained from Holstein bulls

Key words: cattle, spermatozoa, staining

M229 Insulin sensitivity correlates with parameters of hepatic lipid metabolism, and is lower in older dairy cows. H. A. van Dorland[1], M. Graber[1,2], S. Kohler[2], T. Kaufmann[3], and R. M. Bruckmaier*[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Bern, Switzerland, [2]Department of Animal Science, Swiss College of Agriculture, Zollikofen, Bern, Switzerland, [3]Clinic for Ruminants, Vetsuisse Faculty, University of Bern, Bern, Bern, Switzerland.*

Insulin sensitivity may be estimated by the “Revised Quantitative Insulin Sensitivity Check Index” (RQUICKI), which is based on plasma concentrations of insulin, glucose, and free fatty acids (NEFA). It was indicated before that RQUICKI might be used to identify lactating cows with disturbed insulin function. In the present study, data from a field study were used to investigate the association between RQUICKI and the parity of the dairy cows, and of parameters involved in hepatic metabolism. Blood and liver samples were obtained from 185 dairy cows in wk 3 ante partum (-wk3) and in wk 4 (+4wk) and 13 postpartum (+13wk). Blood plasma was assayed for concentrations of NEFA, glucose, and insulin. Liver was analyzed for mRNA expression levels by qRT-PCR encoding 27 enzymes and nuclear receptors related to carbohydrate and lipid metabolism. The results show that cows of >3 parities have a significant lower RQUICKI across sampling points than cows with <3 parities ($P < 0.001$). In addition, RQUICKI was lower in +4wk than in −3wk and +13wk ($P < 0.001$). Significant ($P < 0.01$) Spearman Rank Correlation Coefficients were observed between RQUICKI and mRNA abundance of liver X receptor α (LXRα), sterol regulatory element binding factor 1 (SREBF1), ATP citrate lyase, fatty acid synthase (FASN), Glycerol-3-phophate acyltransferase (GPAM), 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR), which may illustrate the pathological changes in the liver through infiltration of fat as observed to be associated with disturbed insulin function in man.

Key words: insulin resistance, metabolism, liver

M230 Intrauterine position and adjacent fetal sex status influences fetal and placental growth but not embryonic viability under crowded uterine conditions in pigs. B. A. Freking* and C. A. Lents, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Intrauterine position and sex of adjacent fetuses in litter bearing species have been implicated in physiological and behavioral differences in males and females. Our objective was to quantify influences of uterine position and sex status of flanking fetuses under crowded uterine conditions and test the impact on fetal and placental growth rate. Gilts were subjected to unilateral-hysterectomy-ovariectomy surgery at 160 d of age and mated at approximately 280-d of age. Gilts were assigned to be harvested at d 45, 65, 85, or 105 of gestation. A total of 297 pregnancies were evaluated in 4 contemporary groups. Position in the uterus relative to the cervix, fetal status (alive, dead, mummy), fetal weight, and placental weight were recorded at harvest. Data were coded to test when each fetus was adjacent to 0, 1, or 2 opposite sex fetuses. Data were analyzed by mixed-model ANOVA procedures fitting contemporary group, line, and flanking fetal sex code as fixed effects and sire as a random effect. Nonlinear functions were fitted to the fetal and placental weight data to establish unique growth curves for each flanking sex status code. When considering only observations that had an opportunity to be flanked by 2 adjacent fetuses, the fraction of live fetuses represented by each classification (0, 1, 2) were 26.4%, 50.1%, and 23.4%, respectively, indicating no impact on fetal survival. Fetal weight was not influenced by flanking sex status code at d 45, but was significant ($P < 0.05$) by d 65, and became highly significant ($P < 0.001$) by d 105. Least squares means at d 105 were 800.0 ± 20.3, 748.5 ± 17.8, and 672.7 ± 25.2 g, respectively for flanking sex status codes 0, 1, 2. Placental weight was also similarly influenced by flanking sex status code, but only apparent ($P < 0.01$) by d 105. Fetal growth development in pigs is influenced by sex status of adjacent fetuses, and could be a potential source of variation in behavioral and reproductive differences later in life.

Key words: fetal growth, pigs, survival

M231 The effect of teasing rams with a ewe stimulus prior to semen collection. A. G. Fahey*[1], P. Duffy[1], and S. Fair[2], *[1]University College Dublin, Belfield, Dublin 4, Ireland, [2]University of Limerick, Limerick, Ireland.*

The objective of this study was to determine if exposing rams to a ewe stimulus for 1 h before semen collection could improve the rams' libido and/or semen quality. The experiment was carried out during the breeding season. Rams (European breeds; 1.5 to 4 years of age) were allocated to one of 3 treatments according to breed and age: Treatment 1 (Control); rams (n = 5) were exposed to a ewe not in estrus for 1 h and were subsequently allowed to mount another ewe in estrus for semen collection. Treatment 2 (Non novel ewe); rams (n = 6) were exposed to a ewe in estrus for 1 h after which the same ewe was restrained on a ramp for semen collection. Treatment 3 (Novel ewe); rams (n = 6) were exposed to a ewe in estrus for 1 h after which the rams were allowed to mount a different ewe in estrus for semen collection. Rams did not have tactile contact with the teaser ewe during the 1 h exposure time and the experiment was repeated on each of 5 consecutive days. Libido was measured by the rams' reaction time (time from first foot on the ramp to when ejaculation into the artificial vagina had occurred) and the number of mounts taken before ejaculation. Each ejaculate was assessed for volume, concentration, wave motion and progressive linear motion after 1 h. Data were analyzed using ANOVA with repeated measures using the MIXED procedure of SAS. There were no significant effects of treatment, day or their interaction on reaction time, the number of mounts or on wave motion or progressive linear motion of sperm. There was no significant effect of treatment on semen volume, however, there was a significant effect of day ($P < 0.05$) and a treatment × day interaction ($P < 0.05$). Semen concentration and total sperm number were significantly affected by treatment ($P < 0.05$) and day ($P < 0.01$), however, there was no treatment × day interaction. Exposing rams to an estrus ewe before semen collection does not improve ram libido but does assist in improving the sperm number in the ejaculate.

Key words: ram, libido, semen

M232 Effects of supplemental progesterone and timing of initiation of resynchronization on fertility in lactating dairy cows. T. R. Bilby*[1], R. G. S. Bruno[1], K. J. Lager[1], R. C. Chebel[2], J. G. N. Moraes[2], P. M. Fricke[3], G. Lopes[3], J. O. Giordano[3], J. E. P. Santos[4], F. S. Lima[4], J. S. Stevenson[5], and S. L. Pulley[5], *[1]Texas AgriLife Research and Extension, Texas A&M System, Stephenville, [2]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [3]Department of Dairy Science, University of Wisconsin, Madison, [4]Department of Animal Sciences, University of Florida, Gainesville, [5]Department of Animal Sciences and Industry, Kansas State University, Manhattan.*

Our objective was to determine the effect of exogenous progesterone (P_4) within a timed artificial insemination (TAI) protocol initiated at 2 different times post-AI on pregnancies per AI (P/AI) in lactating dairy cows. Lactating cows (n = 1,982) from 5 commercial dairy herds were assigned randomly at 31 ± 3 d post-AI, at non-pregnancy diagnosis, in a 2 × 2 factorial arrangement of 4 resynchronization treatments initiated early (EP; 31 ± 3 d) or late (LP; 39 ± 3 d) post-AI. Cows were either treated with a CIDR (C) insert or not (NC) as part of an Ovsynch-56 protocol (GnRH, 7 d later $PGF_{2\alpha}$, 56 h GnRH, 16 h TAI). Therefore, the 4 treatments were: 1) EPNC (n = 509), open cows at 31 ± 3 d post-AI and not receiving a CIDR; 2) EPC (n = 501), open cows at 31 ± 3 d post-AI and receiving a CIDR; 3) LPNC (n = 485), open cows at 39 ± 3 d post-AI and not receiving a CIDR; and 4) LPC (n = 487), open cows at 39 ± 3 d post-AI and receiving a CIDR. Cows were inseminated if observed in estrus before TAI. Pregnancies per AI were determined 31 and 60 d after TAI. In a subgroup of cows (n = 1,101), blood samples were collected and ovarian structures were examined at first GnRH (G1) and $PGF_{2\alpha}$ of the Ovsynch-56 protocol. Percentage of cows with CL at G1 was not affected by treatment but percentage of cows with CL at $PGF_{2\alpha}$ was greater ($P < 0.01$) for EP vs.. LP cows (87.9 vs.. 79.4%). In addition, percentage of cows with P_4 concentration > 1 ng/mL at G1 was not affected by treatment but was increased ($P < 0.01$) for EP vs.. LP cows at $PGF_{2\alpha}$ (86.5 vs.. 74.3%). Treatment did not affect ovulation to G1 and P/AI 31 d after resynchronized TAI (EPNC = 30.1, EPC = 28.8, LPNC = 27.5, LPC = 30.5%). An interaction was detected ($P < 0.04$) between timing of initiation of resynchronization and supplemental P_4 at d 60 with the CIDR tending ($P = 0.11$) to increase P/AI in late (LPNC = 23.7 vs.. LPC = 28.0%), but not in early (EPNC = 26.9 and EPC = 24.2%) cows. Embryo loss was unaffected by treatment. In conclusion, addition of a CIDR insert within the Ovsynch-56 protocol initiated late (d 39 ± 3) but not early (d 31 ± 3) post-AI improved P/AI.

Key words: dairy cows, resynchronization, CIDR

M233 Effect of circulating progesterone (P4) and two different GnRH doses on LH secretion in lactating dairy cows. J. O. Gior-

dano*, P. M. Fricke, J. N. Guenther, G. Lopes, M. M. Herlihy, and M. C. Wiltbank, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Our objectives were: 1) to determine the effect of circulating P4 (high P4; HP4 vs.. low P4; LP4), and 2) increasing the GnRH dose from 100 (LD) to 200 (HD) μg on LH secretion in HP4 and LP4 in lactating cows (n = 24). Double-Ovsynch (Presynchronization; GnRH-7d-PGF-3d-GnRH; 7d later Breeding-Ovsynch; GnRH-7d-PGF-48h-GnRH-16h-TAI) was used to create the HP4 and LP4 environments. At the 1st GnRH of Breeding-Ovsynch (HP4) all cows having a CL ≥20 mm received either a LD or HD of GnRH. At the 2nd GnRH of Breeding-Ovsynch (LP4) cows randomly received a LD or HD of GnRH. Blood samples (BS) were collected every 15 min from −15 to 180 min after GnRH, and then hourly until 5 h after GnRH. As expected, mean P4 in HP4 was greater than LP4 (2.8 vs. 0.2 ng/mL; $P < 0.01$). Mean LH for LD cows (n = 12) was affected by P4 (1.7 vs. 7.4 ng/mL for HP4 and LP4; $P < 0.01$), time ($P < 0.01$) and treatment by time ($P < 0.01$). Circulating P4 in LD cows also affected the LH peak (3.4 vs. 17.7 ng/mL for HP4 and LP4; $P < 0.01$) and area under the curve (AUC; 488.0 vs. 2346.9 ng for HP4 and LP4 ng; $P < 0.01$). Mean LH for HD cows (n = 10) was also affected by P4 (3.5 vs. 9.6 ng/mL for HP4 and LP4; $P < 0.01$), time ($P < 0.01$) and treatment by time ($P = 0.04$). Circulating P4 in HD cows decreased LH peak (7.9 vs. 21.3 ng/mL for HP4 and LP4; $P = 0.02$) and AUC (1065.9 vs. 2933.3 ng for HP4 and LP4 ng; $P = 0.01$). In HP4 (n = 24), mean LH was affected by GnRH dose (1.7 vs. 3.7 ng/mL for LD and HD; $P < 0.01$), time ($P < 0.01$), and treatment by time ($P < 0.01$). Dose of GnRH affected LH peak (3.3 vs. 8.5 ng/mL for LD and HD; $P < 0.01$), time to LH peak (1.3 vs. 1.8 h for LD and HD; $P = 0.04$), and AUC (501.0 vs. 1177.8 ng for LD and HD; $P < 0.01$). In LP4 (n = 22), mean LH was affected by GnRH dose (6.9 vs. 10.7 ng/mL for LD and HD; $P < 0.01$), time ($P < 0.01$), and treatment by time ($P < 0.01$). Likewise, GnRH dose affected LH peak (15.7 vs. 23.6 ng/mL for LD and HD; $P = 0.01$) and AUC (2186.4 vs. 3443.2 ng for LD and HD; $P < 0.01$). We conclude that circulating P4 reduces GnRH-induced LH secretion, and a higher dose of GnRH can increase LH secretion both in a high and low P4 environment. Supported by Hatch project WIS01171.

Key words: LH secretion, progesterone, GnRH

M234 Assessment of an accelerometer system (Heatime) for detection of estrus and timing of insemination in lactating dairy cows. A. Valenza, G. Lopes*, J. O. Giordano, J. N. Guenther, and P. M. Fricke, *Department of Dairy Science University of Wisconsin-Madison, Madison.*

Two experiments were conducted on a commercial dairy in Wisconsin to evaluate an accelerometer system (Heatime) to manage reproduction. In the first experiment, lactating Holstein cows (n = 54) received an i.m. injection of GnRH (100 μg) from 35 to 49 DIM followed 7 d later by an i.m. injection of PGF2α (PGF; 25 mg). Beginning 48 h after PGF, blood samples were collected for progesterone (P4) analysis and ovaries were monitored using ultrasound at 8 h intervals for 120 h. Ovulatory response to GnRH treatment was greater ($P = 0.027$) for cows with <0.5 ng/mL P4 (96.2%, 25/26) than for cows with ≥0.5 ng/mL P4 (66.7%, 16/24). Cows were removed from the analysis if they were detected in estrus by the system before PGF (n = 6) or if they did not regress their CL after PGF (n = 6). For the 42 cows included in the analysis, 26% (11/42) underwent luteal regression but did not ovulate (5% were detected in estrus by Heatime; 21% were not), whereas 74% (31/42) regressed their CL and ovulated (67% were detected in estrus by Heatime; 7% were not). Peak accelerometer activity occurred 67.1 ± 2.5 h after PGF, and cows were inseminated 9.9 ± 2.3 h after peak activity. Ovulation occurred 85.9 ± 2.4 h after PGF, 20.9 ± 3.1h after peak activity and 10.7 ± 2.5 h after AI. In the second experiment, cows (n = 426) were assigned by odd or even ID number to receive an i.m. injection of GnRH (G, 100 μg) at AI detected by the Heatime system (n = 401 AI) or no treatment (control, C; n = 482 AI). Pregnancy diagnosis was performed by the herd veterinarian 30 d after AI using ultrasonography. Based on logistical regression analysis, pregnancies per AI (P/AI) was affected ($P < 0.001$) by parity (35.2 vs.. 22.3% for primiparous vs.. multiparous cows) and season (34.7 vs.. 22.6% for cool vs.. warm seasons); however, treatment with GnRH at AI did not affect P/AI (29.8 vs.. 26.8% for C vs.. G cows, respectively). We conclude that the Heatime system determined the correct timing of AI for most of the cows that displayed estrus and that treatment with GnRH at the time of AI determined by the Heatime system did not affect fertility in lactating dairy cows.

Key words: estrous detection, GnRH, Heatime

M235 Presynchronization with double-Ovsynch improves conception at first postpartum AI in primiparous lactating dairy cows. M. M. Herlihy*[2,3], J. O. Giordano[1], A. H. Souza[1], A. Keskin[1], A. B. Nascimento[1], J. N. Guenther[1], M. A. Crowe[3], S. T. Butler[2], and M. C. Wiltbank[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]Animal and Bioscience Research Department, Teagasc, Moorepark, Cork, Ireland, [3]School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Ireland.*

Lactating dairy cows (n = 739; 341 primiparous, 398 multiparous) were enrolled in a study to test the hypothesis that improved pregnancies per AI (P/AI) following Ovsynch can be achieved in first service, first parity cows through the use of Double-Ovsynch for presynchronization compared with Presynch-Ovsynch. Cows were randomly assigned to: Double-Ovsynch (DO, n = 366; GnRH-7d-PGF-3d-GnRH-7d-Ovsynch-56[GnRH-7d-PGF-56h-GnRH-16hTAI]) or Presynch-Ovsynch (PS, n = 373; PGF-14d-PGF-12d-Ovsynch-56). Progesterone (P4) was determined at GnRH1 of Ovsynch-56. Pregnancy was diagnosed by palpation per rectum at 39 d and late embryo loss rate was determined at 74 d. Treatment effects were analyzed by logistic regression using the GLIMMIX Procedure of SAS. Explanatory variables in the statistical model included treatment, parity (1, ≥ 2), body condition score (BCS) (low ≤2.50; high >2.50), treatment*parity and treatment*BCS interactions. Presynchronization with DO tended ($P = 0.06$) to improve P/AI (DO = 46.6%, 171/366 vs.. PS = 41.5%, 155/373). One-tailed contrasts revealed improved ($P = 0.04$) P/AI for first parity cows treated with DO (DO = 56.3%, 95/168 vs.. PS = 47.4%, 82/173), with no improvement ($P > 0.05$) observed for older animals (DO = 38.1%, 75/198 vs.. PS = 36.3%, 73/200). There was no effect ($P > 0.05$) of presynchronization treatment on incidence of late embryo loss after first service (9.1 vs.. 6.1%). Presynchronization at first service had no effect ($P > 0.05$) on P/AI at second service (33.1 vs.. 34.9%). DO increased the percentage of cows with P4 ≥ 0.5 ng/mL at GnRH1 of Ovsynch (DO = 93.7%, 343/366 vs.. PS = 75.3%, 281/373; $P < 0.001$) with similar effects in all parities. A treatment by BCS interaction ($P < 0.05$) was observed for serum P4 at GnRH1, with low BCS cows having greater P4 if assigned to DO than PS (1.90 vs.. 2.44ng/mL; $P < 0.05$). Thus, presynchronization with Double-Ovsynch induced cyclicity in cows of all parities; however, Double-Ovsynch increased fertility only in first parity cows and not older cows. The physiology underlying this parity difference is not yet clear.

Key words: presynchronization, Ovsynch, dairy cow

M236 Effect of GnRH and double AI (24h apart) on fertility of high-producing cows detected in estrus by professional tail chalk service. D. Cunningham[1], A. Fisher[1], A. H. Souza*[2,1], H. Rivera[1], A. Skidmore[3], and M. C. Wiltbank[2], *[1]Accelerated Genetics, Baraboo, WI, [2]Department of Dairy Science, University of Wisconsin, Madison, [3]Intervet/Schering-Plough Animal Health, Summit, NJ.*

The objective of this study was to evaluate the effects of double AI and supplemental GnRH given at AI in Holstein cows detected in estrus by daily tail chalk. Lactating cows from 2 commercial herds in WI (n = 1,101), DIM = 166 ± 3, in their 1st to 14th postpartum breedings were randomly assigned in a 2 × 2 factorial design as follows: SAI) Single AI when tail chalk was rubbed off at 0h (standard tail chalk procedure); DAI) Double AI (at 0h and 24h) with second AI done regardless of chalk been rubbed off again after 1st AI; SAI+GnRH) Single AI at 0h plus supplemental GnRH treatment simultaneously to AI at 0h; DAI+GnRH) Double-AI (at 0h and 24h) plus GnRH at 0h second AI performed regardless of further chalk reading after 1st AI. Estrus detection based on daily tail chalk reading was performed by 2 experienced technicians. Pregnancy was diagnosed by ultrasound at 30 ± 3d after AI. Factorial design comparison was analyzed with procedure Glimmix of SAS, with cow treated as a random effect and interaction between number of AI and GnRH forced into the statistical model. In addition, final model also took into account main effects and the interactions for farm, parity, DIM at AI, and month of breeding. There was no interaction ($P > 0.10$) between number of AIs and GnRH treatment on pregnancies per AI (P/AI). Similarly, main effects of number of AIs (SAI = 30%; DAI = 32%) and GnRH treatment (no-GnRH 31%; yes-GnRH = 30%) did not alter P/AI. Further analysis using only hard breeders (cows not conceiving until 200DIM; n = 239) also showed no significant interaction between treatments; or effect of number of AI (SAI = 23%; DAI = 22%) and GnRH at 1st AI (no-GnRH = 22%; yes-GnRH = 23%). In conclusion, blanket use of double breeding and/or GnRH at the time of AI failed to enhance fertility in lactating Holstein cows detected in estrus by professional AI technicians doing AI service based on tail chalk removal.

Key words: artificial insemination, GnRH, dairy cow

M237 Paraoxonase expression and activity in bovine granulosa cells and follicular fluid. A. Schneider[1,2], V. A. Absalon-Medina[2], G. Esposito[3,2], M. N. Corrêa[1], and W. R. Butler*[2], *[1]Universidade Federal de Pelotas, Pelotas, RS, Brazil, [2]Cornell University, Ithaca, NY, [3]University of Naples Federico II, Naples, Italy.*

The aim of this work was to evaluate expression of paraoxonase (PON) 1, 2 and 3 in bovine granulosa cells and activity in follicular fluid (FFL). The PON enzyme family possesses anti-oxidant and anti-inflammatory effects and is highly expressed in liver. In plasma PON1 is bound to HDL and is reduced during pathophysiological challenges during the peripartum transition period. Ovaries were collected from cows during slaughter and follicles were used for expression analysis (7 estrogen-active follicles [EAF] and 7 atretic follicles [ATF]) and enzyme activity in FFL (10 EAF and 21 ATF). Follicles were dissected from the stroma, FFL was aspirated and the follicle walls immersed in RNALater. To recover granulosa cells, follicular walls were removed from the RNALater, halved, scraped and washed with cold saline into a Petri dish. Granulosa cells were recovered by centrifugation at 2000 x g for 3 min. Total RNA was isolated and real-time PCR used to evaluate PON 1, 2 and 3 mRNA expression according to the ΔΔCt method. Estradiol (E2), progesterone (P4), HDL, LDL, cholesterol and PON1 were evaluated in FFL. Additionally, FFL from 15 EAF was aspirated in Holstein cows to compare PON1 activity in FFL and plasma. In granulosa cells PON2 and 3 mRNA expression was not different between EAF and ATF, PON1 being undetectable. In EAF and ATF, FFL E2 concentration was 133 ± 33 and 12 ± 3 ng/mL, with E2/P4 ratio of 2 and 0.2, respectively. PON1 activity was higher ($P < 0.05$) in EAF (83 ± 8 kU/L) than ATF (62 ± 5 kU/L), as well as HDL, LDL and cholesterol concentrations ($P < 0.05$). E2 concentration in FFL was correlated to PON3 expression ($r = 0.59$, $P < 0.05$) and PON1 activity ($r = 0.50$, $P < 0.01$). PON1 activity in FFL (61 ± 5 kU/L) was lower ($P < 0.01$) than in plasma (123 ± 11 kU/L), but correlated ($r = 0.69$, $P < 0.01$). In summary, although PON1 activity in FFL increases with E2 concentration, its origin appears to be from plasma since it is not expressed in granulosa cells. Moreover, increased PON1 activity in FFL in association with increased concentration of HDL and cholesterol indicates that this is due to a higher transfer rate of the protein from plasma in EAF.

Key words: granulosa cells, PON, HDL

M238 Development of a lentiviral RNA interference (RNAi) system for interleukin–1 beta (IL1B) expressed in elongating porcine embryos. D. J. Mathew*, E. M. Newsom, R. D. Geisert, and M. C. Lucy, *University of Missouri, Columbia.*

Most embryonic loss in pigs occurs during conceptus elongation and attachment. During this time, pig conceptuses increase expression of IL1B but the function of this molecule in embryonic development is unknown. There appear to be at least 2 IL1B genes – the prototypical IL1B cytokine (secreted by macrophages and other immune cells) and an embryonic IL1B (IL1BE) expressed by the pig conceptus. Our ultimate objective is to assess the function of IL1BE by developing an in vivo RNAi lentivirus-based system that specifically knocks down IL1BE in porcine embryos. As a first step, we screened oligonucleotides for their capacity to knock down IL1BE but not IL1B in vitro. Full-length cDNA for IL1B and IL1BE were cloned into an expression vector that contained a luciferase reporter for monitoring RNAi (psi–CHECK1; Promega, Madison, WI). We then identified 8 19 bp oligonucleotides that were complimentary to IL1BE but not IL1B mRNA using the siRNA Target Designer program (Promega). Based on these original sequences, longer oligonucleotides that were designed to form short hairpin RNA (shRNA) were annealed to their complimentary oligonucleotides and inserted into the pGeneClip U1 expression vector (Promega). Baby Hamster Kidney (BHK–21) cells were simultaneously transfected with the psi–CHECK1 vector containing either IL1B or IL1BE and one of 8 shRNA vectors. After 48 h, cells were lysed and assayed for luciferace activity. In cells transfected with the IL1BE, 7 of 8 shRNA decreased ($P < 0.01$) luciferase activity compared with the positive control. Two of the shRNA that knocked down IL1BE did not knockdown IL1B (i.e., they were specific for IL1BE). Luciferase activity was reduced by >90% ($P < 0.001$) by the 2 shRNA specific for IL1BE. Luciferase activity in cells transfected with IL1BE and a vector containing scrambled shRNA was not different ($P > 0.10$) from the positive control. We conclude that IL1BE can be specifically knocked down in vitro by using RNAi. This project was supported by National Research Initiative Competitive Grant no. 2007–35203–17836 from the USDA National Institute of Food and Agriculture.

Key words: embryo, pig, expression

M239 Differential gene expression in liver of lactating (L) and non-lactating (NL) primiparous Holstein cows during early pregnancy. J. Green*, E. Newsom, C. Okamura, and M. Lucy, *University of Missouri, Division of Animal Science, Columbia.*

The objective was to determine the physiological effect of lactation on hepatic mRNA expression in primiparous Holstein cows during early pregnancy. Liver was collected from cows that were either L (n = 22) or NL (n = 18) and were either d 28 (n = 6 L and 6 NL), d 35 (n = 8 L and 6 NL), or d 42 (n = 8 L and 6 NL) of gestation. Hepatic RNA was submitted to the University of Missouri DNA core for microarray analysis (Bovine Genechip; Affymetrix, Santa Clara, CA). Data were analyzed by using JMP Genomics 4.1 (SAS Inst., Cary NC). Data Analyses identified 299 targets that were differentially expressed ($P < 0.001$) between L and NL. Gene lists were analyzed for functional significance by using the iPATH software (Letunic et al. 2008, Trends Biochem Sci. 33:101–3). The L cows had greater hepatic mRNA expression for enzymes involved in gluconeogenesis, cholesterol synthesis, lipid synthesis, and cholesterol metabolism compared with NL cows. Quantitative real time reverse transcription PCR (qRTPCR) assays were used to confirm microarray results. The qRTPCR assays were validated by DNA sequencing of the amplified product and by performing serial dilutions of a single sample to assess efficiency. Based on qRTPCR, there was an effect of lactation because L cows had greater expression of ATP citrate lyase (Acly; $P < 0.02$), acyl-CoA synthetase long-chain family member 1 (Acsl1; $P < 0.06$), acyl-CoA synthetase short-chain family member 2 (Acss2; $P < 0.03$), apolipoprotein A-1 (Apoa1; $P < 0.003$), cytochrome P450scc (Cyp11a1; $P < 0.05$), fatty acid synthase (Fasn; $P < 0.05$), HMG-CoA reductase (Hmgcr; $P < 0.002$), pyruvate carboxylase (Pc; $P < 0.08$), phosphoenolpyruvate carboxykinase 1 (Pck1; $P < 0.001$), stearoyl-CoA desaturase-1 (Scd; $P < 0.01$), and suppressor of cytokine signaling 2 (Socs2; $P < 0.001$) while NL cows had greater mRNA transcript levels of protein phosphatase 1 regulatory subunit 3C (Ppp1r3c; $P < 0.001$). There was no effect of lactation for cyclophilin (housekeeping gene). There were no effects of d of pregnancy on gene expression. In conclusion, lactation had a large effect on gene expression in liver that was not affected by d of pregnancy.

Key words: lactation, metabolism, Holstein

M240 Immunohistochemical evidence for the presence of G protein-coupled receptor 43 in cattle rumen epithelium but not in the pancreatic islets of Langerhans. A. Wang[1], R. M. Akers[2], and H. Jiang*[1], *[1]Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg, [2]Department of Dairy Science, Virginia Tech, Blacksburg.*

Volatile fatty acids (VFAs) are the major products of microbial fermentation in the rumen. Besides serving as substrates for energy generation, VFAs are also known to stimulate rumen development, increase serum insulin and glucagon concentrations, and regulate gene expression in cattle and sheep. The mechanisms underlying these regulatory effects of VFAs are unknown, but recent discovery that VFAs can bind to G protein-coupled receptor 43 (GPR43) and 41 (GPR41) suggests that the regulatory effects of VFAs may be mediated by these receptors in VFA target tissues. As a step toward testing this possibility, we determined whether GPR43 was expressed in bovine rumen wall and the pancreatic islets of Langerhans. Rabbit antiserum against a bovine GPR43 peptide was generated. The specificity of the antiserum for binding to GPR43 was confirmed by Western blotting analysis of recombinant bovine GPR43 protein. Immunohistochemical analyses using this antiserum revealed the presence of GPR43-immunoreactive cells in the epithelium of both adult and newborn cattle rumen, but not in the mucosa, submucosa, or muscle layer. The same immunohistochemical analyses did not reveal any GPR43-immunoreactive cells in the bovine islets of Langerhans or the surrounding exocrine tissue. These data suggest that the effect of VFAs on rumen development in cattle may be mediated by GPR43 in the rumen epithelial cells and that the effects of VFAs on serum insulin and glucagon concentrations, however, unlikely involve binding to GPR43 in the pancreas.

Key words: receptor, rumen, VFA

M241 Effects of protein supplementation during heifer development on reproductive characteristics and success in beef heifers. A. S. Summers*[1], R. A. Cushman[2], S. P. Weber[1], M. L. Spangler[1], and A. S. Cupp[1], *[1]University of Nebraska-Lincoln, Lincoln, [2]USDA-ARS Roman L. Hruska U.S. Meat Animal Research Center, Clay Center, NE.*

A 2-yr study was conducted to determine the effects of feeding different protein supplements during heifer development on reproductive traits and performance. Our hypothesis was that protein supplementation would enhance reproductive performance in heifers with below average reproductive characteristics. Heifers from 2 herds at the University of Nebraska Animal Development and Research Center were used with heifers (Angus and Angus x Simmental hybrids) from the teaching herd (n = 56) being fed a modified dried distillers grain (MOD) supplement at 1.36 kg/d from weaning (mid September) through May. Heifers (MARC III x Red Angus) from the physiology herd (n = 173) were randomly assigned to groups and fed dried distillers grain-based (DDG) or corn gluten feed-based supplement (CFG) offered at 0.59% and 0.78% BW, respectively, from mid-November through May. Supplements were formulated to be isocaloric but differed in undegradable protein. All heifers were fed ad libitum meadow hay through winter while grazing dormant pasture. Prior to breeding, heifers were transrectally ultrasounded to determine antral follicle count (AFC), uterine horn diameter (UHD), ovarian size, presence of a CL, and to determine reproductive tract score (RTS). Heifers developed on MOD diet were 23 d older ($P < 0.01$) and had greater ($P < 0.01$) ovarian area, total AFC, and percent of CL present compared with other groups. However, MOD heifers had lower ($P < 0.01$) UHD compared with other groups. There was no difference ($P = 0.19$) in proportions of heifers bred to A.I.; however, overall pregnancy rates were lower ($P < 0.01$) for MOD compared with other groups. There was a positive effect of small follicle counts on RTS [RTS = 3.9 + 0.01(small follicles); $P < 0.01$, r2 = 0.04] and AFC [AFC = 4.9 + 0.8(small follicles); $P < 0.01$, r2 = 0.86]. Although MOD and DDG diets were similar, results from these groups varied, suggesting that age led to some variation in response to these supplements. We also conclude that RTS and AFC are influenced by small follicle counts. USDA is an equal opportunity provider and employer.

Key words: antral follicle counts, beef cattle, reproduction

M242 Effect of parity on thermal response and energy balance (EB) of sows housed at 24-27°C during lactation. W. R. Martin*, T. J. Safranski, D. E. Spiers, and M. C. Lucy, *University of Missouri, Columbia.*

An earlier study showed that parity 1 sows (P1) were more sensitive to heat stress compared with greater parity sows as indicated by rectal temperature (RT) and respiration rate (RR). To confirm this relationship, a second trial was designed to measure RT and RR of P1 (n =

7), parity 2 (P2; n = 4) and parity 6 (P6; n = 2) sows in one farrowing room. Sows entered 1wk before farrowing and remained until 4 d after weaning. Ear temperature (ET), shoulder temperature (ST), RT and RR were measured daily at 1400 h. Room temp was 24–27°C. Pregnant sows housed in the room served as a non-farrowed control group. Sow BW and litter wt were measured weekly. Feed offered and refused (kg) were recorded. EB (Mcal ME) was estimated from BW, litter wt, and feed consumed. There were effects of parity ($P < 0.05$) and d of lactation (DOL; $P < 0.001$) on RT. The RT increased after farrowing (38.2 ± 0.1°C on d −1 to 39.1 ± 0.1°C on d 0) and remained elevated during lactation (38.8 ± 0.1 to 39.3 ± 0.1°C). Before farrowing, RT was unaffected by parity ($P > 0.1$; 38.3 ± 0.1°C) but during lactation, RT was greatest in P1 sows (39.4 ± 0.1, 39.0 ± 0.1, 38.8 ± 0.2°C for P1, P2, and P6). Despite greater RT during lactation, P1 sows did not have greater RR (50 ± 1 breaths per min; BPM) or ET (37.3 ± 0.1°C), but ST was greater (36.5 ± 0.1, 36.2 ± 0.1, and 36.2 ± 0.2°C for P1, P2, and P6; $P < 0.05$). Control sows (pregnant, not lactating) had lesser RT (38.3 ± 0.1°C; $P < 0.001$), RR (41 ± 2 BPM; $P < 0.005$), ET (35.9 ± 0.1°C; $P < 0.001$), and ST (34.8 ± 0.2°C; $P < 0.001$) compared with lactating sows. There was an effect of DOL on EB during lactation, but parity had no effect. Sow EB increased from d 0 (−8.5 ± 1.2 Mcal ME) to d 5 (−1.9 ± 1.2 Mcal ME), but then decreased to d 9 (−3.8 ± 1.2 Mcal ME) and then achieved neutrality by d 11. Previous trial results showing greater RT in younger sows were confirmed. Greater RT in younger sows may be due to thermal insensitivity as result of metabolic heat production for growth. This may partially explain summertime infertility in P1 sows. This project was supported by National Research Initiative Competitive Grant no. 2007–55203–18261 from the USDA National Institute of Food and Agriculture.

Key words: sow, heat stress, parity

M243 Effects of progesterone concentrations at the end of a fixed-time AI protocol and time of administration of PGF2α in fixed-time AI and ET protocols in lactating dairy cows. M. Pereira[1], A. Rodrigues[1], T. Martins[1], F. Aono[1], P. Borges[2], T. Guzella[1], C. Sanchez[1], M. Veras[2], F. Aragon[2], and J. L. M. Vasconcelos*[1], *[1]FMVZ-UNESP, Botucatu, SP, Brazil, [2]Pioneiros Veterinary Clinic, Carambei, PR, Brazil.*

Two experiments were performed in lactating Holstein cows. Experiment 1 (n = 565) evaluated the influence of progesterone (P4) concentrations at removal of the P4 intravaginal device (CIDR) on pregnancy rates of cows assigned to the following estrous synchronization protocol + fixed-time AI: d 0 – 2 mg of estradiol benzoate and insertion of a new or used CIDR (previously used once or twice, originally containing 1.9 g of P4); d 7 – 25 mg PGF2α injection; d 8 - removal of the CIDR and administration of 1 mg of estradiol cypionate; d 10 – fixed-time AI. Blood samples were collected concurrently with CIDR removal for P4 analysis. Experiment 2 (n = 610) evaluated if administration of PGF2α at d 7 (PG7) or d 8 (PG8) of the same protocol utilized in Exp. 1 affects pregnancy rates in cows submitted to fixed-time AI or ET. Data from Exp. 1 and 2 were analyzed with the PROC LOGISTIC of SAS. In Exp. 1, the number of the CIDR use did not affect ($P > 0.05$) P4 concentrations at CIDR removal (1.47, 1.29 and 1.16 ng/mL of P4 for new, used once, or used twice CIDR) or pregnancy rates (27, 26, and 32% of pregnant cows/total cows for new, used once, or used twice CIDR). There was no effect ($P > 0.05$) of P4 concentration on d 8, independently of CIDR usage, on subsequent pregnancy rates (P4 < 1.0 ng/mL = 27% pregnant cows/total cows; P4 between 1.0 and 2.0 ng/mL = 28% pregnant cows/total cows; and P4 > 2.0 ng/mL = 32% pregnant cows/total cows). In Exp. 2, PG7 cows had greater ($P < 0.05$) pregnancy and conception rates to fixed-time AI and ET, respectively, compared with PG8 cows (35 vs.. 25% pregnant cows/total cows at fixed-time AI, respectively; 54 vs.. 46% pregnant cows/transplanted cows at fixed-time ET, respectively). In conclusion, in synchronization protocols where age of follicles are similar, the interval between beginning of circulating P4 decrease and ovulation may affect pregnancy rates in lactating dairy cows.

Key words: progesterone, prostaglandin, dairy cows

M244 Period of dominance of the ovulatory follicle influences conception rates in Nelore pubertal heifers detected in estrus. T. Martins[1], A. Rodrigues[1], F. Aono[1], M. Pereira[1], R. Peres[2], H. Graff[2], E. Carvalho[2], and J. L.M. Vasconcelos*[1], *[1]FMVZ-UNESP, Botucatu, SP, Brazil, [2]Agropecuaria Fazenda Brasil, Nova Xavantina, MT, Brazil.*

Length of dominance of the ovulatory follicle and exposure to estradiol during proestrus can affect fertility in beef females. The aim of this study was to compare intravaginal progesterone devices (CIDR; containing 1.9 g of progesterone) non-previously (CIDR1) or previously used for 18 d (CIDR3) during estrous synchronization, as well as effects of timing of CIDR removal on conception rates of pubertal Nelore heifers. Cycling Nelore heifers (n = 705) were randomly assigned to receive on d 0 either CIDR1 or CIDR3 and 2 mg of estradiol benzoate. On d 7 all heifers received 12.5 mg of PGF2α and were assigned within CIDR1 and CIDR3 to CIDR removal on d 7 (D7; n = 335) or d 9 (D9; n = 370). Estrus detection was performed twice daily after CIDR removal and heifers were inseminated 12 h after being detected in estrus. At insemination, the largest follicle was measured by transrectal ultrasonography. Pregnancy diagnosis was performed on d 61 also via transrectal ultrasonography. Data were analyzed with PROC LOGISTIC and PROC MIXED of SAS. Conception rates were not affected by CIDR use ($P > 0.05$) but were affected ($P < 0.05$) by timing of CIDR removal (57.8 vs.. 66.5% of pregnant heifers/inseminated heifers for D7 and D9, respectively). Estrus detection rate was 60.9% for D7 and 67.0% for D9 ($P < 0.10$). Follicle diameter at AI was affected ($P < 0.01$) by CIDR use (11.4 vs.. 12.0 mm for CIDR 1 and CIDR3, respectively). Further, follicle diameter was greater for cows assigned to CIDR3 and removal on d 9 ($P < 0.05$) compared with all other treatment combinations. Interval between CIDR removal and heat detection was also affected ($P < 0.01$) by CIDR use (3.62 vs.. 2.92 d for CIDR1 and CIDR3, respectively) and timing of CIDR removal (3.71 vs.. 2.83 d for D7 and D9, respectively). According to these results, variation in the period of dominance of the ovulatory follicle influences fertility of heifers inseminated after estrus detection.

Key words: conception rates, Nelore heifers, progesterone

M245 Impacts of L-arginine on ovarian function and reproductive performance at the time of maternal recognition of pregnancy in ewes. C. Schauer*[1], C. Saevre[1,2], A. Meyer[2], M. VanEmon[1,2], J. Kirsch[2], M. Kapphahn[2], J. Luther[3], J. Caton[2], and D. Redmer[2], *[1]Hettinger Research Extension Center, North Dakota State University, Hettinger, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Department of Animal and Food Science, University of Wisconsin-River Falls, River Falls.*

Objectives were to determine if arginine supplementation surrounding the time of maternal recognition of pregnancy enhances ovarian function and minimizes early reproductive losses. Ewes received L-arginine HCL (equivalent to 27 mg of L-arginine/kg of BW; ARG; n = 47) or saline (CON; n = 47) i.v. once daily from d 9 to d 14 following

estrus (d 0). Daily blood samples were obtained from a subset of 10 ewes/group to assess progesterone (P4) concentrations and at −0.5, 0, 0.5, 1, 2, 4, 6, and 8 h following treatment on d 10 to determine serum amino acid concentrations. Reproductive losses were determined with B–mode ultrasonography on d 25, 45, and 65 of gestation. On d 10, serum concentrations of arginine (nmol/mL) were elevated in ARG vs.. CON ewes at 0, 0.5, 1, 2, and 4 h ($P < 0.001$), but were similar ($P \geq 0.70$) at −0.5, 6, and 8 h. Despite similarities in the number of corpora lutea (CL) per ewe (ARG, 1.69 ± 0.12 and CON, 1.67 ± 0.16; $P > 0.05$), serum progesterone concentration (ng/mL) was greater in this subset of CON compared with ARG ewes on d 9 ($P < 0.02$) and 10 ($P < 0.005$), but similar for the remaining treatment period ($P \geq 0.06$). On d 12, there were no differences in pulsatility index and resistance index in those ewes treated with arginine in the ovarian hilus or the CL ($P > 0.05$). Treatment with arginine increased overall pregnancy rate at d 25 (ARG, 55% and CON, 30%). Pregnant ewes were similar in CL number per ewe (ARG, 1.69 ± 0.12 vs.. CON, 1.67 ± 0.13; $P > 0.05$) and embryo number (ARG, 1.62 ± 0.12 vs.. CON, 1.53 ± 0.13; $P > 0.05$) at d 25 of gestation. As pregnancy progressed to d 45, similar ($P > 0.05$) number of embryos per ewe were observed in pregnant ARG ewes (1.45 ± 0.14) vs.. pregnant CON (1.50 ± 0.15) with overall pregnancy rate remaining greater ($P \leq 0.02$) in ARG (47%) compared with CON (26%). In summary, treatment with arginine surrounding the time of maternal recognition of pregnancy may have prevented pregnancy loss, but did not enhance ovarian hemodynamics or progesterone concentration.

Key words: L-arginine, ovarian hemodynamics, sheep

M246 Failure of differences in prepubertal dietary intake to affect ovarian development in pubertal beef heifers. S. E. Echternkamp*, D. R. Eborn, and R. A. Cushman, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Developing replacement heifers on lower energy diets to a lighter body weight at first breeding can reduce input costs but may impede follicular development and onset of puberty. The objective was to determine whether lower dietary intake prepubertally impedes ovarian development in purebred or crossbred heifers. In 2009 and 2010, 8-mo-old Angus and composite MARC II heifers were assigned equally by body weight and genetic line (n = 120 / line) to receive either a low- (LE) or high- (HE) energy diet to achieve an ADG of 0.45 or 0.9 kg/d for 180 d or 55 vs.. 65% of mature BW at 14 mo of age. At 14 mo, heifers were monitored twice daily for estrus behavior for 21 d. Total number of antral follicles (AFC), ovarian length and height, and preovulatory follicle diam. were measured by transrectal ultrasonography at about 12 h after estrus; corpus luteum (CL) diam. was measured 7 to 14 d later. Uterine horn diam. was only measured in 2010. Data were analyzed by ANOVA with diet, line, and year as independent variables and their 2-way interactions. At 14 mo, HE heifers were heavier (419.4 vs.. 364.9 ± 7.1 kg) and fatter (6.8 vs.. 5.5 ± 0.1 BCS) than LE heifers ($P < 0.01$); LE heifers were 11% heavier in 2010 than 2009 (diet x year; $P < 0.01$). Puberty occurred in 94.6% of heifers by 14 mo of age. Size of preovulatory follicle (13.8 ± 0.2 mm), AFC (22.2 ± 0.6), ovary (length = 26.5 ± 0.3 mm; height = 15.1 ± 0.2 mm), CL (19.3 ± 0. Three mm), and uterine horn diam. (11.6 ± 0.2 mm) did not differ between HE and LE, but follicle diam. (14.3 vs.. 13.2 ± 0. Two mm; $P < 0.01$) and ovarian length (26.4 vs.. 25.3 ± 0.4 mm; $P = 0.07$) were greater for MARC II vs.. Angus heifers. AFC was correlated with ovarian length ($r = 0.56$; $P < 0.01$), and CL diam. was correlated with preovulatory follicle diam. ($r = 0.34$; $P < 0.01$). Results indicate that AFC and ovarian size in pubertal heifers are not influenced by differences in prepubertal growth and body condition associated with diet. USDA is an equal opportunity provider and employer.

Key words: beef heifers, diet, ovarian follicles

M247 Follicular fluid composition of the preovulatory follicle in beef cows grazing different forage allowances of native pastures. M. Carriquiry*[1], P. Soca[1], A. C. Espasandín[1], A. Meikle[2], and C. Viñoles[3], *[1]School of Agronomy, UdelaR, Montevideo, Uruguay, [2]School of Veterinary Sciences, UdelaR, Montevideo, Uruguay, [3]National Research Institute for Agriculture, Tacuarembó, Uruguay.*

The follicular microenvironment has been shown to play a critical role in determining follicular fate. To evaluate the effect of long-term nutrition on metabolite follicular fluid composition in beef cows on grazing conditions, multiparous cows (Angus, Hereford and F1 crossbred, n = 32) at 2 forage allowances of native pastures throughout the year (6 vs.. 10 kgDM/100kgBW/d; LO vs.. HI) were used in a complete randomized block design. At the end of the third year, at 178 ± 15 d postpartum, cows were synchronized with 2 prostaglandin (PG) injections 11 d apart and slaughtered 32 ± 1 h after the last PG injection. Cows were classified as cyclic or in anestrus based on the presence of a corpus luteum on the ovaries. Ovaries of cyclic cows were collected (n = 16 and n = 12 for HI and LO, respectively) and largest follicle present on the ovarian surface was dissected, and follicular fluid was aspirated for metabolite analyses. At slaughter, cow BCS did not differ ($P = 0.32$) between groups and averaged 3.9 ± 0.08. The preovulatory follicle was larger for HI than LO cows (13.1 ± 0.8 vs.. 10.3 ± 1.3 mm; $P < 0.05$). Glucose (23.1 vs.. 25.9 ± 5.4 mg/dL), NEFA (0.79 vs.. 0.57 ± 0.11 mmol/L) and urea (19.6 vs..19.1 ± 2.4 mg/dL) concentrations in follicular fluid did not differ ($P > 0.74$) due to forage allowance. However, follicular fluid cholesterol concentrations were greater in LO than HI cows (112 vs.. 79 ± 8 mg/dL, $P = 0.01$). Glucose and cholesterol concentrations increased ($P < 0.02$) with size of the preovulatory follicle (3.3 ± 1.3 mg/dL of glucose and 6.4 ± 1.8 mg/dL of cholesterol for each mm of increase in follicle size). Results showed minor effects of long-term nutrition in follicle fluid composition of the preovulatory follicle of beef cows grazing different forage allowances of native pastures.

Key words: cattle, grazing, ovary

M248 Longitudinal assessment of the somatotropic axis in free-ranging, juvenile Steller sea lions. K. D. Hebert*[1], J. P. Richmond[1,2], L. D. Rea[3], and S. A. Zinn[1], *[1]University of Connecticut, Storrs, CT, USA, [2]University of North Florida, Jacksonville, FL, USA, [3]Alaska Department of Fish and Game, Fairbanks, AK, USA.*

The decline of the Western population (144 degrees west longitude) of Steller sea lions is hypothesized to be the result of impaired nutritional status and decline of growth rate, especially in juveniles, and subsequent natality. Because changes in components of the somatotropic axis can be predictive of nutritional status and growth rate in this species, 2 groups of free-ranging juvenile Steller sea lions were captured in Prince William Sound, AK. Group 1 (n = 30) was initially captured at 5 mo and recaptured at 10 mo of age, whereas group 2 (n = 9) was captured at 7 and 8 mo of age. At capture, animals were anesthetized, age estimated, and blood and BW collected. Concentrations of GH and IGF-I were quantified (ng/mL) using RIA and IGFBP-2 and −3 were quantified [Arbitrary Units, (AU)] using Western ligand blots. Data were analyzed using the Mixed Procedure in SAS. Mass of Steller sea lions increased ($P < 0.01$) with age from 69 ± 1.3 kg at 5 mo to 100

± 2.8 kg at 10 mo (group 1) and 93 ± 5.8 kg at 7 mo to 101 ± 5.7 kg at 8 mo (group 2). Concentrations of IGFBP-2 decreased with age from first to second capture (group 1; 37.8 ± 2.5 vs.. 36.0 ± 2.5; group 2; 43.7 ± 4.8 vs.. 39.8 ± 4.4 AU; $P < 0.01$) and across all animals GH, IGF-I and IGFBP-3 averaged 1.6 ± 0.1 ng/mL, 165.7 ± 10.4 ng/mL, 304.0 ± 13.4 AU respectively, but there was no effect ($P > 0.1$) of age on concentrations of these hormones. Greater concentrations of IGFBP-3 were positively associated with greater growth rate ($P = 0.06$) across all animals. In group 2, the increase in IGF-I concentrations between captures was positively correlated with growth rate ($P < 0.05$), indicating that changes in IGF-I and IGFBP-3 may be useful indicators of growth rate in juvenile Steller sea lions. These data provide a more detailed description of the changes in the components of the somatotropic axis and their relationship with growth rate in juvenile Steller sea lions, and may provide insight into survival and the continued decline of the Western population.

Key words: somatotropic axis, Steller sea lions, insulin-like growth factor binding proteins

M249 Analysis of bovine liver transcriptomics data due to level of prepartal dietary energy using two bioinformatics approaches. K. Shahzad*, M. Bionaz, and J. J. Loor, *University of Illinois, Urbana.*

We used a newly-developed approach (dynamic impact analysis, DIA) that allows visualizing the dynamic adaptations of pathways, and the well-established enrichment analysis using DAVID to evaluate at the transcriptomic level the impact of prepartal plane of energy intake [overfed (OF) or restricted (RE)] on biological pathways in liver. Both approaches rely on freely-available pathway databases from the KEGG database. Analysis of variance with a false discovery rate (FDR) correction resulted in 4,111 genes with a time × diet interaction (FDR <0.05, DEG). For the DIA analysis the whole data set with Entrez gene IDs, FDR, fold-change, and post-hoc *P*-value between the 2 treatments at each time point were uploaded. For the DAVID analysis a list of up-and downregulated genes with Entrez Gene ID was uploaded. A cut-off of FDR = 0.05 and *P* -value = 0.05 was applied in both approaches. Among DEG between OF vs. RE, DAVID analysis uncovered oxidative phosphorylation as the most significantly-enriched (FDR < 0.05) pathway followed by ribosome and proteasome. Without multiple correction (i.e., simple *P*-value < 0.05) other enriched pathways included fatty acid metabolism, glycan biosynthesis, lysosome, and complement, which were more induced in RE vs. OF; whereas, base excision repair, ubiquitination, and ECM receptor were more induced in OF vs. RE. The DIA approach revealed that RE vs. OF led to a higher utilization of glucose, amino acids (AA), and fatty acids (FA) to produce energy (e.g., more impacted/induced TCA cycle, oxidative phosphorylation, and FA metabolism together with degradation of most of AA). Dietary OF vs. RE resulted in large induction of cell cycle, protein turnover, glycan metabolism, with larger ECM receptor activity (e.g., glycan degradation, ubiquitin, Wnt and Notch signaling pathways). Overall, results from the 2 bioinformatics approaches indicated that OF vs. RE prepartum increased liver proliferation and ECM components while reducing utilization of energy and protein synthesis. This adaptation might partly explain the greater liver lipid accumulation due to OF vs. RE postpartum.

Key words: systems biology, pathway analysis, transition cow

M250 Follicle-stimulating hormone induces the canonical WNT/beta-catenin pathway in bovine granulosa cells. B. I. Castañon*, A. D. Stapp, L. J. Spicer, C. A. Gifford, and J. A. Hernandez Gifford, *Oklahoma State University, Stillwater.*

The WNTs are a family of secreted glycoproteins that evoke a response by interacting with specific 7 transmembrane frizzled (FZD) receptors. In the canonical WNT/β-catenin pathway, WNT binding to a FZD receptor leads to inactivation of the β-catenin (CTNNB1) degradation complex. Disruption of the destruction complex allows CTNNB1 to accumulate in the cytoplasm and translocate to the nucleus where it activates transcription by contact with T-cell factor and lymphoid enhancer-binding factor. Several WNT and FZD transcripts are expressed at defined stages of follicular development in the adult ovary. However, the role of the WNT/CTNNB1 pathway in folliculogenesis remains to be elucidated. This study evaluates FSH regulation of the WNT signaling pathway components that contribute to steroid production in bovine granulosa cells. Granulosa cells were isolated from small ovarian follicles (1–5 mm) and plated ($2.3–4 \times 10^5$ cells/35 mm dish) in DMEM/F12 medium. At 48 h after plating, cells were incubated in the presence or absence of 100 ng/ml FSH for 24 or 48 h (n = 6). Expression of *WNT2* mRNA was induced 3.75 (±0.68) fold after 24 h of FSH stimulation compared with controls (0.12 ± 1.09; $P < 0.05$). Likewise, at 48 h *WNT2* tended to be induced (3.14 vs. 1.00 ± 1.03; $P < 0.06$) with FSH treatment. Analysis of other members of the WNT/CTNNB1 signaling pathways did not demonstrate hormone-regulated expression. Granulosa cells and follicular fluid were collected from large mid-luteal antral follicles (8–22 mm) and classified as estrogen active (n = 8) (>25 pg/mL) or estrogen inactive (n = 5). Nuclear and cytoplasmic protein fractions were enriched and CTNNB1 was analyzed using Western blot. Preliminary evidence indicates estrogen active follicles have greater amounts of nuclear CTNNB1 compared with estrogen inactive follicles. Together, these data demonstrate FSH regulates WNT signaling pathway components which are important in granulosa cell steroidogenesis.

Key words: WNT, beta-catenin, follicle-stimulating hormone

M251 Effects of organic versus inorganic trace mineral supplementation on bull semen quality before and after freezing. M. P. Rowe*, C. L. Williams, R. J. Page, T. D. Lester, C. F. Rosenkrans, E. B. Kegley, J. G. Powell, and R. W. Rorie, *University of Arkansas, Fayetteville.*

Limited information is available on the effects of organic trace mineral supplementation on bull fertility. The objective of this study was to evaluate the effect of trace mineral supplementation on bull semen quality before and after freezing, as measured by computer-assisted sperm analysis (CASA). Angus and Balancer bulls were assigned to inorganic (n = 9) and organic (n = 10) trace mineral treatments, based on semen quality, breed, body weight, and age. The bulls were maintained in a dry lot pen and fed mixed grass hay. Three times a week bulls were individually fed a grain supplement that served as the carrier for treatments containing trace mineral for 123 d (May to September). Treatments were supplemental Zn (450 mg/d), Cu (150 mg/d), Co (12 mg/d), Mn (300 mg/d), Se (3 mg/d), and I (5 mg/d) as either inorganic or as a portion of the same levels as organic sources. Starting on d 60, semen was collected by electro-ejaculation on wk 1, 4, and 8. Semen was evaluated by CASA for percent motile and progressive sperm within 5 min of each collection. Sperm was extended, slowly cooled to 4°C, loaded into 0.5 mL straws, and frozen in liquid nitrogen. After thawing, semen was washed to remove extender and then re-suspended in TALP media. Semen was then evaluated using CASA at 0 and 2 h post-thaw. Data was analyzed by treatment, week and their

interaction, using PROC GLM. Week and treatment by week were not significant ($P > 0.05$), so they were dropped from the analysis. At collection, motile (69.1 vs. 55.2%) and progressive (50.3 vs. 38.5%) sperm were greater ($P < 0.05$) for bulls in the organic than the inorganic groups. After thawing, motile (16.3 vs. 7.9%) and progressive (8.9 vs. 4.1%) sperm were also higher ($P < 0.05$) for semen from bulls in the organic vs. inorganic treatments, respectively. At 2 h post-thaw, motile sperm remained higher (8.5 vs. 3.7% $P < 0.05$) but progressive sperm (4.2 vs. 1.7%) was similar ($P > 0.05$) for the organic and inorganic groups, respectively. Although post-thaw motility was low for both treatments, results suggest organic trace mineral supplementation may improve bull semen quality.

Key words: fertility, bulls, trace minerals

M252 Exposure of beef females to the biostimulatory effects of bulls prior to AI. K. E. Pfeiffer*[1], J. A. Binversie[1], J. D. Rhinehart[2], and J. E. Larson[1], *[1]Mississippi State University, Mississippi State, [2]University of Tennessee, Nashville.*

The objective of this study was to evaluate the biostimulatory effect of bull exposure on the expression of estrus and pregnancy rate to AI in cattle. Beef heifers (n = 86) and cows (n = 193) during 2 consecutive yr were allocated to one of 3 treatments: 1) no bull exposure (CON; n = 95), 2) exposure to a bull with a surgically deviated penis for 21 d before AI (SB; n = 88), or 3) exposure to a vasectomized bull for 21 d before AI (VB; n = 96). The SB treatment provided the physical presence of the bull but prevented intromission whereas the VB treatment allowed for intromission and deposition of seminal plasma but not spermatozoa. The estrous cycles of all females were synchronized using the Hybrid-Synch+CIDR protocol ($GnRH^{+}$CIDR insertion-7 d-CIDR removal+$PGF_{2\alpha}$, visual detection of estrus 3 × daily with AI 12 h later for 82 h, and clean-up TAI+GnRH at 82 h). Blood samples were collected on d −17 and −7 relative to the initial injection of GnRH and analyzed for concentrations of progesterone to determine cyclicity status at the initiation of the experiment (at least one sample ≥1 ng/mL). Pregnancy was detected by transrectal ultrasonography on d 35 post-AI. At the onset of the experiment, 75.7% of heifers and 86.1% of cows were cycling. The percentages of females that displayed estrus after CIDR removal were increased ($P < 0.001$) in Year 1 (52.3%) compared with Year 2 (23.1%) as well as increased ($P < 0.05$) in nulliparous (52.3%) compared with primiparous and multiparous females (26.0 and 31.5%, respectively). The percentages of females that displayed estrus were similar ($P = 0.15$) among treatments (31.6, 39.8, and 39.6% for CON, SB, and VB, respectively). Pregnancy rates were increased ($P < 0.01$) in Year 2 (55.8%) compared with Year 1 (42.4%) and were increased ($P < 0.05$) in females treated with CON and SB (49.5 and 59.1%, respectively) compared with females treated with VB (40.6%). In conclusion, a similar percentage of females among treatments displayed estrus during the 82 h detection period but pregnancy rates were decreased in females exposed to a vasectomized bull compared with those exposed to either no bull or a bull presence only.

Key words: beef cattle, biostimulatory effects, bull exposure

M253 Effect of selenium and a glucogenic precursor on fertility in Creole Rodeo cows synchronized with CIDR, PGF2α, eCG, and GnRH. C. Sanchez-Arcineiga*, J. A. Ramirez-Godinez, D. Dominguez-Diaz, A. Flores-Mariñelarena, E. Santellano-Estrada, J. A. Grado-Ahuir, G. Corral-Flores, and L. A. Borunda-Pacot, *Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico.*

The objective was to evaluate the effect of calcium propionate (CaP) and sodium selenium (Se) on average daily gain (ADG), backfat thickness (BF), body condition (BCS) and pregnancy rate (PR) in Creole Rodeo cows (CC) supplemented for 60 d with 2 Kg of a concentrate (29 ± 1.6% CP) every other day. Forty-five dry CC were randomly assigned to T1 (n = 11), concentrate only; T2 (n = 11), concentrate + 10.95 mg of Se/50 Kg BW; T3 (n = 11), concentrate + 100 g of CaP and T4 (n = 12), 10.95 mg of Se/50 Kg of BW + concentrate + 100 g of CaP. Cows selected across treatments based on the presence of a palpable corpus luteum (n = 34, 9 from T1, 7 from T2, 9 from T3, and 9 from T4) received a 8 d CIDR. Later, 25 mg of Lutalyse were injected at CIDR removal, and 18 cows (5 from T1, 3 from T2, 6 from T3, and 4 from T4) were treated with 400 IU of eCG. All CC received 100 mg of GnRH 56h after CIDR removal, and fixed-time AI (TAI). Data were analyzed under a 2x2 factorial design with repeated measures. For PR a chi-squared test was used to analyze the effect of eCG. BCS was similar ($P > 0.05$) between treatments, CaP supplementation had a negative effect ($P < 0.0001$) on ADG over time (T) and the interaction CaP*T was significant ($P = 0.0192$). BF was similar between treatments ($P > 0.05$). The use of Se had no effect on BCS, ADG and BFT. Supplementing Se or CaP had no effect ($P > 0.05$) on PR; similarly, the use of eCG at CIDR removal did not improved fertility (44.1% and 55.8%, $P > 0.05$, respectively) in GnRH treated CC at TAI.

Key words: Creole cattle cow, calcium propionate, eCG

M254 Effects of heat stress on skeletal muscle insulin responsiveness in lactating Holstein cows. L. C. Cole[1], M. V. Skrzypek[1], S. R. Sanders[1], M. R. Waldron[3], L. H. Baumgard[2], and R. P. Rhoads*[1], *[1]University of Arizona, Tucson, [2]Iowa State University, Ames, [3]University of Missouri, Columbia.*

Multiparous cows (n = 12; parity = 2; 136 ± 8 DIM, 560 ± 32 kg BW) housed in climate chambers were fed a TMR consisting primarily of alfalfa hay and steam-flaked corn. Cows were subjected to 2 experimental periods (P): 1) thermoneutral (TN) conditions (18°C, 20% humidity) with ad libitum intake for 9d and 2) either heat-stress (HS) conditions (cyclical temperature 31.1–38.9°C, 20% humidity: min THI = 73, max THI = 80.5) fed for ad libitum intake (n = 6), or TN conditions, pair-fed (PF) with a HS animal (n = 6) for 9d. Rectal temperature (Tre) and respiration rate (RR) were measured thrice daily at 0430, 1200 and 1630h. To evaluate skeletal muscle insulin responsiveness, biopsies were obtained immediately before and after an insulin tolerance test (ITT). Insulin receptor (IR), insulin receptor substrate (IRS), Akt/protein kinase B (AKT) and phosphorylated AKT (P-AKT) were measured by Western blot analyses. During P2, HS cows had ($P < 0.01$) a 1.48°C increase in Tre and a 2.4-fold increase in RR compared with PF cows. HS reduced ($P < 0.01$) DMI by 8 kg/d and by design PF cows had similar intake reductions. Milk yield was decreased similarly (30%) in HS and PF cows and both groups entered into a similar (−4.5 Mcal/d) calculated negative energy balance during P2. Compared with P1 ($P < 0.05$), basal glucose levels increased (5%) in PF cows, but decreased (5%) in HS cows during P2. The ITT caused a greater glucose disposal in P1 compared with P2 ($P < 0.05$), but did not differ between environments in P2. Protein abundance of the IR, IRS and AKT remained stable between periods and environments. Insulin increased P-AKT in each period ($P < 0.05$), but this response tended to decline in P2 for PF animals ($P = 0.10$), but not during HS. These results indicate that mild insulin resistance during HS may be related to reduced nutrient intake. Moreover, a reduction in skeletal muscle insulin responsiveness may stem from a post-receptor signaling defect.

Key words: heat stress, lactation, insulin

M256 Effects of heat-stress and fresh or frozen semen on reproductive efficiency in dairy cows treated with rbST throughout lactation. E. Sepúlveda*[1], O. Ange-García[1], CA Meza-Herrera[2], FG Veliz[1], and M. Mellado[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Universidad Autonoma Chapingo, Bermejillo, Durango, México.*

The objective of this study was to assess the effect of high ambient temperature and the use of fresh or frozen semen on reproduction performance of dairy cows in a hot arid environment. Reproductive variables (n = 18,037 services) of a large Holstein dairy herd in northern Mexico were evaluated with respect to the average temperature-humidity index [(ITH = (0.8 x temperature + (relative humidity/100) x (temperature - 14.4) + 46)] of the 1 and 3 d before breeding, the day of breeding, and 1 and 3 d following breeding. Increased ITH from < 70 to > 95 was associated with a decrease in pregnancy rate from 47% to 26%. Pregnancy rates for cows serviced on days with an ITH 85–90 but cooler temperatures before breeding were 6 percent points higher than cows exposed to higher ITH before breeding. Pregnancy rates for cows serviced on days with an ITH 80-85 but cooler temperatures before breeding were 3-4 percent points higher than cows exposed to higher ITH before insemination. Pregnancy rates for cows serviced on days with an ITH 75-80 but cooler temperatures before breeding did not differ compared to cows exposed to higher ITH before insemination. With ITH cooler the days after insemination pregnancy rates were also higher for all ITH classes the day of breeding. Pregnancy rates were higher ($P < 0.05$) from January to March compared with all other months of the year. On the other hand, the average number of inseminations per pregnancy was higher from May to July (3.0-3.4) than from all other months of the year (2.1 to 3.0). Pregnancy rate was higher (36 vs. 28%) with insemination with fresh semen (natural mating) than frozen semen, although this difference was noted only during the warmest period of the year. It was concluded that the climatic conditions of the site where this dairy operation is located, drastically hampers the reproductive performance of Holstein cows subjected to three milking and treated with somatotropin throughout lactation. This data also show that natural service markedly increases pregnancy rate during the warm months of the year, compared to AI with frozen semen.

Key words: heat stress, pregnancy rate, natural service

M257 Expression patterns of eNOS in 13 different tissues shows a new isoform in bovine brain stem. M. De Donato*[1], M. A. Adefenwa[1,2], and I. G. Imumorin[1], *[1]Dept of Animal Science, Cornell University, Ithaca, NY, [2]Dept of Cell Biology and Genetics, University of Lagos, Lagos, Nigeria.*

Endothelial nitric oxide synthase (eNOS), along with inducible nitric oxide synthase (iNOS) and neuronal nitric oxide synthase (nNOS), catalyze the generation of nitric oxide, a reactive free radical which acts as a biologic mediator in several processes, including neurotransmission and antimicrobial and antitumoral activities. Expression of eNOS mRNA is restricted to the endothelial cell layer of arterial blood vessels, and is a critical mediator of cardiovascular homeostasis through regulation of the diameter of blood vessels and maintenance of an antiproliferative and antiapoptotic environment in the vasculature. Here we report the expression pattern of eNOS in 13 different bovine tissues as a first step to study possible association of different isoforms with animal performance and health. We used semiquantitative PCR to assess expression with specific primers that amplified exons 5 and 6, with GAPDH as control. Similar expression was detected in cerebellum, cerebral cortex, heart, skeletal muscle, lung, kidney, spleen, liver, pancreas, stomach, placenta and ovary. However, in brain stem tissue, a larger fragment, which represents the unspliced section of exon 5, intron 5 and exon 6, was the major expressed isoform, with low expression of the smaller isoform. Small amounts of this larger isoform were also seen in the cerebral cortex, skeletal muscle, kidney, placenta and ovary. The presence of this isoform as a major protein product in the brain stem could indicate a more specialized function of the gene in this tissue. Further studies will be needed to confirm this observation and compare differences in the function of this protein.

Key words: eNOS, bovine, brain stem

M258 Analysis of bovine adipose transcriptomics data during the transition from pregnancy to early lactation using two bioinformatics approaches. K. Shahzad*[1], J. Sumner-Thomson[2], J. P. McNamara[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Washington State University, Pullman.*

We used a newly-developed approach (dynamic impact analysis, DIA) that allows visualizing the dynamic adaptations of pathways, and the well-established enrichment analysis using DAVID to evaluate the impact of change in physiological state on biological pathways in adipose tissue of Holstein dairy cattle. Both approaches rely on freely available pathway information from the KEGG database. RNA was hybridized to Affymetrix Bovine Gene Array containing 14,200 elements. Analysis of variance with a false discovery rate (FDR) correction resulted in 1,692 genes with a time effect (FDR <0.10, DEG). For the DIA analysis the whole data set (encompassing −21, −7, 7, and 28 d relative to parturition) with Entrez gene IDs, FDR, fold-change, and post-hoc P value between time points was uploaded. For the DAVID analysis a list of up-and downregulated genes with Entrez Gene ID was uploaded. A cut-off of FDR = 0.05 and P-value = 0.05 was applied in both approaches. Among DEG between time points, DAVID analysis uncovered that fatty acid biosynthesis, linoleic acid metabolism, biotin metabolism, and glycerolipid metabolism were markedly inhibited postpartum than prepartum; whereas, complement and coagulation cascades and riboflavin metabolism were the only pathways with sustained induction postpartum than prepartum. The DIA approach revealed that the onset of lactation resulted in a gradual decrease in the utilization (metabolism) of glucose, lactate, and acetate to produce energy (e.g., most impacted pathways included TCA cycle, Pyruvate metabolism). Furthermore, fatty acid biosynthesis, desaturation, elongation, and PPAR signaling were markedly inhibited during lactation. Overall, the combined results from both bioinformatics approaches indicated that the adipogenic capacity of adipose tissue is quite robust during late pregnancy while the innate immune response of the tissue becomes predominant during early lactation. The latter may be a response of the tissue to stressors including cytokines/hepatokines, NEFA, and/or pathogens. Alternatively, it may represent a mechanism associated with tissue remodeling.

Key words: systems biology, transition cow

M259 Reproduction of dairy cows receiving 1 vs. 3 timed AI (TAI) when not observed for estrus and subjected to natural service (NS). F. S. Lima*[1], R. S. Bisinotto[1], E. S. Ribeiro[1], H. Ayres[1], L. F. Greco[1], C. A. Risco[2], W. W. Thatcher[1], and J. E. P. Santos[1], *[1]Animal Sciences Department, University of Florida, Gainesville, [2]Large Animal Clinical Sciences, University of Florida, Gainesville.*

Objectives were to determine the effects 1 vs. 3 TAI followed by NS on time to pregnancy of lactating dairy cows not observed for estrus. Holstein cows, 1,050 received the double Ovsynch TAI program (d −27 GnRH, d −20 PGF2a, d −17 GnRH, d −10 GnRH, d −3 PGF2a, d −1 GnRH, and d 0 AI) for first AI. On the day of first AI, cows were blocked by parity and randomly assigned to receive one (1TAI, n = 533) or 3 TAI (3TAI, n = 517) before subjected to NS. Cows were moved to NS 7 d after the first or third AI according to treatment. Pregnancy was evaluated 32 d after TAI and each 28 d during NS. Nonpregnant cows in 3TAI were resynchronized with the Ovsynch program starting on d 32 after the previous insemination, such that the re-insemination interval was 42 d. Pregnant cows were re-evaluated for pregnancy 28 d after the initial diagnosis. Cows were scored for body condition 32 d after the first AI. All cows had a period of 231 d after the first AI to become pregnant, and non- pregnant cows were censored. Data were analyzed with the Cox's proportional hazard model or by Logistic regression using SAS. Models included the effects of treatment, parity, body condition and season. As expected, pregnancy at the first TAI did not differ between 1TAI and 3TAI on d 60 after insemination (30.9 vs. 33.4%). Cows receiving 3TAI had greater ($P = 0.04$) rate of pregnancy than those in 1TAI (AHR = 1.15; 95% CI = 1.01–1.31). This resulted in median d open of 142 (95% CI = 130–150) and 123 (95% CI = 121–144) for 1TAI and 3TAI, respectively. Primiparous cows had greater ($P < 0.01$) pregnancy rate than multiparous cows (AHR = 1.44; 95% CI = 1.16–178). Cows receiving the first TAI in the cool season had greater ($P < 0.01$) pregnancy rate than cows exposed to heat stress (AHR = 1.77; 95% CI = 1.53–2.05). Finally, cows with BCS > 2.75 had greater ($P < 0.01$) pregnancy rate than those with BCS < 3.0 (AHR = 1.59; 95% CI = 1.38–1.84). In conclusion, in spite of the long re-insemination interval, cows receiving 3TAI had improved reproductive performance than those receiving 1TAI.

Key words: dairy cow, natural service, timed AI

M260 Effect of intravaginal progesterone insert on GnRH-induced GnRH-induced LH release, follicle growth, and plasma progesterone, estradiol, and inhibin concentrations. L. G. D. Mendonça*[1], M. Amstalden[2], and R. C. Chebel[1], *[1]Department of Veterinary Population Medicine, University of Minnesota, St. Paul, [2]Department of Animal Science, Texas A&M, College Station.*

The objectives of this experiment were to evaluate the effect of treatment with a controlled internal drug release (CIDR) insert containing 1.38 g of progesterone (P4) at the time of GnRH injection on GnRH-induced GnRH-induced LH release, follicular growth and plasma concentrations of P4, estradiol and inhibin. Non-pregnant lactating Holstein cows were randomly assigned to one of 3 treatments after balancing for parity, body condition score and 305-d projected milk yield. The treatments were control (CON, n = 7), 1GP4 (n = 10) and 2GP4 (n = 10). All cows were presynchronized with a CIDR insert for 5 d, one day before and upon CIDR removal cows received a 25mg PGF injection, and 2 d later a 100µg GnRH injection. The day of the GnRH injection was considered d0 of the estrous cycle. On d6, CON cows received 100µg of GnRH, 1GP4 cows received 100µg GnRH injection and a CIDR insert, and 2GP4 cows received 200µg of GnRH and a CIDR insert. Ovaries were scanned 0, 10, and 20h after the GnRH given on d6. Blood was sampled at 0, 15, 30, 60, 120, 240, 345, 600, and 1200 min after the GnRH given on d6. Data were analyzed by ANOVA for repeated measures. Although LH concentration from 0 to 345 min was greater ($P < 0.01$) for 2GP4 cows (3.1 ± 0.2ng/ml) than CON (2.1 ± 0.3ng/ml) and 1GP4 cows (2.2 ± 0.2ng/ml), that was mainly because at 60 (CON = 2.6 ± 0.4, 1GP4 = 2.7 ± 0.3, 2GP4 = 3.7 ± 0.3ng/ml) and 120 (CON = 4.6 ± 0.8, 1GP4 = 5.1 ± 0.6, 2GP4 = 7.6 ± 0.6ng/ml) min LH concentrations were ($P < 0.01$) greatest for 2GP4 cows. Progesterone concentrations were smaller ($P < 0.01$) for CON cows (1.9 ± 0.3ng/ml) than 1GP4 (3.3 ± 0.2ng/ml) and 2GP4 (3.4 ± 0.2ng/ml) cows, but there were no ($P = 0.82$) differences between 1GP4 and 2GP4 cows. There were no differences ($P = 0.75$) among treatments in size of the dominant follicle at 10 and 20 h after the GnRH injection given on d6. Treating cows with intra-vaginal P4 concurrently with GnRH does not decrease LH concentration or peak, but treatment with 200µg of GnRH results in earlier rise in LH and greater LH peak concentration than treatment with 100 µg of GnRH.

Key words: dairy cow, CIDR, LH

M261 Environmental effects on semen quality of beef bulls used for artificial insemination. D. O. Stepp*, K. J. Stutts, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Semen quality, like other phenotypic expressions, consists of a genetic component, an environmental component, and a variety of interactions between the 2. The objective of this study was to evaluate environmental effects on semen quality of beef bulls used for artificial insemination. Angus and Brangus bulls (n = 76) that were housed at a commercial collection facility in southeast Texas were used in this study. Bulls were collected twice per week with 2 collections attempted on each collection day. Following collection, volume, concentration, and motility of the sample were evaluated. The sample was then cooled, extended, and frozen in liquid nitrogen following standard protocol of the collection facility. A post-thaw analysis of the sample was performed the following day. Data collected on each sample included: motility immediately after thawing (MOT0), motility 3 h post-thaw (MOT3), and the number of primary, secondary, and tertiary morphological abnormalities. Mean ambient temperature and relative humidity were recorded for the time of collection and the preceding 60 d. ANOVA was performed using Minitab15.1. All main effects and all 2-way interactions were included in the model. There was a significant effect of season on MOT0, MOT3, and number of primary, secondary, tertiary, and total abnormalities. MOT0 was higher ($P < 0.05$) in the winter (34.2%) and spring (33.6%) than in the fall (32.2%). MOT3 was higher ($P < 0.01$) in the spring (31.60%) than in the winter (29.77%) and fall (29.61%). Total abnormalities were highest ($P < 0.03$) in the summer (28.05%), followed by the fall (25.47%), spring (23.74%) and winter (23.35%). Season also had significant effects on ejaculate volume and concentration. Ejaculate volume was higher ($P < 0.01$) in the fall than in the winter, and sperm cell concentration was highest ($P < 0.01$) in the spring. These results indicate that environmental factors have a negative effect on semen characteristics of beef bulls. Semen quality is most degraded in the summer and fall seasons after exposure to a combination of high ambient temperatures and high relative humidity in southeast Texas.

Key words: beef bulls, semen quality, environment

M262 Plasma progesterone concentration and follicle dynamics of lactating Jersey cows treated with 1 or 2 intra-vaginal progesterone insert. J. G. N. Moraes*, P. R. B. Silva, N. Bortoletto, A. L. A. Scanavez, and R. C. Chebel, *Department of Veterinary Population Medicine, University of Minnesota, St. Paul.*

The objectives of the current study were to determine the progesterone (P4) concentration and the follicle dynamics of lactating Jersey cows treated with 1 or 2 intra-vaginal P4 insert. Cows were enrolled in the study at 34 ± 3 DIM and were paired by parity, BCS (3.1 ± 0.1), body weight (421.7 ± 5.2kg), and milk yield (28.8 ± 0.6kg/d). All cows were presynchronized with an injection of GnRH concurrent with controlled internal drug release (CIDR) insert containing 1.38 g of P4 and 5 and 6 d later all cows received a PGF2α injection. The day of the first PGF2α injection was determined d −2 of the study. Cows assigned to the 1CIDR treatment received a CIDR insert from d 0 to 8, cows assigned to the 2CIDR treatment received 2 CIDR inserts from d 0 to 8, and control cows did not receive further treatment. Cows were examined by ultrasound and ovarian structures were measured and mapped on d −2 and daily from d 0 to 8. Blood samples were collected for determination of P4 on d −2 and daily from d 0 to 8 and blood samples were collected for determination of estradiol concentration from d 0 to 8. Average P4 concentration from d 0 to 8 was ($P < 0.01$) smallest for control cows (0.73 ± 0.17 ng/ml) followed by 1CIDR (1.37 ± 0.10ng/ml) and 2CIDR (2.21 ± 0.09ng/ml) cows, respectively. Diameter of the largest follicle on d 0 (16.2 ± 0.6mm) was not different ($P = 0.14$) among treatments, but percentage of cows that developed codominant follicles was smallest for 1CIDR cows (1CIDR = 8.0, 2CIDR = 30.8, control = 50%; $P = 0.02$). Percentage of cows ovulating the dominant follicle identified on d 0 was greatest for control cows (1CIDR = 0, 2CIDR = 3.9, control = 80%; $P < 0.01$) and the interval to ovulation was 96 h from d −2 for the 2CIDR cow and averaged 123.0 ± 12.4 h from d −2 for control cows. Control cows were more likely to develop a new dominant follicle from study d 0 to 8 (1CIDR = 12, 2CIDR = 7.7, control = 60%; $P < 0.01$), but there was no ($P = 0.65$) difference in interval to identification of the new dominant follicle (106.9 ± 9.9h from d −2). Treatment with CIDR insert results in increase in P4 similar to those described for Holstein cows.

Key words: progesterone, Jersey cow, follicle

M263 Effect of a rumen-protected niacin product on lactation performance by dairy cows during summer in Wisconsin. K. Yuan*, R. Shaver, M. Espineira, and S. Bertics, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Research suggests that supplemental dietary niacin may improve the ability of lactating dairy cows for coping with heat stress. However, niacin is extensively degraded in the rumen. With advances in vitamin encapsulation technology, a niacin product, NiaShure, was developed to protect niacin from rumen degradation (Balchem Corp., New Hampton, NY). The objective of this study was to evaluate the effect of this rumen-protected niacin product on lactation performance by dairy cows during the summer in Wisconsin. Eighty lactating cows (63 ± 29 DIM) were used in a 10-wk lactation trial (a 2-wk pretreatment covariate period followed by an 8-wk treatment period). Cows were stratified by breed, parity and DIM, and randomly assigned to 10 pens of 8 cows each. Pens were assigned randomly either to control (C) or 12 g/d per cow rumen-protected niacin (RPN) TMR group. Ambient temperature and humidity were monitored weekly to calculate temperature-humidity index (THI) and individual cow rectal temperatures were measured weekly, to characterize heat stress conditions during the experiment. Data were analyzed as a completely randomized design with a covariate using SAS Proc Mixed. Milk yield (48.6 vs. 48.4 kg/d), milk fat percent (3.41 vs. 3.35%), milk protein percent (2.90 vs. 2.92%), milk fat yield (1.66 vs. 1.62 kg/d), milk protein yield (1.41 vs. 1.41 kg/d), milk lactose percent (4.89 vs. 4.87%), dry matter intake (27.2 vs. 27.3 kg/d), body weight (714 vs. 717 kg), body condition score (2.81 vs. 2.78) and rectal temperature (38.4 vs. 38.4°C) were not different ($P > 0.05$) between RPN and C. In summary, under summer conditions in Wisconsin, dietary supplementation with 12g/d per cow RPN did not affect lactation performance or body temperature of dairy cows.

Key words: dairy cow, heat stress, rumen-protected niacin

M264 Body condition score at calving affected milk yield and blood metabolites in Holstein dairy cows. Y. Moharrami[1], G. R. Ghorbani[1], H. R. Rahmani[1], S. M. Nasrollahi[1], and C. Li*[2], *[1]Department of Animal Sciences, Isfahan University of Technology, Isfahan, Iran, [2]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

A study was conducted to evaluate the effect of body condition score (BCS) on milk yield and blood metabolites in Holstein dairy cows. Three hundred and 12 multiparous Holstein dairy cows from 2 commercial dairy farms were scored for body condition beginning at one month before dry-off. Cows were scored monthly before calving and bi-weekly after calving until 120 DIM. Body condition score were assigned by 2 independent individuals ranging from 1 (thin) to 5 (obese) using the visual technique. The experiment was designed as a 2 × 2 factorial arrangement of treatment included farm (1 and 2), and BCS (<3.5; low and ≥ 3.5; high). Milk yield and fat were recorded for individual cows. Plasma glucose, insulin, leptin, triglyceride, NEFA and BHBA were determined a week before and a week after parturition. Data were analyzed using the PROC MIXED in SAS. The effects of farm, BCS and the interaction were considered as fixed effects and cow was considered as random effect in the model. There were no interactions between farm and BCS, and no differences were observed between the 2 farms on milk production and blood metabolites. Cows calving with high BCS produced more milk (high vs. low BCS; 41.3 vs. 40.0 kg/d; $P < 0.07$) with higher milk fat content (high vs. low BCS; 3.43 vs. 3.18%; $P < 0.01$); consequently produced more 4%FCM (high vs. low BCS; 37.6 vs. 35.5 kg/d; $P < 0.01$) compared with the low BCS group. Plasma glucose was higher (high vs. low BCS; 59 vs. 55 mg/dl; $P < 0.03$) but other blood metabolites were not different between the low and high BCS groups. The results indicated that managing adequate BCS during the dry period or early lactation improved milk production and milk fat content. Calving with BCS ≥3.5 may be suitable for more milk fat production.

Key words: BCS, milk yield and milk fat content, dairy cows

M265 Body condition score at calving affected reproductive performance and metabolic disorders in Holstein dairy cows. Y. Moharami[1], G. Ghorbani[1], H. Rahmani[1], S. M. Nasrollahi[1], and C. Li*[2], *[1]Department of Animal Sciences, Isfahan University of Technology, Isfahan, Iran, [2]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada.*

A study was conducted to investigate whether body condition score (BCS) at calving affect reproduction performance and metabolic disorders in high producing dairy cows. Three hundred and 12 multiparous Holstein dairy cows from 2 commercial dairy farms were used. The experiment was designed as a 2 × 2 factorial arrangement of treatment included farm (1 and 2), and BCS (<3.5; low and ≥3.5; high). Reproduction performance including conception at first service, days from calving to first insemination, open days, services per conception and conception rate were recorded. Metabolic disorders including dystocia, retained placenta, LDA, laminitis and mastitis were recorded within 120 DIM. Metabolic disorder and conception data were analyzed using the GENMOD procedure of SAS. Other data were analyzed using the mixed model procedure of SAS to account for farm, BCS and the interaction as fixed effects and cows as random effect. There were no interactions between farm and BCS, and no differences were observed between the 2 farms. Days from calving to the first insemination was reduced ($P < 0.02$) by 7 d with high versus low BCS. Similarly, cows with high BCS at calving had less ($P < 0.05$) open days (90 d) compared with low BCS (103 d). Conception at first service, services per conception and conception rate were not different between high and low BCS groups. BCS of 3.5 or higher at calving were associated with an increased (56%; $P < 0.02$) risk for laminitis which could be due to heavier BW on the legs. Incidence of dystocia, retained placenta, LDA and mastitis were not different between the low and high BCS groups. Results suggest that the adequate BCS may reduce interval between calving and first insemination and open days, but had limited influence on metabolic disorders. The calving BCS at 3.5 point or slightly higher may be suitable for transition period management.

Key words: BCS, reproduction performance, dairy cows

M266 Effects of bovine somatotropin (rbST) at 250 mg or 500 mg administered to crossbred cows (*Bos taurus* x *Bos indicus*). B. G. Campos*[1,2], S. G. Coelho[1], A. M. Q. Lana[1], E. Rabelo[3], E. A. Alvarenga[1], and B. F. Silper[1], *[1]Escola de Veterinária da Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brasil, [2]Fundação de Amparo à Pesquisa do Estado de Minas Gerais, Belo Horizonte, Minas Gerais, Brasil, [3]Recursos Humanos no Agronegócio, Belo Horizonte, Minas Gerais, Brasil.*

Numerous studies been conducted to determine the effects of rbST in *Bos taurus* dairy cows, however, there are a few studies evaluating the rbST response in crossbred cows ((*Bos taurus* × *Bos indicus*). Since the Brazilian herd is compound mostly by crossbred cows (*Bos taurus* × *Bos indicus*), the objective of this study was to evaluate the effects of the 250 or 500 mg rbST on milk production and milk composition, body weight and body condition score of crossbred cows of 3/4 and 7/8 (*Bos taurus* × *Bos indicus*). The 57 animals were assigned to 3 treatments: T0- control (7 primiparous and 12 multiparous), without administration of rbST; T250- 250 mg rbST (5 primiparous and 12 multiparous and T500- 500 mg rrbST (21 cows (8 primiparous and 13 multiparous). Cows received 16 consecutive rbST injections of 500 mg or 250 mg, respectively (BOOSTIN 500 mg or HILAC-250 250 mg - Schering-Plough/Intervet), starting at 63+3.5 d of lactation, administered at 14-d intervals. Milk production was measured twice weekly and milk composition every 15 d; BW and body condition scores were evaluated monthly. All animals were under the same nutritional management with confinement in the winter and rotational grazing in the summer and milked twice daily. The study was conducted as a completely randomized design. To test differences between means of milk yield, milk composition and body weight, the Dunnett test ($P < 0.05$) was used. Regression analysis was used for the evaluation times. For the analysis of body condition scores the Friedman and Kruskal-Wallis test ($P < 0.05$) were used for groups and days evaluation respectively. Milk production was higher for T500 (21.8 ± 7.0 kg/day) compared with T0 (20.0 ± 5,8 kg/day) and T250 (19.2 ± 7.1 kg/day) treatment ($P < 0.05$). All treatments had the same rate of decrease in production of 0.043 kg milk / day ($P > 0.05$). There were no differences between treatments for milk composition, body weight and body condition scores at different times evaluated ($P > 0.05$). Research supported by FAPEMIG - APQ 01005/08.

Key words: crossbred, milk composition, milk production

M267 Effect of pen change on daily milk yield of dairy cows. A. Zwald* and R. D. Shaver, *University of Wisconsin-Madison, Madison.*

The objective of this experiment was to determine the effect of pen change on daily milk yield by dairy cows over the first 10 d after changing pens in a commercial setting. The study was conducted during fall of 2010 in a 4,000 cow Jersey and Holstein x Jersey crossbred herd. Study cows were stratified by parity (multi- or primiparous). Two pens of 420 animals under the same management were evaluated. Animals were either Jerseys or Holstein x Jersey crossbreds. Pens were stocked at 100 percent. Animals were evaluated by days in milk (DIM) and cows between 65 and 170 DIM were eligible for enrollment. Ten percent of the pen was enrolled to the non-move (NM) group and 10 percent of the pen was enrolled to the move (M) group. The day of the move, the 42 animals enrolled to the M group in pen one switched places with the M group of pen 2. New cows were enrolled and this procedure was repeated once, 4 weeks after the initial move. Weights were taken from each milking in the parlor from the Boumatic meter system and downloaded to DairyComp 305. If a milking was missing, the weekly average weight was used. Animals were removed from the trial if more than 5 full days on either side of the move were missing. Data were analyzed using Proc Mixed of SAS with starting pen, parity, treatment, day, and treatment*day interaction as fixed effects and cow within treatment as a random effect. The least squares means for the average daily milk yield for the NM group were 32.5, 31.5, 32.3 kg/cow for the 5 d prior, day of, and 5 d after pen change, respectively. Least squares means for average daily milk yield for the M group were 32.0, 31.3, and 32.0 kg/cow for the same time periods. The least squares means for average daily milk yield for the 5 d before and 5 d after regrouping were not different ($P > 0.10$). The least squares means for the M and the NM groups were not different ($P > 0.10$) during any period. Changing pens with large groups of animals does not appear to have a detrimental effect on production.

Key words: grouping, milk yield, dairy cow

M268 Milking management of crossbred Holstein x Gyr (F1) cows without calf on production performance. L. H. Oliveira[1], J. M. S. Filho[1], F. L. B. Toral[1], and R. B. Reis*[1,2], *[1]Federal University of Minas Gerais (UFMG), Belo Horizonte, Minas Gerais, Brazil, [2]FAPEMIG, Belo Horizonte, Minas Gerais, Brazil.*

Crossbred Holstein (*Bos taurus*) × Gyr (*Bos indicus*) cows for milk and calf production is very popular in Brazil because production and adaptation in tropical conditions. However, these animals have strong link with their offspring turning them susceptible to lactation failure if milked in absence of their calf. Exogenous oxytocin injection has been used to stimulate milk ejection without calf presence during the milking. The objective of this research was to compare the effect of exogenous oxytocin injection or calf presence during milking on milk production and composition, lactation persistency of crossbred Holstein × Gyr (F1) cows. Seventy 4 multiparous cows were randomly assigned to 1 of 2 experimental groups. Group (BP) cows were milked in the presence of their calf and suckled post-milking for 30 min (n = 36). The cows in group (OT) were milked in the absence of the calf and injected in the mammary vein with 2.0 IU of oxytocin (Postipofisin, Hertape Calier), immediately before milking (n = 38). Cows were weekly checked for milk yield and milk samples were collected for milk composition and Somatic Cell Count (SCC). The adjustment of the lactation curve was performed using incomplete gamma function proposed by Wood (1967) and the parameters of each function estimated by the NLIN procedure of SAS. Accumulated milk yield at 30, 60, 90 120 and 150 d, initial milk yield, milk production at peak, protein, lactose, total solids % and SCC did not differ between groups ($P > 0.05$). The group OT did not have the milk production reduced due to absence of their calf. The peak of lactation occurred at 24.3 DIM. Group OT had a higher lactation persistency (K = 0.00383 vs. K = 0.00480; $P = 0,01$) and higher fat content at 90 DIM (2.40+0.35 vs. 3.77+0.19; $P < 0.05$) and 120 DIM (2.78+0.27 vs. 3.45+0.17; $P < 0.05$). The cows receiving oxytocin injection showed better performance, indicating that this practice is a valuable management tool for milking Holstein × Gyr F1 cows in the absence of calf.

Key words: oxytocin, milk production, crossbred cows

M269 Risk management practices by Idaho dairy producers. R. J. Norell*[1], C. W. Gray[2], and M. Chahine[2], *[1]University of Idaho, Idaho Falls, [2]University of Idaho, Twin Falls.*

A mail-in survey was conducted to evaluate risk management strategies and practices on Idaho dairies. The survey was mailed to every dairy producer registered in the state of Idaho (n = 489) and 140 surveys were returned (28.6% response rate). Survey data were compared with Proc GLM and Proc Freq in SAS (SAS Inst. Inc., Cary, NC). Dairies were categorized as small (n < 250 cows, 45.7%), medium (n = 250 to 749 cows, 25.7%) or large (n > 749 cows, 28.5%). Eighty percent of dairies have utilized one or more risk management strategies with 41 ± 4% using 1 to 3 strategies and 39 ± 4% using 4 or more. Large dairies utilized more strategies at a higher frequency of use ($P < 0.0001$) than small dairies with medium dairies intermediate.

Overall use of risk management practices were: feed contracts (70 ± 4%), milk contracts (63 ± 4%), hedge milk (42 ± 4%), hedge corn (38 ± 4%), hedge soybean meal (27 ± 4%), put options (26 ± 4%), put + call options (22 ± 4%) and Livestock Gross Margin (12 ± 3%). Eighty 2 percent have a current lender and 36 ± 5% are encouraged by their lender to use risk management strategies. Producers utilized on average 4.7 ± 0.2 sources of market information and the number of sources did not differ between herd size groups ($P > 0.25$). Market information sources included: Chicago Mercantile Exchange (87 ± 3%), magazines (86 ± 3%), processors (81 ± 3%), extension newsletters (67 ± 4%), commercial newsletters (64 ± 4%), newspaper (53 ± 4%), and broker (35 ± 4%). Respondents were interested in 4 educational programs: how to hedge (70 ± 4%), how to use options (71 ± 4%), how to protect dairy margins (80 ± 3%), and Dairy Livestock Gross Margin program (76 ± 4%). Small operations were less interested in hedging and options education than large and medium operations ($P < 0.05$). Producers preferred educational training methods in the following order: producer meetings (80 ± 3%), one on one (66 ± 4%), newsletters (56 ± 4%), magazine articles (48 ± 4%), web based materials (46 ± 4%), and webinars (29 ± 4%). Preference for educational method did not differ between herd size categories ($P > 0.25$). We conclude that risk management strategies are an important management tool for Idaho dairy producers and further risk management training is desired by the industry.

Key words: risk management, educational methods

M270 High diurnal fluctuations of ambient temperature do not improve the adaptation of dairy cows to heat stress. H. Khelil[1,2], P. Faverdin[1,2], and A. Boudon*[1,2], *[1]INRA, UMR1080 Production du Lait, Saint-Gilles, France, [2]Agrocampus Ouest, UMR1080 Production du Lait, Rennes, France.*

Climate change should increase the frequency of heat stress periods in temperate conditions. This study was designed to compare the effects of 2 types of heat stress (constant or variable within day) to thermoneutral conditions, on 8 cows either in early (73 d in milk) or mid (155 d in milk) lactation. The patterns of ambient temperature were a constant temperature of 18.0°C (thermoneutrality, TN), a constant temperature of 29.0°C (High Temperature Constant, HTConst), a variable temperature of 32.2°C between 6:00 and 17:00 and 21.5°C between 18:00 and 4:00 with a daily average of 28.4°C (High Temperature Variable, HTVar). Patterns were compared according to a crossover design, with 2 climatic rooms containing each, 2 early and 2 mid lactation cows during 3 periods of 15 d. Recovery periods of 15 d at a constant temperature of 18°C were included between measurement periods. Daily average of temperature-humidity index (THI) was 63 for TN, 75 for HTConst and 76 for HTVar with THI exceeding 78 between 6:00 and 17:00. Between 6:00 and 17:00, cows increased their respiration rate from 29.0 respirations/s at TN to 53.5 at HTConst and 66.5 at HTVar ($P < 0.001$) and their vaginal temperature from 38.5°C at TN to 39.2°C at HTConst and 39.5°C at HTVar ($P < 0.001$). Daily average of vaginal temperature increased from 38.6 to 39.3 C° from TN to HT ($P < 0.001$) with no differences between HTConst and HTVar. Dry matter intake decreased from 21.8 kg at TN to 18.4 kg at HT ($P < 0.01$). Daily milk yield averaged 28.6 kg and was not significantly affected by the temperature pattern even though morning milk yield decreased from 18.7 kg at TN to 16.3 kg at HT ($P < 0.05$). Milk fat and protein contents decreased from 42.2 and 30.5 g/kg respectively at TN to 40.0 and 28.7 g/kg at HT ($P < 0.001$) with no significant differences between HTConst and HTVar. Proportion of eating time between 6:00 and 17:00 decreased at HTVar compared with TN and HT Const (0.41 vs. 0.55, $P < 0.001$). In conclusion, high diurnal fluctuations of ambient temperature did not improve cow performance compared with a constant temperature with a similar daily average.

Key words: heat stress, temperature-humidity index, dairy cow

M271 Assessment of long-term nitrogen runoff reduction from dairy pastures. R. White* and J. L. Capper, *Washington State University, Pullman.*

A 20-yr assessment was run simulating a pasture on a dairy to determine the effect of various harvesting techniques on Nitrogen (N) removal from the system. The aim was to identify a treatment that resulted in the greatest uptake of N by plant matter thereby diminishing N loss through runoff. Grass, shrubs and trees were modeled to function as they would in a riparian system, grass diffused water to allow absorption by soil, whereas shrubs and trees functioned to absorb nutrients. The pasture was located next to a dairy from which runoff inputs were given as N, Carbon and water sources. Other inputs to the system were historical data for monthly rainfall, temperature and soil attributes. The output was expressed as N runoff from the soil profile. The model was run over 20 yrs to view the long-term consequences of treatments. Mowing, grazing and planting were hypothesized to stimulate a grass density increase inhibiting water flow from the system while pruning and burning plants were thought to stimulate growth and increase nutrient uptake from the soil. These hypotheses were tested via 5 treatments: mowing grass to a stubble height of 0.1 m^2, pruning 1 m^2 from trees and 0.5 m^2 from shrubs, planting 90 kg of grass/acre, grazing of 450 kg of cattle/acre, and burning 70% of the biomass. A total of 4.335 kg N per acre was calculated to runoff during the 20-yr time period. Annual planting in October, burning before yr 5 and pruning after yr 3 were all found to significantly decrease N runoff. When grazing during the spring N runoff increased to 5.16 kg; however, during the winter, runoff did not significantly increase. Mowing did not change N runoff. The most effective reduction resulted from annual fires in the first 5 yrs, pruning annually in August starting in yr 7, grazing cattle annually starting in yr 6 and annual planting of grass in October. This combination of treatments resulted in a runoff reduction to 1.09 kg N, nearly a 75% decrease. This reduction shows that good riparian area management, including use by cattle, can reduce N runoff from dairy pastures.

Key words: nitrogen, runoff, dairy

M272 Milk, fat, and protein production in relationship to herd linear somatic cell score in Minnesota. R. F. Leuer* and J. K. Reneau, *University of Minnesota, St. Paul.*

The impact of herd average udder heath on production is significant. It has long been recognized that herds with low somatic cell counts also excel in other aspects of herd management that contribute to overall herd productivity. Linear somatic cell score (LSCS) has been shown to be highly related to milk and other yield characteristics of individuals within a herd. The objective of this study was to evaluate the relationship between herd test day average LSCS and rolling herd average milk production (RHAM), rolling herd average fat production (RHAF), and rolling herd average protein production (RHAP). Minnesota DHIA monthly average herd records were collected from January 2007 to November 2010. Monthly tests with fewer than 30 cows and without SCC, milk, fat, and protein information were removed. Herds averaging less than 10 tests per year over the collection period were also removed. Monthly records (n = 62,582) were analyzed using PROC REG. The equation for rolling herd averages are: RHAM =

12,449.5 Kg – 916*LSCS, RHAF = 419 Kg – 28.8*LSCS, RHAP = 372.7 Kg – 24.9*LSCS. The R2 for the regressions were RHAM = 0.13, RHAF = 0.11, RHAP = 0.11. Herds with a lower LSCS produced a greater volume of milk, fat, and protein. Herd linear somatic cell score gives insight to overall management level and production ability.

Key words: linear somatic cell score, milk quality

M273 Effects of water total dissolved solids on milk-fed calves weight gain, feed intake and weaning age in winter. R. Ramezankhani[1], A. Alizadeh[1], A. Nasserian[2], M. Chehrazi[3], and B. Saremi*[4], *[1]Department of Animal Science, Islamic Azad University, Saveh Branch, Saveh, Iran, [2]Department of Animal Science (Excellent Center of Animal Nutrition), Faculty of Agriculture, Ferdowsi University of Mashhad, Mashhad, Iran, [3]Epidemiology and Reproductive Health Department, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, [4]Institute of Animal Science, Physiology and Hygiene unit, University of Bonn, Bonn, Germany.*

In some areas of Iran dairy farms use drinking water that containing elevated total dissolved solids (TDS). Reliable information concerning water TDS on calves' performance is limited, especially in winter. The aim of this study was to compare 3 water TDS groups ; High TDS (HTDS) ≈3000 ppm, Medium (MTDS) ≈1100 ppm and Low (LTDS) ≈160 ppm used as calf drinking water. Holstein calves (n = 21) were randomly assigned to 3 groups in a commercial dairy farm (Laban, Qom, Iran) during winter. Calves were subjected to different treatments from 3 d after birth up to 30 ± 2 d old (0.5 L per day). Thereafter, ad libitum access to drinking treatments was available until weaning. Dairy calves were weaned after they reached 1kg starter intake for 3 consecutive days. Data were analyzed by SPSS 17. Mean ambient temperature during the experiment was 12°C. Calves in the HTDS group had highest water consumption (Table1), although this group had the lowest starter intake. Body weight of calves for the MTDS group was highest on d 60. Weaning weight did not differ among treatments. Weaning day was affected by water TDS and calves in the MTDS group weaned earlier than HTDS. Urine pH decreased linearly as TDS increased. Body temperature, height, and body length were similar among treatments. This study indicated that water TDS can increase feed intake with a reduction in water intake. Decreased milk feeding period was a consequence of increased feed intake. TDS values at 160ppm are recommended in winter.

Table 1. Performance, feed and water consumption and urine pH of dairy calves receiving several water TDS contents

Item	LTDS	MTDS	HTDS	SE
Water consumption (L/d)	1.95 ^{b}	2.05 ^{ab}	2.24 ^{a}	0.19
Feed intake(g/d)	540 ^{a}	545 ^{a}	525 ^{b}	7.6
Body weight- 60 d (kg)	63.7 ^{b}	65.6 ^{a}	61.7 ^{b}	1.24
Weaning day(d)	69.8 ^{ab}	68.7 ^{b}	73.7 ^{a}	0.9
Urine pH	6.55 ^{a}	6.52 ^{b}	6.49 ^{c}	0.006

$^{a-c}$Values with differing letters within the same row are significantly different ($P < 0.05$).

Key words: water total dissolved solids, calf, winter

M274 Occurrence of milk unstable protein in dairy farms from southeastern region of Brazil. L. C. Roma Junior*[1], A. C. O. Rodrigues[2], T. G. R. Amaral[2], F. Cardoso[2,3], and P. F. Machado[2], *[1]APTA Centro Leste, Ribeirao Preto, Sao Paulo, Brazil, [2]Clinica do Leite/ESALQ/USP, Piracicaba, Sao Paulo, Brazil, [3]Department of Animal Science, University of Illinois, Urbana.*

Milk quality is important to achieve good dairy industrialized products. The stability of milk protein is one of the most important factors. During the industrialization process thermal treatment (heat) is applied to milk. Milk characterized as unstable protein (UP) is affected by thermal treatment and has negative impacts on dairy farmers, industry and consumers. UP is defined as low casein stability resulting in precipitation during the alcohol test without the presence of acidity on milk. The present study had the objective of evaluating the quality of milk protein regarding its thermal stability in the Brazilian Southeastern Region. This evaluation was carried through by quantification of the problem of UP and the analysis of the factors related to the occurrence. During the years 2005/2006, 2,970 bulk tank milk samples from individual farms were processed. In this period, samples were classified by identifying and quantifying the UP occurrence. Finally, the characteristics of both the facilities and factors which would affect the occurrence of the problem were verified. As a result, 7% of the total volume of produced milk, throughout one year, showed the UP problem, without any kind of geographic influence. However the season of the year had an influence on this occurrence ($P < 0.05$), being identified the beginning of the Autumn and the end of the Winter as the periods with higher numbers of occurrence. Reduction of lactose level ($P < 0.05$) was present in samples with UP that also presented a reduction of its the thermal stability, without presenting any kinds of raised acidity. This problem was related to animals, which were in advanced periods of lactation or presented a reduction of their corporal score due to the low consumption of dry matter, specifically for diets with low energy levels, resulting in the reduction of lactose in milk.

Key words: milk quality, thermal stability, dairy nutrition

M275 Alternative cooling of dairy cows by wetting the udder. J. A. Binversie*[1], J. D. Davis[1], K. G. Gebremedhin[2], C. N. Lee[3], and J. E. Larson[1], *[1]Mississippi State University, Mississippi State, [2]Cornell University, Ithaca, NY, [3]University of Hawaii, Honolulu.*

Heat stress is a major inhibitor of production in livestock operations, causing severe economic loss. The objective of this study was to determine whether spraying the udder with water, with or without fans blowing air onto the udder, cools the body as effectively as spraying water on the back of the animal with or without fans blowing air on the back. Twelve pregnant, lactating Holstein cows were used over 4 d with 4 applications of each treatment each d. Treatments included wetting of the back with a fan (B+F, n = 24), and without a fan (B+NF, n = 72) blowing air on the back; wetting of the udder, with a fan (U+F, n = 24) or without a fan (U+NF, n = 72) blowing air on the udder. The back or udder of each animal was sprayed with water for 1 min, and in appropriate treatment groups, air from identical fans was blown on the wetted area for the duration of the treatment and measurement time periods. Rectal temperature, respiration rate, and surface skin temperature of the back and udder were collected 10 min after treatment application. Data were analyzed using the Mixed Procedure of SAS with the replication during each day analyzed as a repeated measurement and Black globe humidity index (BGHI) used as a covariate. Mean BGHI and Temperature Humidity Index for the period were 80.3 ± 0.3 and 81 ± 0.3, respectively. Rectal temperatures and respiration rates were not different ($P > 0.05$) among treatments. The LSMeans and SEM of rectal temperatures were 39.8 ± 0.1, 39.6 ± 0.2, 39.6 ± 0.1, and 39.6 ± 0.2°C and the respiration rates were 110.6 ± 1.6, 106.1 ± 2.9, 109.0

± 2.9 and 109.0 ± 1.6 breaths/min for cows treated with B+NF, B+F, U+NF, and U+F treatments, respectively. Skin surface temperatures of the back were similar among treatments. Interestingly, cows that received B+F had a cooler udder surface temperature (38.1 ± 0.3°C; $P \geq 0.05$) compared with all other treatments: 38.5 ± 0.2, 38.7 ± 0.3, and 38.5 ± 0.2°C for cows receiving U+NF, U+F, and B+NF, respectively. In conclusion, efforts to abate heat stress by spraying the udder with water either with or without a fan is as effective as spraying the back with water.

Key words: dairy cows, heat stress, wetting

M276 Effect of essential oils on production and reproduction in early lactating cows during heat exposure. U. Serbester[1], M. Çmar[1], A. Ceyhan[1], H. Erdem[2], M. Görgülü[3], H. R. Kutlu[3], L. Baykal Çelik[3], Ö. Yücelt[4], P. W. Cardozo*[5], and M. Blanch[5], *[1]Bor Vocational School, University of Nigde, Turkiye, [2]Department of Obstetrics and Gynecology, Faculty of Veterinary Medicine, University of Selcuk, Turkiye, [3]Department of Animal Science, Faculty of Agricultural, University of Cukurova, Turkiye, [4]Ekol Company, Turkiye, [5]Novus International Inc., St. Charles, MO.*

Twenty-five Holstein cows (8 primiparous and 17 multiparous, DIM 37.4 ± 3.1 d; milk yield 29.8 ± 1.23 kg/d) were used for 78 d to evaluate the effect of essential oil compound mixture (EOCM; containing cinnamaldehyde and diallyl disulfide; Novus International, Inc.) on productive performance and pregnancy rate during heat exposure. The early lactation dairy cows were subjected to presynch-ovsynch protocol 12 d apart and inseminated to timed AI (TAI). Cows were individually fed a total mixed ration comprising (DM basis) 60% concentrate and 40% silage of common vetch with triticale. The concentrate differed only in the addition of EOCM as 25 mg/kg concentrate (as fed). Ambient temperature and relative humidity were recorded, and temperature-humidity index (THI) was calculated throughout the study. Dry matter intake, milk production were measured daily, milk samples were taken twice a week, blood samples were collected weekly, and ultrasonography was performed at 29 and 42 d post-TAI to determine conception rate. Results were analyzed using PROC MIXED for repeated measures and conception rates were analyzed utilizing GENMOD procedure of SAS. Differences were declared at $P < 0.05$. Average of ambient temperature, relative humidity and THI were 25.9°C, 73.4% and 76.8%, respectively. Even with addition of EOCM, body weight, DMI, milk yield, milk composition, serum glucose, IGF-I, progesterone concentrations and conception rate were not affected ($P > 0.05$); however, EOCM supplementation increased ($P < 0.01$) insulin concentration, and tended to decrease ($P = 0.07$) serum total cholesterol concentrations, and increase ($P = 0.10$) NEFA concentrations. Results indicate that at the level offered, EOCM did not affect milk production and conception rate of early lactating dairy cows during heat stress. The increase of insulin and reduction of total cholesterol observed in EOCM group needs to be confirmed with further research.

Key words: essential oils, dairy cows, conception rate

M277 The relationship between milk urea nitrogen with milk yield and protein percentage categories for Iranian Holstein cows. F. Fatehi*[1], M. Honarvar[2], M. Dehghan-Banadaky[1], A. Zali[1], and A. Young[3], *[1]1Department of Animal Science, Campus of Agriculture and Natural Resource, University of Tehran, Karaj, Iran, [2]Islamic Azad University, Shahriar_Shahr_e_Qods Branch, Shahriar, Iran, [3]Department of Animal, Dairy, and Veterinary Sciences, Utah State, Logan.*

Considerable interest has developed in using MUN as a monitor of the efficiency of nitrogen utilization by dairy cows. However, the association between MUN and both nutritional management and performance should be determined under field conditions using commercial testing procedures. To investigate these associations, a measure of the Production Variables factors affecting MUN is needed. The objectives of this study were to determine the relationships among MUN, milk yield, and milk protein in Iranian Holstein cows. Milk production was grouped by increments of 9.1 kg/d with the upper grouping of 63.6 kg and greater for Holstein cows. Also for milk protein the categories were less than 3.0%, 3.01 to 3.2%, and >3.2% milk protein. Multivariate mixed linear regression models using the Proc Mixed procedure in SAS (SAS, 2004) was used to determine the association between MUN (dependent variable) and milk yield and protein categories (independent variables). Multiple comparisons were made with P-values adjusted using Tukeys procedure. In Iranian Holstein cows, MUN was lower when milk protein was > 3.2% (vs. < 3.0% or 3.01 to 3.2%). Also, MUN was lower for cows with milk protein 3.01 to 3.2% than the group of <3.0% milk protein for all milk yields (Table 1). Because of these relationships, milk protein percentage should be considered in addition to MUN concentration as a management tool to determine if rations are properly balanced.

Table 1. Least squares means and SE of MUN concentration by milk yield and protein percentage categories for Iranian Holstein cows

	≤ 3.0%		3.01-3.2%		> 3.2%	
Milk Category, kg	MUN	SE	MUN	SE	MUN	SE
9.0-18.2	16.1[a]	0.18	15.0[b]	0.05	14.3[c]	0.1

M278 Stage of lactation is associated with differences in the metabolic profiles and innate immunity in dairy cows transitioning to an organic management system. J. F. Odhiambo*, Q. Zebeli, S. Iqbal, D. A. Mansmann, U. Farooq, S. Sharma, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Negative energy balance during early lactation is a major concern in organic dairy herds due to restrained use of concentrates. Metabolic profiles and plasma haptoglobin (Hp) in dairy cows transitioning from conventional to organic management system were evaluated during the following periods: dry period (DP), 0–30, 30–60, and 60–90 DIM (n = 7 cows per period). Blood samples were obtained from cows by tail venipuncture once during the period and utilized for metabolite analysis by colorimetric methods. Data were evaluated by the mixed procedures of SAS. Concentrations of NEFA were elevated ($P < 0.01$) between 0 to 30 DIM, but did not differ between 30 to 60 and 60 to 90 DIM, and DP (259.9 ± 19.9, 201.6 ± 21.7, 210.4 ± 23.2 and 186.3 ± 19.8 μEq/L, respectively). Concentrations of BHBA in the serum were also

greater ($P < 0.001$) between 0 to 30 DIM, intermediate between 30 to 60 and 60 to 90 DIM, and were lower in the DP (1037.7 ± 45.7, 908.6 ± 50.1, 860.9 ± 53.2 and 775.0 ± 45.5 μmol/L, respectively). Serum concentrations of cholesterol increased ($P < 0.001$) with increasing DIM and returned to nadir levels during DP (153.8 ± 6.9, 194.9 ± 7.4, 217.8 ± 7.7, and 146.9 ± 6.9 mmol/L, for 0–30, 30–60, 60–90 DIM, and DP, respectively). Low glucose concentrations were observed 0 to 30 DIM, levels were intermediate during 30 to 60 and 60 to 90 DIM, and peaked during DP (51.6 ± 1.3, 55.5 ± 1.4, 57.3 ± 1.5, and 61.9 ± 1.3 mg/dL, respectively, $P < 0.001$). Concentrations of lactate tended ($P = 0.08$) to be higher during the DP but remained unchanged from 0 to 90 DIM. Serum concentrations of Hp were elevated during the DP; reached peak levels during 0 to 30 DIM and decreased gradually with increasing days postpartum (344.9 ± 32.3, 415.2 ± 32.4, 333.8 ± 35.6, and 267.6 μg/mL, for dry, 0–30, 30–60, 60–90 DIM, respectively, $P < 0.001$). Taken together, these data indicate that metabolic changes associated with initiation of lactation are preceded by an acute phase response in dairy cows under an organic management system.

Key words: stage of lactation, metabolic profile, organic dairy cows

M279 Delayed effect of heat stress on dry matter intake and milk yield in dairy cows. A. S. Atzori* and A. Cannas, *Dipartimento di Scienze Zootecniche, Università di Sassari, Sassari 07100, Italy.*

During summer, dairy cows in Sardinia (Italy) have marked declines of milk production even if the area in which most farms are located is considered at medium risk of heat stress. Thus, this work studied the main meteorological variables involved in the cow response to heat stress. From June to September 2009 the data related to daily herd consistency, feed supplied and refused, and milk yield (MY) were obtained from a farm management software (Ecostalla, J-Service, Arborea, Italy) currently used in one farm of Arborea (OR, Sardinia, Italy). During the same period, mean air temperature (T_m) and relative humidity (RH) were recorded, 2 m above the feed bunk, every 2 h, and the temperature-humidity index (THI) was calculated (Kliber, 1964). The daily mean values of recorded variables (range within parenthesis) were: number of lactating cows 161 ± 0.5; DMI 20.2 ± 0.1 (18.3–22.5) kg/cow per d; MY 26.2 ± 0.1 (23.9–28.0) L/cow per d; T_m 24.9 ± 2.0 (20.7–31.7) °C; RH 67.1 ± 7.6% (38.6–77.8); THI 73.3 ± 2.8 (67.7–78.6) °F. DMI was negatively correlated with T_m (−0.38; $P < 0.001$) and THI (−0.44; $P < 0.001$). MY was poorly associated with the same day weather variables. Correlations were higher when DMI or MY were associated to previous days T_m and THI. The highest correlation were observed with a delay of 3 d for DMI (r = −0.56 and −0.61 with T_m and THI, respectively; $P < 0.001$), and with a delay of 5 d for MY (r = −0.58 and −0.63; for T_m and THI respectively; $P < 0.001$). Estimated delayed stress was equal to −0.23 kg of DMI/cow per d and −0.174 kg of MY/cow per d per increased unit of THI above the threshold of 70°F (21°C). The RH was significant only combined with T_m in the THI. The MY on a certain day was best predicted as MY (L/cow per d) = 25.2 - 0.095 × THI_{-5} (°F) + 0.391 × SSI_{-2} (kg/cow per d) ($r^2 = 52.6$), where the subscripts −5 and −2 indicate the days before MY. This study suggest that delayed MY losses due to heat stress can be minimized if appropriate actions are taken as soon as THI increases above the threshold.

Key words: temperature humidity index, threshold, short-time stress

M280 Effect of feed-line soaking and Niashure (NI) on heat–stressed lactating Holsteins housed in an evaporative tunnel ventilated barn in Thailand. S. Rungruang*, J. Collier, and R. Collier, *University of Arizona, Tucson.*

Total of 86 lactating Holstein cows (28.2 ± 4.6kg/d) were assigned to a completely randomized design to evaluate the impact of feed-line soaking in conjunction with 12 g/d Niashure (NI) supplementation on body temperature indices, feed intake and production parameters. All cows were housed in an evaporative tunnel ventilated barn for 21 d Jul–Aug 2010 in Nakhon Ratchasima, Thailand. The Temperature Humidity Index (THI) values inside the barn ranged from 72 – 82 and average humidity values were more than 90%. Cows had access to feed-line soaking from 12:00 to 06:00 each day and were randomly assigned to one of 2 groups, control or NI supplement. Groups were balanced for parity, days in milk and milk yield. Rectal, skin and vaginal temperatures were recorded on a subset of 10 cows per group.NI doses were split and top–dressed on ration by feeding 6 g at 06:00 and 6 g at 13:00. Feeding NI with soaking significantly reduced skin temperature but not rectal and core body temperature during peak THI periods. Dietary NI decreased shaved (30.9 vs. 32.8°C, $P < 0.01$) and unshaved shoulder (30.6 vs. 31.9°C, $P < 0.02$) skin temperature and also decreased shaved rump skin temperature (32.0 vs. 33.3°C, $P < 0.03$) at 14:00. Milk yield in NI group was lower than controls (26.2 vs. 28.5 kg/d, $P < 0.04$). We did not detect an effect of feeding NI on dry matter intake (DMI) or milk composition. Feeding NI did not lower mean core body temperature but soaking reduced body temperature and respiratory rate. Soaking decreased average rectal temperatures and respiratory rates of both groups to lowest values at 14:00 compared with 08:00, 11:00 and 16:00 (38.9°C, $P < 0.02$ and 59 breath/min $P < 0.03$). Use of NI with soaking numerically reduced average rectal temperature to the lowest values at 14:00 compared with other time points and lower when compared with control group. Results indicate that the effect of feed–line soaking reduced body temperature indices while NI supplementation in addition to soaking did not further reduce core temperatures of lactating dairy cows.

Key words: heat-stressed, niacin, soaking

M281 Economic assessment of postpartum milking frequencies on dairy farms. F. Soberon*, D. M. Galton, and T. R. Overton, *Cornell University, Ithaca, NY.*

The additional milk yield associated with increased milking frequency (IMF) during lactation has been well-documented, but implementation of this management technique depends upon the balance between potential revenue and cost. We compared the marginal profitability of cows milked 4x for 21 d followed by 2x for the remainder of the lactation (4x-2x) and cows milked 3x throughout the entire lactation (3x) to cows milked 2x throughout the entire lactation (2x). Energy-corrected milk (ECM; 3.5% fat and 3.2% true protein) increases were assumed to be 1.5 and 3.0 kg/d of ECM for 4x-2x and 3x, respectively, compared with 2x and were determined according to results from a large study on commercial farms focused on 4x-2x milking and literature reports for 3x milking. The model analysis included marginal feed cost, farm size (number of cows), parlor size (cows per hour), parlor efficiency (worker equivalents per hour of milking time), energy usage ($20.00 per hour of milking) and other milking supplies ($0.15/cow per milking). For an example smaller farm with 200 milking cows, an assumption of 2.5 workers per hour, a milking capacity of 50 cows per hour, 3x milking is more profitable than 2x milking at all milk prices greater than $15.70/45.4 kg; however, 4x-2x milking is more profitable than 2x milking at all milk prices greater than $8.35/45.4 kg. When milk prices are higher than $23.40/45.4 kg 3x milking is more profitable

than 4x-2x milking. For an example larger farm of 1,000 milking cows and 5 workers per hour with a milking capacity of 200 cows per hour, 3x milking is more profitable than 2x when milk prices are above $9.35/45.4 kg and 4x-2x milking is more profitable than 2x at milk prices above $5.90/45.4 kg. A 3x milking scheme on larger farms was more profitable than 4x-2x milking at milk prices above $13.00/45.4 kg. We conclude that management decisions regarding milking frequency on any given farm should consider herd size, parlor efficiency, current milk prices along with other facility- and management-related factors that are beyond the scope of this analysis.

Key words: milking frequency, economics

M282 Milk fat and protein:fat ratio in California dairies. N. Silva-del-Río*[1], A. Lago[2], B. Verboort[3], and H. Selvaraj[3], *[1]University of California Cooperative Extension, Tulare, [2]APC Inc., Ankeny, IA, [3]AgriTech Analytics, Visalia, CA.*

The aim of this study was to report the prevalence of herds: a) with low milk fat, and b) at risk of ketosis in California dairies. Dairy Herd Improvement Association records were obtained from AgriTech Analytics (Visalia, CA). Information included milk composition at herd level [51 Jersey (JE) and 534 Holstein (HO) herds], and at cow level (2,321,563 observations from 138 HO herds) from Nov-09 to Oct-10. Milk fat (MF) depression was evaluated based on herd averages below 3.2% (HO) and 4.2% (JE), and on the proportion of cows below 2.5% of MF at any given test. The risk of ketosis was evaluated based on the proportion of cows within a herd that at first test had protein:fat ratio (P/F) less than 0.75. During the study period, 39.2% (n = 51) of the JE herds and 22.0% (n = 534) of the HO herds had at least one MF test below 4.2% and 3.2%, respectively. The proportion of JE and HO herds that had more than 25% of the tests with MF below 4.2% and 3.2% was 14.5% and 7%, respectively. The percentile distribution of cows within herd with MF <2.5% was Q1 = 2.8%, Q2 = 4.3%, Q3 = 5.8% of the cows. In 6.3% of all the tests conducted more than 10.0% (up to 27.1%) of the cows had MF <2.5%. A total of 26.1% of the herds had at least one monthly test where more than 10% of the cows tested had MF content below 2.5%. Eleven herds (8.0%) had more than 25% of their tests with at least 10% of the cows with MF <2.5%. The percentage of herds with more than 10% of the cows with MF <2.5% ranged from 3.3% in Apr and 9.5% in Nov. The risk of ketosis was evaluated and 79.0% of the herds had at least one test where cows with P/F < 0.75 at first test represented more than 40% of the herd. A large proportion of herds (25.0%) had 75% to 100% of their tests with more than 40% of the cows having P/F < 0.75. The percentage of herds with more than 40% of the cows with P/F < 0.75 ranged by month from 25.9% in Aug to 52.0% in Feb. At a given test, herds were identified where all the cows at first test had a P/F <0.75 (4 herds) or P/F > 0.75 (5 herds). This information suggests that milk fat depression and subclinical ketosis need further evaluation in California dairy herds.

Key words: milk fat, protein fat ratio, DHIA records

M283 Performance of post-weaned Holstein heifers fed a grain mix with free choice hay or a total mixed ration (TMR) containing sweet corn cannery waste, hay and dried distillers grains. D. Schimek*[1], D. Ziegler[2], B. Ziegler[1], H. Chester-Jones[2], M. Raeth-Knight[3], and G. Golombeski[3], *[1]Hubbard Feeds Inc., Mankato, MN, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]University of Minnesota, St. Paul.*

Two consecutive studies were conducted to evaluate post-weaned heifer performance when fed TMR diets containing sweet corn cannery waste (SCCW), hay and dried distillers grains (DDGS). In study 1, 112 4-mo old Holstein heifers (av.136.5 ± 1.03 kg) were assigned to 1 of 8 pens (7 heifers/pen) and 1 of 2 treatments for 56 d. Treatments included: 1) Control 16% CP grain mix fed at 2.27 kg/hd daily with free choice (FC) hay; 2) Free choice ensiled TMR (33% SCCW, 33% hay, 33% DDGS, DM basis) top-dressed with 0.75 kg protein pellet at feeding. Heifers fed the TMR had higher ($P < 0.05$) ADG (1.2 vs. 0.98 kg/d), hip height gain (+1.22 cm), body condition score change (+0.44), and gain/feed (0.23 vs. 0.17 kg BW/kg DMI) compared with those fed the control diet. For study 2, dietary composition of the TMR was modified to reduce heifer gain to approximately 1 kg/d and 126 3-mo old Holstein heifers (av. 114.3 ± 0.93 kg) were assigned to 1 of 6 pens (7 heifers/pen) and 1 of 3 treatments for 84 d. Treatments included: 1) Control 16% CP grain mix fed at 2.27 kg/hd daily with FC hay; 2) Free choice ensiled TMR (40% SCCW, 28% hay, 32% DDGS, DM basis) top-dressed with 0.14 kg mineral mix at feeding; 3) Ensiled SCCW mixed daily with hay and distillers grains (40% SCCW, 28% hay, 32% DDGS, DM basis) top-dressed with 0.14 kg mineral mix at feeding. Heifers fed the TMR diets had higher ($P < 0.05$) ADG (1.05 vs.0.93 kg/d), hip height gain (14.1 vs. 13.1 cm), BCS change (+0.87 vs. +0.77) and gain/feed (0.28 vs. 0.22 kg BW/kg DMI) than those fed the control diet. Heifers fed the TMR diets performed similarly but a higher refusal rate was evident when the TMR was mixed daily. Under the conditions of these studies preparing a complete SCCW, hay and DDGS ensiled TMR or mixing a TMR daily with individual ingredients offers a lower cost alternative feed for post weaned heifers from 3 to 6 months of age compared to limit feeding a grain mix with FC hay.

Key words: Holstein heifers, performance, total mixed rations

M284 Effect of feeding duration on growth of group fed dairy calves during transition to an organic production system. B. J. Heins*, D. G. Johnson, and E. A. Bjorklund, *University of Minnesota, St. Paul.*

Heifer calves (n = 61) were used to evaluate the effect of early life feeding duration in a group management system on body weight and hip height. Calves were assigned to feeding groups of 10 in super hutches by birth order, and were born at the University of Minnesota West Central Research and Outreach Center, Morris, Minnesota from March to June 2010. Breed groups of calves were: Holsteins (n = 9) selected for high production (HO), Holsteins (n = 14) maintained at 1964 breed average level (H64), crossbreds (n = 28) including combinations HO, Montbeliarde, and Swedish Red selected for high production (HMS), and crossbreds (n = 10) including combinations of HO, Jersey, and Swedish Red selected for durability (HJS). Early weaning (EW) groups were fed 1.5% of birth weight 13% total solids organic milk once daily until the youngest calf in the group was 4 weeks old, reduced to 0.75% of birth weight for 1 week, and then weaned when the group consumption averaged 0.91 kg starter/calf/day. Late weaning (LW) groups were fed 1.5% of birth weight of organic milk once daily, and then weaned when the group consumed 0.91 kg of starter/calf/day, and the youngest calf in the groups was 9 weeks old. Body weight and hip height were recorded at birth, weaning, and d 90 and 120. Independent variables for statistical analysis were the fixed effects of weaning group (EW or LW) and breed group. Weaning group performance was weaning age (days), EW (44.6) vs. LW (63.6) ($P < 0.01$); gain per day (kg), EW (0.42) vs. LW (0.59) ($P < 0.01$); weaning weight (kg), EW (56.4) vs. LW (73.5), ($P < 0.01$); weaning hip height (cm), EW (83.3) vs. LW (90.4) ($P < 0.01$); 90-d weight (kg), EW (91.1) vs. LW (99.7)

($P < 0.05$); and 120-d weight (kg), EW (113.3) vs. LW (118.5) ($P > 0.25$). The HO (0.51; 67.2), H64 (0.44; 60.8), HMS (0.54; 69.4), and HJS (0.53; 62.3) calves were not significantly different for gain per day (kg) or weaning weight (kg), respectively. In summary, EW calves had less body weight and hip height compared with LW calves during organic transition.

Key words: organic, crossbreeding, calf

M285 Pre- and post-weaning performance and health of dairy heifer calves fed calf starters and grain mixes with glycerol as a replacement for corn. D. Ziegler*[1], H. Chester-Jones[1], A. Doering[2], D. Timmerman[2], M. Raeth-Knight[3], and G. Golombeski[3], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]Agricultural Utilization Research Institute, Waseca, MN, [3]Unversity of Minnesota, St. Paul.*

In phase 1, 120 (2–4 d old) individually fed Holstein heifer calves (40.3 ± 0.08 kg BW) were randomly assigned to 1 of 4 treatments for 56-d. Our objective was to evaluate the use of glycerol as a replacement for corn in calf starters (CS) by evaluating its impact on performance and health pre-(d 1–42) and post-weaning (d 43–56). Treatments were: 1) Complete texturized 18% CP control CS (CON); 2) Complete pellet 18% CP control CS (CONP); 3) 18% CP pelleted CS containing 3% glycerol (27.3 kg/ton; 3%GLY) and 4)18% CP pelleted CS containing 6% glycerol (54.6 kg/ton; 6%GLY). All calves were fed a 20:20 (CP:fat) milk replacer at 0.28 kg/d powder in 2 L water 2 X daily d 1 to 35 and once daily d 36 to 42 weaning. There were no treatment differences ($P > 0.05$) in pre- and post weaning calf performance. Average daily gain and feed/gain for the nursery phase were 0.61kg/d and 1.88 kg feed/kg BW for d 1 to 56, respectively. Health treatment costs were highest ($P < 0.05$) for calves on 6%GLY. Calves were transitioned to group pens and fed the CON CS for 7 d. One-hundred-36 calves (av. 84.7 ± 0.71 kg) were assigned to 6 replicate pens (7 calves/pen) each of 3 limit-fed grain mixes with free choice hay for a 112-d study. Treatments included: 1) 16% CP corn and pellet grain mix fed at 2.73 kg/hd daily for 56 d and 2.27 kg/hd daily from 57 to 84 d; 2) 16% CP corn and pellet mix with 3% added glycerol fed as in 1; and 3), 16% CP corn and pellet mix with 6% added glycerol fed as in 1 and 2. From d 85 to 112 all group pens were fed a common 16% CP grain mix at 2.27 kg/hd daily with free choice hay. There were no overall treatment effects on calf ADG or feed/gain ($P > 0.05$) averaging 1.04 kg/d and 4.39 kg feed/kg BW respectively. Hay intake was lowest ($P = 0.02$) for calves fed the grain mixes with glycerol. Under conditions of this study, glycerol was an effective alternative energy source when partially replacing corn in CS or grain mix formulations.

Key words: calf performance, glycerol, feed formulations

M286 Effect of lactation number, year and season of initiation of lactation on milk yield of rbST-treated cows hormonally induced into lactation. M. Mellado*[1], E. Antonio-Chirino[2], C. Meza-Herrera[3], F. G. Veliz[2], and J. R. Arevalo[4], *[1]Autonomous Agrarian University Antonio Narro, Department of Animal Nutrition, Saltillo, México, [2]Autonomous Agrarian University Antonio Narro, Faculty of Veterinary Medicine, Torreon, Mexico, [3]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, México, [4]University of La Laguna, Department of Parasitology, Ecology and Genetics, La Laguna, Spain.*

Records representing 1,500 barren Holstein cows from a dairy farm in northern Mexico were used to determine the effects of lactation number and season and year of initiation of lactation on milk yield of cows induced hormonally into lactation and treated with rbST throughout lactation. Peak and 305-d milk yield were also assessed as predictors of total milk yield in cows. Variables related with milk yield were analyzed using the MIXED procedure of SAS. Treatment means were separated using the PDIFF option of SAS. Regression analyses were applied to discern relationships between peak milk yield and total milk yield. A significant quadratic relationship was found between 305-d milk yield and number of lactation (7,607 ± 145 and 9,548 ± 181kg for first and ≥ 6 lactation cows, respectively; mean ± SEM) with the highest production occurring in the 5th lactation. Total milk yields of cows with ≤ 2 lactations were approximately 4,500 kg less than milk yields of adult cows (the overall average ± SD milk yield was 13,544 ± 5491 kg per lactation and the average lactation length was 454 ± 154 d). 305-d milk production was depressed ($P < 0.01$) in cows induced into lactation in spring (8,804 ± 153 kg; mean ± SEM) and summer (8,724 ± 163 kg) than in fall (9,079 ± 151 kg) and winter (9,085 ± 143 kg). Partial regression coefficients for 305- milk yield and peak milk yield indicated an increment of 157 kg of milk per lactation per every kg increase in peak milk yield ($r^2 = 0.69$). Neither peak milk yield ($r^2 = 0.18$) or 305-d milk yield ($r^2 = 0.29$) were accurate for predicting total milk yield per lactation. It was concluded that year, parity, and season effects are significant influences on milk yield of cows induced into lactation and treated with rbST throughout lactation, and that peak milk yield can assist in the prediction of 305-d milk yield, but not total milk yield. This study also shows that hormonal induction of lactation is a reliable, practical and affordable technique in countries where rbST treatment and prolonged steroid administration of dairy cows is legally permitted.

Key words: lactation induction, extended lactation, somatotropin

M287 Impact of corn processing method and soy glycerin on fecal shedding from cattle inoculated with *Escherichia coli* O157:H7. D. Paulus*, R. Fink, F. Diez-Gonzalez, J. Jaderborg, G. Crawford, and A. DiCostanzo, *University of Minnesota, St. Paul.*

An experiment was conducted comparing the effects of soy glycerin (GLY), dry rolled corn (DRC), and steam flaked corn (SFC) on *Escherichia coli* O157:H7 shedding in cattle. Twenty-eight Holstein steer calves (160 ± 18 kg) were assigned randomly to one of 4 dietary treatment resulting from a 2 × 2 factorial arrangement (DRC vs. SFC and GLY vs. no GLY) of treatments in a completely randomized design. Diets contained (DM basis): 35% modified distillers grains with solubles, 8% grass hay, 9% supplement, and either 0 or 10% soy glycerin, with the balance of the diet made up of either SFC or DRC. Soy glycerin replaced corn in the 10% soy glycerin treatments. Cattle were inoculated with a dose of 10^{11} cfu per calf with a cocktail of 4 *E. coli* O157:H7 strains resistant to 2 specific antibiotics (nalidixic acid and rifampin) at the start of the 20-d experiment. Individual fecal samples from each animal were collected 3 times weekly over the course of the experiment. Concentrations of *E. coli* O157:H7 in fecal samples were determined through enumeration on selective medium and reported in cfu/g. Data were analyzed using the Proc Mixed procedure of SAS. No significant differences ($P \geq 0.05$) in *E. coli* O157:H7 concentrations were found between the treatments. Overall average fecal counts of *E. coli* O157:H7 decreased ($P \leq 0.05$) over time from 4.5 to less than 1.0 log cfu/g 20 d after inoculation. Results from this experiment indicate that neither soy glycerin inclusion nor corn processing method stimulated the shedding of artificially inoculated of *E. coli* O157:H7. Therefore, under the conditions of our experiment, we conclude that feeding soy glycerin and processed corn had little impact on the colonization of cattle by *E. coli* O157:H7.

Key words: cattle, *Escherichia coli*, glycerin

M288 Different levels of urea in concentrate supplementation of grazing cattle during the transition period of dry to rainy seasons under tropical conditions. A. G. Silva[1], H. J. Fernandes*[2], L. O. Tedeschi[3], M. F. Paulino[1], S. A. Lopes[1], and A. A. Rocha[1], *[1]Federal University of Viçosa, Viçosa, MG, Brazil, [2]State University of Mato Grosso do Sul, Aquidauana, MS, Brazil, [3]Texas A&M University, College Station.*

The objectives of this study were to evaluate the effect of concentrate supplementation and of levels of urea in this concentrate on the nutrient intake and nutrient digestibility of grazing animals during the transition period of dry to rainy seasons. Five young bulls with average BW of 286 ± 21 kg were used in a 4 × 4 Latin square design, with an extra animal. The animals were housed in *Brachiaria decumbens* stapf. pasture and received one of the following supplements during each period: ad libitum mineral (control) or 1.5 kg/d of concentrated supplements (32% of CP) formulated with corn, soybean meal, and 0, 4, or 8% of urea. Each experimental period had 9 d for adaptation and 3 d for consumption and digestibility evaluation. A commercial isolated, purified, and enriched lignin product (LIPE©) was used as the fecal excretion marker and the indigestible NDF was used as an indicator of intake. The concentrate DMI was measured directly. The pastures were hand sampled. The feces samples were collected during 3 d at different times. The effect of the concentrate supplementation and the linear and quadratic effects of the urea levels were evaluated by orthogonal contrasts. The concentrate supplementation reduced the pasture DM and the NDF intakes and increased the CP intake without affect the total DMI. These results showed a substitution effect of the concentrate consumption, reducing the pasture consumption. The digestibility was not affected by the concentrate supplementation. The urea level did not affect the intake or the digestibility of any nutrient.

Table 1. Intake and digestibility in animals supplemented with concentrate with different urea levels

	Supplements				CV (%)	*P*-value		
		Urea level in concentrate						
	Control	0%	4%	8%		Concentrate effect	Linear effect of urea	Quadratic effect of urea
Intake, kg/d

M289 Effects of monensin on rumen metabolism of steers fed 60% dried distillers grains diets. T. L. Felix*[1], N. A. Pyatt[2], and S. C. Loerch[1], *[1]The Ohio State University, Wooster, [2]Elanco Animal Health, Greenfield, IN.*

The S in dried distillers grains with solubles (DDGS) may cause sulfide toxicosis either by inhalation of hydrogen sulfide gas (H_2S) or absorption of sulfides across the rumen wall. Inhalation of H_2S causes S-induced polioencephalomalacia (PEM). Therefore, methods of mitigating H_2S production are needed. Monensin affects acetogenic bacteria by reducing acetate and hydrogen ions. Reduction in hydrogen ions may decrease H_2S formation. Results are conflicting regarding the role of ionophores on H_2S production in vitro. The objectives of this study were to determine the effects of monensin on ruminal pH, H_2S, and organic acids. Eight ruminally fistulated steers (BW = 610 ± 56 kg) were used in a replicated 4 × 4 Latin Square design and assigned to 1 of 4 treatments: 1) 0 mg monensin/kg diet, 2) 22 mg monensin/kg diet, 3) 33 mg monensin/kg diet, and 4) 44 mg monensin/kg diet. The diet was 60% DDGS, 10% corn silage, 15% supplement, and 15% corn on a DM basis and was offered once per day. Calculated dietary S concentration was 0.48%. Periods were 14 d for diet adjustment and 1 d for sample collections (0, 1.5, 3, 6, 9, 12 and 18 h post-feeding). There was no effect ($P = 0.99$) of monensin on DM intake. There was no effect ($P = 0.40$) of monensin on ruminal H_2S concentration. Ruminal H_2S increased from an average of 1913 ppm at 0 h to 4682 ppm within 1.5 h after feeding and remained elevated up to 12 h after feeding for all treatments. Rumen pH was not affected by treatment; however, mean rumen pH dropped from 6.04 to 5.09 within 1.5 h after feeding and was below 5.0 for all treatments up to 12 h after feeding. Despite the low rumen pH and high H_2S concentrations, steers did not suffer clinical symptoms of acidosis or PEM. Rumen liquid sulfide was not affected by time or treatment (range: 14.0 to 38.7 ppm). Rumen concentrations of acetate (A), propionate (P), and A:P were not affected ($P > 0.05$) by monensin supplementation (means at 3 h post-feeding: 53.9 µmol/mL, 57.0 µmol/mL, and 0.95, respectively). Contrary to some in

vitro data, our study suggests that monensin does not increase the risk of S-induced PEM when cattle are fed 60% DDGS diets.

Key words: cattle, dried distillers grains, monensin

M290 Carcass composition of mature cows subjected to a nutritional restriction and two levels of compensatory growth. K. O. Barros[1], H. J. Fernandes*[1], G. L. D. Feijó[2], M. A. Rezende[2,3], H. O. A. Santana[1], E. Rosa[1], L. M. Paiva[1], and J. C. Souza[4], *[1]State University of Mato Grosso do Sul, Aquidauana, MS. Brazil, [2]EMBRAPA Beef Cattle Center, Campo Grande, MS. Brazil, [3]Federal University of Grande Dourados, Dourados, MS. Brazil, [4]Federal University of Mato Grosso do Sul, Aquidauana, MS. Brazil.*

The objective of this study was to evaluate the effect of nutritional restriction followed by 2 ADG rates (0.5 and 1.5 kg/d) during the compensatory growth phase. Fifteen Nellore mature cows were maintained on pasture during May to August in 2010 (dry season). Five cows were kept under maintenance level (i.e., without BW variation) and 10 cows were kept under nutritional restriction by adjusting the stocking rate of the pastures. In August, the animals were moved to a feedlot and had their diet adjusted according to the following 3 treatments: animals in the maintenance group were fed to maintained no BW change (Control) and animals in nutritional restriction group were divided into 2 groups that received diets to allow ADG of 0.5 (T1) or 1.5 (T2) kg/d. Cows were slaughtered after 84 d. The percentage of bone, muscle, and fat tissues were estimated using the composition of the 9–11th rib section (Hankins and Howe procedure). The effects of the nutritional restriction and of the ADG after nutritional restriction were evaluated by orthogonal contrasts. Animals subjected to nutritional restriction (T1 and T2) had more bone tissues (13.4%) than those in the control group (11.5%) ($P = 0.022$). In animals subjected to nutritional restriction, those inT1 had greater (14.5%) content of bone than those in T2 (12.4%) ($P = 0.043$). Animals in T1 and T2 showed a lower content of adipose tissue in the carcass (28.9%) than the control ones (35.5%) ($P = 0.031$). The ADG after nutritional restriction did not affect the fat content in the carcass. The content of muscle in the carcass was not affected by the nutritional restriction or the ADG after this nutritional restriction.

Key words: cattle, nutritional restriction, growth

M291 Combined use of ionophore and virginiamycin on feeding behavior of Nellore steers fed high concentrate diets. A. J. C. Nuñez*[1], V. V. Almeida[2], R. C. Gomes[1], F. T. Mercado[1], I. E. Borges[1], J. Guerra[1], F. Pinese[1], P. R. Leme[1], and J. C. M. Nogueira Filho[1], *[1]USP/FZEA, Pirassununga, SP, Brazil, [2]USP/ESALQ, Piracicaba, SP, Brazil.*

The objective in this research was to evaluate feeding behavior of zebu cattle fed high grain diets and supplemented with salinomycin (SL), virginiamycin (VM) or their combinations. Eight ruminally cannulated Nellore steers, weighing 321 ± 25 kg, were randomly allocated in a 4 × 4 replicated Latin square design (16-d periods), in a 2 × 2 factorial arrangement, with 2 SL levels (0 and 13 ppm) and 2 VM levels (0 and 15 ppm). Animals were housed in individual pens and fed a total mixed ration once daily at 0800 h, with 80% concentrate (60.1% dry ground corn) on DM basis. Feeding behavior was monitored visually over a 24-h period, when eating and ruminating activities were noted every 5 min and assumed to persist for the entire 5-min interval. Total chewing time was calculated as the sum of total time spent eating and ruminating, and total resting time was calculated as the difference between 1440 min and total chewing time. A ruminating bout was defined as at least 5 min of ruminating activity followed by at least 5 min of any other activity. Statistical analyses were conducted using the GLM procedure of SAS. There were no interactions between SL and VM levels for any analyzed variable. Total time spent eating (min/d) and number of ruminating bouts per day were not influenced ($P > 0.05$) by treatments. Steers receiving VM spent 47.8 min/d longer ruminating (376.9 ± 62.9 vs. 424.7 ± 52.9 min/d for 0 and 15 ppm of VM, respectively; $P < 0.01$) and tended to spend 2.5 min more per ruminating bout (27.1 ± 2.5 vs. 29.6 ± 2.0 min/bout for 0 and 15 ppm of VM, respectively; $P = 0.06$) when compared with non-supplemented animals. As a result of longer rumination time, VM treated animals also spent more time chewing (580.3 ± 72.6 vs. 625.9 ± 74.8 min/d for 0 and 15 ppm of VM, respectively; $P = 0.03$) and less time resting (859.7 ± 72.6 vs. 814.1 ± 74.8 min/d for 0 and 15 ppm of VM, respectively; $P = 0.03$) in comparison with non-supplemented steers. These results suggest that Nellore steers receiving 15 ppm of VM may spend more time chewing as a consequence of a healthier ruminal environment.

Key words: antibiotics, beef cattle, salinomycin

M292 Performance and carcass traits of beef bulls fed crude glycerin in the diet. J. P. I. S. Monnerat, P. V. R. Paulino*, S. C. Valadares Filho, I. M. De Oliveira, L. H. P. Da Silva, R. Mezzomo, M. S. Duarte, and S. F. Dos Reis, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The purpose of this study was to evaluate the effect of replacing corn grain with crude glycerin (CG) on performance, carcass traits, and yield of commercial carcass cuts of beef bulls finished on feedlot. The CG used was derived from soybean biodiesel production (84.41% glycerol, 6.94% fat, and 8.64% methanol). Thirty-four Nellore × Angus bulls were used in the study, with an average initial body weight of 343.9 ± 16.56 kg. Four animals were randomly chosen and slaughtered at the beginning of the experiment to determine initial dressing percent. The remaining animals (n = 30) were randomly distributed into 5 treatments (6 replicates): 0, 5, 10, 15 and 20% of CG on diet DM, replacing finely ground corn in the concentrate. The animals were fed isoproteic diets (13% CP) containing 50% corn silage and 50% concentrate, DM basis. At the end of the experiment, all animals were slaughtered, and their gastrointestinal tracts were emptied to determine their empty body weight (EBW). Statistical analyses were conducted using PROC GLM of SAS. No significant effects ($P > 0.05$) of increasing CG levels on the diet were observed for most of the variables evaluated: average daily gain (1.98 kg), dry matter intake (9.56 kg/d), feed efficiency (0.207), EBW gain (2.04 kg/d), carcass daily gain (1.45 kg/d), subcutaneous fat thickness (5.28 mm), rib eye area (75.08 cm^2) and dressing (59.72%). On the other hand carcass length increased linearly ($P < 0.05$), chuck yield increased quadratically, while shoulder clod yield decreased in a quadratic manner ($P < 0.05$) as CG inclusion in the diet increased. There was no effect ($P > 0.05$) of CG inclusion on the diet on the yield of other carcass cuts: flank (13.75%), sirloin (17.82%) and round (27.47%). It can be concluded that CG inclusion up to 20% of DM on beef bulls diets (roughage to concentrate ratio of 50:50) of DM does not compromise animal performance and carcass traits.

M293 Effect of dietary urea-N levels on growth performance and blood biochemical indexes of growth-finishing cattle. L. Jiang*, Y. L. Huo, L. P. Ren, Z. M. Zhou, and Q. X. Meng, *State Key Labora-*

tory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing 100193, China.

As an economic non protein nitrogen (NPN) source, urea is widely used as a substitute of intact feed proteins in ruminant animals, especially in beef cattle. A 91-d feeding trial was conducted using 60 growing-finishing Limousin crossbred bulls to determine the effect of dietary urea levels on growth performance and blood biochemical indexes in a randomized complete block design. The treatment diets were 6 supplemental urea levels in the diets (% DM basis): 0, 0.4, 0.8, 1.2, 1.6 and 2.0, respectively. All experimental diets (60: 40 ratio of concentrate to roughage) were iso-nitrogenous (14% CP on DM basis) with urea-N accounting for 0, 8, 16, 24, 32 and 40% of total dietary N on DM basis. The concentrations of dietary metabolic energy (ME) were balanced at similar levels (ranged from 2.70 to 2.74 Mcal/kg) by using different level of corn grains, corn starch and cottonseed meal. The results showed that as dietary urea level increased, daily DM intake and feed conversion efficiency were not affected significantly ($P > 0.10$), but ADG was quadratically decreased (Q; $P < 0.01$) with a breaking point appearing at 24% urea-N level, suggesting urea-N level at less than 24% of total dietary N had no adverse effect on growth performance of growing bulls. Increasing dietary urea-N level from 24% to 40% resulted in remarkable increased concentrations of blood biochemical indexes such as serum urea-N (Q; $P < 0.05$), total proteins (Q; $P < 0.01$), free ammonia (L; $P < 0.01$), alanine aminotransferase (ALT) (L; $P < 0.01$), aspartate aminotransferase (AST) (L; $P < 0.001$) and creatine kinase (L; $P < 0.05$), respectively. These observations indicated that when urea included diets with about 2.7 Mcal ME/kg DM and 14% CP were fed growing-finishing crossbred bulls, the dietary urea-N up to 24% of total dietary N may have somewhat adverse effect on their physiological or metabolic functions. In conclusion, when safe and effective utilization of dietary urea-N was considered for growth-finishing cattle, the urea-N supplementation level at less than 24% of total dietary N should be recommended in practice.

Key words: growing-finishing cattle, growth performance, urea

M294 In situ ruminal protein degradability of distiller's grain varying grain source and milling process in beef cattle. C. Li*[1,2], W. Z. Yang[1], J. Q. Li[2], Y. L. Li[3], and A. Furtado[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China, [3]Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China.*

An in situ study was conducted to determine ruminal protein degradability of grain and dried distillers grains with solubles (DDGS) varying grain sources (corn vs. wheat) and milling processes (traditional vs. fractional) using fistulated steers. Five different batches of wheat, wheat DDGS (WDDGS), corn, corn DDGS (CDDGS) and fractional DDGS (FDDGS) were collected from 3 different plants located in western Canada or USA. The cattle were fed a diet containing 60% barley silage and 40% barley concentrate. Ruminal microbes were labeled using $^{15}N(NH_4)_2SO_4$ to correct the ruminal bacterial contamination. Five grams of feed were incubated in situ in the rumen of 3 steers for 0, 2, 4, 6, 12, 16, 24 and 48 h. The model $y = a+b(1-e^{-ct})$ was fitted to determine degradation kinetics of CP, where y is CP degraded, a is soluble fraction, b is slowly degradable fraction, c is degradation rate constant, and t is incubation time. Effective degradability (ED) was determined by $ED = a+ [bc/(c+k)]$, where $k = 0.06$/h. Protein contents were 16, 38, 8, 29 and 42% of DM, respectively, for wheat, WDDGS, corn, CDDGS and FDDGS. The fraction a was the highest ($P < 0.05$) for wheat (27%), WDDGS (27%), corn (28%), the medium for CDDGS (24%), and the lowest for FDDGS (7%). In contrast, the fraction b was higher ($P < 0.05$) for FDDGS (60%) than for CDDGS (49%), and was not different for other 3 feeds (66 to 72%). The degradation rate varied ($P < 0.01$) substantially from 3 to 23%/h among 3 feeds. The ED of CP was reduced ($P < 0.01$) by 35%, 28% and 45%, respectively, for WDDGS, CDDGS and FDDGS compared with the parent grains. Correction for bacterial CP contamination on the in situ residues increased ($P < 0.01$) 10% of the ED for corn and FDDGS, but had no change in the ED of other 3 feeds. The results indicate that ruminal CP degradability of DDGS vary considerably with grain source and milling process.

Key words: DDGS, in situ, ruminal protein degradation

M295 Effects of monensin and probiotics on finishing Nellore bulls performance, carcass characteristics, and liver abscesses. C. Sitta[1], A. M. Pedroso[2], G. B. Mourão[1], R. Carareto[1], J. R. R. Dórea[1], T. G. Neri[1], D. A. Rodrigues[1], W. F. Angolini[1], and F. A. P. Santos*[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]Embrapa Catle Southeast, São Carlos, SP, Brazil.*

The objective of the present study was to determine the effect of feeding no feed additives, monensin, yeast culture and a commercially available combination of yeast and probiotic bacteria, on performance and carcass characteristics of cattle fed high starch diets. Ninety-three Nellore bulls with an initial BW of 320 kg were used in a 109-d randomized complete block design feeding trial. Animals were blocked by initial BW and assigned randomly to 16 pens. Animals were raised on pasture and they were adapted to the final diet during the first 21 d of the experimental period. The final diet contained (%DM): 12% tifton grass hay, 78.1% finely ground corn, 6% sugar cane molasses, 1.4% urea, 2.5% mineral and vitamin premix and respective feed additives. Treatments consisted in: 1) Control (no feed additives); 2) Sodium monensin, 30mg/kg DM; 3) Yeast (*Saccharomyces cerevisiae*), 10 g/animal/ day (10^9 cfu/g); 4) Yeast + probiotic bacteria, 3 g/animal/day [*Saccharomyces cerevisiae* (3.33×10^5 cfu/g) + *Bifidobacterium bifidum* (3.33×10^6 cfu/g), *Lactobacillus acidophilus* (3.33×10^6 cfu/g), *Lactobacillus plantarum* (1.66×10^6 cfu/g), *Enterococcus faecium* (1.66×10^6 cfu/g)]. Data were analyzed using the mixed procedure of SAS (1999) with pen as experimental unit. Monensin decreased DMI ($P < 0.1$) compared with the control diet. Average daily gain, feed efficiency and carcass characteristics were not affected by treatments ($P > 0.05$), however, the not significant ($P > 0.05$) 6% better feed conversion for monensin compared with the control diet is in agreement with most of the literature data. The NE values of the diets for BW maintenance and gain (calculated based on DMI, BW and ADG) were not affected by treatments ($P > 0.05$). No liver abscesses were observed.

Table 1. Performance and carcass characteristics of finishing bulls fed differing feed additives for a 109-d period

	Control	Monensin	Yeast	Yeast + bacteria	*P*-value
Initial BW, kg	321.5	321.5	321.4	321.5	0.587
Final BW, kg	485.71	474.98	488.91	481.2	0.743
DMI, kg	9.35	8.25	9.33	9.20	0.094
ADG, kg	1.50	1.41	1.53	1.46	0.758
DMI/ADG	6.27	5.89	6.09	6.28	0.652
Dressing, %	52.06	55.36	53.56	55.9	0.524
Fat thickness, mm	3.43	3.50	3.60	3.59	0.985
LM area, cm^2	70.81	67.51	69.30	69.0	0.368
NEm, (Mcal/kg DM)	1.87	1.98	1.90	1.86	0.34
NEg, (Mcal/kg DM)	1.23	1.33	1.25	1.22	0.31

M296 Effect of feeding alfalfa hay and starter concentrate containing two different levels of fiber on feed intake, body weight gain and feed efficiency. A. Salary Neya*, M. H. Fathi, H. Naeemipour, and H. Farhangfar, *Birjand University, Birjand, Southern Khorasan, Iran.*

The experiment was conducted to determine the effect of alfalfa hay and starter fiber on feed intake, feed efficiency and daily gain. In this study, 32 male Holstein calves at the age of 3 d were assigned to 4 diets with a 2 × 2 factorial completely randomized design, with 8 replications. The experiment was ended 3 weeks after weaning. Two main factors included adding alfalfa hay to diet and the level of Starter fiber, so the 4 experimental treatments were as follows: T1: starter with low fiber and without hay, T2: starter with low fiber along with hay, T3: starter with high fiber and without hay, and T4: starter with high fiber along with hay. The data were analyzed by a linear model in which the effects of fiber and alfalfa and interaction between them were included. Statistical comparisons among different means were carried out by Tukey-Cramer test. The model was fit by SAS software. Results showed that effect of adding hay to the diet and level of starter fiber had no significant effect on feed intake before weaning, after weaning, and throughout entire trial. The level of fiber on Starter had significant on daily gain of calves in the whole period ($P < 0.05$), so that T2 and T4 had greater weight gain than T1 and T3 as well as feed efficiency after weaning and during the entire period by treatments was affected significantly so that T2 and T4 had a higher efficiency than T1 and T3 ($P < 0.05$). It could be therefore concluded that addition of starter fiber to the diets of young calves appears to favorably alter the rumen environment, resulting in an increased daily gain and feed efficiency.

Key words: male Holstein calves, fiber, starter

M297 Effects of supplementation of organic, inorganic or a 50/50 mix of selenium on gene expression profiles in the longissimus dorsi muscle of maturing Angus beef heifers. K. M. Brennan*[1], J. A. Boling[2], R. Xiao[1], D. Mallonee[1], R. F. Power[1], and J. C. Matthews[2], *[1]Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY, [2]Department of Animal and Food Sciences, University of Kentucky, Lexington.*

The aim of this study was to investigate gene expression patterns in the longissimus dorsi (LD) muscle of beef heifers in response to different sources of selenium (Se) supplementation. Forty Angus heifers were assigned (n = 10) to 4 Se treatments for 224d. The basal diet contained 0.08 mg Se/d, whereas the mineral supplements provided no additional Se (control, C), or 3 mg Se/d as inorganic (sodium selenite, SS), organic (Sel-Plex, SP), or a 50/50 mix (Mix). On d224, heifers were slaughtered and samples (~1g) were taken from the LD and flash frozen. Se content in the LD was greater in SP and Mix heifers than C or SS ($P \leq 0.01$). Gene expression profiles were evaluated using the Affymetrix bovine genome array. In the LD, 79, 127 and 170 genes were differentially expressed ($P \leq 0.05$, fold-change ≥ 1.2) in SS, SP and Mix heifers, respectively. Of these genes, only 19 were commonly affected by all 3 Se treatments. Ingenuity pathway analysis revealed that heifers supplemented with SS, SP or Mix had both common and differential pathway enrichment. Top biological functions (molecular and cellular function) upregulated with SS supplementation included cell cycle, cell death and amino acid metabolism. Top upregulated biological functions associated with SP included cell morphology, cellular assembly and organization, and cellular development. Top upregulated biological functions associated with Mix supplementation included lipid metabolism, molecular transport and small molecule biochemistry. All 3 Se sources commonly affected the top biological functions: cellular movement, cell cycle and cell to cell signaling and interaction. Taken together these data indicate that gene expression patterns in longissimus dorsi tissue of beef heifers are dependent on both Se supplementation and on Se source.

Key words: selenium, beef heifer, microarray

M298 Effect of zilpaterol hydrochloride supplementation feeding duration on growth performance and carcass characteristics of feedlot heifers. J. C. Robles-Estrada*[1], H. Dávila-Ramos[1], A. Estrada-Angulo[1], A. Plascencia[2], F. G. Ríos[1], and R. A. Zinn[3], *[1]Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México, [2]Universidad Autónoma de Baja California, Mexicali, B.C., México, [3]University of California-Davis, El Centro.*

Forty-eight crossbred heifers (392.1 ± 24 kg) were used in a 50-d feeding trial (4 pens per treatment in a randomized complete design to performance and hot carcass weight as covariate in carcass traits) to evaluate the effect of feeding duration of zilpaterol hydrochloride (0.15 mg/kg of live weight daily) on growth performance and carcass characteristics. Heifers were fed a diet based on steam flaked corn (2.07 Mcal of NE_m /kg). Cattle fed zilpaterol for the last 0, 20, 25 or 30 d at the end of the finishing period and withdrawn from zilpaterol for the last 3 d on feed. Daily DMI averaged 8.11 ± 0.73 kg and was not affected ($P \geq 0.84$) by treatments. Compared with the controls, zilpaterol increased ($P = 0.01$) carcass adjusted final live weight (3.62%), ADG (27%, $P = 0.03$), gain:feed ratio (28.4%, $P < 0.01$) and apparent dietary NE_m (17.2%, $P < 0.01$). Zilpaterol supplementation did not affect yield grade ($P = 0.09$), USDA quality grade ($P = 0.17$), fat thickness ($P = 0.30$) and KPH fat ($P = 0.73$), but compared with the control group, increased HCW (2.9%, $P = 0.02$), carcass dressing percentage (2.5%, $P = 0.04$) and LM area (8.2%, $P = 0.05$). Reducing zilpaterol feeding duration from 30 to 20 d did not affect ($P > 0.45$) both, growth performance or carcass characteristics. We conclude that zilpaterol administration improved growth performance, HCW, carcass dressing percentage and LM area. Responses to zilpaterol supplementation could be observed since 20 d of zilpaterol supplementation.

Key words: heifers, performance, zilpaterol

M299 Feeding tannins to reduce nitrogen losses from feedlot cattle fed high protein diets containing distillers grains 1. Animal performance and plasma urea nitrogen. K. M. Koenig*, K. A. Beauchemin, and S. M. McGinn, *Agriculture and Agri-Food Canada, Research Centre, Lethbridge, Alberta, Canada.*

Inclusion of distillers grains as an energy source in diets of feedlot cattle increases the protein concentration to levels often exceeding requirements. Excess feed N is largely excreted as urea in urine, a labile form of N with potential for loss to the environment. A completely randomized design with 148 crossbred steers (425 ± 4.3 kg, initial BW) was conducted to determine the effects of feeding condensed tannins (CT), recognized for protein binding effects, with high protein diets on performance and plasma urea N (PUN). Steers were allocated to 16 pens with 4 pens per treatment. The basal diet contained 92% barley grain concentrate and 8% barley silage (DM basis) and was fed as a total mixed ration once per day. The 4 dietary treatments included control (no corn distillers dried grains and solubles, DG0), 20% DG (DG20), 40% DG (DG40) and 40% DG with 2.5% CT (DG40CT) from *Acacia mearnsii* (black wattle tree). Cattle were weighed on 2 d at the start and end of the experiment and on 1 d every 3 wk in between. The DMI was determined from feed offered daily and orts at the end of each 3-wk period. Blood samples were collected from 5 cattle per pen when they were weighed, and PUN was determined as a relative indicator of protein status and urinary excretion of urea N. Data for DMI for each pen, BW, ADG, G:F and PUN for each animal were analyzed as a mixed linear model with diet, time (repeated measure) and diet x time as fixed effects and pen as the experimental unit. The CP content of the diets was 13.2, 15.9, 20.4 and 19.4% for DG0, DG20, DG40 and DG40CT, respectively. There was no effect ($P > 0.05$) of the treatments on DMI (12.0 ± 4.3 kg/d), final BW (621 kg ± 2.5), ADG (1.98 ± 0.07 kg/d), G:F (165 ± 5 g/kg) and carcass traits. The PUN ($P < 0.05$, SEM 6.0 mg N/L) was lowest in cattle fed DG0 (113 mg N/L), highest in cattle fed DG40 (170 mg N/L) and intermediate in cattle fed DG20 (153 mg N/L) and DG40CT (146 mg N/L). Feeding CT to beef cattle fed a high protein diet reduced PUN without altering performance, suggesting lower urinary urea N excretion.

Key words: condensed tannins, distillers grains, finishing cattle

M300 Feeding tannins to reduce nitrogen losses from feedlot cattle fed high protein diets containing distillers grains 2. Nutrient digestibility and route of nitrogen excretion. K. M. Koenig*, K. A. Beauchemin, and S. M. McGinn, *Agriculture and Agri-Food Canada, Research Centre, Lethbridge, Alberta, Canada.*

Eight ruminally cannulated beef heifers (427 ± 41 kg, initial BW) were used in a replicated 4 × 4 Latin square to determine the effects of feeding condensed tannins (CT) with high protein diets containing corn distillers grains on nutrient digestibility and route of N excretion. Periods were 5 wk with 2 wk for transition to the diet, 1 wk for adaptation to CT and 2 wk for measurements. The basal diet contained 92% barley grain concentrate and 8% barley silage (DM basis) and was fed as a total mixed ration once per day. Dietary treatments included control (no corn distillers dried grains and solubles, DG0), 20% DG (DG20), 40% DG (DG40) and 40% DG with 2.5% CT (DG40CT) from *Acacia mearnsii* (black wattle tree). Data were analyzed using a mixed linear model with diet as a fixed effect, and square, period within square and animal within square as random effects. The CP content of the diets was 12.9, 16.8, 20.4 and 20.5% for DG0, DG20, DG40 and DG40CT, respectively. Feed offered and refused were measured daily. Urine and feces were quantitatively collected for 5 d. There was no effect ($P > 0.05$) of CT on DMI, but the inclusion of 40% DG (without and with CT) in the diet decreased ($P < 0.05$) DMI compared with 20% DG. As a result, N intake was similar among heifers fed DG20, DG40 and DG40CT (313 g N/d), and was lower ($P < 0.05$, SEM 18 g N/d) for heifers fed DG0 (220 g N/d). Total tract digestibility of N was similar ($P > 0.05$, SEM 1.1%) among heifers fed DG0, DG20 and DG40 (78.4%), and due to the protein binding effects of CT, was reduced ($P < 0.05$) in heifers fed DG40CT (70.6%). Reduction of N digestibility reflected a shift in N excretion from urine to feces in heifers fed DG40CT compared with DG40 ($P < 0.05$). Feeding CT with 40% DG reduced the amount of N excreted in urine by 17% compared with heifers fed 40% DG and was equivalent to the amount excreted by heifers fed 20% DG. Feeding CT to cattle fed high protein diets shifted the route of N excretion from urine to feces, although there was a 3% decrease ($P < 0.05$) in total tract OM digestibility.

Key words: condensed tannins, distillers grains, nitrogen excretion

M301 Potential modulation of the inflammatory response associated with enteropathogenic *Escherichia coli* infections in young calves using Actigen. A. Aris[1], E. Rodriguez*[1], A. Tort[1], M. Terré[1], F. Fàbregas[1], K. A. Jacques[3], and A. Bach[1,2], *[1]Ruminant Production, Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Caldes de Montbui, Barcelona, Spain, [2]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Barcelona, Spain, [3]Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY.*

Ten male Holstein calves were distributed in 2 groups to evaluate the potential of Actigen (Alltech) to modulate the inflammatory response elicited by enteropathogenic *Escherichia coli* (EPEC). The control (CTR) calves were fed a basal milk replacer, and Actigen (ACT) calves were fed the same milk replacer plus Actigen at the rate of 1g/head/day. After 42 d, calves were euthanized and segments of mid-jejunum harvested. Explants were retreated again with 0.5 mg Actigen ex vivo or incubated with a control media for 1 h at 37°C. Tissues were then either incubated in a control medium (CTR) or the same medium with $1x10^8$ cfu of EPEC for 7h in a 5% CO_2 at 37°C. Supernatant and tissue samples were taken to analyze cytokines. Data were analyzed using a mixed-effects model accounting for the fixed effects of in vivo, ex vivo, infection, and all their 2-way interactions, and the random effect of animal nested within the interaction between in vivo and ex vivo. The ex vivo infection with EPEC infection triggered an inflammatory response by increasing ($P < 0.05$) the levels of pro-inflammatory cytokines IL–1β (135.64 and 206.44 pg/ml for CTR and EPEC, respectively) and IFN-γ (30.80 and 46.51 pg/ml for CTR and EPEC, respectively) and decreasing ($P < 0.05$) the levels of anti-inflammatory cytokine TGF-γ (107.77 and 68.72 mRNA ratio to β-actin for CTR and EPEC, respectively). Both Actigen supplementation in vivo and in vivo plus ex vivo modulated EPEC inflammatory response through the downregulation of IFN-γ (12.39, 0.07, and 1.18 pg/ml for CTR, ACT in vivo, and ACT in vivo-ex vivo, respectively) and the upregulation of IL-10 (1.16 and 1.46 mRNA ratio to β-actin for CTR and ACT in vivo-ex vivo, respectively). At tissue level the production of IL-1β was lower ($P < 0.05$) in ACT (121.51 pg/ml) than in CTR (230.44 pg/ml). These results indicate that Actigen has a positive effect on intestinal tract, regulating not only the inflammatory response triggered by an infection, but also modulating the basal inflammatory response of the tissue.

Key words: inflammation, EPEC infection, Actigen

M302 Effects of crude protein levels on the concentrate supplement on gas production from carbohydrate in vitro degradation of Elephant grass. M. A. C. Danes*, J. R. R. Dorea, and F. A. P. Santos, *University of Sao Paulo/Esalq, Piracicaba, SP, Brazil.*

The trial was conducted to evaluate the effects of concentrate crude protein (CP) levels on gas production from carbohydrate in vitro degradation of Elephant grass (*Penisetum purpureum*) intensively managed. Hand-plucked samples of intensively managed Elephant grass 'Cameron' (18.5% CP; 58.7% NDF) were dried at 55°C, ground at 1 mm and incubated alone or in a 60:40 forage:concentrate ratio with concentrates based on fine ground corn and soybean meal with 3 levels of CP (8.7 – only corn, 13.4 and 18.1% DM). Ruminal inoculum was collected from a protein supplemented grazing animal. Degradation rates (kd) were estimates by the cumulative gas production semi-automated method (Mauricio et al., 1999). Gas pressure was measured at 1, 2, 3, 4, 6, 8, 10, 12, 14, 17, 20, 24, 28, 36, 48, 72 96 and 120 h after incubation. The final gas volume and kd from fibrous (F) and non-fibrous (NF) carbohydrate and lagtime were calculated according to Pell and Schofield (1993) model. The energy concentrate (8.7% CP) affected fibrous degradation, increasing ($P < 0.05$) its kd, decreasing ($P < 0.05$) lagtime and increasing ($P < 0.05$) gas production per unit of NDF incubated (corrected fibrous carbohydrate volume, cFvol). Those results suggest that the limiting nutrient in diets based on intensively managed tropical grasses is the energy and the supply of that nutrient through an energetic concentrate can improve fiber degradation and might result in better animal performance. The addition of protein through soybean meal did not result in any further improvements and reduced cFvol, most likely due to lack of energy.

Table 1. Volume of gas (vol; mL) and kd (%/h) from non-fibrous (NF) and fibrous (F) carbohydrates, corrected Fvol (mL/g FDN) and lagtime (h) of Elephant grass (P) incubated alone or mixed with concentrates with 8.7, 13.4 or 18.1% CP

M303 Effect of 2,4-thiazolidinedione in finishing beef cattle growth performance and carcass traits. M. Arévalo*, L. González-Dávalos, A. Kunio, J. D. Garza, J. L. Dávalos, O. Mora, and A. Shimada, *Universidad Nacional Autónoma de México, Querétaro, Querétaro, México.*

Thiazolidinediones (TZDs) are insulin sensitizing agents, which are used as adipogenic agents. 2, 4-TZD, is a synthetic ligand of peroxisome proliferator activated receptor- γ (PPARγ the main adipogenic transcription factor). The objective of this study was to evaluate the effect of 2, 4-TZD on bovine carcass characteristics. Seventeen Limousin bulls (18 mo old and 350 kg BW) were assigned into 2 treatments: control and 2, 4-TZD (8mg/70 kg BW). The bulls received daily 2 kg of alfalfa hay and 6 kg of a 15% CP; 2.8 Mcal ED/kg DM supplement based on corn, sorghum, soybean meal; the amount offered was adjusted throughout the feeding trial. Orts were removed, weighed, and recorded daily. Bulls were weighed and blood samples obtained from the coccygeal vein at 28-d intervals to determine glucose, triglycerides, and 2, 4-TZD. Animals were slaughtered when they reached 500 kg BW. DNA, RNA and protein were determined in liver, subcutaneous, kidney and omental adipose tissue and skeletal muscle to determine protein synthesis rate and cellular size. PPAR α, δ and γ mRNA expression was measured by qPCR in liver and skeletal muscle and PPARγ mRNA expression in subcutaneous adipose. All data were statistically analyzed, growth performance and carcass data as a randomized blocks; laboratory measurements were analyzed using a model for a completely randomized design. No significant differences were found ($P > 0.1$) in productive (daily weight gain, days at feedlot) and carcass quality (carcass yield, rib eye area, fat thickness) parameters. Muscle synthesis was greater in control animal ($P < 0.05$), while size was greater in 2, 4-TZD treatment ($P < 0.05$). Respect to PPARs expression in liver PPAR α, δ and γ were lower in 2, 4-TZD treatment vs. control ($P < 0.01$), in muscle; in subcutaneous adipose tissue no differences were found for PPARγ mRNA expression. The results suggest the potential use of 2, 4-TZD in beef cattle diets, because it not only improves adipose tissue differentiation, but also liver and muscle fatty acid oxidation (by an increase in PPARα expression), that therefore could result in improvements in energy efficiency.

Key words: TZD, PPAR, beef cattle

M304 Evaluation of rumen protozoa counting under influence of a polyclonal antibody preparation against lactate-producing and proteolytic bacteria in cows fed different energy sources. C. Marino*[2], W. Otero[1], C. Barreto[3], V. Pellizari[3], F. Ferreira[1], M. Arrigoni[2], and P. Rodrigues[1], *[1]University of Sao Paulo, FMVZ-USP, Pirassununga, Sao Paulo, Brazil, [2]University of Sao Paulo State, FMVZ-UNESP, Botucatu, Sao Paulo, Brazil, [3]University of Sao Paulo, ICB II-USP, Sao Paulo, Sao Paulo, Brazil.*

Nine ruminally cannulated cows fed different energy sources were used to evaluate an avian-derived polyclonal antibody preparation (PAP) against specific ruminal bacteria *Streptococcus bovis*, *Fusobacterium necrophorum*, *Clostridium aminophilum*, *Peptostreptococcus anacrobius* and *Clostridium sticklandii* and monensin (MON) on rumen protozoa counting. The experimental design was 3 Latin squares 3 × 3 distinguished by the main energy source in the diet [dry-ground corn grain (CG), high moisture corn silage (HMCS) or citrus pulp (CiPu)]. Inside each Latin square, animals received one of the feed additives per period (21 d) [none (CON), MON or PAP]. Sample collection for quantitative protozoa analysis were performed at 21 d of each period at 4 h after morning meal collected by manual scanning of rumen floor. Data were analyzed by MIXED procedure, which separated the effects of interaction between feed additive and energy source, effect of feed additive, effect of energy source as well as effects of period and animal inside the square. Mean effects were separated by PDIFF. Differences were declared at $P < 0.05$. Relative count of *Entodinium* was influenced by the type of energy source ($P = 0.0467$). Animals treated with CG and HMCS showed greater values of these protozoa when compared with animals receiving CiPu but do not differ between them. It was observed feed additive effect for *Isotricha* ($P = 0.0404$). The group treated with PAP showed great values for relative count compared with CON. The MON group did not differ from the others 2. Also, it was observed an energy source effect for *Isotricha* ($P = 0.0008$), where the animals fed CiPu showed greater relative count than animals fed HMCG and CG that did not differ between them. Polyclonal antibodies plus CiPu addition in the diet resulted in

an increase of relative counting of *Isotricha* protozoa that indicates a possible effect on ruminal microbial population.

Key words: feed additive, microorganism, passive immunization

M305 Inclusion of triticale dried distiller grains with or without oilseeds reduces growth performance but increase alpha-linolenic acid and lowers *trans* 10 C18:1 fatty acid of subcutaneous fat in finishing beef cattle. M. L. He*[1,2], T. A. McAllister[1], H. Sultana[1], M. Oba[3], M. E. R. Dugan[4], J. P. Kastelic[1], and J. J. McKinnon[2], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]University of Alberta, Edmonton, AB, Canada, [4]Lacombe Research Centre, Agriculture and Agri-Food Canada, Lacombe, AB, Canada.*

Flaxseed (FS) and sunflower seed (SS) have been included in finishing diets of beef cattle to increase beef omega-3 fatty acids. Triticale dried distiller's grain with solubles (TDGGS) is a byproduct of the ethanol industry that has been substituted for barley grain in finishing diets. Steers (n = 90; 455 ± 31 kg) were housed in individual pens (n = 15 per treatment) and given ad libitum access to 1 of 6 diets: 1) control (CON) diet (DM basis) consisted of 90% barley grain - 10% barley silage, with barley concentrate substituted for; 2) 30% TDDGS; 3) 10% FS; 4) 30% TDDGS – 8.5% FS (FS+TDDGS); 5) 10% SS; and 6) 30% TDDGS – 8.5% SS (SS+TDDGS). The diets provided 1.3, 1.4, 1.3, 1.4, 1.4 and 1.5 Mcal NEg per kg, 13, 20, 14, 21, 14 and 21% CP, and 3, 4, 7, 8, 8 and 8% EE (DM basis), respectively. During a 12-wk feeding period SQ fat biopsies were collected once monthly for fatty acid analysis. Inclusion of TDDGS in the diet decreased ($P < 0.01$) ADG and feed conversion (FC), whereas inclusion of oil seeds improved ($P < 0.05$) FC. After 12 wk, the concentration of α-linolenic acid (ALA) increased ($P = 0.02$), whereas C18:1 t10 - a major *trans* fatty acid decreased ($P < 0.01$) in SQ fat in cattle fed TDDGS. Inclusion of oilseeds also increased ($P < 0.01$) ALA in SQ fat. In conclusion, inclusion of 30% TDDG in a barley grain finishing diet with or without FS or SS, lowered growth performance but increased omega-3 fatty acids and lowered *trans* fatty acids.

Key words: beef cattle, triticale dried distiller grains, fatty acid

M306 Substitution of wheat dried distiller grains with solubles for barley silage in a barley based finishing diet increases beef alpha-linolenic acid. M. L. He*[1,3], W. Z. Yang[1], T. A. McAllister[1], M. E. R. Dugan[2], K. A. Beauchemin[1], and J. J. McKinnon[3], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Lacombe Research Centre, Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [3]University of Saskatchewan, Saskatoon, SK, Canada.*

Wheat dried distiller grain with solubles (WDDGS) contains low levels of starch but is high in protein and fiber, and has been used as a substitute for barley grain in beef cattle finishing diets. This study investigated the effects of WDDGS on carcass quality and the meat fatty acid profile when it was substituted for barley silage in a barley based finishing diet. Steers (n = 200; 489 ± 30 kg) were fed one of 4 finishing diets consisting of barley concentrate (barley grain plus additives), barley silage and WDDGS (dry matter basis) in ratios of 85:15:0 (CON), 65:10:25 (DG25), 65:5:30 (DG30), and 65:0:35 (DG35) over a 12 wk period. Carcass quality parameters including weight, dressing percentage, back fat thickness, rib eye area, marbling score, quality grade, and meat yield, did not differ among treatments. Substitution of WDDGS for barley silage improved *pars costalis diaphragmatis* (PCD) muscle fatty acid profiles through increasing ($P < 0.01$) concentrations of total polyunsaturated fatty acids (PUFA) including α-linolenic acid (ALA) without affecting major trans fatty acids. WDDGS replacement of 10 and 15% silage in addition to 20% barley grain in the diets increased ($P < 0.05$) ALA from 0.32 g in CON to 0.40 and 0.41 g per 100 g total fatty acids with 24.4 and 26.6% improvement in DG30 and DG35, respectively. The results indicate that replacement of barley silage with up to 35% WDDG increases total PUFA and omega-3 fatty acids in beef without affecting carcass quality.

Key words: beef cattle, wheat dried distiller grains, carcass quality

M307 Effect of early grain feeding on ADG and signaling proteins for protein synthesis in the muscle tissues of beef animals. W. A. D. Nayananjalie*, M. Bell, J. M. Scheffler, H. Jiang, M. A. McCann, D. E. Gerrard, J. Escobar, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Early weaning followed by a period of high grain feeding in beef cattle enhances growth rate and reduces lifetime feed intake. High grain feeding leads to absorption of more glucose precursors which can enhance muscle protein synthesis by signaling through mammalian target of rapamycin (mTOR). This response is partially mediated by insulin, but glucose can also improve ATP levels leading to inactivation of AMP-activated protein kinase and induction of mTOR signaling. The objective of this study was to investigate the effects of early weaning followed by a period of high-grain feeding on signaling protein phosphorylation in muscle. Twelve fall-born, Angus × Simmental steers were either weaned at 106 ± 4 d of age in December (EW, n = 6) and fed a high-gain diet as a group for 148 d or remained with their dams (NW, n = 6) on pasture until weaning at 251 ± 5 d of age in May. Both groups were on pasture (predominantly tall fescue) from 253 ± 5 d to 392 ± 5 d of age. Longissimus muscle tissue biopsies were collected at 253 ± 5 and 392 ± 5 d of age. Total and phosphorylated forms of Akt (Ser473), ribosomal protein S6 (rpS6, Ser235/236), eukaryotic initiation factor 4E binding protein 1 (4EBP1, Thr37/46), and eukaryotic elongation factor 2 (eEF2, Thr56) were determined by Western immunoblotting. The experimental unit was steer. Total:phosphorylated forms and ADG were statistically analyzed for effects of treatment using the MIXED procedure of SAS. ADG was regressed on period and total:phosphorylated forms. EW calves had greater ADG (1.4 ± 0.01 kg/d) during the early grain feeding period than NW calves (0.9 ± 0.01 kg/d; $P < 0.01$). However, NW calves had greater ADG during the subsequent grazing period (0.7 ± 0.04 vs. 0.3 ± 0.04 kg/d; $P < 0.01$). There were no treatment differences in signaling protein phosphorylation ratios for either sampling time. Phosphorylation ratios of Akt, 4EBP1, rpS6 and eEF2 were not correlated with ADG. In conclusion, early weaned calves gained more weight during the early grain feeding period than normal weaned calves and grazing ADG was greater for normal weaned calves.

Key words: ADG, signaling proteins, weaning

M308 Slow release urea can replace nitrogen from soybean meal in dry-rolled corn-based finishing diets for yearling steers. B. P. Holland*[1] and J. S. Jennings[2], *[1]Department of Animal and Range Sciences, South Dakota State University, Brookings, [2]Alltech Inc., Brookings, SD.*

One hundred 92 British crossbred steers (initial BW = 410 ± 23.6 kg) were blocked by BW and allotted to 3 pens within block (12 or 13

steers/pen). Pens were allotted to 3 experimental diets (n = 5 pens per treatment). Diets were dry-rolled corn-based with 3 sources of supplemental CP (N basis): 100% soybean meal (SBM); 50:50 blend of soybean meal and Optigen® (SBM/OPT), a slow release urea; or 100% (OPT). All diets contained a supplement that provided 1.25% equivalent CP from non-protein N, and were formulated to target 12% CP. Steers were individually weighed on (d −1 and 0) and implanted with Revalor-S. Steers were fed at 0800 daily and weighed on a pen basis on d 29, 57, 85, and 117 and individually one day before slaughter (d 117 for blocks 3, 4, and 5 and d 145 for blocks 1 and 2). Blood samples were collected 4 h after feeding on d 1, 22, 50, and 78 (6 steers/pen) for plasma urea N (PUN) analysis. Mixed models were used to analyze data and repeated measures were used to analyze PUN data. Slaughter date x N source interactions were not observed for any variables. Final BW, ADG, DMI, and G:F were similar across N sources ($P \geq 0.31$). However, steers fed SBM/OPT tended to gain faster (1.64 vs. 1.41 kg/d; $P = 0.10$) and be more efficient (0.163 vs. 0.146; $P = 0.08$) than OPT steers from d 57 to 85. Standard carcass measurements were similar ($P \geq 0.22$) across treatments. No interaction ($P = 0.11$) between N source and sampling day were observed in PUN, but concentrations were greatest ($P < 0.001$) on d 1 (15.0 mg/100 mL), intermediate on d 50 (13.7 mg/100 mL) and 78 (13.6 mg/100 mL), and least on d 22 (11.0 mg/100 mL). When supplemental N was provided by OPT, PUN concentrations increased ($P < 0.001$). Plasma urea N concentrations were 11.9, 13.4, and 14.6 mg/100 mL when N was supplied by SBM, SBM/OPT, and OPT, respectively. Data suggest SBM nitrogen can be replaced by OPT in dry-rolled corn-based finishing diets, but increased PUN in steers fed OPT may indicate decreased N efficiency.

Key words: beef cattle, nitrogen, plasma urea N

M309 Acetate clearance rates and postabsorptive capacity to utilize acetate by beef steers. W. A. D. Nayananjalie*, T. R. Wiles, S. Arriola, M. Aguliar, J. Escobar, M. A. McCann, D. E. Gerrard, M. L. McGilliard, and M. D. Hanigan, *Virginia Polytechnic Institute and State University, Blacksburg.*

Weaning beef calves at 200 d of age may not be economically advantageous in all management systems. Early weaning followed by high-grain feeding can improve performance and increase marbling deposition. Because fat synthesis utilizes acetate as a substrate, we hypothesized that early grain feeding may enhance acetate conversion to fat. The objective of this study was to determine the effects of early grain feeding on acetate utilization in growing steers. Eight Angus x Simmental steers were weaned at 105 ± 4 d of age and fed a high-grain diet for 148 d (EW, n = 4) or remained with their dams on pasture until 249 ± 5 d of age (NW, n = 4). Both groups were on grass from 251 ± 5 to 393 ± 5 d of age. Acetate clearance was assessed at 114 ± 5 d (129 ± 12 kg, P1), 141 ± 5 d (160 ± 14 kg, P2), 227 ± 5 d (276 ± 18 kg, P3) and 348 ± 5 d (330 ± 17 kg, P4) of age. A bolus of acetate (4 mmol/kg of BW) was infused into the jugular vein. Jugular blood was collected at −15 min, at 5-min intervals over the first 30 min and 15-min intervals over the next 60 min. Plasma acetate levels were determined by isotope dilution using a GC-MS and plasma glucose levels were determined using a YSI glucose analyzer. Acetate clearance and appearance rate constants were determined by steer by fitting a one-pool model to the data using the Nelder Mead algorithm in acslX. Resulting rate constants were statistically analyzed for fixed effects of period, treatment and period by treatment and blood glucose concentrations were analyzed for fixed effects of treatment, period, time and the covariate effect of acetate concentration using the GLIMMIX procedure of SAS. Acetate clearance rate constants were less ($P = 0.06$) and appearance rate greater ($P < 0.05$) in EW steers during grain feeding. Acetate appearance rate constants were greater ($P < 0.05$) in NW steers in P4. Blood glucose concentrations were greater in NW steers ($P < 0.05$) only in P1. Infusion of acetate did not significantly affect glucose concentrations. Grain feeding increases rates of acetate appearance, yet reduces acetate clearance and suggests feeding high concentrate diets alters acetate metabolism in growing steers.

Key words: acetate, glucose, weaning

M310 Blood profile of bulls fed different levels of crude glycerin. J. R. R. Carvalho, M. M. Ladeira*, M. L. Chizzotti, T. M. Gonçalves, D. M. Oliveira, P. D. Teixeira, A. Nogueira Neto, and P. T. Silva, *Federal University of Lavras, Lavras, MG, Brazil.*

This study was carried out to analyze the effect of crude glycerin on blood concentrations of the enzymes aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl aminotransferase (GGT), creatine kinase (CK) and glucose and creatinine metabolites, after 84 d on feedlot. Forty-four Red Norte bulls received the following levels of crude glycerin (83% glycerol): 0, 6, 12 and 18% of DM. The basal diet consisted of 30% of corn silage, 12% of soybean meal, 56% of ground corn grain and 2% of mineral mixture. Glycerin was added to partially replace corn and corn gluten meal (21% of CP) was added to maintain diets isonitrogenous. Blood samples were collected on d 84 of the experimental period, after 16 h of overnight fasting. The experiment was conducted in a completely randomized design and data were analyzed using PROC GLM of SAS 9.1. The levels of glycerol did not affect the blood concentration of enzymes and metabolites (Table 1). Increased levels of blood glucose could be expected due to gluconeogenic pathway. However, the absence of this effect indicates that glycerol could be used by the liver and enteric tissues. The AST enzyme showed high concentration, which could indicate liver injury, which can be attributed to the low forage:concentrate ratio and absence of ionophores or buffers in the diet. The GGT enzyme appeared in normal concentrations There was not effect for ALT, which is normally present in low concentrations in large animals.. Creatinine remained low and within normal limits, which may indicate absence of toxic effect of methanol (0.02% in glycerin). The level of 18% of crude glycerin in diet DM did not result in health impairment and could be used in feedlot diets. Funded by Fapemig, CNPq, CAPES, and INCT-CA

Table 1. Biochemistry of the blood of bulls fed different levels of crude glycerin

	Crude glycerin level, DM basis					
Item	0%	6%	12%	18%	SEM	*P*-value

M311 Effect of specific polyclonal antibody preparation doses on ruminal variables in cattle fed high concentrate diets. J. Bastos*[2], C. Marino[1], D. Millen[2], R. Pacheco[2], J. Magalhaes[1], J. Carvalho[3], M. Arrigoni[2], and P. Rodrigues[1], [1]*University of Sao Paulo,*

FMVZ-USP, Pirassununga, Sao Paulo, Brazil, [2]University of Sao Paulo State, FMVZ-UNESP, Botucatu, Sao Paulo, Brazil, [3]Nutribeef Consultancy, Botucatu, Sao Paulo, Brazil.

The objective of the present study was to evaluate the effects of different doses of polyclonal antibody preparation (PAP) against specific ruminal bacteria *Streptococcus bovis*, *Fusobacterium necrophorum*, *Clostridium aminophilum*, *Peptostreptococcus anacrobius* and *Clostridium sticklandii* on rumen fermentation parameters (pH, total concentration of volatile fatty acids (tVFA) which included acetate, propionate and butyrate, ammonia nitrogen (NH3-N) and lactate) in cattle fed high concentrate diets. Eight rumen cannulated cows were used in a latin square 4x4, twice replicated. The treatments were T1: 0.0 g/anim/d, (control); T2: 1.5 g/anim/d; T3: 3.0 g/anim/d; T4: 4.5 g/d with 4 experimental periods with 21 d each. Sample collection was carried out at the last day of each period with 2 h of interval between each collection. Data were analyzed by MIXED procedure, which separated the effects of treatments, period, animal nested in square and square. The effect of treatments was evaluated by polynomial regression. Differences were declared at $P < 0.05$. There was no interaction between time and treatment ($P > 0.05$) for any of the rumen variables studied. Independently from time of sampling, there was no linear or quadratic effect on rumen pH, tVFA, molar proportion of acetate, propionate and butyrate and NH3-N. Thus, it can be concluded that different levels of PAP were not sufficient to alter rumen environment with the necessity of more studies to validate or not this observation.

Key words: feed additive, passive immunization, ruminal fermentation

M312 Corn grain processing methods and forage levels in finishing diets for Nellore bulls. R. Carareto[1], F. A. P. Santos*[1], G. Mourão[1], A. M. Pedroso[2], C. Sitta[1], M. P. Soares[1], M. R. Paula[1], R. S. Marques[1], and M. C. Soares[1], *[1]University of Sao Paulo, Piracicaba, São Paulo, Brazil, [2]Embrapa Cattle Southeast, Sao Carlos, São Paulo, Brazil.*

The trial was conducted at the Animal Sciences Department of the University of São Paulo in Piracicaba, SP. One hundred and 90 2 (192) finishing Nellore bulls (403 kg) BW in 32 pens were fed for 99 d to compare diets containing fine ground (FG), dry rolled (DR), high moisture (HM) or steam flaked flint corn (SF) and 2 levels (12 or 20% on DM) of sugar cane bagasse. Data were analyzed as a randomized complete block using the Mixed procedure of SAS, with pens serving as the experimental units. There was no interaction between corn processing methods and diet forage levels ($P > 0.05$). DMI was greater ($P < 0.05$) for dry rolled corn compared with the other 3 processing methods (Table 1). ADG was greater ($P < 0.05$) for steam flaked and high moisture corn than for ground or rolled corn (Table 1). Feed efficiency (ADG/DMI) was greater ($P < 0.05$) for steam flaked corn than for fine ground or dry rolled corn, and greater ($P < 0.05$) for high moisture and ground corn than for dry rolled corn. The greatest ($P < 0.05$) diet net energy values were observed for steam flaked and high moisture corn. DMI was less and ADG, feed efficiency, dressing and diet energy values were greater for cattle fed 12% than 20% forage diets ($P < 0.05$). Forage level had no effect on diet starch digestibility ($P > 0.05$). In conclusion, steam flaked corn and high moisture corn are the greatest, ground corn is intermediate and dry rolled corn is the least in net energy for finishing Nellore bulls. Performance of finishing Nellore bulls is improved with 12% sugar cane bagasse forage diets compared with 20% forage diets.

Table 1. Influence of corn processing on growth performance of feedlot Nellore bulls and dietary net energy values

Variable	FG	DR	HMC	SF	SE	Pr>F
ADG, kg/d	1.12^{b}	1.09^{b}	1.21^{a}	1.25^{a}	0.031	0.0057
DMI, kg	9.37^{b}	10.18^{a}	9.41^{b}	9.26^{b}	0.168	0.0034
ADG/DMI	0.121^{b}	0.108^{c}	0.129^{ab}	0.136^{a}	0.004	<0.001

M313 Effect of sugar and sodium propionate for barley grain in dairy calves starter on weaning and performance. H. Beiranvand, M. Khorvash, G. R. Ghorbani*, A. Homayouni, M. Mirzaei, and S. Kargar, *Isfahan University of Technology, Isfahan, Iran.*

Replacing dietary starch with sugar and sodium-propionate has been reported to improve performance in ruminant animals. This experiment was conducted to determine the effects of replacing different sources of energy with barley grain in dairy calves′ starter on weaning, dry matter intake, average daily gain (ADG), feed efficiency, skeletal growth, and fecal score. A total of 21 male calves (42 ± 4 kg; mean ± SD) were assigned randomly to one of 3 following treatments: 1) no replacing (Control); 2) replacing sugar at 5% of dietary DM with barley (Sugar); and 3) replacing sodium-propionate at 5% of dietary DM with barley (Propionate). These parameters were measured and reported during 3 time periods (d 1 to 42, 43 to 70 and 1 to 70). All data were analyzed as completely randomized design using the MIXED procedure of SAS (SAS, 2003). Each calf was housed in an individual box with unlimited access to water. All dietary treatments were provided ad-libitum in addition to milk (4 kg/head/day). The base of weaning was consumption of 1 kg solid feed during 3 consecutive days. Feeding Sugar significantly decreased age of weaning compared with Propionate (50 vs. 60 d), however, Propionate negatively affected this variable compared with Control ($P < 0.02$). Dry matter intake, ADG, feed efficiency, skeletal growth indices and fecal score were not affected by treatments. Results of current experiment showed that using sugar but not sodium-propionate as an alternative for barley grain in dairy calves starter can be an option based on its cost and availability.

Key words: dairy calves, propionate, sugar

M314 Evaluation of content and epithelial attached bacterial community in the rumen of steers differing in susceptibility to rumen acidosis. Y. Chen*, M. Oba, and L. L. Guan, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

Rumen acidosis is a common digestive disorder problem in ruminant livestock industry. The objective of this study was to determine if ruminal bacteria diversity and density are different between acidosis-susceptible (AS) and acidosis-resistant (AR) beef cattle. Six steers were selected from a pool of 17 steers fed a feedlot diet containing grain at 85% of dietary DM. Based on continuous rumen pH measurements for a 3-d period, steers that were highest (n = 3) and lowest (n = 3) in severity of rumen acidosis, indicated by the area under pH 5.8 (pH units × min/d), were classified as AS and AR animals, respectively. Rumen papillae and digesta were collected at 0, 2, 4 and 6h after feeding and bacterial diversity was characterized using PCR-denaturing gradient gel electrophoresis (PCR-DGGE) and quantitative real time PCR (qRT-PCR) analysis. Bacterial profiles of rumen digesta samples from AR group was 69.7% similar to those from AS group while the epimural bacterial (bacteria attached to the ruminal papillae) profiles from AR group was 73.5% similar to those from AS group. The copy number of total 16S rRNA genes in the rumen digesta of AS steers was 10-fold higher than that of AR steers, while it was not different between AR and AS epimural communities. However, the copy number of 16S rRNA gene of *Selenomonas ruminantium* was higher for AS compared with AR steers ($P = 0.05$) for both digesta and epimural samples. In addition, the copy number of total 16S rRNA genes of epimural bacteria was positively correlated with ruminal pH (r = 0.59, $P = 0.04$) and negatively correlated with total VFA concentration (r = −0.59, $P = 0.05$) for AR steers, but no such relationship was found for AS animals. Furthermore, the copy number of total 16S rRNA genes of content bacteria was positively correlated with molar proportion of butyrate (r = 0.74, $P = 0.006$) for AR animals, while it was negatively correlated with molar proportion of butyrate (r = −0.73, $P = 0.007$) for AS animals. These results suggest that the diversity and population of some bacterial species can be different between AS and AR animals.

M315 Supplementing rumen-protected Met and Lys in alfalfa and red clover silage diets fed to lactating dairy cows. G. A. Broderick*[1], R. P. Walgenbach[1], M. J. de Veth[2], and N. D. Luchini[3], *[1]U.S. Dairy Forage Research Center, Madison, WI, [2]Balchem Corporation, New Hampton, NY, [3]Adisseo, Alpharetta, GA.*

Action of polyphenol oxidase reduces NPN formation in red clover silage (RCS). In 7 previous trials, RCS averaged (% of total N) 36% NPN vs. 54% NPN in alfalfa silage (AS). Feeding RCS increased intestinal protein absorption but with no improvement in N utilization, suggesting depressed utilization of one or more essential AA. This trial tested effects of adding rumen-protected Met (RPM) and Lys (RPL) to AS and RCS diets. Forty-eight lactating Holstein cows were blocked by DIM and parity into 6 squares in an incomplete 8x8 Latin square with a 2x2x2 arrangement of diets: AS or RCS, with or without RPM (15 g/d of Smartamine-Mproviding 10.5 g/d of total Met), with or without RPL (69 g/d of AminoShure-L providing 26 g/d of total Lys). Diets were formulated to contain (DM basis): 50% AS and 20% corn silage or 63% RCS and 7% corn silage; plus 24% corn, 3% solvent soybean meal; and 16% CP and 31% NDF. Periods were 4-wk (total 16 wk); data from the last 2 wk were analyzed using Proc Mixed in SAS. LS-means are reported in the table. Feeding AS increased DMI, yield of ECM, milk fat content and yield, and protein content. However, RCS improved ECM/DMI and MUN. RPM increased DMI and milk fat and protein content. No responses to RPL were detected but RPM × RPL interactions suggested differential responses to RPL versus RPL plus RPM. Lack of silage × RPAA interactions suggested there was no specific impairment of Met or Lys utilization on RCS.

Table 1.

	Forage			RPM, g/d			RPL, g/d

M316 Steam-flaked soybeans in lactating dairy cow diets. H. R. Bruns*[1], K. F. Kalscheur[1], D. J. Schingoethe[1], R. Rosenboom[2],

G. Doppenberg[2], and A. R. Hippen[1], *[1]South Dakota State University, Brookings, [2]Deluxe Feeds, Sheldon, IA.*

While most soybean feedstuffs have been extensively investigated for use in ruminant diets, there is a lack of information regarding steam-flaked soybeans (Deluxe Feeds – EnRG Flakes; Sheldon, IA). This research evaluated various inclusion rates of steam-flaked soybeans (SFSB) in lactating dairy cattle diets. Twelve multiparous Holstein cows (103 ± 39 DIM) were used in a 4 × 4 Latin-square experiment with 28-d periods, 14-d for diet transitioning followed by a 14-d sampling period. Treatments were inclusion of SFSB at 0, 5, 10 and 15% of dietary DM, replacing a mixture of soybean meal, soyhulls, calcium salts of fatty acids, and choice white grease. Animals were fed typical lactating dairy cow diets formulated to be isonitrogenous and isoenergetic containing 60% of DM as forage and 40% of DM as concentrate. Dry matter intake (30 kg/d) was similar for all treatments and milk production was also not different with 42.1, 43.1, 41.9, and 41.9 kg/d for 0, 5, 10, and 15% SFSB, respectively. Milk fat percentage (3.6%) and yield (1.5 kg/d) was similar across treatments. Milk protein percentages (3.6%) and yields (1.15 kg/d) and lactose concentrations (4.9%) were also unaffected by the amount of SFSB in the diet. Feed efficiency (1.4 kg milk / kg DMI) was consistent throughout all dietary treatments. Milk urea nitrogen concentration and yield decreased linearly (14.6, 14.2, 13.9 and 13.3 mg/dL and 6.2, 6.2, 5.8 and 5.6 g/d; $P < 0.01$) as the amount of SFSB in the diet increased. Body weight changes (−3.69, 3.43, 7.97 and 14.8 kg; $P < 0.10$) tended to increase linearly, and body condition score changes (0.07, 0.06, 0.03 and −0.03; $P < 0.05$) decreased linearly as the amount of SFSB in the diet increased. This research demonstrates that steam-flaked soybeans can be substituted for soybean meal and commercial fat sources while maintaining milk and milk fat production and significantly decreasing milk urea nitrogen production.

Key words: steam-flaked soybeans, full-fat soybeans, lactating cows

M317 Effects of different amounts of dietary protected and unprotected niacin on intake and milk production. F. C. Cardoso*[1], J. Garrett[2], and J. K. Drackley[1], *[1]University of Illinois, Urbana, [2]QualiTech, Chaska, MN.*

Oral supplementation of niacin has been reported to increase milk yield in dairy cows. However, its effects on milk yield and components have been variable among studies. Protection of niacin against degradation by rumen microbiota might help achieve consistent response to niacin. Our objective was to determine the effects of 3 levels of protected niacin (PN) in comparison with unprotected niacin (UN) either in the diet or infused into the abomasum. Six multiparous rumen–cannulated Holstein cows (BW = 656 kg) after peak lactation (128 ± 23 d in milk) were assigned to 1 of 6 treatments in a completely randomized 6 × 6 Latin Square with an extra period to measure carryover effects. Periods consisted of a 7-d adaptation period followed by a 7-d measurement period. Cows were fed according to NRC (2001) recommendations. Treatments were: CON, no niacin; INF, abomasal infusion of 12 g unprotected niacin (UN); N12, 12 g UN; BN3, 3 g PN; BN6, 6 g PN; and BN12, 12 g PN. Treatments N12, BN3, BN6, and BN12 were top-dressed on the TMR twice daily. The daily dose of treatment INF was divided in 5 equal portions and infused during the day every 4 h. Cows receiving treatments other than INF were infused with the same volume of water at the same time. Statistical analysis was performed using the MIXED procedure of SAS. Least squares means were separated using the Tukey adjustment. Milk yield tended ($P = 0.06$) to be greater for N12 (37.1 ± 2.3 kg) than for BN12 (33.4 ± 2.3 kg). The DMI was lower ($P = 0.02$) for BN12 (21.5 ± 1 kg) than for N12 (24.3 ± 1 kg). The linear effect among BN3, BN6, and BN12 was significant ($P = 0.04$) for DMI. Feed efficiency (FE = energy-corrected milk/DMI) was greater ($P = 0.04$) for BN12 (1.7 ± 0.1) than for N12 (1.5 ± 0.1).Furthermore, the positive linear effect among BN3, BN6, and BN12 was significant ($P = 0.03$) for FE. The milk fat/protein ratio (F/P) was higher ($P = 0.03$) for BN12 (1.28 ± 0.09) than for N12 (1.15 ± 0.09). The positive linear effect among BN3, BN6, and BN12 was significant ($P < 0.01$) for F/P. In conclusion, cows receiving BN12 had higher F/P and FE but lower milk yield than cows receiving the same amount of UN.

Key words: niacin, milk yield, feed efficiency

M318 Effect of malate supplementation to dairy cows on milk production: A meta-analysis. J. Alcañiz*[1], J. J. Mallo[1], M. Puyalto[1], M. I. Gracia[2], and J. Sánchez[2], *[1]Norel, S.A., Madrid, Spain, [2]Imasde Agroalimentaria, S.L., Madrid, Spain.*

We evaluated the effect of malate supplementation on milk production in lactating dairy cows. Four trials involving 516 dairy cows assessed the efficacy of malate. A blocked design was applied in each study with 2 treatments: 1) Control, and 2) Malate (48–84 g/cow/day). The studies were similar in basic design and each treatment group (T1 Control and T2 Malate) equivalence in terms of parity, pretrial milk yield and days in milk. Three trials supplemented the additive at 48 g/cow/day in the TMR and one study at 84 g/cow/day in the concentrate. Milk production was recorded daily during 71–90 d of lactation and averages calculated in a weekly basis. Data were tested for homogeneity, pooled and combined in a meta-analysis. Data were analyzed using mixed models ANOVA with terms included for the fixed effect of treatment and the random effect of study. Animal (cow) within treatment and study were considered as a random effects. Pretrial milk yield and DIM were included as a covariate. A repeated measures ANOVA was conducted with time. Malate supplementation significantly increased milk production by 2.3% across the lactation weeks studied (41.81 vs. 42.85 kg/d; $P = 0.0107$, SE = 0.33). An interaction between lactation week and treatment was detected ($P = 0.0015$). Malate supplementation increased milk production from the beginning of the trial until the fourth week of trial (41.8 vs. 41.1 kg/d, SE = 0.46; 42.2 vs. 42.3 kg/d, SE = 0.45; 41.6 vs. 42.1 kg/d, SE = 0.44; 41.5 vs. 42.7 kg/d, SE = 0.42; for wk 1 to wk 4, respectively), maintaining the improvement afterward. It can be concluded that the supplementation of dairy cow rations with malate increases milk production under farm conditions.

Key words: dairy cows, malate, milk yield

M319 Independent effects of diet chemical fiber and physical measurements on dairy cows. D. Sauvant*[1], W. Z. Yang[2], D. R. Mertens[3], and K. A. Beauchemin[2], *[1]AgroParisTech-INRA, Paris, France, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]Innovation & Research, Belleville, WI.*

Fiber effectiveness has been defined by peNDF, which is the product of NDF and the fraction retained on a 1.18-mm sieve. To evaluate the concept of using an index (product of fiber and particle size) for predicting cow responses, a meta-analysis was performed to assess the independent and interaction effects of chemical fiber (NDF) and alternative physical measurements (PM). A database was compiled from 24 published experiments using lactating dairy cows and 104 (n) treatments where dietary NDF and PM were reported. Forages were long, chopped or grounded. Dietary NDF averaged 35.3 ± 7.1% of DM.

Three PM were considered: mean particle size (MPS; 3.72 ± 2.02 mm, n = 44), particles retained on a 2-mm sieve (P2; 42.4 ± 15.5% DM, n = 40) or on 19-mm and 8-mm sieves of the Penn State Particle Separator (P8; 49.5 ± 12.7% DM, n = 36). As the PM was not measured with the same criteria across the experiments, a dummy variable (0 or 1) was created to systematically code the short or long PM, respectively. The effects of NDF and PM were tested on chewing index (CI; 37.5 ± 11.9 min/kg DMI, n = 78), rumen pH (6.08 ± 0.26, n = 60), acetate to propionate ratio (A:P; 2.70 ± 0.73, n = 52), milk yield (MY; 29.0 ± 10.6 kg/d, n = 96) and milk fat percentage (MF; 3.75 ± 0.62%, n = 82). Meta analyses were carried out using GLM procedure including the effects of experiment, NDF, PM and the interaction. NDF was a continuous covariable. The mean differences between treatments were: NDF = 4.3%DM; MPS = 1.31mm; P2 = 7.5%DM; and P8 = 8.6%DM. Experiment was systematically significant ($P < 0.01$). For CI, pH and A:P, influences of NDF and PM were significant ($P < 0.01$), but there was no interaction between them. For MY and MF, only the effect of NDF was significant ($P < 0.01$). As expected, MF was negatively affected ($P < 0.01$) by pH (MF = −1.05 + 0.76 pH, n = 48, RMSE = 0.05%). In conclusion, the effects of NDF and PM appeared to be additive in published trials, which questions the principle and the validity of their product (peNDF) for predicting lactating cow responses.

Key words: effective fiber, meta-analysis, dairy cattle

M320 Effect of feeding *Camelina sativa* seeds or meal on lactation performance and milk fatty acid composition in lactating dairy cows. J. P. Sarramone*[1,2], C. Benchaar[3], Y. Lebeuf[1,2], R. Gervais[1], and P. Y. Chouinard[1,2], *[1]Département des sciences animales, Université Laval, Québec, QC, Canada, [2]Institute of Nutraceuticals and Functional Foods (INAF), Québec, QC, Canada, [3]Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC, Canada.*

Camelina sativa and flaxseed are both sources of *c*9,*c*12,*c*15–18:3. The objective of the current study was to evaluate the effects of feeding camelina seeds, camelina meal, flaxseed, or dried distillers grains with solubles (source of *c*9,*c*12–18:2) on milk yield and composition in lactating dairy cows. Four Holstein cows were used in a 4 × 4 Latin square design with 21-d periods, including 14 d of adaptation followed by 7 d of sampling. Four isolipidic dietary treatments (4.5% fat) were formulated: DDGS) 18% corn dried distillers grains with solubles; CM) 9.5% camelina meal; CS) 4.2% camelina seeds; FS) 4.7% flaxseed (DM basis). Differences between treatments were declared significant at $P \leq 0.05$ using the Tukey correction for multiple comparisons. Body weight, DM intake, milk protein content and yield, milk lactose content, MUN, and SCC were similar among treatments. Milk yield was higher for DDGS (37.4 kg/d;*b*), intermediate for CM (37.0 kg/d;*ab*), and CS (36.5 kg/d;*ab*), and lower for FS (35.6 kg/d;*a*). Milk fat content and yield were lower for CM (2.71%, 1000 g/d;*a*) compared with DDGS (3.63%, 1355 g/d;*b*), FS (3.73%, 1328 g/d;*b*), and CS (3.48%, 1258 g/d;*b*). Concentrations (mg/g FA) of *c*11–20:1 and *c*13–22:1 were lower for DDGS (0.9*c* and 0.2*c*), and FS (0.5*c* and 0.1*c*), intermediate for CS (3.4*b* and 1.0*b*), and higher for CM (8.1*a* and 1.8*a*). Cows fed FS had a higher content of *c*9,*c*12,*c*15–18:3 (6.4*a*) in milk fat compared with DDGS (3.5*c*), CM (4.5*bc*), and CS (5.0*b*). Feeding CM and FS increased milk fat content of *c*9,*t*11,*c*15–18:3 compared with DDGS and CS (0.4*a*, 0.4*a*, 0.2*b*, and 0.3*b*, respectively). Milk fat contents of *t*11,*c*15–18:2, *c*9,*t*13–18:2, and *t*13/*t*14–18:1 were higher for CM (7.2*a*, 2.9*a*, and 17.6*a*) intermediate for CS (2.3*b*, 1.9*ab*, 13.4*b*) and lower for FS (1.2*bc*, 1.5*b*, and 8.0*c*) and DDGS (0.8*c*, 1.6*b*, and 8.2*c*). Milk fat contents of *t*10–18:1 and *t*11–18:1 were higher for CM (22.0*a* and 29.2*a*) compared with DDGS (5.4*b* and 17.9*b*), CS (6.4*b* and 17.2*bc*), and FS (3.2*b* and 8.6*c*). In conclusion, FS was more efficient to increase *c*9,*c*12,*c*15–18:3 in milk fat compared with camelina fed as meal or seeds.

Key words: *Camelina sativa*, linseed, milk fatty acids

M321 Milk fatty acid profile of dairy goats fed increasing levels of an unprotected conjugated linoleic acid (UCLA) supplement. D. Fernandes[1], J. Souza[2], M. M. Almeida[3], M. Baldin[1], R. Dresch[1], F. Batistel[2], E. Ticiani[2], M. A. S. Gama[4], and D. E. Oliveira*[2,1], *[1]Centro de Ciências Agroveterinárias, UDESC, Lages, SC, Brasil, [2]Centro de Educação Superior do Oeste, UDESC, Chapecó, SC, Brasil, [3]Universidade Federal de Juiz de Fora, Juiz de Fora, MG, Brasil, [4]Embrapa, CNPGL, Juiz de Fora, MG, Brasil.*

The aim of this study was to evaluate the dose-response changes in milk fatty acid profile associated with the reduction observed in milk fat content and yield of dairy goats fed increasing levels of UCLA (Fernandes et al., 2010, JDS, 93:456). Eight Toggenburg goats (4 primiparous and 4 multiparous; 120–150 DIM) received 4 levels of UCLA in a 4 × 4 Latin square (LS) design. The treatments were: 1) Control: 45 g/d of calcium salts of soybean oil (CSSO); 2) CLA15: 30 g/d of CSSO plus 15 g/d of UCLA; 3) CLA30: 15 g/d of CSSO plus 30 g/d of UCLA and 4) CLA45: 45 g/d of UCLA. Each experimental period lasted 12 d, with 6 d of washout intervals. The UCLA contained 29% of t-10, c-12 CLA and 29% of c-9, t-11 CLA. Lipid supplements were mixed into the concentrate (1.0 kg/d) fed twice a day. Milk samples were collected on the last day of each experimental period for fatty acid analysis. Data were analyzed using GLM procedures, including animal, period, LS, and treatment as sources of variation. The UCLA reduced linearly the desaturase indexes (Table 1). Concentration of fatty acids < 16C in milk fat was linearly reduced as the CLA dose increased, suggesting that inhibition of de novo synthesis was more pronounced with the highest CLA dose. The secretion of t-10, c-12 CLA in milk increased with the CLA dose (Control = 0.02g/d; CLA15 = 0.08g/d; CLA30 = 0.13g/d; CLA45 = 0.17g/d; $r^2 = 0.77$; $P < 0.001$). The transfer efficiency of t-10, c-12 CLA into milk fat decreased with the CLA dose (CLA15 = 1.82%; CLA30 = 1.48%; CLA45 = 1.33%; $r^2 = 0.71$; $P < 0.001$). The milk fatty acid profile was changed in a dose-response way.

M322 Performance and milk fatty acid profile of dairy goats fed a total mixed ration (TMR) containing an unprotected conjugated linoleic acid (UCLA) supplement. M. Baldin[1], J. Souza[2], M. M. Almeida[3], R. Dresch[1], D. Fernandes[1], F. Batistel[2], E. Ticiani[2], F. C. F. Lopes[4], M. A. S. Gama[4], and D. E. Oliveira*[2,1], *[1]Centro de Ciências Agroveterinárias, UDESC, Lages, SC, Brasil, [2]Centro de Educação Superior do Oeste, UDESC, Chapecó, SC, Brasil, [3]Universidade Federal de Juiz de Fora, Juiz de Fora, MG, Brasil, [4]Embrapa, CNPGL, Juiz de Fora, MG, Brasil.*

Lactating goats have been shown to be less prone to trans-10 cis-12 CLA-induced milk fat depression (MFD) than cows and ewes on a metabolic live-weight basis. This study aimed to evaluate the effects of UCLA, fed as a TMR ingredient, on performance and milk fatty acid (FA) profile of dairy goats. Eighteen Toggenburg goats (83 ± 17 DIM) were used in a crossover design with 14 d experimental periods and 6 d washout interval. The treatments were: 1) Control (C): 30 g/d of calcium salts of soybean oil or 2) CLA: 30 g/d of UCLA (29% of trans-10 cis-12 CLA). Lipid supplements were mixed into 1.0 kg of concentrate and then with corn silage (50:50, DM basis) and fed 3 times a day. After complete consumption, corn silage was fed ad libitum and orts recorded. Milk samples were taken every 2 d to determine its solid contents and on the last day of each experimental period for milk FA analysis. Data were analyzed as a repeated measurement design using PROC MIXED of SAS, assuming period and treatment sequence as random effects. Milk yield (1.91 vs. 1.90 kg/d, SEM = 0.28), body weight (45.6 vs. 45.2 kg, SEM = 10.5), dry matter intake per metabolic weight (7.66 vs. 7.53%, SEM = 0.87), milk protein content (2.80 vs. 2.81%, SEM = 0.18) and milk protein yield (51.3 vs. 51.4 g/d, SEM = 7.06) were unchanged ($P > 0.05$) by CLA. CLA reduced ($P < 0.001$) milk fat content (4.10 vs. 3.29%, SEM = 0.39) and yield (75.0 vs. 61.1 g/d, SEM = 9.5). CLA reduced the concentrations of C4:0 to C14:0 chain FA (24.8 vs. 29.0%, SEM = 1.58) and C16:0 (22.9 vs. 26.6, SEM = 1.27), but increased long chain FA in milk fat (45.9 vs. 38.7%, SEM = 2.41, $P < 0.001$). Milk fat trans-10 cis-12 CLA was strongly increased by CLA (0.42 vs. 0.02%, SEM = 0.03, $P < 0.001$), whereas all desaturase indexes were reduced ($P < 0.05$). Results showed that milk fat synthesis was partially reduced despite the large increase in milk fat trans-10 cis-12 CLA content, corroborating previous data indicating that goats are less responsive to CLA-induced MFD than cows and ewes (Acknowledgment: FAPEMIG).

M323 Effects of feeding levels of a milk replacer on growth performance, digestion and metabolism of nutrients, and serum biochemical markers in calves. X. Xu, J. Wang, Y. Tu*, N. Zhang, C.-G. Jiang, and Q. Diao, *Key Laboratory of Feed Biotechnology of Ministry of Agriculture/Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, P. R. China.*

This study investigated the effect of feeding levels of a milk replacer on growth, digestion and absorption of nutrients and serum biochemical markers in calves. Twenty-four newborn Holstein calves were allotted to 3 groups with 8 calves each and each group was fed a milk replacer at 9.5%(group L), 11.0% (group M) or 12.5% (group H) of body weight (BW), respectively, for 8 weeks. Feed intake(FI), BW and body measurement of the calves were measured and blood samples were collected at 0, 2, 4, 6 and 8 weeks of age. A digestion trial was conducted by total collection of feces and urine during 3–4 and 5–6 weeks of age, respectively. Data were analyzed by GLM progress of SAS software. FI differed among 3 groups (519.8, 625.5 and 711.1 g/d, $P < 0.05$). The average daily gain of calves from group M or H was greater than that from group L (357.6 or 349.3 vs. 250.0 g/d, $P < 0.05$) during 3–4 weeks of age. Body length, wither height and heart girth did not differ among 3 groups. During 3 to 4 weeks of age, the apparent digestibility of dry matter (DMD) or organic matter (DOM) were greater in group L than in group H (84.16% vs. 80.69% or 86.55% vs. 82.02%, $P < 0.05$), and the apparent digestibility of crude protein was greater in group M than in group H (68.65% vs. 61.51%, $P < 0.05$). During 5 to 6 weeks of age, DMD, DOM and the apparent digestibility of calcium were greater in group M than in group H (87.11% vs. 85.40%, 88.07% vs. 86.70%, and 67.75 vs. 58.04%, $P < 0.05$). At 2 weeks of age, the serum albumin concentration was greater in group L or M than that in group H (31.49 or 31.38 vs. 29.40 g/L, $P < 0.05$), the serum triglyceride concentration was greater in group H than in group L ($P < 0.05$), and serum urea nitrogen was greater in group M than in group L (3.43 vs. 2.59 mmol/L, $P < 0.05$). At the other ages, serum biochemical markers were not influenced by the treatments. The milk replacer fed at 11.0%BW was better than those fed at 9.5 or 12.5%BW in growth of the calves, especially at 2–4 weeks of age. But the digestion and absorption of nutrients decreased as feeding level increased.

Key words: calves milk replacer, feeding level, growth and digestion

M324 Effect of dietary starch content on response to an intravenous glucose tolerance test in early lactation dairy cows. B. H. Nelson*, K. W. Cotanch, R. J. Grant, and H. M. Dann, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Multiparous Holstein cows (n = 24) were used to evaluate the effect of dietary starch content in corn silage-based diets fed from 1 to 21 d in milk (DIM) on blood metabolites following an intravenous glucose tolerance test (GTT). Cows were fed either 1) a low-starch diet (L; 21.0% starch; 76.5% in vitro 7-h starch digestibility (IVSD); 1.65 Mcal NE_L/kg), 2) a medium-starch diet (M; 23.2%; 76.7% IVSD; 1.67 Mcal NE_L/kg), or 3) a high-starch diet (H; 25.5%; 74.5% IVSD; 1.68 Mcal NE_L/kg). Corn meal was replaced partially with soyhulls and wheat middlings in the L and M diets. The GTT was done on d 15 ± 2. Cows were fasted 1 h before and during the GTT. Glucose (dextrose 50% w/v) was infused via a jugular catheter at 0.25g/kg of body weight. Blood samples were collected at −15, −10, 0, 10, 15, 20, 25, 30, 45, 60, 90, 120, 150, and 180 min relative to glucose administration and analyzed for plasma glucose, serum insulin, and serum nonesterified fatty acids (NEFA). The NLIN procedure of SAS was used to fit exponential curves for [glucose] during the first 60 min of the GTT to calculate clearance rate (CR), time to reach half maximal concentration ($T_{1/2}$), and time to reach basal level (T_{basal}). Area under the curve (AUC) was calculated using the trapezoidal method and actual concentration values discounted for the mean basal concentration (mean of −15, −10, and 0 min). Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS using treatment as a fixed factor and cow within treatment as a random factor. Treatment did not affect ($P > 0.10$) peak [glucose] (218 ± 13 mg/dL), nadir [glucose] (46 ± 3 mg/dL), CR_{60} (3.46 ± 0.38%/min), $T_{1/2}$ (21.4 ± 2.0 min), Tbasal (42.1 ± 1.7 min), AUC_{60} (3018 ± 203 mg/dL × min) or AUC_{180} (2782 ± 366 mg/dL × min). The insulin response (peak: 119 ± 21 μIU/mL; AUC_{60}: 2905 ± 534 μIU/mL × min; AUC_{180}: 2657 ± 518 μIU/mL × min) was unaffected ($P > 0.10$) by treatment. The peak (1151 ± 211 μEq/L) and nadir (212 ± 1 μEq/L) [NEFA] were not different ($P > 0.10$) among treatments. Dietary starch content did not affect glucose metabolism in early lactation cows.

Key words: starch, transition cow, glucose tolerance test

M325 Effect of milk feeding level on pre- and post-weaning performance of dairy calves. E. K. Miller-Cushon[1], R. Bergeron[2], K. E. Leslie[3], and T. J. DeVries*[1], *[1]Dept. Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [2]Dept. Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada, [3]Dept. Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

There is evidence that milk feeding level influences growth and solid feed intake of calves early in life. The objective of this study was to determine the effects of milk feeding level on intake and growth of calves, particularly once transitioned to a novel diet post milk-weaning. Twenty individually housed Holstein bull calves were randomly assigned at birth to a daily milk allotment, fed via a teat for 6 wk: 1) ad libitum (ADL), or 2) a rate of 5 L/d, in 2 feedings (LIM). Concentrate was provided ad libitum during the milk-feeding stage. Calves were weaned during wk 7 by reducing milk allotment by 15%/d. After milk weaning, all calves were fed a complete pelleted diet ad libitum for 7 wks. Intake was recorded daily and calves were weighed 2x/wk. Data was analyzed using a repeated measures mixed model. During milk-feeding, ADL calves consumed more milk (12.2 L/d vs. 4.9 L/d, SE = 0.8, $P < 0.001$), but LIM calves had greater DMI (0.48 vs. 0.09 kg/d, SE = 0.08, $P < 0.001$). ADL calves had greater ADG than LIM during milk-feeding (1.2 vs. 0.6 kg/d, SE = 0.07, $P < 0.001$); before weaning, ADL calves had greater weights (94.2 vs. 68.2 kg, SE = 4.8, $P < 0.001$). During the 7 d of weaning, LIM calves experienced no growth check, while ADL calves plateaued in weight gain (0.7 vs. −0.03 kg/d, SE = 0.15, $P < 0.001$). Upon transition to solid feed, DMI was similar between all calves (in wk 8, 1.9 kg/d, $P = 0.2$), indicating that differences in early feed intake did not influence later willingness to consume a novel ration. Calves had similar ADG immediately after weaning (in wk 8, 0.7 kg/d, $P = 0.9$) and there was no long-term treatment effect on ADG (post-weaning mean of 1.2 kg/d, $P = 0.9$). Thus, greater body weights for calves previously fed ADL were maintained in the post-weaning period (in wk 14, 143.5 vs. 123.5 kg, SE = 5.5, $P = 0.002$); daily DMI as a % of body weight was less for ADL calves (2.7 vs. 3.3%, SE = 0.2, $P = 0.01$), indicating greater efficiency of growth during that time period. The results indicate that calves fed different milk levels had similar long-term intakes and ADG; however, ADL calves maintained their advantage in body weight during the post-weaning period.

Key words: dairy calf, milk feeding level, growth

M326 Effects of methionine hydroxy copper supplementation on lactation performance, fertility, nutrients digestibility and some metabolic indices in dairy cows. F. Wang[1], S. L. Li*[1], Y. J. Wang[1], X. Jin[1], H. Cao[2], F. C. Guo[2], and Y. M. Wan[2], *[1]State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China, [2]Novus International Research Center, Beijing, China.*

The objective of the study was to investigate the effects of chelated copper ((HMTBA)2-Cu; MINTREX Cu Novus International Inc., St. Charles, MO) on lactation and reproductive performance of dairy cow. Thirty lactating Holstein cows were assigned into 3 groups using randomized block design: 1) S: 12 ppm Cu in concentrate provided by CuSO4; 2) SM: 6 ppm Cu provided by CuSO4 plus 6 ppm by (HMTBA)2 Cu; 3) M: 12 ppm Cu provided by (HMTBA)2 Cu, and the level of diet Cu was determined according to NRC (2001) requirement. The trial was completed in 120 d, including 20 d for adaptation. The results showed that the average milk yield and 4% FCM yield of cows in SM were increased significantly compared with those in the S and M($P = 0.08$; $P = 0.06$). Cows fed SM had lower milk lactose compared with S or M fed cows. Reproductive performance showed that the number of follicles and ovarian score of SM and M increased numerically ($P > 0.05$) . ADF apparent digestibility of SM increased compared with S ($P < 0.1$), while the digestibility of NDF increased compared with M ($P < 0.1$). According to the comprehensive analysis of serum at fasting and hours 1, 2, and 4 after first feeding, Significantly decrease was observed for serum Cu concentration of SM ($P < 0.01$) while significantly increase was observed for serum K concentration in SM and M compared with S ($P < 0.05$). It is concluded that feeding 6 ppm chelated Cu plus 6 ppm CuSO4 optimized performance of dairy cows.

Key words: fertility, methionine hydroxy copper, nutrient digestibility

M327 Effects of methionine hydroxy zinc supplementation on lactation performance, fertility, nutrients digestibility and some metabolic indices in dairy cows. F. Wang[1], S. L. Li*[1], H. Cao[2], F. C. Cao[2], and Y. M. Wang[2], *[1]State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China, [2]Novus International Research Center, Beijing, China.*

The objective of the study was to investigate the effects of chelated zinc ((HMTBA)2-Zn; MINTREX Zn Novus International, Inc., St. Charles, MO) on lactation and reproductive performance of dairy cow. Thirty lactating Holstein cows were assigned into 3 groups using randomized block design: 1) S: 42 ppm Zn in concentrate provided by ZnSO4; 2) SM: 21 ppm Zn provided by ZnSO4 plus 21 ppm by HMTBA)2 Zn; 3) M: 42 ppm Zn provided by HMTBA)2 Zn, and the level of diet Zn was determined according to NRC (2001) requirement. The trial was completed in 120 d, including 20 d for adaptation. The results showed that milk yields of the 3 groups showed slight downward trends overall and the average milk yield of all cows during the trail was 29.89kg/d. The average milk yield and 4%FCM of S (28.79kg; 29.28kg) were lower than the SM (30.40kg; 32.49kg) and the M (30.49kg; 31.04kg), but no significant difference were found between groups ($P = 0.42$; $P = 0.53$). Cows fed SM had lower milk lactose compared with S or M fed cows ($P = 0.08$). Numerically, the apparent digestibility of organic matter, crude protein, crude fat and acid detergent fiber of S were the lowest The serum alkaline phosphatase and Lactate dehydrogenase contents in M cows were significantly higher than the S and the SM ($P < 0.05$). According to the comprehensive analysis of serum at fasting and hours1, 2, and 4 after first feeding, the serum zinc concentration of S was significantly lower than SM and M group ($P = 0.01$), while K ion content was significantly higher than the SM and M ($P = 0.04$). It is concluded that feeding 42 ppm of chelated zinc optimized the performance and Zn status of dairy cows.

Key words: fertility, methionine hydroxy zinc, nutrient digestibility

M328 Effect of metabolizable protein level on milk production and composition of early lactating Holstein cows. A. Laki, K. Rezayazdi, and M. Dehghan-Banadaky*, *Animal Science Department, Campus of Agricultural and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

The objective of present study was to investigate the effects of metabolizable protein (MP) levels on milk production and milk composition in early lactating cows. Twenty 4 Holstein cows in early lactation (days

in milk = 30.67) were assigned to 4 diets with different MP levels included: 1) 10.60%, 2) 11.07%, 3) 11.54%, and 4) 12.00% basis of dry matter (DM). MP values for diets were determined by CNCPS software (V 5.2). Experiment lasted in 8 weeks. Cows were milked 3 times a day and milk yield was recorded at each milking times. Milk samples were taken every week. Milk compositions were analyzed by infrared test method. The results of this study showed that fat corrected milk (FCM) yield and protein yield increased as MP level increased until 11.54% (DM) and then decreased ($P < 0.05$). Milk fat percentage and yield not affected by MP level ($P > 0.05$). Milk lactose, solids not fat, total solids percentage and yield were the highest at 11.54% (DM) level (diet 3). Increasing MP level more than 11.54% (DM) did not improve milk composition. Milk urea nitrogen increased linearly as MP level increased. We conclude that nitrogen efficiency decrease linearly as MP level increased and relationship between FCM yield and milk protein yield with MP level is nonlinear.

Table 1. Effects of MP offered to dairy cows in early lactation on milk yield and milk composition

Item	1	2	3	4	SEM
Milk yield (kg/d)	34.78^{b}	35.0^{b}	36.01^{a}	36.44^{a}	0.60

M329 The effect of reducing dietary phosphorus on bone metabolism in lactating dairy cows. L. Puggaard[1], A. Liesegang[2], J. Sehested*[1], and P. Lund[1], *[1]Department of Animal Health and Bioscience, Aarhus University, Tjele, Denmark, [2]Vetsuisse Faculty, University of Zurich, Zurich, Switzerland.*

The effect of dietary phosphorus (P) on P balance and concentration of bone resorption marker carboxyterminal cross-linking telopeptide of Type 1 bone collagen (CTX) and bone formation marker osteocalcin (OC) were investigated in 18 Danish Holstein cows (676 ± 73 kg BW) in the period −6 to 36 weeks relative to calving. However, only data from wk 2, 6 and 12 will be presented here. Cows were blocked by calving date and randomly assigned to one of 3 dietary treatments: Low P (LP), Medium P (MP) or High P (HP) providing 2.2, 2.8 and 3.5 g P/kg DM. A pre-mix LP concentrate was composed of sugar beet pulp, soybean meal, molasses, rapeseed oil, feed salt and urea. The LP ration was composed of (g/kg DM): 461 (premix), 287 (corn silage), 163 (grass silage) and 88 (molasses). MP and HP diets were obtained by adding NaH2PO4 to the LP pre-mix. All diets were fed ad libitum. Individual P balances (difference between P intake and P in milk, feces and urine) were recorded at wk 2, 6 and 12 relative to calving. Milk yield and DMI were recorded over 2 d and corresponding fecal outputs were estimated by grab sampling and feed INDF as marker. Urinary output was estimated from 6 h quantitatively sampling. Blood samples were collected from the tail vein. Concentrations of CTX and OC were determined in serum using commercial available immunoassays. Intake of DM (kg/d) was significantly ($P = 0.0003$; SEM = 1.2) lower in LP (15.4) compared with HP (21.4) and MP (20.3). Milk production was similar among treatments (33.8 kg/d, $P = 0.51$; SEM = 3.0). Concentration of CTX (ng/mL) was significantly ($P = 0.005$; SEM = 1.3) higher in LP (5.4) compared with HP (2.7) and MP (2.9), whereas OC was similar among treatments (58.6 ng/mL, $P = 0.41$; SEM = 12.1). Balance of P (g/d) was significantly ($P = 0.01$; SEM = 5.8) lower in LP (−24.4) compared with HP (−10.2) and tended ($P = 0.06$) to be lower in MP (−19.5) compared with HP. The results suggest that cows were not able to maintain DMI at LP. The results also indicate that plasma CTX reflects P balance, which is influenced by dietary P level in early lactation.

Key words: bone markers, CTX and OC, phosphorus balance

M330 Evaluation of rumen microbial diversity population under influence of a polyclonal antibody preparation against lactate-producing and proteolytic bacteria in cows fed different energy sources. C. Marino*[2], W. Otero[1], C. Barreto[3], V. Pellizari[3], F. Ferreira[1], M. Arrigoni[2], and P. Rodrigues[1], *[1]University of Sao Paulo, FMVZ-USP, Pirassununga, Sao Paulo, Brazil, [2]University of Sao Paulo State, FMVZ-UNESP, Botucatu, Sao Paulo, Brazil, [3]University of Sao Paulo, ICB II-USP, Sao Paulo, Sao Paulo, Brazil.*

Nine ruminally cannulated cows fed different energy sources were used to evaluate an avian-derived polyclonal antibody preparation (PAP) against specific ruminal bacteria *Streptococcus bovis*, *Fusobacterium necrophorum*, *Clostridium aminophilum*, *Peptostreptococcus anaerobius* and *Clostridium sticklandii* and monensin (MON) on rumen protozoa counting. The experimental design was 3 Latin squares 3 × 3 distinguished by the main energy source in the diet [dry-ground corn grain (CG), high moisture corn silage (HMCS) or citrus pulp (CiPu)]. Inside each Latin square, animals received one of the feed additives per period (21 d) [none (CON), MON or PAP]. The ruminal content was collected in the d 21 of each trial at 4 h after feeding for the analysis of microbial ruminal diversity by the denaturing gradient gel electrophoresis (DGGE). Data were analyzed by MIXED procedure, which separated the effects of interaction between feed additive and energy source, effect of feed additive, effect of energy source as well as effects of period and animal inside the square. Mean effects were separated by PDIFF. Differences were declared at $P < 0.05$. An interaction between feed additive and energy source ($P = 0.0423$) was observed for the count of bands that were amplified in DGGE for *Archaea* community. In animals fed HMCS, the number of bands amplified in DGGE for *Archaea* community was greater in CON group (5.67) compared with MON (2.33) and PAP (2.67). In general lines, in the present experiment, it was not possible to assign that there was a pattern in the structures of amplification by *Bacteria* and *Archaea* communities of the ruminal content of animals treated with 2 different rumen modifiers or 3 distinct energetic sources.

Key words: denaturing gradient gel by electrophoresis, ionophore, microorganism

M331 Effect of poly-unsaturated fatty acid on plasma and milk fatty acid composition in early lactating dairy cows. B. Vlaeminck*[1], M. Hostens[2], E. Colman[1], S. De Campeneere[3], G. Opsomer[2], and V. Fievez[1], *[1]Laboratory for Animal Nutrition and Animal Product Quality, Ghent University, Melle, Belgium, [2]Department of Reproduction, Obstetrics and Herd Health, Ghent University, Merelbeke, Bel-*

gium, [3]Department of Animal Sciences, Institute for Agricultural and Fisheries Research, Melle, Belgium.

Twenty 4 Holstein cows were randomly assigned to 3 groups to evaluate the effect of feeding n-6 (18:2n-6 or 20:4n-6, from 2 weeks before expected calving date to 2 weeks after parturition, period 1 (P1)) followed by n-3 poly-unsaturated fatty acids (FA) (18:3n-3 or 22:6n-3, P2) on plasma and milk FA. FA (140 g/d 18:2n-6 or 18:3n-3 and 22 g/d 20:4n-6 or 22:6n-3) were supplied as plant (soybean oil and extruded linseed; treatment 1) or as marine oils (Vevodar and DHA-gold, treatment 2). In the control treatment, palm prills were used to obtain iso-energetic, isoproteinic and isolipidic diets. Milk parameters were monitored weekly during the first 7 weeks of lactation in milk samples obtained during 4 consecutive milkings per week. Plasma was sampled on day −14, −7, 0, 8, 14, 20, 26, 33, 40 and 46 relative to parturition. Supplementation with 18:2n-6 (P1) did not increase plasma FA proportions (g/100g FA) of 18:2n-6 whereas trans-10–18:1 (0.07 vs. 0.12, $P < 0.01$) and trans-11–18:1 (0.44 vs. 0.73, $P < 0.05$) increased compared with the control. Supplementation with 20:4n-6 (P1) increased its proportion in plasma (3.13 vs. 3.78, $P < 0.05$). In P2, 18:3n-3 supplementation increased 18:3n-3 (5.4 vs. 8.6, $P < 0.001$). Feeding 22:6n-3 increased trans-10–18:1 (0.07 vs. 0.63, $P < 0.001$), trans-11–18:1 (0.40 vs. 1.55, $P < 0.001$) and 22:6n-3 (0.16 vs. 0.87, $P < 0.001$), whereas 18:0 decreased (12.4 vs. 10.1, $P < 0.001$). Changes in plasma FA were largely reflected in milk with an increase in 18:3n-3 (0.36 vs. 0.68, $P < 0.001$) when 18:3n-3 was supplemented. Feeding 22:6n-3 increased trans-10–18:1 (0.57 vs. 2.03, $P < 0.001$), trans-11–18:1 (1.18 vs. 3.24, $P < 0.001$) and 22:6n-3 (0.02 vs. 0.05, $P < 0.001$), whereas 18:0 decreased (12.0 vs. 8.5, $P < 0.001$). The increase in plasma 20:4n-6 in P1 was not reflected in milk whereas 18:2n-6 in milk fat increased (1.52 vs. 1.74, $P < 0.05$) through 18:2n-6 supplementation despite similar proportions in plasma FA. In the current experiment, supplementation of n-3 FA from 2 to 7 weeks in lactation increased their plasma concentration in a form which allows extraction by other tissue as shown by changes in milk FA.

Key words: dairy, fatty acids

M332 Effect of extruded flaxseed or alfalfa protein concentrate in interaction with two levels of concentrate on milk protein and Ca synthesis. C. Hurtaud*[1], G. Chesneau[2], D. Coumier[3], and J. L. Peyraud[1], *[1]INRA-Agrocampus Ouest UMR1080 Production du Lait, Saint-Gilles, France, [2]Valorex, Combourtillé, France, [3]Desialis, Paris, France.*

Feeding extruded flaxseed (FLAX) and alfalfa protein concentrate (APC) to dairy cows increased milk omega-3 content but their effect on other milk components is not known yet. The objective of this study was to compare the effect of FLAX and APC in interaction with the level of concentrate on milk protein composition and Ca content. The corn silage based diets were composed with 30% (C0) or 65% concentrate (C+) and supplemented with FLAX (1 kg.d^{-1}) or APC (2 kg.d^{-1}). The diets supplied the same level of energy, protein and Ca. The trial was carried out according a nested reversed design using 24 dairy cows averaging 117 ± 14 DIM with 2 periods of 14 d. Data were analyzed according a split plot design using proc mixed procedure. The significance threshold was set at $P \leq 0.05$. There was no significant interaction between the sources of omega 3 and the level of concentrate. C+ significantly increased milk yield (+ 3.7 kg), milk protein content (0.16%) and yield (141 g.d^{-1}). C+ largely decreased casein/protein ratio (−2.6% units) and increased total and colloidal Ca (respectively +172 and +148 mg.kg^{-1}). Increase in milk soluble protein might reflect a loss of integrity of mammary epithelium and/or a production of inflammatory proteins (such as haptoglobulin) associated with subacute ruminal acidosis. High level of concentrate could have induced bone mobilization to produce bicarbonate thus making more available Ca for mammary gland. Compared with FLAX, APC tended to decrease milk yield (0.9 kg.d^{-1}, $P = 0.061$), despite no effect on DMI. APC increased both total protein and casein contents without impact on casein/protein ratio and protein yield. It decreased milk urea content. These results suggest that APC might have not changed the total supply of metabolic protein while reducing the supply of ruminal soluble nitrogen. APC decreased soluble Ca content. This result suggests that biodisponibility of Ca is lower for APC than for CaCO3 and minerals. This experiment shows that the source of omega-3 affects milk casein content whereas large increase of concentrate level does not increase milk casein content even though protein content increased.

Key words: concentrate, lipids, milk Ca

M333 Effect of cow variation on the efficiency of nitrogen recycling to the rumen in dairy cattle. M. Aguilar*[1], M. E. Van Amburgh[2], W. A. D. Nayananjalie[1], and M. D. Hanigan[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Cornell University, Ithaca, NY.*

Milk urea nitrogen (MUN) and blood urea nitrogen (BUN) are correlated with nitrogen balance and nitrogen excretion. Wood et al. (2003) found that cows in lactations 1, 2, and 3 had a heritability for MUN of 0.44, 0.59, and 0.48, respectively. The genetic components of MUN concentrations may be associated with differences among urea transporters in the kidney and the rumen wall. We hypothesized that on a common diet, MUN concentrations would be inversely correlated with gastrointestinal entry rates (GER) of urea. Eight lactating cows with similar milk production but varying MUN levels were selected for the study. Cows remained on a common diet, and nitrogen balance and urea kinetics (using [^{15}N^{15}N] urea) were assessed during a 4 d period. Urea synthesis (UER), GER, and urinary urea excretion (UUE) were calculated from ^{15}N enrichments (Lobley, 2000). MUN levels ranged from 10.3 – 16.7 mg/dl and averaged 14.91 ± 2.06 mg/dl. Milk yield and body weight averaged 26.34 ± 4.39 and 505.64 ± 61.87 kg, respectively. N intake and fecal N output averaged 0.51 ± 0.06 and 0.49 ± 0.09 kg of DM, respectively. Despite the common diet and similar milk production, UER was variable averaging 21.26 ± 2.61g/h. GER, UUE, and UUE/UER were also variable averaging 13.57 ± 1.98 g/h, 7.69 ± 2.01 g/h, and 0.36 ± 0.08, respectively. UER was positively correlated with GER, but not with N intake due to minimal dietary N variation, indicating GER is a significant determinant of UER. Further, UER was also positively correlated with MUN ($P = 0.03$) indicating MUN variation is driven by UER. MUN was also positively correlated with UUE ($P = 0.1$), but contrary to our hypothesis, MUN was not correlated with GER ($P = 0.42$). GER variation may be driven more by fermentable carbohydrate supply, than by urea concentrations in blood. Thus MUN was driven by UER, and UUE was driven by blood urea concentrations as reflected by MUN. MUN was not an indicator of GER.

Key words: gut entry rate, recycling, urea

M334 Effect of enhanced feeding rates of conventional milk replacer on pre- and post-weaning performance and health of dairy calves. D. Carlson*[1], B. Ziegler[2], D. Schimek[2], M. Raeth-Knight[3], G. Golombeski[3], J. Linn[3], N. Litherland[3], D. Ziegler[4], and H. Chester-Jones[4], *[1]Milk Products, Chilton, WI, [2]Hubbard Feeds Inc.,*

Mankato, MN, [3]University of Minnesota, St. Paul, [4]University of Minnesota, Southern Research and Outreach Center, Waseca.

Holstein heifer calves [n = 100, 2–4 d old, average bodyweight (BW) = 39.9 kg] were used in an experiment to evaluate the effects of enhanced (ENH) feeding rates of conventional milk replacer (MR) on calf growth, starter intake, and health during pre- (d 1–42) and post-weaning (d 43–56) periods. Calves were housed in individual calf pens within a naturally ventilated barn with curtain sidewalls. All calves were fed a 20% CP, 20% fat all-milk MR reconstituted to 15% solids, an 18% CP (as-fed basis) texturized calf starter and free-choice water. Calves were assigned randomly to 1 of 4 treatments: 1) 0.57 kg/d (as-fed MR powder weight) d 1–35 and 0.28 kg/d d 36–42 (CON), 2) 0.68 kg/d d 1–21, 0.45 kg/d d 21–35 and 0.23 kg/d d 36–42 (ENH21), 3) 0.68 kg/d d 1–28, 0.45 kg/d d 28–35 and 0.23 kg/d d 36–42 (ENH28), and 4) 0.68 kg/d d 1–35 and 0.34 kg/d d 36–42 (ENH35). Calf BW on d 56 was greater ($P < 0.05$) for ENH35 (79.2 kg) and ENH28 (78.5 kg) calves compared with CON (75.1 kg), whereas BW of ENH21 (76.6 kg) calves did not differ from CON. Average daily gain from d 1–56 tended to be greater ($P = 0.10$) for ENH35 (0.70 kg/d) than for CON (0.63 kg/d) calves, with ENH21 (0.65 kg/d) and ENH28 (0.69 kg/d) calves having intermediate growth rates. Frame growth from d 1–56 also differed due to treatment; ENH35 (10.5 cm) and ENH28 (9.91 cm) calves had greater ($P < 0.05$) hip height gain than CON (8.81 cm), while ENH21 (9.47 cm) calves had similar changes in frame growth compared with CON. Coinciding with decreased MR intake, calves on the ENH21 treatment had greater ($P < 0.05$) starter intake from d 22–35 compared with ENH35, whereas ENH28 calves consumed more ($P < 0.05$) starter than ENH35 calves from d 29–35. Overall, starter intake from d 1–42 and 1–56 did not differ ($P > 0.10$) among treatment. Total MR intake (as-fed) was 22.6, 22.9, 24.5, and 26.6 kg/calf for CON, ENH21, ENH28, and ENH35, respectively. Health parameters did not differ among treatments. Compared with CON, feeding ENH rates of a conventional MR (0.68 kg/d) for at least 28 d increased d 56 BW and d 1–56 hip height gain without affecting starter intake.

Key words: calves, milk replacer, feeding rate

M335 Form of trace mineral supplementation on complete lactation performance, reproduction, and locomotion in Holstein cows. G. I. Zanton*[1], D. E. Diaz[1], M. Vazquez-Anon[1], and J. E. Nocek[2], *[1]Novus International Inc., St. Charles, MO, [2]Spruce Haven Farm and Research Center, Auburn, NY.*

When formulating to meet the absorbable trace mineral requirements of the cow, the level of trace mineral required in the diet can vary depending on source and form due to differences in bioavailability. The objective of this experiment was to evaluate the effects of feeding the chelated trace mineral, Mintrex (Zn, Cu, and Mn) at a reduced level compared with inorganic trace minerals (ITM) supplied as sulfates on a commercial level, on complete lactation (305 d) performance, reproductive performance, and locomotion in Holstein cows. To accomplish this objective, 216 Holstein cows were housed in 4 pens (2/treatment) for a complete lactation and fed diets containing ITM formulated to supplement Zn, Cu, and Mn at commercial levels or all ITM replaced by Mintrex and formulated to supplement at approximately half commercial levels. Group DMI and individual milk production was monitored daily, milk composition was evaluated monthly, locomotion scores were evaluated at 150 and 300 DIM, and reproduction performance was monitored. Data were analyzed with pen as the experimental unit and treatment differences are considered significant when $P < 0.05$ and trending toward significance when $P < 0.15$. Twenty-six percent of cows were removed from the trial for various reasons, but the number removed ($P > 0.67$), time of removal ($P > 0.95$) and reason for removal ($P > 0.35$) did not differ between treatments. Complete lactation performance did not differ between treatments ($P > 0.60$) with milk yield, fat, and protein percent averaging 36.75 kg, 3.53%, and 3.04%, respectively. Somatic cell count linear score tended to be reduced in cows fed Mintrex (ITM: 3.11, Mintrex: 2.70; $P < 0.11$). Conception at each individual service did not differ between treatment ($P > 0.16$) and days open also did not differ ($P > 0.25$), however ordinal logistic analysis indicated the cows fed Mintrex tended to have greater odds to conceive at earlier services ($P < 0.08$). Locomotion scores did not differ between treatment ($P > 0.24$). In conclusion, cows fed Mintrex at reduced levels with no dietary ITM had similar performance as cows fed higher levels of ITM.

Key words: trace minerals, lactation performance, reproduction

M336 Effect of replacing corn grain and soybean meal with a treated wheat grain on the performance of dairy cows. J. Benninghoff*[1], G. Hamann[2], H. Steingaß[3], F.-J. Romberg[2], K. Landfried[2], and K.-H. Südekum[1], *[1]University of Bonn, Bonn, Germany, [2]DLR Westpfalz, Münchweiler/Alsenz, Germany, [3]University of Hohenheim, Stuttgart, Germany.*

This study evaluated a wheat grain which was treated to reduce ruminal degradation of starch and crude protein. The wheat grain (WeiPass) was treated with xylose in aqueous Ca-Mg lignosulphonate solution at elevated temperatures. Two isocaloric and isonitrogenous diets were formulated with, on dry matter (DM) basis, either 16% corn grain and 6.4% soybean meal (control group, CON) or 17.8% WeiPass and 4.6% soybean meal (wheat group, WHEAT). The DM of both diets contained 30.6% grass silage, 16.4% corn silage, 6.8% grass hay, 16% barley-wheat grain mixture, 6.4% rapeseed meal, and 1.4% mineral and vitamin mixture. Diets were offered as total mixed rations. Thirty-six German Holstein dairy cows were assigned to one of the 2 groups according to parity, body weight after calving, and milk yield during the previous lactation. The DMI and milk production were recorded from 20 d in milk (DIM) to 120 DIM. Blood samples were obtained from each cow 21 d before the expected calving date to 14 DIM at weekly intervals and then every second week until 120 DIM. Response variables were DM intake (DMI), milk production and composition, and blood metabolites. All data were analyzed using a mixed model procedure with treatment, lactation number, calving month, and week of lactation as fixed factors, and cow as random factor. The average of DMI, energy-corrected milk (ECM) yield, and milk fat and protein yields (all given as kg/day) were 18.9, 28.7, 1.25, and 1.02 for CON cows and 19.3, 32.5, 1.36, and 1.11 for WHEAT cows, respectively. Only ECM and milk protein yields were greater ($P < 0.05$) for WHEAT cows, all other variables were similar ($P > 0.10$) for both groups. Blood metabolites indicated that cows in both groups were healthy throughout the trial and no differences were observed between groups. In conclusion, a treated wheat grain could replace corn grain and part of the soybean meal in a diet for lactating dairy cows and overall performance might be slightly improved. Thus, treated wheat grain may be an alternative to corn grain in diets of lactating dairy cows depending on availability and costs of grain sources.

Key words: dairy cow, grain, starch

M337 Comparison of models to predict ruminal methane from milk fatty acids. J. M. Castro-Montoya, V. Fievez, and B. Vlae-

minck*, *Laboratory of Animal Nutrition and Animal Product Quality, Gent University, Gent, Belgium.*

Increased awareness of livestock's contribution to the greenhouse effect enhanced interest in monitoring methane emissions from dairy cattle through models based on milk fatty acids (FA). A first aim of this study was to assess the correlation between these models using a data set from 12 experiments (n = 180), covering a wide range of diets. These FA data allowed to compare 3 models described by Castro-Montoya et al. (2011) with CH_4 proportions (mmol/mol total VFA) predicted from the odd- and branched-chain FA (OBCFA) *iso* C14:0, *iso* C15:0, C15:0, *iso* C16:0 and the sum of C17:0 and *cis*–9 C17:1; Weill et al. (2009) with CH_4 (g/L milk) = Sum FA ≤ C16 × 11.37 × (milk production (kg/year) $^{-0.427}$) (model 1); and Dijkstra et al. (2011) with CH_4 (g/kg DMI) = 25.5 + (0.302 × C18:0) – (10.2 × *cis*–11 C18:1) – (2.5 × *trans*–10+11 C18:1) (model 2). Pearson correlations between CH_4 output from the OBCFA–model and model 1 (r = 0.2) and 2 (r = 0.54) were poor to modest which could be related to differences in units to express methane, inclusion of additional variables (e.g., milk production) and dietary conditions from which models were developed. To overcome the differences in units, multiple linear regression with forward variable selection and 7–fold cross validation was performed to predict CH_4 (mmol/mol total VFA) based on the milk fatty acids retained in each of the models. A random experiment effect was included. The models developed from Dijkstra et al. [CH_4 = 323.3 – (18.8 × *cis*-11 C18:1) – (72.2 × *trans*-10+11 C18:1)] and from OBCFA [CH_4 = 329.9 + (221 × *iso* C14:0) + (116.5 × *iso* C15:0) – (38.9 × C15:0) – (61.9 × *iso* C16:0) – (33 × C17:0 + *cis*-9 C17:1)] performed similarly (Adj R^2 = 0.67; RMSPE = 4%). A third model from regression of the sum of FA ≤ C16 correlated modestly with CH_4 proportions (Adj R^2 = 0.52; RMSPE = 5.0%). Finally, by individually introducing 17 FA ≤ C16, the model CH_4 = 283 + (12.6 × C8:0) + (147.7 × *iso* C14:0) + (104.6 × *iso* C15:0) – (7.6 × C14:1) – (49.9 × C15:0) – (20 × *iso* C16:0) + (0.9 × C16:0) performed similarly to the former two models (Adj R^2 = 0.73; RMSPE = 3.7%). In this last model the predominance of OBCFA worth notice.

Key words: methane, milk fatty acids

M338 Effects of methionine analog supplementation on milk yield and composition of primiparous dairy cows in a Brazilian dairy herd. L. Alegransi[1], V. L. Souza[1], M. C. Doska[1], G. F. Zanetti[1], E. M. Ribas[2], A. Ostrensky[3], and R. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]Nutron Alimentos, Brazil, [3]Pontifícia Universidade Católica do Paraná, Curitiba, PR, Brazil.*

The objective of this trial was to evaluate the effects of methionine analog supplementation on milk yield and composition in a commercial dairy herd at Paraná State, south of Brazil. Eighty-eight Holsteins and 12 Brown Swiss primiparous cows were paired blocked based on breed, milk yield, and days in milk. The treatment consisted on the daily supplementation of 25 g of methionine hydroxyl analog (MFP, Novus International, Inc., USA). Both groups, with 50 first-lactation cows each, were fed simultaneously twice daily the same basal diet in a TMR, had received bST injections every 10 d and were milked thrice daily. Each group of cows was housed in a side of a free stall and no cow entrance was allowed during the trial. Cows (220 DIM and 31.5 mo) were allocated to a sequence of 2 treatments in a crossover design with 42-d periods, and the response variables were measured on d 40 to 42 of treatment allocation. Twenty-six cows were lost due to dry off, death, and mastitis treatment. Data was analyzed with the GLM of SAS with a model containing the effects of block, cow within block, period, and treatment. The DM, CP and NDF contents of the offered diets were similar between treatments, as well as cow′s body condition score. The estimated nutritional levels of this diet using CPM-Dairy were 45.2%DM, 1.73 Mcal/kg NE_{lac}, 17.6% CP, 34.9% NDF, 19.7% ADF, 21.7% $_{pe}$NDF, 37.8% NFC, 5.2% EE, 0.80% Ca, and 0.43% P. With the MFP® supplementation, the estimated lysine:methionine relationship was 3,10:1 (6,40% Lys and 2,07% Met). Milk yield was 33.3 kg for Control and 34.2 kg for methionine-treated cows (P = 0.19). MFP treated cows produced 53 g more fat yield per day (P = 0.03) than non-treated cows. It was observed a tendency (P < 0.10) of methionine-treated cows produced more 3.5%fat-corrected milk, more energy-corrected yield, 30 g more protein yield, and a higher total solids content. Supplementation with methionine analog did not increase milk yield, but it was shown a tendency of higher milk components on methionine-treated cows.

Key words: amino acids, metabolizable protein, nitrogen balance

M339 Dry matter digestibility of dairy goats diets during pregnancy. A. R. Rivera*, I. A. M. A. Teixeira, C. J. Härter, L. D. Lima, D. S. Castagnino, T. R. Delphino, H. G. O. Silva, T. T. Berchielli, and K. T. Resende, *Universidade Estadual Paulista, Jaboticabal, SP, Brasil.*

Physiological stage influences feed intake and digestibility of nutrients and has been observed that during pregnancy females change their feeding pattern and intake. Many studies have focused on late pregnancy and/or early lactation of cows and ewes, with scarce results evaluating the diet digestibility during the entire pregnancy. Thus the objective of this study was to evaluate the effect of number of fetuses on the diet digestibility of 2 dairy goat breeds during the pregnancy. A total of 12 multiparous goats with average body weight of 52.3 ± 9.56kg were used. At the beginning of pregnancy (d 35 post mating) the goats were distributed into 4 groups, as such: 1-fetus-Saanen (n = 3), 2-fetuses-Saanen (n = 3), 1-fetus-Oberhasli (n = 3) and 2-fetuses-Oberhasli. Four digestibility assays were performed (initiating at 45, 75, 105 and 135 d of pregnancy) with the goats allocated into digestibility cages that allowed total feces collection in a 5-d period. Statistical analyses were performed considering a repeated measure design. A significant interaction between breed and fetuses number (P < 0.05) was observed for apparent dry matter (DM) digestibility. In Saanen goats, DM digestibility with 2-fetuses was significantly lower (70.9 ± 3.21%). than 1-fetus (77.2 ± 1.88%). The significant interaction between days of pregnancy and fetus number (P < 0.05) indicated that the number of fetuses influenced DM digestibility with a linear increase as pregnancy advanced in single pregnant goats. On the other hand, in twin pregnancies the DM digestibility showed a quadratic pattern as pregnancy progressed. These previous results indicates that stage and type of pregnancy have major effects on digestibility which probably is modified to allow better nutrient absorption to meet the extra nutrient demand due to pregnancy. This research is in progress (Fapesp project number 2008/57302–0).

Key words: days of pregnancy, goats, nutrient absorption

M340 Effect of different levels of a mycotoxin deactivating feed additive on Holstein crossbred dairy cows in Southeast Asia fed rations naturally contaminated with mycotoxins. U. Hofstetter*[1], I. Rodrigues[1], and K. Kiyothong[2], *[1]Biomin Holding GmbH, Herzogenburg, Austria, [2]School of Agriculture, Food and Rural Development, University of Newcastle, Newcastle, UK.*

The objectives of this study, carried out in Thailand, were to determine the impact of mycotoxins on lactating dairy cows and to evaluate the effects of different levels of a mycotoxin deactivating product. Twenty-four early lactating multiparous Holstein-Friesian x local dairy cows with an average body weight of 420kg and an average daily milk yield of 13.7kg were allocated according a randomized complete block design (RCBD) with 4 dietary treatments and 6 animals per treatment. The trial consisted of a 2-week adaptation period followed by a 10-week experimental period. Diets were fed as a total mixed ration (TMR). Mycotoxin analyses showed a contamination of 38µg/kg aflatoxin B1, 541µg/kg zearalenone, 720µg/kg deoxynivalenol, 701µg/kg fumonisin B1, 270µg/kg T-2 toxin and 74µg/kg ochratoxin A. The trial groups consisted of the contaminated TMR and contained different levels of the feed additive (groups 1–4 with 0, 15, 30 or 45g/cow/day). Data were subjected to ANOVA procedure for a randomized complete block design experiment using the general linear model (GLM) of the SAS System. Treatment means were compared using Duncan's New Multiple Range test. Total milk yield and milk protein yield were significantly higher ($P < 0.05$) in cows fed rations containing the mycotoxin deactivator. Cows in treatments 2, 3 and 4 produced approximately 2kg more milk than cows fed the unsupplemented ration (see table). Milk from cows in treatment 1, the negative control, contained 0.7µg/kg of AFM1. Milk from cows fed any of the 3 rations containing the feed additive had non-detectable levels of AFM1 . Additionally somatic cell count was significantly lower ($P < 0.05$) in these groups, which is a strong indicator that the immune system of the cows was improved by eliminating the immune suppressing effects of mycotoxins. The results confirm that mycotoxin contaminated rations impair health and performance of lactating dairy cows by affecting somatic cell count and milk production. The trial results also demonstrate that a feed additive can ameliorate these detrimental effects.

Table 1. Milk production and quality

Parameter	Treatment 1 (neg. control)	Treatment 2	Treatment 3	Treatment 4
Milk yield [kg/cow/day]	12.6[a]	14.7[b]	14.7[b]	14.9[b]
Protein [g/kg]	31.0[a]	34.2[b]	34.3[b]	36.1[b]
AFM1 [µg/kg] (detection limit = 0.06 µg/kg)	0.7	nd	nd	nd
Somatic cell count [x 10^3 cell/ml]	547[a]	385[b]	346[c]	346[c]

M341 Voluntary selection of starter ingredients offered separately to nursing calves. C. Montoro*[1] and A. Bach[1,2], *[1]Ruminant Production, IRTA, Caldes de Montbui, Barcelona, Spain, [2]ICREA, Barcelona, Spain.*

An experiment was conducted to determine whether calves exposed to different ingredients would consume the similar amounts of nutrients to calves offered all ingredients in a single starter. Forty Holstein male calves (initial BW = 41.5 ± 0.9 kg, age = 7 ± 0.5 d) individually housed on wood shavings were randomly assigned to either Control (CTR): a common starter ad libitum composed of ground corn (47.2%), soybean meal (20%), oats (11%), barley (10.1%), soybean hulls (8%) and soybean full fat (1.2%), or Choice (CH): the same 6 ingredients offered in separate buckets to each animal ad libitum. All calves were offered 2 L of milk replacer (MR) at 12.5% DM twice daily in a bucket during the 5 wk of study. Differences between treatments in total daily feed consumption, nutrient consumption (CP, EE, NFC, and NDF), and individual consumption of each ingredient were analyzed using a mixed-effects model with repeated measures that included initial BW as a covariate, dietary treatment, time (day or week of study) and their 2-way interaction as fixed effects, and animal as a random effect. Time entered the model as a repeated measure. No differences were observed between treatments on total DM, NDF, and NFC consumption (Table 1). Contrary, consumptions of CP and EE were greater ($P < 0.01$) in CH animals than in CTR calves. These differences in nutrient intakes were a consequence of a greater ($P < 0.01$) consumption of soybean full fat by CH calves (159 g/wk) and a lesser ($P < 0.01$) consumption of corn (194 g/wk) and oats (12 g/wk) compared with CTR calves (15, 573, and 133 g/wk, respectively). It is concluded that calves showed a marked preference for soybean full fat and rejected carbohydrate-rich ingredients such corn and oats. Further research is needed to determine whether this preference was due to hedonic or metabolic control.

Table 1. Nutrient composition of total solid DM consumed (g/d) as affected by treatment

	DM	CP	EE	FND	NFC
Control	247	44[a]	10[a]	50	159
Choice	261	77[b]	16[b]	61	137

[ab]Values with different superscripts within column differ at $P < 0.05$.

Key words: regulation, nutrient, intake

M342 Duodenal flows and milk yields of odd- and branched-chain fatty acids in response to N underfeeding and energy source in dairy cows. R. Gervais*[1], B. Vlaeminck[2], A. Fanchone[3], P. Nozière[4], M. Doreau[4], and V. Fievez[2], *[1]Département des sciences animales, Université Laval, Québec, Québec, Canada, [2]Lanupro, Ghent University, Melle, Belgium, [3]Unité de Recherches Zootechniques, INRA, Petit Bourg, Guadeloupe, France, [4]Unité de Recherche sur les Herbivores, INRA, Theix, St-Genès-Champanelle, France.*

To assess the effects of a decrease in dietary N supply in dairy cows and its interaction with the nature of energy (E) on the duodenal flows of odd- and branched-chain fatty acids (OBCFA), and secretions in milk, 4 Holstein cows, fitted with rumen, duodenum, and ileal cannulas, were used in a 4 × 4 Latin square design (28-d periods). Treatments were 2 N levels (low and high) combined with 2 E sources rich in starch (S) or fiber (F). The high level of N met 110% of N requirements, with an adequate supply in rumen degradable N, whereas the low level covered 80% of N requirements with a shortage in rumen degradable N. The 4 isoenergetic diets had a forage:concentrate ratio of 60:40. No interaction between level of N and E source was observed for OBCFA duodenal flows, and milk yields. Compared with high N, low N diets reduced the duodenal flows of iso (7.2 vs. 9.4 g/d; $P < 0.01$), and linear odd-chain fatty acids (FA; 7.6 vs. 9.6; $P < 0.01$) and tended to reduce the flow of anteiso FA (8.0 vs. 10.0; $P = 0.06$). Low N diets decreased milk yield of iso FA (7.5 vs. 9.1 g/d; $P < 0.05$) and tended to reduce milk anteiso (7.4 vs. 8.8; $P = 0.09$) and linear odd-chain FA (12.7 vs. 14.5; $P = 0.08$). Compared with S, F diets increased duodenal flow of iso FA (8.9 vs. 7.7 g/d; $P < 0.05$), and tended to increase the flow of linear-odd chain FA (9.3 vs. 7.9; $P = 0.06$). Feeding F diets increased milk iso (9.6 vs. 6.9 g/d; $P < 0.01$) and linear odd-

chain FA (15.2 vs. 12.1; $P < 0.05$), and tended to increase milk anteiso FA (9.0 vs. 7.3 g/d; $P = 0.08$). N supply had no effect on the apparent transfer of duodenal iso, anteiso, and linear odd-chain FA to milk, and no interaction with E source was observed. Compared with F, S diets decreased the apparent transfer of anteiso FA by 25% ($P < 0.05$), and tended to reduce transfer of iso FA (−17%; $P = 0.07$). In conclusion, because the apparent transfer of some OBCFA from the duodenum to milk was affected by treatments, further research is needed to establish which milk OBCFA can be used as robust markers to estimate OBCFA and microbial protein flow at the duodenum and/or which corrections should be applied.

Key words: duodenal flow, milk fatty acids, OBCFA

M343 Effects of a direct-fed microbial and fibrolytic enzyme product on somatic cell counts in milk produced by crossbred dairy cows in the Brazilian Cerrado. R. D. Sainz*[1,2], C. U. Magnabosco[3,4], E. A. Filgueiras[5], R. Guimarães[3], F. M. C. Freitas[4,6], and L. R. Mattos[4,6], *[1]University of California, Davis, [2]Embrapa, Brasilia, DF, Brazil, [3]Embrapa Cerrados, Planaltina, DF. Brazil, [4]Embrapa Arroz e Feijão, Santo Antonio de Goiá, GO, Brazil, [5]Biofórmula, Goiânia, GO, Brazil, [6]Embrapa Gado de Leite, Juiz de Fora, MG, Brazil.*

Two experiments were conducted on commercial dairy farms to test the effect of a product (Bioformula, Goiania, Brazil) containing direct-fed microbial (DFM) and fibrolytic enzymes on milk quality. In Exp. 1, 38 Holstein cows were fed corn silage on an *ad libitum* basis, and received up to 6 kg/d concentrate according to production level. In Exp. 2, 22 Girolando (crossbred Holstein x Gir) cows grazed *Panicum maximum* cv. Mombaça pastures plus corn silage and received up to 5 kg/d concentrate according to production level. In both experiments, cows were blocked by age, parity, stage of lactation and current production level into control and treated groups. Treated group cows received 2 g/d of a product containing live yeast (1 × 109 cfu/g), mannan oligosaccharide (10%), and *Lactobacillus acidophilus*, *Bacillus subtilis*, and *Enterococcus faecium* (2 × 107 total cfu/g), plus cellulose (6 U/g), hemicellulase (10 U/g), and xylanase (3U/g) while controls received 2 g/d of the vehicle alone. Milk composition was monitored weekly for 16 wk. Data were analyzed by ANOVA, with treatment as main effect and initial composition as the covariate. Somatic cell counts were log-transformed to overcome non-normality, but back-transformed data are presented here. There were no differences in milk production, or in the percentages of fat, protein, lactose, and non-fat solids, nor in total bacterial count, throughout both experiments ($P > 0.10$). In Exp 1 SCC in milk increased ($P < 0.05$) over time in both experiments, from 247,172 to 606,736 (controls) or 260,016 (treated). In Exp. 2 it increased ($P < 0.05$) from 117,490 to 584,490 (controls) or 270,396 (treated). In both experiments, SCC were similar ($P > 0.10$) for the first 8 weeks, then diverged. These results suggest that DFM may enhance immune function and improve milk quality in crossbred dairy cows under tropical conditions.

Key words: direct-fed microbials, somatic cell counts, tropics

M344 Effects of abomasal dosing of ferrous lactate in lactating dairy cows. O. N. Genther*, J. A. Zyskowski, T. H. Herdt, and D. K. Beede, *Michigan State University, East Lansing.*

We hypothesize that the majority of Fe naturally occurring in drinking water is in the ferrous (Fe^{2+}) state, and if present in great enough concentrations, could negatively affect Fe status and potentially cause toxicity. Our objective was to evaluate the short-term effects of abomasally infused ferrous lactate on Fe status of mid-lactation dairy cows given amounts to simulate total daily Fe intake from high-Fe drinking water. Six mid-lactation Holstein cows were assigned in a replicated 3 × 3 Latin Square balanced for treatment sequences. There were 7 d between experimental periods. Treatments were: 1) 0 mg Fe; 2) 0.75 mg of Fe from ferrous lactate per kg BW; and, 3) 1.5 mg of Fe from ferrous lactate per kg BW. Treatments were calculated to approximate 0, 4.5 and 9 ppm Fe concentrations in drinking water, respectively. All treatments were iso-lactate. Treatments were dosed in ~1 min directly into the abomasum via the ruminal fistula in 1 L of deionized water to avoid any potential ruminal impacts on Fe valence. Blood samples were taken hourly before dosing via jugular catheter for 6 h, and post-dosing hourly for 12 h. Liver biopsies were taken at 0 (before dosing), 18 and 36 h of each period. Mean of the pre-dosing blood samples was used as a covariate for each dependent variable in statistical analysis. There were no treatment by time interactions ($P > 0.10$) for serum Fe, unsaturated iron-binding capacity (UIBC), total iron-binding capacity (TIBC), percent Fe saturation, α-tocopherol, and Cu concentrations, as well as for liver Fe, Cu and Zn. There was no main effect of treatment on any response variables. There was an effect of hour pooled across treatments on serum Fe ($P = 0.022$), UIBC ($P = 0.012$), percent Fe saturation ($P < 0.0001$); and, for liver Cu ($P = 0.023$) and Zn concentrations ($P = 0.022$). There was a treatment by time interaction for serum Zn concentration ($P = 0.055$) and a tendency for liver Cu concentration ($P = 0.155$). Results indicate that infusion of ferrous Fe at rates used in this study do not have major impacts on short-term Fe status of lactating dairy cows.

Key words: iron, lactating dairy cows, iron status

M345 Glycerin as a replacement for corn in dairy Holstein cows diets. J. B. D. Sancanari*[1,2], J. M. B. Ezequiel[1], E. H. C. B. van Cleef[1,2], V. R. Fávaro[1], A. P. D'Áurea[1,2], A. C. Homem[1], Z. F. Silva[1], D. A. V. Silva[1,2], and J. W. Cattelan[1], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]FAPESP, São Paulo, São Paulo, Brazil.*

Six multiparous dairy Holstein cows cannulated in the rumen, after the peak of lactation, were used to evaluate the effect of inclusion of glycerin, originated from the biodiesel production, replacing the dietary corn on milk production (MP), milk composition and DMI. Cows were housed at individual tie-stall barn and fed with 3 isoenergetic and isonitrogenous diets containing 0 (G0), 15 (G15) and 30% (G30) of crude glycerin in diets dry matter. The experiment was a double 3 × 3 Latin Square, where each period lasted 23 d. Milk samples were obtained from 2 milking on the 18th and 19th d of each period. The MP obtained were 17.1, 16.4, and 18.9 kg/d ($P > 0.05$) for G0, G15, and G30, respectively. DMI was depressed ($P < 0.05$) in the G30 without affecting the MP, resulting in increased feed efficiency ($P < 0.05$). Cows fed with G0 and G15, respectively, the DMI showed 17.1 and 13.8% higher than G30. This effect could be attributed to the high salt content (6%, which 99% were NaCl) present in glycerin. Furthermore, it was observed that the milk urea nitrogen (MUN) was influenced ($P < 0.05$) by treatments, being 31% higher in G15 compared with G30, indicating greater efficiency of utilization of dietary protein on the G30. The concentrations of milk fat were 3.2, 3.3, and 3.2%, respectively, for G0, G15, and G30 ($P > 0.05$). Lactose obtained in G15 (4.7%) were 4% higher ($P < 0.05$) than the other treatments (4.5%). The crude protein of milk was 15.6 and 12.9% higher ($P < 0.05$) in G0 (3.2%) and G15 (3.1%), respectively, than in G30 (2.7%). This reduction can be caused by NFC deficiency in the diets and decrease in digestibility due to the high ratio NDF/NFC caused by replacement

of corn (main source of NFC in the diet) by glycerin. Possible deficiencies of essential amino acids, particularly methionine and lysine in duodenal digesta, must also be taken into account. It was concluded that the inclusion of 30% of glycerin in the diet improves feed efficiency, but may alter some components of milk. Further studies are needed to elucidate this mechanism.

Key words: biodiesel, co-products, milk composition

M346 Rolled barley grain treated with lactic acid and heat altered postprandial rumen mineral availability in lactating dairy cows. U. Farooq*, A. Mazzolari, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, Alberta, Canada.*

Presence of phytic acid (PA) in the grain kernels is associated with decreased bioavailability of phosphorus (P), calcium (Ca), and magnesium (Mg) as well as increased P loss in feces of dairy cow. Treating grain with lactic acid and heat might increase bioavailability of those minerals. Therefore, the objective of this investigation was to evaluate rumen mineral bioavailability in cows fed rolled barley grain steeped in lactic acid (LA) and treated with heat. Eight clinically healthy, rumen-fistulated primiparous Holstein cows (153 - 179 DIM) were assigned to a paired 2 × 2 crossover design. Each period consisted of 11 d of adaptation and 10 d of measurements. All cows were fed once daily a TMR containing rolled barley grain (31.5% in DM) steeped for 48 h in equal quantity of tap water (CTR) or in 1.0% LA and heat at 55°C (LAH). Rumen fluid samples were taken on the last day of the experimental period (d 21) at 0, 2, 4, 6, 8, 10, and 12 h after the morning feeding. Samples were analyzed by atomic absorption spectrometry for Ca, Mg, sodium (Na), and potassium (K) and a modified colorimetric method for inorganic P (P*i*). Statistical analyses were performed by JMP using the GLM procedure. Because there was a carryover effect only results from the 1st period were considered. Overall data showed that concentrations of P*i* ($P < 0.05$; CTR, 278.5; LAH, 231.1 mg/L), Ca ($P < 0.01$; CTR, 87.35; LAH, 64.55 mg/L), and Mg ($P < 0.01$; CTR, 98.13; LAH, 75.52 mg/L) in the ruminal fluid were lower in LAH cows versus CTR group. Furthermore, concentration of Na in the ruminal fluid was greater ($P < 0.01$; CTR, 80.15; LAH, 90.09 Meq/L) in LAH cows, whereas no changes in the concentration of K were observed among the 2 groups. Postprandial time influenced ($P < 0.01$) concentrations of all ruminal minerals, except for P*i*. In conclusion, results of this study indicated that treating rolled barley grain with LA and heat increased the bioavailability of P*i*, Ca, and Mg and has the potential to be used by dairy industry to lower mineral supplementation and environmental pollution.

Key words: barley grain, lactic acid and heat, rumen minerals

M347 Phosphorus feeding for second lactation dairy cows. V. R. Moreira*[1], L. K. Zeringue[1], C. Leonardi[2], and M. E. McCormick[1], *[1]Louisiana State University Agricultural Center, Franklinton, [2]Louisiana State University - Health Sciences Center, New Orleans.*

The objective of this experiment was to evaluate the effect of dietary P on production performance of 28 s lactation cows. Cows were fed either 0.38% or 0.42% ± 0.01% P (DM basis; averages ± standard deviation) from 3 to 45 DIM (treatment period). Both groups of cows were fed 0.42% ± 0.01% P thereafter until the end of the experiment at 110 DIM (carry-over period). Both treatment diets contained 16.5% ± 0.52% CP, and 0.80% ± 0.12% Ca. Pregnant cows were brought to the barn at least 21 d before expected calving. Cows were housed in a free-stall barn fit with electronic gates. Close-up TMR containing 0.28% ± 0.05% Ca and 0.34% ± 0.03% P (DM basis) was fed until 2 d after calving date. Treatments were randomly assigned to cows before their first lactation, when these cows were subjected to similar treatments. Intake and milk yield were recorded daily. Weekly averages during treatment period (wk 3 to 6) and carry-over period (wk 7 to 15) were analyzed as repeated measurements using the Mixed procedure (SAS, version 9.2). Cows fed diet containing 0.42% P tended ($P = 0.09$) to eat more than those fed 0.38% diet during the treatment period but intake was similar ($P = 0.86$) during carry-over period. Milk yield was not significantly ($P = 0.12$) different throughout the experiment, although cows fed 0.42% P produced 3.5 kg more than those in the treatment containing 0.38% P. Following a similar pattern from their first lactation, the 2 groups of cows peaked in milk production 2 weeks apart, on wk 4 and 6, respectively for treatments 0.42% P and 0.38% P. Percentages of milk components were similar ($P \geq 0.16$) between the 2 treatments. Milk fat and protein percentages averaged 3.42% and 2.83%, respectively. Performance of second lactation cows was not significantly different between the 2 levels of P fed during this trial.

Key words: phosphorus, dairy cow, second lactation

M348 Biochemical blood parameters of dairy cows fed with increasing concentration of glycerin. J. B. D. Sancanari*[1,2], J. M. B. Ezequiel[1], E. H. C. B. van Cleef[1,2], V. R. Fávaro[1], A. P. D'Áurea[1,2], A. C. Homem[1], Z. F. Silva[1], D. A. V. Silva[1,2], and J. W. Cattelan[1], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]FAPESP, São Paulo, São Paulo, Brazil.*

Blood parameters have been used to assess the health status of animals. The blood biochemical composition reflects the balance between the inflow, the discharge and the metabolism of nutrients in animal tissue. Six multiparous Holstein cows cannulated in the rumen, after the peak of lactation were used in this trial. The animals were distributed in a double 3 × 3 Latin Square to evaluate the effect of inclusion of 0 (G0), 15 (G15), and 30% (G30) of crude glycerin in the diet dry matter (replacing corn) on the blood biochemical parameters. The cows were fed 3 isoenergetic and isonitrogenous diets twice daily. Blood samples were taken on 23 d of each period, by puncturing the coccygeal vein 3 h after the morning milking. There was no effect ($P > 0.05$) on the liver enzymes alanine aminotransferase (ALT), aspartate aminotransferase (AST) and alkaline phosphatase (ALP), with average values of 34.6, 65.6 and 142.7 U/mL, respectively, however, the enzyme gamma-glutamyltransferase (GGT) was changed ($P < 0.05$). GGT concentrations obtained for G0, G15 and G30 were 40.7, 34.4 and 46.8 U/mL, with a superiority of 14.7 and 35.5% in G30 ($P < 0.05$) compared with G0 and G15, respectively. Thus, this can indicate that possible liver changes may have occurred, however, the animals did not showed clinical symptoms of intoxication, probably due to short supplementation period. There were no differences ($P > 0.05$) on plasma concentrations of total protein (TP), albumin (ALB), urea (U), creatinine (CREA), glucose (GLUC), triglycerides (TG) and cholesterol (COL) suggesting no effects on protein and energy metabolism. The average values were 8.4 and 2.1 g/dL, 24.5, 1.2, 70.4, 13.1 and 71.1 mg/dL, respectively, for TP, ALB, U, CREA, GLUC, TG and COL. Further studies are needed to evaluate the effect of inclusion of glycerin in the diet on the metabolism of dairy cows, with particular attention to the supplement for longer periods.

Key words: biodiesel, blood, ruminants

M349 Treating barely grain with lactic acid and heat modulated pre-prandial rumen calcium and magnesium availability in lactating dairy cows. U. Farooq*, A. Mazzolari, S. M. Dunn, and B. N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Phytic acid (PA), present in grain kernels, is able to bind minerals and lower their availability to the host, especially those of calcium (Ca) and magnesium (Mg). Treating barley grains with lactic acid and heat might increase rumen degradation of PA, consequently increase availability of Ca and Mg in the rumen fluid. Therefore, this study sought to evaluate rumen availability of selected minerals in lactating dairy cows fed rolled barley grain steeped in lactic acid (LA) and treated with heat. Eight, rumen-fistulated primiparous Holstein cows (153 - 179 DIM) were assigned to a paired 2 × 2 crossover design. Each period consisted of 11 d of adaptation and 10 d of measurements. All cows were fed once daily a TMR containing barley silage (40% DM basis) and rolled barley grain (31.5% DM basis) steeped for 48 h in equal quantity of tap water (CTR) or in 1.0% LA and heat at 55°C (LAH). Rumen fluid samples were taken on d 1, 3, 5, and 7 before morning feeding. Samples were analyzed by atomic absorption spectrometry for Ca, Mg, sodium (Na), and potassium (K) and a modified colorimetric method for inorganic phosphorous (P*i*). Statistical analyses were performed by JMP using the GLM procedure. Results of this study demonstrated that concentrations of Ca ($P < 0.01$; CTR, 39.21; LAH, 24.91 mg/L), and Mg ($P < 0.05$; CTR, 15.21; LAH, 8.02 mg/L) in the ruminal fluid were lower in LAH cows versus the CTR group. Moreover, there was an interaction between treatment and day of sampling for Ca ($P < 0.05$), Mg ($P < 0.01$), and Na ($P < 0.01$). Furthermore, day of sampling effected ($P < 0.01$) concentrations of all minerals, whereas no changes in the concentrations of P*i*, Na, and K were observed among the 2 groups. Overall, treating rolled barley grain with LA and heat improved the bioavailability of Ca and Mg and has the potential to be used by dairy industry to lower mineral supplementation and pollution of the environment.

Key words: barley grain, lactic acid and heat, rumen minerals

M350 Performance variables of dairy cattle fed a commercial micronutrient supplement during the peripartum period. N. Barkley*, A. Kenny, E. Adkins, X. Revelo, and M. Waldron, *University of Missouri, Columbia.*

A time course study was completed to determine the effects of feeding the nutritional supplement OmniGen AF on dry matter intake (DMI), body condition score (BCS), body weight, milk yield, feed to milk conversion efficiency, milk composition [fat, protein, solids–not–fat (SNF), milk urea nitrogen (MUN), 4.0% fat-corrected milk (FCM), somatic cell score (SCS)], plasma concentrations of the metabolites glucose, nonesterified fatty acids (NEFA) and β–hydroxybutyrate (BHBA) in peripartum dairy cattle. Twenty multiparous Holstein cows were fed diets formulated to meet or exceed NRC recommendations for the appropriate physiologic state. Cows were randomly assigned to one of 2 treatment groups (control 56g/cow/day soybean hulls; n = 12 or supplemented 56g/cow/day OmniGen AF; n = 8) balanced for mature equivalent 305-d milk production. Treatment was issued with 225g of sweet feed as a top dressing from d –46 ± 1 through d +31 relative to calving. Feed issue and refusal weights were collected daily to determine DMI. Average BCS (assessed by 2 independent evaluators) and body weights were collected weekly. Blood was sampled on d –47 ± 1, –30 ± 1, –20 ± 1, –11 ± 1, 1, 7, 14 and 30 relative to parturition for plasma glucose, NEFA, and BHBA analysis. Milk yield was recorded daily and milk composition samples were collected during 2 consecutive milkings weekly. All performance variables were analyzed in SAS using mixed model ANOVA procedures with repeated measures. Pretreatment covariates were utilized for BCS, body weight, and all plasma metabolites. No treatment differences or treatment by time interactions were observed for DMI, BCS, body weight, milk yield, feed to milk conversion efficiency, milk composition and plasma metabolites glucose, NEFA and BHBA ($P > 0.10$). Feeding OmniGen AF as a micronutrient supplement during the peripartum period had no statistical effect on the performance variables examined within this study.

Key words: OmniGen AF, micronutrient, dairy

M351 Effect of whole versus chopped sugar cane on dry matter intake in dry dairy cows. J. E. Pérez-De La Ossa[1] and R. P. Lana*[1,2], *[1]Univesidade Federal de Viçosa, MG, Brazil, [2]CNPq and INCT-CA, Brasília, DF, Brazil and Viçosa, MG, Brazil.*

The objective was to evaluate the possibility of use non processed sugarcane in the diet of dry dairy cows. Four crossbred Holstein-Gyr cows with 450 ± 10 kg body weight were used to evaluate the effect of whole vs. chopped sugar cane on intake in dry dairy cows. The animals were housed in individual stalls (24 m^2) with free access to water. Diets consisted in either chopped or whole ad libitum sugarcane plus low intake supplement (400 g/cow/day) containing 25% urea, 25% mineral salt and 50% of a mix of corn meal and soybean meal as nitrogen source. Cows were randomly allocated to a crossover design with 2 animals per treatment in 2 periods of 20 d. In the second period, the treatments changed between the animals, totalizing 4 replicates per treatment or 8 experimental units. Each period consisted of 10 d for adaptation and 10 d for data collection. The experiment was analyzed as a complete randomized design. There was no effect ($P > 0.10$) of sugar cane processing on intake, with values of 22.8 versus 25.5 kg as fed/cow/day for whole and chopped sugarcane, respectively, or 5.24 versus 5.86 kg dry matter/cow/day. Therefore, sugarcane can be fed in a whole form to dry dairy cattle. Feeding whole sugarcane may help to reduce feed costs by reducing machinery use and labor. Also, without processing, the sugarcane decreases losses by fermentation and increases life time of conservation in the feedbunk.

Key words: dry cows, feed, sugarcane

M352 On-farm dry matter testing to improve feed delivery precision on dairy farms. K. R. French* and R. A. Kohn, *University of Maryland, College Park.*

Silage comprises a major portion of total mixed rations (TMR) in most dairy operations. The content of the TMR that is offered to the animals differs from the intended ration. The uncertainty of rations may affect feed efficiency, and consequently milk production, feed expenses, and environmental losses. When silage is measured by weight, unaccounted for changes in silage dry matter (DM) content may substantially change a fed ration. The objective of this study was to measure variation in silage DM on selected dairy farms and determine the potential usefulness of an electronic method of on-farm DM analysis. A field survey of 31 Maryland dairy producers obtained data about on-farm DM analysis frequency, DM analysis methods, ration analysis frequency, feeding regimen, milk production, and number of cows. Of those surveyed, 83% reported testing forage DM more than once per year by any method, and 63% reported testing DM by an on-farm method; mean number of cows was 103, and mean reported RHA was 22,100 lbs. Eight surveyed producers volunteered to collect

on-farm DM data for 21 d. Producers performed daily DM analysis using a Farmex 1210 electronic silage tester, recorded observations on rain events, and recorded ration changes related to the daily DM analysis. Silage samples corresponding to the on-farm DM analyses were retained, and were analyzed for DM after drying at 55°C followed by 100°C (as standard method) and electronic tester (in-lab). There were large differences among farms in how well different methods of DM analysis compared. The difference between on-farm DM (electronic) and standard DM had a mean of 1.82% and SD of 4.99%. Ninety-five percent of observations fell within the limits of agreement (1.96 x SD ± mean) of −7.97 and 11.60%. The electronic method did not compare well to laboratory DM analysis for most farms.

Key words: dry matter, silage, total mixed ration

M353 Effects of the source and amount of sulfur in prepartum diets on plasma metabolites of periparturient Holstein cows. E. Manidari, H. Amanlou, M. Frozanmehr, H. Mirzaei Alamouti*, and M. Shahir, *Department of Animal Science, University of Zanjan, Iran.*

The objective of this study was to determine the effects of concentration and source of sulfur in close-up diets on plasma metabolites in periparturient period. Twenty-four multiparous Holstein cows (body weight (BW), 687.9 ± 32.33 kg) were used in a completely randomized design and assigned to 3 diets: 1) 0.21% sulfur (control, without sulfur supplementation), 2) 0.41% sulfur (with 0.79% magnesium sulfate) and 3) 0.41% sulfur (with 0.57% magnesium sulfate + rumen protected methionine (25 g/d, Mepron, Degussa Corp., Kennesaw, GA)). Cows were individually fed the total mixed ration with similar net energy for lactation (1.58 Mcal/kg dry matter), crude protein (13.3%) and dietary cation-anion difference (−32 mEq/kg dry matter) from 21.9 ± 2.47 d relative to expected calving until calving. After calving, all cows received the same lactation diet until 21 d in milk. Blood metabolites were measured at −21, 1 and 21 d relative to calving. Data were analyzed using MIXED Procedure from SAS and cows nested in the diets were as random effects. Different variance-covariance error structures were tested. Diet with 0.41% sulfur from magnesium sulfate (diet 2) compared with diets 1 and 3 significantly decreased dry matter intake at periparturient period (8.7 vs. 7.4 and 9.7 ± 0.36 at prepartum and 10.7 vs. 8.1 and 10.9 ± 0.65 kg/d at postpartum, for the diets 1, 2,and 3, respectively). The Diet 2 significantly decreased plasma concentration of calcium, cupper, albumin, glucose; although increased urea, bilirubin, β-hydroxybutyrate, aspartate aminotransferase, creatin phosphokinase in periparturient period. The Diet 2 also significantly increased phosphorus, total protein and nonesterified fatty acids concentration of plasma in prepartum period. In summary, increasing sulfur concentration (0.41% of DM) using magnesium sulfate in close-up diets compared with other diets used in this study compromised metabolism of periparturient cows.

Key words: Holstein cows, prepartum diet, sulfur

M354 Intake, digestibility and metabolism of nitrogen compounds of dairy cows fed with different urea levels in diets based on sugar cane. A. M. F. Santiago*[1], J. M. de S. Campos[2], A. S. Oliveira[3], S. A. Santos[4], and S. M. Souza[4], *[1]Instituto Federal de Tecnologia, Rio Pomba, MG, Brazil, [2]Universidade Federal de Pernambuco, Guaranhus, PE, Brazil, [3]Universidade Federal de Mato Grosso, Sinop, MT, Brazil, [4]Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

Twelve multiparous Holstein cows (12.6 ± 0.5 kg/d of yield milk, 225 ± 90 DIM and 589 ± 53 kg BW) were distributed in 3 4x4 Latin squares by DIM, with 4 periods of 18 d to evaluate the effect of 4 levels of the mixture urea:ammonium sulfate (9:1) (urea) in diet (0, 1, 2 and 3% of DM) on intake, digestibility and metabolism of N. Diets TMR were isonitrogen (11.8% of CP), containing 74.7% of DM sugar cane (*Saccharum officinarum*, L., RB 73–9735, 21.9o Brix, 28.3% of DM, 2.6% of CP, 42.2% of aNDFom and 50.5% of NFC.). Fecal samples were collected once daily at 1000, 1200, 1400, 1600 e 1800 h, of 12 to 16 d of each period. Indigestible NDF (after 264 h of ruminal incubation) was used to estimate fecal. Milk samples were collected on 14 and 15 d of each period at am and pm milking. Spot urine samples were obtained approximately 4 h postfeeding on 13 d of each period. Urine volume was estimated using creatinine concentration as marker. Data were analyzed using model mixed (PROC MIXED, SAS Inst. Inc., Cary, NC). The urea inclusion increased NNP diet (10.8, 31.6, 51.7 and 69.4% of N). DM (14.1 kg/d), CP (1.6 kg/d), aNDFom (4.8 kg/d) and NFC (7.8 kg/d) intakes were not affected by urea ($P > 0.05$). DM (72.1%), OM (73.3%), CP (80.0%), NDF (44.1%) and NFC (92.2%) digestibility of diets were not affected by urea ($P > 0.05$). The urea used (0% vs. 1 + 2 + 3% of DM) increased ($P < 0.05$) blood urea-N (7.76 vs. 13.15 mg/dL), urinary N-urea (46.7 vs. 98.8 g/d), urinary N (37.8 vs. 53.0% of N intake) and urinary N/yield milk (7.7 vs. 11.2 g of N/kg of milk). However, the urea level (1 at 3% of DM) did not affect ($P > 0.05$) N excretion and efficiency of N utilization for milk production. Although of linear increase ($P < 0.05$) of blood urea-N with urea level from 1 to 3% of DM, the maximum observed (14.31 mg/dL) was below the recommended borderline maximum by NRC (2001) of 20 mg/dL. In diets based on sugar cane with higher NFC, the increased of urea level of 1 to 3% of DM can be used in dairy cows with production below 15 kg/day, without affecting intake, digestibility and efficiency of N diet.

Key words: nitrogen non-protein

M355 Effects of barley grain processing on milk yield and composition of early lactating Holstein cows. H. Amanlou, H. Mirzaei Alamouti*, and A. Aslani, *Department of Animal Science, University of Zanjan, Iran.*

To determine the effects of barley grain processing on milk yield and composition, 12 multiparous Holstein dairy cow; body weight, 560 ± 48.5 kg and days in milk, 31 ± 11.9, were used in an incomplete block design with 4 diets, 3 periods, 4 blocks and 3 cows per block. The diets were different in size of ground barley grain. 1) coarse size with 92.2% processing index (PI), volume weight of barley after processing as a percentage of whole barley, 2) medium size with 76% PI, floury size with 73% PI, and floury and extruded with 54% PI. Cows were individually fed diets containing 70% concentrate and 30% alfalfa hay during 63 d (21 d in each period). Daily milk yield and composition and periodically blood metabolites were determined. Apparent nutrients digestibility of the diets were determined. Data were analyzed using the MIXED procedure of SAS. Dry matter intake, milk yield and composition, and blood metabolites were not different between diets. Extruded barley grain increased ($P < 0.05$) the apparent dry matter digestibility, neutral detergent fiber and non-fiber carbohydrates. Cows fed the extruded barley grain had higher ($P < 0.05$) feed efficiency. Effective rumen degradability of organic matter and protein were increased ($P < 0.05$) by extruding of barley grain. In general, this study showed that although different size of grounded barley grain did not influence milk production and composition, extruding of barley grain can increase the total digestible nutrients.

Key words: barley grain, cows, feed processing

M356 Fate of phosphorus in large intestine of dairy heifers. P. P. Ray*, M. D. Hanigan, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective was to investigate the disappearance of phosphorus (P) from the large intestine of dairy heifers. Uncertainty about the availability of P in different feeds may limit implementation of dietary strategies to reduce fecal P excretion by dairy cows. Derivation of intestinal P digestion and total tract P absorption data are limited by our lack of knowledge of the dynamics of P digestion and absorption in the large intestine. Data on the fate of organic P flowing to the large intestine are especially scarce. Eight ruminally and ileally cannulated Holstein heifers were used in two 4 × 4 Latin squares with 9 d periods including 3 d of washout. All heifers were fed a high forage diet containing 0.14% total P. Ytterbium-labeled corn silage and Co–EDTA were dosed daily as particulate and liquid phase markers, respectively, to measure ileal digesta flow. Markers were mixed with rumen digesta 4 times daily throughout the study. On d 1 to 4 of each period heifers were infused ileally with 0, 5, 15, and 25 g/d of phytate-P solution (0, 1.41, 4.22, and 7.04 g/d P, respectively). Total fecal collection was conducted during the 4 d infusion. When infusion ceased (d 5 and 6) ileal digesta was sampled to measure P flow to the ileum from the basal diet. Feces and digesta samples were dried and ground, digested (nitric-perchloric), and analyzed for total P with the molybdovanadate yellow method. The effect of phytate infusion on fecal P excretion was evaluated using solution statements in Proc Mixed, with basal ileal P flow as a covariate. Fecal excretion of total P increased with increasing phytate P infused ($P \leq 0.0001$). The slope coefficient for infused phytate P to feces was 1.09 ± 0.21 indicating complete P transfer to feces. In contrast, the slope coefficient for the flow of ileal P (from the basal diet) to feces was 0.22 ± 0.24 indicating net absorption from the large intestine. Thus the form of P (e.g., phytate, inorganic, microbial) entering the large intestine may affect absorption from that segment. These data will support mechanistic modeling efforts to improve prediction of P digestion allowing more accurate estimation of P bioavailability in feeds.

Key words: heifer, large intestine, phosphorus

M357 Peripheral blood leukocyte population dynamics during the peripartum period in dairy cattle fed a commercial micronutrient supplement. A. Kenny*, N. Barkley, X. Revelo, and M. Waldron, *University of Missouri, Columbia.*

A time course study was conducted to determine the effects of a dietary micronutrient supplement on blood leukocyte populations in peripartum dairy cows. Twenty Holstein cows were offered diets formulated to meet or exceed NRC recommendations and randomly assigned to one of 2 treatment groups from d –46 ± 1 through d 31 relative to calving: Control (56g/cow/day soybean hulls; n = 12) or Supplemented (56 g/cow/day OmniGen-AF; n = 8). Blood was sampled on d –47 ± 1, –30 ± 1, –20 ± 1, –11 ± 1, 1, 7, 14 and 30 relative to parturition. Leukocytes were isolated and incubated with monoclonal antibodies that identified cells positive for CD4, CD8α, CD14, CD21 or TcR1-N12 markers which represented helper T cells, cytotoxic T cells, monocytes, B cells and γδ T cells, respectively. The percentage of leukocytes positive for these markers was determined by flow cytometry and analyzed using SAS by mixed model ANOVA with repeated measures. A treatment by time interaction was detected with lower percentages of γδ T cells observed in supplemented cows on d –47 and 1 ($P < 0.05$). The proportion of γδ T cells on d –47 was greater ($P < 0.05$) and on d 1 was less ($P < 0.05$) than most time points. A decrease ($P < 0.05$) in the percentage of lymphocytes and an increase ($P < 0.05$) in the percentage of neutrophils was also observed on d 1 compared with most time points. The percentage of cytotoxic T cells on d 1 and 7 decreased ($P < 0.05$) compared with d –30, –11 and 30. The proportion of B cells was greater ($P < 0.05$) during all prepartum samples than all postpartum samples, and was greater ($P < 0.05$) in supplemented cows on d 30. The percentage of helper T cells was greater ($P < 0.05$) on d –47, –20 and 30 than on d –1 and 14. However, the percentage of monocytes on d –47 and –30 was less ($P < 0.05$) than all other time points. The percentage of monocytes was decreased ($P < 0.05$) in supplemented cows on d –30. OmniGen-AF had minimal effects on the blood leukocyte populations of peripartum dairy cattle. However, changes in the proportion of each cell type over time were observed, especially on the day after parturition.

Key words: OmniGen-AF, leukocyte, dairy

M358 Peripheral blood leukocyte population dynamics in peripartum dairy cattle managed under different dry period nutritional strategies. A. Kenny*, N. Barkley, X. Revelo, and M. Waldron, *University of Missouri, Columbia.*

A time course study was conducted to determine changes in blood leukocyte populations in peripartum dairy cows managed under a one– or 2–group dry period nutritional strategy. Twenty-three Holstein cows were randomly assigned to receive a single diet from d –51 ± 2 to parturition (OG; n = 12) or a far–off diet from d –51 ± 2 to d –28 ± 2 and a close–up diet from d –28 ± 2 to parturition (TG; n = 11). The NE_L of the OG diet was 1.43 Mcal/kg and the NE_L for the far–off and close–up diets of TG was 1.21 and 1.32 Mcal/kg, respectively. Blood was sampled on Days –51 ± 2, –29 ± 1, –18 ± 1, –8 ± 1, 1 and 7 relative to parturition. Leukocytes were isolated and incubated with monoclonal antibodies that identified cells positive for CD4, CD8α, CD14, CD21 or TcR1-N12 markers which represented helper T cells, cytotoxic T cells, monocytes, B cells and γδ T cells, respectively. The percentage of leukocytes positive for these markers was determined by flow cytometry and analyzed using SAS by mixed model ANOVA with repeated measures. A treatment by time interaction ($P < 0.05$) was observed in B cells and cytotoxic T cells. The proportion of B cells on d –18 and –8 was greater ($P < 0.05$) in the TG treatment group, and on d 7 the proportion of cytotoxic T cells increased in the TG group and decreased in the OG group ($P = 0.03$). The B cell percentage on d 7 of both treatment groups was less ($P < 0.05$) than on d –51, –29 and –8. On d 1 the proportion of lymphocytes was lower ($P < 0.05$) and the proportion of neutrophils was greater ($P < 0.05$) than all other sample days. The percentage of monocytes was less on d –51 and –29 than all other sample days ($P < 0.05$) and was also less on d –18 and –8 than on d 1 ($P < 0.05$). The proportion of helper T cells was greater on d –51 and –29 than on d 1 and 7. No differences were detected in γδ T cells. The dynamics of most peripheral blood leukocyte populations was similar between dairy cattle managed under a one– or 2–group dry period nutritional strategy. Variations in B cell dynamics were detected during the dry period and also in cytotoxic T cells after parturition.

Key words: far-off, close-up, leukocyte

M359 Digestion and rumen fermentation in precision-fed dairy heifers on low or high forage rations at four levels of dry distillers grain. F. X. Suarez-Mena*, G. J. Lascano, and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

The objective of this study was to determine the effects of forage to concentrate ratio (F:C) and corn dry distillers grain with solubles (DDGS) at various inclusion levels in precision-fed dairy heifer diets on digestion and rumen fermentation. A split plot design with F:C as whole plot and DDGS inclusion level as sub–plot was administered in a 4-period (19 d) 4 × 4 Latin square. Eight ruminally cannulated Holstein heifers (344 ± 15 kg BW) housed in individual stalls were allocated to 2 F:C (50:50 LF or 75:25 HF; DM basis) and to a sequence of DDGS inclusion (0, 7, 14 and 21%; DM basis). Diets were fed to provide equal amounts of nutrients allowing 800 g/d BW gain and fed 1X/d. Ruminal contents were sampled at –2, 0, 2, 4, 6, 8, 10, 12, and 20 h after feeding. Statistical analysis was conducted using the MIXED procedure of SAS. LF rations had greater apparent digestibility (AD) of DM (66.7 vs. 63.2 ± 0.8%; $P = 0.02$) and OM (69.0 vs. 65.2 ± 0.6%; $P < 0.01$). AD responded quadratically for DM, OM, ADF and NDF with 14% DDGS inclusion level having the highest values. Rumen concentration of ammonia tended to be higher for HF (7.68 vs. 6.48 ± 0.44 mg/dL; $P = 0.07$) and tended to increase as DDGS increased (6.46 to 8.14 ± 0.62 mg/dL; $P = 0.08$). Molar proportions (% of total VFA) of acetate tended to be greater for HF (65.8 vs. 64.0 ± 0.6%; $P = 0.07$) and decreased as DDGS increased (65.4 to 63.9 ± 0.5%; $P < 0.01$); propionate increased as DDGS increased (18.8 to 20.6 ± 0.3%; $P < 0.01$). Acetate to propionate ratio decreased as DDGS increased (3.49 to 3.11 ± 0.06; $P < 0.01$). Rumen protozoa count decreased as DDGS increased (24.42 to 11.94 ± 3.15 × 10^4/mL; $P < 0.01$). We conclude that nutrient AD had a greater response when included at 14% DDGS. Ammonia concentration and molar proportion of propionate increased; while molar concentration of acetate, acetate to propionate ratio, and rumen protozoa number decreased with increasing levels of DDGS. LF rations had greater DM and OM AD.

Key words: digestion, dry distillers grain with solubles, fermentation

M360 Effect of live-cell yeast at two dosages on lactation performance by dairy cows. L. F. Ferraretto*, R. D. Shaver, and S. J. Bertics, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

The objective of this trial was to evaluate the effect of live-cell yeast (LCY; Procreatin-7; Lesaffre Feed Additives) at 2 dosages in high starch (HS) diets (30% starch DM basis) on lactation performance by dairy cows versus HS and low starch (LS; 20% starch DM basis) control diets. Sixty-four multiparous Holstein cows, 114 ± 37 DIM and 726 ± 74 kg BW at trial initiation, were randomly assigned to 32 electronic gate feeders, which were randomly assigned to 1 of 4 treatments in a completely randomized design; a 2-wk covariate adjustment period with cows fed a 50:50 mixture of the HS and LS diets followed by a 12-wk treatment period with cows fed their assigned treatment diets. The HS diets were fed without (HS0) and with 2 (HS2) or 4 (HS4) g/cow/d of LCY. The LS diet did not contain LCY (LS0) and was formulated by partially replacing dry ground shelled corn with soy hulls. Data were analyzed using Proc Mixed in SAS with covariate, treatment, wk and treatment x wk interaction as fixed effects and gate (treatment) as a random effect. Cows fed LS0 consumed ($P < 0.01$) 2.5 kg/d more DM than HS2, and tended ($P < 0.07$) to consume 1.7 kg/d more than HS4. Milk yield averaged 44.3 kg/d and was unaffected ($P > 0.10$) by treatment. Solids- and energy- corrected milk yields tended ($P < 0.09$) to be 2.2 kg/d greater for HS4 than HS2. Milk fat content was greater ($P < 0.03$) for LS0 than HS0, and tended ($P < 0.09$) to be greater for HS2 and HS4 than HS0. Milk fat yield for cows fed LS0 was greater ($P < 0.05$) than HS0 and HS2, but not different than HS4 ($P > 0.10$). Milk protein content tended ($P < 0.08$) to be greater for HS4 than LS0. The MUN contents were greater ($P < 0.02$) for cows fed LS0 than the HS diets. Feed conversion (kg Milk / kg DMI) was 9% greater for HS2 than LS0 ($P < 0.05$), and tended ($P < 0.08$) to be 8% greater for HS0 than LS0. The BW, BW change, and BCS measurements were unaffected by treatment ($P > 0.10$). The LS0 diet increased DMI and milk fat content and yield, but reduced feed conversions. The addition of LCY to HS diets tended to increase milk fat content in dairy cows.

Key words: yeast, lactating cow, starch

M361 Differences in nutrients formulated and nutrients supplied on three California dairies. H. A. Rossow[1], R. J. van Hoeij[2], and G. Acetoze*[1], *[1]University of California, Davis, [2]Utrecht University, Utrecht, the Netherlands.*

Computer models used in ration formulation assume that nutrients supplied by a ration formulation are the same as the nutrients presented in front of the cow in the final ration. Deviations in nutrients due to feed management effects such as dry matter changes (i.e., rain), loading, mixing and delivery errors are assumed to not impact delivery of nutrients to the cow and her resulting milk production. To estimate how feed management impacts nutrients supplied to the cow, weekly total mixed ration (TMR) samples were collected and analyzed (Analab, Fulton, IL) for 4 pens (close up cows, fresh cows and 2 high milk producing cows pens) for 7 weeks on 3 California dairies. Differences among nutrient analyses from these samples and nutrients from the formulated rations were analyzed by GLM procedure of SAS (SAS Institute, 2007). Deviations in nutrients formulated and supplied were significantly different ($P > 0.05$) among dairies except for fat % (mean 0.25, 0.047, 0.074, SE 0.13, 0.12, 0.11), ash % (mean 0.048, 0.39, 1.2, SE 0.28, 0.26, 0.24), magnesium % (mean 0.036, 0.020, 0.015, SE 0.015, 0.014, 0.013) and chloride % (mean 0.071, 0.00097, 0.14, SE 0.026, 0.025, 0.023). Therefore feed management practices on all 3 dairies impacted nutrients supplied to the cow. Differences among all formulated and supplied nutrients were also significantly different among pens and were 6.14 for DM %, 1.39 for crude protein %, 0.55 for ADF %, 2.2 for NDF %, 3.1 for starch %, 0.088 for fat %, 0.67 for lignin % and 0.60 for ash %. However, differences among nutrients supplied due to diet changes for a pen were not significant. Therefore feed management impacts nutrient delivery to the cow but most diet adjustments are small relative to differences among pen rations.

Key words: feed management, nutrient supply, ration formulation

M362 Effect of dietary protein level and rumen-protected amino acids supplementation on ruminal fermentation and nitrogen utilization in lactating dairy cows. C. Lee*[1], A. N. Hristov[1], K. Heyler[1], T. Cassidy[1], H. Lapierre[2], G. A. Varga[1], and C. Parys[3], *[1]Pennsylvania State University, University Park, [2]Agriculture and Agri–Food Canada, Sherbrooke, QC, Canada, [3]Evonik Degussa GmbH, Hanau, Germany.*

The objective of this experiment was to investigate the effect of dietary protein level and rumen–protected amino acid supplementation on ruminal fermentation and N utilization in lactating dairy cows. The experiment utilized 8 ruminally cannulated Holstein cows (102 ± 28 DIM) in a replicated 4 × 4 Latin square design trial with 21-d periods. Treatments were: 15.6% CP diet [HighCP; metabolizable protein (MP) balance: –24 g/d], 14.0% CP diet (LowCP; MP balance: –283 g/d), 14.0% CP diet supplemented with 100 g/cow/d rumen-protected Lys (AminoShure-L, 24 g/d estimated digestible Lys supply; LowCPLys),

and 14.0% CP diet supplemented with 100 g/cow/d rumen-protected Lys plus 24 g/cow/d rumen-protected Met (Mepron, 15 g/d estimated digestible Met supply; LowCPLysMet). Dry matter intake (26.0 ± 0.79 kg/d), milk yield (40.9 ± 1.46 kg/d), milk composition, and rumen fermentation (pH, VFA and ammonia concentrations) were not affected by diet. Blood and milk urea-N concentrations were lower ($P = 0.03$) for the LowCP diets compared with HighCP. Cows on the LowCP diets had lower N intake (585 vs. 641 g/d, $P < 0.001$) than on HighCP. Apparent total tract N digestibility tended to be decreased ($P = 0.07$) with the LowCP diets compared with HighCP. Milk N secretion and fecal N excretion were not affected by diet. Compared with HighCP, the LowCP diets decreased urinary N excretion (by 29%; $P = 0.01$) and as proportion of N intake (by 22%, $P = 0.04$). Supplementation with rumen–protected amino acids did not further decrease N losses. Whole animal N retention did not differ among diets. Ammonia emission from manure was decreased (by 35%; $P = 0.001$) by the LowCP diets compared with HighCP. In this short-term experiment, dietary CP level or rumen-protected Lys and Met supplementation had no effect on ruminal fermentation, nutrient digestibility (except N), and cow productivity. However, urinary N losses as well as ammonia emission from manure were significantly reduced with the LowCP diets.

Key words: dairy cow, dietary protein, rumen-protected amino acid

M363 Effects of additive treatment and glycerol supplementation on in vitro digestibility and fermentation of a total mixed ration. J. H. Han*[1,2], S. C. Kim[2], D. H. Kim[1,2], J. J. Romero[1], H. J. Lee[1,2], J. H. Shin[1], O. C. M. Queiroz[1], K. G. Arriola[1], C. R. Staples[1], and A. T. Adesogan[1], *[1]Department of Animal Sciences, Institute of Food and Agricultural Sciences, University of Florida, Gainesville, [2]Department of Animal Sciences, Institute of Agricultre and Life Sciences, Gyeongsang National University, Gyeongnam, Jinju South Korea.*

Little is known about effects of glycerol supplementation on ruminal fermentation and whether additives can mitigate potential negative impacts. The objective was to estimate effects of additive treatment and glycerol addition on the in vitro DM and NDF digestibilities and fermentation of a TMR for lactating dairy cows. Two isonitrogenous corn silage (34.5%) and alfalfa hay (10.8%)-based TMR containing 0 or 10% glycerol (DM basis) were treated without (Control, CON) or with 4 additives (0.35 g/L of Procreatin 7 yeast, Prince Agri, YE; 500 mg/L of Dry Apex essential oil, EO, BFI Liquid Feeds; 5 mg/kg of monensin, MO, Sigma; or 3.75 mg/L of sodium bicarbonate, SB, Sigma) and incubated for 48 h in buffered-rumen fluid in triplicate. The experimental design was completely randomized. Treatments had a 2 (glycerol) × 5 (additives) factorial structure and both terms and the interactions were included in the statistical model. No glycerol x additive interaction was detected. Adding glycerol tended to increase molar proportion of propionate ($P = 0.07$, 20.7 vs. 19.5), tended to decrease pH ($P = 0.06$, 6.57 vs. 6.75), and decreased molar proportions of acetate ($P = 0.04$, 46.5 vs. 49.4), and iso-butyrate ($P = 0.05$, 5.46 vs. 5.79). In vitro DMD (67.2 vs. 60.1%) and NDFD (63.5 vs. 26.9%) were greatest ($P < 0.05$) for SB and least for MO-treated fermentation. Compared with other treatments, EO and MO produced greater pH ($P < 0.05$, 6.83 vs. 6.62), lower total VFA concentrations ($P < 0.001$, 92.2 vs. 104.0 mM), and less methane ($P < 0.001$; 22.3 vs. 27.7 mol/100 mol of VFA) whereas MO resulted in lower NH3-N ($P < 0.05$; 13.8 vs. 16.3 mg/dl). Butyrate and valerate molar proportions were lowest for MO-treated fermentations ($P < 0.05$; 9.35 vs. 10.2 and 4.07 vs. 4.85). *Streptococcus bovis* counts on de Man, Rogosa, Sharpe broth were greater for EO than for other treatments ($P < 0.05$; 1.7 vs. 1.43 log cfu/ml). Glycerol addition improved the energetic efficiency of ruminal fermentation. SB produced the greatest DMD and NDFD values but MO and EO decreased the extent of fermentation and YE had minimal effects on the fermentation.

Key words: glycerol, essential oil, monensin

M364 Use of an anti-inflammatory additive in preweaning Holstein calves. L. A. Borunda*[1], D. Domínguez[1], G. Villalobos[1], I. Arteaga[1], E. Santellano[1], M. Cook[2], and M. Yang[2], *[1]Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México, [2]Aova Technologies Inc., Madison, WI.*

The use of anti-inflammatory additives to regulate the excess of gut inflamation in Holstein calves is a modern approach to maximize nutrient utilization on growth and production. The objective was to determine the impact on animal performance when BIG CALF (Aova Technologies) was fed at 0% (T0), 1% (T1; 5.54 g/a/d) or 2% (T2; 9.08 g/a/d) to Holstein calves during the preweaning period. Forty-four Holstein female calves averaging 35.2 kg (±6.04) were randomly assigned to treatments after colostrum feeding. Calves were housed in individual hutches and fed daily 3 L of raw milk during the first 15 d of trial and then 4 L until weaning. Half daily doses of BIG CALF were mixed with both of the 2 raw milk meals. Calves received ad libitum a commercial starter concentrate (18% CP) after 5 d of age. The length of experimental period was 56 d. Starter concentrate and water intake were recorded daily and individually, as well as disease incidence, body weight, average daily gain, and feed conversion every 14 d. Statistical analysis of animal performance data was done by repeated measures, and disease incidence by chi-squared analysis. Starter concentrate intake (kg) tended ($P \leq 0.10$) to increase by 30.3% in calves of T1 (0.524 ± 0.052) vs. T0 (0.402 ± 0.050). Average daily gain (kg) was not affected by treatments, means for T0, T1 and T2 were 0.417 ± 0.049, 0.529 ± 0.052, and 0.402 ± 0.049, respectively. However, average daily gain during the last period of trial (42 to 56 d) was 46.8% higher ($P \leq 0.01$) for T1 (0.963 ± 0.090) vs. T0 (0.656 ± 0.087). Final body weight (kg) was superior by 14.3% ($P \leq 0.0003$) for calves of T1 (64.4 ± 1.51) vs. T0 (56.3 ± 1.46), and 12.9% ($P \leq 0.0008$) for calves of T1 vs. T2 (57.04 ± 1.46), respectively. Feed conversion tended ($P \leq 0.10$) to improve by 16.3% in animals of T1 vs. T0 (1.751 ± 0.150 vs. 2.094 ± 0.145). Feeding BIG CALF did not affect daily water intake (L), means were 2.785 ± 0.236, 2.386 ± 0.248, and 2.808 ± 0.237 for T0, T1 and T2, respectively. Diarrhea incidence was 28.9% lower ($P \leq 0.046$) in calves of T1 (23.9%) vs. T0 (33.6%). Feeding BIG CALF at 1% increased animal performance compared with control treatment, but did not at 2%.

Key words: animal performance, anti-inflammatory, Holstein calves

M365 Effect of dietary *trans* fatty acids on milk yield and milk composition of early lactating dairy cows. J. S. Watts*, D. L. Sevier, S. M. Clark, M. A. McGuire, and P. Rezamand, *Department of Animal and Veterinary Science, University of Idaho, Moscow.*

Trans fatty acids (tFA) result from either industrial hydrogenation of oils or from biohydrogenation of unsaturated fat in the rumen. The objective was to determine the effect of supplemental dietary tFA on milk yield and composition compared with saturated fat (sFA). Holstein dairy cows 7 d in milk (n = 12) were randomly assigned to a sequence of treatments in a 3x3 Latin square design. Three treatments containing 0, 1.5, and 3% tFA (Virtus Nutrition; Corcoran, Ca), and 3, 1.5, and 0% sFA (Virtus Nutrition; Corcoran, Ca) respectively were

included in a lactation ration. Animals were fed individually and feed intake and milk yield were recorded daily. Each period lasted 14 d. Milk samples were collected on d 10 and 14 of each period with a baseline sample taken on d 0 (pretreatment). Milk composition was determined by near-infrared analysis (Washington DHIA; Burlington, WA) and milk fatty acid (FA) composition was determined by gas chromatography (GC). Data were analyzed with the MIXED procedure of SAS with significance at $P < 0.05$. Addition of tFA had no detectable effect on milk yield or dry matter intake. Additionally, supplementation of tFA did not significantly affect percentages of milk fat, protein, lactose, SNF, or somatic cell count. Dietary tFA linearly increased the total percentage of unsaturated FA in milk ($P = 0.001$) but had no effect on total percentage of saturated FA. Within the saturated FA, C15:0 and C20:0 increased with increasing tFA ($P < 0.02$), whereas C16:0 decreased. Within the unsaturated FA, tFA increased monounsaturated FA ($P = 0.002$), but not polyunsaturated FA. Importantly, total concentrations of 18:1 trans isomers increased in milk with increasing tFA ($P < 0.0001$) with 18:1 t6-t12 all increasing linearly. Overall, inclusion of tFA up to 3% of DM had a significant effect on the FA composition of milk, increasing the percentage of unsaturated FA including 18:1 *trans* isomers. These changes in the FA composition of milk could have negative implications for human health, as consumption of *trans* fat from industrial hydrogenation is associated with increased risk of several chronic diseases.

Key words: *trans* fatty acid, milk composition, transition cow

M366 Effect of nicotinamide on milk yield and retention of cows on commercial California dairies. P. D. French*[1], M. A. DeGroot[2], and J. C. Woodworth[3], *[1]French Consulting, Bon Air, VA, [2]DeGroot Dairy Consulting, Visalia, CA, [3]Lonza Inc., Enterprise, KS.*

A field study was carried out on 8 commercial dairy farms located around Hanford, CA from July 2008 to January 2009. Average herd size was 2,000 milking cows and ranged from 1000 to 5000 milking cows. Farm was the experimental unit and 2 treatments were equally randomized across farm with a 6-wk period sequence of on-off-on-off and off-on-off-on in a double reversal design; where on is close-up dry cow rations with 4 g of added nicotinamide (NM) per kg DM and off is rations without supplemental NM. Supplementation was targeted to deliver 48 g NM/cow/day during the last week of gestation. Data were edited to include only those cows that received the prepartum ration for a minimum of 17 d. Individual cow data were collected using DairyComp 305. All data, except for culling and pregnancy, were analyzed using the MIXED procedure of SAS. Culling and reproductive data were analyzed using the GLIMMIX procedure of SAS. One farm was excluded from the analysis because of failure to follow the daily feeding protocol. Although the culling percentage from calving through 30 DIM did not differ, cull rate from calving through 60 DIM was lower for NM (6.21 vs. 8.81%; $P < 0.05$). Cows that received NM during the prefresh period were 0.68 times as likely to be culled during the first 60 DIM ($P < 0.05$) compared with the controls. Milk fat percentage at 30 DIM was greater ($P < 0.01$) for cows the received NM prefresh and tended ($P < 0.10$) to be greater at 60 DIM. The difference in milk fat percentage along with a numerical difference in milk yield at 30 DIM lead to a very significant increase of 3.4 kg of 3.5% FCM for NM ($P < 0.01$). Nicotinamide did not affect mortality, DIM at culling, or pregnancy rate. Results of this study indicate that feeding nicotinamide during the close-up period reduces early lactation culling and increases FCM yield.

Key words: niacin, prefresh, culling

M367 Periparturient supplementation of saturated and unsaturated fat sources differentially alters the fatty acid profile of colostrum and milk fat of Holstein cows. M. Garcia*[1], L. F. Greco[1], A. Lock[1,2], J. E. P. Santos[1], and C. R. Staples[1], *[1]University of Florida, Gainesville, [2]Michigan State University, East Lansing.*

Information is limited on the effect of supplemental fat on the fatty acid (FA) profile of colostrum. Fat supplements were saturated free FA (SAT; 38% C16:0, 41% C18:0, 7% C18:1cis-9, and 0.7% C18:2n-6 of total FA) or Ca salts of primarily unsaturated FA (USFA) of palm and soybean oil (32% C16:0, 5% C18:0, 23% C18:1cis-9, 27% C18:2n-6, and 3.5% C18:3n-3 of total FA). Prepartum cows (n = 27 fed no supplemental FA; n = 26 fed SAT at 1.7% of dietary DM; n = 24 fed USFA at 2% of dietary DM) were allocated randomly to diets (1.7% FA for base diet, DM basis) starting at 60 d before calculated calving date through 90 DIM. Within 2 h of calving, cows were milked and colostrum was sampled and stored at −20C for later analysis of FA using gas-liquid chromatography. Concentration of total FA (7.4, 6.0, and 7.2% of DM for control, SAT, and USFA, respectively) and proportion of individual shorter chain (C4:0 to C14:0) saturated FA (19.9, 18.9, and 18.1% of FA) were not affected by supplement. Feeding fat decreased ($P < 0.05$) proportion of C14:1 (1.89, 1.70, and 1.57% of FA) and C16:1 (0.54, 0.43, and 0.40% of FA), increased proportion of C18:0 (8.4, 9.6, and 9.6% of FA), but had no effect on proportions of C16:0 (38.1, 37.4, and 37.1% of FA) and C18:1 cis-9 (22.2, 22.6, and 22.1% of FA). Colostrum from cows fed USFA had greater proportions of C18:2n-6 (2.25, 2.31, and 3.35% of FA), total C18:1 trans (1.60, 1.58, and 2.06% of FA), and CLA cis-9, trans-11 (0.20, 0.17, and 0.27%) but not of C18:3n-3 (0.38, 0.39, and 0.41%). The effect of dietary fat source on the FA profile of milk collected wk 5 to 7 postpartum from cows fed the same 3 dietary supplements was different compared with their effects on colostrum. Proportion of each medium chain FA (C10:0, C12:0, and C14:0) was lower and that of C18:0 was elevated by fat supplementation to lactating cows. As with colostrum, feeding USFA increased proportions of total C18:1 trans, C18:2n-6, and CLA cis-9, trans-11 in milk fat. In conclusion, fat supplementation influenced the FA profile of colostrum fat and milk fat differently.

Key words: colostrum, milk, fatty acids

M368 Effects of reduced dietary protein and supplementing rumen protected amino acids on the nitrogen efficiency of dairy cows. A. L. Bell*[1], M. J. de Veth[2], T. R. Wiles[1], O. Becvar[3], and M. D. Hanigan[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Balchem Corporation, New Hampton, NY, [3]Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

When fed to meet National Research Council (2001) protein recommendations, dairy cows consume an excess of many amino acids (AA) resulting in approximately 75% of dietary nitrogen (N) being lost to the environment as urine and feces. Reductions in environmental N release could be attained through an improvement of N efficiency in dairy cows. The objective of this study was to determine if the typical reduction in milk yield associated with feeding a low protein diet to lactating dairy cows could be avoided by dietary supplementation with one or more ruminally protected (RP) AA. Fourteen multiparous and 10 primiparous Holstein cows and 24 multiparous Holstein × Jersey crossbred cows were used in a Youden square design consisting of 8 treatments and 3 periods. The 8 dietary treatments were 1) a standard diet containing 17% crude protein (CP) (+Con), 2) a 14% CP diet (-Con), 3) -Con plus RP methionine (+Met, 16g/d), 4) -Con plus RP lysine (+Lys, 47g/d), 5) -Con plus RP leucine (+Leu, 181g/d), 6) -Con

plus RP methionine and lysine (+Met+Lys), 7) -Con plus RP methionine and leucine (+Met+Leu), and 8) -Con plus RP methionine, lysine, and leucine (+Met+Lys+Leu). Cows given the -Con and +Met+Lys+Leu diets had significantly lower milk production and milk protein yield than the +Con cows. The yield of milk and milk protein for all other AA treatments were not different from either the -Con or +Con treatments. Dry matter intake decreased for cows given the +Met+Leu diet, but all other treatments were not different from the +Con treatment. Milk urea N was significantly decreased for all diets compared with the +Con indicating N efficiency was improved for the low protein diets. Plasma isoleucine and valine were significantly reduced when CP was reduced. Leucine concentrations increased for the +Met+Leu treatment compared with -Con. All other AA were unchanged. In conclusion, supplementation of the individual AA or combinations of 2 AA, but not a combination of all 3 prevented a reduction in milk yield when dietary protein levels were reduced to 14% of dietary dry matter.

Key words: nitrogen efficiency, rumen-protected amino acids, milk production

M369 The effect of direct-fed microbial supplementation on reproductive and production performance of primiparous Holstein heifers. M. B. Cattell[1], A. J. Nelson[1], J. E. Nocek[2], and L. C. Solórzano*[3], *[1]Dairy Research and Technology LLC, Windsor, CO, [2]Spruce Haven Farm and Research Center, Union Springs, NY, [3]Chr. Hansen Inc., Milwaukee, WI.*

The effects of supplementing a direct-fed microbial (DFM) to primiparous dairy cows during the transition period were evaluated. Approximately 2 hundred Holstein primiparous cows were group housed and fed close-up and lactating diets without or with 2 g/cow/d of DFM. Direct-fed microbial supplementation contained approximately 5×10^9 cfu of bacteria (2 specific *Enterococcus faecium* strains) and 2×10^9 cfu of live viable yeast (*Saccharomyces cerevisiae*) incorporated into a limestone carrier. Supplemented cows were fed the DFM at least 7 d before calving and continued through 60 d postpartum. Statistical analyses were conducted by SAS JMP utilizing split-plot-in-time ANOVA for repeated measures. A Wilcoxon test was used to test treatment effects. Although no significant ($P > 0.1$) reproductive responses were observed, cows supplemented with DFM had 5 less days open than non-supplemented cows (140 vs. 145 d) and a lower incidence of retained placentas (2 vs. 5.3%). In addition, cows supplemented with DFM had a numerical ($P > 0.1$) decrease in the incidence of displaced abomasums (2 vs. 6.4%). Cows supplemented with DFM produced milk containing a higher ($P < 0.05$) percentage of milk fat (3.58 vs. 3.49%) and milk protein (3.04 vs. 2.99%), and a higher ($P < 0.1$) milkfat yield than nonsupplemented cows (1.01 vs. 0.98 kg/cow/d). Data suggests that DFM supplementation improves the transitional health of primiparous cows and their subsequent lactational performance.

Key words: direct-fed microbial, reproduction, production

M370 Rumination behavior and its relationship to feeding behavior in Holstein dairy cows prepartum. K. Schirmann*[1,2], N. Chapinal[1], D. M. Weary[1], W. Heuwieser[2], and M. A. G. von Keyserlingk[1], *[1]Animal Welfare Program, Faculty of Land and Food Systems, The University of British Columbia, Vancouver, BC, Canada, [2]Clinic for Animal Reproduction, Faculty of Veterinary Medicine, Freie Universität Berlin, Berlin, Germany.*

The objective of this study was to describe the rumination behavior, feeding behavior and feed intake in dairy cows. Rumination was monitored electronically using Vocal Tags and feeding behavior and intake were monitored using Insentec feed bins, by 2-h period, for 42 multiparous Holstein cows for a minimum of 9 d in the early dry period. Pearson correlations used to test the association, within cow, among 2-h periods, first examining the relationship within a single period, and then modeling how this relationship changes with a lag of 2, 4 or 6 h. We then investigated if daily rumination times were associated with feeding time and DMI among cows. Periods when cows spent more time ruminating were associated with lower feeding times and lower DMI ($r = -0.71$, $P < 0.001$, and $r = -0.72$, $P < 0.001$, respectively), likely because cows were unable to feed and ruminate simultaneously. The correlations with rumination time changed from negative to positive when lags of 2, 4 and 6 h were modeled ($r = -0.09$, 0.24, 0.15, $P < 0.01$, and $r = -0.16$, 0.23, 0.17, $P < 0.001$ for feeding time and DMI at lags of 2, 4, and 6 h, respectively). The results indicate that following periods of high feeding times and intakes cows spent more time ruminating, and that this relationship peaks at approximately 4 h after feeding. Among cows, animals that spent more time spend ruminating per day, spent less time feeding ($r = -0.34$, $P = 0.03$) with no effect on DMI ($r = 0.11$, $P = 0.48$). Overall these data indicate that rumination time can be used to estimate within cow variation in DMI, but that the use of daily summaries of rumination behavior to estimate DMI should be viewed with caution.

Key words: feeding time, dry matter intake, welfare

M371 Performance of dairy calves offered alternative preweaning feeding programs. S. L. Gelsinger*, P. C. Hoffman, and D. K. Combs, *University of Wisconsin, Madison.*

Sixty Holstein or Holstein × Jersey heifers were randomly assigned at birth to one of 3 milk feeding programs: (1) Control - calves fed 3.8 L/d whole pasteurized milk (WPM) and ad libitum complete calf starter from 3 d to 6 wk of age (2) Limit starter - calves offered a maximum of 115 g DM/d of calf starter from 3 d of age until 3 d before weaning and 3.8 L/d WPM during wk 1, 5.7 L/d WPM during wk 2 and 3, and 7.6 L/d WPM during wk 4, 5 and 6, and (3) Hay - calves offered alfalfa hay, but no calf starter until 3 d before weaning and fed WPM similarly to Limit starter calves. For 3 d before weaning, calves were fed 0.9 L WPM per feeding and provided ad libitum calf starter. Dry hay was replaced by calf starter for Hay treatment calves. The study was from November, 2010 to February, 2011. Calves were in individual calf hutches and fed milk twice daily and provided water. Body weight, body measurements and starter intake were recorded. Data was analyzed as a completely randomized design by the proc mixed procedure in SAS with treatment a fixed effect and calf the random effect. Calves assigned to the 3 treatments had similar (mean +/− SE) body weight, heart girth, hip height and body length at birth (39.5 kg +/− 0.9, 80.6 cm +/− 0.8, 77.6 cm +/− 0.9, and 69.9 cm +/− 1.1, respectively). At 6 weeks of age, weaning weights of calves fed Control (68.2 kg) and Limit (70.5 kg) were similar, but greater ($P < 0.05$) than calves on Hay (65.5 kg). Limit starter calves had higher ($P < 0.05$) 6wk hip height (93.7 cm) than Control calves (90.9 cm) and hip height of Hay calves (89.5 cm) was less ($P < 0.05$) than either other treatment. Total starter consumption during the first 5 weeks was 11.6, 3.6 and 0 kg per calf on Control, Limit and Hay, respectively. Starter consumption during the week of weaning was highest ($P < 0.01$) for Control (6.7kg/7 d), intermediate for limit (1.9 kg/7d) and least (1.1 kg/7d) for Hay. Calves on the Limited starter treatment protocol performed similarly to calves limit fed milk and calf starter ad libitum. Calves consuming no starter until 3 d before weaning were smaller, and consumed the least starter during the week of weaning.

Key words: calf, feeding, weaning

M372 Effect of *Origanum vulgare* L. leaves on production and milk fatty acid composition in lactating dairy cows. A. N. Hristov*[1], C. Lee[1], T. Cassidy[1], K. Heyler[1], J. A. Tekippe[1], G. A. Varga[1], and B. Corl[2], *[1]Pennsylvania State University, University Park, [2]Virginia Polytechnic Institute and State University, Blacksburg.*

This experiment investigated the effects of dietary supplementation with *Origanum vulgare* L. leaves (oregano; OL) on production and milk fatty acid (FA) composition in dairy cows. The experimental design was a replicated 4 × 4 Latin square with 8 ruminally-cannulated Holstein cows (DIM, 160 ± 38) and 20-d experimental periods. Treatments were: control (no OL supplementation), 250 g/cow/d OL (LOR), 500 g/d OL (MOR), and 750 g/d OL (HOR). The oregano leaves were supplemented to the basal TMR replacing an alfalfa-cottonseed hulls mix. The basal TMR (14.7% CP, 36.2% NDF) contained (DM basis) 58% forage (corn silage, alfalfa haylage, and a grass-straw mix). Oregano supplementation linearly decreased ($P = 0.02$; SEM = 1.80) DMI: 28.3, 28.3, 27.5, and 26.7 kg/d, control, LOR, MOR, and HOR, respectively. Milk yield tended to increase ($P = 0.07$; SEM = 7.43) quadratically with OL supplementation: 43.4, 45.2, 44.1, and 43.4 kg/d, respectively. As a result, feed efficiency was increased ($P < 0.001$) for all OL diets (1.59, 1.60, and 1.63, respectively) compared with the control (1.46). Milk protein and lactose concentrations and yields and FCM yield were not different among diets. Milk fat content tended to be increased ($P = 0.07$) by HOR compared with the control (3.57 vs. 3.26%, respectively), but OL tended to linearly reduce ($P = 0.07$) milk fat. Milk urea-N concentrations were lower ($P = 0.04$) for all OL diets (7.95 to 8.49 mg/dL) compared with the control (9.26 mg/dL). Rumen fermentation (pH, VFA, and ammonia concentrations) was not affected by treatment. Apparent total tract digestibility of nutrients was also not affected by OL, except NDF digestibility was slightly decreased ($P = 0.04$) by all OL diets compared with the control (49.3 vs. 51.3%, respectively). OL had no effect on milk FA composition. In this short-term study, oregano leaves fed at 250 to 750 g/d decreased linearly DMI and tended to quadratically increase milk yield in dairy cows. Feed efficiency was increased with all OL inclusion levels. Oregano leaves had no effect on ruminal fermentation and milk FA composition.

Key words: *Origanum vulgare*, feed efficiency, dairy cow

M373 Evaluation of algae as livestock feed. C. P. Payne*, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University.*

Cultivation of algae for biofuel would result in the production of significant amounts of post-extraction algal residue (PEAR). The economic viability of algae as source of biofuel is dependent on deriving value from PEAR. Livestock feed is an attractive option for PEAR because of the successful utilization of other co-products by ruminants. While sufficient quantities of PEAR were not available for analysis, we evaluated 2 strains of algae that, based on their lipid content and growth characteristics, possess potential as a source of biofuel. Algae samples, unknown wild algae (WA) and *Neochloris oleoabundans* (NO), were analyzed for ash, crude protein, amino acid profile, total fat content (ether extract), fatty acid profile, fat soluble vitamins, macro- and micro-minerals, and heavy metals (n = 1). Samples were observed to have relatively high levels of ash, 30.5 and 43.2% for WA and NO, respectively. As expected, Na content of each sample was high, 10.3 (WA) and 10.8% (NO). The Ca and P contents were 0.67 and 0.43% for WA and 1.02 and 0.26% for NO, accordingly. Algae samples WA and NO contained 34.2 and 48.6 ppm Cu, 848 and 756 ppm Fe, and 20.1 and 62.3 ppm Zn, respectively. WA and NO contained significant quantities of aluminum at 840 and 858 ppm, accordingly. Analysis of algal CP content, 17.4 WA and 20.6% NO, indicates that PEAR may serve as a source of N in ruminant diets. Samples contained similar amounts of methionine (0.31 and 0.32%; WA and NO, respectively) and lysine (1.00 and 1.18%; WA and NO, respectively). Total fat content was 9.1 and 11.8% WA and NO, respectively. Fatty acids (% total fat) were profiled for WA and NO, correspondingly: Palmitic, 21.3 and 32.0; Oleic, 34.1 and 15.6; Trans-vaccenic, 7.7 and 5.6; Linoleic, 11.3 and 19.8; α-Linolenic, 16.3 and15.4%. Vitamin A content was high for both samples, with WA measuring 6614 and 5203 IU/kg for NO. Vitamin E content was 56.5 for WA and 87.7 IU/kg for NO. Future nutritive evaluations of algae and the resulting PEAR should focus on its value as a source of N in ruminant diets.

Key words: algae, coproduct

M374 Hourly changes in fatty acid profile of ruminal contents in continuous cultures as soybean oil is added and removed from the diet. C. M. Klein*, S. K. Thurmond, P. H. Morris, and T. C. Jenkins, *Clemson University, Clemson, SC.*

The objective of this experiment was to determine how quickly biohydrogenation patterns change in ruminal contents in response to the addition and removal of unsaturated fat from the diet. Four dual-flow continuous fermenters were fed 60 g/d of 1:1 forage (alfalfa hay) to concentrate mix in 2 equal portions at 0800 and 1600 h. Diets were fed to flasks for 4 12-d periods each divided into 3 phases; 1) a control diet for d 1–4 (CON1), 2) a diet with 4% added soybean oil for d 5–8 (SBO), and 3) the control diet for d 9–12(CON2). Samples of culture contents were taken at 0 (just before feeding), 2, and 4 h after the morning feeding on all days except d 5 and d 9. On d 5 and d 9, samples were taken hourly for 12 h starting just before the morning feeding. Results are expressed as g fatty acid/100 g total fatty acids. Differences among sampling times were declared if $P < 0.05$ and determined in SAS using single degree of freedom contrasts. During the CON1 phase, changes in fatty acid profile occurred daily after each feeding that were characterized by increased ($P < 0.05$) proportions of C18:2 and *cis*-9, *trans*-11 CLA, and decreased ($P < 0.05$) proportions of stearic acid, *trans*-10 C18:1 and *trans*-10, *cis*-12 CLA. Linoleic acid averaged 11.5 ± 1.4% during CON1 and peaked at 33.3 ± 1.1% immediately after the addition of soybean oil (d4h1). Linoleic acid averaged 26.1 ± 1.1% and 16.4 ± 2.6% during SBO and CON2 phases, respectively. Stearic acid showed little change from SBO to CON2 phases (averaging 9.6 ± 1.7 and 9.5 ± 1.9%, respectively). *Trans*-10, *cis*-12 CLA proportions averaged 0.61 ± 0.08% during CON1, increased gradually over the SBO phase, and peaked at 5.38 ± 1.51% at the start of CON2 (d 8h 0). *Trans*-10 C18:1 averaged 0.62 ± 0.12% over CON1 and peaked at 6.12 ± 1.62% during CON2 (d9h0). The results of this study show that the introduction of soybean oil into the diet causes an immediate increase in linoleic acid concentration in ruminal contents that is accompanied by little change in stearic acid and slow-developing increases in *trans*-10, *cis*-12 CLA and *trans*-10 C18:1.

Key words: biohydrogenation, soybean oil, conjugated linoleic acid

M375 Effects of tannin extracts on in vitro growth of selected food-borne pathogenic bacteria. B. J. Min[1], B. R. Min[1], J. M. Sieg[2], J.-S. Eun*[2], D. R. ZoBell[2], and D. C. Tice[1], [1]*Department of Agricultural and Environmental Sciences, Tuskegee University, Tuskegee, AL,* [2]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan.*

An in vitro study was conducted to assess the growth inhibition of tannin extracts (TE) against *Escherichia coli* O157:H7, *Salmonella typhimurium*, *Listeria monocytogenes*, and *Staphylococcus aureus* in pure culture. Commercially available quebracho (QT; mainly condensed tannins), chestnut (CNT; containing 80% hydrolysable tannins), and mimosa tannins (MT; containing about 70% condensed tannins) (Chemtan, Exter, NH) were tested. An agar diffusion assay was used to evaluate the antimicrobial activity of TE at 1 mg TE/4 mL ethanol solution (1:5 dilution) and 1 mg TE/49 mL ethanol solution (1:50 dilution) against the bacteria. The in vitro experiment was performed in a 3 (source of TE) × 4 (pathogenic bacteria) × 2 (dilution rate) factorial design (n = 3). An aliquot of 10 mL hard tryptic soy broth was used to inoculate *E. coli* O157:H7 and *S. typhimurium*, whereas 10 mL hard brain heart infusion broth was used to inoculate *L. monocytogenes* and *S. aureus* at $10^{5–6}$ cfu/mL. Plates were incubated at 37°C for 48 h, and the disc with ethanol only was used as a control. After incubation, the diameter of inhibition zones was measured at least 3 cross-section points, and mean value was used for inhibition zone. At 1:5 dilution, CNT depicted the most inhibitory response (2.05 mm) followed by MT (1.44 mm) ($P < 0.05$). The CNT elicited an inhibitory effect across all pathogenic bacteria (*E. coli* O157:H7 = *S. typhimurium* > *L. monocytogenes* > *S. aureus*) ($P < 0.05$). Mimosa tannins had less inhibitory effects compared with CNT, while QT did not affect bacterial growth. At 1:50 dilution, only the CNT inhibited bacterial growth (*E. coli* O157:H7 = *S. typhimurium* > *L. momcytogenes*), but the overall response was lower than that in 1:5 dilution (1.10 vs. 2.05 mm). Results from this in vitro experiment showed that the CNT exerted a greater inhibition of pathogenic bacterial growth than the MT and the QT.

Key words: pathogenic bacteria, tannin extracts, growth inhibition

M376 Tannin extracts decrease in vitro growth of ruminal acidosis-causing bacteria in pure culture. J.-S. Eun*[1], B. R. Min[2], J. M. Sieg[1], D. R. ZoBell[1], and A. J. Young[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan,* [2]*Department*

of Agricultural and Environmental Sciences, Tuskegee University, Tuskegee, AL.

Antimicrobial activity of tannins has been well documented. However, there is lack of detailed knowledge to explore potential effects of tannin extracts (TE) on the growth of ruminal acidosis-causing bacteria (RACB) in beef steers. Two strains of RACB were used in a 2 (strain of RACB) × 4 (source of TE) factorial designed experiment (n = 3) to determine the effects of sources of TE on growth of RACB. Two strains of RACB, *Selenomonas ruminantium* JY35 (SR) and *Streptococcus bovis* S81 A Xy2 (SB), were tested in pure culture, as the 2 bacteria have been considered as main microbes causing ruminal acidosis in finishing beef steers. The bacterial growth was measured by OD_{550} readings during 24-h incubation at 39°C in Hungate tubes under CO_2 with a typical beef steer finishing TMR extracted using an artificial saliva in the growth medium containing soluble protein and carbohydrate. Commercially available quebracho (QT; mainly condensed tannins), chestnut (CNT; containing 80% hydrolysable tannins), and mimosa tannins (MT; containing about 70% condensed tannins) (Chemtan, Exter, NH) were used as sources of TE. Overall growth pattern of the RACB differed in response to TE ($P < 0.05$ for RACB × TE interactions). Adding TE decreased growth of SR starting at 2 h, and CNT was most effective to decrease growth of SR at 12 and 24 h followed by MT and QT ($P < 0.05$). At 24 h, the CNT decreased growth of SR at 48%. Growth of SB was inhibited by adding TE beginning at 4 h. At 12 and 24 h, the CNT elicited the least growth of SB followed by the MT and the QT ($P < 0.05$). The CNT decreased growth of SB at 73% at 24 h. Results of this study indicate that supplementing TE in a beef steer finishing diet decreased in vitro growth of SR and SB, and the CNT was the most effective in inhibiting the growth of RACB.

Key words: ruminal acidosis-causing bacteria, tannin extracts, bacterial growth

M377 Effects of wheat dried distillers grains with solubles (DDGS) and cinnamaldehyde (CIN) on fermentation and protein degradation in Rusitec. Y. L. Li[1,2], M. L. He[1], K. A. Beauchemin[1], and W. Z. Yang*[1], *[1]Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China.*

A study was conducted to evaluate the effect of wheat DDGS and CIN on in vitro fermentation using the Rusitec. The experiment was designed as a completely randomized block with a 2x2 factorial arrangement of treatment with 4 replications in each treatment. The control diet (10% barley silage, 90% barley concentrate, DM basis) and wheat DDGS diet (10% silage, 60% barley concentrate, and 30% wheat DDGS) were combined with 0 and 300 mg CIN/L of culture fluid. Experiment consisted of 10 d of adaptation and 7 d of data collection. Interactions of DDGS with CIN on fermentation and nutrient disappearances were not significant. Replaced barley grain with DDGS increased the concentration of total VFA (45 vs. 38 mM; $P < 0.04$), and molar proportions of acetate (46 vs. 41%; $P < 0.01$), propionate (19 vs. 17%; $P < 0.02$), and NH_3-N (15 vs. 10 mg/100 mL; $P < 0.01$) without altering ratio of acetate to propionate and CH_4. Disappearance of DM (48 vs. 45%; $P < 0.03$) and bacterial protein production (72 vs. 51 g; $P < 0.01$) were greater, whereas the disappearances of CP (46 vs. 50%) and NDF (17 vs. 24%) were less ($P < 0.01$) with DDGS than with control diet. With addition of CIN, concentration of total VFA decreased (33 vs. 49 mM; $P < 0.01$) and fermentation pattern changed to greater ($P < 0.01$) acetate and less ($P < 0.01$) propionate molar proportions. Supplementation of CIN overall reduced ($P < 0.05$) the nutrient disappearance by 10 to 15% depending on the nutrient studied. Consequently, the production of bacterial N reduced ($P < 0.01$) by 14%. The results indicate that substitution of wheat DDGS for barley grain or supplementation of CIN in finishing diet potentially increased protein in the intestine as a result of increased CP supply and RUP. However, decreased NDF disappearance with DDGS or CIN may reduce feeding value of the diet especially DDGS is high in NDF.

Key words: cinnamaldehyde, fermentation, wheat DDGS

M378 In vitro digestion and gas production of wheat grain varying processing. W. Z. Yang*[1], T. A. McAllister[1], and M. Oba[2], *[1]Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

Rapid starch digestion in the rumen may lower rumen pH, depress fiber digestion and cause digestive disturbances. The rate and extent of DM digestion varies among wheat sources and with the extent of processing, but seldom have both of these properties been studied in the same experiment. Eight wheat samples collected from various location in Alberta were either ground (1-mm) or dry-rolled, and fermentability was assessed by measuring in vitro gas production (GP) and DM disappearances (DMD) at 0, 4, 8, 14, 24 and 48 h of incubation. The DMD increased ($P < 0.01$) from 21 to 81%, and from 12 to 53%, respectively, for ground and rolled wheat with increasing incubation time from 4 to 48 h. There was no interaction between wheat source and processing on GP and DMD at 24 h of incubation, whereas it was significant ($P < 0.01$) at 48 h of incubation. Variations in GP and DMD among wheat samples were substantial. The GP (ml/g OM) varied from 226 to 311 for ground wheat and from 95 to 194 for rolled wheat, and the DMD ranged from 60 to 81% for ground wheat, and from 30 to 50% for rolled wheat. As expected, GP and DMD were greater ($P < 0.01$) for ground wheat (279 and 64%) than for rolled wheat (141 and 34%) after 24 h of incubation. Similarly, VFA concentration in the culture fluid was higher ($P < 0.01$) for ground (102 m*M*) than for rolled wheat (90 mM). However, ratio of acetate to propionate was lower ($P < 0.01$) for ground (2.3) than for rolled wheat (3.4), indicate that more starch is available to be fermented for ground wheat. This work demonstrates that there is substantial variation in the digestive value of commercially available wheat grain and emphasize the need to have an accurate and rapid means of quality assessment at the point of sale.

Key words: wheat grain, DM digestion, batch culture

M379 The effect of DDGS when replacing corn or soybean meal on rumen microbial growth in vitro as measured using real-time PCR. E. Castillo-Lopez* and P. J. Kononoff, *University of Nebraska-Lincoln, Lincoln.*

Ethanol byproducts are a good source of energy and protein in ruminant diets. The aims were to evaluate the effect of dried distillers grains and solubles (DDGS) and in vitro fermentation time on the growth of rumen bacteria and protozoa, and to measure the contribution of yeast originating from DDGS to total microbial crude protein (MCP). Treatments were: 1) CONT, control with no DDGS, but with alfalfa hay, corn silage (CS), ground corn (GC) and soybean meal (SBM) included at 25% (DM basis); 2) RC, 20% (DM Basis) DDGS replacing GC; 3) RS, 20% (DM basis) DDGS replacing SBM; 4) RCS, 20% DDGS replacing 10% GC and 10% SBM (DM basis). For each treatment, 1 g of substrate was incubated in vitro in 100 mL of inoculum in duplicate. At 0, 4, 16, 32, 48 and 96 h of fermentation DNA was extracted from

each treatment and MCP was measured by real-time PCR. Microbial markers used are from the 16S rRNA gene, 18S rRNA gene and the II chromosome; for bacteria, protozoa and yeast, respectively. Data were analyzed as a completely randomized design with repeated measures to test the effects of treatments and fermentation time. Treatment did not affect ($P = 0.18$) mean bacterial CP which was observed to be 157.22 ± 16.53 mg/g DM across treatment. However, a treatment by time interaction was observed ($P < 0.05$). Specifically, at 16 h the RCS diet yielded higher ($P < 0.01$) bacterial CP than CONT (306.32 and 141.37 ± 49.97 mg/g DM for RCS and CONT respectively). However, at 32 h only the RS yielded higher ($P < 0.01$) bacterial CP than the CONT (393.08 and 251.15 ± 49.97 mg/g DM for RS and CONT respectively). In addition, compared with the CONT, bacterial CP of RCS tended ($P = 0.07$) to increase (343.67 and 251.15 ± 49.97 mg/g DM for RCS and CONT respectively). At 32 h the RS and RCS diet yielded higher ($P < 0.01$) protozoa CP when compared with the CONT (209.31, 165.38 and 117.64 ± 15.01 mg/g DM for RS, RCS and CONT respectively). Treatment did not affect ($P = 0.51$) yeast CP and averaged 0.03 ± 0.02 mg/g DM. Overall, bacterial and protozoal growth was improved when DDGS replaced SBM and it was maintained when DDGS replaced GC.

Key words: DDGS, microbial crude protein, real-time PCR

M380 Effects of semi-arid medicinal herb essential oils on growth of pure culture of *Butyrivibrio fibrisolvens* SH13. H. Jahani-Azizabadi*[1], M. Danesh Mesgaran[1], A. R. Vakili[1], and K. Rezayazdi[2], *[1]Dept. of Animal Science, Excellence Center for Animal Science, Faculty of Agriculture, Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran, [2]Dept. of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, Tehran, Iran.*

The objective of the present study was to investigate the effect of some semi-arid medicinal herb essential oils (EO) on Butyrivibrio fibrisolvens SH13 growth characteristics. The liquid version of Hobson's M2 medium (Hobson, 1969) in Hungate tubes was used to estimate sensitivity of *Butyrivibrio fibrisolvens* SH13 to semi-arid native cinnamon, thyme and coriander essential oils. *Butyrivibrio fibrisolvens* SH13 stock culture was grown anaerobically in M2 medium in 125-mL bottles for 16 h at 38.6°C before testing. *Butyrivibrio fibrisolvens* SH13 was obtained from the Rowett Research Institute (Aberdeen, UK) culture collection. After the medium was autoclaved, each essential oil was applied to give a concentration ranging from 0.0 (as control) to 10, 20, 40, 80, 120, 180, 240, and 360 ppm (4replicates). Essential oils were previously dissolved in equal volume of ethanol. All cultures were grown anaerobically at 38.6°C using an inoculum from stationary phase of stock culture (5% of v/v) for 24 h. The concentration of a EO at which the *Butyrivibrio fibrisolvens* SH13 growth was half of that measured in the control (IC50) was recorded during 24 h of incubation. *Butyrivibrio fibrisolvens* SH13 growth was measured by hourly reading optical density of the medium at 650 nm (OD650). As presented in Table 1, when each EO applied to the culture medium inhibited the growth of *Butyrivibrio fibrisolvens* SH13 at the concentration of higher than 240 ppm. An increase in the concentration of coriander EO (UP to 240 ppm) led to increase *Butyrivibrio fibrisolvens* SH13 OD650 compared with those of the control ($P < 0.05$). Results of the present study demonstrated that the essential oils might alter growth pattern of *Butyrivibrio fibrisolvens* SH13.

Table 1. The concentration of semi-arid medicinal plant essential oils at which the *Butyrivibrio fibrisolvens* SH13 growth was half of that measured in the control (IC50) during 24 h of incubation

	IC50 of EO (ppm)
Cinnamon	≥360
Coriander	>360
Thyme	≥240

M381 Effects of microbial contamination on in situ estimates of ruminal degradability of fiber fractions. J. M. Arroyo, J. Guevara-González, F. Díaz-Royon*, and J. González, *Universidad Politécnica de Madrid, Madrid, Spain.*

Measures of ruminal digestibility of fiber constituents are usually considered as truly estimates. However, vegetable feeds are subjected, during its rumen residence, to a microbial contamination, which is especially high in rich fibrous feeds. Therefore, errors may occur if the fiber determination methods are not able to remove this contamination, as it is normally assumed. The microbial contamination of the neutral and acid detergent fractions (NDF and ADF) and of their N components (NDIN and ADIN, respectively) of in situ incubated residues of a fibrous Italian ryegrass (*Lolium multiflorum*) hay was determined as well as the associated effects on the ruminal degradation estimates. Hay samples (ground to pass a 2-mm screen) were incubated for 72 h in nylon bags (46 μm pore size) on 3 ruminally cannulated wethers fed with 75 g /$Kg^{0.75}$ of a 40:60 Italian ryegrass hay to concentrate diet. Incubations were performed in stable conditions of ^{15}N infusion (30 mg ^{15}N per day) and solid-associated bacteria were isolated and used as reference sample to control contamination. Analyses of NDF, ADF, as well as of N and ^{15}N abundance of both fiber fractions were performed. Effects of microbial contamination were determined by one-way variance analysis. Microbial contribution to NDF, ADF, NDIN and ADIN in the tested sample was 4.14, 0.45, 65.1 and 15.9%, respectively. The lack of contamination correction led to underevaluations of ruminal degradation: 22.4% (89.8 vs. 69.7%) for NDIN, 4.7% (79.4 vs. 75.7%) for ADIN, 2.3% (65.0 vs. 63.5%) for NDF and 0.3% (63.6 vs. 63.4%) for ADF ($P < 0.001$). The procedures of fiber fractioning with detergent solutions do not promote the total detachment of microorganisms adhered to fiber residues of rumen incubated samples leading to large errors for the concentration and degradation of NDIN and ADIN. The associated errors are moderate for NDF and very low for ADF.

Key words: fiber, microbial contamination, ruminal degradation

M382 Measurement of dry matter degradation of sugar cane molasses in rumen of bovine using nylon bag technique. J. J. Lomeli*[1], L. R. Flores[1], R. H. Ley[1], J. E. Guerra[2], I. Quintero[1], J. E. Borbolla[1], and R. Barajas[1], *[1]FMVZ-Universidad Autonóma de Sinaloa, Culiacán, Sinaloa, México, [2]FA-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

With the objective of determine the degradation of dry matter of sugar cane molasses in the rumen of bovine using nylon bag technique 2 experiments were performed. Two cows fitted with 10 cm ID cannula and fed a 70% concentrate diet (14.7% CP; NEm 1.73 Mcal/kg) containing 10% of sugar cane molasses were used. Exp. 1: Nylon bags (10 x15 cm) were filled with a combination of ground corn and rewashed oven-dried river-sand in proportions of 100, 90, 80, 70, 60, 50, 40, 30,

20, 10, and 0% of corn and complete to 100% with sand. Bags were incubated during 24 h in rumen. Compared by orthogonal contrasts, corn-DM disappearance was not affected (P = 0.98) by sand level, with values of 61.7% vs. 61.1% for only corn, and all other levels, respectively. Exp 2: Ground corn and cane molasses were mixed in proportion of 0, 20, 40, 60, and 100% molasses. To prevent the outflow of molasses from the bags, it was blend with dried river-sand. Nylon bags (10 x15 cm) bags were filled to contain the equivalent of 5 g of sample once discounted river-sand. Then were placed in rumen during 3, 6, 9, 12, 18 or 24 h. Data of rumen DM degradation for treatments containing from 0 to 60% of molasses at each time were used to calculate by linear regression the corresponding DM of molasses as 100% of DM. Calculated values were contrasted by regression against observed DM disappearance of 100% molasses treatment. The kinetics of degradation of molasses-DM was calculated by exponential regression. Molasses DM solubility was 69% and calculated by regression was 72%. Molasses DM effectively degraded in rumen was 98.5% at degradation rate of 84%/h (r = 0.97; $P < 0.0001$), and requires proximately 2 h. Predicted by regression and observed values shown a highly linear relationship (r = 0.99; $P < 0.01$). It is concluded that almost totality of molasses DM is degraded in rumen in the first 2 h after feeding

Key words: cane molasses, ruminal degradation, nylon bag

M383 Ruminal degradation of the dry matter of the sugar cane silage. J. A. Reyes-Gutierez[1,2], O. D. Montañez-Valdez*[1], R. Rodríguez Macías[2], E. Salcedo Pérez[2], M. A. Ruiz López[2], and M. R. Rodriguez-Ramirez[3], *[1]Centro Universitario del Sur de la Universidad de Guadalajara, Ciudad Guzmán, Jalisco, México, [2]Centro Universitario de Ciencias Biológicas y Agropecuarias de la Universidad de Guadalajara, Las Agujas, Zapopan, Jalisco, México, [3]Instituto Nacional de Investigaciones Agricolas y Pecuarias, Tecomán, Colima,México.*

The objetive of this work was to study the rumen degradability of dry matter (DM) of sugarcane (*Saccharum officinarum*) in 2 forms for use in ruminant nutrition: T1) fresh sugar cane (FSC) and T2) sugar cane silage (SCS). The digestibility was determined in situ using the technique of nylon bag with 4 Holstein cows fitted with ruminal cannula, which were fed only with each, FSC or SCS and supplemented with 1 kg of commercial dairy concentrate. Five grams of ground sample of FSC and SCS were incubated in nylon bags for periods of 0, 8, 12, 24, 36, 48, 72 and 96 h. Treatments were distributed in a completely randomized design with 6 replicates per treatment. It was found that in situ digestibility of dry matter was higher ($P \leq 0.05$) for FSC in most incubation periods with respect to SCS, except at 24 h of incubation ($P \geq 0.05$, Table 1). Ruminal pH showed no significant differences ($P \geq 0.05$) between treatments. We hypothesized that the degradation of the DM and OM in SCS was higher by the additive and inoculum use, although FSC showed the higher values on this study, the major problem is the daily harvest, sugarcane sours rapidly and becomes unpalatable if left unattended after chopping. Ensiling of sugarcane may solve these problems. However, knowledge on the feeding value of ensiled sugarcane is limited and most studies have been conducted with this forage.

Table 1. Coefficients of digestibility in situ of experimental materials (%)

Component	FSC	SCS	EE

M384 A novel method to measure rumen stability of three rumen protected products. M. Sakkers*[1], P. H. Robinson[2], L. J. Erasmus[1], J. Garrett[3], and R. Meeske[4], *[1]University of Pretoria, Pretoria, South Africa, [2]University of California, Davis, Davis, [3]Quali Tech Inc., Chaska, MN, [4]Western Cape Department of Agriculture, Western Cape, South Africa.*

There are currently a large number of rumen protected products (RPP) on the market, designed to achieve precision delivery of key nutrients post-ruminally. There is however no method to assess the quantitative stability of these products in the rumen. The objective was to determine the stability of 3 RPP using a novel in vivo dual fluid phase marker technique. Three RPP were evaluated, being ascorbic acid, lysine (L) and niacin, composed of 62.3% nutrient (51.87% for L), 8.9% Co-EDTA (8.65% for L) and 28.8% fat matrix (39.48% for L) (specific gravity approximately 1.21). Four ruminally cannulated Jersey cows were fed a common total mixed ration composed of chopped lucerne hay, maize stover, maize meal, soybean oilcake, hominy chop, molasses, urea, Megalac and a vitamin/mineral premix containing 18% CP, 31.7% NDF and 21.3% starch on a dry matter basis. The experiment was a 4 × 4 Latin Square design with 4 14-d periods. Cows were ruminally dosed on d 11 with Cr-EDTA and one of the 3 RPP to deliver 2.4 g of Co and 2.4 g of Cr. Rumen fluid samples were collected before dosing, at 2 h intervals through 25 h, and then every 4 h until 49 h post-dosing. These samples were analyzed for Co, Cr and pH. Ruminal pH was unaffected by treatment and averaged 5.88, with diurnal variation between 5.65 and 6.40. Animal performance was unaffected by treatment with average milk production of 24.6 L/day, milk fat of 4.18% and milk protein of 3.56%. The stability of the RPP within the rumen was measured as the proportion of the area under the curve of rumen clearance of Co (in the RPP as Co-EDTA) relative to the clearance of the Cr (as free Cr-EDTA). The rumen stability of RP Niacin was the highest (P = 0.06) at 66.7% relative to RP Lysine at 55.0%, but only tended (P = 0.14) to differ from RP Ascorbic acid at 58.7%. Simultaneous in sacco incubations of the RPP showed that the appropriate incubation time to estimate the in vivo rumen stability was approximately 24 h. Results show that this in vivo method can be utilized to quantitate rumen stability of RPP, and indicate the most appropriate rumen in sacco incubation time to reflect that measurement.

Key words: area under curve, clearance rate, stability

M385 Biohydrogenation of docosahexaenoic acid into unsaturated 22-carbon fatty acid intermediates in ruminal batch cultures. C. M. Klein*, W. C. Bridges, and T. C. Jenkins, *Clemson University, Clemson, SC.*

Docosahexaenoic acid (DHA) disappears from the rumen indicating that it is converted into other compounds; however, there is limited information on what these compounds are. In this study batch cultures of mixed ruminal microorganisms were injected with 0, 0.5, or 1% DHA and incubated for 0, 6, 24, or 48h to determine if pathways similar to linoleic acid biohydrogenation are responsible for the decrease in DHA. Triplicate cultures were lyophilized and fatty acids were analyzed by GC. Molecular weights were determined by GC/MS using chemical ionization. Statistical analysis was completed using SAS 9.2. A LSmeans ANOVA in proc GLM was used to test time and treatment effects, and proc GLIMMIX was used to test changes in fatty acid profile. At 48h, trans-11 18:1 increased with increasing DHA supplementation with levels of 0.85, 1.59, and 1.86mg for 0, 0.5, and 1% DHA ($P < 0.05$). Stearic acid levels at 48h decreased when DHA was supplemented from 7.91mg with 0% DHA to 4.26 and 4.23mg at 0.5 and 1% DHA ($P < 0.05$). By 48h, 95 and 92% of DHA had disappeared from cultures for the 0.5 and 1% treatment groups respectively indicating biohydrogenation of DHA was occurring as seen in vivo. At 48h, ketostearate increased from 0.10mg with 0% DHA to 0.50 and 0.54mg at 0.5, and 1% DHA respectively ($P < 0.05$). In cultures supplemented with 0.5, 1, 2, or 3% U-13C DHA there was no label in ketostearate at 48h indicating that although ketostearate increases with DHA supplementation it is not produced from DHA ($P > 0.05$). In DHA cultures, up to 5 isomers of C22:5, 6 isomers of C22:4, 5 isomers of C22:3, and 5 isomers of C22:1 were isolated in 6, 24 or 48h cultures. No unsaturated 22 carbon fatty acids were isolated from cultures when DHA was not added. Over time, the isotope profiles changed from 55% C22:5 and 23% C22:4 at 6h to 35% C22:3 and 29% 22:1 at 48h ($P < 0.05$). The time course appearance of unsaturated 22 carbon fatty acids indicates that biohydrogenation of DHA in ruminal batch cultures occurs by pathways of isomerization and hydrogenation resulting in a variety of unsaturated 22 carbon intermediates.

Key words: rumen, docosahexaenoic acid (DHA), biohydrogenation

M386 Effect of a handmade inoculum and additive on in vitro dry matter digestibility of sugar cane silage. O. D. Montañez-Valdez*[1], J. A. Reyes-Gutierrez[1], G. Rocha-Chavez[1], J. M. Tapia-Gonzalez[1], J. A. Martinez-Ibarra[1], C. E. Guerra-Medina[2], J. J. Tinajero-Martinez[4], J. H. Avellaneda-Cevallos[3], and R. Santibañez-Escobar[1], *[1]Centro Universitario del Sur, Ciudad Guzmán, Jalisco, México., [2]Centro Universitario del la Costa Sur, Autlán de la Grana, Jalsico, México., [3]Universidad Técnica Estatal de Quevedo, Los Ríos, Ecuador., [4]Facultad de Ciencias Agrícolas, Universidad Autónoma de Chiapas, México.*

The objective of this study was to evaluate the effect of adding inoculum and an additive handmade in sugar cane silage (SCS) on the in vitro digestibility of DM and OM. The treatments were: T1) sugar cane silage with 1% inoculum and 1% additive; T2) sugar cane silage with 3% inoculum and 3% additive were incubated for 48 h incubations. Data were analyzed by mean comparison using a T Student test. The inoculum consists of 10% molasses, 1.0% of yogurt, 5.0% chicken manure, 0.5% urea and 83.0% water and the additive was formulated with 1.0% urea, 0.1% ammonium sulfate and 0.25% phosphorus on DM basis. There were differences ($P \leq 0.05$) between treatments on the in vitro digestibility of DM. T1 shows higher percentages of DM (41.93 ± 0.024 vs. 35.06 ± 0.030), but we do not found change in OM (84.18 ± 0.48 vs. 85.28 ± 0.39); these in vitro results were not reflected improved of inclusion of higher levels of inoculum and additive in sugar cane silage. These results possibly demonstrate that although the primary objective of the addition of inoculums and additives to the sugar cane silages is for avoiding an alcoholic fermentation, these additives can affect negatively the ruminal environment and decrease the animal production.

Key words: additive, inoculum, sugar cane

M387 Effects of dietary probiotics on growth performance, nutrient digestibility, blood profiles, fecal gas emission, fecal microflora and diarrhea index in weanling pigs. S. M. Hong*[1], T. X. Zhou[1], I. H. Kim[1], and Y. H. Park[2], *[1]Dankook University, Cheonan, Choongnam, South Korea, [2]Yeungnam university, Daedong, Gyeongsang, South Korea.*

This study was conducted to investigate the effects of dietary probiotics on growth performance, nutrient digestibility, blood profiles, fecal gas emission, fecal microflora and diarrhea index in weanling pigs. A total of 140 weanling pigs (7.90 ± 0.92kg, initial body weight) were used for 4 weeks. Dietary treatments included: 1) NC (free antibiotics diet), 2) PC (free antibiotics diet + 0.01% tyromix), 3) P1 (NC + 0.1% probiotics), and 4) P2 (NC + 0.2% probiotics). Each treatment had 7 replicates of 5 pigs per pen in a randomized complete block design. From 0 to 2 weeks, the ADG was higher ($P < 0.05$) in PC treatment than NC treatment. PC and P1 treatments were higher than NC treatment in ADG through the entire experiment period.PC treatment was higher than other treatments in nitrogen digestibility ($P < 0.05$) and P1 treatment was higher than NC treatment in gross energy digestibility ($P < 0.05$) at the end of 2 weeks. At the end of 4 weeks, nitrogen digestibility was higher in PC, P1 and P2 treatments ($P < 0.05$) than those in NC treatment. And gross digestibility was higher ($P < 0.05$) in P1 and P2 treatments than NC and PC treatments. P1 treatment had a higher blood lymphocyte percentage than NC treatment. IgG concentration was higher in PC, P1 and P2 treatments than NC treatment ($P < 0.05$). Dietary probiotics supplementation decreased ammonia, total mercaptan and hydrogen sulfide of fecal gas emission ($P < 0.05$). Lactobacillus of fecal microflora was higher in P1 treatment than those in NC and PC treatments ($P < 0.05$) No significant difference was noted in *Escherichia coli* among treatments ($P > 0.05$). Diarrhea index was lower in P1 treatment than that in NC treatment ($P < 0.05$). In conclusion, dietary probiotics supplementation can improve growth performance, nutrient digestibility, blood profiles, fecal gas emission, Lactobacillus in fecal microflora and prevent diarrhea.

Key words: growth performance, nutrient digestibility, probiotics

M388 The response of urea-N^{15} in ruminal content influenced by essential oils. S. Zhao, J. Wang*, D. Bu, and Y. Zhang, *State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agriculture Sciences, Beijing, China.*

Urea-N is an important and cost-less nitrogen source for ruminant, because rumen microorganisms have the ability to hydrolyze urea to ammonia which is used for microbial protein synthesis. Essential oils were found that they regulated nitrogen metabolism and fermentation in rumen. However the effect of essential oils on urea-N metabolism in rumen is limited. The purpose of this study is to reveal the distribution of urea-N in rumen and its changes influenced by the essential oils in vitro. Garlic oil, tea tree oil, and eucalyptus oil were added

into different serum bottles (containing 1.5 g TMR diet, 100 mL McDougall′s buffer, 50 mL strained ruminal fluid and 0.015 g urea-N^{15}) to the final concentrations of 300 mg/L respectively. All bottles were inoculated in a 39°C shaking water bath. Blanks without essential oils were included. All treatments were incubated in triplicate. The content of each bottle was collected at 0, 6, 12 and 24 h of incubation. The microorganisms were isolated by differential centrifugation, and the abundance of N^{15} was analyzed by mass spectrometer. The results showed that the abundance of urea-N^{15} in fermentation fluid decreased following the incubation time, but which in solid-associated and liquid-associated microorganisms increased with time. The 3 kinds of essential oils had no significant effect on urea-N^{15} distribution in solid-associated and liquid-associated microorganisms from 0 to 12 h. However, the abundance of urea-N^{15} from garlic oil treatment decreased significantly compared with tea tree and eucalyptus oil treatment in solid-associated and liquid-associated microorganisms, at 24 h. The concentration of ammonia nitrogen from garlic oil treatment in fermentation fluid decreased significantly at 24 h. DGGE revealed that bacterial population can be changed by 3 kinds of essential oils. The Shannon′s diversity index of bacteria was 2.86, 3.66, 3.82 and 2.78 for blank, garlic oil, tea tree oil and eucalyptus oil treatment. In conclusion, urea-N is accumulated by microorganism and can be influenced by garlic oil with the increase of incubation time.

Key words: essential oils, urea-N^{15}, rumen

M389 Effects of polyclonal antibody against urease on ruminal fermentation and microbiota diversity in vitro. S. Zhao, J. Wang*, D. Bu, and Y. Zhang, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Microbial urease plays an important role in the nitrogen metabolism in rumen for ruminants. However the problem is the hydrolysis rate of urea exceeds the utilization of ammonia. Therefore, many nutritionists are eager to look for inhibitors of urea hydrolysis in the rumen. The purpose of this study is to evaluate the effect of urease antibody on ruminal fermentation and bacterial diversity. Urease gene was linked to pET-30 vector and expressed in *E.coli* BL21 (DE3). The purified urease protein was injected into rabbits to prepare antibody against urease from blood. Rabbit antibodies were dosed (0, 0.5 and 1 mL/bottle) into serum bottles containing 0.25 g TMR diet, 20 mL McDougall′s buffer, 10 mL strained ruminal fluid, 30 mg urea and inoculated at 39°C. The contents of each bottle were collected at 0, 1, 2, 4, 8 and 12 h of incubation. The total microbial DNA in content was extracted by the method of Repeated Bead Beating Plus Column (RBB+C), and analyzed by DGGE to reveal bacterial diversity. The results showed that about 10 mg purified urease protein was obtained. The titer of polyclonal antibody against urease was about 1: 51200 by ELISA analysis. Antibody had a significant effect on the concentration of urea and ammonia. Compared with that of 0 mL/bottle of antibodies, the rates of urea disappearance and subsequent ammonia formation from 1 mL/bottle of antibodies descended 70.3% and 17.9% respectively ($P < 0.05$). In addition, there were 10.9%, 9.4%, 11.8%, 6.5%, 21.4%, 45.2% increases in total VFA, acetate, propionate, butyrate, valerate, isovalerate between 0 and 1 mL/bottle of antibodies ($P < 0.05$). DGGE revealed that the microbial spices were changed, with 51% identity, after added with antibody. Shannon diversity index in 0.5 mL/bottle of antibodies (3.04) and 1 mL/bottle of antibodies (2.92) differed significantly from non-addition of antibody (3.24). In conclusion, antibody against urease could slow down the rate of urea hydrolysis, which may be caused by changes of microorganism.

Key words: microbiota diversity, rumen, urease

M390 Effects of nitrate on microbial communities and rumen fermentation characteristic by using consecutive culture system. Z. Zhou*[1], Z. Yu[2], and Q. Meng[1], *[1]College of Animal Science and Technology and State Key Laboratory of Animal Nutrition, China Agricultural University, Beijing, 100193, China, [2]The MAPLE Research Initiative, Department of Animal Sciences, The Ohio State University, Columbus.*

The primary objective of the study was to investigate the effect of sodium nitrate on population shift of methanogen and 3 cellulolytic species (*Ruminococcus albus*, *Fibrobacter succinogenes*, and *Ruminococcus flavefaciens*), methane production and fermentative characteristic in consecutive culture system. The effects of nitrate on rumen fermentation were compared during 6 24 h consecutive cultures of ruminal microbes. When consecutive culture inoculated with 12 mM nitrate, the cumulative CH_4 production was drastically increased ($P > 0.05$) in the 3rd and 4th series culture, and decreased in the 5th and 6th series culture. Analysis of volatile fatty acids at the end of the consecutive incubation revealed no ($P > 0.05$) or minor effects of nitrate treatment on acetate accumulations, no effect ($P > 0.05$) on propionate accumulations and ratio of acetate/propionate. Real-time polymerase chain reaction (PCR) was used to quantify for mean values of relative population size (RPS, the percent of bacterial 16S rRNA copy number) of methanogens and 3 cellulolytic species. In the consecutive bath culture, methanogens distinctly decrease (RPS > 88.08%) was shown from the 2nd incubation series. The abundance of *R. flavefaciens* was also decreased to nearly undetermined level from the 2nd incubation series. The mean RPS values of *R. albus* were not significantly decreased by nitrate addition consecutive incubation series. *F. succinogens* showed a general trend to increase in the consecutive culture. These data suggest that nitrate inhibited ruminal methane production in our in vitro system but their effects on fermentation differed. Nitrate inhibit populations of methanogens, *F. succinogenes* and *R. flavefaciens*, but have hardly effect on total bacteria and *R. albus*.

Key words: cellulolytic species, methanogene, nitrate

M391 Effects of lipid sources on performance and carcass traits of beef cattle finished at pasture. T. T. Berchielli*[1,2], I. P. C. Carvalho[1,2], G. Fiorentini[1,2], and J. F. Lage[1,2], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]FAPESP– Fundação de Amparo á Pesquisa do Estado de São Paulo, São Paulo, SÃo Paulo, Brazil.*

This study was carried out to evaluate the effects of lipid sources added to protein-energy supplements on performance and carcass traits of finishing beef steers kept at pasture. Forty-five Nellore steers (initial average body weight of 440 ± 14 kg) were assigned to 5 treatments of a completely randomized design. The animals were divided in to 10 paddocks (2 paddocks per treatment) of *Brachiaria brizantha* 'Xaraés'. The lipid sources: linseed oil, palm oil, soybean grain and by-pass fat (Lactoplus) were added to a supplement offered to the animals once a day (amount of 1,0% of the body weight) trying to complete 6% of ether extract on the total diet. The control treatment was composed of an energy-protein supplement with no additional fat. The supplements were based on corn and soybean meal. All the concentrate containing 20% CP and 10% EE (except the control supplement, which contained 3% EE). The experimental period was 90 d and the animals were weighed every 28 d and slaughtered at 495.6 kg. The treatments were compared by analyzing variables using the GLM procedure (SAS

9.1, SAS Institute, Inc., Cary, NC). Average daily gain (ADG) was not affected ($P > 0.05$) by the lipid sources, with mean of 0.601 kg/d. The hot carcass yield (HCY), hindquarter yield (HY), spare ribs yield (SRY) and forequarter yield (FY) were also not affected ($P > 0.05$) by the lipid source on the supplement (57.0, 48.3, 12.1 and 39.7% respectively). There was no effect ($P > 0.05$) on fat thickness, loin eye area (LEA) and LEA/100 kg of BW. The average values obtained for these traits were 7.78mm, 73.40 cm^2 and 14.83 cm^2 respectively. These results suggest that the addition of lipid sources on supplements for grazing beef cattle do not influence the performance and carcass traits when the fat level on the total diet is above 6% of ether extract.

Key words: carcass yield, fat thickness, loin eye area

M392 Effect of the different lipid sources on the carcass traits of the steers finished in a feedlot. T. T. Berchielli*[1,2], G. Fiorentini[1,2], I. P. C. Carvalho[1,2], J. F. Lage[1,2], and R. C. Canesin[1,2], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]FAPESP– Fundação de Amparo á Pesquisa do Estado de São Paulo, São Paulo, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of the different lipidic sources on the carcass traits of the steers finished in feedlot. Forty-five Nellore steers (average initial body weight of 423 ± 15 kg, 16 mo of age) were fed with 60% of roughage basis of corn silage and 40% concentrate, with 7.0% of ether extract level. The fat sources were: soybean grain, protected fat (Lactoplus), linseed oil and palm oil plus a control, without additional fat. The supplements were based on corn and soybean meal. The animals were housed in individual stalls, for 90 d and slaughtered at 497.96 kg. The study was in a completely randomized design, with 5 treatments and 9 replications, and the averages were compared by the Tukey test at 5%. The carcass traits were evaluated: weight at slaughter (WS, kg), hot carcass yield (HCY, %), cold carcass yield (CCY, %), forequarter yield (FY, %), special hindquarter yield (SHY, %), spare rib performance (SRP, %), pH (24 h post slaughter), loin eye area (LEA, cm^2) and fat thickness (FT, mm). No effects of diets were observed ($P > 0.05$) in relationship to FY, SRP, pH, LEA and FT, with mean of 36.75, 9.39, 5.77, 82.41 and 6.48 respectively. However the other traits were different between treatments ($P < 0.05$) the WS was lower in animals that received the palm oil than the animals fed with linseed oil, protected fat, soybean grain and control (436.44, 494.57, 523.56, 510.22 and 522.67, respectively). Consequently the HCY and CCY were also affected and animals receiving the diet with protected fat had a greater yield than the animals fed with palm oil. The palm oil diet showed an increase of SHY compared with diet control (55.19% versus 53.31%, respectively). These results suggest that the addition of lipid sources at the level of 7.0% in diet influence the carcass traits of feedlot steers.

Key words: fat thickness, loin eye area, protected fat

M393 Blood biochemical constituents in growing lambs fed on orange pulp ensiled with exogenous enzymes. A. Z. M. Salem*[1,4], H. M. Gado[2], N. E. Odongo[3], and B. E. Borhami[1], *[1]Department of Animal Production, Faculty of Agriculture (El-Shatby), Alexandria University, Alexandria, Egypt, [2]Department of Animal Production, Faculty of Agriculture, Ain Shams University, Cairo, Egypt, [3]Animal Production and Health Section, Joint FAO/IAEA Division of Nuclear Techniques in Food and Agriculture, International Atomic Energy Agency, Vienna, Austria, [4]Centro Universitario UAEM-Temascaltepec, Universidad Autónoma del Estado de México, Estado de México, México.*

Twenty-four Ossimi male lambs were used to evaluate effects of feeding ensiled orange pulp (EOP) in lamb diets either with or without addition of exogenous enzymes (ZADO of anaerobic bacterium origin-ENZ) on blood protein (g/100 mL), globulin (g/100 mL), albumin (g/100 mL), cholesterol (mg/100 mL), urea (mg/100 mL), serum glutamic-oxaloacetic transaminase (GPT, units/ml) and glutamic-pyruvic transaminase (GOT, units/ml) concentrations. Lambs (21.1 ± 1.01 kg of BW) were assigned to one of 3 groups of 8 animals/group in a randomized complete block design being: Control (0 g/kg EOP), EOP (Control with 150 g/kg EOP without enzymes) or EOP+ENZ (EOP with 5 g/kg of ZADO®). Feeding lambs with EOP diet did not affect blood protein, albumin, urea, GPT and GOT concentrations (Table 1), whereas addition of ENZ during ensilage of orange pulp increased blood globulin concentration ($P = 0.048$) and reduced cholesterol level ($P = 0.043$). Data suggested that addition of enzymes to the EOP could improve the animal immunity and health.

Table 1. Blood biochemical constituents of lambs fed diets containing ensiled orange pulp (EOP) in the presence (EOP+ENZ) or absence (EOP) of an exogenous enzymes mixture

	Diets				
	Control	EOP	EOP+ENZ	SEM	*P*-value
Protein	7.2	7.1	7.4	0.61	0.26
Globulin	52.5[b]	54.6[ab]	60.8[a]	5.82	0.048
Albumin	3.8	4.0	3.9	0.32	0.34
Cholesterol	109.1[a]	103.7[a]	94.5[b]	11.41	0.043
Urea	33.6	34.2	35.9	10.62	0.28
GPT	40.3	43.4	47.2	6.23	0.23
GOT	24.5	25.3	24.8	4.36	0.36

[a,b]Means in the same row with different letters differ significantly ($P < 0.05$).

Key words: lambs, orange pulp, silage

M394 Effect of propionate on urea and glucose kinetics in sheep. U. Agarwal*, K. Somers, K. Bailey, Q. Hu, and B. J. Bequette, *University of Maryland, College Park.*

Feeding and post-ruminal infusion of propionate is known to increase N retention in growing ruminants, possibly through increasing urea recycling and/or gluconeogenesis. The aim of this study was to determine whether ruminal propionate increases urea recycling, gluconeogenesis or both in growing sheep. Wether sheep (n = 6, 32.5 kg BW), fitted with a rumen cannula, were fed to 1.8 × maintenance energy intake a pelleted ration (130 g CP/kg, 9.3 MJ ME/kg) and infused into the rumen with isoenergetic (1 MJ/d) solutions of either Na-Acetate (control) or Na-Propionate for 10-d periods in a balanced crossover design. [$^{15}N_2$]Urea was continuously infused i.v. for the last 5 d, and all urine and feces collected, and subsampled. Over the last 12 h, [$^{13}C_6$] glucose was infused i.v. and hourly blood samples collected during the last 5 h. Compared with background (no infusion), Acetate infusion increased ($P = 0.07$) rumen acetate but decreased ($P = 0.07$) butyrate, whereas Propionate infusion increased ($P < 0.05$) rumen propionate. Dietary DM digestibility was not different (70%). Propionate infusion increased ($P < 0.05$) plasma urea concentration (4.1 vs. 3.4 m*M*). Urea synthesis (14.2 vs. 14.3 g urea-N/d), urinary urea excretion (10.2 vs. 9.5 g urea-N/d) and urea recycled to the gastrointestinal tract (4.3 vs. 4.6 g urea-N/d) were not different between Propionate and Acetate (control) infusions. Propionate infusion increased plasma glucose entry rate (3.7 vs. 4.4 g/kg BW/d, $P < 0.01$) and gluconeogenesis (2.44 vs. 3.1 g/kg BW/d, $P < 0.01$) but did not affect glucose (Cori) recycling. Under the dietary conditions of this study, infusion of propionate into the rumen did not affect urea synthesis and recycling compared with the isoenergetic control (Acetate), despite the fact that plasma urea concentration was higher with Propionate infusion. The increase in gluconeogenesis with Propionate infusion increased the supply of glucose for peripheral tissue metabolism and likely spared amino acids for protein synthesis.

Key words: isoenergetic, gluconeogenesis, urea kinetics

M395 Duodenal flow of nitrogenous compounds by wethers fed a fresh ryegrass-based diet intraruminally infused with *Acacia mearnsii* tannins. F. Hentz*[1], C. J. Härter[2], G. V. Kozloski[1], M. P. Mezzomo[1], and A. C. Fluck[1], *[1]Universidade Federal de Santa Maria, Santa Maria, RS, Brazil, [2]Universidade Estadual Paulista, Jaboticabal, SP, Brazil.*

Four Polwarth × Texel wethers (30 ± 4.8 kg BW) fitted with chronic rumen catheter and duodenal cannula, housed in metabolic cages and offered fresh ryegrass (*Lolium multiflorum*) ad libitum (10% refusals) were used in a 4 × 4 Latin Square design experiment to evaluate the effects of ruminal infusion of *Acacia mearnsii* tannin extract (0.625 g/g of condensed tannins) on duodenal flow of N compounds and efficiency of microbial protein synthesis (EMPS). Treatments consisted of no tannin (0) or intraruminal infusion of 20, 40 or 60 g tannin extract/kg of DMI, according to the DMI of the previous day. Experimental periods lasted for 15 d (10 d adaptation, 5 d collection periods). Feed, orts, feces and urine output were recorded daily on d 10 to 15 and samples collected and composited within animal and period. On d 15, duodenal digesta samples (100 mL) were collected at 3 h intervals over a 24 h period and composited within animal and period. Duodenal flow of N compounds (g/d) was calculated by multiplying their concentrations in duodenal digesta (g/kg of DM) by duodenal flow of DM (g/d). Duodenal microbial N flow was estimated from urinary excretion of purine derivatives. Data were analyzed using the MIXED procedures of SAS. When the treatment effect by ANOVA was significant ($P < 0.05$) or tended to be significant ($0.05 < P \leq 0.10$), linear and quadratic effects of treatments were tested by regression analysis. Duodenal flow of total N ($P = 0.108$), α-amino N ($P = 0.305$) and ammonial N were not affected ($P = 0.568$) by tannins. There was a linear reduction ($P = 0.020$) in duodenal microbial N flow (from 6.2 to 2.9 g/d) whereas the EMPS was not affected linear ($P = 0.298$) or quadratically ($P = 0.143$) by the increasing levels of tannin infusion. In conclusion, although dietary inclusion of tannin extract from *Acacia meanrsii* in concentrations up to 60 g/kg of DMI significantly reduced microbial N flow,

it does not affect the amount of duodenal α-amino N supply and the EMPS in wethers fed a temperate grass-based diet.

Key words: condensed tannins, microbial N, sheep

M396 Effect of germinated and ensiling sorghum grain on digestion and ruminal fermentation by sheep. D. García[1], F. Castrejón[1], G. Mendoza[2], and L. Corona*[1], *[1]Universidad Nacional Autónoma de México, Cd. Universitaria, DF, México, [2]Universidad Autónoma Metropolitana, Xochimilco, DF, México.*

To evaluate the influence of sorghum grain germinated and ensiling on nutrient digestion and ruminal fermentation of sheep, 5 Pelibuey lambs (38 ± 2.84 kg BW) with cannulas in the rumen and proximal duodenum were used, in a Latin square 5 × 5. Treatments consisted of a basal finished diet containing 72% sorghum grain (% DM basis) as: 1)dry whole sorghum (DWS); 2) zero days germinated sorghum and ensiled for 42d, (GSE (G0); 3) 1d GSE (G1); 4) 3d GSE (G3); 5) 5d GSE (G5). G1, G3 and G5 showed higher ruminal OM digestion ($P < 0.01$, 25.6%), ruminal starch digestion, RSD ($P < 0.01$, 25.6%) and ruminal NDF digestion, RNDFD ($P = 0.17$, 4.31%) but smaller protein efficiency, PE ($P < 0.05$, 18.65%) and postruminal OMD($P < 0.05$, 9.88%) compared with DWS (percentages are the differences between treatments). G1, G3 and G5 had higher RNDFD ($P < 0.05$, 14.63%), but smaller RSD ($P < 0.10$, 5.20%) and PE ($P < 0.05$, 18.04%), compared with SG0E. The treatments G1, G3 and G5 showed bigger total digestion of OM ($P < 0.05$, 3.42%), total starch digestion, TSD ($P = 0.18$, 2.12%) and total nitrogen digestion, TND ($P < 0.10$, 3.65%) compared with DWS and this higher TOMD ($P = 0.11$, 2.61%), total NDF digestion, TNDFD ($P < 0.10$, 24.79%) regarding SG0E. The TSD ($P = 0.13$, 2.9%) was higher for G0 and TNDFD was lower ($P < 0.05$, 27.62%) compared with DWS. The increasing of germinated days, decrease (lineal effect, $P < 0.05$) TSD. The digestible energy DE (Mcal/kg) values were higher for G1, G3 and G5 ($P < 0.05$, 4.39%) compared with DWS. The ruminal pH was bigger ($P < 0.05$, 5.78%) for G1, G3 and G5 compared with DWS. The germination days increased (lineal effect, $P < 0.01$) acetate and reduced propionate (lineal effect, $P < 0.01$). Germination days increased (lineal effect, $P < 0.05$) methane production. It was concludes that the treatments with germinated sorghum and ensiled presented higher total digestion of OM, starch, N, DE and ruminal pH compared with whole sorghum grain, due mainly to an increment of the ruminal digestion. When increasing the days of germination decrease the starch digestion. The best treatment in terms of digestion of starch, ruminal pH and energy value was G1.

Key words: digestion, germinated sorghum, lambs

M397 Concentration of some elements in blood serum of nonlactating goats in a subtropical region of Southwest of México State. A. Olmedo, R. Rojo, A. Z. M. Salem, J. Cedillo-Monrroy*, J. Morales-Diaz, J. L. Tinoco-Jaramillo, J. L. Martínez-Benitez, and F. Vázquez-Armijo, *Centro Universitario UAEM-Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México.*

A study was conducted to determinate the P, Ca, Mg, K, Na, Cu and Zn nutritional status of grazing nonlactating goats during 2 different season (dry and rainy of 2008) in 4 localities (Tejupilco, Amatepec, Luvianos and Tlatlaya) at south-western of México State. Eighty-four nonlactating goats (>2 calving, BW 39 ± 8), were sampled before morning feeding. Blood mineral concentration were assayed and data were analyzed using one way ANOVA test; significant differences between means were tested by Tukey. Amatepec region registered the higher ($P < 0.01$) P concentration (4.79 mg/dL). Ca concentration was higher ($P < 0.01$) during rainy season (11.20 mg/dL), than dry period (9.54 mg/dL). There were no differences ($P > 0.05$) among season*localities. Luvianos showed the highest ($P < 0.01$) Na value during dry season (411.76 mg/dL) and Tejupilco presented the lowest values at the same season (322.0 mg/dL). K concentration was different ($P < 0.01$) during dry season. Tlatlaya showed the highest ($P < 0.01$) K value (29.50 mg/dL) and Tejupilco had the lowest (17.31 mg/dL). Tlatlaya recorded the highest ($P < 0.05$) serum Cu concentration during dry season compared with rainy season (0.192 vs. 0.080 mg/dL, respectively). The rest of regions, showed similar Cu concentration and ranged between 0.082 and 0.111 mg/dL. Zn concentration showed the same trend as most of minerals. The interaction season*localities, was highly significant ($P < 0.0004$), with Luvianos that showing higher concentration during dry season (0.117 mg/dL) versus rainy season (0.056 mg/dL), whereas for the rest of regions had a different concentration (from 0.059 to 0.096 mg/dL). P and Ca from the 4 regions in both seasons had low values, suggesting deficiency of these elements. K and in particular Na, were above normal levels reported in the literature. Based on results for Cu and Zn, nonlactating goats could be have reproductive problems due to the deficient or marginal levels in blood serum.

Key words: mineral status, blood serum, nonlactating goats

M398 Exogenous phytase effects on performance of weaned Dorper x Pelibuey lambs. G. Buendía-Rodríguez[1], S. S. González-Muñoz*[2], G. D. Mendoza-Martínez[3], L. Y. Bernal-Zamora[3], R. Basurto-Gutiérrez[1], M. M. Crosby-Galván[2], and J. J. A. Méndez-Romero[4], *[1]CENIDFyMA INIFAP, Ajuchitlán, Querétaro, México, [2]Colegio de Postgraduados, Montecillo, Estado de México, México, [3]Universidad Autónoma Metropolitana–Xochimilco, México DF, [4]Universidad La Salle Bajío, Guanajuato, México.*

The objective of this study was to evaluate the effect of an exogenous phytase (FINASE, AB Enzymes, from *Trichoderma reesei*; 40,000 FTU/g) on in vitro residual phosphorus concentration and performance of 30 weaned 3/4 Dorper × 1/4 Pelibuey lambs (12.12 ± 1.46 kg BW). In vitro treatments were: 0 and 0.12 mg phytase per g of sorghum, corn gluten meal (CGM), alfalfa hay and experimental diet (70% ground sorghum grain, 16.9% CGM, 12% alfalfa hay, 11% calcium carbonate). The experimental design was completely randomized and Tukey test ($P \leq 0.05$) was used to determine differences for residual P concentration (%) between 0 and 0.12 mg phytase: 1) at 24 h (incubation), 0.086^{a} and 0.050^{b} sorghum, 0.259^{a} and 0.119^{b} CGM, 0.365 and 0.240 alfalfa, 0.276^{a} and 0.240^{b} diet; 2) at 48 h, 0.054 and 0.048 sorghum, 0.178 and 0.161 CGM, 0.198^{a} and 0.131^{b} alfalfa, 0.237^{a} and 0.211^{b} diet. For the performance trial (60 d) lambs were fed the experimental diet and 0, 6 or 12 g/t phytase (treatments). The experimental design was completely randomized (10 lambs per treatment), data collected over time was analyzed as repeated measurements using the MIXED option of SAS, and means were compared with the Tukey test ($P \leq 0.05$). Variables were average daily gain (ADG), dry matter intake (DMI), feed conversion (FC), apparent DM digestibility (DMD), plus P fecal excretion (PFE). Phytase did not change ($P \geq 0.05$) ADG (251, 294 and 266 g/d), DMI (905, 1119 and 975 g/d) or FC (4.06, 4.37 and 3.94). However, phytase addition increased ($P \leq 0.05$) DMD (72.34^{b}, 82.54^{a} and 82.57^{a} %) and PFE (1.01^{b}, 1.09^{ab} and 1.26^{a} g/d). Therefore, it may be concluded that apparent DM digestibility as well as phosphorus fecal excretion were affected when an exogenous phytase was added to a 70% sorghum grain diet, fed to weaned Dorper × Pelibuey lambs during 60 d.

Key words: phytase, weaned lambs, performance and fecal phosphorus

M399 Calcium propionate and grain level effects on performance, ruminal variables and plasma glucose of finishing lambs. H. A. Lee-Rangel[1], S. S. González-Muñoz*[1], G. D. Mendoza-Martínez[2], A. Hernández-Garay[1], and M. M. Crosby-Galván[1], *[1]Colegio de Postgraduados, Montecillo, Estado de México, México, [2]Universidad Autónoma Metropolitana–Xochimilco, México DF, México.*

The aim of this trial (42 d) was to evaluate the effect of calcium propionate and grain level on performance, ruminal variables and plasma glucose concentration in 32 finishing Criollo lambs (28.14 ± 2.34 kg initial BW). The experimental design was completely randomized with a factorial arrangement of treatments 2 × 2 (55 and 65% grain; 0 and 1% calcium propionate). Grain was a 50:50 mixture of corn and sorghum grain. Data collected over time were analyzed using MIXED procedure (SAS) and treatment means were compared with Tukey test ($P \leq 0.05$). There were no differences ($P \geq 0.05$) between treatments for DMI, ADG, feed conversion, rib eye area and ruminal pH. Carcass yield was increased ($P \leq 0.06$) in lambs fed 65% grain without calcium propionate (52.79 vs. 50.62%) and 55% grain with calcium propionate (52.48 vs. 50.06%). Ruminal concentration of propionate was increased ($P \leq 0.05$) in lambs fed 55 or 65% grain plus calcium propionate. However, concentration of acetate or butyrate in the rumen and plasma glucose did not change ($P \geq 0.05$). Therefore, it may be concluded that calcium propionate could partially replace the energy from the grain on diets for finishing lambs.

Key words: calcium propionate, finishing lambs, weight gain and carcass variables

M400 Effects of zilpaterol hydrochloride and genotype on performance of finishing lambs. F. Montoya[1], R. Castañeda[1], S. S. González-Muñoz*[2], G. Buendía-Rodríguez[1], R. Basurto[1], P. Partida[1], and H. Jiménez-Severiano[1], *[1]CENIDFyMA INIFAP, Ajuchitlán, Qerétaro, México, [2]Colegio de Postgraduados, Montecillo, Estado de México, México.*

Zilpaterol hydrochloride (zilpaterol), a β-adrenergic agonist, has been approved for finishing cattle, but few data are available for lambs. Therefore, the objective of this study was to determine the effects of zilpaterol and genotype on performance of 28 finishing lambs during 32 d. Genotypes were Pelibuey × Blackbelly and Pelibuey × Dorset, and lambs (32.7 ± 4.9 kg BW) were randomly assigned to experimental diets (16% CP and 2.75 Mcal ME/kg DM): Control (no zilpaterol); diet plus 6 ppm zilpaterol. Variables evaluated were ADG, DM intake (DMI), feed efficiency (FE; ADG/DMI) and final BW (FBW). The statistical model included zilpaterol and genotype effects and interaction; besides, initial BW was used as a covariable. Data collected over time was analyzed as repeated measurements using the MIXED option of SAS; and LS means are shown. Zilpaterol × genotype interactions were not significant ($P \geq 0.05$). There was no effect ($P \geq 0.05$) of zilpaterol on ADG (315 vs. 318 g/d; SEM = 0.012), DMI (1.57 vs. 1.55 kg/d; SEM = 0.031), FE (0.200 vs. 0.205; SEM = 0.007) and FBW (42.7 vs. 42.4 kg; SEM = 0.38) for control and zilpaterol diets, respectively. Regarding genotype, Pelibuey × Dorset lambs showed a higher ($P \leq 0.05$) ADG (0.336 vs. 0.284; SEM = 0.012), DMI (1.62 vs. 1.55; SEM = 0.031) and FBW (43.4 vs. 41.8 kg; SEM = 0.38) as compared with Pelibuey × Blackbelly. Therefore, the results of this trial suggest that addition of zilpaterol did not change performance of finishing lambs, but there were differences between lamb genotypes.

Key words: finishing lambs, genotype, zilpaterol

M401 Feed intake and performance by yearling Boer goat doelings consuming deep-stacked or ensiled broiler litter. A. L. Goetsch*, G. D. Detweiler, B. Bah, T. Sahlu, and J. Hayes, *American Institute for Goat Research, Langston University, Langston, OK.*

Boer goat doelings (48; 8 per treatment), 10.4 ± 0.13 mo of age and 27.1 ± 0.98 kg BW, were used in a 9-wk experiment to compare feeding value of deep-stacked (DS) and ensiled (EN) broiler litter. Broiler litter was processed for 82 d before feeding. Temperature in the upper area of the DS bay was 55–65°C for 2 wk and that in the lower area was 45–57°C for 10 wk; EN temperature ranged from 0 to 20°C. Treatments were feeding 1% BW (DM) of a 3:1 corn-soybean meal mixture and moderate to high-quality grass hay free-choice (Cont-Hay), 1% BW hay and concentrate mixture free-choice (Cont-Conc), 1% BW hay, 1.1% BW corn, and DS or EN free-choice (DS-L and EN-L, respectively), and 1% BW hay and DS or EN free-choice (DS-H and EN-H, respectively). Daily samples of DS and EN averaged 70.9 and 73.3% OM (DM basis), 21.8 and 23.2% CP, and 34.0 and 37.2% NDF, respectively. Total DM intake was less for H vs. L treatments, similar between DS-L and EN-L, and greater ($P < 0.05$) for EN-H than for DS-H (1.13, 1.28, 0.98, 1.13, 0.59, and 0.80 kg/d Cont-Hay, Cont-Conc, DS-L, EN-L, DS-H, and EN-H, respectively; SE = 0.072). There were similar differences in ADG (126, 234, 58, 75, −46, and −8 g; SE = 10.1) and the ratio of ADG:DM intake (118, 188, 60, 66, −84, and −11 g/kg for Cont-Hay, Cont-Conc, DS-L, EN-L, DS-H, and EN-H, respectively; SE = 12.7). There appeared to be more adaptation over time to EN-H than DS-H, with similar DM intake in wk 1–3 (0.48 and 0.64; SE = 0.082) but greater values in wk 4–6 (0.65 and 0.88; SE = 0.076) and 7–9 (0.64 and 0.87 kg/d for DS-H and EN-H, respectively; SE = 0.080). Likewise, ADG was similar between DS-H and EN-H treatments in periods 1 (−60 and −42 g; SE = 18.5) and 2 (6 and 27 g; SE = 12.5) and greater for EN-H in wk 7–9 (−83 and −9 g for DS-H and EN-H, respectively; SE = 22.2). In conclusion, feeding value of DS and EN for yearling meat goat doelings appears similar with moderate dietary levels, but with limited consumption of other feedstuffs, feeding value of EN may be greater.

Key words: goat, broiler litter, performance

M402 Effects of night-locking on intake, digestion, behavior, and energy use by meat goat does grazing grass/legume pasture. I. Tovar-Luna[1,2], R. Puchala*[1], T. A. Gipson[1], G. D. Detweiler[1], L. J. Dawson[3], T. Sahlu[1], A. Keli[4], and A. L. Goetsch[1], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]Universidad Autonoma Chapingo, Unidad Regional Universitaria de Zonas Aridas, Bermejillo, Durango, Mexico, [3]College of Veterinary Medicine, Oklahoma State University, Stillwater, [4]Department of Animal Production and Pastoralism, National School of Agriculture, Meknes, Morocco.*

Boer × Spanish does (24), 8 with ruminal cannula, were confined at night with access to grass/legume pasture from 0700 to 1900 h (R) or had continual access (C) in a completely randomized design with repeated measures. Data collection periods (15 d) were in late gestation (L-G; 137 d), early lactation (E-L; 43 d), late lactation (L-L; 97 d), the dry period (Dry), and early gestation (L-G; 65 d). Most does had a litter size of 2, and kids were weaned at 118 d. Pasture access treatment did not affect ingesta composition; CP (20, 13, 15, 13, and 20%) and NDF (51, 59, 63, 61, and 38% in L-G, E-L, L-L, Dry, and E-G, respectively) varied among periods. Kid ADG tended ($P < 0.08$) to be greater for C vs. R (138 vs. 118 g). Fat-corrected (4%) milk yield was greater ($P < 0.05$) for C vs. R in E-L but not L-L (2.04, 0.86, 3.27, and 1.23 kg/d for R/E-L, R/L-L, C/E-L, and C/L-L, respectively). Intake of ME was greater ($P < 0.05$) for R vs. C (823 vs. 735 kJ/kg $BW^{0.75}$). Treatment affected ($P < 0.05$) time lying (12.4 and 10.5), grazing (4.5 and 5.8), and resting (18.5 and 16.7 h for R and C, respectively). Energy expenditure (EE) was greater ($P < 0.05$) for C vs. R (754 vs. 687 kJ/kg $BW^{0.75}$) and recovered energy (RE) in tissue gain was similar between treatments. The RE of lactation (RE_l) from dietary ME was greater ($P < 0.05$) for C vs. R (244 vs. 194 kJ/kg $BW^{0.75}$); however, RE_l from mobilized tissue differed between treatments ($P < 0.05$) in E-L but not L-L (54, 15, 175, and 11 kJ/kg $BW^{0.75}$ in L-G, E-L, L-L, Dry, and E-G, respectively). The EE of activity tended to be greater ($P < 0.07$) for C vs. R (243 vs. 202 kJ/kg $BW^{0.75}$). In conclusion, R decreased activity EE to an extent less than it lessened ME intake, and greatest R impact was in E-L, with reduced RE_l and a tendency for lower kid ADG.

Key words: goat, grazing, energy

M403 Effects of replacing different levels of alfalfa hay and corn silage with sunflower residue silage on feed intake and nutrient digestibility in Mohabadi dairy goats. A. Gholami-Yangije[1], R. Pirmohammadi[1], J. Amini Jabal Kandi[2], and H. Khalilvandi-Behroozyar*[1,3], *[1]Department of Animal Science, Urmia University, Urmia, West Azerbahjan, I. R. Iran, [2]Department of Animal Science, West Azerbaijan Agriculture and Natural Resource Research Center, Urmia, West Azerbahjan, I. R. Iran, [3]Department of Animal Science, University of Tehran, Karaj, Tehran, I. R. Iran.*

Efficient inclusion of agricultural byproducts in ruminants diets is economically and environmentally beneficial. Annual production of sunflower residues in Iran reached 3 million tons in 2005. This study was conducted to determine digestibility of diets where alfalfa hay and corn silage are replaced with sunflower residue silage (SRS) at 4 rates: 0 (control, group 1), 30 (group 2), 60 (group 3) and 90% (group 4). Diets had similar NDF, ADF, CP, ME content and forage: concentrate ratio (81:19) in DM basis. Silages were made by addition of urea and dried whey (0.5% of DM from each) to chopped heads and stalks (3–5 cm, 60:40 ratio). Eight lactating dairy goats (BW = 60 ± 3) in second lactation, were divided into 4 groups of similar BW in 2 4 × 4 Latin square design, with lactation period considered as row block and goat as cloum block. Each Experimental period include 14 d for adaptation and 7 d for sample collection. Diets were formulated according to NRC 2007, prepared each day and provided in 2 equal meals (0800 and 1600h). Animals had ad-libitum access to water. Dry matter intake (DMI) and total fecal excretion of the goats was recorded daily and feed and fecal samples were withdrawn at regular intervals for chemical analysis. Nutrient intake was corrected with nutrient contents of the ort. Data were analyzed by GLM procedure of SAS 9.1 with reapeted Latin square design and duncan test ($P \leq 0.05$). DM intake decreased with increasing levels of SRS, that can be partly due to increased NDF contents in the rations and large particle size of the sunflower stalks. DM and OM digestibility decreased with increasing levels of SRS. Differences in CP and NDF digestibility were statistically significant and highest and lowest values were obtained in group 3 and 4, respectively. This experiment indicated that sunflower residue silage is an acceptable forage for dairy goat and can be replaced with forages up to 60 percent as an uncommon feedstuff in dairy goat rations.

Table 1. DMI and nutrient digestibility of experimental diets

Traits	Group 1	Group 2	Group 3	Group 4	SEM
DMI (kg/d)	1.43[a]	1.45[a]	1.37[a]	1.06[b]	0.06
DM digestibility (%)	75.51[a]	75.48[a]	72.83[a]	57.49[b]	1.86
CP digestibility (%)	76.97[a]	76.57[a]	78.55[a]	65.95[b]	1.62
OM digestibility (%)	77.17[a]	75.55[a]	74.96[a]	57.32[b]	1.89
NDF digestibility (%)	69.59[a]	70.87[a]	73.39[a]	46.18[b]	2.34

M404 Effects of inclusion of different levels of sunflower residue silage in dairy goat diets on milk production and composition. A. Gholami-Yangije[1], R. Pirmohammadi[1], J. Amini Jabal Kandi[2], and H. Khalilvandi-Behroozyar*[1,3], *[1]Department of Animal Science, Urmia University, Urmia, West Azerbahjan, I. R. Iran, [2]Department of Animal Science, West Azerbaijan Agriculture and Natural Resource Research Center, Urmia, West Azerbahjan, I. R. Iran, [3]Department of Animal Science, University of Tehran, Karaj, Tehran, I. R. Iran.*

Ruminant species occupy an important niche in modern agriculture because of their unique ability to digest certain feedstuffs, especially agricultural byproducts, efficiently. Sunflower residues is one of these materials that its annual production in Iran reached above 3 million tons. Present study was carried out to determine potential of sunflower residues silage (SRS) in support of lactation instead of alfalfa hay and corn silage at 4 rates: 0 (control, group 1), 30 (group 2), 60 (group 3) and 90 percent of dry matter (group 4). Diets had similar NDF, ADF, CP, ME content and forage:concentrate ratio (81:19) in DM. Silages were made by addition of urea and dried whey (0.5 percent of dry matter from each) to chopped heads and stalks (3–5 cm, 60:40 ratio). Eight lactating dairy goats (BW of 60 ± 3 kg) in second lactation, were divided into 4 groups of similar BW in 2 4 × 4 Latin square design, which lactation period considered as row block and goat as column block. Each experimental period consisted 14 d for adaptation and 7 d for sample collection. Diets were formulated by NRC 2007, prepared each day and provided in 2 equal meals (0800 and 1600), with ad libitum access to water. Goats were milked twice a day and milk production data were recorded and milk sampled daily and analyzed with milkoscan apparatus. DM intake was recorded daily. Data were analyzed by GLM procedure of SAS 9.1 with repeated Latin square design and Duncan test ($P \leq 0.05$). DM intake decreased with increasing levels of SRS. Milk yield decrease with increasing levels of SRS and differences were statistically significant with highest substitution level compared with control. Milk composition percentage was similar across diets but daily milk components production decreased with 60 and 90 percent SRS replacement. Also, there were a significant difference between morning and evening milk fat and total solid percentage. According to these results, sunflower residue silage is an acceptable feed for dairy goat and can be replaced with forages up to 30 percent without affecting milk production and composition.

Table 1. Milk yield and milk composition of sunflower residue silage consuming goats

Traits	Group 1	Group 2	Group 3	Group 4	SEM
Milk yield (kg/day)	1.126[a]	1.103[a]	0.902[ab]	0.763[b]	0.071

M405 Effect of protein restriction on body characteristics and fat storage in Awassi sheep. S. F. Abi Saab[1,2], F. T. Sleiman[3], F. Ayoub[2], and P. Y. Aad*[4], *[1]Lebanese University, Faculty of Agricultural & Veterinary Sci., Dekwaneh, Lebanon, [2]Holy Spirit University of Kaslik, Faculty of Agricutural Sci., Kaslik, Lebanon, [3]American University of Beirut, Faculty of Agricultural &Food Sci., Beirut, Lebanon, [4]Notre Dame University, Faculty of Natural & Applied Sci., Louaizeh, Lebanon.*

Awassi sheep, the predominant fat-tail breed in Lebanon, stores fat mainly in the tail, resulting in leaner meat. Little research exists on the importance of these fat reserves in compensating for arid rearing during the dry summer months. The objective of this study was to determine the effect of different dietary protein levels on BW, fat distribution and storage in Awassi sheep. Twenty-four rams (7–9 mo) weighing 53.7 ± 6.4 kg were distributed in 3 groups fed 12% (Control-C), 9% (moderately restricted-MR), and 6% (highly restricted-HR) protein diets. Body weight and girth, caudal volume and circumference, organ weights as well as fat distribution were measured over a period of 7 mo at the Agricultural Research and Education Center (AREC) of the American University of Beirut (AUB). Data were analyzed using MSTATC and presented as means ± SEM. Final BW of C (84.3 ± 5.35 kg) and MR (78.3 ± 6.68 kg) was higher ($P < 0.05$) than HR (65.3 ± 7.62 kg), whereas carcass weight was higher ($P < 0.05$) in C (38.0 ± 3.46 kg) than in MR (34.3 ± 1.91 kg) or HR (28.8 ± 3.42 kg). Girth measurement of C (98.6 ± 3.37 cm) and MR (97.7 ± 0.84 cm) was higher ($P < 0.05$) than HR (92.3 ± 4.24 cm). Both caudal volume and circumference were higher ($P < 0.05$) in C (10.5 ± 0.51 L; 58.1 ± 3.01 cm) and MR (9.3 ± 0.91 L; 54.5 ± 2.85 cm) than in HR (7.2 ± 1.63 L; 49.6 ± 4.28 cm), respectively. Abdominal and tail fat weight were greater ($P < 0.05$) in C (2.27 ± 1.05 and 7.94 ± 2.03 kg) and MR (2.0 ± 0.7 and 7.2 ± 1.2 kg) than in HR (0.9 ± 0.3 and 5.0 ± 1.4 kg) whereas organ weights (heart, kidneys, pancreas and testicles) did not vary ($P > 0.05$) among groups. Altogether, these results indicate that moderate protein restriction in diet of Awassi sheep does not greatly affect lean body composition except for the abdominal and tail fat deposition. However, a high restriction of dietary protein greatly depletes Awassi sheep fat reserves as well as significantly affects the carcass weight. We concluded that Awassi sheep uses the stored abdominal and tail fat to compensate for protein dietary restrictions without much decrease in carcass characteristics.

Key words: Awassi, abdominal and tail fat, body characteristics

M406 Nutrient intake and performance of lambs fed diets with different levels of inactive dry yeast. L. D. A. Rufino[1], O. G. Pereira*[1], K. G. Ribeiro[2], S. C. V. Filho[1], and L. L. Cardoso[1], *[1]Fed-*

eral University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Minas Gerais, Brazil.

Inactive dry yeast is a co-product obtained during the process of sugarcane alcoholic fermentation that is used as high protein ingredient for animal feed. The objective of this study was to evaluate the nutrient intakes and productive performance of Santa Ines lamb fed diets containing different levels of inactive dry yeast (0, 33, 67 and 100%, DM basis) in substitution of soybean meal. Diets consisted of 60% concentrate and 40% corn silage (DM basis), formulated to be isonitrogenous (15.5% CP, DM basis). Thirty-six lambs non-castrated, averaging 20 kg BW were allotted in a randomized blocks design with 9 replicates. The animals were kept in individual pens with protected feeders and waterers. The experiment lasted 78 d, divided in 3 periods of 21 d after 15 d of adaptation. Dry matter, organic matter, crude protein and ether extract intakes were not affected by yeast levels ($P > 0.05$), registering average values of 947, 905, 151 and 18 g/day, respectively. However, NDF intake decreased linearly ($P < 0.05$) as yeast levels increased in diets. The average daily gain, carcass daily gain, feed conversion and dressing percentage were not affected by yeast levels ($P > 0.05$), which were, on average, 203 g/day, 88 g/day, 4.74 and 44%, respectively. Our results suggest that inactive dry yeast can replace 100% of the soybean meal in diets of lamb. However, the utilization of this co-product depends on economic factors, because more than 90% of the Brazilian production of inactive dry yeast is traded for European countries. Financial support by CNPq and FAPEMIG.

Key words: average daily gain, crude protein, carcass dressing

M407 Effect of low and high oil corn distillers grain on rumen fermentation, growth performance and carcass characteristics of lambs. A. S. O'Hara*[1], A. V. Chaves[1], A. Tanner[2], T. A. McAllister[3,1], D. J. Gibb[3], F. van Herk[3], and R. D. Bush[1], *[1]Faculty of Veterinary Science, The University of Sydney, Sydney, NSW, Australia, [2]Faculty of Agriculture, Food and Natural Resources, University of Sydney, Sydney, NSW, Australia, [3]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada.*

The objective of this study was to determine the effect of replacing a mixture of canola meal and barley grain in the diet with (low and high oil) corn distillers grains with solubles (DDGS) or wheat DDGS on rumen fermentation, feed intake, daily gain, feed conversion and hot carcass weight in lambs. Seventy Canadian Arcott lambs (24.7 ± 3.21 kg) were used in a completely randomized block design over a 14-week trial. Experimental diets were provided ad libitum as pelleted total mixed rations (TMR). In the treatment diets, canola meal and barley grain were replaced with 200 g/kg of dietary DM of either high oil corn DDGS, low oil corn DDGS or wheat DDGS. A positive control diet was added to match the lipid content of 39 g/kg DM of the high oil corn DDGS diet. Average daily gain (ADG) was determined by dividing weight gain by the number of trial days. Feed conversion was calculated as the ratio between DMI and ADG (g of DMI/g of LW gain. An in vitro rumen digestibility trial was conducted using ruminal fluid obtained from 3 nonlactating Holstein dairy cows. Rumen contents were also collected from each lamb at the time of slaughter for testing in vivo rumen fermentation. Data from both the in vivo and in vitro results were analyzed using the MIXED procedure of SAS. The in vitro incubations revealed both corn DDGS diets produced less microbial N and microbial DM than all other diets, however this difference was too minimal to affect growth performance. Similarly, there was no dietary effect on ($P > 0.05$) on in vivo ruminal fermentation or hot carcass weight ($P \geq 0.19$) of the lambs. Lambs fed low oil corn DDGS had lower average daily gains ($P < 0.03$) than those fed either high oil corn DDGS or wheat DDGS, however they did not differ from those fed the control. This research demonstrated that replacing canola meal and portions of barley grain with 200 g/kg DM of either high oil corn DDDGS, low oil corn DDGS or wheat DDGS in finishing lamb ratios could effectively maintain healthy rumen function, growth performance and hot carcass weight.

Key words: barley grain, ruminal fermentation, sheep supplementation

M408 Nutrient intake and performance of lambs fed diets containing different levels of rumen degradable protein. J. L. Silva[1], K. G. Ribeiro*[1], O. G. Pereira[2], S. C. V. Filho[2], D. S. Pina[3], and P. V. R. Paulino[2], *[1]Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Minas Gerais, Brazil, [2]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [3]Federal University of Mato Grosso, Sinop, Mato Grosso, Brazil.*

The objective of this study was to evaluate the nutrient intake and productive performance of Santa Ines lambs in feedlot fed diets containing different levels of RDP. Thirty-one lambs non-castrated, averaging 22 ± 1.94 kg BW were allotted in a randomized blocks design with 8 replicates. The treatments consisted of diets with 40% corn silage and 60% concentrate formulated to contain 4 levels of RDP (9.15, 9.97, 10.79 and 11.61%, in DM basis), corresponding to 14.25, 15.50, 16.75 and 18.00% of CP. The animals were kept in individual cages with protected feeders and waterers. The experiment lasted 48 d, after 10 d of adaptation. The animals were weighed every 14 d until reaching the predetermined weight of 30 kg when they were slaughtered. The DM, EE, NDF and TDN intakes were not affected ($P > 0.05$) by RDP levels in diets, registering average values of 1,056.5, 34.7, 294.9 and 803.1 g/animal/day, respectively. However, CP, RDP and RUP intakes increased linearly ($P < 0.05$) with increasing levels of RDP in the diets. The daily weight gain was not affected ($P > 0.05$) by RDP levels which was, on average, 217 g/day. The carcass yield obtained in relation to empty body weight and feed conversion were not affected ($P > 0.05$) by RDP levels which were, on average 53.7% and 5.1, respectively. The conversion of protein (kg CP intake/kg gain in BW) increased linearly ($P < 0.05$) with increasing levels of RDP, according to the equation $Y = -0.1565 + 0.094*PDR$. In conclusion, the RDP levels evaluated did not change the lamb performance, being able to use the lowest level of RDP (9.15% DM with 14.25% CP), contributing to reduction of nitrogen excretion in environment and feeding costs. Financial support by CNPq and FAPEMIG.

Key words: average daily gain, carcass yield, crude protein

M409 Diet preference of lambs offered a choice of concentrate diets containing different proportions of wheat dried distillers grain with solubles. E. K. R. Charles, A. V. Chaves, E. Jonas, and A. S. O'Hara*, *Faculty of Veterinary Science, The University of Sydney, Sydney, NSW, Australia.*

This study determined if lambs showed an intake preference for diets, that differed in their grain component. The grain consisted of either 20% or 40% wheat dried distiller's grain with solubles (WDDGS) or 60% barley. The study used 36 lambs that were assigned at random to one of 3 groups at 105 d of age (live weight 33.5 ± 4.6kg). All diets were formulated with NRC requirements for growing lambs in mind. Each group was offered the choice of all 3 diets on an ad libitum basis

for a 45 d period with the groups randomly rotated between pens every 7 d to ensure all lambs had access to all pens and all feeders. Daily feed intake, eating patterns, live weight change and wool characteristics were measured. The automatic feeders allowed the evaluation of the total feed intake, total time spent in a feeder and total time eating in the feeder. This allowed the evaluation of an intake preference for a particular diet, accounting for particular behavior of single sheep. Intake preference data was analyzed as a completely randomized design using the proc MIXED procedure of SAS. Means for intake were compared using the LSMEANS/DIFF with treatment, week and the interaction of treatment × week as fixed terms; lambs nested within groups as a random block effect, and week as a repeated measure. Dietary intake preference (as measured by total intake and time spent eating) over the course of the trial varied on a weekly basis (interaction treatment by week $P < 0.001$). The final live weight (39.8 ± 1.88 kg) and wool production was the same for the 3 groups of lambs. There was a tendency for lambs to prefer diets supplemented with WDDGS when compared with the barley grain control diet. There are several possible explanations as to why the lambs may have preferred the WDDGS diets over the control, including the aspects of feed novelty, variety and palatability, as well as the higher crude protein (CP) content of the WDDGS diets.

Key words: wheat distillers, ethanol by-products, sheep

M410 Effect of inclusion of dried citrus pulp on in vitro ruminal fermentation kinetics of a total mixed ration for goats. J. Hernández*[1,2], R. Rojo[1], A. González[2], A. Z. M. Salem[1], F. Lucero[2], J. L. Tinoco[1], A. Carreón[2], and J. F. Vázquez[1], *[1]Centro Universitario UAEM-Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México, [2]Unidad Académica Multidisciplinaria AgronomÍa y Ciencias, Centro Universitario Victoria, Universidad Autónoma de Tamaulipas, Ciudad Victoria, Tamaulipas, México.*

A completely randomized design was used to evaluate the effect of different levels inclusions (0, 100, 200 and 300 g/kg DM) of dried citrus pulp (orange): Control (%): Sorghum grain: 25, Soybean meal: 9, Urea: 1, Molasses: 2, Mineral premix: 3, Buffel grass hay: 60, Dried citrus pulp: 0, T1 (%): Sorghum grain: 15, Soybean meal: 9, Urea: 1, Molasses: 2, Mineral premix: 3, Buffel grass hay: 60, Dried citrus pulp: 10, T2 (%): Sorghum grain: 10, Soybean meal: 9, Urea: 1, Molasses: 2, Mineral premix: 3, Buffel grass hay: 55, Dried citrus pulp: 20, T3 (%): Sorghum grain: 10, Soybean meal: 9, Urea: 1, Molasses: 2, Mineral premix: 3, Buffel grass hay: 45, Dried citrus pulp: 30, on in vitro ruminal fermentation kinetics of total mixed rations balanced for lactating goats (CP 15.5%). One ± 0.002 g of DM of each treatments was weighed in triplicate into 160-mL serum bottles and incubated with ruminal inoculums of 4 goats feeding with a forage (50):concentrate (50) diet. Cumulative gas production was taken at 2, 4, 6, 8, 10, 12, 15, 19, 24, 30, 36, 48, 72 and 96 h post incubation at 39°C. Data of in vitro rumen gas production profiles were analyzed using a completely randomized design and the difference among means the Tukey test was used. Gas production (GP) at 24, 48 and 96 h was higher ($P < 0.01$) in the T3, showing a linear effect ($P < 0.01$). Inclusion of dried citrus pulp in the diet increased (linear effect ($P < 0.0$) the gas production (b) (ml/g DM). Fractional rate of gas production was different among treatments, T1 and T2 had the highest values, control and T3 presented the same values (quadratic effect $P < 0.01$). Lag time (h) had linear effect ($P < 0.01$), control diet had the highest value respect to the others treatments. The inclusion of dried citrus pulp in the diet for goats improved the gas productions parameters, and then this subproduct could be considered as potential feed to ruminant nutrition.

Key words: dried citrus pulp, ruminal fermentation kinetics, goats

M411 The under-nourishment of the Alpine-French goats does not diminish reproductive outcomes, but does affect dynamics of the offspring-growth. R. Rivas-Muñoz[1], E. Carrillo[1], C. A. Meza-Herrera[2], C. Leyva[3], H. Zermeño-González[1], R. Rodríguez-Martínez[3], M. Mellado[3], F. G. Véliz[3], and G. Arellano-Rodriguez*[3], *[1]Instituto Tecnológico de Torreón, Torreón, Coahuila, México, [2]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México, [3]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México.*

The aim of this study was to determine whether under-nourishment decreased the sexual response of Alpine-French goats, as well as to characterize both litter size and offspring -growth dynamics at weaning. Since April 1, a group of females (n = 10) received an experimental diet to provide 70% of their maintenance requirements (T-70), while the other group (n = 10) received a diet to cover 100% of their maintenance requirements (T-100). On October 1, both weight (42.4 ± 1.6 kg) and body condition (3.6 ± 0.1 units) of T-100 were higher ($P < 0.05$) in the T-100 as compared with the T-70 group (28.7 ± 1.1 and 1.8 ± 0.2). On October 9, both groups of females were exposed to one males which was changed every 12 h. Males remained in contact with females during 16 d. The total proportion of females which depicted estrus behavior and kidding were compared by Fisher exact test. Prolificity between groups was compared with the Student *t*-test. Weight data of the offspring were subjected to an ANOVA with repeated measures on 2 factors (Group * Time). All tests were performed using the statistical package SYSTAT 10. The number of estrous females was 100% in both groups ($P > 0.05$). Most of the females kidded in both groups (100 and 90%, T-70 and T-100, respectively, $P > 0.05$). However, the prolificity was higher in the T-100 as compared with the T-70 group (1.8 ± 0.1 vs. 1.1 ± 0.1, respectively, $P < 0.01$). Body weight of offering at birth was similar (2.7 ± 0.1 vs. 2.4 ± 0.2, T-100 and T-70, respectively; $P > 0.05$), however, there was a time by group interaction ($P < 0.05$), final weight was also different (7.6 ± 0.4 vs. 6.1 ± 0.8, T-100 and T-70, respectively; $P > 0.05$).. These results suggest that, irrespective of nutritional level, reproductive outcomes of Alpine-French goats were similar. Nonetheless, both litter size and offspring-growth dynamics at weaning favored the well-nourished females goats.

Key words: goats, under-nourishment, sexual activity

M412 Evaluation of crude glycerin on performance and carcass characteristics of growing meat goats. K. B. Tuoho*[1], N. K. Gurung[1], S. G. Solaiman[1], B. R. Min[1], J.-S. Eun[2], and W. H. McElhenney[1], *[1]Tuskegee University, Tuskegee, AL, [2]Utah State University, Logan.*

Today's high feed costs especially corn price have forced many goat producers to seek alternative energy sources. Crude glycerin (CG), a byproduct of the biodiesel production, is becoming increasingly available in the US and has a potential to partially replace high-starch containing ingredients such as corn. Research has shown that glycerin is converted to propionate in the rumen and acts as a precursor for hepatic glucose synthesis. Therefore, objectives of this were to determine the effects of varying levels of CG inclusion on feed intake, growth performance, feed efficiency, and carcass characteristics in meat goats.

Twenty 4 Boer crossbred intact male goats (23.93 ± 0.98 kg initial BW and 4 to 5 mo of age) were randomly assigned to one of the 4 experimental diets (n = 6) containing 30% bermudagrass hay plus 70% concentrate mix with 0, 5, 10 or 15% CG in the diet on an as-is basis. Feed was offered once a day and water was provided at all times. Goats were weighed every 2 weeks. At the end of 84-d feeding, goats were harvested and carcass characteristics were determined. Feed intake, average daily gain, gain: feed ratio, and carcass data were analyzed as a completely randomized design. Initial BW ($P = 0.99$), final BW ($P = 0.98$), ADG ($P = 0.91$), DM intake ($P = 0.35$), and G:F ratio ($P = 0.32$) were not different among treatments. No differences were observed ($P > 0.05$) in HCW ($P = 0.33$), chilled carcass weight ($P = 0.37$), or kidney and pelvic fat ($P = 0.07$), backfat thickness ($P = 0.71$), body wall fat thickness ($P = 0.94$), LM area ($P = 0.30$) and dressing percent ($P = 0.17$) and shrinkage ($P = 0.98$) among treatments. Results suggest that CG is a viable feedstuff for meat goats and up to 15% of CG can be included in the diet on as-is basis, for growing goats without any compromise in DM intake, growth performance, and carcass quality.

Key words: goats, crude glycerin, growth, carcass characteristics

M413 A meta-analysis for comparing dry matter intake prediction models in dairy goats. G. Caja, X. Roca, A. K. K. Salama, and M. Rovai*, *G2R, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Intake prediction is a key factor in dairy goats due to its effects on goat performances and ration costs. Currently available models for dairy goats (INRA, 2007; NRC, 2007; Cannas and Pulina, 2008) estimate daily dry matter intake (DMI) depending on body weight (BW) and daily milk yield (MY). A direct comparison of these models for a similar BW (50 kg) showed marked differences (0.4 to 0.8 kg DM/d) in predicted DMI depending on MY (0 to 6 L/d) and breed type. A meta-analysis of the available data on dairy goat intake from articles published in scientific journals indexed in PubMed and Science Direct through December 2010 was performed to calculate the differences between actual and predicted values across studies. Data were extracted from 125 papers (335 data) from which 219 values obtained under controlled conditions and using conventional diets (i.e., forage:concentrate >30%) were finally retained. Milk yield was standardized to 3.5% milk fat ($MY_{3.5\%}$) and data were normally distributed. Goat performances were, on average, 51.3 ± 0.7 kg BW (29.0 to 85.5), 2.7 ± 0.4 $MY_{3.5\%}$ L/d (0.4 to 6.2) and 2.22 ± 0.04 kg DMI/d (0.8 to 3.5). A stepwise regression was performed to estimate DMI (kg DM/d) from $MY_{3.5\%}$ (L/d) and BW (kg). Prediction models were (±SEM; $P < 0.001$): DMI (± 0.099) = 1.233 (± 0.050) + 0.370 (± 0.017) × $MY_{3.5\%}$; $R^2 = 0.69$; DMI (± 0.075) = 0.553 (± 0.092) + 0.277 (± 0.018) × $MY_{3.5\%}$ + 0.018 (± 0.002) × BW; $R^2 = 0.76$. Comparison of actual data with the results obtained from the meta-analysis data model showed the lowest mean error of the prediction (–0.030 kg DM/d), being lower than the underestimation obtained with the Pulina and Cannas (2008; –0.092 kg DM/d) and INRA (2007; –0.101 kg DM/d) models. On the contrary, the NRC (2007) prediction overestimated DMI on average (+0.185 kg DM/d). Despite agreeing at the intercept (MY = 0) and at high milk yield (MY = 6), the greatest differences between INRA and NRC predictions were observed around the mean. The oposite was observed with the model of Cannas and Pulina (2008). In conclusion, the INRA (2007) model showed the greatest agreement with the results of the meta-analysis.

Key words: feed intake, dairy goat, meta-analysis

M414 Intake and digestibility of rations containing dry yeast in Saanen goats during peripartum. C. R. Alcalde*, B. S. L. Molina, L. R. Lima, L. C. Gomes, and R. Souza, *Universidade Estadual de Maringá, Maringá, Paraná, Brazil.*

The objective to evaluate the intake and digestibility of rations containing dry yeast (sugar cane) as a substitute of soybean meal in Saanen goats. Twenty-four Saanen goats (15 multiparous and 9 primiparous) were used during the peripartum period, distributed in a completely randomized design in factorial arrangement (2 parity order × 3 rations), analyzed in SAEG system. The rations, similar in crude protein (16% CP), were composed of: soybean meal (SB), soybean meal plus dry yeast (SBDY) or dry yeast (DY) as a protein source, and remaining ingredients: ground corn, corn silage, limestone and mineral mixture, and the roughage:concentrate was 40:60. The marker used to estimate the digestibility was the indigestible neutral detergent fiber. After an adaptation period of 10 d, data were collected during the 21 d before and after the partum. Were collected partial samples of feces in the rectum, during 6 d in both periods (prepartum and postpartum). The intake of dry matter and nutrients was higher ($P < 0.05$) for multiparous goats in both evaluated periods. Among the rations, the intake ether extract with the ration SB was higher ($P < 0.05$) than the others, just to the goats in postpartum. The digestibility of dry matter and nutrients were not modified by the parity order to the goats in prepartum. However, in the postpartum primiparous obtained the best digestibility coefficients to dry matter, organic matter, crude protein and total carbohydrate, which resulted in higher ($P < 0.05$) total digestible nutrients (79.77%) related to the multiparous (74.95%) in the same physiological period. Among the rations, the addition of dry yeast reduced the digestibility of ether extract in both evaluated periods, however, the SBDY ration resulted in higher total digestible nutrients (77.02% in prepartum and 78.26% in postpartum) compared with the others rations. Dry yeast can replace soybean meal in rations, providing good nutritional value to Saanen goats in peripartum.

Key words: ruminant, *Saccharomyces cerevisiae*, transition

M415 Net protein requirements for growth of female Saanen goat kids. F. O. M. Figueiredo*, I. A. M. A. Teixeira, K. T. Resende, T. T. Berchielli, L. D. Lima, O. Boaventura Neto, B. Biagioli, and A. R. Rivera, *UNESP - São Paulo State University, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to determine net protein requirements for growth of female Saanen goat kids using comparative slaughter technique. A total of 30 female goats kids with initial body weight (BW) of 30 kg were used. Six animals were slaughtered at beginning of the experiment (baseline animals), another 6 animals were slaughtered when they reached 38 kg of body weight (intermediate slaughter). The remainder was randomly allocated into 6 groups of 3 animals (0%, 30% and 60% of feed restriction) and each group was considered a block. The animals of each group were slaughtered when the animal set in the 0% feed restriction reached 45 kg of body weight. Animals fed ad libitum (initial, intermediate and 0% of feed restriction) were used to estimate body composition and net protein requirements for gain. To estimate net protein maintenance requirements were used the animals subjected to feed restriction (0, 30 and 60% of feed restriction). Logarithmized allometric equations were used to calculate protein body composition through the relationships between protein content and empty body weight (EBW), based on the following equation: Log_10_Protein, g = 2.33 + 0.48 x Log_10_EBW, kg. The protein body composition ranged from 40.48 to 31.40 g/ kg EBW. Net

protein requirements for gain (NP_g_) ranged from 10.99 to 11.30 g/100 g of body weight gain. The net protein requirements for maintenance (NP_m_) was estimated through the equation Retained Protein, g/EBW0.75/d = −0.37 + 0.092 x CP intake, as NP_m_ = 2.03 g/kg0,75BW/day. The total net protein requirement for growth of female Saanen goat kids with body weight ranging from 30 to 45 kg can be estimated by the followed model: Total net protein, g/g of ADG/day = (2.03 xBW00.75) + (1.47 + 0.11 * ADG). (Fapesp project number 2009/06588–4).

Key words: comparative slaughter, gain, maintenance

M416 Net energy requirements for growth of female Saanen goat kids. F. O. M. Figueiredo*, I. A. M. A. Teixeira, K. T. Resende, T. T. Berchielli, C. J. Harter, A. N. Mendonça, S. F. Souza, R. A. Gomes, D. S. Castagnino, and T. F. V. Bompadre, *UNESP - São Paulo State University, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to determine net energy requirements for growth of female Saanen goat kids using comparative slaughter technique. A total of 30 female goats kids with initial body weight (BW) of 30 kg were used. Six animals were slaughtered at beginning of the experiment (baseline animals), another 6 animals were slaughtered when they reached 38 kg of body weight (intermediate slaughter). The remainder was randomly allocated into 6 groups of 3 animals (0%, 30% and 60% of feed restriction) and each group was considered a block. The animals of each group were slaughtered when the animal set in the 0% feed restriction reached 45 kg of body weight. Animals fed ad libitum (initial, intermediate and 0% of feed restriction) were used to estimate body composition and net energy requirements for gain. To estimate net energy maintenance requirements were used the animals subjected to feed restriction (0, 30 and 60% of feed restriction). Logarithmized allometric equations were used to calculate energy body composition through the relationships between energy content and empty body weight (EBW), based on the following equation: log Energy, kcal = 2.60 + 1.59 Log EBW, kg. The energy body composition ranged from 2630.425 to 3508.741 kcal / kg EBW. Net energy requirements for gain (NEg) ranged from 346.61 e 503.62 kcal / 100 g of body weight gain. The net energy requirements for maintenance (NEm) was estimated through the equation Log Heat Production, kcal/EBW0.75/d = 2.02 + 0.00152*EM intake, as NEm = 88.74 kcal/kg0.75 BW0.75/day. The total net energy requirement for growth of female Saanen goat kids with body weight ranging from 30 to 45 kg can be estimated by the followed model: Total Net Energy, kcal/g of ADG/day = (88.84* BW0.75) + (10.78 + 4.84 * ADG) (Fapesp project number 2009/06588–4).

Key words: comparative slaughter, maintenance, gain

M417 Effect of Clinoptilolite (zeolite) substituting for corn-soybean meal on productive performance and carcass characteristics of Pelibuey sheep. A. Estrada-Angulo*, J. D. Urías-Estrada, J. A. Aguilar, J. L. Bolado, H. Davila-Ramos, J. J. Portillo, J. C. Robles, and F. G. Rios, *FMVZ-UAS, Culiacan, Sinaloa, Mexico.*

To determine the effect of 4 levels of clinoptilolite (Zeolite) substituting for corn-soybean meal on growth performance of sheep, 20 Pelibuey ram lambs (BW = 32.6 kg ± 2.2 kg) were fed for 42 d in a randomized block design (experiment). The animals were weighed and blocked by weight in individual form, placed into 20 (2 × 3 m) floor pens, and assigned to one of 4 (4) diets: 1) Control had 16.43% CP and 2.92 Mcal ME/kg, and contained 7.5% corn straw, 5% alfalfa hay, 62% cracked corn grain, 14% soybean meal, 9% sugarcane molasses, and 2.5% mineral premix; 2) similar (like) Control, (ZEO5) had 16.23% CP and 2.91 Mcal of ME/kg, but contained 0.5% zeolite, 61.75% cracked corn grain, and 13.75% soybean meal; 3) like Control, (ZEO10) had 16.03% CP and 2.89 Mcal of ME/kg, but contained 1.0% zeolite and 61.5% cracked corn grain and 13.5% soybean meal; and 4) like Control, (ZEO15) had 15.83% CP and 2.87 Mcal ME/kg, but contained 1.5% zeolite and 61.25% cracked corn grain. Feed was offered twice daily under free access conditions. In daily feed intake, zeolite treatments decreased 6% respect to Control treatment (1187 vs. 1116 g/d). In average daily gain zeolite treatments increased (14.3% than Control group (216 vs. 189 g/d). About feed conversion, zeolite treatments improved in 20.5% respect to Control group (5.21 vs. 6.28). Hot carcass weight, cold carcass weight and dressing percent tended to improve ($P < 0.08$) in zeolite treatments respect to Control group. Rib eye area, carcass characteristics, fat thickness and primary cuts were similar in all treatments ($P > 0.05$). It is concluded, that zeolite is an ingredient of low price and appropriate substitute for a mix of cracked corn grain and soybean meal in diets for Pelibuey sheep.

Key words: clinoptilolite, zeolite, Pelibuey sheep

M418 Effect of live yeast *Saccharomyces cerevisiae* (strain Sc 47) on fattening efficiency and blood parameters of growing Mehraban lambs. N. Baleghi[1], A. Taghizadeh[2], A. FarahAvar[3], and H. Khalilvandi-Behroozyar*[3,4], *[1]Islamic Azad University, Maragheh Branch, [2]Department of Animal Science,University of Tabriz, [3]Department of Animal Science, University of Tehran, [4]Department of Animal Science, Urmia University.*

Yeast (*Saccharomyces cerevisiae*) products may exert beneficial effects on ruminant productivity by either increasing fermentability of fiber and/or allowing rumen microbes to more effectively metabolize end products of ruminal starch fermentation. The objective was to evaluate the possible effects of live yeast on live weight gain and selected blood parameters of growing Mehraban lambs. Twelve male lambs (average BW 34+4.2 kg) randomly assigned to 3 groups: a) control, without additive b) 1 g/day/head and c) 1.5 g/day/ head *Saccharomyces cerevisiae* (strain Sc 47) with 8×10^9 cfu per gram. Additives supplemented via gelatin capsules to TMR ration (alfalfa hay, wheat straw, barley grain, canola meal, wheat bran, Mineral-vitamin mix, calcium carbonate and salt) formulated for 200 g/d weight gain using CNCPS-S. Animals fed experimental rations for a period of 60 d in 2 equal meals. Lambs were weighting after 2 week adaptation period and in weekly intervals after feed restriction. Blood samples withdrawn via heparinized vacuum venoject tubes through Jugular vein in last day of the experiment and analyzed for selected parameters via an autoanalyzer apparatus and commercial kits. Data were analyzed by GLM procedure of SAS 9.1 with CRD design and duncan test ($P \leq 0.05$). addition of 1.5 g/day/head of *Saccharomyces cerevisiae* caused significant increase in daily weight gain. Addition of different levels of *Saccharomyces cerevisiae* failed o induce a statistically significant difference in white and red blood cells, hemoglobin, hematocrit, mean cell volume, mean cell hemoglobin, platelet number, lymphocytes, lymphocytes and monocytes, but a tendency ($P \leq 0.1$) for reduction of white blood cells was determined and supplementation of 1 g/day/head was resulted in least value of white blood cells (70+6, 15.66 ± 2.13 and 32.66 ± 2.13, respectively for control, 1g/day/head and 1.5g/day/head group). These results indicated that supplementation of 1.5 g/day/head of yeast can be beneficial for maximizing live weight gain and improve health status.

Table 1. Characteristics of live weight gain in sheep fed *Saccharomyces cerevisiae*

Item	Group 1	Group 2	Group 3	SEM
Initial weight (kg)	35.36	35.55	36.71	3.15
Final weight (kg)	45.00	45.12	49.12	3.51
Average daily weight gain (g/day)	160.67^{b}	159.51^{b}	206.83^{a}	36.25

Means within a row that do not have a common superscript are different ($P < 0.05$), 1: control, 2: 1 g/day/head *Saccharomyces cerevisiae*, 3: 1.5 g/day/hd *Saccharomyces cerevisiae*.

M419 Relationship of blood enzymes and metabolites to residual feed intake of lambs. F. A. Rodriguez-Almeida*, C. Arzola, J. A. Grado-Ahuir, A. Corral, P. I. Ochoa, and G. Jasso-Diaz, *Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico.*

The aim of this study was to identify blood enzymes and metabolites (BEM) that do relate to residual feed intake (RFI) as predictor of feed efficiency. A total of 111 F_1 lambs (males and females) weaned at 90 d (BW = 17 ± 3.7 kg), sired by Charollais, Dorper, Hampshire, Suffolk and Texel rams bred to estrus synchronized-Pelibuey and Blackbelly ewes, were utilized. Lambs were fed an ad libitum mixed ration and weighed every 14 d until they reached a minimum BW of 42 kg (81 ± 18 d) for males and 40 kg (110 ± 24 d) for females. At the onset of the feeding trial, blood was collected and creatinine, blood urea nitrogen (BUN), cholesterol, triglycerides, albumin, globulins, glutamate-oxaloacetate transaminase (GOT), glutamate-pyruvate transaminase (GPT), albumin/globulin, GOT/aspartate aminotransferase (AST), GPT/Alanine transaminase (ALT), alkaline phosphatase (ALP), lactate dehydrogenase (LDH), gamma-glutamyl transpeptidase (GGT), creatinine phosphokinase (CPK), BUN/creatinine, and AST/ALT were determined in serum. Residuals of the regression of standardized ADFI on ADG, mid term BW and back fat at slaughter were regarded as RFI (R^2 = 0.55). Animals were classified into 3 categories according to RFI: efficient (first quartile; n = 29), medium (second and third quartile; n = 54), and inefficient (fourth quartile; n = 28). A stepwise analysis was carried out to identify BEM to discriminate animals into feed efficiency groups at the beginning of the feeding period. Entering variables were then analyzed with PROC GLM of SAS, fitting a linear model that included class effects of efficiency group, breed of sire, breed of dam, sex, number weaned (1 or more), 2 way interactions and initial body weight as a covariate. Variables in the discriminant function were ALP, GPT/ALT, CPK, and albumin (R^2 = 0.24). When fat was taken out of the regression equation to predict RFI, the variables in the discriminant function were ALP, AST/ALT and LDH (R^2 = 0.13). It may be concluded that most related variables to feed efficiency groups as defined by RFI were ALP, GPT/ALT, CPK, AST/ALT and LDH.

Table 1. Least squares means for variables affected by growth efficiency groups as defined by RFI: efficient (1st. quartile), medium (2nd. and 3rd. quartile), and inefficient (4th. quartile)

Group	n	ALP ($P < 0.05$)	GPT/ALT ($P < 0.05$)	CPK ($P < 0.05$)	AST/ALT ($P < 0.08$)	LDH ($P < 0.07$)
Efficient	29	170 ± 12^{b}	10 ± 0.8^{b}	200 ± 39^{b}	9.9 ± 0.7^{a}	800 ± 24^{b}
Medium	54	207 ± 9^{a}	13 ± 0.6^{a}	232 ± 29^{b}	8.8 ± 0.5^{ab}	858 ± 17^{a}
Inefficient	28	179 ± 12^{b}	13 ± 0.8^{a}	345 ± 39^{a}	7.7 ± 0.7^{b}	873 ± 23^{a}

M420 Nutritive value of *Vicia panonica* forage and its effect on ram Kurdish lamb performance. F. Fatahnia[1], M. Moeini[1], F. Moradi[1], R. Ebnabasi[1], and H. Mirzaei Alamouti*[2], *[1]Department of Animal Science, University of Ilam, Iran, [2]Department of Animal Science, University of Zanjan, Iran.*

This study was conducted to determine chemical composition of *Vicia panonica* forage and its effect on ram Kurdish lamb performance. Male lambs (n = 16; 29 ± 4.3 kg BW; 120 ± 5 d of age) were assigned randomly to one of 4 dietary treatments (7 lambs/dietary treatment). Experimental diets consisted of control diet (without *V. panonica* forage) and diets containing 15, 22.5 or 30% of *V. panonica* forage (DM basis). The experiment lasted for 100 d. Animals were housed in individual shaded pens and fed twice daily with diets (as total mixed ration). *V. panonica* forage used in this experiment had 94.04, 15.55, 1.2, 19.6, 9.5, 1.52 and 0.29% of DM, CP, ether extract, crude fiber, ash, calcium and phosphorus respectively. Data were analyzed using the MIXED procedure of SAS. Dry matter intake was not affected by experimental diets ($P > 0.05$). Average daily gain (ADG) was higher in lambs fed control or 15% *V. panonica* forage containing diets than others ($P < 0.05$). Feed conversion ratio (FCR) was higher ($P < 0.05$) for control and 15% *V. panonica* forage containing diets. Average final weight was similar among all treatment diets. These data indicate that feeding Kurdish lambs diets containing up to 15% *V. panonica* forage did not affect growth performance.

Key words: lambs, nutrition, *Vicia panonica*

M421 Daily supplementation of *Saccharomyces cerevisiae* (strain Sc 47) can cause reduction of blood cholesterol. N. Baleghi[1], A. Taghizadeh[2], A. FarahAvar[3], and H. Khalilvandi-Behroozyar*[3,4], *[1]Islamic Azad University, Maragheh Branch, [2]Department of Animal Science,University of Tabriz, [3]Department of Animal Science, University of Tehran, [4]Department of Animal Science, Urmia University.*

east (*Saccharomyces cerevisiae*) products may exert beneficial effects on ruminant productivity by either increasing fermentability of fiber and/or allowing rumen microbes to more effectively metabolize end products of ruminal starch fermentation. The objective was to evaluate the possible effects of live yeast on live weight gain and selected blood parameters of growing Mehraban lambs. Twelve male lambs (average BW 34+4.2 kg) randomly assigned to 3 groups: a) control, without additive b) 1 g/day/head and c) 1.5 g/day/ head *Saccharomyces cerevisiae* (strain Sc 47) cfu 8 × 102. Additives supplemented via gelatin capsules to TMR ration (alfalfa hay, wheat straw, barley grain, canola meal, wheat bran, Mineral-vitamin mix, calcium carbonate and salt) formulated for 200 g/d weight gain using CNCPS-S. Animals fed experimental rations for a period of 60 d in 2 equal meals. Lambs were weighting after 2 week adaptation period and in weekly intervals after feed restriction. Blood samples withdrawn via heparinized vacuum venoject tubes through Jugular vein in last day of the experiment and analyzed for selected parameters via an autoanalyzer apparatus and commercial kits. Data were analyzed by GLM procedure of SAS 9.1 with CRD design and Duncan test ($P \leq 0.05$). dietary treatments were failed to exert any statistically significant differences in blood urea, glucose, creatinine, albumin, total protein, TG, SGPT and alkaline phosphatase, but there was a trend ($P \leq 0.1$) for increase in blood alkaline phosphates levels. Daily supplementation of *Saccharomyces cerevisiae* was resulted in lower blood cholesterol levels (69.5 ± 4.06, 62.00 ± 4.06 and 51.75 ± 4.06, respectively for control, 1 and 1.5 g/day/head supplementation groups). Also, *Saccharomyces cerevisiae* increased aspartate aminotransferase levels from 102 ± 6.48 to

130 ± 6.48 IU/L in control and 1 g/day/ head supplementation groups, respectively.

Key words: *Saccharomyces cerevisiae*, cholesterol, Mehraban lambs

M422 Cull pinto bean as a supplement to pregnant-lactating hair ewes. F. Castillo*, G. Villalobos, D. Dominguez, J. E. Cruz, A. Anchondo, and J. A. Ortega, *Facultad de Zootecnia y Ecología. Universidad Autonoma de Chihuahua., Chihuahua, Chihuahua, México.*

Cull pinto bean (CPB; *Phaseolus vulgaris*) is a feeding option for sheep producers in northern Mexico. The objective was to evaluate the effect of 3 CPB levels (0, 25 and 50% of concentrate DM) on performance of ewes in late pregnancy (LP) and lactation (L). One-hundred 60 8 pelibuey ewes, 105 multiparous (M), and 63 primiparous (P), were randomly allotted to 1 of 24 pens (8 replications per treatment). Treatments were: 1) Control (C; 0% CPB) Low CPB (L; 25% CPB), and High CPB (H; 50% CPB). Supplements (LP: 0.45 kg; 2.8 Mcal/ Kg DM ME; 15.4% CP; L: 0.95 kg; 2.8 Mcal/Kg DM ME; 21.8% CP) and forage (ad libitum) were offered daily. Ewes were weighed 8 d before calving and each 14 d after it; dry matter intake (DMI) was measured daily; body condition score (BCS) was measured at the end of pregnancy and lactation. Lambs were weighed at birth and each 14 d until weaning. Data for pregnancy DMI (PDMI), lactation DMI (LDMI), pregnancy body weight (PBW), start of lactation body weight (SLBW), end of lactation body weight (ELBW), pregnancy BCS (PBCS) and lactation BCS (LBCS) was analyzed with PROC GLM in a completely randomized design; data for lamb average daily gain (LADG) was analyzed by PROC MIXED in a completely randomized design with repeated measures in the time. Models included treatment and kind of ewe as main effects and their interaction. Interaction effect was not found in any variable ($P > 0.05$). Data for PDMI (C: 1.7, L: 1.7, and H: 1.6 kg), LDMI (C: 2.4, L: 2.3, and H: 2.4 kg), PBW (C: 44, L: 42.7, and H: 42.8 kg), SLBW (C: 41.9, L: 39.6, and H: 40.2 kg), ELBW (C: 39.3, L: 39.2, and H: 38.8 kg), PBCS (C: 2.7, L: 2.6, and H: 2.7) and LBCS (C: 2.8, L: 2.8, and H: 2.8) was not different among treatments ($P > 0.05$). Differences among kind of ewe for PBW (M: 49.5; P: 36.8 kg), SLBW (M: 45.9; P: 35.2 kg), and ELBW (M: 45.1; P: 33.1 kg), were found ($P < 0.05$). No differences ($P > 0.05$) among treatments were found for LADG, lsmeans (kg) were (C: 0.21, L: 0.23, and H: 0.22). Due to the cost of CPB, and equal ewe performance to treatments, CPB use is a recommendable alternative in hair ewe feeding for these productive stages.

Key words: Cull pinto bean, hair ewes, pregnancy-lactation

M423 Effect of different sources of lipid on blood parameters of sheep. E. H. C. B. van Cleef*, D. A. V. Silva, A. C. Homem Júnior, and J. M. B. Ezequiel, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Twenty crossbred sheep (19.5 ± 2.9 kg BW) were used to evaluate the effect of different lipid sources on hemogram and serum concentrations of AST, GGT, triglycerides, cholesterol, glucose and urea. The animals were confined for 80 d, in individual pens and received 5 experimental diets containing sunflower grain (SG), peanuts grain (PG), peanut oil (PO) or protected fat (PF) and a control diet without added lipid (CON), formulated in roughage: concentrate ratio of 40: 60, with corn silage as roughage and concentrate composed of corn, soybean meal, citrus pulp and mineral supplement. The blood samples were taken when the animals reached 37 kg BW, 3 h before and after feeding by jugular vein puncture. The statistical design was a completely randomized and the contrasts among treatments and control × lipid sources were analyzed. The lipid sources did not alter ($P > 0.05$) the serum concentrations of GGT triglycerides and urea, comparing to the control diet. Although some contrasts show significant differences ($P < 0.05$) in blood parameters studied, the results are within normal ranges as suggested by the literature. However, it is emphasized that the animals that received PO diet showed increases ($P < 0.05$) in cholesterol value and decrease in erythrocyte and hemoglobin, comparing to grain diets studied (PG and SG), which may indicate damage to animal health and consequent production decrease. The protected fat caused decrease ($P < 0.05$) in erythrocyte count and hemoglobin concentration. All the parameters analyzed showed minimum variations in serum concentrations when compared with normal indicated by the literature. The increase serum levels of AST and cholesterol in pure oil diets ($P < 0.05$) can indicate possible liver alterations. It was concluded that the inclusion of lipids from oil seeds is better for animal health than oil, and that the control diet conducted to more favorable results of serum AST and cholesterol.

Key words: blood, feedlot, ruminant

M424 Use of ionophores in Santa Inês lambs diet for meat production. P. M. França[1], J. R. O. Pérez[1], V. A. A. Reis[1], I. F. Furuscho-Garcia*[1], R. F. Leite[2], F. Oliveira[3], S. P. Greca[1], and I. Leopoldino Junior[1], *[1]Universidade Federal de Lavras, Lavras, Minas Gerais, Brasil, [2]Universidade Paulista Júlio de Mesquita Filho, Jaboticabal, São Paulo, Brasil, [3]Universidade Paulista Júlio de Mesquita Filho, Botucatu, São Paulo, Brasil.*

The experiment was carried out at the Sheep Production Sector of Federal University of Lavras (UFLA), Brazil, to evaluate the effect of adding ionophores (monensin and lasalocid) in the diet on performance, digestibility, carcass and meat quality characteristics in lambs on feedlot. Eighteen lambs were used in a Completely Randomized Design and the animals were allotted to 3 treatments (control diet, diet plus monensin, diet plus lasalocid), with 6 replicates per treatment. The ionophore dose was based on the rumen content using the equation: y = −0.0014 x2 + 0.2034 × −0.8376, that is obtained through a compilation of data on rumen content (kg) relative to body weight (kg) from several experiments conducted in the Department of Sheep Production, (UFLA). A reference dose of 14.85 mg per kg of rumen contents was given. The lambs were slaughtered at 45 kg live weight. Data were analyzed using GLM procedure of SAS and the means compared using the *t*-test. The use of ionophores, monensin and lasalocid increased the average daily weight gain of lambs, but did not affect consumption. In the digestibility trial, the intake and the dry matter, crude protein, neutral detergent fiber and acid detergent fiber digestibility were not influenced by additives. Initial and final pH, color, tenderness, cooking loss, and chemical composition of meat were not affected by ionophores. The concentration of the fatty acid C18:2 C9T11 (CLA) in Longissimus lumborum muscle increased with the use of monensin and lasalocid, which may be a promising tool to further improve the nutritional value of meat and an important strategy to promote this product. In conclusion, the use of ionophores in the diet of confinement lambs can produce favorable results if used properly.

Key words: carcass, meat quality, sheep

M425 Evaluation of behavior and apparent dry matter intake of sheep in tropical pasture. F. P. Portilho*[1,2], J. M. S. Diogo[1], and S.

L. S. Cabral Filho[1], [1]*University of Brasilia, Brasilia, DF, Brazil,* [2]*Agrodefesa, Rio Verde, GO, Brazil.*

The aim of this study was to evaluate the ingestive behavior (size of bite, bite rate and grazing time) and apparent dry matter intake in sheep grazing *Cynodon dactylon* 'Coastcross' and *Panicum maximum* 'Aruana'. For the evaluation of feeding behavior, adult male, crossbred Santa Inês (n = 3; 42 kg) were used (one animal per plot). Data were collected on the DM content (%), canopy height (cm), the availability of dry matter (kg DM / ha), the percentage of leaves (%), the percentage of stem (%) and the percentage of dead material (%), leaf: stem and leaf, dead material. The data were analyzed using the T TEST procedure in SAS, and correlations were generated through excel. The plots of Aruana (2,113 and 2,121 kg DM / ha) and Coastcross (1,545 and 2,619 kg DM / ha; February and June cuts, respectively) did not differ ($P > 0.05$). In February there were no differences ($P > 0.05$) among the grasses or the average percentage of leaf, stem and dead material. However, there were differences ($P < 0.05$) in average canopy height and average content of dry matter. The canopy height was higher ($P < 0.05$) in Aruana compared with Coastcross, 68cm and 35cm, respectively. The DM content was higher in Coastcross (42%) compared with Aruana (36%). In June there were no differences ($P > 0.05$) among the forages in average canopy height, average content of dry matter and mean percentage of dead material. In this period differences in mean percentage of leaves and average percentage of stems were observed ($P < 0.05$). On the other hand, no significant difference was observed related to the intake behavior of sheep in both forages, in those evaluation periods. The plots of both forages did not differ ($P > 0.05$) in the size of bite between the evaluation periods. The correlation between apparent consumption and bite size of the Aruana (0.92) and Coastcross (0.86) were positive. The *Panicum maximum* and *Cynodon dactylon* were similar regarding the pattern of intake behavior and apparent consumption of sheep, regardless of the evaluation period. The dry matter content influenced positively the grazing time and bite rate of sheep, in both forages.

Key words: forage, sheep, Santa Inês

M426 Palatability of sainfoin (*Onobrychis viciifolia* Scop.) in sheep. H. Khalilvandi-Behroozyar*[1,2], M. Dehghan-Banadaky[1], and K. Rezayazdi[1], [1]*Department of Animal Science, University of Tehran, Karaj, Tehran, Iran,* [2]*Department of Animal Science, University of Urmia, Urmia, West Azerbaijan, Iran.*

Sainfoin is a tanniferous legume forage. Reports about sainfoin CT contents and effects are very variable. Along with possible beneficial effects of tannins, adverse effects on palatability could be demonstrated. An experiment was carried out to evaluate palatability of sainfoin hay compared with control forage (alfalfa), using 6 nonlactating Zandi ewes (45 ± 5 kg BW). Diets were formulated to meet 110% of maintenance energy requirements, using CNCPS-S software and fed 2 equal meals per day at 0800 and 2000 h. Sainfoin and alfalfa provided exactly half of ME. The experiment started with the morning feeding on the first day and finished after the morning feeding on the tenth day. First 3 d were considered as preliminary period. The allocation of the 2 forages was switched between troughs for evening meals, to avoid association of place, forage type, and time of day by the animals. To evaluate the palatability of the sainfoin in comparison with alfalfa, intakes of 2 diets were measured by weighing the boxes at a fixed time (t). Based on preliminary tests, t was set to 10 min after feeding, that was approximately equivalent to the time needed to consume about half of the total feed. Palatability index (PI) was calculated according to Ben Salem et al. (1994) as amount of test forage consumed compared with control forage following the equation: PI (t) = [ITT (t)/ICtr (t)].100, where ITT (t) equals intake of sainfoin after time t per total intake after half a day, and ICtr (t) equals intake of control (alfalfa) eaten after time t per total intake after half a day. Total phenolic, total tannin and condensed tannin contents of sainfoin were 39.4, 38.5 and 21.3 g/ kg of DM, respectively. Palatability index of sainfoin compared with alfalfa, was 274%. Sainfoin CT was reported to have a different monomeric constitution and a higher degree of polymerization than others, that can be responsible for this result. It can be concluded that the chemical properties of CT may be important than the CT content in determining palatability.

Key words: sainfoin, palatability, sheep

M427 Effect of feeding tannin-containing pine bark on fecal bacterial population and methane gas production in Kiko-cross goats. B. R. Min*, S. Solaiman, R. Shange, and R. Ankumah, *Tuskegee University, Tuskegee, AL.*

Eighteen Kiko-cross meat goats (33.4 ± 0.98 kg; n = 6) were used to determine DM intake, fecal DM output, fecal bacterial and in vitro methane gas production. Animals were fed condensed tannins (CT)-containing pine bark (PB) for 83 d and total fecal was collected for 7 d with 2 periods. Experimental treatments included: the control diet – 0% PB and 30% wheat straw (WS; 0.17% CT DM); 15% PB and 15% WS (1.6% CT DM) and 30% PB and 0% WS (3.2% CT DM) as fed. Freshly dried PB and WS were finely (1.5–3 mm) ground and incorporated in the grain mix to provide 0, 16, and 32 g CT/kg DM in 0, 15, and 30% PB diets, respectively. Fecal bacterial populations were measured using a 16S-based pyrosequencing technique to characterize and elucidate changes in bacterial diversity among the diets. Fecal samples collected from each goat were pulled for each treatment for sequencing analysis. In vitro methane gas production was measured as plunger displacement (mL) at 0 to 24 h incubation periods with fecal inoculants that were obtained from experimental animals. Total methane gas production was estimated from total fecal DM output and in vitro methane gas production per unit of fecal material. Fecal DM output was linearly increased ($P < 0.04$) with PB supplementation (375, 386, and 460 g DM/animal for 0, 15 and 30% PB diets respectively), but estimated methane gas (291, 158, and 51 mL/goat per d; $P < 0.01$) and in vitro methane (0.77, 0.42, and 0.11 mL/g of feces) gas production decreased (linear; $P < 0.001$) as the level of PB increased in the diet. Predominant fecal genera were Flavobacteriaceae (up to 18%), Oscillibacter (up to 15%), and Oscillibacter spp. (up to 17%) of microbial population in 0, 15 and 30% PB diets, respectively. The proportion of Flavobacteriaceae (25, 4.5, and 3%), Acinetobacter (4.6, 3.1, 4.1%), Acinetobacter-baumannii (4.9, 3.0, and 5.8%), Moraxellaceae (4.4, 1.1, 1.2%), and *E. coli* (6.3, 2.1, and 2.1%) population decreased as the level of PB supplement increased in the diet. These results indicated that feeding PB reduced methane gas and *E. coli* population and modified fecal bacterial population.

Key words: fecal bacteria, methane gas, pine bark

Animal Behavior and Well-Being Symposium: Novel Techniques for Euthanasia

8 Euthanasia—An overview of the AVMA's criteria and recommendations. G. C. Golab*, *American Veterinary Medical Association, Schaumburg, IL.*

Since 1963 the AVMA has convened a Panel on Euthanasia to evaluate methods and potential methods of euthanasia for the purpose of creating guidelines for veterinarians who carry out or oversee the euthanasia of animals. More than 70 individuals, including veterinarians and non-veterinarians with expertise across a range of disciplines and species, were engaged to research and create the 2011 update to the Panel′s report (its eighth edition) titled the *AVMA Guidelines on Euthanasia*. Euthanasia techniques should result in rapid loss of consciousness followed by cardiac or respiratory arrest and the ultimate loss of brain function. In evaluating methods of euthanasia, the Panel used the following criteria: (1) ability to induce loss of consciousness and death with a minimum of pain distress, anxiety or apprehension; (2) time required to induce loss of consciousness; (3) reliability; (4) safety of personnel; (5) irreversibility; (6) compatibility with requirement and purpose; (7) emotional effect on observers or operators; (8) compatibility with subsequent evaluation, examination, or use of tissue; (9) drug availability and human abuse potential; (10) compatibility with species, age, and health status; (11) ability to maintain equipment in proper working order; (12) safety for predators/scavengers should the carcass be consumed; (13) legal requirements; and (14) environmental impacts of methods or carcass disposition. The various sections of the Guidelines address particular euthanasia techniques (e.g., inhalant agents, non-inhalant pharmaceutical agents, and physical methods) and the application of those techniques to various animal types, species, and uses (e.g., companion animals, food animals, laboratory animals, wildlife, aquatics). This edition of the Guidelines has been expanded and includes more detail about the techniques, covers more species, and more comprehensively considers the special needs and challenges posed by the range of environments and conditions under which euthanasia is conducted. This presentation will summarize the creation and content of the 2011 version of the *AVMA Guidelines on Euthanasia*.

Key words: euthanasia, *AVMA Guidelines on Euthanasia*

9 Euthanasia of livestock: Public perception and influence. S. R. Niekamp*, *National Pork Board, Clive, IA.*

While livestock producers strive to maintain good health of all animals in their care, it is inevitable that an animal will become ill or injured. Euthanasia may be the best option for the animal′s well-being in situations where ill or injured animals cannot be successfully treated. As the US population has become more urbanized, the contemporary consumer has become less familiar with the practices associated with raising livestock. There is currently a trend in the marketplace for certain consumer demographics to proactively learn more about the source of their food and how it was produced. Additionally, consumers have unlimited access to internet resources that depict livestock production practices. These resources often depict the production practice being performed incorrectly which raises more questions than they answer. While surveys indicate that customers do not hold retailers responsible for how animals are raised, consumers often look to their preferred food retailer for assurances and answers to their questions about how animals are treated on the farm. In effort to provide these assurances, retail and foodservice customers turn to their suppliers for answers regarding on-farm practices. The euthanasia process has increasingly become a topic of interest for customers and consumers. Specifically, their questions focus on the timely application of euthanasia, the effectiveness and the aesthetics of the method used, and the attitude of the caretaker euthanizing the animal. Scientific validation of current methods of euthanasia, identifying and validating new and novel methods that account for aesthetics are 2 key aspects needed to effectively answer customer and consumer questions. Caretaker training is another key aspect as caretakers must know when it is appropriate to euthanize an animal that is ill or injured and how to properly apply the method so to minimize pain and suffering. The ability of livestock producers to effectively answer questions about euthanasia and other on-farm practices will help to build consumer trust in today′s food system.

Key words: euthanasia, consumer, perception

10 The signs of unconsciousness and death: How can we recognize them on the farm? T. M. Widowski*[1], T. M. Casey-Trott[1], and M. A. Erasmus[2], *[1]Campbell Centre for the Study of Animal Welfare, University of Guelph, Guelph, Ontario, Canada, [2]Michigan State University, Lansing.*

All methods for euthanasia should begin with rapid loss of consciousness followed by full loss of brain function, respiratory failure and cardiac arrest. To ensure that death occurs without pain or distress, animals must be monitored for signs of unconsciousness until cardiac arrest is confirmed. The brainstem and cortex are primary brain regions associated with consciousness and arousal; therefore brainstem and nociceptive reflexes, similar to those used to determine effective stunning at slaughter or depth of anesthesia during surgery, are practical measures for determining loss of consciousness on the farm. Brainstem reflexes include corneal, palpebral, and pupilary light reflexes and the nictitating membrane reflex in birds. Unconscious animals do not blink in response to touching the eyelid or cornea and their pupils remain fixed and dilated when exposed to light. However, ocular reflexes are not always reliable indicators of anesthesia (pigs), and corneal reflexes can be observed during unconsciousness even after damage to the cerebral cortex if the brain stem remains intact (e.g., head only electrical stunning). Therefore, using a combination of measures including nociceptive reflexes, such as the pedal and anal reflexes (withdrawal response to a sharp pinch or prick) is most useful. If the animal is not paralyzed and is able to show a motor response, absence of withdrawal responses to painful stimuli indicates that the animal no longer perceives pain. In addition to the sensory reflexes, several types of behavioral observations can be used for assessing effectiveness of euthanasia. These include absence of rhythmic breathing and absence of vocalizations. Collapse and loss of muscle tone occurs with the onset of unconsciousness and a limp jaw or tongue is a reliable indicator of insensibility in pigs and cattle. Clonic muscle spasms (seizures), characterized by kicking, wing flapping or paddling, and tonic muscle spasms, characterized by rigid extension of the limbs, are associated with some euthanasia techniques. These neuromuscular spasms are involuntary, and should not be confused with deliberate movements or escape attempts.

Key words: euthanasia, unconsciousness, reflexes

11 Novel euthanasia technologies for the pig. S. T. Millman*, *Veterinary Diagnostic & Production Animal Medicine, Iowa State University, Ames.*

In a systematic review of the scientific literature, there are relatively few studies providing empirical data about on-farm swine euthanasia. Recently, specific calls for research proposals have been issued for swine euthanasia, and several novel technologies are emerging. Furthermore, researchers are refining techniques to measure the aversiveness and efficacy of euthanasia methods. Mechanical methods of euthanasia, including penetrating and non-penetrating captive bolt technologies, are based on disruption of brain function resulting from impact of a solid object with the skull. Postmortem examinations indicate that head injuries are likely to be fatal when there is hemorrhage within the brain stem. The AVMA Guidelines for Euthanasia (2007) states "non-penetrating captive bolt must not be used as a sole method of euthanasia," but recent research results indicate new devices are capable of inducing death without risk of return to consciousness for some weight classes of pig. In the OIE Terrestrial Code, it is recommended that penetrating captive bolt be followed by pithing or bleeding when used for swine, but a new generation of captive bolt device has been shown to be an effective single step euthanasia method for all but the largest weight class of pig. Euthanasia using gases such as carbon dioxide and argon have been developed for the suckling and market weight pig, and present some advantages over mechanical methods. Novel gas delivery systems for on-farm use may provide opportunities to refine flow rates and gas mixtures for more humane induction of insensibility. Novel electrical methods have been explored for suckling pigs and breeding stock. Since all euthanasia techniques have trade offs, there is no Gold Standard for on-farm swine euthanasia and considerations for animal welfare, worker health, carcass disposal and public health must be weighed in each situation. Further research is needed to address challenges associated with swine euthanasia including reliable techniques for the mature sow and boar, methods of restraint, tools for decision making about humane endpoints, safeguards for safety and psychosocial effects imposed on those performing this task.

Key words: animal welfare, euthanasia, swine

12 Euthanasia techniques for dairy and beef cattle. J. K. Shearer*[1], J. P. Reynolds[2], D. D. Griffin[3], and G. Johnson[4], *[1]Iowa State University, Ames, [2]Western Veterinary College, Pomona, CA, [3]University of Nebraska, Lincoln, [4]Reedsburg, Wisconsin.*

The physical methods for conducting euthanasia in cattle include gunshot and captive bolt. Euthanasia may also be accomplished by the parenteral administration of an anesthetic in an amount capable of causing death. This latter method requires a veterinarian to administer the drug and creates residue problems that limit carcass disposal options. There are few methods as humane as gunshot or penetrating captive bolt combined with a secondary step to ensure death such as exsanguination, the rapid intravenous injection of a saturated solution of potassium chloride or possibly pithing of the brain and upper spinal cord. When properly performed, both gunshot and captive bolt meet the objectives of inducing immediate loss of consciousness and rapid death without pain or distress to the animal. In most circumstances on the farm or ranch, gunshot is the most practical method of euthanasia. A 0.22 long rifle solid point bullet fired from either a pistol or rifle is sufficient for young animals. Higher caliber firearms are required for consistent results with adult animals. Proper placement of the bullet is essential and best achieved by holding the firearm within 12 to 24 inches of the intended target. Firearms should never be held flush with the skull. On the other hand, when penetrating captive bolt is used, the device must be held flush over the intended anatomical site. The preferred anatomical site is on the intersection of 2 lines each drawn from the rear corner of the eye to the base of the opposite horn.

Key words: euthanasia, euthanasia techniques, cattle euthanasia

13 Weaning management of newly received beef calves with or without continuous exposure to a persistently infected bovine viral diarrhea virus pen mate: Effects on rectal temperature, peripheral blood leukocytes and serum proinflammatory cytokine concentrations. J. T. Richeson*[1], E. B. Kegley[1], J. G. Powell[1], R. G. Schaut[2], R. E. Sacco[3], and J. F. Ridpath[3], *[1]University of Arkansas, Fayetteville, [2]Iowa State University, Ames, [3]USDA-ARS, National Animal Disease Center, Ames, IA.*

Exposure to animals persistently infected (PI) with bovine viral diarrhea virus (BVDV) results in immunomodulation in cohorts. It is hypothesized that the extent of modulation differs for preconditioned (PC) vs. auction market (AM) cattle. Our objective was to compare immune responses of PC or AM calves in presence (PI) or absence (CON) of a PI-BVDV pen mate using a 2 × 2 factorial arrangement. Crossbred PC steers (n = 27) from a single ranch-origin were selected randomly, weaned, dewormed, vaccinated, tested for PI-BVDV, and kept on the ranch for 61 d. Subsequently, PC steers were transported to a stocker receiving unit (RU), weighed (282 ± 1.6 kg), stratified by d −1 BW, and assigned randomly to treatment (PCPI or PCCON) with no additional processing. Simultaneously, crossbred AM calves (n = 27) were assembled from regional auction markets and delivered to the RU 24 h before PC arrival. The AM calves were weighed (268 ± 2.3 kg), stratified by gender and d −1 BW, processed under the same regimen used for PC steers at their origin ranch except bull calves were castrated, then assigned randomly to treatment (AMPI or AMCON). Treatment pens (50 m × 15 m) were arranged spatially so that PI did not have fence-line contact with CON. For cytokine and hemagram analyses, serum or whole blood was analyzed from d 0, 1, 3, 5 (hemagram only), 7, and 14. In AM calves, RT increased ($P < 0.001$) sharply on d 1. Exposure to PI cohort decreased ($P = 0.01$) the percentage of neutrophils, and increased ($P = 0.02$) percentage lymphocytes resulting in a tendency ($P = 0.07$) for a decreased neutrophil:lymphocyte ratio. Serum concentrations of TNF-α tended to increase ($P = 0.09$) for PI cohort. Interferon-γ concentrations on d 7 and 14, IL-6 concentrations on d 14, and platelets on d 7 were greatest for AMPI ($P \leq 0.05$). Results indicate weaning management and PI exposure alter the immune status of newly received calves. These effects may be additive because alterations were greatest for AMPI.

Key words: bovine viral diarrhea virus, cytokine

14 Effect of oral meloxicam on performance and health of stocker calves after castration. J. F. Coetzee*[1], L. N. Edwards[1], R. A. Mosher[1], A. M. O'Connor[2], B. Wang[2], B. KuKanich[1], and D. A. Blasi[1], *[1]Kansas State University, Department of Animal Science and Industry, Manhattan, [2]Iowa State University, Ames.*

Castration of weaned calves affects profitability by reducing ADG and increasing susceptibility to disease. This study investigated the effect of meloxicam on performance and health of stocker calves after surgical castration. British × Continental calves (n = 258; BW = 193 – 285 kg) were transported for 12 h in 3 truckloads (d −1), weighed and randomly treated with either lactose placebo (CONT; 1 mg/kg) or meloxicam (MEL; 1 mg/kg). Doses were suspended in water and administered per os 24 h before castration. On d 0, bulls were surgically castrated (CAST) and steers were submitted to simulated castration (SHAM). Plasma meloxicam concentrations at the time of castration (d 0) were determined by LC-MS. DMI and ADG determined using BW obtained on d 14 and d 28 were analyzed using PROC GLIMMIX in SAS. Animals were classified as sick based on a depression score of ≥2 on a 5-point scale and a rectal temperature of ≥39.78°C. Relative risk of disease was calculated using PROC NLMIXED in SAS and cumulative pull rate, crude morbidity and BRD morbidity were compared using Kaplan-Meier survival analysis and log-rank tests. On d 0, 1 and 14, calf temperament in the squeeze chute was evaluated using a 4-point scale. Plasma meloxicam concentrations at the time of castration were not significantly different ($P = 0.87$). Castration was found to reduce ADG and DMI over the first 14 d after surgery ($P < 0.001$) but meloxicam administration did not significantly improve performance parameters compared with placebo-treated control calves ($P = 0.48$). Meloxicam treatment significantly reduced the first pull rate in castrated calves ($P = 0.04$) and tended to reduce the BRD morbidity rate ($P = 0.14$). Also, more CONT-CAST calves were pulled ($P = 0.016$) and treated for BRD ($P = 0.023$) over time than MEL-CAST calves. There were a greater percentage of CAST calves with a temperament score ≥2 as compared with SHAM calves. These findings suggest that meloxicam administration before castration in post-weaning calves may reduce the number of animals identified as requiring treatment by feedlot personnel and may extend the time to first treatment for BRD.

Key words: castration, NSAID, performance

15 Characterization and antibiotic susceptibility of *Mycoplasma* isolates from mastitic buffaloes. I. Hussain*[1], S. ur Rahman[2], F. A. Atif[1], and M. Arif[1], *[1]University College of Agriculture, University of Sargodha., Sargodha, Punjab, Pakistan, [2]University of Agriculture Faisalabad, Faisalabad, Punjab, Pakistan.*

The objective of the study was isolation and identification of *Mycoplasma* isolates from mastitic buffaloes and to evaluate the antibiotic resistance of *Mycoplasma bovis* in Faisalabad, Pakistan. A total of 235 buffalo milk samples were collected from 4 private small holder dairy farms located around Faisalabad district of Pakistan. Clinical samples were identified through visual changes and sub-clinical samples with surf field mastitis test. The overall occurrence of mastitis was 40.42% (95/235). The incidence of clinical and sub clinical mastitis was 24.21% (23/95) and 75.78% (72/95) respectively. Mastitic samples were subjected to various passages for the purification of *Mycoplasma* species. *Mycoplasma* species were identified based on colony characteristics and biochemical tests. A total of 19 isolates belonged to 2 species i.e., *Mycoplasma bovis* (18) and *Mycoplasma dispar* (1) were isolated. *Mycoplasma bovis* and *M. dispar* were prevalent in 8.33 and 1.67 % respectively. Highest antibiotic resistance was observed for Tylosin (MIC50 = 8µg/ml) followed by Tetracycline (MIC50 = 7µg/ml), Spiromicin (MIC50 = 4µg/ml) and Gentamicin (MIC50 = 3µg/ml). The results of the study suggested that there should be testing for *Mycoplasma* in routine bacterial examination, while considering other causes of mastitis.

Key words: mastitis, *Mycoplasma*, antibiotic

16 Development of detecting kit for bovine myeloperoxidase using enzyme-linked immunosorbent assay. J. Shi, Q.-Z. Li*, Y. Yang, Y. Lv, and X.-J. Gao, *Key Laboratory of Dairy Science of Ministry of Education, Northeast Agricultural University, P.R. China.*

Myeloperoxidase (MPO) is a heme glucoprotein found in the primary granules of mammalian neutrophils. At the site of infection, MPO is

released extracellularly or into phagocytic vacuoles. It has shown that MPO is abundant in milk taken from mammary glands of cows with mastitis and that the amount of MPO in milk is well correlated with the somatic cell count in mastitis milk. To evaluate the potential of using MPO in the diagnosis of mastitis in cows, this study developed a specific enzyme immunoassay for MPO in milk. Bovine MPO was isolated and purified from bovine whole blood by Sephadex G-200 chromatography and ConA-Sephrose 4B affinity chromatography. Antiserum against bovine MPO were produced using the purified MPO with conA as a coated "antibody," and mouse anti-bovine antiserum against MPO as a second detection antibody, and chicken HRP-labeled polyclonal antibody as a anti-antibody, a special sandwich ELISA for MPO was established. ELISA kit was developed. Evaluating kit by methodology showed good specificity, reproducibility (variant coefficient: 1.09% ~7.2% in batch and 1.47% ~6.7% between batches), and the detection limit was 1.1ug/mL. The experiment certified that this kit could maintain over one year and the detection time of the kit was about 3.5h.

Key words: bovine myeloperoxidase, purification, ELISA kit

17 The identification of candidate genes and candidate gene structural variation for bovine spongiform encephalopathy. J. Thomson*, V. Bowles, J. Choi, P. Stothard, and S. Moore, *University of Alberta, Edmonton, AB, Canada.*

Previous work in our lab identified several regions throughout the bovine genome associated with classical BSE in European cattle. There are a total of 64 regions found to be associated with BSE incidence ($P < 0.05$). All of the genes under those regions were analyzed using gene ontology information as well as current literature findings and 100 candidate genes were identified. Data from 10 mRNA sequence libraries and 2 whole genome sequences, created using the SOLiD next generation sequencing system from Applied Biosystems, was interrogated to identify structural variation in these candidate genes. mRNA seq libraries including liver, adipose, hypothalamus, muscle, duodenum, kidney, lung, peyers patch, cortex, and blood were used for single nucleotide polymorphism identification. Whole genome re-sequencing was performed on both a Holstein and a Black Angus bull. Utilizing both the mRNA-sequence libraries and the whole genome re-sequencing, structural variation was found in 98 of the 100 candidate genes identified as positional candidates for BSE susceptibility. This structural variation included 107 non-synonymous mutations, 18 synonymous mutations, 111 intronic mutations, and 19 3′and 5′ UTR region mutations. The identified polymorphisms will be tested in a family based data set of 302 BSE affected and 179 unaffected half-sib Holsteins from 6 sire families. The results of this research will give indicators of the gene pathways underlying BSE disease progression and enhance our understanding of the disease in its host species.

Key words: BSE, single nucleotide polymorphisms, animal health

18 Genomic regions associated with incidence of disease in cattle using DNA pooling and a high-density single nucleotide polymorphism array. E. Casas*, L. A. Kuehn, T. G. McDaneld, T. P. L. Smith, and J. W. Keele, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Genomic regions associated with general disease (respiratory disease, foot rot, and pinkeye) in beef cattle were identified using treatment records on 2,849 animals. General disease cases included animals treated for bovine respiratory disease, foot rot, or pinkeye. Untreated cohorts, matched on breed composition and contemporary group, for cases were included as controls. Fifteen pools of DNA with 102 cases/pool and 13 pools with an average of 101 controls/pool were genotyped using 777,000 single nucleotide polymorphisms (SNP). Mixed model methods were used to estimate differences in allele frequency between cases and controls while accounting for technical variation (specific to SNP array platform), binomial sampling and pool construction error. Hidden population structure unaccounted by the matching procedure was considered statistically using eigenvectors of the correlation among pools across all SNP. Single nucleotide polymorphisms residing on chromosomes 3, 6, 7, 20, 23, and X were highly significant (nominal $P < 0.00001$). Three of these SNPs reside on chromosome 3 between 25 megabase (Mb) and 26 Mb. Fourteen additional SNPs were also significant ($P < 0.001$) in this chromosomal region. On chromosome 6, one highly significant SNP ($P < 0.00001$) is located between 63 and 64 Mb. In this genomic region, 10 additional SNPs were also significant ($P < 0.001$). Two SNPs were highly significant ($P < 0.00001$) on chromosome 7. One resides on Mb 56, while the other resides on the telomeric end of the chromosome. One SNP was highly significant ($P < 0.00001$) on chromosome 20 (on 55 Mb), and one on chromosome 23 (on 20 Mb). Three SNPs on chromosome X were highly significant ($P < 0.00001$). These SNPs reside at 12, 21, and 94 Mb. Results from this study, combined with future studies in a meta-analysis, should provide strong evidence for these genomic regions as harboring genes associated with defense mechanisms against pathogens.

Key words: cattle, diseases, DNA pooling

19 In vitro and in vivo anthelmintic activity of *Amomum subulatum* Roxb. seeds. Z. Iqbal*, N. Badar, M. Khan, and Z. Sindhu, *Department of Parasitology, University of Agriculture, Faisalabad, Punjab-Pakistan.*

This study was carried out to validate the anthelmintic activity of *Amomum subulatum* seeds used in traditional veterinary medicine in Pakistan. Crude aqueous methanol extract (CAME) and its different solvent fractions were tested in vitro employing adult motility assay and egg hatch tests using mature *Haemonchus contortus* and its eggs, respectively. In vivo, CAME and crude powder (CP) were tested employing fecal egg count reduction test in sheep naturally parasitized with gastrointestinal nematodes. In adult motility assays, 73.3% mature H. contortus exposed to CAME @ 50 mg/ml were found dead compared with no mortality in the worms kept in PBS by 10 h post-exposure. There was 100% mortality of worms exposed to the standard drug (levamisole) @ 0.5 mg/ml. Ethyle acetate fraction of CAME was the most effective resulting in 100% mortality of worms @ 50 mg/ml followed by chloroform (76.7%), aqueous (50%) and petroleum spirit (46.7%) fractions. In egg hatch test, CAME was found an effective ovicidal with LC_{50} 13.1872 µg/ml. Chloroform and ethyle acetate fractions had comparable LC_{50} values (18.1413 and 18.6102 µg/ml, respectively) which followed in increasing order by aqueous (20.4178 µg/ml) and petroleum spirit (253.9106 µg/ml) fractions. The LC_{50} values of plant extracts were, however, far greater than that of standard drug, albendazole (0.0345 µg/ml). The maximum reduction (74.45%) in eggs per gram of feces (EPG) was recorded in sheep treated with CAME @ 3 g/kg body weight on d 12 post-treatment (PT). CP was less effective as maximum reduction in EPG was recorded as 57.45% @ 3 g/kg body weight on d 12 PT. There was 100% reduction in EPG by d 8 PT in sheep treated with standard drug, levamisole. Therefore, use of *A. subulatum* seeds in traditional veterinary medicine as an anthel-

mintic is valid. Large-scale control studies, however, are suggested to identify the active principles in the plant material tested in this study.

Key words: *Amomum subulatum*, anthelmintic, sheep

20 Lentisk (*Pistacia lentiscus* L.) browse prevents gastro-intestinal nematode infection in goats. S. Y. Landau*[1], A. H. Azaizeh[2], H. Muklada[1], T. A. Glasser[3], E. D. Ungar[1], and A. Marcovics[4], *[1]Agricultural Research Organization, the Volcani Center, Department of Agronomy and Natural Resources, Bet Dagan, Israel, [2]Institute of Applied Research, The Galilee Society (Affiliated with University of Haifa), Shefa-Amr, Israel, [3]The Ramat Hanadiv Nature Park, Zikhron Ya'akov, Israel, [4]Department of Parasitology, Kimron Veterinary Institute, Bet Dagan, Israel.*

Gastro-enteritis caused by infection with gastro-intestinal nematodes (GIN) is widespread among goats in the Middle-East. It is characterized by extreme emaciation, diarrhea, and mortality. In a 2-year survey, we observed that the Damascus and Mamber breeds of goats that graze on brushland rich in lentisk (*Pistacia lentiscus* L.) had very low fecal egg counts (FEC). Lentisk contains 20% polyethylene glycol (PEG, MW 4,000)-binding tannins on a dry matter basis. We tested possible mechanisms of protection against GIN. In a series of in vitro experiments, we showed that ethanol 70% and, to a less extent, water and ethanol 100% extracts of lentisk prevent exsheathment of L3 larvae, thus impairing nematode maturation to the egg-producing adult stage. In addition, we showed that feeding lentisk foliage to young goats infected with mixed GIN species resulted in a drastic decrease in FEC (241 vs. 1293, $P < 0.001$; n = 14). When goats were administered daily 20 g of PEG (which binds to and thereby neutralizes the tannins), the effect of lentisk on FEC was approximately halved to 705 epg. This suggests that tannins are not the only anthelmintic moiety in lentisk. The daily intake of tannins needed to eliminate fecal egg excretion was 1 g·kg BW^{-1} d^{-1}. After lentisk feeding was stopped, FEC returned to the control level, implying that the effect of lentisk on GIN was suppressive but not lethal. Our data suggest that daily ingestion of lentisk—5 to 15% of DM ingested—prevents egg formation and possibly larval maturation all year-round, resulting in effective control of GIN populations. This seems to be a passive mechanism, and not an active mechanism of adaptive feeding behavior to a worm challenge.

22 Occurrence of paratuberculosis in the hilly regions of Himachal Pradesh, India. J. S. Sohal*, S. V. Singh, P. K. Singh, and A. V. Singh, *Central Institute for Research on Goats, Mathura, UP, India.*

In India paratuberculosis has been studied widely in the plain regions, however, to our knowledge there have been no reports from hilly regions. Present study was attempted to study the occurrence of paratuberculosis in hilly regions of northern parts of country. A total of 4 flocks (sheep and goat) belonging to Chamba District of Himachal Pradesh, India were studied in the present investigation. These flocks usually come to plain regions of the state in search of fodder in the winter season. A total of 52 animals were sampled for feces from these flocks. In total 12 (8- sheep, 4- goats), 15 (10- sheep, 5- goats), 9 (7- sheep and 2- goats) and 16 (12- sheep, 4- goats) animals belong to flock 1, 2, 3 and 4, respectively. Animals were tested for direct fecal examination, fecal DNA PCR and culture for the presence of MAP. The positive PCR samples were subjected to IS1311 PCR-REA to know the genotype of infecting strain.

Key words: paratuberculosis, hilly regions, genotyping

23 Status of *Mycobacterium avium* subspecies *paratuberculosis* Infection in the Cow Shelters (Goshalas/Pinjarapoles) in India. S. V. Singh*[1], A. V. Singh[1], P. K. Singh[1], B. Singh[1], A. Kumar[1], B. S. Chandel[3], A. Srivastav[2], S. Gupta[1], H. Singh[1], A. Mittal[1], and S. Yadav[2], *[1]Central Institute for Research on Goats, Mathura, Uttar Pradesh, India, [2]College of Veterinary Sciences, Mathura, Uttar Pradesh, India, [3]College of Veterinary Science, Dantiwada, Gujarat, India.*

India possesses huge population (>480 million) of domestic livestock, however, per animal productivity remains poor. Due to poor per animal productivity, large number of low or unproductive goats, sheep and buffaloes go for early slaughter. Slaughtering of cows (even those suffering from incurable diseases) is banned in India. Such cows are either let off or sent to Cow Shelters by farmers. Cow shelters (or Goshalas in North India and Pinjarapoles in Western India) provide shelters for un-productive and homeless cows. Number of these cow shelters is very large in country and depend on charity money. Cows in these shelters survive on low plane of nutrition and are in poor health and suffer from varieties of health problems and are rarely screened for diseases including Johne's disease. Mycobacterium avium subspecies paratuberculosis (MAP), the cause of JD, is responsible for huge losses in production and is endemic in farm and farmer's herds. Study estimated status of MAP in 4 Goshalas in Mathura, UP (region A) and 3 in Dantiwada, Gujarat (region B) using microscopy, indigenous ELISA kit and Blood PCR. 211, 143 and 183 cows were screened by microscopic examination (feces), ELISA (serum) and PCR (blood), respectively. Whereas, of the 3 Goshalas in region B, 37 and 135 cows were screened by microscopy (fecal) and ELISA (serum), respectively. In region A, 57.4 and 55.9 and 36.1% cows were positive in microscopy, ELISA and PCR, respectively. In region B, 48.6 and 62.2% cows were positive by microscopy and ELISA, respectively. Load of MAP infection was high in cow shelters and serve as reservoir and need special attention for the control of MAP at National level.

Key words: Johne's disease, ruminants, prevalence

24 Finishing performance and carcass traits of heifers previously managed with three respiratory disease protocols. J. L. Wahrmund*[1], D. B. Burken[1], B. K. Wilson[1], S. J. Terrill[1], C. R. Krehbiel[1], D. L. Step[2], S. M. Trost[3], C. L. Goad[4], and C. J. Richards[1], *[1]Oklahoma State University, Department of Animal Sciences, Stillwater, [2]Oklahoma State University, Department of Veterinary Clinical Sciences, Stillwater, [3]Strategic Solutions International, Stillwater, OK, [4]Oklahoma State University, Department of Statistics, Stillwater.*

This experiment evaluated the finishing performance and carcass traits of 331 heifers (BW = 351 ± 51 kg) previously managed for 56 d with 3 bovine respiratory disease (BRD) health management protocols. The protocols were: visual monitoring (CON), visual and ruminal temperature monitoring (TEMP), or visual monitoring following a d 0 metaphylactic treatment (MET). Heifers were blocked by BW and randomly allotted to 24 pens for the receiving phase. At finishing, 169 heifers from 12 pens were blocked by BW and reallocated to 30 pens based on receiving treatment, and all heifers were adapted to a 94% concentrate diet. Percentage of heifers receiving 0, 1 or 2 treatments for BRD were 57, 37 and 8% for CON; 26, 49 and 25% for TEMP;

and 81, 10 and 9% for MET; respectively. Heifers treated twice for BRD began the finishing phase weighing 16.9 kg less ($P < 0.01$) than all other heifers. Interactions were observed between health protocol and number of times treated for final BW and overall ADG ($P \leq 0.02$). Final BW of CON heifers treated twice was 32.2 kg less ($P \leq 0.04$) than other CON heifers, while number of times treated did not affect ($P \geq 0.13$) final BW of TEMP and MET heifers. CON heifers treated twice gained 0.16 kg/d less ($P = 0.01$) than other CON heifers. TEMP heifers treated twice gained 0.11 kg/d more ($P = 0.03$) than those never treated and MET heifers' ADG was unaffected ($P \geq 0.12$) by times treated. Heifers treated twice for BRD had 11.4 kg lighter ($P \leq 0.04$) HCW than those receiving 0 or 1 treatment. Heifers not treated for BRD had 1.1% greater dressing percent ($P < 0.01$), 7.6% greater marbling score ($P \leq 0.04$) and 0.25 cm greater fat thickness ($P \leq 0.02$) compared with those treated once or twice. Carcass value showed a health protocol × number of times treated interaction ($P = 0.04$). Carcasses from CON heifers treated twice were valued at $91.48 less ($P \leq 0.02$) than those from other CON heifers, while carcass value of TEMP and MET heifers was not affected ($P \geq 0.27$) by number of times treated. Results indicate that metaphylaxis and remote temperature monitoring may spare some of the detrimental effects of BRD on performance and carcass value.

Key words: respiratory disease, performance, carcass

Beef Species and Ruminant Nutrition Joint Symposium: Cow Size, Genetics, Management and The Beef Industry

25 Management and genetic factors affecting efficiency of cattle in a grazing environment. A. J. Roberts*, J. T. Mulliniks, R. C. Waterman, T. W. Geary, L. J. Alexander, M. K. Petersen, and M. D. MacNeil, *USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

Much of current efforts to improve efficiency in cattle use measures of individual feed intake in combination with weight gain as an indication of efficiency. This approach provides pertinent information concerning efficiency during the growing phase, but the relationship to cow efficiency remains to be determined. Efficiency in grazing cows is much more complex, especially when considering input and output traits associated with efficiency as functions of genetics and environmental factors, and interactions of these factors. The most critical output influencing efficiency of beef cattle production is reproductive rate, which is a cumulative process requiring years to establish. Nutrition and management components of environment are more complex in range settings and subject to greater seasonal and annual variation than in confined settings relying solely on harvested feed with greater homogeneity. Methodology to measure feed intake while grazing under range conditions are lacking. Seasonal and annual variations in quantity and quality of forage can result in greater distinctions between biological and economic efficiency in the cow-calf phase compared with other segments. For example, cows that consume more calories during the growing season and gain sufficient weight to exist on less harvested feed inputs during winter may require less total economic input than cows with greater biological efficiency that consumes less during the growing season, but require more calories from harvested feed later. Efficiency of beef cattle production requires a balance between nutritional inputs and prolonged optimal output. A provocative question to consider is whether traditional approaches of providing sufficient feed to a herd of cows to achieve a relative high rate of reproduction results in improved efficiency or not? Is this analogous to selecting a type of cattle and managing the environment to sustain the type? What happens when cattle are managed corresponding to restriction imposed by a limited environment and provided relatively minimal inputs rather than feed for a desired level of production associated with a resource rich environment?

Key words: genetics, management, efficiency

26 Genetics of postweaning performance of beef cattle on forage. M. A. Brown*[1], J. W. Holloway[2], D. L. Lalman[3], C. Dobbs[3], and S. M. Clifton[4], *[1]USDA-ARS, Grazinglands Research Laboratory, El Reno, OK, [2]Texas AgriLife Research, San Angelo, [3]Oklahoma State University, Stillwater, [4]Redlands Community College, El Reno, OK.*

Increases in the costs of feed grains have revived interest in increasing use of forages to either market as forage-finished beef or to produce heavy calves that will finish on less grain. However, little is known about the interactions of animal genetics and grazing environment that allows the most efficient use of resources and has the best potential to be economically efficient. Determination of the optimal combination of animal genetics and production environment requires that the target end-points of production are well-defined and it requires knowledge about available animal genetics and the intended production environment. Animal genetics is loosely defined by rate of maturing, milk production potential, and level of tropical adaptation. In addition, knowledge of breed combination, gender, and genetic merit is helpful. Environmental effects that must be considered include nutritional value of the forage, climate, geography, time, and management. With this information, robust systems can be developed considering the interactions of environmental effects, interactions of genetic effects, and the interactions of genetic and environmental effects. Not only do these systems need to appropriately match genetics and environment, they need to be low-capital systems that are simple to implement . Attributes of animal genetics that might be desirable include efficiency of forage utilization, adaptation not only heat and cold conditions but also adaptable to rapid changes in climate. To fit within the current commodity beef system, it is desirable that cattle in these systems marble early with respect to their mature weight, and that they have sufficient growth to produce acceptable carcass weights by 18 to 24 mo of age. It seems reasonable that selection of appropriate genetics will match frame size to forage quality with lower quality forages requiring more moderate frame size. The use of crossbreeding in these systems will require a closer evaluation of genetic effects. The incorporation of tropical adaptation into efficient forage-based beef production systems will be dependent on forage quality, climate, and pressure from external parasites.

Key words: beef cattle, forage, genotype x environment

27 A historical perspective on the influence of the beef industry on mature cow size. B. McMurry*, *Cargill Animal Nutrition, Minneapolis, MN.*

Between 1975 and 2005 efficiency as measured by pounds of beef produced per beef cow increased dramatically. Driven by technological advancements in nutrition, health, reproduction, growth physiology, breeding and genetics, weight gain increases were realized in every industry segment, Calves weaned heavier, stocker and background cattle gained more rapidly, average daily gain and feed conversion in feedlots improved than previous to 1975. During the 30-year period carcass weights of steers and heifers increased 144 and 194 pounds, respectively. The average steer and heifer carcass weights in 1975 were 673 and 556 pounds, by 2005 they had reached 817 and 750 pounds, respectively. Calculated live weights increased for steers and heifers, respectively from 1068 and 869 pounds in 1975 to 1297 and 1172 pounds in 2005. Genetics of European breeds and the advent of EPDs underpinned growth and carcass weight increases. The introduction of faster-growing, later maturing breeds and heavy selection pressure toward growth also had an impact on the US beef cow herd. Selection criteria favored higher growth rates and EPDs for yearling weight, which are highly correlated with mature weight. Consequently, from 1975 to 2005 carcass weights of bulls and cows increased 223 and 146 pounds, respectively. Average bull and cow carcass weights in 1975 were 682 and 475 pounds, by 2005 they had reached 905 and 621 pounds, respectively. Calculated live weights at harvest increased for bulls and cows respectively from 1047 and 1340 pounds in 1975 to 1350 and 1769 pounds in 2005. Additionally during this period, to improve weaning weights, cow/calf producers selected for increased milk production, and, along with increased mature weight, raised the average beef cow's forage dry matter requirements by approximately 25%. During this same 3year period the producing beef cow population declined 13.4 million head or 28.6%, however total DM required to support the US cowherd only declined 6% (from 186 million to 174

million tons); the impact of increasing mature size and milk production. Consequently, limited forage resources constitute a significant barrier for increasing beef cow inventories and domestic beef supplies.

Key words: mature size, beef cattle, efficiency

28 Conclusion: Cow size and keeping perspective. R. H. Pritchard*, *South Dakota State University, Brookings.*

There are enumerable considerations to be accounted when idealizing mature cow weight (MW). Some inputs such as bulls, vaccines, labor are fixed per cow, regardless of MW and cannot be overlooked. Oftentimes we evaluate cow size by creating 2 component production ratios that are considered efficiencies. We express WW per cow or WW per cow BW and get different rankings. Divide these ratios by calving interval and rankings change again, depending on a production environment. Rankings created by using efficiency ratios to identify optimum MW will vary with the nutritional environment, management inputs, and climatic stressors. Alternatively we could work backward from a desirable carcass weight to determine an appropriate cow size. If 385 kg is an appropriate carcass weight, then the cow MW weight may be 580 kg. This average may not be ideal or justifiable in all production situations and includes many assumptions. It is subject to correction (lower) for the use of anabolics; higher for high growth genetics used in an accelerated production system; or lower for progeny reared in a deferred production system. Declining cow numbers have led to lighter and especially younger feeder cattle placements in feedlots. This has created pressures that ultimately increase cow MW. How the feedlot industry responds to greater competition for corn may elicit new influences on the direction of cow size.

Key words: beef, cow, size

Breeding and Genetics: Genomic Selection and Whole-Genome Association I

29 Effect of different genomic relationship matrices on accuracy and scale. I. Misztal*[1], C. Y. Chen[2], I. Aguilar[5], Z. G. Vitezica[3], A. Legarra[3], and W. M. Muir[4], *[1]University of Georgia, Athens, [2]Newsham Choice Genetics, Chesterfield, MO, [3]INRA, Castanet-Tolosan, France, [4]Purdue University, West Lafayette, IN, [5]INIA, Las Brujas, Uruguay.*

Phenotypic data on body weight (BW) and breast meat area (BM) were available on up to 287,614 broilers. A total of 4,113 animals were genotyped for 57,636 SNP. The records were analyzed by a single step genomic BLUP (ssGBLUP), which accounts for all phenotypic, pedigree and genomic information. The genomic relationship matrix (G) in ssGBLUP was constructed using either equal (0.5; GE) or current (GC) allele frequencies, and with either all SNP or SNP with minor allele frequencies (MAF) below multiple thresholds (0.1, 0.2, 0.3, and 0.4) ignored. Additionally, a pedigree based relationship matrix for genotyped animals (A_{22}) was available. The matrices and their inverses were compared with regard to average diagonal (AvgD) and off-diagonal (AvgOff) elements. In A_{22}, AvgD was 1.00 and AvgOff was 0.01. In GE, both averages decreased with the increasing thresholds for MAF; AvgD decreasing from 1.37 to 1.02 and AvgOff decreasing from 0.72 to 0.03. In GC, AvgD was around 1.01 and AvgOff was 0.00 for all MAF. For inverses of relationship matrices, all AvgOff were close to 0; AvgD was 2.4 in A_{22}, varied from 11.6 to 13.0 for GE, and increased from 8.7 to 12.9 for GC as the threshold for MAF increased. Predictive abilities with all GE and GC were similar. Compared with BLUP, EBVs of genotyped animals in ssGBLUP were, on average, biased up to 1 additive SD higher with GE and down by 2 additive SD with GC. The bias was eliminated by adding constant 0.014 (equal to AvgOff in A_{22}) to GC. This constant is equivalent to twice the mean relationship between gametes in the genotyped and ungenotyped populations. Reduction of SNP with low MAF has a low effect on the realized accuracy. Unbiased evaluation in ssGBLUP may be obtained with GC scaled for compatibility with A_{22}.

Key words: genomic selection, single step, bias

30 Comparisons of numerator and genomic and relationship matrices. H. Wang* and I. Misztal, *University of Georgia, Athens.*

The objective of this study was to quantify differences between the numerator (A) and genomic (G) relationship matrices for possible application in detection of pedigree and genotyping errors. Data were obtained from Cobb-Vantress, including 2422 individuals in 3 generations from the same line and genotyped for 57,636 SNP. The A matrix was constructed using pedigrees for 3 generations. The G matrix was constructed using current allele frequencies and scaled for identical means of diagonal and off-diagonal elements of A for the common animals. In A (G), the mean diagonal (AvgD) element was 1.01 ± 0.015, ranging from 1.00 to 1.09 (1.01 ± 0.07, ranging from 0.48 to 1.86). The mean of the off-diagonal elements (AvgOff) was 0.031 ± 0.051, ranging from 0 to 0.062 (0.031 ± 0.055, ranging from −0.13 to 0.69). For G–A, AvgD was 0 ± 0.073, ranging from −0.52 to 0.86, and AvgOff was 0 ± 0.032, ranging from −0.50 to 0.52. The distribution of AvgOff for G–A was approximately normal with long tails, with only 0.53% elements outside the range from −0.10 to 0.10. The SD of the off diagonal elements of G–A increased from 0.03 where aij < 0.01 to 0.04 where aij > 0.10. Visually, matrix A contained blocks with elements close to 0 and blocks with higher correlations. Similar blocks occurred in G; however, the blocks with elements close to 0 were smaller. Moreover, G–A showed several rows and columns with high values. After removing animals with the average relationship to other animals >0.030, the differences between G and A decreased. When A is obtained with long generation pedigrees and G is scaled for compatibility with A, differences between G and A are very small. Larger differences may indicate pedigree errors, genotyping errors, or mixing of lines/breeds.

Key words: genomic selection, genomic relationship matrix, errors

31 A recursive method of approximation of the inverse of genomic relationships matrix. P. Faux*[1], N. Gengler[1,2], and I. Misztal[3], *[1]University of Liege, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium, [2]National Fund for Scientific Research, Brussels, Belgium, [3]University of Georgia, Animal and Dairy Science Department, Athens.*

Genomic evaluations by some procedures such as genomic BLUP (GBLUP) or single-step GBLUP (ssGBLUP) use the inverse of the genomic relationship matrix (G). The cost to create such an inverse is cubic and becomes prohibitively expensive after 30–100k genotypes. The purpose of this study was to develop methodologies, which eventually could compute a good approximation of G^{-1} at reduced cost. A recursive approximation of the inverse is based on a decomposition similar to that for the pedigree-based relationship: $G^{-1} = (T^{-1})'D^{-1}T^{-1}$, where T is a triangular and D a diagonal matrix. In the first step, animals are processed from the oldest to the youngest. For each animal, a subset of ancestors is selected with coefficients of genomic relationship to that animal greater than a threshold. A system of equations is created where the coefficients of G for the selected ancestors are in the left hand side and the coefficients of G for the given animal corresponding to the ancestors are the right hand side. The solution to that system of equation is stored in one line of T. Then, D is computed as diagonal elements of $T^{-1}G(T^{-1})'$. If off-diagonals of D are too large, the approximation to G can be improved by repeated applications of $G^{-1} = (T^{-1})'D^{-1}T^{-1}$ and $D = T^{-1}G(T^{-1})'$. After n rounds, the approximation of G inverse is a product of 2n triangular matrices and one diagonal matrix. This recursive method has been assessed on a sample of 1,718 genotyped dairy bulls. The correlation between GEBV using the complete or approximated G were 0.54 in the first round, 0.96 in the second, and 0.99 in the third. The cost of the proposed method depends on the population structure. It is likely to be high for closely related animals but lower for populations where few animals are strongly related. Additional research is needed to identify near-sparsity in T and D to eliminate unimportant operations.

32 Adapting Bayesian mixture model algorithms to estimate hyperparameters that characterize genetic architecture in genomic selection models. R. J. Tempelman*[1], W. Yang[1], J. P. Steibel[1], and N. M. Bello[2], *[1]Michigan State University, East Lansing, [2]Kansas State University, Manhattan.*

Various genomic selection models (e.g., BLUP, BayesA, BayesB) have been formally compared with each other with the understanding that different traits are better fit by one model versus another. However, it has been generally underappreciated that BLUP and BayesA are

merely special cases of BayesB; that is, certain key hyperparameters can be estimated rather than arbitrarily specified. These key hyperparameters are: 1) the proportion (π) of single nucleotide polymorphism (SNP) markers that are directly associated with causal variants, 2) the scale parameter that determines the typical genetic variance for each non-null SNP marker, and 3) a degrees of freedom parameter that determines how much heterogeneity there exists in this genetic variability across SNPs. We demonstrate the use of fundamental Bayesian mixture model algorithms for estimating these key hyperparameters from the data, highlighting, in particular, methods based on slab and spike priors as well as the stochastic search and variable selection algorithm. We use simulation studies to demonstrate the properties of these methods on estimates of these 3 key hyperparameters. First, we consider simulated populations assuming linkage equilibrium between all markers with a proportion π of the markers being synonymous with causative variants. These simulations provide a positive control for which the model for both data generation and analysis are in near agreement; we subsequently demonstrate that inferences were in good agreement with the true values specified for each hyperparameter. We then consider more extensive comparisons between the various methods under more realistic linkage disequilibrium situations between SNP markers with different levels of marker density ($0.15 < r^2 < 0.30$). In general, estimates of all 3 hyperparameters decreased as marker density increased, thereby further highlighting the need to infer upon these hyperparameters rather than arbitrarily specifying them.

Key words: genetic architecture, genomic selection, mixture models

33 Improving accuracy of genomic selection by hierarchical Bayesian modeling of spatially correlated chromosomal effects. W. Yang* and R. J. Tempelman, *Michigan State University, East Lansing.*

Hierarchical mixed effects models have been effectively used to predict genomic merit of livestock using high density SNP marker panels. Two currently popular approaches, BayesA and BayesB, are based on specifying all SNP-associated effects to be independent of each other. BayesB has been particularly effective as it extends BayesA in allowing a large proportion of SNP markers to be associated with null effects. We propose extensions of these 2 models to attempt to specify these effects as spatially correlated due to the chromosomally proximal effects of causal variants. These 2 methods, respectively labeled ante-BayesA and ante-BayesB, are based on a first order unstructured antedependence specification between SNP effects. Based on a simulation study with 10 replicated data sets, each differing by 6 different LD levels ranging from $r^2 = 0.16$ to 0.30, the antedependence methods had significantly ($P < 0.001$) higher accuracies than their corresponding classical counterparts at higher LD levels ($r^2 > 0.27$) with differences exceeding 3%. A cross-validation comparison was also conducted on the heterogeneous stock mice data resource (http://mus.well.ox.ac.uk/mouse/HS/) using 6 week weights as the phenotype. The data set included 2,296 individuals and 950 randomly selected SNPs to ensure an adjacent average pair-wise LD $r^2 = 0.3$, as representative of current livestock data. The antedependence methods increased cross-validation prediction correlations by up to 3.6% compared with their classical counterparts ($P < 0.001$). We used a final set of simulation studies to demonstrate that it is possible to infer upon key parameters (e.g., proportion of SNPs with null effects, average genetic variance at each SNP) that define the genetic architecture of our antedependence methods. In general, ante-BayesA and ante-BayesB required less than 10% greater computational time compared with their classical counterparts such that they should become increasingly attractive for whole genome selection, particularly as the density of SNP chips increases.

Key words: Bayesian inference, genomic selection, antedependence

34 Incorporating molecular breeding values with variable call rates into genetic evaluations. S. D. Kachman*[1], G. L. Bennett[2], K. J. Hanford[1], L. A. Kuehn[2], E. J. Pollak[2], W. M. Snelling[2], M. L. Spangler[1], and R. M. Thallman[2], *[1]University of Nebraska, Lincoln, [2]U.S. Meat Animal Research Center, Clay Center, NE.*

A partial genotype (PG) for an animal can result from panels with low call rates used to calculate a molecular breeding value (MBV). A MBV can still be calculated using PG by replacing the missing marker covariates with their mean value. This approach is expected to change the distribution of the MBV by reducing the variance and percentage of genetic variation explained by the MBV. Under independence, the variance of a MBV is $2\Sigma b_i 2p_i(1-p_i)$ where b_i and p_i are the effect and the allelic frequency of marker i, respectively. For animal a the proportion, P_a, of the complete genotype (CG) MBV variance accounted for by PG is then the ratio of the variances calculated by summing over the partial and the complete set of markers. Similarly, the genetic covariance between a trait and PG MBV is also proportional to Pa. The proportion of CG covariance between animals a and b with PG was assumed to be proportional to P_aP_b. The PG model for the MBV of animal a, scales the CG genetic effect by P_a and adds a missing genotype effect with variance $P_a(1-P_a)$ times the CG genetic variance. A weaning weight MBV was constructed from 159 Single Nucleotide Polymorphisms using genotype and weaning weight data from 3,327 Cycle VII calves from the US Meat Animal Research Center. Genotype (n = 2,503) and weaning weight (n = 148,897) data from purebred calves of 7 breeds were used to evaluate the MBV. The genotype data had an average call rate of 85.2% (11.3–100%). Two trait analyses were run for each breed separately, both with and without accounting for PG in the model. Overall, MBV heritabilities and its genetic correlation with weaning weight were larger when the effects of PG were incorporated into the analysis (Table 1).

Table 1. Estimated genetic parameters

		Heritability			
	Heritability	Molecular Breeding Value		Genetic Correlation	
Breed	Weaning Weight	Without	With	Without	With
Angus	0.23±0.02	0.87±0.16	0.75±0.12	0.00±0.10	0.15±0.11
Red Angus	0.24±0.03	0.67±0.16	0.89±0.14	0.10±0.10	0.14±0.11

35 Impacts of inclusion of foreign data in genomic evaluation of dairy cattle. K. M. Olson*[1], P. M. VanRaden[2], and D. J. Null[2], *[1]National Association of Animal Breeders, Columbia, MO, [2]Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

The accuracy of genomic predictions tends to increase with larger numbers of animals in the training data set. Because of this, many countries have combined data to increase the size of their training populations. The objective of this study was to investigate different meth-

ods of combining the data using domestic data, a combined domestic and foreign training population, and a domestic and foreign multi-trait method. Foreign bulls with US daughters were considered domestic in this study. The combined foreign and domestic training data set was comprised of bulls and cows that were proven (had daughter or own information) as of August, 2007 and totaled 9,874 Holsteins and 1,473 Brown Swiss. The domestic training animals included cows and bulls and totaled 8,674 Holsteins and 741 Brown Swiss. The foreign training data set had 1,200 Holsteins and 732 Brown Swiss. Over 90% of the foreign data from Holsteins were from Canada, which has a very high genetic correlation to the United States. Most the Brown Swiss data were from Germany and Switzerland, but animals from 6 other countries were included in the data. The validation data sets consisted of US bulls that were unproven as of August, 2007 and proven with daughters in at least 10 herds as of December, 2010. There were 3,094 and 115 Holstein and Brown Swiss validation bulls, respectively. Genetic correlations for the multi-trait method were computed as the weighted average of countries genetic correlation with the United States based from Interbull. Results show a general increase of about 2% from inclusion of foreign data over domestic data only in the Holstein population and an increase of 5% in the Brown Swiss. Multi-trait methodology was beneficial for Brown Swiss and most traits gained reliability and some traits gained as much as 6%. Multi-trait was not advantageous in Holsteins, probably due to the high genetic correlation between the 2 countries. It is recommended that countries with high genetic correlations be treated as a single population. Diverse populations may benefit from the implementation of multi-trait methodology.

Key words: country, dairy cattle, genomic evaluation

36 Optimization of principal component extraction for direct genomic value prediction in a multibreed population. N. P. P. Macciotta*[1], M. A. Pintus[1], R. Steri[1], G. Gaspa[1], D. Vicario[2], E. Santus[3], J. T. H. Van Kaam[4], and P. Ajmone Marsan[5], *[1]Università di Sassari, Sassari, Italy, [2]ANAPRI, Udine, Italy, [3]ANARB, Bussolengo, Italy, [4]ANAFI, Cremona, Italy, [5]Università Cattolica del Sacro Cuore, Piancenza, Italy.*

A joint use of data coming from different breeds is a strategy for mitigating the huge unbalance between number of markers and number of phenotypes in genomic selection (GS) programmes. A further reduction of data asymmetry can be obtained by using Principal component analysis to derive new synthetic variables to be used as predictors in the calculation of direct genomic values (DGV). In the present work the PC approach is used for predicting DGV for dairy traits in bulls of 3 breeds farmed in Italy: 863 Holstein (H), 749 Brown Swiss (BS), 479 Simmental (S), respectively. Animals were genotyped with the 54K Illumina beadchip. SNPs retained after edits were 39,225. PC were extracted from the joint data set of the 3 breeds or separately by each breed. Extraction was carried out by chromosome. Different amounts of PC were retained on the basis of the explained variance: 0.50, 0.70, 0.80 and 0.90. Effect of PC on polygenic EBV was estimated in the reference population with a BLUP model. Traits considered were milk yield, fat and protein percentages. Reference animals were considered those born before 2000. Accuracies were calculated as correlation between DGV and polygenic EBV. The increase of number of retained PC (from 1,255 to 8,452, corresponding to 0.5 and 0.9 of explained variance, respectively) resulted in an increase of DGV accuracy. Higher DGV accuracies were obtained for milk yield in the Simmental bulls (0.45–0.55 depending on the number of PC used) even though this trait showed the highest variability. On average, the increase was more relevant for protein percentage and in the BS bulls. The use of a multibreed approach did not result in an increase of DGV accuracy compared with single breed estimation. Actually values tend to remain similar in the 2 approaches or, as in the case of Brown Swiss for milk yield, to decrease markedly. These results may be linked to the reduced size of the sample but may be also related to the different genetic structure and selection history of the 3 breeds.

Key words: genomic selection, multibreed, principal component

37 Adjustment of deregressed values from cow evaluations to have the similar mean and variance as bull deregressed values. G. R. Wiggans*, P. M. VanRaden, and T. A. Cooper, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Traditional evaluations of cows with genotypes have been adjusted since April 2010 to be compatible with evaluations of bulls to improve their accuracy in estimation SNP effects. This adjustment made them not comparable with traditional evaluations of cows. Recent work has improved the adjustment by using a bull only direct genomic value to group cow according to the amount of adjustment required. This adjustment cannot be applied to all cows because the grouping requires a genotype and adjustments based on genotyped cows probably would over adjust other cows. To create an adjustment for all cows, Mendelian sampling (MS), the difference between PTA and parent average (PA), was calculated for milk, fat, and protein. These were deregressed by dividing by a function of reliability with the reliability from parent average removed. Standard deviations (SD) of these values were grouped by reliability. A linear function of reliability was estimated as a multiplicative adjustment to reduce the SD from cows to that of bulls with similar reliability. Averages of PA by birth year were subtracted from PA to create within year PA deviation groups and mean deregressed MS was calculated for bulls and cows by group. These means for bulls fell and those for cows rose with increasing deviation. The differences were fit by linear regression on PA deviation and used to adjust cow deregressed MS. Adjusted cow evaluations were propagated to the PA of progeny. This adjustment reduced the PTA of cows with high PA and increased those of cows with low PA, but did not change the estimates of genetic trend because the adjustment was within birth year. It also reduced the within birth year variance of cow evaluations. This adjustment does not replace the adjustment of evaluations of genotyped cows because the use of bull only direct genomic values more precisely tailors the adjustment to the individual cow. However, it reduces the amount of the genotype based adjustment so should improve the comparability of evaluations of cows with and without genotypes.

Key words: cow evaluation, genomics, Mendelian sampling

38 Effectiveness of genomic selection on milk flow traits in dairy cattle. K. A. Gray*[1], J. P. Cassady[1], A. Rossoni[2], and C. Maltecca[1], *[1]North Carolina State University, Raleigh, [2]Italian Brown Breeders Association, Bussolengo, VR, Italy.*

The objective of this study was to estimate the effect of genomic selection on accuracy of prediction for traits associated with milkability. Milk flow measures for total milking time (TMT), time of plateau (TP), descending time (DT), average milk flow (AVGF) and maximum milk flow (MMF) were collected on 37,213 Italian Brown cows. Estimated breeding values were obtained through standard BLUP techniques. Heritabilies were estimated to be 0.11, 0.31, 0.06, 0.28, 0.41 for TMT, TP, DT, AVGF and MMF, respectively. For 696 sires included in the phenotypic analysis, genomic information for 35,044

informative markers were obtained. Genotyped sires had on average 37 ± 3.9 daughters, and a reliability of ~0.60 averaged across all flow traits. Genotyped sires were partitioned based on their TMT EBV reliabilities into a discovery set (TMT EBV reliability >0.70, n = 381) and a prediction set (TMT EBV reliability <0.70, n = 315). Pseudo-phenotypes for these sires were obtained by EBV de-regression and subsequently employed in obtaining genomic breeding values through a multiple trait GBLUP model. The GEBV reliabilities in the prediction set were compared with de-regressed parental averages (PA) and breeding values obtained using traditional BLUP methods (EBV) on the same individuals. The GEBV reliabilities in the prediction set were 0.64 (0.27 PA), 0.62 (0.28 PA), 0.69 (0.20 PA), 0.71 (0.28 PA), and 0.67 (0.29 PA) for TMT, TP, DT, AVGF and MMF, respectively. Average gain in reliability from genomic information was 0.37, 0.34, 0.49, 0.43 and 0.38. The EBV reliabilities in the prediction set were 0.46, 0.50, 0.29, 0.49, and 0.51 for TMT, TP, DT, AVGF, and MMF, respectively. Loss in accuracy when compared with the genomic model was 0.18, 0.12, 0.40, 0.22 and 0.16 for TMT, TP, DT, AVGF, and MMF, respectively. For all traits, use of a genomic model resulted in increased accuracy of prediction for sires with little or no progeny information. Gain in accuracy increased as heritability decreased. Inclusion of genomic information increased accuracy of prediction for milk flow measures.

Key words: genomic selection, accuracy of prediction, milk flow

39 Visualization of associations between single nucleotide polymorphisms and economically important dairy traits using biplot analysis. A. I. Vazquez[1], K. A. Weigel*[2], G. J. M. Rosa[2], D. Gianola[2], and D. B. Allison[1], *[1]University of Alabama, Birmingham, [2]University of Wisconsin, Madison.*

In food animal species, the breeding objective consists of several interrelated traits, and implementation of genomic selection requires estimation of single nucleotide polymorphism (SNP) effects on these traits. When the number of markers is large and multiple traits are considered, extracting meaningful information from the results is challenging. Biplot analysis is an important tool for this purpose in plant breeding, but its features have not yet been explored in animal breeding. A biplot is a scatter plot that approximates and graphically displays a 2-way table, such that relationships between rows, relationships between columns, and interactions between rows and columns can be visualized simultaneously. Biplots can uncover patterns in estimated SNP effects (rows) on phenotypic traits (columns) and shed light on the causes of genetic correlations between traits. In this study, phenotypes were predicted transmitting abilities for milk, fat, protein, daughter pregnancy rate, somatic cell score, productive life, and lifetime net merit for 3,305 Holstein sires, and genotypes were 32,518 SNP markers. The 32,518 × 7 matrix of estimated SNP effects was decomposed into principal components (PC), of which the first and second explained 42 and 29% of the total variation, respectively. A biplot of the first and second PC showed that SNP effects for milk, fat, and protein tended to lie on a common axis, whereas SNP effects for daughter pregnancy rate, somatic cell score, and productive life tended to lie on a second axis that was nearly perpendicular to the first. Estimated SNP effects for lifetime net merit represented a compromise between the 2; however, sets of individual SNPs had correlations between performance and fitness that were negative, neutral, or positive. The SNPs with largest estimated effects for lifetime net merit differed from those with largest estimated effects for the 6 biological traits. Our study suggests that biplots may facilitate interpretation of genomic data and assist animal breeders in incorporating information about individual SNPs into selection decisions.

Key words: genomic selection, dairy cattle, biplot analysis

40 Using single nucleotide polymorphism to detect selection signature in Hereford beef cattle. Y. Huang*[1], C. Maltecca[1], M. D. MacNeil[2], and J. P. Cassady[1], *[1]Department of Animal Science, North Carolina State University, Raleigh, [2]USDA-ARS, Fort Keogh Livestock and Range Research Laboratory, Miles City, MT.*

The objective of this study was to investigate selection signature in 2 sources of purebred Hereford beef cattle. Data were available from 240 Line 1 Herefords (L1) born between 1953 to 2008, and 311 Industry Herefords (IH) born between 1970 and 2008. Line 1 Herefords were sampled from a closed line mainly selected for post weaning gain. Industry Herefords were a sample of registered US purebred Herefords. A genome-wide scan using 52,156 SNPs revealed different characteristics in L1 and IH. Average minor allele frequency of SNPs was 0.19 ± 0.168 in L1 and 0.23 ± 0.161 in IH. Number of homozygous markers was of 11,382 in L1 and 5,745 in IH. The fixation index was 0.260 and 0.031 for L1 and IH, respectively. To detect differences in selection between the 2 populations, pooled heterozygosity (Hp) was calculated for sliding windows of 6 SNPs across the genome. Low Hp values are indicative of a high degree of fixation and putative selective sweeps. High Hp values can be the result of ongoing selection sweeps, balancing selection, or selection for multiple traits. Average Hp was 0.26 ± 0.10 for L1 and 0.29 ± 0.08 for IH. 225 low Hp windows (Hp <0.05) were identified in L1 while only 25 in IH. Fifty-four known QTLs were previously found to be associated with traits including birth weight and weaning weight, co-localized with low Hp windows that were common in L1 and IH on BTA 1, 3, 6, 13, 14, 15, 16, 18, and 25. Fifty-six known QTLs associated with growth traits such as average daily gain and yearling weight co-localized with low Hp windows that were only found in L1 in BTA 2, 5, 14, 17, 21, and 26. Number of high Hp windows (Hp >0.46) was of 155 in L1 and 78 in IH. This might reflect that L1 being selected for only one trait, while IH was selected on several traits with multiple concurring sweeps. Differences in number of high Hp windows might also indicate regional balancing selection. Based on these results it was concluded that there had been a loss of heterozygosity in Line 1 Herefords. The low Hp windows indicated putative selective sweeps in L1. Further investigations are needed to explain the high Hp windows across the genome.

Key words: Hereford, selection signature, SNP

Extension Education Symposium: Reinventing Extension as a Resource—What Does the Future Hold?

41 National Institute of Food and Agriculture (NIFA) grants and extension: Expectations for integrated projects. M. A. Mirando* and K. M. Whittet, *National Institute of Food and Agriculture, U.S. Department of Agriculture, Washington, DC.*

The Food, Conservation, and Energy Act of 2008 (Public Law 110–246, i.e., the 2008 Farm Bill) established NIFA within the USDA and the Agriculture and Food Research Initiative (AFRI) within NIFA. AFRI is the USDA's largest competitive grants program and is authorized at a funding level of $700 million; however, Congressional appropriation to AFRI in fiscal year 2010, its second year of existence, was approximately $262 million. The Farm Bill requires NIFA to expend at least 30% of the funds appropriated to AFRI in support of projects that integrate at least 2 of the 3 functions of the agricultural knowledge system (i.e., research, education, and extension). In fiscal year 2010, approximately 44% of AFRI funds were expended on integrated projects. Programs supporting integrated projects are located primarily within the 5 AFRI Challenge Area requests for applications. Strong integrated project proposals are stakeholder driven, issue focused, and outcome based. Applications for integrated projects must include the elements of a logic model detailing the activities, outputs, and outcomes of the proposed project. Integrated proposals should contain objectives for each function of the project and no more than 2-thirds of the budget may support a single function. For proposals integrating research and extension, applied research integrates best into an extension program. Integrated extension and research applications can propose extension programming as the first objective(s) and social science research to evaluate and report on the effectiveness of the extension programming (e.g., did the extension program result in behavioral change of the target audience). Peer review panels for all AFRI programs soliciting integrated projects are required to have substantial representation by individuals with expertise in extension. In programs that solicit both research and integrated project proposals, the 2 types of applications are evaluated separately because of the distinct nature of the 2 types of proposals

Key words: competitive grants, extension, integrated projects

42 Integrating extension and research projects. D. J. Patterson*, *University of Missouri, Columbia.*

Projects that integrate extension and research are required to be outcome oriented, stakeholder driven, and problem focused. These expectations create opportunities to generate new knowledge and apply existing knowledge quickly. This approach and the synergy that results from it parallel the fundamental basis upon which extension and the Land Grant System were founded: The use and application of what we know to create knowledge. Integrated projects are and will continue to be essential in the transfer of new agricultural technologies that involve complex biological systems and their associated economic impact related to industry adoption. Furthermore, as research leads to the development of even more sophisticated and complex technologies that fewer people understand or perhaps trust, the need for highly trained professionals that are capable of serving a dual role in research and extension will become even greater. Our approach was to focus on an integrated plan to augment our current understanding of reproductive biology and manipulation of the estrous cycle in the beef heifer, concomitant with the transfer of existing methods that precisely control the time of ovulation relative to fixed-time AI in postpartum beef cows. The specific aims of the project were based on the economic need to improve the competitive position of the US beef industry through an increase in adoption of reproductive procedures that facilitate improvements in reproductive management and adoption of AI. We focused our efforts on integrating the fundamental aspects of control of the estrous cycle in beef cattle with wide-scale application of the technology in the field, both of which are required to enhance competitiveness of the US livestock industry. Justification for this approach centered on the concern that continuation of low adoption rates of these technologies in the US will ultimately erode the competitive position of the US cattle industry. The specific aims of the project facilitated implementation of integrated animal production systems that will contribute to sustainability of beef cattle production and are key to future application of biotechnologies in the beef cattle sector.

Key words: extension, integrated projects, research

43 The role of eXtension in delivering research results to producers and allied industry partners through a national platform. D. M. Amaral-Phillips* and N. L. McGill, *University of Kentucky.*

Today, more than ever, researchers, university instructors, and extension educators need to truly embrace national collaboration to deliver cutting-edge, research-based information and educational programs to our clientele. This collaboration can result in the development and implementation of solutions to problems facing animal agriculture across the United States. eXtension offers the national platform necessary to develop and deliver such integrated programs to these end-users including, but not limited to, producers, allied industry partners, extension and instructional educators, and consumers. Resource materials and educational programs can be delivered via interactive forms such as eXtension's Ask the Expert tool, webinars, live chats, and blogs, or through more classical information delivery systems such as learning lessons, videos, written articles, research summaries, decision aids in the form of spreadsheets, and frequently asked questions. All of these resources are designed to deliver the very best research-based, peer-reviewed information, which is available 24/7 from any internet-ready device. At the current time, resources through eXtension (and supporting communities of practice) are available on animal manure management, beef cattle, dairy cattle, goats, horses, swine, organic farming, and small meat processors, with additional livestock commodities to be added in the future. To learn more about the materials available to the public through eXtension, visit www.extension.org. Each of the commodity groups looks forward to collaborating with research, industry, and educational partners through integrated grants (information can be found at http://about.extension.org) or integrated projects.

Key words: extension, integrated grants, resource materials

44 How can extension use media to connect to and maintain connections and conversations with farmers, ranchers, and producers? J. Blue* and N. Arthur, *Truffle Media Networks, Indianapolis, IN.*

Americans are increasing their use of the internet for news and information. Forty-four percent of Americans say they got news through

one or more internet or mobile digital sources (PEW, 2011). This trend will continue in the foreseeable future. American's use of Facebook and Twitter is also increasing (PEW, 2011), paralleling the digital news consumption. In agriculture, there are numerous groups and individuals using Facebook, Twitter, and LinkedIn. These data provide support for communications plans and actions Extension can develop to connect with their constituents. Extension needs actionable information and resources to address: finding who are producers in the audience, implementing approaches to managing producer / extension connections, locating places on the internet to develop and maintain connections with farmers and ranchers, learning when to stop using one tool and start using another, and discovering what value there is to agriculture and Extension in caring about new, social, and participatory media. In agriculture, more than 80% of large producers are connected with broadband, providing the ability to receive lots of information and make faster decisions. Roughly half the principal farm operators are over 45 years old. Conversely, just under half the principle operators are under 45 years old and their numbers are growing. Digital information means people can read, listen, watch, or participate when they want, where they want, and how they want. For audio and visual media, the number one reason for listening or watching a new media series is flexibility in time. However, new tools are constantly being created to help connect like-minded people to common interests or causes. Three years ago Foursquare, Quora, and Groupon did not exist. Three years ago Twitter and Facebook, combined, had less than 50 million registered users. Saying what will happen with media and communication tools in the next 3 would be very speculative. However, there are approaches for Extension, and others in agriculture, to discover, grow, and maintain connections with farmers and ranchers.

Key words: communication, digital media, new social participatory media

45 Opportunities and challenges associated with the use of technology in extension programming. J. M. Bewley*, *University of Kentucky, Lexington.*

For extension to remain a viable resource for producers in the future, extension educators will need to determine how to best incorporate new technologies into extension programming. Resources such as webinars, social media, online video sharing, blogs, listservs, phone applications, and online document search engines provide new ways to reach extension clientele. In a 2008 survey of Kentucky dairy producers, respondents were asked to identify their preferred delivery method. The most effective delivery methods were printed farm magazines (81.0%), agricultural newspapers (77.4%), printed newsletters from county agricultural agents (75.7%), printed newsletters from university extension (65.0%), and local or regional meetings (55.8%). The least effective delivery methods were university Web sites (11.9%), indirect access through allied industry consultants (11.5%), webinars (2.7%), podcasts (0.4%), and blogs (0.4%). In transitioning to electronic communication methods, it is important to remember that building personal relationships with producers has been an integral part of what has made the Cooperative Extension Service so successful over the past century. People are much more likely to open an email message or attend a webinar if they know the person who is delivering it. Precision Livestock Farming technologies used for physiological and behavioral monitoring of animals also provide an opportunity for extension professionals to demonstrate concepts and conduct applied research projects. For example, Kentucky researchers have used lying behavior monitors as a tool in cow comfort demonstrations and multi-herd research projects. Visual analytic dashboards and spreadsheets can be used to help producers make more informed and economically sound decisions. Lastly, extension professionals can play a critical role in helping producers improve their technical capabilities through training programs for Internet resources, spreadsheet decision making tools, farm-specific software, and Precision Livestock Farming technologies.

Key words: extension, internet, technology

Food Safety Symposium: Safe Food Production: Zoonotic Disease-Control, Responsibility, and Liability

46 Safe food production: Zoonotic disease-control, responsibility, and liability. C. Custer*, *Independent Consultant.*

In the past few decades, the responsibility for food safety has slowly moved from consumers (APHA v. Butz 1974 - "Just cook it") to processors ("Mega Reg") to producers. The "Good News" is that producers are not alone and there are precedents. Dairy products have a long history of quality and safety with proven programs. Animal and plant diseases also have strict controls and those principles can be applied to zoonoses. The Extension Service has also helped farmers and ranchers use science to improve the health and production of crops. In the past 2 decades the Agricultural Research Service and industry associations have given greater focus to "Preharvest" safety. The "Bad News" is that science and technology doesn't always trickle down to the farms, feedlots, and grow out houses. The increase in foodborne outbreaks implicating fruits and vegetables is one example. When STEC are implicated in a produce outbreak, one has to ask, "Were the ruminants up stream, up wind, or in the next field"? Another example is the recent outbreak implicating eggs. Two decades ago, Penn State took the lead when *Salmonella* Enteritidis hit Pennsylvania hatcheries. Extension Service scientists developed control programs that solved the problem. Others adopted those programs but somehow Iowa did not. If there are publicly available control programs and they are not implemented does liability ensue? When does a voluntary program become mandatory to cover one's liability? Where is the line between consumer innocence and responsibility?

47 Fundamentals of foodborne illness litigation – Are you at risk? P. Waller*, *Epidemiologist, Marler Clark Law Firm.*

Each year the Centers for Disease Control and Prevention estimates there are 48 million illnesses, 128,000 hospitalizations, and 3,000 deaths attributable to foodborne illness. Only a small percentage of injured persons pursue legal action as a result of their illness, but it is important for all food-industry players to understand the basis of a legal claim arising out of foodborne illness and injury. The rule of strict liability is the basis behind foodborne illness litigation. Food-industry entities such as growers, processors, and retail establishments can be held liable if the food they produce and serve is unsafe and causes injury. The speaker will discuss the fundamentals of foodborne illness liability such as how liability is determined, the liability process, and why ignorance is a bad defense.

Forages and Pastures: Improving Silage Conservation, Utilization and Performance of Grazing Ruminant

48 Effect of microbial inoculants on the quality and stability of bermudagrass haylage. K. G. Arriola*[1], O. C. M. Queiroz[1], J. J. Romero[1], J. Kivipelto[1], E. N. Muniz[1,2], J. C. Hamie[1], M. A. Zarate[1], L. G. Paranhos[1], and A. T. Adesogan[1], *[1]Department of Animal Sciences, Institute of Food and Agricultural Sciences, University of Florida, Gainesville, [2]Embrapa Tabuleiros Costeiros, Aracaju, SE Brazil.*

The objective was to compare the efficacy of 4 bacterial inoculants at improving the fermentation, and aerobic stability of bermudagrass haylage. Bermudagrass (4-wk regrowth) was harvested, chopped (approximately 2 cm) and treated with 1) deionized water (CON); 2) Buchneri 500 (B500) containing 1×10^5 of *Pediococcus pentosaceus* and 4×10^5 *Lactobacillus buchneri* 40788, 3) Biotal Plus II (BPII) containing $1.2 \times 10^5$of *P. pentosaceus* and *Propionibacteria freudenreichii*; 4) Silage Inoculant II (SI) containing 1×10^5 of *L. plantarum* and *P. pentosaceus* and 5) SiloK (SK), containing 1×10^5 of *L. plantarum*, *Enterococcus faecium*, and *P. pentosaceus*, respectively. Four replicate round bales (441 ± 26 kg) per treatment were wrapped with 7 layers of plastic and stored for 112 d. Four additional bales per treatment were prepared and analyzed for pH after 3, 7 and 30 d of ensiling. The experiment had a completely randomized design and data were analyzed with Proc Mixed of SAS. The pH of Control and inoculated d 3 silages was similar ($P > 0.05$) but B500 had lower pH than SK by d 3, and B500 and BPII had lower pH ($P < 0.001$; 5.79 ± 0.07 vs. 6.16 ± 0.07; 5.02 ± 0.23 vs. 5.69 ± 0.23, respectively) than other treatments by d 7 and 30. Treatments B500, BPII, and SI had lower pH than the Control ($P = 0.003$; 4.76 ± 0.16 vs. 5.2 ± 0.16) after 112 d but SK had similar pH to other treatments. No difference ($P > 0.05$) was found among treatments in NDF digestibility, DM losses, DM, lactic and acetic acid concentrations, and yeast and coliform counts. Other VFA were not detected. Treatments B500, BPII, SI, and SK improved ($P < 0.001$) aerobic stability by 195%, 161%, 162%, and 75%, respectively compared with the Control (273 ± 36 vs. 110 ± 36 h). Treatment B500 and SI had lower mold counts than other treatments ($P = 0.02$; 2.19 ± 1.01 vs. 3.68 ± 1.01 cfu/g), while SK had lower clostridia counts than the Control ($P = 0.02$; 1.15 ± 0.43 vs. 2.42 ± 0.43 cfu/g). All treatments improved the fermentation and aerobic stability of bermudagrass haylage to varying extents.

Key words: bermudagrass, haylage, inoculants

49 The impact of aerobic deterioration of corn silage on feed intake by goats. K. Gerlach*, F. Roß, W. Büscher, and K.-H. Südekum, *University of Bonn, Bonn, Germany.*

This study evaluated the impact of aerobic deterioration of corn silage on feed intake. Corn was harvested at 2 stages of maturity in October 2009 and chopped. Eight whole-crop corn silages were produced differing in dry matter (DM) content (34% and 40%), chopping length (10 mm and 21 mm) and packing density in the silo (high, 275 kg DM/m^3; low, 256 kg TM/m^3). Each factor combination, i.e., treatment, was ensiled in 6 110-L plastic tons for at least 3 mo. At the day of silo opening (d 0) and then at 2-d intervals (d 2, 4, 6, and 8) the following measurements were conducted: temperature, sensory evaluation, chemical composition and microbiological testing. For use in preference trials, samples of silages were taken and stored anaerobically in evacuated and vacuum-sealed polyethylene bags. Eight preference trials with goats (n = 6) were conducted, each one lasting 21 days. Each possible pair of the five silages (days 0, 2, 4, 6, and 8) and one standard alfalfa hay (n = 15 pairs), were offered for 3 hours in the morning. Data were analyzed by analysis of variance and multidimensional scaling (MDS), which was used to develop a spatial arrangement representing the differences expressed as selective forage intake by the animals. For most treatments, the animals showed a strong preference for silages from days 0, 2 and 4 and avoided silages exposed to air for 6 and 8 days ($P < 0.05$). Analysis of variance was conducted after averaging silage intake across all pairs by each animal. During 3 h, average intake for silages from day 0 ranged from 580 to 723 g DM per goat, while the average intake of day 8 silage was between 136 and 464 g DM. Using the Waller-Duncan k-ratio t-test, the minimum significant difference (ranging from 82 g to 128 g DM, $P < 0.05$) was calculated for each treatment. Average DM intake (DMI) by goats (y) was linearly related to silage temperature at the different days of aerobic storage (x, expressed as the difference to ambient temperature): $y = 662.61 - 11.669$ x; $R^2 = 0.6808$; $P < 0.0001$. This study demonstrated the negative impact of aerobically deteriorated silage on preference and DMI by goats.

Key words: aerobic deterioration, corn silage, preference trial

50 Caloric content of brown midrib sorghum silage harvested at two maturities, fed with concentrate at two levels of intake using in vivo, in vitro and prediction equation methods as related to rumen fermentation and fractional passage. J. Lim, M. A. Froetschel*, and L. O. Ely, *The University of Georgia, Athens.*

Four rumen fistulated Holstein yearling steers, were fed brown midrib (BMR) forage sorghum (*Sorghum bicolor* (L.) Moench) harvested at 2 maturities (earlier maturity (EM), flowering stage or later maturity (LM), milk to soft dough stage), in total mixed rations (TMR), 60% BMR sorghum silage (% DM) and were fed at 2 levels of intake (~1.5x maintenance or free access for 5 h/d), to compare methods of estimating digestible energy (DE) as related to rumen fermentation and fractional passage of particulate. A 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments was used. The concentrate consisted mainly of corn and soybean meal with chromic oxide as a digestibility marker. Periods were 14 d, 7 d to adapt and 7d for data collection. Daily DMI was measured, feed and fecal samples were collected at incremental 12 h intervals from d 8 to 13. On d 14, rumen contents of steers were evacuated 5, 11, 17 and 23 h after feeding, weighed, sampled for nutrient analysis and returned. Ruminal fluid was collected for ammonia and volatile fatty acid analysis (VFA). The EM silage had less grain development and more NDF (60.7 VS 56.7 ± 0.74), ADF (33.3 VS 31.8 ± 0.41) but lower ADL (4.11 VS 5.12 ± 0.25) and ash (7.16 VS 6.18 ± 0.45) than the LM silage. Apparent DE, and DM digestibility (DMD) were not influenced by BMR maturity or intake. Fractional disappearance rate (FDR) of ruminal DM, NDF, NDS, OM and ash were not influenced by BMR maturity but increased in steers fed at higher intake ($P \leq 0.01$). Apparent DE, DMD and FDR of ruminal DM, NDF, NDS, OM and ash were not influenced by BMR maturity ($P \geq 0.05$). The DE predicted using NRC method correlated with in vitro DE ($y = 0.684x+.838$; $r^2 = 0.82$, $P \leq 0.01$) but not apparent DE. Rumen NH3 was higher at lower intakes and VFA were higher at greater intakes ($P \leq 0.01$). In vitro DE appears to be as accurate as the NRC prediction method to assess caloric content of a 60% BMR (DM%) TMR. DE content of total mixed rations with 60%

BMR sorghum (% DM) as a basal forage was minimally influenced forage maturity.

Key words: forage quality, digestible energy, in vitro

51 Intake and digestibility in steers fed sugarcane ensiled with different levels of calcium oxide. F. H. M. Chizzotti*[1], O. G. Pereira[2], S. C. Valadares Filho[2], M. L. Chizzotti[1], and R. T. S. Rodrigues[3], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [3]Universidade Federal do Vale do São Francisco, Petrolina, PE, Brazil.*

A trial was conducted to evaluate the effects of calcium oxide levels (CO) as additive for sugarcane silage on intake and nutrient digestibility. Thirty-five crossbred steers (Holstein x Nellore), averaging 350 ± 18.3 kg BW, distributed in 7 randomized blocks were used. Diets consisted of 50% roughage and 50% concentrate, formulated to be isonitrogenous (12% CP, DM basis). The 5 treatments consisted of sugarcane ensiled with 4 CO levels (0, 0.5, 1.0, and 1.5%, as fed basis) and a standard diet with corn silage. The experiment lasted 99 d. DMI was measured daily and individually. Indigestible ADF was used as an internal marker to estimate apparent nutrient digestibility and fecal output. A mixed model with random effect of blocks was used. There was a quadratic positive effect ($P < 0.05$) of levels of CO on OM, NDF, non-fiber carbohydrates (NFC) and TDN intakes. The highest TDN intake (6.17 kg) was observed at 0.5% of CO in sugarcane silage. The TDN intake of corn silage diet was similar to TDN intake of diet with 0.5% of CO. There were positive linear effects ($P < 0.05$) of CO levels on apparent total digestibility of DM, OM, CP, NDF and % of TDN of the diets. There was no difference ($P > 0.05$) of DM, OM, and NDF digestibilities of sugarcane silage with CO and corn silage. The addition of calcium oxide (up to 1.5%) in silage improves sugarcane silage quality, increasing apparent digestibility of DM, OM, CP and NDF. However, the TDN intake decreased for CO levels above 0.5% which may decrease animal performance. Sponsored by CNPq/INCT-CA and Fapemig, Brazil.

Key words: additive, feedlot, roughage supplementation

52 Effects of co-grazing dairy heifers with goats on animal performance, pasture composition, and dry matter yield. T. S. Dennis*, M. K. Neary, L. J. Unruh-Snyder, J. E. Tower, and T. D. Nennich, *Purdue University, West Lafayette, IN.*

Various pasture management systems, such as co-grazing, may offer alternative methods for rearing dairy heifers. The objective of this study was to determine the effects of co-grazing dairy heifers with goats on animal performance, pasture composition, and forage DM yield. Twenty-four Holstein heifers (BW = 168.0 ± 1.7 kg) and 6 Boer x Kiko goats (BW = 33.7 ± 0.9 kg) were allocated to 6 paddocks and used to evaluate 2 grazing strategies (heifers grazed alone (HO) or heifers co-grazed with goats (HG)). Additionally, 6 goats were randomly assigned to 2 paddocks and grazed alone to compare parasitism between grazing strategies. Heifers were weighed biweekly and measured monthly for body condition score, hip and withers heights, and heart girth. Blood samples were collected monthly from heifers to measure plasma urea nitrogen (PUN) and glucose. Fecal egg counts (FEC), FAMACHA scores, and PUN were measured monthly in goats. Forage heights before and after grazing were measured to calculate pasture DMI. Pasture samples were collected monthly by manually harvesting forage and photographs were taken to visually estimate composition. Data were analyzed by paddock as repeated records using PROC MIXED of SAS. Total and pasture DMI were greater for HO than HG heifers ($P < 0.01$); however, ADG and feed efficiency were similar between grazing strategies. Final hip and withers heights were greater for HO heifers ($P < 0.01$). Heifer PUN concentrations tended to be greater for HG heifers at 8 wks ($P < 0.10$), and blood glucose concentrations tended to be less for HG heifers over the entire study ($P < 0.10$). Overall FEC, FAMACHA scores, and PUN concentrations were also similar between grazing strategies for goats. Grass and total DM yield tended ($P < 0.10$) to be greater in HO pastures compared with HG pastures after 2 rotations. Using visual estimation, HO pastures had 3.5 times greater weed presence than HG pastures ($P < 0.05$) at the conclusion of the study. In summary, co-grazing did not affect weight gains or feed efficiency of heifers, indicating that dairy heifers can be successfully co-grazed with other livestock species.

Key words: dairy heifer, goat, grazing

53 Forage mineral concentrations and mineral status of beef cattle grazing cool season pastures in northwestern Florida, emphasizing magnesium. J. N. Carter[2], L. R. McDowell*[1], R. O. Myer[2], M. K. Maddox[2], and M. Brennan[2], *[1]University of Florida, Gainesville, [2]University of Florida, Marianna.*

This study evaluated mineral status (particularly Mg) of grazing beef cows (42 Angus, Brangus and Romosinuano crosses in early lactation) on annual ryegrass (*Lolium multiflorum* 'Rio') or oat pastures (*Avena sativa* 'Horizon 474'). The fertilizer used on the oat and ryegrass pastures was 355 kg of 3–7-28 at time of planting per ha. Forage, blood and urine were collected every 2 weeks, while liver biopsies were taken on d 68. From urine was determined creatinine-corrected urine (CCU), Mg and K and fractional clearance ratio (FCR) for Mg. Mineral data for blood, urine and forage samples were analyzed as a completely randomized design with repeated measures over time. Forage mineral concentrations of P, K, Na, Fe, Mn and Mo were normally greater than critical levels for beef cattle, while Mg (<0.20%), Ca (<0.30%), Cu (<10ppm), Co (<0.10ppm), Zn (<30ppm) and Se (<0.10ppm) were at deficient levels. In general ryegrass had greater concentrations of Ca, Mg, P, K, Cu, Mn and Zn than oats. As examples Ca, P and Cu were higher ($P < 0.05$) for 3 collection dates in ryegrass than oats. All plasma mineral levels were greater than critical levels, but plasma Mg was borderline to slightly deficient, (<2.0 mL%). Cows grazing oats had the lowest plasma Mg. There were no difference in liver Cu, Fe, Mn and Se between forage treatment types ($P > 0.05$). The FCR for oats was less than the critical recommended level of 10%, which indicates Mg deficiency, until d 41. However, ryegrass treatment had greater FCR values for all collection days except d 1. Except for d 55, CCU Mg for oats treatment was less than 1.0 mmol/L throughout the trial, the level at which cattle generally respond to Mg supplementation. The ryegrass treatment had higher values than for all oat treatment values; except at d 1. In conclusion higher mineral concentrations are found in ryegrass versus oats. Special attention should be given to Mg supplementation because forages are deficient and contain excess K.

Key words: oats, ryegrass, mineral status

54 In vitro rumen fluid digestion activity of grazing cows as related to productivity and days postpartum. E. G. Tesfaye, M. A. Froetschel*, L. O. Ely, N. S. Hill, and M. J. Mathis, *The University of Georgia, Athens.*

In vitro rumen fluid digestion activity and indigestible fecal NDF were measured in 10 multiparous Angus cows averaging 8 ± 3 years of age, with ≥5 calves from a pure-bred herd (104 cows). Five cows with the lowest and 5 cows with the highest life-time weaning weight ratio (WWR) records (lowest = 6% below herd average; highest = 9.4% above herd average) were selected using breed association data. The cows, were managed with the herd, grazing permanent pasture of primarily Tall Fescue or Bermuda grass depending on seasonality. Rumen fluid was collected by stomach tube from each cow at 3 dates (March 14th, June 25th, and September 23rd, 2008) averaging 64, 167 and 257 d postpartum and used for in vitro incubations. Data was analyzed according to cow productivity and date of sampling in a 2 × 3 factorial designed experiment. Two stage incubations were conducted for 24 and 48 h, in quadruplicate, using a modified Tilley and Terry procedure. A composite sample of mixed pasture grass, collected the previous year (68.7% NDF and 12.1% CP) was used as substrate. In vitro DM and NDF digestion (IVDMD and IVNDFD) were determined as differences in DM and NDF of particulate. Volatile fatty acid (VFA) and soluble protein (SP) production (μ moles/24 or 48 h) were determined from differences in VFA and SP during the time of the incubations (24 and 48 h). Rumen fluid from cows, selected for productivity as based on WWR did not impact IVDMD, IVNDFD and IVSP production ($P \geq 0.05$). The acetate to propionate ratio (A/P) was 6.9% lower in rumen fluid from more productive cows. In vitro propionate and butyrate production (μ moles/24 h) were 9.8 and 16.7% greater and A/P was 9.8 % lower with rumen fluid from more productive cows ($P \leq 0.05$). IVDMD was 9.6% greater with rumen fluid sampled 167 and 257 d post- partum ($P \leq 0.01$). Potentially digestible NDF tended to be lower (29% vs. 33%) in feces from higher productivity cows ($P \leq 0.13$). In vitro rumen fluid digestion activity and fecal parameters were influenced by cow productivity and sampling time postpartum.

Key words: in vitro, cow performance, digestion

55 Forage characteristics and animal performance of beef heifers grazing ′Mulato II′ brachiariagrass in North-Central Florida. J. M. B. Vendramini*[1], G. C. Lamb[2], L. E. Sollenberger[3], J. L. Foster[4], and M. Maddox[2], *[1]UF/IFAS Range Cattle Research and Education Center, Ona, [2]UF/IFAS North Florida Research and Education Center, Marianna, [3]Agronomy Department, Gainesville, FL, [4]Texas Agrilife Research and Education Center, Beeville.*

Mulato II (*Brachiaria* sp.) is a warm-season grass adapted to tropical regions and it has superior nutritive value when compared with other warm-season grasses. The objective of this study was to compare forage production, nutritive value, and animal performance of beef heifers grazing Mulato II, pearl millet (*Pennisetum glaucum* 'Tifleaf 3'), or sorghum-sudangrass (*Sorghum bicolor* 'Hay Day') pastures. The study was conducted in Marianna, Florida (30.7° N) from June to August 2008 and June to September 2009 in a completely randomized design with 3 replicates. Pastures (0.6 ha) were sampled to determine herbage mass (HM), crude protein, and in vitro organic matter digestion (IVODM) every 14 d. Pastures were continuously stocked using a variable stocking rate with 2 testers per pasture [heifers; 426 ± 40 kg initial body weight (BW)]. Additional animals were added to maintain similar stubble height, 30 cm. The data was analyzed using PROC MIXED, by year, with treatment as fixed effect and replicates as random effect. The data was analyzed by year due to the different experimental periods within year. Single degree of freedom contrasts were used to detect difference among treatments. In 2008, there was no difference ($P > 0.10$) in HM (1600 ± 300 kg/ha), IVDOM (62 ± 1 %), CP (18 ± 0.5 %), herbage allowance (HA, 0.9 ± 0.1 kg DM/kg BW), and ADG (0.5 ± 0.05 kg/d) among treatments. Gain per ha was greater ($P = 0.08$, SE = 20) for sorghum-sudangrass (240 kg) than pearl millet (168 kg) and Mulato II (130 kg). In 2009, despite the use of ′put and take′ animals, Mulato II had greater HM ($P < 0.01$, SE = 0.3; 3000 vs. 1500 kg/ha), HA ($P = 0.02$, SE = 0.1; 2.0 vs. 0.8 kg DM/kg BW), IVDOM ($P = 0.06$, SE = 0.1; 65 vs. 59%), and ADG ($P = 0.02$, SE = 0.08; 0.7 vs. 0.4 kg/d) than pearl millet and sorghum-sudangrass. There was no difference in CP concentration ($P > 0.10$; 20 ± 0.4 %) and gain per ha ($P > 0.10$; 302 ± 28 kg) among treatments. Mulato II may be a feasible option as a warm-season annual grass in North Florida for beef cattle.

Key words: Mulato II, pearl millet, sorghum

56 Bermudagrass–legume forage systems for summer stockers. B. M. Nichols[1], C. A. Moffet[1], J. T. Biermacher[1], T. J. Butler[1], R. R. Reuter[1], J. K. Rogers[1], J. A. Guretzky[2], and J. R. Blanton Jr.*[1], *[1]The Samuel Roberts Noble Foundation, Ardmore, OK, [2]University of Nebraska, Lincoln.*

Stocker cattle grazing warm season perennial grasses is an important agricultural enterprise in the Southern Great Plains. Increases in the price of nitrogen fertilizer (N) lead to questions of whether or not alternate grazing systems including the use of legumes differ from the conventional practice of N fertilization. The objective of this study was to determine the effects of interseeding legumes in bermudagrass on performance of stocker cattle compared with N fertilization. Research was initiated in the fall of 2007 at The Noble Foundation Pasture Demonstration Farm on Midland bermudagrass stands established in 1965 near Ardmore, OK and continued for a 3-yr period. Treatments were applied to pastures (1.29 ± 0.11-ha) in a CRD with 3 replications that included 1) N- fertilized bermudagrass (112 kg/ha; control); 2) 18 kg pure live seed (PLS)/ha "Bulldog 505" alfalfa interseeded into bermudagrass (BG+A); and 3) 14.4 kg PLS/ha "AU early cover" hairy vetch, 9 kg PLS/ha "Dixie" crimson clover, and 6 kg PLS/ha "Apache" arrowleaf clover interseeded into bermudagrass (BG+L). The paddocks were stocked with 4 steers in 2008 (3.21 ± 0.30 steers/ha; initial BW = 221 ± 15.9 kg) and 3 steers in 2009 and 2010 (2.35 ± 0.22 steers/ha) with initial BW of 254 ± 5.1 and 321 ± 11.6 kg, respectively. Paddocks were initially stocked to provide 1.15 kg forage per kg animal BW. Grazing days per hectare, ADG, and BW gain per hectare were analyzed by ANOVA with year and paddock considered random. Means were compared using the PDIFF function of SAS. Grazing days did not differ ($P = 0.14$) between control, BG+L, and BG+A (244, 184, and 221 ± 20.4 d/ha, respectively). Average daily gain was not significantly different ($P = 0.92$) between control, BG+L, and BG+A (0.77, 0.78, and 0.74 ± 0.06 kg/d, respectively); and BW gain per hectare was also not different among forage systems ($P = 0.15$; 199, 151, and 148 ± 19.7 kg/ha, respectively). Overall, interseeding bermudagrass pastures with legumes has the potential to decrease the need for producers to employ costly N inputs while maintaining similar animal performance.

Key words: stocker cattle, grazing systems, legumes

57 Stocker production systems utilizing warm-season perennial grass pasture: Cattle performance and nitrogen use efficiency. B. W. Wallis*, P. A. Lancaster, E. D. Sharman, D. B. Arnall, J. G. Warren, T. E. Ochsner, S. R. Lancaster, and G. W. Horn, *Oklahoma Agricultural Experiment Station, Stillwater.*

In grazing systems only 5–10% of ingested nitrogen (N) is retained in BW gain of growing beef cattle. The objective of this study was to evaluate the effects of levels of N fertilizer and source of N for growing beef cattle on N use efficiency of stocker cattle grazing systems using warm-season perennial grass pastures. Mixed-breed heifers (n = 235; 274 ± 33 kg) grazed Plains Old World bluestem pastures (3 pastures/system) in a completely randomized design (Proc GLM of SAS) comparing 4 summer grazing systems: (1) non-fertilized, low stocked (336 kg of BW/ha) pastures (CONT); (2) N fertilized (90 kg N/ha), high stocked (672 kg of BW/ha) pastures (NFERT); (3) N and phosphorus (P) fertilized (39 kg P/ha), high stocked pastures (NPFERT); and (4) non-fertilized, high stocked pastures plus supplementation of dried distillers grains with solubles (DDGS; 0.75% BW•hd^{-1}•d^{-1}). Heifers grazed for 135 d from May 18 to Sept. 28, 2010. Heifers grazing non-DDGS supplemented pastures were fed a protein supplement (0.45 kg•hd^{-1}•d^{-1}) beginning on d 66 to meet the DIP requirement of heifers grazing late-summer forage. Gain per hectare (kg/ha) was greatest for treatment 4 and least for treatment 1 (Table 1). N recovery (%) was greatest for treatment 1 due to low N inputs. However, replacing N fertilizer with DDGS supplementation improved N recovery 2.00 and 1.95-fold compared with treatments 2 and 3, respectively. These data indicate that DDGS can be effectively used to replace N fertilizer in stocker cattle grazing systems to increase stocking rates, increase BW gain/ha, and increase N use efficiency of the production system.

Table 1. Cattle performance and nitrogen use efficiency of stocker grazing systems

Item	CONT	NFERT	NPFERT	DDGS	SEM
Gain, kg/heifer	128[a]	114[b]	117[b]	136[a]	3.54
Gain, kg/ha	162[a]	284[b]	291[b]	344[c]	7.17
N inputs, kg/ha	8.0[a]	99.6[b]	99.8[b]	38.2[c]	0.26
N retention[1], kg/ha	3.4[a]	6.2[b]	6.3[b]	7.1[c]	0.12
N recovery, %	42.6[a]	6.2[b]	6.3[b]	18.6[c]	0.75

[1]Calculated as N in BW gain of heifers using NRC (1996) equations. [a,b,c]Within a row, means without a common superscript letter differ ($P < 0.01$).

58 Effect of protein supplementation on intake and digestion of three bermudagrass hays of divergent quality by beef cattle. C. P. Payne*, T. M. Warnock III, J. E. Sawyer, and T. A. Wickersham, *Texas A&M University, College Station.*

Quality of bermudagrass (*Cynodon dactylon*) varies in response to management and environmental factors. Supplementation decisions are complicated by this variability. Therefore, our objective was to determine the effect of 4 protein supplementation levels (0, 82, 119 and 155 mg N/kg BW) on the utilization of 3 bermudagrass hays (5.6, 6.3, and 8.1% CP). Thirteen ruminally fistulated Angus × Hereford steers (BW = 330 ± 19 kg) were used in a 13 × 4 incomplete Latin square with 13 treatments and 4 periods. Treatments were arranged as a 3 × 4 factorial plus a control bermudagrass hay (10.8% CP). Hay was provided ad libitum and protein supplements were offered as range cubes once daily. Periods were 15-d long with intake determinations made on d 10 through d 13 to correspond with fecal grab samples collected from d 11 through d 14. Acid detergent insoluble ash was used as an internal marker of fecal output. Eleven contrasts were used to separate treatment means. Hay OM intake in unsupplemented steers increased quadratic ($P = 0.05$) from 75 to 77, 96 and 94 g/kg BW$^{0.75}$ as hay CP content increased from 5.6 to 6.3, 8.1 and 10.8% CP hays, respectively. There was a linear increase ($P < 0.01$) in total digestible OM intake in response to hay nutritive value from 35 to 45, 51, and 60 g/kg BW$^{0.75}$ for 5.6, 6.3, 8.1, and 10.8% CP hays, respectively. A significant ($P = 0.04$) supplemental × hay CP content interaction was observed for forage OM intake and total OM intake. Forage OM intake of the 6.3% CP hay tended to increase linearly with supplemental protein ($P = 0.08$). Total OM intake increased linearly ($P < 0.01$) when CP was supplemented to the 6.3% CP hay from 77 to 88, 92, and 98 g/kg BW$^{0.75}$ for 0, 82, 119, and 155 mg N/kg BW, respectively. No supplement × hay CP interaction was apparent ($P > 0.10$) for total digestible OM intake; however, supplemental protein tended to increase total digestible OM intake (linear, $P = 0.07$) We conclude that forage quality was the primary driver in determining total digestible OM intake, and the effect of protein supplementation was dependent on forage digestibility and protein content.

Key words: bermudagrass, supplementation, cattle

59 Effect of level and frequency of protein supplementation on utilization of South Texas grass hay. G. R. Monson[1], J. E. Sawyer[1], R. O. Dittmar III[1], M. L. Drewery[1], C. P. Payne[1], K. C. McCuistion[2], and T. A. Wickersham*[1], *[1]Texas A&M University, College Station, [2]Texas A&M University-Kingsville, Kingsville.*

Reducing frequency of supplementation may effectively reduce costs of delivery; however, little research has evaluated the level of supplemental protein required with infrequent supplementation. Our objective was to quantify forage utilization when graded levels of protein were delivered infrequently. Five ruminally cannulated Angus × Hereford steers (BW = 410 ± 43 kg) were used in a 5 × 4 incomplete Latin square. Steers were provided ad libitum access to grass hay (2.3 % CP, 81.8% NDF). Supplemental protein, provided as a range cube (40.7% CP), was fed at 0645h to provide a specified level of N (0, 160, 320, or 480 mg of N/kg BW) daily (/d) or every third day (/3d), resulting in the following treatment combinations: 0/d, 160/d, 160/3d, 320/3d, and 480/3d. Experimental periods were 18 d long. Forage intake was determined from d 10 through 15 to correspond with fecal grab samples collected from d 11 to d 16. Acid detergent insoluble ash was used as an internal marker to estimate fecal output. On d 16 to d 18 of each period ruminal fermentation profiles were evaluated. Hay OM intake was 4.41, 6.18, 5.46, 6.10, and 6.27 kg/d for 0/d, 160/d, 160/3d, 320/3d, and 480/3d. Intake increased linearly ($P < 0.01$) with increasing protein per 3 d, but the 160/d rate did not differ from 160/3d, 320/3d, and 480/3d ($P > 0.05$) provision. Total OM intake responded in a similar fashion, but was lower for 160/3d than 160/d ($P < 0.05$; 7.08 and 5.83 kg/d, respectively). Total digestible OM intake increased quadratically ($P = 0.06$) with increasing protein provision per 3 d (2.02, 2.82, 3.59, and 3.34 kg/d for 0/d, 160/3d, 320/3d, and 480/3d, respectively). When protein was provided at 160/d, total digestible OM intake was 3.30 kg/d, which did not differ from any treatment receiving supplement. There were no significant effects ($P > 0.05$) on digestibility. Reduced levels of protein supplemented infrequently may be an effective means of capturing additional cost savings.

Key words: frequency, protein, cattle

Graduate Student Competition: ADSA Dairy Foods Oral Competition

60 Effect of salt replacers and flavor enhancers to reduce sodium in Cheddar cheese on aging and sensory properties. J. E. Grummer* and T. C. Schoenfuss, *University of Minnesota, Department of Food Science and Nutrition, St. Paul.*

The objective of this study was to produce 60% reduced sodium Cheddar cheese by using salt replacers and flavor enhancers and investigate the effects on aging and sensory properties. Replacement salts were added at levels to create the same water activity as control. Treatments were KCl only, KCl and one of 4 different flavor enhancers or masking agents (hydrolyzed vegetable protein/yeast extract, a bitter blocker, disodium inosinate (IMP) and disodium guanylate (GMP)), and modified KCl only. In duplicate, salt and salt replacer treatments were applied to create 2 different salt-to-moisture ratios (S/M). Target sodium content was 600 mg/100 g cheese for control and 240 mg/100 g cheese for all reduced-sodium cheeses. In reduced sodium cheeses, KCl was applied at 2.45 times the rate of NaCl (wt./wt.) for the high S/M and 2.16 times for the low S/M. Descriptive sensory analysis was conducted by a trained panel over 4 mo of aging in a replicated Latin square design and analyzed by SAS (SAS Institute, Inc., Cary, NC) software. Gross composition and mineral content (sodium, potassium, magnesium, calcium) were determined, and monthly tests conducted during 4 mo of aging (moisture, pH, water activity, water soluble nitrogen, texture profile analysis, and lactic acid bacteria (LAB) counts). Data was analyzed by XLSTAT (Addinsoft; New York, NY) software using 2-way ANOVA with repeated measures. Umami was higher in cheeses with IMP and GMP. Sulfur and sour dairy notes were higher in reduced-sodium cheeses. Sensory differences were observed between the 2 salt-to-moisture ratios, but the number of significant differences declined during aging. Despite similar moisture levels and water activity between reduced sodium and control cheese, differences in pH, LAB and texture were observed indicating that KCl may not have the same effect on reactions as salt. However, sensory analysis showed that salty, bitter and metallic flavors were not significantly different in reduced-sodium cheeses compared with control.

Key words: Cheddar cheese, sodium reduction, salt replacers

61 The influence of NaCl reduction on the properties of cheddar cheese where moisture contents were kept constant. K. V. Grant*[1], S. Govindasamy-Lucey[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[1], *[1]University of Wisconsin, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

In producing an acceptable reduced NaCl cheese, it is important to have a good understanding of the effects of reducing NaCl on various cheese properties. We previously studied the properties of Cheddar cheese made with reduced and low NaCl levels without altering the cheese make procedure; which resulted in differences in moisture contents. The objective of this study was to investigate the impact of NaCl reduction on cheese properties independent of moisture content. Duplicate trials were conducted resulting in Cheddar cheese with 3 NaCl levels: normal (~1.7%), reduced (~1.2%), and low (~0.7%). Moisture contents (at 3 wk) and pH (at 4 d) were: 36.7% and 5.01, 37.3% and 5.02, and 38.0% and 5.00, in normal, reduced, and low NaCl cheeses, respectively. Different manufacturing procedures (ripening time, curd size, and salting wait times) were used to correct for the moisture contents. Cheeses were analyzed at 4 d, 3 wk, 5 wk, 3 and 6 mo.

Key words: NaCl reduction, Cheddar

62 Concentration of casein micelles: Changes in renneting functionality in the presence of sodium caseinate. P. Krishnankutty Nair*[1,2] and M. Corredig[1], *[1]Department of Food Science, University of Guelph, Guelph, Ont., Canada, [2]Department of Dairy Development, Government of Kerala, India.*

The changes in processing functionality of concentrated milk are caused by several factors, among the most important, the ionic equilibrium and the increase in the interactions between the casein micelles because of their increased volume fraction. This work reports the use of osmotic stressing as a noninvasive method to study concentrated milk, to preserve the ionic balance while reaching very high levels of protein concentration. Objective of the research was to observe the changes in the renneting functionality of casein micelles in the presence of sodium caseinate added either before or after concentration. Protein levels of about 10% were obtained by osmotic concentration for 18h at 4°C, using poly ethylene glycol in permeate. Untreated skim milk with sodium caseinate at 0.2% was concentrated using osmotic stressing. Alternatively, sodium caseinate was added at a similar ratio after concentration. The formation of the rennet-induced gel was followed using rheology and diffusive wave spectroscopy. The amount of soluble casein was quantified using ion exchange chromatography. All experiments were done in triplicate. After 45 min of gelation, the G' were 505 ± 56, 382 ± 41 and 5 ± 5 Pa for control, sodium caseinate added before and after respectively. Similarly, turbidity parameter was 7.26 ± 0.24, 6.21 ± 0.29 and 4.9 ± 0.14 mm^{-1} and self diffusion coefficient was 1.34×10^{-14}, 7.89×10^{-14} and 2.76×10^{-13} m^2s^{-1} observed for control, sodium caseinate added before and after respectively. Analysis of the supernatants confirmed a 10% increase in the area of caseins in samples where the sodium caseinate was added after concentration. Interestingly, the soluble casein added before concentration seemed to re-gain renneting functionality, perhaps because of a higher incorporation in the casein micelles during concentration. This research brings new insights on the rearrangements that may occur to casein micelles during concentration, with important consequences for a better understanding of membrane filtration processes and for the use of casein micelles as functional delivery systems.

Key words: casein micelles, sodium caseinate, renneting

63 Impact of transglutaminase on the functionality of micellar casein concentrate in process cheese product applications. P. Salunke* and L. E. Metzger, *Midwest Dairy Foods Research Centre, South Dakota State University, Brookings.*

Microfiltration (MF) is used for producing micellar casein concentrate (MCC) from skim milk. MCC is an ingredient that has been evaluated in process cheese product (PCP) manufacture. However, MCC provides inferior functionality relative to rennet casein. A potential method to modify the functional properties of milk proteins is to crosslink them utilizing tranglutaminase (TGase, EC 2.3.2.13). The objective of the study was to evaluate the impact of TGase on the functionality of MCC when used in PCP applications. In this study the impact of TGase (Ajinomoto Food Ingredients LLC, Chicago, IL, 100U activity/g) treatment of skim milk before MF as well as TGase treatment after MF was evaluated. Three treatments were utilized and included: TGase treatment (7U/g of protein) before MF (T1); TGase

treatment (7U/g of protein) after MF (T2); and a control. After addition of TGase each of the samples was incubated for 20 min at 50°C, then heated to 70°C and held for 10 min. MF was performed at 20°C using a laboratory scale tangential flow MF system (NCSRT Inc., Apex, NC). A volume concentration factor of 6.2 with diafiltration of 100% of the original skim milk volume was utilized. The experiment was replicated 3 times using 3 different lots of skim milk. After MF each treatment was freeze-dried and subsequently utilized as an ingredient in PCP manufacture. The PCP was formulated to have moisture, fat, salt and protein of 44.0, 25.0, 1.8, and 18.25%, respectively. The ingredients in each formulation were mixed in a Kitchen Aid and PCP was produced using a Rapid Visco Analyzer (RVA). The PCP was analyzed for pH, RVA-Viscosity, Texture profile analysis (TPA) and Dynamic stress rheology. The RVA-Viscosity and TPA-Hardness of PCP made from the TGase treatments was significantly ($P < 0.05$) higher than the control. Additionally the G′, G″, G* and transition temperature of PCP produced from T2 were significantly ($P < 0.05$) higher than T1 and the control. This study demonstrated that TGase treatment modifies the functional properties of MCC when used as an ingredient in PCP.

Key words: transglutaminase, micellar casein concentrate, process cheese product

64 Production of a high concentration liquid micellar casein concentrate (18% protein) with a long refrigerated shelf-life. I. Amelia* and D. M. Barbano, *Cornell University, Ithaca, NY.*

Our objective was to develop a multistage process to produce a high concentration liquid micellar casein concentrate (18% protein-MCC18) with a long refrigerated shelf-life. MCC is a novel milk protein ingredient produced by fractionating skim milk using the filtration technology. To have a long refrigerated shelf-life, the processing of MCC18 was designed to maximize the removal of low molecular weight compounds, e.g., lactose, nonprotein nitrogen (NPN) which can be easily metabolized by microbes for nutrient sources, while minimizing the microbial count in the final product. The production of MCC18 was done over a period of 5 d. The experiment was replicated 3 times with a different batch of raw milk. The raw milk was pasteurized, and skim milk was produced. Skim milk was ultrafiltered to remove more than a half of the lactose and NPN. The UF milk retentate was diluted with RO water and then microfiltered in 4 stages (including 3 stages of diafiltration) to remove approximately 95% of the serum protein and further remove lactose and NPN. The retentate from the last stage of MF was ultrafiltered to concentrate the protein to 18% and batch pasteurized. The final MCC18 contained 18.04% true protein, 0.31% NPN and 0.13% lactose. MCC18 was collected immediately after processing in sterile plastic vials and stored at 4°C. MCC18 at the day of processing contained 100 cfu/mL, 84 cfu/mL, and 190 cfu/mL of total aerobic bacteria and 360 cfu/mL, 62 cfu/mL, and 440 cfu/mL of total spores for replicate 1, 2, and 3, respectively, using the 3M Petrifilm Aerobic Count method. MCC18 was analyzed for the total aerobic bacteria count each week for the 16-week shelf-life at 4°C. The bacterial count didn't change significantly with time (week), however the effect of replicate was significant, as analyzed using the PROC GLM of SAS. The production of MCC could be used to balance excess skim milk supply by concentrating the valuable casein portion, and storing it at refrigeration temperature. This strategy avoids the cost of hauling excess skim milk to a drying plant and the high energy cost of evaporation and drying.

Key words: micellar casein, microfiltration, shelf-life

65 Serum protein removal from skim milk with a 3-stage, 3X ceramic Isoflux membrane process at 50°C. M. Adams* and D. M. Barbano, *Cornell University, Ithaca, NY.*

Our objective was to quantify the capacity of 0.14 μm ceramic Isoflux microfiltration (MF) membranes to remove serum proteins (SP) from skim milk. A 3-stage, 3X, feed-and-bleed MF study with diafiltration in the latter 2 stages was conducted at 50°C using Isoflux membranes to determine cumulative SP removal percentages after each processing stage. The experiment was replicated 3 times starting with different batches of raw milk. The Proc GLM procedure of SAS was used for statistical analysis. In contrast to 3X MF theoretical cumulative SP removal percentages of 68%, 90%, and 97% after 1, 2, and 3 stages, respectively, the 3X Isoflux MF process removed only 39.5%, 58.4%, and 70.2% of SP after 1, 2, and 3 stages, respectively. Previous research has been published that provides the skim milk SP removal capacities of 3-stage, 3X 0.1 μm ceramic Membralox uniform transmembrane pressure (UTP), 0.1 μm ceramic Membralox graded permeability (GP), and 0.3 μm polymeric polyvinylidene fluoride spiral-wound (PVDF SW) MF systems at 50°C. No difference in cumulative SP removal percentage after 3 stages was detected ($P > 0.05$) between the Isoflux and previously published PVDF SW (70.3%) values, but SP removal was lower ($P < 0.05$) than published GP (96.5%) and UTP (98.3%) values. To remove 95% of SP from 1000 kg of skim milk in 12 h it would take 7, 3, 3, and 7 stages with 6.86, 1.91, 2.82, and 14.24 m^2 of membrane surface area for the Isoflux, GP, UTP, and PVDF SW systems, respectively. The MF systems requiring more stages would produce additional permeate at lower protein concentrations. The ceramic MF systems requiring more surface area would incur higher capital costs. Possible reasons why SP removal with the Isoflux membranes was lower than theoretical include: a range of membrane pore sizes existed (i.e., some pores were too small to pass SP), the selective layer modification and reverse flow conditions at the membrane outlet combined to reduce the effective membrane surface area, and the geometric shape of the Isoflux flow channels promoted fouling of the membrane and rejection of SP by the foulant.

Key words: microfiltration, serum protein, ceramic membrane

66 The manufacture of linoleic acid-modified chitosan/β-lactoglobulin nanoparticles as a delivery system of quercetin. H.-K. Ha*, M.-R. Lee, and W.-J. Lee, *Division of Applied Life Sciences (Institute of Agriculture and Life Science), Gyeongsang National University, Jinju, Korea.*

The nutritional delivery and absorption of poorly bioavailable materials, such as quercetin, can be improved by entrapping such nutrients inside of nanoparticles. The hypothesis of this study was that attractive forces between chitosan and β-lactoglobulin (β-lg) may play a critical role in the formation and physicochemical properties of linoleic acid-modified chitosan (CS-LA)/β-lg nanoparticles containing nutrients with low bioavailability, such as quercetin. The objective of this research was to investigate how manufacturing variables, such as degree of substitution (DS) of CS-LA and incubation temperature, affect the formation and physicochemical properties of CS-LA/β-lg nanoparticles. CS-LAs with different DS (2.7, 4.6, and 8.4%) determined by ^{1}H NMR were synthesized via carbodiimide-mediated coupling reaction. CS-LA/β-lg mixtures at pH 4.4 were incubated at 5, 10, 15, and 20°C for 30 min. The morphological and chemical properties of CS-LA/β-lg nanoparticles were determined by atomic force microscopy and electrophoretic light scattering spectrophotometer. Encapsulation efficiency of quercetin was determined by high perfor-

mance liquid chromatography. In atomic force microscopy images, spherically-shaped particles with a diameter from 170 to 350 nm were observed indicating that nanoparticles were successfully formed. Zeta-potential value of nanoparticles was ~+18 mV. As DS was increased from 2.7 to 8.4%, which may enhance hydrophobic attractions between chitosan and β-lg, the size of CS-LA/β-lg nanoparticles was significantly ($P < 0.05$) increased from 275 to 351 nm and encapsulation efficiency of quercetin was significantly ($P < 0.05$) increased from 52 to 56%, respectively. As incubation temperature was increased from 5 to 20°C, a significant ($P < 0.05$) increase in the size of CS-LA/β-lg nanoparticles from 183 to 319 nm was observed while encapsulation efficiency of quercetin was significantly ($P < 0.05$) decreased from 56 to 53%. In conclusion, DS and incubation temperature were the major key-parameters determining the size of nanoparticles and encapsulation efficiency of quercetin.

Key words: β-lactoglobulin, chitosan, nanoparticles

67 Alternative bleaching methods for 80% whey protein concentrate. E. J. Kang* and M. A. Drake, *North Carolina State University, Raleigh.*

Whey protein concentrate (WPC) is an important ingredient in the food industry due to its nutritional and functional properties, including a bland flavor and color. To remove residual annatto colorant, fluid whey is bleached during processing to WPC. Recent studies have shown that the 2 approved bleaching agents in the United States, hydrogen peroxide (HP) and benzoyl peroxide, remove color but negatively impact flavor. The objective of this study was to evaluate alternative methods for bleaching WPC80: UV radiation (UV), acid-activated bentonite (BT) and Maxibright (MB). Cheddar cheese colored with annatto (15mL/454kg milk; 3% norbixin content) was manufactured following standard procedures and liquid whey was collected. Following pasteurization and fat separation, liquid whey was subjected to one of 5 treatments: control (CT) (no bleaching; 50°C, 60 min), HP (250 mg/kg; 50°C, 60 min), UV (1 mL/min exposure; 50°C), BT (0.5% w/w; 50°C, 60 min), or MB (2 dairy bleaching units/mL with 0.5mM HP; 35°C, 30 min). The treated whey was then ultrafiltered, diafiltered at 50°C, and spray-dried to make WPC80. The entire experiment was replicated 3 times. Color (norbixin extraction), descriptive sensory and instrumental volatile analysis were conducted on WPC80. Norbixin recovery rates were 73, 61, 21, and 10% for HP, UV, BT and MB treatments, respectively. Bleaching reduced sweet aromatic flavor in WPC80 compared with CT WPC80 regardless of bleaching agent ($P < 0.05$). The HP WPC80 had higher cardboard and fatty flavors compared with CT WPC80 while the UV and MB WPC80 displayed distinctive mushroom/burnt or potato flavor, respectively. Consistent with sensory results, guiacol (smoky/burnt) and methional (potato) were detected, respectively, in the UV and MB WPC80. Volatile lipid oxidation products were higher in HP, UV and MB WPC80 compared with BT and CT WPC80, respectively ($P < 0.05$). Based on bleaching efficacy and flavor profiles of WPC80, BT and MB may be potential alternatives to HP for bleaching whey.

Key words: WPC80, bleaching, flavor

68 Impact of bleaching whey on the sensory and functional properties of 80% whey protein concentrate. S. M. Jervis*[1], R. E. Campbell[1], K. Wojciechowski[2], D. M. Barbano[2], and M. A. Drake[1], *[1]North Carolina State University, Raleigh, [2]Cornell University, Ithaca, NY.*

Whey is a highly functional food that has found wide-spread use in a variety of food and beverage applications. Whey proteins used in such applications are largely from annatto colored Cheddar cheese, where the resulting color is undesirable and must be bleached. The objective of this study was to compare 2 commercially approved bleaching agents, benzoyl peroxide (BP) and hydrogen peroxide (HP), and their effects on the flavor and functionality of whey protein concentrate 80 % (WPC80). Colored and uncolored liquid whey were bleached with BP or HP, ultrafiltered, diafiltered and spray-dried. WPC80 from unbleached colored and uncolored Cheddar whey were manufactured as controls. All treatments were manufactured in triplicate. WPC80 were evaluated by sensory, instrumental analyses, functionality, color, and proximate analysis. HP bleached WPC80 were higher in lipid oxidation compounds than other bleached or unbleached WPC80, specifically hexanal, heptanal, octanal, nonanal, decanal, dimethyl disulfide, and 1-octen-3-one ($P < 0.05$). HP treatments were higher in fatty and cardboard flavors compared with the unbleached and BP bleached samples ($P < 0.05$). WPC80 bleached with BP had lower norbixin concentrations compared with WPC80 bleached with HP ($P < 0.05$). Hunter CIE Lab color values (L* a* b*) of WPC powders were distinct on all 3 color scale parameters and HP bleached WPC80 had the highest L* values. Iron concentration was lower in the HP-bleached WPC80 ($P < 0.05$), all other mineral and proximate values were not different among treatments ($P > 0.05$). HP treatments had more soluble protein after 10 min of heating at 90oC at pH 4.6 and pH 7 than the unbleached and BP treatments. Overall, HP bleaching caused more lipid oxidation products than BP bleaching but enhanced the solubility of the WPC80.

Key words: whey protein, bleaching, flavor

69 The complete genome sequence of *Bifidobacterium animalis* ssp. *animalis* ATCC 25527^T and analysis of growth in milk. J. R. Loquasto*[1], R. Barrangou[2,1], E. G. Dudley[1], and R. F. Roberts[1], *[1]The Pennsylvania State University, University Park, [2]Danisco USA Inc., Madison, WI.*

Bifidobacteria are putative probiotic organisms commonly added to fermented dairy products. The number of complete bifidobacterial genomes is increasing and analysis of these genomes has provided important insight into the physiology of these organisms. The objective of this work was to sequence the genome of *B. animalis* ssp. *animalis* ATCC 25527^T with the aim of providing insight into the genetic diversity responsible for phenotypic differences reported between *B. animalis* ssp. *animalis* (Baa) and *B. animalis* ssp. *lactis* (Bal). The genome of ATCC 25527^T was shotgun sequenced using 454 technology. After contig assembly, alignment and several rounds of gap closing, the complete 1,932,963 bp genome was determined and verified by comparison to a *Kpn*I optical map. The genome was annotated using Rapid Annotation using Subsystems Technology (RAST) and at NCBI. Comparative analysis of the Baa ATCC 25527^T and Bal DSMZ 10140^T genomes revealed high degrees of both synteny and homology. Comparison of the Baa and Bal genomes for differential content revealed 108 and 121 genes that were unique to and absent in, the BAA genome, respectively. Unique genes were identified as having less than 10% amino acid identity between protein sequences of both genomes, as detected by RAST. Among the differential gene content are a set of unique CRISPR-associated genes and a novel CRISPR locus containing 31 spacers in the genome of Baa. Although previous research has suggested one of the defining phenotypic differences between Baa and Bal is the ability of Bal strains to grow in milk and milk-

based medium, no obvious differences in gene content responsible for this phenotype were identified between the 2 genomes. Furthermore, growth and acid production in milk and milk-based medium did not differ significantly in experiments examining Bal (DSMZ 10140^T and Bl04) and Baa (ATCC 25527^T). These data suggest that this widely accepted defining phenotypic trait may not distinguish the subspecies.

Key words: bifidobacteria, probiotics, genome sequencing

70 Ruminal fermentation characteristics and lactational performance of Holstein dairy cows fed whole safflower seeds. C. M. Dschaak*[1], C. T. Noviandi[1], J.-S. Eun[1], V. Fellner[2], A. J. Young[1], D. R. ZoBell[1], and C. E. Israelsen[3], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Department of Animal Science, North Carolina State University, Raleigh, [3]Cooperative Extension, Utah State University, Logan.*

A lactation trial was conducted to determine the effects of supplementing whole safflower seeds (SS) on ruminal fermentation and lactational performance. Nine multiparous Holstein cows (DIM = 110 ± 20) were used in a replicated 3 × 3 Latin square design. Each period lasted 21 d with 14 d of adaptation and 7 d of data collection. Within square, cows were randomly assigned to a sequence of 3 dietary treatments as follows: cottonseed TMR (CST), conventional SS (variety S-208) TMR (CSST), and Nutrasaff SS (Safflower Technologies International, Sidney, MT) TMR (NSST). Diets contained approximately 63% forage (36% alfalfa hay, 4% grass hay, and 23% corn silage) and 37% concentrate supplemented with 2% cottonseed to the CST and 3% conventional or Nutrasaff SS to the CSST or the NSST, respectively. Intake of DM averaged 21.8 kg/d and did not differ ($P > 0.10$) across diets. Digestibility of DM was similar ($P > 0.10$) between diets, whereas feeding the CSST decreased ($P < 0.05$) fiber digestibility compared with the CST and the NSST. Milk yield was greater ($P = 0.03$) with the NSST (31.4 kg/d) when compared with the CST (30.2 kg/d). Milk protein increased with the NSST compared with the CST ($P = 0.05$). Diets had no effect ($P > 0.10$) on total or molar proportions of ruminal VFA and ammonia-N. Ruminal C16:0 and C18:0 concentrations increased with the CST ($P < 0.02$). Feeding the CST also increased milk C16:0 concentration, whereas C18:0, C18:1 cis-9, C18:1 trans-9, and C18:1 cis-11 increased with the NSST ($P < 0.03$). Supplementing whole SS in dairy diets at 3% of dietary DM can be an effective strategy of fat supplementation to lactating dairy cows without negative impacts on lactational performance.

Key words: safflower seeds, ruminal fermentation, lactational performance

71 The effects of NPH insulin and insulin glargine on milk yield and composition by lactating dairy cows. L. A. Winkelman* and T. R. Overton, *Cornell University, Ithaca, NY.*

Our study investigated the effects of neutral protamine hagedorn insulin (H) and insulin glargine (L) on milk composition in 30 cows (88 ± 25 DIM). Cows were blocked into 2 groups, balanced for DIM and production, and randomly assigned to 1 of 3 treatments (Control (C), H, and L). Subcutaneous injections of 0.2 IU/kg BW for H and L were given 2x/d every 12 h for 10 d. Blood samples were taken 2x/d, immediately before the morning injection and 6 h postinjection. Mammary tissue was biopsied on d 11. Cows were milked 2x/d and milk composition was determined on d 2, 4, 6, 8, and 10. Treatment means herein are presented in the following order: C, H, and L. Milk yield ($P = 0.46$) and DMI ($P = 0.58$) did not differ by treatment. Treatment with H and L increased milk protein content (3.00, 3.20, and 3.29 (±0.05)%; $P = 0.001$) and milk protein yield was increased by L (1.46, 1.49, and 1.54 (±0.03) kg/d; $P = 0.08$). Fat content (3.17, 3.32, 3.50 (±0.11)%; contrast C vs. L: $P = 0.04$) and yield (1.50, 1.55, 1.65 (±0.05) kg/d; contrast C vs. L: $P = 0.05$) were increased by L. Milk lactose content was reduced (4.84, 4.76, 4.70 (±0.02)%; $P = 0.001$) by treatment. Lactose yield was reduced by L ($P = 0.02$) but not H ($P = 0.13$) and averaged 2.34, 2.26, and 2.21 (±0.04) kg/d. Casein content ($P = 0.02$) and yield ($P = 0.09$) were increased by treatment with H and L, but casein as a percent of true protein did not differ ($P = 0.70$). Plasma glucose was reduced by treatment with H and L (56.8, 52.0, and 48.1 (±0.99) mg/dl; $P < 0.001$). Plasma urea nitrogen was reduced by L ($P = 0.004$) but not H ($P = 0.57$). Plasma NEFA was higher for cows treated with H (166, 197, and 181 (±9) μEq/L; $P = 0.013$). Western blot of mammary protein lysates indicated that the ratio of phosphorylated Akt:total Akt differed by treatment and was greatest for H (1.16, 1.72, 0.96 (±0.62) arbitrary units; $P = 0.05$) but the ratio of phosphorylated rpS6:total rpS6 did not differ by treatment ($P = 0.60$). Overall, H and L improved milk component production, but more research needs to be conducted to further elucidate the mechanism underpinning the effects of insulin on milk composition.

Key words: insulin, milk protein

72 The effects of degradable nitrogen level and degradation rate on nitrogen balance and urea kinetics in Holstein steers. V. B. Holder*[1], J. Tricarico[2], D. H. Kim[1], N. B. Kristensen[3], and D. L. Harmon[1], *[1]University of Kentucky, Lexington, [2]Alltech, Brookings, SD, [3]Aarhus University, Tjele, Denmark.*

The objective of this study was to compare nitrogen metabolism and urea kinetics between diets containing either rapidly degrading or slow degrading non protein nitrogen (NPN) at varying levels of degradable intake protein (DIP). Treatments were slow release urea (Optigen II, OPT) fed at 101 and 114% and feed grade urea (Urea) fed at 89 and 100% of calculated DIP requirements. Eight Holstein steers (209 ± 15 kg) implanted with Synovex Plus were used in a replicated 4 × 4 Latin square. Periods were 27 d, with 19 d adaptation followed by 7 d of urine and fecal collection and 1 d of blood sampling. Continuous (78h) intravenous infusion of $^{15}N^{15}N$-urea allowed estimation of urea kinetics. Dry matter intake was not different between treatments (7.2 kg/d). Increasing DIP had a tendency to increase dry matter digestibility (DMD) for both Urea and OPT. Urea had higher DMD than OPT. Increasing DIP increased urinary N output, and increased N-retention with OPT but not Urea. Increasing DIP increased urea–N entry rate (UER) and urinary urea-N excretion (UUE) for both OPT and Urea. Gastrointestinal entry of urea-N, urea-N lost to feces and urea-N apparently used for anabolism were not different between treatments. Plasma urea concentration was greater in higher DIP diets and higher for Urea than OPT at 100% DIP. Therefore increasing DIP level will increase N-excretion related to higher urea production and excretion in urine but may also increase diet digestibility. Most changes in N metabolism were driven by N intake; however, providing a slow release DIP source may allow for greater N retention when DIP is not limiting.

Table 1. Experiment results

	Treatment					Contrasts		
Item	114% DIP OPT	101% DIP OPT	100% DIP Urea	89 % DIP Urea	SEM	114% vs. 101%, OPT	100% vs. 89 %, Urea	100% Urea vs. 101% OPT

73 Effects of monensin on metabolic parameters, feeding behavior, and productivity of transition dairy cows. C. R. Mullins*[1], L. K. Mamedova[1], M. J. Brouk[1], C. E. Moore[2], H. B. Green[2], K. L. Perfield[2], J. F. Smith[1], J. P. Harner[1], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Elanco Animal Health, Greenfield, IN.*

The effects of monensin on transition cow metabolism may be dependent on modulation of feeding behavior, ruminal pH, and/or expression of metabolic genes. Multiparous Holstein cows (n = 16 per treatment) were alternately assigned, based on calving date, to control or monensin (400 mg/d) treatments 21 d before expected calving date, and cows remained on treatments through 21 d postpartum. Feeding behavior and water intake data were collected daily. Liver biopsies were obtained, after assessing BCS and BW, on d −21, −7, 1, 7, and 21 relative to calving (RTC), for analysis of triglyceride (TG) content and mRNA abundance of phosphoenolpyruvate carboxykinase 1(PCK1) and carnitine palmitoyltransferase 1a (CPT1a). Blood samples were collected on d −21, −7, −4, 1, 4, 7, 14, and 21 RTC for plasma NEFA, β-hydroxybutyrate (BHBA), glucose, insulin, and haptoglobin analyses. Ruminal pH was collected every 5 min on d 1 to 7 RTC by a wireless indwelling probe. On d 7 RTC, a caffeine clearance test was performed to assess liver function. Data were analyzed using mixed models with repeated measures over time. Monensin decreased mean plasma BHBA (734 vs. 616 ± 40 μM; $P < 0.05$) and peak concentrations (1076 vs. 777 ± 70 μM on d 4 RTC; $P < 0.01$). Monensin also decreased time between meals prepartum (143 vs. 126 ± 5.0 min; $P < 0.03$) and postpartum (88.8 vs. 81.4 ± 2.9 min; $P < 0.08$), which was likely related to a smaller ruminal pH variance in the first day after cows changed to a lactation ration (SD = 0.31 vs. 0.26 ± 0.015 units; $P < 0.02$). Monensin increased liver mRNA abundance of CPT1a (0.10 vs. 0.15 ± 0.002 arbitrary units; $P < 0.04$), which corresponded with a slower rate of liver TG accumulation from d −7 to +7 RTC (412 vs. 128 ± 83 mg TG/g protein per 2 wk, $P = 0.03$). There were no significant effects of monensin supplementation on milk production, liver PCK1, plasma NEFA, glucose, insulin, or haptoglobin. No effects on disease incidence were detected, but sample size was small for detecting such effects. Overall, results confirm that the effects of monensin on transition cows extend beyond altered propionate flux.

Key words: monensin, transition cow, feeding behavior

74 The effect of ketoprofen following left displaced abomasum surgery on lying behaviour and ketosis. N. C. Newby*[1], S. J. LeBlanc[1], K. E. Leslie[1], D. L. Pearl[1], M. A. G. von Keyserlingk[2], and T. F. Duffield[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]University of British Columbia, Vancouver, British Columbia, Canada.*

Surgical correction of left displaced abomasum (LDA) is common in lactating dairy cattle, but it is not common practice to administer analgesia following LDA surgery although surgery is normally associated with pain. The objectives of this research were to examine the effect of administering a label dose of the non-steroidal anti-inflammatory drug ketoprofen on lying behavior and ketosis (blood β-hydroxybutyrate (BHB)), as well as on farmer's perception of recovery following LDA surgery. A total of 148 Holstein cows were enrolled in a field study following LDA surgery (standing right flank (RF) or paramedian (P) approaches). Using a double-blind randomized method, each animal was assigned to receive either 3 mg ketoprofen/kg body weight or saline by intramuscular injection, immediately following surgery and 24 h post-operatively. A subset of cows (n = 37) were fitted with a 3-axis accelerometer on the hind leg to access lying activity. Farmers were asked to provide information on the cow's appetite in the days following surgery. Lying time data were analyzed using multivariable linear models with a random effect for cow and binary outcomes were analyzed using a mixed logistic model. Cows subjected to P surgery lay down less (β = −3.8 h; 95% C.I.: −2.3, −5.4 h; $P < 0.01$) in the first 3 d, and had higher heart rate (β = 9.4 beats/min; 95% C.I.: 6.9 – 12 beats/min; $P < 0.05$) 2–4 d after surgery, compared with animals that underwent RF surgery. In all cows, regardless of surgical procedure or ketoprofen treatment, BHB significantly decreased from surgery to d 2–4 (β = −1.9; 95% C.I.: −2.1, −1.7; $P < 0.001$) and d 8–10 (β = −2.0; 95% C.I.: −0.2.2, −1.8; $P < 0.001$). Based on observations by producers (who were blinded to treatment status), animals that received ketoprofen were more likely to begin eating when provided fresh feed on the first 3 d following surgery compared with those that received saline (OR = 4.2; 95% C.I.: 1.4, 12.5; $P = 0.01$). These results suggest that that P surgery of LDA may result in more pain than the RF approach. Further investigation of assessment and management of post-surgical pain is warranted.

75 Ruminal fermentation and nutrient digestion by dairy cows fed different concentrations of forage and dried distillers grains with solubles. S. D. Ranathunga*, K. F. Kalscheur, A. R. Hippen, and D. J. Schingoethe, *South Dakota State University, Brookings, South Dakota, USA.*

The study objective was to investigate the effects of concentrations of forages and dried distillers grains with solubles (DG) on ruminal fermentation and nutrient digestion in lactating dairy cows. Four Holstein cows with ruminal fistula were assigned to a 4 × 4 Latin square in a 2 × 2 factorial arrangement of treatments. Diets were formulated containing low forage (LF; 41% of diet DM) or high forage (HF; 60% of diet DM) and DG at 0 or 18% of diet DM. Ground corn and soybean feeds were partially replaced by DG from 0% DG diets to formulate 18% DG diets. Average DMI was not affected by diets (23.8 kg/d). Rumen evacuation at 4h post-feeding showed that rumen digesta DM were greater for cows fed HF regardless of the addition of DG. There was a tendency for digesta NDF (7.00 vs. 7.49 kg) to be less for cows fed LF compared with HF, whereas digesta starch (0.53 vs. 0.33 kg) were greater for cows fed LF compared with HF. Lower ruminal pH

(6.10 vs. 6.34) was observed in cows fed LF whereas there was no DG effect on ruminal pH. Cows fed LF had greater total VFA concentration compared with cows fed HF (122 vs. 116 mM). Acetate concentrations were lesser for LF (57.5 vs 62.6 mol/100 mol) and 18% DG (61.3 vs 58.7 mol/100 mol) diets whereas propionate concentration were greater for LF (26.0 vs 20.1 mol/100 mol) and 18% DG (21.9 vs 24.2 mol/100 mol) diets. Greater acetate:propionate ratio was observed in HF and 0% DG diets. Total tract digestibility for DM, NDF, CP, and starch was not affected by diets. Results suggest that forage and DG concentration in diets affect ruminal degradability of nutrients.

Table 1.

	LF	LF	HF	HF		
Item	0DG	18DG	0DG	18DG	SEM	P-value a
Digesta DM, kg	11.2	13.2	13.9	12.9	1.84	F

76 On-farm validation of two rapid methods to estimate IgG in bovine colostrum. K. M. Morrill*[1], E. Conrad[1], A. Lago[2], J. D. Quigley[2], and H. D. Tyler[1], *[1]Iowa State University, Ames, [2]APC Inc., Ankeny, IA.*

Our objective was to validate a rapid, cow-side method to estimate IgG in bovine maternal colostrum (MC) based on caprylic acid (CA) fraction of MC followed by refractometry of the IgG-rich supernatant. Samples of MC (n = 827) were collected from 67 farms in 12 states. Samples were fresh (not stored; n = 196), previously frozen (n = 490) or refrigerated (n = 152). One ml of MC was added a tube containing 75 µL CA and 1 mL 0.06 M acetic acid and refractive index (nD) of the IgG-rich supernatant was determined. We also measured nD of whole (non-fractionated) MC and IgG of whole MC by radial immunodiffusion. Correlation of nD of CA supernatant to IgG (r = 0.53) was low, whereas the correlation between nD of whole MC and IgG was greater (r = 0.73). Correlations of nD of CA supernatant and IgG (r = 0.93) and nD of whole MC and IgG (r = 0.89) of MC samples that and were not stored before analysis (n = 146) were much greater, suggesting that storage of MC impaired our ability to measure nD or IgG. Correlations of whole nD of MC and IgG were similar for Holsteins (r = 0.77) and Jerseys (r = 0.80). Regression equations were used to estimate the IgG concentration of samples based on the nD of CA supernatant or whole MC. The equation created from nD of CA supernatant resulted in 34.3% of samples accurately estimated within 10 mg/ml, 23.7% of samples estimated within 10–20 mg/ml, 14.5% of samples estimated within 20–30 mg/ml and 27.5% of samples estimated to greater than 30 mg/ml of actual IgG concentration. Equation created from the nD of whole MC resulted in 43.8% of samples estimated within 10 mg/ml, 28.0% of samples within 10–20 mg/ml, 14.4% of samples within 20–30 mg/ml and 13.8% of samples greater than 30 mg/ml compared with actual IgG concentration. These results suggest that the nD of whole MC provides a more accurate estimation of colostral IgG concentration than the nD of CA supernatant and both tests are most accurate on fresh colostrum samples.

77 Physiological and transcriptional adaptations in adipose tissue of dairy cows in response to prepartal plane of dietary energy. P. Ji*, J. S. Osorio, J. K. Drackley, and J. J. Loor, *University of Illinois, Urbana.*

Our objective was to determine the effect of prepartal energy overfeeding during the close-up period on physiological and transcriptional responses of adipose tissue (AT) of dairy cows during the transition period. Multiparous Holstein cows (n = 14) were randomly assigned to either a controlled-energy diet (CON; NE_L = 1.30 Mcal/kg DM) for the entire dry period or CON during the far-off period (d −50 to −21 relative to expected parturition) followed by a moderate-energy diet (Overfed; NE_L = 1.49 Mcal/kg DM) during the close-up period (d −21 to calving). Both groups were fed the same lactation diet postpartum (NE_L = 1.67 Mcal/kg DM). Blood samples were collected before morning feeding twice weekly. Subcutaneous AT was biopsied from tail-head regions at d −10, 7, and 21 for total RNA extraction. Quantitative RT-PCR was utilized to analyze mRNA expression of 50 genes. Overfeeding energy increased DMI ($P = 0.05$) and serum insulin concentration ($P < 0.01$) during the close-up period, but tended to increase serum BHBA concentration postpartum ($P = 0.06$). Overfed cows experienced more marked increases in serum NEFA and BHBA postpartum ($P < 0.05$). Milk yield did not differ ($P = 0.89$) between diets. Compared with CON, close-up overfeeding led to greater expression of genes ($P < 0.05$) associated with fatty acid (FA) biosynthesis (ACLY, ACACA, and FASN), FA import, FA activation and desaturation (LPL, ACSS2, ACSL1, and SCD), NADPH production (G6PD and IDH1), triglyceride synthesis (GPAM and DGAT2), transcriptional regulation of lipogenesis (PPARG, CEBPA, and THRSP) and basal lipolysis (PNPLA2 and ABHD5) at d −10. Abundance of mRNA for these genes decreased between d −10 and d 7. The expression of IRS1, AKT2, GLUT4, and INSIG1 was downregulated in both groups at d 7 compared with d −10 ($P < 0.05$). Overall, overfeeding energy during the close-up period may increase both lipid accumulation and basal lipolysis in AT through transcriptional regulation. Decreased circulating insulin and lower expression of IRS1, AKT2, and GLUT4 in the early postpartum period may contribute to the downregulation of lipogenic genes.

Key words: adipose tissue, energy overfeeding, transition period

78 Expression of novel, putative stem cell markers in prepubertal and lactating bovine mammary glands. R. K. Choudhary*[1], C. M. Evock-Clover[2], and A. V. Capuco[2,1], *[1]Department of Animal Sciences, University of Maryland, College Park, [2]Bovine Functional Genomics Lab, USDA-ARS, Beltsville, MD.*

Mammary stem cells (MaSC) are essential for growth and maintenance of the mammary epithelium. Two main phases of mammary growth include ductal elongation before puberty and lobulo-alveolar growth during pregnancy. Some studies utilized morphological characteristics and retention of bromodeoxyuridine (BrdU) label to identify MaSC. However, these approaches may not be feasible or require considerable expertise. An alternative approach to identify resident MaSC is based on detection of appropriate protein markers by immunohisto-

chemistry. The focus of this study was to evaluate staining patterns (in prepubertal and lactating mammary tissue) of 3 novel, candidate markers for bovine MaSC. These proteins were identified as candidate MaSC markers because their transcripts were highly expressed in laser microdissected-MaSC, which were identified by BrdU label retention and basal location within the mammary epithelium. The 3 novel candidate markers for MaSC were: nuclear receptor subfamily 5 group A member 2 (NR5A2), nucleoporin 153 (NUP153) and fibronectin type III domain containing 3B (FNDC3B). We also evaluated presumptive MaSC markers [aldehyde dehydrogenase 1 (ALDH1) and Musashi 1 (Msi1)] and differentiation factors [Notch 3 receptor (Notch3) and cytokeratins (CK) 14 and19] that have been used in other species. We found that NR5A2 and NUP153-positive nuclei were more abundant in prepubertal than lactating mammary glands and their distributions were consistent with expectations for a MaSC marker. FNDC3B was localized mainly in the nucleus prepubertally and in the cytoplasm during lactation. Preliminary results showed colocalization of the novel markers with label retaining MaSC. Abundant expression of ALDH1 precludes its use as a marker for bovine MaSC, whereas Msi1 staining was distributed in a fashion consistent with MaSC localization. Additionally we noted that onset of lumen formation in terminal ducts of prepubertal glands were coincident with Notch3 expression in luminal cells. This study demonstrates that nuclear expression of NR5A2, NUP153 and FNDC3B are potential markers for bovine MaSC.

Key words: mammary stem cell, novel biomarker

79 Effect of dietary protein level and rumen-protected methionine supplementation on performance of lactating dairy cows. C. Lee*[1], A. N. Hristov[1], T. Cassidy[1], H. Heyler[1], H. Lapierre[2], G. A. Varga[1], and C. Parys[3], *[1]Pennsylvania State University, University Park, [2]Agriculture and Agri–Food Canada, Sherbrooke, QC, Canada, [3]Evonik Degussa GmbH, Hanau, Germany.*

The objective of this experiment was to investigate the effect of rumen–protected Met (RPMet) supplementation of a low-CP diet on dairy cow performance. The experiment was conducted for 12 wks with 36 Holstein cows (95 ± 6.2 DIM). Following a 2-wk covariate period, cows were assigned to one of the following treatments: 15.6% CP diet [HighCP; metabolizable protein (MP) balance: +26 g/d], 14.0% CP diet (LowCP; MP balance: –313 g/d) supplemented with 100 g/cow/d of rumen-protected Lys (AminoShure-L, 24 g/d estimated digestible Lys supply), and 14.0% CP diet supplemented with rumen-protected Lys plus 24 g/cow/d RPMet (Mepron, 15 g/d estimated digestible Met supply; LowCPMet). DMI and milk yield were not affected by treatment (24.8 ± 0.40 kg/d and 38.4 ± 0.80 kg/d, respectively). Compared with HighCP, LowCP decreased milk protein content ($P = 0.02$); with LowCPMet the effect was not significant ($P = 0.07$). Milk protein yield was not different ($P = 0.22$) among diets. Milk urea–N concentration was decreased (by 15%; $P = 0.05$) by LowCP and LowCP-Met compared with HighCP. Plasma Lys and Met concentrations were not affected by treatment. His and Val concentrations were 48 and 22% lower ($P = 0.001$ and 0.016) and Thr, Arg, Phe, and Gln tended to be lower ($P = 0.08$ to 0.05) for the LowCP diets compared with HighCP. The LowCP diets decreased ($P = 0.01$) blood urea–N concentrations and NDF and ADF apparent digestibilities compared with HighCP. Urinary excretion of purine derivatives was lower (by 13%; $P = 0.03$) for LowCP compared with HighCP. Compared with HighCP, the LowCP diets resulted in lower ($P < 0.001$) urinary total (by 31%) and urea-N (by 51%) excretions. Ammonia emission from LowCP manure was 37% lower ($P < 0.001$) compared with HighCP manure. In conclusion, the LowCP diets, supplemented with rumen–protected amino acids maintained milk production similar to the HighCP diet, except that protein concentration was significantly decreased without RPMet supplementation. Nitrogen losses and ammonia emissions from manure were decreased with the LowCP diets.

Key words: dietary protein, rumen-protected methionine, dairy cow

80 Summer assessment and validation of metabolic profile reference values for transition Holstein dairy cattle. K. J. Lager*[1,2], E. R. Jordan[1], and D. R. Topliff[2], *[1]Texas AgriLife Extension Service, Texas A&M System, College Station, [2]West Texas A&M University, Canyon.*

Dairy cattle genetics and management continue to evolve over time, but it is not known whether the available diagnostic tools have kept pace with the ever changing industry. The objective of this project was to assess the validity of current metabolic profile reference values in relation to current dairy cattle genetics and management strategies. Blood samples (n = 1787) were collected between late August and mid-September, 2010 from cows within the transition period via coccygeal vessel venipuncture into nonheparinized vacuum blood tubes at morning feeding on 8 commercial dairies ranging in approximate size from 1800 to over 5000 head of lactating cows. One day per dairy was utilized to collect blood samples for cows within the transition period. Samples were placed on ice immediately following collection until processing. Following centrifugation, samples were stored frozen (−20°C) in duplicate before laboratory analysis for calcium, phosphorus, magnesium, albumin, urea, glucose, cholesterol, sodium, potassium, chloride, and nonesterified fatty acids. Data points were excluded for cows experiencing dystocia, retained placenta, displaced abomasum, twin births, and stillbirths, as well as for cows being dry <40 d or >80 d. Mean lactation number and days dry were 3.0 ± 1.2 and 57.8 ± 7.5, respectively. Serum phosphorus values (mg/dl) for wk −3, −2, −1, 1, 2, and 3 relative to calving were 5.23 ± 0.83, 5.43 ± 0.74, 5.48 ± 0.95, 5.39 ± 1.2, 4.90 ± 0.88, 5.31 ± 0.80, respectively; while calcium values (mg/dl) were at 8.94 ± 0.43, 8.87 ± 0.54, 8.87 ± 0.54, 8.26 ± 0.86, 8.76 ± 0.74, 9.08 ± 0.53, respectively. Nonesterified fatty acids were numerically greatest in wk 1 (0.67 mEq/l ± 0.36), while sodium and chloride were reacted similarly (143.65 mEq/l ± 2.4 and 108.89 mEq/l ± 2.6, respectively) at wk −1 relative to calving. Serum cholesterol concentrations were numerically lowest in wk 1 (74.54 mg/dl ± 17.8), displaying a non-static trend similar to that of other metabolic profile analytes for the duration of the transition period.

Key words: dairy cow, metabolic profile, transition cow

81 Effect of follicular wave and progesterone (P4) concentration during follicle growth on fertility of dairy cows. R. S. Bisinotto*[1], H. Ayres[1], M. R. Carvalho[1], E. S. Ribeiro[1], R. L. A. Cerri[2], L. F. Greco[1], F. S. Lima[1], M. G. Favoreto[1], A. P. Monteiro[1], M. C. Perdomo[1], W. W. Thatcher[1], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]University of British Columbia, Vancouver, BC, Canada.*

Effects of wave of the ovulatory follicle and P4 concentration during follicle growth on corpora lutea (CL) function and conceptus development were evaluated in dairy cows. Nonlactating Holstein cows had their estrous cycles synchronized with GnRH and a controlled internal drug release (CIDR) device containing P4, followed 7 d later by CIDR removal and 2 injections of $PGF_{2\alpha}$ 24 h apart. All cows received GnRH 1 d after the 2nd $PGF_{2\alpha}$ which, for cows induced to ovulate a first wave follicle (FW, n = 13) or a FW follicle supplemented with P4 (FWP4, n = 8), was the 1st GnRH of the timed artificial insemination (AI)

protocol (d-9 GnRH, d-2 and d-1 $PGF_{2\alpha}$, d0 GnRH and AI, d1 AI). Cows induced to ovulate a second wave follicle (SW, n = 12) received the timed AI protocol beginning 6 d after the previous GnRH. Cows in FWP4 received 3 CIDR, one at 12, 24 and 48 h after the GnRH (d-9), that were removed at the $PGF_{2\alpha}$ (d-2). Blood was sampled from d-9 to 17 for P4 and estradiol (E2) analyses. Cows were slaughtered on d17 and uteri flushed. Interferon-tau (INF-τ) on uterine flush was quantified. Concepti IFN-τ mRNA expression was accessed by RT-PCR. Orthogonal comparisons were performed to determine the effects of P4 (FW vs. FWP4+SW) and follicle wave (SW vs. FWP4). Ovulation of a FW follicle reduced pregnancy and this effect was mediated by low P4 concentration during their development. Luteal function during early gestation, concepti elongation and their ability to produce IFN-τ were not compromised by ovulation of follicles developing under low concentrations of progesterone.

Table 1.

	Treatment			*P*-value

82 Production response to corn silage produced from normal, brown midrib, or waxy corn hybrids. J. S. Barlow*, J. K. Bernard, and N. A. Mullis, *The University of Georgia, Tifton.*

The starch in Waxy corn hybrids is 100% amylopectin which has been suggested to be more digestible than that of normal corn hybrids, but the production response to feeding silage produced from these hybrids has been inconsistent. In contrast, brown midrib (BMR) corn varieties have lower lignin concentrations and have been shown to support higher DMI and milk yield. The objective of this study was to evaluate the nutrient intake and milk production response of lactating dairy cows to diets based on corn silage produced from 3 different types of corn hybrids. Thirty-six multiparous and primiparous Holstein cows (77 DIM and 37.1 kg/d milk) were used in an 11 wk completely randomized design trial during the fall of 2009. Experimental diets contained 36.4% of the dietary DM from corn silage from either a normal (Agratech 1021), BMR (Mycogen F2F797), or Waxy (Master's Choice 590) hybrid. All cows were fed the diet containing normal corn silage during the first 2 wk of the trial before being assigned to one of 3 treatments for the following 9 wk. Data collected during the first 2 wk were used as a covariate in the statistical analysis. No difference ($P = 0.81$) was observed in DMI among treatments which averaged 22.6 kg/d. Milk yield was highest ($P = 0.03$) for cows fed BMR (37.6 kg/d) compared with Waxy (35.2 kg/d) but similar to control (36.2 kg/d). Milk fat percentage tended to be lower ($P = 0.10$) for cows fed control (3.28%) compared with BMR (3.60%) or Waxy (3.55%) corn silage. Milk protein percentage ($P = 0.07$) tended to be lower for cows fed normal (2.79%) compared with Waxy (2.89%) but similar to BMR (2.85%). No differences were observed in yield of milk components. Energy-corrected-milk (ECM) yield, dairy efficiency (ECM/DMI), and BW change did not differ among treatments. Results of this trial are consistent with previous reports in which cows fed diets based on corn silage produced from BMR hybrids have higher milk yield compared with other hybrids. Corn silage produced from the waxy hybrid supported similar yield of ECM because of higher milk components, but milk yield was not improved compared with the normal.

Key words: waxy corn silage, BMR corn silage, milk yield

83 Ruminal escape and intestinal digestibility of experimental ruminal protected lysine supplements. Z. Wu*[1], J. K. Bernard[1], R. B. Eggleston[2], and T. C. Jenkins[3], *[1]University of Georgia, Tifton, [2]University of Georgia, Athens, [3]Clemson University, Clemson, SC.*

Recent research has focused on the development of LYS supplements that resist ruminal degradation but are digestible in the small intestine using various fat coatings. Hydrogenated fats are poorly digested in the small intestine, so inclusion of polyunsaturated fatty acids (PFA) such as oleic acid may improve digestibility in the small intestine. The objective of this study was to determine the effect of the addition of 2 or 4% PFA to a hydrogenated fat coating applied to an experimental supplement with 55 or 58% supplemental LYS on ruminal escape and intestinal absorption of LYS. Two lactating Holstein cows (103 DIM and 45.1 kg/d milk) previously fitted with ruminal and duodenal cannula were individually housed and fed a corn silage based ration. In situ and mobile bag techniques were utilized as outlined in NRC (2001) to evaluate the 4 test products. Twenty 10 × 20 cm nylon bags of each product (5 g each) were incubated for 16 h in each cow. After ruminal incubation, products were repackaged (0.8g) into 5 × 10 cm nylon bags (20 per test product), soaked in pepsin/HCl solution for 2 h before inserting into the duodenum and subsequently collected in the feces. All samples were analyzed for DM, N, LYS and acid hydrolysis fat concentrations. The percentage of DM and fat escaping the rumen decreased ($P < 0.001$) as PFA increased from 2 to 4% or as the proportion of supplemental lysine increased. An interaction ($P < 0.01$) was observed between PFA and LYS proportion because of a greater reduction of N and LYS escaping ruminal fermentation and flowing to the small intestine for the product with 58% supplemental lysine and 4% PFA in comparison to the other products. No differences were observed in intestinal digestibility of DM, N, LYS, or fat or the amount of lysine digested in the small intestine. Results of this trial indicate that increasing the proportion of PFA in the coating applied to supplemental lysine increases ruminal degradation. The extent of the degradation increases as the proportion of lysine in the product increases.

Key words: rumen protected lysine, ruminal escape, intestinal digestibility

84 Effect of sample processing on in situ protein degradability of distillers grains. M. L. Drewery*[1], J. E. Sawyer[1], N. M. Kenney[1], W. E. Pinchak[2], and T. A. Wickersham[1], *[1]Texas A&M University, College Station, [2]Texas AgriLife Research, Vernon.*

Precise measurements of nutrient availability are important when formulating rations. The high moisture content of wet distillers' grains (DG) creates challenges for nutrient analysis and sample processing. Therefore, our objective was to determine how sample processing affects measures of rate and extent of protein degradation in wet DG samples. Three ruminally cannulated steers were fed a ration (15% CP) containing 38.5% corn, 28% hay, and 28% dried DG. Samples of wet DG were divided and a portion was frozen at −20°C while the remainder was dried at 55°C in a forced-air oven for 96 h. Dried samples were ground to pass a 2-mm screen. Five g of each sample was placed in Dacron bags, pre-incubated in tepid water, placed in a weighted mesh polyester bag, and incubated in the rumen for 4, 6, 12, 24, 48 and 72 h. Samples were rinsed in cold water and dried at 60°C. Nitrogen content was determined. Protein was fractionated into A, B, and C fractions. Degradation rate of the B fraction was calculated as the slope of the natural log of N remaining against time. Rate of passage was set at 3%/h. The A fraction was greater ($P < 0.01$) for frozen (43.3%) than dried samples (24.0%). In contrast, the B fraction was less ($P < 0.01$) for frozen than dried samples 52.1 and 70.0%, respectively. The C fraction differed ($P = 0.01$) between frozen and dried; however, the magnitude of this difference was small 4.5 and 5.9%, respectively. Degradation rate of the B fraction was greater ($P < 0.01$) for frozen than dried samples 1.31 versus 1.86%/h, respectively. Accordingly, estimated degradability was observed to be greater ($P < 0.01$) for frozen than dry samples 59.4 and 51.1%, accordingly. These results suggest drying wet DG impacts the measures of protein degradability.

Key words: distillers grains, degradability, protein

85 Effects of heat stress and increased protein and energy fed in milk replacers on health parameters of neonatal Holstein bull calves. A. J. Krenek*[1], G. A. Holub[1], T. A. Tomaszewski[1], and C. C. Stanley[2], *[1]Texas A&M University, College Station, [2]Land O Lakes Purina Feed, Amarillo, TX.*

The objectives were to evaluate if calves in non-heat stress environment (NHS) were healthier than calves in heat stress environment (HS) or if feeding increased protein and fat in milk replacer (HPMR; 1135 g/d, 28% CP, 20% fat) verses a conventional milk replacer (CMR; 454 g/d, 20% CP, 20% fat) diet affected the health status of calves in the 2 environments. Calves were fed 6 L of HPMR or 4 L of CMR per day. Holstein bull calves (n = 52) < 3 d of age were assigned to a 2 X 2 factorial trial based on initial BW, physical health score, and total serum protein levels. Half of each nutrition group was housed indoors with temperature control non-heat stress (NHS) or outside under a metal roof in heat stress (HS) environment. The study was conducted for 56 d from, June 19 to August 13, 2010. The average Thermal Heat Index (THI) was calculated for each day by averaging the 24 recorded temperatures and RH%. The 56 d average, low, and high range THI for the HS was 79, 67, and 86 respectively, while THI for the NHS was 69, 66, and 74 respectively. Fecal scores (FS) of 1 to 4 (1 = hard, firm, 2 = soft, firm, 3 = no form, and 4 = watery) were recorded d to monitor scouring. Calves with a FS of 4 were considered to have diarrhea requiring treatment. Respiration rates (RR) were recorded at 0600 (AM) and 1800 (PM) d to monitor respiratory challenges while rectal temperatures (RT) were also measured using a digital thermometer daily in AM and PM to monitor febrile events. If RT was greater than 39.2°C for NHS calves and 39.7°C for HS calves, they were treated for fever (FE). The calves in HS had a higher RT AM, RT PM, RR AM, and RR PM ($P = < 0.01$) than calves in NHS (38.87 vs. 38.77 ± 0.02), (39.03 vs. 38.79 ± 0.05), (35.79 vs. 32.77 ± 0.3), and (55.73 vs. 38.58 ± 0.6) respectively. The calves in NHS had a higher FE ($P = < 0.01$) than the HS calves (6.24 vs. 2.33 ± 0.94). The HPMR calves had a higher FS ($P = < 0.01$) than the CMR calves (2.05 vs. 1.73 ± 0.03). This indicates calves in HS were experiencing higher RT AM, RT PM, RR AM, and RR PM. Also, the increased amount of protein and energy fed to the HPMR treatment had higher FS.

Key words: calf, milk replacer, heat stress

86 Effects of resistant starch in milk replacer on health and performance of neonatal Holstein heifer calves. B. L. Fisher*, B. F. Jenny, C. C. Williams, C. F. Hutchison, A. H. Dolejsiova, and R. G. Morell, *LSU AgCenter, Baton Rouge, LA*.

Forty-two female Holstein calves were assigned to one of 3 treatments at d 2 of age to study the effects of adding resistant starch (RS) to the milk replacer on health and performance. Treatments were control (no RS), 4g RS, or 8g RS mixed into the reconstituted replacer. Calves were housed in individual calf hutches and fed milk replacer once daily until d 42 of age. An 18% crude protein calf starter and water were offered ad libitum beginning d 3 throughout the duration of the trial. Calves remained in their hutches until 56 d of age to determine immediate postweaning performance. Body weights were measured at birth and d 14, 28, 42, and 56 of age. Wither height (WH), hip height (HH), and hip width (HW) were measured on d 14, 28, 42 and 56 of age. Feed intake, body temperatures, and fecal scores were recorded once daily through d 56. On d 14, 28, 42, and 56, fecal samples were collected for analysis of pH and volatile fatty acids (VFA), and blood was collected for analysis of plasma urea nitrogen (PUN) and total protein (TP). PUN and TP did not differ ($P > 0.05$) and were within normal ranges suggesting that there were no major metabolic problems. There was no effect ($P > 0.05$) of treatment on body weight, HH, HW, WH, or body temperatures. There was a treatment by week interaction ($P < 0.01$) and a week effect ($P < 0.01$) for grain intake, with all calves increasing intake throughout the duration of the study. There was a treatment by week interaction ($P < 0.01$) and a week effect ($P < 0.01$) for fecal scores, with calves having lower fecal scores at the end of the study compared with the beginning. Fecal pH increased as calves aged ($P < 0.01$). There was a treatment by week interaction ($P < 0.05$) with an effect of both week ($P < 0.01$) and treatment ($P < 0.05$) for propionate concentration in the feces. There was an effect of week ($P < 0.01$) for acetate and butyrate concentrations as well as on total VFA concentration in the feces. Overall, incorporation of RS in the milk replacer of neonatal dairy calves did not show any significant effects on growth or gut health of Holstein dairy calves.

Key words: dairy calves, resistant starch, milk replacer

87 Potential for estrus detection in dairy cattle using reticular temperature monitors. W. A. Smith*, W. J. Silvia, and J. M. Bewley, *University of Kentucky, Lexington.*

An experiment was designed to evaluate the utility of reticular (RT) and vaginal (VT) temperatures in predicting the time of ovulation in dairy cows. Lactating Holstein and crossbred (n = 30) cows were synchronized using an OVSYNCH protocol preceded by G6G. The first injection of prostaglandin Fα (PGF) was administered 40 to 90 d postpartum. OVSYNCH was modified by omitting the last injection of GnRH. The RT and VT were monitored using SmartBoluses (TenXsys Inc., Eagle, ID) inserted at least 5 d before anticipated estrus. Boluses were placed in the reticulum according to the manufacturer. Boluses were fixed to CIDR devices lacking progesterone (Pfizer Animal Health, NY) and inserted into the vagina using the CIDR speculum. Beginning at 48 h after the PGF injection of OVSYNCH, jugular venous blood samples were collected at 2 h intervals for LH and rectal temperatures were measured. After each sampling, cows were observed for estrus behavior. Beginning 72 h after PGF, ultrasonography was performed every 4 h to determine time of ovulation. Intensive sampling was maintained for 60 h or until ovulation was confirmed. Venous blood samples were collected daily for progesterone as an indicator of ovulation. The time intervals from injection of the OVSYNCH PGF, onset of estrus, LH surge, peak rectal temperature, and first detected increase in RT and VT to ovulation were determined. The mean and standard deviation for each interval was calculated. Only 18 cows ovulated within the sampling time frame and were used in this analysis. The average intervals in hours (±SD) from injection of the OVSYNCH PGF, onset of estrus, LH surge, peak rectal temperature, first detected increase in RT and VT to ovulation were 93 ± 11, 31 ± 8, 24 ± 6, 46 ± 11, 47 ± 31, 45 ± 27, respectively. The most precise predictor of interval to ovulation was the LH surge. The variation associated with the interval estimates based on RT and VT was high and precludes their usefulness as reliable predictors of the time of ovulation. Supported by the KY Agr Expt Stn and Genex Cooperative, Inc., Shawano, WI.

Key words: temperature, estrus, ovulation

Lactation Biology Symposium: Circadian Clocks and Photoperiod in Mammary Development and Lactation

88 Circadian timekeeping mechanisms. P. Hardin*, *Texas A&M University, College Station.*

Animals, plants, fungi and even some prokaryotic organisms display daily rhythms in physiology, metabolism and behavior. These rhythms are not passively driven by environmental cycles (e.g., light) but are controlled by endogenous circadian clocks that keep time even in the absence of environmental time cues. Environmental cycles are nevertheless required to entrain these clocks so that they activate rhythmic processes at the appropriate time of day. Circadian clocks are comprised of an input pathway that receives environmental cues and transmits them to the circadian oscillator, a circadian oscillator that keeps circadian time and activates output pathways, and output pathways that control various metabolic, physiological and behavioral processes. Considerable effort has been focused on determining how the circadian oscillator keeps time. Genetic and molecular studies in the fruit fly, *Drosophila melanogaster*, have contributed significantly to our understanding of the circadian oscillator. Identification and isolation of the first clock gene from Drosophila, period, and subsequent analysis of its expression led to the first molecular model of the circadian oscillator - an autoregulatory feedback loop in gene expression. Discovery of additional clock genes in Drosophila not only support the feedback loop model, but add to its mechanistic detail and complexity. Importantly, many components of the Drosophila circadian feedback loop have orthologs and/or functional equivalents in mammals, thus making Drosophila a useful model for circadian oscillators in higher organisms. New methods of identifying clock genes in Drosophila promise to uncover novel oscillator components that may be amenable to pharmacological manipulation. In animals, circadian oscillators reside in a variety of tissues, including the brain and numerous internal organs. Although these oscillators are largely photoreceptive and directly light-entrainable in Drosophila, oscillators in peripheral tissues of mammals are synchronized by systemic cues from the light-entrained central clock in the brain. Consequently, local oscillators and systemic cues control rhythms in mammalian physiology and metabolism.

Key words: circadian clock, molecular mechanisms, peripheral tissues

89 Circadian clocks in mammary gland development and differentiation. W. Porter*, *Texas A&M University, College Station.*

Biological clocks play a key role in how an organism adapts to daily and annual changes in the environment by regulating rhythmic fluctuations in metabolism, hormone and neurotransmitter release, sensory capabilities and a variety of behaviors. In vertebrates, these physiological responses are controlled by the suprachiasmatic nucleus (SCN) of the anterior hypothalamus. In addition, peripheral tissues including the liver, heart, kidney and mammary gland contain functional endogenous clocks. These peripheral clocks, which regulate numerous physiological processes including proliferation and apoptosis, are similar to the central clock and are influenced by the SCN via a combination of neural and hormonal signals. We have recently shown that members of the molecular clock are differentially regulated during mammary gland development and present new data demonstrating their involvement in normal virgin ductal morphogenesis and functional differentiation during lactation. Moreover, these responses are intrinsic to the mammary gland and not dependent upon the central clock. Furthermore, we have also found that the molecular clock cross-talks with other transcription factor pathways to regulate lactation-dependent gene expression. Together, these results suggest that the peripheral mammary clock is required for normal mammary gland development and function.

Key words: mammary gland, circadian rhythms

90 Circadian clocks as mediators of the homeorhetic response to lactation. T. Casey* and K. Plaut, *Purdue University, West Lafayette, IN.*

The transition from pregnancy to lactation is the most stressful period of a cow's life. During this transition, homeorhetic adaptations are coordinated across almost every organ and are marked by tremendous changes in hormones and metabolism to accommodate for the increased energetic demands of lactation. Recent data from our lab showed that changes in circadian clocks occur in multiple tissues during the transition period in rats and suggest that the circadian system regulates the coordinated changes in the dam's physiology needed to support lactation. Circadian rhythms coordinate the timing of physiological processes and synchronize these processes with the animal's environment. Circadian rhythms are generated by molecular circadian clocks located in the master clock of the hypothalamus and peripherally in every organ of the body. The master clock receives environmental and physiological cues and in turn synchronizes internal physiology by coordinating endocrine rhythms and metabolism through peripheral clocks. The effect of the circadian clock on lactation may be inferred by the photoperiod effect on milk production, which is accompanied by coordinated changes in the dam's endocrine system and metabolic capacity in response to changes in day length. We have shown that bovine mammary epithelial cells possess a functional clock that can be synchronized by external stimuli, and the expression of ARNTL, a positive limb of the core clock, is responsive to prolactin in bovine mammary explants. Others showed that 7% of genes expressed in breasts of lactating women had circadian patterns of expression, and we report that the diurnal variation of composition of cow's milk is associated with changes in expression of mammary core clock genes. Together these studies suggest that the circadian system coordinates the metabolic and hormonal changes needed to initiate and sustain lactation, and that the dam's capacity to produce milk and cope with metabolic stresses in early lactation is related to her ability to set circadian rhythms during the transition period.

Key words: homeorhesis, lactation, circadian

91 Effects of photoperiod on mammary gland development and lactation. G. E. Dahl*, S. Tao, and I. M. Thompson, *University of Florida, Gainesville.*

Photoperiod, or the daily sequence of light and dark, has dramatic effects on many physiological systems across animal species. Light patterns alter melatonin secretion profiles and subsequently the release profiles and circulating concentrations of several hormones that influence a variety of physiological responses. Although the impact of photoperiod on reproductive processes is perhaps the most common example, it is often the seasonal aspects of ovulation and anestrus that

are considered. However, in cattle, the final phase of reproduction, i.e., lactation, is significantly influenced by photoperiod. In contrast to short days (SD; 8h light:16 h dark), exposure to long days (LD) of 16 to 18 h of light and 6–8 h of darkness increase milk yield 2–3 kg/d, regardless of the stage of lactation. There is evidence that this LD effect is due to increased circulating insulin-like growth factor-I independent of any effect on growth hormone concentrations. Cows that are housed under SD during the dry period have increased mammary growth and produce 3–4 kg/d more milk in the subsequent lactation compared with cows on LD when dry. While on SD, circulating prolactin (PRL) diminishes but expression of PRL-receptor increases in mammary, liver and immune cells. Moreover, PRL signaling pathways within those tissues are affected by photoperiod. Further, replacement of PRL to cows on SD partially reverses the effects of SD on production in the next lactation. Thus, effects on dry cows are mediated through a PRL dependent pathway. Before maturity, LD improve mammary parenchymal accumulation and lean body growth which lead to greater yields in the first lactation. The accumulated evidence supports the concept that photoperiod manipulation can be harnessed to improve the efficiency of production across the life cycle of the dairy cow.

Key words: prolactin, insulin-like growth factor I, milk yield

92 Supplemental dietary phytase alters gut microbiota of weanling pigs. L. Wang and X. G. Lei*, *Cornell University, Ithaca, NY.*

Past phytase research has been largely focused on nutritional values of the enzyme, and has not explored its impact on gut microbiota of animals. The objective of this study was to determine effects of supplemental *Escherichia coli* AppA2 and *Aspergillus niger* PhyA phytases on composition changes of the 4 major intestinal bacteria in weanling pigs. A total of 30 crossbreds (3-week old, Yorkshire-Landrace-Hampshire) were allotted to 3 groups (n = 10) and fed a corn-soybean-mean basal diet (BD, supplemented with 0.35% inorganic phosphorus), the BD plus 3,500 units of AppA2/kg (Optiphos, JBS United, Sheridan, IN), or the BD plus 3,500 units of PhyA/kg (Natuphos, BASF, Florham Park, NJ) for 6 weeks. At the end, 8 pigs of each treatment group were killed to collect ileum and colon adherent samples for terminal restriction fragments length polymorphism analysis of 16s rRNA genes. After the total genomic DNA was extracted, the 16s rRNA genes were isolated using PCR with universal primer sets. Compared with the BD, both phytases increased ($P < 0.05$) *Bifidobacteria*, *Clostridium*, *E. coli*/*Salmonella*, and lactobacilli in ileum. There was no consistent effect of either phytase on any of the detectable bacteria in colon except for that pigs fed AppA2 had slightly higher ($P < 0.05$) *Bifidobacteria* content than those fed PhyA. In conclusion, both AppA2 and PhyA phytases showed a stronger impact on microbiota in ileum than in colon. Our finding reveals a novel function of phytase beyond nutrition.

Key words: microbiota, phytase, swine, T-RFLP

93 Effects of phytase on standardized total tract digestibility of P in copra expellers, palm kernel expellers, and palm kernel meal fed to growing pigs. B. L. Almaguer*[1], R. C. Sulabo[2], and H. H. Stein[2], *[1]Universidad Autónoma de Querétaro, Mexico, [2]University of Illinois, Urbana.*

A total of 66 barrows (initial BW: 27 ± 3 kg) were used to determine the effects of phytase on standardized total tract digestibility (STTD) of P in copra expellers (CE), Asian palm kernel expellers from Indonesia (PKE-IN), African palm kernel expellers from Costa Rica (PKE-CR), African palm kernel meal from Costa Rica (PKM), and in soybean meal (SBM). Pigs were housed individually in metabolism cages and allotted to a randomized complete block design with 11 diets and 6 replicate pigs per diet. Five diets were formulated by mixing cornstarch and sucrose with CE, PKE-IN, PKE-CR, PKM, or SBM. Five additional diets identical to the initial 5 diets with the exception that they contained 500 units of phytase (OptiPhos 2000, Enzyvia, Sheridan, IN) were formulated. A P-free diet was used to measure basal endogenous P losses (EPL). Feces were collected for 5 d based on the marker to marker approach after a 5-d adaptation period. Analyzed total P in CE, PKE-IN, PKE-CR, PKM, and SBM was 0.52, 0.51, 0.53, 0.54, and 0.67%, respectively. Phytate P was calculated to be 0.22, 0.35, 0.38, 0.32, and 0.44% in CE, PKE-IN, PKE-CR, PKM, and SBM, respectively. Addition of phytase increased ($P < 0.05$; SEM = 5.0) the ATTD of P from 60.6 to 80.8, 39.1 to 56.5, 38.2 to 59.9, 48.9 to 64.1, and 48.7 to 73.5% in CE, PKE-IN, PKE-CR, PKM, and SBM, respectively. The basal EPL was estimated to be 216 ± 70 mg/kg DMI. The STTD of P increased ($P < 0.05$; SEM = 5.7) from 70.6 to 90.3, 49.4 to 66.4, 48.7 to 69.9. 57.9 to 73.5, and 57.3 to 81.1% in CE, PKE-IN, PKE-CR, PKM, and SBM, respectively, with added phytase. In summary, added phytase increased P digestibility of all the test ingredients, and CE had greater STTD of P than PKE, PKM, and SBM when fed to growing pigs.

Key words: alternative feedstuffs, phosphorus, pigs

94 Supplementing a xylanase alone or a combination of xylanase and β-glucanase on growth performance, health, and nutrient digestibility of nursery pigs. Y. Han* and A. Ludger, *Nutreco R & D, Boxmeer, the Netherlands.*

It remains questionable if non-starch polysaccharide degrading enzymes should be used in pig diets. Two experiments were conducted to investigate the impact of adding a xylanase alone or a combination of xylanase and β-glucanase (XG) on nursery pigs fed a wheat-based diet. In Exp 1, 200 weaned piglets (28 d old, 7.1kg BW) were allocated to 10 blocks of 4 pens (5/pen). The 4 dietary treatments included a control diet and control with Xylanase (4000 U/kg), XG1 (xylanase 1500 U/kg, β-glucanase 200 U/kg) or XG2 (xylanase 2500 U/kg, β-glucanase 200 U/kg). All diets were pelleted and fed for 5 wks in a 2-phase program (d7–21, d22–42). In Exp 2, 32 piglets (28 d old, 8.5kg BW) were housed individually in metabolic cages. The same diets as in Exp 1 were used with 3% SiO_2 included as the marker for digestibility. A similar feeding program was followed. Fecal samples were collected in each phase and the ileal content was collected at the end of the study. In Exp 1, pigs fed the XG2 diet showed significant improvement on the cumulative feed efficiency in comparison to the control and the Xylanase diet. Compared with the control group, adding XG2 improved feed efficiency by 3.8% ($P < 0.035$). The Xylanase and XG2 treatment also reduced diarrhea incidence compared with the control ($P < 0.049$). In Exp 2, the treatment did not impact ileal digestibility. However, fecal digestibility differed significantly. Both XG1 and XG2 treatment improved ash digestibility ($P < 0.042$). Organic matter ($P < 0.004$) and NDF digestibility ($P < 0.001$) were improved by all 3 enzymes. While Xylanase and XG1 improved ADF digestibility ($P < 0.002$), energy digestibility was significantly enhanced by Xylanase and XG2. Besides, XG2 addition tended to increase protein digestibility ($P = 0.08$). In conclusion, Xylanase alone increased nutrient digestibility but failed to improve growth performance. A combination of xylanase and β-glucanase XG2 improved nutrient digestibility, feed efficiency and health of the animal.

Key words: piglets, xylanase, β-glucanase

95 Effect of different dietary calcium concentrations on the digestive and metabolic response of growing pigs to microbial phytase. X. Rousseau*[1,2], M. P. Letourneau-Montminy[3], M. Magnin[2], A. Narcy[1], and C. Pomar[3], *[1]INRA UR[83] Poultry Research, Nouzilly, France, [2]BNA Animal Nutrition, Chateau-Gontier, France, [3]Agriculture and Agrifood, Lennoxville, QC, Canada.*

An experiment was conducted to assess the effect of dietary calcium (Ca) concentration on the response of growing pigs to microbial phytase in terms of phosphorus (P) and Ca utilization at the digestive and metabolic levels. Sixty 3 pigs, for each period, were fed a 2-phase feeding experiment (25–50 and 50–80 kg BW) according to a 3 × 3 factorial arrangement in which dietary Ca (5.8, 7.2, 8.4 g/kg for phase 1 and 4.1, 5.8, 7.4 g/kg for phase 2) and microbial phytase (0, 350 and 700 FTU/kg for both phases) were provided at constant P concentrations (4.8 g/kg and 3.9 for phases 1 and 2, respectively). Pigs

were individually fed while raised in one large group. At the beginning and at the end of each period pigs were weighed and 4 pigs per treatments scanned with Dual energy x-ray absorptiometry (DXA) to estimate total body and lumbar spine region (L2-L4) bone mineral content (BMC) and density (BMD). After slaughter, femur was removed and scanned with DXA. No differences were observed among treatments for ADG and ADFI during the first feeding period, whereas during the second period ADG was depressed by dietary Ca concentration (P = 0.003) while ADG and ADFI were both increased by phytase (respectively, P = 0.036, P = 0.026). Total body and L2-L4 BMD (respectively, $P < 0.001$, P = 0.002) and BMC ($P < 0.001$, $P < 0.05$) were linearly increased by microbial phytase. Similarly, femur BMD and BMC were linearly increased by microbial phytase for first (respectively, P = 0.021; $P < 0.001$) and second (respectively, $P < 0.001$; $P < 0.001$) feeding periods. Regardless of the feeding phase, dietary Ca concentration had no effect on bone mineralization. This last criterion was improved by microbial phytase independently of Ca.

Key words: calcium, phytase, pigs

96 Effects of supplemented NSP-degrading enzymes on nutrient digestibility of diets containing wheat and wheat millrun fed to grower pigs. D. Shrestha*[1], J. Broz[2], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*DSM Nutritional Products, Animal Nutrition and Health R&D, Basel, Switzerland.*

A critical issue of current swine production is high feed cost that might be ameliorated by co-products including wheat millrun. However, feedstuffs such as millrun have physicochemical limitations such as a high non starch polysaccharide (NSP) content. The NSP hinder nutrient digestibility but are also a potential energy source if hydrolyzed by bacteria or NSP-degrading enzymes. The objective was to determine the effect of NSP-degrading enzymes on diets containing wheat or wheat and wheat millrun on nutrient digestibility. Effects of diet (96% wheat or 56% wheat plus 40% wheat millrun) and xylanase (0 or 16,000 units xylanase and 15,600 units β-glucanase/kg of feed) were investigated in a 2 × 2 factorial arrangement with a N-free control diet for a total of 5 diets. Five pigs were fed 5 diets in a 5 × 5 Latin square. Arabinoxylans constituted 50 and 57% of the total NSP in wheat and millrun, respectively. The wheat used in this study contained 3.80 Mcal DE/kg of DM, 16% CP, and 11% NSP, whereas the millrun contained 2.90 Mcal DE/kg of DM, 17% CP, and 25% NSP. Supplementation of NSP-degrading enzymes to the wheat diet did not alter the apparent ileal digestibility (AID) of energy, AID of CP, or the apparent total tract digestibility (ATTD) of energy. Supplementation of NSP-degrading enzymes to the wheat millrun diet increased ($P <$ 0.05) the AID of energy and CP by 5% and increased ($P < 0.05$) the ATTD of energy by 5%. The improved energy digestibility of the millrun diet was supported by an increase ($P < 0.05$) of the AID and ATTD of NSP by 36 and 47%, respectively. Supplementation of NSP-degrading enzymes increased ($P < 0.05$) the content of ileal digested energy and DE of millrun by 0.34 and 0.41 Mcal/kg of DM. In conclusion, exogenous NSP-degrading enzymes match with the NSP contained in wheat millrun and can improve energy and protein digestibility of diets containing wheat millrun for grower pigs.

Key words: pig, wheat millrun, xylanase

97 Capillary electrophoresis coupled with inductively coupled plasma mass spectrometry (CE-ICP-MS) enables identification and quantification of copper and manganese glycinate complexes in enriched feed samples and the study of their bioavailability. C. Ionescu*[1], V. Vacchina[2], R. Lobinski[3], and D. Bravo[1], [1]*Pancosma, Geneva, Switzerland,* [2]*UT*[2]*A, Pau, France,* [3]*CNRS, Pau, France.*

Copper and Manganese glycinate complexes (BT Cu and BT Mn) are introduced in feeds, but up to date, there was no analytical method enabling their identification and quantification in such matrixes. The first objective was to check if capillary electrophoresis coupled with inductively coupled plasma mass spectrometry (CE-ICP-MS) could be used to do so.

Key words: traceability, glycinate complexes, feed

98 Effects of feeding tribasic copper chloride or copper sulfate on growth and efficiency of nursery pigs. E. A. Koutsos*[1], G. L. Allee[2], and T. J. Prince[3], [1]*Micronutrients, Indianapolis, IN,* [2]*PorkTech LLC, Columbia, MO,* [3]*Prince Nutrition Service LLC, Auburn, AL.*

Tribasic copper chloride (TBCC) is a covalently bonded copper source that has been shown to have significantly higher bioavailability in monogastrics and ruminants than copper sulfate ($CuSO_4$). The objective of this trial was to determine the effects of adding graded levels of copper (Cu) from TBCC on performance of nursery pigs and compare TBCC to 200 ppm Cu from $CuSO_4$. 1188 pigs weaned at 20 +/− 2 d of age were allotted by weight and sex into 48 pens (8 reps of 6 treatments, 24–25 pigs/pen). Treatments were added Cu levels from TBCC at 15, 61.25, 107.5, 153.75, or 200 ppm and 200 ppm Cu from $CuSO_4$. Pigs were fed complex diets for phase 1 (0–7 d) and phase 2 (7–21 d) and a corn-soy diet for phase 3 (21–42 d). Added Zn levels (from ZnO) were 3000 ppm in phase 1 and 2500 ppm in phase 2 and all diets contained an AGP. Increasing dietary Cu from TBCC linearly increased BW at d 7 ($P < 0.04$), d 21 ($P < 0.01$) and d 42 ($P < 0.01$). Addition of Cu from TBCC increased ADG for 0–7 d ($P < 0.02$), 0–21 d ($P < 0.01$) and 0–42 d ($P <$ 01). G:F improved linearly ($P <$ 01) with increasing Cu from TBCC for 0–42 d. Feeding 200 ppm Cu from TBCC increased BW ($P < 0.06$), ADG ($P < 0.02$), and improved G:F ($P < 0.12$) for phase 1 compared with 200 ppm Cu from $CuSO_4$. Break-point analysis showed the optimum level of Cu from TBCC to be 150 ppm for ADG at d 0–21, 143 ppm for ADG at 0–42 d, and 133 ppm for the 0–42 d G:F. Cu from TBCC is effective for improving ADG and G:F of nursery pigs.

Table 1.

Cu Source	TBCC					$CuSO_4$	Significance (P <)	
Cu level, ppm	15	61.25	107.5	153.75	200	200	Linear	Cu source
Init. Wt., kg	5.28	5.27	5.27	5.28	5.28	5.27		
D21 Wt., kg	11.44	11.51	11.80	11.87	12.02	11.94	0.01	0.70
Final Wt., kg	22.46	23.06	23.75	24.05	24.44	23.97	0.01	0.29

99 Intestinal, liver, kidney, serum and biliary Cu concentrations in piglets fed Cu proteinate or $CuSO_4$. B. Aldridge*[1], R. F. Power[2], K. A. Dawson[2], and S. Radcliffe[1], *[1]Purdue University, Department of Animal Science, West Lafayette, IN, [2]Center for Animal Nutrigenomics and Applied Animal Nutrition, Alltech, Nicholasville, KY.*

Eighty crossbred barrows were weaned at 20 ± 1 d of age and used in 2 blocks (5 reps/block) of a 2 × 3 factorial experiment to investigate the effects of Cu source ($CuSO_4$ and Bioplex Cu, Alltech Inc.) and concentration (4, 25, and 125 ppm Cu) on growth performance, serum ceruloplasmin activity and Cu concentration in proximal jejunum (PJ), liver, kidney, serum and gall bladder contents (GBC). A negative control diet containing no supplemental Cu was also fed. Pigs were blocked by BW and randomly assigned to diets offered in 2 daily feedings at 9% of metabolic BW for 14 d. The PROC MIXED procedure in SAS was used to determine the main and interactive effects of Cu source and concentration. In addition, PROC GLM linear and quadratic contrasts were determined for increasing Cu concentrations. Pig served as the experimental unit. Overall ADG and G:F did not differ between Cu sources ($P > 0.05$).However, ADG and G:F approached a positive linear trend ($P = 0.12$ and $P = 0.11$, respectively) as dietary Cu was increased from 0 to 125 ppm Cu. During wk2, ADG and G:F (227.8, 227.9, 267.1 and 260.7 g/d, $P = 0.07$; and 0.59, 0.56, 0.68 and 0.65, $P = 0.06$, respectively) tended to increase in a quadratic fashion for pigs fed 0, 4, 25, or 125 ppm from Bioplex Cu. Serum ceruloplasmin activity was not altered ($P > 0.05$) by Cu source or concentration fed. An interaction ($P < 0.02$) between Cu source and concentration was observed for serum Cu concentrations. When dietary Cu was fed at 125 ppm, serum [Cu] was 12% higher for Bioplex Cu fed pigs compared with $CuSO_4$ fed pigs was observed in the serum, compared with $CuSO_4$, though when fed. However, at 25 ppm, serum [Cu] was 10% lower for Bioplex Cu fed pigs. There were no ($P > 0.10$) interactive effects of Cu source and concentration, nor were there any effects of Cu source observed for Cu concentrations in PJ, liver, kidney and gall bladder. However, increasing dietary Cu linearly increased ($P < 0.001$) Cu concentration in the PJ, liver, kidney, serum and gall bladder contents. These data suggest that Cu from $CuSO_4$ and Bioplex Cu accumulate in a positive linear fashion in the PJ, liver, kidney and GBC, but can differ in the serum.

Key words: copper, pig, absorption

100 Effect of dietary calcium on gastric ulceration in yearling horses. C. W. Waters*[1], D. H. Sigler[1], N. D. Cohen[2], and P. G. Gibbs[1], *[1]Texas A&M University Department of Animal Science, College Station, [2]Texas A&M University College of Veterinary Medicine, College Station.*

Equine gastric ulcer syndrome (EGUS) is a complex and common disorder observed in horses used in many different events, from part-time show horses to performance and race horses. Previous studies have indicated alfalfa hay to be beneficial in reducing severity of EGUS. Due to possible buffering effect of significantly higher concentration of calcium in alfalfa hay compared with Bermuda grass hay, understanding the role of calcium in gastric ulceration is needed. The objective of this study was to evaluate the effect of high Ca diet on severity of EGUS in young horses. Nineteen yearling Quarter Horses were used in a randomized cross over study, and were fed either a high Ca (1.85%) diet or a normal (1.03% Ca) pelleted diet for 28-d periods, separated by a 21-d washout period. At the beginning and end of both periods, horses were evaluated endoscopically and EGUS scores were assigned by a veterinary practitioner using a 1–4 scoring system. Initial EGUS score averaged 1.4 at the beginning of the trial and were not different between treatment groups. Horses tended to increase (more severe) in EGUS score while confined in dry lots and individually fed either control or high Ca diet for 28-d. Diet had no effect on EGUS ($P = 0.334$), or on change in EGUS score ($P = 0.42$). The sequence in which diets were fed tended to effect EGUS score ($P = 0.095$) with a mean ulcer score of 2.3 for horses fed the treatment diet followed by control vs. 1.9 for horses fed control followed by treatment. Horses that received the control diet initially had a longer period to adjust to the lower Ca diet before being put on the high Ca diet. Reported causes of EGUS are multiple and are interrelated to stress and diet. In this study, there appeared to be little effect of added Ca on severity of EGUS. Other nutrient differences between alfalfa and coastal Bermuda grass hay warrant further investigation.

Key words: equine gastric ulcer syndrome, EGUS

101 Ovarian follicular development, luteal function, and fertility in lactating Holstein cows treated with 14dCIDR_PGF or 2xPGF_Ovsynch56 for first insemination timed AI (TAI). R. C. Escalante*, S. E. Poock, D. J. Mathew, W. R. Martin, E. M. Newsom, J. L. Denbigh, E. C. Adkins, and M. C. Lucy, *University of Missouri-Columbia, Columbia.*

Progesterone-containing devices (CIDR) inserted for 14 d can be used to presynchronize the estrous cycle in heifers before TAI ("14-day CIDR-PG" program; http://beefrepro.unl.edu). The objective was to test a similar program for lactating dairy cows. Holstein cows (n = 71; 35 to 60 d postpartum) were assigned to 2xPGF_Ovsynch56 (Control program; $PGF_{2\alpha}$, 14 d, $PGF_{2\alpha}$, 12 d, GnRH, 7 d, $PGF_{2\alpha}$, 56 h, GnRH, 16 h, TAI; n = 34) or 14dCIDR_PGF (14dCIDR_PGF program; CIDR in, 14 d, CIDR out; 19 d; $PGF_{2\alpha}$, 56 h, GnRH, 16 h, TAI; n = 37) that began on d 0 and ended on d 36 with TAI. Ultrasound exams and blood sample collections were performed on d 0, 14, 19, 26, 28, 33, and 35 and blood sampling alone was done on d 42 to monitor follicular development, ovulation and the corpus luteum. After the presynchronization step (CIDR or 2xPGF; d 0 to 14), the percentages of cows observed in estrus (47%) and having ovulation within 5 d (73%) were similar for 14dCIDR_PGF and control. The interval to estrus after CIDR removal/PGF injection (d 14), however, was less (50 ± 5 and 75 ± 5 h; $P < 0.001$) and the size of the largest follicle (LF) at CIDR removal/$PGF_{2\alpha}$ injection (d 14) was greater (20.4 ± 0.8 and 16. ± 8.8 mm; $P < 0.01$) for 14dCIDR_PGF compared with control. Plasma progesterone concentrations (P4) increased ($P < 0.001$) after the presynchronization step from 0.9 ± 0.3 (d 19) to 7.0 ± 0.3 (d 33) ng/mL. There was a tendency ($P < 0.10$) for 14dCIDR_PGF cows to have greater P4 than control from d 26 to d 33 (6.6 ± 0.6 and 5.2 ± 0.6 ng/mL for 14dCIDR_PGF and control, respectively). Diameters of the LF at $PGF_{2\alpha}$ (d 33; 15.6 ± 0.7 mm) and before the GnRH injection (d 35; 17.0 ± 0.6 mm) were similar for 14dCIDR_PGF and control. Percentages of cows ovulating (89%) and becoming pregnant after TAI (48%) were similar for 14dCIDR_PGF and control. Conclusions were that the 14dCIDR_PGF program was effective for synchronizing lactating dairy cows for TAI. Greater P4 during the luteal phase before TAI (theoretically advantageous to fertility) in 14dCIDR_PGF may be explained by the ovulation of a persistent follicle after CIDR withdrawal.

Key words: estrous synchronization, dairy, cow

102 Prostaglandin $F_{2\alpha}$ and GnRH administration increase progesterone, luteal number, and proportion of dairy cows with corpora lutea before a timed AI program. J. S. Stevenson*, S. L. Pulley, and H. I. Mellieon Jr., *Kansas State University, Manhattan.*

The objective was to increase the proportion of cows having a functional corpus luteum (CL) and elevated progesterone (P4) at the onset of the Ovsynch protocol. Postpartum Holsteins in 1 herd were stratified by parity at calving (Sep. 2009 to Oct. 2010) and assigned randomly to 2 treatments: 1) PRE (n = 134): 2 25-mg injections of PGF2α (PG) 14 d apart (Presynch); and 2) PG3 (n = 134) one 25-mg injection of PG 3 d before 100 μg GnRH (PreGnRH) with the PG injection administered at the same time as the second PG in the PRE treatment (10 d before Ovsynch). Cows were enrolled in the Ovsynch protocol (injection of GnRH 7 d before [GnRH-1] and 56 h after [GnRH-2] PG with AI 16 to 18 h after GnRH-2) 10 d after the last or only PG injection. Blood samples for P4 analysis (103 cows per treatment) were collected at d −34, −31, −20, −17, −10, −3, 0 (GnRH-2), and d 1. Ovarian structures were measured by ultrasonography on d −17, −10, −3, 0, and 7 to determine ovulation and follicle diameters. Although P4 concentration did not differ between treatments before PreGnRH injection, number of CL per cow and proportion of cows having at least 1 CL were greater for PG3 than PRE cows, and more cows ovulated after PreGnRH than ovulated spontaneously in PRE. At GnRH-1, P4 concentration, number of CL per cow, and proportion of cows with at least 1 CL were greater for PG3 than PRE. Neither follicle diameter nor percentage of cows ovulating after GnRH-1 differed between treatments. At PG injection during the week of AI, P4 concentration tended to be greater for PG3 than PRE and PG3 had more CL per cow than PRE. Pregnancy rates per AI at d 32 for PG3 vs. PRE cows were 58.2 vs. 50.0% for 103 and 106 cows inseminated during nonsummer months ($P = 0.28$) and 7.7 vs. 8.8% for 39 and 34 cows inseminated during summer ($P = 0.28$), respectively. We concluded that the PreG treatment effectively increased ovulation and luteal function 7 d before the onset of Ovsynch resulting in improved follicular synchrony and potentially predisposing improved pregnancy rates per AI in lactating dairy cows.

Table 1.

Item	PG3	PRE	*P*-value

103 Evaluation of LH release after the intrauterine administration of gnrh in lactating dairy cattle. S. Bas*, C. G. Pinto, M. L. Day, and G. M. Schuenemann, *The Ohio State University, Columbus.*

The purpose of this study was to determine the preovulatory release of LH and ovulatory response after the intrauterine (i.u.) administration of GnRH (Gonadorelin) in lactating dairy cattle. Lactating cows (n = 23) were presynchronized with 2 injections of PGF2α given 14 d apart (starting at 26 ± 3 DIM) followed by Ovsynch (OV; GnRH-7 d-PGF2α-56 h-GnRH 16 h-timed-AI; TAI) 12 d later. Ovarian structures were recorded and a blood sample collected for each animal at the time of first GnRH of OV. Only those cows presenting a CL ≥15 mm and at least one follicle ≥10 mm in diameter remained in the study. Additionally, blood samples were collected and ovarian structures recorded at the time of PGF2α of OV. At the time of the second GnRH of OV (h 0), cows were blocked by parity and randomly assigned to 1 of 3 groups: 1) control group (CON; n = 7) received 2 mL, i.m., of sterile water, 2) intramuscular group (IM; n = 8) received 100 μg, i.m., of GnRH, and 3) intrauterine group (IU; n = 8) received 100 μg, i.u.,

of GnRH. Blood samples for determination of LH serum concentrations were collected at h 0, 0.5, 1, 1.5, 2, 3 and 4. Furthermore, ultrasonography was performed twice daily (12 h interval) from h 0 to 60 for determination of ovulation. Serum progesterone concentrations at h 0 did not differ ($P > 0.05$) between groups. Concentrations of LH were greater ($P < 0.05$) in the IM than IU and CON groups at h 0, 0.5, 1, 1.5, 2, and 4 h but not at h 3 between the IM and IU group. Cows in IU started increasing LH concentrations at 1 h reaching maximum levels at 2–3 h post GnRH while LH concentrations did not increase during this period in CON cows. The proportion of cows that ovulated by h 60 was greater ($P < 0.05$) for the IM (8/8) and IU (7/8) groups as compared with CON cows (2/7). Administration of GnRH i.u. resulted in lower serum concentrations of LH than in the IM group, but the proportion of cows that ovulated by h 60 did not differ between treatments. In summary, these findings provide evidence that i.u. administration may be an alternative route of delivery for treatment with GnRH to synchronize ovulation in estrous synchronization programs.

Key words: dairy cow, intrauterine GnRH, ovulation

104 Effect of presynchronization strategy prior to ovsynch on fertility at first service in lactating dairy cows. A. Keskin[1], G. Yilmazbas-Mecitoglu*[1], E. Karakaya[1], A. Alkan[2], H. Okut[3], A. Gumen[2], and M. C. Wiltbank[4], *[1]Department of Obstetrics and Gynecology, Faculty of Veterinary Medicine, University of Uludag, Bursa, Turkey, [2]Tarfas Company, Bursa, Turkey, [3]Biometry and Genetics, Faculty of Agriculture, University of Yuzuncu Yil, Van, Turkey, [4]Department of Dairy Science, University of Wisconsin-Madison, Madison.*

The aim of this study was to evaluate the effect of presynchronization with or without detection of estrus on first service Pregnancy per Artificial Insemination (P/AI) and Ovsynch outcome in lactating dairy cows. A total of 511 cows were divided randomly but unevenly into 3 treatment groups at 44–50 d in milk (DIM). Ovsynch was started at the same time in all 3 groups (69–75 DIM). Cows in the Ovsynch group (n = 126) received no presynchronization before Ovsynch and all cows were bred by TAI. Cows in Presynch with estrus detection (PED) and Presynch with only TAI (PTAI) groups received 2 doses of $PGF_{2\alpha}$ 14 d apart starting at 44–50 -DIM- and Ovsynch was initiated 11 d after the last $PGF_{2\alpha}$ treatment. Cows in PED (n = 267) received AI if estrus was detected after either $PGF_{2\alpha}$ injection and cows that were not detected in estrus after $PGF_{2\alpha}$ received Ovsynch and TAI. Cows in PTAI (n = 118) were not inseminated to estrus with all cows receiving TAI after Ovsynch. Ovulatory response to the first GnRH of Ovsynch was different ($P = 0.002$) among treatment groups (83.1% in PTAI, 72.6% in PED, and 62.7% in CON). However, ovulatory response to the second GnRH of Ovsynch did not differ among treatments. A total 132 of 267 PED cows (49.4%) exhibited estrus and were inseminated. The P/AI at the 31 d pregnancy diagnosis was not different between cows with AI after estrus (37.8%; 50/132) or Ovsynch (34.1%; 46/135) in the PED group. The P/AI for the Ovsynch group (46.8%; 59/126) was greater than the PED group ($P < 0.05$) with Ovsynch greater ($P = 0.04$) than PED cows receiving TAI but not than PED cows bred to estrus ($P = 0.16$). The cows in PTAI had greater P/AI (55.9%; 66/118) at the 31 d pregnancy diagnosis than PED ($P < 0.01$; either estrus or TAI) and tended to be greater ($P = 0.08$) than Ovsynch. Thus presynchronization with $PGF_{2\alpha}$ (PTAI) increased ovulatory response to Ovsynch and improved P/AI in dairy cows. Interestingly, breeding of cows to estrus during Presynch reduced fertility to the TAI. These results indicate that maximal fertility is obtained when all cows receive TAI after the Presynch protocol.

Key words: dairy cow, presynchronization, Ovsynch

105 Effects of presynchronization (PRE) and length of proestrus (LP) on pregnancy per AI (P/AI) of grazing dairy cows subjected to the 5d-Cosynch protocol. E. S. Ribeiro*, A. P. A. Monteiro, F. S. Lima, R. S. Bisinotto, H. Ayres, L. F. Greco, M. Favoreto, R. S. Marsola, W. W. Thatcher, and J. E. P. Santos, *University of Florida, Gainesville.*

Objectives were to compare the effects of method of PRE and LP on fertility of grazing dairy cows subjected to the 5d-Cosynch protocol. Lactating cows (n = 1,754) were blocked by breed, parity, and d postpartum, and randomly assigned to 1 of 2 PRE protocols: Presynch, 2 injections of PGF given 14 d apart, on study d −24 and −10, and starting the timed AI protocol (TAI) 10 d later; or Double-Ovsynch (DO), study d −17 GnRH, d −10 PGF, d −7 GnRH, and starting the TAI protocol 7 d later. The TAI protocol consisted of GnRH on d 0, PGF on d 5 and 6, and $GnRH^{+}AI$ either at 58h (COS58) or 72h (COS72) after the d5 PGF. Ovaries were scanned twice before enrollment in the study. Blood was sampled and analyzed for estradiol on the day of AI. The P/AI was determined 30 and 65 d after TAI. Data were analyzed using PROC GLIMMIX. Presynch increased ($P = 0.02$) estrus at AI compared with DO (25.9 vs. 20.8%), but it did not affect estradiol concentration at AI (6.0 vs. 7.1 pg/mL), or P/AI on d 30 (59.1 vs. 56.8%, $P = 0.39$) and 65 (51.2 vs. 51.7%, $P = 0.30$) after insemination. The COS72 increased estrus (28.5 vs. 10.8%, $P < 0.01$) and estradiol concentration at AI (7.2 vs. 5.8 pg/mL, $P = 0.04$) compared with COS58. The LP did not affect P/AI on d 30 (58.7 vs. 56.1%, $P = 0.20$), but COS72 was superior ($P = 0.04$) than COS58 on d 65 (52.8 vs. 48.1%). This difference was caused by a tendency ($P = 0.08$) for interaction between PRE and LP, in which COS58 resulted in smaller P/AI in Presynch than DO cows (43.9 vs. 52.4%), whereas COS72 resulted in greater P/AI in Presynch than DO cows (54.2 vs. 51.4%). Pregnancy loss was greater for Presynch than DO (12.7 vs. 8.3; $P = 0.01$) and for COS58 than COS72 (13.5 vs. 9.4%; $P = 0.03$). Anovular cows had smaller ($P < 0.01$) P/AI than cyclic cows on d 30 (35.4 vs. 61.6%) and 65 (30.4 vs. 54.8%), but no interaction ($P > 0.50$) between cyclic status and either PRE or LP treatments were detected. Presynch and DO resulted in similar fertility, but extending the LP to 72h improved fertility in the 5-d Cosynch protocol, primarily in cows receiving Presynch.

Key words: cow, presynchronization, proestrus

106 Two- and three-wave estrous cycles in dairy cows, investigated with a mechanistic mathematical model. M. Boer*[1,3], S. Röblitz[2], C. Stötzel[2], R. Veerkamp[1], B. Kemp[3], and H. Woelders[1], *[1]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Lelystad, the Netherlands, [2]Computational Systems Biology Group, Zuse Institute Berlin, Berlin, Germany, [3]Adaptation Physiology Group, Department of Animal Sciences, Wageningen University, Wageningen, the Netherlands.*

A normal bovine estrous cycle contains 2 or 3 waves of follicle development. However, it is unknown how the number of waves per cycle is regulated. Some studies report a better fertility of 3-wave cycles compared with 2-wave cycles, suggesting that older and larger ovulatory follicles in cycles with 2 waves contain oocytes of less quality than cycles with 3 waves. A better understanding of the endocrine mechanisms regulating follicle development is important to obtain more precise control of the estrous cycle, which can help to improve pregnancy rates. Our aim was to investigate which mechanisms are likely can-

didates for regulation of the number of waves. A mechanistic mathematical model that describes the dynamics of the bovine estrous cycle, using a set of 13 linked differential equations with 57 parameters, was developed. The model includes the processes of follicle and corpus luteum development and the working of key hormones that interact to control these processes. In the bovine, the follicle that is dominant at the moment of corpus luteum regression ovulates. Therefore, it was hypothesized that the number of follicle waves in a cycle is determined by follicle growth rate and time point of corpus luteum regression. Ten parameters related to these mechanisms were tested, of which 6 had an effect on the number of waves. The model output changed from 3 to 2 waves in a cycle when the effect of follicle stimulating hormone or of progesterone on follicle growth was changed, or when the time course of the luteal phase was changed. In the simulations, 2-wave cycles had a shorter cycle length compared with 3-wave cycles. Depending on the parameterization, the model simulated repeated as well as alternated cycles with 2 or 3 waves. Intermediate values of parameters related to follicle growth rate frequently resulted in irregularities, while gradual shifts in the length of the luteal phase often still resulted in a regular cycle. Therefore, these simulation results suggested that a cycle has a ′default′ number of waves based on follicle growth rate, which can be influenced by the time point of corpus luteum regression.

Key words: bovine estrous cycle, follicle waves, mathematical model

Production, Management and the Environment: Dairy Production I

107 A meta-analysis of the impact of stocking rate on the productivity of pasture-based milk production systems. B. McCarthy*[1,2], L. Delaby[3], K. M. Pierce[2], F. Journot[1], and B. Horan[1], *[1]Animal and Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland, [2]School of Agriculture, Food Science and Veterinary Medicine, University College Dublin, Belfield, Dublin, Ireland, [3]INRA, AgroCampus Ouest, UMR 1080, Production du Lait, Saint-Gilles, France.*

The objective of this paper is to quantify the milk production response per cow and per hectare (ha) for an incremental stocking rate (SR) change, based on a meta-analysis of published research papers. Suitable experiments for inclusion in the database required a comparison of at least 2 SRs under the same experimental conditions in addition to details on experimental length and milk production results per cow and per ha. Each additional increased SR treatment was also described in terms of the relative milk production change per cow and per ha compared with the lower base SR. A database containing 109 experiments of various lengths with 131 comparisons of SR was subdivided into: Type I experiments (common experimental lengths) and Type II experiments (variable experimental lengths). Actual and proportional changes in milk production according to SR change were analyzed using linear mixed model procedures with study included as a random effect in the model. Low residual standard errors indicated a good precision of the predictive equations with the exception of proportional change in milk production per cow. For all milk yield variables analyzed, the results illustrate that while production per cow is reduced, a strong positive relationship exists between SR and milk production per ha. A SR increase of one cow/ha resulted in a decrease in daily milk yield per cow of 7.4% and 8.7% for Type I and II data respectively, while milk yield per ha increased by 20.1% and 19.6%, respectively. Within the Type II data set, a one cow/ha increase in SR also resulted in a 15.1% reduction in lactation length (equivalent to 42 d). The low predictability of proportional change in milk production per cow according to the classical SR definition of cows/ha over a defined period suggests that SR may be more appropriately defined in terms of the change in available feed offered per animal within each treatment.

Key words: dairy cow, stocking rate, meta-analysis

108 Claw length and angle in lactating Jersey cattle, field measurements. D. J. Tomlinson*[1], L. Rodriguez[1], M. L. McGilliard[2], and K. Burgi[3], *[1]Zinpro Performance Minerals, Eden Prairie, MN, [2]Virginia Tech, Blacksburg, [3]Dairyland Hoof Care Institute Inc., Baraboo, WI.*

Low claw angle and/or long toe length may lead to development of claw lesions. Previous research and field observations indicate claws of Holstein cattle typically have an angle of 48 to 50 degrees and length of 75 to 85 mm. However, little information is available for Jersey cattle. The objective of this study was to determine length and angle of the dorsal wall of lateral claws of Jersey cows. Observations were made (n = 1654) on 7 Jersey dairy farms located in Hilmar, California. Measurement of dorsal wall angle and length were made on the lateral claw of the rear feet. Measures were made with a digital angle gauge and caliper in the milking parlor. All measures were made over the course of 3 d. Observations represented 56% first lactation cows, 20% second and 24% older animals. Mean lateral toe length of the rear claw was 71 mm with angle of 43 deg, for cows 121 d DIM and milk yield (MY; 27 kg/d). Toe length was correlated with angle −0.44, MY 0.30, and DIM 0.16. Stepwise regression of toe length, with farm and lactation number held in the model, eliminated non-significant dependent variables from a list of angle, DIM, MY, with their squares and cross-products. The model contained linear and quadratic angle, DIM and DIM*angle for an R2 = 0.49. The Glimmix procedure of SAS 9.2 indicated no interactions of these variables with farm. Our final model contained random effects of farm and residual (variances of 1.6 and 14.2), a lactation effect, and regressions on linear (−1.58) and quadratic (0.0129) foot angle, DIM (0.045) and DIM*angle (−0.00075). LSmeans for toe length were 68.6, 72.4, 74.5 mm for first through third+ lactation with SE of 0.50. Relative to average toe length, toe length at 50 DIM was 6 mm longer at 32 deg angle and 5 mm shorter at 56 degree angle, whereas toe length at 450 DIM was 15 mm longer at 32 deg angle and 4 mm shorter at 56 deg angle. There was a slight quadratic effect of angle and its interaction with DIM but no interaction with lactation number. This study demonstrated that Jersey cattle in these 7 CA dairies have a lower claw angle and shorter dorsal wall length than reported in Holstein cattle.

Key words: claw angle, claw length, lameness

109 A ranking system based on stochastic modeling to identify efficient dairy farms using farm-level inputs. A. S. Atzori*[1], A. Cannas[1], and L. O. Tedeschi[2], *[1]Dipartimento di Scienze Zootecniche, Università di Sassari, Sassari, Italy, [2]Department of Animal Science, Texas A&M University, College Station.*

A ranking system to classify dairy cow farms based on their production efficiency and profit using on-farm measurements was developed. A development database (dDB) containing 135 dairy farm from Sardinia, Italy, was gathered from Oct 09 to Sep 10. Input variables (IV, n = 18) were collected monthly either by the farmers' association (e.g., physiological stages (PS), #of lactating, dry, and culled cows, 305-d equivalent milk yield, age at first calving and culling, #of calves, and d open) or from a milk processing plant (e.g., milk sold (MkS), milk quality and price). Revenue was milk revenue plus $70/calf sold and feeding costs were based on NEl requirement and $0.195/Mcal of the diet. Income over feeding cost (IOFC, $/L) was revenue minus feeding costs. The annual average of IV for each farm was used. The distributions and correlations of IV from the dDB were used to obtain data (n = 5000) via Monte Carlo technique and stored into a database (sDB). The sDB data were used to obtain the standardized eigenvalues using the principal component analysis. Two regressions were obtained: selected principal components (PC) were regressed on the observed IOFC (REG1) and eigenvectors of the selected PC were used to compute PC values for each farm in the dDB (REG2). This computed PC values were then used with REG1 coefficients to predict IOFC, which was the ranking index (RI). Four PC were identified for milk efficiency (PS and MkS), milk quality and payment (milk quality and price), management (longevity, genetic level, SCC), and reproduction; and explained 37.4, 20.2, 15.6, and 4.4% of the sDB variance, respectively. The RI had a β distribution (mean = 0.119, SD = 0.0187) and explained 72% of the IOFC variance in the sDB. Farm allocation based on RI was 20 farms in [<-1SD], 30 in]-1SD, 0], 70 in]0, 1SD[, and 15 in [>1SD]. RI explained 79% of the IOFC variance in the dDB (root of mean square error = 0.012 $/L and 90% random errors). This approach provided a broad ranking system because it accounts for possible variability of the input variables and different weights can be used for each PC depending on the long-term goal of the dairy farm.

Key words: profitability, simulation, Monte Carlo

110 Predictors of primiparous and multiparous transition cow success from an automatic milking system. R. F. Leuer*, J. K. Reneau, J. M. Lukas, and M. I. Endres, *University of Minnesota, St. Paul*.

Analysis of performance early in lactation gives insight to future success. The objective of this retrospective study was to identify best indicators of transition success by parity and week. Lactation records (n = 191) from a Holstein dairy herd in Minnesota with a voluntary milking system were collected to identify factors associated with the success or failure of the primiparous (n = 51) and multiparous (n = 140) transition period. Metrics available were lactation number (LAC), milk production (MP), moving average production (MA), milk production average to week (MW), daily milkings (DM), milking refusals (REF), milking failures (FAI), concentrate feed consumed (CF), unconsumed concentrate feed (UCF), activity (ACT), rumination minutes (RM), and body weight (WT). Daily totals of each metric were used to calculate weekly averages. Total milk produced by 100 d was used to evaluate success of the transition period. To identify key metrics that indicate a successful transition period, best subsets regression was used to identify the combination of predictor variables for the first, second, and third week in the lactation. Fit was assessed with Mallows' Cp. Predictor variables for first week in lactation for primiparous cows ($R^2 = 0.60$), were mean MP and maximum UCF and ACT. Predictors for first week for multiparous cows($R^2 = 0.49$) were mean REF, maximum MP, CF, and UCF, and standard deviation REF and UCF. Predictor variables for second week for primiparous cows ($R^2 = 0.77$) were minimum UCF, mean MA, REF, and ACT, maximum MA, REF, FAI, and ACT, and standard deviation FAI and RM. Predictors for second week for multiparous cows ($R^2 = 0.54$) were LAC, minimum MA, maximum MA, and standard deviation of MA and DM. Finally, predictors for the third week for primiparious cows ($R^2 = 0.85$) were MW, minimum MP and RM, mean of MA and UCF, and maximum MA and RM whereas predictors for multiparous cows ($R^2 = 0.75$) were minimum WT, mean MA and UCF, maximum MA, MP, and UCF, and standard deviation of MP and UCF. Significant predictors changed week to week and between primiparous and multiparous cows.

Key words: precision dairy farming, automatic milking system, transition cow success

111 Effects of sodium bicarbonate or calcium magnesium carbonate on intake, digestibility and milk yield and composition of high producing dairy cows. R. E. Rauch*[1,2], P. H. Robinson[2], D. D. Simms[3], and L. J. Erasmus[1], *[1]University of Pretoria, Pretoria, South Africa, [2]University of California, Davis, [3]MIN-AD, Amarillo, TX.*

The rumen buffer sodium bicarbonate (SB) is a common dairy feed supplement, although recent research of its efficacy in modern low starch diets is limited. In California, new environmental regulations limit salt (including sodium) discharge from dairies. Our aim was to determine effects of SB or calcium magnesium carbonate (CMC; a potential alternative not classed as a salt), on performance of early lactation high producing Holstein cows. The study was a Latin square design with 3 periods of 28 d, 3 treatments (i.e., control (C), SB, CMC) and 3 pens of ~310 cows. The total mixed ration was supplemented with 0.8% dry matter SB or CMC, and contained 51.9% DM and 15.8% CP, 33.4% aNDF and 16.0% starch (all DM basis). Dietary cation anion difference (DCAD) for the C, SB and CMC diet was 195, 276 and 202 mEq (Na^+K-Cl^-S)/kg DM, respectively. Dry matter intake for C, SB and CMC did not differ (28.2, 28.5, 28.6 kg/d, respectively), and feed intake patterns during early (07:00–08:50 h) and late (08:50–11:00 h) morning were similar between treatments (time*treatment interaction: $P = 0.18$). The SB diet tended ($P = 0.053$) to reduce DM digestibility (63.7 vs. 65.6%) and increase ($P = 0.09$) fecal pH (6.65 vs. 6.60) compared with C. CMC cows had a higher ($P < 0.0001$) fecal pH than C cows (6.76 vs. 6.60), but digestibility did not differ. SB cows had lower ($P < 0.01$) milk yield (45.2 vs. 46.2 kg/d) and higher ($P < 0.01$) milk fat % (3.56 vs. 3.43%), but milk fat yield did not differ (1.60 vs. 1.58 kg/d) compared with C. CMC and C cows did not differ in milk yield (45.7 vs. 46.2 kg/d) or composition. Changes in body condition score were similar for C, SB and CMC (−0.08, −0.08, −0.04 units/30 d), and net energy (NEl) output (41.1, 40.9, 41.3 Mcal/d) and diet NEl concentration (1.46, 1.44, 1.44 Mcal/kg DM) for C, SB and CMC did not differ. Results suggest that SB buffered the rumen and/or improved acid base balance by increased DCAD, and that CMC buffered the abomasum and lower gastrointestinal tract. However, for diets and conditions comparable to this study, use of neither supplement is supported.

113 Quantification of phytate in dairy digesta and feces using alkaline extraction and high performance ion chromatography. P. P. Ray*, C. Shang, J. P. Jarrett, and K. F. Knowlton, *Virginia Polytechnic Institute and State University, Blacksburg.*

The quantification of phytate in feed, digesta, and feces from dairy cows is important in nutrition and environmental research. Development of accurate, sensitive, robust, and inexpensive quantification methods for undigested phytate in ruminant feces and digesta samples is essential to advance knowledge of phytate degradation and phosphorus (P) excretion in ruminants. Established quantification methods give satisfactory results for feedstuffs and nonruminants manures but recovery of phytate is incomplete for ruminant feces and digesta samples because of complex sample matrix and low ratio of phytate to inorganic P. The objective was to develop a robust, accurate, sensitive, and inexpensive method to analyze phytate in wide variety of samples including ruminant feces and digesta. Diets varying in phytate content were fed to dairy heifers, dry cows and lactating cows to generate digesta and feces samples of widely varying composition to challenge extraction and quantification methods. Samples were extracted with 0.5 M HCl and 0.25 M $NaOH^+$0.05 M EDTA, independently. Acid extracts were mixed with a 20% NaCl solution, alkaline extracts were acidified to final acidity of 0.35 M and then both extracts were clarified via elution through C_{18} cartridges. High performance ion chromatography (HPIC) was used to quantify phytate. In feed samples, phytate in alkaline extracts was comparable to that in acid extracts (2965 vs 3085 μg/g DM). In digesta and feces samples, alkaline extraction yielded greater estimates of phytate content than in acid extracts (40.7 vs 33.6 and 202.9 vs 144.4 μg/g DM). Acidification and C_{18}–cartridge elution of alkaline extracts overcame the interference from sample matrix allowing HPIC analysis. Pure phytate added to dry samples before extraction was almost complete recovered (88 to 105%). This indicates higher extraction efficiency, no adverse effect of pretreatment and accurate quantification of phytate. The proposed method is rapid, inexpensive, and robust and allows more accurate phytate quantification in ruminant feces and digesta samples.

Key words: high performance ion chromatography, dairy feces, phytate

114 Use of rumen fluid to inoculate dairy excrement for bio-fuel production by anaerobic digestion. C. L. Ross*, K. C. Das, and M. A. Froetschel, *University of Georgia, Athens.*

A series of in vitro fermentations were conducted to test the viability of rumen fluid inoculations for anaerobic digestion utilizing different sources of rumen fluid, different sources of dairy excrement, and activated charcoal in buffered and un-buffered systems. To test the viability of rumen fluid to inoculate anaerobic digestion, rumen fluid from dairy cattle and fresh excrement were tested using a 3x3 factorial design. Three dilutions (w/v, H2O) of excrement were inoculated with 3 mixtures of viable and nonviable (heated to 80°C) rumen fluid (100% viable, 50:50 viable-nonviable, and 100% nonviable). A phosphate-carbonate buffer was used in buffered systems. Dry matter and gross energy digestion, volatile fatty acids, pH, and methane (CH4) production were measured after 2d and 7d incubations. All measurements were corrected for rumen fluid contributions. Results of the un-buffered system were highly variable but the effects of rumen fluid inoculation were still evident. After 2d fermentations the viable rumen fluid had 34% to 47.4% greater acetate ($P = 0.0001$) tended to produce more CH4 (67%; $P = 0.21$) than fermentations inoculated with nonviable ($P = 0.21$). 7d fermentations inoculated with viable rumen fluid produced 137.6% more CH4 when un-buffered and 182.2% more CH4 when buffered compared with fermentations inoculated with nonviable ($P = 0.07$). Another in vitro experiment using different sources of rumen fluid and activated charcoal vs. buffer to enhance anaerobic digestion was conducted. Rumen fluid inoculants from feedlot, grazing, and dairy cattle were incubated with dried dairy excrement as substrate using a 3x2 factorial design with 3 levels of activated charcoal (0%, 1.5%, and 15%) and 2 levels of buffer in 2d fermentations. Measurements were conducted as described previously. Final pH of all fermentations were above 6.0 and digestion, VFA, and CH4 were unaffected by buffer or activated charcoal indicating dried excrement was not as fermentable and as suited a substrate for modeling anaerobic digestion as fresh excrement. These results provide evidence that inoculation and buffering conditions can stimulate methane production for anaerobic digestion of dairy excrement.

Key words: anaerobic digestion, biofuel production, rumen fluid inoculation

115 Effects of corn processing method and dietary inclusion of wet distillers grain with solubles on carbon-nitrogen balance of finishing cattle. K. E. Hales*[1], N. A. Cole[1], and J. C. MacDonald[2], *[1]USDA-ARS-CPRL, Bushland, TX, [2]Texas Agrilife Research Center, Amarillo.*

The growing ethanol industry in the Southern Great Plains has increased the use of wet distillers grains with solubles (WDGS) in beef cattle finishing diets. Effects of corn processing method and WDGS on carbon (C) and nitrogen (N) balance were evaluated in 4 Jersey steers using respiration calorimetry chambers. A 2 × 2 factorial arrangement of treatments was used in a Latin square design. The factors consisted of corn processing method (steam flaked corn [SFC] or dry-rolled corn [DRC]) and inclusion of corn-based WDGS (0 or 30% on a DM basis). Thus, the 4 treatment combinations consisted of: (1) SFC-based diet with 0% WDGS (SFC-0); (2) SFC-based diet with 30% WDGS (SFC-30); (3) DRC-based diet with 0% WDGS (DRC-0); and (4) DRC-based diet with 30% WDGS (DRC-30). Diets were balanced for DIP and fat. Total C (including gaseous-C) excretion ($P < 0.01$) and methane-C ($P < 0.04$) were greater for cattle consuming DRC than SFC-based diets, and cattle consuming SFC diets retained a greater ($P < 0.01$) quantity of C than those consuming DRC diets. Inclusion of WDGS did not affect ($P > 0.52$) C balance, except that cattle consuming diets containing 30% WDGS excreted more ($P < 0.01$) C in the urine than cattle consuming diets with no WDGS. No differences in N balance were detected ($P > 0.19$) between grain processing methods, although apparent N digestibility was greater ($P = 0.02$) for cattle consuming DRC- than SFC-based diets and N retained tended ($P = 0.10$) to be greater for cattle consuming DRC than SFC-based diets. Due in part to greater N intake, cattle consuming diets containing 30% WDGS excreted more ($P = 0.01$) total N and excreted a greater ($P < 0.01$) quantity of N in the urine. Apparent N digestibility (g/d and % of N intake; $P < 0.03$) and N retained ($P < 0.05$) were also greater in cattle consuming 30 compared with 0% WDGS. From these results we conclude that finishing cattle excrete a greater amount of C when fed DRC compared with SFC-based diets, and that dietary inclusion of 30% WDGS increases urinary N excretion when diets are balanced for equal DIP concentration.

Key words: distillers grain, corn processing, nitrogen

116 Effects of corn processing method and dietary inclusion of wet distillers grain with solubles on energy metabolism and enteric methane emissions of finishing cattle. K. E. Hales*[1], N. A. Cole[1], and J. C. MacDonald[2], *[1]USDA-ARS-CPRL, Bushland, TX, [2]Texas Agrilife Research Center, Amarillo.*

Few studies have used steam-flaked corn (SFC)-based diets to evaluate the effects of wet distillers grains with solubles (WDGS) in finishing cattle diets, and a reliable estimate of the net energy value of WDGS has yet to be determined. Effects of corn processing method and WDGS on energy metabolism and enteric methane (CH_4) production were evaluated in 4 Jersey steers using respiration calorimetry chambers. A 2 × 2 factorial arrangement of treatments was used in a Latin square design. The factors consisted of corn processing method (SFC or dry-rolled corn [DRC]) and inclusion of corn-based WDGS (0 or 30% on a DM basis). Thus, the resulting 4 treatment combinations consisted of: (1) SFC-based diet with 0% WDGS (SFC-0); (2) SFC-based diet with 30% WDGS (SFC-30); (3) DRC-based diet with 0% WDGS (DRC-0); and (4) DRC-based diet with 30% WDGS (DRC-30). The diets were balanced for DIP and fat. Each Latin square period consisted of 14 d diet adaptation and 7 d of fecal, urine, and gas (oxygen consumption, and carbon dioxide and CH_4 production) collections. As a proportion of gross energy (GE) intake, grain processing method did not affect ($P > 0.12$) fecal, digestible, urinary, and metabolizable energy or heat production. In contrast, retained energy tended to be greater ($P = 0.09$) for cattle consuming SFC- than DRC-based diets. Inclusion of WDGS did not affect ($P > 0.17$) fecal, digestible, urinary, metabolizable, and retained energy, or heat production as a proportion of GE intake. Steers consuming SFC diets produced less ($P < 0.04$) CH_4 (L/kg of DMI, % of GE intake) than steers consuming DRC diets. No differences were noted ($P > 0.55$) for CH_4 production between inclusion levels of WDGS. Results suggest that cattle consuming SFC diets produce less CH_4 and retain more energy than cattle fed DRC diets; however, dietary inclusion of WDGS at 30% seems to have little effect on CH_4 production and energy metabolism when diets are balanced for DIP and fat.

Key words: distillers grain, corn processing, methane

117 Effects of spoilage of wet distillers grains plus solubles on feedlot performance. J. L. Harding*, B. N. Nuttleman, K. R. Rolfe, T. J. Klopfenstein, and G. E. Erickson, *University of Nebraska-Lincoln.*

A study was conducted using 60 individually fed crossbred steers (399 ± 30 kg initial BW) in a CRD to evaluate the impact of spoilage of wet distillers grains plus solubles (WDGS) on feedlot performance. The 3 treatments included a dry-rolled corn based diet (control) and 2 diets containing 40% WDGS replacing DRC. The WDGS was purchased from the same ethanol plant on the same day and split equally within semi-load into either an uncovered bunker (spoiled WDGS) or into a silo bag and stored anaerobically (non-spoiled WDGS). Storage occurred 38 d before the initiation of the experiment. To ensure representative quality, samples of both WDGS were collected daily after allowing the WDGS to mix alone in the truck before diet mixing. Samples were composited by week for nutrient analysis. Composition of non-spoiled WDGS was 33.4% DM, 5.6% ash, 14.8% fat, 31.7% NDF, 30.8% CP, and a pH of 4.2. Composition of spoiled WDGS was 35.2% DM, 6.4% ash, 14.1% fat, 33.3% NDF, 30.8% CP, and a pH of 4.8. Nutrient analyses on the non-spoiled and spoiled WDGS samples were used to calculate nutrient loss for the spoiled WDGS. Calculations suggest 12% of DM was lost during storage of spoiled WDGS, with 16% fat and 8% NDF also lost compared with non-spoiled WDGS. No differences were observed in mycotoxins between spoiled and non-spoiled WDGS. Feeding control, non-spoiled WDGS, or spoiled WDGS did not affect DMI ($P = 0.50$). No differences ($P \geq 0.26$) in ADG (1.39 ± 0.30 kg), final BW (571 ± 46 kg), or G:F were observed between non-spoiled and spoiled WDGS treatments with 0.135 and 0.140 observed for G:F, respectively. However, both WDGS treatments were greater ($P \leq 0.04$) in ADG, final BW, and G:F compared with control (1.17 ± 0.24 kg ADG, 550 ± 43 kg final BW, and 0.117 G:F). No differences were observed for LM area ($P = 0.35$), fat ($P = 0.86$), marbling ($P = 0.57$), or yield grade ($P = 0.67$). Even though spoiled WDGS changed in nutrient composition, it did not affect feedlot performance of finishing steers.

Key words: cattle, spoilage, wet distillers grains plus solubles

118 Effect of partially replacing barley grain with wheat bran alone or in combination with condensed liquid whey on performance of backgrounding steers. A. D. Friedt*[1], T. A. McAllister[2], B. Wildeman[3], and J. J. McKinnon[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge Research Centre, AB, Canada, [3]Pound-Maker Agventures Ltd., Lanigan, SK, Canada.*

Debranning of wheat can increase starch throughput and thus increase the efficiency of ethanol production. It also generates a unique byproduct, wheat bran (WB) that can potentially be used as cattle feed. Few published results are available on WB as a feed source for cattle, particularly in combination with other byproducts such as condensed liquid whey (CLW). The objective of this trial was to evaluate the use of WB as a replacement for rolled barley (RB) in backgrounding diets, alone or in conjunction with CLW. Angus cross steers (n = 312, 303 ± 65 kg) were randomly assigned to 1 of 24 pens and fed 1 of 6 diets in a 2x3 factorial design. Dietary treatment included 2 levels of CLW (0 and 4.5%) and 3 levels of WB (0, 14 and 28%). Diet 1 consisted of 31.8% RB, 40.6% grass hay, 13.5% barley silage, 7.3% corn/wheat blend DDGS and 6.9% supplement (DM basis). Diet 2 was identical to diet 1 except 4.5% of RB was replaced with CLW. In the remaining diets, at each level of CLW, WB replaced RB at 14 and 28% (DM basis). Performance data over a 90 d period was analyzed as a completely randomized design with a factorial treatment arrangement with pen as the experimental unit. No ($P > 0.10$) WB by CLW interactions were detected. As well, no ($P > 0.10$) influence of CLW was seen on any performance parameter. Dry matter intake (DMI) was increased ($P < 0.01$) at each level of WB. Average daily gain (ADG) was not ($P > 0.05$) affected by treatment, however gain:feed was reduced ($P < 0.01$) at each level of WB inclusion. As a result, NE_m and NE_g of the diets, calculated based on animal performance was lower ($P < 0.01$) in the WB diets. Ultrasound l. dorsi area and subcutaneous fat thickness were not ($P > 0.10$) affected by treatment. The results of this study indicate that WB from front end processing of wheat at ethanol production facilities is a viable source of energy for growing cattle when fed with or without CLW. However, dietary NE_g concentration will be up to 16% lower when WB is fed as a replacement for RB at levels up to 28% of diet DM.

Key words: wheat bran, NE_g, backgrounding

119 Effects of wet distillers grains plus solubles on health and performance of high-risk calves. J. J. Wagner*, C. R. Krehbiel, D. B. Burken, B. K. Wilson, D. L. Step, and C. J. Richards, *Oklahoma State University, Stillwater.*

A randomized complete block design utilizing 180 high-risk crossbred yearling steers (initial BW = 212.3 ± 1.9 kg) was used to study the effects of including wet distillers grains plus solubles (WDGS) in a receiving diet on ADG, DMI, G:F, and morbidity over a 42-d period. Steers were sorted into light and heavy weight blocks and randomly assigned within block to 15 pens, each with 6 animals. Experimental treatments consisted of diets with inclusion of 0%, 15%, or 30% WDGS. Pens were considered the experimental unit and each treatment diet was fed to calves in 10 pens. Cattle were fed 2 times daily with approximately 50% of the daily allowance fed at each feeding. Feed refusals were measured following adverse weather and on weigh days. Steers were individually weighed at the start of the experiment, on d 14, and on d 42. During the experiment, 3 steers on the 0% treatment were diagnosed as chronically morbid with bovine respiratory disease (BRD) and were removed from the experiment. Average daily gain ($P < 0.20$; 0.96, 1.13, and 1.14 kg/d), DMI ($P < 0.27$; 4.75, 5.16, and 5.04 kg/d), G:F ($P < 0.79$; 0.222, 0.213, and 0.212), and animals treated for BRD ($P < 0.20$; 0.19, 0.20, 0.23) did not differ among treatments for 0, 15, or 30% WDGS, respectively. There were 3 chronics and no deaths during this experiment. Feeding WDGS receiving diets to high-risk calves did not impact animal health or performance. We conclude that up to 30% WDGS can be included in receiving diets for high-risk calves.

Key words: WDGS, high-risk calves, yearling steers

120 Effect of feeding crude glycerin on prevalence of *E. coli* O157:H7 in growing cattle. C. Aperce*, J. Heidenreich, C. J. Schneider, and J. S. Drouillard, *Kansas State University, Manhattan, Kansas.*

The objective of this study was to evaluate the effect of crude glycerin inclusion on *E. coli* O157:H7 prevalence in feces of cattle fed growing diets. Three levels of crude glycerin, 0, 4 or 8%, were added to growing diets containing dry-rolled corn, corn silage, alfalfa hay, and corn steep liquor. Each treatment was represented by 16 pens, each containing 7 to 8 heifers. Fecal grab samples were taken once/wk for 6 wk during summer of 2010. One gram of feces was incubated for 6 h at 40°C in gram-negative broth with cefixime (0.05 mg/L), cefsulodin (10 mg/L), and vancomycin (8 mg/L). One milliliter of broth was then added to *E. coli* O157 beads, subjected to immunomagnetic separation (IMS), and plated onto MacConkey agar with sorbitol, cefixime, and tellurite (CT-SMAC). After overnight incubation at 37°C, non-sorbitol fermenting colonies were picked and tested for indole production and O157 antigen agglutination. Positive colonies for both tests were confirmed as *E. coli* O157:H7 using the API 20E kit. Treatment effects and interactions were analyzed using Proc Glimmix of SAS. There was no interaction between sampling day and level of crude glycerin ($P > 0.2$). Percentages of samples that tested positive for *E. coli* O157:H7 were 1.3, 0.8, 4.3, 8.8, 4.3, and 5.8% during wk 1 through 6, respectively (effect of sampling day, $P < 0.01$). Fecal incidence rates of *E. coli* O157:H7 were 5.8, 4.3, and 2.4% for heifers fed 0, 4, and 8% glycerin, respectively (Linear, $P < 0.01$). Prevalence in heifers fed 4% glycerin tended to differ from that of cattle fed 8% glycerin ($P = 0.06$), but was not different from that of cattle fed the diet with 0% glycerin. Glycerin previously has been shown to inhibit the activity of cellulolytic bacteria in the rumen. Consequently, changes in fecal prevalence of *E. coli* O157:H7 observed in this study might be explained by alterations in gastrointestinal flora, with higher levels of glycerin producing a less favorable environment for the proliferation of pathogenic *E. coli*. Glycerin may be useful as a means of decreasing fecal prevalence of *E. coli* O157:H7 in cattle.

Key words: *E. coli* O157:H7, glycerin

121 Effects of distillers grain with soluble and supplemental copper and molybdenum on ammonia emissions and nitrogen retention. L. D. Cross*, S. R. Rust, and W. J. Powers, *Michigan State University.*

When moderate to high levels of DGS are fed, dietary CP is elevated, which may contribute to environmental pollution from increased nitrogen (N) emissions. A study was conducted to evaluate the effects of dried distillers grain with soluble (DDGS) on ammonia (NH_3) emissions. Twelve Holstein steers were housed in environmentally controlled rooms; 4 steers per dietary treatment. Three dietary treatments were fed; 0% DDGS (control), 40% DDGS, and 40% DDGS plus 6 ppm molybdenum (Mo) and 60 ppm copper (Cu) added to the diet. The

diet supplemented with Mo and Cu will be referred to as 40% DDGS plus. The study was divided into phases; phase 1 monitored emissions data for 22 d from the animal and manure (feces and urine mixture) and phase 2 monitored emissions for 4 d while steers were fitted with fecal bags to separate feces from urine. Ammonia emissions across all treatments were reduced from 74.8 mg/g N intake (NI)/d during phase 1 to 11.2 mg/g NI/d during phase 2 ($P < 0.01$). Within phase 1, both 40% DDGS diets had significantly greater NH_3 emissions at 83.0 mg/g NI/d compared with the control diets at 58.5 mg/g NI/d ($P < 0.01$). The 40% DDGS diet also differed in NH_3 emissions from 76.3 mg/g NI/d to 89.7 mg/g NI/d in 40% DDGS plus ($P = 0.05$). Total N balance was calculated from data collected during phase 2. Nitrogen intake increased from 129.8 g/d to 214.1 g/d in both 40% diets ($P < 0.01$). Nitrogen loss from gas (NH_3, NO_2, and NO^-) and feces were similar among treatments; however urine increased from 43.2 g/d to 78.1 g/d in both 40% DDGS diets ($P < 0.01$). The 40% DDGS plus diets had the greatest levels of total expelled N at 155.4 g/d compared with the control diets at 108.1 g/d. Additionally, inclusion of DDGS at 40% increased N retention from 21.7 g/d in the control diets to 69.3 g/d in the 40% DDGS diet ($P = 0.03$). The 40% DDGS plus diets had a mean N retention of 57.0 g/d, which was not significantly different from the control diets.

Key words: distillers grain with soluble, ammonia & nitrogen, molybdenum & copper

122 Effect of adding rumen degradable protein to a dried distillers grain supplement on growth performance and body composition in yearling Angus and Brangus heifers. E. N. Alava*, A. M. Monari, M. J. Hersom, and J. V. Yelich, *University of Florida, Gainesville.*

The objective of the experiment was to evaluate addition of a RDP source to a dried distillers grain (DDG) supplement in Angus (n = 30; 229 ± 4 kg) and Brangus (n = 30; 250 ± 4 kg) yearling heifers. On d 0, heifers were stratified by BW, breed, and sire to 12 pens of 5 heifers per pen and pens were randomly assigned to one of 3 supplementation treatments: DDG only (DDG), DDG plus soybean meal at 7.5% of total supplement (DDG+7.5), and DDG plus soybean meal at 15% of total supplement (DDG+15). Heifers were supplemented at a rate of 0.75% of BW, based on mean pen BW, and adjusted on a 28 d basis. All treatment groups also received ad libitum access to bermudagrass (*Cynodon dactylon*) round bale silage. Supplement was offered 3 d/wk. From d 0 to 140, BW and BCS were collected every 14 d and hip height (HH) every 28 d. On d 0 and 140 ultrasound measurements of the LM area (REA), 13th rib fat thickness (RIBFT), rump fat thickness (RMPFT), and intramuscular fat (IMF) were taken. Data were analyzed using MIXED procedure of SAS. There were no treatment differences ($P > 0.05$) in BW (351 ± 4.1 kg), BCS (5.6 ± 0.05) or HH (121 ± 0.5 cm) at d 140. Hip height was greater ($P \leq 0.05$) for Brangus than Angus at d 0 (115 ± 1.4 vs. 109 ± 1.4 cm) and d 140 (123 ± 1.2 vs. 118 ± 1.2 cm), respectively. There were no treatment differences ($P > 0.05$) for d 140 IMF, REA/100 kg BW, RMPFT, RIBFT, or ADG. However, DDG+15 (61.5 ± 1.6 cm^2) had a larger ($P \leq 0.05$) REA than DDG+7.5 (57.0 ± 1.6 cm^2) and DDG (57.2 ± 1.6 cm^2). Angus heifers had greater d 140 IMF ($P \leq 0.05$; 4.8 ± 0.2 vs. 3.1 ± 0.2 %), smaller REA ($P \leq 0.05$; 54.3 ± 1.3 vs. 62.8 ± 1.3 cm^2), smaller REA/100 kg BW ($P \leq 0.05$; 15.8 ± 0.3 vs. 17.5 ± 0.3 cm^2), and less RMPFT ($P \leq 0.05$; 0.54 ± 0.02 vs. 0.31 ± 0.25 cm) than Brangus, respectively. Final pregnancy rates were similar ($P > 0.05$; DDG = 95.0, DDG+7.5 = 78.9, DDG+15 = 80.0%) across treatments. Addition of RDP to a DDG supplement provided no additional benefit to growing yearling Angus or Brangus heifers.

123 Feeding distillers grains containing elevated sulfur concentration depresses performance of feedlot steers. S. Uwituze[1], C. L. Van Bibber*[1], K. A. Miller[1], K. K. Karges[2], L. C. Hollis[1], J. J. Higgins[3], and J. S. Drouillard[1], *[1]Department of Animal Sciences and Industry Kansas State University, Manhattan, [2]Poet Nutrition, Sioux Falls, SD, [3]Department of Statistics Kansas State University, Manhattan.*

Crossbred yearling steers (n = 50; 462 ± 26.6 kg BW) were used in a finishing trial to evaluate effects of feeding dried distillers grains with solubles (DDGS) containing elevated sulfur levels on feed consumption, growth performance, and carcass traits. The study was a randomized complete block design with 3 treatments: chronic high S (CHS; 0.60% DM), chronic intermediate S (CIS; 0.50% DM), and sporadic intermediate S (SIS; 0.40 or 0.60% DM). Two DRC-based finishing diets (0.40 and 0.60% S) containing 30% DM of DDGS were mixed each morning. The CIS diet was made by mixing (50:50) 0.40 and 0.60% S diets. The SIS treatment consisted of intermittent feeding of either 0.40 or 0.60% S based on a random feeding schedule. The CIS and SIS treatments delivered same S content over the entire study period. Steers were blocked by weight and randomly assigned within block to treatments and 50 individual concrete surfaced pens equipped with feed bunks and water fountains that allowed free access to feed and clean water. Steers were fed once daily at approximately 0800 h and feed refusals were determined at approximately 0700 h the following day, thus making it possible to determine actual daily DMI. Steers were harvested on d 100 (n = 27) and 135 (n = 23). There were no treatment effects on carcass traits ($P > 0.10$). Treatment effects on growth performance are summarized below. Elevated dietary S depresses feed intake by feedlot cattle.

Table 1. Treatment effects on performance of feedlot steers

	Treatments				
Item	CHS	CIS	SIS	SEM	*P*-value
DMI, kg/d[1]	9.8[a]	10.9[b]	10.4[b]	0.28	0.02
ADG, kg/d	1.19	1.41	1.33	0.072	0.09
G:F	0.119	0.128	0.127	0.006	0.46

124 Effects of crude glycerin in byproducts diets on performance and carcass characteristics of feedlot cattle. E. H. C. B. van Cleef*[2], S. Uwituze[1], C. L. Van Bibber[1], K. A. Miller[1], C. C. Aperce[1], K. L. Blaine[1], J. J. Higgins[1], and J. S. Drouillard[1], *[1]Kansas State University, Manhattan, [2]São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Crossbred heifers (n = 374; 334 ± 37 kg BW) were used to evaluate feedlot performance and carcass traits when fed diets containing 0, 7.5, or 15% crude glycerin. Treatments (5 diets) consisted of a control diet containing 31% dry-rolled corn, 10% corn silage, 35% wet corn gluten feed, 20% soybean hulls, 0.3% salt, and 3.7% supplement, and diets containing 7.5 or 15% glycerin (DM basis) with and without 0.3% salt. Glycerin replaced dry-rolled corn. Heifers were vaccinated against common viral and clostridial diseases, de-wormed, implanted,

and stratified by initial BW. Within strata, heifers were assigned randomly to 25 feedlot pens (5/treatment). Over a period of 21 d, heifers were transitioned from diets containing 50% concentrate to their respective 90% concentrate finishing diets using 4 step-up diets that contained progressively greater proportions of concentrate. Final diets provided 14% CP, 0.7% Ca; 0.5 mg/d melengestrol acetate, 300 mg/d monensin, and 90 mg/d tylosin. Zilpaterol was included in the diet starting 23 d before harvest, and fed for 20 d, and cattle were harvested on d 125. Data were analyzed using the Mixed procedure of SAS, with treatment as a fixed effect and weight strata as a random effect. Removing salt from glycerin-based diets did not impact finishing performance ($P \geq 0.50$). Glycerin did not influence ADG ($P \geq 0.3$), but resulted in a linear decrease in DMI (12.4, 11.8, and 11.3 kg/d for 0, 7.5, and 15% glycerin, respectively; $P \leq 0.01$) and a linear improvement in gain efficiency (0.148, 0.151, and 0.158; $P \leq 0.05$). Carcass weight, USDA yield grade, LM area, and % KPH were unaffected ($P \geq 0.10$) by diet. Twelfth rib fat thickness was less for heifers fed 15% glycerin without salt compared with other treatments ($P \leq 0.05$), but the remaining treatments did not differ ($P \geq 0.10$). Marbling was less for heifers fed diets containing glycerin compared with heifers fed the control diet (linear effect of glycerin, $P \leq 0.01$; quadratic effect, $P \leq 0.05$). Including glycerin in byproduct-based diets improves feed efficiency by decreasing feed intake, but also depresses marbling score and quality grade.

Key words: byproducts, glycerin, salt

125 Use of corn or crude glycerol as energy source to supplement holstein calves fed with sorghum silage ad-libitum. P. Chilibroste*[1], A. Elías[2], and J. P. Marchelli[1], *[1]Agronomy Faculty, EEMAC, Paysandu, Uruguay, [2]Instituto de Ciencia Animal, San Jospe de las Lajas, La Habana, Cuba.*

An experiment was conducted to determine the BW and DMI of Holstein calves fed sorghum silage as the only fiber source and supplemented or not with a concentrate based either in corn grain or crude glycerol as energy source. The experiment took place between October 26 and December 21 of 2010 at the Experimental Station M. A. Cassinoni, Agronomy Faculty of the Republic University in Uruguay. Data were analyzed in a completely randomized block design with a repeated measurement in time model. Twenty-four 6.6 ± 1.2 mo old Holstein female dairy calves were randomly assigned to one of the following 3 treatments: TS = whole crop sorghum silage fed ad-libitum, TSC = TS plus a corn based supplement (10g/kg LW), TSG = TS plus a glycerol based supplement (10g/kg LW). Chemical composition of sorghum silage, corn and glycerol based supplement are shown in Table 1. BW of calves at the beginning of the experiment was 181.5 ± 14.2 kg. Feeds were offered once a day and orts were collected, weighed and sampled daily before the new offer. Animals were weighed every 15 d with overnight fasting. Average daily gains (kg/day) were significantly higher ($P < 0.01$) for TSC (0.518) and TSG (0.571) than TS (0.189) while TSC and TSG were not significantly different between them. Mean silage intake (as fed) was 16.6 ± 2.84 kg/day with no significant difference between treatments neither in the mean value nor in the slope heterogeneity test . We conclude that both supplements (TSC and TSG) can be used to feed Holstein calves with similar efficiency.

Table 1. Feeds chemical composition

Fraction	Sorghum silage	Corn based supplement	Glycerol based supplement
CP %	7.0±0.67	31.6±3.2	30.3±5.6
NDF %	73.9±1.62	22.3±2.3	16.5±0.7
ADF %	45.9±2.5	9.15±1.2	9.05±2.76

Key words: corn, crude glycerol, Holstein calves

126 Substitution of distillers grains and glycerin for steam-flaked corn in finishing cattle diets on performance and carcass characteristics. J. Jaderborg*, D. M. Paulus, G. I. Crawford, and A. DiCostanzo, *University of Minnesota, St. Paul.*

This study was designed to determine the effect of substituting modified distillers grains (DGS) or soy glycerin for steam-flaked corn (SFC) in finishing diets on performance and carcass characteristics of yearling cattle. Forty-eight crossbred yearling cattle (21 steers and 27 heifers) averaging 380 kg initial BW were blocked by sex and allotted to one of 48 individual feed bunks. Nine animals were removed from the study; one for health reasons, and the others were confirmed outliers resulting from feed stealing. Cattle were fed one of 4 dietary treatments once daily at 0800. Treatments resulted from the 2 × 2 factorial arrangement of DGS at 0% or 35% of diet DM and glycerin at 0% or 10% of diet DM in SFC (0.47 kg/L flake density) and grass hay (10% of diet DM) diets: 1) DGS and no glycerin, 2) no DGS and no glycerin, 3) DGS and glycerin, 4) no DGS and glycerin. Diets contained 16.5% CP, 1.48 Mcal NEg/kg DM, 0.75% Ca, 0.47% P, and from 0.17% to 0.25% S. Dry matter intake was greater ($P < 0.003$) for cattle fed diets containing DGS than for those fed diets without DGS (9.97 vs. 8.43 kg/d). Carcass-adjusted ADG (1.41 ± 0.24 kg) was not affected ($P > 0.10$) by feeding either co-product. A tendency ($P = 0.06$) for greater carcass-adjusted G:F (0.171 vs. 0.145) was observed for cattle consuming diets without DGS . Carcass-adjusted G:F was similar ($P > 0.10$) for cattle fed glycerin and those fed no glycerin (0.157 vs. 0.159). Hot carcass weight (370 ± 28 kg), LM area (82.6 ± 6.45 cm2), 12th rib fat depth (1.40 ± 0.37cm), yield grade (2.74 ± 0.64) and marbling score (530 ± 60) were not ($P > 0.10$) affected by dietary treatment. However, KPH was greater ($P < 0.01$) for cattle fed DGS diets than for those fed diets without DGS (2.71% vs. 2.42%). Iterated ME values of diets containing DGS were 13% lower ($P < 0.05$) than those without DGS. At the inclusion levels in this study, soy glycerin had a similar energy value and DGS a lesser energy value than SFC.

Key words: cattle, distillers grains, glycerin

127 Effect of linoleic acid supplementation to Holstein dams and calves on immune measures of calves. M. Garcia*, L. F. Greco, J. E. P. Santos, and C. R. Staples, *University of Florida, Gainesville.*

The aim of this study was to evaluate supplementing linoleic acid (LA) to cows during the last 2 mo of pregnancy and their calves from birth to 60 d of age on calf immune measures. Cows (n = 96) were fed a basal diet formulated to supply a minimum amount of LA and supplemented without fat, with saturated fatty acids (SFA at 1.75% of dietary DM, or with Ca salts of primarily unsaturated fatty acids enriched in LA (EFA; Megalac-R, Church and Dwight, Co.) at 2% of dietary DM. Within 2 h of birth, calves were fed 4 L of colostrum from their own dam or from a dam of the same dietary treatment using an esophageal feeder. Calves were blocked by gender and dam diet and assigned randomly to receive a milk replacer (MR) with low (0.56% LA; LLA) or high concentration of LA (1.78% LA; HLA, DM basis) for 60 d. Milk replacer was fed twice daily at 6.7 g of fat per kg of metabolic BW and amounts were adjusted weekly. A single grain mix of minimum LA concentration was offered in ad libitum amounts starting at 31 d of age. The effect of feeding HLA-MR to calves was not influenced by fat supplementation of their dams (interaction of MR by dam diet was not detected). Calves born from cows fed fat tended ($P = 0.06$) to have a greater plasma concentration of haptoglobin (1.05 vs. 0.94 OD x 100). Blood neutrophils from calves born from cows fed EFA had greater ($P = 0.04$) mean florescence intensity for phagocytosis of *E. coli* (122 vs. 113). Concentration of WBC was not affected by diet of cows or calves, but calves fed HLA-MR had greater ($P = 0.04$) concentration of blood lymphocytes (4608 vs. 4201/uL) and tended ($P = 0.07$) to have greater concentration of eosinophils at 7 and 14 d than calves fed LLA-MR. Mean plasma concentration of acid soluble protein was lower ($P = 0.01$) for the HLA-MR group (94.3 vs. 106 ug/mL). Production of interferon-gamma by isolated peripheral blood mononuclear cells stimulated with Con-A in vitro tended ($P = 0.13$) to be increased (27.8 vs. 17.6 pg/mL) in calves fed HLA-MR. Supplementing LA to pregnant cows and to newborn calves appeared to have some pro-inflammatory effects in the calves.

Key words: calves, fat, immunity

128 Effect of replacing solvent-extracted canola meal with high-oil traditional canola, high-oleic acid canola, or high-erucic acid rapeseed meals on milk production and milk fatty acid composition in lactating dairy cows. A. N. Hristov*[1], C. Domitrovich[1], A. Wachter[1], T. Cassidy[1], C. Lee[1], K. J. Shingfield[2], P. Kairenius[2], J. Davis[3], and J. Brown[3], *[1]Pennsylvania State University, University Park, [2]MTT Agrifood Research Finland, Jokioinen, Finland, [3]University of Idaho, Moscow.*

The objective of this experiment was to investigate the effects of replacing solvent-extracted conventional canola meal (Control) with high-oil content, mechanically-extracted conventional canola meal (Canola), high-oleic, low-polyunsaturated fatty acids (FA) canola meal (HOLL), and high-erucic acid, low-glucosinolate rapeseed meal (Rape) on milk production, rumen function, digestibility, and milk FA composition in lactating dairy cows. The experiment was a replicated 4 × 4 Latin square design with 8 lactating dairy cows (109 ± 15.1 DIM). Oilseed meals were included at 12 to 13% of dietary DM. Fat and CP concentrations (% of DM) of the meals were: 3.1 and 43%, 16.1 and 32.8%, 13.7 and 45.2%, and 17.9 and 34.3%, respectively. Relative to the control, inclusion of high-oil seed meals in the diet lowered ($P = 0.006$) ruminal acetate concentration and decreased DMI (30.9 vs. 28.8 kg/d, respectively; $P = 0.001$). Milk yield was lower ($P = 0.047$) for Canola and Rape than the Control (44.9, 45.0, and 47.1 kg/d, respectively). Treatments had no effect on milk composition, other than an increase ($P < 0.001$) in MUN for HOLL. Urinary urea N losses and ammonia emission from manure were increased ($P = 0.03$) by HOLL. Replacing solvent-extracted canola meal with the high-oil meals decreased milk fat 12:0, 14:0, 16:0 and total saturated FA content and enhanced cis-9 18:1 and total monounsaturated FA concentrations ($P < 0.05$). Relative to the control, Canola increased ($P = 0.03$) total trans FA in milk, while inclusion of HOLL increased ($P = 0.009$ and 0.003) trans-11 18:1 and cis-9,trans-11 CLA content. Rape increased milk fat cis-13 22:1 content from 0.07 to 2.33 g/100 g FA. In conclusion, high-oil canola or rapeseed meals, which are likely to come from small-scale biodiesel plants where oil is cold pressed without hexane extraction, fed at levels at or above 12 to 13% of dietary DM may decrease feed intake and milk production, but can be used to alter milk FA composition in lactating dairy cows.

Key words: canola meal, rapeseed meal, dairy cow

129 Chain length of dietary saturated fatty acids affects meal patterns and plasma metabolite and hormone concentrations of cows varying in milk yield. M. Hollmann*, M. S. Allen, and D. K. Beede, *Department of Animal Science, Michigan State University, East Lansing.*

Dietary saturated medium-chain fatty acids (FA; $\leq C_{12}$) in coconut oil (CO) often depress DMI of cows but the underlying mechanisms are not well understood. Eight cows were blocked by milk yield (HIGH: 53 to 59 kg/d; LOW: 24 to 35 kg/d) and assigned to treatment sequence in a crossover design experiment. Dietary treatments were 3.35% (dry basis) of CO or saturated long-chain FA (Energy Booster 100®, EB). Diets contained 58% forage (corn silage, and alfalfa hay and haylage), 26.3% NDF, and 14.5% CP (dry basis). Periods were 27 d, and cows were milked twice and fed once daily. Blood samples were collected before feeding and hourly post-feeding for 6 h on d 17 through 20. Feeding behavior was measured from d 21 through 24. CO reduced daily DMI by 18% ($P < 0.01$) regardless of production level (interaction: $P > 0.4$) and increased the size of the first meal following feeding (conditioned meal) as a proportion of daily DMI (33 vs. 22%; $P < 0.01$) and amount (tendency: 6.0 vs. 5.2 kg; $P < 0.13$). However, hunger ratio (meal size per preceding inter-meal interval) of the first spontaneous meal following the conditioned meal tended to be lower for cows fed CO than EB (1.7 vs. 2.6 kg/h; $P < 0.07$). CO increased plasma concentrations of insulin, NEFA, and BHBA ($P < 0.01$), but did not affect glucose and glucagon concentrations compared with EB. Concentrations of insulin and BHBA did not differ between treatments before feeding but CO increased concentrations after the first meal more rapidly than EB. The rapid elevation of BHBA following the conditioned meal is consistent with increased hepatic FA oxidation for CO compared with EB. Feeding behavior results are consistent with control of feed intake by hepatic oxidation of FA because the reduction in DMI by CO was only for spontaneous meals when plasma BHBA concentration was elevated.

Key words: feeding behavior, hepatic oxidation, DMI regulation

130 Effects of different amounts of dietary protected and unprotected niacin on responses of blood metabolites to an epinephrine challenge in dairy cows. F. C. Cardoso*[1], J. Garrett[2], and J. K. Drackley[1], [1]*University of Illinois, Urbana,* [2]*QualiTech, Chaska, MN.*

Niacin may modulate lipolytic responses in adipose tissue but is highly degradable in the rumen so that oral administration leads to unknown quantities absorbed. We determined responses to epinephrine (EPI) challenge as affected by 3 levels of protected niacin (PN) or unprotected niacin (UN) in the diet or infused abomasally. Six multiparous rumen–cannulated Holstein cows (BW = 656 kg; 128 ± 23 d in milk) were used in a completely randomized 6 × 6 Latin Square with an extra period to quantify carry-over effects. Periods consisted of 7 d for adaptation followed by 7 d for measurements. Cows were fed according to NRC (2001) recommendations. Treatments were: CON, no niacin; INF, abomasal infusion of 12 g UN; N12, 12 g UN; BN3, 3 g PN; BN6, 6 g PN; and BN12, 12 g PN. Treatments N12, BN3, BN6, and BN12 were top-dressed on the TMR twice daily. Treatment INF was divided in 5 equal portions and infused every 4 h. Cows receiving treatments other than INF were infused with the same volume of water at the same times. On d 12 cows received an i.v. infusion of EPI (1.4 μg/kg BW). Blood was sampled at −45, −30, −20, −10, and −5 min before EPI infusion and 2.5, 5, 10, 15, 20, 30, 45, 60, 90, and 120 min after. Total area under the curve (AUC) responses of NEFA and glucose concentrations in plasma were calculated. Statistical analysis was performed using the MIXED procedure of SAS. Least squares means were separated using the Tukey adjustment. A quadratic effect existed among treatments BN3, BN6, and BN12 ($P = 0.01$) for NEFA AUC. Time to peak NEFA concentration tended ($P = 0.08$) to be greater for N12 (22.1 ± 3.2 min) than for BN12 (14.8 ± 3 min). For glucose, INF resulted in greater AUC than N12 ($P = 0.04$) and BN12 tended to have greater AUC than N12 ($P = 0.07$). Glucose AUC displayed a quadratic response among treatments BN3, BN6, and BN12 ($P = 0.03$). Time to peak and peak concentration of glucose, as well as NEFA peak concentration, did not differ ($P > 0.1$). In conclusion, dietary PN unexpectedly resulted in greater lipid mobilization in response to EPI challenge compared with cows receiving equivalent dietary UN.

Key words: niacin, lipolysis, epinephrine

131 Chain length of saturated fatty acids affects intake and ruminal turnover of NDF and chewing activity in lactating cows varying in milk yield. M. Hollmann*, M. S. Allen, and D. K. Beede, *Department of Animal Science, Michigan State University, East Lansing.*

Coconut oil (CO), a source of dietary saturated (90%) medium-chain fatty acids (FA; 60% of FA ≤ C_{12}), reduces DMI and NDF digestibility. To test effects of CO compared with Energy Booster 100® (EB; 90% of FA C_{16} and C_{18}; 90% saturated) on ruminal NDF turnover and pool size and chewing activity, 8 cows were blocked by milk yield (53 to 59 vs. 24 to 35 kg/d) and fed diets containing either 3.35% (dry basis) CO or EB in a crossover design. Diets contained 58% forage (55% corn silage, 45% alfalfa hay and haylage) and 26.3% NDF (86% from forage), dry basis. Periods were 27 d, and cows were fed once daily. Feeding behavior was monitored and feed ingredients, orts, and milk were sampled d 21 through 24. Rumens were evacuated and digesta sampled 4 h after feeding on d 25 and 2 h before feeding on d 27. Reported results differed at $P < 0.05$. Cows fed CO consumed 18% less DM and NDF daily compared with those fed EB and no interaction was detected between treatment and production level. However, the conditioned meal after feeding was numerically greater for CO compared with EB (6.0 kg vs. 5.2 kg; $P < 0.13$). CO decreased NDF turnover rate (3.7 vs. 4.6%/h) and increased NDF turnover time (29 vs. 23 h) compared with EB, but ruminal NDF pool size was similar between treatments. Digesta weight and volume did not differ but digesta density was greater for CO compared with EB. CO reduced molar concentration of ruminal acetate (66 vs. 80 mM) and acetate-to-propionate ratio (2.3 vs. 3.1), but not propionate (28 mM), and decreased ruminal pH post-feeding (5.3 vs. 5.7), but not pre-feeding (6.0) compared with EB. Cows fed CO spent more time ruminating (8.9 vs. 7.4 h/d) and chewing (13.2 vs. 12.1 h/d) than those fed EB. Increased turnover time may have been because CO decreased ruminal NDF digestibility and passage rate (not measured). Although CO reduced DMI while maintaining rumen pool size of digesta, lack of interaction of treatment by production level and the numerical increase in DMI for the conditioned meal do not support rumen distention as a mechanism for lower DMI for CO.

Key words: NDF digestion, saturated fatty acid, rumination

132 Performance and milk fatty acid profile of Holstein dairy cows in response to dietary fat supplements and forage:concentrate ratio. S. Kargar[1], M. Khorvash[1], G. R. Ghorbani*[1], M. Alikhani[1], and D. J. Schingoethe[2], [1]*Isfahan University of Technology, Isfahan, Iran,* [2]*South Dakota State University, Brookings.*

The objective of this experiment was to investigate the lactation performance of dairy cows fed hydrogenated palm oil and yellow grease. The experiment was conducted with alfalfa-based diets containing whole cotton seed, with different forage to concentrate (F:C) ratios being fed supplemented with hydrogenated palm oil or yellow grease. The experiment used 8 lactating Holstein cows in a replicated 4 × 4 Latin square with 3 wk periods. Treatments were: 1) no added fat and 34:66 F:C ratio (Control); 2) 2% hydrogenated palm oil and 34:66 F:C ratio (HPO); 3) 2% yellow grease and 34:66 F:C ratio (YG); or 4) 2% yellow grease and 45:55 F:C ratio (YGHF). All data were analyzed using the MIXED procedure of SAS. Preplanned statistical contrasts were used to test the effect of fat supplementation (Control vs. HPO + YG); the effect of source of fat supplement (HPO vs. YG); and the effect of forage to concentrate ratio within diets supplemented with yellow grease (YG vs. YGHF). Feeding fat and increasing F:C ratio had no effect on milk yield but fat source influenced milk yield ($P < 0.05$). Fat supplementation tended ($P < 0.06$) to increase milk fat content and yield but were not affected by increasing F:C ratio. Feeding fat and source of fat tended ($P < 0.07$) to increase and increased ($P < 0.01$) total milk fat conjugated linoleic acid without affecting desaturase indices, respectively. Fat supplementation decreased milk short-chain FA and increased long-chain FA (LCFA) with significant changes in C18:0 and cis-9 C18:1 concentration. Furthermore, YG decreased medium-chain FA and increased LCAF and total unsaturated FA of milk fat relative to HPO. Total tract digestibility of organic matter was greater ($P < 0.05$) in the YG diet than HPO, however, it was not affected by fat compared with control and also F:C ratio. Feeding yellow grease had no detrimental effects on nutrient digestibility but increased production responses and improved milk FA profile without inducing milk fat depression. Increasing F:C ratio did not affect production performance and increased saturated FAs of milk fat.

Key words: yellow grease, forage to concentrate ratio, CLA

133 Effect of a high palmitic acid fat supplement on ruminal fermentation and milk production in high- and low-producing dairy cows. D. E. Rico* and K. J. Harvatine, *The Pennsylvania State University, University Park.*

Two experiments tested the effect of fatty acid (FA) supplements on milk production and composition. In experiment 1, 24 Holstein dairy cows were blocked by production level (High > 40 kg/d and Low < 30 kg/d) and in a replicated 3x3 Latin Square design. Treatments were control (no supplemental fat), Ca-Salts of palm FA (Ca-FA; Megalac; 2.4% of DM), and free FA high in palmitic acid (PA; BergaFat F100; 2% of DM). The statistical model included the random effect of period, cow and sequence, and the fixed effect of treatment, block and the interaction of block and treatment. There was a treatment by block interaction ($P < 0.05$) for fat percent but not for milk yield or other milk components. In high producing cows, milk fat percent was not different between control and PA, but was lower for the Ca-FA compared with PA (2.87 and 3.21%, $P < 0.01$). In contrast, in low producing cows, treatment had no effect on the concentration or yield of milk fat. Treatment did not affect milk yield or DMI (42.1 ± 2.6 kg/d and 26.3 ± 1.36, respectively) in the high producing block; concentration and yield of milk components was also no affected. For low producing cows, DMI was higher in the control compared with the PA treatment (24.1 and 22.9 kg/d, $P < 0.05$), but was not different between PA and Ca-FA. In experiment 2, 16 high producing cows (>40 kg milk/d) were used in a crossover design with 14 d periods. Treatments were Ca-FA and PA fed as described above. The statistical model included the random effect of cow nested in sequence and period and the fixed effect of treatment. Milk yield was significantly higher in the PA compared with Ca-FA treatment (45.8 vs. 44.1 kg/d, $P < 0.01$). There was no effect of treatment on DMI. Yields of fat, protein, and lactose were higher ($P < 0.05$) in PA vs Ca-FA. Our results show that Ca-FA decreases milk fat content relative to PA in high producing cows but not in low producing cows. Under some circumstances, PA can increase yield of milk and of milk components.

Key words: dairy cows, palmitic acid

134 Effect of extruded flaxseed or alfalfa protein concentrate in interaction with two levels of concentrate on milk fat production. C. Hurtaud*[1], G. Chesneau[2], D. Coulmier[3], and J. L. Peyraud[1], *[1]INRA-Agrocampus Ouest UMR[1080] Production du Lait, Saint-Gilles, France, [2]Valorex, Combourtillé, France, [3]Desialis, Paris, France.*

Increasing milk omega-3 fatty acids (FA) content is desirable for human health. Our objective was to study the effect of 2 supplements rich in omega-3 in interaction with the proportion of concentrate in the diet on milk FA composition. The 2 sources of omega 3 were extruded flaxseed (FLAX, 1 kg.d^{-1}) and alfalfa protein concentrate (APC, 2 kg.d^{-1}) supplying respectively 115 and 49 g.d^{-1} omega-3 per cow. The cows were fed a corn silage based diet with 30% (C0) or 65% (C+) cereal based concentrate. The trial was carried out according a nested reversed design using 24 dairy cows averaging 117 ± 14 DIM with 2 periods of 14 d. Data were analyzed according a split plot design using proc mixed procedure. There was no significant interaction between the level of concentrate and the form of omega-3. C+ largely decreased milk fat content (−1.15 %) and yield (−301 g.d^{-1}), the proportion of saturated FA (especially C16:0, C18:0, C4:0, C6:0 and C8:0) and increased trans C18:1, (especially t9, t10 and t12). Compared with FLAX, APC increased milk fat content (0.33 %), saturated FA (especially C4 to C12, C14:0 and C16:0) and decreased cis and all trans C18:1 isomers. Actually, FLAX induced high levels of cis and trans C18:1 isomers, c9t11CLA and C18:2 isomers. Transfer rate of C18:3 from feed to milk was much higher for APC (15.3 vs 4.7%) and increased with C+ when FLAX was fed. Decrease in milk fat content with C+ is classical and is due to the large amount of concentrate that had probably increased rumen propionic acid and t10 FA. It seems that these nutrients could have had a negative additive effect on milk fat content and yield. Especially, t10 FA could have inhibited FA synthesis in mammary gland. Decrease in milk fat content with FLAX is a consequence of heat seed treatment that increases oil release in the rumen, limiting ruminal biohydrogenation and inducing more trans FA. Positive effect of APC on transfer rate could be due to its manufacturing process inducing a lipid-proteic coagulum protecting FA. The effect of nature and protection of lipids on biohydrogenation depends on level of concentrates.

Key words: concentrate, lipids, milk fatty acids

135 Abomasal infusion of butterfat during CLA induced milk fat depression in lactating dairy cows. D. Vyas*[1], U. Moallem[2], B. B. Teter[1], P. Delmonte[3], and R. A. Erdman[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]Agriculture Research Organization, Bet Dagan, Israel, [3]U.S. Food and Drug Administration, Center for Food Safety and Applied Nutrition, College Park, MD.*

During diet induced milk fat depression (MFD), the short and medium chain fatty acids (SMCFA), which are synthesized de novo in the mammary gland, are reduced to a much greater extent than the long-chain fatty acids(LCFA) which originate from the diet. Our hypothesis was that increased availability of SMCFA might rescue conjugated linoleic acid (CLA) induced MFD in lactating dairy cows. To test that hypothesis, 4 rumen fistulated lactating Holstein cows (128 ± 23 DIM) were used in 4 × 4 Latin square design with 3 wk experimental periods. Treatments were applied in 2 × 2 factorial arrangement during the last 2 wk of each period and included abomasal infusion 3X daily of a total of: 1) 230 g/d of long chain FA (LCFA, blend of 59% cocoa butter, 36% olive oil and 5% palm oil); 2) 420 g/d butterfat (BF); 3) 230 g/d LCFA with 27 g/d CLA (LC-CLA) containing 10 g/d of t10, c12 CLA and 4) 420 g/d butterfat with 27 g/d CLA (BF-CLA). Data were analyzed using Mixed procedure in SAS using treatments as fixed whereas period and cows as random factors in the model. $P \leq 0.05$ was considered statistically significant. Butterfat provided 50% of C16:0 and similar amounts of C18 FA as found in LCFA such that the difference between the BF and LCFA treatments were 190g/d SMCFA. No effects were observed on DMI or milk yield. Milk fat content was significantly reduced ($P = 0.001$) by 41% with LCCLA and 32% with BF-CLA and milk fat yield was reduced ($P < 0.001$) by 41% and 38% with LCCLA and BF-CLA compared with their respective controls. Milk FA composition showed significant reduction of de-novo synthesized FA (DNFA) with CLA infusion. Milk fat percent and DNFA yields were greater for BF-CLA compared with the LC-CLA ($P = 0.09$). In conclusion, the increased availability of SMCFA from BF during CLA induced MFD was able to rescue 21% and 7% of milk fat content and yields, respectively but differences were not significant. Milk fat responses suggest potential limitation of SMCFA however increased availability of the respective FA might not completely rescue MFD.

Table 1.

Item	BF	BF-CLA	LCFA	LC-CLA	SEM
DMI (kg/d)	24.9	24.0	25.4	22.6	1.26
Milk yield (kg/d)	49.2	46.0	47.9	46.9	5.84
Milk fat (%)	3.38[a]	2.30[b]	3.36[a]	1.99[b]	0.21
Milk fat yield (g/d)	1640[a]	1013[b]	1600[a]	937[b]	169.7

136 The partial replacement of soya and rapeseed meal with urea or a slow release urea source (Optigen) and its effect on intake, performance and metabolism in dairy cows. L. A. Sinclair*, P. Griffin, G. H. Jones, and C. W. Blake, *Harper Adams University College, Newport, Shropshire, UK.*

The objectives of the study were to determine the effect of partially replacing soya and rapeseed meal with urea or a slow release urea source (Optigen; Alltech UK) on the intake, performance and metabolism in dairy cows. Forty-two Holstein-Friesian dairy cows were allocated to one of 3 treatments in each of 3 periods of 5 wk duration in a Latin square design. The first 28 d of each period allowed adaptation to the dietary treatments with measurements during the final 7 d. Cows receiving the control treatment (C) received a mixed ration that included (DM basis) 38% corn silage, 18% grass silage, 29% concentrates and 15% of a 60:40 mix of soya and rapeseed meal. Cows on the Urea (U) or Optigen (O) treatments received the same basal ration but with the replacement of 1.1 kg/cow/d of the soya/rapeseed meal mix with either 100 g of feed grade urea or 110 g of Optigen respectively. There was no effect ($P > 0.05$) of treatment on dry matter intake or milk yield (mean values of 22.5 and 33.9 kg/d respectively). There was a trend ($P = 0.09$) for cows fed U or O to have a higher milk fat content (average of 40.1 g/kg for U and O vs. 38.9 g/kg for C). Milk true protein concentration and yield were not affected by treatment ($P > 0.05$) but milk urea content tended to be lower ($P = 0.07$) in cows fed C compared with U or O. Hourly plasma urea concentrations were higher ($P < 0.05$) in cows fed U and lowest in C, but there was no effect ($P > 0.05$) of treatment on plasma ammonia levels. Cows fed O had a higher ($P < 0.01$) efficiency of N use (kg milk N/kg N intake) and food conversion ratio (kg fat-corrected milk/kg DM intake) ($P < 0.001$) and tended ($P = 0.07$) to have a higher live weight gain than those fed C, with cows receiving U having intermediate values. In conclusion, the replacement of a mixture of soya and rapeseed meal with feed grade urea or Optigen can be achieved without affecting milk performance, with N and feed efficiency being higher and live weight gain tending to be higher in animals fed Optigen compared with a soya/rapeseed meal mixture.

Key words: dairy cow, slow release urea, performance

137 Effect of added fat to diets for dairy cattle on production performance and dry matter intake. A. R. Rabiee[1], K. Brienhild[1], W. Scott[1], H. M. Golder[1], E. Block[2], and I. J. Lean*[1], *[1]SBScibus, Camden, New South Wales, Australia, [2]Church & Dwight Co. Inc., Princeton, NJ.*

It was hypothesized that effects of different dietary fats on production performance of dairy cattle differ and are influenced by diet composition. Literature provided 39 studies containing 86 comparisons of control diets to diets with different fat sources. Only randomized controlled trials were included, if these provided: information on fat treatment and diet, data on outcomes of interest and a measure of variance. Fats were evaluated in 5 groups; tallow and greases; oilseeds (cotton, soy, sunflower), Ca salts of palm fatty acids (Capalm), other Ca salts (fish, linseed, flaxseed and others), and prilled fats. Statistical evaluation used a random effects analysis to estimate the effect size (ES) and 95% confidence interval (95% CI) for milk, fat and protein yields and DMI. The ES in milk production was increased 0.265 (95%CI = 0.101 to 0.429; $P = 0.002$) and the weighted mean difference (WMD) was 0.659 kg per day (95% CI = 0.115 to 1.203). Increase in ES for Capalm, oilseeds and other Ca-salts were significant ($P < 0.1$). Milk fat yield ES was 0.144 (95% CI = −0.010 to 0.298; $P = 0.07$) and the WMD was 0.03 kg per day (95% CI = 0.004 to 0.051). ES for fat yield was positive ($P < 0.05$) for CaPalm and Oilseeds, ES for milk protein yield was −0.004 (95% CI = −0.198 to 0.191; $P = 0.971$) and the WMD was −0.006 kg per day (95% CI = −0.022 to 0.010). The ES for DMI was −0.335 (95% CI = −0.467to −0.202, $P < 0.0001$). The WMD for DMI was −0.571 kg per day (95% CI = −0.851to 0.290). These results, were heterogenous ($P < 0.002$), indicating that responses were not consistent across trials. Responses among different fat sources varied. All fat sources negatively affected DMI. The largest effects on WMD were from Tallow and other Ca-salts at −0.8 and −1.7 kg/d, respectively. Univariate meta-regression analysis showed that the different fat sources were not sources of heterogeneity for milk yield ($P = 0.658$), and milk protein yield ($P = 0.681$), but were for milk fat yield ($P = 0.002$) and DMI ($P = 0.052$). This study provides good evidence that use of fats improves the efficiency of milk production performance, but results are influenced by types of fat used and other factors.

Key words: dietary fats, meta-analysis

138 Effect of dietary fat blend and monensin supplementation on dairy cattle performance, milk fatty acid profiles and milk fat depression. M. He[1], K. L. Perfield[2], H. B. Green[2], and L. E. Armentano*[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]Elanco Animal Health, Greenfield, IN.*

The effect of feeding increasing levels of $C_{18:1}$ and $C_{18:2}$ both independently and together, with or without monensin, was evaluated. Fifty-six Holsteins were blocked by parity. Pairs of cows (1 high and 1 low production) of the same parity were assigned to a single feeding station and cow pair was the experimental unit. Cow pairs were assigned to monensin (15.9 g/ton DM) or control as main plot. The 7 cow pairs in each of the Monensin/Parity groups were further assigned to a sequence of fat blend diets as split plot. Seven fat blend treatments in the split plot 7 × 7 Latin Square were no added fat (NoFAT), or diets with increasing levels of $C_{18:1}$ or $C_{18:2}$: 1.0% $C_{18:1}$, 1.5% $C_{18:2}$ (LOLL); 1.0% $C_{18:1}$, 2.7% $C_{18:2}$ (LOML); 1.0% $C_{18:1}$, 3.9% $C_{18:2}$ (LOHL); 2.1% $C_{18:1}$, 1.5% $C_{18:2}$ (MOLL); 2.2% $C_{18:1}$, 2.7% $C_{18:2}$ (MOML); 3.3% $C_{18:1}$, 1.5% $C_{18:2}$ (HOLL). Each period had 21 d with last 4 d for sample collection. Data reported were analyzed using the mixed model of SAS (Y = covariate + monensin + parity + monensin × parity + fat + fat × monensin + fat × parity + period + period × monensin + period × parity + production). Monensin feeding did not affect milk fat concentration and yield but decreased the proportion of $C_{<16}$ (21.0 vs. 22.9%), increased the proportion of total C_{18} (49.7 vs. 47.7%), increased the proportion of t-10, c-12 CLA (0.07 vs. 0.05%), and increased the proportion and yield of t-10 $C_{18:1}$ (5.2 vs. 3.5% and 40.0 vs. 28.1 g/d, respectively) in milk FA. As either $C_{18:1}$ or $C_{18:2}$ increased beyond these 2 FA present in LOLL, milk fat concentration and yield and milk $C_{<16}$ yield decreased, and milk t-10 $C_{18:1}$ yield increased. When dietary total FA and FA other than $C_{18:1}$ and $C_{18:2}$ were similar,

$C_{18:2}$-rich diets decreased milk fat yield compared with $C_{18:1}$-rich diets (LOML vs. MOLL; LOHL vs. HOLL), indicating that $C_{18:2}$ is more potent than $C_{18:1}$ on milk fat depression. Increasing dietary FA content from NoFAT to LOLL, which increased primarily $C_{18:1}$ and $C_{18:2}$, reduced the yield of $C_{<16}$ while increasing total C_{18} yield in milk. Few significant monensin × fat interactions were detected on milk composition parameters analyzed.

ADSA-SAD Dairy Foods Undergraduate Competition

139 Milk fats in the American diet. R. Pomeroy*, *North Carolina State University, Raleigh.*

The USDA-FNS [United States Department of Agriculture - Food and Nutrition Services] has recently proposed a rule to revise the Nutrition Standards in the National School Lunch and School Breakfast Programs, this revision is based on the 2005 USDA - HHS [Health and Human Services] Dietary Guidelines for Americans, and consistent with the recently released 2010 edition. One of the rulings requires schools to include either fat-free or 1% milk instead of the variety of milk fats offered currently as part of reimbursable meals. Compiled information from many scientific reviews, USDA abstracts and primary sources examine the potential health benefits of milk fats and the health concerns of whole milk. The USDA suggests 3 servings of fat-free or low fat dairy products per day; this suggestion is consistent with the objective to decrease obesity and blood cholesterol levels in Americans, which could contribute to cardiovascular disease. The opposing concern on this issue relates to the potential health benefits of milk fats; such as anti-carcinogen effects and the availability of good unsaturated fatty acids. There are many differing opinions for the nation's health at large, and the implications of this research shows that while some individuals may benefit from the extra energy provided from the fats in whole milk, most Americans do not need these extra calories in their daily food pattern.

Key words: skim milk, whole milk, milk

140 Fortification of omega-3 milk. K. C. Smith*, D. R. Winston, B. A. Corl, and K. M. Waterman, *Virginia Polytechnic Institute and State University, Blacksburg.*

Omega-3 fatty acids (n3) are polyunsaturated fatty acids essential to the human diet. Omega-3 fatty acids have been proven to play major roles in various functions of the body, such as brain development, prevention of cardiovascular disease, Alzheimer's disease and depression. Examples of n3 fatty acids include docosahexaenoic acid (DHA), docosapentaenoic acid (DPA), eicosapentaenoic acid (EPA), eicosatetraenoic acid (ETA) and stearidonic acid (SDA). Adequate intakes of n3 fatty acids (g/d) for adults consuming a 2000 kilocalorie diet are 6.67 for α-linolenic acid and approximately 0.22 for both DHA and EPA. These n3 fatty acids cannot be made by consuming α-linolenic acid, an essential fatty acid only synthesized by plants. Very long chain n3 fatty acids are also obtained from fish including tuna or salmon. Milk can be fortified with n3 fatty acids by fortifying at the plant or by supplementing the cow's diet. However, both these processes have complications. Marine oil additions to processed milk often add an off-flavor and smell, and consumers tend to shy away from a product that is not sensually stimulating. Marine oils or genetically modified soybeans supplemented into the diet of the dairy cow can supply n3 fatty acids, but rumen microbes tend to biohydrogenate unprotected polyunsaturated fatty acids, resulting in absorption of saturated fatty acids. Long chain n3 fatty acids also have poor transfer into milk fat reducing total absorption into milk. Fortifying milk with n3 fatty acids may not be as beneficial as enriching other agricultural commodities such as eggs or chicken because of off flavors, expense of rumen-protected feeds, and lack of transfer efficiency into milk.

Key words: omega-3, fortification

141 The promise of bovine lactoferrin for breast cancer prevention. E. Schaffel* and J. Fain, *Clemson University, Clemson, SC.*

Studies have shown the numerous benefits of milk and other dairy products on human health. In particular, bovine lactoferrin (bLF), an iron-binding whey protein, has been discovered to act as an antiviral, antifungal, anti-inflammatory, antioxidant, and antiparasite agent. In addition to milk, lactoferrin can be found in other tissues or secretions, such as tears, saliva, and blood. In the past several years, researchers have encountered the protein's ability to inhibit the growth of certain tumors and metastasis. Cancer is a result of several alterations in normal cells: the ability to be self sufficient in growth signals; to avoid antigrowth signs and apoptosis; to obtain an endless ability to replicate; to maintain angiogenesis; to evade tissues; and to form metastases. In one research trial, rodents receiving oral administration of bovine lactoferrin experienced significantly reduced tumorigenesis in varying organs (esophagus, tongue, lung, liver, colon, and bladder). This shows promise for future human health benefits as last year, over one million people were diagnosed with breast cancer and 460,000 people died of breast cancer worldwide, making it the second leading cause of cancer death in women and on the top 10 causes of death in high income countries worldwide. In a recent study, lactoferrin's tumor suppressing properties were observed on 2 types of human breast cancer cells: HS578T and T47D, the more aggressive form being the HS578T cells. The cells were either treated or untreated for varying periods of time with differing lactoferrin concentrations, which ranged from 0.125 μM to 125 μM. Researchers studied cell viability, apoptosis, migration, and proliferation. Although the specific results from each of these areas differed and the exact mechanisms are not completely understood, overall results highlight the whey protein's disruptive effects on vital steps in cancer development. Increasing research on the benefits of bovine biologically active food components have helped scientists better predict preventative methods to inhibit the spread of chronic diseases and show promises for combating the breast cancer epidemic.

Key words: bovine lactoferrin, breast cancer, prevention

142 Market research to boost dairy product demand. A. N. Waldeck*, *University of Kentucky, Lexington.*

Market research can provide dairy processors with knowledge to boost dairy product sales. Asking consumers about new products, improved products, and product positioning helps to generate more dairy industry revenue. Over the past 25 years, total dairy product consumption has increased while fluid milk consumption has decreased. The dairy checkoff program creates new partnerships to increase dairy product demand. The dairy industry has partnered with other corporations to boost sales through mutually beneficial marketing arrangements. Starbucks, Yoplait, and McDonald's all have incorporated dairy processing technology to ensure that dairy products remain a prominent ingredient in each of these company's product lines. The dairy industry has also partnered with Domino's and McDonald's to increase cheese consumption. For example, 2 slices of cheese are included on each McDonald's Angus Third Pounder. This item was only supposed to be on the menu for a limited time, but the product was popular enough that it is now on the menu permanently. An estimated 532 million pounds of milk is used annually for this product alone. Pizza companies purchase 25 percent of the cheese produced in the United States (DMI 2009 Annual Report). Domino's was the first pizza chain to add

extra cheese to their pizzas. As other pizza chains have observed the increase in sales resulting from this change, the number of chains offering and promoting extra cheese on the menu has increased. Market research also allows dairy processors, such as Dean Foods, to generate valuable information about targeted market segments. This information can be used to refine and focus advertising, promotion, and new product launches to these targeted populations to increase revenues. This research may also be helpful in communicating human nutrition benefits of dairy products. Market research is a multi-step process that requires considerable planning to ensure that effective information is collected and used. Market research has and will continue to contribute to dairy product consumption through product innovations, corporate collaborations, and marketing campaigns.

Key words: market research, dairy product demand, consumer

143 Dairy super foods: Antioxidants could make the difference. S. B. Weimer* and D. R. Olver, *Pennsylvania State University, University Park.*

Antioxidants are substances that reduce oxidative damage caused by free radicals, which are highly reactive molecules or atoms that attack and modify the chemical structure of cells. Because of the damages they prevent, antioxidants have been linked to fighting cancer, heart disease, and even aging. Foods naturally rich in antioxidants and those fortified with antioxidants are becoming more popular. Dairy foods are entering the antioxidant race. Fortifying dairy products such as yogurt with antioxidants has the potential to bolster sales by providing an even more appealing value-added product. Foods such as yogurt may be excellent carriers for antioxidant extracts because dairy products have the ability to mask the bitter taste of certain antioxidants. In a Uruguayan study (Ares et al., 2009), researchers compared sucrose, sucralose, polydextrose, and milk for their abilities to reduce the bitterness, astringency, and characteristic flavors of antioxidant extracts from 2 native plants. The study found that each reduced the strong flavors of the antioxidants, but that effectiveness was dependent on the type and concentration of the antioxidant extract being considered. For one of the plant extracts, milk was most effective at masking bitterness and astringency; however, for the other plant extract, sucrose was the best inhibitor of strong flavors. As a result, the study concluded that "sweetened dairy products could be interesting carriers for the development of functional foods containing polyphenolic-rich antioxidant extracts." Development of antioxidant enhanced food products is rapidly increasing. Mintel, a market research company, reported an increase of 1,616 products in the antioxidant-enhanced food and beverage category between 2005 and 2009. Companies from across the world and in the United States are beginning to offer dairy products with added antioxidant benefits.

Key words: antioxidants, dairy product innovation

144 What you don′t know can hurt you: Unlocking the secrets of milk. T. Hippman*, *Louisiana State University, Baton Rouge.*

Milk and milk products are an excellent source of vitamins and minerals. Vitamins in milk include vitamin A, thiamin, riboflavin, niacin, and vitamin B6. Minerals contained in milk include calcium, phosphorous, potassium, copper, iron, and zinc. A lack of these in the diet can cause a variety of problems such as paralysis, osteoporosis, hypertension, blindness, skin problems, irritability, and fatigue. Milk is an ideal source of these vitamins and minerals, not only because it is rich in them, but also because it contains them in the proper ratios to facilitate absorption. Of these vitamins and minerals, research has shown calcium and vitamin D to be extremely important in the diet. Research shows that vitamin D deficiency and rickets are re-emerging as health problems in infants and children. Therefore it is extremely important to maintain a healthy intake of milk and milk products on a daily basis to reduce the risk of a vitamin or mineral deficiency and thus the potential occurrence of disease.

Key words: vitamins, minerals, milk

145 The effect of an exogenous amylase on performance and total tract digestibility in lactating dairy cows. M. M. McCarthy*[1], M. A. Engstrom[2], E. Azem[3], and T. F. Gressley[1], *[1]University of Delaware, Newark, [2]DSM Nutritional Products Inc., Parsippany, NJ, [3]DSM Nutritional Products, Ltd., Basel, Switzerland.*

The objective of this trial was to determine performance and digestibility response of lactating dairy cows to a reduced starch diet containing a commercial amylase product. Twenty-six Holstein cows (82 ± 60 DIM) were blocked by parity and DIM and assigned to treatments in a 3 × 3 Latin square design, with 28-d periods. Treatments were normal starch TMR (NS), reduced starch TMR (RS), and reduced starch TMR with exogenous amylase (RSE). The hypothesis was that RS would decrease milk production and diet digestibility compared with NS and that RSE would alleviate some of this decrease. Rations were 41% concentrate and the NS TMR contained 12.8% corn grain, 2.9% soyhulls, and 2.9% citrus pulp. The RS and RSE TMR contained 6.0% corn grain, 6.9% soyhulls, and 6.9% citrus pulp. Starch concentrations in NS, RS, and RSE TMR were 27.5, 23.2, and 22.4%, respectively. Milk production and DMI were measured daily and milk composition was measured weekly. Fecal grab samples were collected at the end of each period and digestibility of DM and nutrients were determined. Data were analyzed using a mixed model containing the fixed effects of treatment, week, period, and their interactions, and the random effects of cow and block. Contrast statements were used to evaluate effects of dietary starch (NS vs. RS + RSE) and enzyme (RS vs. RSE). There was no effect of starch or enzyme on DMI, milk composition, or starch digestibility ($P > 0.10$). Increased dietary starch increased yields of milk (47.6 vs. 46.2 kg/d, $P = 0.03$), protein (1.38 vs. 1.34 kg/d, $P = 0.03$), and lactose (2.25 vs. 2.18 kg/d, $P = 0.02$) and tended to increase fat yield (1.33 vs. 1.28 kg/d, $P = 0.02$). Addition of amylase did not affect any production parameters. Increased starch reduced NDF digestibility (41.4 vs. 47.0%, $P < 0.01$). Addition of amylase increased digestibility of DM (72.1 vs. 70.1%, $P = 0.02$) and CP (73.4 vs. 71.1%, $P = 0.05$), and tended to increase OM digestibility (73.4 vs. 72.0%, $P = 0.10$). Although addition of exogenous amylase increased nutrient digestibility in a low starch TMR, this was not reflected by improved animal performance.

Key words: amylase, starch, by-product feeds

146 Spoilage yeasts in silage have the potential to directly impact rumen fermentation. M. C. Santos*[1], A. L. Lock[2], G. D. Mechor[3], and L. Kung Jr.[1], *[1]University of Delaware, Newark, [2]Michigan State University, East Lansing, [3]Elanco Animal Health, Greenfield, IN.*

Yeasts associated with aerobic spoilage of high moisture corn (HMC) and corn silage (CS) were isolated and characterized to determine their potential for direct effects on rumen fermentation. Samples were obtained from 21 US dairy farms; HMC averaged 6.3 and CS averaged 5.4 $\log_{10}$ cfu of yeasts/g of fresh forage. *Candida valida* (CV) was the most predominant species accounting for 35 and 31% of total isolates in HMC and CS, respectively. One isolate of CV was added to in vitro culture tubes containing TMR, buffer and rumen fluid at theoretical concentrations of 0, 4.4, 6.4 and 8.4 $\log_{10}$ cfu/ml; the 6.4 dose was equivalent to a cow consuming 30 kg of fresh CS with 7.0 $\log_{10}$ cfu/g. After 12 and 24 h of incubation at 39°C, samples were analyzed for pH, yeast number, NDF-D, volatile fatty acids (VFA) and fatty acids (FA). Culture pH declined from 6.8 at 0 h to 6.4 and 6.3 after 12 and 24 h, respectively ($P < 0.01$). After 24 h, numbers of viable yeasts for the control treatment decreased from 2.4 to 0.4 $\log_{10}$ cfu/ml. For the other levels, the measured numbers at time 0 decreased from 4.0, 5.9 and 8.1 to 2.2, 3.9 and 5.3 $\log_{10}$ cfu/ml after 24h, respectively. Inoculation with CV caused a linear decrease in NDF-D at 12 and 24 h ($P < 0.01$). After 12 h, NDF-D for the highest CV addition was 34 vs 44% for control and after 24h NDF-D was 52 vs 58%. At 24 h, the concentration of total VFA, acetate and propionate was 106, 57 and 29 mM for the highest CV dose whereas for control the concentrations were 98, 53 and 25 mM, respectively ($P < 0.05$). FA analysis of CV indicated that it contained ~25% SFA, 60% cis MUFA, and 15% cis PUFA. Overall, the biohydrogenation of unsaturated FA was not altered across treatments and declined over time with an increase in the accumulation of SFA, especially stearic acid; under the conditions tested, CV did not alter the formation of BH intermediates. The results of this study indicate that addition of CV, especially in high levels, can decrease NDF-D and may alter the concentration of propionate and acetate. However, no changes in the production of BH intermediates were detected under the in vitro conditions tested.

Key words: *Candida valida*, NDF-D, biohydrogenation

147 The effects of PPAR-gamma agonist and conjugated linoleic acid on mammary and hepatic lipid metabolism in lactating mice. D. Vyas*[1], B. B. Teter[1], P. Delmonte[2], and R. A. Erdman[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]U.S. Food and Drug Administration, Center for Food Safety and Applied Nutrition, College Park, MD.*

Previous studies have demonstrated the antagonizing effects of PPAR-gamma agonists on conjugated linoleic acid (CLA) induced hepatic steatosis and adipose tissue lipodystrophy. We hypothesized that the PPAR-gamma agonist, Rosiglitazone (ROSI), might also antagonize the CLA induced reduction in milk fat synthesis in lactating mice. Our objective was to investigate the interaction of ROSI and CLA on mammary and hepatic lipid metabolism in lactating C57Bl/6J mice. Nineteen lactating mice were randomly assigned to one of 4 treatments (n = 4–5 per treatment) applied from Day 6 to 10 postpartum. Treatments included: 1) Control (C) diet; 2) Control plus 1.5% dietary CLA (CLA); 3) Control plus intra-peritoneal (IP) ROSI injections (10 mg/kg BW) (ROSI); and 4) CLA plus ROSI (ROSI-CLA). Mice on the C and CLA diets received IP phosphate buffered saline (PBS). Day 6 values were used as covariates for milk fat and pup body weight in the 2 × 2 factorial analysis of covariance. Food intakes were similar among treatments although there was a trend ($P = 0.09$) for increased intake with ROSI. Milk fat was depressed 42% by CLA ($P < 0.001$). ROSI significantly reduced milk fat ($P = 0.05$) and the depression was greater with ROSI-CLA. Liver weights were increased by CLA ($P < 0.001$) and reduced ($P = 0.005$) by ROSI. Pup weight gain was reduced 44% by CLA ($P < 0.001$) but not affected by ROSI. Rosiglitazone corrected the apparent steatosis effect of CLA but had no effect on CLA induced milk fat depression. As ROSI is an insulin sensitizing agent, reduced liver lipid accumulation and increased fat oxidation, along with increased glucose uptake by adipose tissue might explain reduced liver weights with ROSI treatment. Since glucose is used as a precursor for de novo fatty acid synthesis in rodents, the reduction in milk fat with ROSI-CLA could have been due to increased glucose utilization in peripheral tissues thereby reducing glucose availability for triglyceride synthesis in the mammary gland.

Table 1.

Item	Control	ROSI	CLA	ROSI-CLA	SEM
Dam food intake, g/d	6.76	7.73	5.61	6.69	0.62
Milk fat (%)	35.47[a]	34.42[a]	21.94[b]	18.48[c]	1.02
Liver weight, % of BW	8.54[b]	7.46[c]	10.54[a]	8.72[b]	0.51
Pup weight gain, g/d	0.44[a]	0.38[a]	0.23[b]	0.23[b]	0.03

148 Expression of T-box (Tbx) 3 in bovine mammary epithelial cells. M. L. Procopio*, A. C. Lopez, K. M. McFadden, T. A. Hoagland, G. W. Kazmer, and K. E. Govoni, *Department of Animal Science, University of Connecticut, Storrs.*

Development of the bovine mammary gland is a complex process that is regulated by several hormones, growth factors and transcription factors. Tbx3 is a transcription factor that is required for mammary gland development in humans, regulates cell cycle, and is overexpressed in many breast cancer cell lines. We recently demonstrated that growth hormone (GH) treatment increases the mRNA expression of Tbx3 in osteoblast cells independent of insulin-like growth factor (IGF)-I. Based on the critical role of Tbx3 in mammary gland development and its response to GH, we hypothesize that GH treatment will increase Tbx3 expression in bovine mammary epithelial cells (MEC). Primary bovine MEC were isolated from lactating cows at slaughter and cultured in Dulbecco′s Modified Eagle Medium (DMEM) supplemented with fetal bovine serum. In addition, MAC-T cells, a well established MEC line, were cultured under similar conditions. Prior to treatment, cells were serum starved in phenol red free media for 24 h. Cells were treated with control (CON) media (DMEM + 0.2% BSA), and GH (500 ng/μL) or IGF-I (200 ng/μL) for 24 h and RNA was extracted. mRNA expression was determined by real-time RT-PCR and data were analyzed using students *t*-test. Expression of Tbx3 was similar between MEC and MAC-T cells ($P = 0.7363$), therefore the primary MEC were used for additional experiments. Surprisingly, we did not observe a significant change in Tbx3 expression in cells treated with GH ($P = 0.10$). However, IGF-I treatment reduced Tbx3 expression 1.5-fold compared with CON ($P < 0.05$). In summary, we did not observe any effect of GH on Tbx3 expression in MEC, however a slight decrease was observed with IGF-I treatment. These findings are in contrast to the role of Tbx3 in mediating GH in the osteoblast, thus demonstrating that Tbx3 action may be cell and/or tissue specific.

Key words: mammary epithelial cells, growth hormone, transcription factors

ADSA-SAD Dairy Production Undergraduate Competition

149 Colostrum replacers in neonatal dairy calf management. E. Eckelkamp*, *Louisiana State University, Baton Rouge.*

Colostrum, the first and most important feed given to a newborn calf, is the primary source of nutrients for the calf and also provides essential and irreplaceable antibodies. The main concern with colostrum in general is its concentration of immunoglobulins, particularly IgG. A colostrometer is used to measure colostrum quality, with a 50 g/L concentration of IgG considered the benchmark for good quality colostrum. Maternal colostrum varies in quality, and not all colostrum is good enough to feed to a calf to provide adequate immune protection. Colostrum replacers provide alternatives to feeding maternal colostrum. Colostrum replacers are intended to contain the same amount of IgG as good maternal colostrum. When comparing colostrum replacers and maternal colostrum, it is important to consider serum IgG and total protein concentrations in the calf as well as the incidence of failure of the passive transfer of immunity. There are advantages to each type of colostrum product, and these must be carefully evaluated when determining which to use. Colostrum replacers are uniform, with an adequate amount of IgG present for the calf. Maternal colostrum is already present on the dairy and does not have to be purchased. In addition it contains IgG for diseases that are endemic to a specific dairy. There are 2 primary methods of obtaining the immunoglobulins in colostrum replacer. The first is by drying bovine maternal colostrum with a high IgG content, and the second is obtained from dried bovine serum. Several studies have compared the effectiveness of maternal colostrum and colostrum replacers. The colostrum replacers varied in their ability to provide adequate immune protection depending on the concentration of globulin fed. In conclusion, when fed in the correct amounts, colostrum replacers and maternal colostrum are comparable in quality for providing passive transfer of immunity in neonatal dairy calves.

Key words: colostrum, colostrum replacers, dairy calves

150 Genomics: A tool for commercial dairy producers. L. Ellison*, *University of Florida, Gainesville.*

Vigorous, high-producing cows are what dairy producers look for everyday to keep their herds healthy and productive. Cattle have been selected based on best productive traits for centuries, first with observations of phenotypic traits, then with Predict Transmitting Ability data from pedigrees and progeny data. With today's technology, we now have Genomics. Genomics was officially established as a form of genetic selection in January 2009 after a group of researchers developed the bovine genome by sequencing all DNA markers that compose dairy genetics. From 2003 to 2006, geneticists have strove to identify gene sequences within an animal's DNA that directly influence certain traits such as milk production or productive life. Genomics testing currently comes in the form of 3 tests: 3k, 50k, or 800k SNP (single nucleotide polymorphism) tests. For commercial producers, there is a great advantage in using 3k SNP tests in determining future production. Dairy producers can rank animals at an early age assisting them in keeping their best animals for future production and worst ranked animals for culling, or potentially breed to a higher ranked bull for improvement. Producers can make more accurate mating decisions with their heifers and young bulls and use genetically superior bulls with even more reliability. With this knowledge, producers can make better decisions for higher profitability.

Key words: genomics, genetic selection

151 Implementing an accelerated heifer program: Is it worth the risk? S. E. Fraley* and E. L. Karcher, *Michigan State University, East Lansing.*

Increasing feed costs and lower than average milk prices are inhibitory factors making it increasingly difficult for dairy producers to make a profit. With 15–20% of expenses on farms linked to heifer programs (Whitlock et al., 2002), many producers are considering accelerated growth programs for heifers to minimize costs and maximize profits. Our objective was to determine the effect of accelerated growth programs on mammary development and milk production later in life. Increasing dietary energy in prepubertal heifers inhibits mammary growth relative to body growth in a time-dependent manner (Rincker et al., 2008). Brown et al., (2005) observed increases in mammary parenchyma in calves fed milk replacer with 4.4 kcal of ME/g DM and 30.3% CP as well as a starter grain that was 25% CP from 2 to 8 wk of age. Rapid somatic growth after puberty and associated reduced mammary development, are associated with lifetime milk production. Heifers grown at a faster rate than 680 g/d produced 5–10% less milk than heifers not grown at an accelerated rate (Van Amburgh et al., 1998). Heifers on an accelerated growth program would cost the producer less in overall feed and labor because of the decrease in nonproductive day. However, the potential loss in milk production could result in a negative profit, especially if that loss occurred over the complete productive life (Vandehaar, 2001). Although accelerated heifer growth may be an effective tool to reduce replacement heifer costs, the potential loss in income makes this a risky program for dairy producers. Before deciding to implement an accelerated growth program on farm, producers need to weigh all the options and decide if the benefits offset the risks.

Key words: heifer, accelerated growth

152 Genomic testing as a tool for herd development. L. Krueger* and J. Robison, *California State University-Fresno, Fresno.*

The need for an efficient method of herd development has been made apparent through the difficulties in maintaining profitability after a sizeable herd expansion. Breeding programs on herds nationwide have utilized the potential transmitting abilities of sires available for artificial insemination by selecting animals for production based on pedigree. The artificial insemination industry increased efficiency by moving from selection based on pedigree and performance to selection based on genetic potential, determined through genomic testing. Since the beginning of this movement in 2004, the ability to accurately project genetic potential has improved, with a 3000 single-nucleotide polymorphism (SNP) genomic test offered as an alternative to a 50,000 SNP test for practical purposes, at 20% of the cost. The practicality of this technology has also improved with the combination of ear tissue collection and identification establishment. For the producer, genomic testing means the ability to act on advance information that would otherwise take 3 years (heifer development and one lactation) to discover. Due to the availability and practicality of these developments, genomic testing is on the verge of becoming commonplace in the rearing of replacement herd animals as a tool in increasing efficiency and profitability.

Key words: genomics, test, herd development

153 Impact and control of claw lesions in dairy cattle. T. A. Reiter* and J. M. Bewley, *University of Kentucky, Lexington.*

Untreated claw lesions, a leading cause of dairy cattle lameness, are a growing problem for the dairy industry. The cost of a clinical case of lameness has been estimated to be $128 to $627. Although producers may only consider the economic impact of lameness, it is also important for dairy cow welfare. Drendel et al. (2004) reported that 74.5% of heifers had claw lesions before they were 12 mo old and 85.7% had lesions a month before calving. Heifers that had lesions before calving were more likely to have lesions during lactation. Heifers that had lesions during their first lactation had significantly lower milk yields (2,496 kg less per lactation), even if they were not showing signs of lameness. Additionally, claw lesions increase the rate of premature culling and reduce estrus expression and reproductive performance. The claw is softer during lactation causing it to be more susceptible to lesions. Lesions can be categorized as infectious or noninfectious. Infectious lesions include digital dermatitis, heel erosion, and foot rot. Noninfectious lesions include white line lesions, sole ulcers, and sole hemorrhages. In establishing a prevention plan for claw lesions, dairy producers should consider environmental exposure risks. Wet environments with excessive mud and manure lead to soft and worn hooves and increase the spread of infectious agents. Housing or management conditions that result in excessive standing times cause the claw to weaken because the supportive tissue begins to break down and the horn changes shape. Nutritional factors may also contribute to claw lesions including high levels of ruminally available carbohydrates, lack of fiber, inadequate trace minerals, ration sorting, and inconsistent feeding schedules. Footbaths, typically placed in parlor exit alleys, can be used for prevention and treatment of infections using chemical solutions. Producers should work with their veterinarians and hoof trimmers to understand the cause of lesions in their herd to establish herd-specific prevention and treatment plans.

Key words: claw lesions, lameness, hoof care

154 Bacteriophages as a potential treatment for mastitis. E. G. Sumners*, D. R. Winston, and I. K. Mullarky, *Virginia Polytechnic Institute and State University, Blacksburg.*

Mastitis is the most costly disease in dairy cattle. With consumer preferences against the use of antibiotics, the dairy industry needs to identify alternatives treatments for mastitis. Bacteriophages may be an effective alternative method for treating mastitis. The use of bacteriophages has been studied in humans, mice, and dairy cattle. Bacteriophages are viruses that attack and lyse specific bacteria. However, they do not affect normal microflora. Specific bacteriophage isolates have been studied that lyse an important mastitis pathogen, Staphylococcus aureus. A study that compared multiple bacteriophage isolates ability to lyse specific strains of S. aureus in milk. The study also implied that some bacteriophages may lyse at all stages of bacterial growth and others lyse at particular stages of growth. However, another study examined the efficacy of treating S. aureus infected quarters with bacteriophages and found a 16.7% cure rate. Thirteen cows and 18 quarters where treated with bacteriophage isolates for 5 d. The results for the latter study do not support the use of bacteriophage therapy at this time. Future studies should be conducted evaluating different treatment periods and other bacteriophage isolates. Benefits that bacteriophages have over antibiotics include: no affect on microflora; ecologically purity; no side effects; and natural enemies of bacteria. With the use of bacteriophages dairy producers may have a better way to treat mastitis without concern about potential residues and consumer preferences.

Key words: bacteriophages, mastitis, antibiotic-resistant bacteria

155 Heat. C. Hoffner*, *North Carolina State University, Raleigh.*

Providing a comfortable atmosphere for high-producing animals is a necessity. The Southeastern United States is notorious for having hot and humid summer days, which can drastically affect dairy cows and their milk production. Because of this, heat stress is a huge concern among dairy farmers in our area. Cows subjected to heat stress have reduced feed intake, lower activity, higher respiratory rate, increased peripheral blood flow, and higher water loss. These behaviors have a harmful result on the milk production and the physiologic standing of the animal (J.W. West, 2002). Through observation and research, scientists have determined that a balance of environmental changes, genetic enhancements, and proper nutrition will be the answer for maintaining high milk producing dairy cows in this climate. One experiment concluded that shaded cows yielded 10% more milk than non-shaded cows (J.W. West, 2002); results of another study indicated that cows increased milk yield by 11.6% when sprayed with water for 90 s every 15 min (Strickland, et al., 1988). Genetic adjustments can be altered by monitoring cows of different hair colors. A Florida- based study specified that light-haired cows have a lower body temperature and a greater milk yield than those who are dark-haired (Hansen, 1990). Currently, more research is being conducted to determine if a heat tolerant gene can be used in dairy breeding in the future (J.W. West, 2002). Nutritional advances are emerging for boosting milk production from cows in these environments. It has been reported that providing chilled water to dairy cows improves milk yield by dropping the body temperature through absorbed heat energy (Milam, et al. 1986). Overall, heat stress can adversely affect milk production and also be harmful to the health of dairy cows. With moderate adjustments over time, cows in hot and humid climates can be more comfortable leading to more money in farmers' wallets.

Key words: heat stress, milk production, humid environment

156 Direct-fed microbials: Decreasing scrutiny and increasing productivity. A. Sassard* and J. Fain, *Clemson University, Clemson, SC.*

With increasing concerns regarding safety of the US food supply, producers are increasingly under scrutiny to reduce the use of antibiotics and growth hormones throughout the dairy industry, from calf to cow. Producers are taking the right steps forward with novel health management practices focusing on prevention of problems and promotion of animal welfare while increasing economic productivity. Direct-fed microbials (DFMs), which are biologically active microorganisms that may be used as supplements, have the potential to replace antibiotics in health management programs. Microorganisms utilized as DFMs can be either bacteria, such as *Megasphaera elsdenii*, or fungal, such as *Saccharomyces cerevisiae*. Current methods of using DFMs for dairy cattle range from treating sickly calves to stabilizing the rumen of dairy cows in lactation. Studies investigating the usage of DFMs in adult dairy cattle confer their ability to decrease metabolic problems associated with transition cattle and those receiving a high concentrate ration. It appears that DFMs affect the cow through many complex methods of action, which are dependent on the microbe used and its method of delivery. Research has found that transition cows gain the most benefit from supplementation, with DFMs reducing both sub

acute rumen acidosis (SARA) and helping to protect the cow against an acute rumen acidosis challenge. SARA can cost the dairy industry up to $1.12 per cow per d, causing permanent losses in productivity and building a foundation for additional challenges such as laminitis. DFMs provide a non-medicated method of supplementing cattle to effectively tolerate dietary changes; tempering rumen bacteria to the presence of lactate and modifying fermentation while increasing productivity by as much as 2.3 kg/d with more effective utilization of fermentation products, namely propionate. Ultimately DFMs have the potential to become a new option to combat current issues plaguing the dairy industry, from food safety concerns to animal welfare, while at the same time making production more efficient and improving a producer's profit margin.

Key words: DFMs, acidosis, food safety

157 Genetic selection for feed efficiency in dairy cows. A. M. Yeiser* and C. D. Dechow, *Pennsylvania State University, University Park.*

Feed costs are the single largest expense on dairy farms, and profitability of dairy farms has been limited by rapidly rising feed prices. Collections of dry matter intake (DMI) from a large number of individual cows can be cost prohibitive, but genetic markers for feed intake could be developed from fewer cows and allow selection for feed utilization. Feed efficiency is defined in different ways. Gross feed efficiency (GFE) is the amount of energy corrected milk produced per unit of DMI. Heritability estimates for GFE range from 0.14 to 0.37. However, GFE does not consider other cow factors such as body tissue mobilization which could inflate GFE estimates. Residual feed intake (RFI) is DMI adjusted for yield and body weight change. RFI has been considered by some researchers because it was thought to reflect differences in basal metabolic rate. Heritability estimates for RFI vary widely (0.01 to 0.69). Some evaluations of genetic variation for RFI consider change in body weight (BW) and body tissue composition, whereas others consider only change in BW. Studies that account for body tissue composition tend to find less genetic variation in RFI. This suggests that basal metabolic rate might not be changed by selection for RFI. BW and body condition score had unfavorable correlations with feed efficiency in one study, with genetic correlation estimates ranging from −0.64 to −0.70. Cows with a smaller body size were more efficient than larger and fatter cows at equivalent levels of production due to the dilution of maintenance requirements. More recently, researchers have suggested evaluating residual yield, which identifies cows with high yield at similar intake and body tissue mobilization of less efficient cows. Regardless of how feed efficiency is defined, there is evidence that genetic selection can allow dairy producers to increase the efficiency of feed utilization in dairy cows.

Key words: feed efficiency, heritability

ADSA-SAD Original Research Undergraduate Competition

158 Assessment of ruminal fermentation characteristics under normal or high fermentative temperature in continuous cultures. C. C. King*[1], C. M. Dschaak[1], J.-S. Eun[1], V. Fellner[2], and A. J. Young[1], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Department of Animal Science, North Carolina State University, Raleigh.*

A dual-flow continuous culture system was used to investigate effects of ruminal temperature and forage-to-concentrate (FC) ratio in lactation dairy diets on ruminal fermentation. The experiment was a 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments (n = 4). Diets based on alfalfa hay and corn silage as forage sources were formulated to maintain different FC ratios (60:40 or 40:60, DM basis) in the high forage (HF) or the low forage (LF) diet, respectively. Four treatments were tested: HF under normal ruminal temperature (NRT; 39°C), LF under NRT, HF under high ruminal temperature (HRT; 41°C), and LF under HRT. Each independent run lasted 10 d (7 d of treatment adaptation and 3 d of data collection). The temperature of the HRT treatment was chosen to mimic ruminal fermentative environment when cows are under heat stress. Increasing ruminal temperature increased ($P < 0.01$) culture pH from 5.73 to 5.82 on average, but decreasing forage proportion in the diets decreased ($P < 0.01$) culture pH regardless of ruminal temperature. Total VFA concentration decreased ($P = 0.05$) in the HRT compared with the NRT, however, ruminal temperature did not affect molar proportion of VFA. Digestibilities of DM and NDF were not affected by ruminal temperature, whereas the HRT tended to decrease ($P = 0.14$) OM digestibility compared with the NRT (66.6 vs. 67.4%). The HRT increased ($P < 0.01$) methane production (mmol/d and mmol/g NDF digested) and ammonia-N concentration and flow. The HRT treatment also increased the concentration of C18:0, but decreased that of the C18:1 trans-11. Overall results suggest that during HRT as experienced by cows under heat stress nutrient digestion, energy utilization, and microbial protein synthesis are altered.

Key words: ruminal temperature, microbial fermentation, continuous culture

159 Supplemental butyrate does not enhance selective permeability of ruminal epithelia in sheep. D. J. Wilson*, T. Mutsvangwa, and G. B. Penner, *University of Saskatchewan, Saskatoon, SK, Canada.*

The aim of this study was to determine if increasing the intra-ruminal butyrate concentration would improve the selective permeability of ruminal epithelia. Suffolk wether lambs (n = 18) fed a common diet were randomly assigned to 1 of 3 in vivo butyrate supplementation levels: 0% (CON); 1.25%; and 2.50% butyrate as a proportion of DMI. After a 14-d feeding period, lambs were killed and ruminal epithelia from the ventral sac was prepared for mounting in Ussing chambers with separate mucosal (pH 6.2) and serosal (pH 7.4) buffer solutions. 1-^{14}C butyrate and D-1-^{3}H mannitol (both 74 kBq/10 mL) were added to the mucosal side and used to measure mucosal to serosal flux (J_{ms}) over 2 60-min flux periods with simultaneous measurement of transepithelial conductance (G_t). For the first (challenge) flux period, the mucosal buffer solution was either acidified to pH 5.2 (ACID) or used as a control (pH 6.2; SHAM). Buffer solutions were replaced for the second flux period (recovery). In vitro data were analyzed as a split-plot design with in vivo treatment as the main-plot, in vitro treatment as the sub-plot, and flux period as a repeated measure. Ruminal VFA was higher ($P < 0.001$) in lambs fed 2.50% compared with CON or 1.25% (31.3, 36.2, and 52.4 mM, respectively). Feeding supplemental butyrate increased ($P = 0.001$) ruminal butyrate by 6.3 and 20.8 mM for lambs fed 1.25% and 2.50% compared with CON (butyrate = 5.6 mM). The $J_{ms\text{-}butyrate}$ was lower ($P = 0.013$) for lambs fed 1.25% and 2.50% butyrate (3.00 and 3.12 μmol/(cm^2 × h), respectively) than CON (3.91 μmol/(cm^2 × h)). However, no differences ($P = 0.33$) were observed for $J_{ms\text{-}mannitol}$ and G_t with average values of 0.30 nmol/(cm^2 × h) and 3.99 mS/cm^2. There was an in vitro treatment × flux period interaction ($P = 0.003$) for $J_{ms\text{-}butyrate}$, where $J_{ms\text{-}butyrate}$ was not different during the challenge period for ACID and SHAM (3.84 vs 3.39 μmol/(cm^2 × h)), but $J_{ms\text{-}butyrate}$ was lower for ACID relative to SHAM (2.70 vs. 3.44 μmol/(cm^2 × h)) during the recovery period. These results indicate that increasing intraruminal butyrate concentration does not enhance the selective permeability of ruminal epithelia.

Key words: butyrate, ruminal epithelia

160 Effect of feeding a C16:0-enriched fat supplement on milk fatty acid composition. K. E. DeLand*, C. L. Preseault, M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing.*

Dietary C16:0 has been reported to increase milk fat (MF) concentration and yield. This study evaluated the effect of a dietary C16:0-enriched fat supplement on the fatty acid (FA) composition of MF, in particular saturated FA (SFA) composition and concentration, in a crossover experiment with 21 d periods. The hypothesis was that an increase in MF yield would be due to an increase in C16:0 incorporation into MF, which would increase the MF concentration of SFA. Sixteen midlactation Holstein cows (249 ± 33 DIM) were assigned to treatment sequence; treatments were a C16:0-enriched (~85% C16:0) fat supplement (FAT, 2% DM) or a control diet (CON) containing no supplemental fat. Milk samples were collected on d 18 to 21 of each period. FAT increased MF concentration and yield by 7.6 and 8.1%, respectively ($P < 0.001$). This was due to a 26% increase in FA yield (mmol/d) of C16 FA (C16:0 + C16:1 cis-9, $P < 0.001$); the yield of de novo (<C16) and preformed (>C16) FA were not different between treatments (both $P > 0.25$). On a concentration basis, the FA profile (g/100 g FA) of MF for CON and FAT was 26.8 and 23.4 < C16 FA, 36.7 and 43.5 C16 FA, and 36.5 and 33.1 > C16 FA, respectively (all $P < 0.001$). The C16:0 concentration of MF increased 19% (35.4 to 42.1 g/100 g FA, CON vs. FAT, $P < 0.001$). This only resulted in a 3% increase in total SFA (70.2 to 72.1 g/100 g FA, CON vs. FAT, $P < 0.01$) because concentrations of SFA from C6:0 to C14:0 were reduced (all $P < 0.01$). There was a reduction in MF cis polyunsaturated FA concentration (2.8 to 2.5 g/100 g FA, CON vs. FAT, $P < 0.01$), and a trend for a reduction in total cis monounsaturated FA concentration (22.8 to 21.8 g/100 g FA, CON vs. FAT, $P = 0.08$). Total trans C18:1 concentration and yield was lower with FAT (17 and 10%, respectively, $P < 0.05$), with lower concentrations of all major trans C18:1 isomers ($P < 0.01$). Results demonstrate that although FAT increased the concentration and yield of C16:0, changes in other FA resulted in minimal differences in the concentration of total SFA in MF. Overall, the FA profiles of MF from CON and FAT were within recently published survey values for currently available dairy products.

Key words: milk fatty acids, palmitic acid, saturated fat

161 Impact of water intake on dairy cattle reticulorumen temperature. M. Cornett*, D. Ray, and J. Bewley, *University of Kentucky.*

Concerns remain about the effect of water intake on temperatures collected within the reticulorumen. The dramatic drop in reticulorumen temperature (RT) following water intake has been well documented; however, the time required for RT to return to pre-drinking baseline temperature (BT) has not been quantified. The objective of this study was to quantify the relationship between water intake quantity and BT. Four mid-lactation, multiparous, Holstein-Friesian dairy cows were equipped with SmartBolus transponders (TenXSys, Eagle, ID) set to record RT at 2-min intervals. Cows were housed in a tie-stall barn at the University of Kentucky Coldstream Dairy Research Farm. A TMR ration was provided ad lib at 05:30 and 14:00. One Poly Water bowl (SMB MFG, Wallenstein, ON) equipped with a range water meter Recordall Badger Meter (Badger Meter, Milwaukee, WI) was assigned to each tie stall to assess water intake. Drinking behavior was monitored by 2 observers for 48 consecutive hours. The termination of a drinking bout was established when 30 min elapsed without another drink. Quantities consumed within each drinking bout were used for analysis. Mean (±SD) volume of water consumed per drinking event was 0.27 ± 0.31 L. Mean (±SD) temperature drop (TD) across all drinking events was 2.29 ± 1.82°C. Mean (±SD) RT at the beginning of the drinking event was 39.76 ± 0.49°C (n = 84), while mean water temperature (WT) 15 min before the drinking event was 3.63 ± 3.14°C. Mean (±SD) BT, identified in 50 drinking events (59.5% of total drinking bouts), was 57.75 ± 38.70 min. The BT was moderately correlated with pre-drinking RT (r = 0.57, $P < 0.01$), TD (r = 0.49, $P < 0.01$), and WT (r = −0.28, $P < 0.05$).The TD was moderately correlated with the pre-drinking RT (r = 0.57, $P < 0.01$), the amount of water consumed (r = 0.53, $P < 0.01$), and BT (r = 0.49, $P < 0.01$). Regression was performed with the GLM procedure of SAS (SAS, Cary, NC) to assess factors influencing BT ($r^2 = 0.36$). The quantity of water consumed ($P = 0.03$), and the RT before a drinking bout affected BT, while WT did not ($P = 0.92$).

Key words: temperature monitoring, reticular temperature, water intake

162 Genotype and breed trend influences on citric acid and coagulation times of raw milk. M. Looney*[1], A. Laubscher[1], J. Medrano[2], R. Jimenez-Flores[1], and G. Rincon[2], *[1]California Polytechnic State University, San Luis Obispo, [2]University of California, Davis, Davis.*

Citric acid or citrate in milk plays a very important role while processing milk to produce cheese or yogurt. The objective of this study was to determine if citric acid levels measured in milk was related to genetic variants of various genes identified in Holstein and Jersey cows and its effect on gel formation. We collected milk samples from both Holstein and Jersey cows from the Cal Poly Dairy Farm, San Luis Obispo. Citric acid levels, protein, fat, lactose, and minerals were measured using FTIR methods with the FOSS Milkoscan FT2 on each sample. Genotypes were obtained for the DGAT 1, β-LG, ACLy and ACO1 loci using polymerase chain reaction and an enzymatic digestion using primarily the MwoI restriction enzyme. This procedure distinguishes the A and G variants of DGAT 1, A and B variants of β-LG gene and several variants of the other genes. Results from Holstein and Jersey cows indicated that citric acid level, as a percentage, was higher for the Jersey than for the Holstein cows–0.18 and 0.14, respectively. Protein and percent fat were included as independent variables in the statistical model, the difference between Holstein and Jersey for citric acid level was then considered for the different loci variants. Our preliminary data indicates the differences due to gene variants. All the samples were tested for gel forming kinetics using the ReoRex system. These experiments show the influence that citrate levels have on gel formation induced by chymosin.

Key words: citrate, DGAT, gel formation

163 Effects of different flooring options in outside pens of hutches on dairy calf growth. K. A. Hoeing*[1], M. A. Laws[1], T. S. Dennis[1], M. M. Schutz[1], S. D. Eicher[2], and T. D. Nennich[1], *[1]Purdue University, West Lafayette, IN, [2]USDA-ARS, West Lafayette, IN.*

Growth rates of dairy calves may vary due to many different factors, including housing. The objective of this study was to determine if calf growth was affected by different flooring options in the outside pen area of a calf hutch. For this study, 33 hutches were blocked in groups of 3 by location and the outside pen area was randomly assigned to 1 of 3 treatments: soil and lime (CONTROL), solid black rubber mats (SOLID), and black rubber mats with 2.5 cm holes (HOLES). Thirty-three heifer calves in the study were assigned sequentially by birth date to the next available hutch. The study was conducted during the summer of 2010 at the Purdue Dairy Research and Education Center. Calves were fed according to standard protocols and received 2 L of milk replacer per day and ad libitum access to calf starter and water. Body weight, heart girth circumference, hip height (HH), wither height (WH), and body temperature (TEMP) were measured when the calves entered the study and every 2 wk until weaning or 8 wk of age. Calves were observed 2 times/wk to determine behavior, calf cleanliness, flooring cleanliness, and hutch bedding cleanliness. Flooring temperature was determined using infrared temperature guns. Data were analyzed with Proc Mixed of SAS using repeated measures. Two calves, on treatments SOLID and CONTROL, died for reasons unrelated to treatment and were removed from the study. At 8 wk of age, BW was greater ($P < 0.05$) for HOLES and CONTROL than for SOLID (72.5, 69.2, and 64.0 kg, respectively), and HH and WH were greater for HOLES ($P < 0.05$) than for CONTROL and SOLID. Heart girth circumference and TEMP were similar among treatments ($P > 0.20$). Mat temperatures were similar for SOLID and HOLES (46.5 and 46.0°C, respectively) and were greater ($P < 0.001$) than CONTROL (37.7°C). Calf and bedding cleanliness were similar among treatments, though flooring tended ($P < 0.10$) to be dryer for HOLES at the beginning and dirtier in the middle of the study. Flooring options in the outside pen of calf hutches affected calf BW, HH, and WH at weaning, with rubber mats with holes improving calf growth compared with a lime and soil mixture or solid mats.

Key words: dairy, calf, housing

164 Alterations in the rate of progesterone clearance induced by insulin-like growth factor-I in the mouse hepatocyte. C. L. Varela*, K. D. Baldock, W. G. Squire, and D. L. Smith, *Eastern New Mexico University, Portales.*

Circulating concentrations of progesterone are at least, a critical indicator of potential embryonic survival, or maybe more importantly, contribute directly to pregnancy retention. In our previous research, we have shown insulin reduces the clearance of progesterone; thus potentially increasing embryonic survival. Further, the reduction in progesterone clearance was due to an insulin-mediated reduction in the cytochrome P450 enzymes that catabolize progesterone. It has been shown Insulin-like growth factor-I (IGF-I), produced by the hepato-

cytes, has no receptors in the liver, however there are insulin receptors. Insulin-like growth factor-I has been shown to bind to insulin receptors but with a lower affinity than insulin binding to its own receptor. The objective of this experiment is to determine the effect of different concentrations of IGF-I on the rate of progesterone clearance by hepatocytes. To determine the rate of progesterone clearance in response to challenge with different concentrations of IGF-I, mouse hepatocytes (10^5 per well) were plated in 10, 12 well plates with 5 ng/ml of progesterone added to the culture medium. To calculate the fractional rate of decay for progesterone, media was harvested at 0, 1, 2, 3 and 4 h following the addition of treatment. Cells were cultured in the presence of IGF-I (0, 6.25, 12.5, 25, 50, 100, 200 and 400 ng/ml). The conditioned media concentrations of progesterone were determined by enzyme-linked immunosorbent assay. Progesterone clearance was increased ($P < 0.05$) with the addition of 12.5 ng/ml IGF-I compared with control. Furthermore, there was a greater increase ($P < 0.05$) in progesterone clearance in response to 25, 50, 100, and 200 ng/ml IGF-I compared with the control, 6.25, and, 400 ng/ml IGF-I. These results indicate that hepatocytes in the presence of increasing concentrations of IGF-I, increase progesterone clearance and consequently could potentially reduce embryonic survival.

Key words: insulin-like growth factor-I, progesterone, hepatocyte

165 The effects of protease enzymes and storage on the ensiling and nutritive value of corn silage. K. M. Young*, M. C. Der Bedrosian, J. M. Lim, A. P. T. P. Roth, S. A. Santos, and L. Kung Jr., *The University of Delaware.*

The objective of this study was to evaluate the effects of adding protease enzymes to chopped whole plant corn on silage fermentation and nutritive value after varying lengths of storage. Chopped and processed whole plant corn (Mycogen TMR2W726, Dow AgroScience, Indianapolis, IN) was harvested (36.3% DM) and ensiled without enzymes or treated with one of 2 different proteases (E85 or E86; AB Vista, Wiltshire, UK) at one times (1X) or one hundred times (100X) the manufacturer's recommended dosage. The enzymes were mixed with a phosphate buffer and applied to chopped forage while mixing. Replicated-treated piles of forage were prepared for each enzyme treatment. Four bags of forage were vacuumed and heat-sealed for each enzyme treatment and storage time and allowed to ensile at 23 ± 2°C for 45 and 150 d. The hypothesis was that in the silo, proteases would liberate starch and increase starch digestibility (Starch-D). The statistical analysis included the main effects of enzyme treatments, days of storage and their interactions. When compared with untreated silage, there was no effect of protease or length of storage (45 vs. 150 d) on pH, concentrations of CP, ADF, NDF, or starch. At 45 and 150 d, treatment with proteases did not affect NDF-D or the concentrations of lactic acid, acetic acid or ethanol when compared with untreated silage. Ammonia-N and soluble-N (% of CP) contents increased after ensiling compared with levels at harvest and were greater ($P < 0.01$) for the 100X enzyme doses when compared with untreated silage at both storage times (45 and 150 d). Starch-D (ruminal in vitro, 7 h) was 66.3% for freshly chopped corn plants. After 45 d of ensiling, treatment with E86 100X had greater ($P < 0.01$) starch-D (80.6%) than all other treatments except it was similar to E85 100X. After 150 d of ensiling, E85 1X (81.9%), E85 100X (82.9%) and E86 100X (88.6%) had greater ($P < 0.01$) starch-D than untreated silage (74.0%). Effects of the proteases on amino acid content and for longer periods of storage will be determined. The data obtained to date suggests that exogenous proteases could be used to improve in vitro ruminal starch-D in corn silages.

Key words: corn silage, protease

166 Differences in the rumen methanogen population exist between Jerseys and Holsteins. E. King*, R. Smith, and A.-D. Wright, *University of Vermont, Burlington.*

Holstein and Jersey breeds account for the vast majority of cows within the dairy industry. While the population of rumen methanogens has been sequenced and analyzed in the Holstein, to our knowledge, a direct comparison has not yet been done between Holsteins and Jerseys. The molecular diversity of rumen methanogens in Holstein and Jersey dairy cows were investigated using 16S rRNA gene libraries prepared from pooled PCR products from the rumens of 9 Holsteins and 10 Jersey cows from Vermont. A total of 365 clones were generated, 180 clones from the Holsteins and 185 clones from the Jerseys. Approximately 99% of all clones identified belonged to the genus *Methanobrevibacter*, with 43% of these clones closely related to *Methanobrevibacter ruminantium*. Based upon 98% sequence identity, these 365 clones were assigned to 55 different OTUs. Twenty OTUs (85% of the clones) were common in both breeds. However, the Holstein cows revealed 23 OTUs not found in the Jersey cows, and the Jersey cows revealed 12 OTUs not found in the Holsteins. Shannon index and Libshuff analysis indicate that significant differences exist between the composition ($P = 0.01$) and diversity ($P < 0.05$) of the methanogens recovered from the 16S rRNA gene libraries from these 2 dairy breeds. These results suggest that breed and differences in feed utilization efficiency may account for the different rumen methanogen populations from these 2 dairy breeds.

Key words: methanogens, *Methanobrevibacter*, dairy cows

167 The association of electrical conductivities and California Mastitis Tests on a robotic dairy farm. A. M. Brigham*[1], C. D. Dechow[1], and B. Carter[2], *[1]Pennsylvania State University, University Park, [2]Keseca Veterinary Clinic, Geneva, NY.*

With the introduction of robotic milking systems there is less daily handling of each cow and producers must rely on computer generated udder health reports. The objective of this study was to determine if measures of electrical conductivity (EC) could be used to define a more sensitive and specific report. Over the course of 4 weeks, 227 cows from one farm were evaluated with a California Mastitis Test (CMT) after being flagged by the herd's software system. The robotic system recorded EC separately for each quarter. A list of cows suspected of having mastitis was generated daily and included cows with EC deviations of greater than 21% from their baseline. Cows were also flagged if there was an abnormal milk color or extreme deviation in milk yield from the previous day. In total, 20% of cows on the automatically generated report had a negative CMT result and the false positives create an unnecessary management burden for the herd. The association of CMT scores with quarter EC and the ratio of a quarter's EC to the cow's lowest quarter EC, or inter-quartile ratio (IQR), was determined using the mixed procedure in SAS. Least-squares-means for cows with a negative CMT result were 70.1 and 1.04 for EC and IQR, respectively, which were significantly ($P < 0.0001$) lower than results for cows that were strong positives (95.3 for EC and 1.37 for IQR). Subsequent analysis indicated that IQR had higher sensitivity than EC, whereas EC and IQR were similar for specificity. Milk cultures were also conducted for 53 quarters with positive CMT, and bacteria were isolated for 64 percent of samples. Least squares means for IQR and EC were not higher for CMT positive quarters with a positive

bacteria culture than CMT positive quarters with a negative bacteria culture. Measures of EC are helpful in identifying cows with mastitis in robotic milking herds, but need further development to create more management friendly reports with higher sensitivities and specificities.

Key words: electrical conductivity, California Mastitis Test

168 Effects of shade on heat stress reduction in Holstein dairy calves. S. S. Thibeau*[1], L. B. Sage[1], C. C. Williams[2], B. F. Jenny[2], and A. H. Dolejsiova[2], *[1]Louisiana State University, Baton Rouge, [2]LSU AgCenter, Baton Rouge, LA.*

Heat stress, a particular concern to southern dairy producers, can cause a variety of homeostatic alterations that can inhibit optimal calf development and prohibit full production potential. Therefore the objective of this study was to determine the effect of shade on performance and metabolic indicators of heat stress in neonatal dairy calves. Sixteen (n = 16) neonatal Holstein heifers were assigned to either a non-shaded (NS) or shaded (SS) hutch for an 8 week period. Rectal temperatures, surface temperatures and respirations were measured at 0830 h and 1600 h 3 times per week. Average daily starter intake (ADI), water intake and fecal scores were measured twice daily. Body weight, hip and wither height were measured at birth and at wk 1, 2, 4, 6, and 8. Blood was collected at birth and then weekly for analysis of plasma urea nitrogen (PUN) and packed cell volume (PCV). As expected for a normal growing calf, ADI, body weight, hip height, and wither height increased ($P < 0.01$) with age while fecal scores decreased ($P < 0.05$) over time. However, there were no observable treatment effects ($P > 0.1$) on these parameters. Calves in NS hutches drank more ($P = 0.1$) water than shaded calves. Calves also drank more water ($P < 0.01$) as they aged. A treatment by time interaction ($P = 0.05$) was observed for rectal temperature, with afternoon measurements being higher in NS calves. A treatment by time interaction ($P < 0.01$) was also observed for surface temperature with lowest values in the SS calves in the morning. Likewise, there was a treatment by time interaction for respiration rates, with afternoon values for NS calves and morning values for SS calves being the highest. Surface temperature and respiration rates decreased ($P < 0.01$) as calves aged. There was no significant ($P > 0.1$) treatment effect on PUN, although PUN levels increased ($P < 0.05$) as calves aged. There was treatment by week interaction ($P < 0.05$) on PCV, with NS calves having greater values after wk 3. While differences were observed in physiological parameters, there were no improvements in performance of these calves with addition of shade as a management practice.

Key words: heat stress, shade, dairy calves

169 Xylose absorption in dairy calves supplemented with sodium butyrate in milk replacer. N. M. Larson*[1], S. I. Kehoe[1], S. Moreland[2], and D. Shields[3], *[1]University of Wisconsin-River Falls, River Falls, [2]Nutriad, Inc., Elgin, IL, [3]Merrick's, Inc., Union Center, WI.*

Sodium butyrate has been reported to enhance intestinal development in neonates during growth. The objective of this research was to evaluate whether sodium butyrate supplementation in milk replacer would enhance intestinal absorption in growing dairy calves thereby improving production and health parameters. Seventy 2 bull calves were fed 280 g/d DM of milk replacer twice daily and treatments consisted of no supplementation (C), 0.44% sodium butyrate supplementation (L) and 0.88% sodium butyrate supplementation (H; Nutriad, Inc.). Growth (body weight, withers height, hip height, and heart girth) and health parameters (fecal scores, treatments, milk refusals) were monitored and blood was obtained from half of the calves and analyzed for glucose, blood urea nitrogen (BUN), and creatinine. At wk 3, calves were dosed with xylose and blood was taken 4 h after dosing. Least squares means were analyzed using repeated measures of the mixed procedure of SAS 8.2 with week as a repeated effect. Growth measurements at arrival and blood measurements during wk 0 were used as covariates for growth and blood analyses. Plasma xylose concentrations were not significantly different between treatments (27.6, 24.2, and 17.19 mg/dl, for C, L, and H, respectively). There were no significant differences between treatments in glucose, BUN, and creatinine concentrations. Growth parameters were also not different however heart girth tended to be lower for H calves. Average daily gain was not different, however, feed efficiency was significantly lower for C calves (1.6, 0.96, 0.97 kg feed/kg gain, for C, L, and H, respectively). Health parameters were not different between treatments. The supplementation of sodium butyrate did not appear to enhance any growth, health or metabolic parameters in this model.

Key words: calves, sodium butyrate, intestinal health

ADSA Southern Section Symposium: Producing Quality Milk in Hot, Humid Climates

170 Extension programming in Kentucky to address somatic cell count challenges and opportunities. J. M. Bewley*, *University of Kentucky, Lexington.*

Recent market changes have renewed interest in lowering bulk tank somatic cell counts (SCC), particularly in the southeastern US states where the highest SCC in the country are observed. Extension programming efforts focused on SCC reduction increased around the country in 2010 and 2011. In Kentucky, we have implemented a multifaceted approach to extension programming for SCC reduction. The University of Kentucky Dairy Extension team has worked closely with the Kentucky Dairy Development Council in a farm-based program entitled M.I.L.K. Counts. The intent of the program is to provide direct, on-farm technical assistance to producers struggling with SCC through evaluation of DHIA records, milking procedures, management protocols, animal hygiene and housing, and dry cow treatment and handling. The M.I.L.K. Counts program incorporates a team-based problem solving approach with emphasis on the economic impact of resulting recommendations. Microbiological culturing is performed by the University of Kentucky Veterinary Diagnostic Livestock Laboratory. Approximately 25 producers have participated in the program with SCC reductions as high as 400,000 cells/mL. YouTube videos were developed (http://www.youtube.com/user/UKAgriculture) to demonstrate recommended milking procedures and to provide virtual tours of farms that consistently maintain low SCC. A visual analytics dashboard (http://tinyurl.com/UKMilkBonus) was created to illustrate the potential for increased income through SCC reductions. Kentucky herds with annual mean SCC < 250,000 were surveyed to summarize management practices employed by farms successful at maintaining low SCC. When asked to identify the management practice that contributed the most to their low SCC level, the most frequently cited practices were (1) keeping cows and facilities clean (n = 31), (2) maintaining dry, clean bedding (n = 14), (3) adhering to a consistent milking routine (n = 10), (4) forestripping (n = 7), and (5) pre and post dipping (n = 6). Lastly, a series of SCC reduction workshops were conducted across the state working with county extension agents and milk cooperative field people.

Key words: extension, SCC, milk quality

171 Dairy producer adoption of mastitis control technologies for reducing herd somatic cell counts. S. C. Nickerson*, *University of Georgia, Athens.*

Mastitis continues to be a major livestock disease affecting the dairy industry. In the US alone, this disease results in economic losses approaching $2 billion annually due to reduced milk production, milk discard, veterinary services, antibiotic use, increased labor, and reduced cow sale value. As the industry strives to improve milk quality to meet consumer as well as exportation demands, the legal limit for the somatic cell count (SCC) will likely be reduced from 750,000/mL to 400,000/mL in the near future. It is estimated that between 10 and 20% of US dairy farms, mostly located in the south, are currently at or above the 400,000/mL SCC limit and will have to adopt stricter methods for controlling mastitis in their milking herds, dry cows, and heifers. The 5-point plan of mastitis control has provided the basics of managing this disease for over 4 decades, and includes 1) teat dipping, 2) dry cow therapy, 3) functionally adequate milking machines, 4) therapy of clinical infections, and 5) culling of chronic cows. However, additional measures of control will have to be implemented to reduce mastitis prevalence and the associated elevation in SCC. Such management practices include vaccination, dietary supplementation, and mastitis control in heifers. The adoption of both the proven traditional methods and the more novel technological approaches toward mastitis management by dairy producers is dependent on several factors, and is based on what motivates the implementation of mastitis prevention and control practices.

Key words: dairy producer, mastitis, somatic cell count

172 Effect of micronutrients on the regulation of the immune system and its role in milk quality. W. Weiss*, *OARDC/The Ohio State University, Wooster.*

All cells and tissues require micronutrients to function properly, however immune cells and the immune system are particularly sensitive to the supply of many micronutrients. Stimulated neutrophils and macrophage produce prodigious quantities of free radicals, and metallo-enzymes (containing copper, selenium, or zinc), B-carotene and vitamin E have direct major antioxidant functions that are needed to control those radicals. Marginal deficiencies of Cu, B-carotene and vitamin E reduce the killing ability of bovine neutrophils and these affects are probably caused by impaired antioxidant status. A marginal deficiency of Se reduces both the migration and killing ability of bovine neutrophils. The Se effect on killing ability is probably via antioxidant status but migration effects may be via non-antioxidant selenoproteins. A marginal deficiency of Zn has not been shown to affect killing ability of neutrophils but has reduced migration and phagocytic activity in humans and rodents. Experiments with bovines are limited or lacking, but studies with humans and rodents have shown that Cu, Se, Zn, and vitamins A, D, and E affect gene expression of pro- and anti-inflammatory cytokines and their receptors resulting in altered immune cell function, cell populations, and acquired immune response. Experiments measuring gross lymphocyte responses in bovines generally has found enhanced proliferation of cytotoxic T-cells when chromium is supplemented; increased lymphocyte proliferation with supplemental Se; little effect on lymphocyte proliferation with supplemental Cu; and highly variable lymphocyte responses to supplemental vitamin A, B-carotene and vitamin E. Many micronutrients have profound effects on immune function, however, effects on mammary gland health and milk quality are often less evident. This is likely because control diets may not have been low enough in the nutrient of interest to impair immune function. Diets that are adequate (but not excessive) in Cu, Se, Zn, B-carotene, and vitamins A and E are necessary for good mammary gland health and most studies indicate current NRC recommendations are appropriate for those nutrients.

Key words: vitamins, trace minerals, mastitis

173 Use of records to investigate and monitor mastitis in dairies. M. W. Overton*, *University of Georgia, Athens.*

Mastitis is an infection of the mammary gland that can occur in both clinical and subclinical states and with each, somatic cell counts (SCC) rise and milk quality declines. Changes in SCC that occur as a result of infection can be used to track changes across time. It is helpful to

remember that a herd's SCC is largely the result of 2 things: 1) How many cows get mastitis? 2) How long do cows maintain mastitis? This presentation will demonstrate how SCC and clinical mastitis history can be used to investigate and monitor mastitis issues within a dairy herd. One approach is to identify the herd's clinical mastitis risk by month and by parity to assess the impact of seasonality and age on clinical case risk. Many herds do not accurately or consistently record clinical cases but do utilize monthly DHIA testing. As such, one can use the monthly data to examine changes within a cow and within a group relative to a cut-point of 200,000 SCC. This approach is illustrated in the following table and can give a quick assessment of udder health status and potential sources for further investigation.

Table 1. Common metrics for monitoring mastitis

Item	Description	Goal
Monthly clinical mastitis incidence	% of all milking cows each month that are recorded with one or more cases of clinical mastitis	< 2%
Heifer new infection risk	% of fresh heifers >200,000 SCC at first test	<15%
Dry cow new infection risk	% of cows <200,000 SCC at the last test before dry off that calve and have a first test SCC >200,000	<15%
Dry cow cure risk	% of cows with an SCC >200,000 at the last test of the prior lactation that calve with a first SCC test <200,000	>75%
New mastitis case risk	% of cows that were <200,000 SCC at the previous test but now have SCC >200,000	<9%
Cure risk	% of cows that were >200,000 SCC at the previous test but now have an SCC <200,000	>30%
Chronic cow risk	% of cows with the last two consecutive, monthly tests of >200,000 SCC	<12%
Chronic cow attributable risk	% of current cows >200,000 SCC that were also >200,000 SCC at the previous test	<65%
Uninfected cows	% of cows that with 2 consecutive tests that were <200,000 SCC at both tests	>70%

174 Advancing mastitis research: Using proteomics to identify biomarkers and evaluate adjunctive therapies. J. L. Boehmer*, *U.S. Food and Drug Administration Center for Veterinary Medicine, Laurel, MD.*

Mastitis remains a major focus of dairy cattle disease research due largely to associated economic losses and the limited availability of effective treatment options. Coliform mastitis caused by gram-negative bacteria is particularly problematic because of the fever, pain, and profound host inflammatory response induced by lipopolysaccharide (LPS), a cell wall component of gram-negative bacteria released into the mammary gland following pathogen invasion. The bovine innate immune system is very effective at eliminating gram-negative bacterial species, but a need exists to identify effective adjunctive therapies to treat the secondary local and systemic inflammatory responses caused by LPS. To facilitate new veterinary drug approvals, the Food and Drug Administration (FDA) Center for Veterinary Medicine (CVM) is looking to biomarker discovery, or the identification of a biological marker that can be measured in a fluid such as milk, and that could serve as an indicator of health or disease, or of responses to drug treatment. Historically, characterization of the bovine host response to LPS has been attempted using enzyme-linked immunosorbent assays (ELISAs), but reliance on antibodies can hinder biomarker discovery because the commercial availability of bovine-specific antibodies is limited. Proteomic strategies, including liquid chromatography coupled to mass spectrometry (LC-MS/MS) have emerged as one of the most promising approaches to identifying biomarkers of disease and novel drug targets, primarily because proteomics affords large-scale protein identification, and is not reliant on antibody availability. At CVM, the latest proteomic methodologies are being utilized to identify potential biomarkers of inflammation in bovine milk. The identification of biomarkers of inflammation related to coliform mastitis could advance current knowledge of the disease; biomarkers could also provide the regulatory criteria needed to evaluate the efficacy of potential adjunctive therapies for coliform mastitis, including non-steroidal anti-inflammatory drugs (NSAIDs).

Key words: mastitis, proteomics, inflammation

175 Effects of oxytocin administration in early life on the behavioral and physiological stress response of swine. J. L. Rault*[1], C. S. Carter[2], J. P. Garner[1], J. N. Marchant-Forde[3], B. T. Richert[1], and D. C. Lay[3], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]Department of Psychiatry, University of Illinois at Chicago, Chicago, [3]USDA-ARS-Livestock Behavior Research Unit, West Lafayette, IN.*

The swine industry is moving toward the group-housing of sows. However, group-housing can result in increased aggression and social stress, with detrimental effects on swine health and productivity. In contrast, positive social relationships can reduce the adverse effects of social stress. This could be mediated by oxytocin (OT), a neuropeptide underlying social behavior, possibly by buffering the hypothalamic-pituitary-adrenal (HPA) axis. We hypothesized that stimulating the oxytocinergic system of piglets early in life, by chronic postnatal OT administration, could provide long-term protective effects against social stress. In each of 6 litters, 2 piglets per litter received 0.25 mL (24 IU or 50 µg) of OT intranasally (OT) and 2 control littermates received 0.25 mL of saline (SAL) on postnatal d 1, 2 and 3. Each piglet was weaned at d 19 and mixed into a pen with 4 unfamiliar piglets. This social mixing was repeated from the nursery to growing phase at 8 wk of age. On each occasion, we collected videos to analyze behavior and blood samples to analyze cortisol, adrenocorticotropic hormone (ACTH), and immunological parameters over 3 d post-mixing. The pigs were then submitted twice to a resident-intruder test at 10 wk of age, and finally to a dexamethasone-corticotropic releasing hormone (Dex-CRH) challenge at 11 wk of age. Results were analyzed using a mixed model in SAS. Pigs given OT had higher ACTH concentrations than SAL pigs 24 h after weaning ($P < 0.05$) and mixing at 8 wk ($P < 0.1$). Yet, cortisol concentrations did not differ between treatments ($P > 0.1$). The Dex-CRH challenge revealed that OT pigs were less responsive to dexamethasone than SAL pigs ($P < 0.05$). At 24 h after weaning, OT barrows had a higher neutrophil:lymphocyte ratio compare with other pigs ($P < 0.05$). The behavior of OT pigs did not differ from SAL pigs after mixing ($P > 0.1$), nor did weight gain from birth to slaughter ($P > 0.1$). Administrating OT in early life modified the HPA axis. Contrary to our prediction, OT may have dysregulated the negative feedback loop of the HPA axis, leading to detrimental consequences in coping with social stress.

Key words: group-housing, oxytocin, behavior

176 Flavor preferences in sucking piglets conditioned by prenatal flavor exposure through the maternal gestation diet. J. Figueroa*, D. Solà-Oriol, R. Davin, X. Manteca, and J. F. Pérez, *Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain.*

Volatile compounds of the maternal diet are known to be transmitted to the gravid uterus during pregnancy. Such uterine experience may affect later olfactory preferences. The aim of this study was to examine the influence of prenatal flavor exposure via mother's diet in the flavor preferences on sucking piglets. During late gestation (14d) 20 sows were assigned to one of 2 treatments; a flavored diet (Anis, 0.075% or Vanilla, 0.15%; n = 10) and an unflavored diet (n = 10). Eighty male/female piglets coming from these 20 sows (4 piglets/litter) were used to test their attraction for 3 olfactory stimuli (triple-choice feeding test) using a Triple-U-Testing Arena (TUTA) located in an isolated room at d 14, 21 and 26 (2-postweaning days) after farrowing. Olfactory cues tested included strips impregnated with anis, vanilla, and water in the middle as negative control. The mother's gestational feed flavor (MFF) and control flavor (CF) were identified in each sow depending on the flavored pregnancy diet. The position of MFF and CF were rotated in each test. Piglets were tested in litter-pairs. Each test lasted 7 min, during which, the time spent by piglets in nasal contact with each strip was measured by direct observation. The average of the 2 couples per sow was analyzed using the GENMOD procedure of SAS. Piglets born to flavor-treated sows showed preferential responses toward MFF at d 14 (3.6 s/couple), 21 (3.8 s/couple) and 26 (2.9 s/couple) as compared with CF (0.7, $P < 0.001$; 0.55, $P < 0.001$ and 0.11, $P < 0.01$ s/couple) and water (0.3, $P < 0.001$; 0.95, $P < 0.01$ and 0.2, $P < 0.001$ s/couple). No different preferences were observed among flavors for control piglets. These results show that prenatal exposure to flavors via maternal diet influences piglet's preferences, probably through a positive association between the flavor and the hedonic power of the uterine experience. These preferences acquired before birth are highly resistant to extinction. This may help to spark interest for novel feeds by reducing neophobia, such as during sucking or weaning period occurs.

Key words: amniotic fluid, flavors, preference

177 Preference in weanling pigs for sweet or umami taste after in utero exposure. S. J. Chavez*[1], E. van Heugten[1], I. Ipharraguerre[2], and G. B. Huntington[1], *[1]North Carolina State University, Raleigh, [2]R&D Feed Additives, Lucta S.A., Barcelona, Spain.*

Weaning is a very stressful time transitioning the pig from a milk diet to solid feed. The addition of familiar flavors to the piglet diet has reduced stress and improved animal performance during the first several days post-weaning. The objectives of the experiment were to investigate the role of taste perception associated or not with increased nutrient supply in determining preference after weaning and determine if the taste of gestation or lactation diets influence weanling preference. Twenty sows in second or greater parity were randomly assigned to 1 of 5 diets and blocked into a sweet or umami group with a control (CON) in each group. The sweet group consisted of the CON, sucrose (SU), and non-caloric sweetener (SW), while the umami group consisted of CON, monosodium glutamate (MSG), and glutamate-free umami additive (UM). The SU was added at 5.0% of the diet, SW at 0.1%, MSG at 1.5%, and UM at 0.05%. Sows were fed 2.27 kg/d of their respective treatment diet beginning on d 10 of gestation. At farrowing, sows were given a lactation diet in the same treatment, while pigs were cross-fostered across treatments within sweet or umami groups. Pigs were weaned at 21-d and placed into pens (1.73m x 0.83m) of 2–4 pigs/pen with 2 feeders/pen. Pens were given 3-d double-choice preference tests. Data were analyzed using the t-Student test with significance at $P < 0.05$. In the sweet group, when SU was provided, pigs chose SU over 75% of the time for all preference tests that included SU. In the umami group, when MSG was provided, pigs chose MSG 80% of the time for all preference tests with MSG. Pigs in the UM group preferred ($P < 0.02$) MSG over CON, preferred ($P < 0.03$) MSG over UM, but there was no preference ($P > 0.16$) for UM over CON. The SU and SW pigs preferred ($P < 0.02$) SU over CON, control pigs preferred ($P < 0.01$) SW over CON, and SU and control pigs preferred ($P < 0.02$) SU over SW. In conclusion, pigs had a stronger preference for sweet and

umami tastes associated with increased nutrient supply, which likely resulted from the expected interplay between chemosensory perception and post-ingestive effects.

Key words: preference, sweet, umami

179 Glucosamine:chondroitin or ginger root extract have little effect on articular cartilage in swine. D. C. Lay Jr.*[1], J. N. Marchant-Forde[1], B. T. Richert[2], and K. A. McMunn[1], *[1]Livestock Behavior Research Unit; Agricultural Research Service-USDA, West Lafayette, IN, [2]Purdue University, West Lafayette, IN.*

Sows are culled at a high rate from breeding herds due to musculoskeletal problems and lameness. Research in our laboratory has shown that even first-parity sows have significant amounts of osteochondritic lesions of their articular cartilage. Glucosamine chondroitin and ginger root extract have both been proposed as cartilage building supplements. Gilts (n = 30) were assigned to receive a daily dose of 1,500 mg glucosamine + 1,200 mg chondroitin complex (GC sows); 300 mg ginger root extract; or serve as controls. All gilts started on treatments at 3 mo of age and were maintained on diets through 2nd parity. After weaning, they were slaughtered to evaluate their articular cartilage. Cartilage was scored on scale from 0 to 4, defined as smooth to severely damaged. Hooves were scored on a scale from 0 to 3, defined as minimum cracks to deep splits. Cartilage thickness was measured by weighing 4, 6 mm biopsies taken from the articular cartilage. In addition, cross sections on the head of the femur and humerus were used to measure cartilage thickness. Cortical bone thickness was measured on both the femur and the humerus. Blood samples were collected every 4 wk (3 times) during gestation to measure differential leucocyte counts and erythrocyte sedimentation rate. Cartilage on the head of the humerus was thicker ($P < 0.02$) for sows on ginger root supplement compared with sows on control diets, with GC sows being intermediate ($P < 0.05$). However, no other measures of the quantity or thickness of cartilage or bone were different between treatments ($P > 0.10$). Osteochondritic lesions were evident in 100% of the animals on study. Erythrocyte sedimentation rate only tended to be slower for control sows compared with either supplemented group ($P < 0.12$); while mean corpuscular volume was lower ($P < 0.02$) for controls compared with gingerroot sows with GC sows intermediate. These data indicate that the level and duration of these supplements used in this study are not effective in making appreciable differences in the joint health of swine, and thus will not prove effective in increasing sow longevity and soundness through 2 parities.

Key words: swine, lameness, cartilage

180 Market pig transport losses, surface temperatures and trailer air temperatures with medium or heavy bedding on the trailer. A. Sapkota*[1], B. L. Davis[1], A. Butters-Johnson[2], and J. J. McGlone[1], *[1]Texas Tech University, Lubbock, [2]Iowa State University, Ames.*

The USA Trucker Quality Assurance program calls for the use of bedding in the trailers during transport of market pigs. Level of bedding typically varies with season and weather. The amount of bedding used during transportation of market weight pigs is not based on available science. Bedding use in different quantities may be both an economic and animal welfare concern. The objective of this study was to evaluate different amounts bedding during cold weather transport of market pigs (outside air temperatures −13.4 to 13.9 C). Trailers (n = 32 loads of approximately 165 pigs each) were fit with 6 (M) or 12 (H) bales (1 bale = 0.2 m3) of wood shavings to be used in the trailers during transportation (representing depths of 16 and 26 mm). Measures included surface temp of pigs at finishing site and at packing plant, changes in temp. inside truck during loading, trip, stops during trip, wait at plant, unloading, and number of dead on arrival (DOA), killed on arrival (KOA), dead in pen (DIP), non-ambulatory non-injured (NANI), non-ambulatory injured (NAI). Pigs were transported for 225 to 450 min. Trucks were 60% to 95% boarded (vents in the sides of trailers blocked). Statistical model included effects of bedding level, observer, bedding*observer interaction, and unloading times and boarding as covariates. Trailers at times arrived at farm sites with bedding frozen. During pig loading, inside trailer temp. increased 0.32 and 0.18 C/min for H and M, respectively ($P < 0.001$). During transport, H trailers increased ($P < 0.001$) inside air temp. (0.01 C/min) while M trailers did not increase inside air temp. (−0.008 C/min). Inside trailer air temp. when trailers arrived at the plant were 9.5 ± 1.9 C warmer ($P < 0.01$) for H than M trailers. Rates of DOA+KOA+DIP were 0.5 ± 0.2 and 0.1 ± 0.1 for H and M trailers ($P > 0.05$). Surface temp. of pigs upon arrival were 20.3 ± 1.4 C and 19.7 ± 1.6 C for H and M trailers ($P > 0.05$). More data are needed to clarify effects and data collection is ongoing. More bedding may provide a warmer inside air temp. but may pose a risk of increased pig deaths during cold weather transport.

Key words: pigs, animal welfare, transport

181 Brain lesions and time to death resulting from application of a non-penetrating captive bolt to anaesthetized nursery piglets. T. M. Casey-Trott[1], R. Brooks[2], P. V. Turner[1], S. G. Nykamp[1], M. Litman[1], S. T. Millman[2], and T. M. Widowski*[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Iowa State University, Ames.*

A previous study indicated that a non-penetrating captive bolt (NPCB) was effective for euthanasia of 100 neonatal piglets based on immediate and sustained insensibility until full cardiac arrest. The objective of the current study was to assess the brain lesions caused by a NPCB in 20 piglets in 4 weight classes (n = 5 piglets: 3, 5, 7, or 9 kg) as compared with brain lesions of the neonatal piglets from the previous study. Since this was a novel technique for piglets ≥5.5 kg, they were anaesthetized with 71.4 mg/ml ketamine, 14.3 mg/ml xylazine and 1.4 mg/ml butorphanol 0.2 mL/kg IM before NPCB application to ensure insensibility. The NPCB was placed on the frontal bone between the eyes and fired twice in rapid succession, followed by one shot to the back of the skull behind the ear. Piglets were monitored for rhythmic breathing, neuromuscular leg spasms, and heart beat until full cardiac arrest. Macroscopic, histological, and CT scans were scored post mortem to assess degree of skull fracture and hemorrhage. One piglet required an additional shot following a misfire due to presence of rhythmic breathing. Breathing was immediately absent in all other piglets. Leg spasms ceased in 148 s (±12.4 SE). An alternative method (sodium pentobarbital 100 mg/kg) was required for one piglet due to sustained heartbeat. All other piglets reached full cardiac arrest in 371 s (±17.9 SE). Moderate to severe macroscopic damage was reported in ≥90% of piglets. Histological analysis showed moderate to severe subdural (SD) hemorrhage and mild to moderate parenchymal (P) hemor-

rhage. Fracture displacement (FD) averaged 9.38 mm (±0.84 SE). In comparison to the brain lesions of neonatal piglets, damage was less severe in anaesthetized piglets (Mann-Whitney test for ordinal data: SD: $P = 0.007$; P: $P = 0.041$) despite greater FD (t-test: $P = 0.019$). Although brain damage in the anaesthetized piglets was less severe than that of the conscious neonates, the NPCB still caused parenchymal brain lesions and effectively induced cardiac arrest. The next trial will test the effectiveness of the NPCB on conscious piglets up to 9 kg.

Key words: euthanasia, piglet, brain lesion

Animal Health: Johne's Disease

182 Bayesian analysis of longitudinal Johne's disease diagnostic data without a gold standard test. C. Wang*[1], B. Turnbull[2], S. Nielsen[3], and Y. Gröhn[2], *[1]Iowa State University, Ames, [2]Cornell University, Ithaca, NY, [3]University of Copenhagen, Frederiksberg, Denmark.*

A Bayesian methodology was developed based on a latent change-point model to evaluate the performance of milk ELISA and fecal culture tests for longitudinal Johne's Disease diagnostic data. The situation where there is no perfect reference test was considered, i.e., no "gold standard." A change-point process with a Weibull survival hazard function was used to model the progression of the hidden disease status. The model adjusted for the fixed effects of covariate variables and random effects of subject on the diagnostic testing procedure. Markov chain Monte Carlo methods were used to compute the posterior estimates of the model parameters that provide the basis for inference concerning the accuracy of the diagnostic procedure. Based on the Bayesian approach, the posterior probability distribution of the change-point onset time can be obtained and used as a criterion for infection diagnosis. An application is presented to an analysis of ELISA and fecal culture test outcomes in the diagnostic testing of paratuberculosis (Johne's disease) for a Danish longitudinal study from January 2000 to March 2003. The posterior probability criterion based on the Bayesian model with 4 repeated observations has an area under the receiver operating characteristic curve (AUC) of 0.984, and is superior to the raw ELISA (AUC = 0.911) and fecal culture (sensitivity = 0.358, specificity = 0.980) tests for Johne's disease diagnosis.

Key words: Johne's disease, longitudinal, no gold standard

183 Environmental contamination with *Mycobacterium avium* ssp. *paratuberculosis* in endemically infected dairy herds. R. L. Smith*[1], Y. H. Schukken[1], A. K. Pradhan[1], J. M. Smith[2], R. H. Whitlock[3], J. S. Van Kessel[4], D. R. Wolfgang[5], and Y. T. Grohn[1], *[1]Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY, [2]Department of Animal Science, University of Vermont, Burlington, [3]Department of Clinical Studies, New Bolton Center, School of Veterinary Medicine, University of Pennsylvania, Kennett Square, [4]Environmental Microbial and Food Safety Laboratory, ANRI, USDA-ARS, Beltsville, MD, [5]Department of Veterinary and Biomedical Science, Penn State University, University Park.*

Environmental contamination with *Mycobacterium avium* ssp. *paratuberculosis* (MAP) is thought to be one of the primary sources of infection for dairy cattle. The exact link between fecal shedding of MAP by individual cows and environmental contamination at the herd level was explored with a cross-sectional analysis of longitudinally collected samples on 3 dairy farms. Composite samples from multiple environmental sites in 3 commercial dairy herds in the Northeast US were cultured quarterly for MAP, providing 898 samples (113 (12.6%) were culture-positive), and all adult animals in the herds were tested biannually by fecal culture (FC), for 6 years. Of the environmental sites sampled, manure storage areas and shared alleyways were most likely to be culture-positive. Environmental sample results were compared with FC results from either the concurrent or previous sampling date at both the herd and the pen level. At the herd level, a 1 log unit increase in average fecal shedding increased the odds of a positive environmental sample by 3.5 and increased the average amount of MAP in the sample by 2.1 cfu/g. At the pen level, the odds were increased by a factor of 3 and the average amount of MAP was increased by 1.1 cfu/g. There was no significant relationship between environmental site status and the distance between shedding animals and the site, and neighboring pens did not affect the results of the pen-level analysis. The amount of MAP in pen-level samples was positively correlated with the number of animals in the pen shedding >30 cfu/g of MAP. At least 6 environmental samples met the criteria for the US Voluntary Bovine Johne's Disease Control Program on 45 of the 65 testing dates; of these, 16 of the 42 FC-positive testing dates were positive by the 6-sample environmental testing method, resulting in a herd sensitivity of 0.38 (95% CI: 0.23 to 0.52), and 0 of the 3 FC-negative testing dates were positive by this method. Although environmental sampling can be used as a tool in understanding the level of MAP infection in a herd or pen, it does not appear to be a sensitive diagnostic method for herd positivity and should be used with caution.

Key words: Johne's disease

184 *Mycobacterium avium* ssp. *paratuberculosis* promotes rapid IL-1β release and macropahge transepithelial migration. E. Lamont*[1], S. O'Grady[1], W. Davis[2], T. Eckstein[3], and S. Sreevatsan[1], *[1]University of Minnesota, [2]Washington State University, [3]Colorado State University.*

Pathogen processing by the intestinal epithelium involves a dynamic innate immune response initiated by pathogen-epithelial cell cross-talk, which may be augmented by interactions between host pathways and/or cell types. Studies investigating *Mycobacterium avium* ssp. paratuberculosis, the causative agent of chronic enteritis in ruminants, focus solely on the macrophage and largely neglect responses within the epithelium. We show that *M. avium* ssp. *paratuberculosis* induces phagosome acidification within bovine epithelial (MAC-T) cells as early as 10 min, resulting in upregulation of IL-1β at transcript and protein levels. Previous studies report that IL-1β is a potent macrophage chemoattractant. These initial host-pathogen interactions may dictate a form of cooperative self-destruction in which the host is deceived into reacting to the benefit of *M. avium* ssp. *paratuberculosis*; thereby, setting the tone for the ensuing infection. We hypothesized that *M. avium* ssp. *paratuberculosis* harnesses host responses to recruit macrophages to the site of infection to ensure its survival and dissemination. We investigated macrophage recruitment in response to *M. avium* ssp. *paratuberculosis* using a MAC-T-bovine macrophage coculture system. Within 10 min of infection, macrophages were recruited to the apical side of MAC-T cells. Inhibition of phagosome acidification and IL-1β abrogated this response, while MCP-1/CCL2 blocking had no effect. IL-1β processing was dependent upon Ca^{2+}uptake from the extracellular media and intracellular Ca^{2+}oscillations as determined by EGTA and BAPTA-AM treatments. Thus, *M. avium* ssp. *paratuberculosis* guidance of phagosome-acidification enlists IL-1β processing in an extracellular calcium dependent manner to efficiently transverse the epithelium and into its niche—the macrophage.

Key words: *Mycobacterium avium* ssp. *paratuberculosis*, interleukin 1 beta, macrophage recruitment

185 Real-time estimation of the lacto-presence of *Mycobacterium avium* subspecies *paratuberculosis* in milk and milk products originating from goat and cattle herds endemic for Johne's disease. S. V. Singh*[1], T. Raghuvanshi[1], R. B. Sharma[1], B. Singh[1], A. V.

Singh[1], P. K. Singh[1], A. Kumar[1], and A. Srivastav[2], *[1]Central Institute for Research on Goats, Mathura, Uttar Pradesh, India, [2]College of Veterinary Sciences, Mathura, Uttar Pradesh, India.*

Mycobacterium avium subspecies paratuberculosis (MAP) is the cause of Johne's disease in ruminants and is endemic in countries where investigated including India. Live MAP has been recovered from raw and pasteurized milk and milk products. Information on the status of MAP in the milk and milk products is extremely limited. Real time estimate of lacto-presence of MAP were studied in milk and milk products originating from herds endemic for Johne's disease. Forty eight and 23 individual milk samples were collected from two goat farms (Farm A. and Farm B) and a cattle farm (Farm C) in Mathura region of North India. Eighteen pooled goat milk samples from the Farm A. and B. and 24 paneer (raw cheese from pooled milk) samples were collected. Samples were screened using microscopy, indigenous ELISA kit and IS900 PCR to estimate lacto-presence of MAP. Tests showed variable lacto-presence of MAP in milk and milk products. Using microscopy, 25, 4.2, 5.6 and 12.5%, of milk samples of Farm A. and B, pooled milk and paneer samples were positive, respectively. In milk-ELISA, 25% of individual milk samples of Farm A. and B. were positive, whereas, none of the pooled milk samples were positive for MAP. Screening of 9 and 3 individual milk samples of Farm A. and B, 3 pooled milk samples and 2 samples of paneer by IS900 PCR, one milk sample of Farm A. was positive. Lacto-presence of MAP was higher in milk samples originating from cattle herds and of 23 milk samples, 56.5, 86.9 and 30.4% were positive in microscopy, ELISA and PCR, respectively. Lacto-presence of MAP in the two goat farms was low to moderate and was high in the cattle herd. Load of MAP in livestock herds had significant correlation with presence of MAP in milk and milk products originating from herds endemic for JD, thereby posing serious health risk to human population.

Key words: milk and milk products, lacto-prevalence, *Mycobacterium avium* subspecies *paratuberculosis*

186 Association of Bsa I polymorphism of MHC Class II DRB gene with *Mycobacterium avium* ssp.*paratuberculosis* bacterimia in Jamunapari breed of goats. S.V. Singh, P. Rai, P. K. Singh*, A. V. Singh, M. K. Singh, and J. S. Sohal, *Central Institute for Research on Goats, Mathura, Uttar Pradesh, India.*

Johne's disease (JD) caused by *Mycobacterium avium* subspecies *paratuberculosis* (MAP) is responsible for huge economic losses in livestock productivity worldwide. Failure to detect early infection and lack of effective vaccine hamper control of disease. Studies on variations in host genetics that contribute to resistance or susceptibility to disease may potentially help to control disease effectively. Polymorphism in exon-2 of caprine MHC Class II DRB region further elucidated the effect of genetic variation in this region on MAP bacteremia in Jamunapari goats. Blood samples from 38 adult goats of Jamunapari farm (Central Institute for Research on Goats in Mathura) endemic for JD were analyzed to detect MAP infection using IS900 PCR and characterize MHC class II DRB region using Bsa I. PCR-RFLP. Of 38 goats 26 (68.4%) were positive for presence of MAP in blood. Three genotypes for Bsa I, namely BB, Bb and bb (with genotypic frequency of 0.711, 0.025 and 0.265, respectively) and two alleles B. and b (with allelic frequency of 0.843 and 0.157, respectively) were observed in the DRB second exon region of Jamunapari goats. Non-significant effect of Bsa I. MHC class II alleles with MAP bacteremia was found ($\chi^2 = 1.950$, df = 2, $P = 0.005$). There was no significant difference in distribution of all three genotypes (BB, Bb and bb) between goats positive or negative for MAP DNA in blood. Distribution of homozygous BB alleles was approximately significant ($\chi^2 = 3.779$, $P = 0.052$) in MAP positive group of goats. Genetic variation of MHC Class II DRB region may regulate MAP infection; therefore, a comprehensive study on substantial goat population is needed to get some conclusive impact of BsaI based single nucleotide polymorphism and others of DRB region alleles on JD susceptibility and / or resistance.

Key words: paratuberculosis, MHC class II DRB gene, polymorphism

187 Johne′s program—Impact on education and outreach activities. K. E. Olson*, *KEO Consulting, Schaumburg, IL.*

Federal investment in the Voluntary Bovine Johne′s Disease Control Program declined from $21m in 2003 to $6.8m in FY09. Primary metrics have included number of herds in the program and samples tested in approved labs; however, it is anticipated that program investments have produced other activities that will enhance efforts to address the disease. State Designated Johne′s Coordinators (DJCs), Dairy Herd Improvement Association (DHIA) service units and, dairy and beef producer organizations were surveyed to document program participation changes and identify current activities that will affect the producer′s ability to deal with the disease. Responses were received from 32 DJCs, 16 beef organizations, 5 dairy cooperatives, 12 DHIA organizations and 3 dairy records processing centers. The following program impacts resulting from funding reductions were reported by DJCs: 25 ran fewer individual samples; 25 had fewer Risk Assessments and Management Plans (RAMPs) completed; 24 certified or re-certified fewer veterinarians; 22 conducted fewer educational events; 19 had fewer committee meetings. The DJC survey quantified activities not measured in program metrics that affect producer knowledge and ability to deal with the disease including: 1,434 Johne′s certified veterinarians available to work with producers; 56 meetings with 9.721 participants; 10,720 copies of 27 publications distributed; 13 internet sites devoted to Johne′s information delivery; 12 reported articles in trade publications reaching 9,656 readers. Producer organizations reported:1 beef meeting with 250 producers; 20 dairy meetings with 975 producers; 6 DHIAs trained technicians and 4 met with producers; 207,033 milk ELISA samples run by DHIA, a 10% increase. Research is currently funded by one breed association and JDIP is providing competitive grants that have leveraged additional outside funds. A concern identified is the need for additional communication between program leadership and producers relative to program operation with reduced funding. Program resources have developed a strong infrastructure to assist producer efforts, but additional planning is needed to find ways to maintain needed resource and make them available to producers.

Key words: Johne's, JDIP

188 Mathematical modeling of *Mycobacterium avium* subspecies *paratuberculosis* infection transmission in dairy cattle: Current status and future directions. Z. Lu*[1], R. Mitchell[1], R. Smith[1], Y. Schukken[1], Y. Gröhn[1], K. Ahmadizadeh[2], M. Teose[2,3], T. Damoulas[2], and C. Gomes[2], *[1]Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY, [2]Department of Computer Science, Cornell University, Ithaca, NY, [3]Center for Applied Mathematics, Cornell University, Ithaca, NY.*

The objective of this presentation is to review the current status and to outline the future research directions of mathematical modeling of *Mycobacterium avium* subspecies *paratuberculosis* (MAP) infections

in dairy cattle. As one of the most important infectious diseases in dairy cattle, MAP infections cause considerable economic losses in the dairy industry and pose a potential threat to public health. Control of MAP is difficult due to the long incubation period and poor diagnostic tests for early MAP infections. To have a better understanding of MAP transmission dynamics and to evaluate the effectiveness of MAP control strategies in dairy cattle, several within-herd mathematical compartment models on the basis of MAP infection history have been developed using deterministic and stochastic modeling approaches. We reviewed these mathematical models and examined their usefulness and limitations. Subsequently, we identified 4 potential research directions in mathematical modeling of MAP infection at different levels of organization. The first is to investigate how MAP is transmitted between herds in a large spatial region. In the United States, studies showed that at least 70% of dairy herds were infected with MAP. To understand this high herd-level MAP prevalence and find effective control strategies for MAP at herd level, construction of a network structure of animal movements will be necessary. The second research direction is to continue modeling the within-herd level of MAP infection, considering more challenging problems such as MAP strain competition, co-infection, and the importance of environmental transmission. The third research direction is to study the infection process of MAP and host immune response at the individual animal level. Mathematical models at this level will be particularly helpful for understanding the potential mechanism of MAP vaccines. The fourth direction is to build individual-based economic optimization models and to find optimized MAP control strategies within a herd.

Key words: paratuberculosis, mathematical modeling, dairy cattle

189 Vertical transmission or increased susceptibility to MAP? E. Knupfer[1], R. M. Mitchell*[2], A. K. Pradhan[2,3], A. Kramer[1], J. Dieguez[4], R. H. Whitlock[5], T. Fyock[5], and Y. H. Schukken[2], *[1]Utrecht University, Utrecht, the Netherlands, [2]Cornell University, Ithaca, NY, [3]University of Maryland, College Park, [4]Universidade de Santiago de Compostela, Spain, [5]University of Pennsylvania, New Bolton Center.*

MAP-infected dairy cattle are assumed to be a high risk for transmitting infection to their daughters. Alternatively, if both dam and daughter are genetically more susceptible to MAP, they may be both infected but not necessarily due to vertical transmission. Using strain typing techniques including multi locus short sequence repeat (MLSSR) typing allows a potential distinction between vertical transmission and genetic susceptibility. Analyzing strain diversity in longitudinal data sets provides additional insight into within-herd infection dynamics, including the transmission of MAP from dams to daughters. To investigate the importance of vertical transmission, we identified 12 pairs of dams and daughters for which both animals are known MAP infected from the Regional Dairy Quality Management Alliance (RDQMA) study herd in NY. All adult animals were tested for MAP via fecal culture semi-annually for seven years. Tissue samples were available on a subset of cull animals. Animals were considered MAP-infected if they ever cultured positive or if any of their tissues cultured positive at slaughter. Cultures were performed at University of Pennsylvania on HEYM solid media. Positive cultures were substreaked and processed for MLSSR typing. Following genotyping, isolates from each dam-daughter pair were compared to determine whether they shared the same MAP genotype. Environmental MAP burden at birth was assessed via typing of MAP-positive environmental samples (collected four times a year) and known MAP-infected animals present on the farm during the high-risk first year of life. Of the 12 infected dam-daughter pairs, 9 had identical strains shared between the dams and daughters. In addition, 2 daughters had the dam's strain as well as another circulating strain. Overall, there were 7 strains represented in the daughters that did not come from dams (2 daughters had multiple strains which did not originate from the dam). These results lend additional importance to the impact of genetics on susceptibility, as 5 of 12 daughters carried different strains of MAP than their dams, even when concurrently infected with the dam's strain.

Key words: *Mycobacterium avium* subspecies *paratuberculosis*, vertical transmission, strain typing

190 MAP co-infection or evolution? R. M. Mitchell*[1], E. Knupfer[2], A. K. Pradhan[1,3], A. Kramer[2], J. Dieguez[4], R. H. Whitlock[5], T. Fyock[5], and Y. H. Schukken[1], *[1]Cornell University, Ithaca, NY, [2]Utrecht University, Utrecht, the Netherlands, [3]University of Maryland, College Park, MD, [4]Universidade de Santiago de Compostela, Spain, [5]University of Pennsylvania, New Bolton Center.*

Co-infection is important in human tuberculosis (Htb), especially in high prevalence environments where multiple exposures increases likelihood of infectious progression. This phenomenon is not often studied in bovine mycobacterial infections, partially due to the lack of differentiation between host-specific strains of MAP. However, as illustrated by recent research on cull animals and longitudinal sampling on dairy farms which includes tissue samples at slaughter, cattle live in a very high prevalence environment. If the many subclinically infected animals which are in close contact with herdmates are intermittently shedding throughout their lives, this will result in multiple exposures. We examined whether animals shed the same MAP strain throughout their lifespan. All animals on the NY farm in the Regional Dairy Quality Management Alliance (RDQMA) were tested for MAP using fecal sampling semi-annually for seven years. Tissue samples were available on a subset of cull animals. Cultures were performed at University of Pennsylvania on HEYM solid media. All positive fecal cultures and one or more positive tissue sample from each animal were evaluated by multilocus short sequence repeat typing (MLSSR) for each animal. Strain types were assigned based on number of repeats at each MLSSR locus selected. In the 96 animals with at least one positive fecal or tissue culture over the course of the longitudinal study, there were 13 strain types identified. Of the 59 animals with only one sample processed, 4 (7%) had mixed infections (clear evidence of two sequences of differing repeat lengths) when analyzed. Of the 37 animals with more than one sample analyzed, 19 (51%) had more than one MAP strain throughout life including 17 with mixed infections. This close study of within-farm dynamics reveals that it is not uncommon for animals to be infected with multiple strains of MAP. The often close relationship between strains in multiple infections brings to mind the possibility that what we are seeing in MAP is really within host evolution of MAP strains rather than (mixed) co-infection in a portion of multiply infected animals.

Key words: *Mycobacterium avium* subspecies *paratuberculosis*, strain typing, multiple infections

191 Towards understanding endemicity of MAP infection in dairy herds. R. M. Mitchell*[1], G. F. Medley[2], and Y. H. Schukken[1], *[1]Cornell University, Ithaca, NY, [2]Warwick University, Coventry, UK.*

Maintenance of MAP infection on dairy farms is non-trivial in terms of infectious dynamics. Indeed a large portion of animals do not shed MAP throughout their lifetimes despite being truly infected when their tissues are cultured at slaughter. In this study we incorporate the

infection biology of MAP into a mathematical model which takes into account age and dose dependent infectious progression. The model incorporates a large proportion of truly infected but never shedding animals which are observed as MAP positive in tissue culture studies but not in fecal shedding. We modified our current models of MAP in Matlab to incorporate a slow-progressing latent category based on previously published data on dose and age dependent infection probabilities. In this model, animals either shed shortly following exposure and enter an early shedding compartment, or do not shed early and enter a slow-progressing latent state- where they remain for an extended period of time. Animals which shed early have a shorter duration of latency following this early compartment and progress to late shedding. Infectious progression is modeled differently for animals which receive high or low initial doses of MAP. Animals which receive high doses of MAP spend a longer period of time in the early shedding compartment and are therefore more likely to come into contact with susceptible young animals during this time of increased infectiousness. Model output indicates that endemic MAP infection is possible at transmission rates that would not allow successful entry of MAP in a fully susceptible population. Indicating that MAP endemicity is driven by different infection dynamics than the initial establishment of MAP in a dairy herd. Our model indicates that there are 2 sustainable MAP infection equilibria at relative contact rates of less than one between adult animals and calves. This structure appears to be unique to dairy cattle, and may explain why endemically MAP infected herds occur frequent. Our findings explain why slaughter samples show a dramatically higher prevalence of MAP infection in tissue samples compared with MAP fecal shedding.

192 *Mycobacterium avium* subspecies *paratuberculosis*-infected macrophages have different protein and transcriptome profiles than control or uninfected culture mates. E. Kabara* and P. Coussens, *Michigan State University, East Lansing.*

Previously, our group presented evidence that *Mycobacterium avium* subspecies *paratuberculosis* (MAP)-infected macrophages are significantly less apoptotic than uninfected, culture mates (bystander macrophages) found in a MAP-infected culture. This mirrors the apoptotic status of Mycobacterium tuberculosis (TB)-infected macrophages and bystander cells found in TB-infected cultures. Currently, little published work has been done studying apoptotic pathway regulation in TB and MAP-infected macrophages. Therefore, our goal was to investigate the mycobacterial specific mechanism and corresponding host reactions that are employed to prevent apoptosis in mycobacterium-infected macrophages. We hypothesize that MAP-infected macrophages have differential expression of several apoptotic when compared with bystander macrophages. Two distinct methods were undertaken to test this hypothesis. First, we used flow cytometry with fluorescent labeling of MAP bacteria and antibody labeling of host proteins to study the expression and phosphorylation status of host proteins of MAP-infected, bystander, and control macrophages with and without stimulation. Among our many observations, we saw no significant differences in MAPK protein expression and phosphorylation in unstimulated control and MAP-infected macrophages which is in agreement with previous publications on this subject. Second, we isolated RNA from control and MAP-infected macrophages cultures where over 90% of the cells are infected to study a population of MAP-infected macrophages without bystander cells. These samples were used in RT-qPCR testing of apoptosis pathway transcripts. We observed significant upregulation of Caspase 3 and 9 mRNA expression in MAP-infected macrophages as compared with controls while seeing no significant difference in caspase 8 expression between the 2 samples (P-value <0.05).

193 Effect of changes in management practices on the risk of Johne's disease in Minnesota Johne's disease demonstration dairy herds. L. A. Espejo*, S. Godden, and S. J. Wells, *University of Minnesota, Department of Veterinary Population Medicine, St. Paul.*

Certain management practices have been recommended to minimize transmission of Johne's disease between infected and susceptible cattle. The objective of this study was to evaluate the risk of testing positive and its association with changes in recommended management practices in different birth cohorts. Eight dairy herds and approximately 6,000 cows were enrolled in the Minnesota Johne's Disease Demonstration Herd Program. Herds were monitored for a period between 5 to 10 years. Annual testing for *Mycobacterium avium* ssp. *paratuberculosis* was performed for all cows that calved, using bacterial culture and serum ELISA. Risk assessments were performed annually to measure the level of implementation of the recommended management practices. Eight birth cohorts were defined based on the date of cow enrollment in the program. Birth cohorts −2 and −1 corresponded to cows that were born 2 and 1 year before the beginning of the program, respectively, and cohorts 0 to 5 corresponded to cows that were born 0 to 5 years after the beginning to the program. The annual risk assessment score was used to quantify the level of exposure by birth cohort and herd. A time dependent Cox's regression model was used to model the time to test positive, explained by herd, birth cohort and birth cohort exposure level. Compared with birth cohort −2, there was a reduction of the hazard ratio (95%CI) of bacterial culture positivity of 0.65 (0.49 to 0.85), 0.56 (0.42 to 0.73), 0.66 (0.48 to 0.90), 0.38 (0.26 to 0.58), 0.22 (0.14 to 0.35), 0.22 (0.14 to 0.34), and 0.20 (0.13 to 0.32), for birth cohorts −1, 0, 1, 2, 3, 4, and 5, respectively. Similar results were obtained for serum ELISA. The instantaneous hazard of testing positive for both tests increased with the level of exposure, however, the strength of this association decreased over time. There was a reduction in the transmission of Johne's disease associated with the level of implementation of the recommended management practices.

Key words: Johne's disease, disease control

194 Zinc-finger nucleases: Innovations in custom-designed modification of the swine genome. J. J. Whyte*, J. Zhao, K. D. Wells, M. S. Samuel, K. M. Whitworth, E. M. Walters, M. H. Laughlin, and R. S. Prather, *University of Missouri, Columbia.*

Genetically modified swine hold great promise in the fields of medicine and agriculture. Pigs are similar to humans in anatomy and physiology and they reproduce rapidly to provide a reliable source of research animals. By combining emerging gene modification technologies with the completion of the swine genome, custom-designed pigs will provide urgently needed organs and therapeutic proteins for patients, realistic models of human disease, and high quality, efficiently produced food to meet the nutritional demands of the ever-expanding world population. Conventional gene targeting (adding foreign DNA via homologous recombination) is highly inefficient in mammalian somatic cells and provides little control over the site of transgene integration. The landscape of gene modification has recently changed with the use of zinc-finger nucleases (ZFNs) to enhance targeting efficiencies up to 10,000-fold. ZFNs consist of a nonspecific endonuclease domain and a sequence-specific zinc-finger DNA binding domain. Custom pairs of ZFNs heterodimerize upon binding DNA at predetermined gene loci to form a catalytically active nuclease complex. The resulting cleavage triggers DNA repair pathways that can be exploited to either disrupt gene coding or enhance insertion of exogenous DNA constructs. ZFNs have been used to genetically alter organisms such as plants, insects, zebra fish and rats. Recent publication of the first genetic modification in pigs by combining ZFN technology with somatic cell nuclear transfer has opened the door to genome targeting with a precision that was not previously possible in a large animal model. A preliminary report describing ZFN-based knockout of the α1,3-galactosyltransferase gene in porcine fibroblast cells raises the possibility of model pigs with selective knockout of endogenous genes without introducing any transgenic sequence into the genome. This presentation will provide an overview of ZFNs, emphasizing their potential to accelerate the production of genetically modified pigs of agricultural and biomedical importance. Current methods of ZFN design, important considerations for their safe and effective use in modification of the swine genome, and future innovative applications of this technology in pigs will be discussed.

195 Improved RNA quantitation and applications to animal science. C. D. Haudenschild*, *Illumina Inc., Hayward, CA.*

In the past few years we have seen numerous significant changes in the way we approach the study of organism development and the biology of diseases in model and non model organisms. What was mostly a gene-centric method that relied on following simple expression patterns is now largely a statistically based science. With the introduction of next generation sequencing methods to the study of gene expression, we can now rely on whole genome views of the transcriptome leading to ever increasing data volumes and compare large sample numbers. Due to the variety of information sources we can now interrogate, we are able to start appreciating the true complexity of cells and the significance of the variables involved. In the study of gene expression, one now considers temporal expression in conjunction with what particular alleles are transcribed in what tissue and which splice variants are predominant. The analysis of translation state also became available and can provide essential pertinent information. Analyzing whole genome sequences in conjunction with sequence based expression profiles on large segregating populations should also allow for better QTL characterizations. The data permits the enhancement of usability of newly assembled genome by better defining gene structure annotation and thus allowing for better comparison across closely related species. Numerous protocols are available and examples of applications will be described.

196 Informatics-driven biological research: Infectious diseases as an example. B. Sobral*, *Virginia Bioinformatics Institute at Virginia Tech, Blacksburg.*

Infectious disease researchers have to deal with diverse types of data to develop hypotheses about candidate macromolecules that can be used to design countermeasures (diagnostics, vaccines and therapeutics). Even considering only molecular data, it is a challenge to access all the public information available to them and implement workflows that support their analysis needs. I will use the example of *Brucella* spp. to illustrate how public, open, freely available resources can be designed, developed, and implemented in support of such infectious disease research and development goals. There are now 40 genomes of *Brucella* (Alphaproteobacteria; Rhizobiales) sequenced, sampling all known species and biovars of this facultative intracellular pathogen. A phylogenomic analysis of these genomes united all *Brucella* when they were compared with outgroups including *Ochrobactrum*, *Bartonella*, *Mesorhizobium* and *Agrobacterium*. Although the *Brucella* genomes are united, there is some interesting diversity. A well-studied group of *Brucella* species are united in a clade separated by a long branch. This large clade has little phylogenetic depth, but species within this group are known to have specific host preferences. Sub-branching patterns within this group reflect these host preferences and specific protein families unique to, and absent from, these groups were identified. Two novel strains, *Brucella inopinata* BO1T and BO2, were recently identified and isolated from human patients. Genomes from these strains, as well as 2 new isolates isolated from Australian rodents (*Brucella* spp. NF2653 and 83/13), are quite unique and separated from the rest of the *Brucella*. Although they share many similarities with the other *Brucella* species, they are missing many large areas of their genomes that can be seen in other *Brucella*. Analyses of these areas using new bioinformatic tools and data resources have shown that some of these missing areas include previously identified genomic islands and virulence factors, and there are novel findings as well that impact biochemical pathways and unique changes in the synthesis of lipopolysaccharide.

Breeding and Genetics Symposium: Really Big Data: Processing and Analysis of Very Large Datasets

197 High performance computing and really big datasets: Overview and best practices. F. Foertter*, *Genus plc, Hendersonville, TN.*

More often than not, researchers today find themselves overwhelmed with increasingly large data sets. It has become difficult to develop efficient workflows to edit and then analyze large data sets to extract meaningful results. Whereas desktop computers have sufficed in the past, data sets involving high density SNP or sequence data are growing so large that new high performance computing (HPC) methods are under development to allow efficient data housing, searching and analysis. This presentation will provide scientists an insight on how Genus is using HPC to manage large data sets in both research and genomic evaluation. Topics will include a review of hardware choices, including power/temperature and scalability considerations, and data storage and density. Also important are the financial and security considerations between owned clusters, university and national laboratory clusters, and commercial options such as pay-as-you-go clouds. Software issues will also be addressed, including the advantages and disadvantages of commercial versus Open Source and discussion on building in-house codes. Relevant setup scenarios and industry best practices related to Genus' implementation will also be presented. Finally we will demonstrate how Genus is currently leveraging HPC to decrease time-to-results in research, increase accuracy in genomic evaluations, and therefore increasing the rates of genetic improvement.

Key words: computation, genomics, analysis

198 Data structures and visualization. J. B. Cole*, *Animal Improvement Programs Laboratory, ARS, USDA, Beltsville, MD.*

Genomic tools for genetic improvement have been rapidly adopted in many livestock species over the past few years. This presents new challenges for data collection and management, as well as opportunities for analysis and presentation. The US national dairy database currently includes genotypes for 83,117 bulls and cows and 2,620 imputed dams representing 3 different densities and 4 chip versions. Storage requirements for these genotypes are modest, even when high-density (>500,000K) genotypes are imputed from lower densities. However, storage requirements for intermediate and results files for genetic evaluations are much more substantial, particularly when multiple runs must be stored for research and validation studies. Full-sequence data will be available at reasonable cost in the near future, and will require much more storage. The greatest gains in accuracy from genomic selection have been realized for traits of low heritability, such as fertility and longevity, and there is increasing interest in new health and management traits. In addition to data on novel traits, potentially useful economic and demographic information is being collected by on-farm computer and analytical systems. There is increasing interest in traits such as feed efficiency and resistance to climate change, but the collection of sufficient phenotypes to produce accurate evaluations may take several years, and high-reliability proofs for older bulls are needed to precisely estimate marker effects. As traits proliferate and the number of genotyped animals continues to grow increasingly sophisticated analytical approaches will be tractable. Machine learning algorithms may be useful in identifying previously unrecognized relationships among traits, and the analysis of genetic (co)variances among loci could help identify important gene networks. Improved visualization tools, particularly those capable of processing very large volumes of data in a reasonable amount of time, are needed to help better understand the results of analyses. The challenges and opportunities presented by growing amounts of phenotypic and genomic data are generally similar regardless of the species in question.

Key words: genomics, data structures, visualization

199 Computational challenges in genetic evaluation with really big datasets. I. Aguilar*[1] and I. Misztal[2], *[1]Instituto Nacional de Investigación Agropecuaria, INIA Las Brujas, Canelones, Uruguay, [2]Animal & Dairy Science Department, University of Georgia, Athens.*

Genomic selection poses new computational problems. Genotypes for each individual require a large amount of storage and this amount will increase with larger SNP chips and eventually with individual genome scans. Computations in genomic selection using this data seem to require even more computing power especially when large fractions of population will be genotyped. Looking back in the history of animal breeding, 2 choices exist, brute force or new theoretical developments. For example, storing large A matrices required massive computers and inverting those seemed impossible. Rules to create A^{-1} explicitly by Henderson made these computations trivial. Even with A^{-1}, creating the mixed models explicitly required large resources. The iteration on data algorithm decreased the required resources drastically. Developments in sparse matrix inversion and of the AI algorithm made fast REML a reality. The genomic selection is most likely no different. While the genomic data seems huge, use of larger SNP chips results in limited gains. Sampling for best subset of SNP as in BayesX is time consuming, but methods based on the genomic relationship matrix G seem as efficient especially with larger data sets. In fact, given G the genomic selection may be another BLUP in the form of single-step GBLUP where computations are not much greater than in regular BLUP. The limiting factor in ssGBLUP is constructing and inverting G for many genotypes. Careful programming makes these operations much less expensive. For example, a regular algorithm for creating G for about 14k genotyped individuals required about a day. After using custom libraries and exploiting parallel computing via OpenMP, the computing time was reduced to 15 min. It is possible that G can be made sparse for large number of genotypes and that the number of useful genotypes for prediction will be limited. Hardware improvements have resulted in machines with multiple cores, with much faster speed and bigger cache memory and with more memory. Nevertheless, for successful implementations of large genetic evaluations, improvements in methodology were as important as advances in computer power.

Key words: genetic evaluation, computing methods, genomic selection

200 The implementation of analysis of large data. M. Coffey*, *Scottish Agricultural College, Penicuik, Midlothian, UK.*

Developments in DNA based technologies have led to large amounts of genotype data being available for farmed livestock. This has created great excitement among those engaged in research since data equals papers. However, for those engaged in national genetic evaluations

the logistics of handling so-called large data sets creates unique challenges that generate little scientific interest. These challenges must be overcome to exploit these new technologies and must be overcome in a way that does not create disruption during the transition from conventional evaluations to genomic EBVs (GEBVs). What constitutes large is ill defined but data in the terabytes is now routinely available. It is impractical to throw out existing systems at a whim and business development must take place to generate revenue that stimulates adoption. Thus genetic evaluation centers need to adopt different computing strategies to account for genotype data within systems that run routinely month after month. Data storage cost is not a real issue but processing time is, especially as systems are developed that run in real time for farmers to decide which animals to genotype via web based services and receive GEBVs as a result. This paper will highlight the practical aspects of implementing genomic evaluations.

Key words: genomic breeding value, genetic evaluation

Dairy Foods: Filtration and Drying

201 Impact of annatto color and bleaching of whey and microfiltration permeate on ultrafiltration processing characteristics during production of 80% protein concentrates. M. Adams[1], J. Zulewska*[2], and D. M. Barbano[1], [1]*Cornell University, Ithaca, NY,* [2]*University of Warmia and Mazury, Olsztyn, Poland.*

Our objective was to determine if annatto color or bleaching had any influence on ultrafiltration (UF) flux during production of 80% whey protein concentrate (WPC) or 80% serum protein concentrate (SPC). Cheddar cheese whey (18 vats using 900 kg of whole milk each) and microfiltration (MF) permeate of skim milk (18 processing runs using 1000 kg of skim milk each) were produced. The 18 runs were divided into 3 replicates with 6 different treatments within each replicate. The 6 treatments within either the whey or MF permeate replicates were: 1) no annatto (NA), 2) NA + benzoyl peroxide (BPO), 3) NA + H_2O_2, 4) annatto (A), 5) A + BPO, and 6) A + H_2O_2. Approximately 700 kg of separated, treated whey or treated MF permeate was heated to 50°C and processed with the UF system in batch recirculation mode using a polyethersulfone spiral wound UF membrane (Model 3838, GEA NIRO Inc., Hudson, WI) with a nominal pore size of 10,000 Da. Addition of annatto color had little or no effect ($P > 0.05$) on UF flux. Bleaching separated Cheddar cheese whey or MF permeate with or without added color improved ($P < 0.05$) UF flux during processing to produce 80% protein concentrates. Generally, H_2O_2 produced higher fluxes than BPO treatments ($P < 0.05$) and BPO increased SPC production fluxes to a lesser extent ($P < 0.05$) than it did WPC production fluxes. Relative to the flux of unbleached whey (about 15 L/m^2h), the bleached whey had a flux of about 20 to 23 L/m^2h. Water flux before processing, after processing, and after final cleaning were measured at 50°C. The water flux after cleaning restored flux to the level before processing whey or permeate. The flux after processing (i.e., fouled water flux) demonstrated differences in fouling and loss of water permeability that were consistent with differences resulting from the bleaching treatments. Little, if any, effect of the annatto on fouled water flux was observed.

Key words: whey bleaching, ultrafiltration flux, annatto

202 Functional properties of milk serum protein concentrates with varying levels of β-casein. L. Coppola*[1], S. Rankin[1], M. Molitor[2], and J. Lucey[1], [1]*University of Wisconsin-Madison, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

Microfiltration (MF) can isolate serum proteins (MSP) from milk. The dissociation of β-casein from casein micelles at <8°C in combination with MF is a means to create MSP concentrates (MSPC) with varying levels of β-casein. MF permeates were produced at ~23°C (MSPC1) and ~5°C (MSPC2) using polymeric, cross-flow MF, concentrated and spray dried (~85% protein). Composition, browning, volatile profiles, and sensory characters of MSPC before and after accelerated storage (50°C for 28d) were compared with whey protein concentrate (WPC) and WPC samples. Significant effects were declared at $P \leq 0.05$. MSPC1 and MSPC2 contained different levels of β-casein (1.0 vs 20% of the total solids composition, respectively). WPC samples contained more fat than both MSPC. Browning was determined by colorimetry (CIELAB) of powders and optical density of rehydrated samples. Pre-storage L* values were not different between samples, but a* and b* values of MSPC were lower than WPC. After storage, MSPC had higher L* and lower a* values than WPC. Rehydrated MSPC exhibited smaller changes in browning during storage than WPC. SPME/GC-MS of rehydrated samples showed fewer types of volatiles were present pre-storage and that fewer types increased in intensity following storage for MSPC samples compared with WPC. Descriptive sensory analysis indicated that turbidity, odor, and astringency were not affected by storage and were higher in WPC. MSPC2 had lower sweetness than other samples pre-storage but not post-storage. Pre-storage, WPC samples had higher levels of cardboard and residual flavors. With storage, MSPC1 had a trend toward increased milkfat flavor and MPSC2 had an increase in cucumber flavor while WPC increased in salty, acid, sweet, milkfat, cooked, cabbage, and cucumber flavors. Principal component analysis (PCA) indicated marked differences between MSPC and WPC samples both pre-and post-storage, with WPC described by more off-flavor descriptors. MSPC differed in browning, volatiles, composition, and sensory properties compared with WPC samples, likely to make them attractive in food applications where fewer off-flavors and increased storage stability are desired.

Key words: milk serum protein, β-casein, whey

203 Impact of microfiltration temperature on the composition and functionality of casein concentrates. J. R. Koch*[1], J. A. Lucey[1], K. J. Burrington[2], and M. Molitor[2], [1]*University of Wisconsin, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

Microfiltration (MF) is used to separate serum proteins from caseins. There is a trend of performing membrane filtration at cold temperatures to reduce microbial growth. Our objective was to investigate if performing MF at cold or warm temperatures impacted the protein composition and functionality of casein concentrates. Five samples were produced using polymeric spiral wound MF (~0.08 μm) - 2 samples of warm (24°C) temperature MF (WMF) and 3 of cold (5°C) temperature MF (CMF). At cold temperatures β-casein dissociates from casein micelles, which could result in more β-casein in the serum phase. Retentates were concentrated to attain powders with ~80% protein. A milk protein concentrate (MPC) was also produced using ultrafiltration. Reverse-phase HPLC was used to determine the protein composition. The casein to whey ratio was 17:1 and 11.5:1 in the WMF and CMF concentrates, respectively. The β-casein to αs-casein ratio was 4:5 and 5:7 in the WMF and CMF concentrates, respectively. A low concentration of κ-casein was found in all MF permeates likely due to heat-induced complexation of κ-casein with β-lactoglobulin. Solubility of casein concentrates increased with an increase in the temperature of hydration and with the time of hydration. Foams were made from 5% protein solutions, and physical properties (over-run and stability) and rheological properties (vane geometry) were determined. There was no significant difference ($P < 0.05$) in over-run for all samples. Both WMF and CMF concentrates had higher foam stability compared with foams made with MPC. Samples with a higher proportion of β-casein had greater foam stiffness. The foam made from WMF concentrate had significantly higher foam stability and foam stiffness compared with CMF concentrate. Producing casein concentrates at different separation temperatures alters the protein profile. Both separation temperatures reduced the whey (serum) protein content in casein concentrates, but at cold temperature the β-casein content was also reduced. Casein concentrates separated at various temperatures had different functional properties, which could be useful for specific food applications.

Key words: casein concentrate, microfiltration

204 Spiral wound microfiltration process for production of micellar casein concentrate. C. Marella*, P. Salunke, and L. E. Metzger, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings*

Micellar casein concentrate (MCC) is the retentate obtained from microfiltration (MF) of skim milk. Previous research has indicated that MF of skim milk with ceramic membranes result in improved membrane performance relative to spiral wound membranes. However, spiral wound polymeric units have an advantage in terms of capital and operating costs relative to ceramic units. Moreover spiral wound polymeric units are currently extensively used in the US dairy industry. The objective of this study was to evaluate impact of operating pressure and level of diafiltration on membrane performance during MF of skim milk using spiral wound polymeric membranes. Preliminary lab scale experiments were conducted using three levels of transmembrane pressure (TMP) and four levels of diafiltration (DF). Skim milk was microfiltered at 23.3 °C to a volume reduction of 4, using 0.5 µ Polyvinylidene fluoride membrane in a flat sheet configuration. During the experiments, process flux was maintained within 80% of the initial flux by addition of DF water at 6 intervals so as to control the viscosity of the retentate. The effect of TMP and effectiveness of DF were assessed by measuring overall flux, serum protein removal (SP removal), casein to total protein ratio (CN/TKN), casein to true protein ratio (CN/TP), and rejection of casein and serum protein. CN/TKN ratio of MCCs ranged from 0.87 to 0.96 while CN/TP ratio ranged from 0.89 – 0.96. The rejection of casein ranged from 0.97 to 1.0 while the rejection of SP ranged from 0.1 to 0.53. SP removal ranged from 35 – 81.45%. The highest ratio of CN/TKN, CN/TP, SP removal and the lowest rejection of SP were obtained with the use of 35.4 kPa TMP and 150% DF. These are the lowest TMP and highest DF used in the experiments. SP removal data were fitted into a model in which SP removal was expressed as a function of DF and square of TMP. The model predicted SP removal within 90-95% of actual SP removal obtained during pilot trials using various TMP and DF levels. With appropriate selection of TMP and DF level, the efficiency of polymeric MF membranes can be optimized for production of MCC.

Key words: micellar casein concentrate, spiral wound MF, serum protein

205 Characterization of α-lactalbumin and β-lactoglobulin powders obtained from serum whey. C. Marella*, P. Salunke, L. E. Metzger, and K. Muthukumarappan, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

The composition and functional properties of conventional whey protein products can vary widely due to variability in the cheese manufacturing processes. However, variations in the composition and functionality of whey protein products obtained from microfiltration (MF) of skim milk should be minimal since whey proteins are harvested before cheese manufacture. The objective of the present study was to evaluate the functional properties of α-Lactalbumin (α-La) and β-Lactoglobulin (β-Lg) enriched powders, serum protein concentrate (SPC) and a conventional WPI. The α-La, β-Lg and SPC were obtained from MF of skim milk. All the powders were produced at SDSU dairy plant using a combination MF, ultrafiltration, reverse osmosis and spray drying. Functionality testing was conducted in triplicate. Solubility (1% protein solutions); thermal aggregation (heating 1% protein solutions at pH 3 and 7 at 80 oC for 5 min, with out and with added CaCl2, gel strength and syneresis (10% protein solutions heated at 80 oC for 30 min, with and without CaCl2, NaCl); and foaming properties (5% protein solutions) were studied. All the powders were fully soluble at pH 3.0 and 7.0. Heating at pH 3 didn't cause any loss in solubility, whereas none of the solutions at pH 7 could withstand heating in the presence of added CaCl2. The α-La, β-Lg and SPC powders exhibited much higher gel strength (3.5 to 7 fold higher) and lower syneresis when compared with WPI. Among these powders, α-La powder had the lowest syneresis and β-Lg powder has the highest gel strength and moderate syneresis in the presence of added CaCl2. Foam over run (FOR) and foam stability of the α-La, β-Lg and SPC powders were higher than those of conventional WPI. The α-La powder has the highest foam over run of 1070%, which was 43% higher than WPI and about 30% higher than the β-Lg and SPC. The results of this study demonstrate that α-La and β-Lg powders may have value in applications that require high gel strength, low syneresis and high foaming properties.

Key words: α-lactalbumin, β-lactoglobulin, functional properties

206 Effects of washing/diafiltration on milk protein concentrate (MPC) functionality. J. Du* and J. A. Lucey, *University of Wisconsin-Madison, Madison.*

The production of milk protein concentrate (MPC) has grown in recent years and MPC is produced by removing some of the lactose from skim milk (by ultrafiltration, UF) before drying. However, high protein MPC powders often have low solubility and they can exhibit a decrease in solubility during storage, especially at high storage temperatures. In high protein MPC products, washing or diafiltration (DF) is required to further reduce the lactose content. We were interested in understanding if extensive washing reduces the concentration of casein-bound calcium as this could be involved in the impaired functionality of MPC. The objectives of this study were to understand the changes that occur in soluble and bound calcium during UF/DF and the effects of the calcium status on the solubility of MPC products. Four MPC samples were produced from skim milk that was subjected to between one to 4 cycles of UF/DF. We wanted to keep the lactose content constant in all the powders, as that also impacts solubility, so water with 5.4% lactose was used as the washing solution during DF instead of water. Milks were concentrated to 1.67 fold with UF membranes (10k Da) and then back diluted (washed) to the original protein solids level with lactose solution. The retentate was then freeze-dried and the calcium equilibrium and structure of casein micelles were determined. The soluble calcium levels in these retentates were significantly impacted by the protein level used for rehydration ($P < 0.05$); the lower the protein level used for rehydration, the higher the measured soluble calcium content. The ratio of bound calcium to casein decreased with the number of DF cycles but after 3 DF cycles the ratio became nearly constant. Scanning electron microscopy indicated that the casein micelles became much smaller in samples with 3 DF cycles compared with the less washed samples. Casein micelle size was determined by Malvern Zetasizer and the average size of the casein micelles was reduced with increased number of (DF) washing. Further research is investigating the impact of washing cycles on powder solubility.

Key words: milk protein concentrate, solubility, calcium

207 Effect of adding NaCl or KCl during manufacture of MPC80 on its physico-chemical properties. V. Sikand*[1], P. S. Tong[1], S. Vink[1], and J. Walker[2], *[1]Dairy Products Technology Center, Cal Poly State University, San Luis Obispo, [2]Dept. of Statistics, Cal Poly State University, San Luis Obispo.*

Milk protein concentrate (MPC) powder with equal to or greater than 80% protein concentration has been shown to have poor solubility. The poor solubility of MPC limits its potential usage in the food industry. In a previous study in our lab, we have shown that the addition of 50–150mM NaCl into diafiltration water can improve the solubility of MPC80. However, adding NaCl into diafiltration water may impact other functional properties. The objective of this study was to determine the impact of addition of 150mM KCl and NaCl during MPC manufacture on solubility and other functional properties (foaming stability, turbidity and heat stability) on the resulting MPC powders. The powder samples were reconstituted at room temperature to contain 5% total solids. Percent solubility was tested after 3 h of mixing and was calculated as total solids in the supernatant to total solids in the original solution. Percent foaming stability, expressed as collapse of foam, was tested after 5 min to initial mass of foam. Turbidity was measured in Nephelos Turbidity Units (NTU) using a calibrated nephelometer. Heat stability was determined by measuring the heat coagulation time of 2 mL samples immersed in a oil bath set at 140°C. Our results indicate that higher solubility($P < 0.001$) was found in NaCl (100%) and KCl-treated MPC80 (98.8%) than in control MPC80 (90%). Foaming stability($P < 0.001$) was found to be highest in KCl-treated MPC (21.8%) followed by NaCl-treated MPC (10.6%) and then followed by control MPC (4.6%). Higher heat stability ($P < 0.001$) was observed in control MPC80 (23.7 min) when compared with NaCl (16.5 min) and KCl-treated MPC80 (16.4 min). Lower turbidity($P < 0.001$) was observed in NaCl (129 NTU) and KCl-treated MPC (117 NTU) as compared with control MPC (564.2 NTU). Our results indicate that the functional properties of MPC80 powders are influenced by addition of KCl or NaCl in the manufacture of MPC. These results suggest that the functional properties of MPC80 powders can be modified by changing its mineral composition during its manufacture.

208 Determination of the drying behavior of dairy products to improve the process, energy costs and the quality of the dairy powders. P. Schuck[1,2], A. Dolivet[1,2], S. Mejean[1,2], P. Zhu*[1,3], E. Blanchard[3], and R. Jeantet[2,1], *[1]INRA, UMR1253, Rennes, France, [2]Agrocampus Rennes, UMR1253, Rennes, France, [3]Laiterie de Montaigu, Montaigu, France.*

The most frequently used technique for dehydration of dairy products is spray drying. This is an effective method for preserving biological products as it does not involve severe heat treatment and it allows storage of powders at an ambient temperature. Due to the variety and complexity of the concentrates to be dried, a more rigorous understanding of spray-drying based on physico-chemical and thermodynamic properties have now become necessary. At the same time, the current state of the art and knowledge do not allow determination of the parameters of spray-drying of dairy products. The only way to determine these parameters is to perform several complex and expensive experiments with a pilot scale spray-dryer. The aims of this study were to propose a new indirect method that determines the ratio of bound to unbound water. The results, combined with thermodynamic and physico-chemical parameters (such as absolute and relative humidity of air, total solids and temperature of concentrate, air flow rate, etc.), provide more precise determination of certain spray-drying parameters such as inlet air temperature and mass flow rate. We performed more than 50 experiments to correlate calculated and measured parameters in a pilot plant dryer (Bionov, Rennes, France) using water, skim milk, caseinate, crystallized whey and maltodextrin. The results show that the difference between the calculated and measured inlet air temperature was below 5%, the determination coefficient being close to 0.96. The economic interest of this system is obvious, because it is easy to anticipate the spray-drying parameters by using a controller integrating the water availability of the concentrate and certain thermodynamic parameters. Software based on this step was developed (SD2P®, Spray Drying Parameters Simulation & Determination) and registered.

Dairy Foods Symposium: Technological Advancements in the Reduction of Pathogens and Spoilage Organisms in Milk

209 Technological advancements in the reduction of pathogens and spoilage organisms in milk—Introduction and challenges. D. R. McCoy*, *Dairy Research Institute, Rosemont, IL.*

The introduction of pasteurization in 1886 improved both the safety and keeping quality of milk and milk products. Newer methods like ESL and UHT treatments have further increased the safety and the shelf-life of modern dairy foods as well as allowing non-refrigerated distribution. However, there are still challenges such as further widening the distribution opportunities for milk, reducing energy requirements, and improving the flavor of longer life products. As new technologies are explored, it is important to recognize not only the science but also the regulatory requirements for successful implementation. Well-designed experimental approaches can expedite both scientific discovery and regulatory review. Finally, it should be recognized that many plant operations reduce microbial load but do not need to meet the high safety standard inherent in being an alternative to pasteurization, which may allow implementation earlier in the regulatory process.

Key words: pasteurization, milk, processing

210 Reduction of cooked and oxidized flavors in UHT milk. D. G. Peterson*, *University of Minnesota, St. Paul.*

Fluid milk is thermally processed to reduce the microbial load for both product safety and stability. Multiple thermal treatment options are available, such as pasteurization, extended shelf-life (ESL), and ultra-high temperature (UHT) processing. UHT techniques provide the longest shelf-life and allow non-refrigerated distribution. Despite these notable benefits, UHT processing negatively influences milk flavor quality due to the generation of thermally catalyzed off-flavor compounds, primarily by Maillard chemistry. This presentation will focus on the application of common food phenolic compounds (i.e., in cocoa, tea, and soybeans) to suppress off-flavor development and improve acceptability in UHT products. Optimization of the phenolic structure-reactivity to suppress Maillard-type off-flavor development in UHT milk will also be reviewed.

Key words: UHT, off-flavor, reduction

211 CHIEF/pulse electric field technology—A unique processing system. R. Ruan*[1,3], S. Deng[1], Y. Cheng[1], X. Lin[2,3], P. Chen[1], and L. Metzger[4], *[1]University of Minnesota, St. Paul, [2]Fuzhou University, Fuzhou, Fujian, China, [3]Nanchang University, Nanchang, Jiangxi, China, [4]South Dakota State University, Brookings.*

Consumers are increasingly aware of the taste, flavor, color, nutritional value, as well as safety of the foods they eat. They demand safe foods that are both fresh and natural. Therefore, food processes must be designed to render minimal adverse effects on food quality and nutrition values while ensuring safety. Conventional thermal processing not only kills spoilage and pathogenic microorganisms but also degrades the taste, color, flavor, and nutrients of the food. Non-thermal methods are alternatives which offer possibilities of preparing fresh-like, minimally processed safe foods. Among all emerging non-thermal processes, high intensity pulsed electric field (PEF) is considered the best. Nonetheless, the PEF process has few large scale industrial applications to date chiefly because PEF equipment and process are very specialized and costly. Concentrated high intensity electric field (CHIEF) developed at the University of Minnesota is a technology similar to PEF. Both of them use high intensity electrical field to inactivate the bacteria through the well accepted electroporation and other mechanisms. Compared with traditional PEF technique, CHIEF uses much cheaper power supply, and does not have electrode erosion and contamination issues. Our research on juice and milk indicates that CHIEF has a great potential of becoming a commercial process for non-thermal pasteurization of fresh liquid foods. The advantages and disadvantages of the two technologies will be compared and the potential commercialization applications in milk processing will be discussed.

Key words: PEF, CHIEF, electric field

212 UV light inactivation of bacteria and spores in milk to enhance shelf-life. J. S. Cullor*, P. V. Rossitto, J. Crook, and J. Parko, *University of California at Davis, Tulare.*

Thermal pasteurization of milk achieves safe and high quality product that is acceptable to consumers. Thermo-tolerant spoilage organisms though do survive pasteurization restricting the shelf-life of products as evidenced by code dates of 14 to 18 d. Spoilage organisms include gram-positive, gram-negative and aerobic spore-forming bacteria of the genera *Bacillus*, *Paenibacillus*, and *Geobacillus*. These spores can and do survive pasteurization, germinate, multiply and cause spoilage in milk, milk products and UHT products after processing. Delivery of germicidal UV light at 254 nm inactivates microbes in milk. Though UV light inactivation of microbes in water is an established technology that currently has many commercial applications, utilization of this technology in foods is somewhat new. Introduction of the alternative technology of UV germicidal light in milk has been validated in laboratory studies on milk with 3.5% and 2% fat and shown to increase microbial shelf life. UV log killing values or D-Values have been established for gram-positive spore forming bacteria and the pathogens *E. coli* O157:H7, *Salmonella enterica* serovar Senftenberg, *Yersinia enterolitica*, *Staphylococcus aureus*, *Campylobacter jejuni*, *Serratia marcescens*, *Aeromonas hydrophila*, and *Listeria monocytogenes*.

213 Electrical resistive heating versus conventional UHT technologies. D. J. McMahon*[1], B. Ganesan[1], M. Qian[2], and C. Brothersen[1], *[1]Western Dairy Center, Utah State University, Logan, [2]Food Science and Technology Department, Oregon State University, Corvallis.*

Electrical resistive (ER) heating involves release of heat as an electrical current is passed through a conductor such as milk. This induces very rapid volumetric heating without exposure of the milk to hot steam or metal heat transfer surfaces. Such heating provides opportunities for processing of heat-sensitive materials as well as fluids containing particulates and these are briefly reviewed. Current ultra-high temperature (UHT) processing of milk uses indirect plate (or tube) heat exchanger (PHE) or direct steam injection or infusion (DSI). In USA, pasteurized milk is preferred over UHT milk because of flavor development induced by UHT heating and exacerbated by long ambient temperature

storage. Milk was UHT-processed (140°C, 4 s) by ER, DSI and PHE and stored for 8 mo at room temperature (22°C) for flavor attributes and consumer preferences. Fresh pasteurized milk acted as control for sensory evaluation and was most preferred by consumers. The ER milk was liked more than DSI or PHE milks initially and at 1 mo. All UHT milks were equally liked at 4 mo, while at 8 mo the ER and DSI milks were liked more than PHE milk. After 8 mo, DSI and PHE milks were considered more bitter than pasteurized or ER milks, while all UHT milks were more brothy than pasteurized milk. Overall, ER milk was preferred more than DSI or PHE milks. SPE gas chromatography-mass spectrometry analysis of volatile compounds showed that volatile sulfurs generally decreased during storage, while dimethylsulfide increased by 0.5-fold in DSI milk. Dimethylsulfide was the most abundant volatile sulfur compound and was found 2 to 4-fold higher at 1 wk in PHE milk than others. Methanethiol, dimethyldisulfide, and dimethyltrisulfide highly varied over time in UHT milks. Carbonyls other than hexanal increased in ER milk during storage but remained low in DSI and PHE milks. In conclusion, we found that ER produced better-flavored UHT milk than current UHT processes, but the flavor changes did not correlate with changes in known volatile sulfur or carbonyl compounds. ER heating also has potential to rapidly heat milk to higher temperatures for UHT heating with shorter required hold times.

Key words: ultra-high temperature, milk, electrical resistance

214 Continuous flow microwave heating for pasteurization and sterilization of dairy products. J. Simunovic*, *North Carolina State University, Raleigh.*

Over the last dozen years, continuous flow microwave heating of foods has progressed from a bench top concept to an industrial scale technology used commercially in thermal sterilization and aseptic packaging of low acid vegetable purees. Feasibility testing protocols have also been developed and implemented for sterilization of a variety of dairy products ranging from milk to sour cream and cream cheese. Developed equipment, procedures and processes will be presented and anticipated future applications discussed.

Forages and Pastures: Alternative Forages and Improving Forage Quality and Characterization

215 Gain from selection for 16- and 96-h in vitro ndf digestibility of alfalfa stems. H. G. Jung* and J. F. S. Lamb, *USDA-Agricultural Research Service, St. Paul, MN.*

Alfalfa is a high quality forage, but stems are high in NDF and of limited digestibility. A gain from selection study with alfalfa populations selected for divergent in vitro NDF digestibility (IVNDFD) was planted at St. Paul and Becker, MN. Two cycles of selection were conducted starting with a base population created by mixing seed from 6 commercial varieties. Individual plants (n = 2000) were harvested twice (spring and first regrowth) at late flower for 2 years. Plants consistently low or high for 16- or 96-h IVNDFD were crossed to create 4 cycle one IVNDFD populations: low 16-h/low 96-h (LL), low 16-h/high 96-h (LH), high 16-h/low 96-h (HL), and high 16-h/high 96-h (HH). Cycle one populations were planted and harvested twice annually for 2 years to identify plants with appropriate IVNDFD combinations and crossed to create cycle 2 populations. Near-infrared reflectance spectroscopy calibrations were developed for NDF, ADL, Klason lignin, cell wall polysaccharide components, and 16- and 96-h IVNDFD based on 470 samples from the base population, cycle 2, and other experiments. Data were analyzed as a randomized complete block with 4 replicates, 2 locations and 9 populations, and 2 harvests arranged as repeated measures. The least significant difference test ($P < 0.05$) was used to compare population means when the F-test was significant. After 2 cycles of selection, 16-h IVNDFD increased from 19.3% for the base population to 20.1% for the HH population. The LL population (19.0% 16-h IVNDFD) differed from the HH population after 2 cycles, but not from the base. Both LL (50.3%) and HH (55.8%) differed for 96-h IVNDFD from the base (52.4%) after 2 cycles. The LH and HL populations did not differ significantly from the base; however, means shifted in the direction of the positive selection criterion. Selection for greater IVNDFD resulted in less NDF, cell wall, and lignin (ADL and Klason) in the cycle 2 HH than the base and cycle 2 LL populations. Cellulose and pectin increased for HH cycle 2 and hemicellulose declined in cycle 2 LL compared with the base. Genetic selection in alfalfa was successful in improving IVNDFD of stems.

Key words: alfalfa, fiber, digestibility

216 The nutritive value of mature corn silage from BMR, non-BMR and a 50:50 mix ensiled for varying lengths of time. J. M. Lim*[1], M. C. Santos[1], J. P. Riguera[1], M. C. Der Bedrosian[1], K. E. Nestor Jr.[2], and L. Kung, Jr.[1], *[1]University of Delaware, Newark, [2]Mycogen Seeds, Indianapolis, IN.*

The effects of hybrid type (H) and storage length (LEN) on the nutrient value of corn silage were studied. Hybrids were 1) brown midrib (BMR, Mycogen F2F700, Dow AgroScience, Indianapolis, IN), 2) non-BMR (NML, Mycogen TMF2W726) and 3) a 50:50 mixture (MIX). The BMR and NML were planted separately whereas MIX was produced by planting alternate rows of each H. Five replicated rows of plants (at about 40% DM) for each H were chopped (~20 mm length) and processed. Forage was ensiled (25°C) in vacuum-sealed bags and 5 replicates were opened after 200 and 400 d. All silages fermented well (pH <3.7). Ammonia-N increased for all treatments from d 0 to 200 but did not change between 200 to 400 d. Lignin content was lowest for BMR, highest for NML and intermediate for MIX and the difference ($P < 0.01$) was greater after 400 vs. 200 d of ensiling. The NDF content of BMR (42.5%) was higher ($P < 0.01$) than the NML (34.6%) and MIX (37.74%) at d 0 but this difference diminished over ensiling time. Over time, silage NDF-D did not change but was different ($P < 0.01$) among the treatments and was highest for BMR (63.7%), intermediate for MIX (59.8%) and lowest for NML (51.7%). Starch content was lower ($P < 0.01$) for BMR (36.8%) than NML (40.7%) and MIX (42.3%) from 0 to 200 d but not on 400 d of ensiling. Starch digestibility (Str-D) was lower ($P < 0.01$) for BMR (65.3%) than NML (68.5%) and MIX (68.5%) for 0 and 200 d but was not different on 400 d of storage. Str-D increased by 6% for all treatments from d 0 to 200. From d 200 to 400 of ensiling, Str-D did not change for the NML but increased by 6 and 20% more for MIX and BMR, respectively. This study showed that NDF-D of silage was influenced by hybrid type but not length of storage. Length of storage increased Str-D, which proved that prolonged storage enhanced the nutritive value of corn silage. Planting NML yielded more ($P < 0.01$) DM than BMR (22.6 vs. 17.3 t/ha). Interplanting and harvesting BMR and NML together was not detrimental to silage quality and produced an acceptable DM yield (19.3 t/ha).

Key words: silage, BMR

217 Concentrations and apparent digestibility of lignin and carbohydrate fractions in cell walls of whole-crop cereal silages. J. Wallsten* and R. Hatfield, *US Dairy Forage Research Center, Madison, WI.*

Whole-crop cereal silage (WCCS) of oats generally have lower fiber digestibility than WCCS of barley. When investigated more closely the difference seems to mainly be in the digestibility of the hemicellulosic fraction (HC), where HC is calculated as neutral detergent fiber (NDF) minus acid detergent fiber (ADF). The objective of this study was to see if the difference is true or a result of losses during analysis. A set of 27 WCCS samples of barley, wheat and oats harvested at 3 different maturity stages and 54 corresponding fecal samples (from dairy heifers fed the respective silages) were analyzed for cell wall (CW) composition. Analysis included NDF, ADF and total CW, recovered by washing the samples in different aqueous and organic solvents. The CW residues were used to analyze ash, acetyl bromide lignin and neutral sugar composition. The data were analyzed with proc reg and proc mixed in SAS. The CW concentration was higher than the NDF concentration in both forages and feces. The correlation between the 2 fiber fractions was lower in forages (R = 0.63) than in feces (R = 0.94), possibly due to soluble fiber fractions that were included in forage CW, but not in the forage NDF. The lignin concentration in the silages was higher ($P < 0.001$) in oats (111 g/kg DM) than in barley (88 g/kg DM) and wheat (91 g/kg DM). Also in the feces oats (190 g/kg DM) had higher lignin concentration ($P < 0.001$) than barley (168 g/kg DM) and wheat (168 g/kg DM). There was an apparent loss of 20–40% of the lignin during digestion and the losses were higher in more immature silages. The correlation between xylose and HC concentrations was lower than expected in both forages (R = 0.63) and feces (R = 0.65). However, the correlation between xylose and HC digestibilities was high (R = 0.91). The high apparent digestion of lignin is probably a result of losses from the feces during analysis rather than actual digestion in the animal. The trend with higher losses for more immature silages is of concern as that will overestimate fiber and possibly in vitro DM digestibility for these silages.

Key words: neutral detergent fiber, xylose, acetyl bromide lignin

218 Construction of a recombinant *Pichia pastoris* integrating a two-copy xylanase gene from *Thermomonospora fusca* and characterization of its secreted protein. Q. Wang*[1], M. Z. Ma[1], X. Y. Weng[2], J. Y. Sun[1], and J. X. Liu[1], *[1]MOE Key Laboratory of Molecular Animal Nutrition, College of Animal Sciences, Zhejiang University, Hangzhou, P.R. China, [2]College of Life Science, Zhejiang University, Hangzhou, P.R. China.*

Endo-β-1, 4-xylanases are key glycosidases in the degradation of xylan, the most abundant natural polysaccharide after cellulose. The study was designed to construct a recombinant strain expressing thermostable xylanases. Due to its good thermostability, a gene from *Thermomonospora fusca* xylanase (tfx) was employed to generate a yeast expression vector pGAPZαA-tfx. Then, the resulting vector was linearized with AvrII and inserted into *Pichia pastoris* GS115 at the locus of GAP promoter by electroporation (1500V, 5.2 ms). Transformants were spread onto YPD plates (1% yeast extract, 2% peptone, 2% dextrose, 2% agar) with 500–2000 ug/ml Zeocin. Seven putative multicopy recombinants exhibiting high resistance to Zeocin were selected to determine gene copy number. The strain GS115/33 was identified as a 2-copy recombinant by Southern blotting and real-time PCR, and used for protein expression. Subsequently, scale-up expression was achieved for 96 h in a 2-L baffled shaking flask containing 100 mL YPD medium. The recombinant xylanase TFX, driven by the GAP promoter and *Saccharomyces cerevisiae* α-mating factor, was constitutively secreted into culture medium. The specific xylanase activity in culture supernatant reached 89.8 U/mg, and purification by 6 × His tagged Ni-NTA agarose resulted in 10-fold increase in specific activity (932.5 U/mg). After being incubated at 70°C for 5 min, the residual activity retained more than 70%. SDS-PAGE analysis revealed that the molecular weight of TFX was about 43 kDa, while the unglycosylated protein was 32 kDa after treatment with Endoglycosidase H. Three potential N-glycosylation sites (N5, N183 and N230) may contribute to the extra molecular weight. A weak protein interaction was observed between TFX and rice xylanase inhibitor (RIXI), a main xylanase inhibitor in cereals, by using yeast 2-hybrid. Because of its high specific activity and good tolerance to temperature and xylanase inhibitor, TFX produced by GS115/33 would be an attractive candidate for the feed and biofuel industries.

219 Screening exogenous fibrolytic enzyme products for improved in vitro ruminal fiber digestibility of bermudagrass. J. J. Romero*, K. G. Arriola, M. A. Zarate, and A. T. Adesogan, *Department of Animal Sciences, IFAS, University of Florida, Gainesville.*

Eighteen exogenous fibrolytic enzyme products (EFE) from 5 companies were evaluated for their effect on digestibility of a 4-week regrowth of Tifton 85 bermudagrass haylage (68.1, 34.2, 3.7 and 18.7% NDF, ADF, ADL, and CP, respectively). All EFE were evaluated with a 24-h in vitro ruminal digestibility assay using bermudagrass haylage as substrate. EFE were diluted in citrate–phosphate buffer (pH 6) and applied in quadruplicate to the substrate at the manufacturer–recommended rates. The suspensions were incubated at 25°C for 24 h before addition of buffered rumen fluid (39°C) and further incubation for 24 h. The run was repeated once (Experiment 1). Compared with the Control (buffer and substrate alone), 6 EFE had greater DMD (%) (54.2 ± 0.4 vs. 52.4 ± 0.4; $P < 0.05$), 6 EFE had greater NDFD (%; 40.8 ± 0.6 vs. 38 ± 0.6; $P < 0.05$), 4 had greater ADFD (%; 43.3 ± 0.3 vs. 40.8 ± 0.7; $P < 0.05$), 8 had greater hemicellulose digestibility (%; 38.1 ± 1.3 vs. 35.1 ± 0.6; $P < 0.05$), 5 had greater cellulose digestibility (%; 46.3 ± 0.3 vs. 44.3 ± 0.6; $P < 0.05$), 2 had lower pH (7.33 ± 0.01 vs. 7.40 ± 0.02; $P < 0.01$) and 11 had greater pH (7.5 ± 0.03 vs. 7.4 ± 0.02; $P < 0.05$). In Experiment 2, the 12 EFE with the greatest NDFD from Experiment 1 were tested using similar procedures. Compared with the Control, 5 EFE had greater DMD (55.2 ± 0.7 vs. 51.2 ± 0.8; $P < 0.05$), 10 had greater NDFD (36.4 ± 2.0 vs. 30 ± 0.9; $P < 0.05$), 8 had greater ADFD (39.3 ± 1.3 vs. 34.4 ± 1.0; $P < 0.05$), 10 had greater hemicellulose digestibility (34.8 ± 2.2 vs. 28.9 ± 0.9; $P < 0.05$), 9 had greater cellulose digestibility (42.9 ± 0.9 vs. 36.8 ± 1.2; $P < 0.05$), 11 had lower pH (6.97 ± 0.03 vs. 7.05 ± 0.01; $P < 0.05$), and 1 had lower ruminal NH_3 (mg/dl; 42.1 ± 0.76 vs. 44.1 ± 0.66; $P < 0.05$). Several promising EFE candidates to improve the digestibility of bermudagrass haylage were identified in this experiment.

Key words: forage, enzyme, screening

220 Relationships between exogenous fibrolytic enzyme product activities and in vitro ruminal digestibility of bermudagrass. J. J. Romero*, K. G. Arriola, M. A. Zarate, and A. T. Adesogan, *University of Florida, IFAS, Department of Animal Sciences, Gainesville.*

The objective was to examine relationships between exogenous fibrolytic enzyme activities (EFE) and digestibility values of bermudagrass haylage treated with the enzymes. The protein concentration (PR) and endoglucanase (EN), exoglucanase (EX), β–glucosidase, (BG), and xylanase (XY) activities of 18 EFE from 5 companies were measured using carboxymethylcellulose, avicel, cellobiose, and oat spelt xylan, as substrates, respectively. The EFE were diluted in citrate - phosphate buffer (pH 6) and applied in quadruplicate at manufacturer–recommended rates to ground (1 mm) Tifton 85 bermudagrass haylage (4–week regrowth; 68.1, 34.2, 3.7 and 18.7% NDF, ADF, ADL, and CP, respectively). Suspensions were incubated for 24 h at 25°C and for a further 24 h at 39°C after addition of buffered–rumen fluid. The run was repeated once (Experiment 1). A similar second experiment was conducted with the 12 EFE with the greatest NDFD in Experiment 1. Stepwise regressions of digestibility of DM, NDF, ADF, hemicellulose (HEM) and cellulose (CELL) on enzyme activities and protein content of 18 (Experiment 1) and 12 (Experiment 2) EFE were conducted. Experiment 1 did not yield any accurate relationships ($R^2 < 0.07$; $P < 0.01$). In Experiment 2, PR (mg/g EFE) and enzyme activities (μmol/min/mg EFE) explained ($P < 0.01$) 56, 81, 68, 82, and 47% of the variation in DMD, NDFD, ADFD, and HEM and CELL digestibility, respectively. Prediction equations were as follows: $DMD = 51.2 - 0.001XY - 3.37EX - 1.28BG + 0.^{32}PR + 0.00000204EN^2 + 0.0000000130XY^2 + 0.05BG^2 - 0.00197PR^2$; $NDFD = 30.7 + 0.00853EN - 0.0009448XY - 5.76EX - 2.32BG + 0.43PR + 0.00000167EN^2 + 0.05612BG^2 - 0.00280PR^2$; $ADFD = 34.7 + 0.01594EN - 0.00093598XY - 11.66EX - 2.6BG + 0.41PR + 1.53EX^2 + 0.06BG^2 - 0.00267PR^2$; HEM digestibility $= 29.0 + 0.01067EN^2 - 0.00113XY - 6.73EX - 3.07BG + 0.51137PR + 0.00000205EN^2 + 0.07819BG^2 - 0.00343PR^2$; CELL digestibility $= 38.2 - 0.00067827XY - 2.5EX - 0.66BG + 0.27PR + 0.00000218EN^2 - 0.00161PR^2$. Important relationships between enzymatic activities and PR concentration and enzyme effects on in vitro digestibility were developed.

Key words: enzyme, forage, regression

221 Effect of rate of application of various exogenous fibrolytic enzyme products on in vitro ruminal fiber digestibility of bermudagrass. J. J. Romero*, K. G. Arriola, M. A. Zarate, and A. T. Adesogan, *Department of Animal Sciences, IFAS, University of Florida, Gainesville.*

The objective was to examine the effects of the dose rate of 5 exogenous fibrolytic enzyme products (EFE; E1, E2, E3, E4, and E5) from 3 companies on the digestibility of a 4–wk regrowth of Tifton 85 bermudagrass haylage (66.8, 33.2, 3.7 and 18.7% NDF, ADF, ADL, and CP, respectively). Application rates were 0x (Control), 0.5x, 1x, 2x and 3x; where 1x was the respective manufacturer–recommended dose (10, 15, 2.25, 2.25, and 15 g/kg substrate). Enzymes were diluted in citrate–phosphate buffer (pH 6) and applied in quadruplicate to ground (1 mm) bermudagrass haylage. The suspension was incubated for 24 h at 25°C and for a further 24 h at 39°C after addition of buffered rumen fluid. The run was repeated once. Data for each enzyme were analyzed separately as a completely randomized block design. The model included effects of dose, run, and the interaction. Polynomial contrasts were used to determine dose rate effects and the Fisher's LSD test was used to compare EFE means. Increasing the dose rate had the following effects: produced non-linear increases in DMD (%) of E2 and E4 (cubic; $P < 0.01$) and E1 and E3 (quadratic; $P < 0.01$); increased NDFD (%) of E1, E2 and E4 (cubic; $P < 0.01$) and E3 (quadratic; $P < 0.01$); increased ADFD (%) of E2, E4 and E5 (cubic, $P < 0.05$), E3 (quadratic, $P < 0.05$), and E1 (linear, $P < 0.01$); increased hemicellulose digestibility (%) of E1 and E2 (cubic, $P < 0.01$), E3 and E5 (quadratic, $P < 0.01$), and E4 (linear, $P < 0.01$); increased cellulose digestibility (%) of E2, E3, E4 and E5 (cubic, $P < 0.05$), and E1 (linear, $P < 0.01$) and increased pH of E2 and E4 (cubic, $P < 0.01$), E1 (quadratic, $P < 0.01$) and E3 (linear, $P < 0.05$). The optimal doses (and % increases compared with the control) for improving the DMD of E1, E2, E3 and E4 were 1x (2.8), 0.5x (2.5), 1x (1.5) and 2x (1.1), respectively. Optimal doses (and % increases compared with the control) for improving NDFD were 1x (5.7), 0.5x (4.7), 1x (2.9) and 2x (2.6), respectively. Enzyme application increased the DMD and NDFD of bermudagrass haylage but the optimal application rate varied with the enzyme.

222 Alternative approaches of replication for estimating in vitro starch disappearance. D. R. Mertens*[1] and R. Ward[2], *[1]Mertens Innovation & Research LLC, Belleville, WI, [2]Cumberland Valley Analytical Services Inc., Maugansville, MD.*

Measuring disappearance kinetics of starch and other substrates as they ferment is expensive and labor intensive because replicated serial measurements are needed. Assuming starch is 100% digested, rates of disappearance could be calculated theoretically from measurements at a single time by assuming that disappearance is zero at a fixed and assumed lag time. However this approach is dependent on removal of outliers and high precision in the measurement of in vitro starch digestion (IVSD). Our objective was to evaluate alternative strategies for minimizing the number of IVSD needed to measure starch disappearance rate. The IVSD of 6 samples of corn grain or silage (4-mm grind) were measured in quadruplicate on 3 consecutive days by Cumberland Valley Analytical Services, Inc. using a composite inoculum from 3 donors fed TMR. Measurements were made at 2, 4, 6, 12, 18, and 24 h. Local regression (Proc LOESS in SAS) was used to detect outliers. LOESS has the advantage that not only the observations replicated within day, but also those from repeated days and serial times can be used to detect outliers. Proc NLIN of SAS was used to fit a model with a single exponential pool with discrete lag to the results. Rate and lag estimates were generated for each replicate within day. Proc MIXED of SAS was used to test day effects with random replicates. There was no difference among consecutive days for rates ($P = 0.13$) but a 1 h difference in lags ($P = 0.04$). All 72 measurements for each feed were used to estimate the overall rate of starch disappearance, which varied from 0.114 to 0.168/h for the 6 corn sources. Deviations from the overall rate for each source were calculated by using 4 replicates within each day or 2 replicates from each of 2 d. There was no difference in deviations, absolute deviations or squared deviation for within-day or among-day rate estimates. When 2 replicates within day were compared with 1 replicate from 2 d there was no difference in replication approach. For consecutive-day in vitro, it appears that replications within day are as accurate as between day replicates for estimating rate.

Key words: in vitro, starch, kinetics

223 Microbial protein synthesis and partitioning of nutrients of native species from semiarid regions of North Mexico. M. Guerrero-Cervantes[1,3], M. A. Cerrillo-Soto*[1,3], A. S. Juárez-Reyes[1,3], H. Bernal-Barragán[2,3], and R. G. Ramírez[2], *[1]Universidad Juárez del Estado de Durango, Durango, México, [2]Universidad Autónoma de Nuevo León, Nuevo León, México, [3]Red Internacional de Nutrición y Alimentación en Rumiantes.*

The aim of this study was to determine the partitioning of nutrients and microbial protein synthesis of fruits and foliage of 3 cacti: (*Opuntia imbricata*, *O. leptocaulis* and *O. leucotricha*), fruits of 3 browse: (*Acacia shaffneri*, *Prosopis leavigata* and *Atriplex canescens*), and foliage of 4 forbs: (*Coldenia greggii*, *Dalea bicolor*, *Jatropha dioica* and *Panthenium incanum*), which are commonly consumed by range small ruminants in semiarid regions of Mexico. Foliage was obtained from 10 distinct plants at early stages of growth, dried and milled (1 mm). Triplicate samples (500 mg) were incubated in 100 mL glass syringes, using buffered rumen fluid. Gas production was recorded at 0,3,6,9,12 and 24 h. After incubation, contents of syringes were centrifuged. An aliquot from the supernatant (5 mL) was utilized for determination of volatile fatty acids (VFA = mmol/40 mL incubation medium) using gas chromatography. The solid residue was lyophilized and subjected to the determination of purine content (μmol) using spectrophotometry. Efficiency of microbial protein synthesis (EMPS) was calculated as μmol purines/mmol VFA. Incubation residues from a separate set of syringes were refluxed with neutral detergent fiber solution and the partitioning factor (PF) was calculated as the ratio of mg substrate truly degraded/ml gas produced$_{24h}$ in vitro. Data were analyzed by ANOVA using PROC GLM. Mean differences were separated using Tukey′s test. The PF and purine values were similar among groups of feedstuffs ($P > 0.05$). Total VFA were in average higher ($P < 0.05$) for the foliage of cacti (930 mmol/40 mL) and lower for forbs (657 mmol/40 mL). The EMPS for fruits of browse (9.30) was almost twice the value for Opuntia foliage (4.67; $P < 0.05$), while values for fruits and foliage of forbs were similar. These data support the potential of native species as feed resources in harsh environments. The data obtained might be utilized for the establishment of feeding systems for small ruminants in semiarid regions.

Table 1. Efficiency of microbial protein synthesis and partitioning of nutrients of native plants

Species	PF	Purines (μmol)	Total VFA	EMPS (μmol purine/mmol VFA)
Fruits of Opuntia	2.89[a]	6.25[a]	805[ab]	7.48[ab]
Foliage of Opuntia	2.98[a]	4.68[a]	930[a]	4.67[b]
Fruits of browse	3.02[a]	6.01[a]	739[ab]	9.30[a]
Foliage of forbs	2.90[a]	4.31[a]	657[b]	7.05[ab]
Mean	2.95	5.31	783	7.12
sem	0.28	2.55	245	3.01

[a,b] Means in columns with unlike letter differ ($P < 0.05$); PF=Partitioning factor; VFA=Volatile fatty acids; EMPS=Efficiency of microbial protein synthesis

224 Effects of species and season on chemical composition and ruminal crude protein and organic matter degradability of some multi-purpose tree species by West African Dwarf rams. O. M. Arigbede*[1,2], U. Y. Anele[1,2], K.-H. Südekum[2], J. Hummel[2], A. O. Oni[1], J. A. Olanite[1], and A. O. Isah[1], *[1]University of Agriculture, Abeokuta, Nigeria, [2]University of Bonn, Bonn, Germany.*

Seasonal chemical composition and ruminal organic matter (OM) and crude protein (CP) degradabilities were determined in 4 tropical multipurpose tree species (MTPS), namely *Pterocarpus santalinoides*, *Grewia pubescens*, *Enterolobium cyclocarpum*, and *Leucaena leucocephala*. Three West African Dwarf rams fitted with permanent rumen cannula were used for the degradability trials. Foliage samples were randomly collected from 6 plants per MPTS 4 times to represent seasonal variations: January – mid dry; April – late dry; July – mid rainy, and October – late rainy seasons. Samples were analyzed for oven DM at 60°C for 96 h, milled (2.5 mm) and weighed (5 g) into 9 × 18 cm nylon bags. Bags were incubated in triplicate for 6, 12, 24, 48, 72 and 96 h in the rumen of 3 West African dwarf rams (35 kg body weight). Another portion of the dried foliage samples and residues after in sacco incubation were milled through a 1 mm sieve and stored until required for chemical analysis and ruminal in situ OM and CP degradability estimation. All samples had high CP (161 - 259 g/kg DM) and moderate fiber concentrations (neutral detergent fiber (ash-free), 300 - 501 g/kg DM; acid detergent fiber (ash-free), 225 - 409 g/kg DM and acid detergent lignin, 87 - 179 g/kg DM as well as low contents of secondary metabolites (13.5 to 33.5, 0.8 to 11.5 and 3.0 to 17.4 g/kg DM for tannins, trypsin inhibitors, and phytic acid respectively). Interaction effects between species and season were observed for DM, CP and secondary metabolite contents except for trypsin inhibitor ($P = 0.614$). Ruminal degradability of OM and CP showed that more than 50% were degraded at 24 h and the undegraded fraction varied from 17.5 to 47.6%. This implied that the MPTS were highly degradable and their incorporation into ruminant feeding systems as dry season forage supplement is recommended.

Key words: multi-purpose tree species, chemical composition, ruminal degradation

225 Effect of land clearing and tillage methods on growth and yield of maize-cassava intercrop. A. H. Ekeocha*, *University of Ibadan, Ibadan, Oyo, Nigeria.*

One of the prevailing problems facing developing countries today is that of producing enough food to meet their ever increasing population. It is in view of this that this work was carried out to evaluate the effect of land clearing and tillage methods on growth and yield of a maize-cassava intercrop. The experiment was carried out at the International Board for Soil Research and Management, Epemakinde, Nigeria. (4° 45 ^{0} E, 6° 45° N) after 3 cropping years. The experimental design was a split-split plot in a randomized complete block design with 3 replicates. Three land clearing methods namely manual slash and burn (SB), bulldozed not windrowed (BNW) and bulldozed windrowed (BW) constituted the main treatments while 4 tillage methods namely (zero, conventional, traditional and minimum tillage) constituted the sub-treatments. There were a total of 12 treatment combinations per block. The plot size for each land clearing treatment was 20m × 30m each. Data were subjected to ANOVA and significant means separated using the least significant difference. The results indicate that maize grain yield was not different ($P > 0.05$) among land clearing and tillage methods. Traditional and minimum tillage had more grain (2.94 and 2.59 t ha^{-1}) on average, representing 22.5% and 7.9% increase in yield above conventional tillage (2.40 t/ha). Cassava fresh weight was significantly ($P < 0.05$) affected by the land clearing method, SB and BNW (21.94 and 21.20 t ha^{-1}) having higher yields than BW representing 44.1% and 39.2% increase in cassava fresh weight above BW (15.23 t ha^{-1}). Similar results were obtained under tillage practices where there were differences ($P < 0.05$) among the tillage practices and minimum tillage and zero tillage had higher fresh weight (21.31 t/ha) and (20.61 t/ha) on average representing 28.6% and 24.4% increase in fresh weight above traditional tillage (16.57 t/ha). In conclusion, SB under minimum tillage treatment and BNW under zero tillage treatment gave better maize and cassava yield and appear to be the better options.

Key words: land clearing, tillage methods, growth and yield

226 Toll-like receptors expression in the gastro-intestinal tract of dairy calves. N. Malmuthuge*[1], M. Li[1], P. Fries[2], P. Griebel[2], and L. L. Guan[1], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatchewan, Saskatoon, Canada.*

Toll-like receptors (TLRs) are a family of pattern recognition receptors which sense pathogen associated molecular patterns to initiate innate immune responses and maintain intestinal homeostasis. However, the understanding of baseline TLRs expression within specific regions of the gastro-intestinal tract (GIT) of dairy calves and possible age-related expression changes are not well understood. In this study, TLRs expression patterns were investigated throughout the GIT of newborn and weaned dairy calves. Total RNA was extracted from rumen, jejunum, ileum, cecum and colon tissues of 3 weeks old (n = 8) and 6 mo old Holstein male calves (n = 8). Expression of 10 TLRs (TLR1-TLR10) was evaluated relative to β-actin expression in each region using quantitative real time PCR. Gene expression (ΔC_T) data were analyzed using MIXED procedure of SAS and statistical model include gut location and age as fixed effects. Analysis of TLRs data revealed TLR10 expression was significantly ($P < 0.01$) higher in ileum than other GIT regions of 3 week-old calves. TLRs 2, 4 and 10 ($P < 0.01$) were differentially expressed among GIT regions of 6 mo old calves and TLR10 expression was again highest in the ileum. Future studies are required to understand the biological significance of TLR10 in the bovine ileum, which is an important site for B cell development. Expression of most TLRs was lower in rumen than other GIT regions, irrespective of age, supporting the importance of intestinal epithelium in enteric immune responses. Moreover, expression of many TLRs, except TLRs 3, 5 and 6, was significantly downregulated after weaning. The observed downregulation in TLRs expression in weaned calves may reflect host mechanisms to control inflammatory responses to commensal microflora and pathogens as well as development of other immune mechanisms to regulate TLRs signaling. In conclusion, our study indicates that bovine TLRs expression varies throughout the GIT and is age-dependent. These findings are critical for understanding innate immune responses to both commensal microflora and enteric pathogens in dairy calves.

227 Soybean meal substitution by a microbial protein source in dairy cattle diets. J. A. Sabbia*[1], K. F. Kalscheur[1], A. Garcia[1], A. Gehman[2], and J. M. Tricarico[2], [1]*South Dakota State University, Brookings,* [2]*Alltech Inc., Brookings, SD.*

The objective of this study was to examine the effect of a source of microbial protein (DEMP, Alltech, Nicholasville, KY) on milk production, DMI, rumen and blood parameters on high-producing dairy cows as replacement for soybean meal (44% CP). Sixteen Holstein cows with 93 + 37 DIM were used in a 4 × 4 Latin square design. Diets contained 40% corn silage, 20% alfalfa hay, and 40% concentrate mix. Cows were fed one of 4 treatments: 0, 1.14, 2.28, or 3.41% of the diet DM with DEMP. DMI showed a cubic effect (25.9, 27.1, 25.9, 26.6 kg/day; $P = 0.04$), as DEMP in the diets increased. Milk production (41.1 kg/d) was not affected by treatment, whereas energy-corrected milk tended to respond quadratically (39.5, 41.5, 41.8, 41.0 kg/d; $P = 0.09$). Milk fat percentage (3.53, 3.66, 3.62, 3.53%; $P = 0.06$) and yield (1.35, 1.45, 1.49, 1.42 kg/d; $P = 0.07$) also tended to show a quadratic response. A similar quadratic response was shown for total solids percentage (12.3, 12.5, 12.5, 12.3%; $P = 0.02$) and yield (4.87, 5.11, 5.12, 5.03 kg/d; $P = 0.08$). Milk urea nitrogen also responded in a quadratic manner (13.4, 13.7, 13.5, 12.9 mg/dl; $P = 0.05$). There was no effect on milk protein and lactose percentage or yield, nor was there an effect on feed efficiency. NEFA concentration in plasma was similar between treatments, whereas plasma glucose (63.7 to 68.5 mg/dl; $P = 0.06$) and BHBA (11.5 to 13.1 mg/dl; $P = 0.04$) increased linearly. Inclusion of DEMP had no effect on most ruminal VFA concentration, except isovalerate which decreased linearly ($P < 0.001$). Ruminal pH was unaffected by DEMP inclusion, but ammonia concentration tended to decrease linearly from 14.1 to 11.7 mg/dl ($P = 0.09$). Ruminal N fractionation showed a cubic response in total free amino acids (12.1, 10.4, 14.1, 11.2 mg/L; $P = 0.02$). There was a quadratic response for peptides that weighed between 3 and 10 kDa (9.1, 14.9, 12.3, 12.0%; $P = 0.05$) and for those less than 3 kDa (30.8, 28.3, 27.7, 29.4%; $P = 0.03$) when expressed as percentage of total nitrogen. In conclusion, soybean meal substitution with DEMP can improve milk and total solids production in high-producing dairy cows.

Key words: microbial protein, nitrogen fractionation, milk production

228 Effect of timing of initiation of Resynch and presynchronization with GnRH on fertility of resynchronized inseminations in lactating dairy cows. G. Lopes Jr.*, J. O. Giordano, A. Valenza, M. M. Herlihy, J. N. Guenther, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Lactating Holstein cows (n = 1,512) were randomized to a 2x2 factorial design resulting in 4 Resynch treatments: 1) Ovsynch (GnRH–7 d–PGF–56 h–GnRH–16 h–TAI) initiated d 32 ± 3 d after AI (GPG32); 2) presynchronization with 100 μg GnRH 25 ± 3 d after AI and Ovsynch initiated 32 ± 3 d after AI at nonpregnancy diagnosis (GGPG32); 3) Ovsynch initiated 39 ± 3 d after AI (GPG39); 4) presynchronization with 100 μg GnRH 32 ± 3 d after AI at nonpregnancy diagnosis and Ovsynch initiated 39 ± 3 d after AI (GGPG39). Overall, 296 cows were inseminated to estrus between enrollment (25 ± 3 d after AI) and initiation of Resynch treatments, and 1,216 cows (GPG32 = 315, GGPG32 = 360, GPG39 = 248 and GGPG39 = 293) received TAI. Blood samples were collected from all cows at the first GnRH injection of Resynch (G1), and ovarian structures were evaluated and blood samples were collected at G1, PGF, and TAI of the Resynch protocols in a subgroup of cows (GPG32 = 105, GGPG32 = 119, GPG39 = 93 and GGPG39 = 113). Based on logistical regression analysis, pregnancies per AI (P/AI) 32 d after AI was not affected by parity and did not differ among treatments [GPG32, 33.3% (105/315); GGPG32, 36.1% (130/360); GPG39, 32.7% (81/248); GGPG39, 39.3% (115/293)]. When analyzed as main effects, presynchronization with GnRH increased ($P = 0.05$) P/AI [33.0% (186/563) vs. 37.7% (245/653) for GPG vs. GGPG], whereas timing of initiation of Resynch did not [34.7% (235/675) vs. 35.9% (196/541) for Day 32 vs. Day 39]. Presynchronization with GnRH increased ($P = 0.007$) the proportion of cows with high P4 (>0.5 ng/mL) at G1 [72.6% (403/556) vs. 79.3% (519/653) for GPG vs. GGPG], and cows with high P4 at G1 had greater ($P = 0.006$) P/AI than cows with low P4 [37.5% (346/922) vs. 28.6% (82/287)]. Ovulation to G1 decreased ($P = 0.039$) luteal regression after PGF [87.5% (121/139) vs. 78.5% (143/183)], and high P4 at G1 decreased ($P < 0.001$) ovulation to G1 [68.4% (67/98) vs. 40.9% (136/332)]. We conclude that presynchronization with GnRH

7 d before initiation of Resynch increased fertility of resynchronized dairy cows whereas timing of initiation of Resynch did not.

Key words: resynchronization, GnRH, progesterone

229 Somatic cell count and management benchmarks in Minnesota dairy herds. R. F. Leuer* and J. K. Reneau, *University of Minnesota, St. Paul.*

Dairy Herd Improvement Association (DHIA) tests provide a large amount of information about herd milk production and milk quality. Many guidelines have been given about farm SCC performance and its relationship to mastitis and milk quality, however associations are lacking. The objective of this study was to investigate the relationship between herd SCC level and performance rank for mastitis and milk quality benchmarking. Minnesota DHIA monthly average herd records were collected from January 2007 to November 2010. Herd tests without SCC information were removed and only herds with an average of 10 tests per year were included. Herds were divided into 4 categories based on average herd SCC over the collection period. Low herds (L) with less than 200,000 SCC (n = 325), medium low (ML) herds between 200,000 and 300,000 SCC (n = 547), medium high herds (MH) herds between 300,000 and 400,000 SCC (n = 470), and high herds (H) above 400,000 SCC (n = 438). Cows > 200,000 SCC were considered infected. Monthly records (n = 66,296) were analyzed using PROC GLM with significant differences determined at $P < 0.05$ using Tukey's multiple comparisons test. The 4 categories were all significantly different in average SCC (L = 157,000, ML = 251,000, MH = 350,000, H = 513,000), average of total cows on test day (L = 116, ML = 141, MH = 110, H = 86), percent infected (L = 16.4, ML = 24.7, MH = 32.9, H = 43.4), percent of current cows with new infections (L = 8.1, ML = 10.5, MH = 12.5, H = 14.2), percent of fresh cows with chronic infections (L = 6, ML = 11.2, MH = 17.6, H = 27.4), percent of current cows with chronic infections (L = 8.3, ML = 14.2, MH = 20.4, H = 29.2), percent infected <30 d in milk (L = 1.7, ML = 2.3, MH = 2.8, H = 3.3), percent infected between 30 and 220 d in milk (L = 7.7, ML = 11.7, MH = 15.4, H = 20), percent infected >220 d in milk (L = 7, ML = 10.7, MH = 14.7, H = 20.1), percent of herd >220 d in milk (L = 35.4, ML = 36.7, MH = 38.5, H = 40.5), rolling herd average (RHA) milk production (L = 10,351, ML = 9,944, MH = 9,201, H = 8,440 kg), RHA protein production (L = 315, ML = 304, MH = 284, H = 263 kg), and RHA fat production (L = 386, ML = 371, MH = 348, H = 325 kg). The 4 categories demonstrated differences that contribute to herd SCC.

Key words: benchmarking, DHIA, SCC

230 Effect of dietary trans fatty acids on selected inflammatory mediators in early lactating dairy cows. J. S. Watts*, D. L. Sevier, J. K. Kinch, S. M. Clark, M. A. McGuire, and P. Rezamand, *Department of Animal and Veterinary Science, University of Idaho, Moscow.*

Trans fatty acids (tFA) contribute to inflammation. The mechanism responsible is not well understood; however, it is thought to involve integration of tFA into cell membranes of immune cells, affecting membrane fluidity and cell signaling. The objective of this study was to investigate the effects of a ration supplemented with tFA on the fatty acid (FA) profile of peripheral blood mononuclear cells (PBMC) and the gene expression of inflammatory markers in early lactating dairy cows. tFA (Virtus Nutrition; Corcoran, Ca) was fed at 0, 1.5, and 3% of dry matter replacing (1:1 wt:wt) saturated fatty acids (sFA). Multiparous lactating Holstein cows 7 d in milk (n = 12) were randomly assigned to a treatment sequence in a 3x3 Latin square design. Each period lasted 14 d. Heparinized blood was collected on d0 (pretreatment) and on d 10 and 14 of each period. Plasma was collected and solid phase extraction was used to isolate plasma phospholipids. Additionally, PBMCs were isolated for FA analysis by gas chromatography and gene expression analysis by RT-PCR using bovine RPS9 as the endogenous control. Data were analyzed using the MIXED procedure of SAS with significance at $P < 0.05$. As dietary tFA increased, the percentage of 18:1 trans isomers increased with linear increases in the t9 and t12 isomers in plasma phospholipids ($P < 0.002$). In PBMCs, both t10 and t12 isomers of 18:1 increased linearly ($P < 0.02$). Dietary tFA had no detectable effect on mRNA expression of pro-inflammatory TNF-α or IL-6, although pretreatment expression of IL-6 and ICAM-1 differed among groups. Expression of IL-1β and ICAM-1 decreased linearly with increasing tFA and a treatment x day interaction in expression of ICAM-1 was detected. Overall, dietary tFA linearly increased the tFA present in plasma phospholipids and PBMCs; however, dietary tFA decreased PBMC expression of some of the pro-inflammatory markers in early lactating dairy cows.

Key words: trans fatty acids, inflammation, transition cow

231 Effects of physical preparation of diets and level of modified wet distillers grains with solubles on production and rumen measurements of lactating dairy cows. J. C. Ploetz*[1], W. C. Hornback[1], D. E. Beever[2], P. H. Doane[3], M. J. Cecava[3], M. R. Murphy[1], and J. K. Drackley[1], *[1]University of Illinois, Urbana, [2]Keenan Systems, Borris, Ireland, [3]Archer Daniels Midland Company, Decatur, IL.*

Our objective was to determine if methods for preparing TMR (Keenan MechFiber [KMF] technology vs. vertical auger [VA] mixer) would alter physical form of the TMR and enable increased utilization of modified wet distillers grains with solubles (MWDGS). Holstein cows (n = 24 with 12 ruminally cannulated; 144 DIM ± 31 d at start) were used in a split-plot design with mixer type as the whole plot and MWDGS levels as subplots in a 3 × 3 Latin square arrangement with 35-d periods. Inclusion rates of MWDGS were 10, 20, and 30% of diet DM, primarily replacing corn, SBM and whole cottonseed. Feed DMI tended to be less for KMF ($P = 0.06$) but was unaffected by MWDGS level ($P = 0.39$). However, a mixer x MWDGS quadratic interaction ($P = 0.14$) was observed; DMI increased as MWDGS increased when mixed using VA but not when using KMF. Milk production did not differ ($P = 0.75$) by level of MWDGS or interaction of MWDGS x mixer ($P = 0.18$). Milk protein content tended ($P = 0.09$) to decrease linearly with increasing MWDGS. Milk protein yield at 30% MWDGS inclusion decreased for KMF but increased for VA (interaction of mixer x linear effect of MWDGS, $P = 0.05$). Milk fat percentage declined with increasing MWDGS ($P = 0.003$) but the interaction between mixer wagon and MWDGS ($P = 0.006$) showed that decreases were larger with VA mixing. Cows fed the diet containing 30% MWDGS mixed with KMF averaged 3.45% (1.24 kg/d) milk fat whereas cows fed the same diet mixed with VA averaged 2.81% (1.10 kg/d) fat. Particle size of the TMR did not explain differences in milk fat. Feed conversion efficiency (FCE; energy-corrected milk/DMI) decreased linearly ($P = 0.007$) with MWDGS, but FCE tended to be maintained when higher MWDGS diets were mixed using KMF vs. VA (mixer, $P = 0.12$; mixer x MWDGS quadratic, $P = 0.13$). Ruminal pH tended ($P = 0.13$) to be greater for KMF than for VA; ruminal pH ($P = 0.05$) and ammonia concentration ($P < 0.001$) decreased linearly as MWDGS increased. Using the KMF mixer wagon resulted in better FCE with higher amounts of MWDGS primarily because milk fat content and yield were not depressed.

Key words: TMR mixer, distillers grains, milk fat

232 Modifying the double-Ovsynch protocol to include human chorionic gonadotropin to synchronize estrus in lactating dairy cows. J. A. Binversie*, K. E. Pfeiffer, and J. E. Larson, *Mississippi State University, Mississippi State.*

The objectives of this study were to determine whether conception, ovulation or presynchronization rates were altered, or follicle and CL characteristics were altered after modifying the double-Ovsynch (DO) protocol to include human chorionic gonadotropin (hCG) compared with the DO protocol. Holstein (n = 146) and Jersey (n = 37) cows were blocked by parity and randomly assigned to 1 of 2 treatments. Cows received either an injection of 100 μg of GnRH (n = 91) or 2000 IU of hCG (n = 92) at the initiation of the Pre-Ovsynch (PO) portion of the DO protocol (PO: GnRH/hCG-7d-$PGF_{2\alpha}$-3d-GnRH). After 7 d, cows started the Breeding-Ovsynch (BO) portion of the DO protocol (BO: GnRH-7d-$PGF_{2\alpha}$-56h-GnRH-16h-TAI with sex-sorted semen). Transrectal ultrasonography and blood samples were used to assess ovarian structures, ovulation, pregnancy diagnosis (at d 32 post TAI), and circulating concentrations of progesterone (P4). Conception rates were similar for cows treated with GnRH or hCG (32.2 and 25.0%; $P > 0.1$). Ovulation rates at the onset of PO were increased in cows treated with hCG compared with GnRH (77.2 and 62.2%; $P < 0.05$). Concentrations of P4 7 d post hCG/GnRH treatment for cows that ovulated were greater in cows treated with hCG compared with those treated with GnRH (LSMeans ± SEM; 5.1 ± 0.3 and 3.8 ± 0.4 ng/ml; $P < 0.05$). The size of the largest follicle 7 d post hCG/GnRH treatment for cows that had ovulated was smaller in cows treated with hCG compared with cows treated with GnRH (12.4 ± 0.5 and 13.8 ± 0.6 mm; $P < 0.05$). Luteal regression (P4 < 1.0 ng/ml) from the injection of $PGF_{2\alpha}$ of PO did not differ between GnRH and hCG treated cows (67.0 and 60.9%; $P > 0.1$). Although more cows ovulated to hCG, a greater proportion of these cows tended to fail to have undergone luteolysis by 3 d post $PGF_{2\alpha}$ compared with cows that had ovulated to GnRH (29.6 and 16.1%; $P = 0.09$). Therefore, the overall percentage of cows which were synchronized to the PO did not differ between GnRH and hCG treated cows (61.5 and 52.2%; $P > 0.1$). In conclusion, no improvement was achieved by replacing the first injection of GnRH in the DO protocol with hCG.

Key words: double-Ovsynch, hCG, presynchronization

233 Fibroblast growth factor 9 influences steroidogenesis and gene expression in ovarian granulosa and theca cells of cattle. N. B. Schreiber* and L. J. Spicer, *Oklahoma State University, Stillwater.*

Ovarian cysts result in the loss of millions of dollars to the dairy industry annually because of increased number of days open, reduced milk production, and increased culling rate. Fibroblast growth factor 9 (FGF9) is downregulated in cystic follicles versus normal dominant follicles in cattle. Therefore, experiments were conducted to evaluate the role of FGF9 in hormone-stimulated steroidogenesis, proliferation and gene expression in bovine ovarian granulosa and theca cells from antral follicles of cattle. Quantitative PCR was used to measure gene expression of side-chain cleavage enzyme (CYP11A1), aromatase (CYP19A1), 17-hydroxylase (CYP17A1), LH receptor (LHCGR) and/or FSH receptor (FSHR). Small (1–5 mm) follicle granulosa cells (SMGC), large (8–22 mm) follicle theca cells (LGTC) and large follicle granulosa cells (LGGC) were grown in vitro and treated for 48 h with 0, 3, 10, or 30 ng/mL of recombinant human FGF9 to evaluate the effects on steroid production, cell proliferation, and gene expression. In SMGC, FGF9 (30 ng/mL) decreased ($P < 0.05$) estradiol and progesterone production by 80% and 56.4%, respectively, after cells were stimulated with 30 ng/mL of FSH and IGF1. In LGTC, FGF9 (30 ng/mL) decreased ($P < 0.05$) progesterone and androstenedione production by 71% and 79%, respectively, after cells were stimulated with 30 ng/mL of LH and IGF1. In contrast, IGF1-induced SMGC and LGTC proliferation was further stimulated ($P < 0.05$) 1.8- and 1.5-fold by FGF9, respectively. FGF9 decreased ($P < 0.05$) CYP11A1 and FSHR mRNA abundance and had no effect on CYP19A1 mRNA abundance in SMGC and LGGC treated concomitantly with FSH and IGF1. FGF9 decreased ($P < 0.05$) abundance of CYP11A1, CYP17A1, and LHCGR mRNA by 97%, 77%, and 97%, respectively, in LGTC treated concomitantly with LH and IGF1. In conclusion, FGF9 regulates ovarian function in cattle by stimulating cell proliferation and inhibiting steroidogenesis of both granulosa and theca cells. FGF9 inhibition of steroid production is likely via attenuation of both gonadotropin receptor and steroidogenic enzyme gene expression.

Key words: cystic follicles, granulosa cells, theca cells

234 Relationships among temperature, moisture, bacterial counts, and animal hygiene in compost bedded pack barns. R. A. Black*, J. L. Taraba, G. B. Day, F. A. Damasceno, M. C. Newman, K. A. Akers, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this study was to assess the relationships among temperature, moisture, bacterial counts, and animal hygiene for composted material collected from compost bedded pack (CBP) barns. Compost samples were collected from 54 CBP barns in Kentucky from October 2010 to February 2011. A composite sample was collected from 9 evenly distributed sampling areas throughout each barn for analysis of nutrient composition and bacterial counts. Compost moisture was measured using an oven at 75°C. Compost temperatures (CT) were measured 10.2 cm below the pack surface. Subjective hygiene scores were collected by the same observer for 50.4 ± 16.1 cows per herd using a 4 point scoring system described by Cook (2007, 1-clean, 4-dirty). Producers reported their most recent SCC. The MEANS procedure of SAS® (Cary, NC) was used to calculate mean (±SD) SCC (238,162.2 ± 81,701.5 cells per ml, n = 37), hygiene score (2.22 ± 0.46, n = 43), moisture (54.9 ± 12.5%, n = 51), CT (30.5 ± 11.4°C, n = 52), coliform (6.09 ± 0.63 $\log_{10}$ cfu/g, n = 54), *Escherichia coli* (5.73 ± 0.68 $\log_{10}$ cfu/g), streptococcal species (7.00 ± 0.68 $\log_{10}$ cfu/g, n = 54), staphylococcal species (7.60 ± 0.49 $\log_{10}$ cfu/g, n = 53), and bacillus species (7.30 ± 0.56 $\log_{10}$ cfu/g, n = 54). Moisture was highly correlated with ambient temperature ($r = -0.73$, $P < 0.01$). Moisture was negatively correlated with CT ($r = -0.38$, $P < 0.01$) and positively correlated with hygiene score ($r = 0.68$, $P < 0.01$). Hygiene score and CT were also negatively correlated ($r = -0.42$, $P < 0.01$). *Escherichia coli* count was moderately correlated with CT, moisture, SCC, and hygiene score ($r = 0.62$, $P < 0.01$; $r = -0.41$, $P < 0.01$; $r = 0.42$, $P < 0.01$; and $r = -0.39$, $P < 0.02$). No significant correlations between coliform, staphylococcal species, streptococcal species, and bacillus species counts and CT ($P > 0.10$) were observed. These results suggest that high CT and low moisture are important for maintaining a dry resting surface for cows and may contribute to pack bacterial counts.

Key words: compost bedded pack barn, bacterial analysis, SCC

235 Objective assessment of pain in dairy cattle with clinical mastitis. C. E. Fitzpatrick*[1], N. Chapinal[1,2], C. S. Petersson-Wolfe[3], and K. E. Leslie[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]University of British Columbia, Vancouver, British Columbia, Canada, [3]Virginia Polytechnic Institute and State University, Blacksburg.*

Clinical mastitis has negative effects on profitability and cow welfare, with significant discomfort and pain. This study was conducted to objectively assess pain in cases of experimentally induced clinical mastitis, involving 24 (12 primiparous and 12 multiparous) lactating Holstein cows enrolled in an LPS endotoxin challenge study. Each animal was challenged in one rear mammary quarter by intramammary infusion with 25 µg of *E. coli* LPS. Subsequently, a subcutaneous injection of either a placebo (n = 12) or NSAID treatment (meloxicam) (n = 12) was randomly allocated and administered using, yet to be identified, double-blind methods (Treatments A and B). The animals were monitored for 2 d before, and 2 d following, the intramammary challenge. Several behavioral, physiological and performance parameters were monitored throughout the study period, including activity, rumination, body temperature, milk weights, DMI, SCC and clinical scores of milk, udder edema, pain sensitivity of the mammary glands, serum amyloid A and haptoglobin. During the first 6 h after inoculation and treatment, cows ruminated 14.6 ± 2.1 min/2 h interval ($P < 0.001$) less compared with the same baseline time period before challenge. Overall, multiparous cows were found to ruminate 6.1 ± 1.6 min/2h ($P = 0.001$) more than primiparous cows. There was no difference in rumination between treatment groups. Using a pain pressure algometer, the difference between the pressures applied to the control quarter was compared with the challenge quarter for each sampling time period before, and after inoculation. There was an effect at hour 6 after inoculation and treatment as compared with the baseline readings. For Treatment A animals, more pressure could be applied on their challenge quarter than their control quarter (1.9 ± 0.9 lbs; $P = 0.0445$). Treatment B animals registered more pressure applied to the control quarter than the challenge quarter (2.5 ± 0.9 lbs.; $P < 0.01$). These results indicate the potential for using continuous measurement of rumination and pain pressure sensitivity for objective assessment of pain due to illness in cases of clinical mastitis.

Key words: mastitis, pain management, behavior

236 Herd reproductive performance with an automated activity monitoring system versus a synchronized breeding program in 3 commercial dairy herds. R. C. Neves*, K. E. Leslie, J. S. Walton, and S. J. LeBlanc, *University of Guelph, Guelph, ON, Canada.*

The objective of this study was to compare overall herd reproductive performance with an automated activity monitoring system relative to a synchronized breeding program. A pen-level randomized trial was performed over 1 year using 3 commercial herds in Ontario, Canada, in which cows were housed in a primiparous and a multiparous pen on each farm. Pens were randomly assigned to an automated heat detection (AHD) system based on monitoring activity levels (Heatime, SCR Engineers Ltd.) or a timed artificial insemination program (TAI; Ovsynch), and a crossover occurred after 6 mo of the trial to avoid confounding treatment with parity. Insemination based on additional detection of estrus by observation was practiced in all pens. Herds A, B, and C milked 495, 305 and 260 cows on average, respectively. Herd A had 1476 AI, herd B 781 AI, and Herd C 988 AI throughout the study period. Analyses of the 3 herds were conducted using pen as the experimental unit. The proportion of TAI in the TAI pen was 49%, 71% and 55% for herds A, B and C. The proportion of AI in the AHD group after a heat signaled by the AHD system was 64%, 52% and 61% for herds A, B, and C. Conception risks for TAI and AHD were 32% and 32% in herd A, 40% and 44% in herd B and 26% and 29% in herd C. The mean annual 21-d pregnancy rates across the 3 herds were analyzed utilizing least squares means controlling for herd effect. There was no difference ($P = 0.25$) in the overall mean pregnancy rates between TAI program (15.9%) and AHD system (14.6%). Under the conditions in which a substantial minority of AI in both groups was based on visually detected estrus, herd pregnancy rate was not different between a TAI program and an AHD system. Further investigation of variables that may influence herd performance and of cow-level performance is required.

Key words: reproduction management, estrus detection, pregnancy rate

237 Effects of time and storage conditions on Johne's disease milk ELISA test results. C. M. Innes*, D. F. Kelton, D. L. Pearl, and T. F. Duffield, *University of Guelph, Guelph, Ontario, Canada.*

The Ontario Johne's Education and Management Assistance Program (OJEMAP) utilizes an individual cow milk ELISA test for antibody to *Mycobacterium avium* subspecies *paratuberculosis* (MAP) to determine the Johne's disease status of participating herds. Concerns were raised about the age of the samples at the time of testing and the temperature extremes that milk samples could be subjected to while being transported to the Dairy Herd Improvement (DHI) laboratory, and the impact on integrity of test results. This objective of this study was to investigate the impact of storage time and conditions (room temperature, frozen, refrigerated) on Johne's disease milk ELISA test results. Milk ELISA tests were completed using a commercially available kit following standard manufacturer instructions on days one, 4, 7 and 10 post collection. The time between collection and storage of the samples and the differences between storage conditions were compared graphically and statistically using the paired *t*-test, with a level of significance of $P < 0.05$. There were no significant differences in test results for any of the storage conditions for up to 7 d post collection. Based on these results, samples could be stored under various conditions for up to a week with no significant changes in test results.

Key words: Johne's, storage, ELISA

238 The evaluation of bulk tank tests for the surveillance of Johne's disease. C. M. Innes*, D. F. Kelton, D. L. Pearl, and T. F. Duffield, *University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to evaluate the utility of bulk tank tests to detect the presence of *Mycobacterium avium* subspecies *paratuberculosis* (MAP) antibody in dairy herds for the purpose of Johne's disease surveillance. Individual cow milk samples were collected by CanWest Dairy Herd Improvement customer service representatives in herds across Ontario, Canada. These samples along with bronopol preserved bulk tank samples collected by milk transporters from herds participating in the Ontario Johne's Education and Management Assistance Program (OJEMAP), a producer funded Johne's control scheme. The bulk tank ELISA results were expressed as percentage S/P (sample to positive). A S/P ratio of ≥ 30% was considered positive for MAP and a ratio of 20–30% was considered to be suspect for MAP.

The individual cow ELISA results were expressed as an optical density value, with a positive result having an optical density of 0.1 or higher. There were 309 farms tested, with herd size from 15 to 986 milking cows. The relative sensitivity and specificity of the bulk tank ELISA test when a positive herd was defined as 1 or more positive cows was 54.7% and 90.6%, respectively. When 2 or more positive cows defined a positive herd, the relative sensitivity increased to 63.3% while the specificity decreased to 84.2%.

Key words: Johne's, bulk milk, ELISA

Graduate Student Symposium: Becoming Your Own Best Advocate: How to Expand and Communicate Your Skills and Qualifications

239 Preparing an effective CV for an academic position. M. T. See*, *North Carolina State University, Raleigh.*

Your application for an academic job should be completed with the position description in mind. Position descriptions indicate what skills and experiences are valued and you want to present your information with that in mind. When applying for an academic position you will be asked to submit a cover letter that may include a statement of interest in teaching, research or extension, curriculum vitae (CV) and a list of professional references. Most institutions also have an online job application system. Thoughtful preparation of the cover letter should not be underestimated. An effective cover letter clearly and concisely answers 3 questions; 1) Why am I writing? 2) What do I have to offer in this position? 3) What are my significant achievements? A good cover letter summarizes the CV while highlighting your unique qualifications for the position you are applying to. Effective CVs are well organized and packed with relevant information that match and support your academic objective. The CV is a comprehensive record of what you have done. There is no set format for a CV and this allows you the opportunity to be creative. Also consider preparing the CV specifically for the job for which you are applying. The information that is most relevant for the position should be first. Don't make the search committee search through your CV to find out why you should be considered. State the reasons up front. Contact information goes first followed by education and work experience. You may include clear concise interest statements describing research or teaching goals. Categories to include in the CV are professional activities, teaching experience, memberships, honors and awards, grants, presentations and research publications. Within categories list each entry in reverse chronological order. Place references at the end, include phone numbers and e-mail addresses. It is good to show a breadth of connections with other people but stay within academia unless there is an excellent reason to list someone outside. Always have a variety of people proofread your CV before submitting. Remember there is no required length for a CV and this is an important first step to an interview and the position you seek.

Key words: student, CV, job

240 Grantsmanship—How to write a successful grant proposal. T. Davis*, *Baylor College of Medicine, Children's Nutrition Research Center, Houston, TX.*

Writing a successful grant application for submission to any funding agency requires considerable planning and action. This talk will provide tips on how to get started writing a grant proposal. Each section of the application will be discussed, focusing on the importance of the various sections and the specific information considered necessary in the abstract, specific aims, background, preliminary studies, and research design and methods sections. The grant review process and the criteria used by reviewers to evaluate applications will be described. Common problems and how to avoid these will be presented. Options for what to do if the submission of an application is not successful also will be discussed.

Key words: grant, writing, academia

241 Maximizing your graduate experience. N. C. Whitley*, *North Carolina A&T State University, Greensboro.*

The description of individual graduate experiences can be as varied and colorful as those queried; however, most would likely agree that the expected product of a successful graduate experience would be a satisfying job or career. If you agree with Henley that we are the master of our fates, the captain of our souls, then you may also believe that we, as individuals, have a great part to play in maximizing our experiences to achieve the success we seek. The objective of this presentation will be to discuss the kind of things that can be done to play that role to its fullest. Making informed, educated choices about the University you attend, your program or focus area and your advisor or mentor(s) within that program or focus area is a major first step. If that step has already been taken, you should look for opportunities within or even outside of the program to allow you to excel. It is important to never underestimate the value of networking, collaborating or even professional socializing on your part, or on the part of your advisor and/or mentors in finding or developing opportunities (and future jobs). There are many types of people who might become part of your network, so being able to communicate on a broad level and show people you value them for their unique skill set is important. Keeping well informed about current research topics in your focus area will assist you in networking and also demonstrate your enthusiasm for your field of study. Future mentors and employers are always looking for bright, educated and independent thinkers; therefore you need to do your best to set yourself apart from the competition. There are many ways to maximize your graduate experience so that it leads you down the path to success; with knowledge of some of these, you can more easily navigate that path.

Key words: graduate program, success, job

242 Becoming your own personal brand: How to market your talents and experiences for maximum results. C. Johnson*[1] and C. Luhman[2], *[1]Director Talent Acquisition & Diversity, Land O' Lakes, Inc, Arden Hills, MN, [2]Land O' Lakes Purina Feed, LLC, Gray Summit, MO.*

To stand out as a competitive potential employee, you must be able to portray your experiences and enthusiasm in a transparent and convincing manner. This seminar will address how to portray your own personal brand to potential employers for maximum results. We will specifically address the 3 main components of marketing your brand: 1. standing out on paper, 2. allowing your references and reputation to set you apart, and 3. impressing in person. With online, email, and mail application processes, your CV is often your first impression, and therefore, content and layout are critically important. Ways to convey your precise experiences, talents, and abilities in a concise, well laid out CV will be addressed. Potential employers will also become familiar with you through your references and your reputation, often before meeting you. Careful selection of references along with providing them with adequate and current information regarding your experiences and how you would meet the company's needs will help distinguish you from other candidates. How to protect your reputation as a professional will be addressed. Finally, when you get the oppor-

tunity to interview, be prepared to impress the potential employer. Think about potential interview questions and be prepared to answer with concise and accurate experiences and insightful answers. Also, become informed about the company and have thoughtful questions to ask the interviewer. By marketing yourself you improve your chances of successfully obtaining your perfect position.

243 Plane of dietary protein during late gestation in beef cows alters longissimus lumborum adipogenic gene expression in the offspring. S. Moisa*, D. Shike, D. B. Faulkner, and J. J. Loor, *University of Illinois, Urbana.*

The aim of this study was to evaluate potential carryover effects of the maternal diet on offspring performance, intramuscular adipogenic gene expression, and carcass characteristics. Two groups of pregnant Angus cows were fed a control diet (%DM = TDN 63.2, CP 9.48) or a higher-protein diet containing wet distiller's grain with solubles (WDGS; % DM = TDN 67.0, CP 13.0) during the last 96 d of gestation. Data were analyzed as a factorial design (maternal nutrition and stage of growth) with repeated measures using PROC MIXED in SAS. Seven early-weaned offspring (116 ± 6 d of age at weaning) from each group of cows were fed the same high-starch diet during a ~100-d growing phase. Subsequently, both groups of steers received the same diet during the finishing phase. Biopsies of the longissimus lumborum (LL) were collected at 0 (before start of growing phase), 100, 200 (mid-way through finishing), and 1 wk before harvest. Expression of the adipogenic transcription regulator peroxisome proliferator-activated receptor γ (PPARG), the lipogenic transcription regulators sterol responsive element binding factor 1 (SREBF1) and MLX interacting protein-like (MLXIPL), and the lipogenic enzymes fatty acid synthase (FASN) and stearoyl-CoA desaturase (SCD) was evaluated via quantitative PCR. Results showed no significant differences ($P > 0.05$) of maternal nutrition on offspring BW or ADG (1.4 and 1.6 kg/d during growing and finishing phases). At 100 d, steers from dams fed more dietary protein during pregnancy had greater (maternal diet × time $P < 0.05$) expression of PPARG, SREBF1, FASN, and SCD. In contrast, steers from cows fed the control diet during pregnancy had an increase (maternal diet × time $P < 0.05$) in expression between 100 and 200 d on study. Results indicated a precocious pro-adipogenic response during the growing phase in LL of steers born from cows fed a higher level of protein in the diet.

Key words: lipogenesis, marbling, gene expression

244 Oleic acid enhances G protein-coupled receptor 43 (GPR43) in cultured bovine intramuscular adipocytes. K. Y. Chung*[1], S. B. Smith[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Texas A&M University, College Station.*

G protein-coupled receptor 43 (GPR43) is a 7-transmembrane domain receptor that can be activated by fatty acids and regulates cAMP signal pathways in bovine adipocytes. The GPR43 is highly expressed in isolated murine adipocytes but lowly expressed in stromal-vascular cells. Our previous results did not detect the GPR43 protein in bovine perirenal or subcutaneous (s.c.) adipose tissues but the protein was present in bovine intramuscular (i.m.) adipose tissue. We hypothesized that oleic acid (18:1n-9) may regulate adipogenesis of bovine i.m. adipose tissue. Primary cultures of i.m. and s.c. preadipocytes were isolated from adipose tissues dissected from bovine longissimus muscle. Data were analyzed as a completely randomized design using the MIXED model, each treatment performed in triplicate. Means were considered different at $P < 0.05$. Preadipocytes were treated with various levels of oleic acid (1μM, 10μM, 100μM, and 500μM) for C/EBPβ, PPARγ, stearoyl CoA desaturase (SCD), and GPR43 protein and mRNA analysis. Real-time quantitative PCR was used to measure mRNA contents. The mRNA concentrations of C/EBPβ, PPARγ, and GPR43 were increased ($P < 0.05$) in the i.m. adipocyte by oleic acid, but no effects were observed in the s.c. adipocytes ($P > 0.05$). Western blot analysis revealed that treatment with oleic acid enhanced PPARγ protein in both i.m. and s.c. adipocytes in a dose-dependent manner. Relative GPR43 per GAPDH protein levels in i.m. adipocytes tended to be increased ($P = 0.10$) by treatment with oleic acid. Interestingly, mRNA concentrations of SCD were decreased with oleic acid treatment ($P < 0.05$). These data indicate that oleic acid alters mRNA and protein concentrations of C/EBPβ, PPARγ, and SCD in bovine i.m. adipocytes, and these effects may be mediated through the GPR43 receptor.

Key words: G protein-coupled receptor 43, adipocyte, oleic acid

245 Effect of stearoyl-CoA desaturase 1 inhibiters on lipid metabolism and cellular proliferation in primary bovine adipocytes. A. K. G. Kadegowda*, T. A. Burns, S. L. Pratt, and S. K. Duckett, *Clemson University, Clemson, SC.*

Objectives were to determine the effects of sterculic acid (SA) and trans-10, cis-12 conjugated linoleic acid (t10c12 CLA), known stearoyl-CoA desaturase 1 (SCD1) inhibitors, on lipid metabolism and cellular proliferation in primary bovine adipocytes. Bovine primary preadipocyte cultures were isolated from intermuscular fat of 18 mo-old Angus crossbred heifers (n = 3) and differentiated (D0) in differentiation media [DMEM containing 10% fetal calf serum, 2.5 μg/mL insulin, 0.25 μM dexamethasone (DEX), 20 μM troglitasone, 0.5 mM isobutylmethylxanthine (IBMX), and 10 mM acetate] for 2 d. Cells were further differentiated from D2 to D6 in media without DEX and IBMX. From D0 to D6, cells were treated with 1 of 4 levels (0, 50, 100, or 200 μM) of SA or t10c12 CLA. In Expt. 1, trans-11 18:1 was added at 0 or 100 μM to the media on D4 and the cells harvested for fatty acid (FA) analysis after 48h. In Expt. 2, stearic acid-^{13}C18 was added at 100 μM on D4 and cells harvested at 0, 6, 12, 24, and 48h for FA analysis by GC-MS. The effect of SA and t10c12 CLA on cell proliferation of undifferentiated pre-confluent cells was assayed using Cell Counting Kit-8 at 24, 48, and 72h post incubation. The experimental design was 2 × 4 factorial and data were analyzed by PROC MIXED (SAS). The total cellular FA yield (minus supplemented FA) did not change due to SA or t10c12 CLA (except 200 μM). The desaturation of trans-11 18:1 to c9t11 CLA was decreased ($P < 0.05$) up to 95% by both SA and t10c12 CLA compared with Control (0 μM). Stearic acid-^{13}C18 was enriched up to 75% by 6h of incubation. The enrichment of labeled oleate increased ($P < 0.05$) from 4.1% at 6 h to 28.4% at 48h in the control (0 μM SA). The SA inhibited the conversion of labeled stearate to oleate at all the supplemented levels and time points ($P < 0.05$). The SA and t10c12 CLA treatments did not affect the cell viability at the tested concentrations. Results showed both SA and t10c12 CLA inhibit SCD1 activity/expression at 50 μM concentration without affecting adipose lipid content. Also, SCD1 inhibition does not affect bovine preadipocyte viability.

Key words: stearoyl-CoA desaturase 1, adipocyte, inhibition

246 Palmitoleic acid (C16:1), not an elongation product, decreases lipogenesis and desaturation in bovine adipocyte cultures. T. A. Burns*, C. M. Klein, S. K. Duckett, S. L. Pratt, and T. C. Jenkins, *Clemson University, Clemson, SC.*

Our objective was to confirm the identity of fatty acids elongated from C16:1 and to determine if C16:1 or an elongated fatty acid is

responsible for decreased desaturation and lipogenesis rates previously seen in cultured bovine adipocytes supplemented with C16:1. Bovine stromal vascular cultures were isolated, propagated, and tested for their capacity to differentiate into adipocytes. Cells were passaged 4 times, allowed to reach confluence, and held for 2 d. On D0, primary differentiation media [Dulbecco's Modified Eagle's Medium (DMEM) containing 10% fetal calf serum (FCS), and 2X antibiotic/antimycotic (AB/AM), insulin at 2.5 μg/mL, 0.25 μM dexamethasone, 20 μM troglitasone (TRO), 0.5 mM isobutylmethylxanthine, and 10 mM acetate] was applied for 2 d and replaced with secondary media {DMEM, 10% FCS, 2X AB/AM, insulin at 2.5 μg/mL, 5 μM TRO, 10 mM acetate, containing 1 of 4 levels of fatty acid [0 μM (CON), 150 μM C16:0, 150 μM C16:1, or 150 μM C18:1cis11]} for 4 d. On D6, cells were harvested for fatty acid analysis. In addition, cells were incubated with ^{13}C2, ^{13}C18:0, or ^{13}C16:1 on D6 to estimate lipogenesis and desaturation rates and confirm elongation products of C16:1 using GLC-MS. Data were analyzed using Proc GLM of SAS 9.2. In C16:1-supplemented cells, C16:1, C18:1cis11, and C20:1 were elevated ($P < 0.05$) compared with CON cells. In C18:1cis11-supplemented cells, C18:1cis11 and C20:1 were elevated ($P < 0.05$) compared with CON, but C16:1 was not. The C18:1cis9/C18:0 ratio was decreased ($P < 0.05$) in C16:1 cells compared with all other treatments. Incorporation of ^{13}C16:1 into cells and presence of ^{13}C label in C18:1cis11 and C20:1 confirmed them as elongation products of C16:1 in bovine adipocytes. By 12 h of ^{13}C18:0 incubation, cells supplemented with C16:1 had reduced ($P < 0.05$) ^{13}C18:1cis9 compared with all other treatments. Similarly, ^{13}C16:0 was reduced ($P < 0.05$) in C16:1-treated cells compared with CON and C18:1cis11-treated cells following ^{13}C2 incubation. Therefore, inhibition of desaturation and lipogenesis can be attributed to C16:1 and not its elongation products; C18:1cis11 or C20:1.

Key words: bovine, adipocyte, palmitoleic acid

247 Palmitic and stearic acids induce adipogenic gene expression in single- or co-cultures of bovine intramuscular preadipocyte and satellite cells. S. H. Choi*[1], K. Y. Chung[2], B. J. Johnson[2], K. H. Kim[3], and S. B. Smith[1], *[1]Texas A&M University, College Station, [2]Texas Tech University, Lubbock, [3]National Institute of Animal Science, Suwon, Gyunggi, Korea.*

We hypothesized that saturated fatty acids would stimulate lipogenic gene expression in single- and cocultured intramuscular (i.m.) preadipocytes and myoblasts. Bovine satellite cells (BSC) and i.m. preadipocytes were isolated from 14-mo-old crossbred steers. Both cell types were cultured with 10% fetal bovine serum (FBS)/Dulbecco's modified eagle medium (DMEM), and 1% antibiotics during the 3-d proliferation period. After proliferation, BSC and i.m. preadipocytes were treated with 3% horse serum DMEM or 5% FBS/DMEM with antibiotics, respectively, for 4 d. Finally, single or combined BSC and i.m. preadipocytes were cultured with 40 μM palmitic, palmitoleic, stearic, oleic, or linoleic acids for 2 h. The endogenous 40S ribosomal protein S9 (RPS9) control was used to normalize the expression of AMP-activated protein kinase-α (AMPKα), C/EBPβ, carnitine palmitoyltransferase I - β (CPT1β), peroxisome proliferator activated receptor-γ (PPARγ), glucose transporter type 4 (GLUT4), and stearoyl-CoA desaturase (SCD). Data were analyzed as a 2 × 2 factorial ANOVA with chemical treatment and culture method as the main effects. Palmitic and stearic acids significantly stimulated C/EBPβ ($P < 0.0001$) and CPT1β ($P = 0.02$ and $P = 0.001$, respectively) gene expression in single- and co- cultured i.m. preadipocytes. Also, oleic and linoleic acids depressed SCD gene expression in single- and cocultured i.m. preadipocytes ($P < 0.0001$). In myoblasts, palmitic acid significantly enhanced C/EBPβ gene expression in both single- ($P = 0.036$) and cocultured ($P = 0.028$) myoblasts. Expression of GLUT4 in single- ($P = 0.006$) and co- ($P = 0.016$) cultured myoblasts was depressed by oleic and linoleic acids. Oleic acid and linoleic acid decreased SCD gene expression in both single- and cocultured myoblasts($P < 0.0001$). Saturated fatty acids stimulate genes associated with differentiation of i.m. preadipocytes, but have less effect in differentiating myoblasts. Funded in part by Beef Check-off dollars.

Key words: fatty acid, preadipocyte, satellite cell

248 The effect of chromium propionate on bovine intramuscular and subcutaneous preadipocytes and muscle satellite cells. R. J. Tokach*[1], W. Rounds[2], K. Y. Chung[1], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Kemin Industries Inc., Des Moines, IA.*

Chromium (Cr) propionate is a feed ingredient that has been used in the livestock industry to improve immune efficiency of livestock species, increase pork quality, and increase milk yield in dairy cattle. The aim of these in vitro experiments was to determine the effect of chromium propionate (Kemin Industries, Des Moines, IA) on changes in transcription factors and receptors important in adipose tissue differentiation and skeletal muscle growth. We hypothesized that Cr would increase mRNA expression of glucose transporter 4 (GLUT4) in intramuscular (IM) preadipocytes and protein expression in bovine muscle satellite cells (BSC). Intramuscular and subcutaneous (SC) preadipocytes and BSC were isolated from the semimembranosus to determine the effect of treatment on GLUT4 and peroxisome proliferator-activated receptor gamma (PPARγ) mRNA and GLUT4 protein abundance. Preadipocyte cultures were treated with differentiation media plus 0.1 μM, 1 μM, or 10 μM concentrations of Cr or 10 μM, of sodium propionate for 96, 120, and 144 h before harvest. Data were analyzed as a randomized complete block design using the MIXED model. Real-time quantitative PCR was used to measure the relative level of mRNA. For the IM and SC preadipocyte cultures, GLUT4 mRNA abundance tended to increase ($P = 0.10$) after 144 h of treatment with differentiation media plus either 1 μM or 10 μM of Cr. In the SC preadipocyte cultures, the GLUT4 mRNA abundance increased ($P \leq 0.05$) for the average of the 3 levels of Cr as compared with the differentiation media alone and this increase tended ($P = 0.10$) to be linear. These results indicated that Cr altered glucose uptake mechanisms regardless of adipose tissue type. The mRNA abundance for PPARγ increased ($P \leq 0.01$) when differentiation media was added to the preadipocyte cultures at 144 h. The GLUT4/GAPDH protein abundance decreased ($P \leq 0.01$) in a dose-dependent manner when Cr was added to the BSC. The results indicated that Cr may have caused a feedback mechanism in skeletal muscle, due to increased efficiency of glucose transport caused by the Cr supplementation.

Key words: chromium propionate, glucose transporter 4, preadipocyte

249 Effect of rate of gain during grazing on gene expression of adipose tissue in growing beef cattle. P. A. Lancaster*, E. D. Sharman, G. W. Horn, C. R. Krehbiel, and U. DeSilva, *Oklahoma Agricultural Experiment Station, Stillwater.*

The stocker cattle production phase could benefit by influencing adipose tissue development before finishing. Previous research indicates that nutritional management can affect fat deposition in growing cattle. Our objective was to evaluate rate of gain to a common initial finishing BW on gene expression of adipose tissue in growing cattle. Angus

steers (n = 72; 259 ± 28 kg BW) were blocked by BW and sire and allotted to 4 treatments: (1) grazing dormant native range (NR) plus a protein supplement (1.0 kg/d) followed by season-long grazing NR (CON), (2) grazing dormant NR plus a corn-based supplement (1% of BW) followed by short-season grazing NR (CORN), (3) grazing wheat pasture (WP) at a high stocking rate (3.0 steers/ha) for a moderate ADG (LGWP), and (4) grazing WP at a low stocking rate (1.0 steers/ha) for a high ADG (HGWP). Supplements were fed individually 5 d/wk. Four steers per treatment were harvested at an estimated HCW of 200 kg before finishing, and subcutaneous (SC), perirenal (PR), and intramuscular (IM) adipose tissue collected. Gene expression was determined using qRT-PCR. Performance and carcass data are presented in a companion abstract (Sharman et al., 2011). MANOVA revealed a treatment × adipose tissue interaction ($P < 0.05$) for genes involved in lipogenesis and adipogenesis. Canonical variate analysis indicated that treatment did not affect lipogenic or adipogenic gene expression in IM, but in general, lipogenic and adipogenic gene expression in SC and PR was greater in HGWP and LGWP than CON and CORN. The lipogenic genes fatty acid synthase and diacylglycerol acyltransferase 2 were highly correlated ($P < 0.01$) with the canonical variate (0.91 and 0.64, respectively). The adipogenic genes peroxisome proliferator activated receptor gamma, sterol regulatory element binding protein, and CAATT/ enhancer binding protein β were correlated ($P < 0.05$) with the canonical variate (0.65, 0.95, and 0.32, respectively). In summary, moderate to high rates of gain of cattle grazing wheat pasture significantly increased lipogenesis and adipogenesis in SC and PR, but development of IM was not affected.

Key words: adipose tissue, gene expression, stocker cattle

250 Effect of ewe body condition during mid to late gestation on mammary growth and composition of female progeny. K. E. Boesche*, A. L. Hunter, K. M. O'Diam, S. C. Loerch, and K. M. Daniels, *The Ohio State University, Ohio Agricultural Research and Development Center, Wooster.*

The foundation for functional mammary secretory tissue, parenchyma (PAR), is established early in life; amount of PAR directly relates to future milk production. Dam body condition score (BCS) during mid to late gestation may affect progeny postnatal mammary growth and composition via in utero metabolic programming events. Pregnant ewes (n = 96; ≈80 d of gestation) were allotted to treatment groups based on initial BCS of 2, 3, or 4 (on a 1 to 5 scoring system with 1 being extremely thin and 5 being extremely fat). Ewes were housed in 18 pens (6 pens per treatment) and fed a maintenance diet of limit-fed corn silage (1.1 kg DMI/d), to which whole shelled corn was supplemented at 0.12, 0.26, and 0.47 kg DMI/d for BCS groups 2, 3, and 4, respectively. Diets were adjusted every 2 wk to maintain desired BCS throughout pregnancy. Prior to weaning, lambs nursed their mothers and were fed a common starter. Lambs were weaned (≈56 d of age; 23.59 kg) and placed on a common finishing diet that met NRC requirements. Female progeny from the 3 BCS groups (n = 73) were slaughtered at similar BW (46.9 ± 0.5 kg; $P = 0.913$), and age (126.3 ± 2.8 d; $P = 0.159$). Udders were removed and mammary tissue subjected to biochemical analysis. Total mammary gland weights (179.2, 167.4, and 175.6 ± 8.8 g for BCS 2, 3, 4, respectively) did not differ by treatment ($P = 0.615$). However, PAR weight of progeny from BCS 2 ewes (25.3 g) was greater ($P = 0.074$) than that of BCS 3 (18.5 g) or BCS 4 (18.8 g) progeny. Protein mass within PAR (BCS 2 = 1.43, 3 = 1.02, and 4 = 1.07 ± 0.13 g) varied by treatment ($P = 0.053$), as did DNA mass within PAR (BCS 2 = 134.8, 3 = 93.1, and 4 = 103.0 ± 13.4 mg; $P = 0.072$). Lipid mass within PAR did not differ by treatment and averaged 7.10 ± 1.17 g ($P = 0.228$). Despite detectable differences in PAR due to treatment, no differences in weight or composition of the mammary fat pad were found. Factors that promote mammary PAR growth may have a positive impact on future milk production. Our observations suggest that BCS during gestation may have important lactation performance implications for female progeny.

Key words: body condition score, sheep, mammary

251 Defining maturity of Nellore cattle based on growth and body composition. M. Marcondes*[1,3], L. Tedeschi[2], S. V. Filho[1,3], M. Gionbelli[1], and L. F. Silva[1], *[1]Universidade Federal de Viçosa/INCT-CA, Viçosa, MG, Brazil, [2]Texas A&M University, College Station, [3]INCT - Ciência Animal, Viçosa, MG, Brazil.*

The aim of this study was to understand the growth development and chemical composition of empty BW (EBW), soft tissues, and bone, and to determine a system to define maturity of Nellore cattle. A database containing carcass and body compositions of 249 animals from 11 studies was used. There were 63 intact males, 105 steers, and 81 heifers of Nellore breed. Allometric regressions were used to predict body water, CP, and ash; except for ether extract (EE) in which an exponential equation was used to fit the data. The maturity was defined as the point of which no significant accretion of protein in the fat-free DM (FFDM) was observed. The water in the soft tissue (STW) was regressed on Logistic, Gompertz, and brake lines equations whereas the fitting for bone chemical composition was performed using an exponential equation. Sex effect was evident on empty body water ($P = 0.057$) and EE ($P < 0.001$), therefore, this effect was not included in the analysis of fat-free DM, evidencing that maturity is more correlated with breed than sex. The fitting of the exponential equation suggested that Nellore cattle reach maturity with 445 kg and the break line analysis indicated a plateau around 429 kg. At this point, the relationship between CP and ash in the FFDM is 79.62:20.38. A high relationship between STW and EE in the soft tissue (STEE) was observed (STEE = 0.920 – 1.147 × STW; $P < 0.001$), but the soft tissue was not a good predictor for maturity because it depends on the type of diet. The analysis of bone chemical composition showed that EE, water, and ash become constant between 400 and 500 kg of EBW whereas CP in the bone is always constant at 19.1%. Our data also suggested that bone composition could be a good predictor of maturity; however due to the great variability in the database, it was not possible to determine a BW at which these components become constant with a reliable precision. We concluded that Nellore cattle reach maturity between 429 and 445 kg of EBW and that CP in the FFDM and CP, water, and ash in the bone are good predictors of maturity; however soft tissue composition alone cannot be used to predict maturity.

Key words: prediction, development, composition

252 Population dynamics of leukocytes during immune activation of the chicken immune system by *E. coli*. V. Arias* and K. Klasing, *University of California, Davis.*

The innate and adaptive systems must have appropriate levels of nutrients to support changes in leukocyte numbers and function during an immune response. As a first step at understanding the dynamics of these changes, we examined a time course of peripheral leukocytes in blood of adult Hyline chickens injected IV with dead *E. coli* at 1 × 10^{10} cfu/ml. After primary injection, blood was collected and total white blood cells (WBC), T cell ($CD4^+$ and $CD8^+$), B cell (IgM^+ and IgG^+), macrophage/monocyte, and thrombocyte cell numbers were determined. Data were analyzed by one-way ANOVA, and differences among treatments were determined by means contrasts. An increase in total WBC numbers occurred at 5 d, 7 d, and 10 d post-injection compared with baseline ($P = 0.01$, $P < 0.01$, $P = 0.04$). $CD4^+$ numbers increased compared with baseline at 7 d, 10 d, and 14 d post-injection ($P < 0.01$, $P < 0.01$, $P = 0.01$). However, $CD8^+$ cell numbers showed no difference. IgM^+ cell numbers increased compared with baseline at 5 d, 7 d, and 10 d post-injection ($P < 0.01$ for each day). IgG^+ cell numbers increased at 5 d, 7 d, 10 d, and 14 d post-injection compared with baseline ($P < 0.01$ for each day). Macrophage/monocyte cell numbers increased 3 d, 5 d, 7 d, 10 d, and 14 d post-injection compared with baseline ($P = 0.02$, $P < 0.01$, $P < 0.01$, $P < 0.01$, $P < 0.01$). Thrombocyte cell numbers increased at 5 d and 7 d post-injection compared with baseline. ($P = 0.01$, $P < 0.01$). Maximal percent increase in cell numbers for WBC, $CD4^+$, IgM^+, IgG^+, macrophage/monocyte, and thrombocyte were 83%, 66%, 117%, 336%, 214%, and 102%, respectively. These data indicate an increase in most cellular components of the avian immune system during systemic activation compared with naïve birds (maintenance). Supported by USDA Regional Research project 1013.

253 Effects of dietary seaweed extract supplementation in sows and post-weaned pigs on performance, intestinal morphology, intestinal microflora and immune status. S. G. Leonard, T. Sweeney, B. Bahar, and J. V. O'Doherty*, *University College Dublin, Dublin, Ireland.*

The present experiment investigated the effects of dietary supplementation of a seaweed extract (SWE) to sows and weaned pigs on post-weaning growth performance, intestinal morphology, intestinal microflora, volatile fatty acid (VFA) concentrations, and immune status of pigs at d 11 and 117 post-weaning. Gestating sows (n = 20) were supplemented with SWE (0 vs. 10.0 g/d) from d 107 of gestation until weaning (d 26). At weaning, pigs (4 pigs/sow) were divided into 2 groups based on sow diet during lactation and supplemented with SWE (0 vs. 2.8 g/kg diet), giving 4 treatment groups; 1) BB (basal sows-basal pigs); 2) BS (basal sows-treated pigs); 3) SC (treated sows-basal pigs); and 4) SS (treated sows-treated pigs). Pigs weaned from SWE-supplemented sows had a higher ADG between d 0–21 ($P < 0.05$) post-weaning compared with pigs weaned from non SWE-supplemented sows. Pigs offered post-weaning diets containing SWE had decreased colonic *E. coli* populations on d 11 ($P < 0.01$) and decreased colonic *Enterobacteriaceae* numbers on d 117 ($P < 0.05$). Pigs offered post-weaning diets containing SWE had a greater mRNA abundance of MUC2 in the colon at d 11 post-weaning ($P < 0.05$) compared with pigs offered un-supplemented diets. In conclusion, these results demonstrate that SWE supplementation post-weaning provides a dietary means to improve gut health and enhance growth performance in starter pigs. Dietary SWE supplementation increased ADG during the grower-finisher (GF) phases. However, there was no growth response to SWE inclusion in the GF diets when pigs were weaned from SWE-supplemented sows.

Key words: sow, fucoidan, laminarin

254 Effect of maternal seaweed extract supplementation on suckling piglet growth, humoral immunity, selected microflora, and immune response after an ex vivo lipopolysaccharide challenge. S. G. Leonard, T. Sweeney, B. Bahar, and J. V. O'Doherty*, *University College Dublin, Dublin, Ireland.*

The present study was conducted to investigate the effect of maternal dietary supplementation (n = 10 sows/treatment) with seaweed extract (SWE: 0 vs. 10.0 g/d) from d 107 of gestation until weaning (d 26) on neonatal piglet growth, humoral immunity, intestinal morphology, and selected intestinal microflora. Furthermore, this study examined the effect of dietary treatment on the immune response following an ex vivo *Escherichia coli* lipopolysaccharide (LPS) tissue challenge at weaning in a 2 × 2 factorial arrangement. The main factors consisted of sow dietary treatment (SWE or control) and immunological challenge (yes or no). The SWE supplement (10.0 g/d) contained laminarin (1.0 g), fucoidan (0.8 g), and ash (8.2 g). The SWE-supplemented sows had greater colostrum IgA ($P < 0.01$) and had a trend for greater IgG ($P = 0.062$) concentrations compared with non SWE-supplemented sows. Piglets suckling SWE-supplemented sows had greater serum IgG ($P < 0.05$) concentrations on d 14 of lactation compared with those suckling non-SWE supplemented sows. Dietary SWE supplementation decreased fecal *Enterobacteriaceae* populations in sows at parturition ($P < 0.05$) and piglets suckling SWE-supplemented sows had a lower colonic *E. coli* population at weaning ($P < 0.01$) compared with non SWE-supplemented sows. Lipopolysaccharide challenge increased the mRNA abundances of the pro-inflammatory cytokines IL-1α and IL-6 ($P < 0.01$) in ileal tissue and TNF-α in colonic ($P < 0.01$) tissue. Piglets suckling SWE-supplemented sows had greater TNF-α mRNA expression following ex vivo LPS challenge compared with non SWE-supplemented sows ($P < 0.05$). However, there was no effect of sow dietary treatment on TNF-α mRNA expression in the unchallenged ileum tissue. In summary, these results demonstrate an important immunomodulatory role of SWE supplementation characterized by enhanced colostral IgA and IgG concentrations, greater piglet circulatory IgG concentrations and enhanced TNF-α mRNA expression in the ileum following an ex vivo LPS challenge.

Key words: sow, immunity, laminarin

255 Plant extracts for weaned pigs experimentally infected with porcine reproductive and respiratory syndrome virus. 1: Effect on growth performance and immune responses. Y. Liu*[1], J. J. Lee[1], M. Song[1], T. M. Che[1], J. A. Soares[1], D. Bravo[2], W. G. Van Alstine[3], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]Pancosma SA, Geneva, Switzerland, [3]Purdue University, West Lafayette, IN.*

A study evaluated the effects of 3 different plant extracts (PE) on growth performance and immune responses of weaned pigs experimentally infected with porcine reproductive and respiratory syndrome

virus (PRRSV). Weaned pigs (n = 64, 7.8 ± 0.3 kg BW, 21 d old) were used in a 2 × 4 factorial arrangement. The first factor was with or without PRRSV challenge (10^5 intranasal dose; 50% tissue culture infective dose). The second factor was 4 diets: a nursery basal diet (CON), 10 ppm capsicum oleoresin (CAP), garlic (GAR), or turmeric oleoresin (TUR). Pigs were housed in disease containment chambers for 28 d: 14 d before and 14 d after the inoculation (d 0). Rectal temperatures (RT) were measured every 3 or 4 d post-inoculation (PI). The ADG, ADFI, and G:F were measured on d −14 to 0, 0 to 7, and 7 to 14. Blood was collected on d 0, 7, and 14 to detect serum viral load (SVL) by qPCR and PRRSV antibody titer (AT) by ELISA. The PRRSV infection decreased ($P < 0.01$) ADG and ADFI from d 0 to 7, d 7 to 14, and d 0 to 14, and G:F from d 7 to 14 and d 0 to 14, and increased ($P < 0.05$) RT on d 7, 9, 11, and 14 PI, SVL on d 7 and 14 PI, and AT on d 14 compared with the unchallenged group. In the PRRSV challenged group, CAP reduced ($P < 0.05$) RT (39.67 vs. 40.18°C) on d 4 and SVL (Ct, 18.94 vs. 16.15) on d 7; GAR increased ($P < 0.05$) ADG (328 vs. 236 g/d) from d 0 to 7 and reduced ($P < 0.05$) RT (39.67 vs. 40.18°C) on d 4; TUR increased ($P < 0.05$) ADG (469 vs. 333 g/d) from d 7 to 14, G:F from d 7 to 14 (0.70 vs. 0.42) and from d 0 to 14 (0.58 vs. 0.42), PRRSV AT (2.09 vs. 1.69 S/P ratio), and decreased SVL on d 7 (Ct, 18.97 vs. 16.15) and d 14 (Ct, 23.84 vs. 21.54). In the unchallenged group, all piglets were PRRSV negative during the overall period PI. The CAP increased ($P < 0.05$) ADFI from d 0 to 7 and overall period PI, and final weight of piglets compared with the CON. In conclusion, the 3 PE tested showed different effects on growth efficiency and humoral immune responses, and TUR might strengthen immune responses and efficiency of pigs infected with PRRSV.

Key words: plant extracts, PRRSV, weaned pigs

256 Plant extracts for weaned pigs experimentally infected with porcine reproductive and respiratory syndrome virus. 2: Effect on peripheral blood immune cells and inflammatory mediators. Y. Liu*[1], J. J. Lee[1], M. Song[1], T. M. Che[1], J. A. Soares[1], D. Bravo[2], W. G. Van Alstine[3], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]Pancosma SA, Geneva, Switzerland, [3]Purdue University, West Lafayette, IN.*

A study evaluated the effects of 3 different plant extracts (PE) on peripheral blood immune cells and inflammatory mediators of weaned pigs experimentally infected with porcine reproductive and respiratory syndrome virus (PRRSV). Weaned pigs (n = 64, 7.8 ± 0.3 kg BW, 21 d old) were used in a 2 × 4 factorial arrangement. The first factor was with or without PRRSV challenge (10^5 intranasal dose; 50% tissue culture infective dose). The second factor was 4 diets: a nursery basal diet (CON), 10 ppm capsicum oleoresin (CAP), garlic (GAR), or turmeric oleoresin (TUR). Pigs were housed in disease containment chambers for 28 d: 14 d before and 14 d after the inoculation (d 0). Blood was collected on d 0, 7, and 14 to measure the total and differential white blood cells (WBC), and serum tumor necrosis factor-α (TNF-α), C-reactive protein (CRP), and haptoglobin (HP). Compared with the unchallenged pigs, the PRRSV infection reduced ($P < 0.01$) WBC and lymphocytes (LYM) on d 7, monocytes (MONO) on d 7 and d 14, and the ratio of neutrophils to LYM (NEU/LYM) on d 14, but increased NEU/LYM on d 7, WBC and LYM on d 14, and the levels of serum TNF-α, CRP, and HP. In the PRRSV challenged group, CAP reduced ($P < 0.05$) TNF-α (146.2 vs. 179.5 pg/ml) and CRP (27.9 vs. 41.0 μg/ml) on d 7, and increased ($P < 0.05$) HP (1503 vs. 890 μg/ml) on d 14; GAR increased ($P < 0.05$) HP (1485 vs. 890 μg/ml) on d 14; TUR reduced ($P < 0.05$) TNF-α (139.4 vs. 179.5 pg/ml) on d 7 compared with the CON. The 3 PE tested did not influence the populations of peripheral immune cells. In the unchallenged group, CAP increased ($P < 0.05$) LYM on d 7; GAR increased ($P < 0.05$) MONO and CRP (27.6 vs. 16.8 μg/ml) on d 7 and NEU/LYM (1.86 vs. 0.92) on d 14, but reduced ($P < 0.05$) MONO on d 14 (1.01 vs. 1.66 x10^3/μl), compared with the CON. In conclusion, the 3 PE tested showed different effects on immune responses of piglets with or without PRRSV infection, and CAP and TUR modulate the inflammatory mediators of pigs infected with PRRSV.

Key words: plant extracts, PRRSV, weaned pigs

257 Effects of spray-dried plasma on pregnancy rate and growth performance of mated female mice after transport as a model for stressed sows. M. Song*[1], T. M. Che[1], Y. Liu[1], J. A. Soares[1], J. J. Lee[1], J. M. Campbell[2], J. Polo[2], J. C. O'Connor[3], and J. E. Pettigrew[1], *[1]University of Illinois, Urbana, [2]APC Inc., Ankeny, IA, [3]University of Texas Health Science Center, San Antonio.*

Transportation stress can reduce implantation, impair embryo development, and decrease pregnancy rate after breeding of animals. A study evaluated the effects of spray-dried plasma (SDP) on pregnancy rate and growth performance of mated female mice (C57BL/6 strain) after transport as a model for stressed sows. The mated female mice (n = 250; 16 ± 1.2 g BW; 4 replicated groups, 62 or 63 mice/group) were shipped from Bar Harbor, ME to Urbana, IL on the day the vaginal plug was found (gestation day (GD) 1), arriving at the laboratory on GD 3. They were housed in individual cages, randomly assigned to dietary treatments with or without 8% SDP (SDP or CON), and fed for 2 wk. The diets were formulated to similar ME, CP, and AA levels without antibiotics. Measurements were pregnancy rate and growth performance (GD 3 to 17). Pregnancy was determined on GD17 on the basis of BW and shape of abdomen, and was confirmed by inspection post-mortem. The SDP markedly improved ($P < 0.05$) pregnancy rate compared with the CON (Table). The SDP also improved ($P < 0.05$) ADG (non-pregnant mice: 0.142 vs. 0.106 ± 0.008 g/d; pregnant mice: 0.712 vs. 0.638 ± 0.018 g/d) and G:F (non-pregnant mice: no data; pregnant mice: 0.223 vs. 0.202 ± 0.006) compared with the CON, but did not affect ADFI. In conclusion, SDP improved pregnancy rate of the mated female mice after transportation stress and growth performance of pregnant mice.

Table 1. Effect of SDP on pregnancy rate of mated female mice after transportation stress*

	CON			SDP		
Group	Pregnant	Total	% Pregnancy	Pregnant	Total	% Pregnancy
1	8	31	26	15	32	47
2	2	31	7	19	31	61
3	5	50	10	5	13	39
4	2	48	4	5	14	36
Overall	17	160	11	44	90	49

*Data are number of mice and analyzed by chi-squared test.

Key words: mice, pregnancy rate, spray-dried plasma

258 Dietary phosphate supplementation to neonatal pigs affects satellite cell proliferation and progression through their myogenic lineage. L. S. Alexander*, B. S. Seabolt, and C. H. Stahl, *North Carolina State University, Raleigh.*

Severe neonatal dietary phosphate (PO_4) deficiency reduces the proliferation of satellite cells (Alexander, 2010). The objective of this study was to examine the impact of dietary PO_4 on the growth, sera parameters, and tissue-specific stem cell proliferation in the neonatal pig. Seventy-five 1-d old pigs were pair-fed either a 25% PO_4 deficient (PD), a PO_4 adequate (PA), or a 25% PO_4 excessive (PE) liquid diet over an 18d period. Circulating PO_4 was lower ($P < 0.05$) in PD fed animals throughout the trial when compared with PA and PE fed animals. Sera Ca concentrations were higher ($P < 0.05$) in PD fed animals at all time points when compared with their PE fed counterparts. Increased ($P < 0.05$) sera PTH was observed among pigs fed the PE diet when compared with both the PD and PA fed groups. PD fed animals had lower ADG ($P < 0.05$) and G:F ($P < 0.05$) than PA and PE fed animals. Dietary PO_4 restriction reduced the in vivo proliferation of satellite cells, but no differences were seen between the PA and PE treatment groups. Satellite cells were additionally cultured to evaluate the effect of dietary PO_4 on their developmental programming. Altered gene and protein expression of muscle regulatory factors (Pax7, MyoD, and Myogenin) was observed among the satellite cells based on the PO_4 status of the pigs from which they were isolated. Our previous research demonstrated reduced satellite cell proliferation during severe PO_4 deficiency, and similar results were also seen in this study with a mild PO_4 deficiency. Although excess dietary PO_4 did not result in increased proliferation in vivo, differences in both proliferation and markers of the progression of these cells through their myogenic lineage was affected by excess dietary PO_4. Additional research is needed to further clarify how PO_4 status affects satellite cell activity and the subsequent impact on growth.

Key words: pig, phosphate, satellite cell

259 Flavour preferences conditioned by the effects of porcine digestible peptides (PDP) and soybean concentrate in post-weaned piglets. J. Figueroa*[1], D. Solà-Oriol[1], S. L. Vinokurovas[1], E. Borda[2], and J. F. Pérez[1], *[1]Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain, [2]Bioibérica, Barcelona, Spain.*

It has been shown in mammals that an initially arbitrary or aversive flavor can become strongly preferred after a learned association between the flavor and the positive consequences of its consumption (hedonic or post-ingestive). In this experiment, 480 non-deprived weaning piglets (10 piglets/pen) were trained during 6 d (alternate sessions) with one flavor in odd days as a positive conditioned stimulus (CS+) when mixed into a protein solution (2% Soybean Protein Concentrate (SPC) or 2% Porcine Digestible Peptides (PDP)) and another flavor on even days (CS-) mixed into a neutral solution (water). Flavor products used (anis or garlic, 0.075%) were paired with each solution and counterbalanced across subjects to act as the CS+ or CS- flavor. Double choice test between the CS+ and CS- flavors were performed at d15 and d22 after weaning (in water) and at d29 after weaning (in feed). Solution and feed intakes were measured after 30 min. Data were analyzed using the GLM procedure of SAS. Preference was calculated as the percentage contribution of the CS+ solution to the total solution intake. Piglets preferred protein-paired flavors at all 3 d; they showed higher preference for the CS+ flavor in the SPC group (55%, 57% and 57%) and PDP group (60%, 62% and 55%) on d 15, 22 and 29, respectively ($P < 0.05$). No differences were observed between the conditioning power of PDP and SPC. The present results indicate that weanling piglets can acquire strong flavor preferences resistant to extinction through conditioning strategies by using protein products. Establishing a preference for a flavored solution by conditioning may enhance intake due to hedonic or post-ingestive effects driven by this association, and this could be a useful strategy to increase voluntary intake in critical periods, such as weaning.

Key words: flavors, conditioning, weaning

260 Influence of length of storage on parameters used to measure the quality of soybean meal. S. Sueiro[1], M. P. Serrano[2], M. González[1], M. Hermida[1], P. G. Rebollar[2], and G. G. Mateos*[2], *[1]Laboratorio de Mouriscade, Pontevedra, Spain, [2]Universidad Politécnica de Madrid, Madrid, Spain.*

Methods used by the Industry to estimate protein quality of soybean meal (SBM) include KOH solubility (KOHsol), protein dispersibility index (PDI), urease activity (UA), and trypsin inhibitor activity (TIA). In general, meals with KOHsol values between 78 and 85%, PDI values between 15% and 35%, and UA values between 0.00 and 0.10 mg/g are considered of acceptable quality. Similarly, TIA values of less than 2.5–4.0 mg/g are considered best. However, there is no agreement among the different Institutions and publications with respect to the more suitable values for these variables in commercial SBM. The reasons for the wide range of values for these variables are not well understood. It is known that protein solubility and TIA changes with the methodology used and explain in part the high variability existing among laboratories. Also, length and environmental conditions during storage might influence protein solubility and thus, KOHsol and PDI values. In a previous study, we observed that protein solubility of SBM samples from the USA or Latin America stored for 24, 48, and 80 wk under room conditions (12–15°C) had significantly lower PDI values than the original SBM. An experiment was conducted to determine the influence of length of storage on different parameters that define the protein quality of SBM. Eight samples (500 g) of SBM (55–56% CP on DM basis) were collected weekly during June–July 2010 directly from the crusher (USA). Samples were analyzed at arrival to the Spanish port and then, every 30 d of storage at 12 ± 2°C and 70 ± 3% humidity. Length of storage did not affect KOHsol, UA, or TIA values. However, PDI values decreased with time (21.8, 21.4, 20.1, 18.7, and 17.7% for 0, 30, 60, 90, and 120 d, respectively; $P \leq 0.001$). Therefore, care should be taken when comparing PDI values to evaluate the protein quality of SBM samples that have been stored for different lengths of time.

Key words: length of storage, soybean meal, protein quality traits

261 Effects of an abrupt change from mash to pellets and vice-versa on growth performance in finishing pigs. C. B. Paulk*[1], J. D. Hancock[1], J. C. Ebert[2], and J. J. Ohlde[2], *[1]Kansas State University, Manhattan, [2]Key Feeds, Clay Center, KS.*

A total of 200 finishing pigs (avg initial BW of 60 kg) were used in a 58-d growth assay to determine the effects of an abrupt change from mash to pellets and pellets to mash on growth performance and carcass measurements. The experiment was designed as a randomized complete block with 5 pigs/pen and 10 pens/treatment. Treatments were mash to mash, mash to pellets, pellets to mash, and pellets to pellets for phases 1 and 2 of the experiment. For phase 1 (d 0 to 36), pigs fed the pelleted diet had 4% greater ADG and 8% greater G:F ($P < 0.02$) compared with pigs fed mash. For phase 2 (d 36 to 58) and overall (d 0 to 58), pigs fed the mash diet had lower ($P < 0.02$) G:F than pigs fed the pelleted treatments. Indeed, pigs fed pellets the entire experiment had ADG and G:F that were 5 and 8% better, respectively, than that of pigs fed mash the entire experiment. Pigs fed mash during phase 1 then pellets during phase 2 had greater ($P < 0.01$) ADG and G:F for phase 2

compared with pigs fed pellets then mash. However, the overall effect was for pigs fed pellets for either phase 1 or 2, but not both, tended to have growth performance intermediate to those fed mash and pellets for the entire experiment. With hot carcass weight used as a covariate, no differences ($P > 0.15$) were observed in dressing percentage, fat thickness, or percentage fat free lean index (FFLI). In conclusion, pigs fed pellets tended to have the greatest growth performance, pigs fed mash the worst, and pigs fed pellets for only part of the grow-finish phase fell in between.

Table 1.

Item	Mash to mash	Mash to pellet	Pellet to mash	Pellet to pellet	SE
Phase 1 (d 0 to 36)					
ADG, g	1,124	N/A	N/A	1,167	23
G:F, g/kg	393	N/A	N/A	423	4
Phase 2 (d 36 to 58)					
ADG, g	1,163	1,230	1,117	1,240	25
G:F, g/kg	403	441	404	431	9
Overall (d 0 to 58)					
ADG, g	1,134	1,168	1,148	1,195	22
G:F, g/kg	393	414	416	426	6
Dress, %	74.6	74.3	74.2	74.4	0.3

262 The effect of weaning group-housed calves over a different length of time fed by automatic feeding machine. K. Shore* and A. Roy, *Grober Nutrition, Cambridge, Ontario, Canada.*

Pre-weaned dairy replacement calves were evaluated for growth and health differences when weaned off of milk replacer from an automatic calf feeding machine over a different number of days. Thirty 6 calves (BW 45.8 ± 3.1 kg; height 82.7 ± 5.3 cm) were used in a 1-way ANOVA model and randomly assigned at arrival to one of 2 treatments: 5 d short weaning (SW) (n = 18), and 10 d long weaning (LW) (n = 18). Calves were housed in 4 groups of 9; 2 groups had access to 1 feeding machine. All calves were offered 9 L of milk replacer (1.35 kg of dry matter) on a daily basis. Milk intakes were recorded; body weights and heights were measured weekly. Health was evaluated daily using an adapted version of the University of Wisconsin calf scoring sheet. Calves were on trial for 10 wk, 8 wk on milk replacer, grain and hay and 2 wk on grain and hay only. Water was offered free choice. Milk intake was not different between treatments before weaning (SW = 7.40 ± 0.71 L; LW = 7.43 ± 0.79 L). Body weight gain was not different between the groups over the entire 10 wk (SW = 51.5 ± 9.9 kg; LW = 55.1 ± 7.8 kg). However, BW gain was greater in the LW group ($P = 0.006$) over the weaning period (SW = 9.7 ± 5.6 kg; LW = 14.2 ± 3.0 kg). The LW group gained more while consuming less milk (SW = 4.45 ± 0.34 L/d; LW = 3.46 ± 0.17 L/d) and more grain (SW = 0.799 ± 0.484 kg/d; LW = 1.38 ± 0.313 kg/d). ADG was not different between treatments during weaning; it was higher in the LW group ($P = 0.04$) post weaning (SW = 0.747 ± 0.456 kg/d; LW = 1.01 ± 0.256 kg/d). There was no difference in height gain. Health was measured by the number of events, there was no difference between treatments during the weaning period; however, the LG group had fewer health events post weaning ($P = 0.04$). In summary, weaning calves over a longer period when fed by automatic feeding machine seemed to encourage higher body weight gains during weaning, improved average daily gains and less health events post weaning.

Key words: calf, group housing, weaning

263 Effect of 72 h temporary calf removal and/or equine chorionic gonadotropin (eCG) before timed AI on follicle development, concentrations of LH and estradiol, and ovulation rate in suckled beef cows. G. H. L. Marquezini*[1], V. R. G. Mercadante[1], J. S. Stevenson[2], G. A. Perry[3], and G. C. Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, [2]Department of Animal Sciences and Industry, Kansas State University, Manhattan, [3]Department of Animal and Range Sciences, South Dakota State University, Brookings.*

We hypothesized that temporary calf removal (CR) and/or eCG at CIDR removal of an ovulation synchronization protocol may improve follicle development and alter patterns of LH, estradiol (E2), and progesterone (P4) secretion. Thirty-five multiparous crossbred cows in a 4.8 (range 4 to 7) BCS, and 29.2 (range 19 to 40) d postpartum, were assigned randomly to treatments: 1) 100 µg GnRH and a CIDR insert (d −7), 25 mg $PGF_{2\alpha}$ (PG) and CIDR removal (d 0), and 72 h later by GnRH and AI (d 3; Control; n = 9); 2) same as Control but calves were removed from their dams for 72 h between d 0 and 3 (CR; n = 9); 3) same as Control but cows received 300 IU eCG on d 0 (eCG; n = 9); 4) same as CR but cows received 300 IU eCG on d 0 (eCGCR; n = 8). Blood samples were collected every 4 h from d 0 to 3 and once on d 10 to determine concentrations of hormones. Transrectal ultrasonography was performed on d 0, 1, 2, 3, 4, and 10 to determine follicle diameters and to confirm ovulation. Control cows had decreased ($P < 0.05$) ovulation incidence compared with COCR, eCG, and eCGCR between d 0 and 4 (22, 78, 67, and 88%, respectively), and between d 0 and 10 (67, 100, 78, 100%, respectively). The COCR and eCGCR treatments had a shorter ($P < 0.05$) interval between PG and LH peak compared with Control, whereas eCG was intermediate (72.4 ± 2.3, 65.3 ± 2.3, 70.2 ± 2.3, and 66.5 ± 2.4 h, for Control, COCR, eCG, and eCGCR respectively). The COCR, eCG, and eCGCR treatments had greater ($P < 0.05$) follicle diameter on d 2 compared with Control (11.9 ± 0.7, 14.1 ± 0.7, 14.7 ± 0.6, and 15.6 ± 1.0 mm, for Control, COCR, eCG, and eCGCR, respectively) and concentrations of P4 on d 10 (1.4 ± 0.4, 2.7 ± 0.4, 2.7 ± 0.4, and 2.8 ± 0.4 ng/mL for Control, COCR, eCG, and eCGCR, respectively). We conclude that CR reduced the interval to the LH peak and both CR and eCG at CIDR removal enhanced follicle growth, ovulation incidence, and P4 concentrations in early postpartum suckled beef cows.

Key words: equine chorionic gonadotropin, calf removal, beef cows

264 Evidence that prostaglandin administration at the onset of a 5-day CO-Synch + CIDR synchronization protocol markedly improves fixed-time AI pregnancy rates in *Bos indicus*-influenced cattle. G. Williams*[1,2], R. Stanko[1,3], C. Allen[1,2], R. Cardoso[1,2], L. Prezotto[1,2], J. Thorson[1,2], and M. Amstalden[2], *[1]Texas AgriLife Research, Beeville, [2]Texas A&M University, College Station, [3]Texas A&M University-Kingsville, Kingsville.*

Protocols in the US for synchronization of ovulation and fixed-time AI (TAI) in beef cattle have emphasized recently the combined use of the controlled intravaginal drug-releasing insert (CIDR), GnRH and prostaglandin F-2α (PG) or its analogs. Together, these can be used effectively to control the corpus luteum (CL) and synchronize a new follicular wave in *Bos taurus* females. Using the 7-Day CO-Synch + CIDR (7-Day) or 5-Day CO-Synch + CIDR (5-Day) protocols, TAI pregnancy rates in *Bos taurus* beef cows often exceed 50% (7-Day), and frequently exceed 60% (5-Day). However, use of the 7-Day protocol in *Bos indicus*-influenced cattle has resulted consistently in TAI pregnancy rates of <40%. Initial objectives were to determine whether the 5-Day protocol in *Bos indicus*-influenced beef cows could improve TAI pregnancy rates compared with historical rates obtained with 7-Day. In Exp. 1, 79 postpartum (PP) Braford cows at least 45 d postpartum at TAI and BCS ≥ 5, and 21 nulliparous Braford and Brangus heifers (BCS ≥ 5), were administered the 5-Day protocol [5-Day CIDR; 2x PG (50 mg Lutalyse; Pfizer) at CIDR removal on Day 5; TAI + 100 Âµg GnRH 72 h later]. Pregnancy rate to TAI was not improved (cows, 30.3%; heifers, 42.9%) relative to 7-Day. In Exp. 2, we compared the standard 5-Day procedure to the 5-Day in which PGF was administered at CIDR insertion to regress mature CL (Bee Synch + CIDR; Bee Synch). *Bos indicus*-influenced beef cows (n = 150) as in Exp. 1 were stratified by days PP and assigned randomly to receive either the standard 5-Day or Bee Synch protocol. Pregnancy rate to TAI was greater ($P < 0.05$) in Bee Synch (52.4%) than in 5-Day (35.7%). In Exp. 3, 119 Braford and Brangus cows were treated with Bee Synch, with TAI at 66 h. Pregnancy rate to TAI was 52.1%. Eliminating data from a pasture containing cows (n = 37) having extreme temperaments increased pregnancy rate to 58% (n = 98). Results indicate a marked benefit of Bee Synch in *Bos indicus*-influenced cattle, with number of times through the chute remaining at 3.

Key words: 5-day CO-Synch + CIDR, prostaglandin, *Bos indicus*

265 Determination of appropriate delivery of $PGF_{2\alpha}$ in the 5-day Co-Synch + CIDR protocol in lactating beef cows. G. A. Bridges*[1], L. H. Cruppe[2], J. F. Currin[3], M. L. Day[2], P. J. Gunn[4], J. R. Jaeger[5], G. C. Lamb[6], A. E. Radunz[7], P. Repenning[8], J. S. Stevenson[5], J. C. Whittier[8], and W. D. Whittier[3], *[1]University of Minnesota, [2]The Ohio State University, [3]Virginia Tech, [4]Purdue University, [5]Kansas State University, [6]University of Florida, Marianna, [7]University of Wisconsin, Madison, [8]Colorado State University.*

The objective of this experiment was to determine if 2 doses of $PGF_{2\alpha}$ (PG) administered at CIDR removal was an efficacious method for delivery of PG in the 5-d CO-Synch + CIDR protocol. Postpartum beef cows (n = 2465; 67 ± 0.4 dpp) from 13 herds in 8 states were enrolled in the 5-d CO-Synch + CIDR protocol and assigned to receive either 2 doses of PG (25 mg/dose) 8 h apart with the initial injection given at CIDR removal (8hPG), 2 doses (25 mg/dose) of PG delivered in 2 injection sites with both administered at CIDR removal (CoPG), or a single 25-mg dose of PG at CIDR removal (1xPG). Cows were TAI 72 h after CIDR removal at second GnRH administration. Estrous cycling status (54% cyclic) was determined by evaluation of progesterone in 2 blood samples taken on d −10 and 0 relative to CIDR insertion. Determination of pregnancy was performed by transrectal ultrasonography 39 ± 0.1 d after TAI and after the conclusion of the breeding season. Data were analyzed with the Glimmix procedure of SAS, where herd was included as a random effect. Timed AI pregnancy rates were greater ($P < 0.05$) for the 8hPG (55%) than the 1xPG (48%) treatment, with the CoPG (51%) treatment intermediate and not different from the other treatments. Contrast analysis demonstrated that cows receiving 50 mg of PG (8hPG and CoPG) had greater ($P < 0.05$) TAI pregnancy rates than those receiving 25 mg (1xPG). Pregnancy rates to TAI were greater ($P < 0.05$) in cyclic (55%) than non-cyclic (47%) and greater ($P < 0.05$) in mature (≥3 y of age; 54%; n = 1940) than 2-y-old cows (40%; n = 525). Luteolysis following PGF treatment was assessed in a subset of cows (n = 277) and did not differ ($P = 0.13$)

among the 8hPG (96%), CoPG (93%), and 1xPG (88%) treatments. Breeding season pregnancy rates (88%) did not differ among treatments but was greater ($P < 0.01$) in mature (90.4%) than 2-y-old cows (77.7%). In summary, 50 mg of PG was required in the 5 d CO-Synch + CIDR protocol; however, TAI pregnancy rates did not differ when 50 mg of PG was administered simultaneously with CIDR removal or at 0 and 8 h following CIDR removal.

Key words: beef cow, estrus synchronization, prostaglandin

266 Comparison of long-term progestin-based protocols to synchronize estrus and ovulation prior to fixed-time AI in postpartum beef cows. J. M. Nash*, D. A. Mallory, C. C. Selby, T. M. Taxis, M. R. Ellersieck, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

We compared follicular dynamics, ovulatory response to GnRH, steroid hormone concentration patterns, and synchrony of estrus and ovulation among estrous–cycling and anestrous postpartum beef cows after treatment with 2 long–term progestin–based protocols. Beef cows (n = 38) were assigned to treatments based on age, days postpartum (DPP), BCS and estrous cyclicity status. CIDR Select (T1, n = 19) treated cows received a controlled internal drug release insert (CIDR; 1.38 g of progesterone) from d 0 to 14 followed by GnRH (100 μg, i.m.) on d 23, and prostaglandin $F_{2\alpha}$ (PG; 25 mg, i.m.) on d 30. Cows assigned to the Show–Me–Synch (T2, n = 19) treatment received a CIDR insert from d 0 to 14 and PG on d 30. Blood samples were taken on d −8 and 0 of treatment to determine estrous cyclicity status (progesterone ≥ 0.5 ng/mL). HeatWatch estrus detection transmitters were fitted one day before CIDR removal for continuous estrus detection. Ultrasound was used to determine response to GnRH for T1 treated cows or follicle turnover for T2 treated cows coincident with timing of GnRH for T1; follicle size at GnRH, PG and AI; and pregnancy diagnoses. AI was performed 72 h after PG for cows in each treatment and all cows were administered GnRH at AI. Follicle turnover on d 25 was higher among T1 than T2 treated cows ($P < 0.001$); however, progesterone at PG did not differ between treatments ($P = 0.64$). Mean dominant follicle diameter at GnRH and AI did not differ between treatments ($P > 0.05$), but T2 treated cows had larger follicles at PG than cows in T1 ($P = 0.06$). Estrous response after CIDR removal and PG did not differ between treatments; and variances for interval to estrus after CIDR removal and PG were similar for both treatments. T2 treated cows had higher pregnancy rates resulting from FTAI and final pregnancy rates than T1 treated cows ($P = 0.05$). In summary, future studies are needed to further evaluate long-term progestin based protocols in postpartum beef cows. This project was supported by National Research Initiative Competitive Grant no. 2005–55203–15750 from the USDA National Institute of Food and Agriculture.

Key words: fixed-time AI, beef cow, CIDR

267 Comparison of long- versus short-term progestin-based protocols to synchronize estrus and ovulation prior to fixed-time AI in postpartum beef cows. J. M. Nash*, D. A. Mallory, M. R. Ellersieck, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment compared pregnancy rates in postpartum beef cows resulting from fixed–time AI (FTAI) after treatment with controlled internal drug release (CIDR)–based protocols to synchronize estrus and ovulation. Angus cows were assigned to one of 2 treatments by age, days postpartum (DPP) and BCS. Cows assigned to the 14-d CIDR-PG (Show-Me-Synch; T1, n = 167) treatment received CIDR inserts (1.38 g of progesterone) from d 0 through 14 followed by administration of prostaglandin $F_{2\alpha}$ (PG, 25 mg, i.m.) on d 30. Cows assigned to the 7-d CO-Synch + CIDR treatment (T2, n = 177) received GnRH (100 μg, i.m.) and CIDR inserts on d 0. CIDR inserts were removed 7 d later at the time PG was administered (d 7). Blood samples were collected on d −10 and 0 of treatment to determine pretreatment estrous cyclicity status of cows (progesterone ≥ 0.5 ng/mL estrous cycling; T1, 97/167 = 58%; T2, 96/177 = 54%). Continuous estrus detection was performed using HeatWatch beginning at PG and concluding at FTAI. AI was performed at predetermined fixed times (72 h, T1; 66 h, T2) and all cows were administered GnRH at AI. There were no differences between treatments for age, BCS, or DPP. Pregnancy rates resulting from FTAI did not differ ($P > 0.10$) between technicians; AI sires; or on the basis of pretreatment estrous cyclicity status. Pregnancy rates were greater ($P < 0.01$) among cows that exhibited estrus before FTAI than for those that did not (91/124 = 73% and 99/220 = 45%, respectively). However, anestrous cows in T1 were 2 times more likely to become pregnant to FTAI than to not become pregnant. Pregnancy rates resulting from FTAI did not differ between treatments ($P = 0.87$; T1 91/167 = 55%, T2 99/177 = 56%) and neither did final pregnancy rates ($P = 0.49$; T1 147/167 = 88%, T2 160/176 = 91%). In summary, pregnancy rates resulting from FTAI following treatment with T1 and T2 were similar among postpartum beef cows. This project was supported by National Research Initiative Competitive Grant no. 2005–55203–15750 from the USDA National Institute of Food and Agriculture.

Key words: fixed-time AI, beef cow, CIDR

897 Estrogenicity of sugar beet by-products used as animal feeds. N. W. Shappell*[1], E. M. Lenneman[1,2], and M. S. Mostrom[2], *[1]USDA-ARS, Fargo, ND, [2]North Dakota State University, Fargo.*

A veterinarian conducting embryo transfer observed reduction in transfer success rates on both a beef and dairy farm in Minnesota, which were both feeding sugar beet by-products. Beet tailings and pelletized post-extraction beet pulp purchased commercially were submitted for analysis of estrogenicity by E-Screen (proliferative assessment of non-transfected MCF-7 BOS cells). Samples were found to be estrogenic, with pelletized sample containing ~4 fold the estradiol equivalents of the unprocessed sample (3.8 and 1.2 E^2Eq μg/kg DM, respectively). Samples of whole beets, beet pellets and shreds were then obtained from several Midwest US locations, dried, extracted, and assessed for estrogenicity. All pellets examined were found to be estrogenic, with a wide range of concentrations (0.1 – 2.0 μg E^2Eq/kg dry matter) a mean of 0.46 μg, and median of 0.28 μg (n = 9). Relative E^2Eq for the other sample types ranked as follows: pellets > shreds (n = 3) > most unprocessed plant material (n = 7). These by-products are sold both within the United States and abroad, and are used as feed predominantly for cattle (both beef and dairy), but also for horses and elk. Using the recommended feeding regimen guidelines for these feedstuff cattle could consume 0.3 to 6.8 μg E^2Eq per day, however, these guidelines are often exceeded for financial reasons. Calculating possible blood concentrations from consumption of by-product containing 5 μg E^2Eq, a conservative estimate of 10% absorption, and 500 kg body weight, the resultant 12.5 pg/mL E^2Eq is similar to the 10 pg/mL estradiol typical of cows during estrus.

Key words: MCF-7, estrogenicity, fertility

268 Effect of length of the preovulatory period on estradiol, progesterone, ISG-15 and Mx2 in cows. L. H. Cruppe*[1], L. A. Souto[1], M. Maquivar[1], F. M. Abreu[1], M. L. Mussard[1], T. L. Ott[2], J. L. Pate[2], and M. L. Day[1], *[1]The Ohio State University, Columbus, [2]The Penn State University, State College.*

Postpartum primiparous beef cows (n = 23) were used to investigate the effect of preovulatory estradiol concentrations (Pre-E2) on ISG-15 and Mx2 mRNA expression in peripheral blood mononuclear cells (PBMC) from d 15 to 30 after ovulation. Estrus was synchronized, follicular aspiration was performed 5.5 ± 0.1 d later (d −7 of experiment) and cows received 25 mg PGF2α on either d −3 (high estradiol treatment; Hi-E), or on d −2 (low estradiol treatment; Lo-E). All cows received 100 μg of GnRH on d 0, creating a preovulatory period of either 3 or 2 d. Ultrasonography was performed on d −7, −3, 0, 2 and 6 to monitor follicular growth, ovulation and CL formation after GnRH. Blood samples collected at 12 h intervals from d −3 to d −0.5 and at d −0.25 and d 0 were used to determine Pre-E2. Blood samples collected every other day from d −3 to 13 were analyzed for progesterone (P4). Daily samples, collected from d 14 to 30, were processed for both P4 and mRNA analysis in PBMC. Embryos were implanted into cows in the Hi-E (Hi-E-ET, n = 6) and Lo-E (Lo-E-ET, n = 9). Cyclic control animals did not receive embryos (Hi-E-0, n = 4; Lo-E-0, n = 4). Gene expression was determined using RT-PCR for ISG-15 and Mx2. Diameter of the ovulatory follicle (13.4 ± 1.1 mm) did not differ between treatments. While Pre-E2 were greater ($P < 0.05$) in the Hi-E than Lo-E on d −2.5 and −2, they did not differ thereafter, and appeared to peak and then decline in most animals before GnRH. Furthermore, luteal P4 did not differ between Hi-E and Lo-E. Relative amount of mRNA did not differ between the Hi-E and Lo-E, but was greater in pregnant than cyclic cows for both ISG-15 and Mx2 after d 18 through d 30. A biphasic pattern of gene expression was observed for both ISG-15 and Mx2, where maximum amounts of gene expression in pregnant cows was detected by d 20 followed by a decrease, increase and finally a second decrease to d 30. In conclusion, decreasing the length of the preovulatory period appeared not to limit Pre-E2 in this study. Greater amounts of mRNA for ISG-15 and Mx2 were detected in pregnant cows after d 18 and followed a biphasic pattern thereafter to d 30

Key words: estradiol, ISG-15, Mx2

269 Effect of follicle age on conception rate in beef heifers. F. M. Abreu*[1,2], L. H. Cruppe[1], M. Maquivar[1], M. D. Utt[1], C. A. Roberts[2], M. L. Mussard[1], M. L. Day[1], and T. W. Geary[2], *[1]The Ohio State University, Columbus, [2]USDA-ARS Fort Keogh LARRL, Miles City, MT.*

The objective of this study was to determine the effect of age of the ovulatory follicle on fertility. Ovulation (d 0) was synchronized in post pubertal heifers in Montana (n = 153; MT) and Ohio (n = 152). All heifers received estradiol benzoate (EB; 1mg/500kg BW) on d 6 and were assigned to either receive PGF (25 mg, i.m.) 5 d (d 11 of the experiment; "young" follicle, YF, n = 154) or 9 d (d 15 of the experiment; "mature" follicle, MF, n = 151) after EB. Estrus was detected for 5 d after PGF with AI approximately 12 h after estrus. Ovarian ultrasonography (MT only) was performed on d 6, 11, 15 (MF only) and at AI. Heifers that failed to initiate a new follicular wave after EB (MT only) were excluded from further analyses (n = 11). Heifers from the MF treatment in MT that initiated a second follicular wave after EB, but before PGF on d 15 (n = 14, MF2) remained in the analyses. Estrous response and conception rate were analyzed using a model that included location, treatment, and their interaction, with the GLIMMIX procedure of SAS. Interval from PGF to estrus was analyzed with the MIXED procedure of SAS. In a second analysis, heifers with 2 follicular waves after EB (MF2) were compared with the MF heifers with one wave, and the YF treatment in MT. Interval from PGF to estrus was similar between treatments in MT (65.5 ± 1.6) but was greater ($P < 0.05$) in the YF (78.5 ± 1.4) than MF (53.6 ± 2.2) treatment in OH (trt x loc, $P < 0.01$). Estrous response (89%) and conception rate did not differ ($P > 0.10$) for MF (64.1%) and YF (67.2%) heifers. The MF2 heifers in MT had a greater ($P < 0.01$) interval to estrus and smaller ($P < 0.01$) ovulatory follicles at AI than MF heifers with a single follicular wave after EB. When MF2 heifers were removed from analyses, interval from PGF to estrus in MT was greater ($P < 0.01$) but follicle diameter was smaller ($P = 0.01$) in YF than MF heifers. Furthermore, this interval was similar for MF heifers between locations (54.6 ± 1.7), but was greater ($P < 0.01$) for YF heifers in OH (78.5 ± 1.4) than MT (67.4 ± 1.5). In conclusion, manipulation of age of the ovulatory follicle at spontaneous ovulation did not influence conception rate.

Key words: follicle age, heifers, conception rate

270 Effect of various doses of prostaglandin $F_{2\alpha}$ on estrous behavior and blood progesterone in beef cows. A. Ahmadzadeh*, K. Carnahan, T. Robison, and C. Autran, *University of Idaho, Moscow.*

Research indicates that 2 doses of prostaglandin $F_{2\alpha}$ (PGF), rather than one dose of PGF increased pregnancy rates when utilized with a 5-d CO-Synch + CIDR protocol. The objectives were to determine the effect of 3 PGF treatment protocols on estrual behavior and serum progesterone (P4) concentrations of suckled beef cows synchronized with a modified 5-d CO-Synch + CIDR protocol. The experiment was conducted over 2 consecutive breeding seasons. Ninety-seven Charolais cows received a CIDR (d 0) for 5 d. On d 5 CIDR's were removed, and cows were assigned randomly to receive one of 3 treatments; 1) Control; a single injection of 25 mg PGF (dinoprost tromethamine; n = 32), 2) Large; a single injection of 37.5 mg PGF (n = 32), or 3) Split; 2 injections of 12.5 mg PGF 7 h apart (n = 33). All cows were fitted with estrus detection aids, observed for behavioral estrus at least 3 times daily, and inseminated according to the am- pm rule after detected in estrus. Animals that were not detected in estrus received 100 μg GnRH and timed AI 96 h after PGF injection. Blood was collected on d 0 and d 7 (56 h after PGF treatment) to measure P4 concentrations. There was no effect of treatment by year interaction on any dependent variable. Mean P4 concentration on d 0 was not different between treatments. At 56 h post-PGF treatment, mean P4 concentrations were < 1 ng/mL for all groups and were not different between treatments. The mean interval from PGF treatment to detected estrus was different ($P < 0.05$) among treatments: Control = 60.5 ± 3.4 h, Large = 64.0 ± 2.8 h and Split = 52.8 ± 2.8 h. The proportion of cows detected in estrus was different between treatments ($P < 0.05$) and were 65.6, 84.4, and, 90.5%, for Control, Large, and Split groups, respectively. These results indicate that either 2 injections of 12.5 mg PGF 7 h apart or a single injection of 37.5 mg PGF effectively causes luteolysis 56 h post PGF treatment. However, the split dose of 2 injections of 12.5 mg PGF 7 h apart shortened the intervals from treatment to estrus, and increased proportion of cows detected in estrus.

Key words: beef cows, prostaglandin $F_{2\alpha}$, estrus

271 The use of ruminal temperature for the prediction of estrus in beef cows. B. H. Boehmer*, T. A. Pye, and R. P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater.*

Ruminal temperature (RuT) is a measure of core body temperature and can be used for identification of physiological events in beef cows. The usefulness of RuT for predicting estrus, parturition, heat stress, and animal health may be influenced by elevated ambient temperature. Ruminal temperature increases when cows are exposed to an ambient temperature greater than 32°C. The objective of this experiment was to evaluate the use of RuT to predict estrus in beef cows in June and July. Angus cows (n = 58) were administered ruminal temperature boluses (SmartStock, LLC.) which were programed to transmit every hour. Cows were synchronized with $PGF_{2\alpha}$ at 60 to 90 d postpartum. Onset of estrus was determined as an increase of 0.7°C in RuT during 8 h compared with the preceding 72 h. Cows were artificially inseminated 8 to 16 h after estrus was determined by RuT. Progesterone was quantified daily in plasma samples and onset of estrus was recorded by HeatWatch (CowChips, LLC.). Ambient temperature was recorded hourly (www.mesonet.org). Ruminal temperature was evaluated using the MIXED procedure (SAS). Maximum daily ambient temperature was 27.5 ± 3.9°C (range 19 to 35°C). Mean RuT for all cows was 38.5 ± 0.8°C. Ruminal temperature was greater ($P < 0.05$) during the 8 h at the onset of estrus when determined by RuT or HeatWatch (39.2 ± 0.1°C, 38.8 ± 0.1°C, respectively) compared with the same daily hours the day before (38.5 ± 0.1°C, 38.4 ± 0.1°C) or after (38.7 ± 0.1°C, 38.4 ± 0.1°C) onset of estrus. Ruminal temperature correctly identified estrus in 33 of 58 cows as determined by HeatWatch. Ruminal temperature determined that the onset of estrus was within 24 h of the onset of estrus as determined by HeatWatch in 62% of the cows. Based on plasma concentrations of progesterone, RUT identified estrus in 57% of cows and 43% of non estrous cows were identified as estrus. Pregnancy rate was 40% when estrus was identified by RUT and cows were AI. Elevated ambient temperature may influence the usefulness of RuT to detect estrus in beef cows.

Key words: ruminal temperature, estrus, beef cow

272 Effect of acetylsalicylic acid on vasodilatation of uterine arteries, right external iliac arterial blood flow, and pregnancy in beef cows. H. L. Sanchez-Rodriguez*, R. C. Vann, E. Baravik-Munsell, S. T. Willard, and P. L. Ryan, *Mississippi State University, Mississippi State.*

B-mode and Duplex Doppler ultrasound were used to determine the effects of acetylsalicylic acid (ASA) on uterine arteries diameter, external iliac artery Resistance Index (RI), and subsequent pregnancy rate in open, cycling Angus crossbred cows [4.27 ± 1.22 yr old; 568.76 ± 46.56 kg BW (mean ± SD)]. Acetylsalicylic acid (2,500 mg, ASA; n = 19) was administered twice daily in the feed from d −9.5 to 45 (d 0 = AI date). Control cows (CN; n = 19) received 5 g/d of dry molasses in flakes (placebo) in the feed during the same period. Dimensions of both uterine arteries were recorded once daily during d −10.5, −2.5, 0, 3, 6, 10, 16, 20, 25, 32 in a subsample of 16 cows (8/treatment). Pregnancies were confirmed at d 45 post AI. Jugular vein blood samples were collected after each ultrasound sampling for serum progesterone, and plasma prostaglandin F2α and prostaglandin E2 analyses. No difference ($P = 0.31$) in the diameter was observed between right and left side uterine arteries within a cow. In general, cows receiving ASA had larger diameter of uterine arteries than cows receiving the placebo (4.67 ± 0.04 and 4.54 ± 0.04 mm, respectively; $P = 0.01$). Uterine arterial diameters were larger in the ASA than in CN cows during sampling d −2.5 (4.61 ± 0.12 vs. 4.23 ± 0.12 mm; $P = 0.03$) and d 0 (4.52 ± 0.12 vs. 4.10 ± 0.10 mm; $P = 0.04$). During sampling d 10, ASA cows tend to have larger uterine arterial diameter values than did CN cows (4.86 ± 0.18 and 4.41 ± 0.16 mm, respectively; $P = 0.06$). Acetylsalicylic acid-treated cows achieved a pregnancy rate ($P = 0.18$) of 73.7% (14/19) in comparison with 52.6% (10/19) for CN cows. In a subsample of 12 cows (6/treatment), the RI in the right external iliac artery was recorded. The RI values were higher ($P = 0.04$) in the ASA-treated compared with the CN cows (0.78 ± 0.02 and 0.72 ± 0.02, respectively).These preliminary findings demonstrate that treatment with acetylsalicylic acid improves uterine arterial blood perfusion in beef cows and thus, may be an economical means of enhancing reproductive efficiency in postpartum cows.

Key words: acetylsalicylic acid, beef cows, blood flow

273 Antimicrobial resistance and prevalence of virulence factor genes in fecal *Escherichia coli* of Holstein calves fed milk with and without antimicrobials. R. V. V. Pereira*, T. M. A. Santos, M. L. Bicalho, V. S. Machado, R. C. Bicalho, and L. S. Caixeta, *Department of Population Medicine and Diagnostic Science, College of Veterinary Medicine, Cornell University, Ithaca, NY.*

Diarrhea in calves has a significant impact on the dairy industry. A common management practice for preventing and reducing diarrhea in preweaned calves is by adding antimicrobials in the milk. In this study, *Escherichia coli* antimicrobial resistance in fecal samples collected from calves 2 to 8 d of age that had received or not received antimicrobials in the milk and that presented or did not present signs of diarrhea were investigated. Resistance of *E. coli* isolates to individual antimicrobials, multiresistance patterns, and presence of virulence factors were analyzed. *E. coli* isolates were tested for 12 antibiotics, by use of a Kirby-Bauer disk diffusion assay, and categorized as susceptible, intermediate or resistant according to interpretive breakpoints described previously. The study was conducted at 3 farms, one administering antimicrobials (GPA) in the milk (n = 154) and 2 not adding antimicrobials in the milk (NGPA) (n = 97). To analyze the effect of GPA on the inhibition zone diameter a general linear model was fitted to the data using the MIXED procedure of SAS (SAS Inst., Cary,NC). Ordinal logistic regression models, one for each antibiotic, were fitted to the data using the ologit procedure of STATA (STATA 9.2, Statacorp, TX).Chi-squared tests were performed in Jump® (SAS Inst., Cary,NC) to assess the difference in the presence of genes encoding virulence factors between isolates. For all statistical models and tests, variables were considered statistically significant when a $P < 0.05$ was observed. All isolates were susceptible to ciprofloxacin and cefepime. From the total isolates tested, 84% (n = 251) were resistant to at least 2 antimicrobials and 81% (n = 251) were resistant to 3 or more antimicrobials. When antimicrobial resistance was compared between GPA and NGPA, it was observed that the GPA group had higher odds of antimicrobial resistance for most of individual antimicrobial tested. No significant correlation of virulence factors in GPA or NGPA and diarrheic or non-diarrheic fecal samples was found.

274 Somatic cell count and management benchmarks in Minnesota dairy herds. R. F. Leuer* and J. K. Reneau, *University of Minnesota, St. Paul.*

Dairy Herd Improvement Association (DHIA) tests provide a large amount of information about herd milk production and milk quality. Many guidelines have been given about farm SCC performance and its relationship to mastitis and milk quality, however, statistics quantifying that association is lacking. The objective of this study was to investigate the relationship between herd SCC level and performance rank for mastitis and milk quality benchmarking on dairy farms. Minnesota DHIA monthly average herd records were collected from January 2007 to November 2010. Herd tests without SCC information were removed and only herds with an average of 10 tests per year were included. Herds were divided into 4 categories based on average herd SCC over the collection period. Low herds (L) with less than 200,000 SCC (n = 325), medium low (ML) herds between 200,000 and 300,000 SCC (n = 547), medium high herds (MH) herds between 300,000 and 400,000 SCC (n = 470), and high herds (H) above 400,000 SCC (n = 438). Monthly records (n = 66,296) were analyzed using PROC GLM with significant differences determined at $P < 0.05$ using Tukey's multiple comparisons test. The 4 categories were all significantly different in average SCC (L = 157,000, ML = 251,000, MH = 350,000, H = 513,000), average of total cows on test day (L = 116, ML = 141, MH = 110, H = 86), percent infected (L = 16.4, ML = 24.7, MH = 32.9, H = 43.4), percent of current cows with new infections (L = 8.1, ML = 10.5, MH = 12.5, H = 14.2), percent of fresh cows with chronic infections (L = 6, ML = 11.2, MH = 17.6, H = 27.4), percent of current cows with chronic infections (L = 8.3, ML = 14.2, MH = 20.4, H = 29.2), percent infected <30 d in milk (L = 1.7, ML = 2.3, MH = 2.8, H = 3.3), percent infected between 30 and 220 d in milk (L = 7.7, ML = 11.7, MH = 15.4, H = 20), percent infected >220 d in milk (L = 7, ML = 10.7, MH = 14.7, H = 20.1), percent of herd >220 d in milk (L = 35.4, ML = 36.7, MH = 38.5, H = 40.5), rolling herd average (RHA) milk production (L = 10,351, ML = 9,944, MH = 9,201, H = 8,440 kg), RHA protein production (L = 315, ML = 304, MH = 284, H = 263 kg), and RHA fat production (L = 386, ML = 371, MH = 348, H = 325 kg). The 4 categories demonstrated differences that contribute to herd SCC.

Key words: benchmarking, DHIA, SCC

275 Heritability of rectal temperature and genetic correlations with production and reproduction traits in dairy cattle. S. Dikmen*[1], J. B. Cole[2], D. J. Null[2], and P. J. Hansen[3], *[1]Department of Animal Science, Faculty of Veterinary Medicine, Uludag University, Bursa, Turkey, [2]Animal Improvement Programs Laboratory Agricultural Research Service, USDA, Beltsville, MD [3]Department of Animal Sciences, University of Florida, Gainesville.*

Heat stress affects production and reproduction in dairy cattle. Genetic selection for body temperature might help to decrease the effects of heat stress on those traits. Objectives of the current study were a) to estimate genetic parameters of rectal temperature in dairy cows under heat stress conditions, and b) to determine genetic and phenotypic correlations of rectal temperature with production and fitness traits. Rectal temperature was measured between 1500 and 1700 h in 1,695 lactating Holstein cows sired by 509 bulls during the summer in north central Florida. Genetic parameters were estimated with GIBBS1F90 and breeding values were estimated with MTDFREML. The heritability of rectal temperature was estimated as 0.21. Annual genetic trend for rectal temperature was positive and increased 0.000068 oC/year from birth year 2002 to 2008. Genetic correlations of rectal temperature with other traits were close to zero. However, 305-d actual somatic cell score (SCS) was positively correlated ($r = 0.056 \pm 0.024$, $P < 0.05$) with rectal temperature. On the other hand, productive life ($r = -0.058 \pm 0.024$, $P < 0.05$), daughter pregnancy rate ($r = -0.036 \pm 0.024$, $P < 0.05$) and net merit ($r = -0.030 \pm 0.024$, $P < 0.05$) were negatively correlated with rectal temperature. Phenotypic correlations among rectal temperature and production traits were positive and often significant. In conclusion, rectal temperature during heat stress is moderately heritable and generally does not have strong genetic correlations with economically important traits. Selection for rectal temperature would result an increase in health and fitness traits without adversely affecting production traits.

Key words: heritability, dairy cattle, rectal temperature

276 Analysis of twinning, abortion and calf mortality in Irish Holstein and Friesian populations. A. M. Doyle[1], R. D. Evans[2], and

A. G. Fahey*[1], [1]*University College Dublin, Belfield, Dublin 4, Ireland,* [2]*Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland.*

Twinning is associated with unfavorable effects such as lower calf survival, dystocia, increased incidence of retained placentas, occurrence of freemartins and longer calving intervals. However twinning in dairy animals is also associated with increased milk production and the potential for obtaining more progeny from genetically superior females. The objective of this study was to determine the factors associated with twin births, stillbirths, abortion, and calf death before 28 d of age in the Irish Holstein and Friesian populations. Data were obtained from the Irish Cattle Breeding Federation and consisted of calving and mortality records from Holstein (n = 1,388,840) and Friesian animals (n = 217,786) in Ireland from 2004 to 2009. Logistical regression was used to determine factors associated with twinning, stillbirths, abortions and calf death before 28 d of age. The twinning rate was 2.1% for Holsteins and 2.4% for Friesians. Twinning increased as the parity of the dam increased (odds ration (OR) = 2.13 for Holstein parity 5 vs. Parity 1; OR = 2.24 for Friesian parity 5 vs. Parity 1). Season affected twinning rate, with an increase in the rate of twins born in summer for both Holstein (OR = 1.45 summer vs. winter) and Friesian animals (OR = 1.32 summer vs. winter). Calf stillbirth was higher for twins births than for single births in Holstein (OR = 5.33 twin vs. single birth) and Friesian animals (OR = 4.63 twin vs. single birth). Calving difficulty greatly influenced the odds of stillbirth occurring, particularly in twins births, where Holstein (OR = 10.33 calving score 4 vs. calving score 1) and Friesian (OR = 12.44 calving score 4 vs. calving score 1). Abortion is also more likely for twin births than single births for in Holstein animals (OR = 2.72 twin vs. single birth). Season of birth, year or birth and dam parity also effected the odds of abortion occurring. The odds of calf death before 28 d was increased for twin births when compared with singles and were also affected by dam parity, season, sex of calf and year of calving. These results could be used in herd management to minimize the incidence of twins and calf mortality in the dairy herd.

Key words: twinning, mortality, abortion

277 Nation-wide evaluation of quality and composition of colostrum fed to dairy calves in the United States K. M. Morrill*[1], E. Conrad[1], A. Lago[2], J. D. Quigley[2], and H. D. Tyler[1], [1]*Iowa State University, Ames,* [2]*APC Inc., Ankeny, IA.*

The objective of this study was to characterize the quality (IgG and nutrient content) of maternal colostrum (MC) fed to newborn dairy calves in the United States. Samples of MC (n = 827) were collected immediately before feeding from 67 farms in 12 states between June and October, 2010. Samples were collected from Holsteins (n = 494), Jerseys (n = 87), crossbred (n = 7) and unidentified cattle (n = 239) from 1st (n = 49), 2nd (n = 174), 3rd and later (n = 128) and unknown (n = 476) lactations. Samples were identified as fresh (n = 196), refrigerated (n = 152) or frozen (n = 479) before feeding. Samples of MC were analyzed for IgG by radial immunodiffusion (Triple J Farm; Bellingham, WA), protein, fat, lactose, other solids, total solids and somatic cell count (Dairy Laboratory Service; Dubuque, IA). IgG in MC ranged from <1 to 200 mg/ml, with a mean IgG concentration of 68.8 mg/ml (SD = 32.8). Thirty percent of MC was < 50 mg of IgG/ml. IgG concentration increased ($P < 0.05$) with parity (42.4, 68.6, 95.9 mg/ml in 1st, 2nd, and 3rd and later lactations, respectively). No differences in IgG were observed across breeds or storage method. Fat content ranged from 1.0 to 21.7% with a mean content of 5.6% (SD = 3.2). Protein ranged from 2.6 to 20.5%, with a mean content of 12.7% (SD = 3.3). Lactose content ranged from 1.2 to 4.5%, with a mean content of 2.9% (SD = 0.5). No nutritional differences were observed across breed; however fat content was greater ($P < 0.05$) in MC from 1st lactation compared with other lactations (6.6, 4.2 and 5.1%, respectively). Lactose and total solids were greater ($P < 0.05$) in MC from 1st and 3rd+ lactation cows compared with 2nd lactation cows. Somatic cell count (SCC) ranged from 6,000 to 20,901,000 cells/ml with a mean of 2,531,655 cells/ml. Log SCC decreased ($P < 0.05$) from 1st to 2nd and 2nd to 3rd+ lactation MC (5.9, 5.6 and 5.3, respectively). These data suggest that a minimum of 30% of dairy calves are currently being fed colostrum classified below industry standards for IgG content (<50 mg/ml), and are at a greater risk of failure of passive transfer, mortality and morbidity.

Key words: colostrum, calves, passive transfer

278 Milk production and somatic cell counts: A cow level analysis. K. J. Hand*[1], A. Godkin[2], and D. F. Kelton[3], [1]*Strategic Solutions Group, Puslinch, ON, Canada,* [2]*Ontario Ministry of Agriculture, Food and Rural Affairs, Elora, ON, Canada,* [3]*University of Guelph, Guelph, ON, Canada.*

The objectives of this study were to determine milk loss at the lactation and 24 h level due to subclinical and clinical mastitis. Milk loss was determined by quantifying the relationship between 24 h milk yield (kg) and somatic cell count (SCC, 103 cells / ml) in a cow level analysis. Milk production as a risk factor was also examined. The study data consisted of test day records for the year 2009 from 2835 Holstein herds in Ontario, Canada. The average herd size was 73 animals. Data were model in 2 stages, beginning with a general linear model to estimate the change in 24 h milk (kg) per unit change in ln(SCC), (b1LSCC), accounting for the effects of 24 h fat production (kg), days in milk (DIM) and the quadratic effect of DIM for every animal in the study. In stage 2, the estimated b1LSCC's were analyzed in a mix model that included the covariates within herd milk production quartile (MQ), parity (P, for parities 1, 2 and 3 to 5) and a random effect of herd. The estimated slopes from the mixed model analysis were used to estimate milk loss (kg) by comparing to a referent animal with an SCC value of 100. Lactation milk loss (kg) for all completed lactations was calculated using the estimates of 24 h milk loss (kg) and by accounting for the intervals between test days. As expected, 24 h milk loss increased with increased in SCC. In general first parity animals were found to exhibit less milk loss than multiparous animals. Furthermore, higher producing animals within the herd exhibited greater milk loss. Lactation milk loss (kg) increased as lactation average SCC increased. Lactation milk loss (kg) is approximately 50% more in older animals than compared with first parity animals.

Key words: SCC, production, dairy

279 Daily Markov-chain simulation model for selection of reproductive management programs in dairy herds. J. O. Giordano*, P. M. Fricke, M. C. Wiltbank, and V. E. Cabrera, *Department of Dairy Science, University of Wisconsin-Madison, Madison.*

Our objectives were to: (1) present a daily Markov-chain model that simulated dairy herd dynamics and economic performance, and (2) compare the economic value of 2 reproductive programs. A dairy herd was represented by Markov-chains simulation of events with every cow following daily probabilistic events of aging, culling, mortality, pregnancy, abortion, calving, and starting a new lactation. Daily milk yield was determined based on parity (1 to 9), DIM (1 to 1020 d), and reproductive status (open vs. 1 to 282 d pregnant). Cows culled and

dying were replaced to maintain herd size constant. The probability of pregnancy depended on the combination of insemination risk (IR) and conception risk (CR) for each program. All open cows had a probability of pregnancy between the end of the VWP and a cut-off for breeding at 330 DIM. After the cut-off, cows were labeled as "do not breed" until their milk production was below 27 kg/d when they were culled. A large algorithm containing > 2.5 million equations was iterated until the number of cows in each specific state remained unchanged (steady state). The value of a program was calculated daily for each cow as the sum of 5 factors: milk income over feed cost (IOFC), culling and mortality cost, income from newborns, and AI costs. The model compared the economic value of a program performing AI after estrus detection (ED; A) vs. another combining timed AI (TAI) with ED (B). Program A had a 21 d IR of 50% and CR of 30% for 1st postpartum AI and 28% for subsequent AI. Program B combined AI after ED for all AI (60% of cows bred on ED with 28% CR) with Presynch-Ovsynch for 1st AI postpartum (42% CR) and Ovsynch initiated 32 d after a previous AI for subsequent AI (30%). Economically Program B outperformed A by 14.5 $/cow/y. Program B had slightly lower IOFC (-$3.9), and higher AI costs ($3.5), but lower culling cost (-$7.9) and greater income from newborns ($13.9). Program B had more pregnant cows (3.7%) and fewer days open (13 d). Under the conditions of the case study the model indicated that the program combining ED with TAI (B) was economically and reproductively superior to the program with ED only.

Key words: economics, reproduction, dairy

280 Timing to reach the new level of pregnancy and milk yield after an improvement in reproductive management in dairy herds. G. M. Schuenemann*[1], P. Federico[2], A. De Vries[3], and K. N. Galvão[3], *[1]The Ohio State University, Columbus, [2]Capital University, Columbus, [3]University of Florida, Gainesville.*

The objective of this study was to assess the impact of improving 10% in both compliance (COM) and the accuracy of estrous detection (ED) on the timing to reach the new level of pregnancy and milk yield using an individual cow-based stochastic model for a dairy herd. Programs evaluated were: 1) ED: ED only; 2) Pre-Ov: Ovsynch preceded by Presynch with 2 injections of PGF 14 d apart, and Ovsynch for resynchronization of open cows at 32 d after AI; 3) Pre-Ov-ED: same as Pre-Ov for first AI, but cows undergo ED and AI after first AI, and cows diagnosed open 32 d after AI are resynchronized using Ovsynch. Cows were not inseminated after 365 DIM and open cows were culled after 450 DIM. Culled cows were immediately replaced with a primiparous cow. Herd was maintained at 1,000 cows. Mortality was set at 6% and abortion at 11.3%. The dry period and VWP was 60 d. Conception rate to first service was set to 30% (decreased by 2.5% for every subsequent service), and ED was set to 60%. Accuracy of ED (85% or 95%), and COM with each injection (85% or 95%) were evaluated. Simulations were performed at 85% (for COM and accuracy of ED) for 3,000 d, then the model was set at 95% for the subsequent 2,000 d to calculate the new values for pregnancy and milk yield. The first day the new mean was reached was taken as the time since the change was made. Average values from 10 runs were used. At 95% COM and 95% accuracy of ED, the time length to reach the new level of pregnancy for ED, Pre-Ov, and Pre-Ov-ED was 3.4 mo, 6.7 mo, and 4.1 mo, respectively. The time length to reach the new level of milk yield for ED, Pre-Ov, and Pre-Ov-ED took an additional 5.4 mo, 8.8 mo, and 7.5 mo from pregnancy, respectively. According to the model, the new level of pregnancy should be evident around 3 to 6 mo post-change with an additional 5 to 8 mo for milk yield. Assuming that the herd size remains constant, the timing to event (new level of pregnancy and milk yield) provides a timeline to monitor the expected true benefits when an improvement in reproductive management is made (to improve COM and accuracy of ED) at the farm level.

Key words: compliance, dairy cow, estrous detection

281 Economic comparison of reproductive programs for dairy herds using estrus detection (ED), Ovsynch, or a combination of both. K. N. Galvao*[1], P. Federico[3], A. De Vries[1], and G. M. Schuenemann[2], *[1]University of Florida, Gainesville, [2]The Ohio State University, Columbus, [3]Capital University, Columbus, OH.*

Objective was to compare the economic outcome of reproductive programs using ED, Ovsynch, or a combination of both using a stochastic dynamic model. Programs evaluated: 1) ED: ED only; 2) Pre-Ov: Presynch-Ovsynch for first AI, and Ovsynch for resynchronization of open cows at 32 d after AI; 3) Pre-Ov-ED: same as Pre-Ov for first AI, but cows undergo ED and AI after first AI, and cows diagnosed open 32 d after AI are resynchronized using Ovsynch. Cows were not AI after 365 DIM and open cows were culled after 450 DIM. Culled cows were immediately replaced. Herd was maintained at 1000 cows. Death losses were set at 6% and abortion at 11.3%. Dry period of 60 d. Net daily value was calculated by subtracting the costs with replacement heifers ($1,800/heifer), feeding costs ($0.25/Kg of lactating cow diet; $0.25/Kg of dry cow diet), breeding costs ($0.1/cow/d for ED; $2.5/dose PGF; $3.0/dose GnRH; $0.17/injection administration), and other costs ($3.5/d) from the daily income with milk sales ($0.31/Kg milk), cow sales ($0.75/Kg live weight), and calf sales ($200/calf). Simulation was performed until steady-state was reached (3000 d), then average daily values for the subsequent 2000 d was used to calculate profit/cow/yr. first AI CR was set to 30% (decreased by 2.5% for every subsequent AI), and ED was set to 60%. Accuracy of ED (95 or 85%), and compliance with each injection (95 or 85%) were evaluated. Inaccurate ED resulted in 0% CR. Missing a Presynch injection resulted in loss of 50% of the benefit (40% increase to first AI), and missing an Ovsynch injection resulted in decrease in CR by 70%. At 95% accuracy of ED and 95% compliance, the profits for ED, Pre-Ov, and Pre-Ov-ED were $410, $379, and $485, respectively. At 85% accuracy of ED and 85% compliance, the profits were $347, $260, and $421, respectively. ED only is better than Ovsynch, but Ovsynch with good compliance is better than ED with poor accuracy. Combination of Ovsynch with ED resulted in the greatest profit even with low accuracy and low compliance. Dairies should consider their accuracy of ED and compliance before implementing a program.

Key words: economics, reproductive programs, dairy cows

Ruminant Nutrition: Beef: Additives and Supplements

282 The effect of Bovamine on feedlot performance of finishing cattle: A meta-analysis. K. J. Hanford*[1], W. M. Kreikemeier[2], and D. R. Ware[2], *[1]Department of Statistics - UNL, Lincoln, NE, [2]Nutrition Physiology Co. LLC, Overland Park, KS.*

A meta-analysis of the effect of Bovamine (Nutrition Physiology Co., LLC) on performance of finishing cattle was conducted. Bovamine contains a patented combination of a lactic acid-producing bacterium (Lactobacillus acidophilus NP51) and a lactic acid-utilizing bacterium (Propionibacterium freudenreichii NP 24). Summary data from 18 feeding trials comparing control vs Bovamine were included. PROC GLIMMIX (SAS Institute) was used with a model including the fixed effect of treatment (Control vs Bovamine), a covariate of initial body weight, a treatment by covariate interaction and a random study effect. Any non-significant ($\alpha > 0.05$) interaction or covariate terms were dropped from the final model. Meta-analytical methods that weight responses by size of the study and precision of result were used. A subset analysis of those studies that included a corn processing by-product was also performed (7 trials). Initial body weight was significantly linearly associated with hot carcass weight (HCW) in the full analysis (b = 0.3457). DMI was not different between Bovamine and Control (95% CI = −0.010 to 0.116, $P = 0.0949$). Cattle fed Bovamine had higher ADG by 0.041 kg (95% CI = 0.027 to 0.054, $P < 0.0001$) and HCW by 3.51 kg (95% CI = 2.38 to 4.65, $P = 0.0001$) and lower feed to gain ratio (F:G) by −0.09 (95% CI = −0.132 to −0.049, $P = 0.0002$). Similar results were found for the analysis of studies that included feeding a corn processing by-product. DMI was not different between Bovamine and Control (95% CI = −0.023 to 0.177, $P = 0.1087$). Cattle fed Bovamine had higher ADG by 0.031 kg (95% CI = 0.010 to 0.051, $P = 0.0104$) and HCW by 4.32 kg (95% CI = 2.35 to 6.29, $P = 0.0025$) and lower F:G by −0.07 (95% CI = −0.130 to −0.013, $P = 0.0239$). These results quantify the effects of Bovamine on performance of feedlot cattle.

Key words: meta-analysis, feedlot cattle, direct fed microbial

283 Effects of Min-Ad on growth performance and carcass characteristics of finishing steers. J. O. Wallace*[1], M. S. Brown[1], D. D. Simms[2], C. W. Coufal[1], C. L. Maxwell[1], J. C. Simroth-Rodriguez[1], K. J. Kraich[1], and S. L. Thomas[1], *[1]West Texas A&M University, Canyon, [2]Min-Ad Inc., Amarillo, TX.*

Crossbred steers (n = 280; initial BW = 368 ± 10.7 kg) were used to evaluate the effects of feeding wet corn distillers grains (WCDG) and a commercial source of calcium–magnesium carbonate (MA, Min-Ad Inc., Amarillo, TX) on growth performance and carcass characteristics. Cattle were adapted to a common finishing diet, blocked by BW, implanted with Revalor-IS, and assigned to treatments of MA supplementation (0 or 1% of diet DM) and WCDG concentration (0 or 15% of diet DM). Cattle were housed in 28 soil–surfaced pens. Diets were fed twice/d for 169 d and cattle were reimplanted with Revalor–200 on d 48. Interactions existed for both shrunk initial BW and LMA ($P = 0.02$ and 0.04 respectively); however, there were no effects of either MA or WCDG on either variable ($P \geq 0.26$). Cattle fed MA consumed less feed and had lower ADG on a live basis (1.47 vs. 1.52 kg/d); SE = 0.061) and carcass-adjusted (CA) ADG resulting in a lower final BW and CA final BW ($P \leq 0.02$) than cattle not fed MA. Cattle fed MA had lighter HCW ($P = 0.03$); however, their marbling scores were higher ($P = 0.04$) than cattle not fed MA. Cattle fed WCDG consumed more feed and had higher ADG and CA ADG ($P \leq 0.06$) than cattle not receiving WCDG, resulting in heavier final BW and CA final BW, and improved F:G ($P \leq 0.07$) for cattle fed WCDG. Feeding WCDG also increased HCW, although dressing percent was decreased by feeding WCDG ($P = 0.07$ and 0.05, respectively). An interaction for USDA average yield grade (YG) ($P = 0.13$) was evident; however, there were no effects of either MA or WCDG ($P \geq 0.11$) on USDA average YG and these data followed the same numeric trend as BF thickness. No interactions existed for YG or quality grade distributions. Feeding MA increased the percentage of premium carcasses ($P = 0.07$) and feeding WCDG decreased the percentage of YG 2 carcasses ($P = 0.03$). There were no differences in water consumption by treatment. Results suggest that there are no performance benefits from including MA in the diet at 1% of DM under the conditions of this study; however, supplementing an SFC-based diet with 15% WCDG on a DM basis may improve carcass-adjusted performance.

Key words: feedlot cattle, wet corn distillers grains, Min-Ad

284 Ractopamine hydrochloride reduces urinary nitrogen excretion of both implanted and non-implanted finishing beef cattle. M. M. Kappen*, J. Ham, H. Han, and S. L. Archibeque, *Colorado State University, Ft. Collins.*

The effects of ractopamine hydrochloride (RAC) and a steroidal implant (IMP), on whole body N metabolism were evaluated in 24 Hereford × Angus steers (BW 554.4 ± 26.8 kg). The experimental design was a completely randomized block design with a 2 × 2 factorial arrangement of treatments. Factors included: 1) RAC (0.0 or 400 mg × hd-1 × d-1) and 2) IMP (0.0 or 200 mg trenbolone acetate and 28 mg of estradiol benzoate). Steers were housed in individual pens and allowed ad libitum access to feed and water throughout the experiment. Steers were acclimated to the metabolism barn by bringing in, tying and currying for 12 d before the initiation of the experiment. Once cattle had been implanted for 48 d and had received RAC for 21 d a nutrient balance study was conducted for 6 d. An IMP × RAC interaction tended ($P < 0.09$) to exist for DMI. Implanted steers receiving RAC tended to have lower DMI compared with non-IMP steers receiving RAC as well as IMP steers not receiving RAC. N intake ($P > 0.11$) and fecal N ($P > 0.18$) were not different due to treatment, yet numerically reflected the trend noted for DMI. Urinary N excretion was decreased by feeding RAC ($P < 0.01$). There tended ($P < 0.08$) to be an IMP × RAC interaction for urinary N excretion. Implanted steers receiving RAC tended to have less urinary N than steers receiving an implant only. Similarly, urine urea N excretion was decreased by RAC treatment ($P < 0.02$) and excretion was greater in steers that had also received IMP (IMP × RAC interaction; $P < 0.08$). Overall N retention was not affected by treatment ($P > 0.14$). These results indicate that urinary N excretion may be reduced by incorporating RAC according to labeled usage during the final phase of the finishing period. However, further studies will be required to elucidate the potential interactions of RAC with implant status and various types of implants.

Key words: ractopamine hydrochloride, trenbolone acetate, urinary nitrogen

285 Impact of sorting prior to feeding zilpaterol hydrochloride on feedlot performance and carcass characteristics of yearling steers. E. M. Hussey*[1], G. E. Erickson[1], W. A. Griffin[1], B. L. Nuttleman[1], T. J. Klopfenstein[1], and K. J. Vander Pol[2], *[1]University of*

Nebraska-Lincoln, Lincoln, [2]Intervet/Schering-Plough Animal Health, De Soto, KS.

Crossbred yearling steers (342 ± 10 kg initial BW) were assigned randomly to pens with 3 arrival blocks (25 steers/pen, 40 pens) to evaluate sorting and feeding zilpaterol on feedlot performance and carcass characteristics. Five treatments included an unsorted negative control (-CON), unsorted zilpaterol fed positive control (+CON); and 3 treatments where the heaviest 20% within the pen were sorted and marketed 28 d early and the remaining 80% were fed zilpaterol. The 20% were identified at the beginning (EARLY), 100 d from slaughter (MIDDLE), or 50 d from slaughter (LATE) by weighing individuals. Because of sorting, remaining steers in sorted treatments were fed 14 d longer than -CON and +CON. Steers fed zilpaterol were fed Zilmax at 8.3 mg/kg DM for 20 d followed by a 3 d withdrawal. Data were analyzed using Proc Mixed using a protected F-test and 3 preplanned contrasts. Steers fed +CON were 12 kg heavier ($P < 0.01$) than steers fed -CON. Steers sorted EARLY, MIDDLE, and LATE were 33, 25, and 32 kg heavier ($P < 0.01$) than -CON, respectively. Gain and G:F were greater ($P \leq 0.03$) for +CON than -CON, but not different between +CON and sorted treatments. Steers fed +CON had 15 kg greater HCW than -CON. Steers sorted EARLY, MIDDLE, and LATE had 28, 24, and 24 kg heavier ($P < 0.01$) HCW than -CON, respectively. Carcass weight SD was greater ($P = 0.01$) for +CON than -CON, but not different ($P = 0.16$) between -CON and zilpaterol sorted treatments. Percentage of overweight carcasses was greater ($P \leq 0.05$) in sorted treatments than -CON. Fat depth was lower ($P = 0.02$) in +CON than -CON, but not different between -CON and zilpaterol sorted treatments. LM area was greater ($P < 0.01$) in +CON and zilpaterol sorted treatments than -CON, and similar ($P = 0.57$) for all treatments fed zilpaterol. Marbling score was lower ($P < 0.01$) for +CON than -CON, but not different ($P = 0.60$) between -CON and zilpaterol sorted treatments. Feeding Zilpaterol in combination with sorting to identify heavy carcasses increased HCW without increasing variation and equalized marbling score compared with a negative control.

Key words: feedlot cattle, sorting, zilpaterol

286 Effect of feeding Micro-Aid in diets containing wet distillers grains plus solubles to finishing cattle on performance and nutrient mass balance fed during the summer. A. J. Doerr*[1], B. L. Nuttelman[1], G. E. Erickson[1], T. J. Klopfenstein[1], W. A. Griffin[1], and M. J. Rincker[2], *[1]University of Nebraska-Lincoln, [2]DPI Global, Porterville, CA.*

Ninety-six calves (321 ± 8.5 kg) were stratified by BW, and assigned randomly to 12 pens to evaluate the impact of feeding Micro-Aid in diets containing wet distillers grains plus solubles (WDGS) to finishing cattle on performance and N mass balance. Micro-Aid is manufactured from an all-natural plant extract, which contains saponins that have natural detergent and surfactant properties. Steers were fed for 160 d from May to November. Dietary treatments consisted of 35% WDGS, 55% corn, 5% straw, and 5% supplement (CON), with Micro-Aid being added in the treatment supplement at an inclusion of 1g per steer daily (TRT). Nitrogen excretion was determined by the difference between N intake and individual steer N retention. Total N lost was calculated by subtracting manure and runoff N from excreted N. Intake, ADG, and G:F were similar among treatments ($P \geq 0.67$), as well as carcass characteristics. Nitrogen intake, retention, and excretion were also similar ($P \geq 0.73$). There was no difference ($P \geq 0.95$) in the amount of DM and N removed during pen cleaning. N runoff was not different ($P = 0.20$) between treatments at 3.68% of N excretion. The amount of N lost via volatilization was similar among treatments (24.0 kg and 24.5 kg for the CON and Micro-Aid, respectively). Therefore, the percent N loss expressed as a percentage of N excretion was 71.9% for the CON group and 73.8% for the Micro-Aid group. ($P = 0.60$) Treatment did not affect amount of OM removed ($P = 0.64$), with 125 kg for the CON group and 104 kg for cattle fed Micro-Aid. Performance and carcass characteristics were similar between the CON and TRT cattle. Additionally, inclusion of Micro-Aid in the diet fed during the summer has no effect on N and OM removed. However, this contradicts the previous winter experiment in which feeding Micro-Aid led to less N volatilization.

Key words: nitrogen, mass balance, saponins

287 Rumen-protected arginine supplementation alters vascular hemodynamics in forage-fed steers. A. M. Meyer*[1], C. B. Saevre[1], D. V. Dhuyvetter[2], R. E. Musser[3], and J. S. Caton[1], *[1]Center for Nutrition and Pregnancy, Department of Animal Science, North Dakota State University, Fargo, [2]Ridley Block Operations, Mankato, MN, [3]SODA Feed Ingredients LLC, Mankato, MN.*

We hypothesized that Arg supplementation would alter vascular hemodynamics and increase systemic blood flow through its role in nitric oxide synthesis. To test this, 4 steers were used in a 4 × 4 Latin square with the following twice daily treatments: ad libitum grass hay (7.2% CP and 67.6% NDF; CON), hay and 27 mg Arg/kg BW injected intravenously (Arg-INJ), hay with 90 mg rumen-protected Arg/kg BW (Arg-180), and hay with 180 mg rumen-protected Arg/kg BW (Arg-360). Arginine in Arg-180 was estimated to be equal to Arg-INJ. Each period consisted of a 7-d adaptation then 14 d of Arg treatments. Blood flow and hemodynamics of the carotid and caudal arteries were determined using color Doppler ultrasonography on d −1 (baseline), 5, 9, and 14 of Arg treatment. Data were analyzed as repeated measures with treatment, day, and their interaction as fixed effects and steer and period as random effects. As expected, daily serum Arg was greater ($P < 0.001$) in Arg-INJ than all other treatments. Additionally, serum Arg was greater ($P = 0.005$) in Arg-360 than CON, with Arg-180 intermediate. Pulsatility index (PI) and resistance index (RI) percent changes from baseline were affected ($P \leq 0.08$) by treatment in the carotid and caudal arteries. Steers fed Arg-180 had decreased ($P \leq 0.02$) carotid RI and caudal PI compared with CON and Arg-360, indicating reduced vascular resistance and increased tissue blood perfusion. Carotid PI also decreased ($P \leq 0.06$) in Arg-180 compared with CON and Arg-INJ. Furthermore, caudal RI decreased ($P \leq 0.01$) and caudal end diastolic velocity increased ($P \leq 0.06$) in Arg-180 compared with all other treatments. Steers receiving Arg-INJ had decreased ($P < 0.10$) carotid RI compared with CON and decreased ($P = 0.04$) caudal RI compared with Arg-360. There was no effect ($P > 0.19$) of treatment on carotid or caudal flow volume, peak systolic velocity, mean velocity, or cross sectional area. Heart rate, stroke volume, and cardiac output were also unaffected ($P > 0.15$) by treatment. These data suggest that 180 mg rumen-protected Arg/kg BW improved vascular hemodynamics and tissue perfusion without altering serum Arg concentration.

Key words: arginine, blood flow, vascular hemodynamics

288 Effect of supplemental vitamin C on performance and antioxidant capacity of cattle fed varying concentrations of dietary sulfur. D. J. Pogge* and S. L. Hansen, *Iowa State University, Ames, IA, USA.*

Increased dietary sulfur (S) may create oxidative stress which negatively affects performance of feedlot cattle and may contribute to S toxicosis. Therefore, the effect of supplemental rumen-protected vitamin C (Vit C) on antioxidant capacity of cattle consuming high S diets was evaluated in a finishing trial utilizing 120 Angus crossbred steers. Steers were stratified by initial BW (354.9 ± 22.6 kg), and assigned to treatments (4 steers per pen, 5 pens per treatment). Treatments included: 1) low S, corn-based diet, 2) low S + Vit C, 3) medium S, 40% DDGS diet, 4) medium S + Vit C, 5) high S, medium S + 0.3% S from sodium sulfate and 6) high S + Vit C. Diets were formulated to average 0.2, 0.4 and 0.6% S, for low, medium and high S, respectively, and Vit C supplementation was targeted at 10 $g \cdot h^{-1} \cdot d^{-1}$. Rumen hydrogen sulfide concentrations and blood sulfhemoglobin concentrations (n = 5 per treatment) were measured on d 14, 28 and 90. Data were analyzed as repeated measures, and both hydrogen sulfide and sulfhemoglobin concentrations were greater ($P < 0.05$) in steers receiving medium and high S diets compared with steers receiving low S diets. Initial antioxidant status was not different due to treatment (n = 5 per treatment); however, plasma antioxidant capacity measured on d 90 was decreased ($P < 0.01$) in steers receiving medium or high S diets versus low S steers. Increasing dietary S concentrations resulted in a linear decrease ($P < 0.05$) in 12th rib back fat and percent intramuscular fat as determined by ultrasound on d 90. Dry matter intake and ADG for the 112 d period were not affected by Vit C supplementation; however, ADG was negatively affected ($P < 0.05$) by the linear increase of dietary S. In conclusion, medium or high dietary S decreased total antioxidant capacity of steers compared with those fed low S diets, which may contribute to increased susceptibility to S toxicosis when cattle are fed high S diets.

Key words: antioxidant, sulfur, vitamin C

289 Use of MTB-100, provided through a mineral mix, to reduce toxicity when lactating beef cows graze endophyte-infected tall fescue. M. E. Hoar*, D. K. Aaron, D. G. Ely, M. M. Simpson, and A. K. Lunsford, *University of Kentucky, Lexington.*

Sixty, 3 to 5 yr-old, Angus and Angus × Beefmaster cows and their calves were used in a 3-yr study to evaluate response to gradient levels of a nutritional supplement produced from a carbohydrate-based toxin adsorbent (MTB-100 Alltech, Inc., Nicholasville, KY). The supplement was carried in a mineral mix and was available to cows ad libitum. The MTB-100 was mixed with a complete mineral, diluted with white salt, so daily intake was projected to be either 0, 20 or 40 g/cow. The grazing season began on May 8 each yr. From this date until July 10 (Period 1), cows and calves were managed in 9, endophyte-infected (>90%) KY 31 tall fescue pastures (3 pastures/supplement level, re-randomized each yr) stocked with 10 to 16 cow/calf pairs each. On July 10 each yr, 21 pre-designated cow/calf pairs were allotted to individual, 1.6-ha plots of equivalent pasture (7 plots/supplement, re-randomized each yr). Cows continued their respective supplement regimens from this date until calves were weaned on September 13 (Period 2). Cow weight changes in Period 1 were −11.7, −1.9 and −3.2 kg/hd ($P = 0.19$) for 0, 20 and 40 g supplement levels. Although corresponding weight changes in Period 2 showed no significant trend, total cow weight changes from May 8 to September 13 were −7.4, −0.5 and 0.5 kg/hd for 0, 20 and 40 g supplement levels. Cow BCS did not change from May 8 to July 10 (Period 1). Cow BCS on July 10 (5.5, 5.6 and 5.0) decreased to 5.1, 5.4 and 5.0 ($P = 0.03$) for 0, 20 and 40 g treatments (Period 2). Rectal temperatures were not affected by MTB-100^{TM} consumption. Calf weights for Period 1 were 53, 56 and 56 kg/hd (NS) for the 0, 20 and 40 g levels. Calf gains in Period 2 were not different. Overall calf gains from May 8 to September 13 were 109, 112 and 111 kg/hd for 0, 20 and 40 g MTB-100. These results show MTB-100^{TM} consumption, through a mineral mix available ad-libitum, did not increase performance of cows and calves grazing endophyte-infected tall fescue forage.

Key words: adsorbent, cows, fescue

290 In vitro mitigation of rumen hydrogen sulfide. M. Ruiz-Moreno*, E. Seitz, and M. D. Stern, *University of Minnesota, St. Paul.*

Excessive release of rumen hydrogen sulfide (H_2S) has been associated with sulfur-induced polioencephalomalacia. Bismuth subsalicylate (BSS) has been used to decrease H_2S production in humans but its effect on rumen H_2S production is unknown. An in vitro rumen incubation was conducted to assess the effect of 5 levels of BSS on H_2S release and rumen metabolism during 2 consecutive 24-h periods. A diet consisting of 50% corn, 40% dried distillers grains, 9.75% hay and 0.25% mineral premix provided substrate for microbial metabolism. Chemical grade BSS was added to a final concentration of 0 (Control), 0.5, 1, 2 and 4% of DM. Rumen fluid was obtained from a cannulated dairy cow and mixed with McDougall's saliva to a 1:2 ratio. Treatments were assigned in 5 replicates to 120-mL serum bottles containing 50 mL of the inoculum mix and 0.5 g of dietary DM. Bottles were flushed with N_2, crimp sealed and incubated during 24 h at 39.1°C. At the end of incubation, gas volume and H_2S in the headspace of bottles were quantified. Final pH was recorded and incubation fluid was analyzed for NH_3-N and VFA. Data were analyzed as a randomized complete block design using ANOVA with Bonferroni correction. Final pH increased ($P < 0.05$) with 2 and 4% BSS by 0.06 and 0.22 pH units, respectively. No effect ($P > 0.05$) of BSS on NH_3-N concentration was observed. At 4% of DM, BSS decreased ($P < 0.05$) total VFA concentration by 15% and molar proportion of propionic acid by 5.7% while increasing acetic acid by 1.5% and the A:P ratio from 2.4 to 2.6, compared with the control. With 2% BSS, molar proportion of butyric acid was 9% lower than the control ($P < 0.05$). Concentration of branched-chain VFA was 19% higher ($P < 0.05$) with the addition of 0.5% BSS, compared with the control. All levels of BSS increased ($P < 0.05$) valeric acid molar proportion compared with 0% BSS. Compared with the control, gas production decreased ($P < 0.05$) with the addition of 2 and 4% BSS by 12 and 25%, respectively. All concentrations of BSS reduced ($P < 0.05$) H_2S production by 18, 24, 82 and 99% for 0.5, 1, 2 and 4% BSS, respectively. Results indicate that BSS can markedly decrease H_2S production.

Key words: rumen, hydrogen sulfide, bismuth subsalicylate

291 Utilizing crop residues in winter feeding systems for beef cows. A. D. Krause*[1] and H. A. Lardner[1,2], [1]*University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*Western Beef Development Centre, Humbolt, Saskatchewan, Canada.*

An experiment was conducted to evaluate the effects of winter feeding system on beef cow performance, reproductive efficiency and economics. Winter feeding systems were grazing pea (*Pisum sativum* cv. Performance 40–10) crop residue (PEA) (TDN = 47.7%; CP = 7.3%), grazing oat (Avena sativa cv. Baler) crop residue (OAT) (TDN = 44.9%; CP = 2.3%), and grass-legume hay fed in drylot pens (DL) (TDN = 52.8%; CP = 9.1%). Ninety dry, pregnant Angus cows (629 kg ± 74 kg) stratified by body weight (BW) and days pregnant were allocated to 1 of 3 replicated (n = 3) treatments. Statistical analysis was conducted as a one way ANOVA using the Proc Mixed Model

procedure of SAS. Experimental design for feeding was a completely randomized design. Cows were allocated crop residue in field on a 3-d basis and supplemented oat grain daily at 0.4-0.6% of BW depending on environmental conditions. Dry matter intake (DMI) was measured for each treatment using the herbage weight disappearance method. Cow BW, body condition score (BCS), and rib and rump fat were measured at start and end of trial. Cow BW was corrected for conceptus gain based on calving data. Reproductive performance data collected included calf birth weight, calf birth date, calving span and calving rate. Cow BW was different ($P = 0.0001$) between all grazing systems. Drylot system cows had the greatest positive BW change (66 kg), and cows in the PEA system had the lowest positive BW change (10 kg). Rib and rump fat were also different ($P = 0.002$) between systems. Rib and rump fat changes were greater for the DL cows compared to cows in the PEA wintering system. Estimated DMI averaged over the winter feeding period was 13.1, 7.1 and 6.9 kg for DL, OAT and PEA cows, respectively. Mean calf birth weights for DL, OAT and PEA cows were 40.9, 36.8 and 40.3 kg, respectively. Winter feeding system costs per cow per day were $1.34, $1.07 and $2.78 for PEA, OAT and DL treatments, respectively. Results of this study indicate that it is possible to maintain cow BW during winter months in western Canada while grazing crop residues, which have the potential to reduce winter feeding costs associated with winter cow management.

Key words: pea crop residue, oat crop residue, beef cows

292 Effect of supplementing dried distillers grains to cattle consuming low-quality South Texas forage. M. C. Briggs*[1], K. C. McCuistion[1], R. O. Dittmar III[2], J. E. Zradicka[1], D. Kinkel[1], and T. A. Wickersham[2], *[1]Texas A&M University, Kingsville, Kingsville, [2]Texas A&M University, College Station.*

Protein supplementation is often used in South Texas to improve cow performance on dormant forage. However, little data are available evaluating the use of dried distillers grains (DDG) as a source of supplemental protein. Therefore, we used 13 ruminally fistulated steers in a 13 × 4 incomplete Latin square with 13 treatments and 4 periods. Steers were provided ad libitum access to low-quality (3.6% CP, 72.7% NDF) mixed grass hay. Treatments were arranged in a 3 × 4 factorial plus a positive control, alfalfa. The first factor compared 3 supplemental protein sources: cotton seed meal (CSM; 42.2% CP, 30.0% NDF), DDG (25.2% CP, 32.4% NDF) and DDG plus urea (DDGU; 35.6% CP, 32.4% NDF). The second factor consisted of 4 levels of the 3 supplemental protein sources provided at 0, 52, 104, and 156 mg N/kg of initial BW. Experimental periods were 16 d long with 10 d for adaptation. Forage OM intake (FOMI) increased linearly with DDGU ($P \leq 0.02$; 44.9, 52.4, 52.2, and 56.1 g/kg $BW^{0.75}$, for 0, 52, 104, and 156 mg N/kg BW, respectively) and CSM ($P < 0.01$; 46.9, 49.3, 53.3, and 57.1 g/kg $BW^{0.75}$, for 0, 52, 104, and 156 mg N/kg BW, respectively). However, increasing provision of DDG did not significantly affect FOMI ($P \geq 0.32$). In contrast, there was a linear ($P < 0.01$) increase in total OM intake (TOMI) when DDG was supplemented, with intakes increasing from 45.2 to 51.7, 60.2, and 63.0 g/kg $BW^{0.75}$, for 0, 52, 104, and 156 mg N/kg BW, respectively. Similar linear increases in TOMI were observed for CSM ($P < 0.01$) and DDGU ($P < 0.01$). Ruminal ammonia concentrations increased linearly with CSM ($P < 0.01$) and DDGU ($P < 0.01$) but were not affected by DDG ($P \geq 0.44$) supplementation. Both CSM and DDGU were effective at stimulating TOMI, with a portion of this response attributable to increased FOMI. In contrast, DDG was effective at increasing TOMI, but this was largely driven by the intake of supplement. Supplementation with DDG alone may be most effective when forage quantity is limited and substitution is desirable.

Key words: cattle, dried distillers grains, forage

293 A mechanistic model of enteric methane emissions from ruminants. R. A. Kohn* and S.-W. Kim, *University of Maryland, College Park.*

Most models of microbial metabolism assume kinetic control wherein rates of reactions depend on substrate or enzyme activity, and enzyme activity may in turn be controlled by gene expression. However, such models are frequently unstable and inaccurate. Thermodynamic control occurs when concentrations of metabolites build up relative to concentrations of reactants, such as when there is a high degree of competition for substrate and limited opportunity for removal of products. The second law of thermodynamics explains why certain profiles of volatile fatty acids (VFA) and gases (e.g., CH_4, CO_2 and H_2) occur in the rumen. According to current dogma, methane is produced from CO_2 and $4H_2$ in the rumen, but from degradation of acetate to CO_2 and CH_4 in anaerobic digesters. It was thought that rapid dilution rates wash out the slow-growing acetate-degrading (acetoclastic) organisms from the rumen. However, calculations of ΔG show that the reactions: acetic acid $\longleftrightarrow 2CO_2 + 4H_2$ and $CH_4 + 2H_2O \longleftrightarrow CO_2 + 4H_2$ are near equilibrium on forage-based diets. Thus, rate of acetic acid degradation is limited by thermodynamics and not kinetics. The gases in the rumen under 1 atm pressure ultimately limit degradation of acetic acid. Rumen microbes degraded acetic acid when incubated under partial vacuum or N_2. We are developing an integrated thermodynamic and kinetic model to predict methane emissions from VFA concentrations, which are in turn predicted from VFA production rates and VFA absorption and passage. These rates are in turn predicted from organic matter digestion in the rumen. An explanation for the decrease in ratio of concentration of acetate to propionate follows: [acetic acid] / $\{[CO_2]^2[H_2]^4\} = K_{eq}$ so as acid concentration builds up with high grain diets, H_2 pressure builds up (as observed) to maintain equilibrium. The greater H_2 concentration increases the equilibrium concentrations of VFA, particularly of propionate, thereby decreasing production of CO_2 and H_2 as precursors for methane. The model explains mechanisms of some factors that change methane emissions and suggests ways to decrease enteric methane emissions.

Key words: methane emissions, mathematical model, thermodynamics

294 Impact of free-choice or restricted water intake during the pre-weaning and early post-weaning period on calf performance and health. A. Manthey*[1], D. Ziegler[2], H. Chester-Jones[2], M. Raeth-Knight[3], G. Golombeski[3], and J. Linn[3], *[1]University of Wisconsin-River Falls, River Falls, [2]University of Minnesota, Southern Research and Outreach Center, Waseca, [3]University of Minnesota, St. Paul.*

Two studies were conducted to compare the impact of free choice versus restricted water intake during the milk replacer (MR) feeding period and 2 wk following weaning on calf performance. Study 1 was conducted spring of 2009 and study 2, summer of 2010. A total of 114 (study 1 = 44; study 2 = 70) 2 to 4 d old Holstein calves were assigned to 1 of 2 treatments: 1) Free choice water intake for 56 d (CON) or 2) Restricted water intake (RW). The RW treatment was no water available the first 36 d of the study followed by limited amount offered (2.3 kg/d) d 36 to 42 and free choice d 42 to 56. All calves were fed 0.28 kg of a 20:20 MR powder in 2 kg water twice daily d 1 to 35 and once daily d 36 until weaning at 42 d. Medicated MR was utilized in study 1 and non-medicated MR in study 2. An 18% CP calf starter (CS) was offered free choice d 1 to 56. Water, MR and CS intakes along with fecal scores were recorded daily. Body weight (BW) was measured d 1, 14, 28, 42 and 56 and hip height d 1 and 56. Data were analyzed as repeated measures using the PROC MIXED procedures of SAS. Study was included in the model as a blocking factor and initial BW was used as a covariate. During the MR feeding period (d 1–42), CON calves in study 1 and 2 consumed more water ($P < 0.05$) per d than the RW calves (study 1 = 0.54 vs. 0.22 kg/d; study 2 = 1.9 vs. 0.34 kg/d). Due to differences in season between studies, CON calves in study 2 consumed 1.4 kg more water per d than CON calves in study 1 from d 1 to 42 ($P < 0.05$). Average daily water intake from d 1 to 56 was similar for calves on the CON and RW treatment in study 1 averaging 1.6 kg water/d, but in study 2, CON calves consumed 1.0 kg more water per d ($P < 0.05$) compared with RW calves (2.9 vs. 1.9 kg/d). In both studies, differences in water intake between CON and RW treatments did not affect daily gain, CS or total DM intake from d 1 to 42 or d 1 to 56. Across studies, overall CS intake, total DM intake and daily gain averaged 0.66, 0.91, and 0.55 kg/d, respectively. Under conditions of these studies restricting water intake in the first 42 d did not affect calf performance.

Key words: dairy calves, water intake

295 Effects of free-access feeding of acidified milk replacer on the performance and general health of veal calves. C. G. Todd*[1], T. J. DeVries[2], K. E. Leslie[1], J. M. Sargeant[1], N. G. Anderson[3], K. Shore[4], and S. T. Millman[5], *[1]Department of Population Medicine, University of Guelph, Guelph, ON, Canada, [2]Department of Animal Poultry Science, University of Guelph, Kemptville Campus, Kemptville, ON, Canada, [3]Ontario Ministry of Agriculture, Food and Rural Affairs, Elora, ON, Canada, [4]Grober Nutrition, Cambridge, ON, Canada, [5]Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames.*

The aim of this research was to examine the effects of milk replacer acidification for free-access feeding on the performance, morbidity and mortality of veal calves. Holstein male calves were randomly assigned at birth to free-access feeding of A) milk replacer (22% CP, 17% fat; n = 32) or B) acidified milk replacer (n = 31). Acidified milk replacer was prepared using formic acid (target pH: 4.0 to 4.5). Calves were weaned off milk replacer at 42 d of age. Milk replacer, starter ration and water intakes were measured daily from birth until weaning. Preweaning BW gain was determined weekly. After weaning, calves were transitioned to a growing/finishing diet for grain-fed veal, weighed every 2 weeks and slaughtered at 6 mo of age. At slaughter, the lungs of each calf were collected and evaluated for gross pathological changes. Dressed carcass weights were obtained. Multivariable regression models were constructed to examine the effects of treatment on milk replacer intake, time to onset of starter consumption, BW gain and carcass weight. Differences between treatment groups for disease events and death were tested using Pearson's $\times^2$ or Fisher's exact. Calves assigned to the acidified treatment consumed less milk replacer (10.1 vs. 11.3 L/d, SE = 0.2, $P < 0.01$) and began consuming starter ration earlier (32.0 vs. 39.5 d, $P < 0.05$) than the control calves. Milk replacer acidification tended to be associated with reduced preweaning ADG (0.9 vs. 1.0 kg/d, SE = 0.1, $P < 0.1$), but did not affect BW at weaning (85.1 vs. 87.8 kg, SE = 2.0, $P > 0.05$), postweaning ADG (1.2 vs. 1.2 kg/d, SE = 0.01, $P > 0.05$) or carcass weight (150.2 vs. 149.2 kg, SE = 3.3, $P > 0.05$). Calves did not differ for diarrhea occurrence (A vs. B: 36.1 vs. 42.6%, $P > 0.05$) or death (A vs. B: 3.2 vs. 1.6%, $P > 0.05$). There was, however, a tendency for fewer acidified-fed calves to have lung tissue affected with lesions of pneumonia (6.9 vs. 19.0%, $P < 0.10$). These results indicate that under free-access feeding conditions, acidification limits the intake of milk replacer, but does not negatively affect long-term calf performance, and may support improved respiratory health.

Key words: acidified, calf, milk replacer

296 Effect of Celmanax SCP on calf performance when fed in the milk replacer and grower phase. R. J. Dennis[1] and S. Jalukar*[2], *[1]Kent Nutrition Group Product Development Center, Muscatine, IA, [2]Varied Industries Corporation, Mason City, IA.*

Effect of supplementing Celmanax SCP, an ultra-concentrated product consisting of yeast culture and hydrolyzed yeast cell wall, in milk replacer and starter feed on dairy calves was evaluated. Fifty, day-old calves were allotted based on body weight to following 2 treatment a) calf milk replacer (MR) (20%CP:20% fat; non-medicated fed 568g daily) for 6 wk and control starter and grower diet from wk 7–20 and b) MR + 1g/h/d of Celmanax SCP for 6 wk and starter and grower diet + 2 g/h/d Celmanax SCP from wk 7–20. Calves were housed individually through d42 and in super hutches with 5–6 calves/hutch and bunk fed starter (18%CP) till d56. In grower phase (d57–84) calves were penned in 2 groups (control and SCP) and fed a 14% grower diet via self feeders. Serum protein analysis and vaccination to BVD was done for each calf. Along with the MR, control calves were treated upon arrival with Sulfamethoxazole-trimethoprim antibiotic tablets for the first 3 d and Celmanax SCP calves were fed 3g/h/d SCP for the first 2 d. Thereafter, Celmanax SCP was fed at 1g/h/d to the treatment group. Weight gain, milk replacer and starter intake, and feed efficiency of the calves were recorded. Data were analyzed by ANOVA for a completely randomized design using Statistix 8 analytical software. MR intake was similar for both treatments but there was a trend for starter intake to be higher with Celmanax SCP treatment. Starter intake was 29.12 kg and 57.24 kg after 6 and 8 wk for Celmanax SCP verses 25.58 kg and 53.48 kg after 6 and 8 wk for the control calves ($P \geq 0.18$). Average weights at the start and end of the trial were 37.43 kg and 186 kg for the calves receiving Celmanax SCP verses 36.86 kg and 181.99 kg for control treatment respectively. Throughout the experiment, calves

on Celmanax SCP showed numerically higher weight gains and they were 2.4 kg and 4.0 kg heavier at the end of 8 wk and 20 wk ($P \geq 0.2$) compared with control. The feed efficiency (F/G) was also numerically lower compared with control ($P \geq 0.2$). In conclusion, calves supplemented with Celmanax SCP showed numerical improvement in starter intake, weight gain, and feed efficiency.

Key words: calves, yeast, milk replacer

297 Effect of different forage sources on performance and feeding behavior of Holstein calves. L. l. Castells*[1], A. Bach[1,2], G. Araujo[1], and M. Terré[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]ICREA, Barcelona, Spain.*

One hundred and 70 9 Holstein male calves participated in a series of 3 studies to evaluate the effect of different forage sources on performance and feeding behavior. Each study was conducted involving 60 calves (initial BW 45.0 ± 5.33 kg and 14.1 ± 4.17 d of age). Animals were randomly assigned to one of 3 different dietary treatments: control (CTR) calves were fed concentrate without any forage provision (this treatment was repeated in each of the 3 studies), and the 2 other treatments consisted on the same concentrate plus a forage source depending on the study: chopped alfalfa (AH) or rye-grass hay (RH); chopped oats hay (OH) or chopped barley straw (BS); corn silage (CS) or triticale silage (TS). All calves were offered 2 L of milk replacer (MR) at 12.5% DM twice daily via a bottle until 50 d of age, and 2 L of MR at 12.5% DM during the week before weaning (57 d of age). Starter, MR, and forage intakes were recorded daily and BW was recorded weekly. Calves were individually housed and bedded with wood shavings. Performance data were analyzed with an ANOVA with repeated measures, and behavior data were analyzed with a Poisson regression analysis. Compared with CTR, animals receiving OH, TS and BS consumed more ($P < 0.01$) starter (880 vs. 1140, 1170, 1060 ± 28 g/d, respectively) and grew faster ($P < 0.01$; 722 vs. 926, 880, 876 ± 38.3 g/d, respectively). On average, animals in treatments RH, BS, CS, and TS consumed 51 g/d of DM of forage, that was less ($P < 0.01$) than that obtained with AH (120 ± 19.8 g/d) and OH (101 ± 19.8 g/d). Compared to CTR calves, animals in AH and RH treatments spent more ($P < 0.01$) time ruminating (odds ratio vs CTR: 5.24 and 5.40, respectively), calves AH, RH devoted less ($P < 0.01$) time to perform non-nutritive oral behavior (odds ratio vs CTR: 0.38, 0.34, respectively), and TS calves tended ($P = 0.06$) to devote less time to perform non-nutritive oral behavior (odds ratio vs CTR: 0.21). In conclusion, free-choice provision of a forage source to young calves improves feed intake, performance, and, depending on forage source, reduces non-nutritive oral behaviors and stimulates rumination.

Key words: forage, calves, performance

298 Effect of fatty acid intake by dairy calves on performance, health, and markers of immunity. T. M. Hill*[1], M. J. VandeHaar[2], L. M. Sordillo[2], H. G. Bateman II[1], and R. L. Schlotterbeck[1], *[1]Nurture Research Center, Provimi North America, Lewisburg, OH, [2]Department of Animal Science, Michigan State University, East Lansing, [3]Department of Large Animal Clinical Sciences, Michigan State University, East Lansing.*

The aim of the present study was to determine the effect of supplementing milk replacer (MR) with 1% NeoTec4, a commercially available blend of butyric, coconut, and flax oil, on calf growth, feed efficiency, and indices of immune function when the calves were fed 28% CP MR at a high rate of intake (powder fed at 2% of BW). In the Trial 1a, 48 calves were fed either a MR which contained only animal fat (control) or the same MR with NeoTec4 (treatment). In Trial 1b, weaned calves from Trial 1a, were fed dry feed for 28 d without NeoTec4, then half the calves fed NeoTec4 for 28 d. Data were analyzed as a completely randomized design with repeated measures using PROC MIXED and NPAR1WAY. In Trial 1a, NeoTec4 improved ADG, feed intake, feed efficiency, reduced the number days with scours, and tended ($P = 0.06$) to reduce treatments for Clostridium. In addition, NeoTec4 lessened the inflammatory response to vaccination with Pasteurella at 5-wk-old, as observed by reduced hyperthermia and hypophagia and alleviation of the TNF-α response. In addition, NeoTec4 tended ($P = 0.09$) to increase the post-Pasteurella challenge response in IL-4 in mononuclear cells, increased serum globulin protein. Post-booster vaccination titers for BVD and PI3 were increased in calves fed NeoTec4. In Trial 1b, there were no differences in performance during the first 28 d when no calves received NeoTec4, but calves receiving NeoTec4 in the second 28 d had greater ADG and feed efficiency. We conclude that supplementation of MR with NeoTec4, a blend of butyrate, coconut and flax oils, improves some immune responses, which may partly explain the reduction in scours and concurrent improvements in growth rate and feed efficiency.

Key words: dairy calves, immunity, fatty acids

299 Impact of feeding various fats and fatty acids on dairy calf performance, health, and markers of immunity. T. M. Hill*, H. G. Bateman II, J. M. Aldrich, and R. L. Schlotterbeck, *Nurture Research Center, Provimi North America, Lewisburg, OH.*

We evaluated the impact of feeding various fats and fatty acids on castrated Holstein calf performance in 3 56-d trials. PROC MIXED and NPAR1WAY were used and $P < 0.05$ was considered significant in all trials. In Trial 1, 48 3-d old calves were fed a milk replacer with 2 fat types (all animal or a blend of animal, coconut, and soy fats) and with or without 1.25% of a blend of butyrate, medium chain fatty acids, and linolenic acid (NeoTec4, Provimi North America, Lewisburg, OH) in a completely randomized design in a 2 × 2 factorial arrangement with repeated measures. Fat type did not affect performance. Calf ADG, starter intake, feed efficiency, hip width change, and post-booster serum titers to BVD and PI3 vaccines were greater in calves fed NeoTec4. The rectal temperature increase to a Pasteurella vaccine was greater in calves fed the fat blend vs. all animal fat. Post-vaccination rectal temperatures increase was less in calves fed MR with NeoTec4 vs. without NeoTec4. In Trial 2, 48 3-d old calves were fed starters with A) 0.5% NeoTec4, 0% soy oil, B) 0.5% NeoTec4, 2.0% soy oil, and C) 0% NeoTec4, 0% soy oil in a completely randomized design with repeated measures. Calves fed starter A had greater ADG than calves fed starter B or C. Calves fed starter A had greater hip width change than calves fed starter C. In Trial 3, 96 8-wk old calves were fed 4 growers: A) control, B) 0.25% Flaxtech (Virtus Nutrition, Corcoran, CA), C) 0.5% NeoTec4, and D) 1.5% soy oil as a randomized complete block design. There were 2 blocks based on 2 groups of calves starting the trial at different times. Calf ADG was greatest in calves fed NeoTec4 and least in calves fed soy oil. Hip width change was greater in calves fed NeoTec4 than in calves fed the control or soy oil diet. In summary, addition of soy oil to starter and grower feeds reduced ADG while adding NeoTec4 fatty acids to milk replacers, starter and grower feeds increased ADG and hip width change.

Key words: dairy calves, immunity, fatty acids

300 Impact of three times versus twice a day milk replacer feeding on calf performance, likelihood to reach lactation and future milk production in a commercial dairy herd. D. C. Sockett*[1], C. E. Sorenson[2], N. K. Betzold[3], J. T. Meronek[3], and T. J. Earleywine[4], *[1]Wisconsin Veterinary Diagnostic Laboratory, University of Wisconsin, Madison, [2]United Cooperative, Sauk City, WI, USA, [3]University of Wisconsin-Madison, College of Agricultural & Life Sciences, Madison, [4]Land O'Lakes Inc., Cottage Grove, WI.*

Seventy, Holstein heifer calves were enrolled in a trial designed to evaluate both the short and long-term effects of feeding a full potential milk replacer (MR) diet (28% protein, 20% fat) either 3 times or twice a day. Within 6 h of birth, calves were fed a commercial colostrum replacement product made from bovine colostrum that contained 150g of IgG. Calves were randomly assigned to either 3 times or twice a day feeding. A blood sample was collected from each calf 1–3 d after birth. Serum was tested for bovine IgG by single radial immunodiffusion. Calves were housed outdoors in individual calf hutches until they were weaned and moved to group pens at 50–55 d of age. All the calves were fed at 08:00 and 21:00 h. Calves fed 3 times a day received an additional meal at 14:30 h. Calves were fed 815g of MR/day from d 1–7, 1135g of MR/day from d 8–42 divided into either 3 or 2 feedings. Both groups of calves were fed 565g of MR once a day (pre-weaning process) from d 43–49. Calf starter (20% CP as fed) was offered to the calves beginning at 3–4 d of age. Calf starter intake was measured daily. Calves were weighed and had their hip height measured weekly. All the calves remained in the herd unless they died or were culled. Each animal's calving date was recorded and milk production assessed using mature-equivalent 305-d (ME305) milk yield estimated at ≥120 d in milk. Data (birth weight, serum IgG, hip height and weight gain, feed efficiency, calf starter intake, age at first calving and ME305) was evaluated using ANOVA and co-variance using a G.L.M. procedure (NCSS-2007, Kaysville, Utah). The likelihood of calves being weaned, entering lactation and calculation of relative risk was analyzed using 2-way contingency table analysis (JavaStat). Calves fed 3 times a day had improved growth (hip height and weight gain), better feed efficiency, consumed more calf starter during the pre-weaning process and were more likely to enter lactation (relative risk 1.21, 95% C.I. 1.02–1.45) than calves fed twice a day.

Table 1. Results

Item	2x Feeding	3x Feeding	*P*-value
Number calves	35	35	1.0000
Birth weight, kg	40.1	39.8	0.7385
Serum IgG mg/mL	11.2	12.2	0.3459
Calf starter intake, DM (1-42 days), kg	3.3	3.9	0.3448
Calf starter intake, DM (43-49 days), kg	3.8	4.8	0.0122
BW gain (1-42 days), kg	25.1	29.8	0.0001
Hip height gain (1-42 days), cm	8.6	10.3	0.0027
Feed efficiency (gain/DM intake, 1-42 days)	0.52	0.61	0.0001
Number weaned	32	34	0.3070
Number lactating	28	34	0.0250
Age first calving, days	734	718	0.2278

301 Effects of a modified intensive milk replacer program fed two or four times daily on nursery calf performance. A. D. Kmicikewycz*, D. N. da Silva, and N. B. Litherland, *University of Minnesota, St. Paul.*

The objective of this study was to determine if milk replacer (MR) program and feeding frequency (2 vs. 4 meals/day) altered calf performance. Forty-eight Holstein and cross-bred heifer and bull calves were assigned according to body weight (BW), breed, sex, and total protein to 4 treatments (T) (n = 12): T1) 20% CP:20% fat MR fed at 1.5% BW 2 × daily (d); T2) 20:20 MR fed at 1.5% BW 4 × d; T3) 26:18 MR fed at 2.0% BW 2 × d; or T4) 26:18 MR fed at 2.0% BW 4 × d. All calves were fed at 0600 and 1700 h and T2 and T4 were fed additionally at 1100 and 1400 h. Treatments were fed from 1 to 42 d and all MR feeding rates were adjusted weekly to maintain 1.5% or 2.0% of BW reconstituted at 15% DM. Calves were weaned on d 42 by reducing the MR feeding frequency by 50% on d 36. Calves were housed in hutches bedded with straw and offered water and a texturized 18% CP starter ad libitum. Calf growth was measured weekly and starter intake and fecal scores recorded daily. Data were analyzed using Proc Mixed in SAS as a completely randomized design with repeated measures and the least significant difference test was used for mean separations when main effects were significant ($P < 0.05$). Birth BW averaged 41.8 kg. Average daily gain (ADG) d 1–42 was similar ($P = 0.39$) and averaged 0.59, 0.63, 0.69, and 0.71 kg/day for T1, T2, T3 and T4 (SEM = 0.05). ADG from d 1–56 was also similar among treatments ($P = 0.18$) and averaged 0.62, 0.72, 0.78 and 0.75 kg/d for T1, T2, T3, and T4 (SEM = 0.06). Starter intake averaged 0.88 for T1, 1.12 for T2, 0.81 for T3, and 0.75 for T4 (kg/day). T2 had the greatest starter intake on wk 6 and 7 ($P < 0.05$; T × wk). BW was greater for T3 vs. T1 on wk 8 ($P < 0.05$; T × wk). BW gain from d 1 to 42 were similar ($P = 0.4$) and averaged 24.9 and 26.4 kg for T1 and T2, while T3 and T4 calves gained 28.8 and 29.8 kg. BW gain from d 1 to 56 was not different ($P = 0.2$) and averaged 34.9, 40.1, 43.9, and 42.2 kg for T1, T2, T3 and T4. Fecal scores did not differ. Feeding a 20:20 MR 4 times daily resulted in greater starter intake yielding 5.2 kg additional gain through d 56.

Key words: calf, milk replacer, feeding frequency

302 Effect of different levels of alfalfa hay and sodium-propionate supplementation on performance and rumen development of dairy calves. H. Beiranvand, M. Khorvash, G. R. Ghorbani*, A. Riasi, S. Kargar, and M. Mirzaei, *Isfahan University of Technology, Isfahan, Iran.*

Forty 2 male Holstein calves (46 ± 3.0 kg) were used to evaluate the effect of alfalfa hay (as physical factor) inclusion at different levels and sodium-propionate (as chemical factor) supplementation on performance and rumen development. The experiment was conducted as complete randomized design with a 2 × 3 factorial arrangement. Treatments consisted of 1) concentrate only (Control); 2) concentrate plus 5% sodium-propionate (Control + Pro); 3) concentrate + 5% forage only (5% F); 4) 5% forage + 5% sodium-propionate (5%F+ Pro) = ; 5) concentrate + 10% forage only (10% F); and 6) 10% forage + 5% sodium-propionate (10% F+ Pro). All data were analyzed using the MIXED procedure of SAS (SAS, 2003). All dietary treatments were provided ad-libitum in addition to milk (4 kg/head/day). Concentrate was provided as meal form and alfalfa hay was chopped with geometric mean particle size of 2.6 mm. Nine calves from selected treatments (Control, 10% F, and 10% F + Pro; 3 calves per treatment) were euthanized at 70 d of age. Alfalfa hay supplementation increased dry matter intake and average daily gain but propionate effect or propionate ×

forage interaction were not influenced significantly. Adding alfalfa hay reduced feed efficiency ($P < 0.02$). Compared with calves on propionate those fed forage had lower weaning days (61 vs. 45 d). Rumen wall in calves fed forage showed thinner keratin layer and had stronger muscles layer compared with control. Results indicated that adding forage in the form of chopped alfalfa hay positively influenced growth performance and microscopic appearance of the rumen epithelium and rumen wall as well as decrease in weaning ages.

Key words: alfalfa hay, propionate, rumen development

303 Effect of pre-weaning feeding regimens on post-weaning growth performance of Sahiwal calves. S. A. Bhatti*[1], A. Ali[1], D. McGill[2], M. Sarwar[1], H. Nawaz[1], M. Afzal[3], M. S. Khan[1], M. A. Amer[4], R. D. Bush[5], P. C. Wynn[2], H. M. Warriach[2], and H. Nawaz[1], *[1]Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Pakistan, [2]E H Graham Centre (NSW Industry and Investment and Charles Sturt University), Wagga Wagga, Australia, [3]Pakistan Agricultural Research Council, Islamabad, Pakistan, [4]Livestock Production Research Institute, Bahadurnagar, Okara, Pakistan, [5]Faculty of Veterinary Science, University of Sydney, Camden, Australia.*

The objective of the study was to establish the post-weaning growth potential of Sahiwal calves reared on 4 different pre-weaning diets. Sahiwal calves (n = 48; 24 of each sex 3 ± 2 d of age) were divided into 4 groups of 12 animals each (6 of each sex) and were offered one of the following dietary treatments from d 3 ± 2 postpartum: A: whole cow′s milk + starter ration (SR; CP = 20%, TDN = 72%) plus Berseem clover hay (H; *Trifolium alexandrinum*; CP = 21% TDN = 63%); B: Milk + H; C: Milk replacer (MR; reconstituted to specification; Sprayfo) + SR+H and D: MR + H. Milk or MR was offered at the rate of 10% of their body weight until d 56 and then withdrawn gradually until weaned completely by d 84. The SR and H were continued until d 84. During the post-weaning period the calves were fed a single total mixed ration containing 16% CP and 70% TDN, from the 13th to the 24th week of age. This ration was fed ad libitum, daily feed intake was measured and live-weights were recorded weekly. The data were analyzed by MIXED procedures of SAS. The initial live-weight, growth rate, total live-weight gain and final live-weight of calves at 24 weeks of age were 56 ± 1, 47 ± 1, 40 ± 1 and 30 ± 1 kg; 746 ± 33, 660 ± 34, 654 ± 33 and 527 ± 33 g/d; 63.2 ± 2.6, 55.2 ± 2.7, 54.9 ± 2.7 and 44.2 ± 2.6 kg; and 119 ± 4.2, 102 ± 4.3, 95 ± 4.3 and 75 ± 4.2 kg for the pre-weaning treatments A, B, C and D, respectively; these were influenced ($P < 0.05$) by the pre-weaning treatments. Offering whole milk from birth at the rate of at least 10% of bodyweight with concentrates leads to a higher weaning weight and post-weaning growth rate and hence a greater possibility of early maturity.

Key words: calf nutrition, post-weaning growth

POSTER PRESENTATIONS
Animal Health II

T1 Development of kit for bovine myeloperoxidase using enzyme-linked immunosorbent assay. J. Shi*, Y. Yang, Q. Li, and Y. Lv, *Key Laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, China.*

Myeloperoxidase (MPO) is a heme glucoprotein found in the primary granules of mammalian neutrophils. At site of infection, MPO is released extracellularly or into phagocytic vacuoles. It had shown that MPO is abundant in milk taken from mammary glands of cows with mastitis and that the amount of MPO in milk is well correlated with the somatic cell count in mastitis milk. To evaluate the potential of using MPO in the diagnosis of mastitis in cows, this study developed a specific enzyme immunoassay for MPO in milk. Bovine MPO was isolated and purified from bovine whole blood by Sephadex G-200 chromatography and ConA-Sepharose 4B affinity chromatography. Antiserum against bovine MPO were produced using the purified MPO with ConA as a coated "antibody," and mouse anti-bovine antiserum against MPO as a second detection antibody, and chicken HRP-labeled polyclonal antibody as a anti-antibody, a special sandwich ELISA for MPO was established. ELISA kit was developed. Evaluating kit by methodology showed good specificity, reproducibility (variant coefficient: 1.09 to 7.2% in batch and 1.47 to 6.7% between batches), and the detection limit was 1.1ug/ml. The experiment certified that this kit could maintain over one year and the detection time of the kit was about 3.5h.

Key words: bovine myeloperoxidase, purification, ELISA kit

T2 Development of kit for bovine haptoglobin using enzyme-linked immunosorbent assay. Y. Yang*, J. Shi, Q. Li, and Y. Lv, *Key Laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, China.*

Haptoglobin (Hp) is one of the important acute phase proteins of cows with mastitis, the concentration of Hp in milk and blood is closed to the mastitis condition. So the determination of Hp in milk could be an effective diagnostic tool for mastitis. Development of sandwich-ELISA: The haptoglobin in whey was captured with bovine-hemoglobin coated ELISA plates, and the sandwich ELISA using the anti-Hp-antibody and AP-conjugated-antibody was established, the reaction conditions of ELISA were optimized. The concentration of hemoglobin for coating 96-well microtiter plate was 10%, and incubated overnight at 4°C. The plates were subsequently blocked 1 h with 2% BSA-PBST, and then incubated for 1 h with diluted whey samples (1:10), after washing the plates, the diluted anti-Hp-antibody (1:1000) was added and incubated for 1 h at 37°C. The diluted AP-conjugated-antibody (1:500) was added and incubated for 1 h at 37°C, and then substrate of PNPP solution was added for incubation 15 min at 37°C to develop color. The ELISA test gave a cut-off value of 0.996 for detection of 100 Hp-negative whey samples. The threshold for ELISA was OD405nm ≥0.996 for positives, OD405nm <0.901 for negatives, and the other was suspectives. Correlation between analytical results of the ELISA test and the commercial kits test was similar ($R^2 = 0.996$) based on detection of 50 whey samples. The Hp detection limit of ELISA was 0.08 μg/mL. The ELISA test had no cross-reaction with other acute phase proteins of cows with mastitis. Packing and application of the ELISA test kit for Hp: Based on the sandwich-ELISA, the coating condition of the anti-Hp-antibody, AP-conjugated-antibody, the control positive/negative whey samples, the storage conditions of the plates and the kit were explored, and the ELISA test kit were packed. The variant coefficients of ELISA in a batch and between batches were from 3.27% to 4.98% and from 5.46% to 8.31%, respectively. The ELISA test kit provides an available technique for detection Hp of whey samples and a good foundation for the further development and commercialization of the kit.

Key words: haptoglobin, mastitis, sandwich ELISA

T3 Transcriptional factors SP1 and SP3 influence differentially the regulating sequence of the bovine osteopontin gene depending on promoter haplotype. N. Bissonnette* and C. Thibault, *Agriculture and Agri-Food Canada, Dairy Cattle and Swine Research and Development Center, Sherbrooke, Quebec, Canada.*

Osteopontin is a pro-inflammatory molecule which has been involved in numerous physiological aspects, from wound healing to metastasis. In cattle, osteopontin was associated to the paratuberculosis disease. In a previous study, we have identified DNA polymorphisms (SNP) in the osteopontin gene (*SPP1*) associated with the mammary health status of lactating cows. To better understand the factors that govern the expression of this gene, the activity of its regulating sequence (i.e., promoter) was study in vitro. The most prevalent haplotypes (H1–H3) of the *SPP1* promoter were cloned. Two SNP are located in the 5′ untranslated region and one in the first intron. The haplotype promoter sequences were analyzed in silico for identification of transcription regulating sites using the TRANFAC software. The two transcription factors SP1 and SP3 bindings might be affected by the presence of these SNP. The luciferase reporter constructs of the haplotype containing the 1736-bp regulating sequence were compared in cotransfection assays with, without, or in presence of both SP1 and SP3 using the BOMAC (bovine macrophage), MAC-T (bovine mammary epithelial) and the MCF7 (human mammary epithelial) cell lines. The basal activity of H2 was lower than H1 and H3 ($P = < 0.0001$) in BOMAC and MCF7 cells. In MAC-T, the H2 difference for H1 remained significant ($P = 0.031$) but with a tendency for the allele H3 ($P = 0.066$). In presence of the transfection factor SP1, the expression increased globally by ~2-fold in all cell types. The allele H2 was more responsive to SP1 in both BOMAC and MCF7 (H1, $P = 0.009$ and $P = 0.004$); H3, $P = < 0.001$ and $P = 0.021$, respectively), which was also observed in MAC-T ($P = < 0.0001$). In contrast, the transcription factor SP3 had a negative impact on the promoter activity. The co-expression of SP1/SP3 recovered partially the promoter activity. In this study, we demonstrated that the transcription factors SP1 and SP3 impact gene activity through the regulating sequence and that the presence of SNP within the *SPP1* promoter may interfere with osteopontin expression.

Key words: osteopontin, transcription factor SP1/SP3, haplotype

T4 Evaluation of interleukin 5 as a biomarker for parasite resistance in goats pasture exposed to *Haemonchus contortus*. M. M. Corley* and A. A. Saeed, *Virginia State University, Petersburg.*

In the meat goat industry, an animal that exhibits disease resistance characteristics can increase the price of goat from $250 to $800 per head. *Haemonchus contortus*, the blood sucking gastrointestinal nematode (GIN), costs the global livestock industry billions of dollars per year in lost production and anthelmintic drug costs. The annual expenditure on anthelmintics in the US is over $3 billion. Interleukin 5 is one of the cytokines secreted by Th2 immune cells implicated in the process of gut expulsion of GINs from humans, mice and sheep. However, studies on the mechanism of immunity to *Haemonchus contortus* infection and the ability to identify parasite resistance through IL-5 and other cytokine responses need to be assessed in goats. This study evaluated gene expression of IL-5 in selected pasture exposed parasite resistant Spanish and Myotonic goats. Whole blood, and intestinal tissues were harvested from goats exhibiting susceptibility and resistance to *Haemonchus contortus* based on (FAMACHA (FAM) eye color charts, packed cell volume (PCV), fecal egg counts (FEC) and quantitative real time PCR (qPCR) detection. Primers were designed from conserved regions of IL-5 bovine and ovine nucleotide sequence alignments. Total RNA was extracted from homogenized goat intestinal tissues and qPCR was performed to determine IL-5 expression. Results showed that parasite resistant goats expressed more ($P < 0.05$) IL-5 than susceptible goats. Gene expression of IL-5 was higher ($P < 0.05$) in infected Spanish vs. Myotonic goats. Infected does expressed higher ($P < 0.05$) IL-5 than bucks. Pearson correlation coefficients showed that there was a positive correlation between FEC, FAM, PCV ($P < 0.05$) and IL-5 expression. These data indicate that IL-5 expression can be used as a marker to screen for susceptibility or resistance to *Haemonchus contortus* infection in pasture exposed goats, allowing IL-5 based anthelmintic drug development and goat producers the ability to select parasite resistant animals.

Key words: parasite resistance, IL-5, *Haemonchus contortus*

T5 Influence of latency to collect blood samples from beef calves on ex vivo innate immune responses. L. E. Hulbert*[1,2], C. J. Cobb[1], M. D. Sellers[1], D. L. Hanson[1], M. L. Galyean[1], and M. A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [2]Department of Animal Sciences, University of California-Davis, Davis.*

Objective was to evaluate the influence of latency to collect a blood sample from beef calves on the ex vivo innate immune responses. Innate immune responses evaluated included total leukocyte and differential counts, neutrophil L-selectin expression, whole blood (WB) killing of *E. coli* 0111:H8, tumor necrosis factor-α (TNF-α) secretion from lipopolysaccharide (LPS)-stimulated WB, and neutrophil phagocytosis and oxidative burst responses to E. Coli 0111:H8. Within each of 12 pens, whole blood was collected via jugular puncture from the first and last calf (n = 9 to 10 calves/pen; BW = 202 ± 18.7 kg) to enter the squeeze chute. The time from when research personnel entered the pen to move the cattle until the blood sample was collected averaged (±STD) 320 and 746 ± 44.2 s ($P < 0.001$) for the first and last calf in each pen, respectively. There were no treatment differences for secretion of TNF-α from LPS-stimulated WB or neutrophil phagocytosis. Total leukocyte counts tended ($P = 0.075$) to be less for calves sampled last in the pen vs. those sampled first. Although there were no differences between calf neutrophil:lymphocyte ratios ($P = 0.867$), neutrophil L-selectin expression tended ($P = 0.063$) to be less among calves that were sampled last in the pen. Whole blood from the calves sampled last also tended ($P = 0.060$) to kill less *E. coli* 0111:H8. Similarly, the calves sampled last had decreased ($P = 0.043$) neutrophil oxidative burst response to the *E. coli* 0111:H8. These data indicate that it is important to control for the latency until sample collection associated with handling and movement when designing ex vivo immunological studies with beef calves.

Key words: immunity, cattle, stress

T6 Characterization of bovine leukocyte differentiation molecules in Egyptian cattle using flow cytometry. G. S. Abdellrazeq*[1], M. M. El-Naggar[1], and W. C. Davis[2], *[1]Alexandria University, Edfina, Behara province, Egypt, [2]Washington State University, Pullman.*

Evaluation of the efficacy and cross-protectivity of any applied vaccine in Egypt requires preliminary studies to investigate the characteristics of the immune system in a chosen farm animal species including the proportions of subpopulations of leukocytes. In this report, we investigate the comparative changes of leukocytes, T cell subsets and MHC molecules. Twenty ml blood samples were collected from healthy Egyptian cattle from young (age ~6–8 mo, no 4) and adult cattle(age ~3–5 year, no 4). Blood was processed, stained with a panel of monoclonal antibodies (mAbs) and analyzed by flow cytometry (FC). FC analysis revealed that the whole leukocyte population in young animals was composed of granulocytes representing about 30%, monocytes representing about 11% and lymphocytes representing about 59% while in adult animals, the granulocytes represent about 22%, monocytes represent about 7% and lymphocytes represent about 71%. CD4+ T cells represent about 41% of T cells in young animals and the proportion of this cell subset represents about 44% of T cells in adult animals. The CD8+ T cell subset was found to represented about 22% of T cells in young animals while representing about 41% of T cells in adult animals. We conclude that the age-related changes of leukocytes and T cell subsets in Egyptian cattle are basically the same as those found in pure Holstein cattle. These results will serve as a reference value and need to be taken in consideration when attempting to analyze the immune response in Egyptian cattle to M. a. paratuberculosis and other pathogens and their derived vaccines.

Key words: leukocyte differentiation molecules, flow cytometry, Egyptian cattle

T7 Comparative evaluation of gene expression in bovine and caprine neutrophils. M. Worku*, N. Mikiashvili, and H. Ishamel, *North Carolina A&T State University, Greensboro.*

Recognition and destruction of bacteria by polymorphonuclear neutrophil leukocytes (PMN) is a major defense against infections by pathogens. Impaired innate immune defense to gram-negative *Escherichia coli* infections is associated with delayed influx of PMN into the mammary gland. An evaluation of gene expression in response to exposure to *Escherichia coli* O111-B4 lipopolysaccharide (LPS) was conducted in isolated bovine and caprine PMN. Blood samples were collected from 3 Holstein Friesian cows and 3 Spanish × Boer goats. Isolated blood PMN, were incubated with LPS (0, 10 or 100 ng/ml, at 37C for 15 or 30 min in the presence of 95% humidity and 5% CO2).Eight cytokines were measured in cell culture supernatants using Signosis Inflammation ELISA Strips for quantitatively profiling and measuring TNF-α, IFNr, G-CSF, GM-CSF, IL-1a, IL-8, IP-10, and Rantes. Quantitative reverse transcriptase-PCR was employed to test the synthesis of specific mRNAs. Both bovine and caprine neutrophils

expressed TLR4 (452 bp) and CD14 (600bp). Exposure to LPS significantly increased CD14, TLR4 ($P < 0.001$) and TNF α ($P < 0.05$), transcripts in cow PMN. In goat PMN exposure to 100ng LPS for 30 min increased transcripts for CD14 and TNF-α ($P < 0.05$). Changes were not observed with TLR4 transcript levels. Treatment affected secretion of TNF-α, IFNr, G-CSF, GM-CSF, IL-1a, IL-8, IP-10 and Rantes. Exposure to 100ng of *E. coli* LPS caused a strong induction of TNF-α, IFNr, G-CSF, GM-CSF cytokine synthesis, in cows. The concentrations of TNF-α and IL-8 increased 2 fold. Thus in both bovine and caprine neutrophils exposure to LPS results in transcription and translation involving TLR4 CD14, and TNFalpha. This response is affected by dose and exposure time to LPS and varied by species. The role played by neutrophils in immunity might be affected by species variations in gene expression.

Key words: neutrophil, TLR4, ruminant

T8 Detection and expression of the gene encoding low density lipoprotein receptor-related proteins 6 (LRP6) in goat peripheral blood. M. Worku*, H. Mukhtar, and N. Mikiashvilli, *North Carolina Agricultural and Technical State University, Greensboro.*

Previous studies in our lab have reported the identification and expression of Wingless (Wnt) 1 and Frizzled in the goat. Wnt ligands conduct their functions in canonical Wnt signaling by binding to 2 receptors, the single transmembrane low density lipoprotein receptor-related proteins 5 and 6 (LRP5/6) and 7 transmembrane Frizzled receptors. Polymorphisms of the LRP6 gene are associated with bone mineral density. The objectives of this study were to detect the LRP-6 gene and evaluate its expression in goat peripheral blood. Blood from goats (n = 9) was collected on FTA elute cards for DNA extraction and in PAXgene Blood tubes for RNA extraction. RNA samples were reverse-transcribed and the cDNA was obtained. Specific LRP6 primers were used for PCR amplification. The amplified product was run on a 1% agarose gel. GAPDH was used as loading control and primers in the absence of DNA were used as negative controls. Gels were stained with ethidium bromide and visualized. The amplicon was sequenced commercially and the BLAST tool was used to compare the sequence with the NCBI database. An ~400 bp fragment of LRP6 was present in genomic DNA and expressed at the RNA level the amplified sequences had 100% similarity to human LRP6. The results of this study show that LRP-6 is conserved between goats and humans. Human mutations in LRP6 cause early onset coronary disease, osteoporosis, late onset Alzheimer's and cancers. In goats osteoporosis has been reported to occur due to mineral deficiency and gastrointestinal parasitism. Further, the goat has been developed as a large osteoporotic animal model that resembles human osteoporotic changes. Thus, this gene could aid in studies in skeletal development and diseases of goats and humans.

Key words: goat, osteoperosis, Wnt LRP6

T9 Comparison of commercially available enzyme-linked immunosorbent assay with serum neutralization for measuring bovine viral diarrhea virus specific antibodies. M. Gonda*[1], X. Fang[1], G. Perry[1], and C. Maltecca[2], *[1]South Dakota State University, Brookings, [2]North Carolina State University, Raleigh.*

Our laboratory is focused primarily on mapping loci that affect bovine viral diarrhea virus (BVDV) vaccine response in beef cattle. Several methods for measuring humoral BVDV vaccine response are available: 1) a BVDV antibody enzyme linked immunosorbent assay (ELISA) which measures total BVDV antibodies, and 2) serum neutralization (SN) which measures only protective antibodies specific for BVDV-1 or BVDV-2. The SN tests are more biologically relevant, but the ELISA is cheaper and faster for measuring BVDV antibodies, and could be effectively used if the ELISA and SN tests were highly correlated. Our objective was to test if BVDV total antibody ELISA sample-to-positive (S/P) ratios were correlated with BVDV-1 and BVDV-2 SN antibody titers. A total of 406 blood samples were collected from 193 Angus and Angus cross calves raised in 2 South Dakota beef herds that vaccinate cows for BVDV-1 and BVDV-2. Serum or plasma were collected from blood and then BVDV-specific antibody concentration was measured on each sample by 1) IDEXX (Liebefeld-Bern, Switzerland) antibody ELISA, 2) BVDV-1 SN, and 3) BVDV-2 SN. Higher BVDV ELISA S/P ratios were positively correlated with higher BVDV-1 SN ($\rho = 0.809$) and BVDV-2 SN ($\rho = 0.638$) titers ($P < 0.0001$), although the relationship was weaker when SN titers were <1:64. Higher BVDV-1 SN titers were also correlated with higher BVDV-2 SN titers ($\rho = 0.708$; $P < 0.0001$). We conclude that IDEXX BVDV total antibody ELISA S/P ratios can be used as a surrogate for BVDV-1 and BVDV-2 SN antibody titers when mapping loci affecting BVDV vaccine response.

Key words: ELISA, serum neutralization, bovine viral diarrhea virus

T10 Effects of *Camellia* L. plant extract and mannan-oligosaccharide on growth performance, gut health, blood parameters, cecal microflora and immunity of broiler chicks. K. Hatami and M. Zaghari*, *Department of Animal Science, College of Agriculture and Natural Resource, University of Tehran, Karaj, Karaj, Alborz, Iran.*

An experiment was conducted with 128, 1-d-old, male broilers to investigate the effects of saccharicterpenin (composed of triterpenoid saponin and saccharide from the plant Camellia L.; CL) and Techno-Mos (rich in mannan-oligosaccharides and β-1,3-glucanes) on growth performance, gut health, blood parameters, cecal microflora and immune response of broiler chicks. Experiment was done as a completely randomized design with 4 treatments (control, 0.3 and 0.5 g/kg CL and 0.5 g/kg mannan-oligosaccharide), 8 replicates and 4 chicks in each battery cage. Two basal diets were formulated for starter (1 to 21) and grower (22 to 42) periods and levels of CL and MOS were added to basal diet. Body weight gain, feed intake and feed conversion ratio were measured at 21, 35 and 42 d of age. Plasma triglyceride, cholesterol, LDL, VLDL and HDL concentrations were measured at 42 d of age. Differential counting of monocytes, lymphocytes, eosinophils and neutrophils percent were done at 42 d of age. pH of gastrointestinal sections were measured at 42 d of age. Effects of diet on villi length and crypt depth were measured at 42 d of age. Immune response to PHA-P was measured at 35 and to SRBC at 28 and 42 d of age. Supplementation of diets with 0.5 g/kg CL decreased body weight gain, feed intake and feed conversion ratio significantly throughout the experiment ($P < 0.01$). Proventriculus, gizzard and ileum pH differed among the treatment but duodenum and jejunum pH were not affected ($P < 0.05$). Supplementation of diets by CL and MOS affected cholesterol level of plasma but had no effect on plasma levels of triglyceride, LDL, HDL ($P < 0.03$). Cecal microbial population did not differ among treatments. Supplementation of diets with CL and MOS significantly increased villi length and crypt depth ($P < 0.0001$). CL had no effect on immune response against PHA-P at 36 d of age, however an increase was observed with addition of CL and MOS, also CL and MOS decreased antibody titer against SRBC at 28 d of age($P < 0.01$).

Key words: *Camellia* extracts, performance, mannan-oligosaccharide

T11 Gastrointestinal nematode infection in Nelore and crossbred cattle. M. C. S. Oliveira*[1], M. C. D. Beraldo[2], E. Nakandakari[3], L. Boschini[1], M. M. Alencar[1], R. Giglioti[4], A. C. S. Chagas[1], B. Rubert[5], S. C. Bogni[2], and A. M. G. Ibelli[5], *[1]Embrapa Pecuaria Sudeste, São Carlos, SP, Brazil, [2]UNICEP, São Carlos, SP, Brazil, [3]Uniara, Araraquara, SP, Brazil, [4]UNESP, Jaboticabal, SP, Brazil, [5]UFSCAR, São Carlos, SP, Brasil.*

Cattle nematodes in Brazil are mainly controlled through application of anthelminthics. However, this causes concern about the presence of drug residues in meat and dairy products, prompting studies of alternative control methods. Among these, the use of animals that are genetically resistant is a very promising complementary strategy. Resistance to gastrointestinal nematodes was compared in males and females Nellore (NI, n = 28) and a 3 breed cross, 1/2 Angus 1/4 Canchim (5/8 Charolais + 3/8 *Bos indicus*) + 1/4 Nelore (TC, n = 17) that were born from October to December 2008. The animals were kept without treatment, in rotational paddocks of Tanzania grass. Monthly collections were conducted totaling 810 observations (August 2009 to January 2011). The feces samples were collected from each animal for fecal cultures and determination the number of eggs per gram of feces (EPG). Blood samples were collected monthly for packed cell volume determination (PCV) that was an indicator of animal health. The count data of EPG were submitted to log10 (n+1) transformation. The data were analyzed using the MIXED procedure of SAS (2002–2003), according to a model considering repeated measures on the animal, structured with a compound symmetry variance matrix, and also included the effects of genetic group, sex, month/year of collection and 2-way interactions involving these 3 factors. The means of PCV were significantly higher ($P < 0.01$) for NI animals (40.6%) compared with TC (38.6%). No significant effects of genetic groups or interaction between the genetic groups and month/year of collection on the EPG were found, but there was a significant influence of the month/year of collection ($P < 0.01$). The following nematode genera were found in the coprocultures: *Haemonchus*, *Cooperia*, *Esophagostomum* and *Trichostrongylus*, the latter in smallest proportion. There was no significant difference between the genetic groups for averages of all parasites identified, except *Cooperia*, which were present in higher numbers in the animals of the NI group ($P < 0.05$). These data confirm previous findings that showed greater susceptibility of purebred Nellore animals to *Cooperia*.

Key words: nematodes, resistance, cattle

T12 Concentrations of haptoglobin in bovine plasma determined by ELISA or a colorimetric method based on peroxidase activity. R. F. Cooke*[1], B. I. Cappellozza[1], F. N. T. Cooke[1], D. W. Bohnert[1], and J. D. Arthington[2], *[1]Oregon State University–Eastern Oregon Agricultural Research Center, Burns, [2]University of Florida–Range Cattle Research and Education Center, Ona.*

Our laboratory determines plasma concentrations of haptoglobin using a low-cost colorimetric procedure that measures haptoglobin-hemoglobin complexing by estimating differences in peroxidase activity (CPPA). Results are expressed as arbitrary units based on absorption readings, given that the CPPA method does not contain a standard curve. Conversely, commercially available ELISA methods generate results based on standards with known haptoglobin concentrations. Therefore, the objective of this study was to determine if the CPPA method generates results compatible with a commercial ELISA kit. Nine Angus steers were vaccinated against *Mannheimia haemolytica* (One Shot, 2 mL s.c) to stimulate an acute-phase response and blood samples were collected before vaccination (d 0), and on d 1, 3, 5, 7, and 10. Plasma samples were frozen in triplicates at −80°C. One set of the triplicates was analyzed for haptoglobin concentrations using the CPPA procedure. A day effect was detected ($P < 0.01$) given that haptoglobin peaked on d 1, 3, and 7 relative to vaccination. A second set of the triplicates was analyzed using a commercial ELISA kit. A similar day effect ($P < 0.01$) was detected. When Pearson coefficients were calculated among results obtained from CPPA and ELISA methods, a strong correlation was detected (r = 0.98; $P < 0.01$). Based on the ELISA results, the plasma sample with the greatest haptoglobin concentration was serially diluted with PBS (1:1 through 1:32 dilution) and used as known reference to generate a standard curve for samples from the third set of triplicates analyzed with the CPPA method. A linear standard curve was generated ($r^2 = 0.99$) and a day effect ($P < 0.01$) was again detected. However, the values generated by the CPPA procedure with standard curve differed ($P < 0.01$) when compared with those generated by ELISA. In conclusion, assessing concentrations of haptoglobin in bovine plasma using the CPPA method yields results highly correlated to ELISA. Therefore, the CPPA method can be adopted to evaluate plasma haptoglobin concentrations in cattle when absolute values are not required.

Key words: bovine, haptoglobin, assay

T13 Feed and water restriction elicits an acute-phase protein response in beef cattle. B. I. Cappellozza*, R. F. Cooke, C. Trevisanuto, V. D. Tabacow, F. N. T. Cooke, and D. W. Bohnert, *Oregon State University–Eastern Oregon Agricultural Research Center, Burns.*

The acute-phase protein response is an important component of the innate immune system, but can be highly detrimental to cattle productivity. A comprehensive understanding of the causes and mechanisms that stimulate the bovine acute-phase protein response is required for development of management strategies to modulate this immune reaction. Therefore, the objective of this study was to determine if feed and water restriction stimulates an acute-phase protein response in overtly healthy beef steers. Nine Angus × Hereford steers were ranked by initial BW (average 244 ± 8 kg) and assigned to 1 of 2 treatments: 1) CONT - ad libitum access to feed and water during the study (d 0 to d 10), and 2) RESTR - feed and water restriction for 24 h (d 0 to d 1 of the study) and subsequent ad libitum access to feed and water (d 1 to d 10). Blood samples were collected from all steers on d 0 (before restriction period), 1 (at the end of the restriction period), 3, 5, 7 and 10. Samples were harvested for plasma, and immediately stored at −80°C until analyzed for concentrations of haptoglobin and ceruloplasmin. Hay DMI was evaluated daily by measuring refusals. Results were analyzed with the MIXED procedure of SAS. Plasma haptoglobin concentrations tended to be greater ($P = 0.06$) for RESTR steers compared with CONT on d 3 of the study (6.35 vs. 4.62 absorbance at 450 nm × 100, respectively). Plasma ceruloplasmin concentrations tended to be greater ($P = 0.15$) for RESTR steers compared with CONT on d 3 (18.0 vs. 14.4 mg/dL, respectively) and d 7 of the study (19.3 vs. 15.8 mg/dL, respectively). A treatment × day interaction was detected ($P = 0.01$) for hay DMI because RESTR steers had greater ($P < 0.01$) hay DMI on d 1 (2.98 vs. 1.97% of BW, respectively) and tended to have greater ($P = 0.11$) hay DMI on d 2 (2.74 vs. 2.32% of BW, respectively) compared with CONT steers. Results from this study indicate that feed and water restriction elicits an acute-phase protein response in overtly healthy beef cattle, which may detriment subsequent health and productivity parameters.

Key words: acute-phase proteins, feed and water restriction, beef cattle

T14 Natural infestation by external parasites in beef cattle in southern Brazil. M. C. S. Oliveira*[1], E. Nakandakari[2], M. C. D. Beraldo[3], M. M. Alencar[1], A. C. S. Chagas[1], L. Boschini[1], R. Giglioti[4], and A. M. G. Ibelli[5], *[1]Embrapa Pecuaria Sudeste, São Carlos, SP, Brazil, [2]UNIARA, Araraquara, SP, Brazil, [3]UNICEP, São Carlos, SP, Brazil, [4]UNESP, Jaboticabal, SP, Brazil, [5]UFSCAR, São Carlos, SP, Brasil.*

The existence of genetic differences between groups regarding the degree of infestation by external parasites suggests the possibility of using crosses between breeds to increase the benefits of complementarity and heterosis for adaptive traits. In this experiment natural infestations were compared in males and females Nellore (NI, n = 28) and a 3 breed cross, 1/2 Angus 1/4 Canchim (5/8 Charolais + 3/8 *Bos indicus*) + 1/4 Nelore (TC, n = 17) that were born from October to December 2008., regarding the resistance to the tick *Rhipicephalusmicroplus*, to the horn fly (*Haematobia irritans*) and the botfly (*Dermatobia hominis* larvae). The animals were kept without chemical treatment, in rotational paddocks of Tanzania grass. Monthly collections were conducted totaling 810 observations (August 2009 to January 2011), being counted all engorged female ticks with more than 4.5 mm diameter located on the left and the botfly around the animal's body. Horn flies were counted with the aid of photographs of the lumbar region. Blood samples were also collected monthly for packed cell volume determination (PCV) that was an indicator of animal health. The count data of external parasites were submitted to log10 (n +1) transformation and analyzed using the MIXED procedure of SAS (2002–2003) according to a model considering repeated measures on the animal, structure with a compound symmetry variance matrix, and included the effect of genetic group, sex, month/year of collection and interactions involving these factors. The means of PCV were significantly higher for NI animals (40.6%) compared with TC (38.6%), and there was significant influence of collection month/year ($P < 0.01$). Animals of NI group had lower external parasites infestations than TC animals ($P < 0.01$). Means and standard errors for NI and TC animals were, respectively, 0.07 ± 0.01 and 0.36 ± 0.02 for *R. microplus*, 0.86 ± 0.05 and 1.25 ± 0.06 for *H. irritans* and 0.06 ± 0.03 and 0.47 ± 0.04 for *D. hominis* larvae. These results indicate that the control of external parasites should be done differently for each genetic group.

Key words: cattle, parasites, resistance

T15 Cinnamaldehyde enhances in vitro parameters of immunity and reduces severity of in vivo infection against avian coccidiosis. S.-H. Lee[1], H. Lillehoj*[1], S. Jang[1], K. Lee[1], and D. Bravo[2], *[1]Animal and Natural Resources Institute, ARS USDA, Beltsville, MD, [2]Pancosma S.A., Le Grand Saconnex, Geneva, Switzerland.*

We examined the effects of cinnamaldehyde (CINN) on in vitro parameters of immunity (splenocyte proliferation, macrophage activation, and killing of tumor cells and parasites), and in vivo protection against avian coccidiosis (body weight gain, oocysts production, antibody responses, and intestinal cytokine levels). In vitro stimulation of chicken spleen lymphocytes with CINN (25, 50, 100, and 400 ng/ml) induced greater cell proliferation compared with the media control ($P < 0.001$). CINN activated cultured macrophages to produce higher levels of nitric oxide at 1.2, 2.5, and 5.0 μg/ml ($P < 0.001$), inhibited the growth of chicken tumor cells at 0.6, 1.2, and 2.5 μg/ml ($P < 0.001$), and reduced the viability of *Eimeria tenella* parasites at 10 and 100 μg/ml ($P < 0.01$ and $P < 0.001$, respectively), compared with media controls. In in vivo experiments, chickens were fed a non-supplemented diet (control) or a diet supplemented with 14.4 or 125 mg/kg of CINN from hatch for 14 d. The levels of IL-1β, IL-6, IL-15, and IFN-γ transcripts produced by intestinal lymphocytes were 2- to 47-fold higher in CINN-fed chickens compared with controls ($P < 0.001$). To determine the effect of CINN-supplemented diets on body weight gain and excretal oocyst shedding following *E. tenella*, *E. acervulina*, *E. maxima* infection, chickens were fed a non-supplemented diet (control) or diets supplemented with 125 (*E. acervulina*-infected birds) or 14.4 mg/kg (*E. maxima*- or *E. tenella*-infected birds) of CINN from hatch for 24 d, and uninfected or orally infected with 2 × 10,000 sporulated oocysts of the homologous parasites at 14 d of age. CINN-fed chickens showed 16.5% and 41.6% increased body weight gains between 0 and 9 d post-infection (DPI) with *E. acervulina* or *E. maxima*, reduced *E. acervulina* oocyst shedding between 5 and 9 DPI, and increased *E. tenella*-stimulated EtMIC2 antibody responses at 9 DPI compared with controls. This study provides the first evidence that CINN enhances in vitro and in vivo parameters of immunity against experimental avian coccidiosis.

Key words: cinnamaldehyde, chicken, immunity

T16 Comparison of different levels of vitamin premix on chicken meat quality in floor and battery cage broiler raising. M. A. Shahrasb, H. Moravej, and M. Shivazad*, *Department of Animal Science, Faculty of Agriculture and Natural Resources, Tehran University.*

This experiment was conducted to comparison of different levels of vitamin premix (VP) on broiler finisher diets at 29 to 42 d of age on meat quality in floor and battery cage rearing systems. A total of 616 male broiler chicks (Ross 308) were allocated to 7 treatment groups (different levels and access time to VP), with 4 replicates per treatment group and all data were analyzed in a randomized complete block design. The oxidative stability, evaluated by thiobarbituric acid reactive substances (TBARS) on the thigh meat samples that storage 180 d in −20°C. The results of TBARS values in trial floor system showed there are not significant differences between TBARS values of thigh meat samples for birds slaughtered at 35 d of age, however, at 42 d of age TBARS values of treatments without VP were significantly higher than other treatments ($P < 0.05$). The results of TBARS values in trial battery cage system showed the highest TBARS values of treatments belong to the treatment without VP at 35 d of age ($P < 0.05$), although TBARS values of treatments without VP and 33% VP were significantly higher than other treatments of thigh meat samples for birds slaughtered at 42 d of age ($P < 0.05$). Finally, the results of this study demonstrated that (1) it is not possible withdrawal but it can be possible to reduce VP in finisher broiler diets without negative effects on performance and meat quality during the time of freezing in both methods of rearing; (2) it is possible to reduce the VP levels in diet of broilers rearing in floor system more than cage system.

Key words: broiler, vitamin premix, meat quality

T17 Effects of feeding OmniGen-AF to rats on gastrointestinal gene expression: Microarray analysis. B. R. Ou[2], Y. Q. Wang[1], and N. E. Forsberg*[1], *[1]OmniGen Research, Corvallis, OR, [2]Tunghai University, Taichung, Taiwan, ROC.*

OmniGen-AF is widely fed in the United States dairy industry and has been reported to reduce somatic cell counts and improve herd health. Yet, the fundamental mechanism(s) by which this product brings about these benefits remains unknown. Our hypothesis was that, because the product is fed, it alters gastrointestinal (GI) gene expression. To test

this hypothesis, 16 growing male CD rats (ca. 225 g) were assigned to 2 treatments: a control treatment (fed a Teklad 8604 powdered diet) and an OmniGen-AF treatment (Teklad supplemented with 0.5% w/w OmniGen-AF [Prince Agri Products, Quincy, IL]). Rats were maintained on diets for 28 d then euthanized. A 10 cm portion of small intestine was removed from each rat and RNA preserved via Trizol. Quality of RNA was assessed in an Agilent Bioanalyzer. RNA was hybridized to Agilent arrays containing 23000 genes. Normalization of the probe set was performed using the Robust Multiarray Analysis method. Gene expression intensities were compared using a moderated *t*-test and a Bayes smoothing approach. Analysis was performed using the affylmGUI Graphical Interface for the Limma microarray package. Differentially expressed genes and pathways were derived using DAVID functional analysis. Of the 23000 genes on the array, 288 were upregulated and 385 were downregulated ($P < 0.05$). DAVID pathway analysis identified 13 GI pathways which were specifically affected ($P < 0.05$) by the additive. Of these 13 pathways, 6 were related to "immune function." These included complement and coagulation, antigen processing and presentation, autoimmune thyroid disease, allograft rejection, graft versus host disease and viral myocarditis. Other regulated pathways included starch and sucrose metabolism and endocytosis. A limitation of these data are that we do not know which cell type, of the many GI cell types, was affected by feeding the product. Still, these data demonstrate that significant changes in GI metabolism apparently result from feeding the product. We propose that any nutrient or additive will similarly exert changes in GI gene expression. The specific pathways/patterns affected likely underlie efficacy.

Key words: OmniGen-AF, gene expression, intestine

T18 Inhibition of inflammatory processes in Caco-2 intestinal epithelial cells by an ethanolic extract of a polyphenol-rich grape seed meal. R. Ringseis[1], M. Siebers[1], J. Keller[1], A. Steinbeck[2], B. Eckel*[2], and K. Eder[1], *[1]Institute of Animal Nutrition and Nutrition Physiology, Justus-Liebig-University Giessen, Giessen, Germany, [2]Dr. Eckel GmbH, Niederzissen, Germany.*

Several pathologic stimuli, including bacteria and viruses, are known to stimulate inflammatory processes in the intestinal mucosa by cytokine-mediated activation of the proinflammatory transcription factor NF-κB. Through the subsequent release of inflammatory mediators which enter the circulation, the inflammatory process may also affect other tissues, and cause stimulation of protein catabolism in skeletal muscle and formation of acute phase proteins in the liver. Considering that such processes lead to an impairment of animal performance, the inhibition of inflammatory processes in the intestine is a reasonable approach to maintain performance characteristics of livestock animals. Therefore, the objective of the present study was to explore the anti-inflammatory potential of a polyphenol-rich grape seed meal (AntaOx E) using Caco-2 intestinal epithelial cells. Caco-2 cells were grown to confluence, and differentiated for 6 days. Subsequently, the differentiated Caco-2 cells were treated with the cytokine TNFα alone as a control or with TNFα and different dilutions of an ethanolic extract of AntaOx E for 24 h. Cell viability of Caco-2 cells treated with increasing dilutions of the ethanolic extract of AntaOx E was not impaired. Reporter gene assays using an NF-κB-driven reporter plasmid revealed that the lowest dilutions (1.00E-03, 1.00E-04) of the ethanolic extract of AntaOx E inhibited the TNFα-induced transactivation of NF-κB by 35% and 25% ($P < 0.05$), respectively, whereas higher dilutions (1.00E-05, 1.00E-06) had no effect. Moreover, the lowest dilution (1.00E-03) of the ethanolic extract of AntaOx E reduced the TNFα-induced mRNA levels of the NF-κB target genes IL-1β, IL-8, MCP-1 and CXCL10 by 20 to 35% ($P < 0.05$). It is shown that AntaOx E is capable of inhibiting the activation of the proinflammatory transcription factor NF-κB and, thereby, the expression of several inflammation-related genes in intestinal epithelial cells. Thus, polyphenol-rich grape seed meal may be useful in the inhibition of inflammatory processes in the intestinal mucosa of livestock animals.

Key words: inflammation, intestine, phytochemicals

T19 Association of slaughter and dressing traits with ultrasound and computed tomography data in cattle. G. Hollo*[1], J. Tõzsér[2], A. Szentléleki[2], F. Szabo[3], I. Anton[4], T. Somogyi[1], I. Repa[1], and I. Hollo[1], *[1]Kaposvár University, Kaposvár, Hungary, [2]St. István University, Gödöllö, Hungary, [3]Pannon University, Keszthely, Hungary, [4]Research Institute for Animal Breeding and Nutrition, Herceghalom, Hungary.*

The aim of this study was to establish the relationship among slaughter and dressing traits as well as cross sectional imaging data measured by ultrasound (UH) and x-ray CT method (CT) in cattle. Seventy growing-finishing bulls from 6 different genotypes were used. The animals were kept and fed under the same condition. Animals were ultrasound scanned (Falco 100, Pie Medical) for Longissimus muscle area between 12-13th rib (UHLMA), backfat thickness (P8) and rump fat (RF) determinations (average live weight of 398 kg). The target live weight was determined at 600 kg. At slaughter, slaughter weight (SW), hot carcass weight (HCW), kidney fat proportion (KF) and EU beef carcass classification data were recorded. After 24 hr chilling the right sides of carcasses were dissected. For the CT-analysis (Siemens Emotion 6) ribs joint was removed from right half carcasses between 11-13th ribs. Areas and proportions of muscle, fat and bone tissue were calculated and the area of Longissimus muscle (CTLMA) was measured. For estimation of linear association Pearson correlation analysis and multi- and bivariate regression were applied (SPSS 10.0). Slaughter data moderately correlated with UH and CT data. The KF positively related to P8 (r = 0.52) and RF (r = 0.53) as well as CT-fat area (r = 0.77) and CT-fat percentage (r = 0.78). A positive relationship was determined between EU conformation score and UHLMA (r = 0.59) and CTLMA (r = 0.66). The EU fatness score showed a higher relationship with RF (r = 0.42) than P8 (r = 0.57). The lean % and fat % in carcass correlated closer with CT-muscle and CT-fat % in rib joint (r = 0.85; r = 0.92) than UH data (r = 0.39; r = 0.65). Predictors derived from CT alone accounted for a high proportion of the variance in dissected fat proportion (R^2 = 0.85), but lower proportions for dissected lean meat yield (R^2 = 0.77). For predicting lean weight from combinations of HCW and UH measurements the R^2 value found 0.87. R^2 of 0.83 was measured for fat weight using UHLMA and CT fat area. In conclusion, the in vivo UH measurements and CT scanning of rib joint can provide opportunities to estimate the beef carcass value objectively.

Key words: cattle, carcass composition

T20 Effect of arrival health risk status of steer calves on feedlot performance and health during a 61-d preconditioning program. C. Flaig[1], L. Clark[1], O. C. Schunicht[1], M. L. May[1], R. E. Peterson[1], C. W. Booker[1], R. Krehbiel[2], G. K. Jim[1], B. P. Holland[3], and L. O. Burciaga-Robles*[1], *[1]Feedlot Health Management Services Ltd., Okotoks, Alberta, Canada, [2]Department of Animal Science, Oklahoma State University, Stillwater, [3]Department of Animal and Range Sciences, South Dakota State University, Brookings.*

Ranch-direct steer calves (n = 120; BW = 289 ± 6.84 kg; RANCH) and ultra-high risk steer calves (n = 120; BW = 250 ± 6.84 kg; UHR) were allocated to evaluate the effect of risk status at arrival on feedlot performance and health during a 61-d preconditioning program. Arrival processing included a metaphylactic treatment for control of BRD and proprietary health procedures based on animal health risk assessment (Feedlot Health Management Services, Ltd. Okotoks, Alberta, Canada) and individual numbered and electronic ear tags were also applied. Intact males were band castrated. After initial processing, cattle of the same risk group were randomly allocated to one of 6 pens (40 head/pen) equipped with individual feed intake data collection systems (GrowSafe Systems Ltd., Airdrie, Canada) and fed for 61 d. Cattle were observed by trained personnel for detection and treatment of disease during the trial. Cattle were re-weighed on d 30 and d 61. Animal performance was analyzed using PROC GLIMMIX (SAS Institute, NC). Animal was the experimental unit, and the model included the fixed effect of treatment and the random effect of replicate. Initial body weight was heavier for RANCH than UHR (289 vs. 250 ± 6.50 kg; $P < 0.001$) and it was included as a covariate in the model. Animal health parameters were analyzed using the chi-squared procedure of SAS. A total of 24 animals (15 RANCH and 9 UHR) were removed from the trial and not included in the analysis. In addition, 2 (1.67%) RANCH and 1 (0.80%) UHR died ($P = 0.56$) and were removed from the analysis. Treatments for BRD were higher for RANCH vs. UHR calves (22.5 vs. 10.0%; $P = 0.01$). No differences in ADG, DMI, or FG ($P > 0.05$) were observed from d 0 to 30 and d 0 to 61. Based on these data, health risk status at arrival has no effect on feedlot performance; however based on the differential arrival health protocol, RANCH were treated more often for BRD than UHR during a 61-d preconditioning program. Economic modeling is important when determining arrival health protocols and purchase price based on health risk assessments of specific populations of cattle.

Key words: feedlot performance, health risk status, BRD

T21 Effect of residual feed intake on blood urea nitrogen concentration in growing heifers from an Angus-Brahman multi-breed herd. R. O. Myer[1], M. A. Elzo[2], G. C. Lamb[1], and N. DiLorenzo*[1], *[1]University of Florida, NFREC, Marianna, [2]University of Florida, Gainesville.*

Blood urea N can be used as an indicator of N use and excretion by an animal. The objective of this research was to assess the effect of residual feed intake (RFI) on blood plasma concentration of urea N (PUN) in 85 growing beef heifers ranging from 100% Angus to 100% Brahman born in 2008. Calves were assigned to pens in a GrowSafe feeding facility by sire group and fed ad libitum a total mixed ration (62% chopped grass hay, 30% whole corn, 3% cottonseed meal, and 5% molasses-mineral-vitamin supplement; 90% DM, 11% CP, and 68% TDN). The pre-trial adjustment period lasted 14 d. Individual daily feed intake was collected during the 70 d feeding trial; BW were recorded every 2 wk. Blood (jugular) was drawn on d −10, 0, 56, and 70 for PUN. Residual feed intake (RFI) was computed as the difference between actual and expected intakes. Data (PUN) were analyzed using a mixed model. Fixed effects were pen, age, RFI of calf, Brahman fraction of calf, heterozygosity of calf, and daily feed intake. Random effects were sire and residual. Overall ADG was 0.91 ± 0.02 kg/d. Brahman had higher PUN concentrations at each sampling day compared with Angus ($P < 0.01$). Only d −10 PUN concentration was slightly related to RFI ($P = 0.07$), in that low RFI cattle also had low PUN beyond that expected due to the lowered feed intake; the other sampling days were not affected by the RFI of the calf ($P > 0.10$). Results indicate that PUN concentration appeared to be little affected by RFI beyond that accounted for by reduced feed intake.

Key words: beef cattle, blood urea, feed efficiency

T22 Post-weaning feed efficiency of tropically adapted purebred and crossbred calves when fed in either winter or spring. S. W. Coleman*[1], C. C. Chase[1], W. A. Phillips[2], and D. G. Riliey[1], *[1]USDA ARS Subtropical Agricultural Research Station, Brooksville, FL, [2]USDA, ARS, Grazinglands Research Laboratory, El Reno, OK.*

Earlier work has shown that young, tropically adapted (Brahman and Romosinuano) cattle do not gain as rapidly as temperately adapted (Angus) cattle during the winter in OK. The objective for this study was to compare efficiency of gains between tropically- and temperately-adapted cattle breeds. Over 3 yr, 239 purebred and crossbred steers (F1 and 3-way crosses) of Angus, Brahman or Romosinuano breeding were born in Brooksville, FL, transported to El Reno, OK in October each year, and fed in 2 phases to determine individual intake and performance. Phase 1 (W, ~127 d) began in November and phase 2 (S, 56 to 162 d) began in March. A grower diet (14% CP, 1.10 Mcal NEg/kg) was fed in W and a conventional feedlot diet (12.8% CP; 1.33 Mcal NEg/kg) in S. Body weights were recorded at approximately 14 d intervals, ADG was determined by regressing BW on days on feed (DOF) within phase. Daily DMI was then regressed by phase on median BW and ADG to determine residual feed intake (RFI). Gain to feed (GF) was also calculated as a measure of efficiency. The statistical model included fixed effects of yr, harvest group (3 per year), age on test, and a nested term DT(ST x XB) where DT = proportion tropical breeding of dam (0, 0.5, or 1), ST = proportion tropical breeding of sire (1, or 0), and XB whether the calf was straightbred or crossbred. Sire(ST x XB) and pen were random effects. In the W, 100% tropical steers ate less, gained less, and were less efficient (GF) than steers with some Angus breeding ($P < 0.01$), but not ($P > 0.10$) by RFI. Gain and efficiency in the S phase were not different ($P > 0.05$) due to tropical influence. Simple correlations between RFI of the same animal in W and S were 0.51 ($P < 0.01$) whereas that for GF was 0.20 ($P < 0.01$). Poor performance of tropically adapted steers as stockers in OK during the winter apparently resulted from a decrease in both feed intake and feed efficiency.

Key words: tropical adaptation, postweaning feed efficiency, seasonal performance

T23 Finishing steers and bulls with high-vitamin E diets: Effect on circulating immune cells and creatine kinase after a mild stress. C. Reyes, C. Fuentes, and R. E. Larraín*, *Pontificia Universidad Catolica de Chile, Santiago, Chile.*

Release of glucocorticoids to the blood stream after stress may change the number of immune cells circulating in blood within minutes. A stressful event may also increased creatine kinase (CK) in blood if muscle tissue is damaged or mobilized. Vitamin E reduced activation of the hypothalamic-hypophysial-adrenocortical axis in farm animals, so the objective of this study was to test if finishing bovines with a high vitamin E diet modulate changes in immune-cells counts and CK after a mild stress. Thirty-eight steers and bulls were blocked by sex, then grouped in 16 pens of 2 or 3 animals of similar weight, and randomly assign to one of 2 treatments: a control diet design to provide 60 IU vitamin E•animal^{-1}•d^{-1} and the control diet supplemented with 2,000 IU vitamin E•animal^{-1}•d^{-1}. Each pen was considered an experimental unit (n = 8). Feed was offered once daily to each pen to provide ad libitum access to feed. After 105 d of feeding the experimental diets, all animals were subjected to a mild stressor consisting of 45 min restraint in a single-file chute, with 3 brief shots (about 0.5 s each) of an electrical cattle prod at 0, 15, and 30 min. Blood samples were taken by jugular venipuncture at d 0 (to be used as baseline for CK) and after stress. Factors in the model were sex and treatment, and initial BW was included as covariate. Differences were considered significant when ANOVA had $P < 0.05$. We observed no changes in any of the variables analyzed, concluding that feeding 2,000 IU vitamin E•animal^{-1}•d^{-1} produced no changes in immune cells counts and CK after a mild stress.

Table 1. Immune cells (cells/μL) and creatine kinase (CK, U/L) after a mild stress in bovines fed vitamin E

Item	Control	Vitamin E	*P*-value
Leucocytes	9,448 ± 443	10,009 ± 439	0.35
Bacilliform	38.6 ± 23.6	66.1 ± 23.4	0.39
Neutrophils	2,858 ± 316	3,401 ± 313	0.21
Lymphocytes	5,870 ± 260	5,894 ± 258	0.94
Monocytes	99.5 ± 30.2	74.1 ± 30.0	0.53
Eosinophils	396 ± 52.3	345 ± 51.9	0.46
Basophiles	66.8 ± 16.3	32.4 ± 16.1	0.13
Change in CK from d0	−0.41 ± 29.2	−7.35 ± 29.0	0.86

Vitamin E: 2000 IU•animal^{-1}•d^{-1}.

Key words: vitamin E, immune cells, creatine kinase

T24 Quantitative genetics and differential performance and gene expression of half-sib families of hybrid striped bass in communal ponds. S. A. Fuller*, B. H. Beck, M. McEntire, and D. Freeman, *USDA ARS Stuttgart National Aquaculture Research Center, Stuttgart, AR.*

The US is one of the world's largest importers of seafood. A major constraint in producing hybrid striped bass is suboptimal production efficiency due to large performance variation of fish from undomesticated brooders. The objectives of this first-year study were to determine the genetic basis of production traits for selective improvement, and RNaseq superior and inferior performing representatives to identify global expression differences and develop predictive SNP markers as part of a multi-year improvement project. Domesticated F8 white bass and F4 striped bass were bred in a partial diallel breeding design and reared in replicate family tanks until large enough to tag with a PIT tag. Thirty-two fish from each of 44 half-sib families were tagged and initial length and weight was recorded before being randomly assigned to one of 4 0.04 ha communal ponds resulting in 5632 individually tagged fingerlings. Fish were allowed to grow for 115 d before harvest. At harvest tags were scanned to reveal family of origin, final length and weight were taken, fish were humanely sacrificed and a liver and muscle sample were flash frozen for qPCR and RNaseq analyses. Following pond production, hybrid striped bass averaged 235.3 ± 17.8 (SD)mm and 192.1 ± 48.7g across all families and ponds, with a range from 110 to 288mm and 47.3–371.7g. Analyses of covariance demonstrated highly significant differences in length and weight of fish among different paternal and maternal half-sib families with initial weight as the covariate ($P < 0.0001$). Estimates of heritability were high for both traits, with values for weight and length, respective, ranging from 0.74 to 0.97 for dams and 0.52 to 0.99 for sires. Liver RNaseq data are currently being analyzed from high and low performing families and individuals and SNP markers validated to identify markers for future marker assisted selection. Incorporating crossbred offspring performance into a genetic improvement program could be used to successfully produce more rapidly growing hybrid striped bass and improve the profitability of the industry.

Key words: hybrid striped bass, aquaculture, genetic improvement

T25 Effects of transgenic myostatin depression on reproductive parameters and placental superoxide dismutases in mice. S. Yarlagadda, C. N. Lee*, Y. S. Kim, J. Yang, and W. Y. Ho, *University of Hawaii-Manoa, Honolulu.*

Double muscled cattle carrying non-fuctional myostatin mutations have high incidences of dystocia, low calf viability and higher heat intolerance. Myostatin-null mice and transgenic mice with depressed myostatin function by its propeptide overexpression appeared normal in reproduction as no dystocia was observed in our colony. To gain insights into the effects of depressing myostatin on reproduction, we compared pelvic width, uterine length, hormonal profiles and the activities of placental superoxide dismutases (SOD) of transgenic mice overexpressing myostatin propeptide to those of their wild-type littermate controls. Ten pregnant transgenic females (TG, B6SJL strain) and 10 wild type females (WT) of greater than 2 mo old were used. Pelvic width of TG mice at 10 and 16 d of pregnancy was not different from wild type mice. Serum estrogen was not affected by genotypes while TG mice had higher concentrations of serum progesterone at 10 d of pregnancy than WT females (213 ± 38.9 pg/ml vs 101 ± 17.5 pg/ml, $P < 0.05$). However, by d16, WT females had higher serum progesterone vs TG females (447.4 + 37.3 pg/ml vs 318.4 + 37.1 pg/ml). Mn-SOD and Cu/Zn-SOD protein levels in placenta, 2 antioxidant defense proteins, decreased significantly from d 10 to 16 of pregnancy. However, their expression levels in placenta or ovarian tissue were not different between TG and WT mice. These results suggest that myostatin suppression has no effects on placental or ovarian tissue antioxidant proteins, serum estrogens and pelvic development.

Key words: myostatin suppression, superoxide dismutases, reproductive parameters

T26 Study of polymorphism at CSD gene in *Apis mellifera meda*. S. Karimi*[1], A. Nejati Javaremi[1], S. R. Miraei Ashtiani[1], and H. Alizadeh[2], *[1]University of Tehran, University College of Agriculture and Natural Resource, Department of Animal Science, Tehran, Karaj, Iran, [2]University of Tehran, University College of Agriculture and Natural Resource, Agronomy & Plant Breeding Department, Tehran, Karaj, Iran.*

About 20% of animal species have a haplodiploid system of sex determination. Males are haploid from unfertilized and females are diploid from fertilized eggs. It is known that a complementary sex determining (csd) gene is responsible for sex determination in honeybees. In this species, csd acts as the primary sex-determining signal with several alleles segregating in populations. Males are hemizygous and females are heterozygous at this locus; non-reproducing diploid males occur when the locus is homozygous. If inbreeding increases between bees, the possibility of cross between queen with drones with similar alleles at this locus will increase. Other studies indicated that this phenomenon leads to increase in the percentage of diploid drones in population which, in turn, leads to decrease of colony growth and, subsequently, economic losses. Genotypes of 17 queens from several apiaries were determined through genotyping of about 6 of their haploid drone progenies. A total of 108 samples from 16 colonies were made. RNA extraction was done with High pure RNA Isolation kit. Then sscDNA was produced by RevertAid MMulV RT enzyme. EF-1alpha was used as housekeeping gene and positive control. In the next stage with a pair of specific primers, the region between exons 5 and 9 of csd gene with 300 to 400 bp in length in different alleles was reproduced by using polymerase chain reaction. PCR product was run on 1.5% agarose gel and each of the 2 different alleles of each queen were sequenced. In cases where polymorphism could not be recognized by length differences of the PCR products, they were digested using SspI enzyme. Digested products were then run on the 6% polyacrylamide gel. Two different alleles of each queen were selected for sequencing. About 25 samples were sequenced. Seven functionally different alleles were found. Queens within the same apiary have more similar genotypes compared with the genotypes of queens form other apiary. Genotyping of queens of apiaries involved in production of commercial honeybee queens may help reduce the incidence of diploid drones.

Key words: haplodiploid, honeybee, drone

T27 Growth-related differential gene expression in the longissimus thoracis muscle of Iberian × Landrace back-crossed pigs. J. Casellas*[1,2], J. L. Noguera[2], R. N. Pena[2,3], J. M. Folch[1], M. Muñoz[4], and N. Ibáñez-Escriche[2], *[1]Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Genètica i*

Millora Animal, IRTA-Lleida, Lleida, Spain, [3]Departament de Producció Animal, Universitat de Lleida, Lleida, Spain, [4]Departamento de Mejora Genética Animal, SGIT-INIA, Madrid, Spain.

The aim of this study was to identify growth-related differential gene expression in the longissimus thoracis muscle of finished pigs. A total of 102 Iberian (25%) × Landrace (75%) back-crossed pigs were reared under standard management conditions, weighted at 90 d (34.4 ± 0.6 kg), 105 d (43.6 ± 0.7 kg), 120 d (54.3 ± 0.8 kg), 135 d (65.0 ± 1.0 kg), 150 d (74.0 ± 1.1 kg), 165 d (86.8 ± 1.2 kg) and 175 d of age (96.1 ± 1.3 kg), and slaughtered at an average age of 179.9 ± 0.3 d. Samples of the longissimus thoracis muscle were collected at slaughter, snap frozen and stored until analysis. For each sample, total RNA was isolated and individually hybridized in the GeneChip Porcine Genome array (Affymetrix, Santa Clara, CA). After normalizing raw data with the RMA algorithm from the Bioconductor package, gene expression scores from 13,547 probes were analyzed with the GEAMM software under a multivariate mixed linear model accounting for the systematic effect of each array as well as 4 sources of variation modeled under normal priors: probe, sex (male or female), fattening batch (3 levels) and pig growth during fattening (continuous effect). Pig growth was calculated as the regression coefficient (i.e., slope) of pig weight against pig age across all weighting events during fattening (0.59 ± 0.1 kg/d). The Bayesian analysis launched a unique Monte Carlo Markov chain with 110,000 iterations, the first 10,000 of them being discarded as burn-in. Focusing on the link between pig growth and gene expression, 14 probes reached the significance threshold after correcting for multiple testing by false discovery rate ($\alpha = 0.05$; $P < 0.000052$), although 3 of them belonged to the same locus (GAPDH) and showed similar estimates. It is important to highlight that most of the significant loci could be grouped on the basis of their biological pathway, i.e., carbohydrate metabolism (ENO3, GAPDH, LDHA and PGM1), muscle contraction (MYL1 and TNNT3) and ribosomal structure (RPL36A).

Key words: gene expression, longissimus thoracis, pig growth

T28 Path analysis of candidate genes for intramuscular fat in pigs. N. V. L. Serão*[1,3], J. Braccini Neto[2], A. M. F. Ribeiro[3], P. V. Silva[3], S. L. Rodríguez-Zas[1], and S. E. F. Guimarães[3], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil, [3]Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

High levels of intramuscular fat (IMF) have generally a positive influence on the sensory experience associated with eating pork. This study aimed to identify gene expression profiles with direct and indirect association with IMF content in pigs. Longissimus dorsi samples from 72 male and female pigs representing 3 genetic groups slaughtered at different weights were used to quantify the IMF content and to measure the expression of 9 candidate genes: ATN1, EEF1A2, FABP3, LDLR, MGP, OBSCN, PDHB, RYR1 and TRDN. The IMF content was determined by ether extraction and expressed as percentage in fresh meat. Gene expression was measured using real-time PCR. To determine the basic causal model of the path analysis for IMF and associated genes, 10 path models were created. The first model included IMF as the outcome variable and the 9 genes as predictors. The other path models had one gene as outcome variable and the other 8 as predictors, until all 9 genes were used as the outcome variable. Predictor genes were selected in the model following a stepwise method ($P < 0.1$). Using these relations and path analysis, the associations between genes and IMF were inferred using the PATH statement of the TCALIS procedure (SAS version 9.2). The basic causal model was sequentially analyzed, removing the least significant relation at a time until all remaining genes were significant ($P < 0.05$). This model included 29 direct relations, where only FABP3, EEF1A2 and LDLR had direct effects on IMF. After a progressive selection, the final causal model included 13 direct relations ($P < 0.05$). The same direct predictors of IMF were kept, but ATN1 was dropped from the path model. The higher effect was observed from OBSCN to RYR1 (0.7219) and the smallest from MGP to RYR1 (−0.1785). All genes in the model acted as predictors and outcomes, with the exception of MGP (only as predictor). Genes FABP3 through LDLR and PDHB through FABP3 showed indirect effect of their expression on IMF. The results of this analysis provided an intuitive and comprehensive path diagram with estimates of direct associations among candidate genes, and direct and indirect associations between these genes and IMF.

Key words: gene expression, meat quality

T29 Evaluating statistical models to assess differential gene expression in PRRSV infected pigs using plasmode datasets. M. E. Arceo*[1], C. W. Ernst[1], M. Wysocki[2], J. K. Lunney[3], and J. P. Steibel[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]Lehrstuhl für Tierzucht, Technische Universität München, Munich, Germany, [3]Animal Parasitic Diseases Laboratory, ARS, USDA, BARC, Beltsville, MD.*

Porcine reproductive and respiratory syndrome virus (PRRSV) causes substantial economic losses for US farms. The variability of pig response to PRRSV infection suggests a host genetic component involved in the pathogenesis of the disease. With data collected from Hampshire-Duroc cross and NE Index line pigs infected with PRRSV, Petry identified low (LR) vs. high (HR) PRRSV burden pigs (with low vs. high viremia, good vs. low/no weight gain, and few vs. many lung lesions). Microarray technology has been applied to identify differentially expressed genes using RNA from lung and bronchial lymph node (BLN) tissues of HR and LR pigs. The objective of this work was to use this data to assess different statistical models for analyzing microarray data using plasmode data sets. To build the plasmode data sets, we permuted array-treatment labels resulting in 34 independent data sets where no differential expression is expected, but the normal biological variation is conserved. Plasmode data were used to compare linear fixed models to linear mixed models. Test statistics that borrow information from data across all genes (moderated tests) to estimate variances and assess significance were also considered. Type I errors were evaluated at nominal 0.05, 0.01, 0.005, 0.001 and 0.0001 levels. To attain control of nominal type-one error rates, moderated tests required the use of permutations to compute p-values. We modified R/maanova software to obtain such permutations more efficiently (3-fold decrease in elapsed computational time) at the expense of reusing estimated variance components from the data. The most powerful results were obtained from a mixed effects model with moderated tests (Fs test) and unmodified permutation scheme (69 significant genes at FDR 10%). Using the modified permutation scheme resulted in less power than a fixed effects model with unmodified permutations (3 versus 21 significant differences at FDR 10%). In summary, powerful analysis of gene expression data remains a computationally challenging task. This work was supported by the PRRS CAP, USDA NIFA Award 2008–55620–19132.

Key words: PRRSV, microarray, linear models

T30 Structural changes at bovine IgE as related to variation at the DNA level. I. Rivera, M. Pagan*, E. Jimenez, and G. Ortiz, *Department of Animal Industry, University of Puerto Rico at Mayaguez, Mayaguez, PR.*

Bovine immunoglobulin E (IgE) was evaluated as a candidate gene to study potential variations in resistance to parasite infestation and anthelmintic efficiency. A DNA pooling and nucleotide sequence strategy was used to identify single nucleotide polymorphisms (SNPs) at the IgE heavy chain constant region gene (GenBank Accession no.: U63640). General (n = 319 bulls) and individual breed pools were constituted using DNA from Angus (n = 39), Senepol (n = 60), Charbray (n = 43), Charolais (n = 62), Bos Indicus (n = 39), and crossbred (n = 76) cattle. Polymerase chain reaction primers were designed to amplify regions of exons 1–3. At exon 1, a cytosine/guanine transversion and a cytosine/thymine transition resulting in silent mutations (threonine and serine, respectively) were identified. At exon 3, an adenine/guanine transition corresponding to an arginine to glycine amino acid change was recognized (only the Angus bulls were completely homozygous GG for such SNP). Meanwhile, exon 2 was highly polymorphic (n = 5 SNPs). Of the SNPs located in that part of the IgE gene, a cytosine/guanine transversion was silent (alanine). However, a cytosine/thymine substitution changed a polar amino acid (proline) by another (leucine). In this case, all the Charbray animals were classified as homozygous TT. The other 3 SNPs corresponded to a proline (non polar) to histidine (basic), proline to glutamine (polar), and an asparagine (polar) to aspartic acid change. In the last 2, homozygosity was observed within the Angus and Charolais breeds (AA and GG for Pro/Glu and Asp/Asn, respectively). Moreover, the SNP responsible of the Pro/His residue substitution was not segregating in Angus. Because polymorphism at IgE has been implicated in resistance to gastrointestinal nematodes infection in ovines, the structural changes reported herein in bovines needs further evaluation to elucidate potential association with immune response and overall health.

Key words: IgE, polymorphisms, bovine

T31 Association between SNPs in candidate genes and residual feed intake in Angus cattle. A. I. Trujillo*, A. Casal, P. Grignola, J. P. Marchelli, and P. Chilibroste, *Departamento de Produccion Animal y Pasturas, Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay.*

Residual feed intake (RFI) is a measure of feed efficiency which is an economically important trait in livestock. Single nucleotide polymorphisms (SNPs) that show associations with RFI may be useful for marker-assisted selection. There is limited research examining the relationship between specific genes mutations and RFI. Neuropeptide Y (NPY), leptin (LEP) and insulin like growth factor-1 (IGF-1) are candidate genes due to their roles in the regulation of feed intake, energy balance, and growth. This study examined the relationship between SNPs previously identified in NPY (A/G, intron 2), LEP (C/T, exon 2) and IGF-1 (C/T, promoter region) genes with feed efficiency and performance in beef Angus calves. Thirty 8 female calves were selected from a total of 1700 genotyped calves born in spring 2009. Half of the calves were carrying 3 "favorable" alleles simultaneously (V, validation group) while the other half was carrying 3 "unfavorable" alleles (C, control group). Calves were allocated to individual pens in a completely randomized design (initial BW = 186.2 ± 32 kg). Individual feed intake (FI) and body weight (BW) were measured during 56 d. Calves were fed twice daily of a mixed diet (60:40 as fed) compound concentrate: chopped alfalfa hay. FI was estimated daily by difference between feed offered and refused. Phenotypic RFI was calculated as the residuals from a regression model regressing FI on ADG and mid test metabolic weight (MMW). Mean ADG, FI, feed conversion ratio (FCR), and RFI were 1.24 ± 0.19, 7.89 ± 1.19, 6.22 ± 0.73 and 0.00 ± 0.42 kg/d, respectively. Differences among groups in ADG and FCR were not significant ($P = 0.42$, $P = 0.86$, respectively). However, calves of V group tended to have lower FI ($P = 0.065$) and to be more efficient (RFI = −0.115; $P = 0.105$) than animals of C group. RFI was correlated with FI (r = 0.36) and FCR (r = 0.54), but not with ADG or MMW. Our preliminary results show a suggestive association between the SNPs studied and RFI in Angus cattle despite further research is warranted.

Key words: residual feed intake, beef cattle, SNPs

T32 Identification of a JY-1 gene variant in Nellore cattle. G. M. F. de Camargo*[1], A. C. de Freitas[1], A. C. Andrade[1], F. M. M. Gil[1], D. F. Cardoso[1], P. D. S. Fonseca[1], F. R. P. Souza[1], M. Cervini[1], F. Baldi[1], L. G. de Albuquerque[1], L. C. A. Regitano[2], and H. Tonhati[1], *[1]Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil, [2]Brazilian Agricultural Research Corporation - Southeast Cattle Center, Sao Carlos, Sao Paulo, Brazil.*

The JY-1 protein is found in monoovulatory species and was first described in cattle. It is an oocyte specific protein and it plays a key role in the regulation of the granulose cells functions. It also influences the early embryo development. Other genes with similar functions were described in polyovulatory animal. The aim of this study was to analyze a region of the exon 3 of the JY-1 gene in Nellore cattle to investigate possible polymorphisms and their association with reproduction performance. DNA was extracted from tail hair of 298 Nellore heifers by the phenol-chloroform-isoamyl alcohol protocol. The heifers were divided in 2 groups: 149 heifers that conceived at 16 mo of age and 149 heifers that failed to conceive at 16 mo. The primers 5′ATCAAACTGAACAGGGCAGA3′ and 5′AAGTATGACAAGAGATACGGTCAGG3′ were designed to amplify a partial region of exon 3. The fragment amplified by the PCR has 373 bp. After, the RFLP analyses were done with the restriction enzyme SspI whose restriction site is 5′AATATT3′. It was possible to identify 2 genotypes (TT and TC) and characterize 2 variants: T and C (GenBank accession numbers: JF262042 and JF262043). The genotype TT has 2 bands with 208 bp and 165 bp and the genotype TC has 3 bands of 373 bp, 208 bp and 165 bp. The allelic frequencies were 0.97 and 0.03 for variant T and variant C, respectively. The genotypic frequencies were 0.94 and 0.06 for the genotypes TT and TC, respectively. The genotypic frequencies deviated ($P < 0.05$) from Hardy-Weinberg equilibrium, which could be due to the low frequency of variant C. The sequences available at GenBank for this region (NM_001110098.1, EF642497.1 and EF642496.1) characterize the variant C in *Bos taurus taurus*, which is the variant with the lowest frequency in *Bos taurus indicus*. The correlation between the genotypes and the pregnancy at 16 mo was not done because of the divergence between the frequencies and also because of the equal distribution of the patterns between the heifer groups. So, future studies must be done to identify other polymorphisms in JY-1 gene segregating in Nellore cattle and analyze their possible correlations with heifer pregnancy.

Key words: PCR-RFLP, polymorphism, SNP

T33 Novel associations between a SNP in the bovine *DDEF1* gene and production traits in Nellore breed. P. C. Tizioto*[1], S. L.

Meirelles[1], G. B. Veneroni[1], M. M. de Souza[1], F. Siqueira[2], A. do Nascimento Rosa[2], L. O. Campos da Silva[2], R. de Almeida Torres[2], S. R. Medeiros[2], R. R. Tullio[3], M. M. de Alencar[3], G. Feijó[2], and L. C. de Almeida Regitano[3], *[1]Federal Universidade of São Carlos, São Carlos, São Paulo, Brazil, [2]Embrapa Beef Cattle National Center, Campo Grande, Mato Grosso do Sul, Brazil, [3]Embrapa Southeast Cattle Research Center, São Carlos, São Paulo, Brazil.*

Concomitant with the traditional selection, which has produced interesting results, marker assisted selection (MAS) can help breeding programs and improve profiles for economically important traits. The identification of markers associated with interest production traits is a fundamental step for implementing MAS in breeding programs. This project aimed to study the association between a SNP (G/A) in intron 13 of bovine DDEF1 (development and differentiation enhancing factor 1) gene and the traits weaning weight adjusted to 240 d (WW), yearling weight adjusted to 450 d (YW), backfat thickness (BFT), ribeye area (RYA) and shear force at 24 h postmortem (SF), in reference families of Nellore breed. We used about 270 steers, descendants of 20 Nellore bulls selected to represent variability within the Nellore breed. SF measures were available from only 140 steers. At approximately 18 mo of age, animals were transferred from grazing systems to feedlots, where they were finished for about 100 d before slaughtering for meat quality data collection. The genotypes were determined by amplification refractory mutation system (ARMS-PCR). A mixed model with fixed effects of contemporary group and genotypes, and age of the animal at the time of measurement (linear effect) as a covariate and the random effect of bull was used to evaluate the marker effect. For SF data the model also included pH as a covariate. Analyses were done by the maximum restricted likelihood (REML) using PROC MIXED of the Statistical Analysis System (SAS). The SNP in DDEF1 gene showed significant association with WW ($P = 0.0021$), YW ($P = 0.0109$), RYA ($P = 0.0109$) and SF ($P = 0.0083$). It represented 2.18%, 4,61%, 4.28% and 1.13% of total additive variance and 6.16%, 4.32%, 4.74% and 17.51% of total phenotypic variance for WW, YW, RYA and SF, respectively. Therefore, this SNP is a good candidate for application in MAS of meat production and quality traits in Nellore breed.

Key words: beef, SNP, DDEF1

T34 CAPN4751 and UOGCAST effects on feed efficiency, carcass traits and feedlot performance in Nellore (*Bos indicus*) cattle.

R. C. Gomes*[1], M. E. Carvalho[2], M. H. A. Santana[1], S. L. Silva[1], P. R. Leme[1], P. Rossi[3], and J. B. S. Ferraz[1], *[1]Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de São Paulo (FZEA/USP), Pirassununga, SP, Brazil, [2]Escola Superior de Agricultura Luiz de Queiroz, Universidade de São Paulo (Esalq/USP), Piracicaba, SP, Brazil, [3]Departamento de Zootecnia, Universidade Federal do Paraná (UFPR), Curitiba, PR, Brazil.*

The calpain system is related to protein turnover and may affect productive traits in livestock. Thus, the aim was to examine associations among SNP polymorphisms in the calpain and calpastatin genes and carcass traits, growth and feed efficiency in beef cattle. Nellore steers and bulls (n = 290; 378 ± 42 kg BW, 23-mo ± 42d old) were feedlot fed in tests conducted at FZEA/USP, Pirassununga, Brazil, from 2007 to 2010. Dry matter intake (DMI) and average daily gain (ADG) were recorded for 50 to 84 d and carcass traits were assessed by ultrasound. Feed conversion ratio (FCR), gross feed efficiency (GFE), partial efficiency of growth (PEG) and residual feed intake (RFI) were computed. Cattle were genotyped for CAPN4751 (C/T, 6545 bp of AF248054) and UOGCAST (C/G, 282 bp of AY008267) in the calpain and calpastatin genes, respectively. The genotyping was carried out using TaqMan Real Time PCR assays. Association analyses used a linear mixed model with contemporary group, sex and genotype as fixed effects, age as covariate and sire as a random effect. Frequencies for C and T alleles of CAP4751 and C and G alleles of UOGCAST were 0.13, 0.87, 0.55 and 0.45, respectively. Genotypic frequencies were 0.02, 0.22 and 0.76 for CC, CT and TT of CAP4751 and 0.29, 0.51 and 0.20 for CC, CG and GG genotypes of UOGCAST, respectively. Because the low CC frequency, CAP4751 effects were tested by CT vs. TT contrasts. No CAP4751 effects were observed for DMI ($P = 0.11$), GFE ($P = 0.25$), FCR ($P = 0.46$), PEG ($P = 0.67$), RFI ($P = 0.75$), backfat thickness (UBFT; $P = 0.74$) and ribeye area (UREA; $P = 0.76$). There were differences between CT and TT genotypes of CAP4751 on final BW (486 vs. 473 kg, $P = 0.03$), ADG (1.53 vs. 1.44 kg/d, $P = 0.04$) and rump fat thickness (URFT, 7.5 vs. 6.70 mm, $P = 0.04$). UOGCAST did not affect BW ($P = 0.59$), DMI ($P = 0.48$), GFE ($P = 0.12$), FCR ($P = 0.31$), PEG ($P = 0.40$), RFI ($P = 0.45$), UBFT ($P = 0.76$), URFT ($P = 0.90$) and UREA ($P = 0.61$). An additive effect was observed for UOGCAST on ADG (−0.0685 ± 0.026 kg/d, $P = 0.0093$). The UOGCAST and CALP4751 polymorphisms can affect growth and carcass traits in Nellore cattle but not feed efficiency.

Key words: *Bos indicus*, DNA marker, residual feed intake

T35 Bialellic expression studies of *CAST* gene in bovine muscle.

M. M. de Souza[1], S. C. M. Niciura[2], A. M. G. Ibelli[1], S. L. Meirelles[1], M. I. Rocha[1], P. C. Tizioto*[1], G. Gasparin[3], M. E. Carvalho[3], G. B. Veneroni[1], F. A. Bressani[2], P. S. N. de Oliveira[1], F. Siqueira[4], L. L. Coutinho[3], and L. C. de Almeida Regitano[2], *[1]Federal University of São Carlos, São Carlos, São Paulo, Brazil, [2]Embrapa Southeast Cattle Research Center, São Carlos, São Paulo, Brazil, [3]University of São Paulo, Piracicaba, São Paulo, Brazil, [4]Embrapa Beef Cattle National Center, Campo Grande, Mato Grosso do Sul, Brazil.*

Bovine meat tenderness is the main feature appreciated by consumers and is influenced by calpastatin protein activity. This protein is codified by CAST gene and is the main modulator of μ-calpain protease, which in turn, degrades the myofibrillar proteins of skeletal muscle in the post-mortem period. In general, models used for gene-phenotype associations consider equal expression of both alleles. Therefore, departures from biallelic expression patterns must be incorporated in models of quantitative genetic analysis because it may result in differences in males and females breeding values. This study aimed to analyze allelic expression pattern of CAST gene in muscle tissue of Nellore steers immediately after slaughter. A group of 270 animals were genotyped for the polymorphism A/G within the 3′ UTR of CAST gene by using TaqMan probes in real-time PCR. RNA was extracted from muscle of 14 heterozygotes to produce first strand cDNA. The allelic expression has been analyzed by using the same TaqMan probe used for genotyping. A standard curve was made to normalize the specific probe fluorescences for each allele in the TaqMan assay. This was made with dilutions of genomic DNA from 2 homozygous animals AA and BB; the dilutions were 8:1, 4:1, 2:1, 1:1, 1:2, 1:4 and 1:8. For each dilution the log2 (FAM intensity/VIC intensity) was calculated at the last cycle (40) of PCR, thus the allele fluorescence ratio of the 14 steers was extrapolated in the standard curve. Therefore it was possible to measure whether there were differences in allelic expression and whether it was inherited from mother or father. The non-parametric randomization test was used for statistical analysis. Parental origin was not found to affect allele expression ($P > 0.05$). Although the expression of the G allele was 1.4 times that of the A allele, that difference was not significant. Finally, considering that other published papers described

allelic specific gene expression using smaller sample size, it is possible to conclude that the CAST gene shows biallelic expression in skeletal muscle during the post-mortem period in Nellore cattle breed, compatible with general quantitative models for marker-assisted selection.

Key words: CAST, SNP, imprinting

T36 The polymorphism Msp I in intron 3 of the growth hormone gene in Nellore cattle (*Bos taurus indicus*). D. F. Cardoso[1], G. M. F. de Camargo*[1], P. D. S. Fonseca[1], F. M. M. Gil[1], M. G. Chiquitelli[1], F. R. P. de Souza[1], L. G. de Albuquerque[1], M. E. Z. Mercadante[2], and H. Tonhati[1], *[1]Department of Animal Sciences, Sao Paulo State University, Jaboticabal, Brazil, [2]Animal Science Experimental Station, Sertãozinho, SP, Brazil.*

The growth hormone gene is very studied in animals due to its key role in biological functions. In *Bos taurus taurus*, this gene is correlated to growth, body composition and even milk composition. The growth hormone in cattle (bGH) has a polymorphic structure that characterizes it as a potential molecular marker that may assist selection process. The aim of this work was to verify and analyze the polymorphism described in the intron 3 of *Bos taurus taurus* in Nellore cattle (*Bos taurus indicus*) to validate these associations in this breed. The DNA was extracted from blood samples of 238 Nellore cattle belonging to 3 lines selected for growth from the selection program of the Animal Science Experimental Station in Sertãozinho-SP, Brazil. A fragment of 329 bp from intron 3 was amplified by PCR with the primers 5′CCCACGGGCAAGAATGAGGC3′ and 5′TGAGGAACTGCAGGGGCCCA3′. The RFLP was done with the restriction enzyme MspI. It was possible to identify 3 migration patterns, the first one has one fragment of 329 bp and corresponds to the homozygote −/−, the second one has 2 fragments of 224 bp and 105 bp and corresponds to the homozygote +/+, the third one has these 3 fragments above and corresponds to the heterozygote +/−. The allelic frequency was 0.26 to the allele MspI(+) and 0.74 to the allele MspI(−). The genotypic frequencies were 0.06, 0.41 and 0.53 to the genotypes +/+, +/− and −/−, respectively. Although these animals belongs to a selection program, the frequencies are in Hardy-Weinberg equilibrium at 5%, indicating that this locus of the bGH is not affected by selection. It is important to emphasize that the polymorphism recognized by the endonuclease MspI has different frequencies in Zebu and European cattle. The MspI(+) allele that is correlated to milk production and composition has high frequencies in European breeds and low frequencies in *Bos taurus indicus*. The results indicate that the PCR-RFLP/MspI is efficient to detect the polymorphism in the intron 3 of the bGH in Nellore cattle and it may be associated with important economic traits. Financial Support: FAPESP

Key words: molecular marker, beef cattle, RFLP

T37 Polymorphisms of the *IGF1* and *MSTN* genes in Nellore beef cattle (*Bos indicus*) and in their crosses with *Bos taurus*. R. A. Curi[1], M. R. S. Fortes[2], D. M. Vankan[2], J. A. V. Silva*[1], H. N. Oliveira[3], M. D. S. Mota[1], and A. C. Silveira[1], *[1]Faculdade de Medicina Veterinária e Zootecnia, Unesp, Botucatu, São Paulo, Brasil, [2]School of Veterinary Science, University of Queensland, St. Lucia, Queensland, Australia, [3]Faculdade de Ciências Agrárias e Veterinárias, Unesp, Jaboticabal, São Paulo, Brasil.*

The aim of this study was to estimate the segregation of the single nucleotide polymorphism (SNP) AF_017143.1:g.198C > T of the IGF1 gene and AF_320998.1:g.433C > A of the MSTN gene in Nelore (*Bos indicus*) and Nelore × Bos taurus beef cattle, and to evaluate their effects on carcass and meat traits. A total of 300 animals (114 Nelore and 186 crosses) were genotyped and phenotyped for rib eye area (REA), backfat thickness (BT), intramuscular fat (IF), shear force (SF) and myofibrillar fragmentation index (MFI). The allele substitution effects for each of the polymorphisms on the traits of interest were estimated by regression of the phenotypes analyzed on the number of copies of a particular allele using the General Linear Model procedure. The polymorphism of the IGF1 was non-informative in Nelore animals with allele C was found to be fixed. Although association between allele C and greater REA has been verified in animals from crossing ($P < 0.05$), this is no longer significant after the Bonferroni correction of hypothesis tests for multiple comparisons. The allele A of the SNP of the MSTN was absent in Nelore and it is only found in 2 crossbred animals, impairing association studies. The present results suggest the lack of potential for application in marker-assisted selection of the analyzed SNPs in cattle with breed compositions similar to those described here. Furthermore, the absence of these SNPs in Nelore cattle, a situation that may extend to other *Bos indicus* breeds, indicates the need to use other identified polymorphisms or the search for new polymorphisms in the IGF1 and MSTN genes to carry out futures association studies involving this subspecies.

Key words: fat deposition, meat tenderness, molecular markers

T38 Characterization of polymorphism in the ORL1 gene in Nellore cattle (*Bos taurus indicus*) by PCR-RFLP. P. D. da Silva Fonseca[1], F. R. P. de Souza[1], G. M. F. de Camargo*[1], F. M. Gil[1], D. F. Cardoso[1], M. G. Chiquitelli[1], L. G. Albuquerque[1], M. E. Z. Mercadante[2], and H. Tonhati[1], *[1]São Paulo State University, São Paulo State University, Jaboticabal, Brazil, [2]Animal Science Experimental Station, Animal Science Experimental Station, Sertaozinho, Brazil.*

The ORL1 gene, under normal conditions, has low expression in adipocyte cells. In obese animals its expression is higher and it causes an increase in the cholesterol content and promotes the capture of fatty acids. Cholesterol and triglycerides concentration are highly correlated with fat deposition, so the ORL1 gene is a candidate gene to subcutaneous and intramuscular fat deposition in cattle. The aim of this study was to investigate the existence of the ORL1 polymorphism in Nellore cattle and characterize the allelic and genotypic frequencies. The DNA was extracted from blood of 240 animals from Animal Science Experimental Station, Sertaozinho, Brazil. The animals were genotyped by PCR-RFLP using the restriction enzyme *Pst*I. Three genotypes were obtained. The genotypes AA, AC and CC have the frequencies 0.22, 0.25 and 0.53, respectively. The allelic frequencies of A and C were 0.35 and 0.65, respectively. These results indicate that there is a good distribution of the alleles among the animals, therefore permitting verification of the association of the SNP with growth and carcass traits in Nellore cattle. Financial support: CNPq and Fapesp

Key words: PCR-RFLP, adiposity, SNP

T39 Analysis of MUC1 alleles in Nellore cattle using single-allele and multi-allele models. F. R. P. Souza[1], S. Sartore[2], S. Maione[2], D. Soglia[2], V. Spalenza[2], G. M. F. de Camargo*[1], P. Sacchi[2], R. Rasero[2], and M. E. Z. Mercadante[3], *[1]Sao Paulo State University, Jaboticabal, SP, Brazil, [2]University of Torino, Grugliasco, TO, Italy, [3]Instituto de Zootecnia, Sertãozinho, SP, Brazil.*

The aim of the present study was to analyze the association of the highly polymorphic mucin MUC1 with economic traits in Nellore

cattle. A total of 295 Nellore heifers, born between 2003 and 2005, from a selection experiment running at Instituto de Zootecnia, Sertãozinho - São Paulo/Brazil, were used. The animals were genotyped by PCR. The traits analyzed were birth weight (BW), weaning weight (W210), yearling weight (W550), yearling height (YH550), longissimus muscle area (LMA), subcutaneous backfat thickness (BF), and rump fat thickness (RF). Data were analyzed by a mixed model including absence or presence of the allele (coded as 0 and 1, respectively), contemporary group (selection line and year of birth, 1, ..., 9) and month of birth (September, October, November) as fixed effects, age of dam and age at recording (only for YH550 and the carcass traits LMA, BF and RF) as linear covariates, and the random effect of sire (1, ..., 41). Initially, "single-allele" models were used for each trait, subsequently "multi-allele" models, including all alleles, were applied. Five alleles were identified (1–5). Single-allele model results showed that the allele 3 was associated with W550 ($P = 0.03$). Considering the multi-allele model, significant effects of the alleles 1 and 4 were found on BW ($P = 0.02$ and 0.04, respectively), however, allele 3 did not affect W550 significantly. Despite these findings, application of this marker in marker-assisted selection will require more studies with a larger number of animals genotyped to increase the accuracy of the statistical analyses.

T40 Association between a SNP in intron 1 of the ghrelin gene with milk production traits in Murrah buffaloes (*Bubalus bubalis*). F. M. M. Gil, F. R. P. Souza, G. M. F. de Camargo*, P. D. S. Fonseca, D. F. Cardoso, R. R. Aspilcueta-Borquis, G. Stefani, and H. Tonhati, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Ghrelin is a gastrointestinal hormone and a potent release stimulator of growth hormone (GH) in the somatotropic cells of the hypophysis and hypothalamus. It also influences the general metabolism of the body. Studies demonstrated that ghrelin and GH have high plamastic concentration in dairy cows with high breeding value. Other studies consider GH the most important hormone related to milk yield in lactating cows. The characterization of the ghrelin gene (GHRL) in buffaloes is important because it is a candidate gene to identify molecular markers related to growth, carcass and milk production traits. The aim of this study was to associate the SNP A/G in intron 1 (GenBank accession number: GU071074 and GU071075) of the GHRL gene in Murrah buffaloes with milk production traits. The DNA was extracted from hair of 212 dairy buffaloes from one farm in the São Paulo state, Brazil. The animals were genotyped by PCR-RFLP using the restriction enzyme BstUI. Three genotypes were obtained. The genotypes AA, AG and GG have the frequencies 0.37, 0.47 and 0.16, respectively. The allelic frequencies of G and A were 0.4 and 0.6, respectively. In analyses, the GLM procedure of SAS was used, the model included as fixed effects birth season, birth year and genotype, and as a covariable the age of the buffalo. The possible association of the polymorphism with the phenotypic values of milk yield, protein yield, fat yield, protein percentage and fat percentage at a statistical significance of 5% was tested. The results indicate that there is no association of the SNP described with milk yield ($P = 0.3965$), fat yield ($P = 0.2320$), protein yield ($P = 0.5334$), fat percentage ($P = 0.6224$) and protein percentage ($P = 0.1305$) in dairy Murrah buffaloes.

Key words: restriction enzyme, PCR-RFLP, milk yield

T41 Identification of polymorphism in leptin gene in *Bubalus bubalis*. V. A. Ferreira Junior[1], G. M. F. de Camargo*[1], A. L. F. Lima[2], F. M. M. Gil[1], and H. Tonhati[1], *[1]Sao Paulo State University, Jaboticabal, SP, Brazil, [2]Santa Catarina Federal University, Florianopolis, SC, Brazil.*

The leptin is a hormone synthesized by the adipocyte tissue and regulates the feed intake in many species as well as in ruminants. It is highly correlated with body weight and adiposity. The gene of the leptin is a potential molecular marker because it is related to feed intake, a trait that is difficult to be measured especially in systems based on pastures. The trait also has high economic value and is correlated with production traits. The aim of this study was to investigate polymorphisms in partial region of intron 2 of the leptin gene in Murrah buffaloes. The DNA was extracted from hair of 150 dairy buffaloes from one farm in the Sao Paulo state, Brazil. The animals were genotyped by PCR-RFLP. In the PCR reaction the primers used were 5′GTCTGGAGGCAAAGGGCAGAGT3′ and 5′CCACCACCTCTGTGGAGTAG3′ and in the RFLP reaction, the restriction enzyme used was Bsa AI. Three genotypes were obtained. The first one has one fragment of 522 bp and corresponds to the homozygote AA, the second one has 2 fragments of 441 bp and 81 bp and corresponds to the homozygote GG, the third one has 3 fragments (522 bp, 441 bp and 81 bp) and corresponds to the heterozygote AG. The genotypes AA, AG and GG have the frequencies 0.3, 0.52 and 0.18, respectively. The allelic frequencies of A and G were 0.56 and 0.44, respectively. The technique was efficient to detect the SNP A/G in intron 2 in buffaloes. The same SNP is also present in cattle. The genotypic frequencies are in Hardy-Weinberg equilibrium at 5%. This SNP seems to be interesting to be studied because it is a SNP conserved between species and also because the frequencies are well distributed among the animals.

Key words: SNP, buffaloes, PCR-RFLP

T42 Relationship between kappa-casein genotype in inseminated bulls and the milk composition of their daughters. J. Bezdicek*[1] and J. Riha[2], *[1]Agriresearch Rapotin, Ltd., Rapotin, Czech Republic, [2]Research Institute for Cattle Breeding, Ltd., Rapotin, Czech Republic.*

Using genotypes that positively influence cattle milk production is an important breeding aim. The goal of this study was to evaluate the relationship between one milk protein kappa–casein genotype (CSN3) in inseminated Czech Fleckvieh and Holstein bulls, used between the years 1997–2007 and the milk composition of their daughters. We included only cows with a milk yield C100 (5000–7500 L) and H100 (7000–10 000 L). The statistical analysis was done using SPSS 15.0 program for Windows and PowerMarker (Liu, K., Muse, S. V., 2005). The average genotype frequency in the case of Czech Fleckvieh bulls (n = 136) was AA = 0.39; AB = 0.48; AE = 0.01; BB = 0.09; BE = 0.02; and EE = 0.01 and allele frequencies were A = 0.64; B = 0.34 and E = 0.02. Genotype frequencies found in Holstein bulls (n = 60) were AA = 0.55; AB = 0.28; AE = 0.12; BB = 0; BE = 0.03 and EE = 0.02 and allele frequencies were A = 0.75; B = 0.16 and E = 0.09. In the Holstein breed we found a higher frequency of the E allele and a higher frequency of genotypes with this allele. The genetic diversity and heterozygosity in Czech Fleckvieh Bulls were the following 0.47; 0.52. In Holstein Bulls 0.40; 0.43. These results show the higher genetic variability of bulls of the Czech Fleckvieh breed. At the same time we carried out an assessment of the milk fat and protein percentage of the daughters of the observed bulls. The measurement was made on cows in the 1st lactation separately for the Czech Fleckvieh (n =

607 cows) and Holstein (n = 702 cows). Significance of differences is marked as *($P \leq 0.05$), **($P \leq 0.01$). A found higher protein content in Czech Fleckvieh was associated with particular genotypes: BB (3.56%) > AB (3.55%) > *AA (3.48%) > AE (3.43%) > EE (3.41%) > * BE (3.37%). Protein in Holstein: AB (3.32%) > AA (3.31%) > AE (3.30%) > BE (3.28%) > * EE (3.26%). Fat in Czech Fleckvieh: AB (4.2%) > AA (4.14%) > BB (4.11%) > BE (4.09%) > EE (4.05%) > **AE (3.93%). Fat in Holstein: AB (3.86%) > AA (3.85%) > EE (3.83%) > AE (3.82%) > ** BE (3.72%). From the above it is clear that differences between CSN3 genotypes were not considerable and only in some cases significant.

Key words: kappa-casein, milk composition

T43 Effect of DGAT1, TG and leptin gene polymorphisms on milk production traits in Holstein-Friesian cows in Hungary. I. Anton*[1], K. Kovács[1], G. Holló[2], V. Farkas[3], F. Szabó[3], and A. Zsolnai[1], *[1]Research Institute for Animal Breeding and Nutrition, Herceghalom, Hungary, [2]University of Kaposvár, Faculty of Animal Science, Kaposvár, Hungary, [3]University of Pannonia, Georgikon Faculty of Agriculture, Keszthely, Hungary.*

The objective of this study was to estimate the effect of the acylCoA-diacylglycerol-acyltransferase 1 (DGAT1), thyroglobulin (TG) and leptin locus on milk fat, milk protein and milk yield in Hungarian Holstein-Friesian cows. A lysine/alanine (K232A) polymorphism in DGAT1 -a microsomal enzyme that catalyzes the final step of triglyceride synthesis- has been proved to affect milk yield, as well as milk fat and protein content in different dairy cattle breeds. The effect of a 5′-polymorphism of TG gene- which product is the precursor of hormones that influence lipid metabolism- has been shown to affect milk fat content in cattle. Polymorphisms in the leptin gene have been associated with milk protein yield and milk yield. A total of 417 blood samples have been collected from different Holstein-Friesian herds and genotypes were determined by PCR-RFLP (polymerase chain reaction-restriction fragment length polymorphism) assay. Milk production data were recorded throughout 3 consecutive lactations and statistical analyses have been carried out to find association between individual genotypes and milk production traits. The data set was analyzed with SPSS 15.0 for Windows software. Multivariate ANOVA (general linear model, GLM) was applied to determine differences in milk production traits, where DGAT1, TG and leptin genotypes, birth year, number of lactations and calving season were included as fixed effects and 305-d-milk yield, 305-d-milk fat percentage and yield and 305-d-milk protein percentage and yield were considered as dependent variables. In case of DGAT1 locus, AA homozygous animals produced the highest values of fat yield and protein yield ($P < 0.05$). Milk yield decreased consistently ($P < 0.05$) from genotype AA/AA through to GC/GC. Among TG genotypes, TT animals had the highest ($P < 0.05$) 305-d-milk fat percentage and yield values. Referring to leptin polymorphism, CC cows produced higher ($P < 0.05$) 305-d-milk protein values than TC animals. The project was supported by the Hungarian Scientific Research Fund (project 78174).

Key words: DGAT1, TG, leptin

T44 Correlation analysis of hepatic transcript abundance and lactational performance in postpubertal Holstein dairy heifers. J. Doelman, J. M. Kim*, H. Cao, N. G. Purdie, and J. P. Cant, *University of Guelph, Ontario, Canada.*

Dairy genomic research has recently grown in popularity, though investigation into the use of transcript abundance as a marker of future performance remains limited. The objectives of this study were to employ a statistical method to reduce variability within a microarray data set and subsequently identify correlations between gene expression signal intensity and performance measures during first lactation of 81 Holstein dairy heifers. Pearson correlation can be used to determine the underlying structure of a large data set through identification of a data subset that is well correlated to a particular variable. Partial Least Squares regression seeks to model dependent variables by means of a set of predictor variables but has yet to be applied in the field of dairy genomics. These 2 types of analysis were performed on microarray data from previous research that quantified gene expression signal from yearling Holstein heifers. To reduce the total number of genes used in the data set for regression analysis, the linear dependence of all genes in the entire normalized data set was measured against 18 DHI variables using Pearson correlation analysis. Results were pooled to generate 4 lists based on coefficient values and significance of $P < 0.05$. List 4 featured 1541 genes ($r^2 > 0.04$), list 3 contained 453 genes ($r^2 > 0.09$), list 2 was comprised of 140 genes ($r^2 > 0.12$) and list 1 consisted of 31 genes ($r^2 > 0.16$). Test set validation was used to fit the partial least squares model by creating a test and training set using the normalized expression data sets. The strongest correlation coefficients, $r^2 = 0.62$ (protein percentage) and $r^2 = 0.54$ (fat percentage) were obtained using list 1. Strong correlations were also found for 305 d protein yield ($r^2 = 0.40$, list 3) and protein percentage ($r^2 = 0.33$, list 4). Moderate correlation coefficients were also identified for breed class average milk ($r^2 = 0.21$, list 1) and protein ($r^2 = 0.24$, list 1). Identification of gene expression patterns in a predictive nature such as this offers a potential selection tool to be employed by producers.

Key words: heifer, correlation, gene expression

T45 Identification of a SNP in the gene *IL2* and its association with resistance against gastrointestinal infection by nematodes in goat. F. A. Bressani[1,5], P. C. Tizioto*[2], S. L. Meirelles[2], W Malagó Junior[1,2], R. Giglioti[3], A. M. G. Ibelli[2], J. G. G. Gromboni[4], E. Carrilho[5], L. G. Zaros[6], L. da Silva Vieira[7], and L. Correia de Almeida Regitano[1], *[1]Embrapa Southeast Embrapa Southeast Cattle Research Center, São Carlos, São Paulo, Brazil, [2]Federal University of São Carlos - UFSCar, São Carlos, São Paulo, Brazil, [3]State University of São Paulo - UNESP, Jaboticabal, São Paulo, Brazil, [4]UNICEP, São Carlos, São Paulo, Brazil, [5]University of Sao Paulo, São Carlos, São Paulo, Brazil, [6]Federal University of Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil, [7]Embrapa Goats and Sheep, Sobral, Ceará, Brazil.*

The gene IL2 encodes an interleukin which plays a role in inducing the maturation of T and B cells, important factors in the immune response to parasites in several species. Two hundred twenty-nine individuals of a F2 goat population were studied aiming at finding genetic markers for resistance to gastrointestinal infection. To accomplish this, a SNP in the IL2 gene was identified and its association with resistance to gastrointestinal infection was tested. The population investigated was an F2 generated from F1 Saanen (susceptible to gastrointestinal endoparasites), Anglo-nubian (resistant) crosses. Phenotypes consisted of eggs per gram (EPG) and were obtained by parasitological examination of feces samples. The data were transformed as log 10(EPG+1) and analyzed using the mixed procedure of SAS. Fixed effects included in the model were sex, sampling order, and age at sampling; while animal was fitted as random effect. Based on this analysis, 44 individuals with extremes EPG were selected. The gDNA of these animals

was obtained from isolated leukocytes by the salting-out method. Specific oligonucleotides were designed to obtain PCR products from IL2 gDNA which were sequenced in the ABI Prism 3100 Avant Sequencer (Applied Biosystems). The sequences were further analyzed using the Phred, Phrap, and Consed programs. A SNP (G/A) identified within the intron 2 of IL2 gene was analyzed by Fisher test and showed association with resistance against gastrointestinal infection by nematodes ($P = 0.0489$). Further studies with the whole F2 population are in progress to confirm this association.

Key words: IL2, SNP, goat

T46 Effect of the DGAT1 gene polymorphism on the backfat thickness and fat-tailed weight in Iranian Lori-Bakhtiari sheep. H. Mohammadi*, M. Moradi Shahrebabak, and M. Sadeghi, *Department of Animal Science, University College of Agriculture and Natural Resources, University of Tehran, Karaj, Tehran, Iran.*

Backfat thickness refers to the amount of fat over the animals back and strongly associated with percentage of retail product, represents a valuable sheep quality trait, and fat-tail demands sheep industry attention for many reasons. To name a few, lean to fat-tail ratio improvement means better feed conversion efficiency. The DGAT1 catalyzes the final step of triglyceride synthesis and the gene is located on the centromic end of bovine chromosome 14. The DGAT1 gene has been mapped to ovine chromosome 9. Polymorphism in the DGAT1 gene has been associated with milk fat percentage and body fatness. The objective of this study was to evaluate the effect of the DGAT1 gene locus on ovine quality traits in the Lori-Bakhtiari sheep breed in Iran. A total of 152 blood samples were obtained from different sex Lori-Bakhtiari sheep. PCR primers were assumed from previously reported studies (Xu et al., 2008). A 309 bp fragment from exon 17 was amplified and digested by AluI with PCR-RFLP method. The association between genotypes and fat-tailed weight and backfat thickness was analyzed. DGAT1 CC animals showed the highest fat percentage values for fat-tail and backfat thickness, the difference between CC and TT genotypes was significant ($P < 0.05$). The results of this study identified novel associations; The C allele had a positive effect on fat-tail weight and backfat thickness in fat-tailed sheep. The results of this study suggest that the TT genotype of DGAT1 could be regarded as a molecular marker for breeding programs to improve carcass traits in fat-tailed sheep breed.

Key words: DGAT1, single nucleotide polymorphisms (SNP), fat deposition and carcass traits

T47 Identification and evaluation of an IGF-I gene polymorphism in a Zel sheep population using RFLP/HaeII. S. M. Kazemi*[1], C. Amirinia[2], S. Gharaveysi[1], H. Emrani[2], and A. Yilmaz[3], *[1]Department of animal Science, Islamic Azad University, Qaemshahr Branch, Qaemshahr, Mazandaran, Iran, [2]Department of Animal Biotechnology, Animal Science Research Institute of Iran, Karaj, Alborz, Iran, [3]Department of Animal Sciences, The Ohio State University, Columbus.*

The IGFs play an important role in regulating somatic growth, and they are affected by nutritional and other conditions during growth. Polymorphisms of IGF genes are reported to be significantly associated with many traits including growth and reproductive traits. In this study, 142 DNA samples from Zel sheep were used to detect a promoter region polymorphism in the insulin-like growth factor-1 (IGF-1) gene. To extract DNA from blood we used a Salting-out procedure. Primers were obtained for amplification of the specific segment. Polymerase Chain Reaction (PCR) was accomplished after finding the best reaction conditions and the specific segment amplified well. RFLP fragments were used to detect the polymorphism in the segment. RFLP analysis was performed by incubating the PCR products with HaeII restriction enzyme at 37°C for 4 h. Gels (3.5% agarose) were visualized by using ethidium bromide. The polymorphism was observed and the evaluation of the results relieved 2 alleles and 3 genotypes. The alleles were A and B with frequencies of 0.71 and 0.29, respectively. The genotypes AA, BB and AB had frequencies of 0.47, 0.06 and 0.47, respectively. The data were analyzed for genetic variation statistics using PopGene software (version32) and no deviation from Hardy-Weinberg equilibrium was observed in this study.

Key words: Zel sheep, IGF-1, polymorphisms

T48 Haplotype structure of telomerase reverse transcriptase (*turTERT*) gene in the turkey, *Meleagris gallopavo*. A. M. J. B. Adikari*, J. Xu, X. Guan, and E. Smith, *Virginia Polytechnic Institute and State University, Blacksburg.*

The recently released turkey genome sequence offers an opportunity to characterize and define the role of some genes that affect turkey performance and productivity. Our objective for this study was to screen the telomerase reverse transcriptase (*turTERT*) gene for structural variation based on single nucleotide polymorphisms (SNPs) and haplotypes using a diversity panel consisting of birds from heritage, commercial, and wild varieties. The rationale is that TERT influences some metabolic diseases including heart diseases, metabolic syndrome, and hypertension. Further, the levels of functional telomerase are critical for telomere maintenance whose shortening is associated with organismal aging and concomitant metabolic diseases. Primers used for long-range polymerase chain reaction (LR-PCR) were designed using the Primer 3 software. Each amplicon was gel purified, sequenced, and the SNPs detected using standard methods. Linkage disequilibrium (D') among SNPs was estimated using Visual Haplotype software. From 34 kb of *turTERT* gene screened, a total of 4 SNPs were detected in the introns. Allelic diversity ranged from 0.14 to 0.68. A total of 3 haplotypes were derived from the SNPs with frequencies that ranged from 0.09 to 0.59. While the diversity panel maximized detection of variation, both the SNPs and haplotypes appear to show that the Royal Palm's *TERT* alleles appear to be distinct. Visual haplotype analysis revealed that the first 3 SNPs, which were about 300 bp apart, were strongly associated ($r^2 = 0.87–1.00$) while the fourth, about 9 kb from the nearest SNP, was not strongly linked ($r^2 < 0.1$) to the others. The distribution of the SNPs and haplotypes, as well as the D', provide a foundation that will facilitate future association and linkage studies between *turTERT* and metabolic diseases in the turkey.

Key words: Turkey, single nucleotide polymorphisms, linkage disequilibrium

T49 Changes in the proteome and metabolic profiles of broiler chickens during adipose tissue accretion. G. Kelley*, X. Wang, F. Chen, and S. Nahashon, *Tennessee State University, Nashville.*

Fat accretion in poultry directly influences the efficiency of feed utilization and consumer acceptability of poultry and poultry products. Losses estimated at about US$250–300 million are incurred by consumers and processors annually in pollution control, extraction and disposal of excess carcass fat. Understanding underlying mechanisms of excessive fat deposition in poultry will aid in improving carcass

quality and minimize production cost. We hypothesized that chicken adipocity is highly influenced by factors beyond the genome. Therefore, the aim of this study was to employ a proteomics approach to identify proteins that may be associated with fat accretion in broiler chickens. Metabolic profiles of the experimental birds were also evaluated. One hundred and 20 1-d-old broiler chickens were randomly assigned to floor pens and fed standard broiler diet for 8 weeks. At 8 WOA, experimental birds were bled, sacrificed and adipose tissue from the abdominal and visceral areas was collected, weighed and frozen in liquid nitrogen before storage at −80 oC until used. Adipose proteome from the birds with the highest and lowest abdominal fat percentage (8 birds each) was assayed using 2-dimensional differential gel electrophoresis (2D-DIGE) followed by in-gel digestion and Matrix Assisted Laser Desorption/ionization Time-of-Flight (MALDI-TOF) mass spectrometry. A total of 132 spots were found to be differentially expressed between the extreme birds ($P < 0.05$). Several of the proteins are unique and some are involved in metabolic pathways that are associated with fat accretion including vimentin, apolipoprotein, and anexin. Obese birds exhibited high levels of potassium and serum glutamic oxaloacetic transaminase than their lean counterparts. The lean birds on the other hand exhibited higher levels of alkaline phosphatase than obese birds.

Key words: broiler chickens, adipose tissue proteome, metabolic profiles

T50 PCR-RFLP analysis of promoter region of Interferon gamma gene in high and low immunocompetent Aseel native chicken. S. Choudhary*[1], S. Kumar[2], and B. Nautiyal[1], *[1]MJP Rohilkhand University, Bareilly, U.P. India, [2]Central Avian Research Institute, Bareilly, U.P. India.*

Resistance to diseases is under the control of certain immune response genes. Interferon gamma (INFG), a cytokine is one such candidate gene that plays a critical role in immune system function. In this study, DNA polymorphism of INFG gene at promoter region was studied using polymerase chain reaction- restriction fragments length polymorphism (PCR-RFLP) technique in 48 random bred Aseel native chicken, 24 in high and 24 in low immunocompetence index group. Two sets of PCR primer, set I for full length promoter and set II for partial length promoter, amplified product with 670 bp and 495 bp in size, respectively. Agarose gel electrophoresis and DNA sequencing of PCR amplified product confirmed amplification of INFG gene promoter region. PCR-RFLP analysis of full length promoter with enzymes, *Eco*RI and *Taq*I and partial length promoter with enzymes Alu I, Hinf I, Dde I and *Taq*I was monomorphic, whereas, full length promoter with enzyme Tsp509 I was polymorphic. Gene frequencies of 2 alleles, allele A (168, 123, 99, 88, 64 and 54 bp fragments) and allele B (123, 104, 99, 88, 64 and 54 bp fragments) were 0.64 and 0.36. The genotypic frequencies of genotypes AA, AB and BB were 0.17, 0.30 and 0.53, respectively. Heterozygote (AB) demonstrated higher magnitude of all immunocompetence traits. Tsp509 I PCR-RFLP of INFG gene at promoter region was suggestive of development of genetic markers for high humoral immune response in chicken.

Key words: Aseel, PCR-RFLP, interferon gamma

T51 Association of BMPR–IB gene polymorphism with breeding value of growth and reproductive traits in Mazandaran native chicken. Sh. Niknafs*, A. Nejati Javaremi, and M. Sadeghi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

The aim of the current study was to investigate A287G SNP of the chicken BMPR-IB gene and its association with the breeding value of growth and reproductive traits. Hence, a sample of 206 individuals including 10 males and 196 females of Mazandaran native chicken were genotyped using PCR-RFLP technique. On the other hand, for estimating breeding value of the traits, phenotypic information of 18 successive generations of selection in breeding station of Mazandaran native chicken (north of Iran) was analyzed using a univariate animal model in ASREML procedure. Investigated traits included body weight at hatch (35287 records), at 8 (43067), at 12 weeks of age (38297), at sexual maturity (31147), egg number (31349), age at first egg (31349), egg weight of first (27249), of 28 (17225), of 30 (19031), of 32 (18955) weeks of age, average egg weight of first 12 weeks of production (18847), egg mass (28725) and egg production intensity (31349). Finally, marker-trait association analyses were performed using estimated breeding value of the traits, as dependent variable, in GLM procedure of SAS 9.1. The significant differences of least squares means were tested with Tukey-Kramer multiple range tests, and a P-value of < 0.05 was considered statistically significant. Two alleles and 3 genotypes were identified. Genotypic frequency of AA, AG and GG were 0.349, 0.544 and 0.107 respectively. Results showed, for all investigated traits, no significant differences among breeding value LSmeans of the genotypes existed ($P < 0.05$). In conclusion, we found no significant association between BMPR-IB gene and breeding value of the growth and egg production traits in Mazandaran native chicken.

Key words: BMPR-IB gene, SNP, growth and reproductive traits

T52 Association of a single nucleotide polymorphism in NPY gene with growth and reproductive traits in Mazandaran native chicken. S. Niknafs*, A. Fatemi, H. Mehrabani Yeganeh, and A. Nejati Javaremi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

The objective of the current study was to investigate a SNP (with accession number of M87298) for the chicken NPY gene and its association with breeding value of growth and reproductive traits in chicken. A breeding station of Mazandaran native chicken was established in 1988 with 2 main objectives: extension and genetic improvement of the local breed. From 1988 to 2009, 18 generations of selection was done for traits of 8-wk BW (BW8), egg number, age at first egg and average egg weight as selection criteria. Recorded traits consisting of body weight at hatch (35287 records), at 8 (43067), at 12 weeks of age (38297), at sexual maturity (31147), egg number (31349), age at first egg (31349), egg weight of first (27249), of 28 (17225), of 30 (19031), of 32 (18955) weeks of age, average egg weight of first 12 weeks of production (18847), egg mass (28725) and egg production intensity (31349). A total of 206 individuals, from generation 17, were selected at random and genotyped for the SNP using PCR-RFLP technique. Phenotypic information of the 18 generations was analyzed genetically to estimate breeding value of the traits for genotyped individuals. Genetic analysis was performed by univariate animal model in ASREML software. Fixed effects of sex, generation and hatch were considered in the model where would have significant effects. Marker-trait association analysis was done using breeding values (as dependent variable) and SNP genotypes (as independent variables) in GLM procedure of SAS 9.1. Three genotypes of BB, Bb and bb with the frequencies of 0.885, 0.100 and 0.015 were respectively identified. Results suggested that there were significant differences among breeding value LSmeans of genotypes for body weight at sexual maturity. In conclusion, chicken

NPY gene may be associated with body weight and may be considered in MAS program to improve growth performance.

Key words: growth and reproductive traits, NPY gene, SNP

T53 Association of a single nucleotide polymorphism from GnRHR gene with growth and egg production traits in Mazandaran native chicken. S. Niknafs*, A. Fatemi, H. Mehrabani Yeganeh, and A. Nejati Javaremi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

Gonadotropin releasing hormone receptor (GnRHR) is mainly associated with the development and function of the reproductive axis in avian species. To study the association of this gene with growth and egg production traits in Mazandaran birds, a total of 206 individuals were selected at random and PCR-RFLP technique was used to genotype chickens for one SNP (accession number AJ506779) of this gene. Three genotypes of AA, Aa and aa with the frequencies of 0.379, 0.469 and 0.152, respectively, were identified. Association of these genotypes with both breeding values and phenotypic records of growth and egg production traits were examined. Breeding values were estimated by a univariate animal model in ASREML methodology using information that pertained to 18 generations of selection in breeding station of Mazandaran native chicken. A total of 206 genotyped chickens for this study belonged to generation 17. Investigated traits included body weight at hatch (35287 records), at 8 (43067), at 12 weeks of age (38297), at sexual maturity (31147), egg number (31349), age at first egg (31349), egg weight of first (27249), of 28 (17225), of 30 (19031), of 32 (18955) weeks of age, average egg weight of first 12 weeks of production (18847), egg mass (28725) and egg production intensity (31349). Marker-trait association analysis showed no significant differences among phenotypic LSmeans of the genotypes. However, least squares means of breeding value for traits of egg number and egg mass demonstrated significant differences among genotypes. More egg number and egg mass were observed for the genotype AA. In conclusion, GnRHR gene may be associated with egg production traits genetically and additively in Mazandaran native chicken.

Key words: GnRHR gene, SNP, chicken

T54 Investigation of three single nucleotide polymorphisms of STAT5B gene and their association with growth and reproductive traits in Mazandaran native chicken. S. Niknafs*, A. Nejati Javaremi, M. Sadeghi, and A. Fatemi, *Agricultural Faculty, University of Tehran, Karaj, Alborz, Iran.*

The objective of the current study was to investigate the association of 3 SNPs of the STAT5B gene with breeding value of growth and reproductive traits in Mazandaran native chicken (north of Iran) breed. A total of 205 individuals were selected randomly and genotyped for 3 SNPs of STAT5B gene (C4535156T, G4533675C and G4533815A) using PCR-RFLP technique. Phenotypic information of 18 generations was employed in estimating breeding value for different traits using univariate animal models in ASREML. Investigated traits included body weight at hatch (35287 records), at 8 (43067), at 12 weeks of age (38297), body weight at sexual maturity (31147), egg number (31349), age at first egg (31349), egg weight of first (27249), at 28 (17225), at 30 (19031), at 32 (18955) weeks of age, average egg weight of the primary 12 weeks of production (18847), egg mass (28725) and egg production intensity (31349). Marker-trait associations analysis were performed with the GLM procedure of SAS 9.1. Significant differences of least squares means were tested with Tukey-Kramer multiple tests correction, and corrected P-values <0.05 were considered statistically significant. Two alleles and 3 genotypes were observed for each SNP. Alleles of A (0.663) and a (0.337) for C4535156T SNP, B (0.646) and b (0.354) for G4533675C SNP, C (0.804) and c (0.196) for G4533815A SNP were identified. Four significant associations of C4535156T SNP with body weight at hatch, G4533675C SNP with egg weight of first and G4533815A SNP with body weight at 8 and 12 weeks of ages were found ($P < 0.05$).

Key words: STAT5B gene, growth and reproductive traits, chicken

T55 Effect of feeding a combination of galacto-oligosaccharides and a *Bifidobacterium* sp. strain on feline intestinal ecosystem. G. Biagi*[1], I. Cipollini[1], M. Grandi[1], C. Pinna[1], A. Pompei[2], M. Zini[3], and G. Zaghini[1], *[1]Department of Veterinary Medical Sciences, University of Bologna, Ozzano Emilia, Italy, [2]Department of Pharmaceutical Sciences, University of Bologna, Bologna, Italy, [3]Department of Biochemistry, University of Bologna, Bologna, Italy.*

Synbiotics (i.e., the combination of a prebiotic and a probiotic) are recognized means to modulate composition and activities of gut microbiota. The aim of the present study was to evalute the effects derived from the oral administration of a combination of galacto-oligosaccharides (GOS) and a *Bifidobacterium pseudocatenulatum* strain, previously isolated from the feces of a healthy adult cat, on composition and metabolism of feline intestinal microbiota. Growth kinetics of the *B. pseudocatenulatum* strain was determined on 4 different prebiotic substances (GOS, fructo-oligosaccharides, lactitol and pectin). Biomass yield was higher ($P < 0.01$) for GOS than for other treatments. Ten adult healthy cats received for 15 d a synbiotic consisting of the freeze-dried *B. pseudocatenulatum* strain (10^8 cfu/d) and GOS at 1% of the diet. Fecal samples were collected from each cat the day before synbiotic administration started (Day 0) and 1 and 10 d after synbiotic withdrawal (Day 16 and 25, respectively), for chemical and microbiological analysis. Results at Day 0, 16 and 25 were analyzed by one-way ANOVA with time as the main factor. While no difference on fecal moisture and pH was detected, ammonia concentrations were reduced on d 16 and 25 compared with trial start (288 and 281 vs. 353 mmol/g of fecal DM; $P < 0.05$). On Day 16, fecal concentration of acetic acid was increased compared with d 0 (17.1 vs. 13.2 mmol/g of fecal DM; $P < 0.05$). Furthermore, on Day 16, fecal concentrations of lactic, n-valeric and iso-valeric acids were lower than on Day 0 and 25 (0.18 vs. 0.30 and 0.30, 0.15 vs. 1.84 and 1.73, 0.35 vs. 0.65 and 0.62 mmol/g of fecal DM, respectively; $P < 0.05$). Fecal counts of *Cl. perfringens*, enterococci, *Bacteroides* spp., *E. coli* and lactobacilli were not influenced by treatment whereas an increase of bifidobacteria counts was observed on Day 16 and 25 compared with trial start (7.98 and 7.52 vs. 5.63 Log cfu/g of fecal DM; $P < 0.01$). Present results show an overall positive influence derived from the synbiotic administration on feline fecal microbiota.

Key words: bifidobacteria, feline intestinal microbiota, synbiotics

T56 Dietary fiber viscosity may affect insulin and GLP-1 secretion, but does not appear to contribute to the "second meal effect" in healthy adult dogs. P. Deng*[1], A. Wolff[1], A. N. Beloshapka[1], B. M. Vester Boler[1], and K. S. Swanson[1,2], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Division of Nutritional Sciences, University of Illinois, Urbana.*

Viscous dietary fibers have beneficial effects on postprandial glucose metabolism and insulin secretion. However, the effects of fiber viscosity on the "second meal effect" in dogs are unknown. Our objective was to evaluate the effects of dietary fiber type in a morning meal on glucose, insulin, and glucagon-like peptide 1 (GLP-1) responses to a glucose challenge later in the day. Six healthy adult intact female hounds (mean BW = 25 kg) were used in a replicated 3 × 3 Latin square design consisting of 21 d (3 7-d periods). Dogs were randomly assigned to one of 3 treatments containing equal amounts of fiber: a low-viscosity fiber (LVF) diet containing 8% cellulose; a moderate-viscosity fiber (MVF) diet containing 4% cellulose, 2% psyllium, and 2% pectin; or a high-viscosity fiber (HVF) diet containing 4% psyllium and 4% pectin. Dogs were fed 3 times daily (8 a.m.; 12 p.m.; 4 p.m.) to maintain BW. On the last day of each period, dogs were fed at 8 a.m. as usual, then dosed with 25 g of maltodextrin in 120 mL of water at 12 p.m. Blood samples were collected before (0 min) and 10, 20, 30, 45, 60, 90, 120, and 180 min after dosing, and analyzed for glucose, insulin, and GLP-1 concentrations. Baseline and postprandial incremental area under the curve (IAUC) data were analyzed statistically. Baseline GLP-1 concentrations were greater ($P < 0.005$) in dogs fed HVF, while baseline insulin concentrations in dogs fed HVF were lower ($P < 0.05$) than dogs fed MVF, but not different from dogs fed LVF. There were no differences in baseline GLP-1 and insulin concentrations between dogs fed MVF and LVF. No treatment effects were observed in glucose, insulin, and GLP-1 IAUC responses. This might be due to the timing of meals and baseline insulin and GLP-1 effects. In conclusion, while fiber viscosity did not appear to contribute to a second meal effect, dogs fed highly viscous fibers had altered GLP-1 and insulin concentrations 4 h after the morning meal. Further research to determine the effects of fiber viscosity on gut hormone response and mechanisms of action in dogs is needed.

Key words: viscous dietary fibers, second meal effect, dog

T57 Comparison of fecal microbial communities of healthy adult dogs fed raw meat-based or extruded diets using 454 pyrosequencing. A. N. Beloshapka*[1], S. E. Dowd[3], L. Duclos[4], and K. S. Swanson[1,2], *[1]Department of Animal Sciences, University of Illinois, Urbana, [2]Division of Nutritional Sciences, University of Illinois, Urbana, [3]Research and Testing Laboratory, Lubbock, TX, [4]Nature's Variety Inc., Lincoln, NE.*

It is often presumed that feeding a raw meat-based diet will negatively affect the fecal microbial populations of dogs. However, this question has not been well tested in healthy dogs. Thus, the objective of this experiment was to use 454 pyrosequencing to characterize microbial populations of healthy adult dogs fed raw meat-based or extruded diets. Six healthy adult beagles (5.5 ± 0.5 yr; 8.5 ± 0.5 kg) were first fed a commercially available extruded diet (control), then randomly allotted to 1 of 6 raw meat diets in a Latin square design. Diets had varying protein, fat and carbohydrate (including fiber) composition. Following a 14d adaptation phase, a fresh fecal sample was collected on d15 or d16 for each period. Dogs were fed to maintain BW throughout the study. Genomic DNA was extracted from fresh fecal samples and used to create 16S rDNA amplicons, which were then subjected to 454 pyrosequencing. Predominant bacterial phyla in all dogs included Firmicutes, Bacteroidetes, and Fusobacterium. However, dogs fed raw meat-based diets had lower ($P < 0.01$) Firmicutes and Bacteroidetes, but greater ($P < 0.01$) Fusobacteria and Proteobacteria populations. Actinobacteria were also present at low quantities (1.5%), but unchanged by diet. *Clostridium*, *Fusobacterium*, and *Bacteroides* were predominant bacterial genera in all dogs. Dogs fed raw meat-based diets had greater ($P \leq 0.05$) *Fusobacterium* (25.6 vs. 14.8%), but lower ($P \leq 0.05$) *Fecalibacterium* (0.3 vs. 9.7%), *Lactobacillus* (0.02 vs. 8.9%), *Prevotella* (0.2 vs. 8.8%), *Eubacterium* (1.4 vs. 2.8%), and *Enterococcus* (0.2 vs. 1.2%) populations as compared with dogs fed the extruded diet. Although gastrointestinal distress was not observed in dogs fed raw meat-based diets, the dietary changes resulted in great shifts in fecal microbiota. Future studies are required to determine

whether dietary macronutrient composition or form of diet resulted in such changes, and how they may affect long-term health.

Key words: gut microbiota, raw diets, pyrosequencing

T58 Processing techniques to maintain low glycemic index of peas. J. Fouhse*[1], J. Adolphe[2], L. Weber[2], and M. Drew[1], *[1]University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Western College of Veterinary Medicine, Saskatoon, Saskatchewan, Canada.*

Peas have a low glycemic index (GI) due to their low content of rapidly digestible starch (RDS) and high content of slowly digestible (SDS) and resistant starch (RS) fractions. Low GI foods are thought to protect against cardiovascular disease, diabetes and obesity thus, the use of peas as a starch source in dog foods may improve the health of dogs. However, peas intended for canine diets require processing to increase palatability and digestibility, which may affect the GI of peas. An experiment was performed to determine the effect of extrusion processing on pea starch fractions RDS, SDS and RS. The trial used a completely randomized 2 × 2 × 2 × 2 factorial design with 2 levels of temperature (110 vs. 150°C), moisture (20 vs. 28%), particle size (288 vs. 407μm) and cooling method (freezing vs. drying). Extrudates were analyzed for their RDS, SDS and RS contents. Particle size significantly affected RS and RDS portions ($P < 0.05$). There was a significant negative correlation between particle size and RDS and SDS fractions ($P < 0.05$) and a trend toward particle size being positively correlated with RS content ($P = 0.059$). RDS was also positively correlated with temperature ($P < 0.05$). Subsequently, 4 of the 16 extruded pea treatments were selected for the measurement of GI in beagles (n = 6): 1) 150°C, 288 μm, 20% H_2O, dried; 2) 110°C, 288 μm 20% H_2O, dried; 3) 150°C, 407 μm 28% H_2O, frozen; 4) 110°C, 407 μm, 28% H_2O, frozen. All test diets were fed in amounts that provided 10g of available carbohydrate. A 20% glucose solution was used as a control. There was no relationship between GI and particle size, moisture content or cooling rate ($P < 0.05$). However, GI was negatively correlated with temperature ($P < 0.05$). These results suggest that in vitro starch fractions are not good predictors of GI in dogs. However, starch fractions and GI may be manipulated by controlling processing temperature. Further studies are needed to determine the effect of multiple temperatures on the GI of various starch fractions.

Key words: glycemic index, pea starch, extrusion

T59 Acute effects of carbohydrates in dogs. J. L. Adolphe*[1], J. M. Fouhse[2], M. D. Drew[2], and L. P. Weber[1], *[1]Department of Veterinary Biomedical Sciences, Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Department of Animal and Poultry Science, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

In humans, diets containing low glycemic index (GI) carbohydrate sources appear to be protective against cardiovascular disease, diabetes and obesity. However, the effect of carbohydrates on health in dogs is poorly characterized. The purpose of this research was to examine the acute effect that high and low glycemic ingredients and dog foods have on glycemic, insulinemic and cardiovascular responses in dogs. Laboratory beagles (n = 6–7) were used in 2 crossover experiments. First, the GI of 4 carbohydrate sources (corn, barley, rice and peas) was determined. Second, the GI was determined for 2 extruded dog diets containing either a high or low GI carbohydrate source. A glucose solution was used as the control food and foods were fed in amounts that provided 10 g available carbohydrate. Flow-mediated dilation (FMD), a measure of endothelial function and predictor of cardiovascular health, was performed before and 60 min after feeding. The mean GI (±SEM) of the carbohydrate sources were: peas 29 ± 5; corn 47 ± 10; barley 51 ± 7; and rice 55 ± 6. Thus, the peas (lowest GI) and rice (highest GI) were used as the carbohydrate source to formulate the extruded diets in experiment 2. The GI for the extruded pea and rice diets were 46 ± 7 and 63 ± 9, respectively. The area under the insulin response curve was significantly higher for the glucose compared with the carbohydrate sources or extruded diets, but no difference was observed between the carbohydrate sources or diets. FMD did not differ between the carbohydrate sources or diets, but was lowest 60 min after feeding glucose in both experiments. A negative correlation between FMD and serum glucose was found 60 min after feeding the carbohydrate sources ($r = -0.3$; $P = 0.02$), but not for extruded diets ($r = -0.08$; $P = 0.6$). In both studies, peas resulted in a decreased glycemic response. However, once formulated into an extruded dog food, the GI of the peas and rice increased suggesting that the properties of the carbohydrate source were altered due to the presence of other ingredients and/or extrusion. Future studies are needed to determine if the lower GI pea diet offers health benefits in the long-term.

Key words: glycemic index, cardiovascular, flow-mediated dilation

T60 Effects of protease enzyme on diets for growing mink (*Mustela vison*). E. S. Dierenfeld*[1], E. Keith[1], R. Johnson[2], C. Falco[2], B. Roeder[3], and N. Odetallah[1], *[1]Novus International, Inc., St. Charles, MO, [2]FBAC, Sandy, UT, [3]Brigham Young University, Provo, UT.*

Enhanced protein digestion/diet utilization through the use of exogenous enzymes was investigated for application to commercial mink production. A preliminary in vitro study was conducted to determine effects of time (0, 2, 3 or 4 h), temperature (23°, 30°, 35° or 40°C), and enzyme inclusion (0, 0.05% or 0.1%) upon diet matrix viscosity to mimic practical handling/storage/ranch conditions associated with bulk diet preparation, transport to feeding sites, and environmental temperatures of feed on cages. Healthy growing mink kits (n = 24) were assigned randomly to one of 4 diet treatments with 6 replicates. Animals were housed individually in metabolism cages, acclimated for 2 wk and fed a blended diet (150 −230 g) twice daily, with water available ad libitum. Diets were identical with the exception of protease enzyme (CIBENZA DP100) added at 0 (Control), 0.05, 0.1 or 0.2% (wt/wt). Apparent digestibility (D_a) was measured over a 5-da trial using Cr_2O_3 (0.1%) as a marker; daily feed intake and weekly BW were recorded. Kits fed diets containing 0.1% enzyme gained more weight (76 g; $P = 0.11$), demonstrated higher ADG (41 vs. 30 g/d), and consumed less food (20 g/d) than controls, resulting in improved F:G ratios (9 vs. 13; $P = 0.05$). Additionally, they tended toward higher DM digestibility (85.5 vs. 83%; $P = 0.11$) and improved crude protein D_a. Inclusion of 0.1% protease thus resulted in improved utilization of practical diets for growing mink. In the laboratory studies, time ($P < 0.001$) and enzyme concentration ($P < 0.05$, for all temperatures except 35°C) had significant impacts on diet matrix consistency. Direction of change was temperature dependent, suggesting varying protein fractions may have been affected at different temperatures. For minimal effects upon physical characteristics of mink diet containing exogenous CIBENZA DP100, maintain long-term storage at ≤ 4°C, and when feeding, ensure diet is kept at ≤ 30°C for no longer than 2–3 h before consumption.

Key words: mink, protease enzyme

T61 Influence of feeding a fish oil containing diet to mature overweight dogs: Effects on lipid and protein metabolism, postprandial glycemia, and body weight. M. R. C. de Godoy*, K. R. McLeod, and D. L. Harmon, *University of Kentucky, Lexington.*

The aim of this study was to assess the mechanism by which fish oil may alter lipid and protein metabolism, postprandial glycemia, and body weight in mature overweight dogs. Seven female dogs were randomly assigned to 1 of 2 isonitrogenous and isocaloric diets, control (CO) or 2% fish oil (FO), in a crossover design. Experimental periods were 69 d, separated by a wash out period of 30 d. At the beginning of the experiment, and at 30 and at 60 d of feeding the experimental diets, the dogs were infused with D-glucose (2 g/kg body weight) through the intravenous catheter. Blood samples were collected for 3h to perform a glucose tolerance test. Nitrogen balance began at 0700 on d 63 of each experimental period, and ended at 0700 on d 69. On d 66 of each period a single dose (7.5 mg/kg) of ^{15}N-glycine was administered orally to each dog via a gelatin capsule. From d 66 at 0700 through d 69 at 0700 an additional 25% of acidified urine from each dog was separated, composited and frozen for later analysis for ^{15}N enrichment and determination of protein turnover. Incremental area under the curve and glucose concentration at peak did not differ between treatments or overtime within treatment. Glucose clearance from plasma was increased ($P < 0.05$) in the FO treatment on d 30 when compared with baseline (d 0). β-Hydroxybutyrate, NEFA and triglycerides did not differ within or between treatments. Cholesterol decreased ($P < 0.05$) on the FO treatment on d 30, d 60 and d 69 when compared with d 0, as well as on d 60 when compared with d 30 of the same dietary treatment. High density lipoprotein (HDL) decreased in the FO treatment on d 69 when compared with d0. Body weight, food intake, fecal excretion, dry matter and nitrogen digestibilities, nitrogen balance, as well as protein turnover were not different between diets. Overall, the FO diet improved the rate glucose tissue uptake and decreased cholesterol and HDL concentrations in mature overweight dogs.

Key words: dog, fish oil, postprandial glycemia

T62 Influence of feeding a fish oil containing diet to adult lean dogs: Effects on lipid and protein metabolism, postprandial glycemia, and body weight. M. R. C. de Godoy*, C. E. Conway, K. R. McLeod, and D. L. Harmon, *University of Kentucky, Lexington.*

The aim of this study was to assess the mechanism by which fish oil may alter lipid and protein metabolism, postprandial glycemia, and body weight in lean adult dogs. Eight female Beagles were randomly assigned to 1 of 2 isonitrogenous and isocaloric diets, control (CO) or 2% fish oil (FO), in a crossover design. Experimental periods were 69 d in length, separated by a wash out period of 30 d. At the beginning of the experiment, and at 30 and at 60 d of feeding the experimental diets, a baseline blood sample was collected and the dogs were, subsequently, fed their daily ration. Postprandial blood samples were collected for 3h to perform a glycemic response. Nitrogen balance began at 0700 on d 63 of each experimental period, and ended at 0700 on d 69. On d 66 of each period a single dose (7.5 mg/kg) of ^{15}N-glycine was administered orally to each dog via a gelatin capsule. From d 66 at 0700 through d 69 at 0700 an additional 25% of acidified urine from each dog was separated, composited and frozen for later analysis for ^{15}N enrichment and determination of protein turnover. Incremental area under the curve and glucose concentration at peak did not differ between treatments or overtime within treatment. Triglycerides were increased ($P < 0.05$) in both dietary treatments on d 69 when compared with baseline (d 0). Cholesterol was increased ($P < 0.05$) on the CO treatment on d 69 when compared with d 0. Body weight and food intake did not differ between dietary treatments. Dry matter digestibility was decreased ($P < 0.05$) and fat digestibility tended ($P < 0.10$) to decrease in the FO treatment. Nitrogen digestibility and balance, as well as protein turnover were not different between dietary treatments. Overall, feeding a FO containing diet did not appear to improve protein and lipid metabolism, and postprandial glycemia in adult lean dogs.

Key words: dog, fish oil, postprandial glycemia

T63 In vivo and in vitro procedures for measuring coat quality after dietary manipulation in dogs. G. González-Ortiz[1], L. Castillejos*[1], R. Franco-Rosselló[1], J. J. Mallo[3], J. Alcañiz[3], M. A. Calvo[2], and M. D. Baucells[1], *[1]Nutrition and Welfare Service, Department of Animal and Food Science (UAB), Bellaterra, Spain, [2]Departament de Sanitat i d'Anatomia Animals (UAB), Bellaterra, Spain, [3]Norel, S.A., Spain.*

A standardized methodology, noninvasive and practical procedure to asses coat quality in companion animals has not been described in the literature. Beneficial effects of probiotic supplementation on animal and human health have been reported. The objective was to determine whether probiotic supplementation could improve coat quality in healthy dogs using noninvasive procedures. Sixteen beagles were divided in 2 groups of 8 dogs: control (T1) and treatment (T2) supplied with 1 g/kg of ingested food of a mixture of *Bacillus amyloliquefaciens* CECT 5940 and *Enterococcus faecium* CECT4515 (5×10^8 cfu/g each strarin) from Norel S.A. Procedures were carried out after the supplementation period (D1) of 39 d and after 56 d of non probiotic supplementation (D2). Each animal was evaluated by 4 trained observers who recorded different scored parameters (visual brightness, softness and optimum coat feel). These scores resulted in a final hair condition score (HCS) between 3 (less valued) and 7 (more valued). Colorimetry was used for measuring light intensity (L*) in the parietal area by MiniScan 45/0 Lav of HunterLab. Hair samples were taken to perform an in vitro challenge. The ability of Microsporum canis to degrade hair's structure and develop drilling organs was used as resistance or susceptibility indicator. Data was analyzed using the MIXED procedure of SAS. On D1, T1 and T2 had similar HCS (5.34 vs. 5.36). T2 showed lower HCS in D2 than D1 ($P = 0.02$) whereas no differences were found in T1. Concerning L*, the interaction of the main factors was statistically significant ($P = 0.047$). T2 showed greater L* in D1 than D2 (39.19 vs. 36.83 ± 1.873; $P = 0.054$). However, L* values in T1 were not different between days. No drilling organs were observed in T2 on D1, but on D2 they were detected in half of T2 samples. However, T1 showed drilling organs in both sampling periods. Data suggest differences in the coat quality after the nonprobiotic supplementation period. The combination of hair condition score, colorimetry and in vitro hair culture could be used to evaluate changes on hair quality in dogs related to dietary manipulation.

Key words: dogs, hair quality, probiotic

T64 Evaluation of a mixture of *Bacillus amyloliquefaciens* CECT 5940 and *Enterococcus faecium* CECT4515 in adult healthy dogs. G. González-Ortiz[1], L. Castillejos*[1], J. J. Mallo[3], J. Alcañiz[3], M. A. Calvo[2], and M. D. Baucells[1], *[1]Nutrition and Welfare Service, Department of Animal and Food Science (UAB), Bellaterra, Spain, [2]Departament de Sanitat i d'Anatomia Animals (UAB), Bellaterra, Spain, [3]Norel, S.A., Spain.*

Probiotic supplementation has demonstrated beneficial effects such as reestablishment of unbalanced intestinal microbiota, enhanced resistance to colonization by enteropathogens and improving intestinal barrier, among others. The objective of this study was to evaluate the potential effect of a mixture of 2 probiotic strains (*Bacillus amyloliquefaciens* CECT 5940 and *Enterococcus faecium* CECT 4515 at 5×10^8 cfu/g each strain) in adult healthy dogs. Sixteen beagles (8 males and 8 females; between 1 and 7 years of age) housed at the UAB facilities were used. Animals were divided into 2 groups of 8 dogs: control (T1) and treatment (T2) group received daily 1 g of probiotic mixture per kg of the same dry diet for 39 consecutive days. Daily food consumption, weekly body weight and body condition score and fecal score (3 times a week) were assessed as health indicators. Fresh fecal samples were collected on d 1, last day of supplementation period (d 39) and after a withdrawal period of 6 d (d 45). By means of conventional plating methods, total aerobic mesophilic bacteria, *Enterobacteriaceae* spp., *Escherichia coli*, *Clostridium perfringens*, lactic acid bacteria and the 2 probiotic strains were analyzed. Fecal pH was determined. Total fecal samples were collected during 6 d to perform a digestibility trial during the supplementation period according to FEDIAF (2008). Differences were tested by PROC MIXED (SAS, 2002). The 2 probiotic strains were recovered after the supplementation period from fresh fecal samples, but not after the withdrawal period. No statistical differences were detected in any health indicators measured or in digestibility coefficients. No statistical differences were found in microbiota analyzed. However, C. perfringens counts were significantly reduced in T2 after the supplementation period (5.64 vs. 2.94 ± 0.53 log cfu/g feces; $P < 0.0001$). Bacterial counts were in the same range as baseline after the withdrawal period and no differences were detected in fecal pH. The use of probiotics could stabilize dog fecal microbiota, by decreasing pathogenic populations.

Key words: dogs, microbiota, probiotic

T65 Effect of increasing levels of mannoprotein in humoral immunity in dogs. A. F. Chizzotti*, F. M. O. B. Saad, F. S. Ebina, R. C. Silva, J. S. R. Reis, and M. C. Kadri, *Universidade Federal de Lavras, Lavras, MG, Brazil.*

The advances of health sciences have provided a deeper understanding of cellular and molecular mechanisms for normal and abnormal physiological states. At the same time, the relationship between nutrition and health has been studied through the discovery of nutrients and non-nutrients capable of interfering in the pathological process. Nutraceuticals can improve organism functions and some are used as immunomodulators. Nutrients denominated immunonutrients or immunomodulators, such as mannoprotein, obtained from external cell wall of *Saccharomyces cerevisiae*, have shown the ability to preserve the intestinal mucus integrity, improving the immunological response. The aim of this study was to evaluate the effect of increasing levels of fractions of mannoprotein in dog's immune system. This study was conducted at the Department of Animal Science of Federal University of Lavras, Brazil. Twenty-four adult Beagle dogs were randomly assigned to 4 treatments: commercial diet (control) and control plus 300, 600, 900 ppm of fractions of mannoprotein, on dry matter basis. Diets were formulated according to NCR (2006) recommendations, and mannoprotein were added to the diets in capsules. Diets were fed for 37 d. Blood samples were collected from jugular vein on d 0, 10, 23 and 35 in a syringe and were centrifuged to obtain serum which was kept refrigerated until clinical analysis. The blood assessments included complete blood count, quantification of antibodies against leishmaniasis, immunoglobulin IgA, IgG and IgM concentrations, platelets, fibrinogen and C-reactive protein. The animals were exposed to antigen challenge by vaccination against leishmaniasis on d 7. Data were analyzed as repeated measurements in time using PROC MIXED of SAS 9.1. No treatment differences were detected over all variables measured ($P > 0.05$). The use of mannoprotein fractions up to 900 ppm in the diet did not influence humoral immunity of dogs.

Key words: immunonutrients, nutraceuticals, canines

T66 Effect of dietary starch level on protein metabolism in domestic cats. T. J. Wester*[1], K. Weidgraaf[1], M. Hekman[1], N. J. Cave[2], and M. H. Tavendale[3], *[1]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [2]Institute of Veterinary, Animal and Biomedical Sciences, Palmerston North, New Zealand, [3]AgResearch Ltd., Palmerston North, New Zealand.*

Cats evolved eating meat-based diets high in protein and very low in carbohydrates and consequently have high AA requirements and high obligate AA catabolism. Cats must also use AA to produce glucose when dietary carbohydrate is limited. Metabolism may be affected at low protein intake when there is a conflict between AA use for protein synthesis and gluconeogenesis. This study was undertaken to test whether protein utilization in cats would be enhanced if glucose, from dietary starch, is used to replace gluconeogenesis from protein. Adult cats (n = 12) were allocated to either low or high starch diets (0 or 25% starch as-fed) with 15% ME as CP. Diets were fed at maintenance for 3 wk, and then cats were fitted with saphenous and cephalic vein catheters. On the following day, they received primed continuous infusions of [^{13}C]bicarbonate, [1-^{13}C]Leu, and [$^{15}N_2$]urea and [6,6-d_2]glucose from 0 to 120, 120 to 480, and 0 to 480 min, respectively. Cats were fed hourly during infusion and Leu entry rate from diet was calculated. Breath was sampled at 0, 100, 110, 120, 440, 460, and 480 min to measure $^{13}CO2$, with blood sampled at 0, 440, 460, and 480 min to measure ^{13}C enrichments in Leu and ketoisocaproate, and urea and glucose fluxes. There were no differences between treatments for non-oxidative Leu disposal (NOLD, an indicator of protein synthesis), Leu rate of appearance in plasma (Ra, an indicator of protein degradation), and Leu oxidation (Table 1). However, Leu flux and urea production rate (an indicator of net protein catabolism) tended to be lower ($P < 0.1$) in cats fed 25% starch diets indicating that protein utilization for anabolism may be more efficient in cats fed starch.

Table 1.

	Diet (% starch as fed)			
	0	25	SEM	P <
Leu flux, μmol/(kg•h)	243.8	207.6	12.85	0.07
Leu NOLD, μmol/(kg•h)	150.4	129.7	12.67	0.28
Leu Ra, μmol/(kg•h)	157.1	126.1	13.19	0.13
Leu oxidation, μmol/(kg•h)	93.5	77.9	11.82	0.37
Urea production, μmol/(kg•h)	519.0	396.8	46.56	0.09
Glucose flux, μmol/(kg•h)	1,065.3	1920.7	103.74	0.001

Key words: feline nutrition, protein metabolism, urea flux

T67 Effect of glucose infusion and dietary protein level on urea production in the domestic cat. T. J. Wester*[1], K. Weidgraaf[1], M. Hekman[1], N. J. Cave[2], and M. H. Tavendale[3], *[1]Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand, [2]Institute of Veterinary, Animal and Biomedical Sci-*

ences, Palmerston North, New Zealand, [3]AgResearch Ltd., Palmerston North, New Zealand.

Cats are unique among domestic animals as they are obligate carnivores that have evolved eating diets high in protein and very low in carbohydrate. As a carnivore eating a meat-based diet, cats are reliant on gluconeogenesis from protein to meet their glucose requirement even when protein intake is low or at the requirement (15% ME as CP). This study was undertaken to examine the effect of glucose infusion on AA catabolism in cats fed at and above their protein requirement. Our hypothesis was that once the glucose requirement was met by endogenous administration, urea production would reach a minimum. Adult cats (n = 18) were allocated to one of 3 very low carbohydrate diets with 15, 45 or 65% ME intake as CP and fed at maintenance for 3 wk. Cats were then fitted with saphanous and cephalic vein catheters and fasted overnight. The following day they received a primed continuous infusion of [$^{15}N_2$]urea from 0 to 720 min. Starting at 120 min, glucose was continuously infused into the cephalic vein at 0, 0.75, 1.5, 4.0, and 8.0 mg/kg•min for 2 h at each level. Blood was sampled in the last 30 min of each level of glucose infusion. Urea production rate increased with increasing dietary protein ($P < 0.001$), but decreased as glucose level increased only at 45 and 65% ME as CP ($P < 0.001$; Table 1). This drop in urea production as rate of glucose infusion increased was greater at 65 vs. 45% CP as ME ($P < 0.001$). When dietary protein was supplied at its requirement, AA catabolism was low and not affected by glucose infusion. The minimum level of urea produced when glucose was supplied in cats fed 15% ME as CP may represent obligate AA catabolism.

Table 1. Urea production (μmol/kg•h) in cats fed diets containing varying levels of ME intake as CP

Glucose infusion, mg/kg•min	Diet (% ME as CP)		
	15	45	65
0	32.60	466.2	598.8
0.75	325.74	439.8	556.2
1.5	315.56	418.2	510.6
4.0	302.90	401.4	473.4
8.0	307.74	394.2	447.0

Fixed effects of protein level, glucose infusion, and protein×glucose were significant ($P < 0.001$; SEM = 25.08).

Key words: feline nutrition, protein metabolism, urea flux

T68 Effects of sow stocking rate and season on bermudagrass (*Cynodon dactylon*) ground cover. S. Pietrosemoli*[1], J. C. Guevara[2], and J. T. Green[3], [1]*Animal Science Department, North Carolina State University, Raleigh,* [2]*Alternative Swine Research and Extension Project, Raleigh, NC,* [3]*Crop Science Department, North Carolina State University, Raleigh.*

Sustainable outdoor swine production faces management challenges to minimize potential environmental impacts, including the deterioration of vegetative ground cover, soil disturbance, irregular nutrient dispersion and high nutrient loads that can cause soil and water pollution and risk of N-leaching and ammonia volatilization. Ground cover reduces erosion by increasing infiltration, trapping sediments, stabilizing the soil, and reducing the effects of intense rainfall. High stocking rates can accelerate degradation. At the Center for Environmental Farming Systems (CEFS) in Goldsboro, NC, the effects of 3 stocking rate (SR; 10, 15 and 25 sows/ha) on bermudagrass ground cover were evaluated during 3 seasons (S; Jan-March 09 [W09]; Sept-Oct 09 [F09] and Apr-May 10 [S10]). Paddocks of 2020m^2 were divided into 9 sections, with the central section being defined as a heavy use area where shelter and water were provided and with permanent access by the animals. The other sections were managed in a weekly rotational pattern. Yorkshire sows (avg BW: W09: 294; F09: 212; S10: 186 kg) were restrictedly fed concentrate daily in the morning (3 kg, 15% CP). Ground cover components (percent of live vegetation (LV), dead residue (DR), bare soil (BS), and vegetative ground cover (VGC) changes were recorded weekly following a step point technique on transect lines evenly distributed across all sections. The VGC was the sum of LV and DR. The experimental design was a randomized complete block, with 2 field replicates. The SR affected LV (P = 0.09; 41.71^a, 27.97^b and 28.0^b %, respectively, for 10, 15 and 25 sows/ha) whereas BS did not change (P = 0.31; 23.6, 32.7 and 34.4%, respectively, for 10, 15 and 25 sows/ha). Season had a pronounced effect on VGC components: LV W09: 7.2^a, F09: 38.2^b; S10: 52.3^c%; P = 0.0005) and DR (W09: 67.2^a, F09: 23.3^b; S10: 17.9%^{b}; P = 0.0002). Conversely, S had no effect on BS (W09: 22.5; F09:38.4; S10: 52.3%; P = 0.14). Under the conditions of these experiments, S had a more pronounced effect on vegetative ground cover than SR.

T69 Cradle-to-farm gate analysis of milk carbon footprint. A critical review. G. Pirlo*, *Consiglio per la ricerca e sperimentazione in agricoltura, Centro di ricerca per le produzioni foraggere e lattiero-casearie (CRA-FLC), Cremona, Italy.*

Objectives, methods and results of life cycle assessment (LCA) studies about milk production have been examined. The studies considered refer to milk production only and do not include milk transportation to dairies, processing and distribution. Otherwise, the parts of the studies down the milk production have been excluded. Emissions of GHG (CO2, CH4 and N2O) only have been considered, ignoring other environmental impacts such as acidification, eutrophication, land use, energy use, water use, eco-toxicological and human-toxicological pollutants, desertification, biodiversity, PM10 etc. Studies have been classified according to the country, the farm data source (real farms, simulated representative farms, national statistics), functional unit, allocation criteria, LCA tools (databases, models, literature), kind of comparison (milk ability, year, conventional versus organic farming, grazing versus confined, system intensification grade, herd size). Comparisons show a large variability among the GHG emissions associated to the functional unit, caused also by the different methods used in the analyses. Study showed the important role played by production system, stocking rate, and milk ability. LCA seems to be a tool for several scopes: international benchmark, economic and social planning, eco-labeling, verification of technical innovations. Further studies on farm characteristics, consumptions and emissions associated with milk production are needed in order to make LCA a practical tool.

Dairy Foods: Microbiology

T70 Fluid milk quality survey. C. Boeneke*, J. Vargas, and K. Aryana, *Louisiana State University Agricultural Center, Baton Rouge.*

Whole and 2% milks were received from 17 dairy processing plants located in the west, midwest, and southern regions of the United States in duplicates. All milks were shipped overnight in Styrofoam coolers filled with ice to maintain the temperature of the samples. The samples were pasteurized at the processing plants by high-temperature short-time pasteurization. The first set of milk samples was evaluated for standard plate count, coliforms, and psychrotrophic counts using a standard method as well as a rapid method, heat-resistant spore-forming psychrotrophs, aerobic spores, HR testing (HR-1, HR-2 and HR-3), fat percentage, protein percentage, somatic cell count and a sensory evaluation immediately upon arrival. Milks were evaluated for flavor using the Collegiate Dairy Products Evaluation Score Sheet. The duplicate set was evaluated for standard plate count, coliform count and a sensory evaluation at the end of 2 weeks storage time at 7°C. Three replications were conducted. Five percent of the 2% milk samples presented psychrotrophic counts (3 samples in the first replication of the study, 2 samples in the third replication) with a mean values of approximately 2 cfu/ml. For heat resistant spore forming psychrotrophs, 10% of the samples showed the highest counts of approximately 1 cfu/ml, mainly in the second replication of the study. Ninety percent of the samples showed zero counts. Sensory evaluation scores ranged from 1 to 10 out of 10 possible points. The most common flavor criticism found by the panelists was a cooked off-flavor as well as rancid and oxidized criticisms.

Key words: fluid milk, shelf life, flavor

T71 Seasonal variation of psychrotrophic bacteria isolated from raw milk in South Korea. H. A. Lee*, J. H. Myung, Y. H. Park, and Y. K. Shin, *Institute of Dairy Food Research, Seoul Dairy Cooperative, Ansan, Kyunggi, South Korea, 425-838.*

The aim of this study was to examine the distribution and diversity of psychrotrophic bacteria from raw milk sampled from 9 provinces in South Korea by seasons. Raw milk was collected from farms in the central, eastern, western, southern, northern, northern east, southern east Kyunggi, Ansan and Incheon province at 4 different seasons. The samples were diluted and plated on sterile plate count agar and incubated at 7°C for 10 d. Then, 20 colonies per province every season were randomly selected and subcultured at least 3 times at 30°C for 48 h. For bacterial sequencing, 16s rDNA region was amplified using RT-PCR, then the products were sequenced using the 3130 Genetic analyzer. As a result, psychrotrophic counts were higher in winter than in other seasons as 5.43 log cfu/mL ($P < 0.05$). Among 9 provinces, the population in raw milk sampled from Incheon province was in significantly greater numbers and from the western Kyunggi province was in significantly lower numbers than from any other provinces, 5.38 log cfu/mL and 3.56 log cfu/mL, respectively ($P < 0.05$). Among 720 bacterial isolates, the predominant class was Gammaproteobacteria (84.01%) and genus was *Acinetobacter* (36.99%), especially *Acinetobacter johnsonii* (17.24%).

Key words: psychrotrophic bacteria, raw milk, seasonal

T72 Influence of multilayer packaging on pasteurized milk quality. M. da Silva Pinto, A. F. Carvalho*, J. Y. Suda, A. C. P. Silveira, and A. C. dos Santos Pires, *Food Science Department, Federal University of Viçosa, Viçosa, MG, Brazil.*

The type of packaging used for pasteurized milk can substantially affect their quality characteristics by directly controlling the amount of oxygen and light which comes into contact with food or for providing perfect isolation to avoid post-processing contamination by microorganisms. In this study, we tested 3 different high density polyethylene (HDPE) multilayer films and one HDPE monolayer film with the objective to evaluate the effects of the 4 different packaging types on milk quality: (1) multilayer with high barrier to light, high oxygen barrier, high tensile strength; (2) multilayer with high oxygen barrier; (3) multilayer with high barrier packing light, high tensile strength and (4) monolayer. The milk stored in each type of packaging was analyzed as the microbiological (mesophilic and psychrotrophic bacteria), physicochemical (pH, titratable acidity, dry matter content, protein content, fat content, lactose content, density and cryoscopy) and nutritional (fat oxidation and vitamin degradation) characteristics besides sensory acceptance of pasteurized milk stored at 5°C for 21 d. Three replications were analyzed using the general linear models procedure of SAS (SAS Institute Inc., Cary, NC) version 9.1, licensed by University Federal of Viçosa, 2008. The milk quality was in accordance with the Brazilian legislation. The various film properties provided by the different packaging systems demonstrated similar milk characteristics ($P > 0.05$) during the 21 d of storage at 5°C, although there were differences between the barrier packaging. All packaging materials evaluated can provide sufficient protection to the quality of pasteurized milk that can achieve a shelf life of 21 d/ 5°C, considering the conditions of the quality of the raw material and the integrity of the entire cold chain.

Key words: packaging, shelf-life, milk quality

T73 Microbiological quality of UHT dairy products analyzed by rapid, reference, and ATP bioluminescence methods. A. F. Cunha[1], A. D. Lage[1], M. M. P. Araújo[1], C. F. Abreu[2], A. R. Tassinari[2], M. R. Souza[1], C. F. A. M. Penna[1], L. M. Fonseca[1], M. O. Leite[1], and M. M. O. P. Cerqueira*[1], *[1]Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [2]3M do Brazil, Sumaré, São Paulo, Brazil.*

Besides traditional methods used for microbiological analysis of UHT dairy products, rapid methodologies based on ATP bioluminescence have been developed to detect contamination of these products in a shorter time. The use of these new approaches for monitoring the quality of UHT products such as Brazilian flavored milk and milk cream was compared with the traditional microbiological methods. Sixty-six samples of UHT dairy products, from different sources, incubated at 48, 72, and 168 h, were analyzed for the counts of mesophilic and psychrotrophic aerobic microorganisms using plate count agar (PCA) and brain heart infusion (BHI) agar and also PetrifilmAC plates. The data were compared with results of the ATP bioluminescence technique performed by the 3MMicrobial Luminescence System expressed in RLU and submitted to the MacNemar test at 95% of confidence. At all incubation times, the majority of UHT dairy samples showed low counts of mesophilic and psychrotrophic microorganisms and values lower than 150 RLU by ATP bioluminescence. Only one sample showed mesophilic count above the limit established by the Brazilian legislation - 100 cfu/mL - in PCA (2.6×10^2 cfu/mL) and PetrifilmAC (1.1×10^2 cfu/mL) at 168 h. These high counts were also detected by the ATP bioluminescence (416 RLU) and were mathematically equal.

It can be concluded that the ATP bioluminescence results were similar to those obtained by traditional methods. For the dairy industry, the ATP bioluminescence using the MLS system may become an important tool for rapid monitoring of microbiological quality of UHT dairy products, releasing the products in a shorter time than that established by the Brazilian legislation.

Key words: UHT dairy products, ATP bioluminescence, quality

T74 Phylogenic analysis and characterization of bacterial sporeformer isolates obtained from raw milk, pasteurized milk, and dairy farm environments. R. A. Ivy*, M. L. Ranieri, N. H. Martin, H. C. den Bakker, B. M. Xavier, M. Wiedmann, and K. J. Boor, *Cornell University, Ithaca, NY.*

The presence of psychrotolerant bacterial sporeformers represents a major challenge to extending the shelflife of pasteurized dairy products. The objective of this study was to identify prominent phylogenetic groups of psychrotolerant dairy-associated sporeformers from a collection sporeformer isolates from dairy systems (i.e., raw and pasteurized milk and dairy farm environments). Partial *rpoB* sequences of 1425 sporeformer isolates had been obtained previously, and partial 16S rDNA sequencing was used to assign species identifications to unique *rpoB* allelic types (ATs). A maximum likelihood phylogenetic tree was constructed for 288 unique *rpoB* ATs. Major *rpoB* clades consisted of Bacillaceae (i.e., *Bacillus* spp., *Lysinobacillus* spp., and *Viridibacillus* spp.) and *Paenibacillus* spp. Most Bacillaceae isolates grouped into clades with known contaminants of raw milk or with species associated with high altitudes, soil, and organic material. Major *Paenibacillus* clades were identified as *P. ordorifer*, *P. amylolyticus*, and *P. graminis*, and many uncharacterized *Paenibacillus* species were identified. Among the 8 major Bacillaceae clades, only 2 included isolates that grew to >4 log (cfu/ml) in skim milk broth (SMB) at 6°C, whereas 6 out of 8 major *Paenibacillus* clades contained isolates that grew to >4 log(cfu/ml) in SMB at 6°C. Though all *Paenibacillus* clades tested positive for β-galactosidase activity at 32°C and most Bacillaceae clades tested negative, *Bacillus licheniformis* (13% of Bacillaceae isolates) showed variable β-galactosidase activity. β-galactosidase activity alone, therefore, could not reliably distinguish between Bacillaceae and *Paenibacillus*. Therefore, consensus sequences of predominant *Paenibacillus rpoB* ATs indentified in this study will be used to design a DNA-based system to rapidly and specifically detect these psychrotolerant sporeformers in fluid milk and dairy ingredients (e.g., milk powders).

Key words: sporeformers, dairy microbiology, *Paenibacillus*

T75 Spores in dairy products: Characterization and destruction by pulsed light. A. Laubscher* and R. Jimenez-Flores, *California Polytechnic State University, Dairy Products Technology Center, San Luis Obispo.*

The USDA has reported an increase in the consumption of nonfat dry milk and skim milk powders due to the opening of international markets for these products. However, the main limitation to international sales is the spore counts in dairy powders. The objective of this study was to examine the characteristics of the spores in California milk powders, and to evaluate the potential quality improvement using pulsed light covering all wavelengths. We designed our experiments around 4 liquid matrices in which to contain the spores: sterile nanopure water, sterilized whey, non-fat UHT milk, and 2% UHT milk. In addition we tested dry matrices in 6 commercial skim milk and buttermilk powders. The bacteria used to inoculate these medias include ATCC reference strains (*Geobacillus* spp. and *Paenibacillus* spp.) and a collection of aerobic spore-forming bacteria isolated from California milk powders. These strains were selected because they were considered to be highly heat-resistant after exposure to excessive heat treatments. UV treatments with the Xenon pulsed lamp consisted of 4 different levels (1 burst, 2 bursts, 3 s, and 20 s) and included a post 4°C incubation and HTST pasteurization. Protein profiles were obtained for each strain used, and compared before and after treatments. With pure water we observed a seven logarithmic reduction in spores with two bursts of pulsed UV light. However, cloudy solutions were much less permissive of the lethal action of light. These matrices had the same seven logarithmic reductions but only after 3 seconds. Powders were treated with variable success, and much detriment to the flavor and chemical structure. However, while the same reduction of spore viability was achieved, the powder buttermilk was significantly more resistant to off flavor development.

Key words: spores, pulsed light, milk quality

T76 The effect of different sweeteners on growth and survival of *Lactobacillus rhamnosus* GR-1 in milk. S. Hekmat*[1,2] and G. Reid[2], *[1]Brescia University College, London, Ontario, Canada, [2]Canadian Research and Development Center for Probiotics, London, Ontario, Canada.*

There has been an increasing demand by consumers for low-calorie and low-sugar products with functional properties. *Lactobacillus rhamnosus* GR-1 is a probiotic agent with therapeutic properties. The objective of this study was to monitor growth and survival of *L. rhamnosus* GR-1 in milk sweetened with various sweetening agents during storage period. Six formulations of milk (1% fat) with 7% xylitol (X), 0.04% stevia (ST), 5% sucrose (S), 0.04% stevia-inulin-chromium mixture (SIC), 1.25% sucralose (SU) and one with no sweetening agents (C) were prepared. The mixtures were autoclaved for 15 min, cooled to 37°C and inoculated with 1% of starter culture. The samples were then incubated anaerobically at 37°C overnight. Selective MRS agar containing 0.015 g/L fusidic acid was used to enumerate *L. rhamnosus* GR-1 after 1, 14, and 28 d of storage at 4°C. All sweetening agents supported the growth and survival of *L. rhamnosus* GR-1; however, it showed a higher survival rate ($P < 0.05$) in the ST and SIC treatments. After 1 d of storage, the total colony counts of treatments ST and SIC for *L. rhamnosus* GR-1 were 7.4×10^9 and 1.1×10^9 cfu/mL, respectively. The total colony counts for all treatments decreased slightly after 28 d of storage. The results indicate that *L. rhamnosus* GR-1 can remain viable in presence of various sweetening agents during the storage period and there is potential for incorporating these sweetening agents in other probiotic dairy products.

Key words: probiotics, sweeteners, milk

T77 Detection and transfer of the glutamate decarboxylase gene in *Streptococcus thermophilus*. G. Somkuti*, J. Renye, and D. Steinberg, *Eastern Regional Research Center/USDA, Wyndmoor, PA.*

γ-Aminobutyric acid (GABA) is generated from glutamate by the action of glutamic acid decarboxylase (GAD) and characterized by hypotensive, diuretic and tranquilizing effects in humans and animals. The production of GABA by lactic acid starter bacteria would enhance the functionality of fermented dairy foods including cheeses and yogurt. The survey of 42 strains of the yogurt starter culture *Streptococcus thermophilus* by PCR techniques indicated the presence of

a glutamate decarboxylase gene (*gad*) in 15 strains. DNA sequencing data indicated that in the genome of GAD+ *S. thermophilus* strains the *gad* as a rule is flanked by a transposase gene (5′) and a HD-superfamily hydrolase gene (3′). Specific primers were designed to amplify a 1.75-kb genomic fragment in *S. thermophilus* to include *gad* and its putative promoter region. The resulting PCR product was inserted into the 5.48-kb pMEU5a shuttle vector which was used to transform *Escherichia coli* DH5α. Subsequently, the recombinant plasmid pMEU5a-1/*gad* (7.24 kb) was transferred by electroporation into the GAD-negative strain *S. thermophilus* ST128. The ST128 transformants carrying the plasmid-encoded *gad* produced fully functional GAD enzyme as evidenced by the conversion of glutamate to GABA at a rate similar to strains with *gad* located on the chromosome. The results demonstrated the potential to equip non-GABA producing strains *S. thermophilus* and possibly other lactic acid bacteria with the capacity to produce GAD to improve culture performance in the development of functional foods.

Key words: γ-aminobutyric acid, *Streptococcus thermophilus*

T78 Development of a real-time PCR assay for rapid detection of spoilage *Paenibacillus* spp. in fluid milk. M. L. Ranieri*, W. R. Mitchell, R. A. Ivy, N. Martin, M. Wiedmann, and K. J. Boor, *Cornell University, Ithaca, NY.*

Psychrotolerant sporeforming bacteria, specifically *Paenibacillus* spp., represent the current biological limit to the extension of fluid milk shelf-life. *Paenibacillus* have been found in farm environments, raw milk, processing plant environments, and in pasteurized fluid milk across the United States. While typically present at low levels in raw milk, *Paenibacillus* spores can survive conventional pasteurization temperatures, germinate, and grow to numbers capable of negatively impacting the sensory characteristics of refrigerated milk products. A real-time PCR assay was designed to detect *Paenibacillus* spp. in fluid milk and discriminate between *Paenibacillus* and other closely related sporeforming bacteria. Partial 16S rDNA sequences, representing a total of over 1400 *Paenibacillus* and *Bacillus* spp. isolated from dairy farms, milk processing plants, and fluid milk products, were compared with identify appropriate primer and probe regions specific to *Paenibacillus* spp. To confirm specificity, genomic DNA from 16 *Paenibacillus* and 17 *Bacillus* isolates were tested with the assay; these isolates represented the 9 most frequently isolated *Paenibacillus* and *Bacillus* allelic types, plus additional allelic types to include genetic diversity. All 16 *Paenibacillus* isolates were detected with a mean cycle threshold (Ct) of 19.14 (±0.54). While 14/17 *Bacillus* isolates showed no signal (Ct > 40), 3 *Bacillus* isolates showed very weak positive signal (Ct = 38.66 [±0.80]). When total genomic DNA was also extracted from milk samples inoculated with *Paenibacillus*, we found a detection limit of 1,000 *Paenibacillus* cfu/mL. We also showed that this assay could be used to screen colonies collected from standard plate count agar, using crude colony lysates. Despite the additional incubation time necessary to develop colonies on plate media, this method eliminates the time and cost associated with genomic DNA preparations. Overall, this assay represents a specific and rapid tool to identify *Paenibacillus* spp. and therefore provides a method for determination of sources or milk containing spoilage bacteria.

Key words: fluid milk, spoilage, *Paenibacillus*

T79 Genetic analysis of a novel plasmid encoded durancin locus in *Enterococcus durans* 41D. L. Du[1], G. Somkuti*[2], and J. Renye[2], [1]*Nanjing University of Finance and Economics, Nanjing, China,* [2]*Eastern Regional Research Center/USDA, Wyndmoor, PA.*

Enterococcus durans is commonly found in the intestinal tract in humans and animals and several strains are known to produce bacteriocins. Durancin GL, a novel bacteriocin of *Enterococcus durans* 41D with antilisterial activity was isolated from artisanal cheese samples and its genetic determinants were characterized. The bacteriocin operon included the structural (durA) and immunity (durB) genes among the 9 putative ORFs identified on pDGL1, an 8.3-kb plasmid which was fully sequenced. The deduced DurA protein was a 71-amino acid peptide with 74% identity to the class II bacteriocin BacA of *E. faecalis*. DurA had a potential signal peptidase cleavage site indicating the involvement of a sec-dependent transport system in yielding a 7.97 kDa mature peptide. The mature DurA peptide had the typical structure of subclass IIa bacteriocins, including a conserved YYGNG motif and a hydrophobic C-terminal region. The immunity gene (durB) encoded a 94-amino acid peptide with 85% identity to the BacB immunity gene. The minimum requirement for durancin GL production was defined by translationally fusing a 547 bp fragment containing the durAB genes with the *Streptococcus thermophilus* chromosomal promoter P2201 by PCR, and subcloning in vector pMEU5a. Isolates of the yogurt starter culture *S. thermophilus* electrotransformed with the recombinant plasmid pMEU5a-1 secreted durancin GL into the medium and inhibited the growth of *Listeria*. The results showed the possibility of transferring the durancin GL gene into food-grade lactic acid bacteria to serve as the source of a natural bioprotective agent for *Listeria* control.

Key words: durancin, *Listeria*, *Streptococcus thermophilus*

T80 Development of a qPCR method for monitoring strain dynamics during yogurt manufacture. D. Miller*, E. G. Dudley, and R. F. Roberts, *The Pennsylvania State University, University Park.*

Starter cultures used in the manufacture of yogurt consist of multiple strains of *Lactobacillus delbrueckii* ssp. *bulgaricus* (LB) and *Streptococcus thermophilus* (ST). Existing tools for monitoring ST and LB levels during yogurt manufacture rely on conventional plating methods, which require 48–72 h of incubation and do not allow for quantification of individual strains. The objectives of the present work were to i) design and evaluate primers for quantification of individual strains in a commercial starter culture by quantitative polymerase chain reaction (qPCR), ii) to identify an external control for DNA isolation and qPCR, iii) to prepare standard curves with individual starter culture strains and combinations of starter culture strains spiked in bulk starter base, and iv) to evaluate strain balance in bulk starters prepared at 3 different temperatures. Strain-specific primers were designed for 2 ST strains (ST DGCC7796 and ST DGCC7710), one LB strain (DGCC 4078) and one *Lactobacillus delbrueckii* ssp. *lactis* strain (DGCC4550). Primers for the individual ST strains were designed to target unique DNA sequences in clustered regularly interspersed palindromic repeats (CRISPR, GenBank Accession no. EF434468 and EF434469). LB primers targeted a CRISPR locus based on sesquence information provided by the culture supplier. Primers for LL were designed to target mannitol-specific IIbC component of the PTS system (GenBank Accession no. AF496224.1). *Lactobacillus farciminis* ATCC 29644^T (LF) was selected as an external control for the DNA extraction procedure and qPCR because it has a similar peptidoglycan structure as the LB and LL strains. Following evaluation of primer specificity, standard curves relating cell number to cycle threshold (Ct) were prepared for each strain individually and for each strain in 3-strain combinations when spiked bulk starter base, and no significant

differences in the slopes were observed ($\alpha = 0.05$). Strain balance data was collected for bulk starter cultures prepared at 37, 41, and 43°C to demonstrate the potential application of this method for evaluation of the influence of fermentation conditions on strain balance.

Key words: yogurt, qPCR, LB and ST

T81 Binding and efficacy of a natural biopreservative (nisin) in different food matrices. R. Niewohner*, S. Anand, and R. Nauth, *South Dakota State University, Brookings.*

Nisin is a natural biopreservative produced by lactic acid bacteria. We explored its ability to bind in different food matrices and to protect them from bacterial spoilage in ranch sauce, vegetable soup, and hot dogs with a well plate assay. Skim milk was used as a control for these studies. Challenge studies were also conducted by spiking specific spoilage bacteria such as *Lactobacillus plantarum* in ranch sauce and hot dogs, and *Bacillus cereusi* in vegetable soup. The hypothesis of this experiment was that the more recovery of nisin over time of the sample matrix, the fewer bacteria will be able to grow, since the "free nisin" is not bound and available to act against the bacteria. *Lactococcus lactis ssp. cremoris* was used as a test culture in the entire study. All experiments were replicated thrice. In the first part of the experiment, a nisin standard was established using 10, 100, 1,000, and 10,000 IU Recovery studies were conducted at 0 and 24 h intervals in each of the food matrices, including milk, by spiking 1000 IU of nisin. The Dunnett multiple comparisons showed that skim milk had the highest recovery. Ranch sauce showed a slight decrease with about 900 IU recovered, however, in vegetable soup only 20 IU could be recovered. Hot dogs showed a slight decrease, but it was not significantly different from the milk. After 24 h, the ranch sauce and the hot dog proved to not be significantly different than the milk. However, the vegetable soup showed a decreased recovery over time with a final estimate of 5 IU of nisin. In the ranch sauce challenge study, with nisin addition at 1,000 IU, a decrease in *L. plantarum* counts were observed up to 24 d of the storage studies from an initial count of 10^9 cfu/g of the sample. The hot dogs with 1,000 IU of nisin showed a decrease in the number of *L. plantarum* up to 10 d of the storage studies. On the other hand, *Bacillus cereus* (10^4 cfu/g) in vegetable soup challenge test did not show any reduction by nisin at 1,000 IU. The study thus demonstrated variations in the binding of nisin to different food matrices with variable protective effect.

Key words: recovery of nisin, preservative, ranch sauce, hot dog, and vegetable soup

T82 Resistance of membrane biofilms to cleaning and sanitation treatments. D. Singh* and S. K. Anand, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings.*

Previous studies conducted in our lab have established the formation of bacterial biofilms on reverse osmosis (RO) whey concentration membranes. In the present study we evaluated the effectiveness of different chemicals of a cleaning in place (CIP) protocol against the constitutive microflora of biofilms formed on whey RO membranes. Different bacterial isolates that were a part of biofilm consortia of 2 to 12 mo old membranes included *Bacillus* sp., *Escherichia coli*, *Klebsiella oxytoca, Enterococcus* sp., *Streptococcus* sp., *Staphylococcus* sp., *Micrococcus* sp., *Aeromonas* sp., *Corynebacterium* sp., and *Pseudomonas* sp. The CIP protocol tested against the planktonic and 12-h-old biofilms of above microflora included 5 treatment steps based on; alkali, surfactant, acid, enzyme, a second surfactant, and a weekly sanitizer application. The results confirmed the resistance of isolates in both planktonic and embedded states against most of the 5 treatment steps. The only effective step was acid based treatment, which resulted in 5–8 logs reduction in case of planktonic cells, and 2–5 logs reduction against embedded cells in 12 h old biofilms formed under lab conditions. The sanitizer treatment step also showed similar results and caused a reduction of 6–8 logs against planktonic cells. On the other hand, it was much less effective against the embedded cells in biofilms, and resulted in a reduction of only 1 to 3 log counts. *Bacillus* sp. showed highest resistance in planktonic cell, as well as, embedded cell state. Differences were noticed in the resistance pattern of biofilm isolates as the membranes aged. In general, isolates from the older membranes showed higher resistance to CIP chemicals and sanitizer treatment. Data were statistically analyzed using the SAS program. On the basis of these results, it can be concluded that the biofilms formed on the RO whey concentration membranes were resistant to the CIP protocol being used.

Key words: planktonic, biofilm, embedded

T83 Effect of low sonication intensities on the growth of *Streptococcus salivarius* ssp. *thermophilus* ST-M5 subjected to different temperatures. M. Moncada* and K. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

Whether low sonication conditions stimulate the growth of bacterial cultures is not clearly understood. The objective was to study the influence of low sonication intensities on the growth characteristics of *Streptococcus salivarius* ssp. *thermophilus* at different temperatures. Freshly thawed culture was suspended in 0.1% peptone water and 18 mL of sample was sonicated using horn (diameter 13 mm) set at a maximum acoustic power output of 750 W, frequency 24 kHz. The treatments were 4 sonication intensities of 8.07, 14.68, 19.83 and 23.55 Watts/cm^2 randomized over 3 different temperatures (4, 22 and 40°C) of inoculated peptone water before sonication. The energy input (1500 J) was kept constant in all treatments. Control samples did not receive any sonication treatment. Growth of treatment and control samples was determined hourly during 12 h of incubation at 37°C. Data were analyzed using proc mixed model of statistical analysis system (SAS). At all 3 temperatures growth of *Streptococcus thermophilus* ST-M5 subjected to low sonication intensities were significantly ($P < 0.05$) better than control. At 4 and 40°C all low sonication intensities showed better growth than control. At 22°C 8.07, 14.68 and 19.83 Watts/cm^2 showed higher ($P < 0.05$) viable counts than control and 23.55 Watts/cm^2. Some low sonication intensities improved growth of *Streptococcus salivarius* ssp. *thermophilus* ST-M5.

Key words: mild sonication, probiotic

T84 Low sonication intensity influences on the protease activity of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 at different temperatures. M. Moncada* and K. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

Low sonication intensity is an acoustic energy which involves the conversion of an electrical signal into a physical vibration. It uses the sound for modifying the permeability of the cell plasma membrane. *Lactobacillus delbrueckii* ssp. *bulgaricus* is a widely used bacterium used for the production of some fermented dairy products. The objective was to study the influence of low sonication intensities on protease activity of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 at different

temperatures. Freshly thawed culture was suspended in 0.1% peptone water and 18 mL of sample was sonicated using horn (diameter 13 mm) set at a maximum acoustic power output of 750 W, frequency 24 kHz. The treatments were 4 sonication intensities of 8.07, 14.68, 19.83 and 23.55 Watts/cm^2 randomized at 3 different temperatures (4, 22 and 40°C) of inoculated peptone water before sonication. The energy input (1500 Joules) was kept constant in all treatments. Control samples did not receive any sonication treatment. Protease activity was determined at 0, 12 and 24 h of incubation spectrophotometrically at 340 nm. Differences of least squares means were used to determine significant differences at $P < 0.05$ for main effect (low sonication intensity) and interaction effect (low sonication intensity * time * temperature). At 4°C the sonication intensities of 14.68, 23.55 and 19.83 W/cm^2 significantly ($P < 0.05$) increased protease activity compared with the control. At 22°C the sonication intensities of 23.55 and 19.83 W/cm^2 had protease activities significantly ($P < 0.05$) higher than the control. The optical density (OD) values for control bacterium and culture sonicated at 19.83 and 23.55 W/cm^2 at 12 h were 0.38, 0.46 and 0.59 absorbance units respectively. The OD at 24 h for control bacterium and bacterium sonicated at 19.83 and 23.55 W/cm^2 were 0.68, 0.92 and 0.96 absorbance units. At 40°C all treatments exhibited significantly ($P < 0.05$) higher protease activity than control. Protease activity of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 was improved by some low sonication intensities.

Key words: mild sonication, probiotic

T85 Influence of low sonication intensities at different temperatures on the bile tolerance of *Streptococcus salivarius* spp. *thermophilus* ST-M5. M. Moncada* and K. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

Low sonication intensity condition is a non-destructive technique that uses sound waves to cause cavitation in aqueous solutions and may improve the permeability of membrane, speed up the transfer of substrates and promote cellular growth and propagation. Bile tolerance is an important probiotic characteristic. *Streptococcus salivarius* spp. *thermophilus* is widely used in the fermentation of dairy products. The objective was to determine the effect of various low sonication intensities at different temperatures on bile tolerance of *Streptococcus salivarius* spp. *thermophilus*. Freshly thawed culture was suspended in 0.1% peptone water and 18 mL of sample was sonicated using horn (diameter 13 mm) set at a maximum acoustic power output of 750 W, frequency 24 kHz. The treatments were 4 sonication intensities of 8.07, 14.68, 19.83 and 23.55 W/cm^2 randomized over 3 different temperatures (4, 22 and 40°C) of inoculated peptone water before sonication. The energy input (1500 J) was kept constant in all treatments. Control samples did not receive any sonication treatment. Bile tolerance of samples were determined hourly for 12 h of incubation. Data were analyzed using the using proc mixed model of statistical analysis system (SAS). At 22°C culture sonicated at 19.83 W/cm^2 and at 4°C culture sonicated at 8.07 and 14.68 W/cm^2 showed similar bile tolerance compared with control. At 40°C bacterium subjected to intensity of 14.68 W/cm^2 showed significantly ($P < 0.05$) higher bile tolerance at hours 6 to 12 compared with control.

Key words: mild sonication, probiotic

T86 Screening of mild pulsed electric field parameters for enhancing acid tolerance of *Streptococcus salivarius* spp. *thermophilus* ST-M5. N. Najim and K. Aryana*, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

Aim of the present study was to screen mild PEF conditions for increasing acid tolerance. Freshly thawed frozen concentrated culture of *Streptococcus salivarius* spp. *thermophilus* ST-M5 was suspended in 0.1% (wt/vol) sterile peptone water and treated in pilot plant PEF system. A range of mild PEF treatments included positive and negative square unipolar pulse widths of 2, 3, and 4 µs, pulse periods of 0.3 and 0.6 s, voltages of 1 and 3 kV/cm at 2 temperatures, 21.6°C and 40.5°C. The control was run through the PEF system without receiving any pulsed electric field condition. The flow rates of both the control and PEF treated samples were kept constant at 60 mL/min. Samples were individually inoculated in acidified M17 broth at pH 2.0. Samples were plated in duplicates and incubated aerobically at 37°C for 48 h. The acid tolerance was determined at 0, 30, 60, 90 and 120 min of incubation. Three replications were conducted for each experimental condition. The acid tolerances using the 3 positive square unipolar pulses of 2, 3 and 4 µs for both pulse periods of 0.3 and 0.6 s and voltage of 1 kV/cm at both 21.6°C and 40.5°C PEF treatment temperatures were significantly the highest compared with both the control and negative square unipolar pulses at the same PEF conditions. The acid tolerance with positive square unipolar pulse width of 3 µs for both pulse periods of 0.3 and 0.6 s using voltage of 1kV/cm at 40.5°C PEF treatment temperature was significantly higher than both pulses of 2 and 4 µs. Furthermore, the same PEF conditions at 40.5°C PEF temperature showed significantly higher acid tolerance than pulses of 2, 3 and 4 µs at 21.6°C. The acid tolerances using positive square unipolar pulse widths of 2, 3 and 4 µs for both pulse periods of 0.3 and 0.6 s with voltage of 1 kV/cm were significantly higher than both the control and those subjected to voltage of 3 kV/cm at the same PEF conditions. Positive square unipolar pulses significantly improved acid tolerance compared with the negative square unipolar and square bipolar pulses.

Key words: mild pulsed electric fields, probiotic

T87 Mild pulsed electric field conditions identified for improving growth, protease activity and acid tolerance of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 and *Lactobacillus acidophilus* LA-K. N. Najim and K. Aryana*, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

The objective was to determine the effect of mild pulsed electric field (PEF) conditions on acid tolerance, growth and protease activity of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 and *Lactobacillus acidophilus* LA-K. Freshly thawed frozen concentrated cultures were individually inoculated in 0.1% (wt/vol) sterile peptone water and treated in pilot plant PEF system. The treatment was positive square unipolar pulse width of 3 µs, pulse period of 0.5 s, voltage of 1 kV/cm, delay time of 20 µs and flow rate of 60 mL/min at 40.5°C PEF treatment temperature. The control was passed through the PEF system at the same flow rate (60 mL/min) without receiving any pulsed electric field condition. The acid tolerance was determined every 30 min for 120 min of incubation in acidified MRS broth at pH 2. Growth of the cultures was determined hourly for 32 h of incubation of *Lactobacillus acidophilus* LA-K and for hourly for 25 h of incubation of *Lactobacillus delbrueckii* ssp. *bulgaricus*LB-12. Protease activity was determined at 0, 12, 24, 36 and 48 h of incubation. Three replications were conducted. The viability of the control *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 was lost after 30 min of incubation in acidified MRS broth (pH 2), whereas, the bacterium subjected to mild PEF treatment was acid tolerant until the end of 120 min of incubation.

Mild PEF treated cultures of both *Lactobacillus acidophilus* LA-K and *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 reached the logarithmic growth phase an hour earlier than the control. Mild PEF treatment significantly ($P < 0.0001$) enhanced the protease activity of both *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 and *Lactobacillus acidophilus* LA-K compared with the control. Mild PEF conditions studied significantly improved acid tolerance, growth and protease activity of *Lactobacillus delbrueckii* ssp. *bulgaricus* LB-12 and *Lactobacillus acidophilus* LA-K.

Key words: mild pulsed electric fields, probiotic

T88 Impact of mild pulsed electric field conditions on improving bile tolerance, protease activity and growth of *Streptococcus salivarius* ssp. *thermophilus* ST-M5. N. Najim and K. Aryana*, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge.*

Certain mild pulsed electric field (PEF) conditions show promise in enhancing probiotic characteristics and need to be further explored. In an earlier study on screening mild PEF conditions for enhanced acid tolerance, a condition was identified that enhanced acid tolerance. Aim of the present study was to evaluate the identified mild PEF conditions' influence on the bile tolerance, growth and protease activity of this probiotic bacterium. Freshly thawed frozen concentrated culture of *Streptococcus salivarius* ssp. *thermophilus* ST-M5 was suspended in 0.1% (wt/v) sterile peptone water and treated in pilot plant PEF system. Treatment was positive square unipolar pulse width of 3 µs, pulse period of 0.5 s, voltage of 1 kV/cm, delay time of 20 µs and flow rate of 60 mL/min at 40.5°C PEF treatment temperature. Control was passed through the PEF system at the same flow rate (60 mL/min) without receiving any pulsed electric field condition. Growth and bile tolerance of the control and PEF treated samples were determined hourly throughout 20 and 16 h of incubation respectively. Protease activity was determined at 0, 12, 24, 36 and 48 h of incubation at 37°C. Three replications were conducted. The mild PEF conditions had non significant influence on the bile tolerance of *Streptococcus salivarius* ssp. *thermophilus* ST-M5 throughout the entire incubation time period of 16 h. The control and mild PEF treated samples had the same counts of 10.97 (+/− 0.25) log cfu/ml at 0 h of growth. Mild PEF treated samples reached the logarithmic growth phase an hour earlier than the control. Mild PEF treated samples had significantly higher counts compared with the control for all the time points over the logarithmic phase but had nonsignificant ($P > 0.05$) difference for all the time points over both the stationary and the decline phases of the growth curve. *Streptococcus salivarius* ssp. *thermophilus* ST-M5 subjected to mild PEF throughout the incubation time points of 12, 24 and 36 h had significantly enhanced proteolytic activity compared with the control.

Key words: milk pulsed electric fields, probiotic

T89 Resistance of *E. coli* and *L. rhamnosus* to acid stress is affected by the presence of pepsin-treated caseinomacropeptide. G. Robitaille, C. Lapointe, D. Leclerc, and M. Britten*, *Food Research and Development Centre, Agriculture and Agri-Food Canada, St Hyacinthe, Quebec, Canada.*

Caseinomacropeptide (CMP) is a 7 kDa phosphoglycopolypeptide released from κ-casein during milk digestion and during chymosin-induced renneting of caseins. The objective of the study was to analyze the effect of pepsin-treated CMP from cow and goat milk on the resistance of *E. coli* and *L. rhamnosus* during acid stress. Bacterial cells in exponential growth phase were suspended in acidified phosphate buffered saline with or without pepsin-treated CMP. Viability was determined during a 90 min incubation period. Pepsin-treated CMP exhibited bactericidal activity at pH 3.5 when added in a dose dependent manner to *E. coli*, reducing survival by more than 90% within 15 min at 0.25 mg/mL. At pH >4.5 the bactericidal activity was lost indicating that pepsin-treated CMP was efficient at low pH only. The effectiveness of pepsin-treated CMP at pH 3.5 was not affected by the presence of glycoconjugates linked to CMP or by the bovine or caprine origin of milk. In contrast, *L. rhamnosus*, a probiotic, was more resistant to acid stress when pepsin-treated bovine or caprine CMP was added to the media. The viability reached 50% after 60 min incubation at pH 3 compared with 5% survival without additive. Neither the glycosylation extent nor the sequence variations between CMP from bovine and caprine milk affected the protective activity of hydrolysed CMP toward *L. rhamnosus*. This suggests that encrypted bioactive peptides released by the pepsin treatment of CMP was antibacterial toward *E. coli*, and improved acid stress resistance of *L. rhamnosus* in an acidic media that mimicked gastric environment.

Key words: caseinomacropeptide, antibacterial, acid stress

T90 Effect of microencapsulation on survival of *Lactobacillus acidophilus* La5 during simulated gastrointestinal conditions of stirred yoghurt after refrigerated storage. M. C. E. Ribeiro, K. S. Chaves, C. G. M. S.C. Tenório, F. N. Souza, C. R. F. Grosso, and M. L. Gigante*, *State University of Campinas, Campinas, SP/Brazil.*

Microencapsulation is an effective method for maintaining high viability of probiotic bacteria, as it protects probiotics both during food processing and storage as well as in gastric conditions. The aim of this study was to evaluate the viability of *Lactobacillus acidophilus* La5 in both free and microencapsulated forms in stirred yogurt during simulated gastrointestinal transit. Probiotic bacteria were microencapsulated using pectin and whey protein, associating ionotropic gelation and complex coacervation. Three batches of stirred yogurt were made with *L. acidophilus* incorporated into the product in different states: free (1% v/v), moist microcapsules (10% w/v) and rehydrated freeze-dried microcapsules (13% w/v). After 35 d of storage the survival of *L. acidophilus* during the passage through the gastrointestinal tract was determined by exposing the yogurts at 37°C for 420 min to a simulated gastric juice (pH 3.0) containing pepsin and, subsequently, to a simulated intestinal juice (pH 7.0) containing pancreatin, and by monitoring changes in total viable counts. Bile tolerance (1%) at pH 7.0 was evaluated for 300 min. The experiment was repeated 3 times and the results were evaluated by ANOVA and Tukey′s mean comparison tests ($P \leq 0.05$). During the simulation of the passage through gastrointestinal conditions, the counts of viable cells in probiotic yogurts with free *L. acidophilus* reduced 0.38 log cycles while this reduction was 0.17 and 0.18 log cycles when the probiotic was added to the yogurt in moist and rehydrated freeze-dried microcapsules, respectively. After 5 h exposed to a bile solution, there was a reduction of 3.5 log cycles in the viability of *L. acidophilus* when incorporated in yogurt in free form, 1.37 and 0.98 log cycles in yogurt with moist and rehydrated freeze-dried microencapsulated *L. acidophilus*, respectively. Therefore, microencapsulation of *L. acidophilus* La5 can be considered a potentially useful technique for delivering probiotics to the gastrointestinal tract of humans.

Key words: probiotic yoghurt, microencapsulation, gastrointestinal resistance

T91 Viability of free and microencapsulated *Lactobacillus acidophilus* La5 in stirred yoghurt during refrigerated storage. M. C. E. Ribeiro, C. G. M. S.C. Tenório, K. S. Chaves, F. N. Souza, C. R. F. Grosso, and M. L. Gigante*, *State University of Campinas, Campinas, SP/Brazil.*

The aim of this study was to evaluate the characteristics of probiotic stirred yogurt added of *Lactobacillus acidophilus* La5 in both free and microencapsulated forms during refrigerated storage. The probiotic microorganism was microencapsulated by association of ionotropic gelation with Ca^{2+} and complex coacervation using low methoxyl amidated pectin and whey protein as wall materials. The yogurts were manufactured with sterilized, homogenized and standardized milk added of 2.5% (v/v) yogurt starter culture and submitted to the following treatments: 1) addition of 1% (v/v) of free *L. acidophilus*; 2) addition of 10% (w/v) of moist microcapsules containing *L. acidophilus* and 3) addition of 13% (w/v) of rehydrated freeze-dried microcapsules containing *L. acidophilus*. Incubation was carried out at 42°C until fermentation reached pH 4.8 ± 0.05. Yogurts were evaluated once a week over the 5-week storage period for pH and viability of starter culture and probiotic microorganism. A Split-Plot design in a 3 × 6 factorial, in completely randomized blocks, was used with 3 replications. Results were evaluated by ANOVA and Tukey′s mean comparison tests ($P \leq 0.05$). The samples with free cells and with moist microcapsules showed fermentation time of 180 min, while this period was 200 min for microencapsulated rehydrated freeze-dried cells. The yogurts added by microencapsulated *L. acidophilus* showed less post-acidification and higher survival of probiotic microorganism after 35 d storage than yogurt added by free probiotic. The number of free cells was reduced by 0.98 log cycles, while in microencapsulated form for both moist and rehydrated freeze-dried forms the reduction was 0.2 log cycles. The microencapsulation of *Lactobacillus acidophilus* La5 by association of ionotropic gelation with Ca^{2+} and complex coacervation using pectin and whey protein as wall materials provides protection to the microorganism during refrigerated storage of probiotic yogurt.

Key words: probiotic, yoghurt, microencapsulation

T92 In vitro property evaluation of *Propionibacterium* cultures for probiotic applications. W. Y. Yang*, A. Hostetler, C. Nolan, and H. S. Kim, *Culture Systems Inc., Mishawaka, IN.*

The potential use of propionibacteria as a probiotic is getting attention for both humans and animals. Some of the benefits include aiding in the prevention of colon cancer for humans and weight gain for animals. Certain properties are needed for maximizing probiotic effectiveness, such as tolerance in acidic and bile salt conditions and maintenance of viability. The objective of this study was to isolate and screen *Propionibacterium* strains from healthy cow rumen fluid and cheese, and to evaluate their effectiveness as probiotic cultures. The tolerance of propionibacteria strains to acidic environments and bile salt conditions was tested. In addition, the antibiotic susceptibility and growth in a limited fermentation medium were assessed. Finally, the stability of the freeze-dried cultures during storage at 25°C was analyzed. These tests resulted in the selection of 2 *Propionibacterium freudenreichii* strains: *P. freudenreichii* ssp. freudenreichii CS36 and *P. freudenreichii* ssp. shermanii CS39. No loss of viable cell count was observed in any of the *P. freudenreichii* strains during a 3-h treatment at pH 4 or 3. Bile salt at 0.5% concentration had no apparent effect on the cell count of the strains. There was no atypical antibiotic resistance by the 2 strains. The highest concentration of propionic acid was obtained with the limited growth medium. Cell count was stable at 25°C for a one year storage period when strains were properly packaged as a freeze-dried powder. In conclusion, 2 strains of propionibacteria, CS36 and CS39, meet some of the basic property requirements for the use as probiotics or direct fed microbial products.

Key words: propionibacteria, probiotics, colon cancer

T93 Can high quality raw milk have enough microbial load to show a reduction of organisms in a pasteurization adjunct? J. A. Zonneveld*, A. M. Lammert, and R. Jimenez-Flores, *California Polytechnic University, San Luis Obispo.*

UV light treatment may be used in adjunct to pasteurization to further decrease microbial load in milk. The purpose of this study was to determine if fresh raw milk could be used to evaluate the reduction in microbial load of milk treated by pasteurization and UV light and to determine if the microbial reduction was significant. Sixteen hundred gallons of raw Holstein and Jersey milk from the Cal Poly Dairy were standardized to 3.5% fat and stored in a 4.4°C raw milk bulk tank. Control samples were obtained from the raw milk tank and stored without air or agitation. Every 24 h for 4 d milk control samples and raw milk bulk tank samples were analyzed for coliform and aerobic plate counts. The raw bulk tank milk was processed using UV light treatment in addition to pasteurization using traditional pasteurization controls to determine boundaries for future testing. Samples were taken after each variable to determine microbial kill efficiency. After 4 d in the raw milk bulk tank, the aerobic plate counts and coliform counts were >500,000 cfu/mL and 2175 coliforms/mL, respectively, and much higher than the 39,000 cfu/mL and 195 coliforms/mL, respectively, from the initial batch tank samples. Microbial disinfection worked well with all processing methods evaluated. Every variable of treated milk had 0 coliforms/mL and aerobic plate counts below 50 cfu/mL, when combined with pasteurization. Even the minimal UV treatment lowered both aerobic plate counts and coliforms greatly prior to pasteurization; however, the maximum level UV treatment came much closer to traditional pasteurization in effectiveness. When milk was processed with UV light first followed by traditional pasteurization, aerobic plate counts decreased greater than 2 log and coliforms were essentially eliminated from milk leaving only a few cfu/mL if any. This work indicates that 4 d old day raw milk treated with UV light and pasteurization may be used to successfully lower the microbial counts of aerobic bacteria and coliforms.

Key words: fluid milk, ultraviolet light

T94 Effects of prolactin on the expression of genes related to milk protein synthesis in bovine mammary epithelial cells. X. Y. Li, J. Q. Wang*, H. Y. Wei, X. M. Nan, D. P. Bu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The objective of this study was to reveal the role of prolactin (PRL) on the expression of important genes related to milk protein synthesis in bovine mammary epithelial cells. Mammary epithelial cells were isolated from a 3 year old Chinese Holstein dairy cow in mid-lactation (ca.100 d relative to parturition) and cultured in the medium containing a combination of hydrocortisone, insulin, transferrin, bovine epithelial growth factor and PRL (5μg/m L). No PRL was added in medium of control groups. Expressions of genes were measured by RT-qPCR. The content of caseins and lactose were detected by Casein ELISA Kit and HPLC, respectively. All experiments repeated 3 times. The results showed that after treatment with PLR casein synthesis was increased by 20% and lactose synthesis was increased by 25%. The expression of prolactin receptor (PRLR) was significantly increased ($P < 0.01$). *CSN3* and *LALBA* were the most highly expressed casein genes ($P < 0.01$),followed by *CSN1S1*, *CSN2* and *CSN2S2*, but these genes were not increased significantly ($P > 0.05$). The expression of genes related to *JAK2-STAT5* pathway were upregulated, and *JAK2* and *ELF5* expression increased significantly ($P < 0.01$). This study revealed that PRL was necessary for high levels of milk protein genes expression and milk protein synthesis.

Key words: prolactin, bovine mammary epithelial cells, genes expression

T95 The best ratio between lysine and methionine on milk protein synthesis in bovine mammary epithelial cells. X. Y. Li, J. Q. Wang*, H. Y. Wei, X. M. Nan, D. P. Bu, P. Sun, and L. Y. Zhou, *State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This study took the bovine mammary epithelial cells as a model to determine the best ratio between lysine and methionine, focusing on the effects of additional lysine and methionine on the regulation of genes related to milk proteins, genes related to amino acid transporters, and genes related to milk protein synthesis. The expression of important genes related to milk protein synthesis process included the genes of the *JAK2-STAT5* pathway and the *mTOR* signaling pathway. The experiment was conducted with a 5 × 3 factorial design: with lysine (1.0, 1.2, 1.4, 1.5, 1.6 m mol/L in DMEM/F12 medium) and methionine (0.4, 0.5, 0.6 m mol/L in DMEM/F12 medium). All experiments repeated 3 times. The expression of genes and caseins content were detected by RT-qPCR method and Casein ELISA Kit, respectively. Data were analyzed with the PROC GLM and PROC ANOVA. The results showed that when the concentration of lysine was 1.2 m mol/L and the concentration of methionine was 0.4 m mol/L, the content of casein in medium increased significantly ($P < 0.01$) and peaked at 2.95ppm. We measured the genes expression at this ratio (3:1). *CSN1S1* and *LALBA* were the most highly expressed genes encoding caseins and increased more than 2-fold ($P < 0.01$), followed by*CSN2*, *CSN3* and *CSN2S2*, and these genes expression were also upregulated ($P < 0.01$). The expression of genes related to *JAK2-STAT5* pathway were upregulated, and *JAK2*and *ELF5* expression increased significantly ($P < 0.01$).The expression of genes related to *mTOR* signaling pathway was increased, but *S6K* was not significantly ($P > 0.05$). *EIF4E-BP1* expression was significantly downregulated ($P < 0.01$). The expression of amino acid transporter *CAT-1* and *ASCT-2* had no change. These observations together with the fact that genes expression changed in the cells with the ratio between lysine and methionine revealed that the lysine, methionine and the ratio between lysine and methionine may directly regulate the expression of genes related to milk protein transcription and translation, leading to improved milk protein synthesis.

Key words: lysine, methionine, milk protein

T96 Development of safe glue sticks containing whey protein. G. Wang and M. Guo*, *The University of Vermont, Burlington.*

The major whey proteins are small globular proteins that may be undesirable for application in adhesives. However, their structures can be modified using chemical and physical means such as heating. Commercial glue sticks on the market may contain toxic chemical components, which can pose potential health hazards to users. In this study, a new safe glue stick product was developed using whey protein isolate (WPI), polyvinylpyrrolidone K90, propylene glycol, stearic sodium, and sucrose. WPI was first dissolved in distilled water, and then other ingredients were added. The mix was heated to 93–95°C with constant stirring for 30 min until it became homogenous, and then was filled into the push–up tubes. The new product was analyzed for bonding strength and hardness in comparison with a commercial product as a control. Bonding strength of the prototype was 247.63 ± 11.73 N, which was higher than that of the control (241.60 ± 9.49 N), but the difference was not significant ($P > 0.05$). The bonding strength remained stable after 3 mo of storage at 23°C or 40°C. Hardness of the prototype (23.31 ± 2.51 N) was comparable to that of the commercial glue (20.30 ± 1.09 N). The content of total solids of the prototype (52.17 ± 0.67%) was higher ($P < 0.05$) than the control (36.46 ± 0.29%). The new product was easy to be applied on paper, extended and retracted in push–up tubes. There was no growth of mold and yeast on the sticks after 3 mo of storage at 40°C. In conclusion, the new safe glue stick prototype containing whey proteins was comparable to the commercial control in bonding strength and hardness. Shelf life tests are being carried out to determine the storage stability of this new product.

Key words: glue stick, whey protein, safe

T97 Isolation and characterization of prosaposin from milk from four goat breeds. A. Robertson-Byers*, M. Worku, and S. Ibrahim, *North Carolina A&T State University, Greensboro.*

Increased scientific knowledge related to the nutritional, functional and biological activities and health benefits of goat milk is needed to further promote goat farming, goat milk and traditional or innovative neutrceuticals as a basis for socio-economic benefit. Prosaposin, a protein in goat milk is the precursor of the sphingolipid activator proteins. Saposins are small lysosomal proteins required for the hydrolysis of sphingolipids. Prosaposin is important in development and maintenance of the nervous system. Genetic variation may impact nutraceutical properties of milk by altering the biological function of bioactive peptides and antigens. The objectives of this study were to detect prosaposin and the sphingolipid activator proteins (saposins A, B, C, and D) in milk from different breeds of goats. Raw milk was collected at North Carolina A&T State University farm from Alpine, Spanish, Boer, Spanish × Boer goats and from a Holstein Friesian

cow. Whey fractions were separated by centrifugation. Extracts were analyzed by electrophoresis and immunoblotting with anti-prosaposin and anti-saposin HRP conjugated antibodies. Specific proteins were identified using a tetramethylbenzidine substrate. Multiple proteins were observed in whey fractions from all animals tested. Antibodies detected a 65 kDa prosaposin band and a 29 kDa saposin C band. Saposins and their precursor prosaposin are present in milk from different breeds of goats. The possible effect of genetic variation on concentration need further study. These studies will contribute to our knowledge of the therapeutic benefits of goat milk to aid producers in maintaining breeds with the potential to produce prosaposin.

Key words: prosaposin, neutraceutical, goats

T98 Poultry offal meal traceability in meat quail tissues using the technique of stable carbon-13 and nitrogen-15 Isotopes. C. Mori*[2], E. A. Garcia[1], C. Ducatti[1], J. C. Denadai[1], and K. Pelicia[1], *[1]São Paulo State University, Botucatu, São Paulo, Brazil, [2]São Paulo State University, Registro, São Paulo, Brazil.*

Studies on detection of animal byproducts in poultry meat are rare, and non-existent on quail meat. This study aimed at detecting increasing levels of poultry offal meal (POM) in quail meat, using carbon ($^{13}C/^{12}C$) and nitrogen ($^{15}N/^{14}N$) stable isotopes technique. Sixty 4 one-day-old male quails derived from commercial farm were fed experimental diets containing 0, 1.5, 3.0, 4.5, 6.0, 7.5, and 15% of POM. Diets were formulated to contain equal energy, protein, and amino acid levels. Four individuals per treatment were sacrificed at 42 d of age for breast muscle (pectoralis major), keel, and tibia, and subsequently prepared and submitted for isotopic analysis of C and N. Isotopic analyses of feed ingredients, feeds, and tissues were carried out at the Center of Stable Environmental Isotopes of the Biosciences Institute (CIE/IB), UNESP, Botucatu campus. Isotopic carbon ($^{13}C/^{12}C$) and nitrogen ($^{15}N/^{14}N$) ratios were determined in an isotopic ratio mass spectrometer (IRMS) type DELTA-S (Finnigan Mat) coupled to an Elementary Analyzer (EA 1108 CHN). The obtained isotopic results were submitted to multivariate analysis of variance (MANOVA) using GLM (General Linear Model) procedures of SAS statistical software. Data were generated by error matrices for each tissue, which were later graphically distributed in regions (ellipses) with 95% confidence of observing possible differences between experimental treatment means and control treatment means. The inclusion of animal byproducts in quail diets was detected by ^{13}C and ^{15}N analyses in the tissues of the birds, with the lowest detection level of 3% dietary inclusion of poultry offal meal. It was concluded that quail meat can be certified by the technique of stable isotopes.

Key words: quail, stable isotopes, traceability

T99 Use of stable isotopes of carbon-13 and nitrogen-15 in quail eggs. C. Mori*[2], C. Ducatti[1], C. C. Pizzolante[3], S. K. Kakimoto[3], and J. C. Denadai[1], *[1]São Paulo State University, Botucatu, São Paulo, Brazil, [2]São Paulo State University, Registro, São Paulo, Brazil, [3]São Paulo Agency of Agribusiness Tecnology, Brotas, São Paulo, Brazil.*

The objective was to trace the inclusion of bovine meat and bone meal (BMBM) in the diet of quails through the analysis of eggs and their fractions (yolk and albumen), using the stable isotope carbon ($^{13}C/^{12}C$) and nitrogen ($^{15}N/^{14}N$) technique. It was used 120 quails were used in 5 treatments and 4 replications of 5 birds each. After 42 d, 20 eggs were randomly selected per treatment over 3 consecutive days. From these collected eggs, 10 were used for yolk and albumen sampling and the other 10 for the total egg sampling. Treatments were: a control diet based on corn and soybean meal (T0) and other 5 diets containing inclusions of BMBM, namely: 1, 2, 3, 4 and 5%. Isotopic analyses of feed ingredients, feeds, and tissues were carried out at the Center of Stable Environmental Isotopes of the Biosciences Institute (CIE/IB), UNESP, Botucatu campus. Isotopic carbon ($^{13}C/^{12}C$) and nitrogen ($^{15}N/^{14}N$) ratios were determined in a isotopic ratio mass spectrometer (IRMS) type DELTA S (Finnigan Mat) coupled to an Elementary Analyzer (EA 1108 CHN). The obtained isotopic results were submitted to multivariate ANOVA (MANOVA) using GLM (General Linear Model) procedures of statistical software. Data were generated by error matrices for each tissue, which were later graphically distributed in regions (ellipses) with 95% confidence of observing possible differences between experimental treatment means and control treatment means. In the final product (eggs and their fractions) it was possible to detect the inclusion of 1% of BMBM in the diet. Thus, the technique of isotope carbon-13 and nitrogen-15 is able to track the inclusion of 1% of BMBM in diets of laying quails, through the analysis of eggs and their fractions, ensure safe information about the product be consumed, but also allows the certification of origin government agencies.

Key words: egg quail, stable isotopes, traceability

T100 Adsorption capacity and efficacy assessment of bamboo charcoal an alternative adsorbent for aflatoxin B1 in a ruminal batch culture. H. J. Yang* and Y. H. Jiang, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Fifty milligrams of bamboo charcoal (BC), activated charcoal (AC) and smectite power (SP) were weighed into tubes containing 4.5 mL McDougall′s buffer (pH 6.8) in the presence of 4 mg/L aflatoxin B1 (AFB1) and incubated at 39°C. The 5 replicate tubes were incubated for 1, 3, 6, 12, 24, 48 or 72 h, then removed to assess the AFB1 adsorption capacity (Q) and adsorption rate (Y). The mean value of Q did not differ between AC and BC (0.383 vs 0.381 mg/g), which Q means were greater than that of SP ($P < 0.05$). No differences of Y were observed between AC and BC (0.958 vs. 0.955), and a low Y (0.931) occurred in SP ($P < 0.01$). In a separate batch culture (75 mL, rumen fluid: McDougall′s buffer = 1: 2), a 2-factor randomized block design was applied in vitro with 2 binder blocks (SP and BC) at dose rates of 0, 0.1, 1, 10 g/L in the cultures to investigate effects of the binders on fermentation of a grain-rich substrate (*Leymus chinensis* hay: maize meal = 1: 4) in the presence of 1.0 mg/L AFB1. After a 72 h incubation, cumulative gas production was fitted to an exponential model: $Y = A \times [1\text{-}e^{-c \times (\text{time-lag})}]$, and the asymptotic gas production A was greater in BC than in SP ($P < 0.01$), and it increased linearly ($P < 0.01$) and quadratically ($P < 0.01$) against the binder dose rates. Both lag time (h) and the average gas production rate (AGPR, mL/h) did not differ between SP and BC. The residual AFB1 concentration in both binders decreased against the dose rates before a methanol washing procedure ($P < 0.05$), and it was greater in BC than SP after the washing ($P < 0.01$). No differences for pH and ammonia N were observed between the binders or their dose rates. Total VFA was lower in SP than BC ($P < 0.01$). The addition of SP numerically decreased total VFA production, but the addition of BC comparatively increased it. The addition of the binders quadratically increased molar propionate proportion ($P < 0.05$), and molar acetate proportion was greater in BC than SP ($P < 0.01$). These results suggested that the effectiveness of BC was comparable to SP, and that it could be an effective AFB1 sequestering agent.

Key words: bamboo charcoal, aflatoxin B1, rumen fermentation

T101 Occurrence of mycotoxins in feedstuffs and feed samples from 2009-2010. U. Hofstetter*, K. Naehrer, and I. Rodrigues, *Biomin Holding GmbH, Herzogenburg, Austria.*

A survey about the most important mycotoxins in feedstuffs from different countries/regions all over the world, specifically Asian-Pacific, Europe, Middle-East, Africa and Americas was initiated with the objective to identify major mycotoxin occurrence. From January 2009

until December 2010, a total of 3961 samples were analyzed for the presence of aflatoxins (Afla), zearalenone (ZON), deoxynivalenol (DON), fumonisins (FUM) and ochratoxin A (OTA). Samples tested ranged from cereals, to processing by-products (e.g., DDGS) and other fodder like silage or finished feed. Analyses were performed by HPLC (high performance liquid chromatography), ELISA (enzyme-linked immunosorbent assay) or TLC (thin-layer chromatography) according to the standard procedures. For the purpose of data analysis, non-detect levels are based on the quantification limits (LOQ) of the test method for each toxin. The majority of the analyses were performed at Romerlabs (Austria, Singapore, USA) and SAMITEC (Brazil). From all survey samples 33%, 36%, 51%, 55% and 28% tested positive for Afla, ZON, DON, FUM and OTA, respectively. The most frequently detected mycotoxins were the *Fusarium* sp. toxins FUM and DON with an average contamination of all tested samples of 1280 µg/kg (median of all samples tested positive 1034 µg/kg, maximum 53700 µg/kg) and 434 µg/kg (median of all samples tested positive 460 µg/kg, maximum 29300 µg/kg), respectively. In the case of ZON a mean of 83 µg/kg (maximum 16712 µg/kg) was verified. The average contamination of Afla and OTA was 22 µg/kg and 4 µg/kg, respectively. Data were grouped according to occurrence of mycotoxins in different geographical regions, on the occurrence in diverse raw materials and on the co-occurrence of different mycotoxins. From all samples sourced worldwide, only 24% were below the respective detection limits of the analyzed mycotoxins. 76% of all analyzed samples were contaminated with one mycotoxin and 41% were contaminated with more than one mycotoxin.

Key words: mycotoxins, survey

T102 Horizontal transfer of Stx2 gene from *E. coli* O157:H7 to non-pathogenic *E. coli* occurred under feedlot conditions. W. F. Yue, M. Du, W. J. Means, and M. J. Zhu*, *Department of Animal Science, University of Wyoming, Laramie.*

Shiga toxins (Stx) are the key virulence factors of *Escherichia coli* O157:H7 which is responsible for hemorrhagic colitis and serious renal failure. It is commonly believed that *E. coli* O157:H7 picked up stx genes through bacteriophages. *E. coli* O157:H7 genome contains a pool of defective lambdoid prophages including prophages carrying stx genes. We hypothesized that strong UV radiation in combination with high temperature associated with global warming accelerates stx prophages activation, which facilitates the dissemination of stx genes into non-pathogenic *E. coli* in feedlots. Plaque analysis showed that UV radiation increased prophage activation in *E. coli* O157:H7 (EDL933), which was further enhanced by high temperature. Activated prophages were capable of converting non-pathogenic *E. coli* (MG1655) to Shiga toxigenic *E. coli* in culture media. To further confirm horizontal transfer of stxs, EDL933 and kanamycin resistant (Kan^R) MG1655 were mixed into fresh cattle feces and incubated at 37°C for 12 h. Kan^R-MG1655 was recovered by kanamycin antibiotic selection, which were further subjected to in situ hybridization to examine the possible presence of stx2. In situ hybridization results indicated that stx2 were horizontal transferred from EDL933 to MG1655. In summary, data implicated that high temperature combined with UV radiation accelerates the spread of stx genes through enhancing prophage activation. Cattle feedlot sludge is frequently exposed to UV radiation, in combination with elevated temperature associated with global warming, which may provide an environment promoting generation of new Shiga toxigenic *E. coli*. (USDA AFRI, 2010–65201–20599, Agricultural Experiment Station at University of Wyoming, NIH-INBRE P20RR016474).

Key words: *E. coli* O157:H7, prophage, Stx2

T103 Antagonistic intestinal microflora produces antimicrobial substance inhibitory to *Pseudomonas* species and other spoilage organisms. B. Hatew*[1,2], T. Delessa[1,3], V. Zakin[1], and N. Gollop[1], *[1]Agricultural Research Organization of Israel, Bet-Degan, Israel, [2]Wageningen University, Wageningen, the Netherlands, [3]Swiss Federal Institute of Technology, Zurich, Switzerland.*

Today an increase in consumers demand for fresh, natural and chemical preservative-free foods have enhanced attention to antimicrobial substances from Generally Recognized as Safe bacteria. Chicken intestines harbor a vast number of bacterial strains that play an important role in the health of chickens. Many of these bacterial strains produce antimicrobial substances which are active against aerobic spoilage bacteria of refrigerated poultry meat, especially *Pseudomonas* spp. In the present study, an antimicrobial substance produced by lactic acid bacteria isolated from the gastrointestinal tract of healthy chickens was isolated, characterized and purified. Based on 16S rRNA sequencing the bacteria strain was identified as *Lactobacillus plantarum*, and designated as *L. plantarum*-vN. The antimicrobial substance exhibited a broad-spectrum of activity against many important pathogenic and spoilage microorganisms including *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Micrococcus luteus*, *Salmonella typhimurium* and *Erwinia amylovova*. The antimicrobial substance was found to be thermostable, insensitive to pH values ranging from 2.0 to 8.0, resistant to various organic solvents and to enzymatic inactivation. The inhibition kinetics displayed a bactericidal mode of action. This study revealed a new type of antimicrobial substance with low molecular mass of less than 1 kDa and having features not previously reported for lactic acid bacteria isolated from the chicken intestines. The novelty of the substance and its potential to inhibit gram-negative bacteria of spoilage and health significance, not normally inhibited by the majority of bacteriocins of lactic acid bacteria, may be of potential interest to food safety and preservation.

Key words: *Pseudomonas*, antimicrobial substance, *Lactobacillus plantarum*

T104 Microencapsulated feed additives to reduce *Salmonella* shedding. E. Grilli*[1], R. Bari[1], A. Piva[1], B. Tugnoli[1], and T. R. Callaway[2], *[1]University of Bologna, Ozzano Emilia, BO, Italy, [2]Food and Feed Safety Research Unit, ARS/USDA, College Station, TX.*

The reduction of *Salmonella* prevalence in food animals in Europe is regulated by EU Reg. 2160/2003, EU Reg. 1003/2005 and others. The purpose of these regulations is to detect and control *Salmonella* strains that represent a threat to public health and to ensure that preventive measures at each stage of production are taken. In this context, tailored nutritional strategies are now a priority, along with improved management and biosecurity. Aim of the study was to investigate the efficacy of an experimental microencapsulated blend of sorbic acid and naturally identical compounds (SAB) against *S. Typhimurium* in pigs. The active principles of SAB were dissolved in TSB and serial dilutions were prepared to reach final concentration of: 0, 200, 400, 600, 800, 1000, 2000, 3000, 4000, and 5000 mg/L. Each dilution tube was inoculated with *S. Typhimurium* at 10^6 cfu/ml initial concentration. Compared with controls, after 24 h of incubation, SAB at 2000 and 3000 mg/L reduced ($P < 0.05$) *Salmonella* growth by 4–5 Log_{10}, respectively, and SAB at 4000 and 5000 mg/L completely inhibited ($P < 0.05$) its growth. Forty (n = 40) pigs housed in 20 pens were assigned to 4 dietary treatments: control group (challenged, not treated), and 3 treatment groups treated with 300, 3000, 30000 g/ton of SAB, respectively). After 1 week of adaptation pigs were challenged with 10^7 cfu of *S. Typhimurium* mixed to the feed and a second challenge was

repeated via gavage after 7d. After 2d, and every 4d thereafter, fecal samples were collected from each pig and analyzed for *S. Typhimurium* qualitatively and quantitatively. Results demonstrated that 3000 and 30,000 g/ton SAB reduced ($P < 0.05$) *S. Typhimurium* prevalence by 40% and 50% after 2 wk, and at the end of the third week 100% of the animals in the same groups resulted negative for *S. Typhimurium*. This study demonstrated that intestinal delivery of microencapsulated sorbic acid and naturally identical compounds can result in a reduction of *S. Typhimurium* prevalence and fecal shedding in pigs. In-field trials are currently under exploitation to confirm our preliminary small-scale observations.

Key words: *Salmonella*, pig, microencapsulation

T105 Improving voluntary oral interaction of dairy cattle with manila ropes to facilitate *E. coli* O157:H7 monitoring on dairies.
A. F. Pedroso*[2,1], O. C. M. Queiroz[1], and A. T. Adesogan[1], *[1]Department of Animal Sciences, Institute of Food and Agricultural Sciences, University of Florida, Gainesville, [2]Brazilian Agricultural Research Corporation, Embrapa Cattle-Southeast, 13560-970, São Carlos, SP, Brazil.*

This trial aimed to improve the efficacy of the manila rope method for *E. coli* O157:H7 detection on dairy herds. In an initial test, untreated and molasses-treated (3 min immersion in a autoclaved molasses solution - 8.5% in water) manila ropes (0.64 × 80 cm) were tied at alternate positions (30 cm apart) on the railing over feed bunks in 2 pens containing 22, 13.5 mo dairy heifers each. Seven ropes per treatment were placed immediately before feeding (0930 h) and observed from 0940 to 1130 h. Treatment with molasses resulted in a 16% increase in the total number of times the ropes were visited (chewed, licked or touched with the muzzle) in each pen, and in a 19% increase in an "efficacy index" estimated by multiplying the number of visits by the percentage of heifers visiting the ropes (85 and 83%, respectively, for ropes with and without molasses). Subsequently, the effect of rope to animal ratio was evaluated using 89, 11 to 22 mo heifers stratified by weight into 4 pens (19 to 26 animals/pen) and randomly assigned to 4 treatments. Ratios of 1, 3, 6 and 9 ropes/25 animals were tested in each pen. Molasses-treated manila ropes were placed in the pens as mentioned before and monitored from 0800 to 1100 h every 4 d. Increasing the rope to animal ratio linearly increased the percentage of heifers visiting the ropes, increased quadratically the number of visits per pen, and increased exponentially the efficacy index (Table 1). Molasses treatment and increasing rope to animal ratio in pens potentially makes the method more effective.

Table 1. Effect of rope to animal ratio on measures of oral interaction of heifers with manila ropes

No. ropes/ 25 animals	% heifers visiting ropes	No. visits/ pen	Efficacy
1	32.6 ± 6.98^{b}	11.0 ± 9.73^{c}	4.8 ± 8.68^{c}
3	45.6 ± 6.98^{b}	23.5 ± 9.73^{c}	12.0 ± 8.68^{bc}
6	71.8 ± 6.98^{a}	40.8 ± 9.73^{b}	32.3 ± 8.68^{b}
9	83.7 ± 7.82^{a}	72.6 ± 10.79^{a}	62.5 ± 9.74^{a}
Equation	$y = 17.9x - 3.9$	$y = 4.75x^2 - 12.95x + 18.45$	$y = 0.9251e^{0.8582x}$
R^2	0.978	0.997	0.995

T106 Effects of predipping practices on milk iodine concentrations.
S. I. Borucki-Castro[1], R. Berthiaume[1], A. Robichaud[2], and P. Lacasse*[1], *[1]AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada, [2]Food Directorate, Health Canada, Longueuil, QC, Canada.*

A study was conducted to determine the effects of udder preparation before milking on milk iodine concentrations. The study compared the use of pre-dip and post-dip solutions; and determined the effect of an incomplete removal of pre-dip solution on milk iodine. Thirty-two lactating cows were assigned to 4 treatments: no pre-dip (udder wash without iodine; control); pre-dip with a pre-dip solution containing 0.5% iodine (Theratec, GEA Farm Technologies) + complete cleaning with paper towel (complete); pre-dip with a post-dip solution 1% iodine (Teat-Kote, GEA Farm Technologies) + complete cleaning with paper towel (post); and pre-dip with a pre-dip solution 0.5% iodine (Theratec) + incomplete cleaning with paper towel (incomplete). Incomplete cleaning was achieved by cleaning only 3 of the 4 teats. All cows received a diet without goitrogenic feeds, and an iodine concentration of 0.50 mg /kg of feed offered. During the 14d pre-experimental and the 19d experimental periods, non-iodized sanitizers were used for post-milking dipping or flushing of the milking units. The first 2 weeks were used for adaptation to treatments and measurements were done on the final week to ensure a plateau in the milk iodine response. During the pre-experimental period, milk iodine concentrations were similar for all groups and averaged 160.4, 167.3, 157.0 and, 153.0 ± 17.3 µg/kg for control, complete, post and, incomplete; respectively. During the last week of treatment, milk iodine averaged 164, 189, 218 and, 252 ± 9.8 µg/kg for control, complete, post, and incomplete, respectively. Pre-planned orthogonal contrasts indicated that pre-dipping with a 0.5% iodine pre-dip solution (complete) tended to increase milk iodine content above that of control ($P = 0.08$) and, that iodine content of post ($P < 0.05$) and incomplete ($P < 0.001$) were higher than that of the complete treatment. These results indicate that pre-dipping is an acceptable practice but must be performed with the appropriate product and completely wiped out before milking.

Key words: iodophore, milking, milk safety

T107 Effects of natural beta-acids extracted from hops on *Salmonella* and *Campylobacter* pure culture.
N.A. Krueger*[1], R. C. Anderson[1], J. A. Byrd[1], M. D. Flythe[1], and D. J. Nisbet[1], *[1]Food and Feed Safety Research Unit, United States Department of Agriculture, Agriculture Research Service, College Station, TX, [2]Forage Animal Production Research Unit, United States Department of Agriculture, Agriculture Research Service, Lexington, KY.*

Salmonella and *Campylobacter* are important foodborne pathogens that may colonize the gut of food-producing animals. The objective of this experiment was to evaluate the effects of a hops β-acid solution on *S.typhimurium* and *C. jejuni* pure cultures. Nine-milliliter volumes with approximately 10^{-4} colony forming units (cfu) of overnight grown *S. typhimurium* (in tryptic soy broth; TSB) or *C. jejuni* (in Mueller Hinton; MH) added in triplicate to screw top tubes previously loaded with 1 mL MH, TSB, or hops β-acid extract solution to achieve 0, 62.5 (H1) or 125 ppm (H2) hops and were incubated anaerobically at 40°C. After 0, 3 and 6 h incubation, 1 mL sample from each culture was serially diluted and plated to XLT4 or Campy-Cefex agar for quantification of *S. typhimurium* and *C. jejuni*. Log_{10} transformations of *S. typhimurium* colonies enumerated after 24 h incubation and *C. jejuni* colonies enumerated after 48 h microaerobic (85% N_2, 10% CO_2, 5% O_2) incubation were subjected to Mixed Model repeated

measures ANOVA to assess affects of treatment over time. Tubes containing *S. typhimurium* initially contained 3.35 ± 0.202 $\log_{10}$ cfu/mL. Concentrations of *S. typhimurium* in control and H1 cultures increased ($P < 0.05$) by 6 h incubation (5.80 ± 0.175 and 4.97 ± 0.227, respectively); however, S. Typhimurium concentrations in H2 cultures did not differ over time ($P > 0.05$). *Campylobacter jejuni* cultures initially contained 4.41 ± 0.135 log10 cfu/mL. Concentrations of *C. jejuni* in control cultures did not differ ($P > 0.05$) over time whereas *C. jejuni* concentrations in H1 and H2 treated cultures were reduced to below our limit of detection ($\log_{10}$ 1.5) by 3 h incubation and did not recover by 6 h incubation. Results of this study demonstrate that hops β-acids can effectively reduce *C. jejuni* but not *S. typhimurium* concentrations in vitro.

Key words: *Campylobacter*, *Salmonella*, natural beta-acids

T108 *Staphylococcus aureus* virulence and metabolism are dramatically affected by *Lactococcus lactis* in cheese matrix. M. Cretenet[1,2], S. Nouaille[3,4], J. Thouin[1,2], L. Rault[1,2], L. Stenz[5], P. François[5], J. A. Hennekinne[6], M. B. Maillard[1,2], J. Fauquant[1,2], P. Loubière[3,4], S. Lortal*[1,2], Y. Le Loir[1,2], and S. Even[1,2], *[1]INRA, STLO, Rennes, France, [2]Agrocampus Ouest, STLO, Rennes, France, [3]Université de Toulouse; INSA, Toulouse, France, [4]INRA, UMR792, Toulouse, France, [5]University of Geneva Hospitals, Geneva, Switzerland, [6]ANSES, LERQAP, Maisons-Alfort, France.*

In complex environments such as cheeses, the lack of relevant information on the physiology and virulence expression of pathogenic bacteria and the impact of endogenous microbiota has hindered progress in risk assessment and control. Here, we investigated the behavior of *Staphylococcus aureus*, a major foodborne pathogen, in a cheese matrix, either alone or in the presence of *Lactococcus lactis*, as a dominant species of cheese ecosystems. The dynamics of *S. aureus* was explored in situ by coupling a microbiological and, for the first time, a transcriptomic approach. *L. lactis* affected the carbohydrate and nitrogen metabolisms and the stress response of *S. aureus* by acidifying, proteolysing and decreasing the redox potential of the cheese matrix. Enterotoxin expression was positively or negatively modulated by both *L. lactis* and the cheese matrix itself, depending on the enterotoxin type. Among the main enterotoxins involved in staphylococcal food poisoning, sea expression was slightly favored in the presence of *L. lactis*, whereas a strong repression of sec4 was observed in cheese matrix, even in the absence of *L. lactis*, and correlated with a reduced saeRS expression. Remarkably, the agr system was downregulated by the presence of *L. lactis*, in part because of the decrease in pH. This study highlights the intimate link between environment, metabolism and virulence, as illustrated by the influence of the cheese matrix context, including the presence of *L. lactis*, on 2 major virulence regulators, the agr system and saeRS.

Key words: *Staphylococcus aureus*, cheese, bacterial interactions

T109 Characterization of risk of food pathogens in Minas Frescal cheese. R. Freitas[1], A. F. Carvalho*[1], L. A. Nero[1], G. G. Netto[1], and M. A. V. Brito[2], *[1]Federal University of Viçosa, Viçosa, MG, Brazil, [2]EMBRAPA CNPGL, Juiz de Fora, MG, Brazil.*

This work aimed to carry out a characterization of the risk found in the food pathogens *Staphylococcus aureus*, *Listeria monocytogenes* and *Salmonella* sp., in Minas Frescal cheese. The prevalence and level of contamination by microbial agents was studied as well as the presence of microorganisms indicators of hygienic conditions (total coliforms and *Escherichia coli*), in relation to cheese making methods (lactic acidification, acidification by lactic acid and curd) and inspection stamp (federal, state or municipal) to which they were submitted. The magnitude of ingesting this type of cheese by Viçosa consumers for the qualitative estimate of risk of contracting diseases after consuming this product was investigated. Of 99 cheese samples analyzed, 20 were contaminated with *S. aureus*, with microorganism enumeration in 65% being higher than 1.0×10^3 cfu/g. The pathogen *L. monocytogenes* was isolated from one cheese sample, while *Salmonella* sp. was not identified in any of the samples analyzed. High contamination of the product by *E. coli* was also verified in 30.3% of the cheese samples analyzed, in values above the limit allowed by the current legislation, rendering these samples improper for consumption. A high level of cheese ingestion by the population was verified for consumption frequency and amount consumed. Of the total of 400 persons interviewed, 15.5% were in the age range between 11 and 20 years old, 77.5% between 21 and 60 years old and 7% above 60. Among the individuals interviewed, 84 informed that they consumed Minas Frescal cheese, 177 stated they consumed between 2 and 7 d per week, with the 11 to 20 year old, the 21 to 60 and the over 60 groups corresponding, respectively, to 11.9%, 77.4% and 10.7% of high cheese intake. Based on the use of the product by the population surveyed and the presence of S. aureus, Minas Frescal cheese consumption has the potential to contribute to the occurrence of intoxication cases in the population exposed to it, mainly when risk groups are considered. However, for *L. monocytogenes* and *Salmonella* sp. the risk of infection from consuming the product is low.

Key words: Minas Frescal cheese, risk characterization, quality

T110 Inhibition of *Listeria monocytogenes* growth in cheddar cheese by nanofiltration retentate of tryptic extract of whey proteins. V. Demers-Mathieu[1,2], G. Robitaille[1], D. St-Gelais[1], S. Gauthier[2], and M. Britten*[1], *[1]Food Research and Development Centre, Agriculture and Agri-Food Canada, St Hyacinthe, QC, Canada, [2]Centre de recherche STELA & INAF, Département de Sciences des Aliments et de Nutrition, Québec, QC, Canada.*

The objective of the study was to investigate the efficiency of a nanofiltration retentate (RT_{NF}) of trypsin-hydrolyzed whey proteins to control the food-borne pathogen *Listeria monocytogenes* and the non-pathogen *Listeria innocua* in Cheddar cheese models. Reconstituted Cheddar cheeses (37% humidity) containing 0, 10 or 20 mg/g of RT_{NF} and 3.5 or 1.75% salt/Humidity (S/H) were prepared from irradiated cheese powder, and were inoculated with 10^3-10^4 cfu/g of *Listeria* and 10^7 cfu/g of commercial lactic acid starter strains (*Lactococcus lactis* ssp. *cremoris*, *L. lactis* ssp. *lactis* and *Leuconostoc cremoris*). Cheeses were stored 7 d at 30°C or 28 d at 4°C, and bacterial counts during the storage were carried out for *Listeria* species and for lactobacilli. The presence of RT_{NF} in model cheese significantly decreased the survival of *Listeria* strains in a dose-dependent manner. The antimicrobial activity of RT_{NF} in Cheddar cheese was greater against *L. monocytogenes* than against *L. innocua* and was higher at 30°C than at 4°C. Moreover, the combination of 20 mg/g RT_{NF} and 1.75% S/H in cheeses incubated at either 30°C for 7 d or at 4°C for 28 d was the most efficient condition. For instance, *L. monocytogenes* bacterial counts significantly ($P < 0.001$) decreased by 1.1 and 1.5 log, respectively, when compared with model cheeses containing 1.75% or 3.5% S/H without RT_{NF}. Lactobacilli bacterial counts decreased during storage according to salt content, but was not affected by RT_{NF} ($P > 0.05$). It is suggested that the presence of higher lactobacilli content in cheeses containing 1.75% S/H contributes to the decrease of *Listeria* bacterial

content in synergy with RT_{NF}. In conclusion, antimicrobial peptides from trypsin-hydrolyzed whey proteins could be useful as natural preservative to control *L. monocytogenes* growth in reduced-salt cheeses.

Key words: *L. monocytogenes*, antibacterial, cheese

T111 Investigating contamination of bulk tank milk with *Listeria monocytogenes* on a dairy farm. J. C. F. Pantoja*, A. C. O. Rodrigues, C. Hulland, D. J. Reinemann, and P. L. Ruegg, *University of Wisconsin, Madison.*

The objective of this study was to identify the source of bulk tank milk (BTM) contamination with *Listeria monocytogenes* on a dairy farm with a history of isolation of this pathogen from unpasteurized BTM. The herd was comprised of 711 cows that produced an average of 36 kg of milk per day, with BTM SCC of 250,000 cells/mL. Cows were milked in a parallel parlor and milk was stored in 2 bulk tanks after passing through a plate cooler. Free stalls were bedded with sand or manure solids. The farm was visited between September and November, 2010, in 2 study phases. Each phase consisted of 3 weekly visits performed to assess the presence of *L. monocytogenes* in the following samples: environmental (feces, bedding, silage, and water from troughs, hoses, and wells); milking machine (milk filters and swabs from the inner surface of liners, milk hoses, milk meters, milk line, gaskets, and receiver jar); in-line milk of each pen milked; mammary glands; and BTM. Daily BTM and milk filters were also collected. Of all samples collected during the 2 study phases (n = 299), *L. monocytogenes* was isolated from 66% of milk filters (19 of 29), 16% of BTM (7 of 44), 6% of water samples (2 of 33) and 1 of 18 in-line milk samples. No other samples were positive for *L. monocytogenes*. A subset of 27 pairs of BTM and milk filter samples collected on the same day was used to assess the agreement between the isolation of *L. monocytogenes* from these 2 sources. Of 18 *L. monocytogenes*-positive milk filter samples, only 4 (22%) were also BTM positive. Based on these results, the authors recommended that the milk filter be changed at mid-milking, after which daily milk filter and BTM samples were collected for 3 weeks as a follow-up assessment of the prevalence of *L. monocytogenes* in the BTM. No follow-up milk filter (n = 23) or BTM (n = 15) samples were positive. Although a specific on-farm source of BTM contamination could not be identified based on these preliminary data, results suggest that the milk filter is a point of concentration of this zoonotic pathogen.

Key words: listeria, milk quality, zoonosis

T112 Prediction the growth of *Staphylococcus aureus* in raw milk using modified Gompertz and Logistic models. B. Li[2], C. Man[1], M. Guo*[3], Y. Shan[1], F. Zhao[2], S. Yang[2], Y. Jiang[2], Y. Lang[2], and Y. Jiang[1,2], [1]*National Dairy Engineering and Technology Research Center, Northeast Agricultural University, Harbin, Heilongjiang, China,* [2]*Department of Food Science, Northeast Agricultural University, Harbin, Heilongjiang, China,* [3]*Department of Nutrition and Food Sciences, The University of Vermont, Burlington.*

Staphylococcus aureus in dairy foods could cause foodborne illness. Raw milk may be to be kept incorrect temperatures in developing countries where cold storage facilities are lacking. The objective of this study was to predict the growth of *S. aureus* in raw milk produced in different seasons. Nine raw milk samples were collected in winter, spring, and summer, confirmed *S. aureus* free using 3M Petrifilm Staph Express Count Plates and inoculated with *S. aureus* (ATCC 13565) at a final concentration of 10^2 cfu/mL. The inoculated milk samples were incubated at 15°C, 25°C and 37°C with different incubation time and sampling interval according to the temperature. The enumerations of *S. aureus* were carried out in triplicates using the same method mentioned above. Growth data of *S. aureus* were analyzed with both a modified Gompertz model (mG model) and a modified Logistic model (mL model). The performance of each model were evaluated by calculating the root mean square error (RMSE), the Accuracy factor (A_f) and the Bias factor (B_f) between the observed and predicted values. Results showed that the A_f values of the mG model (1.0492_{Sum} and 1.0432_{Win}) were closer to 1.0 than those of the mL model (1.0851_{Sum} and 1.0663_{Win}) during summer and winter. As for the B_f values, the mG model also superior to the mL model (0.9764_{Sum} and 1.0056_{Win} vs. 1.0293_{Sum} and 1.0198_{Win}). The RMSE values of the mG model (0.1032_{Sum} and 0.0936_{Win}) were lower than those of the mL model (0.1857_{Sum} and 0.1498_{Win}). The results indicated a more accurate fitting between measured and predicted values by the mG model in both seasons. The A_f values and RMSE values of the mG model were better than those of the mL model (1.0562 and 0.1057 vs. 1.0945 and 0.1926) for samples collected in spring, although the B_f values of the mL model were closer to 1.0 than those of the mG model (0.9905 vs. 0.9890). The results showed that the mG model seems to be accurate for predicting the growth of *S. aureus* in raw milk of different seasons. This work was supported by the National Key Technology R&D Program of China (2009BADB9B06).

Key words: *Staphylococcus aureus*, prediction, raw milk

T113 Rapid detection of viable *Listeria monocytogenes* in milk by loop-mediated isothermal amplification coupled with propidium monoazide treatment. Y. Jiang[2], C. Man[1], M. Guo*[3], Y. Lu[1], F. Zhao[2], Y. Liu[2], B. Li[2], S. Yang[2], and Y. Jiang[1,2], [1]*National Dairy Engineering and Technology Research Center, Northeast Agricultural University, Harbin, Heilongjiang, China,* [2]*Department of Food Science, Northeast Agricultural University, Harbin, Heilongjiang, China,* [3]*Department of Nutrition and Food Sciences, The University of Vermont, Burlington.*

Listeria monocytogenes is a common foodborne pathogen in dairy foods. DNA-based loop-mediated isothermal amplification (LAMP) method cannot distinguish viable cells from dead ones, resulting in overestimate of *L. monocytogenes* contamination. Propidium monoazide (PMA) inhibits amplification of LAMP due to its ability of tightly binding to the DNA of dead cells. The objective of this study was to develop a procedure using LAMP method coupled with PMA treatment to detect viable *L. monocytogenes* in milk. *L. monocytogenes* (CMCC 54006) was cultured in tryptone soy broth containing 0.6% yeast extract at 37°C to logarithmic growth phase. Part of the cultured suspension was heated at 95°C for 3 min to obtain dead cells. The dead cell suspension was mixed with the viable cell suspension at a ratio of 9:1. The mix was inoculated in UHT sterilized milk with final concentrations of viable cells up to 10^7 cfu/mL. The inoculated milk was treated with PMA (50 μmoL, final concentration) in the dark for 5 min, subsequently exposed to a 650W halogen lamp for 3 min. Then DNA extracted from the PMA treated samples as templates for LAMP. A set of 4 primers, including forward-inner, backward-inner, forward outer, and backward outer, were designed for LAMP to target 6 distinct regions on the hlyA gene of *L. monocytogenes*. The LAMP analysis was carried out in a reaction mixture containing the 4 primers and DNA templates at 63°C for 1 h and heated at 80°C for 2 min to terminate the reaction. The amplified samples were then analyzed by a 1.5% agarose gel electrophoresis and the gel was stained with ethidium bromide. The detection limit for viable *L. monocytogenes* in steril-

ized milk by the PMA-LAMP method was 6.37×10^1 cfu/ml in only 90 min. Results showed that the PMA-LAMP method is a rapid and sensitive technique to detect viable *L. monocytogenes* in milk. This work was supported by the National Key Technology R&D Program of China (2009BADB9B06).

T114 Simultaneous analysis of anions Cl^-, NO_2^-, SO_4^{2-}, NO_3^- and PO_4^{3-} in milk with ion chromatography. D. Liu and Z. Chen*, *Analysis and Testing Center, Shandong University of Technology, Zibo, Shandong Province, China.*

The amount of anions is an important index of milk quality control. Some methods have been reported to determine the concentration of milk anions. However, some methods are time-consuming and susceptible to interference, and only one element can be determined at a time. Ion chromatography (IC) has been developed for the simultaneous analysis of cations and anions in the water, food, atmosphere, etc. Chromatography can yield the precise and reproducible data when the experimental condition is kept constant. In the present studies, the packaged milk was bought in the market, and the anions (Cl^-, NO_2^-, SO_4^{2-}, NO_3^- and PO_4^{3-}) in milk were determined with the technique of IC. A Dionex ICS-2000 ion chromatograph with a Dionex gradient pump, eluent degassing module and conductivity detector was used. Anions were separated on an AS 11 HC ionexchange column, with an AS 11 HC guard column, and detected after suppression with an ASRS 300 anion electrical self-regenerating suppressor. The relative standard deviation (R.S.D.) for Cl^-, NO_2^-, SO_4^{2-}, NO_3^- and PO_4^{3-} was 3.44%, 9.52%, 2.38%, 1.67% and 3.48%, and the percent recovery was ranged from 80.21% to 120.24%. In addition, the concentration of 5 anions in the milk was detected, and the data were expressed as mean ± SD. Statistical analysis was performed by one-way ANOVA followed with comparison test. The concentration of Cl^-, NO_2^-, SO_4^{2-}, NO_3^- and PO_4^{3-} in the milk sample was 440.39 ± 0.15 mg/L, 8.33 ± 0.01 mg/L, 95.14 ± 0.02 mg/L, 2.14 ± 0.01 mg/L and 953.11 ± 0.33 mg/L (n = 6), respectively. There was significant difference among the concentration of Cl^-, NO_2^-, SO_4^{2-}, NO_3^- and PO_4^{3-} ($P < 0.05$). The results indicate that the IC technique is suitable for the rapid, precise and accurate determination of major anions in milk samples. Acceptable detection limits are obtained for the anions, and the time of anions analysis is significantly shortened with the technique of IC.

T115 Evaluation of a screening test for detecting antimicrobial residues in milk by visual reading and by reader equipment. M. M. P. Araújo, M. A. Guerra, A. D. Lage, A. F. Cunha, L. M. Fonseca, M. O. Leite, M. R. Souza, C. F. A. M. Penna, and M. M. O. P. Cerqueira*, *Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

To evaluate the efficiency of Charm MRL BL/TET kit for detecting antimicrobials residues in milk, raw milk samples without antimicrobials were inoculated with 21 drugs in 4 different concentrations including the Brazilian legal limit (MRL) and the detection threshold of the kit. The 21 antimicrobials from 6 different groups and positive and negative controls were tested with 30 repetitions by level. The results obtained by the reader equipment and visual reading were compared by the MacNemar test at 95% of confidence. The temperature of the blocks was monitored and the milk quality was evaluated by total bacterial count; somatic cell count; and fat, protein, lactose, total solids, and solids non fat contents. The temperatures varied from 55 to 57°C in the Charm MRL BL/TET kit and were considered satisfactory. The titratable acidity of the milk samples varied from 14.35 to 16.56°D. Considering all the limit levels of antimicrobial detection (L3) defined by the kit's manufacturer, discrepancies were not observed. The kit detected the different antimicrobials at level 2 that correspond to MRL concentration (Brazilian legislation) and also some detected at level 1 (L1) that was half the L3 concentration. The detection at level 2 (L2) was 100% for the majority of the antimicrobials, exception for cloxacillin (93.3%). Ceftiofur, an important antimicrobial used in Brazil, was detected in 100% of all the milk samples. In relation to L3 level, the Charm MRL Beta/TET kit detected cefalexin in 23.3% and cefapirin in 20.0% of the samples; cefazolin was not detected. Even considered similar ($P > 0.05$), some discrepancies in results evaluated by visual reading and by the kit's reader indicating the presence of antimicrobial residues should be interpreted with caution due to public health hazards and economic problems. It can be concluded that the test kit is efficient for detecting antimicrobials in milk and it can be used as a screening test for monitoring these substances in milk. The kit's reader must be obligatory for screening antimicrobial residues in milk in Brazil.

T116 Descriptive statistics for surface and core temperatures measured with infrared imaging and a digital thermometer on commercial Midwestern US silages. J. P. Goeser*, C. Heuer, and C. M. Wacek-Driver, *Vita Plus Corp., Madison, WI.*

Forage temperature is related to silage nutritional status and DM loss, however limited data exists describing commercial forage temperatures in the US. This study surveyed silage surface and core silage temperatures to calculate population statistics reflecting temperature variations on commercial Midwestern US farms. Farms with horizontal silos of corn silage (n=44) and alfalfa silage (n=33) were measured twice, once during January 14 - April 27 and again during May 25 – August 6 in 2010. Range (maximum minus minimum) in surface temperatures was measured using a thermal imaging camera (FLIR Systems model b40, Boston, MA). Core temperatures were measured at approximately 65cm depth using a digital thermometer. Three core measures were taken: 1.5m from the right and left edge (**R/L Edge**) and one in the center; all core measures were taken 1.2m from the ground. Data were summarized using simple population statistics. Results are presented in Table 1. Range in silage temperatures (measured 200mm beneath silage surface) greater than 5°C above the silage central zone has previously been related to decreased nutritional value, however we observed surface temperature ranges greater than 5°C for all silages measured with an infrared camera. The results showed a numerical interaction for season and crop, with winter temperatures higher for corn silage than summer and vice versa for alfalfa silage. Further, silage temperatures greater than 35°C suffer protein losses and we observed core and surface temperatures exceeding 35°C, suggesting commercial forages are likely suffering protein losses due to heat.

Table 1. Forage silo temperature measures (degrees C)

Season	Crop	Measure Location	Mean	Max	Min	SD
Winter	Corn Silage	R/L Edge Core	19.3	39.0	6.0	6.5
		Center Core	22.2	34.0	13.0	6.0
		Surface Range	11.5	43.0	5.0	7.0
Winter	Alfalfa Silage	R/L Edge Core	21.3	38.0	4.0	6.2
		Center Core	24.9	35.0	8.0	6.2
		Surface Range	13.1	35.0	3.0	8.3
Summer	Corn Silage	R/L Edge Core	21.6	37.0	9.0	6.1
		Center Core	20.0	43.0	9.0	6.7
		Surface Range	8.5	21.0	1.0	5.6
Summer	Alfalfa Silage	R/L Edge Core	27.1	42.0	15.0	7.7
		Center Core	27.7	44.0	15.0	8.3
		Surface Range	10.8	28.0	2.0	8.0
